5 Pin Configuration and Functions

Pin Functions

| PIN | | TYPE | DESCRIPTION |
|-----|-------------|------|--|
| NO. | NAME | | |
| 1 | SW | P | Switching node: power switching node. Connect to the output inductor, re-circulating diode, and bootstrap capacitor. |
| 2 | BST | I | Boost pin (bootstrap capacitor input): an external capacitor is required between the BST and the SW pins. A 0.01- μ F ceramic capacitor is recommended. An internal diode charges the capacitor from V_{CC} . |
| 3 | R_{CL} | I | Current limit OFF time set pin: a resistor between this pin and RTN sets the off-time when current limit is detected. The off-time is preset to 35 μ s if $FB = 0$ V. $T_{off} = 10^{-5} / (0.285 + (FB / 6.35 \times 10^{-6} \times R_{CL}))$ |
| 4 | RTN | G | Ground pin: ground for the entire circuit. |
| 5 | FB | I | Feedback input from regulated output: this pin is connected to the inverting input of the internal regulation comparator. The regulation threshold is 2.5 V. |
| 6 | $R_{ON/SD}$ | I | On-time set pin: a resistor between this pin and V_{IN} sets the switch on-time as a function of V_{IN} . The minimum recommended on-time is 400 ns at the maximum input voltage. This pin can be used for remote shutdown. $T_{on} = 1.25 \times 10^{-10} R_{ON} / V_{IN}$ |
| 7 | V_{CC} | P | Output from the internal high voltage series pass regulator. Regulated at 7 V. If an auxiliary voltage is available to raise the voltage on this pin, above the regulation set point (7 V), the internal series pass regulator will shutdown, reducing the IC power dissipation. Do not exceed 14 V. This voltage provides gate drive power for the internal buck switch. An internal diode is provided between this pin and the BST pin. A local 0.1- μ F decoupling capacitor is recommended. Series pass regulator is current limited to 10 mA. |
| 8 | V_{IN} | P | Input voltage: recommended operating range is 9.5 V to 95 V. |
| — | EP | G | Exposed pad: the exposed pad has no electrical contact. Connect to system ground plane for reduced thermal resistance (WSON package only). |

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

| | MIN | MAX | UNIT |
|---------------------------------------|------|-----|------|
| V _{IN} to GND | −0.3 | 100 | V |
| BST to GND | −0.3 | 114 | V |
| SW to GND (steady-state) | | −1 | V |
| BST to V _{CC} | | 100 | V |
| BST to SW | | 14 | V |
| V _{CC} to GND | | 14 | V |
| All other inputs to GND | −0.3 | 7 | V |
| Storage temperature, T _{stg} | −55 | 150 | °C |

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

| | | VALUE | UNIT |
|--|--|-------|------|
| V _(ESD) Electrostatic discharge | Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾⁽²⁾ | ±2000 | V |
| | Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽³⁾ | ±750 | |

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
 (2) The human body model is a 100-pF capacitor discharged through a 1.5-kΩ resistor into each pin.
 (3) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

| | MIN | MAX | UNIT |
|--|-----|-----|------|
| V _{IN} | 9.5 | 95 | V |
| Operating junction temperature, T _J | −40 | 125 | °C |

6.4 Thermal Information

| THERMAL METRIC ⁽¹⁾ | | LM5008 | | UNIT |

| CURRENT LIMIT | | | | | | |
| Current limit threshold | | T _J = 25°C | 0.51 | | | A |
| | | T _J = -40°C to 125°C | 0.41 | | 0.61 | |
| | Current limit response time | I _{switch} overdrive = 0.1 A, time to switch off | | 400 | | ns |
| | OFF time generator (test 1) | FB = 0 V, R _{CL} = 100 K | | 35 | | μs |
| | OFF time generator (test 2) | FB = 2.3 V, R _{CL} = 100 K | | 2.56 | | μs |
| ON-TIME GENERATOR | | | | | | |
| T _{ON} - 1 | V _{IN} = 10 V, R _{ON} = 200 K | T _J = 25°C | 2.77 | | | μs |
| | | T _J = -40°C to 125°C | 2.15 | | 3.5 | |
| T _{ON} - 2 | V _{IN} = 95 V, R _{ON} = 200 K | T _J = 25°C | 300 | | | ns |
| | | T _J = -40°C to 125°C | 200 | | 420 | |
| | Remote shutdown threshold | Rising | | 0.7 | | V |
| | Remote shutdown hysteresis | | | 35 | | mV |
| MINIMUM OFF-TIME | | | | | | |
| | Minimum off-timer | FB = 0 V | | 300 | | ns |
| REGULATION AND OV COMPARATORS | | | | | | |
| FB reference threshold | Internal reference, trip point for switch ON | T _J = 25°C | 2.5 | | | V |
| | | T _J = -40°C to 125°C | 2.445 | | 2.55 | |
| | FB overvoltage threshold | Trip point for switch OFF | | 2.875 | | V |
| | FB bias current | | | 100 | | nA |
| THERMAL SHUTDOWN | | | | | | |
| T _{sd} | Thermal shutdown temperature | | | 165 | | °C |
| | Thermal shutdown hysteresis | | | 25 | | °C |

- (1) All electrical characteristics having room temperature limits are tested during production with $T_A = T_J = 25^\circ\text{C}$. All hot and cold limits are specified by correlating the electrical characteristics to process and temperature variations and applying statistical process control.
- (2) The V_{CC} output is intended as a self bias for the internal gate drive power and control circuits. Device thermal limitations limit external loading.

6.6 Switching Characteristics

over operating free-air temperature range (unless otherwise noted)

| PARAMETER | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|---------------------------------|---|---------------------------------|------|-----|------|
| Buck switch R _{DS(on)} | I _{TEST} = 200 mA ⁽¹⁾ | T _J = 25°C | 1.15 | | Ω |
| | | T _J = -40°C to 125°C | | | |
| Gate drive UVLO | V _{BST} - V _{SW} rising | T _J = 25°C | 4.5 | | V |
| | | T _J = -40°C to 125°C | 3.4 | | |
| Gate drive UVLO hysteresis | | | 430 | | mV |

- (1) For devices procured in the 8-pin WSON package the R_{DS(on)} limits are specified by design characterization data only.

7 Detailed Description

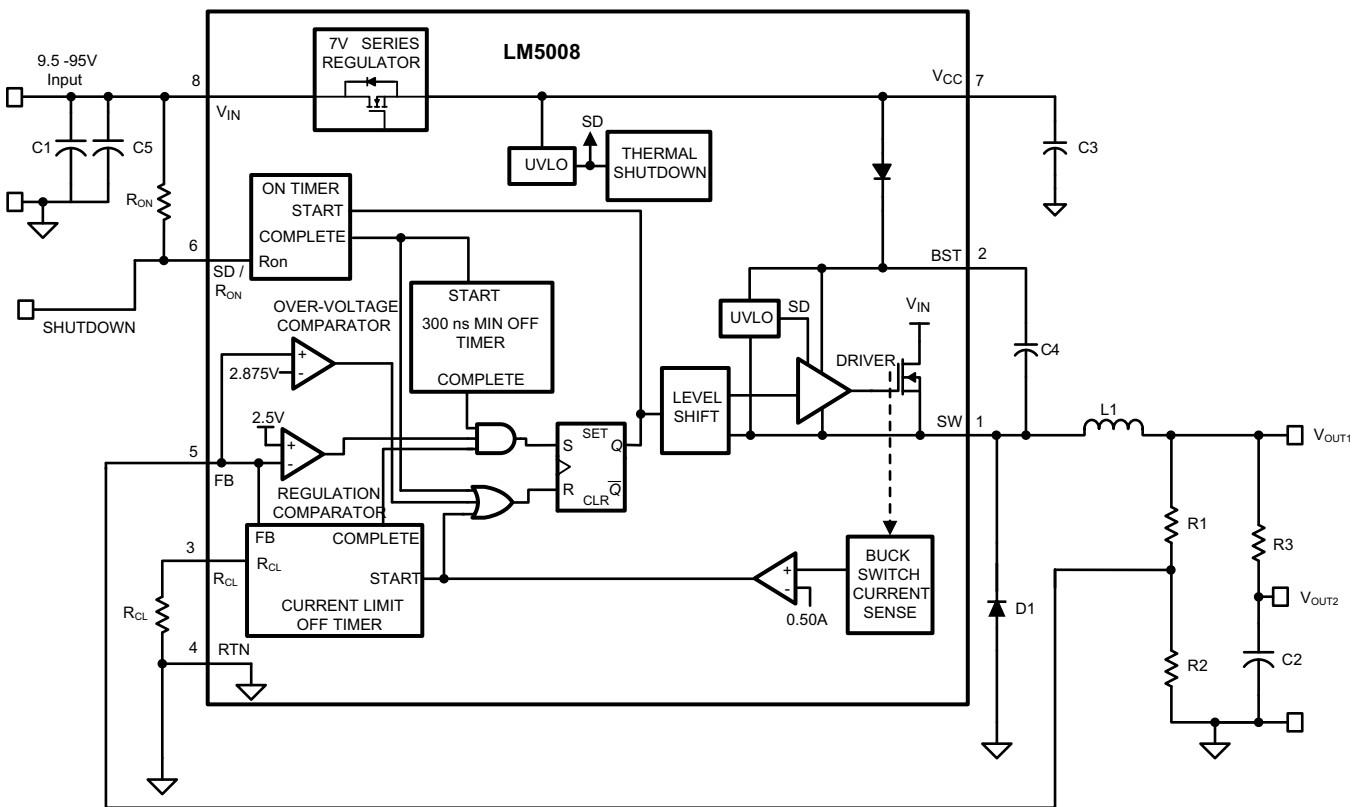

7.1 Overview

The LM5008 regulator is an easy-to-use buck DC-DC converter that operates from 9.5-V to 95-V supply voltage. The device is intended for step-down conversions from 12-V, 24-V, and 48-V unregulated, semi-regulated and fully-regulated supply rails. With integrated buck power MOSFET, the LM5008 delivers up to 350-mA DC load current with exceptional efficiency and low input quiescent current in a very small solution size.

Designed for simple implementation, a nearly fixed-frequency, constant on-time (COT) operation with discontinuous conduction mode (DCM) at light loads is ideal for low-noise, high current, fast transient load requirements. Control loop compensation is not required reducing design time and external component count.

The LM5008 incorporates other features for comprehensive system requirements, including VCC undervoltage lockout (UVLO), gate drive undervoltage lockout, maximum duty cycle limiter, intelligent current limit off timer, a precharge switch, and thermal shutdown with automatic recovery. These features enable a flexible and easy-to-use platform for a wide range of applications. The pin arrangement is designed for simple and optimized PCB layout, requiring only a few external components.

7.3 Feature Description

7.3.1 Hysteretic Control Circuit Overview

The LM5008 is a buck DC-DC regulator that uses a control scheme in which the on-time varies inversely with line voltage (V_{IN}). Control is based on a comparator and the on-time one-shot, with the output voltage feedback (FB) compared to an internal reference (2.5 V). If the FB level is below the reference the buck switch is turned on for a fixed time determined by the line voltage and a programming resistor (R_{ON}). Following the ON period, the switch remains off for at least the minimum off-timer period of 300 ns. If FB is still below the reference at that time, the switch turns on again for another on-time period. This will continue until regulation is achieved.

The LM5008 operates in discontinuous conduction mode at light load currents, and continuous conduction mode at heavy load current. In discontinuous conduction mode, current through the output inductor starts at zero and ramps up to a peak during the on-time, then ramps back to zero before the end of the off-time. The next on-time period starts when the voltage at FB falls below the internal reference; until then, the inductor current remains zero. In this mode the operating frequency is lower than in continuous conduction mode, and varies with load current. Therefore at light loads the conversion efficiency is maintained, because the switching losses reduce with the reduction in load and frequency. The discontinuous operating frequency can be calculated with [Equation 1](#).

$$F = \frac{V_{OUT}^2 \times L \times 1.28 \times 10^{20}}{R_L \times (R_{ON})^2}$$

where

- R_L = the load resistance (1)

In continuous conduction mode, current flows continuously through the inductor and never ramps down to zero. In this mode the operating frequency is greater than the discontinuous mode frequency and remains relatively constant with load and line variations. The approximate continuous mode operating frequency can be calculated with [Equation 2](#).

$$F = \frac{V_{OUT}}{1.25 \times 10^{-10} \times R_{ON}} \quad (2)$$

The output voltage (V_{OUT}) can be programmed by two external resistors as shown in [Functional Block Diagram](#). The regulation point can be calculated with [Equation 3](#).

$$V_{OUT} = 2.5 \times (R_1 + R_2) / R_2 \quad (3)$$

All hysteretic regulators regulate the output voltage based on ripple voltage at the feedback input, requiring a minimum amount of ESR for the output capacitor C2. A minimum of 25 mV to 50 mV of ripple voltage at the feedback pin (FB) is required for the LM5008. In cases where the capacitor ESR is too small, additional series resistance may be required (R_3 in [Functional Block Diagram](#)).

For applications where lower output voltage ripple is required the output can be taken directly from a low-ESR output capacitor, as shown in [Figure 7](#). However, R_3 slightly degrades the load regulation.

Copyright © 2016, Texas Instruments Incorporated

Figure 7. Low-Ripple Output Configuration

Feature Description (continued)

7.3.2 High Voltage Start-Up Regulator

The LM5008 contains an internal high voltage start-up regulator. The input pin (V_{IN}) can be connected directly to the line voltages up to 95 Volts, with transient capability to 100 V. The regulator is internally current limited to 9.5 mA at V_{CC} . Upon power up, the regulator sources current into the external capacitor at V_{CC} (C3). When the voltage on the V_{CC} pin reaches the undervoltage lockout threshold of 6.3 V, the buck switch is enabled.

In applications involving a high value for V_{IN} , where power dissipation in the V_{CC} regulator is a concern, an auxiliary voltage can be diode connected to the V_{CC} pin. Setting the auxiliary voltage to 8 V to 14 V shuts off the internal regulator, reducing internal power dissipation. See Figure 8. The current required into the V_{CC} pin is shown in Figure 1.

Copyright © 2016, Texas Instruments Incorporated

Figure 8. Self-Biased Configuration

7.3.3 Regulation Comparator

The feedback voltage at FB is compared to an internal 2.5-V reference. In normal operation (the output voltage is regulated), an on-time period is initiated when the voltage at FB falls below 2.5 V. The buck switch stays on for the on-time, causing the FB voltage to rise above 2.5 V. After the on-time period, the buck switch stays off until the FB voltage again falls below 2.5 V. During start-up, the FB voltage is below 2.5 V at the end of each on-time, resulting in the minimum off-time of 300 ns. Bias current at the FB pin is nominally 100 nA.

7.3.4 Overvoltage Comparator

The feedback voltage at FB is compared to an internal 2.875-V reference. If the voltage at FB rises above 2.875 V, the on-time pulse is immediately terminated. This condition can occur if the input voltage, or the output load, change suddenly. The buck switch will not turn on again until the voltage at FB falls below 2.5 V.

7.3.5 On-Time Generator and Shutdown

The on-time for the LM5008 is determined by the R_{ON} resistor, and is inversely proportional to the input voltage (V_{IN}), resulting in a nearly constant frequency as V_{IN} is varied over its range. Equation 4 shows the on-time equation for the LM5008.

$$T_{ON} = 1.25 \times 10^{-10} \times R_{ON} / V_{IN} \quad (4)$$

See Figure 2. R_{ON} should be selected for a minimum on-time (at maximum V_{IN}) greater than 400 ns for proper current limit operation. This requirement limits the maximum frequency for each application, depending on V_{IN} and V_{OUT} . See Figure 3.

Feature Description (continued)

The LM5008 can be remotely disabled by taking the R_{ON}/SD pin to ground. See Figure 9. The voltage at the R_{ON}/SD pin is between 1.5 and 3 volts, depending on V_{IN} and the value of the R_{ON} resistor.

Copyright © 2016, Texas Instruments Incorporated

Figure 9. Shutdown Implementation

7.3.6 Current Limit

The LM5008 contains an intelligent current limit off-timer. If the current in the buck switch exceeds 0.5 A the present cycle is immediately terminated, and a non-resettable off-timer is initiated. The length of off-time is controlled by an external resistor (R_{CL}) and the FB voltage (see Figure 4). When FB = 0 V, a maximum off-time is required, and the time is preset to 35 μs. This condition occurs when the output is shorted, and during the initial part of start-up. This amount of time ensures safe short-circuit operation up to the maximum input voltage of 95 V. In cases of overload where the FB voltage is above zero volts (not a short circuit), the current limit off-time will be less than 35 μs. Reducing the off-time during less severe overloads reduces the amount of foldback, recovery time, and the start-up time. The off-time is calculated from Equation 5.

$$T_{\text{OFF}} = \frac{10^{-5}}{0.285 + \frac{V_{\text{FB}}}{(6.35 \times 10^{-6} \times R_{\text{CL}})}} \quad (5)$$

The current limit sensing circuit is blanked for the first 50-70 ns of each on-time so it is not falsely tripped by the current surge which occurs at turnon. The current surge is required by the re-circulating diode (D1) for its turnoff recovery.

7.3.7 N-Channel Buck Switch and Driver

The LM5008 integrates an N-Channel Buck switch and associated floating high voltage gate driver. The gate driver circuit works in conjunction with an external bootstrap capacitor and an internal high voltage diode. A 0.01-μF ceramic capacitor (C4) connected between the BST pin and SW pin provides the voltage to the driver during the on-time.

During each off-time, the SW pin is at approximately 0 V, and the bootstrap capacitor charges from V_{CC} through the internal diode. The minimum off-timer, set to 300 ns, ensures a minimum time each cycle to recharge the bootstrap capacitor.

An external re-circulating diode (D1) carries the inductor current after the internal Buck switch turns off. This diode must be of the ultra-fast or Schottky type to minimize turnon losses and current overshoot.

7.3.8 Thermal Protection

The LM5008 must be operated so the junction temperature does not exceed 125°C during normal operation. An internal thermal shutdown circuit is provided to protect the LM5008 in the event of a higher than normal junction temperature. When activated, typically at 165°C, the controller is forced into a low power reset state, disabling the buck switch and the V_{CC} regulator. This feature prevents catastrophic failures from accidental device overheating. When the junction temperature reduces below 140°C (typical hysteresis = 25°C), the V_{CC} regulator is enabled, and normal operation is resumed.

7.4 Device Functional Modes

7.4.1 Shutdown Mode

The R^{ON}/SD pin provides ON and OFF control for the LM5008. When V_{SD} is below approximately 0.7 V, the device is in shutdown mode. Both the internal LDO and the switching regulator are off. The quiescent current in shutdown mode drops to 76 μA (typical) at V_{IN} = 48 V. The LM5008 also employs VCC bias rail undervoltage protection. If the V_{CC} bias supply voltage is below its UV threshold, the regulator remains off.

7.4.2 Active Mode

LM5008 is in active mode when the internal bias rail, VCC, is above its UV threshold. Depending on the load current, the device operates in either DCM or CCM mode.

Whenever the load current is reduced to a level less than half the peak-to-peak inductor ripple current, the device enters discontinuous conduction mode (DCM). Calculate the critical conduction boundary using [Equation 6](#).

$$I_{\text{BOUNDARY}} = \frac{\Delta I_L}{2} = \frac{V_{\text{OUT}} \cdot (1-D)}{2 \cdot L_F \cdot F_{\text{SW}}} \quad (6)$$

When the inductor current reaches zero, the SW node becomes high impedance. Resonant ringing occurs at SW as a result of the LC tank circuit formed by the buck inductor and the parasitic capacitance at the SW node. At light loads, several pulses may be skipped in between switching cycles, effectively reducing the switching frequency and further improving light-load efficiency.

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The final circuit is shown in [Figure 10](#). The circuit was tested, and the resulting performance is shown in [Figure 12](#) through [Figure 6](#).

8.1.1 Minimum Load Current

A minimum load current of 1 mA is required to maintain proper operation. If the load current falls below that level, the bootstrap capacitor may discharge during the long off-time, and the circuit will either shutdown or cycle on and off at a low frequency. If the load current is expected to drop below 1 mA in the application, the feedback resistors should be chosen low enough in value so they provide the minimum required current at nominal V_{OUT} .

8.2 Typical Application

Figure 10. LM5008 Example Circuit

8.2.1 Design Requirements

A guide for determining the component values will be illustrated with a design example. [Table 1](#) lists the bill of materials for this application. The following steps will configure the LM5008 for:

- Input voltage range (V_{IN}): 12 V to 95 V
- Output voltage (V_{OUT1}): 10 V
- Load current (for continuous conduction mode): 100 mA to 300 mA
- Maximum ripple at V_{OUT2} : 100 mVp-p at maximum input voltage

Typical Application (continued)

Table 1. Bill of Materials (Circuit of Figure 10)

| ITEM | DESCRIPTION | PART NUMBER | VALUE |
|-----------------|------------------------|--------------------------|--------------------|
| C1 | Ceramic Capacitor | TDK C4532X7R2A105M | 1 μ F, 100 V |

8.2.2 Detailed Design Procedure

8.2.2.1 Custom Design With WEBENCH® Tools

[Click here](#) to create a custom design using the LM5008 device with the WEBENCH® Power Designer.

1. Start by entering the input voltage (V_{IN}), output voltage (V_{OUT}), and output current (I_{OUT}) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:

- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WEBENCH.

R1 and R2: From *Functional Block Diagram*, $V_{OUT1} = V_{FB} \times (R1 + R2) / R2$, and because $V_{FB} = 2.5$ V, the ratio of R1 to R2 calculates as 3:1. Standard values of 3.01 k Ω (R1) and 1.00 k Ω (R2) are chosen. Other values could be used as long as the 3:1 ratio is maintained. The selected values, however, provide a small amount of output loading (2.5 mA) in the event the main load is disconnected. This allows the circuit to maintain regulation until the main load is reconnected.

F_s and R_{ON}: The recommended operating frequency range for the LM5008 is 50 kHz to 600 kHz. Unless the application requires a specific frequency, the choice of frequency is generally a compromise because it affects the size of L1 and C2, and the switching losses. The maximum allowed frequency, based on a minimum on-time of 400 ns, is calculated from [Equation 7](#):

$$F_{MAX} = V_{OUT} / (V_{INMAX} \times 400 \text{ ns}) \quad (7)$$

For this exercise, $F_{MAX} = 263$ kHz. From [Equation 2](#), R_{ON} calculates to 304 k Ω . A standard value 357-k Ω resistor is used to allow for tolerances in [Equation 2](#), resulting in a frequency of 224 kHz.

L1: The main parameter affected by the inductor is the output current ripple amplitude. The choice of inductor value therefore depends on both the minimum and maximum load currents, keeping in mind that the maximum ripple current occurs at maximum V_{IN} .

- a. **Minimum load current:** To maintain continuous conduction at minimum I_o (100 mA), the ripple amplitude

(I_{OR}) must be less than 200 mA_{p-p} so the lower peak of the waveform does not reach zero. L1 is calculated using Equation 8.

$$L1 = \frac{V_{OUT1} \times (V_{IN} - V_{OUT1})}{I_{OR} \times F_s \times V_{IN}} \quad (8)$$

At $V_{IN} = 95$ V, L1 (minimum) calculates to 200 μ H. The next larger standard value (220 μ H) is chosen and with this value I_{OR} calculates to 181 mA_{p-p} at $V_{IN} = 95$ V, and 34 mA_{p-p} at $V_{IN} = 12$ V.

- b. **Maximum load current:** At a load current of 300 mA, the peak of the ripple waveform must not reach the minimum value of the LM5008's current limit threshold (410 mA). Therefore the ripple amplitude must be less than 220 mA_{p-p}, which is already satisfied in Equation 8. With L1 = 220 μ H, at maximum V_{IN} and I_O , the peak of the ripple will be 391 mA. While L1 must carry this peak current without saturating or exceeding its temperature rating, it also must be capable of carrying the maximum value of the LM5008's current limit threshold (610 mA) without saturating, because the current limit is reached during start-up.

The DC resistance of the inductor should be as low as possible. For example, if the inductor's DCR is 1 Ω , the power dissipated at maximum load current is 0.09 W. While small, it is not insignificant compared to the load power of 3 W.

C3: The capacitor on the V_{CC} output provides not only noise filtering and stability, but its primary purpose is to prevent false triggering of the V_{CC} UVLO at the buck switch ON/OFF transitions. For this reason, C3 should be no smaller than 0.1 μ F.

C2, and R3: When selecting the output filter capacitor C2, the items to consider are ripple voltage due to its ESR, ripple voltage due to its capacitance, and the nature of the load.

- a. **ESR and R3:** A low ESR for C2 is generally desirable so as to minimize power losses and heating within the capacitor. However, a hysteretic regulator requires a minimum amount of ripple voltage at the feedback input for proper loop operation. For the LM5008 the minimum ripple required at pin 5 is 25 mV_{p-p}, requiring a minimum ripple at V_{OUT1} of 100 mV. Because the minimum ripple current (at minimum V_{IN}) is 34 mA_{p-p}, the minimum ESR required at V_{OUT1} is 100 mV / 34 mA = 2.94 Ω . Because quality capacitors for SMPS applications have an ESR considerably less than this, R3 is inserted as shown in *Functional Block Diagram*. R3's value, along with C2's ESR, must result in at least 25 mV_{p-p} ripple at pin 5. Generally, R3 will be 0.5 to 3 Ω .
- b. **Nature of the Load:** The load can be connected to V_{OUT1} or V_{OUT2} . V_{OUT1} provides good regulation, but with a ripple voltage which ranges from 100 mV (at $V_{IN} = 12$ V) to 500 mV (at $V_{IN} = 95$ V). Alternatively, V_{OUT2} provides low ripple, but lower regulation due to R3.

For a maximum allowed ripple voltage of 100 mV_{p-p} at V_{OUT2} (at $V_{IN} = 95$ V), assume an ESR of 0.4 Ω for C2. At maximum V_{IN} , the ripple current is 181 mA_{p-p}, creating a ripple voltage of 72 mV_{p-p}. This leaves 28 mV_{p-p} of ripple due to the capacitance. The average current into C2 due to the ripple current is calculated using the waveform in Figure 11.

Figure 11. Inductor Current Waveform

Starting when the current reaches I_O (300 mA in Figure 11) half way through the on-time, the current continues to increase to the peak (391 mA), and then decreases to 300 mA half way through the off-time. The average value of this portion of the waveform is 45.5 mA, and will cause half of the voltage ripple, or 14 mV. The interval is one half of the frequency cycle time, or 2.23 μ s. Using the capacitor's basic equation (see Equation 9), the minimum value for C2 is 7.2 μ F.

The ripple due to C2's capacitance is 90° out of phase from the ESR ripple, and the two numbers do not add directly. However, this calculation provides a practical minimum value for C2 based on its ESR and the target spec. To allow for the capacitor's tolerance, temperature effects, and voltage effects, a 15-μF, X7R capacitor is used.

- c. **In summary:** The above calculations provide a minimum value for C2 and a calculation for R3. The ESR is just as important as the capacitance. The calculated values are guidelines, and should be treated as starting points. For each application, experimentation is needed to determine the optimum values for R3 and C2.

$$C = I \times \Delta t / \Delta V \quad (9)$$

R_{CL}: When a current limit condition is detected, the minimum off-time set by this resistor must be greater than the maximum normal off-time which occurs at maximum V_{IN}. Using Equation 4, the minimum on-time is 0.47 μs, yielding a maximum off-time of 3.99 μs. This is increased by 117 ns (to 4.11 μs) due to a ±25% tolerance of the on-time. This value is then increased to allow for:

The response time of the current limit detection loop (400 ns).

The off-time determined by Equation 5 has a ±25% tolerance.

$$t_{\text{OFFCL(MIN)}} = (4.11 \mu\text{s} + 0.40 \mu\text{s}) \times 1.25 = 5.64 \mu\text{s} \quad (10)$$

Using Equation 5, R_{CL} calculates to 264 kΩ (at V_{FB} = 2.5 V). The closest standard value is 267 kΩ.

D1: The important parameters are reverse recovery time and forward voltage. The reverse recovery time determines how long the reverse current surge lasts each time the buck switch is turned on. The forward voltage drop is significant in the event the output is short-circuited as it is only this diode's voltage which forces the inductor current to reduce during the forced off-time. For this reason, a higher voltage is better, although that affects efficiency. A good choice is an ultra-fast power diode, such as the MURA110T3 from ON Semiconductor. Its reverse recovery time is 30 ns, and its forward voltage drop is approximately 0.72 V at 300 mA at 25°C. Other types of diodes may have a lower forward voltage drop, but may have longer recovery times, or greater reverse leakage. D1's reverse voltage rating must be at least as great as the maximum V_{IN}, and its current rating be greater than the maximum current limit threshold (610 mA).

C1: This capacitor's purpose is to supply most of the switch current during the on-time, and limit the voltage ripple at V_{IN}, on the assumption that the voltage source feeding V_{IN} has an output impedance greater than zero. At maximum load current when the buck switch turns on, the current into pin 8 will suddenly increase to the lower peak of the output current waveform, ramp up to the peak value, then drop to zero at turnoff. The average input current during this on-time is the load current (300 mA). For a worst case calculation, C1 must supply this average load current during the maximum on-time. To keep the input voltage ripple to less than 2 V (for this exercise), C1 is calculated with Equation 11.

$$C1 = \frac{I \times t_{\text{ON}}}{\Delta V} = \frac{0.3\text{A} \times 3.72 \mu\text{s}}{2.0\text{V}} = 0.56 \mu\text{F} \quad (11)$$

Quality ceramic capacitors in this value have a low ESR which adds only a few millivolts to the ripple. It is the capacitance which is dominant in this case. To allow for the capacitor's tolerance, temperature effects, and voltage effects, a 1.0-μF, 100-V, X7R capacitor will be used.

C4: The recommended value is 0.01 μF for C4, as this is appropriate in the majority of applications. A high-quality ceramic capacitor, with low ESR is recommended as C4 supplies the surge current to charge the buck switch gate at turnon. A low ESR also ensures a quick recharge during each off-time. At minimum V_{IN}, when the on-time is at maximum, it is possible during start-up that C4 will not fully recharge during each 300-ns off-time. The circuit will not be able to complete the start-up, and achieve output regulation. This can occur when the frequency is intended to be low (for example, R_{ON} = 500 K). In this case C4 should be increased so it can maintain sufficient voltage across the buck switch driver during each on-time.

C5: This capacitor helps avoid supply voltage transients and ringing due to long lead inductance at V_{IN}. A low-ESR, 0.1-μF ceramic chip capacitor is recommended, placed close to the LM5008.

8.2.3 Application Curves

9 Power Supply Recommendations

The LM5008 converter is designed to operate from a wide input voltage range from 9.5 V to 95 V. The characteristics of the input supply must be compatible with the [Absolute Maximum Ratings](#) and [Recommended Operating Conditions](#). In addition, the input supply must be capable of delivering the required input current to the fully-loaded regulator. Estimate the average input current with [Equation 12](#).

$$I_{IN} = \frac{V_{OUT} \cdot I_{OUT}}{V_{IN} \cdot \eta}$$

where

- η is the efficiency (12)

If the converter is connected to an input supply through long wires or PCB traces with large impedance, achieving stable performance requires special care. The parasitic inductance and resistance of the input cables may have an adverse effect on converter operation. The parasitic inductance in combination with the low-ESR ceramic input capacitors form an underdamped resonant circuit. This circuit can cause overvoltage transients at V_{IN} each time the input supply is cycled ON and OFF. The parasitic resistance causes the input voltage to dip during a load transient. If the regulator is operating close to the minimum input voltage, this dip can cause false UVLO fault triggering and a system reset. The best way to solve such issues is to reduce the distance from the input supply to the regulator and use an aluminum or tantalum input capacitor in parallel with the ceramics. The moderate ESR of the electrolytic capacitors helps to damp the input resonant circuit and reduce any voltage overshoots. A capacitance in the range of 10 μF to 47 μF is usually sufficient to provide input damping and helps to hold the input voltage steady during large load transients.

An EMI input filter is often used in front of the regulator that, unless carefully designed, can lead to instability as well as some of the effects mentioned above. The user's guide [Simple Success with Conducted EMI for DC-DC Converters](#) (SNVA489) provides helpful suggestions when designing an input filter for any switching regulator.

10 Layout

10.1 Layout Guidelines

The LM5008 regulation and overvoltage comparators are very fast, and as such responds to short-duration noise pulses. Layout considerations are therefore critical for optimum performance:

1. Minimize the area of the high di/dt switching current loop consisting of the VIN pin, input ceramic capacitor, SW node and freewheeling power diode. Keep the input capacitor as close as possible to the VIN pin and route a short, direct connection to the RTN pin using polygon copper pours.
2. Minimize SW copper area to reduce radiated noise related to high dv/dt.
3. Locate all components as physically close as possible to their respective pins, thereby minimizing noise pickup in the printed-circuit tracks.
4. Locate the FB trace away from noise sources and inductors. Place the resistor close to the FB pin to minimize the length of the FB trace.

If the internal dissipation of the LM5008 converter produces excessive junction temperatures during normal operation, optimal use of the PCB ground plane can help considerably to dissipate heat. The exposed pad on the bottom of the WSON-8 package can be soldered to a ground plane on the PCB, and that plane should extend out from beneath the IC to help dissipate the heat. Additionally, the use of wide PCB traces for power connection can also help conduct heat away from the IC. Judicious positioning of the LM5008 converter within the end product, along with use of any available air flow (forced or natural convection), can help reduce the operating junction temperature.

11.1 器件支持

11.1.1 第三方产品免责声明

TI 发布的与第三方产品或服务有关的信息，不能构成与此类产品或服务或保修的适用性有关的认可，不能构成此类产品或服务单独或与任何 TI 产品或服务一起的表示或认可。

11.1.2 使用 WEBENCH® 工具创建定制设计方案

[请单击此处](#)，使用 LM5008 器件及其 WEBENCH® 电源设计器创建定制设计方案。

1. 首先输入输入电压 (V_{IN})、输出电压 (V_{OUT}) 和输出电流 (I_{OUT}) 要求。
2. 使用优化器拨盘优化该设计的关键参数，如效率、尺寸和成本。
3. 将生成的设计与德州仪器 (TI) 的其他可行的解决方案进行比较。

WEBENCH 电源设计器可提供定制原理图以及罗列实时价格和组件供货情况的物料清单。

在多数情况下，可执行以下操作：

- 运行电气仿真，观察重要波形以及电路性能
- 运行热性能仿真，了解电路板热性能
- 将定制原理图和布局方案以常用 CAD 格式导出
- 打印设计方案的 PDF 报告并与同事共享

有关 WEBENCH 工具的详细信息，请访问 www.ti.com.cn/WEBENCH。

(1) **Status:** For more details on status, see our [product life cycle](#).

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "-" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.
9. Size of metal pad may vary due to creepage requirement.
