具有脉冲计数接口的 LMT01 0.5°C 精度双引脚数字输出温度传感器

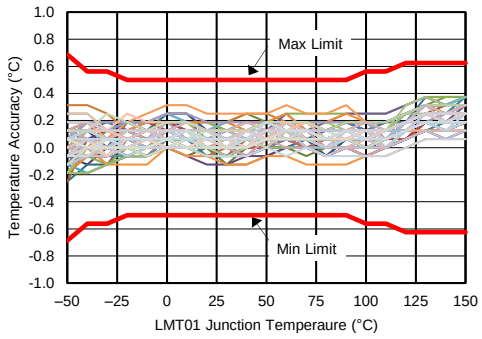

1 特性

- 在 –50°C 至 150°C 宽温度范围内保持高精度
  - –20°C 至 90°C：±0.5°C（最大值）
  - 90°C 至 150°C：±0.625°C（最大值）
  - –50°C 至 –20°C：±0.7°C（最大值）
- 通过双引脚封装简化精密数字温度测量
- 脉冲计数电流环路可由处理器轻松读取。输出脉冲数采用与温度成正比的，分辨率为 0.0625°C
- 通信频率：88kHz
- 转换电流：34µA
- 每次转换的连续加数据传输时间：100ms
- 由具有集成 EMI 抗扰度的 2V 至 5.5V (VP-VN) 悬空电源供电运行
- 多种双引脚封装产品：TO-92/LPG (3.1mm × 4mm × 1.5mm) – 尺寸为传统 TO-92 和具有可湿性侧面的 WSON 的一半

2 应用

- 数字输出接线探针
- 白色家电
- 暖通空调 (HVAC)
- 电源
- 电池管理

LMT01 精度

在曲线中心绘制的典型单元

3 说明

LMT01器件是一款高精度双引脚温度传感器，具备一个易于使用的脉冲计数电流环路接口，因此适用于汽车、工业和消费品市场中的 板载和非板载 应用。LMT01 具有数字脉冲计数输出，可在宽温度范围内实现高精度，因此适合与所有 MCU 配对使用，不仅能够降低软件开销，而且不会影响集成 ADC 的质量或可用性。TI 的 LMT01 器件在 –20°C 至 90°C 的温度范围内支持 ±0.5°C 的最大精度，同时具有极高的分辨率 (0.0625°C)，无需借助系统校准或软硬件补偿。

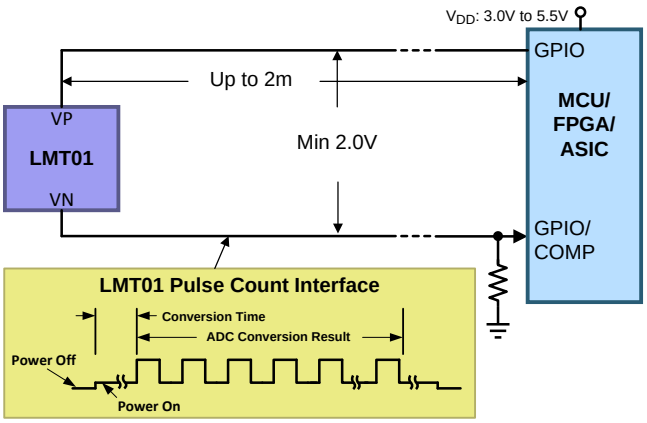

LMT01 的脉冲计数接口设计用于直接连接 GPIO 或比较器输入，从而简化硬件实施。同样，LMT01 具备集成的 EMI 抑制功能和简单的双引脚架构，因而适用于噪声环境中的板载和非板载温度传感。LMT01 器件可轻松转换成双线温度探针，电线长度可达两米。请参阅符合汽车要求的 LMT01-Q1 版本。

器件信息(1)

器件型号	封装	封装尺寸（标称值）
LMT01LPG	TO-92 (2)	4.00mm × 3.15mm
LMT01DQX	WSON (2)	1.70mm × 2.50mm

(1) 如需了解所有可用封装，请参阅数据表末尾的可订购产品附录。

4 修订历史记录

Changes from Revision C (June 2017) to Revision D **Page**

- Added device stamp to the TO-92 pinout top view ... 3
- Changed the TO-92S pin numbers in the *Pin Functions* ... 3

Changes from Revision B (April 2017) to Revision C **Page**

- Removed *Electrical Characteristics: WSON/DQX* table; Combined the LPG and DQX *Electrical Characteristics* tables together ... 5
- Changed I_{OL} maximum value from: 39 µA to: 40 µA ... 5
- Changed leakage value from: 1 µA to 3.5 µA ... 5
- Moved the thermal response time parameters to the *Electrical Characteristics* table ... 5
- Added Missing Cross References ... 13

Changes from Revision A (June 2015) to Revision B **Page**

- 已添加 全新 WSON/DQX 封装（整个数据表中） ... 1
- Changed updated package information. ... 3
- Added Electrical Characteristics - WSON/DQX Pulse Count to Temperature LUT ... 7
- Added -40 for Sample Calculations Table ... 14
- Added missing cross reference ... 15

Changes from Original (June 2015) to Revision A **Page**

- 已添加 完整数据表。 ... 1
- 已添加 澄清说明。 ... 1

6 Specifications

6.1 Absolute Maximum Ratings

See (1)(2).

	MIN	MAX	UNIT
Voltage drop (VP – VN)	−0.3	6	V
Storage temperature, T_{stg}	−65	175	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) Soldering process must comply with Reflow Temperature Profile specifications. Refer to www.ti.com/packaging.

6.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001(1)	±2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101(2)	±750	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

	MIN	MAX	UNIT
Free-air temperature	−50	150	°C
Voltage drop (VP – VN)	2	5.5	V

6.4 Thermal Information

THERMAL METRIC(1)		LMT01		UNIT
		DQX (WSON)	LPG (TO-92)	
		2 PINS	2 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	213	177	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	71	94	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	81	152	°C/W
ψ_{JT}	Junction-to-top characterization parameter	2.4	33	°C/W
ψ_{JB}	Junction-to-board characterization parameter	79	152	°C/W

7 Detailed Description

7.1 Overview

The LMT01 temperature output is transmitted over a single wire using a train of current pulses that typically change from 34 µA to 125 µA. A simple resistor can then be used to convert the current pulses to a voltage. With a 10-kΩ resistor, the output voltage levels range from 340 mV to 1.25 V, typically. A simple microcontroller comparator or external transistor can be used convert this signal to valid logic levels the microcontroller can process properly through a GPIO pin. The temperature can be determined by gating a simple counter on for a specific time interval to count the total number of output pulses. After power is first applied to the device the current level will remain below 34 µA for at most 54 ms while the LMT01 is determining the temperature. When the temperature is determined, the pulse train begins. The individual pulse frequency is typically 88 kHz. The LMT01 will continuously convert and transmit data when the power is applied approximately every 104 ms (maximum).

The LMT01 uses thermal diode analog circuitry to detect the temperature. The temperature signal is then amplified and applied to the input of a ΣΔ ADC that is driven by an internal reference voltage. The ΣΔ ADC output is then processed through the interface circuitry into a digital pulse train. The digital pulse train is then converted to a current pulse train by the output signal conditioning circuitry that includes high and low current regulators. The voltage applied across the pins of the LMT01 is regulated by an internal voltage regulator to provide a consistent Chip V_{DD} that is used by the ADC and its associated circuitry.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Output Interface

The LMT01 provides a digital output in the form of a pulse count that is transmitted by a train of current pulses. After the LMT01 is powered up, it transmits a very low current of 34 µA for less than 54 ms while the part executes a temperature to digital conversion, as shown in *Figure 22*. When the temperature-to-digital conversion is complete, the LMT01 starts to transmit a pulse train that toggles from the low current of 34 µA to a high current level of 125 µA. The pulse train total time interval is at maximum 50 ms. The LMT01 transmits a series of pulses equivalent to the pulse count at a given temperature as described in *Electrical Characteristics - TO-92/LPG Pulse Count to Temperature LUT*. After the pulse count has been transmitted the LMT01 current level will remain low for the remainder of the 50 ms. The total time for the temperature to digital conversion and the pulse train time interval is 104 ms (maximum). If power is continuously applied, the pulse train output will repeat start every 104 ms (maximum).

Copyright © 2015–2018, Texas Instruments Incorporated

Feature Description (continued)

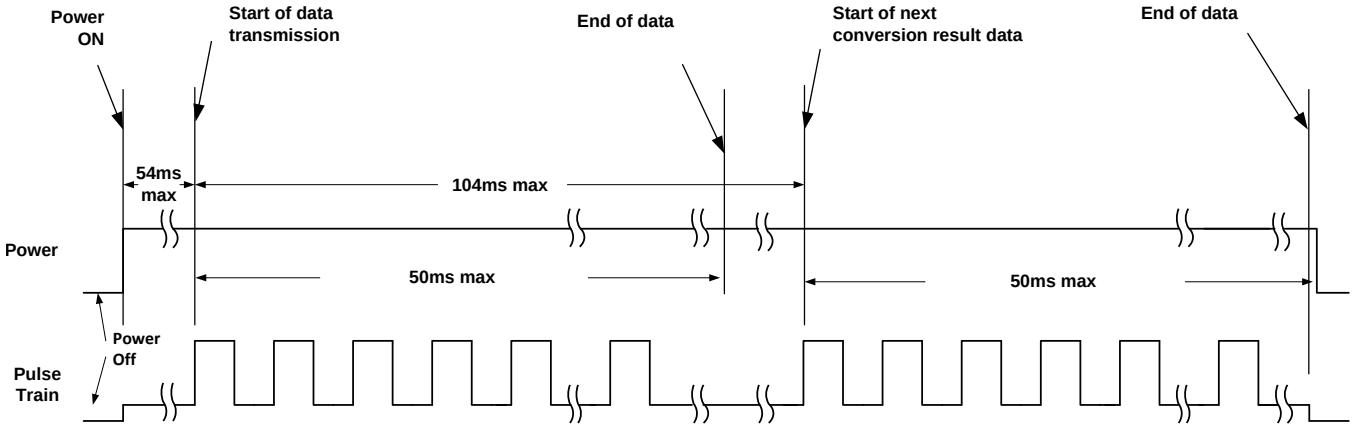

Figure 22. Temperature to Digital Pulse Train Timing Cycle

The LMT01 can be powered down at any time to conserve system power. Take care to ensure that a minimum power-down wait time of 50 ms is used before the device is turned on again.

7.3.2 Output Transfer Function

TheLMT01 outputs at minimum 1 pulse and a theoretical maximum 4095 pulses. Each pulse has a weight of 0.0625°C. One pulse corresponds to a temperature less than –50°C while a pulse count of 4096 corresponds to a temperature greater than 200°C. Note that the LMT01 is only ensured to operate up to 150°C. Exceeding this temperature by more than 5°C may damage the device. The accuracy of the device degrades as well when 150°C is exceeded.

Two different methods of converting the pulse count to a temperature value are discussed in this section. The first method is the least accurate and uses a first order equation, and the second method is the most accurate and uses linear interpolation of the values found in the look-up table (LUT) as described in *Electrical Characteristics - TO-92/LPG Pulse Count to Temperature LUT*.

The output transfer function appears to be linear and can be approximated by Equation 1:

$$\text{Temp} = \left(\frac{\text{PC}}{4096} \times 256°\text{C} \right) - 50°\text{C} \quad (1)$$

where

- PC is the Pulse Count
- Temp is the temperature reading

Table 1 shows some sample calculations using Equation 1.

Table 1. Sample Calculations Using Equation 1

TEMPERATURE (°C)	NUMBER OF PULSES
–49.9375	1
–49.875	2
–40	160
–20	480
0	800
30	1280
50	1600
100	2400
150	3200

Copyright © 2015–2018, Texas Instruments Incorporated

The curve shown in Figure 23 shows the output transfer function using equation Equation 1 (blue line) and the look-up table (LUT) found in *Electrical Characteristics - TO-92/LPG Pulse Count to Temperature LUT* (red line). The LMT01 output transfer function as described by the LUT appears to be linear, but upon close inspection, it can be seen as truly not linear. To actually see the difference, the accuracy obtained by the two methods must be compared.

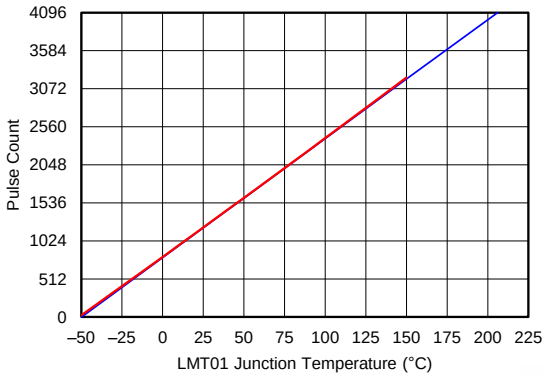

Figure 23. LMT01 Output Transfer Function

For more exact temperature readings the output pulse count can be converted to temperature using linear interpolation of the values found in *Electrical Characteristics - TO-92/LPG Pulse Count to Temperature LUT*.

The curves in Figure 24 and Figure 25, show the accuracy of typical units when using the Equation 1 and linear interpolation using *Electrical Characteristics - TO-92/LPG Pulse Count to Temperature LUT*, respectively. When compared, the improved performance when using the LUT linear interpolation method can clearly be seen. For a limited temperature range of 25°C to 80°C, the error shown in Figure 24 is flat, so the linear equation will provide good results. For a wide temperature range, TI recommends that linear interpolation and the LUT be used.

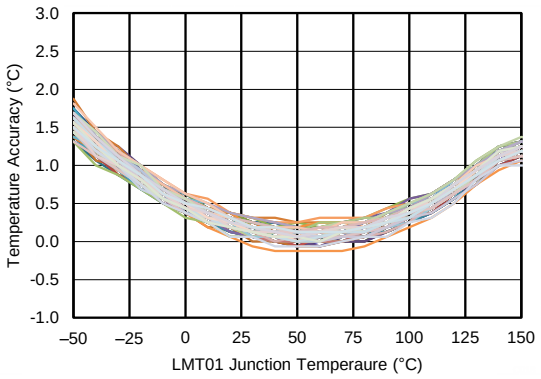

Figure 24. LMT01 Typical Accuracy When Using First Order Equation Equation 1 – 92 Typical Units Plotted at (VP – VN) = 2.15 V

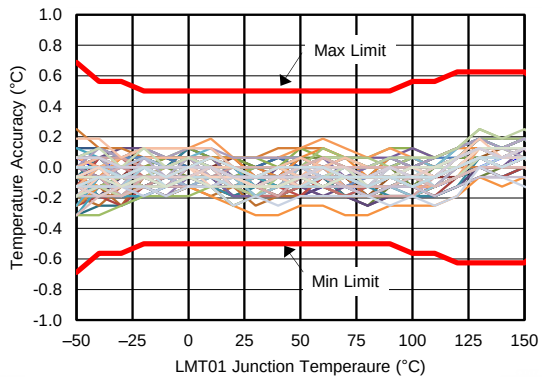

Figure 25. LMT01 Accuracy Using Linear Interpolation of LUT Found In *Electrical Characteristics - TO-92/LPG Pulse Count to Temperature LUT* – 92 typical units plotted at (VP – VN) = 2.15 V

7.3.3 Current Output Conversion to Voltage

The minimum voltage drop across the LMT01 must be maintained at 2.15 V during the conversion cycle. After the conversion cycle, the minimum voltage drop can decrease to 2.0 V. Thus the LMT01 can be used for low voltage applications. See *Application Information* for more information on low voltage operation and other information on picking the actual resistor value for different applications conditions. The resistor value is dependent on the power supply level and the variation and the threshold level requirements of the circuitry the resistor is driving (that is, MCU, GPIO, or Comparator).

Copyright © 2015–2018, Texas Instruments Incorporated

Stray capacitance can be introduced when connecting the LMT01 through a long wire. This stray capacitance influences the signal rise and fall times. The wire inductance has negligible effect on the AC signal integrity. A simple RC time constant model as shown in Figure 26 can be used to determine the rise and fall times.

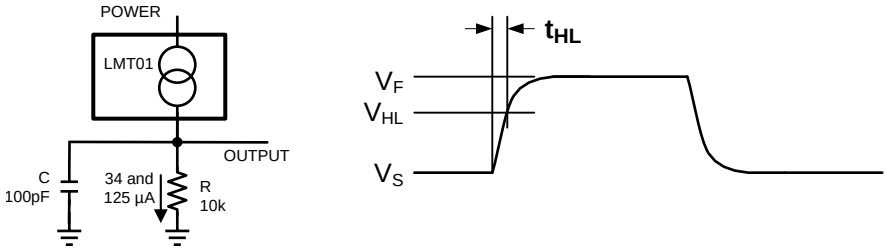

Figure 26. Simple RC Model for Rise and Fall Times

$$t_{HL} = R \times C \times \ln\left(\frac{V_F - V_S}{V_F - V_{HL}}\right)$$

where

- RC as shown in Figure 26
- V_{HL} is the target high level
- the final voltage V_F = 125 µA × R
- the start voltage V_S = 34 µA × R

(2)

For the 10% to 90% level rise time (t_r), Equation 2 simplifies to:

$$t_r = R \times C \times 2.197$$

(3)

Take care to ensure that the LMT01 voltage drop does not exceed 300 mV under reverse bias conditions, as given in the *Absolute Maximum Ratings*.

7.4 Device Functional Modes

The only functional mode the LMT01 has is that it provides a pulse count output that is directly proportional to temperature.

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

8.1.1 Mounting, Temperature Conductivity, and Self-Heating

The LMT01 can be applied easily in the same way as other integrated-circuit temperature sensors. It can be glued or cemented to a surface to ensure good temperature conductivity. The temperatures of the lands and traces to the leads of the LMT01 also affect the temperature reading, so they must be a thin as possible.

Alternatively, the LMT01 can be mounted inside a sealed-end metal tube, and then can be dipped into a bath or screwed into a threaded hole in a tank. As with any IC, the LMT01 and accompanying wiring and circuits must be kept insulated and dry to avoid excessive leakage and corrosion. Printed-circuit coatings are often used to ensure that moisture cannot corrode the leads or circuit traces.

The junction temperature of the LMT01 is the actual temperature being measured by the device. The thermal resistance junction-to-ambient ($R_{\theta JA}$) is the parameter (from *Thermal Information*) used to calculate the rise of a device junction temperature (self-heating) due to its average power dissipation. The average power dissipation of the LMT01 is dependent on the temperature it is transmitting as it effects the output pulse count and the voltage across the device. Equation 4 is used to calculate the self-heating in the die temperature of the LMT01 (T_{SH}).

$$T_{SH} = \left[\left(I_{OL} \times \frac{t_{CONV}}{(t_{CONV} + t_{DATA})} \times V_{CONV}\right) + \left[\left[\left(\frac{PC}{4096} \times \frac{(I_{OL} + I_{OH})}{2}\right) + \left(\frac{(4096 - PC)}{4096} \times I_{OL}\right)\right] \times \frac{t_{DATA}}{(t_{CONV} + t_{DATA})}\right) \times V_{DATA}\right] \times R_{\theta JA} \quad (4)$$

where

- T_{SH} is the ambient temperature
- I_{OL} and I_{OH} are the output low and high current level, respectively
- V_{CONV} is the voltage across the LMT01 during conversion
- V_{DATA} is the voltage across the LMT01 during data transmission
- t_{CONV} is the conversion time
- t_{DATA} is the data transmission time
- PC is the output pulse count
- $R_{\theta JA}$ is the junction to ambient package thermal resistance

Plotted in the curve Figure 27 are the typical average supply current (black line using left y axis) and the resulting self-heating (red and violet lines using right y axis) during continuous conversions. A temperature range of –50°C to +150°C, a V_{CONV} of 5 V (red line) and 2.15 V (violet line) were used for the self-heating calculation. As can be seen in the curve, the average power supply current and thus the average self-heating changes linearly over temperature because the number of pulses increases with temperature. A negligible self-heating of about 45m°C is observed at 150°C with continuous conversions. If temperature readings are not required as frequently as every 100 ms, self-heating can be minimized by shutting down power to the part periodically thus lowering the average power dissipation.

8.2 Typical Application

8.2.1 3.3-V System VDD MSP430 Interface - Using Comparator Input

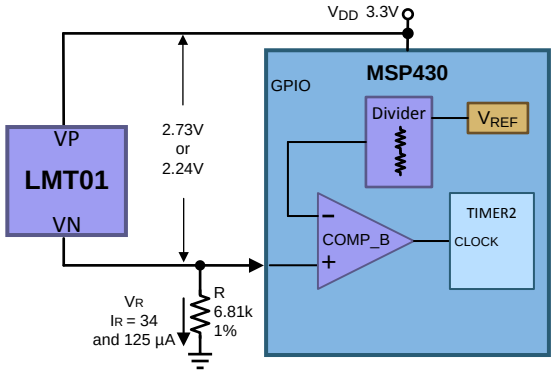

Figure 28. MSP430 Comparator Input Implementation

8.2.1.1 Design Requirements

The design requirements listed in are used in the detailed design procedure.

Table 2. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
VDD	3.3 V
VDD minimum	3.0 V
LMT01 VP – VN minimum during conversion	2.15 V
LMT01 VP – VN minimum during data transmission	2.0 V
Noise margin	50 mV minimum
Comparator input current over temperature range of interest	< 1 uA
Resistor tolerance	1%

Copyright © 2015–2018, Texas Instruments Incorporated

8.2.1.2 Detailed Design Procedure

First, select the R and determine the maximum logic low voltage and the minimum logic high voltage while ensuring that when the LMT01 is converting, the minimum (VP – VN) requirement of 2.15 V is met.

1. Select R using minimum VP-VN during data transmission (2 V) and maximum output current of the LMT01 (143.75 µA)
   - R = (3.0 V – 2 V) / 143.75 µA = 6.993 k the closest 1% resistor is 6.980 k
   - 6.993 k is the maximum resistance so if using 1% tolerance resistor the actual resistor value needs to be 1% less than 6.993 k and 6.98 k is 0.2% less than 6.993 k thus 6.81 k must be used.
2. Check to see if the 2.15-V minimum voltage during conversion requirement for the LMT01 is met with the maximum I_{OL} of 39 µA and maximum R of 6.81 k + 1%:
   - V_{LMT01} = 3 V – (6.81 k × 1.01) × 39 µA = 2.73 V
3. Find the maximum low level voltage range using the maximum R of 6.81 k and maximum I_{OL} of 39 µA:
   - V_{RLmax} = (6.81 k × 1.01) × 39 µA = 268 mV
4. Find the minimum high level voltage using the minimum R of 6.81 k and minimum I_{OH} of 112.5 µA:
   - V_{RHmin} = (6.81 k × 0.99) × 112.5 µA = 758 mV

Now select the MSP430 comparator threshold voltage that enables the LMT01 to communicate to the MSP430 properly.

1. The MSP430 voltage is selected by selecting the internal V_{REF} and then choosing the appropriate 1 of n/32 settings for n of 1 to 31.
   - V_{MID}= (V_{RLmax} – V_{RHmin}) / 2 + V_{RHmin} = (758 mV – 268 mV) / 2 + 268 mV = 513 mV
   - n = (V_{MID} / V_{REF}) × 32 = (0.513 / 2.5) × 32 = 7
2. To prevent oscillation of the comparator, output hysteresis must be implemented. The MSP430 allows this by enabling different n for the rising edge and falling edge of the comparator output. For a falling comparator output transition, N must be set to 6.
3. Determine the noise margin caused by variation in comparator threshold level. Even though the comparator threshold level theoretically is set to V_{MID}, the actual level varies from device to device due to V_{REF} tolerance, resistor divider tolerance, and comparator offset. For proper operation, the COMP_B worst case input threshold levels must be within the minimum high and maximum low voltage levels presented across R, V_{RHmin} and V_{RLmax}, respectively

$$V_{CHmax} = V_{REF} \times (1 + V_REF_TOL) \times \frac{(N + N_TOL)}{32} + COMP_OFFSET \quad (5)$$

where

- VREF is the MSP430 COMP_B reference voltage for this example at 2.5 V
- V_REF_TOL is the tolerance of the VREF of 1% or 0.01,
- N is the divisor for the MSP430 or 7
- N_TOL is the tolerance of the divisor or 0.5
- COMP_OFFSET is the comparator offset specification or 10 mV

$$V_{CLmin} = V_{REF} \times (1 - V_REF_TOL) \times \frac{(N - N_TOL)}{32} - COMP_OFFSET \quad (6)$$

where

- VREF is the MSP430 COMP_B reference voltage for this example at 2.5 V,
- V_REF_TOL is the tolerance of the VREF of 1% or 0.01,
- N is the divisor for the MSP430 for the hysteresis setting or 6,
- N_TOL is the tolerance of the divisor or 0.5,
- COMP_OFFSET is the comparator offset specification or 10 mV

The noise margin is the minimum of the two differences:

(V_{RHmin} – V_{CHmax}) or (V_{CHmin} – V_{RLmax}) (7)

which works out to be 145 mV.

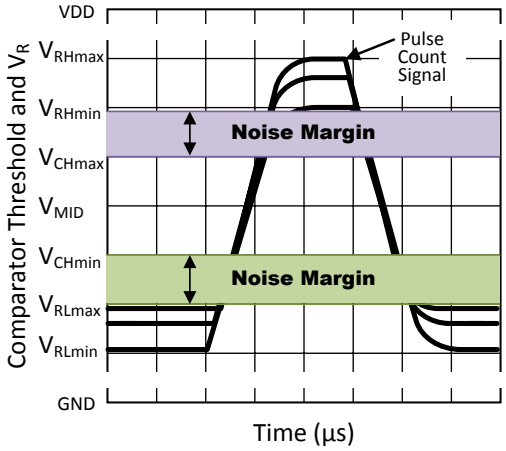

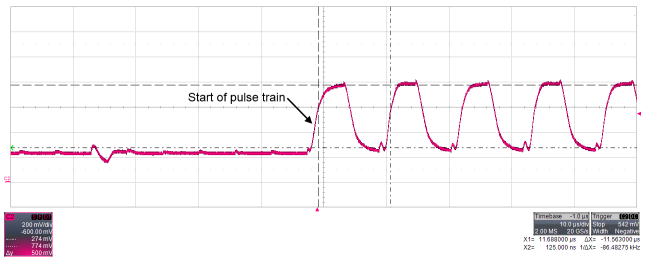

Figure 29. Pulse Count Signal Amplitude Variation

8.2.1.2.1 Setting the MSP430 Threshold and Hysteresis

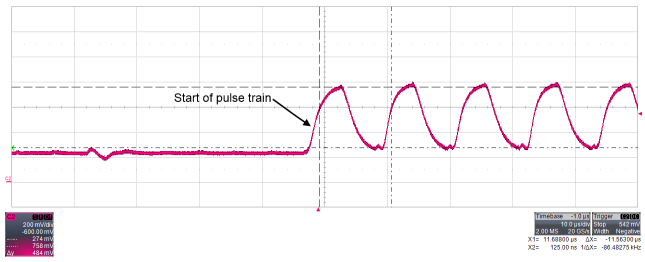

The comparator hysteresis determines the noise level that the signal can support without causing the comparator to trip falsely and resulting in an inaccurate pulse count. The comparator hysteresis is set by the precision of the MSP430 and what thresholds it is capable of. For this case, as the input signal transitions high, the comparator threshold is dropped by 77 mV. If the noise on the signal is kept below this level as it transitions, the comparator will not trip falsely. In addition, the MSP430 has a digital filter on the COMP_B output that be used to further filter output transitions that occur too quickly.

8.2.1.3 Application Curves

Amplitude = 200 mV/div
Time Base = 10 µs/div
Δy at cursors = 500 mV
Δx at cursors = 11.7 µs

Figure 30. MSP430 COMP_B Input Signal No Capacitance Load

Amplitude = 200 mV/div
Time Base = 10 µs/div
Δy at cursors = 484 mV
Δx at cursors = 11.7 µs

Figure 31. MSP430 COMP_B Input Signal 100-pF Capacitance Load

8.3 System Examples

The LMT01 device can be configured in a number of ways. Transistor level shifting can be used so that the output pulse of the device can be read with a GPIO (see Figure 32). An isolation block can be inserted to achieve electrical isolation (see Figure 33). Multiple LMT01 devices can be controlled with GPIOs enabling temperature monitor for multiple zones. Lastly, the LMT01 device can be configured to have a common ground with a high side signal (see Figure 35).

System Examples (continued)

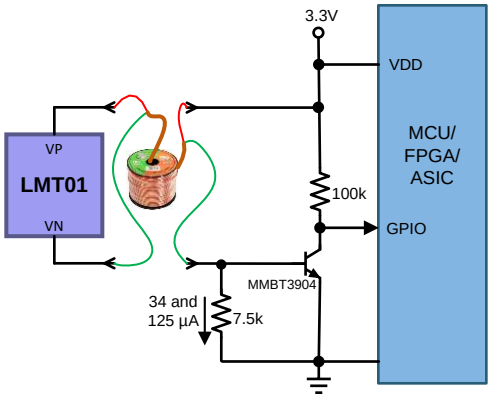

Figure 32. Transistor Level Shifting

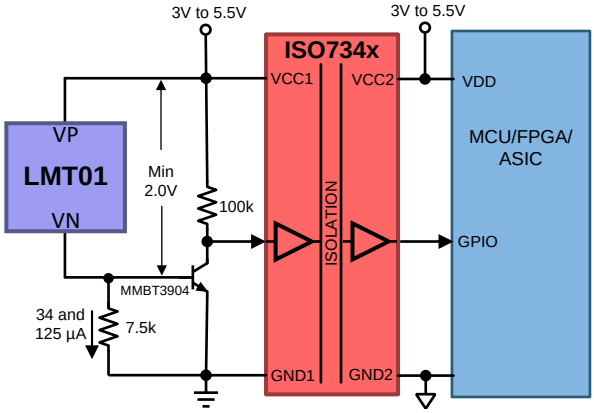

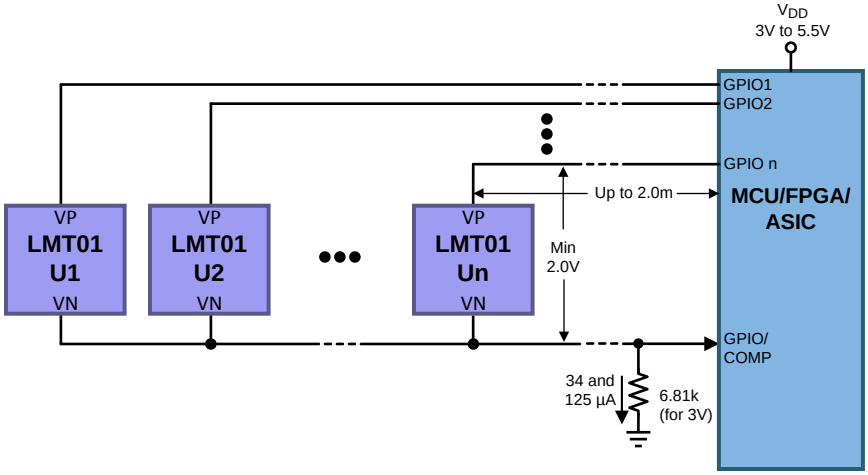

Figure 33. Isolation

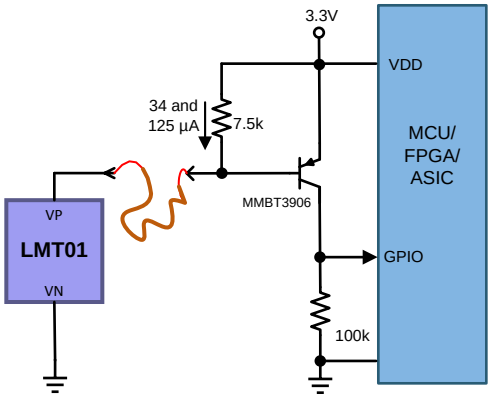

Note: to turn off an LMT01 set the GPIO pin connected to VP to high impedance state as setting it low would cause the off LMT01 to be reverse biased. Comparator input of MCU must be used.

Figure 34. Connecting Multiple Devices to One MCU Input Pin

System Examples (continued)

Note: the VN of the LMT01 must be connected to the MCU GND.

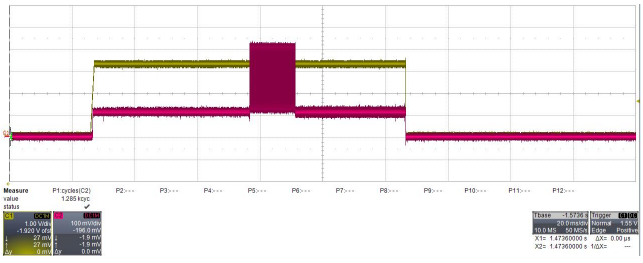

Figure 35. Common Ground With High-Side Signal

9 Power Supply Recommendations

Because the LMT01 is only a 2-pin device the power pins are common with the signal pins, thus the LMT01 has a floating supply that can vary greatly. The LMT01 has an internal regulator that provides a stable voltage to internal circuitry.

Take care to prevent reverse biasing of the LMT01 as exceeding the absolute maximum ratings may cause damage to the device.

Power supply ramp rate can effect the accuracy of the first result transmitted by the LMT01. As shown in Figure 36 with a 1-ms rise time, the LMT01 output code is at 1286, which converts to 30.125°C. The scope photo shown in Figure 37 reflects what happens when the rise time is too slow. In Figure 37, the power supply (yellow trace) is still ramping up to final value while the LMT01 (red trace) has already started a conversion. This causes the output pulse count to decrease from the previously shown 1286, to 1282 (or 29.875°C). Thus, for slow ramp rates, TI recommends that the first conversion be discarded. For even slower ramp rates, more than one conversion may have to be discarded as TI recommends that either the power supply be within final value before a conversion is used or that ramp rates be faster than 2.5 ms.

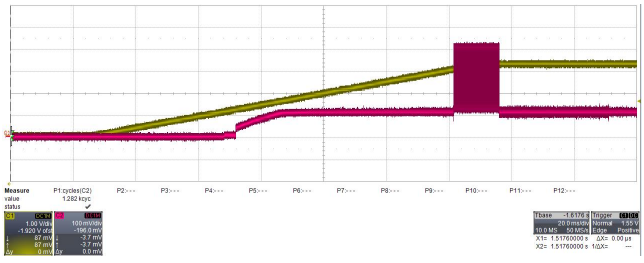

Yellow trace = 1 V/div, Red trace = 100 mV/div, Time Base = 20 ms/div

T_A= 30°C — LMT01 Pulse Count = 1286

VP-VN = 3.3 V — Rise Time = 1 ms

Figure 36. Output Pulse Count With Appropriate Power Supply Rise Time

Yellow trace = 1V/div, Red trace = 100 mV/div, Time base = 20 ms/div

T_A=30°C — LMT01 Pulse Count = 1282

VP-VN=3.3 V — Rise Time = 100 ms

10 Layout

10.1 Layout Guidelines

The LMT01 can be mounted to a PCB as shown in Figure 38 and Figure 39. Take care to make the traces leading to the pads as small as possible to minimize their effect on the temperature the LMT01 is measuring.

11.4 静电放电警告

ESD 可能会损坏该集成电路。德州仪器 (TI) 建议通过适当的预防措施处理所有集成电路。如果不遵守正确的处理措施和安装程序，可能会损坏集成电路。

ESD 的损坏小至导致微小的性能降级，大至整个器件故障。 精密的集成电路可能更容易受到损坏，这是因为非常细微的参数更改都可能会导致器件与其发布的规格不相符。

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
