

# Low-Power, Rail-to-Rail Output, 16-Bit Serial Input DIGITAL-TO-ANALOG CONVERTER

## FEATURES

- **microPower OPERATION: 250 $\mu$ A at 5V**
- **POWER-ON RESET TO ZERO**
- **POWER SUPPLY: +2.7V to +5.5V**
- **ENSURED MONOTONIC BY DESIGN**
- **SETTLING TIME: 10 $\mu$ s to  $\pm 0.003$  FSR**
- **LOW-POWER SERIAL INTERFACE WITH SCHMITT-TRIGGERED INPUTS**
- **ON-CHIP OUTPUT BUFFER AMPLIFIER, RAIL-TO-RAIL OPERATION**
- **SYNC INTERRUPT FACILITY**
- **PACKAGES: MSOP-8 and 3x3 SON-8 (same size as QFN)**

## APPLICATIONS

- PROCESS CONTROL
- DATA ACQUISITION SYSTEMS
- CLOSED-LOOP SERVO-CONTROL
- PC PERIPHERALS
- PORTABLE INSTRUMENTATION
- PROGRAMMABLE ATTENUATION

## DESCRIPTION

The DAC8531 is a low-power, single, 16-bit buffered voltage output Digital-to-Analog Converter (DAC). Its on-chip precision output amplifier allows rail-to-rail output swing to be achieved. The DAC8531 uses a versatile three-wire serial interface that operates at clock rates up to 30MHz and is compatible with standard SPI™, QSPI™, Microwire™, and Digital Signal Processor (DSP) interfaces.

The DAC8531 requires an external reference voltage to set the output range of the DAC. The DAC8531 incorporates a power-on reset circuit that ensures that the DAC output powers up at 0V and remains there until a valid write takes place to the device. The DAC8531 contains a power-down feature, accessed over the serial interface, that reduces the current consumption of the device to 200nA at 5V.

The low power consumption of this part in normal operation makes it ideally suited to portable battery-operated equipment. The power consumption is 2mW at 5V reducing to 1μW in power-down mode.

The DAC8531 is available in both MSOP-8 and 3x3 SON-8 (same size as QFN) packages.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

## ABSOLUTE MAXIMUM RATINGS<sup>(1)</sup>

|                                               |                                      |
|-----------------------------------------------|--------------------------------------|
| $V_{DD}$ to GND .....                         | –0.3V to +6V                         |
| Digital Input Voltage to GND .....            | –0.3V to $V_{DD} + 0.3V$             |
| $V_{OUT}$ to GND .....                        | –0.3V to $V_{DD} + 0.3V$             |
| Operating Temperature Range .....             | –40°C to +105°C                      |
| Storage Temperature Range .....               | –65°C to +150°C                      |
| Junction Temperature Range ( $T_J$ max) ..... | +150°C                               |
| Power Dissipation .....                       | ( $T_J$ max — $T_A$ )/ $\theta_{JA}$ |
| $\theta_{JA}$ Thermal Impedance .....         | 206°C/W                              |
| $\theta_{JC}$ Thermal Impedance .....         | 44°C/W                               |
| Lead Temperature, Soldering:                  |                                      |
| Vapor Phase (60s) .....                       | +215°C                               |
| Infrared (15s) .....                          | +220°C                               |

NOTE: (1) Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. Exposure to absolute maximum conditions for extended periods may affect device reliability.

## ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

## PIN CONFIGURATIONS

## PIN DESCRIPTION

| PIN | NAME              | DESCRIPTION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | $V_{DD}$          | Power-Supply Input, $+2.7V$ to $+5.5V$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2   | $V_{REF}$         | Reference Voltage Input                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 3   | $V_{FB}$          | Feedback connection for the output amplifier.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 4   | $V_{OUT}$         | Analog output voltage from DAC. The output amplifier has rail-to-rail operation.                                                                                                                                                                                                                                                                                                                                                                                                            |
| 5   | $\overline{SYNC}$ | Level-triggered control input (active LOW). This is the frame synchronization signal for the input data. When $\overline{SYNC}$ goes LOW, it enables the input shift register and data is transferred in on the falling edges of the following clocks. The DAC is updated following the 24th clock cycle unless $\overline{SYNC}$ is taken HIGH before this edge, in which case the rising edge of $\overline{SYNC}$ acts as an interrupt and the write sequence is ignored by the DAC8531. |
| 6   | SCLK              | Serial Clock Input. Data can be transferred at rates up to 30MHz.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 7   | $D_{IN}$          | Serial Data Input. Data is clocked into the 24-bit input shift register on the falling edge of the serial clock input.                                                                                                                                                                                                                                                                                                                                                                      |
| 8   | GND               | Ground reference point for all circuitry on the part.                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# TIMING CHARACTERISTICS<sup>(1, 2)</sup>

$V_{DD} = +2.7V$  to  $+5.5V$ ; all specifications  $-40^{\circ}C$  to  $+105^{\circ}C$  unless otherwise noted.

## THEORY OF OPERATION

### DAC SECTION

The architecture consists of a string DAC followed by an output buffer amplifier. Figure 1 shows a block diagram of the DAC architecture.

FIGURE 1. DAC8531 Architecture.

The input coding to the DAC8531 is straight binary, so the ideal output voltage is given by:

$$V_{OUT} = V_{REF} \cdot \frac{D}{65536}$$

where  $D$  = decimal equivalent of the binary code that is loaded to the DAC register; it can range from 0 to 65535.

### RESISTOR STRING

Figure 2 shows the resistor string section. It is simply a string of resistors, each of value  $R$ . The code loaded into the DAC register determines at which node on the string the voltage is tapped off to be fed into the output amplifier by closing one of the switches connecting the string to the amplifier. It is ensured monotonic because it is a string of resistors.

FIGURE 2. Resistor String.

OUTPUT AMPLIFIER

The output buffer amplifier is capable of generating rail-to-rail voltages on its output which gives an output range of 0V to V<sub>DD</sub>. It is capable of driving a load of 2kΩ in parallel with 1000pF to GND. The source and sink capabilities of the output amplifier can be seen in the typical curves. The slew rate is 1V/μs with a full-scale settling time of 8μs with the output unloaded.

The inverting input of the output amplifier is brought out to the V<sub>FB</sub> pin. This allows for better accuracy in critical applications by tying the V<sub>FB</sub> point and the amplifier output together directly at the load. Other signal conditioning circuitry may also be connected between these points for specific applications.

SERIAL INTERFACE

The DAC8531 has a three-wire serial interface (SYNC, SCLK, and D<sub>IN</sub>), which is compatible with SPI, QSPI, and Microwire interface standards as well as most DSPs. See the Serial Write Operation timing diagram for an example of a typical write sequence.

The write sequence begins by bringing the SYNC line LOW. Data from the D<sub>IN</sub> line is clocked into the 24-bit shift register on the falling edge of SCLK. The serial clock frequency can be as high as 30MHz, making the DAC8531 compatible with high-speed (DSPs). On the 24th falling edge of the serial clock, the last data bit is clocked in and the programmed function is executed (i.e., a change in DAC register contents and/or a change in the mode of operation).

At this point, the SYNC line may be kept LOW or brought HIGH. In either case, it must be brought HIGH for a minimum of 33ns before the next write sequence so that a falling edge of SYNC can initiate the next write sequence. Since the

SYNC buffer draws more current when the SYNC signal is HIGH than it does when it is LOW, SYNC should be idled LOW between write sequences for lowest power operation of the part. As mentioned above, it must be brought HIGH again just before the next write sequence.

INPUT SHIFT REGISTER

The input shift register is 24 bits wide, as shown in Figure 3. The first six bits are “don’t cares”. The next two bits (PD1 and PD0) are control bits that control which mode of operation the part is in (normal mode or any one of three power-down modes). There is a more complete description of the various modes in the Power-Down Modes section. The next 16 bits are the data bits. These are transferred to the DAC register on the 24th falling edge of SCLK.

SYNC INTERRUPT

In a normal write sequence, the SYNC line is kept LOW for at least 24 falling edges of SCLK and the DAC is updated on the 24th falling edge. However, if SYNC is brought HIGH before the 24th falling edge, this acts as an interrupt to the write sequence. The shift register is reset and the write sequence is seen as invalid. Neither an update of the DAC register contents or a change in the operating mode occurs, as shown in Figure 4.

POWER-ON RESET

The DAC8531 contains a power-on reset circuit that controls the output voltage during power-up. On power-up, the DAC register is filled with zeros and the output voltage is 0V; it remains there until a valid write sequence is made to the DAC. This is useful in applications where it is important to know the state of the output of the DAC while it is in the process of powering up.

FIGURE 3. Data Input Register.

FIGURE 4. SYNC Interrupt Facility.

## POWER-DOWN MODES

The DAC8531 supports four separate modes of operation. These modes are programmable by setting two bits (PD1 and PD0) in the control register. Table I shows how the state of the bits corresponds to the mode of operation of the device.

| PD1 (DB17) | PD0 (DB16) | OPERATING MODE      |
|------------|------------|---------------------|
| 0          | 0          | Normal Operation    |
| —          | —          | Power-Down Modes    |
| 0          | 1          | Output 1kΩ to GND   |
| 1          | 0          | Output 100kΩ to GND |
| 1          | 1          | High-Z              |

TABLE I. Modes of Operation for the DAC8531.

When both bits are set to 0, the part works normally with its typical current consumption of 250μA at 5V. However, for the three power-down modes, the supply current falls to 200nA at 5V (50nA at 3V). Not only does the supply current fall, but the output stage is also internally switched from the output of the amplifier to a resistor network of known values. This has the advantage that the output impedance of the part is known while the part is in power-down mode. There are three different options. The output is connected internally to GND through a 1kΩ resistor, a 100kΩ resistor, or it is left open-circuited (High-Z). The output stage is illustrated in Figure 5.

FIGURE 5. Output Stage During Power-Down.

All linear circuitry is shut down when the power-down mode is activated. However, the contents of the DAC register are unaffected when in power-down. The time to exit power-down is typically 2.5μs for  $V_{DD} = 5V$ , and 5μs for  $V_{DD} = 3V$ . See the Typical Characteristics for more information.

## MICROPROCESSOR INTERFACING

### DAC8531 TO 8051 INTERFACE

Figure 6 shows a serial interface between the DAC8531 and a typical 8051-type microcontroller. The setup for the interface is as follows: TXD of the 8051 drives SCLK of the DAC8531, while RXD drives the serial data line of the part. The SYNC signal is derived from a bit-programmable pin on the port. In this case, port line P3.3 is used. When data is to be transmitted to the DAC8531, P3.3 is taken LOW. The 8051 transmits data only in 8-bit bytes; thus only eight falling clock edges occur in the transmit cycle. To load data to the DAC, P3.3 is left LOW after the first eight bits are transmitted and a second write cycle is initiated to transmit the second byte of data. P3.3 is taken HIGH following the completion of the third write cycle. The 8051 outputs the serial data in a format which has the LSB first. The DAC8531 requires its data with the MSB as the first bit received. The 8051 transmit routine must therefore take this into account, and "mirror" the data as needed.

FIGURE 6. DAC8531 to 80C51/80L51 Interface.

### DAC8531 TO Microwire INTERFACE

Figure 7 shows an interface between the DAC8531 and any Microwire compatible device. Serial data is shifted out on the falling edge of the serial clock and is clocked into the DAC8531 on the rising edge of the SK signal.

FIGURE 7. DAC8531 to Microwire Interface.

## DAC8531 TO 68HC11 INTERFACE

Figure 8 shows a serial interface between the DAC8531 and the 68HC11 microcontroller. SCK of the 68HC11 drives the SCLK of the DAC8531, while the MOSI output drives the serial data line of the DAC. The  $\overline{\text{SYNC}}$  signal is derived from a port line (PC7), similar to what was done for the 8051.

FIGURE 8. DAC8531 to 68HC11 Interface.

The 68HC11 should be configured so that its CPOL bit is a 0 and its CPHA bit is a 1. This configuration causes data appearing on the MOSI output to be valid on the falling edge of SCK. When data is being transmitted to the DAC, the  $\overline{\text{SYNC}}$  line is taken LOW (PC7). Serial data from the 68HC11 is transmitted in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle. Data is transmitted MSB first. In order to load data to the DAC8531, PC7 is left LOW after the first eight bits are transferred, then a second and third serial write operation is performed to the DAC and PC7 is taken HIGH at the end of this procedure.

## APPLICATIONS

### USING REF02 AS A POWER SUPPLY FOR THE DAC8531

Due to the extremely low supply current required by the DAC8531, an alternative option is to use a REF02 +5V precision voltage reference to supply the required voltage to the part, as shown in Figure 9. This is especially useful if the

FIGURE 9. REF02 as a Power Supply to the DAC8531.

power supply is quite noisy or if the system supply voltages are at some value other than 5V. The REF02 will output a steady supply voltage for the DAC8531. If the REF02 is used, the typical current it needs to supply to the DAC8531 is 250µA. This is with no load on the output of the DAC. When the DAC output is loaded, the REF02 also needs to supply the current to the load. The total current required (with a 5kΩ load on the DAC output) is:

$$250\mu\text{A} + (5\text{V}/5\text{k}\Omega) = 1.29\text{mA}$$

The load regulation of the REF02 is typically 0.005%/mA, which results in an error of 322µV for the 1.29mA current drawn from it. This corresponds to a 4.2LSB error.

### BIPOLAR OPERATION USING THE DAC8531

The DAC8531 has been designed for single-supply operation but a bipolar output range is also possible using the circuit in Figure 10. The circuit shown will give an output voltage range of  $\pm V_{\text{REF}}$ . Rail-to-rail operation at the amplifier output is achievable using an OPA703 as the output amplifier.

The output voltage for any input code can be calculated as follows:

$$V_O = \left[ V_{\text{REF}} \cdot \left( \frac{D}{65536} \right) \cdot \left( \frac{R_1 + R_2}{R_1} \right) - V_{\text{REF}} \cdot \left( \frac{R_2}{R_1} \right) \right]$$

where D represents the input code in decimal (0–65535).

With  $V_{\text{REF}} = 5\text{V}$ ,  $R_1 = R_2 = 10\text{k}\Omega$ :

$$V_O = \left( \frac{10 \cdot D}{65536} \right) - 5\text{V}$$

This is an output voltage range of  $\pm 5\text{V}$  with 0000<sub>H</sub> corresponding to a –5V output and FFFF<sub>H</sub> corresponding to a +5V output. Similarly, using  $V_{\text{REF}} = 2.5\text{V}$ ,  $\pm 2.5\text{V}$  output voltage range can be achieved.

## LAYOUT

A precision analog component requires careful layout, adequate bypassing, and clean, well-regulated power supplies.

As the DAC8531 offers single-supply operation, it will often be used in close proximity with digital logic, microcontrollers, microprocessors, and digital signal processors. The more digital logic present in the design and the higher the switching speed, the more difficult it will be to keep digital noise from appearing at the output.

Due to the single ground pin of the DAC8531, all return currents, including digital and analog return currents, must flow through the GND pin. Ideally, GND would be connected directly to an analog ground plane. This plane would be separate from the ground connection for the digital components until they were connected at the power-entry point of the system.

The power applied to  $V_{DD}$  should be well regulated and low noise. Switching power supplies and DC/DC converters will often have high-frequency glitches or spikes riding on the output voltage. In addition, digital components can create similar high-frequency spikes as their internal logic switches states. This noise can easily couple into the DAC output voltage through various paths between the power connections and analog output.

As with the GND connection,  $V_{DD}$  should be connected to a +5V power-supply plane or trace that is separate from the connection for digital logic until they are connected at the power-entry point. In addition, the  $1\mu\text{F}$  to  $10\mu\text{F}$  and  $0.1\mu\text{F}$  bypass capacitors are strongly recommended. In some situations, additional bypassing may be required, such as a  $100\mu\text{F}$  electrolytic capacitor or even a "Pi" filter made up of inductors and capacitors—all designed to essentially low-pass filter the +5V supply, removing the high-frequency noise.

<sup>(1)</sup> **Status:** For more details on status, see our [product life cycle](#).

<sup>(2)</sup> **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

<sup>(3)</sup> **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

<sup>(4)</sup> **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

<sup>(6)</sup> **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. 8. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.
9. Size of metal pad may vary due to creepage requirement.

## EXAMPLE STENCIL DESIGN

DGK0008A

<sup>TM</sup> VSSOP - 1.1 mm max height

SMALL OUTLINE PACKAGE

SOLDER PASTE EXAMPLE  
SCALE: 15X

4214862/A 04/2023

NOTES: (continued)

11. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
12. Board assembly site may have different recommendations for stencil design.

**DRB 8**

**GENERIC PACKAGE VIEW**

**VSON - 1 mm max height**

PLASTIC SMALL OUTLINE - NO LEAD

Images above are just a representation of the package family, actual package may vary.  
Refer to the product data sheet for package details.

4203482/L

4218876/A 12/2017

## NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.

NOTES: (continued)

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 ([www.ti.com/lit/sluea271](http://www.ti.com/lit/sluea271)).
5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.

# EXAMPLE STENCIL DESIGN

DRB0008B

VSON - 1 mm max height

PLASTIC SMALL OUTLINE - NO LEAD

SOLDER PASTE EXAMPLE  
BASED ON 0.125 mm THICK STENCIL

EXPOSED PAD  
81% PRINTED SOLDER COVERAGE BY AREA  
SCALE:25X

4218876/A 12/2017

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

## IMPORTANT NOTICE AND DISCLAIMER
