具有集成麦克风偏置和输入故障诊断功能的 PCM6xx0-Q1 汽车类、4 通道和 6 通道、768kHz 音频 ADC

ADVANCE INFORMATION

1 特性

- 符合面向汽车 应用的 AEC-Q100 标准
  - 温度等级 1：–40°C ≤ T_A ≤ +125°C
- ADC 性能：
  - 线路差分输入动态范围：110dB
  - 麦克风差分输入动态范围：110dB
  - THD+N：-94dB
  - 通道相加模式可提高 SNR
- ADC 输入电压：
  - 差分 $10V_{RMS}$ 满量程输入
  - 单端 $5V_{RMS}$ 满量程输入
- ADC 采样率 (f_S) = 8kHz 至 768kHz
- 可编程通道设置：
  - 通道增益：0dB 至 42dB，步长 1dB
  - 数字音量控制：–100dB 至 27dB
  - 增益校准分辨率为 0.1dB
  - 相位校准分辨率为 163ns
- 可编程麦克风偏置（5V 至 9V）：
  - 具有集成的高效升压转换器，或
  - 具有外部高电压 HVDD 电源
- 可编程麦克风输入故障诊断：
  - 开路输入或短路输入
  - 接地短路、MICBIAS 或 VBAT
  - 麦克风偏置过流保护
- 低延迟信号处理滤波器选择
- 可编程 HPF 和双二阶数字滤波器
- I^2C 或 SPI 控制
- 音频串行数据接口：
  - 格式：TDM、I^2S 或左平衡 (LJ)
  - 字长：16 位、20 位、24 位或 32 位
  - 主/从接口
- 3.3V 单电源运行
- I/O 电源运行：3.3V 或 1.8V
- 功耗：在 48kHz 下 < 21.5mW/通道

2 应用

- 汽车有源噪声消除
- 汽车音响主机
- 汽车外部放大器

3 说明

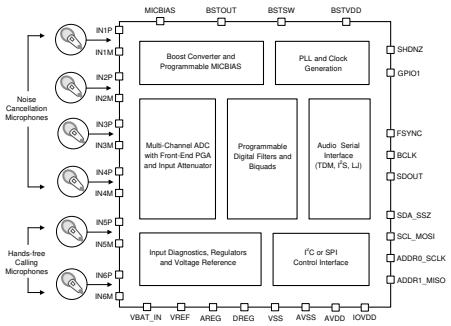

4 通道 PCM6x40-Q1（PCM6240-Q1、PCM6340-Q1）和 6 通道 PCM6x60-Q1（PCM6260-Q1、PCM6360-Q1）是高性能音频模数转换器 (ADC)，支持高达 $10V_{RMS}$ 的模拟输入信号。PCM6x40-Q1 和 PCM6x60-Q1 (PCM6xx0-Q1) 支持线路和麦克风输入，并允许单端和差分输入配置。这类器件具有集成的高电压、可编程麦克风偏置和输入诊断电路，可直接连接到基于麦克风的汽车系统，提供全面的直接耦合输入故障诊断功能。PCM62x0-Q1 集成了一个高效的升压转换器，以通过外部低电压 3.3V 电源产生高电压麦克风偏置；而 PCM63x0-Q1 直接使用系统内随时可用的外部高电压电源 (HVDD)，以产生高电压、可编程的麦克风偏置。PCM6xx0-Q1 集成了可编程通道增益、数字音量控制、低抖动锁相环 (PLL)、可编程高通滤波器 (HPF)、双二阶滤波器、低延迟滤波器模式，并可实现高达 768kHz 的采样率。PCM6xx0-Q1 支持时分多路复用 (TDM)、I^2S 或左平衡 (LJ) 音频格式，并可通过 I^2C 或 SPI 接口进行控制。这些集成的高性能 特性以及 3.3V 单电源运行，使 PCM6xx0-Q1 系列特别适用于空间受限的汽车系统。

器件信息(1)

器件型号	封装	封装尺寸（标称值）
PCM6xx0-Q1	WQFN (32)	5.00mm x 5.00mm，间距为 0.5mm

(1) 如需了解所有可用封装，请参阅数据表末尾的封装选项附录。

简化的应用示意图 (PCM6260-Q1)

Pin Functions: PCM6240-Q1

PIN		TYPE	DESCRIPTION
NO.	NAME		
1	AVDD	Analog supply	Analog power (3.3 V, nominal)
2	AREG	Analog supply	Analog on-chip regulator output voltage for analog supply (1.8 V, nominal)
3	BSTVDD	Analog supply	Boost converter supply voltage (3.3 V, nominal)
4	BSTSW	Analog supply	Boost converter switch input
5	BSTOUT	Analog supply	Boost converter output voltage
6	MICBIAS	Analog	MICBIAS output (programmable output up to 9 V)
7	VREF	Analog	Analog reference voltage filter output
8	AVSS	Analog supply	Analog ground. Short this pin directly to the board ground plane.
9	IN1P	Analog input	Analog input 1P pin
10	IN1M	Analog input	Analog input 1M pin
11	IN2P	Analog input	Analog input 2P pin
12	IN2M	Analog input	Analog input 2M pin
13	IN3P	Analog input	Analog input 3P pin
14	IN3M	Analog input	Analog input 3M pin
15	IN4P	Analog input	Analog input 4P pin
16	IN4M	Analog input	Analog input 4M pin
17	GPI2	Digital input	General-purpose digital input 2 (multipurpose functions such as daisy-chain input, PLL input clock source, and so forth)
18	GPIO3	Digital I/O	General-purpose digital input/output 3 (multipurpose functions such as daisy-chain input, audio data output, PLL input clock source, interrupt, and so forth)
19	GPI1	Digital input	General-purpose digital input 1 (multipurpose functions such as daisy-chain input, PLL input clock source, and so forth)
20	GPIO2	Digital I/O	General-purpose digital input/output 2 (multipurpose functions such as daisy-chain input, audio data output, PLL input clock source, interrupt, and so forth)
21	VBAT_IN	Analog	Analog VBAT input monitoring pin (used for input diagnostics)

7 Specifications

7.1 Absolute Maximum Ratings

over the operating ambient temperature range (unless otherwise noted)(1)

		MIN	MAX	UNIT
Supply voltage	AVDD to AVSS	–0.3	3.9	V
	BSTVDD(2) to VSS (thermal pad)	–0.3	3.9	
	IOVDD to VSS (thermal pad)	–0.3	3.9	
	HVDD(3) to VSS (thermal pad)	–0.3	14	
Ground voltage differences	AVSS to VSS (thermal pad)	–0.3	0.3	V
Battery voltage	VBAT_IN to AVSS	–0.3	18	V
Analog input voltage	Analog input pins voltage to AVSS	–0.3	18	V
Digital input voltage	Digital input pins voltage to VSS (thermal pad)	–0.3	IOVDD + 0.3	V
Temperature	Operating ambient, T_A	–40	125	°C
	Junction, T_J	–40	150	
	Storage, T_{stg}	–65	150	

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) BSTVDD supply is required only for PCM62x0-Q1
(3) HVDD supply is required only for PCM63x0-Q1.

7.2 ESD Ratings

				VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per AEC Q100-002(1)		±2000	V
		Charged-device model (CDM), per AEC Q100-011	Corner package pins	±750	
			All other non-corner package pins	±500	

(1) AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

7.3 Recommended Operating Conditions

		MIN	NOM	MAX	UNIT
POWER					
AVDD(1)	Analog supply voltage to AVSS	3.0	3.3	3.6	V
BSTVDD(2)	Boost converter supply voltage to VSS (thermal pad)	3.0	3.3	3.6	V
IOVDD	IO supply voltage to VSS (thermal pad) - IOVDD 3.3-V operation	3.0	3.3	3.6	V
	IO supply voltage to VSS (thermal pad) - IOVDD 1.8-V operation	1.65	1.8	1.95	
HVDD(3)	MICBIAS LDO supply voltage to VSS (thermal pad)	5.6	11	12	V
INPUTS					
VBAT_IN	VBAT_IN input pin voltage to AVSS	0	12.6	18	V
INxx	Analog input pins voltage to AVSS for line-in recording	0		14.2	V
	Analog input pins voltage to AVSS for microphone recording	0.1		MICBIAS – 0.1	V
	Analog input pins voltage to AVSS during short to VBAT_IN			VBAT_IN	V
	Digital input pins voltage to VSS (thermal pad)	0		IOVDD	V
TEMPERATURE					
T_A	Operating ambient temperature	–40		125	°C

(1) AVSS and VSS (thermal pad); all ground pins must be tied together and must not differ in voltage by more than 0.2 V.
(2) BSTVDD is required only for the PCM62x0-Q1.
(3) HVDD is required only for the PCM63x0-Q1 and the minimum voltage must be 0.6 V higher than the programmed MICBIAS value.

ADVANCE INFORMATION

Copyright © 2020, Texas Instruments Incorporated

Recommended Operating Conditions (continued)

		MIN	NOM	MAX	UNIT
OTHERS					
	GPIOx or GPIx (used as MCLK input) clock frequency			36.864	MHz
C_b	SCL and SDA bus capacitance for I^2C interface supports standard-mode and fast-mode			400	pF
	SCL and SDA bus capacitance for I^2C interface supports fast-mode plus			550	
C_L	Digital output load capacitance		20	50	pF
	Boost converter inductor for 6MHz clocking mode (recommended inductor CIGW201610GL2R2MLE)		2.2		µH

7.4 Thermal Information

THERMAL METRIC(1)		PCM6xx0-Q1 RTV (WQFN) 32 PINS	UNIT
$R_{\theta JA}$	Junction-to-ambient thermal resistance	30.1	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	17.0	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	11.0	°C/W
ψ_{JT}	Junction-to-top characterization parameter	0.2	°C/W
ψ_{JB}	Junction-to-board characterization parameter	10.9	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	1.8	°C/W

(1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report.

7.5 Electrical Characteristics

at T_A = 25°C, AVDD = 3.3 V, IOVDD = 3.3 V, BSTVDD = 3.3 V, HVDD = 11 V (for the PCM63x0-Q1), f_{IN} = 1-kHz sinusoidal signal, f_S = 48 kHz, 32-bit audio data, BCLK = 256 × f_S, TDM slave mode and PLL on (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	NOM	MAX	UNIT
ADC PERFORMANCE FOR LINE INPUT RECORDING						
	Differential input full-scale AC signal voltage	AC-coupled input, input fault diagnostic not supported		10		V_{RMS}
		DC-coupled input, DC common-mode voltage INxP = INxM = 7.1 V, input fault diagnostic not supported				
	Single-ended input full-scale AC signal voltage	AC-coupled input, input fault diagnostic not supported		5		V_{RMS}
		DC-coupled input, DC common-mode voltage INxP = INxM = 7.1 V, input fault diagnostic not supported				
SNR	Signal-to-noise ratio, A-weighted(1)(2)	IN1 differential AC-coupled input selected and AC signal shorted to ground, 0-dB channel gain	TBD	109		dB
		IN1 differential DC-coupled input selected and AC signal shorted to ground, 0-dB channel gain		109		
		IN1 differential DC-coupled input selected and AC signal shorted to ground, 12-dB channel gain		101		
DR	Dynamic range, A-weighted(2)	IN1 differential AC-coupled input selected and –60-dB full-scale AC signal input, 0-dB channel gain		110		dB
		IN1 differential DC-coupled input selected and –60-dB full-scale AC signal input, 0-dB channel gain		109		
		IN1 differential DC-coupled input selected and –72-dB full-scale AC signal input, 12-dB channel gain		101		
THD+N	Total harmonic distortion(2)	IN1 differential AC-coupled input selected and –1-dB full-scale AC signal input, 0-dB channel gain		–94	TBD	dB
		IN1 differential DC-coupled input selected and –1-dB full-scale AC signal input, 0-dB channel gain		–94		
		IN1 differential DC-coupled input selected and –13-dB full-scale AC signal input, 12-dB channel gain		–92		

(1) Ratio of output level with 1-kHz full-scale sine-wave input, to the output level with the AC signal input shorted to ground, measured A-weighted over a 20-Hz to 20-kHz bandwidth using an audio analyzer.
(2) All performance measurements done with 20-kHz low-pass filter and, where noted, A-weighted filter. Failure to use such a filter can result in higher THD and lower SNR and dynamic range readings than shown in the Electrical Characteristics. The low-pass filter removes out-of-band noise, which, although not audible, can affect dynamic specification values.

Electrical Characteristics (continued)

at T_A = 25°C, AVDD = 3.3 V, IOVDD = 3.3 V, BSTVDD = 3.3 V, HVDD = 11 V (for the PCM63x0-Q1), f_{IN} = 1-kHz sinusoidal signal, f_S = 48 kHz, 32-bit audio data, BCLK = 256 × f_S, TDM slave mode and PLL on (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	NOM	MAX	UNIT
	Channel gain control range	Programmable 1-dB steps	0		42	dB
ADC PERFORMANCE FOR MICROPHONE INPUT RECORDING						
	Differential input full-scale AC signal voltage(3)	AC-coupled input, input fault diagnostic not supported. CHx_MIC_RANGE register bit is set to high.				V_{RMS}
		DC-coupled input, DC differential common-mode voltage INxP – INxM > 3.4 V, DC common-mode voltage INxP < (MICBIAS – 1.7 V) and DC common-mode voltage INxM > 1.7 V. CHx_MIC_RANGE register bit is set to high to support AC differential signal max swing > 2 Vrms(4).		10		
SNR	Signal-to-noise ratio, A-weighted(1)(2)	IN1 differential AC-coupled input selected and AC signal shorted to ground, 0-dB channel gain		109		dB
		IN1 differential DC-coupled input selected and AC-signal shorted to ground, DC differential common-mode voltage IN1P – IN1M < 5.0 V, 0-dB channel gain	TBD	109		
DR	Dynamic range, A-weighted(2)	IN1 differential AC-coupled input selected and –60-dB full-scale AC signal input, 0-dB channel gain		110		dB
		IN1 differential DC-coupled input selected and –60-dB full-scale AC signal input, DC differential common-mode voltage IN1P – IN1M < 5.0 V, 0-dB channel gain		109		
THD+N	Total harmonic distortion(2)	IN1 differential AC-coupled input selected and –1-dB full-scale AC signal input, 0-dB channel gain		–94		dB
		IN1 differential DC-coupled input selected and –15-dB full-scale AC signal input, 0-dB channel gain		–90	TBD	
	Channel gain control range	Programmable 1-dB steps	0		42	dB
ADC OTHER PARAMETERS						
	Input impedance	Differential input, between INxP and INxM		50		kΩ
		Single-ended input, between INxP and INxM		25		
	Digital volume control range	Programmable 0.5-dB steps	–100		27	dB
	Output data sample rate	Programmable	7.35		768	kHz
	Output data sample word length	Programmable	16		32	Bits
	Digital high-pass filter cutoff frequency	First-order IIR filter with programmable coefficients, –3-dB point (default setting)		12		Hz
	Interchannel isolation	–1-dB full-scale AC signal line-in input to non measurement channel		–132		dB
	Interchannel gain mismatch	–6-dB full-scale AC signal line-in input, 0-dB channel gain		0.1		dB
	Interchannel phase mismatch	1-kHz sinusoidal signal		0.02		Degrees
PSRR	Power-supply rejection ratio	100-mV_{PP}, 1-kHz sinusoidal signal on AVDD, differential input selected, 0-dB channel gain		89		dB
CMRR	Common-mode rejection ratio	Differential microphone input selected, 0-dB channel gain, 1-V_{RMS} AC input, 1-kHz signal on both pins and measure level at output		80		dB
MICROPHONE BIAS						
	MICBIAS noise	BW = 20 Hz to 20 kHz, A-weighted, 1-µF capacitor between MICBIAS and AVSS		8		$µV_{RMS}$
	MICBIAS voltage	Programmable 0.5-V steps	5		9	V
	MICBIAS current drive	MICBIAS voltage 9 V			80	mA
	MICBIAS load regulation	MICBIAS voltage 9 V, measured up to maximum load	0		1	%

(3) Microphone inputs support a 2 V_{RMS} differential input full-scale AC signal voltage, if the CHx_MIC_RANGE register bit is set to low (default value). However, if the input DC common-mode differential voltage is higher than 4 V, then TI recommends setting the CHx_MIC_RANGE register bit high to avoid any saturation resulting from the high input DC common-mode differential voltage.

(4) If the CHx_MIC_RANGE register bit is set to high (default value is low) in DC-coupled input configuration mode, then the input differential DC common-mode along with input differential AC signal must be less than 10 V_{RMS} for differential input configuration mode. Similarly, for single-ended input configuration mode, the input DC common-mode voltage along with the input AC signal must be less than 5 V_{RMS} .

7.8 Timing Requirements: SPI Interface

at T_A = 25°C, IOVDD = 3.3 V or 1.8 V and 20-pF load on all outputs (unless otherwise noted); see Figure 2 for timing diagram

			MIN	NOM	MAX	UNIT
$t_{(SCLK)}$	SCLK period		40			ns
$t_{H(SCLK)}$	SCLK high pulse duration		18			ns
$t_{L(SCLK)}$	SCLK low pulse duration		18			ns
t_{LEAD}	Enable lead time		16			ns
t_{TRAIL}	Enable trail time		16			ns
t_{DSEQ}	Sequential transfer delay		20			ns
$t_{SU(MOSI)}$	MOSI data setup time		8			ns
$t_{HLD(MOSI)}$	MOSI data hold time		8			ns
$t_{r(SCLK)}$	SCLK rise time	10% - 90% rise time			6	ns
$t_{f(SCLK)}$	SCLK fall time	90% - 10% fall time			6	ns

7.9 Switching Characteristics: SPI Interface

at T_A = 25°C, IOVDD = 3.3 V or 1.8 V and 20-pF load on all outputs (unless otherwise noted); see Figure 2 for timing diagram

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
$t_{a(MISO)}$	MISO access time				21	ns
$t_{d(MISO)}$	SCLK to MISO delay	50% of SCLK to 50% of MISO			21	ns
$t_{dis(MISO)}$	MISO disable time				21	ns

7.10 Timing Requirements: TDM, I²S or LJ Interface

at T_A = 25°C, IOVDD = 3.3 V or 1.8 V and 20-pF load on all outputs (unless otherwise noted); see Figure 3 for timing diagram

			MIN	NOM	MAX	UNIT
$t_{(BCLK)}$	BCLK period		40			ns
$t_{H(BCLK)}$	BCLK high pulse duration (1)		18			ns
$t_{L(BCLK)}$	BCLK low pulse duration (1)		18			ns
$t_{SU(FSYNC)}$	FSYNC setup time		8			ns
$t_{HLD(FSYNC)}$	FSYNC hold time		8			ns
$t_{r(BCLK)}$	BCLK rise time	10% - 90% rise time			10	ns
$t_{f(BCLK)}$	BCLK fall time	90% - 10% fall time			10	ns

(1) The BCLK minimum high or low pulse duration must be higher than 25 ns (to meet the timing specifications), if the SDOUT data line is latched on the opposite BCLK edge polarity than the edge used by the device to transmit SDOUT data.

7.11 Switching Characteristics: TDM, I²S or LJ Interface

at T_A = 25°C, IOVDD = 3.3 V or 1.8 V and 20-pF load on all outputs (unless otherwise noted); see Figure 3 for timing diagram

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
$t_{d(SDOUT-BCLK)}$	BCLK to SDOUT delay	50% of BCLK to 50% of SDOUT			21	ns
$t_{d(SDOUT-FSYNC)}$	FSYNC to SDOUT delay in TDM or LJ mode (for MSB data with TX_OFFSET = 0)	50% of FSYNC to 50% of SDOUT			21	ns
$f_{(BCLK)}$	BCLK output clock frequency; master mode (1)				24.576	MHz
$t_{H(BCLK)}$	BCLK high pulse duration; master mode		14			ns
$t_{L(BCLK)}$	BCLK low pulse duration; master mode		14			ns
$t_{d(FSYNC)}$	BCLK to FSYNC delay; master mode	50% of BCLK to 50% of FSYNC			21	ns
$t_{r(BCLK)}$	BCLK rise time; master mode	10% - 90% rise time			8	ns
$t_{f(BCLK)}$	BCLK fall time; master mode	90% - 10% fall time			8	ns

(1) The BCLK output clock frequency must be lower than 18.5 MHz (to meet the timing specifications), if the SDOUT data line is latched on the opposite BCLK edge polarity than the edge used by the device to transmit SDOUT data.

8 Detailed Description

8.1 Overview

The PCM6xx0-Q1 are a scalable family of devices that consist of high-performance, low-power, flexible, multichannel, audio analog-to-digital converters (ADCs) with extensive feature integration. These devices are intended for automotive applications such as vehicle cabin active noise cancellation, hands-free in-vehicle communication, emergency call, and multimedia applications. The high dynamic range of these devices enables far-field audio recording with high fidelity. These devices integrate a host of features that reduce cost, board space, and power consumption in space-constrained automotive sub-system designs. Package, performance, and device-compatible configuration registers make this family of devices well suited for scalable system designs.

The PCM6xx0-Q1 consist of the following blocks:

- Multichannel, multibit, high-performance delta-sigma (ΔΣ) ADCs
- Configurable single-ended or differential audio inputs with high voltage signal swing
- High-voltage, low-noise programmable microphone bias output
- Highly flexible, comprehensive input fault diagnostic
- Automatic gain controller (AGC)
- Programmable decimation filters with linear-phase or low-latency filter
- Programmable channel gain, volume control, and biquad filters for each channel
- Programmable phase and gain calibration with fine resolution for each channel
- Programmable high-pass filter (HPF) and digital channel mixer
- Integrated low-jitter, phase-locked loop (PLL) supporting a wide range of system clocks
- Integrated digital and analog voltage regulators to support single-supply operation

Communication to the PCM6xx0-Q1 for configuring the control registers is supported using an I^2C or SPI interface. The device supports a highly flexible audio serial interface [time-division multiplexing (TDM), I^2S, or left-justified (LJ)] to transmit audio data seamlessly in the system across devices.

The device can support multiple devices by sharing the common I^2C and TDM buses across devices. Moreover, the device includes a daisy-chain feature and a secondary audio serial output data pin. These features relax the shared TDM bus timing requirements and board design complexities when operating multiple devices for applications requiring high audio data bandwidth.

表 1 lists the reference abbreviations used throughout this document to registers that control the device.

表 1. Abbreviations for Register References

REFERENCE	ABBREVIATION	DESCRIPTION	EXAMPLE
Page y, register z, bit k	Py_Rz_Dk	Single data bit. The value of a single bit in a register.	Page 4, register 36, bit 0 = P4_R36_D0
Page y, register z, bits k-m	Py_Rz_D[k:m]	Range of data bits. A range of data bits (inclusive).	Page 4, register 36, bits 3-0 = P4_R36_D[3:0]
Page y, register z	Py_Rz	One entire register. All eight bits in the register as a unit.	Page 4, register 36 = P4_R36
Page y, registers z-n	Py_Rz-Rn	Range of registers. A range of registers in the same page.	Page 4, registers 36, 37, 38 = P4_R36-R38

ADVANCE INFORMATION

8.3 Feature Description

8.3.1 Serial Interfaces

This device has two serial interfaces: control and audio data. The control serial interface is used for device configuration. The audio data serial interface is used for transmitting audio data to the host device.

8.3.1.1 Control Serial Interfaces

The device contains configuration registers and programmable coefficients that can be set to the desired values for a specific system and application use. All these registers can be accessed using either I^2C or SPI communication to the device. For more information, see the *Programming* section.

8.3.1.2 Audio Serial Interfaces

Digital audio data flows between the host processor and the PCM6xx0-Q1 on the digital audio serial interface (ASI), or audio bus. This highly flexible ASI bus includes a TDM mode for multichannel operation, support for I^2S or left-justified protocols format, programmable data length options, very flexible master-slave configurability for bus clock lines, and the ability to communicate with multiple devices within a system directly.

The bus protocol TDM, I^2S, or left-justified (LJ) format can be selected by using the ASI_FORMAT[1:0], P0_R7_D[7:6] register bits. As shown in 表 2 and 表 3, these modes are all most significant byte (MSB)-first, pulse code modulation (PCM) data format, with the output channel data word-length programmable as 16, 20, 24, or 32 bits by configuring the ASI_WLEN[1:0], P0_R7_D[5:4] register bits.

表 2. Audio Serial Interface Format

P0_R7_D[7:6] : ASI_FORMAT[1:0]	AUDIO SERIAL INTERFACE FORMAT
00 (default)	Time division multiplexing (TDM) mode
01	Inter IC sound (I^2S) mode
10	Left-justified (LJ) mode
11	Reserved (do not use this setting)

表 3. Audio Output Channel Data Word-Length

P0_R7_D[5:4] : ASI_WLEN[1:0]	AUDIO OUTPUT CHANNEL DATA WORD-LENGTH
00	Output channel data word-length set to 16 bits
01	Output channel data word-length set to 20 bits
10	Output channel data word-length set to 24 bits
11 (default)	Output channel data word-length set to 32 bits

The frame sync pin, FSYNC, is used in this audio bus protocol to define the beginning of a frame and has the same frequency as the output data sample rates. The bit clock pin, BCLK, is used to clock out the digital audio data across the serial bus. The number of bit clock cycles in a frame must accommodate multiple device active output channels with the programmed data word length.

ADVANCE INFORMATION

版权 © 2020, Texas Instruments Incorporated

A frame consists of multiple time-division channel slots (up to 64) to allow all output channel audio data transmissions to complete on the audio bus by a device or multiple PCM6xx0-Q1 devices sharing the same audio bus. The device supports up to eight output channels that can be configured to place their audio data on bus slot 0 to slot 63. 表 4 lists the output channel slot configuration settings. In I^2S and LJ mode, the slots are divided into two sets, left-channel slots and right-channel slots, as described in the *Inter IC Sound (I^2S) Interface* and *Left-Justified (LJ) Interface* sections.

表 4. Output Channel Slot Assignment Settings

P0_R11_D[5:0] : CH1_SLOT[5:0]	OUTPUT CHANNEL 1 SLOT ASSIGNMENT
00 0000 = 0d (default)	Slot 0 for TDM or left slot 0 for I^2S, LJ.
00 0001 = 1d	Slot 1 for TDM or left slot 1 for I^2S, LJ.
…	…
01 1111 = 31d	Slot 31 for TDM or left slot 31 for I^2S, LJ.
10 0000 = 32d	Slot 32 for TDM or right slot 0 for I^2S, LJ.
…	…
11 1110 = 62d	Slot 62 for TDM or right slot 30 for I^2S, LJ.
11 1111 = 63d	Slot 63 for TDM or right slot 31 for I^2S, LJ.

Similarly, the slot assignment setting for output channel 2 to channel 6 can be done using the CH2_SLOT (P0_R12) to CH6_SLOT (P0_R16) registers, respectively.

The slot word length is the same as the output channel data word length set for the device. The output channel data word length must be set to the same value for all PCM6xx0-Q1 devices if all devices share the same ASI bus in a system. The maximum number of slots possible for the ASI bus in a system is limited by the available bus bandwidth, which depends upon the BCLK frequency, output data sample rate used, and the channel data word length configured.

The device also includes a feature that offsets the start of the slot data transfer with respect to the frame sync by up to 31 cycles of the bit clock. 表 5 lists the programmable offset configuration settings.

表 5. Programmable Offset Settings for the ASI Slot Start

P0_R8_D[4:0] : TX_OFFSET[4:0]	PROGRAMMABLE OFFSET SETTING FOR SLOT DATA TRANSMISSION START
0 0000 = 0d (default)	The device follows the standard protocol timing without any offset.
0 0001 = 1d	Slot start is offset by one BCLK cycle, as compared to standard protocol timing. For I^2S or LJ, the left and right slot start is offset by one BCLK cycle, as compared to standard protocol timing.
.....	.....
1 1110 = 30d	Slot start is offset by 30 BCLK cycles, as compared to standard protocol timing. For I^2S or LJ, the left and right slot start is offset by 30 BCLK cycles, as compared to standard protocol timing.
1 1111 = 31d	Slot start is offset by 31 BCLK cycles, as compared to standard protocol timing. For I^2S or LJ, the left and right slot start is offset by 31 BCLK cycles, as compared to standard protocol timing.

The device also features the ability to invert the polarity of the frame sync pin, FSYNC, used to transfer the audio data as compared to the default FSYNC polarity used in standard protocol timing. This feature can be set using the FSYNC_POL, P0_R7_D3 register bit. Similarly, the device can invert the polarity of the bit clock pin, BCLK, which can be set using the BCLK_POL, P0_R7_D2 register bit.

8.3.1.2.1 Time Division Multiplexed Audio (TDM) Interface

In TDM mode, also known as DSP mode, the rising edge of FSYNC starts the data transfer with the slot 0 data first. Immediately after the slot 0 data transmission, the remaining slot data are transmitted in order. FSYNC and each data bit (except the MSB of slot 0 when TX_OFFSET equals 0) is transmitted on the rising edge of BCLK. 图 24 to 图 27 illustrate the protocol timing for TDM operation with various configurations.

ADVANCE INFORMATION

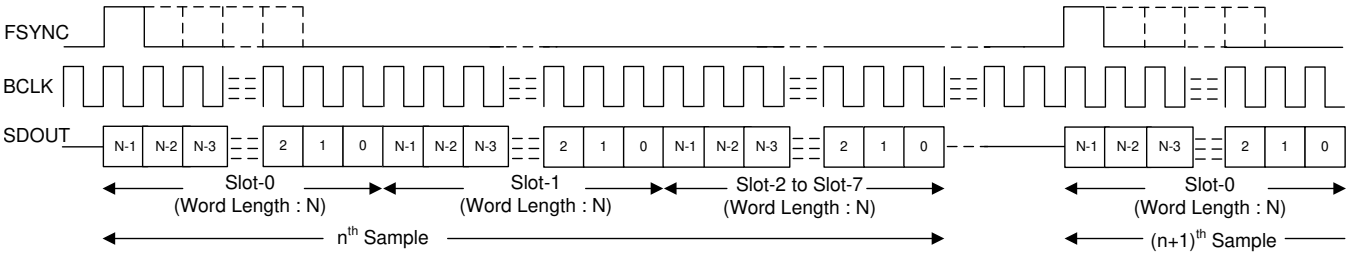

图 24. TDM Mode Standard Protocol Timing (TX_OFFSET = 0)

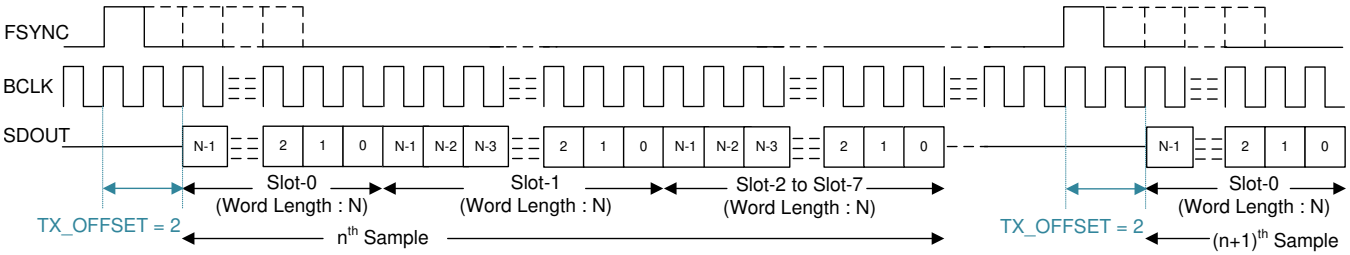

图 25. TDM Mode Protocol Timing (TX_OFFSET = 2)

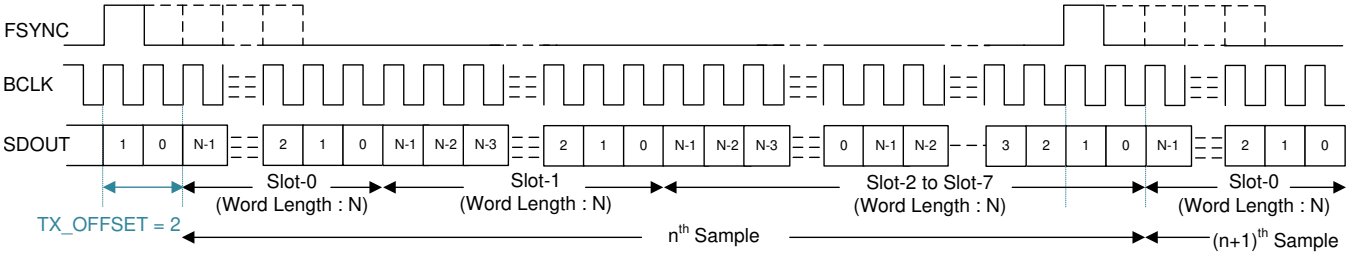

图 26. TDM Mode Protocol Timing (No Idle BCLK Cycles, TX_OFFSET = 2)

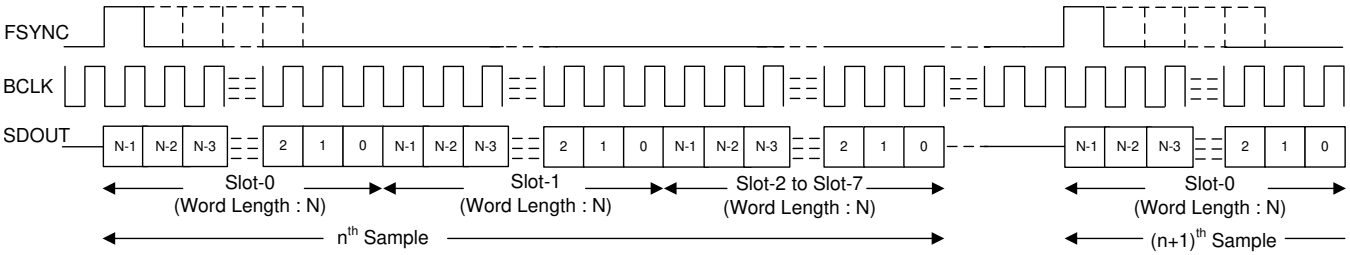

图 27. TDM Mode Protocol Timing (TX_OFFSET = 0 and BCLK_POL = 1)

For proper operation of the audio bus in TDM mode, the number of bit clocks per frame must be greater than or equal to the number of active output channels times the programmed word length of the output channel data. The device supports FSYNC as a pulse with a 1-cycle-wide bit clock, but also supports multiples as well. For a higher BCLK frequency operation, using TDM mode with a TX_OFFSET value higher than 0 is recommended.

ADVANCE INFORMATION

8.3.1.2.2 Inter IC Sound (I^2S) Interface

The standard I^2S protocol is defined for only two channels: left and right. The device extends the same protocol timing for multichannel operation. In I^2S mode, the MSB of the left slot 0 is transmitted on the falling edge of BCLK in the second cycle after the *falling* edge of FSYNC. Immediately after the left slot 0 data transmission, the remaining left slot data are transmitted in order. The MSB of the right slot 0 is transmitted on the falling edge of BCLK in the second cycle after the *rising* edge of FSYNC. Immediately after the right slot 0 data transmission, the remaining right slot data are transmitted in order. FSYNC and each data bit is transmitted on the falling edge of BCLK. 图 28 to 图 31 show the protocol timing for I^2S operation with various configurations.

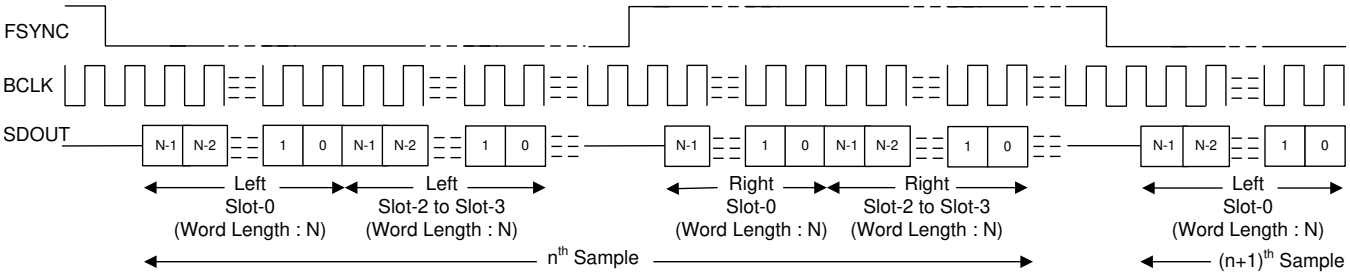

图 28. I^2S Mode Standard Protocol Timing (TX_OFFSET = 0)

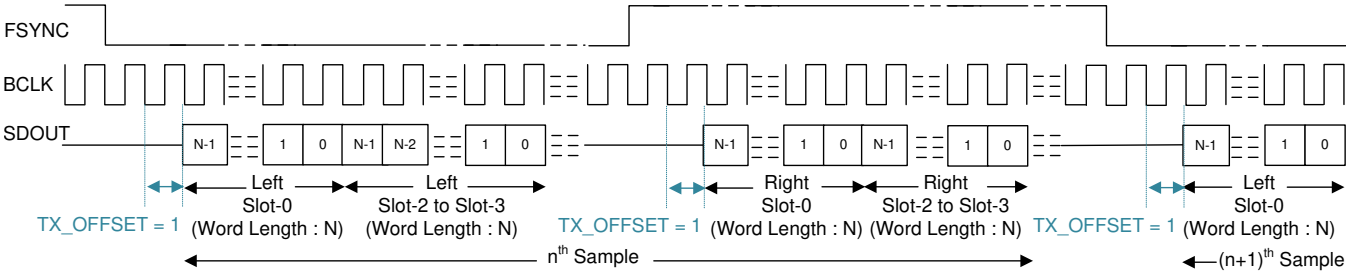

图 29. I^2S Protocol Timing (TX_OFFSET = 1)

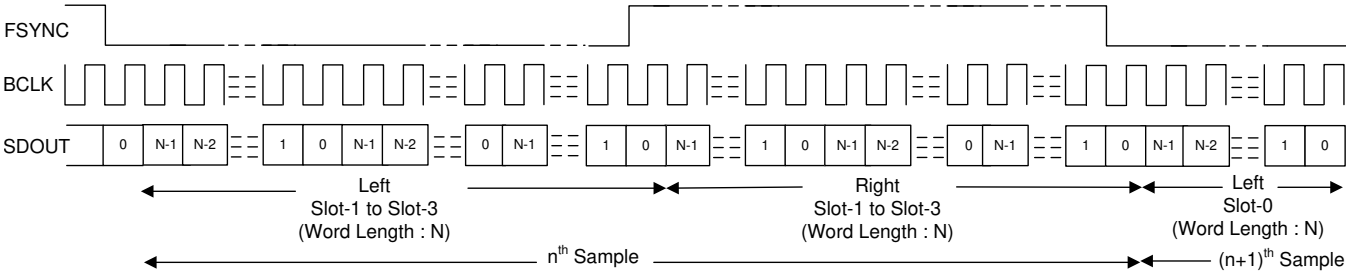

图 30. I^2S Protocol Timing (No Idle BCLK Cycles, TX_OFFSET = 0)

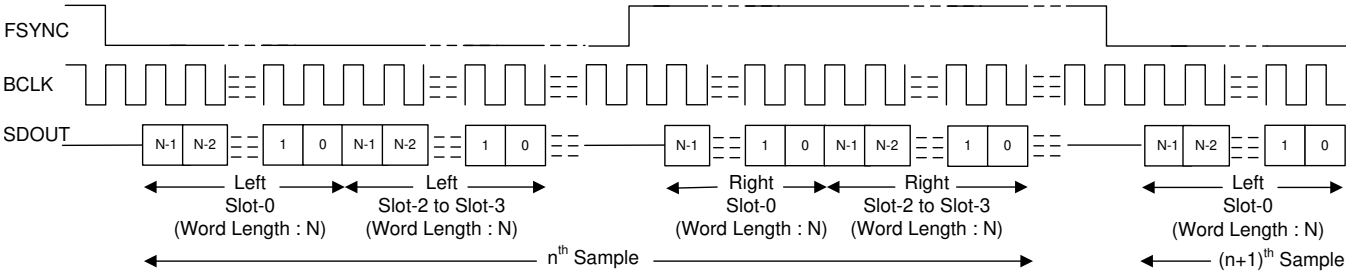

图 31. I^2S Protocol Timing (TX_OFFSET = 0 and BCLK_POL = 1)

ADVANCE INFORMATION

For proper operation of the audio bus in I^{2}S mode, the number of bit clocks per frame must be greater than or equal to the number of active output channels (including left and right slots) times the programmed word length of the output channel data. The device FSYNC low pulse must be a number of BCLK cycles wide that is greater than or equal to the number of active left slots times the data word length configured. Similarly, the FSYNC high pulse must be a number of BCLK cycles wide that is greater than or equal to the number of active right slots times the data word length configured.

8.3.1.2.3 Left-Justified (LJ) Interface

The standard LJ protocol is defined for only two channels: left and right. The device extends the same protocol timing for multichannel operation. In LJ mode, the MSB of the left slot 0 is transmitted in the same BCLK cycle after the *rising* edge of FSYNC. Each subsequent data bit is transmitted on the falling edge of BCLK. Immediately after the left slot 0 data transmission, the remaining left slot data are transmitted in order. The MSB of the right slot 0 is transmitted in the same BCLK cycle after the *falling* edge of FSYNC. Each subsequent data bit is transmitted on the falling edge of BCLK. Immediately after the right slot 0 data transmission, the remaining right slot data are transmitted in order. FSYNC is transmitted on the falling edge of BCLK. 图 32 to 图 35 illustrate the protocol timing for LJ operation with various configurations.

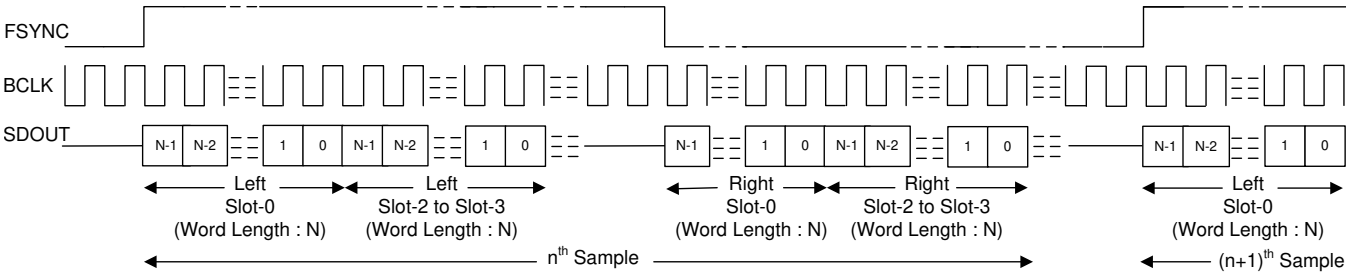

图 32. LJ Mode Standard Protocol Timing (TX_OFFSET = 0)

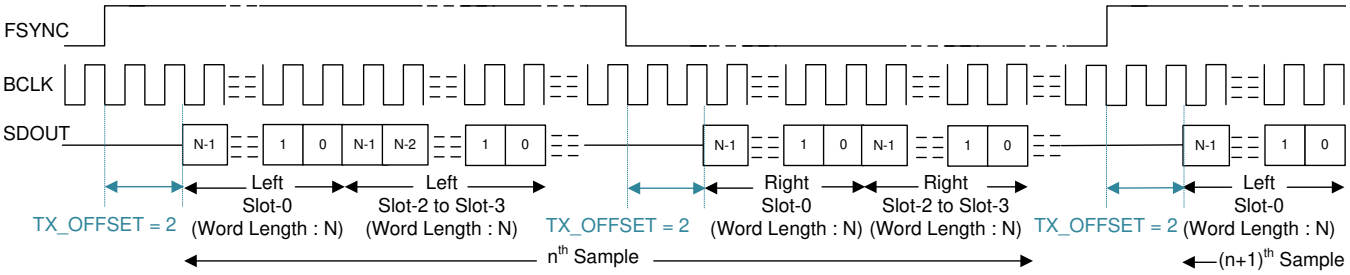

图 33. LJ Protocol Timing (TX_OFFSET = 2)

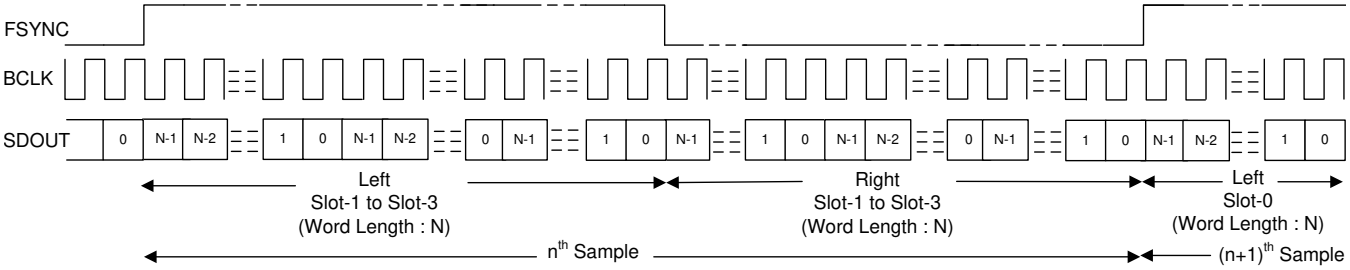

图 34. LJ Protocol Timing (No Idle BCLK Cycles, TX_OFFSET = 0)

ADVANCE INFORMATION

版权 © 2020, Texas Instruments Incorporated

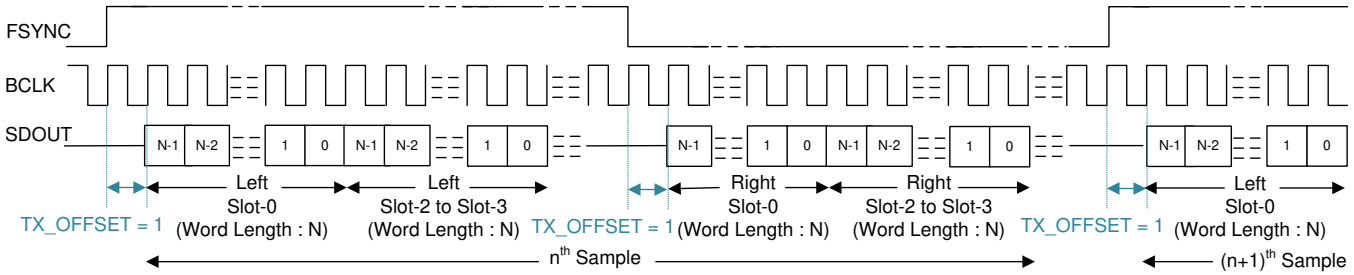

图 35. LJ Protocol Timing (TX_OFFSET = 1 and BCLK_POL = 1)

For proper operation of the audio bus in LJ mode, the number of bit clocks per frame must be greater than or equal to the number of active output channels (including left and right slots) times the programmed word length of the output channel data. The device FSYNC high pulse must be a number of BCLK cycles wide that is greater than or equal to the number of active left slots times the data word length configured. Similarly, the FSYNC low pulse must be number of BCLK cycles wide that is greater than or equal to the number of active right slots times the data word length configured. For a higher BCLK frequency operation, using LJ mode with a TX_OFFSET value higher than 0 is recommended.

8.3.1.3 Using Multiple Devices With Shared Buses

The device has many supported features and flexible options that can be used in the system to seamlessly connect multiple PCM6xx0-Q1 devices by sharing a single common I^2C control bus and an audio serial interface bus. This architecture enables multiple applications to be applied to a system that require a microphone array for beam-forming operation, hands-free in-vehicle communication, car cabin active noise cancellation, and so forth. 图 36 shows a diagram of multiple PCM6xx0-Q1 devices in a configuration where the control and audio data buses are shared.

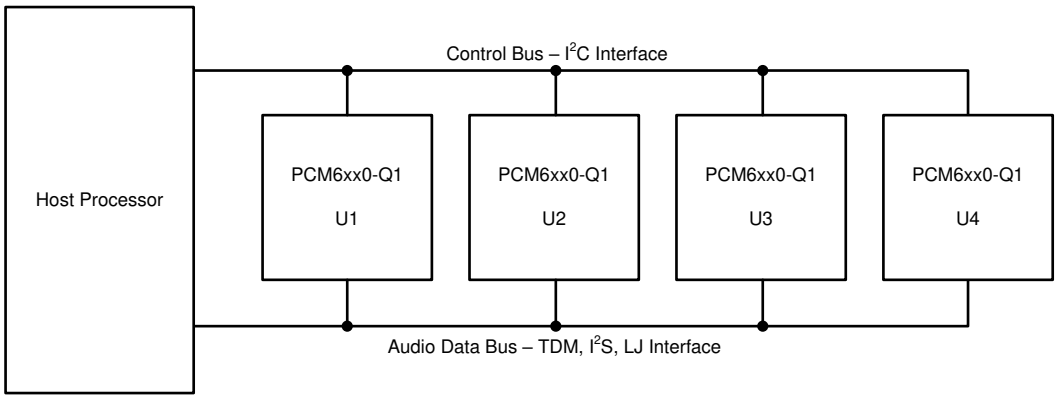

图 36. Multiple PCM6xx0-Q1 Devices With Shared Control and Audio Data Buses

The PCM6xx0-Q1 consist of the following features to enable seamless connection and interaction of multiple devices using a shared bus:

- Supports up to four pin-programmable I^2C slave addresses
- I^2C broadcast simultaneously writes to (or triggers) all PCM6xx0-Q1 devices
- Supports up to 64 configuration output channel slots for the audio serial interface
- Tri-state feature (with enable and disable) for the unused audio data slots of the device
- Supports a bus-holder feature (with enable and disable) to keep the last driven value on the audio bus
- The GPIOx pin can be configured as a secondary output data lane for the audio serial interface
- The GPIOx or GPIx pin can be used in a daisy-chain configuration of multiple PCM6xx0-Q1 devices
- Supports one BCLK cycle data latching timing to relax the timing requirement for the high-speed interface
- Programmable master and slave options for the audio serial interface

ADVANCE INFORMATION

版权 © 2020, Texas Instruments Incorporated

- Ability to synchronize the multiple devices for the simultaneous sampling requirement across devices

See the *Multiple PCM6xx0-Q1 Devices With Shared TDM and I²C Bus* application report for further details.

8.3.2 Phase-Locked Loop (PLL) and Clock Generation

The device has a smart auto-configuration block to generate all necessary internal clocks required for the ADC modulator and the digital filter engine used for signal processing. This configuration is done by monitoring the frequency of the FSYNC and BCLK signal on the audio bus.

The device supports the various output data sample rates (of the FSYNC signal frequency) and the BCLK to FSYNC ratio to configure all clock dividers, including the PLL configuration, internally without host programming. 表 6 and 表 7 list the supported FSYNC and BCLK frequencies.

表 6. Supported FSYNC (Multiples or Submultiples of 48 kHz) and BCLK Frequencies

BCLK TO FSYNC RATIO	BCLK (MHz)								
	FSYNC (8 kHz)	FSYNC (16 kHz)	FSYNC (24 kHz)	FSYNC (32 kHz)	FSYNC (48 kHz)	FSYNC (96 kHz)	FSYNC (192 kHz)	FSYNC (384 kHz)	FSYNC (768 kHz)

ADVANCE INFORMATION

版权 © 2020, Texas Instruments Incorporated

The status register ASI_STS, P0_R21, captures the device auto detect result for the FSYNC frequency and the BCLK to FSYNC ratio. If the device finds any unsupported combinations of FSYNC frequency and BCLK to FSYNC ratios, the device generates an ASI clock-error interrupt and mutes the record channels accordingly.

The device uses an integrated, low-jitter, phase-locked loop (PLL) to generate internal clocks required for the ADC modulator and digital filter engine, as well as other control blocks. The device also supports an option to use BCLK, GPIOx, or the GPIx pin (as MCLK) as the audio clock source without using the PLL to reduce power consumption. However, the ADC performance may degrade based on jitter from the external clock source, and some processing features may not be supported if the external audio clock source frequency is not high enough. Therefore, TI recommends using the PLL for high-performance applications. More details and information on how to configure and use the device in low-power mode without using the PLL are discussed in the *PCM6xx0-Q1 Power Consumption Matrix Across Various Usage Scenario* application report.

The device also supports an audio bus master mode operation using the GPIOx or GPIx pin (as MCLK) as the reference input clock source and supports various flexible options and a wide variety of system clocks. More details and information on master mode configuration and operation are discussed in the *Configuring and Operating the PCM6xx0-Q1 as an Audio Bus Master* application report.

The audio bus clock error detection and auto-detect feature automatically generates all internal clocks, but can be disabled using the ASI_ERR, P0_R9_D5 and AUTO_CLK_CFG, P0_R19_D6, register bits, respectively. In the system, this disable feature can be used to support custom clock frequencies that are not covered by the auto detect scheme. For such application use cases, care must be taken to ensure that the multiple clock dividers are all configured appropriately. Therefore, TI recommends using the PPC3 GUI for device configuration settings; for more details see the *PCM6xx0-Q1 Evaluation module* user's guide and the PurePath™ console graphical development suite.

8.3.3 Input Channel Configuration

The PCM6x60-Q1 consist of six pairs and the PCM6x40-Q1 consist of four pairs of analog input pins (INxP and INxM) that can be configured as either differential or single-ended inputs for the recording channel. These devices support simultaneous recording of up to six channels in the PCM6x60-Q1 and four channels in the PCM6x40-Q1 using the multichannel ADC. The input source for the analog pins can be either analog microphones or line, aux inputs from the system board. 表 8 describes how to set the input configuration for the record channel.

表 8. Input Source Selection for the Record Channel

P0_R60_D[6:5] : CH1_INSRC[1:0]	INPUT CHANNEL 1 RECORD SOURCE SELECTION
00 (default)	Analog differential input for channel 1
01	Analog single-ended input for channel 1
10 or 11	Reserved (do not use this setting)

Similarly, the input source selection setting for input channel 2 to channel 6 can be configured using the CH2_INSRC[1:0] (P0_R65_D[6:5]) to CH6_INSRC[1:0] (P0_R85_D[6:5]) registers bits, respectively.

The device supports the input DC fault diagnostic feature for microphone recording with the DC-coupled inputs configuration; however, the device also supports an option for AC-coupled inputs if the DC diagnostic is not required for the specific input pins. This configuration can be done independently for each channel by setting the CH1_DC (P0_R60_D4) to CH6_DC (P0_R85_D4) register bits.

For the DC-coupled line input configuration, the DC common-mode difference (INxP – INxM) for the analog input pins must be 0 V to support the 10-V_{RMS} full-scale differential input. For the DC-coupled microphone input configuration, the DC common-mode difference (INxP – INxM) for the analog input pins must be within 3.4 V to 5.0 V to support the 2-V_{RMS} full-scale differential input in the default mode of operation. Alternatively, the device has a mode to support more than a 2-V_{RMS} differential DC-coupled microphone signal by setting the CH1_MIC_IN_RANGE, P0_R60_D3, register bit for channel 1 and, similarly, the CH2_MIC_IN_RANGE, P0_R65_D3 to CH6_MIC_IN_RANGE, P0_R85_D3 registers bit (respectively) for channels 2 to 6. If the CH1_MIC_IN_RANGE bit is set high (the recommended setting to support a higher DC common-mode difference and a higher AC signal swing), then the device supports the maximum differential input voltage IN1P–IN1M as high as 8.4 V (for the MICBIAS 9-V setting), including the AC signal and DC differential common-mode voltage. The DC differential common-mode voltage is later filtered out by the digital high-pass filter and the digital output full-scale corresponds to the 10-V_{RMS} AC signal in this case.

ADVANCE INFORMATION

图 37 and 图 38 show how to connect a DC-coupled microphone for a differential and single-ended input, respectively. The value of the external bias resistor, R1, must be appropriately chosen based upon the microphone impedance. For a differential input, the value of the external bias resistor is recommended to be used for half of the microphone impedance, whereas for a single-ended input, the external bias resistor is recommended to be the same as the microphone impedance.

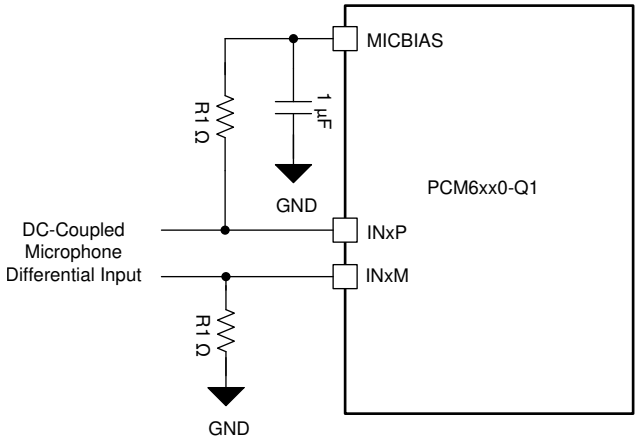

图 37. DC-Coupled Microphone Differential Input Connection

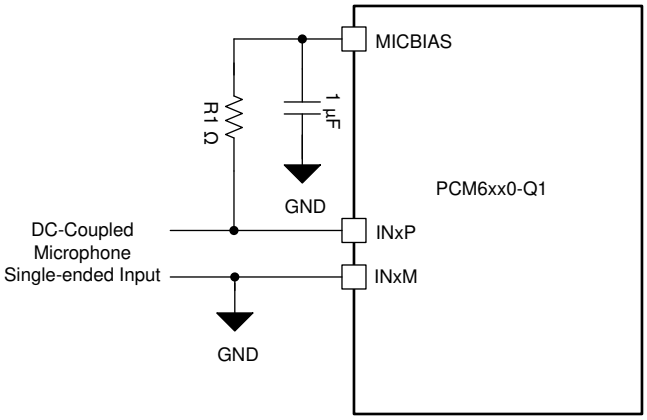

图 38. DC-Coupled Microphone Single-Ended Input Connection

In AC-coupled mode, the value of the coupling capacitor must be so chosen that the high-pass filter formed by the coupling capacitor and the input impedance do not affect the signal content. At power-up, before proper recording can begin, this coupling capacitor must be charged up to the common-mode voltage. For single-ended input configuration, the INxM pin must be grounded after the AC coupling capacitor in AC-coupled mode.

ADVANCE INFORMATION

版权 © 2020, Texas Instruments Incorporated

图 39 and 图 40 show how to connect an AC-coupled microphone or line source for a differential and single-ended input, respectively. In AC-coupled mode, the device input pins INxP and INxM, must be biased appropriately for the DC common-mode value either using the on-chip MICBIAS output voltage along with external bias resistor, R0, or using an external bias generator circuit. The maximum value for resistor R0 depends upon the signal swing and the MICBIAS value programmed. See the *PCM6xx0-Q1 AC-Coupled External Resistor Calculator* to calculate the R0 value for the desired system configuration.

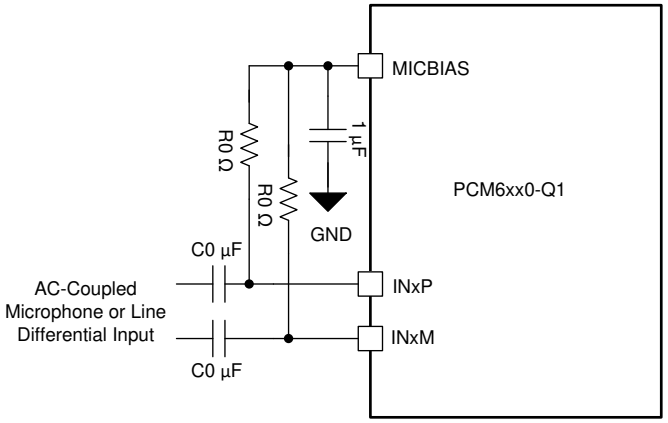

图 39. AC-Coupled Microphone or Line Differential Input Connection

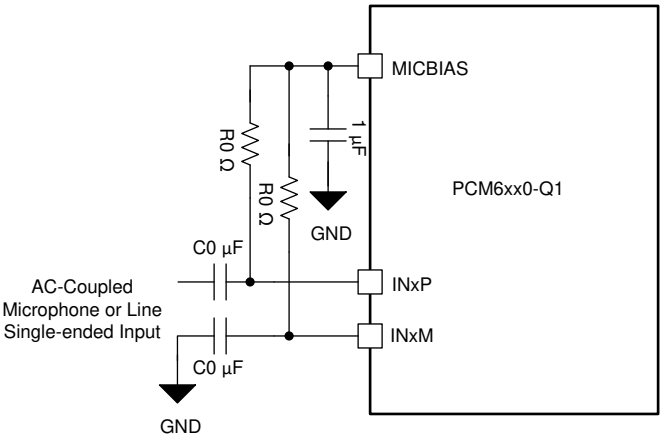

图 40. AC-Coupled Microphone or Line Single-Ended Input Connection

8.3.4 Reference Voltage

All audio data converters require a DC reference voltage. The PCM6xx0-Q1 family achieves its low-noise performance by internally generating a low-noise reference voltage. This reference voltage is generated using a band-gap circuit with a good PSRR performance. This audio converter reference voltage must be filtered externally using a minimum 1-µF capacitor connected from the VREF pin to the analog ground (AVSS).

To achieve low power consumption, this audio reference block is powered down in sleep mode or software shutdown; see the *Sleep Mode or Software Shutdown* section for more details. When exiting sleep mode, the audio reference block is powered up using internal fast-charge scheme and the VREF pin settles to its steady-state voltage after the settling time (a function of the decoupling capacitor on the VREF pin). This time is approximately equal to 3.5 ms when using a 1-µF decoupling capacitor. If a higher value of the decoupling capacitor is used on the VREF pin, the fast-charge setting must be reconfigured using the VREF_QCHG, P0_R2_D[4:3] register bits, which support options of 3.5 ms (default), 10 ms, 50 ms, or 100 ms.

ADVANCE INFORMATION

8.3.5 Microphone Bias

The device integrates a built-in, low-noise, programmable, high-voltage, microphone bias pin (MICBIAS) that can be used in the system for biasing the analog microphone. The integrated bias amplifier supports up to 80 mA of load current, which can be used for multiple microphones and is designed to provide a combination of high PSRR, low noise, and programmable bias voltages to allow the biasing to be fine tuned for specific microphone combinations. The PCM62x0-Q1 have an integrated efficient boost converter to generate the high voltage supply for the programmable microphone bias using an external, low-voltage, 3.3-V BSTVDD supply. However, The PCM63x0-Q1 require an external high-voltage supply, HVDD, which requires at least 600 mV higher than the programmed microphone bias voltage and must be lower than 12 V.

When using the MICBIAS pin for biasing multiple microphones, TI recommends avoiding common impedance on the board layout for the MICBIAS connection to minimize coupling across microphones. 表 9 shows the available microphone bias programmable options.

表 9. MICBIAS Programmable Settings

P0_R59_D[7:4] : MBIAS_VAL[3:0]	MICBIAS OUTPUT VOLTAGE
0000 to 0110	Reserved (do not use these settings)
0111	Set to 5.0 V
1000	Set to 5.5 V
1001	Set to 6.0 V
1010	Set to 6.5 V
1011	Set to 7.0 V
1100	Set to 7.5 V
1101	Set to 8.0 V
1110	Set to 8.5 V
1111	Set to 9.0 V

The microphone bias output can be powered on or powered off (default) by configuring the MICBIAS_PDZ, P0_R117_D7 register bit. Additionally, the device provides an option to configure the GPIOx pins to directly control the microphone bias output power on or power off. This feature is useful in some systems to control the microphone directly without engaging the host for I^2C or SPI communication. The MICBIAS_PDZ, P0_R117_D7 register bit value is ignored if the GPIOx pins are configured to control the microphone bias power on or power off.

8.3.6 Input DC Fault Diagnostics

Each input of the PCM6xx0-Q1 features highly comprehensive DC fault diagnostics that can be configured to detect fault conditions in the DC-coupled input configuration and trigger an interrupt request to a host processor. Diagnostics are enabled for each channel by configuring DIAG_CFG0, P0_R100. For channels with diagnostics enabled, the input pins are scanned automatically by an integrated SAR ADC. The diagnostic processor averages eight consecutive samples per test to improve noise performance. The DC fault diagnostics is not supported in the AC-coupled input configuration.

The device features various programmable threshold registers, P0_R101 to P0_R102, which can by configured by the host processor to define the fault region for a different category of fault condition detection. Additionally, there is also a debounce feature, configured with FAULT_DBNCE_SEL, P0_R103_D3-2. This feature sets the number of consecutive scan counts where the fault condition occurs before the latched status register is tripped, thus reducing false triggers by transient events. The device also has a moving average feature, P0_R104, which continuously averages out the newly measured data with old measured data and thus reduces the false triggers by any short-duration transient events.

8.3.6.1 Fault Conditions

8.3.6.1.1 Input Pin Short to Ground

A short to ground fault occurs when the voltage of the input pin is measured below the threshold voltage with respect to ground (AVSS). The threshold can be set by configuring DIAG_SHT_GND, P0_R102_D7-4.

ADVANCE INFORMATION

版权 © 2020, Texas Instruments Incorporated

8.3.6.1.2 Input Pin Short to MICBIAS

A short to MICBIAS fault occurs when the difference between the voltage measured for the MICBIAS pin and the input pin (MICBIAS – INxx) is less than the threshold. The threshold can be set by configuring DIAG_SHT_MICBIAS, P0_R102_D3-0.

8.3.6.1.3 Open Inputs

In the event that a microphone becomes disconnected from the inputs, the microphone bias resistors pull INxP to MICBIAS and INxM to ground. The combination of INxP shorted to MICBIAS and INxM shorted to ground for the same channel in a diagnostic sweep results in an open input fault condition.

8.3.6.1.4 Short Between INxP and INxM

An input terminal shorted fault occurs when the difference between the voltage measured for the input pin INxP and the input pin INxM of the same channel is less than the threshold. The threshold can be set by configuring DIAG_SHT_TERM, P0_R101_D7-4.

8.3.6.1.5 Input Pin Overvoltage

An input terminal overvoltage fault occurs when the voltage measured for the input pin is above the voltage measured for the MICBIAS pin.

8.3.6.1.6 Input Pin Short to VBAT_IN

A short to VBAT_IN fault occurs when the difference between the voltage measured for the VBAT_IN pin and the input pin, ABS(VBAT_IN – INxx), is less than the threshold or both the VBAT_IN and INxx pin measured voltages are above 11.7 V. The threshold can be set by configuring DIAG_SHT_VBAT_IN, P0_R101_D3-0.

When VBAT_IN is less than MICBIAS, false fault detections can exist based on the signal level of the INxx pin. To minimize false detections there is also a separate debounce count for this condition set by configuring VSHORT_DBNCE, P0_R106_D1.

8.3.6.2 Fault Reporting

Faults are reported in live and latched status registers. The live registers, P1_R45 to P1_R55, are updated continuously with each new scan and report the most recent measurements reported by the diagnostics processor. The latched status of each diagnostic fault is reported by the channel in P0_R46 to P0_R55, and a latched summary by the channel is reported in CHx_LTCH, P0_R45. The latched registers clear upon reading, and are latched if the associated bit in the live fault registers transitions from a ‘0’ to a ‘1’. A transition of any bit in the latched register from a ‘0’ to ‘1’ triggers an interrupt request.

For detecting a persistent fault, an additional mode is available for the latched registers. In this mode, the latched registers are only cleared upon reading if the status bit in the associated live status register is ‘0’ at the time of reading. This mode is enabled by configuring LTCH_CLR_ON_READ, P0_R40_D0 to a ‘1’.

8.3.6.2.1 Overcurrent and Overtemperature Protection

The device has an overcurrent protection circuit that limits the current drawn out of the MICBIAS output to the maximum supported level when an external undesired short event occurs on the MICBIAS pin. The device sets the status flag, P0_R44_D4 bit, on an overcurrent detection. Additionally, the device has an overtemperature detection circuit that is enabled by default and sets the status flag, P0_R44_D5 bit, whenever the die junction temperature goes higher than the supported level.

Additionally, register P0_R58 and P0_R40_D4:3 can be configured to shutdown MICBIAS along with the on-chip boost on an overtemperature detection. TI recommends configuring PD_ON_FLT_CFG, P0_R40_D4-3 to "10" so that on an overtemperature detection, the device powers-down MICBIAS, the on-chip boost, and all ADC channels.

More details and information on fault diagnostics are discussed in the *PCM6xx0-Q1 Fault Diagnostics, Interrupts, and Protection Features* application report.

ADVANCE INFORMATION

8.3.7 Signal-Chain Processing

The PCM6xx0-Q1 signal chain is comprised of very-low-noise, high-performance, and low-power analog blocks and highly flexible and programmable digital processing blocks. The high performance and flexibility combined with a compact package makes the PCM6xx0-Q1 optimized for a variety of end-equipment and applications that require multichannel audio capture. 图 41 shows a conceptual block diagram that highlights the various building blocks used in the signal chain, and how the blocks interact in the signal chain.

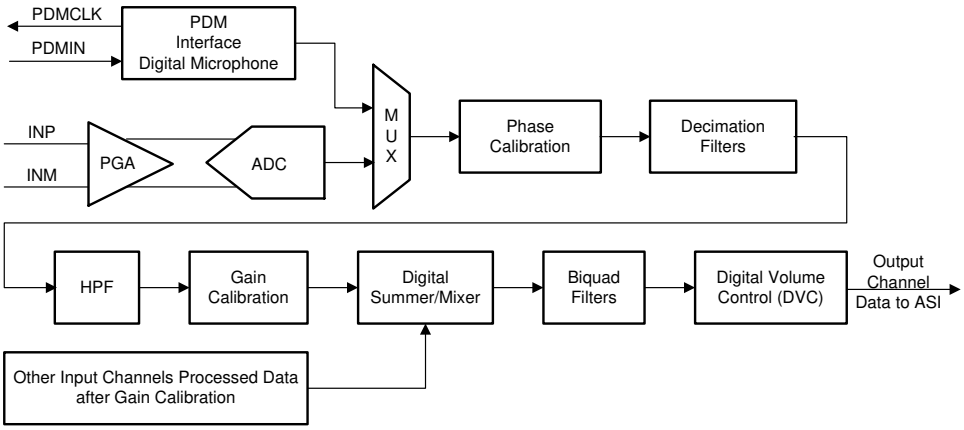

图 41. Signal-Chain Processing Flowchart

The front-end input attenuator allows the device to accept the high-voltage input signal that is attenuated by the input attenuator circuit before being routed to a low-noise programmable gain amplifier (PGA). Along with a low-noise and low-distortion, multibit, delta-sigma ADC, the front-end PGA enables the PCM6xx0-Q1 to record a far-field audio signal with very high fidelity, both in quiet and loud environments. Moreover, the ADC architecture has inherent antialias filtering with a high rejection of out-of-band frequency noise around multiple modulator frequency components. Therefore, the device prevents noise from aliasing into the audio band during ADC sampling. Further on in the signal chain, an integrated, high-performance multistage digital decimation filter sharply cuts off any out-of-band frequency noise with high stop-band attenuation.

The device also has an integrated programmable biquad filter that allows for custom low-pass, high-pass, or any other desired frequency shaping. Thus, the overall signal chain architecture removes the requirement to add external components for antialiasing low-pass filtering, and thus saves drastically on the external system component cost and board space. See the *PCM6xx0-Q1 Integrated Analog Antialiasing Filter and Flexible Digital Filter* application report for further details.

The signal chain also consists of various highly programmable digital processing blocks, such as phase calibration, gain calibration, high-pass filter, digital summer or mixer, biquad filters, and volume control. The details on these processing blocks are discussed further in this section.

The desired input channels for recording can be enabled or disabled by using the IN_CH_EN (P0_R115) register, and the output channels for the audio serial interface can be enabled or disabled by using the ASI_OUT_EN (P0_R116) register. In general, the device supports simultaneous power-up and power-down of all active channels for simultaneous recording. However, based on the application needs, if some channels must be powered-up or powered-down dynamically when the other channel recording is on, then that use case is supported by setting the DYN_CH_PUPD_EN, P0_R117_D4 register bit to 1'b1 but do not power-down channel 1 in this mode of operation.

The device supports an input signal bandwidth up to 80 kHz, which allows the high-frequency non-audio signal to be recorded by using a 176.4-kHz (or higher) sample rate.

For output sample rates of 48 kHz or lower, the device supports all features for 6-channel recording and various programmable processing blocks. However, for output sample rates higher than 48 kHz, there are limitations in the number of simultaneous channel recordings supported and the number of biquad filters and such. See the *PCM6xx0-Q1 Sampling Rates and Programmable Processing Blocks Supported* application report for further details.

ADVANCE INFORMATION

8.3.7.1 Programmable Channel Gain and Digital Volume Control

The device has an independent programmable channel gain setting for each input channel that can be set to the appropriate value based on the maximum input signal expected in the system and the ADC VREF setting used (see the *Reference Voltage* section), which determines the ADC full-scale signal level.

Configure the desired channel gain setting before powering up the ADC channel and do not change this setting while the ADC is powered on. The programmable range supported for each channel gain is from 0 dB to 42 dB in steps of 1 dB. To achieve low-noise performance, the device internal logic first maximizes the gain for the front-end low-noise analog PGA, and then applies any residual programmed channel gain in the digital processing block.

表 10 shows the programmable options available for the channel gain.

表 10. Channel Gain Programmable Settings

P0_R61_D[7:2] : CH1_GAIN[5:0]	CHANNEL GAIN SETTING FOR INPUT CHANNEL 1
00 0000 = 0d (default)	Input channel 1 gain is set to 0 dB
00 0001 = 1d	Input channel 1 gain is set to 1 dB
00 0010 = 2d	Input channel 1 gain is set to 2 dB
…	…
10 1001 = 41d	Input channel 1 gain is set to 41 dB
10 1010 = 42d	Input channel 1 gain is set to 42 dB
10 1011 to 11 1111 = 43d to 63d	Reserved (do not use these settings)

Similarly, the channel gain setting for input channel 2 to channel 6 can be configured using the CH2_GAIN (P0_R66) to CH6_GAIN (P0_R86) register bits, respectively.

The device also has a programmable digital volume control with a range from –100 dB to 27 dB in steps of 0.5 dB with the option to mute the channel recording. The digital volume control value can be changed dynamically while the ADC channel is powered-up and recording. During volume control changes, the soft ramp-up or ramp-down volume feature is used internally to avoid any audible artifacts. Soft-stepping can be entirely disabled using the DISABLE_SOFT_STEP (P0_R108_D4) register bit.

The digital volume control setting is independently available for each output channel, including the digital microphone record channel. However, the device also supports an option to gang-up the volume control setting for all channels together using the channel 1 digital volume control setting, regardless if channel 1 is powered up or powered down. This gang-up can be enabled using the DVOL_GANG (P0_R108_D7) register bit.

表 11 shows the programmable options available for the digital volume control.

表 11. Digital Volume Control (DVC) Programmable Settings

P0_R62_D[7:0] : CH1_DVOL[7:0]	DVC SETTING FOR OUTPUT CHANNEL 1
0000 0000 = 0d	Output channel 1 DVC is set to mute
0000 0001 = 1d	Output channel 1 DVC is set to –100 dB
0000 0010 = 2d	Output channel 1 DVC is set to –99.5 dB
0000 0011 = 3d	Output channel 1 DVC is set to –99 dB
…	…
1100 1000 = 200d	Output channel 1 DVC is set to –0.5 dB
1100 1001 = 201d (default)	Output channel 1 DVC is set to 0 dB
1100 1010 = 202d	Output channel 1 DVC is set to 0.5 dB
…	…
1111 1101 = 253d	Output channel 1 DVC is set to 26 dB
1111 1110 = 254d	Output channel 1 DVC is set to 26.5 dB
1111 1111 = 255d	Output channel 1 DVC is set to 27 dB

ADVANCE INFORMATION

Similarly, the digital volume control setting for output channel 2 to channel 6 can be configured using the CH2_DVOL (P0_R67) to CH6_DVOL (P0_R87) register bits, respectively.

The internal digital processing engine soft ramps up the volume from a muted level to the programmed volume level when the channel is powered up, and the internal digital processing engine soft ramps down the volume from a programmed volume to mute when the channel is powered down. This soft-stepping of volume is done to prevent abruptly powering up and powering down the record channel. This feature can also be entirely disabled using the DISABLE_SOFT_STEP (P0_R108_D4) register bit.

8.3.7.2 Programmable Channel Gain Calibration

Along with the programmable channel gain and digital volume, this device also provides programmable channel gain calibration. The gain of each channel can be finely calibrated or adjusted in steps of 0.1 dB for a range of –0.8-dB to 0.7-dB gain error. This adjustment is useful when trying to match the gain across channels resulting from external components and microphone sensitivity. This feature, in combination with the regular digital volume control, allows the gains across all channels to be matched for a wide gain error range with a resolution of 0.1 dB. 表 12 shows the programmable options available for the channel gain calibration.

表 12. Channel Gain Calibration Programmable Settings

P0_R63_D[7:4] : CH1_GCAL[3:0]	CHANNEL GAIN CALIBRATION SETTING FOR INPUT CHANNEL 1
0000 = 0d	Input channel 1 gain calibration is set to –0.8 dB
0001 = 1d	Input channel 1 gain calibration is set to –0.7 dB
…	…
1000 = 8d (default)	Input channel 1 gain calibration is set to 0 dB
…	…
1110 = 14d	Input channel 1 gain calibration is set to 0.6 dB
1111 = 15d	Input channel 1 gain calibration is set to 0.7 dB

Similarly, the channel gain calibration setting for input channel 2 to channel 6 can be configured using the CH2_GCAL (P0_R68) to CH6_GCAL (P0_R88) register bits, respectively.

8.3.7.3 Programmable Channel Phase Calibration

In addition to the gain calibration, the phase delay in each channel can be finely calibrated or adjusted in steps of one modulator clock cycle for a cycle range of 0 to 255 for the phase error. The modulator clock, the same clock used for ADC_MOD_CLK, is 6.144 MHz (the output data sample rate is multiples or submultiples of 48 kHz) or 5.6448 MHz (the output data sample rate is multiples or submultiples of 44.1 kHz). This feature is very useful for many applications that must match the phase with fine resolution between each channel, including any phase mismatch across channels resulting from external components or microphones. 表 13 shows the available programmable options for channel phase calibration.

表 13. Channel Phase Calibration Programmable Settings

P0_R64_D[7:0] : CH1_PCAL[7:0]	CHANNEL PHASE CALIBRATION SETTING FOR INPUT CHANNEL 1
0000 0000 = 0d (default)	Input channel 1 phase calibration with no delay
0000 0001 = 1d	Input channel 1 phase calibration delay is set to one cycle of the modulator clock
0000 0010 = 2d	Input channel 1 phase calibration delay is set to two cycles of the modulator clock
…	…
1111 1110 = 254d	Input channel 1 phase calibration delay is set to 254 cycles of the modulator clock
1111 1111 = 255d	Input channel 1 phase calibration delay is set to 255 cycles of the modulator clock

Similarly, the channel phase calibration setting for input channel 2 to channel 6 can be configured using the CH2_PCAL (P0_R69) to CH6_PCAL (P0_R89) register bits, respectively.

8.3.7.4 Programmable Digital High-Pass Filter

To remove the DC offset component and attenuate the undesired low-frequency noise content in the record data, the device supports a programmable high-pass filter (HPF). The HPF is not a channel-independent filter setting but is globally applicable for all ADC channels. This HPF is constructed using the first-order infinite impulse response (IIR) filter, and is efficient enough to filter out possible DC components of the signal. 表 14 shows the predefined –3-dB cutoff frequencies available that can be set by using the HPF_SEL[1:0] register bits of P0_R107. Additionally, to achieve a custom –3-dB cutoff frequency for a specific application, the device also allows the first-order IIR filter coefficients to be programmed when the HPF_SEL[1:0] register bits are set to 2'b00. 图 42 shows a frequency response plot for the HPF filter.

表 14. HPF Programmable Settings

P0_R107_D[1:0] : HPF_SEL[1:0]	-3-dB CUTOFF FREQUENCY SETTING	-3-dB CUTOFF FREQUENCY AT 16-kHz SAMPLE RATE	-3-dB CUTOFF FREQUENCY AT 48-kHz SAMPLE RATE
00	Programmable 1st-order IIR filter	Programmable 1st-order IIR filter	Programmable 1st-order IIR filter
01 (default)	0.00025 × f_S	4 Hz	12 Hz
10	0.002 × f_S	32 Hz	96 Hz
11	0.008 × f_S	128 Hz	384 Hz

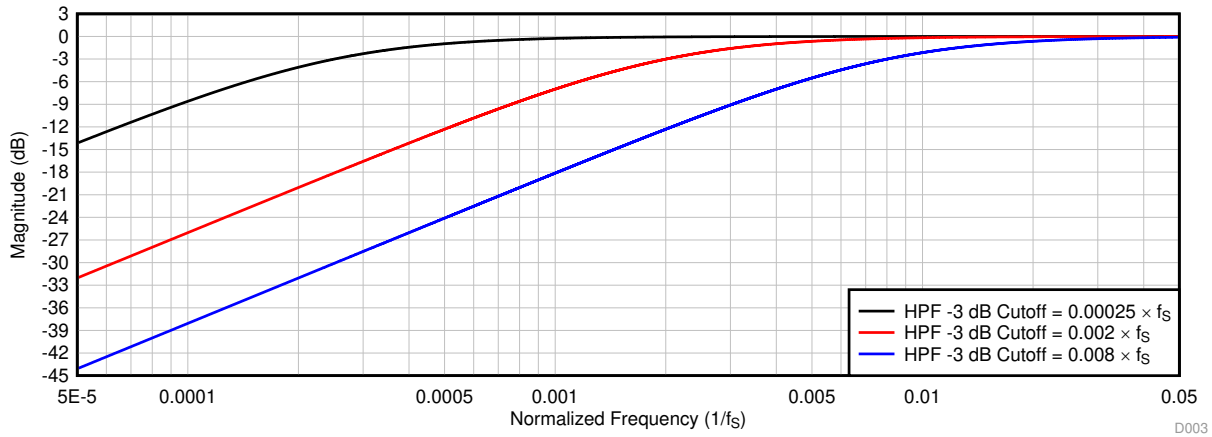

图 42. HPF Filter Frequency Response Plot

公式 1 gives the transfer function for the first-order programable IIR filter:

$$H(z) = \frac{N_0 + N_1 z^{-1}}{2^{31} - D_1 z^{-1}} \quad (1)$$

The frequency response for this first-order programmable IIR filter with default coefficients is flat at a gain of 0 dB (all-pass filter). The host device can override the frequency response by programming the IIR coefficients in 表 15 to achieve the desired frequency response for high-pass filtering or any other desired filtering. If HPF_SEL[1:0] are set to 2'b00, the host device must write these coefficients values for the desired frequency response before powering-up any ADC channel for recording. These programmable coefficients are 32-bit, two's complement numbers. 表 15 shows the filter coefficients for the first-order IIR filter.

表 15. 1st-Order IIR Filter Coefficients

FILTER	FILTER COEFFICIENT	DEFAULT COEFFICIENT VALUE	COEFFICIENT REGISTER MAPPING
Programmable 1st-order IIR filter (can be allocated to HPF or any other desired filter)	N_0	0x7FFFFFFF	P4_R72-R75
	N_1	0x00000000	P4_R76-R79
	D_1	0x00000000	P4_R80-R83

ADVANCE INFORMATION

8.3.7.5 Programmable Digital Biquad Filters

The device supports up to 12 programmable digital biquad filters. These highly efficient filters achieve the desired frequence response. In digital signal processing, a digital biquad filter is a second-order, recursive linear filter with two poles and two zeros. 公式 2 gives the transfer function of each biquad filter:

$$H(z) = \frac{N_0 + 2N_1 z^{-1} + N_2 z^{-2}}{2^{31} - 2D_1 z^{-1} - D_2 z^{-2}} \quad (2)$$

The frequency response for the biquad filter section with default coefficients is flat at a gain of 0 dB (all-pass filter). The host device can override the frequency response by programming the biquad coefficients to achieve the desired frequency response for a low-pass, high-pass, or any other desired frequency shaping. The programmable coefficients for the mixer operation are located in the *Programmable Coefficient Registers: Page = 0x02* and *Programmable Coefficient Registers: Page = 0x03* sections. If biquad filtering is required, then the host device must write these coefficients values before powering up any ADC channels for recording. These programmable coefficients are 32-bit, two's complement numbers. As described in 表 16, these biquad filters can be allocated for each output channel based on the BIQUAD_CFG[1:0] register setting of P0_R108. By setting BIQUAD_CFG[1:0] to 2'b00, the biquad filtering for all record channels is disabled and the host device can choose this setting if no additional filtering is required for the system application. See the *PCM6xx0-Q1 Programmable Biquad Filter Configuration and Applications* application report for further details.

表 16. Biquad Filter Allocation to the Record Output Channel

PROGRAMMABLE BIQUAD FILTER	RECORD OUTPUT CHANNEL ALLOCATION USING P0_R108_D[6:5] REGISTER SETTING		
	BIQUAD_CFG[1:0] = 2'b01 (1 Biquad per Channel)	BIQUAD_CFG[1:0] = 2'b10 (Default) (2 Biquads per Channel)	BIQUAD_CFG[1:0] = 2'b11 (3 Biquads per Channel)
	SUPPORTS ALL 8 CHANNELS	SUPPORTS UP TO 6 CHANNELS	SUPPORTS UP TO 4 CHANNELS
Biquad filter 1	Allocated to output channel 1	Allocated to output channel 1	Allocated to output channel 1

8.3.7.6 Programmable Channel Summer and Digital Mixer

For applications that require an even higher SNR than that supported for each channel, the device digital summing mode can be used. In this mode, the digital record data are summed up across the channel with an equal weightage factor, which helps in reducing the effective record noise. 表 18 lists the configuration settings available for channel summing mode.

表 18. Channel Summing Mode Programmable Settings

P0_R107_D[3:2] : CH_SUM[2:0]	CHANNEL SUMMING MODE FOR INPUT CHANNELS	SNR AND DYNAMIC RANGE BOOST
00 (Default)	Channel summing mode is disabled	Not applicable
01	Output channel 1 = (input channel 1 + input channel 2) / 2	3-dB boost in SNR and dynamic range
	Output channel 2 = (input channel 1 + input channel 2) / 2	
	Output channel 3 = (input channel 3 + input channel 4) / 2	3-dB boost in SNR and dynamic range
	Output channel 4 = (input channel 3 + input channel 4) / 2	
10	Output channel 1 = (input channel 1 + input channel 2 + input channel 3 + input channel 4) / 4	6-dB boost in SNR and dynamic range
	Output channel 2 = (input channel 1 + input channel 2 + input channel 3 + input channel 4) / 4	
	Output channel 3 = (input channel 1 + input channel 2 + input channel 3 + input channel 4) / 4	
	Output channel 4 = (input channel 1 + input channel 2 + input channel 3 + input channel 4) / 4	
11	Reserved (do not use this setting)	Not applicable

The device additionally supports a fully programmable mixer feature that can mix the various input channels with their custom programmable scale factor to generate the final output channels. The programmable mixer feature is available only if CH_SUM[2:0] is set to 2'b00. The mixer function is only supported for input channel 1 to channel 4. 图 43 shows a block diagram that describes the mixer 1 operation to generate output channel 1. The programmable coefficients for the mixer operation are located in the *Programmable Coefficient Registers: Page = 0x04* section. All mixer coefficients are 32-bit, two's complement numbers using a 1.31 number format. The value of 0x7FFFFFFF is equivalent to +1 (0-dB gain), the value 0x00000000 is equivalent to mute (zero data), and any values in between set the mixer attenuation computed using 公式 3. If the MSB is set to '1' then the attenuation remains the same but the signal phase is inverted. All IIR filter programmable coefficients are 32-bit, two's complement numbers.

$$\text{hex2dec (value)} / 2^{31} \quad (3)$$

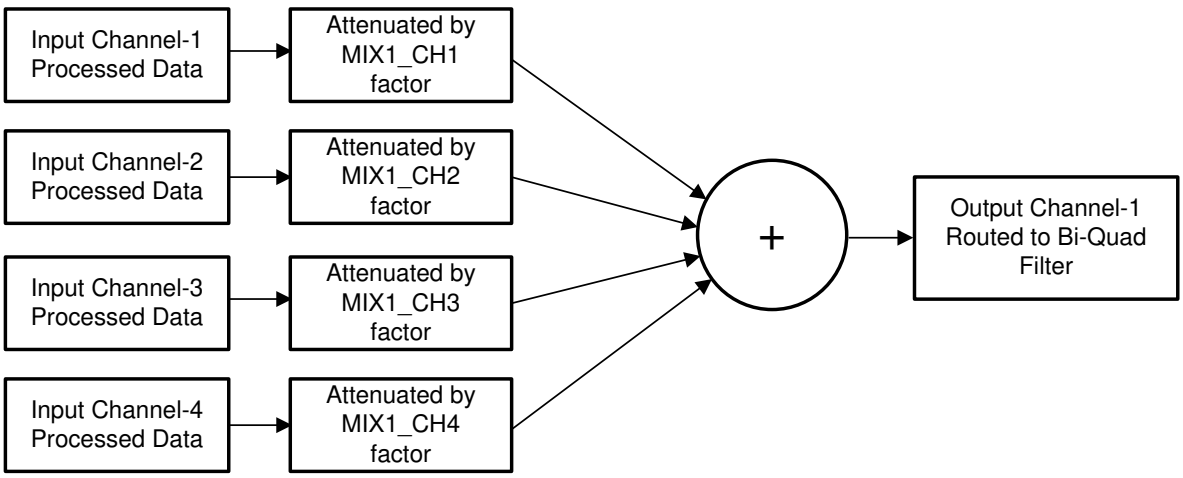

图 43. Programmable Digital Mixer Block Diagram

A similar mixer operation is performed by mixer 2, mixer 3, and mixer 4 to generate output channel 2, channel 3, and channel 4, respectively.

ADVANCE INFORMATION

8.3.7.7 Configurable Digital Decimation Filters

The device record channel includes a high dynamic range, built-in digital decimation filter to process the oversampled data from the multibit delta-sigma (ΔΣ) modulator to generate digital data at the same Nyquist sampling rate as the FSYNC rate. As illustrated in 图 41, this decimation filter can also be used for processing the oversampled PDM stream from the digital microphone. The decimation filter can be chosen from three different types, depending on the required frequency response, group delay, and phase linearity requirements for the target application. The selection of the decimation filter option can be done by configuring the DECI_FILT, P0_R107_D[5:4] register bits. 表 19 shows the configuration register setting for the decimation filter mode selection for the record channel.

表 19. Decimation Filter Mode Selection for the Record Channel

P0_R107_D[5:4] : DECI_FILT[1:0]	DECIMATION FILTER MODE SELECTION
00 (default)	Linear phase filters are used for the decimation
01	Low-latency filters are used for the decimation
10	Ultra-low latency filters are used for the decimation
11	Reserved (do not use this setting)

8.3.7.7.1 Linear Phase Filters

The linear phase decimation filters are the default filters set by the device and can be used for all applications that require a perfect linear phase with zero-phase deviation within the pass-band specification of the filter. The filter performance specifications and various plots for all supported output sampling rates are listed in this section.

8.3.7.7.1.1 Sampling Rate: 8 kHz or 7.35 kHz

图 44 and 图 45 respectively show the magnitude response and the pass-band ripple for a decimation filter with a sampling rate of 8 kHz or 7.35 kHz. 表 20 lists the specifications for a decimation filter with an 8-kHz or 7.35-kHz sampling rate.

8.3.7.7.2 Low-Latency Filters

For applications where low latency with minimal phase deviation (within the audio band) is critical, the low-latency decimation filters on the PCM6xx0-Q1 can be used. The device supports these filters with a group delay of approximately seven samples with an almost linear phase response within the 0.365 × f_S frequency band. This section provides the filter performance specifications and various plots for all supported output sampling rates for the low-latency filters.

8.3.7.7.2.1 Sampling Rate: 16 kHz or 14.7 kHz

图 62 shows the magnitude response and 图 63 shows the pass-band ripple and phase deviation for a decimation filter with a sampling rate of 16 kHz or 14.7 kHz. 表 29 lists the specifications for a decimation filter with a 16-kHz or 14.7-kHz sampling rate.

ADVANCE INFORMATION

8.3.8 Automatic Gain Controller (AGC)

The device includes an automatic gain controller (AGC) for ADC recording that must be used only for the AC-coupled input configuration. As shown in 图 88, the AGC can be used to maintain a nominally constant output level when recording speech. Instead of manually setting the channel gain in AGC mode, the circuitry automatically adjusts the channel gain when the input signal becomes overly loud or very weak, such as when a person speaking into a microphone moves closer to or farther from the microphone. The AGC algorithm has several programmable parameters, including target level, maximum gain allowed, attack and release (or decay) time constants, and noise thresholds that allow the algorithm to be fine-tuned for any particular application.

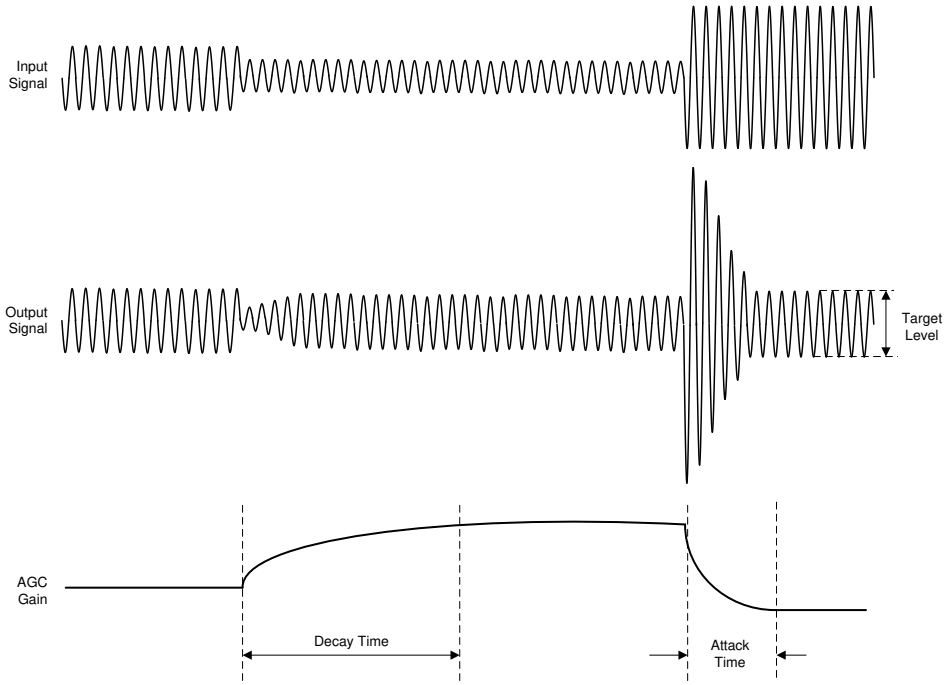

图 88. AGC Characteristics

The target level (AGC_LVL) represents the nominal output level at which the AGC attempts to hold the ADC output signal level. The PCM6xx0-Q1 allows programming of different target levels, which can be programmed from –6 dB to –36 dB relative to a full-scale signal, and the AGC_LVL default value is set to –34 dB. The target level is recommended to be set with enough margin to prevent clipping when loud sounds occur. 表 42 lists the AGC target level configuration settings.

表 42. AGC Target Level Programmable Settings

P0_R112_D[7:4] : AGC_LVL[3:0]	AGC TARGET LEVEL FOR OUTPUT
0000	The AGC target level is the –6-dB output signal level
0001	The AGC target level is the –8-dB output signal level
0010	The AGC target level is the –10-dB output signal level
…	…
1110 (default)	The AGC target level is the –34-dB output signal level
1111	The AGC target level is the –36-dB output signal level

ADVANCE INFORMATION

版权 © 2020, Texas Instruments Incorporated

The maximum gain allowed (AGC_MAXGAIN) gives flexibility to the designer to restrict the maximum gain applied by the AGC. This feature limits the channel gain in situations where environmental noise is greater than the programmed noise threshold. The AGC_MAXGAIN can be programmed from 3 dB to 42 dB with steps of 3 dB and the default value is set to 24 dB. 表 43 lists the AGC_MAXGAIN configuration settings.

表 43. AGC Maximum Gain Programmable Settings

P0_R112_D[3:0] : AGC_MAXGAIN[3:0]	AGC MAXIMUM GAIN ALLOWED
0000	The AGC maximum gain allowed is 3 dB
0001	The AGC maximum gain allowed is 6 dB
0010	The AGC maximum gain allowed is 9 dB
…	…
0111 (default)	The AGC maximum gain allowed is 24 dB
…	…
1110	The AGC maximum gain allowed is 39 dB
1111	The AGC maximum gain allowed is 42 dB

For further details on the AGC various configurable parameter and application use, see the *Using the Automatic Gain Controller (AGC) in PCM6xx0-Q1* application report.

8.3.9 Interrupts, Status, and Digital I/O Pin Multiplexing

Certain events in the device may require host processor intervention and can be used to trigger interrupts to the host processor. Such event are an audio serial interface (ASI) bus error and input DC fault diagnostic faults. The device powers down the record channels if any faults are detected with the ASI bus error clocks, such as:

- Invalid FSYNC frequency
- Invalid SBCLK to FSYNC ratio
- Long pauses of the SBCLK or FSYNC clocks

When an ASI bus clock error is detected, the device shuts down the record channel as quickly as possible. After all ASI bus clock errors are resolved, the device volume ramps back to its previous state to recover the record channel. During an ASI bus clock error, the internal interrupt request (IRQ) interrupt signal asserts low if the clock error interrupt mask register bit INT_MASK0[7], P0_R51_D7 is set low. The clock fault is also available for readback in the live fault status register bit INT_LIVE0, P1_R44 as well as latched to the fault status register bit INT_LTCH0, P0_R44, which is a read-only register. Reading the latched fault status register, INT_LTCH0, clears all latched fault statuses. The device can be additionally configured to route the internal IRQ interrupt signal on the GPIOx pins and also can be configured as an open-drain output so that these pins can be wire-ANDed to the open-drain interrupt outputs of other devices.

When an input DC fault event is detected, the internal IRQ signal is asserted if the interrupt mask registers INT_MASK1, P0_R42 and INT_MASK2, P0_R43 are configured appropriately to unmask all the desired fault diagnostics interrupts. Each input channel can be independently set for an interrupt mask. 表 44 and 表 45 list the mask settings available for the input DC diagnostics fault interrupts.

表 44. Interrupt Mask Register-1 for DC Faults Diagnostic

P0_R42 : INT_MASK1	INTERRUPT MASK REGISTER 1 FOR DC FAULTS DIAGNOSTIC INTERRUPTS
INT_MASK1[7]	Channel 1 input DC faults diagnostic interrupt mask and unmask register bit
INT_MASK1[6]	Channel 2 input DC faults diagnostic interrupt mask and unmask register bit
INT_MASK1[5]	Channel 3 input DC faults diagnostic interrupt mask and unmask register bit

ADVANCE INFORMATION

表 45. Interrupt Mask Register-2 for DC Faults Diagnostic

P0_R43 : INT_MASK2	INTERRUPT MASK REGISTER 2 FOR DC FAULTS DIAGNOSTIC INTERRUPTS
INT_MASK2[7]	Open input fault interrupt mask and unmask register bit for all channels
INT_MASK2[6]	Inputs shorted each other fault interrupt mask and unmask register bit for all channels
INT_MASK2[5]	IN1P input shorted to ground fault interrupt mask and unmask register bit for all channels
INT_MASK2[4]	IN1M input shorted to ground fault interrupt mask and unmask register bit for all channels
INT_MASK2[3]	IN1P input shorted to MICBIAS fault interrupt mask and unmask register bit for all channels
INT_MASK2[2]	IN1M input shorted to MICBIAS fault interrupt mask and unmask register bit for all channels
INT_MASK2[1]	IN1P input shorted to VBAT_IN fault interrupt mask and unmask register bit for all channels
INT_MASK2[0]	IN1M input shorted to VBAT_IN fault interrupt mask and unmask register bit for all channels

The device supports the channel-specific input DC fault latched status registers for all channels from CH1_LTCH, P0_R46 to CH6_LTCH, P0_R51, which are read-only registers. The device also has a consolidated summary status register across channels for the input DC latched fault status register, CHx_LTCH, P0_R45 that the host can read to quickly know which channel fault has occurred. Reading the latched fault status registers, CH1_LTCH to CH6_LTCH, clears all the latched fault status including the summary status register, CHx_LTCH. 表 46 shows various input DC fault diagnostics status bits that are supported by the device.

表 46. Input DC Faults Diagnostic Latched Status

CH1_LTCH[1]	Channel 1 IN1P input shorted to VBAT_IN fault detection status bit (self-clearing bit)
CH1_LTCH[0]	Channel 1 IN1M input shorted to VBAT_IN fault detection status bit (self-clearing bit)

Similarly, the DC faults diagnostic latched status for input channel 2 to channel 6 can be monitored using the CH2_LTCH (P0_R47) to CH6_LTCH (P0_R51) registers, respectively.

The device GPIOx pins can be additionally configured to route the internal IRQ interrupt signal on the GPIOx pins and also can be configured as an open-drain output so that this pin can be wire-ANDed to the open-drain interrupt outputs of other devices.

The IRQ interrupt signal can either be configured as an active low or active high polarity by setting the INT_POL, P0_R40_D7 register bit. This signal can also be configured as a single pulse or a series of pulses by programming the INT_EVENT[1:0], P0_R40_D[6:5] register bits. If the interrupts are configured as a series of pulses, the events trigger the start of pulses that stop when the latched fault status register is read to determine the cause of the interrupt.

The device also supports read-only live status registers that determine if all the channels are powered up or down and if the device is in sleep mode or not. These status registers are located in P0_R118, DEV_STS0 and P0_R119, DEV_STS1.

The device has a GPIO1 multifunction pin that can be configured for a desired specific function. Additionally the PCM6x40-Q1 has two more GPIO pins and two GPI pins supported that can be used in the system for various other features. 表 47 shows all possible allocation of these multifunction pins for all the various features.

表 47. Multifunction Pin Assignments

ROW	PIN FUNCTION	GPIO1	GPIO2	GPIO3	GPI1	GPI2
—	—	GPIO1_CFG [4:0]	GPIO2_CFG [4:0]	GPIO3_CFG [4:0]	GPI1_CFG[4:0]	GPI2_CFG[4:0]
—	—	P0_R33[7:4]	P0_R34[7:4]	P0_R35[7:4]	P0_R36[7:4]	P0_R37[7:4]
A	Pin disabled	S(1)	S (default)	S (default)	S (default)	S (default)
B	General-purpose output (GPO)	S	S	S	NS(2)	NS
C	Interrupt output (IRQ)	S (default)	S	S	NS	NS
D	Secondary ASI output (SDOUT2)	S	S	S	NS	NS
F	MiCBIAS on/off input (BIASEN)	S	S	S	S	S
G	General-purpose input (GPI)	S	S	S	S	S
H	Master clock input (MCLK)	S	S	S	S	S
I	ASI daisy-chain input (SDIN)	S	S	S	S	S

(1) S means the feature mentioned in this row is *supported* for the respective GPIO1, GPOx, or GPIx pin mentioned in this column.
(2) NS means the feature mentioned in this row is *not supported* for the respective GPIO1, GPOx, or GPIx pin mentioned in this column.

Each GPIOx pin can be independently set for the desired drive configurations setting using the GPIOx_DRV[3:0] register bits. 表 48 lists the drive configuration settings.

表 48. GPIOx Pins Drive Configuration Settings

P0_R33_D[3:0] : GPIO1_DRV[3:0]	GPIO OUTPUT DRIVE CONFIGURATION SETTINGS FOR GPIO1
000	The GPIO1 pin is set to high impedance (floated)
001	The GPIO1 pin is set to be driven active low or active high
010 (default)	The GPIO1 pin is set to be driven active low or weak high (on-chip pullup)
011	The GPIO1 pin is set to be driven active low or Hi-Z (floated)
100	The GPIO1 pin is set to be driven weak low (on-chip pulldown) or active high
101	The GPIO1 pin is set to be driven Hi-Z (floated) or active high
110 and 111	Reserved (do not use these settings)

Similarly, the GPIO2 and GPIO3 pins can be configured using the GPIO2_DRV(P0_R34) and GPIO3_DRV(P0_R35) register bits, respectively.

When configured as a general-purpose output (GPO), the GPIOx pin values can be driven by writing the GPIO_VAL P0_R38 registers. The GPIO_MON, P0_R39 register can be used to readback the status of the GPIOx and GPIx pins when configured as a general-purpose input (GPI).

8.4 Device Functional Modes

8.4.1 Hardware Shutdown

The device enters hardware shutdown mode when the SHDNZ pin is asserted low or the AVDD supply voltage is not applied to the device. In hardware shutdown mode, the device consumes the minimum quiescent current from the AVDD supply. All configuration registers and programmable coefficients lose their value in this mode, and I^2C or SPI communication to the device is not supported.

If the SHDNZ pin is asserted low when the device is in active mode, the device ramps down volume on the record data, powers down the analog and digital blocks, and puts the device into hardware shutdown mode in 25 ms (typical). The device can also be immediately put into hardware shutdown mode from active mode if the SHDNZ_CFG[1:0], P0_R5_D[3:2], register bits are set to 2'b00. After the SHDNZ pin is asserted low, and after the device enters hardware shutdown mode, keep the SHDNZ pin low for at least 1 ms before releasing SHDNZ for further device operation.

Assert the SHDNZ pin high only when the IOVDD supply settles to a steady voltage level. When the SHDNZ pin goes high, the device sets all configuration registers and programmable coefficients to their default values, and then enters sleep mode.

8.4.2 Sleep Mode or Software Shutdown

In sleep mode or software shutdown mode, the device consumes very low quiescent current from the AVDD supply and, at the same time, allows the I^2C or SPI communication to wake the device for active operation.

The device can also enter sleep mode when the host device sets the SLEEP_ENZ, P0_R2_D0 bit to 1'b0. If the SLEEP_ENZ bit is asserted low when the device is in active mode, the device ramps down the volume on the record data, powers down the analog and digital blocks, and enters sleep mode. However, the device still continues to retain the last programmed value of the device configuration registers and programmable coefficients.

In sleep mode, do not perform any I^2C or SPI transactions, except for exiting sleep mode in order to enter active mode. After entering sleep mode, wait at least 10 ms before starting I^2C or SPI transactions to exit sleep mode.

8.4.3 Active Mode

If the host device exits sleep mode by setting the SLEEP_ENZ bit to 1'b1, the device enters active mode. In active mode, I^2C or SPI transactions can be done to configure and power-up the device for active operation. After entering active mode, wait at least 1 ms before starting any I^2C or SPI transactions in order to allow the device to complete the internal wake-up sequence.

After configuring all other registers for the target application and system settings, configure the input and output channel enable registers, P0_R115 (IN_CH_EN) and P0_R116 (ASI_OUT_CH_EN), respectively. Lastly, configure the device power-up register, P0_R117 (PWR_CFG). All the programmable coefficient values must be written before powering up the respective channel.

In active mode, the power-up and power-down status of various blocks is monitored by reading the read-only device status bits located in the P0_R117 (DEV_STS0) and P0_R118 (DEV_STS1) registers.

8.4.4 Software Reset

A software reset can be done any time by asserting the SW_RESET bit, P0_R1_D0, which is a self-clearing bit. This software reset immediately shuts down the device, and restores all device configuration registers and programmable coefficients to their default values.

ADVANCE INFORMATION

8.5 Programming

The device contains configuration registers and programmable coefficients that can be set to the desired values for a specific system and application use. These registers are called *device control registers* and are each eight bits in width, mapped using a page scheme.

Each page contains 128 configuration registers. All device configuration registers are stored in page 0, which is the default page setting at power up (and after a software reset). Page 1 consists of the live status registers and input diagnostic successive-approximation register (SAR) data for advanced diagnostic purposes. All programmable coefficient registers are located in page 2, page 3, and page 4. The current page of the device can be switched to a new desired page by using the PAGE[7:0] bits located in register 0 of every page.

8.5.1 Control Serial Interfaces

The device control registers can be accessed using either I^2C or SPI communication to the device.

By monitoring the SDA_SSZ, SCL_MOSI, ADDR0_SCLK, and ADDR1_MISO device pins, which are the multiplexed pins for the I^2C or SPI Interface, the device automatically detects whether the host device is using I^2C or SPI communication to configure the device. For a given end application, the host device must always use either the I^2C or SPI interface, but not both, to configure the device.

8.5.1.1 I^2C Control Interface

The device supports the I^2C control protocol as a slave device, and is capable of operating in standard mode, fast mode, and fast mode plus. The I^2C control protocol requires a 7-bit slave address. The five most significant bits (MSBs) of the slave address are fixed at 10010 and cannot be changed. The two least significant bits (LSBs) are programmable and are controlled by the ADDR0_SCLK and ADDR1_MISO pins. These two pins must always be either pulled to VSS or IOVDD. If the I2C_BRDCAST_EN (P0_R2_D2) bit is set to 1'b1, then the I^2C slave address is fixed to 1001000 in order to allow simultaneous I^2C broadcast communication to all PCM6xx0-Q1 devices in the system. 表 49 lists the four possible device addresses resulting from this configuration.

表 49. I^2C Slave Address Settings

ADDR1_MISO	ADDR0_SCLK	I2C_BRDCAST_EN (P0_R2_D2)	I^2C SLAVE ADDRESS
0	0	0 (default)	1001 000
0	1	0 (default)	1001 001
1	0	0 (default)	1001 010
1	1	0 (default)	1001 011
X	X	1	1001 000

8.5.1.1.1 General I^2C Operation

The I^2C bus employs two signals, SDA (data) and SCL (clock), to communicate between the integrated circuits in a system using serial data transmission. The address and data 8-bit bytes are transferred MSB first. In addition, each byte transferred on the bus is acknowledged by the receiving device with an acknowledge bit. Each transfer operation begins with the master device driving a START condition on the bus and ends with the master device driving a STOP condition on the bus. The bus uses transitions on the data pin (SDA) when the clock is at logic high to indicate START and STOP conditions. A high-to-low transition on SDA indicates a START, and a low-to-high transition indicates a STOP condition. Normal data-bit transitions must occur within the low time of the clock period.

The master device drives a START condition followed by the 7-bit slave address and the read/write (R/W) bit to open communication with another device and then waits for an acknowledgment condition. The slave device holds SDA low during the acknowledge clock period to indicate acknowledgment. When this step occurs, the master device transmits the next byte of the sequence. Each slave device is addressed by a unique 7-bit slave address plus the R/W bit (1 byte). All compatible devices share the same signals via a bidirectional bus using a wired-AND connection.

版权 © 2020, Texas Instruments Incorporated

There is no limit on the number of bytes that can be transmitted between START and STOP conditions. When the last word transfers, the master device generates a STOP condition to release the bus. 图 89 shows a generic data transfer sequence.

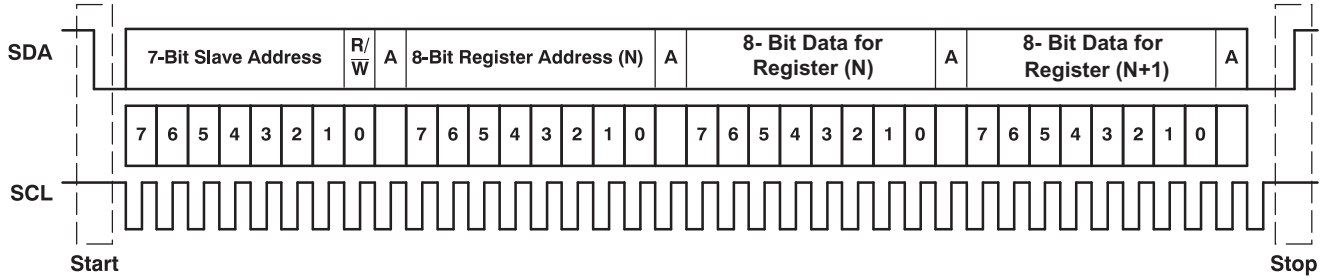

图 89. Typical I²C Sequence

In the system, use external pullup resistors for the SDA and SCL signals to set the logic high level for the bus. The SDA and SCL voltages must not exceed the device supply voltage, IOVDD.

8.5.1.1.2 I²C Single-Byte and Multiple-Byte Transfers

The device I²C interface supports both single-byte and multiple-byte read/write operations for all registers. During multiple-byte read operations, the device responds with data, a byte at a time, starting at the register assigned, as long as the master device continues to respond with acknowledges.

The device supports sequential I²C addressing. For write transactions, if a register is issued followed by data for that register and all the remaining registers that follow, a sequential I²C write transaction takes place. For I²C sequential write transactions, the register issued then serves as the starting point, and the amount of data subsequently transmitted, before a STOP or START condition is transmitted, determines how many registers are written.

8.5.1.1.2.1 I²C Single-Byte Write

As shown in 图 90, a single-byte data write transfer begins with the master device transmitting a START condition followed by the I²C device address and the read/write bit. The read/write bit determines the direction of the data transfer. For a write-data transfer, the read/write bit must be set to 0. After receiving the correct I²C slave address and the read/write bit, the device responds with an acknowledge bit (ACK). Next, the master device transmits the register byte corresponding to the device internal register address being accessed. After receiving the register byte, the device again responds with an acknowledge bit (ACK). Then, the master transmits the byte of data to be written to the specified register. When finished, the slave device responds with an acknowledge bit (ACK). Finally, the master device transmits a STOP condition to complete the single-byte data write transfer.

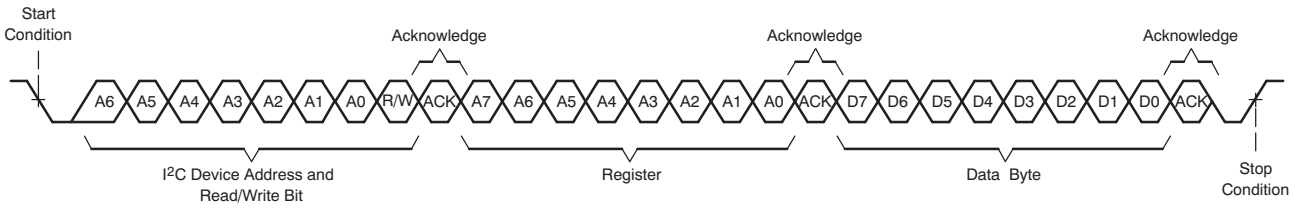

图 90. I²C Single-Byte Write Transfer

ADVANCE INFORMATION

版权 © 2020, Texas Instruments Incorporated

8.5.1.1.2.2 I²C Multiple-Byte Write

As shown in 图 91, a multiple-byte data write transfer is identical to a single-byte data write transfer except that multiple data bytes are transmitted by the master device to the slave device. After receiving each data byte, the device responds with an acknowledge bit (ACK). Finally, the master device transmits a STOP condition after the last data-byte write transfer.

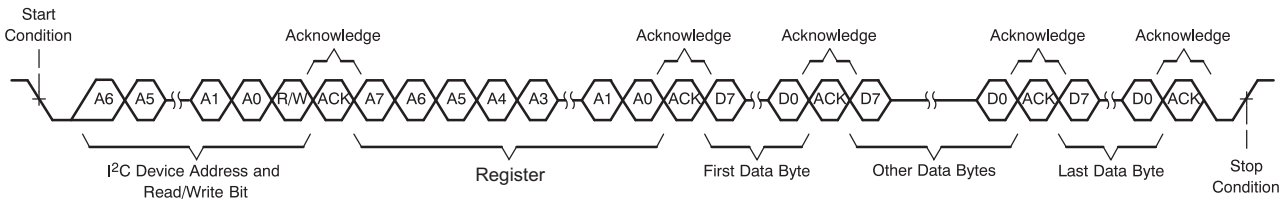

图 91. I²C Multiple-Byte Write Transfer

8.5.1.1.2.3 I²C Single-Byte Read

As shown in 图 92, a single-byte data read transfer begins with the master device transmitting a START condition followed by the I²C slave address and the read/write bit. For the data read transfer, both a write followed by a read are done. Initially, a write is done to transfer the address byte of the internal register address to be read. As a result, the read/write bit is set to 0.

After receiving the slave address and the read/write bit, the device responds with an acknowledge bit (ACK). The master device then sends the internal register address byte, after which the device issues an acknowledge bit (ACK). The master device transmits another START condition followed by the slave address and the read/write bit again. This time, the read/write bit is set to 1, indicating a read transfer. Next, the device transmits the data byte from the register address being read. After receiving the data byte, the master device transmits a not-acknowledge (NACK) followed by a STOP condition to complete the single-byte data read transfer.

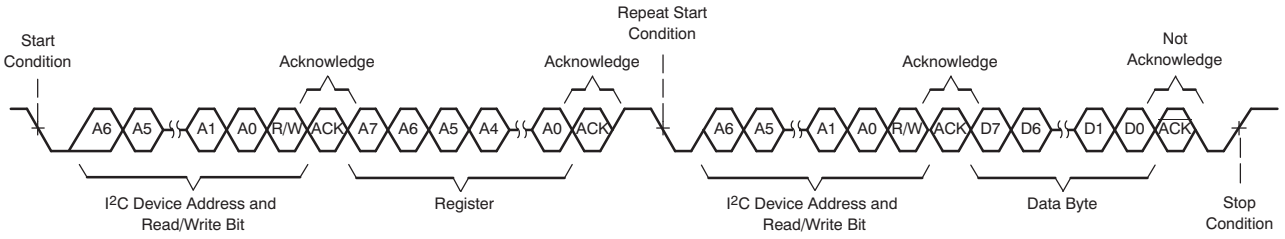

图 92. I²C Single-Byte Read Transfer

8.5.1.1.2.4 I²C Multiple-Byte Read

As shown in 图 93, a multiple-byte data read transfer is identical to a single-byte data read transfer except that multiple data bytes are transmitted by the device to the master device. With the exception of the last data byte, the master device responds with an acknowledge bit after receiving each data byte. After receiving the last data byte, the master device transmits a not-acknowledge (NACK) followed by a STOP condition to complete the data read transfer.

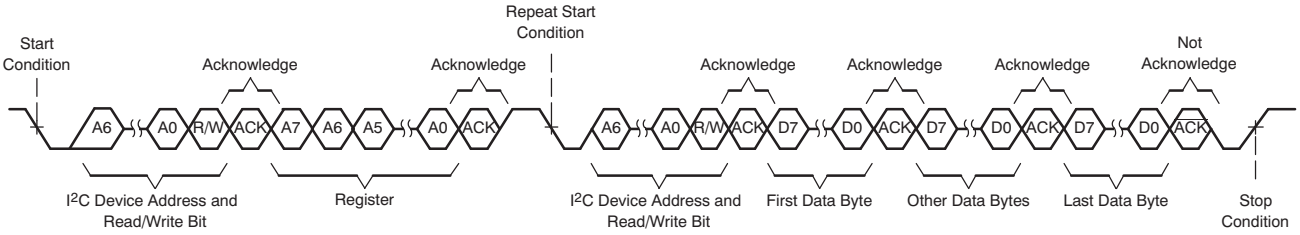

图 93. I²C Multiple-Byte Read Transfer

ADVANCE INFORMATION

8.5.1.2 SPI Control Interface

The general SPI protocol allows full-duplex, synchronous, serial communication between a host processor (the master) and peripheral devices (slaves). The SPI master (in this case, the host processor) generates the synchronizing clock (driven onto SCLK) and initiates transmissions by taking the slave-select pin SSZ from high to low. The SPI slave devices (such as the PCM6xx0-Q1) depend on a master to start and synchronize transmissions. A transmission begins when initiated by an SPI master. The byte from the SPI master begins shifting in on the slave MOSI pin under the control of the master serial clock (driven onto SCLK). When the byte shifts in on the MOSI pin, a byte shifts out on the MISO pin to the master shift register.

The PCM6xx0-Q1 support a standard SPI control protocol with a clock polarity setting of 0 (typical microprocessor SPI control bit CPOL = 0) and a clock phase setting of 1 (typical microprocessor SPI control bit CPHA = 1). The SSZ pin can remain low between transmissions; however, the device only interprets the first eight bits transmitted after the falling edge of SSZ as a command byte, and the next eight bits as a data byte only if writing to a register. The device is entirely controlled by registers. Reading and writing these registers is accomplished by an 8-bit command sent to the MOSI pin prior to the data for that register. 表 50 shows the command structure. The first seven bits specify the address of the register that is being written or read, from 0 to 127 (decimal). The command word ends with an R/W bit, which specifies the direction of data flow on the serial bus.

In the case of a register write, set the R/W bit to 0. A second byte of data is sent to the MOSI pin and contains the data to be written to the register. A register read is accomplished in a similar fashion. The 8-bit command word sends the 7-bit register address, followed by the R/W bit equal to 1 to signify a register read. The 8-bit register data is then clocked out of the device on the MISO pin during the second eight SCLK clocks in the frame. The device supports sequential SPI addressing for a multiple-byte data write/read transfer until the SSZ pin is pulled high. A multiple-byte data write or read transfer is identical to a single-byte data write or read transfer, respectively, until all data byte transfers complete. The host device must keep the SSZ pin low during all data byte transfers. 图 94 shows the single-byte write transfer and 图 95 illustrates the single-byte read transfer.

表 50. SPI Command Word

BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0
ADDR(6)	ADDR(5)	ADDR(4)	ADDR(3)	ADDR(2)	ADDR(1)	ADDR(0)	R/WZ

8.6 Register Maps

This section describes the control registers for the device in detail. All registers are eight bits in width and are allocated to the device configuration and programmable coefficients settings. These registers are mapped internally using a page scheme that can be controlled using either I^2C or SPI communication to the device. Each page contains 128 bytes of registers. All device configuration registers are stored in page 0, which is the default page setting at power up (and after a software reset). Page 1 consists of the live status registers and input diagnostic SAR data for advanced diagnostic purposes. All programmable coefficient registers are located in page 2, page 3, and page 4. The device current page can be switched to a new desired page by using the PAGE[7:0] bits located in register 0 of every page.

Do not read from or write to reserved pages or reserved registers. Write only default values for the reserved bits in the valid registers.

The procedure for register access across pages is:

- Select page N (write data *N* to register 0 regardless of the current page number)
- Read or write data from or to valid registers in page N
- Select the new page M (write data *M* to register 0 regardless of the current page number)
- Read or write data from or to valid registers in page M
- Repeat as needed

8.6.1 Device Configuration Registers

This section describes the device configuration registers for page 0 and page 1.

8.6.1.1 Register Summary Table Page=0x00

ADDRESS	REGISTER	DESCRIPTION	SECTION
0x00	PAGE_CFG	Device page register	PAGE_CFG Register (P0_R0)

0x79	DIAG_MON_LSB_LOAD	Diagnostic MICBIAS load current data LSB nibble register	DIAG_MON_LSB_LOAD Register (P1_R121)

表 51 lists the access codes used for the PCM6xx0-Q1 registers.

表 51. PCM6xx0-Q1 Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-W	R/W	Read or write
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

8.6.1.3 Register Description: Page = 0x00

8.6.1.3.1 PAGE_CFG Register (page = 0x00, address = 0x00) [reset = 0h]

The device memory map is divided into pages. This register sets the page.

Figure 96. PAGE_CFG Register

7	6	5	4	3	2	1	0
PAGE[7:0]							
R/W-0h							

Table 52. PAGE_CFG Register Field Descriptions

Bit	Field	Type	Reset	Description
7-0	PAGE[7:0]	R/W	0h	These bits set the device page. 0d = Page 0 1d = Page 1 ... 255d = Page 255

8.6.1.3.2 SW_RESET Register (page = 0x00, address = 0x01) [reset = 0h]

This register is the software reset register. Asserting a software reset places all register values in their default power-on-reset (POR) state.

Figure 97. SW_RESET Register

7	6	5	4	3	2	1	0
Reserved							SW_RESET
R-0h							R/W-0h

Table 53. SW_RESET Register Field Descriptions

Bit	Field	Type	Reset	Description
7-1	Reserved	R	0h	Reserved
0	SW_RESET	R/W	0h	Software reset. This bit is self-clearing. 0d = Do not reset 1d = Reset

8.6.1.3.3 SLEEP_CFG Register (page = 0x00, address = 0x02) [reset = 0h]

This register configures the regulator, VREF quick charge, I2C broadcast and sleep mode.

ADVANCE INFORMATION

Copyright © 2020, Texas Instruments Incorporated

Figure 98. SLEEP_CFG Register

7	6	5	4	3	2	1	0
Reserved	Reserved		VREF_QCHG[1:0]		I2C_BRDCAST_EN	Reserved	SLEEP_ENZ
RW-0h	RW-0h		RW-0h		RW-0h	R-0h	RW-0h

Table 54. SLEEP_CFG Register Field Descriptions

Bit	Field	Type	Reset	Description
7	Reserved	RW	0h	Reserved
6-5	Reserved	RW	0h	Reserved
4-3	VREF_QCHG[1:0]	RW	0h	The duration of the quick-charge for the VREF external capacitor is set using an internal series impedance of 200 ohm. 0d = VREF quick-charge duration of 3.5 ms (typical) 1d = VREF quick-charge duration of 10 ms (typical) 2d = VREF quick-charge duration of 50 ms (typical) 3d = VREF quick-charge duration of 100 ms (typical)
2	I2C_BRDCAST_EN	RW	0h	I2C broadcast addressing setting. 0d = I2C broadcast mode disabled; the I2C slave address is determined based on the ADDR pins 1d = I2C broadcast mode enabled; the I2C slave address is fixed at 1001 100
1	Reserved	R	0h	Reserved
0	SLEEP_ENZ	RW	0h	Sleep mode setting. 0d = Device is in sleep mode 1d = Device is not in sleep mode

8.6.1.3.4 SHDN_CFG Register (page = 0x00, address = 0x05) [reset = 5h]

This register configures the device shutdown

Figure 99. SHDN_CFG Register

7	6	5	4	3	2	1	0
Reserved				SHDNZ_CFG[1:0]		DREG_KA_TIME[1:0]	
R-0h				RW-1h		RW-1h	

Table 55. SHDN_CFG Register Field Descriptions

Bit	Field	Type	Reset	Description
7-4	Reserved	R	0h	Reserved
3-2	SHDNZ_CFG[1:0]	RW	1h	Shutdown configuration. 0d = DREG is powered down immediately after SHDNZ asserts 1d = DREG remains active to enable a clean shut down until a time-out is reached; after the time-out period, DREG is forced to power off 2d = DREG remains active until the device cleanly shuts down 3d = Reserved
1-0	DREG_KA_TIME[1:0]	RW	1h	These bits set how long DREG remains active after SHDNZ asserts. 0d = DREG remains active for 30 ms (typical) 1d = DREG remains active for 25 ms (typical) 2d = DREG remains active for 10 ms (typical) 3d = DREG remains active for 5 ms (typical)

8.6.1.3.5 ASI_CFG0 Register (page = 0x00, address = 0x07) [reset = 30h]

This register is the ASI configuration register 0.

Figure 100. ASI_CFG0 Register

Table 56. ASI_CFG0 Register Field Descriptions

Bit	Field	Type	Reset	Description
7-6	ASI_FORMAT[1:0]	RW	0h	ASI protocol format. 0d = TDM mode 1d = I2S mode 2d = LJ (left-justified) mode 3d = Reserved
5-4	ASI_WLEN[1:0]	RW	3h	ASI word or slot length. 0d = 16 bits 1d = 20 bits 2d = 24 bits 3d = 32 bits
3	FSYNC_POL	RW	0h	ASI FSYNC polarity. 0d = Default polarity as per standard protocol 1d = Inverted polarity with respect to standard protocol
2	BCLK_POL	RW	0h	ASI BCLK polarity. 0d = Default polarity as per standard protocol 1d = Inverted polarity with respect to standard protocol
1	TX_EDGE	RW	0h	ASI data output (on the primary and secondary data pin) transmit edge. 0d = Default edge as per the protocol configuration setting in bit 2 (BCLK_POL) 1d = Inverted following edge (half cycle delay) with respect to the default edge setting
0	TX_FILL	RW	0h	ASI data output (on the primary and secondary data pin) for any unused cycles 0d = Always transmit 0 for unused cycles 1d = Always use Hi-Z for unused cycles

8.6.1.3.6 ASI_CFG1 Register (page = 0x00, address = 0x08) [reset = 0h]

This register is the ASI configuration register 1.

Figure 101. ASI_CFG1 Register

7	6	5	4	3	2	1	0
TX_LSB	TX_KEEPER[1:0]		TX_OFFSET[4:0]				
RW-0h	RW-0h		RW-0h				

Table 57. ASI_CFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	TX_LSB	RW	0h	ASI data output (on the primary and secondary data pin) for LSB transmissions. 0d = Transmit the LSB for a full cycle 1d = Transmit the LSB for the first half cycle and Hi-Z for the second half cycle
6-5	TX_KEEPER[1:0]	RW	0h	ASI data output (on the primary and secondary data pin) bus keeper. 0d = Bus keeper is always disabled 1d = Bus keeper is always enabled 2d = Bus keeper is enabled during LSB transmissions only for one cycle 3d = Bus keeper is enabled during LSB transmissions only for one and half cycles
4-0	TX_OFFSET[4:0]	RW	0h	ASI data MSB slot 0 offset (on the primary and secondary data pin). 0d = ASI data MSB location has no offset and is as per standard protocol 1d = ASI data MSB location (TDM mode is slot 0 or I2S, LJ mode is the left and right slot 0) offset of one BCLK cycle with respect to standard protocol 2d = ASI data MSB location (TDM mode is slot 0 or I2S, LJ mode is the left and right slot 0) offset of two BCLK cycles with respect to standard protocol 3d to 30d = ASI data MSB location (TDM mode is slot 0 or I2S, LJ mode is the left and right slot 0) offset assigned as per configuration 31d = ASI data MSB location (TDM mode is slot 0 or I2S, LJ mode is the left and right slot 0) offset of 31 BCLK cycles with respect to standard protocol

8.6.2 Programmable Coefficient Registers

8.6.2.1 Programmable Coefficient Registers: Page = 0x02

This register page (shown in Register Description: Page = 0x00) consists of the programmable coefficients for the biquad 1 to biquad 6 filters. To optimize the coefficients register transaction time for page 2, page 3, and page 4, the device also supports (by default) auto-incremented pages for the I^2C and SPI burst writes and reads. After a transaction of register address 0x7F, the device auto increments to the next page at register 0x08 to transact the next coefficient value. These programmable coefficients are 32-bit, two's complement numbers.

8.6.2.2 Programmable Coefficient Registers: Page = 0x03

This register page (shown in 表 185) consists of the programmable coefficients for the biquad 7 to biquad 12 filters. To optimize the coefficients register transaction time for page 2, page 3, and page 4, the device also supports (by default) auto-incremented pages for the I^2C and SPI burst writes and reads. After a transaction of register address 0x7F, the device auto increments to the next page at register 0x08 to transact the next coefficient value. These programmable coefficients are 32-bit, two's complement numbers.

8.6.2.3 Programmable Coefficient Registers: Page = 0x04

This register page (shown in 表 186) consists of the programmable coefficients for mixer 1 to mixer 4 and the first-order IIR filter. All mixer coefficients are 32-bit, two's complement numbers using a 1.31 number format. The value of 0x7FFFFFFF is equivalent to +1 (0-dB gain), the value 0x00000000 is equivalent to mute (zero data) and all values in between set the mixer attenuation computed using 公式 4. If the MSB is set to '1' then the attenuation remains the same but the signal phase is inverted. All IIR filter programmable coefficients are 32-bit, two's complement numbers.

$$\text{hex2dec (value)} / 2^{31} \quad (4)$$

9 Application and Implementation

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The PCM6xx0-Q1 are multichannel, automotive qualified audio ADCs that support output sample rates of up to 384 kHz. The PCM6x60-Q1 support up to six analog microphones and the PCM6x40-Q1 support up to four analog microphones for simultaneous recording applications. The PCM6xx0-Q1 family is intended for automotive applications such as vehicle cabin active noise cancellation, hands-free in-vehicle communication, emergency call, and multi-media applications. These devices integrate a host of features to reduce cost, board space, and power consumption in space-constrained automotive subsystem designs.

Communication to the PCM6xx0-Q1 for configuration of the control registers is supported using an I^2C or SPI interface. The device supports a highly flexible audio serial interface (TDM, I^2S, or LJ) to transmit audio data seamlessly in the system across devices.

9.2 Typical Applications

9.2.1 Four-Channel Analog Microphone Recording Using the PCM6240-Q1

图 228 shows a typical configuration of the PCM6240-Q1 for an application using four analog microphones for simultaneous recording operation with an I^2C control interface and the TDM audio data slave interface.

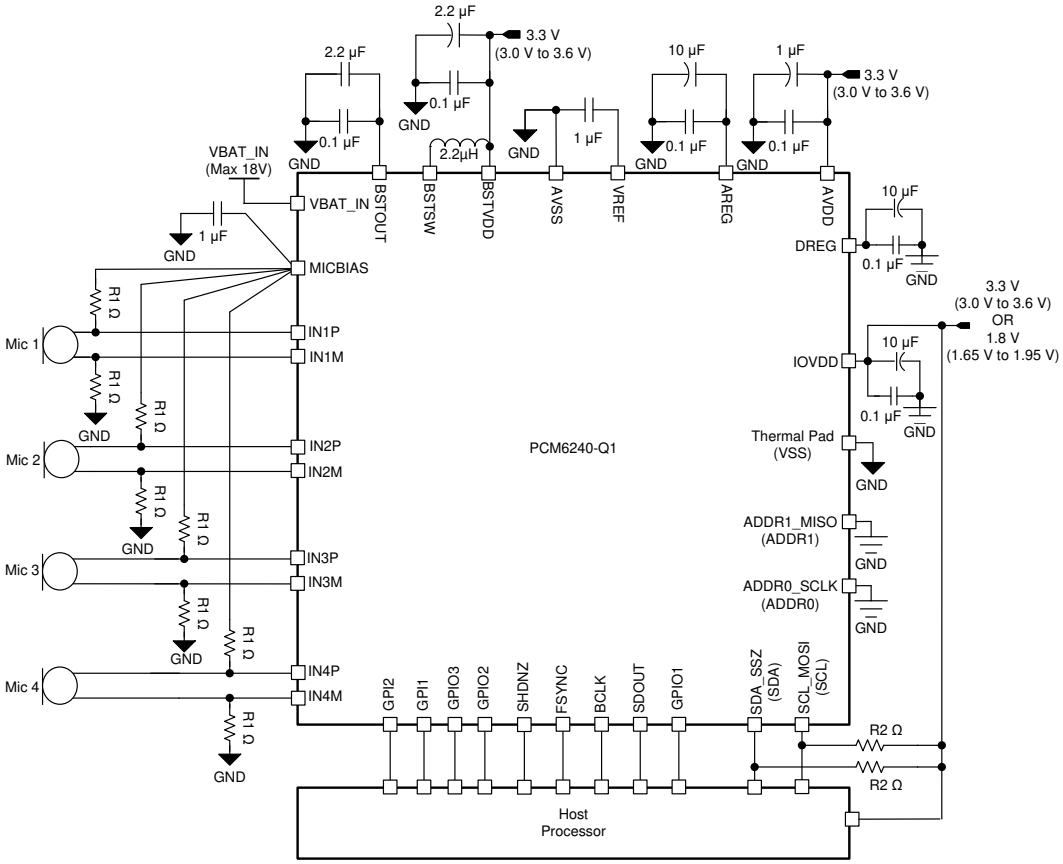

图 228. Four-Channel Analog Microphone Recording

Typical Applications (接下页)

9.2.1.1 Design Requirements

表 187 lists the design parameters for this application.

表 187. Design Parameters

KEY PARAMETER	SPECIFICATION
AVDD, BSTVDD	3.3 V
AVDD supply current	24 mA (PLL on, four-channel record, f_S = 44.1 kHz)
IOVDD	1.8 V or 3.3 V
Maximum MICBIAS current	< 28 mA (MICBIAS voltage = 8 V, microphone impedance = 680 Ω and R1 = 340 Ω)

9.2.1.2 Detailed Design Procedure

This section describes the necessary steps to configure the PCM6240-Q1 for this specific application. The following steps give a sequence of items that must be executed in the time between powering the device up and reading data from the device or transitioning from one mode to other mode of operation.

1. **Apply Power to Device:**
   a. Power up the IOVDD, AVDD, and BSTVDD power supplies, keeping the SHDNZ pin voltage low
   b. The device now goes into hardware shutdown mode (ultra-low-power mode < 1 µA)
2. **Transition From Hardware Shutdown Mode to Sleep Mode (or Software Shutdown Mode):**
   a. Release SHDNZ only when the IOVDD, AVDD, and BSTVDD power supplies settle to steady-state operating voltage
   b. Wait for at least 1 ms to allow the device to initialize the internal registers
   c. The device now goes into sleep mode (low-power mode < 20 µA)
3. **Transition From Sleep Mode to Active Mode Whenever Required for the Record Operation:**
   a. Wake-up the device by writing P0_R2 to disable sleep mode
   b. Wait for at least 1ms to allow the device internal wake-up sequence to complete
   c. *Override the default configuration registers or programmable coefficients value as required (optional)*
   d. Enable all desired input channels by writing P0_R115
   e. Enable all desired audio serial interface output channels by writing P0_R116
   f. Power-up the ADC, MICBIAS, and PLL by writing P0_R117
   g. Apply FSYNC and BCLK with the desired output sample rates and the BCLK to FSYNC ratio

      This specific step can be done at any point in the sequence after step a

      See the *Phase-Locked Loop (PLL) and Clock Generation* section for the supported sample rates and the BCLK to FSYNC ratio
   h. The device recording data are now sent to the host processor via the TDM audio serial data bus
   i. Wait for at least 10 ms to allow the MICBIAS to power up
   j. Enable the fault diagnostics for all desired input channels by writing P0_R100
4. **Transition From Active Mode to Sleep Mode (Again) as Required in the System Low Power:**
   a. Disable the fault diagnostics for all desired input channels by writing P0_R100
   b. Go to sleep mode by writing P0_R2 to enable sleep mode
   c. Wait at least 20 ms to allow the volume to gradually ramp down and for all blocks to power down
   d. Read P0_R119 to check the device shutdown and sleep mode status
   e. If the device P0_R119_D7 status bit is 1'b1, then stop FSYNC and BCLK in the system
   f. The device now goes into sleep mode (low-power mode < 20 µA) and retains all register values
5. **Transition From Sleep Mode to Active Mode (Again) as Required for the Record Operation:**
   a. Wake-up the device by writing P0_R2 to disable sleep mode
   b. Wait for at least 1 ms to allow the device internal wake-up sequence to complete

ADVANCE INFORMATION

c. Apply FSYNC and BCLK with the desired output sample rates and BCLK to FSYNC ratio
d. The device recording data are now sent to the host processor via the TDM audio serial data bus
e. Wait for at least 10 ms to allow the MICBIAS to power up
f. Enable the fault diagnostics for all desired input channels by writing P0_R100

6. **Repeat Step 4 and Step 5 as Required for Mode Transitions**
7. **Assert the SHDNZ Pin Low to Enter Hardware Shutdown Mode (Again) at Any Time**
8. **Follow Step 2 Onwards to Exit Hardware Shutdown Mode (Again)**

9.2.1.2.1 Example Device Register Configuration Script for EVM Setup

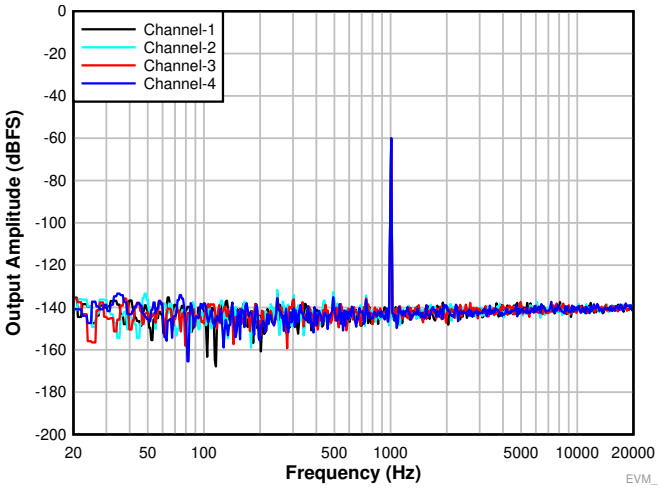

This section provides a typical EVM I^2C register control script that shows how to set up the PCM6240-Q1 in a 4-channel analog microphone record mode with differential inputs.

```
#
# Key: w 98 XX YY ==> write to I2C address 0x98, to register 0xXX, data 0xYY
#               # ==> comment delimiter
#
# The following list gives an example sequence of items that must be executed in the time
# between powering the device up and reading data from the device. Note that there are
# other valid sequences depending on which features are used.
#
# PCM6240-Q1EVM Key Jumper Settings and Audio Connections:
# 1. TBD
# 2. TBD
# 3. TBD
# Differential 4-channel : INP1/INM1 - Ch1, INP2/INM2 - Ch2, INP3/INM3 - Ch3 and INP4/INM4 - Ch4
# High swing mode enabled
# FSYNC = 44.1 kHz (Output Data Sample Rate), BCLK = 11.2896 MHz (BCLK/FSYNC = 256)
######################################################################
#
#
# Power up IOVDD, AVDD and BSTVDD power supplies keeping SHDNZ pin voltage LOW
# Wait for IOVDD, AVDD and BSTVDD power supplies to settle to steady state operating voltage range.
# Release SHDNZ to HIGH.
# Wait for 1ms.
#
# Wake-up device by I2C write into P0_R2 using internal AREG
w 90 02 81
#
# Powerdown MICBIAS and ADC channels on fault detection (overtemperature, and so forth)
w 90 28 10
#
# Configure channel 1 DC-coupled, differential microphone input with high-swing mode
w 90 3C 18
#
# Configure channel 2 DC-coupled, differential microphone input with high-swing mode
w 90 41 18
#
# Configure channel 3 DC-coupled, differential microphone input with high-swing mode
w 90 46 18
#
# Configure channel 4 DC-coupled, differential microphone input with high-swing mode
w 90 4B 18
#
# Enable input channel 1 to channel 4 by I2C write into P0_R115
w 90 73 F0
#
# Enable ASI output channel 1 to channel 4 slots by I2C write into P0_R116
w 90 74 F0
#
# Power-up ADC,MICBIAS and PLL by I2C write into P0_R117
w 90 75 E0
#
# Apply FSYNC = 44.1 kHz and BCLK = 11.2896 MHz and
# Start recording data by host on ASI bus with TDM protocol 32-bit channel word length
#
# Wait for 10 ms.
# Enable diagnostics for channel 1 to channel 4 by I2C write into P0_R100
w 90 64 F0
#
```

9.2.1.3 Application Curves

DC-coupled differential microphone input with DC common-mode 1NxP = ~6 V and INxM = ~2 V, high swing mode enabled, measured using an external audio input source

图 229. FFT With a –60-dBr Input

DC-coupled differential microphone input with DC common-mode 1NxP = ~6 V and INxM = ~2 V, high swing mode enabled, measured using an external audio input source

图 230. THD+N vs Input Amplitude

9.3 What To Do and What Not To Do

In master mode operation with I^2S or LJ format, the device generates FSYNC half a cycle earlier than the normal protocol timing behavior expected. This timing behavior can still function for most of the system, however for further details and a suggested workaround for this weakness, see the *Configuring and Operating the PCM6xx0-Q1 as an Audio Bus Master* application report.

The automatic gain controller (AGC) feature has some limitation when using sampling rates lower than 44.1 kHz. For further details about this limitation, see the *Using the Automatic Gain Controller (AGC) in PCM6xx0-Q1* application report.

ADVANCE INFORMATION

10 Power Supply Recommendations

The power-supply sequence between the IOVDD and AVDD rails can be applied in any order. However, keep the SHDNZ pin low until the IOVDD supply voltage settles to a stable and supported operating voltage range. After the IOVDD and AVDD supplies are stable, set the SHDNZ pin high to initialize the device. BSTVDD (or HVDD for the PCM63x0-Q1) can be either applied along with AVDD or later but before turning on the MICBIAS. 图 231 shows the power supply sequencing requirements.

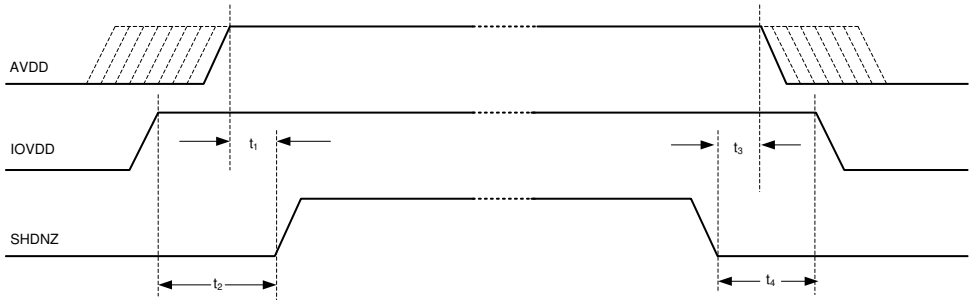

图 231. Power-Supply Sequencing Requirement

For the supply power-up requirement, t_1 and t_2 must be at least 100 µs. For the supply power-down requirement, t_3 and t_4 must be at least 10 ms. This time allows the device to ramp down the volume on the record data, and power down the analog and digital blocks, and lastly put the device into hardware shutdown mode. The device can also be immediately put into hardware shutdown mode from active mode if SHDNZ_CFG[1:0] is set to 2'b00 using the P0_R5_D[3:2] bits. In that case, t_3 and t_4 are required to be at least 100 µs.

Make sure that the supply ramp rate is faster than 1 V/µs and that the wait time between a power-down and a power-up event is at least 100 ms.

After the releasing SHDNZ, or after a software reset, delay any additional I^2C or SPI transactions to the device for at least 2 ms to allow the device to initialize the internal registers. See the *Device Functional Modes* section to operate the device in various modes after the device power supplies are settled to the recommended operating voltage levels.

11 Layout

11.1 Layout Guidelines

Each system design and printed circuit board (PCB) layout is unique. The layout must be carefully reviewed in the context of a specific PCB design. However, the following guidelines can optimize the device performance:

- Connect the thermal pad to ground. Use a via pattern to connect the device thermal pad, the area directly under the device, to the ground planes. This connection helps dissipate heat from the device.
- The boost converter inductor and decoupling capacitors for the power supplies must be placed close to the device pins.
- Route analog differential audio signals differentially on the PCB for better noise immunity. Avoid crossing digital and analog signals to avoid undesirable crosstalk.
- The device internal voltage references must be filtered using external capacitors. Place the filter capacitors near the VREF pin for optimal performance.
- Directly tap the MICBIAS pin to avoid common impedance when routing the biasing or supply for multiple microphones to avoid coupling across microphones.
- An external circuit must be used to suppress or filter the amount of high-frequency electromagnetic interference (EMI) noise found in the microphone input path resulting from long cables (if used) in the system.
- Use ground planes to provide the lowest impedance for power and signal current between the device and the decoupling capacitors. Treat the area directly under the device as a central ground area for the device, and all device grounds must be connected directly to that area.

12.7 静电放电警告

ESD 可能会损坏该集成电路。德州仪器 (TI) 建议通过适当的预防措施处理所有集成电路。如果不遵守正确的处理措施和安装程序，可能会损坏集成电路。

ESD 的损坏小至导致微小的性能降级，大至整个器件故障。 精密的集成电路可能更容易受到损坏，这是因为非常细微的参数更改都可能会导致器件与其发布的规格不相符。

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

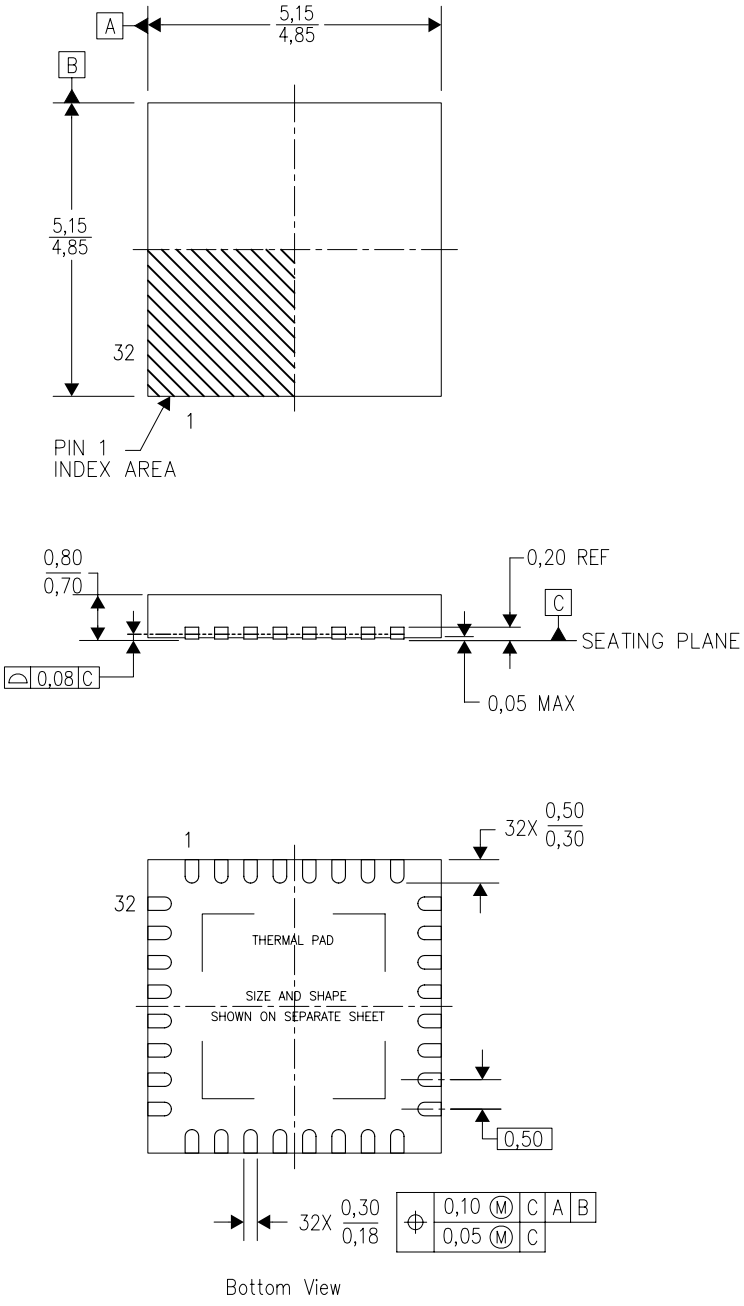

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
