3 Description

The ISOW7721 device is a galvanically-isolated dual-channel digital isolator with an integrated high-efficiency power converter with low emissions. The integrated DC-DC converter provides up to 550 mW of isolated power, eliminating the need for a separate isolated power supply in space-constrained isolation designs. If additional power is needed, the ISOW7721 supports multi-device chaining, increasing the integrated power output to > 1 W using two devices in a system.

5 Description (continued)

The high-efficiency of the power converter allows for operation at a wide operating ambient temperature range of –40°C to +125°C. This device provides improved emissions performance, allowing for simplified board design and has provisions for ferrite beads to further attenuate emissions. The ISOW7721 has been designed with enhanced protection features in mind, including soft-start to limit inrush current, over-voltage and under-voltage lock out, overload and short-circuit protection, and thermal shutdown.

The ISOW7721 provide high electromagnetic immunity while isolating CMOS or LVCMOS digital I/Os. The signal-isolation channel has a logic input and output buffer separated by a double capacitive silicon dioxide (SiO_2) insulation barrier, whereas, power isolation uses on-chip transformers separated by thin film polymer as insulating material. The ISOW7721 has 1 forward channel and 1 reverse channel. If the input signal is lost, the default output is high for the ISOW7721 device without the F suffix and low for the ISOW7721F with the F suffix. The ISOW7721 can operate from a single supply voltage of 3 V to 5.5 V by connecting V_{IO} and V_{DD} together on a PCB. If lower logic levels are required, these devices support 1.71 V to 5.5 V logic supply (V_{IO}) that can be independent from the power converter supply (V_{DD}) of 3 V to 5.5 V. V_{ISOIN} and V_{ISOOUT} need to be connected on board with either a ferrite bead or fed through a LDO.

These devices help prevent noise currents on data buses, such as UART, RS-485, RS-232, and CAN, or other circuits from entering the local ground and interfering with or damaging sensitive circuitry. Through innovative chip design and layout techniques, electromagnetic compatibility of the device has been significantly enhanced to ease system-level ESD, EFT, surge and emissions compliance. The device is available in a 20-pin SOIC wide-body (SOIC-WB) DFM package.

Creepage and clearance on a printed-circuit board become equal in certain cases. Techniques such as inserting grooves, ribs, or both on a printed circuit board are used to help increase these specifications.

7.8 Safety Limiting Values

Safety limiting intends to minimize potential damage to the isolation barrier upon failure of input or output circuitry.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I_S	Safety input, output, or supply current(1)	$R_{\theta JA}$ = 68.5°C/W, V_I = 5.5 V, T_J = 150°C, T_A = 25°C			332	mA
		$R_{\theta JA}$ = 68.5°C/W, V_I = 3.6 V, T_J = 150°C, T_A = 25°C			507	
P_S	Safety input, output, or total power(1)	$R_{\theta JA}$ = 68.5°C/W, T_J = 150°C, T_A = 25°C			1825	mW
T_S	Maximum safety temperature(1)				150	°C

(1) The maximum safety temperature, T_S, has the same value as the maximum junction temperature, T_J, specified for the device. The I_S and P_S parameters represent the safety current and safety power respectively. The maximum limits of I_S and P_S should not be exceeded. These limits vary with the ambient temperature, T_A.
The junction-to-air thermal resistance, $R_{\theta JA}$, in the Thermal Information table is that of a device installed on a high-K test board for leaded surface-mount packages. Use the following equations to calculate the value for each parameter:
$T_J = T_A + R_{\theta JA} \times P$, where P is the power dissipated in the device.
$T_{J(max)} = T_S = T_A + R_{\theta JA} \times P_S$, where $T_{J(max)}$ is the maximum allowed junction temperature.
$P_S = I_S \times V_I$, where V_I is the maximum input voltage.

9 Detailed Description

9.1 Overview

The ISOW7721 family of devices have a low-noise, low-emissions isolated DC-DC converter, and two high-speed isolated data channels. Section 9.2 shows the functional block diagram of the ISOW7721 device.

9.1.1 Power Isolation

The integrated isolated DC-DC converter uses advanced circuit and on-chip layout techniques to reduce radiated emissions and achieve up to 46% typical efficiency. The integrated transformer uses thin film polymer as the insulation barrier. Output voltage of power converter can be controlled to 3.3 V or 5 V using V_{SEL} pin. The DC-DC converter can be switched off using the EN pin to save power. The output voltage, V_{ISOOUT} , is monitored and feedback information is conveyed to the primary side through a dedicated isolation channel. V_{ISOOUT} needs to be connected to V_{ISOIN} to ensure the feedback channel is properly powered to regulate the DC-DC converter. This can be achieved by connecting the pins directly or through an LDO that remains powered up at all times. A ferrite bead is recommended between V_{ISOOUT} and V_{ISOIN} to further reduce emissions. See the Section 10.2 section. The duty cycle of the primary switching stage is adjusted accordingly. The fast feedback control loop of the power converter ensures low overshoots and undershoots during load transients. Undervoltage lockout (UVLO) with hysteresis is integrated on the V_{IO}, V_{DD} and V_{ISOIN} supplies which ensures robust fails-safe system performance under noisy conditions. An integrated soft-start mechanism ensures controlled inrush current and avoids any overshoot on the output during power up.

9.1.2 Signal Isolation

The integrated signal isolation channels employ an ON-OFF keying (OOK) modulation scheme to transmit the digital data across a silicon-dioxide based isolation barrier. The transmitter sends a high frequency carrier across the barrier to represent one state and sends no signal to represent the other state. The receiver demodulates the signal after signal conditioning and produces the output through a buffer stage. The signal-isolation channels incorporate advanced circuit techniques to maximize the CMTI performance and minimize the radiated emissions from the high frequency carrier and IO buffer switching. Figure 9-1 shows a functional block diagram of a typical signal isolation channel. In order to keep any noise coupling from the power converter away from the signal path, power supplies on side 1 for the power converter (V_{DD}) and the signal path(V_{IO}) are kept separate. Similarly on side 2, the power converter output (V_{ISOOUT}) needs to be connected to V_{ISOIN} externally on PCB. Emissions can be further improved by placing a ferrite bead between V_{ISOOUT} and V_{ISOIN} as well as between the GND2 pins. For more details, refer to the Layout Guidelines section.

9.3.1 Electromagnetic Compatibility (EMC) Considerations

The ISOW7721 uses emissions reduction schemes for the internal oscillator and advanced internal layout scheme to minimize radiated emissions at the system level.

Many applications in harsh industrial environment are sensitive to disturbances such as electrostatic discharge (ESD), electrical fast transient (EFT), surge and electromagnetic emissions. These electromagnetic disturbances are regulated by international standards such as IEC 61000-4-x and CISPR 32. Although system-level performance and reliability depends, to a large extent, on the application board design and layout, the ISOW7721 incorporates many chip-level design improvements for overall system robustness. Some of these improvements include:

- Robust ESD protection cells for input and output signal pins and inter-chip bond pads.
- Low-resistance connectivity of ESD cells to supply and ground pins.
- Enhanced performance of high voltage isolation capacitor for better tolerance of ESD, EFT and surge events.
- Bigger on-chip decoupling capacitors to bypass undesirable high energy signals through a low impedance path.
- PMOS and NMOS devices isolated from each other by using guard rings to avoid triggering of parasitic SCRs.
- Reduced common mode currents across the isolation barrier by ensuring purely differential internal operation.
- Power path and signal path separated to minimize internal high frequency coupling and an external filtering knob using ferrite beads available to further reduce emissions
- Reduced power converter switching frequency to 25 MHz to reduce strength of high frequency components in emissions spectrum

9.3.2 Power-Up and Power-Down Behavior

The ISOW7721 has built-in UVLO on the V_{IO}, V_{DD}, and V_{ISOIN} supplies with positive-going and negative-going thresholds and hysteresis. Both the power converter supply (VDD) and logic supply (VIO) need to be present

for the device to work. If either of them is below its UVLO, both the signal path and the power converter are disabled.

When the V_{DD} voltage crosses the positive-going UVLO threshold during power-up, the DC-DC converter initializes and the power converter duty cycle is increased in a controlled manner. This soft-start scheme limits primary peak currents drawn from the V_{DD} supply and charges the V_{ISOOUT} output in a controlled manner, avoiding overshoots. Outputs of the isolated data channels are in an indeterminate state until the V_{IO} and V_{DD} voltage crosses the positive-going UVLO threshold. When the UVLO positive-going threshold is crossed on the secondary side V_{ISOOUT} pin, the feedback data channel starts providing feedback to the primary controller. The regulation loop takes over and the isolated data channels go to the normal state defined by the respective input channels or their default states. Design should consider a sufficient time margin (typically 10 ms with 10-µF load capacitance) to allow this power up sequence before valid data channels are accounted for system functionality.

When either V_{IO} or V_{DD} power is lost, the primary side DC-DC controller turns off when the UVLO lower threshold is reached. The V_{ISOOUT} capacitor then discharges depending on the external load. The isolated data outputs on the V_{ISOIN} side are returned to the default state for the brief time that the V_{ISOIN} voltage takes to discharge to zero.

9.3.3 Protection Features

The ISOW7721 has multiple protection features to create a robust system level solution.

- An over-voltage clamp feature is present on V_{ISOOUT} which will clamp the voltage at 6 V, when VSEL = V_{ISOOUT}, or 4 V, when VSEL = GND2, if there is an increase in voltage seen on V_{ISOOUT}. It is recommended that the V_{ISOOUT} stays lower than the over-clamp voltage for device reliability.
- Over-voltage lock out on V_{DD} will occur when a voltage higher than 7 V is seen. The device will go into a low power state and the EN pin will go low.
- The device is protected against output overload and short circuit. Output voltage starts dropping when the power converter is not able to deliver the current demanded during overload conditions. For a V_{ISOOUT} short-circuit to ground, the duty cycle of the converter is limited to help protect against any damage.
- Thermal protection is also integrated to help prevent the device from getting damaged during overload and short-circuit conditions on the isolated output. Under these conditions, the device temperature starts to increase. When the temperature goes above 165°C, thermal shutdown activates and the primary controller turns off which removes the energy supplied to the V_{ISOOUT} load, which causes the device to cool off. When the junction temperature goes below 150°C, the device starts to function normally. If an overload or output short-circuit condition prevails, this protection cycle is repeated. Care should be taken in the design to prevent the device junction temperatures from reaching such high values.

9.3.4 Multi-Device Chaining for Increased Power Output

The ISOW7721 supports daisy chaining multiple ISOW7721 devices to achive > 110 mA load as shown in Figure 9-4. The below equation provides an estimate for the required number of ISOW7721 devices to meet a target load current.

$$Number\ of\ device = \text{ceil}\left[\frac{\text{Target load current} - Maxiumum\ available\ load\ current}{0.8\ Maxiumum\ available\ load\ current} + 1\right]$$

Example:

Design a multi-device chaning using ISOW7721 to drive a 680 mA load for V_{DD} = 5 V and VSEL = 5 V.

The Maximum avaialble load current for V_{DD} = 5 V, and VSEL = 5 V is 100 mA from page 1.

$$Number\ of\ device = \text{ceil}\left[\frac{680 - 110}{0.8\ (110)} + 1\right] = 8$$

From the above calculation, we need 8 ISOW7721 to drive a 680 mA load.

Follow the procedures below to configure multi-device chaining.

1. Set LF to GND1 to make a device as the leader of the daisy chain (only one leader is allowed in a daisy chain). The CC pin of the leader is configured as an output

2. Set LF to V_{DD} to make the other device as a follower (may use more than one follower to meet your system current requirement). The CC pin of the follower is configured as an input.
3. A voltage change on the LF pin requires a power cycling to put the device into the desired role. Please ensure that all devices are powered during multi-device chaining operation to prevent the VISOOUT pin of an unpowered device from exposing to an overvoltage condition. An unpowered device can cause the VSEL to set to GND and thus the maximum rating for its VISOOUT is 4 V. Device damage is possible if this VISOOUT pin is driven by another 5 V VISOOUT pin for an extensive long time.
4. Connect the CC pin of the leader to the CC pin of the follower (may use more than one follower) and this will allow the leader to synchronize with the follower.
5. Connect all the VISOOUT pins and VISOIN pins together for the leader and the follower(s).
6. Connect all the GISOUT pins together for the leader and the follower(s).
7. Connect all the V_{DD} pins together for the leader and the follower(s).
8. All the VSEL pins should be set to the same logic state.

9.4 Device Functional Modes

Table 9-2 lists the supply configurations for these devices.

Table 9-2. Supply Configuration Function Table

V_{DD}	V_{IO}	VSEL	V_{ISOOUT}[2]

>$V_{DD(UVLO+)}$	<$V_{IO(UVLO+)}$	X	OFF
5 V	1.71 V to 5.5 V	High (shorted to V_{ISOOUT})	5 V
5 V or 3.3 V	1.71 V to 5.5 V	Low (shorted to GND2)[1]	3.3 V

(1) The VSEL pin has a weak pulldown internally. Therefore for V_{ISOOUT} = 3.3 V, the VSEL pin should be strongly connected to the GND2 pin in noisy system scenarios.
(2) V_{ISOOUT} shorted to V_{ISOIN} on PCB and both GND2 and GISOIN pins are shorted to each other and EN=High

Table 9-3 lists the channel isolators functional modes for these devices.

(2) In the default condition, the output is high for the ISOW7721 and low with the F suffix.

10 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information

This device is a high-performance, two channel digital isolator with integrated DC-DC converter. Typically digital isolators require two power supplies isolated from each other to power up both sides of device. Due to the integrated DC-DC converter in the device, the isolated supply is generated inside the device that can be used to power isolated side of the device and peripherals on isolated side, thus saving board space. The device uses single-ended CMOS-logic switching technology. When designing with digital isolators, keep in mind that because of the single-ended design structure, digital isolators do not conform to any specific interface standard and are only intended for isolating single-ended CMOS or TTL digital signal lines. The isolator is typically placed between the data controller (Microcontroller or UART), and a data converter or a line transceiver, regardless of the interface type or standard.

The device is suitable for applications that have limited board space and desire more integration. The device is also suitable for very high voltage applications, where power transformers meeting the required isolation specifications are bulky and expensive.

10.2 Typical Application

For step-by-step design procedure, circuit schematics, bill of materials, printed circuit board (PCB) files, simulation results, and test results, refer to TI Design TIDA-01333, *Eight-Channel, Isolated, High-Voltage Analog Input Module With ISOW7841 Reference Design*.

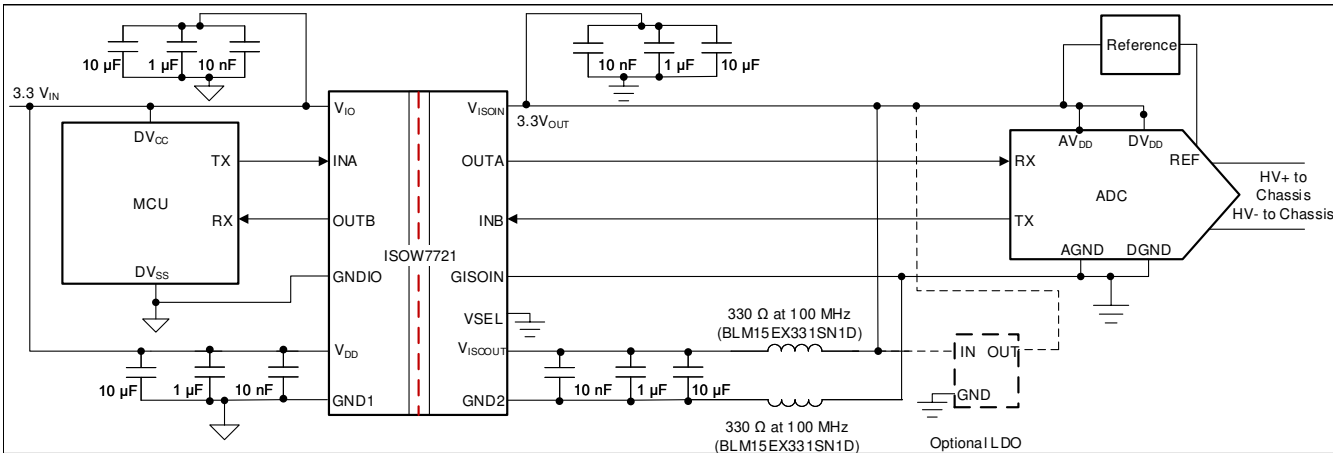

Figure 10-1. Isolated Power and UART for ADC Sensing Application with ISOW7721

10.2.1 Design Requirements

To design with this device, use the parameters listed in Table 10-1.

Table 10-1. Design Parameters

PARAMETER	VALUE
V_{DD} input voltage	3 V to 5.5 V
V_{IO} input voltage	1.71 V to 5.5 V
V_{ISOIN} input voltage	1.71 V to 5.5 V
V_{DD} decoupling capacitors	10 µF + 1 µF + 0.01 µF + optional additional capacitance
V_{IO} decoupling capacitors	0.1 µF + optional additional capacitance
V_{ISOIN} decoupling capacitors	0.1 µF + optional additional capacitance
V_{ISOOUT} decoupling capacitors	10 µF + 1 µF + 0.01 µF + optional additional capacitance
V_{ISOOUT} to V_{ISOIN} series inductor	BLM15ELX9331SN1D
GND2 to GISOIN series inductor	BLM15ELX9331SN1D
V_{IO} series inductor	BLM15ELX9331SN1D
V_{DD} series inductor	BLM15ELX9331SN1D

Because of very-high current flowing through the ISOW7721 V_{DD} and V_{ISOOUT} supplies, higher decoupling capacitors typically provide better noise and ripple performance. Although a 10-µF capacitor is adequate, higher decoupling capacitors (such as 47 µF) on both the V_{DD} and V_{ISOOUT} pins to the respective grounds are strongly recommended to achieve the best performance.

10.2.2 Detailed Design Procedure

The devices requires specific placement of external bypass capacitors and ferrite beads to operate at high performance. These low-ESR ceramic bypass capacitors must be placed as close to the chip pads as possible.

10.2.4 *Insulation Lifetime*

Insulation lifetime projection data is collected by using industry-standard Time Dependent Dielectric Breakdown (TDDB) test method. In this test, all pins on each side of the barrier are tied together creating a two-terminal device and high voltage applied between the two sides; See Figure 10-4 for TDDB test setup. The insulation breakdown data is collected at various high voltages switching at 60 Hz over temperature. For reinforced insulation, VDE standard requires the use of TDDB projection line with failure rate of less than 1 part per million (ppm). Even though the expected minimum insulation lifetime is 20 years at the specified working isolation voltage, VDE reinforced certification requires additional safety margin of 20% for working voltage and 87.5% for lifetime which translates into minimum required insulation lifetime of 37.5 years at a working voltage that's 20% higher than the specified value.

Figure 10-5 shows the intrinsic capability of the isolation barrier to withstand high voltage stress over its lifetime. Based on the TDDB data, the intrinsic capability of the insulation is 1000 V_{RMS} with a lifetime of 1184 years.

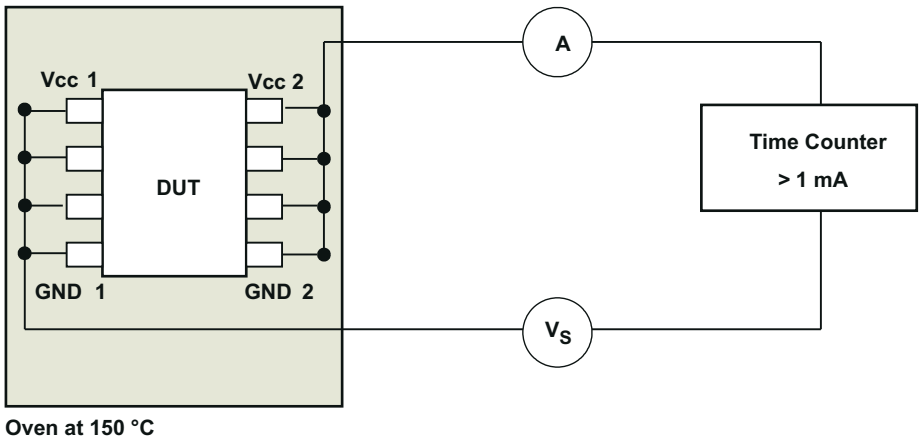

Figure 10-4. Test Setup for Insulation Lifetime Measurement

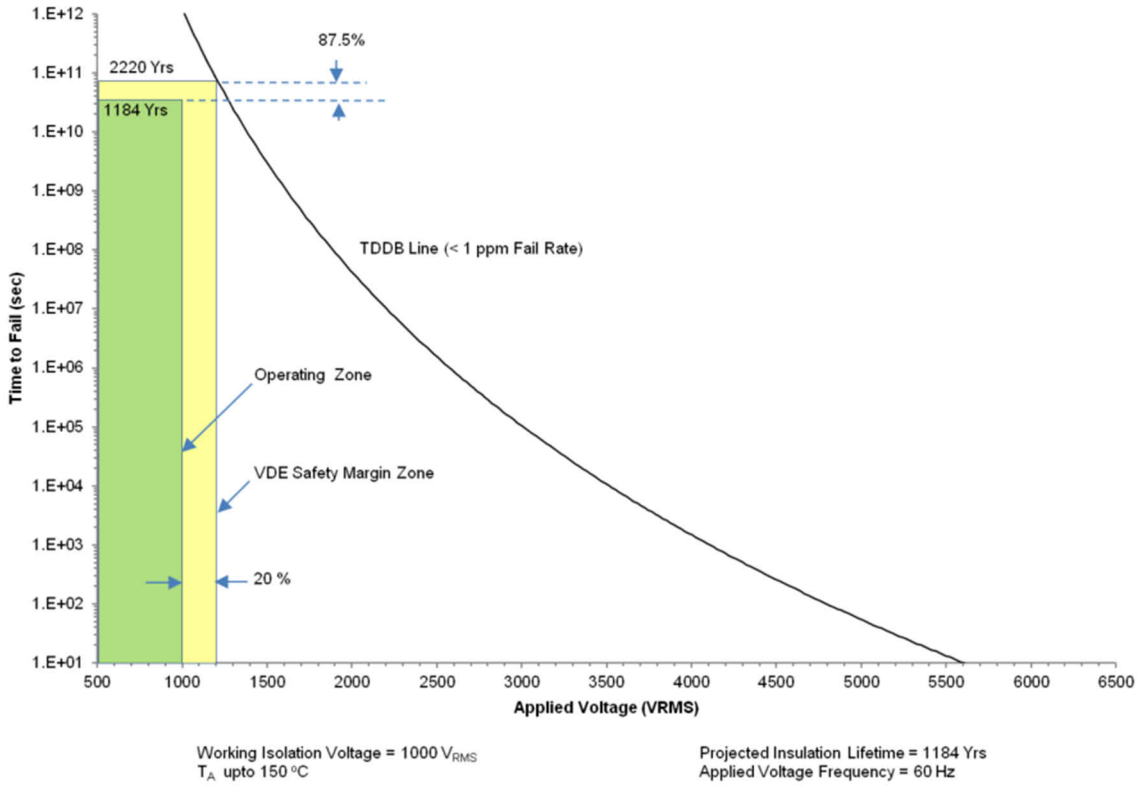

Figure 10-5. Insulation Lifetime Projection Data

11 Power Supply Recommendations

To help make sure that operation is reliable at data rates and supply voltages, adequate decoupling capacitors must be located as close to supply pins as possible. V_{ISOOUT} needs to be connected to V_{ISOIN} to ensure the feedback channel is properly powered to regulate the DC-DC converter. If V_{ISOOUT} and V_{ISOIN} are not connected, the DC-DC converter will run open loop and the V_{ISOOUT} voltage will drift until the over-voltage clamp clamps at 6 V. There are two ways to connect $V_{ISOOUT}$and V_{ISOIN}:

1) Connect V_{ISOOUT} and V_{ISOIN} directly with a ferrite bead. A ferrite bead is recommended between $V_{ISOOUT}$and V_{ISOIN} to further reduce emissions.

2) Connect V_{ISOOUT} and V_{ISOIN} with a ferrite bead through an LDO that remains powered up at all times. If the LDO has an EN pin then keep the EN high at all times.

The input supply (V_{IO} and V_{DD}) must have an appropriate current rating to support output load and switching at the maximum data rate required by the end application. For more information, refer to the Section 10.2 section.

For an output load current of 110 mA, it is recommended to have >600 mA of input current limit and for lower output load currents, the input current limit can be proportionally lower.

12 Layout

12.1 Layout Guidelines

A low cost two layer PCB should be sufficient to achieve good EMC performance:

- Routing the high-speed traces on the top layer avoids the use of vias (and the introduction of their inductances) and allows for clean interconnects between the isolator and the transmitter and receiver circuits of the data link.
- Placing a solid ground plane next to the high-speed signal layer establishes controlled impedance for transmission line interconnects and provides an excellent low-inductance path for the return current flow.
- Placing the power plane next to the ground plane creates additional high-frequency bypass capacitance of approximately 100 pF/in^2.
- Routing the slower speed control signals on the bottom layer allows for greater flexibility as these signal links usually have margin to tolerate discontinuities such as vias.

If an additional supply voltage plane or signal layer is needed, add a second power or ground plane system to the stack to keep it symmetrical. This makes the stack mechanically stable and prevents it from warping. Also the power and ground plane of each power system can be placed closer together, thus increasing the high-frequency bypass capacitance significantly.

Because the device has no thermal pad to dissipate heat, the device dissipates heat through the respective GND pins. Ensure that enough copper is present on both GND pins to prevent the internal junction temperature of the device from rising to unacceptable levels.

Figure 12-1 shows the recommended placement and routing of device bypass capacitors. Below guidelines must be followed to meet application EMC requirements:

- High frequency bypass capacitors 10 nF must be placed close to V_{DD} and V_{ISOOUT} pins, less than 1 mm distance away from device pins. This is very essential for optimised radiated emissions performance. Ensure that these capacitors are 0402 size so that they offer least inductance (ESL).
- Bulk capacitors of atleast 10 µF must be placed on power converter input (V_{DD}) and output (V_{ISOOUT}) supply pins.
- Traces on V_{DD} and GND1 must be symmetric till bypass capacitors. Similarly traces on V_{ISOOUT} and GND2 must be symmetric.
- Place two 0402 size Ferrite beads (Part number: BLM15EX331SN1) on V_{ISOOUT} and GND2 path so that any high frequency noise from power converter output sees a high impedance before it goes to other components on PCB.
- Do not have any metal traces or ground pour within 4 mm of power converter output terminals V_{ISOOUT} pin12 and GND2 pin11. VSEL pin is also in V_{ISOOUT} domain and should be shorted to either pin 11 or pin 12 for output voltage selection.
- Following the layout guidelines of EVM as much as possible is highly recommended for a low radiated emissions design.

12.1.1 PCB Material

For digital circuit boards operating at less than 150 Mbps, (or rise and fall times greater than 1 ns), and trace lengths of up to 10 inches, use standard FR-4 UL94V-0 printed circuit board. This PCB is preferred over cheaper alternatives because of lower dielectric losses at high frequencies, less moisture absorption, greater strength and stiffness, and the self-extinguishing flammability-characteristics.
