5 Parameter Measurement Information

Phase relationships between waveforms were chosen arbitrarily. All input pulses are supplied by generators having the following characteristics: PRR ≤ 1MHz, Z_O = 50Ω, t_t < 6ns.

For clock inputs, f_{max} is measured when the input duty cycle is 50%.

The outputs are measured one at a time with one input transition per measurement.

6 Detailed Description

6.1 Overview

The ’HC164 and ’HCT164 are 8-bit, serial-in, parallel-out, shift registers with asynchronous reset. Data is shifted on the positive edge of Clock (CLK). A LOW on the RESET ($\overline{CLR}$) pin resets the shift register and all outputs go to the LOW state regardless of the input conditions. Two Serial Data inputs (A and B) are provided, either one can be used as a data enable control.

6.3 Device Functional Modes

Truth Table(1)

OPERATING MODE	INPUTS				OUTPUTS	
	$\overline{CLR}$	CLK	A	B	Q_A	Q_B- Q_H
RESET (CLEAR)	L	X	X	X	L	L - L
Shift	H	↑	l	l	L	q_A - q_F
	H	↑	l	h	L	q_A - q_F
	H	↑	h	l	L	q_A - q_F
	H	↑	h	h	H	q_A - q_F

(1) H = High voltage level.
h = High voltage level one set-up time prior to the low-to-high clock transition.
l = Low voltage level one set-up time prior to the low-to-high clock transition.
L = Low voltage level.
X = Don't care.
↑ = Transition from low to high level.
q_n = Lower case letters indicate the state of the reference input clock transition.

7 Power Supply Recommendations

The power supply can be any voltage between the minimum and maximum supply voltage rating, located in the *Recommended Operating Conditions*. Each V_{CC} terminal must have a good bypass capacitor to prevent power disturbance. TI recommends a 0.1 μF capacitor for this device. Paralleling multiple bypass caps is acceptable to reject different frequencies of noise. The 0.1 μF and 1 μF capacitors are commonly used in parallel. The bypass capacitor must be installed as close to the power terminal as possible for better results.

8 Layout

8.1 Layout Guidelines

When using multiple-input and multiple-channel logic devices, inputs must not be left floating. In many cases, functions of digital logic devices, or parts of functions, are unused. For example, when a triple-input AND gate only uses two inputs or the buffer gates only use three of the four buffers. Such unused input pins must not be left unconnected because the undefined voltages at the outside connections result in undefined operational states. All unused inputs of digital logic devices must be connected to a logic high or logic low voltage, as defined by the input voltage specifications, to prevent them from floating. The logic level that must be applied to any particular unused input depends on the function of the device. Generally, the inputs are tied to GND or V_{CC}, whichever makes more sense for the logic function or is more convenient.
