#### 17.5.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM]=00)

If the index event occurs during the forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock.

The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, the eQEP peripheral also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 17-8.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) is set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] must be configured to 00 or 11 when pcrm=0 and the position counter error flag/interrupt flag are generated only in index event reset mode. The position counter value is latched into the IPOSLAT register on every index marker.

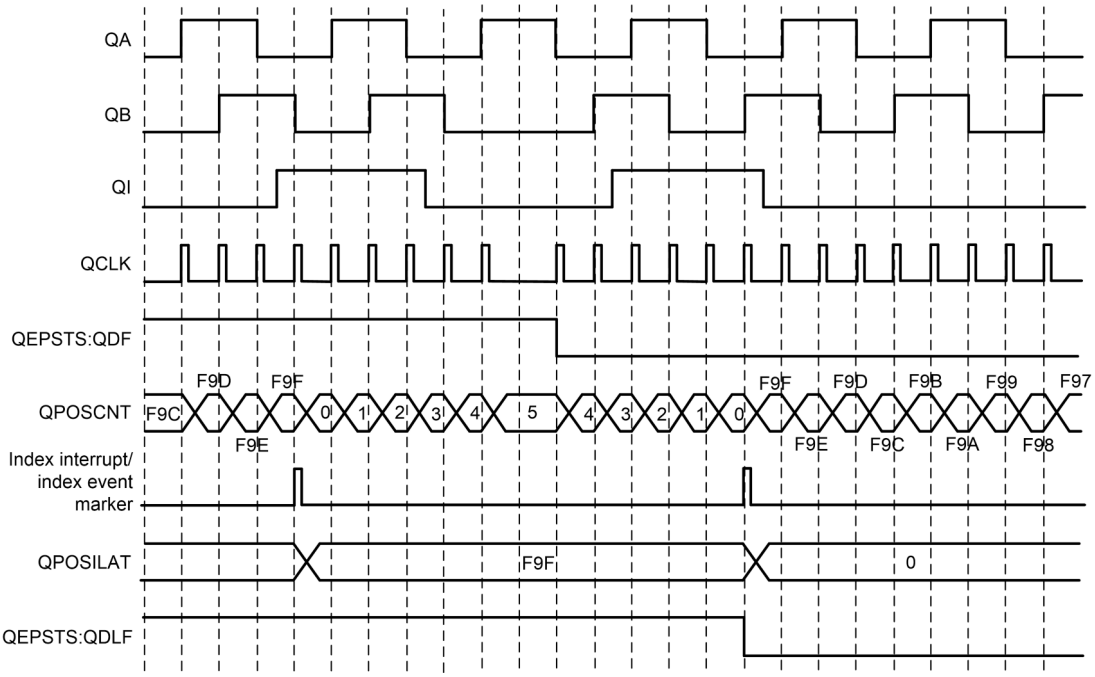

**Figure 17-8. Position Counter Reset by Index Pulse for 1000-Line Encoder (QPOSMAX = 3999 or 0xF9F)**

**Note**

In case of a boundary condition where the time period between the Index Event and the previous QCLK edge is less than SYSCLK period, then QPOSCNT gets reset to zero or QPOSMAX in the same SYSCLK cycle and does not wait for the next QCLK edge to occur.

Copyright © 2024 Texas Instruments Incorporated

#### 17.5.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM]=01)

If the position counter is equal to QPOSMAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position-counter underflow flag is set. Figure 17-9 shows the position-counter reset operation in this mode.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

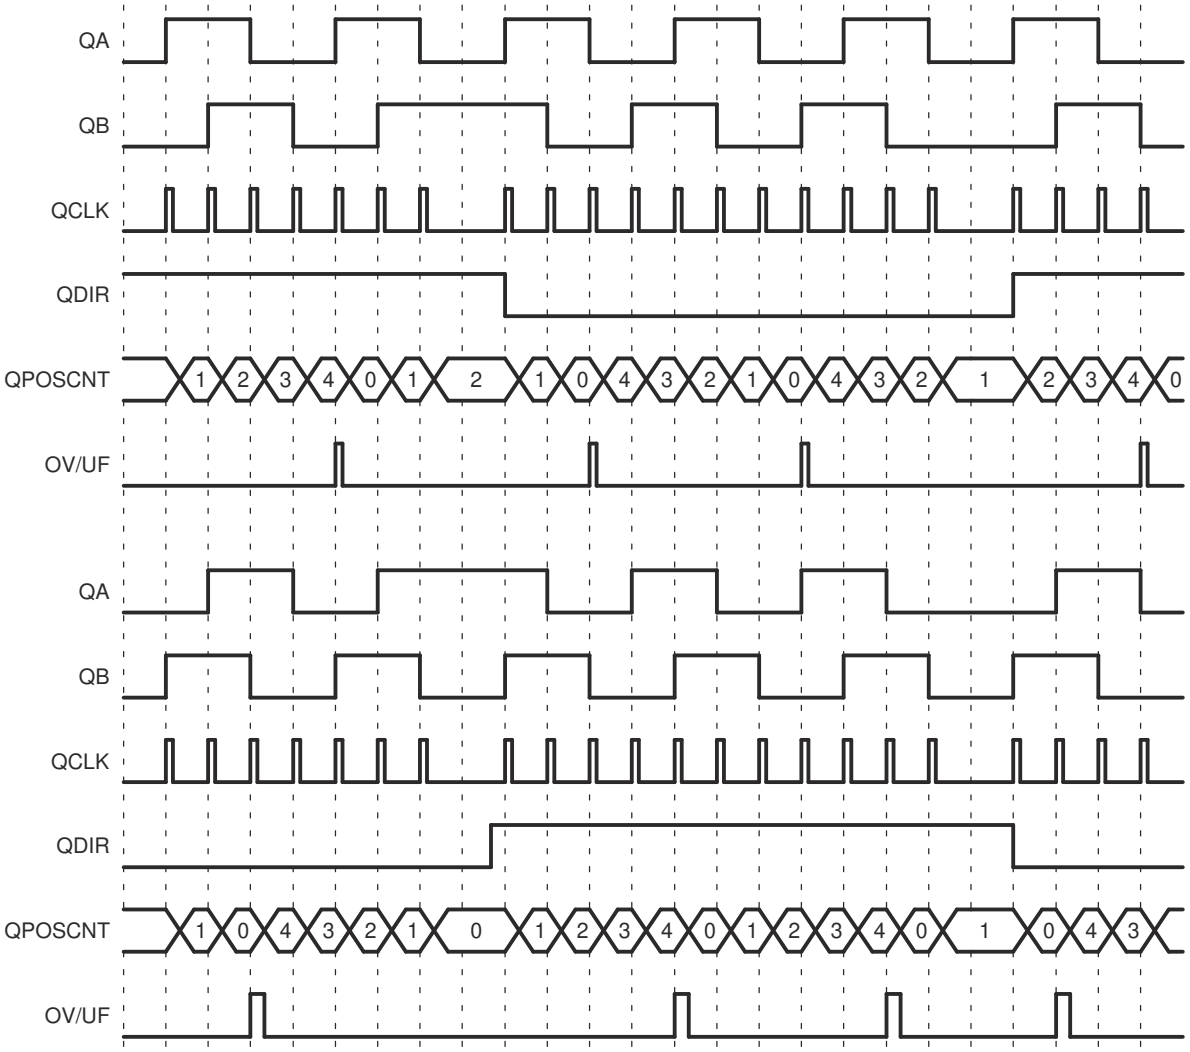

**Figure 17-9. Position Counter Underflow/Overflow (QPOSMAX = 4)**

#### 17.5.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position-counter value is not reset on an index event; rather, the position-counter value is reset based on the maximum position as described in Section 17.5.1.2.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

Copyright © 2024 Texas Instruments Incorporated

#### 17.5.1.4 Position Counter Reset on Unit Time-out Event (QEPCTL[PCRM] = 11)

In this mode, QPOSCNT is set to 0 or QPOMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event. This is useful for frequency measurement.

### *17.5.2 Position Counter Latch*

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

#### 17.5.2.1 Index Event Latch

In some applications, it is not desirable to reset the position counter on every index event and instead it can be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL]=01)
- Latch on Falling edge (QEPCTL[IEL]=10)
- Latch on Index Event Marker (QEPCTL[IEL]=11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTL[IEL]) are ignored when QEPCTL[PCRM] = 00.

| | |
|---|---|
| **Latch on Rising Edge (QEPCTL[IEL]=01)** | The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input. |
| **Latch on Falling Edge (QEPCTL[IEL] = 10)** | The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input. |
| **Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11** | The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and the direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. The eQEP peripheral also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for latching the position counter (QEPCTL[IEL]=11). |

Figure 17-10 shows the position counter latch using an index event marker.

Copyright © 2024 Texas Instruments Incorporated

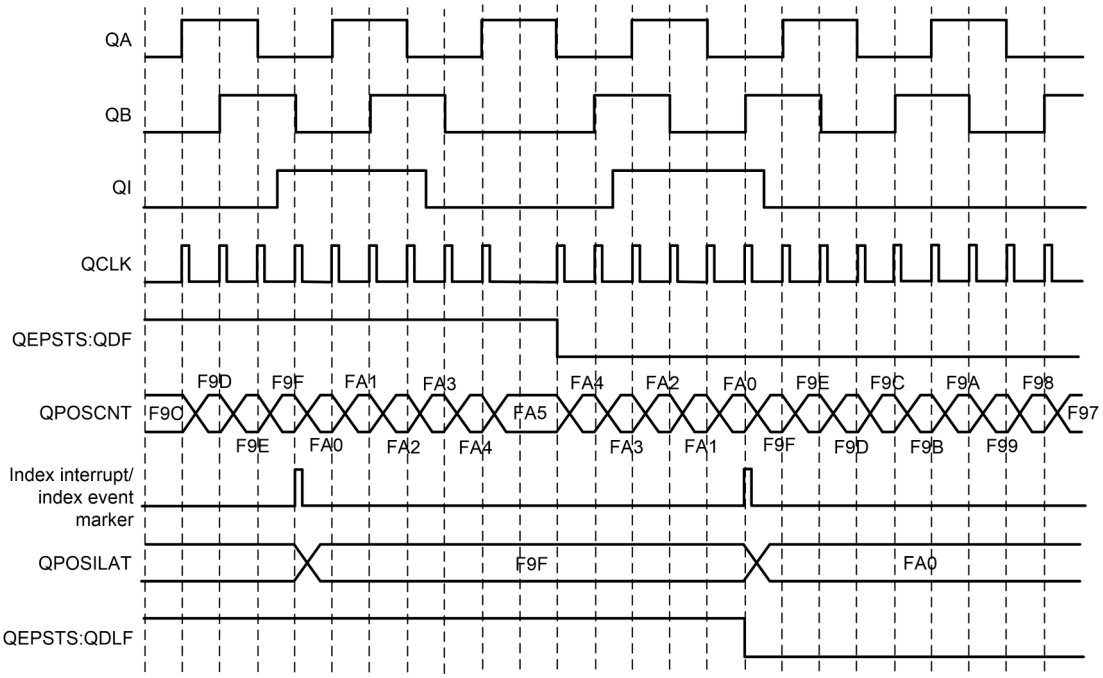

**Figure 17-10. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)**

#### 17.5.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction, and on the falling edge of the strobe input for reverse direction as shown in Figure 17-11.

The strobe event latch interrupt flag (QFLG[SEL) is set when the position counter is latched to the QPOSSLAT register.

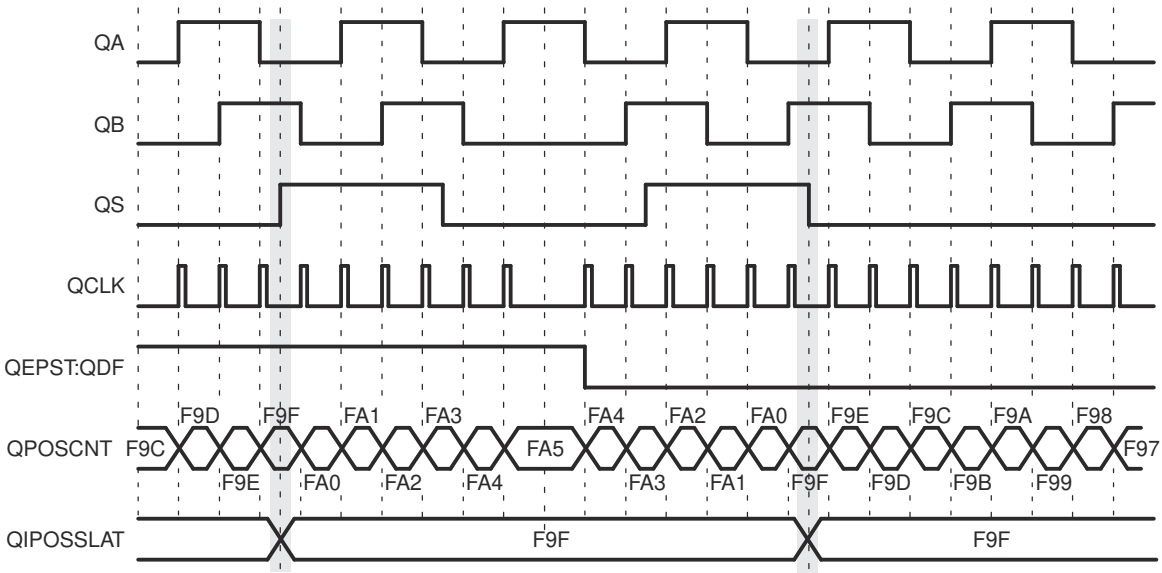

**Figure 17-11. Strobe Event Latch (QEPCTL[SEL] = 1)**

Copyright © 2024 Texas Instruments Incorporated

### 17.5.3 Position Counter Initialization

The position counter can be initialized using the following events:

- Index event
- Strobe event
- Software initialization

| | |
|---|---|
| **Index Event Initialization (IEI)** | The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input. If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of index input. Conversely, if the QEPCTL[IEI] bits are 11, initialization is on the falling edge of the index input. |
| **Strobe Event Initialization (SEI)** | If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.<br>If QEPCTL[SEL] bits are 11, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction. |
| **Software Initialization (SWI)** | The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit. This bit is not automatically cleared. While the bit is still set, if a 1 is written to the bit again, the position counter is re-initialized. |

### 17.5.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and interrupt on a position-compare match. Figure 17-12 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

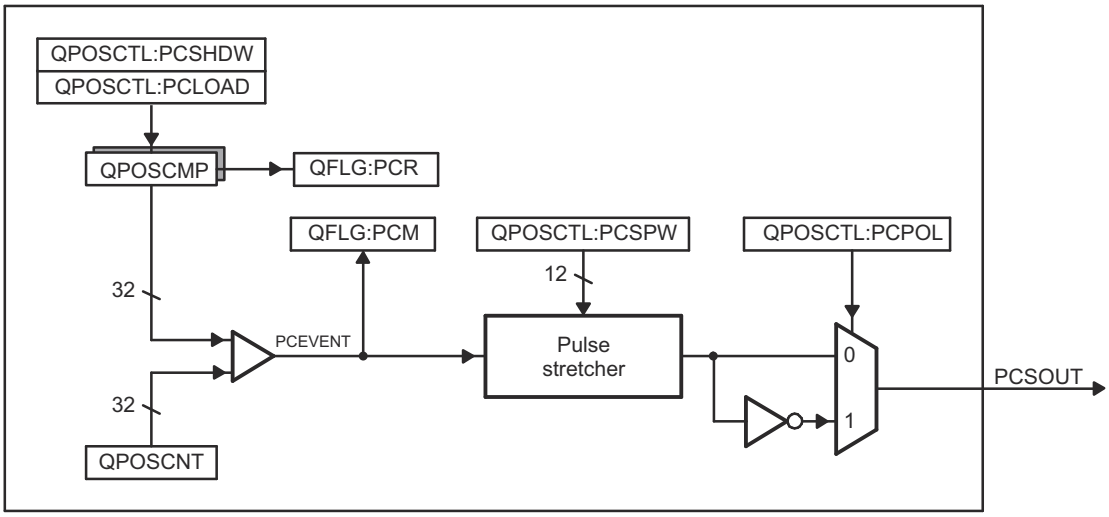

**Figure 17-12. eQEP Position-compare Unit**

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events, and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare-match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 17-13).

See the register section for the layout of the eQEP Position-Compare Control Register (QPOSCTL) and description of the QPOSCTL bit fields.

Copyright © 2024 Texas Instruments Incorporated

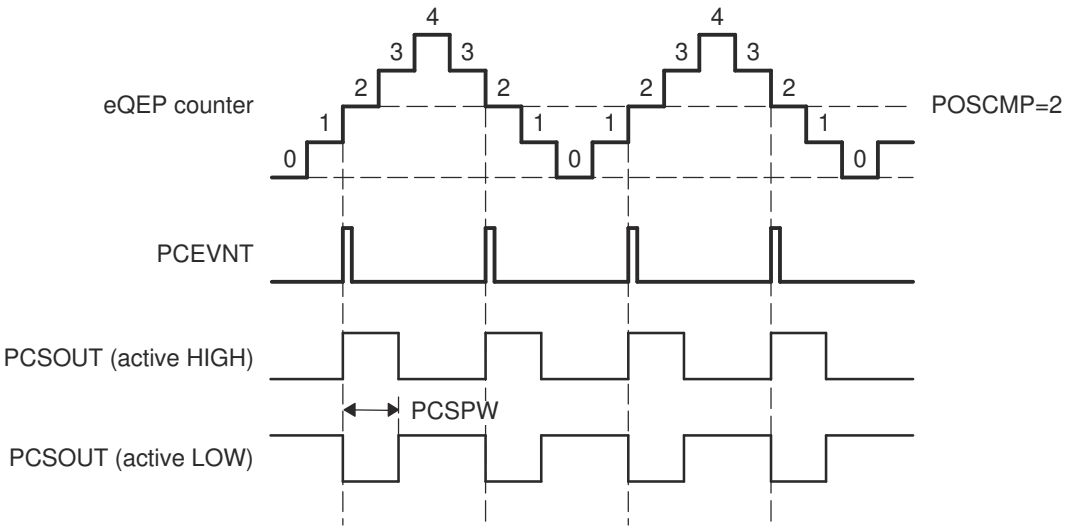

**Figure 17-13. eQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 17-14.

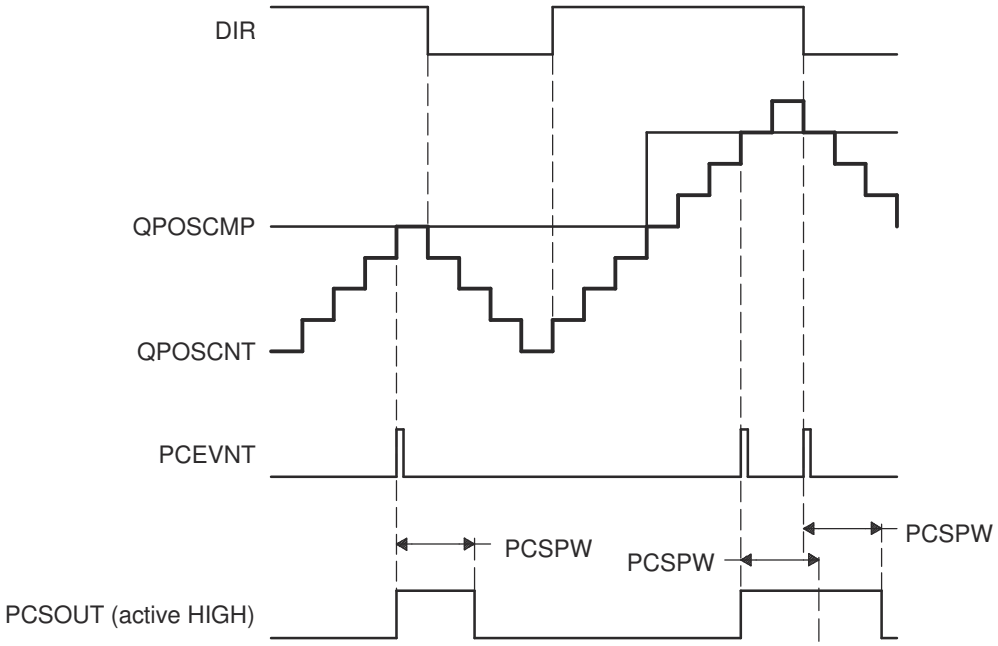

**Figure 17-14. eQEP Position-compare Sync Output Pulse Stretcher**

## 17.6 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in Figure 17-15. This feature is typically used for low-speed measurement using the following formula:

$$v(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (26)$$

where:

- X = Unit position is defined by integer multiple of quadrature edges (see Figure 17-16)
- ΔT = Elapsed time between unit position events
- v(k) = Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled SYSCLKOUT and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement, and clear the flag by writing 1.

Time measurement (ΔT) between unit position events is correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

If the QEP capture timer overflows between unit position events, then the timer sets the QEP capture overflow flag (QEPSTS[COEF]) in the status register and the QCPRDLAT register is set to 0xFFFF. If direction change occurs between the unit position events, then the error flag is set in the status register (QEPSTS[CDEF]) and the QCPRDLAT register is set to 0xFFFF.

The Capture Timer (QCTMR) and Capture Period register (QCPRD) can be configured to latch on the following events:

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

Figure 17-17 shows the capture unit operation along with the position counter.

Copyright © 2024 Texas Instruments Incorporated

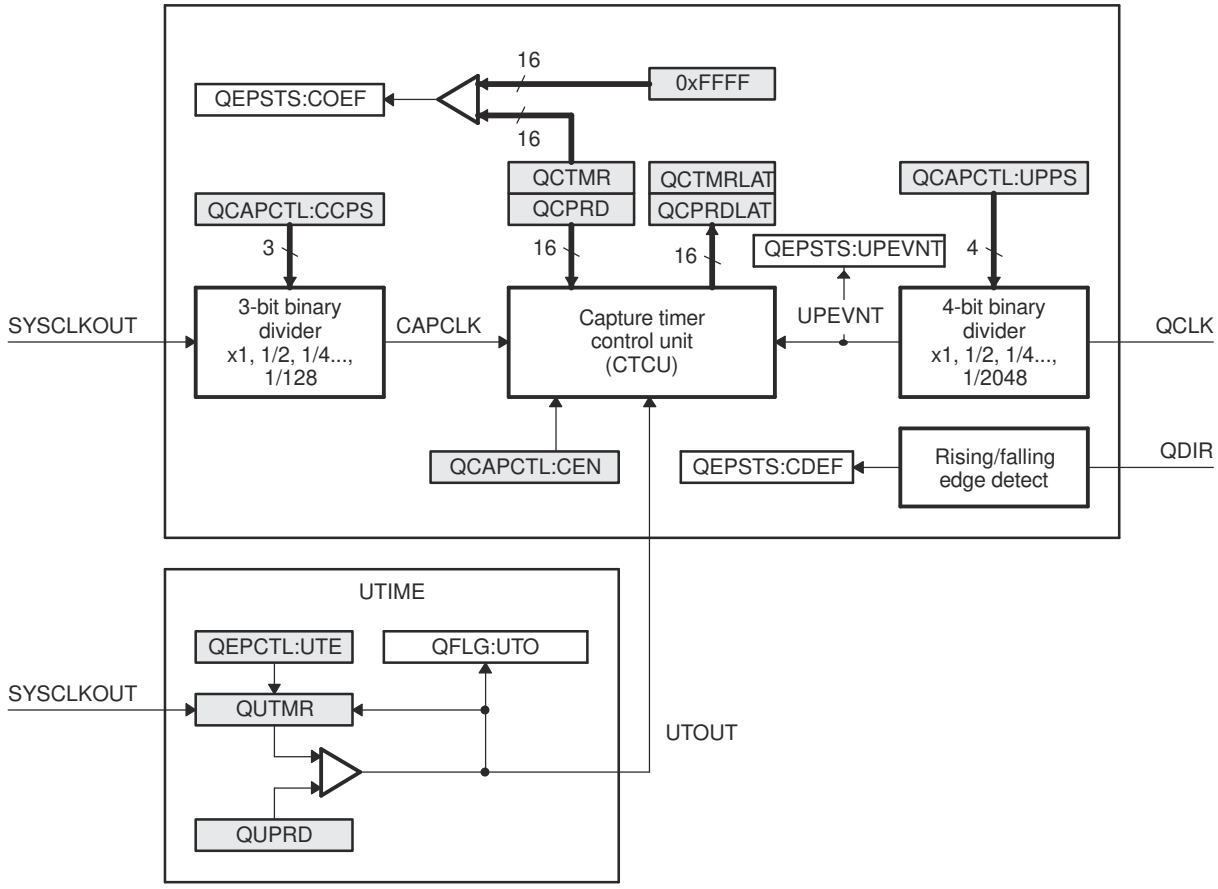

**Figure 17-15. eQEP Edge Capture Unit**

**CAUTION**

The QCAPCTL[UPPS] prescaler cannot be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so can result in undefined behavior. The QCAPCTL[CPPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.

N = Number of quadrature periods selected using QCAPCTL[UPPS] bits

**Figure 17-16. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)**

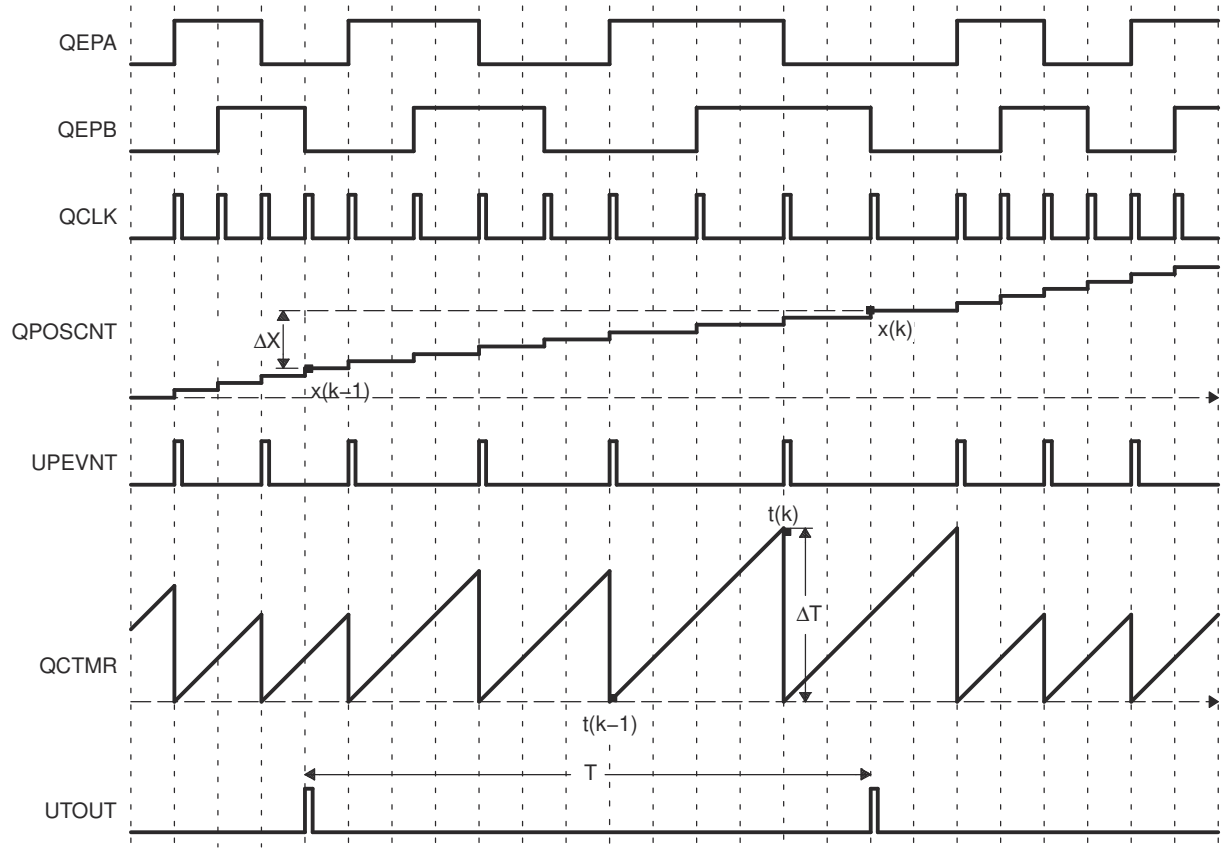

**Figure 17-17. eQEP Edge Capture Unit - Timing Details**

Copyright © 2024 Texas Instruments Incorporated

Velocity calculation equation:

$$v(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \text{ o} \quad (27)$$

where:

- v(k) = Velocity at time instant k
- x(k) = Position at time instant k
- x(k-1) = Position at time instant k-1
- T = Fixed unit time or inverse of velocity calculation rate
- ΔX = Incremental position movement in unit time
- X = Fixed unit position
- ΔT = Incremental time elapsed for unit position movement
- t(k) = Time instant "k"
- t(k-1) = Time instant "k-1"

Unit time (T) and unit period (X) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QPOSLAT and QCPRDLAT registers.

| Parameter | Relevant Register to Configure or Read the Information |
|---|---|
| T | Unit Period Register (QUPRD) |
| ΔX | Incremental Position = QPOSLAT(k) - QPOSLAT(K-1) |
| X | Fixed-unit position defined by sensor resolution and QCAPCTL[UPPS] bits |
| ΔT | Capture Period Latch (QCPRDLAT) |

## 17.7 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer (Figure 17-18) that monitors the quadrature clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer times out and the watchdog interrupt flag is set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

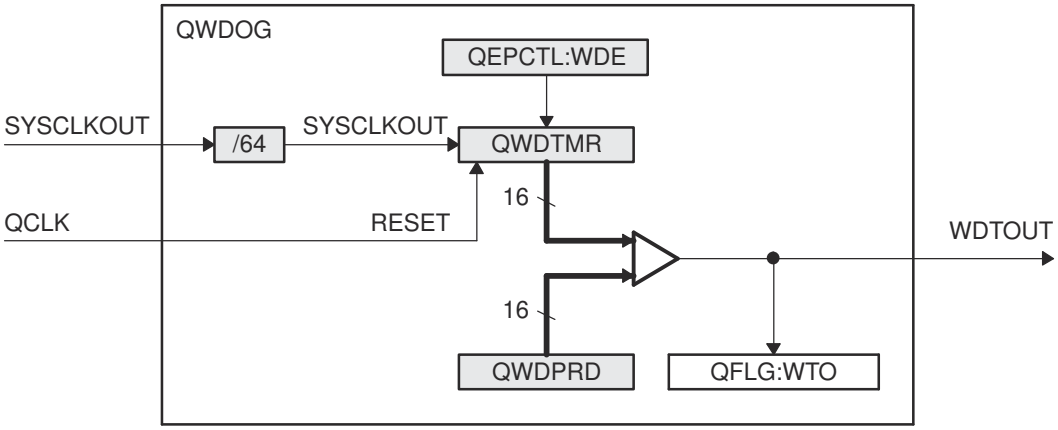

**Figure 17-18. eQEP Watchdog Timer**

## 17.8 eQEP Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations, see Figure 17-19. Whenever the unit timer (QUTMR) matches the unit period register (QUPRD), the eQEP peripheral resets the unit timer (QUTMR) and also generates the unit time out interrupt flag (QFLG[UTO]). The unit timer gets reset whenever timer value equals to configured period value.

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section 17.6.

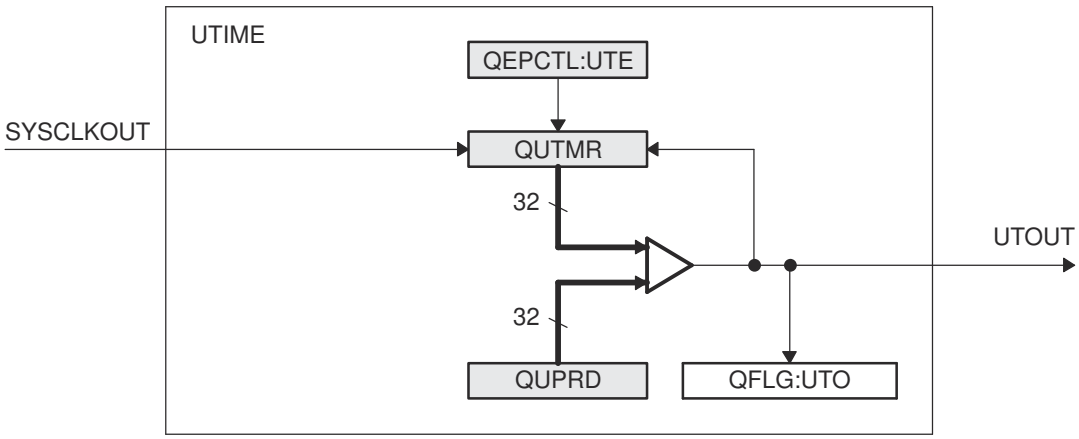

**Figure 17-19. eQEP Unit Timer Base**

Copyright © 2024 Texas Instruments Incorporated

## 17.9 eQEP Interrupt Structure

Figure 17-20 shows how the interrupt mechanism works in the eQEP module.

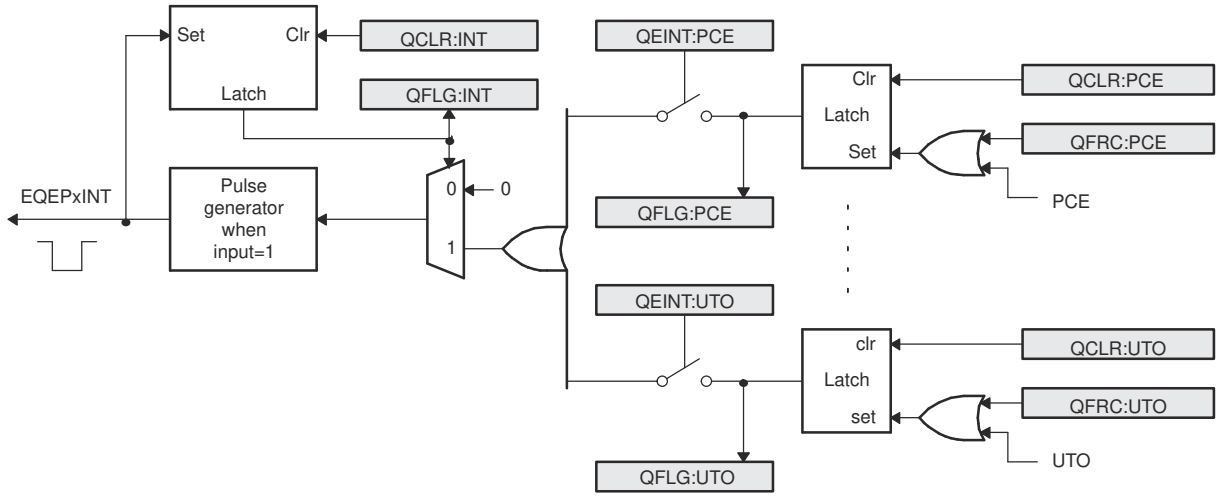

**Figure 17-20. eQEP Interrupt Generation**

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT).

An interrupt pulse is generated to when:

1. Interrupt is enabled for eQEP event inside QEINT register
2. Interrupt flag for eQEP event inside QFLG register is set, and
3. Global interrupt status flag bit QFLG[INT] had been cleared for previously generated interrupt event. The interrupt service routine needs to clear the global interrupt flag bit and the serviced event, by way of the interrupt clear register (QCLR), before any other interrupt pulses are generated. If either flags inside the QFLG register are not cleared, further interrupt events do not generate an interrupt to . You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

## 17.10 eQEP Registers

This section describes the Enhanced Quadrature Encoder Pulse Registers.

### *17.10.1 eQEP Base Addresses*

**Table 17-3. eQEP Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| EQep1Regs | EQEP_REGS | 0x0000_5100 | 0x0000_513F |
| EQep2Regs | EQEP_REGS | 0x0000_5140 | 0x0000_517F |
| EQep3Regs | EQEP_REGS | 0x0000_5180 | 0x0000_51BF |

*Chapter 18*

# *Serial Peripheral Interface (SPI)*

This chapter describes the serial peripheral interface (SPI) which is a high-speed synchronous serial input and output (I/O) port that allows a serial bit stream of programmed length (one to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communications between the MCU controller and external peripherals or another controller. Typical applications include external I/O or peripheral expansion using devices such as shift registers, display drivers, and analog-to-digital converters (ADCs). Multi-device communications are supported by the master or slave operation of the SPI. The port supports a 16-level, receive and transmit FIFO for reducing CPU servicing overhead.

## 18.1 Introduction

### *18.1.1 Features*

The SPI module features include:

- SPISOMI: SPI slave-output/master-input pin
- SPISIMO: SPI slave-input/master-output pin
- $\overline{\text{SPISTE}}$: SPI slave transmit-enable pin
- SPICLK: SPI serial-clock pin

**Note**

All four pins can be used as GPIO if the SPI module is not used.

- Two operational modes: Master and Slave
- Baud rate: 125 different programmable rates. The maximum baud rate that can be employed is limited by the maximum speed of the I/O buffers used on the SPI pins. See the device data sheet for more details.
- Data word length: 1 to 16 data bits
- Four clocking schemes (controlled by clock polarity and clock phase bits) include:
  - Falling edge without phase delay: SPICLK active-high. SPI transmits data on the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
  - Falling edge with phase delay: SPICLK active-high. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge without phase delay: SPICLK inactive-low. SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge with phase delay: SPICLK inactive-low. SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
- Simultaneous receive and transmit operation (transmit function can be disabled in software)
- Transmitter and receiver operations are accomplished through either interrupt- driven or polled algorithm
- 16-level transmit/receive FIFO
- DMA support
- High-speed mode
- Delayed transmit control
- 3-wire SPI mode
- $\overline{\text{SPISTE}}$ inversion for digital audio interface receive mode on devices with two SPI modules

## 18.2 System-Level Integration

This section describes the various functionality that is applicable to the device integration. These features require configuration of other modules in the device that are not within the scope of this chapter.

### *18.2.1 SPI Module Signals*

Table 18-1 classifies and provides a summary of the SPI module signals.

**Table 18-1. SPI Module Signal Summary**

| Signal Name | Description |
|---|---|
| **External Signals** | |
| SPICLK | SPI clock |
| SPISIMO | SPI slave in, master out |
| SPISOMI | SPI slave out, master in |
| $\overline{\text{SPISTE}}$ | SPI slave transmit enable |
| **Control** | |
| SPI Clock Rate | LSPCLK |
| **Interrupt Signals** | |
| SPIINT/SPIRXINT | Transmit interrupt/ Receive Interrupt in non FIFO mode (referred to as SPIINT) |
| | Receive interrupt in FIFO mode |
| SPITXINT | Transmit interrupt in FIFO mode |
| **DMA Triggers** | |
| SPITXDMA | Transmit request to DMA |
| SPIRXDMA | Receive request to DMA |

#### Special Considerations

The $\overline{\text{SPISTE}}$ signal provides the ability to gate any spurious clock and data pulses when the SPI is in slave mode. A HIGH logic signal on $\overline{\text{SPISTE}}$ does not allow the slave to receive data. This prevents the SPI slave from losing synchronization with the master. TI does not recommend that the $\overline{\text{SPISTE}}$ always be tied to the active state.

If the SPI slave does ever lose synchronization with the master, toggling SPISWRESET resets the internal bit counter as well as the various status flags in the module. By resetting the bit counter, the SPI interprets the next clock transition as the first bit of a new transmission. The register bit fields that are reset by SPISWRESET are found in Section 18.6.

#### Configuring a GPIO to Emulate $\overline{\text{SPISTE}}$

In many systems, a SPI master can be connected to multiple SPI slaves using multiple instances of $\overline{\text{SPISTE}}$. Though this SPI module does not natively support multiple $\overline{\text{SPISTE}}$ signals, it is possible to emulate this behavior in software using GPIOs. In this configuration, the SPI must be configured as the master. Rather than using the GPIO Mux to select $\overline{\text{SPISTE}}$, the application can configure pins to be GPIO outputs, one GPIO per SPI slave. Before transmitting any data, the application can drive the desired GPIO to the active state. Immediately after the transmission has been completed, the GPIO chip select can be driven to the inactive state. This process can be repeated for many slaves that share the SPICLK, SPISIMO, and SPISOMI lines.

### 18.2.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

#### 18.2.2.1 GPIOs Required for High-Speed Mode

The high-speed mode of the SPI is available on the specified GPIO mux options in the device data sheet. To enable the high-speed enhancements, set SPICCR.HS_MODE to 1. Make sure that the capacitive loading on the pin does not exceed the value stated in the device data sheet.

When not operating in high-speed mode or if the capacitive loading on the pins exceed the value stated in the device data sheet, SPICCR.HS_MODE can be set to 0.

### 18.2.3 SPI Interrupts

This section includes information on the available interrupts present in the SPI module. The SPI module contains two interrupt lines: SPIINT/SPIRXINT and SPITXINT. When the SPI is operating in non-FIFO mode, all available interrupts are routed together to generate the single SPIINT interrupt. When FIFO mode is used, both SPIRXINT and SPITXINT can be generated.

**SPIINT/SPIRXINT**

When the SPI is operating in non-FIFO mode, the interrupt generated is called SPIINT. If FIFO enhancements are enabled, the interrupt is called SPIRXINT. These interrupts share the same interrupt vector in the Peripheral Interrupt Expansion (PIE) block.

In non-FIFO mode, two conditions can trigger an interrupt: a transmission is complete (INT_FLAG), or there is overrun in the receiver (OVERRUN_FLAG). Both of these conditions share the same interrupt vector: SPIINT.

The transmission complete flag (INT_FLAG) indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced. At the same time this bit is set, the received character is placed in the receiver buffer (SPIRXBUF). The INT_FLAG generates an interrupt on the SPIINT vector if the SPIINTENA bit is set.

The receiver overrun flag (OVERRUN_FLAG) indicates that a transmit or receive operation has completed before the previous character has been read from the buffer. The OVERRUN_FLAG generates an interrupt on the SPIINT vector if the OVERRUNINTENA bit is set and OVERRUN_FLAG was previously cleared.

In FIFO mode, the SPI can interrupt the CPU upon a match condition between the current receive FIFO status (RXFFST) and the receive FIFO interrupt level (RXFFIL). If RXFFST is greater than or equal to RXFFIL, the receive FIFO interrupt flag (RXFFINT) is set. SPIRXINT is triggered in the PIE block, if RXFFINT is set and the receive FIFO interrupt is enabled (RXFFIENA = 1).

**SPITXINT**

The SPITXINT interrupt is not available when the SPI is operating in non-FIFO mode.

In FIFO mode, the SPITXINT behavior is similar to the SPIRXINT. SPITXINT is generated upon a match condition between the current transmit FIFO status (TXFFST) and the transmit FIFO interrupt level (TXFFIL). If TXFFST is less than or equal to TXFFIL, the transmit FIFO interrupt flag (TXFFINT) is set. SPITXINT is triggered in the PIE block, if TXFFINT is set and the transmit FIFO interrupt is enabled in the SPI module (TXFFIENA = 1).

Figure 18-2 and Table 18-2 show how these control bits influence the SPI interrupt generation.

Copyright © 2024 Texas Instruments Incorporated

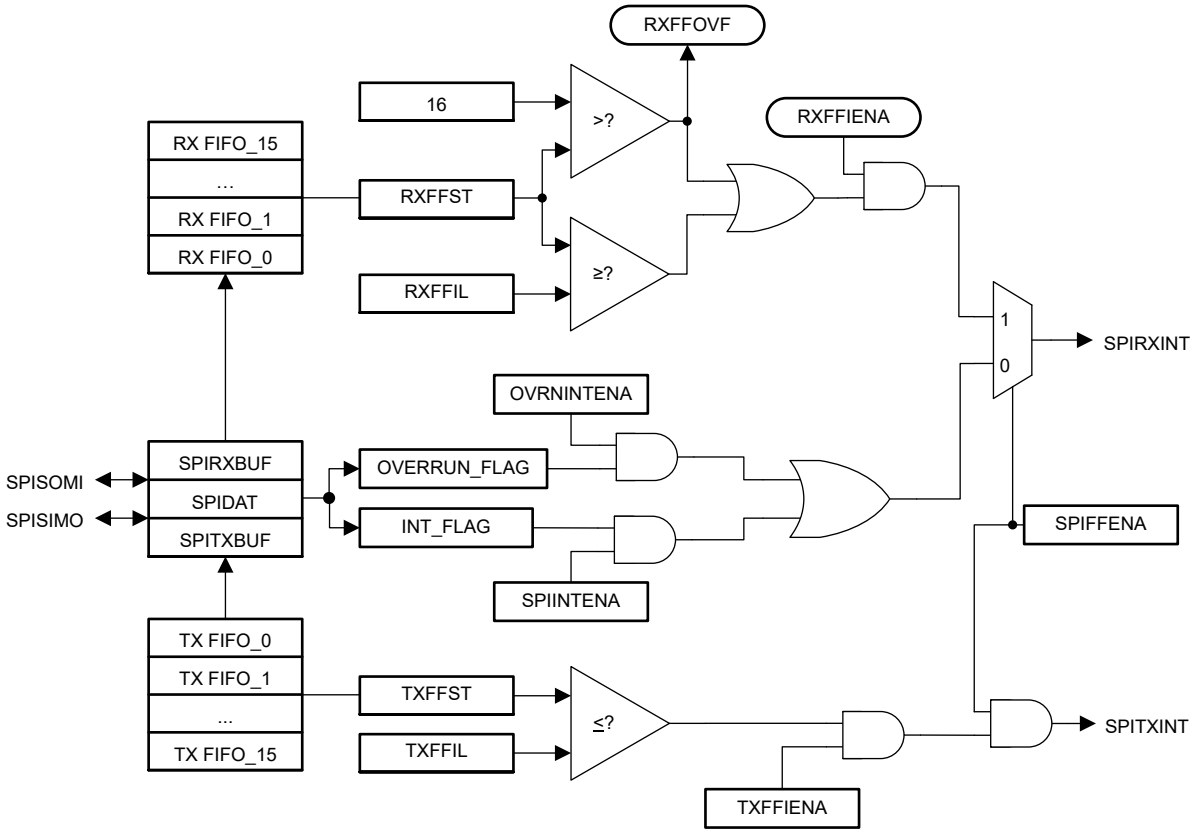

**Figure 18-2. SPI Interrupt Flags and Enable Logic Generation**

**Table 18-2. SPI Interrupt Flag Modes**

| FIFO Options | SPI Interrupt Source | Interrupt Flags | Interrupt Enables | FIFO Enable (SPIFFENA) | Interrupt Line (1) |
|---|---|---|---|---|---|
| SPI without FIFO | Receive overrun | RXOVRN | OVRNINTENA | 0 | SPIRXINT |
| | Data receive | SPIINT | SPIINTENA | 0 | SPIRXINT |
| | Transmit empty | SPIINT | SPIINTENA | 0 | SPIRXINT |
| SPI FIFO mode | FIFO receive | RXFFIL | RXFFIENA | 1 | SPIRXINT |
| | Transmit empty | TXFFIL | TXFFIENA | 1 | SPITXINT |

(1) In non-FIFO mode, SPIRXINT is the same name as the SPIINT interrupt in C28x devices.

Copyright © 2024 Texas Instruments Incorporated

### 18.2.4 DMA Support

Both the CPU and DMA have access to the SPI data registers using the internal peripheral bus. This access is limited to 16-bit register reads and writes. Each SPI module can generate two DMA events, SPITXDMA and SPIRXDMA. The DMA events are controlled by configuring the SPIFFTX.TXFFIL and SPIFFRX.RXFFIL appropriately. SPITXDMA activates when TXFFST is less than the interrupt level (TXFFIL). SPIRXDMA activates when RXFFST is greater than or equal to the interrupt level (RXFFIL).

The SPI must have FIFO enhancements enabled for the DMA triggers to be generated.

For more information on configuring the SPI for DMA transfers, refer to Section 18.3.8.

Figure 18-3 is a block diagram showing the DMA trigger generation from the SPI module.

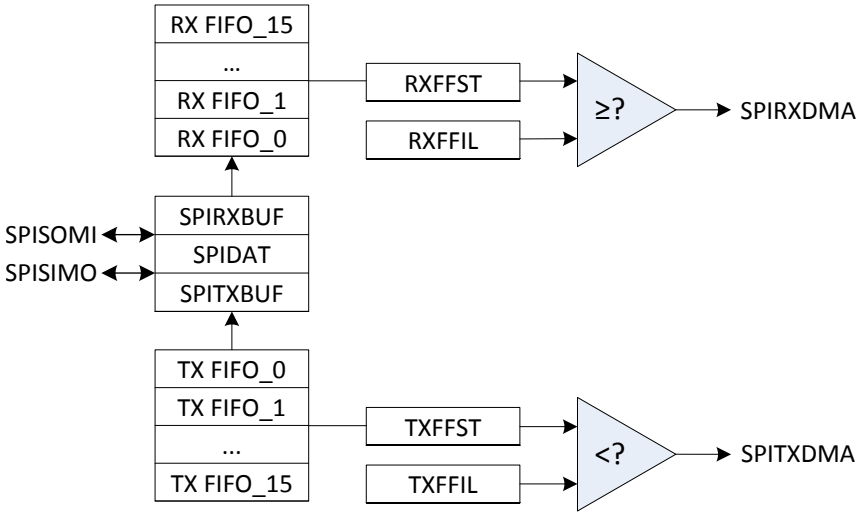

**Figure 18-3. SPI DMA Trigger Diagram**

## 18.3 SPI Operation

This section describes the various modes of operation of the SPI. Included are explanations of the operational modes, interrupts, data format, clock sources, and initialization. Typical timing diagrams for data transfers are given.

### *18.3.1 Introduction to Operation*

Figure 18-4 shows typical connections of the SPI for communications between two controllers: a master and a slave.

The master transfers data by sending the SPICLK signal. For both the slave and the master, data is shifted out of the shift registers on one edge of the SPICLK and latched into the shift register on the opposite SPICLK clock edge. If the CLK_PHASE bit is high, data is transmitted and received a half-cycle before the SPICLK transition. As a result, both controllers send and receive data simultaneously. The application software determines whether the data is meaningful or dummy data. There are three possible methods for data transmission:

- Master sends data; slave sends dummy data.
- Master sends data; slave sends data.
- Master sends dummy data; slave sends data.

The master can initiate data transfer at any time because the master controls the SPICLK signal. The software, however, determines how the master detects when the slave is ready to broadcast data.

The SPI operates in master or slave mode. The MASTER_SLAVE bit selects the operating mode and the source of the SPICLK signal.

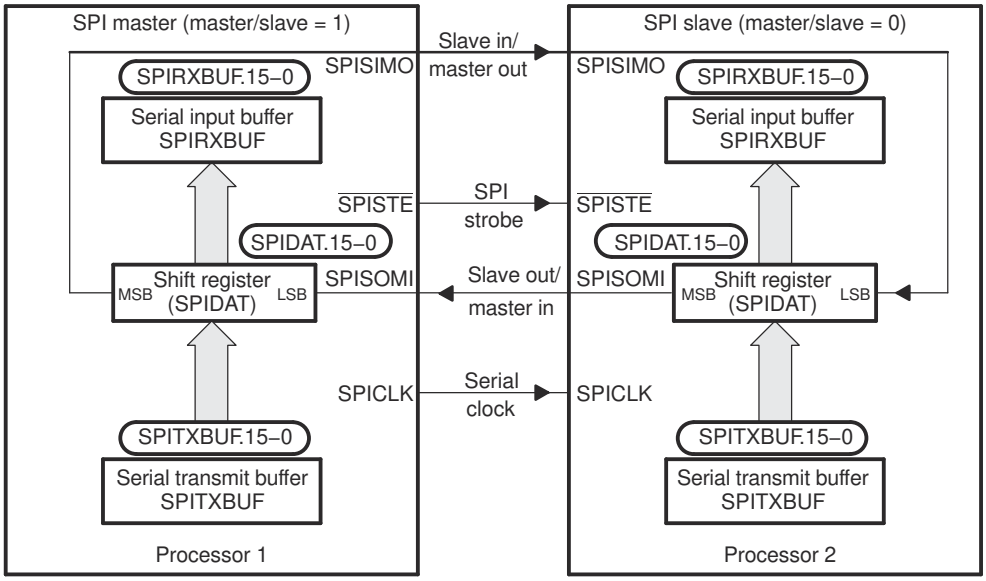

**Figure 18-4. SPI Master/Slave Connection**

Copyright © 2024 Texas Instruments Incorporated

### 18.3.2 Master Mode

In master mode (MASTER_SLAVE = 1), the SPI provides the serial clock on the SPICLK pin for the entire serial communications network. Data is output on the SPISIMO pin and latched from the SPISOMI pin.

The SPIBRR register determines both the transmit and receive bit transfer rate for the network. SPIBRR can select 125 different data transfer rates.

Data written to SPIDAT or SPITXBUF initiates data transmission on the SPISIMO pin, MSB (most-significant bit) first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB (least- significant bit) of SPIDAT. When the selected number of bits has been transmitted, the received data is transferred to the SPIRXBUF (buffered receiver) for the CPU to read. Data is stored right-justified in SPIRXBUF.

When the specified number of data bits has been shifted through SPIDAT, the following events occur:

- SPIDAT contents are transferred to SPIRXBUF.
- INT_FLAG bit is set to 1.
- If there is valid data in the transmit buffer SPITXBUF, as indicated by the transmit buffer full flag (BUFFULL_FLAG), this data is transferred to SPIDAT and is transmitted; otherwise, SPICLK stops after all bits have been shifted out of SPIDAT.
- If the SPIINTENA bit is set to 1, an interrupt is asserted.

In a typical application, the $\overline{\text{SPISTE}}$ pin serves as a chip-enable pin for a SPI slave device. This pin is driven low by the master before transmitting data to the slave and is taken high after the transmission is complete.

Figure 18-5 is a block diagram of the SPI in master mode. The block diagram shows the basic control blocks available in SPI master mode.

Copyright © 2024 Texas Instruments Incorporated

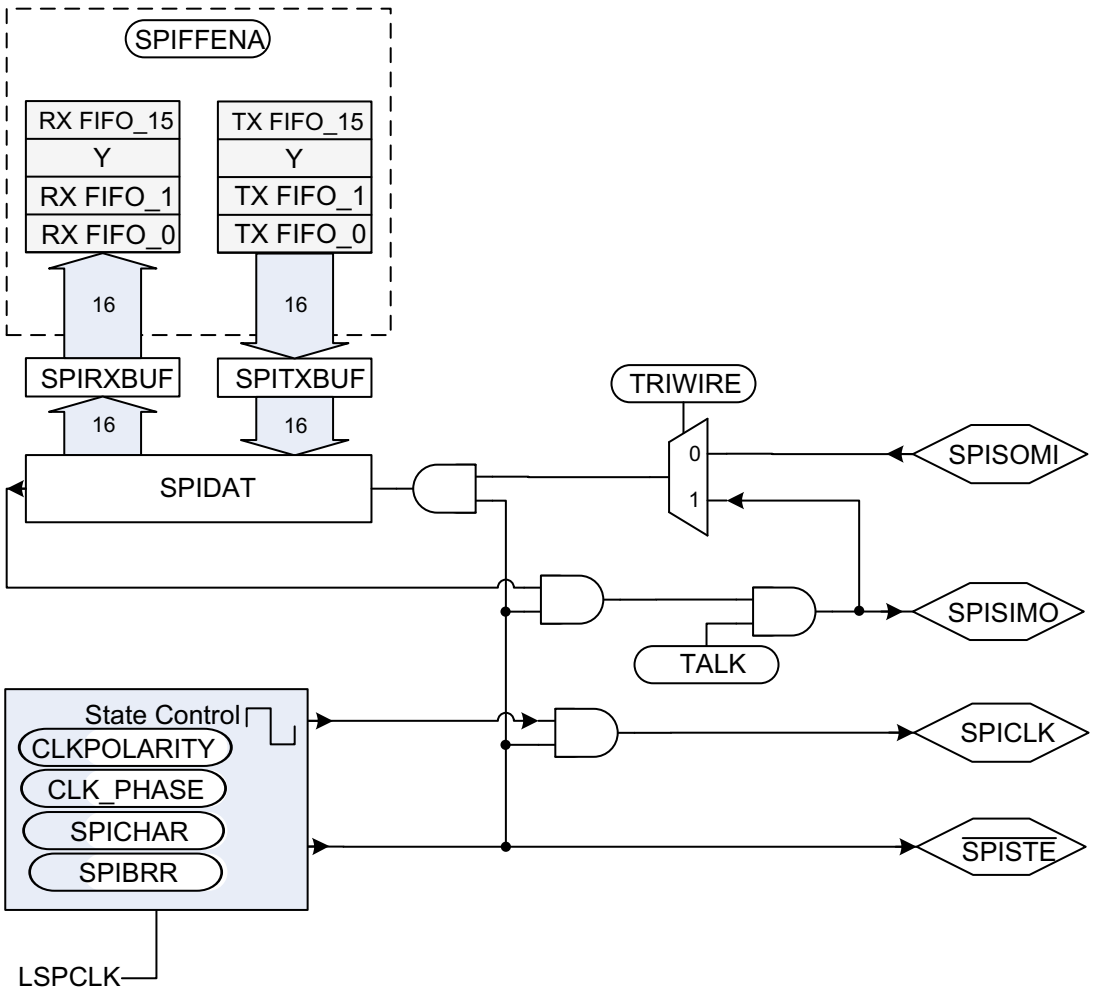

**Figure 18-5. SPI Module Master Configuration**

### *18.3.3 Slave Mode*

In slave mode (MASTER_SLAVE = 0), data shifts out on the SPISOMI pin and in on the SPISIMO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock. The SPICLK input frequency can be no greater than the LSPCLK frequency divided by 4.

Data written to SPIDAT or SPITXBUF is transmitted to the network when appropriate edges of the SPICLK signal are received from the network master. A character written to the SPITXBUF register is copied to the SPIDAT register when all bits of the current character in SPIDAT have been shifted out. If no character was previously copied to SPIDAT, then any character written to SPITXBUF is immediately copied to SPIDAT. If a character was previously copied to SPIDAT, any data written to SPITXBUF is not copied to SPIDAT until the current character in SPIDAT has been shifted out. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts the data on the SPISIMO pin into SPIDAT. If data is to be transmitted by the slave simultaneously, and SPIDAT has not been previously loaded, the character must be written to SPITXBUF before the beginning of the SPICLK signal.

When the TALK bit is cleared, data transmission is disabled, and the output line (SPISOMI) is put into the high-impedance state. If this occurs while a transmission is active, the current character is completely transmitted even though SPISOMI is forced into the high-impedance state. This makes sure that the SPI is still able to

Copyright © 2024 Texas Instruments Incorporated

receive incoming data correctly. This TALK bit allows many slave devices to be tied together on the network, but only one slave at a time is allowed to drive the SPISOMI line.

The $\overline{\text{SPISTE}}$ pin operates as the slave-select pin. An active-low signal on the $\overline{\text{SPISTE}}$ pin allows the slave SPI to transfer data to the serial data line; an inactive-high signal causes the slave SPI serial shift register to stop and the serial output pin to be put into the high-impedance state. This allows many slave devices to be tied together on the network, although only one slave device is selected at a time.

Figure 18-6 is a block diagram of the SPI in slave mode. The block diagram shows the basic control blocks available in SPI slave mode.

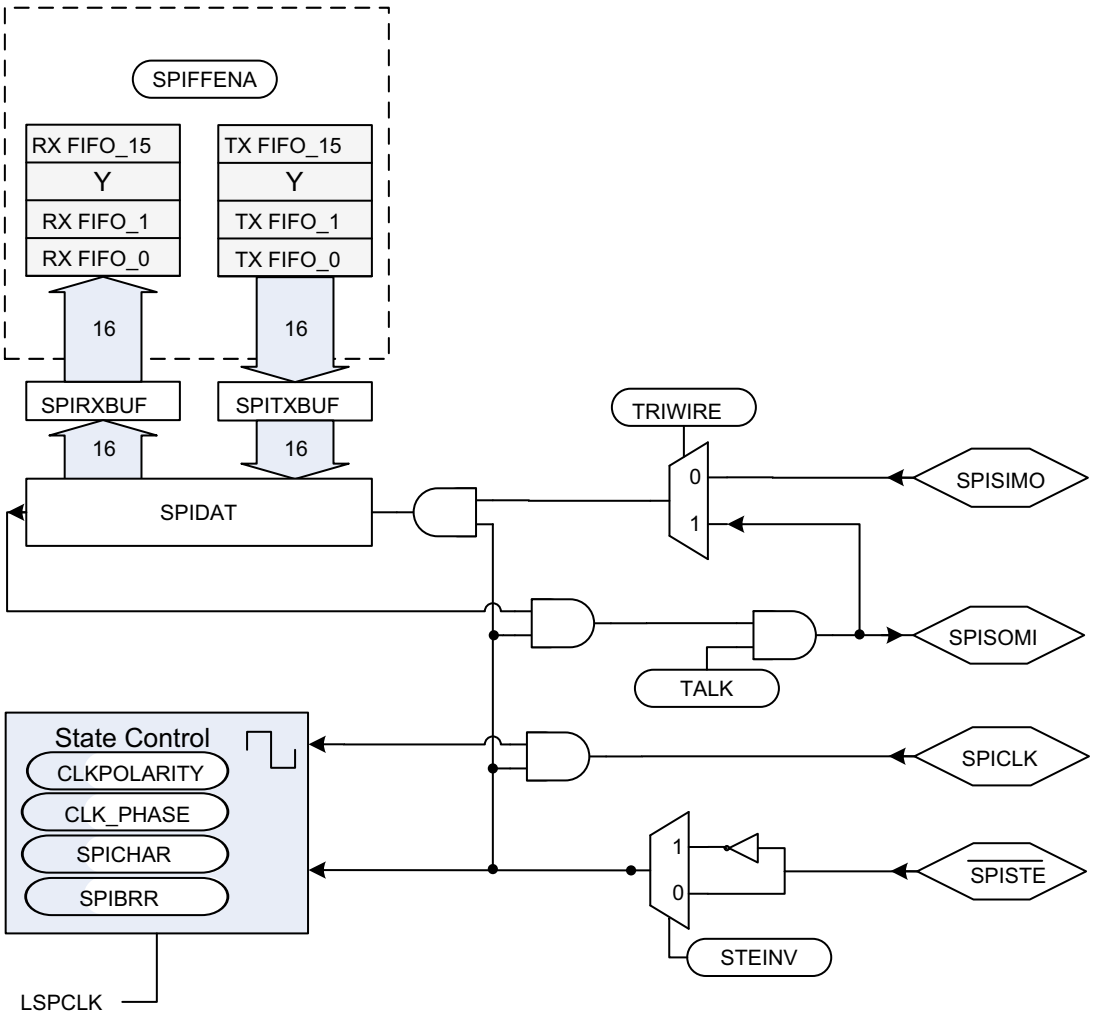

**Figure 18-6. SPI Module Slave Configuration**

### 18.3.4 Data Format

The four-bit SPICHAR register field specifies the number of bits in the data character (1 to 16). This information directs the state control logic to count the number of bits received or transmitted to determine when a complete character has been processed.

The following statements apply to characters with fewer than 16 bits:

- Data must be left-justified when written to SPIDAT and SPITXBUF.
- Data read back from SPIRXBUF is right-justified.
- SPIRXBUF contains the most recently received character, right-justified, plus any bits that remain from previous transmission(s) that have been shifted to the left (shown in Example 18-1).

***Example 18-1. Transmission of Bit from SPIRXBUF***

Conditions:

1. Transmission character length = 1 bit (specified in SPICHAR bits)
2. The current value of SPIDAT = 737Bh

| SPIDAT (before transmission) | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 0 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1 | 1 |
| **SPIDAT (after transmission)** | | | | | | | | | | | | | | | | |
| (TXed) 0 ← | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1 | 1 | x(1) ← (RXed) |
| **SPIRXBUF (after transmission)** | | | | | | | | | | | | | | | | |
| | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1 | 1 | x(1) |

(1) x = 1, if SPISOMI data is high; x = 0, if SPISOMI data is low; master mode is assumed.

Copyright © 2024 Texas Instruments Incorporated

### 18.3.5 Baud Rate Selection

The SPI module supports 125 different baud rates and four different clock schemes. Depending on whether the SPI clock is in slave or master mode, the SPICLK pin can receive an external SPI clock signal or provide the SPI clock signal, respectively.

- In the slave mode, the SPI clock is received on the SPICLK pin from the external source and can be no greater than the LSPCLK frequency divided by 4.
- In the master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin and can be no greater than the LSPCLK frequency divided by 4.

**Note**

The baud rate must be configured to not exceed the maximum rated GPIO toggle frequency. Refer to the device data sheet for the maximum GPIO toggle frequency.

Example 18-2 shows how to determine the SPI baud rates.

Example 18-3 shows how to calculate the baud rate of the SPI module in standard SPI mode (HS_MODE = 0).

***Example 18-2. Baud Rate Determination***

For SPIBRR = 3 to 127:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{(\text{SPIBRR} + 1)}$$

For SPIBRR = 0, 1, or 2:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{4}$$

where:

LSPCLK = Low-speed peripheral clock frequency of the device

SPIBRR = Contents of the SPIBRR in the master SPI device

To determine what value to load into SPIBRR, you must know the device system clock (LSPCLK) frequency (that is device-specific) and the baud rate at which you are operating.

***Example 18-3. Baud Rate Calculation in Non-High Speed Mode (HS_MODE = 0)***

$$SPI\ Baud\ Rate = \frac{LSPCLK}{SPIBRR + 1'} \quad LSPCLK = 50\ MHz$$

$$= \frac{50 \times 10^6}{3 + 1}$$

$$= 12.5\ Mbps$$

### 18.3.6 SPI Clocking Schemes

The clock polarity select bit (CLKPOLARITY) and the clock phase select bit (CLK_PHASE) control four different clocking schemes on the SPICLK pin. CLKPOLARITY selects the active edge, either rising or falling, of the clock. CLK_PHASE selects a half-cycle delay of the clock. The four different clocking schemes are:

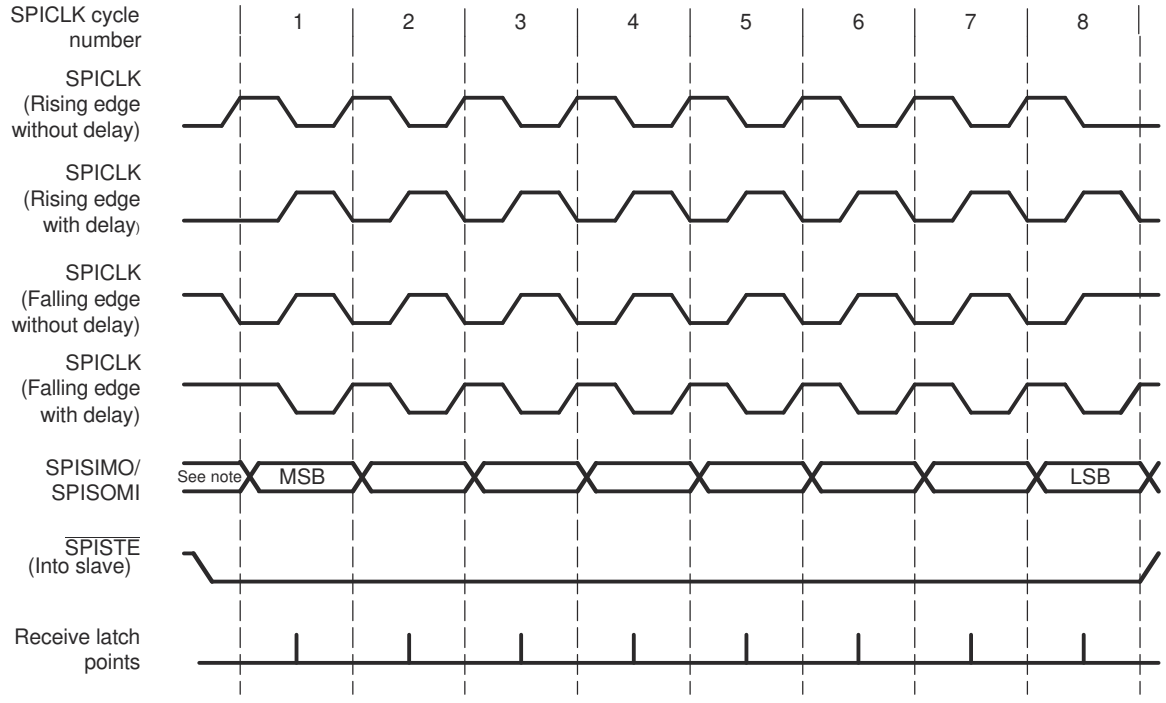
- Falling Edge Without Delay. The SPI transmits data on the falling edge of the SPICLK and receives data on the rising edge of the SPICLK.
- Falling Edge With Delay. The SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge Without Delay. The SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge With Delay. The SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.

The selection procedure for the SPI clocking scheme is shown in Table 18-3. Examples of these four clocking schemes relative to transmitted and received data are shown in Figure 18-7.

**Table 18-3. SPI Clocking Scheme Selection Guide**

| SPICLK Scheme | CLKPOLARITY(1) | CLK_PHASE(1) |
|---|---|---|
| Rising edge without delay | 0 | 0 |
| Rising edge with delay | 0 | 1 |
| Falling edge without delay | 1 | 0 |
| Falling edge with delay | 1 | 1 |

(1) The description of CLK_PHASE and CLKPOLARITY differs between manufacturers. For proper operation, select the desired waveform to determine the clock phase and clock polarity settings.



**Note:** Previous data bit

**Figure 18-7. SPICLK Signal Options**

Copyright © 2024 Texas Instruments Incorporated

SPICLK symmetry is retained only when the result of (SPIBRR + 1) is an even value. When (SPIBRR + 1) is an odd value and SPIBRR is greater than 3, SPICLK becomes asymmetrical. The low pulse of SPICLK is one LSPCLK cycle longer than the high pulse when CLKPOLARITY bit is clear (0). When CLKPOLARITY bit is set to 1, the high pulse of the SPICLK is one LSPCLK cycle longer than the low pulse, as shown in Figure 18-8.

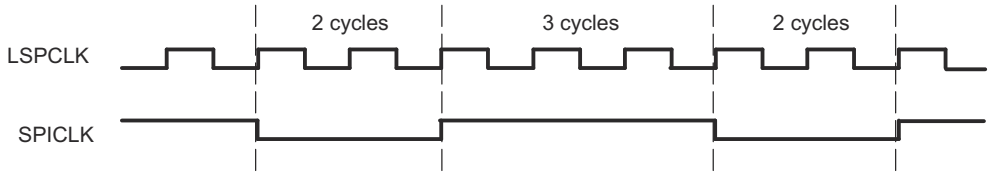


**Figure 18-8. SPI: SPICLK-LSPCLK Characteristic when (BRR + 1) is Odd, BRR > 3, and CLKPOLARITY = 1**

### *18.3.7 SPI FIFO Description*

The following steps explain the FIFO features and help with programming the SPI FIFOs:

1. **Reset.** At reset the SPI powers up in standard SPI mode and the FIFO function is disabled. The FIFO registers SPIFFTX, SPIFFRX and SPIFFCT remain inactive.
2. **Standard SPI.** The standard 28x SPI mode works with SPIINT/SPIRXINT as the interrupt source.
3. **Mode change.** FIFO mode is enabled by setting the SPIFFENA bit to 1 in the SPIFFTX register. SPIRST can reset the FIFO mode at any stage of the operation.
4. **Active registers.** All the SPI registers and SPI FIFO registers SPIFFTX, SPIFFRX, and SPIFFCT are active.
5. **Interrupts.** FIFO mode has two interrupts: one for the transmit FIFO, SPITXINT; one for the receive FIFO, SPIRXINT. SPIRXINT is the common interrupt for SPI FIFO receive, receive error and receive FIFO overflow conditions. The single SPIINT for both transmit and receive sections of the standard SPI are disabled and this interrupt is serviced as SPI receive FIFO interrupt. For more information, refer to Section 18.2.3.
6. **Buffers.** Transmit and receive buffers are each supplemented with a 16-word FIFO. The one-word transmit buffer (SPITXBUF) of the standard SPI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer is loaded from transmit FIFO only after the last bit of the shift register is shifted out.
7. **Delayed transfer.** The rate at which transmit words in the FIFO are transferred to transmit shift register is programmable. The SPIFFCT register bits (7−0) FFTXDLY7−FFTXDLY0 define the delay between the word transfer. The delay is defined in number SPI serial clock cycles. The 8-bit register can define a minimum delay of 0 SPICLK cycles and a maximum of 255 SPICLK cycles. With zero delay, the SPI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 255 clock delay, the SPI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 255 SPICLK cycles between each words. The programmable delay facilitates glueless interface to various slow SPI peripherals, such as EEPROMs, ADC, DAC, and so on.
8. **FIFO status bits.** Both transmit and receive FIFOs have status bits TXFFST or RXFFST that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit (TXFIFO) and receive reset bit (RXFIFO) reset the FIFO pointers to zero when these bits are set to 1. The FIFOs resume operation from start once these bits are cleared to zero.
9. **Programmable interrupt levels.** Both transmit and receive FIFOs can generate CPU interrupts and DMA triggers. The transmit interrupt (SPITXINT) is generated whenever the transmit FIFO status bits (TXFFST) match (less than or equal to) the interrupt trigger level bits (TXFFIL). The receive interrupt (SPIRXINT) is generated whenever the receive FIFO status bits (RXFFST) match (greater than or equal to) the interrupt trigger level RXFFIL. This provides a programmable interrupt trigger for transmit and receive sections of the SPI. The default value for these trigger level bits is 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

### 18.3.8 SPI DMA Transfers

#### 18.3.8.1 Transmitting Data Using SPI with DMA

When using the DMA with the TX FIFO, the DMA Burst Size (DMA_BURST_SIZE) must be no greater than 16 – TXFFIL, to prevent the DMA from writing to an already full FIFO. This leads to data loss and is not recommended.

For complete data transmission, follow these steps:

1. Calculate the total number of words to be transmitted. [NUM_WORDS]
2. Decide the transmit FIFO level. [TXFFIL]
3. Calculate the total number of DMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the DMA Burst. [DMA_BURST_SIZE]
5. Configure DMA using calculated values.
6. Configure SPI with FIFO using the calculated values.

To transfer 128 words to SPI using the DMA:

NUM_WORDS: 128

TXFFIL: 8

DMA_TRANSFER_SIZE: (NUM_WORDS /TXFFIL) – 1 = (128/8) – 1 = 15 (16 transfers)

DMA_BURST_SIZE: (16 – TXFFIL) – 1 = (16 – 8) – 1 = 7 (8 words per burst)

**Note**

Avoid setting TXFFIL to 0h or 10h to make sure of proper DMA configuration.

#### 18.3.8.2 Receiving Data Using SPI with DMA

When using the DMA with the RX FIFO, the DMA Burst Size (BURST_SIZE) must be no greater than RXFFIL to prevent the DMA from reading from an empty FIFO. To make sure that the DMA correctly receives all data from the RX FIFO, the DMA Burst Size can equal RXFFIL and also be an integer divisor of the total number of SPI transmissions.

For complete data reception, follow these steps:

1. Calculate the total number of words to be received. [NUM_WORDS]
2. Calculate the necessary FIFO level [RXFFIL]
3. Calculate the total number of DMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the DMA Burst. [DMA_BURST_SIZE]
5. Configure DMA using the calculated values.
6. Configure SPI with FIFO using the calculated values.

To receive 200 words from SPI using the DMA:

NUM_WORDS = 200

RXFFIL: 4

DMA_TRANSFER_SIZE: (NUM_WORDS /RXFFIL) – 1 = (200/4) – 1 = 49 (50 transfers)

DMA_BURST_SIZE = RXFFIL-1 = 3 (4 words per burst)

**Note**

Avoid setting RXFFIL to 0h to make sure proper DMA configuration.

Copyright © 2024 Texas Instruments Incorporated

### 18.3.9 SPI High-Speed Mode

The SPI module is capable of reaching full-duplex communication speeds up to LSPCLK/4 (where LSPCLK equals SYSCLK). For the maximum rated speed, refer to the device data sheet.

To achieve the maximum full-duplex speeds, the following restrictions are placed on the design:

- Single master to single slave configuration is supported.
- Loading on the pins must not exceed the value stated in the device data sheet.

When configuring the GPIOs to support high-speed mode, refer to Section 18.2.2.1 for more information.

### 18.3.10 SPI 3-Wire Mode Description

SPI 3-wire mode allows for SPI communication over three pins instead of the normal four pins.

In master mode, if the TRIWIRE bit is set, enabling 3-wire SPI mode, SPISIMOx becomes the bi-directional SPIMOMIx (SPI master out, master in) pin, and SPISOMIx is no longer used by the SPI. In slave mode, if the TRIWIRE bit is set, SPISOMIx becomes the bi-directional SPISISOx (SPI slave in, slave out) pin, and SPISIMOx is no longer used by the SPI.

Table 18-4 indicates the pin function differences between 3-wire and 4-wire SPI mode for a master and slave SPI.

**Table 18-4. 4-wire versus 3-wire SPI Pin Functions**

| 4-wire SPI | 3-wire SPI (Master) | 3-wire SPI (Slave) |
|---|---|---|
| SPICLKx | SPICLKx | SPICLKx |
| SPISTEx | SPISTEx | SPISTEx |
| SPISIMOx | SPIMOMIx | Free |
| SPISOMIx | Free | SPISISOx |

Because in 3-wire mode, the receive and transmit paths within the SPI are connected, any data transmitted by the SPI module is also received. The application software must take care to perform a dummy read to clear the SPI data register of the additional received data.

The TALK bit plays an important role in 3-wire SPI mode. The bit must be set to transmit data and cleared prior to reading data. In master mode, to initiate a read, the application software must write dummy data to the SPI data register (SPIDAT or SPIRXBUF) while the TALK bit is cleared (no data is transmitted out the SPIMOMI pin) before reading from the data register.

Figure 18-9 and Figure 18-10 illustrate 3-wire master and slave mode.

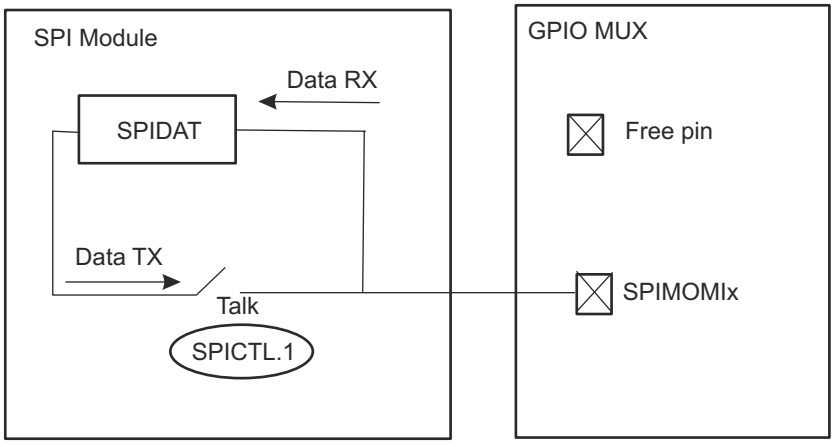

**Figure 18-9. SPI 3-wire Master Mode**

Copyright © 2024 Texas Instruments Incorporated

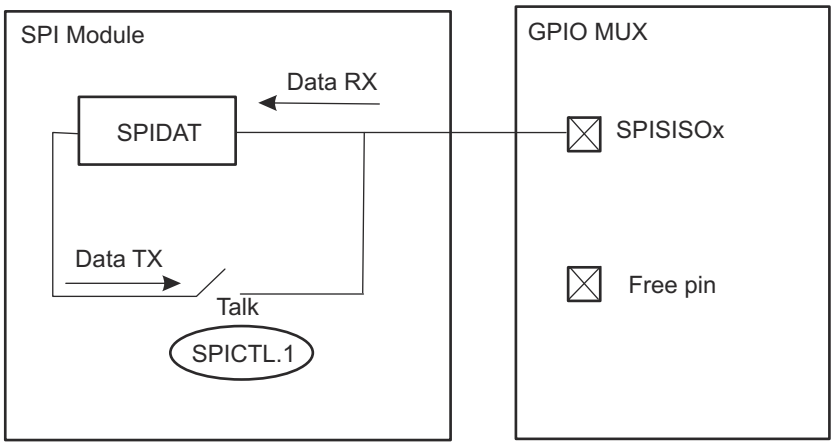

**Figure 18-10. SPI 3-wire Slave Mode**

Table 18-5 indicates how data is received or transmitted in the various SPI modes while the TALK bit is set or cleared.

**Table 18-5. 3-Wire SPI Pin Configuration**

| Pin Mode | SPIPRI[TRIWIRE] | SPICTL[TALK] | SPISIMO | SPISOMI |
|---|---|---|---|---|
| | | **Master Mode** | | |
| 4-wire | 0 | X | TX | RX |
| 3-pin mode | 1 | 0 | RX | Disconnect from SPI |
| | | 1 | TX/RX | |
| | | **Slave Mode** | | |
| 4-wire | 0 | X | RX | TX |
| 3-pin mode | 1 | 0 | Disconnect from SPI | RX |
| | | 1 | | TX/RX |

## 18.4 Programming Procedure

This section describes the procedure for configuring the SPI for the various modes of operation.

### *18.4.1 Initialization Upon Reset*

A system reset forces the SPI peripheral into the following default configuration:

- Unit is configured as a slave module (MASTER_SLAVE = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h

### *18.4.2 Configuring the SPI*

This section describes the procedure in which to configure the SPI module for operation. To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPISWRESET bit before making initialization changes, and then set this bit after initialization is complete. While the SPI is held in reset (SPISWRESET = 0), configuration can be changed in any order. The following list shows the SPI configuration procedure in a logical order. However, the SPI registers can be written with single 16-bit writes, so the order is not required with the exception of SPISWRESET.

**Note**

Do not change the SPI configuration when communication is in progress.

To change the SPI configuration:

1. Clear the SPI Software Reset bit (SPISWRESET) to 0 to force the SPI to the reset state.
2. Configure the SPI as desired:
   - Select either master or slave mode (MASTER_SLAVE).
   - Choose SPICLK polarity and phase (CLKPOLARITY and CLK_PHASE).
   - Set the desired baud rate (SPIBRR).
   - Enable high-speed mode, if desired (HS_MODE).
   - Set the SPI character length (SPICHAR).
   - Clear the SPI Flags (OVERRUN_FLAG, INT_FLAG).
   - Enable $\overline{\text{SPISTE}}$ inversion (STEINV), if needed.
   - Enable 3-wire mode (TRIWIRE), if needed.
   - If using FIFO enhancements:
     - Enable the FIFO enhancements (SPIFFENA).
     - Clear the FIFO Flags (TXFFINTCLR, RXFFOVFCLR, and RXFFINTCLR).
     - Release transmit and receive FIFO resets (TXFIFO and RXFIFORESET).
     - Release SPI FIFO channels from reset (SPIRST).
3. If interrupts are used:
   - In non-FIFO mode, enable the receiver overrun and/or SPI interrupts (OVERRUNINTENA and SPIINTENA).
   - In FIFO mode, set the transmit and receive interrupt levels (TXFFIL and RXFFIL) then enable the interrupts (TXFFIENA and RXFFIENA).
4. Set SPISWRESET to 1 to release the SPI from the reset state.

Copyright © 2024 Texas Instruments Incorporated

### 18.4.3 Configuring the SPI for High-Speed Mode

To achieve the maximum rated speeds, the following settings must be made. This example assumes that the device is operating at 100MHz.

Set LSPCLK equal to SYSCLK:

```
ClkCfgRegs.LOSPCP.bit.LSPCLKDIV = 0;
```

Select the appropriate Pin Mux options in GPIO_CTRL_REGS.

During the SPI configuration procedure:

Set HS_MODE to 1.

```
SpiaRegs.SPICCR.bit.HS_MODE = 0x1;
```

Set SPIBRR to 3. SPICLK = LSPCLK/(SPIBRR+1) = 25MHz

```
SpiaRegs.SPIBRR = 0x3;
```

There are no other differences in the configuration from normal SPI operation. Sending and receiving data, DMA operation, and interrupts operates without change.

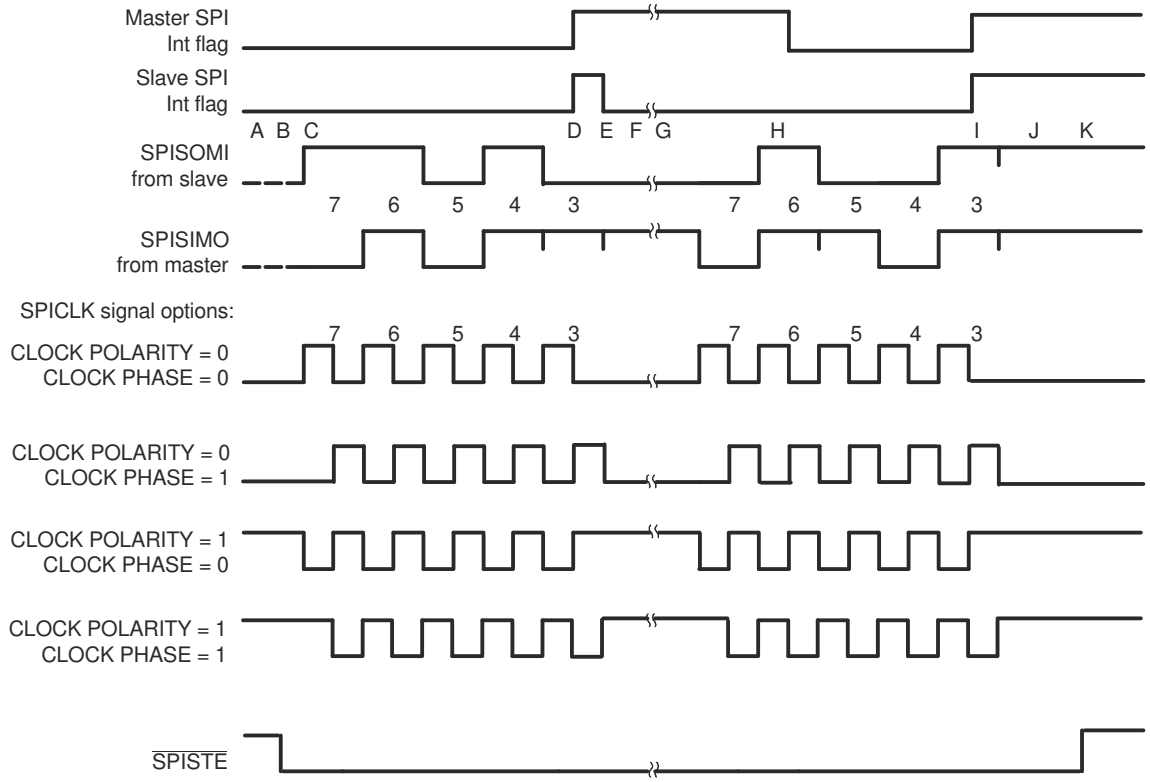
Copyright © 2024 Texas Instruments Incorporated

### 18.4.4 Data Transfer Example

The timing diagram shown in Figure 18-11 shows an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK asymmetrical (Figure 18-8) shares similar characterizations with Figure 18-11 except that the data transfer is one LSPCLK cycle longer per bit during the low pulse (CLKPOLARITY = 0) or during the high pulse (CLKPOLARITY = 1) of the SPICLK.

Figure 18-11 is applicable for 8-bit SPI only and is not for C28x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.



A. Slave writes 0D0h to SPIDAT and waits for the master to shift out the data.
B. Master sets the slave $\overline{\text{SPISTE}}$ signal low (active).
C. Master writes 058h to SPIDAT, which starts the transmission procedure.
D. First byte is finished and sets the interrupt flags.
E. Slave reads 0Bh from the SPIRXBUF (right-justified).
F. Slave writes 04Ch to SPIDAT and waits for the master to shift out the data.
G. Master writes 06Ch to SPIDAT, which starts the transmission procedure.
H. Master reads 01Ah from the SPIRXBUF (right-justified).
I. Second byte is finished and sets the interrupt flags.
J. Master reads 89h and the slave reads 8Dh from the respective SPIRXBUF. After the user software masks off the unused bits, the master receives 09h and the slave receives 0Dh.
K. Master clears the slave $\overline{\text{SPISTE}}$ signal high (inactive).

### 18.4.5 SPI 3-Wire Mode Code Examples

In addition to the normal SPI initialization, to configure the SPI module for 3-wire mode, the TRIWIRE bit (SPIPRI.0) must be set to 1. After initialization, there are several considerations to take into account when transmitting and receiving data in 3-wire master and slave mode. The following examples demonstrate these considerations.

In 3-wire master mode, SPICLKx, $\overline{\text{SPISTE}}$x, and SPISIMOx pins must be configured as SPI pins (SPISOMIx pin can be configured as non-SPI pin). When the master transmits, the master receives the data the master transmits (because SPISIMOx and SPISOMIx are connected internally in 3-wire mode). Therefore, the junk data received must be cleared from the receive buffer every time data is transmitted.

***Example 18-4. 3-Wire Master Mode Transmit***

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data; // Master transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data because
                                                // rx'd same data as tx'd
```

To receive data in 3-wire master mode, the master must clear the TALK (SPICTL.1) bit to 0 to close the transmit path and then transmit dummy data to initiate the transfer from the slave. Because the TALK bit is 0, unlike in transmit mode, the master dummy data does not appear on the SPISIMOx pin, and the master does not receive the dummy data. Instead, the data from the slave is received by the master.

***Example 18-5. 3-Wire Master Mode Receive***

```
Uint16 rdata;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
     SpiaRegs.SPITXBUF = dummy;                 // Send dummy to start tx
     // NOTE: because TALK = 0, data does not tx onto SPISIMOA pin
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data received
     rdata = SpiaRegs.SPIRXBUF;                 // Master reads data
```

In 3-wire slave mode, SPICLKx, SPISTEx, and SPISOMIx pins must be configured as SPI pins (SPISIMOx pin can be configured as non-SPI pin). Like in master mode, when transmitting, the slave receives the data transmitted and must clear this junk data from the receive buffer.

***Example 18-6. 3-Wire Slave Mode Transmit***

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data;                  // Slave transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data
```

Copyright © 2024 Texas Instruments Incorporated

As in 3-wire master mode, the TALK bit must be cleared to 0. Otherwise, the slave receives data normally.

***Example 18-7. 3-Wire Slave Mode Receive***

```
Uint16 rdata;
    SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
    rdata = SpiaRegs.SPIRXBUF;                 // Slave reads data
```

### 18.4.6 SPI STEINV Bit in Digital Audio Transfers

On those devices with two SPI modules, enabling the STEINV bit on one of the SPI modules allows the pair of SPIs to receive both left and right-channel digital audio data in slave mode. The SPI module that receives a normal active-low $\overline{\text{SPISTE}}$ signal stores right-channel data, and the SPI module that receives an inverted active-high $\overline{\text{SPISTE}}$ signal stores left-channel data from the master. To receive digital audio data from a digital audio interface receiver, the SPI modules can be connected as shown in Figure 18-12.

**Note**

This configuration is only applicable to slave mode (MASTER_SLAVE = 0). When the SPI is configured as master (MASTER_SLAVE = 1), the STEINV bit has no effect on the $\overline{\text{SPISTE}}$ pin.

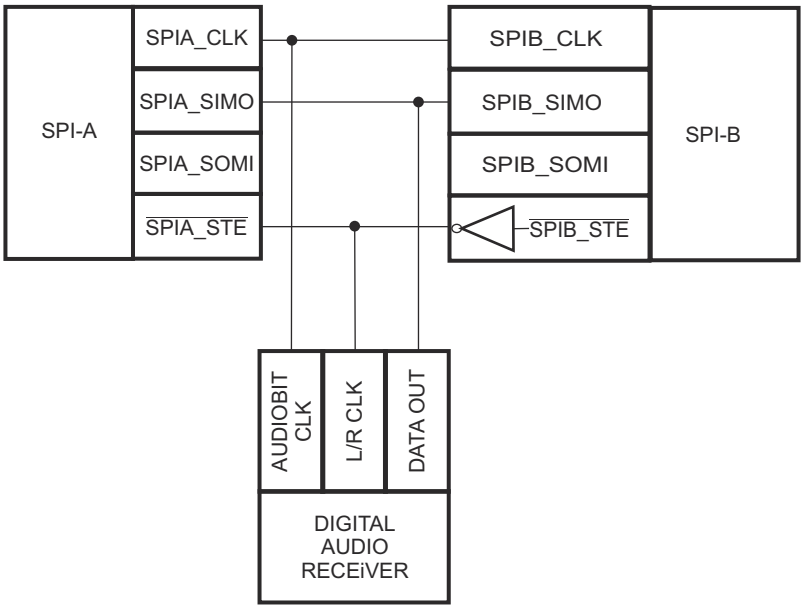

**Figure 18-12. SPI Digital Audio Receiver Configuration Using Two SPIs**

Standard C28x SPI timing requirements limit the number of digital audio interface formats supported using the 2-SPI configuration with the STEINV bit. See the device data sheet electrical specifications for SPI timing requirements. With the SPI clock phase configured such that the CLKPOLARITY bit is 0 and the CLK_PHASE bit is 1 (data latched on rising edge of clock), standard right-justified digital audio interface data format is supported as shown in Figure 18-13.

## 18.5 Software

### *18.5.1 SPI Examples*

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/spi

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

#### 18.5.1.1 SPI Digital Loopback

FILE: spi_ex1_loopback.c

This program uses the internal loopback test mode of the SPI module. This is a very basic loopback that does not use the FIFOs or interrupts. A stream of data is sent and then compared to the received stream. The pinmux and SPI modules are configure through the sysconfig file.

The sent data looks like this:
0000 0001 0002 0003 0004 0005 0006 0007 .... FFFE FFFF 0000

This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

*Watch Variables*

- *sData* - Data to send
- *rData* - Received data

#### 18.5.1.2 SPI Digital Loopback with FIFO Interrupts

FILE: spi_ex2_loopback_fifo_interrupts.c

This program uses the internal loopback test mode of the SPI module. Both the SPI FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

*Watch Variables*

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### 18.5.1.3 SPI Digital External Loopback without FIFO Interrupts

FILE: spi_ex3_external_loopback.c

Copyright © 2024 Texas Instruments Incorporated

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and interrupts are not used in this example. SPIA is configured as a peripheral and SPI B is configured as controller. This example demonstrates full duplex communication where both controller and peripheral transmits and receives data simultaneously.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*
Refer to SysConfig for external connections (GPIO pin numbers) specific to each device

*Watch Variables*
- *TxData_SPIA* - Data send from SPIA (peripheral)
- *TxData_SPIB* - Data send from SPIB (controller)
- *RxData_SPIA* - Data received by SPIA (peripheral)
- *RxData_SPIB* - Data received by SPIB (controller)

#### 18.5.1.4 SPI Digital External Loopback with FIFO Interrupts

FILE: spi_ex4_external_loopback_fifo_interrupts.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and their interrupts are used. SPIA is configured as a peripheral and receives data from SPI B which is configured as a controller.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*
Refer to SysConfig for external connections (GPIO pin numbers) specific to each device

*Watch Variables*
- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### 18.5.1.5 SPI Digital Loopback with DMA

FILE: spi_ex5_loopback_dma.c

This program uses the internal loopback test mode of the SPI module. Both DMA interrupts and the SPI FIFOs are used. When the SPI transmit FIFO has enough space (as indicated by its FIFO level interrupt signal), the DMA will transfer data from global variable sData into the FIFO. This will be transmitted to the receive FIFO via the internal loopback.

When enough data has been placed in the receive FIFO (as indicated by its FIFO level interrupt signal), the DMA will transfer the data from the FIFO into global variable rData.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

Copyright © 2024 Texas Instruments Incorporated

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

*Watch Variables*

- *sData* - Data to send
- *rData* - Received data

#### 18.5.1.6 SPI EEPROM

FILE: spi_ex6_eeprom.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256. Note: SPI character length is configured to 8 bits in SysConfig, and not changed throughout the execution of the program. Runtime updation of character length when CS pin is not controlled by the SPI module can lead to unpredictable behaviour

*External Connections*
*ExternalConnections*

- Connect external SPI EEPROM
- Connect GPIO16 (PICO) to external EEPROM SI pin
- Connect GPIO17 (POCI) to external EEPROM SO pin
- Connect GPIO18 (CLK) to external EEPROM SCK pin
- Connect GPIO11 (CS) to external EEPROM CS pin
- Connect the external EEPROM VCC and GND pins

*Watch Variables*

- writeBuffer - Data that is written to external EEPROM
- readBuffer - Data that is read back from EEPROM
- error - Error count

#### 18.5.1.7 SPI DMA EEPROM

FILE: spi_ex7_eeprom_dma.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI using DMA and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256. Note: Runtime updation of character length when CS pin is not controlled by the SPI module can lead to unpredictable behaviour

*External Connections*
*ExternalConnections*

- Connect external SPI EEPROM
- Connect GPIO16 (PICO) to external EEPROM SI pin
- Connect GPIO17 (POCI) to external EEPROM SO pin
- Connect GPIO18 (CLK) to external EEPROM SCK pin
- Connect GPIO11 (CS) to external EEPROM CS pin
- Connect the external EEPROM VCC and GND pins

*Watch Variables*

- writeBuffer - Data that is written to external EEPROM
- SPI_DMA_Handle.RXdata - Data that is read back from EEPROM when number of received bytes is less than 4
- SPI_DMA_Handle.pSPIRXDMA->pbuffer - Start address of received data from EEPROM
- error - Error count

## 18.6 SPI Registers

This section describes the Serial Peripheral Interface registers. It is important to note that the SPI registers only allow 16-bit accesses.

### *18.6.1 SPI Base Addresses*

**Table 18-6. SPI Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| SpiaRegs | SPI_REGS | 0x0000_6100 | 0x0000_610F |
| SpibRegs | SPI_REGS | 0x0000_6110 | 0x0000_611F |
| SpicRegs | SPI_REGS | 0x0000_6120 | 0x0000_612F |

Copyright © 2024 Texas Instruments Incorporated

### 18.6.2 SPI_REGS Registers

Table 18-7 lists the memory-mapped registers for the SPI_REGS registers. All register offset addresses not listed in Table 18-7 should be considered as reserved locations and the register contents should not be modified.

**Table 18-7. SPI_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | SPICCR | SPI Configuration Control Register | | Go |
| 1h | SPICTL | SPI Operation Control Register | | Go |
| 2h | SPISTS | SPI Status Register | | Go |
| 4h | SPIBRR | SPI Baud Rate Register | | Go |
| 6h | SPIRXEMU | SPI Emulation Buffer Register | | Go |
| 7h | SPIRXBUF | SPI Serial Input Buffer Register | | Go |
| 8h | SPITXBUF | SPI Serial Output Buffer Register | | Go |
| 9h | SPIDAT | SPI Serial Data Register | | Go |
| Ah | SPIFFTX | SPI FIFO Transmit Register | | Go |
| Bh | SPIFFRX | SPI FIFO Receive Register | | Go |
| Ch | SPIFFCT | SPI FIFO Control Register | | Go |
| Fh | SPIPRI | SPI Priority Control Register | | Go |

Complex bit access types are encoded to fit into small table cells. Table 18-8 shows the codes that are used for access types in this section.

**Table 18-8. SPI_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| RC | R<br>C | Read<br>to Clear |
| Write Type | | |
| W | W | Write |
| W1C | W<br>1C | Write<br>1 to clear |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |

### 18.6.2.1 SPICCR Register (Offset = 0h) [Reset = 0000h]

SPICCR is shown in Figure 18-14 and described in Table 18-9.

Return to the Summary Table.

SPICCR controls the setup of the SPI for operation.

**Figure 18-14. SPICCR Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|---|---|---|---|---|---|---|---|
| RESERVED | | | | | | | |
| R-0h | | | | | | | |
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SPISWRESET | CLKPOLARITY | HS_MODE | SPILBK | SPICHAR | | | |
| R/W-0h | R/W-0h | R/W-0h | R/W-0h | R/W-0h | | | |

**Table 18-9. SPICCR Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-8 | RESERVED | R | 0h | Reserved |
| 7 | SPISWRESET | R/W | 0h | SPI Software Reset<br>When changing configuration, you should clear this bit before the changes and set this bit before resuming operation.<br>Reset type: SYSRSn<br>0h (R/W) = Initializes the SPI operating flags to the reset condition. Specifically, the RECEIVER OVERRUN Flag bit (SPISTS.7), the SPI INT FLAG bit (SPISTS.6), and the TXBUF FULL Flag bit (SPISTS.5) are cleared. SPISTE will become inactive. SPICLK will be immediately driven to 0 regardless of the clock polarity. The SPI configuration remains unchanged.<br>1h (R/W) = SPI is ready to transmit or receive the next character. When the SPI SW RESET bit is a 0, a character written to the transmitter will not be shifted out when this bit is set. A new character must be written to the serial data register. SPICLK will be returned to its inactive state one SPICLK cycle after this bit is set. |
| 6 | CLKPOLARITY | R/W | 0h | Shift Clock Polarity<br>This bit controls the polarity of the SPICLK signal. CLOCK POLARITY and POLARITY CLOCK PHASE (SPICTL.3) control four clocking schemes on the SPICLK pin.<br>Reset type: SYSRSn<br>0h (R/W) = Data is output on rising edge and input on falling edge. When no SPI data is sent, SPICLK is at low level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows:<br>- CLOCK PHASE = 0: Data is output on the rising edge of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal.<br>- CLOCK PHASE = 1: Data is output one half-cycle before the first rising edge of the SPICLK signal and on subsequent falling edges of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal.<br>1h (R/W) = Data is output on falling edge and input on rising edge. When no SPI data is sent, SPICLK is at high level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows:<br>- CLOCK PHASE = 0: Data is output on the falling edge of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal.<br>- CLOCK PHASE = 1: Data is output one half-cycle before the first falling edge of the SPICLK signal and on subsequent rising edges of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal. |

### 18.6.2.2 SPICTL Register (Offset = 1h) [Reset = 0000h]

SPICTL is shown in Figure 18-15 and described in Table 18-10.

Return to the Summary Table.

SPICTL controls data transmission, the SPI's ability to generate interrupts, the SPICLK phase, and the operational mode (slave or master).

**Figure 18-15. SPICTL Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

| R-0h | | | R/W-0h | R/W-0h | R/W-0h | R/W-0h | R/W-0h |

**Table 18-10. SPICTL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-5 | RESERVED | R | 0h | Reserved |
| 4 | OVERRUNINTENA | R/W | 0h | Overrun Interrupt Enable<br>Overrun Interrupt Enable. Setting this bit causes an interrupt to be generated when the RECEIVER OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by the RECEIVER OVERRUN Flag bit and the SPI INT FLAG bit (SPISTS.6) share the same interrupt vector.<br>Reset type: SYSRSn<br>0h (R/W) = Disable RECEIVER OVERRUN interrupts.<br>1h (R/W) = Enable RECEIVER_OVERRUN interrupts. |
| 3 | CLK_PHASE | R/W | 0h | SPI Clock Phase Select<br>This bit controls the phase of the SPICLK signal. CLOCK PHASE and CLOCK POLARITY (SPICCR.6) make four different clocking schemes possible (see clocking figures in SPI chapter). When operating with CLOCK PHASE high, the SPI (master or slave) makes the first bit of data available after SPIDAT is written and before the first edge of the SPICLK signal, regardless of which SPI mode is being used.<br>Reset type: SYSRSn<br>0h (R/W) = Normal SPI clocking scheme, depending on the CLOCK POLARITY bit (SPICCR.6).<br>1h (R/W) = SPICLK signal delayed by one half-cycle. Polarity determined by the CLOCK POLARITY bit. |
| 2 | MASTER_SLAVE | R/W | 0h | SPI Network Mode Control<br>This bit determines whether the SPI is a network master or slave. SLAVE During reset initialization, the SPI is automatically configured as a network slave.<br>Reset type: SYSRSn<br>0h (R/W) = SPI is configured as a slave.<br>1h (R/W) = SPI is configured as a master. |

Copyright © 2024 Texas Instruments Incorporated

**Table 18-10. SPICTL Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 1 | TALK | R/W | 0h | Transmit Enable<br>The TALK bit can disable data transmission (master or slave) by placing the serial data output in the high-impedance state. If this bit is disabled during a transmission, the transmit shift register continues to operate until the previous character is shifted out. When the TALK bit is disabled, the SPI is still able to receive characters and update the status flags. TALK is cleared (disabled) by a system reset.<br>Reset type: SYSRSn<br>0h (R/W) = Disables transmission:<br>- Slave mode operation: If not previously configured as a general-purpose I/O pin, the SPISOMI pin will be put in the high-impedance state.<br>- Master mode operation: If not previously configured as a general-purpose I/O pin, the SPISIMO pin will be put in the high-impedance state.<br>1h (R/W) = Enables transmission For the 4-pin option, ensure to enable the receiver's SPISTEn input pin. |
| 0 | SPIINTENA | R/W | 0h | SPI Interrupt Enable<br>This bit controls the SPI's ability to generate a transmit/receive interrupt. The SPI INT FLAG bit (SPISTS.6) is unaffected by this bit.<br>Reset type: SYSRSn<br>0h (R/W) = Disables the interrupt.<br>1h (R/W) = Enables the interrupt. |

Copyright © 2024 Texas Instruments Incorporated

### 18.6.2.3 SPISTS Register (Offset = 2h) [Reset = 0000h]

SPISTS is shown in Figure 18-16 and described in Table 18-11.

Return to the Summary Table.

SPISTS contains interrupt and status bits.

**Figure 18-16. SPISTS Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|---|---|---|---|---|---|---|---|
| RESERVED | | | | | | | |
| R-0h | | | | | | | |
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| OVERRUN_FLAG | INT_FLAG | BUFFULL_FLAG | RESERVED | | | | |
| W1C-0h | RC-0h | R-0h | R-0h | | | | |

**Table 18-11. SPISTS Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-8 | RESERVED | R | 0h | Reserved |
| 7 | OVERRUN_FLAG | W1C | 0h | SPI Receiver Overrun Flag<br>This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit is cleared in one of three ways:<br>- Writing a 1 to this bit<br>- Writing a 0 to SPI SW RESET (SPICCR.7)<br>- Resetting the system<br>If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited.<br>Reset type: SYSRSn<br>0h (R/W) = A receive overrun condition has not occurred.<br>1h (R/W) = The last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application).<br>Writing a '1' will clear this bit. The RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received. |

Copyright © 2024 Texas Instruments Incorporated

**Table 18-11. SPISTS Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 6 | INT_FLAG | RC | 0h | SPI Interrupt Flag<br>SPI INT FLAG is a read-only flag. Hardware sets this bit to indicate that the SPI has completed sending or receiving the last bit and is ready to be serviced. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. The received character is placed in the receiver buffer at the same time this bit is set. This bit is cleared in one of three ways:<br>- Reading SPIRXBUF<br>- Writing a 0 to SPI SW RESET (SPICCR.7)<br>- Resetting the system<br>Note: This bit should not be used if FIFO mode is enabled. The internal process of copying the received word from SPIRXBUF to the Receive FIFO will clear this bit. Use the FIFO status, or FIFO interrupt bits for similar functionality.<br>Reset type: SYSRSn<br>0h (R/W) = No full words have been received or transmitted.<br>1h (R/W) = Indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced. |
| 5 | BUFFULL_FLAG | R | 0h | SPI Transmit Buffer Full Flag<br>This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete.<br>Reset type: SYSRSn<br>0h (R/W) = Transmit buffer is not full.<br>1h (R/W) = Transmit buffer is full. |

### 18.6.2.5 SPIRXEMU Register (Offset = 6h) [Reset = 0000h]

SPIRXEMU is shown in Figure 18-18 and described in Table 18-13.

Return to the Summary Table.

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit of SPISTS. This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

**Figure 18-18. SPIRXEMU Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|---|---|---|---|---|---|---|---|
| ERXBn | | | | | | | |
| R-0h | | | | | | | |
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| ERXBn | | | | | | | |
| R-0h | | | | | | | |

**Table 18-13. SPIRXEMU Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-0 | ERXBn | R | 0h | Emulation Buffer Received Data<br>SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set.<br>This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately.<br>It is recommended that you view SPIRXEMU in the normal emulator run mode.<br>Reset type: SYSRSn |

### 18.6.2.6 SPIRXBUF Register (Offset = 7h) [Reset = 0000h]

SPIRXBUF is shown in Figure 18-19 and described in Table 18-14.

Return to the Summary Table.

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit in SPISTS. If FIFO mode is enabled, reading this register will also decrement the RXFFST counter in SPIFFRX.

**Figure 18-19. SPIRXBUF Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

| 15-0 | RXBn | R | 0h | Received Data<br>Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register.<br>Reset type: SYSRSn |

Copyright © 2024 Texas Instruments Incorporated

### 18.6.2.7 SPITXBUF Register (Offset = 8h) [Reset = 0000h]

SPITXBUF is shown in Figure 18-20 and described in Table 18-15.

Return to the Summary Table.

SPITXBUF stores the next character to be transmitted. Writing to this register sets the TX BUF FULL Flag bit in SPISTS. When the transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no transmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set.
In master mode, if no transmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

**Figure 18-20. SPITXBUF Register**

When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared. Writes to SPITXBUF must be left-justified.<br>Reset type: SYSRSn |

Copyright © 2024 Texas Instruments Incorporated

### 18.6.2.8 SPIDAT Register (Offset = 9h) [Reset = 0000h]

SPIDAT is shown in Figure 18-21 and described in Table 18-16.

Return to the Summary Table.

SPIDAT is the transmit and receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

**Figure 18-21. SPIDAT Register**

Chapter 19

# Serial Communications Interface (SCI)

This chapter describes the features and operation of the serial communication interface (SCI) module. SCI is a two-wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format. The SCI receiver and transmitter each have a 16-level deep FIFO for reducing servicing overhead, and each has a separate enable and interrupt bits. Both can be operated independently for half-duplex communication, or simultaneously for full-duplex communication.

To specify data integrity, the SCI checks received data for break detection, parity, overrun, and framing errors. The bit rate is programmable to different speeds through a 16-bit baud-select register.

## 19.1 Introduction

The SCI interfaces are shown in Figure 19-1.

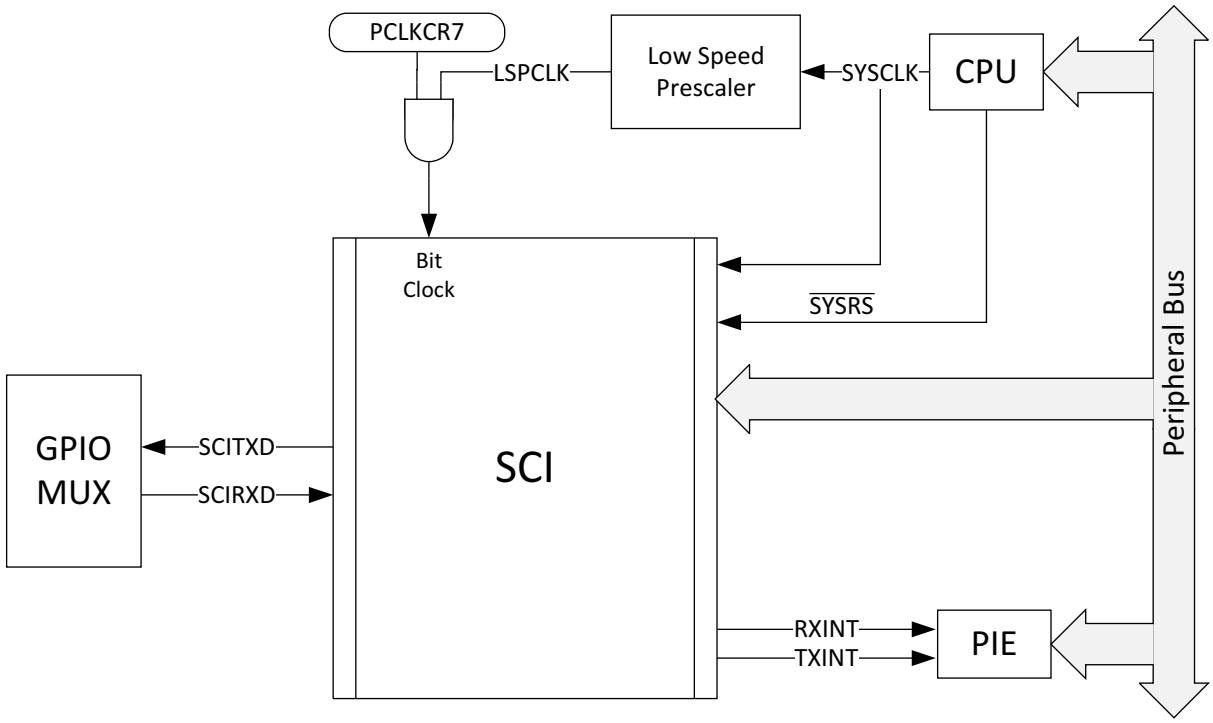

**Figure 19-1. SCI CPU Interface**

### *19.1.1 Features*

Features of the SCI module include:

- Two external pins (both pins can be used as GPIO, if not used for SCI):
  - SCITXD: SCI transmit-output pin
  - SCIRXD: SCI receive-input pin
- Baud rate programmable to 64K different rates
- Data-word format
  - One start bit
  - Data-word length programmable from one to eight bits
  - Optional even/odd/no parity bit
  - One or two stop bits
  - An extra bit to distinguish addresses from data (address bit mode only)
- Four error-detection flags: parity, overrun, framing, and break detection
- Two wake-up multiprocessor modes: idle-line and address bit
- Half- or full-duplex operation
- Double-buffered receive and transmit functions
- Transmitter and receiver operations can be accomplished through interrupt-driven or polled algorithms with status flags
- Separate enable bits for transmitter and receiver interrupts (except BRKDT)
- NRZ (non-return-to-zero) format

Enhanced features include:

- Auto-baud-detect hardware logic
- 16-level transmit/receive FIFO

### 19.1.2 SCI Related Collateral

**Foundational Materials**

- C2000 Academy - SCI
- One Minute RS-485 Introduction (Video)
- RS-232, RS-422, RS-485: What Are the Differences? (Video)

**Getting Started Materials**

- [FAQ] My C2000 SCI is not Transmitting and/or Receiving data correctly, how do I fix this?

### 19.1.3 Block Diagram

Figure 19-2 shows the SCI module block diagram. The SCI port operation is configured and controlled by the registers listed in Section 19.15.

## 19.2 Architecture

The major elements used in full-duplex operation are shown in Figure 19-2 and include:

- A transmitter (TX) and the major registers (upper half of Figure 19-2):
  - SCITXBUF — transmitter data buffer register. Contains data (loaded by the CPU) to be transmitted
  - TXSHF register — transmitter shift register. Accepts data from register SCITXBUF and shifts data onto the SCITXD pin, one bit at a time
- A receiver (RX) and the major registers (lower half of Figure 19-2):
  - RXSHF register — receiver shift register. Shifts data in from SCIRXD pin, one bit at a time
  - SCIRXBUF — receiver data buffer register. Contains data to be read by the CPU. Data from a remote processor is loaded into register RXSHF and then into registers SCIRXBUF and SCIRXEMU
- A programmable baud generator
- Control and status registers

The SCI receiver and transmitter can operate either independently or simultaneously.

## 19.3 SCI Module Signal Summary

A summarized description of each SCI signal name is shown in Table 19-1.

**Table 19-1. SCI Module Signal Summary**

| Signal Name | Description |
|---|---|
| **External signals** | |
| SCIRXD | SCI Asynchronous Serial Port receive data |
| SCITXD | SCI Asynchronous Serial Port transmit data |
| **Control** | |
| Baud clock | LSPCLK Prescaled clock |
| **Interrupt signals** | |
| TXINT | Transmit interrupt |
| RXINT | Receive interrupt |

## 19.4 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 19.5 Multiprocessor and Asynchronous Communication Modes

The SCI has two multiprocessor protocols, the idle-line multiprocessor mode (see Section 19.8) and the address-bit multiprocessor mode (see Section 19.9). These protocols allow efficient data transfer between multiple processors.

The SCI offers the universal asynchronous receiver/transmitter (UART) communications mode for interfacing with many popular peripherals. The asynchronous mode (see Section 19.10) requires two lines to interface with many standard devices such as terminals and printers that use RS-232-C formats. Data transmission characteristics include:

- One start bit
- One to eight data bits
- An even/odd parity bit or no parity bit
- One or two stop bits

Copyright © 2024 Texas Instruments Incorporated

## 19.6 SCI Programmable Data Format

SCI data, both receive and transmit, is in NRZ (non-return-to-zero) format. The NRZ data format, shown in Figure 19-3, consists of:

- One start bit
- One to eight data bits
- An even/odd parity bit (optional)
- One or two stop bits
- An extra bit to distinguish addresses from data (address-bit mode only)

The basic unit of data is called a character and is one to eight bits in length. Each character of data is formatted with a start bit, one or two stop bits, and optional parity and address bits. A character of data with formatting information is called a frame and is shown in Figure 19-3.

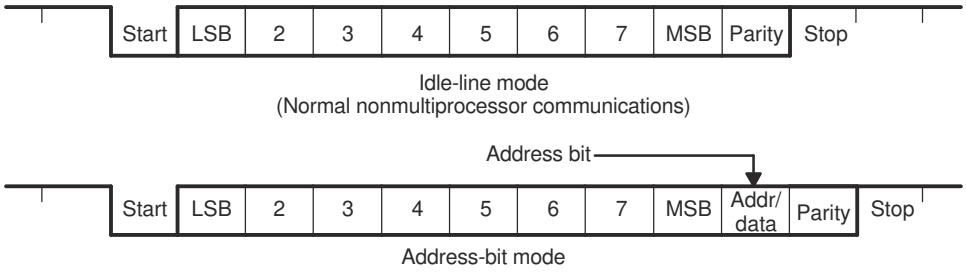

**Figure 19-3. Typical SCI Data Frame Formats**

To program the data format, use the SCICCR register. The bits used to program the data format are shown in Table 19-2.

**Table 19-2. Programming the Data Format Using SCICCR**

| Bits | Bit Name | Designation | Functions |
|---|---|---|---|
| 2-0 | SCICHAR | SCICCR.2:0 | Select the character (data) length (one to eight bits). |
| 5 | PARITYENA (ENABLE) | SCICCR.5 | Enables the parity function if set to 1, or disables the parity function if cleared to 0. |
| 6 | PARITY (EVEN/ODD) | SCICCR.6 | If parity is enabled, selects odd parity if cleared to 0; even parity if set to 1. |
| 7 | STOPBITS | SCICCR.7 | Determines the number of stop bits transmitted—one stop bit if cleared to 0 or two stop bits if set to 1. |

## 19.7 SCI Multiprocessor Communication

The multiprocessor communication format allows one processor to efficiently send blocks of data to other processors on the same serial link. On one serial line, there can be only one transfer at a time. In other words, there can be only one talker on a serial line at a time.

### Address Byte

The first byte of a block of information that the talker sends contains an address byte that is read by all listeners. Only listeners with the correct address can be interrupted by the data bytes that follow the address byte. The listeners with an incorrect address remain uninterrupted until the next address byte.

### Sleep Bit

All processors on the serial link set the SCI SLEEP bit (bit 2 of SCICTL1) to 1 so that the processor is interrupted only when the address byte is detected. When the processor reads a block address that corresponds to the CPU device address as set by your application software, your program must clear the SLEEP bit to enable the SCI to generate an interrupt on receipt of each data byte.

Although the receiver still operates when the SLEEP bit is 1, the receiver does not set RXRDY, RXINT, or any of the receiver error status bits to 1 unless the address byte is detected and the address bit in the received frame is a 1 (applicable to address-bit mode). The SCI does not alter the SLEEP bit; your software must alter the SLEEP bit.

### *19.7.1 Recognizing the Address Byte*

A processor recognizes an address byte differently, depending on the multiprocessor mode used. For example:

- The idle-line mode (Section 19.8) leaves a quiet space before the address byte. This mode does not have an extra address/data bit and is more efficient than the address-bit mode for handling blocks that contain more than 10 bytes of data. The idle-line mode must be used for typical non-multiprocessor SCI communication.
- The address-bit mode (Section 19.9) adds an extra bit (that is, an address bit) into every byte to distinguish addresses from data. This mode is more efficient in handling many small blocks of data because, unlike the idle mode, this mode does not wait between blocks of data. However, at a high transmit speed, the program is not fast enough to avoid a 10-bit idle in the transmission stream.

### *19.7.2 Controlling the SCI TX and RX Features*

The multiprocessor mode is software selectable using the ADDR/IDLE MODE bit (SCICCR, bit 3). Both modes use the TXWAKE flag bit (SCICTL1, bit 3), RXWAKE flag bit (SCIRXST, bit1), and the SLEEP flag bit (SCICTL1, bit 2) to control the SCI transmitter and receiver features of these modes.

### *19.7.3 Receipt Sequence*

In both multiprocessor modes, the receive sequence is as follows:

1. At the receipt of an address block, the SCI port wakes up and requests an interrupt (bit number 1 RX/BK INT ENA-of SCICTL2 must be enabled to request an interrupt in non-FIFO mode of operation. In FIFO mode, RXFFINT serves this purpose and to enable this, RXFFINTEN in SCIFFRX register must be enabled with RXFFIL in the same register set to 1). The SCI reads the first frame of the block, which contains the destination address.
2. A software routine is entered through the interrupt and checks the incoming address. This address byte is checked against the device address byte stored in memory.
3. If the check shows that the block is addressed to the device CPU, the CPU clears the SLEEP bit and reads the rest of the block. If not, the software routine exits with the SLEEP bit still set, and does not receive interrupts until the next block start.

Copyright © 2024 Texas Instruments Incorporated

## 19.8 Idle-Line Multiprocessor Mode

In the idle-line multiprocessor protocol (ADDR/IDLE MODE bit=0), blocks are separated by having a longer idle time between the blocks than between frames in the blocks. An idle time of ten or more high-level bits after a frame indicates the start of a new block. The time of a single bit is calculated directly from the baud value (bits per second). The idle-line multiprocessor communication format is shown in Figure 19-4 (ADDR/IDLE MODE bit is bit 3 of SCICCR).

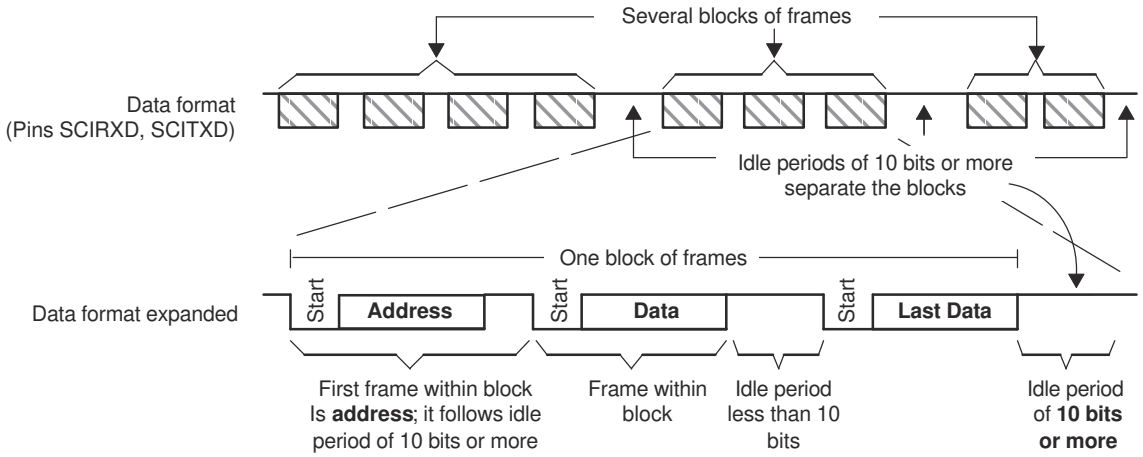

**Figure 19-4. Idle-Line Multiprocessor Communication Format**

### *19.8.1 Idle-Line Mode Steps*

The steps followed by the idle-line mode:

1. SCI wakes up after receipt of the block-start signal.
2. The processor recognizes the next SCI interrupt.
3. The interrupt service routine compares the received address (sent by a remote transmitter) to the ISR address.
4. If the CPU is being addressed, the service routine clears the SLEEP bit and receives the rest of the data block.
5. If the CPU is not being addressed, the SLEEP bit remains set. This lets the CPU continue to execute the main program without being interrupted by the SCI port until the next detection of a block start.

**Note**

In IDLE mode, if the SCI is taking greater than 10 bit periods to read all the RXDATA from the FIFO, the SCI can miss the immediate block start to be detected.

The RXWAKE logic asserts only one time when the SCI identifies 10 bit periods of IDLE. The SCI does not assert again if RXBUF is read (which clears the WAKE condition) even if the line continues to be idle after RXBUF read.

So, if the ISR is taking more than 10 bit periods of time to read all the RXDATA from the FIFO using RXBUF, the SCI can miss to detect the next block start. This is applicable for both FIFO and Non-FIFO mode when the CPU takes greater than 10 bit clocks of SCI to read the data from RXBUF/ FIFO.

To avoid this, either of the following is recommended:

- Set SCICTL1.SWRESET after reading all RX data at the end of the ISR.
- Read and check RXWAKE status bit before reading the RXBUF register. If RXWAKE is set, don't set SLEEP bit for RX at the end of the ISR.

Copyright © 2024 Texas Instruments Incorporated

### 19.8.2 Block Start Signal

There are two ways to send a block-start signal:

- **Method 1:** Deliberately leave an idle time of ten bits or more by delaying the time between the transmission of the last frame of data in the previous block and the transmission of the address frame of the new block.
- **Method 2:** The SCI port first sets the TXWAKE bit (SCICTL1, bit 3) to 1 before writing to the SCITXBUF register. This sends an idle time of exactly 11 bits. In this method, the serial communications line is not idle any longer than necessary. (A don't care byte has to be written to SCITXBUF after setting TXWAKE, and before sending the address, so as to transmit the idle time.)

### 19.8.3 Wake-Up Temporary (WUT) Flag

Associated with the TXWAKE bit is the wake-up temporary (WUT) flag. WUT is an internal flag, double-buffered with TXWAKE. When TXSHF is loaded from SCITXBUF, WUT is loaded from TXWAKE, and the TXWAKE bit is cleared to 0. This arrangement is shown in Figure 19-5.

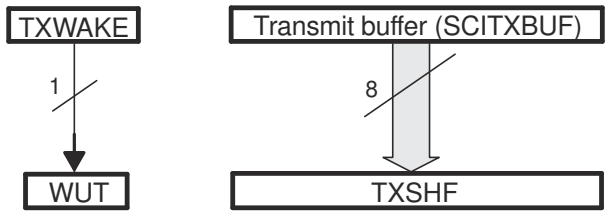

**Figure 19-5. Double-Buffered WUT and TXSHF**

#### 19.8.3.1 Sending a Block Start Signal

To send out a block-start signal of exactly one frame time during a sequence of block transmissions:

1. Write a 1 to the TXWAKE bit.
2. Write a data word (content not important: a don’t care) to the SCITXBUF register (transmit data buffer) to send a block-start signal. (The first data word written is suppressed while the block-start signal is sent out and ignored after that.) When the TXSHF (transmit shift register) is free again, SCITXBUF contents are shifted to TXSHF, the TXWAKE value is shifted to WUT, and then TXWAKE is cleared.

   Because TXWAKE was set to a 1, the start, data, and parity bits are replaced by an idle period of 11 bits transmitted following the last stop bit of the previous frame.
3. Write a new address value to SCITXBUF.

   A don’t-care data word must first be written to register SCITXBUF so that the TXWAKE bit value can be shifted to WUT. After the don’t-care data word is shifted to the TXSHF register, the SCITXBUF (and TXWAKE, if necessary) can be written to again because TXSHF and WUT are both double-buffered.

### 19.8.4 Receiver Operation

The receiver operates regardless of the SLEEP bit. However, the receiver neither sets RXRDY nor the error status bits, nor does it request a receive interrupt until an address frame is detected.

Copyright © 2024 Texas Instruments Incorporated

## 19.9 Address-Bit Multiprocessor Mode

In the address-bit protocol (ADDR/IDLE MODE bit=1), frames have an extra bit called an address bit that immediately follows the last data bit. The address bit is set to 1 in the first frame of the block and to 0 in all other frames. The idle period timing is irrelevant (see Figure 19-6).

### *19.9.1 Sending an Address*

The TXWAKE bit value is placed in the address bit. During transmission, when the SCITXBUF register and TXWAKE are loaded into the TXSHF register and WUT respectively, TXWAKE is reset to 0 and WUT becomes the value of the address bit of the current frame. Thus, to send an address:

1. Set the TXWAKE bit to 1 and write the appropriate address value to the SCITXBUF register.

   When this address value is transferred to the TXSHF register and shifted out, the address bit is sent as a 1. This flags the other processors on the serial link to read the address.
2. Write to SCITXBUF and TXWAKE after TXSHF and WUT are loaded. (Can be written to immediately since both TXSHF and WUT are both double-buffered.
3. Leave the TXWAKE bit set to 0 to transmit non-address frames in the block.

**Note**

As a general rule, the address-bit format is typically used for data frames of 11 bytes or less. This format adds one bit value (1 for an address frame, 0 for a data frame) to all data bytes transmitted. The idle-line format is typically used for data frames of 12 bytes or more.

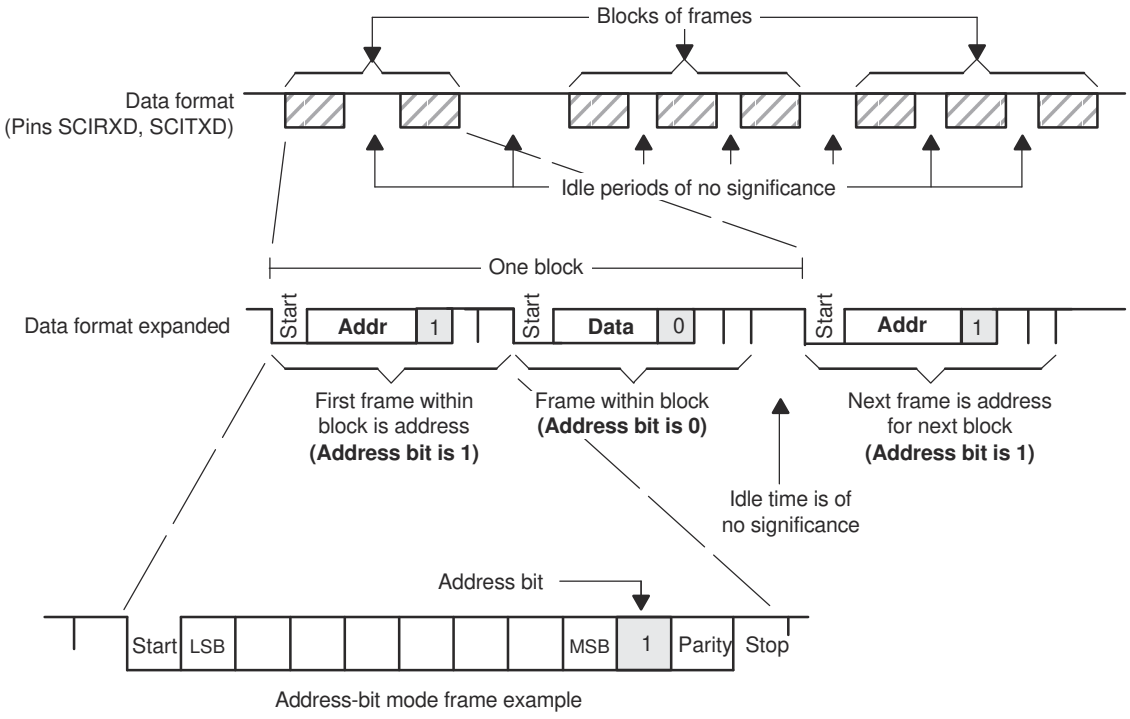

**Figure 19-6. Address-Bit Multiprocessor Communication Format**

Copyright © 2024 Texas Instruments Incorporated

## 19.10 SCI Communication Format

The SCI asynchronous communication format uses either single line (one way) or two line (two way) communications. In this mode, the frame consists of a start bit, one to eight data bits, an optional even/odd parity bit, and one or two stop bits (shown in Figure 19-7). There are eight SCICLK periods per data bit.

The receiver begins operation on receipt of a valid start bit. A valid start bit is identified by four consecutive internal SCICLK periods of zero bits as shown in Figure 19-7. If any bit is not zero, then the processor starts over and begins looking for another start bit.

For the bits following the start bit, the processor determines the bit value by making three samples in the middle of the bits. These samples occur on the fourth, fifth, and sixth SCICLK periods, and bit-value determination is on a majority (two out of three) basis. Figure 19-7 illustrates the asynchronous communication format for this with a start bit showing where a majority vote is taken.

Since the receiver synchronizes to frames, the external transmitting and receiving devices do not use a synchronized serial clock. The clock can be generated locally.

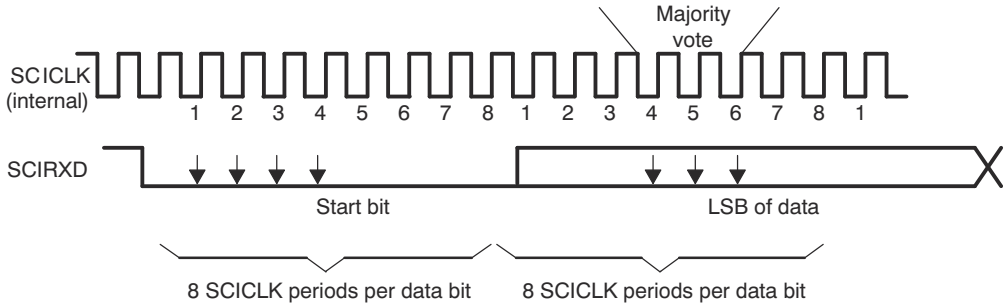

**Figure 19-7. SCI Asynchronous Communications Format**

### 19.10.1 Receiver Signals in Communication Modes

Figure 19-8 illustrates an example of receiver signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Six bits per character

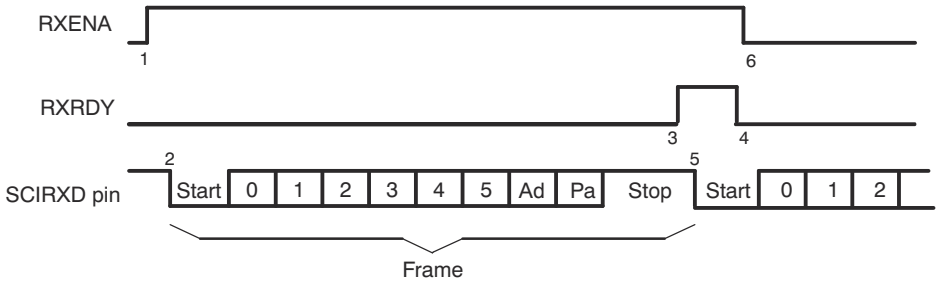

**Figure 19-8. SCI RX Signals in Communication Modes**

Notes:

1. Flag bit RXENA (SCICTL1, bit 0) goes high to enable the receiver.
2. Data arrives on the SCIRXD pin, start bit detected.
3. Data is shifted from RXSHF to the receiver buffer register (SCIRXBUF); an interrupt is requested. Flag bit RXRDY (SCIRXST, bit 6) goes high to signal that a new character has been received.
4. The program reads SCIRXBUF; flag RXRDY is automatically cleared.
5. The next byte of data arrives on the SCIRXD pin; the start bit is detected, then cleared.
6. Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.

Copyright © 2024 Texas Instruments Incorporated

### 19.10.2 Transmitter Signals in Communication Modes

Figure 19-9 illustrates an example of transmitter signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Three bits per character

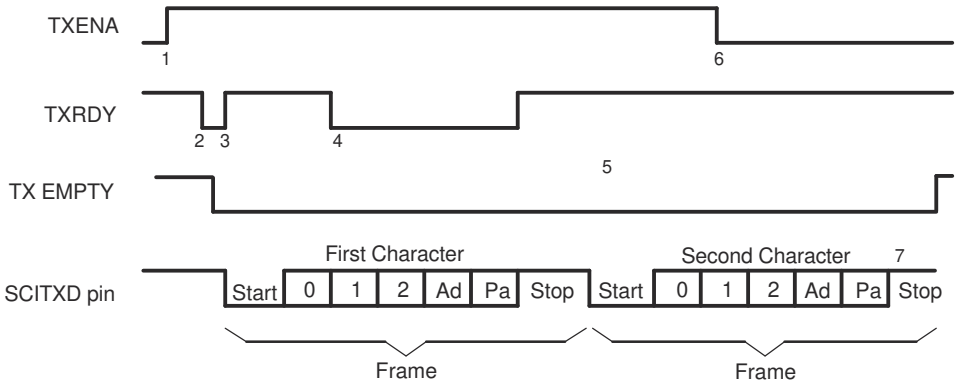

**Figure 19-9. SCI TX Signals in Communications Mode**

Notes:

1. Bit TXENA (SCICTL1, bit 1) goes high, enabling the transmitter to send data.
2. SCITXBUF is written to; thus, (1) the transmitter is no longer empty, and (2) TXRDY goes low.
3. The SCI transfers data to the shift register (TXSHF). The transmitter is ready for a second character (TXRDY goes high), and it requests an interrupt (to enable an interrupt, bit TX INT ENA — SCICTL2, bit 0 — must be set).
4. The program writes a second character to SCITXBUF after TXRDY goes high (item 3). (TXRDY goes low again after the second character is written to SCITXBUF.)
5. Transmission of the first character is complete. Transfer of the second character to shift register TXSHF begins.
6. Bit TXENA goes low to disable the transmitter; the SCI finishes transmitting the current character.
7. Transmission of the second character is complete; transmitter is empty and ready for new character.

Copyright © 2024 Texas Instruments Incorporated

## 19.11 SCI Port Interrupts

The SCI receiver and transmitter can be interrupt controlled. The SCICTL2 register has one flag bit (TXRDY) that indicates active interrupt conditions, and the SCIRXST register has two interrupt flag bits (RXRDY and BRKDT), plus the RX ERROR interrupt flag that is a logical-OR of the FE, OE, BRKDT, and PE conditions. The transmitter and receiver have separate interrupt-enable bits. When not enabled, the interrupts are not asserted; however, the condition flags remain active, reflecting transmission and receipt status.

The SCI has independent peripheral interrupt vectors for the receiver and transmitter. Peripheral interrupt requests can be either high priority or low priority. This is indicated by the priority bits that are output from the peripheral to the PIE controller. When both RX and TX interrupt requests are made at the same priority level, the receiver always has higher priority than the transmitter, reducing the possibility of receiver overrun.

The operation of peripheral interrupts is described in the Peripheral Interrupts section of the *System Control and Interrupts* chapter.

- If the RX/BK INT ENA bit (SCICTL2, bit 1) is set, the receiver peripheral interrupt request is asserted when one of the following events occurs:
  - The SCI receives a complete frame and transfers the data in the RXSHF register to the SCIRXBUF register. This action sets the RXRDY flag (SCIRXST, bit 6) and initiates an interrupt.
  - A break detect condition occurs (the SCIRXD is low for 9.625 bit periods following a missing stop bit). This action sets the BRKDT flag bit (SCIRXST, bit 5) and initiates an interrupt.
- If the TX INT ENA bit (SCICTL2.0) is set, the transmitter peripheral interrupt request is asserted whenever the data in the SCITXBUF register is transferred to the TXSHF register, indicating that the CPU can write to SCITXBUF; this action sets the TXRDY flag bit (SCICTL2, bit 7) and initiates an interrupt.

**Note**

Interrupt generation due to the RXRDY and BRKDT bits is controlled by the RX/BK INT ENA bit (SCICTL2, bit 1). Interrupt generation due to the RX ERROR bit is controlled by the RX ERR INT ENA bit (SCICTL1, bit 6).

Copyright © 2024 Texas Instruments Incorporated

### 19.11.1 Break Detect

A "break" signal (also called a "break detect" or "break sequence") can be sent to the module to signal to the bus a specific condition. This break signal is defined as a low pulse of a certain amount of time, typically at least 1 packet wide (including a missed stop bit). The SCI has two main methods for detecting a "break" signal sent on the line, with certain limitations for each.

The first for break detect method involves reading the SCIRXST.BRKDT bit. A break condition that triggers the BRKDT bit occurs when the SCI receiver data line (SCIRXD) remains continuously low for at least 9.625 bits, beginning after a missing first stop bit. If the SCIRX line goes high at any point during the 9.625 bits then the SCI does not flag a break detect. To trigger the first stop bit missed, the typical method is to hold the RX line low for:

- 1 start bit
- 8 data bits
- (optional) 1 address bit
- (optional) 1 parity bit
- 1 stop bit
- 9.625 bits of additional time held low

This is a total of 19.625 (systems using no parity or address bit), 20.625 (systems using either parity or address bit but not both), or 21.625 (systems using both parity and address bit) bit times held low.

The second method for break detect is to instead use the SCIRXST.FE, SCIRXST.PE and SCIRXBUF.SAR bits to detect a break signal of 10 or 11 bits of low. ISR code can use the following combination of flags and received data to determine if a break detect occurred:

- Break signal = 11 bits low (requires parity enabled)
  - FE==1
  - PE==1 for odd parity, PE==0 for even parity
  - SCIRXBUF.SAR (received character)==0x00
- Break signal = 10 bits low (requires parity disabled)
  - FE==1
  - SCIRXBUF.SAR (received character)==0x00

## 19.12 SCI Baud Rate Calculations

The internally generated serial clock is determined by the low-speed peripheral clock LSPCLK) and the baud-select registers. The SCI uses the 16-bit value of the baud-select registers to select one of the 64K different serial clock rates possible for a given LSPCLK.

See the bit descriptions in the baud-select registers, for the formula to use when calculating the SCI asynchronous baud. Table 19-3 shows the baud-select values for common SCI bit rates. LSPCLK/16 is the maximum baud rate. For example, if LSPCLK is 100MHz, then the maximum baud rate is 6.25Mbps.

**Table 19-3. Asynchronous Baud Register Values for Common SCI Bit Rates**

| | LSPCLK Clock Frequency, 100MHz | | |
|---|---|---|---|
| Baud Rate | BRR | Actual Baud Rate | % Error |
| 2400 | 5207 (1457h) | 2400 | 0 |
| 4800 | 2603 (A2Bh) | 4800 | 0 |
| 9600 | 1301 (515h) | 9601 | 0.01 |
| 19200 | 650 (28Ah) | 19201 | 0.01 |
| 38400 | 324 (144h) | 38462 | 0.16 |

## 19.13 SCI Enhanced Features

The C28x SCI features autobaud detection and transmit/receive FIFO. The following section explains the FIFO operation.

### *19.13.1 SCI FIFO Description*

The following steps explain the FIFO features and help with programming the SCI with FIFOs.

1. **Reset.** At reset the SCI powers up in standard SCI mode and the FIFO function is disabled. The FIFO registers SCIFFTX, SCIFFRX, and SCIFFCT remain inactive.
2. **Standard SCI.** The standard SCI modes work normally with TXINT/RXINT interrupts as the interrupt source for the module.
3. **FIFO enable.** FIFO mode is enabled by setting the SCIFFEN bit in the SCIFFTX register. SCIRST can reset the FIFO mode at any stage of the operation.
4. **Active registers.** All the SCI registers and SCI FIFO registers (SCIFFTX, SCIFFRX, and SCIFFCT) are active.
5. **Interrupts.** FIFO mode has two interrupts; transmit FIFO (TXINT) and receive FIFO (RXINT). The RXINT is the common interrupt for SCI FIFO receive, receive error, and receive FIFO overflow conditions. The TXINT of the standard SCI is disabled and this interrupt serves as SCI transmit FIFO interrupt.
6. **Buffers.** Transmit and receive buffers are supplemented with two 16-level FIFOs. The transmit FIFO registers are 8-bits wide and receive FIFO registers are 10-bits wide. The one-word transmit buffer (SCITXBUF) of the standard SCI functions as a transition buffer before the transmit FIFO and shift register. SCITXBUF is loaded into either the FIFO (when FIFO is enabled) or the TXSHF (when FIFO is disabled). When FIFO is enabled, SCITXBUF loads into the FIFO only after the last bit of the shift register is shifted out, so SCITXBUF cannot be treated as an additional level of buffer. With the FIFO enabled, TXSHF is directly loaded from the FIFO (not TXBUF) after an optional delay value (SCIFFCT). When FIFO mode is enabled for SCI, characters written to SCITXBUF are queued in to SCI-TXFIFO and the characters received in SCI-RXFIFO can be read using SCIRXBUF.
7. **Delayed transfer.** The rate that words in the FIFO are transferred to the transmit shift register is programmable. The SCIFFCT register bits (7−0) FFTXDLY7−FFTXDLY0 define the delay between the word transfer. The delay is defined in the number SCI baud clock cycles. The 8 bit register can define a minimum delay of 0 baud clock cycles and a maximum of 256-baud clock cycles. With zero delay, the SCI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 256 clock delay the SCI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 256 baud clocks between each words. The programmable delay facilitates communication with slow SCI/UARTs with little CPU intervention.
8. **FIFO status bits.** Both the transmit and receive FIFOs have status bits TXFFST or RXFFST (bits 12−8) that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit TXFIFO and receive reset bit RXFIFO reset the FIFO pointers to zero when these bits are cleared to 0. The FIFOs resumes operation from start once these bits are set to 1.
9. **Programmable interrupt levels.** Both transmit and receive FIFO can generate CPU interrupts. The interrupt trigger is generated whenever the transmit FIFO status bits TXFFST (bits 12−8) match (less than or equal to) the interrupt trigger level bits TXFFIL (bits 4−0). This provides a programmable interrupt trigger for transmit and receive sections of the SCI. Default value for these trigger level bits is 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

Figure 19-10 and Table 19-4 explain the operation/configuration of SCI interrupts in nonFIFO/FFO mode.

Copyright © 2024 Texas Instruments Incorporated

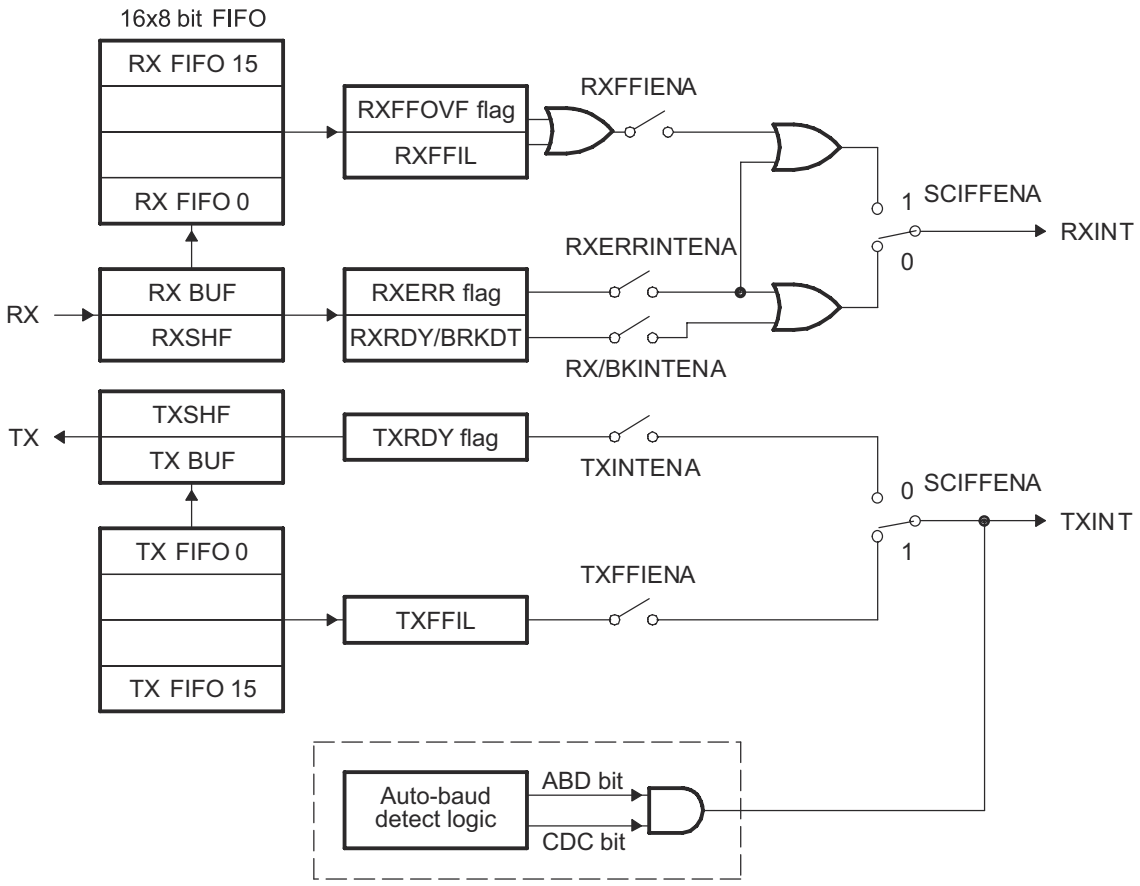

**Figure 19-10. SCI FIFO Interrupt Flags and Enable Logic**

**Table 19-4. SCI Interrupt Flags**

| FIFO Options[1] | SCI Interrupt Source | Interrupt Flags | Interrupt Enables | FIFO Enable SCIFFENA | Interrupt Line |
|---|---|---|---|---|---|
| SCI without FIFO | Receive error | RXERR[2] | RXERRINTENA | 0 | RXINT |
| | Receive break | BRKDT | RX/BKINTENA | 0 | RXINT |
| | Data receive | RXRDY | RX/BKINTENA | 0 | RXINT |
| | Transmit empty | TXRDY | TXINTENA | 0 | TXINT |
| SCI with FIFO | Receive error and receive break | RXERR | RXERRINTENA | 1 | RXINT |
| | FIFO receive | RXFFIL | RXFFIENA | 1 | RXINT |
| | Transmit empty | TXFFIL | TXFFIENA | 1 | TXINT |
| Auto-baud | Auto-baud detected | ABD | Don't care | x | TXINT |

(1) FIFO mode TXSHF is directly loaded after delay value, TXBUF is not used.
(2) RXERR can be set by BRKDT, FE, OE, PE flags. In FIFO mode, BRKDT interrupt is only through RXERR flag.

### 19.13.2 SCI Auto-Baud

Most SCI modules do not have an auto-baud detect logic built-in hardware. These SCI modules are integrated with embedded controllers whose clock rates are dependent on PLL reset values. Often embedded controller clocks change after final design. In the enhanced feature set this module supports an autobaud-detect logic in hardware. The following section explains the enabling sequence for autobaud-detect feature.

### 19.13.3 Autobaud-Detect Sequence

Bits ABD and CDC in SCIFFCT control the autobaud logic. The SCIRST bit can be enabled to make autobaud logic work.

If ABD is set while CDC is 1, which indicates auto-baud alignment, SCI transmit FIFO interrupt occurs (TXINT). After the interrupt service, the CDC bit must be cleared by software. If CDC remains set even after interrupt service, there can be no repeat interrupts.

1. Enable autobaud-detect mode for the SCI by setting the CDC bit (bit 13) in SCIFFCT and clearing the ABD bit (bit 15) by writing a 1 to ABDCLR bit (bit 14).
2. Initialize the baud register to be 1 or less than a baud rate limit of 500Kbps.
3. Allow SCI to receive either character "A" or "a" from a host at the desired baud rate. If the first character is either "A" or "a", the autobaud-detect hardware detects the incoming baud rate and sets the ABD bit.
4. The auto-detect hardware updates the baud rate register with the equivalent baud value hex. The logic also generates an interrupt to the CPU.
5. Respond to the interrupt clear ADB bit by writing a 1 to ABD CLR (bit 14) of SCIFFCT register and disable further autobaud locking by clearing CDC bit by writing a 0.
6. Read the receive buffer for character "A" or "a" to empty the buffer and buffer status.
7. If ABD is set while CDC is 1, which indicates autobaud alignment, the SCI transmit FIFO interrupt occurs (TXINT). After the interrupt service, the CDC bit must be cleared by software.

**Note**

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications can work well, this slew rate can limit reliable autobaud detection at higher baud rates (typically beyond 100k baud) and cause the auto-baudlock feature to fail.

To avoid this, the following is recommended:

- Achieve a baud-lock between the host and C28x SCI boot loader using a lower baud rate.
- The host can then handshake with the loaded C28x application to set the SCI baud rate register to the desired higher baud rate.

## 19.14 Software

### 19.14.1 SCI Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/sci

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

## 19.15 SCI Registers

The section describes the Serial Communication Interface module registers.

### 19.15.1 SCI Base Addresses

**Table 19-5. SCI Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| SciaRegs | SCI_REGS | 0x0000_7200 | 0x0000_720F |
| ScibRegs | SCI_REGS | 0x0000_7210 | 0x0000_721F |
| ScicRegs | SCI_REGS | 0x0000_7220 | 0x0000_722F |
| ScidRegs | SCI_REGS | 0x0000_7230 | 0x0000_723F |

Copyright © 2024 Texas Instruments Incorporated

### 19.15.2 SCI_REGS Registers

Table 19-6 lists the memory-mapped registers for the SCI_REGS registers. All register offset addresses not listed in Table 19-6 should be considered as reserved locations and the register contents should not be modified.

**Table 19-6. SCI_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | SCICCR | Communications control register | | Go |
| 1h | SCICTL1 | Control register 1 | | Go |
| 2h | SCIHBAUD | Baud rate (high) register | | Go |
| 3h | SCILBAUD | Baud rate (low) register | | Go |
| 4h | SCICTL2 | Control register 2 | | Go |
| 5h | SCIRXST | Receive status register | | Go |
| 6h | SCIRXEMU | Receive emulation buffer register | | Go |
| 7h | SCIRXBUF | Receive data buffer | | Go |
| 9h | SCITXBUF | Transmit data buffer | | Go |
| Ah | SCIFFTX | FIFO transmit register | | Go |
| Bh | SCIFFRX | FIFO receive register | | Go |
| Ch | SCIFFCT | FIFO control register | | Go |
| Fh | SCIPRI | SCI priority control | | Go |

Complex bit access types are encoded to fit into small table cells. Table 19-7 shows the codes that are used for access types in this section.

**Table 19-7. SCI_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |

### 19.15.2.1 SCICCR Register (Offset = 0h) [Reset = 0000h]

SCICCR is shown in Figure 19-11 and described in Table 19-8.

Return to the Summary Table.

SCICCR defines the character format, protocol, and communications mode used by the SCI.

**Figure 19-11. SCICCR Register**

### 19.15.2.2 SCICTL1 Register (Offset = 1h) [Reset = 0000h]

SCICTL1 is shown in Figure 19-12 and described in Table 19-9.

Return to the Summary Table.

SCICTL1 controls the receiver/transmitter enable, TXWAKE and SLEEP functions, and the SCI software reset.

**Figure 19-12. SCICTL1 Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

**Table 19-9. SCICTL1 Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 3 | TXWAKE | R/W | 0h | SCI transmitter wake-up method select.<br>The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3)<br>Reset type: SYSRSn<br>0h (R/W) = Transmit feature is not selected. In idle-line mode: write a 1 to TXWAKE, then write data to register SCITXBUF to generate an idle period of 11 data bits In address-bit mode: write a 1 to TXWAKE, then write data to SCITXBUF to set the address bit for that frame to 1<br>1h (R/W) = Transmit feature selected is dependent on the mode, idle-line or address-bit: TXWAKE is not cleared by the SW RESET bit (SCICTL1, bit 5)<br>it is cleared by a system reset or the transfer of TXWAKE to the WUT flag. |
| 2 | SLEEP | R/W | 0h | SCI sleep.<br>The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3). In a multiprocessor configuration, this bit controls the receiver sleep function. Clearing this bit brings the SCI out of the sleep mode.<br>The receiver still operates when the SLEEP bit is set<br>however, operation does not update the receiver buffer ready bit (SCIRXST, bit 6, RXRDY) or the error status bits (SCIRXST, bit 5-2: BRKDT, FE, OE, and PE) unless the address byte is detected. SLEEP is not cleared when the address byte is detected.<br>Reset type: SYSRSn<br>0h (R/W) = Sleep mode disabled<br>1h (R/W) = Sleep mode enabled |
| 1 | TXENA | R/W | 0h | SCI transmitter enable.<br>Data is transmitted through the SCITXD pin only when TXENA is set. If reset, transmission is halted but only after all data previously written to SCITXBUF has been sent. Data written into SCITXBUF when TXENA is disabled will not be transmitted even if the TXENA is enabled later.<br>Reset type: SYSRSn<br>0h (R/W) = Transmitter disabled<br>1h (R/W) = Transmitter enabled |
| 0 | RXENA | R/W | 0h | SCI receiver enable.<br>Data is received on the SCIRXD pin and is sent to the receiver shift register and then the receiver buffers. This bit enables or disables the receiver (transfer to the buffers).<br>Clearing RXENA stops received characters from being transferred to the two receiver buffers and also stops the generation of receiver interrupts. However, this will not stop RX errors from triggering interrupts. To disable interrupts from RX errors use the RXERRINTENA bit. To stop propagation of the BRKDT interrupt use the RXBKINTENA bit.<br>The receiver shift register can continue to assemble characters even while RXENA is cleared. Thus, if RXENA is set during the reception of a character, the complete character will be transferred into the receiver buffer registers, SCIRXEMU and SCIRXBUF.<br>Reset type: SYSRSn<br>0h (R/W) = Prevent received characters from transfer into the SCIRXEMU and SCIRXBUF receiver buffers<br>1h (R/W) = Send received characters to SCIRXEMU and SCIRXBUF |

| 15-8 | RESERVED | R | 0h | Reserved |
| 7 | RXERROR | R | 0h | SCI receiver error flag.<br>The RX ERROR flag indicates that one of the error flags in the receiver status register is set. RX ERROR is a logical OR of the break detect, framing error, overrun, and parity error enable flags (bits 5-2: BRKDT, FE, OE, and PE).<br>A 1 on this bit will cause an interrupt if the RX ERR INT ENA bit (SCICTL1.6) is set. This bit can be used for fast error-condition checking during the interrupt service routine. This error flag cannot be cleared directly<br>it is cleared by an active SW RESET, channel reset (SCIRST), or by a system reset.<br>Reset type: SYSRSn<br>0h (R/W) = No error flags set<br>1h (R/W) = Error flag(s) set |
| 6 | RXRDY | R | 0h | SCI receiver-ready flag.<br>When a new character is ready to be read from the SCIRXBUF register, the receiver sets this bit, and a receiver interrupt is generated if the RX/BK INT ENA bit (SCICTL2.1) is a 1. RXRDY is cleared by a reading of the SCIRXBUF register, by an active SW RESET, channel reset (SCIRST), or by a system reset.<br>Reset type: SYSRSn<br>0h (R/W) = No new character in SCIRXBUF<br>1h (R/W) = Character ready to be read from SCIRXBUF |

Copyright © 2024 Texas Instruments Incorporated

**Table 19-13. SCIRXST Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 5 | BRKDT | R | 0h | SCI break-detect flag.<br>The SCI sets this bit when a break condition occurs. A break condition occurs when the SCI receiver data line (SCIRXD) remains continuously low for at least 9.625 bits, beginning after a missing first stop bit. If the SCIRX line goes high at any point during the 9.625 bits then the SCI will not flag a break detect. In order to trigger the first stop bit missed, the typical method is to hold the RX line low for 1 start bit, 8 data bits, 1 optional address bit, 1 optional parity bit, 1 stop bit, and 9.625 bits of additional time held low. This is a total of 19.625 (no parity/address bit), 20.625 (either parity or address bit), or 21.625 (both parity and address bit) bit times.<br>To instead detect a 'break seq' or 'break sequence' of 11 bits of low voltage level (0), ISR code can use the following combination of flags and received data: FE==1 && PE==1 && SCIRXBUF.SAR (received character)==0x00. This assumes parity enabled and odd parity set. With even parity, PE==0 instead. The detection of 11 bits of low/0 can be reduced to 10 bits of low if no parity bit is used (then PE flag does not matter to detect the sequence).<br>The occurrence of a break causes a receiver interrupt to be generated if the RX/BK INT ENA bit is a 1, but it does not cause the receiver buffer to be loaded.<br>A BRKDT interrupt can occur even if the receiver SLEEP bit is set to 1.<br>BRKDT is cleared by an active SW RESET, SCIRST bit, or by a system reset. It is not cleared by receipt of a character after the break is detected.<br>If Break Detect (BRKDT) is set, then RXRDY won't be set and there will be no further interrupts after the first interrupt where there is an error detected if a SW reset, channel reset, or system reset is not performed. In order to receive more characters, the SCI must be reset by toggling the SW RESET bit, channel reset (SCIRST), or by a system reset.<br>NOTE: If your system is susceptible to break detects, ensure that you have a pull-up resistor on the SCI-RX pin to provide proper return-to-high signal behavior and noise immunity.<br>NOTE: To monitor a break detect, place an oscilloscope on the C2000 SCI-RX line and monitor for a low-signal greater than 9.625 bits wide. If this is found and a break is not expected, please correct the software in the other device that is transmitting to this C2000 device. There should never be a low-signal greater than 9.625 bits wide on the SCI-RX line of the C2000 device unless a break detect is being transmitted purposely.<br>Reset type: SYSRSn<br>0h (R/W) = No break condition<br>1h (R/W) = Break condition occurred |
| 4 | FE | R | 0h | SCI framing-error flag.<br>The SCI sets this bit when an expected stop bit is not found. Only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. The FE bit is reset by a clearing of the SW RESET bit, channel reset (SCIRST), or by a system reset. NOTE: FE will be flagged prior to BRKDT, except when RX is in sleep mode. In sleep mode, when there is no RX WAKEUP and RXD line is low for greater than 10 bits, BRKDT will be flagged while FE will not be flagged.<br>Reset type: SYSRSn<br>0h (R/W) = No framing error detected<br>1h (R/W) = Framing error detected |

**Table 19-13. SCIRXST Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 3 | OE | R | 0h | SCI overrun-error flag.<br>The SCI sets this bit when a character is transferred into registers SCIRXEMU and SCIRXBUF before the previous character is fully read by the CPU or DMAC. The previous character is overwritten and lost. The OE flag bit is reset by an active SW RESET, channel reset (SCIRST), or a system reset.<br>Reset type: SYSRSn<br>0h (R/W) = No overrun error detected<br>1h (R/W) = Overrun error detected |
| 2 | PE | R | 0h | SCI parity-error flag.<br>This flag bit is set when a character is received with a mismatch between the number of 1s and its parity bit. The address bit is included in the calculation. If parity generation and detection is not enabled, the PE flag is disabled and read as 0. The PE bit is reset by an active SW RESET, channel reset (SCIRST), or a system reset.<br>Reset type: SYSRSn<br>0h (R/W) = No parity error or parity is disabled<br>1h (R/W) = Parity error is detected |
| 1 | RXWAKE | R | 0h | Receiver wake-up-detect flag<br>Reset type: SYSRSn<br>0h (R/W) = No detection of a receiver wake-up condition<br>1h (R/W) = A value of 1 in this bit indicates detection of a receiver wake-up condition. In the address-bit multiprocessor mode (SCICCR.3 = 1), RXWAKE reflects the value of the address bit for the character contained in SCIRXBUF. In the idle-line multiprocessor mode, RXWAKE is set if the SCIRXD data line is detected as idle. RXWAKE is a read-only flag, cleared by one of the following:<br>- The transfer of the first byte after the address byte to SCIRXBUF (only in non-FIFO mode)<br>- The reading of SCIRXBUF<br>- An active SW RESET<br>- Channel reset (SCIRST)<br>- A system reset |

### 19.15.2.7 SCIRXEMU Register (Offset = 6h) [Reset = 0000h]

SCIRXEMU is shown in Figure 19-17 and described in Table 19-14.

Return to the Summary Table.

Normal SCI data-receive operations read the data received from the SCIRXBUF register. The SCIRXEMU register is used principally by the emulator (EMU) because it can continuously read the data received for screen updates without clearing the RXRDY flag. SCIRXEMU is cleared by a system reset. This is the register that should be used in an emulator watch window to view the contents of the SCIRXBUF register. SCIRXEMU is not physically implemented
it is just a different address location to access the SCIRXBUF register without clearing the RXRDY flag.

### 19.15.2.8 SCIRXBUF Register (Offset = 7h) [Reset = 0000h]

SCIRXBUF is shown in Figure 19-18 and described in Table 19-15.

Return to the Summary Table.

When the current data received is shifted from RXSHF to the receiver buffer, flag bit RXRDY is set and the data is ready to be read. If the RXBKINTENA bit (SCICTL2.1) is set, this shift also causes an interrupt. When SCIRXBUF is read, the RXRDY flag is reset. SCIRXBUF is cleared by a system reset.

**Figure 19-18. SCIRXBUF Register**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15 | SCIFFFE | R | 0h | SCIFFFE. SCI FIFO Framing error flag bit (applicable only if the FIFO is enabled)<br>Note: 'SCIFFFE' is meant to serve as a flag for the specific set of data being received/read in the SCIRXBUF register. Each set of data received into the FIFO will have this information. The 'FE' bit within the SCIRXST register can be thought off as high level error flag where the flag will get set if any data that has been received has a framing error.<br>Reset type: SYSRSn<br>0h (R/W) = No frame error occurred while receiving the character, in bits 7-0. This bit is associated with the character on the top of the FIFO.<br>1h (R/W) = A frame error occurred while receiving the character in bits 7-0. This bit is associated with the character on the top of the FIFO. |
| 14 | SCIFFPE | R | 0h | SCIFFPE. SCI FIFO parity error flag bit (applicable only if the FIFO is enabled)<br>Note: 'SCIFFPE' is meant to serve as a flag for the specific set of data being received/read in the SCIRXBUF register. Each set of data received into the FIFO will have this information. The 'PE' bit within the SCIRXST register can be thought off as high level error flag where the flag will get set if any data that has been received has a parity error.<br>Note: If the parity is changed in the middle of data reception, the SCI module will not reinterpret the data with the new parity or other settings that may have changed. Therefore, changing the parameter, the FIFO should be cleared or the user should acknowledge that there will most likely be errors in the data caused by the change.<br>Note: If RX parity errors are occurring intermittently this could be due to the length of the SCI ISR. To help prevent this, ensure that interrupt nesting is limited, increase the SCI interrupt priority, and move as much of the processing as possible out of the ISR (to reduce ISR time to the absolute minimum).<br>Reset type: SYSRSn<br>0h (R/W) = No parity error occurred while receiving the character, in bits 7-0. This bit is associated with the character on the top of the FIFO.<br>1h (R/W) = A parity error occurred while receiving the character in bits 7-0. ### 19.15.2.9 SCITXBUF Register (Offset = 9h) [Reset = 0000h]

SCITXBUF is shown in Figure 19-19 and described in Table 19-16.

Return to the Summary Table.

Data bits to be transmitted are written to SCITXBUF. These bits must be rightjustified because the leftmost bits are ignored for characters less than eight bits long. The transfer of data from this register to the TXSHF transmitter shift register sets the TXRDY flag (SCICTL2.7), indicating that SCITXBUF is ready to receive another set of data. If bit TXINTENA (SCICTL2.0) is set, this data transfer also causes an interrupt.

Chapter 20

# Inter-Integrated Circuit Module (I2C)

This chapter describes the features and operation of the inter-integrated circuit (I2C) module. The I2C module provides an interface between one of these devices and devices compliant with the NXP Semiconductors Inter-IC bus (I2C bus) specification version 2.1, and connected by way of an I2C bus. External components attached to this 2-wire serial bus can transmit/receive 1- to 8-bit data to/from the device through the I2C module. This chapter assumes the reader is familiar with the I2C bus specification.

**Note**

A unit of data transmitted or received by the I2C module can have fewer than 8 bits; however, for convenience, a unit of data is called a data byte throughout this chapter. The number of bits in a data byte is selectable by way of the BC bits of the mode register, I2CMDR.

## 20.1 Introduction

The I2C module supports any slave or master I2C-compatible device. Figure 20-1 shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

### 20.1.2 Features

The I2C module has the following features:

- Compliance with the NXP Semiconductors I2C bus specification (version 2.1):
  - Support for 8-bit format transfers
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple master-transmitters and slave-receivers
  - Support for multiple slave-transmitters and master-receivers
  - Combined master transmit/receive and receive/transmit mode
  - Data transfer rate from 10kbps up to 400kbps (Fast-mode)
- Receive FIFO and Transmitter FIFO (16-deep x 8-bit FIFO)
- Supports two ePIE interrupts:
  - I2Cx Interrupt – Any of the following events can be configured to generate an I2Cx interrupt:
    - Transmit-data ready
    - Receive-data ready
    - Register-access ready
    - No-acknowledgment received
    - Arbitration lost
    - Stop condition detected
    - Addressed as slave
  - I2Cx_FIFO interrupts:
    - Transmit FIFO interrupt
    - Receive FIFO interrupt
- Module enable and disable capability
- Free data format mode

### 20.1.3 Features Not Supported

The I2C module does not support:

- High-speed mode (Hs-mode)
- CBUS-compatibility mode

Copyright © 2024 Texas Instruments Incorporated

### 20.1.4 Functional Overview

Each device connected to an I2C bus is recognized by a unique address. Each device can operate as either a transmitter or a receiver, depending on the function of the device. A device connected to the I2C bus can also be considered as the master or the slave when performing data transfers. A master device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave. The I2C module supports the multi-master mode, in which one or more devices capable of controlling an I2C bus can be connected to the same I2C bus.

For data communication, the I2C module has a serial data pin (SDA) and a serial clock pin (SCL), as shown in Figure 20-2. These two pins carry information between the C28x device and other devices connected to the I2C bus. The SDA and SCL pins are both bidirectional and each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

There are two major transfer techniques:

- Standard Mode: Send exactly n data values, where n is a value you program in an I2C module register. See the I2CCNT register in the *I2C Registers* section for more information.
- Repeat Mode: Keep sending data values until you use software to initiate a STOP condition or a new START condition. See the I2CMDR register in the *I2C Registers* section for RM bit information.

The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers and FIFOs to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU
- Control and status registers
- A peripheral bus interface to enable the CPU to access the I2C module registers and FIFOs.
- A clock synchronizer to synchronize the I2C input clock (from the device clock generator) and the clock on the SCL pin, and to synchronize data transfers with masters of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module
- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when the I2C module is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- FIFO interrupt generation logic, so that FIFO access can be synchronized to data reception and data transmission in the I2C module

Figure 20-2 shows the four registers used for transmission and reception in non-FIFO mode. The CPU writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out on the SDA pin one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

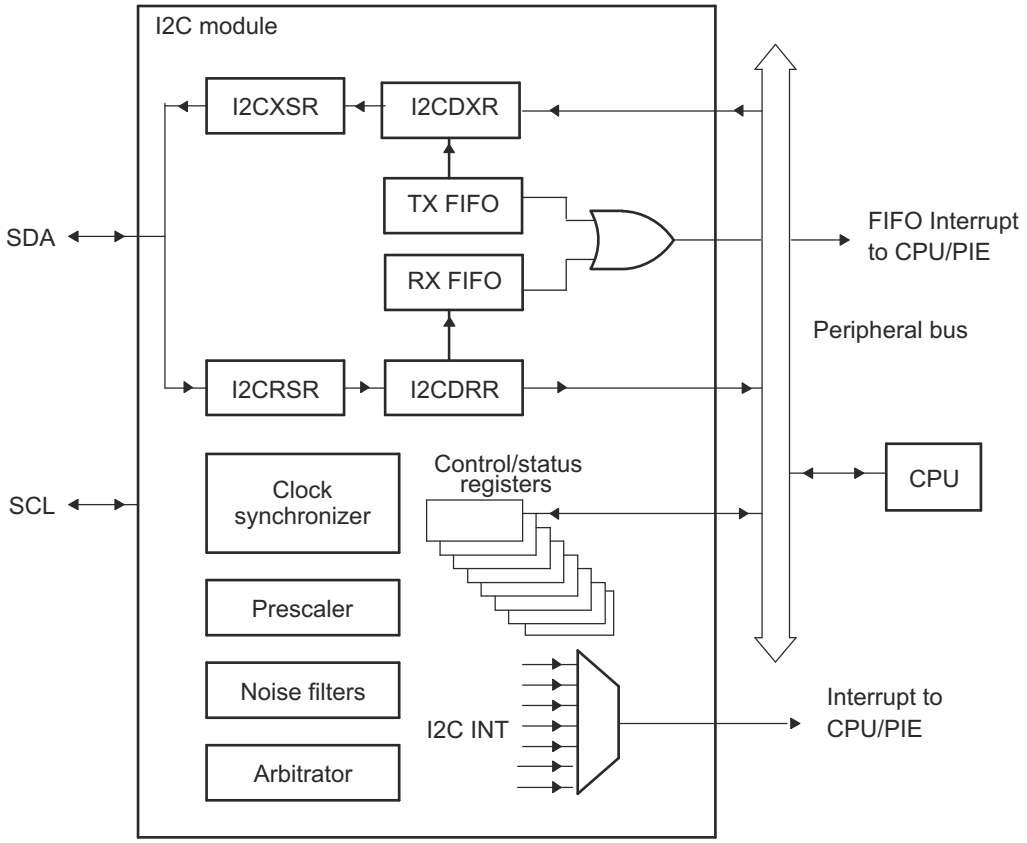

**Figure 20-2. I2C Module Conceptual Block Diagram**

### *20.1.5 Clock Generation*

The I2C module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the SYSCLK to produce the I2C module clock and this I2C module clock is divided further to produce the I2C master clock on the SCL pin. Figure 20-3 shows the clock generation diagram for I2C module.

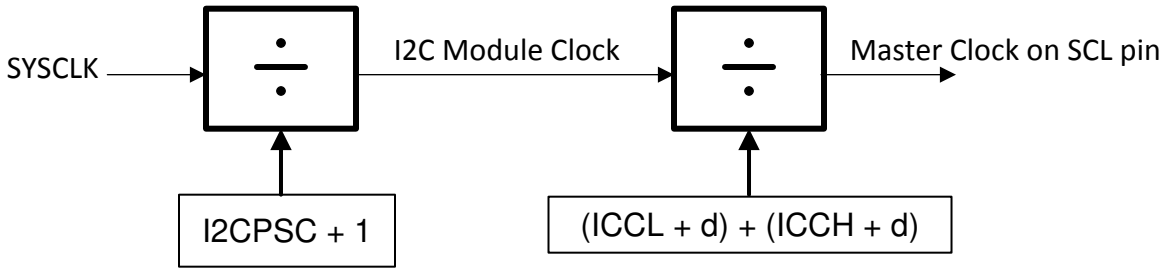

**Figure 20-3. Clocking Diagram for the I2C Module**

**Note**

To meet all of the I2C protocol timing specifications, the I2C module clock must be between 7 to 12MHz.

Copyright © 2024 Texas Instruments Incorporated

To specify the divide-down value, initialize the IPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$\text{I2C Module Clock (Fmod)} = \frac{\text{SYSCLK}}{(\text{I2CPSC} + 1)} \quad (28)$$

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of communication between the I2C module and a slave. As shown in Figure 20-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the ICCL value of I2CCLKL to divide down the low portion of the module clock signal and uses the ICCH value of I2CCLKH to divide down the high portion of the module clock signal. See Section 20.1.6 for the master clock frequency equation.

### *20.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)*

As explained in Section 20.1.5, when the I2C module is a master, the I2C module clock is divided down further to use as the master clock on the SCL pin. As shown in Figure 20-4, the shape of the master clock depends on two divide-down values:

- ICCL in I2CCLKL. For each master clock cycle, ICCL determines the amount of time the signal is low.
- ICCH in I2CCKLH. For each master clock cycle, ICCH determines the amount of time the signal is high.

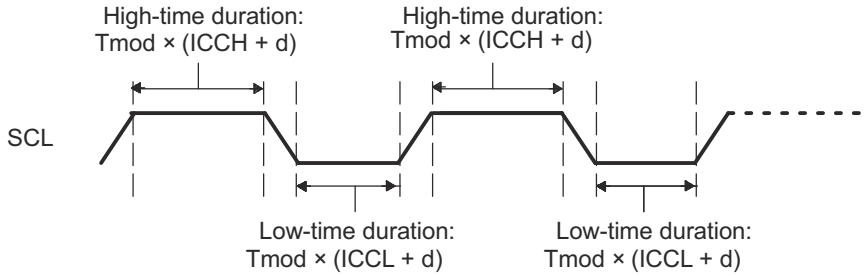

**Figure 20-4. Roles of the Clock Divide-Down Values (ICCL and ICCH)**

#### 20.1.6.1 Formula for the Master Clock Period

The master clock period (Tmst) is a multiple of the period of the I2C Module Clock (Tmod):

$$\text{Master Clock period (Tmst)} = \frac{[\,(\text{ICCH} + d) + (\text{ICCL} + d)\,]}{\text{I2C Module Clock (Fmod)}} \quad (29)$$

where d depends on the divide-down value IPSC, as shown in Table 20-1. IPSC is described in the I2CPSC register.

**Table 20-1. Dependency of Delay d on the Divide-Down Value IPSC**

| IPSC | d |
|---|---|
| 0 | 7 |
| 1 | 6 |
| Greater than 1 | 5 |

## 20.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 20.3 I2C Module Operational Details

This section provides an overview of the I2C bus protocol and how it is implemented.

### *20.3.1 Input and Output Voltage Levels*

One clock pulse is generated by the master device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I2C bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of $V_{DD}$. For details, see the device data sheet.

### *20.3.2 Selecting Pullup Resistors*

The chosen pullup resistor must meet the I2C standard timings. In most circumstances, 2.2kΩ of total bus resistance to VDDIO is sufficient. The value of the pullup resistance used on both the SCL and SDA pins be matched is also recommended. For evaluating pullup resistor values for a particular design, see the *I2C Bus Pullup Resistor Calculation Application Report*.

### *20.3.3 Data Validity*

The data on SDA must be stable during the high period of the clock (see Figure 20-5). The high or low state of the data line, SDA, must change only when the clock signal on SCL is low.

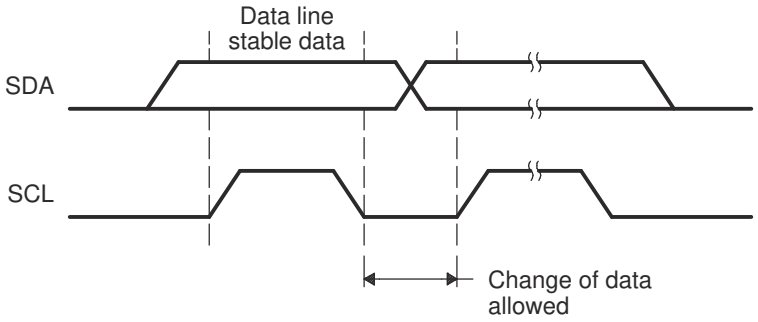

**Figure 20-5. Bit Transfer on the I2C bus**

### *20.3.4 Operating Modes*

The I2C module has four basic operating modes to support data transfers as a master and as a slave. See Table 20-2 for the names and descriptions of the modes.

If the I2C module is a master, the I2C module begins as a master-transmitter and typically transmits an address for a particular slave. When giving data to the slave, the I2C module must remain a master-transmitter. To receive data from a slave, the I2C module must be changed to the master-receiver mode.

If the I2C module is a slave, the I2C module begins as a slave-receiver and typically sends acknowledgment when the I2C module recognizes the slave address from a master. If the master is sending data to the I2C module, the module must remain a slave-receiver. If the master has requested data from the I2C module, the module must be changed to the slave-transmitter mode.

Copyright © 2024 Texas Instruments Incorporated

**Table 20-2. Operating Modes of the I2C Module**

| Operating Mode | Description |
|---|---|
| Slave-receiver mode | The I2C module is a slave and receives data from a master.<br>All slaves begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the master. As a slave, the I2C module does not generate the clock signal, but can hold SCL low while the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received. See Section 20.3.8 for more details. |
| Slave-transmitter mode | The I2C module is a slave and transmits data to a master.<br>This mode can be entered only from the slave-receiver mode; the I2C module must first receive a command from the master. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the slave-transmitter mode if the slave address byte is the same as the address (in I2COAR) and the master has transmitted R/ $\overline{W}$ = 1. As a slave-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the master. While a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted. See Section 20.3.8 for more details. |
| Master-receiver mode | The I2C module is a master and receives data from a slave.<br>This mode can be entered only from the master-transmitter mode; the I2C module must first transmit a command to the slave. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the master-receiver mode after transmitting the slave address byte and R/ $\overline{W}$ = 1. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received. |
| Master-transmitter mode | The I2C module is a master and transmits control information and data to a slave.<br>All masters begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted. |

To summarize, SCL is held low in the following conditions:

- When an overrun condition is detected (RSFULL = 1), in Slave-receiver mode.
- When an underflow condition is detected (XSMT = 0), in Slave-transmitter mode.

I2C slave nodes accept and provide data when the I2C master node requests data.

- To release SCL in slave-receiver mode, read data from I2CDRR.
- To release SCL in slave-transmitter mode, write data to I2CDXR.
- To force a release without handling the data, reset the module using the I2CMDR.IRS bit.

**Table 20-3. Master-Transmitter/Receiver Bus Activity Defined by the RM, STT, and STP Bits of I2CMDR**

| RM | STT | STP | Bus Activity(1) | Description |
|---|---|---|---|---|
| 0 | 0 | 0 | None | No activity |
| 0 | 0 | 1 | P | STOP condition |
| 0 | 1 | 0 | S-A-D..(n)..D. | START condition, slave address, n data bytes (n = value in I2CCNT) |
| 0 | 1 | 1 | S-A-D..(n)..D-P | START condition, slave address, n data bytes, STOP condition (n = value in I2CCNT) |
| 1 | 0 | 0 | None | No activity |
| 1 | 0 | 1 | P | STOP condition |
| 1 | 1 | 0 | S-A-D-D-D. | Repeat mode transfer: START condition, slave address, continuous data transfers until STOP condition or next START condition |
| 1 | 1 | 1 | None | Reserved bit combination (No activity) |

(1) S = START condition; A = Address; D = Data byte; P = STOP condition;

### 20.3.5 I2C Module START and STOP Conditions

START and STOP conditions can be generated by the I2C module when the module is configured to be a master on the I2C bus. As shown in Figure 20-8:

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of a data transfer.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of a data transfer.

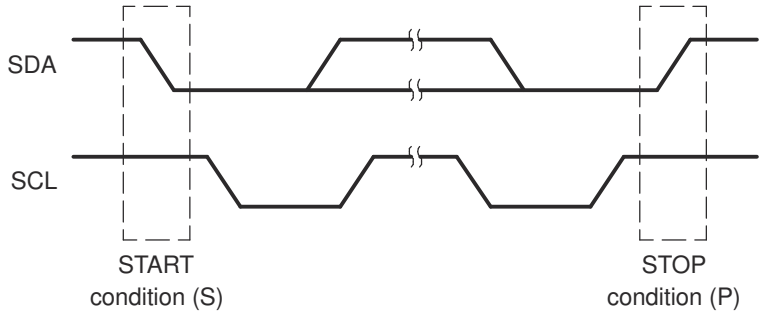

**Figure 20-8. I2C Module START and STOP Conditions**

After a START condition and before a subsequent STOP condition, the I2C bus is considered busy, and the bus busy (BB) bit of I2CSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in I2CMDR must both be 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated. For a description of I2CMDR and the bits (including MST, STT, and STP), see Section 20.7.

The I2C peripheral cannot detect a START or STOP condition while in reset (IRS = 0). The BB bit remains in the cleared state (BB = 0) while the I2C peripheral is in reset (IRS = 0). When the I2C peripheral is taken out of reset (IRS set to 1), the BB bit does not correctly reflect the I2C bus status until a START or STOP condition is detected.

Follow these steps before initiating the first data transfer with I2C:

1. After taking the I2C peripheral out of reset by setting the IRS bit to 1, wait a period larger than the total time taken for the longest data transfer in the application. By waiting for a period of time after I2C comes out of reset, make sure that at least one START or STOP condition has occurred on the I2C bus and has been captured by the BB bit. After this period, the BB bit correctly reflects the state of the I2C bus.
2. Check the BB bit and verify that BB = 0 (bus not busy) before proceeding.
3. Begin data transfers.

Not resetting the I2C peripheral in between transfers makes sure that the BB bit reflects the actual bus status. If users must reset the I2C peripheral in between transfers, repeat steps 1 through 3 every time the I2C peripheral is taken out of reset.

Copyright © 2024 Texas Instruments Incorporated

### 20.3.6 Non-repeat Mode versus Repeat Mode

**Non-repeat mode:**

- When I2CMDR.RM = 0, I2C module is configured in non-repeat mode.
- I2CCNT register determines the number of bytes to be transmitted or received.
- If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0.
- If STP = 1, ARDY bit does not get set and I2C module generates a STOP condition when the internal data counter counts down to 0.

**Note**

In non-repeat mode (RM = 0), if I2CCNT is set to 0, I2C state machine expects to transmit or receive 65536 bytes and not 0 bytes.

**Repeat mode:**

- When I2CMDR.RM = 1, I2C module is configured in repeat mode.
- I2CCNT register contents do not determine the number of bytes to be transmitted or received.
- Number of bytes to be transmitted or received can be controlled by software.
- ARDY bit gets set at end of transmission and reception of each byte.

**Note**

Once you start I2C transaction in non-repeat mode or repeat mode, you cannot switch into another mode until the I2C transaction is completed with a STOP condition.

### 20.3.7 Serial Data Formats

Figure 20-9 shows an example of a data transfer on the I2C bus. The I2C module supports 1 to 8-bit data values. In Figure 20-9, 8-bit data is transferred. Each bit put on the SDA line equates to 1 pulse on the SCL line, and the values are always transferred with the most significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted. The serial data format used in Figure 20-9 is the 7-bit addressing format. The I2C module supports the formats shown in Figure 20-10 through Figure 20-12 and described in the paragraphs that follow the figures.

**Note**

In Figure 20-9 through Figure 20-12, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

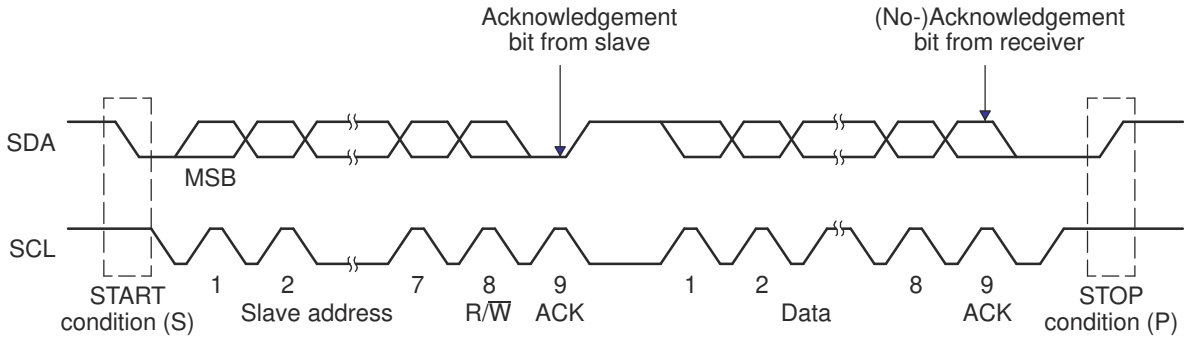

**Figure 20-9. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown)**

Copyright © 2024 Texas Instruments Incorporated

#### 20.3.7.1 7-Bit Addressing Format

The 7-bit addressing format is the default format after reset. Disabling expanded address (I2CMDR.XA = 0) and free data format (I2CMDR.FDF = 0) enables 7-bit addressing format.

In this format (see Figure 20-10), the first byte after a START condition (S) consists of a 7-bit slave address followed by a R/$\overline{W}$ bit. R/$\overline{W}$ determines the direction of the data:

- R/$\overline{W}$ = 0: The I2C master writes (transmits) data to the addressed slave. This can be achieved by setting I2CMDR.TRX = 1 (Transmitter mode)
- R/$\overline{W}$ = 1: The I2C master reads (receives) data from the slave. This can be achieved by setting I2CMDR.TRX = 0 (Receiver mode)

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after each byte. If the ACK bit is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the R/$\overline{W}$ bit). n is a number from 1 to 8 determined by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

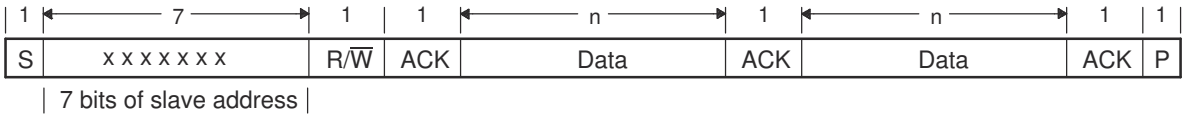

**Figure 20-10. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR)**

#### 20.3.7.2 10-Bit Addressing Format

The 10-bit addressing format can be enabled by setting expanded address (I2CMDR.XA = 1) and disabling free data format (I2CMDR.FDF = 0).

The 10-bit addressing format (see Figure 20-11) is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit slave address, and R/$\overline{W}$. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send acknowledgment after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use a repeated START condition to change the data direction. For more details about using 10-bit addressing, see the NXP Semiconductors I2C bus specification.

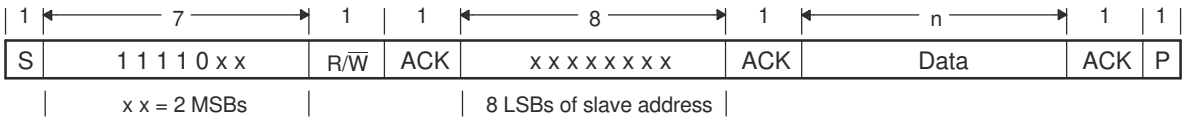

**Figure 20-11. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR)**

Copyright © 2024 Texas Instruments Incorporated

#### 20.3.7.3 Free Data Format

The free data format can be enabled by setting I2CMDR. FDF = 1.

In this format (see Figure 20-12), the first byte after a START condition (S) is a data byte. An ACK bit is inserted after each data byte, which can be from 1 to 8 bits, depending on the BC field of I2CMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

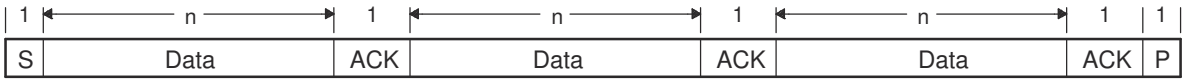

**Figure 20-12. I2C Module Free Data Format (FDF = 1 in I2CMDR)**

**Note**

The free data format is not supported in the digital loopback mode (I2CMDR.DLB = 1).

**Table 20-4. How the MST and FDF Bits of I2CMDR Affect the Role of the TRX Bit of I2CMDR**

| MST | FDF | I2C Module State | Function of TRX |
|---|---|---|---|
| 0 | 0 | In slave mode but not free data format mode | TRX is a don't care. Depending on the command from the master, the I2C module responds as a receiver or a transmitter. |
| 0 | 1 | In slave mode and free data format mode | The free data format mode requires that the I2C module remains the transmitter or the receiver throughout the transfer. TRX identifies the role of the I2C module:<br>TRX = 1: The I2C module is a transmitter.<br>TRX = 0: The I2C module is a receiver. |
| 1 | 0 | In master mode but not free data format mode | TRX = 1: The I2C module is a transmitter.<br>TRX = 0: The I2C module is a receiver. |
| 1 | 1 | In master mode and free data format mode | TRX = 0: The I2C module is a receiver.<br>TRX = 1: The I2C module is a transmitter. |

#### 20.3.7.4 Using a Repeated START Condition

I2C master can communicate with multiple slave addresses without having to give up control of the I2C bus by driving a STOP condition. This can be achieved by driving another START condition at the end of each data type. The repeated START condition can be used with the 7-bit addressing and 10-bit addressing. Figure 20-13 shows a repeated START condition in the 7-bit addressing format.

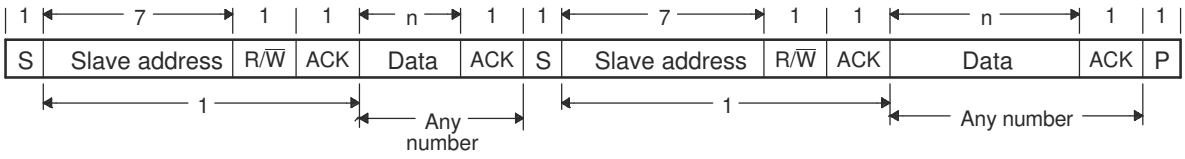

**Figure 20-13. Repeated START Condition (in This Case, 7-Bit Addressing Format)**

**Note**

In Figure 20-13, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

Copyright © 2024 Texas Instruments Incorporated

### 20.3.8 Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more masters and the clock must be synchronized so that the data output can be compared. Figure 20-14 illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start a low period. The SCL is held low by the device with the longest low period. The other devices that finish the low periods must wait for SCL to be released, before starting the high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

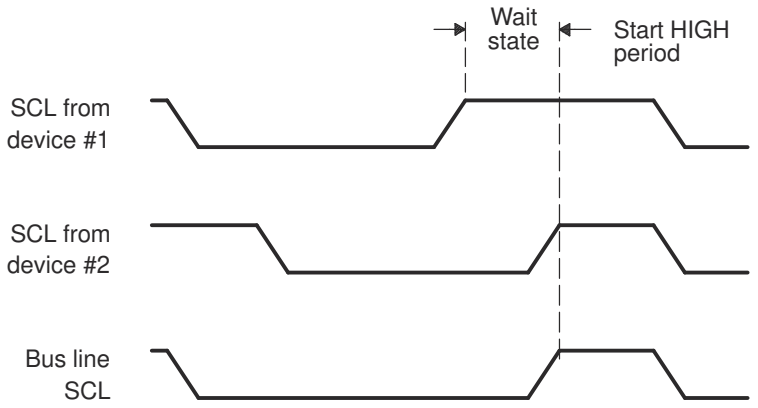

**Figure 20-14. Synchronization of Two I2C Clock Generators During Arbitration**

Copyright © 2024 Texas Instruments Incorporated

### 20.3.9 Arbitration

If two or more master-transmitters attempt to start a transmission on the same bus at approximately the same time, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. Figure 20-15 illustrates the arbitration procedure between two devices. The first master-transmitter that releases the SDA line high is overruled by another master-transmitter that drives the SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing master, the I2c module switches to the slave-receiver mode, sets the arbitration lost (ARBL) flag, and generates the arbitration-lost interrupt request.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the master-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

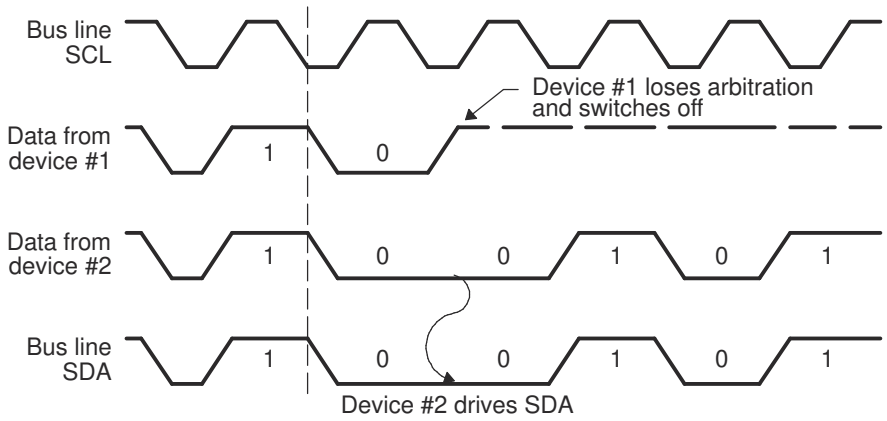

**Figure 20-15. Arbitration Procedure Between Two Master-Transmitters**

### 20.3.10 Digital Loopback Mode

The I2C module support a self-test mode called digital loopback, which is enabled by setting the DLB bit in the I2CMDR register. In this mode, data transmitted out of the I2CDXR register is received in the I2CDRR register. The data follows an internal path, and takes n cycles to reach I2CDRR, where:

n = 8 * (SYSCLK) / (I2C module clock (Fmod))

The transmit clock and the receive clock are the same. The address seen on the external SDA pin is the address in the I2COAR register. Figure 20-16 shows the signal routing in digital loopback mode.

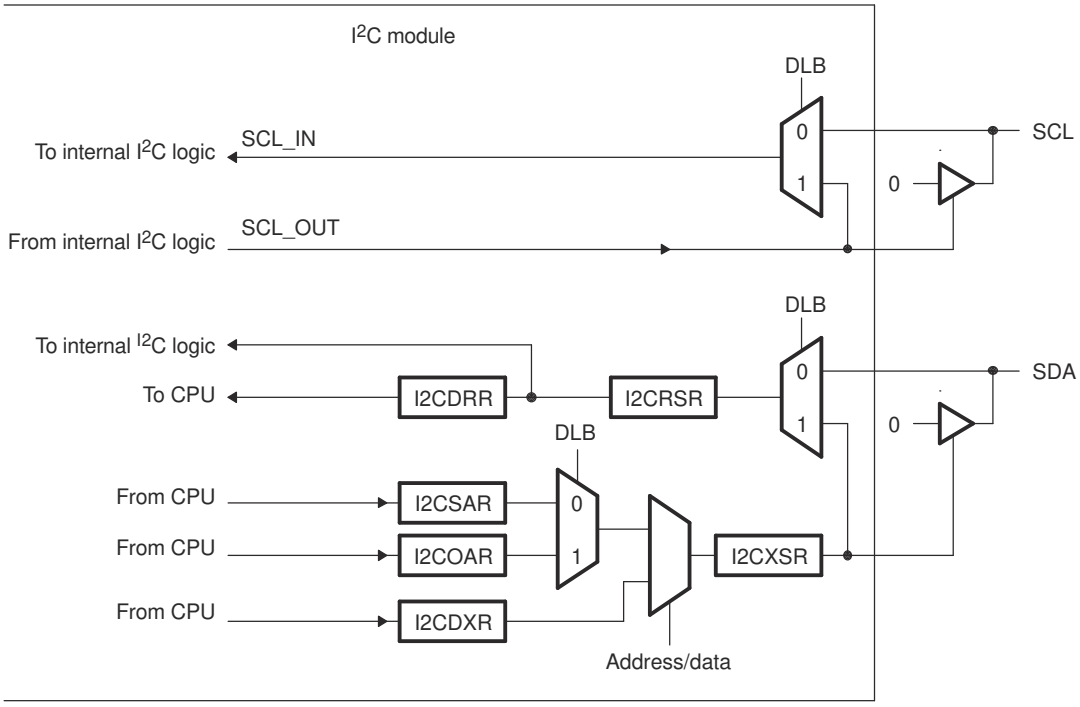

**Figure 20-16. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit**

**Note**

The free data format (I2CMDR.FDF = 1) is not supported in digital loopback mode.

Copyright © 2024 Texas Instruments Incorporated

### 20.3.11 NACK Bit Generation

When the I2C module is a receiver (master or slave), the I2C module can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 20-5 summarizes the various ways you can allow the I2C module to send a NACK bit.

**Note**

When a NACK is sent, the following occurs:

1. The STP in I2CMDR is cleared
2. SCL is held low
3. The NACK in I2CSTR is set

**Table 20-5. Ways to Generate a NACK Bit**

| I2C Module Condition | NACK Bit Generation Options |
|---|---|
| Slave-receiver modes | Allow an overrun condition (RSFULL = 1 in I2CSTR)<br>Reset the module (IRS = 0 in I2CMDR)<br>Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive |
| Master-receiver mode AND<br>Repeat mode (RM = 1 in I2CMDR) | Generate a STOP condition (STP = 1 in I2CMDR)<br>Reset the module (IRS = 0 in I2CMDR)<br>Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive |
| Master-receiver mode AND<br>Nonrepeat mode<br>(RM = 0 in I2CMDR) | If STP = 1 in I2CMDR, allow the internal data counter to count down to 0 and thus force a STOP condition<br>If STP = 0, make STP = 1 to generate a STOP condition<br>Reset the module (IRS = 0 in I2CMDR)<br>Set STP = 1 to generate a STOP condition<br>Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive |

## 20.4 Interrupt Requests Generated by the I2C Module

Each I2C module can generate two CPU interrupts.

1. Basic I2C interrupt: Possible basic I2C interrupt sources that can trigger this interrupt are described in Section 20.4.1.
2. I2C FIFO interrupt: Possible I2C FIFO interrupt sources that can trigger this interrupt are described in Section 20.4.2

Copyright © 2024 Texas Instruments Incorporated

### 20.4.1 Basic I2C Interrupt Requests

The I2C module generates the interrupt requests described in Table 20-6. As shown in Figure 20-17, all requests are multiplexed through an arbiter to a single I2C interrupt request to the CPU. Each interrupt request has a flag bit in the status register (I2CSTR) and an enable bit in the interrupt enable register (I2CIER). When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the request is forwarded to the CPU as an I2C interrupt.

The I2C interrupt is one of the maskable interrupts of the CPU. As with any maskable interrupt request, if the request is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (I2CINT1A_ISR). The I2CINT1A_ISR for the I2C interrupt can determine the interrupt source by reading the interrupt source register, I2CISRC. Then the I2CINT1A_ISR can branch to the appropriate subroutine.

After the CPU reads I2CISRC, the following events occur:

1. The flag for the source interrupt is cleared in I2CSTR. Exception: The ARDY, RRDY, and XRDY bits in I2CSTR are not cleared when I2CISRC is read. To clear one of these bits, write a 1 to the bit.
2. The arbiter determines which of the remaining interrupt requests has the highest priority, writes the code for that interrupt to I2CISRC, and forwards the interrupt request to the CPU.

**Table 20-6. Descriptions of the Basic I2C Interrupt Requests**

| I2C Interrupt Request | Interrupt Source |
|---|---|
| XRDYINT | Transmit ready condition: The data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR).<br>As an alternative to using XRDYINT, the CPU can poll the XRDY bit of the status register, I2CSTR. XRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead. |
| RRDYINT | Receive ready condition: The data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR.<br>As an alternative to using RRDYINT, the CPU can poll the RRDY bit of I2CSTR. RRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead. |
| ARDYINT | Register-access ready condition: The I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used.<br>The specific events that generate ARDYINT are the same events that set the ARDY bit of I2CSTR.<br>As an alternative to using ARDYINT, the CPU can poll the ARDY bit. |
| NACKINT | No-acknowledgment condition: The I2C module is configured as a master-transmitter and did not received acknowledgment from the slave-receiver.<br>As an alternative to using NACKINT, the CPU can poll the NACK bit of I2CSTR. |
| ARBLINT | Arbitration-lost condition: The I2C module has lost an arbitration contest with another master-transmitter.<br>As an alternative to using ARBLINT, the CPU can poll the ARBL bit of I2CSTR. |
| SCDINT | Stop condition detected: A STOP condition was detected on the I2C bus.<br>As an alternative to using SCDINT, the CPU can poll the SCD bit of the status register, I2CSTR. |
| AASINT | Addressed as slave condition: The I2C has been addressed as a slave device by another master on the I2C bus.<br>As an alternative to using AASINT, the CPU can poll the AAS bit of the status register, I2CSTR. |

Copyright © 2024 Texas Instruments Incorporated

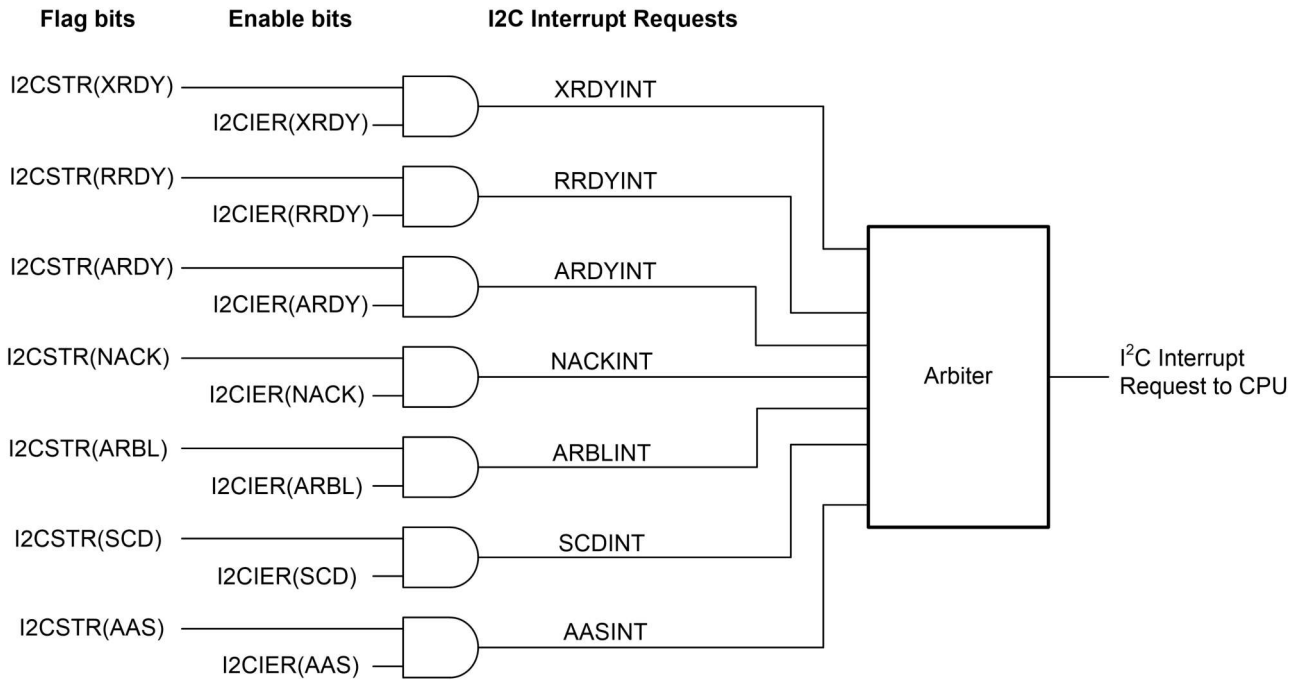

**Figure 20-17. Enable Paths of the I2C Interrupt Requests**

The priorities of the basic I2C interrupt requests are listed in order of highest priority to lowest priority:

1. ARBLINT
2. NACKINT
3. ARDYINT
4. RRDYINT
5. XRDYINT
6. SCDINT
7. AASINT

The I2C module has a backwards compatibility bit (BC) in the I2CEMDR register. The timing diagram in Figure 20-18 demonstrates the effect the backwards compatibility bit has on I2C module registers and interrupts when configured as a slave-transmitter.

### 20.4.2 I2C FIFO Interrupts

In addition to the seven basic I2C interrupts, the transmit and receive FIFOs each contain the ability to generate an interrupt (I2CINT2A). The transmit FIFO can be configured to generate an interrupt after transmitting a defined number of bytes, up to 16. The receive FIFO can be configured to generate an interrupt after receiving a defined number of bytes, up to 16. These two interrupt sources are ORed together into a single maskable CPU interrupt. Figure 20-19 shows the structure of I2C FIFO interrupt. The interrupt service routine can then read the FIFO interrupt status flags to determine from which source the interrupt came. See the I2C transmit FIFO register (I2CFFTX) and the I2C receive FIFO register (I2CFFRX) descriptions.

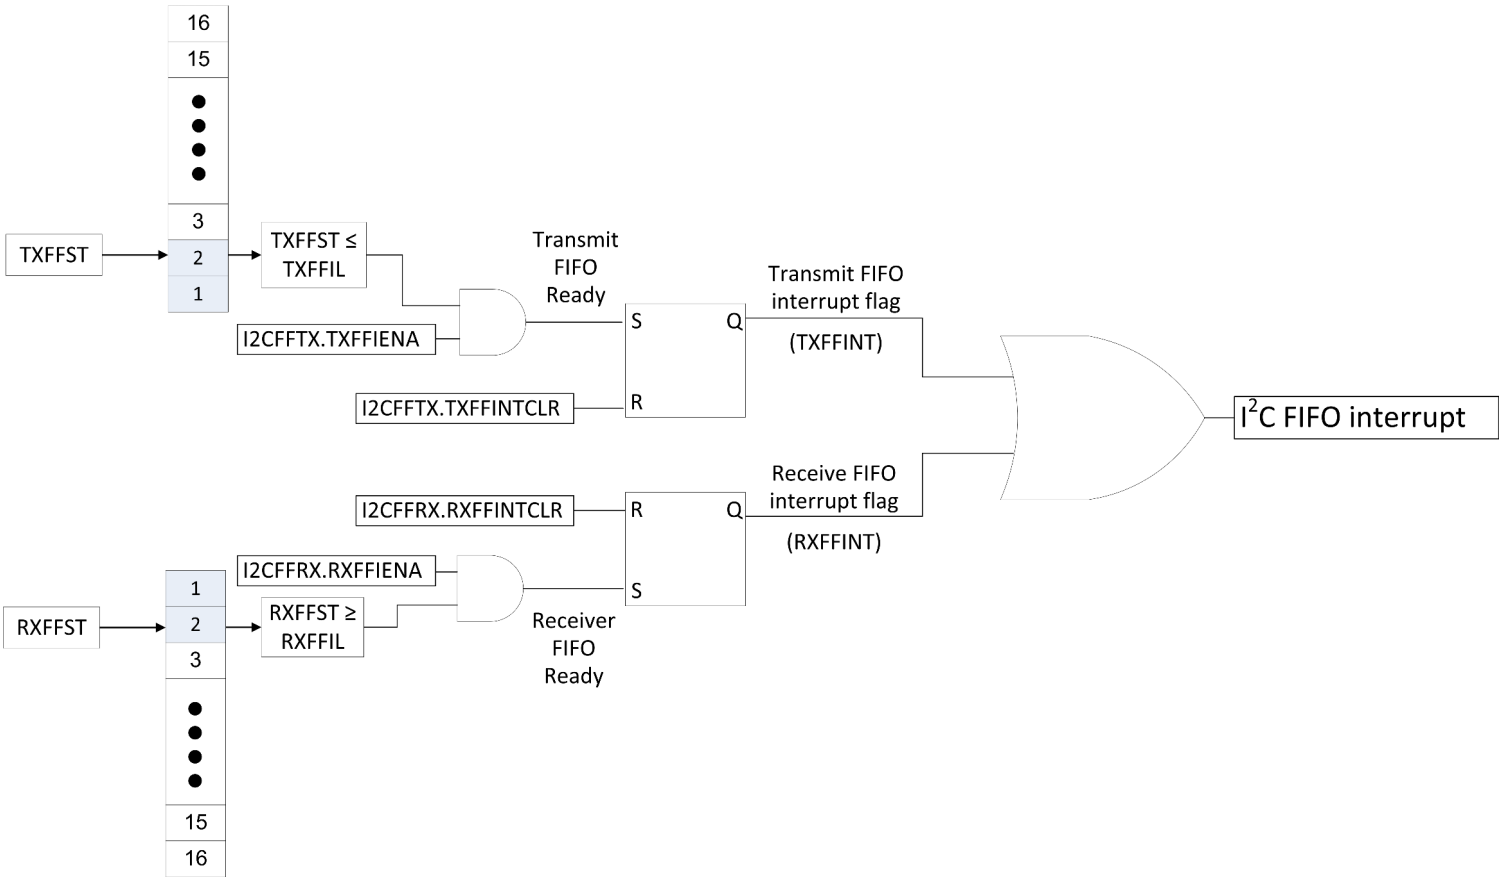

**Figure 20-19. I2C FIFO Interrupt**

## 20.5 Resetting or Disabling the I2C Module

You can reset or disable the I2C module in two ways:

- Write 0 to the I2C reset bit (IRS) in the I2C mode register (I2CMDR). All status bits (in I2CSTR) are forced to the default values, and the I2C module remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high-impedance state.
- Initiate a device reset by driving the $\overline{\text{XRS}}$ pin low. The entire device is reset and is held in the reset state until you drive the pin high. When the $\overline{\text{XRS}}$ pin is released, all I2C module registers are reset to the default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until you write 1 to IRS.

The IRS must be 0 while you configure or reconfigure the I2C module. Forcing IRS to 0 can be used to save power and to clear error conditions.

## 20.6 Software

### *20.6.1 I2C Examples*

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/i2c

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

#### 20.6.1.1 C28x-I2C Library source file for FIFO interrupts

FILE: i2cLib_FIFO_controller_interrupt.c

#### 20.6.1.2 C28x-I2C Library source file for FIFO using polling

FILE: i2cLib_FIFO_polling.c

#### 20.6.1.3 C28x-I2C Library source file for FIFO interrupts

FILE: i2cLib_FIFO_controller_target_interrupt.c

#### 20.6.1.4 I2C Digital Loopback with FIFO Interrupts

FILE: i2c_ex1_loopback.c

This program uses the internal loopback test mode of the I2C module. Both the TX and RX I2C FIFOs and their interrupts are used. The pinmux and I2C initialization is done through the sysconfig file.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

*Watch Variables*

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### 20.6.1.5 I2C EEPROM

FILE: i2c_ex2_eeprom.c

This program will write 1-14 words to EEPROM and read them back. The data written and the EEPROM address written to are contained in the message structure, i2cMsgOut. The data read back will be contained in the message structure i2cMsgIn.

*External Connections*

- Connect external I2C EEPROM at address 0x50
- Connect DEVICE_GPIO_PIN_SDAA on to external EEPROM SDA (serial data) pin
- Connect DEVICE_GPIO_PIN_SCLA on to external EEPROM SCL (serial clock) pin

*Watch Variables*

- *i2cMsgOut* - Message containing data to write to EEPROM

Copyright © 2024 Texas Instruments Incorporated

- *i2cMsgIn* - Message containing data read from EEPROM

#### 20.6.1.6 I2C Digital External Loopback with FIFO Interrupts

FILE: i2c_ex3_external_loopback.c

This program uses the I2CA and I2CB modules for achieving external loopback. The I2CA TX FIFO and the I2CB RX FIFO are used along with their interrupts.

A stream of data is sent on I2CA and then compared to the received stream on I2CB. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
This pattern is repeated forever.

*External Connections*
- Connect SCLA(DEVICE_GPIO_PIN_SCLA) to SCLB (DEVICE_GPIO_PIN_SCLB)
- and SDAA(DEVICE_GPIO_PIN_SDAA) to SDAB (DEVICE_GPIO_PIN_SDAB)
- Connect DEVICE_GPIO_PIN_LED1 to an LED used to depict data transfers.

*Watch Variables*
- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### 20.6.1.7 I2C EEPROM

FILE: i2c_ex4_eeprom_polling.c

This program will shows how to perform different EEPROM write and read commands using I2C polling method EEPROM used for this example is AT24C256

*External Connections*

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM

SCL | DEVICE_GPIO_PIN_SCLA | SCL SDA | DEVICE_GPIO_PIN_SDAA | SDA

Make sure to connect GND pins if EEPROM and C2000 device are in different board.

#### 20.6.1.8 I2C controller target communication using FIFO interrupts

FILE: i2c_ex5_controller_target_interrupt.c

This program shows how to use I2CA and I2CB modules in both controller and target configuration This example uses I2C FIFO interrupts and doesn't using polling

Example1: I2CA as controller Transmitter and I2CB working target Receiver Example2: I2CA as controller Receiver and I2CB working target Transmitter Example3: I2CB as controller Transmitter and I2CA working target Receiver Example4: I2CB as controller Receiver and I2CA working target Transmitter

\b External \b Connections on launchpad should be made as shown below \n Signal | I2CA | I2CB

SCL | DEVICE_GPIO_PIN_SCLA | DEVICE_GPIO_PIN_SCLB

SDA | DEVICE_GPIO_PIN_SDAA | DEVICE_GPIO_PIN_SDAB

*Watch Variables* in memory window
- *I2CA_TXdata*

- *I2CA_RXdata*
- *I2CB_TXdata*
- *I2CB_RXdata* stream for error checking

#### 20.6.1.9 I2C EEPROM

FILE: i2c_ex6_eeprom_interrupt.c

This program will shows how to perform different EEPROM write and read commands using I2C interrupts EEPROM used for this example is AT24C256

*External Connections*

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM

SCL | DEVICE_GPIO_PIN_SCLA | SCL SDA | DEVICE_GPIO_PIN_SDAA | SDA

Make sure to connect GND pins if EEPROM and C2000 device are in different board.

//Example 1: EEPROM Byte Write //Example 2: EEPROM Byte Read //Example 3: EEPROM word (16-bit) write //Example 4: EEPROM word (16-bit) read //Example 5: EEPROM Page write //Example 6: EEPROM word Paged read

*Watch Variables*

- *TX_MsgBuffer* - Message buffer which stores the data to be transmitted
- *RX_MsgBuffer* - Message buffer which stores the data to be received

## 20.7 I2C Registers

This section describes the I2C Module Registers.

### *20.7.1 I2C Base Addresses*

**Table 20-7. I2C Base Address Table (C28)**

| Bit Field Name | | DriverLib Name | Base Address | CPU1 | CPU2 | DMA | CLA | Pipeline Protected |
|---|---|---|---|---|---|---|---|---|
| Instance | Structure | | | | | | | |
| I2caRegs | I2C_REGS | I2CA_BASE | 0x0000_7300 | YES | YES | - | - | YES |
| I2cbRegs | I2C_REGS | I2CB_BASE | 0x0000_7340 | YES | YES | - | - | YES |

Copyright © 2024 Texas Instruments Incorporated

### 20.7.2 I2C_REGS Registers

Table 20-8 lists the memory-mapped registers for the I2C_REGS registers. All register offset addresses not listed in Table 20-8 should be considered as reserved locations and the register contents should not be modified.

**Table 20-8. I2C_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | I2COAR | I2C Own address | | Go |
| 1h | I2CIER | I2C Interrupt Enable | | Go |
| 2h | I2CSTR | I2C Status | | Go |
| 3h | I2CCLKL | I2C Clock low-time divider | | Go |
| 4h | I2CCLKH | I2C Clock high-time divider | | Go |
| 5h | I2CCNT | I2C Data count | | Go |
| 6h | I2CDRR | I2C Data receive | | Go |
| 7h | I2CSAR | I2C Slave address | | Go |
| 8h | I2CDXR | I2C Data Transmit | | Go |
| 9h | I2CMDR | I2C Mode | | Go |
| Ah | I2CISRC | I2C Interrupt Source | | Go |
| Bh | I2CEMDR | I2C Extended Mode | | Go |
| Ch | I2CPSC | I2C Prescaler | | Go |
| 20h | I2CFFTX | I2C FIFO Transmit | | Go |
| 21h | I2CFFRX | I2C FIFO Receive | | Go |

Complex bit access types are encoded to fit into small table cells. Table 20-9 shows the codes that are used for access types in this section.

**Table 20-9. I2C_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| W1C | W<br>1C | Write<br>1 to clear |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 20.7.2.1 I2COAR Register (Offset = 0h) [Reset = 0000h]

I2COAR is shown in Figure 20-20 and described in Table 20-10.

Return to the Summary Table.

The I2C own address register (I2COAR) is a 16-bit register. The I2C module uses this register to specify its own slave address, which distinguishes it from other slaves connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 are used
write 0s to bits 9-7.

**Figure 20-20. I2COAR Register**

### 20.7.2.2 I2CIER Register (Offset = 1h) [Reset = 0000h]

I2CIER is shown in Figure 20-21 and described in Table 20-11.

Return to the Summary Table.

I2CIER is used by the CPU to individually enable or disable I2C interrupt requests.

**Figure 20-21. I2CIER Register**

### 20.7.2.3 I2CSTR Register (Offset = 2h) [Reset = 0410h]

I2CSTR is shown in Figure 20-22 and described in Table 20-12.

Return to the Summary Table.

The I2C status register (I2CSTR) is a 16-bit register used to determine which interrupt has occurred and to read status information.

**Figure 20-22. I2CSTR Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

| 15 | RESERVED | R | 0h | Reserved |
| 14 | SDIR | R/W1C | 0h | Slave direction bit<br>Reset type: SYSRSn<br>0h (R/W) = I2C is not addressed as a slave transmitter. SDIR is cleared by one of the following events:<br>- It is manually cleared. To clear this bit, write a 1 to it.<br>- Digital loopback mode is enabled.<br>- A START or STOP condition occurs on the I2C bus.<br>1h (R/W) = I2C is addressed as a slave transmitter. |
| 13 | NACKSNT | R/W1C | 0h | NACK sent bit.<br>This bit is used when the I2C module is in the receiver mode. One instance in which NACKSNT is affected is when the NACK mode is used (see the description for NACKMOD in<br>Reset type: SYSRSn<br>0h (R/W) = NACK not sent. NACKSNT bit is cleared by any one of the following events:<br>- It is manually cleared. To clear this bit, write a 1 to it.<br>- The I2C module is reset (either when 0 is written to the IRS bit of I2CMDR or when the whole device is reset).<br>1h (R/W) = NACK sent: A no-acknowledge bit was sent during the acknowledge cycle on the I2C-bus. |
| 12 | BB | R | 0h | Bus busy bit.<br>BB indicates whether the I2C-bus is busy or is free for another data transfer. See the paragraph following the table for more information<br>Reset type: SYSRSn<br>0h (R/W) = Bus free. BB is cleared by any one of the following events:<br>- The I2C module receives or transmits a STOP bit (bus free).<br>- The I2C module is reset.<br>1h (R/W) = Bus busy: The I2C module has received or transmitted a START bit on the bus. |

Copyright © 2024 Texas Instruments Incorporated

**Table 20-12. I2CSTR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 11 | RSFULL | R | 0h | Receive shift register full bit.<br>RSFULL indicates an overrun condition during reception. Overrun occurs when new data is received into the shift register (I2CRSR) and the old data has not been read from the receive register (I2CDRR). As new bits arrive from the SDA pin, they overwrite the bits in I2CRSR. The new data will not be copied to ICDRR until the previous data is read.<br>Reset type: SYSRSn<br>0h (R/W) = No overrun detected. RSFULL is cleared by any one of the following events:<br>- I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit.<br>- The I2C module is reset.<br>1h (R/W) = Overrun detected |
| 10 | XSMT | R | 1h | Transmit shift register empty bit.<br>XSMT = 0 indicates that the transmitter has experienced underflow. Underflow occurs when the transmit shift register (I2CXSR) is empty but the data transmit register (I2CDXR) has not been loaded since the last I2CDXR-to-I2CXSR transfer. The next I2CDXR-to-I2CXSR transfer will not occur until new data is in I2CDXR. If new data is not transferred in time, the previous data may be re-transmitted on the SDA pin.<br>Reset type: SYSRSn<br>0h (R/W) = Underflow detected (empty)<br>1h (R/W) = No underflow detected (not empty). XSMT is set by one of the following events:<br>- Data is written to I2CDXR.<br>- The I2C module is reset |
| 9 | AAS | R | 0h | Addressed-as-slave bit<br>Reset type: SYSRSn<br>0h (R/W) = In the 7-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or a repeated START condition. In the 10-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or by a slave address different from the I2C peripheral's own slave address.<br>1h (R/W) = The I2C module has recognized its own slave address or an address of all zeros (general call). |
| 8 | AD0 | R | 0h | Address 0 bits<br>Reset type: SYSRSn<br>0h (R/W) = AD0 has been cleared by a START or STOP condition.<br>1h (R/W) = An address of all zeros (general call) is detected. |
| 7-6 | RESERVED | R | 0h | Reserved |
| 5 | SCD | R/W1C | 0h | Stop condition detected bit.<br>SCD is set when the I2C sends or receives a STOP condition. The I2C module delays clearing of the I2CMDR[STP] bit until the SCD bit is set.<br>Reset type: SYSRSn<br>0h (R/W) = STOP condition not detected since SCD was last cleared. SCD is cleared by any one of the following events:<br>- I2CISRC is read by the CPU when it contains the value 110b (stop condition detected). Emulator reads of the I2CISRC do not affect this bit.<br>- SCD is manually cleared. To clear this bit, write a 1 to it.<br>- The I2C module is reset.<br>1h (R/W) = A STOP condition has been detected on the I2C bus. |

**Table 20-12. I2CSTR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 1 | NACK | R/W1C | 0h | No-acknowledgment interrupt flag bit.<br>NACK applies when the I2C module is a master transmitter. NACK indicates whether the I2C module has detected an acknowledge bit (ACK) or a noacknowledge bit (NACK) from the slave receiver. The CPU can poll NACK or use the NACK interrupt request.<br>Reset type: SYSRSn<br>0h (R/W) = ACK received/NACK not received. This bit is cleared by any one of the following events:<br>- An acknowledge bit (ACK) has been sent by the slave receiver.<br>- NACK is manually cleared. To clear this bit, write a 1 to it.<br>- The CPU reads the interrupt source register (I2CISRC) and the register contains the code for a NACK interrupt. Emulator reads of the I2CISRC do not affect this bit.<br>- The I2C module is reset.<br>1h (R/W) = NACK bit received. The hardware detects that a no-acknowledge (NACK) bit has been received.<br>Note: While the I2C module performs a general call transfer, NACK is 1, even if one or more slaves send acknowledgment. |
| 0 | ARBL | R/W1C | 0h | Arbitration-lost interrupt flag bit (only applicable when the I2C module is a master-transmitter).<br>ARBL primarily indicates when the I2C module has lost an arbitration contest with another master/transmitter. The CPU can poll ARBL or use the ARBL interrupt request.<br>Reset type: SYSRSn<br>0h (R/W) = Arbitration not lost. AL is cleared by any one of the following events:<br>- AL is manually cleared. To clear this bit, write a 1 to it.<br>- The CPU reads the interrupt source register (I2CISRC) and the register contains the code for an<br>AL interrupt. Emulator reads of the I2CISRC do not affect this bit.<br>- The I2C module is reset.<br>1h (R/W) = Arbitration lost. AL is set by any one of the following events:<br>- The I2C module senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously.<br>- The I2C module attempts to start a transfer while the BB (bus busy) bit is set to 1.<br>When AL becomes 1, the MST and STP bits of I2CMDR are cleared, and the I2C module becomes a slave-receiver. |

### 20.7.2.6 I2CCNT Register (Offset = 5h) [Reset = 0000h]

I2CCNT is shown in Figure 20-25 and described in Table 20-15.

Return to the Summary Table.

I2CCNT is a 16-bit register used to indicate how many data bytes to transfer when the I2C module is configured as a transmitter, or to receive when configured as a master receiver. In the repeat mode (RM = 1), I2CCNT is not used.
The value written to I2CCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each byte transferred (I2CCNT remains unchanged). If a STOP condition is requested in the master mode (STP = 1 in I2CMDR), the I2C module terminates the transfer with a STOP condition when the countdown is complete (that is, when the last byte has been transferred).

**Figure 20-25. I2CCNT Register**

### 20.7.2.7 I2CDRR Register (Offset = 6h) [Reset = 0000h]

I2CDRR is shown in Figure 20-26 and described in Table 20-16.

Return to the Summary Table.

I2CDRR is a 16-bit register used by the CPU to read received data. The I2C module can receive a data byte with 1 to 8 bits. The number of bits is selected with the bit count (BC) bits in I2CMDR. One bit at a time is shifted in from the SDA pin to the receive shift register (I2CRSR). When a complete data byte has been received, the I2C module copies the data byte from I2CRSR to I2CDRR. The CPU cannot access I2CRSR directly.
If a data byte with fewer than 8 bits is in I2CDRR, the data value is right-justified, and the other bits of I2CDRR(7-0) are undefined. For example, if BC = 011 (3-bit data size), the receive data is in I2CDRR(2-0), and the content of I2CDRR(7-3) is undefined.
When in the receive FIFO mode, the I2CDRR register acts as the receive FIFO buffer.

### 20.7.2.8 I2CSAR Register (Offset = 7h) [Reset = 03FFh]

I2CSAR is shown in Figure 20-27 and described in Table 20-17.

Return to the Summary Table.

The I2C slave address register (I2CSAR) is a 16-bit register for storing the next slave address that will be transmitted by the I2C module when it is a master. The SAR field of I2CSAR contains a 7-bit or 10-bit slave address. When the I2C module is not using the free data format (FDF = 0 in I2CMDR), it uses this address to initiate data transfers with a slave, or slaves. When the address is nonzero, the address is for a particular slave. When the address is 0, the address is a general call to all slaves. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 of I2CSAR are used
write 0s to bits 9-7.

**Figure 20-27. I2CSAR Register**

### 20.7.2.9 I2CDXR Register (Offset = 8h) [Reset = 0000h]

I2CDXR is shown in Figure 20-28 and described in Table 20-18.

Return to the Summary Table.

The CPU writes transmit data to I2CDXR. This 16-bit register accepts a data byte with 1 to 8 bits. Before writing to I2CDXR, specify how many bits are in a data byte by loading the appropriate value into the bit count (BC) bits of I2CMDR. When writing a data byte with fewer than 8 bits, make sure the value is right-aligned in I2CDXR. After a data byte is written to I2CDXR, the I2C module copies the data byte to the transmit shift register (I2CXSR). The CPU cannot access I2CXSR directly. From I2CXSR, the I2C module shifts the data byte out on the SDA pin, one bit at a time.
When in the transmit FIFO mode, the I2CDXR register acts as the transmit FIFO buffer.

| R/W-0h | R/W-0h | R/W-0h | R/W-0h | R/W-0h | R/W-0h | | |

**Table 20-19. I2CMDR Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15 | NACKMOD | R/W | 0h | NACK mode bit. This bit is only applicable when the I2C module is acting as a receiver.<br>Reset type: SYSRSn<br>0h (R/W) = In the slave-receiver mode: The I2C module sends an acknowledge (ACK) bit to the transmitter during each acknowledge cycle on the bus. The I2C module only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit.<br>In the master-receiver mode: The I2C module sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. At that point, the I2C module sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit<br>1h (R/W) = In either slave-receiver or master-receiver mode: The I2C module sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared.<br>Important: To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit. |
| 14 | FREE | R/W | 0h | This bit controls the action taken by the I2C module when a debugger breakpoint is encountered.<br>Reset type: SYSRSn<br>0h (R/W) = When I2C module is master:<br>If SCL is low when the breakpoint occurs, the I2C module stops immediately and keeps driving SCL low, whether the I2C module is the transmitter or the receiver. If SCL is high, the I2C module waits until SCL becomes low and then stops.<br>When I2C module is slave:<br>A breakpoint forces the I2C module to stop when the current transmission/reception is complete.<br>1h (R/W) = The I2C module runs free<br>that is, it continues to operate when a breakpoint occurs. |
| 13 | STT | R/W | 0h | START condition bit (only applicable when the I2C module is a master). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions (see Table 9-6). Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS = 0.<br>Reset type: SYSRSn<br>0h (R/W) = In the master mode, STT is automatically cleared after the START condition has been generated.<br>1h (R/W) = In the master mode, setting STT to 1 causes the I2C module to generate a START condition on the I2C-bus |
| 12 | RESERVED | R | 0h | Reserved |

Copyright © 2024 Texas Instruments Incorporated

**Table 20-19. I2CMDR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 11 | STP | R/W | 0h | STOP condition bit (only applicable when the I2C module is a master).<br>In the master mode, the RM,STT, and STP bits determine when the I2C module starts and stops data transmissions.<br>Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS=0. When in non-repeat mode, at least one byte must be transferred before a stop condition can be generated. The I2C module delays clearing of this bit until after the I2CSTR[SCD] bit is set. To avoid disrupting the I2C state machine, the user must wait until this bit is clear before initiating a new message.<br>Reset type: SYSRSn<br>0h (R/W) = STP is automatically cleared after the STOP condition has been generated<br>1h (R/W) = STP has been set by the device to generate a STOP condition when the internal data counter of the I2C module counts down to 0. |
| 10 | MST | R/W | 0h | Master mode bit.<br>MST determines whether the I2C module is in the slave mode or the master mode. MST is automatically changed from 1 to 0 when the I2C master generates a STOP condition<br>Reset type: SYSRSn<br>0h (R/W) = Slave mode. The I2C module is a slave and receives the serial clock from the master.<br>1h (R/W) = Master mode. The I2C module is a master and generates the serial clock on the SCL pin. |
| 9 | TRX | R/W | 0h | Transmitter mode bit.<br>When relevant, TRX selects whether the I2C module is in the transmitter mode or the receiver mode.<br>Reset type: SYSRSn<br>0h (R/W) = Receiver mode. The I2C module is a receiver and receives data on the SDA pin.<br>1h (R/W) = Transmitter mode. The I2C module is a transmitter and transmits data on the SDA pin. |
| 8 | XA | R/W | 0h | Expanded address enable bit.<br>Reset type: SYSRSn<br>0h (R/W) = 7-bit addressing mode (normal address mode). The I2C module transmits 7-bit slave addresses (from bits 6-0 of I2CSAR), and its own slave address has 7 bits (bits 6-0 of I2COAR).<br>1h (R/W) = 10-bit addressing mode (expanded address mode). The I2C module transmits 10-bit slave addresses (from bits 9-0 of I2CSAR), and its own slave address has 10 bits (bits 9-0 of I2COAR). |
| 7 | RM | R/W | 0h | Repeat mode bit (only applicable when the I2C module is a master-transmitter or master-receiver).<br>The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions<br>Reset type: SYSRSn<br>0h (R/W) = Nonrepeat mode. The value in the data count register (I2CCNT) determines how many bytes are received/transmitted by the I2C module.<br>1h (R/W) = Repeat mode. A data byte is transmitted each time the I2CDXR register is written to (or until the transmit FIFO is empty when in FIFO mode) until the STP bit is manually set. The value of I2CCNT is ignored. The ARDY bit/interrupt can be used to determine when the I2CDXR (or FIFO) is ready for more data, or when the data has all been sent and the CPU is allowed to write to the STP bit. |

Copyright © 2024 Texas Instruments Incorporated

**Table 20-19. I2CMDR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 6 | DLB | R/W | 0h | Digital loopback mode bit.<br>Reset type: SYSRSn<br>0h (R/W) = Digital loopback mode is disabled.<br>1h (R/W) = Digital loopback mode is enabled. For proper operation in this mode, the MST bit must be 1.<br>In the digital loopback mode, data transmitted out of I2CDXR is received in I2CDRR after n device cycles by an internal path, where: n = ((I2C input clock frequency/module clock frequency) x 8)<br>The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2COAR.<br>Note: The free data format (FDF = 1) is not supported in the digital loopback mode. |
| 5 | IRS | R/W | 0h | I2C module reset bit.<br>Reset type: SYSRSn<br>0h (R/W) = The I2C module is in reset/disabled. When this bit is cleared to 0, all status bits (in I2CSTR) are set to their default values.<br>1h (R/W) = The I2C module is enabled. This has the effect of releasing the I2C bus if the I2C peripheral is holding it. |
| 4 | STB | R/W | 0h | START byte mode bit. This bit is only applicable when the I2C module is a master. As described in version 2.1 of the Philips Semiconductors I2C-bus specification, the START byte can be used to help a slave that needs extra time to detect a START condition. When the I2C module is a slave, it ignores a START byte from a master, regardless of the value of the STB bit.<br>Reset type: SYSRSn<br>0h (R/W) = The I2C module is not in the START byte mode.<br>1h (R/W) = The I2C module is in the START byte mode. When you set the START condition bit (STT), the I2C module begins the transfer with more than just a START condition. Specifically, it generates:<br>1. A START condition<br>2. A START byte (0000 0001b)<br>3. A dummy acknowledge clock pulse<br>4. A repeated START condition<br>Then, as normal, the I2C module sends the slave address that is in I2CSAR. |
| 3 | FDF | R/W | 0h | Free data format mode bit.<br>Reset type: SYSRSn<br>0h (R/W) = Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit.<br>1h (R/W) = Free data format mode is enabled. Transfers have the free data (no address) format described in Section 9.2.5.<br>The free data format is not supported in the digital loopback mode (DLB=1). |

### 20.7.2.13 I2CPSC Register (Offset = Ch) [Reset = 0000h]

I2CPSC is shown in Figure 20-32 and described in Table 20-22.

Return to the Summary Table.

The I2C prescaler register (I2CPSC) is a 16-bit register (see Figure 14-21) used for dividing down the I2C input clock to obtain the desired module clock for the operation of the I2C module. See the device-specific data manual for the supported range of values for the module clock frequency.
IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

## 21.1 Introduction

This device provides up to two high-speed multichannel buffered serial ports (McBSPs) that allow direct interface to codecs and other devices in a system. The McBSP consists of a data-flow path and a control path connected to external devices by six pins as shown in Figure 21-1.

Data is communicated to devices interfaced with the McBSP via the data transmit (DX) pin for transmission and via the data receive (DR) pin for reception. Control information in the form of clocking and frame synchronization is communicated via the following pins: CLKX (transmit clock), CLKR (receive clock), FSX (transmit frame synchronization), and FSR (receive frame synchronization).

The CPU and the DMA controller communicate with the McBSP through 16-bit wide registers accessible via the internal peripheral bus. The CPU or the DMA controller writes the data to be transmitted to the data transmit registers (DXR1, DXR2). Data written to the DXRs is shifted out to the DX pin via the transmit shift registers (XSR1, XSR2). Similarly, receive data on the DR pin is shifted into the receive shift registers (RSR1, RSR2) and copied into the receive buffer registers (RBR1, RBR2). The contents of the receive buffer registers (RBRs) is then copied to the data receive registers (DRRs), which can be read by the CPU or the DMA controller. This allows simultaneous movement of internal and external data communications.

If the serial word length is 8 bits, 12 bits, or 16 bits, the DRR2, RBR2, RSR2, DXR2, and XSR2 registers are not used (written, read, or shifted) For larger word lengths, these registers are needed to hold the most significant bits.

The frame and clock loop-back is implemented at chip level to enable CLKX and FSX to drive CLKR and FSR. If the loop-back is enabled, the CLKR and FSR get their signals from the CLKX and FSX pads; instead of the CLKR and FSR pins.

### *21.1.1 MCBSP Related Collateral*

**Foundational Materials**

- C2000 Academy - McBSP
- *KeyStone Architecture Multichannel Buffered Serial Port (McBSP)*

### *21.1.2 Features of the McBSPs*

The McBSPs feature:

- Full-duplex communication
- Double-buffered transmission and triple-buffered reception, allowing a continuous data stream
- Independent clocking and framing for reception and transmission
- The capability to send interrupts to the CPU and to send DMA events to the DMA controller
- 128 channels for transmission and reception
- Multichannel selection modes that enable or disable block transfers in each of the channels
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices
- Support for external generation of clock signals and frame-synchronization signals
- A programmable sample rate generator for internal generation and control of clock signals and frame-synchronization signals
- Programmable polarity for frame-synchronization pulses and clock signals
- Direct interface to:
  - T1/E1 framers
  - IOM-2 compliant devices
  - AC97-compliant devices (the necessary multiphase frame capability is provided)
  - I2S compliant devices
  - SPI devices

Copyright © 2024 Texas Instruments Incorporated

- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits

**Note**

A value of the chosen data size is referred to as a *serial word* or *word* throughout the McBSP chapter. Elsewhere, *word* is used to describe a 16-bit value.

- µ-law and A-law companding
- The option of transmitting/receiving 8-bit data with the LSB first
- Status bits for flagging exception/error conditions
- ABIS mode is not supported

### *21.1.3 McBSP Pins/Signals*

Table 21-1 describes the McBSP interface pins and some internal signals.

**Table 21-1. McBSP Interface Pins/Signals**

| McBSP-A Pin | McBSP-B Pin | Type | Description |
|---|---|---|---|
| MCLKRA | MCLKRB | I/O | Supplies or reflects the receive clock; supplies the input clock of the sample rate generator |
| MCLKXA | MCLKXB | I/O | Supplies or reflects the transmit clock; supplies the input clock of the sample rate generator |
| MDRA | MDRB | I | Serial data receive pin |
| MDXA | MDXB | O | Serial data transmit pin |
| MFSRA | MFSRB | I/O | Supplies or reflects the receive frame-sync signal; controls sample rate generator synchronization when GSYNC = 1 (see Section 21.4.3) |
| MFSXA | MFSXB | I/O | Supplies or reflects the transmit frame-sync signal |
| **CPU Interrupt Signals** | | | |
| MRINT | | | Receive interrupt to CPU |
| MXINT | | | Transmit interrupt to CPU |
| **DMA Events** | | | |
| REVT | | | Receive synchronization event to DMA |
| XEVT | | | Transmit synchronization event to DMA |

#### 21.1.3.1 McBSP Generic Block Diagram

The McBSP consists of a data-flow path and a control path connected to external devices by six pins as shown in Figure 21-1. The figure and the text in this section use generic pin names.

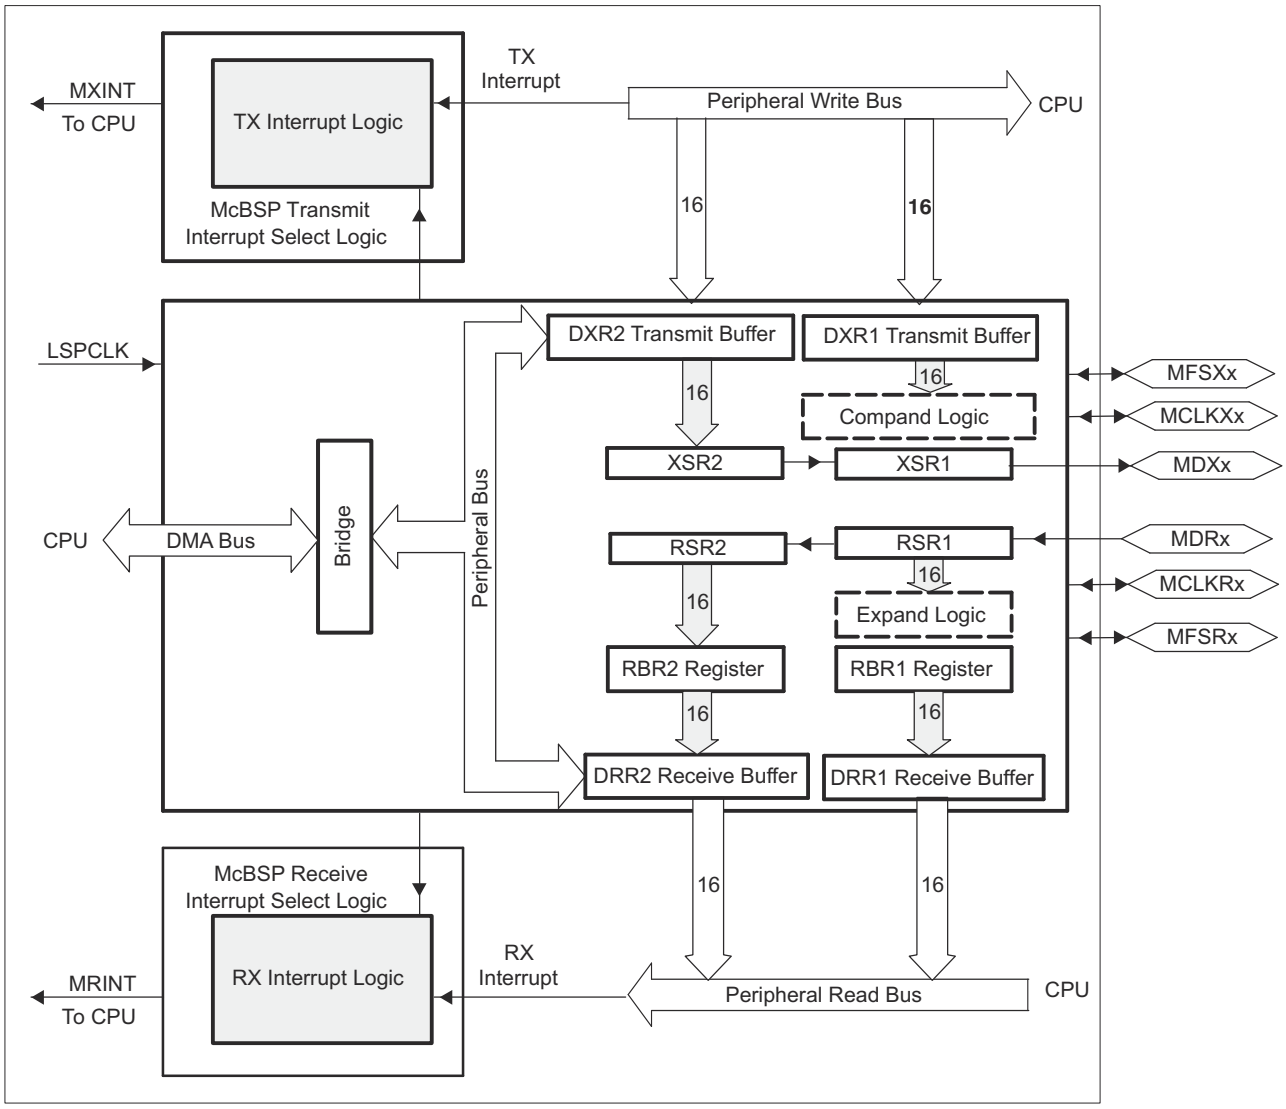
## 21.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

Copyright © 2024 Texas Instruments Incorporated



A. Not available in all devices. See the device-specific data sheet.

**Figure 21-1. Conceptual Block Diagram of the McBSP**

## 21.3 McBSP Operation

This section addresses the following topics:

- Data transfer process
- Companding (compressing and expanding) data
- Clocking and framing data
- Frame phases
- McBSP reception
- McBSP transmission
- Interrupts and DMA events generated by McBSPs

Copyright © 2024 Texas Instruments Incorporated

### 21.3.1 Data Transfer Process of McBSPs

Figure 21-2 shows a diagram of the McBSP data transfer paths. The McBSP receive operation is triple-buffered, and transmit operation is double-buffered. The use of registers varies, depending on whether the defined length of each serial word is 16 bits.

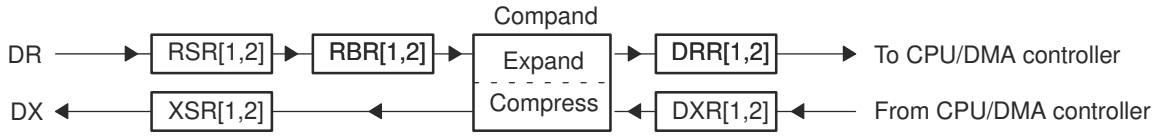


**Figure 21-2. McBSP Data Transfer Paths**

#### 21.3.1.1 Data Transfer Process for Word Length of 8, 12, or 16 Bits

If the word length is 16 bits or smaller, only one 16-bit register is needed at each stage of the data transfer paths. The registers DRR2, RBR2, RSR2, DXR2, and XSR2 are not used (written, read, or shifted).

Receive data arrives on the DR pin and is shifted into receive shift register 1 (RSR1). Once a full word is received, the content of RSR1 is copied to the receive buffer register 1 (RBR1), that is, if RBR1 is not full with previous data. RBR1 is then copied to the data receive register 1 (DRR1), unless the previous content of DRR1 has not been read by the CPU or the DMA controller. If the companding feature of the McBSP is implemented, the required word length is 8 bits and receive data is expanded into the appropriate format before being passed from RBR1 to DRR1. For more details about reception, see Section 21.3.5.

Transmit data is written by the CPU or the DMA controller to the data transmit register 1 (DXR1). If there is no previous data in the transmit shift register (XSR1), the value in DXR1 is copied to XSR1; otherwise, DXR1 is copied to XSR1 when the last bit of the previous data is shifted out on the DX pin. If selected, the companding module compresses 16-bit data into the appropriate 8-bit format before passing it to XSR1. After transmit frame synchronization, the transmitter begins shifting bits from XSR1 to the DX pin. For more details about transmission, see Section 21.3.6.

#### 21.3.1.2 Data Transfer Process for Word Length of 20, 24, or 32 Bits

If the word length is larger than 16 bits, two 16-bit registers are needed at each stage of the data transfer paths. The registers DRR2, RBR2, RSR2, DXR2, and XSR2 are needed to hold the most significant bits.

Receive data arrives on the DR pin and is shifted first into RSR2 and then into RSR1. Once the full word is received, the contents of RSR2 and RSR1 are copied to RBR2 and RBR1, respectively, if RBR1 is not full. Then the contents of RBR2 and RBR1 are copied to DRR2 and DRR1, respectively, unless the previous content of DRR1 has not been read by the CPU or the DMA controller. The CPU or the DMA controller must read data from DRR2 first and then from DRR1. When DRR1 is read, the next RBR-to-DRR copy occurs. For more details about reception, see Section 21.3.5.

For transmission, the CPU or the DMA controller must write data to DXR2 first and then to DXR1. When new data arrives in DXR1, if there is no previous data in XSR1, the contents of DXR2 and DXR1 are copied to XSR2 and XSR1, respectively; otherwise, the contents of the DXRs are copied to the XSRs when the last bit of the previous data is shifted out on the DX pin. After transmit frame synchronization, the transmitter begins shifting bits from the XSRs to the DX pin. For more details about transmission, see Section 21.3.6.

### 21.3.2 Companding (Compressing and Expanding) Data

Companding (COMpressing and exPANDing) hardware allows compression and expansion of data in either μ-law or A-law format. The companding standard employed in the United States and Japan is μ-law. The European companding standard is referred to as A-law. The specifications for μ-law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and μ-law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

Copyright © 2024 Texas Instruments Incorporated

The μ-law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 21-3 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or μ-law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to twos complement format.

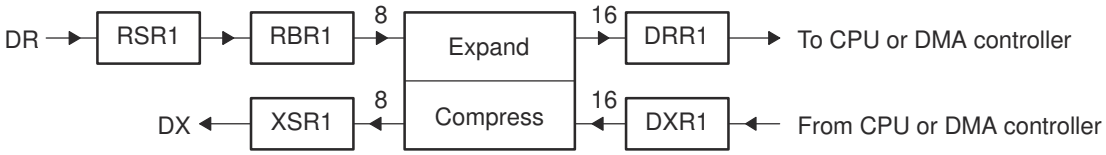

**Figure 21-3. Companding Processes**

#### 21.3.2.1 Companding Formats

For reception, the 8-bit compressed data in RBR1 is expanded to left-justified 16-bit data in DRR1. The receive sign-extension and justification mode specified in RJUST is ignored when companding is used.

For transmission using μ-law compression, the 14 data bits must be left-justified in DXR1 with the remaining two low-order bits filled with 0s as shown in Figure 21-4.

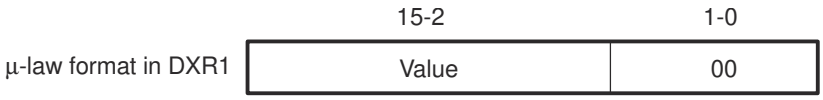

**Figure 21-4. μ-Law Transmit Data Companding Format**

For transmission using A-law compression, the 13 data bits must be left-justified in DXR1, with the remaining three low-order bits filled with 0s as shown in Figure 21-5.

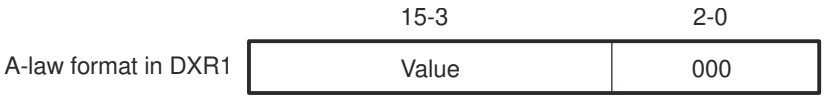

**Figure 21-5. A-Law Transmit Data Companding Format**

#### 21.3.2.2 Capability to Compand Internal Data

If the McBSP is unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. This can be used to:

- Convert linear to the appropriate μ-law or A-law format
- Convert μ-law or A-law to the linear format
- Observe the quantization effects in companding by transmitting linear data and compressing and re-expanding this data. This is useful only if both XCOMPAND and RCOMPAND enable the same companding format.

Figure 21-6 shows two methods by which the McBSP can compand internal data. Data paths for these two methods are used to indicate:

- When both the transmit and receive sections of the serial port are reset, DRR1 and DXR1 are connected internally through the companding logic. Values from DXR1 are compressed, as selected by XCOMPAND, and then expanded, as selected by RCOMPAND. RRDY and XRDY bits are not set. However, data is available in DRR1 within four CPU clocks after being written to DXR1.

Copyright © 2024 Texas Instruments Incorporated

The advantage of this method is the speed. The disadvantage is that there is no synchronization available to the CPU and DMA to control the flow. DRR1 and DXR1 are internally connected if the (X/R)COMPAND bits are set to 10b or 11b (compand using μ-law or A-law).

- The McBSP is enabled in digital loopback mode with companding appropriately enabled by RCOMPAND and XCOMPAND. Receive and transmit interrupts (RINT when RINTM = 0 and XINT when XINTM = 0) or synchronization events (REVT and XEVT) allow synchronization of the CPU or DMA to these conversions, respectively. Here, the time for this companding depends on the serial bit rate selected.

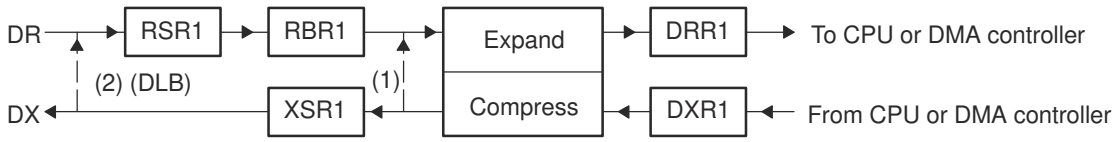

**Figure 21-6. Two Methods by Which the McBSP Can Compand Internal Data**

#### 21.3.2.3 Reversing Bit Order: Option to Transfer LSB First

Generally, the McBSP transmits or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set XCOMPAND = 01b in XCR2, the bit ordering of 8-bit words is reversed (LSB first) before being sent from the serial port. If you set RCOMPAND = 01b in RCR2, the bit ordering of 8-bit words is reversed during reception. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits, and LSB-first ordering is done.

### *21.3.3 Clocking and Framing Data*

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

#### 21.3.3.1 Clocking

**Note**

The McBSP cannot operate at a frequency faster than ½ the LSPCLK frequency. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX and/or CLKR, choose an appropriate input clock frequency and divide down value (CLKDV) (that is, be certain that CLKX or CLKR ≤ LSPCLK/2).

Data is shifted one bit at a time from the DR pin to the RSRs or from the XSRs to the DX pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR) controls bit transfers from the DR pin to the RSRs. The transmit clock signal (CLKX) controls bit transfers from the XSRs to the DX pin. CLKR or CLKX can be derived from a pin at the boundary of the McBSP or derived from inside the McBSP. The polarities of CLKR and CLKX are programmable.

Figure 21-7 shows how the clock signal controls the timing of each bit transfer on the pin.

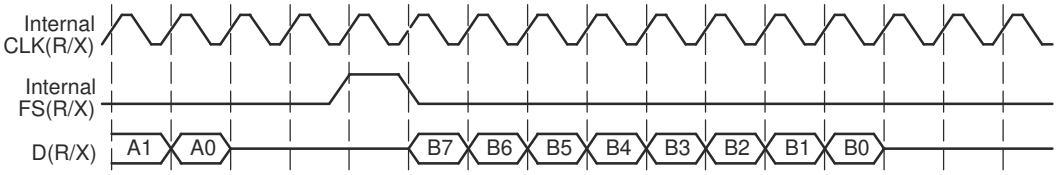

**Figure 21-7. Example - Clock Signal Control of Bit Transfer Timing**

Copyright © 2024 Texas Instruments Incorporated

#### 21.3.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (DR or DX) are transferred in a group called a serial word. You can define how many bits are in a word.

Bits coming in on the DR pin are held in RSR until RSR holds a full serial word. Only then is the word passed to RBR (and ultimately to the DRR).

During transmission, XSR does not accept new data from DXR until a full serial word has been passed from XSR to the DX pin.

In the exmaple in Figure 21-7, an 8-bit word size was defined (see bits 7 through 0 of word B being transferred).

#### 21.3.3.3 Frames and Frame Synchronization

One or more words are transferred in a group called a frame. You can define how many words are in a frame.

All of the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR) signal initiate frame transfers on the DR data pin. Pulses on the transmit frame-sync (FSX) signal initiate frame transfers on DX. FSR or FSX can be derived from a pin at the boundary of the McBSP or derived from inside the McBSP.

In Figure 21-7, a one-word frame is transferred when a frame-synchronization pulse occurs.

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

#### 21.3.3.4 Generating Transmit and Receive Interrupts

The McBSP can send receive and transmit interrupts to the CPU to indicate specific events in the McBSP. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses. Set the appropriate interrupt mode bits to 10b (for reception, RINTM = 10b; for transmission, XINTM = 10b).

##### *21.3.3.4.1 Detecting Frame-Synchronization Pulses, Even in Reset State*

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating RINT when the receiver is in reset). In this case, FSRM/FSXM and FSRP/FSXP still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the CPU clock and then sent to the CPU in the form of RINT and XINT at the point at which they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and after this occurs the CPU can take the serial port out of reset safely.

#### 21.3.3.5 Ignoring Frame-Synchronization Pulses

The McBSP can be configured to ignore transmit and/or receive frame-synchronization pulses. To have the receiver or transmitter recognize frame-synchronization pulses, clear the appropriate frame-synchronization ignore bit (RFIG = 0 for the receiver, XFIG = 0 for the transmitter). To have the receiver or transmitter ignore frame-synchronization pulses until the desired frame length or number of words is reached, set the appropriate frame-synchronization ignore bit (RFIG = 1 for the receiver, XFIG = 1 for the transmitter). For more details on unexpected frame-synchronization pulses, see one of the following topics:

- *Unexpected Receive Frame-Synchronization Pulse* (see Section 21.5.3)
- *Unexpected Transmit Frame-Synchronization Pulse* (see Section 21.5.6)

Copyright © 2024 Texas Instruments Incorporated

You can also use the frame-synchronization ignore function for data packing (for more details, see Section 21.11.2).

#### 21.3.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined by the equation:

$$\text{Frame Frequency} = \frac{\text{Clock Frequency}}{\text{Number of Clock Cycles Between Frame- Sync Pulses}}$$

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

#### 21.3.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined by the equation:

$$\text{Maximum Frame Frequency} = \frac{\text{Clock Frequency}}{\text{Number of Bits Per Frame}}$$

Figure 21-8 shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

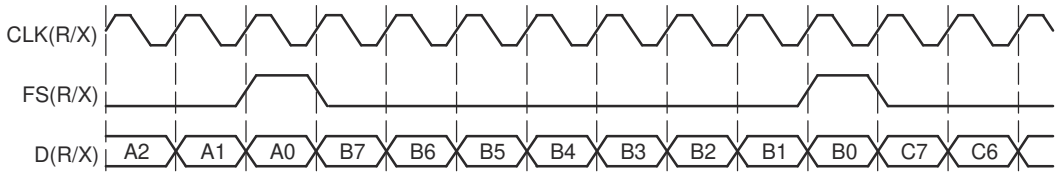

**Figure 21-8. McBSP Operating at Maximum Packet Frequency**

If there is a 1-bit data delay as shown in Figure 21-8, the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, making frame-synchronization pulses redundant. Theoretically, only an initial frame-synchronization pulse is required to initiate a multipacket transfer.

The McBSP supports operation of the serial port in this fashion by ignoring the successive frame-synchronization pulses. Data is clocked into the receiver or clocked out of the transmitter during every clock cycle.

**Note**

For XDATDLY = 0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX). For more details, see Section 21.9.13.

### *21.3.4 Frame Phases*

The McBSP allows you to configure each frame to contain one or two phases. The number of words and the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, you might define a frame as consisting of one phase containing two words of 16 bits each, followed by a second phase consisting of 10 words of 8 bits each. This configuration permits you to compose frames for custom applications or, in general, to maximize the efficiency of data transfers.

Copyright © 2024 Texas Instruments Incorporated

#### 21.3.4.1 Number of Phases, Words, and Bits Per Frame

Table 21-2 shows which bit-fields in the receive control registers (RCR1 and RCR2) and in the transmit control registers (XCR1 and XCR2) determine the number of phases per frame, the number of words per frame, and number of bits per word for each phase, for the receiver and transmitter. The maximum number of words per frame is 128 for a single-phase frame and 256 for a dual-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

**Table 21-2. Register Bits That Determine the Number of Phases, Words, and Bits**

| Operation | Number of Phases | Words per Frame Set With | Bits per Word Set With |
|---|---|---|---|
| Reception | 1 (RPHASE = 0) | RFRLEN1 | RWDLEN1 |
| Reception | 2 (RPHASE = 1) | RFRLEN1 and RFRLEN2 | RWDLEN1 for phase 1 |
| | | | RWDLEN2 for phase 2 |
| Transmission | 1 (XPHASE = 0) | XFRLEN1 | XWDLEN1 |
| Transmission | 2 (XPHASE = 1) | XFRLEN1 and XFRLEN2 | XWDLEN1 for phase 1 |
| | | | XWDLEN2 for phase 2 |

#### 21.3.4.2 Single-Phase Frame Example

Figure 21-9 shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the DX and DR pins are available one clock cycle after FS(R/X) goes active. The figure makes the following assumptions:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0b: 1 word per frame
- (R/X)WDLEN1 = 000b: 8-bit word length
- (R/X)FRLEN2 and (R/X)WDLEN2 are ignored
- CLK(X/R)P = 0: Receive data clocked on falling edge; transmit data clocked on rising edge
- FS(R/X)P = 0: Active-high frame-synchronization signals
- (R/X)DATDLY = 01b: 1-bit data delay

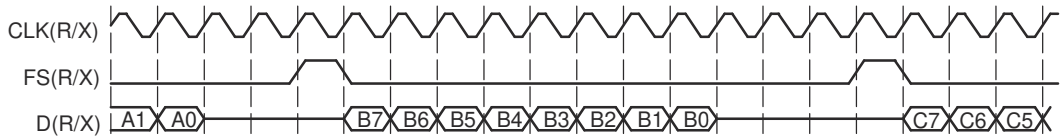

**Figure 21-9. Single-Phase Frame for a McBSP Data Transfer**

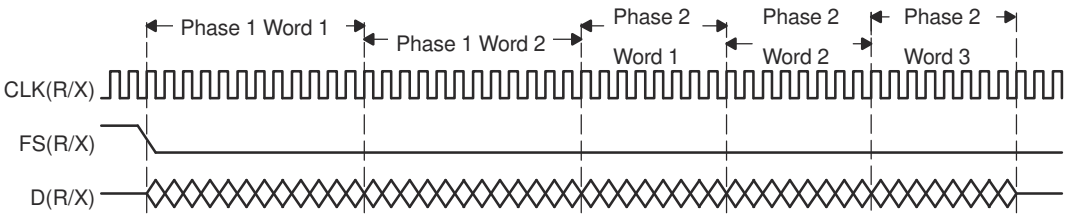
#### 21.3.4.3 Dual-Phase Frame Example

Figure 21-10 shows an example of a frame where the first phase consists of two words of 12 bits each, followed by a second phase of three words of 8 bits each. The entire bit stream in the frame is contiguous. There are no gaps either between words or between phases.



A. XRDY gets asserted once per phase. So, if there are 2 phases, XRDY gets asserted twice (once per phase).

**Figure 21-10. Dual-Phase Frame for a McBSP Data Transfer**

Copyright © 2024 Texas Instruments Incorporated

#### 21.3.4.4 Implementing the AC97 Standard With a Dual-Phase Frame

Figure 21-11 shows an example of the Audio Codec '97 (AC97) standard, which uses the dual-phase frame feature. Notice that words, not individual bits, are shown on the D(R/X) signal. The first phase (P1) consists of a single 16-bit word. The second phase (P2) consists of twelve 20-bit words. The phase configurations are listed after the figure.

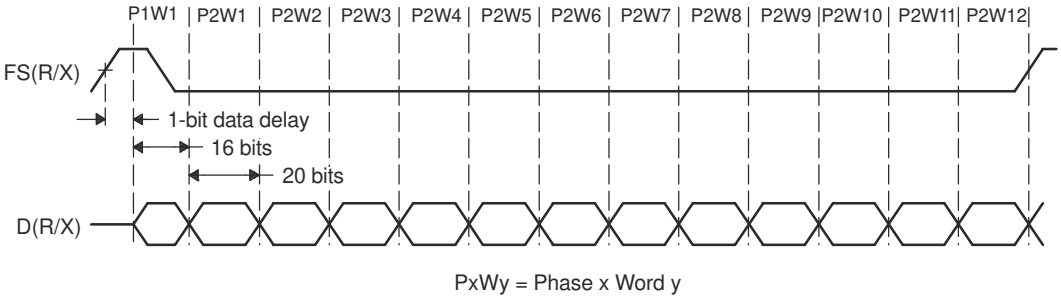


**Figure 21-11. Implementing the AC97 Standard With a Dual-Phase Frame**

- (R/X)PHASE = 1: Dual-phase frame
- (R/X)FRLEN1 = 0000000b: 1 word in phase 1
- (R/X)WDLEN1 = 010b: 16 bits per word in phase 1
- (R/X)FRLEN2 = 0001011b: 12 words in phase 2
- (R/X)WDLEN2 = 011b: 20 bits per word in phase 2
- CLKRP/CLKXP= 0: Receive data sampled on falling edge of internal CLKR / transmit data clocked on rising edge of internal CLKX
- FSRP/FSXP = 0: Active-high frame-sync signal
- (R/X)DATDLY = 01b: Data delay of 1 clock cycle (1-bit data delay)

Figure 21-12 shows the timing of an AC97-standard data transfer near frame synchronization. In this figure, individual bits are shown on D(R/X). Specifically, it shows the last two bits of phase 2 of one frame and the first four bits of phase 1 of the next frame. Regardless of the data delay, data transfers can occur without gaps. The first bit of the second frame (P1W1B15) immediately follows the last bit of the first frame (P2W12B0). Because a 1-bit data delay has been chosen, the transition on the frame-sync signal can occur when P2W12B0 is transferred.

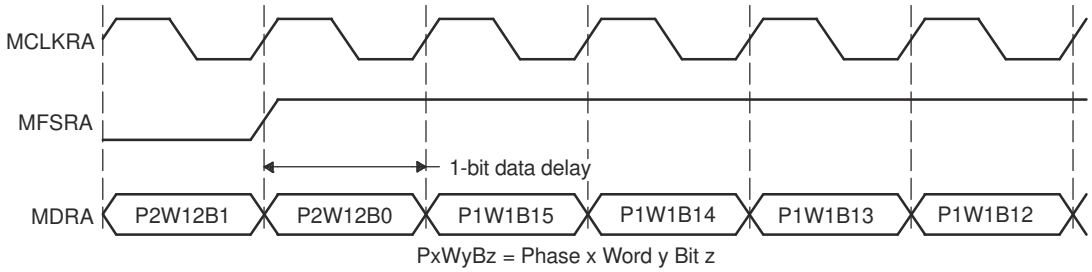

**Figure 21-12. Timing of an AC97-Standard Data Transfer Near Frame Synchronization**

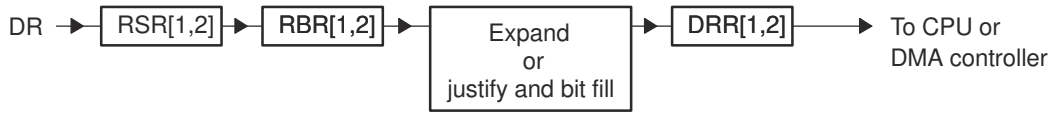
### 21.3.5 McBSP Reception

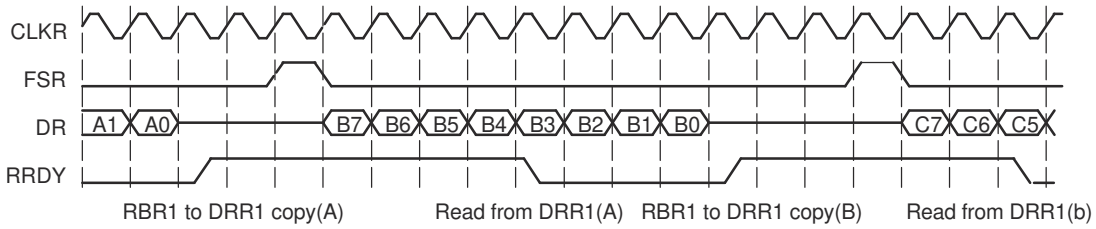
This section explains the fundamental process of reception in the McBSP. For details about how to program the McBSP receiver, see Section 21.8.

Figure 21-13 and Figure 21-14 show how reception occurs in the McBSP. Figure 21-13 shows the physical path for the data. Figure 21-14 is a timing diagram showing signal activity for one possible reception scenario. A description of the process follows the figures.



A. RSR[1,2]: Receive shift registers 1 and 2
B. RBR[1,2]: Receive buffer registers 1 and 2
C. DRR[1,2]: Data receive registers 1 and 2

**Figure 21-13. McBSP Reception Physical Data Path**



A. CLKR: Internal receive clock
B. FSR: Internal receive frame-synchronization signal
C. DR: Data on DR pin
D. RRDY: Status of receiver ready bit (high is 1)

**Figure 21-14. McBSP Reception Signal Activity**

The following process describes how data travels from the DR pin to the CPU or to the DMA controller:

1. The McBSP waits for a receive frame-synchronization pulse on internal FSR.
2. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the RDATDLY bits of RCR2.
   In the preceding timing diagram, a 1-bit data delay is selected.
3. The McBSP accepts data bits on the DR pin and shifts them into the receive shift registers.
   If the word length is 16 bits or smaller, only RSR1 is used. If the word length is larger than 16 bits, RSR2 and RSR1 are used and RSR2 contains the most-significant bits. For details on choosing a word length, see Section 21.8.8.
4. When a full word is received, the McBSP copies the contents of the receive shift registers to the receive buffer registers, provided that RBR1 is not full with previous data.
   If the word length is 16 bits or smaller, only RBR1 is used. If the word length is larger than 16 bits, RBR2 and RBR1 are used and RBR2 contains the most-significant bits.
5. The McBSP copies the contents of the receive buffer registers into the data receive registers, provided that DRR1 is not full with previous data. When DRR1 receives new data, the receiver ready bit (RRDY) is set in SPCR1. This indicates that received data is ready to be read by the CPU or the DMA controller.
   If the word length is 16 bits or smaller, only DRR1 is used. If the word length is larger than 16 bits, DRR2 and DRR1 are used and DRR2 contains the most-significant bits.
   If companding is used during the copy (RCOMPAND = 10b or 11b in RCR2), the 8-bit compressed data in RBR1 is expanded to a left-justified 16-bit value in DRR1. If companding is disabled, the data copied from RBR[1,2] to DRR[1,2] is justified and bit filled according to the RJUST bits.

Copyright © 2024 Texas Instruments Incorporated

6. The CPU or the DMA controller reads the data from the data receive registers. When DRR1 is read, RRDY is cleared and the next RBR-to-DRR copy is initiated.

**Note**

If both DRRs are required (word length larger than 16 bits), the CPU or the DMA controller must read from DRR2 first and then from DRR1. As soon as DRR1 is read, the next RBR-to-DRR copy is initiated. If DRR2 is not read first, the data in DRR2 is lost.

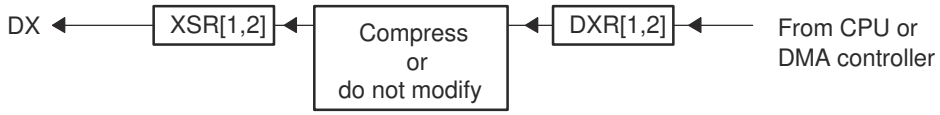
When activity is not properly timed, errors can occur. See the following topics for more details:

- Section 21.5.2
- Section 21.5.3

### *21.3.6 McBSP Transmission*

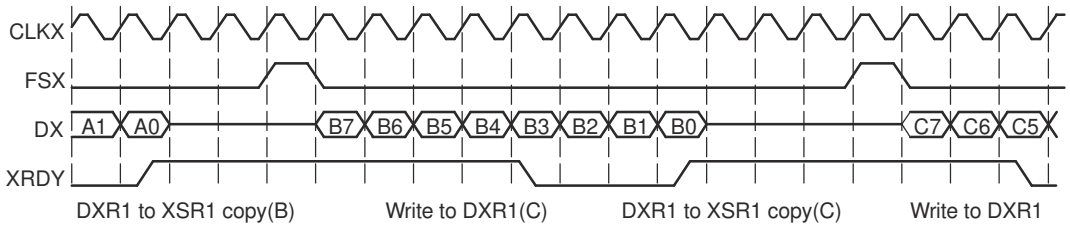
This section explains the fundamental process of transmission in the McBSP. For details about how to program the McBSP transmitter, see Section 21.9.

Figure 21-15 and Figure 21-16 show how transmission occurs in the McBSP. Figure 21-15 shows the physical path for the data. Figure 21-16 is a timing diagram showing signal activity for one possible transmission scenario. A description of the process follows the figures.



A. XSR[1,2]: Transmit shift registers 1 and 2
B. DXR[1,2]: Data transmit registers 1 and 2

**Figure 21-15. McBSP Transmission Physical Data Path**



A. CLKX: Internal transmit clock
B. FSX: Internal transmit frame-synchronization signal
C. DX: Data on DX pin
D. XRDY: Status of transmitter ready bit (high is 1)

**Figure 21-16. McBSP Transmission Signal Activity**

1. The CPU or the DMA controller writes data to the data transmit registers. When DXR1 is loaded, the transmitter ready bit (XRDY) is cleared in SPCR2 to indicate that the transmitter is not ready for new data. If the word length is 16 bits or smaller, only DXR1 is used. If the word length is larger than 16 bits, DXR2 and DXR1 are used and DXR2 contains the most-significant bits. For details on choosing a word length, see Section 21.9.9.

**Note**

If both DXRs are needed (word length larger than 16 bits), the CPU or the DMA controller must load DXR2 first and then load DXR1. As soon as DXR1 is loaded, the contents of both DXRs are copied to the transmit shift registers (XSRs), as described in the next step. If DXR2 is not loaded first, the previous content of DXR2 is passed to the XSR2.

Copyright © 2024 Texas Instruments Incorporated

2. When new data arrives in DXR1, the McBSP copies the content of the data transmit registers to the transmit shift registers. In addition, the transmit ready bit (XRDY) is set. This indicates that the transmitter is ready to accept new data from the CPU or the DMA controller.
   If the word length is 16 bits or smaller, only XSR1 is used. If the word length is larger than 16 bits, XSR2 and XSR1 are used and XSR2 contains the most-significant bits.
   If companding is used during the transfer (XCOMPAND = 10b or 11b in XCR2), the McBSP compresses the 16-bit data in DXR1 to 8-bit data in the μ-law or A-law format in XSR1. If companding is disabled, the McBSP passes data from the DXRs to the XSRs without modification.
3. The McBSP waits for a transmit frame-synchronization pulse on internal FSX.
4. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the XDATDLY bits of XCR2.
   In the preceding timing diagram (Figure 21-16), a 1-bit data delay is selected.
5. The McBSP shifts data bits from the transmit shift registers to the DX pin.

When activity is not properly timed, errors can occur. See the following topics for more details:

- Section 21.5.4
- Section 21.5.5
- Section 21.5.6

### *21.3.7 Interrupts and DMA Events Generated by a McBSP*

The McBSP sends notification of important events to the CPU and DMA via the internal signals shown in Table 21-3.

**Table 21-3. Interrupts and DMA Events Generated by a McBSP**

| Internal Signal | Description |
|---|---|
| RINT | Receive interrupt<br>The McBSP sends a receive interrupt request to the CPU based upon a selected condition in the receiver of the McBSP (a condition selected by the RINTM bits of SPCR1). |
| XINT | Transmit interrupt<br>The McBSP sends a transmit interrupt request to the CPU based upon a selected condition in the transmitter of the McBSP (a condition selected by the XINTM bits of SPCR2). |
| REVT | Receive synchronization event<br>An REVT signal is sent to the DMA when data has been received in the data receive registers (DRRs). |
| XEVT | Transmit synchronization event<br>An XEVT signal is sent to the DMA when the data transmit registers (DXRs) are ready to accept the next serial word for transmission. |

## 21.4 McBSP Sample Rate Generator

Each McBSP contains a sample rate generator (SRG) that can be programmed to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive (DR) pin and/or the data transmit (DX) pin. FSG can be used to initiate frame transfers on DR and/or DX. Figure 21-17 is a conceptual block diagram of the sample rate generator.

Copyright © 2024 Texas Instruments Incorporated

### 21.4.1 Block Diagram

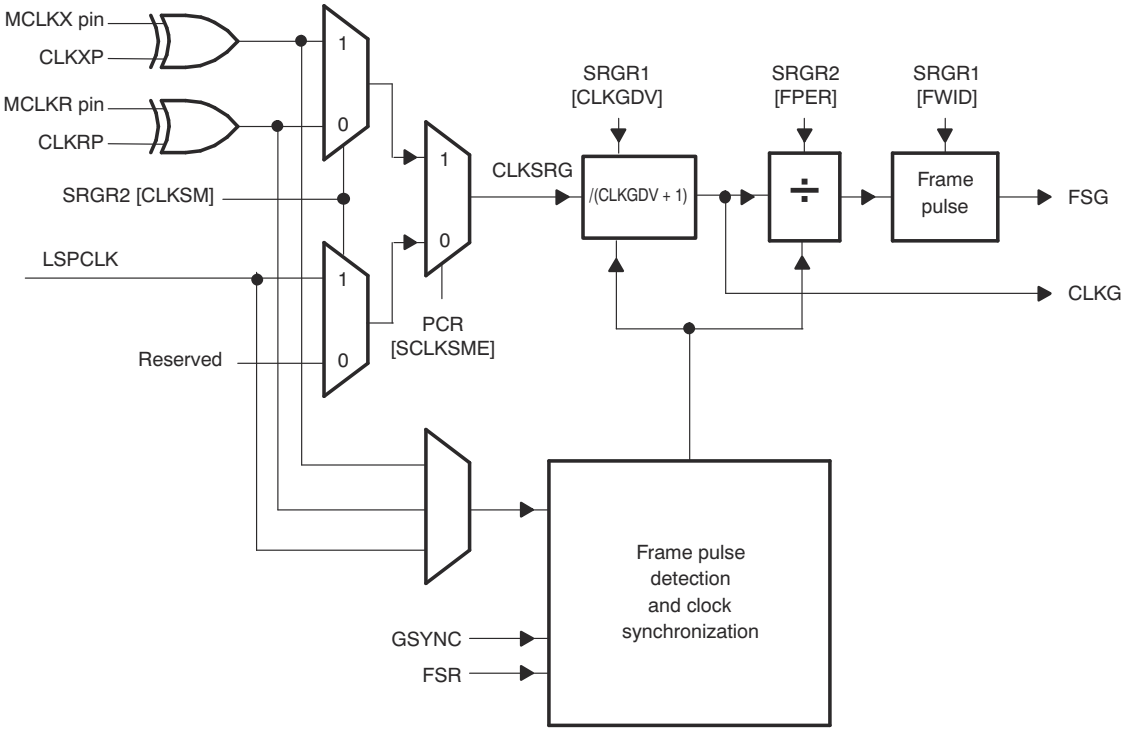


**Figure 21-17. Conceptual Block Diagram of the Sample Rate Generator**

The source clock for the sample rate generator (labeled CLKSRG in the diagram) can be supplied by the LSPCLK, or by an external pin (MCLKX or MCLKR ). The source is selected with the SCLKME bit of PCR and the CLKSM bit of SRGR2. If a pin is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (CLKXP of PCR or CLKRP of PCR).

The sample rate generator has a three-stage clock divider that gives CLKG and FSG programmability. The three stages provide:

- Clock divide-down. The source clock is divided according to the CLKGDV bits of SRGR1 to produce CLKG.
- Frame period divide-down. CLKG is divided according to the FPER bits of SRGR2 to control the period from the start of a frame-pulse to the start of the next pulse.
- Frame-synchronization pulse-width countdown. CLKG cycles are counted according to the FWID bits of SRGR1 to control the width of each frame-synchronization pulse.

**Note**

The McBSP cannot operate at a frequency faster than ½ the source clock frequency. You must choose an input clock frequency and a CLKGDV value such that CLKG is less than or equal to ½ the source clock frequency.

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the FSR pin. This feature is enabled or disabled with the GSYNC bit of SRGR2.

For details on getting the sample rate generator ready for operation, see Section 21.4.4.

Copyright © 2024 Texas Instruments Incorporated

#### 21.4.1.1 Clock Generation in the Sample Rate Generator

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the sample rate generator to drive clocking is controlled by the clock mode bits (CLKRM and CLKXM) in the pin control register (PCR). When a clock mode bit is set to 1 (CLKRM = 1 for reception, CLKXM = 1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal sample rate generator output clock (CLKG).

The effects of CLKRM = 1 and CLKXM = 1 on the McBSP are partially affected by the use of the digital loopback mode and the clock stop (SPI) mode, respectively, as described in Table 21-4. The digital loopback mode (described in Section 21.8.4) is selected with the DLB bit of SPCR1. The clock stop mode (described in Section 21.7.2) is selected with the CLKSTP bits of SPCR1.

When using the sample rate generator as a clock source, make sure the sample rate generator is enabled (GRST = 1).

**Table 21-4. Effects of DLB and CLKSTP on Clock Modes**

| Mode Bit Settings | | Effect |
|---|---|---|
| CLKRM = 1 | DLB = 0<br>(Digital loopback mode disabled) | CLKR is an output pin driven by the sample rate generator output clock (CLKG). |
| | DLB = 1<br>(Digital loopback mode enabled) | CLKR is an output pin driven by internal CLKX. The source for CLKX depends on the CLKXM bit. |
| CLKXM = 1 | CLKSTP = 00b or 01b<br>(Clock stop (SPI) mode disabled) | CLKX is an output pin driven by the sample rate generator output clock (CLKG). |
| | CLKSTP = 10b or 11b<br>(Clock stop (SPI) mode enabled) | The McBSP is a master in an SPI system. Internal CLKX drives internal CLKR and the shift clocks of any SPI-compliant slave devices in the system. CLKX is driven by the internal sample rate generator. |

#### 21.4.1.2 Choosing an Input Clock

The sample rate generator must be driven by an input clock signal from one of the three sources selectable with the SCLKME bit of PCR and the CLKSM bit of SRGR2 (see Table 21-5). When CLKSM = 1, the minimum divide down value in CLKGDV bits is 1. CLKGDV is described in Section 21.4.1.4.

**Table 21-5. Choosing an Input Clock for the Sample Rate Generator with the SCLKME and CLKSM Bits**

| SCLKME | CLKSM | Input Clock for Sample Rate Generator |
|---|---|---|
| 0 | 0 | Reserved |
| 0 | 1 | LSPCLK |
| 1 | 0 | Signal on MCLKR pin |
| 1 | 1 | Signal on MCLKX pin |

#### 21.4.1.3 Choosing a Polarity for the Input Clock

As shown in Figure 21-18, when the input clock is received from a pin, you can choose the polarity of the input clock. The rising edge of CLKSRG generates CLKG and FSG, but you can determine which edge of the input clock causes a rising edge on CLKSRG. The polarity options and their effects are described in Table 21-6.

Copyright © 2024 Texas Instruments Incorporated

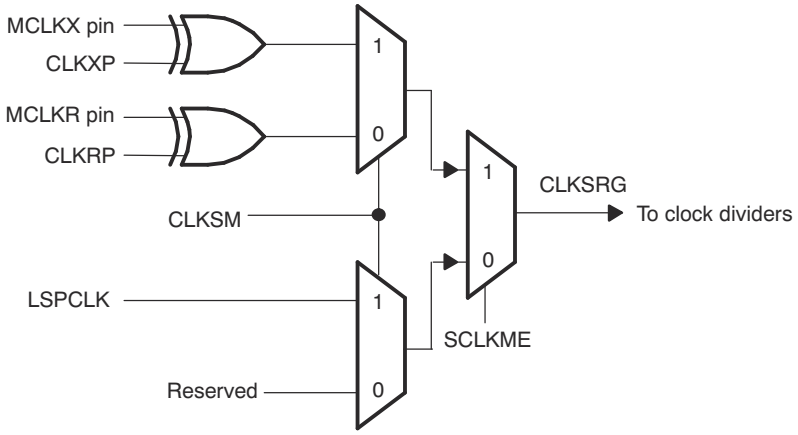

**Figure 21-18. Possible Inputs to the Sample Rate Generator and the Polarity Bits**

**Table 21-6. Polarity Options for the Input to the Sample Rate Generator**

| Input Clock | Polarity Option | Effect |
|---|---|---|
| LSPCLK | Always positive polarity | Rising edge of CPU clock generates transitions on CLKG and FSG. |
| Signal on MCLKR pin | CLKRP = 0 in PCR | Falling edge on MCLKR pin generates transitions on CLKG and FSG. |
| | CLKRP = 1 in PCR | Rising edge on MCLKR pin generates transitions on CLKG and FSG. |
| Signal on MCLKX pin | CLKXP = 0 in PCR | Rising edge on MCLKX pin generates transitions on CLKG and FSG. |
| | CLKXP = 1 in PCR | Falling edge on MCLKX pin generates transitions on CLKG and FSG. |

#### 21.4.1.4 Choosing a Frequency for the Output Clock (CLKG)

The input clock (LSPCLK or external clock) can be divided down by a programmable value to drive CLKG. Regardless of the source to the sample rate generator, the rising edge of CLKSRG (see Section 21.4.1.2) generates CLKG and FSG.

The first divider stage of the sample rate generator creates the output clock from the input clock. This divider stage uses a counter that is preloaded with the divide down value in the CLKGDV bits of SRGR1. The output of this stage is the data clock (CLKG). CLKG has the frequency represented by the following equation:

$$\text{CLKG frequency} = \frac{\text{Input clock frequency}}{(\text{CLKGDV} + 1)}$$

##### *21.4.1.4.1 CLKG Frequency*

Thus, the input clock frequency is divided by a value between 1 and 256. When CLKGDV is odd or equal to 0, the CLKG duty cycle is 50%. When CLKGDV is an even value, 2p, representing an odd divide down, the high-state duration is p+1 cycles and the low-state duration is p cycles.

#### 21.4.1.5 Keeping CLKG Synchronized to External MCLKR

When the MCLKR pin is used to drive the sample rate generator (see Section 21.4.1.2), the GSYNC bit in SRGR2 and the FSR pin can be used to configure the timing of the output clock (CLKG) relative to the input clock. Note that this feature is available only when the MCLKR pin is used to feed the external clock.

GSYNC = 1 ensures that the McBSP and an external device are dividing down the input clock with the same phase relationship. If GSYNC = 1, an inactive-to-active transition on the FSR pin triggers a resynchronization of CLKG and generation of FSG.

For more details about synchronization, see Section 21.4.3.

Copyright © 2024 Texas Instruments Incorporated

### 21.4.2 Frame Synchronization Generation in the Sample Rate Generator

The sample rate generator can produce a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure FSRM = 1. (When FSRM = 0, receive frame synchronization is supplied via the FSR pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- FSXM = 1 in PCR: This indicates that transmit frame synchronization is supplied by the McBSP itself rather than from the FSX pin.
- FSGM = 1 in SRGR2: This indicates that when FSXM = 1, transmit frame synchronization is supplied by the sample rate generator. (When FSGM = 0 and FSXM = 1, the transmitter uses frame-synchronization pulses generated every time data is transferred from DXR[1,2] to XSR[1,2].)

In either case, the sample rate generator must be enabled (GRST = 1) and the frame-synchronization logic in the sample rate generator must be enabled (FRST = 1).

#### 21.4.2.1 Choosing the Width of the Frame-Synchronization Pulse on FSG

Each pulse on FSG has a programmable width. You program the FWID bits of SRGR1, and the resulting pulse width is (FWID + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

#### 21.4.2.2 Controlling the Period Between the Starting Edges of Frame-Synchronization Pulses on FSG

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the sample rate generator:

- If the sample rate generator is using an external input clock and GSYNC = 1 in SRGR2, FSG pulses in response to an inactive-to-active transition on the FSR pin. Thus, the frame-synchronization period is controlled by an external device.
- Otherwise, you program the FPER bits of SRGR2, and the resulting frame-synchronization period is (FPER + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

#### 21.4.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the sample rate generator (see Section 21.4.1.2) , the GSYNC bit of SRGR2 and the FSR pin can be used to configure the timing of FSG pulses.

GSYNC = 1 ensures that the McBSP and an external device are dividing down the input clock with the same phase relationship. If GSYNC = 1, an inactive-to-active transition on the FSR pin triggers a resynchronization of CLKG and generation of FSG.

See Section 21.4.3 for more details about synchronization.

### 21.4.3 Synchronizing Sample Rate Generator Outputs to an External Clock

The sample rate generator can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) based on an input clock signal that is either the CPU clock signal or a signal at the MCLKR or MCLKX pin. When an external clock is selected to drive the sample rate generator, the GSYNC bit of SRGR2 and the FSR pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock.

Make GSYNC = 1 when you want the McBSP and an external device to divide down the input clock with the same phase relationship. If GSYNC = 1:

- An inactive-to-active transition on the FSR pin triggers a resynchronization of CLKG and a pulsing of FSG.
- CLKG always begins with a high state after synchronization.
- FSR is always detected at the same edge of the input clock signal that generates CLKG, no matter how long the FSR pulse is.
- The FPER bits of SRGR2 are ignored because the frame-synchronization period on FSG is determined by the arrival of the next frame-synchronization pulse on the FSR pin.

Copyright © 2024 Texas Instruments Incorporated

If GSYNC = 0, CLKG runs freely and is not resynchronized, and the frame-synchronization period on FSG is determined by FPER.

#### 21.4.3.1 Operating the Transmitter Synchronously with the Receiver

When GSYNC = 1, the transmitter can operate synchronously with the receiver, provided that:

- FSX is programmed to be driven by FSG (FSGM = 1 in SRGR2 and FSXM = 1 in PCR). If the input FSR has appropriate timing so that it can be sampled by the falling edge of CLKG, it can be used, instead, by setting FSXM = 0 and connecting FSR to FSX externally.
- The sample rate generator clock drives the transmit and receive clocking (CLKRM = CLKXM = 1 in PCR).

#### 21.4.3.2 Synchronization Examples

Figure 21-19 and Figure 21-20 show the clock and frame-synchronization operation with various polarities of CLKR and FSR. These figures assume FWID = 0 in SRGR1, for an FSG pulse that is one CLKG cycle wide. The FPER bits of SRGR2 are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the FSR pin. Each of the figures shows what happens to CLKG when it is initially synchronized and GSYNC = 1, and when it is not initially synchronized and GSYNC = 1. Figure 21-20 has a slower CLKG frequency (it has a larger divide-down value in the CLKGDV bits of SRGR1).

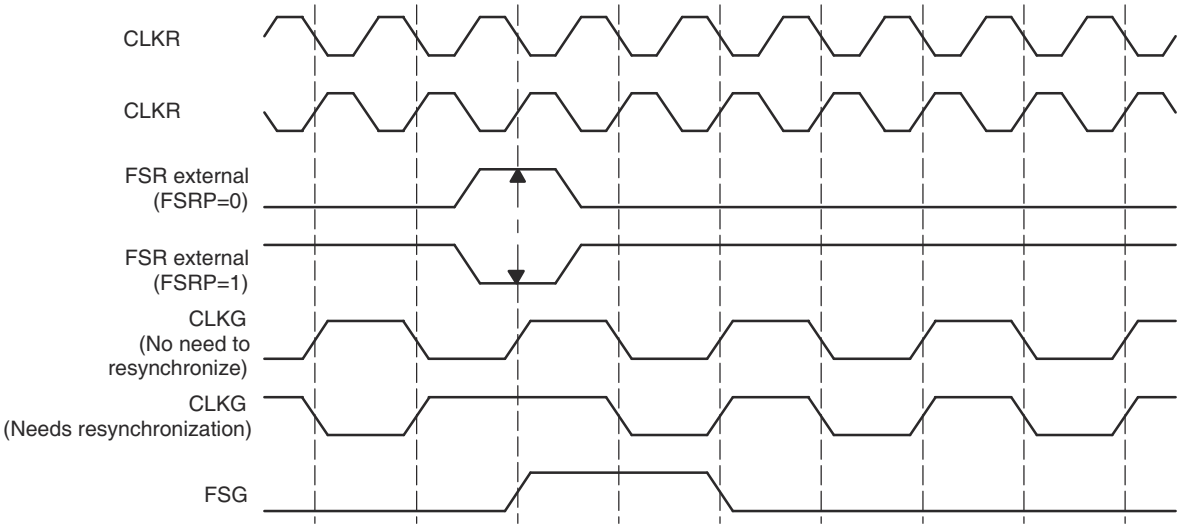

**Figure 21-19. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 1**

Copyright © 2024 Texas Instruments Incorporated

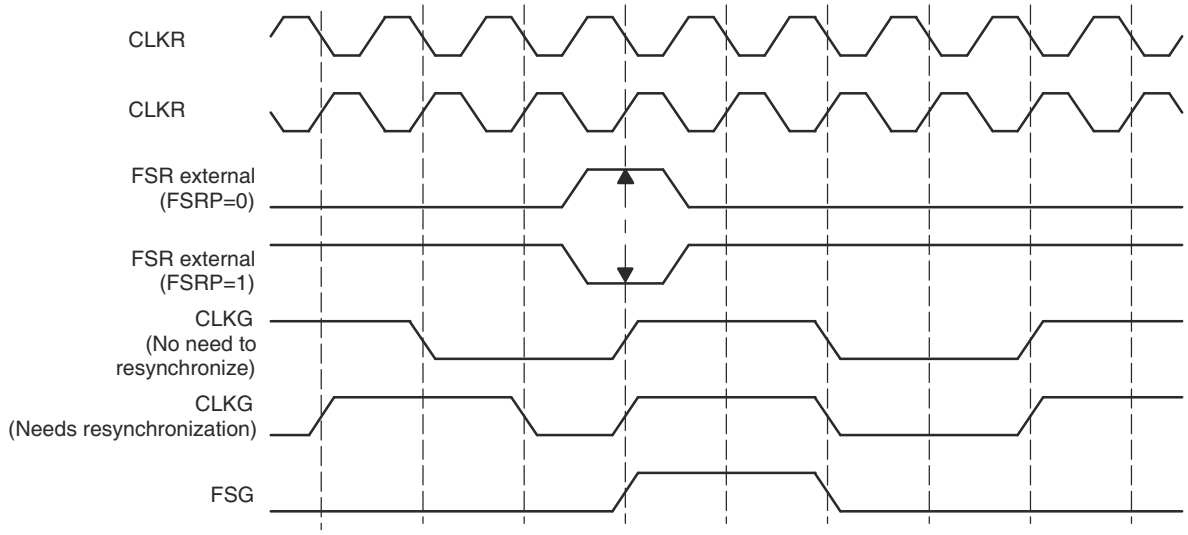

**Figure 21-20. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 3**

### *21.4.4 Reset and Initialization Procedure for the Sample Rate Generator*

To reset and initialize the sample rate generator:

1. Place the McBSP/sample rate generator in reset.

   During a DSP reset, the sample rate generator, the receiver, and the transmitter reset bits (GRST, RRST, and XRST) are automatically forced to 0. Otherwise, during normal operation, the sample rate generator can be reset by setting GRST = 0 in SPCR2, provided that CLKG and/or FSG is not used by any portion of the McBSP. Depending on your system, you can reset the receiver (RRST = 0 in SPCR1) and reset the transmitter (XRST = 0 in SPCR2).

   If GRST = 0 due to a device reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven inactive-low. If GRST = 0 due to program code, CLKG and FSG are driven low (inactive).
2. Program the registers that affect the sample rate generator.

   Program the sample rate generator registers (SRGR1 and SRGR2) as required for your application. If necessary, other control registers can be loaded with desired values, provided the respective portion of the McBSP (the receiver or transmitter) is in reset.

   After the sample rate generator registers are programmed, wait 2 CLKSRG cycles. This makes sure of proper synchronization internally.
3. Enable the sample rate generator (take the sample rate generator out of reset).

   In SPCR2, make GRST = 1 to enable the sample rate generator.

   After the sample rate generator is enabled, wait two CLKG cycles for the sample rate generator logic to stabilize.

   On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to the following CLKG frequency equation:

$$\text{CLKG frequency} = \frac{\text{Input clock frequency}}{(\text{CLKGDV} + 1)}$$

   where the input clock is selected with the SCLKME bit of PCR and the CLKSM bit of SRGR2 in one of the configurations shown in Table 21-7.

Copyright © 2024 Texas Instruments Incorporated

**Table 21-7. Input Clock Selection for Sample Rate Generator**

| SCLKME | CLKSM | Input Clock for Sample Rate Generator |
|---|---|---|
| 0 | 0 | Reserved |
| 0 | 1 | LSPCLK |
| 1 | 0 | Signal on MCLKR pin |
| 1 | 1 | Signal on MCLKX pin |

4. If necessary, enable the receiver and/or the transmitter.

   If necessary, remove the receiver and/or transmitter from reset by setting RRST and/or XRST = 1.
5. If necessary, enable the frame-synchronization logic of the sample rate generator.

After the required data acquisition setup is done (DXR[1,2] is loaded with data), set GRST = 1 in SPCR2 if an internally generated frame-synchronization pulse is required. FSG is generated with an active-high edge after the programmed number of CLKG clocks (FPER + 1) have elapsed.

## 21.5 McBSP Exception/Error Conditions

This section describes exception/error conditions and how to handle them.

### *21.5.1 Types of Errors*

There are five serial port events that can constitute a system error:

- Receiver overrun (RFULL = 1)

  This error occurs when DRR1 has not been read since the last RBR-to-DRR copy. Consequently, the receiver does not copy a new word from the RBRs to the DRRs and the RSRs are now full with another new word shifted in from DR. Therefore, RFULL = 1 indicates an error condition wherein any new data that can arrive at this time on DR replaces the contents of the RSRs, and the previous word is lost. The RSRs continue to be overwritten as long as new data arrives on DR and DRR1 is not read. For more details about overrun in the receiver, see Section 21.5.2.
- Unexpected receive frame-synchronization pulse (RSYNCERR = 1)

  This error occurs during reception when RFIG = 0 and an unexpected frame-synchronization pulse occurs. An unexpected frame-synchronization pulse is one that begins the next frame transfer before all the bits of the current frame have been received. Such a pulse causes data reception to abort and restart. If new data has been copied into the RBRs from the RSRs since the last RBR-to-DRR copy, this new data in the RBRs is lost. This is because no RBR-to-DRR copy occurs; the reception has been restarted. For more details about receive frame-synchronization errors, see Section 21.5.3.
- Transmitter data overwrite

  This error occurs when the CPU or DMA controller overwrites data in the DXRs before the data is copied to the XSRs. The overwritten data never reaches the DX pin. For more details about overwrite in the transmitter, see Section 21.5.4.
- Transmitter underflow ($\overline{\text{XEMPTY}}$ = 0)

  If a new frame-synchronization signal arrives before new data is loaded into DXR1, the previous data in the DXRs is sent again. This procedure continues for every new frame-synchronization pulse that arrives until DXR1 is loaded with new data. For more details about underflow in the transmitter, see Section 21.5.5.
- Unexpected transmit frame-synchronization pulse (XSYNCERR = 1)

  This error occurs during transmission when XFIG = 0 and an unexpected frame-synchronization pulse occurs. An unexpected frame-synchronization pulse is one that begins the next frame transfer before all the bits of the current frame have been transferred. Such a pulse causes the current data transmission to abort and restart. If new data has been written to the DXRs since the last DXR-to-XSR copy, the current value in the XSRs is lost. For more details about transmit frame-synchronization errors, see Section 21.5.6.

Copyright © 2024 Texas Instruments Incorporated

### 21.5.2 Overrun in the Receiver

RFULL = 1 in SPCR1 indicates that the receiver has experienced overrun and is in an error condition. RFULL is set when all of the following conditions are met:

1. DRR1 has not been read since the last RBR-to-DRR copy (RRDY = 1).
2. RBR1 is full and an RBR-to-DRR copy has not occurred.
3. RSR1 is full and an RSR1-to-RBR copy has not occurred.

As described in Section 21.3.5, data arriving on DR is continuously shifted into RSR1 (for word length of 16 bits or smaller) or RSR2 and RSR1 (for word length larger than 16 bits). Once a complete word is shifted into the RSR(s), an RSR-to-RBR copy can occur only if the previous data in RBR1 has been copied to DRR1. The RRDY bit is set when new data arrives in DRR1 and is cleared when that data is read from DRR1. Until RRDY = 0, the next RBR-to-DRR copy does not take place, and the data is held in the RSR(s). New data arriving on the DR pin is shifted into RSR(s), and the previous content of the RSR(s) is lost.

You can prevent the loss of data if DRR1 is read no later than 2.5 cycles before the end of the third word is shifted into the RSR1.

**Note**

If both DRRs are needed (word length larger than 16 bits), the CPU or the DMA controller must read from DRR2 first and then from DRR1. As soon as DRR1 is read, the next RBR-to-DRR copy is initiated. If DRR2 is not read first, the data in DRR2 is lost.

After the receiver starts running from reset, a minimum of three words must be received before RFULL is set. Either of the following events clears the RFULL bit and allows subsequent transfers to be read properly:

- The CPU or DMA controller reads DRR1.
- The receiver is reset individually (RRST = 0) or as part of a device reset.

Another frame-synchronization pulse is required to restart the receiver.

#### 21.5.2.1 Example of Overrun Condition

Figure 21-21 shows the receive overrun condition. Because serial word A is not read from DRR1 before serial word B arrives in RBR1, B is not transferred to DRR1 yet. Another new word ©) arrives and RSR1 is full with this data. DRR1 is finally read, but not earlier than 2.5 cycles before the end of word C. Therefore, new data (D) overwrites word C in RSR1. If DRR1 is not read in time, the next word can overwrite D.

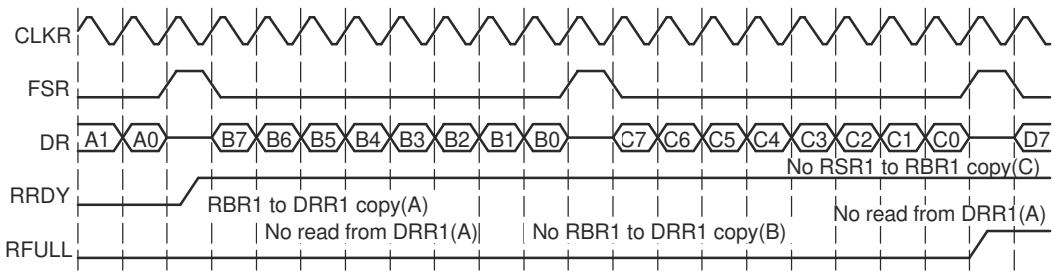

**Figure 21-21. Overrun in the McBSP Receiver**

Copyright © 2024 Texas Instruments Incorporated

#### 21.5.2.2 Example of Preventing Overrun Condition

Figure 21-22 shows the case where RFULL is set, but the overrun condition is prevented by a read from DRR1 at least 2.5 cycles before the next serial word is completely shifted into RSR1. This makes sure that an RBR1-to-DRR1 copy of word B occurs before receiver attempts to transfer word C from RSR1 to RBR1.

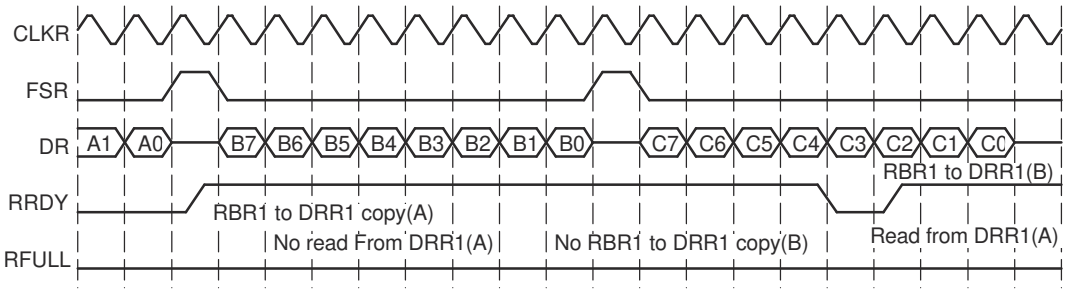

**Figure 21-22. Overrun Prevented in the McBSP Receiver**

### *21.5.3 Unexpected Receive Frame-Synchronization Pulse*

Section 21.5.3.1 shows how the McBSP responds to any receive frame-synchronization pulses, including an unexpected pulse. Section 21.5.3.2 and Section 21.5.3.3 show an example of a frame-synchronization error and an example of how to prevent such an error, respectively.

#### 21.5.3.1 Possible Responses to Receive Frame-Synchronization Pulses

Figure 21-23 shows the decision tree that the receiver uses to handle all incoming frame-synchronization pulses. The figure assumes that the receiver has been started (RRST = 1 in SPCR1). Case 3 shows where an error occurs.

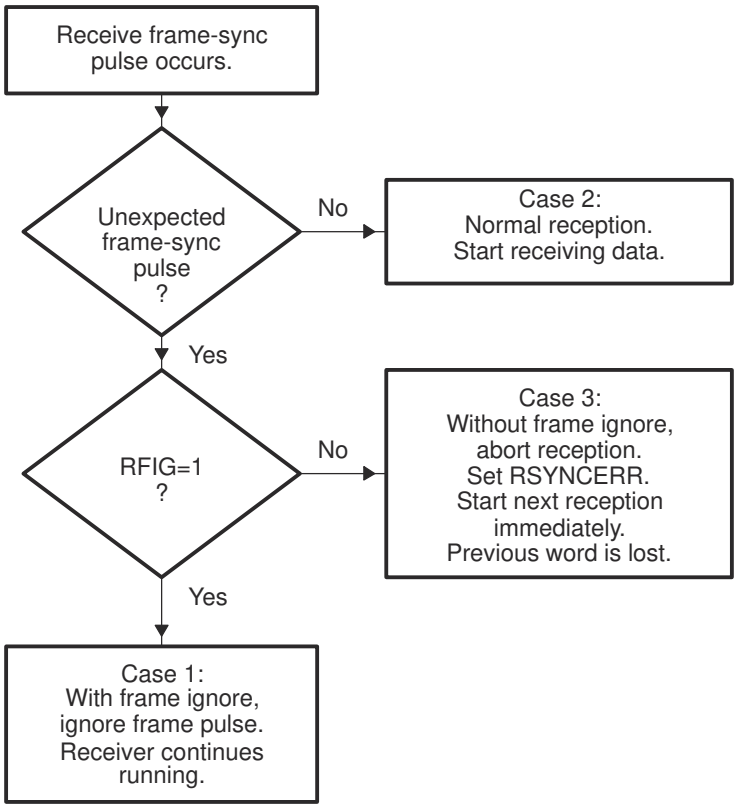

**Figure 21-23. Possible Responses to Receive Frame-Synchronization Pulses**

Copyright © 2024 Texas Instruments Incorporated

Any one of three cases can occur:

- Case 1: Unexpected internal FSR pulses with RFIG = 1 in RCR2. Receive frame-synchronization pulses are ignored, and the reception continues.
- Case 2: Normal serial port reception. Reception continues normally because the frame-synchronization pulse is not unexpected. There are three possible reasons why a receive operation might *not* be in progress when the pulse occurs:
  - The FSR pulse is the first after the receiver is enabled (RRST = 1 in SPCR1).
  - The FSR pulse is the first after DRR[1,2] is read, clearing a receiver full (RFULL = 1 in SPCR1) condition.
  - The serial port is in the interpacket intervals. The programmed data delay for reception (programmed with the RDATDLY bits in RCR2) may start during these interpacket intervals for the first bit of the next word to be received. Thus, at maximum frame frequency, frame synchronization can still be received 0 to 2 clock cycles before the first bit of the synchronized frame.
- Case 3: Unexpected receive frame synchronization with RFIG = 0 (frame-synchronization pulses not ignored). Unexpected frame-synchronization pulses can originate from an external source or from the internal sample rate generator.

  If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit (RSYNCERR) in SPCR1. RSYNCERR can be cleared only by a receiver reset or by a write of 0 to this bit.

  If you want the McBSP to notify the CPU of receive frame-synchronization errors, you can set a special receive interrupt mode with the RINTM bits of SPCR1. When RINTM = 11b, the McBSP sends a receive interrupt (RINT) request to the CPU each time that RSYNCERR is set.

#### 21.5.3.2 Example of Unexpected Receive Frame-Synchronization Pulse

Figure 21-30 shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets. When the unexpected frame-synchronization pulse occurs, the RSYNCERR bit is set, the reception of data B is aborted, and the reception of data C begins. In addition, if RINTM = 11b, the McBSP sends a receive interrupt (RINT) request to the CPU.

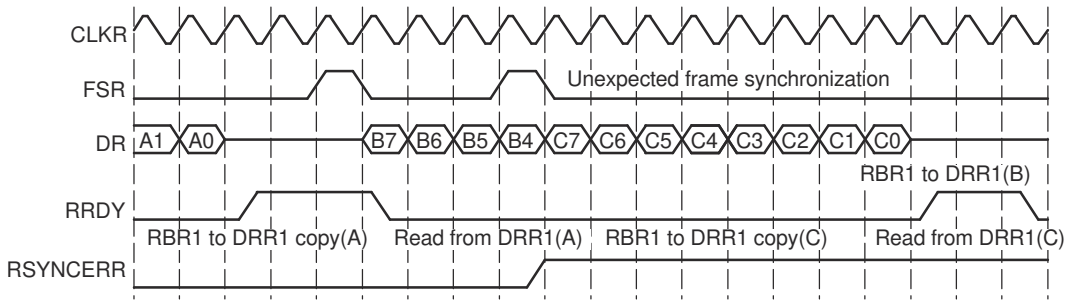

**Figure 21-24. An Unexpected Frame-Synchronization Pulse During a McBSP Reception**

#### 21.5.3.3 Preventing Unexpected Receive Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 MCLKR cycles, depending on the value in the RDATDLY bits of RCR2. For each possible data delay, Figure 21-25 shows when a new frame-synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

Copyright © 2024 Texas Instruments Incorporated

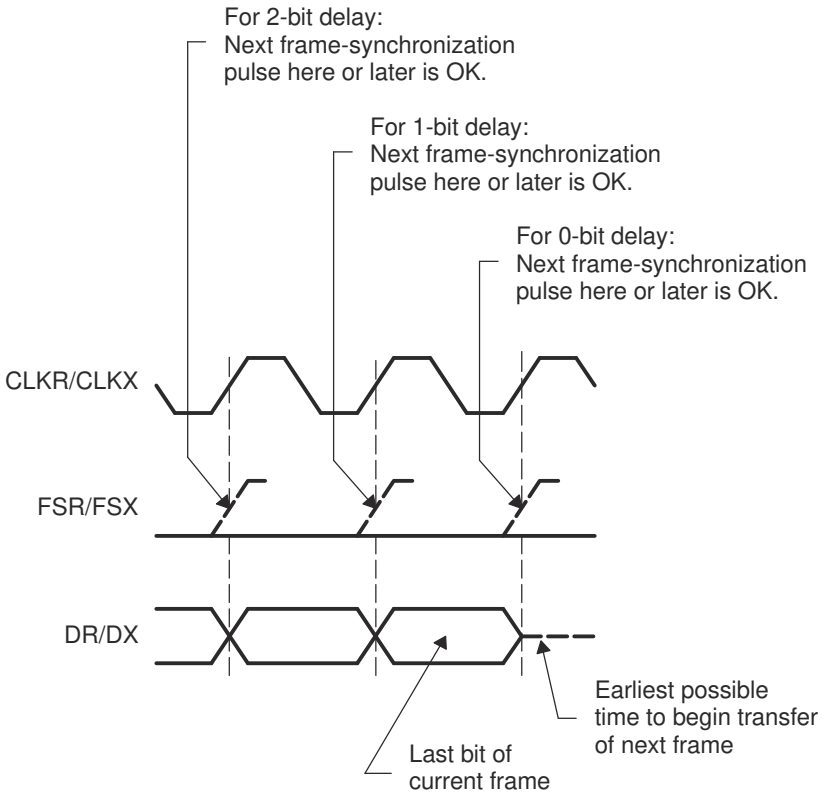

**Figure 21-25. Proper Positioning of Frame-Synchronization Pulses**

### *21.5.4 Overwrite in the Transmitter*

As described in Section 21.3.6), the transmitter must copy the data previously written to the DXR(s) by the CPU or DMA controller into the XSR(s) and then shift each bit from the XSR(s) to the DX pin. If new data is written to the DXR(s) before the previous data is copied to the XSR(s), the previous data in the DXR(s) is overwritten and thus lost.

#### 21.5.4.1 Example of Overwrite Condition

Figure 21-26 shows what happens if the data in DXR1 is overwritten before being transmitted. Initially, DXR1 is loaded with data C. A subsequent write to DXR1 overwrites C with D before C is copied to XSR1. Thus, C is never transmitted on DX.

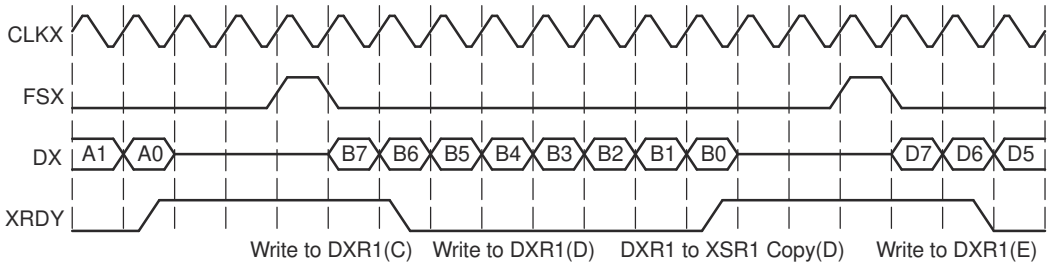

**Figure 21-26. Data in the McBSP Transmitter Overwritten and Thus Not Transmitted**

#### 21.5.4.2 Preventing Overwrites

You can prevent CPU overwrites by making the CPU:

- Poll for XRDY = 1 in SPCR2 before writing to the DXRs. XRDY is set when data is copied from DXR1 to XSR1 and is cleared when new data is written to DXR1.

Copyright © 2024 Texas Instruments Incorporated

- Wait for a transmit interrupt (XINT) before writing to the DXRs. When XINTM = 00b in SPCR2, the transmitter sends XINT to the CPU each time XRDY is set.

You can prevent DMA overwrites by synchronizing DMA transfers to the transmit synchronization event XEVT. The transmitter sends an XEVT signal each time XRDY is set.

### *21.5.5 Underflow in the Transmitter*

The McBSP indicates a transmitter empty (or underflow) condition by clearing the $\overline{\text{XEMPTY}}$ bit in SPCR2. Either of the following events activates $\overline{\text{XEMPTY}}$ ( $\overline{\text{XEMPTY}}$ = 0):

- DXR1 has not been loaded since the last DXR-to-XSR copy, and all bits of the data word in the XSR(s) have been shifted out on the DX pin.
- The transmitter is reset (by forcing XRST = 0 in SPCR2, or by a device reset) and is then restarted.

In the underflow condition, the transmitter continues to transmit the old data that is in the DXR(s) for every new transmit frame-synchronization signal, until a new value is loaded into DXR1 by the CPU or the DMA controller.

**Note**

If both DXRs are needed (word length larger than 16 bits), the CPU or the DMA controller must load DXR2 first and then load DXR1. As soon as DXR1 is loaded, the contents of both DXRs are copied to the transmit shift registers (XSRs). If DXR2 is not loaded first, the previous content of DXR2 is passed to the XSR2.

XEMPTY is deactivated (XEMPTY = 1) when a new word in DXR1 is transferred to XSR1. If FSXM = 1 in PCR and FSGM = 0 in SRGR2, the transmitter generates a single internal FSX pulse in response to a DXR-to-XSR copy. Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on DX.

When the transmitter is taken out of reset (XRST = 1), it is in a transmitter ready (XRDY = 1 in SPCR2) and transmitter empty (XEMPTY = 0) state. If DXR1 is loaded by the CPU or the DMA controller before internal FSX goes active high, a valid DXR-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before DXR1 is loaded, zeros are output on DX.

#### 21.5.5.1 Example of the Underflow Condition

Figure 21-27 shows an underflow condition. After B is transmitted, DXR1 is not reloaded before the subsequent frame-synchronization pulse. Thus, B is again transmitted on DX.

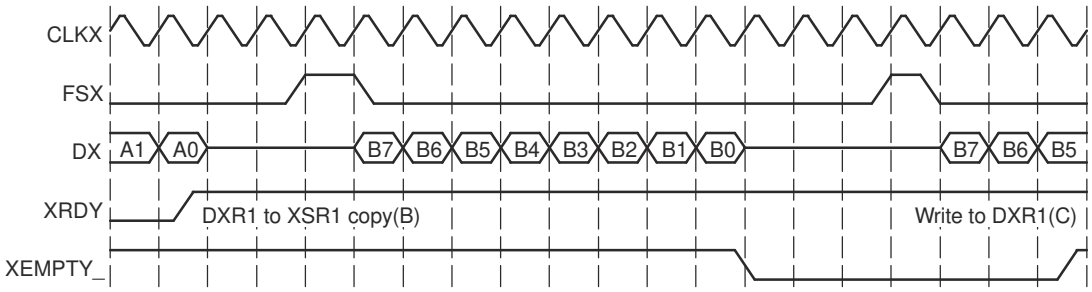

**Figure 21-27. Underflow During McBSP Transmission**

#### 21.5.5.2 Example of Preventing Underflow Condition

Figure 21-28 shows the case of writing to DXR1 just before an underflow condition can otherwise occur. After B is transmitted, C is written to DXR1 before the next frame-synchronization pulse. As a result, there is no underflow; B is not transmitted twice.

Copyright © 2024 Texas Instruments Incorporated

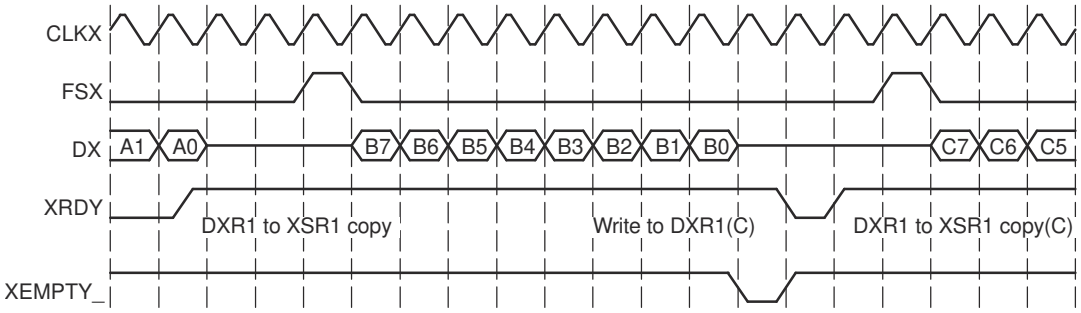

**Figure 21-28. Underflow Prevented in the McBSP Transmitter**

### *21.5.6 Unexpected Transmit Frame-Synchronization Pulse*

Section 21.5.6.1 shows how the McBSP responds to any transmit frame-synchronization pulses, including an unexpected pulse. Section 21.5.6.2 and Section 21.5.6.3 show examples of a frame-synchronization error and an example of how to prevent such an error, respectively.

#### 21.5.6.1 Possible Responses to Transmit Frame-Synchronization Pulses

Figure 21-29 shows the decision tree that the transmitter uses to handle all incoming frame-synchronization pulses. The figure assumes that the transmitter has been started (XRST = 1 in SPCR2). Case 3 shows where an error occurs.

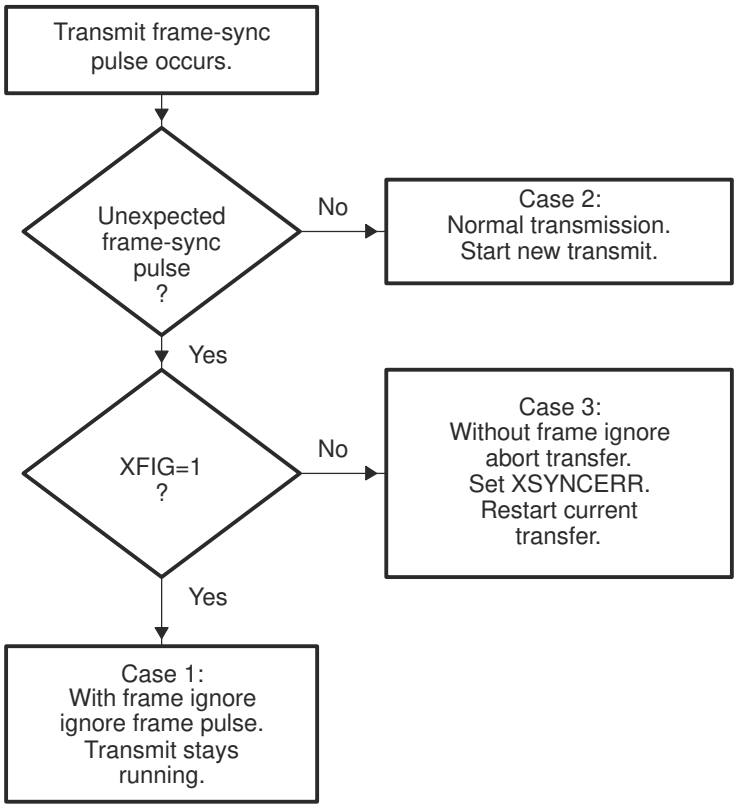

**Figure 21-29. Possible Responses to Transmit Frame-Synchronization Pulses**

Copyright © 2024 Texas Instruments Incorporated

Any one of three cases can occur:

- Case 1: Unexpected internal FSX pulses with XFIG = 1 in XCR2. Transmit frame-synchronization pulses are ignored, and the transmission continues.
- Case 2: Normal serial port transmission. Transmission continues normally because the frame-synchronization pulse is not unexpected. There are two possible reasons why a transmit operations might *not* be in progress when the pulse occurs:

  This FSX pulse is the first after the transmitter is enabled (XRST = 1).

  The serial port is in the interpacket intervals. The programmed data delay for transmission (programmed with the XDATDLY bits of XCR2) may start during these interpacket intervals before the first bit of the previous word is transmitted. Thus, at maximum packet frequency, frame synchronization can still be received 0 to 2 clock cycles before the first bit of the synchronized frame.
- Case 3: Unexpected transmit frame synchronization with XFIG = 0 (frame-synchronization pulses not ignored). Unexpected frame-synchronization pulses can originate from an external source or from the internal sample rate generator.

  If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit (XSYNCERR) in SPCR2. XSYNCERR can be cleared only by a transmitter reset or by a write of 0 to this bit.

  If you want the McBSP to notify the CPU of frame-synchronization errors, you can set a special transmit interrupt mode with the XINTM bits of SPCR2. When XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU each time that XSYNCERR is set.

#### 21.5.6.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Section 21.5.3.2 shows an unexpected transmit frame-synchronization pulse during normal operation of the serial port with intervals between the data packets. When the unexpected frame-synchronization pulse occurs, the XSYNCERR bit is set and the transmission of data B is restarted because no new data has been passed to XSR1 yet. In addition, if XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU.

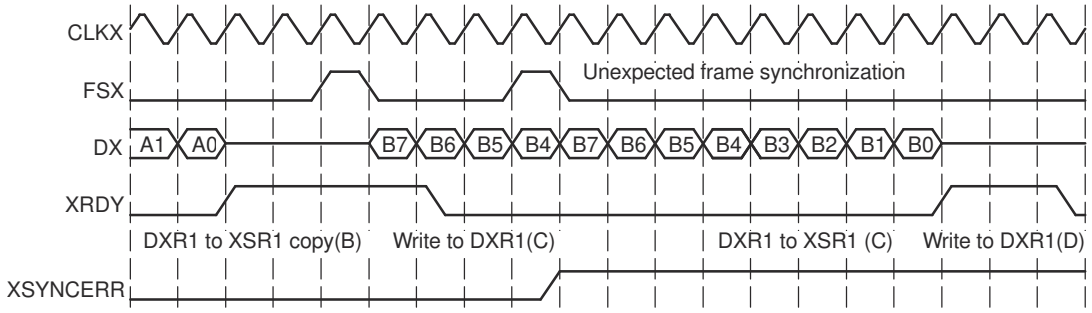

**Figure 21-30. An Unexpected Frame-Synchronization Pulse During a McBSP Transmission**

#### 21.5.6.3 Preventing Unexpected Transmit Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the XDATDLY bits of XCR2. For each possible data delay, Figure 21-31 shows when a new frame-synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

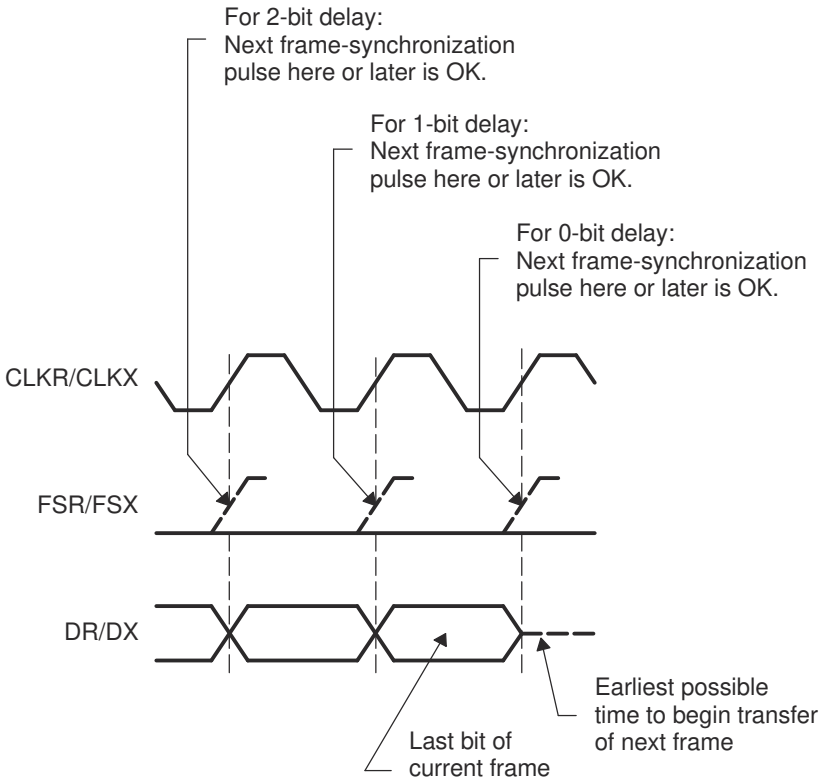

**Figure 21-31. Proper Positioning of Frame-Synchronization Pulses**

## 21.6 Multichannel Selection Modes

This section discusses the multichannel selection modes for the McBSP.

### *21.6.1 Channels, Blocks, and Partitions*

A McBSP channel is a time slot for shifting in/out the bits of one serial word. Each McBSP supports up to 128 channels for reception and 128 channels for transmission.

In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that each contain 16 contiguous channels (see Table 21-8 through Table 21-10):

- It is possible to have two receive partitions (A and B) and 8 transmit partitions (A to H).
- McBSP can transmit/receive on selected channels.
- Each channel partition has a dedicated channel-enable register. Each bit controls whether data flow is allowed or prevented in one of the channels assigned to that partition.
- There are three transmit multichannel modes and one receive multichannel mode.

The blocks are assigned to partitions according to the selected partition mode. In the two-partition mode (described in Section 21.6.4), you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode (described in Section 21.6.5), blocks 0 through 7 are automatically assigned to partitions, A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent. For example, using two receive partitions (A and B) and eight transmit partitions (A to H) is possible.

**Table 21-8. Block - Channel Assignment**

| Block | Channels |
|---|---|
| 0 | 0 -15 |
| 1 | 16 - 31 |
| 2 | 32 - 47 |
| 3 | 48 - 63 |
| 4 | 64 - 79 |
| 5 | 80 - 95 |
| 6 | 96 - 111 |
| 7 | 112 - 127 |

**Table 21-9. 2-Partition Mode**

| Partition | Blocks |
|---|---|
| A | 0, 2, 4, or 6 |
| B | 1, 3, 5, or 7 |

**Table 21-10. 8-Partition Mode**

| Partition | Blocks | Channels |
|---|---|---|
| A | 0 | 0 -15 |
| B | 1 | 16 - 31 |
| C | 2 | 32 - 47 |
| D | 3 | 48 - 63 |
| E | 4 | 64 - 79 |
| F | 5 | 80 - 95 |
| G | 6 | 96 - 111 |
| H | 7 | 112 - 127 |

### 21.6.2 Multichannel Selection

When a McBSP uses a time-division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices, the McBSP may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP has one receive multichannel selection mode (described in Section 21.6.6) and three transmit multichannel selection modes (described in Section 21.6.7).

### 21.6.3 Configuring a Frame for Multichannel Selection

Before you enable a multichannel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (RPHASE/XPHASE = 0). Each frame represents a TDM data stream.
- Set a frame length (in RFRLEN1/XFRLEN1) that includes the highest-numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). If XFRLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

### 21.6.4 Using Two Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions (described in Section 21.6.5). If you choose the 2-partition mode (RMCME = 0 for reception, XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

#### 21.6.4.1 Assigning Blocks to Partitions A and B

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point in time. Similarly, any two of the eight transmit-channel blocks (up 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the RPABLK bits. In the receive multichannel selection mode (described in Section 21.6.6), the channels in this partition are controlled by receive channel enable register A (RCERA).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the RPBBLK bits. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (RCERB).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the XPABLK bits. In one of the transmit multichannel selection modes (described in Section 21.6.7), the channels in this partition are controlled by transmit channel enable register A (XCERA).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the XPBBLK bits. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (XCERB).

Figure 21-32 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0-15 have been assigned to partition A, and channels 16-31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Copyright © 2024 Texas Instruments Incorporated

As explained in Section 21.6.4.2, you can dynamically change which blocks of channels are assigned to the partitions.

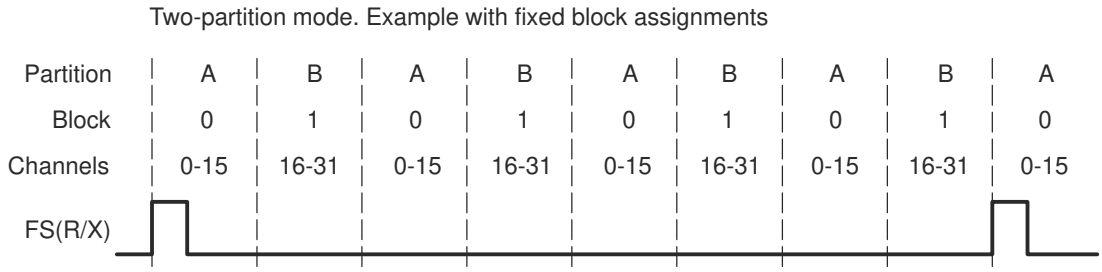

**Figure 21-32. Alternating Between the Channels of Partition A and the Channels of Partition B**

#### 21.6.4.2 Reassigning Blocks During Reception/Transmission

If you want to use more than 32 channels, you can change which channel blocks are assigned to partitions A and B during the course of a data transfer. However, these changes must be carefully timed. While a partition is being transferred, the associated block assignment bits cannot be modified and the associated channel enable register cannot be modified. For example, if block 3 is being transferred and block 3 is assigned to partition A, you cannot modify (R/X)PABLK to assign different channels to partition A, nor (R/X)CERA to change the channel configuration for partition A.

Several features of the McBSP help you time the reassignment:

- The block of channels currently involved in reception and transmission (the current block) is reflected in the RCBLK/XCBLK bits. Your program can poll these bits to determine which partition is active. When a partition is not active, it is safe to change its block assignment and channel configuration.
- At the end of every block (at the boundary of two partitions), an interrupt can be sent to the CPU. In response to the interrupt, the CPU can then check the RCBLK/XCBLK bits and update the inactive partition. See Section 21.6.8.

Figure 21-33 shows an example of reassigning channels throughout a data transfer. In response to a frame-synchronization pulse, the McBSP alternates between partitions A and B. Whenever partition B is active, the CPU changes the block assignment for partition A. Whenever partition A is active, the CPU changes the block assignment for partition B.

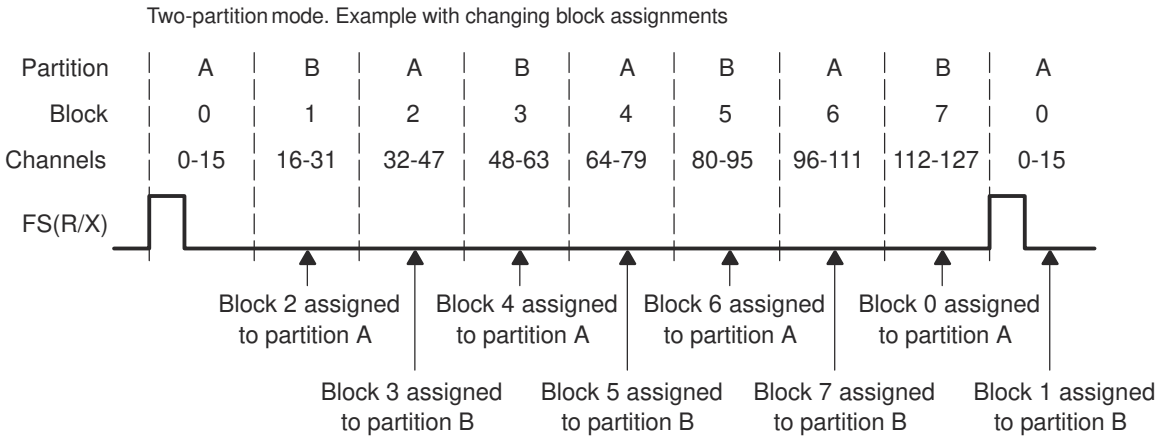

**Figure 21-33. Reassigning Channel Blocks Throughout a McBSP Data Transfer**

### 21.6.5 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions (described in Section 21.6.4). If you choose the 8-partition mode (RMCME = 1 for reception, XMCME = 1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the (R/X)PABLK and (R/X)PBBLK bits are ignored and the 16-channel blocks are assigned to the partitions as shown in Table 21-11 and Table 21-12. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

**Table 21-11. Receive Channel Assignment and Control With Eight Receive Partitions**

| Receive Partition | Assigned Block of Receive Channels | Register Used For Channel Control |
|---|---|---|
| A | Block 0: channels 0 through 15 | RCERA |
| B | Block 1: channels 16 through 31 | RCERB |
| C | Block 2: channels 32 through 47 | RCERC |
| D | Block 3: channels 48 through 63 | RCERD |
| E | Block 4: channels 64 through 79 | RCERE |
| F | Block 5: channels 80 through 95 | RCERF |
| G | Block 6: channels 96 through 111 | RCERG |
| H | Block 7: channels 112 through 127 | RCERH |

**Table 21-12. Transmit Channel Assignment and Control When Eight Transmit Partitions Are Used**

| Transmit Partition | Assigned Block of Transmit Channels | Register Used For Channel Control |
|---|---|---|
| A | Block 0: channels 0 through 15 | XCERA |
| B | Block 1: channels 16 through 31 | XCERB |
| C | Block 2: channels 32 through 47 | XCERC |
| D | Block 3: channels 48 through 63 | XCERD |
| E | Block 4: channels 64 through 79 | XCERE |
| F | Block 5: channels 80 through 95 | XCERF |
| G | Block 6: channels 96 through 111 | XCERG |
| H | Block 7: channels 112 through 127 | XCERH |

Figure 21-34 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

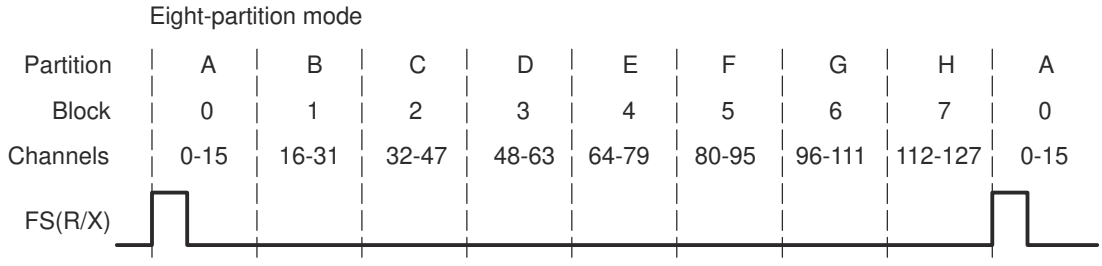

**Figure 21-34. McBSP Data Transfer in the 8-Partition Mode**

### 21.6.6 Receive Multichannel Selection Mode

The RMCM bit of MCR1 determines whether all channels or only selected channels are enabled for reception. When RMCM = 0, all 128 receive channels are enabled and cannot be disabled. When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:

- Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate receive channel enable registers (RCERs). The way channels are assigned to the RCERs depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit of MCR1.
- If a receive channel is disabled, any bits received in that channel are passed only as far as the receive buffer registers (RBRs). The receiver does not copy the content of the RBRs to the DRRs, and as a result, does not set the receiver ready bit (RRDY). Therefore, no DMA synchronization event (REVT) is generated and, if the receiver interrupt mode depends on RRDY (RINTM = 00b), no interrupt is generated.

As an example of how the McBSP behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP:

1. Accepts bits shifted in from the DR pin in channel 0
2. Ignores bits received in channels 1-14
3. Accepts bits shifted in from the DR pin in channel 15
4. Ignores bits received in channels 16-38
5. Accepts bits shifted in from the DR pin in channel 39

Copyright © 2024 Texas Instruments Incorporated

### 21.6.7 Transmit Multichannel Selection Modes

The XMCM bits of XCR2 determine whether all channels or only selected channels are enabled and unmasked for transmission. More details on enabling and masking are in Section 21.6.7.1. The McBSP has three transmit multichannel selection modes (XMCM = 01b, XMCM = 10b, and XMCM = 11b), which are described in Table 21-13.

**Table 21-13. Selecting a Transmit Multichannel Selection Mode With the XMCM Bits**

| XMCM | Transmit Multichannel Selection Mode |
|---|---|
| 00b | No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked. |
| 01b | All channels are disabled unless the channels are selected in the appropriate transmit channel enable registers (XCERs). If enabled, a channel in this mode is also unmasked.<br>The XMCME bit of MCR2 determines whether 32 channels or 128 channels are selectable in XCERs. |
| 10b | All channels are enabled, but the channels are masked unless the channels are selected in the appropriate transmit channel enable registers (XCERs).<br>The XMCME bit of MCR2 determines whether 32 channels or 128 channels are selectable in XCERs. |
| 11b | This mode is used for symmetric transmission and reception.<br>All channels are disabled for transmission unless the channels are enabled for reception in the appropriate receive channel enable registers (RCERs). Once enabled, the channels are masked unless the channels are also selected in the appropriate transmit channel enable registers (XCERs).<br>The XMCME bit of MCR2 determines whether 32 channels or 128 channels are selectable in RCERs and XCERs. |

As an example of how the McBSP behaves in a transmit multichannel selection mode, suppose that XMCM = 01b (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP:

1. Shifts data to the DX pin in channel 0
2. Places the DX pin in the high impedance state in channels 1-14
3. Shifts data to the DX pin in channel 15
4. Places the DX pin in the high impedance state in channels 16-38
5. Shifts data to the DX pin in channel 39

#### 21.6.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The following definitions explain the channel control options:

**Enabled channel** — A channel that can begin transmission by passing data from the data transmit registers (DXRs) to the transmit shift registers (XSRs).

**Masked channel** — A channel that cannot complete transmission. The DX pin is held in the high impedance state; data cannot be shifted out on the DX pin.

In systems where symmetric transmit and receive provides software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.

Copyright © 2024 Texas Instruments Incorporated

| | |
|---|---|
| **Disabled channel** | A channel that is not enabled. A disabled channel is also masked.<br>Because no DXR-to-XSR copy occurs, the XRDY bit of SPCR2 is not set. Therefore, no DMA synchronization event (XEVT) is generated, and if the transmit interrupt mode depends on XRDY (XINTM = 00b in SPCR2), no interrupt is generated.<br>The XEMPTY bit of SPCR2 is not affected. |
| **Unmasked channel** | A channel that is not masked. Data in the XSRs is shifted out on the DX pin. |

#### 21.6.7.2 Activity on McBSP Pins for Different Values of XMCM

Figure 21-35 shows the activity on the McBSP pins for the various XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE = 0: Single-phase frame (required for multichannel selection modes)
- XFRLEN1 = 0000011b: 4 words per frame
- XWDLEN1 = 000b: 8 bits per word
- XMCME = 0: 2-partition mode (only partitions A and B used)

In the case where XMCM = 11b, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively.

In the figure, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

### *21.6.8 Using Interrupts Between Block Transfers*

When a multichannel selection mode is used, an interrupt request can be sent to the CPU at the end of every 16-channel block (at the boundary between partitions and at the end of the frame). In the receive multichannel selection mode, a receive interrupt (RINT) request is generated at the end of each block transfer if RINTM = 01b. In any of the transmit multichannel selection modes, a transmit interrupt (XINT) request is generated at the end of each block transfer if XINTM = 01b. When RINTM/XINTM = 01b, no interrupt is generated unless a multichannel selection mode is on.

These interrupt pulses are active high and last for two CPU clock cycles.

This type of interrupt is especially helpful if you are using the two-partition mode (described in Section 21.6.4) and you want to know when you can assign a different block of channels to partition A or B.

## 21.7 SPI Operation Using the Clock Stop Mode

This section explains how to use the McBSP in SPI mode.

### *21.7.1 SPI Protocol*

The SPI protocol is a master-slave configuration with one master device and one or more slave devices. The interface consists of the following four signals:

- Serial data input (also referred to as master in/slave out, or SPISOMI)
- Serial data output (also referred to as master out/slave in, or SPISIMO)
- Shift-clock (also referred to as SPICLK)
- Slave-enable signal (also referred to as $\overline{\text{SPISTE}}$)

A typical SPI interface with a single slave device is shown in Figure 21-36.

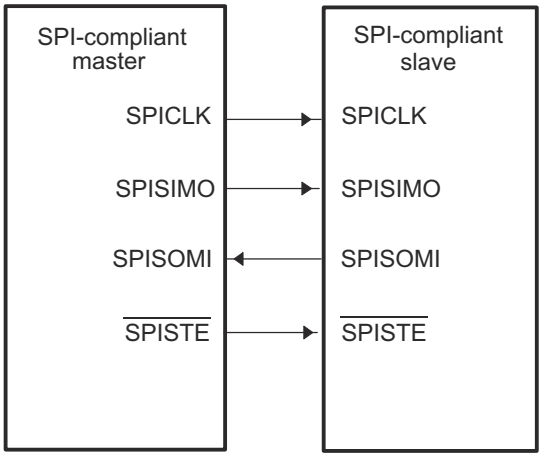

**Figure 21-36. Typical SPI Interface**

The master device controls the flow of communication by providing shift-clock and slave-enable signals. The slave-enable signal is an optional active-low signal that enables the serial data input and output of the slave device (device not sending out the clock).

In the absence of a dedicated slave-enable signal, communication between the master and slave is determined by the presence or absence of an active shift-clock. When the McBSP is operating in SPI master mode and the $\overline{\text{SPISTE}}$ signal is not used by the SPI slave port, the slave device must remain enabled at all times, and multiple slaves cannot be used.

### *21.7.2 Clock Stop Mode*

The clock stop mode of the McBSP provides compatibility with the SPI protocol. When the McBSP is configured in clock stop mode, the transmitter and receiver are internally synchronized so that the McBSP functions as an SPI master or slave device. The transmit clock signal (CLKX) corresponds to the serial clock signal (SPICLK) of the SPI protocol, while the transmit frame-synchronization signal (FSX) is used as the slave-enable signal ($\overline{\text{SPISTE}}$).

The receive clock signal (MCLKR) and receive frame-synchronization signal (FSR) are not used in the clock stop mode because these signals are internally connected to their transmit counterparts, CLKX and FSX.

Copyright © 2024 Texas Instruments Incorporated

### 21.7.3 Enable and Configure the Clock Stop Mode

The bits required to configure the McBSP as an SPI device are introduced in Table 21-14. Table 21-15 shows how the various combinations of the CLKSTP bit and the polarity bits CLKXP and CLKRP create four possible clock stop mode configurations. The timing diagrams in Section 21.7.4 show the effects of CLKSTP, CLKXP, and CLKRP.

**Table 21-14. Bits Used to Enable and Configure the Clock Stop Mode**

| Bit Field | Description |
|---|---|
| CLKSTP bits of SPCR1 | Use these bits to enable the clock stop mode and to select one of two timing variations. (See also Table 21-15.) |
| CLKXP bit of PCR | This bit determines the polarity of the CLKX signal. (See also Table 21-15.) |
| CLKRP bit of PCR | This bit determines the polarity of the MCLKR signal. (See also Table 21-15.) |
| CLKXM bit of PCR | This bit determines whether CLKX is an input signal (McBSP as slave) or an output signal (McBSP as master). |
| XPHASE bit of XCR2 | You must use a single-phase transmit frame (XPHASE = 0). |
| RPHASE bit of RCR2 | You must use a single-phase receive frame (RPHASE = 0). |
| XFRLEN1 bits of XCR1 | You must use a transmit frame length of 1 serial word (XFRLEN1 = 0). |
| RFRLEN1 bits of RCR1 | You must use a receive frame length of 1 serial word (RFRLEN1 = 0). |
| XWDLEN1 bits of XCR1 | The XWDLEN1 bits determine the transmit packet length. XWDLEN1 must be equal to RWDLEN1 because in the clock stop mode. The McBSP transmit and receive circuits are synchronized to a single clock. |
| RWDLEN1 bits of RCR1 | The RWDLEN1 bits determine the receive packet length. RWDLEN1 must be equal to XWDLEN1 because in the clock stop mode. The McBSP transmit and receive circuits are synchronized to a single clock. |

**Table 21-15. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme**

| Bit Settings | Clock Scheme |
|---|---|
| CLKSTP = 00b or 01b<br>CLKXP = 0 or 1<br>CLKRP = 0 or 1 | Clock stop mode disabled. Clock enabled for non-SPI mode. |
| CLKSTP = 10b<br>CLKXP = 0<br>CLKRP = 0 | Low inactive state without delay: The McBSP transmits data on the rising edge of CLKX and receives data on the falling edge of MCLKR. |
| CLKSTP = 11b<br>CLKXP = 0<br>CLKRP = 1 | Low inactive state with delay: The McBSP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of MCLKR. |
| CLKSTP = 10b<br>CLKXP = 1<br>CLKRP = 0 | High inactive state without delay: The McBSP transmits data on the falling edge of CLKX and receives data on the rising edge of MCLKR. |
| CLKSTP = 11b<br>CLKXP = 1<br>CLKRP = 1 | High inactive state with delay: The McBSP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of MCLKR. |

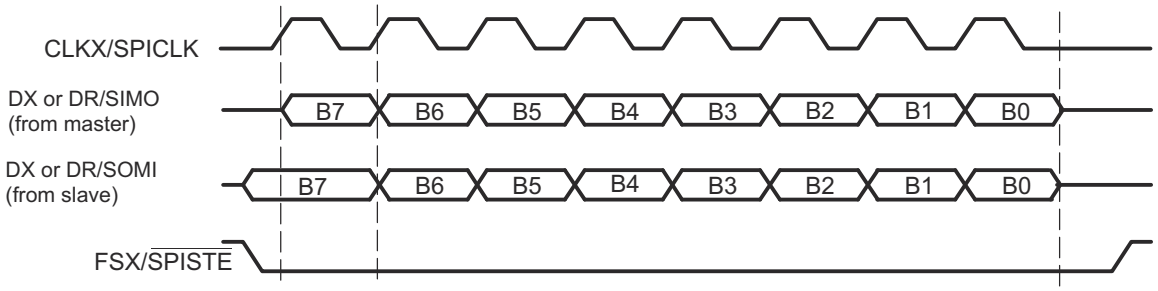
### 21.7.4 Clock Stop Mode Timing Diagrams

The timing diagrams for the four possible clock stop mode configurations are shown here. Notice that the frame-synchronization signal used in clock stop mode is active throughout the entire transmission as a slave-enable signal. Although the timing diagrams show 8-bit transfers, the packet length can be set to 8, 12, 16, 20, 24, or 32 bits per packet. The receive packet length is selected with the RWDLEN1 bits of RCR1, and the transmit packet length is selected with the XWDLEN1 bits of XCR1. For clock stop mode, the values of RWDLEN1 and XWDLEN1 must be the same because the McBSP transmit and receive circuits are synchronized to a single clock.

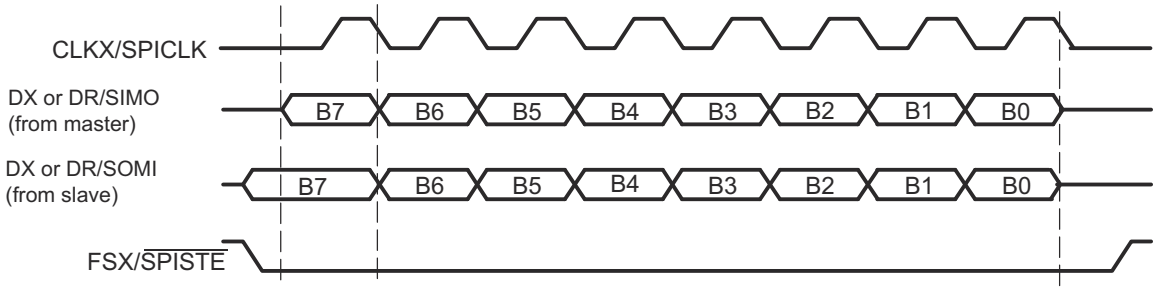
**Note**

Even if multiple words are consecutively transferred, the CLKX signal is always stopped and the FSX signal returns to the inactive state after a packet transfer. When consecutive packet transfers are performed, this leads to a minimum idle time of two bit-periods between each packet transfer.



A. If the McBSP is the SPI master (CLKXM = 1), SIMO = DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.
B. If the McBSP is the SPI master (CLKXM = 1), SOMI = DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

**Figure 21-37. SPI Transfer with CLKSTP = 10b (No Clock Delay), CLKXP = 0, and CLKRP = 0**



A. If the McBSP is the SPI master (CLKXM = 1), SIMO = DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.
B. If the McBSP is the SPI master (CLKXM = 1), SOMI = DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

### 21.7.5 Procedure for Configuring a McBSP for SPI Operation

To configure the McBSP for SPI master or slave operation:

1. Place the transmitter and receiver in reset.
   Clear the transmitter reset bit (XRST = 0) in SPCR2 to reset the transmitter. Clear the receiver reset bit (RRST = 0) in SPCR1 to reset the receiver.
2. Place the sample rate generator in reset.
   Clear the sample rate generator reset bit (GRST = 0) in SPCR2 to reset the sample rate generator.
3. Program registers that affect SPI operation.
   Program the appropriate McBSP registers to configure the McBSP for proper operation as an SPI master or an SPI slave. For a list of important bits settings, see one of the following topics:
   - Section 21.7.6
   - Section 21.7.7
4. Enable the sample rate generator.
   To release the sample rate generator from reset, set the sample rate generator reset bit (GRST = 1) in SPCR2.
   Make sure that during the write to SPCR2, you only modify GRST. Otherwise, you modify the McBSP configuration you selected in the previous step.
5. Enable the transmitter and receiver.
   After the sample rate generator is released from reset, wait two sample rate generator clock periods for the McBSP logic to stabilize.
   If the CPU services the McBSP transmit and receive buffers, then you can immediately enable the transmitter (XRST = 1 in SPCR2) and enable the receiver (RRST = 1 in SPCR1).
   If the DMA controller services the McBSP transmit and receive buffers, then you must first configure the DMA controller (this includes enabling the channels that service the McBSP buffers). When the DMA controller is ready, make XRST = 1 and RRST = 1.
   In either case, make sure you only change XRST and RRST when you write to SPCR2 and SPCR1. Otherwise, you modify the bit settings you selected earlier in this procedure.
   After the transmitter and receiver are released from reset, wait two sample rate generator clock periods for the McBSP logic to stabilize.
6. If necessary, enable the frame-synchronization logic of the sample rate generator.
   After the required data acquisition setup is done (DXR[1,2] is loaded with data), set FRST = 1 if an internally generated frame-synchronization pulse is required (that is, if the McBSP is the SPI master).

### 21.7.6 McBSP as the SPI Master

An SPI interface with the McBSP used as the master is shown in Figure 21-41. When the McBSP is configured as a master, the transmit output signal (DX) is used as the SPISIMO signal of the SPI protocol and the receive input signal (DR) is used as the SPISOMI signal.

The register bit values required to configure the McBSP as a master are listed in Table 21-16. After Table 21-16 are more details about the configuration requirements.

Copyright © 2024 Texas Instruments Incorporated

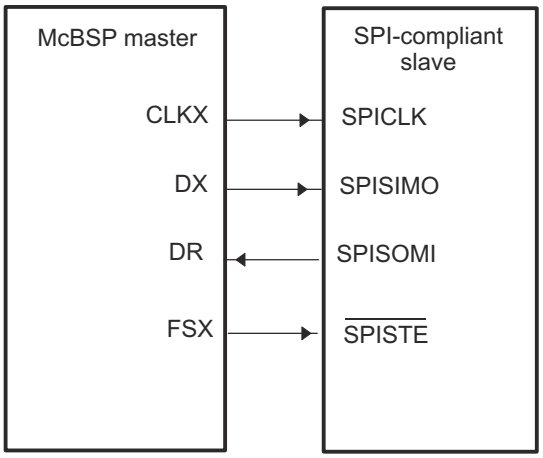

**Figure 21-41. SPI Interface with McBSP Used as Master**

**Table 21-16. Bit Values Required to Configure the McBSP as an SPI Master**

| Required Bit Setting | Description |
|---|---|
| CLKSTP = 10b or 11b | The clock stop mode (without or with a clock delay) is selected. |
| CLKXP = 0 or 1 | The polarity of CLKX as seen on the MCLKX pin is positive (CLKXP = 0) or negative (CLKXP = 1). |
| CLKRP = 0 or 1 | The polarity of MCLKR as seen on the MCLKR pin is positive (CLKRP = 0) or negative (CLKRP = 1). |
| CLKXM = 1 | The MCLKX pin is an output pin driven by the internal sample rate generator. Because CLKSTP is equal to 10b or 11b, MCLKR is driven internally by CLKX. |
| SCLKME = 0 | The clock generated by the sample rate generator (CLKG) is derived from the CPU clock. |
| CLKSM = 1 | |
| CLKGDV is a value from 1 to 255 | CLKGDV defines the divide down value for CLKG. |
| FSXM = 1 | The FSX pin is an output pin driven according to the FSGM bit. |
| FSGM = 0 | The transmitter drives a frame-synchronization pulse on the FSX pin every time data is transferred from DXR1 to XSR1. |
| FSXP = 1 | The FSX pin is active low. |
| XDATDLY = 01b | This setting provides the correct setup time on the FSX signal. |
| RDATDLY = 01b | |

When the McBSP functions as the SPI master, the McBSP controls the transmission of data by producing the serial clock signal. The clock signal on the MCLKX pin is enabled only during packet transfers. When packets are not being transferred, the MCLKX pin remains high or low depending on the polarity used.

For SPI master operation, the MCLKX pin must be configured as an output. The sample rate generator is then used to derive the CLKX signal from the CPU clock. The clock stop mode internally connects the MCLKX pin to the MCLKR signal so that no external signal connection is required on the MCLKR pin and both the transmit and receive circuits are clocked by the master clock (CLKX).

The data delay parameters of the McBSP (XDATDLY and RDATDLY) must be set to 1 for proper SPI master operation. A data delay value of 0 or 2 is undefined in the clock stop mode.

The McBSP can also provide a slave-enable signal ($\overline{\text{SPISTE}}$) on the FSX pin. If a slave-enable signal is required, the FSX pin must be configured as an output and the transmitter must be configured so that a frame-synchronization pulse is generated automatically each time a packet is transmitted (FSGM = 0). The polarity of the FSX pin is programmable high or low; however, in most cases the pin must be configured active low.

When the McBSP is configured as described for SPI master operation, the bit fields for frame-synchronization pulse width (FWID) and frame-synchronization period (FPER) are overridden, and custom frame-synchronization

Copyright © 2024 Texas Instruments Incorporated

waveforms are not allowed. To see the resulting waveform produced on the FSX pin, see the timing diagrams in Section 21.7.4. The signal becomes active before the first bit of a packet transfer, and remains active until the last bit of the packet is transferred. After the packet transfer is complete, the FSX signal returns to the inactive state.

### *21.7.7 McBSP as an SPI Slave*

An SPI with the McBSP used as a slave is shown in Figure 21-42. When the McBSP is configured as a slave, DX is used as the SPISOMI signal and DR is used as the SPISIMO signal.

The register bit values required to configure the McBSP as a slave are listed in Table 21-17. After Table 21-17 are more details about configuration requirements.

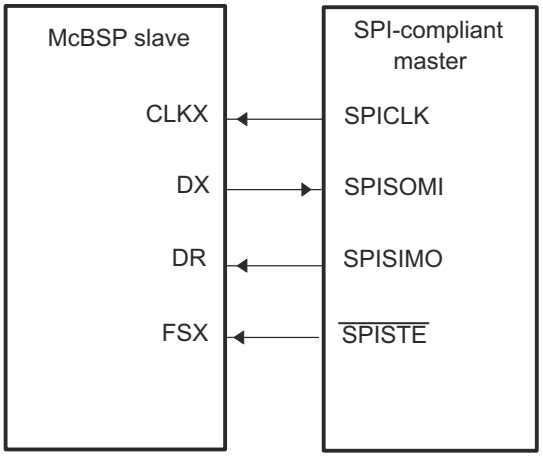

**Figure 21-42. SPI Interface With McBSP Used as Slave**

**Table 21-17. Bit Values Required to Configure the McBSP as an SPI Slave**

| Required Bit Setting | Description |
|---|---|
| CLKSTP = 10b or 11b | The clock stop mode (without or with a clock delay) is selected. |
| CLKXP = 0 or 1 | The polarity of CLKX as seen on the MCLKX pin is positive (CLKXP = 0) or negative (CLKXP = 1). |
| CLKRP = 0 or 1 | The polarity of MCLKR as seen on the MCLKR pin is positive (CLKRP = 0) or negative (CLKRP = 1). |
| CLKXM = 0 | The MCLKX pin is an input pin, so that the pin can be driven by the SPI master. Because CLKSTP = 10b or 11b, MCLKR is driven internally by CLKX. |
| SCLKME = 0<br>CLKSM = 1 | The clock generated by the sample rate generator (CLKG) is derived from the CPU clock. (The sample rate generator is used to synchronize the McBSP logic with the externally-generated master clock.) |
| CLKGDV = 1 | The sample rate generator divides the CPU clock before generating CLKG. |
| FSXM = 0 | The FSX pin is an input pin, so that the pin can be driven by the SPI master. |
| FSXP = 1 | The FSX pin is active low. |
| XDATDLY = 00b<br>RDATDLY = 00b | These bits must be 0s for SPI slave operation. |

When the McBSP is used as an SPI slave, the master clock and slave-enable signals are generated externally by a master device. Accordingly, the CLKX and FSX pins must be configured as inputs. The MCLKX pin is internally connected to the MCLKR signal, so that both the transmit and receive circuits of the McBSP are clocked by the external master clock. The FSX pin is also internally connected to the FSR signal, and no external signal connections are required on the MCLKR and FSR pins.

Although the CLKX signal is generated externally by the master and is asynchronous to the McBSP, the sample rate generator of the McBSP must be enabled for proper SPI slave operation. The sample rate generator must

Copyright © 2024 Texas Instruments Incorporated

be programmed to the maximum rate of half the CPU clock rate. The internal sample rate clock is then used to synchronize the McBSP logic to the external master clock and slave-enable signals.

The McBSP requires an active edge of the slave-enable signal on the FSX input for each transfer. This means that the master device must assert the slave-enable signal at the beginning of each transfer, and deassert the signal after the completion of each packet transfer; the slave-enable signal cannot remain active between transfers. Unlike the standard SPI, this pin cannot be tied low all the time.

The data delay parameters of the McBSP must be set to 0 for proper SPI slave operation. A value of 1 or 2 is undefined in the clock stop mode.

## 21.8 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP/receiver in reset (see Section 21.8.2).
2. Program McBSP registers for the desired receiver operation (see Section 21.8.1).
3. Take the receiver out of reset (see Section 21.8.2).

### *21.8.1 Programming the McBSP Registers for the Desired Receiver Operation*

The following is a list of important tasks to be performed when you are configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields.

- Global behavior:
  - Set the receiver pins to operate as McBSP pins.
  - Enable/disable the digital loopback mode.
  - Enable/disable the clock stop mode.
  - Enable/disable the receive multichannel selection mode.
- Data behavior:
  - Choose 1 or 2 phases for the receive frame.
  - Set the receive word length(s).
  - Set the receive frame length.
  - Enable/disable the receive frame-synchronization ignore function.
  - Set the receive companding mode.
  - Set the receive data delay.
  - Set the receive sign-extension and justification mode.
  - Set the receive interrupt mode.
- Frame-synchronization behavior:
  - Set the receive frame-synchronization mode.
  - Set the receive frame-synchronization polarity.
  - Set the sample rate generator (SRG) frame-synchronization period and pulse width.
- Clock behavior:
  - Set the receive clock mode.
  - Set the receive clock polarity.
  - Set the SRG clock divide-down value.
  - Set the SRG clock synchronization mode.
  - Set the SRG clock mode (choose an input clock).
  - Set the SRG input clock polarity.

Copyright © 2024 Texas Instruments Incorporated

### 21.8.2 Resetting and Enabling the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take the receiver out of reset). Table 21-18 describes the bits used for both of these steps.

**Table 21-18. Register Bits Used to Reset or Enable the McBSP Receiver Field Descriptions**

| Register | Bit | Field | Value | Description |
|---|---|---|---|---|
| SPCR2 | 7 | FRST | | Frame-synchronization logic reset |
| | | | 0 | Frame-synchronization logic is reset. The sample rate generator does not generate frame-synchronization signal FSG, even if GRST = 1. |
| | | | 1 | If GRST = 1, frame-synchronization signal FSG is generated after (FPER + 1) number of CLKG clock cycles; all frame counters are loaded with their programmed values. |
| SPCR2 | 6 | GRST | | Sample rate generator reset |
| | | | 0 | Sample rate generator is reset. If GRST = 0 due to a DSP reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven low (inactive). If GRST = 0 due to program code, CLKG and FSG are both driven low (inactive). |
| | | | 1 | Sample rate generator is enabled. CLKG is driven according to the configuration programmed in the sample rate generator registers (SRGR[1,2]). If FRST = 1, the generator also generates the frame-synchronization signal FSG as programmed in the sample rate generator registers. |
| SPCR1 | 0 | RRST | | Receiver reset |
| | | | 0 | The serial port receiver is disabled and in the reset state. |
| | | | 1 | The serial port receiver is enabled. |

#### 21.8.2.1 Reset Considerations

The serial port can be reset in the following two ways:

1. The DSP reset ($\overline{\text{XRS}}$ signal driven low) places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed ($\overline{\text{XRS}}$ signal released), GRST = FRST = RRST = XRST = 0 keep the entire serial port in the reset state, provided the McBSP clock is turned on.
2. The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the serial port control registers. The sample rate generator can be reset directly using the GRST bit in SPCR2.

Table 21-19 shows the state of McBSP pins when the serial port is reset due to a device reset and a direct receiver/transmitter reset.

For more details about McBSP reset conditions and effects, see Section 21.10.2.

**Table 21-19. Reset State of Each McBSP Pin**

| Pin | Possible States[1] | State Forced By Device Reset | State Forced By Receiver Reset (RRST = 0 and GRST = 1) |
|---|---|---|---|
| MDRx | I | GPIO Input | Input |
| MCLKRx | I/O/Z | GPIO Input | Known state, if input; MCLKR running, if output |
| MFSRx | I/O/Z | GPIO Input | Known state, if input; FSRP inactive state, if output |
| | | | Transmitter reset (XRST = 0 and GRST = 1) |
| MDXx | O/Z | GPIO Input | Low impedance after transmit bit clock provided |
| MCLKXx | I/O/Z | GPIO Input | Known state, if input; CLKX running, if output |
| MFSXx | I/O/Z | GPIO Input | Known state, if input; FSXP inactive state, if output |

(1) In Possible States column, I = input, O = output, Z = high impedance

Copyright © 2024 Texas Instruments Incorporated

### 21.8.3 Set the Receiver Pins to Operate as McBSP Pins

To configure a pin for McBSP functioning, configure the bits of the GPxMUXn register appropriately. In addition to this, bits 12 and 13 of the PCR register must be set to 0. These bits are defined as reserved.

### 21.8.4 Digital Loopback Mode

The DLB bit determines whether the digital loopback mode is on. DLB is described in Table 21-20.

**Table 21-20. Register Bit Used to Enable/Disable the Digital Loopback Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| SPCR1 | 15 | DLB | Digital loopback mode | | R/W | 0 |
| | | | DLB = 0 | Digital loopback mode is disabled. | | |
| | | | DLB = 1 | Digital loopback mode is enabled. | | |

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals, as shown in Table 21-21. This mode allows testing of serial port code with a single DSP device; the McBSP receives the data the McBSP transmits.

**Table 21-21. Receive Signals Connected to Transmit Signals in Digital Loopback Mode**

| This Receive Signal | Is Fed Internally by This Transmit Signal |
|---|---|
| MDR (receive data) | MDX (transmit data) |
| MFSR (receive frame synchronization) | MFSX (transmit frame synchronization) |
| MCLKR (receive clock) | MCLKX (transmit clock) |

### 21.8.5 Clock Stop Mode

The CLKSTP bits determine whether the clock stop mode is on. CLKSTP is described in Table 21-22.

**Table 21-22. Register Bits Used to Enable/Disable the Clock Stop Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| SPCR1 | 12-11 | CLKSTP | Clock stop mode | | R/W | 00 |
| | | | CLKSTP = 0Xb | Clock stop mode disabled; normal clocking for non-SPI mode | | |
| | | | CLKSTP = 10b | Clock stop mode enabled, without clock delay | | |
| | | | CLKSTP = 11b | Clock stop mode enabled, with clock delay | | |

The clock stop mode supports the SPI master-slave protocol. If you do not plan to use the SPI protocol, you can clear CLKSTP to disable the clock stop mode.

In the clock stop mode, the clock stops at the end of each data transfer. At the beginning of each data transfer, the clock starts immediately (CLKSTP = 10b) or after a half-cycle delay (CLKSTP = 11b). The CLKXP bit determines whether the starting edge of the clock on the MCLKX pin is rising or falling. The CLKRP bit determines whether receive data is sampled on the rising or falling edge of the clock shown on the MCLKR pin.

Table 21-23 summarizes the impact of CLKSTP, CLKXP, and CLKRP on serial port operation. In the clock stop mode, the receive clock is tied internally to the transmit clock, and the receive frame-synchronization signal is tied internally to the transmit frame-synchronization signal.

Copyright © 2024 Texas Instruments Incorporated

**Table 21-23. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme**

| Bit Settings | Clock Scheme |
|---|---|
| CLKSTP = 00b or 01b<br>CLKXP = 0 or 1<br>CLKRP = 0 or 1 | Clock stop mode disabled. Clock enabled for non-SPI mode. |
| CLKSTP = 10b<br>CLKXP = 0<br>CLKRP = 0 | Low inactive state without delay: The McBSP transmits data on the rising edge of CLKX and receives data on the falling edge of MCLKR. |
| CLKSTP = 11b<br>CLKXP = 0<br>CLKRP = 1 | Low inactive state with delay: The McBSP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of MCLKR. |
| CLKSTP = 10b<br>CLKXP = 1<br>CLKRP = 0 | High inactive state without delay: The McBSP transmits data on the falling edge of CLKX and receives data on the rising edge of MCLKR. |
| CLKSTP = 11b<br>CLKXP = 1<br>CLKRP = 1 | High inactive state with delay: The McBSP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of MCLKR. |

### *21.8.6 Receive Multichannel Selection Mode*

The RMCM bit determines whether the receive multichannel selection mode is on. RMCM is described in Table 21-24. For more details, see Section 21.6.6.

**Table 21-24. Register Bit Used to Enable/Disable the Receive Multichannel Selection Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| MCR1 | 0 | RMCM | Receive multichannel selection mode | | R/W | 0 |
| | | | RMCM = 0 | The mode is disabled.<br>All 128 channels are enabled. | | |
| | | | RMCM = 1 | The mode is enabled.<br>Channels can be individually enabled or disabled.<br>The only channels enabled are those selected in the appropriate receive channel enable registers (RCERs). The way channels are assigned to the RCERs depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit. | | |

### *21.8.7 Receive Frame Phases*

The RPHASE bit (see Table 21-25) determines whether the receive data frame has one or two phases.

**Table 21-25. Register Bit Used to Choose One or Two Phases for the Receive Frame**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| RCR2 | 15 | RPHASE | Receive phase number | | R/W | 0 |
| | | | Specifies whether the receive frame has 1 or 2 phases. | | | |
| | | | RPHASE = 0 | Single-phase frame | | |
| | | | RPHASE = 1 | Dual-phase frame | | |

Copyright © 2024 Texas Instruments Incorporated

### 21.8.8 Receive Word Lengths

The RWDLEN1 and RWDLEN2 bit fields (see Table 21-26) determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

**Table 21-26. Register Bits Used to Set the Receive Word Lengths**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| RCR1 | 7-5 | RWDLEN1 | Receive word length 1 | | R/W | 000 |
| | | | Specifies the length of every serial word in phase 1 of the receive frame. | | | |
| | | | RWDLEN1 = 000 | 8 bits | | |
| | | | RWDLEN1 = 001 | 12 bits | | |
| | | | RWDLEN1 = 010 | 16 bits | | |
| | | | RWDLEN1 = 011 | 20 bits | | |
| | | | RWDLEN1 = 100 | 24 bits | | |
| | | | RWDLEN1 = 101 | 32 bits | | |
| | | | RWDLEN1 = 11X | Reserved | | |
| RCR2 | 7-5 | RWDLEN2 | Receive word length 2 | | R/W | 000 |
| | | | If a dual-phase frame is selected, RWDLEN2 specifies the length of every serial word in phase 2 of the frame. | | | |
| | | | RWDLEN2 = 000 | 8 bits | | |
| | | | RWDLEN2 = 001 | 12 bits | | |
| | | | RWDLEN2 = 010 | 16 bits | | |
| | | | RWDLEN2 = 011 | 20 bits | | |
| | | | RWDLEN2 = 100 | 24 bits | | |
| | | | RWDLEN2 = 101 | 32 bits | | |
| | | | RWDLEN2 = 11X | Reserved | | |

#### 21.8.8.1 Word Length Bits

Each frame can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 determines the length of the serial words in phase 1 of the frame and RWDLEN2 determines the word length in phase 2 of the frame.

Copyright © 2024 Texas Instruments Incorporated

### 21.8.9 Receive Frame Length

The RFRLEN1 and RFRLEN2 bit fields (see Table 21-27) determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

**Table 21-27. Register Bits Used to Set the Receive Frame Length**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| RCR1 | 14-8 | RFRLEN1 | Receive frame length 1 | | R/W | 000 0000 |
| | | | (RFRLEN1 + 1) is the number of serial words in phase 1 of the receive frame. | | | |
| | | | RFRLEN1 = 000 0000 | 1 word in phase 1 | | |
| | | | RFRLEN1 = 000 0001 | 2 words in phase 1 | | |
| | | | \| | \| | | |
| | | | \| | \| | | |
| | | | RFRLEN1 = 111 1111 | 128 words in phase 1 | | |
| RCR2 | 14-8 | RFRLEN2 | Receive frame length 2 | | R/W | 000 0000 |
| | | | If a dual-phase frame is selected, (RFRLEN2 + 1) is the number of serial words in phase 2 of the receive frame. | | | |
| | | | RFRLEN2 = 000 0000 | 1 word in phase 2 | | |
| | | | RFRLEN2 = 000 0001 | 2 words in phase 2 | | |
| | | | \| | \| | | |
| | | | \| | \| | | |
| | | | RFRLEN2 = 111 1111 | 128 words in phase 2 | | |

#### 21.8.9.1 Selected Frame Length

The receive frame length is the number of serial words in the receive frame. Each frame can have one or two phases, depending on value that you load into the RPHASE bit.

If a single-phase frame is selected (RPHASE = 0), the frame length is equal to the length of phase 1. If a dual-phase frame is selected (RPHASE = 1), the frame length is the length of phase 1 plus the length of phase 2.

The 7-bit RFRLEN fields allow up to 128 words per phase. See Table 21-28 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the RFRLEN fields with [*w minus 1*], where *w* represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into RFRLEN1.

**Table 21-28. How to Calculate the Length of the Receive Frame**

| RPHASE | RFRLEN1 | RFRLEN2 | Frame Length |
|---|---|---|---|
| 0 | 0 ≤ RFRLEN1 ≤ 127 | Don't care | (RFRLEN1 + 1) words |
| 1 | 0 ≤ RFRLEN1 ≤ 127 | 0 ≤ RFRLEN2 ≤ 127 | (RFRLEN1 + 1) + (RFRLEN2 + 1) words |

Copyright © 2024 Texas Instruments Incorporated

### 21.8.10 Receive Frame-Synchronization Ignore Function

The RFIG bit (see Table 21-29) controls the receive frame-synchronization ignore function.

**Table 21-29. Register Bit Used to Enable/Disable the Receive Frame-Synchronization Ignore Function**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| RCR2 | 2 | RFIG | Receive frame-synchronization ignore | | R/W | 0 |
| | | | RFIG = 0 | An unexpected receive frame-synchronization pulse causes the McBSP to restart the frame transfer. | | |
| | | | RFIG = 1 | The McBSP ignores unexpected receive frame-synchronization pulses. | | |

#### 21.8.10.1 Unexpected Frame-Synchronization Pulses and the Frame-Synchronization Ignore Function

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse.

When RFIG = 1, reception continues, ignoring the unexpected frame-synchronization pulses.

When RFIG = 0, an unexpected FSR pulse causes the McBSP to discard the contents of RSR[1,2] in favor of the new incoming data. Therefore, if RFIG = 0 and an unexpected frame-synchronization pulse occurs, the serial port:

1. Aborts the current data transfer
2. Sets RSYNCERR in SPCR1 to 1
3. Begins the transfer of a new data word

For more details about the frame-synchronization error condition, see Section 21.5.3.

Copyright © 2024 Texas Instruments Incorporated

#### 21.8.10.2 Examples of Effects of RFIG

Figure 21-43 shows an example in which word B is interrupted by an unexpected frame-synchronization pulse when (R/X)FIG = 0. In the case of reception, the reception of B is aborted (B is lost), and a new data word C in this example) is received after the appropriate data delay. This condition is a receive synchronization error, which sets the RSYNCERR bit.

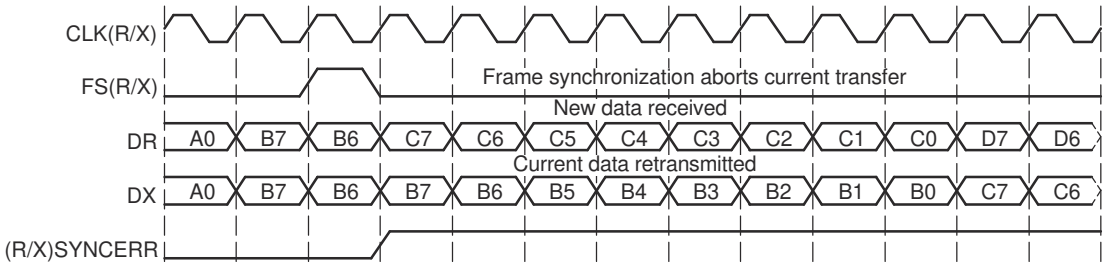

**Figure 21-43. Unexpected Frame-Synchronization Pulse With (R/X)FIG = 0**

In contrast with Figure 21-43, Figure 21-44 shows McBSP operation when unexpected frame-synchronization signals are ignored (when (R/X)FIG = 1). Here, the transfer of word B is not affected by an unexpected pulse.

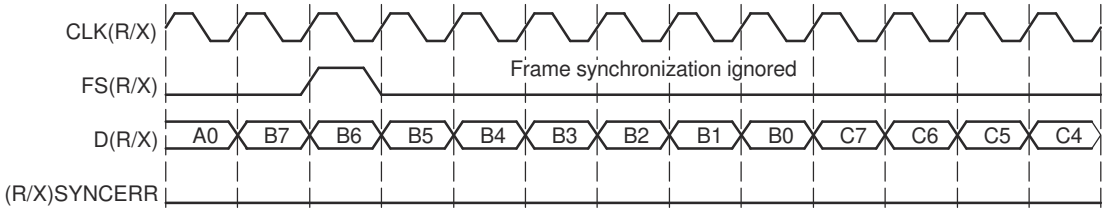

**Figure 21-44. Unexpected Frame-Synchronization Pulse With (R/X)FIG = 1**

### *21.8.11 Receive Companding Mode*

The RCOMPAND bits (see Table 21-30) determine whether companding or another data transfer option is chosen for McBSP reception.

**Table 21-30. Register Bits Used to Set the Receive Companding Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| RCR2 | 4-3 | RCOMPAND | Receive companding mode | | R/W | 00 |
| | | | Modes other than 00b are enabled only when the appropriate RWDLEN is 000b, indicating 8-bit data. | | | |
| | | | RCOMPAND = 00 | No companding, any size data, MSB received first | | |
| | | | RCOMPAND = 01 | No companding, 8-bit data, LSB received first (for details, see Section 21.8.11.4). | | |
| | | | RCOMPAND = 10 | µ-law companding, 8-bit data, MSB received first | | |
| | | | RCOMPAND = 11 | A-law companding, 8-bit data, MSB received first | | |

Copyright © 2024 Texas Instruments Incorporated

#### 21.8.11.1 Companding

Companding (COMpressing and exPANDing) hardware allows compression and expansion of data in either μ-law or A-law format. The companding standard employed in the United States and Japan is μ-law. The European companding standard is referred to as A-law. The specifications for μ-law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and μ-law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

The μ-law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 21-45 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or μ-law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to 2's-complement format.

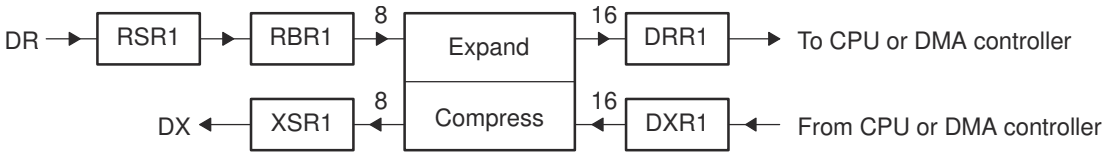

**Figure 21-45. Companding Processes for Reception and for Transmission**

#### 21.8.11.2 Format of Expanded Data

For reception, the 8-bit compressed data in RBR1 is expanded to left-justified 16-bit data in DRR1. The RJUST bit of SPCR1 is ignored when companding is used.

#### 21.8.11.3 Companding Internal Data

If the McBSP is otherwise unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. See Section 21.3.2.2.

#### 21.8.11.4 Option to Receive LSB First

Normally, the McBSP transmits or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set RCOMPAND = 01b in RCR2, the bit ordering of 8-bit words is reversed during reception. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits and LSB-first ordering is done.

Copyright © 2024 Texas Instruments Incorporated

### 21.8.12 Receive Data Delay

The RDATDLY bits (see Table 21-31) determine the length of the data delay for the receive frame.

**Table 21-31. Register Bits Used to Set the Receive Data Delay**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| RCR2 | 1-0 | RDATDLY | Receive data delay | | R/W | 00 |
| | | | RDATDLY = 00 | 0-bit data delay | | |
| | | | RDATDLY = 01 | 1-bit data delay | | |
| | | | RDATDLY = 10 | 2-bit data delay | | |
| | | | RDATDLY = 11 | Reserved | | |

#### 21.8.12.1 Data Delay

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

RDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (RDATDLY = 00b-10b), as described in Table 21-31 and shown in Figure 21-46. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

#### 21.8.12.2 0-Bit Data Delay

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of MCLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on DX. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the DX pin.

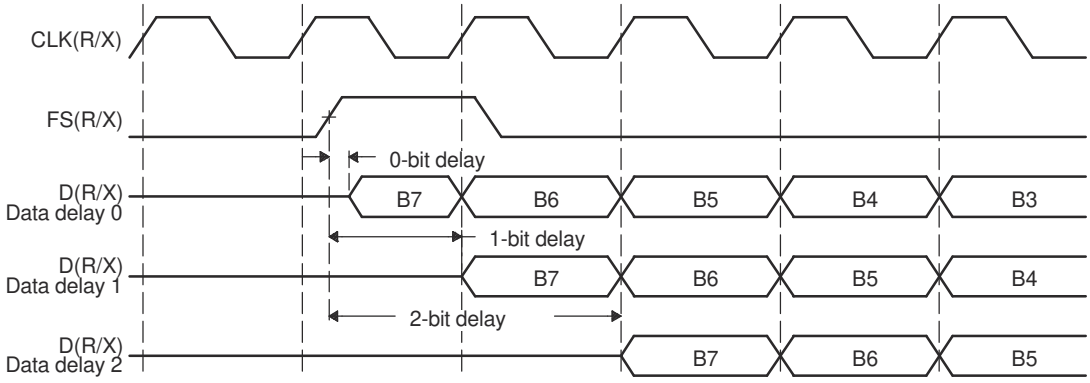

**Figure 21-46. Range of Programmable Data Delay**

Copyright © 2024 Texas Instruments Incorporated

#### 21.8.12.3 2-Bit Data Delay

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 21-47. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

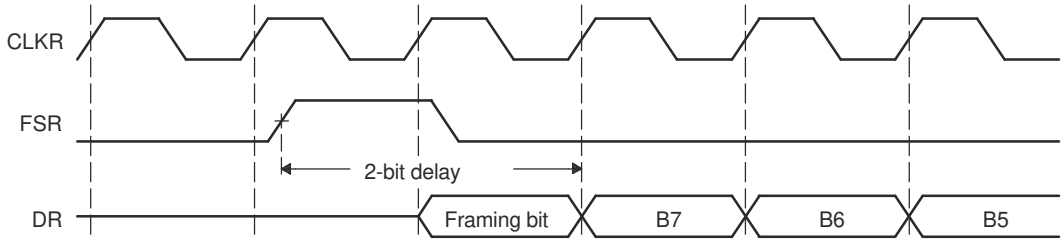

**Figure 21-47. 2-Bit Data Delay Used to Skip a Framing Bit**

Copyright © 2024 Texas Instruments Incorporated

### 21.8.13 Receive Sign-Extension and Justification Mode

The RJUST bits (see Table 21-32) determine whether data received by the McBSP is sign-extended and how the data is justified.

**Table 21-32. Register Bits Used to Set the Receive Sign-Extension and Justification Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| SPCR1 | 14-13 | RJUST | Receive sign-extension and justification mode | | R/W | 00 |
| | | | RJUST = 00 | Right justify data and zero fill MSBs in DRR[1,2] | | |
| | | | RJUST = 01 | Right justify data and sign extend the data into the MSBs in DRR[1,2] | | |
| | | | RJUST = 10 | Left justify data and zero fill LSBs in DRR[1,2] | | |
| | | | RJUST = 11 | Reserved | | |

#### 21.8.13.1 Sign-Extension and the Justification

RJUST in SPCR1 selects whether data in RBR[1,2] is right- or left-justified (with respect to the MSB) in DRR[1,2] and whether unused bits in DRR[1,2] are filled with zeros or with sign bits.

Table 21-33 and Table 21-34 show the effects of various RJUST values. The first table shows the effect on an example 12-bit receive-data value ABCh. The second table shows the effect on an example 20-bit receive-data value ABCDEh.

**Table 21-33. Example: Use of RJUST Field With 12-Bit Data Value ABCh**

| RJUST | Justification | Extension | Value in DRR2 | Value in DRR1 |
|---|---|---|---|---|
| 00b | Right | Zero fill MSBs | 0000h | 0ABCh |
| 01b | Right | Sign extend data into MSBs | FFFFh | FABCh |
| 10b | Left | Zero fill LSBs | 0000h | ABC0h |
| 11b | Reserved | Reserved | Reserved | Reserved |

**Table 21-34. Example: Use of RJUST Field With 20-Bit Data Value ABCDEh**

| RJUST | Justification | Extension | Value in DRR2 | Value in DRR1 |
|---|---|---|---|---|
| 00b | Right | Zero fill MSBs | 000Ah | BCDEh |
| 01b | Right | Sign extend data into MSBs | FFFAh | BCDEh |
| 10b | Left | Zero fill LSBs | ABCDh | E000h |
| 11b | Reserved | Reserved | Reserved | Reserved |

Copyright © 2024 Texas Instruments Incorporated

### 21.8.14 Receive Interrupt Mode

The RINTM bits (see Table 21-35) determine which event generates a receive interrupt request to the CPU.

The receive interrupt (RINT) informs the CPU of changes to the serial port status. Four options exist for configuring this interrupt. The options are set by the receive interrupt mode bits, RINTM, in SPCR1.

**Table 21-35. Register Bits Used to Set the Receive Interrupt Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| SPCR1 | 5-4 | RINTM | Receive interrupt mode | | R/W | 00 |
| | | | RINTM = 00 | RINT generated when RRDY changes from 0 to 1. Interrupt on every serial word by tracking the RRDY bit in SPCR1. Regardless of the value of RINTM, RRDY can be read to detect the RRDY = 1 condition. | | |
| | | | RINTM = 01 | RINT generated by an end-of-block or end-of-frame condition in the receive multichannel selection mode. In the multichannel selection mode, interrupt after every 16-channel block boundary has been crossed within a frame and at the end of the frame. For details, see Section 21.6.8. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated. | | |
| | | | RINTM = 10 | RINT generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in the reset state. This is done by synchronizing the incoming frame-synchronization pulse to the CPU clock and sending the pulse to the CPU using RINT. | | |
| | | | RINTM = 11 | RINT generated when RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see Section 21.5.3. | | |

### 21.8.15 Receive Frame-Synchronization Mode

The bits described in Table 21-36 determine the source for receive frame synchronization and the function of the FSR pin.

#### 21.8.15.1 Receive Frame-Synchronization Modes

Table 21-37 shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the FSR pin. The polarity of the signal on the FSR pin is determined by the FSRP bit.

In digital loopback mode (DLB = 1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the clock stop mode, the internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

Copyright © 2024 Texas Instruments Incorporated

**Table 21-36. Register Bits Used to Set the Receive Frame Synchronization Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 10 | FSRM | Receive frame-synchronization mode | | R/W | 0 |
| | | | FSRM = 0 | Receive frame synchronization is supplied by an external source via the FSR pin. | | |
| | | | FSRM = 1 | Receive frame synchronization is supplied by the sample rate generator. FSR is an output pin reflecting internal FSR, except when GSYNC = 1 in SRGR2. | | |
| SRGR2 | 15 | GSYNC | Sample rate generator clock synchronization mode | | R/W | 0 |
| | | | If the sample rate generator creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the FSR pin. | | | |
| | | | GSYNC = 0 | No clock synchronization is used: CLKG oscillates without adjustment, and FSG pulses every (FPER + 1) CLKG cycles. | | |
| | | | GSYNC = 1 | Clock synchronization is used. When a pulse is detected on the FSR pin:<br>• CLKG is adjusted as necessary so that CLKG is synchronized with the input clock on the MCLKR pin.<br>• FSG pulses FSG only pulses in response to a pulse on the FSR pin. The frame-synchronization period defined in FPER is ignored.<br>For more details, see Section 21.4.3. | | |
| SPCR1 | 15 | DLB | Digital loopback mode | | R/W | 0 |
| | | | DLB = 0 | Digital loopback mode is disabled. | | |
| | | | DLB = 1 | Digital loopback mode is enabled. The receive signals, including the receive frame-synchronization signal, are connected internally through multiplexers to the corresponding transmit signals. | | |
| SPCR1 | 12-11 | CLKSTP | Clock stop mode | | R/W | 00 |
| | | | CLKSTP = 0Xb | Clock stop mode disabled; normal clocking for non-SPI mode. | | |
| | | | CLKSTP = 10b | Clock stop mode enabled without clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX. | | |
| | | | CLKSTP = 11b | Clock stop mode enabled with clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX. | | |

Copyright © 2024 Texas Instruments Incorporated

**Table 21-37. Select Sources to Provide the Receive Frame-Synchronization Signal and the Effect on the FSR Pin**

| DLB | FSRM | GSYNC | Source of Receive Frame Synchronization | FSR Pin Status |
|---|---|---|---|---|
| 0 | 0 | 0 or 1 | An external frame-synchronization signal enters the McBSP through the FSR pin. The signal is then inverted as determined by FSRP before being used as internal FSR. | Input |
| 0 | 1 | 0 | Internal FSR is driven by the sample rate generator frame-synchronization signal (FSG). | Output. FSG is inverted as determined by FSRP before being driven out on the FSR pin. |
| 0 | 1 | 1 | Internal FSR is driven by the sample rate generator frame-synchronization signal (FSG). | Input. The external frame-synchronization input on the FSR pin is used to synchronize CLKG and generate FSG pulses. |
| 1 | 0 | 0 | Internal FSX drives internal FSR. | High impedance |
| 1 | 0 or 1 | 1 | Internal FSX drives internal FSR. | Input. If the sample rate generator is running, external FSR is used to synchronize CLKG and generate FSG pulses. |
| 1 | 1 | 0 | Internal FSX drives internal FSR. | Output. Receive (same as transmit) frame synchronization is inverted as determined by FSRP before being driven out on the FSR pin. |

### *21.8.16 Receive Frame-Synchronization Polarity*

The FSRP bit (see Table 21-38) determines whether frame-synchronization pulses are active high or active low on the FSR pin.

**Table 21-38. Register Bit Used to Set Receive Frame-Synchronization Polarity**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 2 | FSRP | Receive frame-synchronization polarity | | R/W | 0 |
| | | | FSRP = 0 | Frame-synchronization pulse FSR is active high. | | |
| | | | FSRP = 1 | Frame-synchronization pulse FSR is active low. | | |

Copyright © 2024 Texas Instruments Incorporated

#### 21.8.16.1 Frame-Synchronization Pulses, Clock Signals, and Their Polarities

Receive frame-synchronization pulses can be generated internally by the sample rate generator (see Section 21.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSRM, in PCR. FSR is also affected by the GSYNC bit in SRGR2. For information about the effects of FSRM and GSYNC, see Section 21.8.15. Similarly, receive clocks can be selected to be inputs or outputs by programming the mode bit, CLKRM, in the PCR (see Section 21.8.17).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that the outputs are driven by the sample rate generator, the outputs are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and MCLKR is an input pin), the external rising-edge triggered input clock on MCLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

MCLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to make sure of valid setup and hold of data around this edge. Figure 21-48 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

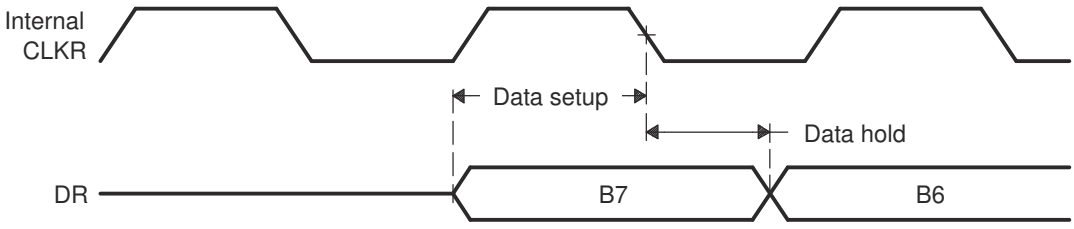

**Figure 21-48. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge**

Set the SRG Frame-Synchronization Period and Pulse Width.

#### 21.8.16.2 Frame-Synchronization Period and the Frame-Synchronization Pulse Width

The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0. Table 21-39 shows settings for FPER and FWID.

Figure 21-49 shows a frame-synchronization period of 16 CLKG periods (FPER = 15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

**Table 21-39. Register Bits Used to Set the SRG Frame-Synchronization Period and Pulse Width**

| Register | Bit | Name | Function | Type | Reset Value |
|---|---|---|---|---|---|
| SRGR2 | 11-0 | FPER | Sample rate generator frame-synchronization period<br>For the frame-synchronization signal FSG, (FPER + 1) determines the period from the start of a frame-synchronization pulse to the start of the next frame-synchronization pulse.<br>Range for (FPER + 1):<br>1 to 4096 CLKG cycles | R/W | 0000 0000 0000 |
| SRGR1 | 15-8 | FWID | Sample rate generator frame-synchronization pulse width<br>This field plus 1 determines the width of each frame-synchronization pulse on FSG.<br>Range for (FWID + 1):<br>1 to 256 CLKG cycles | R/W | 0000 0000 |

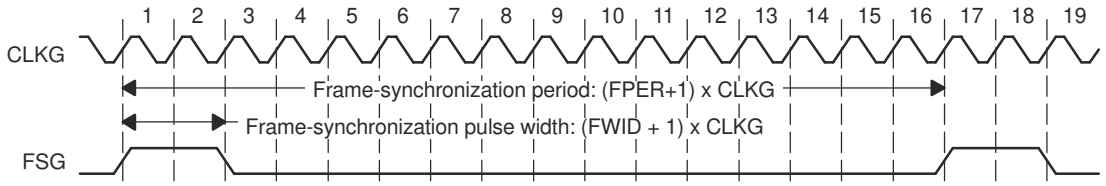

**Figure 21-49. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods**

When the sample rate generator comes out of reset, FSG is in the inactive state. Then, when GRST = 1 and FSGM = 1, a frame-synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until the value reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

### 21.8.17 Receive Clock Mode

Table 21-40 shows the settings for bits used to set receive clock mode.

**Table 21-40. Register Bits Used to Set the Receive Clock Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 8 | CLKRM | Receive clock mode | | R/W | 0 |
| | | | Case 1: Digital loopback mode not set (DLB = 0) in SPCR1. | | | |
| | | | CLKRM = 0 | The MCLKR pin is an input pin that supplies the internal receive clock (MCLKR). | | |
| | | | CLKRM = 1 | Internal MCLKR is driven by the sample rate generator of the McBSP. The MCLKR pin is an output pin that reflects internal MCLKR. | | |
| | | | Case 2: Digital loopback mode set (DLB = 1) in SPCR1. | | | |
| | | | CLKRM = 0 | The MCLKR pin is in the high impedance state. The internal receive clock (MCLKR) is driven by the internal transmit clock (CLKX). Internal CLKX is derived according to the CLKXM bit of PCR. | | |
| | | | CLKRM = 1 | Internal MCLKR is driven by internal CLKX. The MCLKR pin is an output pin that reflects internal MCLKR. Internal CLKX is derived according to the CLKXM bit of PCR. | | |
| SPCR1 | 15 | DLB | Digital loopback mode | | R/W | 00 |
| | | | DLB = 0 | Digital loopback mode is disabled. | | |
| | | | DLB = 1 | Digital loopback mode is enabled. The receive signals, including the receive frame-synchronization signal, are connected internally through multiplexers to the corresponding transmit signals. | | |
| SPCR1 | 12-11 | CLKSTP | Clock stop mode | | R/W | 00 |
| | | | CLKSTP = 0Xb | Clock stop mode disabled; normal clocking for non-SPI mode. | | |
| | | | CLKSTP = 10b | Clock stop mode enabled without clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX. | | |
| | | | CLKSTP = 11b | Clock stop mode enabled with clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX. | | |

#### 21.8.17.1 Selecting a Source for the Receive Clock and a Data Direction for the MCLKR Pin

Table 21-41 shows how you can select various sources to provide the receive clock signal and affect the MCLKR pin. The polarity of the signal on the MCLKR pin is determined by the CLKRP bit.

In the digital loopback mode (DLB = 1), the transmit clock signal is used as the receive clock signal.

Also, in the clock stop mode, the internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

**Table 21-41. Receive Clock Signal Source Selection**

| DLB in SPCR1 | CLKRM in PCR | Source of Receive Clock | MCLKR Pin Status |
|---|---|---|---|
| 0 | 0 | The MCLKR pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP before being used. | Input |
| 0 | 1 | The sample rate generator clock (CLKG) drives internal MCLKR. | Output. CLKG, inverted as determined by CLKRP, is driven out on the MCLKR pin. |
| 1 | 0 | Internal CLKX drives internal MCLKR. To configure CLKX, see Section 21.9.19. | High impedance |
| 1 | 1 | Internal CLKX drives internal MCLKR. To configure CLKX, see Section 21.9.19. | Output. Internal MCLKR (same as internal CLKX) is inverted as determined by CLKRP before being driven out on the MCLKR pin. |

### *21.8.18 Receive Clock Polarity*

Table 21-42 shows which register bits set the Receive Clock Polarity.

**Table 21-42. Register Bit Used to Set Receive Clock Polarity**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 0 | CLKRP | Receive clock polarity | | R/W | 0 |
| | | | CLKRP = 0 | Receive data sampled on falling edge of MCLKR | | |
| | | | CLKRP = 1 | Receive data sampled on rising edge of MCLKR | | |

Copyright © 2024 Texas Instruments Incorporated

#### 21.8.18.1 Frame Synchronization Pulses, Clock Signals, and Their Polarities

Receive frame-synchronization pulses can be generated internally by the sample rate generator (see Section 21.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSRM, in PCR. FSR is also affected by the GSYNC bit in SRGR2. For information about the effects of FSRM and GSYNC, see Section 21.8.15. Similarly, receive clocks can be selected to be inputs or outputs by programming the mode bit, CLKRM, in the PCR (see Section 21.8.17).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that the outputs are driven by the sample rate generator, the outputs are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and MCLKR is an input pin), the external rising-edge triggered input clock on MCLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to make sure of valid setup and hold of data around this edge. Figure 21-50 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

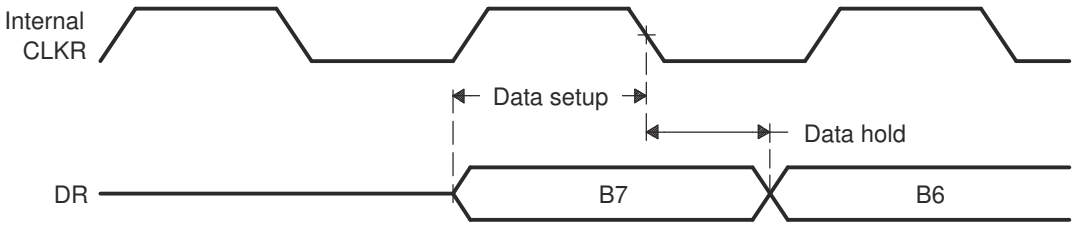

**Figure 21-50. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge**

### 21.8.19 SRG Clock Divide-Down Value

**Table 21-43. Register Bits Used to Set the Sample Rate Generator (SRG) Clock Divide-Down Value**

| Register | Bit | Name | Function | Type | Reset Value |
|---|---|---|---|---|---|
| SRGR1 | 7-0 | CLKGDV | Sample rate generator clock divide-down value<br>The input clock of the sample rate generator is divided by (CLKGDV + 1) to generate the required sample rate generator clock frequency. The default value of CLKGDV is 1 (divide input clock by 2). | R/W | 0000 0001 |

#### 21.8.19.1 Sample Rate Generator Clock Divider

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to 1/(CLKGDV + 1) of sample rate generator input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. When CLKGDV is odd or equal to 0, the CLKG duty cycle is 50%. When CLKGDV is an even value, 2p, representing an odd divide-down, the high-state duration is p + 1 cycles and the low-state duration is p cycles.

### 21.8.20 SRG Clock Synchronization Mode

For more details on using the clock synchronization feature, see Section 21.4.3.

**Table 21-44. Register Bit Used to Set the SRG Clock Synchronization Mode**

| Register | Bit | Name | Function | Type | Reset Value |
|---|---|---|---|---|---|
| SRGR2 | 15 | GSYNC | Sample rate generator clock synchronization<br>GSYNC is used only when the input clock source for the sample rate generator is external—on the MCLKR or MCLKX pin.<br>GSYNC = 0: The sample rate generator clock (CLKG) is free running. CLKG oscillates without adjustment, and FSG pulses every (FPER + 1) CLKG cycles.<br>GSYNC = 1: Clock synchronization is performed. When a pulse is detected on the FSR pin:<br>• CLKG is adjusted as necessary so that CLKG is synchronized with the input clock on the MCLKR or MCLKX pin.<br>• FSG pulses. FSG only pulses in response to a pulse on the FSR pin. The frame-synchronization period defined in FPER is ignored. | R/W | 0 |

Copyright © 2024 Texas Instruments Incorporated

### 21.8.21 SRG Clock Mode (Choose an Input Clock)

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock. Table 21-45 shows the four possible sources of the input clock. For more details on generating CLKG, see Section 21.4.1.1.

**Table 21-45. Register Bits Used to Set the SRG Clock Mode (Choose an Input Clock)**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 7 | SCLKME | Sample rate generator clock mode | | R/W | 0 |
| SRGR2 | 13 | CLKSM | | | R/W | 1 |
| | | | SCLKME = 0<br>CLKSM = 0 | Reserved | | |
| | | | SCLKME = 0<br>CLKSM = 1 | Sample rate generator clock derived from LSPCLK (default) | | |
| | | | SCLKME = 1<br>CLKSM = 0 | Sample rate generator clock derived from MCLKR pin | | |
| | | | SCLKME = 1<br>CLKSM = 1 | Sample rate generator clock derived from MCLKX pin | | |

### 21.8.22 SRG Input Clock Polarity

Table 21-46 shows which register bits set the SRG Input Clock Polarity.

**Table 21-46. Register Bits Used to Set the SRG Input Clock Polarity**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 1 | CLKXP | MCLKX pin polarity | | R/W | 0 |
| | | | CLKXP determines the input clock polarity when the MCLKX pin supplies the input clock (SCLKME = 1 and CLKSM = 1). | | | |
| | | | CLKXP = 0 | Rising edge on MCLKX pin generates transitions on CLKG and FSG. | | |
| | | | CLKXP = 1 | Falling edge on MCLKX pin generates transitions on CLKG and FSG. | | |
| PCR | 0 | CLKRP | MCLKR pin polarity | | R/W | 0 |
| | | | CLKRP determines the input clock polarity when the MCLKR pin supplies the input clock (SCLKME = 1 and CLKSM = 0). | | | |
| | | | CLKRP = 0 | Falling edge on MCLKR pin generates transitions on CLKG and FSG. | | |
| | | | CLKRP = 1 | Rising edge on MCLKR pin generates transitions on CLKG and FSG. | | |

Copyright © 2024 Texas Instruments Incorporated

#### 21.8.22.1 Using CLKXP/CLKRP to Choose an Input Clock Polarity

The sample rate generator can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the sample rate generator must be driven by an input clock signal derived from the CPU clock or from an external clock on the CLKX or MCLKR pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKXP for the MCLKX pin, CLKRP for the MCLKR pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

## 21.9 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP/transmitter in reset (see Section 21.9.2).
2. Program the McBSP registers for the desired transmitter operation (see Section 21.9.1).
3. Take the transmitter out of reset (see Section 21.9.2).

### *21.9.1 Programming the McBSP Registers for the Desired Transmitter Operation*

The following is a list of important tasks to be performed when you are configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

- Global behavior:
  - Set the transmitter pins to operate as McBSP pins.
  - Enable/disable the digital loopback mode.
  - Enable/disable the clock stop mode.
  - Enable/disable transmit multichannel selection.
- Data behavior:
  - Choose 1 or 2 phases for the transmit frame.
  - Set the transmit word length(s).
  - Set the transmit frame length.
  - Enable/disable the transmit frame-synchronization ignore function.
  - Set the transmit companding mode.
  - Set the transmit data delay.
  - Set the transmit DXENA mode.
  - Set the transmit interrupt mode.
- Frame-synchronization behavior:
  - Set the transmit frame-synchronization mode.
  - Set the transmit frame-synchronization polarity.
  - Set the SRG frame-synchronization period and pulse width.
- Clock behavior:
  - Set the transmit clock mode.
  - Set the transmit clock polarity.
  - Set the SRG clock divide-down value.
  - Set the SRG clock synchronization mode.
  - Set the SRG clock mode (choose an input clock).
  - Set the SRG input clock polarity.

Copyright © 2024 Texas Instruments Incorporated

### 21.9.2 Resetting and Enabling the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take the transmitter out of reset). Table 21-47 describes the bits used for both of these steps.

**Table 21-47. Register Bits Used to Place Transmitter in Reset Field Descriptions**

| Register | Bit | Field | Value | Description |
|---|---|---|---|---|
| SPCR2 | 7 | FRST | | Frame-synchronization logic reset |
| | | | 0 | Frame-synchronization logic is reset. The sample rate generator does not generate frame-synchronization signal FSG, even if GRST = 1. |
| | | | 1 | Frame-synchronization is enabled. If GRST = 1, frame-synchronization signal FSG is generated after (FPER + 1) number of CLKG clock cycles; all frame counters are loaded with their programmed values. |
| SPCR2 | 6 | GRST | | Sample rate generator reset |
| | | | 0 | Sample rate generator is reset. If GRST = 0 due to a device reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven low (inactive). If GRST = 0 due to program code, CLKG and FSG are both driven low (inactive). |
| | | | 1 | Sample rate generator is enabled. CLKG is driven according to the configuration programmed in the sample rate generator registers (SRGR[1,2]). If FRST = 1, the generator also generates the frame-synchronization signal FSG as programmed in the sample rate generator registers. |
| SPCR2 | 0 | XRST | | Transmitter reset |
| | | | 0 | The serial port transmitter is disabled and in the reset state. |
| | | | 1 | The serial port transmitter is enabled. |

#### 21.9.2.1 Reset Considerations

The serial port can be reset in the following two ways:

1. A DSP reset ( $\overline{\text{XRS}}$ signal driven low) places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed, GRST = FRST = RRST = XRST = 0, keeping the entire serial port in the reset state.
2. The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the serial port control registers. The sample rate generator can be reset directly using the GRST bit in SPCR2.
3. When using the DMA, the order in which McBSP events must occur is important. DMA channel and peripheral interrupts must be configured prior to releasing the McBSP transmitter from reset.

   The reason for this is that an XRDY is fired when XRST = 1. The XRDY signals the DMA to start copying data from the buffer into the transmit register. If the McBSP transmitter is released from reset before the DMA channel and peripheral interrupts are configured, the XRDY signals before the DMA channel can receive the signal; therefore, the DMA does not move the data from the buffer to the transmit register. The DMA PERINTFLG is edge-sensitive and will fail to recognize the XRDY, which is continuously high.

For more details about McBSP reset conditions and effects, see Section 21.10.2.

### 21.9.3 Set the Transmitter Pins to Operate as McBSP Pins

To configure a pin for McBSP functioning, configure the bits of the GPxMUXn register appropriately. In addition to this, bits 12 and 13 of the PCR register must be set to 0. These bits are defined as reserved.

Copyright © 2024 Texas Instruments Incorporated

### 21.9.4 Digital Loopback Mode

The DLB bit determines whether the digital loopback mode is on. DLB is described in Table 21-48.

**Table 21-48. Register Bit Used to Enable/Disable the Digital Loopback Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| SPCR1 | 15 | DLB | Digital loopback mode | | R/W | 0 |
| | | | DLB = 0 | Digital loopback mode is disabled. | | |
| | | | DLB = 1 | Digital loopback mode is enabled. | | |

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals, as shown in Table 21-49. This mode allows testing of serial port code with a single DSP device; the McBSP receives the data it transmits.

**Table 21-49. Receive Signals Connected to Transmit Signals in Digital Loopback Mode**

| This Receive Signal | Is Fed Internally by This Transmit Signal |
|---|---|
| DR (receive data) | DX (transmit data) |
| FSR (receive frame synchronization) | FSX (transmit frame synchronization) |
| MCLKR (receive clock) | CLKX (transmit clock) |

### 21.9.5 Clock Stop Mode

The CLKSTP bits determine whether the clock stop mode is on. CLKSTP is described in Table 21-50.

**Table 21-50. Register Bits Used to Enable/Disable the Clock Stop Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| SPCR1 | 12-11 | CLKSTP | Clock stop mode | | R/W | 00 |
| | | | CLKSTP = 0Xb | Clock stop mode disabled; normal clocking for non-SPI mode. | | |
| | | | CLKSTP = 10b | Clock stop mode enabled without clock delay | | |
| | | | CLKSTP = 11b | Clock stop mode enabled with clock delay | | |

The clock stop mode supports the SPI master-slave protocol. If you do not plan to use the SPI protocol, you can clear CLKSTP to disable the clock stop mode.

In the clock stop mode, the clock stops at the end of each data transfer. At the beginning of each data transfer, the clock starts immediately (CLKSTP = 10b) or after a half-cycle delay (CLKSTP = 11b). The CLKXP bit determines whether the starting edge of the clock on the MCLKX pin is rising or falling. The CLKRP bit determines whether receive data is sampled on the rising or falling edge of the clock shown on the MCLKR pin.

Table 21-51 summarizes the impact of CLKSTP, CLKXP, and CLKRP on serial port operation. In the clock stop mode, the receive clock is tied internally to the transmit clock, and the receive frame-synchronization signal is tied internally to the transmit frame-synchronization signal.

Copyright © 2024 Texas Instruments Incorporated

**Table 21-51. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme**

| Bit Settings | Clock Scheme |
|---|---|
| CLKSTP = 00b or 01b<br>CLKXP = 0 or 1<br>CLKRP = 0 or 1 | Clock stop mode disabled. Clock enabled for non-SPI mode. |
| CLKSTP = 10b<br>CLKXP = 0<br>CLKRP = 0 | Low inactive state without delay: The McBSP transmits data on the rising edge of CLKX and receives data on the falling edge of MCLKR. |
| CLKSTP = 11b<br>CLKXP = 0<br>CLKRP = 1 | Low inactive state with delay: The McBSP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of MCLKR. |
| CLKSTP = 10b<br>CLKXP = 1<br>CLKRP = 0 | High inactive state without delay: The McBSP transmits data on the falling edge of CLKX and receives data on the rising edge of MCLKR. |
| CLKSTP = 11b<br>CLKXP = 1<br>CLKRP = 1 | High inactive state with delay: The McBSP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of MCLKR. |

### *21.9.6 Transmit Multichannel Selection Mode*

For more details, see Section 21.6.7.

**Table 21-52. Register Bits Used to Enable/Disable Transmit Multichannel Selection**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| MCR2 | 1-0 | XMCM | Transmit multichannel selection | | R/W | 00 |
| | | | XMCM = 00b | No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked. | | |
| | | | XMCM = 01b | All channels are disabled unless the channels are selected in the appropriate transmit channel enable registers (XCERs). If enabled, a channel in this mode is also unmasked.<br>The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs. | | |
| | | | XMCM = 10b | All channels are enabled, but the channels are masked unless the channels are selected in the appropriate transmit channel enable registers (XCERs).<br>The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs. | | |
| | | | XMCM = 11b | This mode is used for symmetric transmission and reception.<br>All channels are disabled for transmission unless the channels are enabled for reception in the appropriate receive channel enable registers (RCERs). Once enabled, the channels are masked unless the channels are also selected in the appropriate transmit channel enable registers (XCERs).<br>The XMCME bit determines whether 32 channels or 128 channels are selectable in RCERs and XCERs. | | |

Copyright © 2024 Texas Instruments Incorporated

### 21.9.7 XCERs Used in the Transmit Multichannel Selection Mode

For multichannel selection operation, the assignment of channels to the XCERs depends on whether 32 or 128 channels are individually selectable by the XMCME bit, as shown in Table 21-53. The table shows which block of channels is assigned to each XCER that is used. For each XCER, the table shows which channel is assigned to each of the bits.

**Note**

When XMCM = 11b (for symmetric transmission and reception), the transmitter uses the receive channel enable registers (RCERs) to enable channels and uses the XCERs to unmask channels for transmission.

**Table 21-53. Use of the Transmit Channel Enable Registers**

| Number of Selectable Channels | Block Assignments | | Channel Assignments | |
|---|---|---|---|---|
| | XCERx | Block Assigned | Bit in XCERx | Channel Assigned |
| 32 (XMCME = 0) | XCERA | Channels n to (n + 15) | XCE0 | Channel n |
| | | | XCE1 | Channel (n + 1) |
| | | | XCE2 | Channel (n + 2) |
| | | | : | : |
| | | When XMCM = 01b or 10b, the block of channels is chosen with the XPABLK bits. When XMCM = 11b, the block is chosen with the RPABLK bits. | XCE15 | Channel (n + 15) |
| | XCERB | Channels m to (m + 15) | XCE0 | Channel m |
| | | | XCE1 | Channel (m + 1) |
| | | | XCE2 | Channel (m + 2) |
| | | | : | : |
| | | When XMCM = 01b or 10b, the block of channels is chosen with the XPBBLK bits. When XMCM = 11b, the block is chosen with the RPBBLK bits. | XCE15 | Channel (m + 15) |
| 128 (XMCME = 1) | XCERA | Block 0 | XCE0 | Channel 0 |
| | | | XCE1 | Channel 1 |
| | | | XCE2 | Channel 2 |

### 21.9.8 Transmit Frame Phases

The XPHASE bit (see Table 21-54) determines whether the transmit data frame has one or two phases.

**Table 21-54. Register Bit Used to Choose 1 or 2 Phases for the Transmit Frame**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| XCR2 | 15 | XPHASE | Transmit phase number | | R/W | 0 |
| | | | Specifies whether the transmit frame has 1 or 2 phases. | | | |
| | | | XPHASE = 0 | Single-phase frame | | |
| | | | XPHASE = 1 | Dual-phase frame | | |

### 21.9.9 Transmit Word Lengths

The XWDLEN1 and XWDLEN2 bit fields (see Table 21-55) determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

**Table 21-55. Register Bits Used to Set the Transmit Word Lengths**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| XCR1 | 7-5 | XWDLEN1 | Transmit word length of frame phase 1 | | R/W | 000 |
| | | | XWDLEN1 = 000b | 8 bits | | |
| | | | XWDLEN1 = 001b | 12 bits | | |
| | | | XWDLEN1 = 010b | 16 bits | | |
| | | | XWDLEN1 = 011b | 20 bits | | |
| | | | XWDLEN1 = 100b | 24 bits | | |
| | | | XWDLEN1 = 101b | 32 bits | | |
| | | | XWDLEN1 = 11Xb | Reserved | | |
| XCR2 | 7-5 | XWDLEN2 | Transmit word length of frame phase 2 | | R/W | 000 |
| | | | XWDLEN2 = 000b | 8 bits | | |
| | | | XWDLEN2 = 001b | 12 bits | | |
| | | | XWDLEN2 = 010b | 16 bits | | |
| | | | XWDLEN2 = 011b | 20 bits | | |
| | | | XWDLEN2 = 100b | 24 bits | | |
| | | | XWDLEN2 = 101b | 32 bits | | |
| | | | XWDLEN2 = 11Xb | Reserved | | |

#### 21.9.9.1 Word Length Bits

Each frame can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, XWDLEN1 selects the length for every serial word transmitted in the frame. If a dual-phase frame is selected, XWDLEN1 determines the length of the serial words in phase 1 of the frame, and XWDLEN2 determines the word length in phase 2 of the frame.

Copyright © 2024 Texas Instruments Incorporated

### 21.9.10 Transmit Frame Length

The XFRLEN1 and XFRLEN2 bit fields (see Table 21-56) determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

**Table 21-56. Register Bits Used to Set the Transmit Frame Length**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| XCR1 | 14-8 | XFRLEN1 | Transmit frame length 1 | | R/W | 000 0000 |
| | | | (XFRLEN1 + 1) is the number of serial words in phase 1 of the transmit frame. | | | |
| | | | XFRLEN1 = 000 0000 | 1 word in phase 1 | | |
| | | | XFRLEN1 = 000 0001 | 2 words in phase 1 | | |
| | | | \| | \| | | |
| | | | \| | \| | | |
| | | | XFRLEN1 = 111 1111 | 128 words in phase 1 | | |
| XCR2 | 14-8 | XFRLEN2 | Transmit frame length 2 | | R/W | 000 0000 |
| | | | If a dual-phase frame is selected, (XFRLEN2 + 1) is the number of serial words in phase 2 of the transmit frame. | | | |
| | | | XFRLEN2 = 000 0000 | 1 word in phase 2 | | |
| | | | XFRLEN2 = 000 0001 | 2 words in phase 2 | | |
| | | | \| | \| | | |
| | | | \| | \| | | |
| | | | XFRLEN2 = 111 1111 | 128 words in phase 2 | | |

#### 21.9.10.1 Selected Frame Length

The transmit frame length is the number of serial words in the transmit frame. Each frame can have one or two phases, depending on the value that you load into the XPHASE bit.

If a single-phase frame is selected (XPHASE = 0), the frame length is equal to the length of phase 1. If a dual-phase frame is selected (XPHASE = 1), the frame length is the length of phase 1 plus the length of phase 2.

The 7-bit XFRLEN fields allow up to 128 words per phase. See Table 21-57 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

**Note**

Program the XFRLEN fields with [*w minus 1*], where w represents the number of words per phase. For example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

**Table 21-57. How to Calculate Frame Length**

| XPHASE | XFRLEN1 | XFRLEN2 | Frame Length |
|---|---|---|---|
| 0 | 0 ≤ XFRLEN1 ≤ 127 | Don't care | (XFRLEN1 + 1) words |
| 1 | 0 ≤ XFRLEN1 ≤ 127 | 0 ≤ XFRLEN2 ≤ 127 | (XFRLEN1 + 1) + (XFRLEN2 + 1) words |

Copyright © 2024 Texas Instruments Incorporated

### 21.9.11 Enable/Disable the Transmit Frame-Synchronization Ignore Function

**Table 21-58. Register Bit Used to Enable/Disable the Transmit Frame-Synchronization Ignore Function**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| XCR2 | 2 | XFIG | Transmit frame-synchronization ignore | | R/W | 0 |
| | | | XFIG = 0 | An unexpected transmit frame-synchronization pulse causes the McBSP to restart the frame transfer. | | |
| | | | XFIG = 1 | The McBSP ignores unexpected transmit frame-synchronization pulses. | | |

#### 21.9.11.1 Unexpected Frame-Synchronization Pulses and Frame-Synchronization Ignore

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse.

When XFIG = 1, normal transmission continues with unexpected frame-synchronization signals ignored.

When XFIG = 0 and an unexpected frame-synchronization pulse occurs, the serial port:

1. Aborts the present transmission
2. Sets XSYNCERR to 1 in SPCR2
3. Reinitiates transmission of the current word that was aborted

For more details about the frame-synchronization error condition, see Section 21.5.6.

#### 21.9.11.2 Examples Showing the Effects of XFIG

Figure 21-51 shows an example in which word B is interrupted by an unexpected frame-synchronization pulse when (R/X)FIG = 0. In the case of transmission, the transmission of B is aborted (B is lost). This condition is a transmit synchronization error, which sets the XSYNCERR bit. No new data has been written to DXR[1,2]; therefore, the McBSP transmits B again.

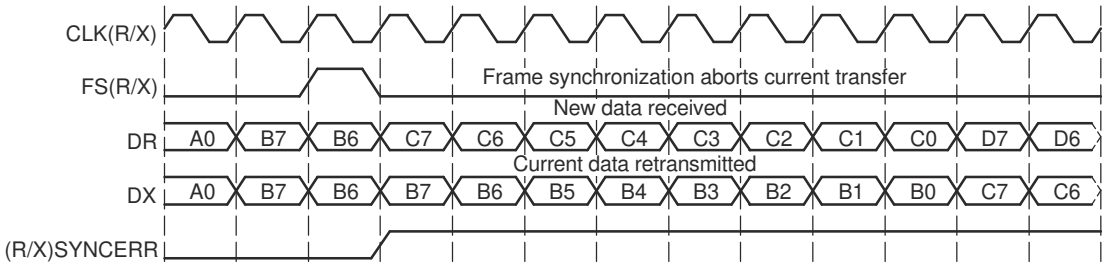

**Figure 21-51. Unexpected Frame-Synchronization Pulse With (R/X) FIG = 0**

In contrast with Figure 21-51, Figure 21-52 shows McBSP operation when unexpected frame-synchronization signals are ignored (when (R/X)FIG = 1). Here, the transfer of word B is not affected by an unexpected frame-synchronization pulse.

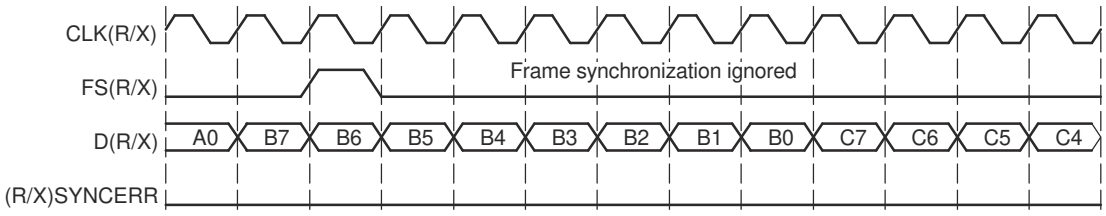

**Figure 21-52. Unexpected Frame-Synchronization Pulse With (R/X) FIG = 1**

Copyright © 2024 Texas Instruments Incorporated

### 21.9.12 Transmit Companding Mode

The XCOMPAND bits (see Table 21-59) determine whether companding or another data transfer option is chosen for McBSP transmission.

**Table 21-59. Register Bits Used to Set the Transmit Companding Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| XCR2 | 4-3 | XCOMPAND | Transmit companding mode | | R/W | 00 |
| | | | Modes other than 00b are enabled only when the appropriate XWDLEN is 000b, indicating 8-bit data. | | | |
| | | | XCOMPAND = 00b | No companding, any size data, MSB transmitted first | | |
| | | | XCOMPAND = 01b | No companding, 8-bit data, LSB transmitted first (for details, see Section 21.8.11.4) | | |
| | | | XCOMPAND = 10b | µ-law companding, 8-bit data, MSB transmitted first | | |
| | | | XCOMPAND = 11b | A-law companding, 8-bit data, MSB transmitted first | | |

#### 21.9.12.1 Companding

Companding (COMpressing and exPANDing) hardware allows compression and expansion of data in either µ-law or A-law format. The companding standard employed in the United States and Japan is µ-law. The European companding standard is referred to as A-law. The specifications for µ-law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and µ-law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

The µ-law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 21-53 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or µ-law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to twos-complement format.

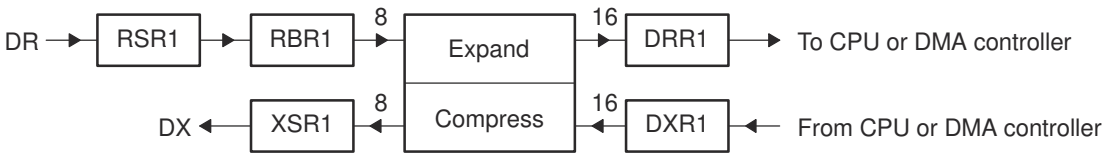

**Figure 21-53. Companding Processes for Reception and for Transmission**

Copyright © 2024 Texas Instruments Incorporated

#### 21.9.12.2 Format for Data To Be Compressed

For transmission using µ-law compression, make sure the 14 data bits are left-justified in DXR1, with the remaining two low-order bits filled with 0s as shown in Figure 21-54.

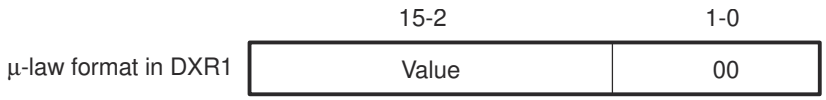

**Figure 21-54. µ-Law Transmit Data Companding Format**

For transmission using A-law compression, make sure the 13 data bits are left-justified in DXR1, with the remaining three low-order bits filled with 0s as shown in Figure 21-55.

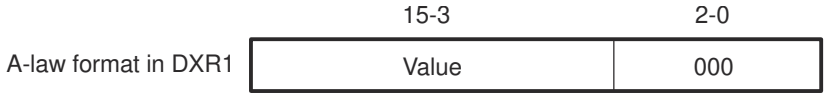

**Figure 21-55. A-Law Transmit Data Companding Format**

#### 21.9.12.3 Capability to Companding Internal Data

If the McBSP is otherwise unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. See Section 21.3.2.2.

#### 21.9.12.4 Option to Transmit LSB First

Normally, the McBSP transmit or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set XCOMPAND = 01b in XCR2, the bit ordering of 8-bit words is reversed (LSB first) before being sent from the serial port. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits and LSB-first ordering is done.

### *21.9.13 Transmit Data Delay*

The XDATDLY bits (see Table 21-60) determine the length of the data delay for the transmit frame.

**Table 21-60. Register Bits Used to Set the Transmit Data Delay**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| XCR2 | 1-0 | XDATDLY | Transmitter data delay | | R/W | 00 |
| | | | XDATDLY = 00 | 0-bit data delay | | |
| | | | XDATDLY = 01 | 1-bit data delay | | |
| | | | XDATDLY = 10 | 2-bit data delay | | |
| | | | XDATDLY = 11 | Reserved | | |

#### 21.9.13.1 Data Delay

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if necessary. This delay is called data delay.

XDATDLY specifies the data delay for transmission. The range of programmable data delay is zero to two bit-clocks (XDATDLY = 00b-10b), as described in Table 21-60 and Figure 21-56. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Copyright © 2024 Texas Instruments Incorporated

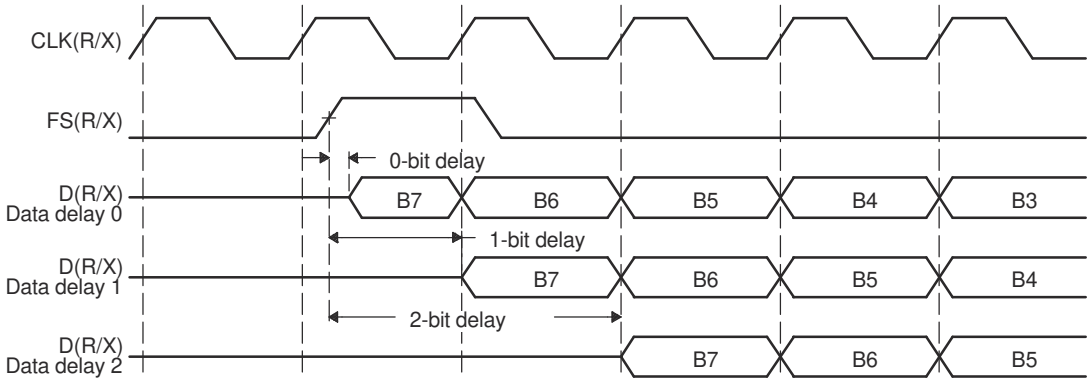

**Figure 21-56. Range of Programmable Data Delay**

#### 21.9.13.2 0-Bit Data Delay

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of serial clock internal CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data can be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception this problem is solved because receive data is sampled on the first falling edge of MCLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus DX. The transmitter then asynchronously detects the frame synchronization, FSX, going active high and immediately starts driving the first bit to be transmitted on the DX pin.

#### 21.9.13.3 2-Bit Data Delay

A data delay of two bit-periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 21-57. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

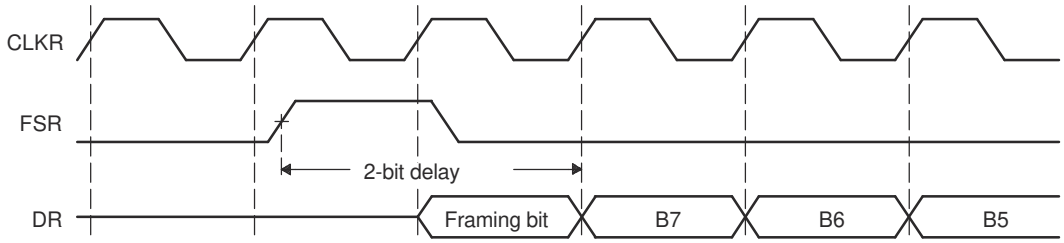

**Figure 21-57. 2-Bit Data Delay Used to Skip a Framing Bit**

Copyright © 2024 Texas Instruments Incorporated

### 21.9.14 Transmit DXENA Mode

Table 21-61 shows which register bit enables the Transmit DXENA (DX Delay Enabler) Mode.

**Table 21-61. Register Bit Used to Set the Transmit DXENA (DX Delay Enabler) Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| SPCR1 | 7 | DXENA | DX delay enabler mode | | R/W | 0 |
| | | | DXENA = 0 | DX delay enabler is off. | | |
| | | | DXENA = 1 | DX delay enabler is on. | | |

The DXENA bit controls the delay enabler on the DX pin. Set DXENA to enable an extra delay for turn-on time. This bit does not control the data itself, so only the first bit is delayed.

If you tie together the DX pins of multiple McBSPs, make sure DXENA = 1 to avoid having more than one McBSP transmit on the data line at one time.

### 21.9.15 Transmit Interrupt Mode

The transmitter interrupt (XINT) signals the CPU of changes to the serial port status. Four options exist for configuring this interrupt. The options are set by the transmit interrupt mode bits, XINTM, in SPCR2.

**Table 21-62. Register Bits Used to Set the Transmit Interrupt Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| SPCR2 | 5-4 | XINTM | Transmit interrupt mode | | R/W | 00 |
| | | | XINTM = 00 | XINT generated when XRDY changes from 0 to 1. | | |
| | | | XINTM = 01 | XINT generated by an end-of-block or end-of-frame condition in a transmit multichannel selection mode. In any of the transmit multichannel selection modes, interrupt after every 16-channel block boundary has been crossed within a frame and at the end of the frame. For details, see Section 21.6.8. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated. | | |
| | | | XINTM = 10 | XINT generated by a new transmit frame-synchronization pulse. Interrupt on detection of each transmit frame-synchronization pulse. This generates an interrupt even when the transmitter is in the reset state. This is done by synchronizing the incoming frame-synchronization pulse to the CPU clock and sending the pulse to the CPU using XINT. | | |
| | | | XINTM = 11 | XINT generated when XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR can be read to detect this condition. For more information on using XSYNCERR, see Section 21.5.6. | | |

Copyright © 2024 Texas Instruments Incorporated

### 21.9.16 Transmit Frame-Synchronization Mode

Table 21-63 shows which register bits enable the Transmit Frame-Synchronization Mode.

**Table 21-63. Register Bits Used to Set the Transmit Frame-Synchronization Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 11 | FSXM | Transmit frame-synchronization mode | | R/W | 0 |
| | | | FSXM = 0 | Transmit frame synchronization is supplied by an external source via the FSX pin. | | |
| | | | FSXM = 1 | Transmit frame synchronization is supplied by the McBSP, as determined by the FSGM bit of SRGR2. | | |
| SRGR2 | 12 | FSGM | Sample rate generator transmit frame-synchronization mode | | R/W | 0 |
| | | | Used when FSXM = 1 in PCR. | | | |
| | | | FSGM = 0 | The McBSP generates a transmit frame-synchronization pulse when the content of DXR[1,2] is copied to XSR[1,2]. | | |
| | | | FSGM = 1 | The transmitter uses frame-synchronization pulses generated by the sample rate generator. Program the FWID bits to set the width of each pulse. Program the FPER bits to set the frame-synchronization period. | | |

Table 21-64 shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

- External frame-synchronization input
- Sample rate generator frame-synchronization signal (FSG)
- Internal signal that indicates a DXR-to-XSR copy has been made

Table 21-64 also shows the effect of each bit setting on the FSX pin. The polarity of the signal on the FSX pin is determined by the FSXP bit.

**Table 21-64. How FSXM and FSGM Select the Source of Transmit Frame-Synchronization Pulses**

| FSXM | FSGM | Source of Transmit Frame Synchronization | FSX Pin Status |
|---|---|---|---|
| 0 | 0 or 1 | An external frame-synchronization signal enters the McBSP through the FSX pin. The signal is then inverted by FSXP before being used as internal FSX. | Input |
| 1 | 1 | Internal FSX is driven by the sample rate generator frame-synchronization signal (FSG). | Output. FSG is inverted by FSXP before being driven out on FSX pin. |
| 1 | 0 | A DXR-to-XSR copy causes the McBSP to generate a transmit frame-synchronization pulse that is 1 cycle wide. | Output. The generated frame-synchronization pulse is inverted as determined by FSXP before being driven out on FSX pin. |

#### 21.9.16.1 Other Considerations

If the sample rate generator creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the FSR pin. For more details, see Section 21.4.3.

In the clock stop mode (CLKSTP = 10b or 11b), the McBSP can act as a master or as a slave in the SPI protocol. If the McBSP is a master and must provide a slave-enable signal ($\overline{\text{SPISTE}}$) on the FSX pin, make sure that FSXM = 1 and FSGM = 0 so that FSX is an output and is driven active for the duration of each transmission. If the McBSP is a slave, make sure that FSXM = 0 so that the McBSP can receive the slave-enable signal on the FSX pin.

### 21.9.17 Transmit Frame-Synchronization Polarity

Table 21-65 shows which register bits enable the Transmit Frame-Synchronization Polarity.

**Table 21-65. Register Bit Used to Set Transmit Frame-Synchronization Polarity**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 3 | FSXP | Transmit frame-synchronization polarity | | R/W | 0 |
| | | | FSXP = 0 | Frame-synchronization pulse FSX is active high. | | |
| | | | FSXP = 1 | Frame-synchronization pulse FSX is active low. | | |

#### 21.9.17.1 Frame Synchronization Pulses, Clock Signals, and Their Polarities

Transmit frame-synchronization pulses can be generated internally by the sample rate generator (see Section 21.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSXM, in PCR. FSX is also affected by the FSGM bit in SRGR2. For information about the effects of FSXM and FSGM, see Section 21.9.16). Similarly, transmit clocks can be selected to be inputs or outputs by programming the mode bit, CLKXM, in the PCR (see Section 21.9.19).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that the outputs are driven by the sample rate generator, the outputs are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected and the polarity bit FS(R/X)P = 1, the internal active-high frame-synchronization signals are inverted before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and MCLKR is an input pin), the external rising-edge triggered input clock on MCLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to make sure of valid setup and hold of data around this edge. Figure 21-58 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

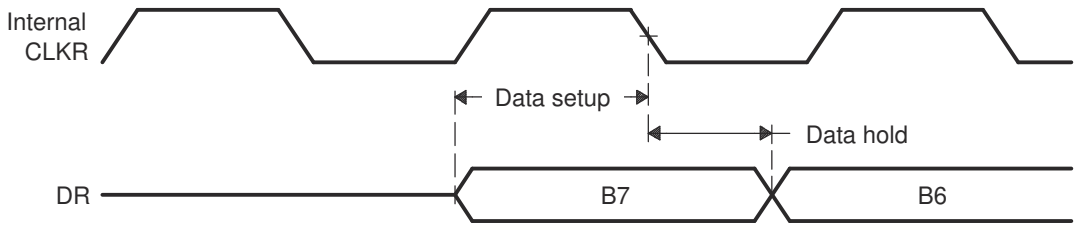

**Figure 21-58. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge**

### *21.9.18 SRG Frame-Synchronization Period and Pulse Width*

Table 21-66 shows which register bits set the SRG Frame-Synchronization Period and Pulse Width.

**Table 21-66. Register Bits Used to Set SRG Frame-Synchronization Period and Pulse Width**

| Register | Bit | Name | Function | Type | Reset Value |
|---|---|---|---|---|---|
| SRGR2 | 11-0 | FPER | Sample rate generator frame-synchronization period<br>For the frame-synchronization signal FSG, (FPER + 1) determines the period from the start of a frame-synchronization pulse to the start of the next frame-synchronization pulse.<br>Range for (FPER + 1): 1 to 4096 CLKG cycles. | R/W | 0000 0000 0000 |
| SRGR1 | 15-8 | FWID | Sample rate generator frame-synchronization pulse width<br>This field plus 1 determines the width of each frame-synchronization pulse on FSG.<br>Range for (FWID + 1): 1 to 256 CLKG cycles. | R/W | 0000 0000 |

#### 21.9.18.1 Frame-Synchronization Period and Frame-Synchronization Pulse Width

The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 21-59 shows a frame-synchronization period of 16 CLKG periods (FPER = 15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

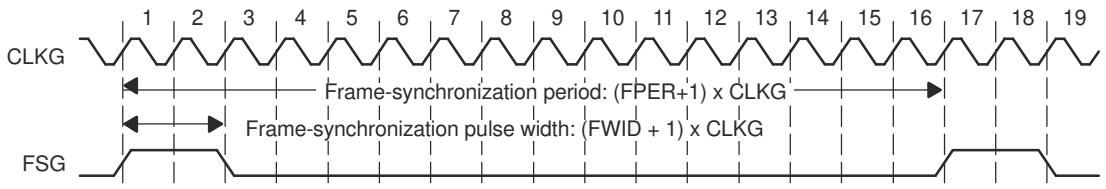

**Figure 21-59. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods**

Copyright © 2024 Texas Instruments Incorporated

When the sample rate generator comes out of reset, FSG is in the inactive state. Then, when GRST = 1 and FSGM = 1, a frame-synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until the value reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

### *21.9.19 Transmit Clock Mode*

Table 21-67 shows which register bits can set the Transmit Clock Mode.

**Table 21-67. Register Bit Used to Set the Transmit Clock Mode**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 9 | CLKXM | Transmit clock mode | | R/W | 0 |
| | | | CLKXM = 0 | The transmitter gets the clock signal from an external source via the MCLKX pin. | | |
| | | | CLKXM = 1 | The MCLKX pin is an output pin driven by the sample rate generator of the McBSP. | | |

#### 21.9.19.1 Selecting a Source for the Transmit Clock and a Data Direction for the MCLKX pin

Table 21-68 shows how the CLKXM bit selects the transmit clock and the corresponding status of the MCLKX pin. The polarity of the signal on the MCLKX pin is determined by the CLKXP bit.

**Table 21-68. How the CLKXM Bit Selects the Transmit Clock and the Corresponding Status of the MCLKX pin**

| CLKXM in PCR | Source of Transmit Clock | MCLKX pin Status |
|---|---|---|
| 0 | Internal CLKX is driven by an external clock on the MCLKX pin. CLKX is inverted as determined by CLKXP before being used. | Input |
| 1 | Internal CLKX is driven by the sample rate generator clock, CLKG. | Output. CLKG, inverted as determined by CLKXP, is driven out on CLKX. |

#### 21.9.19.2 Other Considerations

If the sample rate generator creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the FSR pin. For more details, see Section 21.4.3.

In the clock stop mode (CLKSTP = 10b or 11b), the McBSP can act as a master or as a slave in the SPI protocol. If the McBSP is a master, make sure that CLKXM = 1 so that CLKX is an output to supply the master clock to any slave devices. If the McBSP is a slave, make sure that CLKXM = 0 so that CLKX is an input to accept the master clock signal.

### *21.9.20 Transmit Clock Polarity*

Table 21-69 shows which register bits set the Transmit Clock Polarity.

**Table 21-69. Register Bit Used to Set Transmit Clock Polarity**

| Register | Bit | Name | Function | | Type | Reset Value |
|---|---|---|---|---|---|---|
| PCR | 1 | CLKXP | Transmit clock polarity | | R/W | 0 |
| | | | CLKXP = 0 | Transmit data sampled on rising edge of CLKX. | | |
| | | | CLKXP = 1 | Transmit data sampled on falling edge of CLKX. | | |

Copyright © 2024 Texas Instruments Incorporated

#### 21.9.20.1 Frame Synchronization Pulses, Clock Signals, and Their Polarities

Transmit frame-synchronization pulses can be either generated internally by the sample rate generator (see Section 21.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSXM, in PCR. FSX is also affected by the FSGM bit in SRGR2. For information about the effects of FSXM and FSGM, see Section 21.9.16). Similarly, transmit clocks can be selected to be inputs or outputs by programming the mode bit, CLKXM, in the PCR (see Section 21.9.19).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that the outputs are driven by the sample rate generator, the outputs are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to make sure of valid setup and hold of data around this edge (see Figure 21-58).

Figure 21-60 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

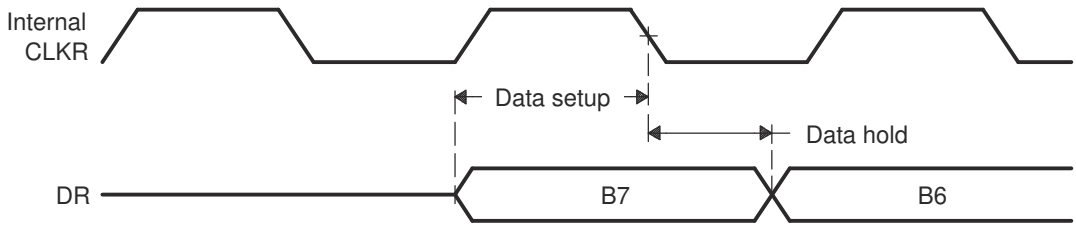

**Figure 21-60. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge**

## 21.10 Emulation and Reset Considerations

This section covers the following topics:

- How to program McBSP response to a breakpoint in the high-level language debugger (see Section 21.10.1)
- How to reset and initialize the various parts of the McBSP (see Section 21.10.2)

### *21.10.1 McBSP Emulation Mode*

FREE and SOFT are special emulation bits in SPCR2 that determine the state of the McBSP when a breakpoint is encountered in the high-level language debugger. If FREE = 1, the clock continues to run upon a software breakpoint and data is still shifted out. When FREE = 1, the SOFT bit is a *don't care.*

If FREE = 0, the SOFT bit takes effect. If SOFT = 0 when breakpoint occurs, the clock stops immediately, aborting a transmission. If SOFT = 1 and a breakpoint occurs while transmission is in progress, the transmission continues until completion of the transfer and then the clock halts. These options are listed in Table 21-70.

The McBSP receiver functions in a similar fashion. If a mode other than the immediate stop mode (SOFT = FREE = 0) is chosen, the receiver continues running and an overrun error is possible.

**Table 21-70. McBSP Emulation Modes Selectable with FREE and SOFT Bits of SPCR2**

| FREE | SOFT | McBSP Emulation Mode |
|---|---|---|
| 0 | 0 | Immediate stop mode (reset condition).<br>The transmitter or receiver stops immediately in response to a breakpoint. |
| 0 | 1 | Soft stop mode<br>When a breakpoint occurs, the transmitter stops after completion of the current word. The receiver is not affected. |
| 1 | 0 or 1 | Free run mode<br>The transmitter and receiver continue to run when a breakpoint occurs. |

### *21.10.2 Resetting and Initializing McBSPs*

This section discusses in greater depth the MCBSP Reset and Initialization configurations.

#### 21.10.2.1 McBSP Pin States: DSP Reset Versus Receiver/Transmitter Reset

Table 21-71 shows the state of McBSP pins when the serial port is reset due to direct receiver or transmitter reset on the 2833x device.

**Table 21-71. Reset State of Each McBSP Pin**

| Pin | Possible States[1] | State Forced by Device Reset | State Forced by Receiver/Transmitter Reset |
|---|---|---|---|
| **Receiver reset (RRST = 0 and GRST = 1)** | | | |
| MDRx | I | GPIO-input | Input |
| MCLKRx | I/O/Z | GPIO-input | Known state if input; MCLKR running if output |
| MFSRx | I/O/Z | GPIO-input | Known state if input; FSRP inactive state if output |
| **Transmitter reset (XRST = 0 and GRST = 1)** | | | |
| MDXx | O/Z | GPIO Input | High impedance |
| MCLKXx | I/O/Z | GPIO-input | Known state if input; CLKX running if output |
| MFSXx | I/O/Z | GPIO-input | Known state if input; FSXP inactive state if output |

(1) In Possible States column, I = Input, O = Output, Z = High impedance. In the C28x family, at device reset, all I/Os default to GPIO function and generally as inputs.

Copyright © 2024 Texas Instruments Incorporated

#### 21.10.2.2 Device Reset, McBSP Reset, and Sample Rate Generator Reset

When the McBSP is reset in either of the above two ways, the machine is reset to its initial state, including reset of all counters and status bits. The receive status bits include RFULL, RRDY, and RSYNCERR. The transmit status bits include XEMPTY, XRDY, and XSYNCERR.

- Device reset. When the whole DSP is reset ( $\overline{\text{XRS}}$ signal is driven low), all McBSP pins are in GPIO mode. When the device is pulled out of reset, the clock to the McBSP modules remains disabled.
- McBSP reset. When the receiver and transmitter reset bits, RRST and XRST, are loaded with 0s, the respective portions of the McBSP are reset and activity in the corresponding section of the serial port stops. Input-only pins such as MDRx, and all other pins that are configured as inputs are in a known state. The MFSRx and MFSXx pins are driven to their inactive state if they are not outputs. If the MCLKR and MCLKX pins are programmed as outputs, they are driven by CLKG, provided that GRST = 1. Lastly, the MDXx pin is in the high-impedance state when the transmitter and/or the device is reset.

  During normal operation, the sample rate generator is reset if the GRST bit is cleared. GRST must be 0 only when neither the transmitter nor the receiver is using the sample rate generator. In this case, the internal sample rate generator clock (CLKG) and its frame-synchronization signal (FSG) are driven inactive low.

  When the sample rate generator is not in the reset state (GRST = 1), pins MFSRx and MFSXx are in an inactive state when RRST = 0 and XRST = 0, respectively, even if they are outputs driven by FSG. This ensures that when only one portion of the McBSP is in reset, the other portion can continue operation when GRST = 1 and its frame synchronization is driven by FSG.
- Sample rate generator reset. The sample rate generator is reset when GRST is loaded with 0.

  When neither the transmitter nor the receiver is fed by CLKG and FSG, you can reset the sample rate generator by clearing GRST. In this case, CLKG and FSG are driven inactive low. If you then set GRST, CLKG starts and runs as programmed. Later, if GRST = 1, FSG pulses active high after the programmed number of CLKG cycles has elapsed.

Copyright © 2024 Texas Instruments Incorporated

#### 21.10.2.3 McBSP Initialization Procedure

The serial port initialization procedure is as follows:

1. Make XRST = RRST = GRST = 0 in SPCR[1,2]. If coming out of a device reset, this step is not required.
2. While the serial port is in the reset state, program only the McBSP configuration registers (not the data registers) as required.
3. Wait for two clock cycles. This makes sure of proper internal synchronization.
4. Set up data acquisition as required (such as writing to DXR[1,2]).
5. Make XRST = RRST = 1 to enable the serial port. Make sure that as you set these reset bits, you do not modify any of the other bits in SPCR1 and SPCR2. Otherwise, you change the configuration you selected in step 2.
6. Set FRST = 1, if internally generated frame synchronization is required.
7. Wait two clock cycles for the receiver and transmitter to become active.

Alternatively, on either write (step 1 or 5), the transmitter and receiver can be placed in or taken out of reset individually by modifying the desired bit.

The previous procedure for reset/initialization can be applied in general when the receiver or transmitter must be reset during normal operation and when the sample rate generator is not used for either operation.

**Note**

1. The necessary duration of the active-low period of XRST or RRST is at least two MCLKR/CLKX cycles.
2. The appropriate bits in serial port configuration registers SPCR[1,2], PCR, RCR[1,2], XCR[1,2], and SRGR[1,2] must only be modified when the affected portion of the serial port is in the reset state.
3. In most cases, the data transmit registers (DXR[1,2]) must be loaded by the CPU or by the DMA controller only when the transmitter is enabled (XRST = 1). An exception to this rule is when these registers are used for companding internal data (see Section 21.3.2.2).
4. The bits of the channel control registers—MCR[1,2], RCER[A-H], XCER[A-H]—can be modified at any time as long as the bits are not being used by the current reception/transmission in a multichannel selection mode.

#### 21.10.2.4 Resetting the Transmitter While the Receiver is Running

Example 21-1 shows values in the control registers that reset and configure the transmitter while the receiver is running.

***Example 21-1. Resetting and Configuring McBSP Transmitter While McBSP Receiver Running***

```
SPCR1 = 0001h SPCR2 = 0030h ;
The receiver is running with the receive interrupt (RINT) triggered by the receiver ready bit
(RRDY).;
The transmitter is in its reset state.;
The transmit interrupt (XINT) will be triggered by the transmit frame-sync error bit (XSYNCERR).;
PCR = 0900h ;
Transmit frame synchronization is generated internally according to the FSGM bit of SRGR2.;
The transmit clock is driven by an external source. ;
The receive clock continues to be driven by sample rate generator. The input clock ;
of the sample rate generator is supplied by the CPU clock. ;
SRGR1 = 0001h SRGR2 = 2000h ;
The CPU clock is the input clock for the sample rate generator. The sample ;
rate generator divides the CPU clock by 2 to generate its output clock (CLKG). ;
Transmit frame synchronization is tied to the automatic copying of data from ;
the DXR(s) to the XSR(s). ;
XCR1 = 0740h XCR2 = 8321h ;
The transmit frame has two phases. Phase 1 has eight 16-bit words. ;
Phase 2 has four 12-bit words. There is 1-bit data delay between the start of a ;
frame-sync pulse and the first data bit transmitted. ;
SPCR2 = 0031h ;
The transmitter is taken out of reset.
```

## 21.11 Data Packing Examples

This section shows two ways to implement data packing in the McBSP.

### *21.11.1 Data Packing Using Frame Length and Word Length*

Frame length and word length can be manipulated to effectively pack data. For example, consider a situation where four 8-bit words are transferred in a single-phase frame as shown in Figure 21-61. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0000011b: 4-word frame
- (R/X)WDLEN1 = 000b: 8-bit words

Four 8-bit data words are transferred to and from the McBSP by the CPU or by the DMA controller. Thus, four reads from DRR1 and four writes to DXR1 are necessary for each frame.

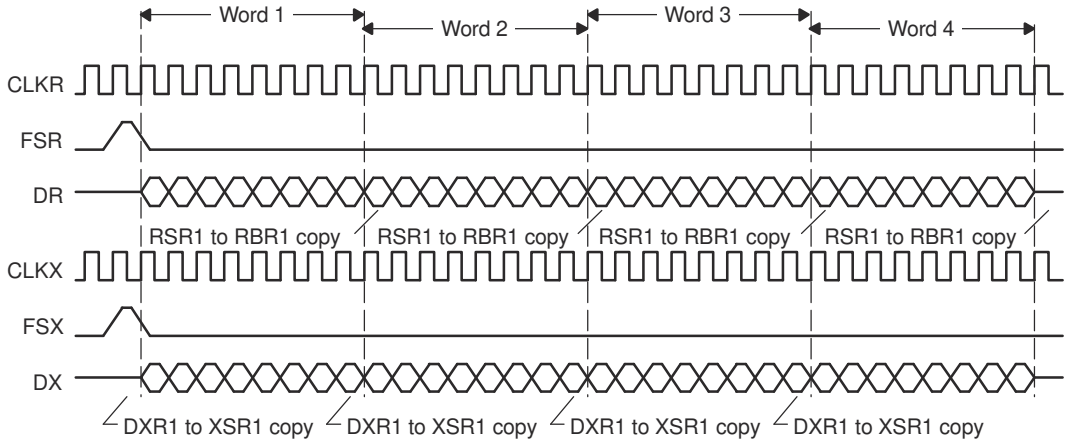

**Figure 21-61. Four 8-Bit Data Words Transferred To/From the McBSP**

Copyright © 2024 Texas Instruments Incorporated

This data can also be treated as a single-phase frame consisting of one 32-bit data word, as shown in Figure 21-62. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0000000b: 1-word frame
- (R/X)WDLEN1 = 101b: 32-bit word

Two 16-bit data words are transferred to and from the McBSP by the CPU or DMA controller. Thus, two reads, from DRR2 and DRR1, and two writes, to DXR2 and DXR1, are necessary for each frame. This results in only half the number of transfers compared to the previous case. This manipulation reduces the percentage of bus time required for serial port data movement.

**Note**

When the word length is larger than 16 bits, make sure you access DRR2/DXR2 before you access DRR1/DXR1. McBSP activity is tied to accesses of DRR1/DXR1. During the reception of 24-bit or 32-bit words, read DRR2 and then read DRR1. Otherwise, the next RBR[1,2]-to-DRR[1,2] copy occurs before DRR2 is read. Similarly, during the transmission of 24-bit or 32-bit words, write to DXR2 and then write to DXR1. Otherwise, the next DXR[1,2]-to-XSR[1,2] copy occurs before DXR2 is loaded with new data.

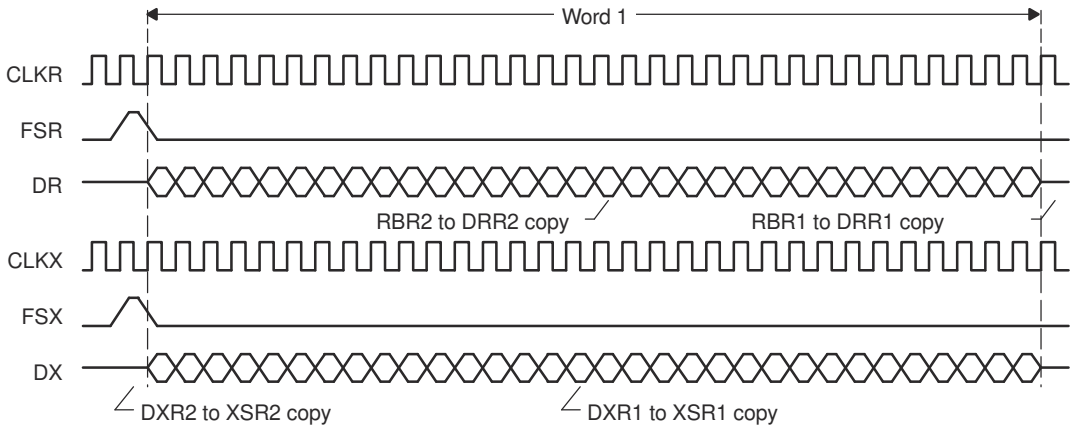

**Figure 21-62. One 32-Bit Data Word Transferred To/From the McBSP**

Copyright © 2024 Texas Instruments Incorporated

### 21.11.2 Data Packing Using Word Length and the Frame-Synchronization Ignore Function

When there are multiple words per frame, you can implement data packing by increasing the word length (defining a serial word with more bits) and by ignoring frame-synchronization pulses. First, consider Figure 21-63, which shows the McBSP operating at the maximum packet frequency. Here, each frame only has a single 8-bit word. Notice the frame-synchronization pulse that initiates each frame transfer for reception and for transmission. For reception, this configuration requires one read operation for each word. For transmission, this configuration requires one write operation for each word.

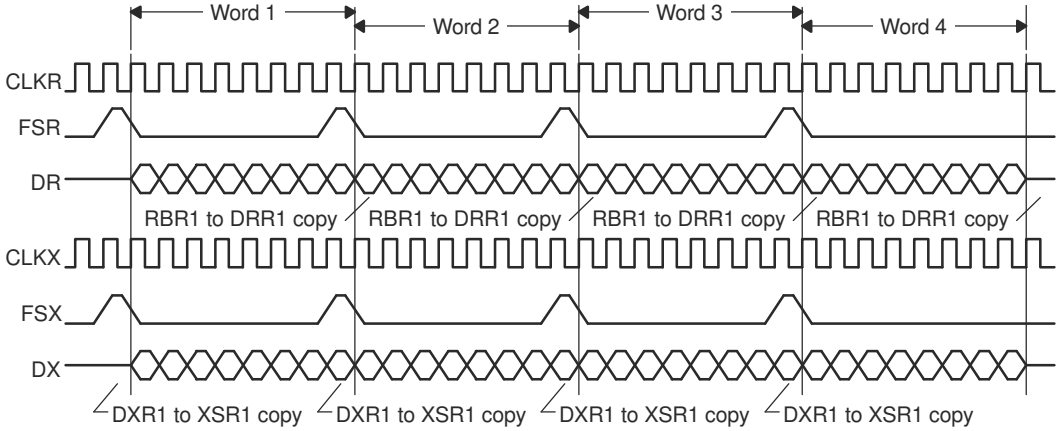

**Figure 21-63. 8-Bit Data Words Transferred at Maximum Packet Frequency**

Figure 21-64 shows the McBSP configured to treat this data stream as a continuous 32-bit word. In this example, the McBSP responds to an initial frame-synchronization pulse. However, (R/X)FIG = 1 so that the McBSP ignores subsequent pulses. Only two read transfers or two write transfers are needed every 32 bits. This configuration effectively reduces the required bus bandwidth to half the bandwidth needed to transfer four 8-bit words.

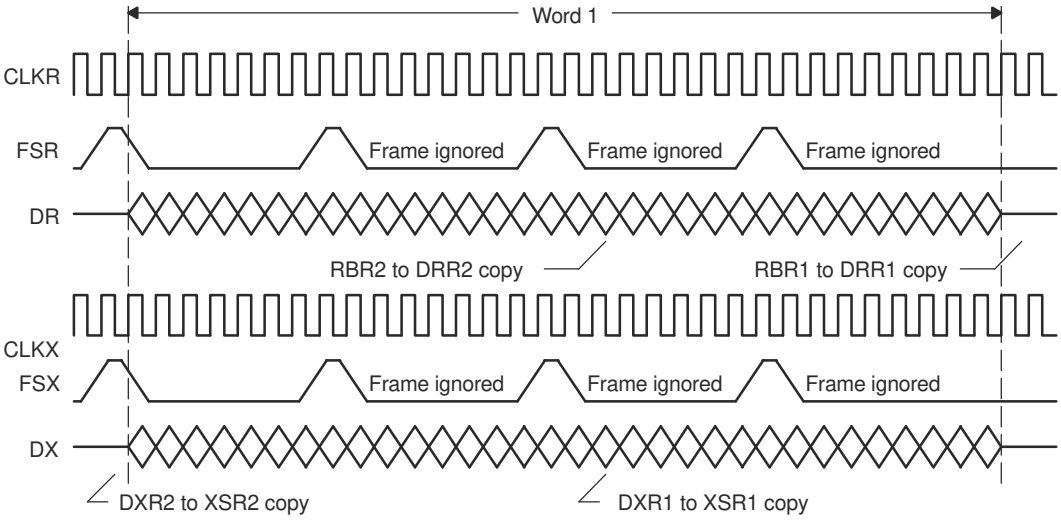

**Figure 21-64. Configuring the Data Stream of Figure 21-63 as a Continuous 32-Bit Word**

Copyright © 2024 Texas Instruments Incorporated

## 21.12 Interrupt Generation

McBSP registers can be programmed to receive and transmit data through DRR2/DRR1 and DXR2/DXR1 registers, respectively. The CPU can directly access these registers to move data from memory to these registers. Interrupt signals are based on these register pair contents and the related flags. MRINT/MXINT generates CPU interrupts for receive and transmit conditions.

### *21.12.1 McBSP Receive Interrupt Generation*

In the McBSP module, data receive and error conditions generate two sets of interrupt signals. One set is used for the CPU and the other set is for DMA.

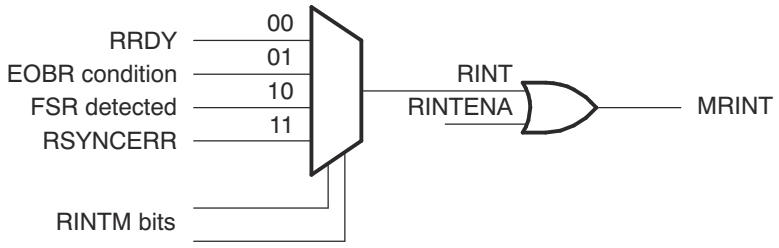

**Figure 21-65. Receive Interrupt Generation**

**Table 21-72. Receive Interrupt Sources and Signals**

| McBSP Interrupt Signal | Interrupt Flags | Interrupt Enables in SPCR1 (RINTM Bits) | Interrupt Enables | Type of Interrupt | Interrupt Line |
|---|---|---|---|---|---|
| RINT | RRDY | 00 | RINTENA | Every word receive | MRINT |
| | EOBR | 01 | RINTENA | Every 16-channel block boundary | |
| | FSR | 10 | RINTENA | On every FSR | |
| | RSYNCERR | 11 | RINTENA | Frame sync error | |

**Note**

Since X/RINT, X/REVTA, and X/RXFFINT share the same CPU interrupt, it is recommended that all applications use one of the above selections for interrupt generation. If multiple interrupt enables are selected at the same time, there is a likelihood of interrupts being masked or not recognized.

Copyright © 2024 Texas Instruments Incorporated

### 21.12.2 McBSP Transmit Interrupt Generation

McBSP module data transmit and error conditions generate two sets of interrupt signals. One set is used for the CPU and the other set is for DMA.

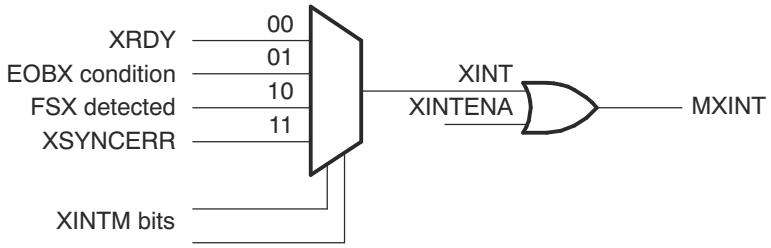

**Figure 21-66. Transmit Interrupt Generation**

**Table 21-73. Transmit Interrupt Sources and Signals**

| McBSP Interrupt Signal | Interrupt Flags | Interrupt Enables in SPCR2 (XINTM Bits) | Interrupt Enables | Type of Interrupt | Interrupt Line |
|---|---|---|---|---|---|
| XINT | XRDY | 00 | XINTENA | Every word transmit | MXINT |
| | EOBX | 01 | XINTENA | Every 16-channel block boundary | |
| | FSX | 10 | XINTENA | On every FSX | |
| | XSYNCERR | 11 | XINTENA | Frame sync error | |

### 21.12.3 Error Flags

The McBSP has several error flags both on receive and transmit channel. Table 21-74 explains the error flags and their meaning.

**Table 21-74. Error Flags**

| Error Flags | Function |
|---|---|
| RFULL | Indicates DRR2/DRR1 are not read and RXR register is overwritten |
| RSYNCERR | Indicates unexpected frame-sync condition, current data reception will abort and restart. Use RINTM bit 11 for interrupt generation on this condition. |
| XSYNCERR | Indicates unexpected frame-sync condition, current data transmission will abort and restart. Use XINTM bit 11 for interrupt generation on this condition. |

## 21.13 McBSP Modes

McBSP, in its normal mode, communicates with various types of Codecs with variable word size. Apart from this mode, the McBSP uses time-division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices. The multichannel mode provides flexibility while transmitting/receiving selected channels or all the channels in a TDM stream.

Table 21-75 provides a quick reference to McBSP mode selection.

**Table 21-75. McBSP Mode Selection**

| No. | McBSP Word Size | Register Bits Used for Mode Selection | | | | Mode and Function Description |
|---|---|---|---|---|---|---|
| | | MCR1 bit 9,0 | | MCR2 bit 9,1,0 | | |
| | | RMCME | RMCM | XMCME | XMCM | |
| | | | | | | **Normal Mode** |
| 1 | 8/12/16/20/24/32 bit words | 0 | 0 | 0 | 0 | All types of Codec interface will use this selection |
| | | | | | | **Multichannel Mode** |
| 2 | 8-bit words | | | | | 2 Partition or 32-channel Mode |
| | | 0 | 1 | 0 | 1 | All channels are disabled, unless selected in X/RCERA/B |
| | | 0 | 1 | 0 | 10 | All channels are enabled,but masked unless selected in X/RCERA/B |
| | | 0 | 1 | 0 | 11 | Symmetric transmit, receive |
| | | | | | | 8 Partition or 128 Channel Mode Transmit/Receive |
| | | | | | | Channels selected by X/RCERA to X/RCERH bits |
| | | | | | | **Multichannel Mode is ON** |
| | | 1 | 1 | 1 | 1 | All channels are disabled, unless selected in XCERs |
| | | 1 | 1 | 1 | 10 | All channels are enabled, but masked unless selected in XCERs |
| | | 1 | 1 | 1 | 11 | Symmetric transmit, receive |
| | | | | | | Continuous mode, transmit |
| | | 1 | 0 | 1 | 0 | **Multi-Channel Mode is OFF** |
| | | | | | | All 128 channels are active and enabled |

## 21.14 Special Case: External Device is the Transmit Frame Master

Care must be taken if the transmitter expects a frame sync from an external device. After the transmitter comes out of reset (XRST = 1), the transmitter waits for a frame sync from the external device. If the first frame sync arrives very shortly after the transmitter is enabled, the CPU or DMA controller cannot have a chance to service DXR. In this case, the transmitter shifts out the default data in XSR instead of the desired value, which has not yet arrived in DXR. This causes problems in some applications, as the first data element in the frame is invalid. The data stream appears element-shifted (the first data word can appear in the second channel instead of the first).

To make sure of proper operation when the external device is the frame master, you must verify that DXR is already serviced with the first word when a frame sync occurs. To do so, you can keep the transmitter in reset until the first frame sync is detected. Upon detection of the first frame sync, the McBSP generates an interrupt to the CPU. Within the interrupt service routine, the transmitter is taken out of reset (XRST = 1). This verifies that the transmitter does not begin data transfers at the data pin during the first frame sync period. This also provides almost an entire frame period for the DSP to service DXR with the first word before the second frame sync occurs. The transmitter only begins data transfers upon receiving the second frame sync. At this point, DXR is already serviced with the first word.

Copyright © 2024 Texas Instruments Incorporated

The interrupt service routine must first be setup, then follow this modified procedure for proper initialization:

1. Make sure that no portion of the McBSP is using the internal sample rate generator signal CLKG and the internal frame sync generator signal FSG (GRST = FRST = 0). The respective portion of the McBSP needs to be in reset (XRST = 0 and/or RRST = 0).
2. Program SRGR and other control registers as required. Make sure the internal sample rate generator and the internal frame sync generator are still in reset (GRST = FRST = 0). Also make sure the respective portion of the McBSP is still in reset in this step (XRST = 0 and/or RRST = 0).
3. Program the XINTM bits to 2h in SPCR to generate an interrupt to the CPU upon detection of a transmit frame sync. Do not enable the XINT interrupt in the interrupt enable register (IER) in this step.
4. Wait for proper internal synchronization. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a master clock, wait for two CLKSRG cycles. In this case, the clock source to the sample rate generator (CLKSRG) is selected by the CLKSM bit in SRGR.
5. Skip this step if the bit clock is provided by the external device. This step only applies if the McBSP is the bit master clock and the internal sample rate generator is used.
   a. Start the sample rate generator by setting the GRST bit to 1. Wait two CLKG bit clocks for synchronization. CLKG is the output of the sample rate generator.
   b. On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to 1/(CLKGDV + 1) of the sample rate generator source clock CLKSRG.
6. A transmit sync error (XSYNCERR) can occur when enabled for the first time after device reset. The purpose of this step is to clear any potential XSYNCERR that occurs on the transmitter at this time:
   a. Set the XRST bit to 1 to enable the transmitter.
   b. Wait for any unexpected frame sync error to occur. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a master clock, wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
   c. Disable the transmitter (XRST = 0). This clears any outstanding XSYNCERR.
7. Setup data acquisition as required:
   a. If the DMA controller is used to service the McBSP, setup data acquisition as desired and start the DMA controller in this step, before the McBSP is taken out of reset.
   b. If CPU interrupt is used to service the McBSP, no action is required in this step.
   c. If CPU polling is used to service the McBSP, no action is required in this step.
8. Enable the XINT interrupt by setting the corresponding bit in the interrupt enable register (IER). In this step, the McBSP transmitter is still in reset. Upon detection of the first transmit frame sync from the external device, the McBSP generates an interrupt to the CPU and the DSP enters the interrupt service routine (ISR). The ISR needs to perform these tasks in this order:
   a. Modify the XINTM bits to the value desired for normal McBSP operations. If CPU interrupt is used to service the McBSP in normal operations, make sure that the XINTM bits are modified to 0 to detect the McBSP XRDY event. If no McBSP interrupt is desired in normal operations, disable future McBSP-to-CPU interrupt in the interrupt enable register (IER).
   b. Set the XRST bit and/or the RRST bit to 1 to enable the respective portion of the McBSP. The McBSP is now ready to transmit and/or receive.
9. Service the McBSP:
   a. If CPU polling is used to service the McBSP in normal operations, CPU polling can do so upon exit from the ISR.
   b. If CPU interrupt is used to service the McBSP in normal operations, upon XRDY interrupt service routine is entered. The ISR must be setup to verify that XRDY = 1 and service the McBSP accordingly.
   c. If DMA controller is used to service the McBSP in normal operations, the DMA controller services the McBSP automatically upon receiving the XEVT and/or REVT.
10. Upon detection of the second frame sync, DXR is already serviced and the transmitter is ready to transmit the valid data. The receiver is also serviced properly by the DSP.

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

## 21.16 McBSP Registers

This section describes the McBSP registers.

### *21.16.1 McBSP Base Addresses*

**Table 21-76. McBSP Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| McbspaRegs | MCBSP_REGS | 0x0000_6000 | 0x0000_603F |
| McbspbRegs | MCBSP_REGS | 0x0000_6040 | 0x0000_607F |

Copyright © 2024 Texas Instruments Incorporated

### 21.16.2 McBSP_REGS Registers

Table 21-77 lists the memory-mapped registers for the McBSP_REGS registers. All register offset addresses not listed in Table 21-77 should be considered as reserved locations and the register contents should not be modified.

**Table 21-77. MCBSP_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | DRR2 | Data receive register bits 31-16 | | Go |
| 1h | DRR1 | Data receive register bits 15-0 | | Go |
| 2h | DXR2 | Data transmit register bits 31-16 | | Go |
| 3h | DXR1 | Data transmit register bits 15-0 | | Go |
| 4h | SPCR2 | Serial port control register 2 | | Go |
| 5h | SPCR1 | Serial port control register 1 | | Go |
| 6h | RCR2 | Receive Control register 2 | | Go |
| 7h | RCR1 | Receive Control register 1 | | Go |
| 8h | XCR2 | Transmit Control register 2 | | Go |
| 9h | XCR1 | Transmit Control register 1 | | Go |
| Ah | SRGR2 | Sample rate generator register 2 | | Go |
| Bh | SRGR1 | Sample rate generator register 1 | | Go |
| Ch | MCR2 | Multi-channel control register 2 | | Go |
| Dh | MCR1 | Multi-channel control register 1 | | Go |
| Eh | RCERA | Receive channel enable partition A | | Go |
| Fh | RCERB | Receive channel enable partition B | | Go |
| 10h | XCERA | Transmit channel enable partition A | | Go |
| 11h | XCERB | Transmit channel enable partition B | | Go |
| 12h | PCR | Pin Control register | | Go |
| 13h | RCERC | Receive channel enable partition C | | Go |
| 14h | RCERD | Receive channel enable partition D | | Go |
| 15h | XCERC | Transmit channel enable partition C | | Go |
| 16h | XCERD | Transmit channel enable partition D | | Go |
| 17h | RCERE | Receive channel enable partition E | | Go |
| 18h | RCERF | Receive channel enable partition F | | Go |
| 19h | XCERE | Transmit channel enable partition E | | Go |
| 1Ah | XCERF | Transmit channel enable partition F | | Go |
| 1Bh | RCERG | Receive channel enable partition G | | Go |
| 1Ch | RCERH | Receive channel enable partition H | | Go |
| 1Dh | XCERG | Transmit channel enable partition G | | Go |
| 1Eh | XCERH | Transmit channel enable partition H | | Go |
| 23h | MFFINT | Interrupt enable | | Go |

Complex bit access types are encoded to fit into small table cells. Table 21-78 shows the codes that are used for access types in this section.

**Table 21-78. McBSP_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| Write Type | | |

**Table 21-78. McBSP_REGS Access Type Codes (continued)**

| Access Type | Code | Description |
|---|---|---|
| W | W | Write |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 21.16.2.1 DRR2 Register (Offset = 0h) [Reset = 0000h]

DRR2 is shown in Figure 21-67 and described in Table 21-79.

Return to the Summary Table.

DRR2 contains the upper 16 bits of the received data to be read by the CPU or DMA. DRR2 is only used if the word length is greater than 16 bits.

**Figure 21-67. DRR2 Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

### 21.16.2.2 DRR1 Register (Offset = 1h) [Reset = 0000h]

DRR1 is shown in Figure 21-68 and described in Table 21-80.

Return to the Summary Table.

DRR1 contains the lower 16 bits of the received data to be read by either the CPU or DMA.

**Figure 21-68. DRR1 Register**

### 21.16.2.3 DXR2 Register (Offset = 2h) [Reset = 0000h]

DXR2 is shown in Figure 21-69 and described in Table 21-81.

Return to the Summary Table.

DXR2 contains the upper 16 bits of the data to be transmitted after being written by the CPU or DMA. DXR2 is only used if the word length is greater than 16 bits.

**Figure 21-69. DXR2 Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

### 21.16.2.4 DXR1 Register (Offset = 3h) [Reset = 0000h]

DXR1 is shown in Figure 21-70 and described in Table 21-82.

Return to the Summary Table.

DXR1 contains the lower 16 bits of the data to be transmitted after being written by the CPU or DMA.

**Figure 21-70. DXR1 Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

### 21.16.2.5 SPCR2 Register (Offset = 4h) [Reset = 0000h]

SPCR2 is shown in Figure 21-71 and described in Table 21-83.

Return to the Summary Table.

SPCR2 conatins control and status bits for various McBSP functions such as emulation modes, transmit interrupt mode control, transmitter status bits, and transmitter and other internal reset controls.

**Figure 21-71. SPCR2 Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|---|---|---|---|---|---|---|---|
| RESERVED | | | | | | FREE | SOFT |
| R-0h | | | | | | R/W-0h | R/W-0h |
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| FRST | GRST | XINTM | | XSYNCERR | XEMPTY | XRDY | XRST |

**Table 21-83. SPCR2 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-10 | RESERVED | R | 0h | Reserved |
| 9 | FREE | R/W | 0h | Free run bit.<br>When a breakpoint is encountered in the high-level language debugger, FREE determines whether the McBSP transmit and receive clocks continue to run or whether they are affected as determined by the SOFT bit. When one of the clocks stops, the corresponding data transfer (transmission or reception) stops.<br>Reset type: SYSRSn |
| 8 | SOFT | R/W | 0h | Soft stop bit.<br>When FREE = 0, SOFT determines the response of the McBSP transmit and receive clocks when a breakpoint is encountered in the high-level language debugger. When one of the clocks stops, the corresponding data transfer (transmission or reception) stops.<br>Reset type: SYSRSn |
| 7 | FRST | R/W | 0h | Frame-synchronization logic reset bit.<br>The sample rate generator of the McBSP includes framesynchronization logic to generate an internal frame-synchronization signal. You can use FRST to take the frame-synchronization logic into and out of its reset state. This bit has a negative polarity<br>FRST = 0 indicates the reset state.<br>Reset type: SYSRSn<br>0h (R/W) = If you read a 0, the frame-synchronization logic is in its reset state.<br>If you write a 0, you reset the frame-synchronization logic.<br>In the reset state, the frame-synchronization logic does not generate a frame-synchronization signal<br>(FSG).<br>1h (R/W) = If you read a 1, the frame-synchronization logic is enabled.<br>If you write a 1, you enable the frame-synchronization logic by taking it out of its reset state.<br>When the frame-synchronization logic is enabled (FRST = 1) and the sample rate generator as a whole is enabled (GRST = 1), the frame-synchronization logic generates the frame-synchronization signal FSG as programmed. |

Copyright © 2024 Texas Instruments Incorporated

**Table 21-83. SPCR2 Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 6 | GRST | R/W | 0h | Sample rate generator reset bit.<br>You can use GRST to take the McBSP sample rate generator into and out of its reset state. This bit has a negative polarity<br>GRST = 0 indicates the reset state.<br>Reset type: SYSRSn<br>0h (R/W) = If you read a 0, the sample rate generator is in its reset state.<br>If you write a 0, you reset the sample rate generator.<br>If GRST = 0 due to a reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven low (inactive). If GRST = 0 due to program code, CLKG and FSG are both driven low (inactive).<br>1h (R/W) = If you read a 1, the sample rate generator is enabled.<br>If you write a 1, you enable the sample rate generator by taking it out of its reset state.<br>When enabled, the sample rate generator generates the clock signal CLKG as programmed in the sample rate generator registers. If FRST = 1, the generator also generates the frame-synchronization signal FSG as programmed in the sample rate generator registers. |
| 5-4 | XINTM | R/W | 0h | Transmit interrupt mode bits.<br>XINTM determines which event in the McBSP transmitter generates a transmit interrupt (XINT) request. If XINT is properly enabled, the CPU services the interrupt request<br>otherwise, the CPU ignores the request.<br>Reset type: SYSRSn<br>0h (R/W) = The McBSP sends a transmit interrupt (XINT) request to the CPU when the XRDY bit changes from 0 to 1, indicating that transmitter is ready to accept new data (the content of DXR[1,2] has been copied to XSR[1,2]).<br>Regardless of the value of XINTM, you can check XRDY to determine whether a word transfer is complete.<br>The McBSP sends an XINT request to the CPU when 16 enabled bits have been transmitted on the DX pin.<br>1h (R/W) = In the multichannel selection mode, the McBSP sends an XINT request to the CPU after every 16- channel block is transmitted in a frame.<br>Outside of the multichannel selection mode, no interrupt request is sent.<br>2h (R/W) = The McBSP sends an XINT request to the CPU when each transmit frame-synchronization pulse is detected. The interrupt request is sent even if the transmitter is in its reset state.<br>3h (R/W) = The McBSP sends an XINT request to the CPU when the XSYNCERR bit is set, indicating a transmit frame-synchronization error.<br>Regardless of the value of XINTM, you can check XSYNCERR to determine whether a transmit framesynchronization error occurred. |
| 3 | XSYNCERR | R/W | 0h | Transmit frame-synchronization error bit.<br>XSYNCERR is set when a transmit frame-synchronization error is detected by the McBSP. If XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU when XSYNCERR is set. The flag remains set until you write a 0 to it or reset the transmitter.<br>Reset type: SYSRSn<br>0h (R/W) = No error<br>1h (R/W) = Transmit frame-synchronization error |

Copyright © 2024 Texas Instruments Incorporated

**Table 21-83. SPCR2 Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 2 | XEMPTY | R | 0h | Transmitter empty bit.<br>XEMPTY is cleared when the transmitter is ready to send new data but no new data is available (transmitter-empty condition). This bit has a negative polarity<br>a transmitter-empty condition is indicated by XEMPTY = 0.<br>Reset type: SYSRSn<br>0h (R/W) = Transmitter-empty condition<br>Typically this indicates that all the bits of the current word have been transmitted but there is no new<br>data in DXR1. XEMPTY is also cleared if the transmitter is reset and then restarted.<br>1h (R/W) = No transmitter-empty condition |
| 1 | XRDY | R | 0h | Transmitter ready bit.<br>XRDY is set when the transmitter is ready to accept new data in DXR[1,2]. Specifically, XRDY is set in response to a copy from DXR1 to XSR1.<br>If the transmit interrupt mode is XINTM = 00b, the McBSP sends a transmit interrupt (XINT) request to the CPU when XRDY changes from 0 to 1.<br>Also, when XRDY changes from 0 to 1, the McBSP sends a transmit synchronization event (XEVT) signal to the DMA controller.<br>Reset type: SYSRSn<br>0h (R/W) = Transmitter not ready<br>When DXR1 is loaded, XRDY is automatically cleared.<br>1h (R/W) = Transmitter ready: DXR[1,2] is ready to accept new data.<br>If both DXRs are needed (word length larger than 16 bits), the CPU or the DMA controller must load DXR2 first and then load DXR1. As soon as DXR1 is loaded, the contents of both DXRs are copied to the transmit shift registers (XSRs), as described in the next step. If DXR2 is not loaded first, the previous content of DXR2 is passed to the XSR2 |
| 0 | XRST | R/W | 0h | Transmitter reset bit. You can use XRST to take the McBSP transmitter into and out of its reset state. This bit has a negative polarity<br>XRST = 0 indicates the reset state.<br>To read about the effects of a transmitter reset, see Section 15.10.2, Resetting and Initializing a McBSP.<br>Reset type: SYSRSn<br>0h (R/W) = If you read a 0, the transmitter is in its reset state.<br>If you write a 0, you reset the transmitter.<br>1h (R/W) = If you read a 1, the transmitter is enabled.<br>If you write a 1, you enable the transmitter by taking it out of its reset state. |

### 21.16.2.6 SPCR1 Register (Offset = 5h) [Reset = 0000h]

SPCR1 is shown in Figure 21-72 and described in Table 21-84.

Return to the Summary Table.

SPCR1 contains control and status bits for various McBSP functions such as digital loopback, receive data justification, clock stop mode, receive interrupt mode, DX pin delay enabler, receiver status bits, and receiver reset control.

**Figure 21-72. SPCR1 Register**

### 21.16.2.7 RCR2 Register (Offset = 6h) [Reset = 0000h]

RCR2 is shown in Figure 21-73 and described in Table 21-85.

Return to the Summary Table.

RCR2 contains control bits for the receiver such as number of phases in each frame, the serial word length and number of words for phase 2 of dual phase frames, receive companding mode, receive frame synchronization ignore function, and the receive data delay.

**Figure 21-73. RCR2 Register**

### 21.16.2.11 SRGR2 Register (Offset = Ah) [Reset = 0000h]

SRGR2 is shown in Figure 21-77 and described in Table 21-89.

Return to the Summary Table.

SRGR2 contains control bits for the sample rate generator such as input clock selection, internal tranmist frame-synchronization source selection, and the period between frame-synchronization pulses.
If an external source provides the input clock source for the sample rate generator, a control bit is provided to make the CLKG synchronized to an external frame synchronization pulse on the FSR pin so that CLKG is kept in phase with the input clock.

### 21.16.2.15 RCERA Register (Offset = Eh) [Reset = 0000h]

RCERA is shown in Figure 21-81 and described in Table 21-93.

Return to the Summary Table.

RCERA contains the receive channel enable registers for the A partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

**Figure 21-81. RCERA Register**

### 21.16.2.16 RCERB Register (Offset = Fh) [Reset = 0000h]

RCERB is shown in Figure 21-82 and described in Table 21-94.

Return to the Summary Table.

RCERB contains the receive channel enable registers for the B partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

**Figure 21-82. RCERB Register**

### 21.16.2.17 XCERA Register (Offset = 10h) [Reset = 0000h]

XCERA is shown in Figure 21-83 and described in Table 21-95.

Return to the Summary Table.

XCERA contains the transmit channel enable registers for the A partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

**Figure 21-83. XCERA Register**

### 21.16.2.18 XCERB Register (Offset = 11h) [Reset = 0000h]

XCERB is shown in Figure 21-84 and described in Table 21-96.

Return to the Summary Table.

XCERB contains the transmit channel enable registers for the B partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

**Figure 21-84. XCERB Register**

### 21.16.2.19 PCR Register (Offset = 12h) [Reset = 0000h]

PCR is shown in Figure 21-85 and described in Table 21-97.

Return to the Summary Table.

PCR contains control bits for the McBSP pins such as frame synchronization modes, clock modes, input clock source selection for the sample rate generator, frame synchronization pulse active polarity, and transmit/receive active edge selection.

**Figure 21-85. PCR Register**

| 9 | CLKXM | R/W | 0h | Transmit clock mode bit.<br>CLKXM determines whether the source for the transmit clock is external or internal, and whether the MCLKX pin is an input or an output. The polarity of the signal on the MCLKX pin is determined by the CLKXP bit.<br>In the clock stop mode (CLKSTP = 10b or 11b), the McBSP can act as a master or as a slave in the SPI protocol. If the McBSP is a master, make sure that CLKX is an output. If the McBSP is a slave, make sure that CLKX is an input.<br>Reset type: SYSRSn<br>0h (R/W) = Not in clock stop mode (CLKSTP = 00b or 01b):<br>The transmitter gets its clock signal from an external source via the MCLKX pin.<br>In clock stop mode (CLKSTP = 10b or 11b):<br>The McBSP is a slave in the SPI protocol. The internal transmit clock (CLKX) is driven by the SPI master via the MCLKX pin. The internal receive clock (MCLKR) is driven internally by CLKX, so that both the transmitter and the receiver are controlled by the external master clock.<br>1h (R/W) = Not in clock stop mode (CLKSTP = 00b or 01b):<br>Internal CLKX is driven by the sample rate generator of the McBSP. The MCLKX pin is an output pin that reflects internal CLKX.<br>In clock stop mode (CLKSTP = 10b or 11b):<br>The McBSP is a master in the SPI protocol. The sample rate generator drives the internal transmit clock (CLKX). Internal CLKX is reflected on the MCLKX pin to drive the shift clock of the SPI-compliant slaves in the system. Internal CLKX also drives the internal receive clock (MCLKR), so that both the transmitter and the receiver are controlled by the internal master clock |
| 8 | CLKRM | R/W | 0h | Receive clock mode bit.<br>The role of CLKRM and the resulting effect on the MCLKR pin depend on whether the McBSP is in the digital loopback mode (DLB = 1).<br>The polarity of the signal on the MCLKR pin is determined by the CLKRP bit.<br>Reset type: SYSRSn<br>0h (R/W) = Not in digital loopback mode (DLB = 0):<br>The MCLKR pin is an input pin that supplies the internal receive clock (MCLKR).<br>In digital loopback mode (DLB = 1):<br>The MCLKR pin is in the high impedance state. The internal receive clock (MCLKR) is driven by the internal transmit clock (CLKX). CLKX is derived according to the CLKXM bit.<br>1h (R/W) = Not in digital loopback mode (DLB = 0):<br>Internal MCLKR is driven by the sample rate generator of the McBSP. The MCLKR pin is an output pin that reflects internal MCLKR.<br>In digital loopback mode (DLB = 1):<br>Internal MCLKR is driven by internal CLKX. ### 21.16.2.20 RCERC Register (Offset = 13h) [Reset = 0000h]

RCERC is shown in Figure 21-86 and described in Table 21-98.

Return to the Summary Table.

RCERC contains the receive channel enable registers for the C partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

**Figure 21-86. RCERC Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

### 21.16.2.21 RCERD Register (Offset = 14h) [Reset = 0000h]

RCERD is shown in Figure 21-87 and described in Table 21-99.

Return to the Summary Table.

RCERD contains the receive channel enable registers for the D partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

**Figure 21-87. RCERD Register**

### 21.16.2.22 XCERC Register (Offset = 15h) [Reset = 0000h]

XCERC is shown in Figure 21-88 and described in Table 21-100.

Return to the Summary Table.

XCERC contains the transmit channel enable registers for the C partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

**Figure 21-88. XCERC Register**

### 21.16.2.23 XCERD Register (Offset = 16h) [Reset = 0000h]

XCERD is shown in Figure 21-89 and described in Table 21-101.

Return to the Summary Table.

XCERD contains the transmit channel enable registers for the D partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

**Figure 21-89. XCERD Register**

### 21.16.2.24 RCERE Register (Offset = 17h) [Reset = 0000h]

RCERE is shown in Figure 21-90 and described in Table 21-102.

Return to the Summary Table.

RCERE contains the receive channel enable registers for the E partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

**Figure 21-90. RCERE Register**

### 21.16.2.25 RCERF Register (Offset = 18h) [Reset = 0000h]

RCERF is shown in Figure 21-91 and described in Table 21-103.

Return to the Summary Table.

RCERF contains the receive channel enable registers for the F partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

**Figure 21-91. RCERF Register**

### 21.16.2.26 XCERE Register (Offset = 19h) [Reset = 0000h]

XCERE is shown in Figure 21-92 and described in Table 21-104.

Return to the Summary Table.

XCERE contains the transmit channel enable registers for the E partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

**Figure 21-92. XCERE Register**

### 21.16.2.27 XCERF Register (Offset = 1Ah) [Reset = 0000h]

XCERF is shown in Figure 21-93 and described in Table 21-105.

Return to the Summary Table.

XCERF contains the transmit channel enable registers for the F partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

**Figure 21-93. XCERF Register**

### 21.16.2.28 RCERG Register (Offset = 1Bh) [Reset = 0000h]

RCERG is shown in Figure 21-94 and described in Table 21-106.

Return to the Summary Table.

RCERG contains the receive channel enable registers for the G partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

**Figure 21-94. RCERG Register**

### 21.16.2.29 RCERH Register (Offset = 1Ch) [Reset = 0000h]

RCERH is shown in Figure 21-95 and described in Table 21-107.

Return to the Summary Table.

RCERH contains the receive channel enable registers for the H partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

**Figure 21-95. RCERH Register**

### 21.16.2.30 XCERG Register (Offset = 1Dh) [Reset = 0000h]

XCERG is shown in Figure 21-96 and described in Table 21-108.

Return to the Summary Table.

XCERG contains the transmit channel enable registers for the G partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

**Figure 21-96. XCERG Register**

### 21.16.2.31 XCERH Register (Offset = 1Eh) [Reset = 0000h]

XCERH is shown in Figure 21-97 and described in Table 21-109.

Return to the Summary Table.

XCERH contains the transmit channel enable registers for the H partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

**Figure 21-97. XCERH Register**

### 21.16.2.32 MFFINT Register (Offset = 23h) [Reset = 0000h]

MFFINT is shown in Figure 21-98 and described in Table 21-110.

Return to the Summary Table.

MFFINT contains the enable bits for both the transmitter and receiver interupts.

**Figure 21-98. MFFINT Register**

Chapter 22

# Controller Area Network (CAN)

This chapter describes the Controller Area Network (CAN) module. CAN is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. The CAN module supports bit rates up to 1 Mbit/s and is compliant with the ISO11898-1 (CAN 2.0B) protocol specification.

Further information can be found in:

- *Programming Examples and Debug Strategies for the DCAN Module Application Report*

**Expert Materials**

- *Configurable Error Generator for Controller Area Network Application Report*

### *22.1.2 Features*

The CAN module implements the following features:

- Complies with ISO11898-1 (Bosch® CAN protocol specification 2.0 A and B)
- Bit rates up to 1Mbps
- Multiple clock sources
- 32 message objects (“message objects” are also referred to as “mailboxes” in this document; the two terms are used interchangeably), each with the following properties:
  - Configurable as receive or transmit
  - Configurable with standard (11-bit) or extended (29-bit) identifier
  - Supports programmable identifier receive mask
  - Supports data and remote frames
  - Holds 0 to 8 bytes of data
  - Parity-checked configuration and data RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus-on, after bus-off state by a programmable 32-bit timer
- Message-RAM parity-check mechanism
- Two interrupt lines

**Note**

For a CAN bit clock of 200MHz, the smallest bit rate possible is 7.8125kbps.

Depending on the timing settings used, the accuracy of the on-chip zero-pin oscillator (specified in the data sheet) may not meet the requirements of the CAN protocol. In this situation, an external clock source must be used.

### 22.1.3 Block Diagram

Figure 22-1 shows a block diagram of the CAN module. Following is a description of some of the main blocks.

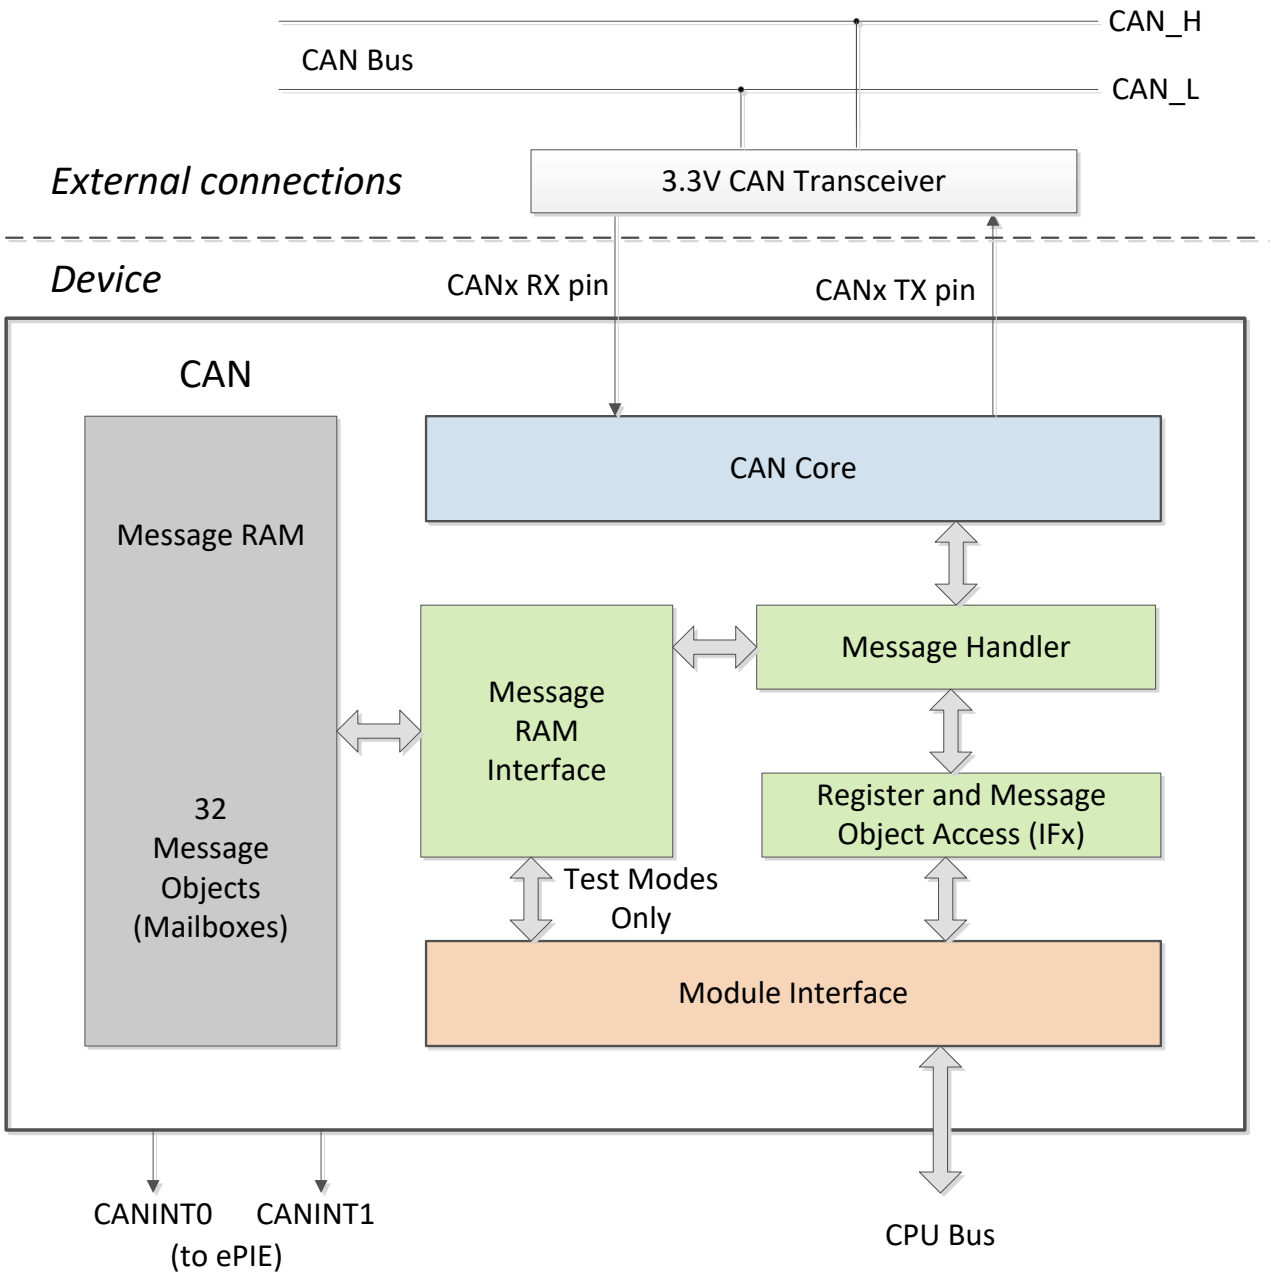

**Figure 22-1. CAN Block Diagram**

Copyright © 2024 Texas Instruments Incorporated

#### 22.1.3.1 CAN Core

The CAN core consists of the CAN Protocol Controller and the Rx/Tx Shift register. It handles all ISO 11898-1 protocol functions.

#### 22.1.3.2 Message Handler

The message handler is a state machine which controls the data transfer between the single-port Message RAM and the CAN Core's Rx/Tx Shift register. It also handles acceptance filtering and the interrupt request generation as programmed in the control registers.

#### 22.1.3.3 Message RAM

The CAN message RAM enables the storage of 32 CAN messages.

#### 22.1.3.4 Registers and Message Object Access (IFx)

Data consistency is provided by indirect accesses to the message objects. During normal operation, all CPU accesses to the message RAM are done through Interface registers. The IFx registers can be thought of as a "window" through which the message objects (mailboxes) are accessed.

Three Interface register sets control the CPU read and write accesses to the Message RAM, see Figure 22-2. There are two Interface register sets for read/write access (IF1 and IF2) and one Interface register set for read access only (IF3). See also Section 22.12. The Interface registers have the same word length as the message RAM.

In a dedicated test mode, the message RAM is memory-mapped and can be directly accessed.

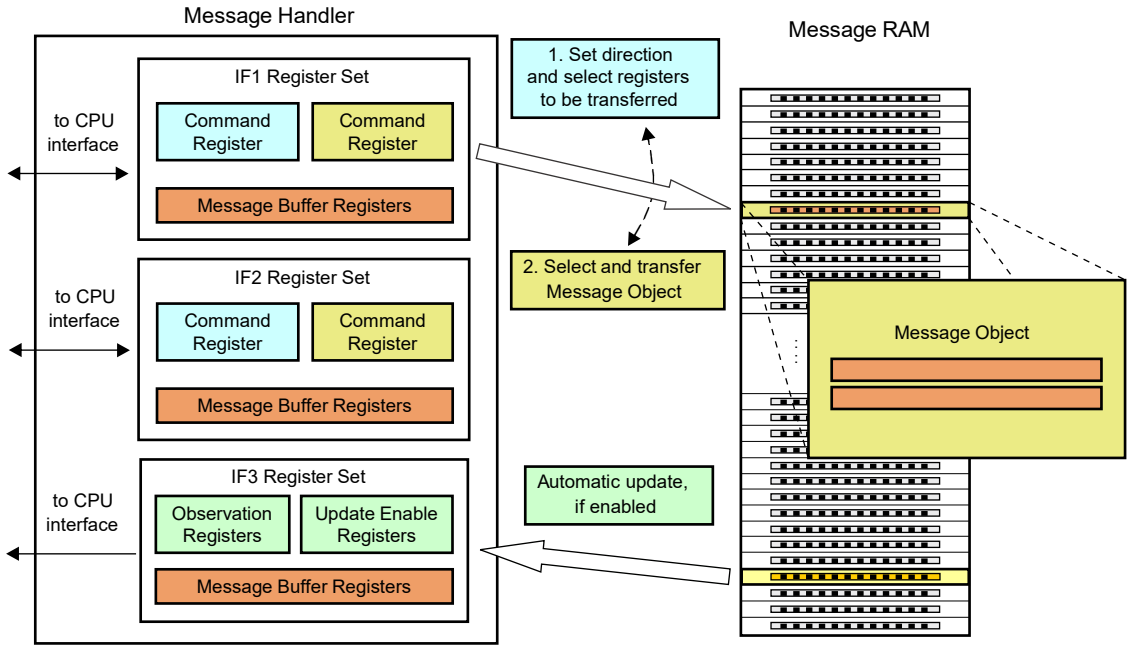

**Figure 22-2. Accessing Message Objects Through IFx Registers**

## 22.2 Functional Description

The CAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1Mbps. A CAN transceiver chip is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the message handler. These functions are: acceptance filtering; the transfer of messages between the CAN Core and the Message RAM; and the handling of transmission requests .

The register set of the CAN can be accessed directly by the CPU through the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

### *22.2.1 Configuring Device Pins*

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some I/O functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pull-ups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

### *22.2.2 Address/Data Bus Bridge*

The CAN module uses a special addressing scheme to support byte accesses.This is the same addressing scheme that is used on the USB module. It is recommended to only use 32-bit accesses to the CAN registers using the *HWREG_BP()* macro that uses the *__byte_peripheral_32()* intrinsic. If 16-bit accesses are to be used, the lower 16-bits must be written to the register's address, and the upper 16-bits must be written to the register's address plus 2.

Because of the bus bridge, the view of the CAN module's register space through the Code Composer Studio™ (CCS) IDE memory window does not always match the actual addressing. When the view mode is 32-bit or 16-bit, even addresses are effectively duplicated; odd addresses can be ignored. When the view mode is 8-bit, even addresses from within the CAN module are duplicated into the odd addresses in the CCS memory view; odd addresses from the module are not displayed.

## 22.3 Operating Modes

### *22.3.1 Initialization*

The initialization mode is entered either by software (by setting the **Init** bit in the CAN_CTL register), by hardware reset, or by going bus-off. While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high). The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

To initialize the CAN controller, the CPU has to configure the CAN bit timing and those message objects that are used for CAN communication. Message objects that are not needed, can be deactivated with the MsgVal bits cleared.

The access to the Bit Timing Register for the configuration of the bit timing is enabled when both **Init** and CCE bits in the CAN Control register are set.

Clearing the Init bit finishes the software initialization. Afterwards, the bit stream processor (BSP) synchronizes to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus Idle) before the BSP can take part in bus activities and start the message transfer. For more details, see Section 22.11.

The initialization of the message objects is independent of the Init bit; however, all message objects must be configured with particular identifiers or set to "not-valid" before the message transfer is started.

It is possible to change the configuration of message objects during normal operation by the CPU. After setup and subsequent transfer of message object from interface registers to message RAM, the acceptance filtering is applied to it when the modified message object number is same or smaller than the previously found message object. This makes sure of data consistency even when changing message objects; for example, while there is a pending CAN frame reception.

Copyright © 2024 Texas Instruments Incorporated

### 22.3.2 CAN Message Transfer (Normal Operation)

Once the CAN is initialized and the Init bit is reset to zero, the CAN Core synchronizes to the CAN bus and is ready for communication.

Received messages are stored into the appropriate message objects, if the messages pass acceptance filtering. The whole message (MSGID, DLC, and up to 8 data bytes) is stored into the message object. As a consequence, for example, if the identifier mask is used, the MSGID bits that are masked to "don't care" can change in the message object when a received message is stored.

The CPU can read or write each message at any time using the interface registers, as the message handler provides data consistency in case of concurrent accesses.

Messages to be transmitted can be updated by the CPU. If a permanent message object (MSGID, control bits set up during configuration, and setup for multiple CAN transfers) exists for the message, it is possible to only update the data bytes. If several transmit messages must be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects can be requested at the same time. The message objects are subsequently transmitted, according to the internal priority. Messages can be updated or set to "not valid" at any time, even if a requested transmission is still pending. However, the data bytes are discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission can be automatically requested by the reception of a remote frame with a matching identifier.

#### 22.3.2.1 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898, 6.3.3 Recovery Management), the CAN provides a mechanism to automatically retransmit frames that have lost arbitration or have been disturbed by errors during transmission. The frame transmission service is not confirmed to the user before the transmission is successfully completed

By default, this automatic retransmission is enabled and can be disabled by setting the DAR bit in the CAN control register. Further details to this mode are provided in Section 22.10.3.

#### 22.3.2.2 Auto-Bus-On

After the CAN has entered the bus-off state, the CPU can start a bus-off-recovery sequence by resetting the *Init* bit. If this is not done, the module stays in the bus-off state.

The CAN provides an automatic auto-bus-on feature that is enabled by the ABO bit. If set, the CAN automatically starts the bus-off-recovery sequence. The sequence can be delayed by a user-defined number of clock cycles.

**Note**

If the CAN module goes Bus-Off due to multiple CAN bus errors, the CAN module stops all bus activities and automatically sets the Init bit. Once the Init bit is cleared by the application (or due to the auto-bus-on feature), the device waits for 129 occurrences of Bus Idle (equal to 129 * 11 consecutive recessive bits) before resuming normal operation. The Bus-Off recovery sequence cannot be shortened by setting or resetting the Init bit. At the end of the bus-off recovery sequence, the error counters reset. After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 Error code is written to the Error and Status Register. This enables the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.

Copyright © 2024 Texas Instruments Incorporated

### 22.3.3 Test Modes

The CAN module provides several test modes that are mainly intended for self-test purposes. Figure 22-3 aids in understanding the various test modes. Figure 22-3 must be viewed as representative of the module behavior, and not as a gate-accurate implementation of the module. Figure 22-3 does not include the GPIO muxing or the I/O buffers.

For all test modes, the Test bit in the CAN control register needs to be set to 1 to enable write access to the CAN_TEST register.

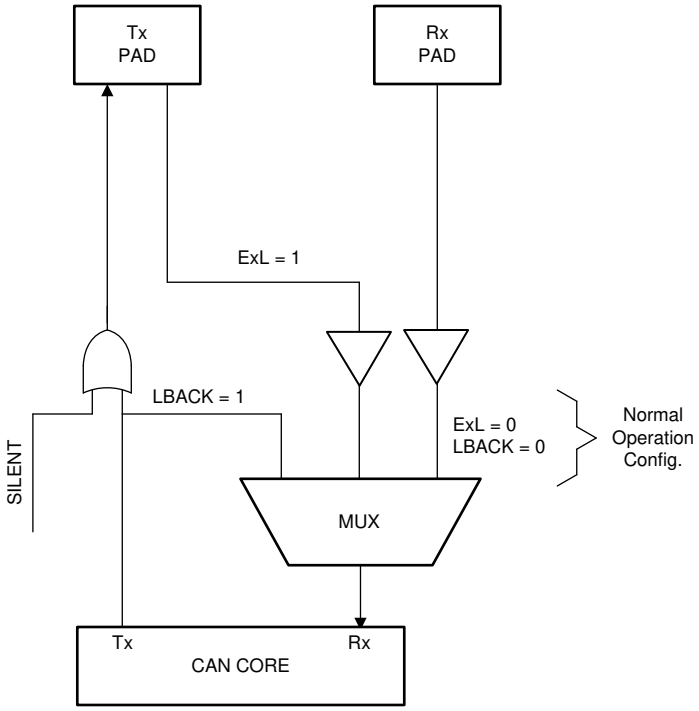

**Figure 22-3. CAN_MUX**

Copyright © 2024 Texas Instruments Incorporated

#### 22.3.3.1 Silent Mode

The silent mode can be used to analyze the traffic on the CAN bus without affecting the CAN by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The CAN is still able to receive valid data frames and valid remote frames, but the CAN does not send any dominant bits. However, the received frames are internally routed to the CAN Core.

Figure 22-4 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the Silent bit in test register (CAN_TEST), to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

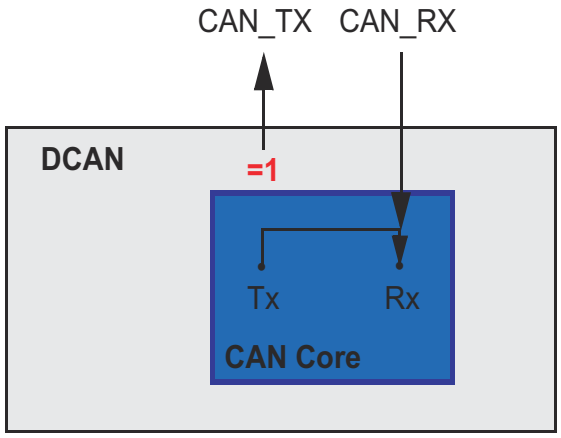

**Figure 22-4. CAN Core in Silent Mode**

Copyright © 2024 Texas Instruments Incorporated

#### 22.3.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if the messages pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages still can be monitored at the CAN_TX pin.

To be independent from external stimulation, the CAN core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loopback mode.

Figure 22-5 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode. Loopback mode can be activated by setting the LBack bit in the CAN_TEST register to 1.

**Note**

In loopback mode, the signal path from the CAN core to the Tx pin, and the signal path from the Tx pin back to the CAN core are disregarded. For including these into the testing, see Section 22.3.3.3.

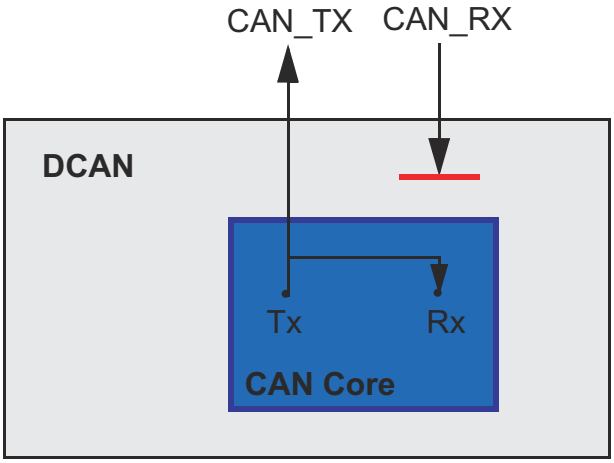

**Figure 22-5. CAN Core in Loopback Mode**

Copyright © 2024 Texas Instruments Incorporated

#### 22.3.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, the external loopback mode includes the signal path from the CAN core to the Tx pin, and the signal path from the Tx pin back to the CAN core. When the external loopback mode is selected, the CAN core is connected to the input buffer of the Tx pin. With this configuration, the Tx pin IO circuit can be tested. External loopback mode can be activated by setting the ExL bit in Test Register to 1.

Figure 22-6 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in external loopback mode.

**Note**

When loopback mode is active (LBack bit set), the ExL bit is ignored.

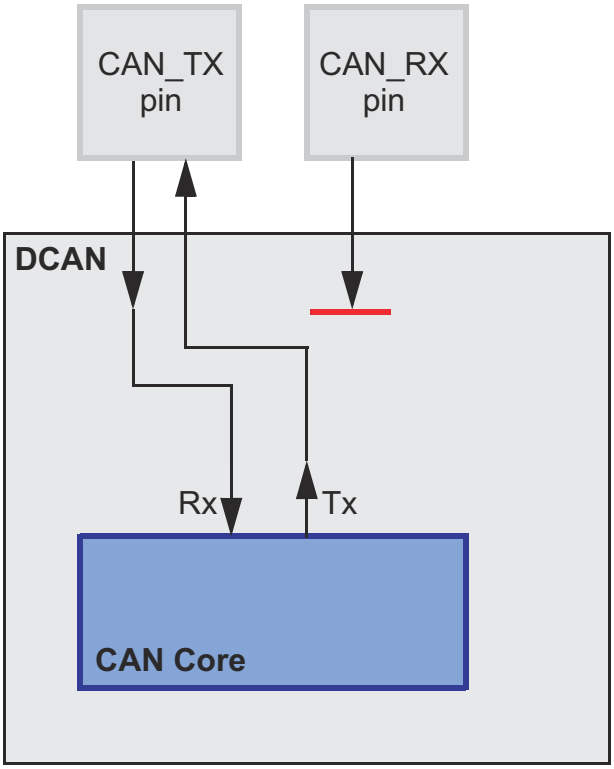

**Figure 22-6. CAN Core in External Loopback Mode**

Copyright © 2024 Texas Instruments Incorporated

#### 22.3.3.4 Loopback Combined with Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. The CAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits are sent on the CAN_TX pin.

Figure 22-7 shows the connection of the signals CAN_TX and CAN_RX to the CAN Core in case of the combination of loopback mode with silent mode.

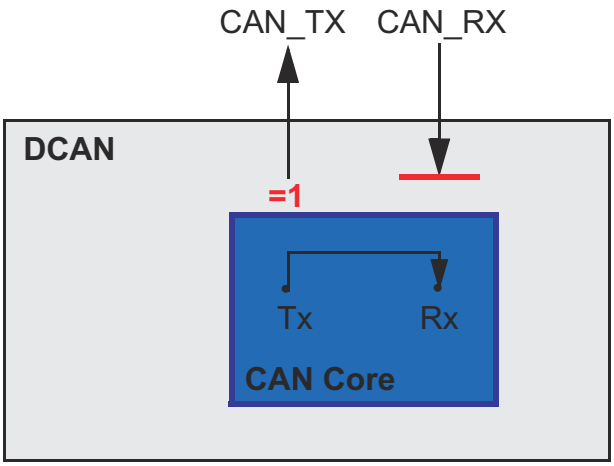

**Figure 22-7. CAN Core in Loopback Combined with Silent Mode**

## 22.4 Multiple Clock Source

Three clock domains are provided to the CAN module for generating the CAN bit timing: the external clock (X1/X2), the system clock (SYSCLK), and the GPIO_AUXCLKIN.

The *System Control and Interrupts* chapter and the device data sheet provide more information on how to configure the relevant clock source registers in the system module.

**Note**

The CAN core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1Mbps an oscillator frequency of 8MHz or higher has to be used.

Copyright © 2024 Texas Instruments Incorporated

## 22.5 Interrupt Functionality

Interrupts can be generated on two interrupt lines: CAN0INT and CAN1INT. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN Control register.

The CAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts. The source of an interrupt can be determined by the interrupt identifiers Int0ID and Int1ID in the CAN_INT Interrupt register. When no interrupt is pending, the register holds the value zero. Each interrupt line remains active until the dedicated field in the Interrupt register (Int0ID or Int1ID) again reaches zero (this means the cause of the interrupt is reset), or until IE0 and IE1 are reset. The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits RxOk, TxOk, and LEC by reading the Error and Status Register, but a write access of the CPU never generates or resets an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects. INT0ID and INT1ID point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine that reads the message from the interrupt source can also read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1 or IF2 Command register). When IntPnd is cleared, the Interrupt register points to the next message object with a pending interrupt.

The CAN module features a module-level interrupt enable and acknowledge mechanism. To enable the CAN0 and CAN1 interrupts, you must set the appropriate bits in the CAN_GLB_INT_EN register. When handling an interrupt, the individual message or status change flag must be cleared prior to acknowledging the interrupt using CAN_GLB_INT_CLR and PIEACK.

### *22.5.1 Message Object Interrupts*

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE which are described in Section 22.13.1. Message object interrupts can be routed to the CAN0INT or CAN1INT line, which is controlled by the Interrupt Multiplexer register.

Note that writing to the IntPnd bit in the CAN_IFnMCTL registers can force an interrupt.

### *22.5.2 Status Change Interrupts*

The events RxOk, TxOk, and LEC in the Error and Status register belong to the status change interrupts. The status change interrupt group can be enabled by the SIE bit in the CAN Control Register. If SIE is set, a status change interrupt is generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration. Status Change interrupts can only be routed to interrupt line CAN0INT which has to be enabled by setting IE0 in the CAN_CTL Register.

### *22.5.3 Error Interrupts*

The events PER, BOff and EWarn, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE. Also, error interrupts can only be routed to interrupt line CAN0INT, which has to be enabled by setting IE0 in the CAN_CTL register.

### *22.5.4 Peripheral Interrupt Expansion (PIE) Module Nomenclature for DCAN Interrupts*

Table 22-3 shows the Peripheral Interrupt Expansion (PIE) module nomenclature for the interrupts.

**Table 22-3. PIE Module Nomenclature for Interrupts**

| Interrupt | CANA | CANB |
|---|---|---|
| CANINT0 | CANA_0 | CANB_0 |
| CANINT1 | CANA_1 | CANB_1 |

Copyright © 2024 Texas Instruments Incorporated

### 22.5.5 Interrupt Topologies

Interrupt topologies for CAN are illustrated in Figure 22-8 and Figure 22-9. Mailbox interrupts for transmit and receive operations can be routed to both CANINT0 and CANINT1. However, error and status interrupts can only be routed to CANINT0.

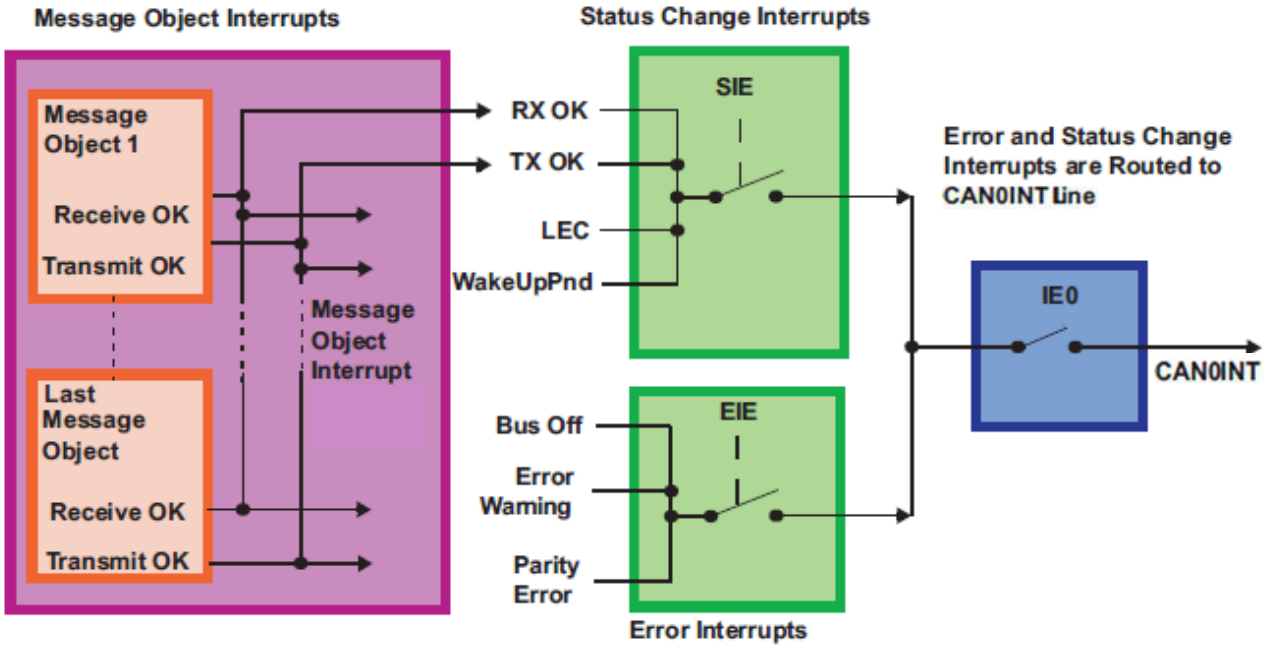

**Figure 22-8. CAN Interrupt Topology 1**

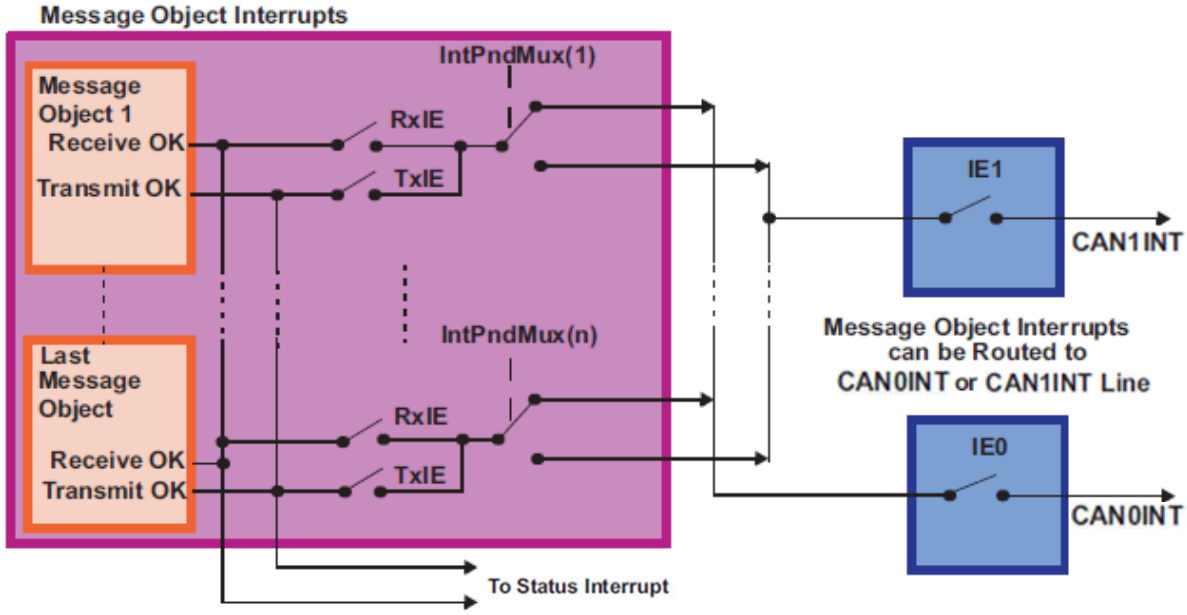

**Figure 22-9. CAN Interrupt Topology 2**

## 22.6 Parity Check Mechanism

The CAN provides a parity check mechanism to make sure data integrity of the message RAM data. For each word (32 bits) in Message RAM, one parity bit is calculated.

Parity information is stored in the Message RAM on write accesses and is checked against the stored parity bit from Message RAM on read accesses.

The parity check functionality can be enabled or disabled by the PMD bit field in the CAN control register. In case of a disabled parity check, the parity bits in message RAM are left unchanged on write access to the data area and no check is done on read access.

If parity checking is enabled, parity bits are automatically generated and checked by the CAN. A parity bit is set if the modulo-2-sum of the data bits is 1. This means that if the parity bit is set, then there are an odd number of 1 bits in the data.

### *22.6.1 Behavior on Parity Error*

On any read access to Message RAM, for example, during the start of a CAN frame transmission, the parity of the message object is checked. If a parity error is detected, the PER bit in the Error and Status register is set. If error interrupts are enabled, an interrupt can also be generated. To avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object is reset.

The message object data can be read by the CPU, independently of parity errors. Thus, the application has to make sure that the read data is valid, for example, by immediately checking the Parity Error Code register on parity error interrupt.

## 22.7 Debug Mode

The module supports the usage of an external debug unit by providing functions like pausing CAN activities and making message RAM content accessible from the debugger. Debug mode is entered automatically when an external debugger is connected and the core is halted.

Before entering Debug mode, the circuit waits until a transmission is started, a reception is finished, or the Bus idle state is recognized. If the IDS bit is set, the debugger immediately interrupts the current transmission or reception. Afterwards, the CAN enters Debug mode, indicated by the InitDbg flag, in the CAN Control register. During debug mode, all CAN registers can be accessed. Reading reserved bits returns a 0; writing to reserved bits has no effect. Also, the message RAM is memory-mapped, so this allows the external debug unit to read the message RAM. For the memory organization (see Section 22.13.3).

**Note**

During debug mode, the Message RAM cannot be accessed using the IFx register sets.

Writing to control registers in Debug mode can influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following CAN registers is disabled:

- Error and Status register (clear of status flags by read)
- IF1/IF2 Command registers

## 22.8 Module Initialization

After hardware reset, the Init bit in the CAN Control register is set and all CAN protocol functions are disabled. The configuration of the bit timing and of the message objects must be completed before the CAN protocol functions are enabled.

For the configuration of the message objects, see Section 22.9.

For the configuration of the Bit Timing, see Section 22.11.2.

The bits MsgVal, NewDat, IntPnd, and TxRqst of the message objects are reset to 0 by a hardware reset. The configuration of a message object is done by programming Mask, Arbitration, Control and Data bits of one of the IF1/IF2 Interface register sets to the desired values. By writing the message object number to bits [7:0] of the corresponding IF1/IF2 Command register, the IF1/IF2 Interface Register content is loaded into the addressed message object in the Message RAM.

The configuration of the bit timing requires that the CCE bit in the CAN Control register is set additionally to Init. This is not required for the configuration of the message objects.

When the Init bit in the CAN Control register is cleared, the CAN Protocol Controller state machine of the CAN Core and the message handler State Machine start to control the CAN's internal data flow. Received messages which pass the acceptance filtering are stored into the Message RAM; messages with pending transmission request are loaded into the CAN Core's Shift register and are transmitted using the CAN bus.

The CPU can enable the interrupt lines (setting IE0 and IE1 to 1) at the same time when the CPU clears Init and CCE. The status interrupts EIE and SIE can be enabled simultaneously.

The CAN communication can be controlled interrupt-driven or in polling mode. The Interrupt Register points to those message objects with IntPnd = 1. The register is updated even if the interrupt lines to the CPU are disabled (IE0 and IE1 are 0).

The CPU can poll all MessageObject's NewDat and TxRqst bits in parallel from the NewData registers and the Transmission Request registers. Polling can be made easier if all Transmit Objects are grouped at the low numbers; all Receive Objects are grouped at the high numbers.

Copyright © 2024 Texas Instruments Incorporated

## 22.9 Configuration of Message Objects

The entire Message RAM must be configured before the end of the initialization; however, it is also possible to change the configuration of message objects during CAN communication.

### *22.9.1 Configuration of a Transmit Object for Data Frames*

Figure 22-10 shows how a transmit object can be initialized.

**Figure 22-10. Initialization of a Transmit Object**

| MsgVal | Arb | Data | Mask | EoB | Dir | NewDat | MsgLst | RxIE | TxIE | IntPnd | RmtEn | TxRqst |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | appl. | appl. | appl. | 1 | 1 | 0 | 0 | 0 | appl. | 0 | appl. | 0 |

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. The arbitration bits define the identifier and type of the outgoing message. If an 11-bit Identifier (standard frame) is used (Xtd = 0), the Identifier is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.
- The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn must not be set before the data is valid.
- If the TxIE bit is set, the IntPnd bit is set after a successful transmission of the message object.
- If the RmtEn bit is set, a matching received remote frame causes the TxRqst bit to be set; the remote frame is autonomously answered by a data frame.
- The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) can be used (UMask = 1) to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit must not be masked. For details, see Section 22.10.8. Identifier masking must be disabled (UMask = 0) if no remote frames are allowed to set the TxRqst bit (RmtEn = 0).

### *22.9.2 Configuration of a Transmit Object for Remote Frames*

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

### *22.9.3 Configuration of a Single Receive Object for Data Frames*

Figure 22-11 shows how a receive object for data frames can be initialized.

**Figure 22-11. Initialization of a Single Receive Object for Data Frames**

| MsgVal | Arb | Data | Mask | EoB | Dir | NewDat | MsgLst | RxIE | TxIE | IntPnd | RmtEn | TxRqst |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | appl. | appl. | appl. | 1 | 0 | 0 | 0 | appl. | 0 | 0 | 0 | 0 |

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. The arbitration bits define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (Xtd = 0), the Identifier is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to 0.
- When the message handler stores a data frame in the message object, the message handler stores the received data length code and the corresponding number of data bytes. If the data length code is less than 8, the remaining bytes of the message object can be overwritten by non-specified values.
- The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) can be used (UMask = 1) to allow groups of data frames with similar identifiers to be accepted. The Dir bit must not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register are overwritten by the bits of the stored data frame.
- If the RxIE bit is set, the IntPnd bit is set when a received data frame is accepted and stored in the message object.
- If the TxRqst bit is set, the transmission of a remote frame with the same identifier as stored in the Arbitration bits is triggered. The content of the Arbitration bits can change if the Mask bits are used (UMask = 1) for acceptance filtering.

Copyright © 2024 Texas Instruments Incorporated

### 22.9.4 Configuration of a Single Receive Object for Remote Frames

Figure 22-12 shows how a receive object for remote frames can be initialized.

**Figure 22-12. Initialization of a Single Receive Object for Remote Frames**

| MsgVal | Arb | Data | Mask | EoB | Dir | NewDat | MsgLst | RxIE | TxIE | IntPnd | RmtEn | TxRqst |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | appl. | appl. | appl. | 1 | 1 | 0 | 0 | appl. | 0 | 0 | 0 | 0 |

- Receive objects for remote frames can be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object does not trigger the transmission of a data frame. Receive objects for remote frames can be expanded to a FIFO buffer, see Section 22.9.5.
- UMask must be set to 1. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) can be set to "must-match" or to "don't care", to allow groups of remote frames with similar identifiers to be accepted. The Dir bit must not be masked in typical applications. For details, see Section 22.10.8.
- The arbitration bits (ID[28:0] and Xtd bit) can be given by the application. The arbitration bits define the identifier and type of accepted received remote frames. If some bits of the Mask bits are set to "don't care", the corresponding bits of the arbitration bits are overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = 0), the Identifier is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] is set to 0.
- The data length code (DLC[3:0]) can be given by the application. When the message handler stores a remote frame in the message object, the message handler stores the received data length code. The data bytes of the message object remain unchanged.
- If the RxIE bit is set, the IntPnd bit is set when a received remote frame is accepted and stored in the message object.

### 22.9.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to form a FIFO , the identifiers and masks (if used) of these message objects are programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number is the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one must be programmed to 0. The EoB bit of the last message object of a FIFO buffer is set to 1, configuring the last message object as the end of the block.

## 22.10 Message Handling

When initialization is finished, the CAN module synchronizes to the traffic on the CAN bus. The CAN module does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application must update the data of the messages to be transmitted and to enable and request the transmission. The transmission is requested automatically when a matching remote frame is received.

The application can read messages that are received and accepted. Messages that are not read before the next messages are accepted for the same message object are overwritten. Messages can be read interrupt-driven or after polling of NewDat.

Copyright © 2024 Texas Instruments Incorporated

### 22.10.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. The message handler state machine performs the following tasks:

- Data transfer from Message RAM to CAN Core (messages to be transmitted).
- Data transfer from CAN Core to the Message RAM (received messages).
- Data transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission request flags
- New data flags
- Interrupt pending flags
- Message valid registers

Instead of collecting above listed status information of each message object using IFx registers separately, these message handler registers provide a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

### 22.10.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the requests are serviced according to the priority of the corresponding message object, so for example, messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object can be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

### 22.10.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx registers and Message RAM, the MsgVal bits in the Message Valid register and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = 0) since the start of the transmission, the TxRqst bit is reset. If TxIE is set, IntPnd is set after a successful transmission. If the CAN has lost the arbitration or if an error occurred during the transmission, the message is retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages are transmitted in the order of the priority.

Copyright © 2024 Texas Instruments Incorporated

If automatic retransmission mode is disabled by setting the DAR bit in the CAN control register, the behavior of bits TxRqst and NewDat in the Message Control register of the Interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object for storage. The remote frames automatically trigger the transmission of a data frame, if the *RmtEn* bit is set in the matching Transmit Object.

### *22.10.4 Updating a Transmit Object*

The CPU can update the data bytes of a transmit object any time using the IF1 and IF2 interface registers; neither MsgVal nor TxRqst need to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register or IF1/IF2 Data B register must be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command register and then the number of the message object is written to bits [7:0] of the Command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that can already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details see Section 22.10.3.

When NewDat is set together with TxRqst, NewDat is reset as soon as the new transmission has started.

### *22.10.5 Changing a Transmit Object*

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects can be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the Interface register. The bits [23:16] of the Command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither MsgVal nor TxRqst need to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, the transmission is continued; however, the transmission is not repeated if the transmission is disturbed.

To update only the data bytes of a message being transmitted, set bits [23:16] of the Command register to 0x87.

**Note**

After the update of the transmit object, the interface register set contains a copy of the actual contents of the object, including the part that had not been updated.

Copyright © 2024 Texas Instruments Incorporated

### 22.10.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the message handler starts to scan the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

### 22.10.7 Reception of Data Frames

The message handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This makes sure that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU must reset the NewDat bit when the CPU reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

### 22.10.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object are considered:

1. Dir = 1 (direction = transmit), RmtEn = 1, UMask = 1 or 0
   The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
2. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 0
   The remote frame is ignored, this message object remains unchanged.
3. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 1
   The remote frame is treated similar to a received data frame. At the reception of a matching remote frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged

### 22.10.9 Reading Received Messages

The CPU can read a received message any time using the IFx interface registers, the data consistency is provided by the message handler state machine.

Typically the CPU writes 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination transfers the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

Copyright © 2024 Texas Instruments Incorporated

The actual value of NewDat shows whether a new message has been received since the last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst is not automatically reset.

### 22.10.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU can request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame can be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

### 22.10.11 Storing Received Messages in FIFO Buffers

Several message objects can be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifiers. Arbitration and Mask registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are 0, in the last bit the EoB bit is 1.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is 0, the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to 0, all further messages for this FIFO Buffer are written into the last message object of the FIFO Buffer (EoB = 1) and therefore overwrite previous messages in this message object.

### 22.10.12 Reading from a FIFO Buffer

Several messages can be accumulated in a set of message objects that are concatenated to form a FIFO buffer before the application program is required (to avoid the loss of data) to empty the buffer. A FIFO buffer of length N stores N-1 plus the last received message since the last time the FIFO buffer was cleared. A FIFO buffer is cleared by reading and resetting the NewDat bits of all the message objects, starting at the FIFO object with the lowest message number. This can be done in a subroutine following the example shown in Figure 22-13.

**Note**

All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality cannot be maintained, since the message objects of a partly read buffer are refilled according to the normal (descending) priority.

Reading from a FIFO Buffer message object and resetting the NewDat bit is handled the same way as reading from a single message object.

## 22.11 CAN Bit Timing

The CAN supports bit rates up to 1000kBit/s.

Each CAN node has a clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods ($F_{osc}$) can be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point can cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

### *22.11.1 Bit Time and Bit Rate*

According to the CAN specification, the Bit time is divided into four segments (see Figure 22-14):

- Synchronization Segment (Sync_Seg)
- Propagation Time Segment (Prop_Seg)
- Phase Buffer Segment 1 (Phase_Seg1)
- Phase Buffer Segment 2 (Phase_Seg2)

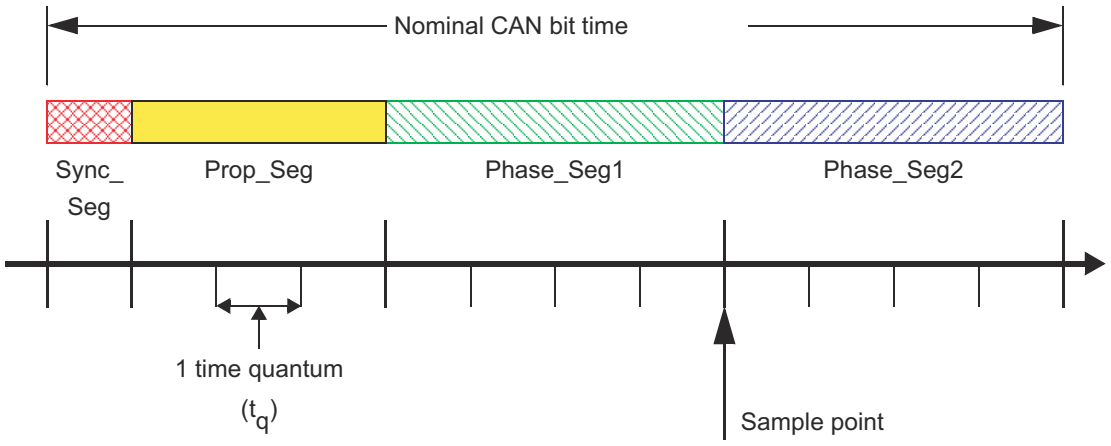

**Figure 22-14. Bit Timing**

Each segment consists of a specific number of time quanta. The length of one time quantum ($t_q$), which is the basic time unit of the bit time, is given by the CAN_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

$t_q$ = Baud Rate Prescaler/CAN_CLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 22-4 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate can be met by different bit time configurations.

Copyright © 2024 Texas Instruments Incorporated

**Table 22-4. Programmable Ranges Required by CAN Protocol**

| Parameter | Range | Remark |
|---|---|---|
| Sync_Seg | 1 $t_q$ (fixed) | Synchronization of bus input to CAN_CLK |
| Prop_Seg | [1 … 8] $t_q$ | Compensates for the physical delay times |
| Phase_Seg1 | [1 … 8] $t_q$ | Can be lengthened temporarily by synchronization |
| Phase_Seg2 | [1 … 8] $t_q$ | Can be shortened temporarily by synchronization |
| Synchronization Jump Width (SJW) | [1 … 4] $t_q$ | Cannot be longer than either phase buffer segment |

**Note**

For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range must be considered.

#### 22.11.1.1 Synchronization Segment

The Synchronization Segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, the distance to the Sync_Seg is called the phase error of this edge.

#### 22.11.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 22-15 shows the phase shift and propagation times between two CAN nodes.

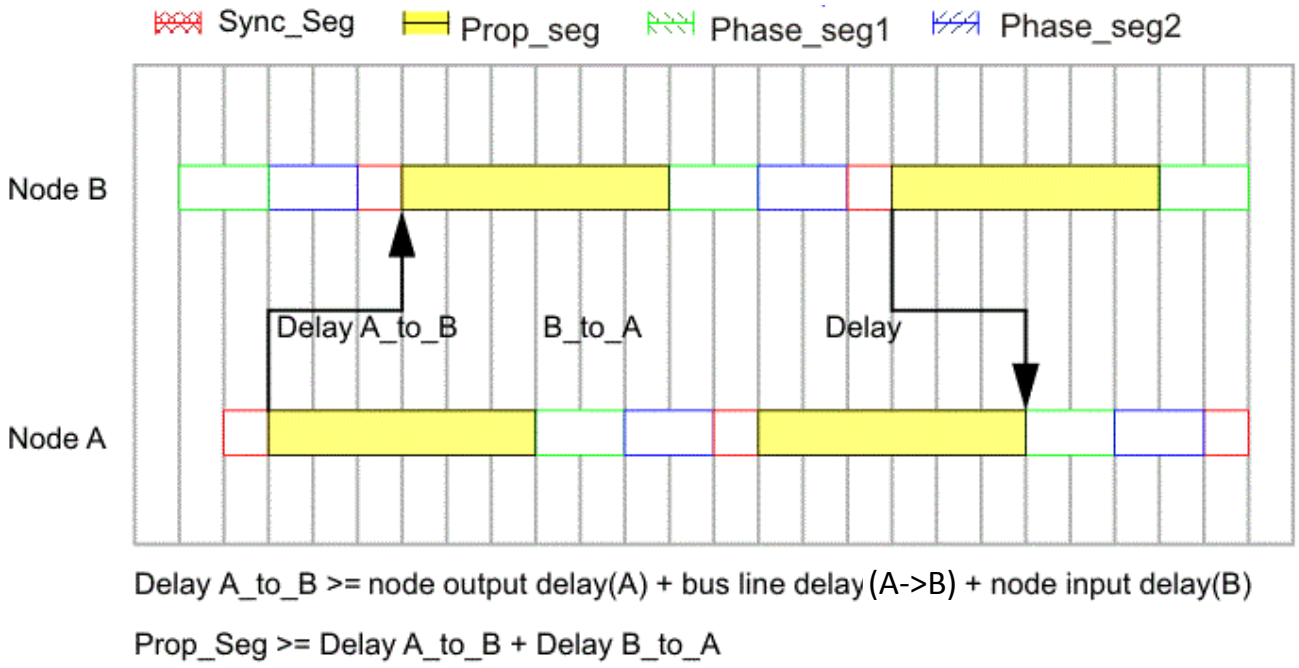

**Figure 22-15. Propagation Time Segment**

Copyright © 2024 Texas Instruments Incorporated

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. Node A has sent a Start of Frame bit less than one bit time earlier than node B, therefore node B has synchronized to the received edge from recessive to dominant. Since node B has received this edge delay (A_to_B) after the bit has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority, so node B wins the arbitration at a specific identifier bit when node B transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B arrives at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's Sample Point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B arrives at node A after the start of Phase_Seg1, node A can potentially sample a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus, which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The CAN module on this device does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 $t_q$, requiring a longer Prop_Seg.

#### 22.11.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point. The phase buffer segments can be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism can move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. The purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing the sample with the bus level at the previous sample point. A synchronization can be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if the edge occurs inside of Sync_Seg; otherwise, the distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative; else, the phase error is positive.

Two types of synchronization exist: hard synchronization and resynchronization. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- **Hard Synchronization:** After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization to lie within the synchronization segment of the restarted bit time.
- **Bit Resynchronization:** Resynchronization leads to a shortening or lengthening of the bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge that causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error; else, Phase_Seg1 is lengthened by SJW.

  When the phase error of the edge that causes resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error; else, Phase_Seg2 is shortened by SJW.

Copyright © 2024 Texas Instruments Incorporated

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

Only one synchronization can be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize "hard" on the edge transmitted by the "leading" transceiver that started transmitting first, but due to propagation delay times, the nodes cannot become completely synchronized. The "leading" transmitter does not necessarily win the arbitration; therefore, the receivers must synchronize themselves to different transmitters that subsequently "take the lead" and that are differently synchronized to the previously "leading" transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers must synchronize to the receiver that "takes the lead" in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration are caused by oscillator tolerance, when the differences in the oscillator's clock periods of transmitter and receivers sum up during the time between synchronizations (at most 10 bits). These summarized differences cannot be longer than the SJW, limiting the oscillator's tolerance range.

The examples in Figure 22-16 show how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a "late" edge, the lower drawing shows the synchronization on an "early" edge, and the middle drawing is the reference without synchronization.

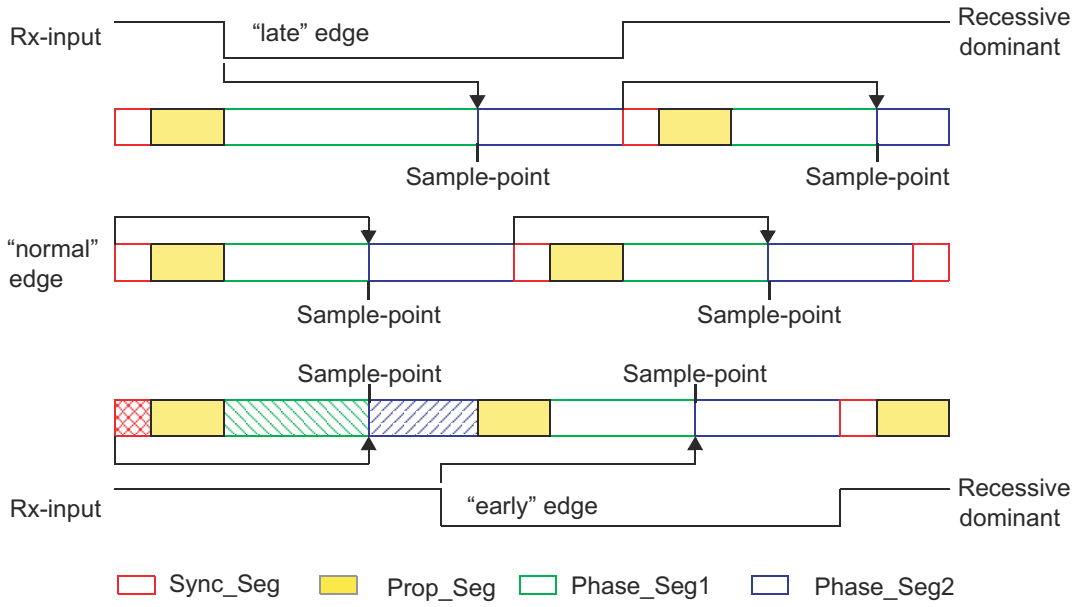

**Figure 22-16. Synchronization on Late and Early Edges**

Copyright © 2024 Texas Instruments Incorporated

In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since the edge occurs after the Sync_Seg. Reacting to the "late" edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as from the Sync_Seg to the sample point if no edge had occurred. The phase error of this "late" edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the "early" edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this "early" edge's phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to the nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an "*early*" edge because the state machine cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

The examples in Figure 22-17 show how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

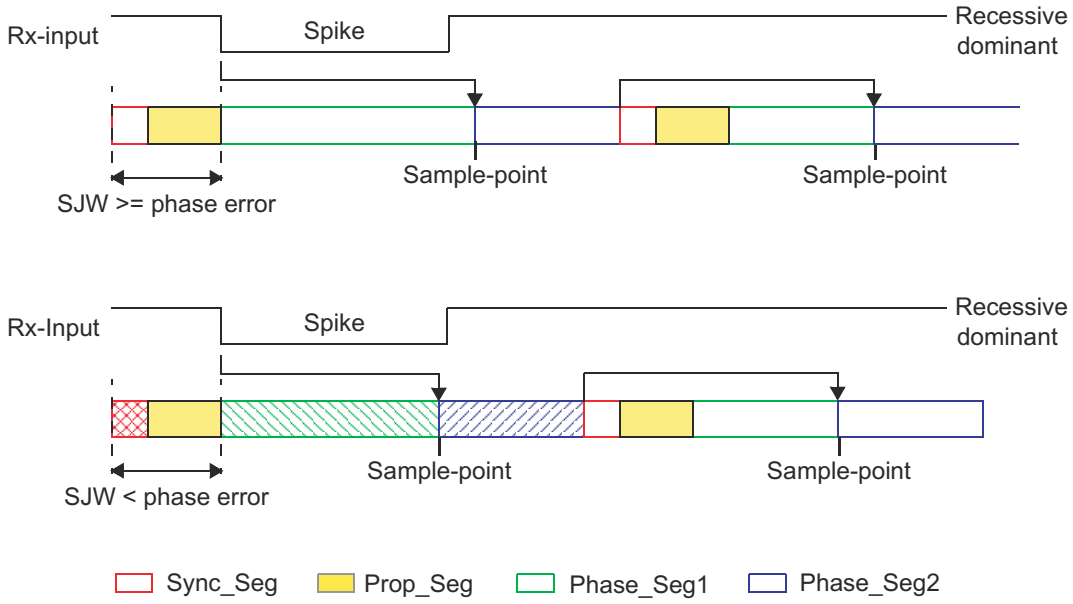

**Figure 22-17. Filtering of Short Dominant Spikes**

#### 22.11.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency $f_{osc}$ around the nominal frequency $f_{nom}$ with:

$$(1 - df) * f_{nom} \leq f_{osc} \leq (1 + df) * f_{nom}$$

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is defined by two conditions (both must be met):

$$df \leq \frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$$

$$df \leq \frac{SJW}{20 \times bit_time}$$

You must consider that SJW cannot be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that can be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not for short bit times; the combination can be used for bit rates of up to 125kBit/s (bit time = 8µs) with a bus length of 40 meters.

### *22.11.2 Configuration of the CAN Bit Timing*

In the CAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BRPE) is provided. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see Figure 22-18).

In this bit timing register, the components TSEG1, TSEG2, SJW, and BRP are programmed to a numerical value that is one less than the functional value; so instead of values in the range of [1…n], values in the range of [0…n-1] are programmed. That way, for example, SJW (functional range of [1…4]) is represented by only two bits.

Therefore the length of the bit time is either:

- (programmed values) [TSEG1 + TSEG2 + 3] $t_q$
- (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] $t_q$

The data in the Bit Timing Register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the Bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the Bit Stream Processor (BSP) state machine, is evaluated once each bit time, at the Sample Point.

The Shift register serializes the messages to be sent and parallelizes received messages. Loading and shifting is controlled by the BSP.

Copyright © 2024 Texas Instruments Incorporated

The BSP translates messages into frames and conversely. The BSP generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT), which is 0 $t_q$ for the CAN.

Generally, the IPT is CAN controller specific, but cannot be longer than 2 $t_q$. The IPT length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 can be shortened to a value less than IPT, which does not affect bus timing.

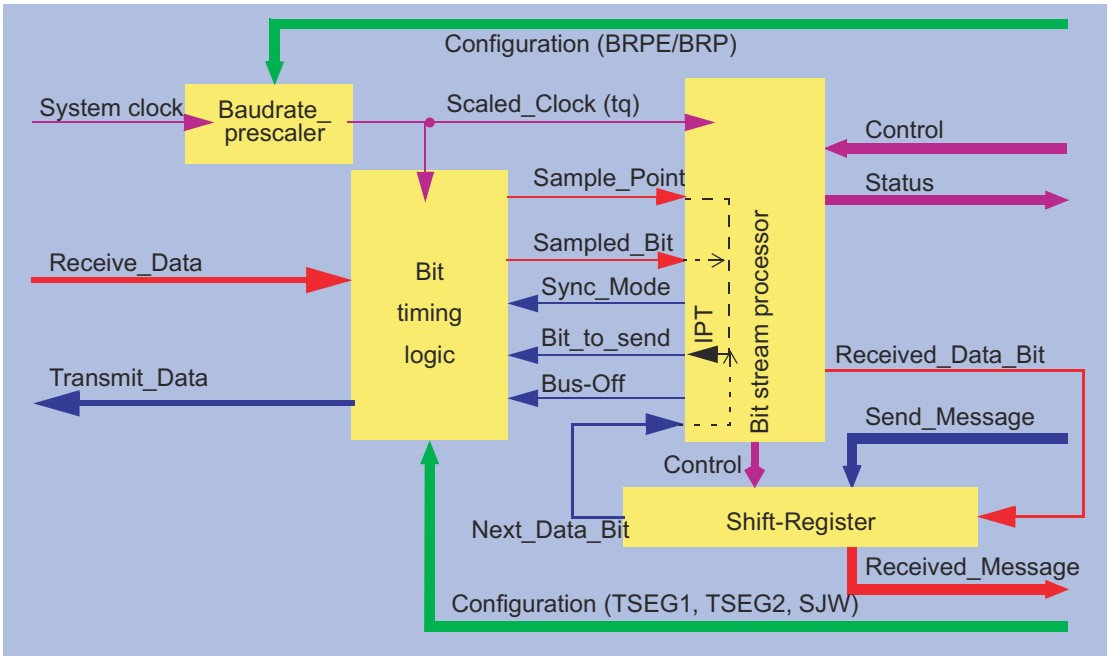

**Figure 22-18. Structure of the CAN Core's CAN Protocol Controller**

#### 22.11.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time (1/Bit rate) must be an integer multiple of the CAN clock period.

**Note**

8MHz is the minimum CAN clock frequency required to operate the CAN at a bit rate of 1MBit/s.

The bit time can consist of 8 to 25 time quanta. The length of the time quantum $t_q$ is defined by the Baud Rate Prescaler with $t_q$ = (Baud Rate Prescaler) / CAN_CLK. Several combinations can lead to the desired bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the Prop_Seg. The length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of $t_q$).

The Sync_Seg is 1 $t_q$ long (fixed), leaving (bit time - Prop_Seg - 1) $t_q$ for the two Phase Buffer Segments. If the number of remaining $t_q$ is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1; else, Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 cannot be shorter than the Information Processing Time of any node in the network, which is device dependent and can be in the range of [0 to 2] $t_q$.

The length of the synchronization jump width is set to the maximum value, which is the minimum of 4 and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Section 22.11.1.4.

If more than one configurations are possible to reach a certain bit rate, choose the configuration that allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation can show that bus length or bit rate has to be decreased or that the oscillator frequency stability has to be increased to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the Bit Timing register:

(Phase_Seg2-1)&(Phase_Seg1+Prop_Seg-1)&(SynchronizationJumpWidth-1)&(Prescaler-1)

Copyright © 2024 Texas Instruments Incorporated

#### 22.11.2.2 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN_CLK is 10MHz, BRP is 0, the bit rate is 1MBit/s.

| | | | |
|---|---|---|---|
| $t_q$ | 100ns | = | $t_{CAN_CLK}$ |
| delay of bus driver | 90ns | = | |
| delay of receiver circuit | 40ns | = | |
| delay of bus line (40m) | 220ns | = | |
| $t_{Prop}$ | 700ns | = | 2*delays = 7 • $t_q$ |
| $t_{SJW}$ | 100ns | = | 1 • $t_q$ |
| $t_{TSeg1}$ | 800ns | = | $t_{Prop}$ + $t_{SJW}$ |
| $t_{TSeg2}$ | 100ns | = | Information Processing Time + 1 • $t_q$ |
| $t_{Sync-Seg}$ | 100ns | = | 1 • $t_q$ |
| bit time | 1000ns | = | $t_{Sync-Seg}$ + $t_{TSeg1}$ + $t_{TSeg2}$ |
| tolerance for CAN_CLK | 0.35% | = | $\frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$ $= \frac{0.1\,\mu s}{2((13 \times 1\,\mu s) - 0.1\,\mu s)}$ |

In this example, the concatenated bit time parameters are $(1\text{-}1)_3$&$(8\text{-}1)_4$&$(1\text{-}1)_2$&$(1\text{-}1)_6$, so the Bit Timing Register is programmed to = 0x0000 0700.

#### 22.11.2.3 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN_CLK is 2MHz, BRP is 1, the bit rate is 100KBit/s.

| | | | |
|---|---|---|---|
| $t_q$ | 1µs | = | 2 • $t_{CAN_CLK}$ |
| delay of bus driver | 200ns | = | |
| delay of receiver circuit | 80ns | = | |
| delay of bus line (40m) | 220ns | = | |
| $t_{Prop}$ | 1µs | = | 1 • $t_q$ |
| $t_{SJW}$ | 4µs | = | 4 • $t_q$ |
| $t_{TSeg1}$ | 5µs | = | $t_{Prop}$ + $t_{SJW}$ |
| $t_{TSeg2}$ | 4µs | = | Information Processing Time + 4 • $t_q$ |
| $t_{Sync-Seg}$ | 1µs | = | 1 • $t_q$ |
| bit time | 10µs | = | $t_{Sync-Seg}$ + $t_{TSeg1}$ + $t_{TSeg2}$ |
| tolerance for CAN_CLK | 1.58% | = | $\frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$ $= \frac{4\,\mu s}{2((13 \times 10\,\mu s) - 4\,\mu s)}$ |

In this example, the concatenated bit time parameters are $(4\text{-}1)_3$&$(5\text{-}1)_4$&$(4\text{-}1)_2$&$(2\text{-}1)_6$, so the Bit Timing register is programmed to = 0x0000 34C1.

## 22.12 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the Message RAM. There are two interface register sets for read and write access (IF1 and IF2) and one Interface Register Set for read access only (IF3).

Due to the structure of the Message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the Message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the Message RAM requires the message handler to perform a read-modifywrite cycle. First those parts of the message object that are not to be changed are read from the Message RAM into the Interface Register set, and after the update the whole content of the Interface Register set is written into the message object.

After the partial write of a message object, those parts of the Interface Register set that are not selected in the Command Register are set to the actual contents of the selected message object. After the partial read of a message object, those parts of the Interface Register set that are not selected in the Command Register are left unchanged.

By buffering the data to be transferred, the Interface Register sets avoid conflicts between concurrent CPU accesses to the Message RAM and CAN message reception and transmission. A complete message object (see Section 22.13.1) or parts of the message object can be transferred between the Message RAM and the IF1/IF2 Register set in one single transfer. This transfer, performed in parallel on all selected parts of the message object, maintains the data consistency of the CAN message.

There is one condition that can cause a write access to the message RAM to be lost. If MsgVal = 1 for the message object that is accessed and CAN communication is ongoing, a transfer from the IFx register to message RAM can be lost. The reason this can happen is that the IFx register write to the message RAM occurs in between a read-modify-write access of the Host Message Handler when in the process of receiving a message for the same message object.

To avoid this issue with receive mail boxes, reset MsgVal before changing any of the following: Id28-0, Xtd, Dir, DLC3-0, RxIE, TxIE, RmtEn, EoB, Umask, Msk28-0, MXtd, and MDir.

To avoid this issue with transmit mail boxes, reset MsgVal before changing any of the following: Dir, RxIE, TxIE, RmtEn, EoB, Umask, Msk28-0, MXtd, and MDir. Other fields not listed above, like Data, can be changed without fear of losing a write to the message RAM.

### *22.12.1 Message Interface Register Sets 1 and 2 (IF1 and IF2)*

The IF1 and IF2 register sets allow data transfers to and from the message objects. The IFxCMD register for an interface control the direction of the data transfer. If the IFxCMD register is set to write, then the message object fields selected by the IFxCMD register are overwritten by values taken from the other IFx registers. If the IFxCMD register is set to read, then the message object fields selected by the IFxCMD register is copied from the message object to the other IFx registers. The interfaces allow for transfers of a complete message object as well as individual parts. The transfer begins with the desired message object number is written to bits 7:0 of the IFxCMD register.

When the CPU initiates a data transfer between the IF1/IF2 registers and Message RAM, the message handler sets the Busy bit in the respective Command Register to 1. After the transfer has completed, the Busy bit is set back to 0 (see Figure 22-19).

Copyright © 2024 Texas Instruments Incorporated

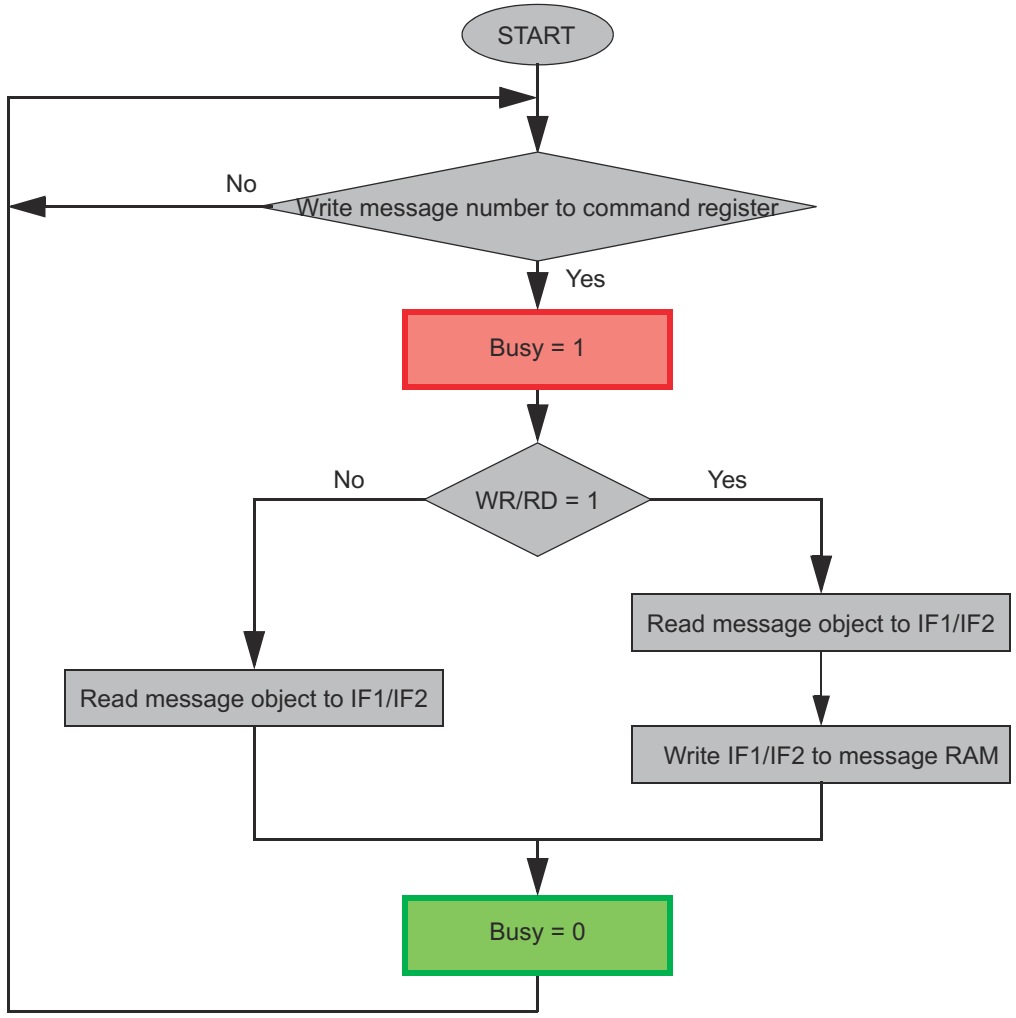

**Figure 22-19. Data Transfer Between IF1 / IF2 Registers and Message RAM**

### *22.12.2 Message Interface Register Set 3 (IF3)*

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The automatic update functionality can be programmed for each message object (see the IF3 Update Enable register).

All valid message objects in Message RAM that are configured for automatic update are checked for active NewDat flags. If such a message object is found, the message objects are transferred to the IF3 register, controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object is reset by a transfer to IF3.

If DCAN internal IF3 update is complete, an IF3 interrupt can also be generated.

**Note**

The IF3 register set cannot be used for transferring data into message objects.

Copyright © 2024 Texas Instruments Incorporated

## 22.13 Message RAM

The CAN Message RAM contains message objects and parity bits for the message objects. There are 32 message objects in the Message RAM.

During normal operation, accesses to the Message RAM are performed using the Interface Register sets, and the CPU cannot directly access the Message RAM.

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third Interface Register set IF3 can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 Register set.

The message handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

The message RAM can only be accessed in debug mode. The message RAM base address is 0x1000 above the base address of the CAN peripheral.

### *22.13.1 Structure of Message Objects*

Figure 22-20 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

**Figure 22-20. Structure of a Message Object**

| Message Object | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| UMask | Msk[28:0] | MXtd | MDir | EoB | unused | NewDat | MsgLst | RxIE | TxIE | IntPnd | RmtEn | TxRqst |
| MsgVal | ID[28:0] | Xtd | Dir | DLC[3:0] | Data 0 | Data 1 | Data 2 | Data 3 | Data 4 | Data 5 | Data 6 | Data 7 |

**Table 22-5. Message Object Field Descriptions**

| Name | Value | Description |
|---|---|---|
| MsgVal | | Message valid |
| | 0 | The message object is ignored by the message handler. |
| | 1 | The message object is to be used by the message handler. |
| | | Note: This bit can be kept at level 1 even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code DLC[3:0] are changed. |
| UMask | | Use Acceptance Mask |
| | 0 | Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering. |
| | 1 | Mask bits are used for acceptance filtering. |
| | | Note: If the UMask bit is set to 1, the message object's mask bits are programmed during initialization of the message object before MsgVal is set to 1.<br>Note: The bit functionality in the DCAN module is the opposite of the Local Acceptance Mask bit functionality in the eCAN module found in older C28x devices, where a 1 means the corresponding bit is not used for filtering and a 0 means the bit is used. |
| ID[28:0] | | Message Identifier |
| | ID[28:0] | 29-bit ("extended") identifier bits |
| | ID[28:18] | 11-bit ("standard") identifier bits |

Copyright © 2024 Texas Instruments Incorporated

**Table 22-5. Message Object Field Descriptions (continued)**

| Name | Value | Description |
|---|---|---|
| Msk[28:0] | | Identifier Mask |
| | 0 | The corresponding bit in the message identifier is not used for acceptance filtering (don't care). |
| | 1 | The corresponding bit in the message identifier is used for acceptance filtering. |
| | | Note: The bit functionality in the DCAN module is the opposite of the Local Acceptance Mask bit functionality in the eCAN module found in older C28x devices, where a 1 means the corresponding bit is not used for filtering, and a 0 means the bit is used. |
| Xtd | | Extended Identifier |
| | 0 | The 11-bit ("standard") identifier is used for this message object. |
| | 1 | The 29-bit ("extended") identifier is used for this message object. |
| MXtd | | Mask Extended Identifier |
| | 0 | The extended identifier bit (IDE) has no effect on the acceptance filtering. |
| | 1 | The extended identifier bit (IDE) is used for acceptance filtering. |
| | | Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered. |
| Dir | | Message Direction |
| | 0 | Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object. |
| | 1 | Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1). |
| MDir | | Mask Message Direction |
| | 0 | The message direction bit (Dir) has no effect on the acceptance filtering. |
| | 1 | The message direction bit (Dir) is used for acceptance filtering. |
| EOB | | End of Block |
| | 0 | The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block. |
| | 1 | The message object is a single message object or the last message object in a FIFO Buffer Block. |
| | | Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to 1. |
| NewDat | | New Data |
| | 0 | No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU. |
| | 1 | The message handler or the CPU has written new data into the data bytes of this message object. |
| MsgLst | | Message Lost (only valid for Message Objects with direction = receive) |
| | 0 | No message was lost since the last time when this bit was reset by the CPU. |
| | 1 | The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten. |
| RxIE | | Receive Interrupt Enable |
| | 0 | IntPnd is not triggered after the successful reception of a frame. |
| | 1 | IntPnd is triggered after the successful reception of a frame. |
| TxIE | | Transmit Interrupt Enable |
| | 0 | IntPnd is not triggered after the successful transmission of a frame. |
| | 1 | IntPnd is triggered after the successful transmission of a frame. |
| IntPnd | | Interrupt Pending |
| | 0 | This message object is not the source of an interrupt. |
| | 1 | This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register point to this message object, if there is no other interrupt source with higher priority. |

Copyright © 2024 Texas Instruments Incorporated

**Table 22-5. Message Object Field Descriptions (continued)**

| Name | Value | Description |
|---|---|---|
| RmtEn | | Remote Enable |
| | 0 | At the reception of a remote frame, TxRqst is not changed. |
| | 1 | At the reception of a remote frame, TxRqst is set. |
| | | Note: See Section 22.10.8 for details on the setup of RmtEn and UMask for remote frames. |
| TxRqst | | Transmit Request |
| | 0 | This message object is not waiting for a transmission. |
| | 1 | The transmission of this message object is requested and is not yet done. |
| DLC[3:0] | | Data length code |
| | 0-8 | Data frame has 0-8 data bytes. |
| | 9-15 | Data frame has 8 data bytes. |
| | | Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, the message handler writes the DLC to the value given by the received message. |
| Data 0 | | 1st data byte of a CAN data frame |
| Data 1 | | 2nd data byte of a CAN data frame |
| Data 2 | | 3rd data byte of a CAN data frame |
| Data 3 | | 4th data byte of a CAN data frame |
| Data 4 | | 5th data byte of a CAN data frame |
| Data 5 | | 6th data byte of a CAN data frame |
| Data 6 | | 7th data byte of a CAN data frame |
| Data 7 | | 8th data byte of a CAN data frame |
| | | Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, the message handler writes all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object can be overwritten by undefined values. |

Copyright © 2024 Texas Instruments Incorporated

### 22.13.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

Message RAM base address + (message object number) * 0x20

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

**Note**

A 0 is not a valid message object number. At address 0x0000, the last message object (32) (with the lowest priority) is located. Writing to the address of an unimplemented message object can overwrite an implemented message object.

Message Object number 1 has the highest priority.

**Table 22-6. Message RAM Addressing in Debug Mode**

| Message Object Number | Offset From Base Address | Word Number | Debug Mode(1) |
|---|---|---|---|
| last implemented (here:32) | 0x0000 | 1 | Parity |

### 22.13.3 Message RAM Representation in Debug Mode

In debug mode, the Message RAM is memory-mapped. This allows the external debug unit to access the Message RAM.

**Note**

During debug mode, the Message RAM cannot be accessed using the IFx register sets.

**Figure 22-21. Message RAM Representation in Debug Mode**

## 22.14 Software

### 22.14.1 CAN Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/can

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

## 22.15 CAN Registers

This section describes the Controller Area Network registers.

### 22.15.1 CAN Base Addresses

**Table 22-7. CAN Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| CanaRegs | CAN_REGS | 0x0004_8000 | 0x0004_87FF |
| CanbRegs | CAN_REGS | 0x0004_A000 | 0x0004_A7FF |

Complex bit access types are encoded to fit into small table cells. Table 22-9 shows the codes that are used for access types in this section.

**Table 22-9. CAN_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| W1C | W<br>1C | Write<br>1 to clear |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 22.15.2.1 CAN_CTL Register (Offset = 0h) [Reset = 00001401h]

CAN_CTL is shown in Figure 22-22 and described in Table 22-10.

Return to the Summary Table.

This register is used for configuring the CAN module in terms of interrupts, parity, debug-mode behavior etc.

**Figure 22-22. CAN_CTL Register**

### 22.15.2.2 CAN_ES Register (Offset = 4h) [Reset = 00000007h]

CAN_ES is shown in Figure 22-23 and described in Table 22-11.

Return to the Summary Table.

This register indicates error conditions, if any, of the CAN module. Interrupts are generated by PER, BOff and EWarn bits (if EIE bit in CAN Control Register is set) and by RxOk, TxOk, and LEC bits (if SIE bit in CAN Control Register is set). A change of bit EPass will not generate an Interrupt.
Reading the Error and Status Register clears the PER, RxOk and TxOk bits and sets the LEC to value '7'. Additionally, the Status Interrupt value (0x8000) in the Interrupt Register will be replaced by the next lower priority interrupt value.
For debug support, the auto clear functionality of Error and Status Register (clear of status flags by read) is disabled when in Debug/Suspend mode.

**Table 22-11. CAN_ES Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 4 | RxOk | R | 0h | Reception status Bit: This bit indicates the status of reception. The bit will be reset after the CPU reads the register.<br>0 No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events.<br>1 A message has been successfully received since the last time when this bit was reset by a read access of the CPU. This bit will be set independent of the result of acceptance filtering.<br>Reset type: SYSRSn |
| 3 | TxOk | R | 0h | Transmission status Bit: This bit indicates the status of transmission. The bit will be reset after the CPU reads the register.<br>0 No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events.<br>1 A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was cleared by a read access of the CPU.<br>Reset type: SYSRSn |
| 2-0 | LEC | R | 7h | Last Error Code<br>The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. This field will be reset to '7' whenever the CPU reads the register.<br>0 No Error<br>1 Stuff Error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.<br>2 Form Error: A fixed format part of a received frame has the wrong format.<br>3 Ack Error: The message this CAN Core transmitted was not acknowledged by another node.<br>4 Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.<br>5 Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).<br>6 CRC Error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).<br>7 No CAN bus event was detected since the last time when CPU has read the Error and Status Register. Any read access to the Error and Status Register re-initializes the LEC to value '7'.<br>Reset type: SYSRSn |

### 22.15.2.4 CAN_BTR Register (Offset = Ch) [Reset = 00002301h]

CAN_BTR is shown in Figure 22-25 and described in Table 22-13.

Return to the Summary Table.

This register is used to configure the bit-timing parameters for the CAN module. This register is only writable if CCE and Init bits in the CAN Control Register are set.
The CAN bit time may be programmed in the range of 8 to 25 time quanta.
The CAN time quantum may be programmed in the range of 1 to1024 CAN_CLK periods.

### 22.15.2.6 CAN_TEST Register (Offset = 14h) [Reset = 00000000h]

CAN_TEST is shown in Figure 22-27 and described in Table 22-15.

Return to the Summary Table.

This register is used to configure the various test options supported. For all test modes, the Test bit in CAN Control Register needs to be set to one. If Test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of CANRX pin and therefore is only readable. All Test Register functions are disabled when Test bit is cleared.
Note: Setting Tx[1:0] other than '00' will disturb message transfer.
Note: When the internal loop back mode is active (bit LBack is set), bit EXL will be ignored.

### 22.15.2.7 CAN_PERR Register (Offset = 1Ch) [Reset = 00000XXXh]

CAN_PERR is shown in Figure 22-28 and described in Table 22-16.

Return to the Summary Table.

This register indicates the Word/Mailbox number where a parity error has been detected. If a parity error is detected, the PER flag will be set in the Error and Status Register. This bit is not reset by the parity check mechanism
it must be reset by reading the Error and Status Register. In addition to the PER flag, the Parity Error Code Register will indicate the memory area where the parity error has been detected. If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

### 22.15.2.13 CAN_TXRQ_X Register (Offset = 84h) [Reset = 00000000h]

CAN_TXRQ_X is shown in Figure 22-34 and described in Table 22-22.

Return to the Summary Table.

With these bits, the CPU can detect if one or more bits in the CAN Transmission Request 21 Register (CAN_TXRQ_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the TxRqst bits of these message objects is set, the corresponding bit in this register will be set.

### 22.15.2.14 CAN_TXRQ_21 Register (Offset = 88h) [Reset = 00000000h]

CAN_TXRQ_21 is shown in Figure 22-35 and described in Table 22-23.

Return to the Summary Table.

This register holds the TxRqst bits of the mailboxes. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific mailbox can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

**Figure 22-35. CAN_TXRQ_21 Register**

### 22.15.2.15 CAN_NDAT_X Register (Offset = 98h) [Reset = 00000000h]

CAN_NDAT_X is shown in Figure 22-36 and described in Table 22-24.

Return to the Summary Table.

With these bits, the CPU can detect if one or more bits in the CAN New Data 21 Register (CAN_NDAT _21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the NewDat bits of these mailboxes are set, the corresponding bit in this register will be set.

### 22.15.2.16 CAN_NDAT_21 Register (Offset = 9Ch) [Reset = 00000000h]

CAN_NDAT_21 is shown in Figure 22-37 and described in Table 22-25.

Return to the Summary Table.

This register holds the NewDat bits of all mailboxes. By reading out the NewDat bits, the CPU can check for which mailboxes the data portion was updated. The NewDat bit of a specific mailbox can be set/reset by the CPU via the IFx 'Message Interface' Registers or by the Message Handler after reception of a Data Frame or after a successful transmission.

**Figure 22-37. CAN_NDAT_21 Register**

### 22.15.2.17 CAN_IPEN_X Register (Offset = ACh) [Reset = 00000000h]

CAN_IPEN_X is shown in Figure 22-38 and described in Table 22-26.

Return to the Summary Table.

With these bits, the CPU can detect if one or more bits in the CAN Interrupt Pending 21 Register (CAN_IPEN_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the IntPnd bits of these mailboxes are set, the corresponding bit in this register will be set.

### 22.15.2.18 CAN_IPEN_21 Register (Offset = B0h) [Reset = 00000000h]

CAN_IPEN_21 is shown in Figure 22-39 and described in Table 22-27.

Return to the Summary Table.

This register holds the IntPnd bits of the mailboxes. By reading out these bits, the CPU can check for pending interrupts in the mailboxes. The IntPnd bit of a specific mailbox can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

**Figure 22-39. CAN_IPEN_21 Register**

### 22.15.2.19 CAN_MVAL_X Register (Offset = C0h) [Reset = 00000000h]

CAN_MVAL_X is shown in Figure 22-40 and described in Table 22-28.

Return to the Summary Table.

With these bits, the CPU can detect if one or more bits in the CAN Message Valid 2_1 Register (CAN_MVAL_21) is set.Each bit in this register represents a group of eight mailboxes. If at least one of the MsgVal bits of these mailboxes are set, the corresponding bit in this register will be set.

### 22.15.2.20 CAN_MVAL_21 Register (Offset = C4h) [Reset = 00000000h]

CAN_MVAL_21 is shown in Figure 22-41 and described in Table 22-29.

Return to the Summary Table.

This registers hold the MsgVal bits of all mailboxes. By reading out the MsgVal bits, the CPU can check which mailbox is valid. The MsgVal bit of a specific mailbox can be set/reset by the CPU via the IF1/2 'Message Interface' Registers.

**Figure 22-41. CAN_MVAL_21 Register**

### 22.15.2.21 CAN_IP_MUX21 Register (Offset = D8h) [Reset = 00000000h]

CAN_IP_MUX21 is shown in Figure 22-42 and described in Table 22-30.

Return to the Summary Table.

The IntMux bit determines for each mailbox, which of the two interrupt lines (CANINT0 or CANINT1) will be asserted when the IntPnd bit of that mailbox is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN Control Register. This will also affect the INT0ID or INT1ID flags in the Interrupt Register.

**Figure 22-42. CAN_IP_MUX21 Register**

### 22.15.2.22 CAN_IF1CMD Register (Offset = 100h) [Reset = 00000001h]

CAN_IF1CMD is shown in Figure 22-43 and described in Table 22-31.

Return to the Summary Table.

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.
If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16- bits.
Note: While Busy bit is one, IF1/IF2 Register sets are write protected.
Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAactive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.
Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

### 22.15.2.23 CAN_IF1MSK Register (Offset = 104h) [Reset = FFFFFFFFh]

CAN_IF1MSK is shown in Figure 22-44 and described in Table 22-32.

Return to the Summary Table.

The bits of the IF1/IF2 Mask Registers mirror the mask bits of a message object.
Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 22.15.2.24 CAN_IF1ARB Register (Offset = 108h) [Reset = 00000000h]

CAN_IF1ARB is shown in Figure 22-45 and described in Table 22-33.

Return to the Summary Table.

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.
A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).
Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.
If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.
Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 22.15.2.26 CAN_IF1DATA Register (Offset = 110h) [Reset = 00000000h]

CAN_IF1DATA is shown in Figure 22-47 and described in Table 22-35.

Return to the Summary Table.

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 22.15.2.28 CAN_IF2CMD Register (Offset = 120h) [Reset = 00000001h]

CAN_IF2CMD is shown in Figure 22-49 and described in Table 22-37.

Return to the Summary Table.

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.
If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16- bits.
Note: While Busy bit is one, IF1/IF2 Register sets are write protected.
Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAactive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.
Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

### 22.15.2.30 CAN_IF2ARB Register (Offset = 128h) [Reset = 00000000h]

CAN_IF2ARB is shown in Figure 22-51 and described in Table 22-39.

Return to the Summary Table.

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.
A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).
Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.
If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.
Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 22.15.2.32 CAN_IF2DATA Register (Offset = 130h) [Reset = 00000000h]

CAN_IF2DATA is shown in Figure 22-53 and described in Table 22-41.

Return to the Summary Table.

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 22.15.2.33 CAN_IF2DATB Register (Offset = 134h) [Reset = 00000000h]

CAN_IF2DATB is shown in Figure 22-54 and described in Table 22-42.

Return to the Summary Table.

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 22.15.2.34 CAN_IF3OBS Register (Offset = 140h) [Reset = 00000000h]

CAN_IF3OBS is shown in Figure 22-55 and described in Table 22-43.

Return to the Summary Table.

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU.
The observation flags (Bits [4:0]) in the IF3 Observation register are used to determine, which data sections of the IF3 Interface Register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 Interface Register set with new data.
Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.
Note: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.
A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 Interface Register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).
With this, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode

### 22.15.2.40 CAN_IF3UPD Register (Offset = 160h) [Reset = 00000000h]

CAN_IF3UPD is shown in Figure 22-61 and described in Table 22-49.

Return to the Summary Table.

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set. Note: IF3 Update enable should not be set for transmit objects.

**Figure 22-61. CAN_IF3UPD Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

## 23.1 Introduction

The USB controller operates as a full-speed function controller during point-to-point communications with the USB host. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. The USB controller has thirty-two endpoints, one-half of them being for IN transactions and one-half of them being for OUT transactions. One IN and one OUT endpoint are fixed-function endpoints used for control transfers; the others are defined by firmware. A dynamically sizeable FIFO supports queuing multiple packets. Software-controlled connect and disconnect allow flexibility during USB device startup.

### *23.1.1 Features*

The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12Mbps) operation in host and device modes as well as low-speed (1.5Mbps) operation in host mode
- Integrated PHY
- Three transfer types: Control, Interrupt, and Bulk
- 32 endpoints
  - One dedicated control IN endpoint and one dedicated control OUT endpoint
  - Fifteen configurable IN endpoints and fifteen configurable OUT endpoints
- 4KB dedicated endpoint memory

### 23.1.3 Block Diagram

The USB block diagram is shown in Figure 23-1.

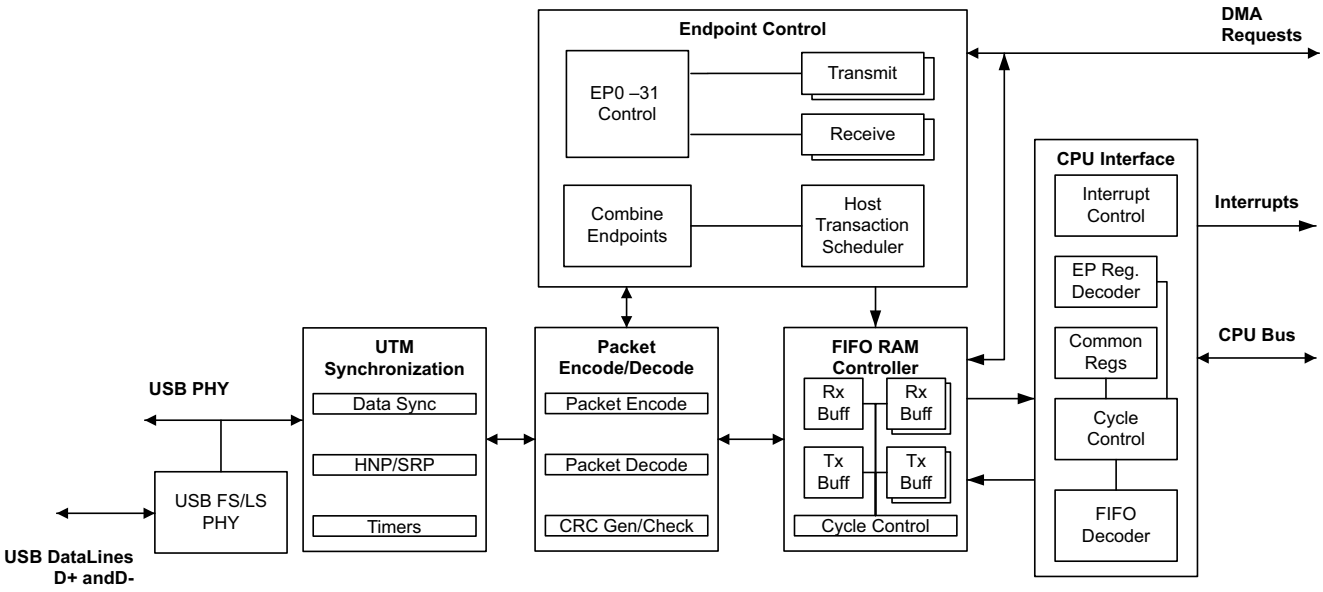

**Figure 23-1. USB Block Diagram**

#### 23.1.3.1 Signal Description

The USB controller requires a total of three signals (D+, D-, and $V_{Bus}$) to operate in device mode and two signals (D+, D-) to operate in embedded host mode. Because of the differential signaling needed for USB, the D+ and D- pins have special buffers to support USB. As such, the position on the chip is not user-selectable. The D+ and D- pins at reset are, by default, GPIOs and must be configured before being used as USB function pins. Bits 10 and 11 in the GPIO B Analog Mode Select register (GPBAMSEL) must be set to choose the USB function. The signals USB bus voltage ($V_{BUS}$), external power enable (EPEN), and power fault (PFLT) are not hardwired to any pin and some applications require these signals be implemented in software using a GPIO. Software that implements these signals is available in the USB software library.

#### 23.1.3.2 VBus Recommendations

Most applications do not need to monitor $V_{Bus}$. Because of this, a dedicated $V_{Bus}$ monitoring pin was not included on this microcontroller. If you are designing a bus-powered device application or an embedded host application, you do not need to monitor $V_{Bus}$. If you are designing a self-powered device, you need to actively monitor the state of the $V_{Bus}$ pin to make sure compliance with the USB specification. In Section 7.1.5 and Section 7.2.1 of the USB Specification Revision 2.0™:

- "The voltage source on the [speed identification] pull-up resistor must be derived from or controlled by the power supplied on the USB cable such that when $V_{BUS}$ is removed, the pull-up resistor does not supply current on the data line to which it is attached.
- When $V_{BUS}$ is removed, the device must remove power from the D+/D- pull-up resistor within 10 seconds.
- Later in the timing tables (Section 7.3.2) of the USB Specification 2.0, it is also stated that the D+/D- pull-up resistor must be applied within 100 ms of $V_{Bus}$ reaching a valid level."

Meeting the above specification is easy because of the slow timing requirements. The hardware part of the $V_{Bus}$ monitoring is discussed in this chapter. The corresponding software is discussed briefly, but for examples and an explanation, consult the USB software guide.

The pins of this microcontroller are not 5V tolerant, and because of this, the $V_{Bus}$ signal cannot be directly connected to a GPIO pin. Directly connecting 5V to a pin of the microcontroller destroys the I/O buffer of the pin

Copyright © 2024 Texas Instruments Incorporated

and possibly more of the chip. The most cost-effective way of making any pin capable of reading a 5V input is to use a series resistance in conjunction with the ESD diode clamps already present inside the device on every pin. Also, use a 100kΩ series resistor between the $V_{Bus}$ signal and the pin chosen to monitor the pin. A diagram of this setup is shown in Figure 23-2.

In Figure 23-2, if $V_{Bus}$ is above 3.3V or below 0V, one of the ESD clamp diodes is forward-biased, allowing current to flow through the 100kΩ resistor. The purpose of the diode clamps is to protect the pins of the microcontroller from very short over voltage spikes of a high magnitude. The diode clamps do this by clamping the voltage excursion to one of the supply rails. We are effectively requiring the ESD clamps to do the same thing the clamps were designed to do, but instead of a short high magnitude pulse, we are giving the clamps a long low magnitude static value using the 100kΩ resistor.

Any pin that has digital input and output functionality can potentially be used to monitor $V_{Bus}$, but the use of an interrupt-capable GPIO is recommended. A pin that does not have external interrupt capability can also be used, but the input state of the pin must be polled periodically by the application software to make sure appropriate action is taken whenever $V_{Bus}$ is applied or removed. If an interrupt-capable GPIO is chosen, the GPIO can be configured to generate an interrupt on both the rising and falling edge. More information on external interrupts can be found in the *System Control and Interrupts* chapter. Example code that implements $V_{Bus}$ monitoring using external interrupts and takes the appropriate actions is documented in the USB Software Guide and can be found in the associated USB software package.

## 23.2 Functional Description

The USB controller can be configured to act as either a dedicated host or device. However, when the USB controller is acting as a self-powered device, a GPIO input or analog comparator input must be connected to $V_{BUS}$ and configured to generate an interrupt when the $V_{BUS}$ level drops. This interrupt is used to disable the pullup resistor on the USB0DP signal.

**Note**

When a USB is used in the system, the minimum system frequency is 30MHz.

### *23.2.1 Operation as a Device*

This section describes how the USB controller performs when the USB controller is being used as a USB device. IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of start of frame (SOF) are all described.

When in device mode, IN transactions are controlled by the endpoint transmit interface and uses the transmit endpoint registers for the given endpoint. OUT transactions are handled with the endpoints receive interface and use the receive endpoint registers for the given endpoint. When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint. Note the following:

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint for a USB device. However, in most cases the USB device must use the dedicated control endpoint on the USB controller’s endpoint 0.

#### 23.2.1.1 Control and Configurable Endpoints

When operating as a device, the USB controller provides two dedicated control endpoints (IN and OUT). The remaining available configurable endpoints (one-half IN and one-half OUT) can be used for communications with a host controller. The endpoint number and direction associated with an endpoint is directly related to the register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface. Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions.
The remaining six endpoints can be configured as control, bulk, or interrupt endpoints. The six endpoints can be treated as three configurable IN and three configurable OUT endpoints. The endpoint pairs are not required to have the same type for the IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair can be a bulk endpoint, while the IN portion of that endpoint pair can be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

Copyright © 2024 Texas Instruments Incorporated

#### 23.2.1.1.1 IN Transactions as a Device

When operating as a USB device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the configurable IN endpoints are determined by the USB Transmit FIFO Start Address (USBTXFIFOADD) register. The maximum size of a data packet that can be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the USB Maximum Transmit Data Endpoint n (USBTXMAXPn) register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

**Note**

The maximum packet size set for any endpoint must not exceed the FIFO size. The USBTXMAXPn register cannot be written to while data is in the FIFO as unexpected results can occur.

**Single-Packet Buffering**

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ) register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the USB Transmit Control and Status Endpoint n Low (USBTXCSRLn) register must be set. If the AUTOSET bit in the USB Transmit Control and Status Endpoint n High (USBTXCSRHn) register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

**Double-Packet Buffering**

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the USBTXCSRLn register must be set. If the AUTOSET bit in the USBTXCSRHn register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the USBTXCSRLn register at this point indicates how many packets can be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

**Note**

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

Copyright © 2024 Texas Instruments Incorporated

#### 23.2.1.1.2 Out Transactions as a Device

When in device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the configurable OUT endpoints are determined by the USB Receive FIFO Start Address (USBRXFIFOADD) register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the USB Maximum Receive Data Endpoint n (USBRXMAXPn) register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

**Note**

In all cases, the maximum packet size must not exceed the FIFO size.

**Single-Packet Buffering**

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the USB Receive Control and Status Endpoint n Low (USBRXCSRL[*n*]) register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the USB Receive Control and Status Endpoint n High (USBRXCSRH[*n*]) register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

**Double-Packet Buffering**

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the USBRXCSRL[*n*] register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

**Note**

The FULL bit in USBRXCSRL[*n*] is not set when the first packet is received. The FULL bit is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the USBRXCSRH[*n*] register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

**Note**

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

Copyright © 2024 Texas Instruments Incorporated

#### 23.2.1.1.3 Scheduling

The device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

#### 23.2.1.1.4 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

**Stalled Control Transfer**

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the USB Control and Status Endpoint 0 Low (USBCSRL0) register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what must have been the last packet.
3. The Host sends more than USBRXMAXPn bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

**Zero Length OUT Data Packets**

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets must only be received after the entire length of the device request has been transferred. However, if the Host sends a zero-length OUT data packet before the entire length of device request has been transferred, the Host is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the USBCSRL0 register.

**Setting the Device Address**

When a Host is attempting to enumerate the USB device, the Host requests that the device change the address from zero to some other value. The address is changed by writing the value that the Host requested to the USB Device Functional Address (USBFADDR) register. However, care must be taken when writing to USBFADDR to avoid changing the address before the transaction is complete. This register must only be set after the SET_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the device has left the STATUS phase. In the case of a SET_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the device has responded to the IN request, the USBFADDR register must be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

**Note**

If the USBFADDR register is set to the new value as soon as the device receives the OUT transaction with the SET_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the device.

Copyright © 2024 Texas Instruments Incorporated

#### 23.2.1.1.5 Device Mode Suspend

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the USB Interrupt Enable (USBIE) register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the USB Power (USBPOWER) register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling. To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state.

#### 23.2.1.1.6 Start of Frame

When the USB controller is operating in device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the USB Frame Value (USBFRAME) register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the USBFRAME register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

#### 23.2.1.1.7 USB Reset

When the USB controller is in device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the USBFADDR register
- Clears the USB Endpoint Index (USBEPIDX) register
- Flushes all endpoint FIFOs
- Clears all control/status registers
- Enables all endpoint interrupts
- Generates a RESET interrupt

#### 23.2.1.1.8 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the SOFTCONN bit of the USBPOWER register. When the SOFTCONN bit is set, the PHY is placed in the normal mode, and the USB0DP/USB0DM lines of the USB bus are enabled. At the same time, the USB controller is placed into a state that does not respond to any USB signaling except a USB RESET. When the SOFTCONN bit is cleared, the PHY is put into non-driving mode, USB0DP and USB0DM are tristated, and the USB controller appears to other devices on the USB bus as if the USB controller has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the SOFTCONN bit has been set. The application software can then choose when to set the PHY into the normal mode. Systems with a lengthy initialization procedure can use this to make sure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the SOFTCONN bit has been set, the USB controller can be disconnected by clearing this bit.

**Note**

The USB controller does not generate an interrupt when the device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

Copyright © 2024 Texas Instruments Incorporated

### 23.2.2 Operation as a Host

When the USB controller is operating in Host mode, the USB controller can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub. Control, bulk, and interrupt transactions are supported. This section describes the USB controller's actions when the USB controller is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in device mode, the FIFOs for endpoints must take into account the maximum packet size for an endpoint.

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint to communicate with a device. However, in most cases the USB controller must use the dedicated control endpoint to communicate with a device's endpoint 0.

#### 23.2.2.1 Endpoint Registers

The endpoint registers are used to control the USB endpoint interfaces which communicate with devices that are connected. The endpoints consist of a dedicated control IN endpoint and a dedicated control OUT endpoint. The remaining available endpoints are configurable, with one-half of them being OUT endpoints, and one-half of them being IN endpoints. See Section 23.1.1 for the number of available endpoints on this device.

The dedicated control interface can only be used for control transactions to endpoint 0 of devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, or interrupt endpoints.

These USB interfaces can be used to simultaneously schedule as many as 15 independent OUT and 15 independent IN transactions to any endpoints on any device. The IN and OUT controls are paired together in the same set of registers for the respective endpoints. However, the IN and OUT controls can be configured to communicate with different types of endpoints and different endpoints on devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a device's bulk OUT endpoint 1, while the IN portion is communicating with a device's interrupt IN endpoint 2.

Before accessing any device, whether for point-to-point communications or for communications using a hub, the relevant USB Receive Functional Address Endpoint n (USBRXFUNCADDRn) or USB Transmit Functional Address Endpoint n (USBTXFUNCADDRn) registers must be set for each receive or transmit endpoint to record the address of the device being accessed.

The USB controller also supports connections to devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

Copyright © 2024 Texas Instruments Incorporated

#### 23.2.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in device mode except that the transaction first must be initiated by setting the REQPKT bit in the USBCSRL0 register, indicating to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the USBCSRL0 register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the USBRXCSRHn register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in USBRXCSRHn causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. When the RXRDY bit is cleared, the controller sends an acknowledge to the device. When there is a known number of packets to be transferred, the USB Request Packet Count in Block Transfer Endpoint n (USBRQPKTCOUNTn) register associated with the endpoint must be configured to the number of packets to be transferred. The USB controller decrements the value in the USBRQPKTCOUNTn register following each request. When the USBRQPKTCOUNTn value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, USBRQPKTCOUNTn must be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the USBRXMAXPn register) such as can occur at the end of a bulk transfer.

If the device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the USBCSRL0 register. If the target device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the USBCSRL0 register.

#### 23.2.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in device mode. The TXRDY bit in the USBTXCSRLn register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the USBTXCSRHn register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO.

If the target device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the USBTXCSRLn register. If the target device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the USBTXCSRLn register.

#### 23.2.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every 255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a device is not responding.

The USB controller maintains a frame counter. If the target device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target device is a low-speed device, a K state is transmitted on the bus to act as a keep-alive to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt transaction occurs per endpoint every n frames, where n is the interval set using the USB Host Transmit Interval Endpoint n (USBTXINTERVAL[*n*]) or USB Host Receive Interval Endpoint n (USBRXINTERVAL[*n*]) register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process makes sure that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target device before the endpoint times out.

#### 23.2.2.5 USB Hubs

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed device is connected to the USB controller using a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding USB Receive Hub Address Endpoint n (USBRXHUBADDRn) and USB Receive Hub Port Endpoint n (USBRXHUBPORTn) or the USB Transmit Hub Address Endpoint n (USBTXHUBADDRn) and USB Transmit Hub Port Endpoint n (USBTXHUBPORTn) registers. In addition, the speed at which the device operates (full or low) must be recorded in the USB Type Endpoint 0 (USBTYPE0) (endpoint 0), USB Host Configure Transmit Type Endpoint n (USBTXTYPEn), or USB Host Configure Receive Type Endpoint n (USBRXTYPEn) registers for each endpoint that is accessed by the device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB devices. To maximize the number of devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to device functions must be made following the completion of any on-going transactions on the endpoints affected.

#### 23.2.2.6 Babble

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

#### 23.2.2.7 Host SUSPEND

If the SUSPEND bit in the USBPOWER register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

#### 23.2.2.8 USB RESET

If the RESET bit in the USBPOWER register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20 ms to make sure of correct resetting of the target device. After the CPU has cleared the bit, the USB Host controller starts the frame counter and transaction scheduler.

#### 23.2.2.9 Connect/Disconnect

A session is started by setting the SESSION bit in the USB device Control (USBDEVCTL) register, enabling the USB controller to wait for a device to be connected. When a device is detected, a connect interrupt is generated. The speed of the device that has been connected can be determined by reading the USBDEVCTL register where the FSDEV bit is set for a full-speed device, and the LSDEV bit is set for a low-speed device. The USB controller must generate a RESET to the device, and then the USB Host controller can begin device enumeration. If the device is disconnected while a session is in progress, a disconnect interrupt is generated.

### 23.2.3 DMA Operation

The USB module DMA trigger signals are not supported on this device. The DMA controller can be used to read and write the USB FIFOs using software triggering. See the *Direct Memory Access (DMA)* chapter for more details about programming the DMA controller. See the *USB DMA Event Trigger* advisory in the device errata for more information.

### 23.2.4 Address/Data Bus Bridge

This USB controller was originally designed to connect to an ARM AHB bus, but has been modified to function with the C28x device bus architecture. The modifications made are largely invisible to the user application, but there are some things to note.

- The USB memory space is 8 bits wide, while the C28x memory space is 16 bits wide.
- 32- and 16-bit accesses (r/w) are completely transparent to the user application code, no changes need be made.
- The C28x core only supports 8 bit accesses through a byte intrinsic type. This can be used to perform 8 bit reads or writes to the USB controller.
  - int &__byte(int *array, unsigned int byte_index);
  - *array = ptr to address to access, byte_index = always 0 (for USB)
    See Table 23-1 for example.
  - See the *TMS320C28x Optimizing C/C++ Compiler User's Guide* and the *TMS320C28x Assembly Language Tools User's Guide*
- Because of the bridge, the memory view of the USB controller memory space in CCS is not a 1:1 representation of what is in the controller
  - When the view mode is
    - 32 bit or 16 bit, even address are effectively duplicated, ignore odd addresses.
    - 8 bit, even addresses from within the controller are duplicated into odd address in the view window; old addresses from within the controller are not displayed.
      See Table 23-2 for example.

## 23.3 Initialization and Configuration

To use the USB controller, the peripheral clock must be enabled using the System Control module PCLKCR11 register. In addition, the USB PHY signals must be connected to the respective pins using the GPIO module GPBAMSEL register. Set bits 10 and 11 for USB0DM (GPIO42) and USB0DP (GPIO43).

Set up the auxiliary PLL so a 60MHz output clock is provided to the USB module. This fixed frequency is required for all USB operations. See the *System Control and Interrupts* chapter for more details.

In host mode, the USB controller is responsible for supplying power to the bus. To avoid incorrectly supplying voltage to the bus, the external power control signal, USB0EPEN, must be kept inactive on start-up. This can be done by connecting the USB0EPEN and USB0PFLT pins to the USB controller as soon as possible.

### *23.3.1 Pin Configuration*

To give more flexibility, the signals External Power Enable (EPEN) and Power Fault (PFLT) were not implemented in hardware and the user must implement these signals in software. Examples of how to implement these signals in software can be found in the USB Software Guide located in C2000Ware in the \libraries\communications\usb\ directory.

When using the device controller portion of the USB controller in a system that also provides host functionality, the power to $V_{BUS}$ must be disabled to allow the external host controller to supply power. Usually, the EPEN signal is used to control the external regulator and must be negated to avoid having two devices driving the $V_{BUS}$ power pin on the USB connector.

When the USB controller is acting as a host, the USB controller is in control of two signals that are attached to an external voltage supply that provides power to $V_{BUS}$. The Host controller uses the EPEN signal to enable or disable power to the $V_{BUS}$ pin on the USB connector. An input pin, PFLT, provides feedback when there has been a power fault on $V_{BUS}$. The PFLT signal can be configured to either automatically negate the EPEN signal to disable power, or the PFLT signal can generate an interrupt to the interrupt controller to allow software to handle the power fault condition. The polarity and actions related to both EPEN and PFLT are fully configurable in the USB controller. The controller also provides interrupts on device insertion and removal to allow the Host controller code to respond to these external events.

### 23.3.2 Endpoint Configuration

To start communication in Host or device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a device. In device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because the endpoint is a fixed-function, fixed-FIFO-size endpoint. In device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, or interrupt mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. The maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 4 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a device, the USB device controller's soft connect must be enabled when the device is ready to start communications, indicating to the host controller that the device is ready to start the enumeration process. If operating as a Host controller, the device soft connect must be disabled and power must be provided to $V_{BUS}$ using the USB0EPEN signal.

## 23.4 USB Global Interrupts

Global interrupt enable, flag, and clear registers have been added to make sure that no interrupt is missed. The USB interrupt can be enabled or blocked using the INTEN bit. The INTFLG bit indicates whether an interrupt has occurred or not. Finally, the INTFLGCLR bit clears the INTFLG when a value of 1 is written to the field.

## 23.5 Software

### 23.5.1 USB Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/usb

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

## 23.6 USB Registers

This section describes the Universal Serial Bus (USB) Controller registers.

### 23.6.1 USB Base Address

**Table 23-3. USB Base Address Table (C28)**

| DriverLib Name | Base Address | CPU1 | CPU2 | DMA | CLA | Pipeline Protected |
|---|---|---|---|---|---|---|
| USB_BASE | 0x0004_0000 | YES | - | - | - | YES |

### 23.6.2 USB Register Map

Table 23-4 lists the registers. All addresses given are relative to the USB base address of 0x0000_5E00.

**Note**

The USB controller clock must be enabled before the registers can be programmed (see the *System Control and Interrupt* chapter).

(1) This register is used in Device mode. Some registers are used for both Host and Device mode and can have different bit definitions depending on the mode.

(2) This register is used in Host mode. Some registers are used for both Host and Device mode and can have different bit definitions depending on the mode. The USB controller is in Device mode upon reset, so the reset values shown for these registers apply to the Device mode definition.

### 23.6.3 Register Descriptions

#### 23.6.3.1 USB Device Functional Address Register (USBFADDR), offset 0x000

The USB function address 8-bit register (USBFADDR) contains the 7-bit address of the device part of the transaction.

When the USB controller is being used in device mode (the HOST bit in the USBDEVCTL register is clear), this register must be written with the address received through a SET_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

**Mode(s):** Device

For special considerations when writing this register, see the *Setting the Device Address* in Section 23.2.1.1.4.

USBFADDR is shown in Figure 23-3 and described in Table 23-5.

**Figure 23-3. USB Device Functional Address Register (USBFADDR)**

| 7 | 6 | 0 |
|---|---|---|
| Reserved | FUNCADDR | |
| R-0 | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 23-5. USB Device Functional Address Register (USBFADDR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 7 | Reserved | 0 | Reserved |
| 6-0 | FUNCADDR | 0-7Fh | Function Address of Device as received through SET_ADDRESS. |

#### 23.6.3.2 USB Power Management Register (USBPOWER), offset 0x001

The power management 8-bit register (USBPOWER) is used for controlling SUSPEND and RESUME signaling, and some basic operational aspects of the USB controller.

**Mode(s):** Host Device

USBPOWER in Host Mode is shown in Figure 23-4 and described in Table 23-6.

#### 23.6.3.3 USB Transmit Interrupt Status Register (USBTXIS), offset 0x002

**Note**

Use caution when reading this register. Performing a read may change bit status.

The USB transmit interrupt status 16-bit read-only register (USBTXIS) indicates which interrupts are currently active for control endpoint 0 and the transmit endpoints 1–15. The meaning of the EPn bits in this register is based on the mode of the device. The EP1 through EP15 bits always indicate that the USB controller is sending data; however, in Host mode, the bits refer to OUT endpoints; while in Device mode, the bits refer to IN endpoints.

**Note:**The EP0 bit is special in Host and Device modes and indicates that either a control IN or control OUT endpoint has generated an interrupt. Both the control IN and control OUT endpoints are captured in the EP0 bit of the USBTXIS register.

**Mode(s):** Host Device

USBTXIS is shown in Figure 23-6 and described in Table 23-8.

**Figure 23-6. USB Transmit Interrupt Status Register (USBTXIS)**

#### 23.6.3.4 USB Receive Interrupt Status Register (USBRXIS), offset 0x004

**Note**

Use caution when reading this register. Performing a read may change bit status.

The USB receive interrupt status 16-bit read-only register (USBRXIS) indicates which interrupts are currently active for receive endpoints 1–15.

**Note:** The USBRXIS register does not have a bit for EP0. See the USBTXIS register for EP0 use.

**Note:** Bits relating to endpoints that have not been configured always return 0. All active interrupts are cleared when this register is read.

**Mode(s):** Host Device

USBRXIS is shown in Figure 23-7 and described in Table 23-9.

**Figure 23-7. USB Transmit Interrupt Status Register (USBRXIS)**

#### 23.6.3.5 USB Transmit Interrupt Enable Register

#### (USBTXIE), offset 0x006

The USB transmit interrupt enable 16-bit register (USBTXIE) provides interrupt enable bits for the interrupts in the USBTXIS register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the USBTXIS register is set. When a bit is cleared, the interrupt in the USBTXIS register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

**Note:** The EP0 bit is special in Host and Device modes. Both the control IN and control OUT endpoints are captured in the EP0 bit of the USBTXIE register.

**Mode(s):** Host Device

USBTXIS is shown in Figure 23-8 and described in Table 23-10.

**Figure 23-8. USB Transmit Interrupt Status Enable Register (USBTXIE)**

### 23.6.3.8 USB Interrupt Enable Register (USBIE), offset 0x00B

**CAUTION**
Use caution when reading this register. Performing a read may change bit status.

The USB interrupt enable 8-bit register (USBIE) provides interrupt enable bits for each of the interrupts in USBIS. At reset interrupts 1 and 2 are enabled in device mode.

**Mode(s):** Host Device

USBIE in Host Mode is shown in Figure 23-12 and described in Table 23-14.

**Figure 23-12. USB Interrupt Enable Register (USBIE) in Host Mode**

**Table 23-14. USB Interrupt Enable Register (USBIE) in Host Mode Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 7 | VBUSERR | | Enable VBUS Error Interrupt |
| | | 0 | The VBUSERR interrupt is suppressed and not sent to the interrupt controller. |
| | | 1 | An interrupt is sent to the interrupt controller when the VBUSERR bit in the USBIS register is set. |
| 6 | SESREQ | | Enable Session Request |
| | | 0 | The SESREQ interrupt is suppressed and not sent to the interrupt controller. |
| | | 1 | An interrupt is sent to the interrupt controller when the SESREEQ bit in the USBIS register is set. |
| 5 | DISCON | | Enable Disconnect Interrupt |
| | | 0 | The DISCON interrupt is suppressed and not sent to the interrupt controller. |
| | | 1 | An interrupt is sent to the interrupt controller when the DISCON bit in the USBIS register is set. |
| 4 | CONN | | Enable Connect Interrupt |
| | | 0 | The CONN interrupt is suppressed and not sent to the interrupt controller. |
| | | 1 | An interrupt is sent to the interrupt controller when the CONN bit in the USBIS register is set. |
| 3 | SOF | | Start of Frame |
| | | 0 | The SOF interrupt is suppressed and not sent to the interrupt controller. |
| | | 1 | An interrupt is sent to the interrupt controller when the SOF bit in the USBIS register is set. |
| 2 | BABBLE | | Babble Detected |
| | | 0 | The BABBLE interrupt is suppressed and not sent to the interrupt controller. |
| | | 1 | An interrupt is sent to the interrupt controller when the BABBLE bit in the USBIS register is set. |
| 1 | RESUME | | RESUME Signaling Detected. This interrupt can only be used if the USB controller's system clock is enabled. If the user disables the clock programming, the USBDRRIS, USBDRIM, and USBDRISC registers should be used. |
| | | 0 | The RESUME interrupt is suppressed and not sent to the interrupt controller. |
| | | 1 | An interrupt is sent to the interrupt controller when the RESUME bit in the USBIS register is set. |

#### 23.6.3.9 USB Frame Value Register (USBFRAME), offset 0x00C

The frame number 16-bit read-only register (USBFRAME) holds the last received frame number.

**Mode(s):** Host Device

USBFRAME is shown in Figure 23-14 and described in Table 23-16.

**Figure 23-14. USB Frame Value Register (USBFRAME)**

| 15 | 11 | 10 | 0 |
|---|---|---|---|
| Reserved | | FRAME | |
| R-0 | | R-0 | |

LEGEND: R = Read only; *-n* = value after reset

**Table 23-16. USB Frame Value Register (USBFRAME) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 15-11 | Reserved | 0 | Reserved |
| 10-0 | FRAME | 0-7FFh | Last received frame number |

#### 23.6.3.10 USB Endpoint Index Register (USBEPIDX), offset 0x00E

Each endpoint buffer can be accessed by configuring a FIFO size and starting address. The endpoint index 16-bit register (USBEPIDX) is used with the USBTXFIFOSZ, USBRXFIFOSZ, USBTXFIFOADD, and USBRXFIFOADD registers.

**Mode(s):** Host Device

USBEPIDX is shown in Figure 23-15 and described in Table 23-17.

**Figure 23-15. USB Endpoint Index Register (USBEPIDX)**

#### 23.6.3.11 USB Test Mode Register (USBTEST), offset 0x00F

The USB test mode 8-bit register (USBTEST) is primarily used to put the USB controller into one of the four test modes for operation described in the USB Specification 2.0 , in response to a SET FEATURE: USBTESTMODE command. This register is not used in normal operation.

**Note:** Only one of these bits should be set at any time.

**Mode(s):** Host Device

USBTEST in Host Mode is shown in Figure 23-16 and described in Table 23-18.

**Figure 23-16. USB Test Mode Register (USBTEST) in Host Mode**

| 7 | 6 | 5 | 4 | 0 |
|---|---|---|---|---|

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 23-18. USB Test Mode Register (USBTEST) in Host Mode Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 7 | FORCEH | | Force Host Mode. While in this mode, status of the bus connection may be read using the DEV bit of the USBDEVCTL register. The operating speed is determined from the FORCEFS bit. |
| | | 0 | No effect |
| | | 1 | Forces the USB controller to enter Host mode when the SESSION bit is set, regardless of whether the USB controller is connected to any peripheral. The state of the USB0DP and USB0DM signals is ignored. The USB controller then remains in Host mode until the SESSION bit is cleared, even if a Device is disconnected. If the FORCEH bit remains set, the USB controller re-enters Host mode the next time the SESSION bit is set. |
| 6 | FIFOACC | | FIFO Access |
| | | 0 | No effect |
| | | 1 | Transfers the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO. |
| 5 | FORCEFS | | Force Full-Speed Mode |
| | | 0 | The USB controller operates at Low Speed. |
| | | 1 | Forces the USB controller into Full-Speed mode upon receiving a USB RESET. |

#### 23.6.3.12 USB FIFO Endpoint n Register (USBFIFO[0]-USBFIFO[3])

**Note**

Use caution when reading these registers. Performing a read may change bit status.

The USB FIFO endpoint *n* 32-bit registers (USBFIFO[*n*]) provide an address for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

Transfers to and from FIFOs can be 8-bit, 16-bit or 32-bit as required, and any combination of accesses is allowed provided the data accessed is contiguous. All transfers associated with one packet must be of the same width so that the data is consistently byte-, halfword- or word-aligned. However, the last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

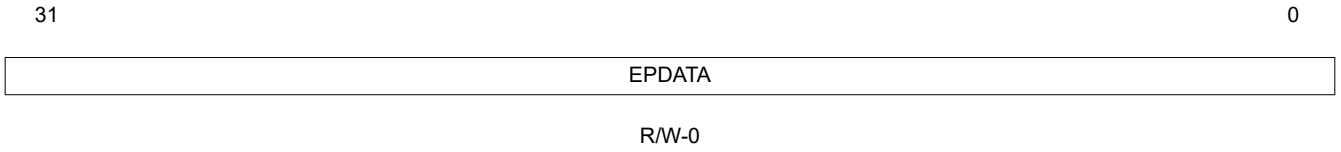
Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering (see *Single-Packet Buffering* in Section 23.2.1.1.2). Burst writing of multiple packets is not supported as flags must be set after each packet is written.

Following a STALL response or a transmit error on endpoint 1–3, the associated FIFO is completely flushed.

**Mode(s):** Host Device

USBFIFO0-3 are shown in Figure 23-18 and described in Table 23-20.

**Figure 23-18. USB FIFO Endpoint *n* Register (USBFIFO[*n*])**



LEGEND: R/W = Read/Write; -*n* = value after reset

**Table 23-20. USB FIFO Endpoint *n* Register (USBFIFO[*n*]) Field Descriptions**

| Bit | Field | Reset | Description |
|---|---|---|---|
| 31-0 | EPDATA | 0x0000.0000 | Endpoint Data. Writing to this register loads the data into the Transmit FIFO and reading unloads data from the Receive FIFO. |

#### 23.6.3.13 USB Device Control Register (USBDEVCTL), offset 0x060

The USB device control 8-bit register (USBDEVCTL) is used for controlling and monitoring the USB VBUS line. If the PHY is suspended, no PHY clock is received and the VBUS is not sampled. In addition, in Host mode, USBDEVCTL provides the status information for the current operating mode (Host or Device) of the USB controller. If the USB controller is in Host mode, this register also indicates if a full- or low-speed Device has been connected.

**Mode(s):** Host Device

USBDEVCTL is shown in Figure 23-19 and described in Table 23-21.

**Figure 23-19. USB Device Control Register (USBDEVCTL)**

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| DEV | FSDEV | LSDEV | VBUS | | HOSTMODE | HOSTREQ | SESSION |
| R-1 | R-0 | R-0 | R-0 | | R-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 23-21. USB Device Control Register (USBDEVCTL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 7 | DEV | | Device mode |
| | | 0 | The USB controller is operating on the OTG A side of the cable. |
| | | 1 | The USB controller is operating on the OTG B side of the cable. |
| | | | Only valid while a session is in progress. |
| 6 | FSDEV | | Full-Speed Device Detected |
| | | 0 | A full-speed Device has not been detected on the port. |
| | | 1 | A full-speed Device has been detected on the port. |
| 5 | LSDEV | | Low-Speed Device Detected |
| | | 0 | A low-speed Device has not been detected on the port. |
| | | 1 | A low-speed Device has been detected on the port. |
| 4-3 | VBUS | 0-3h | These read-only bits encode the current VBus level as follows: |
| | | 0 | Below Session End. VBUS is detected as under 0.5 V. |
| | | 1h | Above Session End, below AValid. VBUS is detected as above 0.5 V and under 1.5 V. |
| | | 2h | Above AValid, below VBusValid. VBUS is detected as above 1.5 V and below 4.75 V. |
| | | 3h | Above VBusValid. VBUS is detected as above 4.75 V. |
| 2 | HOSTMODE | | This read-only bit is set when the USB controller is acting as a Host. |
| | | 0 | The USB controller is acting as a Device. |
| | | 1 | The USB controller is acting as a Host. |
| | | | Only valid while a session is in progress. |
| 1 | HOSTREQ | | When set, the USB controller will initiate the Host Negotiation when Suspend mode is entered. It is cleared when Host Negotiation is completed. |
| | | 0 | No effect |
| | | 1 | Initiates the Host Negotiation when SUSPENDmode is entered. |

Copyright © 2024 Texas Instruments Incorporated

**Table 23-21. USB Device Control Register (USBDEVCTL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 0 | SESSION | | Session Start/End<br>When operating as a Host: |
| | | 0 | When cleared by software, this bit ends a session. |
| | | 1 | When set by software, this bit starts a session. |
| | | | When operating as a Device: |
| | | 0 | The USB controller has ended a session. When the USB controller is in SUSPEND mode, this bit may be cleared by software to perform a software disconnect. |
| | | 1 | The USB controller has started a session. When set by software, the Session Request Protocol is initiated. |
| | | | Clearing this bit when the USB controller is not suspended results in undefined behavior. |

#### 23.6.3.14 USB Transmit Dynamic FIFO Sizing Register (USBTXFIFOSZ), offset 0x062

The USB transmit dynamic FIFO sizing 8-bit register (USBTXFIFOSZ) allows the selected TX endpoint FIFOs to be dynamically sized. USBEPIDX is used to configure each transmit endpoint's FIFO size.

**Mode(s):** Host Device

USBTXFIFOSZ is shown in Figure 23-20 and described in Table 23-22.

**Figure 23-20. USB Transmit Dynamic FIFO Sizing Register (USBTXFIFOSZ)**

### 23.6.3.15 USB Receive Dynamic FIFO Sizing Register (USBRXFIFOSZ), offset 0x063

The USB receive dynamic FIFO sizing 8-bit register (USBRXFIFOSZ) allows the selected RX endpoint FIFOs to be dynamically sized.

**Mode(s):** Host Device

USBRXFIFOSZ is shown in Figure 23-21 and described in Table 23-23.

**Figure 23-21. USB Receive Dynamic FIFO Sizing Register (USBRXFIFOSZ)**

#### 23.6.3.16 USB Transmit FIFO Start Address Register (USBTXFIFOADD), offset 0x064

The USB transmit FIFO start address 16-bit register (USBTXFIFOADD) controls the start address of the selected transmit endpoint FIFOs.

**Mode(s):** Host Device

USBTXFIFOADDR is shown in Figure 23-22 and described in Table 23-24.

**Figure 23-22. USB Transmit FIFO Start Address Register (USBTXFIFOADDR])**

### 23.6.3.17 USB Receive FIFO Start Address Register (USBRXFIFOADD), offset 0x066

The USB receive FIFO start address 16-bit register (USBRXFIFOADD) controls the start address of the selected receive endpoint FIFOs.

**Mode(s):** Host Device

USBRXFIFOADDR is shown in Figure 23-23 and described in Table 23-25.

#### 23.6.3.18 USB Connect Timing Register (USBCONTIM), offset 0x07A

The USB connect timing 8-bit configuration register (USBCONTIM) specifies connection and negotiation delays.

**Mode(s):** Host Device

USBCONTIM is shown in Figure 23-24 and described in Table 23-26.

**Figure 23-24. USB Connect Timing Register (USBCONTIM)**

#### 23.6.3.19 USB Full-Speed Last Transaction to End of Frame Timing Register (USBFSEOF), offset 0x07D

USB full-speed last transaction to end of frame timing 8-bit configuration register (USBFSEOF) specifies the minimum time gap allowed between the start of the last transaction and the EOF for full-speed transactions.

**Mode(s):** Host Device

USBFSEOF is shown in Figure 23-25 and described in Table 23-27.

**Figure 23-25. USB Full-Speed Last Transaction to End of Frame Timing Register (USBFSEOF)**

| 7 | 0 |

| Bit | Field | Reset | Description |
|---|---|---|---|
| 7-0 | FSEOFG | 77h | The full-speed end-of-frame gap field is used during full-speed transactions to configure the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. The default corresponds to 63.46 µs. |

#### 23.6.3.20 USB Low-Speed Last Transaction to End of Frame Timing Register (USBLSEOF), offset 0x07E

The USB low-speed last transaction to end of frame timing 8-bit configuration register (USBLSEOF) specifies the minimum time gap that is to be allowed between the start of the last transaction and the EOF for low-speed transactions.

**Mode(s):** Host Device

USBLSEOF is shown in Figure 23-26 and described in Table 23-28.

**Figure 23-26. USB Low-Speed Last Transaction to End of Frame Timing Register (USBLSEOF)**

#### 23.6.3.21 USB Transmit Functional Address Endpoint n Registers (USBTXFUNCADDR[0]-USBTXFUNCADDR[*n*])

The transmit functional address endpoint *n* 8-bit registers (USBTXFUNCADDR[*n*]) record the address of the target function to be accessed through the associated endpoint (EP*n*). USBTXFUNCADDRx must be defined for each transmit endpoint that is used.

**Note:** USBTXFUNCADDR0 is used for both receive and transmit for endpoint 0.

**Mode(s):** Host

The USBTXFUNCADDR[*n*] registers are shown in Figure 23-27 and described in Table 23-29.

**Figure 23-27. USB Transmit Functional Address Endpoint *n* Registers (USBTXFUNCADDR[*n*])**

| 7 | 6 | 0 |

#### 23.6.3.22 USB Transmit Hub Address Endpoint n Registers (USBTXHUBADDR[0]-USBTXHUBADDR[*n*])

The transmit hub address endpoint *n* 8-bit read/write registers (USBTXHUBADDR[*n*]), like USBTXHUBPORT[*n*], must be written only when a USB device is connected to transmit endpoint EP*n* via a USB 2.0 hub. This register records the address of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** USBTXHUBADDR0 is used for both receive and transmit for endpoint 0.

**Mode(s):** Host

The USBTXHUBADDR[*n*] registers are shown in Figure 23-27 and described in Table 23-29.

**Figure 23-28. USB Transmit Hub Address Endpoint *n* Registers (USBTXHUBADDR[*n*])**

#### 23.6.3.23 USB Transmit Hub Port Endpoint n Registers (USBTXHUBPORT[0]-USBTXHUBPORT[*n*])

The transmit hub port endpoint *n* 8-bit read/write registers (USBTXHUBPORT[*n*]), like USBTXHUBADDR[*n*], must be written only when a full- or low-speed Device is connected to transmit endpoint EP*n* with a USB 2.0 hub. This register records the port of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** USBTXHUBPORT0 is used for both receive and transmit for endpoint 0.

**Mode(s):** Host

The USBTXHUBPORT*n* registers are shown in Figure 23-29 and described in Table 23-31.

#### 23.6.3.24 USB Receive Functional Address Endpoint n Registers (USBRXFUNCADDR[1]-USBRXFUNCADDR[*n*])

The receive functional address endpoint *n* 8-bit read/write registers (USBRXFUNCADDR[*n*]) record the address of the target function to be accessed through the associated endpoint (EP*n*). USBRXFUNCADDRx must be defined for each receive endpoint that is used.

**Note:** USBTXFUNCADDR0 is used for both receive and transmit for endpoint 0.

**Mode(s):** Host

The USBRXFUNCADDR[*n*] registers are shown in Figure 23-30 and described in Table 23-32.

**Figure 23-30. USB Receive Functional Address Endpoint *n* Registers (USBFIFO[*n*])**

#### 23.6.3.25 USB Receive Hub Address Endpoint n Registers (USBRXHUBADDR[1]-USBRXHUBADDR[*n*])

The receive hub address endpoint *n* 8-bit read/write registers (USBRXHUBADDR[*n*]), like [*n*], must be written only when a full- or low-speed Device is connected to receive endpoint EP*n* with a USB 2.0 hub. Each register records the address of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** USBTXHUBADDR0 is used for both receive and transmit for endpoint 0.

**Mode(s):** Host

The USBRXHUBADDR[*n*] registers are shown in Figure 23-31 and described in Table 23-33.

#### 23.6.3.26 USB Receive Hub Port Endpoint n Register (USBRXHUBPORT[1]-USBRXHUBPORT[*n*])

The receive hub port endpoint *n* 8-bit read/write registers (USBRXHUBPORT[*n*]), like USBRXHUBADDR[*n*], must be written only when a full- or low-speed device is connected to receive endpoint EP*n* with a USB 2.0 hub. Each register records the port of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** USBTXHUBPORT0 is used for both receive and transmit for endpoint 0.

**Mode(s):** Host

The USBRXHUBPORT*n* registers are shown in Figure 23-32 and described in Table 23-34.

### 23.6.3.27 USB Control and Status Endpoint 0 Low Register (USBCSRL0), offset 0x102

The USB control and status endpoint 0 low 8-bit register (USBCSRL0) provides control and status bits for endpoint 0.

**Mode(s):** Host Device

USBCSRL0 in Host mode is shown in Figure 23-33 and described in Table 23-35.

**Figure 23-33. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Host Mode**

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; *-n* = value after reset

**Table 23-35. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Host Mode Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 7 | NAKTO | | NAK Timeout. Software must clear this bit to allow the endpoint to continue. |
| | | 0 | No timeout |
| | | 1 | Indicates that endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the USBNAKLMT register. |
| 6 | STATUS | | Status Packet. Setting this bit ensures that the DT bit is set in the USBCSRH0 register so that a DATA1 packet is used for the STATUS stage transaction. |
| | | 0 | No transaction |
| | | 1 | Initiates a STATUS stage transaction. This bit must be set at the same time as the TXRDY or REQPKT bit is set. |
| | | | This bit is automatically cleared when the STATUS stage is over. |
| 5 | REQPKT | | Request Packet. This bit is cleared when the RXRDY bit is set. |
| | | 0 | No request |
| | | 1 | Requests an IN transaction. |
| 4 | ERROR | | Error. Software must clear this bit. |
| | | 0 | No error |
| | | 1 | Three attempts have been made to perform a transaction with no response from the peripheral. The EP0 bit in the USBTXIS register is also set in this situation. |
| 3 | SETUP | | Setup Packet. Setting this bit always clears the DT bit in the USBCSRH0 register to send a DATA0 packet. |
| | | 0 | Sends an OUT token. |
| | | 1 | Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. |
| 2 | STALLED | | Endpoint Stalled. Software must clear this bit. |
| | | 0 | No handshake has been received. |
| | | 1 | A STALL handshake has been received. |
| 1 | TXRDY | | Transmit Packet Ready. If both the TXRDY and SETUP bits are set, a setup packet is sent. If just TXRDY is set, an OUT packet is sent. |
| | | 0 | No transmit packet is ready. |
| | | 1 | Software sets this bit after loading a data packet into the TX FIFO. The EP0 bit in the USBTXIS register is also set in this situation. |

Copyright © 2024 Texas Instruments Incorporated

**Table 23-35. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Host Mode Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 0 | RXRDY | | Receive Packet Ready. Software must clear this bit after the packet has been read from the FIFO to acknowledge that the data has been read from the FIFO. |
| | | 0 | No receive packet has been received. |
| | | 1 | Indicates that a data packet has been received in the RX FIFO. The EP0 bit in the USBTXIS register is also set in this situation. |

USBCSRL0 in Device mode is shown in Figure 23-34 and described in Table 23-36.

**Figure 23-34. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Device Mode**

**Table 23-36. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Device Mode Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 7 | SETENDC | | Setup End Clear |
| | | 0 | No effect |
| | | 1 | Writing a 1 to this bit clears the SETEND bit. |
| 6 | RXRDYC | | RXRDY Clear |
| | | 0 | No effect |
| | | 1 | Writing a 1 to this bit clears the RXRDY bit. |
| 5 | STALL | | Send Stall. |
| | | 0 | No effect |
| | | 1 | Terminates the current transaction and transmits the STALL handshake. |
| | | | This bit is cleared automatically after the STALL handshake is transmitted. |
| 4 | SETEND | | Setup end. |
| | | 0 | A control transaction has not ended or ended after the DATAEND bit was set. |
| | | 1 | A control transaction has ended before the DATAEND bit has been set. The EP0 bit in the USBTXIS register is also set in this situation. |
| | | | This bit is cleared by writing a 1 to the SETENDC bit. |
| 3 | DATAEND | | Data end. |
| | | 0 | No effect |
| | | 1 | Set this bit in the following situations:<br>• When setting TXRDY for the last data packet<br>• When clearing RXRDY after unloading the last data packet<br>• When setting TXRDY for a zero-length data packet<br>This bit is cleared automatically. |
| 2 | STALLED | | Endpoint Stalled. Software must clear this bit. |
| | | 0 | A STALL handshake has not been transmitted. |
| | | 1 | A STALL handshake has been transmitted. |

### 23.6.3.28 USB Control and Status Endpoint 0 High Register (USBCSRH0), offset 0x103

The USB control and status endpoint 0 high 8-bit register (USBCSRH0) provides control and status bits for endpoint 0.

**Mode(s):** Host Device

USBCSRH0 in Host mode is shown in Figure 23-35 and described in Table 23-37.

**Figure 23-35. USB Control and Status Endpoint 0 High Register (USBCSRH0) in Host Mode**

| Bit | Field | Value | Description |
|---|---|---|---|
| 7-3 | Reserved | 0 | Reserved |
| 2 | DTWE | | Data Toggle Write Enable. This bit is automatically cleared once the new value is written. |
| | | 0 | The DT bit cannot be written. |
| | | 1 | Enables the current state of the endpoint 0 data toggle to be written (see DT bit). |
| 1 | DT | | Data Toggle. When read, this bit indicates the current state of the endpoint 0 data toggle.<br>If DTWE is set, this bit may be written with the required setting of the data toggle. If DTWE is Low, this bit cannot be written. Care should be taken when writing to this bit as it should only be changed to RESET USB endpoint 0. |
| 0 | FLUSH | | Flush FIFO. This bit is automatically cleared after the flush is performed. |
| | | 0 | No effect |
| | | 1 | Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared.<br>**Note:** This bit should only be set when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted. |

Copyright © 2024 Texas Instruments Incorporated

USBCSRH0 in Device mode is shown in Figure 23-36 and described in Table 23-38.

#### 23.6.3.29 USB Receive Byte Count Endpoint 0 Register (USBCOUNT0), offset 0x108

The USB receive byte count endpoint 0 8-bit read-only register (USBCOUNT0) indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the RXRDY bit is set.

**Mode(s):** Host Device

USBCOUNT0 is shown in Figure 23-37 and described in Table 23-39 .

**Figure 23-37. USB Receive Byte Count Endpoint 0 Register (USBCOUNT0)**

| 7 | 6 | 0 |
|---|---|---|

| Bit | Field | Value | Description |
|---|---|---|---|
| 7 | Reserved | 0 | Reserved |
| 6-0 | COUNT | 0 | FIFO Count. COUNT is a read-only value that indicates the number of received data bytes in the endpoint 0 FIFO. |

#### 23.6.3.30 USB Type Endpoint 0 Register (USBTYPE0), offset 0x10A

The USB type endpoint 0 8-bit register (USBTYPE0) must be written with the operating speed of the targeted Device being communicated with using endpoint 0.

**Mode(s):** Host

USBTYPE0 is shown in Figure 23-38 and described in Table 23-40.

**Figure 23-38. USB Type Endpoint 0 Register (USBTYPE0)**

#### 23.6.3.31 USB NAK Limit Register (USBNAKLMT), offset 0x10B

The USB NAK limit 8-bit read-only register (USBNAKLMT) sets the number of frames after which endpoint 0 should time out on receiving a stream of NAK responses. (Equivalent settings for other endpoints can be made through their USBTXINTERVAL[*n*] and USBRXINTERVAL[*n*] registers.)

The number of frames selected is 2(m-1) (where m is the value set in the register, with valid values of 2–16). If the Host receives NAK responses from the target for more frames than the number represented by the limit set in this register, the endpoint is halted.

**Note:** A value of 0 or 1 disables the NAK timeout function.

**Mode(s):** Host

USBNAKLMT is shown in Figure 23-39 and described in Table 23-41.

**Figure 23-39. USB NAK Limit Register (USBNAKLMT)**

| 7 | 5 | 4 | 0 |

#### 23.6.3.32 USB Maximum Transmit Data Endpoint n Registers (USBTXMAXP[1]-USBTXMAXP[*n*])

The USB maximum transmit data endpoint *n* 16-bit registers (USBTXMAXP[*n*]) define the maximum amount of data that can be transferred through the selected transmit endpoint in a single operation.

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the USB Specification on packet sizes for bulk and interrupt transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

If this register is changed after packets have been sent from the endpoint, the transmit endpoint FIFO must be completely flushed (using the FLUSH bit in USBTXCSRLn) after writing the new value to this register.

**Note:** USBTXMAXP[*n*] must be set to an even number of bytes for proper interrupt generation in DMA Basic Mode.

**Mode(s):** Host Device

The USBTXMAXP[*n*] registers are shown in Figure 23-40 and described in Table 23-42.

**Figure 23-40. USB Maximum Transmit Data Endpoint *n* Registers (USBTXMAXP[*n*])**

#### 23.6.3.33 USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[1]-USBTXCSRL[*n*])

The USB transmit control and status endpoint *n* low 8-bit registers (USBTXCSRL[*n*]) provide control and status bits for transfers through the currently selected transmit endpoint.

**Mode(s):** Host Device

The USBTXCSRL[*n*] registers in Host Mode are shown in Figure 23-41 and described in Table 23-43.

**Figure 23-41. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Host Mode**

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| NAKTO | CLRDT | STALLED | SETUP | FLUSH | ERROR | FIFONE | TXRDY |
| R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; -*n* = value after reset

**Table 23-43. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Host Mode Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 7 | NAKTO | | NAK Timeout. Software must clear this bit to allow the endpoint to continue. |
| | | 0 | No timeout |
| | | 1 | Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[*n*] register. |
| 6 | CLRDT | | Clear DataToggle |
| | | 0 | No effect |
| | | 1 | Writing a 1 to this bit clears the DT bit in the USBTXCSRH[*n*] register. |
| 5 | STALLED | | Endpoint Stalled. Software must clear this bit. |
| | | 0 | A STALL handshake has not been received |
| | | 1 | Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared. |
| 4 | SETUP | | Setup Packet. |
| | | 0 | No SETUP token is sent. |
| | | 1 | Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. |
| | | | **Note:** Setting this bit also clears the DT bit in the USBTXCSRH[*n*] register. |
| 3 | FLUSH | | Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. |
| | | 0 | No effect |
| | | 1 | Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. |
| | | | **Note:** This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted. |
| 2 | ERROR | | Error. Software must clear this bit. |
| | | 0 | No error |
| | | 1 | Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed in this situation. |
| | | | **Note:** This bit is valid only when the endpoint is operating in Bulk or Interrupt mode. |
| 1 | FIFONE | | FIFO Not Empty |
| | | 0 | The FIFO is empty |
| | | 1 | At least one packet is in the transmit FIFO. |

#### 23.6.3.34 USB Transmit Control and Status Endpoint n High Register (USBTXCSRH[1]-USBTXCSRH[*n*])

The USB transmit control and status endpoint *n* high 8-bit registers (USBTXCSRH[*n*]) provide additional control for transfers through the currently selected transmit endpoint.

**Mode(s):** Host Device

The USBTXCSRH[*n*] registers in Host Mode are shown in Figure 23-43 and described in Table 23-45.

**Figure 23-43. USB Transmit Control and Status Endpoint n High Register (USBTXCSRH[*n*]) in Host Mode**

#### 23.6.3.35 USB Maximum Receive Data Endpoint n Registers (USBRXMAXP[1]-USBRXMAXP[*n*])

The USB maximum receive data endpoint *n* 16-bit registers (USBRXMAXP[*n*]) define the maximum amount of data that can be transferred through the selected receive endpoint in a single operation.

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the USB Specification on packet sizes for bulk and interrupt transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

**Note:** USBRXMAXP[*n*] must be set to an even number of bytes for proper interrupt generation in DMA Basic Mode.

**Mode(s):** Host Device

The USBRXMAXP[*n*] registers are shown in Figure 23-45 and described in Table 23-47.

**Figure 23-45. USB Maximum Receive Data Endpoint *n* Registers (USBRXMAXP[*n*])**

#### 23.6.3.36 USB Receive Control and Status Endpoint n Low Register (USBRXCSRL[1]-USBRXCSRL[*n*])

The USB receive control and status endpoint *n* low 8-bit register (USBRXCSRL[*n*]) provides control and status bits for transfers through the currently selected receive endpoint.

**Mode(s):** Host Device

The USBCSRL[*n*] registers in Host mode are shown in Figure 23-46 and described in Table 23-48.

**Figure 23-46. USB Receive Control and Status Endpoint n Low Register (USBRXCSRL[*n*]) in Host Mode**

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| CLRDT | STALLED | REQPKT | FLUSH | DATAERR / NAKTO | ERROR | FULL | RXRDY |
| W1C-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; W = Write only; -*n* = value after reset

**Table 23-48. USB Receive Control and Status Endpoint n Low Register (USBRXCSRL[*n*]) in Host Mode Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 7 | NAKTO | | Clear Data Toggle. |
| | | 0 | No effect |
| | | 1 | Writing a 1 to this bit clears the DT bit in the USBRXCSRH[*n*] register. |
| 6 | STALLED | | Endpoint Stalled. Software must clear this bit. |
| | | 0 | No handshake has been received. |
| | | 1 | A STALL handshake has been received. The EP*n* bit in the USBRXIS register is also set. |
| 5 | REQPKT | | Request Packet. This bit is cleared when the RXRDY bit is set. |
| | | 0 | No request |
| | | 1 | Requests an IN transaction. |
| 4 | FLUSH | | Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO.<br>**Note:**This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. |
| | | 0 | No effect |
| | | 1 | Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared. |
| 3 | DATAERR / NAKTO | | Data Error / NAK Timeout |
| | | 0 | Normal operation |
| | | 1 | Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[*n*] register. Software must clear this bit to allow the endpoint to continue. |
| 2 | ERROR | | Error. Software must clear this bit.<br>**Note:** This bit is only valid when the receive endpoint is operating in Bulk or Interrupt mode. |
| | | 0 | No error |
| | | 1 | Three attempts have been made to receive a packet and no data packet has been received. The EP*n* bit in the USBRXIS register is set in this situation. |
| 1 | FULL | | FIFO Full |
| | | 0 | The receive FIFO is not full. |
| | | 1 | No more packets can be loaded into the receive FIFO. |

#### 23.6.3.38 USB Receive Byte Count Endpoint n Register (USBRXCOUNT[1]-USBRXCOUNT[*n*])

The USB receive byte count endpoint *n* 16-bit read-only registers hold the number of data bytes in the packet currently in line to be read from the receive FIFO. If the packet is transmitted as multiple bulk packets, the number given is for the combined packet.

**Note:** The value returned changes as the FIFO is unloaded and is only valid while the RXRDY bit in the USBRXCSRLn register is set.

**Mode(s):** Host Device

The USBRXCOUNT[*n*] registers are shown in Figure 23-50 and described in Table 23-52.

**Figure 23-50. USB Receive Byte Count Endpoint n Register (USBRXCOUNT[*n*])**

#### 23.6.3.39 USB Host Transmit Configure Type Endpoint n Registers (USBTXTYPE[1]-USBTXTYPE[*n*])

The USB host transmit configure type endpoint *n* 8-bit registers (USBTXTYPE[*n*]) must be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently selected transmit endpoint, and its operating speed.

**Mode(s):** Host

The USBTXTYPE[*n*] registers are shown in Figure 23-51 and described in Table 23-53.

**Figure 23-51. USB Host Transmit Configure Type Endpoint n Registers (USBTXTYPE[*n*])**

#### 23.6.3.40 USB Host Transmit Interval Endpoint n Registers (USBTXINTERVAL[1]-USBTXINTERVAL[*n*])

The USB host transmit interval endpoint *n* 8-bit registers (USBTXINTERVAL[*n*]), for interrupt transfers, define the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The USBTXINTERVAL[*n*] registers values define a number of frames, as follows:

**Table 23-54. USB Host Transmit Interval Endpoint *n* Registers (USBTXINTERVAL[*n*]) Frame Numbers**

| Transfer Type | Speed | Valid Values (m) | Interpretation |
|---|---|---|---|
| Interrupt | Low-speed or Full-speed | 0x01-0xFF | The polling interval is *m* frames. |
| Bulk | Full-speed | 0x02-0x10 | The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function. |

**Mode(s):** Host

The USBTXINTERVAL[*n*] registers are shown in Figure 23-51 and described in Table 23-53.

**Figure 23-52. USB Host Transmit Interval Endpoint *n* Registers (USBTXINTERVAL[*n*])**

| 7 | 0 |
|---|---|
| TXPOLL / NAKLMT | |
| R/W-0 | |

#### 23.6.3.41 USB Host Configure Receive Type Endpoint n Register (USBRXTYPE[1]-USBRXTYPE[*n*])

The USB host configure receive type endpoint *n* 8-bit registers (USBRXTYPE[*n*]) must be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently selected receive endpoint, and its operating speed.

**Mode(s):** Host

The USBRXTYPE[*n*] registers are shown in Figure 23-53 and described in Table 23-56.

**Figure 23-53. USB Host Configure Receive Type Endpoint n Register (USBRXTYPE[*n*])**

| 7 | 6 | 5 | 4 | 3 | 0 |
|---|---|---|---|---|---|
| SPEED | | PROTO | | TEP | |
| R/W-0 | | R/W-0 | | R/W-0 | |

LEGEND: R/W = Read/Write; -*n* = value after reset

#### 23.6.3.42 USB Host Receive Polling Interval Endpoint n Registers (USBRXINTERVAL[1]-USBRXINTERVAL[*n*])

The USB host receive polling interval endpoint *n* 8-bit registers (USBRXINTERVAL[*n*]), for interrupt transfers, define the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The USBRXINTERVAL[*n*] registers values define a number of frames, as follows:

**Table 23-57. USB Host Receive Polling Interval Endpoint *n* Registers (USBRXINTERVAL[*n*]) Frame Numbers**

| Transfer Type | Speed | Valid Values (m) | Interpretation |
|---|---|---|---|
| Interrupt | Low-speed or Full-speed | 0x01-0xFF | The polling interval is *m* frames. |
| Bulk | Full-speed | 0x02-0x10 | The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function. |

**Mode(s):** Host

The USBRXINTERVAL[*n*] registers are shown in Figure 23-51 and described in Table 23-53.

**Figure 23-54. USB Host Receive Polling Interval Endpoint *n* Registers (USBRXINTERVAL[*n*])**

#### 23.6.3.43 USB Request Packet Count in Block Transfer Endpoint n Registers (USBRQPKTCOUNT[1]-USBRQPKTCOUNT[*n*])

The USB receive packet count in block transfer endpoint *n* 16-bit read/writer registers are used in Host mode to specify the number of packets that are to be transferred in a block transfer of one or more bulk packets to receive endpoint *n*. The USB controller uses the value recorded in this register to determine the number of requests to issue where the AUTORQ bit in the USBRXCSRH[*n*] register has been set. For more information about IN transactions as a host, see Section 23.2.2.2.

**Note:** Multiple packets combined into a single bulk packet within the FIFO count as one packet.

**Mode(s):** Host

The USBRQPKTCOUNT[*n*] registers are shown in Figure 23-55 and described in Table 23-59.

**Figure 23-55. USB Request Packet Count in Block Transfer Endpoint *n* Registers (USBRQPKTCOUNT[*n*])**

#### 23.6.3.44 USB Receive Double Packet Buffer Disable Register (USBRXDPKTBUFDIS), offset 0x340

The USB receive double packet buffer disable 16-bit register (USBRXDPKTBUFDIS) indicates which of the receive endpoints have disabled the double-packet buffer functionality (see *Double-Packet Buffering* in Section 23.2.1.1.1).

**Note:** The USBRXDPKTBUFDIS register is not applicable to the control IN and control OUT endpoints, therefore the EP0 bit does not exist for the USBRXDPKTBUFDIS register.

**Mode(s):** Host Device

USBRXDPKTBUFDIS is shown in Figure 23-56 and described in Table 23-60.

**Figure 23-56. USB Receive Double Packet Buffer Disable Register (USBRXDPKTBUFDIS)**

#### 23.6.3.45 USB Transmit Double Packet Buffer Disable Register (USBTXDPKTBUFDIS), offset 0x342

The USB transmit double packet buffer disable 16-bit register (USBTXDPKTBUFDIS) indicates which of the transmit endpoints have disabled the double-packet buffer functionality (see *Double-Packet Buffering* in Section 23.2.1.1.1).

**Note:** The USBTXDPKTBUFDIS register is not applicable to the control IN and control OUT endpoints, therefore the EP0 bit does not exist for the USBTXDPKTBUFDIS register.

**Mode(s):** Host Device

USBTXDPKTBUFDIS is shown in Figure 23-57 and described in Table 23-61.

### 23.6.3.46 USB External Power Control Register (USBEPC), offset 0x400

The USB external power control 32-bit register (USBEPC) specifies the function of the two-pin external power interface (USB0EPEN and USB0PFLT). The assertion of the power fault input may generate an automatic action, as controlled by the hardware configuration registers. The automatic action is necessary because the fault condition may require a response faster than one provided by firmware.

**Mode(s):** Host Device

USBEPC is shown in Figure 23-58 and described in Table 23-62.

**Figure 23-58. USB External Power Control Register (USBEPC)**

| 31 | 10 | 9 | 8 |
|---|---|---|---|
| Reserved | | PFLTACT | |

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| Reserved | PFLTAEN | PFLTSEN | PFLTEN | Reserved | EPENDE | EPEN | |
| R-0 | R/W-0 | R/W-0 | R/W-0 | R-0 | R/W-0 | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 23-62. USB External Power Control Register (USBEPC) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-10 | Reserved | 0 | Reserved |
| 9-8 | PFLTACT | | Power Fault Action. This bit field specifies how the USB0EPEN signal is changed when detecting a USB power fault. |
| | | 0h | Unchanged. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits. |
| | | 1h | Tristate. USB0EPEN is undriven (tristate). |
| | | 2h | Low. USB0EPEN is driven Low. |
| | | 3h | High. USB0EPEN is driven High. |
| 7 | Reserved | 0 | Reserved |
| 6 | PFLTAEN | | Power Fault Action Enable. This bit specifies whether a USB power fault triggers any automatic corrective action regarding the driven state of the USB0EPEN signal. |
| | | 0 | Disabled. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits. |
| | | 1 | Enabled. The USB0EPEN output is automatically changed to the state specified by the PFLTACT field. |
| 5 | PFLTSEN | | Power Fault Sense. This bit specifies the logical sense of the USB0PFLT input signal that indicates an error condition.<br>The complementary state is the inactive state. |
| | | 0 | Low Fault. If USB0PFLT is driven Low, the power fault is signaled internally (if enabled by the PFLTEN bit). |
| | | 1 | High Fault. If USB0PFLT is driven High, the power fault is signaled internally (if enabled by the PFLTEN bit). |
| 4 | PFLTEN | | Power Fault Input Enable. This bit specifies whether the USB0PFLT input signal is used in internal logic. |
| | | 0 | Not Used. The USB0PFLT signal is ignored. |
| | | 1 | Used. The USB0PFLT signal is used internally |
| 3 | Reserved | 0 | Reserved |

Copyright © 2024 Texas Instruments Incorporated

**Table 23-62. USB External Power Control Register (USBEPC) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 2 | EPENDE | | EPEN Drive Enable. This bit specifies whether the USB0EPEN signal is driven or undriven (tristate). When driven, the signal value is specified by the EPEN field. When not driven, the EPEN field is ignored and the USB0EPEN signal is placed in a high-impedance state.<br>The USB0EPEN signal is undriven at reset because the sense of the external power supply enable is unknown. By adding the high-impedance state, system designers can bias the power supply enable to the disabled state using a large resistor (100 kΩ) and later configure and drive the output signal to enable the power supply. |
| | | 0 | Not Driven. The USB0EPEN signal is high impedance. |
| | | 1 | Driven. The USB0EPEN signal is driven to the logical value specified by the value of the EPEN field. |
| 1-0 | EPEN | | External Power Supply Enable Configuration. This bit field specifies and controls the logical value driven on the USB0EPEN signal. |
| | | 0h | Power Enable Active Low. The USB0EPEN signal is driven Low if the EPENDE bit is set. |
| | | 1h | Power Enable Active High. The USB0EPEN signal is driven High if the EPENDE bit is set. |
| | | 2h | Power Enable High if VBUS Low. The USB0EPEN signal is driven High when the A device is not recognized. |
| | | 3h | Power Enable High if VBUS High. The USB0EPEN signal is driven High when the A device is recognized. |

### 23.6.3.47 USB External Power Control Raw Interrupt Status Register (USBEPCRIS), offset 0x404

The USB external power control raw interrupt status 32-bit register (USBEPCRIS) specifies the unmasked interrupt status of the two-pin external power interface.

**Mode(s):** Host Device

USBEPCRIS is shown in Figure 23-59 and described in Table 23-63.

**Figure 23-59. USB External Power Control Raw Interrupt Status Register (USBEPCRIS)**

| 31 | 1 | 0 |
|---|---|---|

#### 23.6.3.48 USB External Power Control Interrupt Mask Register (USBEPCIM), offset 0x408

The USB external power control interrupt mask 32-bit register (USBEPCIM) specifies the interrupt mask of the two-pin external power interface.

**Mode(s):** Host Device

USBEPCIM is shown in Figure 23-60 and described in Table 23-64.

**Figure 23-60. USB External Power Control Interrupt Mask Register (USBEPCIM)**

| 31 | 1 | 0 |

### 23.6.3.49 USB External Power Control Interrupt Status and Clear Register (USBEPCISC), offset 0x40C

The USB external power control interrupt status and clear 32-bit register (USBEPCISC) specifies the unmasked interrupt status of the two-pin external power interface.

**Mode(s):** Host Device

USBEPCISC is shown in Figure 23-61 and described in Table 23-65.

**Figure 23-61. USB External Power Control Interrupt Status and Clear Register (USBEPCISC)**

| 31-1 | Reserved | 0 | Reserved. Reset is 0x0000.000. |
| 0 | PF | | USB Power Fault Interrupt Status and Clear.<br>This bit is cleared by writing a 1. Clearing this bit also clears the PF bit in the USBEPCISC register. |
| | | 0 | The PF bits in the USBEPCRIS and USBEPCIM registers are set, providing an interrupt to the interrupt controller. |
| | | 1 | No interrupt has occurred or the interrupt is masked. |

Copyright © 2024 Texas Instruments Incorporated

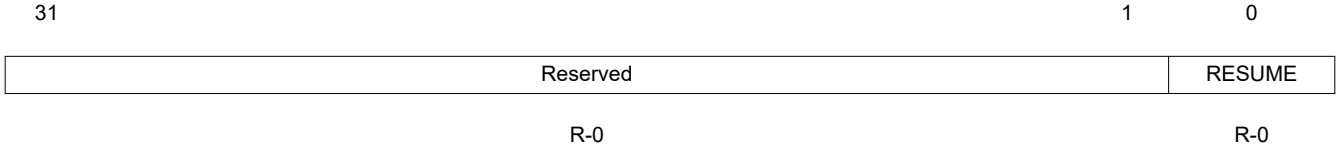
#### 23.6.3.50 USB Device RESUME Raw Interrupt Status Register (USBDRRIS), offset 0x410

The USB device RESUME raw interrupt status register (USBDRRIS) is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

**Mode(s):** Host Device

USBDRRIS is shown in Figure 23-62 and described in Table 23-66.

**Figure 23-62. USB Device RESUME Raw Interrupt Status Register (USBDRRIS)**



LEGEND: R = Read only; *-n* = value after reset

**Table 23-66. USB Device RESUME Raw Interrupt Status Register (USBDRRIS) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved. Reset is 0x0000.000. |
| 0 | PF | | RESUME Interrupt Status<br>This bit is cleared by writing a 1 to the RESUME bit in the USBDRISC register. |
| | | 0 | A RESUME status has been detected. |
| | | 1 | An interrupt has not occurred. |

Copyright © 2024 Texas Instruments Incorporated

### 23.6.3.51 USB Device RESUME Raw Interrupt Mask Register (USBDRIM), offset 0x414

The USB device RESUME raw interrupt status register (USBDRIM) is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

**Mode(s):** Host Device

USBDRIM is shown in Figure 23-63 and described in Table 23-67.

**Figure 23-63. USB Device RESUME Raw Interrupt Status Register (USBDRRIS)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | RESUME |

|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved. Reset is 0x0000.000. |
| 0 | PF | | RESUME Interrupt Mask |
| | | 0 | The raw interrupt signal from a detected RESUME is sent to the interrupt controller. This bit should only be set when a SUSPEND has been detected (the SUSPEND bit in the USBIS register is set). |
| | | 1 | A detected RESUME does not affect the interrupt status. |

Copyright © 2024 Texas Instruments Incorporated

#### 23.6.3.52 USB Device RESUME Interrupt Status and Clear Register (USBDRISC), offset 0x418

The USB device RESUME interrupt status and clear register (USBDRRIS) is the raw interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

**Mode(s):** Host Device

USBDRISC is shown in Figure 23-64 and described in Table 23-68.

**Figure 23-64. USB Device RESUME Interrupt Status and Clear Register (USBDRISC)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | RESUME |

#### 23.6.3.53 USB General-Purpose Control and Status Register (USBGPCS), offset 0x41C

The USB general-purpose control and status register (USBGPCS) provides the state of the internal ID signal.

When the USB controller is used as either a dedicated Host or Device, the DEVMODOTG and DEVMOD bits in the USB General-Purpose Control and Status (USBGPCS) register should be used to connect the ID inputs to fixed levels internally. For proper self-powered Device operation, the VBUS value must be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

**Mode(s):** Host Device

USBGPCS is shown in Figure 23-65 and described in Table 23-69.

**Figure 23-65. USB General-Purpose Control and Status Register (USBGPCS)**

| 31 | 2 | 1 | 0 |

## 24.1 Introduction

The universal parallel port (uPP) peripheral is a high-speed parallel interface with dedicated data lines and minimal control signals. It is designed to interface cleanly with high-speed analog-to-digital converters (ADCs) or digital-to-analog converters (DACs) with 8-bit data width. It can also be interconnected with field-programmable gate arrays (FPGAs) or other uPP devices to achieve high-speed digital data transfer. It can operate in receive mode or transmit mode (simplex mode).

This peripheral includes an internal DMA controller to maximize throughput and minimize CPU overhead during high-speed data transmission. All uPP transactions uses internal DMA to feed data to or retrieve data from the I/O channels. Even though there is only one I/O channel, DMA controller includes two DMA channels to supports data interleave mode, in which all DMA resources service a single I/O channel.

On this device, uPP is dedicated resource for CPU1 subsystem and CPU1, CPU1.CLA1 and CPU1.DMA have access to this module. There are two dedicated DATA RAMs (also known as MSG RAMs), each of 512B, tightly coupled with uPP module (one for each, TX and RX). These DATA RAMs are used to store bulk of data to avoid frequent interruption to CPU. Only CPU1 and CPU1.CLA1 has access to these DATA RAMs. Figure 24-1 shows the integration of uPP on this device.

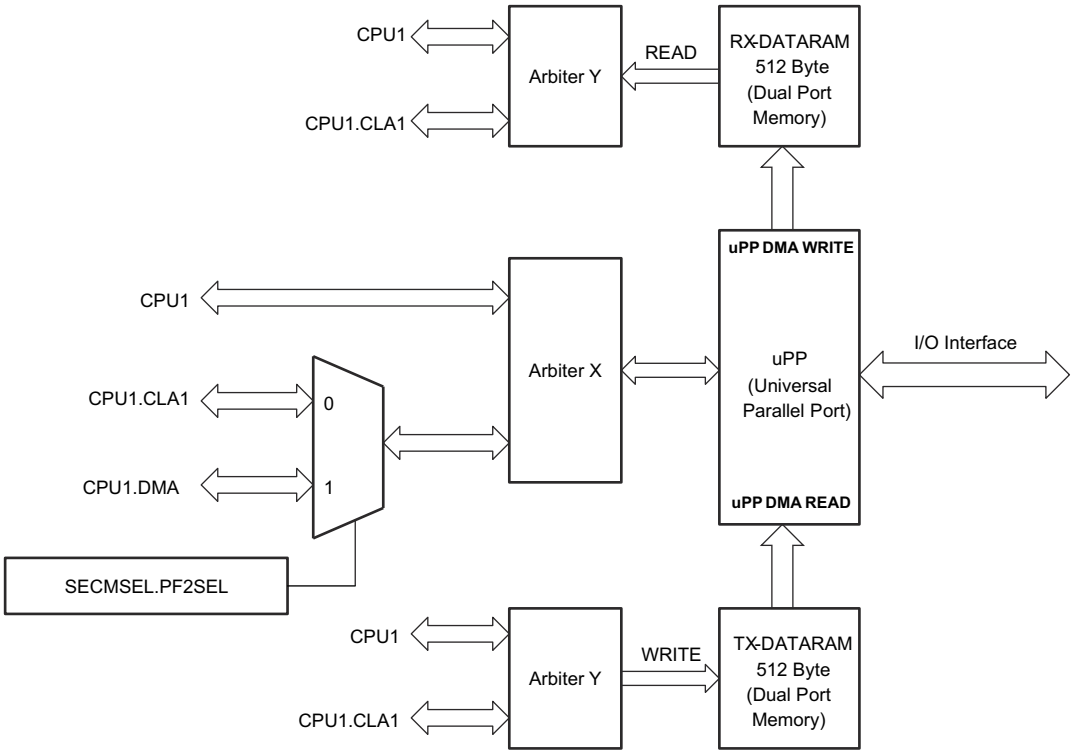

**Figure 24-1. uPP Integration**

**Note**

In some other TI devices, uPP IP is also called the Radio Peripheral Interface (RPI) module.

### *24.1.1 Features Supported*

- Supports mainstream high-speed data converters with parallel conversion interface.
- Supports mainstream high-speed streaming interface with frame START indication.
- Supports mainstream high-speed streaming interface with data ENABLE indication.
- Supports mainstream high-speed streaming interface with synchronization WAIT signal.
- Supports SDR (single-data-rate) or DDR (double-data-rate, interleaved) interface.
- Supports multiplexing of interleaved data in SDR transmit case.

Copyright © 2024 Texas Instruments Incorporated

- Supports de-multiplexing and multiplexing of interleaved data in DDR case.
- Supports I/O interface clock frequency up to 50 MHz for SDR case, and 25 MHz for DDR.
- Supports single-channel 8-bit input receive or output transmit mode.
- Max throughput is 50MB/s for pure read or pure write.
- Available as a DSP to FPGA general purpose streaming interface.

## 24.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification m,ust be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 24.3 Functional Description

### *24.3.1 Functional Block Diagram*

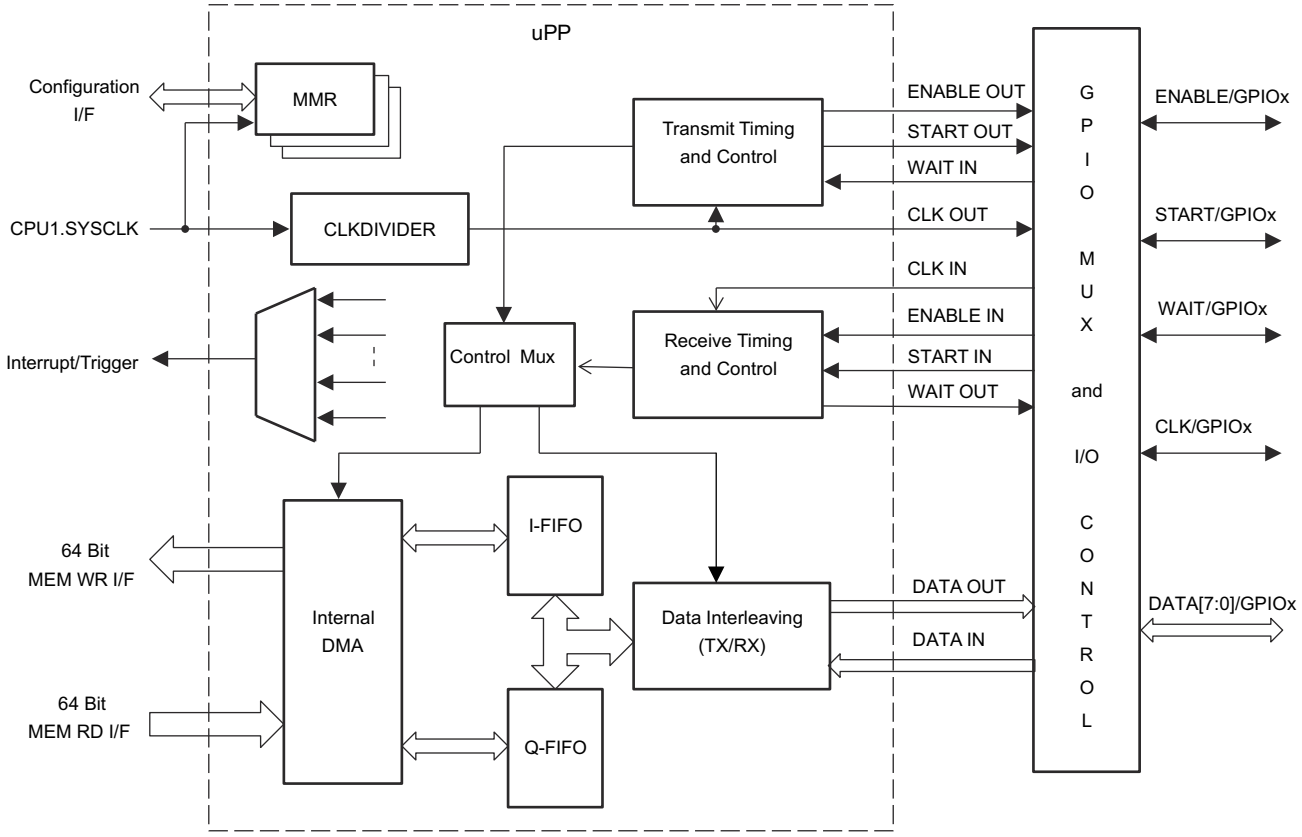

**Figure 24-2. Functional Block Diagram**

The uPP IP supports internal FIFO to store the data to and from IOs. To alleviate the load of data transfer from system memory to and from the uPP FIFOs, the IP supports internal DMA. The internal DMA has two channels: channel I and channel Q.

Copyright © 2024 Texas Instruments Incorporated

### 24.3.2 Data Flow

The following naming conventions are followed regarding channel numbering:

- Only one I/O channel and that is labeled as “channel A”
- DMA channel are labeled as “channel I and channel Q”.

Figure 24-3 explains the data flow for receive in SDR mode and DDR non-demux mode. In this case, only one DMA channel (channel I) get used.

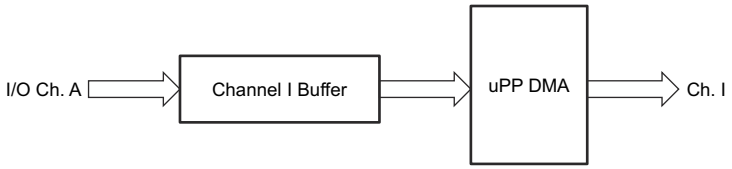

**Figure 24-3. RX in SDR or DDR (Non-Demux) Mode**

Figure 24-4 explains the data flow for receive in DDR demux mode. In this case, both DMA channels (channel I and channel Q) are used.

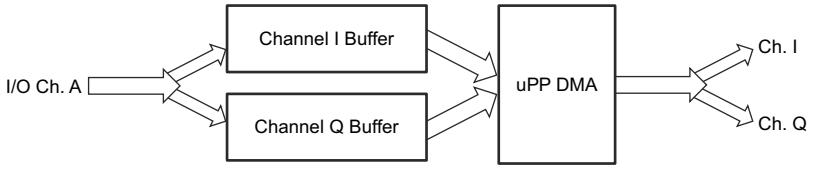

**Figure 24-4. RX in DDR (Demux) Mode**

Figure 24-5 explains the data flow for transmit in SDR non-interleave or DDR non-demux mode. In this case, only one DMA channel (channel I) get used.

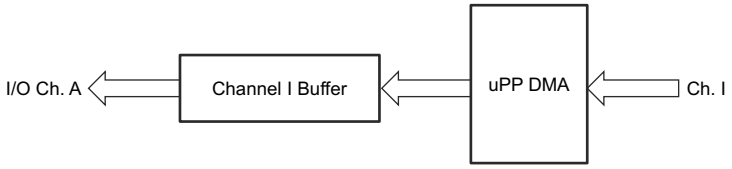

**Figure 24-5. TX in SDR (Non-Interleave) or DDR (Non-Demux) Mode**

Figure 24-6 explains the data flow for transmit in SDR interleave or DDR demux mode. In this case, both DMA channels (channel I and channel Q) are used.

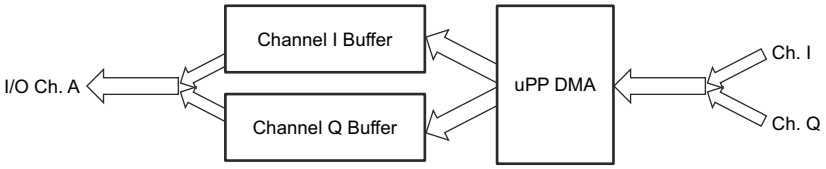

**Figure 24-6. TX in SDR (Interleave) or DDR (Demux) Mode**

### 24.3.3 Clock Generation and Control

The uPP peripheral uses three different clocks:

- A module clock that controls the internal logic and CPU interface. This is driven by CPU1.SYSCLK.
- A transmit clock (internally divided clock from the module clock) that runs the interface channel and drives the CLK pin out in transmit mode.
- A receive clock (input using CLK pin) that runs the interface channel in receive mode.

Figure 24-7 shows the output clock generation system in transmit mode.

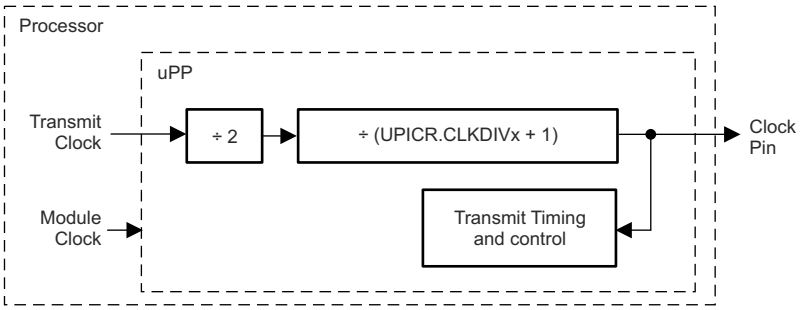

**Figure 24-7. IO Output Clock Generation for TX Mode**

Output Clock = Module Clock/(2 × (CLKDIVn + 1))

The fixed divisor restricts the maximum speed of the I/O clock to 1/2 the device CPU clock speed. For DDR mode operation, the CLK output frq must be one eighth (1/8) or less of module clock.

For receive mode, the channel requires an external clock to drive the CLK pin. The incoming clock is not divided, and the maximum allowed speed is one fourth (¼) the module clock speed for SDR mode and one eighth (1/8) the module clock speed for DDR mode. Figure 24-8 shows the clock generation system for a channel configured in receive mode.

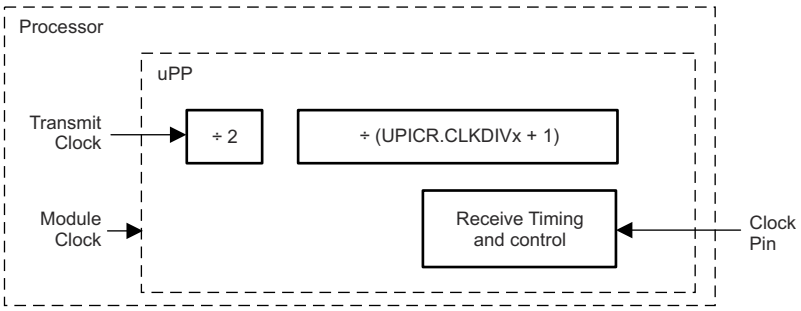

**Figure 24-8. IO Input Clock for RX Mode**

Copyright © 2024 Texas Instruments Incorporated

## 24.4 IO Interface and System Requirements

The uPP module provides interfacing logic to external streaming data, both inbound and outbound flow of data are supported. The interface protocol is a simple streaming interface and is built on top of the existing high-speed data converters, and captures most of the high-speed data converters protocol.

The input receive mode and output transmit mode protocol are symmetrical, and source synchronous, that is, clock is supplied by the transmitter and the same clock is used to receive the data.

Table 24-1 describes the functionality of all the input/output (IO) signals of uPP module.

**Table 24-1. uPP Signal Description**

| Signal | Description |
|---|---|
| CLK | • Transmit or receive clock<br>• Input in receive mode<br>• Output in transmit mode (Clock divider programmable) |
| START | • Input in receive mode<br>• Output in transmit mode<br>• Polarity programmable<br>• Indicates first data word of each line (frame)<br>• This is optional signal and if this feature is not used, external receiver can ignore this signal. |
| ENABLE | • Input when in receive mode<br>• Output in transmit mode<br>• Polarity programmable<br>• Indicates data received is valid, or data transmitted is valid<br>• Can be programmed to be ignored in receive mode but in transmit mode always drive active in sync with valid data. |
| WAIT | • Input in transmit mode<br>• Output in receive mode but always drive inactive by uPP in this case<br>• Polarity programmable<br>• In transmit mode when active, indicates that target is not ready to receive data. uPP stops transmitting data at next clock cycle right after the Wait signal is sampled as active. uPP module can be programmed to ignore this in transmit mode.<br>**Note**<br>The WAIT needs to be asserted for one full cycle of IO clock by external device. |
| DATA[7:0] | • 8-bit inputs in receive mode<br>• 8-bit output in transmit mode |

### *24.4.1 Pin Multiplexing*

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. To determine how pin multiplexing affects the uPP peripheral, see the device-specific data manual.

### *24.4.2 Internal DMA Controller Description*

The uPP peripheral includes an internal DMA controller separate from any device-level DMA. The internal DMA controller consists of two DMA channels, channel I and channel Q, which moves data to and from the uPP peripheral interface (I/O) channels in all operating modes. This section describes how to program the internal DMA channels.

Copyright © 2024 Texas Instruments Incorporated

#### 24.4.2.1 DMA Programming Concepts

The uPP internal DMA controller uses a simplified programming model similar to 2D transfers performed by any other DMA at system level. Each DMA channel may be configured with four parameters: window address, byte count, line count, and line offset address.

- Window Address (CHxDESC0.ADDR) - The location in uPP data memory of the first byte in the data buffer. When the uPP operates in receive mode, the DMA channel begins writing to this address as it takes incoming data from the uPP I/O channel. When the uPP operates in transmit mode, the DMA channel begins reading from this address and pass the data to the uPP I/O channel. The window address must be aligned to a 64-bit boundary (that is, the three LSBs must equal 0). Non-aligned addresses are automatically adjusted to a properly aligned value when written to configuration register.
- Byte Count (CHxDESC1.BCNT) - The number of bytes per line. The byte count must be an even number.
- Line Count (UPxDESC1.LCNT) - The number of lines per window. The total number of bytes transferred equals B x L, where B is the byte count per line and L is the line count.
- Line Offset Address (CHxDESC2.LOFFSET) - The offset address between the first byte in successive Lines. The line offset address cannot exceed 65528 (FFF8h) bytes, and must be aligned to a 64-bit boundary in memory (that is, the three LSBs must equal 0).

Figure 24-9 shows a typical DMA window defined by these parameters.

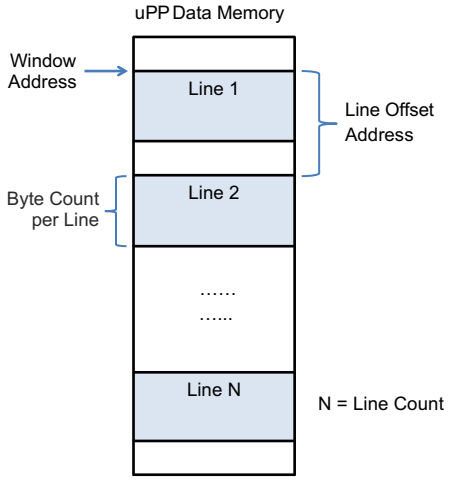

**Figure 24-9. Structure of DMA Window and Lines in Memory**

Certain values of the line offset address have special implications on the structure of the data buffer:

- Line Offset Address = Byte Count : Data buffer is a contiguous block in memory with size equal to (Line Count) x (Byte Count).
- Line Offset Address = 0 : Data buffer consists of a single line, with total size equal to Byte Count. If the I/O channel is configured in transmit mode, this line is transmitted (Line Count) consecutive times before the DMA transfer completes. If the I/O channel is configured in receive mode, the buffer is repeatedly written and overwritten by incoming data.

To program a DMA transfer, write the appropriate fields in the DMA channel descriptor registers for DMA Channel I or for DMA Channel Q. If the associated I/O channel is initialized and idle, the DMA transfer and I/O transaction begins immediately. Section 24.4.10 describes a step-by-step process for configuring the I/O channel and DMA channels to start a uPP transfer.

Each DMA channel allows a second descriptor to be queued while the previously programmed DMA transfer is still running. The PEND status bit in channel status register reports whether a new set of DMA parameters may be written to the DMA descriptor registers. Each DMA channel can have at most one active transfer and one queued transfer. This allows each I/O channel to perform uninterrupted, consecutive transactions across DMA transfer boundaries.

Copyright © 2024 Texas Instruments Incorporated

This DMA controller does not support automatically reloading DMA transfer descriptors. Each successive descriptor set must be explicitly written to the configuration registers by software. All uPP interrupt events originate in the internal DMA controller. Section 24.4.6 lists and explains all uPP interrupt events.

The internal DMA controller always writes data in bursts of 64 bytes. However, DMA read operations have configurable burst size, which may be set per channel using the RDSIZEI and RDSIZEQ bits in the uPP threshold configuration register. A DMA channel waits until the specified number of bytes leaves its internal buffer before performing another burst read from memory.

Note that the TXSIZEA bit in threshold configuration register is not DMA parameters; instead, it control transmit thresholds for the uPP interface channel.

#### 24.4.2.2 Data Interleave Mode

The data interleave mode is a special configuration that maps both DMA channels to a single interface I/O channel. There are two variants on data interleave mode, each with special conditions:

- Single Data Rate (SDR) Interleave
  - Single Data Rate (DRA = 0)
  - Transmit Only (MODE = 1)
  - SDR Transmit interleave enabled (SDRTXILA = 1)
- Double Data Rate (DDR) Interleave
  - Double Data Rate (DRA = 1)
  - Transmit or Receive (MODE = 0/1)
  - SDR Transmit interleave disabled (SDRTXILA = 0)
  - DDR interleave enabled (DEMUXA = 1)

In data interleave mode, I/O channel is associated with two data buffers, each serviced by its own DMA channel (I and Q). In SDR interleave mode, the START signal is used as a buffer selection line: START = 1 indicates that the current word comes from DMA Channel I; START = 0 indicates that the current word comes from DMA Channel Q. In DDR Interleave mode, the data buffers alternate every word beginning with Channel I: Channel I Word 0, Channel Q Word 0, Channel I Word 1, Channel Q Word 1, and so forth. Section 24.4.10 shows signal diagrams for both data interleave modes.

### *24.4.3 Protocol Description*

The uPP peripheral on this device has one I/O channel with 8 data lines, which can be configured to run in transmit or receive mode. A channel may also be configured to ignore certain control signals using the uPP interface configuration register. By default it uses all four control signals, unless otherwise configured.

#### 24.4.3.1 DATA[7:0] Signals

DATA[7:0] comprise the channel's entire data bus. In transmit mode, these pins are outputs that transmit data supplied by the channel's associated DMA channel. While the channel is idle, their behavior depends on the TRISENA bit in IFCFG register. These pins can be configured to drive an idle value (TRISENA = 0, VALA field in the uPP interface idle value register (IFIVAL)) or be in a high-impedance state while idle (TRISENA = 1). In receive mode, these pins are inputs that provide data to the channel's associated DMA channel.

#### 24.4.3.2 START Signal

The uPP transmitter asserts the START signal when it transfers the first word of a data line. A line is defined in terms of the channel's associated DMA channel; for more on DMA programming concepts, see Section 24.4.2. The START signal is active-high by default, but its polarity is controlled by the STARTPOLA bit in IFCFG register.

In transmit mode, START is an output signal and is always driven, in receive mode, START is an input signal and may be disabled using the STARTA bit in IFCFG register. When the channel is configured in transmit mode with data interleave enabled (SDRTXILA = 1 in CHCTL register), the START signal function changes completely. The START signal now asserts on every data word that is provided by DMA Channel I. For this alternative behavior, see Section 24.4.3.6.

Copyright © 2024 Texas Instruments Incorporated

#### 24.4.3.3 ENABLE

The uPP transmitter asserts the ENABLE signal when it transfers a valid data word. The ENABLE signal is active-high by default, but its polarity is controlled by the ENAPOLA bit in IFCFG register. In transmit mode, ENABLE is an output signal and is always driven; in receive mode, ENABLE is an input signal and may be disabled using the ENAA bit in IFCFG register.

#### 24.4.3.4 WAIT Signal

The WAIT signal allows the receiver to request a temporary halt in data transmission. When the receiver asserts WAIT, the transmitter responds by stopping transmission (starting with the next word) until WAIT is released. The receiver ignores all incoming data until WAIT is released. Once WAIT is released, the transmitter can resume transmission on the next word. Section 24.4.3 shows WAIT signal timing. The WAIT signal is active-high by default, but its polarity is controlled by the WAITPOLA bit in IFCFG register. In transmit mode, WAIT is an input signal and may be disabled using the WAITA bit in IFCFG register; in receive mode, WAIT is an output signal and always driven inactive by uPP.

#### 24.4.3.5 CLOCK Signal

The uPP transmitter drives the CLOCK signal to align all other uPP signals. By default, other signals align on the rising edge of CLOCK, but the polarity is controlled by the CLKINVA bit in IFCFG register. The active edges of CLOCK must always slightly precede transitions of other uPP signals. In transmit mode, CLOCK is an output signal; in receive mode, CLOCK is an input signal. For more information on clock generation and allowed frequencies, see Section 24.4.2.

#### 24.4.3.6 Signal Timing Diagrams

In the following diagrams, signals are marked (i) to indicate that the signals are inputs to the uPP peripheral and are marked (o) to indicate that the signals are outputs from the uPP peripheral. Data words from a single DMA channel are designated Dx, while data words that must come from a specific DMA channel are designated Ix or Qx to indicate DMA Channel I or Q, respectively. For more information on DMA channels and data interleave mode, see Section 24.4.2.

All signal diagrams are drawn with signal polarities in their default states. All signals except DATA are independently configurable in the uPP interface configuration register (IFCFG).

### 24.4.4 Data Format

On this device, uPP only supports an 8-bit interface; hence, no data packing is performed. In this case, make the appropriate connection externally, if needed. For example, if a 4-bit ADC is used, then tie the upper 4-bits of the uPP data inputs to 0 or 1, as needed. If external FPGA is connected, then make sure that 8-bit data (or appropriate tie-offs) is driven out from the FPGA. By default, uPP supports little-endian data format but to support the data format of one of the TI devices (CC1260), a configuration bit is provided to select 16-bit big-endian mode also.

Figure 24-15 and Figure 24-16 describe how data goes out and comes in based on these modes.

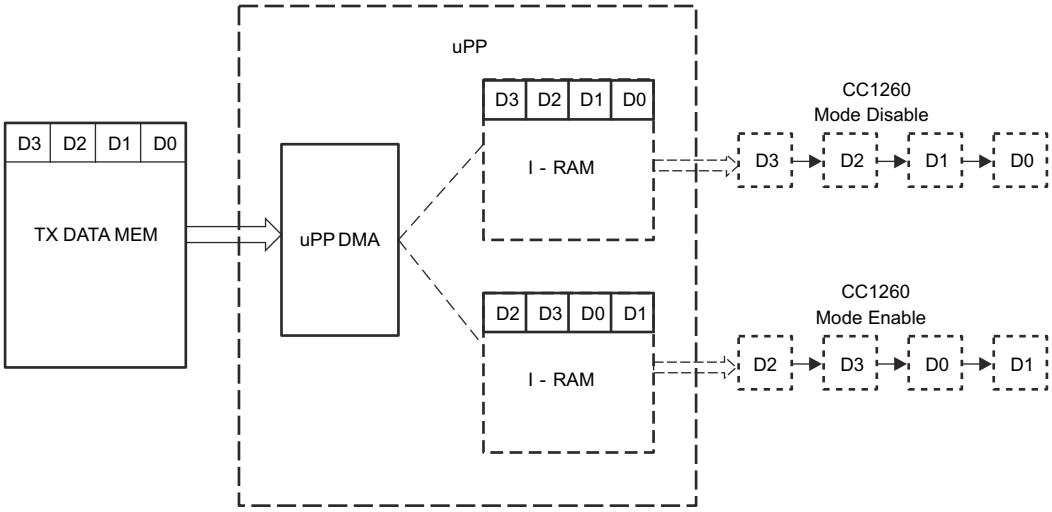

**Figure 24-15. uPP Tx Data Pattern in Non-Interleaved Mode**

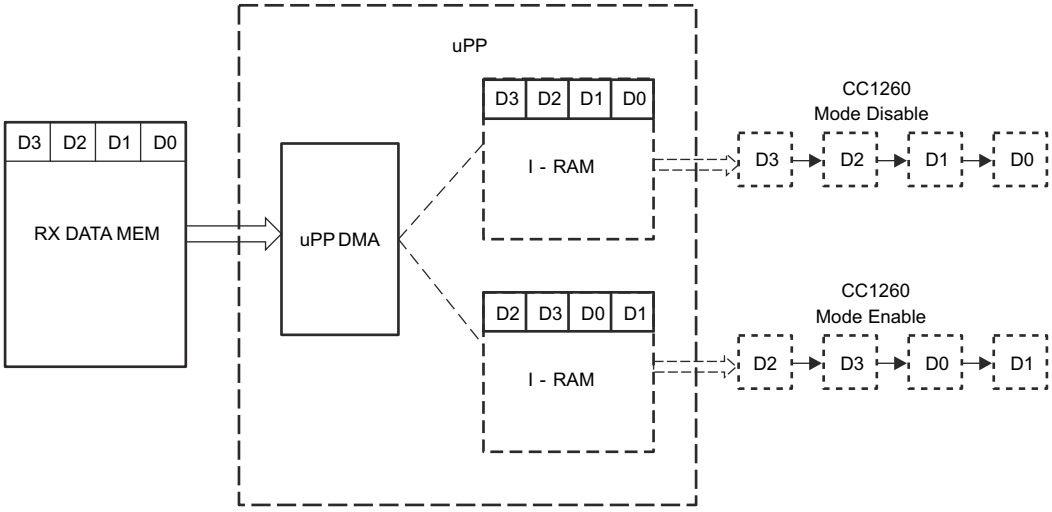

**Figure 24-16. uPP Rx Data Pattern in Non-Interleaved Mode**

### 24.4.5 Reset Considerations

#### 24.4.5.1 Software Reset

Software reset clears the uPP internal state machines but does not reset the contents of the uPP registers. The following procedure performs a software reset on the uPP peripheral:

1. Write the PEREN bit in the uPP PERCTL register to 0 (disables the uPP).
2. Poll the DMAST bit in uPP PERCTL register for activity; wait until DMA controller is inactive and idle.
3. Write the SOFTRST bit in uPP PERCTL register to 1 (places uPP in software reset).
4. Write the SOFTRST bit in uPP PERCTL register to 0 to (brings uPP out of software reset).

**Note**

In receive mode, uPP IO input clock must be running to have effect of soft reset.

#### 24.4.5.2 Hardware Reset

When the processor XRSn (or CPU1.SYSRSn) pin is asserted, the entire processor is reset and is held in the reset state until the RESET pin is released. As part of a device reset, the uPP state machines are reset, and the uPP registers are forced to their default states. For default states, see the register section.

**Note**

There is no SW method to apply a hard reset to the UPP module on this device.

### 24.4.6 Interrupt Support

The uPP peripheral generates multiple interrupt events, all tied to internal DMA Channels I and Q. The uPP peripheral automatically combines all interrupt events into a single chip-level interrupt driven to CPU1 and CPU1.CLA1. Individual events may be enabled using the uPP interrupt enable set register (INTENSET) and disabled using the uPP interrupt enable clear register (INTENCLR). Only enabled events generate interrupts and assert bits in the enabled interrupt status register (ENINTST). Disabled events do not generate interrupts but do assert bits in the raw interrupt status register (RAWINTST). An interrupt service routine (ISR) may be assigned to handle uPP CPU-level interrupts using the interrupt controller module. If uPP events occur in close proximity to one another, a single CPU interrupt (and a single call to the ISR) may represent multiple interrupt events. Thus, the uPP ISR must meet certain structural requirements:

- The ISR must be able to handle multiple events before returning
- The ISR must handle any subsequent events that occur after it is called but before it returns

Like CPU ISR, CLA tasks can be assigned based on these interrupt events.

#### 24.4.6.1 End of Line (EOL) Event

This event occurs each time when DMA channel reaches the end of a line in the data window. Note that if the associated uPP interface channel is operating in transmit mode, this event may occur before the line's final bytes are actually transmitted over the data pins.

For small line size and fast data transfer, it is possible to "miss" EOL events if they occur faster than the user's code can handle them. This does not hinder uPP operation; the uPP peripheral continue processing data uninterrupted until the EOW event or some error condition is encountered.

Copyright © 2024 Texas Instruments Incorporated

#### 24.4.6.2 End of Window (EOW) Event

This event occurs when the DMA channel reaches the end of the current data window. Note that if the associated uPP interface channel is operating in transmit mode, this event can occur shortly before the window's final bytes are actually transmitted over the data pins.

When an EOW event occurs, the DMA channel automatically begins the next DMA transfer if one has been pre-programmed into the channel descriptor registers. If no new transfer is preprogrammed, the DMA channel becomes idle. For small window size and fast data transfer, code overhead can make it impossible to maintain a constant flow of data through the uPP interface channel. This problem can be solved by increasing the DMA window size or decreasing the peripheral clock speed.

#### 24.4.6.3 Underrun or Overflow (UOR) Event

This event occurs when the DMA channel fails to keep up with incoming or outgoing data on the associated interface channel. Typically, this error indicates that background system activity has interfered with normal operation of the peripheral. This error does not occur simply when a channel is allowed to idle. After encountering this error, the uPP peripheral must be reset when this event occurs.

This error must primarily occur when operating the uPP at high speed with significant system loading. To avoid this error, run the uPP at slower speeds or reduce background activity, such as non-uPP peripheral or DMA transactions. Additional tuning tips are given in Section 24.4.10.1.

#### 24.4.6.4 DMA Programming Error (DPE) Event

This event occurs when the DMA channel descriptors are programmed while the PEND bit in the uPP DMA channel status register is set to 1. A channel's descriptors must only be programmed while the channel's PEND bit is cleared to 0.

### *24.4.7 Emulation Considerations*

The uPP peripheral stops running if any of three conditions are met:

- Peripheral Disable - EN bit in the uPP peripheral control register (PERCTL) is 0.
- Clock Stop – Clock to uPP is disabled using PCLKCR.
- Emulation Suspend - JTAG emulator halts chip while FREE = 0 and SOFT = 1 in uPP PERCTL register.

For other settings of FREE and SOFT, the uPP peripheral continues running during emulation halt. When the uPP encounters a stop condition, it completes the current DMA burst transaction (if one is active) before stopping.

I/O channel, configured in transmit mode, immediately places its pins in a high-impedance state and preserves the state of its internal state machines. Unless some reset event occurs (see Section 24.4.5), the channel can resume where it left off when the stop condition is cleared. I/O channel configured in receive mode only captures one additional data word. Further incoming data words are ignored as long as the stop condition persists.

### *24.4.8 Transmit and Receive FIFOs*

Each of the uPP peripheral I/O channels has a 512-byte FIFO. In receive mode, the FIFO is divided into eight 64-byte blocks. In transmit mode, the FIFO is divided into blocks that can be set to 64, 128, or 256 bytes, configured by the TXSIZEA field in the uPP threshold configuration register (THCFG).

Transmission will not begin until the channel has loaded enough data to fill at least one full FIFO block. The internal DMA channels may also be configured to use a read threshold of 64, 128, or 256 bytes using the RDSIZEI or RDSIZEQ field in uPP THCFG register. The DMA write threshold is fixed at 64 bytes.

Copyright © 2024 Texas Instruments Incorporated

### 24.4.9 Transmit and Receive Data (MSG) RAM

On this device, uPP internal DMA does not have access to system memories. Instead, there are two dedicated DATA RAMs (also called as MSGRAM) that have been provided: one for each RX and TX; each of these DATA RAMs are 512B. Since the CPU/CLA operates in 16-bit addressing mode, whereas, the uPP internal DMA operates in byte addressing mode, the addresses for these RAMs are different for different views.

Table 24-2 describes the addresses for these RAMs for two different views.

**Table 24-2. CPU/CLA/uPP-DMA Address Map**

| Data (MSG) RAM | CPU/CLA Address | | uPP DMA (Programming) Address | |
|---|---|---|---|---|
| | Start Address | End Address | Start Address | End Address |
| TX DATA RAM | 0x6C00 | 0x6CFF | 0x6C00 | 0x6DFF |
| RX DATA RAM | 0x6E00 | 0x6EFF | 0x7000 | 0x71FF |

Table 24-3 describes the different access type for both the DATA(MSG) RAMs.

**Table 24-3. CPU/CLA/uPP-DMA Address Map**

| Master/Data RAM | TX Data (MSG) RAM | | RX Data (MSG) RAM | |
|---|---|---|---|---|
| | Read | Write | Read | Write |
| CPU1 | Yes | Yes | Yes | Yes (Debug Mode Only) |
| CPU1.CLA1 | Yes | Yes | Yes | No |
| uPP-DMA | Yes | No | No | Yes |

**Note**

The message RAMs clocks are gated off when uPP clock is gated by the PCLKCR configuration. Thus, the message RAMs are not accessible by CPU/CLA when RPI clock is disabled by CPU.

Copyright © 2024 Texas Instruments Incorporated

### 24.4.10 Initialization and Operation

This section provides step-by-step instructions for initializing and running the uPP peripheral in various modes. These instructions are given assuming that the device has just come out of a power-on reset (POR) state.

1. Apply the appropriate pin multiplexing settings. For more information, see the device-specific data manual, and (or) pin multiplexing utility.
2. Enable the clocks to the uPP peripheral. For more information, see the Clock Control section of this TRM.
3. Wait for few (approximately 32) device clock cycles, and then clear the “Soft Reset” bit to 0 to bring the module out of reset.
4. Program the following uPP configuration registers: CHCTL, IFCFG, IFIVAL, THCFG.
   a. uPP Channel Control Register (data format, SDR/DDR, TX/RX, single/dual channel, interleave, demux)
   b. uPP Interface configuration Register (IO signal enable, polarity, clock divisor)
   c. uPP Interface idle value register (to drive value in idle mode for Tx)
   d. uPP Threshold configuration register (TX Size, DMA read burst size)
5. Program the uPP interrupt enable set register to interrupt generation for the desired events. Register an interrupt service routine (ISR) if desired; otherwise, polling is required.
6. Set the “PerEn” bit in the uPP peripheral control register (PCR) to 1 to turn on the uPP peripheral.
7. Allocate or initialize data buffers for use with uPP.
8. Program the DMA channels with their first transfers using the uPP DMA channel descriptor register0, 1 and 2 (byte count, line count, line offset).
9. Once the DMA descriptors are written, the module starts to receive and transmit data, and performs DMA transfers. Following is a simple description of how the DMA works.
10. Watch for interrupt events. Reprogram the DMA as necessary. (check that the PEND bit in the uPP DMA channel status is 0).
    a. If polling, check uPP Interrupt enabled status register. Reading a bit as 1 indicates the corresponding event has occurred. Write the corresponding bit with 1 to clear.
    b. If using ISR, check ENINTST inside your ISR

Once the channel is started, the initial latency between the time when the first data is received or transmitted on the pin, and the time when the first DMA burst is transferred on the CBA bus, is unpredictable. This initial latency is determined by several factors:

- Clock ratio between system clock and uPP clock
- Various threshold values being programmed
- Chip-level traffic activities level

However, once the data is moving, all subsequent data movement is continuous (streaming). If such data movement cannot be maintained, then DMA under-run or over-flow situation can occur.

Copyright © 2024 Texas Instruments Incorporated

#### 24.4.10.1 System Tuning Tips

The uPP peripheral can operate at high speed and transfer data at a very high rate. When operating the uPP near the upper limits, tuning certain parameters can help decrease the incidence of errors and the software overhead incurred servicing uPP data. Table 24-4 lists several parameters that can be useful in system tuning. A parameter is defined as a “coarse” adjustment, if changing the parameter directly alters the peripheral throughput. A “fine” adjustment does not change the peripheral throughput, but the adjustment does affect general system performance.

**Table 24-4. uPP Parameters Useful for System Tuning**

| Parameter | Register | Register Field | Edge Value | Safe Value | Description |
|---|---|---|---|---|---|
| Data Rate | CHCTL | DRA | 1 | 0 | Double data rate increases data transfer by a factor of 2 and greatly increases system loading for the same clock divisor. This is a coarse adjustment and is probably fixed due to design constraints. |
| Clock Division | IFCFG | CLKDIVA | 0 | 1+ | Increasing clock division is the most straight-forward way to decrease system loading. This is a coarse adjustment; the difference between CLKDIVx = 0 and 1 is the same (in terms of data rate) as the difference between single and double data rate. |
| DMA Read Burst Size | THCFG | RDSIZEQ RDSIZEI | 0 | 3h | Increasing the DMA read threshold decreases system loading by generating fewer, larger DMA events. This is a fine adjustment. |
| DMA Line Size, Count | CHxDESC1 | LCNT BCNT | 0 | (1) | Condensing uPP transfers into fewer, larger lines generates fewer end-of-line interrupts and, thus, invokes fewer ISR calls. This is a fine adjustment. |
| Total Transfer Size | CHxDESC1 | LCNT BCNT | (1) | (1) | Performing many small uPP transfers can require excessive software overhead (programming DMA descriptors, handling interrupts, and so forth) at high data rates. This is a fine adjustment. |

(1) These values vary per application. One example can be a 16-KB transfer. The same total data can be transferred as 16 1-KB lines or two 8-KB lines.

## 24.5 UPP Registers

### *24.5.1 UPP Base Addresses*

**Table 24-5. UPP Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| UppRegs(1) | UPP_REGS | 0x0000_6200 | 0x0000_62FF |

(1) Only available on CPU1.

### 24.5.2 UPP_REGS Registers

Table 24-6 lists the memory-mapped registers for the UPP_REGS registers. All register offset addresses not listed in Table 24-6 should be considered as reserved locations and the register contents should not be modified.

**Table 24-6. UPP_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | PID | Peripheral ID Register | | Go |
| 2h | PERCTL | Peripheral Control Register | | Go |
| 8h | CHCTL | General Control Register | | Go |
| Ah | IFCFG | Interface Configuration Register | | Go |
| Ch | IFIVAL | Interface Idle Value Register | | Go |
| Eh | THCFG | Threshold Configuration Register | | Go |
| 10h | RAWINTST | Raw Interrupt Status Register | | Go |
| 12h | ENINTST | Enable Interrupt Status Register | | Go |
| 14h | INTENSET | Interrupt Enable Set Register | | Go |
| 16h | INTENCLR | Interrupt Enable Clear Register | | Go |
| 20h | CHIDESC0 | DMA Channel I Descriptor 0 Register | | Go |
| 22h | CHIDESC1 | DMA Channel I Descriptor 1 Register | | Go |
| 24h | CHIDESC2 | DMA Channel I Descriptor 2 Register | | Go |
| 28h | CHIST0 | DMA Channel I Status 0 Register | | Go |
| 2Ah | CHIST1 | DMA Channel I Status 1 Register | | Go |
| 2Ch | CHIST2 | DMA Channel I Status 2 Register | | Go |
| 30h | CHQDESC0 | DMA Channel Q Descriptor 0 Register | | Go |
| 32h | CHQDESC1 | DMA Channel Q Descriptor 1 Register | | Go |
| 34h | CHQDESC2 | DMA Channel Q Descriptor 2 Register | | Go |
| 38h | CHQST0 | DMA Channel Q Status 0 Register | | Go |
| 3Ah | CHQST1 | DMA Channel Q Status 1 Register | | Go |
| 3Ch | CHQST2 | DMA Channel Q Status 2 Register | | Go |
| 40h | GINTEN | Global Peripheral Interrupt Enable Register | | Go |
| 42h | GINTFLG | Global Peripheral Interrupt Flag Register | | Go |
| 44h | GINTCLR | Global Peripheral Interrupt Clear Register | | Go |
| 46h | DLYCTL | IO clock data skew control Register | | Go |

Complex bit access types are encoded to fit into small table cells. Table 24-7 shows the codes that are used for access types in this section.

**Table 24-7. UPP_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| W1C | W<br>1C | Write<br>1 to clear |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |

Copyright © 2024 Texas Instruments Incorporated

**Table 24-7. UPP_REGS Access Type Codes (continued)**

| Access Type | Code | Description |
|---|---|---|
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

**Table 24-9. PERCTL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-8 | RESERVED | R-0 | 0h | Reserved |
| 7 | DMAST | R | 0h | DMA state machine status.<br>0: Idle<br>1: DMA Burst transaction is active.<br>Reset type: CPU1.SYSRSn |
| 6-5 | RESERVED | R-0 | 0h | Reserved |
| 4 | SOFTRST | R/W | 0h | This bit reset all the state machines and certain memory elements inside the RPI module immediately. Software can write this bit to '1', and later write '0' to bring the RPI module out of reset. Note that MMR are NOT reset, except for Interrupt-Raw-Status Register. This reset can be used to recover the RPI from an error condition.<br>To make sure that a graceful or fail-safe reset is performed, software can first disable the 'PerEn' bit, then poll the DMAStatus bit to make sure that all pending VBUSP DMA burst are completed, then perform a software reset.<br>0: De-assert the reset (out of reset).<br>1: Assert the reset (in to reset).<br>Reset type: CPU1.SYSRSn |
| 3 | PEREN | R/W | 0h | This bit can be used to disable or suspend the RPI module. When this bit is programmed to be disabled, the RPI will be stopped (suspended) after all current DMA activity are completed.<br>0: Disable/Suspend the uPP module.<br>1: Enable/Resume the uPP module.<br>Reset type: CPU1.SYSRSn |
| 2 | RTEMU | R/W | 0h | 0: Real Time emulation is disable. Module gets suspended when CPU is supended.<br>1: Real Time emulation is enable.<br>Reset type: CPU1.SYSRSn |

Chapter 25

# External Memory Interface (EMIF)

This chapter describes the external memory interface (EMIF).

Further information can be found in the following documents:

*Accessing External SDRAM on the TMS320F2837x/2807x Microcontrollers Using C/C++ Application Report*

*Design and Usage Guidelines for the C2000™ External Memory Interface (EMIF) Application Report*

**25.1 Introduction**.....2802
**25.2 EMIF Module Architecture**.....2806
**25.3 Example Configuration**.....2836
**25.4 EMIF Registers**.....2844

## 25.1 Introduction

This device supports dual-core architecture. To have a dedicated EMIF for each CPU subsystem, the device supports two EMIF modules — EMIF1 and EMIF2, as shown in Figure 25-1. Both modules are exactly the same with the same feature set, but have different address/data sizes. EMIF1 is shared between the CPU1 and CPU2 subsystem, whereas EMIF2 is dedicated to the CPU1 subsystem.

Table 25-1 gives the configuration for two EMIF modules.

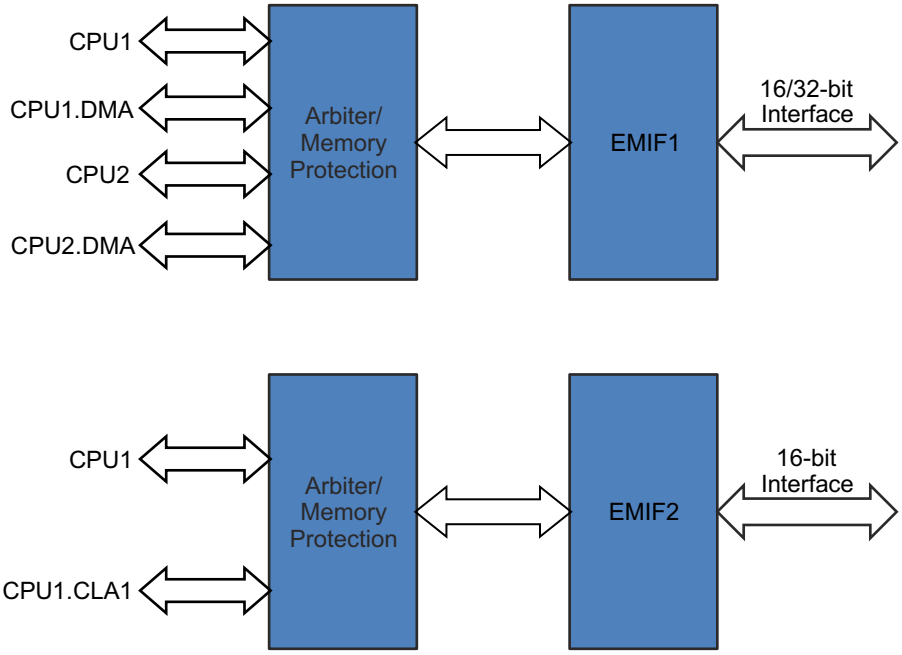

**Figure 25-1. EMIF Module Overview**

**Table 25-1. Configuration for EMIF1 and EMIF2 Modules**

| | EMIF1 | EMIF2 |
|---|---|---|
| 176-Pin Package | Yes | NA |
| 337- Pin Package | Yes | Yes |
| Maximum Data Width | 32 | 16 |
| Maximum Address Width | 22 (Some of the EMIF1 pins are muxed with each other. Refer to Section 25.2.11 for usage) | 12 |
| SDRAM CSx Support | 1 (CS0) | 1 (CS0) |
| ASRAM CSx Support | 3 (CS2/CS3/CS4) | 1 (CS2) |

**Note**

Subsequent sections in this chapter provide the details on the generic EMIF module. Unless otherwise specified, pin names are used from EMIF1 to define the functionality.

On this device, if EMIF1 is chosen to have a 32-bit data width, EMIF2 cannot be used because EMIF2 data pins are muxed with EMIF1 MSB data pins.

### 25.1.1 Purpose of the Peripheral

This EMIF memory controller is compliant with the JESD21-C SDR SDRAM memories utilizing a 32-bit/16-bit data bus. The purpose of this EMIF is to provide a means for the CPU to connect to a variety of external devices including:

- Single data rate (SDR) SDRAM
- Asynchronous devices including NOR Flash and SRAM

A common use for the EMIF is to interface with both a Flash device and an SDRAM device simultaneously. Section 25.3 contains an example of operating the EMIF in this configuration.

### 25.1.2 EMIF Related Collateral

**Foundational Materials**

- C2000 Academy - EMIF

**Getting Started Materials**

### 25.1.3 Features

The EMIF controller includes many features to enhance the ease and flexibility of connecting to the external SDR SDRAM and asynchronous devices.

#### 25.1.3.1 Asynchronous Memory Support

The EMIF controller supports asynchronous:

- SRAM memories
- NOR Flash memories

There is an external wait input that allows slower asynchronous memories to extend the memory access. The EMIF module supports more than one chip select (enable). Each chip select has the following individually programmable attributes:

- Data bus width
- Read cycle timings: setup, hold, strobe
- Write cycle timings: setup, hold, strobe
- Bus turnaround time
- Extended wait option with programmable timeout
- Select strobe option

#### 25.1.3.2 Synchronous DRAM Memory Support

The EMIF module supports 16-bit/32-bit SDRAM in addition to the asynchronous memories listed in Section 25.1.3.1. The EMIF module has a single SDRAM chip select. SDRAM configurations that are supported are:

- One, two and four bank SDRAM devices
- Devices with eight, nine, ten, and eleven column address
- CAS latency of two or three clock cycles
- 16-bit/32-bit data bus width
- 3.3V LVCMOS interface

Additionally, the EMIF supports placing the SDRAM in self-refresh and power-down modes. The self-refresh mode allows the SDRAM to be put in a low-power state while still retaining memory contents, since the SDRAM continues to refresh itself even without clocks from the microcontroller. The power-down mode achieves even lower power, except the microcontroller must periodically wake up and issue refreshes if data retention is required.

Note that the EMIF module does not support mobile SDRAM devices.

### 25.1.4 Functional Block Diagram

Figure 25-2 shows the connections between the EMIF and the internal requesters, along with the external EMIF pins. Section 25.2.2 contains a description of the entities internal to the MCU that can send requests to the EMIF, along with their prioritization. Section 25.2.3 describes the EMIF external pins and summarizes their purpose when interfacing with the SDRAM and asynchronous devices.

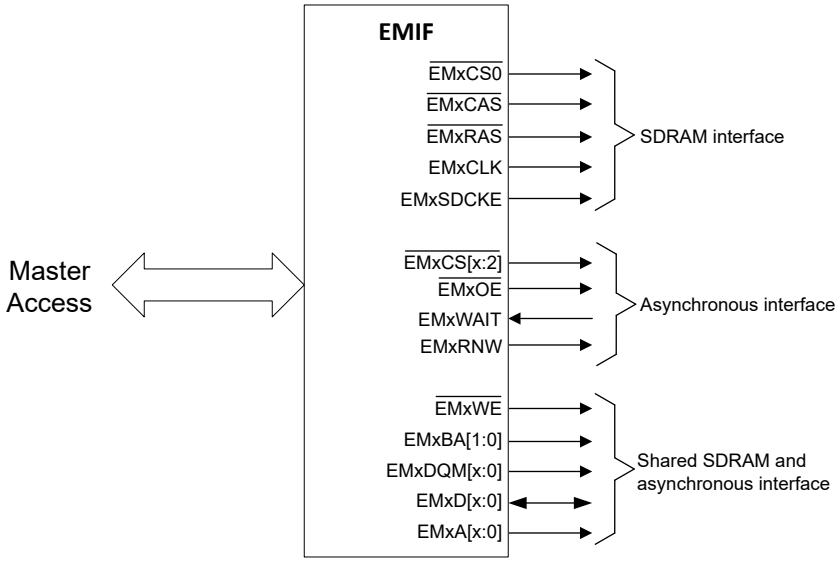

**Figure 25-2. EMIF Functional Block Diagram**

### 25.1.5 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

Copyright © 2024 Texas Instruments Incorporated

## 25.2 EMIF Module Architecture

This section provides details about the architecture and operation of the EMIF. Both the SDRAM and asynchronous interface are covered, along with other system-related configurations such as clock control.

### *25.2.1 EMIF Clock Control*

The EMIF clock is output on the EMxCLK pin and must be used when interfacing to external SDRAM devices. The EMIF module gets the PLLSYSCLK clock domain as the input. The user can choose to run the EMIF at PLLSYSCLK/1 or PLLSYSCLK/2 clock frequency by configuring the EMIFxCLKDIV field in the PERCLKDIVSEL register in the *Clock Control* module.

### *25.2.2 EMIF Requests*

Different sources within the MCU can make requests to the EMIF. These requests consist of accesses to the SDRAM memory, the asynchronous memory, and the EMIF registers. The EMIF can process only one request at a time. Therefore, a high performance master arbitration block exists within the MCU to provide prioritized requests from the different sources to the EMIF. The sources are:

- CPU1
- CPU1.DMA
- CPU2
- CPU2.DMA

If a request is submitted from two or more sources simultaneously, the crossbar switch forwards the highest priority request to the EMIF first. Upon completion of a request, the master arbitration block again evaluates the pending requests and forwards the highest priority pending request to the EMIF.

The master arbitration block always allows RD access from any of the masters. But for WR access (or execute access), the master arbitration block only allows access of masters from a CPU subsystem that takes master ownership of the EMIF module based on the configuration in the EMIF1MSEL register in the *Memory Controller* module. Note that only the EMIF1 has access from both the CPU subsystems; hence, the concept of grab-semaphore is applicable for the EMIF1 only.

When the EMIF receives a request, it is possible that the request is not immediately processed. In some cases, the EMIF performs one or more auto-refresh cycles before processing the request. For details on the EMIF internal arbitration between performing requests and performing auto-refresh cycles, see Section 25.2.13.

### 25.2.3 EMIF Signal Descriptions

This section describes the function of each of the EMIF signals.

**Table 25-2. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories**

| Pins | I/O | Description |
|---|---|---|
| EM1D[x:0] | I/O | **EMIF data bus.** |
| EM1A[x:0] | O | **EMIF address bus.**<br>When interfacing to an SDRAM device, these pins are primarily used to provide the row and column address to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in Table 25-14. EM1A[10] is also used during the PRE command to select which banks to deactivate.<br>When interfacing to an asynchronous device, these pins are used in conjunction with the EM1BA pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in Section 25.2.6.1. |
| EM1BA[1:0] | O | **EMIF bank address.**<br>When interfacing to an SDRAM device, these pins are used to provide the bank address inputs to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in Table 25-14.<br>When interfacing to an asynchronous device, these pins are used in conjunction with the EM1A pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in Section 25.2.6.1. |
| EM1DQM[x:0] | O | **Active-low byte enables.**<br>When interfacing to SDRAM, these pins are connected to the DQM pins of the SDRAM to individually enable/disable each of the bytes in a data access.<br>When interfacing to an asynchronous device, these pins are connected to byte enables. See Section 25.2.6 for details. |
| $\overline{\text{EM1WE}}$ | O | **Active-low write enable.**<br>When interfacing to SDRAM, this pin is connected to the nWE pin of the SDRAM and is used to send commands to the device.<br>When interfacing to an asynchronous device, this pin provides a signal which is active-low during the strobe period of an asynchronous write access cycle. |

**Table 25-3. EMIF Pins Specific to SDRAM**

| Pins | I/O | Description |
|---|---|---|
| $\overline{\text{EM1CS0}}$ | O | **Active-low chip enable pin for SDRAM devices.**<br>This pin is connected to the chip-select pin of the attached SDRAM device and is used for enabling/disabling commands. By default, EMIF keeps this SDRAM chip select active, even if EMIF is not interfaced with an SDRAM device. This pin is deactivated when accessing the asynchronous memory bank and is reactivated on completion of the asynchronous access. |
| EM1RAS | O | **Active-low row address strobe pin.**<br>This pin is connected to the nRAS pin of the attached SDRAM device and is used for sending commands to the device. |
| EM1CAS | O | **Active-low column address strobe pin.**<br>This pin is connected to the nCAS pin of the attached SDRAM device and is used for sending commands to the device. |
| EM1SDCKE | O | **Clock enable pin.**<br>This pin is connected to the CKE pin of the attached SDRAM device and is used for issuing the SELF REFRESH command which places the device in self-refresh mode. See Section 25.2.5.7 for details. |
| EM1CLK | O | **SDRAM clock pin.**<br>This pin is connected to the CLK pin of the attached SDRAM device. See Section 25.2.1 for details on the clock signal. |

Copyright © 2024 Texas Instruments Incorporated

**Table 25-4. EMIF Pins Specific to Asynchronous Memory**

| Pins | I/O | Description |
|---|---|---|
| $\overline{\text{EM1CS}}$[4:2] | O | **Active-low chip enable pins for asynchronous devices.** These pins are meant to be connected to the chip-select pins of the attached asynchronous device. These pins are active only during accesses to the asynchronous memory. |
| EM1WAIT | I | **Wait input with programmable polarity / NAND Flash ready input.** A connected asynchronous device can extend the strobe period of an access cycle by asserting the EM1WAIT input to EMIF as described in Section 25.2.6.6. To enable this functionality, the EW bit in the asynchronous 1 configuration register (ASYNC_CS2_CFG) must be set to 1. In addition, the WP0 bit in ASYNC_CS2_CFG must be configured to define the polarity of the EM1WAIT pin. When the CS2NAND/CS3NAND/CS4NAND/CS5NAND bit in the NAND Flash control register (NANDFCR) is set, this pin instead functions as a NAND Flash ready input. |
| $\overline{\text{EM1OE}}$ | O | **Active-low pin enable for asynchronous devices.** This pin provides a signal which is active-low during the strobe period of an asynchronous read access cycle. |
| EM1RNW | O | **EMIF asynchronous read/write control.** This pin stays high during reads and stays low during writes (same duration as CS). |

### *25.2.4 EMIF Signal Multiplexing Control*

Several EMIF signals are multiplexed with other functions on this microcontroller. Refer to the multiplexing section of the *General-Purpose Input/Output (GPIO)* chapter for more information on how to enable the output of these EMIF signals.

### *25.2.5 SDRAM Controller and Interface*

The EMIF controller provides a glueless interface to most standard SDR SDRAM devices and supports features like self-refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The following sections include details on how to Interface and properly configure the EMIF to perform read and write operations to externally connected SDR SDRAM devices. Also, Section 25.3 provides a detailed example of interfacing the EMIF to a common SDRAM device.

#### 25.2.5.1 SDRAM Commands

The EMIF controller supports the SDRAM commands described in Table 25-5. Table 25-6 shows the truth table for the SDRAM commands, and an example timing waveform of the PRE command is shown in Figure 25-3. EM1A[10] is pulled low in this example to deactivate only the bank specified by the EM1BA pins.

**Table 25-5. EMIF SDRAM Commands**

| Command | Function |
|---|---|
| PRE | **Precharge.** Depending on the value of EM1A[10], the PRE command either deactivates the open row in all banks (EM1A[10] = 1) or only the bank specified by the EM1BA[1:0] pins (EM1A[10] = 0). |
| ACTV | **Activate**. The ACTV command activates the selected row in a particular bank for the current access. |
| READ | **Read.** The READ command outputs the starting column address and signals the SDRAM to begin the burst read operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance. |
| WRT | **Write.** The WRT command outputs the starting column address and signals the SDRAM to begin the burst write operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance. |
| BT | **Burst terminate**. The BT command is used to truncate the current read or write burst request. On this device, all the SDRAM accesses are single access except when EMIF controller splits a single access into multiple access (for example, a 32-bit access from CPU is split into two 16-bit accesses if external SDRAM device is 16 bit (NM =1). |
| LMR | **Load mode register**. The LMR command sets the mode register of the attached SDRAM devices and is only issued during the SDRAM initialization sequence described in Section 25.2.5.4. |
| REFR | **Auto refresh**. The REFR command signals the SDRAM to perform an auto refresh according to the internal address. |
| SLFR | **Self refresh**. The self-refresh command places the SDRAM into self-refresh mode, during which the SDRAM provides a clock signal and auto refresh cycles. |
| NOP | **No operation**. The NOP command is issued during all cycles in which one of the above commands is not issued. |

Copyright © 2024 Texas Instruments Incorporated

**Table 25-6. Truth Table for SDRAM Commands**

| SDRAM Pins: | CKE | nCS | nRAS | nCAS | nWE | BA[1:0] | A[12:11] | A[10] | A[9:0] |

#### 25.2.5.2 Interfacing to SDRAM

The EMIF supports a glueless interface to SDRAM devices with the following characteristics:

- Pre-charge bit is A[10]
- The number of column address bits is 8, 9, 10, or 11.
- The number of row address bits is 13, 14, 15, or 16.
- The number of internal banks is 1, 2, or 4.

Figure 25-4 shows an interface between the EMIF and a 2M × 16 × 4 bank SDRAM device, and Figure 25-5 shows an interface between the EMIF and a 512K × 16 × 2 bank SDRAM device. For devices supporting 16-bit interface, refer to Table 25-7 for list of commonly-supported SDRAM devices and the required connections for the address pins.

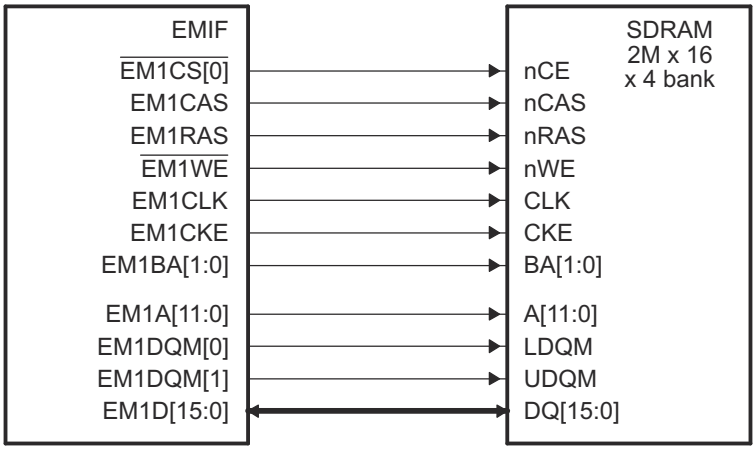

**Figure 25-4. EMIF to 2M × 16 × 4 Bank SDRAM Interface**

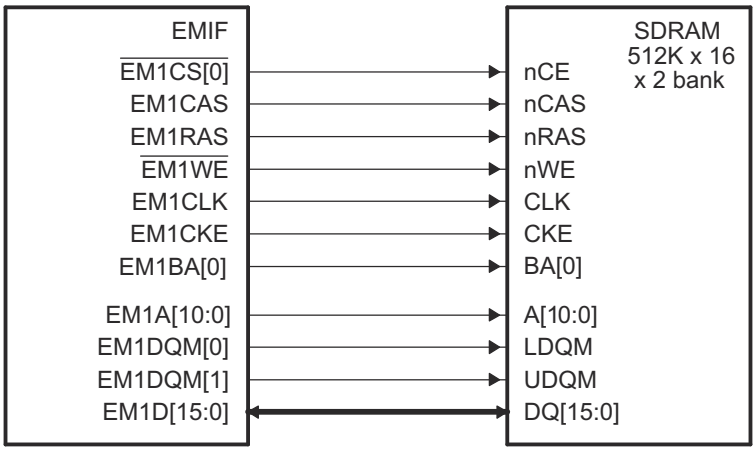

**Figure 25-5. EMIF to 512K × 16 × 2 Bank SDRAM Interface**

Copyright © 2024 Texas Instruments Incorporated

**Table 25-7. 16-bit EMIF Address Pin Connections**

| SDRAM Size | Width | Banks | Device | Address Pins |
|---|---|---|---|---|
| 16M bits | ×16 | 2 | SDRAM | A[10:0] |
| | | | EMIF | EM1A[10:0] |
| 64M bits | ×16 | 4 | SDRAM | A[11:0] |
| | | | EMIF | EM1A[11:0] |
| 128M bits | ×16 | 4 | SDRAM | A[11:0] |
| | | | EMIF | EM1A[11:0] |
| 256M bits | x16 | 4 | SDRAM | A[12:0] |
| | | | EMIF | EM1A[12:0] |
| 512M bits | x16 | 4 | SDRAM | A[12:0] |
| | | | EMIF | EM1A[12:0] |

#### 25.2.5.3 SDRAM Configuration Registers

The operation of the EMIF SDRAM interface is controlled by programming the appropriate configuration registers. This section describes the purpose and function of each configuration register, but Section 25.4 can be referred to for a more detailed description of each register, including the default registers values and bit-field positions. The following tables list the four such configuration registers, along with a description of each of their programmable fields.

**Note**

Writing to any of the fields: NM, CL, IBANK, and PAGESIZE in the SDRAM configuration register (SDRAM_CR) causes the EMIF to abandon whatever the EMIF is currently doing and trigger the SDRAM initialization procedure described in Section 25.2.5.4.

Copyright © 2024 Texas Instruments Incorporated

**Table 25-8. Description of the SDRAM Configuration Register (SDRAM_CR)**

| Parameter | Description |
|---|---|
| SR | This bit controls entering and exiting of the self-refresh mode |
| PD | This bit controls entering and exiting of the power-down mode. If both SR and PD bits are set, the EMIF goes into self-refresh mode. |
| PDWR | Perform refreshes during power down. Writing a 1 to this bit causes the EMIF to exit the power-down state and issue an AUTO REFRESH command every time Refresh May level is set. This bit must be set along with PD when entering power-down mode. |
| NM | **Narrow Mode.** This bit defines the width of the data bus between the EMIF and the attached SDRAM device. When set to 1, the data bus is set to 16-bits. When set to 0, the data bus is set to 32-bits. |
| CL | **CAS latency.** This field defines the number of clock cycles between when an SDRAM issues a READ command and when the first piece of data appears on the bus. The value in this field is sent to the attached SDRAM device using the LOAD MODE REGISTER command during the SDRAM initialization procedure as described in Section 25.2.5.4. Only, values of 2h (CAS latency = 2) and 3h (CAS latency = 3) are supported and must be written to this field. While updating the CL field, BIT11_9LOCK bit field must be set to 1 simultaneously. |
| IBANK | **Number of Internal SDRAM Banks.** This field defines the number of banks inside the attached SDRAM devices in the following way:<br>• When IBANK = 0, 1 internal bank is used<br>• When IBANK = 1h, 2 internal banks are used<br>• When IBANK = 2h, 4 internal banks are used<br>This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See Section 25.2.5.11 for details. |
| PAGESIZE | **Page Size.** This field defines the internal page size of the attached SDRAM devices in the following way:<br>• When PAGESIZE = 0, 256-word pages are used<br>• When PAGESIZE = 1h, 512-word pages are used<br>• When PAGESIZE = 2h, 1024-word pages are used<br>• When PAGESIZE = 3h, 2048-word pages are used<br>This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See Section 25.2.5.11 for details. |

**Table 25-9. Description of the SDRAM Refresh Control Register (SDRAM_RCR)**

| Parameter | Description |
|---|---|
| RR | **Refresh Rate**. This field controls the rate at which attached SDRAM devices are refreshed. The following equation can be used to determine the required value of RR for an SDRAM device:<br>• RR = $f_{EM1CLK}$ / (Required SDRAM Refresh Rate)<br>More information about the operation of the SDRAM refresh controller is found in Section 25.2.5.6. |

**Table 25-10. Description of the SDRAM Timing Register (SDRAM_TR)**

| Parameter | Description |
|---|---|
| T_RFC<br>T_RP<br>T_RCD<br>T_WR<br>T_RAS<br>T_RC<br>T_RRD | **SDRAM Timing Parameters.** These fields configure the EMIF to comply with the AC timing requirements of the attached SDRAM devices. This allows the EMIF to avoid violating SDRAM timing constraints and to more efficiently schedule operations. More details about each of these parameters can be found in the SDRAM_TR register description. These parameters must be set to satisfy the corresponding timing requirements found in the SDRAM data sheet. |

**Table 25-11. Description of the SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG)**

| Parameter | Description |
|---|---|
| T_XS | **Self Refresh Exit Parameter.** The T_XS field of this register informs the EMIF about the minimum number of EM1CLK cycles required between exiting self-refresh and issuing any command. This parameter must be set to satisfy the $t_{XSR}$ value for the attached SDRAM device. |

#### 25.2.5.4 SDRAM Auto-Initialization Sequence

The EMIF automatically performs an SDRAM initialization sequence, regardless of whether the EMIF is interfaced to an SDRAM device, when either of the following two events occur:

- The EMIF comes out of reset. No memory accesses to the SDRAM and asynchronous interfaces are performed until this auto-initialization is complete.
- A write is performed to any of the three least-significant bytes of the SDRAM configuration register (SDRAM_CR)

An SDRAM initialization sequence consists of the following steps:

1. If the initialization sequence is activated by a write to SDRAM_CR, and if any of the SDRAM banks are open, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks. This is done so that the maximum ACTV to PRE timing for an SDRAM is not violated.
2. The EMIF drives EM1SDCKE high and begins continuously issuing NOP commands until eight SDRAM refresh intervals have elapsed. An SDRAM refresh interval is equal to the value of the RR field of the SDRAM refresh control register (SDRAM_RCR), divided by the frequency of EM1CLK (RR/$f_{EM1CLK}$). This step is used to avoid violating the power-up constraint of most SDRAM devices that requires 200 µs (sometimes 100 µs) between receiving stable Vdd and CLK and the issuing of a PRE command. Depending on the frequency of EM1CLK, this step could be insufficient to avoid violating the SDRAM constraint. See Section 25.2.5.5 for more information.
3. After the refresh intervals have elapsed, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks.
4. The EMIF issues eight AUTO REFRESH commands.
5. The EMIF issues the LMR command with the EM1A[9:0] pins set as described in Table 25-12.
6. Finally, the EMIF performs a refresh cycle, which consists of the following steps:
   a. Issuing a PRE command with EM1A[10] held high if any banks are open
   b. Issuing an REF command

**Table 25-12. SDRAM LOAD MODE REGISTER Command**

| EM1A[9:7] | EM1A[6:4] | EM1A[3] | EM1A[2:0] |
|---|---|---|---|
| 0 (Write bursts are of the programmed burst length in EM1A[2:0]) | These bits control the CAS latency of the SDRAM and are set according to CL field in the SDRAM configuration register (SDRAM_CR) as follows:<br>• If CL = 2, EM1A[6:4] = 2h (CAS latency = 2)<br>• If CL = 3, EM1A[6:4] = 3h (CAS latency = 3) | 0 (Sequential Burst Type. Interleaved Burst Type not supported) | These bits control the burst length of the SDRAM and are set according to the NM field in the SDRAM configuration register (SDRAM_CR) as follows:<br>• If NM = 0, EM1A[2:0] = 2h (Burst Length = 4)<br>• If NM = 1, EM1A[2:0] = 3h (Burst Length = 8) |

#### 25.2.5.5 SDRAM Configuration Procedure

There are two different SDRAM configuration procedures. Although the EMIF automatically performs the SDRAM initialization sequence described in Section 25.2.5.4 when coming out of reset, follow one of the procedures before performing any EMIF memory requests.

Procedure A must be followed if the SDRAM power-up constraint was not violated during the SDRAM auto-initialization sequence detailed in Section 25.2.5.4 on coming out of Reset. The SDRAM power-up constraint specifies that 200µs (sometimes 100µs) must exist between receiving stable Vdd and CLK and the issuing of a PRE command.

Procedure B must be followed if the SDRAM power-up constraint was violated. The 200µs (100µs) SDRAM power-up constraint is violated, if the frequency of EM1CLK is greater than 50MHz (100MHz for 100µs SDRAM power-up constraint) during SDRAM Auto-Initialization Sequence. Procedure B must be followed if there is any doubt that the power-up constraint was not met.

**Procedure A** — Following is the procedure to be followed if the SDRAM power-up constraint was not violated:

1. Place the SDRAM into self-refresh mode by setting the SR bit of SDRAM_CR to 1. The SDRAM can be placed into self-refresh mode when changing the frequency of the EM1CLK to avoid incurring the 200µs power-up constraint again.
2. Configure the desired EMIF1 clock (EM1CLK) frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data sheet.
3. Remove the SDRAM from self-refresh mode by clearing the SR bit of the SDRAM_CR to 0.
4. Program SDRAM_TR and SDR_EXT_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
5. Program the RR field of SDRAM_RCR to match that of the attached device's refresh interval. See Section 25.2.5.6.1 details on determining the appropriate value.
6. Program the SDRAM_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in Section 25.2.5.4 to be re-run. This second initialization generally takes much less time due to the increased frequency of EM1CLK.

**Procedure B** — Following is the procedure to be followed if the SDRAM power-up constraint was violated:

1. Configure the desired EM1CLK clock frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data sheet.
2. Program SDRAM_TR and SDR_EXT_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
3. Program the RR field of the SDRAM_RCR such that the following equation is satisfied: $(RR \times 8)/(f_{EM1CLK})$ > 200µs (sometimes 100µs). For example, an EM1CLK frequency of 100MHz requires setting RR to 2501 (9C5h) or higher to meet a 200µs constraint.
4. Program the SDRAM_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in Section 25.2.5.4 to be re-run with the new value of RR.
5. Perform a read from the SDRAM to make sure that step 5 of this procedure occurs after the initialization process has completed. Alternatively, wait for 200µs instead of performing a read.
6. Finally, program the RR field to match that of the attached device's refresh interval. See Section 25.2.5.6.1 details on determining the appropriate value.

After following the above procedure, the EMIF is ready to perform accesses to the attached SDRAM device.

Copyright © 2024 Texas Instruments Incorporated

#### 25.2.5.6 EMIF Refresh Controller

An SDRAM device requires that each of the rows be refreshed at a minimum required rate. The EMIF can meet this constraint by performing auto refresh cycles at or above this required rate. An auto-refresh cycle consists of issuing a PRE command to all banks of the SDRAM device followed by issuing a REFR command. To inform the EMIF of the required rate for performing auto refresh cycles, the RR field of the SDRAM refresh control register (SDRAM_RCR) must be programmed. The EMIF uses this value along with two internal counters to automatically perform auto refresh cycles at the required rate. The auto-refresh cycles cannot be disabled, even if the EMIF is not interfaced with an SDRAM. The remainder of this section details the EMIF's refresh scheme and provides an example for determining the appropriate value to place in the RR field of the SDRAM_RCR.

The two counters used to perform auto-refresh cycles are a 13-bit refresh interval counter and a 4-bit refresh backlog counter. At reset and upon writing to the RR field, the refresh interval counter is loaded with the value from RR field and begins decrementing, by one, each EMIF clock cycle. When the refresh interval counter reaches zero, the following actions occur:

- The refresh interval counter is reloaded with the value from the RR field and restarts decrementing.
- The 4-bit refresh backlog counter increments unless the counter has already reached the maximum value.

The refresh backlog counter records the number of auto refresh cycles that the EMIF currently has outstanding. This counter is decremented by one each time an auto refresh cycle is performed and incremented by one each time the refresh interval counter expires. The refresh backlog counter saturates at the values of 0000b and 1111b. The EMIF uses the refresh backlog counter to determine the urgency with which an auto refresh cycle must be performed. The four levels of urgency are described in Table 25-13. This refresh scheme allows the required refreshes to be performed with minimal impact on access requests.

**Table 25-13. Refresh Urgency Levels**

| Urgency Level | Refresh Backlog Counter Range | Action Taken |
|---|---|---|
| Refresh May | 1-3 | An auto-refresh cycle is performed only if the EMIF has no requests pending and none of the SDRAM banks are open. |
| Refresh Release | 4-7 | An auto-refresh cycle is performed if the EMIF has no requests pending, regardless of whether any SDRAM banks are open. |
| Refresh Need | 8-11 | An auto-refresh cycle is performed at the completion of the current access unless there are read requests pending. |
| Refresh Must | 12-15 | Multiple auto-refresh cycles are performed at the completion of the current access until the Refresh Release urgency level is reached. At that point, the EMIF can begin servicing any new read or write requests. |

#### 25.2.5.6.1 Determining the Appropriate Value for the RR Field

The value that must be programmed into the RR field of the SDRAM_RCR must can be calculated by using the frequency of the EM1CLK signal ($f_{EM1CLK}$) and the required refresh rate of the SDRAM ($f_{Refresh}$). The following formula can be used:

$RR = f_{EM1CLK} / f_{Refresh}$

The SDRAM data sheet often communicates the required SDRAM Refresh Rate in terms of the number of REFR commands required in a given time interval. The required SDRAM Refresh Rate in the formula above can therefore be calculated by dividing the number of required cycles per time interval ($n_{cycles}$) by the time interval given in the data sheet ($t_{Refresh\ Period}$) :

$f_{Refresh} = n_{cycles} / t_{Refresh\ Period}$

Combining these formulas, the value that must be programmed into the RR field can be computed as:

$RR = f_{EM1CLK} \times t_{Refresh\ Period} / n_{cycles}$

The following example illustrates calculating the value of RR. Given that:

- $f_{EM1CLK}$ = 100MHz (frequency of EMIF clock)
- $t_{Refresh\ Period}$ = 64ms (required refresh interval of the SDRAM)
- $n_{cycles}$ = 8192 (number of cycles in a refresh interval for the SDRAM)

RR can be calculated as:

RR = 100MHz × 64ms/8192

RR = 781.25

RR = 782 cycles = 30Eh cycles

### 25.2.5.7 Self-Refresh Mode

The EMIF can be programmed to enter the self-refresh state by setting the SR bit of SDRAM_CR to 1. This causes the EMIF to issue the SLFR command after completing any outstanding SDRAM access requests and clearing the refresh backlog counter by performing one or more auto refresh cycles. This places the attached SDRAM device into self-refresh mode in which the EMIF consumes a minimal amount of power while performing the refresh cycles.

While in the self-refresh state, the EMIF continues to service asynchronous bank requests and register accesses as normal, with one caveat. The EMIF does not park the data bus following a read to asynchronous memory while in the self-refresh state. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state to prevent floating inputs on the data bus. More information about data bus parking can be found in Section 25.2.7.

The EMIF exits from the self-refresh state, if either of the following events occur:

- The SR bit of SDRAM_CR is cleared to 0.
- An SDRAM accesses is requested.

The EMIF exits from the self-refresh state by driving EM1SDCKE high and performing an auto refresh cycle.

The attached SDRAM device must also be placed into self-refresh mode when changing the frequency of EM1CLK. If the frequency of EM1CLK changes while the SDRAM is not in self-refresh mode, Procedure B in Section 25.2.5.5 must be followed to reinitialize the device.

Copyright © 2024 Texas Instruments Incorporated

#### 25.2.5.8 Power-Down Mode

To support low-power modes, the EMIF can be requested to issue a POWER DOWN command to the SDRAM by setting the PD bit in the SDRAM configuration register (SDRAM_CR). When this bit is set, the EMIF continues normal operation until all outstanding memory access requests have been serviced and the SDRAM refresh backlog (if there is one) has been cleared. At this point, the EMIF enters the power-down state. Upon entering this state, the EMIF issues a POWER DOWN command (same as a NOP command but driving the EM1SDCKE low on the same cycle). The EMIF then maintains the EM1SDCKE low until the EMIF exits the power-down state.

Since the EMIF services the refresh backlog before the EMIF enters the power-down state, all internal banks of the SDRAM are closed (precharged) prior to issuing the POWER DOWN command. Therefore, the EMIF only supports precharge power-down. The EMIF does not support active power-down, where internal banks of the SDRAM are open (active) before the POWER DOWN command is issued.

During the power-down state, the EMIF services the SDRAM, asynchronous memory, and register accesses as normal, returning to the power-down state upon completion.

The PDWR bit in the SDRAM_CR indicates whether the EMIF must perform refreshes in power-down state. If the PDWR bit is set, the EMIF exits the power-down state every time the Refresh Must level is set, performs AUTO REFRESH commands to the SDRAM, and returns back to the power-down state. This evenly distributes the refreshes to the SDRAM in power-down state. If the PDWR bit is not set, the EMIF does not perform any refreshes to the SDRAM. Therefore, the data integrity of the SDRAM is not maintained upon power-down exit, if the PDWR bit is not set.

If the PD bit is cleared while in the power-down state, the EMIF comes out of the power-down state. The EMIF:

- Drives EM1SDCKE high
- Enters the idle state

#### 25.2.5.9 SDRAM Read Operation

When the EMIF receives a read request to the SDRAM from one of the requesters listed in Section 25.2.2, the EMIF performs one or more read access cycles. A read access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a READ command while specifying the desired bank and column address. EM1A[10] is held low during the READ command to avoid auto-precharging. The READ command signals the SDRAM device to output data from the specified address while EMIF issues NOP commands. Following a READ command, the CL field of the SDRAM configuration register (SDRAM_CR) defines how many delay cycles are present before the read data appears on the data bus. This is referred to as the CAS latency.

Figure 25-6 shows the signal waveforms for a basic SDRAM read operation in which multiple data is read from a single page. On this device, burst accesses are not supported; hence, the EMIF issues a READ command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM_CR) to 1 and CPU (or any other master) does a 32-bit READ access, a burst access is issued with a size of two.

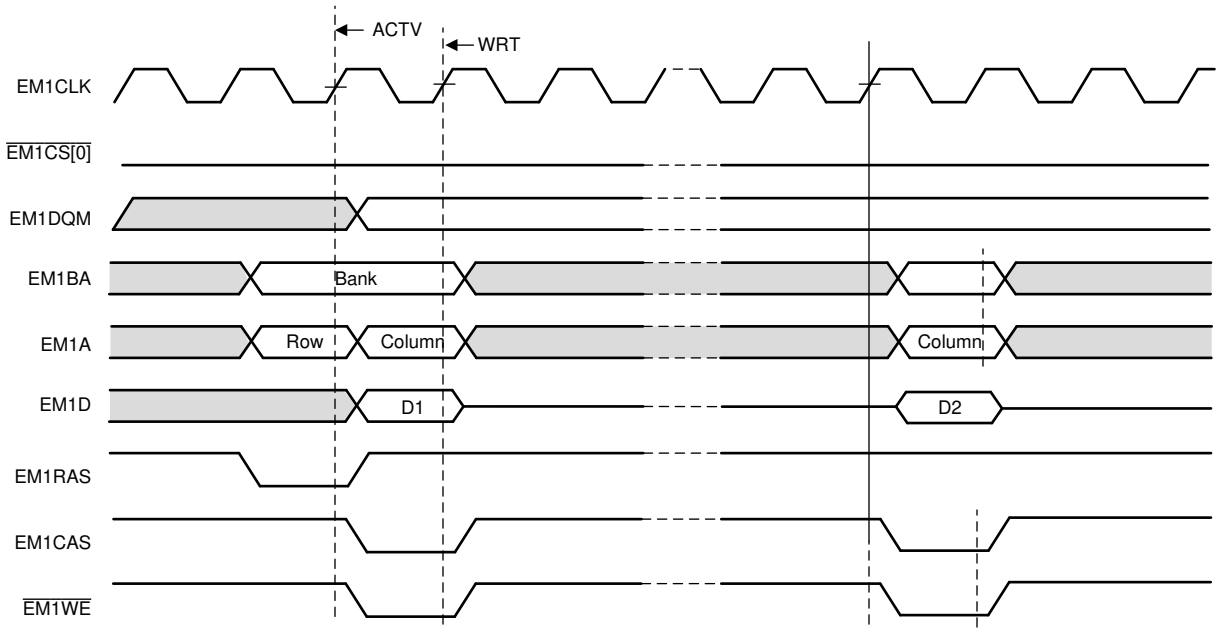

**Figure 25-6. Timing Waveform for Basic SDRAM Read Operation**

Several other pins are also active during a read access. The EM1DQM[x:0] pins are driven low during the READ commands and are kept low during the NOP commands that correspond to the burst request. The state of the other EMIF pins during each command can be found in Table 25-6.

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data manual. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands between various commands during an access. Refer to the register description of SDRAM_TR in the SDTIMER register for more details on the various timing parameters.

Copyright © 2024 Texas Instruments Incorporated

#### 25.2.5.10 SDRAM Write Operations

When the EMIF receives a write request to SDRAM from one of the requesters listed in Section 25.2.2, the EMIF performs one or more write-access cycles. A write-access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a WRT command while specifying the desired bank and column address. EM1A[10] is held low during the WRT command to avoid auto-precharging. The WRT command signals the SDRAM device to start writing the given data to the specified address while the EMIF issues NOP commands. On this device, burst accesses are not supported; hence, the EMIF issues a WRITE command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM_CR) to 1 and CPU (or any other master) does a 32bit WRITE access, a burst access is issued with size of two.

Figure 25-7 shows the signal waveforms for a basic SDRAM write operation.

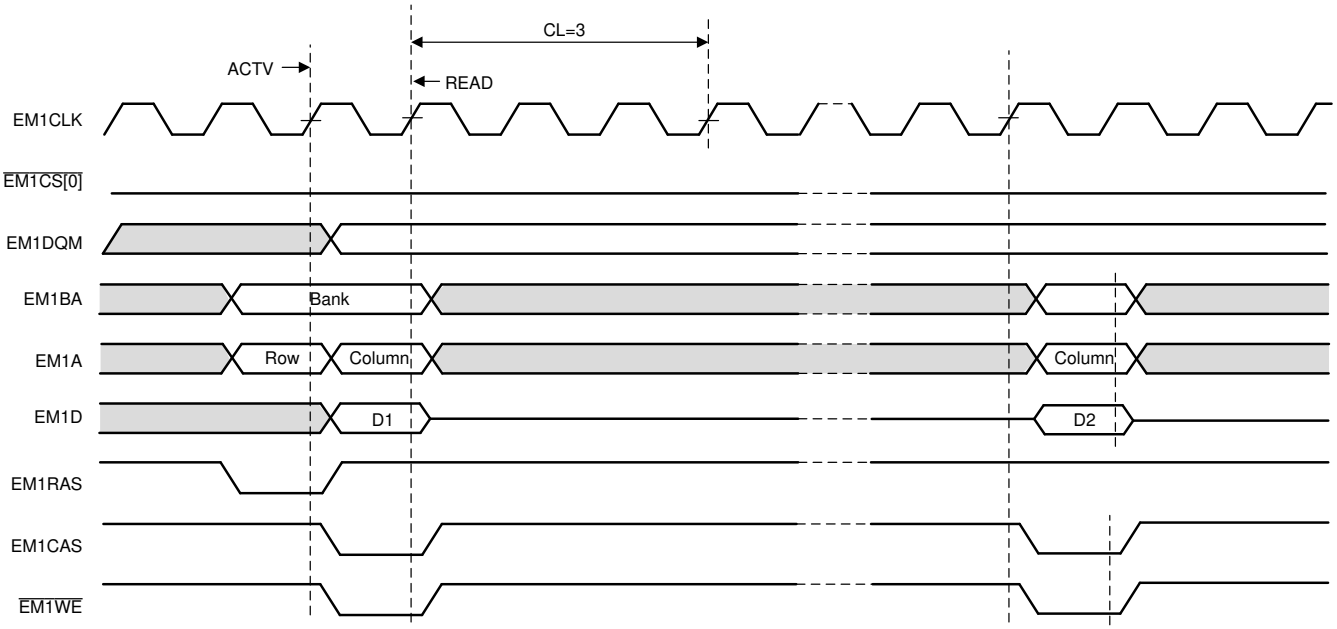

**Figure 25-7. Timing Waveform for Basic SDRAM Write Operation**

The EMIF truncates a series of bursting data if the remaining addresses of the burst are not part of the write request. The EMIF can truncate the burst in three ways:

- By issuing another WRT to the same page
- By issuing a PRE command to prepare for accessing a different page of the same bank
- By issuing a BT command to prepare for accessing a page in a different bank

Several other pins are also active during a write access. The EM1DQM[x:0] pins are driven to select which bytes of the data word are written to the SDRAM device. The pins are also used to mask out entire undesired data words during a burst access. The state of the other EMIF pins during each command can be found in Table 25-6.

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data sheet. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands during various cycles of an access. Refer to the register description of SDRAM_TR in the SDTIMR register for more details on the various timing parameters.

### 25.2.5.11 Mapping from Logical Address to EMIF Pins

When the EMIF receives an SDRAM access request, the EMIF must convert the address of the access into the appropriate signals to send to the SDRAM device. The details of this address mapping are shown in Table 25-14 for 32-bit operation and in Table 25-15 for 16-bit operation. Using the settings of the IBANK and PAGESIZE fields of the SDRAM configuration register (SDRAM_CR), the EMIF determines which bits of the logical address are mapped to the SDRAM row, column, and bank addresses.

As the logical address is incremented by one halfword (16-bit operation), the column address is likewise incremented by one until a page boundary is reached. When the logical address increments across a page boundary, the EMIF moves into the same page in the next bank of the attached device by incrementing the bank address EM1BA and resetting the column address. The page in the previous bank is left open until necessary to close the page. This method of traversal through the SDRAM banks helps maximize the number of open banks inside of the SDRAM and results in an efficient use of the device. There is no limitation on the number of banks that can be open at one time, but only one page within a bank can be open at a time.

The EMIF uses the EM1DQM[3:0] pins during a WRT command to mask out selected bytes or entire words. The EM1DQM[3:0] pins are always low during a READ command.

**Table 25-14. Mapping from Logical Address to EMIF Pins for 32-bit SDRAM**

| IBANK | PAGESIZE | Logical Address | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | 31:27 | 26 | 25 | 24 | 23 | 22 | 21:14 | 13 | 12 | 11 | 10 | 9 | 8:1 | 0 |
| 0 | 0 | - | | | | | | Row Address | | | | | | Col Address | EM1DQM[2]/EM1DQM[3] |
| 1 | 0 | - | | | | | | Row Address | | | | | EM1BA[0] | Col Address | EM1DQM[2]/EM1DQM[3] |
| 2 | 0 | - | | | | | | Row Address | | | | EM1BA[1:0] | | Col Address | EM1DQM[2]/EM1DQM[3] |

**Note**

The upper bit of the row address is used only when addressing 256-Mbit and 512-Mbit SDRAM memories.

### 25.2.6 Asynchronous Controller and Interface

The EMIF easily interfaces to a variety of asynchronous devices including NOR Flash and SRAM. It can be operated in two major modes (see Table 25-16):

- Normal Mode
- Select Strobe Mode

**Table 25-16. Normal Mode vs. Select Strobe Mode**

| Mode | Function of EM1DQM pins | Operation of $\overline{\text{EM1CS}}$[4:2] |
|---|---|---|
| Normal Mode | Byte enables | Active during the entire asynchronous access cycle |
| Select Strobe Mode | Byte enables | Active only during the strobe period of an access cycle |

The first mode of operation is normal mode, in which the EM1DQM pins of the EMIF function as byte enables. In this mode, the $\overline{\text{EM1CS}}$[4:2] pins behave as typical chip select signals, remaining active for the duration of the asynchronous access. See Section 25.2.6.1 for an example interface with multiple 8-bit devices.

The second mode of operation is select strobe mode, in which the $\overline{\text{EM1CS}}$[4:2] pins act as a strobe, active only during the strobe period of an access. In this mode, the EM1DQM pins of the EMIF function as standard byte enables for reads and writes. A summary of the differences between the two modes of operation are shown in Table 25-16. Refer to Section 25.2.6.4 for the details of asynchronous operations in normal mode, and to Section 25.2.6.5 for the details of asynchronous operations in select strobe mode. The EMIF hardware defaults to normal mode, but can be manually switched to select strobe mode by setting the SS bit in the asynchronous *m* (m = 1, 2, 3, or 4) configuration register (CE*n*CFG) (*n* = 2, 3, or 4). Throughout the chapter, *m* can hold the values 1, 2, 3 or 4; and *n* can hold the values 2, 3, or 4.

In both normal mode and select strobe mode, EMIF can be configured to operate in a sub-mode called NAND Flash Mode. In NAND Flash Mode, the EMIF is able to calculate an error correction code (ECC) for transfers up to 512 bytes.

The EMIF also provides configurable cycle timing parameters and an extended wait mode that allows the connected device to extend the strobe period of an access cycle. The following sections describe the features related to interfacing with external asynchronous devices.

#### 25.2.6.1 Interfacing to Asynchronous Memory

Figure 25-8 shows the EMIF's external pins used in interfacing with an asynchronous device. In $\overline{\text{EM1CS}}$[n], n = 2, 3, or 4.

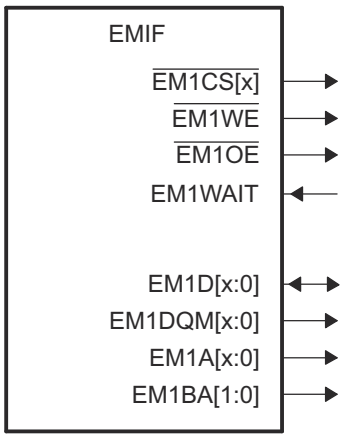

**Figure 25-8. EMIF Asynchronous Interface**

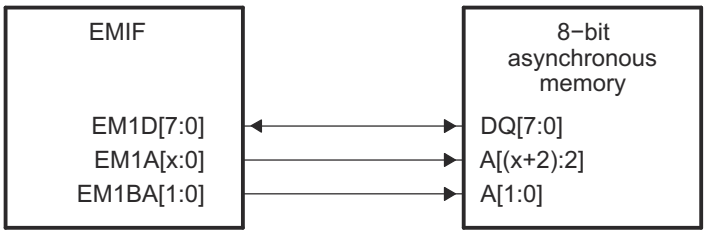
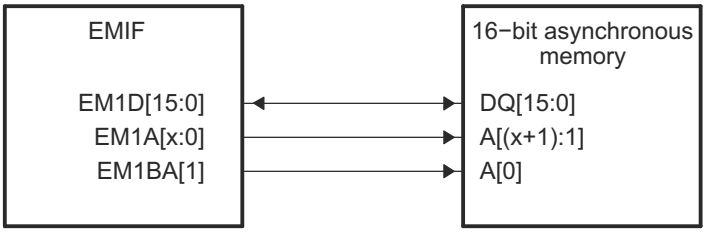
Copyright © 2024 Texas Instruments Incorporated

Of special note is the connection between the EMIF and the external device's address bus. The EMIF address pin EM1A[0] always provides the least-significant bit of a 32-bit word address. Therefore, when interfacing to a 16-bit or 8-bit asynchronous device, the EM1BA[1] and EM1BA[0] pins provide the least-significant bits of the halfword or byte address, respectively. Figure 25-9 and Figure 25-10 show the mapping between the EMIF and the connected device's data and address pins for various programmed data bus widths. The data bus width can be configured in the asynchronous *n* configuration register (ASYNC_CS*n*_CR).

Figure 25-10 shows an interface between the EMIF and an external memory with byte enables. The EMIF must be operated in either normal mode or select strobe mode when using this interface, so that the EM1DQM signals operate as byte enables.



a) EMIF to 8-bit memory interface



b) EMIF to 16-bit memory interface

**Figure 25-9. EMIF to 8-bit/16-bit Memory Interface**

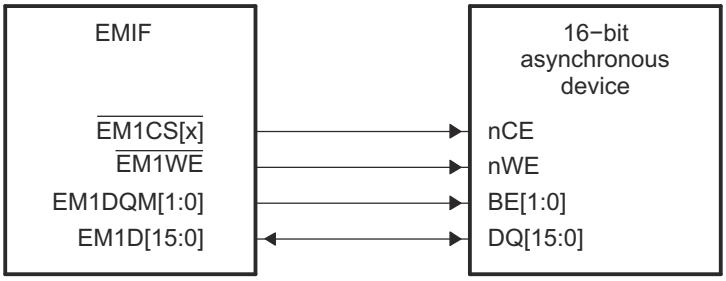


**Figure 25-10. Common Asynchronous Interface**

#### 25.2.6.2 Accessing Larger Asynchronous Memories

If a device such as a large asynchronous Flash needs to be attached to the EMIF, then GPIO pins can be used to control the Flash device upper address lines.

#### 25.2.6.3 Configuring EMIF for Asynchronous Accesses

The operation of the EMIF's asynchronous interface can be configured by programming the appropriate register fields. The reset value and bit position for each register field can be found in Section 25.4. The following tables list the register fields that can be programmed and describe the purpose of each field. These registers can be programmed prior to accessing the external memory, and the transfer following a write to these registers uses the new configuration.

**Table 25-17. Description of the Asynchronous *m* Configuration Register (ASYNC_CSn_CR)**

| Parameter | Description |
|---|---|
| SS | **Select Strobe mode.** This bit selects the EMIF's mode of operation in the following way:<br>• SS = 0 selects Normal Mode<br>– EM1DQM pins function as byte enables<br>– $\overline{\text{EM1CS}}$[4:2] active for duration of access<br>• SS = 1 selects Select Strobe Mode<br>– EM1DQM pins function as byte enables<br>– $\overline{\text{EM1CS}}$[4:2] acts as a strobe. |
| EW | **Extended Wait Mode enable.**<br>• EW = 0 disables Extended Wait Mode<br>• EW = 1 enables Extended Wait Mode<br>When set to 1, the EMIF enables the Extended Wait Mode in which the strobe width of an access cycle can be extended in response to the assertion of the EM1WAIT pin. The WP*n* bit in the asynchronous wait cycle configuration register (AWCC) controls the polarity of the EM1WAIT pin. Extended Wait Mode must not be used while in NAND Flash Mode. See Section 25.2.6.6 for more details on this mode of operation. |
| W_SETUP/R_SETUP | **Read/Write setup widths.**<br>These fields define the number of EMIF clock cycles of setup time for the address pins (EM1A), byte enables (EM1DQM), and asynchronous chip enable ($\overline{\text{EM1CS}}$[4:2]) before the read strobe pin (EM103) or write strobe pin ($\overline{\text{EM1WE}}$) falls, minus one cycle. For writes, the W_SETUP field also defines the setup time for the data pins (EM1D). Refer to the asynchronous device 's data sheet to determine the appropriate setting for this field. |
| W_STROBE/R_STROBE | **Read/Write strobe widths.**<br>These fields define the number of EMIF clock cycles between the falling and rising of the read strobe pin (EM103) or write strobe pin (EM1WEn), minus one cycle. If Extended Wait Mode is enabled by setting the EW field in the asynchronous *n* configuration register (ASYNC_CS*n*_CR), these fields must be set to a value greater than zero. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field. |
| W_HOLD/R_HOLD | **Read/Write hold widths.**<br>These fields define the number of EMIF clock cycles of hold time for the address pins (EM1A and EM1BA), byte enables (EM1DQM), and asynchronous chip enable ($\overline{\text{EM1CS}}$[4:2]) after the read strobe pin (EM103) or write strobe pin ($\overline{\text{EM1WE}}$) rises, minus one cycle. For writes, the W_HOLD field also defines the hold time for the data pins (EM1D). Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field. |
| TA | **Minimum turnaround time.**<br>This field defines the minimum number of EMIF clock cycles between asynchronous reads and writes, minus one cycle. The purpose of this feature is to avoid contention on the bus. The value written to this field also determines the number of cycles that are inserted between asynchronous accesses and SDRAM accesses. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field. |

Copyright © 2024 Texas Instruments Incorporated

**Table 25-17. Description of the Asynchronous *m* Configuration Register (ASYNC_CSn_CR) (continued)**

| Parameter | Description |
|---|---|
| ASIZE | **Asynchronous Device Bus Width.**<br>This field determines the data bus width of the asynchronous interface in the following way:<br>• ASIZE = 0 selects an 8-bit bus<br>• ASIZE = 1 selects a 16-bit bus<br>• ASIZE = 2 selects a 32-bit bus<br>The configuration of ASIZE determines the function of the EM1A and EM1BA pins as described in Section 25.2.6.1. This field also determines the number of external accesses required to fulfill a request generated by one of the sources mentioned in Section 25.2.2. For example, a request for a 32-bit word requires four external access when ASIZE = 0. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field. |

**Table 25-18. Description of the Asynchronous Wait Cycle Configuration Register (ASYNC_WCCR)**

| Parameter | Description |
|---|---|
| WP*n* | **EM_WAIT Polarity.**<br>• WP*n* = 0 selects active-low polarity<br>• WP*n* = 1 selects active-high polarity<br>When set to 1, the EMIF waits if the EM1WAIT pin is high. When cleared to 0, the EMIF waits if the EM1WAIT pin is low. The EMIF must have the Extended Wait Mode enabled for the EM1WAIT pin to affect the width of the strobe period. The polarity of the EM1WAIT signal is not programmable in NAND Flash Mode. |
| MAX_EXT_WAIT | **Maximum Extended Wait Cycles.**<br>This field configures the number of EMIF clock cycles the EMIF waits for the EM1WAIT pin to be deactivated during the strobe period of an access cycle. The maximum number of EMIF clock cycles the EMIF waits is determined by the following formula:<br>Maximum Extended Wait Cycles = (MAX_EXT_WAIT + 1) × 16<br>If the EM1WAIT pin is not deactivated within the time specified by this field, the EMIF resumes the access cycle, registering whatever data is on the bus and proceeding to the hold period of the access cycle. This situation is referred to as an Asynchronous Timeout. An Asynchronous Timeout generates an interrupt, if the interrupt has been enabled in the EMIF interrupt mask set register (INT_MSK_SET). Refer to Section 25.2.9.1 for more information about EMIF interrupts.<br>Extended Wait Mode can not be used while in NAND Flash Mode. |

**Table 25-19. Description of EMIF Interrupt Mask Set Register (INT_MSK_SET)**

| Parameter | Description |
|---|---|
| WR_MASK_SET | **Wait Rise Mask Set.**<br>Writing a 1 enables an interrupt to be generated when a rising edge on EM1WAIT occurs. |
| AT_MASK_SET | **Asynchronous Timeout Mask Set.**<br>Writing a 1 to this bit enables an interrupt to be generated when an Asynchronous Timeout occurs. |

Copyright © 2024 Texas Instruments Incorporated

**Table 25-20. Description of EMIF Interrupt Mast Clear Register (INT_MSK_CLR)**

| Parameter | Description |
|---|---|
| WR_MASK_CLR | **Wait Rise Mask Clear.**<br>Writing a 1 to this bit disables the interrupt, clearing the WR_MASK_SET bit in EMIF interrupt mask set register (INT_MSK_SET). |
| AT_MASK_CLR | **Asynchronous Timeout Mask Clear.**<br>Writing a 1 to this bit prevents an interrupt from being generated when an Asynchronous Timeout occurs. |

**Note**

The EMIF performs SDRAM refreshes even if the SDRAM interface is not used. If using only the ASRAM interface, then SDRAM refreshes impact the ASRAM performance. To avoid this, set PD=1 in the SDRAM_CR register (Emif1Regs.SDRAM_CR.bit.PD=1). This bit can be updated only if there are no pending EMIF accesses.

#### 25.2.6.4 Read and Write Operations in Normal Mode

Normal mode is the asynchronous interface's default mode of operation. It is selected when the SS bit in the asynchronous *n* configuration register (ASYNC_CS*n*_CR) is cleared to 0. In this mode, the EM1DQM pins operate as byte enables. Section 25.2.6.4.1 and Section 25.2.6.4.2 explain the details of read and write operations while in normal mode.

##### *25.2.6.4.1 Asynchronous Read Operations (Normal Mode)*

**Note**

During an entire asynchronous read operation, the $\overline{\text{EM1WE}}$ pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in Section 25.2.2 request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 25.2.13. In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by EMIF until the entire request is fulfilled. The details of an asynchronous read operation in normal mode are described in Table 25-21. Also, Figure 25-11 shows an example timing diagram of a basic read operation.

**Table 25-21. Asynchronous Read Operation in Normal Mode**

| Time Interval | Pin Activity in Normal Mode |
|---|---|
| Turnaround period | Once the read operation becomes the highest priority task for EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CS*n*_CR). Between each access (write or read), the EMIF inserts two cycles of delay even though TA field is programmed as 0.<br>After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation. |
| Start of the setup period | The following actions occur at the start of the setup period:<br>• The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS*n*_CR.<br>• The address pins EM1A and EM1BA become valid and carry the values described in Section 25.2.6.1.<br>• $\overline{\text{EM1CS}}$[4:2] falls to enable the external device (if not already low from a previous operation) |

**Table 25-21. Asynchronous Read Operation in Normal Mode (continued)**

| Time Interval | Pin Activity in Normal Mode |
|---|---|
| Strobe period | The following actions occur during the strobe period of a read operation:<br>1. $\overline{\text{EM1OE}}$ falls at the start of the strobe period<br>2. On the rising edge of the clock that is concurrent with the end of the strobe period:<br>• $\overline{\text{EM1OE}}$ rises<br>• The data on the EM1Dx bus is sampled by EMIF.<br><br>In Figure 25-11, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. Section 25.2.6.6 contains more details on using the EM1WAIT pin. |
| End of the hold period | At the end of the hold period:<br>• The address pins EM1A and EM1BA become invalid<br>• $\overline{\text{EM1CS}}$[4:2] rises (if no more operations are required to complete the current request)<br><br>The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turn-round cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, EMIF instead enters directly into the turnaround period for the pending read or write operation. |

#### 25.2.6.4.2 Asynchronous Write Operations (Normal Mode)

**Note**

During an entire asynchronous write operation, the EM1OE pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in Section 25.2.2 request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 25.2.13. In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in normal mode are described in Table 25-22. Also, Figure 25-12 shows an example timing diagram of a basic write operation.

**Table 25-22. Asynchronous Write Operation in Normal Mode**

| Time Interval | Pin Activity in Normal Mode |
|---|---|
| Turnaround period | Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CS*n*_CR). Between each access (write or read) EMIF inserts two cycles of delay even though TA field is programmed as 0.<br>After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, EMIF terminates the operation. |
| Start of the setup period | The following actions occur at the start of the setup period:<br>• The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CS*n*_CR.<br>• The address pins EM1A and EM1BA and the data pins EM1Dx become valid. The EM1A and EM1BA pins carry the values described in Section 25.2.6.1.<br>• EM1CS[4:2] falls to enable the external device (if not already low from a previous operation). |
| Strobe period | The following actions occur at the start of the strobe period of a write operation:<br>1. EM1WE falls<br>2. The EM1DQM pins become valid as byte enables.<br><br>The following actions occur on the rising edge of the clock that is concurrent with the end of the strobe period:<br>1. EM1WE rises<br>2. The EM1DQM pins deactivate<br><br>In Figure 25-12, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to accept the data. Section 25.2.6.6 contains more details on using the EM1WAIT pin. |
| End of the hold period | At the end of the hold period:<br>• The address pins EM1Ax and EM1BAx become invalid<br>• The data pins become invalid<br>• EM1CS[n] (n = 2, 3, or 4) rises (if no more operations are required to complete the current request)<br><br>The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation. |

#### 25.2.6.5 Read and Write Operation in Select Strobe Mode

Select Strobe Mode is the EMIF's second mode of operation. It is selected when the SS bit of the asynchronous *n* configuration register (ASYNC_CSn_CR) is set to 1. In this mode, the EM1DQM pins operate as byte enables and the $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) pin is only active during the strobe period of an access cycle. Section 25.2.6.4.1 and Section 25.2.6.4.2 explain the details of read and write operations while in select strobe mode.

##### *25.2.6.5.1 Asynchronous Read Operations (Select Strobe Mode)*

**Note**

During the entirety of an asynchronous read operation, the EM1WEn pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in Section 25.2.2 request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 25.2.13. In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous read operation in select strobe mode are described in Table 25-23. Also, Figure 25-13 shows an example timing diagram of a basic read operation.

**Table 25-23. Asynchronous Read Operation in Select Strobe Mode**

| Time Interval | Pin Activity in Select Strobe Mode |
|---|---|
| Turnaround period | Once the read operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CSn_CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0.<br>After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation. |
| Start of the setup period | The following actions occur at the start of the setup period:<br>• The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS*n*_CR.<br>• The address pins EM1A and EM1BA become valid and carry the values described in Section 25.2.6.1.<br>• The EM1DQM pins become valid as byte enables. |
| Strobe period | The following actions occur during the strobe period of a read operation:<br>1. $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1OE}}$ fall at the start of the strobe period<br>2. On the rising edge of the clock that is concurrent with the end of the strobe period:<br>  • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM10E}}$ rise<br>  • The data on the EM1D bus is sampled by EMIF.<br>In Figure 25-13, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give more time to provide the data. Section 25.2.6.6 contains more details on using the EM1WAIT pin. |
| End of the hold period | At the end of the hold period:<br>• The address pins EM1A and EM1BA become invalid<br>• The EM1DQM pins become invalid<br>The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation. |

#### 25.2.6.5.2 Asynchronous Write Operations (Select Strobe Mode)

**Note**

During the entirety of an asynchronous write operation, the $\overline{\text{EM1OE}}$ pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in Section 25.2.2 request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 25.2.13. In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in select strobe mode are described in Table 25-24. Also, Figure 25-14 shows an example timing diagram of a basic write operation.

**Table 25-24. Asynchronous Write Operation in Select Strobe Mode**

| Time Interval | Pin Activity in Select Strobe Mode |
|---|---|
| Turnaround period | Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CSn_CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0.<br>After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, the EMIF terminates the operation. |
| Start of the setup period | The following actions occur at the start of the setup period:<br>• The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CSn_CR.<br>• The address pins EM1A and EM1BA and the data pins EM1D become valid. The EM1A and EM1BA pins carry the values described in Section 25.2.6.1.<br>• The EM1DQM pins become active as byte enables. |
| Strobe period | The following actions occur at the start of the strobe period of a write operation:<br>• $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1WE}}$ fall<br>The following actions occur on the rising edge of the clock which is concurrent with the end of the strobe period:<br>• $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1WE}}$ rise<br>In Figure 25-14, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give more time to accept the data. Section 25.2.6.6 contains more details on using the EM1WAIT pin. |
| End of the hold period | At the end of the hold period:<br>• The address pins EM1A and EM1BA become invalid<br>• The data pins become invalid<br>• The EM1DQM pins become invalid<br>The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation. |

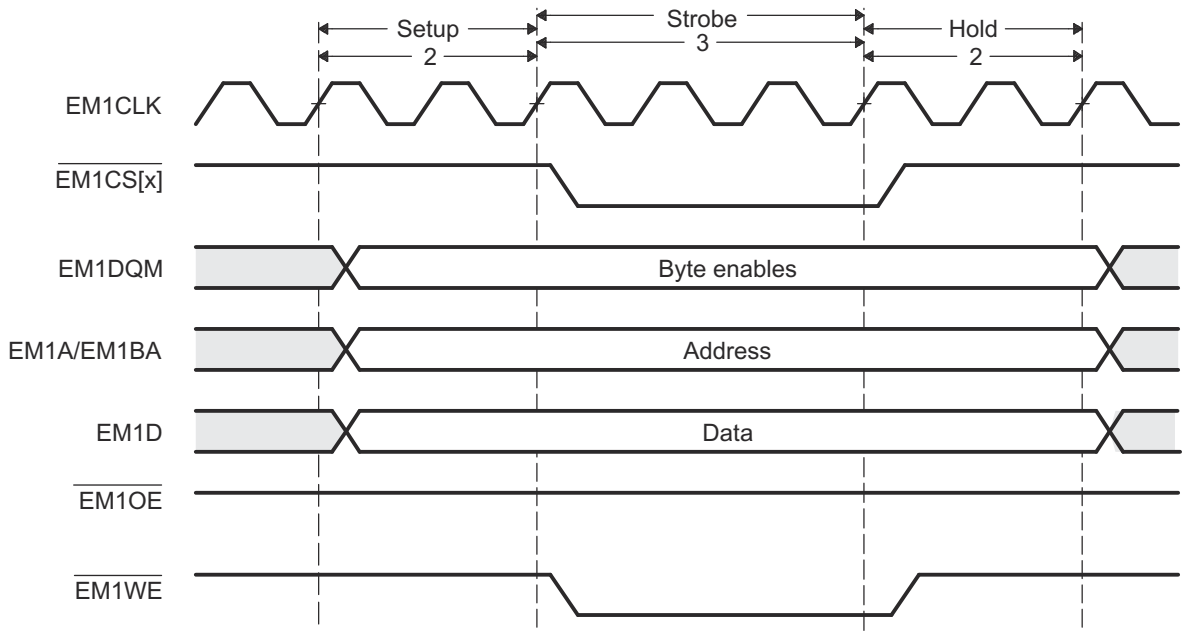

**Figure 25-14. Timing Waveform of an Asynchronous Write Cycle in Select Strobe Mode**

#### 25.2.6.6 Extended Wait Mode and the EM1WAIT Pin

The EMIF supports the extended wait mode. This is a mode that the external asynchronous device can assert control over the length of the strobe period. The extended wait mode can be entered by setting the EW bit in the asynchronous *n* configuration register (ASYNC_CS*n*_CR (*n* = 2, 3, or 4). When this bit is set, the EMIF monitors the EM1WAIT pin to determine if the attached device wishes to extend the strobe period of the current access cycle beyond the programmed number of clock cycles.

When the EMIF detects that the EM1WAIT pin has been asserted, the EMIF begins inserting extra strobe cycles into the operation until the EM1WAIT pin is deactivated by the external device. The EMIF then returns to the last cycle of the programmed strobe period and the operation proceeds as usual from this point. Refer to the device data sheet for details on the timing requirements of the EM1WAIT signal.

The EM1WAIT pin cannot be used to extend the strobe period indefinitely. The programmable MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC) determines the maximum number of EM1CLK cycles the strobe period can be extended beyond the programmed length. When the counter expires, the EMIF proceeds to the hold period of the operation regardless of the state of the EM1WAIT pin. The EMIF can also generate an interrupt upon expiration of this counter. See Section 25.2.9.1 for details on enabling this interrupt.

For the EMIF to function properly in the extended wait mode, the WP*n* bit of AWCC must be programmed to match the polarity of the EM1WAIT pin. In the reset state of 1, the EMIF inserts wait cycles when the EM1WAIT pin is sampled high. When set to 0, the EMIF inserts wait cycles only when EM1WAIT is sampled low. This programmability allows for a glueless connection to larger variety of asynchronous devices.

Finally, a restriction is placed on the strobe period timing parameters when operating in extended wait mode. Specifically, the sum of the W_SETUP and W_STROBE fields must be greater than four, and the sum of the R_SETUP and R_STROBE fields must be greater than four for the EMIF to recognize the EM1WAIT pin has been asserted. The W_SETUP, W_STROBE, R_SETUP, and R_STROBE fields are in ASYNC_CS*n*_CR.

### 25.2.7 Data Bus Parking

The EMIF always drives the data bus to the previous write data value when the EMIF is idle. This feature is called data bus parking. Only when the EMIF issues a read command to the external memory does the EMIF stop driving the data bus. After the EMIF latches the last read data, the EMIF immediately parks the data bus again.

The one exception to this behavior occurs after performing an asynchronous read operation while the EMIF is in the self-refresh state. In this situation, the read operation is not followed by the EMIF parking the data bus. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state, to prevent floating inputs on the data bus. External pull-ups, such as 10-kohm resistors, must be placed on the 16 EMIF data bus pins (that do not have internal pull-ups) if required to perform reads in this situation. The precise resistor value must be chosen so that the worst case combined off-state leakage currents do not cause the voltage levels on the associated pins to drop below the high-level input voltage requirement.

For information about the self-refresh state, see Section 25.2.5.7.

### 25.2.8 Reset and Initialization Considerations

The EMIF memory controller has two active-low reset signals, CHIP_RST_n and MOD_G_RST_n. Both these reset signals are driven by the device system reset signal. This device does not offer the flexibility to reset just the EMIF state machine without also resetting the EMIF controller's memory-mapped registers. As soon as the device system reset is released (driven high), the EMIF memory controller immediately begins its initialization sequence. Command and data stored in the EMIF memory controller FIFOs are lost. Refer to Section 25.2 for more information on conditions that can cause a device system reset to be asserted.

When system reset is released, the EMIF automatically begins running the SDRAM initialization sequence described in Section 25.2.5.4. Even though the initialization procedure is automatic, a special procedure, found in Section 25.2.5.5 must still be followed.

### 25.2.9 Interrupt Support

The EMIF supports a single interrupt to the CPU. Section 25.2.9.1 details the generation and internal masking of EMIF interrupts.

#### 25.2.9.1 Interrupt Events

There are three conditions that can cause the EMIF to generate an interrupt to the CPU. These conditions are:

- A rising edge on the EM1WAIT signal (wait rise interrupt)
- An asynchronous time out
- Usage of unsupported addressing mode (line trap interrupt)

The wait rise interrupt occurs when a rising edge is detected on EM1WAIT signal. This interrupt generation is not affected by the WP*n* bit in the asynchronous wait cycle configuration register (ASYNC_WCCR). The asynchronous time out interrupt condition occurs when the attached asynchronous device fails to deassert the EM1WAIT pin within the number of cycles defined by the MAX_EXT_WAIT bit in AWCC (this happens only in extended wait mode). The EMIF supports only linear incrementing and cache line wrap addressing modes . If an access request for an unsupported addressing mode is received, the EMIF sets the LT bit in the EMIF interrupt raw register (INT_RAW) and treats the request as a linear incrementing request.

Only when the interrupt is enabled by setting the appropriate bit (WR_MASK_SET/AT_MASK_SET/ LT_MASK_SET) in the EMIF interrupt mask set register (INT_MSK_SET) to 1, is the interrupt sent to the CPU. Once enabled, the interrupt can be disabled by writing a 1 to the corresponding bit in the EMIF interrupt mask clear register (INT_MSK_CLR). The bit fields in both the INT_MSK_SET and INT_MSK_CLR can be used to indicate whether the interrupt is enabled. When the interrupt is enabled, the corresponding bit field in both the INT_MSK_SET and INT_MSK_CLR have a value of 1; when the interrupt is disabled, the corresponding bit field has a value of 0.

Copyright © 2024 Texas Instruments Incorporated

The EMIF interrupt raw register (INT_RAW) and the IF interrupt mask register (INT_MSK) indicate the status of each interrupt. The appropriate bit (WR/AT/LT) in INT_RAW is set when the interrupt condition occurs, whether or not the interrupt has been enabled. However, the appropriate bit (WR_MASKED/AT_MASKED/LT_MASKED) in INT_MSK is set only when the interrupt condition occurs and the interrupt is enabled. Writing a 1 to the bit in INT_RAW clears the INT_RAW bit as well as the corresponding bit in INT_MSK. Table 25-25 contains a brief summary of the interrupt status and control bit fields. See for complete details on the register fields.

**Table 25-25. Interrupt Monitor and Control Bit Fields**

| Register Name | Bit Name | Description |
|---|---|---|
| EMIF interrupt raw register (INT_RAW) | WR | This bit is set when an rising edge on the EM1WAIT signal occurs. Writing a 1 clears the WR bit as well as the WR_MASKED bit in INT_MSK. |
| | AT | This bit is set when an asynchronous timeout occurs. Writing a 1 clears the AT bit as well as the AT_MASKED bit in INT_MSK. |
| | LT | This bit is set when an unsupported addressing mode is used. Writing a 1 clears LT bit as well as the LT_MASKED bit in INT_MSK. |
| EMIF interrupt mask register (INT_MSK) | WR_MASKED | This bit is set only when a rising edge on the EM1WAIT signal occurs and the interrupt has been enabled by writing a 1 to the WR_MASK_SET bit in INT_MSK_SET. |
| | AT_MASKED | This bit is set only when an asynchronous timeout occurs and the interrupt has been enabled by writing a 1 to the AT_MASK_SET bit in INT_MSK_SET. |
| | LT_MASKED | This bit is set only when line trap interrupt occurs and the interrupt has been enabled by writing a 1 to the LT_MASK_SET bit in INT_MSK_SET. |
| EMIF interrupt mask set register (INT_MSK_SET) | WR_MASK_SET | Writing a 1 to this bit enables the wait rise interrupt. |
| | AT_MASK_SET | Writing a 1 to this bit enables the asynchronous timeout interrupt. |
| | LT_MASK_SET | Writing a 1 to this bit enables the line trap interrupt. |
| EMIF interrupt mask clear register (INT_MSK_CLR) | WR_MASK_CLR | Writing a 1 to this bit disables the wait rise interrupt. |
| | AT_MASK_CLR | Writing a 1 to this bit disables the asynchronous timeout interrupt. |
| | LT_MASK_CLR | Writing a 1 to this bit disables the line trap interrupt. |

### *25.2.10 DMA Event Support*

The EMIF memory controller is a DMA slave peripheral and therefore does not generate DMA events. Data read and write requests can be made directly, by masters and the DMA.

### *25.2.11 EMIF Signal Multiplexing*

For details on the EMIF signal multiplexing, see the *GPIO* chapter, I/O Multiplexing Module section, of this technical reference manual.

### *25.2.12 Memory Map*

For information describing the device memory-map, see the data sheet.

Copyright © 2024 Texas Instruments Incorporated

### 25.2.13 Priority and Arbitration

Section 25.2.2 describes the external prioritization and arbitration among requests from different sources within the microcontroller. The result of this external arbitration is that only one request is presented to the EMIF at a time. Once the EMIF completes a request, the external arbiter then provides the EMIF with the next pending request.

Internally, the EMIF undertakes memory device transactions according to a strict priority scheme. The highest priority events are:

- A device reset.
- A write to any of the three least significant bytes of the SDRAM configuration register (SDRAM_CR).

Either of these events causes the EMIF to immediately commence the initialization sequence as described in Section 25.2.5.4.

Once the EMIF has completed its initialization sequence, the EMIF performs memory transactions according to the following priority scheme (highest priority listed first):

1. If the EMIF's backlog refresh counter is at the Refresh Must urgency level, the EMIF performs multiple SDRAM auto-refresh cycles until the Refresh Release urgency level is reached.
2. If an SDRAM or asynchronous read has been requested, the EMIF performs a read operation.
3. If the EMIF's backlog refresh counter is at the Refresh Need urgency level, the EMIF performs an SDRAM auto-refresh cycle.
4. If an SDRAM or asynchronous write has been requested, the EMIF performs a write operation.
5. If the EMIF's backlog refresh counter is at the Refresh May or Refresh Release urgency level, the EMIF performs an SDRAM auto-refresh cycle.
6. If the value of the SR bit in SDRAM_CR has been set to 1, the EMIF enters the self-refresh state as described in Section 25.2.5.7.

After taking one of the actions listed above, the EMIF then returns to the top of the priority list to determine the next action.

Because the EMIF does not issue auto-refresh cycles when in the self-refresh state, the above priority scheme does not apply when in this state. See Section 25.2.5.7 for details on the operation of the EMIF when in the self-refresh state.

### 25.2.14 System Considerations

This section describes various system considerations to keep in mind when operating the EMIF.

#### 25.2.14.1 Asynchronous Request Times

In a system that interfaces to both SDRAM and asynchronous memory, the asynchronous requests must not take longer than the smaller of the following two values:

- $t_{RAS}$ (typically 120 µs) - to avoid violating the maximum time allowed between issuing an ACTV and PRE command to the SDRAM.
- $t_{Refresh\ Rate}$ × 11 (typically 15.7 µs × 11 = 172.7 µs) - to avoid refresh violations on the SDRAM.

The length of an asynchronous request is controlled by multiple factors, the primary factor being the number of access cycles required to complete the request. For example, an asynchronous request for 4 bytes requires four access cycles using an 8-bit data bus and only two access cycle using a 16-bit data bus. The maximum request size that the EMIF can be sent is 16 words; therefore, the maximum number of access cycles per memory request is 64 when the EMIF is configured with an 8-bit data bus. The length of the individual access cycles that make up the asynchronous request is determined by the programmed setup, strobe, hold, and turnaround values, but can also be extended with the assertion of the EM1WAIT input signal up to a programmed maximum limit. The user must make sure that an entire asynchronous request does not exceed the timing values listed above when also interfacing to an SDRAM device. This can be done by limiting the asynchronous timing parameters.

### 25.2.15 Power Management

Power dissipation from the EMIF memory controller can be managed by following methods:

- Self-refresh mode
- Power-down mode
- Gating input clocks to the module off

Gating input clocks off to the EMIF memory controller achieves higher power savings when compared to the power savings of self-refresh or power down mode. The input clock to EMIF can be turned off through the use of the Global Clock Module (GCM). Before gating clocks off, the EMIF memory controller must place the SDR SDRAM memory in self-refresh mode. If the external memory requires a continuous clock, the VCLK3 clock domain must not be turned off because this can result in data corruption. See the following subsections for the proper procedures to follow when stopping EMIF memory controller clocks.

#### 25.2.15.1 Power Management Using Self-Refresh Mode

The EMIF memory controller can be placed into a self-refresh state in order to place the attached SDRAM devices into self-refresh mode, which consumes less power for most SDRAM devices. In this state, the attached SDRAM device uses an internal clock to perform its own auto refresh cycles. This maintains the validity of the data in the SDRAM without the need for any external commands. Refer to Section 25.2.5.7 for more details on placing the EMIF into the self-refresh state.

#### 25.2.15.2 Power Management Using Power Down Mode

In the power down mode, the EMIF drives EM1SDCKE low to lower the power consumption. EM1SDCKE goes high when there is a need to send refresh (REFR) commands, after which EM1SDCKE is again driven low. EM1SDCKE remains low until any request arrives. Refer to Section 25.2.5.8 for more details on placing the EMIF in power-down mode.

### 25.2.16 Emulation Considerations

The EMIF remains fully functional during emulation halts in order to allow emulation access to external memory.

## 25.3 Example Configuration

This section presents an example of interfacing the EMIF1 to both an SDR SDRAM device and an asynchronous Flash device.

### 25.3.1 Hardware Interface

Figure 25-15 shows the hardware interface between the EMIF, a Samsung K4S641632H-TC(L)70 64Mb SDRAM device, and a SHARP LH28F800BJE-PTTL90 8Mb Flash memory. The connection between EMIF and the SDRAM is straightforward, but the connection between the EMIF and the Flash deserves a detailed look.

The address inputs for the Flash are provided by three sources. The A[18:0] address inputs are provided by a combination of the EM1A and EM1BA pins according to Section 25.2.6.1, and a set of GPIO pins. The RD/nBY signal from Flash is connected to EM1WAIT pin of the EMIF.

Finally, this example configuration connects the $\overline{\text{EM1WE}}$ pin to the nWE input of the Flash and operates the EMIF in select strobe mode.

Copyright © 2024 Texas Instruments Incorporated

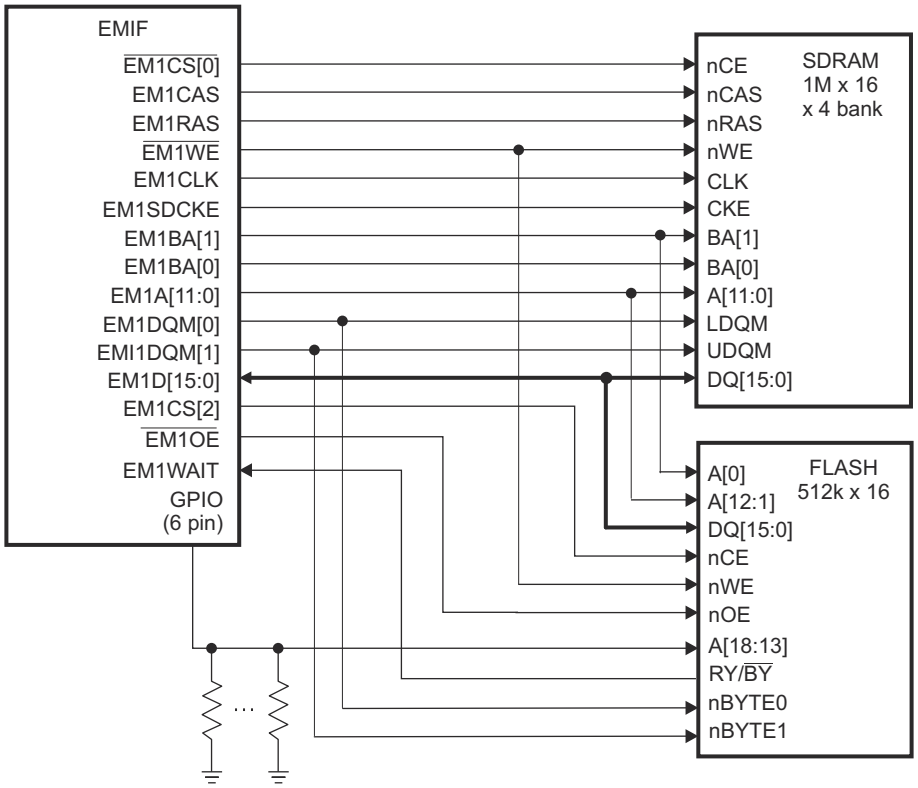

**Figure 25-15. Example Configuration Interface**

### *25.3.2 Software Configuration*

The following sections describe how to configure the EMIF registers and bit fields to interface the EMIF with the Samsung K4S641632H-TC(L)70 SDRAM and the SHARP LH28F800BJE-PTTL90 8Mb Flash memory.

#### 25.3.2.1 Configuring the SDRAM Interface

This section describes how to configure the EMIF to interface with the Samsung K4S641632H-TC(L)70 SDRAM with a clock frequency of $f_{EM1CLK}$ = 100MHz. Procedure A described in Section 25.2.5.5 is followed that assumes that the SDRAM power-up timing constraints were met during the SDRAM auto-initialization sequence after reset.

##### *25.3.2.1.1 PLL Programming for EMIF to K4S641632H-TC(L)70 Interface*

If the system PLL is programmed to provide a SYSCLK frequency > 100MHz, then configure the EMIF1CLKDIV field in the PERSYSCLKDIVSEL register to make EM1CLK = SYSCLK/2 (default configuration). Before doing this, the SDRAM must be placed in self-refresh mode by setting the SR bit in the SDRAM configuration register. Once the EM1CLK frequency has been configured, remove the SDRAM from self-refresh by clearing the SR bit in SDRAM_CR.

**Table 25-26. SR Field Value For EMIF to K4S641632H-TC(L)70 Interface**

| Field | Value | Purpose |
|---|---|---|
| SR | 1 then 0 | To place the EMIF into the self-refresh state |

Copyright © 2024 Texas Instruments Incorporated

#### 25.3.2.1.2 SDRAM Timing Register (SDRAM_TR) Settings for EMIF to K4S641632H-TC(L)70 Interface

The fields of the SDRAM timing register (SDRAM_TR) must be programmed first as described in Table 25-27 to satisfy the required timing parameters for the K4S641632H-TC(L)70. Based on these calculations, a value of 6111 4610h must be written to the SDRAM_TR. Figure 25-16 shows a graphical description of how the SDRAM_TR must be programmed.

**Table 25-27. SDRAM_TR Field Calculations for EMIF to K4S641632H-TC(L)70 Interface**

| Field Name | Formula | Value from K4S641632H-TC(L)70 Data Sheet | Value Calculated for Field |
|---|---|---|---|
| T_RFC | T_RFC >= ($t_{RFC}$ × $f_{EM1CLK}$) - 1 | $t_{RC}$ = 68 ns (min)(1) | 6 |
| T_RP | T_RP >= ($t_{RP}$ × $f_{EM1CLK}$) - 1 | $t_{RP}$ = 20 ns (min) | 1 |
| T_RCD | T_RCD >= ($t_{RCD}$ × $f_{EM1CLK}$) - 1 | $t_{RCD}$ = 20 ns (min) | 1 |
| T_WR | T_WR >= ($t_{WR}$ × $f_{EM1CLK}$) - 1 | $t_{RDL}$ = 2 CLK = 20 ns (min)(2) | 1 |
| T_RAS | T_RAS >= ($t_{RAS}$ × $f_{EM1CLK}$) - 1 | $t_{RAS}$ = 49 ns (min) | 4 |
| T_RC | T_RC >= ($t_{RC}$ × $f_{EM1CLK}$) - 1 | $t_{RC}$ = 68 ns (min) | 6 |
| T_RRD | T_RRD >= ($t_{RRD}$ × $f_{EM1CLK}$) - 1 | $t_{RRD}$ = 14 ns (min) | 1 |

(1) The Samsung data sheet does not specify a $t_{RFC}$ value. Instead, Samsung specifies $t_{RC}$ as the minimum auto refresh period.
(2) The Samsung data sheet does not specify a $t_{WR}$ value. Instead, Samsung specifies $t_{RDL}$ as last data in to row precharge minimum delay.

#### 25.3.2.1.3 SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM self-refresh exit timing register (SDSRETR) must be programmed second to satisfy the $t_{XSR}$ timing requirement from the K4S641632H-TC(L)70 data sheet. Table 25-28 shows the calculation of the proper value to program into the T_XS field of this register. Based on this calculation, a value of 6h must be written to the SDSRETR. Figure 25-17 shows how the SDSRETR must be programmed.

**Table 25-28. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface**

| Field Name | Formula | Value from K4S641632H-TC(L)70 Data Sheet | Value Calculated for Field |
|---|---|---|---|
| T_XS | T_XS >= ($t_{XSR}$ × $f_{EM1CLK}$) - 1 | $t_{RC}$ = 68 ns (min)(1) | 6 |

(1) The Samsung data sheet does not specify a $t_{XSR}$ value. Instead, Samsung specifies $t_{RC}$ as the minimum required time after CKE going high to complete self-refresh exit.

**Figure 25-17. SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### 25.3.2.1.4 SDRAM Refresh Control Register (SDRAM_RCR) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM refresh control register (SDRAM_RCR) can next be programmed to satisfy the required refresh rate of the K4S641632H-TC(L)70. Table 25-29 shows the calculation of the proper value to program into the RR field of this register. Based on this calculation, a value of 61Ah must be written to the SDRAM_RCR. Figure 25-18 shows how the SDRAM_RCR must be programmed.

**Table 25-29. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface**

| Field Name | Formula | Values | Value Calculated for Field |
|---|---|---|---|
| RR | RR ≤ $f_{EM1CLK}$ × $t_{Refresh\ Period}$ / $n_{cycles}$ | From SDRAM data sheet: $t_{Refresh\ Period}$ = 64ms; $n_{cycles}$ = 4096 EMIF clock rate: $f_{EM1CLK}$ = 100MHz | RR = 1562 cycles = 61Ah cycles |

**Figure 25-18. SDRAM Refresh Control Register (SDRAM_RCR)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### 25.3.2.1.5 SDRAM Configuration Register (SDRAM_CR) Settings for EMIF to K4S641632H-TC(L)70 Interface

Finally, the fields of the SDRAM configuration register (SDRAM_CR) must be programmed as described in Table 25-30 to properly interface with the K4S641632H-TC(L)70 device. Based on these settings, a value of 4720h must be written to the SDRAM_CR. Figure 25-19 shows how the SDRAM_CR must be programmed. The EMIF is now ready to perform read and write accesses to the SDRAM.

**Table 25-30. SDRAM_CR Field Values For EMIF to K4S641632H-TC(L)70 Interface**

| Field | Value | Purpose |
|---|---|---|
| SR | 0 | To avoid placing the EMIF into the self-refresh state |
| NM | 1 | To configure the EMIF for a 16-bit data bus |
| CL | 011b | To select a CAS latency of 3 |
| BIT11_9LOCK | 1 | To allow the CL field to be written |
| IBANK | 010b | To select 4 internal SDRAM banks |
| PAGESIZE | 0 | To select a page size of 256 words |

#### 25.3.2.2 Configuring the Flash Interface

This section describes how to configure the EMIF to interface with the SHARP LH28F800BJE-PTTL90 8Mb Flash memory with a clock frequency of $f_{EM1CLK}$ = 100MHz.

##### *25.3.2.2.1 Asynchronous 1 Configuration Register (ASYNC_CS2_CFG) Settings for EMIF to LH28F800BJE-PTTL90 Interface*

The asynchronous 1 configuration register (ASYNC_CS2_CFG) is the only register that is necessary to program for this asynchronous interface. The SS bit must be set to 1 to enable select strobe command and the ASIZE field can be set to 1 to select a 16-bit interface. The other fields in this register control the shaping of the EMIF signals, and the proper values can be determined by referring to the AC Characteristics in the Flash data sheet and the device data sheet. Table 25-31 and Table 25-32 show the pertinent AC Characteristics for reads and writes to the Flash device, and Figure 25-20 and Figure 25-21 show the associated timing waveforms. Finally, Figure 25-22 shows programming the ASYNC_CS2_CFG with the calculated values.

**Table 25-31. AC Characteristics for a Read Access**

| AC Characteristic | Device | Definition | Minimum | Maximum | Unit |
|---|---|---|---|---|---|
| $t_{SU}$ | EMIF | Setup time, read EM1D before EM1OE high | 15 | | ns |
| $t_H$ | EMIF | Data hold time, read EM1D after EM1OE high | 0 | | ns |
| $t_{ELQV}$ | Flash | nCE to Output Delay | | 90 | ns |
| $t_{EHQZ}$ | Flash | nCE High to Output in High Impedance | | 55 | ns |

**Table 25-32. AC Characteristics for a Write Access**

| AC Characteristic | Device | Definition | Minimum | Maximum | Unit |
|---|---|---|---|---|---|
| $t_{AVAV}$ | Flash | Write Cycle Time | 90 | | ns |
| $t_{ELEH}$ | Flash | nCE Pulse Width Low | 50 | | ns |
| $t_{EHEL}$ | Flash | nCE Pulse Width High (not shown in Figure 25-21) | 30 | | ns |

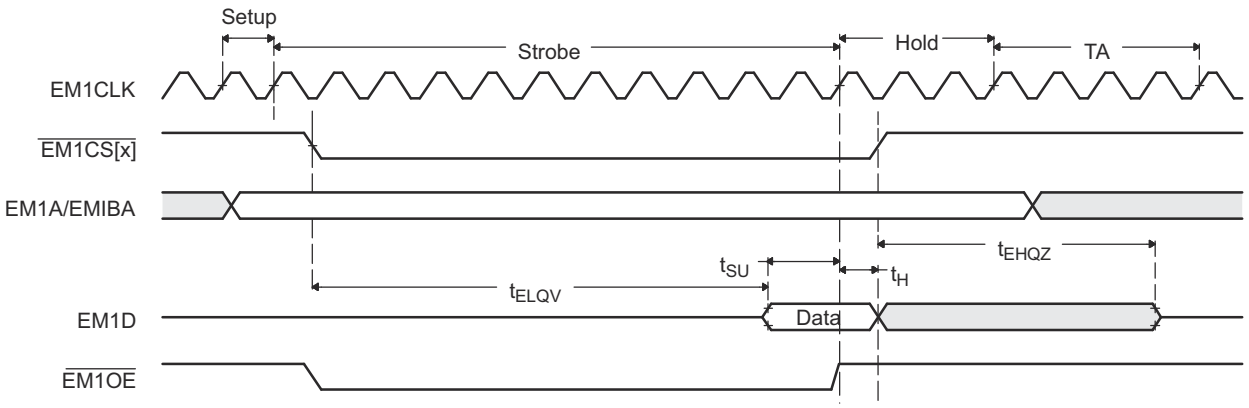

**Figure 25-20. LH28F800BJE-PTTL90 to EMIF Read Timing Waveforms**

Copyright © 2024 Texas Instruments Incorporated

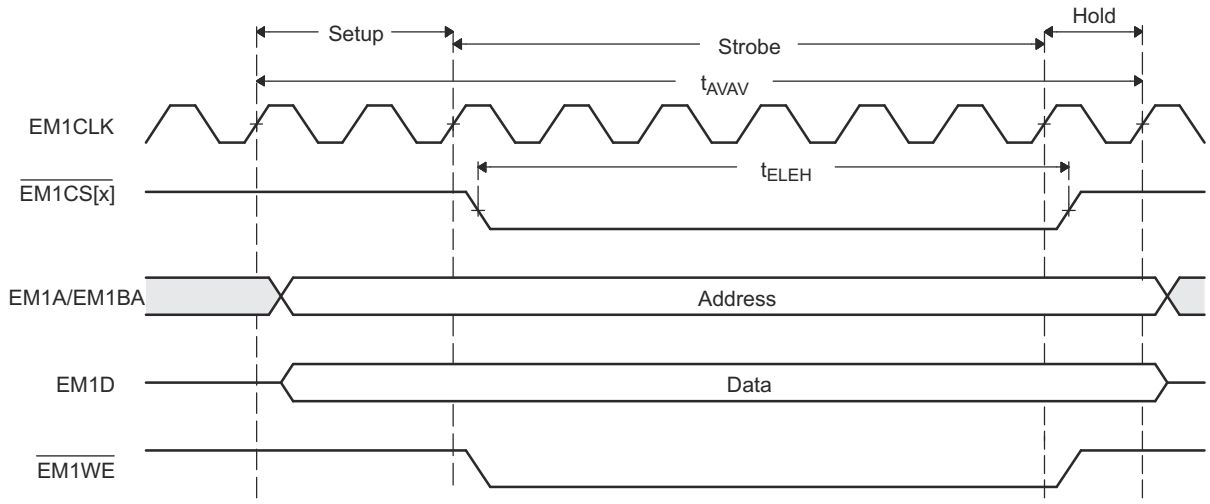

**Figure 25-21. LH28F800BJE-PTTL90 to EMIF Write Timing Waveforms**

The R_STROBE field must be set to meet the following equation:

$R_STROBE >= (t_{ELQV} + t_{SU}) \times f_{EM1CLK} - 1$

R_STROBE >= (90ns + 15ns) × 200MHz - 1

R_STROBE >= 20

R_STROBE = 20

The R_HOLD field must be large enough to satisfy EMIF Data hold time, $t_H$:

$R_HOLD > = t_H \times f_{EM1CLK} - 1$

R_HOLD >= 0ns × 200MHz - 1

R_HOLD >= -1

The R_HOLD field must also combine with the TA field to satisfy the Flash nCE High to Output in High Impedance time, $t_{EHQZ}$:

$R_HOLD + TA >= t_{EHQZ} \times f_{EM1CLK} - 2$

R_HOLD + TA >= 55ns × 200MHz - 2

R_HOLD + TA >= 9

The largest value that can be programmed into the TA field is 3h, therefore the following values must be used:

R_HOLD = 6

TA = 3

For Writes, the W_STROBE field must be set to satisfy the Flash nCE Pulse Width constraint, $t_{ELEH}$:

$W_STROBE >= t_{ELEH} \times f_{EM1CLK} - 1$

W_STROBE >= 50ns × 200MHz - 1

W_STROBE >= 9

Copyright © 2024 Texas Instruments Incorporated

The W_SETUP and W_HOLD fields must combine to satisfy the Flash nCE Pulse Width High constraint, $t_{EHEL}$:

W_SETUP + W_HOLD > = $t_{EHEL}$ × $f_{EM1CLK}$ - 2

W_SETUP + W_HOLD > = 30ns × 200MHz - 2

W_SETUP + W_HOLD > = 4

In addition, the entire Write access length must satisfy the Flash minimum Write Cycle Time, $t_{AVAV}$:

W_SETUP + W_STROBE + W_HOLD >= $t_{AVAV}$ × $f_{EM1CLK}$ - 3

W_SETUP + W_STROBE + W_HOLD >= 90ns × 200MHz - 3

W_SETUP + W_STROBE + W_HOLD >= 15

Solving the above equations for the Write fields results in the following:

W_SETUP = 4

W_STROBE = 10

W_HOLD = 1

Adding a 5ns (1 cycle) margin to each of the periods (excluding TA that is already at the maximum) in this example produces the following recommended values:

W_SETUP = 5h

W_STROBE = Bh

W_HOLD = 2h

R_SETUP = 1h

R_STROBE = 15h

R_HOLD = 7h

TA = 3h

### 25.4.2 EMIF_REGS Registers

Table 25-34 lists the memory-mapped registers for the EMIF_REGS registers. All register offset addresses not listed in Table 25-34 should be considered as reserved locations and the register contents should not be modified.

**Table 25-34. EMIF_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | RCSR | Revision Code and Status Register | | Go |
| 2h | ASYNC_WCCR | Async Wait Cycle Config Register | | Go |
| 4h | SDRAM_CR | SDRAM (EMxCS0n) Config Register | | Go |
| 6h | SDRAM_RCR | SDRAM Refresh Control Register | | Go |
| 8h | ASYNC_CS2_CR | Async 1 (EMxCS2n) Config Register | | Go |
| Ah | ASYNC_CS3_CR | Async 2 (EMxCS3n) Config Register | | Go |
| Ch | ASYNC_CS4_CR | Async 3 (EMxCS4n) Config Register | | Go |
| 10h | SDRAM_TR | SDRAM Timing Register | | Go |
| 18h | TOTAL_SDRAM_AR | Total SDRAM Accesses Register | | Go |
| 1Ah | TOTAL_SDRAM_ACTR | Total SDRAM Activate Register | | Go |
| 1Eh | SDR_EXT_TMNG | SDRAM SR/PD Exit Timing Register | | Go |
| 20h | INT_RAW | Interrupt Raw Register | | Go |
| 22h | INT_MSK | Interrupt Masked Register | | Go |
| 24h | INT_MSK_SET | Interrupt Mask Set Register | | Go |
| 26h | INT_MSK_CLR | Interrupt Mask Clear Register | | Go |

Complex bit access types are encoded to fit into small table cells. Table 25-35 shows the codes that are used for access types in this section.

**Table 25-35. EMIF_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

**Table 25-38. SDRAM_CR Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31 | SR | R/W | 0h | Self Refresh. Writing a 1 to this bit will cause connected SDRAM devices to be placed into Self Refresh mode and the EMIF to enter the self refresh state. In this state the EMIF will service all asynchronous memory accesses immediately but any SDRAM access will take at least t_ras + 1 cycles due to the time required for the SDRAM devices to out of Self Refresh mode. If an SDRAM access immediately follows the setting of the sr bit, the access will take t_ras + t_xs + 2 cycles. If both sr and pd bits are set, the EMIF will go into Self Refresh.<br>Reset type: SYSRSn |
| 30 | PD | R/W | 0h | Power Down. Writing a 1 to this bit will cause connected SDRAM devices to be placed into Power Down mode. If both sr and pd bits are set, the EMIF will go into Self Refresh.<br>Reset type: SYSRSn |
| 29 | PDWR | R/W | 0h | Perform refreshes during Power Down. Writing a 1 to this bit will cause the EMIF to exit the power down state and issue an AUTO REFRESH command every time Refresh May level is set.<br>Reset type: SYSRSn |

### 25.4.3 EMIF1_CONFIG_REGS Registers

Table 25-51 lists the memory-mapped registers for the EMIF1_CONFIG_REGS registers. All register offset addresses not listed in Table 25-51 should be considered as reserved locations and the register contents should not be modified.

**Table 25-51. EMIF1_CONFIG_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | EMIF1LOCK | EMIF1 Config Lock Register | EALLOW | Go |
| 2h | EMIF1COMMIT | EMIF1 Config Lock Commit Register | EALLOW | Go |
| 4h | EMIF1MSEL | EMIF1 Master Sel Register | EALLOW | Go |
| 8h | EMIF1ACCPROT0 | EMIF1 Config Register 0 | EALLOW | Go |

Complex bit access types are encoded to fit into small table cells. Table 25-52 shows the codes that are used for access types in this section.

**Table 25-52. EMIF1_CONFIG_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| WSonce | W<br>Sonce | Write<br>Set once |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

# Configurable Logic Block (CLB)

This chapter describes the features and operation of the configurable logic block (CLB) that is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions.

## 26.1 Introduction

The configurable logic block (CLB) is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions. The CLB is able to enhance existing peripherals through a set of crossbar interconnections, which provide a high level of connectivity to existing control peripherals such as enhanced pulse width modulators (ePWM), enhanced capture modules (eCAP), and enhanced quadrature encoder pulse modules (eQEP). The crossbars also allow the CLB to be connected to external GPIO pins. In this way, the CLB can be configured to interact with device peripherals to perform small logical functions such as simple PWM generators, or to implement custom serial data exchange protocols.

The CLB peripheral is configured through the CLB tool. For more information on the CLB tool, available examples, application reports, and user's guide, refer to the following location in your C2000WARE package (C2000Ware_2_00_00_03 and higher): C2000WARE_INSTALL_LOCATION\utilities\clb_tool\clb_syscfg\doc

## 26.2 Description

The CLB subsystem contains a number of identical tiles. There are four such tiles in the CLB subsystem; other devices can contain more or fewer tiles. Tiles are numbered 1 to N, where N is the total tile count on the device. Each tile contains combinational and sequential logic blocks, as well as other dedicated hardware to be described later in this document. Figure 26-1 shows the structure of the CLB subsystem in the device.

The tile contains the core logic, providing the logic reconfiguration capability. Each CLB tile is associated with a separate CPU interface, which contains the registers needed to control and configure the logic in the tile. The CPU interface also contains data transfer buffers that can be used as part of the configurable logic to exchange data with the rest of the device. Figure 26-2 shows the connections between the tile, the CPU interface, and the device.

### 26.2.1 CLB Clock

In this device, the CLB clock is the same as the ePWM1 clock, and the maximum frequency is 100MHz. When using CLBx, the corresponding EPWMx module clock bit must be enabled. For example, when CLB1 is being used on the device, EPWM1 clock must be enabled. Likewise, EPWM2 clock must be enabled when making use of CLB2. The other CLBs on the device follow similar requirements.

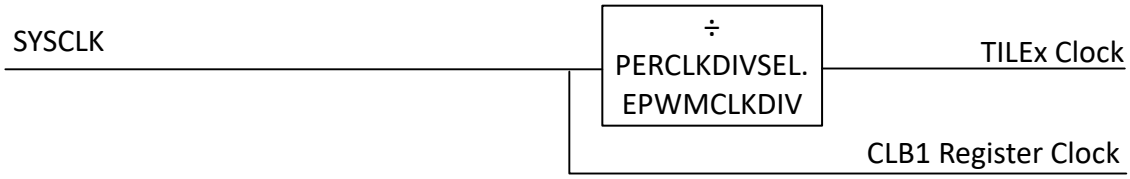

**Figure 26-3. CLB Clocking**

Copyright © 2024 Texas Instruments Incorporated

## 26.3 CLB Input/Output Connection

### *26.3.1 Overview*

There are four instances of the CLB module in the device. Each CLB instance has a common set of input signals referred to as global input signals. Additionally, each CLB instance has a specific set of input signals that are unique to each instance, and are referred to as local input signals. Each of the eight inputs of a CLB can be chosen from any of the global input signals or the local input signals.

**Note**

Signals routed into the CLB using the XBAR must be synchronized within the CLB.

### *26.3.2 CLB Input Selection*

Each CLB module has eight inputs that are applied to the reconfigurable logic cell. Each of these inputs can be selectively driven by a predefined set of signals. A two-level mux structure allows each input of each CLB instance to select a signal.

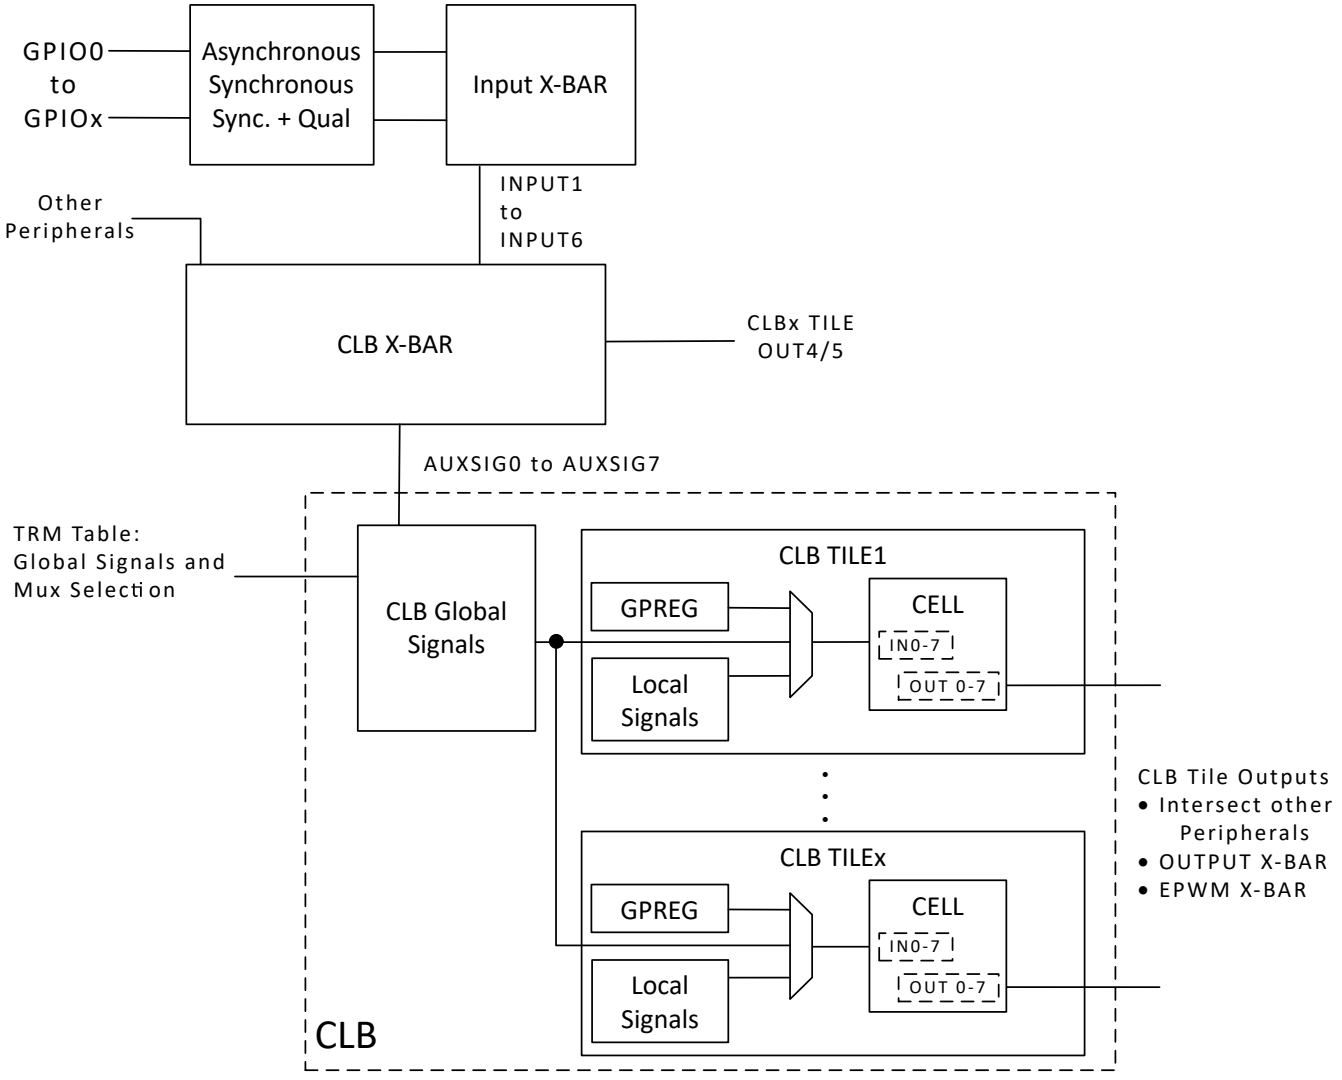

**Figure 26-4. GPIO to CLB Tile Connections**

Copyright © 2024 Texas Instruments Incorporated

A set of signals is common to all the CLB instances. These are referred to as global inputs in Figure 26-5. A separate set of signals is unique to each instance of the CLB. These are referred to as local inputs in Figure 26-5.

Registers CLB_LCL_MUX_SEL_1 and CLB_LCL_MUX_SEL_2 control the local mux selection for each of the eight inputs. The mux control registers CLB_GLBL_MUX_SEL_1 and CLB_GLBL_MUX_SEL_2 control the global mux selection for each of the eight inputs.

The local mux select value of 0 causes the selected global mux input signal to be connected to the corresponding CLB Input. For example, setting CLB_LCL_MUX_SEL_IN_0 = 0 and CLB_GLBL_MUX_SEL_IN_0 = 8 causes the global mux input number 8 to be connected to CLB Input 0. The input filter feature can be used to enable edge detection on the CLB inputs. The input filter feature can also synchronize the input with the CLB clock.

The global mux settings are shown in Table 26-1. The local input mux settings are shown in Table 26-2.

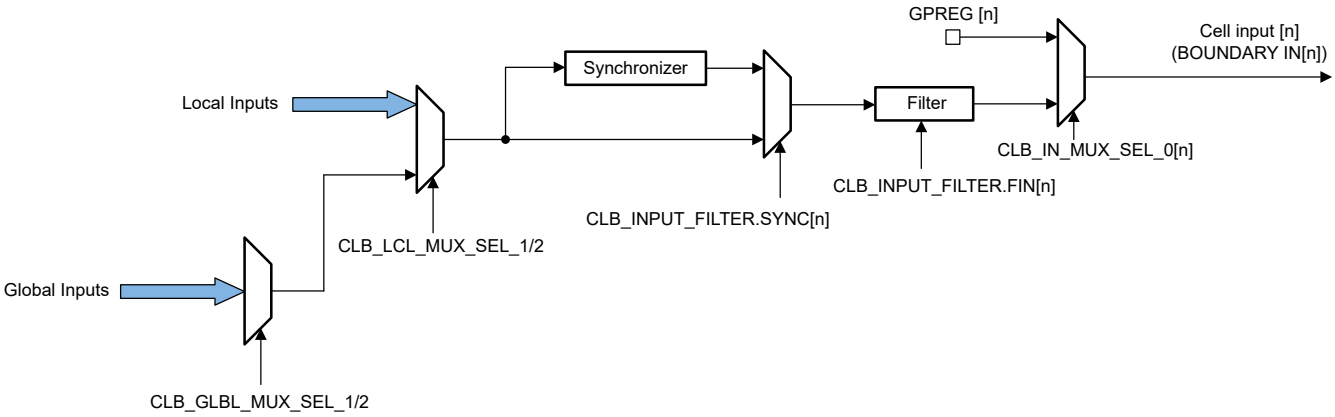

**Figure 26-5. CLB Input Mux and Filter**

Figure 26-6 shows an example of how to use synchronization for an asynchronous signal, in this case the ePWM signal.

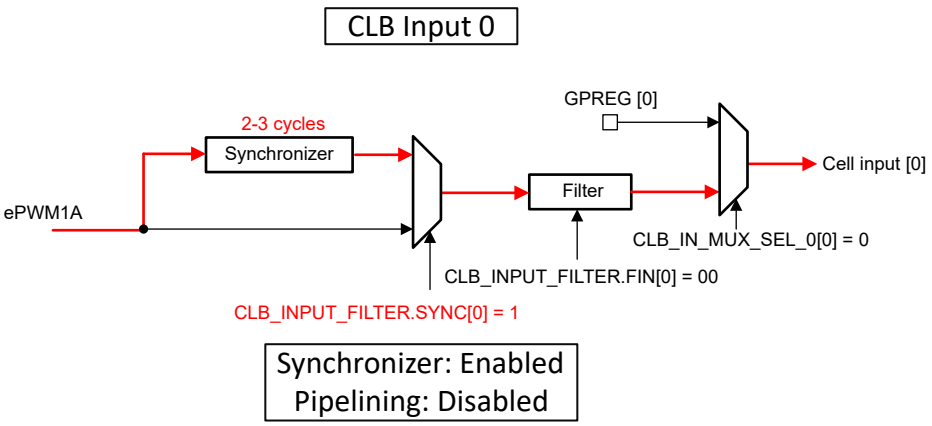

**Figure 26-6. CLB Input Synchronization Example**

Copyright © 2024 Texas Instruments Incorporated

**Note**

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

**Table 26-1. Global Signals and Mux Selection**

| Select Value | CLB1 Input | CLB2 Input | CLB3 Input | CLB4 Input | Synchronization Requirement |
|---|---|---|---|---|---|

The GPREG is accessible by the CPU and the bits of this register can be used as BOUNDARY INPUTs for the CLB Tiles. For example, CLB1s GPREG[0] can be used as BOUNDARY IN0 (Cell Input 0) for the corresponding CLB Tile.

To connect multiple tiles to each other, you can use the CLBx OUT4/5 and connect to CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

Another option is to connect the CLBx OUT0-7 to a GPIO and then use the INPUT X-BAR to bring the signal back in to the device and connect to the CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

To use GPIOs as inputs to the CLB, you must utilize the Input X-BAR and the CLB X-BAR. Figure 26-4 shows how GPIOs can be used as inputs to the CLB tiles.

Copyright © 2024 Texas Instruments Incorporated

### 26.3.3 CLB Output Selection

The eight outputs of the CLB are replicated to create 16 output signals. Each of these 16 outputs has a separate enable bit defined in the CLB output enable register, CLB_OUT_EN. The CLB outputs go to the ePWM, eCAP, eQEP and the crossbar module in the device. This allows the user to enhance the functionality of these modules with the CLB. Figure 26-7 shows the CLB outputs.

**Note**

The output from OUTLUT0 is connected to OUT0 and OUT8. While the signal is the same, each OUTy has access to a different peripheral as shown in Section 26.3.4. Likewise, OUTLUT1 is connected to OUT1 and OUT9, and are the same signal.

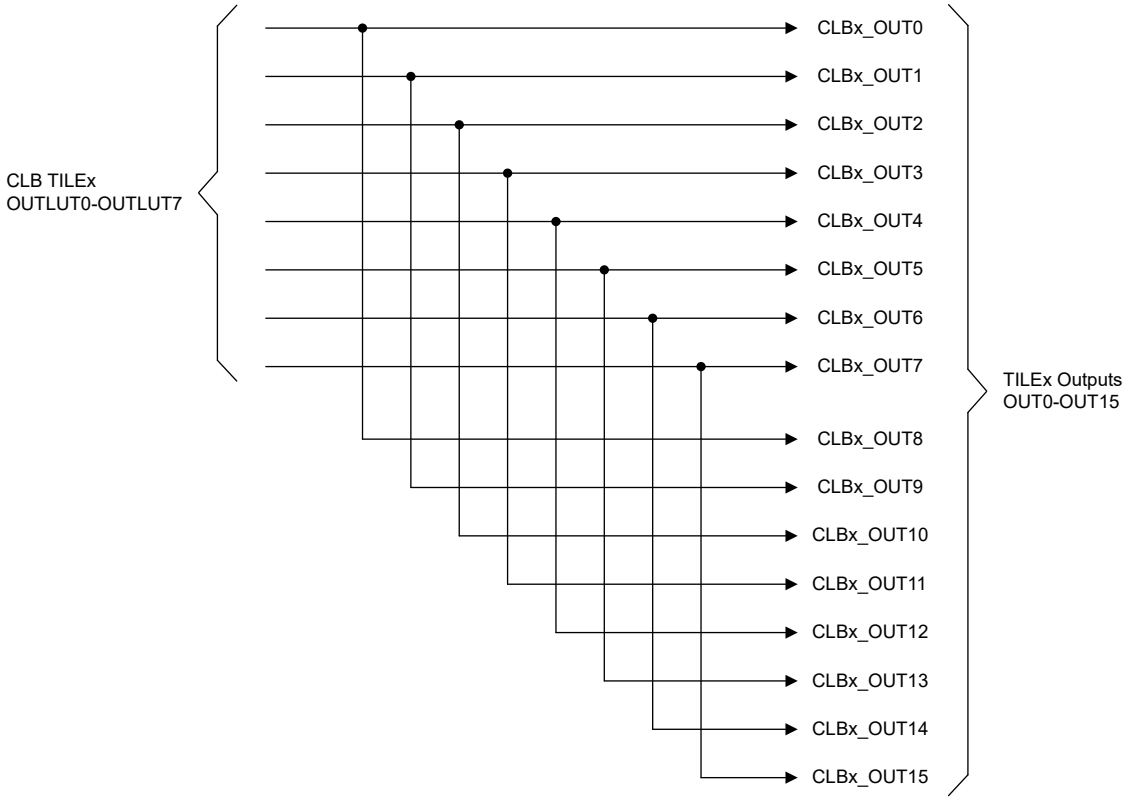

**Figure 26-7. CLB Outputs**

Copyright © 2024 Texas Instruments Incorporated

### 26.3.4 CLB Output Signal Multiplexer

Each CLB output signal passes through an external multiplexer that intersects a specific peripheral signal, see Figure 26-8. The output of the multiplexer is connected to the destination of the original peripheral signal and the default multiplexer setting is that the peripheral signal is passed through. The multiplexer is controlled by bit[n] in the CLB output enable register CLB_OUT_EN.

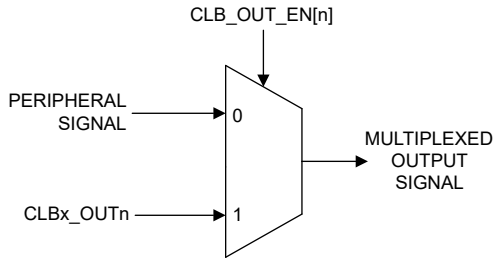

**Figure 26-8. CLB Output Signal Multiplexer**

For example, if the CLB1 OUT0 must override the EPWM1A signal, the OUPTUT ENABLE bit for OUT0 must be set to 1.

Table 26-3 shows the allocation of peripheral signals and the CLB outputs.

**Table 26-3. CLB Output Signal Multiplexer Table**

| CLB Output | CLB OUTLUT | CLB1 Destination | CLB2 Destination | CLB3 Destination | CLB4 Destination |
|---|---|---|---|---|---|
| 0 | OUTLUT0 | EPWM1A | EPWM2A | EPWM3A | EPWM4A |
| 1 | OUTLUT1 | EPWM1A_OE | EPWM2A_OE | EPWM3A_OE | EPWM4A_OE |
| 2 | OUTLUT2 | EPWM1B | EPWM2B | EPWM3B | EPWM4B |

## 26.4 CLB Tile

The purpose of the CLB tile is to provide the logic reconfiguration capability of the CLB. The CLB tile contains the following submodules:

- **Counter:** The counter submodule can be configured as an adder, a counter, or a shifter. When functioning as an adder, the counter submodule can either add or subtract. When functioning as a counter, the counter submodule can count up or count down. When functioning as a shifter, the counter submodule can shift left or shift right. The counter event inputs, as well as the reset input, can be freely connected to any of the other submodules in the same tile. There are three counters in each tile.
- **LUT4:** The LUT4 submodule has a 4-input look-up table functionality and is capable of realizing any combinatorial Boolean equation of up to four inputs. There are three LUT4 submodules in each CLB tile.
- **FSM:** The Finite State Machine (FSM) submodule can be configured either as a single four-state finite state machine, or as two independent two-state finite state machines. The FSM accepts two external inputs, and generates two state outputs and one combination output. When not used as a state machine, the FSM submodule can accept two external inputs and function as a 4-input LUT. There are three FSM submodules in each CLB tile.
- **Output LUT:** The output LUT is a 3-input lookup table submodule capable of realizing any combinatorial Boolean equation of up to three inputs. There are eight such blocks in a CLB tile, each associated with one of the tile outputs.
- **High Level Controller:** The High Level Controller (HLC) submodule is an event-driven block that can handle up to four concurrent events. The event can be an activity on any of the other block outputs. A predefined set of operations is executed when each event occurs. The HLC also provides a data exchange and interrupt mechanism to the CPU subsystem. There are four working registers (R0, R1, R2, and R3) that can be used for basic operations, and to modify or set up values for the three counter blocks. Unlike the other submodules, there is only one HLC in each CLB tile.
- **Static Switch Block:** The static switch block provides dynamic connectivity between all of the blocks listed above. Submodules can be connected by the user, with the only restriction that the submodules must not form a combinational loop within the tile.

A CLB tile consists of three sets each of the counter block, FSM, and LUT4, one high-level controller, and eight output LUT blocks. The submodule numbering is shown in Figure 26-9.

The functionality of the LUT submodules is configured using a register field containing the binary pattern of the output of the desired look-up table. For example, a 4-input LUT has 16 possible input permutations, each of which corresponds to a desired binary 0 or 1 at the output. The register field can, therefore, be 16-bits in length, with each bit representing the desired result of a binary pattern. Input pattern sequences start at 0000 and continue sequentially to 1111. A similar method is used to encode the 16-bit state equations in the FSM submodule.

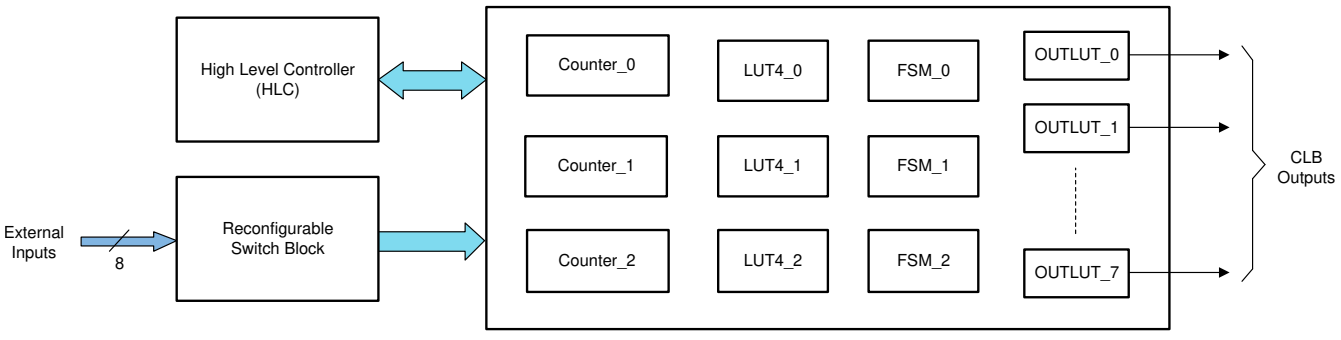

**Figure 26-9. CLB Tile Submodules**

Copyright © 2024 Texas Instruments Incorporated

### 26.4.1 Static Switch Block

The Static Switch Block provides the configurable connectivity between the submodules in the CLB tile. The outputs of all the submodules and the eight external inputs are connected to a common internal bus inside the tile. Every input port has a 32-to-1 multiplexer and an associated 5-bit selection value that allows the user to select one of the inputs on the bus. The only restrictions are certain signals (described below) that are tied off in the design to prevent creation of accidental combinatorial loops.

**Table 26-4. Output Table**

| Bit Position | Signal Connection | Comment |
|---|---|---|
| 0 | Always 0 | This select value is used to tie an input to 0. |
| 1 | COUNTER_0 MATCH2 | |
| 2 | COUNTER_0 ZERO | |
| 3 | COUNTER_0 MATCH1 | |
| 4 | FSM_0 STATE_BIT_0 | |
| 5 | FSM_0 STATE_BIT_1 | |
| 6 | FSM_0 LUT output | |
| 7 | LUT4_0 output | |
| 8 | Always 1 | This select value is used to tie an input to 1. |
| 9 | COUNTER_1 MATCH2 | |
| 10 | COUNTER_1 ZERO | |
| 11 | COUNTER_1 MATCH1 | |
| 12 | FSM_1 STATE_BIT_0 | |
| 13 | FSM_1 STATE_BIT_1 | |
| 14 | FSM_1 LUT output | |
| 15 | LUT4_1 output | |
| 16 | Always ‘0’ | |
| 17 | COUNTER_2 MATCH2 | |
| 18 | COUNTER_2 ZERO | |
| 19 | COUNTER_2 MATCH1 | |
| 20 | FSM_2 STATE_BIT_0 | |
| 21 | FSM_2 STATE_BIT_1 | |
| 22 | FSM_2 LUT output | |
| 23 | LUT4_2 output | |
| 24 | External Input 0 | |
| 25 | External Input 1 | |
| 26 | External Input 2 | |
| 27 | External Input 3 | |
| 28 | External Input 4 | |
| 29 | External Input 5 | |
| 30 | External Input 6 | |
| 31 | External Input 7 | |

Copyright © 2024 Texas Instruments Incorporated

**Table 26-5. Input Table**

| Module Name | Port Name | Description |
|---|---|---|
| Counter Block | RESET | Acts as an active high reset when used as a counter |
| | MODE_0 | Acts as an enable when used as a counter. The counter counts only when this input is 1. |
| | MODE_1 | Acts as a direction control when used as a counter. If this input is 1, then the counter counts up; else, the counter counts down. |
| LUT | IN0 | Input 0 of the 4-input LUT. |
| | IN1 | Input 1 of the 4-input LUT. |
| | IN2 | Input 2 of the 4-input LUT. |
| | IN3 | Input 3 of the 4-input LUT. |
| FSM | EXT_IN0 | Input 0 of the FSM block. |
| | EXT_IN1 | Input 1 of the FSM block. |
| | EXTRA_EXT_IN0 | Extra external input 0 of the FSM block. This input matters only if configured in the LUT mode. |
| | EXTRA_EXT_IN1 | Extra external input 1 of the FSM block. This input matters only if configured in the LUT mode. |

The static switch block allows the user to define the input connection of any submodule to come from any of the outputs in Table 26-4. It is therefore easy to create a combinatorial loop. To prevent this, certain paths are broken in the input path of each submodule. These port positions are tied to 0, as shown in Table 26-6.

**Table 26-6. Ports Tied Off to Prevent Combinatorial Loops**

| Module Name | Ports of Input MUX Tied Off to 0 to Prevent Combinational Loops |
|---|---|
| LUT_0 | LUT_0 , LUT_1, and LUT_2 output, FSM_0, FSM_1, and FSM_2 output. |
| FSM_0 | LUT_1 and LUT_2 output, FSM_0, FSM_1, and FSM_2 output. |
| LUT_1 | LUT_1 and LUT_2 output, FSM_1 and FSM_2 output. |
| FSM_1 | LUT_2 output, FSM_1 and FSM_2 output. |
| LUT_2 | LUT_2 output, FSM_2 output. |
| FSM_2 | FSM_2 output. |

### 26.4.2 Counter Block

#### 26.4.2.1 Counter Description

The counter block is a complex functional submodule that can be configured either as a counter, an adder, or a shifter. Apart from the normal operational control, this block has a dedicated EVENT input, which can trigger an addition, subtraction or shift operation, or load data into the counter register. The inputs to the counter submodule are shown in Figure 26-10.

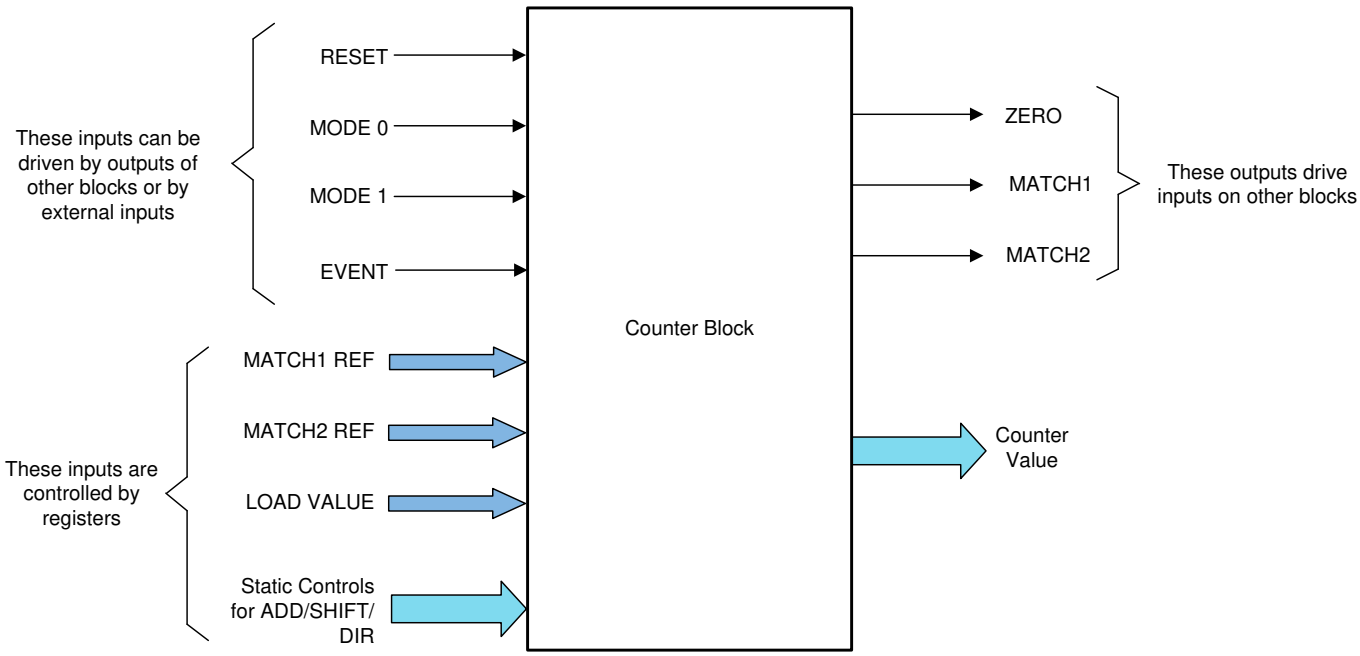

**Figure 26-10. Counter Block**

Copyright © 2024 Texas Instruments Incorporated

#### 26.4.2.2 Counter Operation

At the heart of the counter block is a 32-bit count register. This register can either be loaded statically before counting commences, or dynamically at run time. The operation of the counter submodule is determined by the inputs described below. Note that each of the inputs can be connected to the outputs of any of the other blocks in the CLB tile. These connections are made by configuring the static switch block.

The counter inputs are:

- **RESET:** This is the highest priority input and takes precedence over all other inputs. The input is level sensitive and as long as the input remains high, the counter resets to 0 on the next clock cycle.
- **MODE_0:** This input is an enable for the counter. The counter begins counting (up or down depending on the MODE_1 setting) only when this input is high. If this input is low, then no counting takes place.
- **MODE_1:** This input is the direction control for the counter. If this input is high, then the counter increments on every clock cycle where MODE_0 is high. If this input is low, then the counter decrements on every clock cycle where MODE_0 is high. The counter wraps around to 0x0000 0000 after 0xFFFF FFFF when counting up. The counter wraps around to 0xFFFF FFFF after 0x0000 0000 when counting down. The only exception to this is when an EVENT occurs at exactly the same time, causing a different value to be loaded into the counter.
- **EVENT:** This input is defined for the purpose of triggering actions in the counter based on certain events. The event can be any of the outputs of the other blocks or an external input to the tile. The counter's static control inputs define the behavior of the counter on an active event. An active event is defined as a rising edge on the EVENT input. The counter can be configured to perform one of the following actions:
  - Load a predefined 32-bit value from the LOAD VALUE register into the count register
  - Shift the contents of the counter register left or right by a predefined amount between 0 and 31
  - Add or subtract a predefined 32-bit value. Addition and subtraction are treated as 32-bit unsigned operations and there is no saturation.

  Note that the effect of a rising edge on the EVENT input only lasts for one cycle. On the next cycle, the counter operation continues based on the MODE_0, MODE_1, and RESET inputs.

MATCH1 REF and MATCH2 REF are 32-bit reference values that are used to generate the MATCH1 and MATCH2 outputs. The MATCH1 output becomes active high whenever the counter register value matches the 32-bit MATCH1 REF value. MATCH2 behaves in a similar manner in relation to the MATCH2 REF register. The reference values for MATCH1 and MATCH2 can either be setup once before the start of operation, or can be modified dynamically. The High Level Controller can load desired values into the MATCH1 REF and MATCH2 REF registers.

Note that the counter load and match registers are not memory-mapped. For more information, see Section 26.5.2.

The three logic outputs of the counter block are:

- **ZERO:** This output goes high whenever the counter register is 0.
- **MATCH1:** This output goes high whenever the counter register is equal to the MATCH1 REF input register.
- **MATCH2:** This output goes high whenever the counter register is equal to the MATCH2 REF input register.

The operation of the counter block is controlled by the CFG_MISC_CTRL register. The following three bits of this register are relevant for each counter. The "x" below refers to the counter instance; 0, 1, or 2. For more information, see the CLB_MISC_CONTROL register description located in Section 26.8.

- COUNT_EVENT_CTRL_x: This bit defines whether the counter performs an addition or a shift on an event. A value of 0 means that on an event, the counter loads the static value; 1 means an add/shift operation is performed. This bit must be 0 for indirect loads and HLC loads of the counter to take effect.
- COUNT_ADD_SHIFT_x. 1 means add, 0 means shift.
- COUNT_DIR_x. 1 means left shift or add. 0 means right shift or subtract.

Copyright © 2024 Texas Instruments Incorporated

Table 26-7 shows the logical operation of the counter block in terms of the inputs and control register bits. Count up and down modes are the normal operation with EVENT = 0. The operations on the CNTVAL register are:

Load: CNTVAL = EVENT_LOAD_VAL

Shift right: CNTVAL = CNTVAL >> EVENT_LOAD_VAL

Shift left: CNTVAL = CNTVAL << EVENT_LOAD_VAL

Subtract: CNTVAL = CNTVAL - EVENT_LOAD_VAL

Add: CNTVAL = CNTVAL + EVENT_LOAD_VAL

**Table 26-7. Counter Block Operating Modes**

| EVENT | MODE_0 | MODE_1 | COUNT_EVENT_CTRL_x | COUNT_ADD_SHIFT_x | COUNT_DIR_x | Action on CNTVAL |
|---|---|---|---|---|---|---|
| 0 | 0 | 0 | X | X | X | None |
| 0 | 0 | 1 | X | X | X | None |
| 0 | 1 | 0 | X | X | X | Count down |
| 0 | 1 | 1 | X | X | X | Count up |
| 1 | X | X | 0 | X | X | Load |
| 1 | X | X | 1 | 0 | 0 | Shift right |
| 1 | X | X | 1 | 0 | 1 | Shift left |
| 1 | X | X | 1 | 1 | 0 | Subtract |
| 1 | X | X | 1 | 1 | 1 | Add |

### 26.4.3 FSM Block

The Finite State Machine (FSM) block provides the ability to build programmable finite state machines with up to four states. The FSM block has two register bits and two external inputs, and can be programmed either as two 2-state machines or as a single 4-state machine. For additional flexibility, there are two auxiliary inputs (EXTRA_EXT_IN0 and EXTRA_EXT_IN1) that can be used to create larger combinational functions by giving up a state functionality. The structure of the FSM is shown in Figure 26-11.

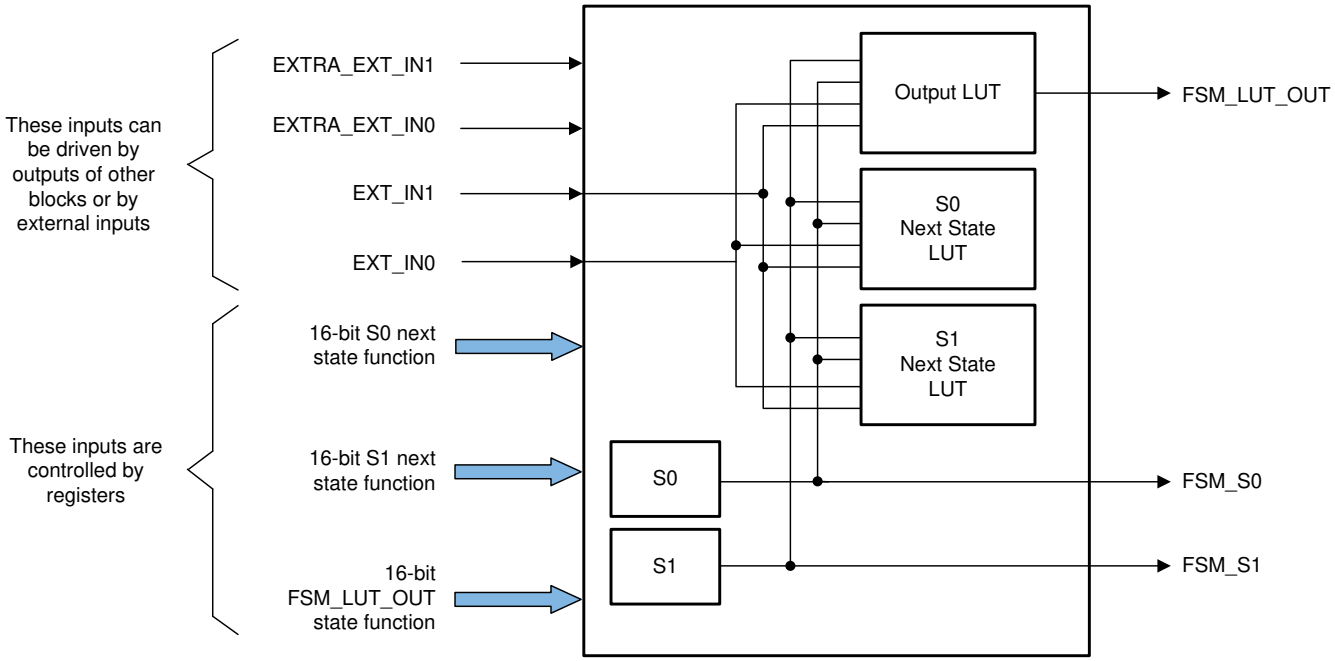

**Figure 26-11. FSM Block**

Copyright © 2024 Texas Instruments Incorporated

The signals and functionality of the FSM block are:

- **EXT_IN0 and EXT_IN1:** These are the two external inputs that can be used to control the output FSM_LUT_OUT or either of the states S0 and S1.
- **S0** and **S1** are two state bits that have independent state control equations.
- **16-bit S0 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S0.
- **16-bit S1 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S1.
- **16-bit output equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the output value of FSM_LUT_OUT. An additional level of configurability is provided such that FSM_LUT_OUT can use extra inputs in case the states S0 and S1 are unused.

  One extra bit is used to select EXTRA_EXT_IN0 instead of S0. One extra bit is used to select EXTRA_EXT_IN1 instead of S1. Using these, one can effectively build 3-input or a 4-input LUT for the FSM_LUT_OUT by giving up one or two state bits, respectively.

The CFG_MISC_CTRL register controls the operation of the FSM block. Two bits in this register are used for each FSM Block to determine whether the FSM output LUT function uses the state variable S0/S1, or the corresponding extra external input signal FSM_EXTRA_EXT_INx. A 0 means use the state bit, and a 1 means use the FSM_EXTRA_EXT_IN0 / FSM_EXTRA_EXT_IN1 signal.

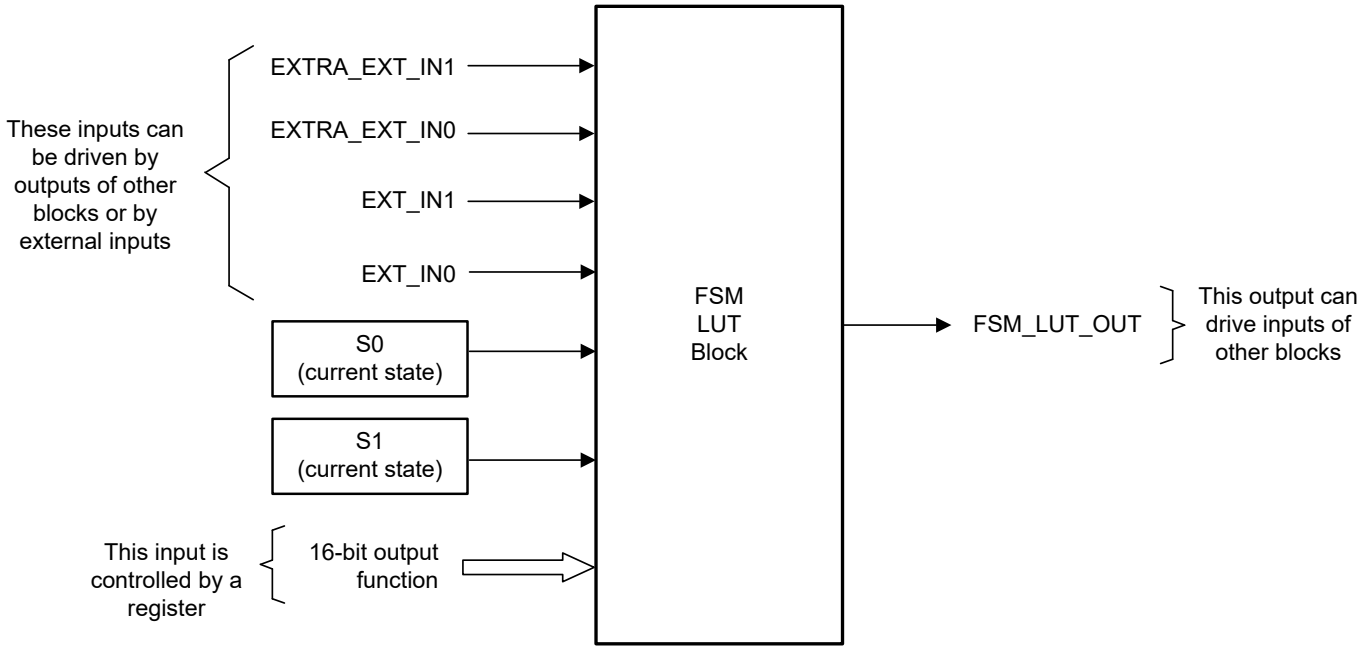

**Figure 26-12. FSM LUT Block**

Copyright © 2024 Texas Instruments Incorporated

### 26.4.4 LUT4 Block

This is a simple four input Look-Up table (LUT) block with inputs IN0, IN1, IN2, and IN3 (see Figure 26-13). Any combinatorial Boolean equation using the four inputs can be realized by programming the 16-bit control register associated with each LUT4 block. For more information, see the LUT4 register descriptions located in Section 26.8.

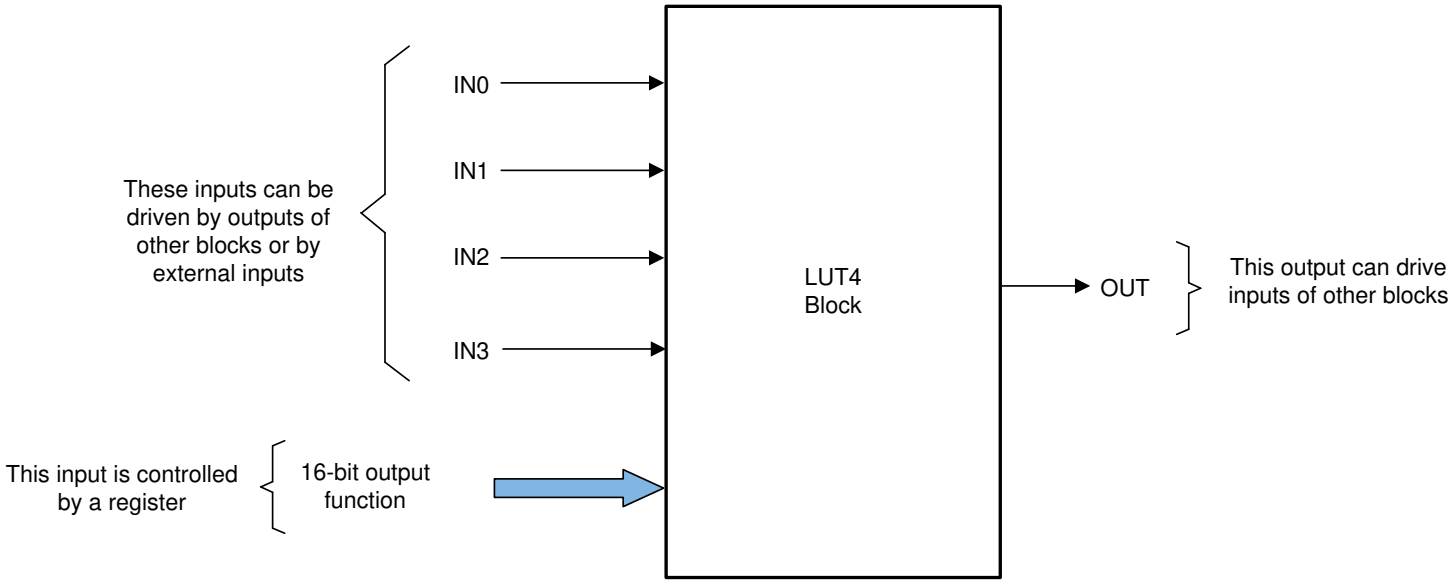

**Figure 26-13. LUT4 Block**

### 26.4.5 Output LUT Block

The output LUT block (Figure 26-14) is very similar in functionality to the LUT4 block, except that the output LUT block has three inputs. Unlike the other sub blocks, the outputs of these blocks are meant to go out of the tile and hence cannot be used by any other block within the tile. Any combinatorial function of the three inputs can be realized by the output LUT block. For more information, see the output LUT register descriptions located in Section 26.8.

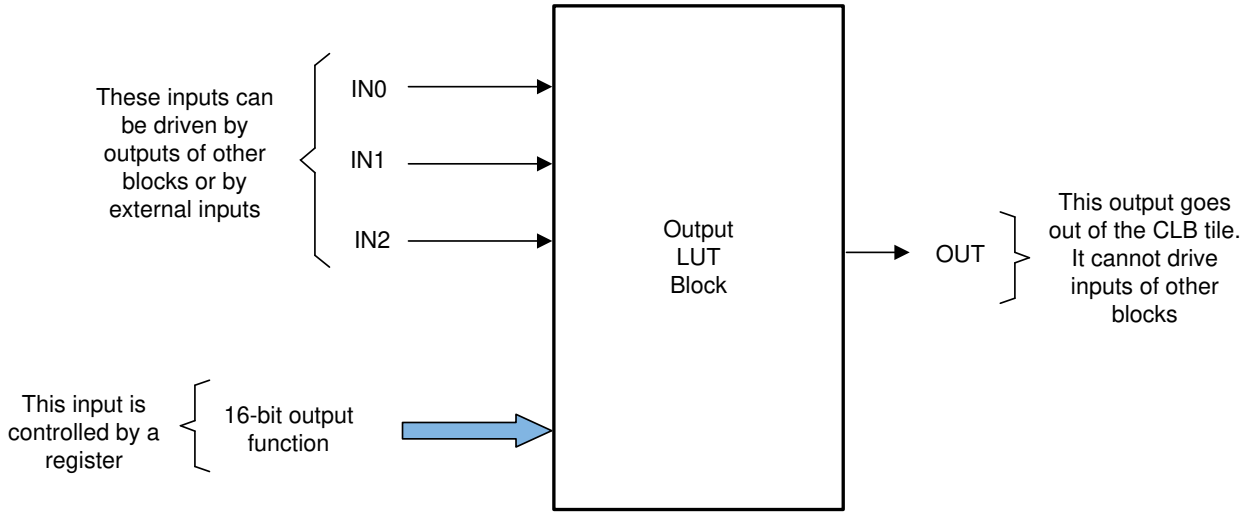

**Figure 26-14. Output LUT Block**

Copyright © 2024 Texas Instruments Incorporated

### 26.4.6 High Level Controller (HLC)

The High Level Controller (HLC) is significantly more complex than the other blocks in the CLB tile. The HLC performs two main functions:

- Provides a means of communication and data exchange with the rest of the device. This is done through two methods: a global access path to four general purpose HLC registers (R0 through R3) and PUSH and PULL FIFOs between the CPU and the HLC. The general-purpose HLC registers are designed to only be written to during device configuration time. To avoid unexpected behavior, the HLC registers must not be written to during run-time operation. The PUSH and PULL FIFOs are the primary avenues of data exchange during run-time, refer to Section 26.4.6.4 for more information.
- Provides a programmable, event-based action system, which performs computation, manipulation of logic functionality, and data movement. In other words, events can be configured to trigger a predefined set of actions in the CLB tile, or to initiate data exchange with the rest of the device.

The architecture of the HLC is shown in Figure 26-15. The HLC is an event-based system capable of handling up to four simultaneous events that can be selected from any outputs of the other blocks within the tile or from an external input.

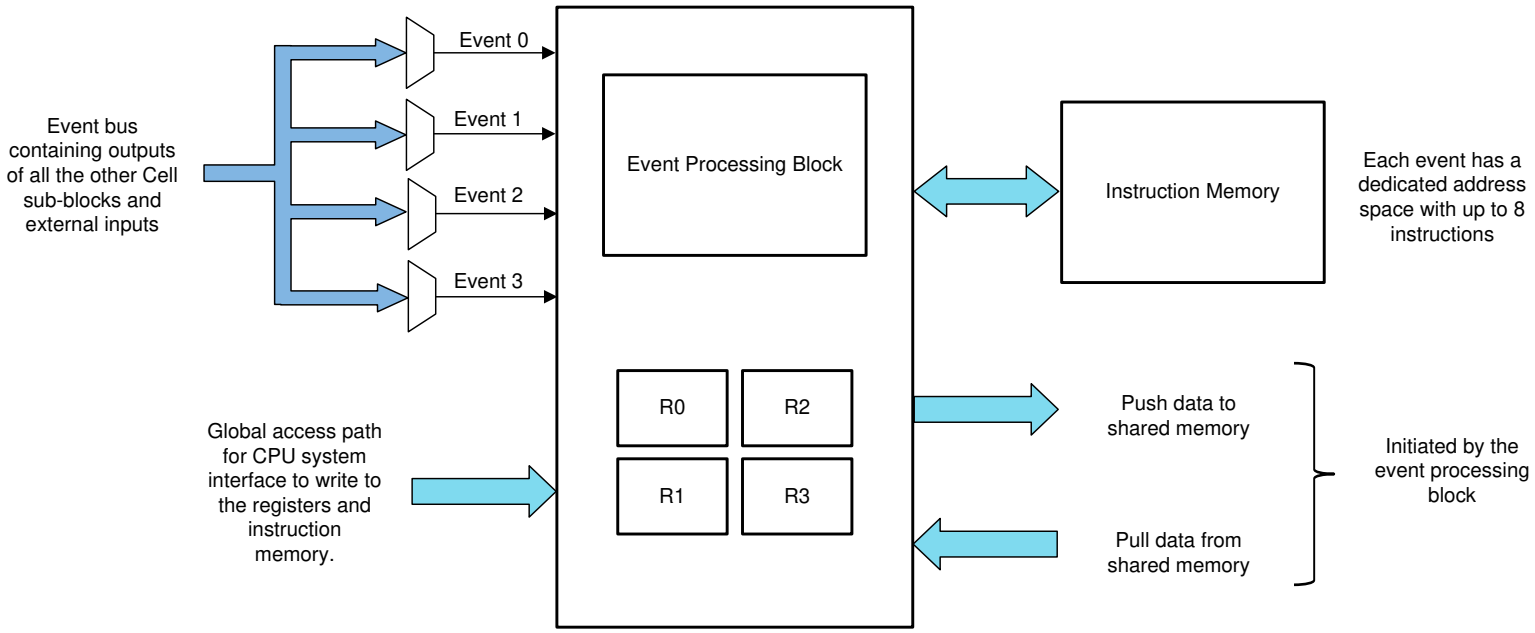

**Figure 26-15. High Level Controller Block**

Copyright © 2024 Texas Instruments Incorporated

#### 26.4.6.1 High Level Controller Events

Each of the four HLC events has a dedicated address from which instructions are executed. Events are selected from the set of signals listed in Table 26-8. The lowest numbered event (Event 0) has the highest priority, and the highest numbered event (Event 3) has the lowest priority.

**Table 26-8. HLC Event List**

| Index | HLC Event Mux |
|---|---|
| 0 | Always 0 |
| 1 | COUNTER_0 MATCH2 |
| 2 | COUNTER_0 ZERO |
| 3 | COUNTER_0 MATCH1 |
| 4 | FSM_0 STATE_BIT_0 |
| 5 | FSM_0 STATE_BIT_1 |
| 6 | FSM_0 LUT output |
| 7 | LUT4_0 output |
| 8 | Always 1 |
| 9 | COUNTER_1 MATCH2 |
| 10 | COUNTER_1 ZERO |
| 11 | COUNTER_1 MATCH1 |
| 12 | FSM_1 STATE_BIT_0 |
| 13 | FSM_1 STATE_BIT_1 |
| 14 | FSM_1 LUT output |
| 15 | LUT4_1 output |
| 16 | Always ‘0’ |
| 17 | COUNTER_2 MATCH2 |
| 18 | COUNTER_2 ZERO |
| 19 | COUNTER_2 MATCH1 |
| 20 | FSM_2 STATE_BIT_0 |
| 21 | FSM_2 STATE_BIT_1 |
| 22 | FSM_2 LUT output |
| 23 | LUT4_2 output |
| 24 | External Input 0 |
| 25 | External Input 1 |
| 26 | External Input 2 |

#### 26.4.6.2 High Level Controller Instructions

The instruction memory supports up to eight instructions per event. Each instruction sequence gets triggered on the rising edge of the corresponding event.

The HLC memory supports up to eight instructions per event, starting at the beginning of the fixed address range shown in Table 26-9. An instruction sequence is triggered on the rising edge of the corresponding event. If two or more events occur simultaneously, the associated instruction sequences each are executed sequentially in priority order.

**Table 26-9. HLC Instruction Address Ranges**

| Address | Instructions for |
|---|---|
| 00000 to 00111 | Event 0 |
| 01000 to 01111 | Event 1 |
| 10000 to 10111 | Event 2 |
| 11000 to 11111 | Event 3 |

The HLC instruction format is shown in Table 26-10.

**Table 26-10. HLC Instruction Format**

| Last Instruction Bit | 5-Bit Opcode | 3-Bit Source | 3-Bit Destination |
|---|---|---|---|
| This bit when set to 1 stops execution after the current instruction. | MOV 00000<br>MOV_T1 00001<br>MOV_T2 00010<br>PUSH 00011<br>PULL 00100<br>ADD 00101<br>SUB 00110<br>INTR 00111 | Source can be R0, R1, R2, R3, C0, C1, C2. | Destination can be R0, R1, R2, R3, C0, C1, C2.<br>Note that for ADD/SUB instructions, only R0, R1, R2, or R3 can be the destination. |

R0, R1, R2, and R3 are four 32-bit general-purpose registers in the HLC. C0, C1, and C2 are three counter registers present in the CLB tile. <Src> is used to indicate the source and <Dest> is used to indicate the destination. Table 26-11 describes the HLC instructions.

**Table 26-11. HLC Instruction Description**

| Instruction | Description |
|---|---|
| ADD <Src>, <Dest> | This instruction performs an unsigned 32-bit addition. <Dest> = <Dest> + <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3. |
| INTR <6-bit constant> | This instruction flags an interrupt through the CPU interface. The 6-bit constant is stored in the interrupt flag register CLB_INTR_TAG_REG. If multiple INTR instructions are called consecutively, only the first one has an effect. When multiple INTR calls are needed, each can be separated by other HLC instructions to make sure the interrupt calls take effect. |
| MOV <Src>, <Dest> | This instruction moves <Src> to <Dest>. Both <Src> and <Dest> can be any of R0, R1, R2, R3, C0, C1, or C2. The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and HLC loads of the counter to take effect. |
| MOV_T1 <Src>, <Dest> | This instruction moves <Src> to the Match1 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match1 register of any of the counters C0, C1, or C2. Examples are:<br>• This instruction moves the count value in C1 into register R0:<br>MOV_T1 C1 R0<br>• This instruction moves the value in R2 into the Match1 register of counter C0:<br>MOV_T1 R2 C0 |
| MOV_T2 <Src>, <Dest> | This instruction is similar to MOV_T1. The instruction moves <Src> to the Match2 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match2 register of any of the counters C0, C1, or C2. |

Copyright © 2024 Texas Instruments Incorporated

**Table 26-11. HLC Instruction Description (continued)**

| Instruction | Description |
|---|---|
| PULL <Dest> | This instruction transfers data from the data exchange pull memory buffer in the CPU interface to the <Dest> register. <Dest> can be any of R0, R1, R2, or R3. The PULL instruction is used as seen from the High Level Controller and a PULL operation reads (pulls) data from an internal 4-word FIFO.<br>**Note**<br>Back-to-back PUSH/PULL instructions cannot be used, if using more than one HLC EVENT channel. |
| PUSH <Src> | This instruction transfers data from <Src> to the data exchange push memory buffer in the CPU interface. <Src> can be any of R0, R1, R2, R3, C0, C1, or C2. The PUSH instruction is used as seen from the High Level Controller and pushes data into an internal 4 word FIFO. |
| SUB <Src>, <Dest> | This instruction performs an unsigned 32-bit subtraction. <Dest> = <Dest> - <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3. |

MOV, MOV_T1, MOV_T2, ADD, SUB, and INTR instructions take one cycle to execute. PUSH and PULL require two cycles to execute. Note that the PUSH and PULL instructions are pipeline protected, meaning that a register can be used immediately after a PUSH/PULL to that register.

For multiple events triggered simultaneously, if the last instruction in the higher priority event is a PUSH or a PULL, there is an additional cycle delay between the end of the higher priority event and the start of the next event. If the last instruction is not a PUSH or PULL, then there is no cycle delay between the events.

If there is the possibility of more than one event coming into the HLC, then PUSH/PULL instructions must not be placed back-to-back. It is necessary to re-order the HLC instructions such that every PUSH and PULL is followed by a non-PUSH/PULL instruction. If only one event can enter the HLC at any time, then back-to-back PUSH/PULL is not an issue.

#### 26.4.6.3 <Src> and <Dest>

Three bits are used to encode the <Src> and <Dest> registers as shown in Table 26-12.

**Table 26-12. HLC Register Encoding**

| Bits | Register |
|---|---|
| 000 | R0 |
| 001 | R1 |
| 010 | R2 |
| 011 | R3 |
| 100 | C0 |
| 101 | C1 |
| 110 | C2 |

Copyright © 2024 Texas Instruments Incorporated

#### 26.4.6.4 Operation of the PUSH and PULL Instructions (Overflow and Underflow Detection)

The PUSH and PULL operations of the HLC are intended for data exchange with the host system. There are separate FIFO buffers for PUSH and PULL operations. For example, a series of PUSH operations write to successive locations in a linearly mapped-memory buffer. The PUSH buffer and the PULL buffer are mapped at address offsets shown in the *Registers* section.

The CPU can read from and write to the PUSH and PULL buffers, respectively, to exchange data with the HLC. Data pushed by the HLC is read by the CPU from the PUSH buffers. Data sent from the CPU to the HLC is written by the CPU to the PULL buffer and is read by the HLC using the PULL instruction.

Refer to *clb_ex13_push_pull* for guidance on properly using the PUSH and PULL buffers. To make use of one of the CLB inputs as a GPREG, have this input indicate when data is written to the FIFO by the CPU.

There are separate PUSH and PULL address pointers that increment each time the HLC performs a PUSH or PULL operation. These address pointers are also memory-mapped so that the CPU can determine the value. These address pointers are also writable and can be reset by the CPU at any time.

Overflow and underflow detection is done by simply reading the values of the PUSH and PULL address pointers.

In the CLB module of the device, the depth of the PUSH and PULL FIFOs is four 32-bit words each. If the CPU starts a fresh data transfer to the PULL buffers and sees the address pointer greater than four, then an underflow has occurred since the HLC has pulled more data than the number of words written by the CPU into the buffer.

**Note**

Back-to-back PUSH and PULL instructions (in either order) do not work, if you have more than one HLC event enabled.

## 26.5 CPU Interface

### *26.5.1 Register Description*

There are three classes of registers that are used to control and configure the CLB tile. This specification only describes the offset addresses of the registers. The absolute register addresses are different for each CLB tile. The three instances of the various blocks (LUT4, FSM, and Counter Block) are numbered 0, 1, and 2.

- **Logic configuration registers (0x000 – 0x0FF):** These registers control the core reconfiguration logic for the tile. All registers in this group are EALLOW protected and also protected by the LOCK register.
- **Top level control registers (0x100 – 0x1FF):** These registers are used for top level and device related control of the CLB. These registers typically control mux selects for inputs, global enables, and so forth, and are accessible by normal memory mapped access. Some of these registers have EALLOW and LOCK protection.
- **Data exchange registers (0x200 – 0x3FF):** These registers are used to exchange data between the CLB and the rest of the device. The registers are accessible by normal memory-mapped access and no EALLOW or LOCK protection exists.

**Note**

EALLOW protection means that the write access to the register is enabled only when the EALLOW instruction has been executed prior to the write access. The complementary EDIS instruction disables access to all registers protected in this way. For more information, see Section 26.8.

Copyright © 2024 Texas Instruments Incorporated

### 26.5.2 Non-Memory Mapped Registers

The memory-mapped CLB registers are described later in this chapter; however, many of the CLB resources including counters, the instruction memory of the High Level Controller, and the HLC general-purpose registers (R0 through R3) are only indirectly accessible through a local interface bus and are not memory-mapped. These registers are accessible through the two memory-mapped registers CLB_LOAD_DATA and CLB_LOAD_ADDR. Note that the general-purpose registers R0 through R3 must only be written to during configuration-time and are not intended to be written to during run-time. Writes during run-time can lead to unexpected behavior. If run-time data exchange is desired, refer to Section 26.4.6.4.

Load the data to be written into the CLB_LOAD_DATA register, then load the appropriate address into CLB_LOAD_ADDR to determine where this data is written. Writing a 1 to bit position 0 in the CLB_LOAD_EN register then causes an internal write operation to be triggered. The address allocation for the CLB_LOAD_ADDR register is shown in Table 26-13.

**Note**

The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and for HLC loads of the counter to take effect.

**Table 26-13. Non-Memory Mapped Register Addresses**

| Address (Binary) | Resource |
|---|---|
| 000000 to 000010 | Counter 0 to 2 Load value |
| 000100 to 000110 | Counter 0 to 2 Match1 value |
| 001000 to 001010 | Counter 0 to 2 Match2 value |
| 001100 to 001111 | R0 to R3 of High Level Controller |
| 100000 to 100111 | Instructions for Event 0 |
| 101000 to 101111 | Instructions for Event 1 |
| 110000 to 110111 | Instructions for Event 2 |
| 111000 to 111111 | Instructions for Event 3 |

Use the following steps to load the value 0x11223344 into the general purpose R0 register:

1. Write 0x11223344 to CLB_LOAD_DATA.
2. Write 0xc to CLB_LOAD_ADDR.
3. Write 0x1 to CLB_LOAD_EN.

**Note**

Even though HLC registers are accessible by the CPU, your application code needs to make sure that no other CLB internal logics are updating the same HLC register at the same time, causing a race condition.

## 26.6 DMA Access

The DMA does not have access to the CLB memory-mapped registers, including the PUSH and PULL FIFO registers. For more information, refer to Section 26.8.

Copyright © 2024 Texas Instruments Incorporated

## 26.7 Software

### *26.7.1 CLB Examples*

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/clb

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

#### 26.7.1.1 CLB Empty Project

FILE: empty.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

#### 26.7.1.2 CLB Combinational Logic

FILE: clb_ex1_combinatorial_logic.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

The objective of this example is to prevent simultaneous high or low outputs on a PWM pair. PWM modules 1 and 2 are configured to generate identical waveforms based on a fixed frequency up-count mode.

#### 26.7.1.3 CLB GPIO Input Filter

FILE: clb_ex2_gpio_input_filter.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example demonstrates use of finite state machines (FSMs) and counters to implement a simple ‘glitch’ filter which might, for example, be applied to an incoming GPIO signal to remove unwanted short duration pulses.

#### 26.7.1.4 CLB Auxilary PWM

FILE: clb_ex3_auxiliary_pwm.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example configures a CLB tile as an auxiliary PWM generator. The example uses combinatorial logic (LUTs), state machines (FSMs), counters, and the high level controller (HLC) to demonstrate the PWM output generation capabilities using CLB.

#### 26.7.1.5 CLB PWM Protection

FILE: clb_ex4_pwm_protection.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example extends the features of example 1 to ensure an active high complementary pair PWM configuration always operates with a minimum value of dead-band irrespective of how the generating PWM module is configured. The example illustrates the configuration of four separate PWM tiles to implement PWM protection on four PWM modules. The outputs of PWM modules 1 to 4 are operated on by CLB tiles 1 to 4, respectively.

#### 26.7.1.6 CLB Event Window

FILE: clb_ex5_event_window.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

Copyright © 2024 Texas Instruments Incorporated

This example uses the counter, FSM, and HLC sub-modules of the CLB to implement an event timing feature which detects whether an interrupt service routine takes too long to respond to an interrupt. The example configures four PWM modules to operate in up-count mode and generate a low-to-high edge on a timer zero match event. The zero match event also triggers a PWM ISR which, for the purposes of this example, contains a dummy payload of variable length. At the end of the ISR, a write operation takes place to a CLB GP register to indicate the ISR has ended.

#### 26.7.1.7 CLB Signal Generator

FILE: clb_ex6_siggen.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example uses CLB1 to generate a rectangular wave and CLB2 to check the rectangular wave generated by CLB1 doesn't exceed the defined duty cycle and period limits.

#### 26.7.1.8 CLB State Machine

FILE: clb_ex7_state_machine.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\Designing With the C2000 CLB.pdf This application report describes the process of creating this CLB example and can be used as guidance on desiging custom logic with the CLB. This example uses all submodules inside a CLB TILE in order to implement a complete system.

#### 26.7.1.9 CLB External Signal AND Gate

FILE: clb_ex8_external_signal_AND_gate.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, two external signals from two GPIOs are passed through the Input X-BAR and the CLB X-BAR to the CLB TILE. Inside the CLB module these two signals are ANDED. The output of the AND gate is then exported to a GPIO, using Output X-BAR.

#### 26.7.1.10 CLB Timer

FILE: clb_ex9_timer.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a COUNTER module is used to create timed events. The use of the GP Register is shown. Through setting/clearing the bits in the GP register, the timer is started, stopped or changes direction. The output of the timer event (1-clock cycle) is exported to a GPIO. Interrupts are generated from the timer event using the HLC module. A GPIO is also toggled inside the CLB ISR. The indirect CLB register access is used to update the timer's event match value and the active counter register to modify the frequency of the timer.

#### 26.7.1.11 CLB Timer Two States

FILE: clb_ex10_timer_two_states.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the timer is setup the same as the previous example. The difference is the use of the FSM submodule to toggle the output of the CLB which is then exported to a GPIO. The FSM module acts as a single bit memory block. Interrupts are setup in the same format as the previous example. The interrupt delay of the CLB can be seen by comparing the output of the CLB and the GPIO toggled in the ISR.

#### 26.7.1.12 CLB Interrupt Tag

FILE: clb_ex11_interrupt_tag.c

Copyright © 2024 Texas Instruments Incorporated

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a timer is setup with two different match values. These two events are used by the HLC submodule to generate interrupts. The interrupt TAG is used to differentiate between the interrupt generated due to the match1 event of the CLB counter and the match2 event of the CLB counter.

#### 26.7.1.13 CLB Output Intersect

FILE: clb_ex12_output_intersect.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the CLB module is set up the same as the external_AND_gate example. However, instead of the output being exported to the GPIO using Output X-BAR, the output is exported to the GPIO by replacing the output of ePWM1. This is done by configuring the GPIO for EPWM1A output, followed by enabling output intersection.

#### 26.7.1.14 CLB PUSH PULL

FILE: clb_ex13_push_pull.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the use of the PUSH-PULL interface is shown. Multiple COUNTER submodules, HLC submodule, FSM submodules, and OUTLUT submodules are used. The PUSH-PULL interface is used alongside the GP register to update the COUNTER submodules' event frequencies.

#### 26.7.1.15 CLB Multi Tile

FILE: clb_ex14_multi_tile.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a CLB TILE is passed to the input of another CLB TILE. The output of the second CLB TILE is then exported to a GPIO, showcasing how two CLB TILEs can be used in series.

#### 26.7.1.16 CLB Tile to Tile Delay

FILE: clb_ex15_tile_to_tile_delay.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a GPIO is taken into the CLB TILE through INPUT XBAR and the CLB XBAR. The signal is forwarded by the TILE to the next TILE. This time the signal only goes through the CLB XBAR and NOT the Input XBAR. This is done to show that delays are added when the signals are passed from TILE to TILE and the delay is NOT characterized. The user should always avoid passing signals with timing requirements between tiles. The COUNTER modules inside the CLBs will count the amount of delay in cycles.

#### 26.7.1.17 CLB based One-shot PWM

FILE: clb_ex17_one_shot_pwm.c

For the detailed description of this example, please refer to :
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

#### 26.7.1.18 CLB Trip Zone Timestamp

FILE: clb_ex29_timestamp.c

This example displays how to timestamp interrupts generated by the CLB. An interrupt is generated when ePWM1 is tripped.

Copyright © 2024 Texas Instruments Incorporated

ePWM1 is configured to be interrupted by TZ1 and TZ2, both one shot trip sources.

The CLB is configured as follows:

- COUNTER0 and COUNTER1 continually count when the program begins.
- COUNTER0 timestamps TZ1 and COUNTER1 timestamps TZ2.
- COUNTER2 increments once when COUNTER0/COUNTER1 overflows using LUT2.
- FSM0/1 are configured to sync counters and stop COUNTER0/1 when an interrupt is received.
- TZ1 (GPIO12) and TZ2 (GPIO13) are routed as inputs through CLBXBAR.
- BOUNDARY.boundaryInput0 denotes TZ1. On rising edge, HLC issues an interrupt with tag 12.
- BOUDNARY.in1 denotes TZ2. On rising edge, HLC issues an interrupt with tag 13.
- BOUNDARY.boundaryInput7 serves as a simultaneous enable for COUNTER0/1 to begin counting.

TZ1 is tripped when GPIO12 is connected to GND. TZ2 is tripped when GPIO13 is connected to GND. When an interrupt occurs, the interrupt handler determines the initial trip source and stores this value in a variable 'initialTripZone'.

View these variables in Debug Expressions tab:

initialTripZone: stores the first TZ to have been tripped tz1Counter64bit: stores the counter value at the instant that TZ1 is tripped. tz2Counter64bit: stores the counter value at the instant that TZ2 is tripped.

## 26.8 CLB Registers

This section describes the Configurable Logic Block Registers.

### *26.8.1 CLB Base Addresses*

**Table 26-14. CLB Base Address Table (C28)**

| Bit Field Name | | DriverLib Name | Base Address |
|---|---|---|---|
| Instance | Structure | | |
| Clb1LogicCfgRegs | CLB_LOGIC_CONFIG_REGS | CLB1_LOGICCFG_BASE | 0x0000_3000 |
| Clb1LogicCtrlRegs | CLB_LOGIC_CONTROL_REGS | CLB1_LOGICCTRL_BASE | 0x0000_3100 |

### 26.8.2 CLB_LOGIC_CONFIG_REGS Registers

Table 26-15 lists the memory-mapped registers for the CLB_LOGIC_CONFIG_REGS registers. All register offset addresses not listed in Table 26-15 should be considered as reserved locations and the register contents should not be modified.

**Table 26-15. CLB_LOGIC_CONFIG_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 2h | CLB_COUNT_RESET | Counter Block RESET | EALLOW, LOCK | Go |
| 4h | CLB_COUNT_MODE_1 | Counter Block MODE_1 | EALLOW, LOCK | Go |
| 6h | CLB_COUNT_MODE_0 | Counter Block MODE_0 | EALLOW, LOCK | Go |
| 8h | CLB_COUNT_EVENT | Counter Block EVENT | EALLOW, LOCK | Go |
| Ah | CLB_FSM_EXTRA_IN0 | FSM Extra EXT_IN0 | EALLOW, LOCK | Go |
| Ch | CLB_FSM_EXTERNAL_IN0 | FSM EXT_IN0 | EALLOW, LOCK | Go |
| Eh | CLB_FSM_EXTERNAL_IN1 | FSM_EXT_IN1 | EALLOW, LOCK | Go |
| 10h | CLB_FSM_EXTRA_IN1 | FSM Extra_EXT_IN1 | EALLOW, LOCK | Go |
| 12h | CLB_LUT4_IN0 | LUT4_0/1/2 IN0 input source | EALLOW, LOCK | Go |
| 14h | CLB_LUT4_IN1 | LUT4_0/1/2 IN1 input source | EALLOW, LOCK | Go |
| 16h | CLB_LUT4_IN2 | LUT4_0/1/2 IN2 input source | EALLOW, LOCK | Go |
| 18h | CLB_LUT4_IN3 | LUT4_0/1/2 IN3 input source | EALLOW, LOCK | Go |
| 1Ch | CLB_FSM_LUT_FN1_0 | LUT function for FSM Unit 1 and Unit 0 | EALLOW, LOCK | Go |
| 1Eh | CLB_FSM_LUT_FN2 | LUT function for FSM Unit 2 | EALLOW, LOCK | Go |
| 20h | CLB_LUT4_FN1_0 | LUT function for LUT4 block of Unit 1 and 0 | EALLOW, LOCK | Go |
| 22h | CLB_LUT4_FN2 | LUT function for LUT4 block of Unit 2 | EALLOW, LOCK | Go |
| 24h | CLB_FSM_NEXT_STATE_0 | FSM Next state equations for Unit 0 | EALLOW, LOCK | Go |
| 26h | CLB_FSM_NEXT_STATE_1 | FSM Next state equations for Unit 1 | EALLOW, LOCK | Go |
| 28h | CLB_FSM_NEXT_STATE_2 | FSM Next state equations for Unit 2 | EALLOW, LOCK | Go |
| 2Ah | CLB_MISC_CONTROL | Static controls for Ctr,FSM | EALLOW, LOCK | Go |
| 2Ch | CLB_OUTPUT_LUT_0 | Inp Sel, LUT fns for Out0 | EALLOW, LOCK | Go |
| 2Eh | CLB_OUTPUT_LUT_1 | Inp Sel, LUT fns for Out1 | EALLOW, LOCK | Go |
| 30h | CLB_OUTPUT_LUT_2 | Inp Sel, LUT fns for Out2 | EALLOW, LOCK | Go |
| 32h | CLB_OUTPUT_LUT_3 | Inp Sel, LUT fns for Out3 | EALLOW, LOCK | Go |
| 34h | CLB_OUTPUT_LUT_4 | Inp Sel, LUT fns for Out4 | EALLOW, LOCK | Go |
| 36h | CLB_OUTPUT_LUT_5 | Inp Sel, LUT fns for Out5 | EALLOW, LOCK | Go |
| 38h | CLB_OUTPUT_LUT_6 | Inp Sel, LUT fns for Out6 | EALLOW, LOCK | Go |
| 3Ah | CLB_OUTPUT_LUT_7 | Inp Sel, LUT fns for Out7 | EALLOW, LOCK | Go |
| 3Ch | CLB_HLC_EVENT_SEL | Event Selector register for the High Level controller | EALLOW, LOCK | Go |

Complex bit access types are encoded to fit into small table cells. Table 26-16 shows the codes that are used for access types in this section.

**Table 26-16. CLB_LOGIC_CONFIG_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |

### 26.8.3 CLB_LOGIC_CONTROL_REGS Registers

Table 26-46 lists the memory-mapped registers for the CLB_LOGIC_CONTROL_REGS registers. All register offset addresses not listed in Table 26-46 should be considered as reserved locations and the register contents should not be modified.

**Table 26-46. CLB_LOGIC_CONTROL_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | CLB_LOAD_EN | Global enable & indirect load enable control, only Global Enable Bit is LOCK protected | LOCK | Go |
| 2h | CLB_LOAD_ADDR | Indirect address | | Go |
| 4h | CLB_LOAD_DATA | Data for indirect loads | | Go |
| 6h | CLB_INPUT_FILTER | Input filter selection for both edge detection and synchronizers | LOCK | Go |
| 8h | CLB_IN_MUX_SEL_0 | Input selection to decide between Signals and GP register | LOCK | Go |
| Ah | CLB_LCL_MUX_SEL_1 | Input Mux selection for local mux | LOCK | Go |
| Ch | CLB_LCL_MUX_SEL_2 | Input Mux selection for local mux | LOCK | Go |
| Eh | CLB_BUF_PTR | PUSH and PULL pointers | | Go |
| 10h | CLB_GP_REG | General purpose register for CELL inputs | | Go |
| 12h | CLB_OUT_EN | CELL output enable register | | Go |
| 14h | CLB_GLBL_MUX_SEL_1 | Global Mux select for CELL inputs | LOCK | Go |
| 16h | CLB_GLBL_MUX_SEL_2 | Global Mux select for CELL inputs | LOCK | Go |
| 20h | CLB_INTR_TAG_REG | Interrupt Tag register | | Go |
| 22h | CLB_LOCK | Lock control register | EALLOW | Go |
| 30h | CLB_DBG_R0 | R0 of High level Controller | | Go |
| 32h | CLB_DBG_R1 | R1 of High level Controller | | Go |
| 34h | CLB_DBG_R2 | R2 of High level Controller | | Go |
| 36h | CLB_DBG_R3 | R3 of High level Controller | | Go |
| 38h | CLB_DBG_C0 | Count of Unit 0 | | Go |
| 3Ah | CLB_DBG_C1 | Count of Unit 1 | | Go |
| 3Ch | CLB_DBG_C2 | Count of Unit 2 | | Go |
| 3Eh | CLB_DBG_OUT | Outputs of various units in the Cell | | Go |

Complex bit access types are encoded to fit into small table cells. Table 26-47 shows the codes that are used for access types in this section.

**Table 26-47. CLB_LOGIC_CONTROL_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| R-1 | R<br>-1 | Read<br>Returns 1s |
| Write Type | | |
| W | W | Write |
| WSonce | W<br>Sonce | Write<br>Set once |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |

Copyright © 2024 Texas Instruments Incorporated

**Table 26-47. CLB_LOGIC_CONTROL_REGS Access Type Codes (continued)**

| Access Type | Code | Description |
|---|---|---|
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | STOP | GLOBAL_EN | LOAD_EN |
| R-0-0h | | | | | R/W-0h | R/W-0h | R/W-0h |

**Table 26-48. CLB_LOAD_EN Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-3 | RESERVED | R-0 | 0h | Reserved |
| 2 | STOP | R/W | 0h | This bit defines the behaviour of the sequential elements in the CELL during debug HALTs of the CPU. If this bit is set to 0, the debug HALT condition is ignored.<br>Reset type: SYSRSn |
| 1 | GLOBAL_EN | R/W | 0h | This bit is a global enable signal for the logic in the CELL. This also acts as a soft reset for the CELL logic. CLB outputs (including LUTs and OUTLUTs) will be gated when this bit is cleared from 1 to 0, i.e., the CLB outputs will be low when GLOBAL_EN is low. Additionally, the FSM and AOC blocks will also be reset. Note that when this bit goes low, the COUNTER blocks and HLC are simply halted, but they will NOT be reset internally. This allows the ability to preload these submodules when GLOBAL_EN is 0. This bit is normally set after all the other configuration settings are completed. This bit is LOCK protected.<br>Reset type: SYSRSn |
| 0 | LOAD_EN | R/W | 0h | A write with this bit set to 1 will pulse the Load Enable signal for the indirect register loads in the CELL.<br>Reset type: SYSRSn |

### 26.8.4 CLB_DATA_EXCHANGE_REGS Registers

Table 26-70 lists the memory-mapped registers for the CLB_DATA_EXCHANGE_REGS registers. All register offset addresses not listed in Table 26-70 should be considered as reserved locations and the register contents should not be modified.

**Table 26-70. CLB_DATA_EXCHANGE_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h + formula | CLB_PUSH_y | CLB_PUSH FIFO Registers (from HLC) | | Go |
| 100h + formula | CLB_PULL_y | CLB_PULL FIFO Registers (TO HLC) | | Go |

Complex bit access types are encoded to fit into small table cells. Table 26-71 shows the codes that are used for access types in this section.

**Table 26-71. CLB_DATA_EXCHANGE_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| Write Type | | |
| W | W | Write |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 26.8.4.1 CLB_PUSH_y Register (Offset = 0h + formula) [Reset = 00000000h]

CLB_PUSH_y is shown in Figure 26-67 and described in Table 26-72.

Return to the Summary Table.

CLB_PUSH FIFO Registers (from HLC)

Offset = 0h + (y * 2h); where y = 0h to 3h

**Figure 26-67. CLB_PUSH_y Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| PUSH | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| R-0h | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

**Table 26-72. CLB_PUSH_y Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | PUSH | R | 0h | FIFO TO System From CLB<br>Note: The PUSH FIFO register does not get reset, so random values are expected upon power-on reset.<br>Reset type: SYSRSn |

#### 26.8.4.2 CLB_PULL_y Register (Offset = 100h + formula) [Reset = 00000000h]

CLB_PULL_y is shown in Figure 26-68 and described in Table 26-73.

Return to the Summary Table.

CLB_PULL FIFO Registers (TO HLC)

Offset = 100h + (y * 2h); where y = 0h to 3h

**Figure 26-68. CLB_PULL_y Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| PULL | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| R/W-0h | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

**Table 26-73. CLB_PULL_y Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | PULL | R/W | 0h | FIFO From system TO CLB<br>Note: The PULL FIFO register does not get reset, so random values are expected upon power-on reset.<br>Reset type: SYSRSn |

### *26.8.5 CLB Registers to Driverlib Functions*

**Table 26-74. CLB Registers to Driverlib Functions**

# Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

| Changes from October 25, 2023 to May 21, 2024 (from Revision J (October 2023) to Revision K (May 2024)) | Page |
|---|---|
| • Change OSCCLK cycles to INTOSC1 cycles in Section 3.9.3 | 120 |
| • Change OSCCLK cycles to INTOSC1 cycles in Section 3.9.4 | 120 |
| • Changed Figure 19-10 | 2313 |
| • Changed Figure 20-18 | 2359 |
| • Moved Figure 25-15 to Section 25.3.1 | 2836 |
