

DAC121S101-SEP 12-Bit, Micro Power, RRO Digital-to-Analog Converter

1 Features

- Radiation tolerance:
 - Total ionizing dose (TID): 30krad (Si)
 - Single-event latch-up (SEL): 43MeV-cm²/mg
 - Single-event functional interrupt (SEFI): 43MeV-cm²/mg
- Space-enhanced plastic (space EP):
 - Outgassing test performed per ASTM E595
 - Vendor item drawing (VID) V62/24641
 - Supports defense and aerospace application temperature range: -55°C to +125°C
 - Controlled baseline
 - One assembly and test site
 - One fabrication site
 - Extended product life cycle
 - Product traceability
- Specified monotonicity
- Low-power operation
- Rail-to-rail voltage output
- Power-on reset to zero-scale output
- Wide power-supply range of 2.7V to 5.5V
- Small package:
 - 8-pin VSSOP (3mm × 3mm)
- Power-down feature
- Key specifications:
 - 12-bit resolution
 - DNL: -0.15LSB, +0.35LSB (typical)
 - 12µs output settling time (typical)
 - 4mV zero-code error (typical)
 - Full-scale error at -0.07%FSR (typical)

2 Applications

- Command and data handling (C and DH)
- Communications payload
- Optical imaging payload
- Radar imaging payload
- Satellite electrical power system (EPS)

3 Description

The DAC121S101-SEP device is a full-featured, general-purpose, 12-bit voltage-output digital-to-analog converter (DAC) that can operate from a single 2.7V to 5.5V supply and consumes just 177µA (typical) of current at 3.6V. The on-chip output amplifier allows rail-to-rail output swing and the three wire serial interface operates at clock rates up to 30MHz over the specified supply voltage range and is compatible with standard SPI, QSPI, MICROWIRE and DSP interfaces.

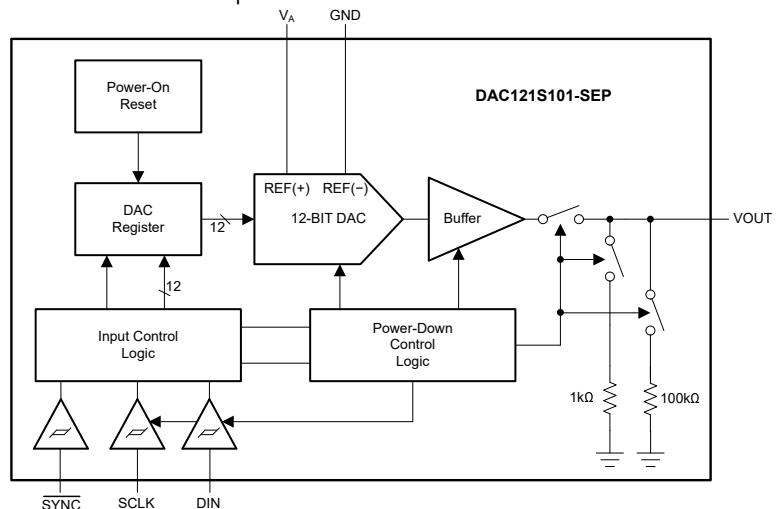

The supply voltage serves as the voltage reference for the DAC121S101-SEP, providing the widest possible output dynamic range. A power-on reset circuit powers up the DAC output to zero volts until there is a valid write to the device. A power-down feature reduces power consumption to less than a microwatt (typical).

Package Information

PART NUMBER	PACKAGE ⁽¹⁾	BODY SIZE ⁽²⁾
DAC121S101-SEP	DGK (VSSOP, 8)	3mm × 3mm

(1) For more information, see [Section 10](#).

(2) The body size (length × width) is a nominal value and does not include pins.

4 Pin Configuration and Functions

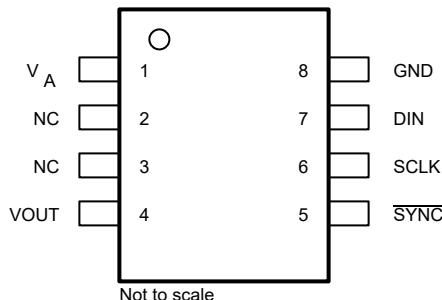

Figure 4-1. DAC121S101-SEP DGK Package, 8-Pin VSSOP (Top View)

Table 4-1. Pin Functions

PIN		TYPE	DESCRIPTION
NO.	NAME		
1	V _A	Power	Power supply and reference input. Decouple to the GND pin.
2	NC	—	Solder this pin to a pad.
3	NC	—	Solder this pin to a pad.
4	VOUT	Output	DAC analog output voltage
5	SYNC	Input	Frame synchronization input for the data input. When this pin goes low, this pin enables the input shift register and data are transferred on the falling edges of SCLK. The DAC is updated on the 16th clock cycle unless SYNC is brought high before the 16th clock, in which case the rising edge of SYNC acts as an interrupt and the write sequence is ignored by the DAC.
6	SCLK	Input	Serial clock input. Data are clocked into the input shift register on the falling edges of this pin.
7	DIN	Input	Serial data input. Data are clocked into the 16-bit shift register on the falling edges of SCLK after the fall of SYNC.
8	GND	Ground	Ground reference for all on-chip circuitry.

5 Specifications

5.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
V _A	Supply voltage, V _A to GND	–0.3	6.5	V
	Voltage on any input pin to GND	–0.3	V _A + 0.3	V
	Input current at any pin ⁽²⁾		10	mA
	Package input current ⁽²⁾		20	mA
	Power consumption at T _A = 25°C		See ⁽³⁾	
	Soldering temperature, infrared, 10s ⁽⁴⁾		235	°C
T _J	Junction temperature		150	°C
T _{stg}	Storage temperature	–65	150	°C

- (1) Operation outside the *Absolute Maximum Ratings* may cause permanent device damage. *Absolute Maximum Ratings* do not imply functional operation of the device at these or any other conditions beyond those listed under *Recommended Operating Conditions*. If used outside the *Recommended Operating Conditions* but within the *Absolute Maximum Ratings*, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.
- (2) When the input voltage at any pin exceeds the power supplies (that is, less than GND, or greater than V_A), the current at that pin must be limited to 10mA. The 20mA maximum package input current rating limits the number of pins that can safely exceed the power supplies with an input current of 10mA to two.
- (3) The absolute maximum junction temperature (T_{JMAX}) for this device is 150°C. The maximum allowable power dissipation is dictated by T_{JMAX}, the junction-to-ambient thermal resistance (θ_{JA}), and the ambient temperature (T_A), and can be calculated using the formula P_{DMAX} = (T_{JMAX} – T_A) / θ_{JA}. The values for maximum power dissipation will be reached only when the device is operated in a severe fault condition (for example, when input or output pins are driven beyond the power supply voltages, or the power supply polarity is reversed). Obviously, such conditions must always be avoided.
- (4) See the section entitled *Surface Mount* found in any post 1986 National Semiconductor Linear Data Book for methods of soldering surface mount devices.

5.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins ⁽¹⁾	±2500	V
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins ⁽²⁾	±500	

(1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _A	Supply voltage to GND	2.7		5.5	V
	Any input voltage to GND ⁽¹⁾	–0.1		(V _A + 0.1)	V
C _L	Output load capacitance	0		1500	pF
f _{SCLK}	SCLK frequency			30	MHz
T _A	Operating ambient temperature	–55		125	°C

- (1) Errors in the conversion result can occur if any input goes greater than V_A or less than GND by more than 100mV. For example, if V_A is 2.7VDC, make sure that –100mV ≤ input voltages ≤ +2.8VDC for accurate conversions.

5.4 Thermal Information

THERMAL METRIC ⁽¹⁾		DAC121S101-SEP	UNIT
		DGK (VSSOP)	
		8 PINS	
R _{θJA}	Junction-to-ambient thermal resistance	240	°C/W

- (1) For information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics application report*.

5.5 Electrical Characteristics

all minimum and maximum values at $-55^{\circ}\text{C} \leq T_A \leq +125^{\circ}\text{C}$ and all typical values at $T_A = 25^{\circ}\text{C}$, $2.7\text{V} \leq V_A \leq 5.5\text{V}$, DAC output pin (VOUT) loaded with resistive load ($R_L = 2\text{k}\Omega$ to AGND) and capacitive load ($C_L = 200\text{pF}$ to AGND), $f_{\text{SCLK}} = 30\text{MHz}$, and input code range: 48d to 4047d (unless otherwise noted)

6 Detailed Description

6.1 Overview

The DAC121S101-SEP device is a full-featured, general-purpose, 12-bit voltage-output digital-to-analog converter (DAC) with a 12 μ s (typ) settling time. Control of the output of the DAC is achieved over a 3-wire SPI. After the DAC output is set, additional communication with the DAC is not required unless the output condition must be changed. Likewise, the DAC121S101-SEP power-on state is 0V. The DAC output remains at 0V until a valid write sequence is made.

A unique benefit of the DAC121S101-SEP is the logic levels of the SPI input pins. The logic levels of SCLK, DIN, and SYNC are independent of V_A . As a result, the DAC121S101-SEP can operate at a supply voltage (V_A) that is higher than the microcontroller controlling the DAC. This feature is advantageous in applications where the analog circuitry is being run at 5V to maximize signal-to-noise ratio, and digital logic is running at 3V to conserve power.

6.2 Functional Block Diagram

6.3 Feature Description

6.3.1 DAC Section

The DAC121S101-SEP is fabricated on a CMOS process with an architecture that consists of switches and a resistor string that are followed by an output buffer. The power supply serves as the reference voltage. The input coding is straight binary with an ideal output voltage of [Equation 1](#):

$$V_{OUT} = V_A \times \left(\frac{D}{4096} \right) \quad (1)$$

where

- D is the decimal equivalent of the binary code that is loaded into the DAC register and can take on any value between 0 and 4095.

6.3.2 Resistor String

Figure 6-1 shows the resistor string. This string consists of 4096 equal-valued resistors with a switch at each junction of two resistors, plus a switch to ground. The code loaded into the DAC register determines which switch is closed, connecting the proper node to the amplifier. This configuration keeps the DAC monotonic.

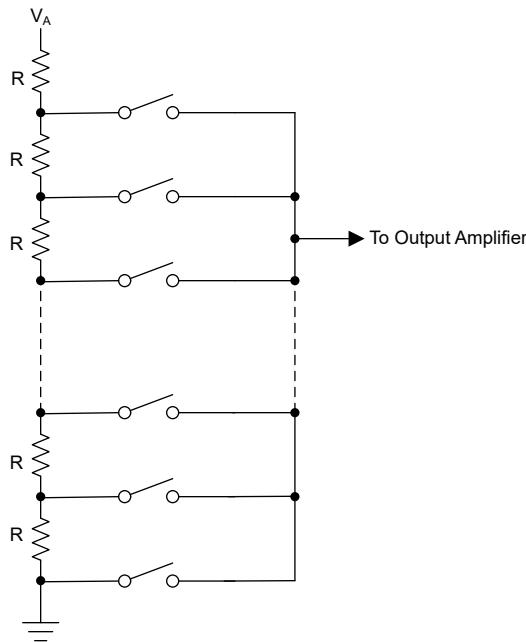

Figure 6-1. DAC Resistor String

6.3.3 Output Amplifier

The output buffer amplifier is a rail-to-rail type, providing an output voltage range of 0V to V_A . All amplifiers, even rail-to-rail types, exhibit a loss of linearity as the output approaches the supply rails (0V and V_A , in this case). For this reason, linearity is specified over less than the full output range of the DAC. The output capabilities of the amplifier are described in the *Electrical Characteristics*.

6.4 Device Functional Modes

6.4.1 Power-On Reset

The power-on reset circuit controls the output voltage during power-up. Upon application of power the DAC register is filled with zeros and the output voltage is 0V and remains there until a valid write sequence is made to the DAC.

6.4.2 Power-Down Modes

Table 6-1 lists the DAC121S101-SEP four modes of operation. These modes are set with two bits (DB13 and DB12) in the control register.

Table 6-1. Modes of Operation

DB13	DB12	OPERATING MODE
0	0	Normal operation
0	1	Power-down with 1kΩ to GND
1	0	Power-down with 100kΩ to GND
1	1	Power-down with Hi-Z

When both DB13 and DB12 are 0, the device operates normally. For the other three possible combinations of these bits the supply current drops to the power-down level and the output is pulled down with either a 1kΩ or a 100kΩ resistor, or is in a high-impedance state, as described in [Table 6-1](#).

The bias generator, output amplifier, the resistor string and other linear circuitry are shut down in any of the power-down modes. However, the contents of the DAC register are unaffected when in power-down; therefore, when coming out of power down, the output voltage returns to the same voltage before entering power down. Minimum power consumption is achieved in the power-down mode with SCLK disabled and SYNC and DIN idled low. The time to exit power-down (the wake-up time) is typically t_{WU} (μs) as stated in the *Dynamic Performance* section of the *Electrical Characteristics* table.

6.5 Programming

6.5.1 Serial Interface

The three-wire interface is compatible with SPI, QSPI and MICROWIRE, as well as most DSPs. See [Figure 5-1](#) for information on a write sequence.

A write sequence begins by bringing the SYNC line low. After SYNC is low, the data on the DIN line is clocked into the 16-bit serial input register on the falling edges of SCLK. On the 16th falling clock edge, the last data bit is clocked in, and the programmed function (a change in the mode of operation, a change in the DAC register contents, or both) is executed. At this point, the SYNC line can be kept low or brought high. In either case, bring the SYNC line high for the minimum specified time before the next write sequence because a falling edge of SYNC can initiate the next write cycle.

The SYNC and DIN buffers draw more current when high; therefore, idle these buffers low between write sequences to minimize power consumption.

6.5.2 Input Shift Register

The input shift register, [Figure 6-2](#), has sixteen bits. The first two bits are *don't care* bits, and are followed by two bits that determine the mode of operation (normal mode or one-of-three power-down modes). The contents of the serial input register are transferred to the DAC register on the sixteenth falling edge of SCLK. See also [Figure 5-1](#).

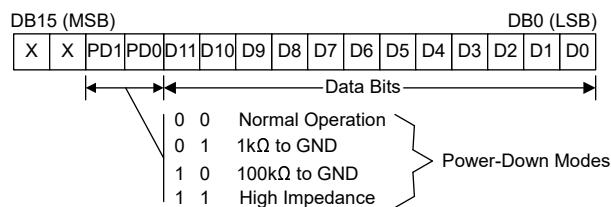

Figure 6-2. Input Register Contents

Normally, the SYNC line is kept low for at least 16 falling edges of SCLK and the DAC is updated on the 16th SCLK falling edge. However, if SYNC is brought high before the 16th falling edge, the shift register is reset and the write sequence is invalid. In this case, the DAC register is not updated, and there is no change in the mode of operation or in the output voltage.

7 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

7.1 Application Information

7.1.1 Bipolar Operation

The DAC121S101-SEP is designed for single-supply operation, and thus has a unipolar output. However, a bipolar output can be obtained with the circuit in [Figure 7-1](#). This circuit provides an output voltage range of $\pm 5V$.

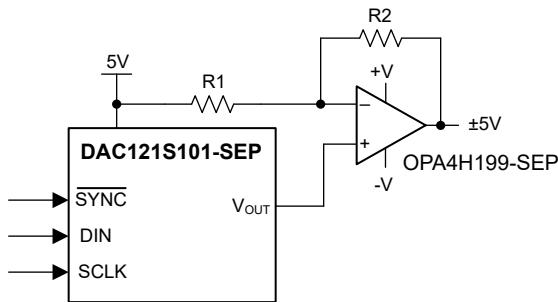

Figure 7-1. Bipolar Operation

The output voltage of this circuit for any code is found using [Equation 2](#):

$$V_0 = V_A \times \left(\frac{D}{4096} \right) \times \left(\frac{R1 + R2}{R1} \right) - V_A \times \frac{R2}{R} \quad (2)$$

where

- D is the input code in decimal form.

With $V_A = 5V$ and $R1 = R2$, [Equation 3](#) shows the result:

$$V_0 = \left(\frac{10 \times D}{4096} \right) - 5V \quad (3)$$

7.2 Typical Application

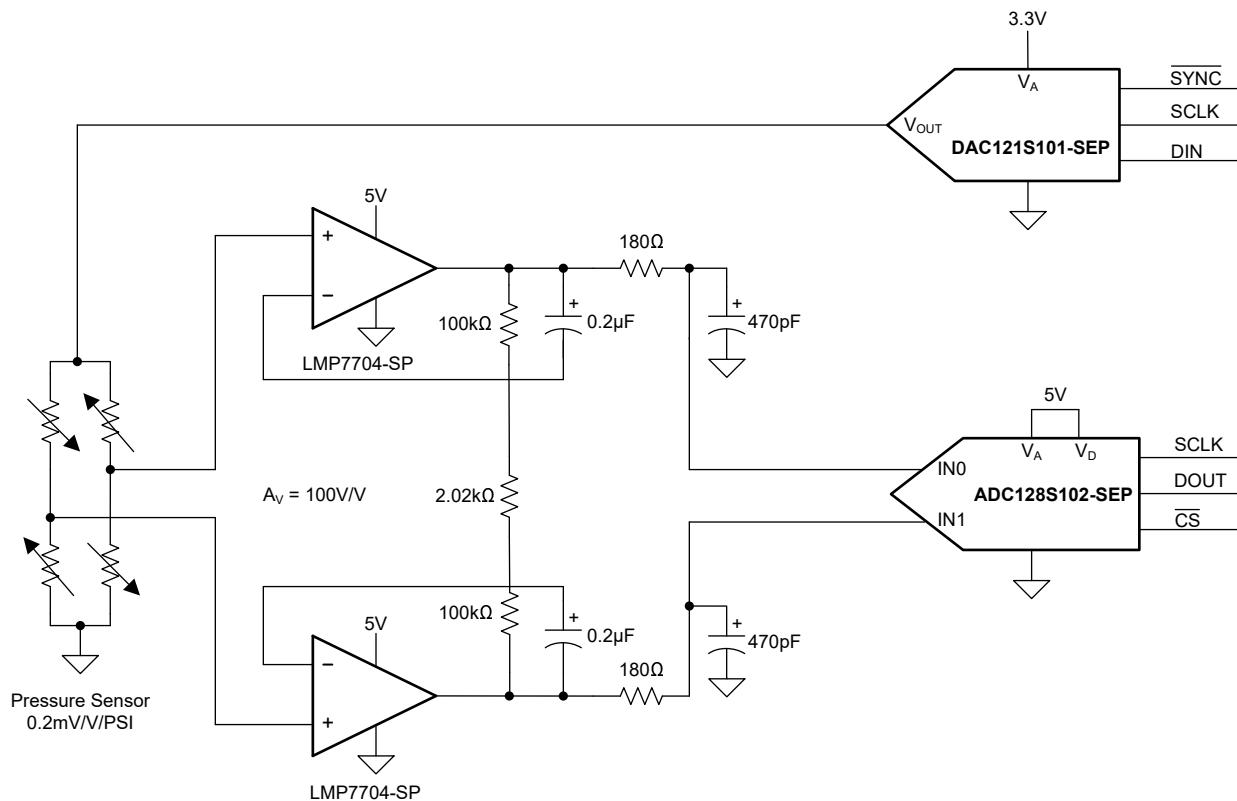

Figure 7-2. Pressure Sensor Gain Adjust

7.2.1 Design Requirements

Design a single supply data acquisition system capable of digitizing a pressure sensor output. In addition to digitizing the pressure sensor output, use the DAC121S101-SEP to correct gain errors in the pressure sensor output by adjusting the bias voltage to the bridge pressure sensor. [Table 7-1](#) lists the design parameters for DAC121S101-SEP.

Table 7-1. DAC121S101-SEP Design Parameters

PARAMETER	VALUE
V _A	3.3V to 5V
DAC output range	0V to 5V

7.2.2 Detailed Design Procedure

Equation 4 shows that the output of the pressure sensor is relative to the imbalance of the resistive bridge times the output of the DAC121S101-SEP, thus providing the desired gain correction.

$$\text{Pressure Sensor Output} = \text{DAC_Output} \times \left[\left(\frac{R1}{R1 + R2} \right) - \left(\frac{R4}{R3 + R4} \right) \right] \quad (4)$$

Likewise for the ADC128S102-SEP, Equation 5 shows that the ADC output is function of the pressure sensor output times relative to the ratio of the ADC input divided by the DAC121S101-SEP output voltage.

$$\text{ADC128S102-SEP Output} = \left(\text{Pressure Sensor Output} \times \left(\frac{100}{2 \times VREF} \right) \right) \times 2^{12} \quad (5)$$

7.2.3 Application Curve

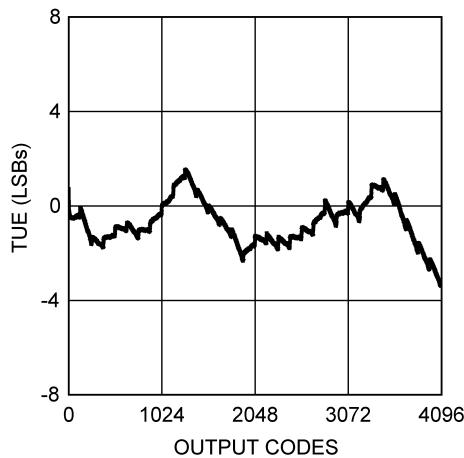

Figure 7-3. Total Unadjusted Error vs Output Code

7.3 Power Supply Recommendations

A precision analog component requires careful layout, adequate bypassing, and clean, well-regulated power supplies. The power applied to the V_A pin must be well regulated and low noise. Switching power supplies and DC/DC converters often have high-frequency glitches or spikes riding on the output voltage. In addition, digital components can create similar high-frequency spikes as internal logic states switch. This noise can easily couple into the DAC output voltage through various paths between the power connections and analog output. As with the ground connection, connect V_A to a power supply plane or trace that is separate from the connection for digital logic until V_A is connected at the power entry point.

Bypass the DAC121S101-SEP power supply with $10\mu\text{F}$ and $0.1\mu\text{F}$ capacitors, as close as possible to the device with the $0.1\mu\text{F}$ directly at the device supply pin. The $0.1\mu\text{F}$ capacitor must be a low ESL, low ESR type. Decouple the power supply of DAC121S101-SEP from noisy circuits.

7.4 Layout

7.4.1 Layout Guidelines

For best accuracy and minimum noise, the printed-circuit-board (PCB) that contains the DAC121S101-SEP must have separate analog and digital areas. The areas are defined by the locations of the analog and digital power planes. Both of these planes must be located in the same board layer. Use a single ground plane; a single ground plane is preferred if digital return current does not flow through the analog ground area. Frequently a single ground plane design uses a *fencing* technique to prevent the mixing of analog and digital ground current. Only use separate ground planes when the fencing technique is inadequate. Connect the separate ground planes in one place, preferably near the DAC121S101-SEP. Take special care to make sure digital signals with fast edge rates do not pass over split ground planes. The digital signals must always have a continuous return path below the traces.

Avoid crossover of analog and digital signals and keep the clock and data lines on the component side of the board. The clock and data lines must have controlled impedance.

8 Device and Documentation Support

8.1 Documentation Support

8.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. Click on *Notifications* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

8.3 Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

8.4 Trademarks

TI E2E™ is a trademark of Texas Instruments.

All trademarks are the property of their respective owners.

8.5 Electrostatic Discharge Caution

 This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

8.6 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

9 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

DATE	REVISION	NOTES
December 2024	*	Initial Release

10 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable part number	Status (1)	Material type (2)	Package Pins	Package qty Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)
DAC121S101DGKTSEP	Active	Production	VSSOP (DGK) 8	250 SMALL T&R	Yes	NIPDAU	Level-2-260C-1 YEAR	-55 to 125	121S
DAC121S101DGKTSEP.A	Active	Production	VSSOP (DGK) 8	250 SMALL T&R	Yes	NIPDAU	Level-2-260C-1 YEAR	-55 to 125	121S
V62/24641-01XE	Active	Production	VSSOP (DGK) 8	250 SMALL T&R	Yes	NIPDAU	Level-2-260C-1 YEAR	-55 to 125	121S

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided.
