About This Manual.....	13
Notational Conventions.....	13
Glossary.....	13
Support Resources.....	13
Trademarks.....	13
<b>1 Architecture</b> .....	14
1.1 Architecture Overview.....	15
1.2 Bus Organization.....	15
1.3 Platform Memory Map.....	17
1.3.1 Code Region.....	17
1.3.2 SRAM Region.....	17
1.3.3 Peripheral Region.....	20
1.3.4 Subsystem Region.....	20
1.3.5 System PPB Region.....	20
1.4 Boot Configuration.....	20
1.4.1 Configuration Memory (NONMAIN).....	20
1.4.2 Boot Configuration Routine (BCR).....	22
1.4.3 Bootstrap Loader (BSL).....	28
1.4.4 NONMAIN Layout Types.....	30
1.4.5 NONMAIN_TYPEEA Registers.....	31
1.4.6 NONMAIN_TYPEEE Registers.....	60
1.4.7 NONMAIN_TYPEEF Registers.....	101
1.5 Factory Constants.....	140
1.5.1 FACTORYREGION Layout Types.....	140
1.5.2 FACTORYREGION_TYPEEA Registers.....	142
1.5.3 FACTORYREGION_TYPEEF Registers.....	161
1.5.4 FACTORYREGION_TYPEEG Registers.....	189
<b>2 PMCU</b> .....	208
2.1 PMCU Overview.....	209
2.1.1 Power Domains.....	210
2.1.2 Operating Modes.....	210
2.2 Power Management (PMU).....	214
2.2.1 Power Supply.....	214
2.2.2 Core Regulator.....	214
2.2.3 Supply Supervisors.....	215
2.2.4 Bandgap Reference.....	216
2.2.5 VBOOST for Analog Muxes.....	216
2.2.6 Peripheral Enable.....	219
2.3 Clock Module (CKM).....	221
2.3.1 Oscillators.....	221
2.3.2 Clocks.....	233
2.3.3 Clock Tree.....	242
2.3.4 Clock Monitors.....	244
2.3.5 Frequency Clock Counter (FCC).....	247
2.4 System Controller (SYSCTL).....	250
2.4.1 Resets and Device Initialization.....	250
2.4.2 Operating Mode Selection.....	258
2.4.3 Asynchronous Fast Clock Requests.....	260

2.4.4 SRAM Write Protection.....	262
2.4.5 Flash Wait States.....	262
2.4.6 Flash Bank Address Swap.....	263
2.4.7 Shutdown Mode Handling (if present).....	263
2.4.8 Configuration Lockout.....	263
2.4.9 System Status.....	264
2.4.10 Error Handling.....	264
2.4.11 SYSCTL Events.....	266
2.5 SYSCTL_G350x_G310x_G150x_G110x Registers.....	268
2.6 SYSCTL_G351x_G151x Registers.....	326
2.7 SYSCTL_G511x_G5187 Registers.....	386
2.8 Quick Start Reference.....	445
2.8.1 Default Device Configuration.....	445
2.8.2 Leveraging MFCLK.....	446
2.8.3 Optimizing Power Consumption in STOP Mode.....	446
2.8.4 Optimizing Power Consumption in STANDBY Mode.....	446
2.8.5 Increasing MCLK Precision.....	446
2.8.6 Configuring MCLK for Maximum Speed.....	447
2.8.7 High Speed Clock (SYSPLL, HFCLK) Handling in Low-Power Modes.....	447
2.8.8 Optimizing for Lowest Wakeup Latency.....	447
2.8.9 Optimizing for Lowest Peak Current in RUN/SLEEP Mode.....	448
<b>3 CPU.....</b>	<b>449</b>
3.1 Overview.....	450
3.2 Arm Cortex-M0+ CPU.....	450
3.2.1 CPU Register File.....	451
3.2.2 Stack Behavior.....	454
3.2.3 Execution Modes and Privilege Levels.....	454
3.2.4 Address Space and Supported Data Sizes.....	454
3.3 Interrupts and Exceptions.....	455
3.3.1 Peripheral Interrupts (IRQs).....	456
3.3.2 Interrupt and Exception Table.....	459
3.3.3 Processor Lockup Scenario.....	462
3.4 CPU Peripherals.....	462
3.4.1 System Control Block (SCB).....	462
3.4.2 System Tick Timer (SysTick).....	463
3.4.3 Memory Protection Unit (MPU).....	464
3.5 Read-Only Memory (ROM).....	465
3.6 CPUSS Registers.....	466
3.7 WUC Registers.....	500
<b>4 SECURITY.....</b>	<b>502</b>
4.1 Overview.....	502
4.1.1 Secure Boot.....	503
4.1.2 Customer Secure Code (CSC).....	503
4.2 Boot and Startup Sequence.....	503
4.2.1 CSC Programming Overview.....	504
4.3 Secure Key Storage.....	505
4.4 Flash Memory Protection.....	506
4.4.1 Bank Swapping.....	506
4.4.2 Write Protection.....	506
4.4.3 Read-Execute Protection.....	507
4.4.4 IP Protection.....	507
4.4.5 Data Bank Protection.....	508
4.4.6 Hardware Monotonic Counter.....	508
4.5 SRAM Protection.....	508
4.6 SECURITY Registers.....	510
<b>5 Direct Memory Access (DMA).....</b>	<b>521</b>
5.1 DMA Overview.....	522
5.2 DMA Operation.....	523
5.2.1 Addressing Modes.....	523
5.2.2 Channel Types.....	525
5.2.3 Transfer Modes.....	526

5.2.4 Extended Modes.....	528
5.2.5 Initiating DMA Transfers.....	530
5.2.6 Stopping DMA Transfers.....	531
5.2.7 Channel Priorities.....	531
5.2.8 Burst Block Mode.....	531
5.2.9 Using DMA with System Interrupts.....	531
5.2.10 DMA Controller Interrupts.....	532
5.2.11 DMA Trigger Event Status.....	532
5.2.12 DMA Operating Mode Support.....	532
5.2.13 DMA Address and Data Errors.....	533
5.2.14 Interrupt and Event Support.....	533
5.3 DMA Registers.....	535
<b>6 NVM (Flash).....</b>	<b>583</b>
6.1 NVM Overview.....	584
6.1.1 Key Features.....	584
6.1.2 System Components.....	584
6.1.3 Terminology.....	584
6.2 Flash Memory Bank Organization.....	585
6.2.1 Banks.....	585
6.2.2 Flash Memory Regions.....	585
6.2.3 Addressing.....	585
6.2.4 Memory Organization Examples.....	586
6.3 Flash Controller.....	587
6.3.1 Overview of Flash Controller Commands.....	588
6.3.2 NOOP Command.....	588
6.3.3 PROGRAM Command.....	588
6.3.4 ERASE Command.....	593
6.3.5 READVERIFY Command.....	594
6.3.6 BLANKVERIFY Command.....	595
6.3.7 Command Diagnostics.....	596
6.3.8 Overriding the System Address With a Bank ID, Region ID, and Bank Address.....	596
6.3.9 FLASHCTL Events.....	597
6.4 Write Protection.....	597
6.4.1 Write Protection Resolution.....	597
6.4.2 Static Write Protection.....	597
6.4.3 Dynamic Write Protection.....	598
6.5 Read Interface.....	599
6.5.1 Bank Address Swapping.....	599
6.5.2 ECC Error Handling.....	599
6.6 FLASHCTL_G350x_G310x_G150x_G110x Registers.....	600
6.7 FLASHCTL_G351x_G151x Registers.....	649
6.8 FLASHCTL_G511x_G5187 Registers.....	700
<b>7 Events.....</b>	<b>751</b>
7.1 Events Overview.....	752
7.1.1 Event Publisher.....	752
7.1.2 Event Subscriber.....	752
7.1.3 Event Fabric Routing.....	752
7.1.4 Event Routing Map.....	754
7.1.5 Event Propagation Latency.....	755
7.2 Events Operation.....	756
7.2.1 CPU Interrupt.....	756
7.2.2 DMA Trigger.....	756
7.2.3 Peripheral to Peripheral Event.....	757
7.2.4 Extended Module Description Register.....	758
7.2.5 Using Event Registers.....	758
<b>8 IOMUX.....</b>	<b>761</b>
8.1 IOMUX Overview.....	762
8.1.1 IO Types and Analog Sharing.....	762
8.2 IOMUX Operation.....	765
8.2.1 Peripheral Function (PF) Assignment.....	765
8.2.2 Logic High to Hi-Z Conversion.....	765

8.2.3 Logic Inversion.....	766
8.2.4 SHUTDOWN Mode Wakeup Logic.....	766
8.2.5 Pullup/Pulldown Resistors.....	767
8.2.6 Drive Strength Control.....	767
8.2.7 Hysteresis and Logic Level Control.....	767
8.3 IOMUX Registers.....	769
<b>9 General-Purpose Input/Output (GPIO).....</b>	<b>772</b>
9.1 GPIO Overview.....	773
9.2 GPIO Operation.....	773
9.2.1 GPIO Ports.....	774
9.2.2 GPIO Read/Write Interface.....	774
9.2.3 GPIO Input Glitch Filtering and Synchronization.....	774
9.2.4 GPIO Fast Wake.....	775
9.2.5 GPIO DMA Interface.....	776
9.2.6 Event Publishers and Subscribers.....	776
9.3 GPIO Registers.....	777
<b>10 MATHACL.....</b>	<b>885</b>
10.1 Overview.....	885
10.2 Data Format.....	885
10.2.1 Unsigned 32-bit integers.....	885
10.2.2 Signed 32-bit integers.....	886
10.2.3 Unsigned 32-bit numbers.....	886
10.2.4 Signed 32-bit numbers.....	886
10.3 Basic Operation.....	887
10.4 Configuration Details with Examples.....	887
10.4.1 Sine and Cosine (SINCOS).....	887
10.4.2 Arc Tangent (ATAN2).....	888
10.4.3 Square Root (SQRT).....	890
10.4.4 Division (DIV).....	891
10.4.5 Multiplication.....	893
10.4.6 Multiply-Accumulate (MAC).....	897
10.4.7 Square Accumulate (SAC).....	900
10.5 MATHACL Registers.....	902
<b>11 TinyEngine™ NPU.....</b>	<b>914</b>
11.1 Overview.....	914
11.2 NPU Operation.....	914
11.3 NPU Toolchain.....	916
<b>12 AES.....</b>	<b>918</b>
12.1 AES Overview.....	919
12.1.1 AES Performance.....	919
12.2 AES Operation.....	920
12.2.1 AES Register Access Rules.....	921
12.2.2 Loading the Key.....	922
12.2.3 Loading Data.....	922
12.2.4 Reading Data.....	922
12.2.5 Triggering an Encryption or Decryption.....	922
12.2.6 Single Block Operations.....	922
12.2.7 Block Cipher Mode Operations.....	925
12.2.8 AES Events.....	938
12.3 AES Registers.....	941
<b>13 AES.....</b>	<b>982</b>
13.1 AES Overview.....	983
13.1.1 AESADV Performance.....	984
13.2 AESADV Operation.....	984
13.2.1 Loading the Key.....	984
13.2.2 Writing Input Data.....	984
13.2.3 Reading Output Data.....	984
13.2.4 Operation Descriptions.....	985
13.2.5 AES Events.....	1002
13.3 AESADV Registers.....	1004
<b>14 CRC.....</b>	<b>1074</b>

14.1 CRC Overview.....	1075
14.1.1 CRC16-CCITT.....	1075
14.1.2 CRC32-ISO3309.....	1075
14.2 CRC Operation.....	1075
14.2.1 CRC Generator Implementation.....	1076
14.2.2 Configuration.....	1076
14.3 CRCP0 Registers.....	1078
<b>15 Keystore.....</b>	<b>1091</b>
15.1 Overview.....	1092
15.2 Detailed Description.....	1092
15.3 KEYSTORECTL Registers.....	1093
<b>16 TRNG.....</b>	<b>1100</b>
16.1 TRNG Overview.....	1101
16.2 TRNG Operation.....	1101
16.2.1 TRNG Generation Data Path.....	1101
16.2.2 Clock Configuration and Output Rate.....	1102
16.2.3 Behavior in Low Power Modes.....	1102
16.2.4 Health Tests.....	1102
16.2.5 Configuration.....	1104
16.3 TRNG Registers.....	1108
<b>17 Temperature Sensor.....</b>	<b>1125</b>
<b>18 ADC.....</b>	<b>1127</b>
18.1 ADC Overview.....	1128
18.2 ADC Operation.....	1129
18.2.1 ADC Core.....	1130
18.2.2 Voltage Reference Options.....	1130
18.2.3 Generic Resolution Modes.....	1131
18.2.4 Hardware Averaging.....	1131
18.2.5 ADC Clocking.....	1132
18.2.6 Common ADC Use Cases.....	1132
18.2.7 Power Down Behavior.....	1134
18.2.8 Sampling Trigger Sources and Sampling Modes.....	1134
18.2.9 Sampling Period.....	1136
18.2.10 Conversion Modes.....	1137
18.2.11 Data Format.....	1138
18.2.12 Advanced Features.....	1138
18.2.13 Status Register.....	1143
18.2.14 ADC Events.....	1143
18.3 ADC12 Registers.....	1146
<b>19 COMP.....</b>	<b>1223</b>
19.1 Comparator Overview.....	1224
19.2 Comparator Operation.....	1226
19.2.1 Comparator Configuration.....	1226
19.2.2 Comparator Channels Selection.....	1226
19.2.3 Comparator Output.....	1227
19.2.4 Output Filter.....	1227
19.2.5 Sampled Output Mode.....	1228
19.2.6 Blanking Mode.....	1228
19.2.7 Reference Voltage Generator.....	1229
19.2.8 Window Comparator Mode.....	1230
19.2.9 Comparator Hysteresis.....	1232
19.2.10 Input SHORT Switch.....	1232
19.2.11 Interrupt and Events Support.....	1233
19.3 COMP0 Registers.....	1236
<b>20 DAC.....</b>	<b>1265</b>
20.1 DAC Introduction.....	1266
20.2 DAC Operation.....	1267
20.2.1 DAC Core.....	1267
20.2.2 DAC Output.....	1267
20.2.3 DAC Voltage Reference.....	1267
20.2.4 DAC Output Buffers.....	1267

20.2.5 DAC Data Formats.....	1268
20.2.6 Sample Time Generator.....	1268
20.2.7 DAC FIFO Structure.....	1269
20.2.8 DAC Operation With DMA Controller.....	1269
20.2.9 DAC Operation With CPU.....	1271
20.2.10 Data Register Format.....	1271
20.2.11 DAC Output Amplifier Offset Calibration.....	1272
20.2.12 Interrupt and Event Support.....	1273
20.3 DAC12 Registers.....	1276
<b>21 OPA.....</b>	<b>1306</b>
21.1 OPA Overview.....	1307
21.2 OPA Operation.....	1308
21.2.1 Analog Core.....	1308
21.2.2 Power Up Behavior.....	1309
21.2.3 Inputs.....	1309
21.2.4 Output.....	1309
21.2.5 Clock Requirements.....	1309
21.2.6 Chopping.....	1310
21.2.7 OPA Amplifier Modes.....	1310
21.2.8 OPA Configuration Selection.....	1316
21.2.9 Burnout Current Source.....	1317
21.3 OA Registers.....	1318
<b>22 GPAMP.....</b>	<b>1328</b>
22.1 GPAMP Overview.....	1329
22.2 GPAMP Operation.....	1329
22.2.1 Analog Core.....	1329
22.2.2 Power Up Behavior.....	1330
22.2.3 Inputs.....	1330
22.2.4 Output.....	1330
22.2.5 GPAMP Amplifier Modes.....	1330
22.2.6 Chopping.....	1332
22.3 GPAMP Registers.....	1332
<b>23 VREF.....</b>	<b>1333</b>
23.1 VREF Overview.....	1334
23.2 VREF Operation.....	1335
23.2.1 Internal Reference Generation.....	1336
23.2.2 External Reference Input.....	1336
23.2.3 Analog Peripheral Interface.....	1336
23.3 VREF Registers.....	1338
<b>24 UART.....</b>	<b>1347</b>
24.1 UART Overview.....	1348
24.1.1 Purpose of the Peripheral.....	1348
24.1.2 Features.....	1348
24.1.3 Functional Block Diagram.....	1349
24.2 UART Operation.....	1350
24.2.1 Clock Control.....	1350
24.2.2 Signal Descriptions.....	1350
24.2.3 General Architecture and Protocol.....	1350
24.2.4 Low Power Operation.....	1365
24.2.5 Reset Considerations.....	1366
24.2.6 Initialization.....	1366
24.2.7 Interrupt and Events Support.....	1366
24.2.8 Emulation Modes.....	1369
24.3 UART Registers.....	1370
<b>25 I<sup>2</sup>C.....</b>	<b>1427</b>
25.1 I <sup>2</sup> C Overview.....	1428
25.1.1 Purpose of the Peripheral.....	1428
25.1.2 Features.....	1428
25.1.3 Functional Block Diagram.....	1429
25.1.4 Environment and External Connections.....	1429
25.2 I <sup>2</sup> C Operation.....	1430

25.2.1 Clock Control.....	1430
25.2.2 Signal Descriptions.....	1431
25.2.3 General Architecture.....	1431
25.2.4 Protocol Descriptions.....	1439
25.2.5 Reset Considerations.....	1450
25.2.6 Initialization.....	1451
25.2.7 Interrupt and Events Support.....	1451
25.2.8 Emulation Modes.....	1453
25.3 I2C Registers.....	1454
<b>26 SPI.....</b>	<b>1518</b>
26.1 SPI Overview.....	1519
26.1.1 Purpose of the Peripheral.....	1519
26.1.2 Features.....	1519
26.1.3 Functional Block Diagram.....	1520
26.1.4 External Connections and Signal Descriptions.....	1520
26.2 SPI Operation.....	1522
26.2.1 Clock Control.....	1522
26.2.2 General Architecture.....	1522
26.2.3 Protocol Descriptions.....	1527
26.2.4 Reset Considerations.....	1532
26.2.5 Initialization.....	1532
26.2.6 Interrupt and Events Support.....	1532
26.2.7 Emulation Modes.....	1534
26.3 SPI Registers.....	1535
<b>27 UNICOMM.....</b>	<b>1578</b>
27.1 Overview.....	1579
27.1.1 Block Diagram.....	1580
27.2 Unicom Architecture.....	1580
27.2.1 Serial Peripheral Group (SPG) Configurations.....	1581
27.2.2 Enables & Resets.....	1581
27.3 High-Level Initialization.....	1582
27.4 UNICOMM/SPGSS Registers.....	1582
27.4.1 UNICOMM Registers.....	1582
27.4.2 SPG Registers.....	1588
<b>28 UNICOMM-UART.....</b>	<b>1598</b>
28.1 UNICOMM-UART Overview.....	1599
28.1.1 Purpose of the Peripheral.....	1599
28.1.2 Features.....	1599
28.1.3 Functional Block Diagram.....	1600
28.2 UART Operation.....	1600
28.2.1 Clock Control.....	1600
28.2.2 General Architecture and Protocol.....	1601
28.2.3 Additional Protocol and Feature Support.....	1610
28.3 UNICOMMUART Registers.....	1626
<b>29 UNICOMM-I2C.....</b>	<b>1673</b>
29.1 UNICOMM-I2C Overview.....	1674
29.1.1 Purpose of the Peripheral.....	1674
29.1.2 Features.....	1674
29.1.3 Functional Block Diagram.....	1676
29.1.4 Environment and External Connections.....	1677
29.2 UNICOMM Common Infrastructure.....	1678
29.3 Peripheral Functional Description.....	1678
29.3.1 Clock Control.....	1678
29.3.2 Signal Descriptions.....	1679
29.3.3 General Architecture.....	1679
29.3.4 Protocol Descriptions & Initialization.....	1695
29.3.5 Reset Considerations.....	1707
29.3.6 Initialization.....	1708
29.3.7 Interrupt and Events Support.....	1708
29.3.8 Emulation Modes.....	1711
29.4 UNICOMM I2C Registers.....	1712

29.4.1 UNICOMMI2CC Registers.....	1713
29.4.2 UNICOMMI2CT Registers.....	1754
<b>30 UNICOMM-SPI.....</b>	<b>1796</b>
30.1 UNICOMM-SPI Overview.....	1797
30.1.1 Purpose of the Peripheral.....	1797
30.1.2 Features.....	1797
30.1.3 Functional Block Diagram.....	1798
30.1.4 External Connections and Signal Descriptions.....	1798
30.2 SPI Operation.....	1800
30.2.2 General Architecture.....	1801
30.2.3 FIFO Operation.....	1803
30.2.4 Suspend communication.....	1804
30.2.5 Internal Loopback Operation.....	1805
30.2.6 Repeat Transfer mode.....	1806
30.2.7 Receive Timeout.....	1806
30.2.8 Line Timeout.....	1807
30.2.9 Protocol Descriptions.....	1807
30.2.11 Module configuration.....	1812
30.2.12 Reset Considerations.....	1812
30.2.14 Interrupt and Events Support.....	1813
30.2.15 Emulation Modes.....	1815
30.3 UNICOMMSPI Registers.....	1817
<b>31 CAN-FD.....</b>	<b>1850</b>
31.1 MCAN Overview.....	1851
31.1.1 MCAN Features.....	1852
31.2 MCAN Environment.....	1852
31.3 CAN Network Basics.....	1853
31.4 MCAN Functional Description.....	1855
31.4.1 Clock Setup.....	1856
31.4.2 Module Clocking Requirements.....	1857
31.4.3 Interrupt Requests.....	1857
31.4.4 Operating Modes.....	1859
31.4.5 Software Initialization.....	1861
31.4.6 Transmitter Delay Compensation.....	1862
31.4.7 Restricted Operation Mode.....	1864
31.4.8 Bus Monitoring Mode.....	1865
31.4.9 Disabled Automatic Retransmission (DAR) Mode.....	1866
31.4.10 Clock Stop Mode.....	1866
31.4.11 Test Modes.....	1872
31.4.12 Timestamp Generation.....	1873
31.4.13 Timeout Counter.....	1874
31.4.14 Safety.....	1875
31.4.15 Tx Handling.....	1877
31.4.16 Rx Handling.....	1887
31.4.17 Rx FIFOs.....	1891
31.4.18 Dedicated Rx Buffers.....	1893
31.4.19 Message RAM.....	1893
31.5 MCAN Integration.....	1904
31.6 Interrupt and Event Support.....	1905
31.6.1 CPU Interrupt Event Publisher (CPU_INT).....	1905
31.7 MCAN Registers.....	1906
<b>32 USB.....</b>	<b>2036</b>
32.1 USB Overview.....	2037
32.1.1 Features.....	2037
32.1.2 USB Related Collateral.....	2037
32.1.3 Block Diagram.....	2037
32.1.4 VBus Recommendations.....	2038
32.2 Functional Description.....	2040
32.2.1 Operation as a Device.....	2040

## About This Manual

This manual describes the modules and peripherals of the MSPM0G family of devices. Each description presents the module or peripheral in a general sense. Not all features and functions of all modules or peripherals are present on all devices. In addition, modules or peripherals can differ in their exact implementation on different devices. Pin functions, internal signal connections, and operational parameters differ from device to device. See the device-specific data sheet for these details.

## Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

## Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

## Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

## 1.1 Architecture Overview

MSPM0 G-series MCUs (MSPM0Gxx) combine 32-bit compute performance together with precision analog to enable a wide variety of sensing, interface, control, and housekeeping applications. The device architecture supports both high-performance and low-power applications through a flexible, easy-to-configure power management and clocking system.

MSPM0 G-series devices also offer enhanced robustness with ECC-protected flash memory, parity-protected SRAM, available dual window-watchdog timers, and support for 125°C ambient temperature and AEC-Q100 Grade 1 qualification.

This chapter introduces the device architecture, including an overview of the [power domains and bus organization](#), the [platform memory map](#), and the [device boot configuration](#).

## 1.2 Bus Organization

There are three main power domains on MSPM0Gxx devices:

- PD1 (power domain 1) which contains the CPU subsystem, memory interfaces, and high-speed peripherals
- PD0 (power domain 0) which contains the low-speed low-power peripherals
- The supply voltage (VDD) which powers IOs, analog modules, and limited logic directly from the supply

The PD1 domain supports higher clock speeds for performance, and is disabled in certain operating modes to minimize power consumption. The PD0 domain supports ultra-low-power performance and is always enabled in operating modes in which the core regulator is operating.

There are four main data buses on MSPM0Gxx devices:

- The AHB bus matrix, which interfaces the CPU to the device memory systems (ROM, SRAM, and flash memory) and the peripheral buses
- The PD1 (power domain 1) CPU-only peripheral bus, clocked from [MCLK](#)
- The PD1 (power domain 1) peripheral bus, clocked from [MCLK](#)
- The PD0 (power domain 0) peripheral bus, clocked from [ULPCLK](#)

The CPU and the DMA controller are the only two bus controllers in the device. Arbitration between the CPU and the DMA for shared peripherals happens between the CPU-only PD1 peripheral bus and the CPU/DMA PD1 peripheral bus. The DMA does not have access to peripherals on the CPU-only PD1 peripheral bus or the CPU bus matrix (the green components in the bus diagram). As such, the CPU can access peripherals on the CPU-only PD1 peripheral bus at the same time that the DMA is processing a transaction on the PD1 or PD0 bus.

Likewise, the CPU can access SRAM or flash memory through the AHB bus matrix at the same time that the DMA is processing a transaction, so long as the DMA is not accessing the same memory that the CPU is attempting to access. Arbitration between the CPU and the DMA for memory systems (SRAM or flash memory) happens at the memory interface itself. All arbitration between the CPU and DMA is done on a round-robin basis.

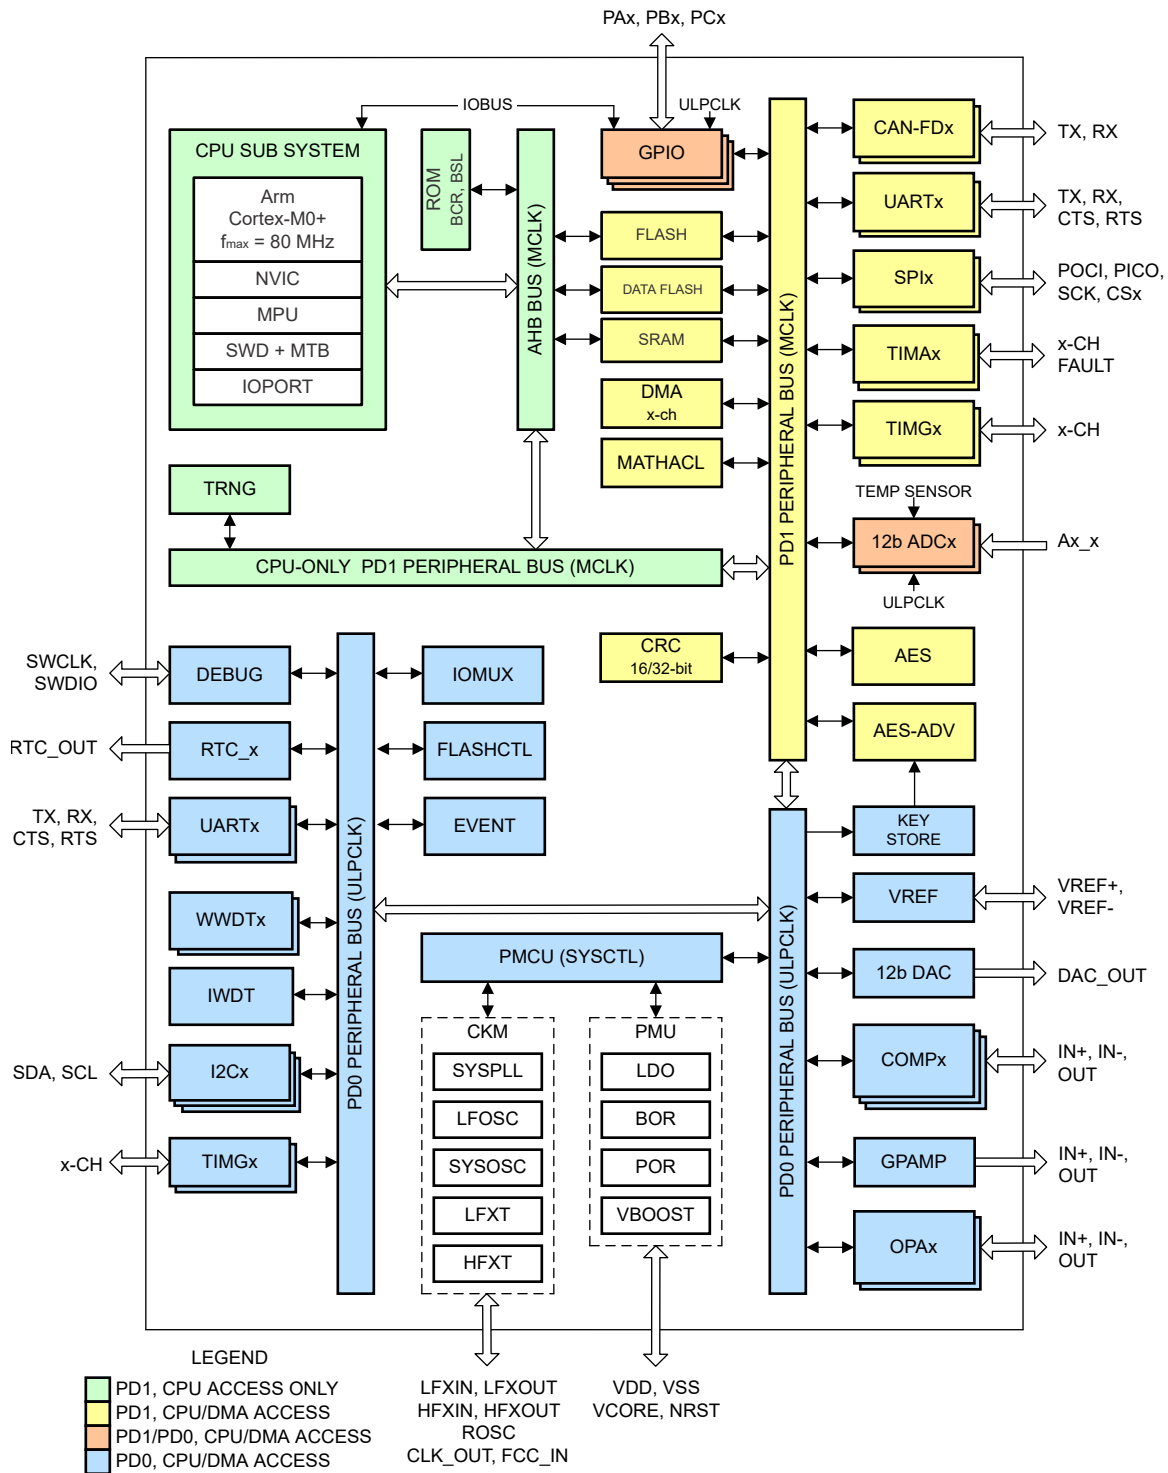

Figure 1-1. MSPM0Gxx Bus Organization

### Note

This is a generic diagram of the typical peripherals on an MSPM0Gxx device and their respective bus locations. Not all devices have all peripheral options shown here. To determine the peripherals which are available on a given device, see the device-specific data sheet.

The GPIO and ADC peripherals (the orange components in the bus diagram) have special capabilities to enable both fast register access from the CPU and operation in low power operating modes.

- GPIO peripherals interface to the system through two mechanisms: the PD1 peripheral bus, and the Arm® Cortex®-M0+ single-cycle high-speed IO bus.
  - Accesses from the CPU to any GPIO registers are transacted through the single-cycle IO bus for best performance, enabling fast toggling of IO under software control.
  - The GPIO DOUT registers (data out) are also available on the PD1 peripheral bus, primarily so that the DMA can be used to load values to the GPIO DOUT registers.
  - While the bus interfaces to the GPIO peripherals are in the PD1 power domain (for best read/write performance), the GPIO logic itself is in the PD0 power domain so that it is available in all operating modes in which the core regulator is active.
- ADC peripherals interface to the system through the PD1 peripheral bus but contain functional logic in the PD0 power domain.
  - ADC peripheral register accesses are processed through the PD1 peripheral bus (for best read/write performance)
  - The the ADC conversion logic is in the PD0 power domain to enable running timer-triggered ADC conversions without CPU interaction in certain low-power modes when PD1 is disabled.

## 1.3 Platform Memory Map

All MSPM0Gxx devices share a common platform memory map. Peripherals are assigned a fixed address space and have the same address space on all devices within the family. The memory map is compliant with the standard Arm Cortex-M memory regions.

**Table 1-1. Top Level Memory Map**

Memory Region	Start Address	End Address	Description
Code	0x0000.0000	0x1FFF.FFFF	Flash memory and ROM
SRAM	0x2000.0000	0x3FFF.FFFF	SRAM
Peripheral	0x4000.0000	0x5FFF.FFFF	Global peripheral memory-mapped registers and global nonexecutable data memory
Subsystem	0x6000.0000	0x7FFF.FFFF	Local CPU subsystem memory-mapped registers
System PPB	0xE000.0000	0xE00F.FFFF	Arm private peripheral bus

### 1.3.1 Code Region

The code region contains the flash memory used to store executable code and data. Accesses to the flash memory from the CPU through the code region are processed through the AHB bus matrix to the flash read interface directly. The flash memory is aliased to two address spaces in the code region: one returning ECC-corrected data, the other providing uncorrected (raw) data. See [Section 6.2.3.1](#) for the detailed flash memory map.

The code region also contains the read-only memory (ROM) used for the TI device boot code and the bootstrap loader. The ROM is only available during the initial device boot process.

### 1.3.2 SRAM Region

The SRAM region contains the system memory (SRAM). The SRAM supports zero wait state access at the maximum MCLK frequency (80MHz). Accesses to the SRAM from the CPU are processed through the AHB bus matrix to the SRAM interface directly. See the device-specific data sheet for the amount of SRAM present on a given device.

Certain devices optionally support parity or parity and ECC checking of the SRAM. Refer to the device-specific data sheet to determine if a device supports ECC or parity checked SRAM. For information on how parity and ECC errors are handled by the device, see [Section 2.4.10](#).

### Parity Checking

In the case of parity checking (if available), 1 parity bit is provided per 8 data bits. Parity checking is capable of detecting a single bit error in the corresponding 8 bits of data (SED). Writing data to a parity checked address updates the corresponding parity bits based on the new data. Reading data from a parity checked address checks the read data against the corresponding parity bits. Upon a read, if the data does not match the corresponding parity bits, a parity error is generated. For information on how parity errors are handled by the device, see [Section 2.4.10](#).

### ECC Checking

In the case of ECC checking (if available), 8 ECC bits are provided per 64 data bits. ECC is capable of correcting single bit errors (SEC) and detecting dual bit errors (DED) in the corresponding 64 data bits. Writing data to an ECC checked address updates the corresponding ECC code based on the new data. Reading data from an ECC checked address checks the read data against the corresponding ECC code. If a single bit error is found, it is corrected automatically and a correctable ECC error is generated. If a dual bit error is found, an uncorrectable ECC error is generated.

### Aliased Subregions

The physical SRAM on a device is aliased into multiple address subregions in the overall SRAM region, as shown in the following table. The default, parity checked, and unchecked address subregions all map to the same physical SRAM memory. The difference between each aliased subregion is in the type of integrity checks which are applied to the access. For example, writing data to address 0x2000.0000 (the default subregion) will cause the same data to appear at address 0x2020.0000 (the unchecked subregion).

The default subregion (0x2000.0000) is available on all MSPM0 devices, and when used, provides the highest level of integrity checking available on the device. The parity checked subregion (0x2010.0000) is available on devices which support ECC or parity checking, and accesses are always processed with parity checking. The unchecked subregion (0x2020.0000) is available on all devices, and when using this subregion, no integrity checks are performed. The parity/ECC code subregion (0x2030.0000) is available on devices with ECC or parity checking, and it returns the parity or ECC code which corresponds to the address being read.

#### Note

To improve robustness, there is no mechanism provided to disable parity checking of the parity-checked SRAM address space. To operate without parity checking, link the application against the unchecked SRAM address space.

**Table 1-2. SRAM Region Memory Map**

Subregion	Start	End (Maximum)	Description
Default	0x2000.0000	0x200F.FFFF	The highest available integrity check on the device is always applied to accesses in this subregion: <ul style="list-style-type: none"> <li>If the device supports ECC, this subregion is ECC checked.</li> <li>If the device only supports parity (no ECC), this subregion is parity checked and accesses are equivalent to accesses to the parity checked subregion.</li> <li>If the device does not support ECC or parity, no checks are applied to accesses in this subregion and the region is equivalent to the unchecked subregion.</li> </ul>
Parity checked	0x2010.0000	0x201F.FFFF	If the device supports parity, accesses to this subregion are parity checked.

**Table 1-2. SRAM Region Memory Map (continued)**

Subregion	Start	End (Maximum)	Description
Unchecked	0x2020.0000	0x202F.FFFF	No ECC or parity checks are applied to accesses in this subregion.
Parity/ECC code	0x2030.0000	0x203F.FFFF	<p>If the device supports parity or ECC, the parity or ECC codes may be directly accessed through this subregion:</p> <ul style="list-style-type: none"> <li>If the device supports ECC, access to any address within a 64-bit boundary returns the 8 bits corresponding to the ECC code (if the application is linked against the default region) or the parity bits (one per byte) if the application is linked against the parity checked region.</li> <li>If the device supports parity only, access to any address within a 32-bit boundary returns the 4 parity bits (one per byte) if the application is linked against the default region or parity checked region.</li> <li>If the device does not support ECC or parity, access to this region always returns zeros.</li> </ul>

**Note**

In some devices, the SRAM is organized into two or more banks. Not all the banks may have have ECC and/or parity. Typically, the first bank will include ECC and/or parity while additional banks may or may not include ECC/parity. In such cases, the size of each subregion will depend on the device-specific SRAM configuration. For example, if a device features 128KB of SRAM with the first 64KB having ECC/parity protection and the second 64KB without ECC/parity, then the size of ECC protected subregion, the parity checked subregion and the codes region is each 64KB while the unchecked region will be 128KB in size. In all cases, the unchecked subregion is contiguous and of the full size, allowing applications to link code and data freely in this subregion.

**Note**

When ECC checking is used on devices which support ECC, writes to the SRAM require two cycles to complete. Read accesses only require a single cycle and do not incur any additional performance penalty.

On devices supporting parity or ECC, it is possible for application software to partition the usage of the physical SRAM into arbitrary zones which are intended to be ECC checked, parity checked, or unchecked. For example, if a device has 32KB of total SRAM memory, and it supports ECC and parity checking, it is possible to configure the application software to link against two subregions, one being ECC checked and the other being parity checked.

**Note**

It is not recommended to mix and match ECC checked, parity checked, and unchecked accesses to the same memory locations, as this can result in unintended parity/ECC errors. For example, if an SRAM memory location is written to through the parity checked subregion on a device which supports ECC, and then later that location is read through the default (ECC checked) subregion, an ECC error may be generated because the data was written with parity stored to the ECC/parity code memory, as opposed to the correct ECC code being stored.

### Note

The SRAM contents may be random at power-up or when existing SHUTDOWN mode. A read of an SRAM location through an ECC/parity checked region which has not yet been written to may result in a ECC/parity error being detected, causing a hard fault in the processor. Ensure that all SRAM locations are initialized first before being read.

If the application is using only the unchecked memory region, then the Parity/ECC code region can be used for additional application SRAM memory.

### 1.3.3 Peripheral Region

The peripheral region contains the memory-mapped peripherals on the [three peripheral buses](#). The flash memory is also aliased in the peripheral region.

**Table 1-3. Peripheral Region Memory Map**

Type	Start	End	Description
Peripherals	0x4000.0000	0x40FF.FFFF	Memory-mapped registers of peripherals on the peripheral buses
Aliased flash memory	0x4100.0000	0x41FF.FFFF	See <a href="#">Section 6.2.3.1</a>

### 1.3.4 Subsystem Region

The subsystem region contains memory-mapped registers which are specific to the CPU subsystem and do not need to be accessed globally. See the [CPU subsystem chapter](#) for the memory-mapped registers in the subsystem region.

### 1.3.5 System PPB Region

The system private peripheral bus (PPB) region contains memory-mapped registers on the Arm private peripheral bus. These registers are tightly coupled to the CPU and are the interface for peripherals such as the memory protection unit (MPU), SysTick timer, and CPU power management and reset functions.

## 1.4 Boot Configuration

After a [BOOTRST](#), the device executes the start-up boot routines to configure the device for operation before starting the main application. Boot routines are executed from read-only memory (ROM) before the main application is started. There are two boot routines: the boot configuration routine (BCR), and the bootstrap loader (BSL). The boot configuration routine sets up the device security policies, configures the device for operation, and optionally starts the BSL if it presents. The BSL, if started by the BCR, can be used to program or verify the device memory (flash and SRAM) through the use of a standard serial interface (UART or I2C).

After the start-up routines have successfully completed execution, the CPU is reset and the application is started by unconditionally fetching the stack pointer (SP) and reset vector from 0x0000.0000 and 0x0000.0004 of the flash memory. To enable secure boot, this single point of entry into the application code is enforced by the boot sequence. It is not possible to boot into a different memory location.

### 1.4.1 Configuration Memory (NONMAIN)

The NONMAIN is a dedicated region of flash memory which stores the configuration data used by the BCR and BSL to boot the device. The region is not used for any other purpose. The BCR and BSL both have configuration policies which can be left at their default values (as is typical during development and evaluation), or modified for specific purposes (as is typical during production programming) by altering the values programmed into the NONMAIN flash region.

The BCR and BSL configuration data structures are both contained within a single flash sector in the NONMAIN flash memory region. To change any parameter in the boot configuration, it is necessary to erase the entire NONMAIN sector and re-program both the BCR and BSL configuration structures with the desired settings.

The configuration data in the NONMAIN flash region is not affected by a mass erase command, but it is erased and re-programmed to factory defaults by a factory reset command sent to the BCR via the debug sub system mailbox (DSSM) over SWD.

The NONMAIN flash is also erased by a factory reset command sent to the BSL using the UART or I2C BSL interface. However, unlike the DSSM factory reset, the BSL factory reset does not program TI factory defaults to the NONMAIN memory following the erase. As such, it is the responsibility of the host which is connected to the MSPM0 target (via the BSL interface) to re-program the NONMAIN memory with a valid configuration before terminating the BSL session.

---

#### Note

If a factory reset command is executed through the BSL, and a valid NONMAIN configuration is not programmed back into the device before the BSL session is terminated, the device will assume a maximally restrictive state upon the next reset cycle, and it will not be possible to access the device via SWD or the BSL. Always ensure that a valid NONMAIN configuration is programmed back when using the BSL factory reset command.

---

The address ranges for the NONMAIN data structures are given in the *NONMAIN Registers* section. A detailed breakdown of the NONMAIN region is provided at the end of this section.

#### 1.4.1.1 CRC-Backed Configuration Data

The BCR configuration data and BSL configuration data structures in the NONMAIN memory each include a CRC value corresponding to the CRC digest of the respective structure. During the device boot process, the BCR will compute the CRC digest of the data structures and compare it with the stored CRC values before the data contained within the structures is trusted for use.

CRC calculation:

- Polynomial should be as per the chosen standard (CRC32-ISO3309 or CRC16-CCITT). Please refer to related datasheet.
- Input reflected
- Output reflected
- Initial value should be 0xFFFFFFFF
- Final XOR value should be 0x0

#### BCR Configuration CRC Fail Handling

In the event that the BCR configuration data (which contains the SWD policies, BSL enable/disable policy, and flash memory protection and integrity check policies) fails its CRC check during boot, a catastrophic boot error results and the following limitations are imposed:

- The error cause will be logged in the CFG-AP as a boot diagnostic
- The BSL will not be invoked, even if it was configured to be enabled
- The user application is not started
- No application debug access is enabled
- A pending SWD factory reset command, if enabled or enabled with password, is honored
- A pending TI failure analysis flow entry, if enabled, is honored
- The boot process will re-attempt up to 3 times
  - If the 2nd or 3rd attempt pass, the device boots normally
  - If the 3rd attempt does not pass, no further boot attempts are made until the next BOR or POR

The benefit of this CRC check is that any bit flips in configuration data, such as the static write protection configuration (which is a pillar of secure boot), may be detected with high confidence during the boot process. The fail handling procedure explicitly prevents the BSL and user application from running, and the only supported options (SWD factory reset and TI FA) are protected by [16-bit pattern-match fields](#).

## BSL Configuration CRC Fail Handling

If the BSL configuration data (which contains the BSL password and BSL policies) fails the CRC check during BSL invocation, a catastrophic boot error results and the following limitations are imposed:

- The error cause is logged in the CFG-AP as a boot diagnostic
- The BSL is not invoked, even if it was configured to be enabled
- The user application is not started
- No application debug access is enabled
- The boot process re-attempts up to 3 times
  - If the 2nd or 3rd attempt pass, the device boots normally
  - If the 3rd attempt does not pass, no further boot attempts are made until the next BOR or POR

The benefit of this CRC check is that any bit flips in the BSL configuration data may be detected with high confidence during the invoke process. The failure handling procedure prevents the BSL from starting with invalid data which could lead to a loss of security.

## TI Factory Trim Data CRC Fail Handling

In addition to the user-specified configuration data, if the TI factory trim fails its CRC check during boot, a catastrophic boot error will also result with the following limitations:

- The error cause will be logged in the CFG-AP as a boot diagnostic
- The BSL will not be invoked, even if it was configured to be enabled
- The user application is not started
- No application debug access is enabled
- A pending TI failure analysis flow entry, if enabled, is honored
- The boot process will re-attempt up to 3 times
  - If the 2nd or 3rd attempt pass, the device boots normally
  - If the 3rd attempt does not pass, no further boot attempts are made until the next BOR or POR

### 1.4.1.2 16-bit Pattern Match for Critical Fields

Critical policies in the BCR configuration memory, such as the SWD security policies, are implemented as 16-bit pattern-match fields in the NONMAIN memory, with the following characteristics:

- An exact pattern match is required to enable lower security states
- Any value in the 16-bit field not matching the exact defined patterns results in a maximally secure state for the respective parameter

This behavior prevents single bit flips from causing the device to enter a lower security state than that which was originally specified.

## 1.4.2 Boot Configuration Routine (BCR)

The boot configuration routine is the first firmware to run on the device after a [BOOTRST](#). The BCR manages the following at boot time:

- Configuring the debug interface security policy
- Optionally executing a mass erase
- Optionally executing a factory reset
- Configuring the flash memory [static write protection](#) policy
- Optionally verifying the integrity of some or all of the application firmware (with a 32-bit CRC)
- Optionally starting the [bootstrap loader \(BSL\)](#)

### 1.4.2.1 Serial Wire Debug Related Policies

The serial wire debug related policies configure the functionality which is available through the device's physical debug interface (SWD). By default, MSPM0 devices come from TI in an unrestricted state. This state allows for easy production programming, evaluation, and development. However, this unrestricted state is not recommended for mass production, as it leaves a large attack surface present. To accommodate a variety of

needs while keeping the configuration process simple, MSPM0 devices support three generic security levels: no restrictions ([Level 0](#)), custom restrictions ([Level 1](#)), and fully restricted ([Level 2](#)). [Table 1-4](#) shows the three generic security levels, from least restrictive to most restrictive.

There are 4 main uses of the SWD interface for which protection needs to be considered:

- Application debug access, which includes:
  - Full access to the processor, memory map, and peripherals through the AHB-AP
  - Access to the device EnergyTrace+ state information through the ET-AP
  - Access to the device power state controls for debug through the PWR-AP
- Mass erase access, which includes:
  - Ability to send a command through SWD to erase the MAIN memory region while leaving the NONMAIN device configuration memory intact
- Factory reset access, which includes:
  - Ability to send a command through SWD to erase the MAIN memory region and reset the NONMAIN device configuration memory to TI factory defaults (Level 0)
- TI failure analysis access, which includes:
  - Ability for TI to initiate a failure analysis return flow through SWD (note that the TI FA flow always forces a factory reset before FA access is given to TI; this ensures that TI does not have any mechanism to read proprietary customer information stored in the device flash memory when a failure analysis flow is initiated)

**Table 1-4. Generic Security Levels**

Level	Scenario	SW-DP Policy	App Debug Policy	Mass Erase Policy	Factory Reset Policy	TI FA Policy
0	No restrictions	EN	EN	ENEN,	EN	EN
1	Custom restrictions	EN	EN, EN with PW, DIS	EN, EN with PWDIS	EN, EN with PW, DIS	EN, DIS
2	Fully restricted	DIS	Don't care (access not possible with SW-DP disabled) <sup>(1)</sup>			

(1) When the SW-DP policy is **SW-DP disabled**, the mass erase and factory reset policies are a don't care from the point of view of the SWD interface. However, if the bootstrap loader (BSL) is enabled, the mass erase and factory reset policies do impact what functionality is available through the BSL. See the BSL security section for details on securing the BSL.

#### 1.4.2.1.1 SWD Security Level 0

SWD security level 0 is the least restrictive SWD security state. This is the default state of a new device from TI, and it is also the state of a device following a successful factory reset. There are no restrictions on application debug access, mass erase, factory reset, for failure analysis in this state.

##### When to Use This State

Level 0 is well suited for prototyping and development, as it allows programming of the device memory and debug of the processor and peripherals.

##### When to Not Use this State

Level 0 should not be used in mass production. An attacker would have full freedom to read the contents of the device memory, manipulate the execution of the device, and possibly change the flash memory contents (depending on the flash memory write protection scheme).

#### 1.4.2.1.2 SWD Security Level 1

SWD security level 1 allows for a customized security configuration. The physical debug port (SW-DP) is left enabled, and each function (application debug, mass erase command, factory reset command, and TI failure analysis) may be individually enabled, disabled, or (in some cases) enabled through password authentication, providing considerable flexibility to tailor the device behavior to specific use-cases.

## When to Use This State

Level 1 is well suited for restricted prototyping/development scenarios and for mass production scenarios where the desire is to retain certain SWD functions (such as factory reset and TI failure analysis) while disabling other functions (such as application debug). Common examples of Level 1 customized configurations are given in [Table 1-5](#).

**Table 1-5. Examples of Level 1 Configurations**

Level 1 Scenario	Configuration			
	App Debug	Mass Erase	Factory Reset	TI FA
This scenario restricts debug access with a user-specified password, but it leaves the factory reset and TI failure analysis available. This configuration allows field debug (with password), and it also allows the device to be brought back to the default "Level 0" state through factory reset.	EN with PW	DIS	EN	EN
This scenario does not allow debug. It does allow factory reset, but only with a user-specified password. This provides a way to open up a device in the field by clearing the MAIN memory contents and bringing the device back to a "Level 0" state if the password is known. Importantly, even if the factory reset password were compromised, it would not be possible for an attacker to read proprietary information in the MAIN flash memory.	DIS	DIS	EN with PW	EN
This scenario does not allow debug and it does not allow TI failure analysis. This prevents TI from performing a factory reset and further FA activities on the device, unless the user executes a factory reset with their user-specified password before returning the devices to TI for FA.	DIS	DIS	EN with PW	DIS

### Note

Level 1 is the recommended configuration for most standard production use-cases. For applications which do not require secure boot, TI recommends using Level 1 in production with factory reset left enabled (with password) and TI failure analysis left enabled. In such a configuration, the device may be recovered to a less restrictive state after provisioning either by the user (with password) or by TI (through the failure analysis return flow). In use-cases requiring maximum secure boot assurance, a more restrictive Level 1 or Level 2 may be used for production, with the trade-off that devices may not be recoverable to a less restrictive state once provisioned.

## When to Not Use this State

Level 1 should not be used during prototyping if complete access to the device is desired; in such a case, Level 0 should be used instead.

Level 1 should also not be used in a mass production scenario where a maximally restrictive state is desired and no SWD functions are to be enabled; in such a case, Level 2 should be used instead as it directly disables the complete SWD physical interface and minimizes the possibility of misconfiguration.

### Note

If a device is configured with application debug and factory reset disabled, the only way for a user to restore debug access to the device is if the user application code provides a mechanism to change the NONMAIN configuration to a less restrictive state. If the [NONMAIN is locked through static write protection](#) then the state is not reversible and there is no way for a user to re-gain debug access.

### 1.4.2.1.3 SWD Security Level 2

SWD security level 2 configures the device in a maximally restrictive state. The physical debug port (SW-DP) is completely disabled, and all of the SWD-accessible functions (application debug, mass erase, factory reset, and TI failure analysis) are not accessible through SWD, regardless of their individual configuration.

When level 2 is selected (SW-DP disabled), the application debug configuration and TI failure analysis configuration fields are don't care fields which do not impact the device configuration.

If the BSL is disabled, then the mass erase and factory reset configuration fields are also don't care fields. However, if the BSL is enabled, then the mass erase and factory reset configuration fields are still used by the BSL to authorize mass erase or factory reset commands originating from the BSL interface.

### When to Use This State

Use Level 2 only for mass production when no further access to any SWD functions is required and a maximally secure state is desired for the device.

### When to Not Use this State

Do not use Level 2 in the following cases:

- Future application debug or reprogramming through SWD is required
- So that TI can perform failure analysis on the device
- To remove proprietary information from the flash memory by sending a mass erase or factory reset command through SWD

---

#### Note

After a device is configured for level 2 (SW-DP disabled), further access to the device through SWD **is not possible**. The only way to bring a device back to a level 0 or level 1 state with SWD access restored is if the BSL and factory reset are both enabled (allowing a BSL factory reset command to be sent), or a mechanism in the user application code is included which can change the NONMAIN configuration to a less restrictive state. In either scenario, if the [NONMAIN is locked through static write protection](#) then the level 2 state is not reversible and there is no way to re-gain SWD access.

---

#### 1.4.2.2 SWD Mass Erase and Factory Reset Commands

The BCR provides mass erase and factory reset functionality through commands sent to the device over SWD from a debug probe using the [debug subsystem mailbox \(DSSM\)](#). These commands are not available in SWD security level 2, but they are optionally available in security level 0 and 1. When the device is not configured for SWD security level 2, the mass erase and factory reset commands can be individually configured to be enabled, enabled with a unique 128-bit password, or disabled. By default, both commands are enabled.

The SWD mass erase and factory reset DSSM commands superseded any static write protection policies. For example, if SWD factory reset is configured to be enabled or enabled with password, the BCR configuration data can be reset even if it is statically write protected.

#### SWD Mass Erase

A SWD mass erase is an erase of the MAIN flash regions only, which typically includes the user application. The BCR and BSL policies stored in the NONMAIN flash region are not affected by a mass erase. A mass erase is useful for erasing all application code and data while leaving the device configuration itself intact.

To set the mass erase command mode and password, configure the BOOTCFG3.MASSERASECMDACCESS field and the PWDMASSERASE password fields in the NONMAIN memory.

#### SWD Factory Reset

A SWD factory reset is an erase of the MAIN flash regions followed by a reset of the NONMAIN flash region to default values. Such an erase is useful for completely resetting the BCR and BSL device boot policies while also erasing the application code and data.

To set the factory reset command mode and password, configure the BOOTCFG3.FACTORYRESETCMDACCESS field and the PWDFACTORYRESET password fields in the NONMAIN memory.

### 1.4.2.3 Flash Memory Protection and Integrity Related Policies

The flash memory protection and integrity policies specify which sectors of flash memory are locked from modification, as well as which sectors are to be checked for integrity during the boot process before the user application is started.

#### 1.4.2.3.1 Locking the Application (MAIN) Flash Memory

MSPM0 MCUs implement a static write protection scheme to lock out user defined sectors in the MAIN flash region from any program or erase operations at runtime. The desired static write protection scheme is configured as a part of the boot security policies in the NONMAIN flash region.

#### Purpose

Static write protection enables placement of a fixed, user-defined, application in the flash memory that has the following characteristics:

- Once programmed and locked, the application is not modifiable by the application code or ROM bootloader
- If placed at the beginning of the flash memory, the application is the first code that executes when the ROM boot configuration routine transfers execution to the user application

MSPM0 static write protection supports both characteristics, which must be satisfied to implement a secure boot image manager.

#### Capabilities

Any sector that is configured in the NONMAIN to be write-locked is functionally immutable when the boot configuration routine transfers execution to either the bootstrap loader or the user application code in MAIN flash. Any attempt to program or erase a statically protected sector by the application code or the bootstrap loader results in a hardware flash operation error, and the sector is not modified.

While static write protection prevents any modification by application code or the bootloader, a mass erase or factory reset command sent through the SWD interface is honored. If this behavior is not desired, the mass erase or factory reset SWD commands can be protected with unique passwords or disabled (see the [SWD policies](#)). To completely remove any means of modifying statically write protected MAIN flash sectors, the mass erase and factory reset commands (or the SW-DP) must be disabled, and the NONMAIN boot configuration memory must also be statically write protected to prevent application code from changing the underlying write protection scheme by modifying the contents NONMAIN region. This is discussed in the following section.

#### 1.4.2.3.2 Locking the Configuration (NONMAIN) Flash Memory

MSPM0 MCUs implement a static write protection scheme to lock out the NONMAIN flash region from any program/erase operations at runtime. The write protection scheme is configured as a part of the boot security policies in the NONMAIN flash region.

#### Purpose

By default, the NONMAIN configuration memory (which contains the user-specified boot security policies and bootstrap loader policies) is not write protected. This enables the NONMAIN to be erased by the user during provisioning and re-programmed with the user-specified policies to use in mass production.

In many cases, it is desirable for the configuration memory to be locked after it has been provisioned. Locking the configuration memory has the benefit of preventing any unauthorized modification of the security policies, bootstrap loader policies, and static write protection policies by either the bootstrap loader or the application code. In most applications, devices in mass production do not require modification of the configuration memory, even when the device firmware is updated.

#### Capabilities

When configured to be protected, the entire NONMAIN region will be write-locked and will be functionally immutable when the boot configuration routine transfers execution to either the bootstrap loader or the user application code in MAIN flash. Any attempt to program or erase the NONMAIN by the application code or the bootstrap loader will result in a hardware flash operation error, and the sector will not be modified.

While static write protection prevents any modification by application code or the boot loader, a factory reset command sent through the SWD interface would still be honored. If this behavior is not desired, the factory reset SWD command may be protected with a unique password or disabled altogether (see the [SWD policies](#)). To completely remove any means of modifying the NONMAIN configuration memory, the factory reset command and TI FA (or the SW-DP) must be disabled.

---

#### Note

When the NONMAIN is statically write protected, and the factory reset command and TI FA (or the SW-DP) are disabled, the NONMAIN is equivalent to immutable read-only memory, and it is no longer possible to change the device configuration by any means. Further, if any MAIN memory region sectors are configured with static protection, these sectors also cannot be modified by any means and may be considered as immutable.

---

#### 1.4.2.3.3 Static Write Protection NONMAIN Fields

Write protection may be enabled on a per-sector basis for the first 32 sectors of the MAIN flash memory. For the remaining sectors of flash memory, if present, write protection may be enabled per 8 sectors. To set a static write protection policy, configure the FLASHSWP0 and FLASHSWP1 fields in the NONMAIN memory.

---

#### Note

[Mass erase and factory reset commands](#) [Factory reset command](#) sent to the BCR via the debug sub system mailbox (DSSM) will override the specified static write protection policy. If this behavior is not desired, configure the mass erase and factory reset commands to be enabled with password or disabled. Note that mass erase and factory reset commands sent to the BSL will respect the specified static write protection policy (the BSL has the same permissions as application code).

---

#### 1.4.2.4 Application CRC Verification

The BCR supports executing a complete CRC32 integrity check of the application code and data contained in the MAIN flash regions during the boot process before starting the user application. This is useful to ensure the integrity of some or all of the application code and data before executing it.

To enable the CRC32 integrity check at boot, the following information must be programmed into the BCR configuration in NONMAIN flash memory:

- 32-bit starting address of the CRC check (APPCRCSTART.ADDRESS field)
- The length of the application (specified in bytes) for which the CRC check is applied (APPCRCLEN.LENGTH field)
- The precalculated 32-bit CRC value to test against (APPCRC.DIGEST field)
- The enabled key value for the CRC check (BOOTCFG3.APPCRCMODE field)

In the event that an application CRC check fails at boot, the application in MAIN flash is not started. If the boot strap loader is enabled, it is entered. If the BSL is not enabled, then the boot fails.

#### 1.4.2.5 Fast Boot

The execution time of the BCR can be reduced by enabling fast boot mode. Fast boot mode, when enabled, speeds up the boot process using the following methods:

- Limiting the BSL entry methods. When fast boot mode is enabled, only the SYSCTL register invoke method and the DSSM invoke method can be used to enter the bootloader. The other BSL invoke conditions are not tested (for example, pin based invoke).
- Bypassing the [application CRC check](#) (even if the application CRC check is enabled).

To enable fast boot mode, set the fast boot mode to enabled in the BOOTCFG2.FASTBOOTMODE field in the NONMAIN flash memory.

#### 1.4.2.6 Bootstrap Loader (BSL) Enable/Disable Policy

The bootstrap loader (BSL) provides a means to program and verify the device memory through a standard serial interface (UART or I2C), as opposed to the serial wire debug interface. The BSL has its own configuration policy, but the BCR determines if the BSL is enabled to be invoked, or if it is to be disabled (noninvokable).

Since the BSL presents an additional attack surface, if it is not used in an application it may be disabled in the user-specified boot security policies. If the BSL is used in an application, then the BSL security settings (including the BSL access password) are managed in the [BSL configuration policy](#).

##### 1.4.2.6.1 BSL Enable

The bootstrap loader ([BSL](#)) can be enabled or disabled by setting the bootloader mode to enabled or disabled in the BOOTCFG2.BSLMODE field in the NONMAIN flash memory. When the BSL is disabled, the bootloader cannot be entered through any invocation mechanism.

#### 1.4.3 Bootstrap Loader (BSL)

The bootstrap loader (BSL) provides a method to program and/or verify the device memory through a standard UART or I2C serial interface. Key features of the BSL which are accessible through the serial interface include:

- Programming and erase of flash memory
- Ability to return a firmware version number through a pointer to the main flash
- Ability to specify a hardware invoke GPIO
- Ability to enable code/data read-out (disabled by default)
- Ability to return a 32-bit CRC of a code/data region (1KB minimum region size) to verify programming
- Access is always protected with a 256-bit password
- Configurable security alert handling for resisting brute force attacks
- Support for MAIN flash plug-ins to enable additional interfaces beyond UART and I2C

For a complete description of the BSL features, see the BSL user's guide.

The BSL can be completely disabled if desired by properly configuring the BSL mode in the BCR configuration in the NONMAIN flash. See the [BSL Enable](#) section for details on enabling or disabling the BSL.

##### 1.4.3.1 GPIO Invoke

The bootloader supports hardware invoking after a BOOTRST through the use of a GPIO. The BSL configuration in the NONMAIN flash memory contains the pad, pin, and polarity definition for the GPIO invocation. Devices come configured from TI for a specific GPIO and polarity, but software can change this default by modifying the GPIO pin configuration in the BSL configuration in NONMAIN flash memory.

To specify the polarity of the BSL\_invoke pin, configure the BSLCONFIG0.BSLIVK\_LVL field in the NONMAIN memory.

To specify the device pin to be used for BSL\_invoke, configure the following fields in the NONMAIN memory:

- Store the IOMUX PINCMx index into the BSLCONFIG0.BSLIVK\_PAD\_NUM field
- Store the GPIO port (A or B) into the BSLCONFIG0.BSLIVK\_GPIOPORT field
- Store the GPIO pin (0-31) into the BSLCONFIG0.BSLIVK\_GPIOPIN field

See the device specific data sheet to determine the default BSL invoke GPIO.

##### 1.4.3.2 Bootstrap Loader (BSL) Security Policies

The BSL security policies are interpreted by the boot loader when it is invoked, and include the following parameters:

- BSL access password, described in [Section 1.4.3.2.1](#)
- BSL read-out policy, described in [Section 1.4.3.2.2](#)
- BSL security alert policy (tamper detection), described in [Section 1.4.3.2.3](#)

#### 1.4.3.2.1 BSL Access Password

Access to the BSL is always protected by a 256-bit user-specified password. There is no option to disable the password. The password must be provided to the BSL after invocation for access to most BSL functions to be granted. When the password is not provided, the only BSL commands allowed are *Get Identity* and *Start Application*.

If a wrong password is provided to the BSL, the BSL halts for 2 seconds, after which an additional attempt can be made to send the correct password. After three failed password attempts, the security alert function is activated (see [Section 1.4.3.2.3](#)).

#### 1.4.3.2.2 BSL Read-out Policy

The BSL optionally supports read-out of the device memory for debug and/or diagnostic purposes (after access to the BSL has been granted with a [correct password match](#)). By default, this capability is disabled for security to prevent extraction of sensitive code and/or data from the device. When the BSL read-out policy is disabled, the only information which may be provided to a host through the BSL interface is a CRC32 digest of a memory segment with a minimum segment length of 1 kilobyte. If direct read-out of the device memory is desired, it may be enabled in the BSL configuration.

#### 1.4.3.2.3 BSL Security Alert Policy

The BSL provides an alert mechanism for taking action when tampering is suspected. Specifically, if an incorrect password is passed to the BSL 3 times during one BSL session, the security alert is activated and the BSL may respond in one of three different ways based on the specified security alert policy:

1. Issue a factory reset (erasing the MAIN flash and resetting the NONMAIN flash regions)
2. Disable the BSL (leaves the MAIN flash intact but re-configures the NONMAIN to block BSL access)
3. Ignore (do not modify the configuration and allow password attempts to continue)

---

#### Note

Options 1 and 2 require that the NONMAIN flash region not be statically write protected (see [Section 1.4.2.3.2](#)).

When option 1 is selected, any MAIN memory region which is configured to be statically write protected (see [Section 1.4.2.3.1](#)) will not be erased during the factory reset.

---

#### 1.4.3.3 Application Version

The BSL supports returning an application version number through the BSL serial interface. This allows the BSL host to interrogate the firmware version without being able to read the firmware. The version field is 32 bits in length. To link the application version command to a version number programmed in the main flash, program the address of the version number in the BSLAPPVER.ADDRESS field in NONMAIN flash memory. The version data is only returned if the address specified in BSLAPPVER.ADDRESS corresponds to a valid flash memory address.

#### 1.4.3.4 BSL Triggered Mass Erase and Factory Reset

It is possible to send a mass erase or factory reset command to the BSL. The commands work in a similar way as the [SWD mass erase and factory reset commands](#), with several key exceptions.

#### BSL Mass Erase

A mass erase command sent to the BSL will erase the MAIN flash memory. Any MAIN flash memory sectors which are configured to be statically write protected (via the FLASHSWP0 and FLASHSWP1 fields in the NONMAIN configuration memory) will not be erased. The NONMAIN device configuration memory is never erased by a mass erase.

## BSL Factory Reset

A factory reset command sent to the BSL will first perform a BSL mass erase to erase the main flash memory (excluding any sectors which are statically write protected). Then, it will additionally erase the NONMAIN device configuration memory.

A BSL factory reset command is only accepted if the following are true:

1. The NONMAIN memory itself is not currently configured to be statically write protected (BOOTCFG4.NONMAINSWP field in the NONMAIN is set to not protected)
2. The factory reset command is not configured to be disabled (BOOTCFG3.FACTORYRESETCMDACCESS field in the NONMAIN is not set to disabled)

The BSL host must program valid configuration data back into the NONMAIN (via BSL commands) before terminating the BSL session, or the device may enter an unrecoverable state.

### Note

If the NONMAIN is left unprogrammed after a BSL factory reset, the device will assume a maximally restrictive state on the next reset cycle, any application code in MAIN flash will not be started, and it will not be possible to access the device via any means. To prevent lockout, always ensure that valid configuration data is programmed into NONMAIN following a BSL factory reset.

### 1.4.4 NONMAIN Layout Types

The below table shows which NONMAIN layout type to use with which devices. The MSPM0-SDK includes a configurator tool to help the user configure NONMAIN contents.

**Table 1-6. NONMAIN Layout Types**

NONMAIN Layout Type	Overview	Supported Devices
Type A	<ul style="list-style-type: none"> <li>• No CSC support</li> <li>• Passwords stored in plaintext format</li> <li>• App integrity check has CRC32 support only</li> </ul>	<ul style="list-style-type: none"> <li>• MSPM0G110x</li> <li>• MSPM0G150x</li> <li>• MSPM0G310x</li> <li>• MSPM0G350x</li> </ul>
Type E	<ul style="list-style-type: none"> <li>• Includes CSC support</li> <li>• Passwords stored in SHA256 hashed format</li> <li>• App integrity check has CRC32 or SHA256 hash option</li> <li>• UART default baudrate configuration</li> <li>• Disable NRST in BSL</li> </ul>	<ul style="list-style-type: none"> <li>• MSPM0G511x</li> <li>• MSPM0G5187</li> </ul>
Type F	<ul style="list-style-type: none"> <li>• Includes CSC support</li> <li>• Passwords stored in SHA256 hashed format</li> <li>• App integrity check has CRC32 or SHA256 hash option</li> <li>• UART default baudrate configuration</li> </ul>	<ul style="list-style-type: none"> <li>• MSPM0G151x</li> <li>• MSPM0G351x</li> <li>• MSPM0G352x</li> </ul>

### 1.4.5 NONMAIN\_TYPEA Registers

Table 1-7 lists the memory-mapped registers for the NONMAIN\_TYPEA registers. All register offset addresses not listed in Table 1-7 should be considered as reserved locations and the register contents should not be modified.

**Table 1-7. NONMAIN\_TYPEA Registers**

Offset	Acronym	Register Name	Group	Section
41C0000 0h	BCRCONFIGID	Configuration ID of BCR Structure		<a href="#">Go</a>
41C0000 4h	BOOTCFG0	Serial wire debug (SWD) lock policy.		<a href="#">Go</a>
41C0000 8h	BOOTCFG1	TI Failure Analysis (FA) mode and BSL invoke pin policies.		<a href="#">Go</a>
41C0000 Ch + formula	PWDDEBUGLOCK[y]	Debug Lock Password. This password is used when the BOOTCFG0.DEBUGACCESS field is configured as Enable with password.		<a href="#">Go</a>
41C0001 Ch	BOOTCFG2	Fast boot mode policy and BSL mode policy		<a href="#">Go</a>
41C0002 0h	BOOTCFG3	Mass erase and factory reset mode policies. These policies affect SWD initiated and BSL initiated mass erase and factory reset commands. If the SW-DP is disabled (SWDP_MODE is disabled), SWD initiated commands are not allowed as the SW-DP is fully disabled. If the BSL is disabled (BSLMODE is disabled), these settings are a a don't care for BSL initiated commands as the BSL is not enabled to be invoked.		<a href="#">Go</a>
41C0002 4h + formula	PWDMASSERASE[y]	SWD mass erase command password (must be provided via DSSM to authenticate a mass erase command)		<a href="#">Go</a>
41C0003 4h + formula	PWDFACTORYRESET[y]	SWD factory reset command password (must be provided via DSSM to authenticate a factory reset command)		<a href="#">Go</a>
41C0004 4h	FLASHSWP0	Static write protection policy for the first 32kB of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code		<a href="#">Go</a>
41C0004 8h	FLASHSWP1	Static write protection policy for additional sectors of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code.		<a href="#">Go</a>
41C0004 Ch	BOOTCFG4	Nonmain protection and Application CRC check policies		<a href="#">Go</a>
41C0005 0h	APPCRCSTART	Start address of the application CRC check (must be an address in a MAIN flash region).		<a href="#">Go</a>
41C0005 4h	APPCRCLENGTH	Length of the application area to include in the application CRC check (in bytes), starting from APPCRCSTART.		<a href="#">Go</a>
41C0005 8h	APPCRC	Expected application CRC check digest (CRC-32) to test against during boot.		<a href="#">Go</a>

**Table 1-7. NONMAIN\_TYPEA Registers (continued)**

Offset	Acronym	Register Name	Group	Section
41C0005 Ch	BOOTCRC	CRC digest of the BCR configuration portion of the NONMAIN memory.		<a href="#">Go</a>
41C0010 0h	BSLCONFIGID	Configuration ID of BSL Structure		<a href="#">Go</a>
41C0010 4h	BSLPINCFG0	BSL UART PIN Configuration. The reset value of these fields differ for each device, based on the pins used.		<a href="#">Go</a>
41C0010 8h	BSLPINCFG1	BSL I2C PIN Configuration. The reset value of these fields differ for each device, based on the pins used.		<a href="#">Go</a>
41C0010 Ch	BSLCONFIG0	BSL invoke pin configuration and memory read-out policy.		<a href="#">Go</a>
41C0011 0h + formula	PWDBSL[y]	BSL access password		<a href="#">Go</a>
41C0013 0h	BSLPLUGINCFG	Defines the presence and type of a BSL plug-in in MAIN flash memory.		<a href="#">Go</a>
41C0013 4h + formula	BSLPLUGINHOOK[y]	Function pointers for plug-in init, receive, transmit, and de-init functions.		<a href="#">Go</a>
41C0014 4h	BSLCONFIG1			<a href="#">Go</a>
41C0014 8h	SBLADDRESS	Address of an alternate BSL.		<a href="#">Go</a>
41C0014 Ch	BSLAPPVER	Address of the application version word.		<a href="#">Go</a>
41C0015 0h	BSLCONFIG2	Configures the BSL Alert Configuration and I2C Slave address of BSL.		<a href="#">Go</a>
41C0015 4h	BSLCRC	CRC digest of the BSL_CONFIG portion of the NONMAIN memory.		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 1-8](#) shows the codes that are used for access types in this section.

**Table 1-8. NONMAIN\_TYPEA Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

**1 BCRCONFIGID (Offset = 41C0000h) [Reset = 0000000h]**

BCRCONFIGID is shown in [Figure 1-2](#) and described in [Table 1-9](#).

31-0	CONFIG	R/W	0h	Configuration ID of the BCR Structure

## 2 BOOTCFG0 (Offset = 41C00004h) [Reset = AABBAABBh]

BOOTCFG0 is shown in [Figure 1-3](#) and described in [Table 1-10](#).

Return to the [Summary Table](#).

Serial wire debug (SWD) lock policy.

**Figure 1-3. BOOTCFG0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWDP_MODE																DEBUGACCESS															
R/W-AABBh																W-AABBh															

**Table 1-12. BOOTCFG0 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	SWDP_MODE	R/W	AABBh	The serial wire debug port (SW-DP) access policy. This policy sets whether any communication is allowed with the device via the SWD pins (to any DAP). When disabled, no SWD communication is possible regardless of the configuration of the DEBUGACCESS field. AABBh = The SW-DP is enabled and device access is set by the additional policies in NONMAIN FFFFh = The SW-DP is fully disabled and no device access is possible via the SW-DP (Any value other than 0xAABB)
15-0	DEBUGACCESS	W	AABBh	The debug access policy for accessing the AHB-AP, ET-AP, and PWR-AP debug access ports. Note that if SWDP_MODE is set to DISABLED, the value of this field is ignored and the debug port will remain fully locked AABBh = Access to AHB-AP, ET-AP, and PWR-AP via SWD is enabled CCDDh = Access to AHB-AP, ET-AP, and PWR-AP via SWD is only enabled when the correct password is provided via the DSSM before BCR execution FFFFh = Access to AHB-AP, ET-AP, and PWR-AP via SWD is disabled (Any value other than 0xCCDD or 0xAABB)

### 3 BOOTCFG1 (Offset = 41C00008h) [Reset = AABBAABBh]

BOOTCFG1 is shown in [Figure 1-4](#) and described in [Table 1-11](#).

Return to the [Summary Table](#).

TI Failure Analysis (FA) mode and BSL invoke pin policies.

**Figure 1-4. BOOTCFG1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BSL_PIN_INVOKE																TI_FA_MODE															
R/W-AABBh																R/W-AABBh															

**Table 1-14. BOOTCFG1 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	BSL_PIN_INVOKE	R/W	AABBh	Boot strap loader (BSL) pin invoke method enable/disable policy AABBh = The BSL_INVOKE pin is checked during boot FFFFh = The BSL_INVOKE pin is not checked during boot (Any value other than 0xAABB)
15-0	TI_FA_MODE	R/W	AABBh	Sets the TI failure analysis enable/disable policy. If enabled, a re-test request through DSSM is allowed, else it is not allowed. Note that if SWDP_MODE is set to disabled, this field is ignored and failure analysis is not possible. AABBh = TI failure analysis is allowed FFFFh = TI failure analysis is not allowed (Any value other than 0xAABB)

#### 4 PWDDEBUGLOCK[y] (Offset = 41C0000Ch + formula) [Reset = FFFFFFFFh]

PWDDEBUGLOCK[y] is shown in [Figure 1-5](#) and described in [Table 1-12](#).

Return to the [Summary Table](#).

Debug Lock Password. This password is used when the BOOTCFG0.DEBUGACCESS field is configured as Enable with password.

Offset = 41C0000Ch + (y \* 4h); where y = 0h to 3h

**Figure 1-5. PWDDEBUGLOCK[y]**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W-FFFFFFFh																															

**Table 1-16. PWDDEBUGLOCK[y] Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	PASSWORD	R/W	FFFFFFFh	Debug Lock Password

## 5 BOOTCFG2 (Offset = 41C0001Ch) [Reset = AABBFfFh]

BOOTCFG2 is shown in [Figure 1-6](#) and described in [Table 1-13](#).

Return to the [Summary Table](#).

Fast boot mode policy and BSL mode policy

**Figure 1-6. BOOTCFG2**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BSLMODE																FASTBOOTMODE															
R/W-AABbh																R/W-FFFFh															

**Table 1-18. BOOTCFG2 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	BSLMODE	R/W	AABbh	BSLMODE configures the boot strap loader enable/disable policy AABbh = The BSL is enabled FFFFh = The BSL is disabled (Any value other than 0xAABB)
15-0	FASTBOOTMODE	R/W	FFFFh	FASTBOOTMODE configures the fast boot mode enable/disable policy AABbh = Fast boot mode is enabled FFFFh = Fast boot mode is disabled. (Any value other than 0xAABB)

## 6 BOOTCFG3 (Offset = 41C00020h) [Reset = AABBAABBh]

BOOTCFG3 is shown in [Figure 1-7](#) and described in [Table 1-14](#).

Return to the [Summary Table](#).

Mass erase and factory reset mode policies. These policies affect SWD initiated and BSL initiated mass erase and factory reset commands. If the SW-DP is disabled (SWDP\_MODE is disabled), SWD initiated commands are not allowed as the SW-DP is fully disabled. If the BSL is disabled (BSLMODE is disabled), these settings are a don't care for BSL initiated commands as the BSL is not enabled to be invoked.

**Figure 1-7. BOOTCFG3**

## 9 FLASHSWP0 (Offset = 41C00044h) [Reset = FFFFFFFFh]

FLASHSWP0 is shown in [Figure 1-10](#) and described in [Table 1-17](#).

Return to the [Summary Table](#).

Static write protection policy for the first 32kB of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code

**Figure 1-10. FLASHSWP0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															
R/W-FFFFFFFh																															

**Table 1-26. FLASHSWP0 Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	FFFFFFFh	1 bit per sector 0h = A value of 0 indicates the write protection is applied to the corresponding sector 1h = A value of 1 indicates the sector is un-protected

**10 FLASHSWP1 (Offset = 41C00048h) [Reset = FFFFFFFFh]**

FLASHSWP1 is shown in [Figure 1-11](#) and described in [Table 1-18](#).

Return to the [Summary Table](#).

Static write protection policy for additional sectors of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code.

**Figure 1-11. FLASHSWP1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-0	DATA	R/W	FFFFFFFh	1 bit per 8 sectors. This is used to protect Flash memory from (32 to 256 kb) 0h = A value of 0 indicates the write protection is applied to the corresponding sectors 1h = A value of 1 indicates the sector is un-protected

## 11 BOOTCFG4 (Offset = 41C0004Ch) [Reset = FFFFFFFFh]

BOOTCFG4 is shown in [Figure 1-12](#) and described in [Table 1-19](#).

Return to the [Summary Table](#).

Nonmain protection and Application CRC check policies

**Figure 1-12. BOOTCFG4**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
APPCRCMODE																NONMAINSWP															
R/W-FFFFh																R/W-FFFFh															

**Table 1-30. BOOTCFG4 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	APPCRCMODE	R/W	FFFFh	APPCRCMODE enables or disables the boot time CRC check of a segment of MAIN flash memory. AABBh = The boot time MAIN flash CRC check is enabled. If the boot time CRC check passes, the application code in MAIN flash is started unless the reset vector or stack pointer are blank (unprogrammed). In the event of a failing CRC check, the application code in MAIN flash will not be started and the boot process fails. FFFFh = The boot time MAIN flash CRC check is disabled. The application code in MAIN flash is always started unless the reset vector or stack pointer are blank (unprogrammed).
15-0	NONMAINSWP	R/W	FFFFh	Static write protection policy for entire NONMAIN device configuration memory. Only Bit 0 is used. 0h = Protected, does not allow program/erase of the NONMAIN by all means other than a SWD-initiated factory reset 1h = Unprotected, allows program/erase of the NONMAIN by normal means.

**12 APPCRCSTART (Offset = 41C00050h) [Reset = FFFFFFFFh]**

APPCRCSTART is shown in [Figure 1-13](#) and described in [Table 1-20](#).

Return to the [Summary Table](#).

Start address of the application CRC check (must be an address in a MAIN flash region).

**Figure 1-13. APPCRCSTART**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS

RESERVED																ALTBSLCONFIG															
R-0h																R/W-FFFFh															

**Table 1-54. BSLCONFIG1 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	FFFFh	
15-0	ALTBSLCONFIG	R/W	FFFFh	Controls the invocation of alternate BSL in main flash region. AABBh = Uses the alternate BSL FFFFh = Does not use alternate BSL. Uses ROM BSL.

**24 SBLADDRESS (Offset = 41C00148h) [Reset = FFFFFFFFh]**

SBLADDRESS is shown in [Figure 1-25](#) and described in [Table 1-32](#).

Return to the [Summary Table](#).

Address of an alternate BSL.

**Figure 1-25. SBLADDRESS**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS																															
R/W-FFFFFFFh																															

**Table 1-56. SBLADDRESS Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	ADDRESS	R/W	FFFFFFFh	Address of the alternate BSL, if present.

**25 BSLAPPVER (Offset = 41C0014Ch) [Reset = FFFFFFFFh]**

BSLAPPVER is shown in [Figure 1-26](#) and described in [Table 1-33](#).

Return to the [Summary Table](#).

Address of the application version word.

**Figure 1-26. BSLAPPVER**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS																															
R/W-FFFFFFFh																															

**Table 1-58. BSLAPPVER Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	ADDRESS	R/W	FFFFFFFh	Address of the application version word (must be a valid flash address to be returned). If the given flash address is not programmed, then 0h will be returned.

## 26 BSLCONFIG2 (Offset = 41C00150h) [Reset = 0048FFFFh]

BSLCONFIG2 is shown in [Figure 1-27](#) and described in [Table 1-34](#).

Return to the [Summary Table](#).

Configures the BSL Alert Configuration and I2C Slave address of BSL.

**Figure 1-27. BSLCONFIG2**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
I2CTARGETADDR																ALERTACTION															
R/W-48h																R/W-FFFFh															

**Table 1-60. BSLCONFIG2 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	I2CTARGETADDR	R/W	0048h	I2C target address to be used for the ROM BSL I2C communication.
15-0	ALERTACTION	R/W	FFFFh	Action to take upon a security alert condition. AABBh = Trigger a factory reset. Note that if sectors in MAIN or NONMAIN flash are write protected they will not be affected by the BSL factory reset CCDDh = Re-configure the NONMAIN region to disable the BSL. This is not supported if the NONMAIN region is configured to be write protected 000FFFFh = Ignore the security alert condition (Any value other than 0xAABB)

**27 BSLCRC (Offset = 41C00154h) [Reset = XXXXXXXXh]**

BSLCRC is shown in [Figure 1-28](#) and described in [Table 1-35](#).

Return to the [Summary Table](#).

CRC digest of the BSL\_CONFIG portion of the NONMAIN memory.

**Figure 1-28. BSLCRC**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIGEST																															
R/W-X																															

**Table 1-62. BSLCRC Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DIGEST	R/W	X	BSL configuration data CRC digest. 32 bit CRC Digest, if the device supports CRC32-ISO3309. Otherwise 16 bit CRC digest, using polynomial CRC16-CCITT. Configuration to be used for CRC calculation: 1. Polynomial should be as per the chosen standard, 2. Input reflected, 3. Output reflected, 4. Initial value should be 0xFFFFFFFF, 5. Final XOR value should be 0x0.  xxxxxxx

### 1.4.6 NONMAIN\_TYPEE Registers

Table 1-36 lists the memory-mapped registers for the NONMAIN\_TYPEE registers. All register offset addresses not listed in Table 1-36 should be considered as reserved locations and the register contents should not be modified.

**Table 1-63. NONMAIN\_TYPEE Registers**

Offset	Acronym	Register Name	Group	Section
41C0000 0h	BCRCONFIGID	Configuration ID of BCR Structure		<a href="#">Go</a>
41C0000 4h	BOOTCFG0	Serial wire debug (SWD) lock policy.		<a href="#">Go</a>
41C0000 8h	BOOTCFG1	TI Failure Analysis (FA) mode and BSL invoke pin policies		<a href="#">Go</a>
41C0000 Ch	FLASHSWP0	Static write protection policy for the first 32kB of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code		<a href="#">Go</a>
41C0001 0h	FLASHSWP1	Static write protection policy for additional sectors of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code		<a href="#">Go</a>
41C0001 4h	BOOTCFG4	Configures Static write protection policy for Configuration flash memory(NONMAIN) and Debug Hold Policy		<a href="#">Go</a>
41C0001 8h	BOOTCFG5	Configures the existence of Customer Secure Code(CSC) and Flash Bank Swap Policy		<a href="#">Go</a>
41C0001 Ch	BOOTCFG2	Fast boot mode policy and BSL mode policy		<a href="#">Go</a>
41C0002 0h	BOOTCFG3	Mass erase and factory reset mode policies. These policies affect SWD initiated and BSL initiated mass erase and factory reset commands. If the SW-DP is disabled (SWDP_MODE is disabled), SWD initiated commands are not allowed as the SW-DP is fully disabled. If the BSL is disabled (BSLMODE is disabled), these settings are a don't care for BSL initiated commands as the BSL is not enabled to be invoked.		<a href="#">Go</a>
41C0002 4h + formula	PWDMASSERASE[y]	SHA2-256 Digest of the SWD mass erase command password (must be provided via DSSM to authenticate a mass erase command)		<a href="#">Go</a>
41C0004 4h + formula	PWDFACTORYRESET[y]	SHA2-256 digest of the SWD factory reset command password (must be provided via DSSM to authenticate a factory reset command)		<a href="#">Go</a>
41C0006 4h + formula	PWDDEBUGLOCK[y]	SHA2-256 Digest of the Debug Lock Password. This password is used when the BOOTCFG0.DEBUGACCESS field is configured as Enable with password.		<a href="#">Go</a>
41C0008 4h	BOOTCFG6	Application digest check policy		<a href="#">Go</a>

**Table 1-63. NONMAIN\_TYPEE Registers (continued)**

Offset	Acronym	Register Name	Group	Section
41C0008 8h	APPDIGESTSTART	Start address of the application CRC/SHA Digest check (must be an address in a MAIN flash region).		<a href="#">Go</a>
41C0008 Ch	APPDIGESTLENGTH	Length of the application to be include in the application CRC/SHA Digest check (in bytes), starting from APPDIGESTSTART		<a href="#">Go</a>
41C0009 0h + formula	APPDIGEST[y]	Expected application CRC32/SHA2-256 digest to test against during boot. Note: If CRC check is enabled only the first 32bit word of this DIGEST is used.		<a href="#">Go</a>
41C000 B0h	FLASHSWP2	Static write protection policy for additional sectors of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code		<a href="#">Go</a>
41C000 B4h	BOOTCRC	CRC digest of the BCR configuration portion of the NONMAIN memory.		<a href="#">Go</a>
41C0010 0h	BSLCONFIGID	Configuration ID of BSL Structure		<a href="#">Go</a>
41C0010 4h	BSLPINCFG0	BSL UART PIN Configuration. The reset value of these fields differ for each device, based on the pins used.		<a href="#">Go</a>
41C0010 8h	BSLPINCFG1	BSL I2C PIN Configuration. The reset value of these fields differ for each device, based on the pins used.		<a href="#">Go</a>
41C0010 Ch	BSLCONFIG0	BSL invoke pin configuration and memory read-out policy.		<a href="#">Go</a>
41C0011 0h	PWDBSL0	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0011 4h	PWDBSL1	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0011 8h	PWDBSL2	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0011 Ch	PWDBSL3	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0012 0h	PWDBSL4	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0012 4h	PWDBSL5	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0012 8h	PWDBSL6	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0012 Ch	PWDBSL7	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0013 0h	BSLPLUGINCFG	Defines the presence and type of a BSL plug-in in MAIN flash memory.		<a href="#">Go</a>
41C0013 4h + formula	BSLPLUGINHOOK[y]	Function pointers for plug-in init, receive, transmit, and de-init functions.		<a href="#">Go</a>
41C0014 4h	BSLCONFIG1			<a href="#">Go</a>
41C0014 8h	SBLADDRESS	Address of an alternate BSL.		<a href="#">Go</a>
41C0014 Ch	BSLAPPVER	Address of the application version word.		<a href="#">Go</a>

**Table 1-63. NONMAIN\_TYPEE Registers (continued)**

Offset	Acronym	Register Name	Group	Section
41C0015 0h	BSLCONFIG2	Configures the BSL Alert Configuration and I2C Slave address of BSL.		<a href="#">Go</a>
41C0015 4h	BSLCONFIG3	Disable NRST policy		<a href="#">Go</a>
41C0015 8h	RESERVED			
41C0015 Ch	BSLCRC	CRC digest of the BSL_CONFIG portion of the NONMAIN memory.		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 1-37](#) shows the codes that are used for access types in this section.

**Table 1-64. NONMAIN\_TYPEE Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

**1 BCRCONFIGID (Offset = 41C00000h) [Reset = 00000000h]**

BCRCONFIGID is shown in [Figure 1-29](#) and described in [Table 1-38](#).

Return to the [Summary Table](#).

Configuration ID of BCR Structure

**Figure 1-29. BCRCONFIGID**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CONFIG																															
R/W-0h																															

**Table 1-66. BCRCONFIGID Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CONFIG	R/W	0h	Configuration ID of the BCR Structure

## 2 BOOTCFG0 (Offset = 41C00004h) [Reset = AABBAABBh]

BOOTCFG0 is shown in [Figure 1-30](#) and described in [Table 1-39](#).

Return to the [Summary Table](#).

Serial wire debug (SWD) lock policy.

**Figure 1-30. BOOTCFG0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWDP_MODE																DEBUGACCESS															
R/W-AABBh																W-AABBh															

**Table 1-68. BOOTCFG0 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	SWDP_MODE	R/W	AABBh	The serial wire debug port (SW-DP) access policy. This policy sets whether any communication is allowed with the device via the SWD pins (to any DAP). When disabled, no SWD communication is possible regardless of the configuration of the DEBUGACCESS field. AABBh = The SW-DP is enabled and device access is set by the additional policies in NONMAIN FFFFh = The SW-DP is fully disabled and no device access is possible via the SW-DP (Any value other than 0xAABB)
15-0	DEBUGACCESS	W	AABBh	The debug access policy for accessing the AHB-AP, ET-AP, and PWR-AP debug access ports. Note that if SWDP_MODE is set to DISABLED, the value of this field is ignored and the debug port will remain fully locked AABBh = Access to AHB-AP, ET-AP, and PWR-AP via SWD is enabled CCDDh = Access to AHB-AP, ET-AP, and PWR-AP via SWD is only enabled when the correct password is provided via the DSSM before BCR execution FFFFh = Access to AHB-AP, ET-AP, and PWR-AP via SWD is disabled (Any value other than 0xCCDD or 0xAABB)

### 3 BOOTCFG1 (Offset = 41C00008h) [Reset = AABBAABBh]

BOOTCFG1 is shown in [Figure 1-31](#) and described in [Table 1-40](#).

Return to the [Summary Table](#).

TI Failure Analysis (FA) mode and BSL invoke pin policies

**Figure 1-31. BOOTCFG1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BSL_PIN_INVOKE																TI_FA_MODE															
R/W-AABBh																R/W-AABBh															

**Table 1-70. BOOTCFG1 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	BSL_PIN_INVOKE	R/W	AABBh	Boot strap loader (BSL) pin invoke method enable/disable policy AABBh = The BSL_INVOKE pin is checked during boot FFFFh = The BSL_INVOKE pin is not checked during boot (Any value other than 0xAABB)
15-0	TI_FA_MODE	R/W	AABBh	Sets the TI failure analysis enable/disable policy. If enabled, a re-test request through DSSM is allowed, else it is not allowed. Note that if SWDP_MODE is set to disabled, this field is ignored and failure analysis is not possible. AABBh = TI failure analysis is allowed FFFFh = TI failure analysis is not allowed (Any value other than 0xAABB)

#### 4 FLASHSWP0 (Offset = 41C0000Ch) [Reset = FFFFFFFFh]

FLASHSWP0 is shown in [Figure 1-32](#) and described in [Table 1-41](#).

Return to the [Summary Table](#).

Static write protection policy for the first 32kB of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code

**Figure 1-32. FLASHSWP0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															
R/W-FFFFFFFh																															

**Table 1-72. FLASHSWP0 Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	FFFFFFFh	1 bit per sector 0h = A value of 0 indicates the write protection is applied to the corresponding sector 1h = A value of 1 indicates the sector is un-protected

## 5 FLASHSWP1 (Offset = 41C00010h) [Reset = FFFFFFFFh]

FLASHSWP1 is shown in [Figure 1-33](#) and described in [Table 1-42](#).

Return to the [Summary Table](#).

Static write protection policy for additional sectors of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code

**Figure 1-33. FLASHSWP1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															
R/W-FFFFFFFh																															

**Table 1-74. FLASHSWP1 Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	FFFFFFFh	1 bit per 8 sectors. This is used to protect Flash memory from (0 to 256 kb) 0h = A value of 0 indicates the write protection is applied to the corresponding sectors 1h = A value of 1 indicates the sector is un-protected

## 6 BOOTCFG4 (Offset = 41C00014h) [Reset = AABBAABBh]

BOOTCFG4 is shown in [Figure 1-34](#) and described in [Table 1-43](#).

Return to the [Summary Table](#).

Configures Static write protection policy for Configuration flash memory(NONMAIN) and Debug Hold Policy

**Figure 1-34. BOOTCFG4**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DEBUGHOLD																NONMAINSWP															
R/W-AABBh																R/W-AABBh															

**Table 1-76. BOOTCFG4 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	DEBUGHOLD	R/W	AABBh	Controls the release of debug access until INITDONE is issued by Customer Secure Code(CSC). This configuration is applicable only when DEBUGACCESS and CSCEXISTS is enabled. AABBh = Debug Hold is disabled. Debug access should be available during CSC execution. FFFFh = Debug Hold is enabled. Debug access will not be available during CSC execution. Access will be available for application debug after CSC INITDONE. (Any value other than 0xAABB)
15-0	NONMAINSWP	R/W	AABBh	Static write protection policy for entire NONMAIN device configuration memory. AABBh = Protection is disabled. Allows program/erase of the NONMAIN by normal means. FFFFh = Protection is enabled. Does not allow program/erase of the NONMAIN by all means other than a SWD-initiated factory reset (Any value other than 0xAABB)

**7 BOOTCFG5 (Offset = 41C00018h) [Reset = AABBAABBh]**

 BOOTCFG5 is shown in [Figure 1-35](#) and described in [Table 1-44](#).

 Return to the [Summary Table](#).

Configures the existence of Customer Secure Code(CSC) and Flash Bank Swap Policy

**Figure 1-35. BOOTCFG5**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSCEXISTS															
R/W-AABBh															

**Table 1-78. BOOTCFG5 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	FLASHBANKSWAPPOLICY	R/W	AABBh	Controls the Flash Bank Swap Policy. This configuration is valid only, if CSCEXISTS is enabled. AABBh = Flash Bank swap policy is disabled. In CSC Banks cannot be swapped. Complete Main flash region has Read, Write, Execute access. FFFFh = Flash Bank swap policy is enabled. In CSC Banks can be swapped. One bank will have Read, Execute access and other Bank will have Read/Write access, as per the CSC configuration.
15-0	CSCEXISTS	R/W	AABBh	Controls the existence of Customer Secure Code(CSC). AABBh = CSC does not exist. INITDONE will be already SET. FFFFh = CSC Exists. INITDONE will be SET by the CSC.

### 8 BOOTCFG2 (Offset = 41C0001Ch) [Reset = AABBFfFh]

BOOTCFG2 is shown in [Figure 1-36](#) and described in [Table 1-45](#).

Return to the [Summary Table](#).

Fast boot mode policy and BSL mode policy

**Figure 1-36. BOOTCFG2**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BSLMODE																FASTBOOTMODE															
R/W-AABh																R/W-FFFh															

**Table 1-80. BOOTCFG2 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	BSLMODE	R/W	AABh	BSLMODE configures the boot strap loader enable/disable policy AABh = The BSL is enabled FFFh = The BSL is disabled (Any value other than 0xAAB)
15-0	FASTBOOTMODE	R/W	FFFh	FASTBOOTMODE configures the fast boot mode enable/disable policy AABh = Fast boot mode is enabled FFFh = Fast boot mode is disabled. (Any value other than 0xAAB)

## 9 BOOTCFG3 (Offset = 41C00020h) [Reset = AABBAABBh]

BOOTCFG3 is shown in [Figure 1-37](#) and described in [Table 1-46](#).

Return to the [Summary Table](#).

Mass erase and factory reset mode policies. These policies affect SWD initiated and BSL initiated mass erase and factory reset commands. If the SW-DP is disabled (SWDP\_MODE is disabled), SWD initiated commands are not allowed as the SW-DP is fully disabled. If the BSL is disabled (BSLMODE is disabled), these settings are a don't care for BSL initiated commands as the BSL is not enabled to be invoked.

**Figure 1-37. BOOTCFG3**

ADDRESS																															
R/W-FFFFFFFh																															

**Table 1-132. SBLADDRESS Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	ADDRESS	R/W	FFFFFFFh	Address of the alternate BSL, if present.

**35 BSLAPPVER (Offset = 41C0014Ch) [Reset = FFFFFFFFh]**

BSLAPPVER is shown in [Figure 1-63](#) and described in [Table 1-72](#).

Return to the [Summary Table](#).

Address of the application version word.

**Figure 1-63. BSLAPPVER**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS																															
R/W-FFFFFFFh																															

**Table 1-134. BSLAPPVER Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	ADDRESS	R/W	FFFFFFFh	Address of the application version word (must be a valid flash address to be returned). If the given flash address is not programmed, then 0h will be returned.

### 36 BSLCONFIG2 (Offset = 41C00150h) [Reset = 0048FFFFh]

BSLCONFIG2 is shown in [Figure 1-64](#) and described in [Table 1-73](#).

Return to the [Summary Table](#).

Configures the BSL Alert Configuration and I2C Slave address of BSL.

**Figure 1-64. BSLCONFIG2**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
I2CTARGETADDR																ALERTACTION															
R/W-48h																R/W-FFFFh															

**Table 1-136. BSLCONFIG2 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	I2CTARGETADDR	R/W	48h	I2C target address to be used for the ROM BSL I2C communication.
15-0	ALERTACTION	R/W	FFFFh	Action to take upon a security alert condition. AABBh = Trigger a factory reset. Note that if sectors in MAIN or NONMAIN flash are write protected they will not be affected by the BSL factory reset CCDDh = Re-configure the NONMAIN region to disable the BSL. This is not supported if the NONMAIN region is configured to be write protected 000FFFFh = Ignore the security alert condition (Any value other than 0xAABB)

**37 BSLCONFIG3 (Offset = 41C00154h) [Reset = FFFFFFFh]**

 BSLCONFIG3 is shown in [Figure 1-65](#) and described in [Table 1-74](#).

 Return to the [Summary Table](#).

Disable NRST policy

**Figure 1-65. BSLCONFIG3**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																DISABLENRST															
R-0h																R/W-FFFFh															

**Table 1-138. BSLCONFIG3 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	FFFFh	
15-0	DISABLENRST	R/W	FFFFh	Disables NRST Pin during the Bootloader execution if configured. Pin will be disabled when device enters the BSL, and gets re-enabled after POR. AABBh = Disables NRST Pin FFFFh = Keeps the NRST pin enabled

**38 BSLCRC (Offset = 41C0015Ch) [Reset = XXXXXXXXh]**

BSLCRC is shown in [Figure 1-66](#) and described in [Table 1-75](#).

Return to the [Summary Table](#).

CRC digest of the BSL\_CONFIG portion of the NONMAIN memory.

**Figure 1-66. BSLCRC**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIGEST																															
R/W-X																															

**Table 1-140. BSLCRC Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DIGEST	R/W	X	BSL configuration data CRC digest. 32 bit CRC Digest, if the device supports CRC32-ISO3309. Otherwise 16 bit CRC digest, using polynomial CRC16-CCITT. Configuration to be used for CRC calculation: 1. Polynomial should be as per the chosen standard, 2. Input reflected, 3. Output reflected, 4. Initial value should be 0xFFFFFFFF, 5. Final XOR value should be 0x0.  xxxxxxx

### 1.4.7 NONMAIN\_TYPEF Registers

#unique\_57/unique\_57\_Connect\_42\_NONMAIN\_TYPEF\_NONMAINECC\_TABLE\_1\_TABLE lists the memory-mapped registers for the NONMAIN\_TYPEF registers. All register offset addresses not listed in #unique\_57/unique\_57\_Connect\_42\_NONMAIN\_TYPEF\_NONMAINECC\_TABLE\_1\_TABLE should be considered as reserved locations and the register contents should not be modified.

**Table 1-141. NONMAIN\_TYPEF Registers**

Offset	Acronym	Register Name	Group	Section
41C0000 0h	BCRCONFIGID	Configuration ID of BCR Structure		<a href="#">Go</a>
41C0000 4h	BOOTCFG0	Serial wire debug (SWD) lock policy.		<a href="#">Go</a>
41C0000 8h	BOOTCFG1	TI Failure Analysis (FA) mode and BSL invoke pin policies		<a href="#">Go</a>
41C0000 Ch	FLASHSWP0	Static write protection policy for the first 32kB of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code		<a href="#">Go</a>
41C0001 0h	FLASHSWP1	Static write protection policy for additional sectors of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code		<a href="#">Go</a>
41C0001 4h	BOOTCFG4	Configures Static write protection policy for Configuration flash memory(NONMAIN) and Debug Hold Policy		<a href="#">Go</a>
41C0001 8h	BOOTCFG5	Configures the existence of Customer Secure Code(CSC) and Flash Bank Swap Policy		<a href="#">Go</a>
41C0001 Ch	BOOTCFG2	Fast boot mode policy and BSL mode policy		<a href="#">Go</a>
41C0002 0h	BOOTCFG3	Mass erase and factory reset mode policies. These policies affect SWD initiated and BSL initiated mass erase and factory reset commands. If the SW-DP is disabled (SWDP_MODE is disabled), SWD initiated commands are not allowed as the SW-DP is fully disabled. If the BSL is disabled (BSLMODE is disabled), these settings are a don't care for BSL initiated commands as the BSL is not enabled to be invoked.		<a href="#">Go</a>
41C0002 4h + formula	PWDMASSERASE[y]	SHA2-256 Digest of the SWD mass erase command password (must be provided via DSSM to authenticate a mass erase command)		<a href="#">Go</a>
41C0004 4h + formula	PWDFACTORYRESET[y]	SHA2-256 digest of the SWD factory reset command password (must be provided via DSSM to authenticate a factory reset command)		<a href="#">Go</a>
41C0006 4h + formula	PWDDEBUGLOCK[y]	SHA2-256 Digest of the Debug Lock Password. This password is used when the BOOTCFG0.DEBUGACCESS field is configured as Enable with password.		<a href="#">Go</a>

**Table 1-141. NONMAIN\_TYPEF Registers (continued)**

Offset	Acronym	Register Name	Group	Section
41C0008 4h	BOOTCFG6	Application digest check policy		<a href="#">Go</a>
41C0008 8h	APPDIGESTSTART	Start address of the application CRC/SHA Digest check (must be an address in a MAIN flash region).		<a href="#">Go</a>
41C0008 Ch	APPDIGESTLENGTH	Length of the application to be include in the application CRC/SHA Digest check (in bytes), starting from APPDIGESTSTART		<a href="#">Go</a>
41C0009 0h + formula	APPDIGEST[y]	Expected application CRC32/SHA2-256 digest to test against during boot. Note: If CRC check is enabled only the first 32bit word of this DIGEST is used.		<a href="#">Go</a>
41C000 B0h	FLASHSWP2	Static write protection policy for additional sectors of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code		<a href="#">Go</a>
41C000 B4h	BOOTCRC	CRC digest of the BCR configuration portion of the NONMAIN memory.		<a href="#">Go</a>
41C0010 0h	BSLCONFIGID	Configuration ID of BSL Structure		<a href="#">Go</a>
41C0010 4h	BSLPINCFG0	BSL UART PIN Configuration. The reset value of these fields differ for each device, based on the pins used.		<a href="#">Go</a>
41C0010 8h	BSLPINCFG1	BSL I2C PIN Configuration. The reset value of these fields differ for each device, based on the pins used.		<a href="#">Go</a>
41C0010 Ch	BSLCONFIG0	BSL invoke pin configuration and memory read-out policy.		<a href="#">Go</a>
41C0011 0h	PWDBSL0	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0011 4h	PWDBSL1	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0011 8h	PWDBSL2	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0011 Ch	PWDBSL3	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0012 0h	PWDBSL4	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0012 4h	PWDBSL5	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0012 8h	PWDBSL6	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0012 Ch	PWDBSL7	SHA2-256 Digest of BSL password.		<a href="#">Go</a>
41C0013 0h	BSLPLUGINCFG	Defines the presence and type of a BSL plug-in in MAIN flash memory.		<a href="#">Go</a>
41C0013 4h + formula	BSLPLUGINHOOK[y]	Function pointers for plug-in init, receive, transmit, and de-init functions.		<a href="#">Go</a>
41C0014 4h	BSLCONFIG1			<a href="#">Go</a>
41C0014 8h	SBLADDRESS	Address of an alternate BSL.		<a href="#">Go</a>

**Table 1-141. NONMAIN\_TYPEF Registers (continued)**

Offset	Acronym	Register Name	Group	Section
41C0014 Ch	BSLAPPVER	Address of the application version word.	<a href="#">Go</a>	
41C0015 0h	BSLCONFIG2	Configures the BSL Alert Configuration and I2C Slave address of BSL.	<a href="#">Go</a>	
41C0015 4h	BSLCRC	CRC digest of the BSL_CONFIG portion of the NONMAIN memory.	<a href="#">Go</a>	

Complex bit access types are encoded to fit into small table cells. [#unique\\_57/unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_LEGEND\\_TABLE](#) shows the codes that are used for access types in this section.

**Table 1-142. NONMAIN\_TYPEF Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

**1 BCRCONFIGID (Offset = 41C0000h) [Reset = 0000000h]**

BCRCONFIGID is shown in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BCRCONFIGID\\_TABLE](#)

and described in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BCRCONFIGID\\_TABLE\\_TABLE](#).

Return to the [Summary Table](#).

Configuration ID of BCR Structure

**Figure 1-67. BCRCONFIGID**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CONFIG																															
R/W-0h																															

**Table 1-144. BCRCONFIGID Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CONFIG	R/W	0h	Configuration ID of the BCR Structure

## 2 BOOTCFG0 (Offset = 41C00004h) [Reset = AABBAABBh]

BOOTCFG0 is shown in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG0\\_FIGURE\\_TABLE](#)

and described in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG0\\_TABLE\\_TABLE](#).

Return to the [Summary Table](#).

Serial wire debug (SWD) lock policy.

**Figure 1-68. BOOTCFG0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWDP_MODE																DEBUGACCESS															
R/W-AABBh																W-AABBh															

**Table 1-146. BOOTCFG0 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	SWDP_MODE	R/W	AABBh	The serial wire debug port (SW-DP) access policy. This policy sets whether any communication is allowed with the device via the SWD pins (to any DAP). When disabled, no SWD communication is possible regardless of the configuration of the DEBUGACCESS field. AABBh = The SW-DP is enabled and device access is set by the additional policies in NONMAIN FFFFh = The SW-DP is fully disabled and no device access is possible via the SW-DP (Any value other than 0xAABB)
15-0	DEBUGACCESS	W	AABBh	The debug access policy for accessing the AHB-AP, ET-AP, and PWR-AP debug access ports. Note that if SWDP_MODE is set to DISABLED, the value of this field is ignored and the debug port will remain fully locked AABBh = Access to AHB-AP, ET-AP, and PWR-AP via SWD is enabled CCDDh = Access to AHB-AP, ET-AP, and PWR-AP via SWD is only enabled when the correct password is provided via the DSSM before BCR execution FFFFh = Access to AHB-AP, ET-AP, and PWR-AP via SWD is disabled (Any value other than 0xCCDD or 0xAABB)

### 3 BOOTCFG1 (Offset = 41C00008h) [Reset = AABBAABBh]

BOOTCFG1 is shown in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG1\\_FIGURE\\_TABLE](#)

and described in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG1\\_TABLE\\_TABLE](#).

Return to the [Summary Table](#).

TI Failure Analysis (FA) mode and BSL invoke pin policies

**Figure 1-69. BOOTCFG1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BSL_PIN_INVOKE																TI_FA_MODE															
R/W-AABBh																R/W-AABBh															

**Table 1-148. BOOTCFG1 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	BSL_PIN_INVOKE	R/W	AABBh	Boot strap loader (BSL) pin invoke method enable/disable policy AABBh = The BSL_INVOKE pin is checked during boot FFFFh = The BSL_INVOKE pin is not checked during boot (Any value other than 0xAABB)
15-0	TI_FA_MODE	R/W	AABBh	Sets the TI failure analysis enable/disable policy. If enabled, a re-test request through DSSM is allowed, else it is not allowed. Note that if SWDP_MODE is set to disabled, this field is ignored and failure analysis is not possible. AABBh = TI failure analysis is allowed FFFFh = TI failure analysis is not allowed (Any value other than 0xAABB)

#### 4 FLASHSWP0 (Offset = 41C0000Ch) [Reset = FFFFFFFFh]

FLASHSWP0 is shown in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_FLASHSWP0\\_FIGURE\\_TABLE](#)

and described in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_FLASHSWP0\\_TABLE\\_TABLE](#).

Return to the [Summary Table](#).

Static write protection policy for the first 32kB of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code

**Figure 1-70. FLASHSWP0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															
R/W-FFFFFFFh																															

**Table 1-150. FLASHSWP0 Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	FFFFFFFh	1 bit per sector 0h = A value of 0 indicates the write protection is applied to the corresponding sector 1h = A value of 1 indicates the sector is un-protected

## 5 FLASHSWP1 (Offset = 41C00010h) [Reset = FFFFFFFFh]

FLASHSWP1 is shown in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_FLASHSWP1\\_TABLE](#)

and described in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_FLASHSWP1\\_TABLE\\_TABLE](#).

Return to the [Summary Table](#).

Static write protection policy for additional sectors of flash memory. When protected, sectors will not be available for program or erase by either the bootloader or application code

**Figure 1-71. FLASHSWP1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															
R/W-FFFFFFFh																															

**Table 1-152. FLASHSWP1 Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	FFFFFFFh	1 bit per 8 sectors. This is used to protect Flash memory from (0 to 256 kb) 0h = A value of 0 indicates the write protection is applied to the corresponding sectors 1h = A value of 1 indicates the sector is un-protected

## 6 BOOTCFG4 (Offset = 41C00014h) [Reset = AABBAABBh]

BOOTCFG4 is shown in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG4\\_FIGURE\\_TABLE](#)

and described in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG4\\_TABLE\\_TABLE](#).

Return to the [Summary Table](#).

Configures Static write protection policy for Configuration flash memory(NONMAIN) and Debug Hold Policy

**Figure 1-72. BOOTCFG4**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DEBUGHOLD																NONMAINSWP															
R/W-AABBh																R/W-AABBh															

**Table 1-154. BOOTCFG4 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	DEBUGHOLD	R/W	AABBh	Controls the release of debug access until INITDONE is issued by Customer Secure Code(CSC). This configuration is applicable only when DEBUGACCESS and CSCEXISTS is enabled. AABBh = Debug Hold is disabled. Debug access should be available during CSC execution. FFFFh = Debug Hold is enabled. Debug access will not be available during CSC execution. Access will be available for application debug after CSC INITDONE. (Any value other than 0xAABB)
15-0	NONMAINSWP	R/W	AABBh	Static write protection policy for entire NONMAIN device configuration memory. AABBh = Protection is disabled. Allows program/erase of the NONMAIN by normal means. FFFFh = Protection is enabled. Does not allow program/erase of the NONMAIN by all means other than a SWD-initiated factory reset (Any value other than 0xAABB)

**7 BOOTCFG5 (Offset = 41C00018h) [Reset = AABBAABh]**

 BOOTCFG5 is shown in [#unique\\_57/](#)
[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG5\\_FIGURE\\_TABLE](#)

 and described in [#unique\\_57/](#)
[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG5\\_TABLE\\_TABLE](#).

 Return to the [Summary Table](#).

Configures the existence of Customer Secure Code(CSC) and Flash Bank Swap Policy

**Figure 1-73. BOOTCFG5**

FLASHBANKSWAPPOLICY															
R/W-AABh															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSCEXISTS															
R/W-AABh															

**Table 1-156. BOOTCFG5 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	FLASHBANKSWAPPOLICY	R/W	AABh	Controls the Flash Bank Swap Policy. This configuration is valid only, if CSCEXISTS is enabled. AABh = Flash Bank swap policy is disabled. In CSC Banks cannot be swapped. Complete Main flash region has Read, Write, Execute access. FFFh = Flash Bank swap policy is enabled. In CSC Banks can be swapped. One bank will have Read, Execute access and other Bank will have Read/Write access, as per the CSC configuration.
15-0	CSCEXISTS	R/W	AABh	Controls the existence of Customer Secure Code(CSC). AABh = CSC does not exist. INITDONE will be already SET. FFFh = CSC Exists. INITDONE will be SET by the CSC.

## 8 BOOTCFG2 (Offset = 41C0001Ch) [Reset = AABBFfFh]

BOOTCFG2 is shown in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG2\\_TABLE](#)

and described in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG2\\_TABLE\\_TABLE](#).

Return to the [Summary Table](#).

Fast boot mode policy and BSL mode policy

**Figure 1-74. BOOTCFG2**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BSLMODE																FASTBOOTMODE															
R/W-AABh																R/W-FFFh															

**Table 1-158. BOOTCFG2 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	BSLMODE	R/W	AABh	BSLMODE configures the boot strap loader enable/disable policy AABh = The BSL is enabled FFFh = The BSL is disabled (Any value other than 0xAAB)
15-0	FASTBOOTMODE	R/W	FFFh	FASTBOOTMODE configures the fast boot mode enable/disable policy AABh = Fast boot mode is enabled FFFh = Fast boot mode is disabled. (Any value other than 0xAAB)

## 9 BOOTCFG3 (Offset = 41C00020h) [Reset = AABBAABBh]

BOOTCFG3 is shown in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG3\\_FIGURE\\_TABLE](#)

and described in [#unique\\_57/](#)

[unique\\_57\\_Connect\\_42\\_NONMAIN\\_TYPEF\\_NONMAINECC\\_BC\\_CONFIG\\_BOOTCFG3\\_TABLE\\_TABLE](#).

Return to the [Summary Table](#).

Mass erase and factory reset mode policies. These policies affect SWD initiated and BSL initiated mass erase and factory reset commands. If the SW-DP is disabled (SWDP\_MODE is disabled), SWD initiated commands are not allowed as the SW-DP is fully disabled. If the BSL is disabled (BSLMODE is disabled), these settings are a don't care for BSL initiated commands as the BSL is not enabled to be invoked.

DIGEST																															
R/W-X																															

**Table 1-216. BSLCRC Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DIGEST	R/W	X	BSL configuration data CRC digest. 32 bit CRC Digest, if the device supports CRC32-ISO3309. Otherwise 16 bit CRC digest, using polynomial CRC16-CCITT. Configuration to be used for CRC calculation: 1. Polynomial should be as per the chosen standard, 2. Input reflected, 3. Output reflected, 4. Initial value should be 0xFFFFFFFF, 5. Final XOR value should be 0x0.  xxxxxxxx

## 1.5 Factory Constants

All devices include a memory-mapped FACTORY region which provides read-only data describing the capabilities of a device as well as any factory-provided trim information for use by application software.

Key data provided in the FACTORY memory region includes:

- The device unique 96-bit identity
- The default BSL pins
- The total MAIN region flash memory size (in KB)
- The total DATA region flash memory size (in KB), if present
- The flash bank count
- The total SRAM memory size (in KB)
- The temperature sensor calibration value
- The SYSPLL startup parameters

### 1.5.1 FACTORYREGION Layout Types

The below table shows which FACTORYREGION layout type to use with which devices. The MSPM0-SDK includes a configurator tool to help the user configure FACTORYREGION contents.

**Table 1-217. FACTORYREGION Layout Types**

NONMAIN Layout Type	Supported Devices
Type A	<ul style="list-style-type: none"> <li>• MSPM0G110x</li> <li>• MSPM0G150x</li> <li>• MSPM0G310x</li> <li>• MSPM0G350x</li> </ul>
Type F	<ul style="list-style-type: none"> <li>• MSPM0G511x</li> <li>• MSPM0G5187</li> </ul>

**Table 1-217. FACTORYREGION Layout Types (continued)**

<b>NONMAIN Layout Type</b>	<b>Supported Devices</b>
Type G	<ul style="list-style-type: none"><li>• MSPM0G151x</li><li>• MSPM0G351x</li><li>• MSPM0G352x</li></ul>

### 1.5.2 FACTORYREGION\_TYPEA Registers

Table 1-116 lists the memory-mapped registers for the FACTORYREGION\_TYPEA registers. All register offset addresses not listed in Table 1-116 should be considered as reserved locations and the register contents should not be modified.

**Table 1-218. FACTORYREGION\_TYPEA Registers**

Offset	Acronym	Register Name	Group	Section
41C4000	TRACEID 0h	Defined by TI, during ATE, based on wafer		<a href="#">Go</a>
41C4000	DEVICEID 4h	Device identifier		<a href="#">Go</a>
41C4000	USERID 8h	Device variant identifier		<a href="#">Go</a>
41C4000	BSLPIN_UART Ch	BSL UART Pin Configuration		<a href="#">Go</a>
41C4001	BSPIN_I2C 0h	BSL I2C Pin Configuration		<a href="#">Go</a>

PART							
R-X							

**Table 1-261. USERID Field Descriptions**

Bit	Field	Type	Reset	Description
31	START	R	1h	
30-28	MAJORREV	R	X	Monotonic increasing value indicating a new revision of the SKU significant enough that users of the device may have to revise PCB or or software design x
27-24	MINORREV	R	X	Monotonic increasing value indicating a new revision of the SKU that preserves compatibility with lesser minorrev values. New capability may be introduced such that lesser minorrev numbers may not be compatible with greater if the new capability is used. x
23-16	VARIANT	R	X	Bit pattern uniquely identifying a variant of a part. This is used to indicate memory or package variations of the same part number. This number shall be selected at random among the remaining numbers for the relevant combination of IDCODE.device and USERCODE.part such that the order of creation cannot be inferred by the number. The variant number does not encode specifics of the variant directly. x
15-0	PART	R	X	Bit pattern that uniquely identifying a part. This is used to identify the specific part based on the die identified in DEVICEID.device. This number shall be selected at random among the remaining numbers for DEVICEID.device such that the order of creation cannot be inferred by the number. This value does not encode the part number directly. x

#### 4 BSLPIN\_UART (Offset = 41C400Ch) [Reset = XXXXXXXXh]

BSLPIN\_UART is shown in [Figure 1-124](#) and described in [Table 1-140](#).

Return to the [Summary Table](#).

BSL UART Pin Configuration

**Figure 1-124. BSLPIN\_UART**

**Table 1-315. USERID Field Descriptions**

Bit	Field	Type	Reset	Description
31	START	R	1h	
30-28	MAJORREV	R	X	Monotonic increasing value indicating a new revision of the SKU significant enough that users of the device may have to revise PCB or or software design x
27-24	MINORREV	R	X	Monotonic increasing value indicating a new revision of the SKU that preserves compatibility with lesser minorrev values. New capability may be introduced such that lesser minorrev numbers may not be compatible with greater if the new capability is used. x
23-16	VARIANT	R	X	Bit pattern uniquely identifying a variant of a part. This is used to indicate memory or package variations of the same part number. This number shall be selected at random among the remaining numbers for the relevant combination of IDCODE.device and USERCODE.part such that the order of creation cannot be inferred by the number. The variant number does not encode specifics of the variant directly. x
15-0	PART	R	X	Bit pattern that uniquely identifying a part. This is used to identify the specific part based on the die identified in DEVICEID.device. This number shall be selected at random among the remaining numbers for DEVICEID.device such that the order of creation cannot be inferred by the number. This value does not encode the part number directly. x

#### 4 BSLPIN\_UART (Offset = 41C400Ch) [Reset = XXXXXXXXh]

BSLPIN\_UART is shown in [Figure 1-150](#) and described in [Table 1-168](#).

Return to the [Summary Table](#).

BSL UART Pin Configuration

**Figure 1-150. BSLPIN\_UART**

## 2.1 PMCU Overview

The power management and clock unit (PMCU) provides all power, clocking, reset, and system control services for the device. The PMCU contains three submodules to provide this functionality: the power management unit (PMU), the clock module (CKM), and the system controller (SYSCTL).

The PMU is an analog submodule that generates the internal regulated supplies for the device and supervises the condition of the external supply. The PMU also contains voltage and current reference circuits used by the on-chip regulators and analog peripherals.

The CKM is an analog submodule that provides clock sources (internal and external oscillators) and presents these clock sources to SYSCTL. SYSCTL distributes these clock sources to the CPU, buses, and peripherals on the device.

The SYSCTL is a digital submodule that provides the control logic for all functions in the PMCU. In addition, SYSCTL contains the memory-mapped registers used by software to configure power management and clocks, assess the status of the device, and control resets. SYSCTL also provides general-purpose memory that is retained in SHUTDOWN mode and can be used to store status information in SHUTDOWN mode when SRAM and register contents are lost.

Figure 2-1 shows the interfaces between the PMCU and the device supplies, clocks, and signals. Configuration of the PMCU by software is always done through memory-mapped registers in the SYSCTL submodule.

Figure 2-1. PMCU Top-Level Diagram

### Note

Not all devices have all of the PMCU features shown in Figure 2-1. For example, not all devices have LFXT (low-frequency crystal oscillator), HFXT (high-frequency crystal oscillator), and CANCLK. See the device-specific data sheet to understand the features present on a given device.

### Using this Guide

The PMU, CKM, and SYSCTL sections of this chapter describe the functionality provided by each submodule in detail.

The [quick start](#) section describes overall system level operation of the PMCU and how to configure the PMCU for different application scenarios.

### 2.1.1 Power Domains

Two core power domains are provided on the device: PD1 and PD0. PD1 is always powered in RUN and SLEEP modes, but is disabled in all other modes. PD0 is always powered in RUN, SLEEP, STOP and STANDBY modes. PD1 and PD0 are both disabled in SHUTDOWN mode.

- The PD1 domain includes the CPU subsystem, the SRAM memory, PD1 peripherals, and the PD1 peripheral bus, which runs from MCLK (including the DMA). While PD1 is disabled in STOP and STANDBY mode, the CPU registers, SRAM, and peripheral configuration registers are maintained in retention such that they are available to resume operation immediately when STOP or STANDBY modes are exited.
- The PD0 domain includes the PD0 peripherals and PD0 bus segment which runs from ULPCLK in RUN and SLEEP mode, 4MHz in STOP mode, and 32kHz in STANDBY mode. The PD0 domain is powered in all modes except SHUTDOWN and can be thought of as an "always-on" domain.

The device-specific data sheet describes which peripherals on a device are in PD1 and which are in PD0.

The device also has a primary external supply (VDD) domain that provides power to the IO and analog peripherals.

The device also has a primary external supply (VDD) domain that provides power to the IO and analog peripherals.

### 2.1.2 Operating Modes

Various operating modes (power modes) are provided to allow for optimization of the device power consumption based on application requirements. In order of decreasing power, the modes are: RUN, SLEEP, STOP, STANDBY and SHUTDOWN. The following figure shows the interaction between the modes.

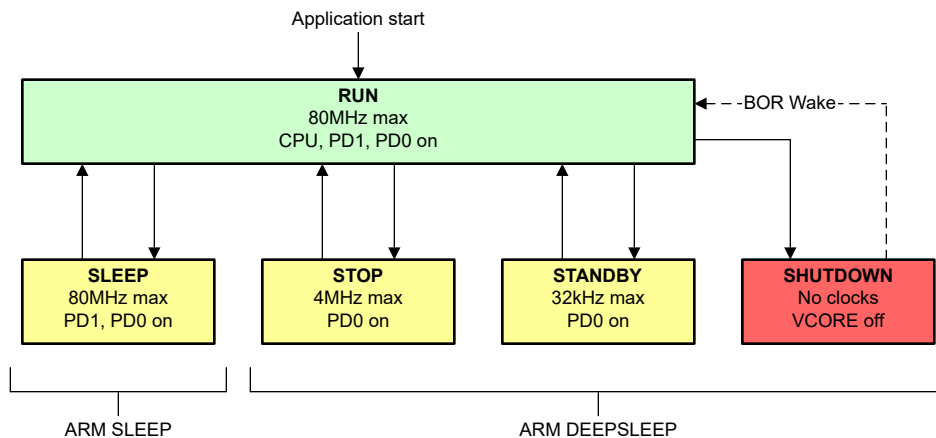

Figure 2-2. MSPM0Gxx Operating Modes

[Section 2.1.2.6](#) indicates what functions are available in each operating mode of the device. See the [operating mode selection](#) section for information on how to configure the device for a particular operating mode.

### Operating Mode Concept

MSPM0 MCUs implement a policy-based power and clock management scheme. Policies can be configured through application software for how the clocking is to be managed in each operating mode to obtain the best balance of power and performance for a given application.

After the operating policy for each mode is configured, application software can enter and exit the various operating modes through simple register commands, and SYSCTL automatically manages all the necessary PMU states, oscillator and clock enable and disables, and the SYSOSC frequency according to the software-defined policies and software-selected mode.

A variety of hardware-triggered low-power mode suspension mechanisms also exist to enable on-demand access to a fast clock when requested by supported peripherals, as well as functions such as DMA and ADC triggering from low-power modes.

The policy-driven operating mode scheme together with the asynchronous low-power mode suspension mechanisms enable application software to select the operating mode and corresponding policy that provide the lowest possible power consumption for background activities, with transient foreground activities either bringing up the DMA, bringing up a fast clock, or bringing the device to RUN (in the case of an IRQ) for burst handling.

#### 2.1.2.1 RUN Mode

In RUN mode, the CPU is active executing code and any peripheral can be enabled.

There are three RUN mode policy options: RUN0, RUN1, and RUN2.

- **RUN0:** The MCLK and the CPUCLK run from a fast clock source (SYSOSC, HFCLK, or SYSPLL).
- **RUN1:** The MCLK and the CPUCLK run from LFCLK (at 32kHz) to reduce active power, but SYSOSC is left enabled to service analog modules such as an ADC.
- **RUN2:** The MCLK and the CPUCLK run from LFCLK (at 32kHz), and SYSOSC is completely disabled to save power. This is the lowest power state with the CPU running.

---

#### Note

SYSPLL is not automatically disabled, and needs to be manually disabled through the HSCLKEN.SYSPLLEN field within the SYSCTL registers in order to reduce power consumption

---

#### 2.1.2.2 SLEEP Mode

In SLEEP mode, the CPU is disabled (clock gated) but otherwise the device configuration is the same as RUN. There are three SLEEP mode policy options: SLEEP0, SLEEP1, and SLEEP2. The SLEEPx policy is determined by the current RUNx policy when SLEEP mode is entered.

- **SLEEP0:** Identical to RUN0, with the CPU disabled.
- **SLEEP1:** Identical to RUN1, with the CPU disabled.
- **SLEEP2:** Identical to RUN2, with the CPU disabled.

---

#### Note

SYSPLL is not automatically disabled, and needs to be manually disabled through the HSCLKEN.SYSPLLEN field within the SYSCTL registers in order to reduce power consumption

---

#### 2.1.2.3 STOP Mode

In STOP mode, the CPU, SRAM, and PD1 peripherals are disabled and in retention (if applicable). PD0 peripherals are available with a max ULPCLK frequency of 4MHz. SYSOSC can run at higher frequencies to support operation of analog peripheral (such as an ADC), but ULPCLK will be automatically limited to the 4MHz SYSOSC output by SYSCTL. For details on peripheral availability, please refer to the "supported functionality by operating mode" table within the device-specific datasheet.

---

#### Note

SYSPLL is not automatically disabled, and needs to be manually disabled through the HSCLKEN.SYSPLLEN field within the SYSCTL registers in order to reduce power consumption

---

DMA is available to be triggered. A DMA trigger wakes the PD1 power domain to make the SRAM and DMA available for processing the DMA transfer, and the DMA transfer is processed at the current MCLK rate. After the transfer completes, the SRAM is returned to retention and PD1 is disabled automatically.

STOP mode is the lowest power mode that supports the operation of analog peripherals.

The policy options for STOP mode are: STOP0, STOP1, and STOP2.

- **STOP0:** The SYSOSC is left running at the current frequency when entering STOP mode. ULPCLK is always limited to 4MHz automatically by hardware, but SYSOSC is not disturbed to support consistent operation of analog peripherals.
  - NOTE: If STOP0 is entered from RUN1 (SYSOSC enabled but MCLK sourced from LFCLK), SYSOSC remains enabled as in RUN1, and ULPCLK remains at 32kHz as in RUN1.
  - NOTE: If STOP0 is entered from RUN2 (SYSOSC was disabled and MCLK was sourced from LFCLK), SYSOSC remains disabled as in RUN2, and ULPCLK remains at 32kHz as in RUN2.
- **STOP1:** The SYSOSC is [gear shifted](#) from its current frequency to 4MHz for the lowest power consumption in STOP mode with SYSOSC running. SYSOSC and ULPCLK both run at 4MHz.
- **STOP2:** The SYSOSC is disabled and the ULPCLK is sourced from LFCLK at 32kHz. This is the lowest power state in STOP mode.

#### 2.1.2.4 STANDBY Mode

In STANDBY mode, the CPU, SRAM, and PD1 peripherals are disabled and in retention. PD0 peripherals, with the exception of the ADC, DAC, and OPA are available with a maximum ULPCLK frequency of 32kHz. High-speed oscillators such as (SYSPLL, HFXT, HFCLK\_IN) and SYSOSC are disabled. Wakeup sources includes digital peripherals like I<sup>2</sup>C, UART start detection, PD0 timers elapsing, RTC wakeup, GPIO toggle.

#### Note

SYSPLL is not automatically disabled, and needs to be manually disabled through the HSCLKEN.SYSPLLEN field within the SYSCCTL registers in order to reduce power consumption

STANDBY mode supports asynchronous fast clock request to switch to STOP mode and back to STANDBY. In the case of an event generating an interrupt, the device continues to RUN mode.

DMA is available to be triggered. A DMA trigger wakes the PD1 power domain to make the SRAM and DMA available for processing the DMA transfer, and the DMA transfer is processed at the current MCLK. After the transfer completes, the SRAM is returned to retention and PD1 is disabled automatically.

Analog peripherals (such as an ADC, 12-bit DAC, OPA, and high-speed COMP) are not supported in STANDBY mode. For details on peripheral availability, please refer to the "supported functionality by operating mode" table within the device-specific datasheet.

There are 2 policy options for STANDBY mode: STANDBY0 and STANDBY1.

- **STANDBY0:** All PD0 peripherals receive the ULPCLK and LFCLK, while the RTC receives the RTCCLK.
- **STANDBY1:** Only a few general purpose timers receive ULPCLK or LFCLK, see the device-specific data sheet to determine them. If the device contains an RTC module, it continues to receive RTCCLK. A general timer interrupt, RTC interrupt, or ADC trigger in STANDBY1 always triggers an [asynchronous fast clock request](#) to wake the system. Other PD0 peripherals (such as UART, I<sup>2</sup>C, GPIO, and low-power COMP) can also wake the system upon an external event through an asynchronous fast clock request, but they are not actively clocked in STANDBY1.

#### 2.1.2.5 SHUTDOWN Mode

In SHUTDOWN mode, no clocks are available. The core regulator is completely disabled and all SRAM and register contents are lost, with the exception of the general-purpose memory in SYSCCTL that can be used to store state information. The BOR and bandgap circuit are disabled.

Specific IO configuration settings are retained in the SHUTDOWN operating mode.

- Drive strength
- Pullup enable
- Pulldown enable

- Input enable
- Output enable
- Output state

The device can wake through a wake-up capable IO, a debug connection, or NRST.

SHUTDOWN mode has the lowest current consumption of any operating mode. Exiting SHUTDOWN mode triggers a BOR.

#### 2.1.2.6 Supported Functionality by Operating Mode

Supported functionality in each operating mode is given in *Supported Functionality by Operating Mode* table in the detailed description section of the device-specific data sheet.

#### 2.1.2.7 Suspended Low-Power Mode Operation

Some peripherals can be configured to temporarily suspend STOP or STANDBY mode operation to handle a temporary activity or process an event. There are two ways in which STOP or STANDBY mode can be suspended:

- An [asynchronous fast clock request](#)
- A DMA trigger

#### Suspended STOP or STANDBY for an Asynchronous Fast Clock Request

An asynchronous fast clock request temporarily suspends any active low-power mode and runs the [MCLK](#) and [ULPCLK](#) tree at 32MHz, sourced from [SYSOSC](#). Asynchronous fast clock requests are also functional in RUN and SLEEP mode if MCLK is sourced from either [LFCLK](#) at 32kHz or SYSOSC at a frequency lower than 32MHz.

This functionality enables use cases such as:

- General purpose IOs (GPIO) for glitch filtering
- On-demand UART, I<sup>2</sup>C, or SPI communication
- Timer-triggered ADC sampling from STANDBY mode

#### Suspended STOP or STANDBY for a DMA Trigger

If a DMA trigger is asserted in STOP or STANDBY mode, the low-power mode is temporarily suspended and the PD1 power domain (including the SRAM and flash memory) is enabled to process the DMA request. Unlike the asynchronous fast clock request, DMA transfers do not change the clock tree configuration. A DMA request in STOP or STANDBY mode is processed at the current MCLK rate.

---

#### Note

If a temporary suspension from STOP or STANDBY mode results in an interrupt, then the device will transition to and remain in RUN mode operation to process the interrupt.

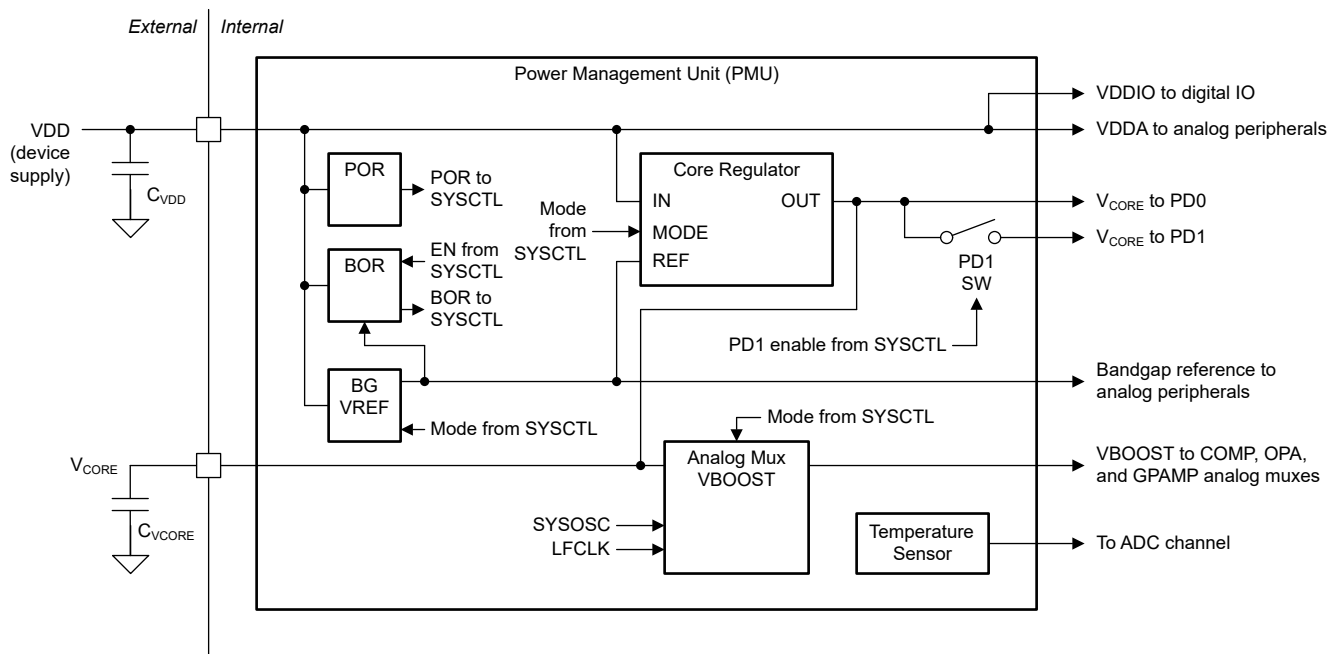

---

## 2.2 Power Management (PMU)

The Power Management Unit (PMU) generates the regulated core supplies for the device and provides supervision of the external supply. It also contains a bandgap voltage reference used by the PMU and other analog peripherals. Refer to the device specific datasheet for the supported PMU features.

Key PMU features include:

- Support for the device across the device operating supply range
- **Core LDO:** Low-dropout linear voltage regulator to generate the internal core logic supply, with multiple operating modes for reducing device current in low-power modes (managed automatically by SYSTCTL)
- Power-on reset (POR) for VDD supply
- Brownout reset (BOR) for VDD supply
- Bandgap voltage reference supporting the BOR, core regulator, and analog peripherals
- Analog mux VBOOST unit for increasing analog mux performance

**Figure 2-3. MSPM0Gxx PMU Block Diagram**

### 2.2.1 Power Supply

Power is supplied to the device through the VDD and VSS connections. A decoupling capacitor ( $C_{VDD}$ ) must be placed across all VDD and VSS supply pairs. See the device-specific data sheet for the correct value and tolerance of  $C_{VDD}$ . Some devices with a higher pincount may feature multiple VDD/VSS power pairs.

VDD is used directly to provide the IO supply (VDDIO) and the analog supply (VDDA). VDDIO and VDDA are internally connected to VDD so that additional power supply pins are not required.

Some devices may feature an independent power supply for device-specific special features such as VBAT (for the low-frequency sub system) and VUSB (for the USB PHY). Refer to the device-specific datasheet for details on the power source for associated IO pins and features.

### 2.2.2 Core Regulator

The PMU uses an on-chip, configurable, low-dropout linear voltage regulator to generate a 1.35V supply rail to power the device core. The core regulator output ( $V_{CORE}$ ) supplies power to the core logic, which includes the CPU, digital peripherals and the device memory. The core regulator requires an external capacitor ( $C_{VCORE}$ )

which is connected between the device V<sub>CORE</sub> pin and VSS (ground). See the device specific data sheet for the correct value and tolerance of C<sub>V<sub>CORE</sub></sub>.

The core regulator is active in all power modes except for SHUTDOWN. In all other power modes (RUN, SLEEP, STOP, and STANDBY) the drive strength of the regulator is configured automatically to support the max load current of each mode. This reduces the quiescent current of the regulator when using low-power modes, improving low power performance. SYSCTL automatically configures the regulator for best power consumption based on the power mode which is currently active.

### 2.2.3 Supply Supervisors

The PMU provides two supply supervisor circuits:

- A power-on reset (POR) circuit to indicate that the external supply has reached sufficient voltage to start the on-chip bandgap reference and BOR circuit
- A user-programmable brownout reset (BOR) circuit which verifies that the external supply is maintained at the specified voltage to support correct operation of the device

#### 2.2.3.1 Power-on Reset (POR)

The power-on reset (POR) circuit assures a proper start-up of the device. During cold power-up, the device is held in a POR state until VDD passes the POR+ threshold. When VDD has passed POR+, the POR state is released and the [bandgap reference](#) and [BOR monitor circuit](#) are started. If VDD drops below the POR- level, then a POR- violation is asserted and the device is again held in a POR reset state.

The POR circuit does not indicate that VDD has reached a level high enough to support correct operation of the device. Rather, it is the first step in the boot process and is used to determine if the supply voltage is sufficient to power up the bandgap reference and BOR circuit, which are then used to determine if the supply has reached a level sufficient to for the device to run correctly.

The POR circuit is active in all power modes including SHUTDOWN and cannot be disabled.

#### 2.2.3.2 Brownout Reset (BOR)

The brownout reset (BOR) supervisor monitors the external supply (VDD) and asserts or deasserts a BOR violation to SYSCTL. The primary responsibility of the BOR circuit is to make sure that the external supply is maintained high enough to enable correct operation of internal circuits, including the core regulator. The BOR threshold reference is derived from the internal bandgap circuit. The threshold is programmable and is always higher than the POR threshold. During cold start, after VDD passes the POR+ threshold, the bandgap reference and BOR circuit are started. The device is then held in a BOR state until VDD passes the BOR0+ threshold. When VDD passes BOR0+, the BOR supervisor releases the device to continue the boot process, and the PMU is started.

There are up to four selectable BOR threshold levels (BOR0-BOR3). During startup, the BOR threshold is always BOR0 (the lowest value) to make sure that the device starts at the specified VDD minimum. After boot, software can optionally reconfigure the BOR circuit to use a different (higher) threshold level (BOR1-BOR3).

---

#### Note

Some devices feature only one BOR threshold level (BOR0).

---

When the BOR threshold is BOR0, a BOR0- violation always generates a BOR- violation signal to SYSCTL, generating a BOR level reset. When the BOR threshold is reconfigured to BOR1, BOR2, or BOR3, the BOR circuit generates a SYSCTL interrupt rather than asserting the BOR- violation. This can be used to give the application an indication that the supply has dropped below a certain level without causing a reset.

To change the BOR level from the default (BOR0), first select the desired value in the LEVEL field of the BORTHRESHOLD register in SYSCTL. Then, activate the threshold set in the LEVEL field by setting the GO bit in the BORCLRCMD register. The change can be validated by testing the BORCURTHRESHOLD field in the SYSSTATUS register, which returns a value corresponding to the currently active BOR threshold. The BOR

threshold change takes approximately 15µs to complete, during this time, the BOR circuit is blind to changes in the supply.

If the BOR is in interrupt mode (a threshold level of BOR1-BOR3), and the supply drops below the corresponding BORx- level, then an interrupt is generated and the BOR circuit automatically switches the BOR threshold level to BOR0 to make sure that a BOR- violation is asserted if VDD drops below BOR0-. Application software can set the BOR level back to the level specified in the LEVEL field of the BORTHRESHOLD register by setting the GO bit again in the BORCLRCMD register.

The BOR supervisor is active in RUN, SLEEP, STOP, and STANDBY modes but is disabled automatically in SHUTDOWN mode.

### 2.2.3.3 POR and BOR Behavior During Supply Changes

When the supply voltage (VDD) drops below POR-, the entire device state is cleared. Small variations in VDD that do not pass below the BOR0- threshold do not cause a BOR- violation, and the device continues to run. Behavior for BORx thresholds other than BOR0 (for example, BOR1-BOR3) is the same as is shown for BOR0, except that the BOR circuit is configured to generate an interrupt rather than immediately triggering a BOR reset. If a BOR1-BOR3 interrupt is generated, the BOR level is automatically switched to BOR0.

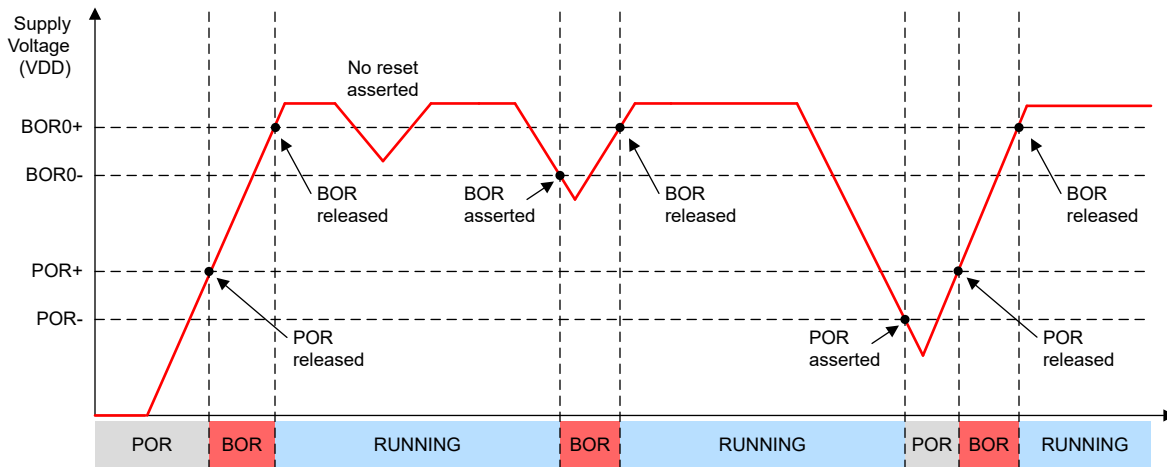

Figure 2-4. POR/BOR vs. Supply Voltage (VDD)

### 2.2.4 Bandgap Reference

The PMU provides a voltage reference that is stable across temperature and VDD supply voltage and is used by the device for internal functions, including:

- Deriving the brownout reset circuit thresholds
- Setting the output voltage for the core regulator
- Deriving the on-chip VREF levels for on-chip analog peripherals

The bandgap reference is enabled in RUN, SLEEP, STOP modes. This reference operates in a sampled mode in STANDBY to reduce power consumption and is disabled in SHUTDOWN mode. SYSCCTL manages the bandgap state automatically; no user configuration is required.

### 2.2.5 VBOOST for Analog Muxes

The VBOOST circuit in the PMU generates an internal VBOOST supply that is used by the analog muxes in specific modules. The VBOOST circuit enables consistent analog mux performance across the external supply voltage (VDD) range.

#### Modules supported by VBOOST

- COMP
- OPA

- GPAMP
- SYSOSC (for FCL-ON external resistor mode operation)
- HFXT

---

**Note**

Refer to the data sheet for device-specific features

---

### Enabling and Disabling VBOOST

SYSCTL automatically manages the enable request for the VBOOST circuit based on the following parameters:

- The COMP, OPA, and GPAMP peripheral PWREN settings
- The ANACPUMPCFG control bits in the GENCLKCFG register in SYSCTL (please refer to the table below)
- The enabling of HFXT as a HFCLK clock source

---

**Note**

If SYSOSC is configured with FCL ON and EXT-R, then VBOOST is kept active through low power modes to provide fast exit out of LPM. This is hardware managed, and not dependent on the ANACPUMPCFG setting

---

VBOOST is disabled by default following a SYSRST. Application software is not required to enable the VBOOST circuit prior to using associated peripherals. When the peripheral is enabled by application software, SYSCTL also enables the VBOOST circuit to support the peripheral.

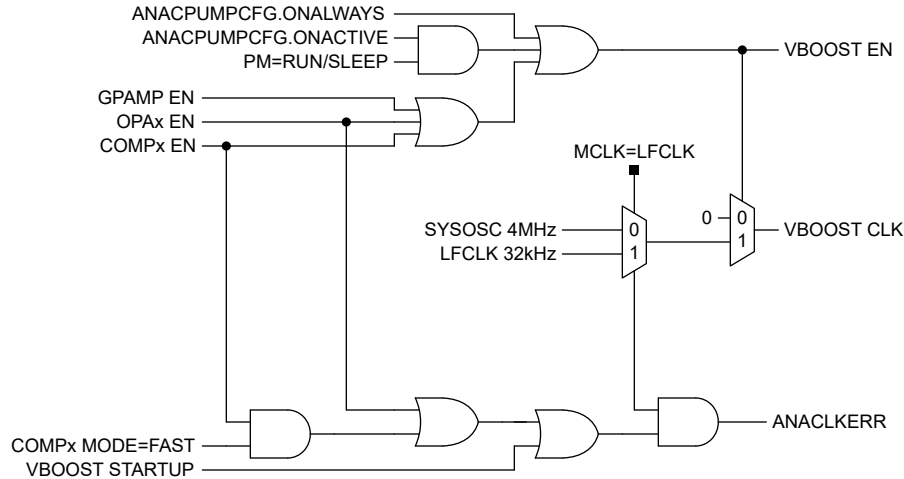

The VBOOST circuit has a startup time requirement to transition from a disabled state to an enabled state. If a peripheral is enabled when VBOOST is disabled, then the corresponding peripheral ready status is not asserted until both the peripheral and the VBOOST circuit are ready. If the startup time of the peripheral is less than the VBOOST startup time, the peripheral startup time is then equivalent to the VBOOST startup time.

Alternatively, application software can force the VBOOST circuit to be enabled at all times (with ANACPUMPCFG=0x2) or while in RUN or SLEEP mode (with ANACPUMPCFG=0x1) so that there is no additional startup delay when enabling a peripheral supported by VBOOST. [Table 2-1](#) gives the behavior of the ANACPUMPCFG control and corresponding application use cases.

**Table 2-1. Forcing VBOOST Enable With ANACPUMPCFG**

VBOOST Control (ANACPUMPCFG)		Behavior	
VAL	MODE	VBOOST Enable	Application Use Case
0x0	ONDEMAND	VBOOST is automatically enabled by SYSCTL only when a supported peripheral is enabled.	This setting provides the lowest power consumption in all modes when fast startup of the peripheral is not critical.
0x1	ONACTIVE	VBOOST is forced to be enabled when the device is in RUN or SLEEP mode. VBOOST is also kept enabled in STOP or STANDBY mode if a supported peripheral is enabled.	This setting provides low power consumption by disabling the VBOOST automatically in STOP and STANDBY modes when no peripherals requiring VBOOST are enabled. VBOOST is automatically re-enabled upon exit to RUN mode to provide fast startup of the supported peripherals in the event that application software enables a said peripheral in RUN mode.
0x2	ONALWAYS	VBOOST is forced to be enabled in all operating modes except SHUTDOWN.	This setting makes sure that the peripherals never incur additional startup latency due to VBOOST startup in applications where fast startup is critical.

The VBOOST enable, VBOOST clock selection, and VBOOST clock error logic is shown in [Figure 2-5](#).

**Figure 2-5. VBOOST Request Logic**

**VBOOST Clock**

The VBOOST circuit requires a functional clock to operate. VBOOST is clocked by either the SYSOSC (4MHz output) or the LFCLK (32kHz) based on the currently active MCLK and ULPClk tree source. The VBOOST clock is selected by automatically by SYSCTL according to the logic shown in Figure 2-5 and described here:

- When the MCLK and ULPClk are sourced from LFCLK (32kHz), the VBOOST is also sourced from LFCLK.
- In all other scenarios, VBOOST is sourced from the SYSOSC 4MHz output.

Certain VBOOST operating conditions require that the VBOOST clock be 4MHz (sourced from SYSOSC) and not 32kHz (sourced from LFCLK) for well-designed startup time. Such conditions include:

- OPA operation or fast mode COMP operation
- VBOOST is starting up (transitioning from disabled to enabled)

The application software must make sure that MCLK and ULPClk are not sourced from LFCLK when either of these conditions are present. SYSCTL does not change the current system clock configuration for a VBOOST request. If the MCLK and ULPClk tree is sourced from LFCLK in one of these scenarios, SYSCTL asserts an ANACKERR status in the CLKSTATUS register in SYSCTL to indicate to application software that there is a mismatch between the VBOOST clock requirement and the current MCLK and ULPClk configuration.

The complete clock requirements for VBOOST are given in Table 2-2.

**Table 2-2. VBOOST Clock Requirements**

VBOOST Request		VBOOST Circuit Clock Requirement	MCLK and ULPClk Source Requirement <sup>(1)</sup>	Supported Operating Modes or Policies
No active request (VBOOST is disabled)		N/A	Don't care	Don't care
VBOOST is starting up from a disabled state		4MHz	Not LFCLK	RUN0, SLEEP0, STOP0, STOP1
OPA enabled		4MHz	Not LFCLK	RUN0, SLEEP0, STOP0, STOP1
COMP enabled	Fast mode (FAST)	4MHz	Not LFCLK	RUN0, SLEEP0, STOP0, STOP1
	Ultra-low-power mode (ULP) <sup>(2)</sup>	4MHz or 32kHz	Don't care	RUN0, RUN1, RUN2, SLEEP0, SLEEP1, SLEEP2, STOP0, STOP1, STOP2, STANDBY0
GPAMP enabled <sup>(2)</sup>		4MHz or 32kHz	Don't care	RUN0, RUN1, RUN2, SLEEP0, SLEEP1, SLEEP2, STOP0, STOP1, STOP2, STANDBY0

**Table 2-2. VBOOST Clock Requirements (continued)**

VBOOST Request	VBOOST Circuit Clock Requirement	MCLK and ULPClk Source Requirement <sup>(1)</sup>	Supported Operating Modes or Policies
VBOOST running with no peripheral request active (due to ANACPUMPCFG!=0x0) <sup>(2)</sup>	4MHz or 32kHz	Don't care	RUN0, RUN1, RUN2, SLEEP0, SLEEP1, SLEEP2, STOP0, STOP1, STOP2, STANDBY0
HFXT	4MHz or 32kHz	Don't care	RUN0, SLEEP0, STOP0, STOP1
SYSOSC (with FCL ON and EXT-R)	4MHz or 32kHz	Don't care	RUN0, SLEEP0, STOP0, STOP1

- (1) Application software must make sure that the clock system is configured as stated in the previous table to support proper VBOOST operation for each scenario. SYSCTL **does not change the system clock configuration when VBOOST is requested**. If a VBOOST request requires the VBOOST clock to be 4MHz and MCLK is sourced from LFCLK, SYSCTL asserts an ANACKERR to indicate to the application that the current system clock configuration is not valid to support the current VBOOST request.
- (2) If no OPA is enabled and no COMP is enabled and configured in FAST mode, the VBOOST **does not require a 4MHz clock** and VBOOST can run from LFCLK to reduce power consumption. However, if the VBOOST was previously disabled (no request present) and it is requested by a peripheral becoming enabled or by application software (ANACPUMPCFG!=0x0), **a 4MHz VBOOST clock is required for VBOOST startup**. After VBOOST startup is complete, the VBOOST clock can be 32kHz sourced from LFCLK if no OPA is enabled and no COMP is enabled in FAST mode. Changing the MCLK source to LFCLK during VBOOST startup can lead to incorrect operation of the VBOOST and inconsistent analog peripheral performance. When the VBOOST circuit has started and is ready, the ANACPUMPGOOD bit is set in the SYSSTATUS register in SYSCTL.

### 2.2.6 Peripheral Enable

All peripherals on a device, with the exception of infrastructure peripherals such as SYSCTL itself and the IOMUX, require two user actions to enable the peripheral to be ready for operation:

- Peripheral Write Enable
  - Provided by the peripheral write enable control register (PWREN) with a KEY and ENABLE field.
  - Before any other peripheral registers are configured by software, the peripheral itself must be enabled by writing the ENABLE bit together with the appropriate KEY value to the peripheral's PWREN register
  - When the PWREN.ENABLE bit is cleared, the peripheral's registers are not accessible for read/write operations.
- Peripheral Function Enable
  - Peripherals may have a functional enable bit in the corresponding register map to provide access to power or for operation

#### Note

After setting the ENABLE | KEY bits in the PWREN register to enable a peripheral, wait at least 4 ULPClk clock cycles before accessing the rest of the peripheral's memory-mapped registers. The 4 cycles allow for the bus isolation signals at the peripheral's bus interface to update.

#### 2.2.6.1 Automatic Peripheral Disable in Low Power Modes

Peripherals in power domain 1 (PD1) will be forced to a disabled state by SYSCTL upon entry into a STOP or STANDBY low-power mode. As such, these peripherals will not be available for use in STOP or STANDBY.

Most PD1 peripherals will retain their configuration settings after being automatically disabled, such that re-configuration is not required upon exit from STOP or STANDBY mode. See the peripheral-specific chapter in this guide for details on which peripheral registers are retained through STOP and STANDBY mode for PD1 peripherals.

If a PD1 peripheral was multiplexed to an IO pin (through the IOMUX) in an output configuration, the last valid output state (logic 0 or logic 1) from the peripheral to the IO is latched upon entry to STOP or STANDBY mode. This prevents external circuits from being disturbed by SYSCTL disabling a peripheral during low-power

operation. Upon exit from STOP or STANDBY mode, the IO is again connected to the peripheral as the peripheral becomes re-enabled.

## 2.3 Clock Module (CKM)

The clock module contains the internal and external [oscillators](#), the [clock monitors](#), and the [clock selection and control logic](#). A [frequency clock counter](#) is also provided for checking and/or calibrating the frequency of high-speed clocks against either the LFXT/LFCLK\_IN or a reference period/pulse provided on an IO pin (FCC\_IN).

### 2.3.1 Oscillators

Several internal and external oscillators are provided for generating low to high frequency clocks for use by the system. The CKM contains all the oscillators in the device and uses them to generate the system clocks. See the device specific data sheet for whether external oscillators are available.

#### Internal Oscillators

- **LFOSC**: low frequency oscillator (32kHz typical frequency)
- **SYSOSC**: system oscillator (up to 32MHz frequency)
- **SYSPLL**: system PLL (phase-locked loop) with programmable frequency (optional)
- **USBFLL**: USB FLL (frequency-locked loop) for crystal-less USB operation (optional)

#### External Oscillators

- **LFXT**: low frequency, low power crystal oscillator (32kHz typical frequency)
- **HFXT**: high frequency crystal oscillator (up to 48MHz typical frequency)

In addition to the oscillators, low frequency (LFCLK\_IN) and high frequency (HFCLK\_IN) digital clock inputs are provided to support cases where the LFXT or HFXT is not used and a direct digital clock is supplied to the device.

##### 2.3.1.1 Internal Low-Frequency Oscillator (LFOSC)

The low-frequency oscillator (LFOSC) is an on-chip low power oscillator which is factory trimmed to a frequency of 32.768kHz. LFOSC provides a stable low frequency clock source in cases where the low frequency crystal oscillator (LFXT) is either not present or not used.

LFOSC can provide higher accuracy when used over a reduced temperature range. See the device-specific data sheet for details.

The LFOSC is active by default after a BOOTRST, sourcing the **LFCLK**. The **LFOSC startup monitor** sets the LFOSCGOOD bit in the CLKSTATUS register when LFOSC is ready.

If user software selects either LFXT or LFCLK\_IN as the LFCLK source, the LFOSC is disabled until the next BOOTRST.

##### 2.3.1.2 Internal System Oscillator (SYSOSC)

The system oscillator (SYSOSC) is an on-chip, accurate high frequency clock source (up to 32MHz). The SYSOSC provides a flexible high-speed clock source to the system in cases where the high frequency crystal oscillator (HFXT) is either not present or not used, or where fast wake-up from a low-power mode is required.

Key features of the SYSOSC include:

- High accuracy when using optional frequency correction loop (FCL) and reference resistor
  - The frequency correction loop may support correction via an external resistor (ROSC) or an internal resistor, depending on the device capabilities. Refer to the device-specific data sheet to determine if a device supports the FCL with an internal or external resistor, or both
- Fast start-up time from a low power state
- Capable of switching from base frequency to low frequency, or low frequency to base frequency, in one clock cycle with no functional interruption (gear shift)
  - Phase-aligned transition to minimize disturbance to peripherals
  - Fast settling to specified accuracy
  - SYCTL can initiate seamless gear shift frequency switch in STOP mode to reduce SYSOSC current

- Refer to the device-specific data sheet to determine if multiple frequency settings for SYSOSC are supported
- The SYSOSC clock source provides a user trimmable frequency start at 16MHz or 24MHz.
  - In-system trimming is supported by the usage of the FCC (frequency clock counter)
- A secondary output with a constant 4MHz frequency for use by MFCLK
  - When  $f_{\text{SYSOSC}} = 4\text{MHz}$ , the MFCLK/MFPCLK output is derived from SYSOSC directly.
  - When  $f_{\text{SYSOSC}}$  is not 4MHz, the MFCLK/MFPCLK output is derived by a digital divider sourcing from SYSOSC with the appropriate ratio
  - SYCTL manages the digital divider on this output to ensure a constant 4MHz output regardless of the user selected SYSOSC frequency.
  - Peripherals using this output see a continuous 4MHz functional clock in RUN, SLEEP, and STOP modes, with reduced current in STOP mode when gear shift is enabled due to SYSOSC running natively at 4MHz.

The SYSOSC is active at the device's base frequency by default after a brownout reset, sourcing MCLK.

### 2.3.1.2.1 SYSOSC Gear Shift

The SYSOSC can shift from base frequency (e.g. 32MHz) to low frequency (4MHz), or low frequency back to base frequency, in a single SYSOSC clock cycle with the frequency change being phase aligned to minimize jitter. This feature is particularly well suited for low power, low cost microcontroller applications because it allows a single oscillator to be used to generate two frequencies:

- A high-speed (e.g. 32MHz) clock (for running the CPU during compute), which is only enabled when needed
- A lower-speed 4MHz clock (for running peripherals such as timers, UART interfaces, and I<sup>2</sup>C interfaces) which is continuously running

When a high-speed clock is needed (for example, in RUN and SLEEP modes), SYSOSC can run at its base frequency to provide high performance. In such a case, SYSOSC can be used directly to source MCLK so that MCLK can be used by the CPU, DMA, and peripherals clocked by the bus. For peripherals that run continuously but do not require the high clock frequency, the middle frequency system clock (MFCLK) is provided at 4MHz by taking the base frequency of SYSOSC and dividing down to achieve 4MHz.

When the fast clock is not needed (for example, if the CPU has completed processing data), then in STOP mode SYSOSC can be gear shifted down to 4MHz in one cycle, and MFCLK switches to being clocked directly by SYSOSC- keeping a continuously running 4MHz clock, but with a reduction in SYSOSC current and no need for a separate oscillator to provide the 4MHz clock. When the CPU is again needed, SYSOSC can be switched back from 4MHz to the base frequency. This transition also occurs in one SYSOSC clock cycle. During the gear shift up, MFCLK switches back to keep the 4MHz constant frequency (with suitable digital division). The timing transition between base frequency and low frequency during a gearshift down request is shown in Figure 2-6.

Figure 2-6. SYSOSC Gearshift Down Timing

The SYSOSC gearshift mode is tightly integrated with the power management scheme and is controlled by SYSCTL. Gearshift mode can be used when switching between RUN mode and STOP mode (gear down) and STOP mode and RUN mode (gear up). To use gearshift in STOP mode to reduce SYSOSC current, set the USE4MHZSTOP bit in the SYSOSCCFG register. Note that if SYSOSC is configured for 4MHz operation in RUN and SLEEP mode as well as STOP mode (no gear shift), then the USE4MHZSTOP bit does not need to be set to keep the SYSOSC at 4MHz when entering STOP mode.

### 2.3.1.2.2 SYSOSC Frequency

SYSOSC comes factory trimmed for operation at either the base frequency or 4MHz. The default frequency of operation is the base frequency. It is possible to run SYSOSC continuously at 4MHz for reduced current operation if 4MHz provides suitable performance for the application. To change the SYSOSC frequency to 4MHz, set the FREQ field in the SYSOSCCFG register to 4M.

---

#### Note

The FREQ field in the SYSOSCCFG register must only be changed when SYSOSC is the MCLK source. Do not change the SYSOSC FREQ configuration when MCLK is sourced from LFCLK or from HSCLK.

---

SYSOSC also supports user-trimmed operation at either 24MHz or 16MHz. No other frequencies are allowed. To run SYSOSC at a user trimmed frequency, first ensure that SYSOSC is running at the base frequency. Then, configure the SYSOSCTRIMUSER register for the target frequency. Finally, select USER in the FREQ field of the SYSOSCCFG register. For trimming, see the [trim procedure](#).

---

#### Note

When running at a user frequency (16MHz or 24MHz), changing the SYSOSC frequency selection to low frequency (4MHz) requires a transition through the base frequency before SYSOSC switches to low frequency. The same is true when switching from low frequency to a user frequency. This change is managed entirely in hardware. Software can directly select the low frequency when running at a user frequency (and the reverse) but the hardware transitions through the base frequency when making the frequency change. If MFCLK (4MHz) is enabled, it will be maintained at 4MHz during the transition.

---

### 2.3.1.2.3 SYSOSC Frequency Correction Loop

The SYSOSC frequency accuracy can be improved through the use of the SYSOSC frequency correction loop (FCL) feature. The FCL circuit uses either an internal resistor or external resistor (populated between the ROSC pin and VSS), to stabilize the SYSOSC frequency by providing a precise reference current for the SYSOSC. The overall frequency accuracy which is achievable depends on the operating temperature range together with the tolerance and temperature drift of the selected reference resistor.

---

#### Note

Not all devices support operation with an internal resistor and an external resistor for FCL. Some devices support external mode, some devices support internal mode, and some devices support both modes. See the device-specific data sheet to determine the features of a given device.

---

---

#### Note

The power consumption of SYSOSC is marginally higher with the FCL enabled due to the reference current that flows through ROSC. Settling time from startup to target accuracy can also be longer. See the device-specific data sheet for startup times.

---

#### 2.3.1.2.3.1 SYSOSC FCL in External Resistor Mode (ROSC)

This section describes the procedure for selecting the external ROSC resistor (including computing the achievable SYSOSC accuracy) as well as the procedure for enabling the mode through the device SYSCTL registers.

## SYSOSC Overall Frequency Accuracy with TI Recommended ROSC Resistor

The device-specific data sheet includes specifications for overall SYSOSC frequency accuracy when the TI-recommended resistor is used for ROSC. The TI-recommended resistor enables a variety of applications, including UART communication. If the overall accuracy values in the device-specific data sheet with the TI-recommended resistor specifications meets the application and cost requirements, then there is no need to compute the accuracy for an alternate resistor or alternate temperature ranges.

However, if a higher accuracy or reduced cost resistor is needed, the designer can use a more precise or less precise resistor for ROSC to balance cost with frequency accuracy for a given application scenario.

## SYSOSC Overall Frequency Accuracy with Designer Selected Resistor

Assuming an ideal (zero error, zero temperature drift) reference resistor, the FCL mode improves the SYSOSC circuit accuracy to the level specified in the  $f_{SYSOSC}$ : "SYSOSC frequency accuracy when frequency correction loop (FCL) is enabled and an ideal ROSC resistor is assumed" section of the SYSOSC specifications table in the device-specific data sheet. The overall SYSOSC frequency accuracy in FCL mode which is achievable for a given external resistor and temperature range is determined by combining the following error sources to determine the total frequency error:

1. The ROSC resistor tolerance (at 25°C); this comes from the resistor specifications
2. The ROSC resistor temperature coefficient of resistance (TCR); this comes from the resistor specifications
3. The minimum and maximum expected operating temperatures for the system being designed
4. The SYSOSC frequency accuracy with an ideal resistor for the desired temperature range (taken from the MSPM0 device-specific data sheet)

The following table gives an example of how to compute the accuracy for different conditions, given the following typical application scenario:

- A target operating temperature range of -40 to 85°C.
- ROSC resistor with a  $\pm 0.1\%$  tolerance and  $\pm 25$  ppm/°C TCR selected

**Table 2-3. Computing Overall SYSOSC FCL Frequency Accuracy based on External Resistor (ROSC) Specifications**

Step	Description	MIN	TYP	MAX	UNIT
1	Define the operating temp range of the application.	-40	25	85	°C
2	Select the target $f_{SYSOSC}$ frequency (4 or 32MHz)		32.00		MHz
3	Look up the corresponding $f_{SYSOSC}$ ideal resistor accuracy from the device-specific data sheet based on the temperature range in Step 1.	-0.80		0.93	%
4	Compute the min and max $f_{SYSOSC}$ with an ideal resistor based on the selected frequency in Step 2 and the accuracy range in Step 3.	31.744		32.298	MHz
5	Select an ROSC resistor with acceptable tolerance (the TI-recommended $\pm 0.1\%$ tolerance used in this example)	99.9	100	100.1	kΩ
6	Note the temperature coefficient of resistance (TCR) of the ROSC resistor.		$\pm 25$		ppm/°C
7	Compute the max temperature variation from 25°C (nominal) based on the temperature range defined in Step 1.	$ 25 - (-40)  = 65$			°C
8	Compute the max ROSC drift over the max temperature variation (from Step 7) and the TCR (from Step 6).	-0.16		0.16	%
9	Compute the min and max ROSC resistance including tolerance (from Step 5) and temperature drift (from Step 8).	99.74		100.26	kΩ
10	Compute the overall ROSC resistor accuracy (in percent), using the overall ROSC resistance range from Step 9 vs. the nominal resistor value.	-0.26		0.26	%
11	Compute the variation in the min and max $f_{SYSOSC}$ by degrading the min/max $f_{SYSOSC}$ computed in Step 4 by the ROSC accuracy computed in Step 10.	31.66		32.38	MHz
12	If desired, convert the raw min/max $f_{SYSOSC}$ computed in Step 11 into a %-based accuracy format relative to the target $f_{SYSOSC}$ from Step 2.	-1.06		1.20	%

## Enabling FCL with an External Resistor (ROSC)

To increase the SYSOSC accuracy with FCL, follow this procedure:

1. Verify that all digital functions on the ROSC pin are disabled in IOMUX (this is the default state after power up).
2. Verify that a ROSC reference resistor that meets the application accuracy requirements is placed between the ROSC pin and the device ground (VSS).
3. Enable FCL mode by setting the SETUSEFCL bit in the SYSOSCFCLCTL register.
  - a. If the device supports both internal resistor and external resistor FCL modes, also set the SETUSEEXRES bit in the SYSOSCFCLCTL register in addition to the SETUSEFCL bit.
4. When the FCL mode is enabled, software cannot disable the mode. A **BOOTRST** is required before a change to the FCL mode.

### 2.3.1.2.3.2 SYSOSC FCL in Internal Resistor Mode

This section describes the procedure for selecting the internal resistor mode through the device SYSCCTL registers. Enabling FCL in internal resistor mode can be beneficial to the user's application which require improved SYSOSC performance while not adding cost to the system for an external resistor.

## Enabling FCL with Internal Resistor

To increase the SYSOSC accuracy with FCL, follow this procedure:

1. Enable FCL mode by setting the SETUSEFCL bit in the SYSOSCFCLCTL register.
  - a. If the device supports both internal resistor and external resistor FCL modes, do not set the SETUSEEXRES bit in the SYSOSCFCLCTL register when setting the SETUSEFCL bit.
2. When the FCL mode is enabled, software cannot disable the mode. A **BOOTRST** is required before a change to the FCL mode.

### 2.3.1.2.4 SYSOSC User Trim Procedure

The SYSOSC can be configured at 16MHz or 24MHz as an alternative to the base frequency. To utilize these configurations, the trim values need to be applied. Trimming is accomplished by manipulating the fields in the SYSOSCTRIMUSER to achieve the target frequency. To trim the SYSOSC, the SYSOSC clock can be brought out externally to a pin using the **CLK\_OUT** unit so that it can be measured.

Use the following procedure to derive the user trim values. The trimmed values can be programmed into the flash memory of the device to be recalled later. Each device must be trimmed individually for accuracy. SYSOSC can also be trimmed internally by using the frequency clock counter (**FCC**).

### Trim procedure using CLK\_OUT with frequency correction loop (FCL) disabled (No ROSC resistor)

1. Enable the **CLK\_OUT** unit and select SYSOSC as the clock source, following the instructions in the **CLK\_OUT** section
2. Set the SYSOSC frequency to BASE to start (ensure that the **FREQ** field in the SYSOSCCFG register is set to 0h for BASE), and leave the FCL mode disabled
3. Program an initial tuning for the target frequency in the SYSOSCTRIMUSER register:
  - a. Set the RESCOARSE trim field in the SYSOSCTRIMUSER register to mid-range
  - b. Set the RESFINE trim field in the SYSOSCTRIMUSER register to mid-range
4. Switch SYSOSC to the user-trimmed frequency by selecting USER in the **FREQ** field of the SYSOSCCFG register
5. Measure the SYSOSC frequency at the **CLK\_OUT** pin
6. Switch SYSOSC back to BASE frequency by selecting BASE in the **FREQ** field of the SYSOSCCFG register. Writing to SYSOSCTRIMUSER requires SYSOSC to be operating at BASE frequency.
7. Adjust the SYSOSCTRIMUSER parameters to close on the target frequency:
  - a. Set the target frequency (16 or 24MHz) in the **FREQ** field of the SYSOSCTRIMUSER register

- b. Adjust trim parameters to achieve 16 or 24 MHz based on the selection made in step 7a
  - i. Increasing the CAP trim field in the SYSOSCTRIMUSER register will reduce the SYSOSC range. For 24MHz, select CAP=0, and for 16MHz select CAP=1
  - ii. Increasing the RESCOARSE trim field in SYSOSCTRIMUSER will reduce the frequency in large steps of approximately 1MHz
  - iii. Increasing the RESFINE trim field in SYSOSCTRIMUSER will decrease the frequency in small steps of approximately 100kHz
8. Repeat steps 4 through 7 until the desired accuracy has been achieved
9. Save the resulting SYSOSCTRIMUSER value for recall

#### **Trim procedure using CLK\_OUT with frequency correction loop (FCL) enabled (ROSC resistor present)**

1. First, complete the FCL disabled trim procedure (defined above) to obtain starting values for the CAP, RESCOARSE, and RESFINE trim fields in the SYSOSCTRIMUSER register
2. Increase the RESCOARSE value by 02h from the value obtained in Step 1
3. With CLK\_OUT still enabled (SYSOSC as the source for CLK\_OUT), ensure that the FREQ field in the SYSOSCCFG register is set to 0h for BASE, and enable the FCL mode by setting the SETUSEFCL bit in the SYSOSCFCLCTL register
4. Set the RDIV trim field in the SYSOSCUSERTRIM register to mid-range
5. Switch SYSOSC to the user-trimmed frequency by selecting USER in the FREQ field of the SYSOSCCFG register
6. Measure the SYSOSC frequency at the CLK\_OUT pin
7. Switch SYSOSC back to BASE frequency by selecting BASE in the FREQ field of the SYSOSCCFG register
8. Adjust trim parameters to close on the target frequency:
  - a. Increasing the RDIV trim field in the SYSOSCTRIMUSER register will increase the frequency in small steps of approximately 50kHz
  - b. Continue increasing or decreasing RDIV if the frequency is in saturation (not appearing to adjust)
9. Repeat steps 5-8 until the desired accuracy has been achieved
10. Save the resulting SYSOSCTRIMUSER value for recall

---

#### **Note**

SYSOSCTRIMUSER parameters only take effect when switching to the USER frequency. Once USER frequency is selected, changes to SYSOSCTRIMUSER have no effect. To refresh the USER values, first switch to BASE frequency, then update SYSOSCTRIMUSER, and then switch SYSOSC back to BASE frequency.

---

#### **2.3.1.2.5 Disabling SYSOSC**

SYSOSC can be disabled in STOP mode by setting the DISABLESTOP bit in the SYSOSCCFG register. Doing so forces the MCLK to use LFCLK in STOP mode. This provides the lowest possible power consumption in STOP mode, as the system runs at 32kHz and SYSOSC consumes no current. When exiting STOP mode to RUN mode, SYSCTL will automatically re-enable SYSOSC and switch MCLK back to SYSOSC.

SYSOSC can be disabled manually by setting the DISABLE bit in the SYSOSCCFG register. When SYSOSCCFG.DISABLE is set, the system will run from LFCLK in all power modes.

---

#### **Note**

The DISABLE and DISABLESTOP bits in SYSOSCCFG are mutually exclusive, and must not be set at the same time.

---

It is not possible to disable SYSOSC when using a different high speed clock to source MCLK (such as HSCLK). This is because SYSOSC is used by SYSCTL logic when MCLK is sourced from HSCLK.

SYSOSC is always disabled automatically in STANDBY and SHUTDOWN modes.

### 2.3.1.3 System Phase-Locked Loop (SYSPLL)

The system phase locked loop (SYSPLL) takes an input reference clock SYSPLLREF and scales the input frequency to produce user-specified high frequency clocks (SYSPLLCLK0, SYSPLLCLK1, and SYSPLLCLK2X) for use by the device. Specifically, the SYSPLL clock outputs can be used as sources to MCLK, CANCLK and USBCLK. [Figure 2-7](#) shows the block diagram of the SYSPLL.

Figure 2-7. SYSPLL Diagram

#### Note

**SYSOSC** must not be disabled when the SYSPLL is enabled for use.

#### 2.3.1.3.1 Configuring SYSPLL Output Frequencies

The SYSPLL accepts an input reference clock from 4-48MHz. The available reference clocks include **SYSOSC** and **HFCLK**. The predivider PDIV scales the selected input reference clock ahead of the PLL feedback loop. PDIV can be selected as /1, /2, /4, or /8 by programming 0x0 to 0x3, respectively, into the PDIV field in the SYSPLLCFG1 register.

The effective divider can be calculated from the PDIV register setting as shown in [Equation 1](#).

$$\text{SYSPLLREF}_{\text{DIV}} = 2^{\text{PDIV}} \quad (1)$$

The PLL feedback loop sets the voltage controlled oscillator (VCO) output equal to the divided input reference clock  $f_{\text{LOOPIN}}$  multiplied by the QDIV feedback divider. The QDIV divider is an integer divider with a valid range of /2 to /127. The desired QDIV divider is selected by programming 0x01 to 0x7E for /2 to /127, respectively, into the QDIV field of the SYSPLLCFG1 register. SYSPLLCFG1.QDIV=0x00 is an invalid configuration. The effective feedback divider can be calculated from the QDIV register setting as shown in [Equation 2](#).

$$\text{SYSPLLF}_{\text{DIV}} = \text{QDIV} + 1 \quad (2)$$

The output frequency of the VCO  $f_{\text{VCO}}$  is given in [Equation 3](#).

$$f_{\text{VCO}} = f_{\text{SYSPLLREF}} \times \text{SYSPLLF}_{\text{DIV}} / \text{SYSPLLREF}_{\text{DIV}} \quad (3)$$

The VCO output sources three separate SYSPLL outputs (SYSPLLCLK0, SYSPLLCLK1, and SYSPLLCLK2X). Each output has its own divider unit to enable generation of up to 3 different output frequencies for use by different modules in the device. The third output (SYSPLLCLK2X) also contains a frequency doubler before the divider unit to provide a wider range of output frequencies and lower power consumption.

For SYSPLLCLK2X, the output divider can be set from /1 to /16 in steps of 1. To set the SYSPLLCLK2X output divider, program 0x0-0xF for /1 up to /16, respectively, into the RDIVCLK2X field in the SYSPLLCFG0 register. [Equation 4](#) shows how to compute the effective SYSPLLCLK2X divider based on a given RDIVCLK2X register setting.

$$\text{SYSPLLCLK2X}_{\text{DIV}} = \text{RDIVCLK2X} + 1 \quad (4)$$

For SYSPLLCLK1 and SYSPLLCLK0, the output dividers can be set from /2 to /32 in steps of 2. To set the SYSPLLCLK0 or SYSPLLCLK1 output divider, program 0x0-0xF for /2 to /32, respectively, into the corresponding RDIVCLKx field in the SYSPLLCFG0 register. Equation 5 shows how to compute the effective SYSPLLCLK0 divider based on a given RDIVCLK0 setting, and Equation 6 shows how to compute the effective SYSPLLCLK1 divider based on a given RDIVCLK1 setting.

$$\text{SYSPLLCLK0}_{\text{DIV}} = 2 \times (\text{RDIVCLK0} + 1) \quad (5)$$

$$\text{SYSPLLCLK1}_{\text{DIV}} = 2 \times (\text{RDIVCLK1} + 1) \quad (6)$$

The SYSPLL output clock frequencies are thus set by the combination of  $f_{\text{VCO}}$  and the respective dividers:

$$f_{\text{SYSPLLCLK0}} = f_{\text{VCO}} / \text{SYSPLLCLK0}_{\text{DIV}} \quad (7)$$

$$f_{\text{SYSPLLCLK1}} = f_{\text{VCO}} / \text{SYSPLLCLK1}_{\text{DIV}} \quad (8)$$

$$f_{\text{SYSPLLCLK2X}} = 2 \times f_{\text{VCO}} / \text{SYSPLLCLK2X}_{\text{DIV}} \quad (9)$$

### Enabling and Disabling the SYSPLL

After configuration, enable the SYSPLL by setting the SYSPLLEN bit in the HSCLKEN register. Before enabling the SYSPLL, make sure that the SYSPLL is in a disabled state by verifying that the SYSPLLOFF bit in the CLKSTATUS register is set. After the SYSPLL is enabled, application software must not disable it until the SYSPLLG00D bit or SYSPLLOFF bit is set in the CLKSTATUS register, indicating that the SYSPLL transitioned to a stable active state or a stable dead state. When the SYSPLL is enabled, the SYSPLL reference clock selection must not be changed.

---

#### Note

**SYSOSC** must be enabled and running at base frequency when the SYSPLL is enabled, even if HFCLK is used as the SYSPLL reference clock.

---

### SYSPLL Usage Example (for CAN protocol)

To illustrate the above relationships, take as an example the following requirements:

- The internal system oscillator (**SYSOSC**) is used as the SYSPLL reference (32MHz)
- The SYSPLL must be configured with an output frequency of 80MHz to source MCLK and 40MHz to source CANCLK

To achieve this, the VCO can be configured for 80MHz through the use of PDIV and QDIV. Then, SYSPLLCLK1 can feed CANCLK with an output divider of /2, and SYSPLLCLK2X can feed MCLK with an output divider of /2.

The steps below describe how to configure the CKM to use SYSPLL in this way:

1. Verify that the SYSPLL is disabled (SYSPLLOFF is set in CLKSTATUS)
2. Make sure that SYSOSC is running at base frequency (32MHz); this is a requirement for SYSPLL operation even if HFCLK is used as the SYSPLL reference clock instead of SYSOSC
3. Set SYSOSC as the SYSPLL reference (make sure that the SYSPLLEFF bit in the SYSPLLCFG0 register is cleared; this is the default state after reset)
4. Select a predivider PDIV to /2 (set SYSPLLCFG1.PDIV to 0x01), setting  $f_{\text{LOOPIN}}$  to 16MHz (32 divided by 2)
5. Load the PLL parameters into SYSPLLPARAM0 and SYSPLLPARAM1 to support  $f_{\text{LOOPIN}}$  of 16MHz
6. Set the feedback divider QDIV to 5 (set SYSPLLCFG1.QDIV to 4), giving  $f_{\text{VCO}}=80\text{MHz}$  (16MHz multiplied by 5)
7. Set the SYSPLL output dividers for SYSPLLCLK1 and SYSPLLCLK2X to /2 (set SYSPLLCFG0.RDIVCLK1 to 0x0 and SYSPLLCFG0.RDIVCLK2X to 0x1) to get 40MHz and 80MHz at SYSPLLCLK1 and SYSPLLCLK2X, respectively
8. Enable SYSPLLCLK1 and SYSPLLCLK2X outputs by setting the ENABLECLK1 and ENABLECLK2X bits in the SYSPLLCFG0 register

9. Select SYSPLLCLK2X as the PLL output to the HSCLK mux by setting MCLK2XVCO in the SYSPLLCFG0 register
10. With SYSOSC enabled and running at base frequency (32MHz, this is the default state out of reset), enable the SYSPLL by setting SYSPLLEN in the HSCLKEN register
11. Wait for the SYSPLLG00D indication by testing SYSPLLG00D in the CLKSTATUS register
12. Select the SYSPLL as the HSCLK source by ensuring that the HSCLKSEL bit is cleared in the HSCLKCFG register (this is the default state)
13. Select the high-speed clock (HSCLK) as the source for MCLK by setting the USEHSCLK bit in the MCLKCFG register. This will switch MCLK from SYSOSC to HSCLK. MCLK is now running from SYSPLLCLK2X at 80MHz.
14. To configure the CANCLK, set the CANCLKSRC bit in the GENCLKCFG register.

The SYSPLL divider values used in this example are summarized below for reference.

**Table 2-4. SYSPLL Divider Example Settings**

Parameter	Register	Bit Field	Bit Field Value	Actual Divider
Input reference clock divider	SYSPLLCFG1	PDIV	0x1	/2
VCO feedback loop divider	SYSPLLCFG1	QDIV	0x4	/5
Output clock 1 divider	SYSPLLCFG0	RDIVCLK1	0x0	/2
Output clock 2X divider	SYSPLLCFG0	RDIVCLK2X	0x1	/2

## Tuning Guidelines

In cases where there are multiple combinations of PDIV, QDIV, and RDIVCLKx that provide the desired output frequencies, consider these tuning guidelines to determine the best possible values for an application:

- Lower VCO frequencies ( $f_{VCO}$ ) result in lower power consumption. Refer to the device data sheet for the allowable range of  $f_{VCO}$ .
- Higher feedback loop input frequencies ( $f_{LOOPIN}$ ) have faster startup. For example, if an 80MHz output frequency is desired with  $f_{VCO}=40\text{MHz}$ ,  $f_{VCO} = 40\text{MHz}$  can be derived from a SYSPLLREF clock 32MHz by setting PDIV to /8 and QDIV to /10. However, this gives slower startup because  $f_{LOOPIN}$  is <8MHz. The same result can be achieved by setting PDIV to /4 and QDIV to /5, but because  $f_{LOOPIN}$  is 8MHz in this case (32MHz divided by 4), the [SYSPLL parameters](#) for the higher input range can be used which give faster startup.

### 2.3.1.3.2 Loading SYSPLL Lookup Parameters

Several tuning parameters must be configured in the SYSPLLPARAM0 and SYSPLLPARAM1 registers before using the SYSPLL. The values are determined by PLL feedback loop input clock frequency ( $f_{LOOPIN}$ ).

SYSPLL supports four  $f_{LOOPIN}$  frequency ranges, given in [SYSPLL Parameter Lookup](#). Each frequency range has a 64-bit lookup value in the [FACTORY flash memory region](#) that must be copied from flash into the SYSPLLPARAM0 and SYSPLLPARAM1 registers in SYSCTL before enabling the SYSPLL.

**Table 2-5. SYSPLL Parameter Lookup**

$f_{LOOPIN}$	Lookup Address (PARAM0)	Lookup Address (PARAM1)	SDK Symbol
32MHz ≤ FREQ ≤ 48MHz	0x41C4.0034	0x41C4.0038	DL_SYSCTL_SYSPLL_INPUT_F REQ_32_48_MHZ
16MHz ≤ FREQ < 32MHz	0x41C4.002C	0x41C4.0030	DL_SYSCTL_SYSPLL_INPUT_F REQ_16_32_MHZ
8MHz ≤ FREQ < 16MHz	0x41C4.0024	0x41C4.0028	DL_SYSCTL_SYSPLL_INPUT_F REQ_8_16_MHZ
4MHz ≤ FREQ < 8MHz	0x41C4.001C	0x41C4.0020	DL_SYSCTL_SYSPLL_INPUT_F REQ_4_8_MHZ

### 2.3.1.3.3 SYSPLL Startup Time

The PLL startup time depends on the PLL feedback loop input frequency  $f_{\text{LOOPIN}}$  and if the PLL is starting after previously running (for example, exiting a low-power mode) or starting for the first time after device boot.

Table 2-6 lists an example of how the PLL startup times can be affected by the loop input frequency  $f_{\text{LOOPIN}}$ . Note that  $f_{\text{LOOPIN}}$  is determined by the SYSPLLREF and user-configured PDIV and QDIV.

---

#### Note

These values are used as a relative example only. For specific device performance, please refer to the product datasheet.

---

**Table 2-6. SYSPLL Startup Times (example)**

$f_{\text{LOOPIN}}$	Condition	SYSPLL Startup Time ( $\mu\text{s}$ )	SYSPLL Startup Time on Exit From Low-Power Mode ( $\mu\text{s}$ )
$32\text{MHz} \leq \text{FREQ}$	SYSPLLREF=32MHz, PDIV=0, QDIV=4	13	11
$16\text{MHz} \leq \text{FREQ} < 32\text{MHz}$	SYSPLLREF=32MHz, PDIV=1, QDIV=9	16	14
$8\text{MHz} \leq \text{FREQ} < 16\text{MHz}$	SYSPLLREF=32MHz, PDIV=2, QDIV=19	18	16
$4\text{MHz} \leq \text{FREQ} < 8\text{MHz}$	SYSPLLREF=32MHz, PDIV=3, QDIV=39	26	24

### 2.3.1.4 Low Frequency Crystal Oscillator (LFXT)

The low-frequency crystal oscillator (LFXT) is an ultra-low-power crystal oscillator that supports a standard 32.768kHz watch crystal.

To use the LFXT, place a watch crystal between the LFXIN and LFXOUT pins. Place loading capacitors on both pins to circuit ground (VSS). Size the crystal load capacitors according to the specifications of the crystal being used. A variety of crystal types are supported through a programmable drive mechanism that allows for balancing drive current with the required drive strength for a particular crystal.

The LFXT pins LFXIN and LFXOUT are shared with digital IO functions. To use the LFXT, first configure the IOMUX to support LFXT functionality on the LFXIN and LFXOUT pins. Configure IOMUX to disable any digital IO functionality on the LFXIN and LFXOUT pins. The LFXT defaults to the highest drive strength (LFCLKCFG.XT1DRIVE == 0x03 in SYSCTL), which is recommended for fast reliable start-up of the oscillator. If a crystal with ultra-low capacitance (<3pF) is used, power consumption of the LFXT can be lowered further by setting the LOWCAP bit LFCLKCFG (LOWCAP is cleared by default for compatibility with most crystals).

After completing configuration, start the LFXT by setting the STARTLFXT bit in the LFXCTL register in SYSCTL. When the oscillator has started successfully, the LFXT startup monitor sets the LFXTGOOD bit in the CLKSTATUS register in SYSCTL. Crystal drive strength can then be reduced to conserve power, if desired.

To switch the LFCLK tree to use LFXT as the 32kHz clock source rather than LFOSC, set the SETUSELFXT bit in the LFXCTL register, and SYSCTL permanently switches the LFCLK source to LFXT until a BOR reset or a fatal clock fault occurs.

After the LFXT is enabled, the internal LFOSC is disabled to conserve power. LFOSC cannot be re-enabled and LFCLK thus cannot be switched back to LFOSC other than by a software-triggered POR reset.

---

#### Note

To source MCLK from LFCLK with LFCLK sourced from the LFXT, first configure LFCLK to use LFXT and then configure MCLK to use LFCLK. Do not switch MCLK to LFCLK while LFCLK runs from LFOSC, and then later switch LFCLK to LFXT.

---

---

**Note**

In the event that LFXT is selected for LFCLK at startup but the crystal fails to start properly, it is necessary to execute a POR reset to re-enable the internal LFOSC and run LFCLK from LFOSC or else a 32kHz LFCLK will not be available for the system.

---

---

**Note**

In a scenario where LFXT fails to start, application software may leverage the flash memory to store a flag indicating that the crystal did not start properly, and then execute the POR reset. The flash memory contents can be read following a POR reset and thus in the next startup sequence the application code can decide to keep LFCLK sourced from LFOSC versus the external crystal (in the event that there is a hardware issue with the crystal preventing it from starting).

---

### 2.3.1.5 LFCLK\_IN (Digital Clock)

It is possible to bypass the LFXT circuit and bring in a 32.768kHz typical frequency digital clock into the device to use as the LFCLK source instead of LFOSC or LFXT. To configure LFCLK to use a digital clock input instead of LFXT or LFOSC, first configure the IOMUX to enable the LFCLK\_IN function on the appropriate pin. When IOMUX is configured correctly and the external clock source is outputting a 32kHz clock to LFCLK\_IN, set the SETUSEEXLF bit in the EXLFCTL register in SYSCTL.

LFCLK\_IN is compatible with digital square wave CMOS clock inputs and should have a typical duty cycle of 50%.

When the system is initialized, LFOSC is the primary clock source for LFCLK. Before switching LFCLK to use LFCLK\_IN, it is possible to check for a valid clock signal on LFCLK\_IN by enabling the LFCLK monitor through setting the MONITOR bit in LFCLKCFG register.

After LFCLK\_IN is selected as the LFCLK source, it is not possible to change back to LFOSC or LFXT without going through a BOR reset.

---

**Note**

If MCLK is to be sourced from LFCLK with LFCLK sourced from LFCLK\_IN, first configure LFCLK to use LFCLK\_IN and then configure MCLK to use LFCLK. Do not switch MCLK to LFCLK with LFCLK running from LFOSC, and then later switch LFCLK to LFCLK\_IN.

---

---

**Note**

LFCLK\_IN and LFXT are mutually exclusive and must not be enabled at the same time. Do not set the SETUSEEXLF bit in the EXLFCTL register if the SETUSELFXT bit or the STARTLFXT bit is set in the LFXTCTL register.

---

### 2.3.1.6 High Frequency Crystal Oscillator (HFXT)

The high frequency crystal oscillator (HFXT) can be used with standard crystals and resonators to generate a stable high-speed reference clock for the system. The HFXT can be used to clock the primary device clock tree (MCLK) directly or it can be used as a precision reference to the on-chip PLL where higher frequencies can be generated. In addition, the HFXT can be provided directly to the ADC as the sampling clock source or for other peripherals such as the CAN-FD functional clock source. This allows for a functional clock that is asynchronous from the main system clock (MCLK).

To use the HFXT, a crystal or resonator must be populated between the HFXIN and HFXOUT pins. Loading capacitors must be placed on both pins to circuit ground (VSS). The crystal load capacitors must be sized according to the specifications of the crystal being used. The IOMUX must be configured to enable HFXT functionality on the HFXIN and HFXOUT pins. Configure IOMUX to disable any digital IO functionality on the HFXIN and HFXOUT pins. The HFXT frequency range must be set by configuring the HFXTRSEL bits in the HFCLKCLKCFG register in SYSCTL.

A programmable HFXT startup time is provided with 64 $\mu$ s resolution. Program an appropriate startup time based on the desired crystal or resonator specifications into the HFXTTIME field in the HFCLKCLKCFG register in SYSCTL before starting the HFXT.

Once configured properly, the HFXT is started by setting the HFXTEN bit in the HSCLKEN register in SYSCTL. When the oscillator has started successfully, the [HFCLK startup monitor](#) will assert the HFCLKGOOD bit in the CLKSTATUS register in SYSCTL.

---

**Note**

[SYSOSC](#) must be enabled at base frequency when the HFXT is enabled.

---

After setting HFXTEN to enable the HFXT, application software must verify that either an HFCLKGOOD indication or an HFCLKOFF (off/dead) indication in the CLKSTATUS register was asserted by hardware before attempting to disable the HFXT by clearing HFXTEN. When disabling the HFXT by clearing HFXTEN, the HFXT must not be re-enabled again until the HFCLKOFF bit in the CLKSTATUS register is set by hardware.

To use HFXT as the PLL reference after receiving an HFCLKGOOD status, set the SYSPLLREF bit in the SYSPLLCFG0 register in SYSCTL. If HFXT is selected as a reference for the SYSPLL and the SYSPLL is enabled, then the SYSPLL must be disabled and the SYSPLLOFF bit in the CLKSTATUS register must be set before the HFXT can be disabled.

To use the HFXT directly as the MCLK source after receiving an HFCLKGOOD status, first set the HSCLKSEL bit in the HSCLKCFG register to select HFCLK as the high-speed clock source (rather than the system PLL output). Then, set the USEHSCLK bit in the MCLKCFG register to select the high-speed clock source as the MCLK source. Once USEHSCLK is set, HSCLKCFG must not change and the HFXT must not be disabled until the MCLK source is switched back to SYSOSC by clearing USEHSCLK and verifying that the HSCLKMUX bit in CLKSTATUS is cleared by hardware.

### 2.3.1.7 HFCLK\_IN (Digital clock)

It is possible to bypass the HFXT circuit and bring in an external digital clock signal into the device to use as the HFCLK source instead of HFXT. To configure HFCLK to use a digital clock input, first configure the IOMUX to enable the HFCLK\_IN function on the appropriate pin. When IOMUX is configured correctly and the clock source is outputting a clock to HFCLK\_IN, set the USEEXTHFCLK bit in the HSCLKEN register in SYSCTL.

---

**Note**

[SYSOSC](#) must be enabled at base frequency when the HFCLK\_IN is enabled.

---

The HFCLK\_IN can be used as the reference for SYSPLL. The SYSPLL must be off before changing the configuration of the SYSPLL reference clock source. The user can verify that SYSPLL is off by checking the SYSPLLOFF status bit in the CLKSTATUS register. The user must then select HFCLK\_IN as the HFCLK source (by setting the USEEXTHFCLK bit in the HSCLKEN register) before setting the SYSPLLREF bit in the SYSPLLCFG0 register in SYSCTL. Finally, the SYSPLL can be enabled by using the SYSPLLEN bit in the HSCLKEN register.

To source MCLK from HFCLK\_IN after selecting HFCLK\_IN as the HFCLK source, first set the HSCLKSEL bit in the HSCLKCFG register to select HFCLK as the high-speed clock source. Then, set the USEHSCLK bit in the MCLKCFG register to select the high-speed clock source as the MCLK source. Once USEHSCLK is set, HSCLKCFG must not change and the HFCLK\_IN must not be disabled until the MCLK source is switched back to SYSOSC by clearing USEHSCLK and verifying that the HSCLKMUX bit in CLKSTATUS was cleared by hardware.

HFCLK\_IN is compatible with digital square wave CMOS clock inputs and should have a typical duty cycle of 50%.

---

**Note**

HFCLK\_IN and HFXT are mutually exclusive and must not be enabled at the same time. Do not set the USEEXTHFCLK bit if the HFXTEN bit is also set in HSCLKEN.

---

---

**Note**

When HFCLK\_IN is used, USEMFTICK in the MCLKCFG register is not supported. MFTICK can only be used with SYSOSC.

---

### 2.3.2 Clocks

The CKM takes oscillator outputs and generates a variety of functional clocks for use by the device. Refer to the device specific datasheet to determine the supported functional clocks.

#### Clocks

- System Clocks
  - **MCLK**: Main system clock for PD1 peripherals and PD1 bus
  - **CPUCLK**: CPU clock, derived from MCLK is available only in RUN mode
  - **ULPCLK**: Main system clock for PD0 peripherals and PD0 bus, derived from MCLK
  - **MFCLK**: Fixed 4MHz clock, synchronized to MCLK/ULPCLK
  - **MFPCLK**: Fixed 4MHz clock, utilized for the DAC
  - **LFCLK**: Fixed 32kHz clock, synchronized to MCLK/ULPCLK
  - **HFCLK**: High frequency external clock
  - **HSCLK**: High speed configurable clock for use by MCLK, sourced from SYSPLL or HFCLK
- Peripheral Specific Clocks
  - **ADCCLK**: ADC sampling period clock
  - **CANCLK**: CAN-FD module functional clock
  - **RTCCLK**: Fixed 32kHz clock direct to RTC
- External Clocks
  - **CLK\_OUT**: External clock output with divider for pushing out a clock to external circuits

All clocks are disabled in SHUTDOWN mode.

In addition to the configurable clocks listed above, several direct clock connections are made to analog peripherals (see the [Section 2.3.2.13](#) section).

#### 2.3.2.1 MCLK (Main Clock) Tree

The MCLK is the main system clock and the root point of synchronization for all synchronized clocks (MCLK, CPUCLK, ULPCLK, MFCLK, and LFCLK). It is typically the highest speed clock in the system and supports operation up to 80MHz across the full temperature range of the device. The MCLK tree is the root source for the **CPUCLK** (in RUN mode), the PD1 high speed peripheral bus clock (in RUN and SLEEP modes), and the **ULPCLK** low power bus clock (in RUN, SLEEP, STOP, and STANDBY modes). In addition, the 4MHz **MFCLK** and 32kHz **LFCLK** outputs are synchronized to MCLK.

The MCLK output to PD1 peripherals is enabled in RUN and SLEEP modes, and disabled in all other power modes. While the MCLK output to PD1 is disabled in STOP and STANDBY modes, the MCLK tree is still running to source ULPCLK and to provide synchronization for MFCLK and LFCLK.

The MCLK source is selected with a glitch free clock mux and can be changed dynamically at runtime by user software. It can also be changed automatically by hardware when entering STOP and STANDBY modes or during an [asynchronous fast clock request](#).

The available sources for MCLK include:

- **HSCLK** (high-speed clock) at up to 80MHz which can be sourced by:
  - **SYSPLLCLK0** or **SYSPLLCLK2X** (used to reach the max MCLK speed of 80MHz)
  - **HFCLK** for applications where the main clock needs to be as accurate as possible

- **SYSOSC** at 4, 16, 24, or 32MHz (the default clock source after reset)
- **SYSOSC** at 4MHz with **MDIV** divider (for applications where the peripheral bus and CPU run between 250kHz and 4MHz)
- **LFCLK** at 32kHz for applications where the entire system, including the CPU, runs at 32kHz with low peak operating current

**NOTE:** Set **SYSPLLCLK0** or **SYSPLLCLK2X** as the source of **HSCLK** before setting **HSCLK** as the clock source of **MCLK**, otherwise the device can be in an unpredictable state.

### Using MCLK in RUN and SLEEP Mode

After boot, MCLK is sourced from **SYSOSC** by default. The decision of which oscillator to use to source MCLK is important because MCLK sets both the CPUCLK frequency and the bus clock frequency for PD1 peripherals. As a result, the accuracy and the clock speed of the oscillator selected for MCLK must be appropriate not only for the operation of the CPU but also for the operation of the PD1 peripherals that use the bus clock as their functional clock.

The clock source and frequency selection decisions made for MCLK also affect ULPCLK in RUN and SLEEP modes. See the **ULPCLK** section for more information on how MCLK and ULPCLK are related in RUN and SLEEP mode.

### Using MCLK in STOP and STANDBY Mode

In STOP and STANDBY modes, the MCLK output to PD1 peripherals is disabled, but the **ULPCLK**, which is the bus clock for PD0 peripherals, is still active in STOP and optionally active in STANDBY. See the **ULPCLK** section for more information on how the MCLK source and ULPCLK are related in STOP and STANDBY mode.

### MCLK Source Selection

Application software can change the MCLK source from SYSOSC to the **SYSPLL** or to the HFCLK (which is either **HFXT** or **HFCLK\_IN**) by configuring the MCLKCFG.USEHSCLK and HSCLKCFG.HSCLKSEL register bits appropriately in SYSTL. It is also possible to select LFCLK as the MCLK source in all modes by setting MCLKCFG.USELFCLK, giving the low peak current consumption with the CPU and PD1 peripherals operational. The following table gives the proper register bit configurations for selecting different clocks for MCLK in RUN and SLEEP modes.

**Table 2-7. MSPM0Gxx MCLK Source Selection in RUN and SLEEP Mode**

Desired Source	MCLKCFG.USEHSCLK	MCLKCFG.USELFCLK	HSCLKCFG.HSCLKSEL	SYSPLLCFG0.MCLK2XVCO
SYSOSC	0	0	Don't care	Don't care
SYSPLLCLK0	1	0	0	0
SYSPLLCLK2X	1	0	0	1
HFCLK	1	0	1	Don't care
LFCLK	0	1	Don't care	Don't care

To switch MCLK from SYSOSC to LFCLK in RUN mode:

1. If any high speed oscillators (SYSPLL, HFXT, HFCLK\_IN) are enabled, disable them before proceeding
2. Verify that MCLK is sourced from SYSOSC (CLKSTATUS.CURMCLKSEL is cleared)
3. If SYSOSC is not running at base frequency, and SYSOSC is to be left enabled when switching MCLK to LFCLK, set SYSOSC to base frequency before proceeding
4. Set MCLKCFG.USELFCLK to switch MCLK to LFCLK and leave SYSOSC enabled, or set SYSOSCCFG.DISABLE to switch MCLK to LFCLK and disable SYSOSC

To switch MCLK from LFCLK to SYSOSC in RUN mode:

1. Verify that MCLK is sourced from LFCLK (CLKSTATUS.CURMCLKSEL is set)

2. Clear MCLKCFG.USELFCLK or SYSOSCCFG.DISABLE, whichever was set to switch MCLK to LFCLK

To switch MCLK from SYSOSC to HSCLK:

1. Verify that MCLK is sourced from SYSOSC (CLKSTATUS.HSCLKMUX is cleared).
2. Enable the desired high speed sources (SYSPLL, HFXT, HFCLK\_IN) according to their respective requirements.
3. Select the desired HSCLK source through the HSCLKCFG.HSCLKSEL control
4. Verify that CLKSTATUS.HSCLKGOOD is set, indicating that the selected HSCLK source is valid.
5. Set MCLKCFG.USEHSCLK to switch MCLK to HSCLK.

To switch MCLK from HSCLK to SYSOSC:

1. Verify that MCLK is sourced from HSCLK (CLKSTATUS.HSCLKMUX is set).
2. Clear MCLKCFG.USEHSCLK to switch MCLK to SYSOSC.
3. Wait for CLKSTATUS.HSCLKMUX to clear, indicating that MCLK is now sourced from SYSOSC.
4. If desired, disable any high-speed clock sources (SYSPLL or HFXT)

As shown in [Table 2-7](#), the USELFCLK and USEHSCLK bits in MCLKCFG are mutually exclusive and must not be set at the same time. To switch MCLK from LFCLK to HSCLK, or HSCLK to LFCLK, MCLK is first switched to SYSOSC before switching to the final clock source. The procedures below describe how to switch MCLK from HSCLK to LFCLK or from LFCLK to HSCLK.

To switch MCLK from HSCLK to LFCLK:

1. Verify that MCLK is sourced from HSCLK (CLKSTATUS.HSCLKMUX is set).
2. Clear MCLKCFG.USEHSCLK to switch MCLK to SYSOSC
3. Wait for CLKSTATUS.HSCLKMUX to clear, indicating that MCLK is now sourced from SYSOSC
4. Disable any high speed sources (SYSPLL, HFXT, HFCLK\_IN) which were enabled
5. Wait for CLKSTATUS.HSCLKSOFF to be asserted, indicating that high-speed clocks are off
6. Set MCLKCFG.USELFCLK to switch MCLK to LFCLK while leaving SYSOSC enabled, or set SYSOSCCFG.DISABLE to switch MCLK to LFCLK and disable SYSOSC

To switch MCLK from LFCLK to HSCLK:

1. Verify that MCLK is sourced from LFCLK (CLKSTATUS.CURMCLKSEL is set)
2. Clear SYSOSCCFG.DISABLE or MCLKCFG.USELFCLK, based on which was set previously
3. Wait for CLKSTATUS.CURMCLKSEL to clear, indicating that MCLK is now sourced from SYSOSC
4. Enable the desired high speed oscillators (SYSPLL, HFXT, HFCLK\_IN) according to their respective requirements
5. Select the desired HSCLK source through the HSCLKCFG.HSCLKSEL control
6. Verify that CLKSTATUS.HSCLKGOOD is set, indicating that the selected HSCLK source is valid
7. Set MCLKCFG.USEHSCLK to switch MCLK to HSCLK

---

#### Note

When MCLK is actively sourced by HSCLK (the HSCLKMUX bit in the CLKSTATUS register is set), the HSCLK source selection must not be changed (the HSCLKSEL bit in the HSCLKCFG register and the MCLK2XVCO bit in the SYSPLLCFG0 register must not be changed). To change the HSCLK source, first switch MCLK to SYSOSC using the procedure given above, re-configure the HSCLK source, and then switch MCLK back to HSCLK.

---

### MCLK Divider (MDIV)

An MCLK source divider (MDIV) is provided to enable MCLK operation in between the lowest SYSOSC frequency (4MHz) and the LFCLK frequency (32kHz). MDIV is for applications with a limited peak current but that still require a higher clock speed than 32kHz. MDIV supports dividing the 4MHz SYSOSC frequency by

up to 16, enabling the additional MCLK frequency options given in [Table 2-8](#). For example, a 500kHz MCLK frequency can be obtained by setting SYSOSC to 4MHz and setting MDIV to 7 (divide-by-8).

[Table 2-8](#) shows the MCLK frequency which is realized with /2, /4, /8, and /16 MDIV configurations, but MDIV can be set to any integer divider between /2 and /16 (MDIV register values of 0x1 through 0xF, respectively, with 0x0 disabling the MDIV).

**Table 2-8. Typical MCLK Configurations for Operation Between 4MHz and 32kHz**

MCLK Source	MDIV	MCLK Frequency
SYSOSC (4MHz)	0 (Disabled)	4MHz
	1 (/2)	2MHz
	3 (/4)	1MHz
	7 (/8)	500kHz
	15 (/16)	250kHz

To use MDIV to operate MCLK at an intermediate frequency below 4MHz, follow the steps below:

1. Disable [asynchronous fast clock requests](#) (make sure that the BLOCKASYNCALL bit is set in the in SYSOSCCFG register)
2. Make sure that SYSOSC is selected as the MCLK source
3. Set the SYSOSC frequency to 4MHz (set the FREQ field in the SYSOSCCFG register to 0x01)
4. Delay for 10 MCLK cycles
5. Set the desired divider value in the MDIV field in the MCLKCFG register (from 1 to 15, corresponding to /2 to /16, respectively)

Several rules apply when using MDIV to reduce the MCLK frequency:

- MDIV must not be used when high speed oscillators are used to source MCLK (SYSPLL, HFCLK); if SYSPLL or HFCLK are selected to source MCLK, MDIV must be disabled (MCLKCFG.MDIV=0x00)
- The SYSOSC frequency must be kept at 4MHz when MDIV is enabled
- [Asynchronous requests to change the SYSOSC frequency](#) must remain blocked

To disable MDIV:

1. Disable MDIV (set the MDIV field in the MCLKCFG register to 0x0)
2. Wait for 16 MCLK cycles before changing the SYSOSC frequency from 4MHz to another frequency

#### Note

MDIV does not apply to LFCLK, as MDIV is not in the LFCLK path when LFCLK is selected as the MCLK source. If LFCLK is selected for MCLK, MDIV must be disabled.

#### 2.3.2.2 CPUCLK (Processor Clock)

The processor clock (CPU clock) is always derived directly from MCLK and is active in RUN mode at the MCLK frequency. In all other power modes, CPUCLK is disabled.

#### 2.3.2.3 ULPCLK (Low-Power Clock)

The ULPCLK is the bus clock for peripherals in the PD0 power domain. It supports operation up to 40MHz and is derived directly from the MCLK tree through a clock divider (UDIV) which is enabled only when MCLK is sourced from a high-speed clock (SYSPLL, HFXT, or HFCLK\_IN). The ULPCLK frequency is dependent on the MCLK configuration, the selected power mode, and the selected UDIV divider.

## ULPCLK Behavior in RUN and SLEEP Modes

The PD0 power domain has a frequency limit of 40MHz in **RUN** and **SLEEP** modes. As such, ULPCLK must be maintained to be  $\leq 40\text{MHz}$  at all times. When MCLK is configured to run from SYSOSC or LFCLK, SYSTL disables UDIV automatically and  $f_{\text{ULPCLK}} = f_{\text{MCLK}}$  as these clock sources are always  $\leq 32\text{MHz}$ .

However, when MCLK is configured to run from a high-speed clock (SYSPLL, HFXT, or HFCLK\_IN), hardware cannot ensure that ULPCLK is  $\leq 40\text{MHz}$  because SYSTL does not have knowledge of the MCLK frequency. In this case it is the responsibility of the application software to ensure that ULPCLK is  $\leq 40\text{MHz}$  in RUN and SLEEP modes by configuring UDIV appropriately. By default, the ULPCLK divider is set to divide-by-2 (MCLKCFG.UDIV==0x1) which provides safe operation up to the max MCLK frequency (80MHz). If MCLK is configured to be  $\leq 40\text{MHz}$ , the ULPCLK speed is set equal to the MCLK speed by changing MCLKCFG.UDIV from 0x01 to 0x0 (divide-by-1). When UDIV==0x0, MCLK==ULPCLK and accesses to PD0 peripherals do not incur additional latency.

## ULPCLK Behavior in STOP and STANDBY Modes

SYSTL automatically disables UDIV in **STOP** and **STANDBY** modes.

- In **STOP** mode, the MCLK tree (and by extension, the ULPCLK) can run from SYSOSC with a 4MHz rate (if SYSOSCCFG.DISABLESTOP=0x0) or from LFCLK at 32kHz (if SYSOSCCFG.DISABLESTOP=0x1). When SYSOSC is used (SYSOSCCFG.DISABLESTOP=0x0), SYSTL ensures that ULPCLK is always 4MHz even if SYSOSC is running at a higher frequency (due to user configuration or due to an asynchronous request from a peripheral).
- In **STANDBY** mode, the MCLK tree (and by extension, the ULPCLK) either run from LFCLK (STANDBY0) or are disabled (STANDBY1) to conserve power. In STANDBY1, only a few timer peripherals receive ULPCLK.

**Table 2-9. MSPM0Gxx ULPCLK by Operating Mode**

Selected Power Mode	Configuration	Register Settings	ULPCLK Frequency
<b>RUN</b> or <b>SLEEP</b> (40MHz maximum)	MCLK source is SYSOSC (RUN0, SLEEP0)	MCLKCFG.USEHSCLK=0x0, MCLKCFG.USELFCLK=0x0	ULPCLK is sourced from MCLK according to the MCLK configuration with $f_{\text{ULPCLK}} = f_{\text{MCLK}}$
	MCLK source is HSCLK (SYSPLL, HFXT, or HFCLK_IN) (RUN0, SLEEP0)	MCLKCFG.USEHSCLK=0x1, MCLKCFG.USELFCLK=0x0	ULPCLK is sourced from MCLK according to the MCLK configuration with $f_{\text{ULPCLK}} = f_{\text{MCLK}} / \text{UDIV}$
	MCLK source is LFCLK (RUN1/2, SLEEP1/2)	MCLKCFG.USELFCLK=0x1 or SYSOSCCFG.DISABLE=0x1	ULPCLK is sourced from LFCLK with $f_{\text{ULPCLK}} = f_{\text{LFCLK}} = 32\text{kHz}$
<b>STOP</b> (4MHz maximum)	STOP with SYSOSC enabled (STOP0/1)	SYSOSCCFG.DISABLESTOP = 0x0	ULPCLK is sourced from SYSOSC with $f_{\text{ULPCLK}} = 4\text{MHz}$
	STOP with SYSOSC disabled (STOP2)	SYSOSCCFG.DISABLESTOP = 0x1	ULPCLK is sourced from LFCLK with $f_{\text{ULPCLK}} = f_{\text{LFCLK}} = 32\text{kHz}$
<b>STANDBY</b> (32kHz maximum)	STANDBY with ULPCLK and LFCLK enabled (STANDBY0)	MCLKCFG.STOPCLKSTBY= 0x0	ULPCLK is sourced from LFCLK with $f_{\text{ULPCLK}} = f_{\text{LFCLK}} = 32\text{kHz}$
	STANDBY with ULPCLK and LFCLK disabled (STANDBY1)	MCLKCFG.STOPCLKSTBY= 0x1	ULPCLK is disabled to all peripherals except TIMG0 and TIMG1, which receive $f_{\text{ULPCLK}} = f_{\text{LFCLK}} = 32\text{kHz}$
<b>SHUTDOWN</b> (Off)	-	-	ULPCLK is off

### 2.3.2.4 MFCLK (Middle Frequency Clock)

The MFCLK provides a continuous 4MHz clock to a variety of peripherals on the device. The MFCLK 4MHz rate is always derived from the **SYSOSC**. As the SYSOSC frequency is not fixed (it can be configured for 32, 24, 16, or 4MHz), SYSTL automatically applies a divider to SYSOSC to keep MFCLK at a constant 4MHz rate regardless of the current SYSOSC frequency. MFCLK can be used by peripherals such as timers and serial interfaces that require a constant clock source in RUN, SLEEP, and STOP power modes.

After a SYSRST, MFCLK is initially disabled. MFCLK can be enabled in software by setting USEMFTICK in the MCLKCFG register in SYSCTL. MFCLK is active in RUN, SLEEP, and STOP power modes only, and SYSOSC must be enabled for MFCLK to operate.

All MFCLK edges are synchronized to the main system clocks (MCLK and ULPCLK), meaning that the registers of peripherals clocked by MFCLK can be read or written to at any time without any special handling.

Peripherals can select MFCLK as their functional clock source through their respective [CLKSEL](#) mux. Not all peripherals support running from MFCLK.

### Using MFCLK in STOP Mode

When using MFCLK in STOP mode, SYSOSC can be configured to automatically switch to 4MHz (low frequency) when entering STOP mode and automatically switch back to the previously selected frequency when exiting STOP mode to RUN mode (gear shift mode). As MFCLK is a 4MHz clock source, running SYSOSC at 4MHz in STOP mode reduces power consumption when in STOP mode. To configure SYSOSC for gear shift mode, see [Section 2.3.1.2.1](#).

### Requirements for Using MFCLK

1. When using MFCLK, the MDIV (MCLK divider) must be disabled (set to /1). Disable MDIV by setting MDIV in the MCLKCFG register to 0x0. SYSCTL hardware does not allow MFCLK to run when MCLKCFG.MDIV != 0.
2. When using MFCLK, if MCLK is sourced from a source other than SYSOSC then the MCLK frequency must be  $\geq 32\text{MHz}$  for correct operation of MFCLK.
3. When using MFCLK, if MCLK is to be sourced from the high-speed clock (HSCLK), application software must enable MFCLK by setting the USEMFTICK bit before switching the MCLK source from SYSOSC to HSCLK. Do not change the state of USEMFTICK when MCLK is sourced from HSCLK.
4. When using MFCLK, do not enable MFCLK when MCLK is sourced from the low-frequency clock (LFCLK). Application software must enable MFCLK by setting the USEMFTICK bit before switching the MCLK source from SYSOSC to LFCLK. Software can switch MCLK to LFCLK after USEMFTICK is set. In this case, MFCLK halts when MCLK is sourced from LFCLK, and it resumes when MCLK is switched back to SYSOSC.
5. When MFCLK is enabled by setting USEMFTICK in the MCLKCFG register, it is considered by the hardware as a static policy. Do not clear USEMFTICK.

When MFCLK is configured to be enabled, it is only active when SYSOSC is active and MCLK is not sourced from LFCLK. When MCLK is sourced from LFCLK, MFCLK is stopped by hardware automatically. Note that if the device is in STANDBY, MCLK is always sourced from LFCLK and MFCLK is always disabled by hardware.

[Asynchronous fast clock requests](#), if configured, temporarily enable SYSOSC to handle specific peripheral events and activity. If MFCLK is configured to be enabled (USEMFTICK is set), then MFTICK runs when a peripheral asserts an asynchronous fast clock request.

#### 2.3.2.5 MFPCLK (Middle Frequency Precision Clock)

MFPCLK provides a continuous 4MHz clock to the external clock output ([CLK\\_OUT](#)) mux and 12-bit DAC modules in RUN, SLEEP, or STOP mode. Unlike [MFCLK](#), which also produces a continuous 4MHz clock for use by most peripherals, MFPCLK is asynchronous to MCLK/ULPCLK and it can be sourced from either the SYSOSC or from HFCLK (HFXT or HFCLK\_IN) to provide higher precision to the DACs, improving DAC performance.

The 12-bit DAC modules do not have a clock selection mux. The 12-bit DAC clock source is selected by configuring MFPCLK. To select HFCLK (HFXT or HFCLK\_IN) to source the MFPCLK, set the MFPCLKSRC in the GENCLKCFG register in SYSCTL.

To enable the MFPCLK, set the MFPCLKEN bit in the GENCLKEN register in SYSCTL.

---

**Note**

HFCLK is disabled in STOP mode by SYSCTL automatically when entering STOP mode. If the 12-bit DACs are to be used in STOP mode, then SYSOSC must be the clock source for MFPCLK.

---

**2.3.2.6 LFCLK (Low-Frequency Clock)**

LFCLK provides a continuous 32kHz clock to a variety of peripherals on the device. After a BOOTRST, LFCLK is initially sourced by the internal 32kHz oscillator (**LFOSC**). After boot, LFCLK can be switched by software to either the low-frequency crystal oscillator (**LFXT**) or the low-frequency digital clock input (**LFCLK\_IN**). See the respective oscillator section for instructions on switching the LFCLK source. When the LFCLK source is changed, the change is locked and LFOSC is disabled to save power. It is not possible to again select LFOSC as the LFCLK source without executing a BOOTRST.

---

**Note**

If LFCLK is to be selected as the MCLK source, and LFXT or LFCLK\_IN are to be used as the LFCLK source, configure the LFXT or LFCLK\_IN as the LFCLK source before selecting LFCLK as the source for MCLK.

---

LFCLK is active in RUN, SLEEP, STOP, and STANDBY power modes. It is possible to disable both ULPCLK and LFCLK together to most peripherals in STANDBY mode to achieve the lowest possible STANDBY mode power consumption (STANDBY1). To do so, set the STOPCLKSTBY bit in the MCLKCFG register in SYSCTL before entering STANDBY. In this state, the RTC and a few times are the only clocked peripherals.

LFCLK is a synchronized clock. All LFCLK edges are synchronized to the main system clocks (MCLK and ULPCLK), meaning that the registers of peripherals clocked by LFCLK can be read or written to at any time without any special handling. The RTC is the only exception to this rule, as the RTC receives **RTCCLK** which is the asynchronous LFCLK.

---

**Note**

When MCLK/ULPCLK are not sourced by LFCLK (for example, when they are sourced by SYSOSC) there is a 5 ULPCLK cycle synchronization delay between the low frequency clock source's clock edge and the corresponding LFCLK edge as seen by peripherals running from LFCLK. When the MCLK/ULPCLK frequency is constant, this delay is constant and it does not add jitter to LFCLK. If the MCLK/ULPCLK frequency changes, the synchronization delay changes proportionally and this results in a small single-cycle LFCLK jitter at the MCLK/ULPCLK frequency transition point. This jitter changes the duty cycle of one LFCLK period, but there is no accumulation of error (there is never a change in the number of LFCLK periods, ensuring an accurate LFCLK time base for peripherals). A common case would be MCLK/ULPCLK sourced from SYSOSC at 32MHz, with SYSOSC occasionally switching to 4MHz to reduce power consumption. When SYSOSC (and, by definition, MCLK/ULPCLK) switch from 32MHz to 4MHz, the synchronization delay increases from 0.16µs to 1.25µs (an increase of 1.1µs). Thus, during the SYSOSC frequency transition, one LFCLK period will appear 1.1µs (3.6%) longer than normal. When SYSOSC switches back from 4MHz to 32MHz, one LFCLK period will appear 1.1µs shorter than normal, and the phase shift is recovered and error is not accumulated in the long term.

---

Peripherals can select LFCLK as their functional clock source through their respective **CLKSEL** mux. Not all peripherals support running from LFCLK. It is possible to run the main clock (**MCLK**) from LFCLK, in which case the entire device runs at the LFCLK rate (32kHz).

**2.3.2.7 HFCLK (High-Frequency External Clock)**

The high-frequency external clock (HFCLK) is the output of the high-frequency external clock selection mux, and can be selected as either the high-frequency oscillator (**HFXT**) output or the high-frequency digital clock input (**HFCLK\_IN**).

The HFCLK can be used as the source for the following clocks:

- [HSCLK](#) source (to source MCLK)
- [SYSPLL](#) reference clock
- [CANCLK](#) source
- [ADCCLK](#) source
- [MFPCLK](#) source (with optional divider)

The HFCLK is only available in RUN and SLEEP modes. HFCLK is automatically disabled by SYSCTL in all other modes, along with the HFXT itself (if enabled).

### 2.3.2.8 HSCLK (High Speed Clock)

The high-speed clock (HSCLK) is the output of the high-speed clock selection mux, and can be selected to source MCLK by setting the USEHSCLK bit in the MCLKCFG register. The HSCLK is only a selection option for MCLK; it does not source any other functions. HSCLK can be configured to be sourced from the [SYSPLL](#) (SYSPLLCLK0 or SYSPLLCLK2X) or the HFCLK ([HFXT](#) or [HFCLK\\_IN](#)). By default, the HSCLK is sourced from the SYSPLL. To change the HSCLK source to HFCLK, set the HSCLKSEL bit in the HSCLKCFG register.

The HSCLK is only available in RUN and SLEEP modes. It is automatically disabled by SYSCTL in all other modes, along with the SYSPLL and HFXT (if enabled).

SYSCTL will not switch MCLK to HSCLK, even if requested by software, if the [HSCLK status](#) check indicates that selected HSCLK source was not started correctly.

### 2.3.2.9 ADCCLK (ADC Sample Period Clock)

ADCCLK is used by the ADC module to set the ADC sampling period. The ADCCLK for a given ADC is provided from the CKM to the ADC, but the ADCCLK clock selection is done within each ADC peripheral's configuration registers. See the ADC chapter for information on configuring the ADCCLK. ADCCLK can be selected as ULPCCLK, SYSOSC, or HFCLK ([HFXT](#) or [HFCLK\\_IN](#)).

---

#### Note

On devices which contain more than one ADC, a unique ADCCLK is mapped to each ADC, making it possible for ADCs to have different sampling clocks.

---

### 2.3.2.10 CANCLK (CAN-FD Functional Clock)

The CANCLK is a functional clock provided directly to the CAN-FD module from either the HFCLK ([HFXT](#) or [HFCLK\\_IN](#)) or the SYSPLL (SYSPLLCLK1). This clock is provided as a functional clock to the CAN-FD module asynchronous from the main clock (MCLK) for the highest possible accuracy. The CANCLK source is selected in SYSCTL by configuring the CANCLKSRC bit in the GENCLKCFG register. Additional CAN-FD clock configuration is provided within the CAN-FD peripheral itself (review the *CAN-FD* chapter for more detail).

### 2.3.2.11 RTCCLK (RTC Clock)

RTCCLK is the sole clock source for the real-time clock peripheral. Because of the critical time-keeping nature of the RTC, the RTC is provided LFCLK directly before LFCLK is synchronized to the main clock (MCLK). This also enables the RTC to continue counting even when the system clock tree is completely gated in STANDBY mode to reduce power consumption. No special configuration is required for RTCCLK. Because the RTC logic is clocked asynchronously from the system main clock, special rules apply when reading certain RTC registers. See the RTC chapter to understand the rules for handling RTC registers.

### 2.3.2.12 External Clock Output (CLK\_OUT)

A clock output unit is provided for sending digital clock signals from the device to external circuits or to the [frequency clock counter](#). This feature is useful for clocking external circuitry such as an external ADC that does not have a clock source. The clock output unit has a flexible set of sources to select and includes a programmable divider.

Available clock sources for CLK\_OUT:

- SYSPLLCLK1
- HFCLK
- SYSOSC
- ULPCLK
- MFPCLK
- LFCLK

The selected clock source can be divided by 1 (no divide), 2, 4, 6, 8, 10, 12, 14, or 16 before being output to the pin or to the frequency clock counter.

To use the clock output unit:

1. Configure IOMUX to select the CLK\_OUT function on the device pin with CLK\_OUT.
2. Select the desired clock source in the EXCLKSRC field of the GENCLKCFG register.
3. Set the desired clock divider, if necessary, in the EXCLKDIVVAL field of the GENCLKCFG register, and enable the divider by setting the EXCLKDIVEN bit. This must be done while EXCLKEN=0 (before CLK\_OUT is enabled)
4. Enable the external clock output by setting the EXCLKEN bit in the GENCLKEN register.

---

**Note**

When the CLK\_OUT source is selected as ULPCLK or MFPCLK, the clock divider must be enabled (GENCLKCFG.EXCLKDIVEN must be set).

---

---

**Note**

When clearing the EXCLKEN bit to disable CLK\_OUT, allow the clock source to run for 10 clock cycles to stabilize the EXCLKSRC mux.

---

---

**Note**

When disabling a clock source which is selected for CLK\_OUT, it is recommended to disable the CLK\_OUT function before disabling the clock source if it is important that CLK\_OUT be logic low (0) when the clock source is disabled. If CLK\_OUT is left enabled and the source for CLK\_OUT is disabled, it is possible that CLK\_OUT may stop in a logic high (1) state.

---

---

**Note**

When the CLK\_OUT source is selected as SYSPLLCLK1, the SYSPLLCLK1 output must be  $\leq 48$ MHz. Further speed restrictions can exist depending on the IO capabilities of a specific device and pin; see the Digital IO specifications in the device-specific data sheet for details on supported IO speeds.

---

### 2.3.2.13 Direct Clock Connections for Infrastructure

Several direct clock connections are made in the device to support specific analog functionality:

- [SYSOSC](#) to ADCs
- [SYSOSC](#) to OPAs, if OPAs are present on a device
- [SYSOSC](#) and [LFCLK](#) to PMU analog mux [VBOOST](#) circuit

#### Direct Connections to ADCs

In addition to receiving ADCCLK to set the sampling window, the ADC modules also receive the direct output of SYSOSC. The SYSOSC direct output to the ADCs is used by the charge pump logic in the ADC modules. SYSOSC can be configured at any frequency to support this function. The ADC supports requesting SYSOSC automatically before a conversion, so there is not a requirement for application software to ensure that SYSOSC is running before triggering an ADC conversion.

#### Direct Connections to OPAs

The SYSOSC direct clock connection to the OPAs, if present, enable all OPA operating modes to be used even when the peripheral bus clock (ULPCLK) is running at a lower frequency than what is required by the OPA. Certain OPA modes require that SYSOSC be running at 32MHz. See the OPA section for clocking details. Configuration of SYSOSC to a frequency which supports the selected OPA mode is the responsibility of the application software. If the OPA is enabled and configured for a mode which requires SYSOSC to be running at a certain frequency, and software has not configured SYSOSC to run at this frequency, an OPAMPCLKERR will be asserted in the CLKSTATUS register in SYCTL and the OPA can not function properly.

### Direct Connections to the PMU Analog Mux VBOOST Circuit

Both the SYSOSC and the LFCLK are connected directly to the [analog mux VBOOST circuit](#) in the PMU, which is used to boost the performance of the analog muxes used by the COMPs, OPAs, and GPAMP. The VBOOST circuit is enabled automatically when a peripheral requires it for correct operation. It is the responsibility of the application software to ensure that the SYSOSC or LFCLK are enabled to support correct operation of the VBOOST circuit. If the VBOOST circuit requires SYSOSC or LFCLK, and the clock is not available, an ANACKERR is asserted in the CLKSTATUS register in SYCTL. SYCTL can also be configured to raise a SYCTL interrupt when ANACKERR is asserted, to alert the application that a COMP, OPA, or the GPAMP can not be functioning properly as expected.

### 2.3.3 Clock Tree

The following figure shows the top level clocking tree for MSPM0Gxx family devices. This diagram shows the mapping between oscillators (sources) and clocks (destinations), as well as the SYCTL register bit fields for the selection muxes. Note that not all devices have all clock system features shown in this figure.

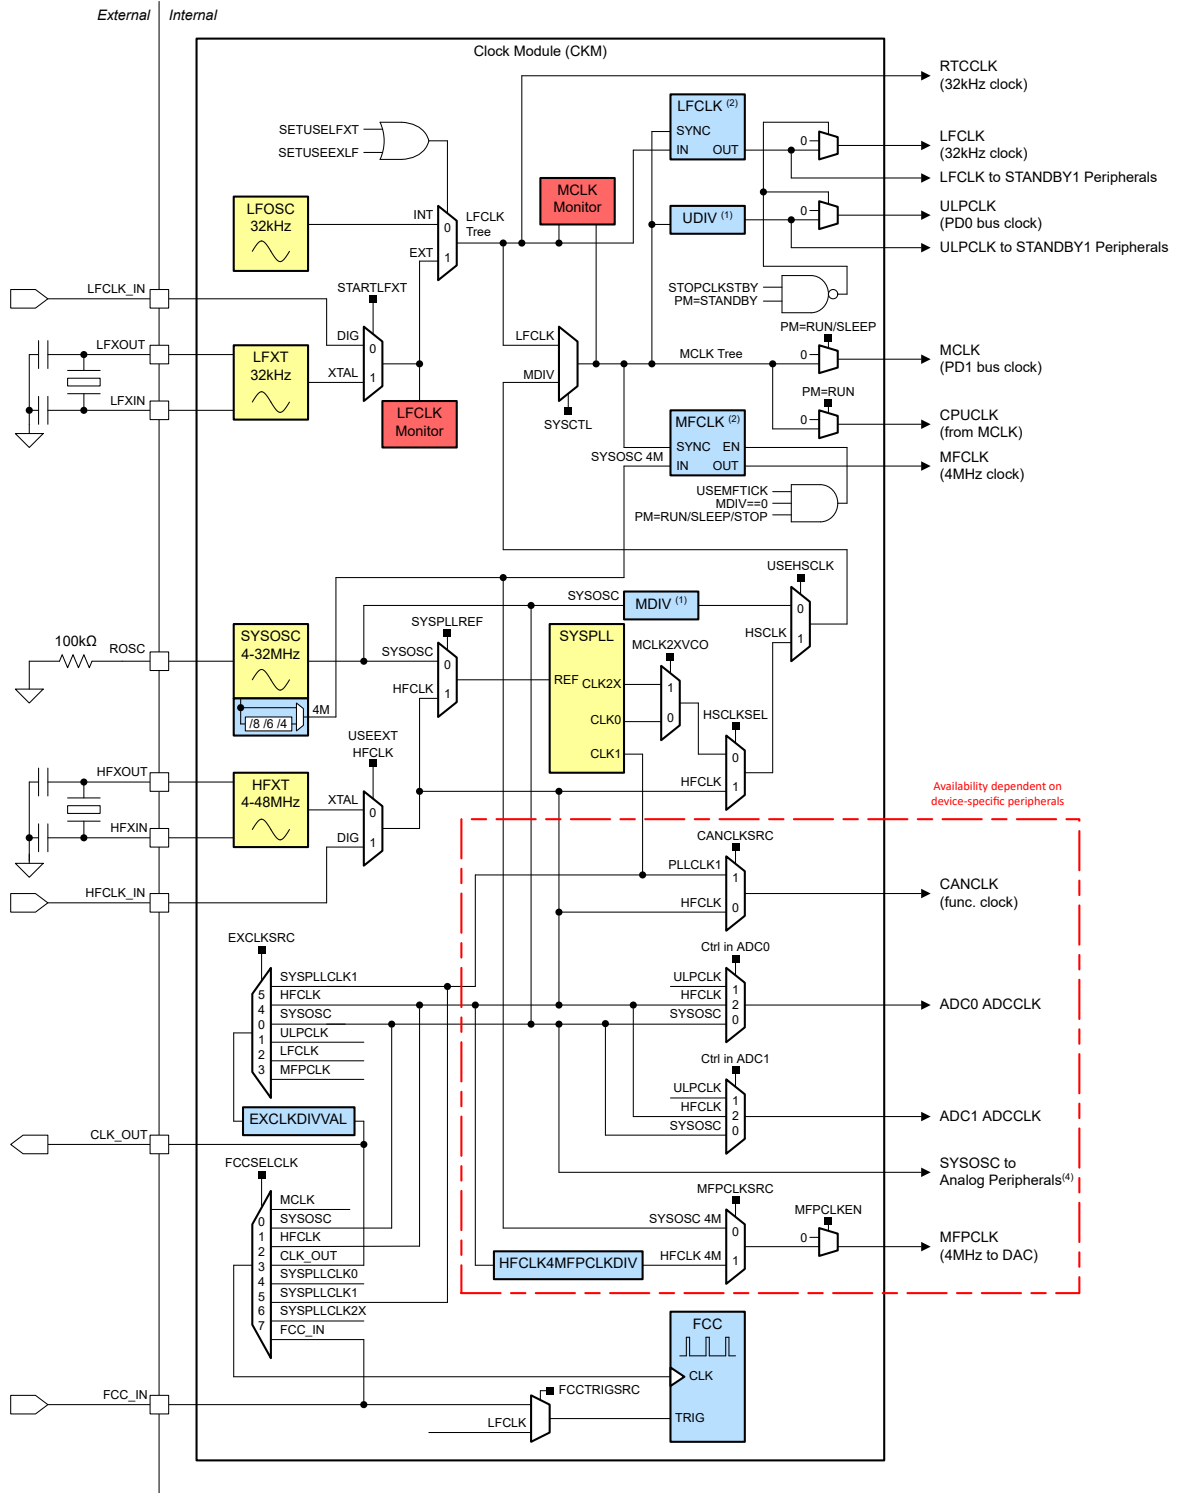

Figure 2-8. MSPM0Gxx Top Level Clocking Tree

1. MDIV and UDIV are clock dividers that support specific use-cases. Review the MCLK and ULPCLK sections, respectively, for specific design considerations regarding MDIV and UDIV.
2. LFCLK and MFCLK are fixed-frequency 32kHz and 4MHz clocks, respectively, that can be selected by certain peripherals for ensuring a constant clock rate even when MCLK or ULPCLK changes source or rate. LFCLK and MFCLK are always synchronized to each other and to MCLK and ULPCLK.
3. Some peripherals (such as select general purpose timers) receive an ungated LFCLK and ULPCLK, enabling them to continue operating even in STANDBY1 when STOPCLKSTBY is asserted to gate the LFCLK and ULPCLK to all other peripherals to save additional power in STANDBY mode.
4. SYSOSC is provided to the OPAs for use directly. The OPAs do not request SYSOSC automatically. It is the responsibility of application software to ensure that SYSOSC is enable and running at the necessary frequency to support correct OPA operation before enabling the OPA.

### 2.3.3.1 Peripheral Clock Source Selection

Most peripherals on the device contain an input clock selection mux which is used to select, and optionally divide down, the functional clock for the peripheral. Figure 2-9 shows the superset peripheral clock selection mux and optional clock divider. Note that not every peripheral has every clock source shown in Figure 2-9. For example, accelerators such as CRC, AES, and DMA run off of the bus clock. There is no option to select MFCLK or LFCLK for these peripherals. To determine the available clock sources for a peripheral, see the chapter for the specific peripheral and review the clock input selections.

**Figure 2-9. Peripheral Clock Selection Mux and Divider**

### Exceptions

There are also several peripherals that have a unique clock selection scheme and do not use the standard peripheral clock mux shown above. Typically this is due to a requirement for a peripheral to have a clock source that is asynchronous to the rest of the system. Cases where this occurs include:

- The real-time clock (RTC), where RTCCLK is used directly and there is not a clock selection option
- An analog-to-digital converter (ADC), where ADCCLK has a special selection mux to take asynchronous clock sources directly (the ADC sampling clock is selected with a special selection in the ADC control registers)
- The CAN-FD controller, where the CANCLK can be the a PLL output or the HFCLK directly (the CAN-FD functional clock source is selected in SYSCTL)
- The DAC, where MFPCLK is used directly and there is not a clock selection option

### 2.3.4 Clock Monitors

Several hardware clock monitors are provided to ensure that the CKM is functioning properly. Clock faults are processed through SYSCTL and result in either a brownout reset (in the event of a fatal fault) or a SYSCTL interrupt.

#### 2.3.4.1 LFCLK Monitor

A low-power analog continuously operating clock monitor is provided to ensure that LFCLK is running when it is not sourced internally (for example, when LFCLK is sourced from [LFXT](#) or [LFCLK\\_IN](#) and not from [LFOSC](#)). The LFCLK monitor is only intended to check for clock stuck faults. It is not intended to be used to verify that the frequency of LFCLK is within a specific tolerance.

## Enabling the LFCLK Monitor

The LFCLK monitor is disabled at startup after a BOR reset or a fatal clock fault reset.

If the STARTLFXT bit in the LFXTCTL register is set, the LFCLK monitor monitors the LFXT. If the STARTLFXT bit is left cleared, the LFCLK monitor monitors the LFCLK\_IN.

Before enabling the LFCLK monitor, make sure that the source clock has started and is operating at 32kHz. If STARTLFXT is set and the monitor is checking the LFXT, wait for the LFXTGOOD indication before enabling the LFCLK monitor. If STARTLFXT is cleared and the monitor is checking the LFCLK\_IN digital clock input, make sure that the external clock signal is active before enabling the LFCLK monitor. If a valid clock is not present when starting the monitor, the monitor will assert a fault.

The LFCLK continuous monitor can be enabled by setting the MONITOR bit in LFCLKCFG register.

---

### Note

The LFCLK monitor requires 100 $\mu$ s to become active after being enabled. The LFCLK monitor can be enabled to monitor LFXT or LFCLK\_IN before switching the LFCLK source from the internal LFOSC.

---

## LFCLK Monitor Fault Handling

If an LFCLK stuck fault is detected, the system responds in one of two ways depending on the system clock configuration:

- If LFCLK is the source for MCLK (for example, if the entire system is running at 32kHz derived from LFCLK), then a LFCLK fault is considered fatal and an elevated BOOTRST is asserted. Following this elevated scenario, LFCLK will be sourced from LFOSC and the LFCLK monitor is disabled.
- If LFCLK is not the source for MCLK at the time of the failure or after the failure, an LFCLK fault asserts a nonmaskable interrupt (NMI) to the processor so that the application can immediately handle the fault and take any necessary action.

---

### Note

A typical BOOTRST does not reset the LFCLK source selection and LFCLK monitor configuration. Only this elevated BOOTRST caused by a fatal clock fault will transition the LFCLK to select LFOSC.

---

---

### Note

In all BOOTRST scenarios, MCLK will be sourced from SYSOSC at BASE frequency.

---

## Falling Back to LFOSC After LFXT Failure

In the event that an LFXT or LFCLK\_IN failure is detected and the failure is due to a system level / PCB level issue that is preventing the external clock source from being able to run reliably, it is possible to fall back to the internal 32kHz LFOSC rather than continuously trying to use the LFXT or LFCLK\_IN. In this case, the following procedure is recommended:

1. Configure the device with LFXT or LFCLK\_IN sourcing LFCLK and with the LFCLK monitor enabled, per the procedure given above in **Enabling the LFCLK Monitor**.
2. In the event of an LFCLK monitor fault detection:
  - a. If MCLK is sourced from LFCLK, the failure will generate a BOOTRST automatically.
  - b. If MCLK is not sourced from LFCLK, an NMI will be generated. In the NMI handling, application software can switch MCLK to LFCLK when the LFCLK fault is detected. This action will trigger the hardware to generate a BOOTRST automatically. Switching the MCLK source to LFCLK may be done by changing the operating mode from RUN0 to RUN1/RUN2 or STOP2/STANDBY.
3. Following the BOOTRST, MCLK will be sourced from SYSOSC at BASE frequency, and LFCLK will be sourced from LFOSC. Application software can check the cause of the reset was a fatal clock fault and decide what action to take.

- a. Application software may attempt again to use LFXT/LFCLK\_IN. If the LFCLK fails again, application software can return to step 2 above to again switch LFCLK back to LFOSC.
- b. To track the number of LFCLK failures, application software can store diagnostic information in the [shutdown memory](#) of the device. The SHUTDNSTOREx memory locations are retained through a BOOTRST. As such, it is possible for the application software to track how many LFCLK failures have occurred, and if that number exceeded some threshold, application software can elect to remain with LFOSC as the LFCLK source rather than again attempting to use the LFXT/LFCLK\_IN.

### 2.3.4.2 MCLK Monitor

A digital clock monitor can be used with MCLK. The MCLK monitor asserts an MCLK fault if there is no MCLK activity for a period of 1-12 LFCLK cycles. An MCLK fault is always considered fatal to the system and generates a BOOTRST.

The MCLK monitor can be enabled after the LFCLK is configured and running. To enable the MCLK monitor, set the MCLKDEADCHK bit in the MCLKCFG register in SYSCTL. When enabled, the MCLK monitor runs in all operating modes except for STANDBY1 and SHUTDOWN.

### 2.3.4.3 Startup Monitors

Clock startup monitors are provided for application software to check that the LFOSC, LFXT/LFCLK\_IN, HFXT/HFCLK\_IN, SYSPLL, and HSCLK sources are alive before they are selected by software to be used to source a clock in the system. When a clock source has started successfully and is ready, a GOOD indication is given in the CLKSTATUS register in SYSCTL and an interrupt is generated. The startup monitors only provide a status indication when a related clock system configuration change is made. When an initial GOOD indication is given, the clock is not continuously monitored by the startup monitor. Continuous monitoring is provided for [LFCLK](#) and [MCLK](#).

#### 2.3.4.3.1 LFOSC Startup Monitor

The LFOSC is started automatically after a BOOTRST. Please refer to the device-specific data sheet for the LFOSC startup time. A startup monitor is provided to indicate to the application software when LFOSC startup has completed, at which time the LFCLK is available for use by peripherals. When LFOSC startup has completed, the LFOSC startup monitor asserts the LFOSCGOOD bit in the CLKSTATUS register in SYSCTL and the LFOSCGOOD interrupt is asserted to alert the application.

#### 2.3.4.3.2 LFXT Startup Monitor

The [LFXT](#) takes time to start after being enabled. A startup monitor is provided to indicate to the application software that the LFXT has successfully started, at which point the LFXT can be selected as the LFCLK source. Once the LFXT startup has completed, the LFXT startup monitor will assert the LFXTGOOD bit in the CLKSTATUS register in SYSCTL and the LFXTGOOD interrupt will be asserted to alert the application. See the device-specific data sheet for the LFXT startup time.

#### 2.3.4.3.3 HFCLK Startup Monitor

The [HFXT](#) takes time to start after being enabled. A startup monitor is provided to indicate to the application software if the HFXT has successfully started, at which point the [HFCLK](#) can be selected to source a variety of system functions. The HFCLK startup monitor also supports checking the [HFCLK\\_IN](#) digital clock input for a clock stuck fault.

To enable the HFCLK startup monitor, clear the HFCLKFLTCHK bit in the HFCLKCLKCFG register in SYSCTL (the default state is disabled).

When HFXT is started or the HFCLK\_IN is selected as the HFCLK source, the HFCLKGOOD and HFCLKOFF bits in the CLKSTATUS register in SYSCTL are cleared.

In the case of HFXT being used, after the specified HFXT startup time has expired the HFXT status is tested. If the HFXT started successfully, the HFXT startup monitor asserts the HFCLKGOOD bit in the CLKSTATUS

register and the HFCLKGOOD interrupt is also asserted. If the HFXT did not start within the specified startup time, the HFCLKOFF bit is set, indicating that the HFXT was dead at startup.

In the case of HFCLK\_IN being used, after HFCLK\_IN is selected a clock stuck check is performed. If the clock is alive, the HFCLKGOOD bit is set in the CLKSTATUS register and the HFCLKGOOD interrupt is also asserted. If the HFCLK\_IN signal was stuck, the HFCLKOFF bit in CLKSTATUS register is set, indicating that the HFCLK\_IN is dead.

If desired, checking of the HFCLK by the HFCLK startup monitor can be left disabled by keeping the HFCLKFLTCHK bit set in the HFCLKCLKCFG register in SYSCTL.

---

#### Note

The HFCLK must be in a stable state before attempting to enter STOP or STANDBY low power modes. Before entering STOP or STANDBY, make sure that either the HFCLKGOOD bit or the HFCLKOFF bit is set.

---

#### 2.3.4.3.4 SYSPLL Startup Monitor

The [SYSPLL](#) takes time to start and settle after being enabled. A startup monitor is provided to indicate to the application software if the SYSPLL has successfully started, at which point the clock outputs from the SYSPLL can be selected to source a variety of system functions.

When the SYSPLL is started, the SYSPLLGOOD and SYSPLLOFF bits in the CLKSTATUS register in SYSCTL are cleared. After the startup/settling time has expired, the SYSPLL status is tested. If the SYSPLL started successfully, the SYSPLL startup monitor will assert the SYSPLLGOOD bit in the CLKSTATUS register and the SYSPLLGOOD interrupt will also be asserted. If the SYSPLL did not start within the specified time, the SYSPLLOFF bit will be set, indicating that the SYSPLL was dead at startup.

---

#### Note

The SYSPLL must be in a stable state before attempting to enter STOP or STANDBY low power modes. Before entering STOP or STANDBY, make sure that either the SYSPLLGOOD bit or the SYSPLLOFF bit is set.

---

#### 2.3.4.3.5 HSCLK Status

The [HSCLK](#) is sourced from the HFCLK or the SYSPLL. The CLKSTATUS register in SYSCTL provides HSCLKGOOD and HSCLKDEAD indications, which indicate if the selected HSCLK source started successfully with a GOOD status or failed with a DEAD status, respectively. SYSCTL will not switch MCLK over to HSCLK, even if requested, if HSCLKGOOD is not set.

In addition, the HSCLKSOFF bit is provided in CLKSTATUS to indicate if all HSCLK sources (SYSPLL, HFCLK) are either off (disabled) or started with a DEAD status.

#### 2.3.5 Frequency Clock Counter (FCC)

The frequency clock counter (FCC) enables flexible in-system testing and calibration of a variety of oscillators and clocks on the device. The FCC counts the number of clock periods seen on the selected source clock within a known fixed trigger period (derived from a secondary reference source) to provide an estimation of the frequency of the source clock.

Application software can use the FCC to measure the frequency of the following source oscillators and clocks (selected through the FCCSELCLK field in the GENCLKCFG register):

- MCLK
- SYSOSC
- HFCLK
- CLK\_OUT
- SYSPLL (any of the two SYSPLL outputs)
- The external FCC input (FCC\_IN)

The reference clock used to set the trigger time over which pulses of the source clock are counted is configurable (through the FCCTRIGSRC field in the GENCLKCFG register), and can be driven by:

- The external FCC input (FCC\_IN)
- LFCLK
- The output of the mux of LFOSC, LFXT, or LFCLK\_IN (32kHz)

The trigger time period can be set in one of two ways (through the FCCLVLRIG field in the GENCLKCFG register):

- Level triggered (one rising edge to one falling edge of the reference clock input). Please note that LFCLK\_IN cannot be used as a trigger clock source if using level triggering.
- Rising-edge to rising-edge triggered, for a defined number of clock periods of the reference clock (selectable from 1 to 32 through the FCCTRIGCNT field in the GENCLKCFG register)

When the trigger source is selected as the external FCC input in level-triggered mode, a user-specified counting period can be set by applying a logic high pulse on the FCC\_IN pin of the desired trigger length.

When the trigger source is selected as the LFXT, using rising-edge to rising-edge triggering causes the FCC to capture the number of source clock pulses which occurred within 1 to 32 32.768kHz clock periods of the LFXT (30.5µs).

The FCC counter is 22 bits and supports counting from 0 up to  $2^{22} - 1 = 4,194,303$ .

While the external FCC input (FCC\_IN function) can be used as either the FCC clock source or the FCC trigger input, the signal cannot be used for both functions during the same FCC capture. FCC\_IN must be configured as either the FCC clock source or the FCC trigger.

### 2.3.5.1 Using the FCC

#### Rising-Edge to Rising-Edge Triggered Mode with FCC\_IN Trigger

The following steps describe how to use the FCC to count the number of source clock pulses within the trigger period set by the reference clock, with the FCC\_IN pin being selected as the reference clock and the SYSOSC being selected as the source clock. This example would be useful for calibrating the SYSOSC frequency with respect to an accurate clock source provided to the FCC\_IN pin externally.

1. Set the source clock to SYSOSC by configuring the FCCSELCLK field in the GENCLKCFG register.
2. Set the reference clock to FCC\_IN by clearing the FCCTRIGSRC bit in the GENCLKCFG register.
3. Select rising-edge to rising-edge triggering by clearing the FCCLVLRIG bit in the GENCLKCFG register.
4. Select the desired number of reference clock periods to count the source clock over in the FCCTRIGCNT field in the GENCLKCFG register.
5. Ensure that **SYSOSC** is enabled at the desired frequency, and that the external clock source connected to FCC\_IN is constantly running before continuing.
6. Write the GO bit and KEY field to the FCCCMD register to start the FCC capture on the next trigger clock period.
7. Poll the FCCDONE status bit in the CLKSTATUS register. When the capture completes, FCCDONE will be set by hardware. FCCDONE is read-only and is automatically cleared by hardware when a new capture is started.
8. Extract the resulting count from the 22-bit DATA field in the FCC register.

---

#### Note

For an accurate count of FCC cycles, it is best to wait at least 6 pulses of FCC before setting FCCTRIGCNT=0x0

---

### Rising-Edge to Rising-Edge Triggered Mode with LFXT Trigger

The following steps describe how to use the FCC to count the number of source clock pulses within the reference clock period, with the LFXT being selected as the reference clock and the SYSOSC being selected as the source clock. This example would be useful for calibrating the SYSOSC frequency with respect to an accurate 32.768kHz watch crystal.

1. Set the source clock to SYSOSC by configuring the FCCSELCLK field in the GENCLKCFG register.
2. Set the reference clock to LFXT by setting the FCCTRIGSRC bit in the GENCLKCFG register.
3. Select rising-edge to rising-edge triggering by clearing the FCCLVLTRIG bit in the GENCLKCFG register.
4. Select the desired number of reference clock periods to count the source clock over in the FCCTRIGCNT field in the GENCLKCFG register.
5. Ensure that **SYSOSC** is enabled at the desired frequency, and that the **LFXT** is running correctly before continuing.
6. Write the GO bit and KEY field to the FCCCMD register to start the FCC capture on the next trigger clock period.
7. Poll the FCCDONE status bit in the CLKSTATUS register. When the capture completes, FCCDONE will be set by hardware. FCCDONE is read-only and is automatically cleared by hardware when a new capture is started.
8. Extract the resulting count from the 22-bit DATA field in the FCC register. If SYSOSC was running at 32MHz and FCCTRIGCNT was set to '0' (one reference clock period), the result should be approximately 976 cycles counted within the single 32.768kHz period.
  - a. To calibrate SYSOSC for 24MHz operation, the SYSOSC user trim must be adjusted until approximately 732 cycles are counted.
  - b. To calibrate SYSOSC for 16MHz operation, the SYSOSC user trim must be adjusted until approximately 488 cycles are counted.

In general, increasing the FCCTRIGCNT value increases the accuracy of the measurement, at the expense of longer measurement time.

### Level Triggered Mode with FCC\_IN Trigger and HFCLK\_IN Clock

The following steps describe how to use the FCC to count the number of source clock pulses within one external reference pulse window, with HFCLK\_IN being selected as the source clock. This example would be useful for measuring the frequency of an external clock source with respect to a fixed pulse width driven by an external signal.

1. Set the source clock to HFCLK by configuring the FCCSELCLK field in the GENCLKCFG register.
2. Set the trigger clock to the FCC\_IN pin function by clearing the FCCTRIGSRC bit in the GENCLKCFG register.
3. Set level triggering by setting the FCCLVLTRIG bit in the GENCLKCFG register.
4. Ensure that IOMUX is configured for FCC\_IN, that HFCLK is configured for HFCLK\_IN, and that an external clock is sourcing HFCLK\_IN.
5. Write the GO bit and KEY field to the FCCCMD register to start the FCC capture when FCC\_IN goes logic high. Note that if FCC\_IN is already logic high when GO is asserted, counting starts immediately. When using level mode, FCC\_IN should be low when GO is set, and the trigger pulse should be sent to FCC\_IN after GO is set.
6. Poll the FCCDONE status bit in the CLKSTATUS register. When the capture completes, FCCDONE will be set by hardware. FCCDONE is read-only and is automatically cleared by hardware when a new capture is started.
7. Extract the resulting count from the 22-bit DATA field in the FCC register.

#### 2.3.5.2 FCC Frequency Computation and Accuracy

The frequency of the source clock can be computed after capture if the trigger time is known. The frequency is computed by dividing the number of source clock cycles captured by the trigger time. For example, if the trigger

source was a 32.768kHz clock, the trigger mode was rising-edge to rising-edge, and the period count was 1, then the trigger time is one 32.768kHz clock period (30.5μs). If the captured source count were to come back as 122, the frequency of the source clock is computed as 122 divided by 30.5μs, giving a source clock frequency of approximately 3.99MHz.

$$f_{\text{source}} = \text{FCC.DATA} / ((\text{GENCLKCFG.FCCTRIGCNT}+1) / f_{\text{ref}}) \quad (10)$$

The FCC accuracy is dependent on the trigger clock accuracy as well as the total number of clock cycles captured. The FCC intrinsic error is  $\leq 2$  source clock cycles per capture due to synchronization of the trigger to the source clock. Therefore, the impact of these two clock cycles is reduced as more cycles are counted (as the trigger time is increased and/or the source clock frequency is increased). Approximate intrinsic error of the FCC for various source clock frequencies captured against one 32.678kHz period (FCCTRIGCNT=0) and 32 clock periods (FCCTRIGCNT=31) are given in [Table 2-10](#).

**Table 2-10. FCC Error**

Use Case (Source Clock Frequency)	FCC Trigger Time	FCC Count Result	FCC Count Uncertainty	Approximate FCC Intrinsic Uncertainty Error
4MHz source clock	30.5μs	122	2 cycles	1.6%
	976.6μs	3906		0.05%
16MHz source clock	30.5μs	488		0.4%
	976.6μs	15625		0.01%
24MHz source clock	30.5μs	732		0.27%
	976.6μs	23437		0.01%
32MHz source clock	30.5μs	976		0.20%
	976.6μs	31250		0.01%
80MHz source clock	30.5μs	2441		0.08%
	976.6μs	78125		0.003%
200MHz source clock	30.5μs	6100		0.03%
	976.6μs	195200		0.001%

**Note**

When using the FCC\_IN signal, it is recommended to have a fast slew rate of 10ns or less on the FCC\_IN pin to minimize measurement uncertainty.

## 2.4 System Controller (SYSCTL)

The system controller (SYSCTL) contains all control logic for managing the configuration and state of the PMU and CKM analog circuitry. SYSCTL also provides reset management, NRST and SWD pin mux control, flash bank swap control, and the ECC error handling for flash and SRAM.

All power, clock, and reset configuration is done through the SYSCTL memory-mapped register interface.

### 2.4.1 Resets and Device Initialization

The SYSCTL manages device reset levels and device initialization.

#### 2.4.1.1 Reset Levels

The device has five reset levels:

1. Power-on reset ([POR](#))
2. Brownout reset ([BOR](#))
3. Boot reset ([BOOTRST](#))

4. System reset (SYSRST)
5. CPU reset (CPURST)

The relationships between reset levels are given in Figure 2-10.

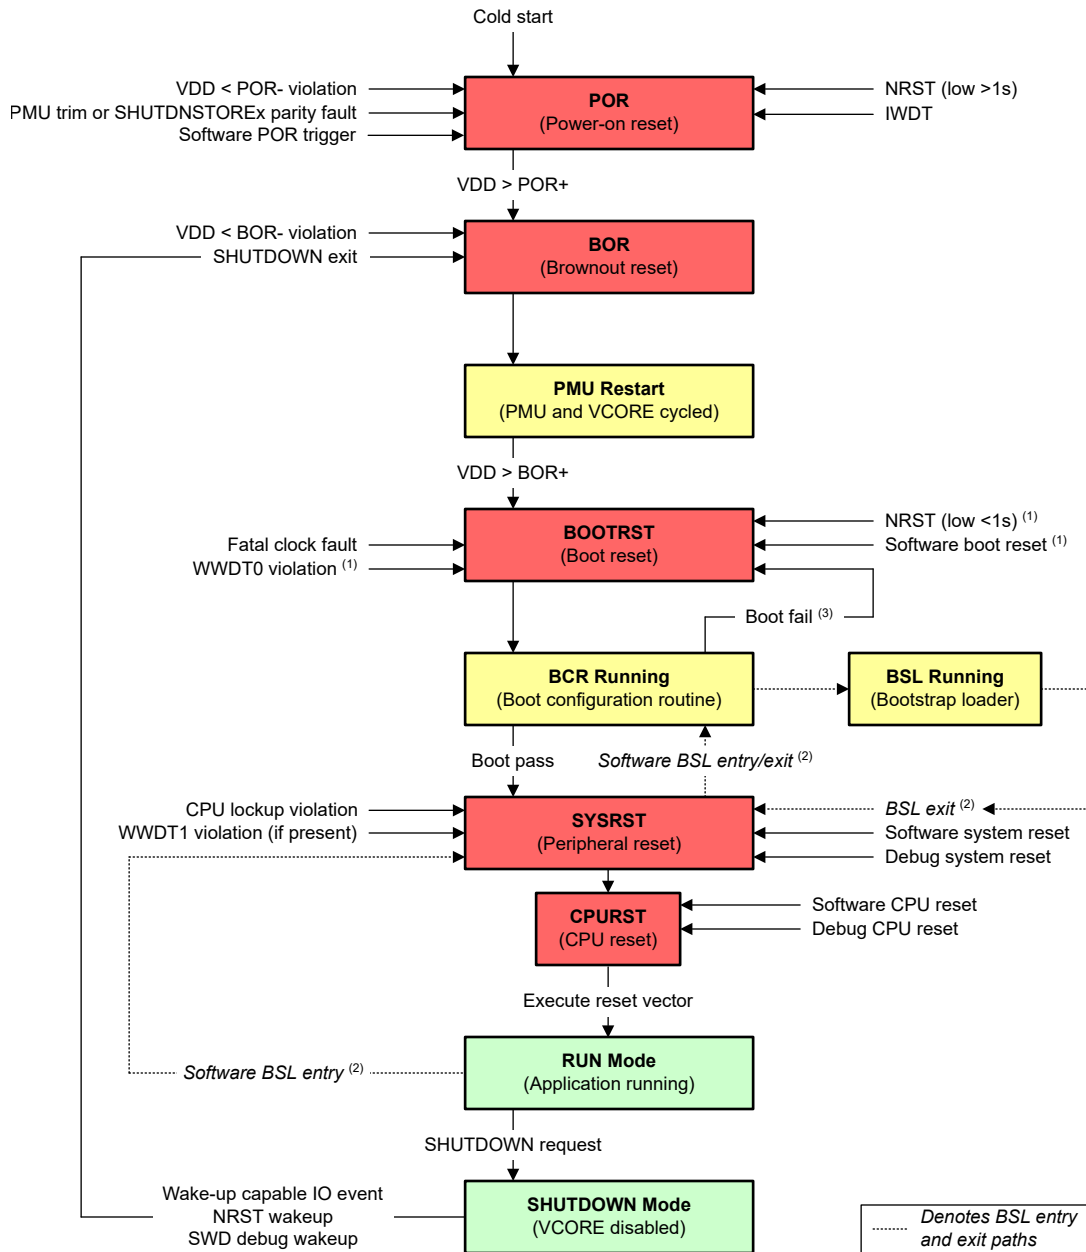

Figure 2-10. Device Reset Levels

(1) An NRST (low <1 s), software boot reset, or WWDT0 violation triggered BOOTRST runs the boot configuration routine. This does not reset the RTC, LFXT, LFCLK, LFCLK\_IN, and IOMUX configuration of any IO pins used by LFXT or LFCLK\_IN. This allows the RTC to keep time through an external reset trigger.

(2) A software-triggered bootstrap loader (BSL) entry command first triggers a SYSRST, after which the boot configuration routine (BCR) is run to authenticate the BSL entry before starting the BSL. After the BSL execution concludes, a SYSRST is generated and the BCR executes again. When the BCR completes, a final SYSRST is issued and the application is started. This entire process does not reset the RTC, LFXT/LFCLK/LFCLK\_IN,

the IOMUX configuration of any IO pins used by LFXT or LFCLK\_IN, and SYSOSC FCL enable configurations, as only a SYSRST reset level is asserted throughout the process. This allows the RTC to keep time through an external reset trigger.

<sup>(3)</sup> If a boot fail occurs during execution of the boot configuration routine, a BOOTRST can be generated by SYSCTL to attempt the boot process again from the BOOTRST level. See [Section 2.4.1.8](#).

---

**Note**

SLEEP, STOP, and STANDBY operating modes are not shown in this diagram. These modes originate from and return to RUN mode unless an exception occurs which causes a reset level to be asserted or a mode to be suspended.

---

#### **2.4.1.1.1 Power-on Reset (POR) Reset Level**

A power-on reset (POR) is a complete device reset.

The following conditions generate a POR:

- The device powers up (cold start)
- A *POR-supply monitor violation* (VDD drops below the POR supply monitor negative-going threshold)
- A parity fault on PMU trim data or the *shutdown memory*
- Software triggers a POR through SYSCTL (*RESETLEVEL 0x03*)
- The NRST pin is held low for more than one second when in NRST mode
- Independent Watchdog Timer (IWDT)

A POR always resets the *shutdown memory*, re-enables the NRST/SWD pin functions (if disabled), and triggers a BOR.

#### **2.4.1.1.2 Brownout Reset (BOR) Reset Level**

A brownout reset (BOR) resets the device power management unit (PMU). All regulated core logic powered from VCORE are power cycled.

The following conditions generate a BOR:

- A *POR*
- A *BOR0- Supply Monitor Violation* (VDD drops below the BOR0- supply monitor lower threshold voltage level)
- An exit from SHUTDOWN mode (through a wakeup-capable IO, NRST, or SWD) if SHUTDOWN mode is active

The following are not reset by a BOR:

- The shutdown memory (SHUTDNSTOREx) if SHUTDOWN mode is present in the device
- The NRST state, if disabled by software
- The SWD state, if disabled by software
- The latched IO pin state, when SHUTDOWN mode is active, and the cause of the BOR is an exit from SHUTDOWN mode (see *SHUTDOWN mode handling*)

A BOR always triggers a *BOOTRST* when  $VDD > BOR0+$  (brownout supply monitor upper threshold voltage level).

---

**Note**

Not all the devices support SHUTDOWN mode, check the device specific data sheet to determine if it's present or not.

---

#### **2.4.1.1.3 Boot Reset (BOOTRST) Reset Level**

A boot reset (BOOTRST) triggers execution of the device [boot configuration routine](#) and resets the majority of the core logic, system memory (SRAM), and [SYSOSC FCL mode](#) (if enabled).

The BOOTRST does not reset the low-power clocking configuration (RTC, LFCLK, LFXT, LFCLK\_IN, and related IOMUX configuration for these features) in the system, unless the BOOTRST was due to a fatal clock fault.

As a result, if LFCLK is configured to run from the LFXT or LFCLK\_IN, an NRST pin BOOTRST condition or a software triggered BOOTRST condition does not reset LFCLK to the default internal oscillator (LFOSC). LFCLK continues to run from LFXT or LFCLK\_IN and cannot be reconfigured. This lets the RTC maintain a time base through an external reset.

The following conditions generate a BOOTRST:

- A [BOR](#)
- A fatal clock failure (see [LFCLK Monitor](#) and [MCLK Monitor](#))
- A WWDT0 violation
- Software triggers a [BOOTRST through SYSCTL \(RESETLEVEL 0x01\)](#)
- The NRST pin is held low for longer than the minimum reset pulse time but less than one second when in NRST mode
- A BOOTRST followed by a boot failure (re-attempt of a failed boot sequence)

The following are not reset by a BOOTRST:

- The shutdown memory (SHUTDOWNSTOREx) if SHUTDOWN mode is present
- The [NRST disable state](#), if disabled by software
- The [SWD disable state](#), if disabled by software
- The RTC, LFCLK, LFXT, LFCLK\_IN, and related IOMUX configuration for these features (if the cause of the BOOTRST was not a fatal clock fault)

Following a BOOTRST, a [SYSRST](#) is always triggered upon successful completion of the boot configuration routine. If the boot configuration routine fails to complete successfully, a BOOTRST is again generated and the boot process is attempted again from the BOOTRST point. The boot process attempts to complete successfully up to 3 times, after which the device state locks until a BOR or POR reset occurs (see [Section 2.4.1.8](#)).

#### 2.4.1.1.4 System Reset (SYSRST) Reset Level

A system reset clears the state of the CPU and all the peripherals, with the exceptions listed below.

The following conditions generate a SYSRST:

- A [BOOTRST](#) followed by a boot pass
- Software triggers a [SYSRST with BSL entry through SYSCTL \(RESETLEVEL 0x02\)](#)
- A bootstrap loader (BSL) exit (if present), which is always followed by execution of the boot configuration routine (BCR)
- A CPU lockup violation
- A WWDT1 violation (if present)
- Software triggers a [SYSRST through SYSCTL \(RESETLEVEL 0x00\)](#)
- The debug subsystem triggers a system reset

The following are not reset by a SYSRST:

- The shutdown memory (SHUTDOWNSTOREx) (if present)
- The [NRST state](#), if disabled by software
- The [SWD state](#), if disabled by software
- The RTC, LFCLK, and LFXT/LFCLK\_IN configuration, including the IOMUX settings for any IO pins configured to be used by LFXT/LFCLK\_IN
- The SYSOSC frequency correction loop ([FCL](#)), if enabled by software

In most cases, the device is in RUN mode after a SYSRST, and the CPU executes the reset vector and begins execution of the application software.

There are exceptions to this:

- If the SYSRST was triggered with a BSL entry request, the BCR runs followed by the BSL.

- If the SYSRST was triggered due to a BSL exit request, the BCR runs, followed by an additional SYSRST, after which the application software starts.

#### 2.4.1.1.5 CPU-only Reset (CPURST) Reset Level

A CPU-only reset clears the state of the CPU logic only. Peripheral states are not affected by a CPU reset. A CPU reset is only generated by software through the CPU AIRCR local register or by the debug subsystem.

#### 2.4.1.2 Initial Conditions After Power-Up

After a POR, when the boot process completes and the CPU starts the application, the initial device conditions are as follows:

- The NRST pin is configured in NRST mode
- Serial wire debug (SWD) IO are configured in SWD mode (SWDIO is pulled high, and SWCLK is pulled low)
- All other configurable I/O pins are high impedance (Hi-Z)
- Peripheral modules are reset as described in the respective chapters of this manual
- The device is in RUN mode
- MCLK is sourced from the internal SYSOSC at base frequency
- LFCLK is sourced from the internal LFOSC (note that LFOSC requires time to start up before LFCLK can be used)
- MFCLK is disabled
- MFPCLK is disabled
- SYSPLL is disabled
- HFXT is disabled
- Peripherals are disabled
- Any flash sectors configured to be write protected at boot are write protected

#### 2.4.1.3 NRST Pin

After a cold start, the NRST pin is configured in NRST mode. The NRST pin must be high for the device to boot successfully. There is no internal pullup resistor on NRST. External circuitry (either a pullup resistor to VDD or a reset control circuit) must actively pull NRST high for the device to start. After the device is started, a low pulse on NRST <1 second in duration triggers a BOOTRST. If a low pulse on NRST is held for >1 second, a POR is triggered.

Some low pin count devices support reconfiguring the NRST pin to be a GPIO pin. See the pin configuration of the device-specific data sheet to see if GPIO functionality is shared with NRST. Application software can disable the NRST functionality of the NRST pin, allowing GPIO functionality to be enabled. To disable NRST, set the DISABLE bit in the EXRSTPIN register along with the KEY. Then configure IOMUX for the desired functionality.

After the NRST pin function is disabled, only after a POR reset can the NRST pin function be re-enabled.

---

#### Note

When the NRST pin is shared with the I2C open-drain pin, the user's system must be designed such that the device is powered up and in I2C mode before any transactions occur on the I2C bus. The device can be inadvertently reset due to a low signal on the shared reset or I2C SDA line before this point.

To prevent this, pullups on the NRST pin that are shared with an I2C open-drain IO must be selected to meet the I2C pullup requirements for minimum and maximum values.

---

#### 2.4.1.4 SWD Pins

There are two serial wire debug (SWD) pins present on all devices: SWDIO and SWCLK

After a cold start, the SWD pins are configured in SWD mode to allow a debug connection to be established.

- SWDIO (serial wire data input/output) pin is configured in the IOMUX and the pull-up is enabled

- SWCLK (serial wire clock) pin is configured in the IOMUX and the pull-down is enabled

It is possible to re-configure the SWD pins as general purpose IO (GPIO) in software to enable use of these pins in an application when debug support is no longer required. To disable SWD functionality, set the DISABLE bit in the SWDCFG register in SYSCTL along with the KEY. Then configure IOMUX for the desired functionality.

Once the SWD pin functions are disabled, they can only be re-enabled by triggering a POR.

#### 2.4.1.5 Generating Resets in Software

Software can generate a software POR, a software BOOTRST, a software SYSRST with bootstrap loader (BSL) entry, or a software SYSRST by issuing the appropriate command to SYSCTL. To issue a reset, first select the desired reset level in the RESETLEVEL register in SYSCTL. Then set the GO bit in the RESETCMD register along with the KEY value.

**Table 2-11. Software Generated SYSCTL Reset Commands**

LEVEL	Action
0x0	Software SYSRST
0x1	Software BOOTRST
0x2	Software SYSRST with BSL entry
0x3	Software POR

A CPU-only reset (CPURST) which does not reset the peripherals can also be triggered in software within the device CPU by setting the SYSRESETREQ bit in the AIRCR local CPU register. See the CPU Sub System chapter for more information.

#### Starting the BSL From Software (if present)

The software-triggered BSL entry (*RESETLEVEL 0x02*) is a special case of the SYSRST which provides a mechanism for the application software to start the ROM bootstrap loader (BSL). It is not possible to jump to the bootloader code directly during normal software execution in RUN mode. When application software commands a software-triggered BSL entry (*RESETLEVEL 0x02*), a SYSRST is generated first, followed by execution of the boot configuration routine (for authentication), after which the BSL is started (if the device security policy has the BSL configured to be enabled).

Once the BSL has completed execution, a second SYSRST is issued and the BCR is executed. When the BCR completes, a final SYSRST is asserted to return control of the system back to the application software.

If the BSL was disabled by the user configuration, and a software-triggered BSL entry is invoked, the device will issue a standard SYSRST instead and return control of the system back to the application software.

Any system configuration which is not reset by a SYSRST is maintained through this entire process. As such, the RTC can continue to run without disruption during execution of a software-triggered BSL entry and exit.

#### 2.4.1.6 Reset Cause

After a device reset occurs, the lowest level reset cause which occurred during reset processing is captured in hardware so that application software can interrogate the reason for the reset and take any appropriate action when starting the application. The lowest level reset cause is encoded into a 5-bit field in the reset cause register in SYSCTL. The contents of the reset cause register are always cleared upon a read, and return zero after being read if no reset has occurred after the read. The reset cause encodings are given in [Table 2-12](#).

**Table 2-12. Reset Cause Encoding**

Reset Level	Reset		Device Modules Reset											
	Cause ID	Reset Cause	NRST/SWD Disables	SHUTDN STOREx	Core Regulator	Debug Subsystem	RTC, LFXT, LFCLK State	SRAM	BCR Execution	IOMUX	EVENT, DMA, FLASHCTL, SYSCTL	Peripherals	CPU	
	0x00	0	No reset since last read											
POR	0x01	1	VDD < POR- violation			R	R	R	R	R	R	R	R	R
			PMU trim parity fault											
			SHUTDNSTOREx parity fault (if present)											
	0x02	2	NRST pin reset (>1s)			R	R	R	R	R	R	R	R	R
			IWDT			R	R	R	R	R	R	R	R	
	0x03	3	Software-triggered POR			R	R	R	R	R	R	R	R	
BOR	0x04	4	VDD < BOR- violation					R	R	R	R	R	R	
	0x05	5	Wake from SHUTDOWN (if present)					R	R	R	R <sup>(1)</sup>	R	R	
	0x06	6	Reserved											
	0x07	7	Reserved											
BOOTRST	0x08	8	Reserved											
	0x09	9	Fatal clock fault						R	R	R	R	R	R
	0x0A	10	Reserved											
	0x0B	11	Reserved											
	0x0C	12	NRST pin reset (<1 s)						R	R	R <sup>(2)</sup>	R	R	R
	0x0D	13	Software-triggered BOOTRST						R	R	R <sup>(2)</sup>	R	R	R
	0x0E	14	WWDT0 violation						R	R	R <sup>(2)</sup>	R	R	R
	0x0F	15	Reserved											
SYSRST	0x10	16	BSL exit (if present)							R	R <sup>(2)</sup>	R <sup>(3)</sup>	R	R
	0x11	17	BSL entry (if present)							R	R <sup>(2)</sup>	R <sup>(3)</sup>	R	R
	0x12	18	Reserved											
	0x13	19	WWDT1 violation								R <sup>(2)</sup>	R <sup>(3)</sup>	R	R
	0x14	20	Reserved											
	0x15	21	CPU lockup violation								R <sup>(2)</sup>	R <sup>(3)</sup>	R	R
	0x16	22	Reserved

0x1B	27	Software-triggered SYSRST								R <sup>(2)</sup>	R <sup>(3)</sup>	R	R	
CPURST	0x1C	28	Debug-triggered CPURST										R	
	0x1D	29	Software-triggered CPURST										R	
	0x1E	30	Reserved											

**Table 2-12. Reset Cause Encoding (continued)**

Reset Level	Reset		Device Modules Reset									
	Cause ID	Reset Cause	NRST/SWD Disables	SHUTDN STOREx	Core Regulator	Debug Subsystem	RTC, LFXT, LFCLK State	SRAM	BCR Execution	IOMUX	EVENT, DMA, FLASHCTL, SYSCTL	Peripherals
	0x1F	31	Reserved									

- (1) In the case of a SHUTDOWN mode exit, the IOMUX registers are always reset but the IOs retain the last state from the point of entry into SHUTDOWN until the user clears the RELEASE bit in the SHDNIOREL register in SYSCTL. This enables application software to be able to reconfigure IOMUX and any corresponding peripherals before releasing the IO after a SHUTDOWN exit. See [shutdown mode handling](#) and [IOMUX wake](#).
- (2) IOMUX is reset, but if LFXT or LFCLK\_IN are enabled then the IOMUX settings for these pads does not reset. The RTC, LFXT, LFCLK\_IN, and LFCLK continue to operate without interruption.
- (3) The SYSOSC frequency correction loop ([FCL](#)) is not reset (if enabled by software)

If two reset causes occur simultaneously, the lowest cause reset ID value is prioritized and reported. For example, if a WWDT0 violation (cause 0x0E) occurs at the same time that a VDD < BOR- violation (cause 0x04) occurs, the reported reset cause is a BOR- violation (cause 0x04), as this is a lower level reset which clears additional aspects of the device state.

The reset cause encoding enables simple software handling during application startup. The reset cause value can be read by application software and tested to be within a certain value range to determine if the following occurred:

- **RESETCAUSE==0x00:** No reset since last read
- **RESETCAUSE<0x04:** The NRST/SWD disable state was reset and can need to be reconfigured
- **RESETCAUSE<0x04:** The SHUTDNSTOREx memory (if present) was reset and can need to be reconfigured
- **RESETCAUSE<0x08:** The regulated VCORE domain was power cycled
- **RESETCAUSE<0x0C:** The RTC and low frequency clock configuration were reset and can need to be reconfigured
- **RESETCAUSE<0x10:** The SRAM is reinitialized and the contents were lost
- **RESETCAUSE<0x1C:** The peripherals were reset and can need to be reconfigured

The following example shows how the reset cause can be tested to take specific actions when starting an application after a reset:

```
// Read reset cause into SRAM variable
uint8_t cause = RESETCAUSE;

// Handle device re-configuration based on reset cause level
if (cause!=0)
{
    if (cause<0x04)
    {
        // NRST/SWD disable state was lost
        // SHUTDNSTOREx memory state was lost
        // PMU/VCORE domain state was lost
        // RTC/LFXT/LFCLK state was lost
    }
}
```

```

    if (cause<0x0C)
    {
        // RTC/LFXT/LFCLK state was lost
    }
    if (cause<0x1C)
    {
        // The peripherals were reset
    }
}

```

#### 2.4.1.7 Peripheral Reset Control

Each peripheral on a device contains a reset control register (RSTCTL) and a status register (STAT).

The STAT register is a read-only register which contains a RESETSTKY bit, indicating if the peripheral was reset. This bit can be read by application software to determine if a peripheral was reset and needs to be re-configured. The RESETSTKY bit is cleared by writing the RESETSTKYCLR bit together with the KEY value to the RSTCTL register.

Application software can also force a reset of the peripheral by writing the RESEASSERT bit together with the KEY value to the RSTCTL register. This action resets the peripheral to the default state and sets the RESETSTKY bit in the STAT register.

---

#### Note

The RSTCTL register does not reset the FPUB and FSUB registers for a given peripheral. Use SYSRST or directly modify FPUB and FSUB directly of the peripheral to reset the publisher and subscriber event registers.

---

#### 2.4.1.8 Boot Fail Handling

If a boot fails during execution of the boot configuration routine (BCR), SYSCTL asserts a BOOTRST to attempt another boot. A boot fail can be caused by the following:

- Boot configuration data integrity error
- Device trim integrity error
- BCR timeout (BCR takes significantly longer than expected to complete for any other reason)

Up to three attempts to successfully boot the device are made by hardware. If the first, second, or third boot attempt is successful, the application starts normally. If the third attempt fails, then the boot process fails, no further boot attempts are made, and the application software is not started.

The purpose of the additional boot attempts is to allow the device to boot correctly if a transient (temporary) error was the cause of the boot fail. If three boot attempts are not successful, a steady-state error condition is likely present and the application is not started to prevent unexpected operation.

---

#### Note

If a device is locked due to three failed attempts to boot, and a BOR- violation occurs, a BOR and BOOTRST are still generated (by definition) and a single boot attempt is made. Under the same conditions, if power is completely removed from the device (triggering a POR- violation), then the device again attempts to boot up to three times.

---

### 2.4.2 Operating Mode Selection

The device operating mode is configured through the use of the following:

1. Policy bits in the SYSOSCCFG and MCLKCFG registers in SYSCTL (to control the behavior of SYSOSC in RUN, SLEEP, and STOP modes)
2. Policy bits in the PMODECFG register in SYSCTL (to set the deep sleep level of STOP, STANDBY or SHUTDOWN (if present))
3. SLEEPDEEP policy bit in the SCR local CPU register (to select whether a WFI instruction triggers SLEEP mode or STOP/STANDBY/SHUTDOWN mode (if present))

- Use of the Arm WFI (wait for interrupt) CPU instruction (to enter the configured SLEEP/STOP/STANDBY/SHUTDOWN state (if present))

Before entering an operating mode where the CPU is disabled, make sure that the appropriate peripheral that can wake the CPU from sleep has been configured to generate a CPU interrupt on the desired event.

For a detailed description of the behavior of each operating mode, see the [operating modes](#) section.

### Policy Bit Configuration

**Table 2-13** defines how to configure the relevant policy bits for each operating mode. All values are indicated in binary format. A dash (-) indicates that the particular policy bit is a don't care for the specified operating mode.

**Table 2-13. Operating Mode Policy Bit Configuration**

Operating Mode Policy Control		RUN			SLEEP <sup>(2)</sup>			STOP			STANDBY		SHUTDOWN (if present)
Register	Bit	RUN0	RUN1	RUN2	SLEEP0	SLEEP1	SLEEP2	STOP0	STOP2 (if present)	STOP2	STANDBY0	STANDBY1	
SYSOSCCFG	DISABLE <sup>(1)</sup>	0	0	1	0	0	1	-	-	1 <sup>(3)</sup>	-	-	-
	USE4MHZSTOP	-	-	-	-	-	-	0	1	0	-	-	-
	DISABLESTOP	-	-	-	-	-	-	0	0	1 <sup>(3)</sup>	-	-	-
MCLKCFG	USELFCLK <sup>(1)</sup>	0	1	-	0	1	-	0	0	-	-	-	-
	STOPCLKSTBY	-	-	-	-	-	-	-	-	-	0	1	-
PMODECFG	DSLEEP	-	-	-	-	-	-	00	00	00	01	01	10
SCR	SLEEPDEEP	0	0	0	0	0	0	1	1	1	1	1	1

- The SYSOSCCFG.DISABLE and MCLKCFG.USELFCLK policy bits take effect immediately after being configured, as these bits affect the RUN mode behavior. Other policy bits only take effect when the CPU is put into deep sleep.
- SLEEP mode behavior is always identical to RUN mode, except with the CPUCLK disabled. As such, the SLEEP behavior is determined by the configuration of RUN mode.
- The STOP2 policy for STOP mode can be configured by setting the DISABLESTOP bit or DISABLE bit in the SYSOSCCFG register before entering DEEPSLEEP. When DISABLESTOP is set and DISABLE is cleared, SYSOSC is only disabled when DEEPSLEEP is requested. SYSOSC continues to run in RUN and SLEEP modes. When DISABLE is set, DISABLESTOP becomes a don't care, and SYSOSC is disabled immediately and is kept disabled in STOP mode.

### Entering SLEEP Mode

Entering **SLEEP** mode disables the CPU, but otherwise maintains the same configuration as **RUN**. To enter **SLEEP** mode:

- Configure the CPU for SLEEP by clearing the SLEEPDEEP bit in the local SCR register.
- Enter sleep mode by executing the WFI (wait for interrupt) CPU instruction.

### Entering STOP or STANDBY Modes

To enter **STOP** or **STANDBY** mode:

- Configure the PMODECFG register in SYSCTL to 0b00 (STOP) or 0b01 (STANDBY).
- Configure the CPU for DEEP SLEEP by setting the SLEEPDEEP bit in the local SCR register.
- Enter sleep mode by executing a WFI (wait for interrupt) CPU instruction.

## Entering SHUTDOWN Mode (if present)

To enter **SHUTDOWN** mode:

1. Configure the PMODECFG register in SYSCTL to 0b10 (SHUTDOWN).
2. Configure the CPU for DEEP SLEEP by setting the SLEEPDEEP bit in the local SCR register.
3. Enter sleep mode by executing a WFI (wait for interrupt) CPU instruction.

### 2.4.3 Asynchronous Fast Clock Requests

Peripherals are configured to asynchronously assert a hardware request to the SYSCTL for a fast clock source if the device is operating in lower power states (such as RUN2, SLEEP1/2, STOP0/1/2, or STANDBY0/1).

This mechanism is for applications where the MCLK/ULPCLK tree is normally sourced from either LFCLK (at 32kHz) or SYSOSC, but a faster clock is temporarily needed to quickly handle a peripheral event (for example, a timer IRQ or GPIO IRQ) or peripheral activity (such as serial communication or an ADC conversion).

Asynchronous fast clock requests are also useful for scenarios where the device is running in STANDBY1 mode. In STANDBY1 (when STOPCLKSTBY is set), the ULPCLK and LFCLK are disabled to all peripherals except for a few TIMGx, leaving the supported TIMGx and RTC as the only clocked peripherals. To wake up the device from this state where the PD0 bus clock (ULPCLK) is disabled, a TIMGx or RTC interrupt request forces an asynchronous fast clock request to wake the device to RUN mode. Other peripherals can also wake the device from this state if support for detecting an asynchronous event (for example GPIO, comparator, and serial interfaces) is configured.

Asynchronous fast clock requests temporarily provide peripherals with bus clock ( [MCLK/ULPCLK](#)), sourced from the [SYSOSC](#), for the duration of the request. [MFCLK](#), if enabled for use, is also enabled during the asynchronous request.

### Asynchronous Fast Clock Behavior

When configured, SYSCTL responds to a peripheral fast clock request in the following way:

1. If the device is currently in a STOP or STANDBY mode, the low power state is temporarily suspended to support running the PD0 bus clock ([ULPCLK](#)) at the [SYSOSC](#) base frequency.
2. If disabled, SYSOSC is forced to be enabled; if SYSOSC is already running but at a different frequency than base frequency, SYSOSC is forced to base frequency.
3. The [MCLK/ULPCLK](#) tree is forced to be sourced from [SYSOSC](#) at the base frequency; if the device is in RUN mode then the [CPUCLK](#) is also switched to the SYSOSC rate (the CPUCLK is always derived from MCLK)
4. If the [MFCLK](#) is configured to be used, MFCLK is activated

After the configuration above is applied, values are held for the duration of time that the asynchronous request remains asserted plus approximately 1µs after the request is removed. The system then returns to the configuration which existed before the fast clock request, provided the CPU did not change the configuration during the request.

Asynchronous fast clock requests are ignored and results in no effect on the device configuration if any of the following are true:

- MCLK is already sourced from SYSOSC at base frequency
- MCLK is sourced from [HSCLK](#) ([HFCLK](#) or [SYSPLL](#))
- Asynchronous fast clock requests are globally blocked by setting the BLOCKASYNCALL bit in the SYSOSCCFG register in SYSCTL

### Peripheral Support

An asynchronous event can occur from various sources listed below. The purpose, request source, and configuration requirements for these peripherals are given in [Table 2-14](#).

- Timers such as RTC, TIMGx, and TIMBx
- GPIO
- Comparator
- Serial interfaces such as UART, I2C, SPI
- ADC

**Table 2-14. Peripheral Support for Asynchronous Fast Clock Requests**

Peripheral	Purpose	Request Source	Configuration
RTC	Fast CPU wake from RTC event	RTC IRQ to CPU	The RTC can be configured to generate an asynchronous fast clock request in response to an RTC IRQ in any operating mode by clearing the BLOCKASYNC bit in the RTC CLKCFG register; this provides the lowest latency RTC event response. In STANDBY1 mode, an RTC IRQ event always generates an asynchronous fast clock request; this is needed to wake the device as the main ULPCLK is disabled to reduce power consumption.
TIMGx	Fast CPU wake from TIMGx event	TIMGx, IRQ to CPU	An IRQ event from TIMGx generates an asynchronous fast clock request when the corresponding IMASK interrupt is set in the TIMG registers. This is needed to wake the device as the ULPCLK is disabled to reduce power consumption. This request is also supported in STANDBY1 mode for specific TIMGx peripherals.
TIMBx	Fast CPU wake from TIMBx event	TIMBx, IRQ to CPU	An IRQ event from TIMBx generates an asynchronous fast clock request when the corresponding IMASK interrupt is set in the TIMB registers. This is needed to wake the device as the ULPCLK is disabled to reduce power consumption. This request is also supported in STANDBY1 mode for specific TIMBx peripherals.
GPIO	Fast CPU wake from GPIO event	GPIO activity	The GPIO generates an asynchronous fast clock request through the GPIO configuration registers. This is for applications where GPIO wake from lower power modes is desired, as the fast clock request results in the GPIO digital glitch filters running at SYSOSC base frequency. In addition to configuring the GPIO registers to request the fast clock, the BLOCKASYNCALL bit must be cleared in the SYSOSCCFG register to allow the request to propagate.
Comparator	Fast wake from a comparator event	Comparator event	A comparator event generates an asynchronous fast clock request to provide the lowest latency comparator event response. The BLOCKASYNC bit in the CLKCFG register of the respective comparator must be disabled.
SPI	Temporarily use fast clock for bit clock generation	SPI activity	SPI activity generates an asynchronous fast clock request when the BLOCKASYNC bit is cleared in the CLKCFG register of the respective SPI peripheral.
I2C	Temporarily use fast clock for bit clock generation	I2C activity	I2C activity generates an asynchronous fast clock request when the BLOCKASYNC bit is cleared in the CLKCFG register of the respective I2C peripheral.
UART	Temporarily use a fast clock for baud rate generation	UART activity	UART activity generates an asynchronous fast clock request when the BLOCKASYNC bit is cleared in the CLKCFG register of the respective UART peripheral.
ADC	Temporarily run the SYSOSC to support timer-triggered ADC operation from a low-power mode	ADC	If an ADC conversion is triggered when SYSOSC is disabled, an asynchronous fast clock request is generated to enable the SYSOSC (SYSOSC is required for correct ADC operation).

## Fast CPU Event Handling

In addition to the peripheral event and activity fast clock request triggers, the SYSCTL can be configured to generate an asynchronous fast clock request upon any IRQ request to the CPU. This provides the lowest latency interrupt handling when the system is running at the LFCLK rate (32kHz), as the IRQ request propagates through the wake-up logic at the SYSOSC rate vs. the LFCLK rate (32kHz). When the FASTCPUEVENT bit

is set in the SYSOSCCFG register in SYSCTL, any interrupt request to the CPU also generates a fast clock request.

### Asynchronous Fast Clock Request Logic

The logic for asserting a fast clock request is given in the following figure.

**Figure 2-11. Asynchronous Fast Clock Request Logic**

#### Note

Check the device specific data sheet to determine which peripherals are present and supported.

#### 2.4.4 SRAM Write Protection

SRAM Write Protection Control for this device is implemented in the Global Security Controller (GSC). Please refer to the related chapter for more information.

#### 2.4.5 Flash Wait States

Flash wait states are managed automatically by SYSCTL when MCLK is running from SYSOSC or LFCLK. If MCLK will not be switched to SYSPLL, HFXT, or HFCLK\_IN, no wait state configuration is required. Application software is not required to configure any wait states for proper operation of the device.

If MCLK is to be configured to run from one of the high-speed clock sources such as SYSPLL, HFXT, or HFCLK\_IN, the flash wait state configuration in MCLKCFG.FLASHWAIT is applied. By default, MCLKCFG.FLASHWAIT is set to 0x2 (2 wait states) which supports operation at the maximum MCLK frequency of 80MHz. If MCLK is configured to run from a high-speed clock but the MCLK frequency allows operation with fewer than 2 wait states, then MCLKCFG.FLASHWAIT can be reduced.

Refer to the *Recommended Operation Conditions* section of the device specific data sheet to determine the max clock frequency supported with 0 or 1 wait state.

#### 2.4.6 Flash Bank Address Swap

Devices with multiple flash banks provide a mechanism for swapping the address space of the upper banks with the address space of the lower banks to enable firmware updates, where the firmware image has no knowledge of the containing memory bank, to be able to execute properly on the hardware.

To swap the addresses of the upper flash banks with the addresses of the lower flash banks, set the USEUPPER bit in the FLBANKSWAP register while also writing the KEY value.

Special care must be taken when swapping the flash bank address space. See the nonvolatile memory system chapter for additional considerations when using flash bank address swapping.

#### 2.4.7 Shutdown Mode Handling (if present)

When the device is configured to enter SHUTDOWN mode, the core regulator is powered down and the device register contents and SRAM contents are lost. An exit from SHUTDOWN mode generates a [BOR level reset](#). Two mechanisms are provided to preserve the device state when entering SHUTDOWN mode: IO latching and a small shutdown memory.

#### Shutdown IO State

The digital IO pin states (output low/high, pullup/pulldown, Hi-Z, drive configuration) are latched and retained upon entry to SHUTDOWN. After exiting SHUTDOWN mode, the IOs are held in the previous state until released by application software setting the RELEASE bit in the SHDNIOREL register along with the matching KEY value. When exiting SHUTDOWN mode, application software must first re-configure the IO to their proper state, then release the IO. To determine at startup if the cause of a reset was an exit from SHUTDOWN mode, application software must read the [RSTCAUSE register in SYSCTL](#).

---

#### Note

When exiting SHUTDOWN, **the IOs specific to serial wire debug (SWD) pins are released from their latched state regardless of the RELEASE bits being set or not**. This is to ensure that the user can enable a debugger connection.

---

---

#### Note

When exiting SHUTDOWN, the bootstrap loader (BSL) invoke pin must be held at a logic low level to prevent unintended entry into the BSL during exit from SHUTDOWN. An entry to the BSL during SHUTDOWN exit prevents the application code from starting, the BSL interfaces are not be available, and a SWD connection is possible as the IO states remain latched through SHUTDOWN exit until application software releases the IOs.

---

#### Shutdown Memory

To enable saving of application state information before entering SHUTDOWN mode, 4 bytes of shutdown memory are provided in SYSCTL. These memory locations are retained in SHUTDOWN mode and are readable by the application after exiting SHUTDOWN. To save data to the SHUTDOWN memory, write to the SHUTDNSTORE0-SHUTDNSTORE3 registers in SYSCTL.

#### 2.4.8 Configuration Lockout

Configuration registers in SYSCTL can be locked out from writes to add a layer of robustness against unintended changes to the PMCU at runtime. To lock out the configuration registers from writes, set the ACTIVE bit in the WRITELOCK register in SYSCTL.

All SYSCTL registers are protected by the WRITELOCK functionality except for those listed below:

- WRITELOCK

- PMODECFG
- FCC, FCCCMD
- FLBANKSWAP (if present)
- RSTCAUSE (read-to-clear), RESETLEVEL, RESETCMD
- BORTHRESHOLD, BORCLRCMD
- SHDNIORL (if present)
- PMUOPAMP
- SHUTDOWNSTOREx (if present)

In addition to the overall SYSCTL configuration write lock feature, many SYSCTL registers also require a KEY value to be written in conjunction with the desired configuration data for the write to take effect.

### 2.4.9 System Status

The status of various aspects of the PMCU can be polled by software by reading the CLKSTATUS and SYSSTATUS registers in SYSCTL.

#### Checking Clock Status (CLKSTATUS)

The CLKSTATUS register in SYSCTL is a read-only register which indicates the current configuration and status of the clock module. Key status information provided in CLKSTATUS includes:

- The current SYSOSC frequency
- The current HSCLK selection
- The current LFCLK selection
- The current MCLK selection
- The HFCLK and SYSPLL (if present) status
- The LFXT status
- The LFOSC status
- Indications that the HSCLK, HFCLK, and SYSPLL (if present) are disabled
- Error indications if a peripheral requested a clock and the clock cannot be generated

This status information is useful to validate that a requested clock change has completed successfully, or to check the true SYSOSC frequency in applications where SYSOSC can have asynchronous activation or frequency requests issued by peripherals.

#### Checking System Status (SYSSTATUS)

The SYSSTATUS register in SYSCTL is a read-only register which indicates flash ECC errors (SED and DED) along with other peripheral-specific status information. ECC error bits in SYSSTATUS are sticky (they remain set when an ECC error occurs even if future reads do not have errors). These bits can be reset (cleared) by setting the ALLECC bit in the SYSSTATUSCLR register along with the KEY value.

The SYSSTATUS register in SYSCTL is a read-only register which indicates the peripheral-specific status information.

### 2.4.10 Error Handling

MSPM0 devices include several diagnostic mechanisms to detect errors at runtime. [Table 2-15](#) lists error sources and their corresponding handling mechanisms.

---

#### Note

Not all MSPM0 devices support all diagnostic features. For example, some devices do not have ECC/parity on memories and some devices do not have dual watchdog timers. Always refer to the device-specific data sheet to understand which diagnostic features are available for a given device. In the PMCU registers section, register maps are also provided for each MCU subfamily detailing the specific registers available for a given device.

---

**Table 2-15. Error Sources and Handling Mechanisms**

Error Source	Error	Handling Mechanism
Flash (if device has ECC)	Non-correctable ECC error (if device has ECC)	<ul style="list-style-type: none"> <li>For a CPU or DMA request, a FLASHDED nonmaskable interrupt is generated to the processor or a SYSRST is generated depending on configuration of the FLASHECCRSTDIS bit</li> <li>The FLASHDED sticky bit is set in the SYSSTATUS register in SYSCTL</li> </ul>
	Correctable ECC error (if device has ECC)	<ul style="list-style-type: none"> <li>A FLASHSEC interrupt is also generated in SYSCTL</li> <li>The FLASHSEC sticky bit is set in the SYSSTATUS register in SYSCTL</li> </ul>
SRAM	Non-correctable ECC error (if device has ECC)	<ul style="list-style-type: none"> <li>An SRAMEDD nonmaskable interrupt is generated to the processor</li> </ul>
	Correctable ECC error (if device has ECC)	<ul style="list-style-type: none"> <li>A SYSCTL SRAMSED interrupt is generated to the processor</li> </ul>
	Parity error (if device has parity)	<ul style="list-style-type: none"> <li>Nonmaskable interrupt is generated to the processor if the request was from the CPU</li> <li>DMA data error interrupt is generated if the request was from the DMA</li> </ul>
	Address error on CPU access	<ul style="list-style-type: none"> <li>A hard fault is generated in the CPU</li> </ul>
	Address error on DMA access	<ul style="list-style-type: none"> <li>A DMA address error interrupt is generated in the DMA controller</li> </ul>
	ECC error on CAN SRAM (if device has CAN-FD)	<ul style="list-style-type: none"> <li>An interrupt is generated in the CAN-FD peripheral</li> </ul>
SHUTDNSTOREx Memory (if present)	Parity error	<ul style="list-style-type: none"> <li>A <b>POR</b> is generated</li> </ul>
CKM	MCLK failure	<ul style="list-style-type: none"> <li>A <b>BOOTRST</b> is generated</li> </ul>
	LFCLK failure (if present)	<ul style="list-style-type: none"> <li>A <b>BOOTRST</b> is generated if LFCLK is sourcing MCLK</li> <li>An LFCLKFAIL nonmaskable interrupt is generated in the SYSCTL NMI registers.</li> </ul>
CPUSS (if device has MPU)	Memory protection unit violation	<ul style="list-style-type: none"> <li>A hard fault is generated in the CPU</li> </ul>
WWDT	WWDT0 violation	<ul style="list-style-type: none"> <li>A <b>BOOTRST</b> is generated or a nonmaskable interrupt is generated in the SYSCTL NMI registers depending on configuration of the WWDTLPORSTDIS bit</li> </ul>
	WWDT1 violation (if present)	<ul style="list-style-type: none"> <li>A <b>BOOTRST</b> is generated or a nonmaskable interrupt is generated in the SYSCTL NMI registers depending on configuration of the WWDTLP1RSTDIS bit</li> </ul>
PMU	Trim parity error	<ul style="list-style-type: none"> <li>A <b>POR</b> is generated</li> </ul>
	POR0- supply error	<ul style="list-style-type: none"> <li>A <b>POR</b> is generated</li> </ul>
	BOR0- supply error	<ul style="list-style-type: none"> <li>A <b>BOR</b> is generated</li> </ul>
	BOR1/2/3- supply error (if present)	<ul style="list-style-type: none"> <li>A BORLVL nonmaskable interrupt is generated in the SYSCTL NMI registers</li> </ul>
CPUSS	Memory protection unit violation (if present)	<ul style="list-style-type: none"> <li>A hard fault is generated in the CPU</li> </ul>

## Configurable NMI Triggers

Error sources can be configured to trigger either a nonmaskable interrupt or a different handling mechanism. The SYSTEMCFG register in SYSCTL may be used to specify the desired error handling mechanism. For example, the WWDT0 may be configured to generate either a BOOTRST or an NMI, with BOOTRST being the default case. Refer to the SYSTEMCFG register for the relevant device subfamily for the available error handling options.

### 2.4.11 SYSCTL Events

The SYSCTL module contains two event publishers and no event subscribers. One event publisher manages SYSCTL interrupt requests (IRQs) to the CPU subsystem. The second publisher manages nonmaskable interrupts to the CPU subsystem for critical diagnostics.

The SYSCTL events are summarized in [SYSCTL Events](#).

**Table 2-16. SYSCTL Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
CPU interrupt	Publisher	SYSCTL	CPU Subsystem	Static route	SYSCTL interrupt registers	Fixed interrupt route from SYSCTL to CPU
CPU nonmaskable interrupt (NMI)	Publisher	SYSCTL	CPU Subsystem	Static route	NMI interrupt registers	Fixed interrupt route from SYSCTL to CPU

#### 2.4.11.1 CPU Interrupt Event (CPU\_INT)

The SYSCTL module provides several interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the SYSCTL are given in [Table 2-17](#).

**Table 2-17. SYSCTL CPU Interrupt Event Sources**

Index (IIDX)	Name	Description
0	NONE	No interrupt pending.
1	LFOSCGOOD	Indicates when LFOSC is ready during startup, as LFOSC takes ≈1ms to start.
2	ANACLKERR	Indicates that an analog function was enabled and expecting a SYSOSC to be operation at a certain frequency, but SYSOSC was either not available or not operating at the required frequency.
3	FLASHSEC	Indicates that a flash memory single-bit correctable error was detected
4	SRAMSEC	Indicates that a SRAM single-bit correctable error was detected
5	LFXTGOOD	Indicates when the low frequency external clock (either the LFXT oscillator or LFCLK_IN digital clock) are ready. This indication is useful when starting the clock system and waiting for LFXT or LFCK_IN to be ready before switching the LFCLK source from LFOSC to an external source.
6	HFCLKGOOD	Indicates when the high frequency external clock (either the HFXT oscillator or HFCLK_IN digital clock) are ready. This indication is useful when starting the clock system and waiting for HFCLK to be ready before switching the MCLK source to HFCLK or before starting the SYSPLL with HFCLK as the SYSPLL reference.
7	SYSPLLGOOD	Indicates when the SYSPLL is ready and available for use. This indication is useful when starting the clock system and waiting for SYSPLL to be ready before switching the MCLK source to SYSPLL.

**Table 2-17. SYSCTL CPU Interrupt Event Sources (continued)**

Index (IIDX)	Name	Description
8	HSCLKGOOD	Indicates when the HSCLK (sourced by either HFCLK or a SYSPLL output) is ready. This indication is useful when waking up from STOP or STANDBY mode when HSCLK is configured as the MCLK source in RUN/SLEEP mode. When waking from STOP or STANDBY, MCLK will run from SYSOSC until the HSCLK is available, at which time SYSCTL automatically switches the MCLK source to the selected HSCLK source. This interrupt communicates that after wake-up from STOP/STANDBY, MCLK has switched over to the desired HSCLK source and it is now possible to use timing-sensitive peripherals sourced by MCLK.

The CPU interrupt event configuration is managed with the SYSCTL IIDX, IMASK, RIS, MIS, ISET, and ICLR event management registers. See [Section 7.2.5](#) for guidance on configuring these registers for CPU interrupts.

#### 2.4.11.2 Nonmaskable Interrupt Event (NMI)

The SYSCTL module provides x interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the SYSCTL are given in [Table 2-17](#).

**Table 2-18. Nonmaskable Interrupt Event Table**

Index (IIDX)	Name	Description
0	NONE	No NMI pending.
1	BORLVL	Indicates that VDD has dropped below the specified VBOR- threshold.
2	WWDT0	A WWDT0 violation occurred.
3	WWDT1	A WWDT1 violation occurred.
4	LFCLKFAIL	Indicates that the LFXT or LFCLK_IN clock source is dead. This indication is useful for handling LFCLK errors when LFCLK is not sourcing MCLK but is sourcing a peripheral (for example, the RTC)
5	FLASHDED	Indicates that a flash memory double-bit uncorrectable error was detected.
6	SRAMDED	Indicates that an SRAM double-bit uncorrectable error was detected.

The CPU nonmaskable interrupt event configuration is managed with the NMIIIDX, NMIRIS, NMISET, and NMIICLR event management registers. See [Section 7.2.5](#) for guidance on configuring the interrupt management registers.

## 2.5 SYSCTL\_G350x\_G310x\_G150x\_G110x Registers

Table 2-19 lists the memory-mapped registers for the SYSCTL\_G350x\_G310x\_G150x\_G110x registers. All register offset addresses not listed in Table 2-19 should be considered as reserved locations and the register contents should not be modified.

**Table 2-19. SYSCTL\_G350X\_G310X\_G150X\_G110X Registers**

Offset	Acronym	Register Name	Group	Section
1020h	IIDX	SYSCTL interrupt index		<a href="#">Go</a>

**Table 2-42. SYSOSCCFG Field Descriptions**

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	
17	FASTCPUEVENT	R/W	1h	FASTCPUEVENT may be used to assert a fast clock request when an interrupt is asserted to the CPU, reducing interrupt latency. 0h = An interrupt to the CPU will not assert a fast clock request 1h = An interrupt to the CPU will assert a fast clock request
16	BLOCKASYNCALL	R/W	0h	BLOCKASYNCALL may be used to mask block all asynchronous fast clock requests, preventing hardware from dynamically changing the active clock configuration when operating in a given mode. 0h = Asynchronous fast clock requests are controlled by the requesting peripheral 1h = All asynchronous fast clock requests are blocked
15-11	RESERVED	R	0h	
10	DISABLE	R/W	0h	DISABLE sets the SYSOSC enable/disable policy. SYSOSC may be powered off in RUN, SLEEP, and STOP modes to reduce power consumption. When SYSOSC is disabled, MCLK and ULPClk are sourced from LFCLK. 0h = Do not disable SYSOSC 1h = Disable SYSOSC immediately and source MCLK and ULPClk from LFCLK
9	DISABLESTOP	R/W	0h	DISABLESTOP sets the SYSOSC stop mode enable/disable policy. When operating in STOP mode, the SYSOSC may be automatically disabled. When set, ULPClk will run from LFCLK in STOP mode and SYSOSC will be disabled to reduce power consumption. 0h = Do not disable SYSOSC in STOP mode 1h = Disable SYSOSC in STOP mode and source ULPClk from LFCLK
8	USE4MHZSTOP	R/W	0h	USE4MHZSTOP sets the SYSOSC stop mode frequency policy. When entering STOP mode, the SYSOSC frequency may be automatically switched to 4MHz to reduce SYSOSC power consumption. 0h = Do not gear shift the SYSOSC to 4MHz in STOP mode 1h = Gear shift SYSOSC to 4MHz in STOP mode

**Table 2-42. SYSOSCCFG Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7-2	RESERVED	R	0h	
1-0	FREQ	R/W	0h	Target operating frequency for the system oscillator (SYSOSC) 0h = Base frequency (32MHz) 1h = Low frequency (4MHz) 2h = User-trimmed frequency (16 or 24 MHz)

## 12 MCLKCFG (Offset = 1104h) [Reset = 000XX2X0h]

MCLKCFG is shown in [Figure 2-23](#) and described in [Table 2-32](#).

Return to the [Summary Table](#).

Main clock (MCLK) configuration

**Figure 2-23. MCLKCFG**

31	30	29	28	27	26	25	24

**Table 2-44. MCLKCFG Field Descriptions**

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	
22	MCLKDEADCHK	R/W	0h	MCLKDEADCHK enables or disables the continuous MCLK dead check monitor. LFCLK must be running before MCLKDEADCHK is enabled. 0h = The MCLK dead check monitor is disabled 1h = The MCLK dead check monitor is enabled
21	STOPCLKSTBY	R/W	0h	STOPCLKSTBY sets the STANDBY mode policy (STANDBY0 or STANDBY1). When set, ULPCCLK and LFCLK are disabled to all peripherals in STANDBY mode, with the exception of TIMG0 and TIMG1 which continue to run. Wake-up is only possible via an asynchronous fast clock request. 0h = ULPCCLK/LFCLK runs to all PD0 peripherals in STANDBY mode 1h = ULPCCLK/LFCLK is disabled to all peripherals in STANDBY mode except TIMG0 and TIMG1
20	USELFCLK	R/W	0h	USELFCLK sets the MCLK source policy. Set USELFCLK to use LFCLK as the MCLK source. Note that setting USELFCLK does not disable SYSOSC, and SYSOSC remains available for direct use by analog modules. 0h = MCLK will not use the low frequency clock (LFCLK) 1h = MCLK will use the low frequency clock (LFCLK)
19-17	RESERVED	R	0h	
16	USEHSCLK	R/W	0h	USEHSCLK, together with USELFCLK, sets the MCLK source policy. Set USEHSCLK to use HSCLK (HFCLK or SYSPLL) as the MCLK source in RUN and SLEEP modes. 0h = MCLK will not use the high speed clock (HSCLK) 1h = MCLK will use the high speed clock (HSCLK) in RUN and SLEEP mode
15-13	RESERVED	R	0h	

**Table 2-44. MCLKCFG Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12	USEMFTICK	R/W	0h	USEMFTICK specifies whether the 4MHz constant-rate clock (MFCLK) to peripherals is enabled or disabled. When enabled, MDIV must be disabled (set to 0h=/1). 0h = The 4MHz rate MFCLK to peripherals is enabled 1h = The 4MHz rate MFCLK to peripherals is disabled.
11-8	FLASHWAIT	R/W	2h	FLASHWAIT specifies the number of flash wait states when MCLK is sourced from HSCLK. FLASHWAIT has no effect when MCLK is sourced from SYSOSC or LFCLK. 0h = No flash wait states are applied 1h = One flash wait state is applied 2h = 2 flash wait states are applied
7-6	RESERVED	R	0h	
5-4	UDIV	R/W	1h	UDIV specifies the ULPClk divider when MCLK is sourced from HSCLK. UDIV has no effect when MCLK is sourced from SYSOSC or LFCLK. 0h = ULPClk is not divided and is equal to MCLK 1h = ULPClk is MCLK/2 (divided-by-2) 2h = ULPClk is MCLK/3 (divided-by-3)
3-0	MDIV	R/W	0h	MDIV may be used to divide the MCLK frequency when MCLK is sourced from SYSOSC. MDIV=0h corresponds to /1 (no divider). MDIV=1h corresponds to /2 (divide-by-2). MDIV=Fh corresponds to /16 (divide-by-16). MDIV may be set between /1 and /16 on an integer basis.

### 13 HSCLKEN (Offset = 1108h) [Reset = 0000XXXXh]

**Table 2-78. CLKSTATUS Field Descriptions**

Bit	Field	Type	Reset	Description
31	ANACKERR	R	0h	ANACKERR is set when the device clock configuration does not support an enabled analog peripheral mode and the analog peripheral may not be functioning as expected. 0h = No analog clock errors detected 1h = Analog clock error detected
30	OPAMPCLKERR	R	0h	OPAMPCLKERR is set when the device clock configuration does not support an enabled OPA mode and the OPA may not be functioning as expected. 0h = No OPA clock generation errors detected 1h = OPA clock generation error detected
29	SYSPLLBLKUPD	R	0h	SYSPLLBLKUPD indicates when writes to SYSPLLCFG0/1 and SYSPLLPARAM0/1 are blocked. 0h = writes to SYSPLLCFG0/1 and SYSPLLPARAM0/1 are allowed 1h = writes to SYSPLLCFG0/1 and SYSPLLPARAM0/1 are blocked
28	HFCLKBLKUPD	R	0h	HFCLKBLKUPD indicates when writes to the HFCLKCLKCFG register are blocked. 0h = Writes to HFCLKCLKCFG are allowed 1h = Writes to HFCLKCLKCFG are blocked
27-26	RESERVED	R	0h	
25	FCCDONE	R	0h	FCCDONE indicates when a frequency clock counter capture is complete. 0h = FCC capture is not done 1h = FCC capture is done
24	FCLMODE	R	0h	FCLMODE indicates if the SYSOSC frequency correction loop (FCL) is enabled. 0h = SYSOSC FCL is disabled 1h = SYSOSC FCL is enabled
23	LFCLKFAIL	R	0h	LFCLKFAIL indicates when the continuous LFCLK monitor detects a LFXT or LFCLK_IN clock stuck failure. 0h = No LFCLK fault detected 1h = LFCLK stuck fault detected

**Table 2-78. CLKSTATUS Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
22	RESERVED	R	0h	
21	HSCLKGOOD	R	0h	HSCLKGOOD is set by hardware if the selected clock source for HSCLK started successfully. 0h = The HSCLK source did not start correctly 1h = The HSCLK source started correctly
20	HSCLKDEAD	R	0h	HSCLKDEAD is set by hardware if the selected source for HSCLK was started but did not start successfully. 0h = The HSCLK source was not started or started correctly 1h = The HSCLK source did not start correctly
19-18	RESERVED	R	0h	
17	CURMCLKSEL	R	0h	CURMCLKSEL indicates if MCLK is currently sourced from LFCLK. 0h = MCLK is not sourced from LFCLK 1h = MCLK is sourced from LFCLK
16	CURHSCLKSEL	R	0h	CURHSCLKSEL indicates the current clock source for HSCLK. 0h = HSCLK is currently sourced from the SYSPLL 1h = HSCLK is currently sourced from the HFCLK
15	RESERVED	R	0h	
14	SYSPLLOFF	R	0h	SYSPLLOFF indicates if the SYSPLL is disabled or was dead at startup. When the SYSPLL is started, SYSPLLOFF is cleared by hardware. Following startup of the SYSPLL, if the SYSPLL startup monitor determines that the SYSPLL was not started correctly, SYSPLLOFF is set. 0h = SYSPLL started correctly and is enabled 1h = SYSPLL is disabled or was dead startup
13	HFCLKOFF	R	0h	HFCLKOFF indicates if the HFCLK is disabled or was dead at startup. When the HFCLK is started, HFCLKOFF is cleared by hardware. Following startup of the HFCLK, if the HFCLK startup monitor determines that the HFCLK was not started correctly, HFCLKOFF is set. 0h = HFCLK started correctly and is enabled 1h = HFCLK is disabled or was dead at startup
12	HSCLKSOFF	R	0h	HSCLKSOFF is set when the high speed clock sources (SYSPLL, HFCLK) are disabled or dead. It is the logical AND of HFCLKOFF and SYSPLLOFF. 0h = SYSPLL, HFCLK, or both were started correctly and remain enabled 1h = SYSPLL and HFCLK are both either off or dead
11	LFOSCGOOD	R	0h	LFOSCGOOD indicates when the LFOSC startup has completed and the LFOSC is ready for use. 0h = LFOSC is not ready 1h = LFOSC is ready
10	LFXTGOOD	R	0h	LFXTGOOD indicates if the LFXT started correctly. When the LFXT is started, LFXTGOOD is cleared by hardware. After the startup settling time has expired, the LFXT status is tested. If the LFXT started successfully the LFXTGOOD bit is set, else it is left cleared. 0h = LFXT did not start correctly 1h = LFXT started correctly
9	SYSPLLGOOD	R	0h	SYSPLLGOOD indicates if the SYSPLL started correctly. When the SYSPLL is started, SYSPLLGOOD is cleared by hardware. After the startup settling time has expired, the SYSPLL status is tested. If the SYSPLL started successfully the SYSPLLGOOD bit is set, else it is left cleared. 0h = SYSPLL did not start correctly 1h = SYSPLL started correctly

**Table 2-78. CLKSTATUS Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	HFCLKGOOD	R	0h	HFCLKGOOD indicates that the HFCLK started correctly. When the HFXT is started or HFCLK_IN is selected as the HFCLK source, this bit will be set by hardware if a valid HFCLK is detected, and cleared if HFCLK is not operating within the expected range. 0h = HFCLK did not start correctly 1h = HFCLK started correctly
7-6	LFCLKMUX	R	0h	LFCLKMUX indicates if LFCLK is sourced from the internal LFOSC, the low frequency crystal (LFXT), or the LFCLK_IN digital clock input. 0h = LFCLK is sourced from the internal LFOSC 1h = LFCLK is sourced from the LFXT (crystal) 2h = LFCLK is sourced from LFCLK_IN (external digital clock input)
5	RESERVED	R	0h	
4	HSCLKMUX	R	0h	HSCLKMUX indicates if MCLK is currently sourced from the high-speed clock (HSCLK). 0h = MCLK is not sourced from HSCLK 1h = MCLK is sourced from HSCLK
3-2	RESERVED	R	0h	
1-0	SYSOSCFREQ	R	0h	SYSOSCFREQ indicates the current SYSOSC operating frequency. 0h = SYSOSC is at base frequency (32MHz) 1h = SYSOSC is at low frequency (4MHz) 2h = SYSOSC is at the user-trimmed frequency (16 or 24MHz) 3h = Reserved

### 30 SYSSTATUS (Offset = 1208h) [Reset = XXXXXX0h]

SYSSTATUS is shown in [Figure 2-41](#) and described in [Table 2-50](#).

Return to the [Summary Table](#).

System status information

**Table 2-142. SYSOSCCFG Field Descriptions**

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	
17	FASTCPUEVENT	R/W	1h	FASTCPUEVENT may be used to assert a fast clock request when an interrupt is asserted to the CPU, reducing interrupt latency. 0h = An interrupt to the CPU will not assert a fast clock request 1h = An interrupt to the CPU will assert a fast clock request
16	BLOCKASYNCALL	R/W	0h	BLOCKASYNCALL may be used to mask block all asynchronous fast clock requests, preventing hardware from dynamically changing the active clock configuration when operating in a given mode. 0h = Asynchronous fast clock requests are controlled by the requesting peripheral 1h = All asynchronous fast clock requests are blocked
15-11	RESERVED	R	0h	
10	DISABLE	R/W	0h	DISABLE sets the SYSOSC enable/disable policy. SYSOSC may be powered off in RUN, SLEEP, and STOP modes to reduce power consumption. When SYSOSC is disabled, MCLK and ULPClk are sourced from LFCLK. 0h = Do not disable SYSOSC 1h = Disable SYSOSC immediately and source MCLK and ULPClk from LFCLK
9	DISABLESTOP	R/W	0h	DISABLESTOP sets the SYSOSC stop mode enable/disable policy. When operating in STOP mode, the SYSOSC may be automatically disabled. When set, ULPClk will run from LFCLK in STOP mode and SYSOSC will be disabled to reduce power consumption. 0h = Do not disable SYSOSC in STOP mode 1h = Disable SYSOSC in STOP mode and source ULPClk from LFCLK
8	USE4MHZSTOP	R/W	0h	USE4MHZSTOP sets the SYSOSC stop mode frequency policy. When entering STOP mode, the SYSOSC frequency may be automatically switched to 4MHz to reduce SYSOSC power consumption. 0h = Do not gear shift the SYSOSC to 4MHz in STOP mode 1h = Gear shift SYSOSC to 4MHz in STOP mode

**Table 2-142. SYSOSCCFG Field Descriptions (continued)**

R-0h		R/W-1h			R/W-0h		

**Table 2-144. MCLKCFG Field Descriptions**

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	
22	MCLKDEADCHK	R/W	0h	MCLKDEADCHK enables or disables the continuous MCLK dead check monitor. LFCLK must be running before MCLKDEADCHK is enabled. 0h = The MCLK dead check monitor is disabled 1h = The MCLK dead check monitor is enabled
21	STOPCLKSTBY	R/W	0h	STOPCLKSTBY sets the STANDBY mode policy (STANDBY0 or STANDBY1). When set, ULPCCLK and LFCLK are disabled to all peripherals in STANDBY mode, with the exception of TIMG0 and TIMG1 which continue to run. Wake-up is only possible via an asynchronous fast clock request. 0h = ULPCCLK/LFCLK runs to all PD0 peripherals in STANDBY mode 1h = ULPCCLK/LFCLK is disabled to all peripherals in STANDBY mode except TIMG0 and TIMG1
20	USELFCLK	R/W	0h	USELFCLK sets the MCLK source policy. Set USELFCLK to use LFCLK as the MCLK source. Note that setting USELFCLK does not disable SYSOSC, and SYSOSC remains available for direct use by analog modules. 0h = MCLK will not use the low frequency clock (LFCLK) 1h = MCLK will use the low frequency clock (LFCLK)
19-17	RESERVED	R	0h	
16	USEHSCLK	R/W	0h	USEHSCLK, together with USELFCLK, sets the MCLK source policy. Set USEHSCLK to use HSCLK (HFCLK or SYSPLL) as the MCLK source in RUN and SLEEP modes. 0h = MCLK will not use the high speed clock (HSCLK) 1h = MCLK will use the high speed clock (HSCLK) in RUN and SLEEP mode
15-13	RESERVED	R	0h	

**Table 2-144. MCLKCFG Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12	USEMFTICK	R/W	0h	USEMFTICK specifies whether the 4MHz constant-rate clock (MFCLK) to peripherals is enabled or disabled. When enabled, MDIV must be disabled (set to 0h=/1). 0h = The 4MHz rate MFCLK to peripherals is enabled 1h = The 4MHz rate MFCLK to peripherals is disabled.
11-8	FLASHWAIT	R/W	2h	FLASHWAIT specifies the number of flash wait states when MCLK is sourced from HSCLK. FLASHWAIT has no effect when MCLK is sourced from SYSOSC or LFCLK. 0h = No flash wait states are applied 1h = One flash wait state is applied 2h = 2 flash wait states are applied
7-6	RESERVED	R	0h	
5-4	UDIV	R/W	1h	UDIV specifies the ULPCLK divider when MCLK is sourced from HSCLK. UDIV has no effect when MCLK is sourced from SYSOSC or LFCLK. 0h = ULPCLK is not divided and is equal to MCLK 1h = ULPCLK is MCLK/2 (divided-by-2)
3-0	MDIV	R/W	0h	MDIV may be used to divide the MCLK frequency when MCLK is sourced from SYSOSC. MDIV=0h corresponds to /1 (no divider). MDIV=1h corresponds to /2 (divide-by-2). MDIV=Fh corresponds to /16 (divide-by-16). MDIV may be set between /1 and /16 on an integer basis.

### 13 HSCLKEN (Offset = 1108h) [Reset = 0000XXXXh]

HSCLKEN is shown in [Figure 2-73](#) and described in [Table 2-84](#).

Return to the [Summary Table](#).

**Table 2-162. GENCLKCFG Field Descriptions**

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	
28-24	FCCTRIGCNT	R/W	0h	FCCTRIGCNT specifies the number of trigger clock periods in the trigger window. FCCTRIGCNT=0h (one trigger clock period) up to 1Fh (32 trigger clock periods) may be specified.
23-22	ANACPUMPCFG	R/W	0h	ANACPUMPCFG selects the analog mux charge pump (VBOOST) enable method. 0h = VBOOST is enabled on request from a COMP, GPAMP, or OPA 1h = VBOOST is enabled when the device is in RUN or SLEEP mode, or when a COMP/GPAMP/OPA is enabled 2h = VBOOST is always enabled
21	FCCLVLTRIG	R/W	0h	FCCLVLTRIG selects the frequency clock counter (FCC) trigger mode. 0h = Rising edge to rising edge triggered 1h = Level triggered
20	FCCTRIGSRC	R/W	0h	FCCTRIGSRC selects the frequency clock counter (FCC) trigger source. 0h = FCC trigger is the external pin 1h = FCC trigger is the LFCLK
19-16	FCCSELCLK	R/W	0h	FCCSELCLK selects the frequency clock counter (FCC) clock source. 0h = FCC clock is MCLK 1h = FCC clock is SYSOSC 2h = FCC clock is HFCLK 3h = FCC clock is the CLK_OUT selection 4h = FCC clock is SYSPLLCLK0 5h = FCC clock is SYSPLLCLK1 6h = FCC clock is SYSPLLCLK2X 7h = FCC clock is the FCCIN external input

**Table 2-162. GENCLKCFG Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
15-12	HFCLK4MFPCLKDIV	R/W	0h	HFCLK4MFPCLKDIV selects the divider applied to HFCLK when HFCLK is used as the MFPCLK source. Integer dividers from /1 to /16 may be selected. 0h = HFCLK is not divided before being used for MFPCLK 1h = HFCLK is divided by 2 before being used for MFPCLK 2h = HFCLK is divided by 3 before being used for MFPCLK 3h = HFCLK is divided by 4 before being used for MFPCLK 4h = HFCLK is divided by 5 before being used for MFPCLK 5h = HFCLK is divided by 6 before being used for MFPCLK 6h = HFCLK is divided by 7 before being used for MFPCLK 7h = HFCLK is divided by 8 before being used for MFPCLK 8h = HFCLK is divided by 9 before being used for MFPCLK 9h = HFCLK is divided by 10 before being used for MFPCLK Ah = HFCLK is divided by 11 before being used for MFPCLK Bh = HFCLK is divided by 12 before being used for MFPCLK Ch = HFCLK is divided by 13 before being used for MFPCLK Dh = HFCLK is divided by 14 before being used for MFPCLK Eh = HFCLK is divided by 15 before being used for MFPCLK Fh = HFCLK is divided by 16 before being used for MFPCLK
11-10	RESERVED	R	0h	
9	MFPCLKSRC	R/W	0h	MFPCLKSRC selects the MFPCLK (middle frequency precision clock) source. 0h = MFPCLK is sourced from SYSOSC 1h = MFPCLK is sourced from HFCLK
8	CANCLKSRC	R/W	0h	CANCLKSRC selects the CANCLK source. 0h = CANCLK source is HFCLK 1h = CANCLK source is SYSPLLCLK1
7	EXCLKDIVEN	R/W	0h	EXCLKDIVEN enables or disables the divider function of the CLK_OUT external clock output block. 0h = Clock divider is disabled (passthrough, EXCLKDIVVAL is not applied) 1h = Clock divider is enabled (EXCLKDIVVAL is applied)
6-4	EXCLKDIVVAL	R/W	0h	EXCLKDIVVAL selects the divider value for the divider in the CLK_OUT external clock output block. 0h = CLK_OUT source is divided by 2 1h = CLK_OUT source is divided by 4 2h = CLK_OUT source is divided by 6 3h = CLK_OUT source is divided by 8 4h = CLK_OUT source is divided by 10 5h = CLK_OUT source is divided by 12 6h = CLK_OUT source is divided by 14 7h = CLK_OUT source is divided by 16
3	RESERVED	R	0h	
2-0	EXCLKSRC	R/W	0h	EXCLKSRC selects the source for the CLK_OUT external clock output block. ULPCLK and MFPCLK require the CLK_OUT divider (EXCLKDIVEN) to be enabled 0h = CLK_OUT is SYSOSC 1h = CLK_OUT is ULPCLK (EXCLKDIVEN must be enabled) 2h = CLK_OUT is LFCLK 3h = CLK_OUT is MFPCLK (EXCLKDIVEN must be enabled) 4h = CLK_OUT is HFCLK 5h = CLK_OUT is SYSPLLCLK1 (SYSPLLCLK1 must be <=48MHz)

Bit	Field	Type	Reset	Description
31	ANACKERR	R	0h	ANACKERR is set when the device clock configuration does not support an enabled analog peripheral mode and the analog peripheral may not be functioning as expected. 0h = No analog clock errors detected 1h = Analog clock error detected
30	RESERVED	R	0h	
29	SYSPLLBLKUPD	R	0h	SYSPLLBLKUPD indicates when writes to SYSPLLCFG0/1 and SYSPLLPARAM0/1 are blocked. 0h = writes to SYSPLLCFG0/1 and SYSPLLPARAM0/1 are allowed 1h = writes to SYSPLLCFG0/1 and SYSPLLPARAM0/1 are blocked
28	HFCLKBLKUPD	R	0h	HFCLKBLKUPD indicates when writes to the HFCLKCLKCFG register are blocked. 0h = Writes to HFCLKCLKCFG are allowed 1h = Writes to HFCLKCLKCFG are blocked
27-26	RESERVED	R	0h	
25	FCCDONE	R	0h	FCCDONE indicates when a frequency clock counter capture is complete. 0h = FCC capture is not done 1h = FCC capture is done
24	FCLMODE	R	0h	FCLMODE indicates if the SYSOSC frequency correction loop (FCL) is enabled. 0h = SYSOSC FCL is disabled 1h = SYSOSC FCL is enabled
23	LFCLKFAIL	R	0h	LFCLKFAIL indicates when the continuous LFCLK monitor detects a LFXT or LFCLK_IN clock stuck failure. 0h = No LFCLK fault detected 1h = LFCLK stuck fault detected
22	RESERVED	R	0h	

**Table 2-182. CLKSTATUS Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
21	HSCLKGOOD	R	0h	HSCLKGOOD is set by hardware if the selected clock source for HSCLK started successfully. 0h = The HSCLK source did not start correctly 1h = The HSCLK source started correctly
20	HSCLKDEAD	R	0h	HSCLKDEAD is set by hardware if the selected source for HSCLK was started but did not start successfully. 0h = The HSCLK source was not started or started correctly 1h = The HSCLK source did not start correctly
19-18	RESERVED	R	0h	
17	CURMCLKSEL	R	0h	CURMCLKSEL indicates if MCLK is currently sourced from LFCLK. 0h = MCLK is not sourced from LFCLK 1h = MCLK is sourced from LFCLK
16	CURHSCLKSEL	R	0h	CURHSCLKSEL indicates the current clock source for HSCLK. 0h = HSCLK is currently sourced from the SYSPLL 1h = HSCLK is currently sourced from the HFCLK
15	RESERVED	R	0h	
14	SYSPLLOFF	R	0h	SYSPLLOFF indicates if the SYSPLL is disabled or was dead at startup. When the SYSPLL is started, SYSPLLOFF is cleared by hardware. Following startup of the SYSPLL, if the SYSPLL startup monitor determines that the SYSPLL was not started correctly, SYSPLLOFF is set. 0h = SYSPLL started correctly and is enabled 1h = SYSPLL is disabled or was dead startup
13	HFCLKOFF	R	0h	HFCLKOFF indicates if the HFCLK is disabled or was dead at startup. When the HFCLK is started, HFCLKOFF is cleared by hardware. Following startup of the HFCLK, if the HFCLK startup monitor determines that the HFCLK was not started correctly, HFCLKOFF is set. 0h = HFCLK started correctly and is enabled 1h = HFCLK is disabled or was dead at startup
12	HSCLKSOFF	R	0h	HSCLKSOFF is set when the high speed clock sources (SYSPLL, HFCLK) are disabled or dead. It is the logical AND of HFCLKOFF and SYSPLLOFF. 0h = SYSPLL, HFCLK, or both were started correctly and remain enabled 1h = SYSPLL and HFCLK are both either off or dead
11	LFOSCGOOD	R	0h	LFOSCGOOD indicates when the LFOSC startup has completed and the LFOSC is ready for use. 0h = LFOSC is not ready 1h = LFOSC is ready
10	LFXTGOOD	R	0h	LFXTGOOD indicates if the LFXT started correctly. When the LFXT is started, LFXTGOOD is cleared by hardware. After the startup settling time has expired, the LFXT status is tested. If the LFXT started successfully the LFXTGOOD bit is set, else it is left cleared. 0h = LFXT did not start correctly 1h = LFXT started correctly
9	SYSPLLGOOD	R	0h	SYSPLLGOOD indicates if the SYSPLL started correctly. When the SYSPLL is started, SYSPLLGOOD is cleared by hardware. After the startup settling time has expired, the SYSPLL status is tested. If the SYSPLL started successfully the SYSPLLGOOD bit is set, else it is left cleared. 0h = SYSPLL did not start correctly 1h = SYSPLL started correctly
8	HFCLKGOOD	R	0h	HFCLKGOOD indicates that the HFCLK started correctly. When the HFXT is started or HFCLK_IN is selected as the HFCLK source, this bit will be set by hardware if a valid HFCLK is detected, and cleared if HFCLK is not operating within the expected range. 0h = HFCLK did not start correctly 1h = HFCLK started correctly

**Table 2-182. CLKSTATUS Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7-6	LFCLKMUX	R	0h	LFCLKMUX indicates if LFCLK is sourced from the internal LFOSC, the low frequency crystal (LFXT), or the LFCLK_IN digital clock input. 0h = LFCLK is sourced from the internal LFOSC 1h = LFCLK is sourced from the LFXT (crystal) 2h = LFCLK is sourced from LFCLK_IN (external digital clock input)
5	RESERVED	R	0h	
4	HSCLKMUX	R	0h	HSCLKMUX indicates if MCLK is currently sourced from the high-speed clock (HSCLK). 0h = MCLK is not sourced from HSCLK 1h = MCLK is sourced from HSCLK
3-2	RESERVED	R	0h	
1-0	SYSOSCFREQ	R	0h	SYSOSCFREQ indicates the current SYSOSC operating frequency. 0h = SYSOSC is at base frequency (32MHz) 1h = SYSOSC is at low frequency (4MHz) 2h = SYSOSC is at the user-trimmed frequency (16 or 24MHz) 3h = Reserved

Bit	Field	Type	Reset	Description
6	PMUIREFGOOD	R	0h	PMUIREFGOOD is set by hardware when the PMU current reference is ready. 0h = IREF is not ready 1h = IREF is ready
5	ANACPUMPGOOD	R	0h	ANACPUMPGOOD is set by hardware when the VBOOST analog mux charge pump is ready. 0h = VBOOST is not ready 1h = VBOOST is ready
4	BORLVL	R	0h	BORLVL indicates if a BOR event occurred and the BOR threshold was switched to BOR0 by hardware. 0h = No BOR violation occurred 1h = A BOR violation occurred and the BOR threshold was switched to BOR0
3-2	BORCURTHRESHOLD	R	0h	BORCURTHRESHOLD indicates the active brown-out reset supply monitor configuration. 0h = Default minimum threshold; a BOR0- violation triggers a BOR 1h = A BOR1- violation generates a BORLVL interrupt 2h = A BOR2- violation generates a BORLVL interrupt 3h = A BOR3- violation generates a BORLVL interrupt
1	FLASHSEC	R	0h	FLASHSEC indicates if a flash ECC single bit error was detected and corrected (SEC). 0h = No flash ECC single bit error detected 1h = Flash ECC single bit error was detected and corrected
0	FLASHDED	R	0h	FLASHDED indicates if a flash ECC double bit error was detected (DED). 0h = No flash ECC double bit error detected 1h = Flash ECC double bit error detected

### 33 DEDERRADDR (Offset = 120Ch) [Reset = 0000000h]

DEDERRADDR is shown in [Figure 2-93](#) and described in [Table 2-104](#).

Return to the [Summary Table](#).

Memory DED Address

**Figure 2-93. DEDERRADDR**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Table 2-246. SYSOSCCFG Field Descriptions**

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	
17	FASTCPUEVENT	R/W	1h	FASTCPUEVENT may be used to assert a fast clock request when an interrupt is asserted to the CPU, reducing interrupt latency. 0h = An interrupt to the CPU will not assert a fast clock request 1h = An interrupt to the CPU will assert a fast clock request
16	BLOCKASYNCALL	R/W	0h	BLOCKASYNCALL may be used to mask block all asynchronous fast clock requests, preventing hardware from dynamically changing the active clock configuration when operating in a given mode. 0h = Asynchronous fast clock requests are controlled by the requesting peripheral 1h = All asynchronous fast clock requests are blocked
15-11	RESERVED	R	0h	
10	DISABLE	R/W	0h	DISABLE sets the SYSOSC enable/disable policy. SYSOSC may be powered off in RUN, SLEEP, and STOP modes to reduce power consumption. When SYSOSC is disabled, MCLK and ULPCCLK are sourced from LFCLK. 0h = Do not disable SYSOSC 1h = Disable SYSOSC immediately and source MCLK and ULPCCLK from LFCLK
9	DISABLESTOP	R/W	0h	DISABLESTOP sets the SYSOSC stop mode enable/disable policy. When operating in STOP mode, the SYSOSC may be automatically disabled. When set, ULPCCLK will run from LFCLK in STOP mode and SYSOSC will be disabled to reduce power consumption. 0h = Do not disable SYSOSC in STOP mode 1h = Disable SYSOSC in STOP mode and source ULPCCLK from LFCLK
8	USE4MHZSTOP	R/W	0h	USE4MHZSTOP sets the SYSOSC stop mode frequency policy. When entering STOP mode, the SYSOSC frequency may be automatically switched to 4MHz to reduce SYSOSC power consumption. 0h = Do not gear shift the SYSOSC to 4MHz in STOP mode 1h = Gear shift SYSOSC to 4MHz in STOP mode

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	
22	MCLKDEADCHK	R/W	0h	MCLKDEADCHK enables or disables the continuous MCLK dead check monitor. LFCLK must be running before MCLKDEADCHK is enabled. 0h = The MCLK dead check monitor is disabled 1h = The MCLK dead check monitor is enabled
21	STOPCLKSTBY	R/W	0h	STOPCLKSTBY sets the STANDBY mode policy (STANDBY0 or STANDBY1). When set, ULPCCLK and LFCLK are disabled to all peripherals in STANDBY mode, with the exception of TIMG0 and TIMG1 which continue to run. Wake-up is only possible via an asynchronous fast clock request. 0h = ULPCCLK/LFCLK runs to all PD0 peripherals in STANDBY mode 1h = ULPCCLK/LFCLK is disabled to all peripherals in STANDBY mode except TIMG0 and TIMG1
20	USELFCLK	R/W	0h	USELFCLK sets the MCLK source policy. Set USELFCLK to use LFCLK as the MCLK source. Note that setting USELFCLK does not disable SYSOSC, and SYSOSC remains available for direct use by analog modules. 0h = MCLK will not use the low frequency clock (LFCLK) 1h = MCLK will use the low frequency clock (LFCLK)
19-17	RESERVED	R	0h	
16	USEHSCLK	R/W	0h	USEHSCLK, together with USELFCLK, sets the MCLK source policy. Set USEHSCLK to use HSCLK (HFCLK or SYSPLL) as the MCLK source in RUN and SLEEP modes. 0h = MCLK will not use the high speed clock (HSCLK) 1h = MCLK will use the high speed clock (HSCLK) in RUN and SLEEP mode
15-13	RESERVED	R	0h	

**Table 2-248. MCLKCFG Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12	USEMFTICK	R/W	0h	USEMFTICK specifies whether the 4MHz constant-rate clock (MFCLK) to peripherals is enabled or disabled. When enabled, MDIV must be disabled (set to 0h=/1). 0h = The 4MHz rate MFCLK to peripherals is enabled 1h = The 4MHz rate MFCLK to peripherals is disabled.
11-8	FLASHWAIT	R/W	2h	FLASHWAIT specifies the number of flash wait states when MCLK is sourced from HSCLK. FLASHWAIT has no effect when MCLK is sourced from SYSOSC or LFCLK. 0h = No flash wait states are applied 1h = One flash wait state is applied 2h = 2 flash wait states are applied
7-6	RESERVED	R	0h	
5-4	UDIV	R/W	1h	UDIV specifies the ULPCLK divider when MCLK is sourced from HSCLK. UDIV has no effect when MCLK is sourced from SYSOSC or LFCLK. 0h = ULPCLK is not divided and is equal to MCLK 1h = ULPCLK is MCLK/2 (divided-by-2)
3-0	MDIV	R/W	0h	MDIV may be used to divide the MCLK frequency when MCLK is sourced from SYSOSC. MDIV=0h corresponds to /1 (no divider). MDIV=1h corresponds to /2 (divide-by-2). MDIV=Fh corresponds to /16 (divide-by-16). MDIV may be set between /1 and /16 on an integer basis.

### 13 HSCLKEN (Offset = 1108h) [Reset = 0000XXXXh]

HSCLKEN is shown in [Figure 2-124](#) and described in [Table 2-137](#).

Return to the [Summary Table](#).

High-speed clock (HSCLK) source enable/disable

**Table 2-282. CLKSTATUS Field Descriptions**

Bit	Field	Type	Reset	Description
31	ANACKERR	R	0h	ANACKERR is set when the device clock configuration does not support an enabled analog peripheral mode and the analog peripheral may not be functioning as expected. 0h = No analog clock errors detected 1h = Analog clock error detected
30	RESERVED	R	0h	
29	SYSPLLBLKUPD	R	0h	SYSPLLBLKUPD indicates when writes to SYSPLLCFG0/1 and SYSPLLPARAM0/1 are blocked. 0h = writes to SYSPLLCFG0/1 and SYSPLLPARAM0/1 are allowed 1h = writes to SYSPLLCFG0/1 and SYSPLLPARAM0/1 are blocked
28	HFCLKBLKUPD	R	0h	HFCLKBLKUPD indicates when writes to the HFCLKCLKCFG register are blocked. 0h = Writes to HFCLKCLKCFG are allowed 1h = Writes to HFCLKCLKCFG are blocked
27-26	RESERVED	R	0h	
25	FCCDONE	R	0h	FCCDONE indicates when a frequency clock counter capture is complete. 0h = FCC capture is not done 1h = FCC capture is done
24	FCLMODE	R	0h	FCLMODE indicates if the SYSOSC frequency correction loop (FCL) is enabled. 0h = SYSOSC FCL is disabled 1h = SYSOSC FCL is enabled
23	LFCLKFAIL	R	0h	LFCLKFAIL indicates when the continuous LFCLK monitor detects a LFXT or LFCLK_IN clock stuck failure. 0h = No LFCLK fault detected 1h = LFCLK stuck fault detected
22	RESERVED	R	0h	

**Table 2-282. CLKSTATUS Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
21	HSCLKGOOD	R	0h	HSCLKGOOD is set by hardware if the selected clock source for HSCLK started successfully. 0h = The HSCLK source did not start correctly 1h = The HSCLK source started correctly
20	HSCLKDEAD	R	0h	HSCLKDEAD is set by hardware if the selected source for HSCLK was started but did not start successfully. 0h = The HSCLK source was not started or started correctly 1h = The HSCLK source did not start correctly
19-18	RESERVED	R	0h	
17	CURMCLKSEL	R	0h	CURMCLKSEL indicates if MCLK is currently sourced from LFCLK. 0h = MCLK is not sourced from LFCLK 1h = MCLK is sourced from LFCLK
16	CURHSCLKSEL	R	0h	CURHSCLKSEL indicates the current clock source for HSCLK. 0h = HSCLK is currently sourced from the SYSPLL 1h = HSCLK is currently sourced from the HFCLK
15	RESERVED	R	0h	
14	SYSPLLOFF	R	0h	SYSPLLOFF indicates if the SYSPLL is disabled or was dead at startup. When the SYSPLL is started, SYSPLLOFF is cleared by hardware. Following startup of the SYSPLL, if the SYSPLL startup monitor determines that the SYSPLL was not started correctly, SYSPLLOFF is set. 0h = SYSPLL started correctly and is enabled 1h = SYSPLL is disabled or was dead startup
13	HFCLKOFF	R	0h	HFCLKOFF indicates if the HFCLK is disabled or was dead at startup. When the HFCLK is started, HFCLKOFF is cleared by hardware. Following startup of the HFCLK, if the HFCLK startup monitor determines that the HFCLK was not started correctly, HFCLKOFF is set. 0h = HFCLK started correctly and is enabled 1h = HFCLK is disabled or was dead at startup
12	HSCLKSOFF	R	0h	HSCLKSOFF is set when the high speed clock sources (SYSPLL, HFCLK) are disabled or dead. It is the logical AND of HFCLKOFF and SYSPLLOFF. 0h = SYSPLL, HFCLK, or both were started correctly and remain enabled 1h = SYSPLL and HFCLK are both either off or dead
11	LFOSCGOOD	R	0h	LFOSCGOOD indicates when the LFOSC startup has completed and the LFOSC is ready for use. 0h = LFOSC is not ready 1h = LFOSC is ready
10	LFXTGOOD	R	0h	LFXTGOOD indicates if the LFXT started correctly. When the LFXT is started, LFXTGOOD is cleared by hardware. After the startup settling time has expired, the LFXT status is tested. If the LFXT started successfully the LFXTGOOD bit is set, else it is left cleared. 0h = LFXT did not start correctly 1h = LFXT started correctly
9	SYSPLLGOOD	R	0h	SYSPLLGOOD indicates if the SYSPLL started correctly. When the SYSPLL is started, SYSPLLGOOD is cleared by hardware. After the startup settling time has expired, the SYSPLL status is tested. If the SYSPLL started successfully the SYSPLLGOOD bit is set, else it is left cleared. 0h = SYSPLL did not start correctly 1h = SYSPLL started correctly
8	HFCLKGOOD	R	0h	HFCLKGOOD indicates that the HFCLK started correctly. When the HFXT is started or HFCLK_IN is selected as the HFCLK source, this bit will be set by hardware if a valid HFCLK is detected, and cleared if HFCLK is not operating within the expected range. 0h = HFCLK did not start correctly 1h = HFCLK started correctly

**Table 2-282. CLKSTATUS Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7-6	LFCLKMUX	R	0h	LFCLKMUX indicates if LFCLK is sourced from the internal LFOSC, the low frequency crystal (LFXT), or the LFCLK_IN digital clock input. 0h = LFCLK is sourced from the internal LFOSC 1h = LFCLK is sourced from the LFXT (crystal) 2h = LFCLK is sourced from LFCLK_IN (external digital clock input)
5	RESERVED	R	0h	
4	HSCLKMUX	R	0h	HSCLKMUX indicates if MCLK is currently sourced from the high-speed clock (HSCLK). 0h = MCLK is not sourced from HSCLK 1h = MCLK is sourced from HSCLK
3-2	RESERVED	R	0h	
1-0	SYSOSCFREQ	R	0h	SYSOSCFREQ indicates the current SYSOSC operating frequency. 0h = SYSOSC is at base frequency (32MHz) 1h = SYSOSC is at low frequency (4MHz) 2h = SYSOSC is at the user-trimmed frequency (16 or 24MHz) 3h = Reserved

### 30 SYSSTATUS (Offset = 1208h) [Reset = XXXX0XX0h]

SYSSTATUS is shown in [Figure 2-141](#) and described in [Table 2-154](#).

Return to the [Summary Table](#).

## 2.8 Quick Start Reference

The PMCU is designed to provide a simple, easy-to-use power management, clocking, and reset management functionality. This section describes the basic operating principles of the PMCU as well as tips and tricks for taking the default configuration out of reset and optimizing it for particular applications.

### 2.8.1 Default Device Configuration

The default operating configuration of the device provides basic functionality which can be suitable for many applications without modification.

MSPM0Gxx devices power up and release reset for execution of application code when the external supply (VDD and VSS) reaches 1.62V. When the application code is released for execution, the device is in RUN mode with MCLK, which is sourced from the internal SYSOSC at 32MHz. The CPUCLK and ULPCLK are also 32MHz, derived from MCLK. LFCLK starts automatically, sourced from the internal LFOSC. In RUN mode with the default configuration, all peripherals are available to be enabled. Peripherals such as the DMA, CRC, and AES run directly from MCLK at the MCLK rate. Other peripherals, such as timers and serial interfaces, can run from the bus clock at 32MHz or from the low-frequency 32kHz clock (LFCLK) based on their [peripheral clock selection](#).

Power consumption can be reduced by entering SLEEP, STOP, STANDBY, or SHUTDOWN mode. By default, these modes behave in the following way:

- In SLEEP mode, the CPUCLK is disabled but all peripherals, including the DMA, continue to run as configured at either 32MHz or 32kHz. This power mode is designed for scenarios where PD1 peripherals are used and having the lowest possible wakeup latency is more important than having the lowest power consumption.

- In STOP mode, (STOP0 by default), the MCLK source to PD1 peripherals is disabled and PD1 peripherals are disabled and in retention (unavailable for use). The default STOP mode is designed for scenarios where power optimization is important but the ADC, OPA, DAC, or a clock faster than 32kHz is needed.
  - SYSOSC by default will continue to run at 32MHz the max operating frequency, but the MCLK tree will run at 4MHz (SYSOSC/8) and peripherals in PD0 which are still active will see the bus clock (ULPCLK) change from 32MHz to 4MHz.
  - PD0 peripherals configured to run from LFCLK continue to run at 32kHz.
  - All OPA modes can be used
  - The ADC will always see SYSOSC at 32MHz for sampling
- In STANDBY mode (STANDBY0 by default), the MCLK tree runs from LFCLK at 32kHz and SYSOSC is disabled. PD0 peripherals running from the bus clock change to 32kHz. PD0 peripherals running from LFCLK continue to run at 32kHz with no change.

### 2.8.2 Leveraging MFCLK

When running with the default PMCU configuration, timers and serial interfaces can select either the bus clock (MCLK/ULPCLK) or the LFCLK as their clock source. LFCLK is always 32kHz in RUN, SLEEP, STOP, and STANDBY, but MCLK/ULPCLK changes to 4MHz in STOP and to 32kHz in STANDBY, meaning that peripherals running from the bus clock see the source clock frequency change when transitioning power modes.

MFCLK, by contrast, works like LFCLK in that it provides a constant frequency clock source for peripherals across RUN, SLEEP, and STOP modes. MFCLK provides a constant 4MHz as an alternative to LFCLK which runs at 32kHz. The 4MHz time base for MFCLK is always derived from SYSOSC. Peripherals, specifically PD0 peripherals that can be used in STOP mode, can select MFCLK as their clock source instead of ULPCLK. MFCLK is maintained at 4MHz in RUN, SLEEP and STOP for peripherals like UART, I2C, and low-power timers that need a consistent clock but require a clock source greater than 32kHz.

For information on using MFCLK, see the [MFCLK section](#).

### 2.8.3 Optimizing Power Consumption in STOP Mode

The STOP mode provides considerable flexibility for tailoring the device to an application's specific power and performance requirements. There are several options available for reducing power consumption in STOP mode:

- Enable SYSOSC gear shift mode in STOP to reduce SYSOSC current. In STOP mode, the MCLK tree (and ULPCLK) are always limited to 4MHz maximum. By default, SYSOSC runs in STOP mode at 32MHz (base frequency) with a divide-by-8 to meet the 4MHz max frequency limit in STOP mode. Alternatively, SYSOSC can be gear shifted to run natively at 4MHz in STOP mode (STOP1), saving SYSOSC current. See [SYSOSC gear shift mode](#).
- If a 32kHz clock is sufficient to run the needed peripherals, it is possible to run in STOP mode with MCLK sourced from LFCLK at 32kHz. SYSOSC can be disabled to conserve power. To disable SYSOSC in STOP mode and run from LFCLK (STOP2), see [disabling SYSOSC](#) and [operating mode selection](#).

### 2.8.4 Optimizing Power Consumption in STANDBY Mode

In STANDBY mode, if only RTC, TIMG0, TIMG1, or asynchronous fast wake from GPIO, comparator (low-power mode), or a serial interface is desired, the lowest possible power consumption can be achieved by configuring the ULPCLK and LFCLK to be disabled when entering STANDBY, leaving only the RTC, TIMG0, TIMG1, (STANDBY1). See the [LFCLK section](#). In this state, RTC, TIMG0, TIMG1, or asynchronous activity/event will trigger an [asynchronous fast clock request](#) to wake the system.

### 2.8.5 Increasing MCLK Precision

If an application requires high clocking accuracy for high-frequency peripherals, the best accuracy is achieved by using an external high-frequency crystal with the [HFXT](#) and sourcing the MCLK tree directly from HFCLK. By sourcing the MCLK directly from HFCLK, the bus clock to all peripherals in PD1 and PD0 will be the HFCLK.

Crystal frequencies up to 48MHz are supported by the HFXT, but because PD0 peripherals using ULPCLK are limited to 40MHz, 40MHz is the highest crystal frequency supported to run the PD1 and PD0 peripherals at the

same frequency. If a 48MHz crystal is used, PD1 peripherals and the CPUCLK can run at 48MHz directly from the crystal, but PD0 peripherals must run at MCLK/2 (24MHz).

If precision clocking is needed for the CAN-FD controller or the ADC (for sampling window generation), and high CPU performance (high MCLK) is also required, it is also possible to source the CAN-FD controller (CANCLK) and the ADC sampling clock (ADCCLK) from HFCLK directly, asynchronous to MCLK, while running MCLK at maximum frequency using the PLL for best compute performance.

### 2.8.6 Configuring MCLK for Maximum Speed

The best CPU compute performance is obtained by using the SYSPLL to generate an 80MHz clock from either the SYSOSC reference or HFXT. To configure the SYSPLL to generate an 80MHz output sourcing MCLK, see the [SYSPLL configuration section](#).

Running MCLK at 80MHz also provides the best possible timer resolution for TIMA and TIMG peripherals in the PD1 domain (12.5ns).

### 2.8.7 High Speed Clock (SYSPLL, HFCLK) Handling in Low-Power Modes

The [SYSPLL](#) and [HFCLK](#) (HFXT, HFCLK\_IN) high speed clock sources are not supported in the [STOP](#) and [STANDBY](#) operating modes. When a high-speed clock source ([SYSPLL](#), [HFCLK](#)) is enabled, entering either the STOP mode or STANDBY mode will cause SYSCTL to automatically disable the SYSPLL and/or HFCLK before entering STOP or STANDBY mode. Upon exit from STOP or STANDBY mode to RUN mode, SYSCTL will automatically re-enable the SYSPLL and/or HFCLK if they were previously enabled before entering the low-power mode.

Before entering STOP or STANDBY for the first time after enabling the SYSPLL or HFCLK, and after waking up from STOP or STANDBY mode, application software must wait to enter STOP or STANDBY mode until any previously enabled high speed clock sources have completed startup.

Application software must check the following before entering STOP or STANDBY mode:

- If the **SYSPLL was enabled**, then application software must wait for the SYSPLL to complete startup. When the SYSPLL startup is complete, the SYSPLLGOOD bit will be set in the CLKSTATUS register in SYSCTL. If the SYSPLL fails to start, the SYSPLLOFF bit will be set instead. The SYSPLLOFF bit indicates that the SYSPLL was dead at startup or was not previously enabled. Ensure that either SYSPLLGOOD or SYSPLLOFF is set before attempting to enter STOP or STANDBY.
- If the **HFCLK was enabled**, then application software must wait for the HFCLK to complete startup. When the HFCLK startup is complete, the HFCLKGOOD bit will be set in the CLKSTATUS register in SYSCTL. If the HFCLK fails to start, the HFCLKOFF bit will be set instead. The HFCLKOFF bit indicates that the HFCLK was dead at startup or was not previously enabled. Ensure that either HFCLKGOOD or HFCLKOFF is set before attempting to enter STOP or STANDBY.

In the event that the MCLK was configured to be sourced from HSCLK before entry to STOP or STANDBY, upon exit from STOP or STANDBY the MCLK will be sourced from SYSOSC initially and the CPU will be released to begin executing code at the SYSOSC frequency. SYSCTL will automatically restore the MCLK configuration to the previously selected high-speed clock when the high-speed clock has started and is ready for use. When MCLK switches back to the high-speed clock, SYSCTL will generate an HSCLK GOOD interrupt to alert the application that MCLK is again running from the high-speed clock.

### 2.8.8 Optimizing for Lowest Wakeup Latency

To ensure the lowest possible wakeup latency from STOP or STANDBY mode to RUN mode, set MCLK to SYSOSC with SYSOSC running at base frequency (32MHz) before entering STOP or STANDBY. SYSOSC always starts at base frequency and latency is minimized if SYSOSC does not need to change to an alternate frequency.

### 2.8.9 Optimizing for Lowest Peak Current in RUN/SLEEP Mode

In applications which are peak current limited, there are two options for reducing active current in RUN and SLEEP modes:

- If 32kHz provides sufficient performance, run MCLK from LFCLK. MCLK can be selected to run from LFCLK with SYSOSC disabled. If no fast handling of events is needed, SYSOSC asynchronous requests can be disabled to ensure that the device always runs from LFCLK. This provides the lowest possible current with the CPU still running (RUN2). See the [MCLK](#), [SYSOSC](#), and [Operating Mode Selection](#) sections.
- If 32kHz does not provide sufficient performance, MCLK can be selected to run from SYSOSC with SYSOSC set to low frequency (4MHz). With MCLK running from SYSOSC, the MDIV divider for MCLK can be applied to reduce current consumption. For example, MCLK can be configured to run as low as 250kHz by setting MDIV to /16 when sourced from SYSOSC running at 4MHz. See the [MCLK](#) section.

The CPU subsystem (MCPUSS) includes the Arm Cortex-M0+ processor, the interrupt logic, and the prefetch and cache logic.

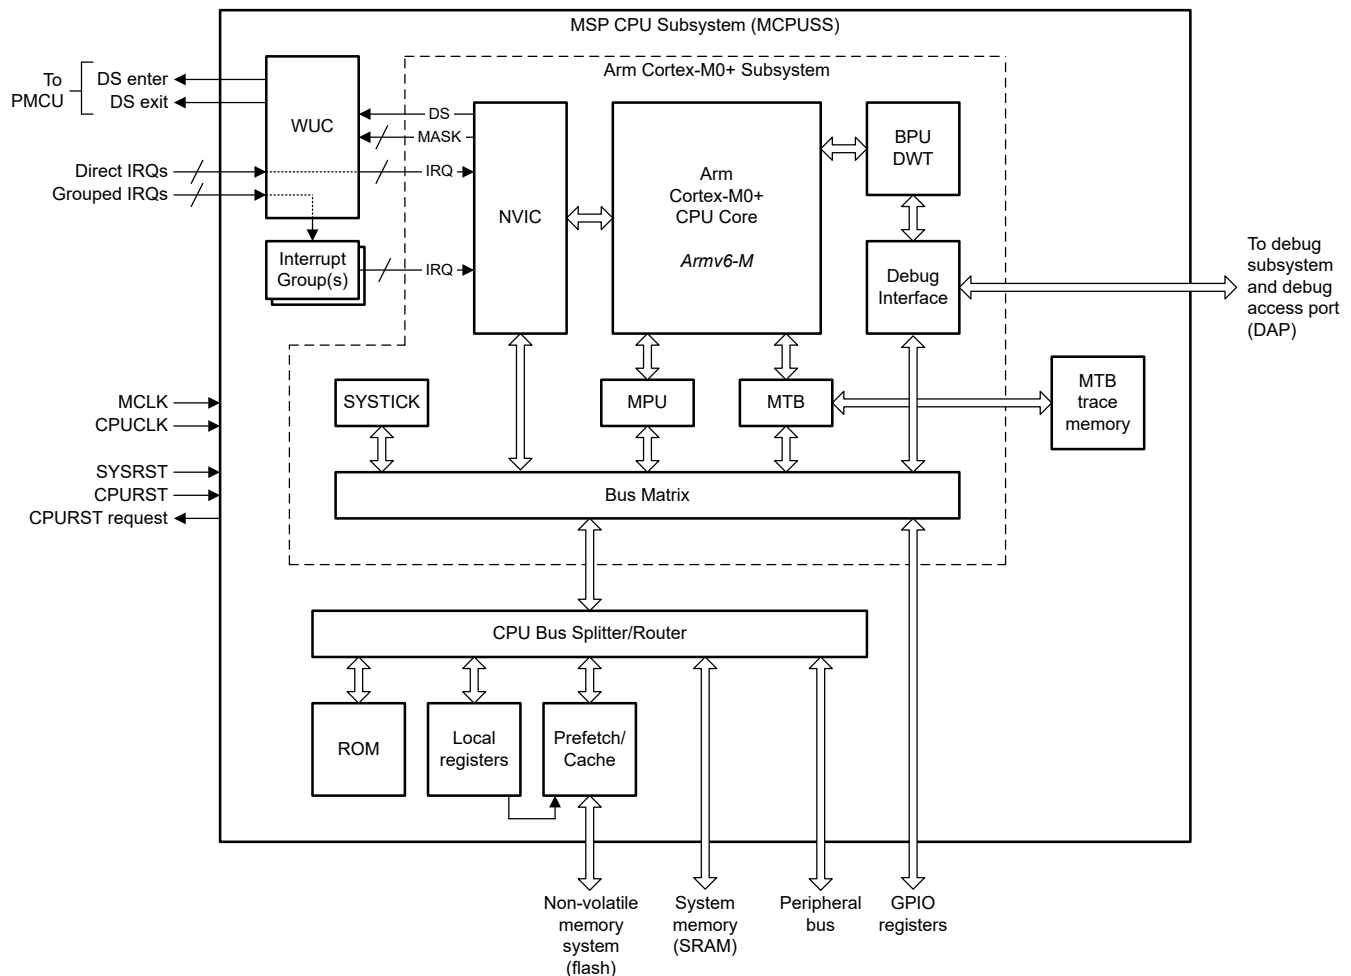

<b>3.1 Overview</b> .....	<b>450</b>
<b>3.2 Arm Cortex-M0+ CPU</b> .....	<b>450</b>

<b>3.7 WUC Registers</b> .....	<b>500</b>

### 3.1 Overview

The MSP CPU subsystem (MCPUSS) contains the central processing unit (CPU) along with associated supporting logic and read-only memory (ROM). The functional blocks that comprise the MCPUSS include:

- The Arm Cortex-M0+ 32-bit CPU and internal peripherals
- The CPU bus splitter and router
- The interrupt management logic and **DEEPSLEEP** entry and exit logic
- The nonvolatile memory system prefetch and cache logic
- The CPU debug interface to the debug subsystem (**DEBUGSS**)
- The **processor trace memory**
- The **read-only memory** (ROM) used for the BCR and BSL

The top level architecture of the MCPUSS is shown in [Figure 3-1](#).

**Figure 3-1. MSPM0Gxx MCPUSS Top Level Diagram**

### 3.2 Arm Cortex-M0+ CPU

The MCPUSS contains an energy-efficient Arm Cortex-M0+ CPU implementing the Armv6-M instruction set architecture (ISA) with support for CPU clock speeds up to 80MHz. The Cortex-M0+ is a Von Neumann style 32-bit processor with a 2-stage ultra-low power pipeline and a single-cycle access port to the GPIO registers for efficient GPIO manipulation.

The Cortex-M0+ implementation on MSPM0Gxx devices has the following features:

- Up to 80MHz execution frequency

- Little-endian (least significant byte at lowest byte address location)
- Support for 32-bit word instruction fetches
- Single cycle 32×32 multiply instruction
- Tightly integrated memory protection unit (MPU)
- User and privileged execution modes
- Integrated 24-bit system tick timer (SYSTICK)
- Four hardware breakpoints and two hardware watchpoints for debug
- Micro trace buffer
- Reset-all-registers support
- Vector table offset support

The Cortex-M0+ architecture enables excellent code density, deterministic interrupt handling, and upwards compatibility with other processor architectures in the Arm Cortex-M family.

A general overview of the Arm Cortex-M0+ is given in this section to provide a basic understanding of the features of the processor. For detailed information on developing with the Arm Cortex-M0+ processor, refer to the *Arm Cortex-M0+ Devices Generic User's Guide*.

### 3.2.1 CPU Register File

The Arm Cortex-M0+ processor instructions operate on registers in the CPU register file. The processor contains a register file consisting of 16 standard registers and 3 special registers as shown in [Figure 3-2](#).

**Figure 3-2. CPU Registers**

### General Purpose Registers (R0-R12)

The processor provides 13 general purpose registers, R0-R12, for operating on data. Registers R0 to R7 (low registers) are accessible by all instructions which specify a general purpose register. Registers R8 to R12 (high registers) are not accessible by 16-bit instructions but are accessible by any 32-bit instructions which specify a general purpose register.

### Stack Pointer Register (R13)

The stack pointer is contained in R13, and can contain the main stack pointer (MSP) or the process stack pointer (PSP). When the processor is running in handler mode, the main stack pointer (MSP) is always used. When the processor is running in thread mode, the MSP or the process stack pointer (PSP) can be used, depending on the configuration of the SPSEL bit in the CONTROL register.

After a CPURST, the processor automatically and unconditionally fetches the default stack pointer from the first address of main flash (0x0000.0000) as the main stack pointer (MSP).

## Link Register (R14)

R14 serves as the link register and contains the return value of function calls as well as exceptions. The link register must be set before being used as it is not reset to any known value. It is accessible in privileged and unprivileged mode.

## Program Counter Register (R15)

The program counter register (R15) contains the address of the next instruction to be executed. The PC is accessible in privileged and unprivileged mode.

After a CPURST, the processor automatically and unconditionally fetches the default PC from the second word of main flash (0x0000.0004).

## Special Registers

Special registers include the program status register (PSR), the interrupt mask register (PRIMASK), and the control register (CONTROL). Special registers are typically accessed by using the CPS, MRS, and MSR system instructions.

- **Program Status Register (PSR):** The PSR is a combination of the application status (APSR), interrupt status (IPSR), and execution status (EPSR) registers. Application software can access the PSR with MRS and MSR instructions, accessing either the complete PSR or a combination of one or more registers, with some restrictions. The PSR registers can be accessed with MRS and MSR instructions using the mnemonics given in [Table 3-1](#).
  - The application status register (APSR) contains the N, Z, C, and V flags which are used by the processor to evaluate conditional branch instructions. These bits are located in BIT31, BIT30, BIT29, and BIT28 of the PSR, respectively.
  - The interrupt status register (IPSR) reports the current exception number for a currently executing exception when in handler mode. In thread mode it reads as zero. The processor ignores writes to this register. The exception number field is presented in from BIT0 to BIT5 of the PSR.
  - The execution status register (EPSR) contains the T bit (BIT24), which defines whether the processor is in Thumb state. This bit cannot be read or written by software, but it is used by the processor.
- **Interrupt Mask Register (PRIMASK):** BIT0 of the PRIMASK register (PM) can be used to mask all interrupts to the processor which have configurable priority (see [Section 3.3](#)). This can be thought of as a global peripheral interrupt mask control. The processor ignores unprivileged writes to PRIMASK. Clearing PM to 0 enables interrupts. Setting PM to 1 disables interrupts. The CPS instruction can be used to change the PM bit value in the PRIMASK register.
- **Control Register (CONTROL):** The control register can be used to define whether code executing in thread mode is privileged or unprivileged by clearing or setting the nPRIV bit (BIT0), respectively. It can also be used to select the stack pointer used in R13 as either the main stack pointer (MSP) or process stack pointer (PSP) by clearing or setting the SPSEL bit (BIT1), respectively. A CPURST clears the CONTROL register to zero. The processor ignores unprivileged writes to the CONTROL register. The SPSEL stack pointer selection bit is updated by the processor automatically when entering and returning from exceptions. Note that software must implement an ISB barrier instruction after writing to CONTROL to ensure that any changes take effect before the next application instruction is executed by the processor.

**Table 3-1. Program Status Register (PSR) Access Mnemonics**

Mnemonic	Subregisters Included
APSR	APSR
IPSR	IPSR
EPSR	EPSR
IAPSR	IPSR and APSR
EAPSR	EPSR and APSR
XPSR	APSR, IPSR, EPSR

**Table 3-1. Program Status Register (PSR) Access Mnemonics (continued)**

Mnemonic	Subregisters Included
IEPSR	IPSR and EPSR

### 3.2.2 Stack Behavior

The Arm Cortex-M0+ processor implements a full descending stack protocol. The stack pointer register (SP) always indicates the location of the last stacked data. When new data is added to the call stack, the SP value is decremented and the data is written to the location indicated by the SP after being decremented.

The Arm Cortex-M0+ supports managing two independent stacks with two pointers: the main stack (MSP) and the process stack (PSP).

### 3.2.3 Execution Modes and Privilege Levels

The processor supports two primary modes of execution:

- **Thread mode** (for executing application software)
- **Handler mode** (for handling processor exceptions and peripheral interrupts)

By default, the processor is in thread mode out of reset. If an exception is issued to the processor, the processor will handle the exception in handler mode and return to thread mode after handler execution is complete. Code running in thread mode can be configured as being privileged or unprivileged, based on the configuration of the processor's internal CONTROL register. Code running in handler mode always executes as privileged.

In general, code which executes as privileged has complete control of the processor configuration, including control of the [MPU](#), [SysTick](#), [NVIC](#), and [SCB](#). Only privileged code can change the privilege level for code running in thread mode.

Code that is executing in thread mode in an unprivileged state cannot access the previously mentioned resources ([MPU](#), [SysTick](#), [NVIC](#), [SCB](#)) and can be subject to MPU restrictions if the MPU is configured and enabled.

### 3.2.4 Address Space and Supported Data Sizes

MSPM0 devices implement a flat memory map with a 32-bit byte-addressable address space. Byte addresses are unsigned numbers ranging from zero to  $2^{32}-1$ .

#### Address Space

The processor sees the address space as containing  $2^{30}$  32-bit words, with each word being word-aligned (4-byte aligned). Pointers are always 32 bits, and stack operations (for example, push, pop) increment the stack pointer by 4 addresses (4 bytes). Address calculations by the processor wrap around if they overflow or underflow the 32-bit memory space.

Instruction fetches by the processor are always 16-bit half-word aligned.

Data reads by the processor must be naturally aligned (for example, words must be word aligned, half words must be half-word aligned, etc.).

#### Supported Data Sizes

The processor supports 8-bit byte, 16-bit half-word, and 32-bit word data sizes. Signed and unsigned data is supported, and signed data is stored in CPU registers in 32-bit two's complement format. The Armv6-M instruction set does not provide native instructions supporting operations on 64-bit double-word data.

Load operations from memory to a CPU register can be signed or unsigned when the data size is less than 32 bits. When loading unsigned half-word or byte data to a CPU register, the value is zero-extended to 32 bits automatically. When loading signed half-word or byte data to a CPU register, the value is sign-extended to 32 bits automatically.

Stores from CPU registers to memory are sign agnostic.

All instruction and data accesses use little endian byte order.

### 3.3 Interrupts and Exceptions

Peripheral interrupt exceptions and system exceptions temporarily pause the processor's normal execution flow so that the processor can be used to handle an event.

The following can cause interruption of normal execution flow:

- A CPURST
- A nonmaskable interrupt (NMI, software trigger or hardware error signal from SYSCTL)
- A fault exception in the system (HardFault)
- Execution of a supervisor call instruction (SVCall)
- Setting of a pending supervisor service request (PendSV)
- A SysTick exception
- An enabled peripheral interrupt (IRQ)
- A breakpoint instruction (for debug)

#### Exception State

Each exception source to the processor will be in one of the below states at any given point in time:

- **Inactive** (not active, not pending)
- **Pending** (waiting to be serviced by the processor)
- **Active** (actively being serviced by the processor)
- **Active and pending** (actively being serviced by the processor when the same source generates another exception)

#### Exception Prioritization, Entry, and Exit

Exceptions are prioritized by the processor together with the nested vectored interrupt controller (NVIC). Each exception has either a fixed priority (reset, NMI, hard fault) or a configurable priority (SVCall, PendSV, SysTick, peripheral IRQs). Exceptions with configurable priority can be disabled by application software running in privileged mode. Exceptions with fixed priority cannot be disabled.

The processor exception model supports preemption, tail-chaining, and late-arrival features to boost exception handling performance:

- In the **preemption** case, if an exception of higher priority is pending when an exception of lower priority is executing, the higher priority exception will preempt the ongoing handler servicing the lower priority exception.
- In the **tail-chaining** case, if a valid-for-entry exception is pending at the time of completion of an exception handler, then the application context is not restored from the stack and control is given immediately to the pending exception.
- In the **late-arriving** case, if a higher priority exception occurs during entry to a lower priority exception, the higher priority exception will be serviced first after the processor state is saved to the stack. Once the higher priority exception handling is complete, the lower priority exception (which is still pending) is serviced based on the tail-chaining procedure.

An exception entry is issued if and when all of the following are true:

- An exception is in a **pending** state
- The priority of the pending exception is higher than the limit set by the exception mask register (PRIMASK)
- The processor is currently in either thread mode (not servicing an exception) or the newly pending exception is higher priority than the exception which is currently being serviced (resulting in a preemption)

Processor exceptions are vectored. When an exception occurs, the current processor state is pushed onto the stack which was active at the time of the event, and execution is vectored to the entry point address in the vector table corresponding to the exception which is to be processed.

If the exception is tail-chained to a previous handler which has completed, then there is no need to push any state to the stack and the interrupt service routine can be vectored to immediately. Likewise, if the exception is higher priority than a previous exception which started entry but did not complete entry, then there is no need to save the context again (late arrival).

Upon completion of an exception handler, if there is no exception pending which needs to be handled then the processor will pop the state from the stack and restore the processor to the previous state which it was in when the exception occurred.

### 3.3.1 Peripheral Interrupts (IRQs)

Peripheral interrupt functionality is managed by several components on the device:

- The nested vectored interrupt controller (NVIC)
- One or more interrupt groups (INT\_GROUP)
- The wake-up controller (WUC)

MSPM0 devices include an Arm nested vectored interrupt controller (NVIC) with the Cortex-M0+ CPU for managing peripheral interrupts. The NVIC operation is tightly integrated with the processor and supports up to 32 native peripheral interrupt sources.

In addition to the NVIC, interrupt grouping modules can be present on a device to enable interfacing of more than 32 peripheral interrupts to the NVIC. High-priority interrupt sources that might require preemption capability are mapped directly to the NVIC and behave like normal NVIC interrupts. Lower priority interrupt sources which do not commonly require preemption capability are mapped to an interrupt grouping module, the output of which is then mapped to the NVIC as a native NVIC interrupt source. This routing arrangement is shown in Figure 3-3.

Figure 3-3. Peripheral Interrupt Hierarchy

The wake-up controller (WUC) determines if the PD1 power domain (containing the processor) needs to be powered up to service a peripheral interrupt if the PD1 domain is powered down in STOP or STANDBY mode.

#### 3.3.1.1 Nested Vectored Interrupt Controller (NVIC)

The nested vectored interrupt controller (NVIC) is an industry-standard Arm component which interfaces peripheral interrupts (which are external to the processor) into the CPU. The NVIC supports connection of up to 32 native peripheral interrupt sources.

The NVIC is configured through memory-mapped registers in the system private peripheral bus (PPB) region. See Table 3-2 for the list of NVIC registers. The software development kit (SDK) provided with the devices supports the standard Arm Cortex Microcontroller Software Interface Standard (CMSIS) register access

definitions for the NVIC. Application software must use 32-bit aligned, word-size transactions when accessing any NVIC register.

In addition to interfacing peripheral interrupts to the processor, the NVIC also supports programmable priority for each interrupt.

### Enabling and Disabling Interrupts

Peripheral interrupt enables can be read, set, and cleared through the interrupt set-enable (ISER) and interrupt clear-enable (ICER) registers in the NVIC. The 32 interrupts are mapped to the ISER and ICER registers with interrupt zero in the BIT0 position (LSB) and interrupt 31 in the BIT31 position (MSB) of each register. To enable an interrupt, set the corresponding enable bit in the ISER register. Writing a '0' to ISER has no effect. It is possible to read the ISER register to determine which interrupts are enabled. Upon a read, a '1' indicates that an interrupt is enabled; a '0' indicates disabled. To disable an interrupt, set the corresponding enable bit in the ICER register. Writing a '0' to ICER has no effect.

---

#### Note

In addition to enabling a peripheral interrupt at the NVIC, it is generally necessary to also configure the interrupt configuration of the corresponding peripheral as well. Most peripherals have multiple interrupt sources, which are merged together in the peripheral to source a single NVIC interrupt. Masking of individual peripheral interrupts is done within the peripheral's interrupt management registers.

---

In the event that an interrupt is disabled in the NVIC, if the interrupt is asserted by the corresponding peripheral then the NVIC interrupt will go to a pending state but the processor is not interrupted. If an interrupt is disabled when in an active state (when a handler is running) it will remain active until the exception handler returns or a reset occurs, but no further activations will happen.

---

#### Note

If a peripheral asserts an interrupt to the NVIC, but that peripheral's interrupt in the NVIC is disabled, the device may remain in a higher power mode than expected as the wake-up controller (WUC) is holding an event for the processor. To prevent this situation, ensure peripheral interrupts are masked at the peripheral directly, versus only masking interrupts at the NVIC.

---

### Setting and Clearing Pending Interrupt Status

Pending interrupt status can be read, set, and cleared through the interrupt set-pending (ISPR) and interrupt clear-pending (ICPR) registers in the NVIC. The 32 interrupts are mapped to the ISPR and ICPR registers with interrupt zero in the BIT0 position (LSB) and interrupt 31 in the BIT31 position (MSB) of each register. To read if an interrupt is pending, read either the ISPR or the ICPR. Upon a read, a '1' indicates that an interrupt is pending; a '0' indicates not pending. To set an interrupt to a pending state through software, set the corresponding bit in the ISPR register. Writing a '0' to ISPR has no effect. To clear an interrupt pending state, set the corresponding bit in the ICPR register. Writing a '0' to ICPR has no effect. Note that if a peripheral interrupt condition is still present, the pending state will be set again by hardware even if it is cleared.

### Setting Interrupt Priority

Interrupts on the NVIC have programmable priority. There are four priority levels possible. Priority is set by programming the eight IPRx registers in the NVIC. Each priority field is 8 bits in length, and the priority for 4 interrupts is configured per 32-bit register. The Arm Cortex-M0+ only implements the most significant 2 bits of each 8-bit priority field (giving the 4 priority levels). Lower priority values have higher priority. System exceptions (reset, NMI, hard fault) have fixed priorities of -3, -2, and -1, respectively. As such, these exceptions always have higher priority than peripheral interrupts. Peripheral interrupt priorities are programmable as 0, 64, 128, or 192, with 0 being highest priority and 192 being lowest priority.

If the processor is currently handling an exception, it can only be preempted by a higher priority exception. In the event that there are multiple exceptions in a pending state which all have the same priority level assigned, the exception with the lowest exception number is taken first.

**Note**

Application software must not change the priority of an interrupt while the corresponding interrupt is either active (being handled) or enabled. Doing so can result in unpredictable behavior.

**Table 3-2. Arm Cortex-M0+ NVIC Registers**

Address	Register	CMSIS	Description
0xE000.E100	NVIC_ISER	NVIC->ISER[0]	Interrupt set-enable register
0xE000.E180	NVIC_ICER	NVIC->ICER[0]	Interrupt clear-enable register
0xE000.E200	NVIC_ISPR	NVIC->ISPR[0]	Interrupt set-pending register
0xE000.E280	NVIC_ICPR	NVIC->ICPR[0]	Interrupt clear-pending register
0xE000.E400	NVIC_IPR0	NVIC->IP[0]	Interrupt priority register (0-3)
0xE000.E404	NVIC_IPR1	NVIC->IP[1]	Interrupt priority register (4-7)
0xE000.E408	NVIC_IPR2	NVIC->IP[2]	Interrupt priority register (8-11)
0xE000.E40C	NVIC_IPR3	NVIC->IP[3]	Interrupt priority register (12-15)
0xE000.E410	NVIC_IPR4	NVIC->IP[4]	Interrupt priority register (16-19)
0xE000.E414	NVIC_IPR5	NVIC->IP[5]	Interrupt priority register (20-23)
0xE000.E418	NVIC_IPR6	NVIC->IP[6]	Interrupt priority register (24-27)
0xE000.E41C	NVIC_IPR7	NVIC->IP[7]	Interrupt priority register (28-31)

**3.3.1.2 Interrupt Groups**

To support mapping of more than 32 peripheral interrupt sources to the NVIC, certain MSPM0 devices include interrupt grouping logic (INT\_GROUP) in the MCPUSS to combine several interrupts together to source one native NVIC interrupt.

The INT\_GROUP interrupt grouping uses the MSPM0 event management register structure with the key difference being that all peripheral interrupt sources to the interrupt group are always unmasked (always enabled) such that no additional enable configuration is needed beyond the peripheral interrupt configuration and the NVIC configuration. The IMASK register itself is read-only and hardwired to enable all sources to the interrupt group. Figure 3-4 shows the INT\_GROUP structure.

**Figure 3-4. Interrupt Group (INT\_GROUP)**

Because no masking control is required, application software only needs to interface with the interrupt index (IIDX) register to efficiently handle a peripheral interrupt which is registered to the NVIC through an INT\_GROUP.

Application software can read the IIDX register in the INT\_GROUP to determine and clear the highest priority pending peripheral interrupt in the group. A read to IIDX will return an index corresponding to the highest priority peripheral which set an interrupt. The read action will also simultaneously clear the RIS and MIS bits

corresponding to the highest priority interrupt whose index was returned by the read. The value read from the IIDX register can then be used in a case statement, as shown below.

```
void GROUP_HANDLER(void)
{
    switch(IIDX)
    {
        case 0:          // no IRQ pending
            break;
        case 1:          // IRQ[0]
            do_peripheral_1_ISR();
            break;
        case 2:          // IRQ[1]
            do_peripheral_2_ISR();
            break;
        default:         // out of range
            illegal();
    }
}
```

## Usage

Because peripheral interrupts that are grouped together into an INT\_GROUP source a single NVIC interrupt, it is not possible to have one peripheral interrupt in a group preempt the execution of an active handler for the interrupt group. For example, take the scenario where the WWDT0 interrupt request line and the PMCU interrupt request line are connected to INT\_GROUP0, and INT\_GROUP0 sources NVIC peripheral interrupt 0. If the WWDT0 interrupt is asserted, INT\_GROUP0 will assert an interrupt request to the NVIC. If no higher priority interrupt is active, the NVIC will vector the processor to the INT\_GROUP0 handler. Application software can then read the INT\_GROUP0 IIDX register to determine that it was the WWDT0 that triggered the INT\_GROUP0 interrupt on the NVIC, and software can jump to the WWDT0 handler function.

If the PMCU asserts its interrupt line while the processor is still in handler mode servicing the WWDT0 function (which is really a part of the INT\_GROUP0 handler), the PMCU interrupt can not preempt the WWDT0 handler. When the WWDT0 handler completes, the INT\_GROUP0 handler will return. At that time, the processor will see that the INT\_GROUP0 request was asserted again (this time, due to the PMCU), and it will tail-chain a second entry to the interrupt handler. This time, application software will read the IIDX and determine that the PMCU was the cause of the INT\_GROUP0 interrupt being asserted to the NVIC.

If there are two or more peripheral interrupts pending to a single interrupt group, software can set the priority with which the interrupts are handled by first reading the RIS or MIS register to test which peripheral interrupts are asserted, followed by executing the software-determined priority. Alternatively, if the interrupt index (IIDX) register is used, the interrupt group hardware will return the highest priority index based on the index order.

### 3.3.1.3 Wake Up Controller (WUC)

The wake up controller (WUC) is responsible for monitoring for assertion of interrupts when the processor is powered down in the STOP or STANDBY operating mode. In these modes, the entire PD1 power domain is power gated, and as such, the processor and NVIC are not available to check for interrupts. The WUC retains a copy of which peripheral interrupt sources to the NVIC were enabled when the processor entered STOP or STANDBY mode. In the event that an enabled interrupt is issued, the WUC will handshake with the PMCU to bring the device out of STOP or STANDBY mode so that the CPU can service the interrupt. The WUC will capture the interrupt state and present it to the NVIC and processor when the processor is brought up, such that the processor will see the interrupt even if the raw interrupt status of the peripheral is removed before the processor finishes powering up to service the interrupt.

The WUC requires no configuration by application software upon entry to or exit from low-power modes, and operation is transparent to application software.

### 3.3.2 Interrupt and Exception Table

The Arm Cortex-M0+ interrupt vector table is 48 words long (192 bytes). The complete platform interrupt and exception table with vector table addresses is given in [Table 3-3](#).

See the device-specific data sheet for a complete list of which interrupts a particular device supports.

**Table 3-3. MSPM0 Platform Processor Interrupt and Exception Table**

Exception Number	NVIC Number <sup>(1)</sup>	Priority Group	Exception or Interrupt	Vector Table Address	Vector Description
-	-	-	-	0x0000.0000	Stack pointer
1	-	-3	Reset	0x0000.0004	Reset vector
2	-	-2	NMI	0x0000.0008	NMI handler
3	-	-1	Hard fault	0x0000.000C	Hard fault handler
4	-	-	Reserved	0x0000.0010	-
5	-	-	Reserved	0x0000.0014	-
6	-	-	Reserved	0x0000.0018	-
7	-	-	Reserved	0x0000.001C	-
8	-	-	Reserved	0x0000.0020	-
9	-	-	Reserved	0x0000.0024	-
10	-	-	Reserved	0x0000.0028	-
11	-	Selectable	SVCcall	0x0000.002C	Supervisor call handler
12	-	-	Reserved	0x0000.0030	-
13	-	-	Reserved	0x0000.0034	-
14	-	Selectable	PendSV	0x0000.0038	Pended supervisor handler
15	-	Selectable	SysTick	0x0000.003C	SysTick handler
16	0	Selectable	Device Interrupt 0	0x0000.0040	Handler for Device Interrupt 0
17	1	Selectable	Device Interrupt 1	0x0000.0044	Handler for Device Interrupt 1
18	2	Selectable	Device Interrupt 2	0x0000.0048	Handler for Device Interrupt 2
19	3	Selectable	Device Interrupt 3	0x0000.004C	Handler for Device Interrupt 3
20	4	Selectable	Device Interrupt 4	0x0000.0050	Handler for Device Interrupt 4
21	5	Selectable	Device Interrupt 5	0x0000.0054	Handler for Device Interrupt 5
22	6	Selectable	Device Interrupt 6	0x0000.0058	Handler for Device Interrupt 6
23	7	Selectable	Device Interrupt 7	0x0000.005C	Handler for Device Interrupt 7
24	8	Selectable	Device Interrupt 8	0x0000.0060	Handler for Device Interrupt 8
25	9	Selectable	Device Interrupt 9	0x0000.0064	Handler for Device Interrupt 9
26	10	Selectable	Device Interrupt 10	0x0000.0068	Handler for Device Interrupt 10
27	11	Selectable	Device Interrupt 11	0x0000.006C	Handler for Device Interrupt 11
28	12	Selectable	Device Interrupt 12	0x0000.0070	Handler for Device Interrupt 12
29	13	Selectable	Device Interrupt 13	0x0000.0074	Handler for Device Interrupt 13
30	14	Selectable	Device Interrupt 14	0x0000.0078	Handler for Device Interrupt 14
31	15	Selectable	Device Interrupt 15	0x0000.007C	Handler for Device Interrupt 15
32	16	Selectable	Device Interrupt 16	0x0000.0080	Handler for Device Interrupt 16
33	17	Selectable	Device Interrupt 17	0x0000.0084	Handler for Device Interrupt 17
34	18	Selectable	Device Interrupt 18	0x0000.0088	Handler for Device Interrupt 18
35	19	Selectable	Device Interrupt 19	0x0000.008C	Handler for Device Interrupt 19
36	20	Selectable	Device Interrupt 20	0x0000.0090	Handler for Device Interrupt 20
37	21	Selectable	Device Interrupt 21	0x0000.0094	Handler for Device Interrupt 21
38	22	Selectable	Device Interrupt 22	0x0000.0098	Handler for Device Interrupt 22
39	23	Selectable	Device Interrupt 23	0x0000.009C	Handler for Device Interrupt 23
40	24	Selectable	Device Interrupt 24	0x0000.00A0	Handler for Device Interrupt 24
41	25	Selectable	Device Interrupt 25	0x0000.00A4	Handler for Device Interrupt 25
42	26	Selectable	Device Interrupt 26	0x0000.00A8	Handler for Device Interrupt 26

**Table 3-3. MSPM0 Platform Processor Interrupt and Exception Table (continued)**

Exception Number	NVIC Number <sup>(1)</sup>	Priority Group	Exception or Interrupt	Vector Table Address	Vector Description
43	27	Selectable	Device Interrupt 27	0x0000.00AC	Handler for Device Interrupt 27
44	28	Selectable	Device Interrupt 28	0x0000.00B0	Handler for Device Interrupt 28
45	29	Selectable	Device Interrupt 29	0x0000.00B4	Handler for Device Interrupt 29
46	30	Selectable	Device Interrupt 30	0x0000.00B8	Handler for Device Interrupt 30
47	31	Selectable	Device Interrupt 31	0x0000.00BC	Handler for Device Interrupt 31

- (1) The NVIC number also indicates the relative interrupt priority if multiple NVIC interrupts have the same group priority. However, an interrupt does not preempt an active handler for another interrupt with the same group priority, even if the interrupt has a higher (numerically lower) NVIC position. For preemption to occur, the new interrupt must be configured to a higher priority group (numerically lower).

### Non-Maskable Interrupt (NMI)

The CPU implements a nonmaskable interrupt, which handles critical interrupts which must be serviced immediately by the processor. The NMI interrupt sources are managed by SYSCTL. See the corresponding NMI information in the SYSCTL section of the PMCU chapter.

### INT\_GROUP0 Peripheral Interrupt Group

The INT\_GROUP0 peripheral interrupt group sources an interrupt to NVIC0 (exception 16) if any peripheral in the group has a pending interrupt. The peripheral interrupts mapped to INT\_GROUP0 are given in [Table 3-4](#).

#### Note

Not all of the devices support Interrupt Group or NMI (non-maskable interrupt). Refer to the device-specific data sheet to see which devices support them.

**Table 3-4. INT\_GROUP0 Interrupts**

Priority	IIDX Index	Interrupt	Description
0	1	WWDT0	WWDT0 interrupt handler
1	2	WWDT1	WWDT1 interrupt handler
2	3	DEBUGSS	Debug subsystem interrupt handler
3	4	FLASHCTL	Flash controller interrupt handler
4	5	WUC FSUB0	Generic event subscriber 0 interrupt handler
5	6	WUC FSUB1	Generic event subscriber 1 interrupt handler
6	7	PMCU (SYSCTL)	PMCU (system controller) interrupt handler
7	8	Reserved	-

### INT\_GROUP1 Peripheral Interrupt Group

The INT\_GROUP1 peripheral interrupt group sources an interrupt to NVIC1 (exception 17) if any peripheral in the group has a pending interrupt. The peripheral interrupts mapped to INT\_GROUP1 are given in [Table 3-5](#).

#### Note

Not all of the devices support Interrupt Group or NMI (non-maskable interrupt). Refer to the device-specific data sheet to see which devices support them.

**Table 3-5. INT\_GROUP1 Interrupts**

Priority	IIDX Index	Interrupt	Description
0	1	GPIO0	GPIO0 interrupt handler
1	2	GPIO1	GPIO1 interrupt handler
2	3	COMP0	COMP0 interrupt handler
3	4	COMP1	COMP1 interrupt handler
4	5	COMP2	COMP2 interrupt handler
5	6	TRNG	TRNG interrupt handler
6	7	Reserved	-
7	8	Reserved	-

### 3.3.3 Processor Lockup Scenario

There are several exception conditions which can cause the processor to enter a lockup state. On MSPM0 devices, a processor lockup is considered a fatal fault which always triggers a [SYSRST](#) to clear the lockup condition and restart the system.

A lockup state is entered by the processor if an SVC (supervisor call) or fault condition occurs while the processor is handling an exception with priority of -1 or higher (numerically lower). Such a fault is considered by the processor to be unexpected under normal operating conditions.

The following examples are conditions that can trigger a lockup state in the processor:

- The processor cannot fetch the stack pointer or reset vector at reset
- The processor cannot fetch the NMI vector
- The processor cannot fetch the hard fault vector
- A memory fault occurs when the processor is already handling an exception with priority of -1 or -2 (hard fault or NMI)
- A supervisor call (SVC) occurs when the processor is already handling an exception with priority of -1 or -2 (hard fault or NMI)
- A usage fault or undefined instruction is fetched when the processor is already handling an exception with priority of -1 or -2 (hard fault or NMI)
- A BKPT instruction is executed when the processor is already handling an exception with priority of -1 or -2 (hard fault or NMI)

## 3.4 CPU Peripherals

The Arm Cortex-M0+ includes tightly coupled peripherals for system timing and memory protection.

### 3.4.1 System Control Block (SCB)

The system control block (SCB) provides system implementation information and system control functionality, as well as configuration, control, and reporting of processor exceptions.

The SCB is configured through memory-mapped registers in the system private peripheral bus (PPB) region. See [Table 3-6](#) for the list of SCB registers. The software development kit (SDK) provided with the devices supports the standard Arm Cortex Microcontroller Software Interface Standard (CMSIS) register access definitions for the SCB. Application software must use 32-bit aligned, word-size transactions when accessing any SCB register.

**Table 3-6. Arm Cortex-M0+ System Control Block Registers**

Address	Register	CMSIS	Description
0xE000.ED00	CPUID	SCB->CPUID	Read-only register indicating the CPU type and revision
0xE000.ED04	ICSR	SCB->ICSR	Provides specific interrupt controls and state
0xE000.ED08	VTOR	SCB->VTOR	Used to specify the vector table offset from 0x0000.0000
0xE000.ED0C	AIRCR	SCB->AIRCR	Used to issue a CPU reset request (SYSRESETREQ)
0xE000.ED10	SCR	SCB->SCR	System control register, used to control low-power mode behavior

**Table 3-6. Arm Cortex-M0+ System Control Block Registers (continued)**

Address	Register	CMSIS	Description
0xE000.ED14	CCR	SCB->CCR	Read-only register indicating behavior of the processor
0xE000.ED1C	SHPR2	SCB->SHP[2]	Used to configure the priority of the SVCcall system handler
0xE000.ED20	SHPR3	SCB->SHP[3]	Used to configure the priority of the SysTick and PendSV system handlers

For detailed information on the system control block register configuration, see the [SCB section of the Arm Cortex-M0+ devices generic user guide](#).

### 3.4.2 System Tick Timer (SysTick)

The system tick timer (SysTick) is a tightly-coupled timer clocked by MCLK, which can be used for system time keeping. The SysTick is available in RUN and SLEEP modes but is not available for use in STOP, STANDBY, or SHUTDOWN modes.

The SysTick is configured through memory-mapped registers in the system private peripheral bus (PPB) region. See [Table 3-7](#) for the list of SysTick configuration registers. The software development kit (SDK) provided with the devices supports the standard Arm Cortex Microcontroller Software Interface Standard (CMSIS) register access definitions for the SysTick.

The SysTick timer can be used in several different ways, including:

- As an RTOS timer which fires at a programmable rate (for example, 100Hz) and invokes a SysTick routine
- A high-speed alarm timer
- A simple counter used to measure time to completion and time used in an application
- A timeout counter to check that a routine has not timed out within a specified period

The SysTick timer is a simple 24-bit down counter, which counts down from its reload value to zero. Upon reaching zero, SysTick will re-load the value programmed into the reload value register (SYST\_RVR) on the next clock cycle, and then again begin counting down to zero.

A SysTick event is generated when the SysTick counter reaches zero, and which point the COUNTFLAG status flag will be set. Reading the SYST\_CSR register will clear the COUNTFLAG status bit. Writing to the current value register (SYST\_CVR) clears the register and the COUNTFLAG status but does not generate an interrupt to the CPU. Reading SYST\_CVR returns the counter value at time of access.

**Table 3-7. SysTick Registers**

Address	Register	CMSIS	Description
0xE000.E010	SYST_CSR	SysTick->CTRL	Control and status register, used to enable/disable SysTick and its related exception, and to check the COUNTFLAG status
0xE000.E014	SYST_RVR	SysTick->LOAD	Reload register used to program the counter reload value to set the SysTick interval in MCLK cycles
0xE000.E018	SYST_CVR	SysTick->VAL	Returns the current value of the SysTick counter; a write clears the counter to zero and clears COUNTFLAG in SYST_CSR
0xE000.E01C	SYST_CALIB	SysTick->CALIB	Not implemented

Application software must only use 32-bit word-aligned word accesses to the SysTick registers. To initialize the SysTick, follow the steps below:

1. Program the desired reload value (example: to generate a flag every 1000 MCLK cycles, program 999) to SYST\_RVR
2. Clear the current value by writing to the SYST\_CVR register
3. Program the SYST\_CSR register to enable SysTick

---

#### Note

The SysTick counter does not decrement when the CPU is halted for debug.

---

### 3.4.3 Memory Protection Unit (MPU)

The memory protection unit (MPU) can be used to check all memory accesses made by the processor against a set of access permission policies which can be defined by the programmer. When used together with the privileged/unprivileged execution modes of the Arm Cortex-M0+, the MPU supports limiting access to certain memory locations to privileged code only. If unprivileged code accesses a nonrestricted region, execution continues as if the MPU was not present. However, if unprivileged code issues an access to a restricted region, a hard fault is generated in the processor. It is also possible to restrict access to both privileged and unprivileged code (no access possible through the processor).

The MPU is configured through memory-mapped registers in the system private peripheral bus (PPB) region. See [Table 3-8](#) for the list of MPU configuration registers. The software development kit (SDK) provided with the devices supports the standard Arm Cortex Microcontroller Software Interface Standard (CMSIS) register access definitions for the MPU.

Because the MPU checks all memory accesses from the processor (including accesses to flash, SRAM, and peripherals), it is well suited for improving reliability and robustness in threaded applications involving an RTOS. The MPU can be used to restrict the memory access of individual threads, including establishing stack boundaries and limiting access to specific peripherals. Key state data used by the RTOS can be protected from modification by unprivileged threads.

---

#### Note

The MPU only monitors access to the memory map which originate from the processor. The MPU does not restrict the access of the DMA controller.

---

---

#### Note

Protecting flash memory regions with the MPU does not protect the flash memory from being read or modified by the [flash controller](#). This is because the flash controller can take control of the flash memory banks directly for read verify, program, and erase operations. Dedicated [write protection functions](#) are provided within the flash controller, and these mechanisms are for use when write protecting the flash memory. Software can configure the MPU to restrict access to the flash controller registers, thus preventing the CPU from configuring or initiating a flash command directly.

---

The MPU provides a mechanism to partition the device memory map into 8 regions (numbered 0-7) plus a default background region. Each region can be configured with access permissions and memory attributes, and regions can be configured to overlap if desired. In the case of overlapping regions, a memory access to a location existing in multiple regions is subjected to the attributes of the region with the highest number.

When the MPU is not enabled (ENABLE bit is cleared in the MPU\_CTRL register), the device uses the default memory map and the CPU has access to the memory map as if the MPU was not present.

When the MPU is enabled for use, access to the vector table and the system control space are always permitted, but access to any other location depends on the following:

- The region configurations
- Whether the access was privileged or unprivileged
- The privileged software default memory map access control configuration (PRIVDEFENA)

Because the Arm Cortex-M0+ is a single-bus CPU architecture, there is no delineation between an instruction fetch and a data access by the MPU. Instructions and data are treated the same.

---

#### Note

If the MPU is enabled (ENABLE bit is set), then PRIVDEFENA must be set to give privileged software access to the memory map, or at least one memory region must be configured and enabled for the CPU to proceed without a hard fault. If PRIVDEFENA is cleared, no regions are defined and enabled, and the MPU is enabled, then the entire memory map is restricted, and any access generates a fault.

---

**Table 3-8. MPU Registers**

Address	Register	CMSIS	Description
0xE000.ED90	MPU_TYPE	MPU->TYPE	Type register indicating that the MPU is present.
0xE000.ED94	MPU_CTRL	MPU->CTRL	MPU control register for enabling and configuring the MPU.
0xE000.ED98	MPU_RNR	MPU->RNR	Region select register for using MPU_RBAR and MPU_RASR.
0xE000.ED9C	MPU_RBAR	MPU->RBAR	Region base address configuration register.
0xE000.EDA0	MPU_RASR	MPU->RASR	Region size and memory attributes register.

For detailed information on the MPU register configuration, see the [MPU section of the Arm Cortex-M0+ Devices Generic User Guide](#).

### 3.5 Read-Only Memory (ROM)

The MCPUSS contains a read-only memory which contains the executable code for the boot configuration routine (BCR) and bootstrap loader (BSL). The ROM is active after a BOOTRST, or after a SYSRST with BSL entry/exit. The ROM is disabled automatically when the application is started and is not accessible by application software.

### 3.6 CPUSS Registers

Table 3-9 lists the memory-mapped registers for the CPUSS registers. All register offset addresses not listed in Table 3-9 should be considered as reserved locations and the register contents should not be modified.

**Table 3-9. CPUSS Registers**

Offset	Acronym	Register Name	Group	Section
10E0h	EVT_MODE	Event Mode		<a href="#">Go</a>
10FCh	DESC	Module Description		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 3-10](#) shows the codes that are used for access types in this section.

**Table 3-10. CPUSS Access Type Codes**

Access Type	Code	Description
<b>Read Type</b>		
R	R	Read
<b>Write Type</b>		
W	W	Write
<b>Reset or Default Value</b>		
-n		Value after reset or the default value

## 1 EVT\_MODE (Offset = 10E0h) [Reset = 0000001h]

EVT\_MODE is shown in [Figure 3-5](#) and described in [Table 3-11](#).

Return to the [Summary Table](#).

Event mode register. It is used to select whether each line is disabled, in software mode (software clears the RIS) or in hardware mode (hardware clears the RIS)

**Figure 3-5. EVT\_MODE**

1-0	INT_CFG	R	1h	Event line mode select 0h = The interrupt or event line is disabled. 1h = Event handled by software. Software must clear the associated RIS flag. 2h = Event handled by hardware. The hardware (another module) clears automatically the associated RIS flag.

## 2 DESC (Offset = 10FCh) [Reset = 27110000h]

DESC is shown in [Figure 3-6](#) and described in [Table 3-12](#).

Return to the [Summary Table](#).

This register identifies the peripheral and its exact version.

**Figure 3-6. DESC**

### 3 IIDX (Offset = 1100h) [Reset = 00000000h]

IIDX is shown in [Figure 3-7](#) and described in [Table 3-13](#).

Return to the [Summary Table](#).

Interrupt index register. This read-only register provides the interrupt index of the pending interrupt with the highest priority. It also indicates if no interrupt is pending. The priority order is fixed: lower index equals higher priority. Alternatively to the use of IIDX, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flags in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt or indicate that no interrupt is pending. Only interrupts which are selected via IMASK are indicated.

**Figure 3-7. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 5 RIS (Offset = 1110h) [Reset = 0000000h]

RIS is shown in [Figure 3-9](#) and described in [Table 3-15](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Figure 3-9. RIS**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 7 ISET (Offset = 1120h) [Reset = 00000000h]

ISET is shown in [Figure 3-11](#) and described in [Table 3-17](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Figure 3-11. ISET**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 9 IIDX (Offset = 1130h) [Reset = 0000000h]

IIDX is shown in [Figure 3-13](#) and described in [Table 3-19](#).

Return to the [Summary Table](#).

Interrupt index register. This read-only register provides the interrupt index of the pending interrupt with the highest priority. It also indicates if no interrupt is pending. The priority order is fixed: lower index equals higher priority. Alternatively to the use of IIDX, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flags in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt or indicate that no interrupt is pending. Only interrupts which are selected via IMASK are indicated.

### 15 IIDX (Offset = 1160h) [Reset = 0000000h]

IIDX is shown in [Figure 3-19](#) and described in [Table 3-25](#).

Return to the [Summary Table](#).

Interrupt index register. This read-only register provides the interrupt index of the pending interrupt with the highest priority. It also indicates if no interrupt is pending. The priority order is fixed: lower index equals higher priority. Alternatively to the use of IIDX, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flags in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt or indicate that no interrupt is pending. Only interrupts which are selected via IMASK are indicated.

## 4.1 Overview

Some MSPM0 devices offer several extensive cybersecurity features as part of the device architecture, including:

- Debug security
- Device identify
- Crypto acceleration
- True random number generation
- Flash write-erase protection
- Flash read-execute protection
- Flash IP protection
- SRAM write-execute mutual exclusion
- Secure boot
- Secure firmware update
- Secure key storage
- Customer secure code

The security architecture decouples mechanisms (controls offered by MSPM0 devices) from policies that are application-defined. This allows for a wide variety of security requirements to be supported.

The overall security configuration offered by MSPM0 devices is implemented in two steps:

1. **Secure Boot** - TI boot code executes on a BOOTRST and configures the requested security policies. Once boot code finishes execution, the system undergoes a SYSRST followed by the start of Step 2.
2. **Customer Secure Code (CSC)** - CSC executes from flash memory to further configure security elements. Note that CSC is customer-owned secure software. This two-step secure boot concept enables application-specific policies to be implemented and managed by CSC while standard security enablers are implemented by boot code. When Step 2 has completed execution, the system undergoes a second SYSRST followed by the start of the main application.

In this security model, both TI boot code and CSC are considered *trusted*. The main application is considered *untrusted*. When execution jumps to the main application, all security elements are expected to have been configured, including restrictions on debug, memory accesses, key management, and so on.

---

### Note

As MSPM0 Security architecture provides a clean separation between policies and mechanisms, it is possible to build applications where no CSC is implemented and the main application execution begins right after BOOTRST.

---

---

### Note

Check the device-specific data sheet to determine if the security architecture features are available.

---

### 4.1.1 Secure Boot

In Step 1, boot ROM code configures a set of security elements based on contents of the configuration memory (NONMAIN). This includes:

- **Debug Security:** Debug access can be allowed unconditionally, disallowed unconditionally or allowed after a successful password verification
- **Mass Erase:** Mass erase operation can be allowed unconditionally, disallowed unconditionally or allowed after a successful password verification
- **Factory Reset:** Factory reset operation can be allowed unconditionally, disallowed unconditionally or allowed after a successful password verification
- **Write-protection of MAIN flash sectors:** MAIN bank contents can be write protected at 1x sector or 8x sector granularity
- **Write-protection of configuration memory (NONMAIN):** Because boot configuration memory (NONMAIN) holds key security configuration settings, this configuration memory can be write protected to avoid inadvertent or malicious downgrading of security.
- **Presence/Absence of Customer Secure Code (CSC):** This attribute controls whether a second level of security and trusted flash-based code is provisioned or not.
- **Bank Swap Policy:** In dual/quad-bank devices, this attribute indicates if the device operates the flash banks in a swap mode or not. If swap mode, then by hardware default, the upper bank (or pair) is enforced read-write access privileges and no execute privilege. The lower bank (or pair) is enforced read-execute access privileges and no write/erase privilege.
- **Delay Debug:** Security applications can disable debug access during the execution of the CSC. This attribute controls whether debug access is delayed until the end of CSC execution or not.

### 4.1.2 Customer Secure Code (CSC)

In this step, customer owned secure code executes and implements additional security capabilities:

- Bank swap decision
- Secure firmware update
- Secure key storage
- Flash read-execute protection
- Flash IP protection
- SRAM write-execute mutual exclusion

CSC specifies which bank holds the more recent authenticated application image. If that bank is physical bank 0 (same bank as where CSC is executing from), then bank 1 is read-write only and does not have execute privilege. If the correct application image is determined to be on physical bank 1, then the CSC must issue a bank-swap request.

Besides image authentication, the CSC sets up additional security configurations that are described later in this document. The CSC indicates the end of CSC execution by writing to the SYSCTL.SECCFG.INITDONE register with a PASS value (0x1) along with a KEY value of 0x9d. Successfully writing to the INITDONE register results in a second SYSRST operation during which the bank-swap takes effect, as well as any additional security configurations.

## 4.2 Boot and Startup Sequence

**Figure 4-1** illustrates the boot and startup sequence in security enabled applications. At BOOTRST, TI boot-code execution commences. After successful boot, boot-code issues BOOTDONE. At this point, SYSCTL issues a SYSRST to the device to trigger execution from flash memory. Depending on the boot configuration record, this leads either to the start of the main application (if CSC does not exist in this configuration) or to the start of the CSC (if CSC is configured).

CSC is responsible for determining execution bank, memory region protections, secure key initialization into the keystore, etc. When the customer secure code issues INITDONE (by writing to SYSCTL.SECCFG.INITDONE MMR), then SYSCTL issues a second SYSRST. The device again starts execution from 0x0 mapped to flash, and the CSC executes a second time. This time, the CSC will find that INITDONE has already been issued

previously (this is determined by reading the SYSCTL.SECCFG.SECSTATUS.INITDONE bit) and it directly calls the main application.

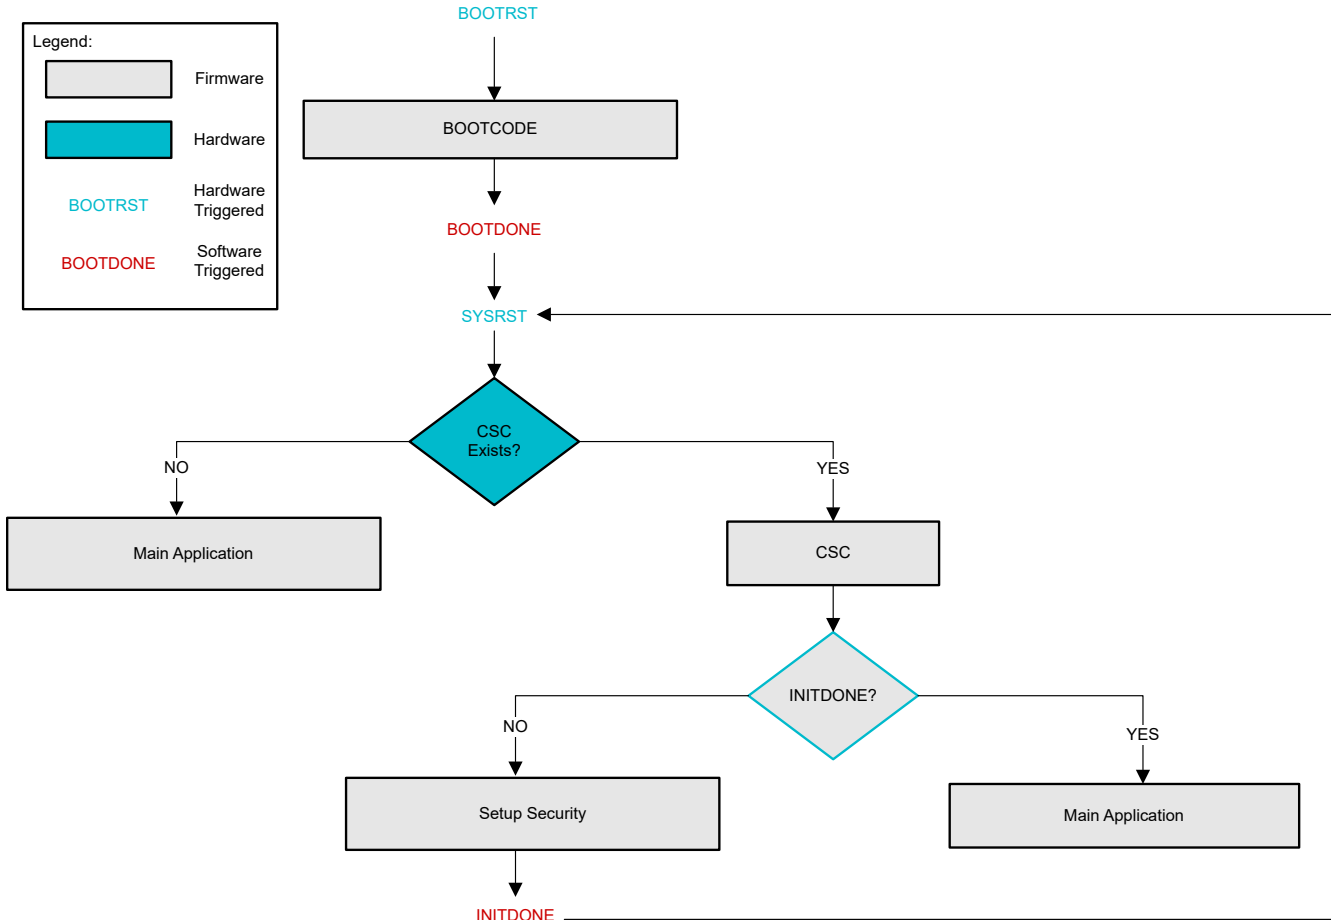

Figure 4-1. Secure Boot and Start Sequence

**Note**

To keep the boot flow compatible with nonsecurity enabled devices, the default settings of boot configuration are set to "CSC does not exist" state.

The secure execution flow is the path where CSC\_EXISTS = YES. In this case, it may be observed that after BOOTRST, two SYSRSTs will be issued before the main application is launched. After first SYSRST, the customer startup code gets to execute. It configures security and issues INITDONE. At this point, the security configuration is locked and enforced. A second SYSRST is issued at this point, restarting startup code execution. At the second SYSRST, since INITDONE is YES, the main application is launched.

**4.2.1 CSC Programming Overview**

The CSC is expected to be a separate image from the main application. This allows a complete isolation of the CSC from the application as opposed to a scheme where the CSC functionality is embedded into the application as a single image.

At the first SYSRST following BOOTDONE, CSC will be invoked via the reset handler at 0x0. The pseudo-code below provides an overview of the CSC programming model.

```

void resetHandler(void)
{

```

```

_asm("b __c_init00"); // this is the call to secure startup, which would issue INITDONE
}

```

The CSC will check if INITDONE has already been issued, and accordingly decide to perform application image authentication and security configuration before launching the authenticated image.

```

bool init_done = (*(volatile long *) (SYSCTL_SECCFG_SECTSTAT)) & 0x1;
If (! Init_done)
{
  setupKeystorage(); // AES symmetric keys
  entry_point = findImageEntryPoint ();
  stack_ptr = findImageStackPtr();
  setBankSwap(0 or 1); // depending on which bank the image is in

  // setup SRAM boundary
  copyFromFlashToSRAM();
  setupSRAMBoundary();
  lockSRAMBoundary();
  setupFlashFirewalls();
  INITDONE = 1; // *(volatile long *) (SYSCTL_SECCFG_INITDONE) = 1 | (0x9D << 24);
  // This triggers a HW-initiated SYSRST
}

// we will come here if INITDONE = 1 after a SYSRST
launchApp(); // using entry_point and stack pointer base from image metadata

```

As outlined, the CSC would perform a set of security configuration actions that include:

- Transferring AES keys from flash memory to the secure key storage
- Identifying the correct application image to run and which bank it is located in. This step requires the startup code to use some pre-defined metadata scheme for where the app may be loaded, how to find the app version, how to authenticate the app, what its entry point is and where the app's vector table is located.
- Set up bank swap information
- Set up SRAM boundary to separate code region from RW region
- Provision required read/write/IP protect flash firewalls
- Mark INITDONE

Note that the SRAM boundary set up is optional and needed only if the application intends to run any code (especially interrupt handlers) out of SRAM. This is motivated by a requirement to keep communications ISRs running while the main flash memory could be busy with integrity checks.

The final step would trigger a second SYSRST and the reset handler gets invoked a second time. Since `init_done` is now found to be set, CSC will simply invoke the main application at this point, using the `entry_point` that the CSC obtained from the application image.

#### Note

Because the CSC enforces additional security policies over and above boot-code, and therefore an attack on CSC execution can disrupt intended security of the application, CSC development should follow the same best practices as TI boot-code. This includes analyzing and hardening CSC against glitching attacks. Also, because the CSC is customer-owned and the time it takes before calling INITDONE is variable, it is recommended that the CSC use a watchdog to ensure that INITDONE is called in a timely manner.

### 4.3 Secure Key Storage

Keys (private keys in asymmetric schemes such as RSA and symmetric schemes such as AES) need to be protected to ensure confidentiality. Only trusted code should be provisioned with a mechanism to securely deposit keys from flash memory to a location that only crypto engines can access. This is the concept of the MSPM0 secure key storage: secure storage that only the CSC can configure keys into. Subsequently, the main application can configure the crypto engine to use one of the stored keys but can never access any stored keys.

The key-store is housed as part of the key-store controller IP. Depending on the device, a certain number of key slots are provisioned. These slots can be used to hold some number of 256-bit and 128-bit keys. Trusted software (CSC) can write to the key-store to deposit keys securely. Writing to the key-store is automatically disabled when INITDONE is issued. Key-store contents are reset at BOOTRST and the store is unlocked for writing. Key-store contents are unaffected by SYSRST and lower order resets.

A key that is required for a crypto accelerator service (such as AES encryption) is transferred to the crypto engine when the application software configures the crypto service. The configuration is performed in the key-store controller and is of the form “transfer the 128-bit key in slot 3 to the AES engine”. This transfer is performed securely and is not visible to the application code, DMA or the debugger.

## 4.4 Flash Memory Protection

In order to meet diverse security requirements, various types of flash memory protection mechanisms are provided.

### 4.4.1 Bank Swapping

In dual-bank/quad-bank devices, based on which bank (or pair) is executable, that bank (pair) gets read-execute privileges and loses write/erase privileges. The other bank (or pair) is readable, and writeable but not executable. This mechanism enforces the policy that any firmware update can only be saved in the writeable bank in the current session but can never be executed.

Upon a subsequent BOOTRST, the CSC runs and needs to authenticate the update and decide if the updated image should be made executable. If yes, then the bank holding the updated image can be configured to become executable (this is done by configuring the SYSCTL.SECCFG.FLBANKSWP.USEUPPER to 1 along with the correct KEY value of 0x58). When the CSC issues INITDONE, this bank-swap will take effect, swapping the execution/write privileges of the upper and lower banks as well as re-mapping the upper bank (or pair) to the lower half of the flash memory address space and re-mapping the upper bank (or pair) to the upper half of the flash memory address space.

Creating swappable configurations is a two-step process.

1. Boot configuration has to indicate that the flash memory will be used in a swappable configuration. Boot-code will read this configuration and write to the SYSCTL.SECCFG.FLBANKSWPPOLICY with the appropriate KEY (0xCA). Note that by hardware default, the swappable configuration is ENABLED.
2. CSC will determine which bank will be the executable bank. If physical bank 0 is going to be the execution bank, then no further action is needed. However, if physical bank 1 is going to be the execution bank, then a bank swap has to be issued by configuring the SYSCTL.SECCFG.FLBANKSWP.USEUPPER to 1 along with the correct KEY value of 0x58.

At any time, status of the bank swap policy and the currently executable bank can be obtained by reading the SYSCTL.SECCFG.SECSTATUS register. Fields FLBANKSWPPOLICY and FLBANKSWP provide this status.

### 4.4.2 Write Protection

There are three levels of write-protection that are provided:

1. Write-protection that is enforced by TI boot-code
2. Write-protection that is enforced by CSC to further protect data that it is allowed to update but that should not be modified by the application
3. Write-protection in the context of bank swap (covered in the Bank Swapping section)

Write-protection enforced by TI boot-code can protect sectors of both the MAIN bank and the boot configuration data held in NONMAIN. The mechanisms are described in the Boot Configuration chapter. In particular, this capability is useful in cases where the CSC needs to be treated as an extension of the root-of-trust and made immutable.

The CSC can further extend the write protection to additional MAIN bank sectors. On every boot, the CSC can perform write/erase operations on sectors holding secure data/metadata and then lock these sectors from any modifications when the application executes.

Configuring write protection of the MAIN bank is done by setting sector-specific bits to 1 in the SYSCTL.SECCFG.FWEPROTMAIN register. The sectors that are already write-protected by boot-code continue to be write-protected. Note that only the first 32KB of flash memory can be configured with additional write protections by the CSC.

---

**Note**

In bank-swappable configuration, the protections are automatically mirrored to both banks.

---

#### 4.4.3 Read-Execute Protection

A region of flash memory can be configured for read-execute protection - read and instruction fetch accesses to this region will return an error. CPU, DMA and debugger accesses are all treated the same way. This is configured by writing to the SYSCTL.SECCFG.FRXPOTMAINSTART and SYSCTL.SECCFG.FRXPOTMAINEND registers with the start and end addresses of the range to be protected respectively. Both addresses are set up for writing at 64B granularity. To enable this protection, the FLRXPOT bit must be ENABLED (1) by writing to SYSCTL.SECCFG.FWENABLE register along with the correct KEY value (0x76).

At any time, status of the RX protection can be obtained by reading the SYSCTL.SECCFG.SECSTATUS register. The FLRXPOT field provide this status.

This mechanism is useful in scenarios where it may be required to prevent re-execution of the CSC. The protected address range of the CSC essentially runs only once at BOOTRST and can not subsequently be re-executed. Note that caution needs to be exercised in configuring the flash memory range that is configured for this protection. Address space that holds the interrupt vectors or the portion of CSC that needs to be able to run a second time after BOOTRST should not be execute-protected.

---

**Note**

In bank-swappable configuration, the protection is automatically mirrored to both banks.

---

#### 4.4.4 IP Protection

A region of flash memory can be configured for read protection - read accesses to this region will return an error while instruction fetch accesses are allowed. CPU, DMA and debugger accesses are all treated the same way. This is configured by writing to the SYSCTL.SECCFG.FIPPROTMAINSTART and SYSCTL.SECCFG.FIPPROTMAINEND registers with the start and end addresses of the range to be protected respectively. Both addresses are set up for writing at 64B granularity. To enable this protection, the FLIPPROT bit must be ENABLED (1) by writing to SYSCTL.SECCFG.FWENABLE register along with the correct KEY value (0x76).

At any time, status of the IP protection can be obtained by reading the SYSCTL.SECCFG.SECSTATUS register. The FLIPPROT field provide this status.

This mechanism is useful in scenarios where it may be required to prevent code read-out of third-party vendor-supplied software IP. Note that code that is meant to be IP-protected must be compiled such that there are no embedded data accesses (literal fetches) to this region. Since data accesses return access errors, such code must be compiled with a flag such as -mexecute-only (TI Clang Compiler flag) to ensure no literal constant accesses are emitted.

---

**Note**

In bank-swappable configuration, the protection is automatically mirrored to both banks.

---

#### 4.4.5 Data Bank Protection

A region of flash DATA bank can be configured for read-write protection- either reads or writes or both types of accesses can be blocked. CPU, DMA and debugger accesses are all treated the same way. This is configured by writing to the SYSCTL.SECCFG.FRWPRTDATA register. Only the first 4KB of the DATA bank can be protected at a sector (1KB) granularity. Each sector can be:

- Read protected
- Write protected
- Both
- Neither

This mechanism allows CSC to hold secret or sensitive data in the DATA bank that it alone can read/modify during start-up.

---

#### Note

Not all devices support a DATA bank. Refer to the device-specific data sheet to determine if the device supports a DATA bank.

---

#### 4.4.6 Hardware Monotonic Counter

Some devices provision a second NONMAIN sector (1KB) that is accessed with the following restrictions:

- It can never be erased (factory reset, mass erase operations included)
- It can be written only until CSC calls INITDONE, and subsequently it can only be read.

This protection serves to implement hardware-based monotone counter feature. Because the sector can only be programmed, it effectively works as a nonvolatile up-counter (or down-counter depending on how the counter value is interpreted by software). The CSC can maintain revision or roll-back protection information in this sector, assuring that a version lower than the counter value cannot be activated.

---

#### Note

Refer to the device-specific data sheet to determine if the device supports a hardware monotonic counter.

---

#### 4.5 SRAM Protection

Buffer overflows are a common source of exploits wherein, for example, a corrupt return address can cause execution to jump to malicious code. In order to mitigate such exploits, an SRAM code protection feature is available, wherein the SRAM can be partitioned into two regions:

- Region 1: Read-Write (RW)
- Region 2: Read-Execute (RX)

This is set up by configuring the SYSCTL.SOCLOCK.SRAMBOUNDARY register with an address A such that:

- **Addresses  $\geq A$**  will be permitted for **read-execute** and not for writes
- **Addresses  $< A$**  will be permitted for **read-write** and not for execution (instruction fetch)

---

#### Note

Configuring A equal to the total SRAM capacity implies that the entire SRAM is for RW only and no code execution from SRAM is enabled.

---

---

#### Note

A = 0 is treated as entire SRAM being RWX. This is the reset state of the SRAM.

---

In security-enabled devices, the SRAMBOUNDARY configuration can be locked by the CSC by configuring the SYSCTL.SECCFG.FWENABLE.SRAMBOUNDARYLOCK bit. Setting the LOCK ensures that the untrusted application can not change the SRAM protection. In devices without the security add-on, the SRAMBOUNDARY functionality is still available but the LOCK functionality is not present. This enables applications to use this feature to catch memory access problems.

## 4.6 SECURITY Registers

Table 4-1 lists the memory-mapped registers for the SECURITY registers. All register offset addresses not listed in Table 4-1 should be considered as reserved locations and the register contents should not be modified.

**Table 4-1. SECURITY Registers**

Offset	Acronym	Register Name	Group	Section
3000h	FWEPROTMAIN	1 Sector Write-Erase per bit starting at address 0x0 of flash		<a href="#">Go</a>

Chapter 5  
**Direct Memory Access (DMA)**

---

The direct memory access (DMA) controller module transfers data from one address to another, without CPU intervention. This chapter describes the operation of the DMA controller.

<b>5.1 DMA Overview</b> .....	<b>522</b>
<b>5.2 DMA Operation</b> .....	<b>523</b>
<b>5.3 DMA Registers</b> .....	<b>535</b>

## 5.1 DMA Overview

The DMA controller transfers data from a source address to a destination address without CPU intervention. For example, the DMA controller can be used to move data from ADC conversion memory to SRAM.

Devices can have up to sixteen DMA channels available. Therefore, depending on the number of DMA channels available, some features described in this chapter are not applicable to all devices. Please refer to the device-specific data sheet for the actual channel count of the DMA.

Using the DMA controller can increase the throughput of peripheral modules. It can also reduce system power consumption by allowing the CPU to remain in a low-power mode, without having to awaken to move data to or from a peripheral.

DMA controller features include:

- Up to sixteen independent transfer channels
- Configurable DMA [channel priorities](#)
- Byte (8-bit), half-word (16-bit), word (32-bit), long-word (64-bit), and long-long-word (128-bit) or mixed byte and word transfer capability
- Transfer counter block size supports up to 64k transfers of any data type
- Configurable [DMA transfer trigger selection](#)
- Seven flexible [addressing modes](#)
- Single or block [transfer modes](#)

The DMA controller block diagram is shown in [Figure 5-1](#).

Figure 5-1. DMA Block Diagram

## 5.2 DMA Operation

The DMA controller is configured with user software. The setup and operation of the DMA is discussed in the following sections.

### 5.2.1 Addressing Modes

The DMA controller has seven addressing modes. The addressing mode for each DMA channel is independently configurable. For example, channel 0 can transfer between two fixed addresses, while channel 1 transfers between two blocks of addresses. The basic addressing modes are shown in [basic address modes](#)

The addressing modes are:

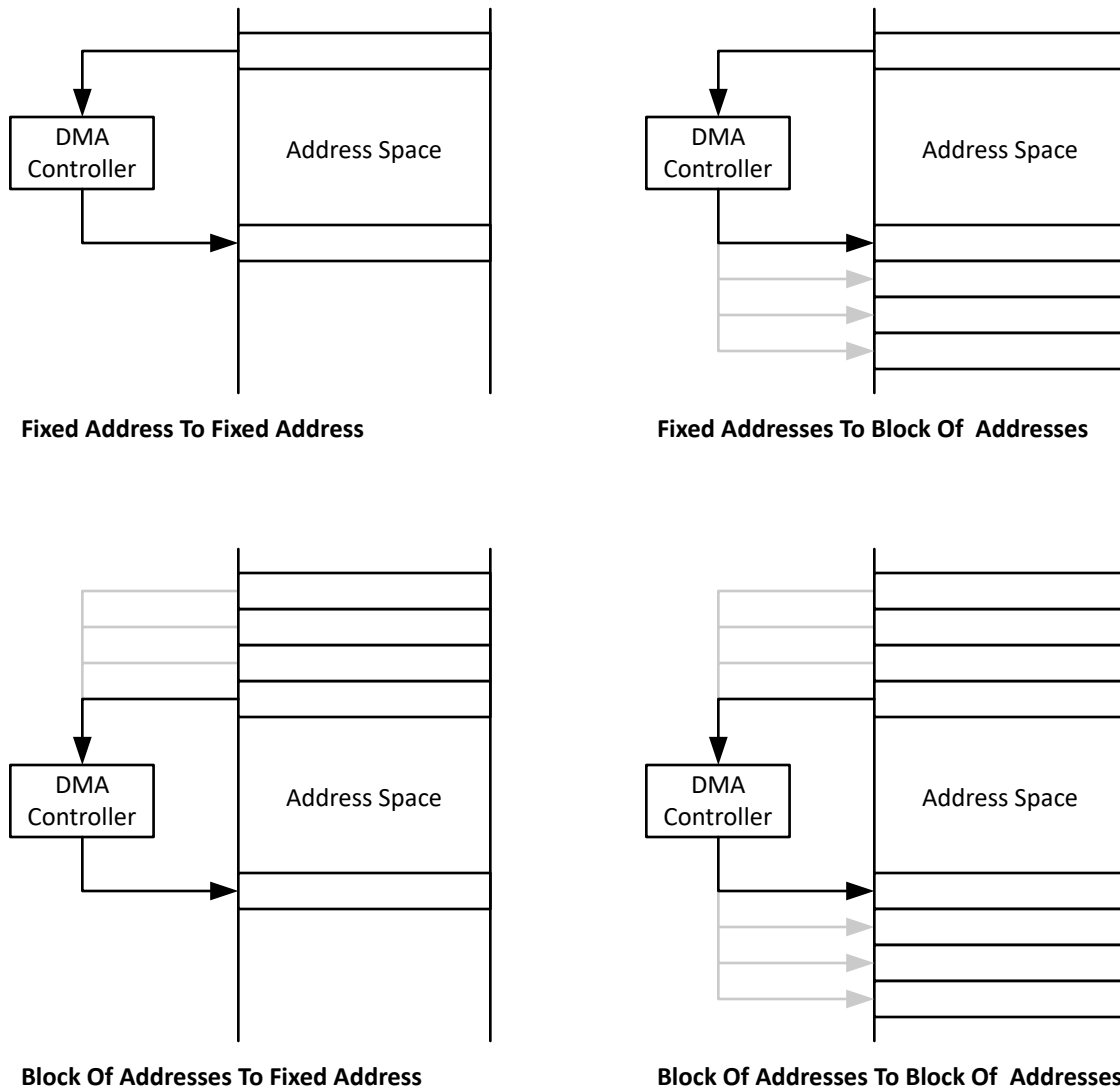

1. Fixed address to fixed address
2. Fixed address to block of addresses
3. Block of addresses to fixed address
4. Block of addresses to block of addresses
5. Fill data to block of addresses
6. Data table to specific address
7. Gather data from address table to fixed address or block of addresses

Addressing modes 1-4 shown above are the basic addressing modes and are simply configured with the DMASRCINCR and DMADSTINCR control bits and are available in all channel types. The DMASRCINCR bits select if the source address is incremented, decremented, or unchanged after each transfer. The DMADSTINCR bits select if the destination address is incremented, decremented, or unchanged after each transfer.

Addressing modes 5 -7 shown above are also configured with the DMASRCINCR and DMADSTINCR control bits along with the help of additional parameters such as DMAEM for leveraging the [extended modes](#) of the DMA. Refer to [Section 5.2.4.1](#) , [Section 5.2.4.2](#) or [Gather Mode] for more details on how to properly configure and use the DMA in Fill-Mode, Table-Mode and Gather-Mode.

Transfers can be byte to byte, half-word to half-word, word to word, long-word to long-word, long-long-word to long-long-word or any combination of the five. When transferring a wider bit width source to a shorter bit width destination, only the lower bits of the destination data transfers. When transferring a shorter bit width source to a wider bit width destination, the upper bytes of the destination data is cleared when the transfer occurs. There is no packing or unpacking support by combining several source byte transfers to one single destination word or the reverse.

**Figure 5-2. Basic DMA Addressing Modes**

### 5.2.2 Channel Types

There are two types of DMA: DMA\_A and DMA\_B. Each DMA supports basic (BASIC) and full-featured (FULL) channels. BASIC channels support only single or block transfers, and FULL channels support repeated single and repeated block transfers with additional features such as early interrupt request generation and extended table, fill and gather modes.

The highest priority DMA channels (starting with DMA0) are FULL channels, and the remaining priority channels are BASIC channels.

**Note**

See the device-specific data sheet to determine the type of DMA and the corresponding FULL and BASIC channels supported

[Feature comparison table](#) shows the features supported in the available basic and full-feature DMA channel types.

**Table 5-1. Feature Comparison of DMA\_A and DMA\_B Channels**

DMA Feature	DMA_A		DMA_B	
	Full-Feature	Basic Channel	Full-Feature	Basic Channel
Repeated mode	–	–	✓	–
Table & fill mode	✓	–	✓	–
Gather mode	–	–	✓	–
Early IRQ notification	✓	–	✓	–
Auto enable	–	–	✓	✓
Long long (128-bit) transfer	–	–	✓	✓
Stride mode	✓	✓	✓	✓
Cascading channel support	–	–	✓	✓

### 5.2.3 Transfer Modes

The DMA controller has four transfer modes selected by the DMATM bits as listed in [DMA transfer mode table](#). Each channel is individually configurable for its transfer mode. For example, channel 0 can be configured in repeated block transfer mode, while channel 1 is configured for block transfer mode, and channel 2 operates in single transfer mode. The transfer mode (single, block, repeat) is configured independently from the addressing mode (decrement, fixed, increment, stride). Any addressing mode can be used with any transfer mode.

Five types of data can be transferred selectable by the DMADSTWIDTH and DMASRCWIDTH control bits. The source and destination locations can be either byte (8-bit), half-word (16-bit), word (32-bit), long-word (64-bit), or long-long-word (128-bit) data. It is also possible to transfer byte to byte, half-word to half-word, word to word, long-word to long-word, long-long-word to long-long-word, or any combination.

Additionally, all transfers modes support a stride mode where the DMA source and destination can be incremented to a higher value to support re-organization of data.

**Table 5-2. DMA Transfer Modes**

DMATM	Transfer Mode	Description	Channel Type
0	Single transfer	Each transfer requires a trigger. DMAEN is automatically cleared when DMASZx transfers have been made.	Basic
1	Block transfer	A complete block is transferred with one trigger. DMAEN is automatically cleared at the end of the block transfer.	Basic
2	Repeated single transfer	Each transfer requires a trigger. The DAMSA, DMADA and DMASZ registers are reloaded to the original value when the DMASZ counted down to zero. DMAEN remains enabled.	Full-feature
3	Repeated block transfer	A complete block is transferred with one trigger and continuous transferring. The DAMSA, DMADA and DMASZ registers are reloaded to the original value when the DMASZ counted down to zero. DMAEN remains enabled.	Full-feature

#### 5.2.3.1 Single Transfer

In single transfer mode (DMATM = 0), each byte, half-word, word, long-word, or long-long-word transfer requires a separate trigger. Single transfer mode is available in basic and full-feature DMA channels.

The DMASZ register defines the number of transfers to be made. The DMADSTINCR and DMASRCINCR bits select if the destination address and the source address are incremented or decremented after each transfer. If DMASZ = 0, no transfers occur.

The DMASA, DMADA, and DMASZ registers are incremented or decremented after each transfer. The DMADSTWIDTH will indicate whether the destination address will increment or decrement by 1, 2, 4, 8, or 16 with each transfer cycle. The same is true for the DMASRCWIDTH and the source address respectively. When the DMASZ register decrements to zero, the corresponding RIS flag is set.

The DMAEN bit is cleared automatically when DMASZ decrements to zero and must be set again for another transfer to occur.

#### 5.2.3.2 Block Transfer

In block transfer mode (DMATM = 1), a transfer of a complete block of data occurs after one trigger. Block transfer mode is available in basic DMA channels only.

The DMASZ register defines the size of the block, and the DMADSTINCR and DMASRCINCR bits select if the destination address and the source address are incremented or decremented after each transfer of the block. If DMASZ = 0, no transfers occur.

The DMADSTWDTH will indicate whether the destination address will increment or decrement by 1, 2, 4, 8 or 16 with each transfer cycle. The same is true for the DMASRCWDTH and the source address respectively. The DMASZ register is decremented after each transfer and shows the number of transfers remaining.

The DMAEN bit is cleared after the completion of the block transfer and must be set again before another block transfer can be triggered. After a block transfer has started, another trigger signal that occurs during the block transfer is ignored.

#### 5.2.3.3 Repeated Single Transfer

In repeated single transfer mode (DMATM = 2), the DMA controller remains enabled with DMAEN = 1, and a transfer occurs every time a trigger occurs. Repeated single transfer modes are available in full-featured DMA channels only.

The DMASA, DMADA, and DMASZ registers are copied into temporary registers. The values of DMASA and DMADA are incremented or decremented after each transfer. The DMASZ register is decremented after each register. The DMADSTWDTH will indicate whether the destination address will increment or decrement by 1, 2, 4, 8 or 16 with each transfer cycle. The same is true for the DMASRCWDTH and the source address respectively. When the DMASZ register decrements to zero, it is reloaded from its temporary register and the corresponding RIS flag is set.

---

#### Note

When using repeated single transfer mode, the DMA does not support pausing and continuing a transfer by disabling a channel (to pause) and then re-enabling the channel (to continue).

---

#### 5.2.3.4 Repeated Block Transfer

In repeated block transfer mode (DMATM = 3), the DMAEN bit remains set after completion of the block transfer. The next trigger after the completion of a repeated block transfer starts another block transfer. Repeated block transfer modes are available in full-featured DMA channels only.

The DMASA, DMADA, and DMASZ registers are copied into temporary registers. The temporary values of DMASA and DMADA are incremented or decremented after each transfer in the block. The DMADSTWDTH will indicate whether the destination address will increment or decrement by 1, 2, 4, 8 or 16 with each transfer cycle. The same is true for the DMASRCWDTH and the source address respectively. The DMASZ register is decremented after each transfer of the block and shows the number of transfers remaining in the block. When the DMASZ register decrements to zero, it is reloaded from its temporary register and the corresponding RIS flag is set.

#### 5.2.3.5 Stride Mode

All transfer modes support a “stride” mode where the DMA source and destination can be incremented to a higher value (rather than +1) after a transfer. This is helpful for re-organizing the order of data between the source and destination.

To support incremental strides, set the DMADSTINCR and/or DMASRCINCR to STRIDE\_n, where n is the number of destination and/or source increments. The real increments are based in terms of the definitions DMADSTWDTH and/or DMASRCWDTH, respectively. For example, if external ADC data is transmitted to the

MCU as a six-word SPI frame, DMADSTINCR can be set to STRIDE\_6 during a block transfer so that the destination address is incremented by 6 and the data is organized to make processing easier.

#### 5.2.4 Extended Modes

In FULL channels, the DMA controller has two extended modes selected by the DMAEM bits as listed in [DMA extended mode table](#). An graphical overview of the extended modes can be seen in [DMA extended mode figure](#). Each channel is individually configurable for the extended mode. For example, channel 0 can be configured in table mode while channel 1 is configured in fill mode.

**Table 5-3. DMA Extended Modes**

DMAEM	Extended Mode	Description
0	Normal mode	Operation is defined by DMATM
1	Gather mode	Used to read data from an address table and copy to configurable address
2	Fill mode	Used to fill predefined data patterns into memory
3	Table mode	Used to help configure a table of peripheral control registers

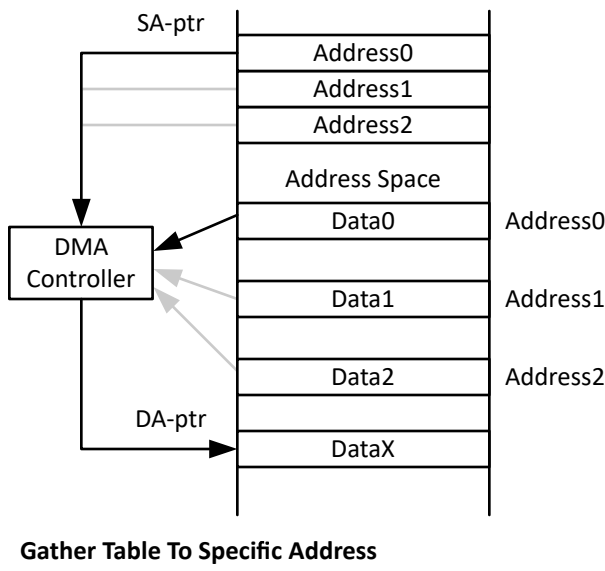

Figure 5-3. DMA Extended Modes Diagram

5.2.4.1 Fill Mode

In fill mode (DMAEM = 2), the DMA controller takes a predefined FILL pattern and writes the pattern to a user defined segment of memory. The DMATM bits are ignored and the automatic transfer mode used is "block transfer".

The DMASAx register is used as the FILL pattern data. The DMASRCINCR bit field is used to indicate whether the FILL pattern data should be constant or incremented/decremented with every write cycle. This feature allows for filling a memory block with a sequential pattern (for example. 0, 1, 2, 3, ...). The DMASRCWDTH bit field indicates the magnitude of increment of the FILL mode data. Refer to Table 5-4 for how to use DMASRCWDTH in fill mode.

Table 5-4. DMASRCWDTH in Fill Mode

DMASRCWDTH	FILL Mode Data Increment Value
0	±1

**Table 5-4. DMASRCWDTH in Fill Mode (continued)**

DMASRCWDTH	FILL Mode Data Increment Value
1	±2
2	±4
3	±8

The destination registers and bit fields DMADAx, DMADSTINCR, and DMADSTWDTH all behave as expected and influence where and how in memory the FILL pattern is written.

#### 5.2.4.2 Table Mode

In table mode (DMAEM = 11b), the DMA controller executes 2 reads from the source and one write to a determined destination. This feature can be leveraged to interpret a table of addresses and data and uses the DMA to efficiently program that data to their associated addresses without CPU intervention. Table mode allows you to parse through a table of addresses and data to configure peripheral memory mapped registers in a single block transfer.

The DMASRCWDTH bit field should be set to "3" (64-bit mode) and the DMADSTWDTH bit field should be set to "2" (32-bit mode). The DMASRCINCR bit field can be set to 10b to decrement the source address or 11b to increment the source address after transfers. DMASZ is set to represent the number of entries in the table and DMATM should be set to "01" for block transfer mode. DMADAx and DMADSTINCR are ignored in table mode and can be treated as "don't care" values.

The DMASAx register needs to be programmed with the start address of the table, which needs to be aligned to 64-bit data (that is, DMASAx[2:0] = "000"). The address stored in the table needs to be on the lower word of a 64-bit data (ADDR[2:0] = "000" while the data needs to be on the upper word of a 64-bit data (ADDR[2:0] = "100"). [Table 5-5](#) is an example of a table in memory compatible with the DMA table mode.

**Table 5-5. Example of an Incremental Table Compatible with DMA Table Mode**

Table Address	Table Data
0x0000	Address 0
0x0004	Data 0
0x0008	Address 1
0x000C	Data 1

#### 5.2.5 Initiating DMA Transfers

Each DMA channel is independently configured for its trigger source with DMATSEL. The DMATSEL bits should be modified only when the DMACTLx.DMAEN bit is 0; otherwise, unpredictable DMA triggers can occur.

See the device-specific data sheet for the list of triggers available, along with their respective DMATSEL values.

When selecting the trigger, the trigger must not have already occurred, or the transfer does not take place.

DMA channels can be internally triggered upon the completion of activity on another channel to support cascading. Completion of activity occurs when a DMA channel's DMASZ counter reaches zero. This is beneficial for applications where data can be retrieved, transferred, and/or error-checked without an interrupt or event configuration.

Set the DMATINT bit to internally trigger the next DMA channel based on the DMATSEL trigger source. Once the DMATSEL trigger occurs, the next DMA channel begins to automatically execute.

For example, if UART data is received and transmitted to SRAM through DMA channel 0 and DMATSEL is set to UART RX, then DMA channel 1 can be internally triggered when the UART is finished receiving data. If DMA channel 1 is configured to transmit the data from SRAM to CRC, then the DMA transfer will trigger once the UART data is received. In this case, the DMA channels are cascaded from Channel 0 to Channel 1.

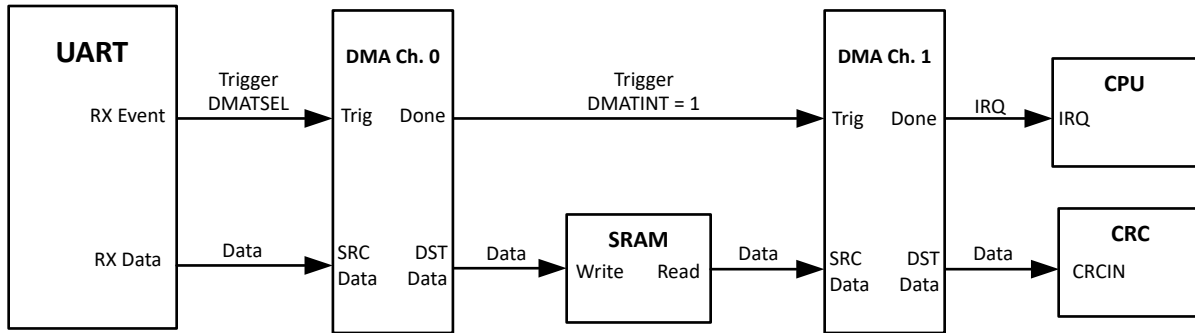

Figure 5-4. DMA Cascading Channels

### 5.2.6 Stopping DMA Transfers

A DMA block transfer in progress can be stopped by clearing the DMAEN bit. The DMA will stop after the completion of the ongoing transfer cycle and all the channel registers will stay in the current state. The block transfer can be continued as originally configured after setting the DMAEN bit again and resending the trigger. Please note that a trigger is necessary for halted transfer to resume.

**Note**

A single transfer in progress cannot be interrupted.

### 5.2.7 Channel Priorities

The default DMA channel priorities are DMA0 through DMA15. If two or three triggers happen simultaneously or are pending, the channel with the highest priority completes its transfer (single or block transfer) first, then the second priority channel, then the third priority channel. Transfers in progress are not halted if a higher-priority channel is triggered. The higher-priority channel waits until the transfer in progress completes before starting.

The DMA channel priorities are configurable with the ROUNDROBIN bit. When the ROUNDROBIN bit is set, the channel that completes a transfer becomes the lowest priority. The order of the priority of the channels always stays the same, DMA0-DMA1-DMA2, for example, for three channels. When the ROUNDROBIN bit is cleared, the channel priority returns to the default priority.

Table 5-6. Round-Robin DMA Priority Example

Current DMA Priority	Transfer Occurs	New DMA Priority
DMA0 - DMA1 - DMA2	DMA1	DMA2 - DMA0 - DMA1
DMA2 - DMA0 - DMA1	DMA2	DMA0 - DMA1 - DMA2
DMA2 - DMA0 - DMA1	DMA0	DMA1 - DMA2 - DMA0

### 5.2.8 Burst Block Mode

The DMA module supports a burst block mode for suspending an active channel after a configurable number of transfers to service other pending channels. The burst block size is configurable by setting DMAPRIO.BURSTSZ to 8, 16, 32, or an infinite number of transfers. If a higher priority channel is pending after the burst block, the DMA will execute the higher priority channel and resume on the suspended channel once the higher priority channel is complete. If no other channel is pending, the priority logic assigns the control back to the block transfer for the next burst.

### 5.2.9 Using DMA with System Interrupts

System interrupt service routines are interrupted by DMA transfers. If an interrupt service routine or other routine must execute with no interruptions, the DMA controller should be disabled before executing the routine.

### 5.2.10 DMA Controller Interrupts

Each DMA channel has its own RIS flag. Each RIS flag is set in any mode when the corresponding DMASZx register counts to zero. If the corresponding MASK and RIS bits are set, an interrupt request is generated.

All RIS flags are prioritized, with DMA0 being the highest, and combined to source a single interrupt vector. The highest-priority enabled interrupt generates a number in the IIDX register. This number can be evaluated or added to the program counter (PC) to automatically enter the appropriate software routine.

Any access, read or write, of the IIDX register automatically resets the highest pending interrupt flag. If another interrupt flag is set, another interrupt is immediately generated after servicing the initial interrupt. For example, assume that DMA0 has the highest priority. If the DMA0-RIS and DMA2-RIS flags are set when the interrupt service routine accesses the IIDX register, DMA0-RIS is reset automatically. After the interrupt service routine is executed, the DMA2-RIS generates another interrupt.

### 5.2.11 DMA Trigger Event Status

The DMA controller supports dedicated DMA events. See [Section 7.2.2](#) for details on the DMA event trigger protocol. The idea is that the DMA can inform the event triggering peripheral about the status of the assigned DMA channel. This will allow the triggering peripheral to issue an interrupt itself after the completion of a repeated transfer, instead of the DMA issuing an interrupt event. The advantage is, that the DMA interrupt service routine does not need to keep track of the assigned function of the channel. As a result, the DMA triggering peripheral interrupt service routine will deal with the completion of the DMA transfer.

The status will reflect the value of the DMASZx register. If the last DMA transfer resulted in a size decrement to zero, the DMA will return the status of 1, indicating the end of the transfer. Otherwise the status will be 0.

Additionally, the DMA module can generate an early interrupt request to the CPU to indicate that a transfer will complete within a configurable number of transfers (1, 2, 4, 8, 32, 64, half-DMASZ).

An early IRQ event is enabled by setting DMAPREIRQ to the desired number of transfers. When the DMA has reached the number of transfers, the corresponding DMA channel's PREIRQ interrupt is set.

Early DMA interrupt generation is useful to:

- Reduce the interrupt latency in timing-critical applications where it would be beneficial to let the DMA preemptively generate the IRQ before the DMA transfer is complete
- Serve as a “progress notification” when scheduling other tasks for the CPU to complete
- Transfer weights of a neural network layer and notify the CPU to complete software configuration writes to the IP
- Implement a ping-pong buffer (by setting DMAPREIRQ to half)

---

#### Note

This feature is available on repeat-capable channels only.

---

### 5.2.12 DMA Operating Mode Support

The DMA supports triggered transfers in RUN mode, as well as in the SLEEP, STOP, and STANDBY low-power modes. Refer to the following sections for more details.

#### 5.2.12.1 Transfer in RUN Mode

In RUN mode the system is fully operational. The CPU and all other peripherals and resources are available, therefore there is no restriction on the DMA functionality in RUN mode.

#### 5.2.12.2 Transfer in SLEEP Mode

In SLEEP mode only the CPU is halted. All other peripherals and resources are available as when in RUN mode, therefore there is no restriction on the DMA functionality in SLEEP mode. All peripherals that can trigger a DMA transfer in RUN mode will also be able to trigger a DMA transfer in SLEEP mode.

### 5.2.12.3 Transfer in STOP Mode

In STOP mode the CPU is halted and the ULPCLK is limited to 4MHz operation. PD1 peripherals are disabled and in retention mode when applicable. Only PD0 peripherals are functional and therefore only PD0 peripherals are able to trigger a DMA transfer in STOP mode. The DMA itself is located in PD1 and is therefore in retention during STOP mode. The event manager will detect a DMA trigger event and request the PMU to enter a "suspended STOP" state. For more info on this state refer to *Suspended Low-Power Mode Operation*. While STOP mode is suspended, the DMA is fully functional and will work on the pending DMA trigger request. Once the DMA transfer is complete, the DMA will acknowledge the pending trigger event and the event subsystem removes the power mode request from the PMU. If the PMU has no other pending requests, the SoC will transition back into normal STOP mode.

### 5.2.12.4 Transfers in STANDBY Mode

In STANDBY mode the CPU is halted and the ULPCLK is limited to 32kHz operation. PD1 peripherals are disabled and in retention mode when applicable. Only PD0 peripherals are functional and therefore only PD0 peripherals are able to trigger a DMA transfer in STANDBY mode. The DMA itself is located in PD1 and therefore in retention during STANDBY mode. The event manager will detect a DMA trigger event and request the PMU to enter a "suspended STANDBY" state. For more info on this state refer to *Suspended Low-Power Mode Operation*. While STANDBY mode is suspended, the DMA is fully functional and will work on the pending DMA trigger request. Once the DMA transfer is complete, the DMA will acknowledge the pending trigger event and the event subsystem removes the power mode request from the PMU. If the PMU has no other pending requests, the SoC will transition back into normal STANDBY mode.

### 5.2.13 DMA Address and Data Errors

The DMA itself has the ability to flag address or data errors. Source or destination address errors can come from accessing a protected or nonexisting memory range. If an address error occurs, the interrupt index IIDX[j].STAT flags a DMA address error (11h). Address error interrupts can be masked, set, and cleared using the ADDERR bit.

---

#### Note

The DMA itself does not perform range checking. If the DMA transfer occurs over a protected memory range, the destination data will report zeros (0h) for each byte of the DMA transaction that overlaps the protected or nonexisting memory range.

---

Data errors can occur in SRAM or flash if it has an ECC or parity error. If a data error occurs, the interrupt index IIDX[j].STAT flags a DMA data error (12h). Data error interrupts can be masked, set, and cleared using the DATERR bit.

### 5.2.14 Interrupt and Event Support

The DMA module contains one [event publishers](#) and two [event subscribers](#).

- One event publisher (CPU\_INT) manages DMA interrupt requests (IRQs) to the CPU subsystem through a [static event route](#).
- The second and third event (GEN\_EVENT) are used to setup the generic event publishers and subscribers through [Generic route](#).

DMA events are summarized in [Table 5-7](#).

**Table 5-7. DMA Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU interrupt</a>	Publisher	DMA	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from TIMx to CPU

**Table 5-7. DMA Events (continued)**

Event	Type	Source	Destination	Route	Configuration	Functionality
Generic publisher event	Publisher	DMA	Other peripherals	Generic route	GEN_EVENT and FPUB_1 registers	Configurable interrupt route from DMA to other peripherals
Generic subscriber event	Subscriber	Other peripherals	DMA	Generic route	FSUB_0	Configurable interrupt route from other peripherals to DMA
Generic subscriber event	Subscriber	Other peripherals	DMA	Generic route	FSUB_1	Configurable interrupt route from other peripherals to DMA

## 5.3 DMA Registers

Table 5-8 lists the memory-mapped registers for the DMA registers. All register offset addresses not listed in Table 5-8 should be considered as reserved locations and the register contents should not be modified.

**Table 5-8. DMA Registers**

Offset	Acronym	Register Name	Group	Section
400h	FSUB_0	Subscriber Port 0		<a href="#">Go</a>
404h	FSUB_1	Subscriber Port 1		<a href="#">Go</a>
444h	FPUB_1	Publisher Port 0		<a href="#">Go</a>

120Ch + formula	DMASZ[j]	DMA Channel Size		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 5-9 shows the codes that are used for access types in this section.

**Table 5-9. DMA Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 5-9. DMA Access Type Codes (continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

**1 FSUB\_0 (Offset = 400h) [Reset = 00000000h]**

FSUB\_0 is shown in [Figure 5-5](#) and described in [Table 5-10](#).

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1	SOFT	R/W	1h	Soft halt boundary control. This function is only available, if <a href="#">FREE</a> is set to 'STOP' 0h = The peripheral will halt immediately, even if the resultant state will result in corruption if the system is restarted 1h = The peripheral blocks the debug freeze until it has reached a boundary where it can resume without corruption
0	FREE	R/W	1h	Free run control 0h = The peripheral freezes functionality while the Core Halted input is asserted and resumes when it is deasserted. 1h = The peripheral ignores the state of the Core Halted input

## 5 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 5-9](#) and described in [Table 5-14](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, . . . IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in RIS [RIS] and MIS [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

Note: The number of DMACH is device dependent. Please consult the datasheet of the specific device to map which channel number is implemented.

**Figure 5-9. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 6 IMASK (Offset = 1028h) [Reset = 0000000h]

IMASK is shown in [Figure 5-10](#) and described in [Table 5-15](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then the corresponding interrupt is un-masked. Un-masking the interrupt causes the raw interrupt to be visible in IIDX [IIDX], as well as MIS [MIS].

Note: The number of DMACH is device dependent. Please consult the datasheet of the specific device to map which channel number is implemented.

## 7 RIS (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 5-11](#) and described in [Table 5-16](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR [ICLR] register bit even if the corresponding IMASK [IMASK] bit is not enabled.

Note: The number of DMACH is device dependent. Please consult the datasheet of the specific device to map which channel number is implemented.

## 9 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 5-13](#) and described in [Table 5-18](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS [RIS] bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS [MIS] bit is also set.

Note: The number of DMACH is device dependent. Please consult the datasheet of the specific device to map which channel number is implemented.

## 11 IIDX (Offset = 1050h) [Reset = 00000000h]

IIDX is shown in [Figure 5-15](#) and described in [Table 5-20](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, . . . IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in RIS [RIS] and MIS [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

Note: The number of DMACH is device dependent. Please consult the datasheet of the specific device to map which channel number is implemented.

## 12 IMASK (Offset = 1058h) [Reset = 0000000h]

IMASK is shown in [Figure 5-16](#) and described in [Table 5-21](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then the corresponding interrupt is un-masked. Un-masking the interrupt causes the raw interrupt to be visible in IIDX [IIDX], as well as MIS [MIS].

Note: The number of DMACH is device dependent. Please consult the datasheet of the specific device to map which channel number is implemented.

### 13 RIS (Offset = 1060h) [Reset = 0000000h]

RIS is shown in [Figure 5-17](#) and described in [Table 5-22](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR [ICLR] register bit even if the corresponding IMASK [IMASK] bit is not enabled.

Note: The number of DMACH is device dependent. Please consult the datasheet of the specific device to map which channel number is implemented.

### 15 ISET (Offset = 1070h) [Reset = 0000000h]

ISET is shown in [Figure 5-19](#) and described in [Table 5-24](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS [RIS] bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS [MIS] bit is also set.

Note: The number of DMACH is device dependent. Please consult the datasheet of the specific device to map which channel number is implemented.

## 6.1 NVM Overview

The nonvolatile memory system provides in-system programmable flash memory for storing executable code and data. This chapter describes the entire functionality provided by the nonvolatile memory system.

### 6.1.1 Key Features

Key features of the nonvolatile memory system include:

- In-circuit program and erase supported across the entire supply voltage range
- Internal programming voltage generation
- 64-bit flash word size (72-bit when optional ECC is present)
- Static write protection (latched at boot and held until BOR or POR)
- Dynamic write protection (configurable at runtime)
- Sector (1KB) and bank (up to 256KB) erase
- Automatic hardware preverification to extend flash bank longevity
- Automatic hardware post-verification of program/erase
- Optional ECC protection (SECDED)
- Optional bank address swap mode (for seamless dual-image firmware updates)
- Optional program register cache for time efficient programming (2, 4, or 8 flash words)

#### Note

To determine if a device has any of the optional features described above, review the nonvolatile memory system detailed description in the corresponding device data sheet.

### 6.1.2 System Components

The nonvolatile memory system consists of three components (listed below):

- One or more flash memory banks (for storing code and data)
- The flash controller (for managing all program/erase operations on the flash banks)
- The read interface (for interfacing the flash banks to the CPU and peripheral bus)

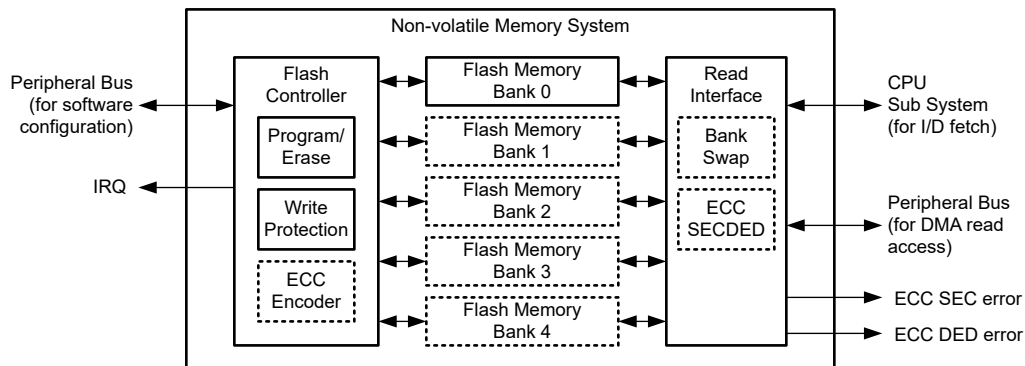

Figure 6-1. Non-volatile Memory System Components

### 6.1.3 Terminology

Key flash bank terms are defined in this section to be used as a reference for the rest of this chapter.

Table 6-1. NVM System Terminology

Term	Definition	Size
Flash word	Basic data size for program and read operations on the flash memory (also the read bus width to the system)	64 data bits (72 bits with ECC)
Word line	Group of flash words within a sector, with maximum program operation limit before sector erase	16 flash words (128 data bytes, optionally 16 ECC bytes)
Sector	Group of word lines that are erased together (minimum erase resolution of the flash memory)	8 word lines (1024 data bytes, optionally 128 ECC bytes)

**Table 6-1. NVM System Terminology (continued)**

Term	Definition	Size
Bank	Group of sectors that can be mass erased in one operation. Only one read, program, erase, or verify operation can run concurrently on a given bank.	Variable
Region	Logical assignment of a region of flash memory from a bank.	Variable

## 6.2 Flash Memory Bank Organization

The flash memory is used for storing application code and data, the device boot configuration, and parameters which are preprogrammed by TI from the factory. The flash memory is organized into one or more banks, and the memory in each bank is further mapped into one or more logical memory regions and assigned system address space for use by the application.

### 6.2.1 Banks

The nonvolatile memory system provides support for up to 5 flash memory banks (enumerated as BANK0 through BANK4). The number of flash banks present is device dependent. To determine the bank scheme of a particular device, review the detailed description section of the specific device data sheet. Most devices implement a single flash bank (BANK0).

On devices with a single flash bank, an ongoing program/erase operation will stall all read requests to the flash memory until the operation has completed and the flash controller has released control of the bank. On devices with more than one flash bank, a program/erase operation on a bank will also stall read requests issued to the bank which is executing the program/erase operation, but it will not stall read requests issued to any other bank. As such, the presence of multiple banks enables application cases such as:

- Dual-image firmware updates (an application can execute code out of one flash bank while a second image is programmed to a second symmetrical flash bank without stalling the application execution)
- EEPROM emulation (an application can execute code out of one flash bank while a second flash bank is used for writing data without stalling the application execution)

### 6.2.2 Flash Memory Regions

The memory within each bank is mapped to one or more logical regions based upon the functions that the memory in each bank supports. There are four regions: FACTORY, NONMAIN (Configuration NVM), MAIN (Flash Memory), and DATA.

**Table 6-2. Flash Memory Regions**

Flash Memory Region	Region Contents	Executable	Used by	Programmed by
FACTORY	Device ID and other parameters	No	Application	TI only (not modifiable)
NONMAIN (Configuration NVM)	Device boot configuration (BCR and BSL)	No	Boot ROM	TI, User
MAIN (Flash Memory)	Application code and data	Yes	Application	User
DATA	Data, or EEPROM emulation	No	Application	User

Devices with one bank implement the FACTORY, NONMAIN, and MAIN regions on BANK0 (the only bank present), and the data region is not available. Devices with multiple banks also implement FACTORY, NONMAIN, and MAIN regions on BANK0, but include additional banks (BANK1 through BANK4) that can implement MAIN or DATA regions.

For a detailed description of the contents of the read-only FACTORY region, see [Section 1.5](#).

### 6.2.3 Addressing

The flash memory regions are assigned to address space in the system memory map.

The NONMAIN, DATA, and FACTORY regions are assigned to the peripheral address space (0x4000.0000) as they do not contain any executable code. The CPU should not fetch executable instructions from this region.

The MAIN region is assigned to both the code address space (0x0000.0000) and the peripheral address space (0x4000.0000). Instruction and data fetches are recommended to always be done through the code address space as this gives the best performance. The CPU should not fetch executable instructions from this region.

## ECC

On devices which have error correction code (ECC) support, the ECC codes for all memory regions are also assigned to address space and it is possible for software to read the ECC codes as data for diagnostic purposes. It is also possible to read the contents of any of the memory regions without ECC correction applied.

### 6.2.3.1 Flash Memory Map

The following table lists the system address space assignments. These assignments are consistent for all devices.

**Table 6-3. Flash Region Memory Map**

Region	Read Type	ECC Behavior	Base Address
NONMAIN	Data read	Corrected	0x41C0.0000
		Uncorrected	0x41C1.0000
		ECC code	0x41C2.0000
MAIN	Instruction fetch or data read	Corrected	0x0000.0000
	Data read	Uncorrected	0x0040.0000
DATA	Data read	Corrected	0x41D0.0000
		Uncorrected	0x41E0.0000
		ECC code	0x41F0.0000
FACTORY	Data read	Corrected	0x41C4.0000
		Uncorrected	0x41C5.0000
		ECC code	0x41C6.0000

NONMAIN, DATA, and FACTORY data reads are processed through the peripheral bus and peripheral address space only. MAIN regions can be accessed through either the CPU bus matrix or through the peripheral bus, depending on whether code address space or peripheral address space is used. The code address space is recommended for CPU accesses (instruction fetches or data reads), as these accesses do not cross the peripheral bus and thus do not compete with the DMA for control of the peripheral bus. See the [bus architecture section](#) for a detailed description of the bus interconnect.

On devices that have ECC, an access to an ECC code address returns the 8-bit ECC value for the entire 64-bit flash word that was accessed. On devices that do not have ECC, accesses to the corrected and uncorrected ECC address spaces with the same offset read the same, and ECC code addresses read as 0x0.

### 6.2.4 Memory Organization Examples

[Figure 6-2](#) is an example of a single bank configuration with a 64KB MAIN region. NONMAIN and FACTORY regions are also included in the single bank (BANK0) with the MAIN region. Most devices with a main region  $\leq 128$ KB in size implement a single-bank configuration.

Figure 6-2. Memory Organization Example - Single Bank Configuration

Figure 6-3 is an example of a three bank configuration with a 512KB MAIN region split across BANK0 and BANK1, with a 16KB DATA region provided in BANK2. Like the single bank example, NONMAIN and FACTORY regions are included in BANK0. This example supports EEPROM emulation in the DATA region without stalling fetches to MAIN, and it also supports dual-image applications where BANK0 main can be written to without stalling fetches to BANK1 main (and the reverse). Most devices with a main region  $\geq 256$ KB in size implement a multibank configuration.

Figure 6-3. Memory Organization Example - Multiple Bank Configuration

### 6.3 Flash Controller

The flash controller manages all program, erase, and verification operations performed on the nonvolatile memory system. It contains memory-mapped registers in the peripheral region of the device memory map which must be configured by software to perform operations on the flash memory.

TI provides software abstraction for the flash controller as a part of the DriverLib layer of the software development kit (SDK). It is recommended to use the DriverLib abstraction layer when operating on the flash memory with software, but it is not mandatory to do so. To use the DriverLib software abstraction layer to perform operations on the flash memory, review the software development kit (SDK) documentation provided separately from this document. To directly operate on the flash memory with using low level register accesses to the flash controller, review the remainder of this section in detail.

#### Note

The FLASHCTL registers may not always be configured to default values after a reset. This may occur if the boot configuration routine (BCR) or boot strap loader (BSL) perform an operation on the flash memory during boot. When configuring the FLASHCTL registers for an operation, ensure that all registers which are relevant for the operation are correctly configured.

### 6.3.1 Overview of Flash Controller Commands

Operations on the flash memory are executed by configuring the CMDTYPE and CMDCTL registers for the desired command, along with any other registers which must be configured for a particular command, and writing 0x01 to the CMDEXEC register to initiate the command.

When 0x01 is set in CMDEXEC, the commanded operation begins executing. While an operation is executing, most configuration registers are blocked for writes until the operation completes. Some registers (for example, mask registers) can change state under hardware control while the operation runs to completion. The flash controller indicates completion of the commanded operation by setting the CMDDONE bit in the STATCMD register. The flash controller also sources an interrupt vector to the CPU subsystem to indicate a “DONE” status when an operation has completed.

The software sequence of setting the CMDEXEC bit and waiting for the CMDDONE response must be executed from either the device SRAM or from a different flash bank from the bank that is being operated on, as the flash controller will take control of the flash bank undergoing the operation. Reads to the flash bank that is being operated on while the flash controller is executing the command are not predictable.

The flash controller provides five basic commands for operating on the flash memory, specified in the COMMAND field of the CMDTYPE register. These commands are described in [Table 6-4](#).

**Table 6-4. Flash Controller Commands**

Command	Description
NOOP	No operation (default setting).
PROGRAM	Selects a program operation on the flash memory.
ERASE	Selects an erase operation on the flash memory.
READVERIFY	Selects a standalone read verify operation.
BLANKVERIFY	Selects a standalone blank verify operation.

#### Note

It is recommended to call clear status command (CMDTYPE = 0x5) before call any flash operation.

### 6.3.2 NOOP Command

When not using the flash controller, it is best to set the COMMAND field to NOOP to prevent any unintentional operations on the flash memory in the event that the VAL bit in CMDEXEC is unintentionally set. Executing a NOOP command has no effect on the flash memory.

### 6.3.3 PROGRAM Command

The program command is used to write (program) the flash memory. Specifically, the purpose of a PROGRAM operation is to configure the flash bits in one or more flash words from the nondeterministic erased state to the deterministic programmed state. Once a byte is programmed using the PROGRAM command, the byte can not be re-programmed unless the sector is erased using the [ERASE](#) command.

All devices support single flash word programming of 64 data bits (plus 8 ECC bits on devices with ECC) at a time, with control to limit the scope of a program operation to specific bytes within a 64-bit flash word.

Some devices additionally have support for a multi-word programming mode where 2, 4, or 8 flash words can be written with a single commanded operation. Multi-word programming, when available, significantly speeds up programming when multiple words need to be programmed (for example, during production programming or firmware updates). See the device-specific data sheet to determine if multi-word programming is supported, and if so, how many flash word buffers are provided.

#### 6.3.3.1 Program Bit Masking Behavior

The flash controller provides a program verification mechanism to extend the lifetime of the flash bank. During program operations, the CMDDATAx registers are used by the flash controller as a programming bit mask to

indicate which specific bits in the flash word require program pulses. As a result, data which is loaded into the CMDDATAx registers before starting the program operation will be lost from the CMDDATAx registers during and/or upon completion of the program operation. If the same data is to be programmed again, the CMDDATAx registers must be re-loaded by software with the correct data values to be programmed.

### 6.3.3.2 Programming Less Than One Flash Word

In general, the simplest way to program the flash memory is one flash word at a time (64 bits plus 8 ECC bits if ECC is present). It is possible to program the flash memory with 32-, 16-, or 8-bit (byte) resolution, but special care must be taken when doing so to ensure the following:

1. On devices with ECC, ECC bits must be [handled properly](#) to prevent inadvertent ECC errors.
2. The number of program operations applied to a given word line must be monitored to ensure that the maximum word line program limit before erase is not violated.
3. Once a byte has been programmed, the sector containing the byte must be erased before attempting to re-program the same byte.

To program less than one flash word, the CMDBYTEN register must be configured to indicate which bytes in the flash word are to be programmed before starting the program operation. Each bit in CMDBYTEN corresponds to a byte in the flash word to be programmed, including the ECC bits.

#### Handling ECC

On devices with ECC, programming 64 bits of data at a time ensures that the 8 ECC bits which correspond to the 64-bit data word are also programmed both correctly and at the same time. Doing so prevents ECC errors from occurring if the memory locations are read by the CPU or DMA after programming.

If use of ECC is planned and partial programming is required, one approach is to mask (not program) the ECC bits until all 64 bits of a flash word are programmed, at which time the ECC bits can also be programmed. Programming of ECC bits is masked by clearing BIT8 (0x100) in the CMDBYTEN register. This prevents a situation where the entire sector must be erased each time a program operation is done to re-program ECC bits to match the new 64-bit data. However, in this case, a read to a partially programmed word where the ECC bits are not yet written would result in an ECC error. To avoid an ECC error, the software must either wait until the full 64-bit flash word and the 8 ECC bits are written, or read the data from the uncorrected address space.

#### Maximum Program Operations per Word Line Before Erase

The device data sheet specifies a maximum limit on the number of program operations per word line before erasure of the sector containing the word line is required. Exceeding this maximum can result in data corruption within the word line.

If 16-bit or greater program operations are performed, and no 16-bit location is programmed more than once before a sector is erased, **the maximum limit will never be reached and thus does not need to be considered.**

If 8-bit (byte) program operations are performed, the maximum program limit per word line must be considered and not exceeded. Program operations performed on ECC locations, if done independently from other program operations, count towards the number of writes before an erase is required.

#### Executing a Program Less Than One Flash Word

To program the flash memory with 16-bits at address 0x1000:

1. Program 16 bit at address 0x1000 (ECC is not programmed at this step):
  - a. CMDATAT0 is written with DATA1, CMDDATA1 is not used.
  - b. CMDBYTEEN = 0x003.
2. Program 16 bit at address 0x1002 (ECC is not programmed at this step):
  - a. CMDATAT0 is written with DATA2, CMDDATA1 is not used.

- b. `CMDBYTEEN = 0x00C`.
3. Program 16 bit at address `0x1004` (ECC is not programmed at this step):
  - a. `CMDATAT1` is written with `DATA3`, `CMDDATA0` is not used.
  - b. `CMDBYTEEN = 0x030`.
4. Program 16 bit at address `0x1006` (ECC is programmed at this step):
  - a. `CMDATAT0` is written with `DATA1` and `DATA2`.
  - b. `CMDATAT1` is written with `DATA3` and `DATA4`.
  - c. `CMDBYTEEN = 0x1FF`.

### 6.3.3.3 Target Data Alignment (Devices with Single Flash Word Programming Only)

For devices which only support single word programming, only the `CMDDATA0`, `CMDDATA1`, and `CMDECC0` registers are used to load data to be programmed to the flash memory. `CMDDATA0` is always loaded with `BIT31-BIT0` of the target data, and `CMDDATA1` is always loaded with `BIT63-BIT32` of the target data. ECC data, if specified directly and not computed automatically, is loaded into `BIT7-BIT0` of `CMDECC0`. No other `CMDDATAx` or `CMDECCx` registers are used, and `CMDDATAINDEX` is not used. If fewer than 64 data bits are being programmed, see the special handling requirements section above for programming less than one flash word.

Single-word program operations must be flash word (64-bit) aligned. This means that the target system address specified in `CMDADDR` must be aligned to a `0b000` boundary (for example, the 3 LSBs in `CMDADDR` must be zero).

### 6.3.3.4 Target Data Alignment (Devices With Multiword Programming)

For devices that support 2-, 4-, or 8-word programming, there are two options for loading data to be programmed: direct mode or indexed mode. The programmer must select the mode that is most suitable to the application requirements.

Additional alignment rules apply when loading data into the `CMDDATAx` and `CMDECCx` registers on devices that support multiword programming, even if the multiword programming feature is not used and only single word programming is not used.

- 1-word program operations must have `CMDADDR` (the target system address) aligned to a `0b000` boundary (for example, the 3 LSBs in `CMDADDR` must be zero).
- 2-word program operations must have `CMDADDR` (the target system address) aligned to a `0b0000` boundary (for example, the 4 LSBs in `CMDADDR` must be zero).
- 4-word program operations must have `CMDADDR` (the target system address) aligned to a `0b0.0000` boundary (for example, the 5 LSBs in `CMDADDR` must be zero).
- 8-word program operations must have `CMDADDR` (the target system address) aligned to a `0b00.0000` boundary (for example, the 6 LSBs in `CMDADDR` must be zero).

### Direct Data Load

To configure a program operation with direct data loading, the target data is loaded into the appropriate `CMDDATAx` registers based on the number of flash words supported by the device, the target address alignment, and the target data size. For example, if a 4-word program operation is to be initiated on a device supporting 4-word programming, the `CMDDATA0-CMDDATA7` registers would be populated with the target data. If ECC is being specified directly (rather than automatically calculated by the flash controller) then the appropriate `CMDECCx` registers also needs to be populated with the ECC values for each data word being programmed.

### Indexed Data Load

Rather than buffering data into all the `CMDDATAx` registers individually, it is possible to use only the `CMDDATA0-CMDDATA1` registers in combination with an index register (`CMDDATAINDEX`) to indicate the flash word offset of the data being loaded. In this way, the index can be adjusted for each word loaded, and each

target data word can be written to the same 64-bit space (CMDDATA0-CMDDATA1). When an index is applied, the loaded data will be mapped by the hardware into the appropriate CMDDATAx register. For example, if a 4-word program operation is to be initiated on a device supporting 4-word programming, the CMDDATA1:0 registers are loaded 4 times with the target data, with CMDDATAINDEX being incremented by one before each new word is loaded into CMDDATA1:0.

### Alignment Rules

The alignment rules for each device configuration (2, 4, or 8 words) is given in the tables below with guidance on how target data must be placed with the CMDDATAx, CMDECCx, and CMDDATAINDEX registers for 1, 2, 4, or 8 word programming operations.

**Table 6-5. Data Load Alignment for Devices Supporting Programming of 2 Flash Words**

Direct Load Registers	Indexed Load Index	1 Word Aligned to 0b000	2 Words Aligned to 0b0000	4 Words Aligned to 0b0.0000	8 Words Aligned to 0b00.0000
CMDDATA1:0 / CMDECC0	CMDINDEX = 0	Target data word 0 if the target address ends in 0b0000	Target data word 0	Not supported	Not supported
CMDDATA3:2 / CMDECC1	CMDINDEX = 1	Target data word 0 if the target address ends in 0b1000	Target data word 1		

**Table 6-6. Data Load Alignment for Devices Supporting Programming of 4 Flash Words**

Direct Load Registers	Indexed Load Index	1 Word Aligned to 0b000	2 Words Aligned to 0b0000	4 Words Aligned to 0b0.0000	8 Words Aligned to 0b00.0000
CMDDATA1:0 / CMDECC0	CMDINDEX = 0	Target data word 0 if the target address ends in 0b0.0000	Target data word 0 if the target address ends in 0b0.0000	Target data word 0	Not supported
CMDDATA3:2 / CMDECC1	CMDINDEX = 1	Target data word 0 if the target address ends in 0b0.1000	Target data word 1 if the target address ends in 0b0.0000	Target data word 1	
CMDDATA5:4 / CMDECC2	CMDINDEX = 2	Target data word 0 if the target address ends in 0b1.0000	Target data word 0 if the target address ends in 0b1.0000	Target data word 2	
CMDDATA7:6 / CMDECC3	CMDINDEX = 3	Target data word 0 if the target address ends in 0b1.1000	Target data word 1 if the target address ends in 0b1.0000	Target data word 3	

**Table 6-7. Data Load Alignment for Devices Supporting Programming of 8 Flash Words**

Direct Load Registers	Indexed Load Index	1 Word Aligned to 0b000	2 Words Aligned to 0b0000	4 Words Aligned to 0b0.0000	8 Words Aligned to 0b00.0000
CMDDATA1:0 / CMDECC0	CMDINDEX = 0	Target data word 0 if the target address ends in 0b00.0000	Target data word 0 if the target address ends in 0b00.0000	Target data word 0 if the target address ends in 0b00.0000	Target data word 0
CMDDATA3:2 / CMDECC1	CMDINDEX = 1	Target data word 0 if the target address ends in 0b00.1000	Target data word 1 if the target address ends in 0b00.0000	Target data word 1 if the target address ends in 0b00.0000	Target data word 1
CMDDATA5:4 / CMDECC2	CMDINDEX = 2	Target data word 0 if the target address ends in 0b01.0000	Target data word 0 if the target address ends in 0b01.0000	Target data word 2 if the target address ends in 0b00.0000	Target data word 2
CMDDATA7:6 / CMDECC3	CMDINDEX = 3	Target data word 0 if the target address ends in 0b01.1000	Target data word 1 if the target address ends in 0b01.0000	Target data word 3 if the target address ends in 0b00.0000	Target data word 3
CMDDATA9:8 / CMDECC4	CMDINDEX = 4	Target data word 0 if the target address ends in 0b10.0000	Target data word 0 if the target address ends in 0b10.0000	Target data word 0 if the target address ends in 0b10.0000	Target data word 4

**Table 6-7. Data Load Alignment for Devices Supporting Programming of 8 Flash Words (continued)**

Direct Load Registers	Indexed Load Index	1 Word Aligned to 0b000	2 Words Aligned to 0b0000	4 Words Aligned to 0b0.0000	8 Words Aligned to 0b00.0000
CMDDATA11:10 / CMDECC5	CMDINDEX = 5	Target data word 0 if the target address ends in 0b10.1000	Target data word 1 if the target address ends in 0b10.0000	Target data word 1 if the target address ends in 0b10.0000	Target data word 5
CMDDATA13:12 / CMDECC6	CMDINDEX = 6	Target data word 0 if the target address ends in 0b11.0000	Target data word 0 if the target address ends in 0b11.0000	Target data word 2 if the target address ends in 0b10.0000	Target data word 6
CMDDATA15:14 / CMDECC7	CMDINDEX = 7	Target data word 0 if the target address ends in 0b11.1000	Target data word 1 if the target address ends in 0b11.0000	Target data word 3 if the target address ends in 0b10.0000	Target data word 7

### 6.3.3.5 Executing a PROGRAM Operation

To program the flash memory:

1. Select the command in the CMDTYPE register:
  - a. Set the COMMAND field in the CMDTYPE register to PROGRAM.
  - b. Set the SIZE field in the CMDTYPE register to the desired size (1, 2, 4, or 8 flash words). If a device does not support multi-word programming, select ONEWORD. If a device supports multi-word programming, and multi-word programming is desired, select the desired size which is less than or equal to the max size supported by the target device. The hardware will not check for invalid configuration of the SIZE field; software must ensure that the selection option is supported by the device. Note that SECTOR and BANK sizes are not valid sizes for PROGRAM operations. These sizes only apply to erase operations.
2. Configure the program command in the CMDCTL register:
  - a. On devices with ECC, the flash controller by default will generate the needed ECC bits from the data during the PROGRAM operation. Optionally, software can override the hardware ECC code generation and manually provide the ECC code to be programmed by setting the ECCGENOVR bit in CMDCTL register.
3. Select the target programming address in the CMDADDR and CMDBYTEN register:
  - a. Load the target system address into the CMDADDR register to indicate the base address from which programming will start. The target address must be a flash word address (64-bit aligned). The flash controller will translate the system address into the applicable flash region, bank ID, and bank address. If desired, after the operation completes the flash region, bank ID, and bank address can be read from the STATADDR register. In a multi-word program, STATADDR will indicate the bank ID and the final address which was programmed.
  - b. If subword programming (programming of less than the full 64 or 72 bit flash word) is desired, configure the CMDBYTEN register to set the bytes within the addressed flash word which are to be programmed. Each bit in CMDBYTEN corresponds to a byte in the addressed flash word to be programmed, including the ECC byte. For example, programming of the ECC code can be masked by clearing bit 8 in CMDBYTEN while programming the data bytes of the flash word. Note that there is a maximum number of program operations allowed per word line before a sector erase must be applied (see the device specific data sheet for the maximum).
4. Load the data to program into the CMDDATAx registers:
  - a. For a single flash word programming operation (64 or 72 bits depending on the presence of ECC), load the data into the CMDDATAx registers consistent with the alignment requirements (for devices which only support single-word programming, CMDDATA0 and CMDDATA1 are always used regardless of the target address).
  - b. For multi-word programming (if available and selected), load data into the CMDDATAx registers consistent with the alignment rules and the size of the multi-word program operation specified in step 1.

- c. If ECCGENOVR in the CMDCTL register was set above (disabling hardware ECC code generation), then write the ECC data in the CMDDATAECC0 register (for single word programming) and optionally additional CMDDATAECCx registers as applicable for multi-word programming.
  - d. Note that the CMDDATA registers are used as bit masking registers by the flash controller during the program operation; after the operation completes, the values written to these registers will have been overwritten by the flash controller.
5. Ensure the [write protection](#) scheme is configured to allow writes to the target addresses (see the write protection section of this guide for additional information on configuring write protection).
  6. Execute the program operation by writing 0x1 to the CMDEXEC register.
  7. Monitor for completion of the program operation:
    - a. The STATCMD register can be polled to determine the status of the program operation. The CMDINPROGRESS bit will be set by hardware as soon as the command is initiated. The CMDDONE bit will be set when the operation terminates.
    - b. When CMDDONE is set, the CMDPASS bit will be reset or set at the same time to indicate whether the operation completed successfully or failed. If a program was attempted on a protected region, the FAILWEPROT or FAILILLADDR bit is asserted depend on dynamic or static write protection. If the program operation cannot be completed successfully within the maximum program pulse count limit FAILVERIFY will be asserted. See the device-specific data sheet for maximum program times.
  8. After completion of a program operation, the flash controller will configure several settings:
    - a. All dynamic write protection registers are set to a protected state (to protect against inadvertent programming)
    - b. All data registers are set to 1.
    - c. All program byte enables are cleared to 0.
  9. Following programming of the flash memory, it is possible that there may be stale data in the processor's cache and prefetch logic. Before reading locations which were programmed, it is recommended to first flush the cache in the CPU subsystem.

### 6.3.4 ERASE Command

The erase command is used to erase individual sectors of flash memory (for MAIN, NONMAIN, or DATA regions) or a complete bank of flash memory (for MAIN regions only). From this erased state, bits can later be programmed to a '0' state or a '1' state as desired using the PROGRAM command. It is not possible to erase with a resolution lower than one sector (1KB) with sector alignment. For devices with multiple banks, a bank erase must be executed on all banks to erase the entire MAIN region on the device.

#### 6.3.4.1 Erase Sector Masking Behavior

The flash controller provides an erase verification mechanism to extend the lifetime of the flash bank. The CMDWEPROTx registers are used as an erase mask and are manipulated by the flash controller during the execution of the erase operation. At the end of all erase operations, the CMDWEPROTx registers are set to a fully protected state to prevent against inadvertent programming and must be re-configured before attempting another program or erase operation.

#### 6.3.4.2 Executing an ERASE Operation

To erase a sector or bank of the flash memory, follow these steps:

1. Select the command in the CMDTYPE register:
  - a. Set the COMMAND field in the CMDTYPE register to ERASE.
  - b. Set the SIZE field in the CMDTYPE register to SECTOR or BANK. Sizes other than SECTOR or BANK (for example, ONEWORD) are not supported by the ERASE command. It is the responsibility of software to check the configuration before issuing an ERASE command.
2. Select the target erase address in the CMDADDR register:

- a. Store the target system address into the CMDADDR register to indicate the base address of the sector or bank to be erased. When performing a bank erase with write protection enabled (such that only unprotected sectors are erased), ensure that the address written to CMDADDR is in an unprotected sector. The flash controller will translate the system address into the applicable flash region, bank ID, and bank address. If desired, after the operation completes the flash region, bank ID, and bank address can be read from the STATADDR register.
3. Ensure the [write protection](#) scheme is configured to allow writes to the target sectors (see the write protection section of this guide for additional information on configuring write protection).
4. Execute the erase operation by writing 0x1 to the CMDEXEC register.
5. Monitor for completion of the erase operation:
  - a. The STATCMD register can be polled to determine the status of the erase operation. The CMDINPROGRESS bit will be set by hardware as soon as the command is initiated. The CMDDONE bit will be set when the operation terminates. When CMDDONE is set, the CMDPASS bit will be reset or set at the same time to indicate whether the operation completed successfully or failed.
  - b. If an erase was attempted on a protected region, the FAILWEPROT bit is asserted.
  - c. If the erase operation cannot be completed successfully within the maximum erase pulse count limit, FAILVERIFY will be asserted.
6. After completion of the erase operation, the flash controller will configure several settings to protect against inadvertent programming:
  - a. All dynamic write protection registers are set to a protected state.

### 6.3.5 READVERIFY Command

The read verify command can be used to read a flash location and compare the data to data which is preloaded into the CMDDATA registers of the flash controller. The command can be applied to a single flash word, multiple flash words (if the device supports multi-word programming), an entire sector, or an entire bank. When performing a read verify on an entire sector or bank, the data in CMDDATAx will be re-used.

#### 6.3.5.1 Executing a READVERIFY Operation

To execute a read verify command, follow these steps:

1. Select the command in the CMDTYPE register:
  - a. Set the COMMAND field in the CMDTYPE register to READVERIFY.
  - b. Set the SIZE field in the CMDTYPE register to the desired size.
2. Configure the read verify command in the CMDCTL register:
  - a. If the desire is to manually provide ECC bits along with the data, set the ECCGENOVR bit in the CMDCTL register. If ECCGENOVR is cleared, the flash controller will generate ECC bits for comparison based on the provided compare data.
3. Select the target address to verify on the CMDADDR register:
  - a. Load the target system address into the CMDADDR register to indicate the base address to be verified. The flash controller will translate the system address into the applicable flash region, bank ID, and bank address. If desired, after the operation completes the flash region, bank ID, and bank address can be read from the STATADDR register.
4. Load the data to verify into the CMDDATAx registers:
  - a. For single word verification, write the data to be verified to the CMDDATA0 and CMDDATA1 registers. For multi-word verification, if available on the target device, write the data to be verified to the appropriate CMDDATAx registers beyond CMDDATA0 and CMDDATA1.
5. Configure the byte enable settings in the CMDBYTEN register:

- a. Any CMDBYTEN bit set to logic “0” will mask the associated data byte from being compared during the execution of the READVERIFY command. This can be used to verify data less than one flash word (less than 64 bits).
6. Execute the read verify operation by writing 0x1 to the CMDEXEC register.
7. Monitor for completion of the read verify operation:
  - a. The STATCMD register can be polled to determine the status of the erase operation. The CMDINPROGRESS bit will be set by hardware as soon as the command is initiated. The CMDDONE bit will be set when the operation terminates. When CMDDONE is set, the CMDPASS bit will be reset or set at the same time to indicate whether the read verification passed or failed.
  - b. The FAILVERIFY bit in STATCMD will be set if any data read from the flash did not match the expected data loaded in CMDDATAx.
8. After completion of the read verify operation, the flash controller will configure several settings:
  - a. All dynamic write protection registers are set to a protected state (to protect against inadvertent programming).
  - b. All data registers are set to ‘1’s.
  - c. All program byte enables are cleared to ‘0’s.

### 6.3.6 BLANKVERIFY Command

The blank verify (BLANKVERIFY) command can be used by application software to verify that a flash word is blank. A blank flash word is defined as a flash word which has been successfully erased with the [ERASE command](#) and not yet programmed away from that nonerased state with the [PROGRAM command](#).

After erase, a flash word is not in a deterministic state until it is programmed using the [PROGRAM command](#). This means that application software can not expect that erased bits will read back as ‘1’s’ after an erase. A memory location must be successfully programmed using the PROGRAM command before a read of that memory location can be considered deterministic and used by application software.

Because it is not possible to determine if a flash word is in an erased state by simply reading the location directly (as an erased location will return nondeterministic data when read), the BLANKVERIFY command can be used to test if a flash word is in a blank state, indicating it has not yet been programmed away from an erased state.

The BLANKVERIFY command can only be applied to a single flash word at a time.

---

#### Note

After erasure, if programming flash with 0xFFFFFFFF, performing a blank verify at this location will also pass.

---

#### 6.3.6.1 Executing a BLANKVERIFY Operation

To execute a blank verify operation, follow these steps:

1. Select the command in the CMDTYPE register:
  - a. Set the COMMAND field in the CMDTYPE register to BLANKVERIFY.
  - b. Set the SIZE field in the CMDTYPE register to one word.
2. Select the target address to verify in the CMDADDR register:
  - a. Store the target system address into the CMDADDR register to indicate the base address to be verified. The flash controller will translate the system address into the applicable flash region, bank ID, and bank address. If desired, after the operation completes the flash region, bank ID, and bank address can be read from the STATADDR register. All 8 data bytes in the specified flash word, and the corresponding ECC byte, will be checked by BLANKVERIFY.
3. Execute the blank verify operation by writing 0x1 to the CMDEXEC register.
4. Monitor for completion of the blank verify operation:

- a. The STATCMD register can be polled to determine the status of the erase operation. The CMDINPROGRESS bit will be set by hardware as soon as the command is initiated. The CMDDONE bit will be set when the operation terminates. When CMDDONE is set, the CMDPASS bit will be reset or set at the same time to indicate whether the blank verification passed or failed.
  - b. The FAILVERIFY bit in STATCMD will be set if the flash location is not erased.
5. After completion of the blank verify operation, the flash controller will configure several settings:
- a. All dynamic write protection registers are set to a protected state ( to protect against inadvertent programming)
  - b. All data registers are set to '1's.
  - c. All program byte enables are cleared to '0's.

### 6.3.7 Command Diagnostics

The flash controller updates several software-readable registers to communicate information about an initiated operation.

#### 6.3.7.1 Command Status

The STATCMD register is a read-only register which provides diagnostic information about an operation which is been initiated or completed. The CMDINPROGRESS bit indicates that an operation is currently ongoing. The CMDDONE bit indicates that an operation has completed. These bits can be polled by software to determine the state of the flash controller during operations.

#### 6.3.7.2 Address Translation

The STATADDR register is a read-only register which can be read to determine the current bank ID, region ID, and bank address which the flash controller is pointing to. These values can increment during execution of certain commands, in which case the value present after the completion of a command indicates the last address touched by the flash controller.

#### 6.3.7.3 Pulse Counts

The STATPCNT register is a read-only register which can be read to determine the current pulse count applied during a program or erase operation.

### 6.3.8 Overriding the System Address With a Bank ID, Region ID, and Bank Address

Normally, flash controller commands are targeted to a specific flash location by loading a system memory map address into the CMDADDR register. This is the recommended way to specify the target address for a PROGRAM, ERASE, READVERIFY, or BLANKVERIFY command. In this mode of operation, the flash controller will automatically translate the system address into the corresponding bank ID, region ID, and bank address which are used to execute the command on the flash memory. Application software does not need to specify these items individually; only the system address is needed.

However, in some circumstances it can be desirable to directly specify the target flash bank, region, and address in the specified bank/region. For example, if the desire is to erase a complete bank when doing a mass erase operation on the device, application software actually does not need to have any knowledge of the system address of the bank to be erased- it only needs to specify the bank ID and region ID to the flash controller to erase the bank.

To use the flash controller to execute a command in address override mode, set the ADDRXLATEOVR bit in the CMDCTL register, and specify the bank ID, region, and bank address before executing the command. To return to system addressed mode, clear ADDRXLATEOVR. ADDRXLATEOVR is cleared by default (supporting system address operation).

### Example Case - Bank Erase with ADDRXLATEOVR

To erase the MAIN region of BANK0 by specifying the bank ID and region instead of the system address, follow the steps in [Section 6.3.4.2](#), but replace step 2 with the alternate steps given below:

1. Set the ADDRXLATEOVR bit in CMDCTL to enable address translation override mode
2. Specify BANK0 by setting the BANKSEL field to 0x1 in the CMDCTL register
3. Specify the MAIN region by setting the REGIONSEL field to 0x1 in the CMDCTL register
4. Set the CMDADDR register to 0x0000.0000

### 6.3.9 FLASHCTL Events

The flash controller contains one [event publisher](#) and no [event subscribers](#). One event publisher (CPU\_INT) manages FLASHCTL interrupt requests (IRQs) to the CPU subsystem through a [static event route](#).

[Table 6-8](#) summarizes the FLASHCTL events.

**Table 6-8. FLASHCTL Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU Interrupt Event</a>	Publisher	FLASHCTL	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from FLASHCTL to CPU

#### 6.3.9.1 CPU Interrupt Event Publisher

The FLASHCTL module provides one interrupt source which can be configured to source a [CPU interrupt event](#). The FLASHCTL interrupt conditions are given in [Table 6-9](#).

**Table 6-9. FLASHCTL CPU Interrupt Conditions**

Index (IIDX)	Name	Description
0	DONE	Indicating that the FLASHCTL operation has completed

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring these registers.

## 6.4 Write Protection

The flash controller provides two write protection mechanisms (one static, one dynamic) which are applied in parallel (logical OR) to protect user-specified sectors during any attempted program or erase operation. If a program or erase operation is issued to a write protected flash sector, the operation will terminate with a FAILWEPROT error reported in the STATCMD register.

### 6.4.1 Write Protection Resolution

The write protection resolution for both the static and dynamic write protection mechanisms is dependent on the flash bank and memory region which is being protected.

**Table 6-10. Write Protection Resolution by Region**

Flash Bank	Memory Region	Write Protection Resolution
0	NONMAIN	512B (entire region)
	MAIN	1KB (1 sector) for first 32KB (32 sectors) 8KB (8 sectors) for remaining sectors
1-4	MAIN	8KB (8 sectors)
	DATA	1KB (1 sector)

### 6.4.2 Static Write Protection

The static write protection scheme is configured and latched during device boot by the immutable ROM boot code before the main application in flash can execute. After a flash sector is configured to be write protected

through the static write protection mechanism, software cannot remove the protection at runtime without a reboot. Thus, sectors protected by static write protection can be thought of as immutable after boot. This type of protection is useful for protecting a custom bootloader in a dual-image application, or for extending the secure root of trust from the ROM boot code into a portion of the main flash region to enable a secure boot manager with locked public keys.

The static write protection scheme is configured by programming the appropriate bits in the NONMAIN flash region, which is read by the boot code before the main application starts. The NONMAIN flash sector can be statically write protected, resulting in a system in which the static write protection scheme is fully permanent and cannot be modified. If the NONMAIN sector is configured to be statically protected, along with any other flash sectors, all statically protected flash sectors can be functionally viewed as read only memory which cannot be updated by any means.

Static write protection can be configured for all sectors of flash memory across all banks present on a device. Program or erase static write protected area will cause illegal address failure, and the FAILILLADDR bit in STATCMD will be set. Instructions for configuring the static write protection, along with the rest of the NONMAIN region, are given in [Section 1.4](#).

### 6.4.3 Dynamic Write Protection

The dynamic write protection scheme is intended to be configured at runtime by software. This scheme provides a simple way for application software to specify sectors to protect from modification by any program or erase operations that are issued with the flash controller. Unlike the static write protection mechanism, the dynamic mechanism is not lockable and thus does not provide any level of data security.

There are two primary uses for dynamic write protection. First, it provides an extra level of robustness against unintentional program or erase of specified sectors in applications that involve in-system programming for either firmware updates or EEPROM emulation. Second, it provides a way to simplify a situation where a bank erase is desired but a small number of sectors should not be erased when a bank erase command is issued. One example would be an application running on a single-bank device in which most of the MAIN region sectors are used to store the executable image, but a few sectors are used to store device-specific data that should not be erased during a firmware update. In that case, the sectors containing the device-specific data can be protected with dynamic write protection, and a bank erase command can be issued to erase all other sectors. This has the benefit that the majority of the MAIN region can be erased with a single command (a bank erase) rather than individual sector-by-sector commands, which would have a longer overall erase time and use more energy.

The dynamic write protection scheme is configured by setting up the CMDWEPROTx registers in the flash controller. The CMDWEPROTx registers cover one flash bank at a time. This means that these registers must be configured with knowledge of which flash bank an attempted program or erase operation will be applied to. Note that the CMDWEPROTx registers are reset to a protected state at the end of all program and erase operations. These registers must be re-configured by software before a new operation is initiated. Program or erase dynamic write protected area will cause write/erase protection failure, and the FAILWEPROT bit in STATCMD will be set.

#### 6.4.3.1 Configuring Protection for the MAIN Region

The CMDWEPROTA register is used to configure the dynamic write protection for the first 32 sectors (32KB) of the MAIN region in BANK0. Each bit corresponds to one sector of the MAIN region, starting from the beginning of the MAIN region. CMDWEPROTA is only applicable to operations on the lower 32 sectors of the MAIN region of BANK0 (sectors 0-31). It is not used during program/erase operations applied to other sectors.

The CMDWEPROTB register is also used to configure the dynamic write protection for the MAIN region. There are two modes in which CMDWEPROTB is applied, depending on whether the program/erase operation is being applied to BANK0 or BANK1-4. In the case of a program/erase operation on BANK0, CMDWEPROTB protects sectors 32-255 in 8-sector increments (1 bit per 8KB), starting from BIT4. BIT0-BIT3 in CMDWEPROTB are ignored. The lower 32 sectors (sectors 0-31 of BANK0) are protected by CMDWEPROTA. In the case of a program/erase operation on BANK1-4, CMDWEPROTB protects sectors 0-255 in 8-sector increments (1 bit per 8 sectors), starting from BIT0 in CMDWEPROTB.

The CMDWEPROTC register configures the dynamic write protection for the MAIN region. For BANK0-4, CMDWEPROTC protects sectors 256-511 in 8-sector increments (1 bit per 8 sectors).

#### 6.4.3.2 Configuring Protection for the NONMAIN Region

The CMDWEPROTNM register protects the NONMAIN region from program and erase. One protection bit is provided per sector. Devices only have one NONMAIN sector and it will be in BANK0.

### 6.5 Read Interface

The read interface provides the read path to the CPU subsystem (for instruction/data fetch), the read path to the peripheral bus (for use by the DMA controller or CPU), main bank address swapping, and detection and reporting of ECC SEC or DED errors.

#### 6.5.1 Bank Address Swapping

Devices that contain more than one bank support swapping of the MAIN regions of the banks within the address space. This mechanism enables two versions of application firmware to be programmed into the device without the firmware needing to know which physical bank it exists in.

Table 6-11 gives an example of the mapping before and after a bank swap is requested for a device with a 512KB main flash split across 2 banks (256KB each).

**Table 6-11. Bank Address Swap Translation**

Bank and Region	Address Space Before Swap	Address Space After Swap
BANK0 MAIN	0x0000.0000 – 0x0003.FFFF	0x0004.0000 – 0x0007.FFFF
BANK1 MAIN	0x0004.0000 – 0x0007.FFFF	0x0000.0000 – 0x0003.FFFF

After a device reset, the MAIN region of the lower bank is always mapped to the lowest address space. The application software is responsible for determining if a bank address swap is to be applied. The bank address swap control is contained within the SYSCTL module; see the SYSCTL chapter for register and bit definitions. During an address swap, the application software must meet the following constraints:

1. The software must disable interrupts before issuing the bank swap command.
2. The software must poll the bank swap status after issuing the bank swap command before proceeding with execution.
3. If the swap command and poll status routines are executing from flash, they must exist at the exact same location in both banks such that execution resumes from where it left off after the bank swap. This restriction does not apply if the bank swap and status polling is done from SRAM and not from flash memory.

#### 6.5.2 ECC Error Handling

The read interface corrects single bit errors in a 64-bit flash word (SEC) and detects dual-bit errors in a 64-bit flash word (DED). ECC checks are ignored for an “all-1’s” scenario or an “all-0’s” scenario.

##### 6.5.2.1 Single bit (correctable) errors

Single bit errors are corrected automatically before the requested data is returned to either the CPU subsystem or the peripheral bus (DMA). Errors occurring as a result of a debug access are not reported.

##### 6.5.2.2 Dual bit (uncorrectable) errors

Dual bit errors are detectable but not correctable and are indicated to SYSCTL. SYSCTL can be configured to generate either a nonmaskable interrupt (NMI) or a reset, as uncorrectable errors can be fatal. Errors occurring as a result of a debug access are not reported.

## 6.6 FLASHCTL\_G350x\_G310x\_G150x\_G110x Registers

Table 6-12 lists the memory-mapped registers for the FLASHCTL\_G350x\_G310x\_G150x\_G110x registers. All register offset addresses not listed in Table 6-12 should be considered as reserved locations and the register contents should not be modified.

**Table 6-12. FLASHCTL\_G350X\_G310X\_G150X\_G110X Registers**

Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

## 1 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 6-4](#) and described in [Table 6-14](#).

Return to the [Summary Table](#).

Interrupt Index Register:

The IIDX register provides the highest priority enabled interrupt index.

PSD compliant register.

Note that it is not recommended to use this register if the system clock is running at a slower clock frequency than the flash wrapper clock. If this is the case, then reading this register may fail to update the RIS register correctly.

The MIS register can be read directly, and a write to ICLR can be used to clear interrupts when this clock relationship is present.

**Table 6-15. IIDX Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	Reserved
0	STAT	R	0h	Indicates which interrupt has fired. 0x0 means no event pending. The priority order is fixed. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flags in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt. 0h (R/W) = No Interrupt Pending 1h (R/W) = DONE Interrupt Pending

## 2 IMASK (Offset = 1028h) [Reset = 00000000h]

IMASK is shown in [Figure 6-5](#) and described in [Table 6-15](#).

Return to the [Summary Table](#).

Interrupt Mask Register: The IMASK register holds the current interrupt mask settings. Masked interrupts are read in the MIS register. PSD compliant register.

### 3 RIS (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 6-6](#) and described in [Table 6-16](#).

Return to the [Summary Table](#).

Raw Interrupt Status Register: The RIS register reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing a 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled. A flag can be set by software by writing a 1 to the ISET register. Reading the IIDX register will also clear the corresponding bit in RIS. PSD compliant register.

0	DONE	R	0h	Flash wrapper operation completed. This interrupt bit is set by firmware or the corresponding bit in the ISET register. It is cleared by the corresponding bit in in the ICLR register or reading the IIDX register when this interrupt is the highest priority. 0h (R/W) = Interrupt did not occur 1h (R/W) = Interrupt occurred

#### 4 MIS (Offset = 1038h) [Reset = 0000000h]

MIS is shown in [Figure 6-7](#) and described in [Table 6-17](#).

Return to the [Summary Table](#).

Masked Interrupt Status Register:

The MIS register is a bit-wise AND of the contents of the IMASK and RIS registers. This is kept mainly for ARM compatibility, and has limited use since the highest priority interrupt index is returned through the IIDX register.

PSD  
compliant register.

### 5 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 6-8](#) and described in [Table 6-18](#).

Return to the [Summary Table](#).

Interrupt Set Register: The ISET register allows software to write a 1 to set corresponding interrupt. Safety: This meets a safety requirement to allow software diagnostics to trigger interrupts. PSD compliant register.

## 9 CMDEXEC (Offset = 1100h) [Reset = 0000000h]

CMDEXEC is shown in [Figure 6-12](#) and described in [Table 6-22](#).

Return to the [Summary Table](#).

Command Execute Register:

Initiates execution of the command specified in the CMDTYPE register.

This register is blocked for writes after being written to 1 and prior to

STATCMD.DONE being set by the flash wrapper hardware.

flash wrapper hardware clears this register after the processing of the command has completed.

**Figure 6-12. CMDEXEC**

## 10 CMDTYPE (Offset = 1104h) [Reset = 0000000h]

CMDTYPE is shown in [Figure 6-13](#) and described in [Table 6-23](#).

Return to the [Summary Table](#).

### Command Type Register

This register specifies the type of command to be executed by the flash wrapper hardware.

This register is blocked for writes after CMDEXEC is written to a 1 and prior to STATCMD.DONE being set by the hardware to indicate that command execution has completed.

**Table 6-35. CMDCTL Field Descriptions**

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	Reserved
21	DATAVEREN	R/W	0h	Enable invalid data verify. This checks for 0->1 transitions in the memory when a program operation is initiated. If such a transition is found, the program will fail with an error without executing the program. 0h (R/W) = Disable 1h (R/W) = Enable
20	SSERASEDIS	R/W	0h	Disable Stair-Step Erase. If set, the default VHV trim voltage setting will be used for all erase pulses. By default, this bit is reset, meaning that the VHV voltage will be stepped during successive erase pulses. The step count, step voltage, begin and end voltages are all hard-wired. 0h (R/W) = Enable 1h (R/W) = Disable
19	ERASEMASKDIS	R/W	0h	Disable use of erase mask for erase. Bit masking will not be used during erase verify. If one or more sectors fail the verify either before (prever) or after (postver) the operation, then all specified flash sectors will receive subsequent erase pulse. 0h (R/W) = Enable 1h (R/W) = Disable
18	PROGMASKDIS	R/W	0h	Disable use of program mask for programming. Bit masking will not be used during program verify. If one or more bits fail the verify either before (prever) or after (postver) the operation, then all specified flash entries will receive subsequent program pulse. 0h (R/W) = Enable 1h (R/W) = Disable

**Table 6-35. CMDCTL Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	ECCGENOVR	R/W	0h	Override hardware generation of ECC data for program. Use data written to CMDDATAECC*. 0h (R/W) = Do not override 1h (R/W) = Override
16	ADDRXLATEOVR	R/W	0h	Override hardware address translation of address in CMDADDR from a system address to a bank address and bank ID. Use data written to CMDADDR directly as the bank address. Use the value written to CMDCTL.BANKSEL directly as the bank ID. Use the value written to CMDCTL.REGIONSEL directly as the region ID. 0h (R/W) = Do not override 1h (R/W) = Override
15	POSTVEREN	R/W	1h	Enable verify after program or erase 0h (R/W) = Disable 1h (R/W) = Enable
14	PREVEREN	R/W	1h	Enable verify before program or erase. For program, bits already programmed to the requested value will be masked. For erase, sectors already erased will be masked. 0h (R/W) = Disable 1h (R/W) = Enable
13	RESERVED	R	0h	Reserved
12-9	REGIONSEL	R/W	0h	Bank Region A specific region ID can be written to this field to indicate to which region an operation is to be applied if CMDCTL.ADDRXLATEOVR is set. 1h (R/W) = Main Region 2h (R/W) = Non-Main Region 4h (R/W) = Trim Region 8h (R/W) = Engr Region
8-5	RESERVED	R	0h	
4	RESERVED	R	0h	Reserved
3-0	MODESEL	R/W	0h	Mode This field is only used for the Mode Change command type. Otherwise, bank and pump modes are set automatically through the NW hardware. 0h = Read Mode 2h = Read Margin 0 Mode 4h = Read Margin 1 Mode 6h = Read Margin 0B Mode 7h = Read Margin 1B Mode 9h = Program Verify Mode Ah = Program Single Word Bh = Erase Verify Mode Ch = Erase Sector Eh = Program Multiple Word Fh = Erase Bank

## 12 CMDADDR (Offset = 1120h) [Reset = 0000000h]

CMDADDR is shown in [Figure 6-15](#) and described in [Table 6-25](#).

Return to the [Summary Table](#).

Command Address Register:

This register forms the target address of a command. The use cases are as follows:

- 1) For single-word program, this address indicates the flash bank word to be programmed.
  - 2) For multi-word program, this address indicates the first flash bank address for the program. The address will be incremented for further words.
  - 3) For sector erase, this address indicates the sector to be erased.
  - 4) For bank erase, the address indicates the bank to be erased.
  - 5) For read verify, the address indications follow program/erase listed above.
- Note the address written to this register will be submitted for translation to the flash wrapper address translation interface, and the translated address will be used to access the bank. However, if the CMDCTL.ADDRXLATEOVR bit is set, then the address written to this register will be used directly as the bank address.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

**Figure 6-15. CMDADDR**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 13 CMDBYTEN (Offset = 1124h) [Reset = 0000000h]

CMDBYTEN is shown in [Figure 6-16](#) and described in [Table 6-26](#).

Return to the [Summary Table](#).

Command Program Byte Enable Register:

This register forms a per-byte enable for programming data. For data bytes to be programmed, a 1 must be written to the corresponding bit in this register.

Normally, all bits are written to 1, allowing program of full flash words.

However, leaving some bits 0 allows programming of 8-bit, 16-bit, 32-bit or 64-bit portions of a flash word.

In addition, the read verify command will ignore data bytes read from the flash in its comparison if the corresponding CMDBYTEN bit is 0.

ECC data bytes are protected by the 1-2 MSB bits in this register, depending on the presence of ECC and the flash word data width.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is written to all 0 after the completion of all flash wrapper commands.

**Figure 6-16. CMDBYTEN**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### 14 CMDDATA0 (Offset = 1130h) [Reset = 0000000h]

CMDDATA0 is shown in [Figure 6-17](#) and described in [Table 6-27](#).

Return to the [Summary Table](#).

##### Command Data Register 0

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 31:0 of flash word data register 0.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 0.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.
- 3) Read Verify - These registers contain data to be verified.

**Figure 6-17. CMDDATA0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 15 CMDDATA1 (Offset = 1134h) [Reset = 0000000h]

CMDDATA1 is shown in [Figure 6-18](#) and described in [Table 6-28](#).

Return to the [Summary Table](#).

#### Command Data Register 1

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 63:32 of flash word data register 0.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 0.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to CMDSTAT.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.
- 3) Read Verify - These registers contain data to be verified.

**Figure 6-18. CMDDATA1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 16 CMDDATA4 (Offset = 1140h) [Reset = 0000000h]

CMDDATA4 is shown in [Figure 6-19](#) and described in [Table 6-29](#).

Return to the [Summary Table](#).

### Command Data Register 4

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 31:0 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 2.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.
- 3) Read Verify - These registers contain data to be verified.

**Figure 6-19. CMDDATA4**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 17 CMDDATA5 (Offset = 1144h) [Reset = 0000000h]

CMDDATA5 is shown in [Figure 6-20](#) and described in [Table 6-30](#).

Return to the [Summary Table](#).

### Command Data Register 5

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 63:32 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 2.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.
- 3) Read Verify - These registers contain data to be verified.

**Figure 6-20. CMDDATA5**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 18 CMDDATA6 (Offset = 1148h) [Reset = 0000000h]

CMDDATA6 is shown in [Figure 6-21](#) and described in [Table 6-31](#).

Return to the [Summary Table](#).

#### Command Data Register 6

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 95:64 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 3.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.
- 3) Read Verify - These registers contain data to be verified.

**Figure 6-21. CMDDATA6**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 19 CMDDATA7 (Offset = 114Ch) [Reset = 0000000h]

CMDDATA7 is shown in [Figure 6-22](#) and described in [Table 6-32](#).

Return to the [Summary Table](#).

### Command Data Register 7

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 127:96 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 3.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.
- 3) Read Verify - These registers contain data to be verified.

## 20 CMDDATA8 (Offset = 1150h) [Reset = 0000000h]

CMDDATA8 is shown in [Figure 6-23](#) and described in [Table 6-33](#).

Return to the [Summary Table](#).

### Command Data Register 8

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 31:0 of flash word data register 2.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 4.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.
- 3) Read Verify - These registers contain data to be verified.

**Figure 6-23. CMDDATA8**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 27 CMDDATA15 (Offset = 116Ch) [Reset = 0000000h]

CMDDATA15 is shown in [Figure 6-30](#) and described in [Table 6-40](#).

Return to the [Summary Table](#).

### Command Data Register 15

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 127:96 of flash word data register 3.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 7.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.
- 3) Read Verify - These registers contain data to be verified.

**Figure 6-30. CMDDATA15**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 28 CMDDATAECC0 (Offset = 11B0h) [Reset = 0000000h]

CMDDATAECC0 is shown in [Figure 6-31](#) and described in [Table 6-41](#).

Return to the [Summary Table](#).

### Command Data Register 0

This register forms the ECC portion of the data for a command. This ECC data in this register covers flash data register 0.

The hardware ECC generation in flash wrapper can be overridden and ECC data developed elsewhere can be used. ECC data is placed in this register.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.
- 3) Read Verify - These registers contain data to be verified.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

## 29 CMDWEPROTA (Offset = 11D0h) [Reset = 00000000h]

CMDWEPROTA is shown in [Figure 6-32](#) and described in [Table 6-42](#).

Return to the [Summary Table](#).

### Command WriteErase Protect A Register

This register allows the first 32 sectors of the main region to be protected from program or erase, with 1 bit protecting each sector. If the main region size is smaller than 32 sectors, then this register provides protection for the whole region.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

**Figure 6-32. CMDWEPROTA**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	FFFFFFFFh	Each bit protects 1 sector. bit [0]: When 1, sector 0 of the flash memory will be protected from program and erase. bit [1]: When 1, sector 1 of the flash memory will be protected from program and erase. . . : bit [31]: When 1, sector 31 of the flash memory will be protected from program and erase. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

### 30 CMDWEPROTB (Offset = 11D4h) [Reset = 00000000h]

CMDWEPROTB is shown in [Figure 6-33](#) and described in [Table 6-43](#).

Return to the [Summary Table](#).

#### Command WriteErase Protect B Register

This register allows main region sectors to be protected from program and erase. Each bit corresponds to a group of 8 sectors.

There are 3 cases for how these protect bits are applied:

#### 1. Single-bank system:

In the case where only a single flash bank is present, the first 32 sectors are protected via the CMDWEPROTA register. Thus, the protection given by the bits in CMDWEPROTB begin with sector 32.

#### 2. Multi-bank system, Bank 0:

When multiple flash banks are present, the first 32 sectors of bank 0 are protected via the CMDWEPROTA register. Thus, only bits 4 and above of CMDWEPROTB would be applicable to bank 0. The protection of bit 4 and above would begin at sector 32. Bits 3:0 of WEPROTB are ignored for bank 0.

#### 3. Multi-bank system, Banks 1-N:

For banks other than bank 0 in a multi-bank system, CMDWEPROTA has no effect, so the bits in CMDWEPROTB will protect these banks starting from sector 0.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

**Figure 6-33. CMDWEPROTB**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	FFFFFFFFh	Each bit protects a group of 8 sectors. When a bit is 1, the associated 8 sectors in the flash will be protected from program and erase. A maximum of 256 sectors can be protected with this register. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

### 31 CMDWEPROTNM (Offset = 1210h) [Reset = 00000000h]

CMDWEPROTNM is shown in [Figure 6-34](#) and described in [Table 6-44](#).

Return to the [Summary Table](#).

#### Command WriteErase Protect Non-Main Register

This register allows non-main region region sectors to be protected from program and erase. Each bit corresponds to 1 sector.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

**Figure 6-34. CMDWEPROTNM**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 32 CMDWEPROTTR (Offset = 1214h) [Reset = 00000000h]

CMDWEPROTTR is shown in [Figure 6-35](#) and described in [Table 6-45](#).

Return to the [Summary Table](#).

Command WriteErase Protect Trim  
Register

This register allows trim region sectors to be protected from program and erase. Each bit corresponds to 1 sector.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Complex bit access types are encoded to fit into small table cells. [Table 6-59](#) shows the codes that are used for access types in this section.

**Table 6-103. FLASHCTL\_G351x\_G151x Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

## 1 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 6-48](#) and described in [Table 6-60](#).

Return to the [Summary Table](#).

Interrupt Index Register:

The IIDX register provides the highest priority enabled interrupt index.

PSD compliant register.

Note that it is not recommended to use this register if the system clock is running at a slower clock frequency than the flash wrapper clock. If this is the case, then reading this register may fail to update the RIS register correctly.

The MIS register can be read directly, and a write to ICLR can be used to clear interrupts when this clock relationship is present.

R-0h							R-0h

**Table 6-105. IIDX Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	Reserved
0	STAT	R	0h	Indicates which interrupt has fired. 0x0 means no event pending. The priority order is fixed. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flags in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt. 0h (R/W) = No Interrupt Pending 1h (R/W) = DONE Interrupt Pending

## 2 IMASK (Offset = 1028h) [Reset = 00000000h]

IMASK is shown in [Figure 6-49](#) and described in [Table 6-61](#).

Return to the [Summary Table](#).

Interrupt Mask Register: The IMASK register holds the current interrupt mask settings. Masked interrupts are read in the MIS register. PSD compliant register.

**Figure 6-49. IMASK**

31-1	RESERVED	R	0h	Reserved
0	DONE	R/W	0h	Interrupt mask for DONE: 0: Interrupt is disabled in MIS register 1: Interrupt is enabled in MIS register 0h (R/W) = Interrupt is masked out 1h (R/W) = Interrupt will request an interrupt service routine and corresponding bit in <a href="#">MIS</a> will be set

### 3 RIS (Offset = 1030h) [Reset = 00000000h]

RIS is shown in [Figure 6-50](#) and described in [Table 6-62](#).

Return to the [Summary Table](#).

Raw Interrupt Status Register: The RIS register reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing a 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled. A flag can be set by software by writing a 1 to the ISET register. Reading the IIDX register will also clear the corresponding bit in RIS. PSD compliant register.

0	DONE	R	0h	Flash wrapper operation completed. This interrupt bit is set by firmware or the corresponding bit in the ISET register. It is cleared by the corresponding bit in in the ICLR register or reading the IIDX register when this interrupt is the highest priority. 0h (R/W) = Interrupt did not occur 1h (R/W) = Interrupt occurred

#### 4 MIS (Offset = 1038h) [Reset = 00000000h]

MIS is shown in [Figure 6-51](#) and described in [Table 6-63](#).

Return to the [Summary Table](#).

Masked Interrupt Status Register:

The MIS register is a bit-wise AND of the contents of the IMASK and RIS registers. This is kept mainly for ARM compatibility, and has limited use since the highest priority interrupt index is returned through the IIDX register.

PSD compliant register.

**Figure 6-51. MIS**

## 5 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 6-52](#) and described in [Table 6-64](#).

Return to the [Summary Table](#).

Interrupt Set Register: The ISET register allows software to write a 1 to set corresponding interrupt. Safety: This meets a safety requirement to allow software diagnostics to trigger interrupts. PSD compliant register.

**Figure 6-52. ISET**

## 9 CMDEXEC (Offset = 1100h) [Reset = 0000000h]

CMDEXEC is shown in [Figure 6-56](#) and described in [Table 6-68](#).

Return to the [Summary Table](#).

Command Execute Register:

Initiates execution of the command specified in the CMDTYPE register.

This register is blocked for writes after being written to 1 and prior to

STATCMD.DONE being set by the flash wrapper hardware.

flash wrapper hardware clears this register after the processing of the command has completed.

**Figure 6-56. CMDEXEC**

## 10 CMDTYPE (Offset = 1104h) [Reset = 0000000h]

CMDTYPE is shown in [Figure 6-57](#) and described in [Table 6-69](#).

Return to the [Summary Table](#).

### Command Type Register

This register specifies the type of command to be executed by the flash wrapper hardware.

This register is blocked for writes after CMDEXEC is written to a 1 and prior to STATCMD.DONE being set by the hardware to indicate that command execution has completed.

**Figure 6-57. CMDTYPE**

This command may only be used with CMDTYPE.SIZE = ONEWORD

## 11 CMDCTL (Offset = 1108h) [Reset = 0000000h]

CMDCTL is shown in [Figure 6-58](#) and described in [Table 6-70](#).

Return to the [Summary Table](#).

**Command Control Register** This register configures specific capabilities of the state machine for related to the execution of a command. This register is blocked for writes after CMDEXEC is written to a 1 and prior to STATCMD.DONE being set by the hardware to indicate that command execution has completed.

**Figure 6-58. CMDCTL**

## 12 CMDADDR (Offset = 1120h) [Reset = 0000000h]

CMDADDR is shown in [Figure 6-59](#) and described in [Table 6-71](#).

Return to the [Summary Table](#).

Command Address Register:

This register forms the target address of a command. The use cases are as follows:

- 1) For single-word program, this address indicates the flash bank word to be programmed.
- 2) For multi-word program, this address indicates the first flash bank address for the program. The address will be incremented for further words.
- 3) For sector erase, this address indicates the sector to be erased.
- 4) For bank erase, the address indicates the bank to be erased.

Note the address written to this register will be submitted for translation to the flash wrapper address translation interface, and the translated address will be used to access the bank. However, if the

CMDCTL.ADDRXLATEOVR bit is set, then the address written to this register will be used directly as the bank address.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

### 13 CMDBYTEN (Offset = 1124h) [Reset = 0000000h]

CMDBYTEN is shown in [Figure 6-60](#) and described in [Table 6-72](#).

Return to the [Summary Table](#).

Command Program Byte Enable Register:

This register forms a per-byte enable for programming data. For data bytes to be programmed, a 1 must be written to the corresponding bit in this register.

Normally, all bits are written to 1, allowing program of full flash words.

However, leaving some bits 0 allows programming of 8-bit, 16-bit, 32-bit or 64-bit portions of a flash word.

During verify, data bytes read from the flash will not be checked if the corresponding CMDBYTEN bit is 0.

ECC data bytes are protected by the 1-2 MSB bits in this register, depending on the presence of ECC and the flash word data width.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is written to all 0 after the completion of all flash wrapper commands.

**Figure 6-60. CMDBYTEN**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### 14 CMDDATA0 (Offset = 1130h) [Reset = 00000000h]

CMDDATA0 is shown in [Figure 6-61](#) and described in [Table 6-73](#).

Return to the [Summary Table](#).

##### Command Data Register 0

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 31:0 of flash word data register 0.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 0.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-61. CMDDATA0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 15 CMDDATA1 (Offset = 1134h) [Reset = 0000000h]

CMDDATA1 is shown in [Figure 6-62](#) and described in [Table 6-74](#).

Return to the [Summary Table](#).

#### Command Data Register 1

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 63:32 of flash word data register 0.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 0.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to CMDSTAT.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-62. CMDDATA1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 16 CMDDATA4 (Offset = 1140h) [Reset = 0000000h]

CMDDATA4 is shown in [Figure 6-63](#) and described in [Table 6-75](#).

Return to the [Summary Table](#).

### Command Data Register 4

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 31:0 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 2.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-63. CMDDATA4**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 17 CMDDATA5 (Offset = 1144h) [Reset = 0000000h]

CMDDATA5 is shown in [Figure 6-64](#) and described in [Table 6-76](#).

Return to the [Summary Table](#).

### Command Data Register 5

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 63:32 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 2.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-64. CMDDATA5**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 18 CMDDATA6 (Offset = 1148h) [Reset = 0000000h]

CMDDATA6 is shown in [Figure 6-65](#) and described in [Table 6-77](#).

Return to the [Summary Table](#).

#### Command Data Register 6

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 95:64 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 3.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-65. CMDDATA6**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 19 CMDDATA7 (Offset = 114Ch) [Reset = 0000000h]

CMDDATA7 is shown in [Figure 6-66](#) and described in [Table 6-78](#).

Return to the [Summary Table](#).

### Command Data Register 7

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 127:96 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 3.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-66. CMDDATA7**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 20 CMDDATA8 (Offset = 1150h) [Reset = 0000000h]

CMDDATA8 is shown in [Figure 6-67](#) and described in [Table 6-79](#).

Return to the [Summary Table](#).

### Command Data Register 8

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 31:0 of flash word data register 2.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 4.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

## 26 CMDDATA14 (Offset = 1168h) [Reset = 0000000h]

CMDDATA14 is shown in [Figure 6-73](#) and described in [Table 6-85](#).

Return to the [Summary Table](#).

### Command Data Register 14

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 95:64 of flash word data register 3.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 7.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-73. CMDDATA14**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 27 CMDDATA15 (Offset = 116Ch) [Reset = 0000000h]

CMDDATA15 is shown in [Figure 6-74](#) and described in [Table 6-86](#).

Return to the [Summary Table](#).

### Command Data Register 15

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 127:96 of flash word data register 3.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 7.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-74. CMDDATA15**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 28 CMDDATAECC0 (Offset = 11B0h) [Reset = 0000000h]

CMDDATAECC0 is shown in [Figure 6-75](#) and described in [Table 6-87](#).

Return to the [Summary Table](#).

### Command Data Register 0

This register forms the ECC portion of the data for a command. This ECC data in this register covers flash data register 0.

The hardware ECC generation in flash wrapper can be overridden and ECC data developed elsewhere can be used. ECC data is placed in this register.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

**Figure 6-75. CMDDATAECC0**

## 29 CMDWEPROTB (Offset = 11D4h) [Reset = 0000000h]

CMDWEPROTB is shown in [Figure 6-76](#) and described in [Table 6-88](#).

Return to the [Summary Table](#).

### Command WriteErase Protect B Register

This register allows main region sectors to be protected from program and erase. Each bit corresponds to a group of 8 sectors.

There are multiple cases for how these protect bits are applied:

1. Single-bank system, CMDWEPROTA register present:

The first 32 sectors are protected via the CMDWEPROTA register. Thus, the protection given by the bits in CMDWEPROTB begin with sector 32.

2. Single-bank system, CMDWEPROTA register not present:

The protection given by the bits in CMDWEPROTB begin with sector 0.

3. Multi-bank system, CMDWEPROTA register present - Bank 0:

The first 32 sectors of bank 0 are protected via the CMDWEPROTA register.

Thus, only bits 4 and above of CMDWEPROTB would be applicable to bank 0.

The protection of bit 4 and above would begin at sector 32. Bits 3:0

of WEPROTB are ignored for bank 0.

4. Multi-bank system, CMDWEPROTA register present, Banks 1-N:

For banks other than bank 0 in a multi-bank system, CMDWEPROTA has

no effect, so the bits in CMDWEPROTB will protect these banks starting

from sector 0.

5. Multi-bank system, CMDWEPROTA register not present:

The bits in CMDWEPROTB will protect any of the banks starting from sector 0.

This register is blocked for writes after a 1 is written to the CMDEXEC

register and prior to STATCMD.DONE being set by the flash wrapper

hardware.

In addition, this register is used to aggregate masking for sectors that do not

require additional erase pulses during bank erase operations, and will be

written to all 1 after the completion of all flash wrapper commands.

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	FFFFFFFFh	Each bit protects a group of 8 sectors. When a bit is 1, the associated 8 sectors in the flash will be protected from program and erase. A maximum of 256 sectors can be protected with this register. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

### 30 CMDWEPROTNM (Offset = 1210h) [Reset = 00000000h]

CMDWEPROTNM is shown in [Figure 6-77](#) and described in [Table 6-89](#).

Return to the [Summary Table](#).

#### Command WriteErase Protect Non-Main Register

This register allows non-main region region sectors to be protected from program and erase. Each bit corresponds to 1 sector.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

### 31 CMDWEPROTTR (Offset = 1214h) [Reset = 00000000h]

CMDWEPROTTR is shown in [Figure 6-78](#) and described in [Table 6-90](#).

Return to the [Summary Table](#).

Command WriteErase Protect Trim  
Register

This register allows trim region sectors to be protected from program and erase. Each bit corresponds to 1 sector.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

## 1 IIDX (Offset = 1020h) [Reset = 0000000h]

IIDX is shown in [Figure 6-94](#) and described in [Table 6-108](#).

Return to the [Summary Table](#).

Interrupt Index Register:

The IIDX register provides the highest priority enabled interrupt index.

PSD compliant register.

Note that it is not recommended to use this register if the system clock is running at a slower clock frequency than the flash wrapper clock. If this is the case, then reading this register may fail to update the RIS register correctly.

The MIS register can be read directly, and a write to ICLR can be used to clear interrupts when this clock relationship is present.

**Table 6-199. IIDX Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	Reserved
0	STAT	R	0h	Indicates which interrupt has fired. 0x0 means no event pending. The priority order is fixed. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flags in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt. 0h (R/W) = No Interrupt Pending 1h (R/W) = DONE Interrupt Pending

## 2 IMASK (Offset = 1028h) [Reset = 00000000h]

IMASK is shown in [Figure 6-95](#) and described in [Table 6-109](#).

Return to the [Summary Table](#).

Interrupt Mask Register: The IMASK register holds the current interrupt mask settings. Masked interrupts are read in the MIS register. PSD compliant register.

**Figure 6-95. IMASK**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	Reserved
0	DONE	R/W	0h	Interrupt mask for DONE: 0: Interrupt is disabled in MIS register 1: Interrupt is enabled in MIS register 0h (R/W) = Interrupt is masked out 1h (R/W) = Interrupt will request an interrupt service routine and corresponding bit in <a href="#">MIS</a> will be set

### 3 RIS (Offset = 1030h) [Reset = 00000000h]

RIS is shown in [Figure 6-96](#) and described in [Table 6-110](#).

Return to the [Summary Table](#).

Raw Interrupt Status Register: The RIS register reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing a 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled. A flag can be set by software by writing a 1 to the ISET register. Reading the IIDX register will also clear the corresponding bit in RIS. PSD compliant register.

31-1	RESERVED	R	0h	Reserved
0	DONE	R	0h	Flash wrapper operation completed. This interrupt bit is set by firmware or the corresponding bit in the ISET register. It is cleared by the corresponding bit in in the ICLR register or reading the IIDX register when this interrupt is the highest priority. 0h (R/W) = Interrupt did not occur 1h (R/W) = Interrupt occurred

#### 4 MIS (Offset = 1038h) [Reset = 00000000h]

MIS is shown in [Figure 6-97](#) and described in [Table 6-111](#).

Return to the [Summary Table](#).

Masked Interrupt Status Register:

The MIS register is a bit-wise AND of the contents of the IMASK and RIS registers. This is kept mainly for ARM compatibility, and has limited use since the highest priority interrupt index is returned through the IIDX register.

PSD  
compliant register.

## 5 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 6-98](#) and described in [Table 6-112](#).

Return to the [Summary Table](#).

Interrupt Set Register: The ISET register allows software to write a 1 to set corresponding interrupt. Safety: This meets a safety requirement to allow software diagnostics to trigger interrupts. PSD compliant register.

**Figure 6-98. ISET**

## 9 CMDEXEC (Offset = 1100h) [Reset = 0000000h]

CMDEXEC is shown in [Figure 6-102](#) and described in [Table 6-116](#).

Return to the [Summary Table](#).

Command Execute Register:

Initiates execution of the command specified in the CMDTYPE register.

This register is blocked for writes after being written to 1 and prior to

STATCMD.DONE being set by the flash wrapper hardware.

flash wrapper hardware clears this register after the processing of the command has completed.

**Figure 6-102. CMDEXEC**

## 10 CMDTYPE (Offset = 1104h) [Reset = 0000000h]

CMDTYPE is shown in [Figure 6-103](#) and described in [Table 6-117](#).

Return to the [Summary Table](#).

### Command Type Register

This register specifies the type of command to be executed by the flash wrapper hardware.

This register is blocked for writes after CMDEXEC is written to a 1 and prior to STATCMD.DONE being set by the hardware to indicate that command execution has completed.

This command may only be used with CMDTYPE.SIZE = ONEWORD

## 11 CMDCTL (Offset = 1108h) [Reset = 0000000h]

CMDCTL is shown in [Figure 6-104](#) and described in [Table 6-118](#).

Return to the [Summary Table](#).

**Command Control Register** This register configures specific capabilities of the state machine for related to the execution of a command. This register is blocked for writes after CMDEXEC is written to a 1 and prior to STATCMD.DONE being set by the hardware to indicate that command execution has completed.

**Figure 6-104. CMDCTL**

Otherwise, bank and pump modes are set automatically through the NW hardware. 0h = Read Mode 2h = Read Margin 0 Mode 4h = Read Margin 1 Mode 6h = Read Margin 0B Mode 7h = Read Margin 1B Mode 9h = Program Verify Mode Ah = Program Single Word Bh = Erase Verify Mode Ch = Erase Sector Eh = Program Multiple Word Fh = Erase Bank

## 12 CMDADDR (Offset = 1120h) [Reset = 0000000h]

CMDADDR is shown in [Figure 6-105](#) and described in [Table 6-119](#).

Return to the [Summary Table](#).

Command Address Register:

This register forms the target address of a command. The use cases are as follows:

- 1) For single-word program, this address indicates the flash bank word to be programmed.
- 2) For multi-word program, this address indicates the first flash bank address for the program. The address will be incremented for further words.
- 3) For sector erase, this address indicates the sector to be erased.
- 4) For bank erase, the address indicates the bank to be erased.

Note the address written to this register will be submitted for translation to the flash wrapper address translation interface, and the translated address will be used to access the bank. However, if the

CMDCTL.ADDRXLATEOVR bit is set, then the address written to this register will be used directly as the bank address.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

**Figure 6-105. CMDADDR**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 13 CMDBYTEN (Offset = 1124h) [Reset = 0000000h]

CMDBYTEN is shown in [Figure 6-106](#) and described in [Table 6-120](#).

Return to the [Summary Table](#).

Command Program Byte Enable Register:

This register forms a per-byte enable for programming data. For data bytes to be programmed, a 1 must be written to the corresponding bit in this register.

Normally, all bits are written to 1, allowing program of full flash words.

However, leaving some bits 0 allows programming of 8-bit, 16-bit, 32-bit or 64-bit portions of a flash word.

During verify, data bytes read from the flash will not be checked if the corresponding CMDBYTEN bit is 0.

ECC data bytes are protected by the 1-2 MSB bits in this register, depending on the presence of ECC and the flash word data width.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is written to all 0 after the completion of all flash wrapper commands.

**Figure 6-106. CMDBYTEN**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### 14 CMDDATA0 (Offset = 1130h) [Reset = 0000000h]

CMDDATA0 is shown in [Figure 6-107](#) and described in [Table 6-121](#).

Return to the [Summary Table](#).

##### Command Data Register 0

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 31:0 of flash word data register 0.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 0.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-107. CMDDATA0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 15 CMDDATA1 (Offset = 1134h) [Reset = 0000000h]

CMDDATA1 is shown in [Figure 6-108](#) and described in [Table 6-122](#).

Return to the [Summary Table](#).

#### Command Data Register 1

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 63:32 of flash word data register 0.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 0.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to CMDSTAT.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-108. CMDDATA1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 16 CMDDATA4 (Offset = 1140h) [Reset = 0000000h]

CMDDATA4 is shown in [Figure 6-109](#) and described in [Table 6-123](#).

Return to the [Summary Table](#).

### Command Data Register 4

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 31:0 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 2.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-109. CMDDATA4**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 17 CMDDATA5 (Offset = 1144h) [Reset = 0000000h]

CMDDATA5 is shown in [Figure 6-110](#) and described in [Table 6-124](#).

Return to the [Summary Table](#).

### Command Data Register 5

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 63:32 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 2.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-110. CMDDATA5**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 18 CMDDATA6 (Offset = 1148h) [Reset = 0000000h]

CMDDATA6 is shown in [Figure 6-111](#) and described in [Table 6-125](#).

Return to the [Summary Table](#).

### Command Data Register 6

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 95:64 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 3.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-111. CMDDATA6**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 19 CMDDATA7 (Offset = 114Ch) [Reset = 0000000h]

CMDDATA7 is shown in [Figure 6-112](#) and described in [Table 6-126](#).

Return to the [Summary Table](#).

#### Command Data Register 7

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 127:96 of flash word data register 1.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 3.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-112. CMDDATA7**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 20 CMDDATA8 (Offset = 1150h) [Reset = 0000000h]

CMDDATA8 is shown in [Figure 6-113](#) and described in [Table 6-127](#).

Return to the [Summary Table](#).

### Command Data Register 8

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 31:0 of flash word data register 2.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 4.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-113. CMDDATA8**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 22 CMDDATA10 (Offset = 1158h) [Reset = 0000000h]

CMDDATA10 is shown in [Figure 6-115](#) and described in [Table 6-129](#).

Return to the [Summary Table](#).

### Command Data Register 10

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 95:64 of flash word data register 2.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 5.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

CMDDATA13 is shown in [Figure 6-118](#) and described in [Table 6-132](#).

Return to the [Summary Table](#).

### Command Data Register 13

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 63:32 of flash word data register 3.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 6.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

## 26 CMDDATA14 (Offset = 1168h) [Reset = 0000000h]

CMDDATA14 is shown in [Figure 6-119](#) and described in [Table 6-133](#).

Return to the [Summary Table](#).

### Command Data Register 14

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 95:64 of flash word data register 3.

For DATAWIDTH == 64: This register represents bits 31:0 of flash word data register 7.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-119. CMDDATA14**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 27 CMDDATA15 (Offset = 116Ch) [Reset = 0000000h]

CMDDATA15 is shown in [Figure 6-120](#) and described in [Table 6-134](#).

Return to the [Summary Table](#).

### Command Data Register 15

This register forms the data for a command.

For DATAWIDTH == 128: This register represents bits 127:96 of flash word data register 3.

For DATAWIDTH == 64: This register represents bits 63:32 of flash word data register 7.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

**Figure 6-120. CMDDATA15**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-0	VAL	R/W	FFFFFFFFh	A 32-bit data value is placed in this field. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

## 28 CMDDATAECC0 (Offset = 11B0h) [Reset = 0000000h]

CMDDATAECC0 is shown in [Figure 6-121](#) and described in [Table 6-135](#).

Return to the [Summary Table](#).

### Command Data Register 0

This register forms the ECC portion of the data for a command. This ECC data in this register covers flash data register 0.

The hardware ECC generation in flash wrapper can be overridden and ECC data developed elsewhere can be used. ECC data is placed in this register.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

Use cases for the CMDDATA\* registers are as follows:

- 1) Program - These registers contain the data to be programmed.
- 2) Erase - These registers are not used.

This register is used to aggregate masking for bits that do not require additional program pulses during program operations, and will be written to all 1 after the completion of all flash wrapper commands.

**Figure 6-121. CMDDATAECC0**

## 29 CMDWEPROTB (Offset = 11D4h) [Reset = 0000000h]

CMDWEPROTB is shown in [Figure 6-122](#) and described in [Table 6-136](#).

Return to the [Summary Table](#).

### Command WriteErase Protect B Register

This register allows main region sectors to be protected from program and erase. Each bit corresponds to a group of 8 sectors.

There are multiple cases for how these protect bits are applied:

1. Single-bank system, CMDWEPROTA register present:

The first 32 sectors are protected via the CMDWEPROTA register. Thus, the protection given by the bits in CMDWEPROTB begin with sector 32.

2. Single-bank system, CMDWEPROTA register not present:

The protection given by the bits in CMDWEPROTB begin with sector 0.

3. Multi-bank system, CMDWEPROTA register present - Bank 0:

The first 32 sectors of bank 0 are protected via the CMDWEPROTA register.

Thus, only bits 4 and above of CMDWEPROTB would be applicable to bank 0.

The protection of bit 4 and above would begin at sector 32. Bits 3:0

of WEPROTB are ignored for bank 0.

4. Multi-bank system, CMDWEPROTA register present, Banks 1-N:

For banks other than bank 0 in a multi-bank system, CMDWEPROTA has

no effect, so the bits in CMDWEPROTB will protect these banks starting

from sector 0.

5. Multi-bank system, CMDWEPROTA register not present:

The bits in CMDWEPROTB will protect any of the banks starting from sector 0.

This register is blocked for writes after a 1 is written to the CMDEXEC

register and prior to STATCMD.DONE being set by the flash wrapper

hardware.

In addition, this register is used to aggregate masking for sectors that do not

require additional erase pulses during bank erase operations, and will be

written to all 1 after the completion of all flash wrapper commands.

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	FFFFFFFFh	Each bit protects a group of 8 sectors. When a bit is 1, the associated 8 sectors in the flash will be protected from program and erase. A maximum of 256 sectors can be protected with this register. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

### 30 CMDWEPROTNM (Offset = 1210h) [Reset = 00000000h]

CMDWEPROTNM is shown in [Figure 6-123](#) and described in [Table 6-137](#).

Return to the [Summary Table](#).

Command WriteErase Protect Non-Main Register

This register allows non-main region region sectors to be protected from program and erase. Each bit corresponds to 1 sector.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

### 31 CMDWEPROTTR (Offset = 1214h) [Reset = 0000000h]

CMDWEPROTTR is shown in [Figure 6-124](#) and described in [Table 6-138](#).

Return to the [Summary Table](#).

Command WriteErase Protect Trim  
Register

This register allows trim region sectors to be protected from program and erase. Each bit corresponds to 1 sector.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

The event manager provides the peripheral-to-peripheral, peripheral-to-DMA, and peripheral-to-CPU (IRQ) event connections.

<b>7.1 Events Overview</b> .....	<b>752</b>
<b>7.2 Events Operation</b> .....	<b>756</b>

## 7.1 Events Overview

The event manager transfers digital events from one entity (for example, a peripheral) to another (for example, a second peripheral, the DMA, or the CPU). The event manager implements event transfer through a defined set of event publishers (generators) and subscribers (receivers) which are interconnected through an event fabric containing a combination of fixed (static) and programmable routes.

Events which are transferred by the event manager include:

- Peripheral event transferred to the CPU as an interrupt request (IRQ)
  - Example: RTC interrupt is sent to the CPU
- Peripheral event transferred to the DMA as a DMA trigger
  - Example: UART data receive trigger to DMA to request a DMA transfer
- Peripheral event transferred to another peripheral to directly trigger an action in hardware
  - Example: TIMx timer peripheral publishes a periodic event to the ADC subscriber port, and the ADC uses the event to trigger start-of-sampling

In addition to providing the event transfer logic, the event manager also interfaces with the power management and clock unit (PMCU) if an event requires the power and/or clock configuration of the device to change to handle the event properly. For example, if a peripheral asserts an event that targets the DMA, and the device is in a STOP or STANDBY operating mode (DMA is disabled), the event manager will handshake with the PMCU to suspend the low power operating mode state temporarily and enable the DMA such that the DMA transfer can be processed.

The event manager configuration is device dependent, as different devices support different peripherals. See the device-specific data sheet for information on the device-specific event implementation.

### 7.1.1 Event Publisher

An event publisher is the source of an event which is propagated on the event fabric. Peripherals contain event publishers for publishing CPU interrupts, DMA triggers and generic events to the event fabric through the publishing port FPUB\_x. Publisher behavior is configured with standardized [event management registers](#).

### 7.1.2 Event Subscriber

Event subscribers are included within the processor, the DMA, and certain peripherals (see [Section 7.1.4](#)). Event subscribers subscribe the events through the subscribing port FSUB\_x. Event subscribers enable modules to be able to subscribe to, and take a predefined action upon, events which are published to the event fabric by an [event publisher](#).

### 7.1.3 Event Fabric Routing

There are three different types of routes through the event fabric which are used to connect a publisher to a subscriber: [CPU interrupt events](#), [DMA trigger events](#), and [generic events](#).

#### 7.1.3.1 CPU Interrupt Event Route (CPU\_INT)

A CPU interrupt event route is a fixed, point-to-point connection between one event publisher (inside a peripheral module) and one event subscriber (the CPU subsystem) used to propagate CPU interrupts.

Figure 7-1. CPU Interrupt (Fixed Event Route)

For each peripheral which is capable of generating a CPU interrupt, a fixed route is provided from the peripheral's masked interrupt status (MIS) register to the CPU subsystem's interrupt management logic.

If software does not clear the interrupt request in the peripheral's event management registers, the request will remain pending to the CPU subsystem. See [Section 7.2.5.3](#) for guidance on setting and clearing interrupt status with the event management registers.

### 7.1.3.2 DMA Trigger Event Route (DMA\_TRIGx)

A DMA route is a fixed route between a peripheral and the DMA controller, which optionally has additional side-band signals to pass a DMA done condition from the DMA controller back to the triggering peripheral to indicate when a DMA activity has run to completion. The DMA trigger route is shown in [Figure 7-2](#).

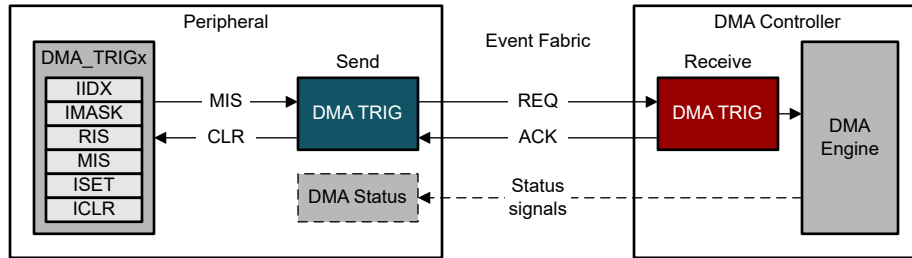

Figure 7-2. DMA Route

Most peripherals capable of generating a DMA trigger have an additional set of [event management registers](#) (in addition to the CPU\_INT registers used for the CPU interrupt and any GEN\_EVENTx generic route publishers). These registers can be used to select which peripheral condition to use for generating the DMA trigger.

When a trigger is received by the DMA, the DMA acknowledges the request and the peripheral clears the request. The DMA also acknowledges the cleared request, after which a new request can be asserted by the peripheral.

The DMA route can also contain status signals (for specific peripherals) to indicate to the triggering peripheral that a DMA transfer sequence has completed. For example, the DMA can be set up to transfer *N* number of bytes from an SRAM buffer into the UART TX data register based on the UART TX DMA trigger. Upon each trigger from the UART, the DMA will acknowledge that the transfer was successful. On the *N*th byte, the DMA will send a complete status signal to the UART, which the UART can use to propagate a transfer completion interrupt to the CPU.

### Special Cases

Certain peripherals (for example, the 12-bit DAC) do not implement an event management register set for managing their DMA triggers. In these cases, the peripheral implements specific DMA configuration logic such that the management registers are not needed to interface with the DMA. [Figure 7-3](#) shows the model when the event management registers are not implemented. See the peripheral-specific section of this document for guidance on how to configure DMA channels in this case.

Figure 7-3. DMA Route without Event Management Registers

### 7.1.3.3 Generic Event Route (GEN\_EVENTx)

A generic route is either a point-to-point (1:1) route or a point-to-two (1:2) splitter route in which the peripheral publishing the event uses one of several available generic route channels to publish its event to another entity (or entities, in the case of a splitter route), where an entity can be another peripheral, a generic DMA trigger event, or a generic CPU event, as shown in [Figure 7-4](#).

**Figure 7-4. Generic Route**

Peripherals capable of generating a generic event have an additional group (our groups) of GEN\_EVENTx event management registers (in addition to the CPU\_INT registers used for the CPU interrupt or DMA\_TRIGx for DMA, if present). These registers can be used to select the peripheral condition to use for publishing a generic event. When configured, the event will broadcast out to the generic route channel selected by the FPUB\_x register. A second peripheral, the DMA, or the CPU can subscribe to this event by configuring its generic subscriber port (FSUB\_x) to listen on the same generic route channel to which the publishing peripheral is connected to.

Generic route channels can be configured with one subscriber (1:1 route) or two subscribers (1:2 splitter route), depending on which channel is selected. See the device data sheet for a complete listing of the available generic route channels and their type (1:1 or 1:2). Generic route channels can only be configured with one publishing peripheral at a time. Once a peripheral subscribes to a 1:1 generic route channel, no other peripheral will be able to select that channel to subscribe to, unless the originally connected peripheral is disconnected first. Generic route channels with splitter capability (1:2) enable exactly two peripherals to subscribe to the channel, after which additional attempts to add subscribers will be blocked by hardware until both of the two connected peripherals are disconnected from the splitter channel.

Each peripheral type has unique capabilities in terms of what can generate an event to publish, and what a subscribed event is capable of triggering within the peripheral. Review the chapter of this guide which corresponds to the peripheral of interest to understand what the publisher and subscriber ports on a given peripheral are capable of.

### 7.1.4 Event Routing Map

The event capabilities of each peripheral type are shown in [Figure 7-5](#). Peripherals such as UART, SPI, and I2C generate CPU interrupt events which are routed to the CPU, and they also generate DMA trigger events which are routed to the DMA. Peripherals such as GPIO and ADC generate CPU interrupt events as well, but they also support generating and receiving events routed through a generic channel. For example, through the use of a generic event channel, it is possible to directly start an ADC conversion from a GPIO event by connecting a GPIO FPUB\_x and ADC FSUB\_0 to the same generic event channel.

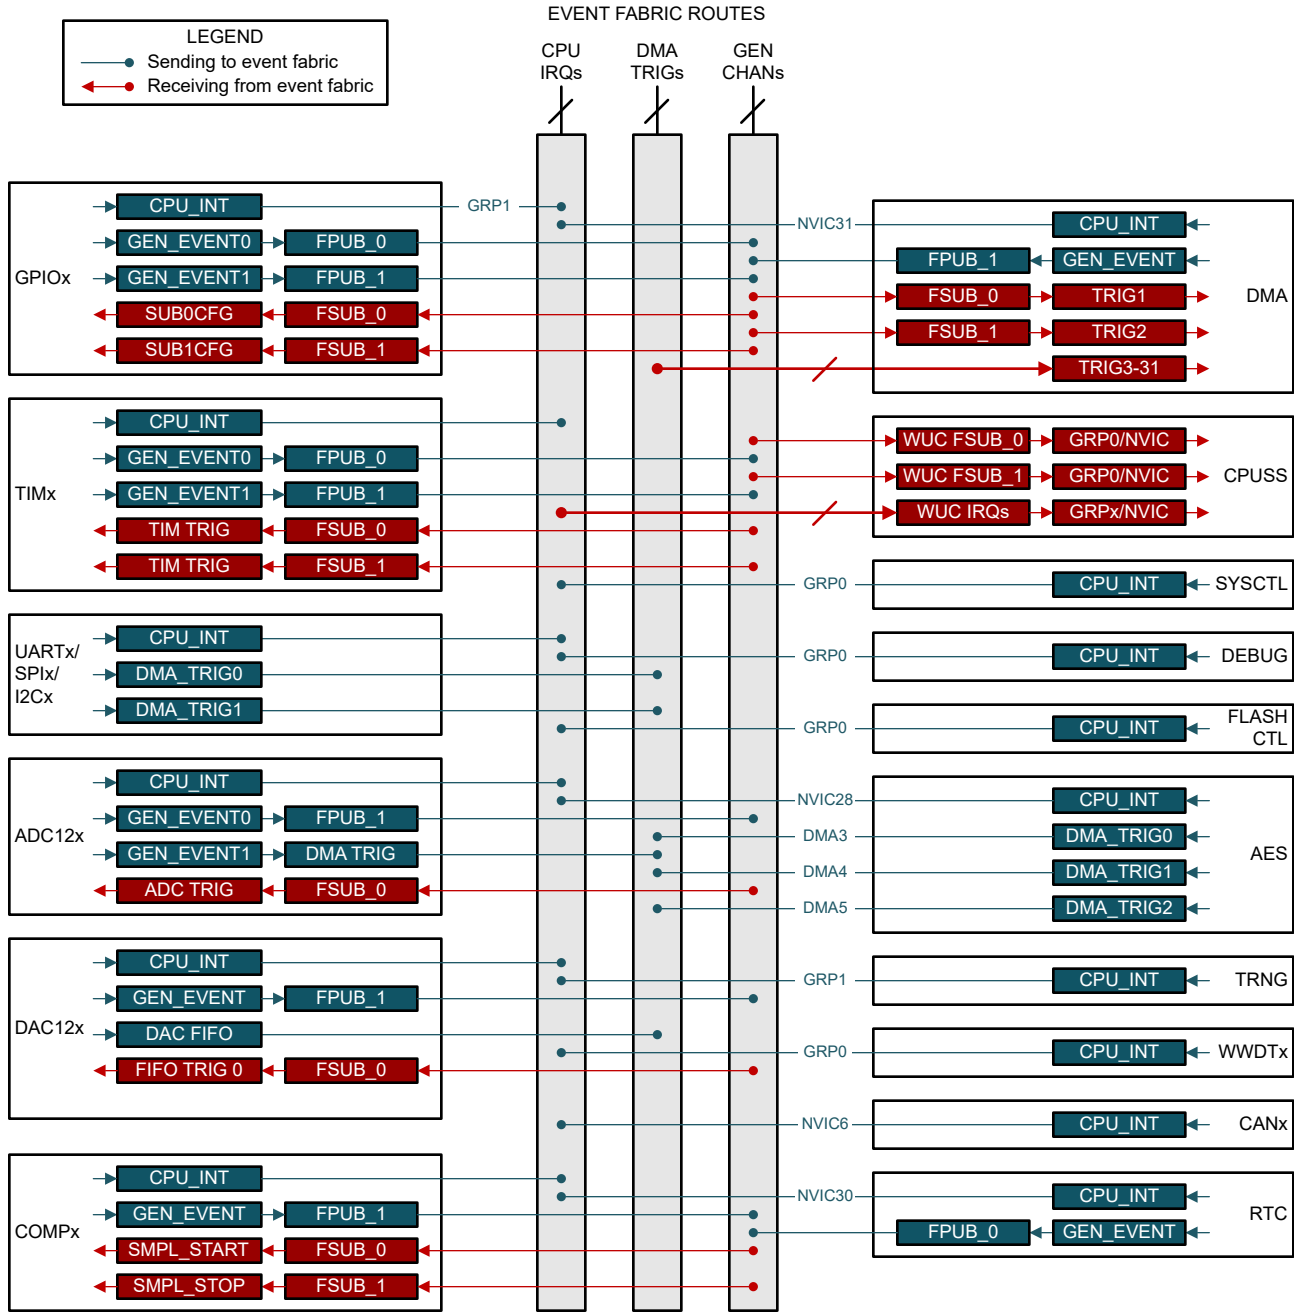

Figure 7-5. Event Map

### 7.1.5 Event Propagation Latency

Generic route channels implement a four-way hardware handshake between the publishing entity and the subscribing entity. This handshake requires four ULPCLK cycles to complete:

1. Request from publisher to subscriber
2. Acknowledge from subscriber to publisher
3. De-assert of request from publisher to subscriber
4. Acknowledge of de-assert from subscriber to publisher

If the publishing peripheral sends two requests and the first request has not cleared the handshake, the second request is dropped.

## 7.2 Events Operation

This section describes how to configure peripherals to use the event manager. Note that the event manager does not contain any configuration registers. All event configuration is done through the publishing and subscribing peripherals.

### 7.2.1 CPU Interrupt

Peripheral interrupt requests (IRQs) are propagated to the CPU subsystem through the event manager. Peripheral interrupt requests use fixed routes, but in addition the CPU subsystem may provide two generic event subscriber ports which can be used to trigger CPU interrupts through a generic route. See the device-specific data sheet for the complete list of interrupt assignments for a given device.

#### Standard CPU Interrupt Requests

No special configuration is required for fixed route interrupts. Interrupts can be managed through the peripheral's CPU\_INT event management registers (IIDX, IMASK, RIS, MIS, ISET, and ICLR) and through the CPU subsystem interrupt configuration (see *Interrupts and Exceptions*).

#### Generic Event Based CPU Interrupt Requests

The CPU subsystem contains two generic event subscriber ports (FSUB\_x) which can be used to source a CPU interrupt from any of the device's generic event channels. This can be used to enable special cases where a particular function on a peripheral generates a dedicated interrupt to the CPU subsystem which is independent from, and in addition to, that peripheral's standard interrupt mechanism.

Consider the GPIO peripheral, which has a standard interrupt request as well as 2 publishers which can route a GPIO event to any of the generic event channels based on a defined state in the GPIO. For example, it can be desirable to have most GPIO events configured to source the standard interrupt, while a single specific GPIO event sources a second dedicated CPU interrupt through a generic route. This enables the application software to have two completely independent interrupt handlers for the GPIO.

To configure the event manager to trigger a CPU interrupt from a generic route, follow the steps below:

1. Configure the GEN\_EVENT registers of the peripheral generating the event to select the desired peripheral state as an event generator.
2. Configure the FPUB\_x register of the peripheral generating the event with the generic route channel ID which is to be used. This channel must not be in use by another peripheral.
3. Configure the FSUB\_x register of the wake up controller (WUC), which captures generic route channel events to forward to the CPU subsystem.
4. Configure the CPU subsystem interrupt management to enable the GENSUBx interrupt.

Note that when generating a CPU interrupt through a generic route, the generic event logic will automatically clear the pending interrupt request as a part of the four-way event handshake. Application software will not be able to read the cause of the interrupt from the peripheral registers, and it does not need to clear any interrupt status bits. Software can only read that the FSUB\_x generic event generated an interrupt. This reduces the interrupt overhead.

### 7.2.2 DMA Trigger

DMA triggers are propagated to the DMA through the event manager. Most DMA triggers use fixed routes, but the DMA does provide two generic event subscriber ports which can be used to trigger DMA transfers through a generic route channel. See the device-specific data sheet for the complete list of DMA trigger assignments for a given device.

#### Standard DMA Triggers

To determine if a particular peripheral on a device provides a fixed DMA trigger (DMA\_TRIGx) from the peripheral directly to the DMA, review the DMA triggers table in the detailed description section of the device-

specific data sheet. Certain peripherals can have more than one DMA trigger (for example, to enable a TX trigger and an RX trigger on a serial communication peripheral).

To select the specific peripheral event which triggers a static DMA route, configure the peripheral's DMA\_TRIGx event management register set (IIDX, IMASK, RIS, MIS, ISET, and ICLR) which corresponds to the targeted DMA route. To determine which DMA\_TRIGx register set corresponds with which DMA trigger, review the relevant chapter of this guide for the corresponding peripheral, or review [Section 7.1.4](#).

Certain peripherals (such as the 12-bit DAC) do not implement a DMA\_TRIGx register set for managing DMA triggers. In these cases, the DMA trigger configuration is done through peripheral-specific configuration registers.

### Generic Event Based DMA Triggers

The DMA contains two generic event subscriber ports (FSUB\_x) which can be used to source a DMA trigger from any of the device's generic event channels. This can be used to enable special cases where a particular function on a peripheral generates a DMA trigger. For example, it can be desirable to trigger a DMA transfer from a timer.

To configure the event manager to trigger a DMA channel from a generic route, follow the steps below:

1. Configure the GEN\_EVENTx registers of the peripheral generating the event to select the desired peripheral state as an event generator.
2. Configure the FPUB\_x register of the peripheral generating the event with the generic event channel ID which is to be used. This channel must not be in use by another peripheral.
3. Configure the FSUB\_x register of the DMA, which captures generic event channel events to be used as triggers in the DMA.
4. Configure the DMA according to the configuration instructions in the DMA chapter.

#### 7.2.3 Peripheral to Peripheral Event

Peripheral to peripheral events enable a condition in one peripheral to trigger an action in a second (or third) peripheral, completely in hardware without any CPU interaction. The device provides a certain number of generic route channels which can be either published to or subscribed to by peripherals which include publisher and subscriber ports. Before establishing a configuration, follow these steps:

1. Review the device specific data sheet to determine the generic route channel count and channel type available on the target device. Select an appropriate channel type (point to point or splitter) based on the desired functionality, and determine the channel number to use for the connection (the channel must not already be used by other peripherals).
2. Review the publisher and subscriber capabilities of the peripherals which are to be connected. Some peripherals have more than one publisher and/or more than one subscriber port, and some peripherals have no publisher or subscriber ports. To understand the available ports for a peripheral, review the peripheral's reference chapter in this guide, or check the generic event channel connections in *Event Routing Map*.

Once the channel to be used is determined, and both the publisher and subscriber ports for the peripherals being connected are known, use the steps below to establish the event connection. In this example, a timer triggered ADC application will be configured, using TIMG0 to publish an event to generic channel 1, with ADC0 subscribing to generic channel 1 as a start-of-conversion trigger.

1. Configure the GEN\_EVENTx event management registers of TIMG0 to set the event request based on the appropriate timer event (for example, a zero event).
2. Store 0x1 into the FPUB\_0 register of TIMG0 to publish the TIMG0 event selected by the GEN\_EVENTx registers to generic route channel 1. Channel 1 must not be in use by another peripheral.
3. Store 0x1 the FSUB\_0 register of ADC0 so that ADC0 is listening for events published by the timer to channel 1.
4. Configure ADC0 to trigger from the subscriber port according to the configuration instructions in *Sampling Trigger Sources and Sampling Modes*.
5. Configure and enable TIMG0.

### 7.2.4 Extended Module Description Register

The DESC\_EX register is a read-only register in the event manager which can be read by application software to determine how many point to point (single) generic route channels and splitter (dual) generic route channels are available on a given device.

### 7.2.5 Using Event Registers

The event management register group is a set of standard registers which are implemented by all peripherals capable of generating events (CPU interrupts, DMA triggers, or generic events). Each event generator in a peripheral contains its own event management register set. For example, if a peripheral supports generating a CPU interrupt and a DMA trigger, it will have an event management register set for the CPU interrupt (with the group name of CPU\_INT) as well as a second event management register set for the DMA trigger (with the group name of DMA\_TRIG).

The event management registers are used to:

- Configure which peripheral conditions are used to generate the event (masking)
- Communicate raw and masked peripheral event status
- Set or clear peripheral event status by software

In the "Registers" section for a given peripheral, the "Group" column displays the Group Name to indicate what functionality is mapped to each event management register group. See [Table 7-1](#) for which event management groups are mapped to specific functions in the group name for a peripheral's "Registers" section.

**Table 7-1. Event Management Group Functionality and Mapping**

Group Name (in Registers)	Functionality
CPU_INT	CPU interrupt (fixed route to the CPU subsystem)
DMA_TRIGx	DMA trigger (fixed route to the DMA controller)
GEN_EVENT	Generic event (programmable route for other module-to-module connections)

#### 7.2.5.1 Event Registers

The event management register set contains 6 standard registers: RIS, IMASK, MIS, ISET, ICLR, and IIDX, given in [Table 7-2](#). The event registers are interconnected as shown in [Figure 7-6](#).

**Figure 7-6. Event Management Register Relationship**

The peripheral generating the event will contain one or more interrupt source signals which connect to the raw interrupt status (RIS) register. Software can poll RIS at any time to check the raw interrupt status. Software can also clear pending interrupts in the RIS register by writing to the corresponding bit position in the ICLR register. The RIS and IMASK registers are combined through a bit-wise AND function in the MIS register (masked interrupt status). To unmask an interrupt, set the corresponding bit in the IMASK register. Once unmasked, a pending interrupt will be indicated in both the RIS and MIS registers, and an event will be generated. The IIDX register will also be updated with the index of the highest priority pending interrupt.

In the case of a CPU interrupt (CPU\_INT) with a [CPU interrupt event route](#), a read of the IIDX register will clear the highest priority pending interrupt in the RIS and MIS registers and return the index of the highest priority pending interrupt to application software.

In the case of a hardware event [DMA trigger route](#) (DMA\_TRIGx) or [generic event route](#) (GEN\_EVENTx), the hardware four-way handshake will send an ACK signal to the ICLR mechanism which will clear the pending interrupt in the RIS and MIS registers.

**Table 7-2. Standardized Event Management Registers (Used for CPU\_INT, DMA\_TRIGx, GEN\_EVENTx Configuration)**

Register	Description	R/W	Functionality
RIS	Raw interrupt status	R	Indicates the current pending interrupt status, with one bit provided per interrupt condition. Writing to ICLR will clear the corresponding bit in the RIS register if the interrupt condition is no longer present.
IMASK	Interrupt mask	RW	Used by application software to configure which interrupt conditions propagate into an event, with one bit provided per interrupt condition.
MIS	Masked interrupt status	R	Indicates the current pending masked interrupt status to software and hardware, with one bit provided per interrupt condition. MIS is the bit-wise AND of the RIS and IMASK registers. Writing to ICLR will clear the corresponding bit in the RIS register if the interrupt condition is no longer present. If RIS is cleared, the corresponding bit in the MIS register is also automatically cleared.
ISET	Software interrupt set control	W	Used by application software to force an interrupt condition for diagnostics. Writing to ISET will set the corresponding bit in the RIS register. If the interrupt condition is enabled in IMASK, the corresponding bit in the MIS register is also set. Writing a '1' to a bit location in ISET sets the respective interrupt status.
ICLR	Software interrupt clear control	W	Used by application software to clear a pending interrupt status in RIS. Writing a '1' to a bit location in ICLR clears the respective interrupt status. If an interrupt is enabled in IMASK, the corresponding bit location in MIS is also cleared automatically when RIS clears. If the interrupt condition is still present, clearing the status has no effect and the RIS will remain set.
IIDX	Pending interrupt index	R	Used by application software to read the highest priority pending interrupt while simultaneously clearing the highest priority interrupt status in RIS and MIS. A read of IIDX returns 0 if no unmasked interrupts are pending (MIS==0), else it returns an index value indicating the highest priority pending interrupt.

### 7.2.5.2 Configuring Events

To configure which peripheral interrupt source is to be used to trigger an event, set the bit which corresponds to the desired interrupt source in the IMASK register which corresponds to the desired event. Setting a bit in IMASK will cause the raw interrupt status in the RIS register to propagate to the MIS register. When an interrupt status bit in the MIS register is set (due to the interrupt being unmasked in the IMASK register and a raw interrupt being pending in the RIS register), an event is generated.

Multiple interrupt sources can be enabled for CPU interrupt events, as application software can determine the cause of the interrupt by reading the IIDX or MIS register.

For hardware events such as DMA triggers and generic event publishers, only one interrupt source should be unmasked in IMASK.

### 7.2.5.3 Responding to CPU Interrupts in Application Software

In the case of an event which generates a CPU interrupt, application software can determine which peripheral interrupt triggered the generation of the event by either reading the IIDX register or by reading the MIS and writing the ICLR registers.

### CPU IRQ Interrupt Service Routine using CPU\_INT IIDX Register

Application software can read the IIDX register in CPU\_INT group to determine and clear the highest priority pending interrupt. A read to IIDX will return an index corresponding to the highest priority interrupt which was both set and unmasked. The read action will also simultaneously clear the RIS and MIS bits corresponding to the

highest priority interrupt whose index was returned by the read. The read value from the IIDX register can then be used in a case statement, as shown below.

```
void ISR_IIDX(void)
{
    switch(IIDX)
    {
        case 0:          // no IRQ pending
            break;
        case 1:          // IRQ[0]
            do_irq0();
            break;
        case 2:          // IRQ[1]
            do_irq1();
            break;
        default:         // out of range
            illegal();
    }
}
```

### CPU IRQ Interrupt Service Routine using CPU\_INT MIS and ICLR Registers

Alternatively, application software can read the MIS register to determine which bits are set, followed by using the ICLR register to clear the pending interrupt status bits.

```
void ISR(void)
{
    uint32_t pending = MIS;
    ICLR = pending;    // clear pending IRQ
    if (pending & 0x01) // IRQ[0]
    {
        do_irq0();
    }
    if (pending & 0x02) // IRQ[1]
    {
        do_irq1();
    }
}
```

#### 7.2.5.4 Hardware Event Handling

In the case of an event which sources a DMA trigger (DMA\_TRIG) or a generic event (GEN\_EVENT), the IIDX register is not used. A four-way event handshake is performed between the peripheral generating the event and the hardware entity which is subscribed to the event (for example, the DMA or a secondary peripheral). The [four-way event handshake](#) will clear the corresponding interrupt status bits in the RIS and MIS registers automatically.

The IOMUX controls the configuration of all device pins with digital input-output (IO) functions, including: digital function selection, inversion control, drive strength (if applicable), the pullup or pulldown resistor (if applicable), and wake-up configuration (if applicable on certain IOs for wakeup from SHUTDOWN mode).

<b>8.1 IOMUX Overview</b> .....	<b>762</b>
<b>8.2 IOMUX Operation</b> .....	<b>765</b>
<b>8.3 IOMUX Registers</b> .....	<b>769</b>

## 8.1 IOMUX Overview

The IOMUX manages the configuration of the digital IO. Refer to the device specific datasheet for supported features. Key functions configured by IOMUX include:

- Selection of which peripheral is multiplexed to each digital IO pin (for example, a GPIO or UART peripheral)
- Digital input path configuration
  - Hysteresis control
  - Input path enable/disable
  - Input logic inversion control
- Digital output path configuration
  - Drive strength control
  - Output connection enable/disable
  - Output logic inversion (control shared with input logic inversion)
  - Logic-high to High-Z output conversion (for open-drain style interfaces)
  - Retention of "last state" when a peripheral connected to an IO is disabled
- Wakeup configuration (for wakeup from SHUTDOWN mode if present)
  - Read wake up source from the wakestat bit from the PINCM Register
  - Wake up compare level
  - Release SHDNIOREL
  - Wakeup enable/disable
- Pullup and pulldown resistor control (if present)

### 8.1.1 IO Types and Analog Sharing

The IOMUX manages the selection of which peripheral function is to be used on a digital IO. It also provides the controls for the output driver, input path, and the wakeup logic for wakeup from SHUTDOWN mode.

#### Digital IO Types

There are several digital IO types which can be included on a given device. Each digital IO type supports different features. [Table 8-1](#) lists the features which are included with each IO type. See the device-specific data sheet for which IO type is used on a given package pin.

**Table 8-1. Digital IO Features by IO Type**

IO Structure	Inversion Control	Drive Strength Control	Hysteresis Control	Pullup Resistor	Pulldown Resistor	Wakeup Logic
Low-drive (SDIO)	Y			Y	Y	
Low-drive with wake (SDIO)	Y			Y	Y	Y
Standard-drive (SDIO)	Y			Y	Y	
Standard-drive with wake (SDIO)	Y			Y	Y	Y
High-drive (HDIO)	Y	Y		Y	Y	Y
High-speed (HSIO)	Y	Y		Y	Y	
5V tolerant open drain (ODIO)	Y		Y		Y	Y

Please note that the IOMUX will not support the inversion control and pseudo-open drain (output-high translated to high-impedance) setting on the SPI POCI pins. Also the IOMUX will not support inversion control on the SPI SCLK pins connected on an HSIO pin. Not all devices support pulldown resistors refer to the device specific data sheet.

#### Digital IO Shared with Analog Functions

Certain pins on a device will be digital only and will not have any analog functions connected to the pin. Other pins can have one or more analog functions connected to the pin in addition to the digital IO functions. Analog

functions are never selected within the IOMUX; they are always configured within of the respective analog peripheral. Analog peripherals have no knowledge of, or interaction with, the IOMUX.

In general, when analog functionality is used on a pin which also has digital functions, the IOMUX configuration for that pin should be left in its default (high-Z) state so as to not interfere with the proper operation of the analog function. However, it is possible to have the IOMUX active on a pin when an analog peripheral is also interacting with the pin, provided that the application software ensures that there is not a conflict between the functions. For example, it is possible to have the pullup or pulldown resistor on an IO enabled at the same time that the ADC is running a conversion on the same IO. However, an invalid configuration would be enabling the output driver on an IO at the same time that an analog peripheral is driving the IO (for example, a DAC or OPA output). This would create an IO conflict.

Application software is responsible for ensuring that the IOMUX settings do not conflict with any analog peripheral functions which can be enabled on a shared pad.

### IO Slice

The mixed-signal IO pin slice diagram for a full featured IO pin is shown in [Figure 8-1](#). Not all pins will have analog functions, wake-up logic, drive strength control, and pullup or pulldown resistors available. See the device-specific data sheet for detailed information on what features are supported for a specific pin.

Figure 8-1. Superset IO Slice

**Default IOMUX State**

The initial state of the IOMUX pin slice for all digital IO after a BOOTRST is as follows:

- The digital IO is in a high-impedance state
- The peripheral function selection field (PF) is cleared (no peripheral function selected) and the peripheral connect (PC) and input enable states are cleared (disabled)
- The inversion logic is disabled
- The Hi-Z output high mode is disabled
- The pullup/pulldown resistors (if present) are disabled
- The input hysteresis control (if present) is disabled to save power
- The drive strength control (if present) is reset

- The wakeup logic (if present) is disabled

---

#### Note

The SWD pins are a specific exception to the above default state. The SWD debug pins are configured in SWD mode by default, and may be switched to an alternate setting after start-up. See *SWD Pins* in the SYSTL section of the PMCU chapter.

---

## 8.2 IOMUX Operation

Each digital IO on a device has a dedicated 32-bit PINCM register in the IOMUX peripheral register space which is used to configure the digital functions of the respective IO. See the device specific data sheet for determining the PINCM register index which corresponds to the IO to be configured.

### 8.2.1 Peripheral Function (PF) Assignment

When setting up the initial IOMUX configuration for an IO after a BOOTRST, application software can select which digital peripheral from the supported options is to be connect to an IO by writing the appropriate peripheral select value to the PF field while simultaneously setting the PC and INENA bits in the PINCMx register corresponding to the targeted pin. The IOMUX configurations for a given peripheral must be set before the peripheral connected to the IOs has been initialized for operation.

To change the peripheral function selection for a digital IO at runtime after a peripheral function has already been configured for that IO, the following procedure should be followed:

1. Disable the currently connected peripheral function
2. Clear the PC bit (input/output connect bit) and INENA (input connect bit) in the corresponding PINCMx register
3. Write 0x0 to the PF field in the PINCMx to clear the logic in the data path
4. Select the new peripheral function by writing the peripheral function ID to the PF register
5. Set the PC and INENA bits in the PINCMx register to connect the newly selected peripheral
6. Enable the newly selected peripheral for operation

At runtime, the INENA bit can be used to mask the input from the IO to the peripheral, if desired. When INENA is cleared, a connected peripheral function will see logic low (0) from the IO, regardless of the external state of the IO. If an IO supports wakeup from SHUTDOWN mode, the INENA bit also controls propagation of the IO state to the SHUTDOWN mode wakeup logic.

If a peripheral is assigned to an IO, but the peripheral is itself in a disabled state, the last valid output conditions (output logic level and Hi-Z state) are latched in the IOMUX output logic. When the peripheral is enabled, the IOMUX will release the latched state to allow the (now enabled) peripheral's output state to propagate to the IO. Note that when the GPIO peripheral is selected by the IOMUX, the DOE[x] field also needs to be enabled to set DOUT and conversely cleared to configure a Hi-Z state. The PMCU indicates to the IOMUX when a peripheral is entering a disabled state via the IORET signal, which is combined with the PC signal via a logic OR to control the output state latches. This mechanism handles preservation of the last valid output state of peripherals in power domain 1 (PD1) when entering STOP or STANDBY mode, as PD1 peripherals are always temporarily disabled upon entry to STOP/STANDBY, and re-enabled upon exit from STOP/STANDBY modes.

When no peripheral function is selected (PF==0) the output latches are put into a reset state, causing the output NMOS and PMOS to be disabled (leaving the IO pin in a Hi-Z state with the exception of any enabled pullup/pulldown resistors). Note that the pullup/pulldown resistors are never controlled by either a connected peripheral or the peripheral muxing logic. They are only controlled by the IOMUX control bits ([see pullup/pulldown](#)).

### 8.2.2 Logic High to Hi-Z Conversion

The IOMUX supports translating an output high signal from a connected peripheral into a Hi-Z output state at the IO pin. This functionality is particularly useful for open-drain digital input/output applications. When this functionality is enabled, the IO pin state as a function of the peripheral output is as shown in [Table 8-2](#).

**Table 8-2. Logic High to Hi-Z Truth Table**

Connected Peripheral Output	IO Pin State (Z1 = 0x0)	IO Pin State (Z1 = 0x1)
Logic low (0)	Output low	Output low
Logic high (1)	Output high	High impedance (Hi-Z)

To enable logic high to Hi-Z conversion on a digital IO, set the Z1 bit in the corresponding PINCMx register.

Note that for 5V tolerant open-drain IO pins, the Z1 control has no effect as there is no high-side driver present. On these pins, a logic high output from the peripheral to the IO pin always results in a Hi-Z state.

### 8.2.3 Logic Inversion

The IOMUX supports logic inversion of the digital input/output path. Logic inversion is useful for scenarios where opposite polarity is required for UART functions or SPI chip select functions.

To enable logic inversion on a digital IO, set the INV bit in the corresponding PINCMx register. To disable logic inversion, clear the corresponding bit. Logic inversion is disabled by default.

When logic inversion is enabled for a 5V tolerant open drain IO, a connected peripheral which outputs a logic low state will cause the IO pin to go to a Hi-Z state. When the peripheral applies a logic high state, the IO pin will go to an output low state.

### 8.2.4 SHUTDOWN Mode Wakeup Logic

In SHUTDOWN mode, the entire regulated core supply of the device is disabled and the device wakes only from a wake-capable IO that is configured for wakeup, from NRST, or from a debug connection. The IO wake mechanism for exiting SHUTDOWN is managed by IOMUX and is level based. The 5V-tolerant open-drain IOs, high-drive IOs, and certain standard-drive IOs include the additional wakeup logic that can be used to wake the device from a SHUTDOWN operating mode upon a level match.

To configure a wake-capable IO for wakeup from SHUTDOWN mode:

1. Set the INENA bit to let the input state propagate from the IO to the wakeup logic.
2. Select the compare level to use for wake by setting or clearing the WCOMP bit in the PINCMx register corresponding to the targeted pin.
3. Enable wakeup by setting the WUEN bit in the PINCMx register corresponding to the targeted pin.

After the previous configuration, SHUTDOWN mode can be entered through the appropriate command in SYSCTL. Pins on the device that contain digital IO controlled by IOMUX retain their current state when the device enters into SHUTDOWN. While the digital IO state is latched upon entry into SHUTDOWN mode, the IOMUX configuration registers (all PINCMx registers) lose their contents as the regulated core supply is shut down.

After SHUTDOWN is entered, a level match on any pin configured for wakeup triggers the exit sequence from SHUTDOWN. When the device exits SHUTDOWN, a BOR-level reset occurs but the state of the digital IO remains latched through the reset, keeping the IO state that was present upon entry into SHUTDOWN. This state is held until the IO are released in SYSCTL. After the BOR, SYSCTL captures the cause of the reset as a SHUTDOWN exit so that software can identify this and take appropriate action to reconfigure the device.

If multiple pins were configured for wakeup from SHUTDOWN, application software can determine which wakeup-configured IO generated the wake by polling the WAKESTATE bit in any IOs that were enabled for wake before the SHUTDOWN exit.

Application software must apply the following process to restore the IO state upon exit from SHUTDOWN:

1. Check which IO triggered the wakeup from SHUTDOWN, if necessary, as follows:
  - a. Reconfigure the PINCMx register corresponding to the IO to be tested for wakeup status and set the peripheral connect (PC) bit (the PC bit gates the WAKESTATE indication).

- b. Test the WAKESTATE bit in the PINCMx register corresponding to the IO to be tested to determine if that particular IO received a WAKE status based on the previously configured WCOMP and WUEN configuration.
2. Reconfigure any remaining IOMUX PINCM registers to the correct states.
3. Reconfigure the peripherals that are connected to pins through IOMUX, and enable them.
4. Release the SHUTDOWN IO lock in SYSCTL.
5. Clear the WUEN bit in the PINCMx register to reset the WAKESTATE status.

---

#### **Note**

After waking from SHUTDOWN, if the WUEN bit not cleared and the shutdown release bit in SYSCTL is not set, then reentering SHUTDOWN results in an immediate wake event, because the WAKESTATE status was not cleared from the previous wake event.

---

### **8.2.5 Pullup/Pulldown Resistors**

Programmable pullup/pulldown resistors are provided on most digital IO types, and are connected to VDD/VSS, respectively. The 5V tolerant open drain digital IO does not provide a pullup resistor due to the open drain configuration.

To enable the pullup or pulldown resistor on a digital IO, set the PIPU or PIPD bit, respectively, in the corresponding PINCMx register. To disable the pullup or pulldown resistor, clear the corresponding bit.

The pullup/pulldown resistors can be enabled at any time, and their configuration is independent from the [peripheral function configuration](#). It is possible to enable a pullup/pulldown resistor while changing the selected peripheral function.

### **8.2.6 Drive Strength Control**

The high-drive and high-speed digital IO types have programmable drive strength (low drive and high drive). The default drive strength is low drive. Application software can request high drive by setting the DRV bit in the PINCMx register corresponding to the target digital IO. Drive strength control is not available for standard drive and open drain IO types.

The drive strength control is completely independent of the selected peripheral function (PF) and can be changed by application software at any time.

For detailed electrical specifications on the drive performance in each drive mode for a given IO, see the Digital IO parameters in the device-specific data sheet.

### **8.2.7 Hysteresis and Logic Level Control**

The 5V-tolerant open drain digital IOs provide a hysteresis and logic level control to enable operation in input mode with standard CMOS logic (hysteresis enabled, CMOS logic levels) and TTL logic (hysteresis disabled, TTL logic levels).

The default mode for the 5V-tolerant open drain digital IO is TTL mode (HYSTEN bit in the PINCMx register is cleared). To use a 5V-tolerant open drain digital IO in CMOS mode with hysteresis enabled, set the HYSTEN bit in the PINCMx register which corresponds to the targeted IO.

The input logic level differences between TTL mode (left) and CMOS mode (right) are shown in [Figure 8-2](#).

Figure 8-2. Input Logic Levels - 5V Tolerant Open Drain Digital IO

### 8.3 IOMUX Registers

Table 8-3 lists the memory-mapped registers for the IOMUX registers. All register offset addresses not listed in Table 8-3 should be considered as reserved locations and the register contents should not be modified.

**Table 8-3. IOMUX Registers**

Offset	Acronym	Register Name	Group	Section
4h	PINCM	Pin Control Management Register in SECCFG region		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 8-4 shows the codes that are used for access types in this section.

**Table 8-4. IOMUX Access Type Codes**

Access Type	Code	Description
<b>Read Type</b>		
R	R	Read
<b>Write Type</b>		
W	W	Write
<b>Reset or Default Value</b>		
-n		Value after reset or the default value

## 1 PINCM (Offset = 4h) [Reset = X]

PINCM is shown in [Figure 8-3](#) and described in [Table 8-5](#).

5-0	PF	R/W	0h	Peripheral Function selection bits 0h = Reserved as unconnected 3Fh = An encoding per function that can be connected to this pin.

## General-Purpose Input/Output (GPIO)

---

The GPIO peripheral provides the user with a means to write data out and read data in to and from the device pins. The GPIO also provides a way to detect wakeup events while the device is in a low power state. This chapter describes the operation of the GPIO peripheral.

<b>9.1 GPIO Overview</b> .....	<b>773</b>
<b>9.2 GPIO Operation</b> .....	<b>773</b>
<b>9.3 GPIO Registers</b> .....	<b>777</b>

## 9.1 GPIO Overview

The GPIO is used to read in digital data from the device pins and to send digital data out to the device pins.

The GPIO module features include:

- Zero wait state MMR access from CPU
- Set/clear/toggle multiple bits without the need of a read-modify-write construct in software
- Direct writes to individual GPIO output bits (DOUT) without the need of a read-modify-write construct in software
- Direct read comparisons of individual GPIO input bits (DIN) without the need to use masking in software
- DOUT serviceable by DMA to generate a predefined output sequence on specified pins
- "FastWake" feature enables low-power wakeup from STOP and STANDBY modes for any GPIO port
- User controlled input filtering (configurable per IO)
- Interconnection to the device event fabric through event publishers and event subscribers

GPIO Block Diagram shows the block diagram of the GPIO peripheral.

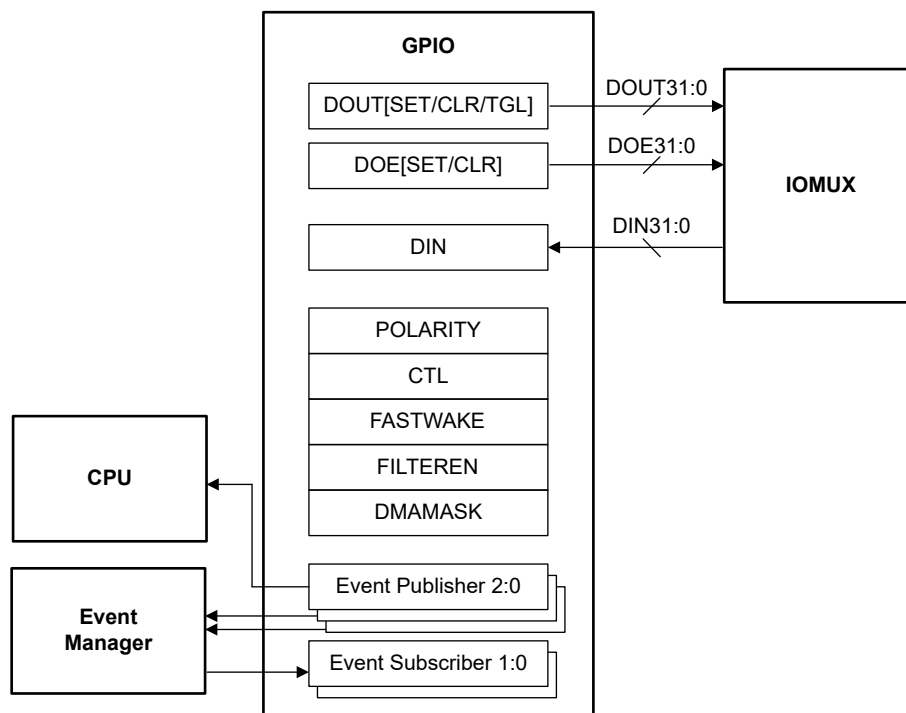

Figure 9-1. GPIO Block Diagram

### Note

The GPIO module for the MSP platform does not manage the complete digital IO functionality (for example, pullup, pulldown, or other functional muxing). For complete digital IO control details, refer to [Chapter 8](#). Similar to any other peripheral, the GPIO has inputs and outputs (with output enable) that allow the GPIO to interface with the IOMUX to make connections to the IO pins.

## 9.2 GPIO Operation

The GPIO peripheral is configured with user software. The setup and operation of the GPIO is discussed in the following sections.

### 9.2.1 GPIO Ports

An instance of the GPIO peripheral in the MSP platform supports up to 32 data input/output (DIO) bits. For devices with greater than 32 GPIOs, multiple instances of the GPIO peripheral are used to address all of the device pins. The GPIO port and bit names are directly mapped to the signal names associated with each device pin in the *Pin Configuration and Functions* section of the device data sheet.

**Table 9-1. GPIO Port and Device Pin Mapping**

GPIO Port and Bit Name	Device Pin Signal Name
GPIO Port A Bit 0 (DIO0)	PA0
GPIO Port A Bit 1 (DIO1)	PA1
GPIO Port B Bit 0 (DIO0)	PB0
GPIO Port B Bit 1 (DIO1)	PB1
GPIO Port x Bit y (DIOy)	Pxy

### 9.2.2 GPIO Read/Write Interface

The GPIO peripheral has features and dedicated registers to allow for advanced bit manipulations without the need to execute a read-modify-write construct in software. These features are outlined below.

### 9.2.3 GPIO Input Glitch Filtering and Synchronization

The GPIO module evaluates the state of input pins at the ULPCLK (PD0 bus clock) rate, synchronizing the pin state to ULPCLK through a 2-stage synchronizer before passing the GPIO state to the input glitch filter.

**Figure 9-2. GPIO Input Synchronizer**

A programmable input glitch filter is provided for suppressing noise on digital input pins. The glitch filter runs at ULPCLK rate. Four levels of user-specified input filtering are possible:

- Sampled input without filtering (the minimum reliably detected pulse width is one ULPCLK cycle due to synchronization of the pin state with ULPCLK +Delay time from edge of asynchronous request to first MCLK edge in case of fast wake enable for STANDBY0/1, STOP1/2 and SLEEP2 modes)
- Synchronized inputs which are not greater than 1 ULPCLK periods are filtered out
- Synchronized inputs which are not greater than 3 ULPCLK periods are filtered out
- Synchronized inputs which are not greater than 8 ULPCLK periods are filtered out

This feature allows users to easily implement input filtering in hardware for cases where fast switching on the input pin is needed to be filtered out. The bit fields in the FILTEREN31\_16 and FILTEREN15\_0 registers allow users to configure the level of filtering needed for the corresponding GPIO bit.

Input pulses of the same pulse length can be passed in some cases while being filtered in other cases, due to 1 ULPCLK cycle of uncertainty in the synchronization.

**Figure 9-3. GPIO Input Synchronizer and Glitch Filtering Scenarios**

- In Scenario A, the input pulse is less than one ULPCLK cycle. Pulses less than one ULPCLK cycle may not be captured. To ensure that GPIO inputs are always captured, the GPIO input pulse width must be greater than the ULPCLK period.
- In Scenario B, the input pulse is nearly two ULPCLK cycles in length, but because the rising edge occurs just after the ULPCLK edge, the GPIO synchronizer only views the input pin as having been high for 1 ULPCLK period. This scenario would not be filtered out by the glitch filter when the glitch filter is disabled, but a glitch filter value of >1 would result in this pulse being filtered. Conversely, the same input pulse width in Scenario C results in the input pin being considered high for two ULPCLK periods, as the rising edge occurred just before the ULPCLK edge. In this case, this scenario would not be filtered out when a glitch filter value of >1 is specified.
- In Scenario D, three ULPCLK cycles are passed to the glitch filter. In this case, the scenario would not be filtered out when a glitch filter value of >1 is specified, but it would be filtered out for a glitch filter value of >3 or >8.

#### Note

When the fast wake mode is enabled (SYSOSC is requested asynchronously upon input pin activity), the ULPCLK will switch from off (as would be the case in STANDBY1) or 32kHz (as would be the case in STANDBY0) to 24MHz/32MHz, resulting in the input synchronization logic and glitch filter running at 24MHz/32MHz after some latency. See the device specific data sheet for the asynchronous fast clock request wake time, and budget this time into any minimum pulse width calculations when using fast wake.

### 9.2.4 GPIO Fast Wake

The fast wake feature in the MSP GPIO peripheral allows the GPIO module to stay in a low-power state and detect interrupt events on the device pins without requiring a high-speed clock. This allows the device to support fast wakeup from low-power modes, such as STOP and STANDBY, on any GPIO pin.

Fast wake can be enabled on a bit-wise basis using the FASTWAKE register. Setting a bit in the FASTWAKE register enables the corresponding device pin signal to support fast wakeup functionality. The CTL register contains a bit field named FASTWAKEONLY which allows for global control of the fast wake feature. Setting the FASTWAKEONLY bit enables all of the bits in the corresponding GPIO port to support fast wakeup functionality.

#### Note

Do not enable fast wake in the GPIO while simultaneously blocking asynchronous fast clock requests in SYSCTL. When fast wake is enabled, the GPIO expects to handshake with SYSCTL for the fast clock. If SYSCTL ignores the request, the GPIO does not receive a clock until SYSCTL completes the asynchronous fast clock request handshake.

### 9.2.5 GPIO DMA Interface

The GPIO peripheral allows the DMA write-access to the DOUT31\_0 register. This functionality allows users to generate predefined output sequences on specified device pins. Some applications require preloaded sequences of GPIO pin changes and the MSP platform allows for the DMA to run that sequence so that the CPU can remain asleep and conserve energy.

The DMAMASK register is used to indicate which GPIO bits the DMA is allowed to modify. Setting a bit in the DMAMASK register enables the corresponding DOUT bit to be modified by the DMA.

---

#### Note

The CPU can write to any DOUT31\_0 bit regardless of the DMAMASK value.

---

In cases where the DMA and the CPU both attempt to access and modify the DOUT31\_0 register concurrently, it is the user's responsibility to manage the DMA and CPU bus transactions that are targeting the same bit to be modified.

- If a DMAMASK bit is set, the DMA will be prioritized to modify the corresponding DOUT bit.
- If a DMAMASK bit is cleared, the CPU will be prioritized to modify the corresponding DOUT bit.

### 9.2.6 Event Publishers and Subscribers

There are three independent event publishers available for GPIOx peripherals:

1. First Event Publisher (CPU\_INT)
  - Used for generating CPU interrupt
  - Interrupt (RIS) flags are cleared upon software reading the IIDX register or writing to the respective ICLR register bits.
  - An event to the CPU can be individually specified for each GPIO bit through the POLARITY register:
    - 0: Disabled
    - 1: Rise Event
    - 2: Fall Event
    - 3: Rise or Fall Event
2. Second Event Publisher (GEN\_EVENT0)
  - Uses the same POLARITY register definition as CPU\_INT
  - Applies to GPIO bits 15 down to 0 (DIO15:0)
3. Third Event Publisher (GEN\_EVENT1),
  - Uses the same POLARITY register definition as CPU\_INT
  - Applies to GPIO bits 31 down to 16 (DIO31:16)

There are **two event subscribers**

1. First Event Subscriber (FSUB\_0)
  - A specific pin can be directed to change state on an event
  - A subscriber event can only cause one single bit to have an action
  - Applies to GPIO bits 15 down to 0 (DIO15:0)
  - SUB0CFG register is used to enable the FSUB\_0 event and define the output policy for a specific GPIO pin
2. Second Event Subscriber (FSUB\_1)
  - A specific pin can be directed to change state on an event
  - A subscriber event can only cause one single bit to have an action
  - Applies to GPIO bits 31 down to 16 (DIO31:16)
  - SUB1CFG register is used to enable the FSUB\_1 event and define the output policy for a specific GPIO pin

### 9.3 GPIO Registers

Table 9-2 lists the memory-mapped registers for the GPIO registers. All register offset addresses not listed in Table 9-2 should be considered as reserved locations and the register contents should not be modified.

**Table 9-2. GPIO Registers**

Offset	Acronym	Register Name	Group	Section

## 10 IIDX (Offset = 1020h) [Reset = 0000000h]

IIDX is shown in [Figure 9-13](#) and described in [Table 9-13](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 9-13. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 12 RIS (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 9-15](#) and described in [Table 9-15](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Figure 9-15. RIS**

#### 14 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 9-17](#) and described in [Table 9-17](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**16 IIDX (Offset = 1050h) [Reset = 0000000h]**

IIDX is shown in [Figure 9-19](#) and described in [Table 9-19](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 9-19. IIDX**

## 17 IMASK (Offset = 1058h) [Reset = 0000000h]

IMASK is shown in [Figure 9-20](#) and described in [Table 9-20](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is unmasked. Unmasking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

### 18 RIS (Offset = 1060h) [Reset = 0000000h]

RIS is shown in [Figure 9-21](#) and described in [Table 9-21](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**22 IIDX (Offset = 1080h) [Reset = 00000000h]**

IIDX is shown in [Figure 9-25](#) and described in [Table 9-25](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 9-25. IIDX**

31-1	RESERVED	R/W	0h	
0	FASTWAKEONLY	R/W	0h	FASTWAKEONLY for the global control of fastwake 0h = The global control of fastwake is not enabled, per bit fast wake feature depends on FASTWAKE.DIN 1h = The global control of fastwake is enabled

### 57 FASTWAKE (Offset = 1404h) [Reset = 0000000h]

FASTWAKE is shown in [Figure 9-60](#) and described in [Table 9-60](#).

Return to the [Summary Table](#).

This is per bit fast wake enable for the bit slice, allows the GPIO module to stay in a low power state and not require high speed clocking of the input synchronizer or filter

7-1	RESERVED	R/W	0h	
0	ENABLE	R/W	0h	This bit is used to enable subscriber 1 event. 0h = Subscriber 1 event is disabled 1h = Subscriber 1 event is enabled

The Math accelerator (MATHACL) is a collection of hardware-accelerated 32-bit math functions to improve system computational throughput. Software running on the CPU invokes MATHACL by writing to the MATHACL registers.

### 10.1 Overview

The MATHACL offloads mathematical calculations performed by the CPU to improve efficiency. The following hardware functions are available in the MATHACL:

- Sine/cosine (SINCOS)
- Arc tangent (ATAN2)
- Square root (SQRT)
- Divide (DIV)
- Multiply with 32-bit result (MPY32)
- Square with 32-bit result (SQUARE32)
- Multiply with 64-bit result (MPY64)
- Square with 64-bit results (SQUARE64)
- Multiply-accumulate (MAC)
- Square-accumulate (SAC)

### 10.2 Data Format

The operands that are used in MATHACL functions are 32-bit fixed point numbers. Operands can be expressed as unsigned 32-bit integers, signed 32-bit integers, unsigned 32-bit numbers, and signed 32-bit numbers.

[Table 10-1](#) summarizes the data formats that are used in the MATHACL.

**Table 10-1. MATHACL data formats**

Data format	Data type	Signed format	Data range
Unsigned 32-bit integers	Uint32_t	2's compliment	0 to $2^{32} - 1$
Signed 32-bit integers	int32_t	2's compliment	$-2^{31}$ to $2^{31} - 1$
Unsigned 32-bit numbers	UQm.n	Signed magnitude	0 to $(2^{32})/2^n$
Signed 32-bit numbers	SQm.n	Signed magnitude	$(-2^{31})/2^n$ to $(2^{31})/2^n$

#### 10.2.1 Unsigned 32-bit integers

An unsigned 32-bit integer is a 32-bit positive number ranging from 0 to  $2^{32}-1$ , and it is expressed as type uint32\_t.

For instance, the number 123456 is equal to 0b 00000000 00000001 11100010 01000000, or 0x0001E240.

### 10.2.2 Signed 32-bit integers

A signed 32-bit integer is a 32-bit positive or negative number ranging from  $-2^{31}$  to  $2^{31} - 1$ , and it is expressed as type `int32_t`. To convert a signed 32-bit integer from decimal:

- Convert the integer to an unsigned 32-bit integer
- Invert the number
- Add 1 to the least significant bit (LSB)

For instance, the number -123456 is equal to `0b 11111111 11111110 00011101 11000000`, or `0xFFFE1DC0`.

### 10.2.3 Unsigned 32-bit numbers

Unsigned 32-bit numbers include an integer component and fractional component using Q number format. It is expressed as `UQm.n`, where:

- **m** is the integer component number of bits
- **n** is the fractional component number of bits

The **m** and **n** components vary depending on the operand type. For instance, an operand in `UQ16.16` format has the signed number components as shown in [Table 10-2](#)

**Table 10-2. Unsigned number components**

Description	Value	Number of Bits	Bits
Integer component	I	m = 16	31:16
Fractional component	F	n = 16	15:0

To generate an unsigned number, such as 4.75 in `UQ16.16`:

1. Express the integer component ( $I = 4$ ) as a number in **m** bits (`0x0004`)
2. Express the fractional component ( $F = 0.75$ ) as a number in **n** bits (`0xC000`)
3. Express the resulting hexadecimal value as an unsigned value (`0x0100C000`)

### 10.2.4 Signed 32-bit numbers

Signed 32-bit numbers include a signed magnitude component, integer component and fractional component using Q number format. It is expressed as `SQm.n`, where:

- **S** is the Sign Bit
- **m** is the integer component number of bits
- **n** is the fractional component number of bits

The **m** and **n** components vary depending on the operand type. For instance, an operand in `SQ15.16` format has the signed number components as shown in [Table 10-3](#).

**Table 10-3. Signed number components**

Description	Value	Number of Bits	Bits
Sign bit	+ or -	S = 1	31
Integer component	I	m = 15	30:16
Fractional component	F	n = 16	15:0

To generate a signed number, such as -1.5 in `SQ15.16`:

1. Express the integer component ( $I = 1$ ) as a number in **m** bits (`0x0001`)

2. Express the fractional component ( $F = 0.5$ ) as a number in  $n$  bits (0x8000)
3. Express the resulting hexadecimal value as an unsigned value (0x00018000)
4. If the number is signed, take the 2's compliment (0xFFFE7FFF)

### 10.3 Basic Operation

#### Power Enable

To power on the MATHACL, write the KEY to the PWREN register and set the ENABLE bit to power on the MATHACL. To reset the MATHACL, write the KEY to the RSTCTL register, set the RESETSTKYCLR bit, and set the RESETASSERT bit.

#### MATHACL Operation

All MATHACL operations follow a similar code sequence to call the functions, begin the compute operations, and read the results:

1. Write to the FUNC, QVAL, OPTYPE, SFACTOR, and NUMITER fields in the CTL register using a single write operation. See [Section 10.4](#) for which fields are required by the function being called.
2. Trigger the function to start computing based on the number of operands required in the operation.
  - a. In case of two operand functions, write to OP2 first, then write to OP1 to trigger the function to start computing.
  - b. In case of single operand functions, write to OP1 to trigger the function to start computing.
3. To read the computed results, read the RES1 and RES2 registers to check when the new data has been returned. Optionally, the STATUS.BUSY flag can be polled until it is 0 to indicate the computation is complete.

---

#### Note

The MATHACL control registers should not be changed while the current operation is ongoing, or else the operation will result in undefined behavior.

---

#### MATHACL Timing

Timing for each MATHACL calculation depends on the number of fractional bits ( $n$ ), number of iterations (NUMITER) in SINCOS, ATAN2, and SQRT functions, or software overhead. See each function example in [Section 10.4](#) for the number of hardware cycles (if available).

### 10.4 Configuration Details with Examples

#### 10.4.1 Sine and Cosine (SINCOS)

Sine and Cosine (SINCOS) functions are computed using the CORDIC algorithm. The algorithm relies on expressing the angle as a sum of angles in per unit format with a configurable number of iterations to incrementally calculate the result. The sine and cosine of the given angle is computed simultaneously for the number of iterations specified in CTL.NUMITER field and stored in the RES1 and RES2 registers.

[Table 10-4](#) shows the configuration registers for SINCOS.

**Table 10-4. Sine/Cosine Configuration registers**

Register (Bit Field)	Value	Description
OP1	User value	Angle in degrees per unit (SQ0.31 format). The angle in per unit is calculated by $n = \text{angle}/180$ , where $n$ is the angle in per unit between $[-1,1)$ and angle is between $[-180,180)$ degrees.

**Table 10-4. Sine/Cosine Configuration registers (continued)**

Register (Bit Field)	Value	Description
CTL.FUNC	1h	SINCOS
CTL.NUMITER	User value	Number of iterations
RES1	32-bit result	Cosine of the angle (SQ0.31 format)
RES2	32-bit result	Sine of the angle (SQ0.31 format)

A higher number of iterations (NUMITER) calculates more accurate results but will take longer to compute.

### Status, Errors, and Overflow

There are no status, error, or overflow bits for SINCOS.

### Configuration

To perform SINCOS:

1. In the CTL register:
  - a. Set FUNC to 1h.
  - b. Set NUMITER to the number of iterations for the calculation.
2. Set the angle per unit (SQ0.31 format) in OP1 to begin the computation.
3. Read the cosine of the angle in RES1 (SQ0.31 format).
4. Read the sine of the angle in RES2 (SQ0.31 format).

### 10.4.2 Arc Tangent (ATAN2)

The arctangent function (ATAN2) computes the arctangent of  $(y/x)$ , where  $y$  and  $x$  are the normalized coordinates. The ATAN2 algorithm relies on expressing the resulting angle as a sum of constituent angles computed by incrementally accumulating the constituent angles until the  $y$ -coordinate value is 0. The number of iterations to calculate the arctangent is specified using the CTL.NUMITER field, and the final result for the angle in per unit is stored in RES1 as a signed number.

Before performing the ATAN2 function, the  $x$ - and  $y$ - coordinates should be normalized to a unit vector, which can be done with various types of normalization algorithms. One normalization algorithm is shown in [Figure 10-1](#).

Figure 10-1. Normalization algorithm for ATAN2 inputs

Table 10-5 shows the configuration registers for the ATAN2 function.

Table 10-5. ATAN2 configuration registers

Register (Bit Field)	Value	Description
OP1	User value	X coordinate (SQ0.31 format)
OP2	User value	Y coordinate (SQ0.31 format)
CTL.FUNC	2h	ATAN2
CTL.NUMITER	User value	Number of iterations

**Table 10-5. ATAN2 configuration registers (continued)**

Register (Bit Field)	Value	Description
RES1	32-bit value	Angle in degrees per unit (SQ0.31 format) . The angle in per unit is calculated by $n = \text{angle}/180$ , where n is the angle in per unit between [-1,1) and angle is between [-180,180) degrees.

A higher number of iterations (NUMITER) calculates more accurate results but will take longer to compute.

### Status, Errors, and Overflow

There are no status, error, or overflow bits for ATAN2.

### Configuration

To perform ATAN2:

1. In the CTL register:
  - a. Set FUNC to 2h.
  - b. Set NUMITER to the number of iterations for the calculation.
2. Set the normalized y-coordinate (SQ0.31 format) in OP2.
3. Set the normalized x-coordinate (SQ0.31 format) in OP1 to begin the computation.
4. Read the normalized arctangent result in RES1 (SQ0.31 format).

### 10.4.3 Square Root (SQRT)

The square root function (SQRT) computes the square root of a number (radicand). The square root is computed incrementally by the number of iterations in the CTL.NUMITER field. A higher number of iterations calculates more accurate results but takes longer to compute.

The radicand must be in UQm.n data type, and it is broken down into two components: an unscaled number (UN) and a scaled number (SN). The unscaled number is the floor of the number, and the scaled number is between 1.0 and 2.0 in UQ2.30 format. The relationship between the scaled number (SN) and unscaled number (UN) is the scale factor (SFACTOR), which is shown in [Equation 11](#).

$$\text{Scaled number (SN)} = \frac{\text{Unscaled number (UN)}}{2^{\text{SFACTOR}}} \quad (11)$$

To calculate the SN and SFACTOR from a radicand in UQm.n format, the algorithm below can be used.

```
//Compute scale factor and scaled number from radicand
UN = floor(radicand);           //unsigned number
SFACTOR = 0;                    //scale factor
count = 2;                      //scaled number must be between 1 and 2
do {
    SFACTOR++;                  //increase SFACTOR
    count <<= 1;                //multiply by 2
} while (count < UN)           //repeat until UN is less than count
SN = radicand / (count >> 1); //scale number = radicand / 2^SN
```

For example, if the 10.375 is the radicand, the unscaled number is 10, SFACTOR = 3 ( $10.375 / 2^3 = 1.297$ ), and 1.297 is the scaled number between 1.0 and 2.0.

[Table 10-6](#) shows the configuration registers for the SQRT function.

**Table 10-6. SQRT configuration registers**

Register (Bit Field)	Value	Description
OP1	User value	Scaled number (SN) in UQ2.30 format. The scaled number is scaled from the unscaled number, and the scaled number has to be between 1.0 and 2.0.
CTL.FUNC	5h	SQRT
CTL.SFACTOR	User value	Scaling factor n. The scaled number (SN) = (Unscaled number)/2 <sup>n</sup> . This is a signed integer and takes a positive value or negative value in two's complement.
CTL.NUMITER	User value	Number of iterations
RES1	32-bit result	Square root of unscaled number in UQ16.16 format.

A higher number of iterations (NUMITER) calculates more accurate results but takes longer to compute.

### Status, Errors, and Overflow

There are no status, error, or overflow bits for SQRT.

### Configuration

To perform a SQRT:

- In the CTL register:
  - Set FUNC to 5h.
  - Set NUMITER to the number of iterations for the calculation.
  - Set SFACTOR to the scaling factor n.
- Set the scaled number (UQ2.30 format) in OP1 to begin the computation.
- Read the square root result in RES1 (UQ16.16 format).

#### 10.4.4 Division (DIV)

The divide function (DIV) computes with a known dividend and divisor.

$$\text{Dividend} = \text{Divisor} * \text{Quotient} + \text{Remainder} \quad (12)$$

$$\text{mod}(\text{Remainder}) < \text{mod}(\text{Divisor}) \quad (13)$$

Table 10-7 shows the data types that the DIV function can perform.

**Table 10-7. DIV Data Types Supported**

Data Type (Dividend and Divisor)	Data Type (Quotient)	Data Type (Remainder)
Uint32_t	Uint32_t	Uint32_t
Int32_t	Int32_t	Int32_t
SQm.n	SQm.n	N/A
UQm.n	UQm.n	N/A

Table 10-8 shows the configuration registers for the DIV function.

**Table 10-8. DIV Configuration Registers**

Register (Bit Field)	Value	Description
OP1	User value	Dividend
OP2	User value	Divisor
CTL.FUNC	4h	DIV

**Table 10-8. DIV Configuration Registers (continued)**

Register (Bit Field)	Value	Description
CTL.QVAL	User value	Number of fractional bits (unsigned or signed number data type only)
CTL.OPTYPE	0 = unsigned operands 1 = signed operands	Operand sign
RES1	32-bit result	Quotient (same data type as dividend and divisor)
RES2	32-bit result	Remainder (same data type as dividend and divisor)

**Note**

OP1 and OP2 must be the same data type or use incorrect results will occur.

Signed integer (int32\_t) calculations requires 4 cycles to compute results in RES1 and RES2 from an OP2 write. Examples of DIV for int32\_t are in [Table 10-9](#).

**Table 10-9. Division Examples for int32\_t Data Type**

Dividend	Divisor	Quotient	Remainder
15 (0x0000000F)	2 (0x00000002)	7 (0x00000007)	1 (0x00000001)
-15 (0xFFFFFFFF1)	2 (0x00000002)	-7 (0xFFFFFFFF9)	-1 (0xFFFFFFFF)
15 (0x0000000F)	-2 (0xFFFFFFFFE)	-7 (0xFFFFFFFF9)	1 (0x00000001)
-15 (0xFFFFFFFF1)	-2 (0xFFFFFFFFE)	7 (0x00000007)	-1 (0xFFFFFFFF)

Signed number (SQm.n) calculations requires n cycles to compute results in RES1 and RES2 from an OP2 write, where n is the number of fractional bits. Examples of DIV for SQ15.16 are in [Table 10-10](#).

**Table 10-10. Division Examples for SQ15.16 Data Type**

Dividend	Divisor	Quotient	Remainder
7.5 (0x00078000)	4.5 (0x00048000)	1.666657 (0x0001AAAA)	N/A
-7.5 (0xFFFF88000)	4.5 (0x00048000)	-1.666657 (0xFFFE5556)	N/A
7.5 (0x00078000)	-4.5 (0xFFFFB8000)	-1.666657 (0xFFFE5556)	N/A
-7.5 (0xFFFF88000)	-4.5 (0xFFFFB8000)	1.666657 (0x0001AAAA)	N/A

**Status, Errors, and Overflow**

If the divisor is 0, then the STATUS.ERR flag is set.

If the result of the operation is more than 32 bits, STATUS.OVF is set to indicate that an overflow has occurred. It will remain set until cleared by writing a 1 to CLR.CLR\_OVF.

For signed operation, if result saturation is enabled (CTL.SATEN = 1) in the case of an overflow, the result will be saturated to the maximum positive result (0x7FFFFFFF) and the minimum negative result (0x80000000).

For unsigned operation, if result saturation is enabled (CTL.SATEN = 1) in the case of an overflow, the result will be saturated to the maximum positive result (0xFFFFFFFF).

**Configuration**

To perform a DIV:

1. In the CTL register:
  - a. Set FUNC to 4h.
  - b. Set OPTYPE to 0 if the data type is unsigned, or 1 if the data type is signed.

- c. Set QVAL to the number of fractional bits (n) for a signed (SQm.n) or unsigned number (UQm.n)
2. Set the divisor in OP2.
3. Set the dividend in OP1 to begin the computation.
4. Read the quotient result in RES1 and remainder result in RES2.

### 10.4.5 Multiplication

Multiplication functions gives the result of multiplying two numbers. There are variations of the multiply function, including multiplying and squaring with 32-bit and 64-bit results.

#### 10.4.5.1 Multiply32 (MPY32)

The Multiply32 (MPY32) function returns the results of multiplying two 32-bit numbers with the 32-bit result in RES1.

The MPY32 function can perform the data types shown in [Table 10-11](#).

**Table 10-11. MPY32 Data Types Supported**

Data type (Multiplicand and Multiplier)	Data type (Product)	Condition
Uint32_t	Uint32_t	Product is $< 2^{32} - 1$
Int32_t	Int32_t	Product is $> -2^{31}$ and $< 2^{31} - 1$
SQm.n	SQm.n	Product is not outside the range representable in the chosen data format
UQm.n	UQm.n	

[Table 10-12](#) shows the operands and descriptions for the MPY32 function.

**Table 10-12. MPY32 Configuration Registers**

Register (Bit Field)	Value	Description
OP1	User value	Multiplicand
OP2	User value	Multiplier
CTL.FUNC	6h	MPY32
CTL.QVAL	User value	Number of fractional bits (unsigned or signed number data type only)
CTL.OPTYPE	0h = unsigned operands 1h = signed operands	Operand sign
RES1	32-bit product	Product

#### Note

OP1 and OP2 must be the same data type or use incorrect results will occur.

Signed integer (int32\_t) calculations requires 1 cycles to compute results in RES1 from an OP2 write. Examples of MPY32 for int32\_t are in [Table 10-13](#).

**Table 10-13. MPY32 Examples Using Signed Integers (int32\_t)**

Multiplicand	Multiplier	Product
15 (0x0000000F)	2 (0x00000002)	30 (0x0000001E)
-15 (0xFFFFFFFF1)	2 (0x00000002)	-30 (0xFFFFFFFFE2)
15 (0x0000000F)	-2 (0xFFFFFFFFFE)	-30 (0xFFFFFFFFE2)
-15 (0xFFFFFFFF1)	-2 (0xFFFFFFFFFE)	30 (0x0000001E)

Signed number (SQm.n) calculations requires n cycles to compute results in RES1 from an OP2 write, where n is the number of fractional bits. Examples of MPY32 for SQ15.16 are in [Table 10-14](#).

**Table 10-14. MPY32 Examples Using SQ15.16 Signed Numbers**

Multiplicand	Multiplier	Product
1.5 (0x00018000)	2.5 (0x00028000)	3.75 (0x0003C000)
-1.5 (0xFFFE8000)	2.5 (0x00028000)	-3.75 (0xFFFC000)
1.5 (0x00018000)	-2.5 (0xFFFD8000)	-3.75 (0xFFFC000)
-1.5 (0xFFFE8000)	-2.5 (0xFFFD8000)	3.75 (0x0003C000)

### Status, Errors, and Overflow

If the result of the operation is more than 32 bits, STAT.OVF is set to indicate that an overflow has occurred. It will remain set until cleared by writing setting CLR\_OVF = 1 in the CLR register.

For signed operation, if result saturation is enabled (CTL.SATEN = 1), in the case of an overflow, the STAT.OVF bit is set and the result saturates to the maximum positive result (0x7FFFFFFF).

For unsigned operation, if result saturation is enabled (CTL.SATEN = 1) in the case of an overflow, the result will be saturated to the maximum positive result (0xFFFFFFFF).

### Configuration

To perform an MPY32:

- In the CTL register:
  - Set FUNC to 6h.
  - Set OPTYPE to 0 if the data type is unsigned, or 1 if the data type is signed.
  - Set QVAL to the number of fractional bits (n) for a signed (SQm.n) or unsigned number (UQm.n)
- Set the multiplicand in OP2.
- Set the multiplier in OP1 to begin the computation.
- Read the product result in RES1.

#### 10.4.5.2 Square32 (SQUARE32)

The Square32 (SQUARE32) function is a variation of the MPY32 function and performs a square operation on operand OP2 with the 32-bit result in RES1.

The SQUARE32 function can perform the data types shown in [Table 10-15](#).

**Table 10-15. SQUARE32 Data Types Supported**

Data type (Base)	Data type (Result)	Condition
Uint32_t	Uint32_t	Result is $< 2^{32} - 1$
Int32_t	Int32_t	Result is $> -2^{31}$ and $< 2^{31} - 1$
SQm.n	SQm.n	Result is not outside the range representable in the chosen data format
UQm.n	UQm.n	

[Table 10-12](#) shows the operands and descriptions for the SQUARE32 function.

**Table 10-16. SQUARE32 Configuration Registers**

Register (Bit Field)	Value	Description
OP1	User value	Base
CTL.FUNC	7h	MPY32
CTL.QVAL	User value	Number of fractional bits (unsigned or signed number data type only)
CTL.OPTYPE	0h = unsigned operands 1h = signed operands	Operand sign

**Table 10-16. SQUARE32 Configuration Registers (continued)**

Register (Bit Field)	Value	Description
RES1	32-bit square result	Square result

Signed integer (int32\_t) calculations requires 1 cycle to compute results in RES1 from an OP2 write. Examples of SQUARE32 for int32\_t data type are in [Table 10-17](#).

**Table 10-17. SQUARE32 Examples Using int32\_t**

Multiplicand/Multiplier	Square
4 (0x00000004)	16 (0x00000010)
-4 (0xFFFFFFF4)	16 (0x00000010)

Signed number (SQm.n) calculations requires n cycles to compute results in RES1 from an OP2 write, where n is the number of fractional bits. Examples of division for SQ15.16 are in [Table 10-18](#).

**Table 10-18. SQUARE32 Examples Using SQ15.16 Signed Numbers**

Multiplicand/Multiplier	Square
1.5 (0x00018000)	2.25 (0x00024000)
-1.5 (0xFFFFE8000)	2.25 (0x00024000)

### Status, Errors, and Overflow

If the result of the operation is more than 32 bits, STAT.OVF is set to indicate that an overflow has occurred. It will remain set until cleared by writing setting CLR\_OVF = 1 in the CLR register.

For signed operation, if result saturation is enabled (CTL.SATEN = 1), in the case of an overflow, the STAT.OVF bit is set and the result saturates to the maximum positive result (0x7FFFFFFF).

For unsigned operation, if result saturation is enabled (CTL.SATEN = 1) in the case of an overflow, the result will be saturated to the maximum positive result (0xFFFFFFFF).

### Configuration

To perform a SQUARE32:

- In the CTL register:
  - Set FUNC to 6h.
  - Set OPTYPE to 0 if the data type is unsigned, or 1 if the data type is signed.
  - Set QVAL to the number of fractional bits (n) for a signed (SQm.n) or unsigned number (UQm.n)
- Set the base in OP1 to begin the computation.
- Read the product result in RES1.

#### 10.4.5.3 Multiply64 (MPY64)

The Multiply64 function (MPY64) returns the results of multiplying two 32-bit numbers with the 64-bit result in RES1 and RES2.

The MPY64 function can perform the types of multiply shown in [Table 10-11](#).

**Table 10-19. MPY64 Data Types Supported**

Data type (Multiplicand and Multiplier)	Data type (Product)	Condition
Uint32_t	Uint64_t	Product is $< 2^{64} - 1$
Int32_t	Int64_t	Product is $> -2^{63}$ and $< 2^{63} - 1$

[Table 10-12](#) shows the operands and descriptions for the multiply function.

**Table 10-20. MPY64 Configuration Registers**

Register (Bit Field)	Value	Description
OP1	User value	Multiplicand
OP2	User value	Multiplier
CTL.FUNC	8h	MPY64
CTL.OPTYPE	0h = unsigned operands 1h = signed operands	Operand sign
RES1	Lower 32 bits of product	Product (64-bit)
RES2	Upper 32 bits of product	

**Note**

OP1 and OP2 must be the same data type or use incorrect results will occur.

**Status, Errors, and Overflow**

There are no status, error, or overflow bits for MPY64.

**Configuration**

To perform an MPY64:

- In the CTL register:
  - Set FUNC to 8h.
  - Set OPTYPE to 0 if the data type is unsigned, or 1 if the data type is signed.
- Set the multiplicand in OP2.
- Set the multiplier in OP1 to begin the computation.
- Read the product result in RES1 and RES2.

**10.4.5.4 Square64 (SQUARE64)**

The Square64 function (SQUARE64) is a variation of the MPY32 function and performs a square operation on operand OP2 with the 64-bit result in RES1 and RES2.

The SQUARE64 function can perform the types of multiply shown in [Table 10-11](#).

**Table 10-21. SQUARE64 data types supported**

Data type (Base)	Data type (Square Result)	Condition
Uint32_t	Uint64_t	Result is $< 2^{64} - 1$
Int32_t	Int64_t	Result is $> -2^{63}$ and $< 2^{63} - 1$

[Table 10-12](#) shows the operands and descriptions for the SQUARE64 function.

**Table 10-22. SQUARE64 configuration registers**

Register (Bit Field)	Value	Description
OP1	User value	Base
CTL.FUNC	9h	MPY64
CTL.OPTYPE	0h = unsigned operands 1h = signed operands	Operand sign
RES1	Lower 32 bits of product	Product (64-bit)
RES2	Upper 32 bits of product	

### Status, Errors, and Overflow

There are no status, error, or overflow bits for SQUARE64.

### Configuration

To perform an SQUARE64:

1. In the CTL register:
  - a. Set FUNC to 8h.
  - b. Set OPTYPE to 0 if the data type is unsigned, or 1 if the data type is signed.
2. Set the base in OP1 to begin the computation.
3. Read the product result in RES1 and RES2.

#### 10.4.6 Multiply-Accumulate (MAC)

Multiply-accumulate (MAC) functions accumulate the results of the product of OP1 and OP2 inside result registers RES1 and RES2 over multiple iterations until the MATHACL is reprogrammed for another function. The MATHACL supports only a 32-bit multiplier and multiplicand operand size, and a 64-bit accumulated result size.

[Figure 10-2](#) shows the operation of the MATHACL in MAC mode.

**Figure 10-2. MAC Operation**

Internal MAC operation performs the following steps:

- OP1 and OP2 are multiplied together, and the result is a 64-bit product
  - If using SQm.n or UQm.n data type, the product has the same number of fractional bits (n) as the operands
- The product result is stored into a Register Stage for correct timing
- The registered value is fed into a 64-bit Adder with the current Result Register value as the other input (Result Register += Register Stage)
- The result of the add operation is stored into RES1 and RES2

**Note**

Write 0 into RES1 and RES2 before starting a MAC operation to get the correct result.

The MAC function can perform the following data types of multiply-accumulate shown in [Table 10-23](#).

**Table 10-23. MAC Data Types Supported**

Data Type (Multiplicand and Multiplier)	Data Type (Product)	Condition
Uint32_t	Uint64_t	MAC result is $< 2^{64} - 1$
Int32_t	Int64_t	MAC result is $> -2^{63}$ and $< 2^{63} - 1$
SQm.n	SQ(32+m).n	MAC result is not outside the range representable in the chosen data format
UQm.n	UQ(32+m).n	

Table 10-24 shows the configuration registers for the MAC function.

**Table 10-24. MAC Configuration Registers**

Register (Bit Field)	Value	Description
OP1	User value	Multiplicand
OP2	User value	Multiplier
CTL.FUNC	Ah	MAC
CTL.QVAL	User value	Number of fractional bits (unsigned or signed number data type only)
CTL.OPTYPE	0 = unsigned operands 1 = signed operands	Operand sign
RES1	Lower 32 bits of result	Multiply-accumulate result (64-bit)
RES2	Upper 32 bits of result	

---

**Note**

OP1 and OP2 must be the same data type or use incorrect results will occur.

---

The final result of the MAC operation can be read after 2 cycles after writing OP2.

### Status, Errors, and Overflow

If the result of the operation is more than 64 bits, STAT.OVF is set to indicate that an overflow has occurred. It will remain set until cleared by writing a 1 to CLR.CLR\_OVF.

For signed operation, if result saturation is enabled (CTL.SATEN = 1) in the case of an overflow, the result will be saturated to the maximum positive result (0x7FFF\_FFFF\_FFFF\_FFFF) and the minimum negative result (0x8000\_0000\_0000\_0000).

For unsigned operation, if result saturation is enabled (CTL.SATEN = 1) in the case of an overflow, the result will be saturated to the maximum positive result (0xFFFF\_FFFF\_FFFF\_FFFF).

### Configuration

To configure the MAC for operation:

1. In the CTL register:
  - a. Set FUNC to Ah.
  - b. Set OPTYPE to 0 if the data type is unsigned, or 1 if the data type is signed.
  - c. Set QVAL to the number of fractional bits (n) for a signed (SQm.n) or unsigned number (UQm.n)
2. Clear the result registers by setting RES1 and RES2 to 0.
3. Set the multiplicand in OP2.
4. Set the multiplier in OP1 to begin the computation.
5. Repeat step 3-4 to continue multiplying and accumulating data in RES1 and RES2.
6. Read the 64-bit product result in RES1 and RES2.

### 10.4.7 Square Accumulate (SAC)

Square-accumulate (SAC) functions accumulates the results of the square of operand OP2 inside result registers RES1 and RES2 over multiple iterations until the MATHACL is reprogrammed for another function. It is a variation of the MAC function and operation details remain the same.

#### Note

Write 0 into RES1 and RES2 before starting a SAC operation to get the correct result.

The SAC function can perform the following data types of square-accumulate shown in [Table 10-25](#).

**Table 10-25. SAC Data Types Supported**

Data Type (Base)	Data Type (Result)	Condition
UInt32_t	UInt64_t	SAC result should be $< 2^{64} - 1$
Int32_t	Int64_t	SAC result should be $> -2^{63}$ and $< 2^{63} - 1$
SQm.n	SQ(32+m).n	SAC result should not be outside the range representable in the chosen data format
UQm.n	UQ(32+m).n	

[Table 10-26](#) shows the configuration registers for the SAC function.

**Table 10-26. SAC configuration registers**

Register (Bit Field)	Value	Description
OP1	User value	Base
CTL.FUNC	Bh	SAC
CTL.QVAL	User value	Number of fractional bits (unsigned or signed number data type only)
CTL.OPTYPE	0 = unsigned operands 1 = signed operands	Operand sign
RES1	Lower 32 bits of result	Square-accumulate result (64-bit)
RES2	Upper 32 bits of result	

The final result of the SAC operation can be read after 2 cycles after writing OP2.

#### Status, Errors, and Overflow

If the result of the operation is more than 64 bits, STAT.OVF is set to indicate that an overflow has occurred. It will remain set until cleared by writing a 1 to CLR.CLR\_OVF.

For signed operation, if result saturation is enabled (CTL.SATEN = 1) in the case of an overflow, the result will be saturated to the maximum positive result (0x7FFF\_FFFF\_FFFF\_FFFF) and the minimum negative result (0x8000\_0000\_0000\_0000).

For unsigned operation, if result saturation is enabled (CTL.SATEN = 1) in the case of an overflow, the result will be saturated to the maximum positive result (0xFFFF\_FFFF\_FFFF\_FFFF).

#### Configuration

To configure the SAC for operation:

1. In the CTL register:
  - a. Set FUNC to Bh.
  - b. Set OPTYPE to 0 if the data type is unsigned, or 1 if the data type is signed.
  - c. Set QVAL to the number of fractional bits (n) for a signed (SQm.n) or unsigned number (UQm.n)
2. Clear the result registers by setting RES1 and RES2 to 0.
3. Set the base in OP1 to begin the computation.
4. Repeat step 3 to continue squaring and accumulating data in RES1 and RES2.
5. Read the 64-bit square result in RES1 and RES2.

## 10.5 MATHACL Registers

Table 10-27 lists the memory-mapped registers for the MATHACL registers. All register offset addresses not listed in Table 10-27 should be considered as reserved locations and the register contents should not be modified.

**Table 10-27. MATHACL Registers**

Offset	Acronym	Register Name	Group	Section
800h	PWREN	Power Enable		<a href="#">Go</a>
804h	RSTCTL	Reset Control		<a href="#">Go</a>
814h	STAT	Status Register		<a href="#">Go</a>
1100h	CTL	Control Register		<a href="#">Go</a>
1118h	OP2	Operand 2 register.		<a href="#">Go</a>
111Ch	OP1	Operand 1 Register		<a href="#">Go</a>
1120h	RES1	Result 1 Register		<a href="#">Go</a>
1124h	RES2	Result 2 Register		<a href="#">Go</a>
1130h	STATUS	Status Register		<a href="#">Go</a>
1140h	STATUSCLR	Status Flag Clear Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 10-28 shows the codes that are used for access types in this section.

**Table 10-28. MATHACL Access Type Codes**

Access Type	Code	Description
<b>Read Type</b>		
R	R	Read
RH	R H	Read Set or cleared by hardware
<b>Write Type</b>		
W	W	Write
WK	W K	Write Write protected by a key
<b>Reset or Default Value</b>		
-n		Value after reset or the default value

## 11.1 Overview

The TinyEngine™ Neural-network Processing Unit (NPU) module is a neural-network processing unit capable of supporting Artificial Intelligence (AI) and Machine Learning (ML) applications.

This NPU is a highly optimized core for deep convolutional neural networks (CNNs), supporting machine learning inference using pre-trained models. The NPU works in conjunction with the on-chip CPU to provide higher performance and lower power consumption for CNNs inference. With the capable of 640–2560MOPS (Mega Operations Per Second), the NPU provides up to two orders of magnitude improvement compared to a purely software-based implementation.

NPU features include:

- Up to 16 MACs/cycle (Multiply-Accumulate Operations Per Cycle) for 4-bit x 4-bit or 8-bit x 2-bit operation, equals to 2560 MOPS
- Batch normalization datapath supporting scaling and shifting operation
- Input data supports signed/unsigned data types and 8-bit/4-bit data length
- Weights support signed data with 8-bit/4-bit/2-bit data length
- Programmable engine with dedicated program and data memory (RAM)
- Read/write from system memory (RAM)
- Interrupt support on certain instruction
- Support 1D, 2D and Transposed Convolution layer
- Support Depthwise and Pointwise Convolution
- Support different strides, padding and kernel dimensions
- Support Average / Max Pooling model
- Support Residual Network
- Support mixed precision models – different layers can be implemented with different input and weight precision

## 11.2 NPU Operation

Figure 11-1 shows the top-level view of the modules within the chip.

Figure 11-1. MSP CPU/NPU System Structure

MSPM0 with NPU system shared the on-chip memory including non-volatile FLASH memory and volatile RAM memory. The system RAM supports read/write with CPU or NPU. Additionally, NPU has a dedicated RAM for CNNs inference. The Edge AI model need fit within available FLASH memory range, and the peak RAM requirements need fit within available system RAM.

The overall task of CNNs inference is split between the MCU and the NPU. Table 11-1 shows each component's main task during CNNs inference:

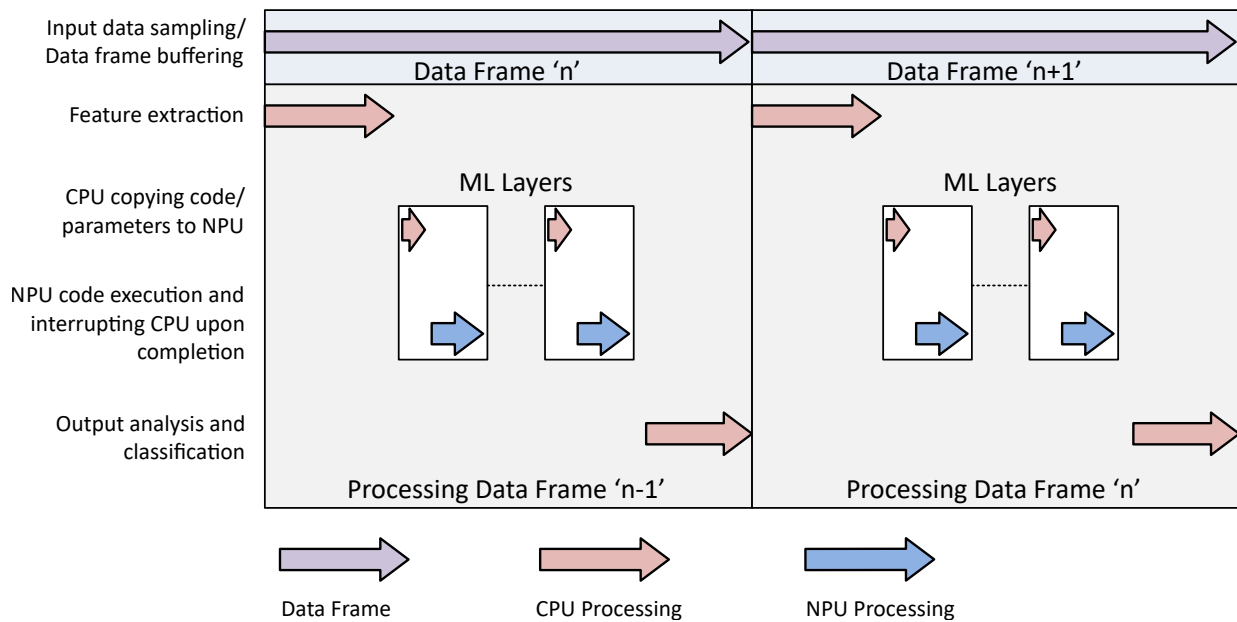

Table 11-1. Component Task Overview

Component	Main Task
FLASH	<ul style="list-style-type: none"> <li>NPU program, and ML parameter storage</li> </ul>
System RAM	<ul style="list-style-type: none"> <li>Shared with CPU and NPU</li> <li>Storage for input data, ML parameters, and output data</li> <li>Storage for NPU inference instructions</li> </ul>
NPU RAM	<ul style="list-style-type: none"> <li>Dedicated program and data memory (RAM) for NPU</li> <li>Storage for NPU inference instructions</li> </ul>
CPU	<ul style="list-style-type: none"> <li>Copies inference code from FLASH to NPU RAM</li> <li>Copies ML parameters from FLASH or System RAM to NPU parameter buffer (RAM)</li> <li>Executes data processing to extract input features from raw data (optional)</li> </ul>
NPU	<ul style="list-style-type: none"> <li>Process the CNNs inference with input data and ML parameters</li> </ul>

**Note**

Upon exit from an LPM such as STOP or STANDBY, the NPU needs to be re-initialized.

Figure 11-2 shows the ML flow where NPU works in conjunction with the on-chip CPU to process CNNs inference.

**Figure 11-2. Data/Program Flow Diagram**

The data is generated in real time and is buffered in system RAM (as data frames). When one data frame is ready for processing, the CPU can do the input feature map extraction (for example, computing the spectral components using FFT). The input features extracted (or raw data in some cases) is then processed by one or more ML layers. This phase can involve multiple sub-phases, in which CPU copies the inference code and ML parameters to NPU RAM and then on NPU completing one sub-phase copies the next set of code and parameters until all the ML layers are computed for the data frame being processed.

In the final phase, CPU can do the analysis of output and necessary classification. As can be seen in the flow diagram, while the processing is being done on the current frame, next frame is being constructed. The processing has to be completed within the time required for one data-frame construction in the real-time application.

### 11.3 NPU Toolchain

For the expert users, train your own model and compile the model with TI Neural Network Compiler. For the catalog users, load and train models with tools from TI: Model Composer GUI or TI's command-line Modelmaker tool for an advanced set of capabilities. Both options automatically generate source code for the MSPM0, eliminating the need to manually write code.

Figure 11-3 shows the toolchain overview and steps to add NPU support to a project, starting with importing or using existing models from TI, training the models, generating the associated software libraries, and integrating into an existing Code Composer Studio™ IDE project.

Figure 11-3. NPU Development Flow

The AES accelerator module accelerates encryption and decryption operations in hardware based on the FIPS PUB 197 advanced encryption standard (AES).

<b>12.1 AES Overview</b> .....	<b>919</b>
<b>12.2 AES Operation</b> .....	<b>920</b>
<b>12.3 AES Registers</b> .....	<b>941</b>

## 12.1 AES Overview

### Note

Not all the MSPM0G devices support support AES. See device-specific datasheet to determine if AES is present.

The AES accelerator module performs encryption and decryption of 128-bit data blocks with a 128-bit or 256-bit key in hardware according to the advanced encryption standard (AES). AES is a symmetric-key block cipher algorithm specified in FIPS PUB 197.

The AES accelerator features include:

- AES 128-bit block encryption and decryption
- DMA trigger support for automating ECB, CBC, OFB, and CFB block cipher modes as defined in NIST SP 800-38
- Support for accelerating CTR cipher mode by encrypting precalculated (nonce || counter) blocks and accelerating XOR of plaintext with the generated key stream
- Support for accelerating CBC-MAC tag computation (CBC DMA mode with zero initialization vector)
- On-the-fly key expansion for encryption and decryption
- Offline key generation for decryption
- Shadow register storing the initial key for all key lengths
- 8-bit byte or 32-bit word access to provide key data, input data, and output data
- AES ready interrupt
- Supported in RUN and SLEEP (see the *Operating Modes* section of the device technical reference manual)

The AES accelerator hardware consists of the 128-bit state memory and associated input/output registers, the AES encryption/decryption core and control logic, and the 256-bit AES key memory and associated input register. The AES hardware is shown in [Figure 12-1](#).

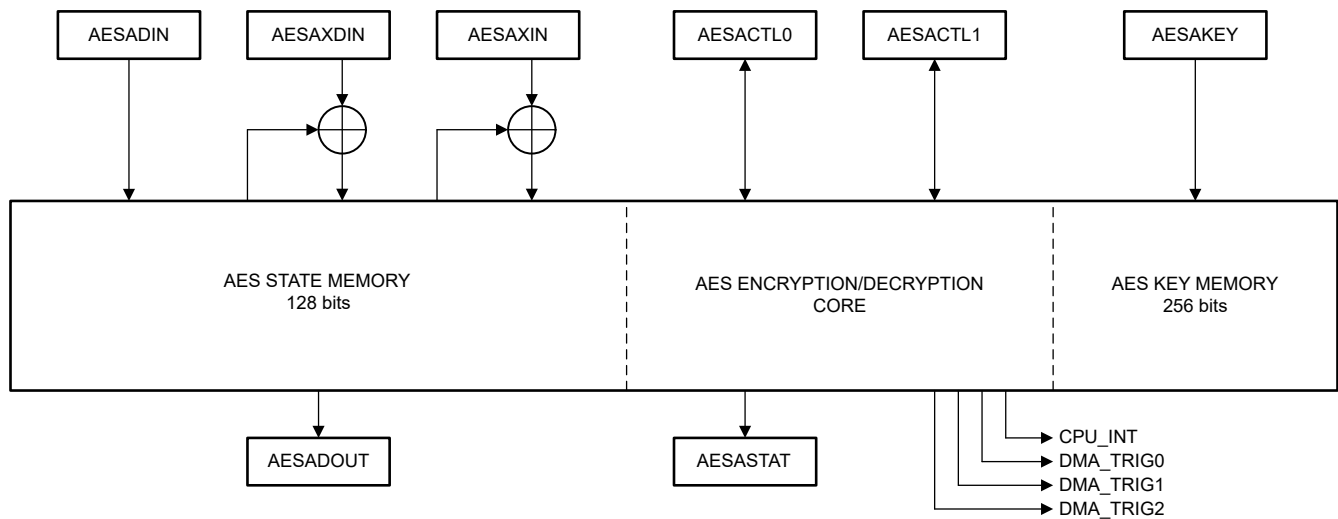

Figure 12-1. AES Accelerator Block Diagram

### 12.1.1 AES Performance

The AES accelerator provides fast encryption and decryption of 128-bit blocks. AES accelerator performance in both cycles and execution time for block encryption and block decryption (with pregenerated decryption key) is given in [Table 12-1](#).

**Table 12-1. AES Hardware Accelerator Key Performance Metrics**

AES Key Length	Encryption (OPx==0x0)			Decryption (OPx==0x3)		
	Cycles	Time (32MHz)	Time (80MHz)	Cycles	Time (32MHz)	Time (80MHz)
128-bit	168	5.25 $\mu$ s	2.10 $\mu$ s	168	5.25 $\mu$ s	2.10 $\mu$ s
256-bit	234	7.31 $\mu$ s	2.93 $\mu$ s	234	7.31 $\mu$ s	2.93 $\mu$ s

## 12.2 AES Operation

The AES accelerator is configured with user software, and has two general modes of operation (configured with the AESACTL0 register):

- **Single block mode**
  - One 128-bit data block is encrypted or decrypted at a time under software control
  - No DMA triggers are generated directly by the AES hardware; application software writes and reads all data or configures DMA to load data with an alternate trigger
  - This mode can also be used to pregenerate the last round key needed for automated decryption in block cipher mode
- **Automated block cipher mode**
  - Multiple 128-bit data blocks can be encrypted or decrypted in an automated way using ECB, CBC, CFB, or OFB block cipher modes of operation
  - DMA triggers are generated to move data in and out of the accelerator automatically for a specified number of blocks with the assistance of 2 or 3 DMA channels (depending on the selected block cipher mode)

Regardless of single block mode or block cipher mode, the key length and operation type are specified by the KL and OP fields in the AESACTL0 register. The KLx and OPx fields are not reset by the AES software reset control (the SWRST bit in the AESACTL0 register). Whenever the KLx or OPx fields are changed, the key memory is reset.

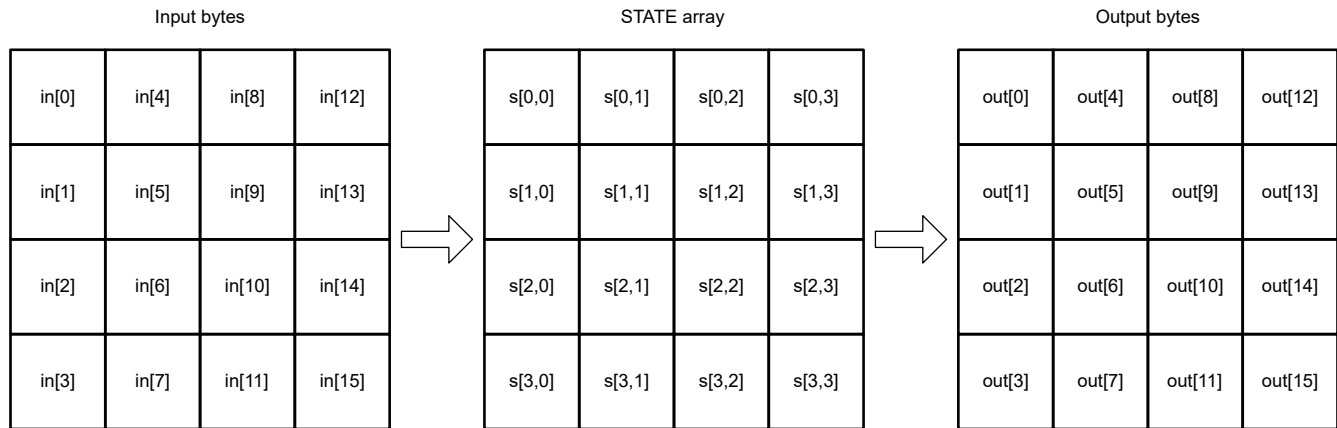

- The KLx field selects the AES key size which is to be used (128 or 256 bits).
- The OPx field selects the AES operation to perform (encrypt, decrypt, generate last round decryption key, decrypt with pregenerated last round decryption key).

The KLx and OPx combination determines the cycle count per block operation, as shown in [Table 12-2](#).

**Table 12-2. AES Operation Overview by OPx (operation) and KLx (key length) Configuration**

AESOPx	AESKLx	Operation	Clock Cycles
00	00	AES128 encryption	168
	10	AES256 encryption	234
01	00	AES128 decryption	215
	10	AES256 decryption	292
10	00	AES128 encryption key schedule is performed (to generate last roundkey)	53
	10	AES256 encryption key schedule is performed (to generate last roundkey)	68
11	00	AES128 decryption (with last roundkey) is performed	168
	10	AES256 decryption (with last roundkey) is performed	234

Internally, the AES algorithm's operations are performed on a two-dimensional array of bytes called the STATE. The STATE consists of four rows of bytes, each containing four bytes, independent of whether AES128 or AES256 is performed. The input is assigned to the STATE array as shown in [Figure 12-2](#), with in[0] being the first data byte written into one of the AES accelerators input registers (AESADIN, AESAXDIN, and AESXIN). The encrypt or decrypt operations are then conducted on the STATE array, after which its final values can be read from the output with out[0] being the first data byte read from the AES accelerator data output register (AESADOUT).

**Figure 12-2. AES State Array Input and Output**

If an encryption is to be performed, the initial state is called plaintext. If a decryption is to be performed, the initial state is called ciphertext.

### 12.2.1 AES Register Access Rules

The AES accelerator must be enabled before being configured for use through the PWREN register (see [peripheral power enable](#)). The AES accelerator is located in power domain 1 (PD1) and as such is only available in RUN and SLEEP modes. If the AES accelerator is enabled by application software, entry into STOP or STANDBY low-power modes will force the AES accelerator to be disabled while the device is in STOP or STANDBY mode, and the AES accelerator register contents will be lost (including any key or state contents).

#### Data Sizes for Reading and Writing Keys and Data

The module allows 32-bit word or 8-bit byte access to all key and data registers (AESAKEY, AESADIN, AESAXDIN, AESAXIN, and AESADOUT). Word and byte access must not be mixed while reading from or writing into one of the registers. However, it is possible to write one of the registers using byte access and another using word access.

#### General Access Restrictions

While the AES accelerator is busy (AESBUSY bit is set in the AESASTAT register):

- AESADOUT always reads as zero.
- The DOUTCNTx counter, the DOUTRD flag, and the DINWR flag are reset.
- Any attempt to change OPx, KLx, DINWR, or KEYWR is ignored.
- Writing to AESAKEY, AESADIN, AESAXDIN, or AESAXIN aborts the current operation, the complete module is reset (except for the IMASK registers, OPx, and KLx), and the AES error flag ERRFG is set.

AESADIN, AESAXDIN, AESAXIN, and AESAKEY are write-only registers and always read as zero.

Writing data into AESADIN, AESAXDIN, or AESAXIN influences the content of the corresponding output data; for example, writing in[0] alters out[0], writing in[1] alters out[1], and so on. However, interleaved operation is possible; for example, first reading out[0] and then writing in[0], and continuing with reading out[1] and then writing in[1], and so on. This interleaved operation must be either byte or word access on in[x] and out[x].

#### Access Restriction With Block Cipher Modes Enabled

When automated block cipher modes are enabled (CMEN is set in AESACTL0) and a cipher block operation is being processed (BLKCNTx > 0), writes to the following bits are ignored, independent of the BUSY bit status: CMEN, CMx, KLx, OPx, and BLKCNTx. Writing to AESAKEY aborts the cipher block mode operation if BUSY = 1, and the complete module is reset (except for the IMASK registers, OPx, and KLx).

### 12.2.2 Loading the Key

The key can be loaded by writing to the AESAKEY register or by setting the KEYWR bit. Depending on the selected key length (KLx in the AESCTL0 register), a different number of bits must be loaded:

- If KLx = 00, the 128-bit key must be loaded using either 16 byte-writes or 4 word-writes to AESAKEY
- If KLx = 10, the 256-bit key must be loaded using either 32 byte-writes or 8 word-writes to AESAKEY

The key memory is reset after changing the KLx bits.

If a key was loaded previously without changing the OPx bits, the KEYWR flag is cleared with the first write access to AESAKEY.

If an operation is triggered without writing a new key, the last key is used. The key must always be written before writing the data.

The AES algorithm operates not only on the STATE but also on the key. To avoid the need to reload the key for each operation, a key buffer is included such that the key expansion operations for round key generation do not remove the cipher key loaded in AESAKEY.

### 12.2.3 Loading Data

The state can be loaded by writing to AESADIN, AESAXDIN, or AESAXIN with 16 byte writes or 4 word writes. Do not mix byte and word mode when writing the state. Writing to a mixture of AESADIN, AESAXDIN, and AESAXIN using the same byte or word data format is allowed. When the 16th byte or 4th word of the state is written, DINWR is set in the AESASTAT register.

When writing to AESADIN, the corresponding byte or word of the state is overwritten. If AESADIN is used to write the last byte or word of the state, encryption or decryption starts automatically.

When writing to AESAXDIN, the corresponding byte or word is XORed with the current byte or word of the state. If AESAXDIN is used to write the last byte or word of the state, encryption or decryption starts automatically.

Writing to AESAXIN has the same behavior as writing to AESAXDIN: the corresponding byte or word is XORed with the current byte or word of the state; however, writing the last byte or word of the state using AESAXIN does not start encryption or decryption.

---

#### Note

The AESAXIN register can be used to accelerate the XOR operation of plaintext with an encrypted key stream (nonce || counter) when using the AES accelerator to assist with implementation of a CTR cipher mode. In a CTR cipher mode scenario, a plaintext block can be loaded to AESAXIN after encryption of the (nonce || counter) value has completed, as the encrypted (nonce || counter) value will be held in the STATE. After loading data into AESAXIN, the (plaintext ⊕ (nonce || counter)) output can be read from AESADOUT.

---

### 12.2.4 Reading Data

The STATE can be read when the BUSY bit in AESASTAT is cleared. The STATE is read using 16 byte reads or 4 word reads from AESADOUT. When all 16 bytes are read, the DOUTRD flag in AESASTAT indicates completion of the read.

### 12.2.5 Triggering an Encryption or Decryption

An encrypt or decrypt operation is triggered if the STATE was completely written in the AESADIN or AESAXDIN registers. Alternatively, the bit DINWR bit in the AESASTAT register can be set to trigger an operation if CMEN is cleared.

### 12.2.6 Single Block Operations

Single block operations include encryption, decryption, and decryption key generation.

### 12.2.6.1 Encryption

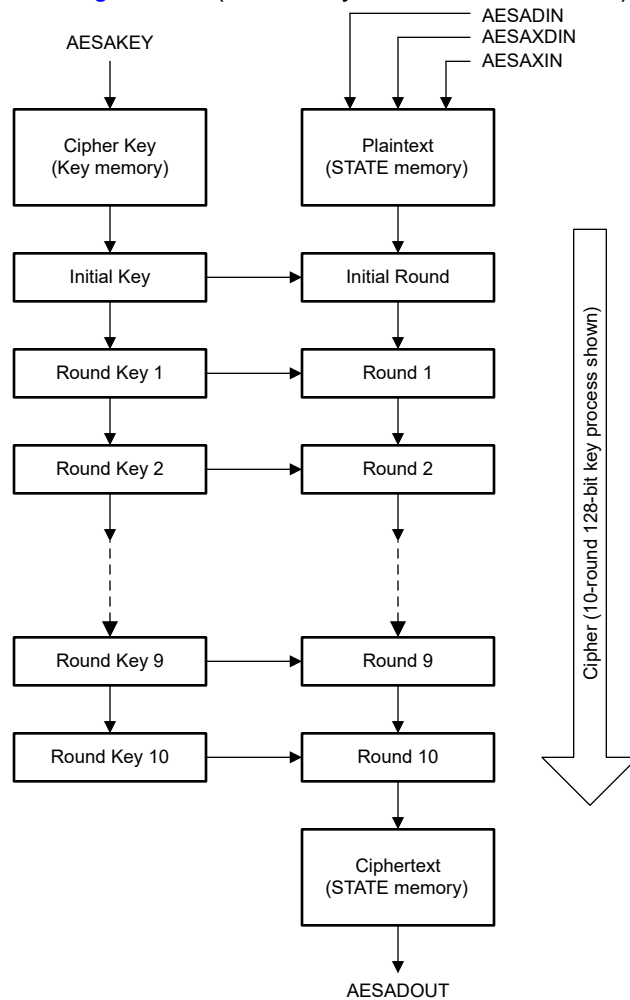

To perform encryption:

1. Set OPx = 0x0 to select encryption. Note that changing the OPx bits clears the KEYWR flag and a new key must be loaded in the next step.
2. Load the key as described in [Section 12.2.2](#).
3. Load the STATE (data) as described in [Section 12.2.3](#). After the data is loaded, the AES module starts the encryption process.
4. Wait for the operation to complete (wait for the BUSY flag to clear).
5. After the encryption is complete, the result can be read from AESADOUT as described in [Section 12.2.4](#).
6. To encrypt additional data with the same key loaded in step 2, write the new data into AESADIN after the results of the operation on the previous data were read from AESADOUT. When an additional 16 data bytes are written, the module automatically starts the encryption using the key loaded in step 2.

#### Note

Setting the DINWR bit in the AESASTAT register triggers another encryption, and the AES accelerator starts the encryption using the output data from the previous encryption as the input data. This is useful in certain block cipher modes with feedback.

The encryption process is given in [Figure 12-3](#) (128-bit key with 10 rounds shown).

**Figure 12-3. AES Encryption (OPx=0x0, 128-bit Key)**

### 12.2.6.2 Decryption

To perform decryption:

1. Set OPx = 0x1 to select decryption using the same key used for encryption, or set OPx = 0x3 if the first round key required for decryption (the last round key used for encryption) is **already pregenerated** and will be loaded in step 2. Changing the OPx bits clears the KEYWR flag, and a new key must be loaded in step 2.
2. Load the key according to [Section 12.2.2](#).
3. Load the STATE (data) according to [Section 12.2.3](#). After the data is loaded, the AES module starts the decryption.
4. Wait for the operation to complete (wait for the BUSY flag to clear).
5. After the decryption is ready, the result can be read from AESADOUT as described in [Section 12.2.4](#).
6. If additional data should be decrypted with the same key loaded in step 2, new data can be written into AESADIN after the results of the operation on the previous data were read from AESADOUT. When additional 16 data bytes are written, the module automatically starts the decryption using the key loaded in step 2.

The decryption process with decryption round key generation is given in [Figure 12-4](#) (128-bit key with 10 rounds shown).

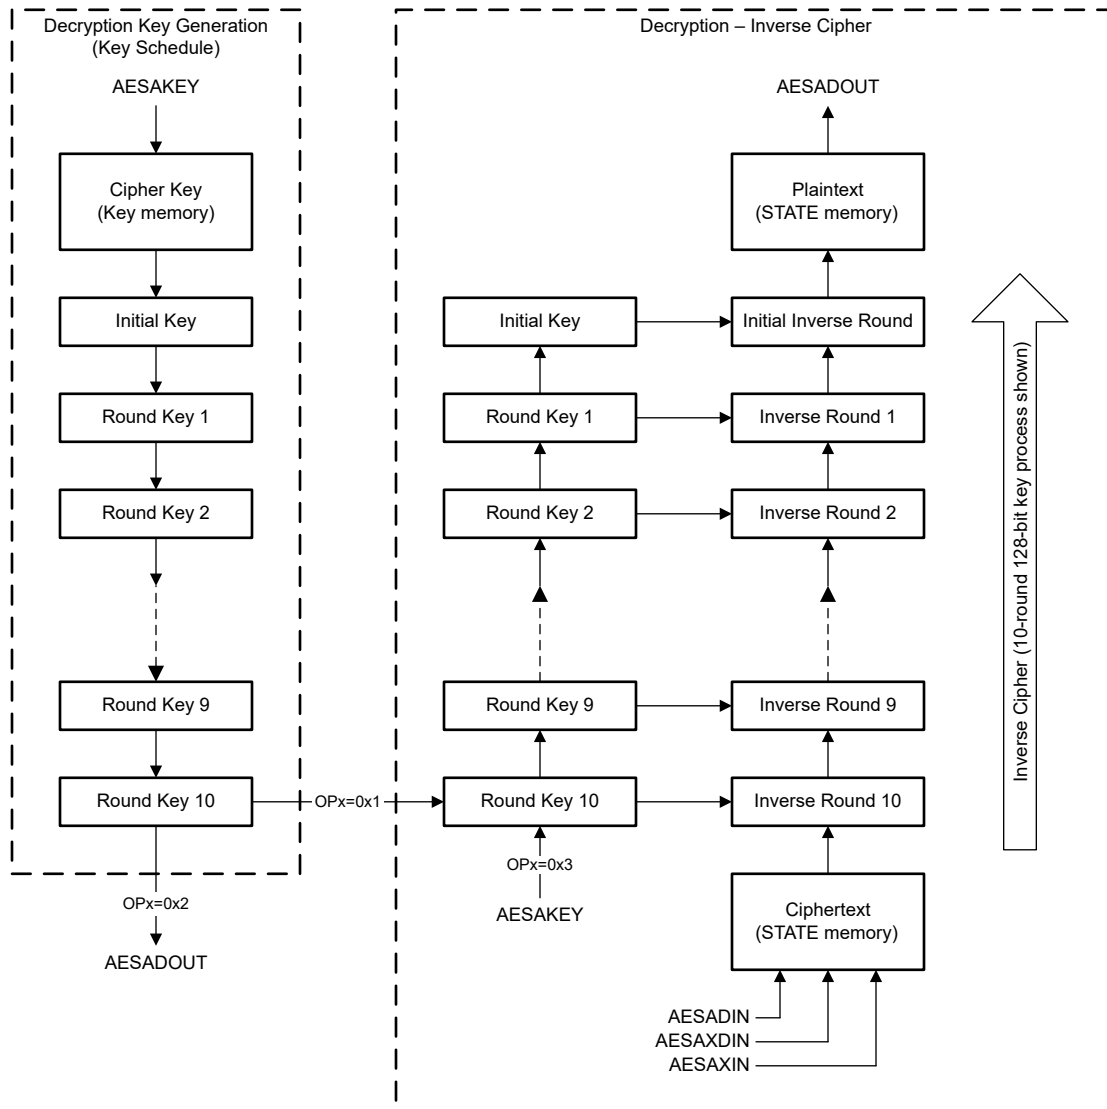

Figure 12-4. AES Decryption (OPx = 0x1, 128-bit Key)

### 12.2.6.2.1 Pregenerating a Decryption Key

When decryption is performed using  $OPx=0x1$ , the original cipher key used for encryption is loaded into AESAKEY. Decryption requires execution of the key schedule to obtain the round key used for the last round of encryption. That final encryption round key is then used by the decryption logic as the first round key for decryption. In the case of  $OPx=0x1$ , before the decryption begins the key schedule will be executed on the key material loaded into AESAKEY to obtain the last round key. Once the last round key used for encryption is generated, the decryption process begins automatically.

While  $OPx=0x1$  is convenient for single block cases (as the original encryption key can be loaded without special handling), it is not efficient for handling multiple blocks, because the key schedule will be executed for each block to obtain the last round key which is needed to start the decryption process. To reduce the cycle count required for decryption, it is possible to pregenerate the last round encryption key using  $OPx=0x2$ . Then that pregenerated round key can be used to immediately start any decryption operations by loading the pregenerated key material and running the  $OPx=0x3$  decryption operation, which assumes that the key material is the round key from the last round of encryption.

To execute the key schedule and obtain the last round key used for encryption (first round key used for decryption) without actually running a decryption operation, follow the steps below:

1. Set  $OPx$  to  $0x2$  to select decryption key generation.
2. Load the cipher key used for encryption into AESAKEY as described in [Section 12.2.2](#). Generation will start as soon as the key material is loaded.
3. While the AES module is busy executing the key schedule, the AESBUSY bit is set. 53 clock cycles are required to complete the key generation for a 128-bit cipher key. After completion, the AESRDY interrupt is set and the 128-bit result can be read from the AESDOUT. AESRDY is cleared when reading AESADOUT or writing to AESAKEY or AESADIN.

Once a decryption first round key is generated, it can be loaded into AESAKEY and used for decryption with  $OPx=3$ .

### 12.2.7 Block Cipher Mode Operations

Block cipher modes are used to implement the electronic code book (ECB), cipher block chaining (CBC), output feedback (OFB) and cipher feedback (CFB) block cipher modes using AES as the underlying block cipher. These modes work together with the DMA through 2 or 3 DMA triggers to support easy and fast encryption or decryption of more than 128 bits.

#### 12.2.7.1 Electronic Codebook (ECB) Mode

The electronic codebook (ECB) cipher is the simplest block cipher mode. The plaintext data is divided into 128-bit blocks, and each block is encrypted and decrypted independently from any other block. The ECB cipher is shown in [Figure 12-5](#). Note that each 128-bit data block can be encrypted or decrypted individually without any knowledge of the other blocks of plaintext or ciphertext.

While ECB is simple to understand and implement, it has a key disadvantage: the same 128-bit plaintext block is always encrypted into the same ciphertext block, allowing patterns in the ciphertext to be detected.

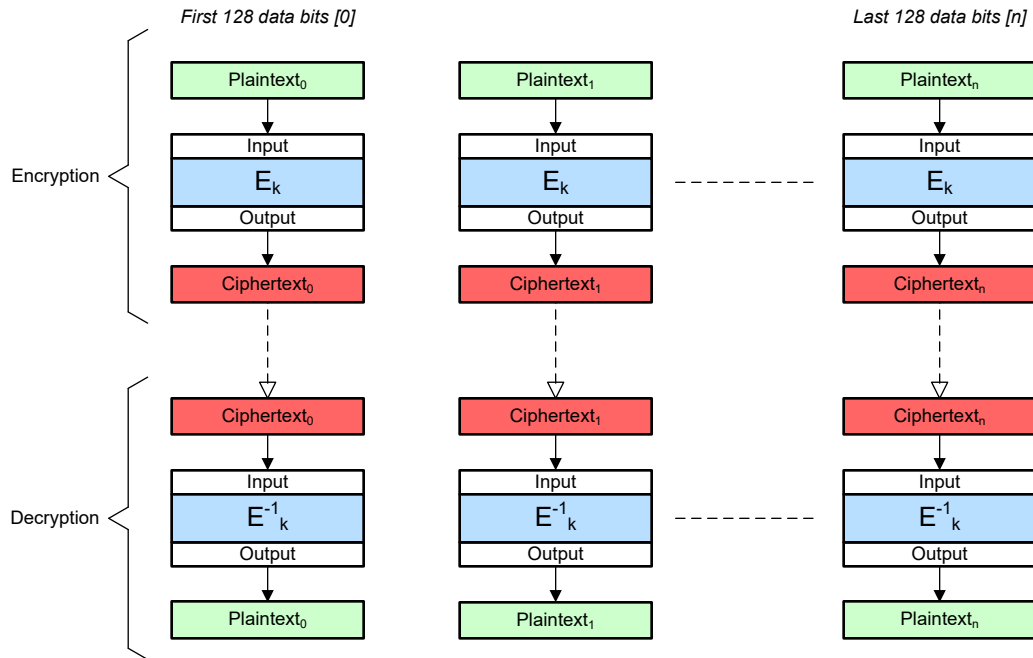

Figure 12-5. ECB Cipher

The AES accelerator supports automated encryption and decryption of more than 128 bits of data in ECB block cipher mode through the use of DMA together with the AES accelerator. ECB mode utilizes two DMA channels (referred to as DMA\_A, DMA\_B in this section) for output and input to the AES accelerator, respectively. The DMA channel usage for ECB mode encryption and decryption operations is given in Table 12-3.

Table 12-3. ECB Block Cipher DMA Behavior

AES Operation			AES DMA Triggers		
CMEN	CMx	OPx	DMA_A (DMA_TRIG0)	DMA_B (DMA_TRIG1)	DMA_C (DMA_TRIG2)
0x1	0x0 (ECB)	0x0 (encryption)	Used to read ciphertext from AESADOUT	Used to write plaintext to AESADIN, which also triggers start of block encryption when 128 bits are written to AESADIN	Not used
		0x1/0x2 (decryption)	Used to read plaintext from AESADOUT	Used to write ciphertext to AESADIN, which also triggers start of block decryption when 128 bits are written to AESADIN	Not used

### 12.2.7.1.1 ECB Encryption

ECB mode encryption of  $N$  blocks of plaintext into  $N$  blocks of ciphertext without CPU interaction is achieved through the use of 2 DMA channels (referred to as DMA\_A and DMA\_B). To implement ECB encryption follow these steps:

1. Configure the AESACTL0 register for block cipher encryption mode using ECB:
  - a. Set CMEN to enable block cipher mode
  - b. Set CMx to ECB mode
  - c. Set OPx to 0x0 (encryption mode)
2. Load key as described in Section 12.2.2
3. Configure DMA\_A channel for saving ciphertext:
  - a. Set DMA channel trigger selection to AES0 trigger
  - b. Set DMA channel source address to AESADOUT
  - c. Set DMA channel destination address to location where ciphertext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N*4$

- e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA0 in the IMASK register of DMA\_TRIG0
4. Configure DMA\_B channel for loading plaintext:
    - a. Set DMA channel trigger selection to AES1 trigger
    - b. Set DMA channel source address to location where plaintext is stored (for example, SRAM)
    - c. Set DMA channel destination address to AESADIN
    - d. Set DMA channel transfer size to  $N*4$
    - e. Set DMA channel mode to single transfer mode
    - f. In the AES event registers, unmask DMA1 in the IMASK register of DMA\_TRIG
- 1
5. Configure and enable the DMA interrupt for the DMA\_A channel in the DMA controller
  6. Start encryption by writing the block count  $N$  to BLKCNTx in the AESACTL1 register
  7. Wait for the DMA\_A channel interrupt which indicates completion of the operation. The ciphertext output will be stored in the location configured in step 3c.

### 12.2.7.1.2 ECB Decryption

ECB mode decryption of  $N$  blocks of ciphertext into  $N$  blocks of plaintext without CPU interaction is achieved through the use of 2 DMA channels (referred to as DMA\_A and DMA\_B). To implement ECB decryption follow these steps:

1. Configure the AESACTL0 register to pregenerate the decryption key (last round key):
  - a. Clear CMEN to disable block cipher mode
  - b. Set OPx to 0x2 (decryption key generation)
  - c. Write key into AESAKEY register as described in [Section 12.2.2](#)
  - d. Wait for the BUSY status in the AESSTAT register to clear, indicating key generation has completed
2. Configure the AESACTL0 register for block cipher decryption mode using ECB:
  - a. Set CMEN to enable block cipher mode
  - b. Set CMx to ECB mode
  - c. Set OPx to 0x3 (decryption mode)
3. Set AESKEYWR bit in AESSTAT (to use pregenerated key from step 1)
4. Configure DMA\_A channel for saving plaintext:
  - a. Set DMA channel trigger selection to AES0 trigger
  - b. Set DMA channel source address to AESADOUT
  - c. Set DMA channel destination address to location where plaintext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N*4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA0 in the IMASK register of DMA\_TRIG

0
5. Configure DMA\_B channel for loading ciphertext:
  - a. Set DMA channel trigger selection to AES1 trigger
  - b. Set DMA channel source address to location where ciphertext is stored (for example, SRAM)
  - c. Set DMA channel destination address to AESADIN
  - d. Set DMA channel transfer size to  $N*4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA1 in the IMASK register of DMA\_TRIG

1
6. Configure and enable the DMA interrupt for the DMA\_A channel in the DMA controller
7. Start decryption by writing the block count  $N$  to BLKCNTx in the AESACTL1 register

- Wait for the DMA\_A channel interrupt which indicates completion of the operation. The plaintext output will be stored in the location configured in step 3c.

### 12.2.7.2 Cipher Block Chaining (CBC) Mode

The cipher block chaining (CBC) cipher mode builds upon the ECB cipher mode to make the ciphertext output for each block dependent not only on the plaintext and the cipher key  $k$ , but also upon the ciphertext of the previous block. The CBC cipher is shown in Figure 12-6. Like ECB mode, the plaintext data is divided into 128-bit blocks. Unlike ECB mode, in CBC mode each new plaintext block is bit-wise XORed with the previous ciphertext block to create the input to the AES block cipher.

In CBC mode, an unpredictable initialization vector (IV) must be provided. The initialization vector is XORed with the first plaintext block, as there is no "previous" ciphertext block to XOR the first plaintext block with.

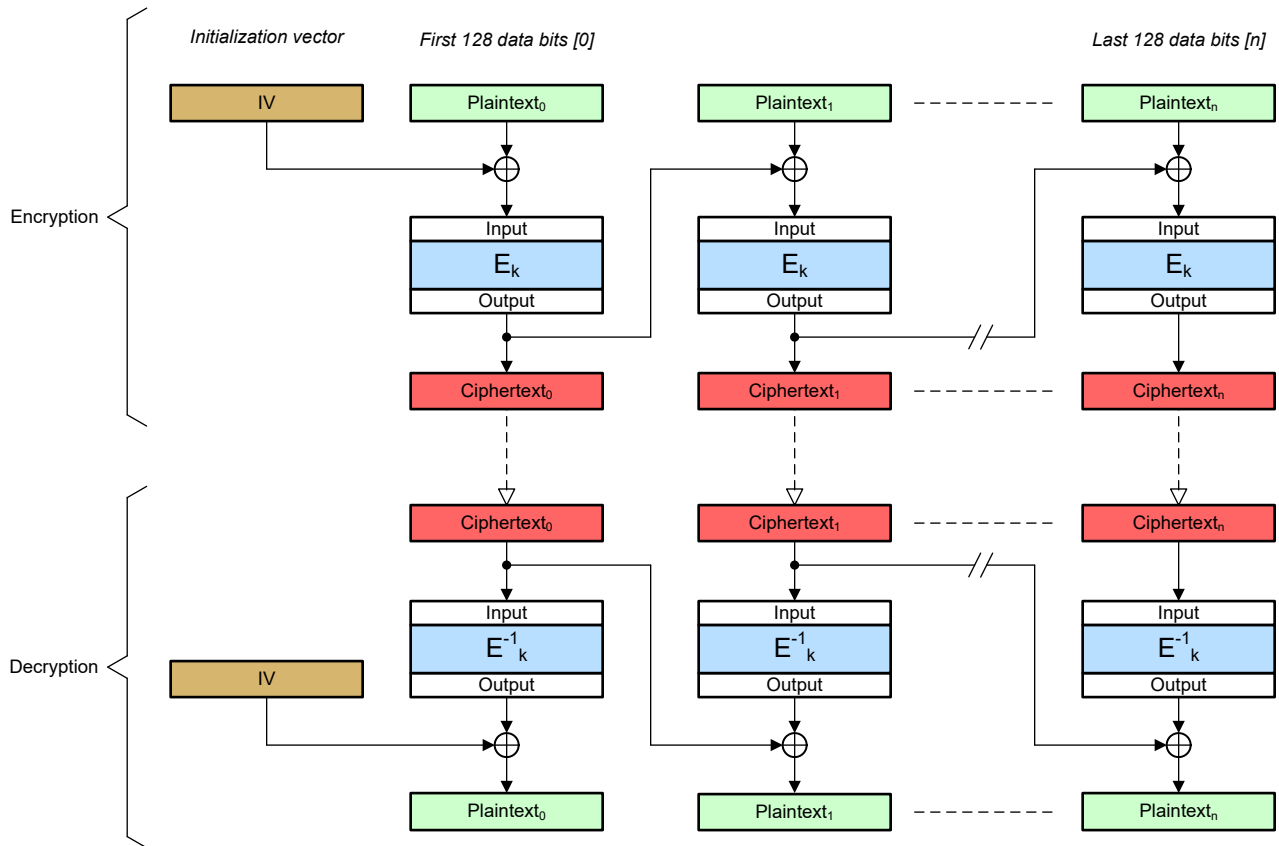

Figure 12-6. CBC Cipher

The AES accelerator supports automated encryption and decryption of more than 128 bits of data in CBC block cipher mode through the use of DMA together with the AES accelerator. CBC mode utilizes two DMA channels (referred to as DMA\_A, DMA\_B in this section) for output and input to the AES accelerator, respectively, when encrypting. CBC mode utilizes three DMA channels (DMA\_A, DMA\_B, and DMA\_C) for input, output, and input to the AES accelerator when decrypting. The DMA channel usage for CBC mode encryption and decryption operations is given in Table 12-4.

Table 12-4. CBC Block Cipher DMA Behavior

AES Operation			AES DMA Triggers		
CMEN	CMx	OPx	DMA_A (DMA_TRIG0)	DMA_B (DMA_TRIG1)	DMA_C (DMA_TRIG2)
0x1	0x1 (CBC)	0x0 (encryption)	Used to read ciphertext from AESADOUT	Used to write plaintext to AESAXIN, which also triggers start of block encryption when 128 bits are written to AESADIN	Not used

**Table 12-4. CBC Block Cipher DMA Behavior (continued)**

AES Operation			AES DMA Triggers		
CMEN	CMx	OPx	DMA_A (DMA_TRIG0)	DMA_B (DMA_TRIG1)	DMA_C (DMA_TRIG2)
		0x1/0x2 (decryption)	Used to write the initialization vector and previous ciphertext block to AESAXIN	Used to read plaintext from AESADOUT	Used to write next ciphertext to AESADIN, which also triggers start of block decryption when 128 bits are written to AESADIN

### 12.2.7.2.1 CBC Encryption

CBC-mode encryption of  $N$  blocks of plaintext into  $N$  blocks of ciphertext without CPU interaction is achieved through the use of 2 DMA channels (referred to as DMA\_A and DMA\_B). To implement CBC encryption follow these steps:

1. Configure the AESACTL0 register for block cipher encryption mode using CBC:
  - a. Reset AES module to clear internal state memory (set SWRST in the AESACTL0 register)
  - b. Set CMEN to enable block cipher mode
  - c. Set CMx to CBC mode
  - d. Set OPx to 0x0 (encryption mode)
2. Load key as described in [Section 12.2.2](#)
3. Load initialization vector (IV) into AESAXIN
  - a. Loading to AESAXIN does not start any encryption
  - b. The STATE must be reset (step 1a above) so that the IV is XORed with zeros when loaded
4. Configure DMA\_A channel for saving ciphertext:
  - a. Set DMA channel trigger selection to AES0 trigger
  - b. Set DMA channel source address to AESADOUT
  - c. Set DMA channel destination address to location where ciphertext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N*4$  words
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA0 in the IMASK register of DMA\_TRIG

0
5. Configure DMA\_B channel for loading plaintext:
  - a. Set DMA channel trigger selection to AES1 trigger
  - b. Set DMA channel source address to location where plaintext is stored (for example, SRAM)
  - c. Set DMA channel destination address to AESAXDIN
  - d. Set DMA channel transfer size to  $N*4$  words
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA1 in the IMASK register of DMA\_TRIG

1
6. Configure and enable the DMA interrupt for the DMA\_A channel in the DMA controller
7. Start encryption by writing the block count  $N$  to BLKCNTx in the AESACTL1 register
8. Wait for the DMA\_A channel interrupt which indicates completion of the operation. The ciphertext output will be stored in the location configured in step 4c.

### 12.2.7.2.2 CBC Decryption

CBC-mode decryption of  $N$  blocks of ciphertext into  $N$  blocks of plaintext without CPU interaction is achieved through the use of 3 DMA channels (referred to as DMA\_A, DMA\_B, and DMA\_C). To implement CBC decryption follow these steps:

1. Configure the AESACTL0 register to pre-generate the decryption key (last round key):
  - a. Clear CMEN to disable block cipher mode
  - b. Set OPx to 0x2 (decryption key generation)
  - c. Write key into AESAKEY register as described in [Section 12.2.2](#)

- d. Wait for the BUSY status in the AESSTAT register to clear, indicating key generation has completed
2. Configure the AESACTL0 register for block cipher decryption mode using CBC:
  - a. Set CMEN to enable block cipher mode (0x1)
  - b. Set CMx to 0x1 (CBC mode)
  - c. Set OPx to 0x3 (decryption mode)
3. Set the AESKEYWR bit in AESSTAT (to use pre-generate key from step 1)
4. Configure DMA\_A channel for loading the initialization vector and ciphertext:
  - a. Set up the ciphertext buffer in memory and pre-pend the initialization vector (IV) to the ciphertext
  - b. Set DMA channel trigger selection to AES0 trigger
  - c. Set DMA channel source address to location where initialization vector is stored in front of the following ciphertext (for example, SRAM)
  - d. Set DMA channel destination address to AESAXIN
  - e. Set DMA channel transfer size to  $N*4$  words
  - f. Set DMA channel mode to single transfer mode
  - g. In the AES event registers, unmask DMA0 in the IMASK register of DMA\_TRIG
5. Configure DMA\_B channel for saving plaintext:
  - a. Set DMA channel trigger selection to AES1 trigger
  - b. Set DMA channel source address to AESADOUT
  - c. Set DMA channel destination address to location where plaintext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N*4$  words
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA1 in the IMASK register of DMA\_TRIG
6. Configure DMA\_C channel for loading ciphertext:
  - a. Set DMA channel trigger selection to AES2 trigger
  - b. Set DMA channel source address to location where ciphertext is stored after the IV (for example, SRAM)
  - c. Set DMA channel destination address to AESADIN
  - d. Set DMA channel transfer size to  $N*4$  words
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA2 in the IMASK register of DMA\_TRIG
7. Configure and enable the DMA interrupt for the DMA\_A and DMA\_B channels in the DMA controller
8. Start decryption by writing the block count  $N$  to BLKCNTx in the AESACTL1 register
9. Wait for the DMA\_B channel interrupt which indicates completion of the operation. The plaintext output will be stored in the location configured in step 5c.

### 12.2.7.3 Output Feedback (OFB) Mode

The output feedback mode leverages an initialization vector (IV) to generate a keystream by repeatedly encrypting the IV with the cipher key. The output ciphertext is obtained by XORing plaintext with the encrypted and re-encrypted versions of the initialization vector. The OFB cipher is shown in [Figure 12-7](#).

In OFB mode, the initialization vector must be a nonce (number used once). To prevent loss of confidentiality, each IV must only be used one time with a given key, and any value passed into the cipher  $E_k$  for a given key  $k$  must not be used as an initialization vector with the same key  $k$ .

---

#### Note

As OFB is a stream cipher, the AES block function is used in the forward (encryption) mode when performing OFB encryption or OFB decryption. When decrypting, the keystream is simply regenerated again to be XORed with the ciphertext, giving back the plaintext.

---

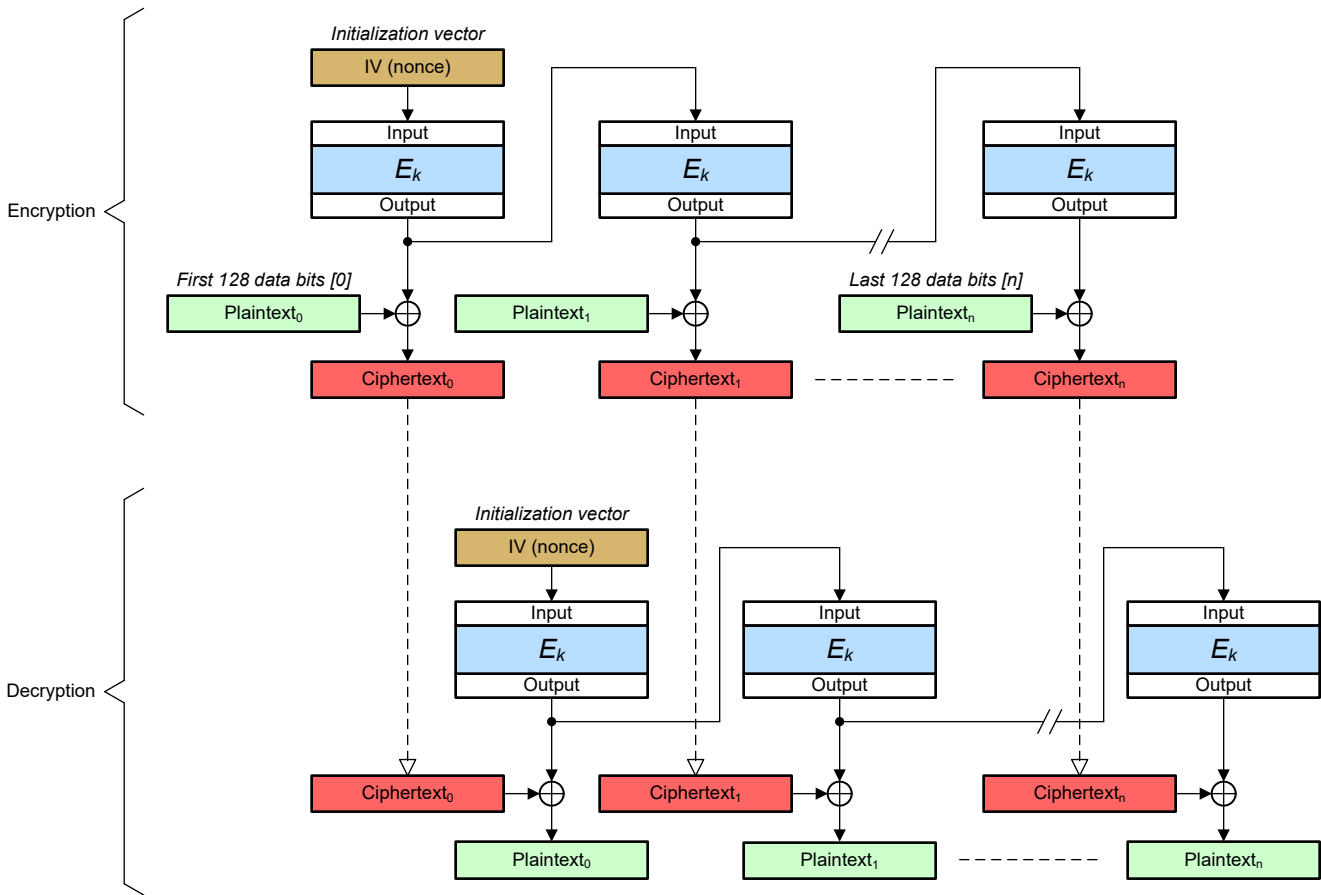

Figure 12-7. OFB Cipher

The AES accelerator supports automated encryption and decryption of more than 128 bits of data in OFB block cipher mode through the use of DMA together with the AES accelerator. OFB mode utilizes three DMA channels (referred to as DMA\_A, DMA\_B, and DMA\_C in this section) for input, output, and input to the AES accelerator, respectively. The DMA channel usage for OFB mode encryption and decryption operations is given in [Table 12-5](#).

Table 12-5. OFB Cipher DMA Behavior

AES Operation			AES DMA Triggers		
CMEN	CMx	OPx	DMA_A (DMA_TRIG0)	DMA_B (DMA_TRIG1)	DMA_C (DMA_TRIG2DMA_TRIG)
0x1	0x2 (OFB)	0x0 (encryption)	Used to write plaintext of the current block to AESAXIN	Used to read ciphertext from AESADOUT	Used to write the plaintext of the current block to AESAXDIN, which also triggers the next encryption
		0x1 (decryption)	Used to write the ciphertext of the current block to AESAXIN	Used to read the plaintext from AESADOUT	Used to write the ciphertext of the current block to AESAXDIN, which also triggers the next decryption

### 12.2.7.3.1 OFB Encryption

OFB mode encryption of  $N$  blocks of plaintext into  $N$  blocks of ciphertext without CPU interaction is achieved through the use of 3 DMA channels (referred to as DMA\_A, DMA\_B, and DMA\_C). To implement OFB encryption follow these steps:

1. Configure the AESACTL0 register for block cipher encryption mode using OFB:

- a. Reset AES module to clear the internal state memory (set SWRST in the AESACTL0 register)
  - b. Set CMEN to enable block cipher mode
  - c. Set CMx to OFB mode (0x2)
  - d. Set OPx to encryption mode (0x0)
2. Load key as described in [Section 12.2.2](#)
  3. Load initialization vector (IV) into AESAXIN
    - a. Loading to AESAXIN does not start any encryption
    - b. The STATE must be reset (step 1a above) so that the IV is XORed with zeros when loaded
  4. Configure the DMA\_A channel for loading plaintext:
    - a. Set the DMA channel trigger selection to AES0 trigger
    - b. Set the DMA channel source address to the location where plaintext is stored (for example, SRAM)
    - c. Set the DMA channel destination address to AESAXIN
    - d. Set the DMA channel transfer size to  $N*4$  words
    - e. Set the DMA channel mode to single transfer mode
    - f. In the AES event registers, unmask DMA0 in the IMASK register of DMA\_TRIG
   
0
  5. Configure the DMA\_B channel for reading ciphertext:
    - a. Set the DMA channel trigger selection for AES1 trigger
    - b. Set the DMA channel source address to AESADOUT
    - c. Set the DMA channel destination address to the location where ciphertext is to be stored (for example, SRAM)
    - d. Set the DMA channel transfer size to  $N*4$  words
    - e. Set the DMA channel mode to single transfer mode
    - f. In the AES event registers, unmask DMA1 in the IMASK register of DMA\_TRIG
   
1
  6. Configure the DMA\_C channel for loading plaintext:
    - a. Set the DMA channel trigger selection for AES2 trigger
    - b. Set the DMA channel source address to the location where plaintext is stored (for example, SRAM)
    - c. Set the DMA channel destination address to AESAXDIN
    - d. Set the DMA channel transfer size to  $N*4$  words
    - e. Set the DMA channel mode to single transfer mode
  7. Configure and enable the DMA interrupt for the DMA\_B channel in the DMA controller
  8. Start encryption by writing the block count  $N$  to BLKCNTx in the AESACTL1 register and setting the DINWR bit in the AESASTAT register
  9. Wait for the DMA\_B channel interrupt which indicates completion of the operation. The ciphertext output will be stored in the location configured in step 5c.

### 12.2.7.3.2 OFB Decryption

OFB mode decryption of  $N$  blocks of ciphertext into  $N$  blocks of plaintext without CPU interaction is achieved through the use of 3 DMA channels (referred to as DMA\_A, DMA\_B, and DMA\_C). To implement OFB decryption follow these steps:

1. Configure the AESACTL0 register for block cipher decryption mode using OFB:
  - a. Reset the AES module to clear the internal state memory (set SWRST in the AESACTL0 register)
  - b. Set the CMEN to enable block cipher mode
  - c. Set CMx to OFB mode (0x2)
  - d. Set OPx to decryption mode (0x1)
2. Load key as described in [Section 12.2.2](#)
3. Load initialization vector IV into AESAXIN
  - a. Loading to AESAXIN does not start any decryption

- b. The STATE must be reset (step 1a above) so that the IV is XORed with zeros when loaded
4. Configure the DMA\_A channel for loading ciphertext:
  - a. Set the DMA channel trigger selection to AES0 trigger
  - b. Set the DMA channel source address to the location where ciphertext is stored (for example, SRAM)
  - c. Set the DMA channel destination address to AESAXIN
  - d. Set the DMA channel transfer size to  $N*4$  words
  - e. Set the DMA channel mode to single transfer mode
5. Configure the DMA\_B channel for reading plaintext:
  - a. Set the DMA channel trigger selection for AES1 trigger
  - b. Set the DMA channel source address to AESADOUT
  - c. Set the DMA channel destination address to the location where plaintext is to be stored (for example, SRAM)
  - d. Set the DMA channel transfer size to  $N*4$  words
  - e. Set the DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA1 in the IMASK register of DMA\_TRIG

1
6. Configure the DMA\_C channel for loading ciphertext:
  - a. Set the DMA channel trigger selection for AES2 trigger
  - b. Set the DMA channel source address to the location where ciphertext is stored (for example, SRAM)
  - c. Set the DMA channel destination address to AESAXDIN
  - d. Set the DMA channel transfer size to  $N*4$  words
  - e. Set the DMA channel mode to single transfer mode
7. Configure and enable the DMA interrupt for the DMA\_B channel in the DMA controller
8. Start decryption by writing the block count  $N$  to BLKCNTx in the AESACTL1 register and setting the DINWR bit in the AESASTAT register
9. Wait for the DMA\_B channel interrupt which indicates completion of the operation. The plaintext output will be stored in the location configured in step 5c.

#### 12.2.7.4 Cipher Feedback (CFB) Mode

The cipher feedback (CFB) mode is similar to the [output feedback \(OFB\) mode](#), with the key difference being that the input block to the block cipher  $E$  used to generate the key stream is taken from the previous ciphertext block (after being XORed with the plaintext), vs. taken before being XORed with the plaintext (as in the case of OFB). As a result, the keystream is dependent upon the plaintext, which is not true of OFB. The CFB cipher is shown in [Figure 12-8](#).

Like OFB, CFB requires an initialization vector (IV). In CFB mode, the initialization vector (IV) must be unpredictable.

---

#### Note

As CFB is a stream cipher, the AES block function is used in the forward (encryption) mode when performing CFB encryption or CFB decryption.

---

Figure 12-8. CFB Cipher

The AES accelerator supports automated encryption and decryption of more than 128 bits of data in CFB block cipher mode through the use of DMA together with the AES accelerator. CFB mode utilizes three DMA channels (referred to as DMA\_A, DMA\_B, and DMA\_C in this section) for input, output, and input to the AES accelerator, respectively. The DMA channel usage for CFB mode encryption and decryption operations is given in [Table 12-6](#).

Table 12-6. CFB Cipher DMA Behavior

AES Operation			AES DMA Triggers		
CMEN	CMx	OPx	DMA_A (DMA_TRIG0)	DMA_B (DMA_TRIG1)	DMA_C (DMA_TRIG2)
0x1	0x3 (CFB)	0x0 (encryption)	Used to write plaintext of the current block to AESAXIN	Used to read ciphertext from AESADOUT, which also triggers the next encryption	Not used
		0x1 (decryption)	Used to write the ciphertext of the current block to AESAXIN	Used to read the plaintext from AESADOUT	Used to write the ciphertext of the current block to AESADIN, which also triggers the next decryption

12.2.7.4.1 CFB Encryption

CFB mode encryption of *N* blocks of plaintext into *N* blocks of ciphertext without CPU interaction is achieved through the use of two DMA channels (referred to as DMA\_A, DMA\_B). To implement CFB encryption follow these steps:

1. Configure the AESACTL0 register for block cipher encryption mode using OFB:
  - a. Reset AES module to clear the internal state memory (set SWRST in the AESACTL0 register)
  - b. Set CMEN to enable block cipher mode

- c. Set CMx to CFB mode (0x3)
- d. Set OPx to encryption mode (0x0)
2. Load key as described in [Section 12.2.2](#)
3. Load initialization vector (IV) into AESAXIN
  - a. Loading to AESAXIN does not start any encryption
  - b. The STATE must be reset (step 1a above) so that the IV is XORed with zeros when loaded
4. Configure the DMA\_A channel for loading plaintext:
  - a. Set the DMA channel trigger selection to AES0 trigger
  - b. Set the DMA channel source address to the location where plaintext is stored (for example, SRAM)
  - c. Set the DMA channel destination address to AESAXIN
  - d. Set the DMA channel transfer size to  $N*4$  words
  - e. Set the DMA channel mode to single transfer mode
5. Configure the DMA\_B channel for reading ciphertext:
  - a. Set the DMA channel trigger selection for AES1 trigger
  - b. Set the DMA channel source address to AESADOUT
  - c. Set the DMA channel destination address to the location where ciphertext is to be stored (for example, SRAM)
  - d. Set the DMA channel transfer size to  $N*4$  words
  - e. Set the DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA1 in the IMASK register of DMA\_TRIG
- 1
6. Configure and enable the DMA interrupt for the DMA\_B channel in the DMA controller
7. Start encryption by writing the block count  $N$  to BLKCNTx in the AESACTL1 register and setting the DINWR bit in the AESASTAT register
8. Wait for the DMA\_B channel interrupt which indicates completion of the operation. The ciphertext output will be stored in the location configured in step 5c.

#### 12.2.7.4.2 CFB Decryption

CFB mode decryption of  $N$  blocks of ciphertext into  $N$  blocks of plaintext without CPU interaction is achieved through the use of 3 DMA channels (referred to as DMA\_A, DMA\_B, and DMA\_C). To implement CFB decryption follow these steps:

1. Configure the AESACTL0 register for block cipher decryption mode using OFB:
  - a. Reset the AES module to clear the internal state memory (set SWRST in the AESCTL0 register)
  - b. Set the CMEN to enable block cipher mode
  - c. Set CMx to CFB mode (0x3)
  - d. Set OPx to decryption mode (0x1)
2. Load key as described in [Section 12.2.2](#)
3. Load initialization vector IV into AESAXIN
  - a. Loading to AESAXIN does not start any decryption
  - b. The STATE must be reset (step 1a above) so that the IV is XORed with zeros when loaded
4. Configure the DMA\_A channel for loading ciphertext:
  - a. Set the DMA channel trigger selection to AES0 trigger
  - b. Set the DMA channel source address to the location where ciphertext is stored (for example, SRAM)
  - c. Set the DMA channel destination address to AESAXIN
  - d. Set the DMA channel transfer size to  $N*4$  words
  - e. Set the DMA channel mode to single transfer mode
5. Configure the DMA\_B channel for reading plaintext:
  - a. Set the DMA channel trigger selection for AES1 trigger
  - b. Set the DMA channel source address to AESADOUT

- c. Set the DMA channel destination address to the location where plaintext is to be stored (for example, SRAM)
  - d. Set the DMA channel transfer size to  $N*4$  words
  - e. Set the DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask DMA1 in the IMASK register of DMA\_TRIG
    - 1
6. Configure the DMA\_C channel for loading ciphertext:
- a. Set the DMA channel trigger selection for AES2 trigger
  - b. Set the DMA channel source address to the location where ciphertext is stored (for example, SRAM)
  - c. Set the DMA channel destination address to AESADIN
  - d. Set the DMA channel transfer size to  $N*4$  words
  - e. Set the DMA channel mode to single transfer mode
7. Configure and enable the DMA interrupt for the DMA\_B channel in the DMA controller
8. Start decryption by writing the block count  $N$  to BLKCNTx in the AESACTL1 register and setting the DINWR bit in the AESASTAT register
9. Wait for the DMA\_B channel interrupt which indicates completion of the operation. The plaintext output will be stored in the location configured in step 5c.

#### 12.2.7.5 Counter (CTR) Mode

The counter mode leverages a nonce (number used once) and a counting integer to generate a keystream by appending the counter to the nonce and encrypting the combined nonce || counter value with the cipher key.

The nonce must only be used once with a given key  $k$ . The counter value can start from any value and is incremented for each 128-bit block of data.

The keystream is derived by encrypting the nonce || counter value for each 128-bit data block with the cipher key  $k$ . The output ciphertext is then obtained by XORing the plaintext with the encrypted nonce || counter value for each data block. The CTR cipher is shown in [Figure 12-9](#).

---

#### Note

As CTR mode is a stream cipher, the AES block function is used in the forward (encryption) mode when performing CTR encryption or CTR decryption. When decrypting, the keystream is simply regenerated again to be XORed with the ciphertext, giving back the plaintext.

---

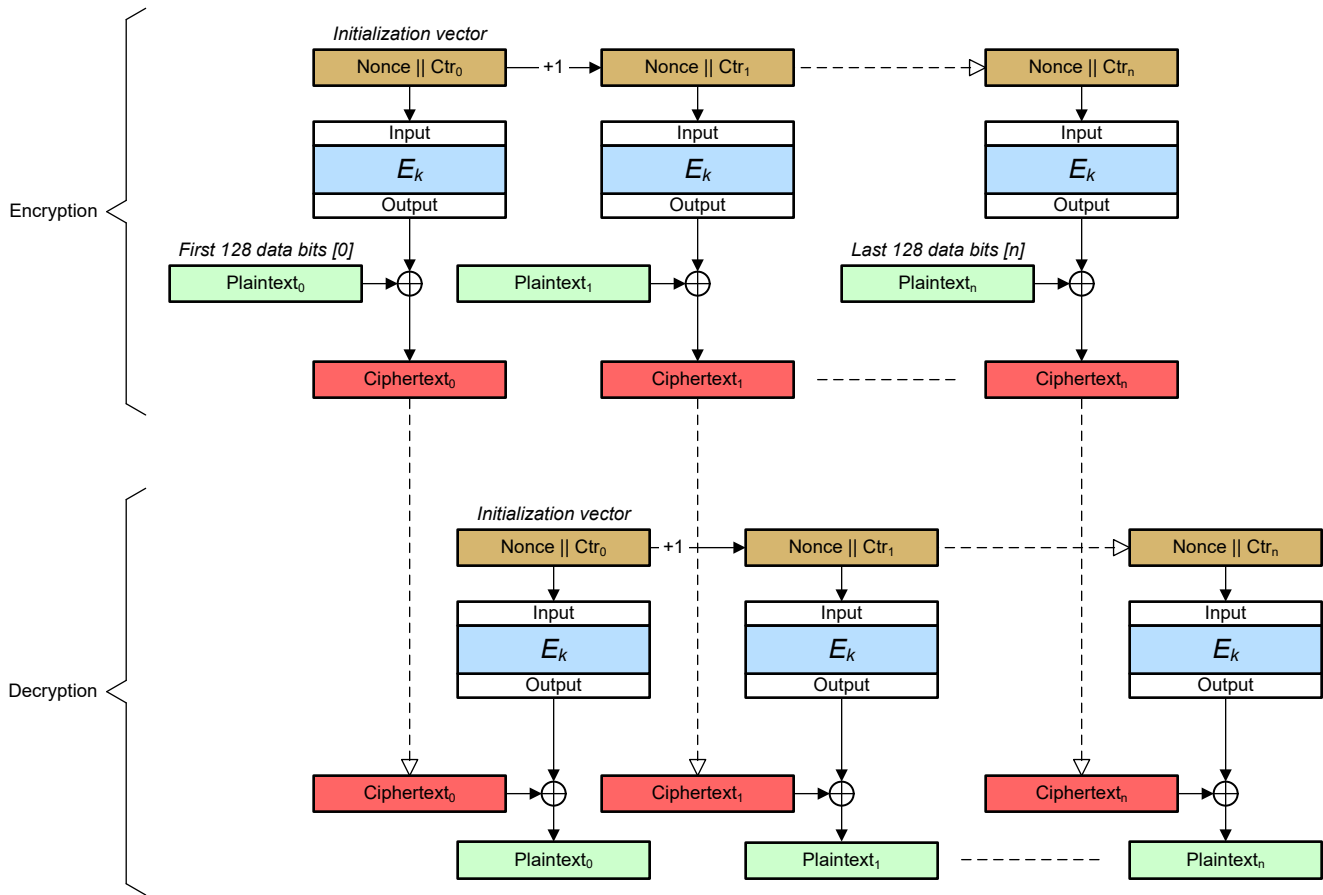

Figure 12-9. CTR Cipher

The AES accelerator can be used to accelerate CTR ciphers by accelerating the encryption of each nonce || counter value with the cipher key  $k$ , and accelerating the XOR operation of the plaintext (in the case of encryption) or ciphertext (in the case of decryption) with the keystream. DMA trigger generation is not supported when implementing a CTR cipher.

#### 12.2.7.5.1 CTR Encryption

CTR-mode encryption of  $N$  blocks of plaintext into  $N$  blocks of ciphertext is achieved by following the steps below:

1. Configure the AESACTL0 register for single block encryption mode:
  - a. Clear CMEN to disable block cipher mode (if previously enabled)
  - b. Set OPx to encryption mode (0x0)
2. Load key as described in [Section 12.2.2](#)
3. Load first (nonce || counter) value into AESADIN as described in [Section 12.2.3](#)
4. Wait for the encryption process to complete (wait for the BUSY flag to clear)
5. The encrypted (nonce || counter) value is now in the STATE. The first ciphertext block can be obtained by XORing the first plaintext block with the keystream in the STATE.
  - a. Load the first plaintext block into AESAXIN (XORing the plaintext with the keystream, but not starting any encryption operation)
6. Read the first block of ciphertext from AESADOUT as described in [Section 12.2.4](#)
7. Repeat steps 3-6 for additional data blocks, incrementing the counter value each time.

### 12.2.7.5.2 CTR Decryption

CTR-mode decryption of  $N$  blocks of ciphertext into  $N$  blocks of plaintext is achieved by following the same steps given for encryption ([Section 12.2.7.5.1](#)), but substituting the ciphertext for the plaintext and the reverse. Note that only the forward cipher is used in CTR mode; the encryption and decryption operations are identical and the same software implementation can be used for both, with substitution of ciphertext for plaintext in the case of decryption.

### 12.2.8 AES Events

The AES module contains four [event publishers](#) and no [event subscribers](#). One event publisher (CPU\_INT) manages AES interrupt requests (IRQs) to the CPU subsystem through a [static event route](#). The second, third, and fourth event publishers (DMA\_TRIG0, DMA\_TRIG1, and DMA\_TRIG2) can be used to publish AES events to the DMA through [DMA event routes](#).

The AES events are summarized in [Table 12-7](#).

**Table 12-7. AES Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU Interrupt Event</a>	Publisher	AES	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from RTC to CPU
<a href="#">DMA Trigger Event 0</a>	Publisher	AES	DMA	<a href="#">DMA route</a>	DMA_TRIG 0 registers	DMA trigger 0 for block cipher modes
<a href="#">DMA Trigger Event 1</a>	Publisher	AES	DMA	<a href="#">DMA route</a>	DMA_TRIG 1 registers	DMA trigger 1 for block cipher modes
<a href="#">DMA Trigger Event 2</a>	Publisher	AES	DMA	<a href="#">DMA route</a>	DMA_TRIG 2 registers	DMA trigger 2 for block cipher modes

In general, the CPU interrupt event is used to communicate completion of an AES operation to the CPU, and the DMA triggers are used together to implement the block cipher modes (ECB, CBC, OFB, and CFB) using the DMA together with the AES accelerator.

When the CMEN bit is set in AESACTL0, the AES module will trigger DMA trigger event 0, DMA trigger event 1, and DMA trigger event 2 to execute different block cipher modes of operation together with the DMA.

For example, when using ECB encryption with AESCMEN=0x1, DMA trigger event 0 is triggered four times for DMA word access to read out AESADOUT, and AES trigger 1 is triggered 4 times to fill the next data into AESADIN. The AES module generates a trigger for each word, and so the DMA must be configured in repeated single channel mode. See the block cipher mode section for details on how the DMA must be configured to support the ECB, CBC, OFB, and CFB block cipher modes.

#### 12.2.8.1 CPU Interrupt Event Publisher (CPU\_EVENT)

The AES module provides four interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the AES are given in [Table 12-8](#).

**Table 12-8. AES CPU Interrupt Event Conditions (CPU\_EVENT)**

Index (IIDX)	Name	Description
0	AESRDY	Indicates that the AES module has completed the selected operation and the results can be read from AESADOUT (if applicable).
1	DMA0	Not to be used for normal operation.
2	DMA1	Not to be used for normal operation.

**Table 12-8. AES CPU Interrupt Event Conditions (CPU\_EVENT) (continued)**

Index (IIDX)	Name	Description
3	DMA2	Not to be used for normal operation.

The CPU interrupt event configuration is managed with the event management registers. See [Section 7.2.5](#) for guidance on configuring these registers for CPU interrupts.

#### 12.2.8.2 DMA Trigger Event Publisher (DMA\_TRIG0)

The AES module provides four trigger sources which can be configured to source DMA trigger 0. In order of decreasing interrupt priority, the DMA0 trigger events from the AES are given in [Table 12-9](#). When the DMA0 channel is needed by the AES for block cipher operations, the DMA0 trigger should be unmasked in the IMASK register of DMA\_TRIG0 and the DMA should be configured as needed to support the AES operation.

**Table 12-9. AES DMA Trigger 0 Event Conditions (DMA\_TRIG0)**

Index (IIDX)	Name	Description
0	AESRDY	Not to be used for normal operation.
1	DMA0	DMA0 trigger indication
2	DMA1	Not to be used for normal operation.
3	DMA2	Not to be used for normal operation.

The DMA trigger 0 event configuration is managed with the DMA\_TRIG0 event management registers. See [Section 7.2.5](#) for guidance on configuring the event registers for DMA triggers.

#### 12.2.8.3 DMA Trigger Event Publisher (DMA\_TRIG1)

The AES module provides four trigger sources which can be configured to source DMA trigger 1. In order of decreasing interrupt priority, the DMA1 trigger events from the AES are given in [Table 12-10](#). When the DMA1 channel is needed by the AES for block cipher operations, the DMA1 trigger should be unmasked in the IMASK register of DMA\_TRIG1 and the DMA should be configured as needed to support the AES operation.

**Table 12-10. AES DMA Trigger 1 Event Conditions (DMA\_TRIG1)**

Index (IIDX)	Name	Description
0	AESRDY	Not to be used for normal operation.
1	DMA0	Not to be used for normal operation.
2	DMA1	DMA1 trigger indication
3	DMA2	Not to be used for normal operation.

The DMA trigger 1 event configuration is managed with the DMA\_TRIG1 event management registers. See [Section 7.2.5](#) for guidance on configuring the event registers for DMA triggers.

#### 12.2.8.4 DMA Trigger Event Publisher (DMA\_TRIG2)

The AES module provides four trigger sources which can be configured to source DMA trigger 2. In order of decreasing interrupt priority, the DMA2 trigger events from the AES are given in [Table 12-11](#). When the DMA2 channel is needed by the AES for block cipher operations, the DMA2 trigger should be unmasked in the IMASK register of DMA\_TRIG2 and the DMA should be configured as needed to support the AES operation.

**Table 12-11. AES DMA Trigger 2 Event Conditions (DMA\_TRIG2)**

Index (IIDX)	Name	Description
0	AESRDY	Not to be used for normal operation.
1	DMA0	Not to be used for normal operation.

**Table 12-11. AES DMA Trigger 2 Event Conditions (DMA\_TRIG2) (continued)**

Index (IIDX)	Name	Description
2	DMA1	Not to be used for normal operation.
3	DMA2	DMA2 trigger indication

The DMA trigger 2 event configuration is managed with the DMA\_TRIG2 event management registers. See [Section 7.2.5](#) for guidance on configuring the event registers for DMA triggers.

## 12.3 AES Registers

Table 12-12 lists the memory-mapped registers for the AES registers. All register offset addresses not listed in Table 12-12 should be considered as reserved locations and the register contents should not be modified.

**Table 12-12. AES Registers**

Offset	Acronym	Register Name	Group	Section
800h	PWREN	Power enable		<a href="#">Go</a>
804h	RSTCTL	Reset Control		<a href="#">Go</a>
814h	STAT	Status Register		<a href="#">Go</a>
1018h	PDBGCTL	Peripheral Debug Control		<a href="#">Go</a>
1020h	IIDX	Interrupt Index Register	CPU_INT	<a href="#">Go</a>
1028h	IMASK	Interrupt mask	CPU_INT	<a href="#">Go</a>
1030h	RIS	Raw interrupt status	CPU_INT	<a href="#">Go</a>
1038h	MIS	Masked interrupt status	CPU_INT	<a href="#">Go</a>
1040h	ISSET	Interrupt set	CPU_INT	<a href="#">Go</a>
1048h	ICLR	Interrupt clear	CPU_INT	<a href="#">Go</a>
1050h	IIDX	Interrupt Index Register	DMA_TRIG0	<a href="#">Go</a>
1058h	IMASK	Interrupt mask	DMA_TRIG0	<a href="#">Go</a>
1060h	RIS	Raw interrupt status	DMA_TRIG0	<a href="#">Go</a>
1068h	MIS	Masked interrupt status	DMA_TRIG0	<a href="#">Go</a>
1070h	ISSET	Interrupt set	DMA_TRIG0	<a href="#">Go</a>
1078h	ICLR	Interrupt clear	DMA_TRIG0	<a href="#">Go</a>
1080h	IIDX	Interrupt Index Register	DMA_TRIG1	<a href="#">Go</a>
1088h	IMASK	Interrupt mask	DMA_TRIG1	<a href="#">Go</a>
1090h	RIS	Raw interrupt status	DMA_TRIG1	<a href="#">Go</a>
1098h	MIS	Masked interrupt status	DMA_TRIG1	<a href="#">Go</a>
10A0h	ISSET	Interrupt set	DMA_TRIG1	<a href="#">Go</a>
10A8h	ICLR	Interrupt clear	DMA_TRIG1	<a href="#">Go</a>
10B0h	IIDX	Interrupt Index Register	DMA_TRIG2	<a href="#">Go</a>
10B8h	IMASK	Interrupt mask	DMA_TRIG2	<a href="#">Go</a>
10C0h	RIS	Raw interrupt status	DMA_TRIG2	<a href="#">Go</a>
10C8h	MIS	Masked interrupt status	DMA_TRIG2	<a href="#">Go</a>
10D0h	ISSET	Interrupt set	DMA_TRIG2	<a href="#">Go</a>
10D8h	ICLR	Interrupt clear	DMA_TRIG2	<a href="#">Go</a>
10E0h	EVT_MODE	Event Mode		<a href="#">Go</a>
1100h	AESACTL0	AES accelerator control register 0		<a href="#">Go</a>
1104h	AESACTL1	AES accelerator control register 1		<a href="#">Go</a>
1108h	AESASTAT	AES accelerator status register		<a href="#">Go</a>
110Ch	AESAKEY	AES accelerator key register		<a href="#">Go</a>
1110h	AESADIN	AES accelerator data in register		<a href="#">Go</a>
1114h	AESADOUT	AES accelerator data out register		<a href="#">Go</a>
1118h	AESAXDIN	AES accelerator XORed data in register		<a href="#">Go</a>
111Ch	AESAXIN	AES accelerator XORed data in register (no trigger)		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 12-13 shows the codes that are used for access types in this section.

**Table 12-13. AES Access Type Codes**

Access Type	Code	Description
<b>Read Type</b>		
R	R	Read
<b>Write Type</b>		
W	W	Write
WK	W K	Write Write protected by a key
<b>Reset or Default Value</b>		
-n		Value after reset or the default value

### 1 PWREN (Offset = 800h) [Reset = 00000000h]

PWREN is shown in [Figure 12-10](#) and described in [Table 12-14](#).

Return to the [Summary Table](#).

Register to control the power state

1	SOFT	R/W	1h	Soft halt boundary control. This function is only available, if <a href="#">FREE</a> is set to 'STOP' 0h = The peripheral will halt immediately, even if the resultant state will result in corruption if the system is restarted 1h = The peripheral blocks the debug freeze until it has reached a boundary where it can resume without corruption
0	FREE	R/W	1h	Free run control 0h = The peripheral freezes functionality while the Core Halted input is asserted and resumes when it is deasserted. 1h = The peripheral ignores the state of the Core Halted input

## 5 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 12-14](#) and described in [Table 12-18](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

### 23 IIDX (Offset = 10B0h) [Reset = 0000000h]

IIDX is shown in [Figure 12-32](#) and described in [Table 12-36](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 12-32. IIDX**

## 24 IMASK (Offset = 10B8h) [Reset = 0000000h]

IMASK is shown in [Figure 12-33](#) and described in [Table 12-37](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is unmasked. Unmasking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

## 25 RIS (Offset = 10C0h) [Reset = 0000000h]

RIS is shown in [Figure 12-34](#) and described in [Table 12-38](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

R-0h				R-0h	R/W-0h	R/W-0h	R-0h

**Table 12-77. AESASTAT Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-12	DOUTCNTx	R	0h	Bytes read from AESADOUT. Reset when AESDOUTRD is reset. If AESDOUTCNTx = 0 and AESDOUTRD = 0, no bytes were read. If AESDOUTCNTx = 0 and AESDOUTRD = 1, all bytes were read. 0h = Smallest possible value Fh = Highest possible value
11-8	DINCNTx	R	0h	Bytes written to AESADIN, AESAXDIN or AESAXIN. Reset when AESDINWR is reset. If AESDINCNTx = 0 and AESDINWR = 0, no bytes were written. If AESDINCNTx = 0 and AESDINWR = 1, all bytes were written. 0h = Smallest possible value Fh = Highest possible value
7-4	KEYCNTx	R	0h	Bytes written to AESAKEY when AESKLx = 00, half-words written to AESAKEY if AESKLx = b10. Reset when AESKEYWR is reset. If AESKEYCNTx = 0 and AESKEYWR = 0, no bytes were written. If AESKEYCNTx = 0 and AESKEYWR = 1, all bytes were written. 0h = Smallest possible value Fh = Highest possible value
3	DOUTRD	R	0h	All 16 bytes read from AESADOUT. AESDOUTRD is reset by PUC, AESSWRST, an error condition, changing AESOPx, changing AESKLx, when the AES accelerator is busy, and when the output data is read again. 0 = Not all bytes read 1 = All bytes read 0h = Not all bytes read 1h = All bytes read
2	DINWR	R/W	0h	All 16 bytes written to AESADIN, AESAXDIN or AESAXIN. Changing its state by software also resets the AESDINCNTx bits. AESDINWR is reset by PUC, AESSWRST, an error condition, changing AESOPx, changing AESKLx, the start to (over)write the data, and when the AES accelerator is busy. Because it is reset when AESOPx or AESKLx is changed it can be set by software again to indicate that the current data is still valid. 0 = Not all bytes written 1 = All bytes written 0h = Not all bytes written 1h = All bytes written

**Table 12-77. AESASTAT Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	KEYWR	R/W	0h	All bytes written to AESAKEY. This bit can be modified by software but it must not be reset by software (1→0) if AESCMEN=1. Changing its state by software also resets the AESKEYCNTx bits. AESKEYWR is reset by PUC, AESSWRST, an error condition, changing AESOPx, changing AESKLx, and the start to (over)write a new key. Because it is reset when AESOPx is changed it can be set by software again to indicate that the loaded key is still valid. 0h = Not all bytes written 1h = All bytes written
0	BUSY	R	0h	AES accelerator module busy; encryption, decryption, or key generation in progress. 0 = Not busy 1 = Busy 0h = Not busy 1h = Busy

**Table 12-87. AESAXIN Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	XIN3x	W	0h	AES data in byte n+3 when AESAXIN is written as word. Do not use these bits for byte access. Do not mix word and byte access. Always reads as zero. 00h = Smallest possible value FFh = Highest possible value
23-16	XIN2x	W	0h	AES data in byte n+2 when AESAXIN is written as word. Do not use these bits for byte access. Do not mix word and byte access. Always reads as zero. 00h = Smallest possible value FFh = Highest possible value
15-8	XIN1x	W	0h	AES data in byte n+1 when AESAXIN is written as word. Do not use these bits for byte access. Do not mix word and byte access. Always reads as zero. 00h = Smallest possible value FFh = Highest possible value
7-0	XIN0x	W	0h	AES data in byte n when AESAXIN is written as word. AES next data in byte when AESAXIN is written as byte. Do not mix word and byte access. Always reads as zero. 00h = Smallest possible value FFh = Highest possible value

The AES accelerator module accelerates encryption and decryption operations in hardware based on the FIPS PUB 197 AES.

<b>13.1 AES Overview</b> .....	<b>983</b>
<b>13.2 AESADV Operation</b> .....	<b>984</b>
<b>13.3 AESADV Registers</b> .....	<b>1004</b>

### 13.1 AES Overview

**Note**

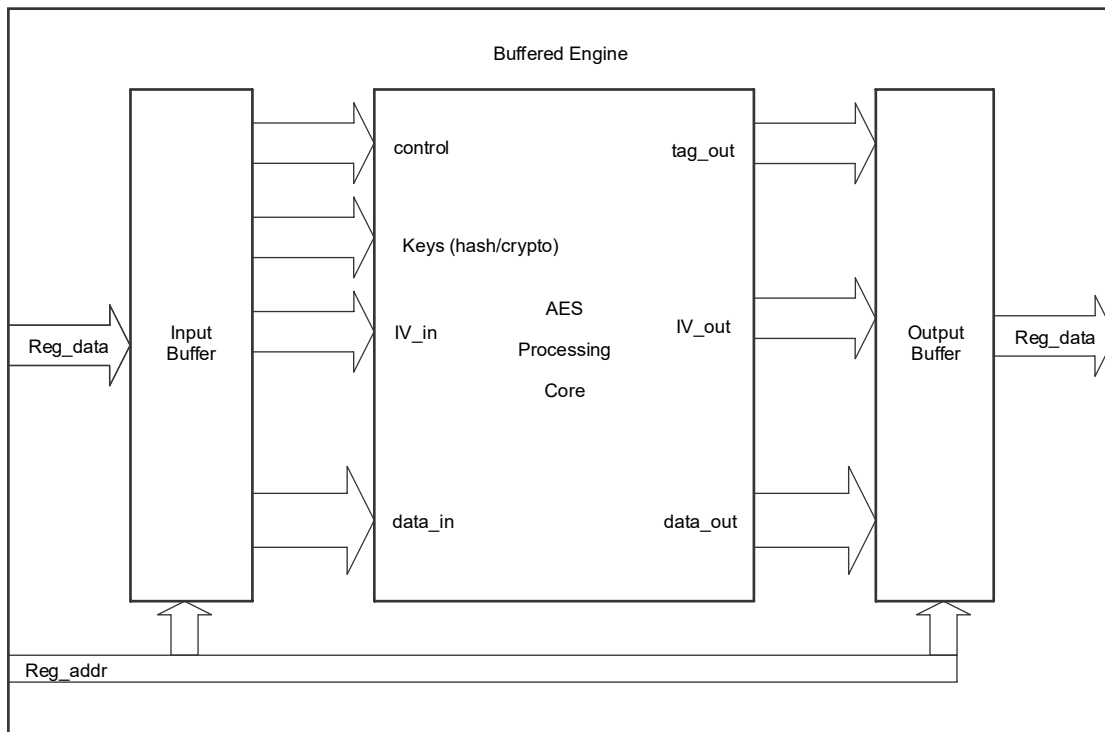

Not all the MSPM0G devices support AES. See device-specific datasheet to determine if AES is present.

The AES accelerator module performs encryption and decryption of 128-bit data blocks with a 128-bit or 256-bit key in hardware. AES is a symmetric-key block cipher algorithm specified in FIPS PUB 197.

The AES accelerator features include:

- AES 128-bit block encryption and decryption
- Key scheduling in hardware
- Enc/decrypt only modes: CBC, CFB-1, CFB-8, CFB-128, OFB-128, CTR/ICM
- Authentication only modes: CBC-MAC, CMAC
- AES-CCM
- AES-GCM
- AES-CCM and AES-GCM modes support continuation with hold/resume of payload data
- 32-bit word access to provide key data, input data, and output data
- AES ready interrupt
- DMA triggers for input/output data
- Supported in RUN and SLEEP (see the *Operating Modes* section of the device technical reference manual)

A high level block diagram of the AES engine is shown in [Figure 13-1](#). The AES engine consists of a processing core that performs both encryption/decryption as well as Galois field multiplication. The core is driven with configuration and data inputs that software will configure via memory mapped registers.

**Figure 13-1. AES Block Diagram**

### 13.1.1 AESADV Performance

The AESADV accelerator provides fast encryption and decryption of 128-bit blocks. AESADV accelerator performance in both cycles and execution time for block encryption and block decryption (with pregenerated decryption key) is given in [Section 13.1](#). This table assumes that there are no system overheads (delays in supplying next input or reading out available output) that stall the engine.

**Table 13-1. AESADV Hardware Accelerator Key Performance Metrics**

AESADV Key Length	Encryption			Decryption		
	Cycles	Time (32MHz)	Time (80MHz)	Cycles	Time (32MHz)	Time (80MHz)
128-bit	76	2.38us	0.95us	76	2.38us	0.95us
256-bit	81	2.53us	1.01us	81	2.53us	1.01us

## 13.2 AESADV Operation

The AESADV engine provides an efficient implementation of the Rijndael cipher (the AES algorithm) and a 128-bit polynomial multiplication (referred here to as 'GHASH', as per the AES-GCM specification). Rijndael is a block cipher with each data block consisting of 128-bits.

AES encryption requires a specific number of rounds depending on the key length. Supported key lengths are 128-bit, and 256 bit, requiring 10, and 14 rounds respectively.

The AESADV engine contains the AES ECB core and a dedicated 32-cycle polynomial multiplication module for performing GHASH operations (when GCM is configured). The polynomial multiplication operates in parallel with the AES core, if there is data available for both modules. This is the case after encryption of the first data block.

### 13.2.1 Loading the Key

Keys can be configured into the engine in one of two ways.

1. Secure key initialization via keystore controller: In this method, the intended AES key is securely transferred from the keystore controller into the engine via a secure private bus connecting the keystore controller and the AES engine. The keystore controller initiates the key transfer and waits for the AES engine to acknowledge transfer completion.
2. Software explicitly configures keys: In this method, software configures the key data into the engine by writing to the KEY0--KEY7 registers, writing 32-bits at a time starting with KEY0. For 128-bit keys, KEY0--KEY3 register will need to be written. For 256-bit keys, KEY0--KEY7 will need to be written.

In order to prevent key stealing attacks by partial modification method, the engine ensures that once a secure key transfer has completed via the keystore, software can no longer explicitly configure/modify the key. This status is provided by the STATUS.KEYWR field. If this field is 0, then software is allowed to write key data. If this field is 1, then software is not allowed to write key data. In order to allow software to write key data, the module has to be reset. The reset operation clears existing key data before new key data can be written by software.

### 13.2.2 Writing Input Data

Input data is written into the engine either through the DATA0, DATA1, DATA2, and DATA3 registers or through the DATA\_IN register. If DMA is not being used to automate the input/output transfers (DMA\_HS is 0), then CPU software can perform the 128-bit data input by writing 32-bit data to each of the registers DATA0, DATA1, DATA2 and DATA3 in sequence.

If DMA is being used to automate the input/output transfers (DMA\_HS is 1), then the DMA channel that is associated with DMA Trigger 0 event must be configured to perform four 32-bit writes to the DATA\_IN register.

### 13.2.3 Reading Output Data

Output data is read from the engine either via the DATA0/1/2/3 registers or via the DATA\_OUT register. If DMA is not being used to automate the input/output transfers (DMA\_HS is 0), then CPU software can read

out the 128-bit data output by reading 32-bit data from each of DATA0, DATA1, DATA2 and DATA3 registers in sequence.

If DMA is being used to automate the input/output transfers (DMA\_HS is 1), then the DMA channel that is associated with DMA Trigger 1 event will need to be configured to perform 4 32-bit reads from the DATA\_OUT register.

### 13.2.4 Operation Descriptions

Both single block and block cipher mode operations are configured by writing the appropriate context to the AESADV registers. Independently, the input and output data can be transferred via CPU software or via DMA.

Block cipher modes are used to implement the ECB, CBC, OFB, and CFB block cipher modes using AES as the underlying block cipher. These modes work together with the DMA using the DMA triggers to support easy and fast encryption or decryption of more than 128 bits.

#### 13.2.4.1 Single Block Operation

A single 128-bit block of data can be encrypted or decrypted by first configuring the context registers and then initiating input data transfer. The following pseudo code describes the actions that are typically executed by CPU software for a basic encryption operation with 128-bit key.

```
wait AES_CTRL.CNTXT_RDY == '1' // wait for CNTXT_RDY to become 1
wait AES_CTRL.INPUT_RDY == '10' // wait for INPUT_RDY to become 1
write AES_KEY0 // first 32 bits of key
write AES_KEY1 // next 32 bits of key
write AES_KEY2 // next 32 bits of key
write AES_KEY3 // final 32 bits of key
write AES_CTRL.SAVE_CNTXT == '0' // clear AES save context
write AES_CTRL.KEYSIZE == '01' // write AES 128 bit mode
write AES_CTRL.DIR == '1' //write AES encrypt mode
write AES_DATA0 // write 32-bit data LSW to supply 128-bit block
write AES_DATA1 // write 32-bit data (LSW + 1) to supply 128-bit block
write AES_DATA2 // write 32-bit data (LSW + 2) to supply 128-bit block
write AES_DATA3 // write 32-bit data MSW to supply 128-bit block
wait AES_CTRL.OUTPUT_RDY == '1' // wait for OUTPUT_RDY to become 1
read AES_DATA0 // read 32-bit data LSW to read out 128-bit encrypted data
read AES_DATA1 // read 32-bit data (LSW + 1) to read out 128-bit encrypted data
read AES_DATA2 // read 32-bit data (LSW + 2) to read out 128-bit encrypted data
read AES_DATA3 // read 32-bit data MSW to read out 128-bit encrypted data
```

#### 13.2.4.2 Electronic Codebook (ECB) Mode

The electronic codebook (ECB) cipher is the simplest block cipher mode. The plaintext data is divided into 128-bit blocks, and each block is encrypted and decrypted independently from any other block. The ECB cipher is shown in [Figure 13-2](#). Note that each 128-bit data block can be encrypted or decrypted individually without any knowledge of the other blocks of plaintext or ciphertext.

While ECB is simple to understand and implement, it has a key disadvantage: the same 128-bit plaintext block is always encrypted into the same ciphertext block, allowing patterns in the ciphertext to be detected.

**Figure 13-2. ECB Cipher**

The AESADV accelerator supports automated encryption and decryption of more than 128 bits of data in ECB block cipher mode either through interrupts or through the use of DMA. Software interrupt-based multi-block handling uses the AESADV interrupt condition reported in the CPU\_INT.IIDX.STAT field. If this field reads 0x2 (INPUTRDY), then the next block of input can be written (as 4 32-bit writes to DATA0/1/2/3). If this field reads 0x1 (OUTPUTRDY), then the output block can be read (as 4 32-bit reads from DATA0/1/2/3).

In DMA mode, ECB uses two DMA channels. Channel bound to DMA\_TRIG0 is the input channel. Channel bound to DMA\_TRIG1 is the output channel. The channels need to be configured to perform one 32-bit read/write per trigger.

#### 13.2.4.2.1 ECB Encryption

ECB mode encryption of  $N$  blocks of plaintext into  $N$  blocks of ciphertext without CPU interaction is achieved through the use of 2 DMA channels (referred to as DMA\_A and DMA\_B). To implement ECB encryption follow these steps:

1. Configure Output DMA channel for saving ciphertext:
  - a. Set DMA channel trigger selection to AES Trig1
  - b. Set DMA channel source address to DATA\_OUT
  - c. Set DMA channel destination address to location where ciphertext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N*4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AESADV event registers, unmask Trig1 in the IMASK register of DMA\_TRIG1
2. Configure Input DMA channel for loading plaintext:
  - a. Set DMA channel trigger selection to AES Trig0
  - b. Set DMA channel source address to location where plaintext is stored (for example, SRAM)
  - c. Set DMA channel destination address to DATA\_IN
  - d. Set DMA channel transfer size to  $N*4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig0 in the IMASK register of DMA\_TRIG0
3. Configure and enable the DMA interrupt for the Output DMA channel in the DMA controller
4. Configure DMA\_HS for DMA based handshake: set  $DMA\_HS[DMA\_DATA\_ACK] = 1$

5. Configure the CTRL register for block cipher encryption mode for ECB:
  - a. Set key size in CTRL[KEY\_SIZ]
  - b. Select Direction for Encryption by CTRL[DIR] = 1
  - c. Select ECB mode by setting rest of the bits in CTRL to 0
6. Load key as described in [Section 13.2.1](#).
7. Start encryption by writing the number of bytes  $N \times 4$  to AES C\_LENGTH\_0 and C\_LENGTH\_1 registers
8. Wait for the DMA channel interrupt which indicates completion of the entire operation. The ciphertext output will be stored in the location configured in step 1c.

**13.2.4.2.2 ECB Decryption**

ECB Mode Decryption configuration is nearly identical to ECB Mode Encryption. The only difference is that the direction bit (CTRL.DIR) has to be set to 0.

**13.2.4.3 Cipher Block Chaining (CBC) Mode**

The cipher block chaining (CBC) cipher mode builds upon the ECB cipher mode to make the ciphertext output for each block dependent not only on the plaintext and the cipher key  $k$ , but also upon the ciphertext of the previous block. The CBC cipher is shown in [Figure 13-3](#). Like ECB mode, the plaintext data is divided into 128-bit blocks. Unlike ECB mode, in CBC mode each new plaintext block is bit-wise XORed with the previous ciphertext block to create the input to the AES block cipher.

In CBC mode, an unpredictable initialization vector (IV) must be provided. The initialization vector is XORed with the first plaintext block, as there is no "previous" ciphertext block to XOR the first plaintext block with.

**Figure 13-3. CBC Cipher**

The AESADV accelerator supports automated CBC mode operation of more than 128 bits of data either through interrupts or through the use of DMA. Software interrupt-based multi-block handling uses the AES interrupt

condition reported in the CPU\_INT.IIDX.STAT field. If this field reads 0x2 (INPUTRDY), then the next block of input can be written (as 4 32-bit writes). If this field reads 0x1 (OUTPUTRDY), then the output block can be read (as 4 32-bit reads).

In DMA mode, CBC utilizes two DMA channels. Channel bound to DMA\_TRIG0 is the input channel. Channel bound to DMA\_TRIG1 is the output channel. The channels need to be configured to perform one 32-bit read/write per trigger.

#### 13.2.4.3.1 CBC Encryption

CBC mode encryption of  $N$  blocks of plaintext into  $N$  blocks of ciphertext without CPU interaction is achieved through the use of 2 DMA channels. To implement CBC encryption follow these steps:

1. Configure Output DMA channel for saving ciphertext:
  - a. Set DMA channel trigger selection to AES Trig1
  - b. Set DMA channel source address to DATA\_OUT
  - c. Set DMA channel destination address to location where ciphertext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N*4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig1 in the IMASK register of DMA\_TRIG1
2. Configure Input DMA channel for loading plaintext:
  - a. Set DMA channel trigger selection to AES Trig0
  - b. Set DMA channel source address to location where plaintext is stored (for example, SRAM)
  - c. Set DMA channel destination address to DATA\_IN
  - d. Set DMA channel transfer size to  $N*4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig0 in the IMASK register of DMA\_TRIG0
3. Configure and enable the DMA interrupt for the Output DMA channel in the DMA controller
4. Configure DMA\_HS for DMA based handshake: set DMA\_HS[DMA\_DATA\_ACK] = 1
5. Load key as described in [Section 13.2.1](#)
6. Load Initialization vector (IV) by writing to IV0, IV1, IV2 and IV3 registers
7. Configure the CTRL register for block cipher encryption mode for CBC
  - a. Select key size via CTRL[KEY\_SIZ]
  - b. Select Direction for Encryption by CTRL[DIR] = 1
  - c. Select CBC mode by setting CTRL[CBC]=1
8. Start encryption by writing the number of bytes  $N*4$  to AES C\_LENGTH\_0 and C\_LENGTH\_1 registers
9. Wait for the DMA channel interrupt that indicates completion of the entire operation. The ciphertext output is stored in the location configured in step 1c.

#### 13.2.4.3.2 CBC Decryption

CBC-mode decryption is nearly identical to CBC-mode encryption setup, with the exception of configuring CTRL[DIR] = 0 for decryption.

#### 13.2.4.4 Output Feedback (OFB) Mode

The output feedback mode leverages an initialization vector (IV) to generate a keystream by repeatedly encrypting the IV with the cipher key. The output ciphertext is obtained by XORing plaintext with the encrypted and re-encrypted versions of the initialization vector. The OFB cipher is shown in [Figure 13-4](#).

In OFB mode, the initialization vector must be a nonce (number used once). To prevent loss of confidentiality, each IV must only be used one time with a given key, and any value passed into the cipher  $E_k$  for a given key  $k$  must not be used as an initialization vector with the same key  $k$ .

**Note**

As OFB is a stream cipher, the AES block function is used in the forward (encryption) mode when performing OFB encryption or OFB decryption. When decrypting, the keystream is simply regenerated again to be XORed with the ciphertext, giving back the plaintext.

**Figure 13-4. OFB Cipher**

The AES accelerator supports automated OFB mode operation of more than 128 bits of data either through interrupts or through the use of DMA. Software interrupt-based multi-block handling uses the AES interrupt condition reported in the CPU\_INT.IIDX.STAT field. If this field reads 0x2 (INPUTRDY), then the next block of input can be written (as 4 32-bit writes). If this field reads 0x1 (OUTPUTRDY), then the output block can be read (as 4 32-bit reads).

In DMA mode, OFB utilizes two DMA channels. Channel bound to DMA\_TRIG0 is the input channel. Channel bound to DMA\_TRIG1 is the output channel. The channels need to be configured to perform one 32-bit read/write per trigger.

**13.2.4.4.1 OFB Encryption**

OFB mode encryption of  $N$  blocks of plaintext into  $N$  blocks of ciphertext without CPU interaction is achieved through the use of 2 DMA channels. To implement OFB encryption follow these steps:

1. Configure Output DMA channel for saving ciphertext:
  - a. Set DMA channel trigger selection to AES Trig1
  - b. Set DMA channel source address to DATA\_OUT
  - c. Set DMA channel destination address to location where ciphertext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N*4$

- e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig1 in the IMASK register of DMA\_TRIG\_DATAOUT
2. Configure Input DMA channel for loading plaintext:
    - a. Set DMA channel trigger selection to AES Trig0
    - b. Set DMA channel source address to location where plaintext is stored (for example, SRAM)
    - c. Set DMA channel destination address to DATA\_IN
    - d. Set DMA channel transfer size to  $N*4$
    - e. Set DMA channel mode to single transfer mode
    - f. In the AES event registers, unmask Trig0 in the IMASK register of DMA\_TRIG0
  3. Configure and enable the DMA interrupt for the Output DMA channel in the DMA controller
  4. Configure DMA\_HS for DMA based handshake: set DMA\_HS[DMA\_DATA\_ACK] = 1
  5. Load key as described in [Section 13.2.1](#)
  6. Load Initialization vector (IV) by writing to IV0, IV1, IV2 and IV3 registers
  7. Configure the CTRL register for block cipher encryption mode for OFB
    - a. Select key size via CTRL[KEY\_SIZ]
    - b. Select Direction for Encryption by CTRL[DIR] = 1
    - c. Select OFB mode by setting CTRL[OFB\_GCM\_CCM\_CONT]=1
  8. Start encryption by writing number of bytes  $N*4$  to AES C\_LENGTH\_0 and C\_LENGTH\_1 registers
  9. Wait for the DMA channel interrupt which indicates completion of the entire operation. The ciphertext output will be stored in the location configured in step 1c.

---

**Note**

OFB\_GCM\_CCM\_CONT bit has dual use. When CCM/GCM modes are not selected, then this bit serves to select OFB mode.

---

#### 13.2.4.4.2 OFB Decryption

OFB-mode decryption is nearly identical to OFB-mode encryption setup, with the exception of configuring CTRL[DIR] = 0 for decryption.

#### 13.2.4.5 Cipher Feedback (CFB) Mode

The cipher feedback (CFB) mode is similar to the [output feedback \(OFB\) mode](#), with the key difference being that the input block to the block cipher  $E$  used to generate the key stream is taken from the previous ciphertext block (after being XORed with the plaintext), vs. taken before being XORed with the plaintext (as in the case of OFB). As a result, the keystream is dependent upon the plaintext, which is not true of OFB. The CFB cipher is shown in [Figure 13-5](#).

Like OFB, CFB requires an initialization vector (IV). In CFB mode, the initialization vector (IV) must be unpredictable.

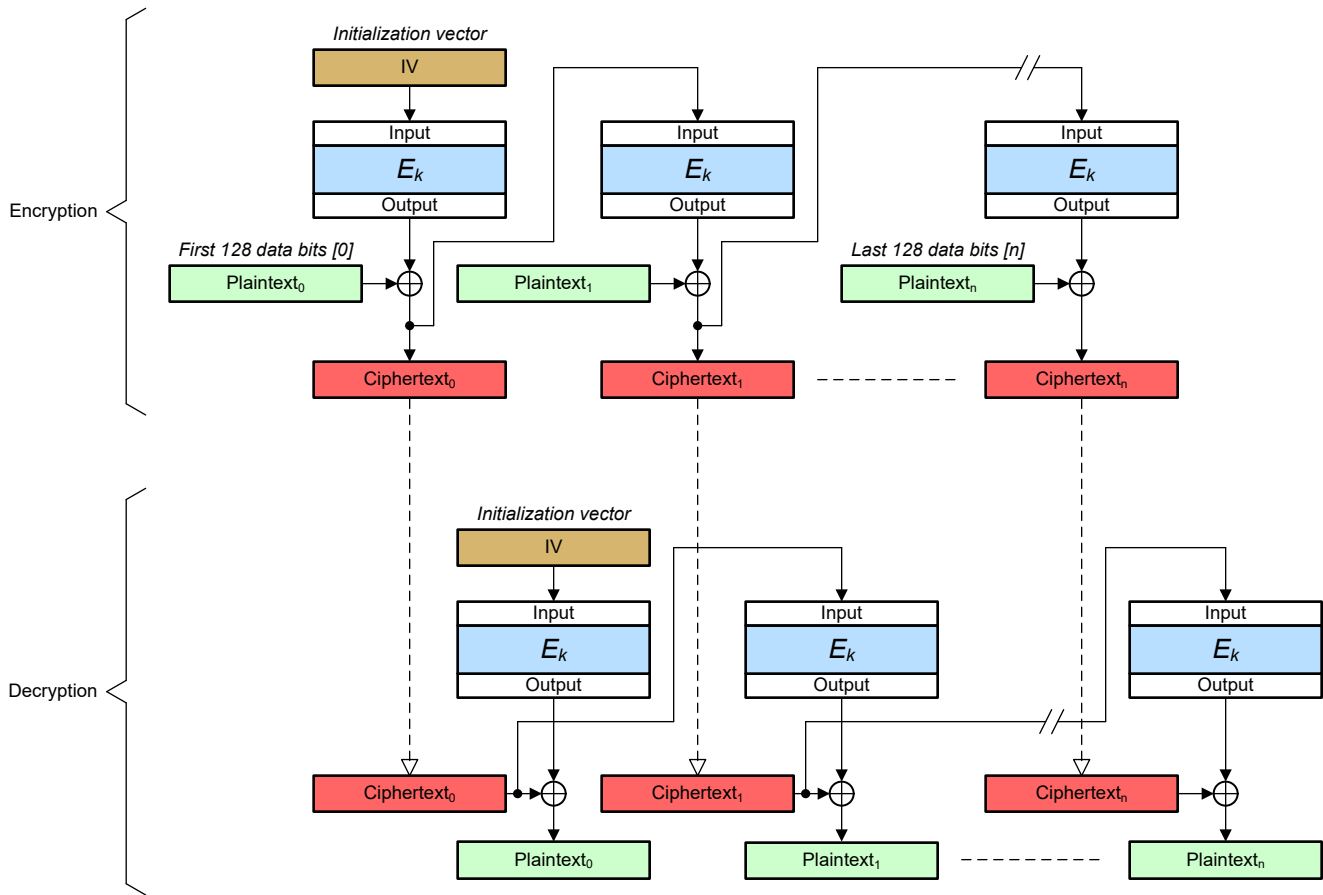

Figure 13-5. CFB Cipher

The AESADV accelerator supports automated CFB mode operation of more than 128 bits of data either through interrupts or through the use of DMA. Software interrupt-based multi-block handling uses the AES interrupt condition reported in the CPU\_INT.IIDX.STAT field. If this field reads 0x2 (INPUTRDY), then the next block of input can be written (as 4 32-bit writes). If this field reads 0x1 (OUTPUTRDY), then the output block can be read (as 4 32-bit reads).

In DMA mode, CFB utilizes two DMA channels. Channel bound to DMA\_TRIG\_DATAIN is the input channel. Channel bound to DMA\_TRIG\_DATAOUT is the output channel. The channels need to be configured to perform one 32-bit read/write per trigger.

#### 13.2.4.5.1 CFB Encryption

CFB mode encryption of  $N$  blocks of plaintext into  $N$  blocks of ciphertext without CPU interaction is achieved through the use of 2 DMA channels. To implement CFB encryption follow these steps:

1. Configure Output DMA channel for saving ciphertext:
  - a. Set DMA channel trigger selection to AES Trig1
  - b. Set DMA channel source address to DATA\_OUT
  - c. Set DMA channel destination address to location where ciphertext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N*4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig1 in the IMASK register of DMA\_TRIG\_DATAOUT
2. Configure Input DMA channel for loading plaintext:
  - a. Set DMA channel trigger selection to AES Trig0
  - b. Set DMA channel source address to location where plaintext is stored (for example, SRAM)
  - c. Set DMA channel destination address to DATA\_IN

- d. Set DMA channel transfer size to  $N \times 4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig0 in the IMASK register of DMA\_TRIG0
3. Configure and enable the DMA interrupt for the Output DMA channel in the DMA controller
  4. Configure DMA\_HS for DMA based handshake: set DMA\_HS[DMA\_DATA\_ACK] = 1
  5. Load key as described in [Section 13.2.1](#)
  6. Load Initialization vector (IV) by writing to IV0, IV1, IV2 and IV3 registers
  7. Configure the CTRL register for block cipher encryption mode for CFB
    - a. Select key size via CTRL[KEY\_SIZ]
    - b. Select Direction for Encryption by CTRL[DIR] = 1
    - c. Select CFB mode by setting CTRL[CFB]=1
    - d. Select feedback width by setting CTRL[CTR\_WIDTH]
      - i. 00b - CFB-128
      - ii. 01b - CFB-1
      - iii. 10b - CFB-8
  8. Start encryption by writing number of bytes  $N \times 4$  to AES C\_LENGTH\_0 and C\_LENGTH\_1 registers
  9. Wait for the DMA channel interrupt that indicates completion of the entire operation. The ciphertext output is stored in the location configured in step 1c.

#### 13.2.4.5.2 CFB Decryption

CFB-mode decryption is nearly identical to CFB-mode encryption setup, with the exception of configuring CTRL[DIR] = 0 for decryption.

#### 13.2.4.6 Counter (CTR) Mode

The counter mode leverages a nonce (number used once) and a counting integer to generate a keystream by appending the counter to the nonce and encrypting the combined nonce || counter value with the cipher key.

The nonce must only be used once with a given key  $k$ . The counter value can start from any value and is incremented for each 128-bit block of data.

The keystream is derived by encrypting the nonce || counter value for each 128-bit data block with the cipher key  $k$ . The output ciphertext is then obtained by XORing the plaintext with the encrypted nonce || counter value for each data block. The CTR cipher is shown in [Figure 13-6](#).

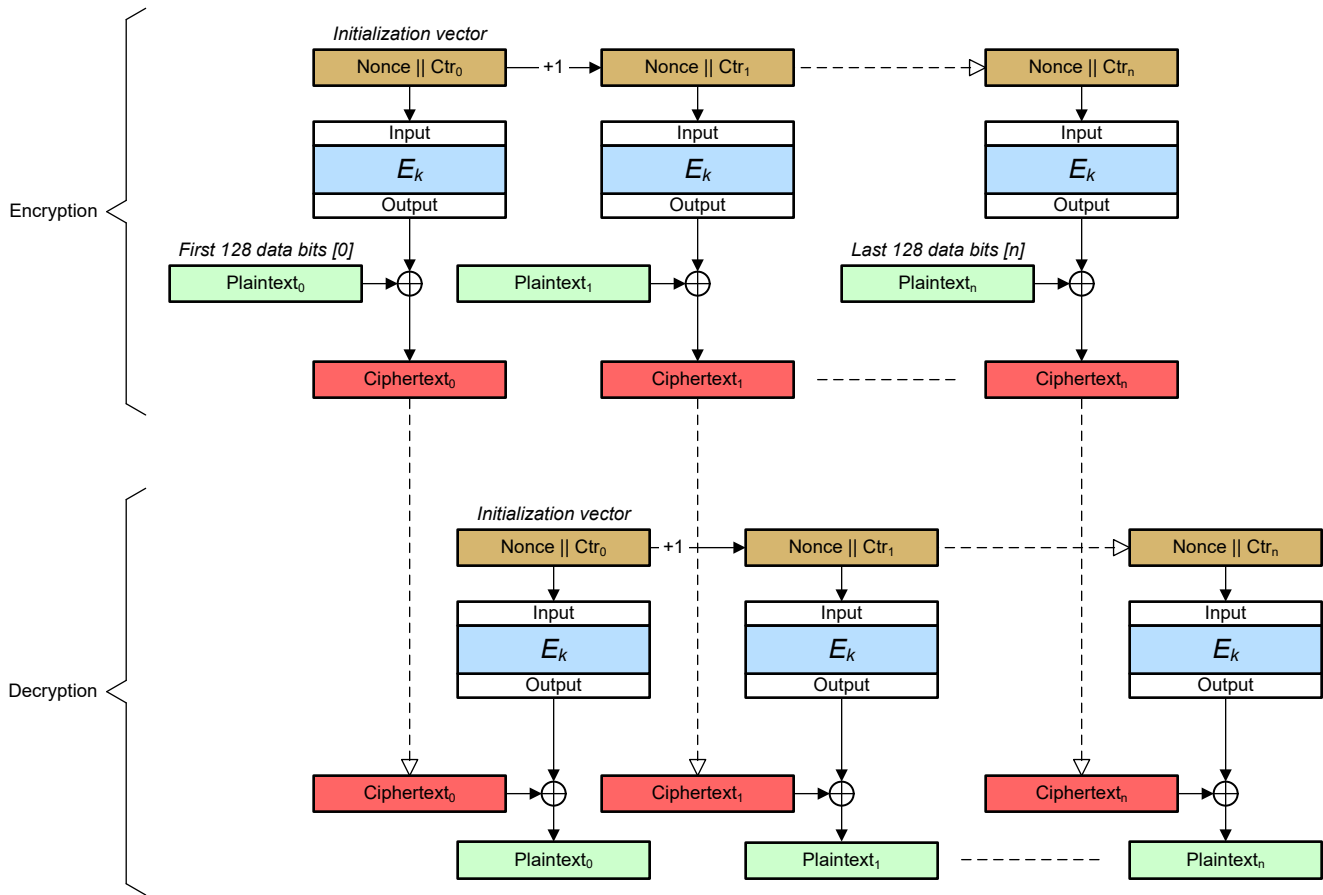

Figure 13-6. CTR Cipher

The AES accelerator implements logic and storage for incrementing and storing nonce || counter from one block to the next.

### 13.2.4.6.1 CTR Encryption

CTR mode encryption of  $N$  blocks of plaintext into  $N$  blocks of ciphertext without CPU interaction is achieved through the use of 2 DMA channels. To implement CTR encryption follow these steps:

1. Configure Output DMA channel for saving ciphertext:
  - a. Set DMA channel trigger selection to AES Trig1
  - b. Set DMA channel source address to DATA\_OUT
  - c. Set DMA channel destination address to location where ciphertext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N*4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig1 in the IMASK register of DMA\_TRIG\_DATAOUT
2. Configure Input DMA channel for loading plaintext:
  - a. Set DMA channel trigger selection to AES Trig0
  - b. Set DMA channel source address to location where plaintext is stored (for example, SRAM)
  - c. Set DMA channel destination address to DATA\_IN
  - d. Set DMA channel transfer size to  $N*4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig0 in the IMASK register of DMA\_TRIG0
3. Configure and enable the DMA interrupt for the Output DMA channel in the DMA controller
4. Configure DMA\_HS for DMA based handshake: set  $DMA\_HS[DMA\_DATA\_ACK] = 1$
5. Load key as described in [Section 13.2.1](#)

6. Load Initialization vector (IV) by writing to IV0, IV1, IV2 and IV3 registers
7. Configure the CTRL register for block cipher encryption mode for CTR
  - a. Select key size via CTRL[KEY\_SIZ]
  - b. Select Direction for Encryption by CTRL[DIR] = 1
  - c. Select CTR mode by setting CTRL[CTR]=1
  - d. Select CTR width by setting CTRL[CTR\_WIDTH]
    - i. 00b -CTR32
    - ii. 01b -CTR64
    - iii. 10b -CTR96
    - iv. 11b -CTR128
8. Start encryption by writing number of bytes  $N \times 4$  to AES C\_LENGTH\_0 and C\_LENGTH\_1 registers
9. Wait for the DMA channel interrupt which indicates completion of the entire operation. The ciphertext output will be stored in the location configured in step 1c.

#### 13.2.4.6.2 CTR Decryption

CTR-mode decryption is nearly identical to CTR-mode encryption setup, with the exception of configuring CTRL[DIR] = 0 for decryption.

#### 13.2.4.7 Galois Counter (GCM) Mode

A GCM protocol operation is a combined operation, consisting of encryption/decryption and authentication. Figure 13-7 illustrates an overview of the GCM operation.

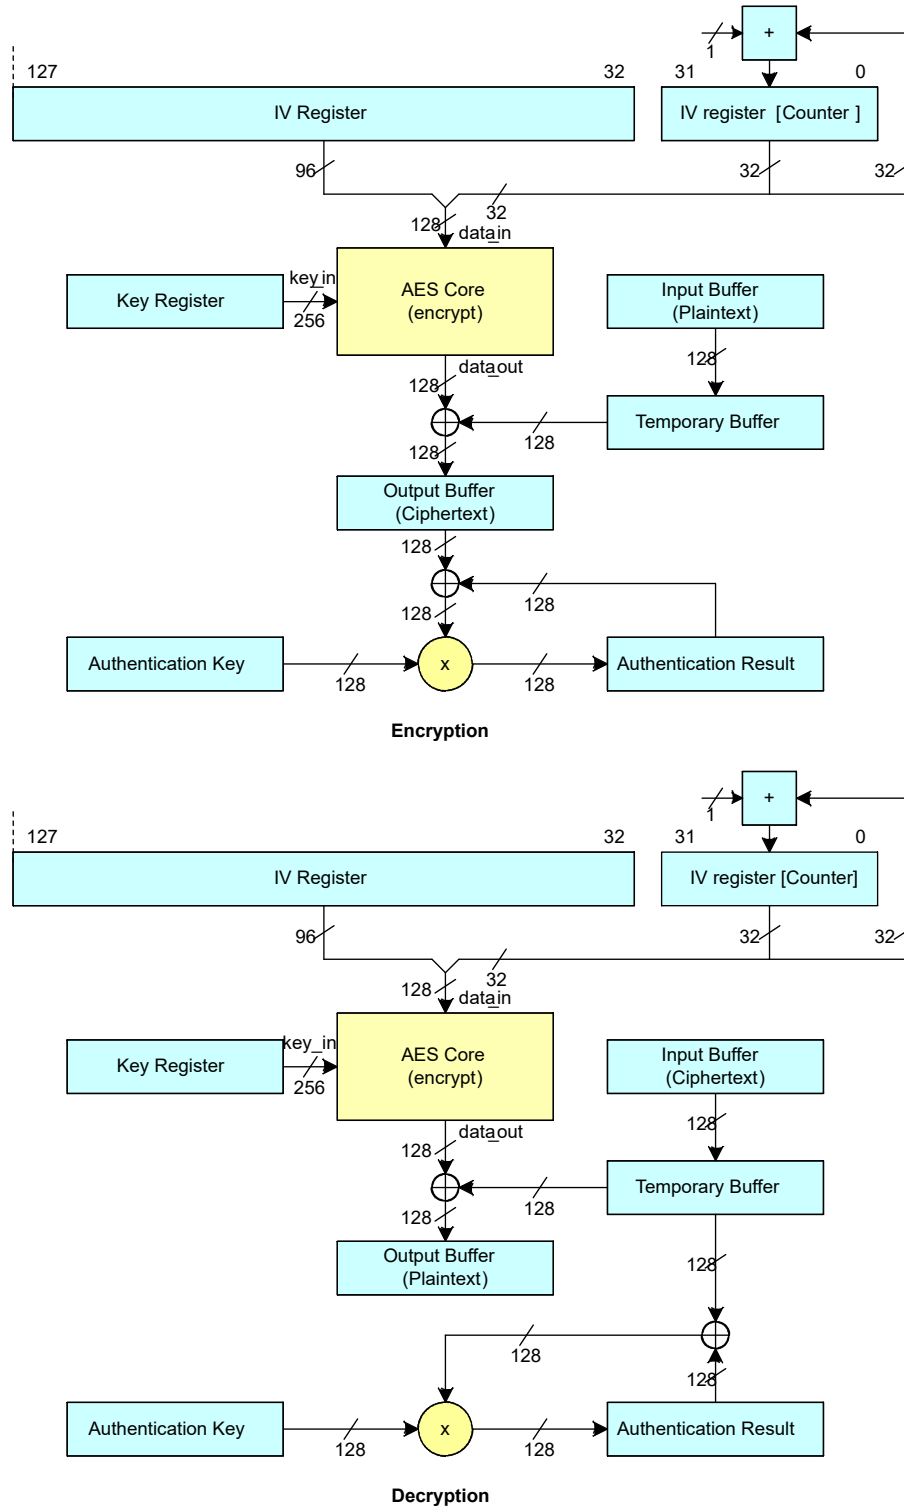

Figure 13-7. GCM Protocol Operation

A part of the input data stream can be authenticated only, while normally most of the input data is encrypted/decrypted and authenticated. The authentication only data always needs to be in front of the data that requires encryption. Within GCM, the authentication only data is called the AAD (Additional Authentication Data). The AAD is fetched independently of the other data.

The intermediate (temp) result data is used as input for the remaining authentication operation. Since the authentication operation does not require the encryption core but only the polynomial multiplication, both encryption/decryption and authentication are performed in parallel. After encryption of the last data block, an additional polynomial multiplication and encryption are required to respectively authenticate a 128-bit length vector and finally encrypt the authentication result.

**Figure 13-8. GCM Operation on a Block**

GMAC operations, as specified in [NIST-SP800-38D], are also supported via the GCM operation. GMAC is a special use of GCM where no crypto data is processed and only AAD data is provided to produce a MAC of the input data. The crypto data length is set to zero for this case.

Figure 13-8 illustrates the operations performed in one round. In one round of a GCM operation for both encryption and decryption, a 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted the same way as CTR mode, by XOR-ing the crypto output with the input. After the encryption/decryption, the ciphertext is XOR-ed with the intermediate authentication result. The XOR-ed result is used as input for the polynomial multiplication to create the next (intermediate) authentication result.

#### 13.2.4.7.1 GHASH Operation

For GHASH operations, the engine performs a modular polynomial multiplication in the GF(2128) field. The result is XOR-ed with the encrypted GCM initialization vector (referred to as 'Y0-encrypted'). Y0-encrypted is only relevant when the engine is performing a complete GCM operation, therefore in other modes the value of Y0-encrypted is forced to zero.

Also, for GCM mode only, the GCM 'Hash key' or 'H' input can be pre-calculated and supplied to the engine directly, or it can be calculated by the engine internally, by encrypting the value '0', using the encryption key.

#### 13.2.4.7.2 GCM Operating Modes

For GCM three cases need to be distinguished.

- The first one is Autonomous GCM Mode where both H and Y0-encrypted are calculated internally. This mode requires that a 128-bit Y0 be provided to the core via the IV together with the mode.

---

#### Note

GCM mode bits must be set to 2'b11.

- The second case is the scenario where H is pre-calculated and Y0 still needs to be encrypted by the engine on a per packet basis. This can be useful when multiple packets use the same AES-key. Since H is constant for all packets using the same key, a pre-calculation saves cycles for each packet using that key. H can simply be calculated by performing a basic AES-ECB encryption with the AES-key and a data block containing all zeros or more formally:  $H = E(K, \{0\})$ . Once H is calculated, it can be loaded with the control data every time a packet is processed that requires the same AES-key.

---

#### Note

GCM mode bits must be set to 2'b10.

- In the last case, neither H nor Y0-encrypted are calculated by the core. In this case, Y0-encrypted is forced to zeros, such that the hash result is not encrypted but provided plain via the TAG output registers. This scenario can be selected if a hash (GHASH) only operation needs to be performed. A scenario where this setting can be used is GCM IV-truncation. The GCM specification [GCM] allows an IV that has a length other than 96-bits. In this case, a basic GHASH operation needs to be performed to calculate a 128-bit Y0. For a basic GHASH operation, H needs to be pre-calculated (as explained in the previous paragraph). If H is available, the GHASH operation is similar to that of a general GCM operation with H pre-calculated, only the crypto input data will not be encrypted or decrypted.

---

#### Note

In the default case a 96-bit IV is combined with a 32-bit counter to create a 128-bit Y0 (meaning:  $Y0 = \{IV || 031 || 1\}$ ).

---

#### Note

GCM mode bits must be set to 2'b01.

#### 13.2.4.7.2.1 Autonomous GCM Operation

In this mode, the engine calculates H and Y0-encrypted internally. At the high-level, the programming involves these steps:

- Provide GCM context (key, IV, lengths and mode).
- Provide AAD data (and wait for calculation of H and encryption of Y0).

- Provide next AAD data.
- Provide last AAD data.
- Provide first crypto data.
- Provide next crypto data.
- Read result data and provide next crypto data.
- ...
- Read result data and provide last crypto data.
- Read result data.
- Read result data.
- Read authentication result (TAG).

To implement GCM encryption over N blocks of plaintext and M blocks of AAD, follow these steps:

1. Configure Output DMA channel for saving ciphertext:
  - a. Set DMA channel trigger selection to AES Trig1
  - b. Set DMA channel source address to DATA\_OUT
  - c. Set DMA channel destination address to location where ciphertext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N \times 4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig1 in the IMASK register of DMA\_TRIG\_DATAOUT
2. Configure Input DMA channel for loading AAD and plaintext:
  - a. Set DMA channel trigger selection to AES Trig0
  - b. Set DMA channel source address to location where plaintext is stored (for example, SRAM)
  - c. Set DMA channel destination address to DATA\_IN
  - d. Set DMA channel transfer size to  $(N+M) \times 4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig0 in the IMASK register of DMA\_TRIG0
3. Configure and enable the DMA interrupt for the Output DMA channel in the DMA controller
4. Configure DMA\_HS for DMA based handshake: set DMA\_HS[DMA\_DATA\_ACK] = 1
5. Load Encryption/Decryption key as described in [Section 13.2.1](#)
6. Load GCMCCM\_TAGn (0,1,2,3) registers with 0s.
7. Load Initialization vector (IV) by writing to IV0, IV1, IV2 and IV3 registers
8. Configure the CTRL register for block cipher encryption mode for GCM
  - a. Select key size via CTRL[KEY\_SIZ]
  - b. Select Direction for Encryption by CTRL[DIR] = 1
  - c. Select GCM mode by setting CTRL[GCM] = 3
  - d. Select CTR mode by setting CTRL[CTR] = 1
  - e. Enable saving of TAG by setting CTRL[SAVE\_CNTXT] = 1
9. Write encryption/decryption byte count  $N \times 4$  to AES C\_LENGTH\_0 and C\_LENGTH\_1 registers
10. Write authentication data (AAD) byte count  $M \times 4$  to AES AAD\_LENGTH register
11. Wait for the DMA output channel interrupt to indicate completion of the entire operation. The output is stored started at the location configured in step 1c.
12. Read out the final TAG from the TAG0, TAG1, TAG2, TAG3 registers

---

**Note**

The AAD and cryptographic data can end misaligned. The CPU must pad both to a 128-bit boundary with zeroes. More formally, the AAD and crypto data padding must satisfy the bit string:  $0^n$ , with  $0 \leq n \leq 127$ . This means that the AAD must be provided as separate blocks to the engine, such that the cryptographic data starts 128-bit aligned. If the AAD/cryptographic data stream is 128-bit aligned no padding is required. Because the engine only supports bytes,  $n$  must be such that  $(n \text{ MOD } 8) = 0$ . Further, because a single DMA channel supplies both AAD and plaintext, the entire data must be organized contiguously in memory with the first  $M$  blocks of AAD followed by  $N$  blocks of plaintext. This memory contiguity restriction is not applicable when CPU software directly provides inputs via interrupt handling.

---

Do not load both length values with zeroes. If a data stream is done and the next data stream uses the same key and control, only the IV and length values need be re-loaded.

**13.2.4.7.2.1.1 GMAC**

GMAC is a special case of GCM wherein there is no payload ( $N=0$ ). AES `C_LENGTH_0` and `C_LENGTH_1` registers are set to 0 in this case.

**13.2.4.7.2.2 GCM With Pre-Calculations**

Pre-calculation of H:

1. Provide AES-ECB context (key and mode)
2. Provide zeros as data
3. Read result data (H)

IV truncation/pre-calculation (GHASH only operation):

- Provide GHASH context (H, lengths and mode)

---

**Note**

GHASH only:  $Y_0$ -encrypted forced to zero, H loaded, and no crypto mode selected

---

1. Provide IV-data-block
2. Provide next IV-data-block
3. Read dummy result and provide next IV-data-block
4. ...
5. Read dummy result data and provide last IV-data-block
6. Read dummy result data
7. Read dummy result data
8. Read authentication result (TAG... this data is  $Y_0$ )

GCM operation with pre-calculated H:

1. Provide GCM context (key,  $Y_0$  as IV, H, lengths and mode)
2. Provide AAD data (and wait for encryption of  $Y_0$ )
3. Provide next AAD data
4. Provide last AAD data
5. Provide first crypto data
6. Provide next crypto data
7. Read result data and provide next crypto data
8. ...
9. Read result data and provide last crypto data
10. Read result data
11. Read result data
12. Read authentication result (TAG)

For GCM with pre-calculated H, select GCM mode by setting CTRL[GCM] = 2

**13.2.4.7.2.3 GCM Operation With Precalculated H- and Y0-Encrypted Forced to Zero**

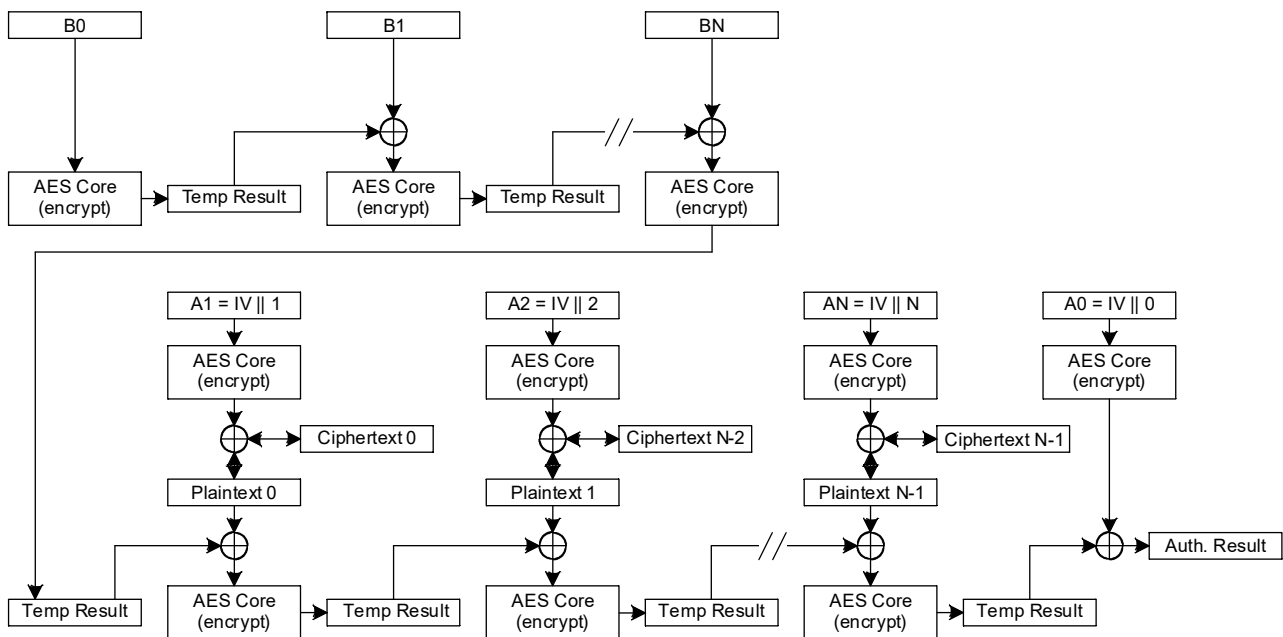

The outline of operations is listed below:

1. Provide GCM context (key, H, lengths and mode)
2. Provide AAD data
3. Provide next AAD data
4. Provide last AAD data
5. Provide first crypto data
6. Provide next crypto data
7. Read result data and provide next crypto data
8. ...
9. Read result data and provide last crypto data
10. Read result data
11. Read result data
12. Read plaintext authentication result

**13.2.4.8 Counter With Cipher Block Chaining Message Authentication Code (CCM)**

The CCM (Counter with CBC-MAC) protocol operation is a combined operation, consisting of encryption/decryption and authentication. Both the authentication and encryption/decryption operations use the crypto core; these are executed sequentially on the AES core. A part of the data stream can require authentication only. The authentication only data always needs to be in front of the data that requires encryption.

Figure 13-9 illustrates the CCM protocol. The authentication starts with the encryption of a pre-defined block B0. This block consists of flags, nonce and message length. The next blocks contain the authentication data length concatenated with the authentication only data. After processing the authentication only data, the encryption/decryption operations are performed, each followed by the related authentication of the plaintext data block (which equals the input in the case of encryption and the output in the case of decryption). The final authentication result needs to be encrypted using the output of the encryption of the IV block A0. This block contains the IV (consisting of flags and nonce) concatenated with the counter, which is zero for A0.

**Figure 13-9. CCM Protocol Operation**

Figure 13-10 shows one round of a CCM operation for both encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as CTR mode, by XOR-ing the crypto core output with the input. Directly after the encrypt-operation, the plaintext is XOR-ed with the intermediate authentication result. The XOR result is used as input for a second encrypt-operation to calculate the next (intermediate) authentication result.

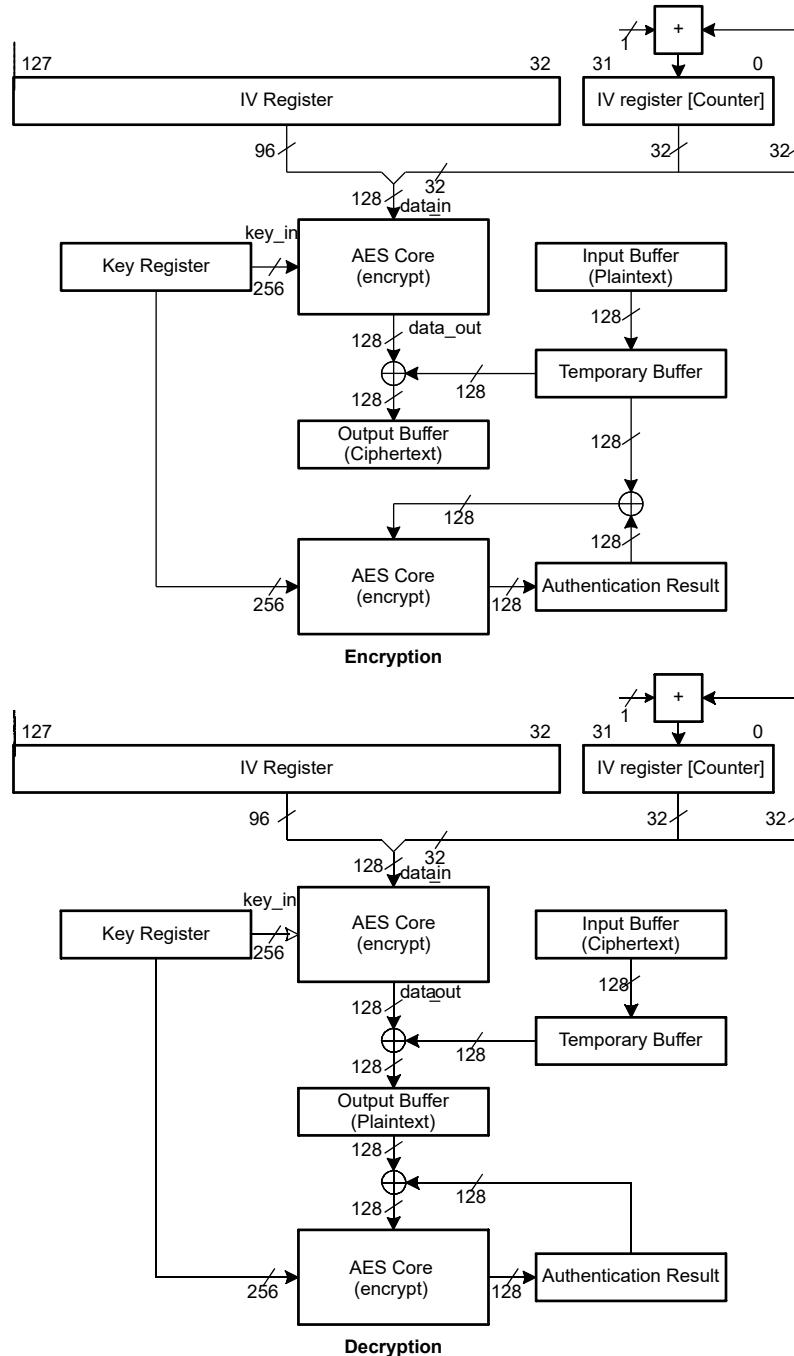

Figure 13-10. CCM Operation

13.2.4.8.1 CCM Operation

At the high-level, CCM operation is performed in the following sequence:

- Provide CCM context (key, IV including flags, lengths and mode)
- Provide hash only data
- Provide next hash only data
- Provide last hash only data
- Provide first crypto data
- Provide next crypto data
- Read result data and provide next crypto data
- ...
- Read result data and provide last crypto data
- Read result data
- Read result data
- Read authentication result (TAG)

The read/write of data can be managed via DMA or by CPU software.

To implement CCM encryption over N blocks of plaintext and M blocks of AAD, follow these steps:

1. Configure Output DMA channel for saving ciphertext:
  - a. Set DMA channel trigger selection to AES Trig1
  - b. Set DMA channel source address to DATA\_OUT
  - c. Set DMA channel destination address to location where ciphertext is to be stored (for example, SRAM)
  - d. Set DMA channel transfer size to  $N \times 4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig1 in the IMASK register of DMA\_TRIG\_DATAOUT
2. Configure Input DMA channel for loading AAD and plaintext:
  - a. Set DMA channel trigger selection to AES Trig0
  - b. Set DMA channel source address to location where plaintext is stored (for example, SRAM)
  - c. Set DMA channel destination address to DATA\_IN
  - d. Set DMA channel transfer size to  $(N+M) \times 4$
  - e. Set DMA channel mode to single transfer mode
  - f. In the AES event registers, unmask Trig0 in the IMASK register of DMA\_TRIG0
3. Configure and enable the DMA interrupt for the Output DMA channel in the DMA controller
4. Configure DMA\_HS for DMA based handshake: set  $\text{DMA\_HS}[\text{DMA\_DATA\_ACK}] = 1$
5. Load Encryption/Decryption key as described in [Section 13.2.1](#)
6. Load Initialization vector (IV) by writing to IV0, IV1, IV2 and IV3 registers (must contain the flags for the cryptographic operation and the NONCE bytes, for both authentication and encryption)
7. Configure the CTRL register for block cipher encryption mode for CCM
  - a. Select key size via  $\text{CTRL}[\text{KEY\_SIZ}]$
  - b. Select Direction for Encryption by  $\text{CTRL}[\text{DIR}] = 1$
  - c. Select CCM mode by setting  $\text{CTRL}[\text{CCM}] = 1$
  - d. Select CTR mode by setting  $\text{CTRL}[\text{CTR}] = 1$
  - e. Enable saving of TAG by setting  $\text{CTRL}[\text{SAVE\_CNTXT}] = 1$
  - f. Configure  $\text{CTRL}[\text{CCML}]$  -- CCM-L can be set to any value, representing a crypto data length field of CCML plus one Bytes.
  - g. Configure  $\text{CTRL}[\text{CTR\_WIDTH}]$  -- Note: CCM-L sets the actual counter field width in the IV register for CCM operations, in the range from 2 (CCM-L = 1) up to and including 8 (CCM-L = 7) Bytes. The actual counter width chosen with the CTR\_WIDTH must be long enough to cover this field. The counter field width must be chosen so that the counter cannot overflow.
  - h. Configure  $\text{CTRL}[\text{CCMM}]$  -- CCM-M can be set to any value and has no effect on the actual processing (other than being present in the special 'B0' block that is encrypted at the start of the operation). The CPU must select the valid TAG bytes from the 128-bit TAG (which are in the least significant  $2 * (\text{CCMM} + 1)$  Bytes).
8. Write encryption/decryption byte count  $N \times 4$  to AES C\_LENGTH\_0 and C\_LENGTH\_1 registers

9. Write authentication data (AAD) byte count  $M \times 4$  to AES AAD\_LENGTH register
10. Wait for the DMA output channel interrupt that indicates completion of the entire operation. The output is stored started at the location configured in step 1c.
11. Read out the final TAG from the TAG0/1/2/3 registers

#### Note

The AAD and cryptographic data can end misaligned. The CPU must pad both to a 128-bit boundary with zeroes. More formally, the AAD and crypto data padding must satisfy the bit string:  $0n$ , with  $0 \leq n \leq 127$ . This means that the AAD must be provided as separate blocks to the engine, such that the cryptographic data starts 128-bit aligned. If the AAD/cryptographic data stream is 128-bit aligned, no padding is required. Because the engine only supports bytes,  $n$  must be such that  $(n \text{ MOD } 8) = 0$ . Further, since a single DMA channel is used to supply both AAD and plaintext, the entire data must be organized contiguously in memory with the first  $M$  blocks of AAD followed by  $N$  blocks of plaintext. This memory contiguity restriction is not applicable when CPU software directly provides inputs via interrupt handling.

Do not write both length values with zeroes. If a data stream is done and the next data stream uses the same key and control, only the IV and length values need be re-loaded.

### 13.2.5 AES Events

The AES module contains three event publishers and no event subscribers. One event publisher (CPU\_INT) manages AES interrupt requests (IRQs) to the CPU subsystem through a static event route. The second, and third event publishers (DMA\_TRIG\_DATAIN, and DMA\_TRIG\_DATAOUT) can be used to publish AES events to the DMA through DMA event routes.

The AES events are summarized in [Table 13-2](#).

**Table 13-2. AES Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
CPU Interrupt Event	Publisher	AES	CPU Subsystem	Static route	CPU_INT registers	Fixed interrupt route from RTC to CPU
DMA Trigger Event 0	Publisher	AES	DMA	DMA route	DMA_TRIG 0 registers	DMA trigger 0: Data Input into engine
DMA Trigger Event 1	Publisher	AES	DMA	DMA route	DMA_TRIG 1 registers	DMA trigger 1: Data Output from engine

In general, the CPU interrupt event is used to communicate completion of an AES operation to the CPU, and the DMA triggers are used together to implement the block cipher modes (ECB, CBC, OFB, CFB, GCM/GMAC, CCM/CMAC) using the DMA together with the AES accelerator.

#### 13.2.5.1 CPU Interrupt Event Publisher (CPU\_EVENT)

The AESADV module provides four interrupt sources which can be configured to source a CPU interrupt event. The CPU interrupt events from the AES are given in [Table 13-3](#).

**Table 13-3. AES CPU Interrupt Event Conditions (CPU\_EVENT)**

Index (IIDX)	Name	Description
0	NO_INTR	No interrupt pending.
1	OUTPUTRDY	This indicates that the engine has an output available to be read out. This should not be used if DMA handshake is used (AES_DMA_HS.DMA_DATA_ACK set to 1)

**Table 13-3. AES CPU Interrupt Event Conditions (CPU\_EVENT) (continued)**

Index (IIDX)	Name	Description
2	INPUTRDY	This indicates that the engine can take new input. This should not be used if DMA handshake is used (AES_DMA_HS.DMA_DATA_ACK set to 1)
3	SAVEDCNTXTRDY	This bit indicates that an AES authentication TAG and/or IV block(s) is/are available for the CPU to retrieve. This bit is only asserted if the 'save_context' bit is set to '1b'. The bit is mutually exclusive with the 'context_ready' bit.
4	CNTXTRDY	This bit indicates that the context data registers can be overwritten, and the CPU is permitted to write new context.

The CPU interrupt event configuration is managed with the event management registers. See *Using Event Registers* for guidance on configuring these registers for CPU interrupts.

### 13.2.5.2 DMA Trigger Event Publisher (DMA\_TRIG\_DATAIN)

The AESADV module provides a trigger source which can be configured to source DMA trigger 0. The DMA0 trigger events from the AES are given in [Table 13-4](#). When the DMA0 channel is needed by the AES for block cipher operations, the DMA0 trigger should be unmasked in the IMASK register of DMA\_TRIG\_DATAIN and the DMA should be configured as needed to support the AES operation.

**Table 13-4. AES DMA Trigger 0 Event Conditions (DMA\_TRIG\_DATAIN)**

Index (IIDX)	Name	Description
0	NO_INTR	No DMA Trig0 event pending
1	TRIG0	DMA Trigger for Data Input

The DMA trigger 0 event configuration is managed with the DMA\_TRIG\_DATAIN event management registers. See *Using Event Registers* for guidance on configuring the event registers for DMA triggers.

### 13.2.5.3 DMA Trigger Event Publisher (DMA\_TRIG\_DATAOUT)

The AES module provides a trigger source which can be configured to source DMA trigger 1. The DMA1 trigger events from the AES are given in [Table 13-5](#). When the DMA1 channel is needed by the AES for block cipher operations, the DMA1 trigger should be unmasked in the IMASK register of DMA\_TRIG\_DATAOUT and the DMA should be configured as needed to support the AES operation.

**Table 13-5. AES DMA Trigger 1 Event Conditions (DMA\_TRIG\_DATAOUT)**

Index (IIDX)	Name	Description
0	NO_INTR	No DMA Trig1 Event Pending
1	TRIG1	DMA Trigger for Data Output

The DMA trigger 1 event configuration is managed with the DMA\_TRIG\_DATAOUT event management registers. See *Using Event Registers* for guidance on configuring the event registers for DMA triggers.

### 13.3 AESADV Registers

Table 13-6 lists the memory-mapped registers for the AESADV registers. All register offset addresses not listed in Table 13-6 should be considered as reserved locations and the register contents should not be modified.

**Table 13-6. AESADV Registers**

Offset	Acronym	Register Name	Group	Section
480h	CPU_CONNECT_0	CPU Connect		<a href="#">Go</a>
800h	PWREN	Power enable		<a href="#">Go</a>

### 5 PDBGCTL (Offset = 1018h) [Reset = 0000000h]

PDBGCTL is shown in [Figure 13-15](#) and described in [Table 13-12](#).

Return to the [Summary Table](#).

AES can not be halted when the core is halted. In order to halt the AES, the DMA shall be halted. This achieves the same effect as a halt feature in the AES: when the AES submits the next DMA trigger, if the DMA is halted, then the AES will automatically halt.

## 6 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 13-16](#) and described in [Table 13-13](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Table 13-97. CTRL Field Descriptions**

Bit	Field	Type	Reset	Description
31	CNTXT_RDY	R	1h	If '1b', this read-only status bit indicates that the context data registers can be overwritten, and the CPU is permitted to write the next context. 0h = Not ready 1h = Ready
30	SAVED_CNTXT_RDY	R	0h	If '1b', this read-only status bit indicates that an AES authentication TAG and/or IV block(s) is/are available for the Host to retrieve. This bit is only asserted if the 'save_context' bit is set to '1b'. The bit is mutually exclusive with the 'context_ready' bit. 0h = Not ready 1h = Ready
29	SAVE_CNTXT	R/W	0h	This bit is used to indicate that an authentication TAG or result IV needs to be stored as a result context. If this bit is set, context output DMA and/or interrupt will be asserted if the operation is finished, and related signals are enabled. Typically, this value must be set for authentication modes returning a TAG (CBC-MAC, GCM and CCM), or for basic encryption modes that require future continuation with the current result IV. If this bit is set, the engine will hold its full context until the TAG and/or IV registers are read. Only after reading the TAG or IV, a new DMA request for a new (input) context will be asserted. If this bit is not set, the engine will assert the context input DMA request signal directly after starting to process the last block with the current context. 0h = No effect 1h = Enable

**Table 13-97. CTRL Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
28	GCM_CONT	R/W	0h	Continue processing of an interrupted AES-GCM or AES-CCM operation in the crypto/payload phase. Set this write-only signal to '1b' together with the regular mode bit settings for a GCM or CCM operation, to continue processing from the next full block (128 bits) boundary. Before setting this bit all applicable context to resume processing must have been loaded into the engine: Keys, IV, intermediate digest/TAG and block counter. The mode can be written together with this bit, as it is part of the same register. 0h = No effect 1h = Enable
27	GET_DIGEST	R/W	0h	Interrupt processing and generate an intermediate digest during an AES-GCM or AES-CCM operation. Set this write-only signal to '1b' to interrupt GCM or CCM processing at the next full block (128 bits) boundary. An intermediate digest may be requested during the encryption/decryption data phase or in the AAD phase. Note: Interruption can only be done on full block (128 bits) boundaries. The minimum number of remaining bytes to resume and finalize the operation, must be greater than or equal to 1. 0h = No effect 1h = Enable
26	OFB_GCM_CCM_CONT	R/W	0h	This bit has a dual use, depending on the selection of CCM/GCM, see bits [18:16]. If CCM/GCM is not selected: If this bit is set to '1b', full block AES output feedback mode (OFB-128) is selected. If CCM/GCM is selected: Continue processing of an interrupted AES-GCM or AES-CCM operation in the AAD phase. Set this write-only signal to '1b' together with the regular mode bit settings for a GCM or CCM operation, to continue processing from the next full AAD block (128 bits) boundary. Before setting this bit all applicable context to resume processing must have been loaded into the engine: Keys, IV, intermediate digest/TAG, block counter and the CCM align data word (the latter is for CCM mode only). The mode can be written together with this bit, as it is part of the same register. 1h = Continue GCM/CCM processing in AAD phase
25	RESERVED	R	0h	
24-22	CCMM	R/W	0h	Defines "M" that indicates the length of the authentication field for CCM operations; the authentication field length equals two times (the value of CCM-M plus one). Note: The engine always returns a 128-bit authentication field, of which the M least significant bytes are valid. All values are supported. 0h = Length is 1 7h = Length is 8
21-19	CCML	R/W	0h	Defines "L" that indicates the width of the length field for CCM operations; the length field in bytes equals the value of CMM-L plus one. All values are supported. 0h = Length is 1 7h = Length is 8
18	CCM	R/W	0h	If set to '1b', AES-CCM is selected, this is a combined mode, using AES for both authentication and encryption. In addition to the CCM bit, the CTR mode bit must be set such that AES-CTR is enabled. Other combinations with CCM are invalid. 0h = Disable CBC mode 1h = Select CBC mode

**Table 13-97. CTRL Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17-16	GCM	R/W	0h	If not set to '00b', AES-GCM mode is selected, this is a combined mode, using the Galois field multiplier GF(2128) for authentication and AES-CTR mode for encryption, the bits specify the GCM mode: 01b = GHASH with H loaded and Y0-encrypted forced to zero 10b = GHASH with H loaded and Y0-encrypted calculated internally 11b = Autonomous GHASH (both H and Y0-encrypted calculated internally) Note: Besides GCM, the CTR mode bits must also be set to '1b' to enable GCM with AES-CTR; if the CTR bit is not set a GHASH (authentication) only operation is performed. A GHASH only operation is only allowed if the GCM mode is set to '01b' and the direction bit is set to '0b'. Other modes may not be selected in combination with GCM. Table 14 below shows the valid combinations for the GCM and CTR mode bits, all other options are invalid and must not be selected. 1h = GHASH with H loaded and Y0-encrypted forced to 0. 2h = GHASH with H loaded and Y0-encrypted calculated internally 3h = Autonomous GHASH (both H and Y0-encrypted calculated internally)
15	CBCMAC	R/W	0h	If set to '1b', AES-CBC MAC is selected, the Direction bit must be set to '1' for this mode. 0h = Disable CBC mode 1h = Select CBC mode
14-11	RESERVED	R	0h	
10	CFB	R/W	0h	If set to '1b', AES cipher feedback mode CFB is selected. Use the ctr_width field to specify the feedback width. 0h = Disable CBC mode 1h = Select CBC mode
9	ICM	R/W	0h	When the CFB bit is set, specifies the CFB mode feedback width: 0h = Disable CBC mode 1h = Select CBC mode
8-7	CTR_WIDTH	R/W	0h	When the CTR bit is set, specifies the counter width for AES-CTR mode. When the CFB bit is set, specifies the CFB mode feedback width: 0h = CFB-128 mode 1h = CFB-1 mode 2h = CFB-8 mode 3h = 128-bit counter
6	CTR	R/W	0h	If set to '1b', AES counter mode (CTR) is selected. Note: This bit must also be set for GCM and CCM, when encryption/decryption is required. 0h = Disable CBC mode 1h = Select CBC mode
5	CBC	R/W	0h	If set to '1b', cipher-block-chaining (CBC) mode is selected. 0h = Disable CBC mode 1h = Select CBC mode
4-3	KEYSIZE	R/W	0h	Specifies the encryption strength / key width 1h = 128-bit key 3h = 256-bit key
2	DIR	R/W	0h	Direction. If set to '1b' an encrypt operation is performed. If set to '0b' a decrypt operation is performed. Note: This bit must be written with a '1b' when CBC-MAC is selected. 0h = Decryption 1h = Encryption
1	INPUT_RDY	R	0h	Ready for input. If '1b', this read-only status bit indicates that the 16-byte input buffer is empty, and the CPU is permitted to write the next block of data. After reset, this bit is '0'. After writing a context, this bit will become '1b'. 0h = Not Ready 1h = Ready

**Table 13-97. CTRL Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	OUTPUT_RDY	R	0h	Output Ready. If '1b', this read-only status bit indicates that an AES output block is available for the CPU to retrieve. 0h = Not Ready 1h = Ready

#### 46 C\_LENGTH\_0 (Offset = 1154h) [Reset = 0000000h]

C\_LENGTH\_0 is shown in [Figure 13-56](#) and described in [Table 13-53](#).

Return to the [Summary Table](#).

Crypto data length (LSW). These registers buffer the Length values to the engine. While processing, the length values decrement to zero. If both lengths are zero, the data stream is finished, and a new context is requested. For basic AES modes (ECB/CBC/CTR/ICM/CFB/OFB), a crypto length of '0' can be written if the context DMA is disabled. Writing a zero length results in continued data requests until a new context is written. For the other modes (GCM and CCM) no (new) data requests are done if the length decrements to or equals zero. It is advised to write a new length per packet. If the length registers decrement to zero, no new data is processed until a new context or length value is written.

When writing a new context without writing the length registers, the length register values from the previous context are reused.

Bit	Field	Type	Reset	Description
31-0	DATA	W	0h	Bits [31:0] of the authentication length register store the authentication data length in bytes for combined modes only (GCM or CCM) Supported AAD-lengths for CCM are from 0 to (216-28) bytes. For GCM any value up to (232-1) bytes can be used. Once processing with this context is started, this length decrements to zero. A write to this register triggers the engine to start using this context for GCM and CCM.

#### 49 DATA0 (Offset = 1160h) [Reset = 0000000h]

DATA0 is shown in [Figure 13-59](#) and described in [Table 13-56](#).

Return to the [Summary Table](#).

Data input (LSW) / Data output (LSW). The Data Input/Output Registers buffer the input/output data blocks to/from the engine. Notice that the data input buffer (AES\_DATA\_IN\_n) and data output buffer (AES\_DATA\_OUT\_n) are mapped to the same address locations. Writes to these addresses load the Input Buffer while reads pull from the Output Buffer. Therefore, for write access, the data input buffer is written; for read access, the data output buffer is read. The data input buffer must be written prior to starting an operation. The data output buffer contains valid data on completion of an operation. All writes from, and reads to, these registers are tracked independently per direction. Therefore, any 128-bit data block can be split over multiple 32-bit word transfers, which can be mixed with other transfers over the external interface.

The cyclic redundancy check (CRC) accelerator generates signatures for a given data sequence based on the CRC16-CCITT polynomial or the CRC32-ISO3309 polynomial.

<b>14.1 CRC Overview</b> .....	<b>1075</b>
<b>14.2 CRC Operation</b> .....	<b>1075</b>
<b>14.3 CRCP0 Registers</b> .....	<b>1078</b>

## 14.1 CRC Overview

The CRC accelerator produces CRC signatures for given sequences of data. The CRC16-CCITT and CRC32-ISO3309 polynomial functions are supported. Identical input data sequences result in identical CRC signatures when the CRC is initialized with a fixed seed value. Different sequences of input data, in general, result in different signatures for a given CRC function.

	CRC	CRC-P
Support for CRC16-CCITT	✓	✓
Support for CRC32-ISO3309 Polynomial	✓	✓
Fast single cycle computation of new CRC output for each data input (no wait states)	✓	X
Support for input / output bit reversal	✓	✓
Support for big endian and little endian operation	✓	✓
Byte, Half-word, or word input to CRCIN	✓	✓
512-word CRCIN_IDX input field in which all addresses are mapped to CRCIN, supporting use of a standard C-style memcpy() routine to load data into the CRC module for data lengths up to 2KB	✓	✓
User-selectable CRC32 polynomial	X	✓

**Figure 14-1. CRC and CRC-P Key Features**

### 14.1.1 CRC16-CCITT

For CRC16-CCITT, the CRC signature is generated based on the polynomial given in the 16-bit CCITT standard, as shown in [the equation below](#).

$$f(x)=x^{16}+x^{12}+x^5+1 \quad (14)$$

The CRC16-CCITT digest size is 16 bits (half-word).

### 14.1.2 CRC32-ISO3309

For CRC32-ISO3309, the CRC signature is generated based on the polynomial given in the ISO3309 Ethernet standard, as shown in [the equation below](#).

$$f(x)=x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1 \quad (15)$$

The digest size for CRC32-ISO3309 is 32 bits.

## 14.2 CRC Operation

The CRC generator is initialized by [configuring the desired mode of operation in the CRCCTRL register](#), followed by writing the seed value to the CRCSEED register. After the seed is loaded to the CRCSEED register, the CRCOUT register will reflect the SEED value loaded to CRCSEED.

### Note

If the endianness mode is configured to big endian before the seed value is written to CRCSEED, then the byte order of the seed value written to CRCSEED is swapped when the seed value is loaded into the CRC module.

Once initialized, data can be input into the CRC generator by writing to the CRCIN register using byte (8-bit), half-word (16-bit), or word (32-bit) writes. The CPU or the DMA can be used to move input data into the CRC accelerator.

---

#### Note

Byte writes need not be word aligned; a byte write to any byte location in CRCIN will be interpreted the same way (adding the 8 written bits to the computed CRC). Half-word writes also need not be word aligned, but they must be half-word aligned. For example, a half-word can be written to BIT0-BIT15 or BIT16-BIT32 of CRCIN, but not to BIT8-BIT23.

---

When using the CRC generator to verify a data set, all data to be included in the CRC calculation must be written to the CRCIN register in the same order as was used to calculate the original CRC signature. When using the CRC generator to create a new signature to be used in the future for verification, be sure to load the data the same way and with the same settings when performing verification.

The current CRC output can be read at any time by reading the CRCOUT register.

### 14.2.1 CRC Generator Implementation

The CRC generator is implemented with a set of XOR trees. After a set of 8, 16, or 32 bits is provided to the CRC accelerator by writing to the CRCIN register, a calculation for the whole set of input bits is performed. When new data is written to CRCIN, the CRC generator updates the CRC output in a single cycle when using the CRC peripheral. CRC-P versions require additional cycles. Bus wait states are not required to load data back-to-back into the CRC generator.

### 14.2.2 Configuration

The CRC accelerator supports polynomial selection, bit reversal selection, and byte order (endianness) selection. This section describes these configuration aspects.

The CRC accelerator must be enabled before being used through the PWREN register (see peripheral power enable).

The CRC accelerator is in power domain 1 (PD1), and as such can only be active in RUN or SLEEP mode. If the CRC accelerator is configured to be enabled by application software, and the device enters STOP or STANDBY mode, SYSCTL will force the CRC into a disabled state until the device exits STOP or STANDBY mode. All CRC register contents are retained when the CRC is forced to a disabled state in STOP or STANDBY mode.

The CRC module only runs from the PD1 bus clock (MCLK).

#### 14.2.2.1 Polynomial Selection

The desired polynomial (CRC16-CCITT or CRC32-ISO3309) is selected with the POLYSIZE bit in the CRCCTRL register. The polynomial to be used must be selected before loading the seed value and any data values.

When the CRC generator is configured for a 16-bit digest (CRC16-CCITT), the following conditions apply:

- The upper half-word (16 bits) of the CRCSEED register are ignored and only the lower half-word is used
- The upper half-word (16 bits) of the CRCOUT register read back as zero and only the lower half-word is valid

When the CRC generator is configured for CRC32-ISO3309, all 32 bits of CRCSEED and CRCOUT are valid.

#### 14.2.2.2 Bit Order

The various CRC standards were defined in the era of main frame computers. At that time, BIT0 was treated as the MSB. In modern computing, BIT0 is typically the LSB.

The Arm Cortex-M0+M33 CPU treats BIT0 as the LSB, as is typical in modern CPUs and MCUs. This sometimes causes confusion, because BIT0 has been treated as the LSB in some cases and as the MSB in other cases. Therefore, the CRC accelerator provides a bit order reversal capability to support both conventions.

Bit order reversal can be enabled by setting the BITREVERSE bit in the CRCCTRL register, giving the following behavior for input and output data:

- **Input data:** The bit order of each input byte written to the CRCIN register is reversed before it is passed to the CRC generator to be used for CRC calculation
- **Output data:** The bit order of the 16-bit or 32-bit CRC result is reversed when read from the CRCOUT register

---

#### Note

If input data must be provided bit-reversed, but the output is to be read not reversed, the BITREVERSE bit can be set before loading data to CRCIN and then cleared after all data is written to CRCIN but before the resulting signature is read from CRCOUT. Likewise, it is possible to load input data to CRCIN with BITREVERSE cleared (not reversed), and flip the output before reading it (by setting BITREVERSE before reading CRCOUT).

---

#### 14.2.2.3 Byte Swap

The bit OUTPUT\_BYTESWAP in the register CRCCTRL can be used to enable or disable CRC output byte swap. This bit controls whether the output is byte-swapped upon a read of the CRCOUT register. If CRCOUT is accessed as a half-word, and the OUTPUT\_BYTESWAP is set to 1, then the two bytes in the 16-bit access are swapped and returned. Using B0, B1, B2 and B3 to identify Byte 0, Byte 1, Byte 2, Byte 3. B1 is returned as B0 and B0 is returned as B1. If CRCOUT is accessed as a word, and the OUTPUT\_BYTESWAP is set to 1, then the four bytes in the 32-bit read are swapped. B3 is returned as B0, B2 is returned as B1, B1 is returned as B2 and B0 is returned as B3.

Note that if the CRC POLYSIZE is 16-bit and a 32-bit read of CRCOUT is performed with OUTPUT\_BYTESWAP enabled, then the output is: MSB LSB 0x0 0x0 B0 B1. If the CRC POLYSIZE is 16-bit and a 32-bit read of CRCOUT is performed with OUTPUT\_BYTESWAP disabled, then the output is: MSB LSB 0x0 0x0 B1 B0.

#### 14.2.2.4 Byte Order

When working with half-word or word input data, the input byte order can be configured as either little endian or big endian. The default configuration is little endian. To reverse the byte order when using half-word or word inputs, set the INPUT\_ENDIANNES bit in the CRCCTRL register.

Reversing the endianness will cause the following translation for half-word and word writes:

**Table 14-1. CRCIN Byte Order Translation**

Endianness	Data Written to CRCIN	Data Applied to CRC Logic
0 (little)	0x1234	0x1234
1 (big)	0x1234	0x3412
0 (little)	0x12345678	0x12345678
1 (big)	0x12345678	0x78563412

---

#### Note

If the ENDIANNES bit is set before the seed value is written to CRCSEED, then the byte order of the seed value written to CRCSEED is also reversed when it is loaded into the CRC, and the seed value will read back reversed when reading the CRCOUT register after writing to the CRCSEED register.

---

#### 14.2.2.5 CRC C Library Compatibility

To simplify loading of data by software into the CRC, the CRC accelerator provides a 512-word (2KB) CRCIN\_IDX region. Within the CRCIN\_IDX region, a write to any word is re-mapped as, and functionally equivalent to, a write to the CRCIN register. This mechanism enables the use of the standard C library *memcpy()* routine to copy data from SRAM or flash into the CRC, provided that the source data is less than 2KB (2,048 bytes).

### 14.3 CRCP0 Registers

Table 14-2 lists the memory-mapped registers for the CRCP0 registers. All register offset addresses not listed in Table 14-2 should be considered as reserved locations and the register contents should not be modified.

**Table 14-2. CRCP0 Registers**

Offset	Acronym	Register Name	Group	Section
800h	PWREN	Power enable		<a href="#">Go</a>
804h	RSTCTL	Reset Control		<a href="#">Go</a>
814h	STAT	Status Register		<a href="#">Go</a>
1004h	CLKSEL	Clock Select		<a href="#">Go</a>
10FCh	DESC	Module Description		<a href="#">Go</a>
1100h	CRCCTRL	CRC Control Register		<a href="#">Go</a>
1104h	CRCSEED	CRC Seed Register		<a href="#">Go</a>
1108h	CRCIN	CRC Input Data Register		<a href="#">Go</a>
110Ch	CRCOUT	CRC Output Result Register		<a href="#">Go</a>
1110h	CRCPOLY	CRC Polynomial configuration register		<a href="#">Go</a>
1800h + formula	CRCIN_IDX[y]	CRC Input Data Array Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 14-3 shows the codes that are used for access types in this section.

**Table 14-3. CRCP0 Access Type Codes**

Access Type	Code	Description
Read Type		
H	H	Set or cleared by hardware
R	R	Read
Write Type		
W	W	Write
WK	W K	Write Write protected by a key
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Return to the [Summary Table](#).

CRC Input Data Register. The Data written to this register is used along with the current CRC result to calculate the next CRC result. This is done in a single clock cycle and requires no wait states. This register can be written as a byte, half word or word transfer and the correct number of bits will be used for the next CRC result. This register is also mapped to a range of registers starting at 0xTDB\_X000 and ending at 0xTDB\_XFFF to allow memcpy to be used instead of DMA for CRC calculations that do not exceed the bounds of the memory range of this register.

**Figure 14-9. CRCIN**

<b>15.1 Overview</b> .....	<b>1092</b>
<b>15.2 Detailed Description</b> .....	<b>1092</b>
<b>15.3 KEYSTORECTL Registers</b> .....	<b>1093</b>

## 15.1 Overview

The Keystore controller provides secure management of the Advanced Encryption Engine (AES) keys. The use model of the keystore controller is to securely deposit keys into it during the execution of customer secure code and to have the AES engine access them subsequently in a secure manner without leaking any key data to observers. Both 128 and 256-bit keys can be stored in the keystore key slots. The keystore and its interaction with the AES engine are designed for secure operation including thwarting partial key modification attacks.

## 15.2 Detailed Description

The keystore supports storage of AES keys. Up to four 128-bit key slots are provisioned and can be used in different software-managed configurations, such as:

- Four 128-bit keys
- Two 256-bit keys
- One 256-bit key and two 128-bit keys

---

### Note

Refer to the device-specific data sheet to determine the number of AES keys supported.

---

This configuration selection is the first to be performed by customer secure code before depositing keys into slots. Configuration is done by writing the number of 256-bit keys into the NK256 field of the CFG register.

After configuration, the key bytes can be written to selected slots in the keystore controller register. This is done by programming the KEYSZSEL (key size selection) and KEYSLOTSEL (key slot selection) fields of the KEYWR register. Note that the hardware expects any 256-bit keys to be store in lower-numbered slots. For example, if the store is configured for one 256-bit key and two 128-bit keys, the 256-bit key must be stored in slots 0 and 1. The IP reports an error (invalid configuration) if any other slot is used for the 256-bit key. If the store is configured for two 256-bit keys, then key 0 occupies slots 0 and 1 and key 1 occupies slots 2 and 3.

Depositing the key bytes into slots is done by writing them to the KEYIN register. Once a key write transaction is initiated, until and unless all the key bytes are written (4 words for a 128-bit key and 8 words for a 256-bit key), the key is not considered valid. Validity of slots is presented via a status register for the application. When customer secure code has deposited the required number of bytes, the key becomes valid and can be used by the application. The STATUS register provides status and validity fields to indicate status of the keystore controller as well as the validity of key slots.

Note that key configuration operations are permitted only while customer secure code is executing. Subsequently, the keystore configuration is locked and can not be modified. The signaling of the end of customer secure code is discussed in the Security Architecture chapter.

At run-time (after the end of customer secure code execution), the application is able to use one of the valid keys for an AES encryption/decryption operation. To configure the AES engine to use a specific key, the application references a key slot and initiates a transfer of the key data into the AES engine via a secure internal bus. This is performed by writing to the KEYSZSEL (key size selection), and KEYSLOTSEL (Key slot selection) fields of the KEYRD register. The selected key data is securely transferred to the AES engine over a private bus that is not accessible by software or the debugger.

The keystore holds the state and key data until a subsequent boot reset. At boot reset, customer startup code configures the keystore. If one or more slots are not used at the end of customer startup code execution, those slots remain unusable for the rest of the application execution.

### 15.3 KEYSTORECTL Registers

Table 15-1 lists the memory-mapped registers for the KEYSTORECTL registers. All register offset addresses not listed in Table 15-1 should be considered as reserved locations and the register contents should not be modified.

**Table 15-1. KEYSTORECTL Registers**

Offset	Acronym	Register Name	Group	Section
1100h	CFG	Keystore configuration		<a href="#">Go</a>
1104h	KEYWR	Key write configuration		<a href="#">Go</a>
1108h	KEYRD	Key read configuration		<a href="#">Go</a>
110Ch	STATUS	Status		<a href="#">Go</a>
1110h	KEYIN	Input key		<a href="#">Go</a>
1114h	KEYLOCK	Keylock		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 15-2 shows the codes that are used for access types in this section.

**Table 15-2. KEYSTORECTL Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write

The true random number generator (TRNG) block is an entropy source which can be used to generate random bit sequences.

<b>16.1 TRNG Overview</b> .....	<b>1101</b>
<b>16.2 TRNG Operation</b> .....	<b>1101</b>
<b>16.3 TRNG Registers</b> .....	<b>1108</b>

## 16.1 TRNG Overview

The true random number generator (TRNG) module securely generates random 32-bit numbers through an internal analog entropy source and digital conditioning/decimation blocks. The TRNG can be used as an entropy source to derive true random seed values when implementing a deterministic random bit generator (DRBG). The TRNG is designed for use in creating a deterministic random bit generator (DRBG) system which can pass the NIST SP800-22 statistical test suite for cryptographic random number generators.

Key features of the TRNG module include:

- 32-bit true random number output
- Functional across the entire device supply range (voltage and temperature)
- $\Delta\Sigma$ -modulator based analog entropy source
- Conditioning block
- Configurable decimation block
- Integrated startup and continuous health tests, compliant to NIST SP800-22
- Dedicated internal LDO regulator to defend against power manipulation attacks

## 16.2 TRNG Operation

The TRNG contains two main components: the analog block (containing the LDO regulator and entropy source), and the digital block (containing the state machine, startup logic, conditioning, decimation, health tests, and register interface). Figure 16-1 shows the TRNG blocks.

Figure 16-1. TRNG Block Diagram

### 16.2.1 TRNG Generation Data Path

The random number generation data path begins in the analog block. The analog block contains a dedicated low drop-out regulator which supplies power to the entropy source, improving resistance to power manipulation attacks on the MCU supply. The sigma-delta entropy source itself derives entropy through delta-sigma modulation of Johnson-Nyquist noise.

During operation, the entropy source output is digitized and the digital output is sent to the digital conditioning block to generate a random bit stream. The conditioning block implements a stream cipher scheme. Following the conditioning block, a decimation block is provided to boost entropy by accumulating the entropy of a configurable number of samples. The output of the decimation block is finally captured in a result word holding register to be read by application software.

#### Note

The purpose of the decimation block is to increase the overall entropy of the TRNG by merging entropy from multiple samples. The decimation block will accumulate bits from the conditioning block, and decimate down to 1 sample every  $n$  samples, where  $n$  is the decimation value. Decimation is implemented as a bit-wise exclusive-or function of  $n$  conditioned bits. The decimation integer  $n$  can be set between 1 and 8.

### 16.2.2 Clock Configuration and Output Rate

The TRNG functional clock is derived from MCLK. The TRNG requires a functional clock which is within a specified frequency range for proper operation. Review the device-specific data sheet for the allowed TRNG frequency range on a given device. A clock divider is included in the TRNG to derive the frequency for the TRNG to use. The clock divider is specified through the `RATIO` field in the `CLKDIVIDE` register in the TRNG. This field must be set after the TRNG is enabled (through the `PWREN` register) but before the TRNG state is moved from the `OFF` state. Running the TRNG at a frequency outside the range specified in the device data sheet can lead to unexpected behavior.

The output rate of the TRNG module is dependent upon the TRNG functional clock frequency and the selected decimation rate. A minimum of 32 cycles of the TRNG functional clock are required to capture 32 random bits when the decimation rate is set to `DECIM_RATE=0x0` (decimate-by-1, or no decimation). When the decimation rate is set to `DECIM_RATE=0x3` (decimate-by-4), 128 cycles are required to capture 32 random bits. At a 10MHz clock rate with the decimation rate set to decimate-by-4, the time required to capture 32 random data bits is 12.8µs. Equation 16 gives the formula for calculating the time required to generate 32 random bits based on the TRNG functional clock frequency and the selected decimation rate.

$$t_{\text{GENERATE}} = (32 * (\text{DECIM\_RATE} + 1)) / f_{\text{TRNG}} \quad (16)$$

---

#### Note

A decimation rate of decimate-by-4 (`DECIM_RATE=0x3`) or greater is required to obtain the minimum entropy which is required to pass the NIST SP800-22 statistical test suite. TI recommends using decimate-by-4 or greater when using the TRNG in cryptographic applications.

---

#### Note

When the `DECIM_RATE` field is changed, a `NORM_FUNC` command must be re-sent to the TRNG for the new rate to take effect (by writing `0x3` to the `CMD` field in the `CTL` register).

---

When 32 bits of random data are captured and available in the `DATA_CAPTURE` register, the TRNG asserts the `IRQ_CAPTURED_RDY` interrupt to indicate to the processor that data is ready. Once the data is read by the processor, capture of the next 32 bits of random data begins.

### 16.2.3 Behavior in Low Power Modes

The TRNG is available for use in `RUN` and `SLEEP` modes. It is not available in any other operating mode, and all TRNG configuration settings and data are lost when the device transitions to any operating mode below `SLEEP`. When using low power operating modes below `SLEEP`, the TRNG must be re-configured for use as needed when waking the device from `STOP`, `STANDBY`, or `SHUTDOWN` mode.

### 16.2.4 Health Tests

Three health test mechanisms are provided: a digital block power-on self-test, analog block power-on self-test, and a runtime self-test. The digital and analog power-on self-tests are executed by sending the corresponding `CMD` to the TRNG state machine when the TRNG is in the `NORM_FUNC` state. The runtime self-test is always running when the TRNG is in the `NORM_FUNC` state.

#### 16.2.4.1 Digital Block Startup Self-Test

The digital startup health test is run by application software when powering up the TRNG module. This built-in self-test verifies that the digital block is functioning properly by running predefined sequences of digital samples through the complete digital block while checking for expected outputs. The test sequence includes eight tests. Each test requires 1024 TRNG clock cycles to complete, as 1024 samples are input to the digital block for each test.

The results of the digital startup self-test are reported in the `DIG_TEST` field of the `TEST_RESULTS` register. Each test reports its status in an individual result bit. As each test passes, the corresponding bit in `DIG_TEST` is set by hardware. Upon completion of the digital start up self test, a pass condition is indicated if all eight bits

in the DIG\_TEST field of the TEST\_RESULTS register are set. If any bit in the DIG\_TEST field is not set, this indicates a failing test. The TRNG is not usable if any of the digital startup health tests fail.

---

**Note**

The digital self-test changes the decimation rate when executing. This is a part of the self-test feature.

---

**Note**

The digital self-test injects deterministic values into the data path as a part of the test sequence. Following completion of the digital block startup self-test, the first data read from the DATA\_CAPTURE register in normal (NORM\_FUNC) operating mode is a deterministic value from the digital self-test, and not a true random number. **Always discard the first DATA\_CAPTURE value after running the digital startup self-test.**

---

#### 16.2.4.2 Analog Block Startup Self-Test

The analog startup health test is run by application software when powering up the TRNG module. This test verifies that the analog block is functioning properly by capturing 4,096 consecutive analog samples and verifying that the samples pass a health test.

If the health test fails, the health fail (IRQ\_HEALTH\_FAIL) and command done (IRQ\_CMD\_DONE) interrupts are both asserted, and the TRNG state machine enters the ERROR state. The result of the analog start up self-test is also reported in the ANA\_TEST bit in the TEST\_RESULTS register. If the test passed, the ANA\_TEST bit is set. If the test failed, the ANA\_TEST bit is left cleared.

If the test does fail, this indicates that a severe loss of entropy in the analog block was detected during the test. This means that the entropy source can not be used in its current state. The probability of this test returning a false positive (probability that a failure was asserted but the analog block is operating correctly) is statistically very low, but not zero. This means that there is a small probability that a failure could be indicated in certain cases even if the TRNG analog block is operating correctly. To ensure that a test failure is legitimate and that there is not a loss of entropy, the analog startup health test can be repeated to validate the failure. In the event of a failure, the following procedure is recommended:

1. Clear the IRQ\_HEALTH\_FAIL interrupt
2. Power off the TRNG
3. Run the analog startup health test again
4. Follow the appropriate action below based on the test result:
  - a. If the test passed, the TRNG can be used
  - b. If the test failed a second time, go to step 1 and attempt to run the test a third time
  - c. If the test failed a third time, there is catastrophic entropy loss and the TRNG should not be used

#### 16.2.4.3 Runtime Health Test

During normal operation of the TRNG, raw data from the entropy source is sent through the health test logic to ensure that there is sufficient entropy present on an ongoing basis. The tests are designed to statistically check for a minimum of 0.3 bits of entropy per sample. The TRNG implements both repetition count and adaptive proportion continuous self-tests.

##### 16.2.4.3.1 Repetition Count Test

The repetition count test quickly detects failures that cause the entropy source to remain stuck on a single output value for an extended period of time. The repetition count test fails if the entropy source outputs the same bit value for 135 consecutive samples.

##### 16.2.4.3.2 Adaptive Proportion Test

The adaptive proportion test detects failures that cause a disproportionate number of samples to be the same bit value and/or bit pattern over a window of 1024 samples. The adaptive proportion test fails any of the conditions

in [Table 16-1](#) are violated. For example, the test will fail if more than 912 samples within a 1024 sample window are the same bit value.

**Table 16-1. Adaptive Proportion Test Bounds**

Bit Pattern	Allowable Range of Bit Pattern Occurrences
1	$112 < n < 912$
10	$211 < n < 341$
001	$97 < n < 192$
1011	$11 < n < 104$

The bit patterns in [Table 16-1](#) used for adaptive proportion testing are designed to effectively detect catastrophic loss of entropy in the TRNG while also minimizing the occurrence of false positive failure detections.

#### 16.2.4.3.3 Handling Runtime Health Test Failures

In the event that the run-time health test identifies that insufficient entropy can be present, the health fail (IRQ\_HEALTH\_FAIL) interrupt is asserted and the TRNG state machine enters the ERROR state. Due to the random nature of the TRNG module, it is possible for a health failure to be indicated in some cases even when the TRNG is working properly. To determine if there is a true loss of entropy, the following procedure is recommended:

1. Clear the IRQ\_HEALTH\_FAIL interrupt
2. Power off the TRNG
3. Power on the TRNG to normal mode again
  - a. If the health failure is not asserted again, the TRNG can be used
  - b. If the health test fails a second time, go to step 1 and attempt to run the test a third time
  - c. If the health test fails a third time, there is catastrophic entropy loss and the TRNG should not be used

The TRNG does provide diagnostic information to indicate which test(s) failed. To determine which runtime test(s) are failing, check the REP\_FAIL and ADAP\_FAIL bits in the STAT register for the repetition test and adaptive proportion test, respectively.

#### 16.2.5 Configuration

The TRNG module is configured and used by application software and is accessed through the PD1 CPU-only peripheral bus. The DMA does not have access to the TRNG.

The TRNG contains a state machine which manages the current operating mode of the TRNG. Application software can configure the TRNG through commands to change the current state. The TRNG also sources an interrupt to the CPU to communicate status.

#### Note

Writing to a TRNG configuration register before a CMD is written to the TRNG can cause an unexpected command fail interrupt request (IRQ\_CMD\_FAIL) to be asserted. Mask the TRNG command fail interrupt when writing to TRNG configuration registers until a CMD is written to the TRNG. Clear the IRQ\_CMD\_FAIL interrupt status after writing the CMD and before enabling the IRQ\_CMD\_FAIL interrupt.

##### 16.2.5.1 TRNG State Machine

The TRNG includes a state machine which manages the current operating state of the TRNG. The TRNG is configured for use by sending commands to the TRNG to change its state. The TRNG has seven states, given in [Table 16-2](#).

**Table 16-2. TRNG States**

Code	State Name	Description
0x0	OFF	Analog block is powered off, digital block is disabled
0x1	PWRUP_ES	TRNG is in the process of powering up the entropy source and will transition to NORM_FUNC.
0x2	PWRDOWN_ES	TRNG is in the process of powering down the entropy source and will transition to OFF.
0x3	NORM_FUNC	TRNG is running and generating random bits normally.
0x7	TEST_DIG	TRNG is running the <a href="#">digital power-on self-test</a> .
0xB	TEST_ANA	TRNG is running the <a href="#">analog power-on self-test</a> .
0xA	ERROR	Operation halted due to an error condition. The analog remains powered but the health and conditioning logic is stopped.

The current TRNG state can be determined by application software. To check the current state, read the FSM\_STATE field in the STAT register of the TRNG.

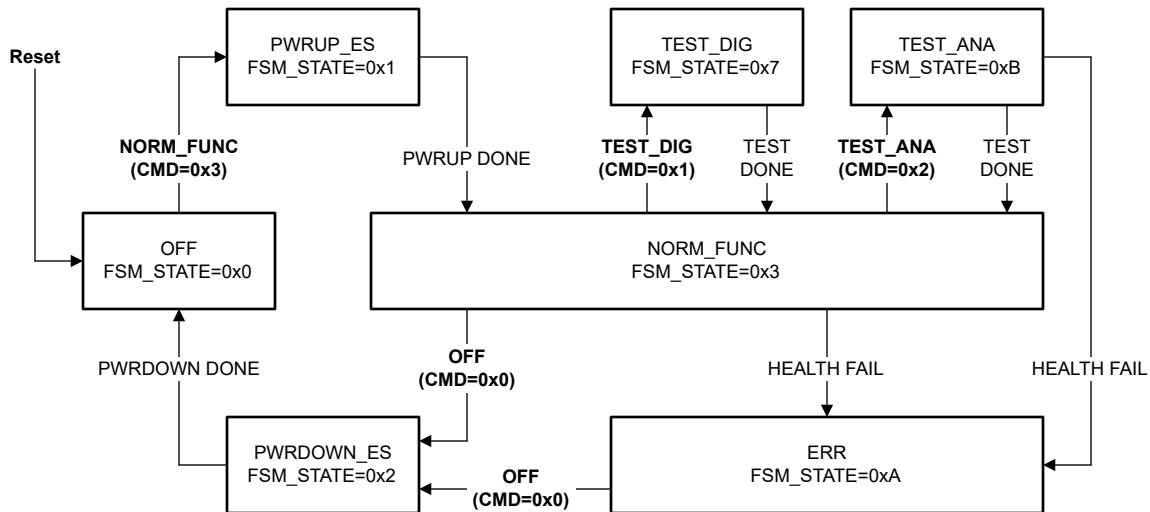

#### 16.2.5.1.1 Changing TRNG States

Application software can set the operating state of the TRNG by writing a new command value to the CMD field in the CTL register. While the TRNG state machine has 7 states, only 4 of the 7 states are entered by user control with CMDs (OFF, TEST\_DIG, TEST\_ANA, and NORM\_FUNC). The other 3 states (PWRUP\_ES, PWRDOWN\_ES, and ERR) are entered by a hardware only when powering up or down the analog block or when an error condition occurs. The operating state change commands for the TRNG are given in [Table 16-3](#).

**Table 16-3. TRNG Operating Mode Commands**

CMD	Mode	Description
0x0	PWROFF	The TRNG analog blocks are powered off, and the TRNG digital blocks are clock gated.
0x1	TEST_DIG	The TRNG digital power-on self-tests are executed and the result is reported in the TEST_RESULTS register.
0x2	TEST_ANA	The TRNG analog power-on self-tests are executed and the result is reported in the TEST_RESULTS register.
0x3	NORM_FUNC	The TRNG is put into normal operating mode, in which samples from the entropy source are collected, conditioned, decimated, and placed in the DATA_CAPTURE register. The continuous statistical health tests run in this mode.

From a given state, only certain state changes are possible. For example, from OFF only a CMD to switch to NORM\_FUNC is supported. From NORM\_FUNC, CMDs to switch to TEST\_DIG, TEST\_ANA, and OFF are supported. From the ERR state, only a switch to OFF is supported. The state flow for the TRNG is given in [Figure 16-2](#).

**Figure 16-2. TRNG State Flow**

A new command can only be written to the CMD field after any previously issued commands have run to completion. If a command is written at an invalid time, it will be rejected and a command fail interrupt will be asserted.

### 16.2.5.2 Using the TRNG

Use the following procedure to start the TRNG:

1. Enable the TRNG by setting the ENABLE bit together with the KEY in the TRNG PWREN register.
2. Configure the TRNG clock divider to ensure that the TRNG functional clock is within the allowable range (10MHz typical, see the device data sheet for additional detail). The clock divider is configured by programming the required value to the RATIO field of the CLKDIVIDE register. As an example, if MCLK is 80MHz, the RATIO field shall be set to 0x7 (divide-by-8) to provide a 10MHz functional clock to the TRNG module.
3. Verify that the TRNG interrupts are disabled (interrupt mask bits are cleared to mask interrupts).
4. Move the TRNG from the default OFF state to the NORM\_FUNC state by writing the NORM\_FUNC command (0x3) to the CMD field in the CTL register of the TRNG. Wait for the IRQ\_CMD\_DONE interrupt flag to be set, indicating that the CMD completed.
5. Run the [digital block start-up self-test routine](#) to ensure the TRNG digital is functioning properly:
  - a. Move the TRNG from the NORM\_FUNC state to the TEST\_DIG state by writing the TEST\_DIG command (0x1) to the CMD field in the CTL register. Wait for the IRQ\_CMD\_DONE interrupt flag to be set, indicating that the digital self-test has completed.
  - b. Check that all 8 digital tests passed by ensuring the DIG\_TEST field in the TEST\_RESULTS register are set (DIG\_TEST=0xFF).
  - c. After the digital test, the TRNG will return to the NORM\_FUNC state automatically.
6. Run the [analog block start-up self-test routine](#) to ensure that the TRNG analog is functioning properly:
  - a. Move the TRNG from the NORM\_FUNC state to the TEST\_ANA state by writing the TEST\_ANA command (0x2) to the CMD field in the CTL register. Wait for the IRQ\_CMD\_DONE interrupt flag to be set, indicating that the analog self-test has completed.
  - b. Check that the analog test passed by verifying that the ANA\_TEST bit in the TEST\_RESULTS register was set.
  - c. After the analog test, if the test passed the TRNG will return to the NORM\_FUNC state automatically. If the test failed, the TRNG enters the ERR state and must be brought to the OFF state before attempting to use it again.
7. Configure the TRNG for normal operation after running start-up self-tests:

- a. Clear the IRQ\_CAPTURED\_RDY\_IRQ status by setting the corresponding ICLR bit, as this may have been set during the self-tests performed earlier.
  - b. Set the decimation rate to the desired value by programming the new decimation rate into the DECIM\_RATE field of the CTL register, followed by sending the NORM\_FUNC command again (by writing 0x3 to the CMD field in the CTL register). A decimation rate of 4 (DECIM\_RATE=0x3) or greater is recommended.
  - c. Enable the health fail interrupt by setting the IRQ\_HEALTH\_FAIL bit in the IMASK register.
  - d. Enable the data captured interrupt by setting the IRQ\_CAPTURED\_RDY bit in the IMASK register.
8. Wait for the first IRQ\_CAPTURED\_RDY\_IRQ, and read the DATA\_CAPTURE register. This value (the first value read from DATA\_CAPTURE after running a startup self-test) is not a true random value and must be read and discarded before collecting true random data from the DATA\_CAPTURE register.
  9. When the IRQ\_CAPTURED\_RDY\_IRQ is again asserted, random bits are available for read-out in the DATA\_CAPTURE register.
  10. If the IRQ\_HEALTH\_FAIL\_IRQ is asserted, a low entropy condition was found and the TRNG will have automatically switched to the ERR state to stop operation. To exit the ERR state, clear the IRQ\_HEALTH\_FAIL interrupt. Then, transition the TRNG to the OFF state by sending an OFF command (0x0) to the CMD field in the CTL register. Wait for the IRQ\_CMD\_DONE interrupt flag to be set, then return to step #2 to power up the TRNG again to test if sufficient entropy is again available.

### 16.2.5.3 TRNG Events

The TRNG module contains one [event publisher](#) and no [event subscribers](#). One event publisher (CPU\_INT) manages TRNG interrupt requests (IRQs) to the CPU subsystem through a [static event route](#).

[Table 16-4](#) lists the TRNG events.

**Table 16-4. TRNG Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU Interrupt Event</a>	Publisher	TRNG	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from TRNG to CPU

#### 16.2.5.3.1 CPU Interrupt Event Publisher (CPU\_INT)

The TRNG module provides four interrupt sources which can be configured to source a [CPU interrupt event](#). [Table 16-5](#) lists the TRNG interrupt conditions.

**Table 16-5. TRNG CPU Interrupt Conditions (CPU\_INT)**

Index (IIDX)	Name	Description
1	IRQ_HEALTH_FAIL	Indicates that a health test has failed.
2	IRQ_CMD_FAIL	Indicates that a CMD which was issued has failed.
3	IRQ_CMD_DONE	Indicates that a CMD which was issued has completed.
4	IRQ_CAPTURED_RDY	Indicates that a new 32-bit data word containing random bits is available to be read by the processor.

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring these registers for CPU interrupts.

## 16.3 TRNG Registers

Table 16-6 lists the memory-mapped registers for the TRNG registers. All register offset addresses not listed in Table 16-6 should be considered as reserved locations and the register contents should not be modified.

**Table 16-6. TRNG Registers**

Offset	Acronym	Register Name	Group	Section
800h	PWREN	Power enable		<a href="#">Go</a>
804h	RSTCTL	Reset Control		<a href="#">Go</a>
814h	STAT	Status Register		<a href="#">Go</a>
1020h	IIDX	Interrupt index	CPU_INT	<a href="#">Go</a>
1028h	IMASK	Interrupt mask	CPU_INT	<a href="#">Go</a>
1030h	RIS	Raw interrupt status	CPU_INT	<a href="#">Go</a>
1038h	MIS	Masked interrupt status	CPU_INT	<a href="#">Go</a>
1040h	ISSET	Interrupt set	CPU_INT	<a href="#">Go</a>
1048h	ICLR	Interrupt clear	CPU_INT	<a href="#">Go</a>
10FCh	DESC	Module descriptions		<a href="#">Go</a>
1100h	CTL	Controls the command and decimation rate		<a href="#">Go</a>
1104h	STAT	Status register that informs health test results and last issued command		<a href="#">Go</a>
1108h	DATA_CAPTURE	Captured word buffer of RNG data		<a href="#">Go</a>
110Ch	TEST_RESULTS	Test results from TEST_ANA and TEST_DIG		<a href="#">Go</a>
1110h	CLKDIVIDE	Clock Divider		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 16-7 shows the codes that are used for access types in this section.

**Table 16-7. TRNG Access Type Codes**

Access Type	Code	Description
<b>Read Type</b>		
R	R	Read
<b>Write Type</b>		
W	W	Write
WK	W K	Write Write protected by a key
<b>Reset or Default Value</b>		
-n		Value after reset or the default value

15-0	RESERVED	R	0h	

#### 4 IIDX (Offset = 1020h) [Reset = X]

IIDX is shown in [Figure 16-6](#) and described in [Table 16-11](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. 0h means no event pending. Interrupt 1 is the highest priority, 2 next highest, 4, 8, ...  $2^{31}$  is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt, if none are pending, then it should display 0h.

**Figure 16-6. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 6 RIS (Offset = 1030h) [Reset = X]

RIS is shown in [Figure 16-8](#) and described in [Table 16-13](#).

Return to the [Summary Table](#).

Raw interrupt status reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

0	IRQ_HEALTH_FAIL	R	0h	Masked interrupt result for HEALTH_FAIL. Indicates to the CPU that any of the health tests have failed for the latest 1024-bit window. 0h = IRQ_CAPTURED_READY did not request an interrupt service routine 1h = IRQ_CAPTURED_READY requests an interrupt service routine

## 8 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 16-10](#) and described in [Table 16-15](#).

Return to the [Summary Table](#).

ISET allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

### 10 DESC (Offset = 10FCh) [Reset = 05110000h]

DESC is shown in [Figure 16-12](#) and described in [Table 16-17](#).

Return to the [Summary Table](#).

This register is used to specify clock source selection for any special modules that need to choose between MCLK and another special clock source. The register is not expected to be present on most standard SVT peripherals but may be present on modules such as the ADC. The register is not present on VDDCOREULP domain peripherals and will be reserved, reading 0.

The PMU provides a basic temperature sensor which can be used to approximate the temperature of the device. The temperature sensor is connected internally to the ADC, and the ADC must be used to perform a temperature measurement. See the device-specific data sheet to determine the correct internal ADC channel to use when measuring the temperature sensor.

The temperature sensor outputs a voltage which has a linear relationship with temperature. The temperature coefficient ( $TS_c$ ) is the slope of the temperature-voltage relationship (given in mV/C), and is given in the specifications section of the device-specific data sheet.

A unit-specific single-point trim value (TEMP\_SENSE0.DATA) is provided in the [factory constants](#) memory of each device. This value indicates the temperature sensor output voltage at the factory trim temperature ( $TS_{TRIM}$ ), in ADC result code format. The ADC result code in TEMP\_SENSE0.DATA is based upon 12-bit sampling mode together with the 1.4V internal voltage reference. The  $TS_{TRIM}$  temperature is also given in the specifications section of the device-specific data sheet.

The approximate temperature of the device can be computed through the use of the following parameters:

- $TS_c$ , taken from the device data sheet
- TEMP\_SENSE0.DATA, taken from the unit-specific factory constants memory
- $TS_{TRIM}$ , taken from the device data sheet
- $V_{SAMPLE}$  (voltage sample of the temperature sensor at time of interest, taken with the ADC)

The temperature is computed through the linear relationship given in [Equation 17](#), where  $V_{SAMPLE}$  is the current temperature sensor voltage, and  $V_{TRIM}$  is the factory calibrated temperature sensor voltage at the  $TS_{TRIM}$  temperature (derived from TEMP\_SENSE0.DATA):

$$T_{SAMPLE} = (1 / TS_c) * (V_{SAMPLE} - V_{TRIM}) + TS_{TRIM} \quad (17)$$

The ADC<sub>CODE</sub> raw result can be converted to a voltage equivalent ( $V_{SAMPLE}$ ) as shown in the relationship in [Equation 18](#), where RES is the ADC resolution in bits, and VREF is the ADC reference voltage.

$$V_{SAMPLE} = (VREF / 2^{RES}) * (ADC_{CODE} - 0.5) \quad (18)$$

### Example

To illustrate the process of converting an ADC sample of the temperature sensor into an approximate device temperature, an example is given below.

Example parameters:

- $TS_c = -2.04\text{mV/C}$
- TEMP\_SENSE0.DATA = 1857 (ADC result code based on 12-bit mode and a 1.4V reference)
- $TS_{TRIM} = 30\text{C}$
- ADC<sub>CODE</sub> = 1677 (ADC result code based on 12-bit mode and a 1.4V reference)

First, the current temperature sensor sample voltage is calculated using [Equation 19](#):

$$V_{SAMPLE} = (1.4\text{V} / 4096) * (1677 - 0.5) = \mathbf{0.5730\text{V}} \quad (19)$$

Then, the single-point calibration voltage is calculated using the same means:

$$V_{\text{TRIM}} = (1.4\text{V} / 4096) * (1857 - 0.5) = \mathbf{0.6345\text{V}} \quad (20)$$

Then, the temperature is approximated using [Equation 21](#):

$$T_{\text{SAMPLE}} = (1 / -0.002044) * (0.5730\text{V} - 0.6345) + 30^{\circ}\text{C} = \mathbf{60^{\circ}\text{C}} \quad (21)$$

---

**Note**

The temperature sensor is not available in STANDBY and SHUTDOWN operating modes.

---

The ADC is a high-performance successive-approximation-register (SAR) analog-to-digital converter. This chapter describes the features and operation of the ADC peripheral.

<b>18.1 ADC Overview</b> .....	<b>1128</b>
<b>18.2 ADC Operation</b> .....	<b>1129</b>
<b>18.3 ADC12 Registers</b> .....	<b>1146</b>

## 18.1 ADC Overview

The ADC supports measure analog signals and convert them to a digital representation with minimal CPU intervention.

The ADC supports fast 12-, 10-, and 8-bit analog-to-digital conversions. It implements a 12-bit SAR core, sample and conversion mode control, and up to 12 independent conversion-and-control buffers. The ADC allows up to 12 independent analog-to-digital converter (ADC) samples to be converted and stored without any CPU intervention.

ADC features include:

- Up to 4-Msps conversion rate at a resolution of 12 bits
- Integrated hardware oversampling for averaging up to 128 samples
- Full-scale ADC operating voltage range
- Sample-and-hold with programmable sampling periods controlled by software or timers
- Two sampling trigger sources: software trigger and event trigger
- Software-selectable on-chip reference voltage of 1.4V or 2.5V
- Configurable ADC reference source: VDD, internal reference, or external reference
- Up to 26 individually configurable analog input channels
- Internal conversion channels for temperature sensing, supply monitoring, and analog signal chain (see the device-specific data sheet for availability and channel mapping)
- Configurable ADC clock source
- Single-channel, repeat-single-channel, sequence (autoscan), and repeat-sequence (repeated autoscan) conversion modes
- 12 conversion-result storage registers (MEMRES0:11)
- Window comparator for low-power monitoring of input signals from conversion-result registers
- DMA support with interrupt event generation on completion of transfer
- Operates in RUN, SLEEP, and STOP modes
- Can be triggered in any operating mode except for SHUTDOWN
- Automatic power, reference, and clock control for low-power operation
- Support for simultaneous and synchronous operation (sample and conversion) of two ADCs in parallel

---

### Note

Refer to the device-specific datasheet for the supported ADC features.

---

Figure 18-1 shows the functional block diagram of the ADC peripheral.

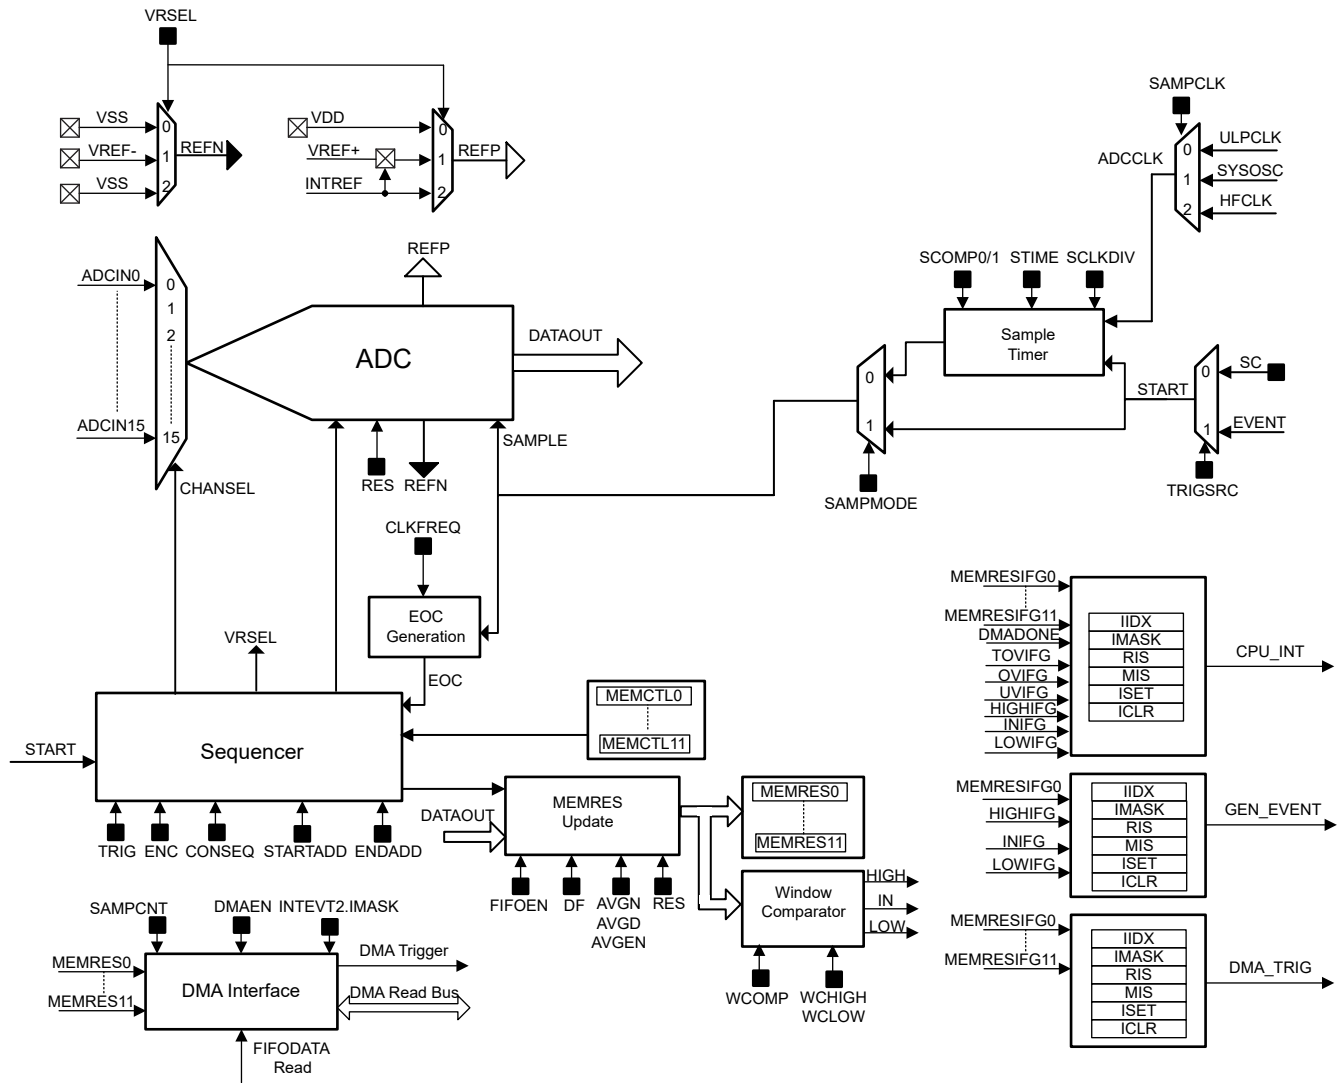

Figure 18-1. ADC Block Diagram

**Note**

The sample clock (SAMPCLK) is sourced from ULPCLK, SYSOSC or HFCLK, the conversion clock (CONVCLK) is sourced from an 80Mhz oscillator within the ADC IP.

**18.2 ADC Operation**

The ADC is configured with user software. The following sections describe the setup and operation of the ADC.

---

**Note**

The ADC result registers (MEMRES) are aliased between two address regions on the device:

- The primary region, through which all ADC registers can be accessed by the CPU or DMA at the ULPCLK rate
- The aliased region, through which the ADC MEMRES registers can be accessed by the CPU or DMA at the MCLK rate for fast read-out of ADC results. The aliased region is in the PD1 power domain.

On devices which run MCLK and ULPCLK at the same frequency, there is not a performance benefit to accessing the ADC MEMRES registers through the aliased region. On device configurations where MCLK is greater than ULPCLK, the aliased region is recommended to be used. However, application software can use the aliased region on all devices for MEMRES access to keep the software implementation consistent.

---

### 18.2.1 ADC Core

The ADC core converts an analog input to its digital representation. The core uses two voltage levels ( $V_{R+}$  and  $V_{R-}$ ) to define the upper and lower limits of the conversion. The digital output ( $N_{ADC}$ ) is full scale when the input signal is equal to or higher than  $V_{R+}$ , and is zero when the input signal is equal to or lower than  $V_{R-}$ . The input channel and the positive reference voltage level ( $V_{R+}$ ) are defined in the conversion-control memory.

Equation 22 below shows the conversion formula for the ADC result,  $N_{ADC}$ , for n-bit resolution mode.

$$N_{ADC} = (2^n - 1) \times \frac{(V_{in} + 0.5LSB) - V_{R-}}{V_{R+} - V_{R-}} \quad \text{Where, } LSB = \frac{V_{R+} - V_{R-}}{2^n} \quad (22)$$

---

**Note**

The supported  $V_{R-}$  for this ADC is 0V. All subsequent equations and sections will reflect this inherent property.

---

Given that  $V_{R-}$  is 0V in this ADC, the equation for  $N_{ADC}$  becomes:

$$N_{ADC} = (2^n - 1) \times \frac{(V_{in} + 0.5LSB)}{V_{R+}} \quad \text{Where, } LSB = \frac{V_{R+}}{2^n} \quad (23)$$

Equation 24 below describes the input voltage at which the ADC output saturates:

$$V_{in} = V_{R+} - 1.5LSB \quad (24)$$

---

**Note**

The ADC is NOT functional in STANDBY or SHUTDOWN mode.

---

### 18.2.2 Voltage Reference Options

The ADC voltage reference ( $V_{R+}$ ) can be configured through the VRSEL bits in the MEMCTL register. Different reference sources can be selected for conversion on different channels. There are three options available for supplying a reference voltage to the ADC:

- External reference supplied to the ADC through the VREF+ and VREF- pins
- MCU supply voltage (VDD)
- Configurable internal reference voltage (INTREF) of 1.4V and 2.5V from Vref module

When supplying an external reference to the ADC, connect the VREF+ pin to the reference source with the appropriate decoupling circuitry, and connect the VREF- pin to ground.

---

**Note**

Using reference options with VREF- will provide better noise performance, as the VREF- provides a dedicated ground for the reference.

---

The internal reference (VREF) is a voltage reference module that is shared by multiple analog peripherals including the ADC peripheral. The internal reference is available on the VREF+ pin and it is recommended to connect a decoupling capacitor of specified value on the device pin. Refer to the device-specific data sheet for the recommended capacitor value. When supplying the internal reference as the reference to the ADC, there is no restriction on the ADC sampling rate and thus can be operated at full speed.

### 18.2.3 Generic Resolution Modes

The ADC supports operation in 12-bit (default), 10-bit, and 8-bit resolution modes. The resolution mode is configured using the RES bits in the CTL2 register.

- When 12-bit mode is selected, the conversion phase requires a total of 12 conversion clock cycles
- When 10-bit mode is selected, the conversion phase requires a total of 10 conversion clock cycles
- When 8-bit mode is selected, the conversion phase requires a total of 8 conversion clock cycles

The conversion clock (CONVCLK) is sourced from an 80MHz oscillator within the ADC IP. The conversion window is based on the resolution mode and the frequency of ADCCLK. For more details, refer to [Figure 18-2](#) and [Figure 18-3](#).

### 18.2.4 Hardware Averaging

This ADC implements digital sample averaging in hardware (HW averaging) to efficiently increase the effective resolution of the ADC without the need for SW or CPU intervention. The HW averaging functionality is configured using the AVGN and AVGD bits in the CTL1 register.

- AVGN defines the number of conversions to accumulate for the current MEMCTLx
- AVGD defines what the accumulated value gets divided by using bit shifting

---

**Note**

The MEMRES result register is a maximum of 16 bits long. If not shifted appropriately, the result will be truncated.

---

**Table 18-1. Available Hardware Averaging Settings**

Bit Field Value	AVGN Settings (number of samples accumulated)	AVGD Settings (number of bits to right shift)
0x0	0	0
0x1	2	1
0x2	4	2
0x3	8	3
0x4	16	4
0x5	32	5
0x6	64	6
0x7	128	7

The averaging configuration is global and it holds for any channel that enables the averaging feature. It is not possible to have different averaging configurations defined per channel. The averaging feature for each individual channel can be enabled through the AVGEN bit in the MEMCTL register. When the sample trigger is received for a channel with averaging enabled, the required number of conversions are performed automatically back-to-back and the final averaged value is stored in the MEMRES register or FIFODAT.

### Note

The data format must be selected as unsigned binary while using the hardware averaging feature.

#### 18.2.5 ADC Clocking

The ADC peripheral clock (ADCCLK) is provided by the [Section 2.4](#) and is used for the sampling clock (SAMPCLK). SYSOSC, HFCLK and ULPCLK are the available clock sources available for ADCCLK, which can support up to 48MHz. Refer to the device-specific data sheet for supported ADCCLK frequencies. Using the ULPCLK, which is the bus clock for all peripherals, is very useful for deterministic start of sampling and simultaneous sampling. Using the HFCLK as the clock source for ADCCLK is useful for when a very accurate, low-jitter, sampling period is needed. The ADC clock source can be selected by programming the SAMPCLK bits in the CLKCFG register. The conversion clock is sourced from a dedicated 80MHz local oscillator which enables high speed 12-bit conversions up to 4MSPs.

SYSOSC needs to be active for the ADC to operate properly. If SYSOSC is not running and the ADC is triggered, the ADC will automatically request SYSCTL to enable and set SYSOSC to base frequency during the conversion. If SYSOSC is already enabled, it will remain the same frequency. The only exception to this is in STOP1 operating mode where SYSOSC will go to base frequency when the ADC is triggered.

In order to provide a way to ensure predictable sample rate operation between power modes, the CCONRUN and CCONSTOP bits can be set to signal the ADC that it can expect that the SYSOSC will already be ON when the device is in RUN and STOP modes respectively. When these bits are set, the ADC will not wait for an ACK from SYSCTL to make sure SYSOSC is running before starting sampling. This feature gives users the flexibility to save power in applications where deterministic sample timing is not a requirement. Refer to [Section 18.2.6](#) for examples on how to properly use the CCONRUN and CCONSTOP control bits.

The user must configure the FRANGE bits in the CLKFREQ register to the appropriate setting based on the expected ADCCLK frequency. The ADC uses the CLKFREQ.FRANGE value and the resolution mode, configured by CTL2.RES bits, to determine how many ADCCLK clock cycles a conversion will take before signaling the End of Conversion (EOC). See [Table 18-2](#) below for more details on how to properly configure the CLKFREQ register and how that impacts the EOC signal generation.

**Table 18-2. CLKFREQ Register Configuration**

CLKFREQ.FRANGE Values	ADCCLK Frequency Range (MHz)	Conversion Duration (Clock cycles)		
		12-bit	10-bit	8-bit
		0	>1 to 4	1
1	>4 to 8	2	2	1
2	>8 to 16	3	3	2
3	>16 to 20	4	4	3
4	>20 to 24	5	4	3
5	>24 to 32	6	6	4
6	>32 to 40	8	7	5
7	>40 to 48	9	8	6

#### 18.2.6 Common ADC Use Cases

There are many ADC use-cases from an operating mode and clocking standpoint but the majority of them fit into one of the items below:

- Triggers in RUN or SLEEP mode
  - If ADC is triggered to start a conversion (software or Event), and the device is in RUN0 or RUN1 or SLEEP0 or SLEEP1 mode (SYSOSC is already running at any frequency), then:
    - Sample clock can be ULPCLK, HFCLK, or SYSOSC in this mode
    - The conversion runs without changing SYSOSC frequency

- 4MHz, 16MHz, 24MHz, or 32MHz SYSOSC frequencies are allowed
- If ADC is triggered to start a conversion (software or Event), and the device is in RUN2 or SLEEP2 mode (SYSOSC is disabled, MCLK = LFCLK = 32kHz), then:
  - Sample clock can be ULPCLK or SYSOSC in this mode
  - SYSCTL interprets the ADC CLK REQ as an asynchronous fast clock request, enabling SYSOSC at 32MHz and forcing MCLK or ULPCLK to 32MHz until the ADC de-asserts the request
  - CCONRUN must be cleared in this use case
  - CCONSTOP must be cleared in this use case
- Triggers in STOP mode
  - Sample clock can be ULPCLK or SYSOSC in this mode
  - If ADC is triggered to start a conversion (Event), and the device is in STOP0 mode (SYSOSC runs at any frequency, ULPCLK = 4MHz), then:
    - The conversion runs without changing SYSOSC frequency
    - 4MHz, 16MHz, 24MHz, or 32MHz SYSOSC frequencies are allowed
  - If ADC is triggered to start a conversion (Event), and the device is in STOP1 mode (SYSOSC was gear shifted to 4MHz), then:
    - SYSCTL forces SYSOSC to BASE (consistent with RUN mode because USE4MHZSTOP was set) when receiving ADC CLK REQ, and SYSCTL releases SYSOSC back to 4MHz after the ADC CLK REQ is removed
    - CCONRUN must be cleared
    - CCONSTOP must be cleared
  - If ADC is triggered to start a conversion (Event), and the device is in STOP2 mode (SYSOSC disabled), then:
    - The trigger event propagates through the event fabric at 32kHz, the ADC receives the trigger and assert the ADC CLK REQ (CPCLK REQ) to SYSCTL, and SYSCTL receives the ADC CLK REQ as an asynchronous fast clock request, suspending STOP, enabling SYSOSC at 32MHz, and forcing MCLK or ULPCLK to 32MHz until the ADC de-asserts the ADC CLK REQ
    - CCONRUN must be cleared
    - CCONSTOP must be cleared
- Triggers in STANDBY mode
  - Sample clock can be ULPCLK or SYSOSC in this mode
  - If ADC is triggered to start a conversion (Event), and the device is in STANDBY0 mode (SYSOSC is disabled but ULPCLK is running), then:
    - The trigger event propagates through event fabric at 32kHz, the ADC receives the trigger and asserts the ADC CLK REQ (CPCLK REQ) to SYSCTL, and SYSCTL interprets the ADC CLK REQ as an asynchronous fast clock request, suspending STANDBY, enabling SYSOSC at 32MHz, and forcing MCLK/ULPCLK to 32MHz until the ADC de-asserts the ADC CLK REQ
    - CCONRUN must be cleared
    - CCONSTOP must be cleared
  - If ADC is triggered to start a conversion (Event-TIMG0 or TIMG1), and the device is in STANDBY1 (ULPCLK is gated with STOPCLKSTBY set), then:
    - The TIMG0 or TIMG1 event triggers an asynchronous fast clock request to suspend STANDBY mode, start SYSOSC at 32MHz, and force MCLK or ULPCLK to 32MHz; there are then 32 SYSOSC cycles for the TIMG0 or TIMG1 event to proceed through the event fabric and for the ADC to capture the timer event and assert the ADC CLK REQ to hold the SYSOSC enabled to run the conversion
    - When the ADC de-asserts the ADC CLK REQ, ULPCLK runs for 32 additional cycles to allow any ADC event (DMA request or IRQ) to propagate, after which SYSCTL resumes STANDBY with STOPCLKSTBY (STANDBY1)
    - CCONRUN must be cleared
    - CCONSTOP must be cleared

### 18.2.7 Power Down Behavior

The ENABLE bit in the PWREN register enables or disables the ADC peripheral. The ADC should be disabled when it is not in use to save power. The PWRDN bit in the CTL0 register selects the ADC power down policy between AUTO and MANUAL. This takes effect when the ADC operates in RUN, SLEEP, and STOP MCU power modes.

PWRDN should be configured based on the max ADC sampling rate required and the operational needs in different MCU power modes. ADC hardware does not force the power down policy to AUTO during operation in STOP mode. It follows the user setting irrespective of the device power modes.

The reset value of PWRDN is 0, which has the default behavior of automatic power down of the ADC peripheral at the end of a conversion and when the next sample signal is not required to be asserted immediately. When the PWRDN bit is set to '1' it selects manual power down behavior. In this setting, the ADC is not powered down at the end of a conversion and remains enabled. This means that the ADC peripheral would only be powered down using the PWREN register.

---

#### Note

Refer to the device-specific data sheet for specifications on the ADC wakeup and enable time.

---

### 18.2.8 Sampling Trigger Sources and Sampling Modes

#### Sample Triggers

There are two sampling trigger sources available which can be selected through the TRIGSRC bit in the CTL1 register; one is a software trigger and the other is an event trigger.

When the software trigger is selected as the source, the application software can set the SC bit in the CTL1 register to initiate the sample phase. When the event trigger is selected as the source, a rising edge on the selected event from the event manager will initiate the sample phase. An event is always edge triggered.

#### Sampling Modes

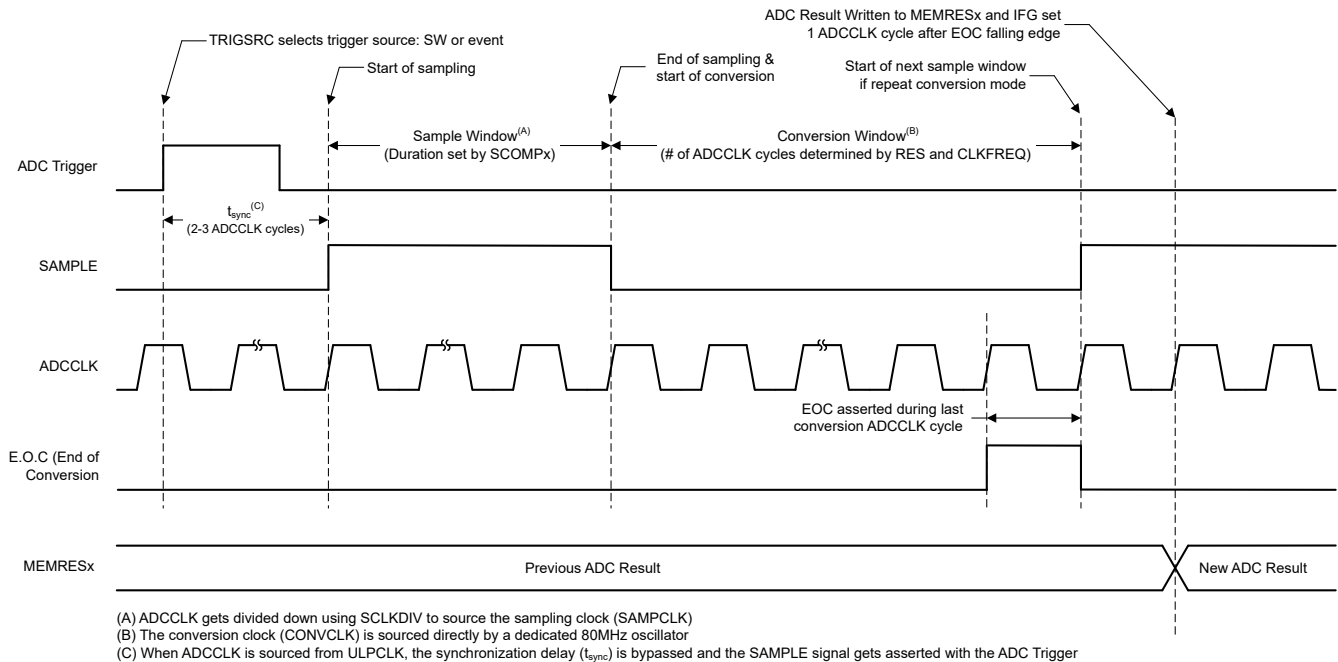

There are two sampling modes available, AUTO and MANUAL, which can be selected through the SAMPMODE bit in the CTL1 register.

##### 18.2.8.1 AUTO Sampling Mode

In AUTO mode, the sample signal is generated synchronous to the sampling clock (SAMPCLK) and can be programmed using an internal sampling timer to determine the duration of the sampling window. The sample timer is 10-bits wide and there are two sample time compare registers (SCOMPx) available to account for various source impedances to measure signals from. One of these two SCOMP registers can be selected using the STIME bit in the MEMCTL register.

There is a 2-3 cycle latency from when the sampling is triggered and when the sampling period starts. This latency can be bypassed by setting ULPCLK as the source for ADCCLK. This synchronization bypass feature is very useful for deterministic sampling and for simultaneous operation of two ADC peripherals.

[Figure 18-2](#) shows the ADC sample and conversion timing diagram when the ADC is configured in AUTO sampling mode.

**Figure 18-2. AUTO Sampling Mode ADC Sample and Conversion Timing Diagram**

**Note**

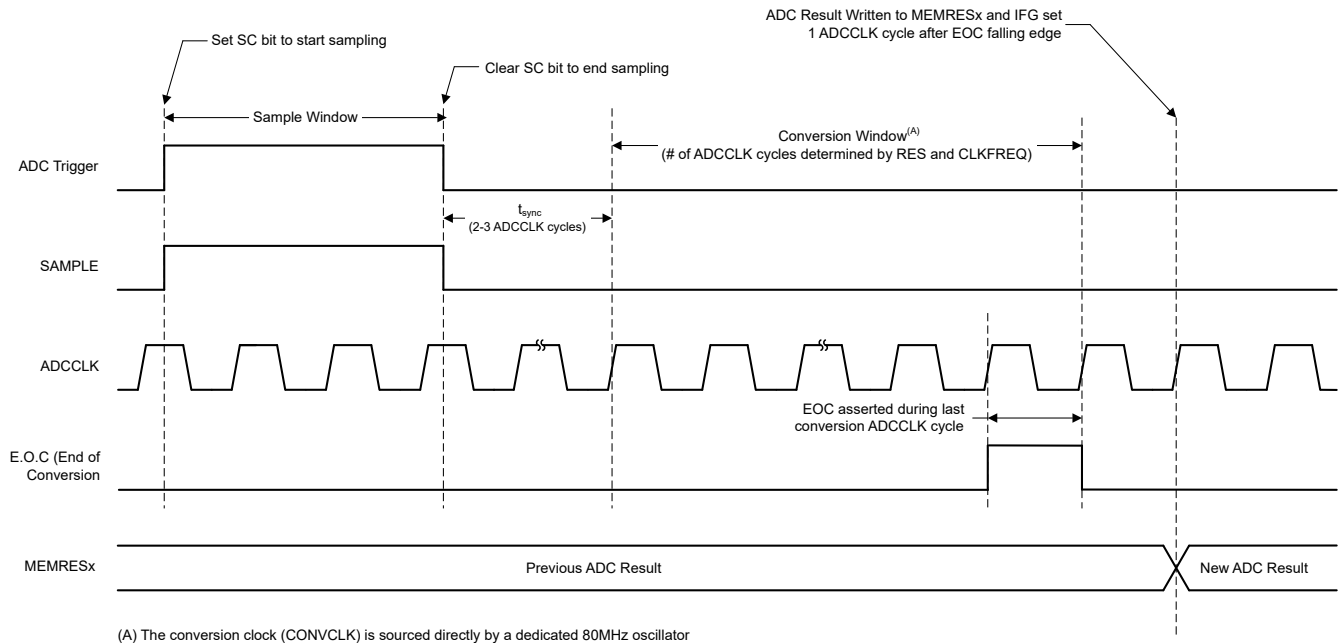

When the reset value of PWRDN is set as '0' which has the default behavior of automatic power down, ADC wakeup/enable time needs to be considered in each sample window. Refer to the device-specific data sheet for specifications on the ADC wakeup/enable time. For example, if the maximum ADC wakeup/enable time is 5uS, it means the duration set by SCOMPx should be > (5uS + Duration for sample window).

**18.2.8.2 MANUAL Sampling Mode**

In MANUAL mode, the sample signal is generated when the SC bit is set which can be asynchronous to the sampling clock. The duration of the sampling window is controlled by software by holding the SC bit high. Because an event is always edge triggered, manual mode with event trigger is not supported for any of the conversion modes. Software trigger with manual sampling mode is supported only for single channel single conversion mode and it is not supported for any of the other three conversion modes.

There is a 2-3 cycle synchronization latency from when the sample window ends to when the conversion window begins.

Figure 18-3 shows the ADC sample and conversion timing diagram when the ADC is configured in MANUAL sampling mode:

**Figure 18-3. MANUAL Sampling Mode ADC Sample and Conversion Timing Diagram**

#### Note

1. In MANUAL sampling mode the CCONRUN bit in the CLKCFG register must be set to 1.
2. When the reset value of PWRDN is set as '0' which has the default behavior of automatic power down, ADC wakeup/enable time needs to be considered before sample window. It means that after setting ENABLE bit in the PWREN register to enable ADC, then application software should set up a delay to wait the ADC wakeup/enable time before starting sampling. Refer to the device-specific data sheet for specifications on the ADC wakeup/enable time.
3. Once SC bit set by software, the SC bit is automatically cleared by hardware after the sample duration, which is the duration during which the analog signal is sampled. If the software attempts to set the SC bit before the sample duration + 2-3 cycles synchronization latency, TOVIFG flag will not be set.

### 18.2.9 Sampling Period

The sampling clock source is selected in the SYSCTL module using the SAMPCLK bits in the CLKCFG register. The desired sampling period for ADC operation can be generated using the internal clock divider and/or the sample timer, which applies to AUTO sampling mode. The internal clock divider is configured using the SCLKDIV bits in the CTL0 register and has divide options of 1, 2, 4, 8, 16, 24, 32, and 48.

The duration of the sampling period can be programmed to one of two user-defined values set by the SCOMP0 and SCOMP1 sample timer registers. The value in SCOMP<sub>x</sub> configures the sampling period by defining the number of sample time clocks to set the sample window to. The default SCOMP<sub>x</sub> sample timer value translates to 1 cycle wide sample pulse which allows the sampling period to be solely based on the sample clock and SCLKDIV. In general, there are three knobs that can be leveraged to control the sample period: SCOMP<sub>x</sub>, SCLKDIV, and the source of the sample clock.

When AUTO power down mode is selected using PWRDN=0, the module enable signal to the ADC peripheral is generated one sampling clock cycle after the sample signal is asserted. This should be considered by the user in the sample window calculation in addition to the ADC power time or settling time needs of other analog modules such as the Temperature Sensor, VREF, etc.

### 18.2.10 Conversion Modes

There are four conversion modes available in the ADC:

1. Single channel single conversion
  - The channel can be selected using MEMCTL
  - The selected channel is sampled and converted only once
  - Multiple conversions are performed when HW averaging is enabled
2. Repeat single channel conversion
  - The channel can be selected using MEMCTL
  - The selected channel is repeatedly sampled and converted until ENC is cleared by software
    - If the TRIG bit is set, a trigger is needed to move to the next conversion
  - Multiple conversions are performed when HW averaging is enabled
3. Sequence of channels conversion
  - Groups of channels can be formed using STARTADD, ENDADD, and MEMCTL registers
  - Each of the channels in the group is sampled and converted only once
  - Multiple conversions are performed on a channel during the sequence when HW averaging is enabled
  - The sequence will complete even if ENC is cleared in the middle of the sequence
4. Repeat sequence of channels conversion
  - Groups of channels can be formed using STARTADD, ENDADD, and MEMCTL registers
  - The group of channels are sampled and converted repeatedly until ENC is cleared by software
    - If the TRIG bit is set, a trigger is needed to move to the next conversion
  - When ENC is cleared the operation stops at the end of the last conversion
  - Multiple conversions are performed on a channel during a sequence when averaging is enabled

The following steps outline the recommended process for configuring the ADC for a desired conversion mode:

1. Use the CONSEQ bits in the CTL1 register to select the desired ADC conversion mode
2. Use the STARTADD bits in the CTL2 register to select which MEMCTLx is used for single conversion or as first MEMCTL for a sequence mode
3. If using a sequence mode, use the ENDADD bits in the CTL2 register to select which MEMCTLx is used for the last conversion of the sequence
4. Assign an ADC input channel to the appropriate MEMCTLx register using the CHANSEL bits
  - For sequence modes, you must assign an ADC input channel for each MEMCTLx that is part of the configured sequence
5. Select HW or SW trigger using the TRIGSRC bit in the CTL1 register
6. Select AUTO or MANUAL sampling mode using the SAMPMODE bit in the CTL1 register
  - If using AUTO mode, program the desired sample timer value in the SCOMPx register and use the STIME bits in the MEMCTLx register to select the appropriate sample timer source (SCOMP0 or SCOMP1)
7. If using repeat single channel or sequence conversion modes, program the TRIG bit in each MEMCTLx register to indicate if a trigger will be needed to step to the next MEMCTL in the sequence
8. Set the ENC bit in the CTL0 register to enable ADC conversions
9. The following table matrix depicts the next step of ADC configuration and usage based on the selected trigger and sampling modes:

**Table 18-3. Trigger and Sample Mode ADC Usage Matrix**

	Trigger Mode	
	SW Trigger	Event Trigger

**Table 18-3. Trigger and Sample Mode ADC Usage Matrix (continued)**

Sampling Mode	Mode	Configuration
Sampling Mode	<b>AUTO</b>	<ul style="list-style-type: none"> <li>Set SC bit to start the sample phase (duration determined by sample timer)</li> <li>Conversion starts once sample phase is over</li> <li>In single channel single conversion, ENC is cleared when conversion is over</li> <li>SC bit is automatically cleared once the trigger is captured</li> <li>For repeat and sequence modes, if TRIG is set in MEMCTL, the SC bit needs to be set for the next conversion to proceed</li> </ul>
	<b>MANUAL</b>	<ul style="list-style-type: none"> <li>Set SC bit to start the sample phase (SC bit is not automatically reset)</li> <li>Clear the SC bit to end the sample phase and start the conversion</li> <li>In single channel single conversion, ENC bit is cleared when conversion is over</li> <li>Repeated/sequential conversion modes and HW averaging are NOT supported in this configuration</li> </ul>

- The ADC results are stored in the MEMRES register of the associated MEMCTL (for example, the MEMCTL0 result is stored in MEMRES0).
  - For repeat conversion modes, the result in MEMRES is updated after every associated MEMCTL conversion
- For repeated conversion modes, clear the ENC bit to stop ADC operation

### 18.2.11 Data Format

The ADC supports two data formats – unsigned binary and 2's complement signed binary. Unsigned binary results are stored right-justified in the MEMRES register or FIFO. Signed binary results are stored left justified in the MEMRES register or FIFO.

**Table 18-4. ADC Data Formats**

Data Format	Resolution	Result Range (decimal)	Result Range (hex)
Unsigned	8-bit	0 to 255	0000h to 00FFh
	10-bit	0 to 1023	0000h to 03FFh
	12-bit	0 to 4095	0000h 0FFFh
Signed	8-bit	-128 to 127	8000h to 7F00h
	10-bit	-512 to 511	8000h to 7FC0h
	12-bit	-2048 to 2047	8000h to 7FF0h

### 18.2.12 Advanced Features

The following sections describe the additional features and benefits provided with the ADC peripheral and how to leverage them in an application.

#### 18.2.12.1 Simultaneous Sampling

Some applications, such as current and voltage sensing, require measurement from multiple analog signals at the exact same time. In these circumstances, using multiple ADCs on a single MCU to perform simultaneous sampling is a requirement. Any device with multiple ADC peripherals in the MSPM0xx platform supports simultaneous sampling.

For this use-case, the ULPCLK should be used as the source for ADCCLK because it is also the clock for all of the peripherals in PD0. This means that it is already synchronized with the bus clock and therefore can ensure deterministic timing for the start of sampling. In addition to using the ULPCLK as the sample clock source for both ADC peripherals, the user is expected to select the same sample trigger and program the clock prescaler and/or SCOMP with the same values on both ADCs.

### 18.2.12.2 Window Comparator

There is one window comparator unit available in the ADC which can be used to check if the input signal is within predefined threshold values set by software. The ADC result that goes into MEMRES or FIFO is what gets checked against the threshold values of the window comparator.

Based on the comparison it can generate 3 interrupt conditions:

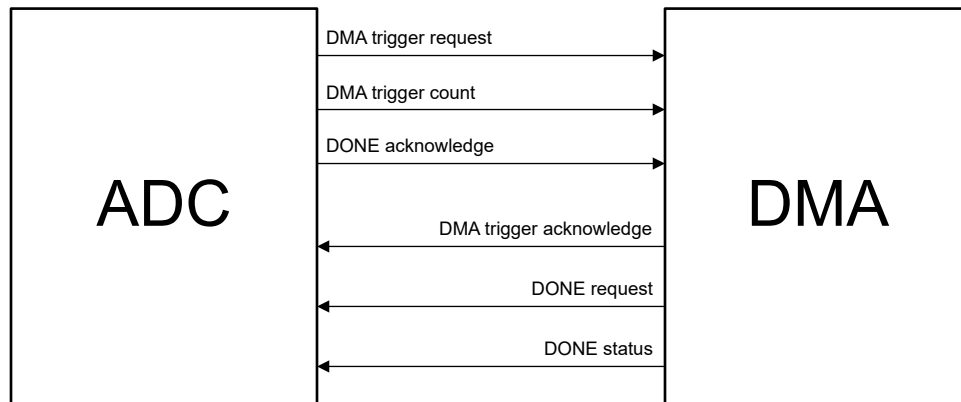

1. LOWIFG – Conversion result is below the Low threshold (WCLOW)
2. HIGHIFG – Conversion result is above the High threshold (WCHIGH)
3. INIFG – Conversion result is in between or equal to the Low and High thresholds

The window comparator low and high threshold values are global for all channels and the window comparison feature can be enabled for each channel as needed using the WINCOMP bit in the MEMCTL register.

When the ADC result data format (CTL2.DF) or resolution (CTL2.RES) configuration is changed, the window comparator threshold values are not reset by hardware and are retained as is. The software application is expected to reconfigure the threshold values as appropriate after changing the data format and/or resolution configuration.

### 18.2.12.3 DMA and FIFO Operation

The ADC has a dedicated interface for communicating to and from the DMA. This interface is useful to offload work from the CPU by using the DMA to store ADC results to memory automatically. [Figure 18-4](#) shows the signals that make up this interface:

**Figure 18-4. Internal ADC-DMA Interface**

#### Note

The “DMA trigger count” signal indicates the number of samples that can be transferred by the DMA upon one trigger request. The “DONE status” signal is used by the ADC to generate the DMA DONE interrupt and it indicates if the DMA data transfer of programmed block size is completed.

The DMAEN bit in the CTL2 register is used to enable the DMA for ADC data transfer. The DMAEN bit is cleared by ADC hardware when the DMA “DONE status” signal is asserted. Software is expected to re-enable the DMA using DMAEN to arm the ADC to generate the next DMA trigger.

The ADC also incorporates an optional First-In-First-Out buffer to provide a way for ADC results to be stored for future use, such as transferring to memory by the DMA. Either the CPU or the DMA can be used to move data

from the ADC regardless of whether the FIFO is enabled or disabled. The memory result flags in the RIS register of the third event publisher serve as the FIFO threshold and can be unmasked to generate the DMA trigger.

The following sections explain the details of using the ADC+DMA/CPU in various conversion modes and with the FIFO enabled or disabled

### ADC-DMA/CPU Operation in Non-FIFO Mode (FIFOEN=0)

#### ADC-DMA/CPU Operation in Non-FIFO Mode (FIFOEN=0)

- Single Conversion and Repeat Single Conversion
  - Configure STARTADD bits to select the desired MEMCTLx register
    - MEMCTLx **is correlated to** MEMRESx
    - MEMRESx **is correlated to** MEMRESIFGx
  - Configure MEMCTL CHANSEL bits to select the desired ADC channel
  - Conversion data is available in MEMRESx
  - MEMRESIFGx can be set to generate a CPU interrupt or the DMA trigger
  - SAMPCNT **must be programmed to 1** by SW for DMA operation
  - The conversion overflow flag OVIFG is set when the ADC updates MEMRESx before the previous sample is read by the CPU or DMA
  - The conversion underflow flag UVIFG is set when the CPU or DMA reads the MEMRESx register before the next conversion result is available
- Sequence Conversion and Repeat Sequence Conversion
  - Configure STARTADD bits to select the first MEMCTL in the sequence
  - Configure ENDADD bits to select the last MEMCTL in the sequence
    - MEMCTLx **is correlated to** MEMRESx
    - MEMRESx **is correlated to** MEMRESIFGx
  - Configure each MEMCTLx CHANSEL bits to select the desired ADC channels
  - Conversion data is available in MEMRESx
  - MEMRESIFGx can be set to generate a CPU interrupt or the DMA trigger
  - SAMPCNT must be programmed by SW to a **suitable value based on number of ADC samples** for DMA operation. Each DMA transfer will be a single ADC result in non-FIFO mode.
  - The conversion overflow flag OVIFG is set when the ADC updates MEMRESx before the previous sample is read by the CPU or DMA
  - The conversion underflow flag UVIFG is set when the CPU or DMA reads the MEMRESx register before the next conversion result is available

---

#### Note

For DMA-based operation in ADC sequence conversion mode, the MEMCTL start address should be smaller than the end address as the DMA source address does not roll back. Repeat sequence conversion mode cannot fill a buffer greater than the number of channels because the DMA does not have a circular mode. Once a sequence is completed, the DMA would need to be manually reconfigured to set the new destination address in order to fill a buffer larger than the number of channels in the sequence.

---

### ADC-DMA/CPU Operation in FIFO Mode (FIFOEN=1)

- Single Conversion and Repeat Single Conversion
  - Configure STARTADD bits to select the desired MEMCTLx register
    - MEMCTLx **is NOT correlated to** MEMRESx
    - MEMRESx **is correlated to** MEMRESIFGx
  - Configure MEMCTL CHANSEL bits to select the desired ADC channel
  - Conversion data is loaded sequentially into MEMRES0,1,2,...N (organized as a FIFO) where N is the number of MEMRES channels in the device.

- The CPU or DMA must read ADC samples from the dedicated FIFODAT register and not from MEMRES registers directly
  - Data in the FIFO is always compacted with two samples and provided as 32-bit data upon a FIFODATA read by CPU or DMA
- MEMRESIFGx should be used as a threshold condition to generate a CPU interrupt or DMA trigger
  - Any MEMRESIFGx can be selected but improper selections can lead to an UVIFG or OVIFG getting set based on DMA speeds and ADC sampling speeds.
- SAMPCNT must be programmed by SW to a **suitable value based on threshold setting** for DMA operation
- The conversion overflow flag OVIFG is set when the ADC updates MEMRESx before the previous sample is read by the CPU or DMA
- The conversion underflow flag UVIFG is set when the CPU or DMA reads the FIFODAT register before the conversion result is available in the MEMRESx registers.

---

#### Note

Single conversion mode with FIFO enabled is not recommended for CPU or DMA based operation. It will lead to underflow condition and unwanted 16-bit data will have to be discarded in software.

---

- Sequence Conversion and Repeat Sequence Conversion
  - Configure STARTADD bits to select the first MEMCTL in the sequence
  - Configure ENDADD bits to select the last MEMCTL in the sequence
    - MEMCTLx is **NOT correlated** to MEMRESx
    - MEMRESx is **correlated** to MEMRESIFGx
  - Configure each MEMCTLx CHANSEL bits to select the desired ADC channels
  - Conversion data is loaded sequentially into MEMRES0,1,2,...N (organized as a FIFO) where N is the number of MEMRES channels in the device.
  - The CPU or DMA must read ADC samples from the dedicated FIFODAT register and not from MEMRES registers directly
    - Data in the FIFO is always compacted with two samples and provided as 32-bit data upon a FIFODATA read by CPU or DMA
  - MEMRESIFGx can be used as a threshold condition to generate a CPU interrupt or DMA trigger
    - Any MEMRESIFGx can be selected but improper selections can lead to an UVIFG or OVIFG getting set based on DMA speeds and ADC sampling speeds.
  - SAMPCNT must be programmed by SW to a **suitable value based on threshold setting** for DMA operation
  - The conversion overflow flag OVIFG is set when the ADC updates MEMRESx before the previous sample is read by the CPU or DMA
  - The conversion underflow flag UVIFG is set when the CPU or DMA reads the FIFODAT register before the conversion result is available in the MEMRESx registers

### Note

- The data in FIFODATA register will shift to the next result upon a read, if there is no new result then the populated value will be 0.
- All available MEMRES are used sequentially in FIFO mode.
- To ensure synchronized reading of bytes from the 32-bit FIFO, which stores 16-bit samples, specific DMA triggers can be used. In particular, selecting MEMRES1, MEMRES3, MEMRES5, MEMRES7, MEMRES9 and MEMRES11 will synchronize the reading of bytes from the FIFO with the corresponding MEMRESx bytes.
  - Set the DMA samples to be transferred upon a trigger to be 1 and set the DMA to repeat single transfer mode. Each trigger will then send 2 ADC samples be synchronized based on when the 2 samples are ready. The synchronization is beneficial as the DMA is commonly faster than the ADC sample and conversion time.
- If the ADC is disabled during either the repeat sequence mode or normal repeat mode, an additional conversion may occur before the ADC completely stops.

**Table 18-5. ADC-DMA/CPU Operation Summary Matrix**

Conversion Mode	FIFO Disabled (FIFOEN=0) Samples not compacted Read from MEMRESx registers directly		FIFO Enabled (FIFOEN=1) Samples always compacted Read from FIFODAT register only	
	CPU Read/Write	DMA Read/Write	CPU Read/Write	DMA Read/Write
<b>Single</b>	Supported	Supported SAMP CNT=1 Sample in 16 bits	Not recommended Underflow flag will set Unwanted 16-bits should be ignored	Not recommended Underflow flag will set Unwanted 16-bits should be ignored
<b>Repeat Single</b>	Supported	Supported SAMP CNT=1 Sample in 16 bits	Supported MEMRESIFG=CPU interrupt FIFODAT read in 32-bits	Supported MEMRESIFG=DMA trigger SAMP CNT=Samples in 32-bits
<b>Sequence</b>	Supported	Supported SAMP CNT=Sample in 16 bits STARTADD<ENDADD	Supported MEMRESIFG=CPU interrupt FIFODAT read in 32-bits	Supported MEMRESIFG=DMA trigger SAMP CNT=Samples in 32-bits
<b>Repeat Sequence</b>	Supported	Not Supported	Supported MEMRESIFG=CPU interrupt FIFODAT read in 32-bits	Supported MEMRESIFG=DMA trigger SAMP CNT=Samples in 32-bits

#### 18.2.12.4 Analog Peripheral Interconnection

The MSPM0 platform of MCUs provides a rich set of high-performance analog peripherals which can interact with each other to perform various analog signal chain functions. The items below describe how the ADC interacts with the other on-board analog peripherals:

#### ADC with Internal Reference Module (VREF)

The ADC has a dedicated enable request and ready interface with the internal voltage reference module. VREF enable is asserted upon sample trigger while internal reference buffer is selected for ADC operation. The ready response from VREF is captured in the ADC status register (REFBUF RDY).

The ready response from VREF **does not** gate the sample phase in the ADC. The ADC sample window is started upon the sample trigger and the settling time of the internal reference buffer needs to be considered in the sample period as appropriate. Software can enable the VREF module using the software enable bit so that it is already settled by the time the ADC starts sampling the input channel. In this case, the sampling time can be smaller and does not have to account for the enable time of VREF.

#### ADC with OPA

The ADC provides a burnout current source (BCS) enable signal to an OPA peripheral when it is selected as the ADC input channel and the BCSEN bit is set in the MEMCTL register. This signal allows the ADC peripheral

to work in unison with the OPA peripheral to monitor sensor health and detect faults. The BCS enable signal remains high for all conversions during hardware averaging operation. The ADC receives a chop request signal and provides a chop state control signal to the OPA peripheral when ADC-assisted OPA chopping is activated and the hardware averaging feature is enabled. The chop state control signal toggles at the end of each conversion during hardware averaging operation. The number of samples averaged should be programmed to an even value when ADC-assisted OPA chopping is activated.

### ADC with Temperature Sensor

The temperature sensor module enable signal is generated by the ADC when the temp sense channel is selected. The settling time of the temperature sensor should be accounted for in the sample period as there is no ready response from the temperature sensor.

#### 18.2.13 Status Register

The ADC status register, STATUS, contains two bits – REFBUFRDY and BUSY.

- REFBUFRDY is set when the ADC receives the ready signal from the internal reference buffer (VREF/REFBUF) after asserting the enable request
- BUSY equaling '1' indicates that the ADC is busy performing a sample or convert operation
  - For **single channel single conversion**, it signals that a trigger has been received and sample or conversion is ongoing. BUSY will be cleared when the conversion completes
  - For **repeat single conversion**, it signals that repeat single operation has begun and has not ended. BUSY will be cleared when ENC is written '0' and the last conversion completes
  - For **sequence of channels conversion**, it signals that the sequence of channels conversion has started. BUSY will be cleared at the end of the sequence
  - For **repeat sequence of channels conversion**, it signals the repeat sequence is ongoing. BUSY will be cleared when ENC is written '0' and the last conversion completes

#### Note

When the ADC is in auto power down mode, the ADC requires a wakeup time before sampling begins. Provide a software delay for the ADC wakeup time, see device datasheet,, before checking the BUSY bit; otherwise a 0 will be read for the BUSY bit.

#### 18.2.14 ADC Events

The ADC peripheral contains three [event publishers](#) and one [event subscriber](#).

One event publisher (CPU\_INT) manages ADC interrupt requests (IRQs) to the CPU subsystem through a [static event route](#). The second event publisher (GEN\_EVENT) can be used to publish ADC events to a subscriber through a [generic event route channel](#). The third event publisher (DMA\_TRIG) can be used as an ADC-to- DMA trigger to send ADC events directly to the DMA through a [DMA event route](#).

The event subscriber (FSUB\_0) can be used to subscribe to events which are published to the event fabric through a [generic event route channel](#).

The ADC events are summarized in [Table 18-6](#).

**Table 18-6. ADC Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU interrupt event</a>	Publisher	ADC	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from ADC to CPU
<a href="#">Generic publisher event</a>	Publisher	ADC	Generic event channel	<a href="#">Generic route</a> (FPUB_0)	GEN_EVENT registers, FPUB_0 register	Trigger generic event channel from ADC

**Table 18-6. ADC Events (continued)**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">DMA trigger event</a>	Publisher	ADC	DMA	<a href="#">DMA route</a>	DMA_TRIG registers	Fixed trigger route from ADC to DMA
<a href="#">Generic subscriber event</a>	Subscriber	Other peripherals	ADC	<a href="#">Generic route(FSUB_0)</a>	FSUB_0	ADC subscription to generic event channel

#### 18.2.14.1 CPU Interrupt Event Publisher (CPU\_INT)

The ADC peripheral provides many interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the ADC are given in [Table 18-7](#).

**Table 18-7. ADC CPU Interrupt Event Conditions (CPU\_INT)**

Index (IIDX)	Name	Description
0x0	NO_INTR	No bit set (IIDX.STAT = 0) means there is no pending interrupt request
0x1	OVIFG	Conversion overflow interrupt flag is set when the ADC updates MEMRESx before the previous sample is read by the CPU or DMA
0x2	TOVIFG	Sequence conversion time overflow interrupt flag is set when the ADC receives a new sampling trigger while the previous sample+conversion is still in progress
0x3	HIGHIFG	High threshold compare interrupt flag is set when the MEMRESx result register is higher than the WCHIGH threshold of the window comparator
0x4	LOWIFG	Low threshold compare interrupt flag is set when the MEMRESx result register is lower than the WCLOW threshold of the window comparator
0x5	INIFG	In-range comparator interrupt flag is set when the MEMRESx result register is within the range of WCLOW and WCHIGH of the window comparator
0x6	DMADONE	DMA done interrupt flag is set when the DMA data transfer of programmed block size is completed
0x7	UVIFG	Conversion underflow interrupt flag, the UVIFG flag is set when the CPU or DMA reads the MEMRESx register before the next conversion result is available
0x9 up to 0x20	MEMRESIFG[0 up to 24] <sup>(1)</sup>	Memory register interrupt flag is set when MEMRESx is loaded with a new conversion result

(1) Refer to the device-specific data sheet to see how many conversion-result storage registers (MEMRES) your device supports.

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. Interrupt (RIS) flags are cleared upon software reading the IIDX register or writing to the respective ICLR register bits. See [Section 7.2.5](#) for guidance on configuring the Event registers for CPU interrupts.

#### 18.2.14.2 Generic Event Publisher (GEN\_EVENT)

The ADC peripheral provides 4 interrupt sources, one of which can be configured to publish an event to a generic event route channel. [Table 18-8](#) lists these interrupt sources.

**Table 18-8. ADC Generic Event Publisher Conditions (GEN\_EVENT)**

Index	Name	Description
0x0	NO_INTR	No bit set means there is no pending interrupt request
0x3	HIGHIFG	High threshold compare interrupt flag is set when the MEMRESx result register is higher than the WCHIGH threshold of the window comparator
0x4	LOWIFG	Low threshold compare interrupt flag is set when the MEMRESx result register is lower than the WCLOW threshold of the window comparator

**Table 18-8. ADC Generic Event Publisher Conditions (GEN\_EVENT) (continued)**

Index	Name	Description
0x5	INIFG	In-range comparator interrupt flag is set when the MEMRESx result register is within the range of WLOW and WHIGH of the window comparator
0x9	MEMRESIFG0	Memory register interrupt flag is set when MEMRES0 is loaded with a new conversion result

The generic event publisher configuration is managed with the GEN\_EVENT event management registers. Interrupt (RIS) flags are cleared based on acknowledgment (ACK) signal from the subscriber module received over the event fabric. See [Section 7.2.5](#) for guidance on configuring the Event registers for generic event publishers.

The generic event channel which GEN\_EVENT is to publish to must be selected by writing the target generic channel ID to the **FPUB\_0** register in the ADC. See [Section 7.1.3.3](#) for guidance on configuring generic event routes.

If this publisher is not used in an application, the FPUB\_0 register can be left in a disconnected state (set equal to zero) and no events should be unmasked through the MIS register in the ADC GEN\_EVENT register set.

#### 18.2.14.3 DMA Trigger Event Publisher (DMA\_TRIG)

The ADC module provides many interrupt sources which can be configured to source the DMA trigger. In order of decreasing interrupt priority, the DMA trigger events from the ADC are given in [Table 18-9](#). When the DMA channel is needed by the ADC, the DMA trigger should be unmasked in the IMASK register of DMA\_TRIG and the DMA should be configured as needed to support the ADC operation.

**Table 18-9. ADC DMA Trigger Event Conditions (DMA\_TRIG)**

Index (IIDX)	Name	Description
0x0	NO_INTR	No bit set (IIDX.STAT = 0) means there is no pending interrupt request
0x9 up to 0x20	MEMRESIFG[0 up to 24] <sup>(1)</sup>	Memory register interrupt flag is set when MEMRESx is loaded with a new conversion result

(1) Check the device-specific data sheet to see how many conversion-result storage registers (MEMRES) your device supports.

The DMA trigger event configuration is managed with the DMA\_TRIG event management registers. The interrupt (RIS) flags are cleared based on ACK from DMA. See [Section 7.2.5](#) for guidance on configuring the Event registers for DMA triggers.

#### 18.2.14.4 Generic Event Subscriber (FSUB\_0)

The ADC peripheral supports receiving events routed through a generic channel from other peripherals. Refer to [Section 7.1.3.3](#) and [Section 7.2.3](#) for how generic event route works.

Once the channel to be used is determined, and both the publisher and subscriber ports for the peripherals being connected are known, use the steps below to establish the event connection. In this example, a GPIO triggered ADC application will be configured, using GPIO Port A to publish an event to generic channel 1, with ADC0 subscribing to generic channel 1 as a start-of-conversion trigger.

1. Configure the GEN\_EVENT registers of GPIO Port A to set the event request based on the appropriate event (for example, a DIN rise event).
2. Store 0x1 into the FPUB\_0 register of GPIO Port A to publish the GPIO event selected by the GEN\_EVENT registers to generic route channel 1. Channel 1 must not be in use by another peripheral.
3. Store 0x1 the FSUB\_0 register of ADC0 so that ADC0 is listening for events published by the timer to channel 1.
4. Configure ADC0 to trigger from the subscriber port according to the configuration instructions in [Section 18.2.8](#)
5. Configure and enable the appropriate GPIO pin to monitor input voltage events

## 18.3 ADC12 Registers

Table 18-10 lists the memory-mapped registers for the ADC12 registers. All register offset addresses not listed in Table 18-10 should be considered as reserved locations and the register contents should not be modified.

**Table 18-10. ADC12 Registers**

Offset	Acronym	Register Name	Section
400h	FSUB_0	Subscriber Configuration Register.	<a href="#">Section 1</a>

Complex bit access types are encoded to fit into small table cells. Table 18-11 shows the codes that are used for access types in this section.

**Table 18-11. ADC12 Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
RH	R H	Read Set or cleared by hardware
Write Type		
W	W	Write
WK	W K	Write Write protected by a key
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

**1 FSUB\_0 Register (Offset = 400h) [Reset = 0000000h]**

 FSUB\_0 is shown in [Figure 18-5](#) and described in [Table 18-12](#).

 Return to the [Summary Table](#).

15-0	RESERVED	R	0h	

## 7 IIDX Register (Offset = 1020h) [Reset = 0000000h]

IIDX is shown in [Figure 18-11](#) and described in [Table 18-18](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. 0x0 means no event pending. Interrupt 1 is the highest priority, 2 next highest, 4, 8, ...  $2^{31}$  is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 18-11. IIDX Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Table 18-27. IMASK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MEMRESIFG23	R/W	0h	Raw interrupt status for MEMRES23. This bit is set to 1 when MEMRES23 is loaded with a new conversion result. Reading MEMRES23 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
30	MEMRESIFG22	R/W	0h	Raw interrupt status for MEMRES22. This bit is set to 1 when MEMRES22 is loaded with a new conversion result. Reading MEMRES22 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
29	MEMRESIFG21	R/W	0h	Raw interrupt status for MEMRES21. This bit is set to 1 when MEMRES21 is loaded with a new conversion result. Reading MEMRES21 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
28	MEMRESIFG20	R/W	0h	Raw interrupt status for MEMRES20. This bit is set to 1 when MEMRES20 is loaded with a new conversion result. Reading MEMRES20 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-27. IMASK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MEMRESIFG19	R/W	0h	Raw interrupt status for MEMRES19. This bit is set to 1 when MEMRES19 is loaded with a new conversion result. Reading MEMRES19 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
26	MEMRESIFG18	R/W	0h	Raw interrupt status for MEMRES18. This bit is set to 1 when MEMRES18 is loaded with a new conversion result. Reading MEMRES18 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
25	MEMRESIFG17	R/W	0h	Raw interrupt status for MEMRES17. This bit is set to 1 when MEMRES17 is loaded with a new conversion result. Reading MEMRES17 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
24	MEMRESIFG16	R/W	0h	Raw interrupt status for MEMRES16. This bit is set to 1 when MEMRES16 is loaded with a new conversion result. Reading MEMRES16 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
23	MEMRESIFG15	R/W	0h	Raw interrupt status for MEMRES15. This bit is set to 1 when MEMRES15 is loaded with a new conversion result. Reading MEMRES15 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
22	MEMRESIFG14	R/W	0h	Raw interrupt status for MEMRES14. This bit is set to 1 when MEMRES14 is loaded with a new conversion result. Reading MEMRES14 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
21	MEMRESIFG13	R/W	0h	Raw interrupt status for MEMRES13. This bit is set to 1 when MEMRES13 is loaded with a new conversion result. Reading MEMRES13 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
20	MEMRESIFG12	R/W	0h	Raw interrupt status for MEMRES12. This bit is set to 1 when MEMRES12 is loaded with a new conversion result. Reading MEMRES12 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-27. IMASK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MEMRESIFG11	R/W	0h	Raw interrupt status for MEMRES11. This bit is set to 1 when MEMRES11 is loaded with a new conversion result. Reading MEMRES11 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
18	MEMRESIFG10	R/W	0h	Raw interrupt status for MEMRES10. This bit is set to 1 when MEMRES10 is loaded with a new conversion result. Reading MEMRES10 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
17	MEMRESIFG9	R/W	0h	Raw interrupt status for MEMRES9. This bit is set to 1 when MEMRES9 is loaded with a new conversion result. Reading MEMRES9 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
16	MEMRESIFG8	R/W	0h	Raw interrupt status for MEMRES8. This bit is set to 1 when MEMRES8 is loaded with a new conversion result. Reading MEMRES8 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
15	MEMRESIFG7	R/W	0h	Raw interrupt status for MEMRES7. This bit is set to 1 when MEMRES7 is loaded with a new conversion result. Reading MEMRES7 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
14	MEMRESIFG6	R/W	0h	Raw interrupt status for MEMRES6. This bit is set to 1 when MEMRES6 is loaded with a new conversion result. Reading MEMRES6 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
13	MEMRESIFG5	R/W	0h	Raw interrupt status for MEMRES5. This bit is set to 1 when MEMRES5 is loaded with a new conversion result. Reading MEMRES5 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
12	MEMRESIFG4	R/W	0h	Raw interrupt status for MEMRES4. This bit is set to 1 when MEMRES4 is loaded with a new conversion result. Reading MEMRES4 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-27. IMASK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MEMRESIFG3	R/W	0h	Raw interrupt status for MEMRES3. This bit is set to 1 when MEMRES3 is loaded with a new conversion result. Reading MEMRES3 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
10	MEMRESIFG2	R/W	0h	Raw interrupt status for MEMRES2. This bit is set to 1 when MEMRES2 is loaded with a new conversion result. Reading MEMRES2 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
9	MEMRESIFG1	R/W	0h	Raw interrupt status for MEMRES1. This bit is set to 1 when MEMRES1 is loaded with a new conversion result. Reading MEMRES1 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
8	MEMRESIFG0	R/W	0h	Raw interrupt status for MEMRES0. This bit is set to 1 when MEMRES0 is loaded with a new conversion result. Reading MEMRES0 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
7	RESERVED	R	0h	
6	UVIFG	R/W	0h	Raw interrupt flag for MEMRESx underflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
5	DMADONE	R/W	0h	Raw interrupt flag for DMADONE. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
4	INIFG	R/W	0h	Mask INIFG in MIS_EX register. 0h = Interrupt is not pending. 1h = Interrupt is pending.
3	LOWIFG	R/W	0h	Raw interrupt flag for the MEMRESx result register being below than the WCLOWx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
2	HIGHIFG	R/W	0h	Raw interrupt flag for the MEMRESx result register being higher than the WCHIGHx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
1	TOVIFG	R/W	0h	Raw interrupt flag for sequence conversion timeout overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

**Table 18-27. IMASK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	OVIFG	R/W	0h	Raw interrupt flag for MEMRESx overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

## 9 RIS Register (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 18-13](#) and described in [Table 18-20](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Table 18-29. RIS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MEMRESIFG23	R	0h	Raw interrupt status for MEMRES23. This bit is set to 1 when MEMRES23 is loaded with a new conversion result. Reading MEMRES23 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
30	MEMRESIFG22	R	0h	Raw interrupt status for MEMRES22. This bit is set to 1 when MEMRES22 is loaded with a new conversion result. Reading MEMRES22 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
29	MEMRESIFG21	R	0h	Raw interrupt status for MEMRES21. This bit is set to 1 when MEMRES21 is loaded with a new conversion result. Reading MEMRES21 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
28	MEMRESIFG20	R	0h	Raw interrupt status for MEMRES20. This bit is set to 1 when MEMRES20 is loaded with a new conversion result. Reading MEMRES20 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-29. RIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MEMRESIFG19	R	0h	Raw interrupt status for MEMRES19. This bit is set to 1 when MEMRES19 is loaded with a new conversion result. Reading MEMRES19 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
26	MEMRESIFG18	R	0h	Raw interrupt status for MEMRES18. This bit is set to 1 when MEMRES18 is loaded with a new conversion result. Reading MEMRES18 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
25	MEMRESIFG17	R	0h	Raw interrupt status for MEMRES17. This bit is set to 1 when MEMRES17 is loaded with a new conversion result. Reading MEMRES17 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
24	MEMRESIFG16	R	0h	Raw interrupt status for MEMRES16. This bit is set to 1 when MEMRES16 is loaded with a new conversion result. Reading MEMRES16 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
23	MEMRESIFG15	R	0h	Raw interrupt status for MEMRES15. This bit is set to 1 when MEMRES15 is loaded with a new conversion result. Reading MEMRES15 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
22	MEMRESIFG14	R	0h	Raw interrupt status for MEMRES14. This bit is set to 1 when MEMRES14 is loaded with a new conversion result. Reading MEMRES14 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
21	MEMRESIFG13	R	0h	Raw interrupt status for MEMRES13. This bit is set to 1 when MEMRES13 is loaded with a new conversion result. Reading MEMRES13 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
20	MEMRESIFG12	R	0h	Raw interrupt status for MEMRES12. This bit is set to 1 when MEMRES12 is loaded with a new conversion result. Reading MEMRES12 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-29. RIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MEMRESIFG11	R	0h	Raw interrupt status for MEMRES11. This bit is set to 1 when MEMRES11 is loaded with a new conversion result. Reading MEMRES11 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
18	MEMRESIFG10	R	0h	Raw interrupt status for MEMRES10. This bit is set to 1 when MEMRES10 is loaded with a new conversion result. Reading MEMRES10 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
17	MEMRESIFG9	R	0h	Raw interrupt status for MEMRES9. This bit is set to 1 when MEMRES9 is loaded with a new conversion result. Reading MEMRES9 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
16	MEMRESIFG8	R	0h	Raw interrupt status for MEMRES8. This bit is set to 1 when MEMRES8 is loaded with a new conversion result. Reading MEMRES8 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
15	MEMRESIFG7	R	0h	Raw interrupt status for MEMRES7. This bit is set to 1 when MEMRES7 is loaded with a new conversion result. Reading MEMRES7 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
14	MEMRESIFG6	R	0h	Raw interrupt status for MEMRES6. This bit is set to 1 when MEMRES6 is loaded with a new conversion result. Reading MEMRES6 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
13	MEMRESIFG5	R	0h	Raw interrupt status for MEMRES5. This bit is set to 1 when MEMRES5 is loaded with a new conversion result. Reading MEMRES5 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
12	MEMRESIFG4	R	0h	Raw interrupt status for MEMRES4. This bit is set to 1 when MEMRES4 is loaded with a new conversion result. Reading MEMRES4 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-29. RIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MEMRESIFG3	R	0h	Raw interrupt status for MEMRES3. This bit is set to 1 when MEMRES3 is loaded with a new conversion result. Reading MEMRES3 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
10	MEMRESIFG2	R	0h	Raw interrupt status for MEMRES2. This bit is set to 1 when MEMRES2 is loaded with a new conversion result. Reading MEMRES2 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
9	MEMRESIFG1	R	0h	Raw interrupt status for MEMRES1. This bit is set to 1 when MEMRES1 is loaded with a new conversion result. Reading MEMRES1 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
8	MEMRESIFG0	R	0h	Raw interrupt status for MEMRES0. This bit is set to 1 when MEMRES0 is loaded with a new conversion result. Reading MEMRES0 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
7	RESERVED	R	0h	
6	UVIFG	R	0h	Raw interrupt flag for MEMRESx underflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
5	DMADONE	R	0h	Raw interrupt flag for DMADONE. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
4	INIFG	R	0h	Mask INIFG in MIS_EX register. 0h = Interrupt is not pending. 1h = Interrupt is pending.
3	LOWIFG	R	0h	Raw interrupt flag for the MEMRESx result register being below than the WCLOWx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
2	HIGHIFG	R	0h	Raw interrupt flag for the MEMRESx result register being higher than the WCHIGHx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
1	TOVIFG	R	0h	Raw interrupt flag for sequence conversion trigger overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

**Table 18-29. RIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	OVIFG	R	0h	Raw interrupt flag for MEMRESx overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

## 10 MIS Register (Offset = 1038h) [Reset = 0000000h]

MIS is shown in [Figure 18-14](#) and described in [Table 18-21](#).

Return to the [Summary Table](#).

Masked interrupt status. This is an AND of the IMASK and RIS registers.

**Table 18-31. MIS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MEMRESIFG23	R	0h	Raw interrupt status for MEMRES23. This bit is set to 1 when MEMRES23 is loaded with a new conversion result. Reading MEMRES23 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
30	MEMRESIFG22	R	0h	Raw interrupt status for MEMRES22. This bit is set to 1 when MEMRES22 is loaded with a new conversion result. Reading MEMRES22 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
29	MEMRESIFG21	R	0h	Raw interrupt status for MEMRES21. This bit is set to 1 when MEMRES21 is loaded with a new conversion result. Reading MEMRES21 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
28	MEMRESIFG20	R	0h	Raw interrupt status for MEMRES20. This bit is set to 1 when MEMRES20 is loaded with a new conversion result. Reading MEMRES20 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-31. MIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MEMRESIFG19	R	0h	Raw interrupt status for MEMRES19. This bit is set to 1 when MEMRES19 is loaded with a new conversion result. Reading MEMRES19 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
26	MEMRESIFG18	R	0h	Raw interrupt status for MEMRES18. This bit is set to 1 when MEMRES18 is loaded with a new conversion result. Reading MEMRES18 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
25	MEMRESIFG17	R	0h	Raw interrupt status for MEMRES17. This bit is set to 1 when MEMRES17 is loaded with a new conversion result. Reading MEMRES17 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
24	MEMRESIFG16	R	0h	Raw interrupt status for MEMRES16. This bit is set to 1 when MEMRES16 is loaded with a new conversion result. Reading MEMRES16 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
23	MEMRESIFG15	R	0h	Raw interrupt status for MEMRES15. This bit is set to 1 when MEMRES15 is loaded with a new conversion result. Reading MEMRES15 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
22	MEMRESIFG14	R	0h	Raw interrupt status for MEMRES14. This bit is set to 1 when MEMRES14 is loaded with a new conversion result. Reading MEMRES14 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
21	MEMRESIFG13	R	0h	Raw interrupt status for MEMRES13. This bit is set to 1 when MEMRES13 is loaded with a new conversion result. Reading MEMRES13 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
20	MEMRESIFG12	R	0h	Raw interrupt status for MEMRES12. This bit is set to 1 when MEMRES12 is loaded with a new conversion result. Reading MEMRES12 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-31. MIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MEMRESIFG11	R	0h	Raw interrupt status for MEMRES11. This bit is set to 1 when MEMRES11 is loaded with a new conversion result. Reading MEMRES11 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
18	MEMRESIFG10	R	0h	Raw interrupt status for MEMRES10. This bit is set to 1 when MEMRES10 is loaded with a new conversion result. Reading MEMRES10 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
17	MEMRESIFG9	R	0h	Raw interrupt status for MEMRES9. This bit is set to 1 when MEMRES9 is loaded with a new conversion result. Reading MEMRES9 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
16	MEMRESIFG8	R	0h	Raw interrupt status for MEMRES8. This bit is set to 1 when MEMRES8 is loaded with a new conversion result. Reading MEMRES8 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
15	MEMRESIFG7	R	0h	Raw interrupt status for MEMRES7. This bit is set to 1 when MEMRES7 is loaded with a new conversion result. Reading MEMRES7 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
14	MEMRESIFG6	R	0h	Raw interrupt status for MEMRES6. This bit is set to 1 when MEMRES6 is loaded with a new conversion result. Reading MEMRES6 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
13	MEMRESIFG5	R	0h	Raw interrupt status for MEMRES5. This bit is set to 1 when MEMRES5 is loaded with a new conversion result. Reading MEMRES5 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
12	MEMRESIFG4	R	0h	Raw interrupt status for MEMRES4. This bit is set to 1 when MEMRES4 is loaded with a new conversion result. Reading MEMRES4 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-31. MIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MEMRESIFG3	R	0h	Raw interrupt status for MEMRES3. This bit is set to 1 when MEMRES3 is loaded with a new conversion result. Reading MEMRES3 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
10	MEMRESIFG2	R	0h	Raw interrupt status for MEMRES2. This bit is set to 1 when MEMRES2 is loaded with a new conversion result. Reading MEMRES2 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
9	MEMRESIFG1	R	0h	Raw interrupt status for MEMRES1. This bit is set to 1 when MEMRES1 is loaded with a new conversion result. Reading MEMRES1 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
8	MEMRESIFG0	R	0h	Raw interrupt status for MEMRES0. This bit is set to 1 when MEMRES0 is loaded with a new conversion result. Reading MEMRES0 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
7	RESERVED	R	0h	
6	UVIFG	R	0h	Raw interrupt flag for MEMRESx underflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
5	DMADONE	R	0h	Raw interrupt flag for DMADONE. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
4	INIFG	R	0h	Mask INIFG in MIS_EX register. 0h = Interrupt is not pending. 1h = Interrupt is pending.
3	LOWIFG	R	0h	Raw interrupt flag for the MEMRESx result register being below than the WCLOWx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
2	HIGHIFG	R	0h	Raw interrupt flag for the MEMRESx result register being higher than the WCHIGHx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
1	TOVIFG	R	0h	Raw interrupt flag for sequence conversion timeout overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

**Table 18-31. MIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	OVIFG	R	0h	Raw interrupt flag for MEMRESx overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

## 11 ISET Register (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 18-15](#) and described in [Table 18-22](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Table 18-33. ISET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MEMRESIFG23	W	0h	Raw interrupt status for MEMRES23. This bit is set to 1 when MEMRES23 is loaded with a new conversion result. Reading MEMRES23 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
30	MEMRESIFG22	W	0h	Raw interrupt status for MEMRES22. This bit is set to 1 when MEMRES22 is loaded with a new conversion result. Reading MEMRES22 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
29	MEMRESIFG21	W	0h	Raw interrupt status for MEMRES21. This bit is set to 1 when MEMRES21 is loaded with a new conversion result. Reading MEMRES21 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
28	MEMRESIFG20	W	0h	Raw interrupt status for MEMRES20. This bit is set to 1 when MEMRES20 is loaded with a new conversion result. Reading MEMRES20 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-33. ISET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MEMRESIFG19	W	0h	Raw interrupt status for MEMRES19. This bit is set to 1 when MEMRES19 is loaded with a new conversion result. Reading MEMRES19 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
26	MEMRESIFG18	W	0h	Raw interrupt status for MEMRES18. This bit is set to 1 when MEMRES18 is loaded with a new conversion result. Reading MEMRES18 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
25	MEMRESIFG17	W	0h	Raw interrupt status for MEMRES17. This bit is set to 1 when MEMRES17 is loaded with a new conversion result. Reading MEMRES17 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
24	MEMRESIFG16	W	0h	Raw interrupt status for MEMRES16. This bit is set to 1 when MEMRES16 is loaded with a new conversion result. Reading MEMRES16 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
23	MEMRESIFG15	W	0h	Raw interrupt status for MEMRES15. This bit is set to 1 when MEMRES15 is loaded with a new conversion result. Reading MEMRES15 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
22	MEMRESIFG14	W	0h	Raw interrupt status for MEMRES14. This bit is set to 1 when MEMRES14 is loaded with a new conversion result. Reading MEMRES14 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
21	MEMRESIFG13	W	0h	Raw interrupt status for MEMRES13. This bit is set to 1 when MEMRES13 is loaded with a new conversion result. Reading MEMRES13 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
20	MEMRESIFG12	W	0h	Raw interrupt status for MEMRES12. This bit is set to 1 when MEMRES12 is loaded with a new conversion result. Reading MEMRES12 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-33. ISET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MEMRESIFG11	W	0h	Raw interrupt status for MEMRES11. This bit is set to 1 when MEMRES11 is loaded with a new conversion result. Reading MEMRES11 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
18	MEMRESIFG10	W	0h	Raw interrupt status for MEMRES10. This bit is set to 1 when MEMRES10 is loaded with a new conversion result. Reading MEMRES10 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
17	MEMRESIFG9	W	0h	Raw interrupt status for MEMRES9. This bit is set to 1 when MEMRES9 is loaded with a new conversion result. Reading MEMRES9 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
16	MEMRESIFG8	W	0h	Raw interrupt status for MEMRES8. This bit is set to 1 when MEMRES8 is loaded with a new conversion result. Reading MEMRES8 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
15	MEMRESIFG7	W	0h	Raw interrupt status for MEMRES7. This bit is set to 1 when MEMRES7 is loaded with a new conversion result. Reading MEMRES7 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
14	MEMRESIFG6	W	0h	Raw interrupt status for MEMRES6. This bit is set to 1 when MEMRES6 is loaded with a new conversion result. Reading MEMRES6 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
13	MEMRESIFG5	W	0h	Raw interrupt status for MEMRES5. This bit is set to 1 when MEMRES5 is loaded with a new conversion result. Reading MEMRES5 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
12	MEMRESIFG4	W	0h	Raw interrupt status for MEMRES4. This bit is set to 1 when MEMRES4 is loaded with a new conversion result. Reading MEMRES4 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-33. ISET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MEMRESIFG3	W	0h	Raw interrupt status for MEMRES3. This bit is set to 1 when MEMRES3 is loaded with a new conversion result. Reading MEMRES3 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
10	MEMRESIFG2	W	0h	Raw interrupt status for MEMRES2. This bit is set to 1 when MEMRES2 is loaded with a new conversion result. Reading MEMRES2 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
9	MEMRESIFG1	W	0h	Raw interrupt status for MEMRES1. This bit is set to 1 when MEMRES1 is loaded with a new conversion result. Reading MEMRES1 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
8	MEMRESIFG0	W	0h	Raw interrupt status for MEMRES0. This bit is set to 1 when MEMRES0 is loaded with a new conversion result. Reading MEMRES0 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
7	RESERVED	R	0h	
6	UVIFG	W	0h	Raw interrupt flag for MEMRESx underflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
5	DMADONE	W	0h	Raw interrupt flag for DMADONE. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
4	INIFG	W	0h	Mask INIFG in MIS_EX register. 0h = Interrupt is not pending. 1h = Interrupt is pending.
3	LOWIFG	W	0h	Raw interrupt flag for the MEMRESx result register being below than the WCLOWx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
2	HIGHIFG	W	0h	Raw interrupt flag for the MEMRESx result register being higher than the WCHIGHx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
1	TOVIFG	W	0h	Raw interrupt flag for sequence conversion timeout overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

**Table 18-33. ISET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	OVIFG	W	0h	Raw interrupt flag for MEMRESx overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

## 12 ICLR Register (Offset = 1048h) [Reset = 0000000h]

ICLR is shown in [Figure 18-16](#) and described in [Table 18-23](#).

Return to the [Summary Table](#).

Interrupt clear. Write a 1 to clear corresponding Interrupt.

**Table 18-35. ICLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MEMRESIFG23	W	0h	Raw interrupt status for MEMRES23. This bit is set to 1 when MEMRES23 is loaded with a new conversion result. Reading MEMRES23 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
30	MEMRESIFG22	W	0h	Raw interrupt status for MEMRES22. This bit is set to 1 when MEMRES22 is loaded with a new conversion result. Reading MEMRES22 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
29	MEMRESIFG21	W	0h	Raw interrupt status for MEMRES21. This bit is set to 1 when MEMRES21 is loaded with a new conversion result. Reading MEMRES21 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
28	MEMRESIFG20	W	0h	Raw interrupt status for MEMRES20. This bit is set to 1 when MEMRES20 is loaded with a new conversion result. Reading MEMRES20 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-35. ICLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MEMRESIFG19	W	0h	Raw interrupt status for MEMRES19. This bit is set to 1 when MEMRES19 is loaded with a new conversion result. Reading MEMRES19 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
26	MEMRESIFG18	W	0h	Raw interrupt status for MEMRES18. This bit is set to 1 when MEMRES18 is loaded with a new conversion result. Reading MEMRES18 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
25	MEMRESIFG17	W	0h	Raw interrupt status for MEMRES17. This bit is set to 1 when MEMRES17 is loaded with a new conversion result. Reading MEMRES17 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
24	MEMRESIFG16	W	0h	Raw interrupt status for MEMRES16. This bit is set to 1 when MEMRES16 is loaded with a new conversion result. Reading MEMRES16 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
23	MEMRESIFG15	W	0h	Raw interrupt status for MEMRES15. This bit is set to 1 when MEMRES15 is loaded with a new conversion result. Reading MEMRES15 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
22	MEMRESIFG14	W	0h	Raw interrupt status for MEMRES14. This bit is set to 1 when MEMRES14 is loaded with a new conversion result. Reading MEMRES14 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
21	MEMRESIFG13	W	0h	Raw interrupt status for MEMRES13. This bit is set to 1 when MEMRES13 is loaded with a new conversion result. Reading MEMRES13 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
20	MEMRESIFG12	W	0h	Raw interrupt status for MEMRES12. This bit is set to 1 when MEMRES12 is loaded with a new conversion result. Reading MEMRES12 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-35. ICLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MEMRESIFG11	W	0h	Raw interrupt status for MEMRES11. This bit is set to 1 when MEMRES11 is loaded with a new conversion result. Reading MEMRES11 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
18	MEMRESIFG10	W	0h	Raw interrupt status for MEMRES10. This bit is set to 1 when MEMRES10 is loaded with a new conversion result. Reading MEMRES10 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
17	MEMRESIFG9	W	0h	Raw interrupt status for MEMRES9. This bit is set to 1 when MEMRES9 is loaded with a new conversion result. Reading MEMRES9 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
16	MEMRESIFG8	W	0h	Raw interrupt status for MEMRES8. This bit is set to 1 when MEMRES8 is loaded with a new conversion result. Reading MEMRES8 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
15	MEMRESIFG7	W	0h	Raw interrupt status for MEMRES7. This bit is set to 1 when MEMRES7 is loaded with a new conversion result. Reading MEMRES7 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
14	MEMRESIFG6	W	0h	Raw interrupt status for MEMRES6. This bit is set to 1 when MEMRES6 is loaded with a new conversion result. Reading MEMRES6 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
13	MEMRESIFG5	W	0h	Raw interrupt status for MEMRES5. This bit is set to 1 when MEMRES5 is loaded with a new conversion result. Reading MEMRES5 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
12	MEMRESIFG4	W	0h	Raw interrupt status for MEMRES4. This bit is set to 1 when MEMRES4 is loaded with a new conversion result. Reading MEMRES4 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-35. ICLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MEMRESIFG3	W	0h	Raw interrupt status for MEMRES3. This bit is set to 1 when MEMRES3 is loaded with a new conversion result. Reading MEMRES3 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
10	MEMRESIFG2	W	0h	Raw interrupt status for MEMRES2. This bit is set to 1 when MEMRES2 is loaded with a new conversion result. Reading MEMRES2 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
9	MEMRESIFG1	W	0h	Raw interrupt status for MEMRES1. This bit is set to 1 when MEMRES1 is loaded with a new conversion result. Reading MEMRES1 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
8	MEMRESIFG0	W	0h	Raw interrupt status for MEMRES0. This bit is set to 1 when MEMRES0 is loaded with a new conversion result. Reading MEMRES0 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
7	RESERVED	R	0h	
6	UVIFG	W	0h	Raw interrupt flag for MEMRESx underflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
5	DMADONE	W	0h	Raw interrupt flag for DMADONE. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
4	INIFG	W	0h	Mask INIFG in MIS_EX register. 0h = Interrupt is not pending. 1h = Interrupt is pending.
3	LOWIFG	W	0h	Raw interrupt flag for the MEMRESx result register being below than the WCLOWx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
2	HIGHIFG	W	0h	Raw interrupt flag for the MEMRESx result register being higher than the WCHIGHx threshold of the window comparator. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.
1	TOVIFG	W	0h	Raw interrupt flag for sequence conversion timeout overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

**Table 18-35. ICLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	OVIFG	W	0h	Raw interrupt flag for MEMRESx overflow. This bit is reset to 0 by IIDX read or when corresponding bit in ICLR_EX is set to 1. 0h = Interrupt is not pending. 1h = Interrupt is pending.

### 13 IIDX Register (Offset = 1050h) [Reset = 0000000h]

IIDX is shown in [Figure 18-17](#) and described in [Table 18-24](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. 0x0 means no event pending. Interrupt 1 is the highest priority, 2 next highest, 4, 8, ...  $2^{31}$  is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 18-17. IIDX Register**

### 15 RIS Register (Offset = 1060h) [Reset = 0000000h]

RIS is shown in [Figure 18-19](#) and described in [Table 18-26](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

## 19 IIDX Register (Offset = 1080h) [Reset = 0000000h]

IIDX is shown in [Figure 18-23](#) and described in [Table 18-30](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. 0x0 means no event pending. Interrupt 1 is the highest priority, 2 next highest, 4, 8, ...  $2^{31}$  is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Table 18-51. IMASK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MEMRESIFG23	R/W	0h	Raw interrupt status for MEMRES23. This bit is set to 1 when MEMRES23 is loaded with a new conversion result. Reading MEMRES23 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
30	MEMRESIFG22	R/W	0h	Raw interrupt status for MEMRES22. This bit is set to 1 when MEMRES22 is loaded with a new conversion result. Reading MEMRES22 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
29	MEMRESIFG21	R/W	0h	Raw interrupt status for MEMRES21. This bit is set to 1 when MEMRES21 is loaded with a new conversion result. Reading MEMRES21 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
28	MEMRESIFG20	R/W	0h	Raw interrupt status for MEMRES20. This bit is set to 1 when MEMRES20 is loaded with a new conversion result. Reading MEMRES20 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-51. IMASK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MEMRESIFG19	R/W	0h	Raw interrupt status for MEMRES19. This bit is set to 1 when MEMRES19 is loaded with a new conversion result. Reading MEMRES19 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
26	MEMRESIFG18	R/W	0h	Raw interrupt status for MEMRES18. This bit is set to 1 when MEMRES18 is loaded with a new conversion result. Reading MEMRES18 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
25	MEMRESIFG17	R/W	0h	Raw interrupt status for MEMRES17. This bit is set to 1 when MEMRES17 is loaded with a new conversion result. Reading MEMRES17 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
24	MEMRESIFG16	R/W	0h	Raw interrupt status for MEMRES16. This bit is set to 1 when MEMRES16 is loaded with a new conversion result. Reading MEMRES16 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
23	MEMRESIFG15	R/W	0h	Raw interrupt status for MEMRES15. This bit is set to 1 when MEMRES15 is loaded with a new conversion result. Reading MEMRES15 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
22	MEMRESIFG14	R/W	0h	Raw interrupt status for MEMRES14. This bit is set to 1 when MEMRES14 is loaded with a new conversion result. Reading MEMRES14 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
21	MEMRESIFG13	R/W	0h	Raw interrupt status for MEMRES13. This bit is set to 1 when MEMRES13 is loaded with a new conversion result. Reading MEMRES13 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
20	MEMRESIFG12	R/W	0h	Raw interrupt status for MEMRES12. This bit is set to 1 when MEMRES12 is loaded with a new conversion result. Reading MEMRES12 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-51. IMASK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MEMRESIFG11	R/W	0h	Raw interrupt status for MEMRES11. This bit is set to 1 when MEMRES11 is loaded with a new conversion result. Reading MEMRES11 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
18	MEMRESIFG10	R/W	0h	Raw interrupt status for MEMRES10. This bit is set to 1 when MEMRES10 is loaded with a new conversion result. Reading MEMRES10 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
17	MEMRESIFG9	R/W	0h	Raw interrupt status for MEMRES9. This bit is set to 1 when MEMRES9 is loaded with a new conversion result. Reading MEMRES9 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
16	MEMRESIFG8	R/W	0h	Raw interrupt status for MEMRES8. This bit is set to 1 when MEMRES8 is loaded with a new conversion result. Reading MEMRES8 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
15	MEMRESIFG7	R/W	0h	Raw interrupt status for MEMRES7. This bit is set to 1 when MEMRES7 is loaded with a new conversion result. Reading MEMRES7 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
14	MEMRESIFG6	R/W	0h	Raw interrupt status for MEMRES6. This bit is set to 1 when MEMRES6 is loaded with a new conversion result. Reading MEMRES6 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
13	MEMRESIFG5	R/W	0h	Raw interrupt status for MEMRES5. This bit is set to 1 when MEMRES5 is loaded with a new conversion result. Reading MEMRES5 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
12	MEMRESIFG4	R/W	0h	Raw interrupt status for MEMRES4. This bit is set to 1 when MEMRES4 is loaded with a new conversion result. Reading MEMRES4 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-51. IMASK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MEMRESIFG3	R/W	0h	Raw interrupt status for MEMRES3. This bit is set to 1 when MEMRES3 is loaded with a new conversion result. Reading MEMRES3 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
10	MEMRESIFG2	R/W	0h	Raw interrupt status for MEMRES2. This bit is set to 1 when MEMRES2 is loaded with a new conversion result. Reading MEMRES2 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
9	MEMRESIFG1	R/W	0h	Raw interrupt status for MEMRES1. This bit is set to 1 when MEMRES1 is loaded with a new conversion result. Reading MEMRES1 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
8	MEMRESIFG0	R/W	0h	Raw interrupt status for MEMRES0. This bit is set to 1 when MEMRES0 is loaded with a new conversion result. Reading MEMRES0 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

## 21 RIS Register (Offset = 1090h) [Reset = 0000000h]

RIS is shown in [Figure 18-25](#) and described in [Table 18-32](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Table 18-55. MIS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MEMRESIFG23	R	0h	Raw interrupt status for MEMRES23. This bit is set to 1 when MEMRES23 is loaded with a new conversion result. Reading MEMRES23 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
30	MEMRESIFG22	R	0h	Raw interrupt status for MEMRES22. This bit is set to 1 when MEMRES22 is loaded with a new conversion result. Reading MEMRES22 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
29	MEMRESIFG21	R	0h	Raw interrupt status for MEMRES21. This bit is set to 1 when MEMRES21 is loaded with a new conversion result. Reading MEMRES21 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
28	MEMRESIFG20	R	0h	Raw interrupt status for MEMRES20. This bit is set to 1 when MEMRES20 is loaded with a new conversion result. Reading MEMRES20 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-55. MIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MEMRESIFG19	R	0h	Raw interrupt status for MEMRES19. This bit is set to 1 when MEMRES19 is loaded with a new conversion result. Reading MEMRES19 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
26	MEMRESIFG18	R	0h	Raw interrupt status for MEMRES18. This bit is set to 1 when MEMRES18 is loaded with a new conversion result. Reading MEMRES18 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
25	MEMRESIFG17	R	0h	Raw interrupt status for MEMRES17. This bit is set to 1 when MEMRES17 is loaded with a new conversion result. Reading MEMRES17 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
24	MEMRESIFG16	R	0h	Raw interrupt status for MEMRES16. This bit is set to 1 when MEMRES16 is loaded with a new conversion result. Reading MEMRES16 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
23	MEMRESIFG15	R	0h	Raw interrupt status for MEMRES15. This bit is set to 1 when MEMRES15 is loaded with a new conversion result. Reading MEMRES15 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
22	MEMRESIFG14	R	0h	Raw interrupt status for MEMRES14. This bit is set to 1 when MEMRES14 is loaded with a new conversion result. Reading MEMRES14 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
21	MEMRESIFG13	R	0h	Raw interrupt status for MEMRES13. This bit is set to 1 when MEMRES13 is loaded with a new conversion result. Reading MEMRES13 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
20	MEMRESIFG12	R	0h	Raw interrupt status for MEMRES12. This bit is set to 1 when MEMRES12 is loaded with a new conversion result. Reading MEMRES12 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-55. MIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MEMRESIFG11	R	0h	Raw interrupt status for MEMRES11. This bit is set to 1 when MEMRES11 is loaded with a new conversion result. Reading MEMRES11 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
18	MEMRESIFG10	R	0h	Raw interrupt status for MEMRES10. This bit is set to 1 when MEMRES10 is loaded with a new conversion result. Reading MEMRES10 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
17	MEMRESIFG9	R	0h	Raw interrupt status for MEMRES9. This bit is set to 1 when MEMRES9 is loaded with a new conversion result. Reading MEMRES9 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
16	MEMRESIFG8	R	0h	Raw interrupt status for MEMRES8. This bit is set to 1 when MEMRES8 is loaded with a new conversion result. Reading MEMRES8 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
15	MEMRESIFG7	R	0h	Raw interrupt status for MEMRES7. This bit is set to 1 when MEMRES7 is loaded with a new conversion result. Reading MEMRES7 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
14	MEMRESIFG6	R	0h	Raw interrupt status for MEMRES6. This bit is set to 1 when MEMRES6 is loaded with a new conversion result. Reading MEMRES6 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
13	MEMRESIFG5	R	0h	Raw interrupt status for MEMRES5. This bit is set to 1 when MEMRES5 is loaded with a new conversion result. Reading MEMRES5 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
12	MEMRESIFG4	R	0h	Raw interrupt status for MEMRES4. This bit is set to 1 when MEMRES4 is loaded with a new conversion result. Reading MEMRES4 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-55. MIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MEMRESIFG3	R	0h	Raw interrupt status for MEMRES3. This bit is set to 1 when MEMRES3 is loaded with a new conversion result. Reading MEMRES3 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
10	MEMRESIFG2	R	0h	Raw interrupt status for MEMRES2. This bit is set to 1 when MEMRES2 is loaded with a new conversion result. Reading MEMRES2 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
9	MEMRESIFG1	R	0h	Raw interrupt status for MEMRES1. This bit is set to 1 when MEMRES1 is loaded with a new conversion result. Reading MEMRES1 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
8	MEMRESIFG0	R	0h	Raw interrupt status for MEMRES0. This bit is set to 1 when MEMRES0 is loaded with a new conversion result. Reading MEMRES0 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
7-0	RESERVED	R	0h	

### 23 ISET Register (Offset = 10A0h) [Reset = 0000000h]

ISET is shown in [Figure 18-27](#) and described in [Table 18-34](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Table 18-57. ISET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MEMRESIFG23	W	0h	Raw interrupt status for MEMRES23. This bit is set to 1 when MEMRES23 is loaded with a new conversion result. Reading MEMRES23 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
30	MEMRESIFG22	W	0h	Raw interrupt status for MEMRES22. This bit is set to 1 when MEMRES22 is loaded with a new conversion result. Reading MEMRES22 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
29	MEMRESIFG21	W	0h	Raw interrupt status for MEMRES21. This bit is set to 1 when MEMRES21 is loaded with a new conversion result. Reading MEMRES21 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
28	MEMRESIFG20	W	0h	Raw interrupt status for MEMRES20. This bit is set to 1 when MEMRES20 is loaded with a new conversion result. Reading MEMRES20 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-57. ISET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MEMRESIFG19	W	0h	Raw interrupt status for MEMRES19. This bit is set to 1 when MEMRES19 is loaded with a new conversion result. Reading MEMRES19 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
26	MEMRESIFG18	W	0h	Raw interrupt status for MEMRES18. This bit is set to 1 when MEMRES18 is loaded with a new conversion result. Reading MEMRES18 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
25	MEMRESIFG17	W	0h	Raw interrupt status for MEMRES17. This bit is set to 1 when MEMRES17 is loaded with a new conversion result. Reading MEMRES17 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
24	MEMRESIFG16	W	0h	Raw interrupt status for MEMRES16. This bit is set to 1 when MEMRES16 is loaded with a new conversion result. Reading MEMRES16 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
23	MEMRESIFG15	W	0h	Raw interrupt status for MEMRES15. This bit is set to 1 when MEMRES15 is loaded with a new conversion result. Reading MEMRES15 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
22	MEMRESIFG14	W	0h	Raw interrupt status for MEMRES14. This bit is set to 1 when MEMRES14 is loaded with a new conversion result. Reading MEMRES14 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
21	MEMRESIFG13	W	0h	Raw interrupt status for MEMRES13. This bit is set to 1 when MEMRES13 is loaded with a new conversion result. Reading MEMRES13 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
20	MEMRESIFG12	W	0h	Raw interrupt status for MEMRES12. This bit is set to 1 when MEMRES12 is loaded with a new conversion result. Reading MEMRES12 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-57. ISET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MEMRESIFG11	W	0h	Raw interrupt status for MEMRES11. This bit is set to 1 when MEMRES11 is loaded with a new conversion result. Reading MEMRES11 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
18	MEMRESIFG10	W	0h	Raw interrupt status for MEMRES10. This bit is set to 1 when MEMRES10 is loaded with a new conversion result. Reading MEMRES10 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
17	MEMRESIFG9	W	0h	Raw interrupt status for MEMRES9. This bit is set to 1 when MEMRES9 is loaded with a new conversion result. Reading MEMRES9 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
16	MEMRESIFG8	W	0h	Raw interrupt status for MEMRES8. This bit is set to 1 when MEMRES8 is loaded with a new conversion result. Reading MEMRES8 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
15	MEMRESIFG7	W	0h	Raw interrupt status for MEMRES7. This bit is set to 1 when MEMRES7 is loaded with a new conversion result. Reading MEMRES7 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
14	MEMRESIFG6	W	0h	Raw interrupt status for MEMRES6. This bit is set to 1 when MEMRES6 is loaded with a new conversion result. Reading MEMRES6 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
13	MEMRESIFG5	W	0h	Raw interrupt status for MEMRES5. This bit is set to 1 when MEMRES5 is loaded with a new conversion result. Reading MEMRES5 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
12	MEMRESIFG4	W	0h	Raw interrupt status for MEMRES4. This bit is set to 1 when MEMRES4 is loaded with a new conversion result. Reading MEMRES4 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-57. ISET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MEMRESIFG3	W	0h	Raw interrupt status for MEMRES3. This bit is set to 1 when MEMRES3 is loaded with a new conversion result. Reading MEMRES3 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
10	MEMRESIFG2	W	0h	Raw interrupt status for MEMRES2. This bit is set to 1 when MEMRES2 is loaded with a new conversion result. Reading MEMRES2 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
9	MEMRESIFG1	W	0h	Raw interrupt status for MEMRES1. This bit is set to 1 when MEMRES1 is loaded with a new conversion result. Reading MEMRES1 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
8	MEMRESIFG0	W	0h	Raw interrupt status for MEMRES0. This bit is set to 1 when MEMRES0 is loaded with a new conversion result. Reading MEMRES0 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-59. ICLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MEMRESIFG23	W	0h	Raw interrupt status for MEMRES23. This bit is set to 1 when MEMRES23 is loaded with a new conversion result. Reading MEMRES23 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
30	MEMRESIFG22	W	0h	Raw interrupt status for MEMRES22. This bit is set to 1 when MEMRES22 is loaded with a new conversion result. Reading MEMRES22 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
29	MEMRESIFG21	W	0h	Raw interrupt status for MEMRES21. This bit is set to 1 when MEMRES21 is loaded with a new conversion result. Reading MEMRES21 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
28	MEMRESIFG20	W	0h	Raw interrupt status for MEMRES20. This bit is set to 1 when MEMRES20 is loaded with a new conversion result. Reading MEMRES20 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-59. ICLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MEMRESIFG19	W	0h	Raw interrupt status for MEMRES19. This bit is set to 1 when MEMRES19 is loaded with a new conversion result. Reading MEMRES19 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
26	MEMRESIFG18	W	0h	Raw interrupt status for MEMRES18. This bit is set to 1 when MEMRES18 is loaded with a new conversion result. Reading MEMRES18 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
25	MEMRESIFG17	W	0h	Raw interrupt status for MEMRES17. This bit is set to 1 when MEMRES17 is loaded with a new conversion result. Reading MEMRES17 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
24	MEMRESIFG16	W	0h	Raw interrupt status for MEMRES16. This bit is set to 1 when MEMRES16 is loaded with a new conversion result. Reading MEMRES16 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
23	MEMRESIFG15	W	0h	Raw interrupt status for MEMRES15. This bit is set to 1 when MEMRES15 is loaded with a new conversion result. Reading MEMRES15 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
22	MEMRESIFG14	W	0h	Raw interrupt status for MEMRES14. This bit is set to 1 when MEMRES14 is loaded with a new conversion result. Reading MEMRES14 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
21	MEMRESIFG13	W	0h	Raw interrupt status for MEMRES13. This bit is set to 1 when MEMRES13 is loaded with a new conversion result. Reading MEMRES13 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
20	MEMRESIFG12	W	0h	Raw interrupt status for MEMRES12. This bit is set to 1 when MEMRES12 is loaded with a new conversion result. Reading MEMRES12 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-59. ICLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MEMRESIFG11	W	0h	Raw interrupt status for MEMRES11. This bit is set to 1 when MEMRES11 is loaded with a new conversion result. Reading MEMRES11 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
18	MEMRESIFG10	W	0h	Raw interrupt status for MEMRES10. This bit is set to 1 when MEMRES10 is loaded with a new conversion result. Reading MEMRES10 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
17	MEMRESIFG9	W	0h	Raw interrupt status for MEMRES9. This bit is set to 1 when MEMRES9 is loaded with a new conversion result. Reading MEMRES9 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
16	MEMRESIFG8	W	0h	Raw interrupt status for MEMRES8. This bit is set to 1 when MEMRES8 is loaded with a new conversion result. Reading MEMRES8 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
15	MEMRESIFG7	W	0h	Raw interrupt status for MEMRES7. This bit is set to 1 when MEMRES7 is loaded with a new conversion result. Reading MEMRES7 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
14	MEMRESIFG6	W	0h	Raw interrupt status for MEMRES6. This bit is set to 1 when MEMRES6 is loaded with a new conversion result. Reading MEMRES6 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
13	MEMRESIFG5	W	0h	Raw interrupt status for MEMRES5. This bit is set to 1 when MEMRES5 is loaded with a new conversion result. Reading MEMRES5 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
12	MEMRESIFG4	W	0h	Raw interrupt status for MEMRES4. This bit is set to 1 when MEMRES4 is loaded with a new conversion result. Reading MEMRES4 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.

**Table 18-59. ICLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MEMRESIFG3	W	0h	Raw interrupt status for MEMRES3. This bit is set to 1 when MEMRES3 is loaded with a new conversion result. Reading MEMRES3 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
10	MEMRESIFG2	W	0h	Raw interrupt status for MEMRES2. This bit is set to 1 when MEMRES2 is loaded with a new conversion result. Reading MEMRES2 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
9	MEMRESIFG1	W	0h	Raw interrupt status for MEMRES1. This bit is set to 1 when MEMRES1 is loaded with a new conversion result. Reading MEMRES1 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
8	MEMRESIFG0	W	0h	Raw interrupt status for MEMRES0. This bit is set to 1 when MEMRES0 is loaded with a new conversion result. Reading MEMRES0 register will clear this bit, or when the corresponding bit in ICLR is set to 1 0h = No new data ready. 1h = A new data is ready to be read.
7-0	RESERVED	R	0h	

## 25 EVT\_MODE Register (Offset = 10E0h) [Reset = 0000000h]

EVT\_MODE is shown in [Figure 18-29](#) and described in [Table 18-36](#).

Return to the [Summary Table](#).

Event mode register. It is used to select whether each line is disabled, in software mode (software clears the RIS) or in hardware mode (hardware clears the RIS)

**Table 18-83. STATUS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1	REFBUFRDY	R	0h	Indicates reference buffer is powered up and ready. 0h = Not ready 1h = Ready
0	BUSY	R	0h	Busy. This bit indicates that an active ADC sample or conversion operation is in progress. 0h = No ADC sampling or conversion in progress. 1h = ADC sampling or conversion is in progress.

The comparator module (COMP) is an analog voltage comparator. This chapter describes the operation of the comparator module.

<b>19.1 Comparator Overview</b> .....	<b>1224</b>
<b>19.2 Comparator Operation</b> .....	<b>1226</b>
<b>19.3 COMP0 Registers</b> .....	<b>1236</b>

## 19.1 Comparator Overview

### Ultra Low Power 3V Comparator Features:

- Ultra low power
- Inverting and noninverting terminal input multiplexer
- Inverting and noninverting terminal short and exchange capabilities
- Software-selectable output filter
- Programmable hysteresis
- Use externally capped VREF or VDD as a voltage reference for internal DAC
- DAC can serve as a reference to either comparator terminal
- Configurable 8-bit reference DAC with two input codes
- Output connected to event system
- Window comparator mode
- Interrupt driven measurement system for low-power operation
- Exchange DAC output reference between inverting and noninverting inputs
- Operating DAC in sample and hold mode will reduce DAC power usage

### High Speed 3V Comparator Features:

- High speed operation
- Inverting and noninverting terminal input multiplexer
- Inverting and noninverting terminal short and exchange capabilities
- Software-selectable output filter
- Programmable hysteresis
- Use externally capped VREF or VDD as a voltage reference for internal DAC
- DAC can serve as a reference to either comparator terminal
- Input of DAC can connect directly to either comparator terminal
- Configurable 8-bit reference DAC with two input codes
- Output connected to event system
- Window comparator mode
- Interrupt driven measurement system for low-power operation
- Exchange DAC output reference between inverting and noninverting inputs

### Ultra Low Power 5V Comparator Features:

- Ultra low power
- Inverting and noninverting terminal input multiplexer
- Software-selectable output filter
- Programmable hysteresis
- Use externally capped VREF or VDD as a voltage reference for internal DAC
- DAC can serve as a reference to the comparator inverting terminal
- Configurable 8-bit reference DAC with two input codes
- Output connected to event system
- Window comparator mode
- Interrupt driven measurement system for low-power operation

### High Speed 5V Comparator Features:

- High speed operation
- Inverting and noninverting terminal input multiplexer
- Software-selectable output filter
- Programmable hysteresis
- Use externally capped VREF or VDD as a voltage reference for internal DAC
- DAC can serve as a reference to either comparator terminal
- Input of DAC can connect directly to either comparator terminal
- Configurable 8-bit reference DAC with two input codes
- Output connected to event system

- Window comparator mode
- Interrupt driven measurement system for low-power operation
- Exchange DAC output reference between inverting and noninverting inputs

Note: Some devices bring the 8-bit reference DAC out to a pin

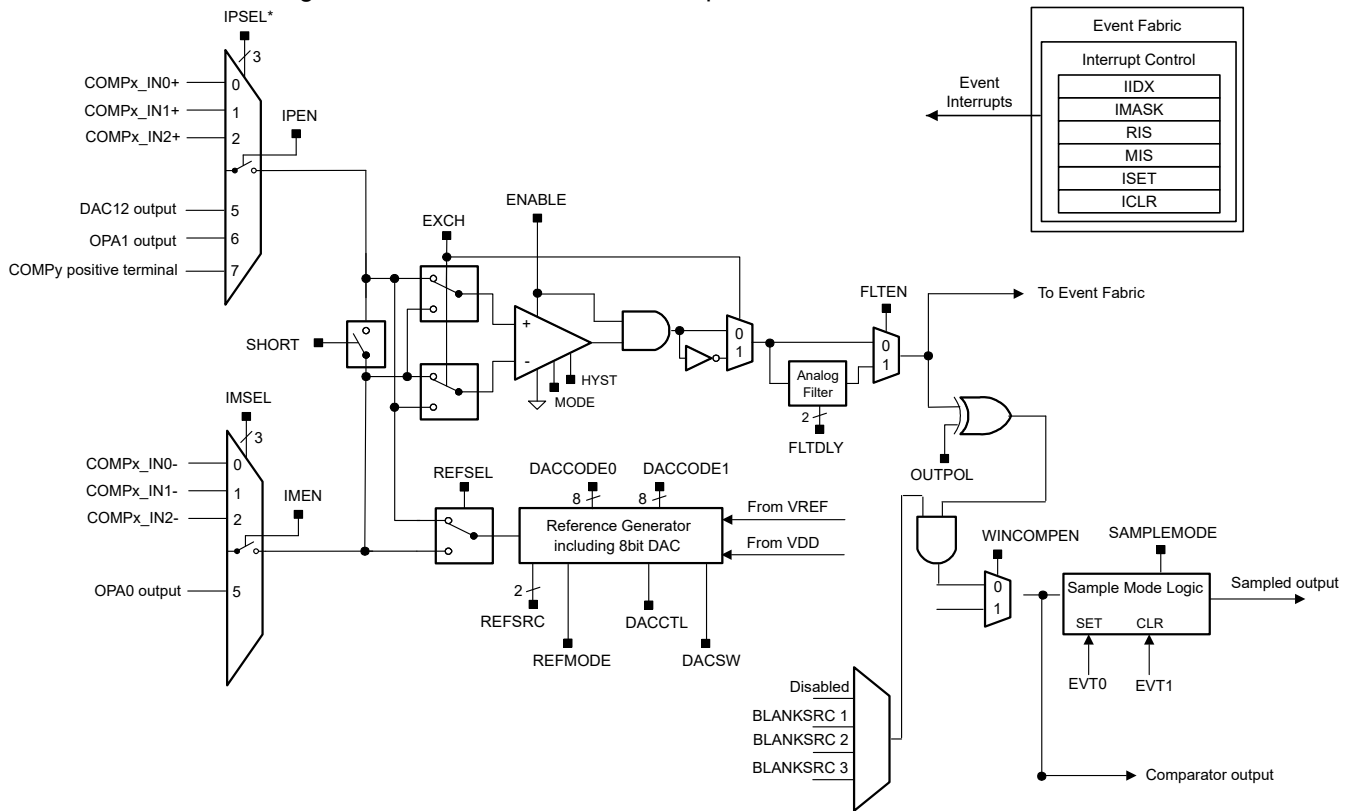

Figure 19-1. Comparator Block Diagram

## 19.2 Comparator Operation

The comparator module is configured by user software. The setup and operation of comparator is discussed in the following sections.

### 19.2.1 Comparator Configuration

The comparator compares the analog voltages at the positive (+) and negative (–) input terminals. If the + terminal is higher than the – terminal, then the output is high. The polarity of the comparator output can be configured by using the OUTPOL bit in COMPx.CTL1 register.

#### Enable Bit

The comparator can be switched on or off using ENABLE bit in COMPx.CTL1 register. The comparator should be switched off when not in use to reduce current consumption. When the comparator is off, OUT is low when OUTPOL bit is set to 0, and OUT is high when OUTPOL bit is set to 1.

#### Fast vs. Ultra Low Power Mode

The comparator can be configured in fast or ultra-low-power mode using MODE bit in COMPx.CTL1 register. The default value of MODE bit is 0 (fast mode). The comparator is configured in ultra-low-power mode when MODE is set to 1.

Fast mode consumes higher current, but response time is faster.

Ultra-low power mode consumes very low current, but response time is slower.

*Please see the device specific data sheets for speed and power specifications, so the best mode can be selected for the application.*

#### Clock Control

The clock control for comparator is managed by System Controller (SYSCTL), SYSCTL knows if comparator module is enabled and it also knows if it is in ultra-low-power mode or fast mode. User needs to ensure the proper bus clock is selected for different comparator operation mode:

- Ultra-low-power mode comparator: Bus clock can be LFCLK, or any of the high speed clocks.
- Fast mode comparator: Bus clock cannot be LFCLK. A clock error interrupt is generated in SYSCTL if you enable a comparator in fast mode and the bus clock is LFCLK.

### 19.2.2 Comparator Channels Selection

The comparator channels on positive terminal is selected through IPSEL bits and enabled through IPEN bit in the register COMPx.CTL0. The comparator channels on negative terminal is selected through IMSEL bits and enabled through IMEN bit. The IPSEL and IMSEL bits can be used to select the comparator channel inputs from device pins or from internal analog modules. The switches in the comparator input channels multiplexer on positive and negative terminals are implemented using break-before-make arrangement to minimize the cross talk when the channel selection changes.

The IPSEL and IMSEL bits allow:

- Connection of an external signal to the positive and negative terminals of the comparator
- Connection of an internal analog signal (like DAC or OPA) to the positive and negative terminals of the comparator
- Connection of one comparator positive terminal signal to another comparator positive terminal in window compare mode

The EXCH bit in COMPx.CTL1 register controls the input multiplexer, exchange the input signals of the comparator positive and negative terminals. Additionally, when the comparator terminals are exchanged, the output signal from the comparator is inverted too. This allows the user to determine or compensate for the comparator input offset voltage.

**Note**

**Comparator Input Connection**

Please see the device data sheet COMP section for the input channel selection configuration.

When the comparator is on, the input terminals should be connected to a signal, power, or ground. Otherwise, floating levels can cause unexpected interrupts and increased current consumption.

**Comparator Configuration**

The configuration of the comparator must not change while it is in operation except for changes in IPSEL, IMSEL and EXCH settings in the register COMPx.CTL0. To change the configuration of the comparator it must be first disabled, reconfigured as needed and then re-enabled.

**19.2.3 Comparator Output**

The comparator output is readable from the OUT bit in COMPx.STAT register. The output is also brought out on device pin. For successful connection of comparator output with the device pin, it is necessary for the software to configure the corresponding device pin in IOMUX module. The comparator output also goes to the Event Interface to generate CPU interrupt event and generic publisher event for internal connects with other modules.

**19.2.4 Output Filter**

The output of the comparator can be used with or without internal filtering. Output filtering can only be enabled while Comparator is in fast mode (COMPx.CTL1.MODE = 0). When FLTEN bit in COMPx.CTL1 register is set, the output is filtered with an on-chip analog filter. The delay of the filter can be adjusted in four different steps using the FLTDLY bits in COMPx.CTL1 register (see [Table 19-1](#)).

**Table 19-1. Typical Output Filter Delay Settings**

FLTDLY bit in COMPx.CTL1	Typical filter delay	Current	Cap
0	60ns	1.4uA	350fF
1	440ns	400nA	350fF
2	1.01us	200nA	350fF
3	2.2us	100nA	350fF

Filter delay settings are an addition to propagation delay outlined in device specific data sheet.

The comparator output oscillates if the voltage difference across the input terminals is small (see [Figure 19-2](#)). Internal and external parasitic effects and cross coupling on and between signal lines, power supply lines, and other parts of the system result in this behavior. The comparator output oscillation reduces the accuracy and resolution of the comparison result. Selecting the output filter can reduce errors associated with comparator oscillation.

**Figure 19-2. Analog Filter Response at the Output of the Comparator**

**Note**

The output filter only works for the comparator when it operates in fast mode.

**19.2.5 Sampled Output Mode**

Sampled mode is a method of operation for the comparator, which compares input signals at discrete time intervals or samples, producing output signals that change only at the sampling points. The SAMPMODE bit in the register CTL2 enables or disables the sampled mode.

To define the sampling window, two events, EVT0 and EVT1, are generated from the timer. The sampling window can be aligned to less noisy phases with the use of these events. EVT0 sets the sampling window, while EVT1 clears it.

In sampled mode, the output of the comparator is captured only when the sampling window is high, and the output is not captured at other times. The captured output is used for interrupt and event generation.

By using sampled mode, the comparator can reduce the effects of noise in the input signals, resulting in more accurate and reliable comparisons. The use of EVT0 and EVT1 to define the sampling window allows for greater flexibility in aligning the window to the least noisy phases of the input signals, further improving the accuracy of the comparisons.

Please note following when internal DAC8 is used in sampled mode and user wants to enter Standby0 mode; for comparator output to work as expected, it is to be ensured that COMP is ready by polling the OUTRDYIFG flag before SoC enters Standby0 mode.

User can follow the below sequence for this scenario.

1. In run/active mode, do all the necessary COMP configurations (DAC8 in sampled mode, COMP in ULP mode, etc.)
2. Set power policy to standby0 (DL\_SYSCTL\_setPowerPolicySTANDBY0)
3. Enable COMP (CTL1.EN bit to be written)
4. Wait for COMP OUTRDYIFG to be set (wait for bit number 3 in RIS register to be 1)
5. Enter Standby0 low power mode (using \_\_WFI() function)

**19.2.6 Blanking Mode**

Due to the noise or other interference, the input signal may fluctuate around the threshold voltage, causing the output to switch rapidly and erratically. This can lead to false triggering. Comparator blanking mode introduces a brief delay between the time the input signal crosses the threshold voltage and the time the output changes state.

When enabled, the blanking source signal acts as an inverted enable for the comparator output. Specifically, when the blanking source is asserted (logic high), the comparator output is forced to its current output state and is prevented from changing state, regardless of the comparator input voltages. Conversely, when the blanking source is de-asserted (logic low), the comparator output is enabled and free to respond to the comparator input voltages. This ensures stable operation during potentially noisy periods. See [Figure 19-3](#) for a block diagram and [Figure 19-4](#) for an example waveform demonstrating this functionality.

**Figure 19-3. Blanking Mode Block Diagram**

**Figure 19-4. Blanking Mode Example Waveform**

During this delay period, the comparator ignores any further changes in the input signal and maintains its current output state. This feature is mainly for uses cases like PWM waves indicated by a timer in motor drive, power control, and so on.

The control bits `BLANKSRC` in the register `CTL2` can be used to configure disable or which source should be working on blanking mode. Refer to the data sheet of the device to see the specific blanking sources supported.

#### Note

The timer is used as the source of comparator blanking mode, there is typically a 1 `TIMCLK` cycle delay between the timer output and the comparator output.

### 19.2.7 Reference Voltage Generator

Figure 19-5 shows the block diagram of the comparator reference voltage generator. The comparator reference voltage generator consists of a 8-bit DAC along with some configuration options. The `REFSRC` bits in `COMPx.CTL2` register are used to select the reference source for the comparator.

- When `REFSRC = 0`, the reference voltage generator is disabled and the reference voltage generator cannot be used for comparator operation.
- When `REFSRC = 1`, the analog supply `VDDA` is selected as the reference input for the DAC and the DAC output is used as reference voltage for the comparator.
- When `REFSRC = 2`, the `VREF` from internal reference module output is selected as the reference input for the DAC and the DAC output is used as reference voltage for the comparator.
- When `REFSRC = 3`, the `VREF` from internal reference module output is used directly as reference voltage for the comparator and the DAC is switched off.

The reference voltage generator output can be applied to either the positive terminal or negative terminal of the comparator using the `REFSEL` bit `COMPx.CTL2` register. If external signals are applied to both comparator input terminals, turn off the internal reference voltage generator to reduce current consumption.

When the reference voltage generator output is applied on a comparator terminal using `REFSEL` bit `COMPx.CTL2` register and the comparator channel (from device pins or from internal analog modules) is also selected on the same terminal using `IPSEL/IPEN` or `IMSEL/IMEN` bits in `COMPx.CTL0` register then the comparator channel selection takes precedence.

`DAC8` output is also connected to the internal analog `OPA` module through `OPAx` (see *OPA Block Diagram*).

Figure 19-5. Reference Voltage Generator Block Diagram

### Integrated 8-bit DAC

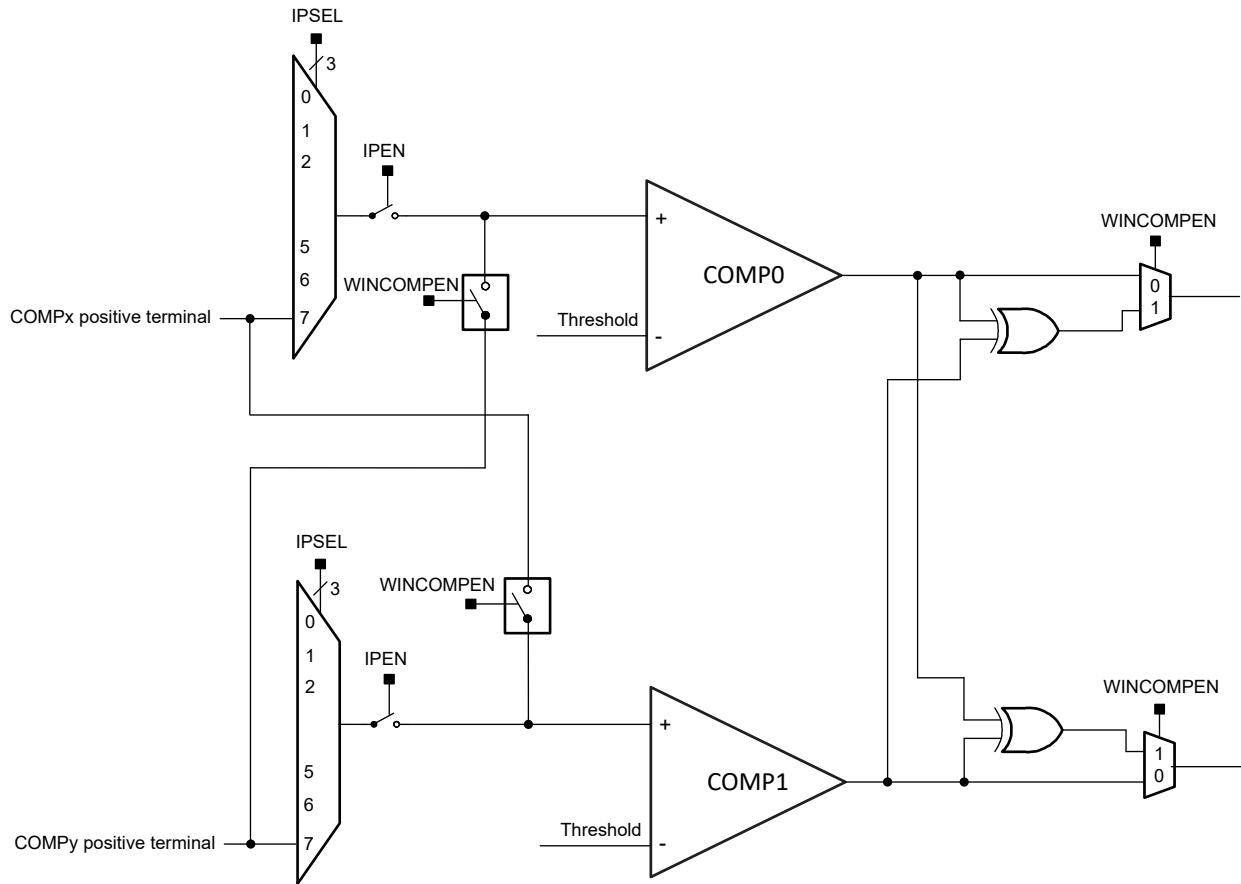

The 8-bit DAC input code can be provided through DACCODE0 or DACCODE1 bits in COMPx.CTL3 register. The DACCTL bit in COMPx.CTL2 register determines if the comparator output or a software control bit DACSW in COMPx.CTL2 register selects DACCODE0 or DACCODE1 bits as input to DAC.

- When DACCTL is 0 the comparator output value selects DACCODE0 or DACCODE1. If the comparator output value is 0, DACCODE0 will be the input to DAC. And DACCODE1 will be the input to DAC if the comparator output value is 1.
- When DACCTL is 1 the DACSW bit value that is programmed by software selects DACCODE0 or DACCODE1. If DACSW is 0, DACCODE0 will be the input to DAC. And DACCODE1 will be the input to DAC if DACSW is 1. With this provision it is possible to generate desired hysteresis levels for the comparator without using external components.
- The REFMODE bit in COMPx.CTL2 register determines if the comparator requests for internal VREF operation in fast or ultra-low-power and also the mode of operation of the 8-bit DAC. When REFMODE bit is 0, the internal VREF is requested for operation in fast mode and the 8-bit DAC in comparator is configured in fast mode as well. When REFMODE bit is 1, the internal VREF is requested for operation in ultra-low-power and the 8-bit DAC in comparator in comparator is configured in ultra-low-power. Operation in fast mode offers higher accuracy but consumes higher current while the ultra-low-power operation consumes lower current but with relaxed reference voltage accuracy. Refer to comparator electrical specifications in device-specific data sheet for details.

### 19.2.8 Window Comparator Mode

The purpose of window comparator mode is to monitor the input signal within a specified threshold range defined by lower and upper thresholds.

As Figure 19-6 shows, COMP0 and COMP1 can combine to create a window comparator. The input signal is connected to the positive terminal of comparators connected together and the upper and lower threshold voltages are connected to the negative terminal of the comparators.

**Figure 19-6. Window Comparator Mode**

Window comparator mode can be enabled by set the WINCOMPEN bit in COMPx.CTL1 register. [Figure 19-7](#) below shows a example of a window mode configuration:

- Configure IPSEL bits in COMP0.CTL0 register to the corresponding input signal pin.
- Set WINCOMPEN bit in COMP0.CTL1 register to 1.
- Clear the WINCOMPEN bit in COMP1.CTL1 register.
- Configure IPSEL bits in COMP1.CTL0 register to 0x07, select the COMP0 positive terminal as the input.

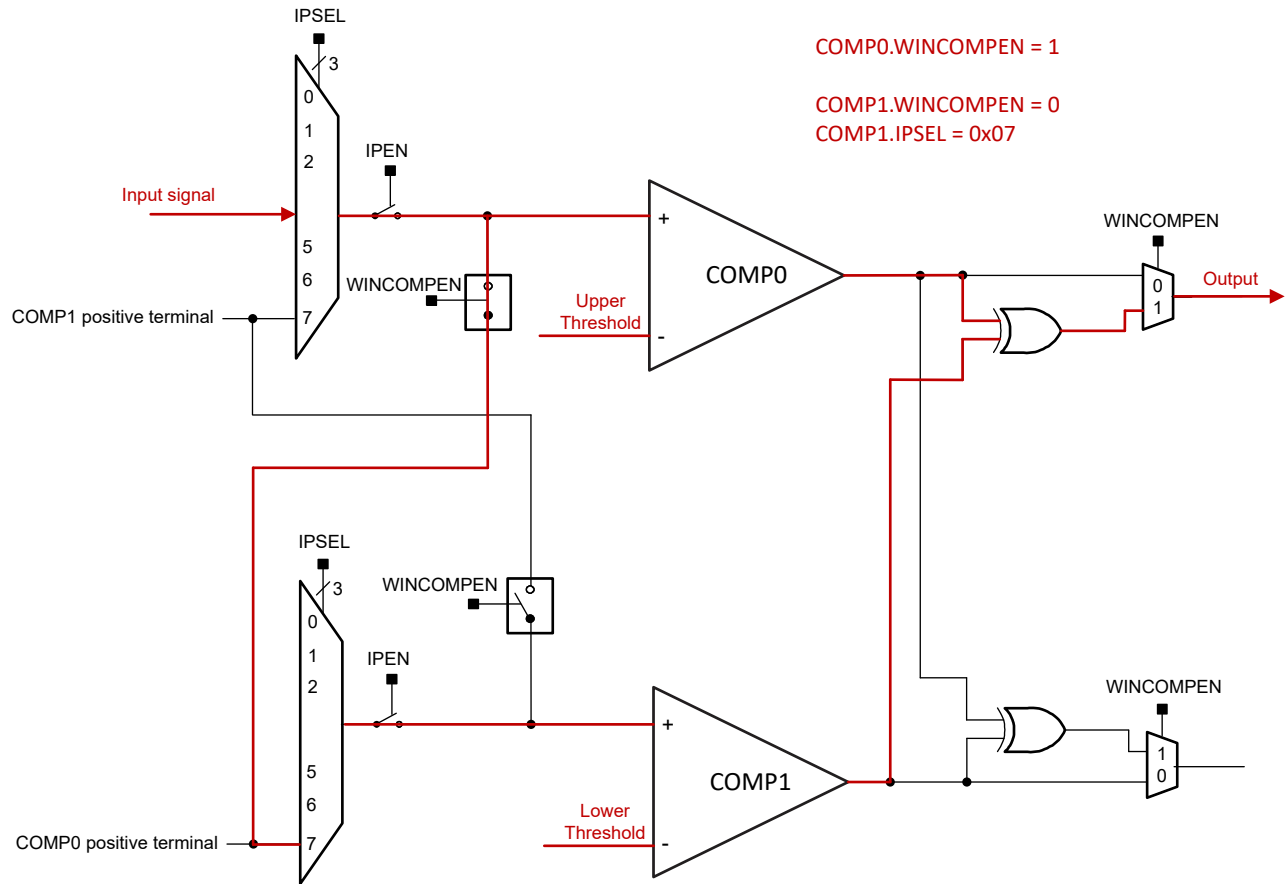

Figure 19-7. Window Comparator Mode Configuration

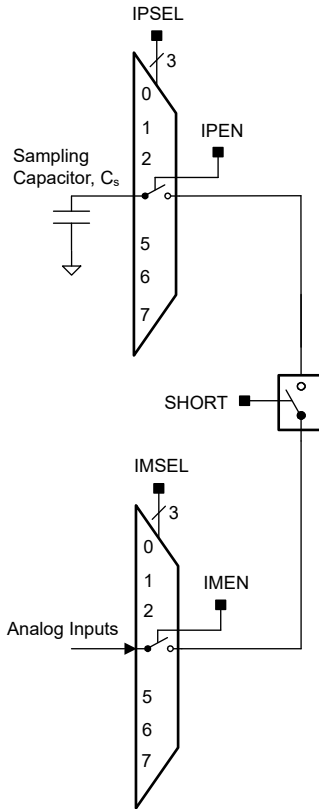

### 19.2.9 Comparator Hysteresis

The comparator supports programmable hysteresis voltages for fast and ultra-low-power modes to avoid spurious output transitions in case of noisy input signals. When HYST bits in COMPx.CTL1 register are 0, the comparator generates no hysteresis. 10mV, 20mV, and 30mV typical hysteresis voltages are generated by the comparator for HYST bits values 1, 2, and 3 respectively.

The hysteresis can also be implemented by using the internal 8-bit DAC. The input of the reference generator 8-bit DAC can be provided by two values DACCODE0 and DACCODE1 in COMPx.CTL3 register. User can configure the DACCTL bit in COMPx.CTL2 register to 1 and the comparator output value will select the DAC input between DACCODE0 and DACCODE1 values. With this provision it is possible to generate desired hysteresis levels for the comparator without using external components. For more information about this configuration please refer to [Integrated 8-bit DAC](#) section.

### 19.2.10 Input SHORT Switch

The SHORT bit shorts the comparator inputs. This can be used to build a simple sample-and-hold for the comparator (see [Figure 19-8](#))

**Figure 19-8. Comparator Short Switch**

The required sampling time is proportional to the size of the sampling capacitor (CS), the resistance of the input switches in series with the short switch (RI) and the resistance of the external source (RS). The sampling capacitor CS should be greater than 100pF. The time constant, Tau, to charge the sampling capacitor CS can be calculated with Equation 25 .

$$T_{au} = (R_I + R_S) \times C_S \tag{25}$$

Depending on the required accuracy, use 3 to 10 Tau as the sampling time. With 3 Tau the sampling capacitor is charged to approximately 95% of the input signals voltage level, with 5 Tau it is charged to more than 99%, and with 10 Tau the sampled voltage is sufficient for 12-bit accuracy.

**19.2.11 Interrupt and Events Support**

The comparator module contains two [event publishers](#) and two [event subscribers](#). One event publisher (CPU\_INT) manages comparator interrupt requests (IRQs) to the CPU subsystem through a [static event route](#). The second event publisher (GEN\_EVENT) is used to setup the generic event publisher through [Generic route](#).

The two event subscribers are used to define the start and stop points in [sampled output mode](#).

The comparator events are summarized in [Table 19-2](#).

**Table 19-2. Comparator Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU interrupt</a>	Publisher	Comparator	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from comparator to CPU

**Table 19-2. Comparator Events (continued)**

Event	Type	Source	Destination	Route	Configuration	Functionality
Generic publisher event	Publisher	Comparator	Other peripherals	Generic route	GEN_EVENT FPUB_1 registers	Configurable route from comparator to other peripherals
Generic subscriber event	Subscriber	Other peripherals	Comparator	Generic route	GEN_EVENT FSUB_0 registers	Configurable route from other peripherals to the comparator start of sample window
Generic subscriber event	Subscriber	Other peripherals	Comparator	Generic route	GEN_EVENT FSUB_1 registers	Configurable route from other peripherals to the comparator stop sampling window

### 19.2.11.1 CPU Interrupt Event Publisher (CPU\_INT)

The comparator module provides 3 interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the comparator are:

**Table 19-3. Comparator CPU Interrupt Event Conditions (CPU\_INT)**

IDX STAT	Name	Description
0x01	COMPIFG	The interrupt flags COMPIFG and COMPINVIFG are set either on the rising or falling edge of the comparator output, selected by the IES bit. When IES bit is 0, rising edge of the comparator output sets the COMPIFG and falling edge sets the COMPINVIFG. When IES bit is 1, falling edge of the comparator output sets the COMPIFG and rising edge sets the COMPINVIFG.
0x02	COMPINVIFG	The interrupt flags COMPIFG and COMPINVIFG are set either on the rising or falling edge of the comparator output, selected by the IES bit. When IES bit is 0, rising edge of the comparator output sets the COMPIFG and falling edge sets the COMPINVIFG. When IES bit is 1, falling edge of the comparator output sets the COMPIFG and rising edge sets the COMPINVIFG.
0x03	OUTRDYIFG	Comparator output ready interrupt. This bit is set when the comparator output is valid.

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers for CPU interrupts.

### 19.2.11.2 Generic Event Publisher (GEN\_EVENT)

A generic route is a route in which the comparator peripheral publishing the event is configured to use one of several available generic route channels to publish its event to another entity (or entities, in the case of a splitter route), where an entity can be another peripheral, a generic DMA trigger event, or a generic CPU event.

The GEN\_EVENT register is used to select a peripheral condition ([Table 19-4](#)) to use for publishing an event. FPUB\_1 is the publisher port register and it is used to configure which generic route channel to use to broadcast the event. A second peripheral, the DMA, or the CPU can subscribe to this event by configuring its subscriber port to listen on the same generic route channel which the publishing peripheral is connected to.

For example, through the use of a generic event channel, it is possible to directly trigger a timer capture from a comparator event, by connecting a comparator FPUB\_1 and TIM FSUB\_x to the same generic event channel. Refer to [Section 7.1.3.3](#) and [Section 7.2.3](#) for how generic event route works.

**Table 19-4. Comparator Generic Event Conditions (GEN\_EVENT)**

IIDX STAT	Name	Description
0x01	COMPIFG	The interrupt flags COMPIFG and COMPINVIFG are set either on the rising or falling edge of the comparator output, selected by the IES bit. When IES bit is 0, rising edge of the comparator output sets the COMPIFG and falling edge sets the COMPINVIFG. When IES bit is 1, falling edge of the comparator output sets the COMPIFG and rising edge sets the COMPINVIFG.
0x02	COMPINVIFG	The interrupt flags COMPIFG and COMPINVIFG are set either on the rising or falling edge of the comparator output, selected by the IES bit. When IES bit is 0, rising edge of the comparator output sets the COMPIFG and falling edge sets the COMPINVIFG. When IES bit is 1, falling edge of the comparator output sets the COMPIFG and rising edge sets the COMPINVIFG.
0x03	OUTRDYIFG	Comparator output ready interrupt. This bit is set when the comparator output is valid.

See [Section 7.2.5](#) for guidance on configuring the Event registers.

### 19.2.11.3 Generic Event Subscribers

The two event subscribers are used to establish the sampling start and stop times when the comparator is used in the [sampled output mode](#).

- FSUB\_0 selects the generic event route at the device level on which the start of sampling window event is sent.
- FSUB\_1 selects the generic event route at the device level on which the stop of sampling window event is sent.

As the sampling window is driven from generic event routes, any peripheral module with generic publisher capabilities can set the comparator sampling window, including timers and GPIO.

### 19.3 COMP0 Registers

Table 19-5 lists the memory-mapped registers for the COMP0 registers. All register offset addresses not listed in Table 19-5 should be considered as reserved locations and the register contents should not be modified.

**Table 19-5. COMP0 Registers**

Offset	Acronym	Register Name	Section

15-0	RESERVED	R	0h	

## 8 IIDX Register (Offset = 1020h) [Reset = 0000000h]

IIDX is shown in [Figure 19-16](#) and described in [Table 19-14](#).

Return to the [Summary Table](#).

Interrupt index register. This read-only register provides the interrupt index of the pending interrupt with the highest priority. It also indicates if no interrupt is pending. The priority order is fixed: lower index equals higher priority. Alternatively to the use of IIDX, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flags in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt or indicate that no interrupt is pending. Only interrupts which are selected via IMASK are indicated.

The DAC module is a 12-bit voltage-output digital-to-analog converter (DAC). This chapter describes the operation of the DAC module.

<b>20.1 DAC Introduction</b> .....	<b>1266</b>
<b>20.2 DAC Operation</b> .....	<b>1267</b>
<b>20.3 DAC12 Registers</b> .....	<b>1276</b>

## 20.1 DAC Introduction

The DAC module is a 12-bit voltage-output DAC. The DAC can be configured in 8-bit or 12-bit resolution setting and can be used in conjunction with the DMA controller.

Features of the DAC include:

- 8-bit or 12-bit voltage-output resolution
- Straight binary or twos-complement data format
- Internal sample time generator for generation of predefined sampling rates
- Two hardware triggers from event fabric for D/A conversion
- 4x12-bits internal FIFO for data flow rate control
- Operation with DMA controller without CPU Intervention
- Selectable voltage reference options
- Output internally connected to analog modules like OPA, ADC and COMP
- Self-calibration option for offset error correction

Figure 20-1 shows the block diagram of DAC module.

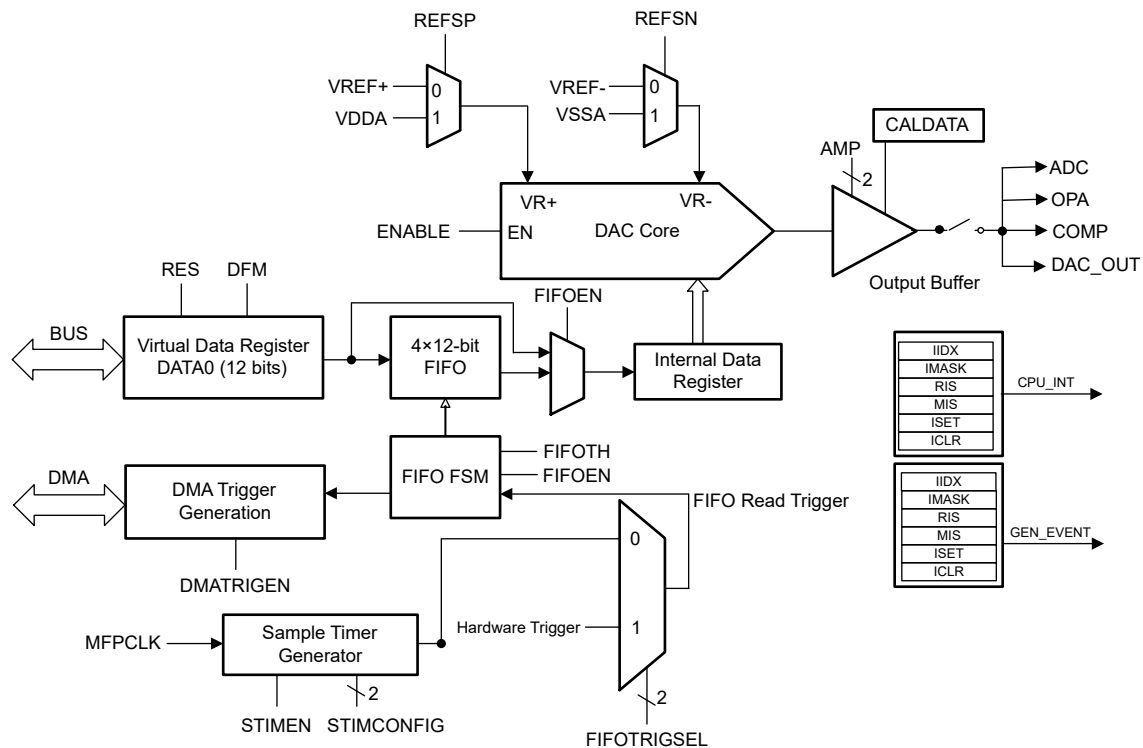

Figure 20-1. DAC Block Diagram

## 20.2 DAC Operation

The DAC module is configured with user software. The setup and operation of the DAC is discussed in the following sections.

### 20.2.1 DAC Core

The DAC can be configured to operate in 8-bit or 12-bit resolution setting using the CTL0.RES bit. The CTL0.DFM bit can be used to select the data format to be straight-binary or twos-complement. When using straight-binary data format, the formula for the output voltage is given in [Table 20-1](#).

**Table 20-1. DAC Full-Scale Range**

Resolution	CTL0.RES	Output Voltage Formula
12-bit	1	$V_{out} = V_{ref} \times (DATA\_VALUE / 4096)$
8-bit	0	$V_{out} = V_{ref} \times (DATA\_VALUE / 256)$

- In 8-bit resolution setting, the maximum useable value for DATA\_VALUE in the DATA0 register is 255 (0xFF).
- In 12-bit resolution setting, the maximum useable value for DATA\_VALUE in the DATA0 register is 4095(0xFFFF).

The DAC can be enabled by setting the CTL0.ENABLE bit . When the DAC is enabled, the DAC core and output buffer start to settle and the module ready interrupt condition (MODRDYIFG) is generated once to indicate that the DAC is ready for use.

---

#### Note

The DAC must be enabled after the configuration of all control registers as required in the application. If a configuration change is required when the DAC is running, the DAC must be disabled first and re-enabled after the new configuration is programmed into the control registers. Any change in control registers while the DAC is running can cause unpredictable results.

---

### 20.2.2 DAC Output

DAC output can be connected to internal analog modules OPA, ADC & COMP or DAC\_OUT pin by setting CTL1.OPS bit. Reset value of bits CTL1.OPS is 0. There are the following scenarios:

- If CTL1.OPS bit is set, DAC output is connected to OPA, ADC, COMP and DAC\_OUT.
- If CTL1.OPS bit is not set, there is no DAC output. The pin DAC\_OUT can be connected to ADC, OPA or COMP.

---

#### Note

The CTL1.OPS bit must be set as 0 when pin DAC\_OUT is configured as the input for ADC, OPA or COMP.

---

### 20.2.3 DAC Voltage Reference

The CTL1.REFSP and CTL1.REFSN bits select the voltage reference for the DAC from the following options.

- Analog supply (VDDA) (see *Power Management (PMU)*).
- An external reference voltage that can be provided on VREF+ and VREF- pins of the device.
- The internal reference voltage from the output of VREF module.

### 20.2.4 DAC Output Buffers

The voltage output buffers of the DAC can be configured to be enabled or disabled by setting the bit CTL1.AMPEN. When disabled, the output amplifier can be set either to ground or high impedance using the bit CTL1.AMPHIZ.

### 20.2.5 DAC Data Formats

The DAC supports both straight-binary and twos-complement data formats. When using straight-binary data format, the full-scale output value is 0xFFF in 12-bit resolution setting and 0xFF in 8-bit resolution settings (see Figure 20-2).

Figure 20-2. Output Voltage vs DAC Data, 12-Bit Straight-Binary Mode

When using twos-complement data format, the range is shifted so that a DAC data value of 0x800 in 12-bit resolution setting and 0x80 in 8-bit resolution settings results in a zero output voltage, 0x0 is the mid-scale output voltage, and 0x7FF in 12-bit resolution setting and 0x7F in 8-bit resolution settings is the full-scale voltage output (see Figure 20-3).

Figure 20-3. Output Voltage vs DAC Data, 12-Bit Twos-Complement Mode

### 20.2.6 Sample Time Generator

There is a sample time generator available in the DAC module. This can be used to generate DAC conversion trigger for certain predefined sampling rates. The sample time generator is disabled by default and it can be enabled by setting the CTL3.STIMEN bit. When the sample time generator is enabled, it automatically requests for the MFPCLK (4MHz) and generates trigger according to the programmed trigger rate. The predefined sampling rates supported are 500sps, 1Ksps, 2Ksps, 4Ksps, 8Ksps, 16Ksps, 100Ksps, 200Ksps, 500Ksps, and 1Msps. These trigger rates are programmed by setting the bit CTL3.STIMCONFIG. The predefined sampling rates are given in Table 20-2

Table 20-2. Predefined Sampling Rates

CTL3.STIMCONFIG	Sampling Rate
0	500sps
1	1Ksps

**Table 20-2. Predefined Sampling Rates (continued)**

CTL3.STIMCONFIG	Sampling Rate
2	2Ksps
3	4Ksps
4	8Ksps
5	16Ksps
6	100Ksps
7	200Ksps
8	500Ksps
9	1Msps

**Note**

When the sample time generator is enabled, the bus clock must be equal to the MFPCLK or samples can be missed in the FIFO.

**20.2.7 DAC FIFO Structure**

The DAC module has an 4x12-bits FIFO. By default the FIFO operation is disabled and it is enabled by setting the CTL2.FIFOEN bit. When the CPU or DMA controller writes into the memory mapped data register DATA0, the data is written into FIFO at the location pointed by the write pointer. The data is read from FIFO and loaded to internal DAC data register when the FIFO read trigger is asserted. The data written into the FIFO can be in binary or twos complement format.

**20.2.7.1 Loading Data From FIFO to Internal DAC Data Register**

The CTL2.FIFOTRIGSEL register is used to select the trigger source for loading data from FIFO into internal DAC data register. There are three triggers sources:

- The sample time generator output can be selected as the trigger source.
- Hardware Trigger, listening for events published through GEN\_EVENT configured in the register FSUB\_0.

For the hardware trigger source, the DAC module can subscribe to the event through the event fabric. Setting CTR2.FIFOTRIGSEL as 1 is to subscribe to the event on FSUB\_0.

When the sample time generator is used, the MFPCLK is used for trigger generation and for transferring the data from FIFO into internal DAC data register. In this scenario, the DAC sampling rate is predictable and has no connection with ULPCLK.

When the sample time generator is not used, the ULPCLK is used for transferring the data from FIFO into internal DAC data register upon the external event trigger. For a predictable DAC sampling rate, the application software must manage ULPCLK frequency to be deterministic. The sampling rate is affected if there is any change in ULPCLK frequency during DAC operation in this scenario.

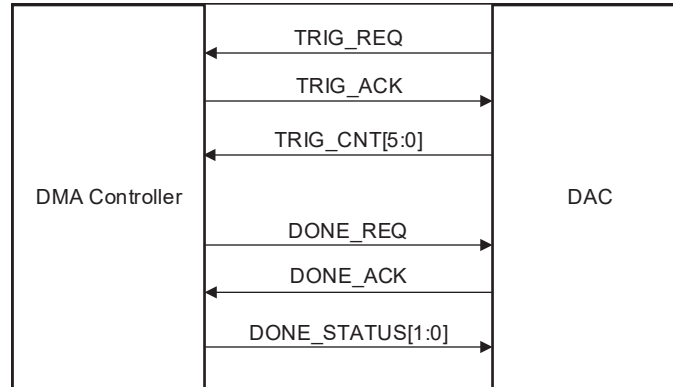

Whenever the selected trigger source is asserted, the data in FIFO pointed by the read pointer is read and loaded into the internal DAC data register for conversion.

**20.2.8 DAC Operation With DMA Controller**

The DMA controller can move data into the DAC from the SRAM. Program the CTL2.DMATRIGEN and CTL2.FIFOEN bits to enable DAC operation with the DMA controller. When the DMA trigger mechanism is enabled in the DAC along with the FIFO, the FIFO hardware state machine evaluates the available empty locations in the FIFO and generates a DMA trigger. The FIFO threshold level can be selected using the CTL2.FIFOTH bits. The available FIFO level settings are empty, 1/4, 1/2, and 3/4.

During operation, empty locations in FIFO are continuously evaluated by the FIFO hardware state machine and are compared with the selected FIFO threshold level. The DAC generates a trigger to the DMA when the number of empty locations matches the programmed FIFO threshold.

The DAC-to-DMA controller interface is shown in [Figure 20-4](#) and explained in the following sections.

**Figure 20-4. DAC Interface With DMA Controller**

### 20.2.8.1 DMA Trigger Interface

There is a defined protocol between DAC and DMA:

1. The DAC generates a trigger TRIG\_REQ to the DMA together with the trigger count TRIG\_CNT. TRIG\_CNT is a 6-bit signal that indicates the number of empty locations available in the DAC FIFO for the DMA to fill. The value of TRIG\_CNT is in accordance with the FIFO element size.
2. When TRIG\_REQ is asserted, the DMA provides a trigger acknowledge signal TRIG\_ACK back to the DAC.

The trigger event and TRIG\_ACK are routed through the event fabric and follow the standard 4-way request, acknowledge handshake protocol.

### 20.2.8.2 DMA Status Interface

When the DAC trigger is captured by DMA and trigger acknowledgment has been provided, both the DAC and the DMA are in triggered state. In this state, the DAC must not generate any new DMA trigger. When DMA starts to service the DAC, the DMA can perform data transfers to the actual value indicated by the trigger count or to a value less than the trigger count (it can be even no transfer). This is not deterministic and depends on factors like DMA bandwidth and channel priorities.

When the DMA performs a certain number of transfers, it asserts a DMA done signal DONE\_REQ to the DAC along with the DMA status side band signal DONE\_STATUS. The DAC module provides a DMA done acknowledgment DONE\_ACK as a response. The DMA done event and DONE\_ACK are routed through the event fabric and follow the standard 4-way request, acknowledge handshake protocol.

### 20.2.8.3 DMA Trigger Generation Scheme

DMA status signal DONE\_STATUS value 0 indicates that DMA has more data elements to transfer to DAC. When DAC observes DONE\_STATUS to be 0, it performs fresh assessment of the number of empty locations in the FIFO and if that matches with the programmed FIFO threshold level it makes the next TRIG\_REQ along with TRIG\_CNT. Then the whole sequence of operations mentioned above repeats.

When the DMA has finished transferring the complete data then it asserts DMA done signal DONE\_REQ along with DMA status signal DONE\_STATUS with a non-zero value. When DAC captures DMA status signal with a non-zero value it sets the DMADONE interrupt flag. This interrupt flag can be used to generate an interrupt to the CPU that owns the DAC for the appropriate action to be taken. CTL2.DMATRIGEN bit should be cleared by software to stop further DMA triggers. This interrupt flag can be used to generate an interrupt to the CPU that owns the DAC for the appropriate action to be taken.

The following section explain the details of using the DAC and DMA with the FIFO enabled

### DAC-DMA Operation in FIFO Mode (CTL2.FIFOEN=1) and Sample Time Generator enabled

- Configure the clock, the MFPCLK should be enabled as Sample Time Generator will be used
- Configure DMA source and destination address. Destination address is FIFO data register DATA0
- Choose the transfer mode and DMA transfer size between byte (8-bit), short word (16-bit), word (32-bit) or long word (64-bit)
- Set DAC resolution (8-bit or 12-bit)
- Configure FIFO Trigger Threshold via the CTL2.FIFOTH bits which supports  $\frac{1}{4}$ ,  $\frac{1}{2}$  and  $\frac{3}{4}$
- Configure and enable DAC and DMA interrupt
- Use CTL2.FIFOTRIGSEL to configure Sample Time Generator as the trigger source for loading data to FIFO data register. Ensure that the clock configurations of MCLK and ULPCLK are properly set to avoid FIFO underrun issues and distortion in the DAC output
  - Make sure that ULPCLK is equal to MFPCLK to maintain synchronization between the clock domains
  - Adjust the FIFO threshold setting to  $\frac{1}{2}$  or  $\frac{3}{4}$  when the source of MCLK is HFCLK or SYSPLL and its frequency is equal to or greater than 32MHz
- Enable DMA Trigger

#### 20.2.9 DAC Operation With CPU

The CPU can directly load data into DAC for conversion which has the following scenarios:

- **Fixed DC voltage output and FIFO disabled:** CPU writes the data into the data register DATA0. This data will pass on to the internal DAC data register for conversion.
- **Fixed DC voltage output and FIFO enabled:** CPU writes the data into the data register DATA0 which is read from FIFO and loaded to internal DAC data register when the FIFO read trigger is asserted.
- **Fixed AC voltage output and FIFO enabled:** CPU writes the data into the data register DATA0 which is read from FIFO and loaded to internal DAC data register when the FIFO read trigger is asserted.

---

#### Note

1. If a fixed AC voltage output is desired, the FIFO must be enabled.
  2. CPU must write into the data register DATA0 with byte-0 for 8-bit DAC resolution and lower half-word (bytes 0 and 1) for 12-bit DAC resolution.
  3. DMA trigger generation mechanism must be kept disabled when CPU is used to load data into DAC.
- 

For the FIFO read triggers, it is possible to use the sample time generator or the external event available for the event fabric.

#### 20.2.9.1 Interrupt conditions for DAC operation with CPU

When the FIFO is enabled and CPU is used to load data into DAC, there are certain FIFO specific interrupt conditions generated in the DAC. These are FIFO empty, FIFO full, FIFO 1/4 empty, FIFO 1/2 empty and FIFO 3/4 empty. The reset value of all these interrupt flags is 0. When the DAC module is enabled along with the FIFO, the internal logic evaluates the FIFO status and updates the FIFO specific interrupt flags accordingly. These interrupt conditions can be enabled appropriately by software so that CPU is notified about the empty locations available in FIFO for loading data into DAC.

#### 20.2.10 Data Register Format

The DAC supports programmable resolution setting and data format . The figures given in this section take DATA0 register as an example and describe the format in which CPU or DMA controller is expected to write data into DATA0 register for one data sample.

The CPU always writes only into DATA0 register. If FIFO is disabled then CPU can write into only byte-0 for 8-bit DAC resolution and lower half-word (bytes 0 and 1) for 12-bit DAC resolution. The upper half-word of DATA0 register is never written.

When the FIFO is enabled, the CPU can write up to 4 data samples into DATA0 register for 8-bit resolution or 12-bit resolution.

Figure 20-5 shows the data format in DATA0 register for 8-bit binary or two's complement data.

**Figure 20-5. 8-Bit Data**

### 20.2.11 DAC Output Amplifier Offset Calibration

The offset voltage of the DAC output amplifier can be positive or negative. When the offset is negative, the output amplifier attempts to drive the voltage negative but cannot do so. The output voltage remains at zero until the DAC digital input produces a sufficient positive output voltage to overcome the negative offset voltage, resulting in the transfer function in Figure 20-6.

**Figure 20-6. Negative Offset**

When the output amplifier has a positive offset, a digital input of zero does not result in a zero output voltage. The DAC output voltage reaches the maximum output level before the DAC data reaches the maximum code (see Figure 20-7).

**Figure 20-7. Positive Offset**

The DAC can self-calibrate the offset voltage of the output amplifier. The application can perform self-calibration of the DAC output buffer to achieve the offset error given in the electrical specification. The CALCTL.CALON bit is used to initiate the offset error calibration. The DAC output is high impedance while the calibration is active. When the calibration is complete, the CALCTL.CALON bit is automatically reset. Software must configure the CTL1.AMP bits before calibration.

For best calibration results, activity on the device pins and in the CPU must be minimized during calibration. Calibration data is loaded into CALDATA; when DAC self-calibration is initiated using the CALCTL.CALON bit, the CALDATA register is continuously updated during the course of calibration. Read the CALDATA register only after the CALCTL.CALON bit is cleared, otherwise incorrect values can be read. The DAC calibration data format is twos complement. Only the lowest byte is used and the upper bytes have no effect on the offset calibration.

**Note**

Recalibrate the DAC output buffer after changing the reference voltage level in the VREF module when DAC is in use.

**20.2.12 Interrupt and Event Support**

The DAC module contains three [event publishers](#) and two [event subscribers](#). One event publisher (CPU\_INT) manages DAC interrupt requests (IRQs) to the CPU subsystem via a [static event route](#). The second event publisher (GEN\_EVENT) can be used to setup the generic event publisher via [Generic route](#). A direct DMA trigger can be used as a DAC-to-DMA trigger to send DAC events to the DMA through DMA event route.

The event subscriber (FSUB\_0) can be used to subscribe to events which are published to the event fabric through a generic event route channel.

The DAC events are summarized in [Table 20-3](#).

**Table 20-3. DAC Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU interrupt</a>	Publisher	DAC	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from DAC to CPU
<a href="#">Generic publisher event</a>	Publisher	DAC	Other peripherals	<a href="#">Generic route (FPUB_0)</a>	GEN_EVENT and FPUB_0 registers	Trigger generic event channel from DAC
<a href="#">DMA Trigger event</a>	Publisher	DAC	DMA	<a href="#">DMA route</a>	DMA_TRIG and FPUB_1 registers	Fixed trigger route from DAC to DMA

**Table 20-3. DAC Events (continued)**

Event	Type	Source	Destination	Route	Configuration	Functionality
Generic subscriber event	Subscriber	Other peripherals	DAC	Generic route (FSUB_0)	FSUB_0	DAC subscription to generic event channel

### 20.2.12.1 CPU Interrupt Event Publisher (CPU\_INT)

The DAC module provides different interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the DAC are:

**Table 20-4. DAC Interrupt Event Conditions (CPU\_INT)**

Index (IIDX)	Name	Description
0x0	NO_INTR	No bit set (IIDX.STAT = 0) means there is no pending interrupt request
0x2	MODRDYIFG	The DAC output is settled after it is turned on using ENABLE in the CTL0 register
0x9	FIFOFULLIFG	FIFO full interrupt flag is set when the FIFO is full
0xA	FIFO1B4IFG	FIFO one fourth empty interrupt flag is set when one fourth of FIFO locations are empty.
0xB	FIFO1B2IFG	FIFO half empty interrupt flag is set when half of the FIFO locations are empty.
0xC	FIFO3B4IFG	FIFO three fourth empty interrupt flag is set when all the locations in FIFO are empty.
0xD	FIFOEMPTYIFG	FIFO empty interrupt flag is set when all data in the FIFO have been shifted out.
0xE	FIFOURUNIFG	FIFO underrun flag is set when the FIFO read trigger is asserted while the FIFO is empty.
0xF	DMADONEIFG	DMA done interrupt flag is set when the DMA data transfer of programmed block size is completed

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. Interrupt (RIS) flags are cleared upon software reading the IIDX register or writing to the respective ICLR register bits.

See [Section 7.2.5](#) section for guidance on configuring the event registers for CPU interrupts.

### 20.2.12.2 Generic Event Publisher (GEN\_EVENT)

The DAC module provides the following interrupt sources, one of which can be configured to publish an event to a generic event route channel.

**Table 20-5. DAC Generic Event Publisher Conditions (GEN\_EVENT)**

Index (IIDX)	Name	Description
0x0	NO_INTR	No bit set (IIDX.STAT = 0) means there is no pending interrupt request
0x2	MODRDYIFG	Module ready interrupt once DAC is enabled and DAC output is settled
0x9	FIFOFULLIFG	FIFO full interrupt flag is set when the FIFO is full
0xA	FIFO1B4IFG	FIFO one fourth empty interrupt flag is set when one fourth of FIFO locations are empty.
0xB	FIFO1B2IFG	FIFO half empty interrupt flag is set when half of the FIFO locations are empty.
0xC	FIFO3B4IFG	FIFO three fourth empty interrupt flag is set when all the locations in FIFO are empty.
0xD	FIFOEMPTYIFG	FIFO empty interrupt flag is set when all data in the FIFO have been shifted out.
0xE	FIFOURUNIFG	FIFO underrun flag is set when the FIFO read trigger is asserted while the FIFO is empty.
0xF	DMADONEIFG	DMA done interrupt flag is set when the DMA data transfer of programmed block size is completed

The generic event publisher configuration is managed with the GEN\_EVENT event management registers. Interrupt (RIS) flags are cleared based on acknowledgment (ACK) signal from the subscriber module received over the event fabric. See [\[Using Event Registers\]](#) for guidance on configuring the event registers for generic event publishers. The generic event channel which GEN\_EVENT is to publish to must be selected by writing

the target generic channel ID to the **FPUB\_0** register in the DAC. See [\[Generic Event Route\]](#) for guidance on configuring generic event routes. If this publisher is not used in an application, the FPUB\_0 register can be left in a disconnected state (set equal to zero) and no events should be unmasked through the MIS register in the ADC GEN\_EVENT register set.

### 20.2.12.3 DMA Trigger Event Publisher

The DAC module provides different interrupt sources which can be configured to source the DMA trigger. In order of decreasing interrupt priority, the DMA trigger events from the DAC are given as the following table. When the DMA channel is needed by the DAC, the DMA trigger should be unmasked in the IMASK register.

#### Note

The DMA trigger from the DAC is a direct trigger in hardware and not a part of the DMA\_TRIG group of configurable event management registers.

To configure the DMA controller to trigger from the DAC, please see [Section 20.2.8](#).

**Table 20-6. DAC DMA Trigger Event Publisher Conditions**

Index (IIDX)	Name	Description
0x0	NO_INTR	No bit set (IIDX.STAT = 0) means there is no pending interrupt request
0x2	MODRDYIFG	Module ready interrupt once DAC is enabled and DAC output is settled
0x9	FIFOFULLIFG	FIFO full interrupt flag is set when the FIFO is full
0xA	FIFO1B4IFG	FIFO one fourth empty interrupt flag is set when one fourth of FIFO locations are empty.
0xB	FIFO1B2IFG	FIFO half empty interrupt flag is set when half of the FIFO locations are empty.
0xC	FIFO3B4IFG	FIFO three fourth empty interrupt flag is set when all the locations in FIFO are empty.
0xD	FIFOEMPTYIFG	FIFO empty interrupt flag is set when all data in the FIFO have been shifted out.
0xE	FIFOURUNIFG	FIFO underrun flag is set when the FIFO read trigger is asserted while the FIFO is empty.
0xF	DMADONEIFG	DMA done interrupt flag is set when the DMA data transfer of programmed block size is completed

### 20.2.12.4 Generic Event Subscriber (FSUB\_0)

The DAC module can trigger FIFO transfers by receiving events routed through a generic channel from other peripherals. When the event is received, the data in the FIFO is loaded into internal DAC data register. Refer to [Generic Event Route](#) and [Peripheral to Peripheral Event](#) for details on how the generic event route works. When the channel to be used is determined, and both the publisher and subscriber ports for the peripherals to connect are known, use the steps below to establish the event connection.

In this example, a GPIO-triggered DAC FIFO transfer is configured, using GPIO Port A to publish an event to generic channel 1, with DAC subscribing to generic channel 1 as a start-of-conversion trigger.

1. Configure the GEN\_EVENT registers of GPIO Port A to set the event request based on the appropriate event (for example, a DIN rise event).
2. Store 0x1 into the FPUB\_0 register of GPIO Port A to publish the GPIO event selected by the GEN\_EVENT registers to generic route channel 1. Channel 1 must not be in use by another peripheral.
3. Store 0x1 the FSUB\_0 register of DAC so that DAC is listening for events published by the timer to channel 1.
4. Configure DAC to trigger from the subscriber port according to the configuration instructions in [Loading Data From FIFO to Internal DAC Data Register](#).
5. Configure and enable the appropriate GPIO pin to monitor input voltage events.

## 20.3 DAC12 Registers

Table 20-7 lists the memory-mapped registers for the DAC12 registers. All register offset addresses not listed in Table 20-7 should be considered as reserved locations and the register contents should not be modified.

**Table 20-7. DAC12 Registers**

Offset	Acronym	Register Name	Group	Section
400h	FSUB_0	Subscriber Port 0		<a href="#">Go</a>

## 6 IIDX (Offset = 1020h) [Reset = 0000000h]

IIDX is shown in [Figure 20-13](#) and described in [Table 20-14](#).

Return to the [Summary Table](#).

Interrupt index register. This read-only register provides the interrupt index of the pending interrupt with the highest priority. It also indicates if no interrupt is pending. The priority order is fixed: lower index equals higher priority. Alternatively, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flags in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt or indicate that no interrupt is pending. Only interrupts which are selected via IMASK are indicated.

**Figure 20-13. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 12 IIDX (Offset = 1050h) [Reset = 0000000h]

IIDX is shown in [Figure 20-19](#) and described in [Table 20-20](#).

Return to the [Summary Table](#).

Interrupt index register. This read-only register provides the interrupt index of the pending interrupt with the highest priority. It also indicates if no interrupt is pending. The priority order is fixed: lower index equals higher priority. Alternatively, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flags in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt or indicate that no interrupt is pending. Only interrupts which are selected via IMASK are indicated.

**Figure 20-19. IIDX**

#### 14 RIS (Offset = 1060h) [Reset = 00001E00h]

RIS is shown in [Figure 20-21](#) and described in [Table 20-22](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Table 20-52. CTL2 Field Descriptions**

Bit	Field	Type	Reset	Description
31-25	RESERVED	R/W	0h	
24	DMATRIGEN	RH/W	0h	This bit enables the DMA trigger generation mechanism. When this bit is set along with FIFOEN, the DMA trigger is generated based on the empty FIFO locations qualified by FIFOTH settings. This bit should be cleared by software to stop further DMA triggers. 0h = DMA trigger generation mechanism is disabled 1h = DMA trigger generation mechanism is enabled
23-18	RESERVED	R/W	0h	
17-16	FIFOTRIGSEL	R/W	0h	These bits select the source for FIFO read trigger. When the selected FIFO read trigger is asserted, the data from FIFO (as indicated by read pointer) is moved into internal DAC data register. 0h = Sample time generator output 1h = Hardware trigger-0 from event fabric 2h = Reserved - unimplemented 3h = Reserved - unimplemented
15-10	RESERVED	R/W	0h	
9-8	FIFOTH	R/W	0h	These bits determine the FIFO threshold. In case of DMA based operation, DAC generates new DMA trigger when the number of empty locations in FIFO match the selected FIFO threshold level. In case of CPU based operation, the FIFO threshold bits are don't care and FIFO level is directly indicated through the respective bits in the RIS register. 0h = One fourth of the FIFO locations are empty 1h = Half of the FIFO locations are empty 2h = Three fourth of the FIFO locations are empty 3h = Reserved value. Defaults to same effect as FIFOTH = 0 (One fourth of the FIFO locations are empty).
7-1	RESERVED	R/W	0h	
0	FIFOEN	R/W	0h	This bit enables the FIFO and the FIFO hardware control state machine. 0h = FIFO is disabled 1h = FIFO is enabled

### 23 CTL3 (Offset = 1130h) [Reset = 0000000h]

CTL3 is shown in [Figure 20-30](#) and described in [Table 20-31](#).

The OPA is a zero-drift chopper stabilized operational amplifier with a programmable gain stage. This chapter describes the features and operation of the OPA peripheral.

<b>21.1 OPA Overview</b> .....	<b>1307</b>
<b>21.2 OPA Operation</b> .....	<b>1308</b>
<b>21.3 OA Registers</b> .....	<b>1318</b>

## 21.1 OPA Overview

The purpose of the OPA peripheral integrated into the MSPM0xx MCU platform is to provide a way to buffer or amplify analog signals in a system without the need of discrete op-amps.

The OPA is based off of a high-performance factory trimmed amplifier core accompanied with a programmable gain stage feedback loop, configurable input muxes, and a burnout current source used to monitor sensor health.

OPA features include:

- Software selectable zero-drift chopper stabilization
- Factory trimming to remove offset error
- Rail-to-rail input & output
- Operation supported in full-scale supply voltage range
- Dual power modes for added flexibility
- Programmable gain amplifier (PGA) up to 32x
- Configurable amplifier modes include General Purpose Mode, Buffer Mode, Inverting/Non-inverting PGA Mode, Difference Amplifier Mode and Cascade Amplifier Mode
- Rich selection of external/internal op-amp terminal input options
- Dual-differential input pairs to connect multiple sensors to a single OPA
- Burnout current source (BCS) integrated to monitor sensor health
- Operates in RUN, SLEEP, and STOP modes

---

### Note

Most devices integrate more than one OPA peripheral. If more than one OPA is present on a device, they all operate identically. Throughout this chapter, nomenclature appears such as OPA<sub>x</sub> and OPA[x-1] to describe different instances of the OPA peripheral.

---

[Figure 21-1](#) shows the functional block diagram of the OPA peripheral.

(A) Available on select devices. See the device-specific data sheet for availability.  
 (B) From VREF module  
 (C) From ADC MMR

Figure 21-1. OPA Block Diagram

## 21.2 OPA Operation

The OPA is configured with application software. The following sections describe the setup and operation of the OPA peripheral.

### 21.2.1 Analog Core

The OPA integrates a high-performance chopper stabilized low-power rail-to-rail input/output operational amplifier. It can be reconfigured in real-time to meet the performance requirements of a specific application. The following table depicts all of the op-amp analog core features and parameters that are configurable:

Table 21-1. OPA Configurable Parameters

Parameter	Configuration Options
Rail-to-Rail Input (RRI)	Enabled / Disabled
Gain Bandwidth Product (GBW)	6MHz (STD Mode) / 1MHz (LP Mode)
Chopping (CHOP)	Disabled/Standard Chop/ADC-assisted Chop

In some basic signal conditioning applications, rail-to-rail input is not required and thus can be disabled to reduce overall power consumption. Rail-to-rail input can be disabled by clearing the RRI bit field in the PMUOPAMP register. The same concept applies to the gain bandwidth product for general purpose applications which require <1MHz GBW. The OPA can be configured to the low power operating mode (LP mode) by clearing the GBW bit in the CFGBASE register.

In some analog sensing applications, high accuracy and low offset drift is a requirement. For these use-cases, chopping can be enabled to significantly improve offset voltage and offset drift performance. Please refer to [Section 21.2.6](#) for more details on how to properly configure and leverage the chopping feature of the OPA.

### 21.2.2 Power Up Behavior

The ENABLE bit in the PWREN register connects the OPA peripheral to the bus and the clock system. The ENABLE bit in the CTL register activates the OPA analog and digital core. There is a ready bit (RDY) in the STAT register which is set when the OPA is ready for use. Please see the device-specific data sheet for the enable time of the OPA peripheral.

---

#### Note

PWREN.ENABLE must be set before writing to CTL.ENABLE or any other OPA memory mapped registers (MMRs).

---

### 21.2.3 Inputs

The OPA uses input muxes P-MUX and N-MUX to provide a selection of input channels for the noninverting and inverting terminals of the amplifier. These inputs are configurable using the PSEL and NSEL control bits.

A generalized depiction of the input channel mapping is included in [Table 21-2](#) below. Please refer to the device-specific data sheet for a more detailed depiction of the available OPAX inputs.

**Table 21-2. General OPAX Input Channels**

PSEL	OPAx Non-inverting Channels	NSEL	OPAx Inverting Input Channels
0x0	Open	0x0	Open
0x1	OPAx_IN0+	0x1	OPAx_IN0-
0x2	OPAx_IN1+	0x2	OPAx_IN1-
0x3	DAC_OUT	0x3	OPA[x-1]_RBOT
0x4	DAC8.x_OUT	0x4	RTAP
0x5	VREF	0x5	RTOP
0x6	OPA[x-1]_RTOP		
0x7	GPAMP Output		
0x8	VSS		

---

#### Note

OPAx and OPA[x-1] refer to instances where there are 2 OPA peripherals in a device. In these cases, the peripherals are paired and the input/outputs are shared as shown in [Table 21-2](#). DAC8.x refers to the paired COMP reference DAC which can be routed to the noninverting input of OPAX.

---

### 21.2.4 Output

The OPA output is connected to a network of complementary switches to allow the amplifier output to be a purely internal signal or allow the signal to be accessed through a device pin. If OUTPIN = 0, the output is internally connected to the programmable gain stage and capable of being routed to other analog peripherals. If OUTPIN = 1, the output goes to the device pin while still maintaining connection to the programmable gain stage and other analog peripherals. Having access to the amplifier output at the device pin allows for external filtering circuitry.

### 21.2.5 Clock Requirements

The OPA requires SYSOSC to be active for proper operation to support features such as chopping and rail-to-rail input. There are no provisions in place for the OPA to automatically request the SYSOSC from SYSCTL so the user must ensure that SYSOSC is enabled to use the OPA. The minimum requirements for the input clock depend on the OPA configuration as shown in the table below.

**Table 21-3.**

RRI	Supported SYSOSC Frequencies
0	4/16/24/32MHz
1	32MHz

**Note**

Application software needs to ensure that SYSOSC is programmed to an appropriate frequency for rail-to-rail input.

**21.2.6 Chopping**

The OPA peripheral implements chopper stabilization to reduce offset, drift, and 1/f noise. CFG.CHOP can be set to 0x1 for standard chopping mode which requires an external filter. Note that the OPA automatically scales the chopping frequency based on CFG.GAIN which is used to select the OPA PGA gain but is also needed with external filter when the standard chopping is used as shown in [Table 21-4](#).

**Table 21-4. Standard Chopping Frequency for OPA**

GAIN	Inverting / Non-inverting Gain	Chopping Frequency (Hz)	Resistor(k $\Omega$ )	Capacitor(nF)
0x0	1x	125k	1	10
0x1	-1x / 2x	62.5k	1	30
0x2	-3x / 4x	31.25k	1	90
0x3	-7x / 8x	15.6k	1	270
0x4	-15x / 16x	7.8k	1	810
0x5	-31x / 32x	3.9k	1	2400

**21.2.7 OPA Amplifier Modes**

The OPA uses an input mux, M-MUX, connected to the programmable gain stage resistor ladder to allow the user to program the OPA for various analog signal chain configurations. These configurations include unity gain buffer, inverting/noninverting amplification, PGA, cascade amplification, and more.

A generalized depiction of the input channel mapping for M-MUX is included in [Table 21-5](#) below. Please refer to the device-specific data sheet for a mode detailed depiction of the available M-MUX inputs.

**Table 21-5. General OPA M-MUX Channel Mapping**

MSEL	OPAx M-MUX Input Channels
0x0	Open
0x1	OPAx_IN1-
0x2	GND
0x3	DAC_OUT
0x4	OPA[x-1]_RTOP

The following sections provide examples of how P-MUX, N-MUX, and M-MUX can be configured for various amplifier modes.

**21.2.7.1 General-Purpose Mode**

The OPA internal muxes support GP mode which allows all input and output terminals to be accessed from device pins. Using this mode with external components enables the amplifier to realize any analog signal chain circuitry that a discrete op-amp can. Dual differential inputs IN0+/- and IN1+/- allow for two different input networks to be connected to the same OPA peripheral.

[Figure 21-2](#) shows the block diagram of the OPA in GP mode.

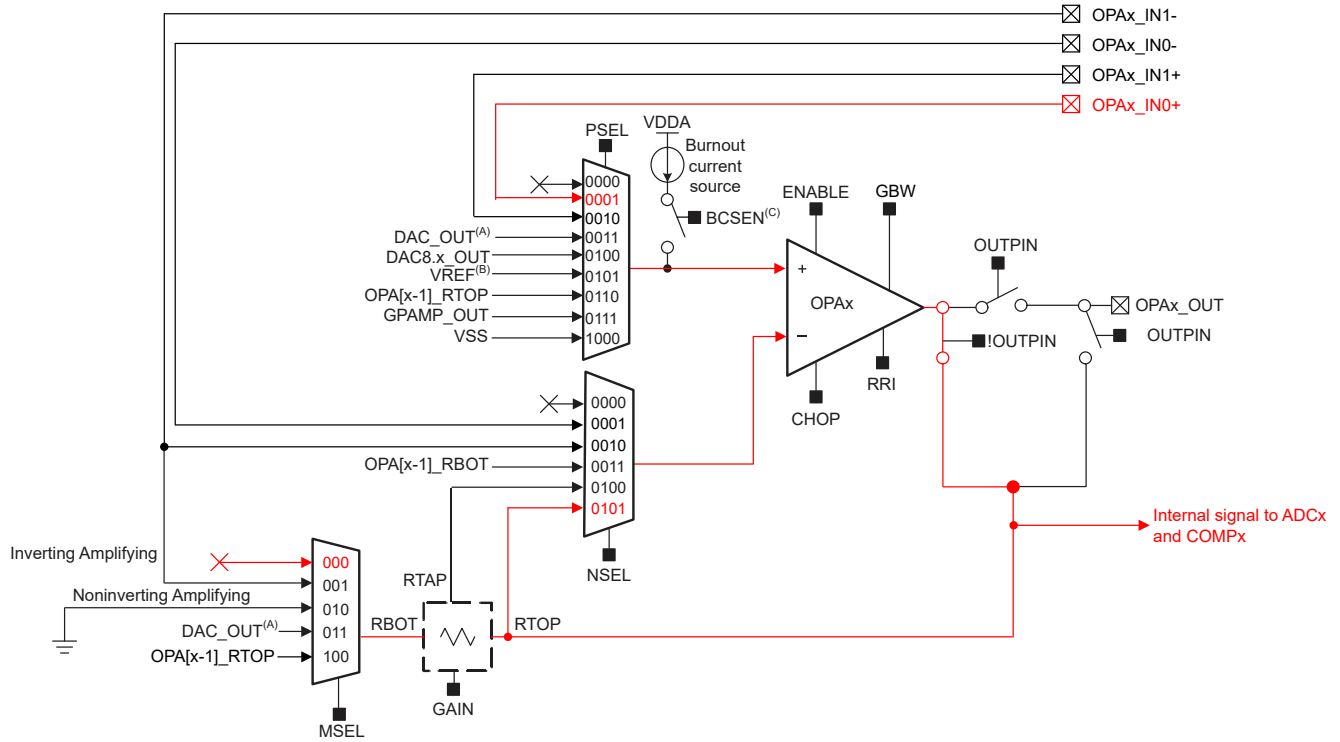

(A) Available on select devices. See the device-specific data sheet for availability.  
 (B) From VREF module  
 (C) From ADC MMR

**Figure 21-2. OPA in General Purpose (GP) Mode**

**21.2.7.2 Buffer Mode**

The internal feedback loop can be programmed to a unity gain configuration to support OPA buffer mode. The noninverting input can be sourced from a variety of signals such as the external OPAx\_INx or the on-board DAC and VREF peripherals. The OPA can output to an external pin by setting OUTPIN = 0x1 or be internally routed to on-board analog peripherals such as the ADC, COMP, and/or paired OPA by setting OUTPIN = 0x0.

Figure 21-3 shows the block diagram of the OPA in buffer mode with external OPAx\_IN0+ as the noninverting input and the output internally routed to the ADC.

(A) Available on select devices. See the device-specific data sheet for availability.  
 (B) From VREF module  
 (C) From ADC MMR

**Figure 21-3. OPA in ADC Buffer Configuration**

Figure 21-4 shows the block diagram of the OPA in buffer mode with DAC8.x\_OUT as the noninverting input and the output routed out to a device pin. This mode enables the user to use the OPA peripheral as an output buffer for the comparator onboard reference DAC.

(A) Available on select devices. See the device-specific data sheet for availability.  
 (B) From VREF module  
 (C) From ADC MMR

Figure 21-4. OPA in DAC Output Buffer Configuration

21.2.7.3 OPA PGA Mode

The OPA integrates a programmable gain stage in the feedback loop to configure the OPA as a PGA (programmable gain amplifier). The gain stage is a feedback resistance ladder and it supports up to 32x amplification. Table 21-6 lists the OPA PGA mode gain settings.

Table 21-6. PGA Mode and Gain Settings

PGA Mode Configuration	GAIN	Gain Value from PGA (Internal Gain)
Inverting PGA Mode	0x0	Not Valid
	0x1	-1x
	0x2	-3x
	0x3	-7x
	0x4	-15x
	0x5	-31x
Non-inverting PGA Mode	0x0	Not valid
	0x1	2x
	0x2	4x
	0x3	8x
	0x4	16x

**Table 21-6. PGA Mode and Gain Settings (continued)**

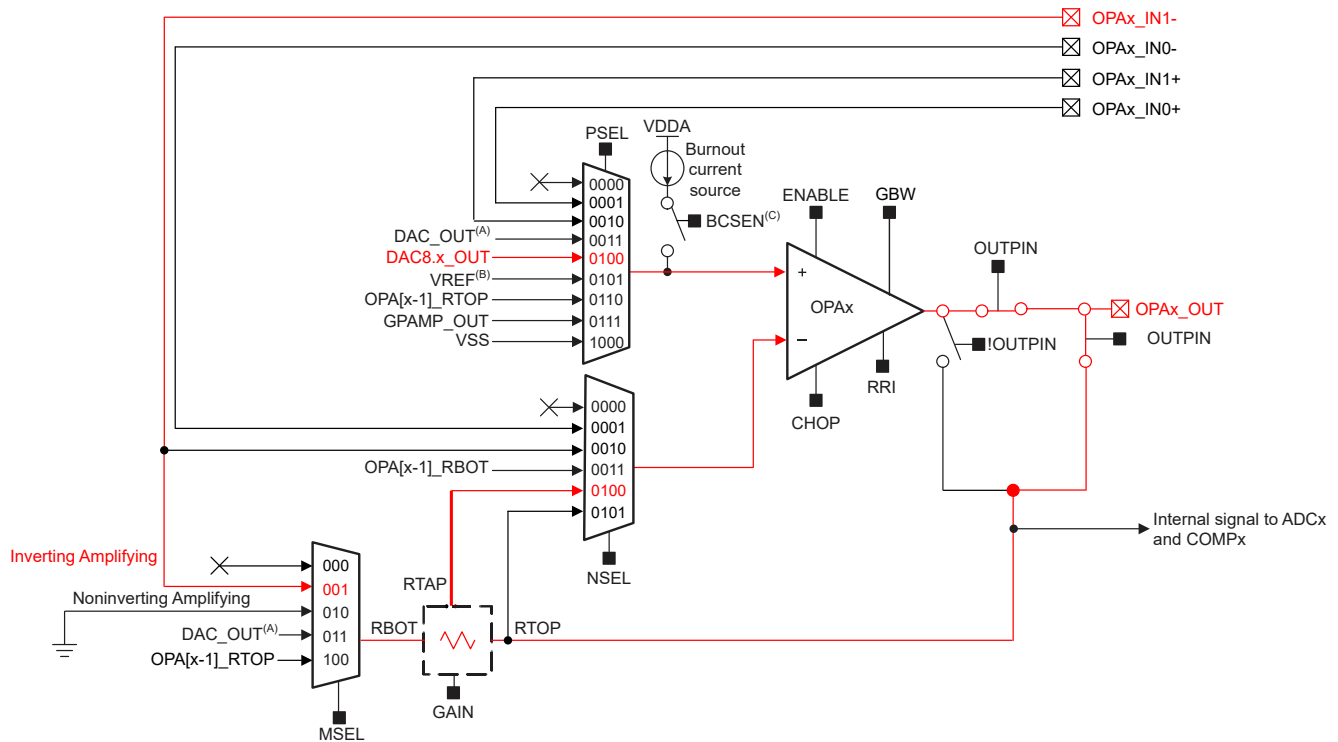

PGA Mode Configuration	GAIN	Gain Value from PGA (Internal Gain)
	0x5	32x

The programmable gain stage works with P-MUX, N-MUX, and M-MUX to support various internal amplifier configurations which are detailed in the following sections.

**21.2.7.3.1 Inverting PGA Mode**

In this mode, the inverting input is sourced from the external OPAX\_IN1- crossing the resistor ladder of the PGA. The MSEL bits select OPAX\_IN1- as the source (MSEL = 0x1) and the NSEL bits must select the RTAP as the inverting input for the amplifier (NSEL = 0x4). Because the OPA is a single supply amplifier, the noninverting input needs to be biased up to ensure that the output stays within the linear range. The noninverting input can be sourced from the external OPAX\_INx+ input or from a DAC input.

Figure 21-5 shows an example of the OPA inverting PGA mode with the 8-bit reference DAC as bias cancellation.

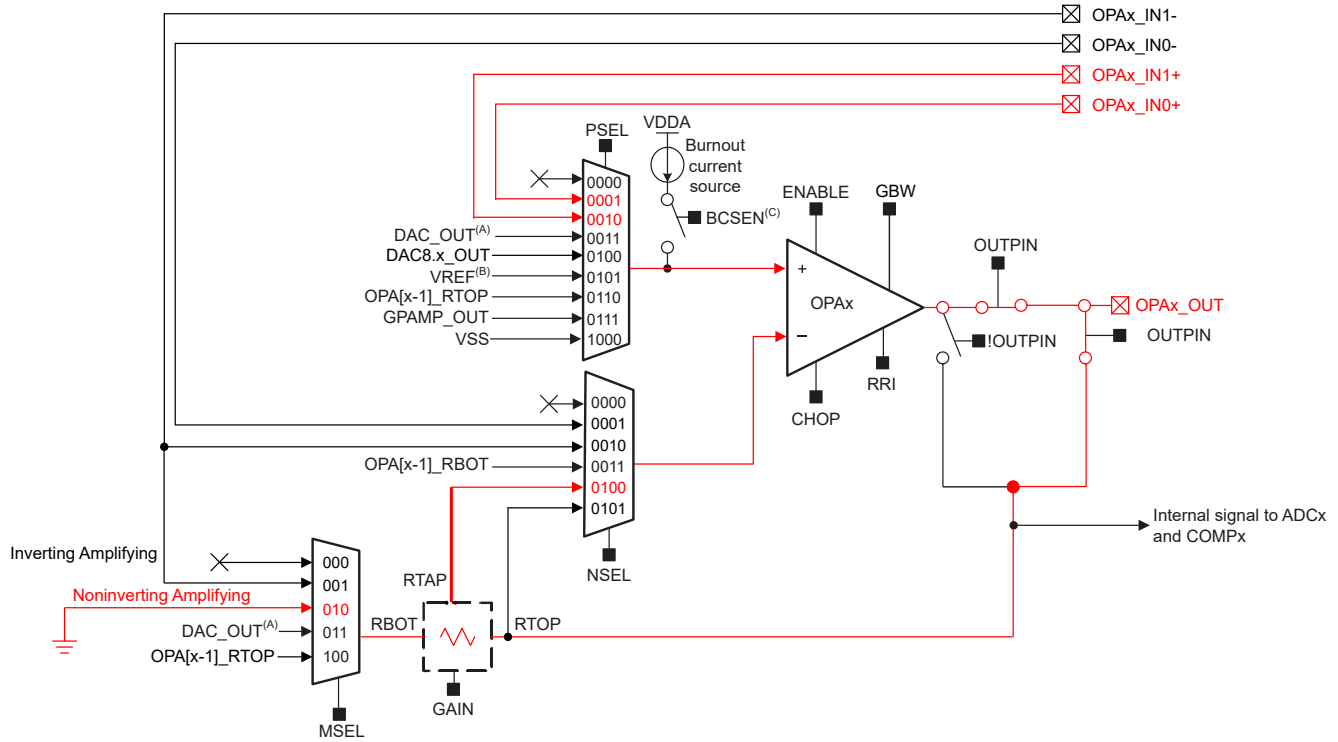

(A) Available on select devices. See the device-specific data sheet for availability.  
 (B) From VREF module  
 (C) From ADC MMR

**Figure 21-5. OPA in Inverting PGA Configuration**

**21.2.7.3.2 Non-inverting PGA Mode**

In this mode, the noninverting input is sourced from the external OPAX\_INx+ input (PSEL = 0x1 or 0x2). The NSEL bits must select RTAP as the inverting input for the amplifier (NSEL = 0x4) and from the MSEL bits a bias is chosen from either ground or the 12-bit buffered DAC (DAC\_OUT).

Figure 21-6 shows an example of the OPA in noninverting PGA mode.

(A) Available on select devices. See the device-specific data sheet for availability.  
 (B) From VREF module  
 (C) From ADC MMR

Figure 21-6. OPA in Non-inverting PGA Configuration

21.2.7.4 Difference Amplifier Mode

When two or more OPAs are available on a device, two can be combined to form a difference amplifier. The output equation for the difference amplifier is given by the  $V_{diff}$  equation in Figure 21-7. The internally connected configuration for two OPAs with the output being sampled by the ADC is shown in Figure 21-8.

Figure 21-7. Two OPA Difference Amplifier Block Diagram and Equation

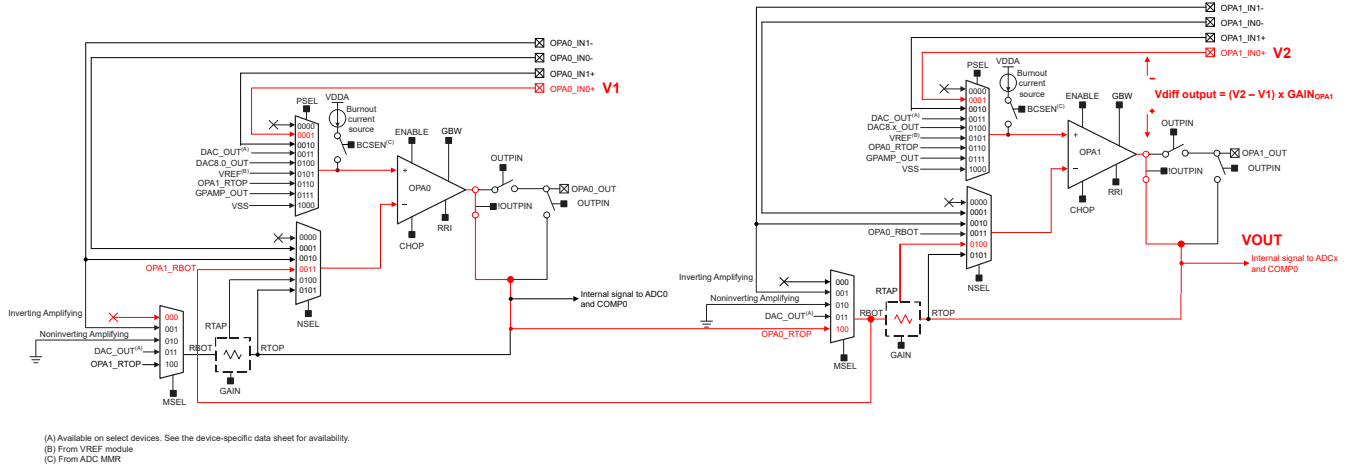

Figure 21-8. Two OPAs in Difference Amplifier Configuration

21.2.7.5 Cascade Amplifier Mode

When two or more OPAs are available on a device, two can be combined to form a multistage or cascaded amplifier. Using the programmable input muxes, all combinations of inverting and noninverting multistage amplifiers can be implemented. The output equation for the noninverting to noninverting cascaded amplifier is given by the  $V_{out}$  equation in Figure 21-9. The internally connected configuration for two OPAs is shown in Figure 21-10.

Figure 21-9. Two OPA Non-inverting to Non-inverting Cascade Amplifier Block Diagram and Equation

Figure 21-10. Two OPAs in Non-inverting to Non-inverting Cascade Amplifier Configuration

21.2.8 OPA Configuration Selection

The OPA peripheral allows customers to dynamically change the OPA gain without disabling OPA functionality by using the register CFG.GAIN enable bits. When using the control bits CFG.GAIN to select between different

gain values, the user must ensure that the additional CFG control bits remain unchanged, and that the CFG.GAIN control bits do not get cleared to 0x0.

To ensure proper operation of the OPA, the configuration settings except the CFG.GAIN bits governed by the CFG register can only be changed when the OPA is disabled. This means that to change OPA inputs or mode within an application, a user must perform the following:

- Clear CTL.ENABLE bit
- Update CFG.MSEL or CFG.NSEL or CFG.PSEL bits
- Set CTL.ENABLE bit

---

**Note**

Applications must take into account OPA enable time when performing this procedure. Please see OPA Specification within the device-specific data sheet for details.

---

---

**Note**

This procedure must also be followed if changing the CFG.GAIN bits to or from a value of 0x0.

---

### 21.2.9 Burnout Current Source

The OPA has a burnout current source (BCS) that can be used when requested by the ADC. The ADC will provide a burnout current source enable signal to the OPA peripheral when it is selected as the ADC input channel and the BCSEN bit is set in the ADC MEMCTL register. When enabled, the burnout current source will inject current into the positive input of the OPA. The ADC should then be used to measure the voltage across the sensor or resistive Wheatstone bridge with the input signal going through the OPA configured in buffer mode (or whichever OPA configuration is normally used). An ADC reading with the burnout current source enabled can then detect if the sensor is open (that is, a broken wire resulting in full range signal) or shorted (0V). The user can periodically enable the burnout current source to check if the sensor is operating properly. It should be turned off during measurements.

## 21.3 OA Registers

Table 21-7 lists the memory-mapped registers for the OA registers. All register offset addresses not listed in Table 21-7 should be considered as reserved locations and the register contents should not be modified.

**Table 21-7. OA Registers**

The GPAMP is a chopper stabilized general purpose operational amplifier with rail-to-rail input and output. This chapter describes the features and operation of the GPAMP peripheral.

<b>22.1 GPAMP Overview</b> .....	<b>1329</b>
<b>22.2 GPAMP Operation</b> .....	<b>1329</b>
<b>22.3 GPAMP Registers</b> .....	<b>1332</b>

## 22.1 GPAMP Overview

The purpose of the GPAMP peripheral integrated into the MSPM0xx MCU platform is to provide a way to buffer or amplify analog signals in a system without the need of discrete op-amps.

The GPAMP is based off of a factory trimmed amplifier core accompanied with a configurable inverting input mux which allows for various analog signal chain configurations.

GPAMP features include:

- Software selectable chopper stabilization
- Rail-to-rail input & output
- Operation supported in full-scale supply voltage range
- Programmable internal unity gain feedback loop
- Operates in RUN, SLEEP, and STOP modes

Figure 22-1 show the functional block diagram of the GPAMP peripheral.

Figure 22-1. GPAMP Block Diagram

## 22.2 GPAMP Operation

The GPAMP peripheral is configured with user software using the PMUOPAMP register which is located in the PMCU region of memory mapped registers. For bit field definitions, you can refer to the end of this chapter or the register section of [PMCU](#). The setup and operation of GPAMP is discussed in the following sections.

### 22.2.1 Analog Core

The GPAMP integrates a chopper stabilized low-power rail-to-rail input/output operational amplifier. It can be reconfigured in real-time to meet the performance requirements of various applications. The following table depicts all of the amplifier analog core features and parameters that are configurable:

Table 22-1. GPAMP Configurable Parameters

Parameter	Configuration Options
Rail-to-Rail Input (RRI)	Mode 0 / Mode 1 / Mode 2
Chopping (CHOPCLKMODE)	Standard Chop / Disabled

In some basic signal conditioning applications, rail-to-rail input is not required and thus can be disabled to reduce overall power consumption. Rail-to-rail input can be disabled by programming the RRI bit field to 0x0 (Mode 0). Refer to the GPAMP specifications in the device specific data sheet for supported common-mode input ranges in the various RRI modes.

In some analog sensing applications, high accuracy and low offset drift is a requirement. For these use-cases, chopping can be enabled to significantly improve offset voltage and offset drift performance. Please refer to [Section 22.2.6](#) for more details on how to properly configure and leverage the chopping feature of the GPAMP.

### 22.2.2 Power Up Behavior

The ENABLE bit in the PMUOPAMP register activates the GPAMP analog and digital core. The GPAMP requires the VBOOST circuit in the PMU to be stabilized before use. Refer to [Section 2.2.5](#) for more details on what the VBOOST circuit is and why it is needed for proper GPAMP operation. Please see the device-specific data sheet for the enable time of the GPAMP peripheral.

### 22.2.3 Inputs

The GPAMP uses an input mux, N-MUX, to provide a selection of input channels for the inverting terminal of the amplifier. These inputs are configurable using the NSEL control bits. The noninverting terminal of the amplifier is enabled using the PCHENABLE control bit and allows the input to be driven from the GPAMP\_IN+ signal on a device pin.

A depiction of the input channel mapping is included in [Table 22-2](#) below.

**Table 22-2. GPAMP Input Channels**

PCHENABLE	GPAMP Non-inverting Input	NSEL	GPAMP Inverting Input Channels
0x0	Open	0x0	GPAMP output pad (GPAMP_OUT)
0x1	GPAMP_IN+	0x1	GPAMP_IN-
		0x2	GPAMP internal amplifier output
		0x3	Open

### 22.2.4 Output

The GPAMP output is connected to a switch to allow the amplifier output to be a purely internal signal or allow the signal to be accessed through a device pin. If OUTENABLE = 1, the amplifier output goes to the device pin while still maintaining connection to the inverting input mux and other analog peripherals. If OUTENABLE = 0, the amplifier output is disconnected from the device pin but is still internally connected to the inverting input mux and other analog peripherals on-board. Having access to the amplifier output at the device pin allows for external filtering circuitry. Refer to the [GPAMP Block Diagram](#) for a detailed schematic of the GPAMP output circuitry.

### 22.2.5 GPAMP Amplifier Modes

The GPAMP uses N-MUX and an internal unity gain feedback loop to allow the user to program the GPAMP for various analog signal chain configurations. These configurations include general purpose mode, ADC buffer, and unity gain mode.

The following sections provide examples of how GPAMP can be configured for these various amplifier modes.

#### 22.2.5.1 General-Purpose Mode

The GPAMP supports general-purpose (GP) mode which allows all input and output terminals to be accessed from device pins. To realize this GP mode NSEL, PCHENABLE, and OUTENABLE must all be set to 0x1. Using this mode requires external components and an appropriate feedback loop to build the circuit desired.

[Figure 22-2](#) shows the block diagram of the GPAMP in GP mode.

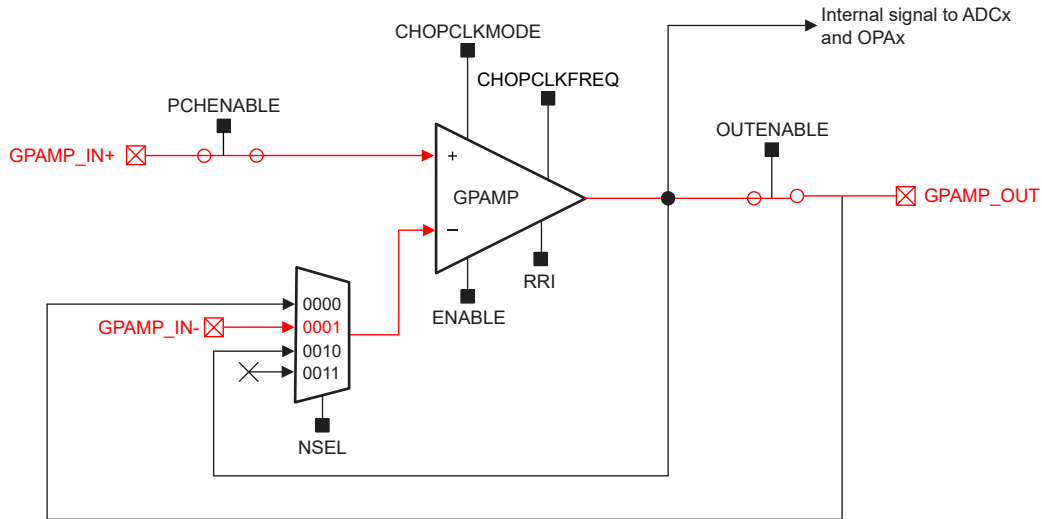

Figure 22-2. GPAMP in General Purpose (GP) Mode

### 22.2.5.2 ADC Buffer Mode

The GPAMP can be used to internally buffer an analog signal into an on-board ADC. To realize this ADC buffer mode, NSEL must be set to 0x2, PCHENABLE must be set to 0x1, and OUTENABLE must be set to 0x0.

Figure 22-3 shows the block diagram of the GPAMP in ADC buffer mode with GPAMP\_IN+ as the noninverting input and the output internally routed to the ADC.

Figure 22-3. GPAMP in ADC Buffer Configuration

### 22.2.5.3 Unity Gain Mode

The internal feedback loop of the GPAMP can be used to implement a unity gain amplifier which can buffer an analog signal to other devices in a system. To realize this unity gain mode, NSEL must be set to 0x0, PCHENABLE must be set to 0x1, and OUTENABLE must be set to 0x1.

Figure 22-4 shows the block diagram of the GPAMP in unity gain mode.

Figure 22-4. GPAMP in Unity Gain Configuration

### 22.2.6 Chopping

The GPAMP peripheral implements chopper stabilization to reduce offset, drift, and 1/f noise. CHOPCLKMODE can be set to 0x1 for standard chopping mode which requires an external filter. See device-specific data sheet for recommended values. The chopping frequency, which is set by CHOPCLKFREQ, needs to scale down as the gain increases. Refer to Table 22-3 for info on what chopping frequency is required for a given gain.

Table 22-3. Standard Chopping Frequency for GPAMP

CHOPCLKFREQ	Supported External Gain Configuration	Chopping Frequency (Hz)
0x0	-1x / 2x	16k
0x1	-3x / 4x	8k
0x2	-7x / 8x	4k
0x3	-15x / 16x	2k

### 22.3 GPAMP Registers

The GPAMP control register (PMUOPAMP) is in the SYSCTL registers.

The VREF module contains a configurable voltage reference buffer which allows users to supply a stable internal reference to on-board analog peripherals. It also supports bringing in an external reference for applications where higher accuracy is required. This chapter describes the features and operation of the VREF module.

<b>23.1 VREF Overview</b> .....	<b>1334</b>
<b>23.2 VREF Operation</b> .....	<b>1335</b>
<b>23.3 VREF Registers</b> .....	<b>1338</b>

## 23.1 VREF Overview

The VREF module for the MSPM0Gxx family is a shared voltage reference module which can be leveraged by a variety of on-board analog peripherals. VREF allows users to choose between using an internally generated reference voltage or using an externally provided reference voltage from outside the MCU. Please reference the device data sheet for specifics about its VREF configuration.

The VREF module features include:

- 1.4V and 2.5V user-selectable internal references
- Support for receiving external reference on VREF+/- device pins
- Internal reference output available on VREF+ device pin
- Sample and hold mode supports VREF operation down to STANDBY operating mode
- Internal reference supports full speed ADC operation

Figure 23-1. MSPM0 VREF Superset Block Diagram

### 23.2 VREF Operation

The VREF module is configured with user software. The setup and operation of VREF is discussed in the following sections.

### 23.2.1 Internal Reference Generation

To use VREF to generate an internal voltage reference, the user must first enable register write access to the module using the ENABLE control bit in the PWREN register, and then enable the reference buffer using the ENABLE control bit in the CTL0 register. The VREF module generates voltage references based on the factory trimmed bandgap coming from the PMU. The bandgap reference is buffered through a noninverting amplifier to generate an internal reference voltage (1.4V or 2.5V). Only one voltage can be selected at a time using the BUFCONFIG control bit in CTL0.

---

#### Note

The internal reference generated by VREF requires an external decoupling capacitor ( $C_{VREF}$ ) for proper operation. Please refer to the device specific data sheet for more information on the value and required placement of  $C_{VREF}$ .

---

After it is enabled and settled, the internal reference can be used as an accurate and stable voltage reference for on-board analog peripherals. Refer to the analog peripheral chapters for more info on how can leverage this reference voltage.

The VREF provides a READY indication bit in the CTL1 register. The first time the VREF is enabled, the READY bit will remain cleared until the VREF is started and settled, after which the READY bit will be set by hardware. If the VREF is disabled, the READY bit will be cleared back to zero by hardware. If the VREF is re-enabled later, the READY bit will not be set, and application software must manage the VREF startup time.

---

#### Note

VREF configuration change from 2.5V to 1.4V mode has a very slow slew rate. If this change is needed; then follow below procedure:

- Disable VREF using the ENABLE bit in the CTL0 register
  - Configure pin PA23(VREF+) as GPIO output and drive this pin to logic low for 100us. A 1uF external capacitor is assumed on the VREF+ pin
  - Re-enable VREF in 1.4V mode by setting the BUGCONFIG bit in the CTL0 register to 1. After VREF is enabled and settled, the internal reference of 1.4V can be used
- 

### 23.2.2 External Reference Input

For circumstances where accuracy is a key requirement, an external reference can be brought in to the MCU from the VREF+ and VREF- device pins. Only one type of reference (internal or external) can be selected at a time. When supplying the MCU with an external reference, it is recommended to connect a decoupling capacitor on the reference pins with a value based on the voltage source.

---

#### Note

Be sure the VREF reference buffer is disabled by clearing the ENABLE control bit in the CTL0 register before applying the external reference to the device pins.

---

### 23.2.3 Analog Peripheral Interface

#### VREF to ADC

The ADC peripheral can leverage the internal configurable reference or an external reference using the VRSEL control bits in the ADC MEMCTL register.

The user must make sure that the VREF reference buffer has settled before triggering an ADC conversion when using an internal reference as the ADC voltage reference (VR+). Refer to the device-specific data sheet for VREF settling times and refer to the ADC chapter for more details on all of the reference options available for the ADC peripheral.

**VREF to COMP**

The comparator peripheral can leverage the internal configurable reference or an external reference using the REFSRC control bits within the CTL2 register associated with the COMP.

Refer to the COMP chapter for more details on all of the reference options available for the comparator peripheral.

**VREF to DAC**

The DAC peripheral can leverage the internal configurable reference or an external reference using the REFSP control bits in the DAC CTL1 register.

Refer to the DAC chapter for more details on all of the reference options available for the DAC peripheral.

**VREF to OPA**

The OPA peripheral can leverage the internal configurable reference or an external reference for setting a voltage bias on the noninverting input terminal of the amplifier using the PSEL control bits in the CFG register. In cases where other devices in a system need to use the same reference as the MCU, the OPA can be used in unity gain buffer configuration to drive the VREF internal reference voltage to the OPA\_OUT pin which can be used as a reference for other devices on the PCB.

Refer to the OPA chapter for more details on all of the channels available for the noninverting amplifier input terminal of the amplifier.

### 23.3 VREF Registers

Table 23-1 lists the memory-mapped registers for the VREF registers. All register offset addresses not listed in Table 23-1 should be considered as reserved locations and the register contents should not be modified.

**Table 23-1. VREF Registers**

31-16	HCYCLE	R/W	0h	Hold cycle count Total cycles of module clock for hold phase when VREF is working in sample and hold mode in STANDBY to save power. Please refer VREF section of datasheet for recommended values of sample and hold times. 0h = smallest hold cycle FFFFh = largest hold cycle
15-0	SHCYCLE	R/W	0h	Sample and Hold cycle count Total cycles of module clock for sample and hold phase when VREF is working in sample and hold mode in STANDBY to save power. This field should be greater than HCYCLE field. The difference between this field and HCYCLE gives the number of cycles of sample phase. Please refer VREF section of datasheet for recommended values of sample and hold times. 0h = smallest sample and hold cycle count FFFFh = largest sample and hold cycle

The universal asynchronous receiver-transmitter (UART) module provides an interface for serial communication protocols.

<b>24.1 UART Overview</b> .....	<b>1348</b>
<b>24.2 UART Operation</b> .....	<b>1350</b>
<b>24.3 UART Registers</b> .....	<b>1370</b>

## 24.1 UART Overview

### 24.1.1 Purpose of the Peripheral

The UART module can share data between devices with asynchronous serial communication protocols such as LIN (local interconnection network), ISO7816 (Smart card protocol), IrDA (infrared data association), and hardware flow control (CTS/RTS).

### 24.1.2 Features

Refer to the device-specific datasheet for the supported features, as some devices may not include support for select features. The following list describes the full complement of features available:

- Fully programmable serial interface:
  - 5, 6, 7 or 8 data bits
  - Even, odd, stick, or no-parity bit generation and detection
  - 1 or 2 stop bit generation
  - LSB-first or MSB-first data transmit and receive
  - Line-break detection
  - Glitch filter on the input signals
  - Programmable baud-rate generation with oversampling (16, 8, or 3)
- Separate transmit and receive 4-byte FIFOs to reduce CPU interrupt servicing
- Supports DMA data transfer
- Standard FIFO-level and End-of-Transmission interrupts
- Active in all low-power modes
- SYSOSC wakeup via an asynchronous fast clock request when operating in low power modes (supports up to 19200 baud rates when using SYSOSC in FCL mode (1% accuracy))
- Loopback mode operation
- Hardware flow control
- 9-bit multi-drop configuration
- Supported protocols:
  - LIN
  - DALI
  - IrDA
  - ISO7816 Smart card
  - RS485
  - Manchester encoding
  - Idle-Line Multiprocessor

There are two types of UART instances: Extend and Main. The following table compares the features of UART Extend and UART Main.

**Table 24-1. UART Extend and Main Features<sup>(1)</sup>**

Features	UART Extend	UART Main (Low-Power Mode Support)	UART Main
Instances	UART0, UART7	UART1, UART2	UART3-UART6
Hardware flow control	Yes	Yes	Yes
Oversampling options	3, 8, 16	3, 8, 16	3, 8, 16
Separate transmit and receive FIFOs	Yes	Yes	Yes
Active in STOP and STANDBY modes	Yes <sup>(2)</sup>	Yes <sup>(2)</sup>	No
Wake-up with start bit	Yes <sup>(3)</sup>	Yes <sup>(3)</sup>	Yes <sup>(3)</sup>
Digital Glitch filter	Yes	No	No
Analog Glitch filter	Yes	Sometimes	No
9-bit multi-drop configuration	Yes	Yes	Yes
Idle-Line Multiprocessor	Yes	Yes	Yes

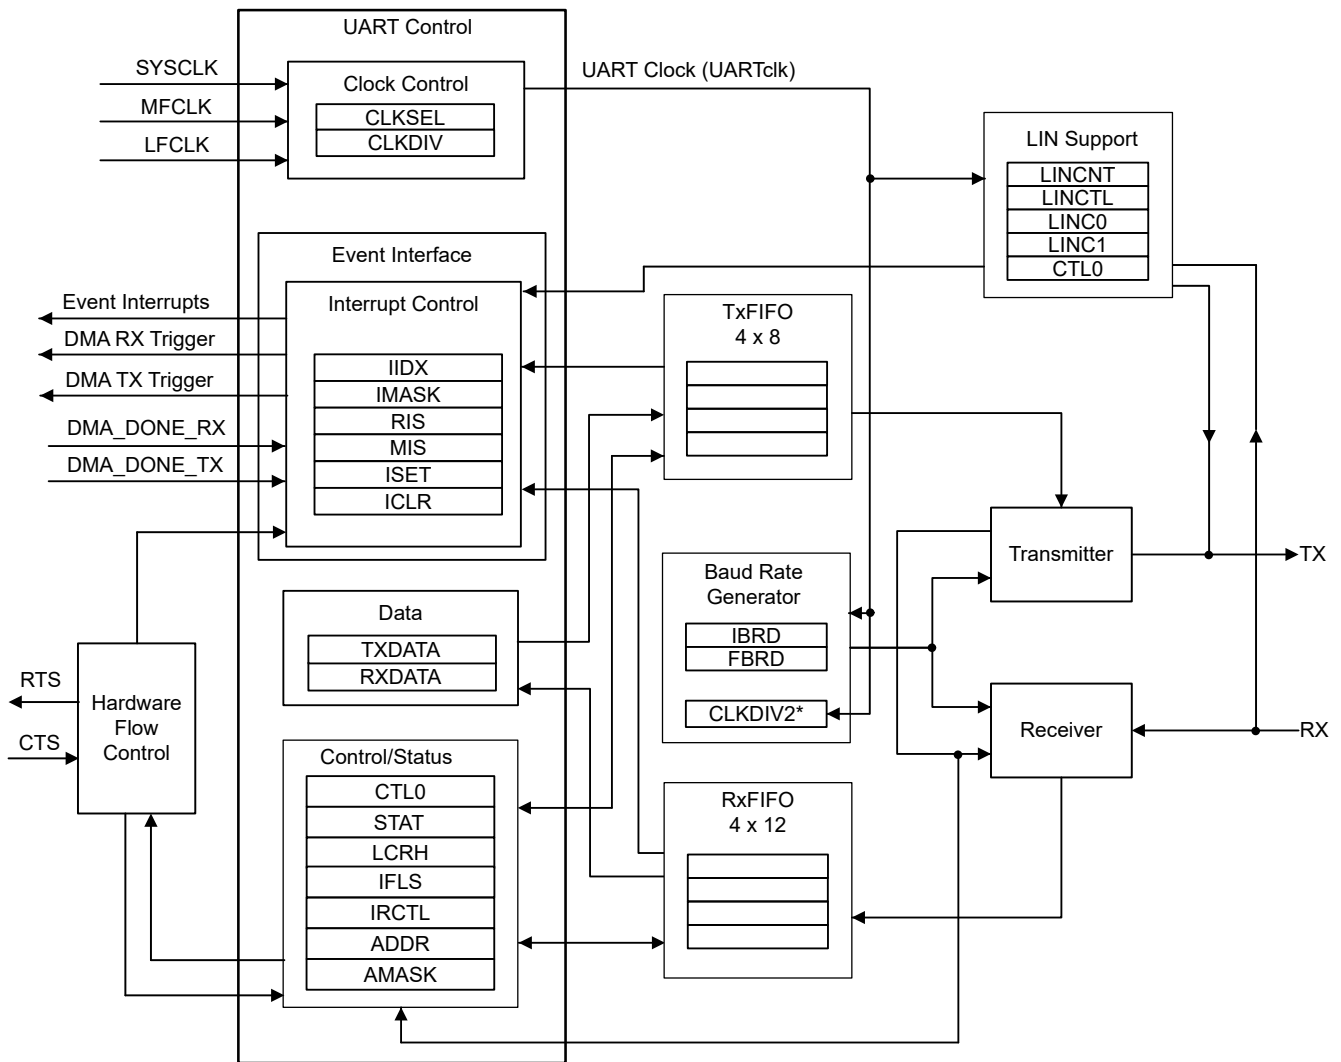

**Table 24-1. UART Extend and Main Features<sup>(1)</sup> (continued)**

Features	UART Extend	UART Main (Low-Power Mode Support)	UART Main
RS-485	Yes	Yes	Yes
Support LIN mode	Yes	-	-
Support DALI	Yes	-	-
Support IrDA	Yes	-	-
Support ISO7816 Smart card	Yes	-	-
Support Manchester code	Yes	-	-

- (1) Refer to the device specific data sheet for configuration and power domain details.,
- (2) UART can be active in all low-power modes including STOP and STANDBY unless it is in power domain 1 (PD1). Refer to the device specific data sheet for configuration and power domain details.
- (3) Only UART instances in power domain 0 (PD0) are active in STOP and STANDBY.

**24.1.3 Functional Block Diagram**

\*CLKDIV2 is for IrDA mode only

**Figure 24-1. UART Functional Block Diagram**

## 24.2 UART Operation

This section describes the operation of the UART peripheral.

### 24.2.1 Clock Control

The UART internal functional clock is selected and divided from the functional clock of the IP.

- Use UARTx.CLKSEL register to select the source of the UART functional clock.
  - BUSSCLK: the current bus clock is selected as the source for UART. The current bus clock depends on power domain. If the UART instance is in power domain 1 (PD1) refer to [MCLK](#), if the UART instance is in power domain 0 (PD0) refer to [ULPCLK](#).
  - MFCLK: MFCLK is selected as the source for UART, refer to [MFCLK](#).
  - LFCLK: LFCLK is selected as the source for UART, refer to [LFCLK](#).
- Use UARTx.CLKDIV register to select the divide ratio of the UART function clock, options are from divide by 1 to 8. For UART Extend, there is a CLKDIV2 register to further divide the UART function clock to support the IrDA mode. When using IrDA mode, CLKDIV2.RATIO must be set to 1h for proper IrDA clocking.

The source clock and frequency depends on the power mode. See the [Clock Module \(CKM\)](#) section for more information. The module is ready to start receiving and transmitting data when the ENABLE bit is set.

### 24.2.2 Signal Descriptions

UART communications require two pins: Receive Data (RX) and Transmit Data (TX):

- RX (Receive Data): RX is the serial data input. Glitch filter and oversampling are available.
- TX (Transmit Data): TX is the serial data output. The TX pin is held high if idling while the module is enabled. Bidirectional protocols like ISO7816 Smart card can use this pin to receive data.

The following pins are available in hardware flow control modes:

- CTS (Clear To Send): This signal blocks data transmission at the end of the current transfer when driven high by external signal
- RTS (Request To Send): This signal indicates the UART is ready to receive data when low.

### 24.2.3 General Architecture and Protocol

UART transmits and receives characters asynchronously. Timing for each character is based on the selected baud-rate.

Control registers should only be programmed when the UART is disabled (ENABLE bit in the UARTx.CTL0 register is cleared). The current transaction gets completed before the UART stops if it is disabled during a transmission or reception. The baud-rate divisor registers (UARTx.IBRD and UARTx.FBRD) can be modified without disabling the UART.

#### 24.2.3.1 Transmit Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration.

The receiver performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO, this is the reason for 12-bit receive FIFO.

UARTx.CTL0.ENABLE bit is used to enable and disable the UART module, UARTx.CTL0.TXE and RXE bits are used to enable the transmit and receive mode, UARTx.LCRH.WLEN bit is used to configure the number of data bits transmitted or received in a frame, UARTx.LCRH.PEN is used to enable parity and UARTx.LCRH.STP2 is used to send two stop bits.

**Figure 24-2. UART Character Frame**

### 24.2.3.2 Bit Sampling

UARTx.CTL0.HSE is set to 0, and 16 oversampling is selected by default. Received bits are expected to have the length of 16 UARTclk cycles. Data is sampled on the 8th UARTclk cycle.

Setting the UARTx.CTL0.HSE bit to 1 selects the 8 oversampling. Received bits are expected to have the length of 8 UARTclk cycles. Data is sampled on the 4th UARTclk cycle.

Setting the UARTx.CTL0.HSE bit to 2 selects the 3 oversampling. Received bits are expected to have the length of 3 UARTclk cycles. Data is sampled on the 2nd UARTclk cycle.

The previous scenarios assume IBRD = 1 and FBRD = 0.

Depending on the application:

- Oversampling by 3 or 8 to achieves higher speeds with UARTclk/8 or UARTclk/3. This reduces the receiver's tolerance to clock deviation.
- Oversampling by 16 to increases the tolerance of the receiver to clock deviations. The maximum speed is limited to UARTclk/16.

16x oversampling mode (HSE = 0)

8x oversampling mode (HSE = 1)

3x oversampling mode (HSE = 2)

Figure 24-3. UART Oversampling mode

### 24.2.3.3 Majority Voting Feature

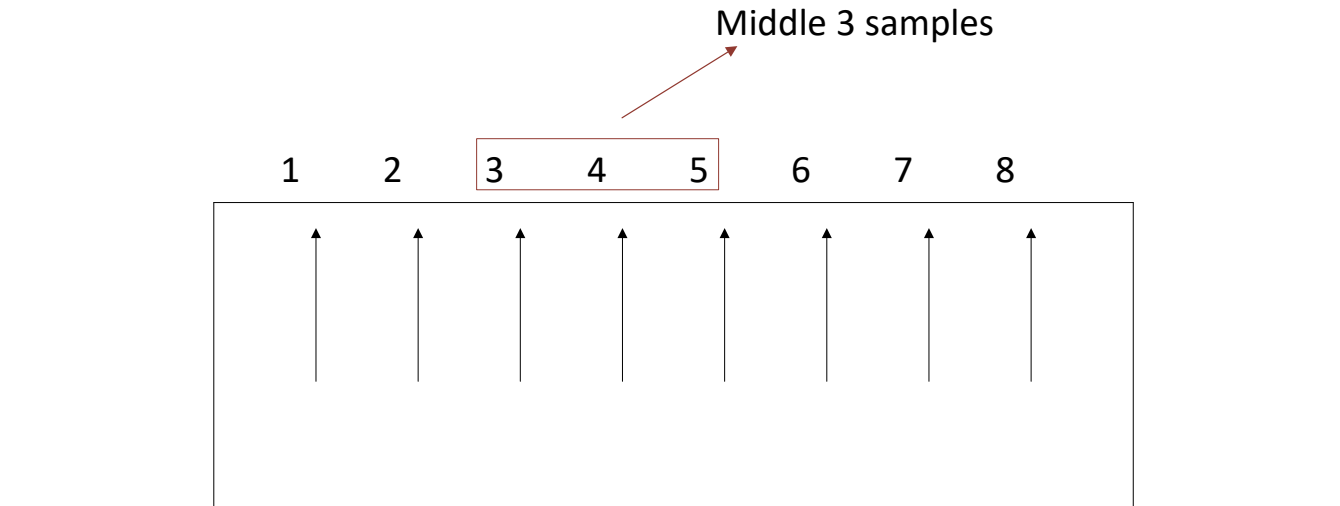

Figure 24-4. Majority voting for 8 oversampling

Majority voting provides noise immunity by sampling each bit 3 times in the center of the bit period.

Majority voting is only for data bits. Select majority voting or single sample using the MAJVOTE control bit in the CTL0 register. Disable majority voting if IrDA or Manchester Encoding modes are used.

**Example 1:** When the UARTx.CTL0.HSE is set to 0 with 16 oversampling; the 7th, 8th and 9th bit are sampled.

**Example 2:** When the UARTx.CTL0.HSE is set to 1 with 8 oversampling; then the 3rd ,4th and 5th bits are sampled and majority value is considered as final value to be sampled. Oversampling with majority voting is only applicable for 16 and 8 oversampling.

In both examples, the majority value is considered as the final value to be sampled.

When the 3 samples used for majority vote are not equal; the RIS.NE (noise error bit) is set. The received data is transferred despite the noise error. The NE bit appends to the received data before storing NE in the RXDATA register at bit position 12.

---

**Note**

Majority voting provides an additional layer of noise immunity on top of hardware noise filters built into the UART module.

---

#### 24.2.3.4 Baud Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer, and a 6-bit fractional part. The number formed by these two values determines the bit sample period. The fractional baud-rate divisor allows the UART to accurately generate standard baud-rates.

The 16-bit integer is loaded into the UART Integer Baud-Rate Divisor UARTx.IBRD register, and the 6-bit fractional part is loaded into the UART Fractional Baud-Rate Divisor UARTx.FBRD register.

The baud-rate divisor can be calculated by using the following formula:

$$\text{BRD} = \text{UART Clock} / (\text{Oversampling} \times \text{Baud rate}) \quad (26)$$

The UART clock is configured by CLKSEL and CLKDIV. Oversampling (by 16, 8 or 3) is selected by the HSE bit in the UARTx.CTL0 register.

- UARTx.IBRD = INT(BRD), integer part of the BRD
- UARTx.FBRD = BRD % 64 , fractional part

---

**Note**

FBRD is ignored when IBRD = 0, and no data gets transferred by the UART. Similarly, when IBRD = 65535 (0xFFFF), then FBRD must not be greater than zero. Exceeding 65535 in FBRD results in an aborted transmission or reception.

---

The following example shows a simple method to calculate IBRD.DIVINT and FBRD.DIVFRAC for a baud rate of 19200 bit/s:

UART Clock = 40 MHz  
Oversampling = 16  
Baudrate = 19200 bit/s

$$\text{BRD} = \frac{\text{UARTclk}}{\text{OVS} \times \text{Baudrate}} = \frac{40\text{MHz}}{16 \times 19200 \text{ bit/s}} = 130.2083333$$

↳ UARTx.IBRD.DIVINT= 130 (=82h)  
 ↳ UARTx.FBRD.DIFRAC  
 = INT((.2083333 x 64) + 0.5)  
 = INT(13.833333)  
 = 13d (= Dh)

Note: The adder '+0.5' ensures rounding to the closest integer value to keep the rounding error as small as possible

**Figure 24-5. Baud Rate Configuration**

The UART.LCRH register must also be written when updating the baud-rate divisor (UARTx.IBRD or UARTx.IFRD). Changes to the baud-rate divisor must be followed by a write to the LCRH register for the changes to take effect.

The contents of the UART.IBRD and UART.FBRD registers are not updated until transmission or reception of the current character is complete.

#### 24.2.3.5 Data Transmission

Data received or transmitted is stored in two FIFOs. The receive FIFO has an extra four bits per character for status information.

##### Transmit data:

If the UART is enabled, and data is written to the FIFO, then a data frame starts transmitting with the parameters indicated in the UARTx.LCRH register. Data continues to be transmitted until there is no data left in the transmit FIFO. The BUSY bit in the UARTx.STAT register is asserted when data is written to the transmit FIFO (if the FIFO is not empty), and remains asserted while data is being transmitted. The BUSY bit is cleared when the transmit FIFO is empty (including the stop bits). The UART can indicate BUSY even though the UART can no longer be enabled. BUSY also is set during the generation of a BREAK signal.

##### Receive data:

When the receiver is idle (the RX signal is continuously 1), and the data input goes low (a start bit has been received), the receive counter begins running. Data is sampled on the different cycle based on the oversampling setting of the HSE bit in UARTx.CTL0 register.

The start bit is recognized if the RX signal is still low after certain number for cycles based on the oversampling setting. Successive data bits are sampled after a valid start bit is detected. The parity bit is checked if parity mode is enabled. Data length and parity are defined in the UART.LCRH register. Oversampling is explained in [Section 24.2.3.2](#).

The valid stop bit is confirmed if the RXD signal is high, otherwise a framing error has occurred. The data is stored in the receive FIFO along with any error bits associated with that word when a full word is received.

#### 24.2.3.6 Error and Status

**For received data:** the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed into the 12-bit wide receive FIFO. The error and status can be retrieved by reading UARTx.RXDATA as showed in [Table 24-2](#).

**Table 24-2. UART Error and Conditions**

Error Condition <sup>(1)</sup>	Bit Field	Description
Framing error	FRMERR	A framing error occurs when a low stop bit is detected. When two stop bits are used, both stop bits are checked for framing error. When a framing error is detected, the FRMERR bit is set.
Parity error	PARERR	A parity error is a mismatch between the number of 1s in a character and the value of the parity bit. When an address bit is included in the character, the address bit is included in the parity calculation. When a parity error is detected, the PARERR bit is set.
Receive overrun	OVRERR	An overrun error occurs when a character is loaded into RXDATA/FIFO before the prior character has been read. When an overrun occurs, the OVRERR bit is set.
Break condition	BRKERR	A break is detected when all received data, parity, and stop bits are 0. When a break condition is detected, the BRKERR bit is set. A break condition can also set the interrupt flag RXINT if the break interrupt enable IMASK.BRKERR bit is set.

(1) Framing errors and break conditions are not set when LIN mode is enabled. This pattern is used to signal a Sync frame for LIN. Break detection is not available for IRDA, Manchester and Dali mode.

UART module flag status can also be checked by reading UARTx.STAT register as showing in [Table 24-3](#).

**Table 24-3. UART Flag Status**

Bit Field	Description
BUSY	This bit is set as soon as the transmit FIFO becomes nonempty (regardless of whether UART is enabled). In IDLE_Line mode the busy signal also stays set during the idle time generation.
RXFE	This bit is set when receive FIFO is empty. If the FIFO is disabled (FEN is 0), the receive holding register is full. If the FIFO is enabled (FEN is 1), the receive FIFO is full.
RXFF	This bit is set when receive FIFO is full. If the FIFO is disabled (FEN is 0), the receive holding register is empty. If the FIFO is enabled (FEN is 1), the receive FIFO is empty.
TXFE	This bit is set when transmit FIFO is empty. If the FIFO is disabled (FEN is 0), the transmit holding register is full. If the FIFO is enabled (FEN is 1), the transmit FIFO is full.
TXFF	This bit is set when transmit FIFO is full. If the FIFO is disabled (FEN is 0), the transmit holding register is empty. If the FIFO is enabled (FEN is 1), the transmit FIFO is empty.
CTS	This bit is set when CTS signal is asserted (low) and cleared when CTS signal is not asserted (high).
IDLE	IDLE mode has been detected in idle line multiprocessor mode. The IDLE bit is used as an address tag for each block of characters. In idle line multiprocessor format, this bit is set when a received character is an address.

### 24.2.3.7 Local Interconnect Network (LIN) Support

This section is only relevant for UART Extend, which supports LIN mode. Refer to the device data sheet for the device-specific configuration of UART extend and UART main.

For supporting local interconnect network (LIN) protocol, the following hardware enhancements are implemented in the UART module:

- 16 bit up-counter (LINCNT) clocked by the UART clock.
- Interrupt capability on counter overflow (CPU\_INT.IMASK.LINOVF).
- 16 bit capture register (LINC0) with two configurable modes
  - Capture of LINCNT value on RXD falling edge. Interrupt capability on capture.
  - Compare of LINCNT with interrupt capability on match.
- 16 bit capture register (LINC1) can be configured:
  - Capture LINCNT value on RXD rising edge. Interrupt capability on capture.

#### LIN transmission

Sending the break signal can be done by setting the BRK bit in UARTx.LCRH register. This bit needs to be set before the data is written into the FIFO or transmit data register TXDATA.

To generate LIN responder signals such as wake signals, the TX pin can be configured by TXD\_OUT and TXD\_CTL\_EN bits in register UARTx.CTL0 to be software controlled. By setting TXD\_CTL\_EN bit to 1, the TX output pin can be controlled by the TXD\_OUT bit if the UART transmit is disabled (CTL0.TXE is cleared).

#### LIN reception

LIN commander issues a break field and sync field at the start of every frame. Hardware must be added such that the LIN responder software driver can reasonably detect BREAK-SYNC and measure the necessary timing parameters to adjust the baud rate or determine an error.

For LIN reception, break field detection and compare mode are needed. To configure these features:

1. Initialize LIN counter to 0 (UARTx.LINCNT = 0)
2. Enable counter compare match mode (UARTx.LINCTL.LINC0\_MATCH = 1)
3. Load UARTx.LINC0 (counter capture 0 register) with counter value corresponding to  $9.5 \times T_{bit}$  (refer to LIN Specification for details on this timing).
4. Enable LINC0 match interrupt (CPU\_INT.IMASK.LINC0 = 1)
5. Setup LIN count control (UARTx.LINCTL):
  - Enable count while low signal on RXD (LINCTL.CNTRXLOW = 1)
  - Enable LIN counter clearing on RXD falling edge (LINCTL.ZERONE = 1)
  - Enable LIN counter (LINCTL.CTRENA = 1)

Optional:

- User can enable the rising edge on UART TX signal interrupt (`CPU_INT.IMASK.RXPE = 1`), when the RXPE interrupt fires, the software can read the LINCTR directly to see the BREAK field timing.
- User can enable the LIN counter overflow interrupt (`CPU_INT.IMASK.LINOVF = 1`) to detect the BREAK field is too long and overflows 16bit counter. The timeout can be calculated as  $t_{\text{Timeout}} = 2^{16} / \text{UART clock}$ .

**Figure 24-6. LIN Break Field Detection**

Sync field validation is required to ensure accuracy of this LIN header part and to calculate the commander baud rate. The synch field consists of the data 0x55 inside a byte field (see [Figure 24-7](#)). After software detects a valid BREAK, it can then set the counter to measure the SYNC field. Both capture registers in LIN counter are used so that software sees fewer interrupts. [Figure 24-7](#) shows the SYNC byte format. The LINCTR should be set to 0 on the start bit falling edge and count continuously. The LINC0 capture or RX falling edge interrupts fire at the falling edges of the RX line. During the interrupt processing, software can measure the individual HIGH-LOW times of the bits themselves using the values in the LINC0 and LINC1 registers to make sure all of the timings are valid.

The following flow describes a possible LIN sync field validation procedure:

1. Initialize LIN counter to 0 (`UARTx.LINCNT = 0`) after detecting a valid break field.
2. Enable interrupt on RX falling edge (`CPU_INT.IMASK.RXNE = 1`)
3. Setup LIN count control (LINCTL):
  - Enable LIN counter capture on raising RX edge (`LINCTL.LINC1CAP = 1`)
  - Enable LIN counter capture on falling RX edge (`LINCTL.LINC0CAP = 1`)
  - Enable LIN counter clearing on RX falling edge (`LINCTL.ZERONE = 1`)
  - Enable LIN counter (`LINCTL.CTRENA = 1`)

**Figure 24-7. LIN SYNC Field Detection**

Actions at each falling edge of the RX line for the sync field as showing below:

1. LIN counter is set to 0 and start counting on the falling RX edge. (`LINCTL.ZERONE = 1`)
2. RX falling edge interrupt trigger (RXNE):
  - Read capture register LINC0 (falling edge) and LINC1 (rising edge) values
  - Verify bit times
3. RX falling edge interrupt trigger (RXNE):
  - Read capture register LINC0 (falling edge) and LINC1 (rising edge) values
  - Verify bit times
4. RX falling edge interrupt trigger (RXNE):
  - Read capture register LINC0 (falling edge) and LINC1 (rising edge) values
  - Verify bit times
5. RX falling edge interrupt trigger (RXNE):

- Read capture register LINC0 (falling edge) and LINC1 (rising edge) values
- Verify bit times
- Calculate the proper baud rate to set. Software must set the baud rate before the start bit of the PID field after sync field.

On each interrupt occurrence, the capture registers must be read and the bit times need to be validated by the application software. In case of a bit time verification error, the sync field analysis process must be aborted and the application software must switch back to break detection.

In case of errors like a breaking commander communication during sync field detection, a timeout interrupt can be generated by enabling the LIN counter overflow (IMASK.LINOVF = 1). When the counter overflows, the interrupt handler can abort the sync field analysis and switch back to break detection. The time the counter overflow interrupt occurs can be calculated as  $t_{\text{Timeout}} = 2^{16} / \text{UART clock}$ .

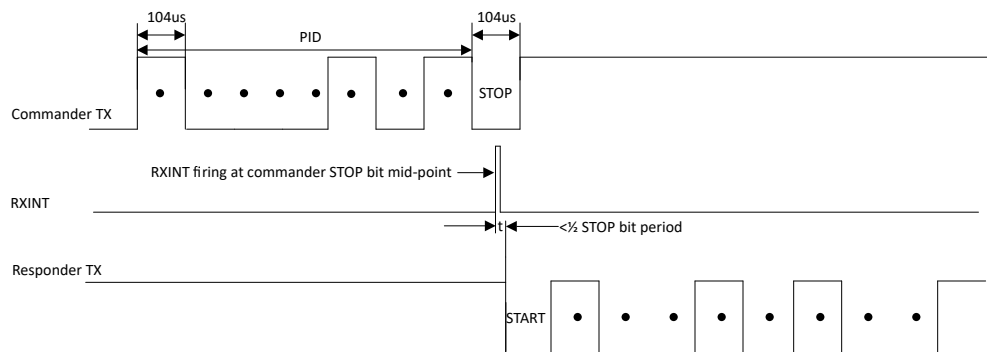

**Note**

The sync field is automatically stored in the RX FIFO and can be misread as the PID. Therefore, flush the RX FIFO after the sync field is received and before the PID is received.

**24.2.3.7.1 LIN Responder Transmission Delay**

The interrupt RXINT for starting the transmission on the responder line always occurs at the mid-point of the commander STOP bit. Depending on the BUSCLK and baud-rate; there might not be enough response space between the STOP bit of commander and START bit of the responder; and the data transmission can start before end of STOP bit.

To overcome this, a delay of half the STOP bit period can be added as response space time to make sure that there is sufficient delay time between STOP and START bit, before start of responder data transmission.

**Figure 24-8. LIN Responder Transmission Delay**

**24.2.3.8 Flow Control**

Hardware flow control provides a mechanism for slow receivers to tell a transmitter to temporarily stop transmitting. This gives the receiver time to catch up, and prevent data loss.

Hardware flow control between two devices is accomplished in UART mode (CTL0.MODE set to 0), by connecting the RTS output to the CTS input on the receiving device, and connecting the RTS output on the receiving device to the CTS input. The RTS output signal is active low, so the CTS input expects a low signal on a send request as shown in [Figure 24-9](#).

**Figure 24-9. Flow Control**

The CTS input controls the transmitter. Data can only be transmitted when the CTS input is set low. When the receiving device's buffer is full, then the receiver's RTS pin is set high. A high RTS pin (connected to CTS of the transmitter) causes transmission to pause.

**For example:** CTS of Device 1 remains low until the preprogrammed RX FIFO level of Device 0 is reached, indicating that the receive FIFO of Device 0 has no space to store additional characters.

The CTSEN and RTSEN bits in the UART.CTL0 register specify the flow control mode as shown in [Table 24-4](#).

**Table 24-4. Flow Control Enable**

CTSEN	RTSEN	Description
1	1	RTS and CTS flow control enabled
1	0	Only CTS flow control enabled
0	1	Only RTS flow control enabled
0	0	Both RTS and CTS flow control disabled

When RTSEN is set to 1, the value of the CTL0.RTS bit is ignored and the RTS output signal is generated by the hardware trigger levels as described below. When RTSEN bit is cleared, the RTS signal output is controlled by the CTL0.RTS bit for SW control.

#### RTS flow control:

The RTS flow control logic is linked to the programmable receive FIFO watermark levels, it can be configured using UARTx.IFLS register. When RTS flow control is enabled, the RTS is asserted (low) until the receive FIFO is filled up to the watermark level. When the receive FIFO watermark level is reached, the RTS signal is de-asserted (high), indicating that there is no more room to receive any more data. The transmission of data is expected to cease after the current character has been transmitted. The RTS signal is reasserted (low) when data has been read out of the receive FIFO so that it is filled to less than the watermark level. If RTS flow control is disabled and the UART is still enabled, then data is received until the receive FIFO is full, or no more data is transmitted to it.

As the RTS signal is de-asserted when the FIFO watermark level is reached by putting the last received character into the FIFO. This means on a back to back transmit another character transfer could already been started by the sender. Therefore, in such cases the watermark level should be set to one level lower to ensure all data can be received and put into the FIFO.

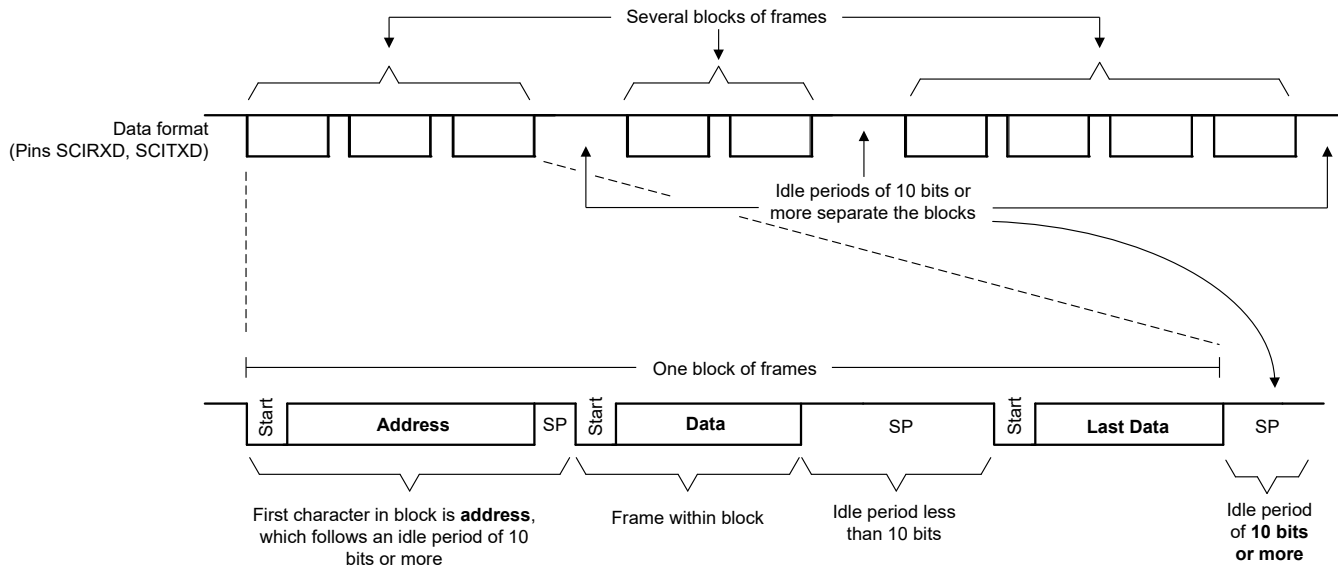

#### CTS flow control:

If CTS flow control is enabled, then the transmitter checks the CTS signal before transmitting the next byte. If the CTS signal is asserted (low), it transmits the byte otherwise transmission does not occur. The data continues to be transmitted while CTS is asserted (low), and the transmit FIFO is not empty. If the transmit FIFO is empty and the CTS signal is asserted (low) no data is transmitted. If the CTS signal is de-asserted (high) and CTS flow control is enabled, then the current character transmission is completed before stopping. If CTS flow control is disabled and the UART is enabled, then the data continues to be transmitted until the transmit FIFO is empty.

#### 24.2.3.9 Idle-Line Multiprocessor

When IDLELINE is set in the CTL0.MODE register bits, the idle-line multiprocessor format is selected. Blocks of data are separated by an idle time on the transmit or receive lines ([Figure 24-10](#)). An idle receive line is

detected when ten or more continuous ones (marks) are received after the one or two stop bits of a character. The baud-rate generator is switched off after reception of an idle line until the next start edge is detected. When an idle line is detected, the IDLE bit in UARTx.STAT is set. In Idle-Line mode the UART receiver operates in no parity mode and the UART word length (UARTx.LCRH.WLEN) must be set to 8bit.

**Figure 24-10. Idle-Line Multiprocessor**

The first character received after an idle period is an address character. The IDLE bit in UARTx.STAT register is used as an address tag for each block of characters.

Address characters are compared against the ADDR register with the AMASK applied. If the received character matches, the address character and all following received characters are transferred into the RXDATA buffer. Interrupts/flags are generated until the next address without a match is received. The IDLE bit in UARTx.STAT register is automatically cleared when the address does match; otherwise the IDLE bit is set until the address is matched.

When there is an ongoing transaction, then a write into SENDIDLE is ignored. Application needs to set SENDIDLE when the UART is idle.

The following procedure sends out an idle frame to indicate an address character followed by associated data:

1. Set SENDIDLE then write the address character to TXDATA. TXDATA must be ready for new data (TXINT interrupt must be 1). This generates an idle period of exactly 11 bits followed by the address character. SENDIDLE is reset automatically when the address character has been transferred (all bits are sent out of shift register).
2. Write desired data characters to TXDATA. TXDATA must be ready for new data (TXINT interrupt must be 1). The data written to TXDATA is transferred to the shift register and transmitted as soon as the shift register is ready for new data.

The idle-line time must not be exceeded between address and data transmission or between data transmissions. Otherwise, the transmitted data is misinterpreted as an address.

BUSY bit in IDLELINE mode:

- TX: BUSY is set during the generation of an IDLELINE signal and while the address and data bytes are sent
- RX: The BUSY signal set during the receive of data and till first 10 idle bits are received.

### 24.2.3.10 9-Bit UART Mode

9-bit mode allows the UART module to communicate in a multidrop mode. The additional bit tells the controller if the transmission is interpreted as an address or data.

9-bit mode is enabled by setting the MODE bit to ADDR9BIT in the UARTx.CTL0 register. In 9-bit UART mode, the parity enable/mode bits are ignored, and the UART word length (UARTx.LCRH.WLEN) must be set to 8 bit.

#### Receive Transaction (9-bit mode):

UART checks for the address qualifier at the location of the parity bit. If set, the received byte is compared with the preprogrammed address in UARTx.ADDR register:

- If the address matches, an interrupt (ADDR\_MATCH) is generated, and the data becomes eligible for reception.
- If the address does not match, then the address and subsequent data bytes are dropped.

The address is set in the UART.ADDR register to match with the received byte. The matching can be extended to a set of addresses using the address mask in the UART.AMASK register. The UART.AMASK is 0xFF by default, so only the set address must match

#### Transmit Transaction (9-bit mode):

All send transactions in 9-bit UART mode are interpreted as either address or data bytes:

- Address bytes (if the 9th bit is set)
- Data bytes (if the 9th bit is cleared)

The 9th bit can be controlled by software. The EPS bit setting of the LCRH register reflects the 9th bit for transmit transactions. To indicate an address byte, the software must set the EPS bit before the byte transmission. To indicate a data byte, the EPS bit must be cleared before the byte transmission. For a complete transmit transaction, the address byte must be transmitted with EPS bit set followed by a data byte burst with EPS bit cleared.

#### 9<sup>th</sup> bit handling:

**Table 24-5. 9th Bit Handling**

PEN	SPS	EPS	9 <sup>th</sup> Bit (Transmitted or Verified)
0	X	X	Not transmitted or verified
1	1	0	0 (= Data)
1	1	1	1 (= Address)

### 24.2.3.11 RS-485 Support

RS-485 can be used effectively over long distances, and in electrically noisy environments. Multiple receivers can be connected to such a network.

An external RS-485 PHY can be controlled using RTS as a direction signal. The signal is automatically set to high when a data transmit is started. It will stay set between bytes if they are sent back to back.

Data exchange sequence as show in [Figure 24-11](#):

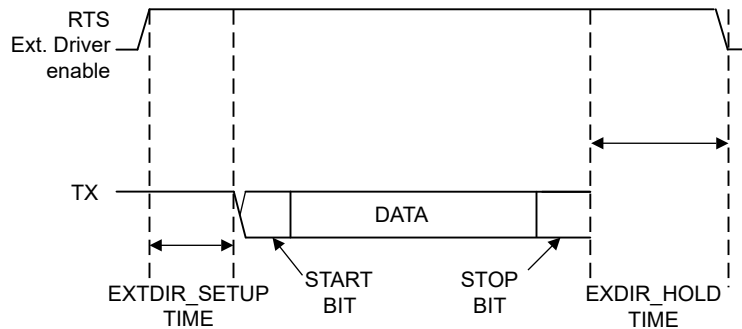

- Wait till an ongoing receive has been finished.
- Activate direction signal to transmit on RTS Pin
- Send data (one or more Bytes)
- Wait till an ongoing receive has been finished.
- Deactivate direction signal to transmit on RTS Pin

**Figure 24-11. RS485 Data Exchange**

Two bit fields in the LCRH register define the setup and hold time of the external driver direction control:

- EXTDIR\_SETUP defines the number of UART clock ticks the signal to control the external driver for the RS485 will be set before the START bit is send. The generated setup time will be between EXTDIR\_SETUP value and EXTDIR\_SETUP + one baud rate cycle
- EXTDIR\_HOLD bits defines the number of UART clock ticks the signal to control the external driver for the RS485 will be reset after the beginning of the stop bit. (If 2 STOP bits are enabled the beginning of the 2nd STOP bit.)

**Figure 24-12. RS485 External Control**

#### 24.2.3.12 DALI Protocol

Digital Addressable Lighting Interface (DALI) is an International Standard (IEC-62386) lighting control system for providing a single interface for lighting controllers.

The UART module supports sending and receiving forward and backward frames. The timing between any forward and backward frame sequence needs to be handled and checked by software.

#### Transmitting a forward or backward frame:

When transmitting a forward frame, a second byte must be written to the buffer before first byte has been shifted out (Otherwise, stop bits are sent like a backward frame). The hardware then sends the two bytes without inserting the stop bits.

#### Receiving data:

The UART module in DALI mode checks the 9th bit after the start bit to detect a forward or backward frame. If this bit has a change of phase (= no stop bit) a forward frame is detected and:

- Address compare is done in hardware based on AMASK
- Address and data are transferred into the RX buffer if there is an address match

Otherwise a backward frame is detected and the data is transferred into the RX Buffer without setting the ADDR\_MATCH interrupt.

The AMASK register can be used as group assignment used during multicast operation with the MSB to indicate if the device is part of a DALI group. To enable the UART in DALI mode to respond on all ADDRESS the AMASK register needs to be cleared.

Figure 24-13. DALI Protocol

The limits for the times T shall be:  $334 \mu\text{s} < T < 500 \mu\text{s}$  according to standard IEC 62386-102. DALI mode requires Manchester encoding to be enabled. When using DALI mode (CTL0.MODE set to DALI), the CTL0 and LCRH register must be set to:

- 8-bit word length (WLEN bit)
- No parity / 2 Stop Bit
- Manchester encoding enabled
- Baud-rate configuration set to match  $2T = 833.33\mu\text{s}$
- DALI mode requires the FIFO to be enabled

#### 24.2.3.13 Manchester Encoding and Decoding

UART can receive and transmit Manchester encoded data. Enable Manchester encoding using the MENC bit in the CTL0 register to generate the IEEE 802.3 compliant waveform. The GPIO control module can invert the signal to generate the G. E. Thomas compliant waveform.

The output signal is generated by XORing the data with UART clock signal. The UART clock needs to be two times faster than the baud-rate. There is an edge at the beginning and the middle of each transmitted data bit. The edge in the middle of the bit is detected to decode the received data.

#### 24.2.3.14 IrDA Encoding and Decoding

The IrDA encoder and decoder are enabled when IREN bit in UARTx.IRCTL register is set. IrDA can only be used with the UART mode (UARTx.CTL0.MODE is 0)

#### IrDA Encoding

The encoder sends a pulse for every zero bit in the transmit bit stream coming from the UART (see [Figure 24-14](#)). The pulse duration is defined by IRTXPL. IRTXPL specifies the number of one-half clock periods of the clock selected by IRTXCLK.

Figure 24-14. IrDA Protocol

### IrDA Decoding

The decoder detects high pulses when IRRXPL = 0, and the decoder detects low pulses when IRRXPL = 1.

A programmable digital filter stage can be enabled by setting UARTx.GFCTL.DGFSEL > 0. The digital glitch filter can be set when IRCTL.IREN is set, so only pulses longer than the programmed filter length are passed, and shorter pulses are discarded. (See the Glitch Suppression chapter on how to set the filter.)

#### 24.2.3.15 ISO7816 Smart Card Support

The UART offers basic support to allow communication with an ISO7816 smart card. The TXD signal is used as a bit clock when the MODE bits of UARTx.CTL0 are configured for smart card. The RXD signal is used as the half-duplex communication line connected to the smart card. Further smart card signals are not supported by the UART.

The clock rate of the UART clock in ISO7816 mode must be within 1MHz to 5MHz when using ISO7816 mode, and the UARTx.LCRH register must be set to:

- 8-bit word length (WLEN bits configured to 0x3)
- Even parity (PEN set and EPS set)
- No stick parity (SPS cleared)

The UART automatically uses 2 stop bits in ISO7816 mode; therefore the STP2 bit of the LCRH register is ignored.

If a parity error is detected during a transmission, then RXD is pulled low during the second stop bit. In that case, the UART aborts the transmission, flushes the transmit FIFO, discards any data it contains, and raises a parity error interrupt. The software can then initiate retransmission of the data.

The UART does not support automatic retransmission on parity errors. If a parity error is detected on transmission, then all further transmit operations are aborted, and software must handle retransmission.

If a parity error occurs, then the receiver drives the line low, and a parity interrupt flag is asserted. The transmitter responds based on the value of this bit.

#### 24.2.3.16 Address Detection

The UARTx.ADDR register sets the address that matches with the receiving address byte. This register is used in conjunction with UARTx.AMASK register. Only bits where the AMASK is set to '1' are considered. This feature is used in DALI, UART 9-Bit, or Idle-Line mode.

Table 24-6. Address Detection

Condition	DALI Mode	Idle Line Mode	9-Bit Mode
Address match	Address and Data is moved to RXDATA	Address and Data is moved to RXDATA	Address and Data is moved to RXDATA
Address mismatch	Address and Data are be dropped	Address and Data are be dropped	Address and Data are be dropped

#### 24.2.3.17 FIFO Operation

The UART has two FIFOs – one for receiving (RXDATA), and one for transmitting (TXDATA). Each FIFO has a depth of 4 entries. Reading RXDATA returns a 12-bit value consisting of 8 data bits and 4 error flags. Writing to TXDATA places 8-bit data bytes into the transmit FIFO.

Both FIFOs are disabled and act as 1-byte-deep holding registers upon leaving reset. The FIFOs are enabled by setting the FEN bit in UARTx.CTL0. FIFO status can be monitored through the UARTx.STAT register and interrupt events.

#### Hardware monitors empty, full and overrun conditions

The UARTx.STAT register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits). The CPU\_INT.RIS register shows overrun status of the receive FIFO through the OVRERR bit. There is no indicator for a transmit FIFO overrun. Writes are lost if data overruns the transmit FIFO. The empty and full flags are set according to the status of the 1-byte-deep holding registers if the FIFOs are disabled. The oldest data is overwritten with the new received data when receiving more data than the FIFO can capture.

The FIFOs generate interrupts at trigger points controlled through the UARTx.IFLS register. Both FIFOs can be individually configured to trigger interrupts at different points. Available configurations for the transmit FIFO are  $\frac{3}{4}$ ,  $\frac{1}{2}$ ,  $\frac{1}{4}$ , and empty. Available configurations for the receive FIFO are  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and full.

**For example:** If the  $\frac{3}{4}$  option is selected for the receive FIFO, the UART generates a receive interrupt after 3 data bytes are received.

Both FIFOs are configured to trigger an interrupt at the  $\frac{1}{2}$  mark directly following a reset. The FIFO integrity is indeterminate under the following conditions:

- After a UART Send Break has been initiated (LCRH.BRK = 1)
- Software disables the UART in the middle of a transmission with data in the FIFO, and then re-enables the UART.

#### 24.2.3.18 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the LBE bit in the UART.CTL0 register. The UART operates with the following behavior when in loopback mode:

- Data transmitted on the TX output is received on the RX input
- Data transmitted on the TX output is not propagated to the TX IO pin
- Data received on the RX IO pin is ignored

Figure 24-15. UART Loopback Mode

#### 24.2.3.19 Glitch Suppression

##### Digital filter

The digital filter is based on the UART functional clock. The DGFSEL bits in the UARTx.GFCTL register can be programmed to provide glitch suppression on the RX line. All signals are delayed internally when glitch suppression is nonzero.

**For Example:** If DGFSEL is set to 0x5, then 5 clocks are added onto the calculation for the expected transaction time. The DGFSEL needs to be configured for the glitch suppression pulse width to be shorter than 1/3 of a normal data pulse to avoid filtering a normal pulse.

##### Analog filter

The analog glitch suppression on the RX line is based on the analog glitch filter, and is selected with the AGFSEL bits in the UARTx.GFCTL register. See the device specific data sheet for selectable glitch filter values. The analog glitch filter is enabled with AGFEN. If AGFEN is not set, then input signals can not be filtered.

#### 24.2.4 Low Power Operation

When the module is instantiated in PD0 domain (always on); UART receive is supported in STOP/STANDBY.

1. Baud rate supported depends on the configured clock. Refer to TRM chapter PMCU section Operating Modes
2. The module can also request for a fast clock by asserting an asynchronous clock request upon detecting a START condition. Upon receiving an asynchronous clock request, SYSCTL provides SYSOSC at 32MHz in M0+ devices; for SYSOSC wakeup time refer to device datasheet
  - a. Asynchronous clock request can be blocked by assert BLOCK\_ASYNC\_CLK\_REQ; in this case, the module will not request for a fast clock and UART data reception will continue at the clock available in that particular power mode

- b. Asynchronous clock is provided to the module as long as `async_clk_req` signal is asserted; typically, the duration of the UART frame and a few extra cycles for loading into FIFO and for FSM transition.
  - c. In case of glitches on the line, it is possible that the UART detects a START condition and requests for a fast clock. In this case, when the receive line is sampled again and an idle condition is observed, FSM moves back to idle and fast clock request is de-asserted and `sysosc` is turned off.
3. For M0+ devices, power mode transition from low power mode to ACTIVE is only upon receiving an enabled interrupt.

### 24.2.5 Reset Considerations

#### Software Reset Considerations

A software reset can be executed by setting `RESETASSERT` with the `KEY` in the `RSTCTL` register. An ongoing transfer is terminated immediately, but leaves the software in an undefined state. Stop transmitting before initiating a software reset.

#### Hardware Reset Considerations

A hardware reset also initializes the IO configuration. This sets the IOs to a high impedance state, and leaves the data lines floating. Pull up or pull down resistors can be required if the application is sensitive to floating data lines.

### 24.2.6 Initialization

Clear the `ENABLE` bit before setup to avoid unpredictable behavior:

Use the following steps to configure and enable the UART:

1. Configure RX and TX pin functions by using the IOMUX registers.
2. Reset the peripheral using `UARTx.RSTCTL` register
3. Enable the power to UART peripheral using the `UARTx.PWREN` register
4. Select the UART function clock source and divide options using `UART.CLKSEL` and `UART.CLKDIV` registers.
5. Disable the UART by clearing the `UART.CTL0.ENABLE` bit.
6. Use the baud-rate equation in [Section 24.2.3.4](#) to calculate the `UARTx.IBRD` and `UARTx.FBRD` registers.
7. Write the integer portion of the BRD to the `UART.IBRD` register.
8. Write the fractional portion of the BRD to the `UART.FBRD` register.
9. Write the desired oversampling and FIFO configuration to the `UART.CTL0` register
10. Write the desired serial parameters to the `UART.LCRH` register.
11. Enable the UART by setting the `UART.CTL0.ENABLE` bit.

### 24.2.7 Interrupt and Events Support

The UART module contains three [event publishers](#) and no [event subscribers](#). One event publisher (`CPU_INT`) manages UART interrupt requests (IRQs) to the CPU subsystem through a [static event route](#). The second and third event publishers (`DMA_TRIG_RX`, `DMA_TRIG_TX`) are used to setup the trigger signaling for the DMA through [DMA event route](#).

The UART events are summarized in [Table 24-7](#).

**Table 24-7. UART Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU interrupt</a>	Publisher	UART	CPU Subsystem	<a href="#">Static route</a>	<code>CPU_INT</code> registers	Fixed interrupt route from UART to CPU

**Table 24-7. UART Events (continued)**

Event	Type	Source	Destination	Route	Configuration	Functionality
DMA trigger	Publisher	UART	DMA	DMA event route	DMA_TRIG_RX registers	Fixed interrupt route from UART to DMA
DMA trigger	Publisher	UART	DMA	DMA event route	DMA_TRIG_TX registers	Fixed interrupt route from UART to DMA

#### 24.2.7.1 CPU Interrupt Event Publisher (CPU\_INT)

The UART module provides 18 interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the UART are:

**Table 24-8. UART CPU Interrupt Event Conditions (CPU\_INT)**

IIDX STAT	Name	Description
0x01	RTOUT	UART receive timeout interrupt, This interrupt is asserted when the receive FIFO is not empty, and no further data is received specified time in the UARTx.IFLS.RXTOSEL bits. More information provided below.
0x02	FRMERR	UART framing error interrupt, see <a href="#">Section 24.2.3.6</a> for more information.
0x03	PARERR	UART parity error interrupt, see <a href="#">Section 24.2.3.6</a> for more information.
0x04	BRKERR	UART break error interrupt, see <a href="#">Section 24.2.3.6</a> for more information.
0x05	OVRERR	UART receive overrun error interrupt, see <a href="#">Section 24.2.3.6</a> for more information.
0x06	RXNE	Falling edge on RX interrupt, this interrupt triggers when there is a falling edge on RX line.
0x07	RXPE	Rising edge on RX interrupt, this interrupt triggers when there is a rising edge on RX line.
0x08	LINC0	LIN capture 0 match interrupt, this interrupt triggers when the defined capture 0 value is reached in LIN counter.
0x09	LINC1	LIN capture 1 match interrupt, this interrupt triggers when the defined capture 1 value is reached in LIN counter.
0x0A	LINOVF	LIN counter overflow interrupt, this interrupt triggers when the 16bit LIN counter overflows.
0x0B	RXINT	UART receive interrupt. More information provided below.
0x0C	TXINT	UART transmit interrupt. More information provided below.
0x0D	EOT	UART end of transmission interrupt, it indicates that the last bit of all transmitted data and status has left the serializer and without any further data in the TX FIFO.
0x0E	ADDR_MATCH	Address match interrupt, used in protocols with address to indicate address match happened.
0x0F	CTS	UART clear to send interrupt, indicate the CTS signal status.
0x10	DMA_DONE_RX	This interrupt is set if the RX DMA channel sends the DONE signal.
0x11	DMA_DONE_TX	This interrupt is set if the TX DMA channel sends the DONE signal.

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers for CPU interrupts.

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received specified time in the IFLS.RXTOSEL bits. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), by reading the interrupt index from IIDX or when a 1 is written to the corresponding bit in the ICLR register.

The receive interrupt (RXINT, 0x0B) changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the RXINT bit is set. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, by reading the interrupt index from IIDX or by writing a 1 to the RXINT bit in ICLR.

- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the RXINT bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, by reading the interrupt index from IIDX or by writing a 1 to the RXINT bit in ICLR.

The transmit interrupt (TXINT, 0x0C) changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the TXINT bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, by reading the interrupt index from IIDX or by writing a 1 to the TXINT bit in ICLR.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the TXINT bit is set. It is cleared by performing a single write to the transmit FIFO, by reading the interrupt index from IIDX or by writing a 1 to the TXINT bit in ICLR.

#### 24.2.7.2 DMA Trigger Publisher (DMA\_TRIG\_RX, DMA\_TRIG\_TX)

DMA\_TRIG\_RX and DMA\_TRIG\_TX registers are used to setup the trigger signaling for the DMA. This can be setup in a flexible way to trigger the DMA for receive or transmit events with the trigger conditions in [Table 24-9](#) and [Table 24-10](#).

DMA\_TRIG\_RX is used for triggering the DMA to do a receive data transfer and DMA\_TRIG\_TX is used for triggering the DMA to do a transmit data transfer.

**Table 24-9. UART DMA Trigger Condition (DMA\_TRIG\_RX)**

IIDX STAT	Name	Description
0x01	RTOUT	UART receive timeout interrupt. This interrupt is asserted when the receive FIFO is not empty, and no further data is received specified time in the UARTx.IFLS.RXTOSEL bits. More information provided below.
0x0B	RXINT	UART receive interrupt. More information provided below.

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received specified time in the IFLS.RXTOSEL bits. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), by reading the interrupt index from IIDX or when a 1 is written to the corresponding bit in the ICLR register.

The receive interrupt (RXINT, 0x0B) changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the RXINT bit is set. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, by reading the interrupt index from IIDX or by writing a 1 to the RXINT bit in ICLR.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the RXINT bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, by reading the interrupt index from IIDX or by writing a 1 to the RXINT bit in ICLR.

**Table 24-10. UART DMA Trigger Condition (DMA\_TRIG\_TX)**

IIDX STAT	Name	Description
0x0C	TXINT	UART transmit interrupt. More information provided below.

The transmit interrupt (TXINT, 0x0C) changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the TXINT bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, by reading the interrupt index from IIDX or by writing a 1 to the TXINT bit in ICLR.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the TXINT bit is set. It is cleared by performing a single write to the transmit FIFO, by reading the interrupt index from IIDX or by writing a 1 to the TXINT bit in ICLR.

The DMA trigger event configuration is managed with the DMA\_TRIG\_RX and DMA\_TRIG\_TX event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers and [Section 7.1.3.2](#) for on how DMA trigger event works.

### 24.2.8 Emulation Modes

The module behavior while the device is in debug mode is controlled by the FREE and SOFT bits in PDBGCTL register.

When the device is in debug mode and set into halt mode below behavior can be configured.

**Table 24-11. Debug Mode Peripheral Behavior**

PDBGCTL.FREE	PDBGCTL.SOFT	Function
1	x	Modules continues operation
0	0	Module stops immediately
0	1	Module stops after the next transfer has been finished

## 24.3 UART Registers

Table 24-12 lists the memory-mapped registers for the UART registers. All register offset addresses not listed in Table 24-12 should be considered as reserved locations and the register contents should not be modified.

**Table 24-12. UART Registers**

Offset	Acronym	Register Name	Group	Section
800h	PWREN	Power enable		<a href="#">Go</a>
804h	RSTCTL	Reset Control		<a href="#">Go</a>
808h	CLKCFG	Peripheral Clock Configuration Register		<a href="#">Go</a>
814h	STAT	Status Register		<a href="#">Go</a>
1000h	CLKDIV	Clock Divider		<a href="#">Go</a>
1008h	CLKSEL	Clock Select for Ultra Low Power peripherals		<a href="#">Go</a>

1	SOFT	R/W	1h	Soft halt boundary control. This function is only available, if <a href="#">FREE</a> is set to 'STOP' 0h = The peripheral will halt immediately, even if the resultant state will result in corruption if the system is restarted 1h = The peripheral blocks the debug freeze until it has reached a boundary where it can resume without corruption
0	FREE	R/W	1h	Free run control 0h = The peripheral freezes functionality while the Core Halted input is asserted and resumes when it is deasserted. 1h = The peripheral ignores the state of the Core Halted input

### 8 IIDX (Offset = 1020h) [Reset = 0000000h]

IIDX is shown in [Figure 24-23](#) and described in [Table 24-21](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 24-23. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 10 RIS (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 24-25](#) and described in [Table 24-23](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

## 12 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 24-27](#) and described in [Table 24-25](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

#### 14 IIDX (Offset = 1050h) [Reset = 0000000h]

IIDX is shown in [Figure 24-29](#) and described in [Table 24-27](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 24-29. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 28 CTL0 (Offset = 1100h) [Reset = 0000038h]

CTL0 is shown in [Figure 24-43](#) and described in [Table 24-41](#).

Return to the [Summary Table](#).

### UART Control Register

The CTL0 register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set. To enable the UART module, the UARTEN bit must be set. If software requires a configuration change in the module, the UARTEN bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping. NOTE: The CTL0 register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the CTL0 register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by clearing bit FEN in the UART control register CTL0.
4. Reprogram the control register.
5. Enable the UART.

19	MSBFIRST	R/W	0h	Most Significant Bit First This bit has effect both on the way protocol byte is transmitted and received. Notes: User needs to match the protocol to the correct value of this bit to send MSb or LSb first. The hardware engine will send the byte entirely based on this bit. 0h = Least significant bit is sent first in the protocol packet 1h = Most significant bit is sent first in the protocol packet
18	MAJVOTE	R/W	0h	Majority Vote Enable When Majority Voting is enabled, the three center bits are used to determine received sample value. In case of error (all 3 bits are not the same), noise error is detected and bits RIS.NERR and register RXDATA.NERR are set. Oversampling of 16 : bits 7, 8, 9 are used Oversampling of 8 : bits 3, 4, 5 are used Disabled : Single sample value (center value) used 0h = Majority voting is disabled 1h = Majority voting is enabled

**Table 24-69. CTL0 Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	FEN	R/W	0h	UART Enable FIFOs 0h = The FIFOs are disabled (Character mode). The FIFOs become 1-byte-deep holding registers. 1h = The transmit and receive FIFO buffers are enabled (FIFO mode).
16-15	HSE	R/W	0h	High-Speed Bit Oversampling Enable <b>NOTE:</b> The bit oversampling influences the UART baud-rate configuration. The state of this bit has no effect on clock generation in ISO7816 smart card mode (the SMART bit is set). 0h = 16x oversampling. 1h = 8x oversampling. 2h = 3x oversampling. IrDA, Manchester and DALI not supported when 3x oversampling is enabled.
14	CTSEN	R/W	0h	Enable Clear To Send 0h = CTS hardware flow control is disabled. 1h = CTS hardware flow control is enabled. Data is only transmitted when the UARTxCTS signal is asserted.
13	RTSEN	R/W	0h	Enable hardware controlled Request to Send 0h = RTS hardware flow control is disabled. 1h = RTS hardware flow control is enabled. Data is only requested (by asserting UARTxRTS) when the receive FIFO has available entries.
12	RTS	R/W	0h	Request to Send If RTSEN is set the RTS output signals is controlled by the hardware logic using the FIFO fill level or TXDATA buffer. If RTSEN is cleared the RTS output is controlled by the RTS bit. The bit is the complement of the UART request to send, RTS modem status output. 0h = Signal not RTS 1h = Signal RTS
11	RESERVED	R/W	0h	
10-8	MODE	R/W	0h	Set the communication mode and protocol used. (Not defined settings uses the default setting: 0) 0h = Normal operation 1h = RS485 mode: UART needs to be IDLE with receiving data for the in EXTDIR_HOLD set time. EXTDIR_SETUP defines the time the RTS line is set to high before sending. When the buffer is empty the RTS line is set low again. A transmit will be delayed as long the UART is receiving data. 2h = The UART operates in IDLE Line Mode 3h = The UART operates in 9 Bit Address mode 4h = ISO7816 Smart Card Support The application must ensure that it sets 8-bit word length (WLEN set to 3h) and even parity (PEN set to 1, EPS set to 1, SPS set to 0) in UARTLCRH when using ISO7816 mode. The value of the STP2 bit in UARTLCRH is ignored and the number of stop bits is forced to 2. 5h = DALI Mode:
7	MENC	R/W	0h	Manchester Encode enable 0h = Disable Manchester Encoding 1h = Enable Manchester Encoding
6	TXD_OUT	R/W	0h	TXD Pin Control Controls the TXD pin when TXD_OUT_EN = 1 and TXE = 0. 0h = TXD pin is low 1h = TXD pin is high
5	TXD_OUT_EN	R/W	1h	TXD Pin Control Enable. When the transmit section of the UART is disabled (TXE = 0), the TXD pin can be controlled by the TXD_OUT bit. 0h = TXD pin can not be controlled by TXD_OUT 1h = TXD pin can be controlled by TXD_OUT

**Table 24-69. CTL0 Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	TXE	R/W	1h	<p>UART Transmit Enable If the UART is disabled in the middle of a transmission, it completes the current character before stopping.</p> <p><b>NOTE:</b> To enable transmission, the UARTEN bit must be set.</p> <p>0h = The transmit section of the UART is disabled. The UARTxTXD pin of the UART can be controlled by the TXD_CTL bit when enabled.</p> <p>1h = The transmit section of the UART is enabled.</p>
3	RXE	R/W	1h	<p>UART Receive Enable If the UART is disabled in the middle of a receive, it completes the current character before stopping. <b>NOTE:</b> To enable reception, the UARTEN bit must be set.</p> <p>0h = The receive section of the UART is disabled.</p> <p>1h = The receive section of the UART is enabled.</p>
2	LBE	R/W	0h	<p>UART Loop Back Enable</p> <p>0h = Normal operation.</p> <p>1h = The UARTxTX path is fed through the UARTxRX path internally.</p>
1	RESERVED	R/W	0h	
0	ENABLE	R/W	0h	<p>UART Module Enable. If the UART is disabled in the middle of transmission or reception, it completes the current character before stopping.</p> <p>If the ENABLE bit is not set, all registers can still be accessed and updated. It is recommended to setup and change the UART operation mode with having the ENABLE bit cleared to avoid unpredictable behavior during the setup or update.</p> <p>If disabled the UART module will not send or receive any data and the logic is held in reset state.</p> <p>0h = Disable Module</p> <p>1h = Enable module</p>

## 29 LCRH (Offset = 1104h) [Reset = 0000000h]

LCRH is shown in [Figure 24-44](#) and described in [Table 24-42](#).

Return to the [Summary Table](#).

UART Line Control Register The LCRH register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register. When updating the baud-rate divisor (UARTIBRD or UARTIFRD), the LCRH register must also be written. The write strobe for the baud-rate divisor registers is tied to the LCRH register.

**Figure 24-44. LCRH**

**Table 24-71. LCRH Field Descriptions**

Bit	Field	Type	Reset	Description
31-26	RESERVED	R/W	0h	
25-21	EXTDIR_HOLD	R/W	0h	Defines the number of UARTclk ticks the signal to control the external driver for the RS485 will be reset after the beginning of the stop bit. (If 2 STOP bits are enabled the beginning of the 2nd STOP bit.) 0h = Smallest value 1Fh = Highest possible value
20-16	EXTDIR_SETUP	R/W	0h	Defines the number of UARTclk ticks the signal to control the external driver for the RS485 will be set before the START bit is send 0h = Smallest value 1Fh = Highest possible value
15-8	RESERVED	R/W	0h	
7	SENDIDLE	R/W	0h	UART send IDLE pattern. When this bit is set an SENDIDLE period of 11 bit times will be sent on the TX line. The bit is cleared by hardware afterward. 0h = Disable Send Idle Pattern 1h = Enable Send Idle Pattern
6	SPS	R/W	0h	UART Stick Parity Select The Stick Parity Select (SPS) bit is used to set either a permanent '1' or a permanent '0' as parity when transmitting or receiving data. Its purpose is to typically indicate the first byte of a package or to mark an address byte, for example in a multi-drop RS-485 network. When bits PEN, EPS, and SPS of UARTLCRH are set, the parity bit is transmitted and checked as a 0. When bits PEN and SPS are set and EPS is cleared, the parity bit is transmitted and checked as a 1. 0h = Disable Stick Parity 1h = Enable Stick Parity

**Table 24-71. LCRH Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5-4	WLEN	R/W	0h	UART Word Length The bits indicate the number of data bits transmitted or received in a frame as follows: 0h = 5 bits (default) 1h = 6 bits 2h = 7 bits 3h = 8 bits
3	STP2	R/W	0h	UART Two Stop Bits Select When in 7816 smart card mode (the SMART bit is set in the UARTCTL register), the number of stop bits is forced to 2. 0h = One stop bit is transmitted at the end of a frame. 1h = Two stop bits are transmitted at the end of a frame. The receive logic checks for two stop bits being received and provide Frame Error if either is invalid.
2	EPS	R/W	0h	UART Even Parity Select This bit has no effect when parity is disabled by the PEN bit. For 9-Bit UART Mode transmissions, this bit controls the address byte and data byte indication (9th bit). 0 = The transferred byte is a data byte 1 = The transferred byte is an address byte 0h = Odd parity is performed, which checks for an odd number of 1s. 1h = Even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits.
1	PEN	R/W	0h	UART Parity Enable 0h = Parity is disabled and no parity bit is added to the data frame. 1h = Parity checking and generation is enabled.
0	BRK	R/W	0h	UART Send Break (for LIN Protocol) 0h = Normal use. 1h = A low level is continually output on the UARTTXD signal, after completing transmission of the current character. For the proper execution of the break command, software must set this bit for at least two frames (character periods).

**30 STAT (Offset = 1108h) [Reset = 0000144h]**

STAT is shown in [Figure 24-45](#) and described in [Table 24-43](#).

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	
9	IDLE	R	0h	IDLE mode has been detected in Idleline-Multiprocessor-Mode. The IDLE bit is used as an address tag for each block of characters. In idle-line multiprocessor format, this bit is set when a received character is an address. 0h = IDLE has not been detected before last received character. (In idle-line multiprocessor mode). 1h = IDLE has been detected before last received character. (In idle-line multiprocessor mode).
8	CTS	R	1h	Clear To Send 0h = The CTS signal is not asserted (high). 1h = The CTS signal is asserted (low).
7	TXFF	R	0h	UART Transmit FIFO Full The meaning of this bit depends on the state of the FEN bit in the CTL0 register. 0h = The transmitter is not full. 1h = If the FIFO is disabled (FEN is 0), the transmit holding register is full. If the FIFO is enabled (FEN is 1), the transmit FIFO is full.
6	TXFE	R	1h	UART Transmit FIFO Empty The meaning of this bit depends on the state of the FEN bit in the CTL0 register. 0h = The transmitter has data to transmit. 1h = If the FIFO is disabled (FEN is 0), the transmit holding register is empty. If the FIFO is enabled (FEN is 1), the transmit FIFO is empty.
5-4	RESERVED	R	0h	
3	RXFF	R	0h	UART Receive FIFO Full The meaning of this bit depends on the state of the FEN bit in the CTL0 register. 0h = The receiver can receive data. 1h = If the FIFO is disabled (FEN is 0), the receive holding register is full. If the FIFO is enabled (FEN is 1), the receive FIFO is full.

**Table 24-73. STAT Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	RXFE	R	1h	UART Receive FIFO Empty The meaning of this bit depends on the state of the FEN bit in the CTL0 register. 0h = The receiver is not empty. 1h = If the FIFO is disabled (FEN is 0), the receive holding register is empty. If the FIFO is enabled (FEN is 1), the receive FIFO is empty.
1	RESERVED	R	0h	
0	BUSY	R	0h	UART Busy This bit is set as soon as the transmit FIFO or TXDATA register becomes nonempty (regardless of whether UART is enabled) or if a receive data is currently ongoing (after the start edge have been detected until a complete byte, including all stop bits, has been received by the shift register). In IDLE_Line mode the Busy signal also stays set during the idle time generation. 0h = The UART is not busy. 1h = The UART is busy transmitting data. This bit remains set until the complete byte, including all stop bits, has been sent/received from/into the shift register.

### 31 IFLS (Offset = 110Ch) [Reset = 0000022h]

IFLS is shown in [Figure 24-46](#) and described in [Table 24-44](#).

Return to the [Summary Table](#).

The IFLS register is the interrupt FIFO level select register. You can use this register to define the levels at which the TX, RX and timeout interrupt flags are triggered. The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered when the receive FIFO is filled with two or more characters. Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**Table 24-85. RXDATA Field Descriptions**

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	
12	NERR	R	0h	Noise Error. Writing to this bit has no effect. The flag is cleared by writing 1 to the NERR bit in the UART EVENT ICLR register. 0h = No noise error occurred 1h = Noise error occurred during majority voting
11	OVRERR	R	0h	UART Receive Overrun Error Writing to this bit has no effect. The flag is cleared by writing 1 to the OVRERR bit in the UART EVENT ICLR register. In case of a receive FIFO overflow, the FIFO contents remain valid because no further data is written when the FIFO is full. Only the contents of the shift register are overwritten. The CPU must read the data to empty the FIFO. 0h = No data has been lost due to a receive overrun. 1h = New data was received but could not be stored, because the previous data was not read (resulting in data loss).
10	BRKERR	R	0h	UART Break Error Writing to this bit has no effect. The flag is cleared by writing 1 to the BRKERR bit in the UART EVENT ICLR register. This error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received. 0h = No break condition has occurred 1h = A break condition has been detected, indicating that the receive data input was held low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).
9	PARERR	R	0h	UART Parity Error Writing to this bit has no effect. The flag is cleared by writing 1 to the PARERR bit in the UART EVENT ICLR register. 0h = No parity error has occurred 1h = The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.

**Table 24-85. RXDATA Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	FRMERR	R	0h	UART Framing Error Writing to this bit has no effect. The flag is cleared by writing 1 to the FRMERR bit in the UART EVENT ICLR register. This error is associated with the character at the top of the FIFO. 0h = No framing error has occurred 1h = The received character does not have a valid stop bit sequence, which is one or two stop bits depending on the UARTLCRH.STP2 setting (a valid stop bit is 1).
7-0	DATA	R	0h	Received Data. When read, this field contains the data that was received by the UART. 0h = Smallest value FFh = Highest possible value

**37 LINCNT (Offset = 1130h) [Reset = 0000000h]**

The I<sup>2</sup>C module provides a standardized serial interface to transfer data between MSP devices and other external I<sup>2</sup>C devices (such as a sensors, memory, or DACs).

<b>25.1 I<sup>2</sup>C Overview</b> .....	<b>1428</b>
<b>25.2 I<sup>2</sup>C Operation</b> .....	<b>1430</b>
<b>25.3 I2C Registers</b> .....	<b>1454</b>

## 25.1 I<sup>2</sup>C Overview

The I<sup>2</sup>C module provides a standardized serial interface to transfer data between MSP devices and other external I<sup>2</sup>C devices (such as a sensors, memory, or DACs).

### 25.1.1 Purpose of the Peripheral

The I<sup>2</sup>C peripheral provides bidirectional data transfer through a two-wire serial bus consisting of a data (SDA) and clock (SCL) line. The I<sup>2</sup>C bus is widely used to interface with devices such as battery management ICs, sensors, other MCUs and so on. This I<sup>2</sup>C peripheral provides the ability to both transmit to and receive from other I<sup>2</sup>C devices on the bus.

### 25.1.2 Features

The controller includes I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a controller or a target with 7-bit addressing.
- Support four I<sup>2</sup>C modes
  - Controller transmit
  - Controller receive
  - Target transmit
  - Target receive
- Supported transmission speeds:
  - Standard-mode (Sm) with a bit rate up to 100 kbps
  - Fast-mode (Fm) with a bit rate up to 400 kbps
  - Fast-mode Plus (Fm+) with a bit rate up to 1 Mbps
- Independent 8-byte FIFOs for reception and transmission
- Dual target address capability
- Glitch suppression
- Independent controller and target interrupt generation
- Controller operation with arbitration, clock synchronization, multiple controller support
- Hardware support for SMBus and PMBus
  - Clock low timeout detection and interrupt
  - Quick command capability
- Hardware support for DMA with separate channels for transmit and receive

### 25.1.3 Functional Block Diagram

Figure 25-1. I2C Functional Block Diagram

#### 25.1.4 Environment and External Connections

The I<sup>2</sup>C mode supports any target or controller I<sup>2</sup>C-compatible device. Figure 25-2 shows an example of an I<sup>2</sup>C bus. Each I<sup>2</sup>C peripheral instance is comprised of both controller and target functions where the target can be addressed with 2 independent user defined addresses. A device connected to the I<sup>2</sup>C bus can be considered as the controller or the target when performing data transfers. A controller initiates a data transfer and generates the clock signal SCL. Any device addressed by a controller is considered a target.

I<sup>2</sup>C data is communicated using the serial data (SDA) pin and the serial clock (SCL) pin. Both SDA and SCL are open-drain bidirectional and must be connected to a positive supply voltage using a pullup resistor.

Figure 25-2. Bus Connection Diagram

## 25.2 I<sup>2</sup>C Operation

This section describes the operation of the I<sup>2</sup>C peripheral.

### 25.2.1 Clock Control

#### 25.2.1.1 Clock Select and I<sup>2</sup>C Speed

Standard, Fast, and Fast Plus modes are selected using a value in the I<sup>2</sup>C Controller Timer Period (I2CMTPR) register that results in a maximum SCL frequency of:

- 100kbps for Standard mode
- 400kbps for Fast mode
- 1Mbps for Fast mode Plus

The I<sup>2</sup>C frequency I2C\_FREQ is determined by the I2C\_CLK frequency and bit fields TPR , SCL\_LP , and SCL\_HP where:

- I2C\_CLK is the functional clock frequency to the I<sup>2</sup>C module. Note that the I<sup>2</sup>C internal functional clock is first divided from the source clock:
  - Use I2Cx.CLKSEL register to select the source of the I<sup>2</sup>C functional clock
    - BUSSCLK: the current bus clock is selected as the source for I<sup>2</sup>C. The current bus clock depends on power domain. If the I<sup>2</sup>C instance is in power domain 1 (PD1) refer to MCLK, if the I<sup>2</sup>C instance is in power domain 0 (PD0) refer to ULPCLK.
    - MFCLK: MFCLK is selected as the source for I<sup>2</sup>C, refer to MFCLK.
  - Use I2Cx.CLKDIV register to select divide ratio of I<sup>2</sup>C function clock, options are from divide by 1 to 8.
- SCL\_LP is the low phase of SCL (which must be fixed at 6)
- SCL\_HP is the high phase of SCL (which must be fixed at 4)
- TPR is the programmed value of the TPR bits in the I2Cx.MTPR register. This value is determined by replacing the known variables in the equation below and solving for TPR

The I<sup>2</sup>C frequency is calculated as follows:

$$I2C\_FREQ = I2C\_CLK / ((1+TPR) \times (SCL\_LP + SCL\_HP)) \quad (27)$$

For example, if the I<sup>2</sup>C functional clock frequency is 32MHz and target SCL frequency is 400kHz:

I2C\_CLK = 32MHz

I2C\_FREQ = 400kHz

SCL\_LP = 6 , SCL\_HP = 4

$TPR = (I2C\_CLK / (I2C\_FREQ * (4 + 6))) - 1$

TPR = 7 (0x07)

**Table 25-1. Examples of Controller Clock Setting for Typical Clock Configurations**

Functional Clock	TPR Bits Standard Mode 100kHz SCL	TPR Bits Fast Mode 400kHz SCL	TPR Bits Fast Mode Plus 1000kHz SCL
4MHz	0x03	-	-
8MHz	0x07	0x01	-
20MHz	0x13	0x04	0x01
32MHz	0x1F	0x07	0x02 <sup>(1)</sup>
40MHz	0x27	0x09	0x03

(1) With 32MHz functional clock, TPR = 0x01 generates 1.6MHz SCL frequency, and TPR = 0x02 generates 1.067MHz SCL frequency.

I<sup>2</sup>C functional clock must be greater than or equal to 20 times the SCL frequency,  $I2C\_CLK \geq 20 \times I2C\_FREQ$ .

The following minimum functional clock frequencies are required when running certain I<sup>2</sup>C clock speeds:

- I2C\_CLK ≥ 2MHz when working with I<sup>2</sup>C speed 0 to 100kHz
- I2C\_CLK ≥ 8MHz when working with I<sup>2</sup>C speed 100 to 400kHz
- I2C\_CLK ≥ 20MHz when working with I<sup>2</sup>C speed 400 kHz to 1MHz

### 25.2.1.2 Clock Startup

The selected clock source is always available and the frequency depends on the power mode, for more information refer to the PMU/Clock section. After enabling the I<sup>2</sup>C module by setting the I2C.PWREN.ENABLE bit, the module is ready to start receiving and transmitting data.

### 25.2.2 Signal Descriptions

The I<sup>2</sup>C bus consists of a clock signal and a data signal. The clock signal can be generated either internally (during controller operation) or externally (during target operation).

**Table 25-2. I<sup>2</sup>C signal descriptions**

Device Pin	Function
I2Cx_SCL	I <sup>2</sup> C clock signal
I2Cx_SDA	I <sup>2</sup> C data signal

### 25.2.3 General Architecture

#### 25.2.3.1 I<sup>2</sup>C Bus Functional Overview

The I<sup>2</sup>C bus uses only two signals: SDA and SCL. SDA is the bidirectional serial data line and SCL is the bidirectional serial clock line. The bus is considered idle when both lines are in high state and no transfer is ongoing.

Every transaction on the I<sup>2</sup>C bus is 9-bits long, consisting of 8 data bits and 1 acknowledge bit. A transfer is defined as the time between a valid START and STOP condition—as described in [Figure 25-3](#). The number of bytes per transfer is unrestricted; however, each data byte must be followed by an acknowledge bit and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state, this process is commonly known as clock stretching. The data transfer continues when the receiver releases the clock SCL.

**Figure 25-3. Module Data Transfer**

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is low (see [Figure 25-4](#)), otherwise START or STOP conditions are generated.

**Figure 25-4. Data Change Period**

### 25.2.3.2 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A high-to-low transition on the SDA line while the SCL is high is defined as a START condition, and a low-to-high transition on the SDA line while SCL is high is defined as a STOP condition. START and STOP conditions are always generated by the controller. The bus is considered busy after a START condition and free after a STOP condition.

**Figure 25-5. START and STOP Conditions**

The STOP bit determines if the transaction stops at the end of the data cycle or continues on to a repeated START condition.

To generate a single transaction, the I<sup>2</sup>C controller target address I2Cx.MSA.SADDR register is written with the desired address, the I2Cx.MSA.DIR bit should be set to 1 to start a receive operation and 0 to start a transmit operation, and the control register (I2Cx.MCTR) is written with ACK = X (0 or 1), STOP = 1, START = 1, and RUN = 1 to perform the operation and generate a STOP at the end. When the operation is completed (or aborted due an error) the interrupt flags are set. When the I<sup>2</sup>C module operates in Controller receiver mode, the ACK bit is normally (in case of no error) set causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the target transmitter. For more information on I<sup>2</sup>C controller mode configuration please refer to [Section 25.2.4.1](#)

When operating in target mode, the START and STOP bits in the CPU\_INT.RIS register indicate detection of start and stop conditions on the bus and the CPU\_INT.IMASK can be configured to allow START and STOP to be promoted to controller interrupts (when interrupts are enabled). For more information on I<sup>2</sup>C target mode configuration please refer to [Section 25.2.4.2](#)

Bus Status Flags:

- BUSBSY is set when a START is detected on the bus and sequentially cleared when a STOP condition is detected on the bus. It is also cleared after a clock timeout I2Cx.MSR.CLKTO is set once both SCL and SDA are pulled to high.
- BUSY is also set after a START/RESTART, and cleared after I2Cx.MCTR.MBLEN bytes of data is transferred. It is also cleared after data is NACK 'd or a STOP.
- IDLE is set when the Controller I<sup>2</sup>C State machine is in the IDLE state indicating no ongoing transfer.

### 25.2.3.3 Data Format with 7-Bit Address

Data transfers follow the format shown in [Figure 25-6](#). After the START condition, a target address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (this bit is only as Controller mode, DIR bit in the I2Cx.MSA register). If the I2Cx.MSA.DIR bit is 0, it indicates a transmit operation (send), and if it is set to 1, it indicates a request to receive data (receive). A data transfer is always terminated by a STOP condition generated by the controller; however, a controller can initiate communications with another device on the bus by generating a repeated START condition and addressing another target without first generating a STOP condition, see section [Repeated Start](#). Various combinations of receive/transmit formats are then possible within a single transfer. The ninth bit is the Acknowledge bit, which is described in [Section 25.2.3.4](#).

**Figure 25-6. Data Format with 7-Bit Address**

With the I2Cx.SCTR.GENCALL bit the I<sup>2</sup>C module can be enabled to respond on a General Call on the I<sup>2</sup>C bus. The General Call is identified by address of 0x00 and the R/W bit set to 0. The General Call interrupt can be enabled with the CPU\_INT.IMASK.GENCALL bit.

**25.2.3.4 Acknowledge**

All bus transactions have a required acknowledge clock cycle that is generated by the controller. During the acknowledge cycle, the transmitter (which can be the controller or target) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The acknowledge cycle must comply with the data validity requirements.

When a target receiver does not acknowledge the target address, SDA must be left high by the target so that the controller can generate a STOP condition and abort the current transfer or generate a repeated START condition to start a new transfer. If the controller device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the target. Because the controller controls the number of bytes in the transfer, it signals the end of data to the target transmitter by not generating an acknowledge on the last data byte. The target transmitter must then release SDA to allow the controller to generate the STOP or a repeated START condition.

A target can generate ACK/NACK manually or automatically. When I2Cx.SACKCTL.ACKOEN=0, the target will send automatic ACK. Note that due to the FIFO, the device will receive and ACK all bytes automatically until the RX FIFO is full. Setting SACKCTL.ACKOEN =1 enables manual ACK. Manual ACK override can be used to evaluate each received byte or to slow down the communication when automatic FIFO reception is not desired. When manual ACK override operation is enabled, the I<sup>2</sup>C target module's clock is pulled low after the last data bit until this SACKCTL.ACKOVAL is written with the indicated response. The reception of new data is indicated by the SRXDONE interrupt flag.

If the controller receives a NACK while transmitting data the NACK and MTXDONE bit will be set in the RIS registers. If there is still data in the FIFO the TXEMPTY bit will not be set to inform software that a TX FIFO flush may be required.

**25.2.3.5 Repeated Start**

The direction of data flow on SDA can be changed by the controller, without first stopping a transfer, by issuing a repeated START condition. This is called a RESTART, see data format in Figure 25-7. After a RESTART is issued, the target address is again sent out with the new data direction specified by the R/W bit.

**Figure 25-7. Data Format with Repeated Start**

A repeated start sequence for a Controller transmit is as follows:

1. When the device is in the idle state, the Controller writes the target address to the I2Cx.MSA register and configures the DIR bit for the desired transfer type.
2. Data is written to the I2Cx.MTXDATA register.
3. When the BUSY bit in the MSR register is 0, the BURSTRUN and START bit in the I2Cx.MCTR register need to be set to initiate a transfer.
4. Wait till the BUSY bit in the I2Cx.MSR register gets 0.

5. The Controller does not generate a STOP condition but instead writes another target address to the I2Cx.MSA register and then sets the BURSTRUN and START bit again with a write operation to initiate the repeated START.

A repeated start sequence for a Controller receive is similar:

1. When the device is in idle, the Controller writes the target address to the I2Cx.MSA register and configures the DIR bit for the desired transfer type.
2. When the BUSY bit in the I2Cx.MSR register is 0, the BURSTRUN and START bit in the I2Cx.MCTR register need to be set to initiate a transfer.
3. The controller reads data from the I2Cx.MRXDATA register.
4. Wait till the BUSY bit in the I2Cx.MSR register gets 0.
5. The Controller does not generate a STOP condition but instead writes another target address to the I2Cx.MSA register and then sets the BURSTRUN and START bit again with a write operation to initiate the repeated START.

#### 25.2.3.6 SCL Clock Low Timeout

The I<sup>2</sup>C target can extend the transaction by pulling the clock low to slow down communication. The I<sup>2</sup>C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the I2CTIMEOUT\_CTL register. The CNTL value programmed in the I2CTIMEOUT\_CTL.TCNTLA register has to be greater than 0x01 to enable the timeout feature. Please note that the low timeout configuration needs to be set only during initialization and not during active state.

The application can program the eight most significant bits of the counter to reflect the acceptable cumulative low period in a transaction. Each count is equal to a timeout period of  $(1 + \text{TPR}) \times 12$  of functional clocks FCLK where the TPR is the programmable timer period. The Timeout counter A counts for the entire time SCL is held Low continuously. When SCL is high, the Timeout counter A is reloaded with the value in the I2CTIMEOUT\_CTL.TCNTLA register bit, and begins counting down from this value at the falling edge of SCL.

The BUSSCLK clock generated for the timeout counter keeps running irrespective of the programmed I<sup>2</sup>C speed even if SCL is held low on the bus.

The I<sup>2</sup>C clock low timeout period is calculated as follows:

- Cumulative clock low period = Timeout counter \* One timeout period
- One timeout period = BUSSCLK period \*  $(1 + \text{TPR}) \times 12$
- Timeout counter = I2CTIMEOUT\_CTL.TCNTLA register (this register contains the upper 8-bits of a 12-bit counter value, the lower 4-bits are set to 0)

As an example, if the BUSSCLK: clock is 20MHz and the I<sup>2</sup>C module was operating at 100kHz speed, the TPR would be equal to 19. See [Section 25.2.1.1](#) on how TPR is calculated. One timeout period is equal to  $(1 / 20\text{MHz}) \times (1 + 19) \times 12$  or 12 $\mu$ s. Programming the I2CTIMEOUT\_CTL.TCNTLA register to 0xDA would translate to the value 0xDA0, because the lower 4-bits are set to 0x0. This would translate to a decimal value of 3488 clocks or a cumulative clock low period of  $3488 \times 12\mu\text{s}$ , or 41.856ms at 100kHz.

The TIMEOUTA bit in the I<sup>2</sup>C Controller Raw Interrupt Status (RIS) register is set when the clock timeout period is reached, allowing the controller to start corrective action to resolve the remote target state. In addition, the BUSBSY bit in the I<sup>2</sup>C Controller Status MSR register is set. This bit is cleared after I<sup>2</sup>C goes to idle or during the I<sup>2</sup>C controller reset. The status of the raw SDA and SCL signals are readable by software through the SDA and SCL bits in the I<sup>2</sup>C Controller Bus Monitor MBMON register to help determine the state of the remote target.

In the event of a timeout condition, application software must choose how it intends to attempt bus recovery. If a timeout is detected before the end of a transfer (receive or transmit), software should flush the FIFO before initializing the next transfer. The clock low timeout is needed for SMBus and PMBus implementation.

---

**Note**

The Controller clock low timeout counter register I2CTIMEOUT\_CNT.TCNTA counts for the entire time SCL is held low continuously. When SCL is high, the counter is reloaded with the value in the I2CTIMEOUT\_CTL.TCNTLA register, and begins counting down from this value at the falling edge of SCL.

---

**25.2.3.7 Clock Stretching**

In controller mode, the clock stretching can be disabled if no targets on the bus support it, allowing the controller to reach the maximum speed on the bus. Otherwise the clock can be slowed by a target keeping the clock low or due to the clock status detection delay within the I<sup>2</sup>C module.

To ensure compliance to the I<sup>2</sup>C specification, clock stretching needs to be enabled. Clock stretching is activated when either the RX FIFO full or TX FIFO empty is set. Clock stretching support can be enabled or disabled by configuring the CLKSTRETCH bit in I2Cx.MCR register.

In the target mode, clock stretching is enabled by default and it is signaled by the TREQ and RREQ bits of the I<sup>2</sup>C target status register I2Cx.SSR.

- When TREQ bit is set, it indicates the I<sup>2</sup>C controller has been addressed as a target transmitter and is using clock stretching to delay the controller until data has been written to the STXDATA FIFO (Target TX FIFO is empty).
  - When RREQ bit is set, it indicates the I<sup>2</sup>C controller has outstanding receive data from the I2C controller and is using clock stretching to delay the controller until the data has been read from the SRXDATA FIFO (Target RX FIFO is full).
- 

**Note**

Clock stretching in target mode may be used together with an [asynchronous fast clock request](#) to support bringing the device into a suspended low power mode state upon detection of an I2C start bit, enabling the I2C module to support 100kHz (standard mode) or 400kHz (fast mode) operation out of low power modes where the bus clock speed is below the minimum oversampling speed required by the respective mode. Refer to the [clock selection and I<sup>2</sup>C speed section](#) for the minimum frequency requirements. When clock stretching is used together with an asynchronous fast clock request, it is possible for the device to wait in STOP or STANDBY mode when the I<sup>2</sup>C is idle, and when an I<sup>2</sup>C bus edge is seen, the fast clock request will requests SYSOSC at base frequency and the bus clock will switch to SYSOSC at base frequency, allowing the I<sup>2</sup>C module to process the bus transaction and wake the processor if an interrupt is generated.

---

**25.2.3.8 Dual Address**

The I<sup>2</sup>C target interface supports dual address capability for the target. An additional programmable I<sup>2</sup>C Target Own Address Register I2CX.SOAR is provided and can be matched if enabled. When dual address disabled (I2Cx.SOAR2.OAR2EN=0), the I<sup>2</sup>C target provides an ACK on the bus if the address matches the OAR field in the I2Cx.SOAR register. In dual address mode (I2Cx.SOAR2.OAR2EN=1), the I<sup>2</sup>C target provides an ACK on the bus if either the OAR field in the I2Cx.SOAR register or the OAR2 field in the I2Cx.SOAR2 register is matched.

The OAR2SEL bit in the I2Cx.SSR register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, it indicates either the primary address match or no OAR2 address match.

**25.2.3.9 Arbitration**

A controller can start a transfer only if the bus is idle. It's possible for two or more controllers to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is high (see [Figure 25-8](#)). The first controller transmitter that generates a logic high is overruled by the opposing controller generating a logic low and the losing controller releases the bus until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both controllers are trying to address the same device, arbitration continues on to the comparison of data bits.

**Figure 25-8. Arbitration Procedure Between Two Controller Transmitters**

When an arbitration lost is detected the I2Cx.MSR.ARBLSST flag is set. It will be reset by the hardware with the next STOP condition detected on the bus. Additionally the ARBLOST flags in CPU\_INT.RIS registers are set.

If arbitration is lost when the I<sup>2</sup>C controller has initiated a transfer, the application should execute the following steps to correctly handle the arbitration loss:

- Flush TX FIFO
- Clear and mask the TX Empty interrupt by the TXEMPTY bit through the IMASK and ICLR register.
- Once the bus is IDLE, the TXFIFO can be filled and enabled, the TXEMPTY bit can be unmasked and a new transaction can be initiated.

### 25.2.3.10 Multiple Controller Mode

When operating in a multiple controller system, the I2Cx.MCR.MMST bit must be set.

During the arbitration procedure, the clocks from the different controllers must be synchronized. A device that first generates a low period on SCL overrules the other devices, forcing them to start their own low periods. SCL is then held low by the device with the longest low period. The other devices must wait for SCL to be released before starting their high periods

In multiple-controller configuration, the clock synchronization (Figure 25-9) during the arbitration is enabled, the SCL high time counts once the SCL line has been detected high. If not enabled the high time counts as soon as the SCL line has been set high by the I<sup>2</sup>C controller which allows the I<sup>2</sup>C to reach the maximum speed by the I2Cx.MTPR register specified speed.

**Figure 25-9. Clock Synchronization**

### 25.2.3.11 Glitch Suppression

The I<sup>2</sup>C module supports glitch suppression on the SCL and SDA lines to meet the 50ns glitch suppression as specified in the I<sup>2</sup>C specification.

## Analog glitch Filter

By default, an analog glitch filter is enabled and configured to suppress spikes with a pulse width up to 50ns. I<sup>2</sup>C spec advises to suppress noise spikes of less than 50ns. The user can disable this filter by clear the I2Cx.GFCTL.AGFEN bit and the suppression pulse width can also be configured by using I2Cx.GFCTL.AGFEN. The analog glitch filter can only be used to wake up the I<sup>2</sup>C in low-power mode.

## Digital glitch Filter

The DGFSEL bits in the I2Cx.GFCTL register can be programmed to provide glitch suppression on the SCL and SDA lines and assure proper signal values. The glitch suppression value is in terms of the I<sup>2</sup>C functional clocks. All signals are delayed internally when glitch suppression is nonzero. For example, if DGFSEL bit is set to 0x7, 31 clocks should be added onto the calculation for the expected transaction time, for more information please see register description. Digital glitch filter can't be used to wake up the I2C from low-power mode.

**Table 25-3. Glitch Suppression Filter**

	Analog Glitch Filter	Digital Glitch Filter
<b>Default</b>	Default enabled with 50ns	Default bypassed
<b>Pulse width of suppressed spikes</b>	Configurable 5ns, 10ns, 25ns, 50ns	Programmable I <sup>2</sup> C clock cycle 1, 2, 3, 4, 8, 16, 31
<b>Benefits</b>	Available without needing clock	<ul style="list-style-type: none"> <li>• Programmable length to provide extra filtering</li> <li>• Stable filtering length</li> </ul>
<b>Limitation</b>	Variation with temperature, voltage, process	Does not work in low-power mode wakeup when there is no sufficient clock .  Enabled only after 3 clock cycles after start of I <sup>2</sup> C packet

### Note

The glitch filter configuration within the register I2Cx.GFCTL should only be modified while the I<sup>2</sup>C module for controller and target is not enabled.

### 25.2.3.12 FIFO operation

The receive data register I2Cx.MRXDATA (for controller mode) and I2Cx.SRXDATA (for target mode) are user accessible and contains the current character to be read from the RX FIFO stack. The last received character from the receive shift register will be push to the end of the FIFO Stack.

The transmit data register I2Cx.MTXDATA (for controller mode) and I2Cx.STXDATA (for target mode) are user accessible and holds the data last written data to the TX FIFO. The TX FIFO contains the data waiting to be moved into the transmit shift register and transmitted on SDA.

FIFOs are available for the controller and target receive and transmit. Each FIFO entry has a width of 8 bits and should be accessed in byte mode. Each FIFO has a programmable threshold point (configured by RXTRIG and TXTRIG bits in the I2Cx.MFIFOCTL register for controller mode and I2Cx.SFIFOCTL register for target mode) which indicates when the FIFO service interrupt should be generated. Additionally, a FIFO receive full and transmit empty interrupt can be enabled in the interrupt mask (IMASK) registers for the controller and target.

The content of the FIFO can be flushed with setting TXFLUSH or RXFLUSH bit to 1 in the I2Cx.FIFOCTL registers. When the I<sup>2</sup>C gets reset the content of the FIFO needs also to be cleared. FIFO clear should only be executed while the I<sup>2</sup>C is in IDLE mode. Before triggering the flush the FIFO interrupts should be disabled and after flush has completed the interrupt flags needs to be checked.

### 25.2.3.12.1 Flushing Stale Tx Data in Target Mode

In most use cases, the user does not want to transmit leftover data of the I<sup>2</sup>C peripheral Tx FIFO from previous frame in the next frame. The device provides a mechanism for the software to choose whether to flush stale data or not.

A status bit SSR.STALE\_TXFIFO represents whether the data present inside I<sup>2</sup>C peripheral TX FIFO is stale or not. A control bit SCTR.TXWAIT\_STALE\_TXFIFO is used to enable modified empty indication to target logic - indicate empty to I<sup>2</sup>C peripheral FSM when Tx FIFO is empty OR stale data present in Tx FIFO. The SCTR.TXEMPTY\_ON\_TREQ control bit allows the RIS.STXEMPTY interrupt to be used to indicate the TREQ condition, the condition when SCL is being stretched waiting for transmit data from the I<sup>2</sup>C peripheral.

#### Recommended Sequence

1. When SCTR.TXWAIT\_STALE\_TXFIFO is set, on STOP, restart, or timeout, I<sup>2</sup>C peripheral FSM gets an empty indication even though stale data is present inside I<sup>2</sup>C peripheral Tx FIFO.
2. I<sup>2</sup>C module doesn't immediately generate an TX FIFO empty interrupt/DMA request. Instead, waits till the controller on the I<sup>2</sup>C bus attempts to read data from the I<sup>2</sup>C peripheral, at which point the I<sup>2</sup>C peripheral clock stretches.
3. The I<sup>2</sup>C peripheral issues the clock stretch (TREQ) interrupt to the CPU when SCTR.TXEMPTY\_ON\_TREQ is set.
4. Application software in the ISR checks for a SSR.STALE\_TXFIFO flag and flushes the TX FIFO using SFIFOCTL.TXFLUSH, which also clears the status of SSR.STALE\_TXFIFO.

### 25.2.3.13 Loopback mode

The I<sup>2</sup>C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the LPBK bit in the I<sup>2</sup>C controller configuration I2Cx.MCR register. In loopback mode, the SDA and SCL signals from the controller part of the I<sup>2</sup>C are tied to the SDA and SCL signals of the target part of the I<sup>2</sup>C module to allow internal testing of the device without having to connect the I/Os. The SWUEN bit should be set to 0 for internal loopback to work correctly.

Figure 25-10. I2C Internal Loopback mode

### 25.2.3.14 Burst Mode

A burst mode is provided for the controller module which allows a sequence of data transfers using the DMA or software to handle the data in the FIFO. The burst mode is enabled by setting the MBLN bits in the controller control register I2Cx.MCTR to a value greater than '1'. This sets the number of bytes transferred by a burst. A copy of this value is automatically written to the MBCNT bits in the I<sup>2</sup>C controller status register I2Cx.MSR to be used as a down-counter during the burst transfer.

The bytes written to the I<sup>2</sup>C FIFO are transferred to the RX FIFO or TX FIFO depending on whether a transmit or receive is being executed. If data is not acknowledged (NACK) during a BURST and the STOP bit is set in the I2Cx.MCTR register, the transfer terminates. If the STOP bit is not set, software must issue a STOP or repeated START when a NACK interrupt is asserted. In the case of a NACK, the MBCNT bits in the I2Cx.MSR register can be used to determine the amount of data that was transferred prior to the burst termination. If the address is not acknowledged (NACK) during a transfer, then a STOP is issued.

### 25.2.3.15 DMA Operation

The I<sup>2</sup>C provides an interface to the DMA controller with two channels. The DMA operation of the I<sup>2</sup>C is enabled through the I<sup>2</sup>C event register and DMA peripheral registers. When the DMA functionality is enabled, the I<sup>2</sup>C asserts a DMA request on the selected channel when the associated FIFO can transfer or receive data.

For more information about I<sup>2</sup>C event and DMA, please refer to [Interrupt and Events Support](#) and [DMA Trigger Publisher](#) sections.

---

#### Note

Per DMA Channel only one event source should be enabled by the IMASK register at the same time. The DMA transaction descriptor needs to match for the selected trigger with a correct setup for either Controller or Target and RX or TX configuration. The DMA trigger should only be changed when no I<sup>2</sup>C transfer is ongoing and a previous triggered DMA transfer has been finished. If this cannot be ensured the I<sup>2</sup>C and DMA channel should be disabled first.

---

### 25.2.3.16 Low-Power Operation

I<sup>2</sup>C supports operation in low-power modes.

Supported power mode for controller mode:

- Controller mode with 100kHz speed can operate in RUN, SLEEP, STOP power mode
- Controller mode with 400kHz speed can operate in RUN, SLEEP power mode
- Controller mode with 1MHz speed can operate in RUN, SLEEP power mode

In low-power mode, the I<sup>2</sup>C interface automatically request the clock selected in the CLKSEL control register after detecting a start condition. The clock request is released after detection of the STOP condition.

Supported power mode and wakeup mode for target mode:

- Target mode with 100kHz speed can operate in RUN, SLEEP, STOP power mode
- Target mode with 100kHz speed can't operate in STANDBY mode because the maximum bus clock in STANDBY mode is 32kHz and support for 100kHz speed requires a minimum 400kHz clock. However, in STANDBY mode the I2C target can still wakeup from the start bit and perform the Asynchronous Fast Clock Requests to temporarily get a 24MHz/32MHz clock to receive the data until the FIFO or address match interrupt wakes up the CPU.
- Target mode with 400kHz speed in RUN, SLEEP power mode
- Target mode with 1MHz speed in RUN, SLEEP power mode

## 25.2.4 Protocol Descriptions

### 25.2.4.1 I<sup>2</sup>C Controller Mode

As showing in the [function block diagram](#) section, I<sup>2</sup>C peripheral has a set of specific controller registers to configure the operation when the module is configured as an I<sup>2</sup>C target mode.

### 25.2.4.1.1 Controller Configuration

The I<sup>2</sup>C Controller Control register I2Cx.MCTR and I<sup>2</sup>C Controller Target Address register I2Cx.MSA are used for controlling controller transmit and receive modes. The following settings can be modified to control the different transactions.

- Length indicates the number of bytes for the transaction and is configured by I2Cx.MCTR.MBLEN bit
- Direction (transmit or receive) is configured by I2Cx.MSA.DIR bit
- ACK generation is configured by I2Cx.MCTR.MBLEN bit
- STOP condition generation is configured by I2Cx.MCTR.STOP bit
- START or repeated START condition generation is configured by I2Cx.MCTR.START bit
- RUN enable the controller transaction and is configured by I2Cx.MCTR.BURSTRUN bit

### Controller send data transactions

**Table 25-4. Start Transmit From Idle Mode**

Length	Direction	ACK	STOP	START	RUN	Format	Comments
n (n>0)	0	x	0 or 1	1	1	START+ADDR+R/W+ DATA*n+(STOP)	Sending of STOP depends on STOP bit

**Table 25-5. Continue Transmit When Last Transmission Finished Without stop**

Length	Direction	ACK	STOP	START	RUN	Format	Comments
n (n>0)	0	x	0 or 1	0	1	DATA*n+ (ACK/NACK)+ (STOP)	Sending of STOP depends on STOP bit

If there is a NACK response from the target, the controller will automatically send out a stop to finish the transmit. The Controller will be unable to send a RESTART after ADDR or DATA NACK.

### Controller receive data transactions

**Table 25-6. Start Receive From Idle Mode**

Length	Direction	ACK	STOP	START	RUN	Format	Comments
n (n>0)	1	0 or 1	0 or 1	1	1	START+ADDR +R/ W+DATA *n +(ACK/NACK) +(STOP)	The last data ACK or NACK depend on ACK bit; additional sending of STOP depends on STOP bit

**Table 25-7. Continue Receive When Last Receive Finished Without STOP or NACK**

Length	Direction	ACK	STOP	START	RUN	Format	Comments
n (n>0)	1	0 or 1	0 or 1	0	1	DATA*n+ (ACK/NACK) + (STOP)	The last data followed by ACK or NACK depend on ACK bit; additional sending of STOP depends on STOP bit

This configuration is not allowed if last transaction ended with NACK, as NACK can only be followed by STOP or RESTART. The ACK and STOP bits should not be set to 1 at the same time, as the target needs to be informed to release bus lines before sending out STOP.

### Controller repeated start transactions

If last transmit or receive finished without stop, a repeat start can be generated to initiate a new transaction

**Table 25-8. Repeated Start Transmit**

Length	Direction	ACK	STOP	START	RUN	Format	Comments
n (n>0)	0	0 or 1	0 or 1	1	1	Restart+ADDR +R/ W+DATA*n +(STOP)	Additional sending of STOP depends on STOP bit

If there is a NACK response from the target, the controller will automatically send out a stop to finish the transmit. The Controller will be unable to send a RESTART after ADDR or DATA NACK.

**Table 25-9. Repeated Start Receive**

Length	Direction	ACK	STOP	START	RUN	Format	Comments
n (n>0)	1	0 or 1	0 or 1	1	1	Restart+ADDR +R/ W+DATA*n +(ACK/NACK) +(STOP)	The last data followed by ACK or NACK depend on ACK bit; additional sending of STOP depends on STOP bit

The ACK and STOP bits should not be set to 1 at the same time, as the target needs to be informed to release bus lines before sending out STOP.

### Controller send STOP only transaction

**Table 25-10. Send STOP only**

Length	Direction	ACK	STOP	START	RUN	Format	Comments
n (n>=0)	X	X	1	0	1	STOP	STOP command

It is only allowed to send after previous transaction success finished, and STOP can't be sent without a NACK to the target if controller is currently in receive mode

### Controller Quick Command transaction

The Quick command could only be sent at the transaction beginning, not following other transactions (without stop) or repeat start.

**Table 25-11. Controller quick command**

Length	Direction	ACK	STOP	START	RUN	Format	Comments
0	0/1	X	1	1	1	START+ADDR +R/ W+STOP	Quick command

#### 25.2.4.1.2 Controller Mode Operation

#### I<sup>2</sup>C Controller Initialization

1. Configure SDA and SCL pin functions and select as input by using the IOMUX registers.
2. Reset the peripheral using I2Cx.RSTCTL register
3. Enable the power to peripheral using I2Cx.PWREN register
4. Select and configure the I<sup>2</sup>C clock using the CLKCTL and CLKDIV registers.
5. Set the desired SCL clock speed of by writing the TPR bit in I2Cx.MTPR register with the correct value. For more information about how to calculate TPR value refer to [Clock Control](#) section. For example, with 20MHz I<sup>2</sup>C clock to achieve 100 kbps SCL clock, TPR value will be 19 (0x13) so we can write the I2Cx.MTPR register with the value of 0x13.
6. Specify the target address and mode (transmit or receive) for the next operation by writing the I2Cx.MSA register. For example, if the target address is 0x3B (MSA.SADDR[7:1] = 0x3B) and we want to transmit (MSA.DIR[0] = 0x0) data then we can write the I2Cx.MSA register with a value of 0x76.
7. If controller is transmitting data, user can place data (byte) to be transmitted in the data register by writing the I2Cx.MTXDATA register with the desired data.

8. Configure the controller transmit or receive mode by writing the I2Cx.MCTR register. For more information on how to configure I2Cx.MCTR register for different mode please see [Controller Configuration](#) section above.
9. Enable desired interrupts and/or DMA event by using CPU\_INT.IMASK register.

## I<sup>2</sup>C Controller Status

User can read the I2Cx.MSR register to check the current state of the I<sup>2</sup>C controller.

**Table 25-12. Controller Status Register**

Bit Field	Description
BUSY	I2C controller busy. The BUSY bit is set during an ongoing transaction.
ERR	I2C error. The error can be from the target address not being acknowledged or the transmit data not being acknowledged.
ADRACK	Acknowledge address. This bit is set if the transmitted address was not acknowledged.
DATACK	Acknowledge data. This bit is set if the transmitted data was not acknowledged.
ARBLST	Arbitration lost. This bit is set if controller lost arbitration.
IDLE	I2C bus idle.
BUSBSY	I2C bus busy. The bit changes based on the START and STOP conditions, set if bus is busy.
CLKTO	Clock timeout error. This bit is set if the clock timeout error has occurred.
MBCNT	I2C controller transaction count. This field contains the current countdown value of the transaction.

## I<sup>2</sup>C Controller Receiver Mode

For controller to start receive data out of the idle mode, user needs to set the START bit in I2Cx.MCTR register to generate the start condition. Then the controller automatically sends the START condition followed by the target address as soon as it detects that the bus is free. All the process below should be followed.

I2Cx.MSA.DIR is set to 1 to enable receive mode, I2Cx.MCTR.START is set to generate start condition, I2Cx.MBLEN can be programmed to indicate the number of bytes (n) for the receive operation. I2Cx.MCTR.ACK and I2Cx.MCTR.STOP bit can be set or clear based on user configuration. I2Cx.MCTR.BURSTRUN is set to start the operation. The packet format is START+ADDR+R+DATA\*n +(ACK/NACK) + (STOP). The last data ACK/NACK depend on ACK bit, additional sending of STOP depends on STOP bit.

After last byte is received, the MRXDONE (0x01) interrupt in CPU\_INT.IIDX register is set to indicate that controller receive transaction is completed. User can use the MRXFIFOTRG (0x03) interrupt in CPU\_INT.IIDX register to read the data from the receive FIFO. This interrupt will trigger when controller RX FIFO contains >= defined bytes, the trigger level can be defined by using RXTRIG bit in I2Cx.MFIFOCTL register. The flow chart of controller receiver mode is shown in [Figure 25-11](#).

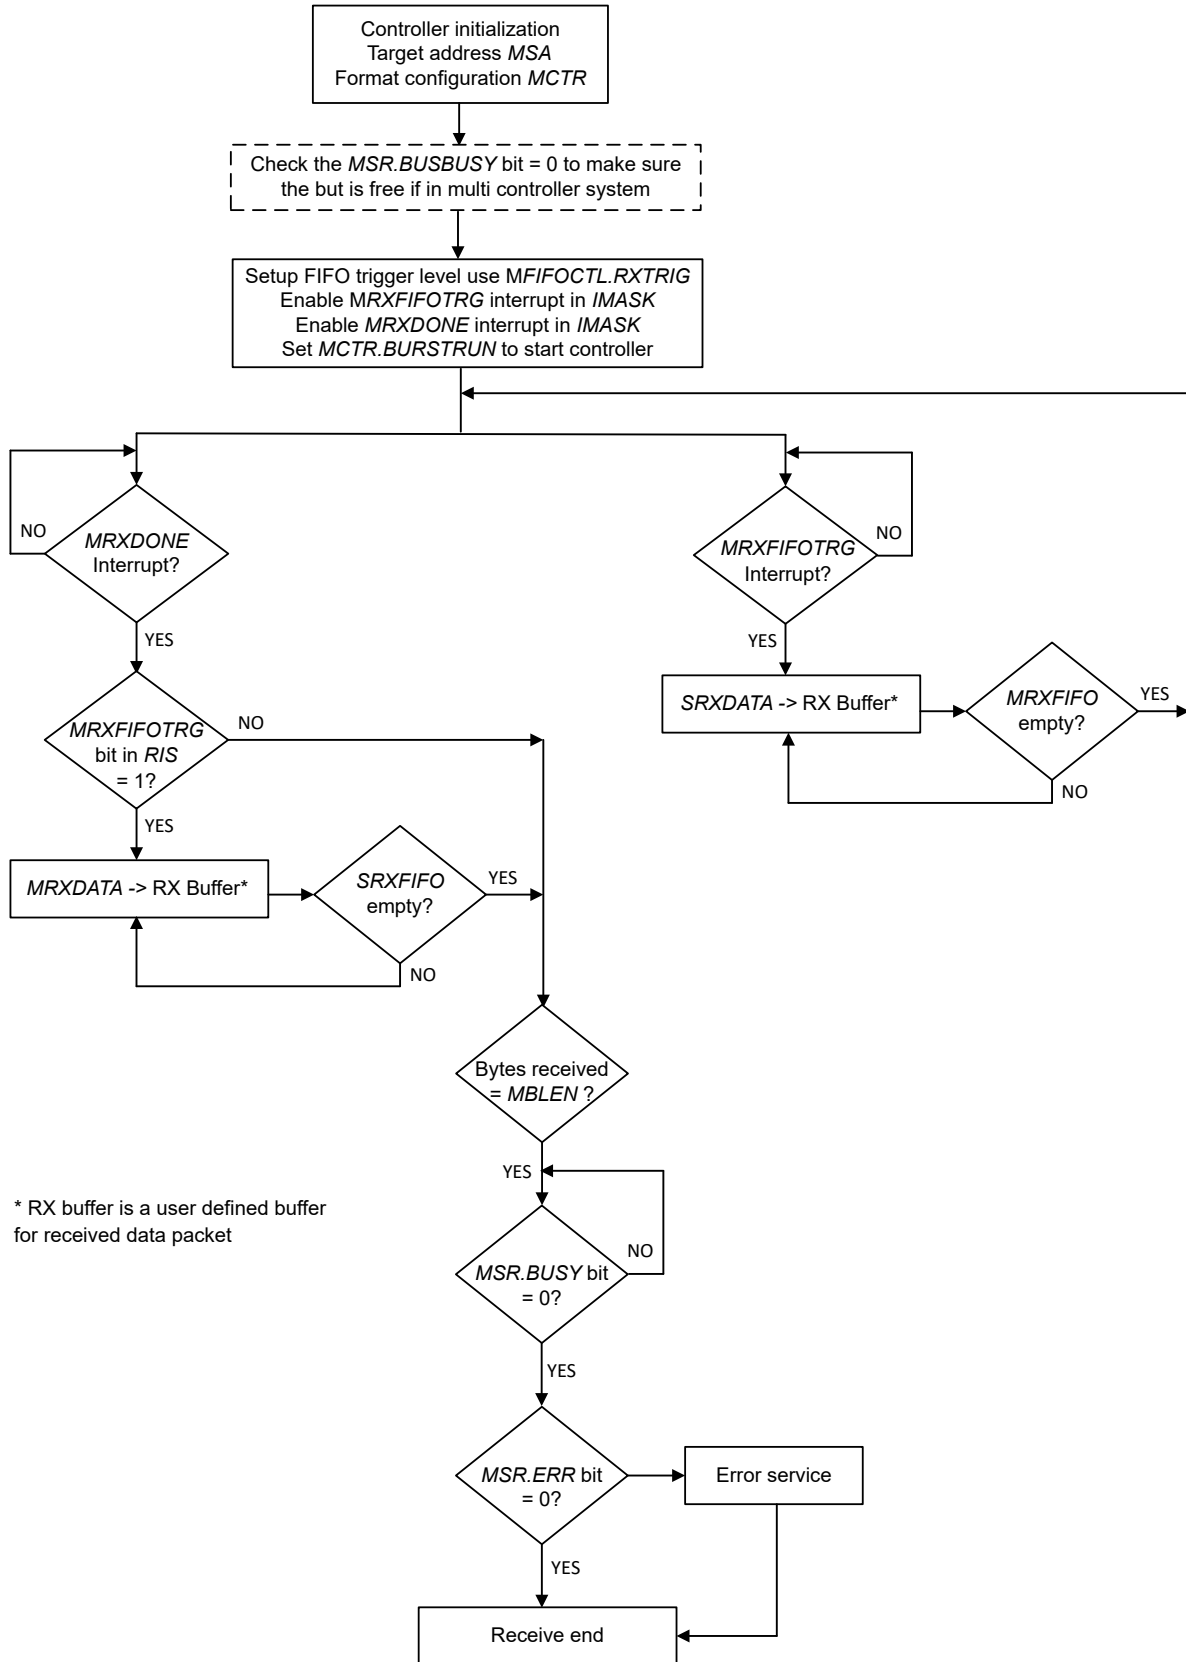

Figure 25-11. Controller Receiver Mode

## I<sup>2</sup>C Controller transmitter Mode

For controller, to start transmit data out of the idle mode, user need to set the START bit in I2Cx.MCTR register to generate the start condition. Then the controller automatically sends the START condition followed by the target address as soon as it detects that the bus is free. The data written into the MTXFIFO is transmitted if arbitration is not lost during transmission of the target address. All the process below should be followed.

I2Cx.MSA.DIR is cleared to enable transmit mode, I2Cx.MCTR.START is set to generate start condition, I2Cx.MBLEN can be programmed to indicate the number of bytes (n) for the transmit operation.

I2Cx.MCTR.STOP bit can be set or clear based on user configuration. I2Cx.MCTR.BURSTRUN is set to start the operation. The packet format is START+ADDR+W+DATA\*n + (STOP), sending of STOP depends on STOP bit.

After last byte is transmitted, the MTXDONE (0x02) interrupt in CPU\_INT.IIDX register is set to indicate that controller transmit transaction is completed. User can also set use the MTXEMPTY (0x06) interrupt in CPU\_INT.IIDX register to see if the MTXFIFO is empty and ready to load more data. This interrupt will trigger if all data in the transmit FIFO have been shifted out. The flow chart of controller transmitter mode is shown in [Figure 25-12](#).

Figure 25-12. Controller Transmitter Mode

25.2.4.1.3 Read On TX Empty

A typical I<sup>2</sup>C transaction must first write the target to set the register number and then do a repeated start + read to read the data value. However, the RD\_ON\_EMPTY flag enables two I<sup>2</sup>C transactions with a single setup of the I<sup>2</sup>C controller. Software can set up both the write and read together, with the limitation being that the "write" phase cannot send more data than fits in the TX FIFO. This is an optimization to minimize interrupt processing requirements. The high-level set up is:

1. Set MSA to target address with RECEIVE = 1 (RD\_ON\_TXEMPTY must have I2C\_MSR\_DIR\_RECEIVE set)
2. Set MCTR to initiate the transaction, in this use case write:

- MBLLEN= size for READ phase
- RD\_ON\_TXEMPTY
- ACK\_DISABLE (NACK+STOP after read)
- STOP\_ENABLE
- START\_ENABLE
- BURST\_ENABLE

The expected behavior with this set up is that the controller does a START, transmits all TXFIFO data, and when TXFIFO is empty automatically does a repeated START, reads the MBLLEN bytes, then STOP.

#### 25.2.4.2 I<sup>2</sup>C Target Mode

##### 25.2.4.2.1 Target Mode Operation

#### I<sup>2</sup>C Target Initialization

1. Configure SDA and SCL pin functions and select as input by using the IOMUX registers.
2. Reset the peripheral using I2Cx.RSTCTL register
3. Enable the power to peripheral using I2Cx.PWREN register
4. Select and configure the I<sup>2</sup>C clock using the CLKCTL and CLKDIV registers.
5. Configure at least one target address by writing the 7-bit address to I2Cx.SOAR register. The additional target address can be enabled and configured by using I2Cx.SOAR2 register.
6. Enable desired interrupts and/or DMA event by using CPU\_INT.IMASK register.
7. The general call response can be enabled by setting the GENCALL bit in I2Cx.SCTR register.
8. Enable the I<sup>2</sup>C target mode by setting the ACTIVE bit in I2Cx.SCTR register.

#### I<sup>2</sup>C Target Status

User can read the I2Cx.SSR register to check the current state of the I<sup>2</sup>C target.

**Table 25-13. Target Status Register**

Bit Field	Description
RREQ	This bit is set if the I2C controller has outstanding receive data from the I2C controller and is using clock stretching to delay the controller until the data has been read from the SRXDATA FIFO (Target RX FIFO is full)
TREQ	This bit is set if the I2C controller has been addressed as a target transmitter and is using clock stretching to delay the controller until data has been written to the STXDATA FIFO (Target TX FIFO is empty).
OAR2SEL	This bit is set if SOAR2.OAR2 address matched and ACKed by the target.
QCMDST	Quick command status value. This bit is 0 if the last transaction was a normal transaction or a transaction has not occurred. This bit is set if the last transaction was a quick command transaction
QCMDRW	Quick command read / write status. This bit only has meaning when the QCMDST bit is set. This bit is 0 if quick command was a write. This bit is set if quick command was a read.

#### I<sup>2</sup>C Target Receiver Mode

Target receiver mode is entered when the target address transmitted by the controller matches its own address and a cleared R/W bit is received. In target receiver mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the controller device. The target device does not generate the clock, but it can hold SCL low if intervention of the CPU is required after a byte has been received.

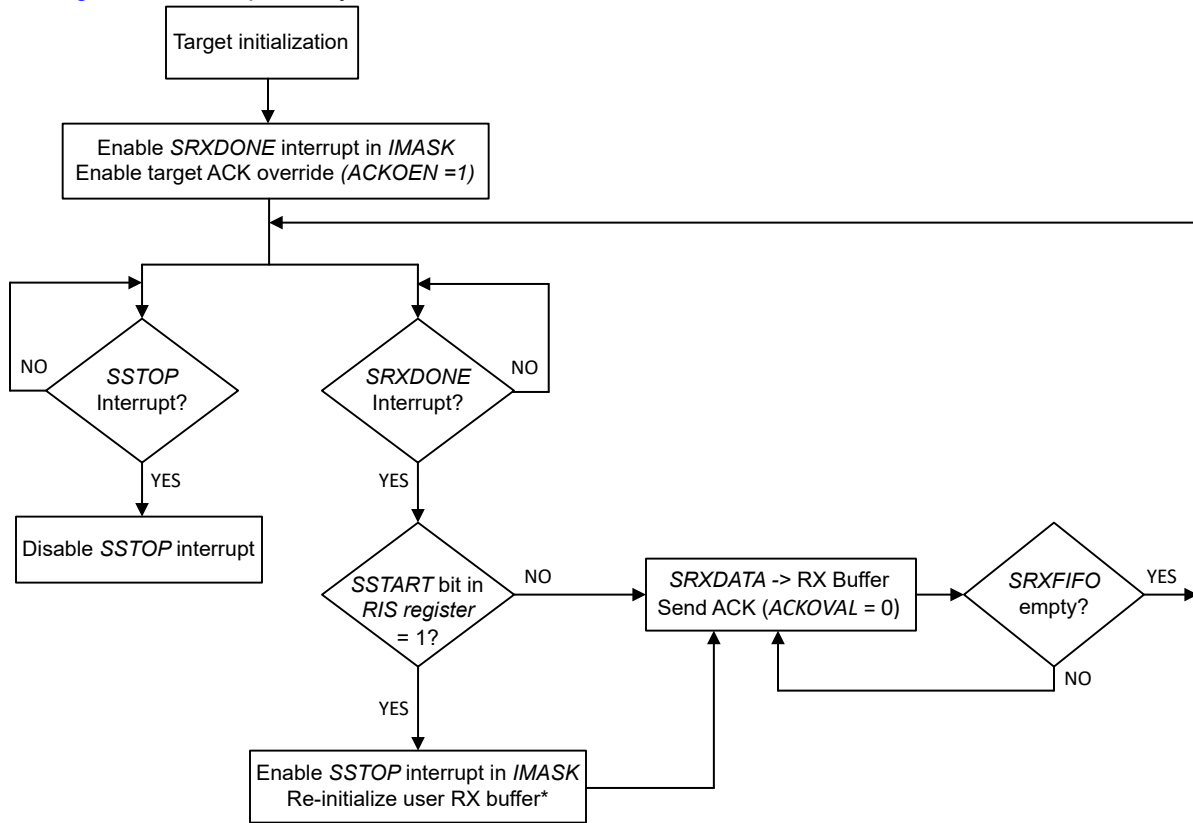

After the a data byte is received, the SRXDONE (0x11) interrupt in CPU\_INT.IIDX register is set to indicate that a byte has been received. The I<sup>2</sup>C module automatically acknowledges the received data or user can choice to manually send acknowledge after each byte received by configuring the I2Cx.SACKCTL register.

When the controller generates a START condition, the SSTART (0x17) interrupt in CPU\_INT.IIDX register is set. When the controller generates a STOP condition, the SSTOP (0x18) interrupt in CPU\_INT.IIDX register is set.

User can also set use the SRXFIFOTRG (0x13) interrupt in CPU\_INT.IIDX register to read the data from the receive FIFO. This interrupt will trigger when receive FIFO contains >= defined bytes, the trigger level can be defined by using RXTRIG bit in I2Cx.SFIFOCTL register.

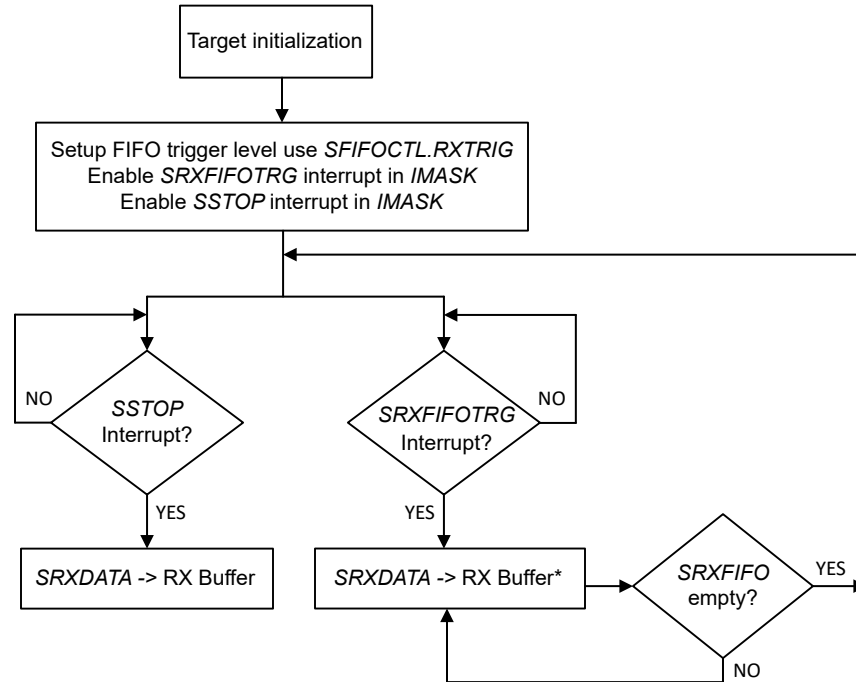

The SRXDONE approach could be used if target wants to slow down communication to evaluate reception of every byte, while the SRXFIFOTRG approach could be used to maximize throughput and avoid clock stretching.

The flow chart of using SRXDONE and SRXFIFOTRG interrupt to read the receive data are shown in Figure 25-13 and Figure 25-14 respectively.

\* RX buffer is a user defined buffer for received data packet

**Figure 25-13. Target Receiver Mode using SRXDONE and ACK override**

\* RX buffer is a user defined buffer for received data packet

**Figure 25-14. Target Receiver Mode using SRXFIFOTRG and automatic ACK**

### I<sup>2</sup>C Target Transmitter Mode

Target transmitter mode is entered when the target address transmitted by the controller is identical to its own address with a set R/W bit. The target transmitter shifts the serial data out on SDA with the clock pulses that are generated by the controller device. The target device does not generate the clock, but it can hold SCL low if intervention of the CPU is required after a byte has been transmitted.

After a data byte is transmitted, the STXDONE (0x12) interrupt in CPU\_INT.IIDX register is set to indicate that a byte has been transmitted.

When the controller generates a START condition, the SSTART (0x17) interrupt in CPU\_INT.IIDX register is set. When the controller generates a STOP condition, the SSTOP (0x18) interrupt in CPU\_INT.IIDX register is set.

User can also set use the STXFIFOTRG (0x14) interrupt in CPU\_INT.IIDX register to load the data to the transmit FIFO. This interrupt will trigger when transmit FIFO contains <= defined bytes, the trigger level can be defined by using TXTRIG bit in I2Cx.SFIFOCTL register.

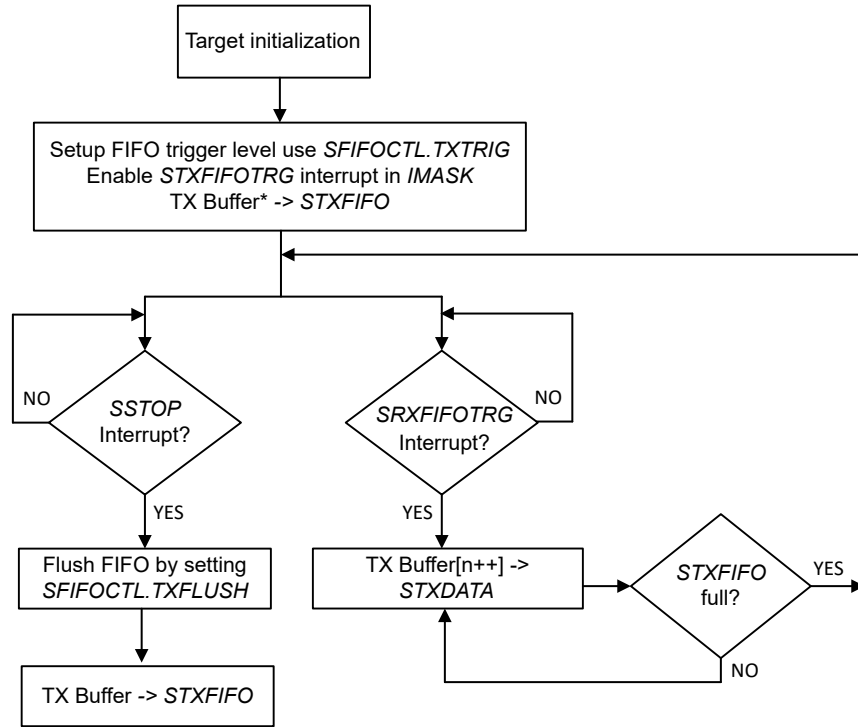

The STXDONE approach could be used if target wants to slow down communication to evaluate reception of every byte, while the STXFIFOTRG approach could be used to maximize throughput and avoid clock stretching.

The flow chat of using STXDONE and STXFIFOTRG interrupt to transmit data are shown in [Figure 25-15](#) and [Figure 25-16](#).

\* TX buffer is a user defined buffer for transmit data packet

**Figure 25-15. Target Transmitter Mode using STXDONE**

\* TX buffer is a user defined buffer for received data packet

Figure 25-16. Target Transmitter Mode using STXFIFOTRG

### 25.2.5 Reset Considerations

#### Software Reset Considerations

A Software reset can be executed by setting the RESETASSERT bit together with the KEY bit in the I2Cx.RSTCTL register. We recommend issues a reset only after terminating a transaction.

#### Hardware Reset Considerations

A hardware reset also initializes the IO configuration. This sets the IOs to a high-impedance state and with the external pullup resistors for I<sup>2</sup>C the lines pulled high.

Table 25-14 shows the behavior of status bits when Controller or Target gets disabled.

Table 25-14. Status Bits When Controller is Disabled

Register	Bit	Behavior When Controller Disabled	Behavior When Target Disabled	Behavior After Controller/Target Enabled
I2Cx.MSR	Busy	Reset State	Don't care	updates Start condition sending
	ERR	Reset State	Don't care	updates on next event detected
	ADRACK	Reset State	Don't care	updates on next event detected
	DATACK	Reset State	Don't care	updates on next event detected
	ARBLST	Reset State	Don't care	updates on next event detected
	IDLE	Reset State	Don't care	updates on next event detected
	BUSBSY	Reset State	Don't care	updates on next Start detected on bus (or SDA or SCL is low)
	CLKTO	Reset State	Don't care	updates on next event detected
	MBCNT	Reset State	Don't care	updates on next event detected
I2Cx.MCLKCNT	CLKCNT	Reset State	Don't care	updates with Controller enable when SCL is high

**Table 25-14. Status Bits When Controller is Disabled (continued)**

Register	Bit	Behavior When Controller Disabled	Behavior When Target Disabled	Behavior After Controller/Target Enabled
I2Cx.MBMON	SCL	Reset State	Don't care	updates with Controller enable
	SDA	Reset State	Don't care	updates with Controller enable

**Table 25-15. Status Bits When Target is Disabled**

Register	Bit	Behavior When Controller Disabled	Behavior When Target Disabled	Behavior After Controller/Target Enabled
I2Cx.SSR	RREQ	Don't care	Reset State	updates on next event detected
	TREQ	Don't care	Reset State	updates on next event detected
	OAR2SEL	Don't care	Reset State	updates on next event detected
	QCMDST	Don't care	Reset State	updates on next event detected
	QCMDRW	Don't care	Reset State	updates on next event detected
I2Cx.SFIFOSR	RXFIFOCNT	Don't care	Unchanged	updates on FIFO access
	TXFIFOCNT	Don't care	Unchanged	updates on FIFO access

### 25.2.6 Initialization

Please see [Section 25.2.4.1.2](#) for controller initialization and [Section 25.2.4.2.1](#) for target initialization.

#### Note

The configuration registers of the I<sup>2</sup>C module (including the clock configuration, mode configuration, and timeout count) must not be modified by application software when an I<sup>2</sup>C data transfer is in progress.

### 25.2.7 Interrupt and Events Support

The I<sup>2</sup>C module contains three [event publishers](#) and no [event subscribers](#). One event publisher (CPU\_INT) manages I<sup>2</sup>C interrupt requests (IRQs) to the CPU subsystem through a [static event route](#). The second and third event publishers (DMA\_TRIG1, DMA\_TRIG0) are used to setup the trigger signaling for the DMA through [DMA event route](#).

The I<sup>2</sup>C events are summarized in [Table 25-16](#).

**Table 25-16. I<sup>2</sup>C Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU interrupt</a>	Publisher	I <sup>2</sup> C	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from I <sup>2</sup> C to CPU
<a href="#">DMA trigger</a>	Publisher	I <sup>2</sup> C	DMA	<a href="#">DMA event route</a>	DMA_TRIG1 registers	Fixed interrupt route from I <sup>2</sup> C to DMA
<a href="#">DMA trigger</a>	Publisher	I <sup>2</sup> C	DMA	<a href="#">DMA event route</a>	DMA_TRIG0 registers	Fixed interrupt route from I <sup>2</sup> C to DMA

### 25.2.7.1 CPU Interrupt Event Publisher (CPU\_INT)

The I<sup>2</sup>C module provides 24 interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the I<sup>2</sup>C are:

**Table 25-17. I<sup>2</sup>C CPU Interrupt Event Conditions for Controller (CPU\_INT)**

IIDX STAT	Name	Description
0x01	MRXDONE	Controller receive transaction completed interrupt
0x02	MTXDONE	Controller transmit transaction completed interrupt
0x03	MRXFIFOTRG	Controller receive FIFO trigger. Trigger when RX FIFO contains >= defined bytes
0x04	MTXFIFOTRG	Controller transmit FIFO trigger. Trigger when Transmit FIFO contains <= defined bytes
0x05	MRXFIFOFULL	Controller RXFIFO full event. This interrupt is set if an RX FIFO is full.
0x06	MTXEMPTY	Controller transmit FIFO empty interrupt. This interrupt is set if all data in the Transmit FIFO have been shifted out and the transmit goes into idle mode.
0x07	MCLKTO	Controller clock timeout interrupt
0x08	MNACK	Address/Data NACK interrupt
0x09	MSTART	Controller START detection interrupt
0x0A	MSTOP	Controller STOP detection interrupt
0x0B	MARBLOST	Controller arbitration lost interrupt
0x0C	MDMA_DONE_TX	Controller DMA TX done signal (see next section for more detail)
0x0D	MDMA_DONE_RX	Controller DMA RX done signal (see next section for more detail)

**Table 25-18. I<sup>2</sup>C CPU Interrupt Event Conditions for Target (CPU\_INT)**

IIDX STAT	Name	Description
0x11	SRXDONE	Target receive transaction completed interrupt
0x12	STXDONE	Target transmit transaction completed interrupt
0x13	SRXFIFOTRG	Target receive FIFO trigger. It will trigger when receive FIFO contains >= defined bytes
0x14	STXFIFOTRG	Target transmit FIFO trigger. It will trigger when transmit FIFO contains <= defined bytes
0x15	SXFIFOFULL	Target RXFIFO full event. This interrupt is set if an RX FIFO is full.
0x16	STXEMPTY	Target transmit FIFO empty interrupt. This interrupt is set if all data in the Target Transmit FIFO have been shifted out and the transmit goes into idle mode.
0x17	SSTART	Target START detection interrupt
0x18	SSTOP	Target STOP detection interrupt
0x19	SGENCALL	General call interrupt
0x1A	SDMA_DONE_TX	Target DMA TX done signal (see next section for more detail)
0x1B	SDMA_DONE_RX	Target DMA RX done signal (see next section for more detail)

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers for CPU interrupts.

### 25.2.7.2 DMA Trigger Publisher (DMA\_TRIG1, DMA\_TRIG0)

DMA\_TRIG1 and DMA\_TRIG0 registers are used to setup the trigger signaling for the DMA. This can be setup in a flexible way to trigger the DMA for Controller or Target and receive or transmit events with the following four trigger conditions:

**Table 25-19. I<sup>2</sup>C DMA Trigger Condition (DMA\_TRIG1 and DMA\_TRIG0)**

IIDX STAT	Name	Description
0x01	MRXFIFOTRG	Controller receive FIFO trigger. Trigger when RX FIFO contains >= defined bytes

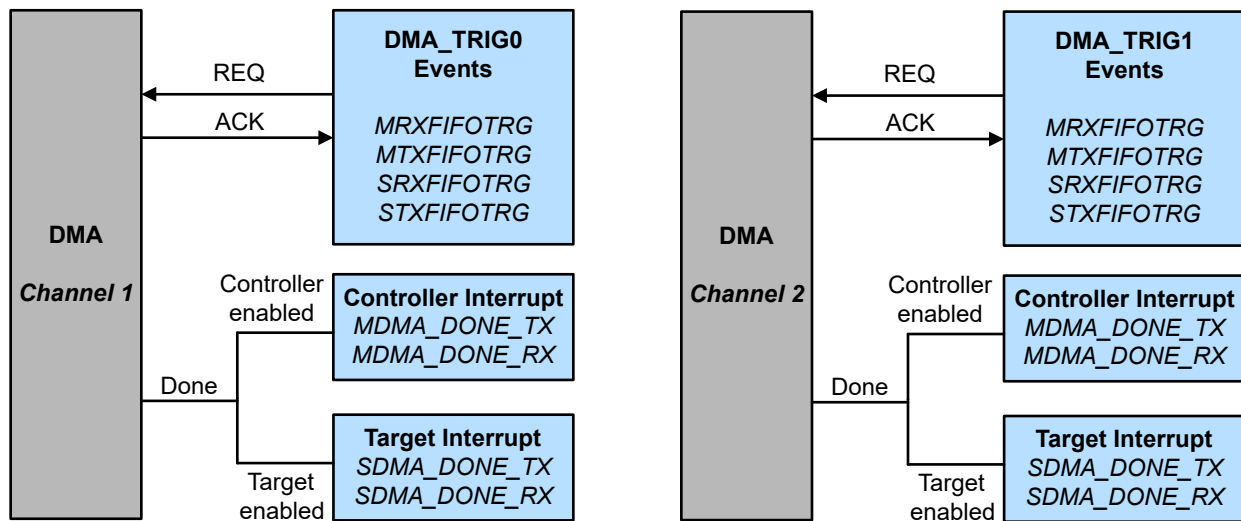

**Table 25-19. I<sup>2</sup>C DMA Trigger Condition (DMA\_TRIG1 and DMA\_TRIG0) (continued)**

IDX STAT	Name	Description
0x02	MTXFIFOTRG	Controller transmit FIFO trigger. Trigger when Transmit FIFO contains <= defined bytes
0x03	SRXFIFOTRG	Target receive FIFO trigger. Trigger when RX FIFO contains >= defined bytes
0x04	STXFIFOTRG	Target transmit FIFO trigger. Trigger when Transmit FIFO contains <= defined bytes

The DMA trigger event configuration is managed with the DMA\_TRIG1 and DMA\_TRIG0 event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers and [Section 7.1.3.2](#) for on how DMA trigger event works. DMA\_TRIG1 and DMA\_TRIG0 are two event management registers that correspond to two DMA channels.

As shown in [Figure 25-17](#), each DMA channel can be triggered by any of the conditions listed in [Table 25-19](#) and it can generate either the controller DMA done signal or target DMA done signal.

For example, the user can configure the DMA\_TRIG1 trigger using MTXFIFOTRG and the DMA\_TRIG0 trigger using SRXFIFOTRG. When the Channel 1 DMA status changes to done, the MDMA\_DONE\_TX and MDMA\_DONE\_RX interrupts will set, and when the Channel 2 DMA status change to done, the SDMA\_DONE\_TX and SDMA\_DONE\_RX interrupts will set.

**Figure 25-17. I<sup>2</sup>C DMA Trigger and Status**

### 25.2.8 Emulation Modes

The module behavior while the device is in debug mode is controlled by the FREE and SOFT bits in PDBGCTL register.

When the device is in debug mode and set into halt mode below behavior can be configured.

**Table 25-20. Debug Mode Peripheral Behavior**

PDBGCTL.FREE	PDBGCTL.SOFT	Function
1	x	Modules continues operation
0	0	Module stops immediately
0	1	Module stops after the next transfer has been finished

## 25.3 I2C Registers

Table 25-21 lists the memory-mapped registers for the I2C registers. All register offset addresses not listed in Table 25-21 should be considered as reserved locations and the register contents should not be modified.

**Table 25-21. I2C Registers**

Offset	Acronym	Register Name	Section
800h	PWREN	Power enable	<a href="#">Section 1</a>
804h	RSTCTL	Reset Control	<a href="#">Section 2</a>
808h	CLKCFG	Peripheral Clock Configuration Register	<a href="#">Section 3</a>
814h	STAT	Status Register	<a href="#">Section 4</a>
1000h	CLKDIV	Clock Divider	<a href="#">Section 5</a>
1004h	CLKSEL	Clock Select for Ultra Low Power peripherals	<a href="#">Section 6</a>
1018h	PDBGCTL	Peripheral Debug Control	<a href="#">Section 7</a>
1020h	IIDX	Interrupt index	<a href="#">Section 8</a>
1028h	IMASK	Interrupt mask	<a href="#">Section 9</a>
1030h	RIS	Raw interrupt status	<a href="#">Section 10</a>
1038h	MIS	Masked interrupt status	<a href="#">Section 11</a>
1040h	ISET	Interrupt set	<a href="#">Section 12</a>
1048h	ICLR	Interrupt clear	<a href="#">Section 13</a>
1050h	IIDX	Interrupt index	<a href="#">Section 14</a>
1058h	IMASK	Interrupt mask	<a href="#">Section 15</a>
1060h	RIS	Raw interrupt status	<a href="#">Section 16</a>
1068h	MIS	Masked interrupt status	<a href="#">Section 17</a>
1070h	ISET	Interrupt set	<a href="#">Section 18</a>
1078h	ICLR	Interrupt clear	<a href="#">Section 19</a>

Complex bit access types are encoded to fit into small table cells. [Table 25-22](#) shows the codes that are used for access types in this section.

**Table 25-22. I2C Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WK	W K	Write Write protected by a key
Reset or Default Value		
-n		Value after reset or the default value

**1 PWREN Register (Offset = 800h) [Reset = 0000000h]**

PWREN is shown in [Table 25-23](#).

Return to the [Summary Table](#).

Register to control the power state

**Table 25-23. PWREN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	KEY	W	0h	KEY to allow Power State Change 26h = KEY to allow write access to this register
23-1	RESERVED	R	0h	
0	ENABLE	R/WK	0h	Enable the power <a href="#">KEY</a> must be set to 26h to write to this bit. 0h = Disable Power 1h = Enable Power

## 2 RSTCTL Register (Offset = 804h) [Reset = 0000000h]

RSTCTL is shown in [Table 25-24](#).

Return to the [Summary Table](#).

Register to control reset assertion and de-assertion

**Table 25-24. RSTCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	KEY	W	0h	Unlock key B1h = KEY to allow write access to this register
23-2	RESERVED	R	0h	
1	RESETSTKYCLR	WK	0h	Clear the RESETSTKY bit in the STAT register <b>KEY</b> must be set to B1h to write to this bit. 0h = Writing 0 has no effect 1h = Clear reset sticky bit
0	RESETASSERT	WK	0h	Assert reset to the peripheral <b>KEY</b> must be set to B1h to write to this bit. 0h = Writing 0 has no effect 1h = Assert reset

### 3 CLKCFG Register (Offset = 808h) [Reset = 0000000h]

CLKCFG is shown in [Table 25-25](#).

Return to the [Summary Table](#).

Peripheral Clock Configuration Register

**Table 25-25. CLKCFG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	KEY	W	0h	KEY to Allow State Change -- 0xA9 A9h = key value to allow change field of GPRCM
23-9	RESERVED	R	0h	
8	BLOCKASYNC	R/W	0h	Async Clock Request is blocked from starting SYSOSC or forcing bus clock to 32MHz 0h = Not block async clock request 1h = Block async clock request
7-0	RESERVED	R	0h	

#### 4 STAT Register (Offset = 814h) [Reset = 00000000h]

STAT is shown in [Table 25-26](#).

Return to the [Summary Table](#).

peripheral enable and reset status

**Table 25-26. STAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-17	RESERVED	R	0h	
16	RESETSTKY	R	0h	This bit indicates, if the peripheral was reset, since this bit was cleared by RESETSTKYCLR in the RSTCTL register 0h = The peripheral has not been reset since this bit was last cleared by RESETSTKYCLR in the RSTCTL register 1h = The peripheral was reset since the last bit clear
15-0	RESERVED	R	0h	

**5 CLKDIV Register (Offset = 1000h) [Reset = 00000000h]**

CLKDIV is shown in [Table 25-27](#).

Return to the [Summary Table](#).

This register is used to specify module-specific divide ratio of the functional clock

**Table 25-27. CLKDIV Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-3	RESERVED	R	0h	
2-0	RATIO	R/W	0h	Selects divide ratio of module clock 0h = Do not divide clock source 1h = Divide clock source by 2 2h = Divide clock source by 3 3h = Divide clock source by 4 4h = Divide clock source by 5 5h = Divide clock source by 6 6h = Divide clock source by 7 7h = Divide clock source by 8

**6 CLKSEL Register (Offset = 1004h) [Reset = 0000000h]**

CLKSEL is shown in [Table 25-28](#).

Return to the [Summary Table](#).

Clock source selection.

**Table 25-28. CLKSEL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	
3	BUSCLK_SEL	R/W	0h	Selects BUSCLK as clock source if enabled 0h = Does not select this clock as a source 1h = Select this clock as a source
2	MFCLK_SEL	R/W	0h	Selects MFCLK as clock source if enabled 0h = Does not select this clock as a source 1h = Select this clock as a source
1-0	RESERVED	R	0h	

**7 PDBGCTL Register (Offset = 1018h) [Reset = 00000000h]**

PDBGCTL is shown in [Table 25-29](#).

Return to the [Summary Table](#).

This register can be used by the software developer to control the behavior of the peripheral relative to the 'Core Halted' input

**Table 25-29. PDBGCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1	SOFT	R/W	1h	Soft halt boundary control. This function is only available, if <b>FREE</b> is set to 'STOP' 0h = The peripheral will halt immediately, even if the resultant state will result in corruption if the system is restarted 1h = The peripheral blocks the debug freeze until it has reached a boundary where it can resume without corruption
0	FREE	R/W	1h	Free run control 0h = The peripheral freezes functionality while the Core Halted input is asserted and resumes when it is deasserted. 1h = The peripheral ignores the state of the Core Halted input

## 8 IIDX Register (Offset = 1020h) [Reset = 0000000h] (CPU\_INT)

IIDX is shown in [Table 25-30](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index.

**Table 25-30. IIDX Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	STAT	R	0h	I2C Module Interrupt Vector Value. This register provides the highest priority interrupt index. A read clears the corresponding interrupt flag in RIS and MISC. 15h-1Fh = Reserved 00h = No interrupt pending 01h = Controller data received 02h = Controller data transmitted 03h = Controller receive FIFO Trigger Level 04h = Controller transmit FIFO Trigger level 5h = RX FIFO FULL Event/interrupt pending 6h = Transmit FIFO/Buffer Empty Event/interrupt pending 08h = Address/Data NACK 09h = Start Event 0Ah = Stop Event 0Bh = Arbitration Lost Ch = DMA DONE on Channel TX Dh = DMA DONE on Channel RX Eh = Controller PEC Receive Error Event Fh = Timeout A Event 10h = Timeout B Event 11h = Target Data Event 12h = Target Data Event 13h = Target receive FIFO Trigger Level 14h = Target transmit FIFO Trigger level 15h = RX FIFO FULL Event/interrupt pending 16h = Transmit FIFO/Buffer Empty Event/interrupt pending 17h = Start Event 18h = Stop Event 19h = General Call Event 1Ah = DMA DONE on Channel TX 1Bh = DMA DONE on Channel RX 1Ch = Target PEC receive error event 1Dh = Target TX FIFO underflow 1Eh = Target RX FIFO overflow event 1Fh = Target arbitration lost event 20h = Interrupt overflow event

## 9 IMASK Register (Offset = 1028h) [Reset = 0000000h] (CPU\_INT)

IMASK is shown in [Table 25-31](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is un-masked. Un-masking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

**Table 25-31. IMASK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	INTR_OVFL	R/W	0h	Interrupt Overflow Interrupt Mask 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
30	TARBLOST	R/W	0h	Target Arbitration Lost 0h = Clear Set Interrupt Mask 1h = Set Interrupt Mask
29	TRX_OVFL	R/W	0h	Target RX FIFO overflow 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
28	TTX_UNFL	R/W	0h	Target TX FIFO underflow 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
27	TPEC_RX_ERR	R/W	0h	Target RX Pec Error Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
26	TDMA_DONE_RX	R/W	0h	Target DMA Done on Event Channel RX 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
25	TDMA_DONE_TX	R/W	0h	Target DMA Done on Event Channel TX 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
24	TGENCALL	R/W	0h	General Call Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
23	TSTOP	R/W	0h	Stop Condition Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
22	TSTART	R/W	0h	Start Condition Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
21	TTXEMPTY	R/W	0h	Target Transmit FIFO Empty interrupt mask. This interrupt is set if all data in the Transmit FIFO have been shifted out and the transmit goes into idle mode. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
20	TRXFIFOFULL	R/W	0h	RXFIFO full event. This interrupt is set if an Target RX FIFO is full. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
19	TTXFIFOTRG	R/W	0h	Target Transmit FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
18	TRXFIFOTRG	R/W	0h	Target Receive FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
17	TTXDONE	R/W	0h	Target Transmit Transaction completed Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask

**Table 25-31. IMASK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
16	TRXDONE	R/W	0h	Target Receive Data Interrupt Signals that a byte has been received 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
15	TIMEOUTB	R/W	0h	Timeout B Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
14	TIMEOUTA	R/W	0h	Timeout A Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
13	CPEC_RX_ERR	R/W	0h	Controller RX Pec Error Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
12	CDMA_DONE_RX	R/W	0h	DMA Done on Event Channel RX 0h = Interrupt disabled 1h = Set Interrupt Mask
11	CDMA_DONE_TX	R/W	0h	DMA Done on Event Channel TX 0h = Interrupt disabled 1h = Set Interrupt Mask
10	CARBLOST	R/W	0h	Arbitration Lost Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
9	CSTOP	R/W	0h	STOP Detection Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
8	CSTART	R/W	0h	START Detection Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
7	CNACK	R/W	0h	Address/Data NACK Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
6	RESERVED	R	0h	
5	CTXEMPTY	R/W	0h	Transmit FIFO Empty interrupt mask. This interrupt is set if all data in the Transmit FIFO have been shifted out and the transmit goes into idle mode. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
4	CRXFIFOFULL	R/W	0h	RXFIFO full event. This interrupt is set if an RX FIFO is full. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
3	CTXFIFOTRG	R/W	0h	Controller Transmit FIFO Trigger Trigger when Transmit FIFO contains <= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
2	CRXFIFOTRG	R/W	0h	Controller Receive FIFO Trigger Trigger when RX FIFO contains >= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
1	CTXDONE	R/W	0h	Controller Transmit Transaction completed Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
0	CRXDONE	R/W	0h	Controller Receive Transaction completed Interrupt 0h = Clear Interrupt Mask 1h = Set Interrupt Mask

## 10 RIS Register (Offset = 1030h) [Reset = 0000000h] (CPU\_INT)

RIS is shown in [Table 25-32](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Table 25-32. RIS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	INTR_OVFL	R	0h	Interrupt overflow interrupt It is set when CSTART or CSTOP interrupts overflow i.e. occur twice without being serviced 0h = Interrupt did not occur 1h = Interrupt occurred
30	TARBLOST	R	0 h	Target Arbitration Lost 0h = Interrupt did not occur 1h = Interrupt occurred
29	TRX_OVFL	R	0h	Target RX FIFO overflow 0h = Interrupt did not occur 1h = Interrupt Occured
28	TTX_UNFL	R	0h	Target TX FIFO underflow 0h = Interrupt did not occur 1h = Interrupt occurred
27	TPEC_RX_ERR	R	0h	Target RX Pec Error Interrupt 0h = Interrupt did not occur 1h = Interrupt ocured
26	TDMA_DONE_RX	R	0h	DMA Done on Event Channel RX 0h = Clear interrupt 1h = Set interrupt
25	TDMA_DONE_TX	R	0h	DMA Done on Event Channel TX 0h = Clear interrupt 1h = Set interrupt
24	TGENCALL	R	0h	General Call Interrupt 0h = Clear Interrupt Mask 1h = Interrupt occurred
23	TSTOP	R	0h	Stop Condition Interrupt 0h = Clear Interrupt 1h = Set interrupt
22	TSTART	R	0h	Start Condition Interrupt 0h = Clear interrupt 1h = Set Interrupt
21	TTXEMPTY	R	0h	Transmit FIFO Empty interrupt mask. This interrupt is set if all data in the Transmit FIFO have been shifted out and the transmit goes into idle mode. 0h = Interrupt did not occur 1h = Interrupt occurred
20	TRXFIFOFULL	R	0h	RXFIFO full event. This interrupt is set if an RX FIFO is full. 0h = Clear Interrupt Mask 1h = Interrupt occurred

**14 IIDX Register (Offset = 1050h) [Reset = 00000000h] (DMA\_TRIG1)**

IIDX is shown in [Table 25-36](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index.

**Table 25-36. IIDX Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	STAT	R	0h	I2C Module Interrupt Vector Value. This register provides the highest priority interrupt index. A read clears the corresponding interrupt flag in RIS and MISC. 15h-1Fh = Reserved 00h = No interrupt pending 01h = Controller receive FIFO Trigger Level 02h = Controller transmit FIFO Trigger level 03h = Target receive FIFO Trigger Level 04h = Target transmit FIFO Trigger level

### 15 IMASK Register (Offset = 1058h) [Reset = 0000000h] (DMA\_TRIG1)

IMASK is shown in [Table 25-37](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is un-masked. Un-masking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

**Table 25-37. IMASK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	
3	TTXFIFOTRG	R/W	0h	Target Transmit FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
2	TRXFIFOTRG	R/W	0h	Target Receive FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
1	CTXFIFOTRG	R/W	0h	Controller Transmit FIFO Trigger Trigger when Transmit FIFO contains <= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
0	CRXFIFOTRG	R/W	0h	Controller Receive FIFO Trigger Trigger when RX FIFO contains >= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask

### 16 RIS Register (Offset = 1060h) [Reset = 00000000h] (DMA\_TRIG1)

RIS is shown in [Table 25-38](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Table 25-38. RIS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	
3	TTXFIFOTRG	R	0h	Target Transmit FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
2	TRXFIFOTRG	R	0h	Target Receive FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
1	CTXFIFOTRG	R	0h	Controller Transmit FIFO Trigger Trigger when Transmit FIFO contains <= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
0	CRXFIFOTRG	R	0h	Controller Receive FIFO Trigger Trigger when RX FIFO contains >= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask

**17 MIS Register (Offset = 1068h) [Reset = 0000000h] (DMA\_TRIG1)**

MIS is shown in [Table 25-39](#).

Return to the [Summary Table](#).

Masked interrupt status. This is an AND of the IMASK and RIS registers.

**Table 25-39. MIS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	
3	TTXFIFOTRG	R	0h	Target Transmit FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
2	TRXFIFOTRG	R	0h	Target Receive FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
1	CTXFIFOTRG	R	0h	Controller Transmit FIFO Trigger Trigger when Transmit FIFO contains <= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
0	CRXFIFOTRG	R	0h	Controller Receive FIFO Trigger Trigger when RX FIFO contains >= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask

**18 ISET Register (Offset = 1070h) [Reset = 0000000h] (DMA\_TRIG1)**

ISET is shown in [Table 25-40](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Table 25-40. ISET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	
3	TTXFIFOTRG	W	0h	Target Transmit FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask

2	TRXFIFOTRG	W	0h	Target Receive FIFO Trigger 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
1	CTXFIFOTRG	W	0h	Controller Transmit FIFO Trigger Trigger when Transmit FIFO contains <= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
0	CRXFIFOTRG	W	0h	Controller Receive FIFO Trigger Trigger when RX FIFO contains >= defined bytes 0h = Clear Interrupt Mask 1h = Set Interrupt Mask

## 26 EVT\_MODE Register (Offset = 10E0h) [Reset = 0000000h]

EVT\_MODE is shown in [Table 25-48](#).

Return to the [Summary Table](#).

Event mode register. It is used to select whether each line is disabled, in software mode (software clears the RIS) or in hardware mode (hardware clears the RIS)

**Table 25-48. EVT\_MODE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	
5-4	EVT2_CFG	R	2h	Event line mode select for event corresponding to none.DMA_TRIG0 0h = The interrupt or event line is disabled. 1h = The interrupt or event line is in software mode. Software must clear the RIS. 2h = The interrupt or event line is in hardware mode. The hardware (another module) clears automatically the associated RIS flag.
3-2	INT1_CFG	R	2h	Event line mode select for event corresponding to none.DMA_TRIG1 0h = The interrupt or event line is disabled. 1h = The interrupt or event line is in software mode. Software must clear the RIS. 2h = The interrupt or event line is in hardware mode. The hardware (another module) clears automatically the associated RIS flag.
1-0	INT0_CFG	R	1h	Event line mode select for event corresponding to none.CPU_INT 0h = The interrupt or event line is disabled. 1h = The interrupt or event line is in software mode. Software must clear the RIS. 2h = The interrupt or event line is in hardware mode. The hardware (another module) clears automatically the associated RIS flag.

**27 INTCTL Register (Offset = 10E4h) [Reset = 0000000h]**

INTCTL is shown in [Table 25-49](#).

Return to the [Summary Table](#).

Interrupt control register

**Table 25-49. INTCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	
0	INTEVAL	W	0h	Writing a 1 to this field re-evaluates the interrupt sources. 0h = The interrupt or event line is disabled. 1h = The interrupt or event line is in software mode. Software must clear the RIS.

## 28 DESC Register (Offset = 10FCh) [Reset = 00000000h]

DESC is shown in [Table 25-50](#).

Return to the [Summary Table](#).

This register identifies the peripheral and its exact version.

**Table 25-50. DESC Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	MODULEID	R	1511h	Module identification contains a unique peripheral identification number. The assignments are maintained in a central database for all of the platform modules to ensure uniqueness. 0h = Smallest value FFFFh = Highest possible value
15-12	FEATUREVER	R	0h	Feature Set for the module *instance* 0h = Smallest value Fh = Highest possible value
11-8	INSTNUM	R	0h	Instance Number within the device. This will be a parameter to the RTL for modules that can have multiple instances 0h = Smallest value Fh = Highest possible value
7-4	MAJREV	R	1h	Major rev of the IP 0h = Smallest value Fh = Highest possible value
3-0	MINREV	R	0h	Minor rev of the IP 0h = Smallest value Fh = Highest possible value

## 29 GFCTL Register (Offset = 1200h) [Reset = 0000000h]

GFCTL is shown in [Table 25-51](#).

Return to the [Summary Table](#).

This register controls the glitch filter on the SCL and SDA lines

**Table 25-51. GFCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-12	RESERVED	R	0h	
11	CHAIN	R/W	1h	Analog and digital noise filters chaining enable. 0h = When 0, chaining is disabled and only digital filter output is available to IP logic for oversampling 1h = When 1, analog and digital glitch filters are chained and the output of the combination is made available to IP logic for oversampling
10-9	AGFSEL	R/W	3h	Analog Glitch Suppression Pulse Width This field controls the pulse width select for the analog glitch suppression on SCL and SDA lines. See device datasheet for exact values. (ULP I2C only) 0h = Pulses shorter than 5ns length are filtered. 1h = Pulses shorter than 10ns length are filtered. 2h = Pulses shorter than 25ns length are filtered. 3h = Pulses shorter than 50ns length are filtered.
8	AGFEN	R/W	1h	Analog Glitch Suppression Enable 0h = Analog Glitch Filter disable 1h = Analog Glitch Filter enable
7-3	RESERVED	R	0h	
2-0	DGFSEL	R/W	0h	Glitch Suppression Pulse Width This field controls the pulse width select for glitch suppression on the SCL and SDA lines. The following values are the glitch suppression values in terms of functional clocks. (Core Domain only) 0h = Bypass 1h = 1 clock 2h = 2 clocks 3h = 3 clocks 4h = 4 clocks 5h = 8 clocks 6h = 16 clocks 7h = 31 clocks

**30 TIMEOUT\_CTL Register (Offset = 1204h) [Reset = 00020002h]**

TIMEOUT\_CTL is shown in [Table 25-52](#).

Return to the [Summary Table](#).

This register contains controls for Timeout Counters A and B

**Table 25-52. TIMEOUT\_CTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	TCNTBEN	R/W	0h	Timeout Counter B Enable 0h = Disable Timeout Counter B 1h = Enable Timeout Counter B
30-24	RESERVED	R	0h	
23-16	TCNTLB	R/W	2h	Timeout Count B Load: Counter B is used for SCL High Detection. This field contains the upper 8 bits of a 12-bit pre-load value for the Timeout B count. NOTE: The value of CNTLB must be greater than 1h. Each count is equal to 1* clock period. For example, with 10MHz functional clock one timeout period will be equal to 1*100ns. 0h = Smallest possible value FFh = Highest possible value
15	TCNTAEN	R/W	0h	Timeout Counter A Enable 0h = Disable Timeout Counter B 1h = Enable Timeout Counter B
14-8	RESERVED	R	0h	
7-0	TCNTLA	R/W	2h	Timeout counter A load value Counter A is used for SCL low detection. This field contains the upper 8 bits of a 12-bit pre-load value for the Timeout A count. NOTE: The value of CNTLA must be greater than 1h. Each count is equal to 520 times the timeout period of functional clock. For example, with 8MHz functional clock and a 100KHz operating I2C clock, one timeout period will be equal to (1 / 8MHz) * 520 or 65 us. 0h = Smallest Value FFh = Highest possible value

**31 TIMEOUT\_CNT Register (Offset = 1208h) [Reset = 00020002h]**

TIMEOUT\_CNT is shown in [Table 25-53](#).

Return to the [Summary Table](#).

This register contains the upper 8 bits of a 12-bit current counter values for counter A and B. The lower four bits of the counter are not user visible and are always 0h.

**Table 25-53. TIMEOUT\_CNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	
23-16	TCNTB	R	2h	Timeout Count B Current Count: This field contains the upper 8 bits of a 12-bit current counter for timeout counter B 0h = Smallest Value FFh = Highest possible value
15-8	RESERVED	R	0h	
7-0	TCNTA	R	2h	Timeout Count A Current Count: This field contains the upper 8 bits of a 12-bit current counter for timeout counter A 0h = Smallest Value FFh = Highest possible value

**32 CSA Register (Offset = 1210h) [Reset = 0000000h]**

 CSA is shown in [Table 25-54](#).

 Return to the [Summary Table](#).

I2C Controller Target Address Register

**Table 25-54. CSA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	CMODE	R/W	0h	This bit selects the addressing mode to be used in Controller mode When 0, 7-bit addressing is used. When 1, 10-bit addressing is used. 0h = 7-bit addressing mode 1h = 10-bit addressing mode
14-11	RESERVED	R	0h	
10-1	TADDR	R/W	0h	I2C Target Address This field specifies bits A9 through A0 of the Target address. In 7-bit addressing mode as selected by MSA.MODE bit, the top 3 bits are don't care 0h = Smallest value 3FFh = Highest possible value
0	DIR	R/W	0h	Receive/Send The DIR bit specifies if the next Controller operation is a Receive (High) or Transmit (Low). 0h = Transmit 1h = Receive 0h = The Controller is in transmit mode. 1h = The Controller is in receive mode.

### 33 CCTR Register (Offset = 1214h) [Reset = 0000000h]

CCTR is shown in [Table 25-55](#).

Return to the [Summary Table](#).

This control register configures the I2C controller operation. The START bit generates the START or REPEATED START condition. The STOP bit determines if the cycle stops at the end of the data cycle or continues to the next transfer cycle, which could be a repeated START. To generate a single transmit cycle, the I2C Controller Target Address (MSA) register is written with the desired address, the RS bit is cleared, and this register is written with ACK = X (0 or 1), STOP = 1, START = 1, and RUN = 1 to perform the operation and stop. When the operation is completed (or aborted due an error), an byte transaction completed interrupt becomes active and the data may be read from the MRXDATA register. When the I2C module operates in Controller receiver mode, a set ACK bit causes the I2C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I2C bus controller requires no further data to be transmitted from the Target transmitter.

**Table 25-55. CCTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	RESERVED	R	0h	
27-16	CBLLEN	R/W	0h	I2C transaction length This field contains the programmed length of bytes of the Transaction. 0h = Smallest value FFFh = Highest possible value
15-6	RESERVED	R	0h	
5	RD_ON_TXEMPTY	R/W	0h	Read on TX Empty 0h = No special behavior 1h = When 1 the Controller will transmit all bytes from the TX FIFO before continuing with the programmed Burst Run Read. If the DIR is not set to Read in the MSA then this bit is ignored. The Start must be set in the MCTR for proper I2C protocol. The Controller will first send the Start Condition, I2C Address with R/W bit set to write, before sending the bytes in the TX FIFO. When the TX FIFO is empty, the I2C transaction will continue as programmed in MCTR and MSA without sending a Stop Condition. This is intended to be used to perform simple I2C command based reads transition that will complete after initiating them without having to get an interrupt to turn the bus around.
4	CACKOEN	R/W	0h	Controller ACK override Enable 0h = No special behavior 1h = When 1 and the Controller is receiving data and the number of bytes indicated in MBLEN have been received, the state machine will generate an rxdone interrupt and wait at the start of the ACK for FW to indicate if an ACK or NACK should be sent. The ACK or NACK is selected by writing the MCTR register and setting ACK accordingly. The other fields in this register can also be written at this time to continue on with the transaction. If a NACK is sent the state machine will automatically send a Stop.
3	ACK	R/W	0h	Data Acknowledge Enable. Software needs to configure this bit to send the ACK or NACK. 0h = The last received data byte of a transaction is not acknowledged automatically by the Controller. 1h = The last received data byte of a transaction is acknowledged automatically by the Controller.
2	STOP	R/W	0h	Generate STOP 0h = The controller does not generate the STOP condition. 1h = The controller generates the STOP condition.
1	START	R/W	0h	Generate START 0h = The controller does not generate the START condition. 1h = The controller generates the START or repeated START condition.

**Table 25-55. CCTR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	BURSTRUN	R/W	0h	I2C Controller Enable and start transaction 0h = In standard mode, this encoding means the Controller is unable to transmit or receive data. 1h = The Controller is able to transmit or receive data.

### 34 CSR Register (Offset = 1218h) [Reset = 0000000h]

CSR is shown in [Table 25-56](#).

Return to the [Summary Table](#).

The status register indicates the state of the I2C bus controller.

**Table 25-56. CSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	RESERVED	R	0h	
27-16	CBCNT	R	0h	I2C Controller Transaction Count This field contains the current count-down value of the transaction. 0h = Smallest value FFFh = Highest possible value
15-7	RESERVED	R	0h	
6	BUSBSY	R	0h	I2C Bus is Busy Controller State Machine will wait until this bit is cleared before starting a transaction. When first enabling the Controller in multi Controller environments, FW should wait for one I2C clock period after setting ACTIVE high before writing to the MTCR register to start the transaction so that if SCL goes low it will trigger the BUSBSY. 0h = The I2C bus is idle. 1h = This Status bit is set on a START or when SCL goes low. It is cleared on a STOP, or when a SCL high bus busy timeout occurs and SCL and SDA are both high. This status is cleared when the ACTIVE bit is low. Note that the Controller State Machine will wait until this bit is cleared before starting an I2C transaction. When first enabling the Controller in multi Controller environments, FW should wait for one I2C clock period after setting ACTIVE high before writing to the MTCR register to start the transaction so that if SCL goes low it will trigger the BUSBSY.
5	IDLE	R	1h	I2C Idle 0h = The I2C controller is not idle. 1h = The I2C controller is idle.
4	ARBLST	R	0h	Arbitration Lost 0h = The I2C controller won arbitration. 1h = The I2C controller lost arbitration.
3	DATAACK	R	0h	Acknowledge Data 0h = The transmitted data was acknowledged 1h = The transmitted data was not acknowledged.
2	ADRACK	R	0h	Acknowledge Address 0h = The transmitted address was acknowledged 1h = The transmitted address was not acknowledged.
1	ERR	R	0h	Error The error can be from the Target address not being acknowledged or the transmit data not being acknowledged. 0h = No error was detected on the last operation. 1h = An error occurred on the last operation.
0	BUSY	R	0h	I2C Controller FSM Busy The BUSY bit is set during an ongoing transaction, so is set during the transmit/receive of the amount of data set in MBLN including START, RESTART, Address and STOP signal generation when required for the current transaction. 0h = The controller is idle. 1h = The controller is busy.

**35 CRXDATA Register (Offset = 121Ch) [Reset = 0000000h]**

CRXDATA is shown in [Table 25-57](#).

Return to the [Summary Table](#).

**I2C Controller RX FIFO Read Data Byte**

This field contains the current byte being read in the RX FIFO stack.

If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

**Table 25-57. CRXDATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	VALUE	R	0h	Received Data. This field contains the last received data. 0h = Smallest value FFh = Highest possible value

### 36 CTXDATA Register (Offset = 1220h) [Reset = 00000000h]

CTXDATA is shown in [Table 25-58](#).

Return to the [Summary Table](#).

I2C Controller Transmit Data Register.

This register is the transmit data register (the interface to the FIFOs). For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO).

**Table 25-58. CTXDATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	VALUE	R/W	0h	Transmit Data This byte contains the data to be transferred during the next transaction. 0h = Smallest value FFh = Highest possible value

### 37 CTPR Register (Offset = 1224h) [Reset = 0000001h]

CTPR is shown in [Table 25-59](#).

Return to the [Summary Table](#).

This register is programmed to set the timer period for the SCL clock and assign the SCL clock to standard mode.

**Table 25-59. CTPR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-7	RESERVED	R	0h	
6-0	TPR	R/W	1h	Timer Period This field is used in the equation to configure SCL_PERIOD : $\text{SCL\_PERIOD} = (1 + \text{TPR}) \times (\text{SCL\_LP} + \text{SCL\_HP}) \times \text{INT\_CLK\_PRD}$ where: SCL_PRD is the SCL line period (I2C clock). TPR is the Timer Period register value (range of 1 to 127). SCL_LP is the SCL Low period (fixed at 6). SCL_HP is the SCL High period (fixed at 4). CLK_PRD is the functional clock period in ns. 0h = Smallest value 7Fh = Highest possible value

**38 CCR Register (Offset = 1228h) [Reset = 0000000h]**

 CCR is shown in [Table 25-60](#).

 Return to the [Summary Table](#).

Controller configuration register

**Table 25-60. CCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8	LPBK	R/W	0h	I2C Loopback 0h = Normal operation. 1h = The controller in a test mode loopback configuration.
7-3	RESERVED	R	0h	
2	CLKSTRETCH	R/W	0h	Clock Stretching. This bit controls the support for clock stretching of the I2C bus. 0h = Disables the clock stretching detection. This can be disabled if no Target on the bus does support clock stretching, so that the maximum speed on the bus can be reached. 1h = Enables the clock stretching detection. Enabling the clock stretching ensures compliance to the I2C standard but could limit the speed due the clock stretching.
1	MCTL	R/W	0h	MultiController mode. In MultiController mode the SCL high time counts once the SCL line has been detected high. If this is not enabled the high time counts as soon as the SCL line has been set high by the I2C controller. 0h = Disable MultiController mode. 1h = Enable MultiController mode.
0	ACTIVE	R/W	0h	Device Active After this bit has been set, it should not be set again unless it has been cleared by writing a 0 or by a reset, otherwise transfer failures may occur. 0h = Disables the I2C Controller operation. 1h = Enables the I2C Controller operation.

### 39 CBMON Register (Offset = 1234h) [Reset = 0000003h]

CBMON is shown in [Table 25-61](#).

Return to the [Summary Table](#).

This register is used to determine the SCL and SDA signal status.

**Table 25-61. CBMON Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1	SDA	R	1h	I2C SDA Status 0h = The I2CSDA signal is low. 1h = The I2CSDA signal is high. Note: During and right after reset, the SDA pin is in GPIO input mode without the internal pull enabled. For proper I2C operation, the user should have the external pull-up resistor in place before starting any I2C operations.
0	SCL	R	1h	I2C SCL Status 0h = The I2CSCL signal is low. 1h = The I2CSCL signal is high. Note: During and right after reset, the SCL pin is in GPIO input mode without the internal pull enabled. For proper I2C operation, the user should have the external pull-up resistor in place before starting any I2C operations.

**40 CFIFOCTL Register (Offset = 1238h) [Reset = 0000000h]**

CFIFOCTL is shown in [Table 25-62](#).

Return to the [Summary Table](#).

I2C Controller FIFO Control

**Table 25-62. CFIFOCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	RXFLUSH	R/W	0h	<p>RX FIFO Flush Setting this bit will Flush the RX FIFO. Before clearing this bit to stop Flush the RXFIFOCNT should be checked to be 0 and indicating that the Flush has completed. 0h = Do not Flush FIFO 1h = Flush FIFO</p>
14-11	RESERVED	R	0h	
10-8	RXTRIG	R/W	0h	<p>RX FIFO Trigger Indicates at what fill level in the RX FIFO a trigger will be generated. Note: Programming RXTRIG to 0x0 has no effect since no data is present to transfer out of RX FIFO. 0h = Trigger when RX FIFO contains &gt;= 1 byte 1h = Trigger when RX FIFO contains &gt;= 2 byte 2h = Trigger when RX FIFO contains &gt;= 3 byte 3h = Trigger when RX FIFO contains &gt;= 4 byte 4h = Trigger when RX FIFO contains &gt;= 5 byte 5h = Trigger when RX FIFO contains &gt;= 6 byte 6h = Trigger when RX FIFO contains &gt;= 7 byte 7h = Trigger when RX FIFO contains &gt;= 8 byte</p>
7	TXFLUSH	R/W	0h	<p>TX FIFO Flush Setting this bit will Flush the TX FIFO. Before clearing this bit to stop Flush the TXFIFOCNT should be checked to be 8 and indicating that the Flush has completed. 0h = Do not Flush FIFO 1h = Flush FIFO</p>
6-3	RESERVED	R	0h	
2-0	TXTRIG	R/W	0h	<p>TX FIFO Trigger Indicates at what fill level in the TX FIFO a trigger will be generated. 0h = Trigger when the TX FIFO is empty. 1h = Trigger when TX FIFO contains ≤ 1 byte 2h = Trigger when TX FIFO contains ≤ 2 byte 3h = Trigger when TX FIFO contains ≤ 3 byte 4h = Trigger when TX FIFO contains ≤ 4 byte 5h = Trigger when TX FIFO contains ≤ 5 byte 6h = Trigger when TX FIFO contains ≤ 6 byte 7h = Trigger when TX FIFO contains ≤ 7 byte</p>

#### 41 CFIFOSR Register (Offset = 123Ch) [Reset = 00000800h]

CFIFOSR is shown in [Table 25-63](#).

Return to the [Summary Table](#).

I2C Controller FIFO Status Register

Note: this Register should only be read when BUSY is 0

**Table 25-63. CFIFOSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	TXFLUSH	R	0h	TX FIFO Flush When this bit is set a Flush operation for the TX FIFO is active. Clear the TXFLUSH bit in the control register to stop. 0h = FIFO Flush not active 1h = FIFO Flush active
14-12	RESERVED	R	0h	
11-8	TXFIFOCNT	R	8h	Number of Bytes which could be put into the TX FIFO 0h = Smallest value 8h = Highest possible value
7	RXFLUSH	R	0h	RX FIFO Flush When this bit is set a Flush operation for the RX FIFO is active. Clear the RXFLUSH bit in the control register to stop. 0h = FIFO Flush not active 1h = FIFO Flush active
6-4	RESERVED	R	0h	
3-0	RXFIFOCNT	R	0h	Number of Bytes which could be read from the RX FIFO 0h = Smallest value 8h = Highest possible value

## 42 \_I2CPECCTL Register (Offset = 1240h) [Reset = 0000000h]

\_I2CPECCTL is shown in [Table 25-64](#).

Return to the [Summary Table](#).

I2C Controller PEC Control Register

**Table 25-64. \_I2CPECCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	
12	PECEN	R/W	0h	<p>PEC Enable</p> <p>This bit enables the SMB Packet Error Checking (PEC). When enabled the PEC is calculated on all bits except the Start, Stop, Ack and Nack. The PEC LSFR and the Byte Counter is set to 0 when the State Machine is in the IDLE state, which occur following a Stop or when a timeout occurs. The Counter is also set to 0 after the PEC byte is sent or received. Note that the NACK is automatically send following a PEC byte that results in a PEC error.</p> <p>The PEC Polynomial is <math>x^8 + x^2 + x^1 + 1</math>.</p> <p>0h = PEC is disabled in Controller mode 1h = PEC is enabled in Controller mode</p>
11-9	RESERVED	R	0h	
8-0	PECCNT	R/W	0h	<p>PEC Count</p> <p>When this field is non zero, the number of I2C bytes are counted (Note that although the PEC is calculated on the I2C address it is not counted at a byte). When the byte count = PECCNT and the state machine is transmitting, the contents of the LSFR is loaded into the shift register instead of the byte received from the Tx FIFO. When the state machine is receiving, after the last bit of this byte is received the LSFR is checked and if it is non-zero, a PEC RX Error interrupt is generated. The I2C packet must be padded to include the PEC byte for both transmit and receive. In transmit mode the FIFO must be loaded with a dummy PEC byte. In receive mode the PEC byte will be passed to the Rx FIFO.</p> <p>In the normal Controller use case, FW would set PECEN=1 and PECCNT=SMB packet length (Not including Target Address byte, but including the PEC byte). FW would then configure DMA to allow the packet to complete unassisted and write MCTR to initiate the transaction.</p> <p>Note that when the byte count = PEC CNT, the byte count is reset to 0 and multiple PEC calculation can automatically occur within a single I2C transaction.</p> <p>Note that any write to the Controller_I2CPECCTL Register will clear the current PEC Byte Count in the Controller State Machine.</p> <p>0h = Minimum Value 1FFh = Maximum Value</p>

### 43 \_PECSR Register (Offset = 1244h) [Reset = 0000000h]

\_PECSR is shown in [Table 25-65](#).

Return to the [Summary Table](#).

Controller PEC Status Register

**Table 25-65. \_PECSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	
17	PECSTS_ERROR	R	0h	This status bit indicates if a PEC check error occurred in the transaction that occurred before the last Stop. Latched on Stop. 0h = Indicates PEC check error did not occur in the transaction that occurred before the last Stop 1h = Indicates if a PEC check error occurred in the transaction that occurred before the last Stop
16	PECSTS_CHECK	R	0h	This status bit indicates if the PEC was checked in the transaction that occurred before the last Stop. Latched on Stop. 0h = Indicates PEC was not checked in the transaction that occurred before the last Stop 1h = Indicates if the PEC was checked in the transaction that occurred before the last Stop
15-9	RESERVED	R	0h	
8-0	PECBYTECNT	R	0h	PEC Byte Count This is the current PEC Byte Count of the Controller State Machine. 0h = Minimum Value 1FFh = Maximum Value

#### 44 TOAR Register (Offset = 1250h) [Reset = 00004000h]

TOAR is shown in [Table 25-66](#).

Return to the [Summary Table](#).

This register consists of seven address bits that identify the I2C device on the I2C bus.

**Table 25-66. TOAR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	TMODE	R/W	0h	This bit selects the addressing mode to be used in Target mode. When 0, 7-bit addressing is used. When 1, 10-bit addressing is used. 0h = Enable 7-bit addressing 1h = Enable 10-bit addressing
14	OAREN	R/W	1h	I2C Target Own Address Enable 0h = Disable OAR address 1h = Enable OAR address
13-10	RESERVED	R	0h	
9-0	OAR	R/W	0h	I2C Target Own Address: This field specifies bits A9 through A0 of the Target address. In 7-bit addressing mode as selected by I2CSOAR.MODE bit, the top 3 bits are don't care 0h = Smallest value 3FFh = Highest possible value

#### 45 TOAR2 Register (Offset = 1254h) [Reset = 0000000h]

TOAR2 is shown in [Table 25-67](#).

Return to the [Summary Table](#).

This register consists of seven address bits that identify the alternate address for the I2C device on the I2C bus.

**Table 25-67. TOAR2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	
22-16	OAR2_MASK	R/W	0h	I2C Target Own Address 2 Mask: This field specifies bits A6 through A0 of the Target address. The bits with value '1' in SOAR2.OAR2_MASK field will make the corresponding incoming address bits to match by default regardless of the value inside SOAR2.OAR2 i.e. corresponding SOAR2.OAR2 bit is a don't care. 0h = Minimum Value 7Fh = Maximum Value
15-8	RESERVED	R	0h	
7	OAR2EN	R/W	0h	I2C Target Own Address 2 Enable 0h = The alternate address is disabled. 1h = Enables the use of the alternate address in the OAR2 field.
6-0	OAR2	R/W	0h	I2C Target Own Address 2 This field specifies the alternate OAR2 address. 0h = Smallest value 7Fh = Highest possible value

#### 46 TCTR Register (Offset = 1258h) [Reset = 0000404h]

TCTR is shown in [Table 25-68](#).

Return to the [Summary Table](#).

I2C Target Control Register

**Table 25-68. TCTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-11	RESERVED	R	0h	
10	TWUEN	R/W	1h	Target Wakeup Enable 0h = When 0, the Target is not allowed to clock stretch on START detection 1h = When 1, the Target is allowed to clock stretch on START detection and wait for faster clock to be available. This allows clean wake up support for I2C in low power mode use cases
9	EN_DEFDEVADR	R/W	0h	Enable Default device address 0h = When this bit is 0, the default device address is not matched. NOTE: it may still be matched if programmed inside SOAR/SOAR2. 1h = When this bit is 1, default device address of 7'h110_0001 is always matched by the Target address match logic.
8	EN_ALRESPADR	R/W	0h	Enable Alert Response Address 0h = When this bit is 0, the alert response address is not matched. NOTE: it may still be matched if programmed inside SOAR/SOAR2 1h = When this bit is 1, alert response address of 7'h000_1100 is always matched by the Target address match logic.
7	EN_DEFHOSTADR	R/W	0h	Enable Default Host Address 0h = When this bit is 0, the default host address is not matched NOTE: it may still be matched if programmed inside SOAR/SOAR2 1h = When this bit is 1, default host address of 7'h000_1000 is always matched by the Target address match logic.
6	RXFULL_ON_RREQ	R/W	0h	Rx full interrupt generated on RREQ condition as indicated in SSR 0h = When 0, RIS:TRXFULL will be set when only the Target RX FIFO is full. This allows the TRXFULL interrupt to be used to indicate that the I2C bus is being clock stretched and that the FW must either read the RX FIFO or ACK/NACK the current Rx byte. 1h = When 1, RIS:TRXFULL will be set when the Target State Machine is in the RX_WAIT or RX_ACK_WAIT states which occurs when the I2C transaction is clock stretched because the RX FIFO is full or the ACKOEN has been set and the state machine is waiting for FW to ACK/NACK the current byte.
5	TXWAIT_STALE_TXFIFO	R/W	0h	Tx transfer waits when stale data in Tx FIFO. This prevents stale bytes left in the TX FIFO from automatically being sent on the next I2C packet. Note: this should be used with TXEMPTY_ON_TREQ set to prevent the Target State Machine from waiting for TX FIFO data without an interrupt notification when the FIFO data is stale. 0h = When 0, the TX FIFO empty signal to the Target State Machine indicates that the TX FIFO is empty. 1h = When 1, the TX FIFO empty signal to the Target State Machine will indicate that the TX FIFO is empty or that the TX FIFO data is stale. The TX FIFO data is determined to be stale when there is data in the TX FIFO when the Target State Machine leaves the TXMODE as defined in the SSR register. This can occur is a Stop or timeout occur when there are bytes left in the TX FIFO.

**Table 25-68. TCTR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	TXTRIG_TXMODE	R/W	0h	<p>Tx Trigger when Target FSM is in Tx Mode</p> <p>0h = No special behavior</p> <p>1h = When 1, RIS:TXFIFOTRG will be set when the Target TX FIFO has reached the trigger level AND the Target State Machine is in the TXMODE as defined in the SSR register.</p> <p>When cleared RIS:TXFIFOTRG will be set when the Target TX FIFO is at or above the trigger level.</p> <p>This setting can be used to hold off the TX DMA until a transaction starts.</p> <p>This allows the DMA to be configured when the I2C is idle but have it wait till the transaction starts to load the Target TX FIFO, so it can load from a memory buffer that might be changing over time.</p>
3	TXEMPTY_ON_TREQ	R/W	0h	<p>Tx Empty Interrupt on TREQ</p> <p>0h = When 0, RIS:TTXEMPTY will be set when only the Target TX FIFO is empty.</p> <p>This allows the TTXEMPTY interrupt to be used to indicate that the I2C bus is being clock stretched and that Target TX data is required.</p> <p>1h = When 1, RIS:TTXEMPTY will be set when the Target State Machine is in the TX_WAIT state which occurs when the TX FIFO is empty AND the I2C transaction is clock stretched waiting for the FIFO to receive data.</p>
2	TCLKSTRETCH	R/W	1h	<p>Target Clock Stretch Enable</p> <p>0h = Target clock stretching is disabled</p> <p>1h = Target clock stretching is enabled</p>
1	GENCALL	R/W	0h	<p>General call response enable</p> <p>Modify only when UCSWRST = 1.</p> <p>0b = Do not respond to a general call</p> <p>1b = Respond to a general call</p> <p>0h = Do not respond to a general call</p> <p>1h = Respond to a general call</p>
0	ACTIVE	R/W	0h	<p>Device Active. Setting this bit enables the Target functionality.</p> <p>0h = Disables the I2C Target operation.</p> <p>1h = Enables the I2C Target operation.</p>

### 47 TSR Register (Offset = 125Ch) [Reset = 0000000h]

TSR is shown in [Table 25-69](#).

Return to the [Summary Table](#).

This register functions as a control register when written, and a status register when read.

**Table 25-69. TSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	
18-9	ADDRMATCH	R	0h	Indicates the address for which Target address match happened 0h = Minimum Value 3FFh = Maximum Value
8	STALE_TXFIFO	R	0h	Stale Tx FIFO 0h = Tx FIFO is not stale 1h = The TX FIFO is stale. This occurs when the TX FIFO was not emptied during the previous I2C transaction.
7	TXMODE	R	0h	Target FSM is in TX MODE 0h = The Target State Machine is not in TX_DATA, TX_WAIT, TX_ACK or ADDR_ACK state with the bus direction set to read. 1h = The Target State Machine is in TX_DATA, TX_WAIT, TX_ACK or ADDR_ACK state with the bus direction set to read.
6	BUSBSY	R	0h	I2C bus is busy 0h = The I2C Bus is not busy 1h = The I2C Bus is busy. This is cleared on a timeout.
5	QCMDRW	R	0h	Quick Command Read / Write This bit only has meaning when the QCMDST bit is set. Value Description: 0: Quick command was a write 1: Quick command was a read 0h = Quick command was a write 1h = Quick command was a read
4	QCMDST	R	0h	Quick Command Status Value Description: 0: The last transaction was a normal transaction or a transaction has not occurred. 1: The last transaction was a Quick Command transaction 0h = The last transaction was a normal transaction or a transaction has not occurred. 1h = The last transaction was a Quick Command transaction.
3	OAR2SEL	R	0h	OAR2 Address Matched This bit gets reevaluated after every address comparison. 0h = Either the OAR2 address is not matched or the match is in legacy mode. 1h = OAR2 address matched and ACKed by the Target.
2	RXMODE	R	0h	Target FSM is in Rx MODE 0h = The Target State Machine is not in the RX_DATA, RX_ACK, RX_WAIT, RX_ACK_WAIT or ADDR_ACK state with the bus direction set to write. 1h = The Target State Machine is in the RX_DATA, RX_ACK, RX_WAIT, RX_ACK_WAIT or ADDR_ACK state with the bus direction set to write.
1	TREQ	R	0h	Transmit Request 0h = No outstanding transmit request. 1h = The I2C controller has been addressed as a Target transmitter and is using clock stretching to delay the Controller until data has been written to the TTXDATA FIFO (Target TX FIFO is empty).

**Table 25-69. TSR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	RREQ	R	0h	Receive Request 0h = No outstanding receive data. 1h = The I2C controller has outstanding receive data from the I2C Controller and is using clock stretching to delay the Controller until the data has been read from the TRXDATA FIFO (Target RX FIFO is full).

**48 TRXDATA Register (Offset = 1260h) [Reset = 0000000h]**

TRXDATA is shown in [Table 25-70](#).

Return to the [Summary Table](#).

**I2C Target RX FIFO Read Data Byte**

This field contains the current byte being read in the RX FIFO stack.

If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

**Table 25-70. TRXDATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	VALUE	R	0h	Received Data. This field contains the last received data. 0h = Smallest value FFh = Highest possible value

**49 TTXDATA Register (Offset = 1264h) [Reset = 0000000h]**

TTXDATA is shown in [Table 25-71](#).

Return to the [Summary Table](#).

I2C Target Transmit Data Register.

This register is the transmit data register (the interface to the FIFOs). For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO).

**Table 25-71. TTXDATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	VALUE	R/W	0h	Transmit Data This byte contains the data to be transferred during the next transaction. 0h = Smallest value FFh = Highest possible value

## 50 TACKCTL Register (Offset = 1268h) [Reset = 0000000h]

TACKCTL is shown in [Table 25-72](#).

Return to the [Summary Table](#).

This register enables the I2C Target to Not Acknowledge (NACK) for invalid data or command or Acknowledge (ACK) for valid data or command. The I2C clock is pulled low after the last data bit until this register is written.

**Table 25-72. TACKCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	RESERVED	R	0h	
4	ACKOEN_ON_PECDONE	R/W	0h	When set this bit will automatically turn on the Target ACKOEN field following the ACK/NACK of the received PEC byte. 0h = No special behavior 1h = When set this bit will automatically turn on the Target ACKOEN field following the ACK/NACK of the received PEC byte.
3	ACKOEN_ON_PECNEXT	R/W	0h	When set this bit will automatically turn on the Target ACKOEN field following the ACK/NACK of the byte received just prior to the PEC byte. Note that when ACKOEN is set the PEC byte will not automatically be ACKed/NACKed by the State Machine and FW must perform this function by writing Target_SACKCTL. 0h = No special behavior 1h = When set this bit will automatically turn on the Target ACKOEN field following the ACK/NACK of the byte received just prior to the PEC byte. Note that when ACKOEN is set the PEC byte will not automatically be ACKed/NACKed by the State Machine and FW must perform this function by writing Target_SACKCTL.
2	ACKOEN_ON_START	R/W	0h	When set this bit will automatically turn on the Target ACKOEN field following a Start Condition. 0h = No special behavior 1h = When set this bit will automatically turn on the Target ACKOEN field following a Start Condition.
1	ACKOVAL	R/W	0h	I2C Target ACK Override Value Note: for General Call this bit will be ignored if set to NACK and Target continues to receive data. 0h = An ACK is sent indicating valid data or command. 1h = A NACK is sent indicating invalid data or command.
0	ACKOEN	R/W	0h	I2C Target ACK Override Enable 0h = A response is not provided. 1h = An ACK or NACK is sent according to the value written to the ACKOVAL bit.

**51 TFIFOCTL Register (Offset = 126Ch) [Reset = 0000000h]**

TFIFOCTL is shown in [Table 25-73](#).

Return to the [Summary Table](#).

I2C Target FIFO Control

**Table 25-73. TFIFOCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	RXFLUSH	R/W	0h	RX FIFO Flush Setting this bit will Flush the RX FIFO. Before clearing this bit to stop Flush the RXFIFOCNT should be checked to be 0 and indicating that the Flush has completed. 0h = Do not Flush FIFO 1h = Flush FIFO
14-11	RESERVED	R	0h	
10-8	RXTRIG	R/W	0h	RX FIFO Trigger Indicates at what fill level in the RX FIFO a trigger will be generated. Note: Programming RXTRIG to 0x0 has no effect since no data is present to transfer out of RX FIFO. 4h = Trigger when RX FIFO contains >= 5 byte 5h = Trigger when RX FIFO contains >= 6 byte 6h = Trigger when RX FIFO contains >= 7 byte 7h = Trigger when RX FIFO contains >= 8 byte
7	TXFLUSH	R/W	0h	TX FIFO Flush Setting this bit will Flush the TX FIFO. Before clearing this bit to stop Flush the TXFIFOCNT should be checked to be 8 and indicating that the Flush has completed. 0h = Do not Flush FIFO 1h = Flush FIFO
6-3	RESERVED	R	0h	
2-0	TXTRIG	R/W	0h	TX FIFO Trigger Indicates at what fill level in the TX FIFO a trigger will be generated. 4h = Trigger when TX FIFO contains ≤ 4 byte 5h = Trigger when TX FIFO contains ≤ 5 byte 6h = Trigger when TX FIFO contains ≤ 6 byte 7h = Trigger when TX FIFO contains ≤ 7 byte

## 52 TFIFOSR Register (Offset = 1270h) [Reset = 00000800h]

TFIFOSR is shown in [Table 25-74](#).

Return to the [Summary Table](#).

I2C Target FIFO Status Register

Note: this Register should only be read when BUSY is 0

**Table 25-74. TFIFOSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	TXFLUSH	R	0h	TX FIFO Flush When this bit is set a Flush operation for the TX FIFO is active. Clear the TXFLUSH bit in the control register to stop. 0h = FIFO Flush not active 1h = FIFO Flush active
14-12	RESERVED	R	0h	
11-8	TXFIFOCNT	R	8h	Number of Bytes which could be put into the TX FIFO 0h = Smallest value 8h = Highest possible value
7	RXFLUSH	R	0h	RX FIFO Flush When this bit is set a Flush operation for the RX FIFO is active. Clear the RXFLUSH bit in the control register to stop. 0h = FIFO Flush not active 1h = FIFO Flush active
6-4	RESERVED	R	0h	
3-0	RXFIFOCNT	R	0h	Number of Bytes which could be read from the RX FIFO 0h = Smallest value 8h = Highest possible value

**53 \_PECCTL Register (Offset = 1274h) [Reset = 0000000h]**

\_PECCTL is shown in [Table 25-75](#).

Return to the [Summary Table](#).

I2C Target PEC Control Register

**Table 25-75. \_PECCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	
12	PECEN	R/W	0h	<p>PEC Enable</p> <p>This bit enables the SMB Packet Error Checking (PEC). When enabled the PEC is calculated on all bits except the Start, Stop, Ack and Nack. The PEC LSFR and the Byte Counter is set to 0 when the State Machine is in the IDLE state, which occur following a Stop or when a timeout occurs. The Counter is also set to 0 after the PEC byte is sent or received. Note that the NACK is automatically send following a PEC byte that results in a PEC error.</p> <p>The PEC Polynomial is <math>x^8 + x^2 + x^1 + 1</math>.</p> <p>0h = PEC transmission and check is disabled 1h = PEC transmission and check is enabled</p>
11-9	RESERVED	R	0h	
8-0	PECCNT	R/W	0h	<p>When this field is non zero, the number of I2C data bytes are counted. When the byte count = PECCNT and the state machine is transmitting, the contents of the LSFR is loaded into the shift register instead of the byte received from the Tx FIFO. When the state machine is receiving, after the last bit of this byte is received the LSFR is checked and if it is non-zero, a PEC RX Error interrupt is generated. The I2C packet must be padded to include the PEC byte for both transmit and receive. In transmit mode the FIFO must be loaded with a dummy PEC byte. In receive mode the PEC byte will be passed to the Rx FIFO.</p> <p>In the normal Target use case, FW would set PECEN=1 and PECCNT=0 and use the ACKOEN until the remaining SMB packet length is known. FW would then set the PECCNT to the remaining packet length (Including PEC bye). FW would then configure DMA to allow the packet to complete unassisted and exit NoAck mode.</p> <p>Note that when the byte count = PEC CNT, the byte count is reset to 0 and multiple PEC calculation can automatically occur within a single I2C transaction</p> <p>0h = Minimum Value 1FFh = Maximum Value</p>

**54 \_PECSR Register (Offset = 1278h) [Reset = 0000000h]**

\_PECSR is shown in [Table 25-76](#).

Return to the [Summary Table](#).

Target PEC Status Register

**Table 25-76. \_PECSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	
17	PECSTS_ERROR	R	0h	This status bit indicates if a PEC check error occurred in the transaction that occurred before the last Stop. Latched on Stop. 0h = Indicates PEC check error did not occur in the transaction that occurred before the last Stop 1h = Indicates PEC check error occurred in the transaction that occurred before the last Stop
16	PECSTS_CHECK	R	0h	This status bit indicates if the PEC was checked in the transaction that occurred before the last Stop. Latched on Stop. 0h = Indicates PEC was not checked in the transaction that occurred before the last Stop 1h = Indicates PEC was checked in the transaction that occurred before the last Stop
15-9	RESERVED	R	0h	
8-0	PECBYTECNT	R	0h	This is the current PEC Byte Count of the Target State Machine. 0h = Minimum Value 1FFh = Maximum Value

The serial peripheral interface (SPI) module provides a standardized serial interface to transfer data between MSPM0 devices and other external devices with SPI interface.

<b>26.1 SPI Overview</b> .....	<b>1519</b>
<b>26.2 SPI Operation</b> .....	<b>1522</b>
<b>26.3 SPI Registers</b> .....	<b>1535</b>

## 26.1 SPI Overview

The SPI module provides a standardized serial interface to transfer data between MSPM0 devices and other external devices using SPI protocols (such as a Sensors, Memory, ADCs, or DACs).

### 26.1.1 Purpose of the Peripheral

The SPI module acts as a controller or peripheral interface for synchronous serial communication with peripheral devices and other controllers. The transmit and receive paths are buffered with internal, independent FIFO memories allowing up to 4 entries with 16-bit width. A DMA interface is also provided to allow the data exchange with the transmit and receive FIFOs.

### 26.1.2 Features

The SPI modules have the following features:

- Configurable as a controller or a peripheral
- Programmable clock bit rate and prescaler
- Separate transmit (TX) and receive (RX) first-in first-out buffers (FIFOs)
- Programmable data frame size from 4-bits to 16-bits (Controller Mode)
- Programmable data frame size from 7-bits to 16-bits (Peripheral Mode)
- Interrupts for transmit and receive FIFOs, overrun and timeout interrupts, and DMA done
- Programmable SPI mode support Motorola SPI or Texas Instruments format
- Direct memory access controller interface (DMA):
  - Separate channels for transmit and receive
  - Transfer complete interrupt

### 26.1.3 Functional Block Diagram

Figure 26-1. SPI Functional Block Diagram

### 26.1.4 External Connections and Signal Descriptions

Figure 26-2 and Table 26-1 show an overview of the pin functions for different operation modes of the SPI module.

Figure 26-2. External Connections for Different SPI Configurations

**Table 26-1. Pin Function Overview**

Standard SPI	Feature
<b>SCLK</b>	<p align="center"><b>SPI clock</b></p> Controller mode: SCLK is an output Peripheral mode: SCLK is an input
<b>PICO</b>	<p align="center"><b>Controller out, peripheral in</b></p> Controller mode: PICO is the data output line Peripheral mode: PICO is the data input line
<b>POCI</b>	<p align="center"><b>Controller in, peripheral out</b></p> Controller mode: POCI is the data input line Peripheral mode: POCI is the data output line
<b>CS0</b>	Chip select signal 0, used in 4-pin mode
<b>CS1</b>	Chip select signal 1, used in 4-pin mode
<b>CS2</b>	Chip select signal 2, used in 4-pin mode
<b>CS3/CD</b>	Chip select signal 3 or Command/Data, used in 4-pin mode

For UNICOMM, to meet timing requirements in controller mode, chip select and clock should be looped back from IOs. This compensates for the IO delays within the SoC. At the device's IOMUX level, CS and SCLK INENA bits will need to be set.

## 26.2 SPI Operation

### 26.2.1 Clock Control

The SPI internal functional clock is selected and divided from the clock sourced to this module.

- Use SPIx.CLKSEL register to select the source of the SPI functional clock.
  - BUSCLK: the current bus clock is selected as the source for SPI. The current bus clock depends on power domain. If the SPI instance is in power domain 1 (PD1) please refer to [MCLK](#), if the SPI instance is in power domain 0 (PD0) refer to [ULPCLK](#).
  - MFCLK: MFCLK is selected as the source for SPI, refer to [MFCLK](#).
  - LFCLK: LFCLK is selected as the source for SPI, refer to [LFCLK](#).
- Use SPIx.CLKDIV register to select the divide ratio of the SPI function clock. Options are from divide by 1 to 8.

The SPI module must be enabled before being configured for use by using the CTL0.EN bit in SPIx.PWREN register (see [peripheral power enable](#)). When the SPI is set up, or the configuration needs to be changed, after enabling power, the SPI peripheral must be configured to the desired configuration and then enabled via CTL0.EN bit to avoid unpredictable behavior during the updates or for the first data received or transmitted afterward.

The maximum SPI frequency supported in the controller and peripheral mode depends on the device clock option and IO option. Please refer to specific device data sheet spec for more information.

### 26.2.2 General Architecture

#### 26.2.2.1 Chip Select and Command Handling

##### 26.2.2.1.1 Chip Select Control

To configure the SPI to be in controller mode by setting the CTL1.CP bit to 1, and to be in peripheral mode by clearing the CTL1.CP bit.

The CTL0.CSSEL bit selects which connected peripheral is addressed by the up to 4 CS signals. The bits are controlled by the SPI module in controller or target/peripheral mode. The selected signal is controlled during the transfers.

The chip select signal needs to be provided by the controller in four-wire mode and the chip select polarity can be inverted by configuring the PINCM.CSx.INV register.

In peripheral mode, the clock is provided by the controller and used by the peripheral to capture the data. The peripheral has the option to operate in 3-wire or 4-wire mode. 4-wire mode only accepts data transfers if the CS is activated.

The CTL0.CSCLR bit controls whether the transmit/receive shift register is automatically cleared when the chip select (CS) signal becomes inactive:

- CTL0.CSCLR = 0: The bit counter state is preserved when CS deactivates the peripheral.
- CTL0.CSCLR = 1: The bit counter is reset to zero when CS deactivates the peripheral.

When using CTL0.CSCLR = 1, observe these timing constraints to ensure proper synchronization:

- CS Inactive Period: Maintain CS in the inactive state for at least two functional clock cycles before reasserting it.
- CS Setup Time: Allow at least 2 SPI functional clock cycles between CS activation and the first clock edge.

These timing requirements help the peripheral resynchronize with the controller after clock-line disturbances or glitches, or during system initialization. This feature applies only when operating in peripheral mode.

---

#### Note

The CSCLR function requires the CS disable pulse to be longer than 2 SPI function clock cycles to properly detect and clear the bit counter in the SPI. The CS lead time (CS active to the first bit clock edge) also needs to be at least 2 SPI function clock cycles.

---

#### 26.2.2.1.2 Command Data Control

When using the Motorola frame format, the CDMODE bit can be set to use the CS3/CD line as signal to distinguish between Command and Data information. This is often used for LCD or data storage devices.

- CD level low: command function
- CD level high: data function

**Command Function:** To send out COMMAND, load CDMODE with 0xF and populate the transmit FIFO with the COMMAND data to be sent; the module will drive CS3/CD low and transmit the COMMAND data on the TX line.

**Data Function with CDMODE as counter:** After the COMMAND data is sent, load CDMODE with the number of data bytes to be transmitted and populate the transmit FIFO with the data to be sent. CS3/CD line will be driven high & data will be transmitted on the TX line; CDMODE will be decremented by 1 after each transmission. CS3/CD line remains high after the counter reaches '0'.

Alternatively, the DATA function can also be implemented in MANUAL mode, by writing CDMODE with a value of '0' and then populating the transmit FIFO. This will pull CS3/CD high and transmit populated in the transmit FIFO.

---

#### Note

1. The CDMODE bit is available only when the CDENABLE configuration bit is set; while the CDENABLE bit can be updated only when the SPI IP is disabled, the CDMODE bit can be updated at any time. 2. The CDMODE bit is not write-locked when counting down; therefore, a write to the CDMODE bit will restart the counter with the new value. 3. Before writing a new value into the CDMODE bit, ensure that the FIFO is empty.

---

### 26.2.2.2 Data Format

The control bit CTL1.MSB defines the direction of data input and output: most-significant-bit (MSB) or least-significant-bit (LSB) first. If the parity is enabled, the parity bits are always received as the last bit.

With the control register bits CTL0.DSS, the bit length per transfer will be defined between 4-16 bits for Controller mode and 7-16 bits for Peripheral mode.

A transfer will be triggered by writing to the TX buffer register. The data write needs to have at least the number of bits of the transfer. For example, if only a byte is written to the TX buffer, but the length of the transfer is > 8, the missing bits will be filled with 0s. On the receive path, the received data will be moved to the RXFIFO or RX buffer after the number of bits defined in the CTL0.DSS register has been received.

The RX and TX buffer shall be accessed with at least the bits covering one transfer.

- 4-8 bits : byte access (Peripheral mode: 7-8 Bits)
- 9-16 bits : 16 bit access

Clock polarity (CTL0.SPO) is used to control the clock polarity when data is not being transferred, and it is only used in the [Motorola SPI frame](#) mode.

- 0h = peripheral produces a steady state LOW value on the CLKOUT pin when data is not being transferred.
- 1h = peripheral produces a steady state HIGH value on the CLKOUT pin when data is not being transferred.

The Clock phase (CTL0.SPH) bit selects the clock edge that captures data and enables the data to change state. It has the greatest impact on the first bit transmitted, either by permitting or not permitting a clock transition before the first data capture edge. Please refer to the [Motorola SPI frame](#) mode section to check the diagrams.

**(Add line here)**

- 0h = Data is captured on the first clock edge transition.
- 1h = Data is captured on the second clock edge transition.

The SPI can be configured to work in Peripheral mode with CTL1.CP bit = 0. In Peripheral mode, the clock is provided by the controller and is available to the peripheral on the CLK pins, which must be configured as inputs. The CS input signal selects/enables the peripheral's data receive path in 4-wire mode.

The SPI can be configured to work in Controller mode with CTL1.CP bit = 1. In Controller mode, the clock needs to be generated by selecting a clock source using the clock select bits. It also needs to control the CS signal depending on the selected protocol.

When setting the CTL1.PEN bit, the last bit will be used as parity to evaluate the integrity of the previous bits. The CTL1.PES bit selects the parity mode (even or odd). When detecting a fault, the interrupt flag RIS.PER is set to mark the data as invalid. Parity checking is a feature to improve the robustness of the communication.

### 26.2.2.3 Delayed data sampling

When the SPI input data arrives late at the POCI pin due to:

- Signal propagation delays
- Slow peripheral response times
- Board routing delays

The controller might sample the wrong data, i.e., it could read the previous bit instead of the current, but at the normal sampling clock edge. The solution for this is to use the CLKCTL.DSAMPLE feature, which allows you to shift the sampling point later within each clock cycle.

### 26.2.2.4 Clock Generation

The SPI includes a programmable bit-rate clock divider and a prescaler to generate the serial output clock (SCLK).

Bit rates supported are up to, the input clocks divided by 2. The input clock selection depends on the specific device, refer to the device data sheet and [Clock Control](#) section.

The SPI functionality can work with any of these selected inputs : BUSCLK, MFCLK and LFCLK

"Functional Clock" is the output after clock division performed according to ratio selected by the CLKDIV register.  
Functional clock = Selected input clock / (1 + CLKDIV)

Functional Clock x 2 (SCLK) is the output after dividing the Functional Clock by the Prescaler value. SCLK =  
Functional Clock / ((1 + SCR )\*2)

#### 26.2.2.5 FIFO Operation

##### Transmit FIFO

The TX FIFO is a 16-bit-wide, 4-location-deep, first-in first-out memory buffer. The CPU writes data to the FIFO by writing the SPI Data Register TXDATA.DATA, and data is stored in the FIFO until the transmission logic reads it out.

When configured as a controller or a peripheral, parallel data is written into the TX FIFO before serial conversion and transmission to the attached peripheral or controller, respectively, through the PICO or POCI pin.

In peripheral mode, the SPI transmits data each time the controller initiates a transaction. If the TX FIFO is empty and the controller initiates a transfer, the peripheral sends undefined/random data to the transmit FIFO. The user or software is responsible for making valid data available to the FIFO as needed. The SPI can be configured to generate an interrupt or a DMA request as configured in the FIFO settings. The transmit FIFO has a TXFIFO\_UNF interrupt to indicate a FIFO underflow condition.

##### Receive FIFO

The RX FIFO is a 16-bit-wide, 4-location-deep, first-in-first-out memory buffer. Data received from the serial interface is stored in the buffer until read by the CPU or DMA, which accesses the read FIFO via the SPIx.RXDATA register.

When configured as a controller or peripheral, serial data is received through the POCI or PICO pin.

With the FIFO fill level trigger signals located in the STAT register (TFE, TNF, RFE, RNF), if the FIFO is full and new data is written to it without first reading data, the RXFIFO overflow event is set. The receive FIFO has an RXFULL interrupt to indicate a FIFO full condition.

#### 26.2.2.6 Loopback mode

The SPI module can be placed into an internal loopback mode for diagnostic or debug work by setting the LBM bit in the CTL1 register. In loopback mode, the data from the TX FIFO can be serially transmitted into the RX FIFO. Data from the RX FIFO can be read to check whether the transmission was correct. External toggling of the IOs has no effect when the module is set to internal loopback mode.

**Figure 26-3. Internal Loop Back Mode**

**26.2.2.7 DMA Operation**

The SPI provides an interface to the DMA controller with separate channels for transmit and receive. The DMA operation of the SPI is enabled through the SPI Event and DMA register. When DMA operation is enabled, the SPI asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data.

For the receive channel a transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured using the RXIFLSEL bit in IFLS register or the receive timeout has triggered, in this case the amount of data received so far will be transmitted.

For the transmit channel a transfer request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level configured using the TXIFLSEL bit in IFLS register. The DMA transfer requests are handled automatically by the DMA controller depending on how the DMA channel is configured.

The DMA transfers can be configured and aligned between the data width of the SPI transfers and the bus accesses width of 8/16 bits to make an efficient usage of the bus. The trigger and transfers are independent for receive and transmit.

See more information about the interrupt and event in [Section 26.2.6.2](#) section.

#### 26.2.2.8 Repeat Transfer mode

With the CTL1.REPEATTX bits the last character transmit will be repeated as defined by the register bits. A value of 0 in CTL1.REPEATTX bits will disable this mode and this function is only available in Controller mode. The transfer will be started with writing a data into the TX Buffer. Then the data will be repeatedly sent with the given value. The behavior is identical as if the data would be written into the TX Buffer that many times as defined by the value here. It can be used to clean a transfer or to pull a certain amount of data from a peripheral.

When REPEATTX is used it needs to be aligned with the data in the FIFO. So the below shown sequence should be used:

- Wait and check till FIFO is empty
- Setup REPEATTX
- Write to TXDATA / FIFO
- Wait till requested data has been received

#### 26.2.2.9 Low Power Mode

The SPI module is located in power domain 1 (PD1) and, as such, is only active in RUN and SLEEP modes. The SPI module needs to be disabled before entering low-power mode. After waking from a low-power mode, the SPI module must be enabled again. If the SPI module is enabled by application software, an entry into STOP or STANDBY low-power mode temporarily disables the SPI module while the device is in STOP or STANDBY mode.

### 26.2.3 Protocol Descriptions

The protocol format mode can be selected by using CTL0.FRF register. The supported options include Motorola 3-wire, Motorola 4-wire, and Texas Instruments Synchronous.

#### 26.2.3.1 Motorola SPI Frame Format

The Motorola SPI interface is a 4-wire interface where the CS signal behaves as a peripheral select. In the 3-wire mode the CS signals is not required and the module behaves as if always selected. The main feature of the Motorola SPI format is that the inactive state and phase of the SCLK signal can be programmed through the SPO and SPH bits in the SPIx.CTL0 control register.

#### SPO Clock Polarity Bit

If the CTL0.SPO clock polarity control bit is clear; it produces a steady-state low value on the SCLK pin when data is not being transferred. If the CTL0.SPO bit is set; it places a steady-state high value on the SCLK pin when data is not being transferred. In 4-wire/controller mode, when CS is idle, SPICLK will be driven to its idle state. In 4-wire/peripheral mode, SCLK is expected to be in the idle state when CD is idle.

#### SPH Phase-Control Bit

The CTL0.SPH phase-control bit selects the clock edge that captures data, and allows it to change state. The state of this bit has the most significant impact on the first bit transmitted, either allowing or preventing a clock transition before the first data capture edge. If the CTL0.SPH phase-control bit is clear, data is captured on the first clock edge transition. If the SPH bit is set, data is captured on the second clock edge transition. In 4-wire mode with SPH =1, the first bit is driven on the CS falling edge and captured on the first clock edge.

#### Motorola SPI Frame Format with SPO = 0 and SPH = 0

[Figure 26-4](#) shows signal sequences for Motorola SPI format with SPO = 0 and SPH = 0.

Q is undefined

**Figure 26-4. Motorola SPI Format With SPO = 0 and SPH = 0**

In this configuration, the following occurs during idle periods:

- SCLK is forced low
- CS is forced high
- The transmit data line PICO is forced low
- When the SPI is configured as a controller, it enables the SCLK pin
- When the SPI is configured as a peripheral, it disables the SCLK pin

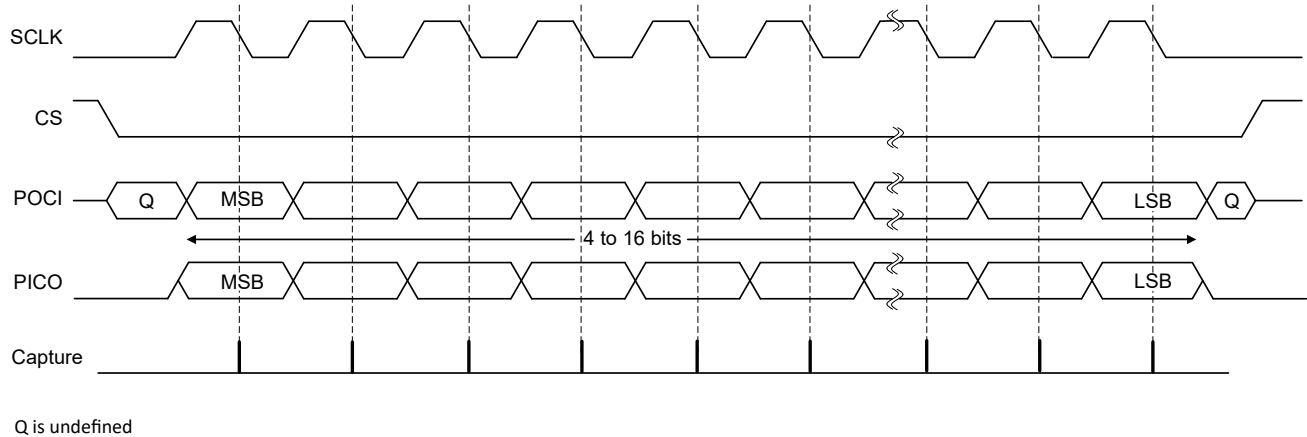

If the SPI is enabled and valid data is in the TX FIFO, the CS controller signal is driven low at the start of transmission which causes enabling of peripheral data onto the POCI input line of the controller. The controller PICO output pin is enabled.

In controller mode, valid controller data is transferred to the PICO pin after one functional clock. Once both the controller and peripheral data are set, the SCLK controller clock pin goes high after an additional one-half SCLK period. The data is captured on the rising edges and propagated on the falling edges of the SCLK signal.

For a single-frame transmission after all bits of the data word are transferred, the CS line is returned to its IDLE high state one SCLK period after the last bit is captured. For continuous back-to-back transmissions, the CS signal must pulse high between each frame word transfer because the peripheral-select pin freezes the data in its serial peripheral register and does not allow altering of the data if the SPH bit is clear. The controller device must raise the CS pin of the peripheral device between each data transfer to enable the serial peripheral data write. When the continuous transfer completes, the CS pin is returned to its IDLE state one SCLK period after the last bit is captured.

### Motorola SPI Frame Format with SPO = 0 and SPH = 1

Figure 26-5 shows the signal sequence for Motorola SPI format with SPO = 0 and SPH = 1.

**Figure 26-5. Motorola SPI Frame Format With SPO = 0 and SPH = 1**

In this configuration, the following occurs during idle periods:

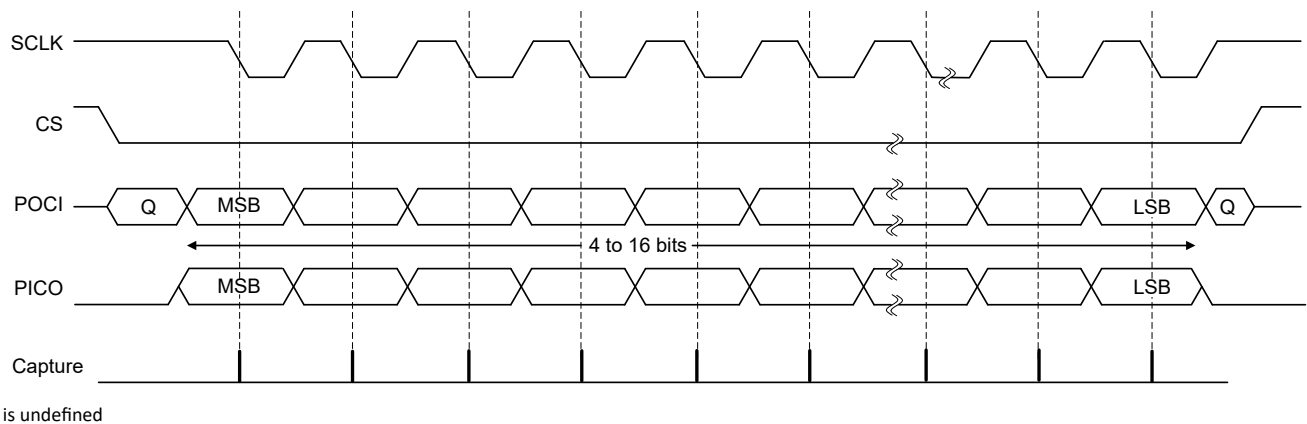

- SCLK is forced low
- CS is forced high
- The transmit data line PICO is forced low
- When the SPI is configured as a controller, it enables the SCLK pin
- When the SPI is configured as a peripheral, it disables the SCLK pin

If SPI is enabled and valid data is present in the TX FIFO, the CS controller signal goes low at the start of transmission. The controller PICO output is enabled.

For a single-frame transfer, after all bits are transferred, the CS line is returned to its IDLE high state one SCLK period after the last bit is captured. For continuous back-to-back transfers, the CS pin is held low between successive data frame and terminates like a single-word transfer.

**Motorola SPI Frame Format with SPO = 1 and SPH = 0**

Figure 26-6 shows signal sequences for Motorola SPI format with SPO = 1 and SPH = 0.

**Figure 26-6. Motorola SPI Frame Format With SPO = 1 and SPH = 0**

In this configuration, the following occurs during idle periods:

- SCLK is forced high
- CS is forced high
- The transmit data line PICO is arbitrarily forced low
- When the SPI is configured as a controller, it enables the SCLK pin
- When the SPI is configured as a peripheral, it disables the SCLK pin

If the SPI is enabled and valid data is in the TX FIFO, the SPI CS controller signal goes low at the start of transmission and transfers peripheral data onto the POCI line of the controller immediately. The controller PICO output pin is enabled.

After one Functional Clock later in controller mode, valid controller data is transferred to the PICO line. When both the controller and peripheral data have been set, the SCLK controller clock pin becomes low after one additional half SCLK period. Data is captured on the falling edges and propagated on the rising edges of the SCLK signal.

For a single-frame transmission after all bits of the data word are transferred, the CS line is returned to its IDLE high state one SCLK period after the last bit is captured. For continuous back-to-back transmissions, the CS signal must pulse high between each data word transfer as the peripheral-select pin freezes the data in its serial peripheral register and keeps it from being altered if the SPH bit is clear. The controller device must raise the CS pin of the peripheral device between each data transfer to enable the serial peripheral data write. When the continuous transfer completes, the CS pin returns to its IDLE state one SCLK period after the last bit is captured.

### Motorola SPI Frame Format with SPO = 1 and SPH = 1

Figure 26-7 shows the signal sequence for Motorola SPI format with SPO = 1 and SPH = 1.

**Figure 26-7. Motorola SPI Frame Format With SPO = 1 and SPH = 1**

In this configuration, the following occurs during idle periods:

- SCLK is forced high
- CS is forced high
- The transmit data line PICO is arbitrarily forced low
- When the SPI is configured as a controller, it enables the SCLK pin
- When the SPI is configured as a peripheral, it disables the SCLK pin

If the SPI is enabled and valid data is in the TX FIFO, the start of transmission is signified by the CS controller signal going low. The controller PICO output pin is enabled. After an additional one-half SCLK period, both controller and peripheral data are enabled onto their respective transmission lines. At the same time, SCLK is enabled with a falling-edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SCLK signal.

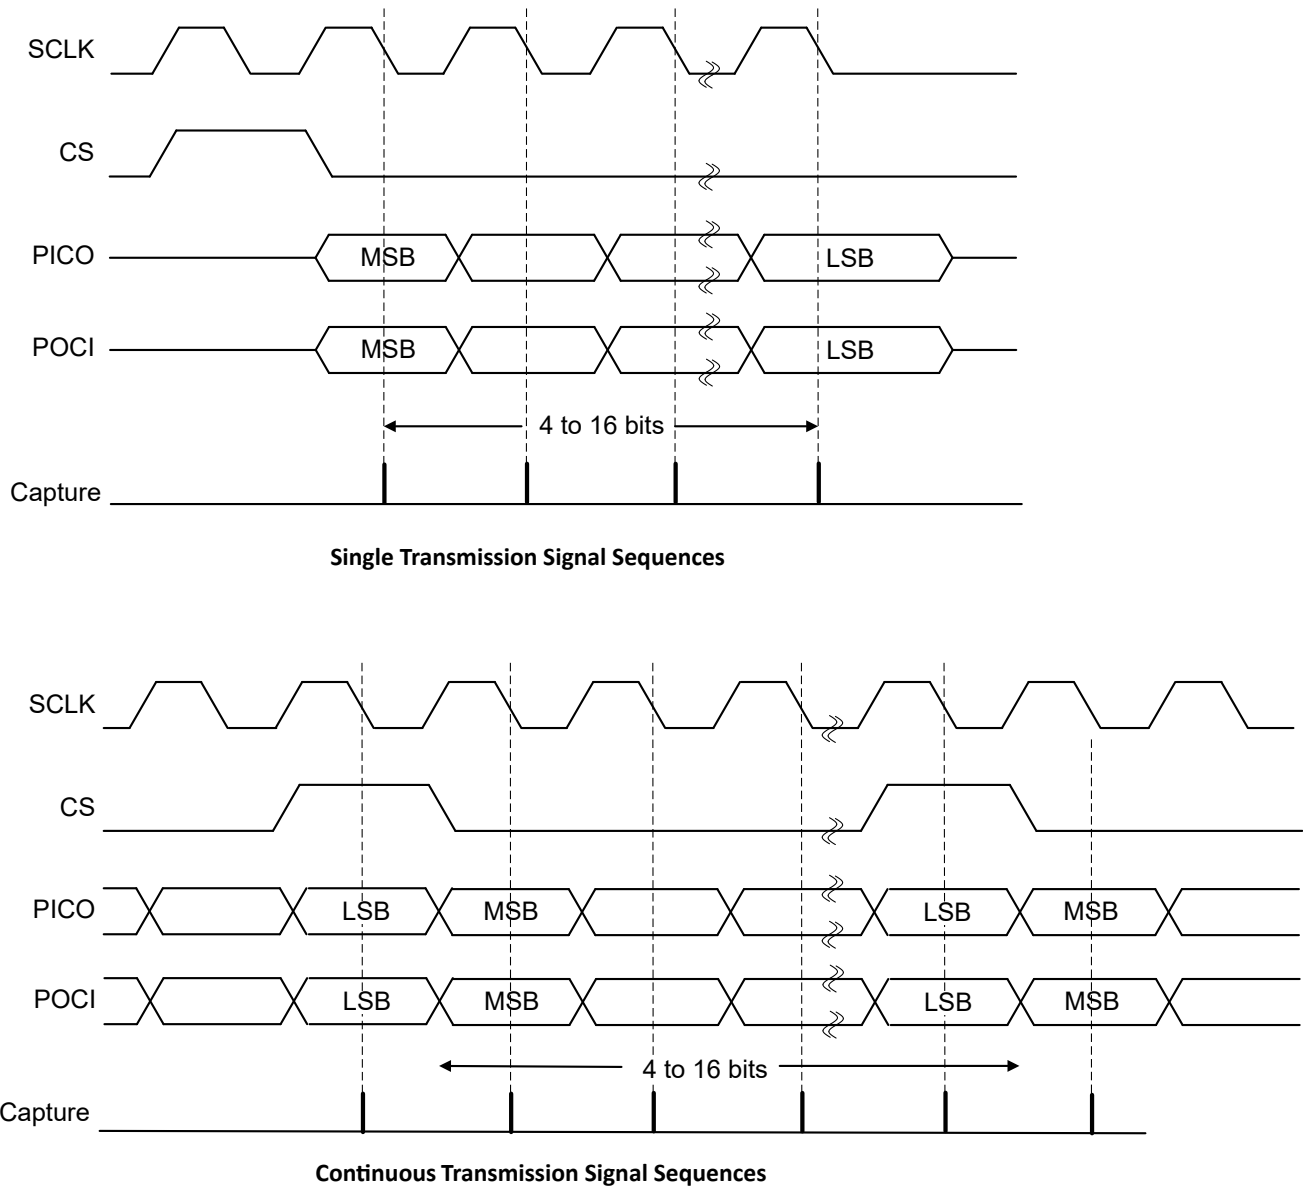

For a single word transmission, after all bits are transferred, the CS line returns to its IDLE high state one SCLK period after the last bit is captured. For continuous back-to-back transmissions, the CS pin remains in its active low state until the final bit of the last word is captured and then returns to its IDLE state. For continuous back-to-back transfers, the CS pin is held low between successive data words and terminates like a single-word transfer.

The serial clock (SCLK) is held inactive while the SPI is idle and SCLK transitions at the programmed frequency only during active transmission or reception of data. The IDLE state of SCLK provides a receive timeout indication that occurs when the RX FIFO still contains data after a timeout period.

**26.2.3.2 Texas Instruments Synchronous Serial Frame Format**

The SPI peripheral is compatible with Texas Instruments Synchronous Serial frame format.

Figure 26-8 shows the TI synchronous serial frame format for a single and continuous transmitted frame.

**Figure 26-8. TI Synchronous Serial Frame Format**

SCLK and CS are forced low and the transmit data line PICO is put in tristate whenever the SPI is idle. When the TX FIFO contains data, CS is pulsed high for one SCLK period. The transmitted value is also transferred from the TX FIFO to the serial shift register of the transmit logic. On the next rising edge of SCLK, the MSB of the 4- to 16-bit data frame is shifted out on the PICO pin. Likewise, the MSB of the received data is shifted onto the POCl pin by the off-chip serial peripheral device. Both the SPI and the off-chip serial peripheral device then

clock each data bit into their serial shifter on each falling edge of SCLK. The received data is transferred from the serial shifter to the RX FIFO on the first rising edge of SCLK after the least significant bit (LSB) is latched.

The serial clock (SCLK) is held inactive while the SPI is idle and SCLK transitions at the programmed frequency only during active transmission or reception of data. The IDLE state of SCLK provides a receive time-out indication that occurs when the RX FIFO still contains data after a time-out period.

### 26.2.4 Reset Considerations

#### Software Reset Considerations

A Software reset can be executed with setting the RESETASSERT together with the KEY in the RSTCTL register. An ongoing transfer will be terminated immediately and can leave the software in an undefined state. Therefore, before requesting a Reset an ongoing Transfer should be terminated.

#### Hardware Reset Considerations

A hardware reset also initializes the IO configuration. This sets the IOs to a high impedance state and the data lines can float. If this is critical for the application or connected devices on the SPI interface external pull up or down resistors might be required.

### 26.2.5 Initialization

To enable and initialize the SPI, the following steps are necessary:

1. Configure the IOMUX with the appropriate GPIO pins for which the SPI signals are multiplexed to

---

#### Note

Pull-ups can be used to avoid unnecessary toggles on the SPI pins, which can take the peripheral to a wrong state. In addition, if the SCLK signal is programmed to steady state High through the SPO bit in the CTL0 register, then software must also configure the GPIO port pin corresponding to the SCLK signal as a pull-up.

---

For each of the frame formats, the SPI is configured using the following steps:

1. Ensure that the ENABLE bit in the CTL1 register is clear before making any configuration changes.
2. Select and configure the clock prescale divisor by writing the CLKSEL and CLKDIV register.
3. Select whether the SPI is a controller or peripheral:
  - For controller operations, set the CP bit in the CTL1 register.
  - For peripheral mode, clear the CP bit in the CTL1 register.
4. Configure the clock divisor by writing the CLKCTL register.
5. Please note that a SPI Software reset ( See section 15.3.4) is required when switching SPI protocol format.
6. Configure the CTL0 and CTL1 register with based on the desired protocol, data width and other special configurations.
7. Optionally configure DMA
8. Enable the SPI by setting the ENABLE bit in the CTL1 register.

### 26.2.6 Interrupt and Events Support

The SPI module contains three [event publishers](#) and no [event subscribers](#). One event publisher (CPU\_INT) manages SPI interrupt requests (IRQs) to the CPU subsystem through a [static event route](#). The second and third event publishers (DMA\_TRIG\_RX, DMA\_TRIG\_TX) are used to setup the trigger signaling for the DMA through [DMA event route](#).

The SPI events are summarized in [Table 26-2](#).

**Table 26-2. SPI Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
CPU interrupt	Publisher	SPI	CPU Subsystem	Static route	CPU_INT registers	Fixed interrupt route from SPI to CPU
DMA trigger	Publisher	SPI	DMA	DMA event route	DMA_TRIG_RX registers	Fixed interrupt route from SPI RX to DMA
DMA trigger	Publisher	SPI	DMA	DMA event route	DMA_TRIG_TX registers	Fixed interrupt route from SPI TX to DMA

### 26.2.6.1 CPU Interrupt Event Publisher (CPU\_INT)

The SPI module provides 9 interrupt sources that can source a [CPU interrupt event](#). [Table 26-3](#) lists the CPU interrupt events from the SPI in order of decreasing priority.

**Table 26-3. SPI CPU\_INT Trigger Condition**

IIDX STAT	Name	Description
0x01	RXFIFO_OVF	RXFIFO overflow event. This interrupt is set if an RX FIFO overflow has been detected.
0x02	PER	Parity error event. This bit is set if a Parity error has been detected.
0x03	RTOUT	Peripheral receive timeout event. When in peripheral mode and not receiving data for the CTL1.RXTIMEOUT selected number of functional clock cycles.
0x04	RX	Receive FIFO event. This interrupt is set if the selected receive FIFO level has been reached.
0x05	TX	Transmit FIFO event. This interrupt is set if the selected transmit FIFO level has been reached.
0x06	TXEMPTY	Transmit FIFO empty interrupt. This is set if all data in the transmit FIFO have been shifted out.
0x07	IDLE	SPI Idle. SPI has done finished transfers and changed into IDLE mode. This bit is set when STAT.BUSY bit goes low.
0x08	DMA_DONE1_RX	This interrupt is set if the RX DMA channel sends the DONE signal.
0x09	DMA_DONE1_TX	This interrupt is set if the TX DMA channel sends the DONE signal.

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers.

### 26.2.6.2 DMA Trigger Publisher (DMA\_TRIG\_RX, DMA\_TRIG\_TX)

DMA\_TRIG\_RX and DMA\_TRIG\_TX registers are used to setup the trigger signaling for the DMA. This can be setup in a flexible way to trigger the DMA for receive or transmit events with the trigger conditions in [Table 26-4](#) and [Table 26-5](#).

DMA\_TRIG\_RX is used for triggering the DMA to do a receive data transfer and DMA\_TRIG\_TX is used for triggering the DMA to do a transmit data transfer.

**Table 26-4. SPI DMA\_TRIG\_RX DMA Trigger Condition**

IIDX STAT	Name	Description
0x03	RTOUT	Peripheral receive timeout event. When in peripheral mode and not receiving data for the CTL1.RXTIMEOUT selected number of functional clock cycles.
0x04	RX	Receive FIFO event. This interrupt is set if the selected receive FIFO level has been reached.

**Table 26-5. SPI DMA\_TRIG\_TX DMA Trigger Condition**

IIDX STAT	Name	Description
0x05	TX	Transmit FIFO event. This interrupt is set if the selected transmit FIFO level has been reached.

The DMA trigger event configuration is managed with the DMA\_TRIG\_RX and DMA\_TRIG\_TX event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers and [Section 7.1.3.2](#) for on how DMA trigger event works.

### 26.2.7 Emulation Modes

The module behavior while the device is in debug mode is controlled by the FREE and SOFT bits in PDBGCTL register.

When the device is in debug mode and set into halt mode below behavior can be configured.

**Table 26-6. Debug Mode Peripheral Behavior**

PDBGCTL.FREE	PDBGCTL.SOFT	Function
1	x	Modules continues operation
0	0	Module stops immediately
0	1	Module stops after the next transfer has been finished

## 26.3 SPI Registers

Table 26-7 lists the memory-mapped registers for the SPI registers. All register offset addresses not listed in Table 26-7 should be considered as reserved locations and the register contents should not be modified.

**Table 26-7. SPI Registers**

Offset	Acronym	Register Name	Group	Section

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1	SOFT	R/W	1h	Soft halt boundary control. This function is only available, if <a href="#">FREE</a> is set to 'STOP' 0h = The peripheral will halt immediately, even if the resultant state will result in corruption if the system is restarted 1h = The peripheral blocks the debug freeze until it has reached a boundary where it can resume without corruption
0	FREE	R/W	1h	Free run control 0h = The peripheral freezes functionality while the Core Halted input is asserted and resumes when it is deasserted. 1h = The peripheral ignores the state of the Core Halted input

### 8 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 26-16](#) and described in [Table 26-16](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 26-16. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 20 IIDX (Offset = 1080h) [Reset = 0000000h]

IIDX is shown in [Figure 26-28](#) and described in [Table 26-28](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 26-28. IIDX**

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	
29-24	RXTIMEOUT	R/W	0h	Receive Timeout (only for Peripheral mode) Defines the number of Clock Cycles before after which the Receive Timeout flag RTOUT is set. The time is calculated using the control register for the clock selection and divider in the Controller mode configuration. A value of 0 disables this function. 0h = Smallest value 3Fh = Highest possible value
23-16	REPEATTX	R/W	0h	Counter to repeat last transfer 0: repeat last transfer is disabled. x: repeat the last transfer with the given number. The transfer will be started with writing a data into the TX Buffer. Sending the data will be repeated with the given value, so the data will be transferred X+1 times in total. The behavior is identical as if the data would be written into the TX Buffer that many times as defined by the value here. It can be used to clean a transfer or to pull a certain amount of data by a peripheral. 0h = Smallest value FFh = Highest possible value
15-12	CDMODE	R/W	0h	Command/Data Mode Value When CTL1.CDENABLE is 1, CS3 line is used as C/D signal to distinguish between Command (C/D low) and Data (C/D high) information. When a value is written into the CTL1.CDMODE bits, the C/D (CS3) line will go low for the given numbers of byte which are sent by the SPI, starting with the next value to be transmitted after which, C/D line will go high automatically 0: Manual mode with C/D signal as High 1-14: C/D is low while this number of bytes are being sent after which, this field sets to 0 and C/D goes high. Reading this field at any time returns the remaining number of command bytes. 15: Manual mode with C/D signal as Low. 0h = Manual mode: Data 0h = Smallest value Fh = Manual mode: Command

**Table 26-66. CTL1 Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	CDENABLE	R/W	0h	Command/Data Mode enable 0h = CS3 is used for Chip Select 1h = CS3 is used as CD signal
10-9	RESERVED	R	0h	
8	PTEN	R/W	0h	Parity transmit enable If enabled, parity transmission will be done for both controller and peripheral modes. 0h = Parity transmission is disabled 1h = Parity transmission is enabled
7	RESERVED	R	0h	
6	PES	R/W	0h	Even Parity Select 0h = Odd Parity mode 1h = Even Parity mode
5	PREN	R/W	0h	Parity receive enable If enabled, parity reception check will be done for both controller and peripheral modes In case of a parity miss-match the parity error flag RIS.PER will be set. 0h = Disable Parity receive function 1h = Enable Parity receive function
4	MSB	R/W	0h	MSB first select. Controls the direction of the receive and transmit shift register. 0h = LSB first 1h = MSB first
3	POD	R/W	0h	Peripheral-mode: Data output disabled This bit is relevant only in Peripheral mode. In multiple-peripheral system topologies, SPI controller can broadcast a message to all peripherals, while only one peripheral drives the line. POD can be used by the SPI peripheral to disable driving data on the line. 0h = SPI can drive the MISO output in peripheral mode. 1h = SPI cannot drive the MISO output in peripheral mode.
2	CP	R/W	1h	Controller or peripheral mode select. This bit can be modified only when SPI is disabled, CTL1.ENABLE=0. 0h = Select Peripheral mode 1h = Select Controller Mode
1	LBM	R/W	0h	Loop back mode 0h = Disable loopback mode 1h = Enable loopback mode
0	ENABLE	R/W	0h	SPI enable 0h = Disable module function 1h = Enable module function

### 30 CLKCTL (Offset = 1108h) [Reset = 0000000h]

CLKCTL is shown in [Figure 26-38](#) and described in [Table 26-38](#).

Return to the [Summary Table](#).

Clock prescaler and divider register. This register contains the settings for the Clock prescaler and divider settings.

**Figure 26-38. CLKCTL**

**Table 26-68. CLKCTL Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	DSAMPLE	R/W	0h	Delayed sampling value. In controller mode the data on the input pin will be delayed sampled by the defined clock cycles of internal functional clock hence relaxing the setup time of input data. This setting is useful in systems where the board delays and external peripheral delays are more than the input setup time of the controller. Please refer to the datasheet for values of controller input setup time and assess what DSAMPLE value meets the requirement of the system. Note: High values of DSAMPLE can cause HOLD time violations and must be factored in the calculations. 0h = Smallest value Fh = Highest possible value
27-10	RESERVED	R	0h	
9-0	SCR	R/W	0h	Serial clock divider: This is used to generate the transmit and receive bit rate of the SPI. The SPI bit rate is (SPI's functional clock frequency)/((SCR+1)*2). SCR is a value from 0-1023. 0h = Smallest value 3FFh = Highest possible value

### 31 IFLS (Offset = 110Ch) [Reset = 00000012h]

IFLS is shown in [Figure 26-39](#) and described in [Table 26-39](#).

Return to the [Summary Table](#).

The IFLS register is the interrupt FIFO level select register. You can use this register to define the levels at which the TX, RX and timeout interrupt flags are triggered. The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered when the receive FIFO is filled with two or more characters. Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**Figure 26-39. IFLS**

### 33 RXDATA (Offset = 1130h) [Reset = 0000000h]

RXDATA is shown in [Figure 26-41](#) and described in [Table 26-41](#).

Return to the [Summary Table](#).

#### RXDATA Register

Reading this register returns value(s) of FIFO. If the FIFO is empty the last read value is returned.

Writing has no effect and is ignored.

When PACKEN=1, two entries of the FIFO are returned as a 32-bit value. When PACKEN=0, 1 entry of FIFO is returned as 16-bit value.

**Figure 26-41. RXDATA**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															
R-0h																															

**Table 26-74. RXDATA Field Descriptions**

**Table 26-76. TXDATA Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	0h	<p>Transmit Data</p> <p>When read, last written value will be returned. If the last write to this field was a 32-bit write (with PACKEN=1), 32-bits will be returned and if the last write was a 16-bit write (PACKEN=0), those 16-bits will be returned.</p> <p>When written, one or two FIFO entries will be written depending on PACKEN value. Data values are removed from the transmit FIFO one value at a time by the transmit logic. It is loaded into the transmit serial shifter, then serially shifted out onto the TXD output pin at the programmed bit rate.</p> <p>When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits.</p> <p>0h = Smallest value            FFFFFFFFh = Highest possible value</p>

The UNICOMM module is a run time configurable peripheral capable of supporting UART, I<sup>2</sup>C and SPI.

<b>27.1 Overview</b> .....	<b>1579</b>
<b>27.2 Unicomm Architecture</b> .....	<b>1580</b>
<b>27.3 High-Level Initialization</b> .....	<b>1582</b>
<b>27.4 UNICOMM/SPGSS Registers</b> .....	<b>1582</b>

## 27.1 Overview

UNICOMM is a unified serial communication peripheral capable of operating in multiple different standard serial protocols including UART, SPI, and I2C. Register settings configure which protocol is selected for a given UNICOMM peripheral instance via the IPMODE field. A UNICOMM instance can only be configured for one protocol mode at a time.

Each UNICOMM instance can be configured to operate in one of the following protocol modes, if available:

- UART - Universal Asynchronous Receiver/Transmitter
- SPI - Serial Peripheral Interface
- I2CC - Inter Integrated Circuit Controller
- I2CT - Inter Integrated Circuit Target

This document commonly uses the abbreviation UC<sub>x</sub> to refer to a specific UNICOMM instance, with x being the unique instance number. Individual UNICOMM instances are grouped together into designated Scalable Peripheral Groupings (SPGs) for high level configurations such as I2C pairings. Each grouping uses the naming scheme SPG<sub>x</sub> (or S<sub>x</sub> in the UNICOMM register blocks) where x represents the group number index that the UNICOMM instance belongs to.

The specific UNICOMM and SPG instances available in a device will vary, so it is best to refer to the device-specific data sheet for an exact representation of available instances and configurations. Each UNICOMM instance will also vary in what power domains they are supported in, and whether Direct Memory Access (DMA) is supported or not. The [Available UNICOMM Configurations Per Instance](#) table below lists the configuration options and peripheral types available for each unique UNICOMM instance. The device-specific datasheet will indicate what SPG<sub>x</sub> index each UC<sub>x</sub> instance is grouped within.

**Table 27-1. Available UNICOMM Configurations Per Instance**

Power Domain	UNICOMM Instance (UC <sub>x</sub> )	Available Peripheral Types				DMA support
		UART	SPI	I2C Controller	I2C Target	
PD0	UC0	Advanced	-	Advanced	Advanced	Y
	UC1	Basic+LIN	-	Advanced	Advanced	Y
	UC4	Advanced	Basic	-	-	Y
	UC5	Minimum+Lin	-	Advanced	Advanced	Y
	UC6	-	-	Advanced	-	Y
	UC7	-	-	-	Advanced	Y
	UC10	Advanced	-	-	-	Y
	UC16	Advanced	Basic	Advanced	Advanced	Y
	UC17	Basic+LIN	Basic	Advanced	Advanced	Y
PD1	UC2	-	Advanced	-	-	Y
	UC3	Basic	Basic	-	-	Y
	UC8	Minimum	Basic	-	-	N
	UC9	Minimum+LIN	-	-	-	N
	UC11	Minimum	-	-	-	N
	UC12	Advanced	-	-	-	Y
	UC13	Basic	Basic	Minimum	Minimum	Y
	UC14	Basic+LIN	-	Advanced	Advanced	Y
	UC15	-	-	Advanced	Advanced	Y
	UC18	Basic+LIN	Advanced	-	-	Y

**Table 27-1. Available UNICOMM Configurations Per Instance (continued)**

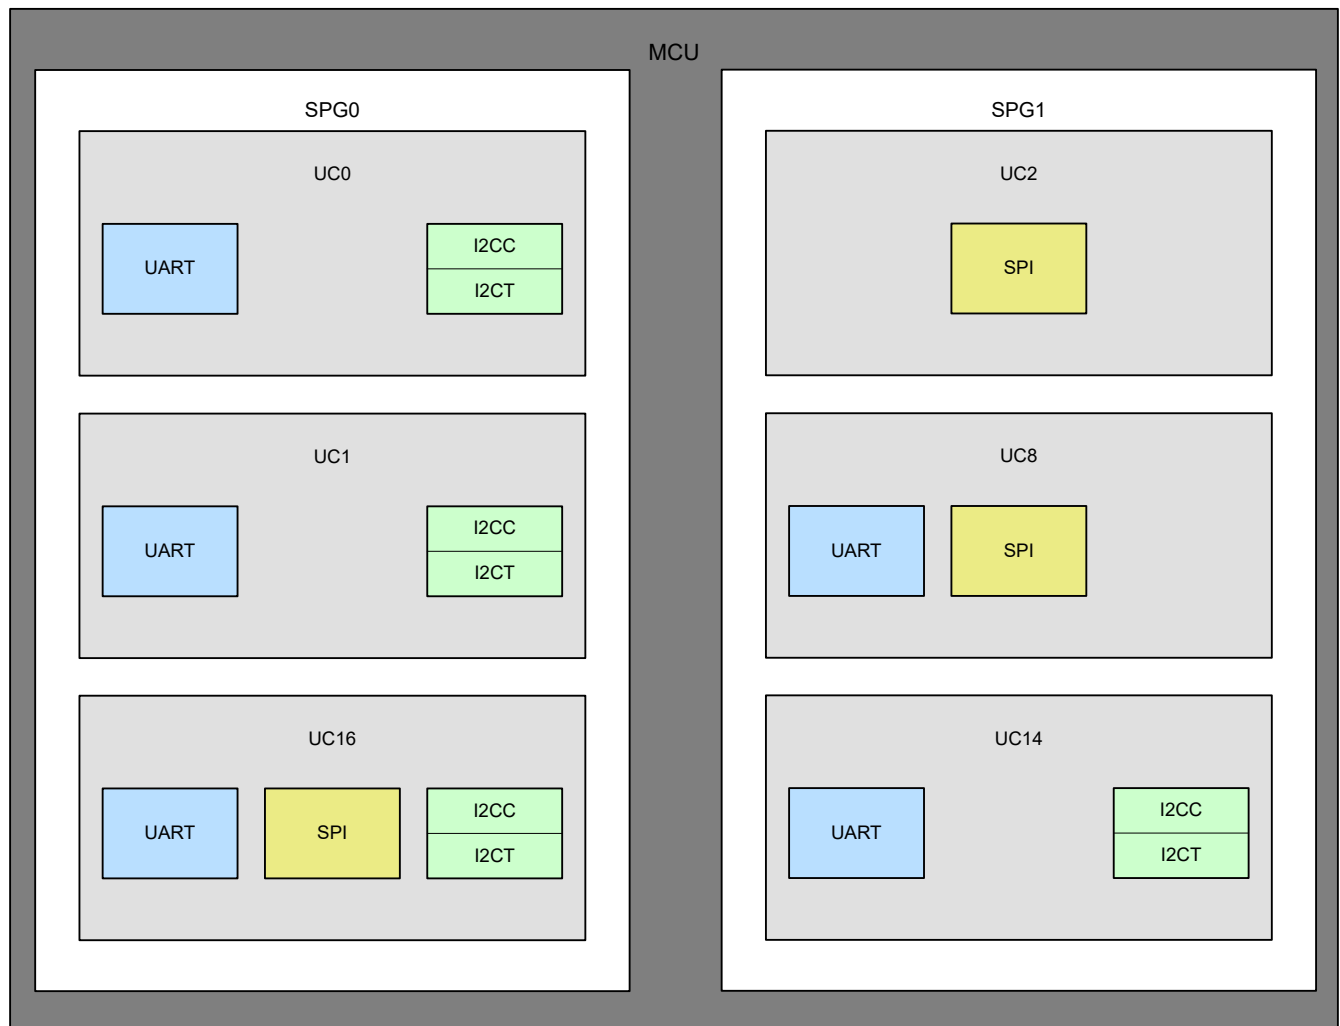

Power Domain	UNICOMM Instance (UCx)	Available Peripheral Types				DMA support
		UART	SPI	I2C Controller	I2C Target	
	UC19	Basic+LIN	-	Advanced	Advanced	Y

This chapter describes all the features and configurations that are common across all UNICOMM instances regardless of the IPMODE configured. This includes FIFO operation, enabling and resetting a UNICOMM instance, the generic transmit and receive sequence, and generic initialization sequence for UNICOMM.

The detailed and protocol-specific operation of each UNICOMM protocol mode is described in each of the below dedicated chapters:

- UART - [UNICOMM-UART](#)
- SPI - [UNICOMM-SPI](#)
- I2CC / I2CT - [UNICOMM-I2C](#)

**27.1.1 Block Diagram**

**Figure 27-1. Unicommm Block Diagram**

**27.2 Unicommm Architecture**

### 27.2.1 Serial Peripheral Group (SPG) Configurations

The Scalable Peripheral Group (SPG) level configurations consist of I2C pairing operation in compliance with the SMBUS protocol, as well as multi-controller systems.

---

#### Note

Users not employing either of the loopback or I2C pairing test features can skip to [Enables & Resets](#) .

---

#### 27.2.1.1 I2C Pairings

I2C pairing supports specialized I2C modes where a controller-target pair are connected to a single external bus. Multi-controller configurations and protocols like SMBus/PMBus require this setup. I2C pairing is available between two UNICOMM instances when both of the below are true:

1. Both UNICOMM modules are configured for I2C communication in the IPMODE register. Controller-Target pairings are supported.
2. Both UNICOMM modules belong to the same SPG instance. Check the *Unicomm Block Diagram* to see which SPG instance the UNICOMM instance belongs to.

I2C pairing connects SDA-to-SDA and SCL-to-SCL lines between two UNICOMM instances within the same SPGSS & they share a single set of SDA/SCL pins at the external pin interface. The I2C pairing control is set through PAIR0 register.

To create an I2C pair within an SPG:

1. Select the UNICOMM to be used as the first I2C (controller) in the loopback and find the local index number of the UNICOMM instance in the SPG.
2. Select the UNICOMM to be used as the second I2C (target) in the loopback and find the local index number of the UNICOMM instance in the SPG.
3. Write the first UNICOMM index to PAIR0.CTL
4. Write the second UNICOMM index to PAIR0.TARGET
5. Enable the loopback by writing a '1' to PAIR0.EN

---

#### Note

The *local* index number of the UNICOMM instance can be found in the UNICOMM detailed description section of the device-specific datasheet. Example: SPG1 may contain two UNICOMM instances (UC2 and UC3) in total. The UC2 would have a local index value of '0' because it is the lowest UNICOMM instance number within the SPG1 module.

---

The I2C pairing feature establishes a controller-target relationship between two UNICOMM modules while maintaining connection to external pins.

When an I2C pair is enabled:

- The SDA/SCL signals from the UNICOMM module specified in PAIR.TARGET are actively propagated to the device pins
- The SDA/SCL signals from the UNICOMM module specified in PAIR.CTL are automatically driven to their IDLE states by the module's internal logic

This configuration allows the TARGET module to control the physical I2C bus while preventing bus contention. Although the PAIR.CTL module's pins are driven to IDLE states internally, these physical pins can still be reassigned through the device's pin multiplexing (pinmux) configuration to serve alternative functions in other peripheral modules if needed.

#### 27.2.2 Enables & Resets

Each UNICOMM instance (UCx) has a dedicated reset and enable bitfield in the UNICOMM\_REGS register group.

The UNICOMM instance can be reset by writing a 1 to the RSTCTL.RESETASSERT bit along with the KEY for RSTCTL. Writing to this field performs a complete reset of the UCx module, which:

- Restores all configuration registers to their default values
- Clears all internal state information
- Empties all FIFO buffers

The STAT.RESETKY bit is set once the UCx module has undergone a reset. To clear the RESETKY bit, write to RSTCTL.RESETSTKYCLR bit and the RESETKY bit won't be set until the next reset is performed.

A UNICOMM instance can be enabled at the UCx level by setting the PWREN.ENABLE bit. Clocking of the UC peripheral-specific registers is not enabled until this PWREN.ENABLE bit is set. Therefore, the IPMODE configuration must be configured after PWREN.ENABLE bit is asserted.

Configure the module by first setting the appropriate protocol mode in the IPMODE register, then proceed to write the specific configuration values into the corresponding protocol registers.

### 27.3 High-Level Initialization

Below are the generic initialization steps to configure a UNICOMM instance and the recommended order for software to execute these steps. Peripheral specific initializations are listed in the respective sections.

1. First, put the UNICOMM instance into reset by setting the RSCTL.RESETASSERT register bit from [UNICOMM Registers](#).
2. Enable power to the UNICOMM instance by writing "0hB1" to the KEY field and setting the EN bit for the PWREN register in [UNICOMM Registers](#).
3. Configure the peripheral mode for the UCx instance in the IPMODE.SELECT field from the [UNICOMM Registers](#) to operate as a UART, SPI, I2C Controller, or I2C Target.
4. (Optionally) Configure the inter-module internal loopback/pairing settings in [SPG Registers](#) between two UCx modules in the same SPG. See the UNICOMM [Block Diagram](#) to understand how UCx pairings are available within a SPG module.
  - a. Configure the loopback pairs (maximum of one pair per SPG module) in the LPBK0 register field.
  - b. Configure the I2C pairs (maximum of one pair per SPG module) in the PAIR0 register field.
5. Enable the pin functionality for each GPIO being used in the peripheral configuration in [IOMUX Registers](#).
6. Configure the below settings in the *UNICOMM-UART Registers / UNICOMM-SPI Registers / UNICOMM-I2C Registers*.
  - a. To enable clocking of the UNICOMM module, configure the clock source in the CLKSEL register to decide the functional clock of UNICOMM.
  - b. Configure the clock divider for the UNICOMM instance's peripheral-specific functional clock in the CLKDIV.RATIO register field. This decides how much to divide down the overall UNICOMM clock source for each specific UNICOMM instance clock.
  - c. Configure the interrupt masks for the peripheral in the CPU\_INT.IMASK register.
  - d. Configure the emulation mode for the peripheral in the PDBGCTL register.
  - e. Perform peripheral-specific initializations (example: SPI peripheral vs. controller mode, UART baud rate etc.) Follow the detailed steps in in the *UART Initialization, SPI Initialization, I2C Controller Initialization, and I2C Target Initialization* chapters.

## 27.4 UNICOMM/SPGSS Registers

### 27.4.1 UNICOMM Registers

This section describes the UNICOMM Registers.

### 27.4.1.1 UNICOMM Registers

Table 27-2 lists the memory-mapped registers for the UNICOMM registers. All register offset addresses not listed in Table 27-2 should be considered as reserved locations and the register contents should not be modified.

**Table 27-2. UNICOMM Registers**

Offset	Acronym	Register Name	Group	Section
800h	PWREN	Power enable		<a href="#">Go</a>
804h	RSTCTL	Reset Control		<a href="#">Go</a>
808h	CLKCFG	Peripheral Clock Configuration Register		<a href="#">Go</a>
814h	STAT	Status Register		<a href="#">Go</a>
1100h	IPMODE	Mode Selection Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 27-3 shows the codes that are used for access types in this section.

**Table 27-3. UNICOMM Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WK	W K	Write Write protected by a key
Reset or Default Value		
-n		Value after reset or the default value

<b>28.1 UNICOMM-UART Overview</b> .....	<b>1599</b>
<b>28.2 UART Operation</b> .....	<b>1600</b>
<b>28.3 UNICOMMUART Registers</b> .....	<b>1626</b>

## 28.1 UNICOMM-UART Overview

The functionality of a UNICOMM module when configured to operate as a UART is described in this section. The protocol mode of a given UNICOMM instance is decided by the programmed SELECT field of the IPMODE register. If a UNICOMM instance is configured for another peripheral mode, the UART functionality on that UNICOMM instance is disabled and unusable.

### 28.1.1 Purpose of the Peripheral

The Universal Asynchronous Receiver/Transmitter (UART) interface is a single-ended, asynchronous serial communication port that transmits (TX) and receives (RX) a programmable length serial bit stream into and out of the device at a programmable baud rate. The UNICOMM UART module can be used to communicate with another device supporting the standard UART protocol.

### 28.1.2 Features

The UNICOMM-UART peripheral mode of the UNICOMM module includes the following features:

- Fully programmable serial interface:
  - 5, 6, 7 or 8 data bits
  - Even, odd, stick, or no-parity bit generation and detection
  - 1 or 2 stop bit generation
  - LSB-first or MSB-first data transmit and receive
  - Line-break detection
  - Glitch filter on the input signal
  - Programmable baud-rate generation with oversampling by 16, 8 or 3
- Separated transmit and receive buffer/FIFO
- Direct Memory Access (DMA) support
- Transmit to receive internal loopback mode operation
- Standard FIFO-level and end-of-transmission interrupts
- Active in all low-power modes (including STOP and STANDBY)
- Support for waking up SYSOSC via an asynchronous fast clock request upon start bit detection when operating in low power modes
- Loopback operation
- Hardware flow control
- 9-bit multi-drop configuration
- Protocols supported:
  - Local Interconnect Network (LIN)
  - DALI
  - IrDA
  - ISO7816 Smart Card
  - RS485
  - Manchester encoding
  - Idle-Line Multiprocessor

Feature	MIN	MIN_LIN	Basic	Basic + LIN	Advanced
Receive timeout / Line timeout	No	No	Yes	Yes	Yes

### 28.1.3 Functional Block Diagram

Figure 28-1. UART Functional Block Diagram

## 28.2 UART Operation

This section describes the operation of the UART peripheral.

### 28.2.1 Clock Control

The UART internal functional clock is selected and divided from the functional clock of the IP.

- Use the CLKSEL register to enable and select the functional clock source for the UNICOMM UART module.
- Use the CLKDIV register to select the divide ratio of the UART functional clock.

The selected source clock is always available and the frequency depends on the power mode, for more information, see the *Clock Module (CKM)* section. After enabling the UART module by setting the CTL0.ENABLE bit, the module is ready to start receiving and transmitting data.

## 28.2.2 General Architecture and Protocol

UART transmits and receives characters at a bit rate that is asynchronous to another device. Timing for each character is based on the selected baud-rate. The transmit and receive functions use the same baud-rate frequency.

Control registers should only be programmed when UART is disabled (ENABLE bit in the CTL0 register is cleared). If UART is operating and gets disabled during transmit or receive operation, the current transaction gets completed before UART stops.

### 28.2.2.1 Signal Descriptions

UART communications require two pins: Receive Data (RX) and Transmit Data (TX):

- RX (Receive Data): The serial data input. Oversampling techniques are used on the receive signal for accuracy of incoming data.
- TX (Transmit Data): The serial data output. When the transmitter is enabled and no data needs to be transmitted, the TX pin is held high (idle). In some bidirectional protocols like ISO7816 Smart card, this pin is also used to receive data.

In hardware flow control mode, the following pins are also used.

- CTS (Clear To Send): The flow control input. When driven high by an external signal, this signal blocks the data transmission at the end of the current transfer.
- RTS (Request To Send): The flow control output. When held low, this signal indicates that the UART is ready to receive data.

### 28.2.2.2 Transmit and Receive Logic

Transmit logic performs parallel-to-serial conversion on data read from transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit, followed by data bits (LSB/MSB first based on configuration), parity bit, and stop bits according to programmed configuration

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and this status accompanies the data that is written to the receive FIFO. Each RX FIFO element is 12-bits wide to include the data bits and all status information.

- CTL0.ENABLE bit is used to enable and disable the UNICOMM-UART module
- CTL0.TXE and RXE bits are used to enable the transmit and receive mode
- LCRH.WLEN bit is used to configure the number of data bits transmitted or received in a frame
- LCRH.PEN is used to enable parity
- CTL0.MSBFIRST is used to send MSB/LSB first
- LCRH.STP2 is used to send one/ two stop bits (one bit is default)

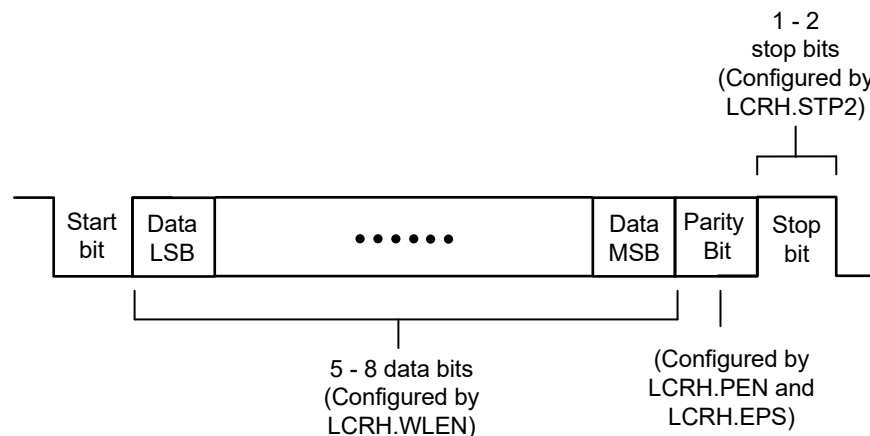

Figure 28-2. UART Character Frame

### 28.2.2.3 Bit Sampling

UNICOMM UART supports oversampling at 3x, 8x, and 16x the UART bus baud-rate.

- By default, CTL0.HSE is set to 0 (16x oversampling). The center sample (sample 8) is used for sampling data on RX line.
- CTL0.HSE set to '1' selects 8x oversampling. The center sample (sample 4) is used for sampling data on RX line.
- CTL0.HSE set to '2' selects 3x oversampling. The center sample (sample 2) is used for sampling data on RX line.

The previously mentioned scenarios assume IBRD =1 and FBRD =0.

Depending on the application:

- Select oversampling by 3 or 8 to achieve **higher speed** with  $UARTclk/8$  or  $UARTclk/3$ . In this case the receiver tolerance to clock deviation is reduced.
- Select oversampling by 16 to increase the **tolerance** of the receiver to clock deviations
  - The maximum speed is limited to  $UARTclk/16$ .

16x oversampling mode (HSE = 0)

8x oversampling mode (HSE = 1)

3x oversampling mode (HSE = 2)

Figure 28-3. UART Oversampling mode

### 28.2.2.4 Majority Voting

Majority voting provides noise immunity by sampling each bit 3 times in the center of the bit period.

For example, when the CTL0.HSE is set to '0' with 16 oversampling; 7th,8th and 9th bit are sampled and majority value is considered as final value to be sampled.

When the CTL0.HSE is set to 1 with 8 oversampling; then 3rd ,4th and 5th bits are sampled and majority value is considered as final value to be sampled. The oversampling is only applicable for 16 and 8 oversampling.

When the 3 selected samples used in majority vote are not the same; RIS.NERR (noise error bit) is set; received data is transferred into the buffer/fifo in spite of noise error. NERR bit will get appended to received data before storing it in receive buffer/FIFO. Majority voting is supported for all data and parity bits. Majority voting or single sample feature can be selected using MAJVOTE control bit in CTL0 register.

---

**Note**

Majority voting should not be enabled for IRDA / MENC mode

---

### 28.2.2.5 Baud Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit sample period. Having a fractional baud-rate divisor allows the UART to generate all of the standard baud-rates very accurately. An example calculation is demonstrated below, however tools like the TI System Configurator can perform these calculations automatically.

The 16-bit integer is loaded through the UART Integer Baud-Rate Divisor IBRD register and the 6-bit fractional part is loaded with the UART Fractional Baud-Rate Divisor FBRD register.

The baud-rate divisor can be calculated by using the following formula:

$$\text{BRD} = \text{UART Clock} / (\text{Oversampling} \times \text{Baud rate}) \quad (28)$$

UART Clock (UARTclk) is the clock output of the UART clock control logic, configured by CLKSEL and CLKDIV. Oversampling is selected by the HSE bit in the CTL0 register and can be configured to 16, 8 or 3.

- IBRD = INT(BRD), integer portion of the BRD
- FBRD = BRD % 64 , fractional portion of the BRD

The integer portion of the BRD is loaded into IBRD register. The 6-bit fractional number must be loaded into the FBRD register.

---

**Note**

When IBRD = 0, FBRD is ignored and no data gets transmitted or received by the UART. Similarly, when IBRD = 65535 (that is 0xFFFF), then FBRD must not be greater than zero. The ongoing transmission or reception is aborted if these requirements are not met.

---

### Baud Rate Configuration

The following example shows a simple method to calculate IBRD.DIVINT and FBRD.DIVFRAC for a baud rate of 19200 bit/s:

$$\text{UARTclk} = \text{CLKDIV} / \text{CLKDIV.RATIO} = 40\text{MHz}$$

$$\text{CRL0.HSE Oversampling} = 16$$

$$\text{Baud Rate} = 19200\text{bit/s}$$

$$\text{BRD} = \text{UARTclk} / (\text{Oversampling} * \text{Baud Rate})$$

$$\text{BRD} = 40\text{MHz} / (16 * 19200 \text{ bit/s}) = 130.2083333$$

Use digits before the decimal to find IBRD.DIVINT:

$$130.208333 \rightarrow \text{IBRD.DIVINT} = 130\text{d} \rightarrow 82\text{h}$$

Use digits after the decimal to find FBRD.DIVFRAC:

$$130.208333 \rightarrow \text{INT}((.2083333 * 64) + 0.5) = \text{INT}(13.833333) = 13\text{d} \rightarrow \text{Dh}$$

---

### Note

The +0.5 adder guarantees rounding to the closest integer value to keep the rounding error as small as possible

---

Baud rate settings (IBRD / FBRD) should only be updated when the module is IDLE. Application must ensure STAT.IDLE is '0' prior to updating IBRD/FBRD settings.

#### 28.2.2.6 Data Transmission

Data received or transmitted is stored in two 16-element FIFOs, where the receive FIFO has an extra four bits per character for status information.

##### Transmit data

- Data is written into TXDATA
  - If UART is enabled, the data frame begins transmitting with the parameters indicated in the LCRH register
  - Data continues to be transmitted until there is no data left in the transmit FIFO
- The BUSY bit in the STAT register is asserted when data is written to the transmit buffer/FIFO and remains asserted while data is being transmitted
- BUSY bit is '0' when transmit buffer/FIFO is empty (the last character has been transmitted to the shift register, including the stop bits)
  - BUSY bit is also is set during the generation of a BREAK signal

##### Receive data

- When the receiver is in an idle state and the data input transitions to a low level (START condition detected), the receive counter starts running and data bits are sampled according to the oversampling settings
  - START/STOP bits are not oversampled
- Each START bit is sampled to verify it reads '0'
  - If START reads '1', the state machine transitions back to IDLE state
- Each STOP bit is sampled to verify it reads '1'
  - If STOP reads '0', a framing error (FRMERR) is set
- When the full word is received, the data is stored in the receive buffer/FIFO along with error bits associated with it
- The BUSY flag is set high when a START condition is detected and is set to low after the full duration of the STOP bit

#### 28.2.2.7 Error and Status

For received data, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive buffer/FIFO. The error and status can be can be retrieved by reading RXDATA register as showing in [Table 28-1](#). Each of the four below conditions can also set the interrupt flag RXINT if the corresponding interrupt bit is enabled in the IMASK register.

**Table 28-1. UART Error and Conditions**

Error Condition	Bit Field	Description
Framing error	FRMERR	A framing error occurs when a low stop bit is detected. When two stop bits are used, both stopbits are checked for framing error. When a framing error is detected, the FRMERR bit is set
Parity error	PARERR	A parity error is a mismatch between the number of 1s in a character and the value of the parity bit. When an address bit is included in the character, it is included in the parity calculation. When a parity error is detected, the PARERR bit is set
Noise error	NERR	A noise error occurs when the 3 sampled values used for majority voting are not the same. When a noise error occurs, NERR bit is set
Break condition	BRKERR	A break is detected when all received data, parity, and stop bits are 0. When a break condition is detected, the BRKERR bit is set

The UART module flag status can also be checked by reading the STAT register.

**Table 28-2. UART Flag Status**

Bit Field	Description
BUSY	This bit is set as soon as the transmit FIFO becomes non-empty (regardless of whether UART is enabled). In IDLELINE mode (when the CTL0.MODE field is configured for IDLELINE), the BUSY signal also stays set during the idle time generation.
RXFE	This bit is set when the receive FIFO is empty.
RXFF	This bit is set when the receive FIFO is full.
TXFE	This bit is set when transmit FIFO is empty.
TXFF	This bit is set when transmit FIFO is full.
CTS	This bit is set when CTS signal is asserted (low) and cleared when CTS signal is not asserted (high).
IDLE	This bit is set when an IDLE line has been detected in idle-line multiprocessor mode. The IDLE bit is used as an address tag for each block of characters. In idle line multiprocessor format, this bit is set when a received character is an address.

### 28.2.2.8 DMA Operation

The UNICOMM-UART provides an interface to the DMA module with separate channels for transmit and receive. The DMA operation of the UART is enabled through the UART Event and DMA registers. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. The DMA transfer requests are handled automatically by the DMA controller based on how the DMA channel is configured (burst size, transfer size, source address etc.).

- For the receive channel, a DMA transfer request is asserted when the amount of data in the receive FIFO is at or above the FIFO trigger level configured using the RXIFLSEL bit in IFLS register or if the receive timeout has triggered. In the receive timeout trigger case, the amount of data received up to that point is transferred.

#### Note

The DMA moves all data present in the RX FIFO once triggered, not just the amount configured by the RXIFLSEL field.

- For the transmit channel, a DMA transfer request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level configured using the TXIFLSEL bit in IFLS register.

### 28.2.2.9 Loopback Operation

The UNICOMM-UART can be placed into an internal loopback mode for diagnostic or debug work by setting the LBE bit in the CTL0 register. In loopback mode, the UART operates with the following behavior:

- Data transmitted on the TX output is received on the RX input
- Data transmitted on the TX output is not propagated to the TX IO pin
- Data received on the RX IO pin is ignored

**Figure 28-4. UART Internal Loopback**

### 28.2.2.10 Resets

The UNICOMM has a general software reset for the UNICOMM module. You can find more information in the [UNICOMM Enables & Resets section](#).

### Hardware Reset Considerations

A hardware reset also initializes the IO configuration. This sets the IOs to a high-impedance state, allowing the data lines to float. If this is critical for the application or connected devices on the SPI interface, external pull-up or pull-down resistors might be required.

### 28.2.2.11 Initialization

Follow the high-level UNICOMM configurations in [Section 27.3](#) before executing the below UART-specific configurations.

To enable and initialize the UART, perform the following initialization steps:

1. Clear the ENABLE bit in the CTL0 register before making any of the below configuration changes.
2. Use the baud-rate equation in [Section 28.2.2.5](#) to calculate the IBRD and FBRD registers.
3. Write the integer portion of the BRD to the IBRD register.
4. Write the fractional portion of the BRD to the FBRD register.
5. Write the desired communication mode settings to the CTL0 register (all CTL0 fields other than ENABLE).
6. Write the desired serial parameter configurations to the LCRH register.
7. Configure the desired FIFO trigger levels in the IFLS register.
8. Enable desired interrupts and/or DMA event by using CPU\_INT, DMA\_TRIG\_RX, DMA\_TRIG\_TX group IMASK registers.
9. (Optionally) Configure the emulation mode for the peripheral in the PDBGCTL register.
10. Enable the UART by setting the CTL0.ENABLE bit.

---

### Note

Before UNICOMM-UART is setup or configuration changes, the CTL0.ENABLE bit must be cleared to avoid unpredictable behavior during the updates or for the first data receive or transmitted afterward.

---

### 28.2.2.12 FIFO Operation

The UNICOMM-UART has two FIFOs (one each for transmit/receive) with configurable depth. FIFOs are accessed via TXDATA & RXDATA registers.

### FIFO Status Bits

Each module will support the below FIFO status bits:

- Receive FIFO Full: when all elements are populated
- Receive FIFO Empty: when there are no elements in the HEAD
- Transmit FIFO Full: when all elements are populated
- Transmit FIFO Empty: when are no elements in the FIFO

In addition to this, FIFO clear status – RXCLR/TXCLR will also be present

### RIS.RXINT Based on FIFO Threshold Settings

On transmit side, data is written by the CPU/DMA master at top most empty FIFO entry and then transferred to serializer. Thresholds are as per elements that can be written into the FIFO.

1. RX\_FIFO full: when all elements are populated
2. RX\_FIFO  $\geq$   $\frac{1}{4}$  full
3. RX\_FIFO  $\geq$   $\frac{1}{2}$  full
4. RX\_FIFO  $\geq$   $\frac{3}{4}$  full
5. RX\_FIFO almost empty:  $\leq$  1 element
6. RX\_FIFO almost full:  $\geq$  (N-1) elements
7. **RX\_FIFO not empty: opposite of empty**

### RIS.TXINT based on FIFO threshold settings

On transmit side, data is written by the CPU/DMA master at topmost empty FIFO entry and then transferred to serializer. Thresholds are as per elements that can be written into the FIFO.

1. TX\_FIFO empty: when there no elements in the FIFO
2. TX\_FIFO  $\leq$   $\frac{3}{4}$  empty
3. TX\_FIFO  $\leq$   $\frac{1}{2}$  empty
4. TX\_FIFO  $\leq$   $\frac{1}{4}$  empty
5. TX\_FIFO almost empty:  $\leq$ 1 element
6. TX\_FIFO almost full:  $\geq$  (N-1) elements
7. **TX\_FIFO not full: opposite of full**

---

#### Note

- Receive FIFO Almost Empty and Transmit FIFO Almost Full options are provided in IFLS setting; however, these should not be used for generating flags based on watermark settings or for DMA usage. Application has to ensure that correct FIFO Thresholds are used.
  - Debugger initiated reads should not pop contents out of the FIFO. However, debugger initiated writes into the transmit FIFO should be treated as valid entries.
- 

### Clearing FIFO Contents

**FIFO clear:** to clear contents of the FIFO, sequence needs to be used:

- Write '1' to CLEAR control bit (TX\_CLEAR / RX\_CLEAR)
- Wait for clear to complete, i.e. CLEAR status bit reflects '1'; poll/check for CLEAR status bit to reflect '1'
- Write '0' to CLEAR control bit

---

#### Note

Randomly changing FIFO levels when FIFO has contents might lead undesired behavior. It is recommended that FIFO is cleared before changing FIFO thresholds

---

### Hardware monitors empty, full and overrun conditions

The STAT register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits), and the RIS register shows overrun status of the receive FIFO via the OVRERR bit. There is no indicator for a transmit FIFO overrun. A write is just lost, in case it overruns the transmit FIFO. If the FIFOs are not present, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

---

**Note**

*Data will be lost if the FIFO is full and overflow flag bit will be set*

---

Out of reset, both FIFOs are configured to trigger an interrupt at half-level mark.

FIFO integrity is not guaranteed if software disables the module in the middle of a transmission with data in the FIFO, and then re-enables it. When the module gets reset the content of the FIFO are also cleared

### 28.2.2.13 Interrupt and Events Support

The UART module contains three event publishers and no event subscribers. One event publisher (CPU\_INT) manages UART interrupt requests (IRQs) to the CPU subsystem through a static event route. The second and third event publishers (DMA\_TRIG\_RX, DMA\_TRIG\_TX) are used to setup the trigger signaling for the DMA through DMA event route.

**Table 28-3. UART Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
CPU interrupt	Publisher	UART	CPU Subsystem	Static route	CPU_INT registers	Fixed interrupt route from UART to CPU
DMA trigger	Publisher	UART	DMA	DMA event route	DMA_TRIG_RX registers	Fixed interrupt route from UART to DMA
DMA trigger	Publisher	UART	DMA	DMA event route	DMA_TRIG_TX registers	Fixed interrupt route from UART to DMA

#### 28.2.2.13.1 CPU Interrupt Event Publisher (CPU\_INT)

The UART module provides 19 interrupt sources which can be configured to source a CPU interrupt event. In order of decreasing interrupt priority, the CPU interrupt events from the UART are:

**Table 28-4. UART CPU Interrupt Event Conditions (CPU\_INT)**

IIDX STAT	Name	Description
0x01	RTOUT	UART receive timeout interrupt. This interrupt is asserted when the RX FIFO is not empty, and no further data is received specified time in the IFLS.RXIFSEL field.
0x02	FRMERR	UART framing error interrupt.
0x03	PARERR	UART parity error interrupt.
0x04	BRKERR	UART break error interrupt.
0x05	OVRERR	UART receive overrun error interrupt.
0x06	RXNE	Falling edge on RX interrupt, this interrupt triggers when there is a falling edge on RX line.
0x07	RXPE	Rising edge on RX interrupt, this interrupt triggers when there is a rising edge on RX line.
0x08	LINC0	LIN capture 0 match interrupt, this interrupt triggers when the defined capture 0 value is reached in LIN counter.
0x09	LINC1	LIN capture 1 match interrupt, this interrupt triggers when the defined capture 1 value is reached in LIN counter.
0x0A	LINOVF	LIN counter overflow interrupt, this interrupt triggers when the 16bit LIN counter overflows.
0x0B	RXINT	UART receive interrupt.
0x0C	TXINT	UART transmit interrupt.
0x0D	EOT	UART end of transmission interrupt indicates that the last bit of all transmitted data and status has left the serializer and without any further data in the TX FIFO.
0x0E	ADDR_MATCH	Address match interrupt, used in protocols with address to indicate address match happened.

**Table 28-4. UART CPU Interrupt Event Conditions (CPU\_INT) (continued)**

<b>IDX STAT</b>	<b>Name</b>	<b>Description</b>
0x0F	CTS	UART clear to send interrupt, indicate the CTS signal status.
0x10	DMA_DONE_RX	This interrupt is set if the RX DMA channel sends the DONE signal.
0x11	DMA_DONE_TX	This interrupt is set if the TX DMA channel sends the DONE signal.
0x12	NERR	The noise error interrupt is set when the 3 sampled values used for majority voting are not the same
0x15	LTOUT	UART line timeout interrupt, This interrupt is asserted when no further data is received specified time in the IFLS.RXTOSEL bits.

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See the *Event Registers* chapter.

The receive timeout interrupt is asserted when the RX FIFO is not empty, and no further data is received specified time in the IFLS.RXIFSEL bits. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), by reading the interrupt index from IIDX or when a 1 is written to the corresponding bit in the ICLR register.

The receive interrupt (RXINT) is set when the RX FIFO progresses through the programmed trigger level. The receive interrupt is cleared by reading data from the RX FIFO until it becomes less than the trigger level, by reading the interrupt index from IIDX, or by writing a '1' to the RXINT bit in ICLR.

The transmit interrupt (TXINT) is set when the TX FIFO progresses through the programmed trigger level. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the TX FIFO until it becomes greater than the trigger level, by reading the interrupt index from IIDX, or by writing a '1' to the TXINT bit in ICLR.

#### **28.2.2.13.2 DMA Trigger Publisher (DMA\_TRIG\_RX, DMA\_TRIG\_TX)**

The DMA\_TRIG\_TX and DMA\_TRIG\_RX group registers are used to setup trigger signaling for the DMA. These registers (IMASK, RIS, MIS, ISET, ICLR) are present for any UCx configured as UART and can be found in the corresponding UNICOMMUART\_REGS register structures. See *DMA Trigger* for how the DMA trigger Event works and can be configured. Each DMA channel can be triggered by any of the conditions listed in the *DMA Trigger Source Options* and can send a DMA\_DONE signal to the corresponding UCx module.

**Table 28-5. UART DMA Trigger Condition (DMA\_TRIG\_RX)**

<b>Name</b>	<b>Description</b>
RTOUT	UART receive timeout trigger, This interrupt is asserted when the RX FIFO is not empty, and no further data is received specified time in the IFLS.RXTOSEL bits.
RXINT	UART RX FIFO level trigger.

The receive timeout trigger is asserted when the RX FIFO is not empty, and no further data is received for the amount of time programmed by the IFSEL.RXTOSEL field. The receive timeout interrupt is cleared when the RX FIFO becomes empty through reading all the data, by reading the interrupt index from IIDX, or when a 1 is written to the RTOUT bit in the ICLR register.

The receive interrupt (RXINT) is set when the RX FIFO reaches the programmed trigger level. The receive interrupt is cleared by reading data from the RX FIFO until the level becomes less than the trigger level, by reading the interrupt index from IIDX, or by writing a '1' to the RXINT bit in ICLR.

**Table 28-6. UART DMA Trigger Condition (DMA\_TRIG\_TX)**

<b>Name</b>	<b>Description</b>
TXINT	UART TX FIFO level trigger..

The transmit interrupt (TXINT) is set when the TX FIFO progresses through the programmed trigger level. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts are generated. The transmit interrupt is cleared by writing

data to the TX FIFO until the level becomes greater than the trigger level, by reading the interrupt index from IIDX, or by writing a '1' to the TXINT bit in ICLR.

#### 28.2.2.14 Emulation Modes

The module behavior while the device is in debug mode is controlled by the FREE and SOFT bits in PDBGCTL register.

When the device is in debug mode and set into halt mode below behavior can be configured.

**Table 28-7. Debug Mode Peripheral Behavior**

PDBGCTL.FREE	PDBGCTL.SOFT	Function
1	x	Modules continues operation
0	1	Module stops after the next transfer has been finished
x	0	SOFT = 0h is <b>not</b> supported

#### Graceful Halt

When emulation mode is set to graceful halt and a halt condition occurs, the IP stops communications after the ongoing frame has finished.

##### Transmitter

1. IP finishes transmitting the ongoing frame; FSM returns to IDLE and stop
2. External line is driven to IDLE condition
3. Removing halt resumes communication

##### Receiver

1. IP receives ongoing frame; FSM returns to IDLE and stop
2. Any new messages are not be processed
3. After halt is removed; FSM begins communications
4. FSM can start reception in the middle of a frame

### 28.2.3 Additional Protocol and Feature Support

#### 28.2.3.1 Local Interconnect Network (LIN) Support

The Local Interconnect Network (LIN) protocol standard is based on the UART serial data link format. The LIN communication protocol is a single-commander/multiple-responder topology with message identification for multicast transmission between network nodes.

## Message Frame

**Figure 28-5. LIN Protocol Message Structure**

The LIN commander issues a BREAK field, SYNC field, and PID (Protected Identifier) field at the start of every frame. The four LIN registers are used so that the LIN responder software driver can reasonably detect BREAK and SYNC fields and measure the necessary timing parameters to adjust the baud rate or detect an error.

See the [LIN Standards and Specifications](#) page for more information about the LIN protocol standards. The UNICOMM-UART module in LIN mode can operate as a LIN commander or a LIN responder when configured properly. To support the LIN protocol while reducing the number of interrupts needed in software, the following hardware enhancements are included in the UNICOMM-UART module:

- **LIN Control** - LINCTL
  - Configuration of LIN mode behavior.
- **LIN Counter** - LINCNT
  - 16-bit up-counter clocked by the UARTclk.
  - CPU\_INT.IMASK.LINOVF flag - Interrupt capability on counter overflow.
- **LIN Capture 0** - LINC0
  - 16-bit Capture 0 with two configurable modes:
    - If LINCTL.LIN0CAP is set - Capture of the LINCNT value on RX pin falling edge. Interrupt capability on capture (CPU\_INT.IMASK.LINC0).
    - If LINCTL.LIN0\_MATCH is set - Compare of the LINCNT with interrupt capability on match (CPU\_INT.IMASK.LINC0).
- **LIN Capture 1** - LINC1: 16-bit Capture 1.
  - Capture LINCNT value on RX pin rising edge. Interrupt capability on capture (CPU\_INT.IMASK.LINC0).

Additionally, software can manually control the logic level output of the UNICOMM-UART TXD pin by writing the CTL0.TXD\_OUT bit when the CTL0.TXD\_OUT\_EN is set to 1 with CTL0.TXE set to 0 (transmits disabled). To generate signals such as wake signals, TX pin can be configured to TXD\_OUT and TXD\_CTL\_EN bits in register CTL0 to be software controlled by setting TXD\_CTL\_EN bit to 1, the TX output pin can be controlled by the TXD\_OUT bit if the UART transmit is disabled (CTL0.TXE is cleared).

### Note

Full hardware support of the LIN protocol is not available in UNICOMM-UART. The above registers are used to aid in a software LIN implementation of the LIN-specific features added on top of the UART protocol.

### 28.2.3.1.1 LIN Commander Transmit

The below highlights how a UNICOMM-UART can implement each portion of the LIN Commander transmission using the registers available in the module.

#### Transmitting the Break Field

The break signal can be sent automatically by the UNICOMM-UART by setting the BRK bit in LCRH register for greater than  $13 \cdot T_{\text{bit}}$ . This bit needs to be set before any data is written into the transmit data register TXDATA.

#### Transmitting the Sync Field

The sync field can be sent by writing 0x55 to the TXDATA register to be transmitted using the standard UNICOMM-UART transmitter.

#### Transmitting the PID Field

Write the ID byte to the TXDATA register to be transmitted using the standard UNICOMM-UART transmitter. Make sure CTL0.TXE is set.

#### Transmitting the Data Fields

Write the data bytes to TXDATA register to be transmitted using the standard UNICOMM-UART transmitter. Make sure CTL0.TXE is set.

#### Transmitting the Checksum

Calculate and write the checksum byte to the TXDATA register to be transmitted using the standard UNICOMM-UART transmitter. Make sure CTL0.TXE is set.

### 28.2.3.1.2 LIN Responder Receive

#### Receiving the Break Field

**Figure 28-6. LIN Break Field Detection**

Use the break field detection and compare modes to receive and validate the BREAK field of a LIN message. The following configurations are needed:

1. Initialize the LIN counter register to 0 (LINCNT = 0)
2. Enable counter compare match mode (LINCTL.LINC0\_MATCH = 1)
3. Load LINC0 (Counter Capture 0 register) with the counter value corresponding to  $9.5 \times T_{\text{bit}}$
4. Enable the LINC0 match interrupt (CPU\_INT.IMASK.LINC0 = 1)
5. Setup LIN count control (configure the LINCTL register):
  - Enable count while low signal on RXD pin (LINCTL.CNTRXLOW = 1)
  - Enable LIN counter clearing on RXD pin falling edge (LINCTL.ZERONE = 1)
  - Enable LIN counter (LINCTL.CTRENA = 1)

Optional:

- Enable the rising edge on UART TX signal interrupt (CPU\_INT.IMASK.RXPE = 1), when the RXPE interrupt fires, the software can read the LINCNT directly to see the BREAK field timing.
- Enable the LIN counter overflow interrupt (CPU\_INT.IMASK.LINOVF = 1) to detect the BREAK field is too long and overflows 16-bit counter. The timeout can be calculated as  $t_{\text{Timeout}} = 2^{16} / \text{UARTclk}$ .

## Receiving the Sync Field

**Figure 28-7. LIN Sync Field Detection**

Sync field validation is required to verify accuracy of the LIN header and to calculate the commander baud rate. The sync field consists of the data 0x55 inside a byte field. After software detects a valid BREAK field, the counter can be set to measure the SYNC field. The LINCNT is set to 0 on the start bit falling edge and counts continuously. The LINC0 capture or RX falling edge interrupt fires at the falling edges of the RX line. During interrupt processing, software can measure the individual HIGH/LOW times of the bits themselves with the values in the LINC0 and LINC1 registers to verify that all of the timings are valid.

The following flow describes a LIN sync field validation procedure:

1. Initialize LIN counter to 0 (LINCNT = 0) after detecting a valid break field.
2. Enable interrupt on RX falling edge (CPU\_INT.IMASK.RXNE = 1)
3. Setup LIN count control (LINCTL):
  - Enable LIN counter capture on raising RX edge (LINCTL.LINC1CAP = 1)
  - Enable LIN counter capture on falling RX edge (LINCTL.LINC0CAP = 1)
  - Enable LIN counter clearing on RX falling edge (LINCTL.ZERONE = 1)
  - Enable LIN counter (LINCTL.CTRENA = 1)

Actions at each falling edge of the RX line for the sync field as showing below:

1. LIN counter is set to 0 and start counting on the falling RX edge. (LINCTL.ZERONE = 1)
2. RX falling edge interrupt trigger (RXNE):
  - Read capture register LINC0 (falling edge) and LINC1 (rising edge) values
  - Verify bit times
3. RX falling edge interrupt trigger (RXNE):
  - Read capture register LINC0 (falling edge) and LINC1 (rising edge) values
  - Verify bit times
4. RX falling edge interrupt trigger (RXNE):
  - Read capture register LINC0 (falling edge) and LINC1 (rising edge) values
  - Verify bit times
5. RX falling edge interrupt trigger (RXNE):
  - Read capture register LINC0 (falling edge) and LINC1 (rising edge) values
  - Verify bit times
  - Calculate the proper baud rate to set. Software must set the baud rate before the start bit of the PID field after sync field.

On each interrupt occurrence, the capture registers must be read and the bit times need to be validated by the application software. In case of a bit time verification error, the sync field analysis process must be aborted and the application software must switch back to break detection.

In case of errors like a breaking commander communication during sync field detection, a timeout interrupt can be generated by enabling the LIN counter overflow (IMASK.LINOVF = 1). When the counter overflows, the interrupt handler can abort the sync field analysis and switch back to break detection. The time the counter overflow interrupt occurs can be calculated as  $t_{\text{Timeout}} = 2^{16} / \text{UART clock}$ .

A new control bit LINCTL.EN\_FRM\_ERR is added to enable frame error generation in LIN MODE; i.e. a frame error is detected if LINCTL.EN\_FRM\_ERR is set and device is in LIN mode. This register bit needs to be enabled after SYNC field detection & should be disabled post checksum detection. In case of EVENT-TRIGGERED frames, if there is a collision, FRAME ERROR will be reported in addition to BREAK FIELD being detected. In these cases, application is expected to ignore the FRAME ERROR.

**Note**

The sync field is automatically stored in the RX FIFO and can be misread as the PID. Therefore, flush the RX FIFO after the sync field is received and before the PID is received.

**Receiving the PID Field**

Read the PID byte from the RXDATA register using the standard UNICOMM-UART receiver. Make sure CTL0.RXE is set.

**Receiving the Data Fields**

Read the data fields from the RXDATA register using the standard UNICOMM-UART receiver. Make sure CTL0.RXE is set.

**Receiving the Checksum Field**

Read the checksum byte from the RXDATA register using the standard UNICOMM-UART receiver and decode the value in software. Make sure CTL0.RXE is set.

**28.2.3.1.3 LIN Wakeup**

Per the LIN specification, any node in a sleeping LIN cluster can request a wake up by transmitting a wake up signal. This signal type is shown in Figure 28-8.

**Note**

$0.25ms \leq T_{WUSIG} \leq 5ms$

**Figure 28-8. LIN Wakeup**

To generate a wake signal on the TX pin with the UNICOMM-UART as a LIN controller, the application must use the CTL0.TXD\_CTL\_EN and CTL0.TXD\_OUT bits. Set the TXD\_CTL\_EN bit to enable register control of the TXD pin, then clear the TXD\_OUT bit for the duration of  $T_{WUSIG}$ .

**28.2.3.2 DALI Protocol**

This section applies to UNICOMM-UART configurations which support the UART-DALI-MANCHESTER feature.

DALI stands for Digital Addressable Lighting Interface. It is an International Standard (IEC 62386) lighting control system, providing a single interface for all electronic control gear (light sources) and electronic control devices (lighting controllers).

The UART module supports the low level DALI Protocol sending and receiving the bit streams for forward and backward frames. The timing between any forward and backward frame sequence needs to be handled and checked by software.

**Transmitting a forward or backward frame:**

When transmitting a forward frame user needs to ensure to write second byte to buffer before first byte has been shifted out. The hardware will then send the two bytes without inserting the stop bits in-between. Otherwise the stop bits will be sent and the data will be handled like a backward frame.

**Receiving data:**

The UART module in DALI mode will check the 9th bit after the start bit to detect a Forward frame or backward frame. If this bit does not have a change of the phase (= no stop bit) a forward frame is detected and:

- Address compare is done in software or hardware depending on MASK
- Address and data are always transferred into the RX Buffer

Otherwise a backward frame is detected and the data is transferred into the RX Buffer without setting the ADDR\_MATCH interrupt.

The AMASK register can be used as group assignment used during multicast operation with the MSB to indicate if the device is part of a DALI group. To enable the UART in DALI mode to respond on all ADDRESS the AMASK register needs to be cleared.

**Figure 28-9. DALI Protocol**

The limits for the times T shall be:  $334 \mu s < T < 500 \mu s$  according to standard IEC 62386-102. DALI mode requires Manchester encoding to be enabled. When using DALI mode (CTL0.MODE set to DALI), the CTL0 and LCRH register must be set to:

- 8-bit word length (WLEN bit)
- No parity / 2 Stop Bit
- Manchester encoding enabled
- Baud-rate configuration set to match  $2T = 833.33 \mu s$

When UART is configured as a DALI Control Device: backward frame is stored in the device only if address match is enabled and there is an address match. Upon an address match, both forward frame and backward frame are stored in the receive FIFO.

**DALI Timing Tolerance Support**

DALI mode requires the UART to accommodate significantly wider bit-width variations (exceeding  $\pm 2.5\%$  typical UART tolerance). For 1200 baud Manchester encoding:

- Nominal timing:  $2T = 833.3\mu\text{s}$ ,  $1T = 417.6\mu\text{s}$
- DALI extremes: Low phase =  $333.3\mu\text{s}$ , High phase =  $500\mu\text{s}$

**Configuration Process:**

1. Configure base timing: Set IBRD/FBRD registers for nominal 1200 baud rate
2. Program lower threshold:
  - a.  $\text{DALI\_LO\_TH} = \lceil (\text{lower\_threshold\_period} \times \text{oversampling\_rate}) / \text{nominal\_bit\_period} \rceil$ ; rounded to the next sample
3. Program upper threshold:
  - a.  $\text{DALI\_HI\_TH} = \lceil (\text{upper\_threshold\_period} \times \text{oversampling\_rate}) / \text{nominal\_bit\_period} \rceil$ ; rounded to the next sample

**Detection Logic:**

- 2T bit valid range:  $(2 \times \text{DALI\_LO\_TH} - 1)$  to  $(2 \times \text{DALI\_HI\_TH})$
- Timeout error: NERR flag sets if no edge detected beyond  $(2 \times \text{DALI\_HI\_TH} + 1)$  samples

**28.2.3.3 IrDA Encoding and Decoding**

This section applies to UNICOMM-UART configurations which support the UART-IRDA feature.

When IREN bit in IRCTL register is set, the IrDA encoder and decoder are enabled and provide hardware bit shaping for IrDA communication. IrDA encoding & decoding should only be used with UART mode (CTL0.MODE is 0). Only odd dividers of CLKDIV are support in this mode.

**IrDA Encoding**

The encoder sends a pulse for every zero bit in the transmit bit stream coming from the UART (see [Figure 28-10](#)). The pulse duration is defined by IRTXPL bits specifying the number of one-half clock periods of the clock selected by IRTXCLK bit.

**Figure 28-10. IrDA Protocol**

**IrDA Decoding**

The decoder detects high pulses when IRRXPL = 0. Otherwise, it detects low pulses.

A programmable digital filter stage can be enabled by setting UARTx.GFCTL.DGFSEL > 0. When IRCTL.IREN is set, also the digital glitch filter should be set so that only pulses longer than the programmed filter length are passed and shorter pulses are discarded. (See the Glitch Suppression chapter on how to set the filter.)

**28.2.3.4 Flow Control**

In UART mode (CTL0.MODE set to 0), hardware flow control between two devices is available.

- Connect the Request-to-Send (RTS) output on the transmitter to the Clear-to-Send (CTS) input on the receiver
- Connect the RTS output on the receiver to the CTS input on the transmitter

The RTS output signal on the transmitter is active low, so the CTS input on the receiver expects a low signal on a send request.

Figure 28-11. Flow Control

- The transmitter may only transmit data when the receiver asserts CTS low
- When RTS flow control is enabled, the receiver RTS output signal indicates the state of the receive buffer/ FIFO
- CTS of the transmitting device remains asserted low until, the preprogrammed watermark level is reached in case of FIFO and receive buffer is full in case of a single buffer, indicating that the receiver has no space to store additional characters

The CTSEN and RTSEN bits in the CTL0 register specify the flow control mode.

Table 28-8. Flow Control Enable

CTSEN	RTSEN	Description
1	1	RTS and CTS flow control enabled
1	0	Only CTS flow control enabled
0	1	Only RTS flow control enabled
0	0	Both RTS and CTS flow control disabled

The RTS bit can be driven by hardware or software. When RTSEN is 1 (i.e. hardware-controlled mode), the value of CTL0.RTS bit is ignored and RTS output signal is generated by hardware trigger levels as described below.

**RTS flow control:**

- The RTS flow control logic is linked to the programmable RX FIFO watermark levels, it can be configured using the IFLS register.
- When RTS flow control is enabled, the RTS is asserted (set low) until the RX FIFO is filled up to the watermark level
  - When the RX FIFO watermark level is reached, the RTS signal is de-asserted (set high), indicating that there is no more room to receive any more data.
  - The transmitter's transmission is expected to cease after the current character has been transmitted
- The RTS signal is reasserted (set low) when data has been read out of the RX FIFO to less than the watermark level.
- If RTS flow control is disabled and the UNICOMM-UART is still enabled, then data is received until the RX FIFO is full, or data is no longer transmitted to it

**Note**

The RTS signal is de-asserted when the FIFO watermark level is reached by putting the last received character into the FIFO. This means that back-to-back transmissions could result in another character transfer after de-asserting RTS. In such cases, the watermark level should be set to one level lower to ensure all data can be received and put into the FIFO. In the case of a single buffer, wait a pre-determined amount of time (or wait for an RTS transition to ensure the receive buffer has been read and a new byte can be sent)

**CTS flow control:**

- If CTS flow control is enabled, transmitter checks CTS signal before transmitting the next byte.
  - If CTS signal is asserted (low), it transmits the byte, otherwise transmission does not occur.

- The data continues to be transmitted while CTS is asserted (low), and transmit FIFO/buffer is not empty
- If transmit FIFO/buffer is empty and the CTS signal is asserted (low), no data is transmitted
- If CTS signal is de-asserted (high) and CTS flow control is enabled, then, the current character transmission is completed before stopping
- If CTS flow control is disabled and the UART is enabled, then the data continues to be transmitted until the transmit buffer/FIFO is empty

### 28.2.3.5 Manchester Encoding and Decoding

This section applies to UNICOMM-UART configurations which support the UART-DALI-MANCHESTER feature.

UART provides option to receive and transmit Manchester encoded data. The function is enabled by the MENC bit in CTL0 register to generate the IEEE 802.3 compliant waveform. With the invert function in GPIO control module the output signals can be inverted to generate the G. E. Thomas compliant waveform.

The output signal is generated by XORing the data with UART clock signal. The UART clock needs to be double the speed of the baud-rate. So for the data transmit there is an edge at the beginning and the middle of each data bit. For the receive signal the edge in the middle of the bit is detected to decode the RX data.

### 28.2.3.6 RS485 Support

The RS485 drive can control an external RS485 PHY. The RTS I/O is used in this mode as the drive enable. The signal is set automatically to high once a data transmit is started. This signal stays high between back-to-back byte transmits. If a data receive operation is ongoing, a new transmit must be delayed until this data has been received and the drive enable has been set to transmit.

The data exchange sequence is as follows (also see RS485 Data Exchange figure):

- Wait until an ongoing receive has been finished.
- Activate drive enable to transmit on RTS Pin
- Send data (one or more bytes)
- Wait till an ongoing receive has been finished.
- Deactivate drive enable to transmit on RTS Pin

**Figure 28-12. RS485 Data Exchange**

Two bit fields to the LCRH register define the setup and hold time of the external driver direction control:

- EXTDIR\_SETUP bits define number of UARTclk between RTS assertion and beginning of START bit
- EXTDIR\_HOLD bits define number of UARTclk between STOP (entire bit duration) and RTS de-assertion

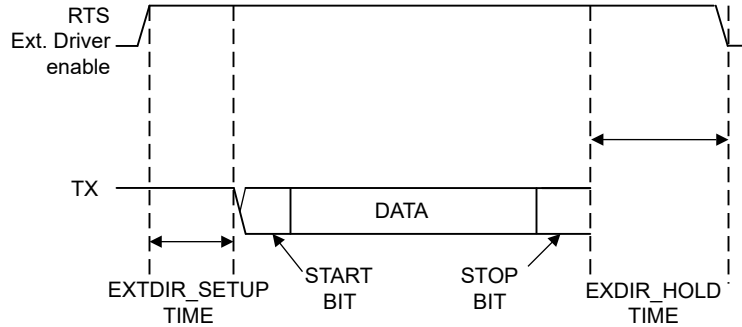

Figure 28-13. RS485 external driver control

### 28.2.3.7 Idle-Line Multiprocessor

This section applies to UNICOMM-UART configurations which support the UART-IDLELINE-MULTIPROC feature.

Idle-line multiprocessor format is selected when IDLELINE is set in the CTL0.MODE register bits.

- Blocks of data are separated by an idle time on the transmit or receive lines.
  - An idle receive line is detected when ten or more continuous ones (marks) are received after the one or two stop bits of a character
- The baud-rate generator is switched off after reception of an idle line until the next start edge is detected. When an idle line is detected, the IDLE bit in UARTx.STAT is set
- In Idle-Line mode the UART receiver operates in no parity mode and the UART word length (UARTx.LCRH.WLEN) must be set to 8bit

Figure 28-14. Idle-Line Multiprocessor

The first character received after an idle period is an address character. The IDLE bit in UARTx.STAT register is used as an address tag for each block of characters.

If an address character is received it is compared against the ADDR register with the AMASK applied. If the received character matches, the address character and all following received characters are transferred into the RXDATA buffer/FIFO and interrupts are generated until the next address without a match is received. The IDLE bit in STAT register is automatically cleared when the address does match; otherwise the IDLE bit is set until the address is matched.

When SENDIDLE control bit is set, the UART inserts an idle period of 11 bit times on the bus. Application has to ensure that there are no active transactions on the transmit line prior to setting SENDIDLE bit.

Once SENDIDLE bit is set, application has to wait for SENDIDLE status bit to be asserted and then clear the SENDIDLE control bit to proceed. The next transfer can then begin with an address character.

The following procedure sends out an idle frame to indicate an address character followed by associated data:

1. Set SENDIDLE then write the address character to TXDATA. TXDATA must be ready for new data (TXINT interrupt must be 1). This generates an idle period of exactly 11 bits followed by the address character. SENDIDLE is reset automatically when the address character has been transferred (all bits are sent out of shift register).
2. Write desired data characters to TXDATA. TXDATA must be ready for new data (TXINT interrupt must be 1). The data written to TXDATA is transferred to the shift register and transmitted as soon as the shift register is ready for new data.

The idle-line time (10 bit periods) must not be exceeded between address and data transmission or between data transmissions. Otherwise, the transmitted data is misinterpreted as an address.

When using IDLELINE mode, the UART Word Length in the LCRH register must be set to:

- 8-bit word length (WLEN bits 6:5 configured to 0x3)

BUSY bit in IDLELINE:

- TX: BUSY is set during the generation of an IDLELINE signal and while the address and data bytes are sent.
- RX: The BUSY signal while receiving data and till first 10 idle bits are received.

#### 28.2.3.8 9-Bit UART Mode

9-bit mode is enabled by setting the MODE field to ADDR9BIT in the CTL0 register. This feature is useful in a multi-drop configuration where a single controller connected to multiple peripherals can communicate with a particular peripheral through the peripheral's programmed address or a set of addresses, along with a qualifier for an address byte. In 9-bit UART mode, the parity enable/mode bits are ignored and the UART word length (LCRH.WLEN) must be set to 8 bits.

#### Receive Transaction:

In 9-bit mode, a UNICOMM-UART peripheral checks for the address qualifier at the location of the parity bit. If set, the received byte is compared with the preprogrammed address in ADDR register:

- If the address matches, a 9-bit mode address match interrupt (ADDR\_MATCH) is generated, if enabled, and further data is received into the RX FIFO.
- If the address does not match, the address byte and the subsequent data bytes are not received into the RX FIFO.

The address is predefined in the ADDR register to match with the received byte. Matching can be extended to a set of addresses using the address mask in the AMASK register. By default, the AMASK is 0xFF, meaning that only the specified address can generate a match.

#### Transmit Transaction:

All the transmits in 9-bit UART mode are interpreted as:

- Address bytes if the 9th bit is set
- Data bytes if the 9th bit is cleared

In 9-bit mode, the 9th bit can be controlled by software. The value set in the EPS bit of the LCRH register determines the value of the 9th bit for transmit transactions. To indicate an address byte, the application must set the EPS bit before the byte transmission. To indicate a data byte, the EPS bit must be cleared before the byte transmission. For a complete transmit transaction, the address byte must be transmitted as a single byte transaction with EPS bit set, followed by a data byte burst where the EPS bit is cleared.

**Table 28-9. 9th Bit Handling**

PEN	EPS	9 <sup>th</sup> Bit (Transmitted or Verified)
0	X	Not transmitted or verified
1	0	0 (= Data)
1	1	1 (= Address)

### 28.2.3.9 ISO7816 Smart Card Support

The UNICOMM-UART Smart Card support feature enables basic communication with an ISO7816 smart card. When configuring the CTL0.MODE field, select the smart card option.

The TXD signal is used as a bit clock, and the RXD signal is used as the half-duplex communication line connected to the smart card. Further smart card signals are not supported by UNICOMM-UART.

The clock rate of the UART clock in ISO7816 mode must be in the range of 1 MHz to 5 MHz when using ISO7816 mode

The LCRH register must be set to:

- 8-bit word length (WLEN bits configured to 0x3)
- Even parity (PEN set and EPS set)
- No stick parity (SPS cleared)

In ISO7816 mode, the UART automatically uses 2 stop bits and 16x oversampling

---

#### Note

---

LCRH.STP2 & CTL0.HSE bits are ignored

- If a parity error is detected during a transmission, the RX line is pulled low during the second stop bit
  - The transmission is aborted and the TX FIFO is flushed
  - Additionally, the module raises a parity error interrupt, allowing the software to detect the problem and initiate retransmission of the affected data, as the UART does not support automatic retransmission in this case
- The UART does not support automatic retransmission on parity errors
  - If a parity error is detected on transmission, all further transmit operations are aborted and software must handle retransmission of the affected byte or message
- In Smartcard Mode, the receiver in case of parity error drives the line low and a parity interrupt flag is asserted.
  - The transmitter responds based on the value of this bit

### 28.2.3.10 Address Detection

This section applies when a UNICOMM-UART module is configured for Idle-line multiprocessor mode or 9-Bit UART mode in the CTL0.MODE register field.

The ADDR register is used to set the specific address that is matched to the received address byte. This register is used in conjunction with AMASK register to form a match for address-byte received. Only bits where the AMASK is set to '1' are considered. So for full address the AMASK register is set to 0xFF.

**Table 28-10. Address Detection**

Condition	Idle Line Mode	9-Bit Mode
Address match	Address and Data is moved to RXDATA	Address and Data is moved to RXDATA
Address mismatch	Address and Data get dropped	Address and Data get dropped

### 28.2.3.11 Glitch Suppression

#### Digital filter

Digital filter is based on the UARTclk. The DGFSEL bits in the GFCTL register can be programmed to provide glitch suppression on the RX line and promote proper signal values. The glitch suppression value is in terms of UARTclks. All signals are delayed internally when glitch suppression is nonzero. For example, if DGFSEL is set to 0x5, 5 clocks must be added onto the calculation for the expected transaction time. The DGFSEL need to be configured for the glitch suppression pulse width to be shorter than 1/3 of a normal data pulse, to avoid a normal pulse is filtered unexpectedly.

### Analog filter

The analog glitch suppression on the RX line is based on the analog glitch filter, and can be selected with the AGFSEL bits in the GFCTL register. The analog glitch filter is enabled with the AGFEN bit. If this is not set, the input signals are passed through to the UART module without filtering.

#### 28.2.3.12 Receive Timeout

When receiving data, if no start edge has been detected for an additional character period (frame period: calculated as per clock and baud rate settings), a receive timeout interrupt (RTOUT) is set even though the FIFO level is not reached. This provides the application a means of reading out the FIFO contents even if the threshold has not been reached. This trigger is also available for DMA transfers.

---

#### Note

RTOUT is not supported in IDLE LINE mode

---

#### 28.2.3.13 LINE Timeout

An additional bit, LTOU (LINE timeout) is provided in UNICOMMUART. When receiving data, if no start edge has been detected for an additional character period (frame period: calculated as per clock and baud rate settings), a line timeout interrupt is set (LTOU) irrespective of FIFO/buffer contents.

---

#### Note

At any given point of time, either RTOUT\_EN or LTOU\_EN can be set. Both cannot be used together.

---

#### 28.2.3.14 Low Power Mode

UNICOMM UART supports a low power mode.

When the module is instantiated in PD0 domain (always on); UART receive is supported in STOP/STANDBY.

1. Baud rate supported depends on the configured clock. *Refer to TRM chapter PMCU section Operating Modes*
2. The module can also request for a fast clock by asserting an asynchronous clock request upon detecting a START condition. Upon receiving an asynchronous clock request, SYSCTL provides SYSOSC at 32MHz in M0+ devices; Refer to device data sheet for SYSOSC wakeup time. The module can also request for a fast clock by asserting an asynchronous clock request upon detecting a START condition.
  - a. Asynchronous clock request can be blocked by assert BLOCK\_ASYNC\_CLK\_REQ; in this case, the module does not request a fast clock and UART data reception continues at the clock available in the power mode
  - b. Asynchronous clock is provided to the module as long as async\_clk\_req signal is asserted; typically, the duration of the UART frame and a few extra cycles for loading into FIFO and for FSM transition
  - c. Glitches on the line can cause the UART to detect a START condition and request a fast clock. In this case, when the receive line is sampled again and an idle condition is observed, FSM moves back to idle and fast clock request is de-asserted and sysosc is turned off
3. For M0+ devices, power mode transition from low power mode to ACTIVE is only upon receiving an enabled interrupt

### 28.2.3.15 Suspend Mode

UNICOMM UART supports a suspend mode.

Suspend is an extreme condition of operation of the IP and application should attempt this mode while taking care of the below conditions. Application can suspend external communication by setting *suspend* control bit; when *suspend* is set, ongoing communication will complete, FSM will return to idle and further external communications are stopped. Transmit line/s will be driven to its idle state and further toggle on receive line/s will not be processed. This provides a safe means for application to suspend operations, clear out receive FIFOs prior to disabling the module

---

#### Note

The suspend bit needs to be cleared prior to re-enabling the module

Following the steps below to suspend communication and disable UNICOMM UART module:

1. UART bus masters have to ensure that the peripheral can reach idle state
2. Hardware ensures that ongoing transactions complete; in case of transmit operation, all the contents of the FIFO will be sent out, prior to hardware raising an idle state
3. Once SUSPEND bit is written into hardware, CPU has to poll status flags to ensure that device has reached idle
4. Drain out receive FIFO
5. Disable the module

Post suspend/disable module, register configurations are retained. Communication can be resumed by following the below steps on re-enabling the module:

1. Clear SUSPEND bit
2. Re-enable the module

#### Suspend Mode Examples

1. LIN
  - a. Transmit side: ensure that checksum has been loaded into transmit buffer
  - b. Receive side: ensure that checksum is received
2. Idleline Multiprocessor
  - a. Transmit side: ensure that line all address & data bytes for the current frame has been loaded into the transmit FIFO
  - b. Receive side: ensure that checksum is received
3. DALI
  - a. Transmit side: ensure that all address & data bytes for the current frame has been loaded into the transmit FIFO
  - b. Receive side: ensure that we stop transmission after receiving the backward frame
4. Frame Control RTS/CTS
  - a. After transferring data from the transmit fifo, transmitting controller has to pull nRTS line high to indicate that there are no further transmissions
  - b. Receiving peripheral should raise its nCTS line high to indicate that it can no longer receive data after receiving the current byte

---

### 28.2.3.16 Asynchronous Clock Request

UART can be configured to wake up from low power mode due to incoming traffic on receive line. Application has to choose a baud rate that takes clock wakeup time and frequency while specifying baud rate.

### 28.2.3.17 Module Pseudo Static Bit Configuration

Application has to setup the configuration registers for desired operation before enabling the module (through ENABLE bits). Configuration bits in Table 7 cannot be updated once ENABLE bit is set. If these bits need to be updated, application would have to disable the module, update the configuration registers and then re-enable the module. When the IP is DISABLED (ensure the sequence SUSPEND → Clear FIFO → DISABLE is followed), it will return the FSM to IDLE, FIFO contents will be cleared and the entire functional clock domain returns to its idle state.

#### Pseudo Static Configuration Registers

### 3 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 28-17](#) and described in [Table 28-15](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 28-17. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 5 RIS (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 28-19](#) and described in [Table 28-17](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Figure 28-19. RIS**

## 18 CTL0 (Offset = 1100h) [Reset = 0000038h]

CTL0 is shown in [Figure 28-32](#) and described in [Table 28-30](#).

Return to the [Summary Table](#).

UART Control Register The CTL0 register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set. To enable the UART module, the UARTEN bit must be set. If software requires a configuration change in the module, the UARTEN bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping. NOTE: The CTL0 register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the CTL0 register. 1. Disable the UART. 2. Wait for the end of transmission or reception of the current character. 3. Clear transmit FIFO 4. Reprogram the control register. 5. Enable the UART.

31-20	RESERVED	R	0h	
19	MSBFIRST	R/W	0h	Most Significant Bit First This bit has effect both on the way protocol byte is transmitted and received. Notes: User needs to match the protocol to the correct value of this bit to send MSb or LSb first. The hardware engine will send the byte entirely based on this bit. 0h = Least significant bit is sent first in the protocol packet 1h = Most significant bit is sent first in the protocol packet
18	MAJVOTE	R/W	0h	Majority Vote Enable When Majority Voting is enabled, the three center bits are used to determine received sample value. In case of error (i.e. all 3 bits are not the same), noise error is detected and bits RIS.NERR and register RXDATA.NERR are set. Oversampling of 16 : bits 7, 8, 9 are used Oversampling of 8 : bits 3, 4, 5 are used Disabled : Single sample value (center value) used 0h = Majority voting is disabled 1h = Majority voting is enabled
17	RESERVED	R	0h	
16-15	HSE	R/W	0h	High-Speed Bit Oversampling Enable 0h = 16x oversampling. 1h = 8x oversampling. 2h = 3x oversampling. IrDA, Manchester, Smartcard and DALI not supported when 3x oversampling is enabled.

**Table 28-48. CTL0 Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
14	CTSEN	R/W	0h	Enable Clear To Send 0h = CTS hardware flow control is disabled. 1h = CTS hardware flow control is enabled. Data is only transmitted when the UARTxCTS signal is asserted.
13	RTSEN	R/W	0h	Enable hardware controlled Request to Send 0h = RTS hardware flow control is disabled. 1h = RTS hardware flow control is enabled. Data is only requested (by asserting UARTxRTS) when the receive FIFO/buffer has available entries.
12	RTS	R/W	0h	Request to Send If RTSEN is set the RTS output signals is controlled by the hardware logic using the FIFO fill level or buffer status. If RTSEN is cleared the RTS output is controlled by the RTS bit. The bit is the complement of the UART request to send, RTS modem status output. 0h = Signal not RTS 1h = Signal RTS
11	RESERVED	R	0h	
10-8	MODE	R/W	0h	Set the communication mode and protocol used. (Not defined settings uses the default setting: 0) 0h = Normal operation 1h = RS485 mode: UART needs to be IDLE with receiving data for the in EXTDIR_HOLD set time. EXTDIR_SETUP defines the time the RTS line is set to high before sending. When the buffer is empty the RTS line is set low again. A transmit will be delayed as long the UART is receiving data. 2h = The UART operates in IDLE Line Mode 3h = The UART operates in 9 Bit Address mode 4h = ISO7816 Smart Card Support The application must ensure that it sets 8-bit word length (WLEN set to 3h) and even parity (PEN set to 1, EPS set to 1, SPS set to 0) in UARTECRH when using ISO7816 mode. The value of the STP2 bit in UARTECRH is ignored and the number of stop bits is forced to 2. 5h = DALI Mode:
7	MENC	R/W	0h	Manchester Encode enable 0h = Disable Manchester Encoding 1h = Enable Manchester Encoding
6	TXD_OUT	R/W	0h	TXD Pin Control Controls the TXD pin when TXD_OUT_EN = 1 and TXE = 0. 0h = TXD pin is low 1h = TXD pin is high
5	TXD_OUT_EN	R/W	1h	TXD Pin Control Enable. When the transmit section of the UART is disabled (TXE = 0), the TXD pin can be controlled by the TXD_OUT bit. 0h = TXD pin can not be controlled by TXD_OUT 1h = TXD pin can be controlled by TXD_OUT
4	TXE	R/W	1h	UART Transmit Enable If the UART is disabled in the middle of a transmission, it completes the current character before stopping. <b>NOTE:</b> To enable transmission, the UARTEEN bit must be set. 0h = The transmit section of the UART is disabled. The UARTxTXD pin of the UART can be controlled by the TXD_CTL bit when enabled. 1h = The transmit section of the UART is enabled.
3	RXE	R/W	1h	UART Receive Enable If the UART is disabled in the middle of a receive, it completes the current character before stopping. <b>NOTE:</b> To enable reception, the UARTEEN bit must be set. 0h = The receive section of the UART is disabled. 1h = The receive section of the UART is enabled.
2	LBE	R/W	0h	UART Loop Back Enable 0h = Normal operation. 1h = The UARTxTX path is fed through the UARTxRX path internally.

**Table 28-48. CTL0 Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	RESERVED	R	0h	
0	ENABLE	R/W	0h	UART Module Enable. If the UART is disabled in the middle of transmission or reception, it completes the current character before stopping. If the ENABLE bit is not set, all registers can still be accessed and updated. It is recommended to setup and change the UART operation mode with having the ENABLE bit cleared to avoid unpredictable behavior during the setup or update. If disabled the UART module will not send or receive any data and the logic is held in reset state. 0h = Disable Module 1h = Enable module

## 19 LCRH (Offset = 1104h) [Reset = 0000000h]

LCRH is shown in [Figure 28-33](#) and described in [Table 28-31](#).

Return to the [Summary Table](#).

UART Line Control Register The LCRH register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

Bit	Field	Type	Reset	Description
31-27	RESERVED	R	0h	
26	SUSPEND	R/W	0h	Suspend external communication 0h = Functional mode resumed 1h = External communication suspended
25-21	EXTDIR_HOLD	R/W	0h	Defines the number of UARTclk ticks the signal to control the external driver for the RS485 will be reset after the beginning of the stop bit. (If 2 STOP bits are enabled the beginning of the 2nd STOP bit.) 0h = Smallest value 1Fh = Highest possible value
20-16	EXTDIR_SETUP	R/W	0h	Defines the number of UARTclk ticks the signal to control the external driver for the RS485 will be set before the START bit is send 0h = Smallest value 1Fh = Highest possible value
15-8	RESERVED	R	0h	
7	SENDIDLE	R/W	0h	UART send IDLE pattern. When this bit is set, SENDIDLE period of 11 bit times will be sent on the TX line. Read STAT.SENDIDLE bit to readback current status of SENDIDLE 0h = Normal operation 1h = Send Idle Pattern
6	SPS	R/W	0h	UART Stick Parity Select The Stick Parity Select (SPS) bit is used to set either a permanent '1' or a permanent '0' as parity when transmitting or receiving data. Its purpose is to typically indicate the first byte of a package or to mark an address byte, for example in a multi-drop RS-485 network. When bits PEN, EPS, and SPS of UARTLCRH are set, the parity bit is transmitted and checked as a 0. When bits PEN and SPS are set and EPS is cleared, the parity bit is transmitted and checked as a 1. 0h = Disable Stick Parity 1h = Enable Stick Parity

**Table 28-50. LCRH Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5-4	WLEN	R/W	0h	UART Word Length The bits indicate the number of data bits transmitted or received in a frame as follows: 0h = 5 bits (default) 1h = 6 bits 2h = 7 bits 3h = 8 bits
3	STP2	R/W	0h	UART Two Stop Bits Select When in 7816 smart card mode (the SMART bit is set in the UARTCTL register), the number of stop bits is forced to 2. 0h = One stop bit is transmitted at the end of a frame. 1h = Two stop bits are transmitted at the end of a frame. The receive logic checks for two stop bits being received and provide Frame Error if either is invalid.
2	EPS	R/W	0h	UART Even Parity Select This bit has no effect when parity is disabled by the PEN bit. For 9-Bit UART Mode transmissions, this bit controls the address byte and data byte indication (9th bit). 0 = The transferred byte is a data byte 1 = The transferred byte is an address byte 0h = Odd parity is performed, which checks for an odd number of 1s. 1h = Even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits.
1	PEN	R/W	0h	UART Parity Enable 0h = Parity is disabled and no parity bit is added to the data frame. 1h = Parity checking and generation is enabled.
0	BRK	R/W	0h	UART Send Break (for LIN Protocol) 1. Break condition is sent on the line for as long as this bit is set 0h = Normal operation 1h = A low level is continually output on the UARTxTXD signal, after completing transmission of the current character. For the proper execution of the break command, software must set this bit for at least two frames (character periods).

**20 STAT (Offset = 1108h) [Reset = 0000000h]**

 STAT is shown in [Figure 28-34](#) and described in [Table 28-32](#).

 Return to the [Summary Table](#).

2	RXFE	R	1h	UART Receive FIFO Empty 0h = The receiver is not empty. 1h = Receive FIFO is empty.
1	RESERVED	R	0h	
0	BUSY	R	0h	UART Busy This bit is set as soon as the transmit FIFO/buffer becomes non-empty or if a receive data is currently ongoing (after the start edge have been detected until a complete byte, including all stop bits, has been received by the shift register). In IDLE_Line mode the Busy signal also stays set during the idle time generation. This bit is set only when the module in enabled. 0h = The UART is not busy. 1h = The UART is busy transmitting data. This bit remains set until the complete byte, including all stop bits, has been sent/received from/into the shift register.

## 21 IFLS (Offset = 110Ch) [Reset = 0000022h]

IFLS is shown in [Figure 28-35](#) and described in [Table 28-33](#).

Return to the [Summary Table](#).

The IFLS register is the interrupt FIFO level select register. You can use this register to define the levels at which the TX, RX and timeout interrupt flags are triggered. The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered when the receive FIFO is filled with two or more characters. Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**Table 28-64. RXDATA Field Descriptions**

Bit	Field	Type	Reset	Description
31-12	RESERVED	R	0h	
11	NERR	R	0h	Noise Error. Writing to this bit has no effect. The flag is cleared by writing 1 to the NERR bit in the UART EVENT ICLR register. 0h = No noise error occurred 1h = Noise error occurred during majority voting
10	BRKERR	R	0h	UART Break Error Writing to this bit has no effect. The flag is cleared by writing 1 to the BRKERR bit in the UART EVENT ICLR register. This error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received. 0h = No break condition has occurred 1h = A break condition has been detected, indicating that the receive data input was held low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).
9	PARERR	R	0h	UART Parity Error Writing to this bit has no effect. The flag is cleared by writing 1 to the PARERR bit in the UART EVENT ICLR register. 0h = No parity error has occurred 1h = The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.
8	FRMERR	R	0h	UART Framing Error Writing to this bit has no effect. The flag is cleared by writing 1 to the FRMERR bit in the UART EVENT ICLR register. This error is associated with the character at the top of the FIFO. 0h = No framing error has occurred 1h = The received character does not have a valid stop bit sequence, which is one or two stop bits depending on the UARTLCRH.STP2 setting (a valid stop bit is 1).

<b>29.1 UNICOMM-I2C Overview</b> .....	<b>1674</b>
<b>29.2 UNICOMM Common Infrastructure</b> .....	<b>1678</b>
<b>29.3 Peripheral Functional Description</b> .....	<b>1678</b>
<b>29.4 UNICOMM I2C Registers</b> .....	<b>1712</b>

## 29.1 UNICOMM-I2C Overview

The UNICOMM-I2CC (Controller) and UNICOMM-I2CT (Target) modules provides a standardized serial interface to transfer data between MSP devices and other external I<sup>2</sup>C devices (such as a sensors, memory, or DACs).

This section describes the functionality of a UNICOMM module when configured to operate as an I2C (either I2C controller or I2C target). The protocol mode of a given UNICOMM instance is determined by the programmed SELECT field of the IPMODE register. If a UNICOMM instance is configured for another peripheral mode, the I2CT/I2CC functionality on that UNICOMM instance is disabled and all register reads return a value of zero.

### 29.1.1 Purpose of the Peripheral

The UNICOMM-I2CC and UNICOMM-I2CT peripherals provides bidirectional data transfer through a two-wire serial bus consisting of a data (SDA) and clock (SCL) line. The I<sup>2</sup>C bus is widely used to interface with devices such as battery management ICs, sensors, other MCUs and so on. This I<sup>2</sup>C peripheral provides the ability to both transmit to and receive from other I<sup>2</sup>C devices on the bus.

### 29.1.2 Features

The UNICOMM-I2CC and UNICOMM-I2CT support the following features:

- 7-bit and 10-bit addressing
- Supported transmission speeds:
  - Standard-mode (Sm) with a bit rate up to 100 kbps
  - Fast-mode (Fm) with a bit rate up to 400 kbps
  - Fast-mode Plus (Fm+) with a bit rate up to 1 Mbps
- UNICOMM-I2CC supports operation with arbitration, clock synchronization, multiple controller support
- Single buffer or 4-entry FIFO depth for transmission and reception
- Glitch suppression
- Low power mode support
- Independent controller and target interrupt generation
- Hardware support for DMA with separate channels for transmit and receive

To support I2C protocol, a UNICOMM module must be configured as either UNICOMM-I2CC (Controller) or UNICOMM-I2CT (Target) at the UNICOMM top level. Additionally, each UNICOMM-I2CC and UNICOMM-I2CT may support the additional features listed in the tables below.

**Table 29-1. UNICOMM I2CC Variants and Features**

Feature	Basic	Advanced

29.1.3 Functional Block Diagram

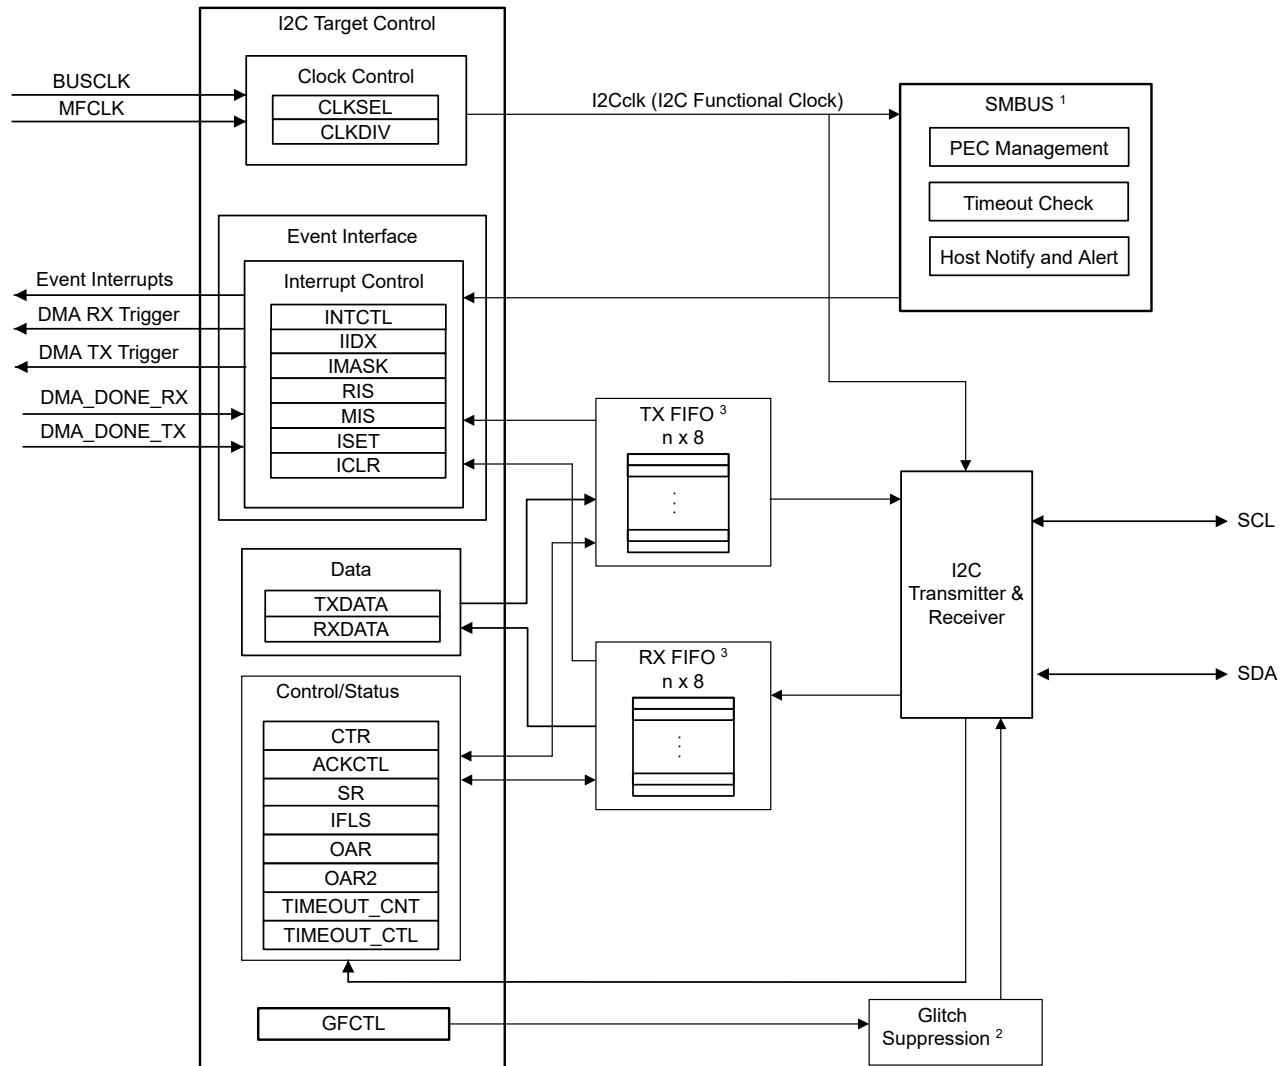

<sup>1</sup> Only Advanced I2CC instances have built-in SMBUS support

<sup>2</sup> Basic I2CC instances have only digital glitch support and Advanced I2CC instances have only analog glitch support

<sup>3</sup> The FIFO depth *n* can be 1 or a multiple of 4

Figure 29-1. I2C Controller Functional Block Diagram

<sup>1</sup> Only Advanced I2CT instances have built-in SMBUS support

<sup>2</sup> Basic I2CT instances have only digital glitch support and Advanced I2CT instances have only analog glitch support

<sup>3</sup> The FIFO depth *n* can be 1 or a multiple of 4

**Figure 29-2. I2C Target Functional Block Diagram**

### 29.1.4 Environment and External Connections

The I<sup>2</sup>C mode supports any target or controller I<sup>2</sup>C-compatible device. Figure 29-3 shows an example of an I<sup>2</sup>C bus. Each UNICOMM-I2C instance is comprised of controller or target functions where the target can be addressed with 2 independent user defined addresses. A device connected to the I<sup>2</sup>C bus can be considered as the controller or the target when performing data transfers. A controller initiates a data transfer and generates the clock signal SCL. Any device addressed by a controller is considered a target.

I<sup>2</sup>C data is communicated using the serial data (SDA) pin and the serial clock (SCL) pin. Both SDA and SCL are open-drain bidirectional and must be connected to a positive supply voltage using a pullup resistor.

Figure 29-3. Bus Connection Diagram

## 29.2 UNICOMM Common Infrastructure

For details on common infrastructure elements refer to SPGSS (Section 27.2).

Sections under common infrastructure are – resets, mode selection, pin overlay, FIFO depth, FIFO operation, Interrupts and Events.

## 29.3 Peripheral Functional Description

### 29.3.1 Clock Control

#### 29.3.1.1 Clock Select and I<sup>2</sup>C Speed

Standard, Fast, and Fast Plus modes are selected using a value in the I<sup>2</sup>C Controller Timer Period (TPR) register that results in a maximum SCL frequency of:

- 100 kbps for Standard mode
- 400 kbps for Fast mode
- 1 Mbps for Fast mode Plus

The I<sup>2</sup>C frequency I2C\_FREQ is determined by the I2Cclk functional clock frequency and the TPR field, as well as the fixed SCL\_LP, and SCL\_HP values where:

- I2Cclk is the functional clock frequency to the I<sup>2</sup>C module. Note that the I<sup>2</sup>C internal functional clock is first divided from the source clock:
  - Use UCx\_I2CC/T.CLKSEL register to select the source of the I<sup>2</sup>C functional clock
    - BUSSCLK: the current bus clock is selected as the source for I<sup>2</sup>C. The current bus clock depends on power domain. If the I<sup>2</sup>C instance is in power domain 1 (PD1) refer to MCLK, if the I<sup>2</sup>C instance is in power domain 0 (PD0) refer to ULPCLK.
    - MFCLK: MFCLK is selected as the source for I<sup>2</sup>C, refer to MFCLK.
    - The selected source clock is always available and its frequency depends on device power mode, for more information please refer to PMU/Clock section.
  - Use UCx\_I2CC/T.CLKDIV register field to select divide ratio of I<sup>2</sup>C functional clock, options are from divide by 1 to 8. The division range is extensible to 64 by using parameter SYS\_EXTEND\_CLKDIV if applied.
- SCL\_LP is the low phase of SCL: This is fixed at a value of 6
- SCL\_HP is the high phase of SCL: This is fixed at a value of 4
- Time Period is the programmed value of the TPR field of the TPR register. This value is calculated in the equation below and has to be programmed into TPR.

The I<sup>2</sup>C frequency is calculated as follows:

$$I2C\_FREQ = I2Cclk / ((1+TPR) * (SCL\_LP + SCL\_HP)) \quad (29)$$

For example, if the I<sup>2</sup>C functional clock frequency is 32 MHz and target SCL frequency is 400 kHz:

I2Cclk = 32 MHz

I2C\_FREQ = 400 kHz

SCL\_LP = 6 , SCL\_HP = 4

TPR = (I2Cclk / (I2C\_FREQ \* (4 + 6))) - 1

TPR = 7 (0x07)

**Table 29-3. Examples of Controller Clock Setting for Typical Clock Configurations**

Functional Clock	TPR Bits Standard Mode 100-kHz SCL	TPR Bits Fast Mode 400-kHz SCL	TPR Bits Fast Mode Pluds 1000-kHz SCL
4 MHz	0x03	-	-
8 MHz	0x07	0x01	-
20 MHz	0x13	0x04	0x01
32 MHz	0x1F	0x07	0x02 <sup>(1)</sup>
40 MHz	0x27	0x09	0x03

(1) With 32-MHz functional clock, TPR = 0x01 generates 1.6-MHz SCL frequency, and TPR = 0x02 generates 1.067-MHz SCL frequency.

The I<sup>2</sup>C functional clock must be greater than or equal to 20 times the SCL frequency, I2Cclk ≥ 20 × I2C\_FREQ.

The following minimum functional clock frequencies are required when running certain I2C clock speeds:

- I2Cclk ≥ 2 MHz when working with I<sup>2</sup>C speed 0 to 100 kHz
- I2Cclk ≥ 8 MHz when working with I<sup>2</sup>C speed 100 to 400 kHz
- I2Cclk ≥ 20 MHz when working with I<sup>2</sup>C speed 400 kHz to 1 MHz

### 29.3.1.2 Clock Startup

The selected module clock source is always available and the frequency depends on the power mode, for more information refer to the PMU/Clock section. After enabling the I<sup>2</sup>C module by setting the PWREN.ENABLE bit from the UNICOMM top level, the module is ready to start receiving and transmitting data.

### 29.3.2 Signal Descriptions

The I<sup>2</sup>C bus consists of a clock signal and a data signal. The clock signal can be generated either internally (during controller operation) or externally (during target operation).

**Table 29-4. I<sup>2</sup>C signal descriptions**

Device Pin	Function
UCx_SCL	I <sup>2</sup> C clock signal
UCx_SDA	I <sup>2</sup> C data signal

### 29.3.3 General Architecture

#### 29.3.3.1 I<sup>2</sup>C Bus Functional Overview

The I<sup>2</sup>C bus uses only two signals: SDA and SCL. SDA is the bidirectional serial data line and SCL is the bidirectional serial clock line. The bus is considered idle when both lines are in high state and no transfer is ongoing.

Every transaction on the I<sup>2</sup>C bus is 9-bits long, consisting of 8 data bits and 1 acknowledge bit. A transaction is defined as the time between a valid START and STOP condition—as described in [Figure 29-4](#). The number of bytes per transaction is unrestricted; however, each data byte must be followed by an acknowledge bit and data must be transferred MSB first. When a receiving device cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitting device into a wait state. This process is commonly known as clock stretching. The data transaction continues when the receiver releases the clock SCL.

**Figure 29-4. Module Data Transfer**

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is low (see [Figure 29-5](#)), otherwise START or STOP conditions are generated.

**Figure 29-5. Data Change Period**

### 29.3.3.2 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A high-to-low transition on the SDA line while the SCL is high is defined as a START condition, and a low-to-high transition on the SDA line while SCL is high is defined as a STOP condition. START and STOP conditions are always generated by the controller. Controller mode support for generating START/STOP bits: use CTR.START, CTR.STOP bits. The bus is considered busy after a START condition and free after a STOP condition.

**Figure 29-6. START and STOP Conditions**

The STOP bit determines if the transaction stops at the end of the data cycle or continues on to a repeated START condition.

To generate a single transaction, the I<sup>2</sup>C controller target address TA.ADDR register is written with the desired address, the TA.DIR bit should be set to 1 to start a receive operation and 0 to start a transmit operation, and the control register (CTR) is written with ACK = X (0 or 1), STOP = 1, START = 1, and FRM\_START = 1 to perform the operation and generate a STOP at the end. When the operation is completed (or aborted due an error) the interrupt flags are set. When the I<sup>2</sup>C module operates in Controller receiver mode, the ACK bit is normally (in case of no error) set causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the target transmitter. For more information on I<sup>2</sup>C controller mode configuration please refer to [Section 29.3.4.1](#).

When operating in target mode, the START and STOP bits in the CPU\_INT.RIS register indicate detection of start and stop conditions on the bus and the CPU\_INT.IMASK can be configured to allow START and STOP to be promoted to controller interrupts (when interrupts are enabled). For more information on I<sup>2</sup>C target mode configuration please refer to [Section 29.3.4.2](#).

Bus Status Flags:

- BUSBSY is set when a START is detected on the bus and is sequentially cleared when a STOP condition is detected on the bus. It is also cleared after a clock timeout is set once both SCL and SDA are pulled to high.
- BUSY is also set after a START/Repeated START, and cleared after CTR.BLEN bytes of data is transferred. It is also cleared after data is NACK 'd or a STOP.
- IDLE is set when the Controller I<sup>2</sup>C state machine is in the IDLE state indicating there is no ongoing transfer.

**29.3.3.3 Dual Address**

The I<sup>2</sup>C target interface supports dual address capability for the Advanced I2CT instances. An additional programmable I<sup>2</sup>C Target Own Address Register 2 (OAR2) is provided and can be matched if enabled. When dual address is disabled (OAR2.OAR2EN=0), the I<sup>2</sup>C target provides an ACK on the bus if the address matches the OAR field in the OAR register. When dual address mode is enabled (OAR2.OAR2EN=1), the I<sup>2</sup>C target provides an ACK on the bus if either the OAR field in the OAR register or the OAR2 field in the OAR2 register is matched.

Matched address is loaded into target status register address match field (TR.ADDRMATCH) and OAR2SEL bit indicates if own address (status bit reads back '0') or own address 2 was matched (status bit reads '1').

**29.3.3.4 Address Format**

I2C protocol supports 7-bit and 10-bit addressing modes. In both controller and target modes, 7-bit and 10-bit modes are supported.

- In controller mode, target address and mode are loaded into TA.ADDR and TA.MODE fields
- In target mode, two sets of address matching options are provided – own address and own address 2
  - Own address (OAR register) can be used for 7-bit or 10-bit addressing
  - Own address 2 (OAR2 register) supports only 7-bit addressing mode; OAR2 also provides an address masking option

**29.3.3.4.1 Data Format with 7-Bit Address**

Data transfers follow the format shown in [Figure 29-7](#). After the START condition, a target address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (this bit is only as Controller mode, DIR bit in the TA register). If the TA.DIR bit is 0, it indicates a transmit operation (send), and if it is set to 1, it indicates a request to receive data (receive). A data transfer is always terminated by a STOP condition generated by the controller; however, a controller can initiate communications with another device on the bus by generating a repeated START condition and addressing another target without first generating a STOP condition, see section [Repeated Start](#). Various combinations of receive/transmit formats are then possible within a single transfer. The ninth bit is the Acknowledge bit, which is described in [Section 29.3.3.5](#).

**Figure 29-7. Data Format with 7-Bit Address**

With the CTR.GENCALL bit the I<sup>2</sup>C module can be enabled to respond on a General Call on the I<sup>2</sup>C bus. The General Call is identified by address of 0x00 and the R/W bit set to 0. The General Call interrupt can be enabled with the CPU\_INT.IMASK.GENCALL bit.

**29.3.3.4.2 Data Format with 10-Bit Address**

Data transfers with 10-bit address follow the format shown in below. After the START condition, a leading **'11110b'** introduces the 10-bit addressing scheme. The last two address bits of the first byte concatenated with the eight bits of the second byte of the whole 10-bit address. Devices which only use 7-bit addressing simply ignore messages with the leading '11110b'. The data direction bit (this bit is only as Controller mode, DIR bit in the TA register) is located in the first 8-bit data.

Figure 29-8. Data Format with 10-Bit Address

A **Controller transmitter** addresses the Target with two address bytes as described below with the RW-Bit='0' followed by data bytes from the Controller.

Figure 29-9. I2C Controller Transmit with 10-Bit Address

The **Controller receiver** transfer is only possible with a Combined Transfer due to the fact that the second address byte can only be transmitted if the RW-Bit of the first address byte is '0'. Hence, the start of a Controller receiver transfer will be the same as a Controller transmitter transfer followed by a repeated start condition and the first byte of address byte with RW-Bit='1' (switching to Target transmitter mode).

Figure 29-10. I2C Controller Receive with 10-Bit Address

### 29.3.3.5 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the controller. During the acknowledge cycle, the transmitter (which can be the controller or target) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The acknowledge cycle must comply with the data validity requirements.

When a target receiver does not acknowledge the target address, SDA must be left high by the target so that the controller can generate a STOP condition and abort the current transfer or generate a repeated START condition to start a new transfer. If the controller device is acting as a receiver during a transaction, it is responsible for acknowledging each transfer made by the target. Because the controller decides the number of bytes in the transaction, it signals the end of data to the target transmitter by not generating an acknowledge on the last data byte. The target transmitter must then release SDA to allow the controller to generate the STOP or a repeated START condition.

In target receive mode, hardware will always generate an ACK after receiving data. A target can generate an ACK/NACK manually or automatically.

- When ACKCTL.ACKOEN=0, the target will send automatic acknowledgements. The I2CT will receive and ACK all bytes automatically until the RX FIFO is full.
- When ACKCTL.ACKOEN =1, manual acknowledgments are enabled. Manual ACK override can be used to evaluate each received byte or to slow down the communication when automatic FIFO reception is not desired. When manual ACK override operation is enabled, the I<sup>2</sup>C target module's clock is pulled low after the last data bit until this ACKCTL.ACKOVAL is written with the indicated response. The reception of new data is indicated by the RXDONE interrupt flag.

**Note**

Manual acknowledge is not supported when clock stretching is disabled for target receive mode.

If the I<sup>2</sup>C controller receives a NACK while transmitting data, the NACK and TXDONE bit will be set in the RIS registers. If there is still data in the TX FIFO, the TXEMPTY bit will remain clear to inform software that a TX FIFO flush may be required.

**29.3.3.6 Repeated Start**

The direction of data flow on SDA can be changed by the controller, without first stopping a transfer, by issuing a repeated START condition. This is called a RESTART, see data format in [Figure 29-11](#). After a RESTART is issued, the target address is again sent out with the new data direction specified by the R/W bit.

**Figure 29-11. Data Format with Repeated Start**

A repeated start sequence for a controller transmit or receive is as follows:

1. When the device is in the idle state, the Controller writes the target address to the TA register and configures the DIR bit for the desired transfer type.
2. Data is written to the TXDATA register (for transmit) or RXDATA register (for receive).
3. When SR.BUSY status reads back as '0', FRM\_START and START bits in the CTR register are set to initiate a transfer.
4. Software waits till BUSY bit in the SR register reads back as '0'.
5. The controller can now change direction of transfer or address another target, by generating a restart condition. Software updates TA register and then, sets FRM\_START. This initiates a repeated start on the line.

**Note**

If there is a NACK for address, a STOP condition will be automatically generated. RESTART cannot be sent in that case.

**29.3.3.7 Clock Stretching**

For a UNICOMM-I2CC, clock stretching can be disabled if none of the targets on the bus support clock stretching, allowing the controller to reach the maximum speed on the bus. Otherwise, the clock can be slowed by a target keeping the clock low or due to the clock status detection delay within the I<sup>2</sup>C module.

For a UNICOMM-I2CT, clock stretching is activated automatically when either the RX FIFO full or TX FIFO empty is set. Clock stretching support can be enabled or disabled by configuring the CR.CLKSTRETCH bit, where the feature is enabled by default. Clock stretching status is indicated by the TREQ and RREQ bits from the SR register described below.

- TREQ
  - When this bit is set, the I<sup>2</sup>C target has been addressed as a target transmitter and is using clock stretching to delay the controller until data has been written to TXDATA.
- RREQ
  - When this bit is set, the I<sup>2</sup>C controller has outstanding receive data from the I2C controller and is using clock stretching to delay the controller until the data has been read from RXDATA.

---

**Note**

When device is in low power mode, clock stretching in target mode may be used together with an asynchronous fast clock request to support bringing the device into a suspended low power mode state upon detection of an I<sup>2</sup>C start bit, enabling the I<sup>2</sup>C module to support 100kHz (standard mode) out of low power modes where the bus clock speed is below the minimum oversampling speed required by the respective mode. Refer to the clock selection and I<sup>2</sup>C speed section for the minimum frequency requirements. When clock stretching is used together with an asynchronous fast clock request, it is possible for the device to wait in STOP or STANDBY mode when the I<sup>2</sup>C is idle, and when an I<sup>2</sup>C bus edge is seen, the fast clock request will requests SYSOSC at base frequency and the bus clock will switch to SYSOSC at base frequency, allowing the I<sup>2</sup>C module to process the bus transaction and wake the processor if an interrupt is generated.

---

**29.3.3.8 Clock Low Timeout**

An I<sup>2</sup>C target can extend the transaction by pulling the clock low to slow down communication. The UNICOMM-I2C module has TCNTA, a 12-bit programmable counter that tracks how long the clock has been held low. The upper 8 bits of the count value are software programmable through the I2CTIMEOUT\_CTL register. The value programmed in the I2CTIMEOUT\_CTL.TCNTLA register field has to be greater than 0x01 to enable the timeout feature.

The application can program the eight most significant bits of the counter to reflect the acceptable cumulative low period in a transaction. Each count is equal to a timeout period of  $(1 + \text{TPR}) \times 12 \text{ I}^2\text{Cclk}$ s where the TPR is the programmable timer period. The Timeout counter A counts for the entire time SCL is held Low continuously. When SCL is high, the Timeout counter A is reloaded with the value in the I2CTIMEOUT\_CTL.TCNTLA register bit, and begins counting down from this value at the falling edge of SCL.

The internal bus clock generated for the timeout counter keeps running at the programmed I<sup>2</sup>C speed even if SCL is held low on the bus. The I<sup>2</sup>C clock low timeout period is calculated as follows:

- Cumulative clock low period = Timeout counter \* One timeout period
- One timeout period = I2Cclk period \*  $(1 + \text{TPR}) * 12$
- Timeout counter = I2CTIMEOUT\_CTL.TCNTLA register (this register contains the upper 8-bits of a 12-bit counter value, the lower 4-bits are set to 0)

As an example, if the functional clock is 20 MHz and the I<sup>2</sup>C module was operating at 100-kHz speed, the TPR would be equal to 19. See [Section 29.3.1.1](#) on how TPR is calculated. One timeout period is equal to  $(1 / 20 \text{ MHz}) \times (1 + 19) \times 12$  or 12  $\mu\text{s}$ . Programming the I2CTIMEOUT\_CTL.TCNTLA register to 0xDA would translate to the value 0xDA0, because the lower 4-bits are set to 0x0. This would translate to a decimal value of 3488 clocks or a cumulative clock low period of  $3488 \times 12 \mu\text{s}$ , or 41.856 ms at 100 kHz.

The TIMEOUTA bit in the I<sup>2</sup>C Controller Raw Interrupt Status CPU\_INT.RIS register is set when the clock timeout period is reached, allowing the controller to start corrective action to resolve the remote target state. In addition, the BUSBUSY bit in the I<sup>2</sup>C Controller Status SR register is set. This bit is cleared after I<sup>2</sup>C goes to idle or during the I<sup>2</sup>C controller reset. The status of the raw SDA and SCL signals are readable by software through the SDA and SCL bits in the I<sup>2</sup>C Controller Bus Monitor BMON register to help determine the state of the remote target.

In the event of a timeout condition, application software must choose how it intends to attempt bus recovery. If a clock low timeout is detected before the end of a transfer (receive or transmit), software should flush the FIFO before initializing the next transfer. The clock low timeout is needed for SMBus and PMBus implementation.

---

**Note**

SCL low timeout configuration needs to be set only during initialization and not during active state.

---

**29.3.3.9 Burst Mode**

I2C Controller burst mode allows a sequence of data transfers using DMA or software to handle the data in the buffer/FIFO. This mode is only available on Advanced I2CC module instances. Burst mode is enabled by

setting the CTR.BLEN bits in the I2CC control register to a value 'N', representing the numbers of bytes in the transfer. 'N' must be greater than '1'. This sets the number of bytes transferred by a burst. A copy of this value is automatically written to the SR.BCNT bits in the I2C controller status register to be used as a down-counter during burst transfer.

Interrupt bits RXDONE and TXDONE are set after a burst of 'N' has been transferred.

### NACK in Controller Burst Transmit Sequence

If data is not acknowledged during a controller transmit burst sequence and the CTR.STOP bit *is* set, the frame transfer is terminated. Upon receiving a no-acknowledge condition, the controller sets the NACK interrupt bit, sends out a STOP condition on the bus, and terminates the transfer.

If data is not acknowledged during a controller transmit burst sequence and CTR.STOP bit *is not* set, hardware waits for software to proceed further. Upon receiving a no-acknowledge condition, the controller NACK interrupt bit is set. Software can read the SR.BCNT field to determine the amount of data that was transferred prior to the burst termination. Then software can send out a STOP condition by setting CTR.STOP or a RESTART condition by setting CTR.FRM\_START.

#### 29.3.3.10 Arbitration

A controller can start a transfer only if the bus is in the IDLE state. It is possible for two or more controllers generate a START condition within the minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line while SCL is high (see Figure 29-12). The first controller transmitter that generates a logic high is overruled by the opposing controller generating a logic low and the losing controller releases the bus until the bus is idle again.

Arbitration can take place over several bits. The first stage is a comparison of address bits, and if both controllers are trying to address the same device, arbitration continues on to the comparison of data bits.

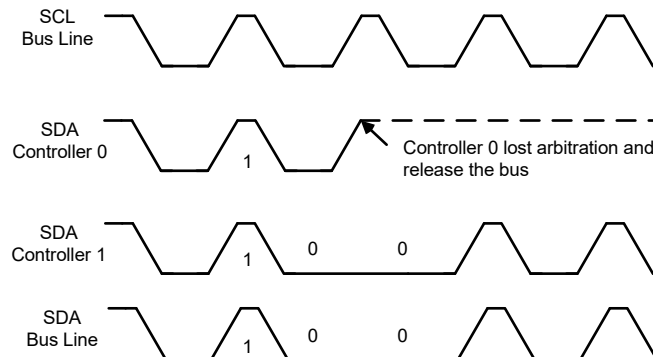

Figure 29-12. Arbitration Procedure Between Two Controller Transmitters

When an arbitration loss is detected, the SR.ARBLSST flag is set. The flag is reset by the hardware with the next STOP condition detected on the bus. Additionally, the ARBLOST flag in CPU\_INT.RIS registers are set.

If arbitration is lost when the I<sup>2</sup>C controller has initiated a transfer, the application software needs to execute the following steps to correctly handle the arbitration loss:

- If transmit FIFO is not empty, clear the TX FIFO by setting IFLS.TXCLR bit
- Once the bus is IDLE, the TX FIFO can be filled and enabled, the TXEMPTY bit can be unmasked, and a new transaction can be initiated.

#### 29.3.3.11 Multiple Controller Mode

To enable multiple-controller mode of operation, the CR.MCTL bit can be set. During the arbitration procedure, the clocks from each different controller must be synchronized. A device that first generates a low period on SCL overrules the other devices, which forces the other devices each to start low periods as well. SCL is then

held low by the device with the longest low period. The other devices must wait until the SCL is released before starting high periods.

**Figure 29-13. Clock Synchronization**

**29.3.3.12 Glitch Suppression**

The I<sup>2</sup>C module supports glitch suppression on the SCL and SDA lines to meet the 50ns glitch suppression as specified in the I<sup>2</sup>C specification.

**Analog glitch Filter**

The analog glitch filter feature is only available for Advanced UNICOMM-I2CC and UNICOMM-I2CT instances.

In Advanced UNICOMM-I2C instances, by default, an analog glitch filter is enabled and configured to suppress spikes with a 50ns pulse width. I<sup>2</sup>C spec advises to suppress noise spikes of less than 50ns. The user can disable this filter by clearing the GFCTL.AGFEN bit. The analog glitch filter can only be used to wake up the I2C in low-power mode.

**Digital Glitch Filter**

The digital glitch filter feature is only available for Basic UNICOMM-I2CC and UNICOMM-I2CT instances.

In Basic UNICOMM-I2C instances, the DGFSEL bits in the GFCTL register can be programmed to provide glitch suppression on the SCL and SDA lines and maintain proper signal values. The glitch suppression value is in terms of the I<sup>2</sup>C functional clock cycles. All signals are delayed internally when glitch suppression is nonzero. For example, if DGFSEL bit is set to 0x7, 31 clocks can be added onto the calculation for the expected transaction time. To disable the digital glitch filter, set the DGFSEL field to zero.

The digital glitch filter can't be used to wake up the I2C from low-power mode.

**Table 29-5. Glitch Suppression Filter**

	Analog Glitch Filter	Digital Glitch Filter
<b>Default</b>	Default enabled with 50ns	Default bypassed
<b>Pulse width of suppressed spikes</b>	Fixed with 50ns	Programmable I <sup>2</sup> C clock cycle 1, 2, 3, 4, 8, 16, 31
<b>Benefits</b>	Available without needing clock	<ul style="list-style-type: none"> <li>• Programmable length to provide extra filtering .</li> <li>• Stable filtering length.</li> </ul>
<b>Limitation</b>	Variation with temperature, voltage, process	<ul style="list-style-type: none"> <li>• Does not work in low-power mode wakeup when there is no sufficient clock .</li> <li>• Only enabled 3 clock cycles after start of I<sup>2</sup>C packet.</li> </ul>

---

**Note**

Modifications to the GFCTL register must only be done while the CR.ENABLE bit is cleared.

---

**29.3.3.13 DMA Operation**

The UNICOMM I<sup>2</sup>C modules, I2CC and I2CT, each provide an interface to the DMA module with separate channels for transmit and receive. The DMA operation of the I<sup>2</sup>C is enabled through the I<sup>2</sup>C DMA Event and DMA module registers. When the DMA functionality is enabled, the I<sup>2</sup>C asserts a DMA request on the selected channel when the associated FIFO can transmit or receive data. The DMA transfer requests are handled automatically by the DMA controller based on how the DMA channel is configured (burst size, transfer size, source address etc.).

For more information about I<sup>2</sup>C event and DMA, please refer to [Interrupt and Events Support](#) and [DMA Trigger Publisher](#) sections.

- For the receive channel, a DMA transfer request is asserted when the amount of data in the receive FIFO is at or above the FIFO trigger level configured using the RXIFLSEL bit in IFLS register.
- For the transmit channel, a DMA transfer request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level configured using the TXIFLSEL bit in IFLS register.

---

**Note**

Per DMA channel, only one event source should be enabled by the IMASK register at the same time. The DMA transaction descriptor needs to match for the selected trigger with a correct setup for either Controller or Target and RX or TX configuration. The DMA trigger should only be changed when no I<sup>2</sup>C transfer is ongoing and a previous triggered DMA transfer has been finished. If this cannot be ensured the I<sup>2</sup>C and DMA channel should be disabled first.

---

**29.3.3.14 FIFO Operation**

UNICOMM-I2CC or UNICOMM-I2CT has two dedicated FIFOs, one for receive operations and one for transmit operations. The TXDATA and RXDATA registers are 8-bit and used to interface with the transmit and receive FIFOs respectively. The FIFO level varies by device, and is indicated in the device-specific data sheet.

**29.3.3.14.1 FIFO Status Flags**

Each of the common available FIFO status bits for UNICOMM-I2CC/T are explained in the table below. All status bits are included in the Status Bits Register (SR) and can be used by application software to poll the FIFO status as needed.

**Table 29-6. FIFO Status Bits**

Status Bit	Description
RXFE	This bit is set when the RX FIFO is empty.
RXFF	This bit is set when the RX FIFO is full.
RXCLR	This bit is set when a clear of the RX FIFO, started by setting the IFLS.RXCLR bit, is complete.
TXFE	This bit is set when TX FIFO is empty.
TXFF	This bit is set when TX FIFO is full.
TXCLR	This bit is set when a clear of the TX FIFO, started by setting the IFLS.TXCLR bit, is complete.

If the FIFOs are not present, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

---

**Note**

A write is lost if it overruns the TX FIFO.

---

---

**Note**

Data is lost if the RX FIFO is full, and the overflow flag bit is set.

---

### 29.3.3.14.2 FIFO Levels

The interrupt FIFO level for UNICOMM-I2CC/T is configured in the IFLS register.

#### Receive FIFO Levels

When a message gets received, the RX FIFO gets filled immediately. The configurable threshold options for the Receive (RX) FIFO are:

1. RX\_FIFO full: when all elements are populated
2. RX\_FIFO  $\geq$   $\frac{1}{4}$  full
3. RX\_FIFO  $\geq$   $\frac{1}{2}$  full
4. RX\_FIFO  $\geq$   $\frac{3}{4}$  full
5. RX\_FIFO almost empty:  $\leq$  1 element
6. RX\_FIFO almost full:  $\geq$  (N-1) elements
7. RX\_FIFO not empty:  $\geq$  1 element

These various conditions are typically used to generate a CPU\_INT or DMA\_TRIG\_RX event where the CPU/RX subsequently reads a specific number of characters into memory from RXDATA. The number of characters read in each Interrupt Service Routine (ISR) equals how many are guaranteed present in the FIFO as indicated by the flag.

---

**Note**

Debugger reads of RXDATA have no effect on the contents in the RX FIFO.

---

#### Transmit FIFO Levels

On the transmit side, data is written by the CPU/DMA at the top most empty FIFO entry and then transferred to serializer. The configurable threshold options for the Transmit (TX) FIFO are:

1. TX\_FIFO empty: when there no elements in the FIFO
2. TX\_FIFO  $\leq$   $\frac{3}{4}$  empty
3. TX\_FIFO  $\leq$   $\frac{1}{2}$  empty
4. TX\_FIFO  $\leq$   $\frac{1}{4}$  empty
5. TX\_FIFO almost empty:  $\leq$  1 element
6. TX\_FIFO almost full:  $\geq$  (N-1) elements
7. TX\_FIFO not full:  $\leq$  (N-1) elements

These various conditions are typically used to generate a CPU\_INT or DMA\_TRIG\_TX event where the CPU/DMA subsequently writes a specific number of characters into the TXDATA register. The number of characters written in each Interrupt Service Routine (ISR) equals how many spots are guaranteed empty in the FIFO as indicated by the flag.

---

**Note**

Debugger writes of TXDATA will add elements to the TX FIFO the same as a CPU write.

---

### FIFO Levels Reset Status

Out of reset, both TX and RX FIFOs are configured to trigger an interrupt at half-level mark, and the content of FIFO are also cleared.

---

#### Note

FIFO integrity is not guaranteed if the software disables the module in the middle of a transmission with data in the FIFO, and then re-enables it.

---

#### 29.3.3.14.3 Clearing FIFO Contents

Setting the IFLS.RXCLR and IFLS.TXCLR register bits clears the contents of each of the respective FIFOs.

Follow the below sequence:

1. Write a 1 to the RXCLR or TXCLR bit in the IFLS peripheral-specific register.
2. Wait until the RXCLR or TXCLR status bit in the STAT register is set to 1.
3. Write a 0 to the RXCLR or TXCLR bit in the IFLS peripheral-specific register.

---

#### Note

Performing the above clear sequence before changing the FIFO level configuration in the RXIFSEL or TXIFSEL fields is recommended.

---

---

#### Note

Avoid performing step 1 repeatedly before full sequence is complete.

---

#### 29.3.3.15 Suspend Communication

Suspend is an extreme condition of operation of the I2C module and application should attempt this mode while taking care of the below conditions. Application can suspend external communication by setting CTR.SUSPEND bit.

When SUSPEND is set, ongoing communication will complete, FSM will return to idle and further external communications are stopped. Transmit line/s will be driven to its idle state and further toggle on receive line/s will not be processed. This provides a safe means for application to suspend operations, clear out receive FIFOs prior to disabling the module. SUSPEND bit needs to be cleared prior to re-enabling the module.

Following the steps below to suspend communication and disable I2C module:

1. I2C bus masters have to ensure that the peripheral can reach idle state (detailed in [I2C Bus Prerequisites](#))
2. Hardware ensures that ongoing transactions complete; in case of transmit operation, all the contents of the FIFO will be sent out, prior to hardware raising an idle state
3. Once SUSPEND bit is written into hardware, CPU has to poll status flags to ensure that device has reached idle
4. Drain out receive FIFO
5. Disable the module

Post suspend/disable module, register configurations are retained. Communication can be resumed by following the below steps on re-enabling the module:

1. Clear SUSPEND bit
2. Re-enable the module

## I2C Bus Prerequisites

To reach IDE state, for I2C module, hardware will ensure that transmit fifo is drained out and will provide an indication that the line is idle– SR.BUSY reads '0'. STOP condition may also need to sent / received as per details below:

1. I2C mode
  - a. Controller mode: ensure either NACK/STOP is received/transmitted on the line.
    - i. Transmitter mode: ensure that receiving target has raised a NACK
    - ii. Receiver mode: 'NACK' has to be sent on the line
    - iii. In mutli-controller systems, ensure that STOP condition has been sent out by the controller.
  - b. Target mode: ensure that a NACK has been received on the line
    - i. Transmitter mode: ensure that receiving controller has raised a NACK
    - ii. Receiver mode: 'NACK' has been sent on the line
2. SMBUS mode
  - a. Controller mode: ensure that STOP is transmitted by the controller
  - b. Target mode: ensure that NACK has been received on the line

### 29.3.3.16 Low Power Operation

I<sup>2</sup>C supports operation in Low Power Modes. In low-power mode, the I<sup>2</sup>C interface automatically request the clock selected in the CLKSEL control register after detecting a start condition. The clock request will be released after detection of the STOP condition.

Supported power mode for controller mode:

- Controller mode with 100kHz speed can operate in RUN, SLEEP, STOP power mode
- Controller mode with 400kHz speed can operate in RUN, SLEEP power mode
- Controller mode with 1MHz speed can operate in RUN, SLEEP power mode

Supported power mode and wakeup mode for target mode:

- Target mode with 100kHz speed can operate in RUN, SLEEP, STOP power mode
- Target mode with 100kHz speed can't operate in STANDBY mode because the maximum bus clock in STANDBY mode is 32kHz and to support 100kHz speed we need minimum 400kHz clock. However, in STANDBY mode I2C target can still wakeup from the start bit and perform the (Asynchronous Fast Clock Requests) to temporarily get a 32MHz clock to receive the data until the FIFO or address match interrupt wakes up the CPU.
- Target mode with 400kHz speed in RUN, SLEEP power mode
- Target mode with 1MHz speed in RUN, SLEEP power mode

---

#### Note

To support STANDBY wakeup with I2C standard mode (100KHz), functional clock should be at 32MHz, i.e. there should not be a further division of 32MHz clock.

---

### 29.3.3.17 SMBUS 3.0 Support

The SMBus protocol reuses a number of features of I2C protocol so that the same device can be used to support SMBus as well. This protocol is used in a lot of industrial applications like Battery Management, Memory SSD and several other use cases. See [SMI Forum SMBus Specifications](#) for the details of the protocol specification. The additional registers and features supporting the SMBus protocol are only present on UNICOMM instances with Advanced I2CC and I2CT capabilities.

### 29.3.3.17.1 Quick Command

Quick Command is a simple, compact SMBus transaction that sends an address and 1-bit of data in the DIR bit of the I2C header byte to communicate a command to the target, typically a "turn off" or "turn on". The controller has the ability to send a Quick Command by writing the target address and direction value into the TA register, followed by setting the START, STOP, and FRM\_START bits in the CTR register and clearing the BLEN field to 0. The target logic also has quick command support built in.

In UNICOMM-I2C Target mode, the TX FIFO must be empty upon receiving a Quick Command and can only be loaded after decoding the received message. Follow the steps below to receive a Quick Command from an I2CT:

1. TX FIFO must be empty
2. Receive and decode a Quick Command message using the SR.QCMDST and SR.QCMDRW bits.
3. If clock stretching is enabled, software must load the TX FIFO with 0xFF to stop clock stretching and allow the I2C Controller to generate a STOP condition.

**Figure 29-14. Quick Command Message**

### 29.3.3.17.2 SMBUS Enhanced Acknowledge Control

#### I2C Target Enhanced ACK Control

The below additional bits in the ACKCTL register provide enhanced acknowledgement functionality. The status bit SR.ACKOEN is updated automatically when the ACKOEN\_ON\_PECDONE, ACKOEN\_ON\_PECNEXT, or ACKOEN\_ON\_START bits in ACKCTL are set. Software has to write ACKCTL.ACKOEN to '0' to clear the acknowledge override condition generated by hardware.

- **ACKOEN\_ON\_PECDONE**
  - When set, this bit automatically turns on the target override mechanism following the ACK/NACK of the received PEC byte. This allows software to manually handle data bytes received after the PEC byte. The sequence is as follows:
    1. Set ACKCTL.ACKOEN\_ON\_PECDONE
    2. SR.ACKOEN bit is automatically set after the PEC byte has been ACK/NACK'd
    3. Receive "n" bytes using manual software ACK
    4. Clear SR.ACKOEN after "n" bytes have been received
    5. Receive next "m" bytes using the automatic hardware ACK
- **ACKOEN\_ON\_PECNEXT**
  - When set, this bit automatically turns on the target override mechanism following the ACK/NACK of the byte received prior to the PEC byte. Software must clear the SR.ACKOEN after ACKing/NACKing the PEC byte. Using this option, software can effectively get the synchronization point by getting an interrupt here (TREQ/RREQ condition with TXEMPTY\_ON\_TREQ/RXFLI\_ON\_RREQ set), and then manually send the ACK/NACK of the PEC. In other words, the software doesn't need to rely on byte granularity RXMODE and TXMODE interrupts and get an interrupt after the entire frame has been TX/RX. The sequence is as follows:
    1. Set ACKCTL.ACKOEN\_ON\_PECNEXT
    2. SR.ACKOEN bit is automatically set before the PEC bytes
    3. Receive the PEC byte and manually ACK/NACK using software
    4. Clear SR.ACKOEN
    5. Receive the entire next frame using automatic hardware ACK until the next PEC byte is received
- **ACKOEN\_ON\_START**
  - When set, this bit automatically turns on the target override mechanism following a START condition. The sequence is as follows:
    1. Set ACKCTL.ACKOEN\_ON\_START

2. SR.ACKOEN bit is automatically set when the START condition is detected
3. Continue receiving bytes with software until remaining bytes are known
4. Clear SR.ACKOEN
5. Receive the rest of the frame using automatic hardware ACK until the next START condition is received

---

#### Note

The I2CT software must wait a bit duration between generating a NACK and disabling the SR.ACKOEN. These operations cannot happen in the same cycle.

---

### I2C Controller Enhanced ACK Control

The I2CC, when in receive mode, can ACK/NACK after "n" number of bytes are received. When CTR.ACKOEN is set and the number of bytes configured by CTR.BLEN are received, an RXDONE interrupt is generated and the transaction is either ACK'd or NACK'd depending on the value of CTR.ACK. To stop the transaction, the CTR.STOP can be set. Otherwise, software can update the CTR.BLEN field to a new value to continue with the transaction.

#### 29.3.3.17.3 Clock Low Timeout Detection

Clock **low** timeout detection is done by setting the TIMEOUT\_CTL.TCNTAEN and configuring the timeout period in the TIMEOUT\_CNT.TCNTLA (the upper 8-bits of a 12-bit period) register field. The TIMEOUT\_CNT.TCNTA register contains the current count value.

Example counter calculations for low SCL timeout detection is shown below.

- For SCL low detect, each count is equal to 520 cycles of the I2Cclk period.
- A pre-multiplier of 520 is used to make the total timeout period greater than 35ms ( $t_{\text{TIMEOUT,MAX}}$  specified by SMBus 3.0), even at the highest clock frequency of 40MHz.
- At 40MHz, 1 count =  $520 * 25\text{ns} = 13\mu\text{s}$
- Max count value =  $12'b1111\_1111\_0000 = 12'd4080$
- Total time configurable =  $4080 * 13\mu\text{s} = 53.04\text{ms}$

#### 29.3.3.17.4 Clock High Timeout Detection

Clock **high** timeout detection is done by setting the TIMEOUT\_CTL.TCNTBEN and configuring the timeout period in the TIMEOUT\_CNT.TCNTLB (the upper 8-bits of a 12-bit period) register field. The TIMEOUT\_CNT.TCNTB register contains the current count value.

Example counter calculations for high SCL timeout detection is shown below.

- For SCL high detection, each count is equal to  $1 * I2Cclk$  period.
- A pre-multiplier of 1 is used to make the accuracy of the counter remain high for  $50 \mu\text{s}$  ( $t_{\text{HIGH,MAX}}$ ) even for low frequency functional clocks ( $I2Cclk$ ).
- At 10MHz, 1 count = 100ns
- Total I2Cclk counts required to count  $50 \mu\text{s} = 500$
- Value of TIMEOUT\_CNT.CNTLB for  $50\mu\text{s}$  bus idle timeout =  $500/16 = 32$

#### 29.3.3.17.5 Cumulative Clock Low Extended Timeout

The below two cumulative timeout event specifications come from SMBus 3.0 for targets and controllers.

- $t_{\text{LOW:SEXT}}$ 
  - This value is defined as the cumulative time a given target device is allowed to extend the clock cycles in one message from the initial START to the STOP. Another target device, or the controller, can also extend the clock causing the combined clock low extend time to be greater than  $t_{\text{LOW:SEXT}}$ . Therefore, this parameter is measured with the target device as the sole target of a full-speed controller.
- $t_{\text{LOW:MEXT}}$ 
  - This value is defined as the cumulative time a controller device is allowed to extend the clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. A target device

or another controller can also extend the clock causing the combined clock low time to be greater than  $t_{LOW:MEXT}$  on a given byte. Therefore, this parameter is measured with a full speed target device as the sole target of the controller.

Cumulative timeout events need to be monitored in software for I2CC and I2CT. In most cases, a single clock stretch SCL timeout can act as a sufficient safeguard against cumulative events.

In controller mode, the UNICOMM-I2CC only clock stretches on byte boundaries. This aligns with the definition of  $t_{LOW:MEXT}$  and the Counter A low timeout method outlined in [Section 29.3.3.17.3](#) can be used.

In target mode, since clock stretch events can happen at different byte boundaries within a transaction for UNICOMM-I2CT, software must use DMA and FIFO capabilities to avoid exceeding  $t_{LOW:SEXT}$ . Typically, software takes a longer time to process the first command byte of an SMBUS frame, so the Counter A method can safeguard against software latencies. The rest of the transaction contains byte transfers that must not have software delays.

### 29.3.3.17.6 Packet Error Checking (PEC)

PEC is a CRC-8 error checking byte which is calculated using all the message bytes of a transaction, including addresses and read/write bits. The ACK/NACK, START, and STOP bits do not contribute to the PEC calculation. The PEC is appended to the message by the device that supplied the last data byte. PEC is cleared upon STOP condition in controller mode, and is cleared upon NACK in target mode.

**Figure 29-15. Send Byte Message with and without PEC**

The PEC Polynomial calculation is the below.

$$x^8 + x^2 + x^1 + 1$$

The PECCTL register on Advanced UNICOMM-I2CC and UNICOMM-I2CT instances supports PEC transmission and checking for both controller and target modes. Each of the fields from the PECCTL register are described below.

- PECEN
  - This bit enables the SMB Packet Error Checking (PEC) mechanism. When enabled, the PEC is calculated on all bits except the START, STOP, and ACK/NACK. The PEC LFSR and the Byte Counter is set to 0 when the State Machine is in the IDLE state, which occurs following a STOP condition or when a timeout occurs. The Counter is also set to 0 after the PEC byte is sent or received.
- PECCNT
  - When this field is set to a non-zero value, the number of I2C data bytes are counted and compared against this value to keep track of each PEC byte in a transmission/reception.

---

**Note**

For a I2C Target, dynamic changes made to PECCNT must be done while the SCL is being stretched and only if the previous PECCNT= 0.

---

---

**Note**

For a I2C Controller, dynamic changes made to PECCNT must be done only if the previous PECCNT=0. A PECCNT value of 1 is an invalid configuration as this indicates one PEC byte and zero data bytes in the transaction, which is not possible per the SMBus standard.

---

For transmitting, an extra byte needs to be inserted into the transmit sequence for each transaction by writing a dummy byte to the TXDATA register. If PECEN is set, I2CC/I2CT calculates the PEC and replaces this dummy byte with the PEC value during transmission when the data byte count reaches the value in PECCNT. For reception, a PEC byte is received the same as a data byte through the RX FIFO. If PECEN is set and the data byte count is equal to the value programmed in PECCNT, the I2CC/I2CT checks the next received byte since that is the PEC. If the PEC byte is non-zero, the PEC\_RX\_ERR flag in RIS is set and a NACK is transmitted on the line automatically.

The PECSR register is also added to provide status flags relating to PEC operation and functionality for both UNICOMM-I2CC and UNICOMM-I2CT. Each of the fields from the PECSR register are described below.

- PECBYTECNT
  - This is the current PEC Byte Count of the I2C controller or target.
- PECSTS\_CHECK
  - This status bit indicates if the PEC was checked in the transaction that occurred before the last STOP. The flag is updated on a STOP condition.
- PECSTS\_ERROR
  - This status bit indicates if a PEC check error has occurred in the transaction before the last STOP condition. The flag is updated on a STOP condition.

In a typical I2C Target use case, software can set PECEN=1 and PECCNT=0 and enabled the manual ACK override feature, by setting the ACKOEN bit, until the remaining packet length is known. Software then can set the PECCNT to the remaining packet length (including the PEC byte). Once transmission/reception of the packet is complete, manual ACK override mode can be disabled by clearing ACKOEN.

**29.3.3.17.7 Host Notify Protocol**

To support the SMBus host notify protocol specifications, UNICOMM-I2CT Advanced instances contain a default host address. When the CTR.EN\_DEFHOSTADR bit is set, the default host address of **7'b000\_1000** is always used by the Target address match logic for comparison. When this bit is cleared, the default host address is not used for matching.

**29.3.3.17.8 Alert Response Protocol**

A Target-only device can signal the host through GPIO that it wants to talk. The host processes the interrupt and simultaneously accesses all compliant devices through the Alert Response Address. Only the device(s) which generated the request will acknowledge the Alert Response Address.

To support the SMBus host notify protocol specifications, UNICOMM-I2CT Advanced instances contain an alert response address. When the CTR.EN\_ALRESPADR bit is set, the alert response address of **7'b000\_1100** is always matched by the Target address match logic. When this bit is cleared, the alert response address is not matched. GPIO signaling for alarm situations must be handled in software.

**Figure 29-16. Alert Response Message**

**29.3.3.17.9 Address Resolution Protocol**

SMBus target address conflicts can be resolved by dynamically assigning a new unique address to each target device. The Address Resolution Protocol (ARP) outlined below is used by the UNICOMM-I2CC in this event.

1. Prepare to ARP
  - a. Controller sends a **Prepare to ARP** command to all the targets on the bus by using the default device address. All targets must ACK this command and clear own addresses.
2. Get UDID
  - a. Controller sends the **Get UDID** command to all the targets on the bus. All targets return the unique UDID back to the controller.

- b. Target arbitration happens since all targets are trying to send a UDID to the controller.
3. Assign address
    - a. Controller sends the **Assign Address** command to all the target UDID's to assign each device with a new unique address. The controller needs to keep track of the used address pool and corresponding UDID's in software during this process. All targets need to monitor the UDID bytes and change the own address to the assigned address in the event of a UDID match. For UNICOMM-I2CT instances, this can be done in software. The commander can repeat Step 2 and 3, until there are no ACK's from a target after sending a **Get UDID** command, meaning all ARP-capable targets now have valid target addresses assigned.

Additionally to support the ARP process, UNICOMM-I2CT Advanced instances contain a default device address. When the CTR.EN\_DEFDEVADR bit is set, a default device address of **7'b110\_0001** is always used by the target address match logic. When this bit is cleared, the default device address is not matched. If arbitration is lost, the RIS.ARBLOST interrupt is set, similar to the arbitration logic of the UNICOMM-I2CC module.

### 29.3.4 Protocol Descriptions & Initialization

#### 29.3.4.1 I<sup>2</sup>C Controller Mode

As showing in the [function block diagram](#) section, UNICOMM-I2CC instance has a set of specific controller registers to configure the I2C operation.

##### 29.3.4.1.1 I2C Controller Initialization

Follow the high-level UNICOMM configurations in [Section 27.3](#) before executing the below I2CC-specific configurations.

1. Clear the ENABLE bit in the CR register before making any of the below configuration changes.
2. Set the desired SCL clock speed by writing the TPR bit in TPR register with the correct value. For example, with a 20MHz I2Cclk and 100kbps desired SCL clock, a TPR value of 19 (0x13) needs to be written to TPR. For more information about how to calculate the TPR value, refer to [Clock Control](#).
3. Configure the desired FIFO trigger levels in the IFLS register.
4. Enable/Disable clock stretching in the CR register.
5. Specify the target address, initial direction of transfer, and addressing mode (7-bit or 10-bit ) by writing the TA register.
6. Enable desired interrupts and/or DMA event by using CPU\_INT, DMA\_TRIG\_RX, DMA\_TRIG\_TX group IMASK registers.
7. (Optionally) Configure the emulation mode for the peripheral in the PDBGCTL register.
8. Enable the I2CC by setting the CR.ENABLE bit.
9. Specify the initial length of transfer, acknowledgement settings, and START/STOP conditions through the CTR register. If operating in controller-transmitter mode, TXDATA can be written with data to be transmitted. Start a frame by writing to the FRM\_START bit.

##### 29.3.4.1.2 I2C Controller Status

The application can read the SR register (detailed in [#unique\\_816/unique\\_816\\_Connect\\_42\\_UNICOMMI2CC\\_PERIPHERALREGION\\_IPSPECIFIC\\_SR\\_TABLE\\_TABLE](#)) to check the current state of the UNICOMM-I2CC. Status bits that are common across all UNICOMM peripherals and relate to the TX and RX FIFOs are explained in [Section 29.3.3.14.1](#) .

##### 29.3.4.1.3 I2C Controller Receive Mode

For an UNICOMM-I2CC to start receiving data out of the idle mode, the user needs to set the START bit in CTR register to generate the START condition. Then the controller automatically sends the START condition followed by the target address as soon as the bus is free.

First, set TA.DIR to 1 to enable receive mode and set CTR.START to 1 to enable the START condition. CTR.BLEN can then be programmed to indicate the number of bytes (n) for the receive operation on Advanced

I2CC instances (for Basic UNICOMM-I2CC instances, this length is hardcoded to 1). The CTR.ACK and CTR.STOP bit can then be set or cleared based on user configuration. CTR.FRM\_START is set to begin the transaction on the line. The packet format is: START + ADDR + R + (DATA\*n) +(ACK/NACK) + STOP. The last data ACK/NACK depends on the ACK bit and an additional STOP condition depends on STOP bit.

After last byte is received, the RXDONE interrupt in the CPU\_INT.IIDX register is set to indicate that Controller-Receive transaction is complete. User can use the RXTRG interrupt in CPU\_INT.IIDX register to read the data from the RX FIFO. This interrupt triggers when the controller RX FIFO contains  $\geq$  defined bytes, the trigger level can be defined by using the RXIFSEL bit in IFLS register. The flow chart of controller receiver mode is shown in [Figure 29-17](#).

<sup>1</sup> RX buffer is a user-defined buffer for the received data packet  
<sup>2</sup> CTR.BLEN usage is only available in Advanced I2CC instances. If using a Basic instance, RXDONE will trigger after every single byte received and logic should be revised

Figure 29-17. Controller Receive Mode

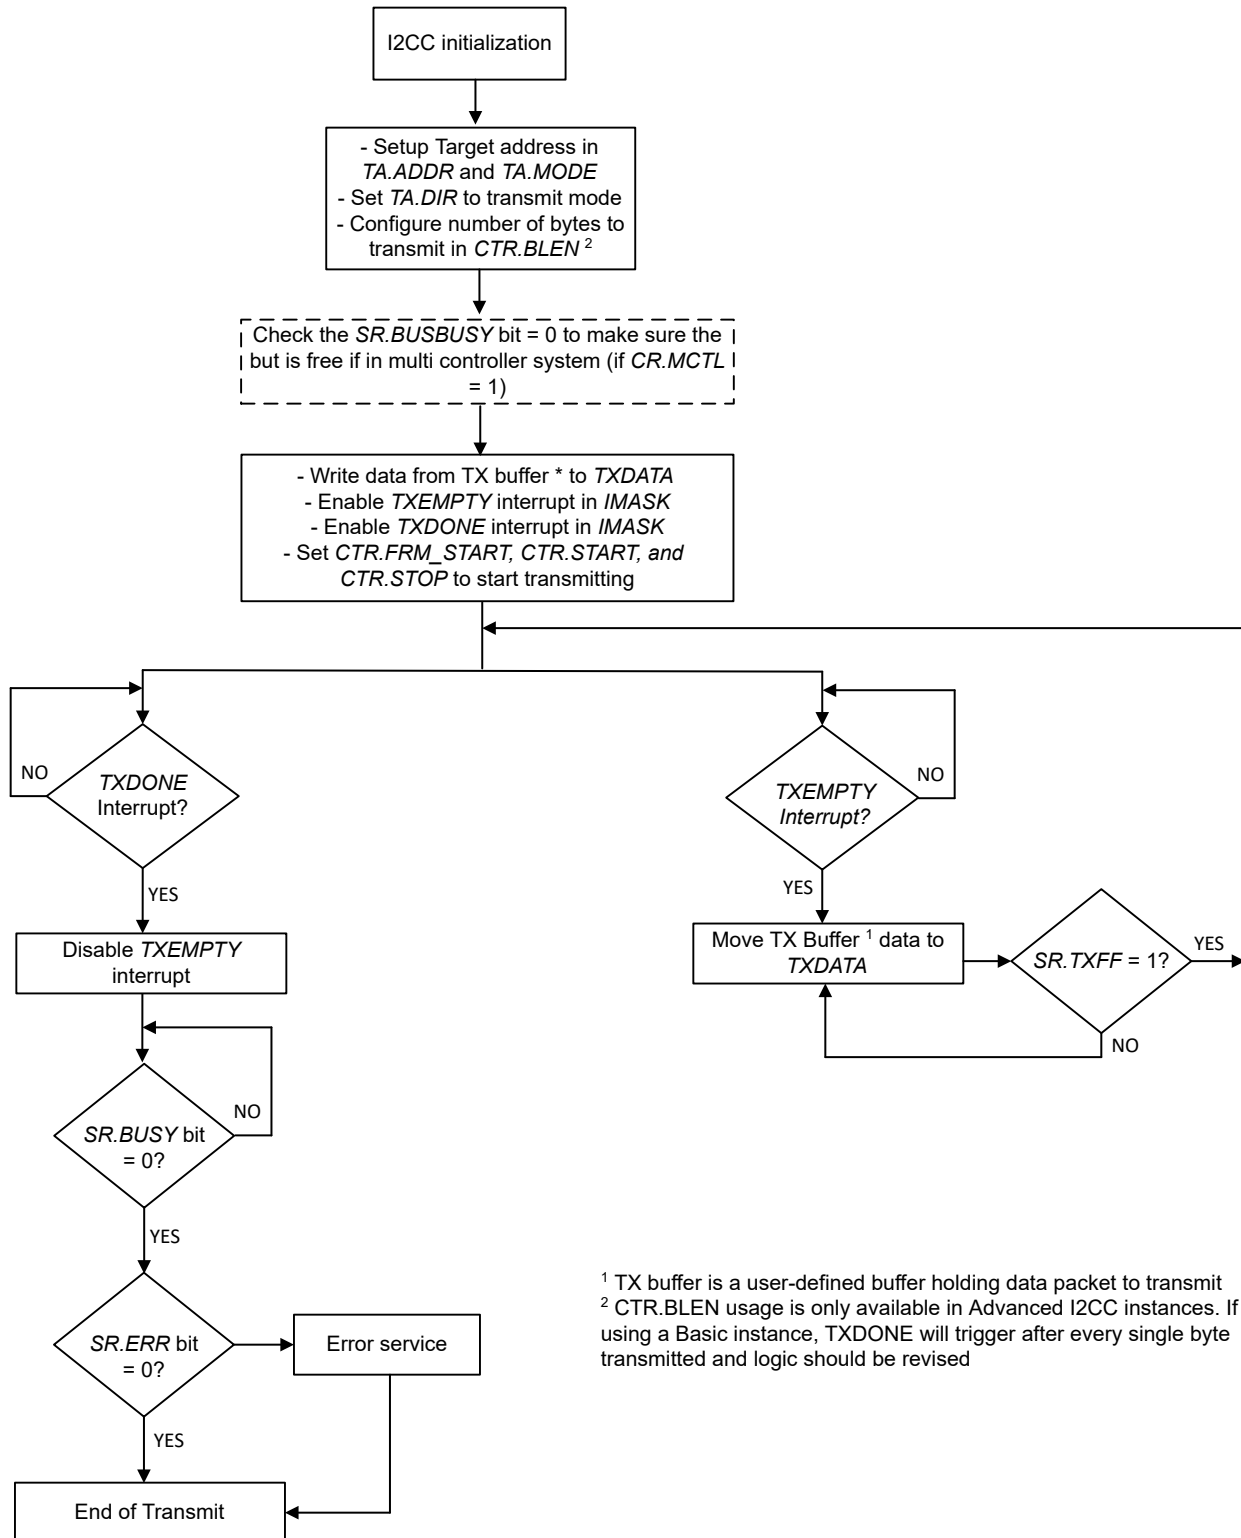

#### 29.3.4.1.4 I2C Controller Transmitter Mode

For a controller to start transmitting data out of idle mode, the user needs to set the START bit in the CTR register to generate the START condition. Then the controller automatically sends the START condition followed by the target address as soon as the bus is free. The data written into TXDATA is transmitted if arbitration is not lost during transmission of the target address.

First, clear TA.DIR to 0 to enable transmit mode and set CTR.START to 1 to enable the START condition. CTR.BLEN can then be programmed to indicate the number of bytes (n) for the transmit operation on Advanced I2CC instances (for Basic instances this length is hardcoded to 1). The CTR.STOP bit can then be set or cleared based on user configuration. CTR.FRM\_START is then set to begin the transaction on the line. The packet format is START + ADDR + W + (DATA\*n) + STOP, where transmission of the STOP condition depends on the STOP bit.

After the last byte is transmitted, the TXDONE interrupt in the CPU\_INT.IIDX register is set to indicate that the controller transmit transaction is completed. The user can also use the TXEMPTY interrupt from the CPU\_INT.IIDX register to see if the TX FIFO is empty and ready to load more data. This interrupt triggers if all data in the transmit FIFO has been shifted out.

The flow chart with the necessary software steps of using TXDONE and TXTRG interrupt for controller-transmitter mode are shown in [Figure 29-18](#) and [Figure 29-19](#) respectively.

<sup>1</sup> TX buffer is a user-defined buffer holding data packet to transmit  
<sup>2</sup> CTR.BLEN usage is only available in Advanced I2CC instances. If using a Basic instance, TXDONE will trigger after every single byte transmitted and logic should be revised

Figure 29-18. Controller Transmitter Mode using TXDONE

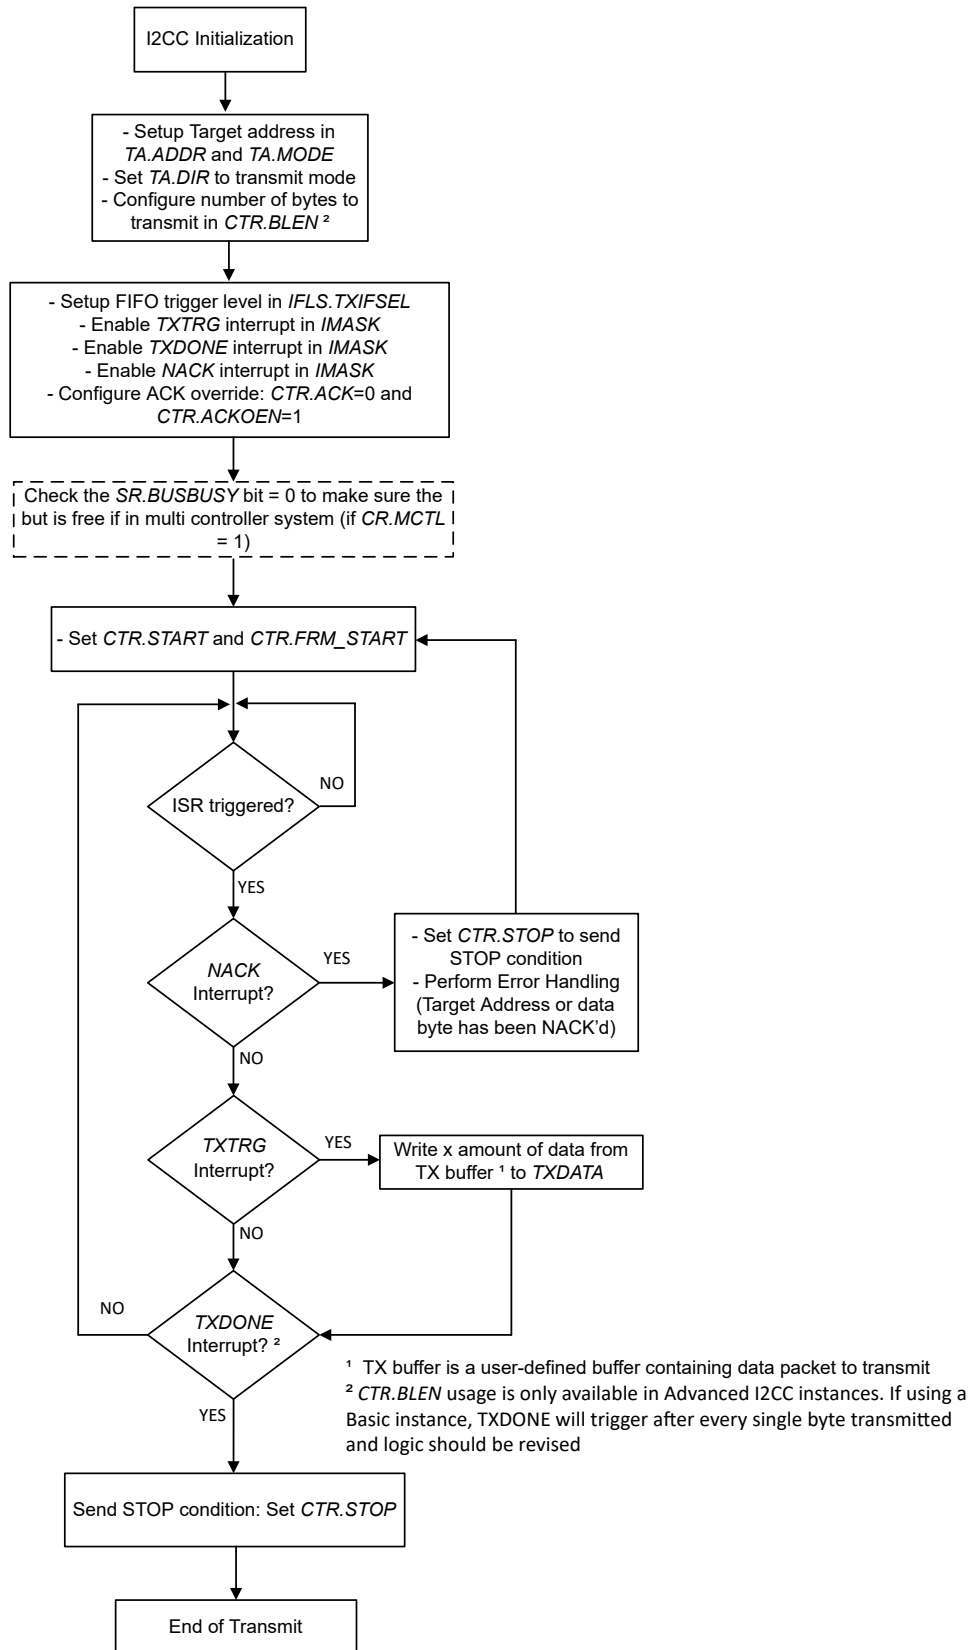

Figure 29-19. Controller Transmitter Mode using TXTRG

### 29.3.4.1.5 Controller Transaction Configurations

The UNICOMM-I2CC control register (CTR) and UNICOMM-I2CC target address register (TA) are used during the application run to setup controller transmit and receive transactions. The following settings can be used to control each transaction before software reads/writes TXDATA and RXDATA.

- Length indicates the number of bytes for the transaction and is configured by CTR.BLEN bits (Only available in Advanced UNICOMM I2CC instances. In Basic I2CC instances, transaction length is fixed at one.)
- Direction (transmit or receive) is configured by TA.DIR bit
- ACK generation is configured by CTR.ACK and CTR.ACKOEN bit.
- STOP condition generation is configured by CTR.STOP bit.
- START or Repeated START condition generation is configured by the CTR.START bit.
- Start of transmission is enabled by the CTR.FRM\_START bit.
- Transmit/Receive status and Error status can be checked with the SR.BUSY and SR.ERR bits respectively.

### Controller Transmit Data Transactions

**Table 29-7. Start Transmit From Idle Mode**

Length	Direction	ACK	STOP	START	FRM_START	Frame Format	Notes
n (n>0)	0	X	0 or 1	1	1	START+ADDR+R/W+DATA*n+STOP	Sending of STOP condition depends on the CTR.STOP bit.

**Table 29-8. Continue Transmit when Last Transmission Finished without STOP**

Length	Direction	ACK	STOP	START	FRM_START	Frame Format	Notes
n (n>0)	0	X	0 or 1	0	1	DATA*n+ ACK/NACK+STOP	Sending of STOP condition depends on the CTR.STOP bit.

If there is a NACK response from the target, the controller automatically sends out a STOP condition to finish the transmit. The Controller is unable to send a RESTART after a ADDR or DATA NACK.

### Controller Receive Data Transactions

**Table 29-9. Start Receive from Idle Mode**

Length	Direction	ACK	STOP	START	FRM_START	Frame Format	Notes
n (n>0)	1	0 or 1	0 or 1	1	1	START+ADDR +R/W+DATA *n +ACK/NACK +STOP	The last data ACK or NACK depends on the CTR.ACK bit; additional sending of STOP condition depends on CTR.STOP bit.

**Table 29-10. Continue Receive when Last Receive Finished without STOP or NACK**

Length	Direction	ACK	STOP	START	FRM_START	Frame Format	Notes
n (n>0)	1	0 or 1	0 or 1	0	1	DATA*n+ ACK/NACK +STOP	The last data ACK or NACK depends on the CTR.ACK bit; additional sending of STOP condition depends on CTR.STOP bit.

This configuration is not allowed if last transaction ended with NACK, since NACK can only be followed by a STOP or RESTART condition. The ACK and STOP bits must not be set to 1 at the same time, as the target needs to be informed to release bus lines before sending out STOP.

### Controller Repeated START Transactions

If the last transmit or receive finished without a STOP, a Repeated START can be generated to initiate a new transaction

**Table 29-11. Repeated Start Transmit**

Length	Direction	ACK	STOP	START	FRM_START	Frame Format	Notes
n (n>0)	0	0 or 1	0 or 1	1	1	Restart+ADDR +R/ W+DATA*n +STOP	Additional sending of STOP depends on CTR.STOP bit.

If there is a NACK response from the target, the controller automatically sends out a STOP condition to finish the transmit. The Controller is unable to send a RESTART after an ADDR or DATA NACK.

**Table 29-12. Repeated Start Receive**

Length	Direction	ACK	STOP	START	FRM_START	Frame Format	Notes
n (n>0)	1	0 or 1	0 or 1	1	1	Restart+ADDR +R/ W+DATA*n +ACK/ NACK+STOP	The last data followed by ACK or NACK depend on CTR.ACK bit; additional sending of STOP depends on CTR.STOP bit.

The ACK and STOP bits must not be set to 1 at the same time, as the target needs to be informed to release bus lines before sending out STOP.

### Controller Transmit STOP-only Transaction

**Table 29-13. Send STOP only**

Length	Direction	ACK	STOP	START	FRM_START	Frame Format	Notes
n (n>=0)	X	X	1	0	1	STOP	STOP command

Only send this transaction after the previous transaction successfully finishes, The STOP condition can't be sent without a NACK to the target if the controller is currently in receive mode.

### Controller Quick Command Transaction

The Quick command can only be sent at the beginning of a transaction, not following other transactions (without a STOP) or repeated start.

**Table 29-14. Controller Quick Command**

Length	Direction	ACK	STOP	START	FRM_START	Frame Format	Notes
0	0/1	X	1	1	1	START+ADDR +R/ W+STOP	Quick command

#### 29.3.4.2 I<sup>2</sup>C Target Mode

As showing in the [function block diagram](#) section, UNICOMM-I2CT instance has a set of specific controller registers to configure the I2C operation.

##### 29.3.4.2.1 I2C Target Initialization

Follow the high-level UNICOMM configurations in [Section 27.3](#) before executing the below I2CC-specific configurations.

1. Disable the I2CT by clearing the CTR.ENABLE bit.

2. Set the desired SCL clock speed by writing the TPR bit in TPR register with the correct value. For example, with a 20MHz I2C\_CLK and 100kbps desired SCL clock, a TPR value of 19 (0x13) needs to be written to TPR. For more information about how to calculate the TPR value, refer to [Clock Control](#).
3. Configure at least one target address by writing the OAR register. An additional target address can be enabled and configured for Advanced I2CT UNICOMM instances using the OAR2 register.
4. Configure acknowledgement settings in the ACKCTL register.
5. Configure clock stretching, TXTRG/RXTRG interrupt modes, default device addresses, and SMBUS feature settings (only available on Advanced I2CT instances) in the CTR register.
6. Configure the desired FIFO trigger levels in the IFLS register.
7. Enable desired interrupts and/or DMA event by using CPU\_INT, DMA\_TRIG\_RX, DMA\_TRIG\_TX group IMASK registers.
8. Enable the I2CT by setting the CTR.ENABLE bit.

#### 29.3.4.2.2 I2C Target Status

The application can read the SR register (detailed in [#unique\\_822/unique\\_822\\_Connect\\_42\\_UNICOMMI2CT\\_PERIPHERALREGION\\_IPSPECIFIC\\_SR\\_TABLE\\_TABLE](#)) to check the current state of the UNICOMM-I2CT. Status bits that are common across all UNICOMM peripherals and relate to the TX and RX FIFOs are explained in [Section 29.3.3.14.1](#).

#### 29.3.4.2.3 I2C Target Receiver Mode

Target receiver mode is entered when the target address transmitted by the controller matches the I2CT's own address and a **low** R/W bit is received. In target receiver mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the controller device. The target device does not generate the clock, but can hold SCL low if intervention of the CPU is required after a byte has been received.

After the a data byte is received, the RXDONE interrupt in CPU\_INT.IIDX register is set. The I<sup>2</sup>C module automatically acknowledges the received data or the user can manually send an acknowledge after each byte received by configuring the ACKCTL register.

When the controller generates a START condition, the START interrupt flag from the CPU\_INT.IIDX register is set. When the controller generates a STOP condition, the STOP interrupt flag from the CPU\_INT.IIDX register is set.

The user can also use the RXTRG interrupt in CPU\_INT.IIDX register to read the data from the receive FIFO. This interrupt triggers when the receive FIFO contains  $\geq$  defined bytes. The FIFO trigger level can be defined in the RXIFSEL bit in the IFLS register.

The RXDONE approach can be used if the target wants to slow down communication to evaluate reception of every byte, while the RXTRG approach is used to maximize throughput and avoid clock stretching.

The flow chart of using RXDONE and RXTRG interrupt to read the receive data are shown in [Figure 29-20](#) and [Figure 29-21](#) respectively.

\* RX buffer is a user defined buffer for the received data packet

Figure 29-20. Target Receiver Mode using RXDONE and ACK Override

Figure 29-21. Target Receiver Mode using RXTRG and Automatic ACK

#### 29.3.4.2.4 I2C Target Transmitter Mode

Target transmitter mode is entered when the target address transmitted by the controller matches the I2CT's own address with a **high** R/W bit. The target transmitter shifts the serial data out on SDA with the clock pulses that are generated by the controller device. The target device does not generate the clock, but can hold SCL low if intervention of the CPU is required after a byte has been transmitted.

After a data byte is transmitted, the TXDONE interrupt in CPU\_INT.IIDX register is set to indicate that a byte has been transmitted.

When the controller generates a START condition, the START interrupt in CPU\_INT.IIDX register is set. When the controller generates a STOP condition, the STOP interrupt in CPU\_INT.IIDX register is set.

The user can also use the TXTRG interrupt from the CPU\_INT.IIDX register to load data to the transmit FIFO. This interrupt triggers when the transmit FIFO contains <= defined bytes. The FIFO trigger level can be defined by using TXIFSEL field in the IFLS register.

The TXDONE approach is used if the target wants to slow down communication to evaluate the transmission of every byte, while the TXTRG approach is used to maximize throughput and avoid clock stretching.

The flow chat of using TXDONE and TXFIFOTRG interrupt to transmit data are shown in [Figure 29-22](#) and [Figure 29-23](#).

\* TX buffer is a user-defined buffer holding data packet to transmit

Figure 29-22. Target Transmitter Mode using TXDONE

Figure 29-23. Target Transmitter Mode using TXFIFOTRG

### 29.3.5 Reset Considerations

#### Software Reset Considerations

A Software reset can be executed in UNICOMM module by setting the RESETASSERT bit together with the KEY bit in the RSTCTL register (UNICOMM Register). Resets must only be issued after terminating a transaction. For more details, refer to Section 27.2.2 .

#### Hardware Reset Considerations

A hardware reset also re-initializes the IO configuration. This sets the IOs to a high-impedance state and with the external pullup resistors for I<sup>2</sup>C, the lines are pulled high.

Table 29-15 and Table 29-16 show the behavior of status bits when Controller or Target gets disabled.

**Table 29-15. Status Bits when Controller is Disabled**

Register	Bit	Behavior when Controller is Disabled	Behavior when Target Disabled	Behavior after Controller/Target is Enabled
SR	BUSY	Reset State	Don't care	Updates START condition sending
	ERR	Reset State	Don't care	Updates on next event detected
	ADRACK	Reset State	Don't care	Updates on next event detected
	DATAACK	Reset State	Don't care	Updates on next event detected
	ARBLST	Reset State	Don't care	Updates on next event detected
	IDLE	Reset State	Don't care	Updates on next event detected
	BUSBSY	Reset State	Don't care	Updates on next START detected on bus (or SDA or SCL is low)
	BCNT	Reset State	Don't care	Updates on next event detected
BMON	SCL	Reset State	Don't care	Updates with Controller enable
	SDA	Reset State	Don't care	Updates with Controller enable

**Table 29-16. Status Bits when Target is Disabled**

Register	Bit	Behavior When Controller Disabled	Behavior When Target Disabled	Behavior After Controller/Target Enabled
SR	RREQ	Don't care	Reset State	Updates on next event detected
	TREQ	Don't care	Reset State	Updates on next event detected
	OAR2SEL	Don't care	Reset State	Updates on next event detected
	QCMDST	Don't care	Reset State	Updates on next event detected
	QCMDRW	Don't care	Reset State	Updates on next event detected

### 29.3.6 Initialization

Please see [Section 29.3.4.1.1](#) for controller initialization and [Section 29.3.4.2.1](#) for target initialization.

### 29.3.7 Interrupt and Events Support

The I<sup>2</sup>C module contains three event publishers and no event subscribers. One event publisher (CPU\_INT) manages I<sup>2</sup>C interrupt requests (IRQs) to the CPU subsystem through a static event route. The second and third event publishers (DMA\_TRIG\_RX, DMA\_TRIG\_TX) are used to setup the trigger signaling for the DMA through DMA event route.

The I<sup>2</sup>C events are summarized in [Table 29-17](#).

**Table 29-17. I2C Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
CPU interrupt	Publisher	I <sup>2</sup> C	CPU Subsystem	Static route	CPU_INT registers	Fixed interrupt route from I <sup>2</sup> C to CPU
DMA trigger	Publisher	I <sup>2</sup> C	DMA	DMA event route	DMA_TRIG_RX registers	Fixed interrupt route from I <sup>2</sup> C to DMA
DMA trigger	Publisher	I <sup>2</sup> C	DMA	DMA event route	DMA_TRIG_TX registers	Fixed interrupt route from I <sup>2</sup> C to DMA

### 29.3.7.1 CPU Interrupt Event Publisher (CPU\_INT)

The I<sup>2</sup>C module provides 15 interrupt sources for I2C controllers and 17 interrupt sources for I2C targets which can be configured to source a CPU interrupt event. In order of decreasing interrupt priority, the CPU interrupt events from the I<sup>2</sup>C are:

**Table 29-18. I<sup>2</sup>C CPU Interrupt Event Conditions for Controller (CPU\_INT)**

<b>IIDX STAT</b>	<b>Name</b>	<b>Description</b>
0x01	RXDONE	Controller receive transaction completed
0x02	TXDONE	Controller transmit transaction completed
0x03	RXTRG	Controller receive trigger, occurs when receive buffer has data
0x04	TXTRG	Controller transmit trigger, occurs when transmit buffer is empty
0x05	RXFULL	Controller RXFIFO full event. This interrupt is set if an RX FIFO is full.
0x06	TXEMPTY	Controller transmit FIFO empty interrupt. This interrupt is set if all data in the Transmit FIFO have been shifted out and the transmit goes into idle mode.
0x08	NACK	Controller Address/Data NACK interrupt
0x09	START	Controller START detection interrupt
0x0A	STOP	Controller STOP detection interrupt
0x0B	ARBLOST	Controller arbitration lost interrupt
0x0C	PEC_RX_ERR	Controller PEC error occurred
0x0D	TIMEOUTA	Controller Timeout A occurred (clock low timeout)
0x0F	TIMEOUTB	Controller Timeout B occurred (clock high timeout)
0x10	DMA_DONE_RX	Controller DMA TX done
0x11	DMA_DONE_TX	Controller DMA RX done

**Table 29-19. I<sup>2</sup>C CPU Interrupt Event Conditions for Target (CPU\_INT)**

<b>IIDX STAT</b>	<b>Name</b>	<b>Description</b>
0x01	RXDONE	Target Receive Data Interrupt
0x02	TXDONE	Target Transmit Transaction completed Interrupt
0x03	RXTRG	Target Receive Trigger
0x04	TXTRG	Target Transmit Trigger
0x05	RXFULL	Target RXFIFO full event. This interrupt is set if an Target RX FIFO is full.
0x06	TXEMPTY	Target Transmit FIFO Empty interrupt mask. This interrupt is set if all data in the Transmit FIFO have been shifted out and the transmit goes into idle mode.
0x07	TX_UNFL	Target TX FIFO underflow
0x08	RX_OVFL	Target RX FIFO overflow
0x09	GENCALL	Target General Call Interrupt
0x0A	START	Target Start Condition Interrupt
0x0B	STOP	Target Stop Condition Interrupt
0x0C	PEC_RX_ERR	Target RX Pec Error Interrupt
0x0D	TIMEOUTA	Target Timeout A Interrupt
0x0E	TIMEOUTB	Target Timeout B Interrupt
0x10	DMA_DONE_RX	Target DMA Done on Event Channel RX
0x11	DMA_DONE_TX	Target DMA Done on Event Channel TX
0x12	ARBLOST	Target Arbitration Lost Interrupt

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See *Event Registers* for guidance on configuring the Event registers for CPU interrupts.

### 29.3.7.2 DMA Trigger Publisher (DMA\_TRIG\_RX, DMA\_TRIG\_TX)

The DMA\_TRIG\_TX and DMA\_TRIG\_RX group registers are used to setup trigger signaling for the DMA. These registers (IMASK, RIS, MIS, ISET, ICLR) are present for any UCx configured as an I2C Commander or an I2C Target and can be found in the corresponding UNICOMMI2CC\_REGS and UNICOMMI2CT\_REGS register structures. See *DMA Trigger* for how the DMA trigger Event works and can be configured. Each DMA channel can be triggered by any of the conditions listed in the *DMA Trigger Source Options* and can send a PRE\_IRQ or DMA\_DONE signal to the corresponding UCx module.

**Table 29-20. I<sup>2</sup>C DMA Trigger Condition (DMA\_TRIG\_RX and DMA\_TRIG\_TX)**

Trigger Name	Register Structure	Register Group	Description
RXTRG	UNICOMMI2CC_REGS	DMA_TRIG_RX	Controller receive FIFO event. Trigger when I2CC-configured UCx module's Receive FIFO contains >= IFLS.RXIFSEL defined bytes
TXTRG	UNICOMMI2CC_REGS	DMA_TRIG_TX	Controller transmit FIFO event. Trigger when I2CC-configured UCx module's Transmit FIFO contains <= IFLS.TXIFSEL defined bytes
RXTRG	UNICOMMI2CT_REGS	DMA_TRIG_RX	Target receive FIFO event. Trigger when I2CT-configured UCx module's Receive FIFO contains >= IFLS.RXIFSEL defined bytes
TXTRG	UNICOMMI2CT_REGS	DMA_TRIG_TX	Target transmit FIFO event. Trigger when I2CT-configured UCx module's Transmit FIFO contains <= IFLS.TXIFSEL defined bytes

The DMA trigger event configuration is managed with the DMA\_TRIG\_RX and DMA\_TRIG\_TX event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers and [Section 7.1.3.2](#) for on how DMA trigger event works. DMA\_TRIG\_RX and DMA\_TRIG\_TX are two event management registers that correspond to two DMA channels.

Take an example where UC0 is configured with the I2CC IPMODE and UC1 is configured with the I2CT IPMODE. To use different DMA channels for each of the operations (controller-transmitter, controller-receiver, target-transmitter, target-receiver) four channels are set up as shown in [Figure 29-24](#). For both UC modules, RXTRG is set as the trigger source for DMA\_TRIG\_RX and TXTRG is set as the trigger source for DMA\_TRIG\_TX. The DMA\_DONE signal is asserted to trigger a CPU interrupt when the DMA operation completes after transferring the preset data length.

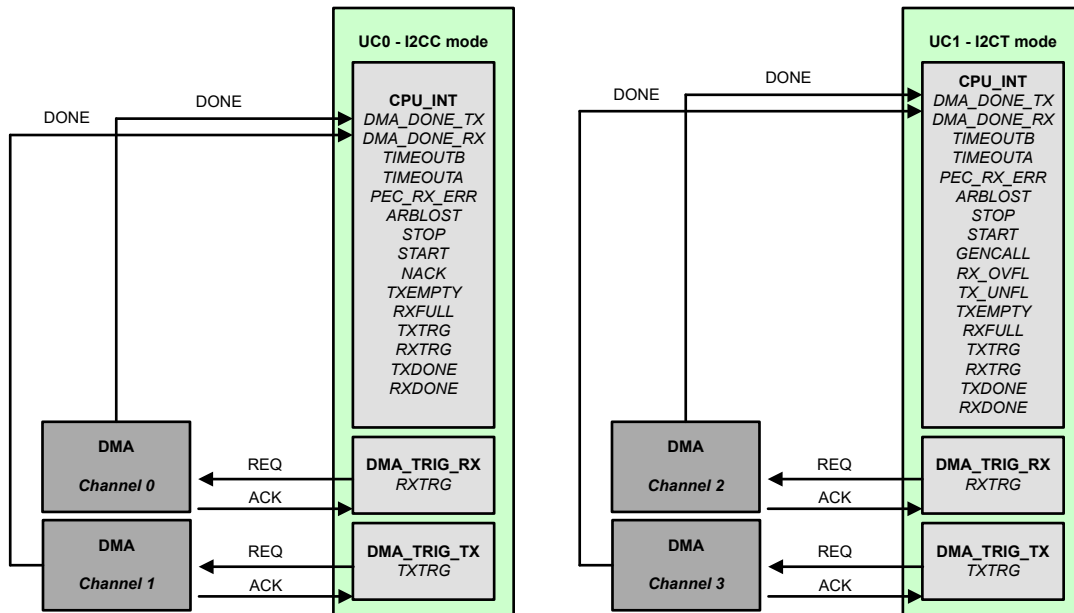

Figure 29-24. I²C DMA Trigger and Status Example

### 29.3.8 Emulation Modes

The UNICOMM I2C module behavior while the device is in debug mode is controlled by the FREE and SOFT bits in PDBGCTL register.

When the device is in debug mode and set into halt mode below behavior can be configured.

Table 29-21. Debug Mode Peripheral Behavior

PDBGCTL.FREE	PDBGCTL.SOFT	Function
1	x	Modules continues operation
0	1	Graceful halt Module stops after the next transfer has been finished
0	0	Not supported

### Graceful Halt

When emulation mode is set to graceful halt and a halt condition occurs, the I2C instance stops communications after the ongoing frame has finished, shown in [Figure 29-25](#).

**Figure 29-25. I2C Graceful Halt Emulation Behavior**

#### Transmitter

- I2C finishes transmitting the ongoing frame and FSM returns to IDLE and stop.
- External lines are driven to IDLE condition.
- Removing halt resumes communication

#### Receiver

- I2C receives ongoing frame and FSM returns to IDLE and stop
- Any new messages are be processed
- After halt is removed, FSM begins communications
- FSM can start reception in the middle of a frame

### 29.4 UNICOMM I2C Registers

This Section describes the UNICOMM-I2C Registers.

### 29.4.1 UNICOMMI2CC Registers

Table 29-22 lists the memory-mapped registers for the UNICOMMI2CC registers. All register offset addresses not listed in Table 29-22 should be considered as reserved locations and the register contents should not be modified.

**Table 29-22. UNICOMMI2CC Registers**

Offset	Acronym	Register Name	Group	Section
1000h	CLKDIV	Clock Divider		<a href="#">Go</a>
1008h	CLKSEL	Clock Select for Ultra Low Power peripherals		<a href="#">Go</a>
1020h	IIDX	Interrupt index	CPU_INT	<a href="#">Go</a>

17	RESERVED	R	0h	
16	DMA_DONE_TX	R/W	0h	I2CC DMA Done on TX Event Channel Interrupt Mask. This interrupt is raised when the DONE signal is sent to the I2CC from a DMA, indicating all the transactions have completed. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
15	DMA_DONE_RX	R/W	0h	I2CC DMA Done on RX Event Channel Interrupt Mask. This interrupt is raised when the DONE signal is sent to the I2CC from a DMA indicating all the transactions have completed. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
14	RESERVED	R	0h	
13	TIMEOUTB	R/W	0h	I2CC Timeout Counter B Interrupt Mask. This interrupt is raised when the SCL line is continuously high for longer than the clock timeout period programmed by the TIMEOUT_CTL.TCNTLB register. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
12	TIMEOUTA	R/W	0h	I2CC Timeout Counter A Interrupt Mask. This interrupt is raised when the SCL line is continuously low for longer than the clock timeout period programmed by the TIMEOUT_CTL.TCNTLA register. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
11	PEC_RX_ERR	R/W	0h	I2CC Receive PEC Error Interrupt Mask. This interrupt is raised when the PEC calculated by the I2CC does not match received PEC. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask

**Table 29-31. IMASK Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10	ARBLOST	R/W	0h	I2CC Arbitration Lost Interrupt Mask. This flag indicates that the I2CC has lost an arbitration contest with another Controller in a multi-controller system. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
9	STOP	R/W	0h	I2CC STOP Detection Interrupt Mask. This interrupt is raised when a STOP condition is detected on the bus, either generated by the current I2CC or another I2C Controller when in multi-master mode. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
8	START	R/W	0h	I2CC START Detection Interrupt Mask. This interrupt is raised when a START condition is detected on the bus, either generated by the current I2CC or another I2C Controller when in multi-master mode. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
7	NACK	R/W	0h	I2CC Address/Data NACK Interrupt Mask. This interrupt is raised when an address or data NACK is received by the I2CC. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
6	RESERVED	R	0h	
5	TXEMPTY	R/W	0h	I2CC TX FIFO Empty Interrupt Mask. This interrupt is raised when all data has been shifted out of the TX FIFO and the I2CC transmitter goes idle. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
4	RXFULL	R/W	0h	I2CC RX FIFO Full Interrupt Mask. This interrupt is raised when the RX FIFO is full. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
3	TXTRG	R/W	0h	I2CC Transmit Trigger Interrupt Mask. This interrupt is raised when the TX FIFO condition, programmed by the IFLS register, is met. When FIFO is not present, this indicates that the buffer is empty. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
2	RXTRG	R/W	0h	I2CC Receive Trigger Interrupt Mask. This interrupt is raised when the RX FIFO condition programmed by the IFLS register is met. When FIFO is not present, this indicates that the buffer is full. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
1	TXDONE	R/W	0h	I2CC Transmit Done Interrupt Mask. This interrupt is raised when a burst length of CTR.BLEN bytes is transmitted. For variants where the BLEN register is not available, it is raised after each byte is transmitted. In the case of a quick command, the interrupt is raised when a quick command with R/Wn bit set to '0'. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask
0	RXDONE	R/W	0h	I2CC Receive Done Interrupt Mask. This interrupt is raised when a burst length of CTR.BLEN bytes is received. For variants where the BLEN register is not available, it is raised after each byte is received. In the case of a quick command, the interrupt is raised when a quick command with R/Wn bit set to '1'. 0h = Clear Interrupt Mask 1h = Set Interrupt Mask

### 5 RIS (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 29-30](#) and described in [Table 29-28](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

7	NACK	R	0h	I2CC Address/Data NACK Interrupt Masked Status. This interrupt is raised when an address or data NACK is received by the I2CC. 0h = Interrupt did not occur or mask was not enabled 1h = Interrupt occurred
6	RESERVED	R	0h	
5	TXEMPTY	R	0h	I2CC TX FIFO Empty Interrupt Masked Status. This interrupt is raised when all data has been shifted out of the TX FIFO and the I2CC transmitter goes idle. 0h = Interrupt did not occur or mask was not enabled 1h = Interrupt occurred
4	RXFULL	R	0h	I2CC RX FIFO Full Interrupt Masked Status. This interrupt is raised when the RX FIFO is full. 0h = Interrupt did not occur or mask was not enabled 1h = Interrupt occurred
3	TXTRG	R	0h	I2CC Transmit Trigger Interrupt Masked Status. This interrupt is raised when the TX FIFO condition, programmed by the IFLS register, is met. When FIFO is not present, this indicates that the buffer is empty. 0h = Interrupt did not occur or mask was not enabled 1h = Interrupt occurred
2	RXTRG	R	0h	I2CC Receive Trigger Interrupt Masked Status. This interrupt is raised when the RX FIFO condition programmed by the IFLS register is met. When FIFO is not present, this indicates that the buffer is full. 0h = Interrupt did not occur or mask was not enabled 1h = Interrupt occurred
1	TXDONE	R	0h	I2CC Transmit Done Interrupt Masked Status. This interrupt is raised when a burst length of CTR.BLEN bytes is transmitted. For variants where the BLEN register is not available, it is raised after each byte is transmitted. In the case of a quick command, the interrupt is raised when a quick command with R/Wn bit set to '0'. 0h = Interrupt did not occur or mask was not enabled 1h = Interrupt occurred
0	RXDONE	R	0h	I2CC Receive Done Interrupt Masked Status. This interrupt is raised when a burst length of CTR.BLEN bytes is received. For variants where the BLEN register is not available, it is raised after each byte is received. In the case of a quick command, the interrupt is raised when a quick command with R/Wn bit set to '1'. 0h = Interrupt did not occur or mask was not enabled 1h = Interrupt occurred

## 7 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 29-32](#) and described in [Table 29-30](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Table 29-59. CTR Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	RESERVED	R	0h	
27-16	BLEN	R/W	0h	I2CC Transaction Length. This field contains the programmed length of bytes of the next transaction. For variants that don't have the BLEN register, the BLEN is hardcoded to a value of 1. 0h = Smallest value FFFh = Highest possible value
15-7	RESERVED	R	0h	
6	SUSPEND	R/W	0h	Suspend External Communication. When this bit is set, I2CC communication on the external bus is suspended after the I2CC FSM goes idle (SR.BUSY reads '0'). 0h = Normal communication 1h = External communication suspended
5	RD_ON_TXEMPTY	R/W	0h	Read on TX EMPTY Enable/Disable. This feature initiates an I2CC write followed by a I2CC read without needing application intervention. 0h = No special behavior 1h = The I2CC will transmit all the bytes from TX FIFO, issue a RESTART and receive data as per programmed burst length (BLEN). This bit is ignored if DIR bit is not set to READ.

**Table 29-59. CTR Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	ACKOEN	R/W	0h	<p>ACK Override Enable When ACKOEN is enabled: 1. I2CC receives data according to the configured burst length (BLEN). 2. Upon receiving the complete data burst, I2CC generates a RXDONE interrupt. 3. The I2CC then holds SCL line low (clock stretching) during the acknowledge phase. 4. This pause gives the application time to update the ACKOVAL register. At this point, application has two options: Option 1: Terminate transaction 1. Set ACKOVAL to send a NACK. 2. The I2CC will automatically generate a STOP condition after the NACK. Option 2: Continue transaction 1. Clear ACKOVAL to send an ACK. 2. Update any other settings as needed. 3. The transaction will proceed based on the new configuration. This mechanism allows the application to control the transaction flow after each data burst is received. Note: In some variants, when BLEN register is not available, the design implements a hardcoded BLEN value of '1'. Consult your device datasheet.</p> <p>0h = No special behavior 1h = Acknowledge Override Feature Enabled</p>
3	ACK	R/W	0h	<p>Final Data Acknowledge Value. Determines whether a ACK or NACK is automatically sent by the I2CC after the last byte, of length 'N', are received from the target. This setting is used when CTR.ACKOEN=0.</p> <p>0h = The last received data byte of a transaction is not acknowledged automatically. 1h = The last received data byte of a transaction is acknowledged automatically.</p>
2	STOP	R/W	0h	<p>Enable STOP Condition Generation. I2CC is enabled to send the STOP condition on the bus at the end of the current transaction, per the I2C protocol.</p> <p>0h = The controller does not generate the STOP condition. 1h = The controller generates the STOP condition.</p>
1	START	R/W	0h	<p>Enable START Condition Generation. I2CC is enabled to send the START condition on the bus per the I2C protocol, when CTR.FRM_START is also set.</p> <p>0h = The controller does not generate the START condition. 1h = The controller generates the START or repeated START condition.</p>
0	FRM_START	R/W	0h	<p>Frame Start. Start the transaction on the I2C bus according to the programmed settings.</p> <p>0h = Write of '0' has no effect. Reads back '0' when there is no ongoing transaction 1h = When written to '1', a new transaction is started. Has no effect if there is an ongoing transaction. Reads back as '1' if the transaction is ongoing</p>

**19 CR (Offset = 1104h) [Reset = 0000000h]**

CR is shown in [Figure 29-44](#) and described in [Table 29-42](#).

Return to the [Summary Table](#).

I2CC Configuration Register. Configures and enables the I2CC.

Bit	Field	Type	Reset	Description
31-3	RESERVED	R	0h	
2	CLKSTRETCH	R/W	0h	Clock Stretching Enable. This bit enables/disables clock stretching detection of the I2CC. 0h = Disables the clock stretching detection. This can be disabled if no Target on the bus does support clock stretching, so that the maximum speed on the bus can be reached. 1h = Enables the clock stretching detection. Enabling the clock stretching ensures compliance to the I2C standard but could limit the speed due the clock stretching.
1	MCTL	R/W	0h	Multi-Controller Mode Enable/Disable. In Multi-Controller mode, the SCL high time begins counting once the SCL line has been detected high. If this bit is not set, the SCL high time begins counting as soon as the SCL line has been set high by the I2CC. 0h = Disable MultiController mode. 1h = Enable MultiController mode.
0	ENABLE	R/W	0h	Enable I2CC module. After this bit has been set, it should not be set again unless it has been cleared by writing a 0 or by a reset, otherwise transfer failures may occur. 0h = Disables operation. 1h = Enables operation.

## 20 SR (Offset = 1108h) [Reset = 0000000h]

SR is shown in [Figure 29-45](#) and described in [Table 29-43](#).

Return to the [Summary Table](#).

I2CC Status Register. This status register indicates the current state of the I2CC.

**Table 29-63. SR Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	BUSBSY	R	0h	I2C Bus Busy Status. Indicates when the external line is busy 1. It is set when there is an ongoing transaction on the bus (i.e. if there is a START condition observed) or if SCL toggles. 2. It is cleared upon a STOP condition or when HIGH TIMEOUT occurs & SCL/SDA are both at their IDLE state. This bit reads back '0' when ACTIVE is cleared. The I2CC will wait until this bit is cleared before starting an I2C transaction. When enabling the controller initially, the application should wait for one I2C clock period, poll BUSBSY and start a transaction. 0h = The I2C bus is idle. 1h = SET
5	IDLE	R	1h	I2CC FSM Idle Status. This bit is set when the internal I2CC state machine, rather than when the external bus, is not busy with an ongoing transaction i.e. there is no transmit/receive of data bytes, START, RESTART, Address or STOP signal generation occurring. 0h = The I2C controller is not idle. 1h = The I2C controller is idle.
4	ARBLST	R	0h	Arbitration Lost Status. This status bit indicates whether or not the I2CC won arbitration on the bus. 0h = The I2C controller won arbitration. 1h = The I2C controller lost arbitration.
3	DATAACK	R	0h	Data Acknowledge Status. This status bit indicates the acknowledgement status of the previously transmitted data byte. 0h = The transmitted data was acknowledged 1h = The transmitted data was not acknowledged.
2	ADRACK	R	0h	Acknowledge Address 0h = The transmitted address was acknowledged 1h = The transmitted address was not acknowledged.
1	ERR	R	0h	NACK Error Status. This status bit indicates the acknowledgement status of the previously transmitted target address or data byte. 0h = No error was detected on the last operation. 1h = An error occurred on the last operation.
0	BUSY	R	0h	I2CC FSM Busy Status. This bit is set when the internal I2CC state machine, rather than when the external bus, is busy with an ongoing transaction i.e. during transmit/receive of data bytes configured as per BLEN including START, RESTART, Address and STOP signal generation. In variants where the BLEN register is not available, the design implements a hardcoded BLEN value of '1'. 0h = The controller is idle. 1h = The controller is busy.

## 21 IFLS (Offset = 110Ch) [Reset = 0000022h]

IFLS is shown in [Figure 29-46](#) and described in [Table 29-44](#).

Return to the [Summary Table](#).

I2CC Interrupt FIFO Level Select Register. The IFLS register is the interrupt FIFO level select register. Use this register to define the levels at which the TX, RX, and Receive timeout interrupt flags are triggered. The interrupts are generated based on a transition through a level rather than being based on the level itself. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered when the receive FIFO is filled with two or more characters. Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	
12	PECEN	R/W	0h	PEC Enable. This bit enables the SMB Packet Error Checking (PEC). When enabled, the PEC is calculated on all bits except the START, STOP, and ACK/NACK. The PEC LSFR and the Byte Counter is set to 0 when the State Machine is in the IDLE state, which occur following a STOP or when a timeout occurs. The Counter is also set to 0 after the PEC byte is sent or received. Note that the NACK is automatically send following a PEC byte that results in a PEC error. The PEC Polynomial is $x^8 + x^2 + x^1 + 1$ . 0h = PEC is disabled 1h = PEC is enabled
11-9	RESERVED	R	0h	
8-0	PECCNT	R/W	0h	PEC Count. When this field is non zero, the number of I2C bytes are counted (Note that although the PEC is calculated on the I2C address it is not counted at a byte). When the byte count = PECCNT and the I2CC is transmitting, the contents of the LSFR is loaded into the shift register instead of the byte received from the TX FIFO. When the state machine is receiving, after the last bit of this byte is received the LSFR is checked and if it is non-zero, a PEC RX Error interrupt is generated. The I2C packet must be padded to include the PEC byte for both transmit and receive. In transmit mode, the FIFO must be loaded with a dummy PEC byte. In receive mode, the PEC byte will be passed to the RX FIFO. In the a typical controller use case, the application would set PECEN=1 and PECCNT=SMB packet length (not including the Target Address byte, but including the PEC byte). The I2CC application would then configure the DMA to allow the packet to complete unassisted and write CTR to initiate the transaction. Note that when the byte count = PECCNT, the byte count is reset to 0 and multiple PEC calculations can automatically occur within a single I2C transaction. Note that any write to the PECCTL register will clear the current PEC byte count in the I2CC state machine. 0h = Minimum Value 1FFh = Maximum Value

### 29.4.2 UNICOMMI2CT Registers

Table 29-55 lists the memory-mapped registers for the UNICOMMI2CT registers. All register offset addresses not listed in Table 29-55 should be considered as reserved locations and the register contents should not be modified.

**Table 29-86. UNICOMMI2CT Registers**

Offset	Acronym	Register Name	Group	Section
1000h	CLKDIV	Clock Divider		<a href="#">Go</a>

**Table 29-123. CTR Field Descriptions**

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	
21	WUEN	R/W	1h	Target Wakeup Enable. 0h = When 0, the Target is not allowed to clock stretch on START detection 1h = When 1, the Target is allowed to clock stretch on START detection and wait for faster clock to be available. This allows clean wake up support for I2C in low power mode use cases
20	CLKSTRETCH	R/W	1h	Clock Stretching Enable. The I2CT will automatically clock stretch on the SCL line if the TX FIFO/buffer is empty in transmit mode or the RX FIFO/buffer is full in receive mode. 0h = clock stretching is disabled 1h = clock stretching is enabled
19-12	RESERVED	R	0h	
11	SUSPEND	R/W	0h	Suspend External Communication. When this bit is set, I2CT communication on the external bus is suspended after the I2CT FSM goes idle (SR.BUSY reads '0'). 0h = Functional mode resumed 1h = External communication suspended
10	RESERVED	R	0h	
9	EN_DEFDEVADR	R/W	0h	Enable Default Device Address. 0h = When this bit is 0, the default device address is not matched. NOTE: it may still be matched if programmed inside OAR/OAR2. 1h = When this bit is 1, default device address of 7'h110_0001 is always matched by the Target address match logic.
8	EN_ALRESPADR	R/W	0h	Enable Alert Response Address. 0h = When this bit is 0, the alert response address is not matched. NOTE: it may still be matched if programmed inside OAR/OAR2 1h = When this bit is 1, alert response address of 7'h000_1100 is always matched by the Target address match logic.

**Table 29-123. CTR Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7	EN_DEFHOSTADR	R/W	0h	Enable Default Host Address. 0h = When this bit is 0, the default host address is not matched NOTE: it may still be matched if programmed inside OAR/OAR2 1h = When this bit is 1, default host address of 7'h000_1000 is always matched by the Target address match logic.
6	RXFULL_ON_RREQ	R/W	0h	RX Full Interrupt on RREQ. This bit setting determines the behavior of the RXFULL interrupt. 0h = When 0, RIS.RXFULL will be set when only the Target RX FIFO is full. This allows the RXFULL interrupt to be used to indicate that the I2C bus is being clock stretched and that the FW must either read the RX FIFO or ACK/NACK the current RX byte. 1h = When 1, RIS.RXFULL will be set when the I2CT FSM is in the RX_WAIT or RX_ACK_WAIT states which occurs when the I2C transaction is clock stretched because the RX FIFO is full or the ACKOEN has been set and the FSM is waiting for FW to ACK/NACK the current byte.
5	TXWAIT_STALE_TXFIFO	R/W	0h	TX Transfer Wait Configuration. This bit setting determines the behavior of the I2CT transmitter, specifically whether or not the transmitter waits when there is stale data in the TX FIFO. This prevents stale bytes left in the TX FIFO from automatically being sent on the next I2C packet. Note: This setting should only be enabled when TXEMPTY_ON_TREQ is set to prevent the I2CT FSM from waiting for TX FIFO data without an interrupt notification when there is stale FIFO data. 0h = When 0, the TX FIFO empty signal to the Target State Machine indicates that the TX FIFO is empty. 1h = When 1, the TX FIFO empty signal to the Target State Machine will indicate that the TX FIFO is empty or that the TX FIFO data is stale. The TX FIFO data is determined to be stale when there is data in the TX FIFO when the Target State Machine leaves the TXMODE as defined in the SR register. A stale TX FIFO occurs if a Stop or timeout condition occurs when there are bytes left in the TX FIFO.
4	TXTRIG_TXMODE	R/W	0h	TX Trigger when I2CT FSM is in TX Mode. This bit setting determines the behavior of the TXTRG DMA trigger. 0h = No special behavior 1h = When 1, RIS.TXTRG is set when the I2CT TX FIFO has reached the trigger level AND the I2CT FSM is in the TX mode, as defined in the SR register. When cleared, RIS.TXTRG is set when the I2CT TX FIFO is at or above the trigger level. This setting can be used to hold off the TX DMA until a transaction starts. This allows the DMA to be configured when the I2CT is idle but have it wait until the transaction starts to load the I2CT TX FIFO, so it can load from a memory buffer that might be changing over time.
3	TXEMPTY_ON_TREQ	R/W	0h	TX Empty Interrupt on TREQ. This bit setting determines the behavior of the TXEMPTY interrupt. 0h = When 0, RIS.TXEMPTY will be set when only the I2CT TX FIFO is empty. This allows the TXEMPTY interrupt to be used to indicate that the I2C bus is being clock stretched and that I2CT TX data is required. 1h = When 1, RIS.TXEMPTY will be set when the I2CT FSM is in the TX_WAIT state which occurs when the TX FIFO is empty AND the I2C transaction is being clock stretched waiting for data to be written to the TX FIFO.
2	RESERVED	R	0h	
1	GENCALL	R/W	0h	General Call/Response Enable. Modify only when UCSWRST = 1. 0b = Do not respond to a general call 1b = Respond to a general call 0h = Do not respond to a general call 1h = Respond to a general call
0	ENABLE	R/W	0h	I2CT Enable. Setting this bit enables the module. 0h = Disables module operation. 1h = Enables module operation.

## 19 ACKCTL (Offset = 1104h) [Reset = 0000000h]

ACKCTL is shown in [Figure 29-75](#) and described in [Table 29-75](#).

Return to the [Summary Table](#).

I2CT Acknowledge Control Register. This register enables the I2CT to Not Acknowledge (NACK) for invalid data/commands or Acknowledge (ACK) for valid data/commands. The I2C SCL is pulled low after the last data bit until this register is written.

**Figure 29-75. ACKCTL**

**Table 29-125. ACKCTL Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	RESERVED	R	0h	
4	ACKOEN_ON_PECDONE	R/W	0h	Acknowledge Override Enable on PEC Done. When set, this bit will automatically turn on target acknowledge enable field following the ACK/NACK of the received PEC byte. Status bit ACKOEN will reflect a value of '1' when automatic override enable is used. 0h = No special behavior 1h = When set this bit will automatically turn on the Target ACKOEN field following the ACK/NACK of the received PEC byte.
3	ACKOEN_ON_PECNEXT	R/W	0h	Acknowledge Override Enable on PEC Next. When set this bit will automatically turn on the I2CT acknowledge override following a ACK/NACK of the byte received just prior to the PEC byte. However, setting ACKCTL.ACKOEN bit will not automatically be ACKed/NACKed by the FSM and firmware must perform this function by writing Target.ACKCTL register. Status bit ACKOEN will reflect a value of '1' when automatic override enable is used. 0h = No special behavior 1h = When set this bit will automatically turn on the Target ACKOEN field following the ACK/NACK of the byte received just prior to the PEC byte. Note that when ACKOEN is set the PEC byte will not automatically be ACKed/NACKed by the State Machine and FW must perform this function by writing ACKCTL.
2	ACKOEN_ON_START	R/W	0h	Acknowledge Override Enable on START. When set this bit will automatically enable target override acknowledge following a Start Condition. Status bit ACKOEN will reflect a value of '1' when automatic override enable is used. 0h = No special behavior 1h = When set this bit will automatically turn on the Target ACKOEN field following a Start Condition.

**Table 29-125. ACKCTL Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	ACKOVAL	R/W	0h	ACK Override Value. Note: Override control is not applicable to Address frame. Bytes following address frame can be acknowledged using ACKOVAL. 0h = An ACK is sent indicating valid data or command. 1h = A NACK is sent indicating invalid data or command.
0	ACKOEN	R/W	0h	I2CT ACK Override Enable. Determines if the I2CT clock stretches and waits for the application to manually ACK/NACK each received byte using the ACKCTL.ACKOVAL bit, or if the ACK/NACK is done automatically. Read SR.ACKOEN to check current status of this bit. 0h = A response is not provided. 1h = An ACK or NACK is sent according to the value written to the ACKOVAL bit.

## 20 SR (Offset = 1108h) [Reset = 0000000h]

SR is shown in [Figure 29-76](#) and described in [Table 29-76](#).

Return to the [Summary Table](#).

I2CT Status Register. This status register indicates the current state of the I2CT.

8	STALE_TXFIFO	R	0h	Stale TX FIFO Status. 0h = TX FIFO is not stale 1h = The TX FIFO is stale. This occurs when the TX FIFO was not emptied during the previous I2C transaction.

**Table 29-127. SR Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7	TXMODE	R	0h	I2CT FSM is in TX Mode. 0h = State Machine is not in TX_DATA, TX_WAIT, TX_ACK or ADDR_ACK state with the bus direction set to read. 1h = State Machine is in TX_DATA, TX_WAIT, TX_ACK or ADDR_ACK state with the bus direction set to read.
6	BUSBSY	R	0h	I2C Bus Busy Status. 0h = The I2C Bus is not busy 1h = The I2C Bus is busy. This is cleared on a timeout.
5	QCMDRW	R	0h	Quick Command Read / Write Status. This bit only has meaning when the QCMDST bit is set. Value Description: 0: Quick command was a write 1: Quick command was a read 0h = Quick command was a write 1h = Quick command was a read
4	QCMDST	R	0h	Quick Command Status. Value Description: 0: The last transaction was a normal transaction or a transaction has not occurred. 1: The last transaction was a Quick Command transaction 0h = The last transaction was a normal transaction or a transaction has not occurred. 1h = The last transaction was a Quick Command transaction.
3	OAR2SEL	R	0h	OAR2 Address Matched Status. This bit gets re-evaluated after every address comparison. 0h = Either the OAR2 address is not matched or the match is in legacy mode. 1h = OAR2 address matched and ACKed by the Target.
2	RXMODE	R	0h	I2CT FSM is in RX Mode. 0h = The Target State Machine is not in the RX_DATA, RX_ACK, RX_WAIT, RX_ACK_WAIT or ADDR_ACK state with the bus direction set to write. 1h = The Target State Machine is in the RX_DATA, RX_ACK, RX_WAIT, RX_ACK_WAIT or ADDR_ACK state with the bus direction set to write.
1	TREQ	R	0h	Transmit Request Status. 0h = No outstanding transmit request. 1h = I2C Target is addressed as a transmitter and is using clock stretching to delay the Controller until data has been written to the TXDATA FIFO (TX FIFO is empty).
0	RREQ	R	0h	Receive Request Status. 0h = No outstanding receive data. 1h = Module has outstanding receive data and is using clock stretching to delay the Controller until the data has been read from the RXDATA FIFO (RX FIFO is full).

## 21 IFLS (Offset = 110Ch) [Reset = 0000022h]

IFLS is shown in [Figure 29-77](#) and described in [Table 29-77](#).

Return to the [Summary Table](#).

I2CT Interrupt FIFO Level Select Register. The IFLS register is the interrupt FIFO level select register. You can use this register to define the levels at which the TX, RX and timeout interrupt flags are triggered. The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered when the RX FIFO is filled with two or more characters. Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**Table 29-147. PECCTL Field Descriptions**

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	
12	PECEN	R/W	0h	PEC Enable. This bit enables the SMB Packet Error Checking (PEC). When enabled, the PEC is calculated on all bits except the START, STOP, ACK and NACK. The PEC internal LSFR and the PECCNT are set to 0 when the I2CT FSM is in the IDLE state, which occurs following a STOP or timeout condition. The PECCNT is also set to 0 after the PEC byte is transmitted or received. Note that the NACK is automatically sent following a PEC byte that results in a PEC error. The PEC polynomial is $x^8 + x^2 + x^1 + 1$ . 0h = PEC transmission and check is disabled 1h = PEC transmission and check is enabled
11-9	RESERVED	R	0h	
8-0	PECCNT	R/W	0h	PEC Counter. When this field is non zero, the number of I2C data bytes are counted. When the byte count = PECCNT and the I2CT FSM is transmitting, the contents of the internal LSFR is loaded into the shift register instead of the byte received from the TX FIFO. When the FSM is receiving, after the last bit of this byte is received into the LSFR and the FSM checks that it is non-zero, a PEC RX Error interrupt is generated. The I2C packet must be padded to include the PEC byte for both transmit and receive. In transmit mode, the FIFO must be loaded with a dummy PEC byte. In receive mode, the PEC byte will be passed to the RX FIFO. In the normal use case, FW would set PECEN=1 and PECCNT=0 and use the ACKOEN until the remaining SMBus packet length is known. FW would then set the PECCNT to the remaining packet length (including the PEC byte). FW would then configure the DMA to allow the packet to complete unassisted and exit the NACK mode. Note that when the byte count = PECCNT, the byte count is reset to 0 and multiple PEC calculation can automatically occur within a single I2C transaction. 0h = Minimum Value 1FFh = Maximum Value

<b>30.1 UNICOMM-SPI Overview</b> .....	<b>1797</b>
<b>30.2 SPI Operation</b> .....	<b>1800</b>
<b>30.3 UNICOMMSPI Registers</b> .....	<b>1817</b>

## 30.1 UNICOMM-SPI Overview

This section describes the functionality of a UNICOMM module when configured to operate as an SPI. The protocol mode of a given UNICOMM instance is determined by the programmed SELECT field of the IPMODE register. If a UNICOMM instance is configured for another peripheral mode, the SPI functionality on that UNICOMM instance is disabled, and all register reads return a value of zero.

The UNICOMM-SPI (Serial Peripheral Interface) module provides a standardized serial interface to transfer data between MSPM0 devices and other external devices with SPI interface. The SPI module provides a standardized serial interface to transfer data between MSPM0/M33 devices and other external devices (such as a Sensors, Memory, ADCs, or DACs) using SPI protocols

### 30.1.1 Purpose of the Peripheral

The SPI module acts as a controller or peripheral interface for synchronous serial communication with peripheral devices and other controllers. The transmit and receive paths are buffered with internal, independent FIFO memories, allowing up to 4 entries with 16-bit width. A DMA interface is also provided to allow the data exchange with the transmit and receive FIFO.

### 30.1.2 Features

The UNICOMM-SPI peripheral mode of the UNICOMM module includes the following features:

- Configurable as a controller or a peripheral
- Programmable clock bit rate and prescaler
- Separate transmit (TX) and receive (RX) buffers/first-in first-out buffers (FIFOs)
  - Availability of buffer / FIFO depends on the variant/overlay chosen
- Programmable data frame size from 4-bits to 16-bits (Controller Mode)
- Programmable data frame size from 7-bits to 16-bits (Peripheral Mode)
- Interrupts for transmit and receive buffers/FIFOs, overrun and timeout interrupts, and DMA completion interrupts
- Programmable SPI mode support for Motorola SPI or Texas Instruments frame format
- Single-bit parity is supported in both transmit and receive paths
- Direct memory access controller interface (DMA)
  - Separate channels for transmit and receive
  - Transfer complete interrupt

**Table 30-1. SPI variants and features**

Feature	Basic	Advanced
Controller / Peripheral mode	Yes	Yes
Controller: 4-16 bits Target: 7-16 bits	Yes	Yes
Parity	Yes	Yes
Repeat Mode	No	Yes
Receive Timeout	No	Yes
Command / Data Control	No	Yes
Support for four chip selects	No	Yes
FIFO	Refer to the device's datasheet	Refer to the device's datasheet
DMA	Refer to the device's datasheet	Refer to the device's datasheet

### 30.1.3 Functional Block Diagram

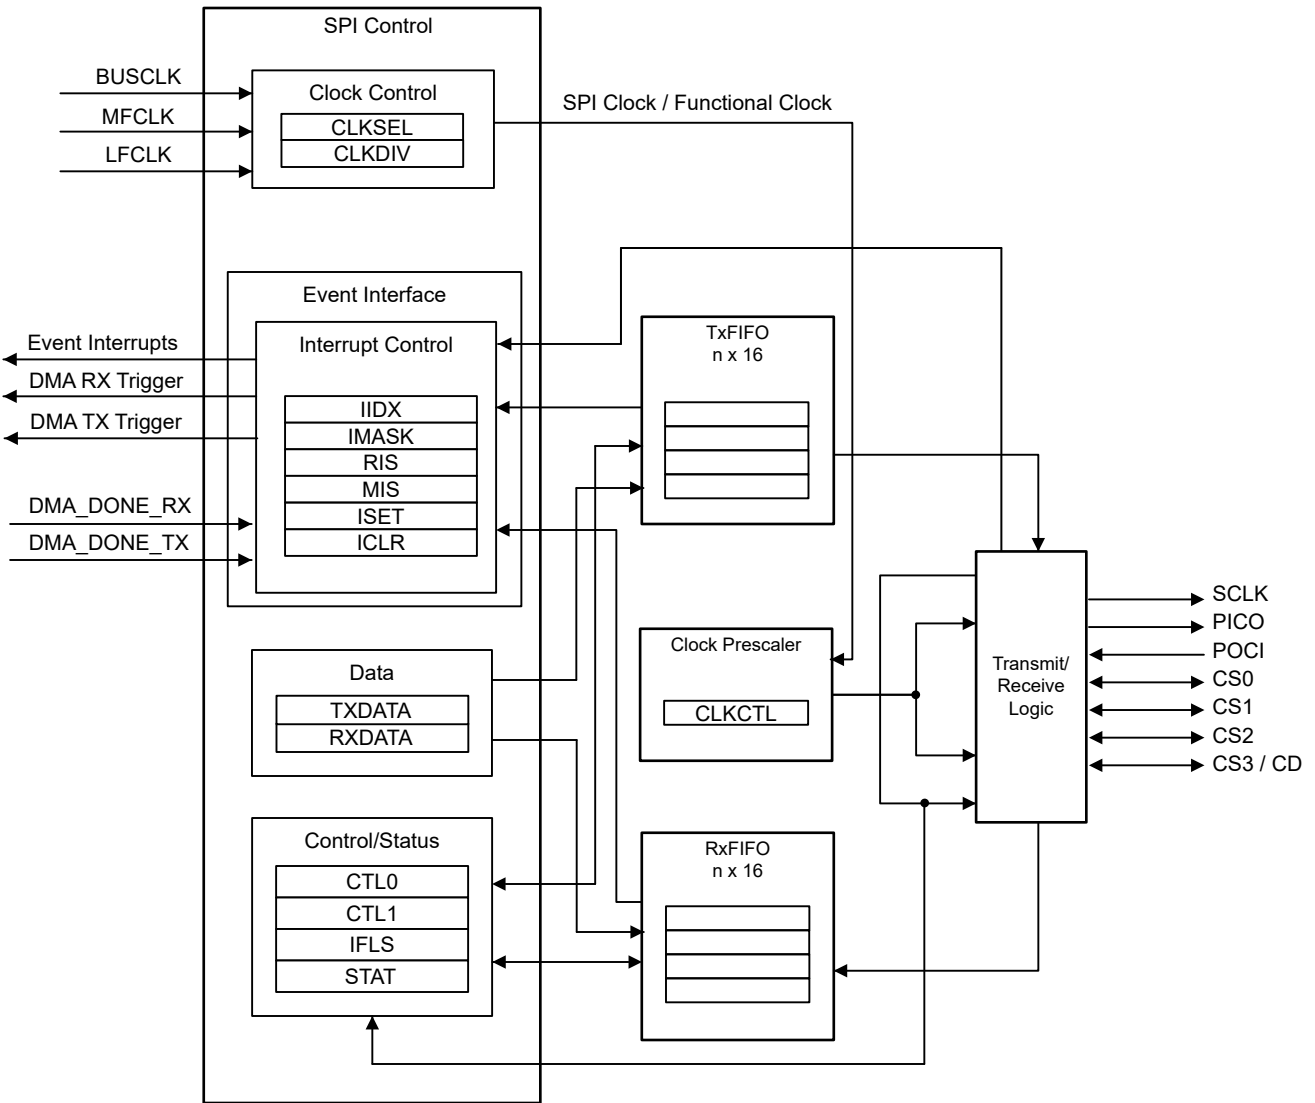

Figure 30-1. SPI Functional Block Diagram

### 30.1.4 External Connections and Signal Descriptions

Figure 30-2 and Table 30-2 show an overview of the pin functions for different operation modes of the SPI module.

Figure 30-2. External Connections for Different SPI Configurations

**Table 30-2. Pin Function Overview**

Standard SPI	Feature
<b>SCLK</b>	<p align="center"><b>SPI clock</b></p> Controller mode: SCLK is an output Peripheral mode: SCLK is an input
<b>PICO</b>	<p align="center"><b>Controller out, peripheral in</b></p> Controller mode: PICO is the data output line Peripheral mode: PICO is the data input line
<b>POCI</b>	<p align="center"><b>Controller in, peripheral out</b></p> Controller mode: POCI is the data input line Peripheral mode: POCI is the data output line
<b>CS0</b>	Chip select signal 0, used in 4-pin mode
<b>CS1</b>	Chip select signal 1, used in 4-pin mode
<b>CS2</b>	Chip select signal 2, used in 4-pin mode
<b>CS3/CD</b>	Chip select signal 3 or Command/Data, used in 4-pin mode

For UNICOMM, to meet timing requirements in controller mode, chip select and clock should be looped back from IOs. This compensates for the IO delays within the SoC. At the device's IOMUX level, CS and SCLK INENA bits will need to be set.

## 30.2 SPI Operation

### 30.2.1 Clock Frequency Support

The maximum UNICOMM-SPI frequency supported with controller and peripheral mode depends on the device clock option and IO option. Please refer to specific device data sheet spec for more information.

There is a limitation on SPI clock frequency in both controller and peripheral modes: SPI frequency that can be supported is utmost half of the incoming clock frequency.

- BUSCLK is used for register programming, FIFO, interrupt generation and for SPGDMA; i.e. all elements within SPGSS.
- The UNICOMM SPI has its own clock, as per selected clock source and the FSM and rest of the logic work off this selected clock (functional clock)

The UNICOMM-SPI internal functional clock is selected and divided from the incoming clock to the UNICOMM.

- Use CLKSEL register to select the source of the functional clock – Check each module for supported clocks.
- Use CLKDIV register to select the divide ratio of the function clock.

The selected source clock is always available and frequency depends on selected power mode; for more information, please refers to [Clock Module chapter](#).

#### 30.2.1.1 SPI Clock Generation

The SPI includes a programmable bit-rate clock divider and a prescaler to generate the serial output clock (SCLK).

Supported bit rates are up to the input clock divided by 2. The input clock selection depends on the specific device; refer to the device data sheet and [Clock Frequency Support](#) section.

**SPI Clock** is the output after clock division performed according to ratio selected by the CLKDIV register.

$$\text{SPI clock} = \text{Selected input clock} / (1 + \text{CLKDIV})$$

SPI Sampling Clock (SCLK) is the output after dividing the SPI Clock by the Pre-scalar value.

$$\text{SCLK} = \text{SPI Clock} / ((1 + \text{SCR}) * 2)$$

If the factor of two (\*2) is set by CLKDIV the input clock must be at least 2 times faster than SPI clock.

### 30.2.2 General Architecture

#### 30.2.2.1 Chip Select and Command Handling

##### 30.2.2.1.1 Chip Select Control

The UNICOMM-SPI can be configured to be in controller mode by setting the CTL1.CP bit to 1, and in peripheral mode by clearing the CTL1.CP bit.

The CTL0.CSSEL bit selects which connected peripheral is addressed by the up to 4 CS signals. The bits are controlled by the UNICOMM-SPI module in controller or target/peripheral mode. The selected signal is controlled during the transfers.

The chip select signal needs to be provided by the controller in four-wire mode, and the chip select polarity can be inverted by configuring the PINCM.CSx.INV register.

In peripheral mode, the clock is provided by the controller and used by the peripheral to capture the data. The peripheral has the option to operate in 3-wire or 4-wire mode. 4-wire mode only accepts data transfers if the CS is activated.

When the CTL0.CSCLR bit is set, the transmit/receive shift register counter is cleared automatically when the CS goes to the inactive state. When using the Motorola 4-wire or National Microwire mode, follow these constraints:

- The CS disable period must be longer than 2 functional clock cycles before the CS pin is reasserted
- The CS lead time (CS active to the first bit clock edge) must be at least 2 SPI functional clock cycles.

Following these constraints helps the peripheral synchronize again with the controller in case of a disturbance or glitch on the clock line or during initialization. This bit is relevant only in the peripheral mode.

- CTL0.CSCLR = 0: The transmit/receive bit counter state is retained when the CS signal disables the peripheral.
- CTL0.CSCLR = 1: The transmit/receive bit counter is cleared when the CS signal disables the peripheral.

---

#### Note

The CSCLR function requires the CS disable pulse to be longer than 2 SPI function clock cycles to properly detect and clear the bit counter in the SPI. The CS lead time (CS active to the first bit clock edge) also needs to be at least 2 SPI function clock cycles. The UNICOMM-SPI module does not support asynchronous clock request generation.

---

#### 30.2.2.2 Command Data Control

When using the Motorola frame format, the CDMODE bit can be set to use the CS3/CD line as a signal to distinguish between Command and Data information. This is often used for LCD or data storage devices.

- CD level low: command function
- CD level high: data function

The CTL1.CDMODE can be written with a value of 1-14 to specify the number of bytes, and the CD line will go low for the given number of bytes, which are sent by the SPI, starting with the next value to be transmitted. After the number of bytes is transmitted, the CD will automatically go high. If a value of 0xF is set, the C/D stays low permanently; a value of 0 sets the CD line to high immediately after the current character has been transmitted.

This option is only available in controller mode. CTL1.CDENABLE can only be updated when the SPI module is disabled, CTL1.CDMODE can be updated between the different data packages. The counter will be reset with

CDENABLE or SPI ENABLE set to disabled before setting a new value in CTL1.CDMODE. The FIFO status should be checked to ensure it is empty.

When writing a new value into CTL1.CDMODE, the internal counter will be reset, and the new value will be used for counting. If the counter counts down to 0 and a new command package needs to be sent, CDMODE needs to be set again; otherwise, the following data is sent with the CD pin signaling data mode.

CTL1.CDMODE will hold the last written value by the application – this field is not updated by hardware; STAT.CDMODE reflects the internal counter value.

### 30.2.2.3 Data Format

The control bit CTL1.CP B defines the direction of data input and output using the most-significant bit (MSB) or the least-significant bit (LSB) first. If the parity is enabled, the parity bits are always received as the last bit.

With the control register bits CTL0.DSS, the bit length per transfer will be defined between 4 and 16 bits in Controller mode and 7 and 16 bits in Peripheral mode.

A transfer will be triggered by writing to the TX buffer register. The data write needs to have at least the number of bits of the transfer. For example, if only a byte is written to the TX buffer, but the length of the transfer is > 8, the missing bits will be filled with 0s. On the receive path, received data will be moved to the RX FIFO or the RX buffer after the number of bits defined in the CTL0.DSS register has been received.

The RX and TX buffers shall be accessed with at least the bits covering one transfer.

- 4-8 bits: byte access (Peripheral mode: 7-8 Bits)
- 9-16 bits: 16-bit access

Clock polarity (CTL0.SPO) is used to control the clock polarity when data is not being transferred, and it is only used in the [Motorola SPI frame](#) mode.

- 0h = peripheral produces a steady-state LOW value on the CLKOUT pin when data is not being transferred.
- 1h = peripheral produces a steady-state HIGH on the CLKOUT pin when data is not being transferred.

The Clock phase (CTL0.SPH) bit selects the clock edge that captures data and determines whether the data can change state. It has the greatest impact on the first bit transmitted, either by allowing or disallowing a clock transition before the first data capture edge. Please refer to the [Motorola SPI frame](#) mode section to check the diagram.

- 0h = Data is captured on the first clock edge transition.
- 1h = Data is captured on the second clock edge transition.

The SPI can be configured to work in Peripheral mode with CTL1.CP bit = 0. In Peripheral mode, the clock is provided by the controller and is available to the peripheral on the CLK pins, which must be configured as inputs. The Clock Select and divider control bits are not used. The CS input signal selects and enables the peripheral's data receive path in 4-wire mode.

The SPI can be configured to work as a Controller with CTL1.CP bit = 1. In Controller mode, the clock needs to be generated by selecting an available clock source using the clock select bits. It also needs to control the CS signal depending on the selected protocol.

When setting the CTL1.PEN bit, the last bit will be used as parity to evaluate the integrity of the previous bits—the CTL1.PES bit selects the parity mode as even or odd. When detecting a fault, the interrupt flag RIS.PER is set to mark the data as invalid. Parity checking is a feature that improves the robustness of communication.

### 30.2.2.4 Delayed data sampling

When the input data arrives at the POCI pin with a delay due to runtime conditions, the previous data is sampled at the sampling clock edge in the following input data sampling stage. To compensate for such a condition, delayed sampling can be enabled via the CLKCTL.DSAMPLE bits. The delayed sampling is only available in controller mode. The delay can be adjusted in steps of SPI input clock steps by setting the control register bits CLKCTL.DSAMPLE. The maximum allowed delay should not exceed the length of one data frame.

Delayed sampling will not be used when CLKCTL.DSAMPLE is set to “zero.”

### 30.2.2.5 DMA Operation

The section applies to UNICOMM-SPI configurations which support the SPI-DMA feature.

The UNICOMM-SPI provides an interface to the DMA module, with separate transmit and receive lines. The DMA operation of the SPI is enabled through the SPI DMA Event and DMA module registers. When DMA operation is enabled, the SPI asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. The DMA transfer requests are handled automatically by the DMA controller based on the DMA channel configurations (burst size, transfer size, source address, etc).

- For the receive channel, a DMA transfer request is asserted when the receive FIFO contains at least the FIFO trigger level configured by the RXIFLSEL bit in the IFLS register.
- For the transmit channel, a DMA transfer request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level configured using the TXIFLSEL bit in the IFLS register.

See more information about the DMA interrupts and events in [Section 30.2.14.2](#) .

### 30.2.3 FIFO Operation

The UNICOMM-SPI module has two FIFOs (one each for transmit/receive) with configurable depth. FIFOs are accessed via the TXDATA & RXDATA registers.

#### 30.2.3.1 FIFO Size

FIFO width will be 16 bits without packing and 32 bits with packing. Refer to the device's datasheet for specific information on the FIFO size.

#### 30.2.3.2 FIFO Status bits

The UNICOMM-SPI module supports the below FIFO status bits:

- Receive FIFO Full: when all elements are populated
- Receive FIFO Empty: when there are no elements in the HEAD
- Transmit FIFO Full: when all elements are populated
- Transmit FIFO Empty: when are no elements in the FIFO

In addition to this, FIFO clear status – RXCLR/TXCLR will also be present (refer to [Clearing FIFO Contents](#)).

#### 30.2.3.2.1 RIS.RX based on FIFO threshold settings

When a message gets received, the RX FIFO gets filled immediately. Below are the available thresholds:

1. RX\_FIFO full: when all elements are populated
2. RX\_FIFO  $\geq \frac{1}{4}$  full
3. RX\_FIFO  $\geq \frac{1}{2}$  full
4. RX\_FIFO  $\geq \frac{3}{4}$  full
5. RX\_FIFO almost empty:  $\leq 1$  element
6. RX\_FIFO almost full:  $\geq (N-1)$  elements
7. **RX\_FIFO not empty: opposite of empty**

#### 30.2.3.2.2 RIS.TX based on FIFO threshold settings

On the transmit side, data is written by the CPU/DMA master at the top most empty FIFO entry and then transferred to serializer. Thresholds are as per elements that can be written into the FIFO.

1. TX\_FIFO empty: when there no elements in the FIFO
2. TX\_FIFO  $\leq \frac{3}{4}$  empty
3. TX\_FIFO  $\leq \frac{1}{2}$  empty
4. TX\_FIFO  $\leq \frac{1}{4}$  empty
5. TX\_FIFO almost empty:  $\leq 1$  element
6. TX\_FIFO almost full:  $\geq (N-1)$  elements
7. **TX\_FIFO not full: opposite of full**

---

**Note**

Receive FIFO Almost Empty and Transmit FIFO Almost Full options are provided in IFLS setting; however, these should not be used for generating flags based on the watermark settings or for DMA usage. The application has to ensure that correct FIFO Thresholds are used.

---

---

**Note**

Debugger initiated reads should not pop contents out of the FIFO. However, debugger initiated writes into the transmit FIFO should be treated as valid entries.

---

### 30.2.3.3 Clearing FIFO contents

To clear the FIFO contents, the following sequence must be used::

- Write '1' to the CLR control bit (TXCLR/ RXCLR).
  - Wait for clear to complete, i.e. CLR status bit reflects '1'; poll/check for CLR status bit to reflect '1'
  - Write '0' to CLR control bit (TXCLR/ RXCLR).
- 

---

**Note**

When a FIFO clear has been initiated, do not try to re-clear it again.

---

---

**Note**

Randomly changing the FIFO levels when the FIFO has contents might lead to undesired behavior. It is recommended that the FIFO is cleared before changing the FIFO thresholds.

---

### 30.2.3.4 Hardware monitors empty, full and overflow conditions

The STAT register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits), and the RIS register shows the overflow status of the receive FIFO via the RXFIFO\_OVF bit. There is no indicator for a transmit FIFO overflow. A write is just lost if it overflows the transmit FIFO. If the FIFOs are not present, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

---

---

**Note**

Data will be lost if the FIFO is full, and the overflow flag bit will be set.

---

Out of reset, both FIFOs are configured to trigger an interrupt at half-level mark.

---

---

**Note**

FIFO integrity is not guaranteed if the software disables the module in the middle of a transmission with data in the FIFO, and then re-enables it.

---

---

**Note**

When the module gets reset the content of the FIFO are also cleared.

---

### 30.2.4 Suspend communication

Suspend is an extreme operating condition for the module, and the application should enter this mode while ensuring the following conditions are met. The application can suspend external communication by setting the suspend control bit.

When suspend is set, ongoing communication will complete, the FSM will return to idle, and further external communication will be stopped. Transmit line/s will be driven to their IDLE state, and further toggle on receive line/s will not be processed. This provides a safe means for the application to suspend operations, clear out receive FIFOs before disabling the module.

---

**Note**

The *suspend* bit needs to be cleared prior to re-enabling the module.

---

To suspend/disable the UNICOMM-SPI module, follow the steps below:

1. The SPI-BUS controller have to ensure that the target can reach the IDLE state (refer to the [SPI Idle State Requirements](#))
2. The hardware ensures that ongoing transactions are completed. In the case of a transmit operation, all the contents of the FIFO will be sent out, prior to hardware raising an IDLE state
3. Once the SUSPEND bit is written into hardware; the CPU has to poll the status flags to ensure that device has reached the IDLE state
4. Drain out receive FIFO
5. Disable the UNICOMM-SPI module

After suspending or disabling the module, the register configurations are retained. Communication can be resumed by following the steps below to re-enable the module:

1. Clear the SUSPEND bit
2. Re-enable the UNICOMM-SPI module

#### **30.2.4.1 SPI IDLE State Requirements**

To reach the IDLE state in the UNICOMM-SPI module, follow the steps below:

1. Controller side: ensure 'CS' is returned to its idle state
2. Peripheral side: ensure 'CS' is read back as idle before reflecting an IDLE state

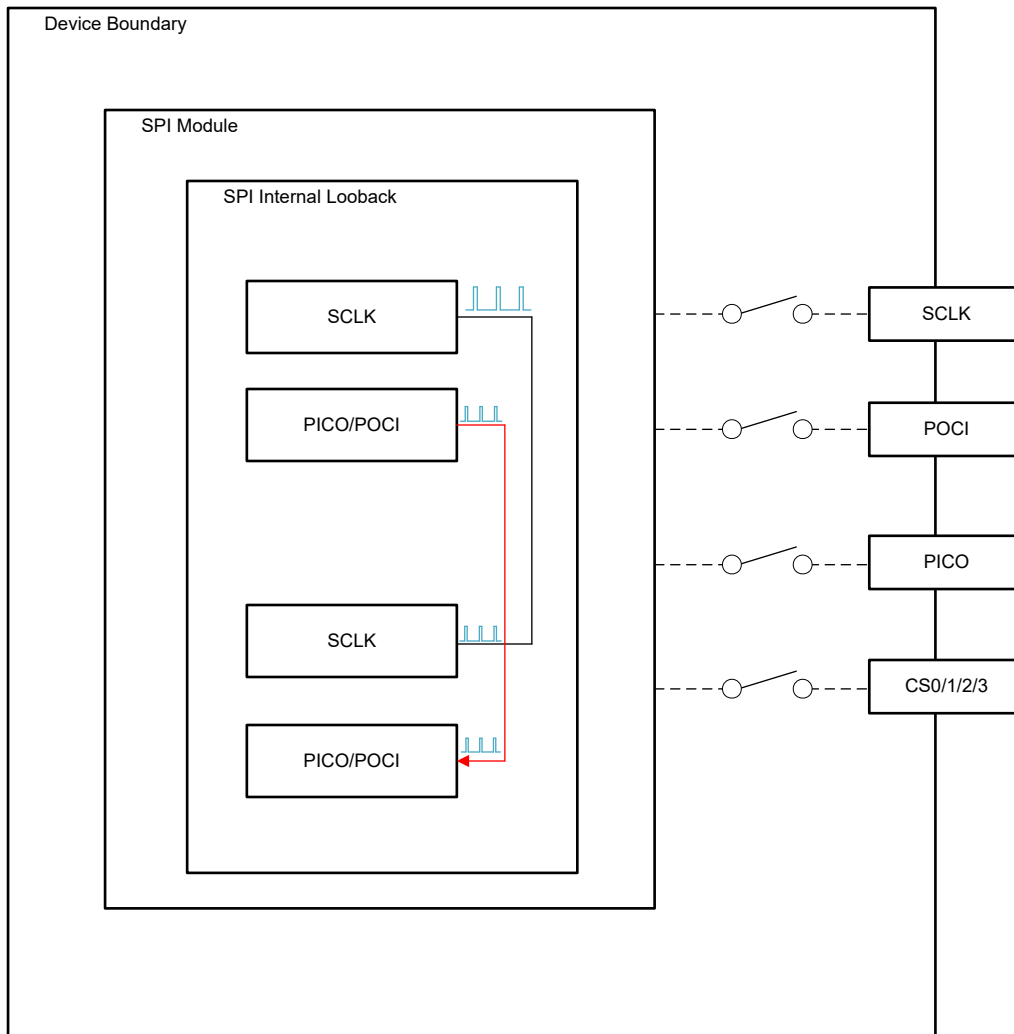

The application must ensure that the idle state can be reached before asserting SUSPEND. Example:

1. Controller mode: Ensure the entire frame, i.e., all commands and data, is transmitted
2. Target mode: Ensure that the entire frame has been received/transmitted

#### **30.2.5 Internal Loopback Operation**

The UNICOMM-SPI module can be placed into an internal loopback mode for diagnostic or debug work by setting the LBM bit in the CTL1 register. In loopback mode, the data from the TX FIFO can be serially transmitted into the RX FIFO. Data from the RX FIFO can be read to determine whether transmission has occurred. External toggling of the IOs has no effect when the module is set to internal loopback mode.

## Internal Loopback Mode

### 30.2.6 Repeat Transfer mode

This function is available only in Controller mode by using the CTL1.REPEATTX bits, the last character transmitted will be repeated as defined by the register bits—a value of 0 in CTL1.REPEATTX bits will disable this mode.

The transfer will start by writing data into the TX Buffer. Then the data will be repeatedly sent with the same given value. The behavior is identical to that of if the data were written into the TX Buffer that many times, as defined by the value here. It can be used to clean a transfer or to pull a certain amount of data from a peripheral.

When the REPEATTX is used, it needs to be aligned with the data in the buffer/FIFO. So, the sequence shown below should be used:

- Wait and check till FIFO is empty. Alternatively, clear out the FIFO
- Setup REPEATTX
- Write to TXDATA / FIFO
- Wait till requested data has been received

### 30.2.7 Receive Timeout

In peripheral mode, the application can detect a receive timeout by programming CTL1.RXTIMEOUT and CLKCTL.SCR. The receive timeout is calculated as the time from the last active clock edge to the programmed

timeout period. The receive timeout flag is raised if there are contents in the FIFO and the receive timeout period has elapsed.

Receive timeout period calculation

- Clock period for timeout calculation =  $\text{SPI clock} / (2 \cdot (1 + \text{SCR}))$
- Timeout period =  $\text{CTL1.RXTIMEOUT} \cdot \text{clock period for timeout calculation}$

### 30.2.8 Line Timeout

An additional bit, LTOOUT (LINE timeout), is provided in the UNICOMM-SPI module. In peripheral mode, if no new transaction is detected during the receive timeout period after the last transaction, a line timeout interrupt (LTOOUT) is set, irrespective of FIFO/buffer contents.

### 30.2.9 Protocol Descriptions

The protocol format mode can be selected by using CTL0.FRF register. The supported options include Motorola 3-wire, Motorola 4-wire, and Texas Instruments Synchronous.

#### 30.2.9.1 Motorola SPI Frame Format

The Motorola SPI interface is a 4-wire interface where the CS signal behaves as a peripheral select. In the 3-wire mode the CS signals is not required and the module behaves as if always selected. The main feature of the Motorola SPI format is that the inactive state and phase of the SCLK signal can be programmed through the SPO and SPH bits in the SPIx.CTL0 control register.

#### SPO Clock Polarity Bit

If the CTL0.SPO clock polarity control bit is clear, the bit produces a steady-state low value on the SCLK pin when data is not being transferred. If the CTL0.SPO bit is set, the bit places a steady-state high value on the SCLK pin when data is not being transferred.

#### SPH Phase-Control Bit

The CTL0.SPH phase-control bit selects the clock edge that captures data, and allows it to change state. The state of this bit has the most impact on the first bit transmitted, by either allowing or not allowing a clock transition before the first data capture edge. If the CTL0.SPH phase-control bit is clear, data is captured on the first clock edge transition. If the SPH bit is set, data is captured on the second clock edge transition.

#### Motorola SPI Frame Format with SPO = 0 and SPH = 0

Figure 30-3 shows signal sequences for Motorola SPI format with SPO = 0 and SPH = 0.

**Figure 30-3. Motorola SPI Format With SPO = 0 and SPH = 0**

In this configuration, the following occurs during idle periods:

- SCLK is forced low
- CS is forced high

- The transmit data line PICO is forced low
- When the SPI is configured as a controller, it enables the SCLK pin
- When the SPI is configured as a peripheral, it disables the SCLK pin

If the SPI is enabled and the TX FIFO contains valid data, the CS controller signal is driven low at the start of transmission, enabling peripheral data onto the POCI input line of the controller. The controller PICO output pin is enabled.

One-half SCLK period later, valid controller data is transferred to the PICO pin. Once both the controller and peripheral data are set, the SCLK controller clock pin goes high after an additional one-half SCLK period. The data is now captured on the rising edges and propagated on the falling edges of the SCLK signal.

For a single-word transmission, after all bits of the data word are transferred, the CS line is returned to its IDLE high state one SCLK period after the last bit is captured. For continuous back-to-back transmissions, the CS signal must pulse high between each data-word transfer because the peripheral-select pin freezes the data in its serial peripheral register and prevents altering the data if the SPH bit is clear. The controller device must raise the CS pin of the peripheral device between each data transfer to enable the serial peripheral data write. When the continuous transfer completes, the CS pin is returned to its IDLE state one SCLK period after the last bit is captured.

### Motorola SPI Frame Format with SPO = 0 and SPH = 1

Figure 30-4 shows the signal sequence for Motorola SPI format with SPO = 0 and SPH = 1.

**Figure 30-4. Motorola SPI Frame Format With SPO = 0 and SPH = 1**

In this configuration, the following occurs during idle periods:

- SCLK is forced low
- CS is forced
- The transmit data line PICO is forced low
- When the SPI is configured as a controller, it enables the SCLK pin
- When the SPI is configured as a peripheral, it disables the SCLK pin

If the SPI is enabled and valid data is present in the TX FIFO, CS controller signal goes low at the start of transmission. The controller PICO output is enabled. After an additional one-half SCLK period, both controller and peripheral valid data are enabled onto their respective transmission lines. At the same time, SCLK is enabled with a rising-edge transition. Data is then captured on the falling edges and propagated on the rising edges of the SCLK signal.

For a single-word transfer, after all bits are transferred, the CS line is returned to its IDLE high state one SCLK period after the last bit is captured. For continuous back-to-back transfers, the CS pin is held low between successive data words and terminates like a single-word transfer.

### Motorola SPI Frame Format with SPO = 1 and SPH = 0

Figure 30-5 shows signal sequences for Motorola SPI format with SPO = 1 and SPH = 0.

**Figure 30-5. Motorola SPI Frame Format With SPO = 1 and SPH = 0**

In this configuration, the following occurs during idle periods:

- SCLK is forced high
- CS is forced high
- The transmit data line PICO is arbitrarily forced low
- When the SPI is configured as a controller, it enables the SCLK pin
- When the SPI is configured as a peripheral, it disables the SCLK pin

If the SPI is enabled and valid data is in the TX FIFO, the SPI CS controller signal goes low at the start of transmission and transfers the peripheral data to the controller's POCI line immediately. The controller PICO output pin is enabled.

One-half SCLK period later, valid controller data is transferred to the PICO line. When both the controller and peripheral data have been set, the SCLK controller clock pin becomes low after one additional half SCLK period. Data is captured on the falling edges and propagated on the rising edges of the SCLK signal.

For a single-word transmission after all bits of the data word are transferred, the CS line is returned to its IDLE high state one SCLK period after the last bit is captured. For continuous back-to-back transmissions, the CS signal must pulse high between each data-word transfer, as the peripheral-select pin freezes the data in its serial peripheral register and prevents it from being altered when the SPH bit is clear. The controller device must raise the CS pin of the peripheral device between each data transfer to enable the serial peripheral data write. When the continuous transfer completes, the CS pin returns to its IDLE state one SCLK period after the last bit is captured.

### Motorola SPI Frame Format with SPO = 1 and SPH = 1

Figure 30-6 shows the signal sequence for Motorola SPI format with SPO = 1 and SPH = 1.

**Figure 30-6. Motorola SPI Frame Format With SPO = 1 and SPH = 1**

In this configuration, the following occurs during idle periods:

- SCLK is forced high
- CS is forced high
- The transmit data line PICO is arbitrarily forced low
- When the SPI is configured as a controller, it enables the SCLK pin
- When the SPI is configured as a peripheral, it disables the SCLK pin

If the SPI is enabled and valid data is in the TX FIFO, the start of transmission is signified by the CS controller signal going low. The controller PICO output pin is enabled. After an additional one-half SCLK period, both controller and peripheral data are enabled onto their respective transmission lines. At the same time, SCLK is enabled with a falling-edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SCLK signal.

For a single word transmission, after all bits are transferred, the CS line returns to its IDLE high state one SCLK period after the last bit is captured. For continuous back-to-back transmissions, the CS pin remains in its active-low state until the final bit of the last word is captured, then returns to its IDLE state. For continuous back-to-back transfers, the CS pin is held low between successive data words and terminates like a single-word transfer.

The serial clock (SCLK) is held inactive while the SPI is idle, and SCLK transitions at the programmed frequency only during data transmission or reception. The IDLE state of SCLK provides a receive timeout indication when the RX FIFO still contains data after the timeout period.

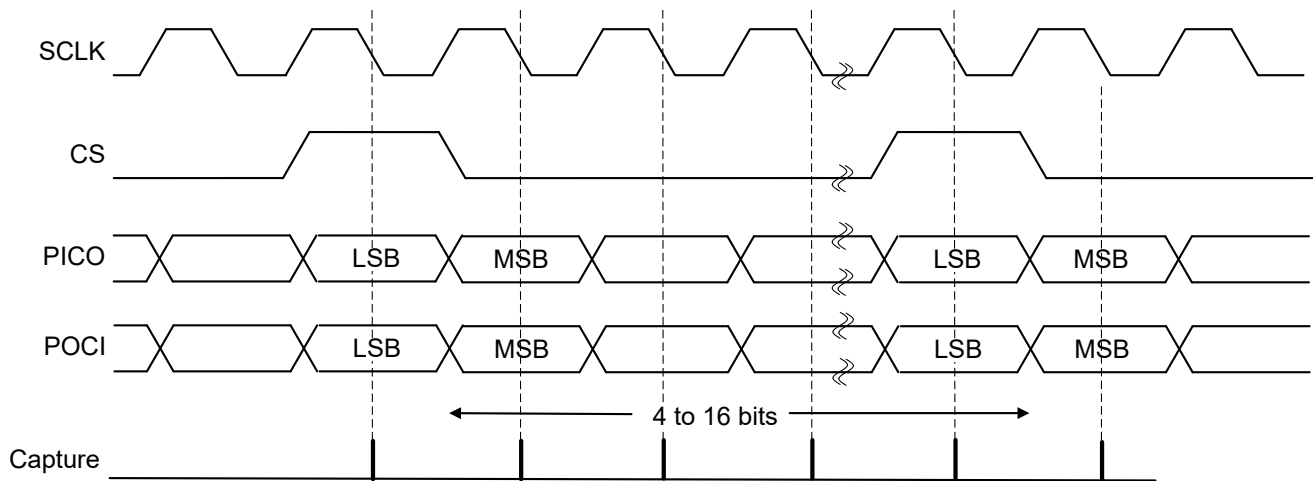

### 30.2.9.2 Texas Instruments Synchronous Serial Frame Format

The SPI peripheral is compatible with Texas Instruments Synchronous Serial frame format.

Figure 30-7 shows the TI synchronous serial frame format for a single and continuous transmitted frame.

Single Transmission Signal Sequences

Continuous Transmission Signal Sequences

Figure 30-7. TI Synchronous Serial Frame Format

SCLK and CS are forced low, and the transmit data line PICO is put in tristate whenever the SPI is idle. When the bottom entry of the TX FIFO contains data, CS is pulsed high for one SCLK period. The transmitted value is also transferred from the TX FIFO to the transmit logic's serial shift register. On the next rising edge of SCLK, the MSB of the 4- to 16-bit data frame is shifted out on the PICO pin. Likewise, the MSB of the received data is shifted onto the POCI pin by the off-chip serial peripheral device. Both the SPI and the off-chip serial peripheral device then clock each data bit into their serial shifter on each falling edge of SCLK. The received data is transferred from the serial shifter to the RX FIFO on the first rising edge of SCLK after the least significant bit (LSB) is latched.

The serial clock (SCLK) is held inactive while the SPI is idle, and SCLK transitions at the programmed frequency only during active transmission or reception of data. The IDLE state of SCLK provides a receive time-out indication when the RX FIFO still contains data after the time-out period.

### 30.2.10 Status Flags

The table below lists the status and their behavior. FIFO status bits are explained in the common SPGSS chapter.

**Table 30-3. SPI variants and features**

Status Bit	Description
BUSY	<p><b>Controller Mode:</b></p> <ol style="list-style-type: none"> <li>1. Busy bit is set ("ACTIVE") when there is an ongoing transmission or reception</li> <li>2. Busy bit is cleared ("IDLE") where there is no ongoing transaction (receive or transmit)</li> </ol> <p><b>Peripheral Mode:</b></p> <ol style="list-style-type: none"> <li>1. BUSY bit is set ("ACTIVE") when there is an ongoing transmission or reception. When POD is set, i.e. peripheral is only receiving data, in this case BUSY is set, when peripheral is receiving data</li> <li>2. Busy bit is cleared ("IDLE") when there is no ongoing transaction (receive or transmit)</li> </ol>
CDMODE	<p>Reflects current counter value and manual status</p> <p>0x0: manual mode – C/D is low (data is being sent)</p> <p>0xf: manual mode – C/D is high (command is being sent)</p> <p>0x0 to 0xe: present byte count</p>

### 30.2.11 Module configuration

The application has to set the configuration registers for the desired operation before enabling the module (through the ENABLE bits). Configuration bits in Table 4 cannot be updated once the ENABLE bit is set. If these bits need to be updated, the application would have to disable the module, update the configuration registers, and then re-enable the module. When the IP is DISABLED (ensure the sequence SUSPEND → Clear FIFO → DISABLE is followed), the FSM returns to IDLE, the FIFO contents are cleared, and the entire functional clock domain returns to its idle state.

#### Note

In controller mode, CSSEL can be changed dynamically. However, in peripheral mode, CSSEL must be configured before enabling the module.

### 30.2.12 Reset Considerations

#### Software Reset Considerations

The UNICOMM has a general software reset for the UNICOMM module. You can find more information in the [UNICOMM Enables & Resets section](#).

#### Hardware Reset Considerations

A hardware reset also initializes the IO configuration. This sets the IOs to a high-impedance state, allowing the data lines to float. If this is critical for the application or connected devices on the SPI interface, external pull-up or pull-down resistors might be required.

### 30.2.13 Initialization

To enable and initialize the SPI, the following steps are necessary:

1. Configure IOMUX with appropriate GPIO pins for which SPI signals are multiplexed to.

---

**Note**

Pull-ups can be used to avoid unnecessary toggles on the SPI pins, which can take the Peripheral to a wrong state. In addition, if the SCLK signal is programmed to steady state High through the SPO bit in the CTL0 register, then software must also configure the GPIO port pin corresponding to the SCLK signal as a pull-up.

---

2. For each of the frame formats, the SPI is configured using the following steps:
  - a. If initializing out of reset, ensure that ENABLE bit in the CTL1 register is clear before making any configuration changes.
  - b. Select and configure the clock pre-scale divisor by writing the CLKSEL and CLKDIV register.
  - c. Select whether the SPI is a Controller or Peripheral
  - d. Configure the clock divisor by writing the CLKCTL register.
  - e. Configure the CTL0 and CTL1 register with based on the protocol, data width and other special configurations.
  - f. Optionally configure DMA
  - g. Enable the SPI by setting the ENABLE bit in the CTL1 register

### 30.2.14 Interrupt and Events Support

The UNICOMM-SPI module contains three event publishers and no event subscribers. One event publisher (CPU\_INT) manages the UNICOMM-SPI interrupt requests (IRQs) to the CPU subsystem through a static event route. The second and third event publishers (DMA\_TRIG\_RX, DMA\_TRIG\_TX) are used to setup the trigger signaling for the DMA through DMA event route.

The SPI events are summarized in the SPI Events table bellow:

**Table 30-4. SPI Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
CPU interrupt	Publisher	SPI	CPU Subsystem	Static route	CPU_INT registers	Fixed interrupt route from SPI to CPU
DMA trigger	Publisher	SPI	DMA	DMA event route	DMA_TRIG_RX registers	Fixed interrupt route from SPI RX to DMA
DMA trigger	Publisher	SPI	DMA	DMA event route	DMA_TRIG_TX registers	Fixed interrupt route from SPI TX to DMA

#### 30.2.14.1 CPU Interrupt Event Publisher (CPU\_INT)

The UNICOMM-SPI module provides 9 interrupt sources that can source a [CPU interrupt event](#). The SPI CPU\_INT Trigger Conditions table lists the CPU interrupt events from the UNICOMM-SPI module in order of decreasing priority.

**Table 30-5. SPI CPU\_INT Trigger Conditions**

IIDX STAT	Name	Description
0x01	PER	Parity error event. This interrupt is set if a Parity error has been detected.
0x02	RXFIFO_OVF	RXFIFO overflow event. This interrupt is set when an RX FIFO overflow is detected.
0x03	RX	Receive FIFO event. This interrupt is set when the selected receive FIFO level is reached.
0x04	RXFULL	RX FIFO full event. This interrupt is set when the RX FIFO is full.
0x05	TXFIFO_UNF	TX FIFO underflow event. This interrupt is set when a TX FIFO underflow is detected.

**Table 30-5. SPI CPU\_INT Trigger Conditions (continued)**

IIDX STAT	Name	Description
0x06	TX	Transmit FIFO event. This interrupt is set when the selected transmit FIFO level is reached.
0x07	TXEMPTY	Transmit FIFO empty interrupt. This is set if all data in the transmit FIFO has been shifted out.
0x09	IDLE	SPI IDLE event. SPI has finished transfers and entered the IDLE mode. This interrupt is set when STAT.BUSY bit goes low.
0x0A	RTOUT	SPI Receive Time-Out event. This interrupt is set when the FIFO still contains data after the timeout period.
0x10	DMA_DONE_RX	This interrupt is set if the RX DMA channel sends the DONE signal.
0x11	DMA_DONE_TX	This interrupt is set if the TX DMA channel sends the DONE signal.
0x15	LTOUT	SPI Line Time-Out event. This interrupt is set after the timeout period has lapsed.

The CPU interrupt event configuration is managed with the CPU\_INT event management registers.

The receive interrupt (SPI.RX) changes state when one of the following events occurs:

- **FIFO Present:** The receive interrupt is set when the receive FIFO is at or above the programmed trigger level. The receive interrupt is cleared by reading data from the receive FIFO until it falls below the trigger threshold, by reading the interrupt index (IIDX read), or by writing a 1 to the receive interrupt bit in ICLR. The receive FIFO should be read until the number of entries in the receive FIFO falls below the programmed threshold in IFLS. This is to ensure that subsequent interrupts are fired correctly.
- **Single Buffer Present:** The receive interrupt is set when data is received, and the receive buffer is full, thereby filling the location. The receive interrupt is cleared by performing a single read of the receive buffer, by reading the interrupt index from IIDX, or by writing a 1 to the RXINT bit in ICLR.

The transmit interrupt (SPI.TX) changes state when one of the following events occurs

- **FIFO Present:** The transmit interrupt bit is set when the transmit FIFO is at or below the programmed trigger level. The transmit interrupt is cleared by writing data to the transmit FIFO until it exceeds the trigger level, by reading the interrupt index from IIDX, or by writing a 1 to the transmit interrupt bit in ICLR. The transmit FIFO should be filled till the number of entries in the FIFO crosses the programmed threshold in IFLS. This is to ensure that subsequent interrupts are fired correctly.
- **Single Buffer Present:** The transmit interrupt bit is set when the buffer is empty, indicating a transmit empty condition. The transmit interrupt is cleared by performing a single write to the transmit buffer, by reading the interrupt index from IIDX, or by writing a 1 to the TXINT bit in ICLR.

#### 30.2.14.2 DMA Trigger Publisher (DMA\_TRIG\_RX, DMA\_TRIG\_TX)

The DMA\_TRIG\_RX and DMA\_TRIG\_TX registers are used to configure trigger signaling for DMA transfers. These registers can be programmed to initiate DMA operations for receive or transmit events based on trigger conditions defined in the corresponding peripheral registers. (PERIPHERAL.DMA\_TRIG\_RX.RIS and PERIPHERAL.DMA\_TRIG\_TX.RIS).

The DMA\_TRIG\_RX register triggers the DMA to perform receive data transfers, while the DMA\_TRIG\_TX register triggers the DMA to perform transmit data transfers.

The DMA trigger event configuration is managed with the DMA\_TRIG\_RX and DMA\_TRIG\_TX event management registers. See [DMA chapter to understand how DMA works](#).

#### DMA configuration for M0+

For reading received data through DMA:

1. Select the DMA n-channel to be used for transfer – refer to the MSPM0's data sheet for the number of DMA channels available
2. Configure trigger source for the selected DMA channel to be the UNICOMM-SPI's Rx event in the DMA\_CH[n].DMATCTL register

3. Configure the UNICOMM-SPI's INT\_EVENTx register to generate a DMA request on a UNICOMM-SPI's Rx event
4. Configure the DMA source address as the UNICOMM-SPI's Rx FIFO in the DMA\_CH[n].DMASA register
5. Configure the DMA destination address as the SRAM location where data is to be copied in the DMA\_CH[n].DMADA register
6. Configure all the triggers for the DMA to be serviced in the DMA\_CH[n].DMASZ register.
7. In the DMA\_CH[n].DMACTL register:
  - a. Configure the transfer's size to be done on each trigger to DMA in the DMADSTWIDTH and DMASRCWIDTH bit-fields – possible options are 8 or 16 bits
  - b. Configure DMASRCINCR to No Change (0h) and DMADSTINCR to 8 or 16 (same as what used for DMADSTWIDTH and DMASRCWIDTH)
  - c. Enable the DMA channel by writing 1 to the DMAEN register

For writing data to be transmitted by UNICOMM through DMA:

1. Select the DMA n-channel to be used for transfer – refer to the MSPM0's datasheet for the number of DMA channels available
2. Configure trigger source for the selected DMA channel to be the UNICOMM-SPI's Tx event in the DMA\_CH[n].DMATCTL register
3. Configure the UNICOMM-SPI's INT\_EVENTx register to generate a DMA request on a UNICOMM-SPI's Tx event
4. Configure the SRAM location where data to be transmitted is present as the DMA source address in the DMA\_CH[n].DMASA register
5. Configure the UNICOMM-SPI's Tx FIFO as the DMA destination address in the DMA\_CH[n].DMADA register
6. Configure all the triggers for the DMA to be serviced in the DMA\_CH[n].DMASZ register.
7. In the DMA\_CH[n].DMACTL register:
  - a. Configure the transfer's size to be done on each trigger to DMA in the DMADSTWIDTH and DMASRCWIDTH bit-fields – possible options are 8 or 16 bits
  - b. Configure DMADSTINCR to No Change (0h) and DMASRCINCR to 8 or 16 (same as what used for DMADSTWIDTH and DMASRCWIDTH)
  - c. Enable the DMA channel by writing 1 to the DMAEN register

### 30.2.15 Emulation Modes

The UNICOMM-SPI module behavior while the device is in debug mode is controlled by the FREE and SOFT bits in the PDBGCTL register.

When the device is in debug mode and set into halt mode, the following behavior can be configured.

**Table 30-6. Debug Mode Peripheral Behavior**

PDBGCTL.FREE	PDBGCTL.SOFT	Function
1	x	Modules continues operation
0	1	Module stops after the next transfer has been finished
0	0	Not supported

#### 30.2.15.1 Graceful Halt

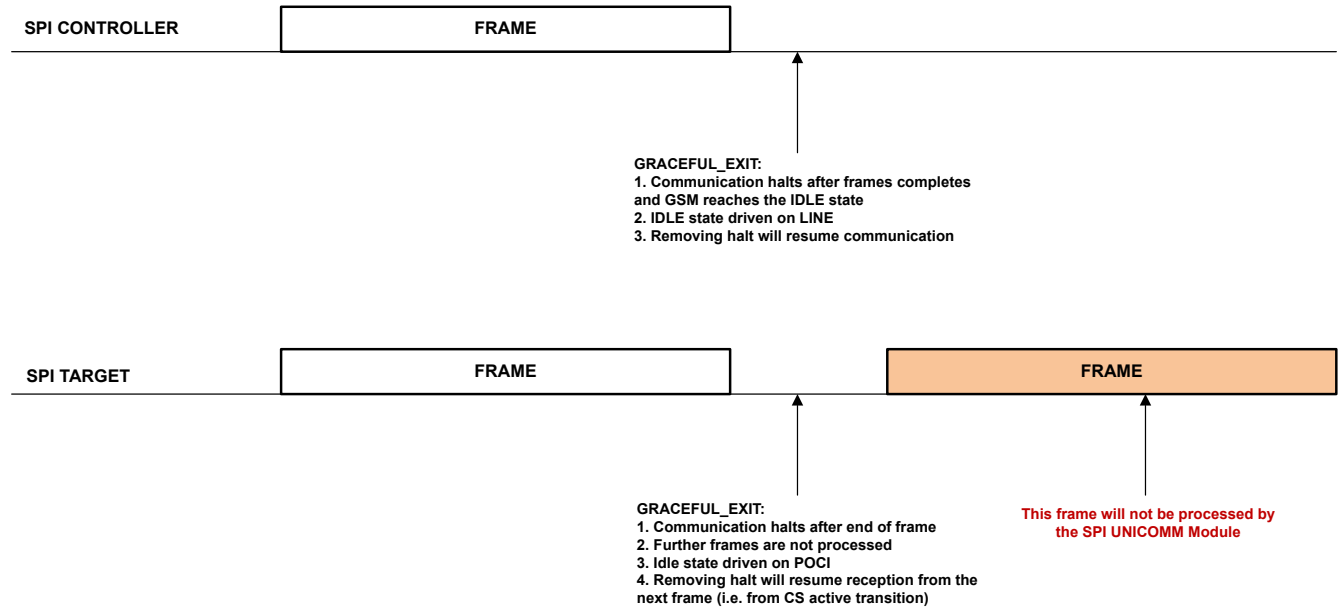

When emulation mode is set to graceful halt, and a halt condition occurs, the IP will stop communications after the ongoing frame has finished.

##### Transmitter

- The UNICOMM-SPI Module will finish transmitting the ongoing frame; FSM will return to IDLE and stop.
- The external line will be driven to the IDLE condition.
- Removing the halt will resume communication.

Receiver

- The UNICOMM-SPI Module will receive an ongoing frame; FSM will return to IDLE and stop
- Any new messages will not be processed
- After the halt is removed, FSM will begin communications
- The FSM may start reception in the middle of a frame

### 30.3 UNICOMMSPI Registers

Table 30-7 lists the memory-mapped registers for the UNICOMMSPI registers. All register offset addresses not listed in Table 30-7 should be considered as reserved locations and the register contents should not be modified.

**Table 30-7. UNICOMMSPI Registers**

Offset	Acronym	Register Name	Group	Section
1000h	CLKDIV	Clock Divider		<a href="#">Go</a>
1008h	CLKSEL	Clock Select for Ultra Low Power peripherals		<a href="#">Go</a>

### 3 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 30-10](#) and described in [Table 30-11](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 30-10. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15	DMA_DONE_RX	R	0h	SPI DMA Done on RX Event Channel Interrupt Raw Status. This interrupt is raised when the DONE signal is sent to the SPI from a DMA indicating all the transactions have completed. 0h = Interrupt did not occur 1h = Interrupt occurred
14-10	RESERVED	R	0h	

**Table 30-18. RIS Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
9	RTOUT	R	0h	SPI Receive Time-Out Interrupt Raw Status. This interrupt is raised when the UNICOMM-SPI is in peripheral mode receiving data, the SCLK line is inactive while the RX FIFO contains at least one element for the timeout period programmed by the CTL1.RXTIMEOUT field, regardless of if the RX FIFO level configured in the IFLS register has been reached. 0h = Interrupt did not occur 1h = Interrupt occurred
8	IDLE	R	0h	SPI Idle Interrupt Raw Status. This interrupt is raised when the SPI has finished transfers and gone into an idle state. 0h = Interrupt did not occur 1h = Interrupt occurred
7	RESERVED	R	0h	
6	TXEMPTY	R	0h	SPI TX FIFO Empty Interrupt Raw Status. This interrupt is raised when all data has been shifted out of the TX FIFO and the SPI transmitter goes idle. 0h = Interrupt did not occur 1h = Interrupt occurred
5	TX	R	0h	SPI Transmit Interrupt Raw Status. This interrupt is raised when the TX FIFO level has met the condition configured in the IFLS register. For variants with only a Buffer, indicates that the buffer is empty. 0h = Interrupt did not occur 1h = Interrupt occurred
4	TXFIFO_UNF	R	0h	SPI TX FIFO Underflow Interrupt Raw Status. This interrupt is raised when the UNICOMM-SPI (in peripheral mode) gets clock edges on the SCLK line from the SPI controller, but the TX FIFO is empty. 0h = Interrupt did not occur 1h = Interrupt occurred
3	RXFULL	R	0h	SPI RX FIFO Full Interrupt Raw Status. This interrupt is raised when the RX FIFO is full. 0h = Interrupt did not occur 1h = Interrupt occurred
2	RX	R	0h	SPI Receive Interrupt Raw Status. This interrupt is raised when the RX FIFO level has met the condition configured in the IFLS register. For variants with only a Buffer, indicates that the buffer has received a character. 0h = Interrupt did not occur 1h = Interrupt occurred
1	RXFIFO_OVF	R	0h	SPI RX FIFO Overflow Interrupt Raw Status. This interrupt is raised when the SPI receiver tries to receive data, but the SPI RX FIFO is full. In this case, new data will be discarded/lost by the SPI receiver. 0h = Interrupt did not occur 1h = Interrupt occurred
0	PER	R	0h	SPI Parity Error Interrupt Raw Status. This interrupt is raised when a character is received with a mismatch between the calculated parity and the received parity. 0h = Interrupt did not occur 1h = Interrupt occurred

## 6 MIS (Offset = 1038h) [Reset = 0000000h]

MIS is shown in [Figure 30-13](#) and described in [Table 30-14](#).

Return to the [Summary Table](#).

Masked interrupt status. This is an AND of the IMASK and RIS registers.

ISET is shown in [Figure 30-23](#) and described in [Table 30-24](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

## 20 IFLS (Offset = 110Ch) [Reset = 0000022h]

IFLS is shown in [Figure 30-27](#) and described in [Table 30-28](#).

Return to the [Summary Table](#).

Interrupt FIFO Level Select. The IFLS register is the interrupt FIFO level select register. You can use this register to define the levels at which the TX, RX and timeout interrupt flags are triggered. The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered when the RX FIFO is filled with two or more characters. Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**Table 30-50. CLKCTL Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	DSAMPLE	R/W	0h	Delayed Sampling Value. In controller mode, data on input pin will be delayed sampled by the defined clock cycles of internal functional clock (SPIClk) hence relaxing the setup time of input data. This setting is useful in systems where the board delays and external peripheral delays are more than the input setup time of the controller. Please refer to the datasheet for values of controller input setup time and assess what DSAMPLE value meets the requirement of the system. Note: High values of DSAMPLE can cause HOLD time violations and must be factored in the calculations. 0h = Delayed sampling is not used Fh = Highest possible value
27-10	RESERVED	R	0h	
9-0	SCR	R/W	0h	Serial Clock Divider. This is used to generate the transmit and receive bit rate of the SPI. The SPI bit rate is $(SPIClk)/((SCR+1)*2)$ . SCR is a value from 0-1023. 0h = Smallest value 3FFh = Highest possible value

## 22 TXDATA (Offset = 1120h) [Reset = 00000000h]

TXDATA is shown in [Figure 30-29](#) and described in [Table 30-30](#).

Return to the [Summary Table](#).

TXDATA Register. Writing puts the data into the TX FIFO. Reading this register returns the last written value. When PACKEN=0, only the lower 16-bits of data written into the register is transferred to one 16-bits wide TX FIFO entry. When PACKEN=1, upper and lower 16-bits of 32-bit write data are transferred to two 16-bits wide TX FIFO entry.

**Figure 30-29. TXDATA**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															
W-0h																															

**Table 30-52. TXDATA Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	W	0h	Transmit Data. When read, last written value will be returned. If the last write to this field was a 32-bit write (with PACKEN=1), 32-bits will be returned and if the last write was a 16-bit write (PACKEN=0), those 16-bits will be returned. When written, one or two FIFO entries will be written depending on PACKEN value. Data values are removed from the TX FIFO one value at a time by the transmit logic. It is loaded into the transmit serial shifter, then serially shifted out onto the TXD output pin at the programmed bit rate. When a data size of less than 16 bits is selected, the user must right-justify data written to the TX FIFO. The transmit logic ignores the unused bits. 0h = Smallest value FFFFh = Highest possible value

### 23 RXDATA (Offset = 1124h) [Reset = 0000000h]

RXDATA is shown in [Figure 30-30](#) and described in [Table 30-31](#).

Return to the [Summary Table](#).

RXDATA Register. Reading this register returns value(s) from the RX FIFO. If the FIFO is empty the last read value is returned. Writing has not effect and is ignored. When PACKEN=1, two entries of the FIFO are returned as a 32-bit value. When PACKEN=0, 1 entry of FIFO is returned as 16-bit value.

**Figure 30-30. RXDATA**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															
R-0h																															

**Table 30-54. RXDATA Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	R	0h	Received Data. When PACKEN=1, two entries of the FIFO are returned as a 32-bit value. When PACKEN=0, 1 entry of FIFO is returned as 16-bit value. As data values are removed by the receive logic from the incoming data frame, they are placed into the entry in the RX FIFO, pointed to by the current FIFO write pointer. Received data less than 16 bits is automatically right justified in the receive buffer. 0h = Smallest value FFFFh = Highest possible value

## 24 CTL1 (Offset = 114Ch) [Reset = 00000004h]

CTL1 is shown in [Figure 30-31](#) and described in [Table 30-32](#).

Return to the [Summary Table](#).

SPI Control Register 1.

**Table 30-56. CTL1 Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	
29-24	RXTIMEOUT	R/W	0h	SPI Receive Interrupt Timeout Select (peripheral mode only). Configures the number of bits (at the programmed baud rate), used by the SPI peripheral when there is no SCLK pulse received, to flag/trigger a timeout condition (RTOUT or LTOUT). A value of 0 disables the timeout functions. 0h = Smallest value 3Fh = Highest possible value
23-16	REPEATTX	R/W	0h	Counter to repeat last transfer. 0: repeat last transfer is disabled. x: repeat the last transfer with the given number. The transfer will be started with writing a data into the TX Buffer. Sending the data will be repeated with the given value, so the data will be transferred X+1 times in total. The behavior is identical as if the data would be written into the TX Buffer that many times as defined by the value here. It can be used to clean a transfer or to pull a certain amount of data by a peripheral. 0h = Smallest value FFh = Highest possible value
15-12	CDMODE	R/W	0h	Command/Data Mode Value. When CTL1.CDENABLE is 1, CS3 line is used as C/D signal to distinguish between Command (C/D low) and Data (C/D high) information. When a value is written into the CTL1.CDMODE bits, the C/D (CS3) line will go low for the given numbers of byte which are sent by the SPI, starting with the next value to be transmitted after which, C/D line will go high automatically 0: Manual mode with C/D signal as High 1-14: C/D is low while this number of bytes are being sent after which, this field sets to 0 and C/D goes high. Reading this field at any time returns the remaining number of command bytes. 15: Manual mode with C/D signal as Low. 0h = Manual mode: Data 0h = Smallest value Fh = Manual mode: Command

**Table 30-56. CTL1 Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	CDENABLE	R/W	0h	Command/Data Mode Enable. 0h = CS3 is used for Chip Select 1h = CS3 is used as CD signal
10	RESERVED	R	0h	
9	SUSPEND	R/W	0h	Suspend External Communication. When this bit is set, SPI communication on the external bus is suspended after the CS has returned to the idle state in controller mode, and after the CS is read as an idle state in peripheral mode. 0h = Functional mode resumed 1h = External communication suspended
8	PTEN	R/W	0h	Parity Transmit Enable. If enabled, parity transmission will be done for both controller and peripheral modes. 0h = Parity transmission is disabled 1h = Parity transmission is enabled
7	RESERVED	R	0h	
6	PES	R/W	0h	Even Parity Select. 0h = Odd Parity mode 1h = Even Parity mode
5	PREN	R/W	0h	Parity Receive Enable. If enabled, parity reception check will be done for both controller and peripheral modes. In case of a parity miss-match the parity error flag RIS.PER will be set. 0h = Disable Parity receive function 1h = Enable Parity receive function
4	MSB	R/W	0h	MSB First Select. Controls the direction of the receive and transmit shift register. 0h = LSB first 1h = MSB first
3	POD	R/W	0h	Peripheral-mode: Data output disabled. This bit is relevant only in Peripheral mode. In multiple-peripheral system topologies, SPI controller can broadcast a message to all peripherals, while only one peripheral drives the line. POD can be used by the SPI peripheral to disable driving data on the line. 0h = SPI can drive the POCI output in peripheral mode. 1h = SPI cannot drive the POCI output in peripheral mode.
2	CP	R/W	1h	Controller or Peripheral Mode Select. This bit can be modified only when SPI is disabled, CTL1.ENABLE=0. 0h = Select Peripheral mode 1h = Select Controller Mode
1	LBM	R/W	0h	Loopback Mode Enable. 0h = Disable loopback mode 1h = Enable loopback mode
0	ENABLE	R/W	0h	SPI Enable. 0h = Disable module function 1h = Enable module function

The Modular Controller Area Network (MCAN) peripheral supports both communication through classic CAN and CAN-FD protocols.

<b>31.7 MCAN Registers</b> .....	<b>1906</b>

### 31.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. CAN has high immunity to electrical interference and the ability to detect various type of errors. In CAN, many short messages are broadcast to the entire network, which provides data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with flexible data-rate) protocols. The CAN FD feature allows higher throughput and increased payload per data frame. Classic CAN and CAN FD devices can coexist on the same network without any conflict provided that partial network transceivers, which can detect and ignore CAN FD without generating bus errors, are used by the classic CAN devices. The MCAN module is compliant to ISO 11898-1:2015.

**Note**

The CAN FD feature is not available on all devices. Refer to the device-specific data sheet for more information.

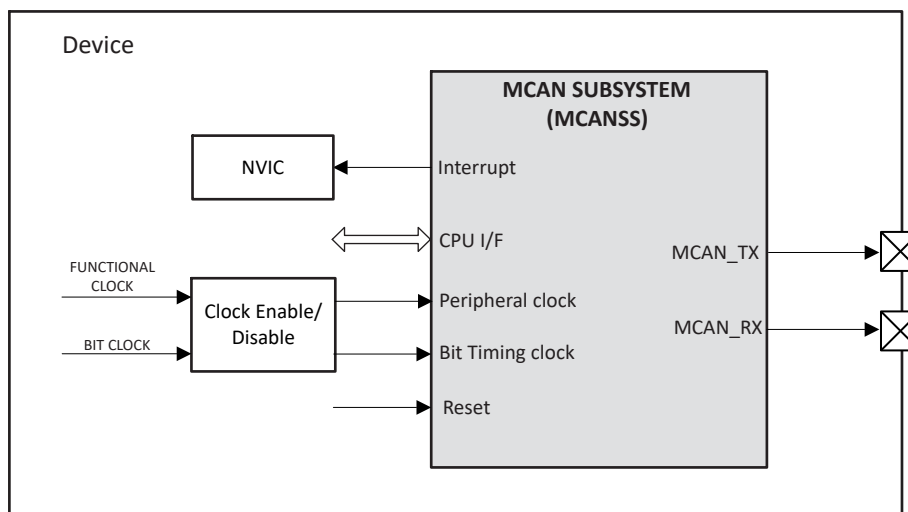

Figure 31-1. MCAN Block Diagram

### 31.1.1 MCAN Features

The MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated transmit buffers
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit Event FIFO, up to 32 elements
- Up to 14 dedicated receive buffers
- Two configurable receive FIFOs, up to 14 elements each with 1kB message RAM.
- Up to 128 filter elements
- Loop-back mode for self-test
- Maskable interrupt
  - 2 configurable interrupt lines
  - Correctable ECC
  - Counter overflow
  - Clock stop or wakeup
- Non-maskable interrupt (uncorrectable ECC)
- Two clock domains (CAN clock and host clock)
- ECC check for Message RAM
- Clock stop and wakeup support
- Timestamp counter
- Up to 1-Mbps nominal bit rate, up to 8-Mbps data bit rate

Non-supported features:

- Host bus firewall
- Clock calibration
- Debug over CAN

### 31.2 MCAN Environment

The CAN network physical layer consists of a two-wire differential bus, usually twisted pair, and provides a high level of interference immunity. An external CAN transceiver IC is needed to access the bus.

[Figure 31-2](#) shows typical MCAN wiring. [Table 31-1](#) describes the external signals of the MCAN module.

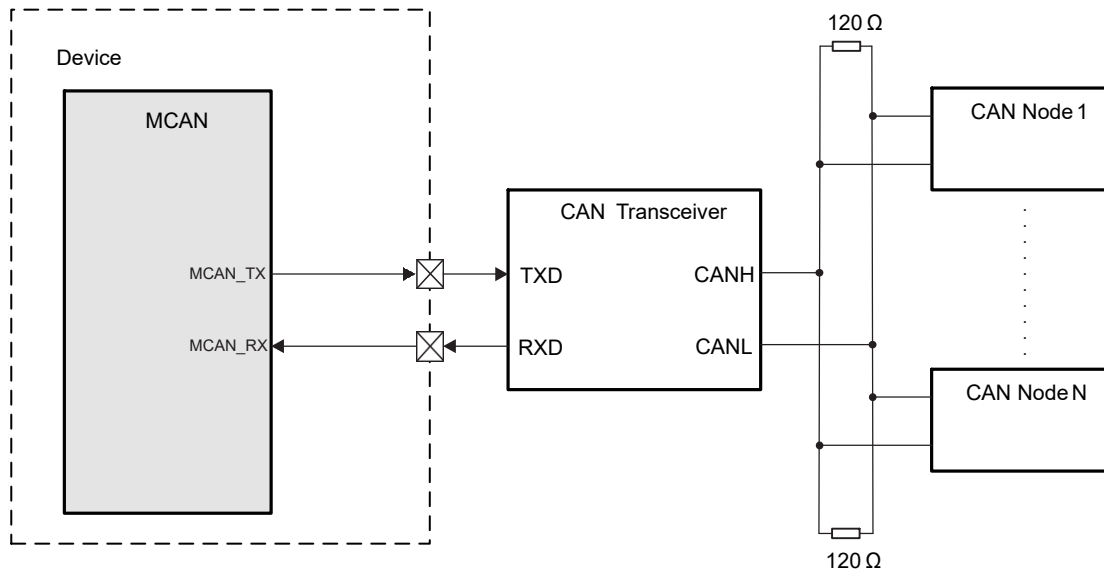

Figure 31-2. MCAN Typical Bus Wiring

Table 31-1. MCAN I/O Description

Module Signal	I/O	Description	Value at Reset
MCAN_RX	Input	Serial data input from external CAN transceiver.	HiZ
MCAN_TX	Output	Serial data output to external CAN transceiver.	HiZ

**Note**

See the *Terminal Configurations and Functions* section in the device data sheet and the *General-Purpose Input/Output (GPIO)* chapter to configure this peripheral to be connected to the device pins.

### 31.3 CAN Network Basics

The network basics are:

- The CAN bus is a 2-wire differential bus using non-return-to-zero (NRZ) encoding and has two states:
  - Recessive state (logical 1)
  - Dominant state (logical 0)
- When the bus is idle, any node can initiate a transmission to any other node. When two or more nodes (ECUs) attempt to transmit at the same time, a nondestructive arbitration technique sends messages in order of priority so that no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier-based, not address-based.
- The content of the message is labeled by the identifier that is unique throughout the network (for example: RPM, temperature, position, pressure, and so forth).
- All nodes on the network receive the message and each performs an acceptance test on the identifier. If the message is relevant, it is processed; otherwise, it is ignored.
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority).
- Data is transmitted and received using message frames, consisting of the following basic fields:
  - Arbitration field
  - Control field

- Data field (up to 8 bytes for classical CAN and up to 64 bytes for CAN FD)
- CRC field
- ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signaling*.

MCAN power up and clock sequence :

1. Select CANCLK from the available clock sources: the HFCLK (HFXT or HFCLK\_IN) or the SYSPLL (SYSPLLCLK1).
2. Enable the corresponding clock source.
3. Wait until the clock source is stable (SYSCTL\_CLKSTATUS[\*GOOD] bit = 1).
4. Enable MCAN power by setting PWREN for MCAN.
5. Wait until MCAN is ready (SYSCTL\_SYSSTATUS[MCAN0READY] = 1).

### 31.4 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values up to 8Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly through the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 31-3 shows the MCAN module block diagram, followed by the description of the MCAN module blocks.

**Figure 31-3. MCAN Block Diagram**

- **CAN Core:** The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler:** the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and Interrupt generation as programmed in the control registers.
- **Message RAM:** the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see [Section 31.4.19](#) ).
- **Message RAM Interface:** enables a connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access:** Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.
- **Module Interface:** The MCAN module registers are accessed by the user's software through a 32-bit peripheral bus interface.
- **Clocking:** Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN\_ICLK) and the peripheral asynchronous clock (functional clock - MCAN\_FCLK).
- **Extension Interface:** All selected internal status and control signals are routed to this interface (except for the indication signals of configuration change enable bit (MCAN\_CCCR.CCE) and Interrupt Register bits (MCAN\_IR).

### **31.4.1 Clock Setup**

Peripheral asynchronous clock (MCAN\_FCLK) for MCAN can be clocked either through HFXT or SYSPLL. This clock configuration has to be done through SYSCTL REGISTERS. *Refer to CANCLK (CAN-FD Functional Clock ) under the Clocks section.*

### 31.4.2 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- Host Clock : peripheral synchronous clock (MCAN\_ICLK) as the general module clock source, and
- CAN Clock: peripheral asynchronous clock (MCAN\_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module, there is a synchronization mechanism implemented to make sure there is safe data transfer between the two clock domains. There is synchronization between the signals from the Host clock domain to the CAN clock domain and conversely, and between the reset signal (MCAN\_RST) to the Host clock domain and to the CAN clock domain.

---

#### Note

MCAN\_ICLK must always be higher or equal to MCAN\_FCLK to achieve a stable functionality of the MCAN module:  $f_{ICLK} \geq f_{FCLK}$

---

The CAN-FD supports higher speeds of operation and as such has more stringent timing requirements than the classic CAN. For performance, TI recommends using the lowest N-divider value that maintains a working PLL REF\_CLK for the system. Lower N-divider values increase the loop bandwidth of the PLL, which in turn improves timing margins for CAN-FD.

The peripheral asynchronous clock (MCAN\_FCLK) can be clocked either through HFXT or SYSPLL. The configuration of this has to be done through the SYCTL registers. Refer to the *Clocks* module for more information

### 31.4.3 Interrupt Requests

The MCAN module generates interrupt requests that are configured through the Host CPU. Placing the MCAN module in suspend mode prevents the interrupt requests from propagating to the Host CPU. The MCAN core has two interrupt lines and 30 internal interrupt sources. Each source can be configured to drive one of the two interrupt lines. The interrupts are 'level high' interrupts. The MCAN core provides two interrupt requests (MCANSS\_INT0 and MCANSS\_INT1).

For more information, see the following registers:

- Interrupt Register (MCAN\_IR)
- Interrupt Enable (MCAN\_IE)
- Interrupt Line Select (MCAN\_ILS)
- Interrupt Line Enable (MCAN\_ILE)

The MCAN module supports an External Timestamp Counter. The External Timestamp Counter produces an interrupt when it rolls over (see [Section 31.4.12.1](#) ).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS\_ICS)
- Interrupt Raw Status Register (MCANSS\_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS\_IECS)
- Interrupt Enable Register (MCANSS\_IE)
- Interrupt Enable Status Register (MCANSS\_IES)
- End Of Interrupt Register (MCANSS\_EOI)
- External Timestamp Prescaler Register (MCANSS\_EXT\_TS\_PRESCALER)
- External Timestamp Unserviced Interrupts Counter Register (MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR)

To clear IRQ\_INT0, IRQ\_INT1 and TS\_WAKE interrupts, write to the EOI bitfield for the corresponding interrupt number that is described in the MCANSS\_EOI register.

After servicing an interrupt (external timestamp, interrupt 0/1), write '1' in the corresponding bit in MCANSS\_EOI register to clear the interrupt. In case of an ECC interrupt, after clearing the ECC interrupt source, application software must also write a '1' to the EOI registers (MCANERR\_SEC\_EOI.EOI\_WR/CANERR\_DED\_EOI.EOI\_WR). For more information see [Section 31.4.14.2](#)

The IRQ sequence is as follows:

1. Enable one of the interrupt sources by setting corresponding bit in IMASK.
2. Set MCANSS\_IE to enable the IRQ, set MCANSS\_ILS for line0 or line1.
3. Wait for the interrupt source to be triggered.
4. The interrupt is triggered and the application jumps into IRQ service routine (ISR).
5. In the ISR, check if IRQ is triggered by the expected source by reading IIDX. Reading IIDX clears the IRQ source, so there is no need to write ICLR to clear the IRQ.

**Due to the design of MCAN, step (6) is required in the ISR to clear IRQ. Check the interrupt source to determine if step 7 is needed:**

6. Write 1 to MCAN\_IR to clear the interrupt.
7. If the source is IRQ\_INT0, IRQ\_INT1, or TS\_WAKE, also clear MCANSS\_EOI, otherwise the next IRQ will not be recognized.

### 31.4.4 Operating Modes

The operating modes are discussed in the following sections.

#### 31.4.4.1 Normal Operation

Once the MCAN module is initialized and the MCAN\_CCCR.INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted, dedicated Tx buffers, and a Tx FIFO or a Tx queue can be initialized or updated.

**Note**

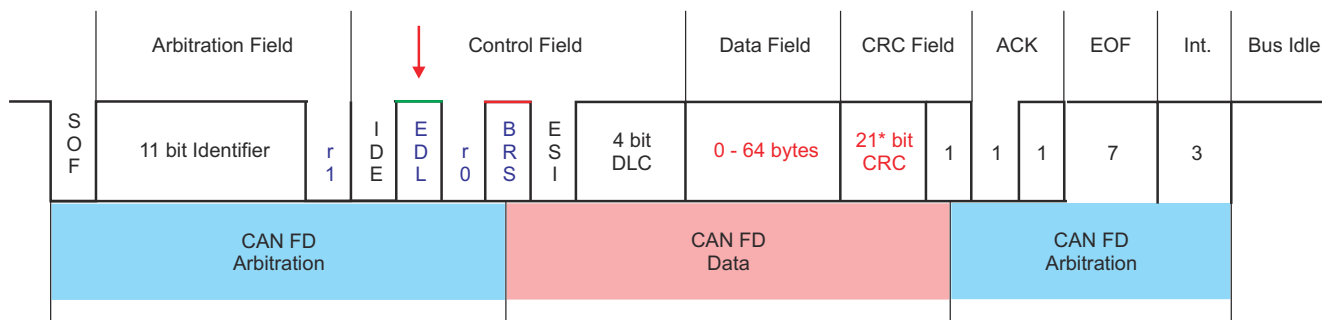

Automated transmission upon reception of remote frames is not supported.

#### 31.4.4.2 CAN Classic

CAN supports transmission of data up to 8 bytes with standard (11 bit) or (29 bit) identifier.

#### 31.4.4.3 CAN FD Operation

The CAN FD standard allows extended frames to be sent, up to 64 data bytes in a single frame at a higher bit rate for the data phase of a frame, up to 8 Mbps. The CAN FD standard introduces the ability to switch from one bit rate to another. Extended Data Length (EDL), as shown in Figure 31-4 and described in Table 31-2, sets a data length of up to 8 or 64 data bytes. Bit Rate Switching (BRS) indicates whether two bit rates (the data phase is transmitted at a different bit rate compared to the arbitration phase) are enabled.

\* 17 bit CRC for data fields with up to 16 bytes

mcan-004a

**Figure 31-4. CAN FD Frame**

**Table 31-2. CAN FD Frame Description**

Bit	Description
SOF	Start of Frame
IDE	Identifier extension (for 29 bit extended ID)
FDF	Flexible Data Format
BRS	Bit Rate Switching
ESI	Error Status Indicator
DLC	Data Length Code
CRC	Cyclic Redundancy check

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames, FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. If the MCAN module receives a frame with FDF = recessive and res = recessive, the MCAN signals a Protocol Exception Event by setting the MCAN\_PSR.PXE bit. When Protocol Exception Handling is enabled (MCAN\_CCCR.PXHD = 0), this causes the operation state to change from Receiver (MCAN\_PSR.ACT = 10) to Integrating (MCAN\_PSR.ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN\_CCCR.PXHD = 1), the MCAN treats a recessive bit as an error and responds with an error frame.

CAN FD operation is enabled by programming the MCAN\_CCCR.FDOE bit. If MCAN\_CCCR.FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured using the FDF bit in the respective Tx Buffer element.

With MCAN\_CCCR.FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN\_CCCR.FDOE and MCAN\_CCCR.BRSE bits can only be changed while the MCAN\_CCCR.INIT and MCAN\_CCCR.CCE bits are both set. With MCAN\_CCCR.FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN\_CCCR.FDOE = 1 and MCAN\_CCCR.BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN\_CCCR.FDOE = 1 and MCAN\_CCCR.BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case, disable the CAN FD bit rate switching option for transmissions.
- During system startup, all nodes are transmitting Classic CAN messages until verified that the nodes are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wakeup messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

The coding of the DLC in the CAN FD format differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN (0 to 8 data bytes), the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to [Table 31-3](#).

**Table 31-3. DLC Coding in CAN FD**

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

## CAN-FD Bit Timing

For CAN FD frames, the bit timing is switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see [Figure 31-5](#)) is used as configured by the Nominal Bit Timing and Prescaler Register (MCAN\_NBTP). In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register (MCAN\_DBTP). The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

**Figure 31-5. CAN Bit Timing**

The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN\_FCLK). Example: with MCAN\_FCLK = 20MHz and the shortest configurable bit time of 4  $t_q$  (time quanta), the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the Error Status Indicator (ESI) bit depends on the transmitter error state (see MCAN\_PSR.RESI bit) monitored at the start of the transmission. If the transmitter has an error passive flag, the ESI bit is transmitted recessive; else, the ESI bit is transmitted dominant.

### 31.4.5 Software Initialization

A software initialization begins when the MCAN\_CCCR.INIT bit is set to 1. This is done either by software or by a hardware reset, when an uncorrected bit error is detected in the Message RAM, or by going to a Bus\_Off state. While the MCAN\_CCCR.INIT bit is set, the message transfer is stopped and the status of the output TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN\_CCCR.INIT bit does not change any configuration register. Resetting the MCAN\_CCCR.INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus\_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN\_CCCR.INIT and MCAN\_CCCR.CCE bits are set (write protection).

The MCAN\_CCCR.CCE bit can only be set/reset while the MCAN\_CCCR.INIT = 1. The MCAN\_CCCR.CCE bit is automatically reset when the MCAN\_CCCR.INIT bit is reset.

The following registers are reset when the MCAN\_CCCR.CCE bit is set:

- MCAN\_HPMS - High Priority Message Status
- MCAN\_RXF0S - Rx FIFO 0 Status
- MCAN\_RFX1S - Rx FIFO 1 Status
- MCAN\_TXFQS - Tx FIFO/Queue Status
- MCAN\_TXBRP - Tx Buffer Request Pending
- MCAN\_TXBTO - Tx Buffer Transmission Occurred
- MCAN\_TXBCF - Tx Buffer Cancellation Finished
- MCAN\_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN\_TOCV.TOC field is preset to the value configured by the MCAN\_TOCC.TOP field when the MCAN\_CCCR.CCE bit is set.

In addition, the Tx Handler and Rx Handler are held in idle state while MCAN\_CCCR.CCE = 1.

The following registers are only writable while MCAN\_CCCR.CCE = 0

- MCAN\_TXBAR - Tx Buffer Add Request
- MCAN\_TXBCR - Tx Buffer Cancellation Request

MCAN\_CCCR.TEST and MCAN\_CCCR.MON bits can only be set by the Host CPU while MCAN\_CCCR.INIT = 1 and MCAN\_CCCR.CCE = 1. Both bits are reset at any time. The MCAN\_CCCR.DAR bit can only be set/reset while MCAN\_CCCR.INIT = 1 and MCAN\_CCCR.CCE = 1.

Table 31-4 shows the steps to configure the MCAN module.

**Table 31-4. Steps to Configure MCAN Module**

Step	Operation	Description	Pseudo Code
1	Initialize MCAN_CCCR	Set MCAN_CCCR.INIT bit and check that the bit has been set	INIT = 1; If INIT ≠ 1, wait until set
2	Unlock protected registers	Set MCAN_CCCR.CCE bit	CCE = 1;
3	Configure CAN mode	Set MCAN_CCCR.FDOE bit to CAN FD	FDOE = 1 for CAN FD FDOE = 0 for Classic CAN
4	Configure Bit Rate Switching	Set MCAN_CCCR.BRSE bit	BRSE = 1 for bit rate switching BRSE = 0 for no bit rate switching
5	Set nominal bit timing <sup>(1)</sup>	Set MCAN_NBTP register	
6	Lock protected registers	Clear MCAN_CCCR.CCE bit	CCE = 0;
7	Return MCAN module to normal operation	Clear MCAN_CCCR.INIT bit and check that the bit has been cleared	INIT = 0; If INIT ≠ 0, wait until cleared

(1) See the MCAN\_NBTP register on how to program CAN bit timing in the *MCAN\_REGS Registers* section.

### 31.4.6 Transmitter Delay Compensation

#### 31.4.6.1 Description

When only one CAN FD node is transmitting and all other nodes are receivers, the length of the bus line has no impact. When transmitting using the TX pin, the MCAN module receives the transmitted data from its CAN transceiver using the RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate for the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN\_DBTP.TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter reacts on this bit error at the next following regular sample point. During the arbitration phase, the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN transmit output TX pin through the transceiver to the receive input RX pin plus the transmitter delay compensation offset configured by the MCAN\_TDCR.TDCO field (see [Figure 31-6](#)). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN\_PSR.TDCV field. This field is cleared when the MCAN\_CCCR\_INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN\_DBTP.TDC bit is set.

mcan-005

Figure 31-6. Transmitter Delay Measurement

### 31.4.6.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming `MCAN_DBTP.TDC = 1`), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit r0. The measurement is stopped when this edge is seen at the receive input RX pin of the transmitter. The resolution of this measurement is one mtq (see [Figure 31-6](#)). The mtq (minimum time quantum) dimension is equal to the CAN clock period (`MCAN_FCLK`).

The use of a transmitter delay compensation filter window can be enabled by programming the `MCAN_TDCR.TDCF` field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the RX pin that result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least `MCAN_TDCR.TDCF` field and the RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (`MCAN_TDCR.TDCO` field) has to be less than six bit times in the data phase.
- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (`MCAN_TDCR.TDCO`) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

### 31.4.7 Restricted Operation Mode

In restricted operation mode, the CAN node is able to receive data and remote frames and give acknowledgment to valid frames, but the node does not send data frames, remote frames, active error frames, or overload frames. In the case of an error condition or overload condition, the node does not send dominant bits; instead the node waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The receive and transmit error counters (`MCAN_ECR.REC` and `MCAN_ECR.TEC`) are frozen while CAN error logging (`MCAN_ECR.CEL`) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting the `MCAN_CCCR.ASM` bit. The bit can only be set by the Host CPU at any time when both `MCAN_CCCR.CCE` and `MCAN_CCCR.INIT` bits are set to 1.

The restricted operation mode is automatically entered when the Tx Handler is not able to read data from the Message RAM in time. To leave restricted operation mode, the Host CPU has to reset the `MCAN_CCCR.ASM` bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case, the application tests different bit rates and leaves the restricted operation mode after the node has received a valid frame.

---

#### Note

The Restricted Operation Mode must not be combined with the Loop Back Mode.

---

### 31.4.8 Bus Monitoring Mode

Entering bus monitoring mode is done by setting the MCAN\_CCCR.MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In bus monitoring mode, the MCAN\_TXBRP register is held in reset state. The bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting the bus by the transmission of dominant bits. [Figure 31-7](#) shows the connection of the TX and RX signals to the MCAN module in bus monitoring mode.

Figure 31-7. Connection of Signals in Bus Monitoring Mode

### 31.4.9 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN\_CCCR.DAR bit).

#### 31.4.9.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically canceled after they have started on the CAN bus. A Tx buffer's Tx Request Pending (MCAN\_TXBRP[xx]) TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred (MCAN\_TXBTO.TOx) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN\_TXBCF.CFx) CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred (MCAN\_TXBTO.TOx) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN\_TXBCF.CFx) CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred (MCAN\_TXBTO.TOx) TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished (MCAN\_TXBCF.CFx) CFx bit is set

In the case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

#### 31.4.10 Clock Stop Mode

Entering the clock stop mode can be achieved by programming one of two bits:

- Clock stop request bit in MCAN\_IP (MCAN\_CCCR.CSR)
- Stop request bit in MCAN\_WRAPPER (MCANSS\_CLKCTL.STOPREQ)

The register bit within the MCAN\_IP (MCAN\_CCCR.CSR) reads as 1 as long as the MCAN\_WRAPPER bit (MCANSS\_CLKCTL.STOPREQ) is asserted.

Figure 31-8. Clock Stop Request

After all pending transmission requests have completed, the MCAN module waits until the bus idle state is detected and then sets MCAN\_CCCR.INIT to 1 to prevent further CAN transfers. The MCAN module then acknowledges the MCAN is ready for power down by setting the clock stop acknowledge bit MCAN\_CCCR.CSA to 1 (MCANSS\_CLKSTS.CLKSTOP\_ACKSTS reflects the same value as well). In this state, before clocks are switched off, further register accesses can be made. However, a write access to the MCAN\_CCCR.INIT bit has no effect. Module clock inputs MCAN\_ICLK and MCAN\_FCLK can now be switched off using MCANSS\_CLKEN.CLK\_REQEN.

To exit the power-down mode, the application has to turn on module clocks before clearing the clock stop request bit (make sure both MCAN\_CCCR.CSR and MCANSS\_CLKCTL.STOPREQ are cleared). MCAN acknowledges removal of the clock request by clearing the MCANSS\_CLKSTS.CLKSTOP\_ACKSTS

and MCAN\_CCCR.CSA bits. The application can now restart CAN communication by clearing the MCAN\_CCCR.INIT bit.

Automatic wakeup from the power-down mode (due to activity on MCAN Rx) is supported through the MCANSS\_CTRL.AUTOWAKEUP and MCANSS\_CTRL.WAKEUPREQEN bits (for more information, see [Section 31.4.10.2](#)).

Clock stop and automatic wakeup is illustrated in [Figure 31-9](#).

**Figure 31-9. Power Down Entry**

**31.4.10.1 Suspend Mode**

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the `MCANSS_CTRL.DBGSUSP_FREE` bit) when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core responds with a clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point, the `MCAN_CCCR.INIT` bit is set and the MCAN core stays Idle. The suspend state can be verified by reading the `MCAN_CCCR.INIT` bit.

The automatic wakeup feature is enabled by setting the `MCANSS_CTRL.AUTOWAKEUP` and `MCANSS_CTRL.WAKEUPREQEN` bits to 1 (for more information, see [Section 31.4.10.2](#)). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the `MCAN_CCCR.INIT` bit is performed to clear the bit.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- `MCAN_ECR.CEL`
- `MCAN_PSR.LEC`
- `MCAN_PSR.DLEC`
- `MCAN_PSR.RESI`
- `MCAN_PSR.RBRS`
- `MCAN_PSR.RFDF`
- `MCAN_PSR.PXE`

#### 31.4.10.2 Wakeup Request

Issuing a clock stop request puts the MCAN module into power-down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the `MCANSS_CTRL.AUTOWAKEUP` and `MCANSS_CTRL.WAKEUPREQEN` bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write is issued to clear the `MCAN_CCCR.INIT` bit and the MCAN core resumes operation. Please note that after clock stop request has been removed by the hardware the first frame (wakeup frame) is not received. This is because after the clock stop is issued; there are no active clocks running into the IP. Therefore after removing the clock stop request; the wakeup frame that enables clock has to be re-transmitted.

If the `MCANSS_CTRL.WAKEUPREQEN` bit is set, the MCAN module provides a wakeup request on the following wakeup event:

- The receive RX pin is dominant (logical 0)

The wakeup request is deasserted when any of the following conditions occur:

- Clock stop request is removed and clock stop acknowledge is deasserted
- A reset is applied to the MCAN module

Figure 31-10. Auto Wakeup Enabled Exit from Power Down

Please note the suggested user notes while issuing a wakeup request.

- If there is a message that is being received on the CAN Bus when a Clock Stop Request (CSR) is issued; it will create a wakeup interrupt at the end of the reception resulting in the MCAN module not entering the clock stop mode. To avoid unnecessary wake ups; the user should check the node activity bit (ACT) in the protocol status register (PSR) ensuring an idle state before setting the request.
- The user should also avoid creating a SW polling loop to only exit with a stop clock acknowledge (CSA) since the timing of the software check and wake up interrupt clearing the CSA could cause an infinite software loop
- If there is excessive noise on the Rx pin, it may cause frequent wake up. To avoid this it is recommended that the user waits for a specified time to see if a wake up was received and if not, assert the clock stop state.
- The wakeup logic can be unexpectedly disabled if MCAN is reset while clock stop request is asserted. Therefore, the user should avoid asserting a soft reset to MCAN while CSR is asserted.

### 31.4.11 Test Modes

The MCAN\_TEST register write access is enabled by setting the test mode enable MCAN\_CCCR.TEST bit to 1. The MCAN\_TEST register allows the configuration of the test modes and test functions.

The transmit (TX) pin has four different output functions which can be selected by programming the MCAN\_TEST.TX field. The default function is the serial data output. The pin can also be driven with a constant dominant or recessive value. It is also possible to drive the sample-point signal to monitor the bit-timing.

The actual value of the receive (RX) pin can be monitored from MCAN\_TEST.RX bit. Both functions can be used to check the physical layer. Due to the synchronization mechanism between the CAN clock (MCANx\_FCLK) and Host clock (MCANx\_ICLK) domain, there can be a delay of several Host clock periods between writing to the MCAN\_TEST.TX field until the new configuration is visible at the output TX pin. This applies also when reading input RX pin by way of the MCAN\_TEST.RX bit.

#### Note

Test modes can be used for self-test only. The software control for TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for an application.

#### 31.4.11.1 External Loop Back Mode

The MCAN module can be set into external loop back mode by programming MCAN\_TEST.LBCK to 1. In loop backmode, the MCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into an Rx Buffer or an Rx FIFO as shown in below figure. Figure shows the connection of the TX and RX pins to the MCAN module in external loop back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the MCAN module ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loop back mode. In this mode, the MCAN module performs an internal feedback from the Tx output to the Rx input. The actual value of the RX input pin is disregarded by the MCAN module. The transmitted messages are monitored at the TX pin.

Figure 31-11. External Loop Back Mode

#### 31.4.11.2 Internal Loop Back Mode

The MCAN module can be set into internal loop back mode by programming MCAN\_TEST.LBCK and MCAN\_CCCR.MON bits to 1. The internal loop back mode is used for a Hot Self-test. The Hot Self-test allows

the MCAN module to be tested without affecting a running CAN system connected to the TX and RX pins. In this mode, the RX pin is disconnected from the MCAN module and the TX pin is held recessive. [Figure 31-12](#) shows the connection of the TX and RX pins to the MCAN module in internal loop back mode.

**Figure 31-12. Internal Loop Back Mode**

### 31.4.12 Timestamp Generation

The MCAN module has an integrated 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler `MCAN_TSCC.TCP` field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable by way of the `MCAN_TSCV.TSC` field. A write access to the `MCAN_TSCV` register resets the counter to zero. When the timestamp counter wraps around the interrupt `MCAN_IR.TSW` flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (`RXTS[15:0]`) or Tx Event FIFO (`TXTS[15:0]`) element. For more information regarding FIFO timestamp configuration, see [Section 31.4.19](#).

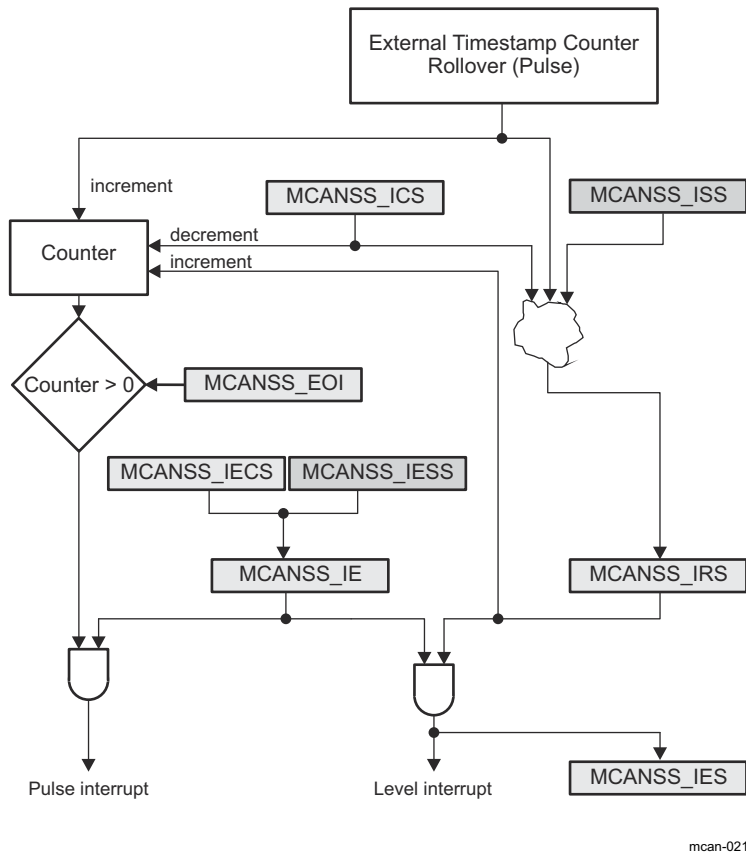

#### 31.4.12.1 External Timestamp Counter

For CAN FD operation mode, the MCAN core requires an external timestamp counter. An externally generated 16-bit vector can substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the `MCAN_TSCC.TSS` field.

The external timestamp counter uses the interface clock (`MCANx_ICLK`) as a reference clock. The MCAN core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see `MCANSS_EXT_TS_PRESCALER.PRESCALER` bit field). The external timestamp counter can be enabled or disabled through the `MCANSS_CTRL.EXT_TS_CNTR_EN` bit. When disabled, the counter is reset back to zero. While enabled, the counter keeps incrementing. When the timestamp rolls over, the `MCAN_IRQ_TS` interrupt is generated.

When the timestamp rolls over, the `MCANSS_IRS` register is set. The `MCANSS_IE` register can be affected by writing to the `MCANSS_IESS` register to set or to the `MCANSS_IECS` register to clear. The `MCANSS_IESS` register is a shadow register mapped to the same address as the `MCANSS_IE` register. The level interrupt is a reflection of both `MCANSS_IRS` and `MCANSS_IE` being set. The `MCANSS_IES` register reflects the level interrupt. When a rollover event occurs, the interrupt counter is incremented. Writing to the `MCANSS_ICS` register to clear the `MCANSS_IRS` register also decrements the interrupt counter. Writing to the `MCANSS_EOI` register issues another pulse, if the interrupt counter is not zero.

The rollover event can be artificially simulated by software through writing to the Interrupt Set Shadow register (MCANSS\_ISS). The MCANSS\_ISS register is a shadow register mapped to the same address as the MCANSS\_IRS register.

**Figure 31-13. External Timestamp Counter Interrupt**

**31.4.13 Timeout Counter**

The MCAN module has an integrated 16-bit timeout counter. The timeout counter is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The timeout counter is configured using the MCAN\_TOCC register and is enabled using the MCAN\_TOCC.ETOC bit. The timeout counter operates as down-counter and uses the same prescaler programmed by the MCAN\_TSCC.TCP field as the timestamp counter. The actual counter value can be monitored from the MCAN\_TOCV.TOC field. The timeout counter can be started only when MCAN\_CCCR.INIT = 0 and stopped when MCAN\_CCCR.INIT = 1 (example: when the MCAN enters Bus\_Off state). The operation mode is selected by the MCAN\_TOCC.TOS field. When continuous mode is selected, the counter starts when MCAN\_CCCR.INIT = 0, a write to the MCAN\_TOCV register presets the counter to the value configured by the MCAN\_TOCC.TOP field and continues down-counting.

In case the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN\_TOCC.TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN\_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN\_IR.TOO flag is set.

In continuous mode, the counter is immediately restarted at the value configured by the MCAN\_TOCC.TOP field.

### Note

The clock signal for the timeout counter is derived from the CAN core sample point signal. Therefore, the point in time where the timeout counter is decremented can vary due to the synchronization/re-synchronization mechanism of the CAN core. If the bit rate switch (BRS) feature in CAN-FD is used, the timeout counter is clocked differently in arbitration and data field.

#### 31.4.14 Safety

The Message RAM (MSG\_RAM) is wrapped in an ECC wrapper providing SECDED parity functionality. The MCAN ECC wrapper is controlled by an ECC aggregator.

##### 31.4.14.1 MCAN ECC Wrapper

The ECC wrapper provides single error correction (SEC) and double error detection (DED) parity to the message memory content. The ECC wrapper has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, the error is noted in a FIFO queue that waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

##### 31.4.14.2 MCAN ECC Aggregator

This section describes the functional details of the MCAN ECC aggregator module.

###### 31.4.14.2.1 MCAN ECC Aggregator Overview

The MCAN ECC aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bits that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

###### 31.4.14.2.2 MCAN ECC Aggregator Registers

There are three groups of registers in the MCAN ECC aggregator module:

- **Global registers:** Aggregator Revision Register (MCANERR\_REV), ECC Vector Register (MCANERR\_VECTOR), Misc Status Register (MCANERR\_STAT), ECC Control Register (MCANERR\_CTRL), and ECC Wrapper Revision Register (MCANERR\_WRAP\_REV).
- **Control and status registers:** ECC Error Control Registers (MCANERR\_ERR\_CTRL1 and MCANERR\_ERR\_CTRL2) and ECC Error Status Registers (MCANERR\_ERR\_STAT1, MCANERR\_ERR\_STAT2, and MCANERR\_ERR\_STAT3).
- **Interrupt registers:** interrupt status, interrupt enable set, interrupt enable clear, and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
  - MCANERR\_SEC\_EOI
  - MCANERR\_SEC\_STATUS
  - MCANERR\_SEC\_ENABLE\_SET
  - MCANERR\_SEC\_ENABLE\_CLR
  - MCANERR\_DED\_EOI
  - MCANERR\_DED\_STATUS
  - MCANERR\_DED\_ENABLE\_SET
  - MCANERR\_DED\_ENABLE\_CLR

### 31.4.14.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as:

1. Software writes value (the ECC RAM ID) to the MCANERR\_VECTOR.ECC\_VECTOR field to select the ECC RAM for control or status.
2. Software writes 1 to the MCANERR\_VECTOR.RD\_SVBUS bit to trigger a read.
3. Software writes read address to the MCANERR\_VECTOR.RD\_SVBUS\_ADDRESS field.
4. Software then polls the MCANERR\_VECTOR.RD\_SVBUS\_DONE bit to check if the bit is 1. This bit indicates that the read operation has completed.
5. Software reads the data from the ECC control or status register. The following clock cycle (MCAN\_ICLK) returns the read data.

### 31.4.14.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described:

1. Software enables the interrupts for the ECC RAM by writing to the MCANERR\_SEC\_ENABLE\_SET/MCANERR\_DED\_ENABLE\_SET register.
2. Software writes the ECC RAM ID in the MCANERR\_VECTOR.ECC\_VECTOR.
3. Software writes the MCANERR\_VECTOR.RD\_SVBUS bit to trigger the read.
4. Software writes the MCANERR\_ERR\_STAT1 register address to the MCANERR\_VECTOR.RD\_SVBUS\_ADDRESS field. Software needs to load the 'read message' in the rMCANERR\_VECTOR register again, if the software needs to read the MCANERR\_ERR\_STAT2 register.
5. Software polls the MCANERR\_VECTOR.RD\_SVBUS\_DONE bit. When this bit is set, a read of the MCANERR\_ERR\_STAT1/MCANERR\_ERR\_STAT2 register is performed.
6. After the interrupt has been serviced, software clears the interrupt status by writing to the MCANERR\_ERR\_STAT1.CLR\_ECC\_SEC or MCANERR\_ERR\_STAT1.CLR\_ECC\_DED bit depending on the type of the ECC error.
7. Software polls the MCANERR\_ERR\_STAT1 register to verify that the status bit has been cleared.
8. Software writes to the MCANERR\_SEC\_EOI/MCANERR\_DED\_EOI register to clear the interrupt.
9. After clearing the ECC interrupt source, the application software must also write 1 to the MCANERR\_SEC\_EOI.EOI\_WR /MCANERR\_DED\_EOI.EOI\_WR bits.

### 31.4.15 Tx Handling

The Tx handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and GetIndex operations. The MCAN module supports up to 32 Tx buffers. These Tx buffers can be configured as dedicated Tx buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx buffers/Tx FIFO or dedicated Tx buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. Table below shows the possible configurations for message transmission.

**Table 31-5. Message Transmission configurations**

MCAN_CCCR Register		Buffer Element		Frame Transmission
BRSE	FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer RequestPending (MCAN\_TXBRP) register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with the lowest Message ID has highest priority.

---

**Note**

AUTOSAR requires at least three Tx Queue buffers and support of transmit cancellation

---

### 31.4.15.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause CAN messages from another ECU to be delayed (paused).

The transmit pause feature is enabled by the MCAN\_CCCR.TXP bit. By default this bit is disabled (MCAN\_CCCR.TXP= 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

### 31.4.15.2 Dedicated Tx Buffers

Dedicated Tx buffers are intended for message transmission under complete control of the Host CPU. There are two options.

- Each dedicated Tx Buffer is configured with a specific Message ID
- Two or more dedicated Tx buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first

After the data section has been updated, a transmission is requested by an Add Request. This is done using the MCAN\_TXBAR[x]ARn bit (where x = 0 to 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

The following table shows the Tx Buffer, Tx FIFO, and Tx Queue Element Size. A Dedicated Tx Buffer allocates element size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN\_TXFQS.TFQP) × Element size to the Tx Buffer start address MCAN\_TXBC.TBSA field

**Table 31-6. Tx Buffer, Tx FIFO, Tx Queue Element Size**

MCAN_TXESC.TBDS	DataField [Bytes]	Element Size [RAM Words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

### 31.4.15.3 Tx FIFO

Tx FIFO mode is configured by setting bit `MCAN_TXBC.TFQM = 0`. The data stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index `MCAN_TXFQS.TFGI` field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level `MCAN_TXFQS.TFFL` field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index `MCAN_TXFQS.TFQP` field. After each Add Request (`MCAN_TXBAR[x] ARn = 1`) the Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (`MCAN_TXFQS.TFQP = MCAN_TXFQS.TFGI`), Tx FIFO Full condition is signaled by bit `MCAN_TXFQS.TFQF = 1`. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx buffers as indicated by the Tx FIFO Free Level `MCAN_TXFQS.TFFL` field.

In case a transmission request for the Tx Buffer referenced by the Get Index is canceled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level `MCAN_TXFQS.TFFL` field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates element size 32-bit words in the Message RAM. The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index `MCAN_TXFQS.TFQP` (from 0 to 31) × Element Size to the Tx Buffer Start Address `MCAN_TXBC.TBSA` field.

#### 31.4.15.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN\_TXBC.TFQM = 1. The data stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS.TFQP field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN\_TXFQS.TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been canceled.

The application may use the MCAN\_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates element size 32-bit words in the Message RAM. The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS.TFQP (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN\_TXBC.TBSA field.

### 31.4.15.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx buffers section in the Message RAM is separated in two parts:

- Dedicated Tx buffers: the number of dedicated Tx buffers is configured by MCAN\_TXBC.NDTB field.
- Tx FIFO: the number of Tx buffers assigned to the Tx FIFO is configured by the MCAN\_TXBC.TFQS field. If the MCAN\_TXBC.TFQS field is empty(zero)- only dedicated Tx buffers are used.

#### Tx prioritization:

- Scan Dedicated Tx buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN\_TXFQS.TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next
- The following figure shows Mixed Dedicated Tx buffers/Tx FIFO example.

**Figure 31-14. Mixed Dedicated Tx Buffers/ Tx FIFO (example)**

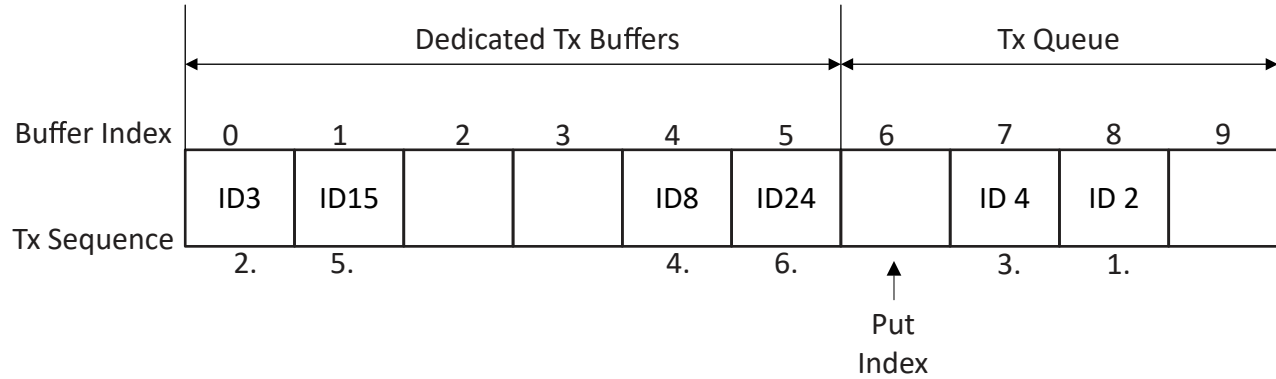

### 31.4.15.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx buffers section in the Message RAM is separated in two parts:

- Dedicated Tx buffers: the number of Dedicated Tx buffers is configured by the MCAN\_TXBC.NDTB field.
- Tx Queue: the number of Tx buffers assigned to the Tx Queue is configured by the MCAN\_TXBC.TFQS field. If MCAN\_TXBC.TFQS field is empty (zero) - only Dedicated Tx buffers are used.

#### Tx prioritization:

- Scan all Tx buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next
- The following figure shows Mixed Dedicated Tx buffers/Tx Queue example.

**Figure 31-15. Mixed Dedicated Tx Buffers/ Tx FIFO (Example)**

### 31.4.15.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN\_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of the MCAN\_TXBCF register (MCAN\_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN\_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN\_TXBTO[n] TOn and MCAN\_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN\_TXBCF[n] CFn = 1.

---

#### Note

If pending transmission is canceled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message that may have a lower priority than the second message in this node.

---

### 31.4.15.8 Tx Event Handling

To support Tx Event Handling, the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. Please see the Tx Event FIFO element chapter. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signaled by the MCAN\_IR.TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN\_TXEFS.EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN\_IR.TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN\_TXEFC.EFWM field, interrupt flag MCAN\_IR.TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN\_TXEFS.EFGI field has to be added to the Tx Event FIFO start address MCAN\_TXEFC.EFSA field.

### 31.4.15.9 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN\_RXF0A, MCAN\_RXF1A, and MCAN\_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. Special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

---

#### **Note**

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

---

### 31.4.16 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

#### 31.4.16.1 Acceptance Filtering

The MCAN module employs two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic bit mask filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register
- Extended ID AND Mask (MCAN\_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in [Section 31.4.19](#)) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN\_ICLK pulse.
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN\_IR.HPM
- Set High Priority Message interrupt flag MCAN\_IR.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32-bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer: New Data flag (MCAN\_NDAT1/MCAN\_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type, see MCAN\_PSR.LEC and MCAN\_PSR.DLEC fields, respectively).
- Rx FIFO: Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type, see MCAN\_PSR.LEC and MCAN\_PSR.DLEC fields, respectively). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in [Section 31.4.17.2](#) have to be considered.

---

#### Note

When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filters used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

---

### 31.4.16.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2  $\geq$  SFID1) respectively in the range from EFID1 to EFID2 (EFID2  $\geq$  EFID1). For more information see [Section 31.4.19.5](#) and [Section 31.4.19.6](#).

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN\_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN\_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN\_XIDAM) is not used for Range Filtering.

### 31.4.16.1.2 Filter for Specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT = 01/Extended Filter Type EFT = 01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information, see [Section 31.4.19.5](#) and [Section 31.4.19.6](#).

### 31.4.16.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT = 10/Extended Filter Type EFT = 10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while the SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) masks out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

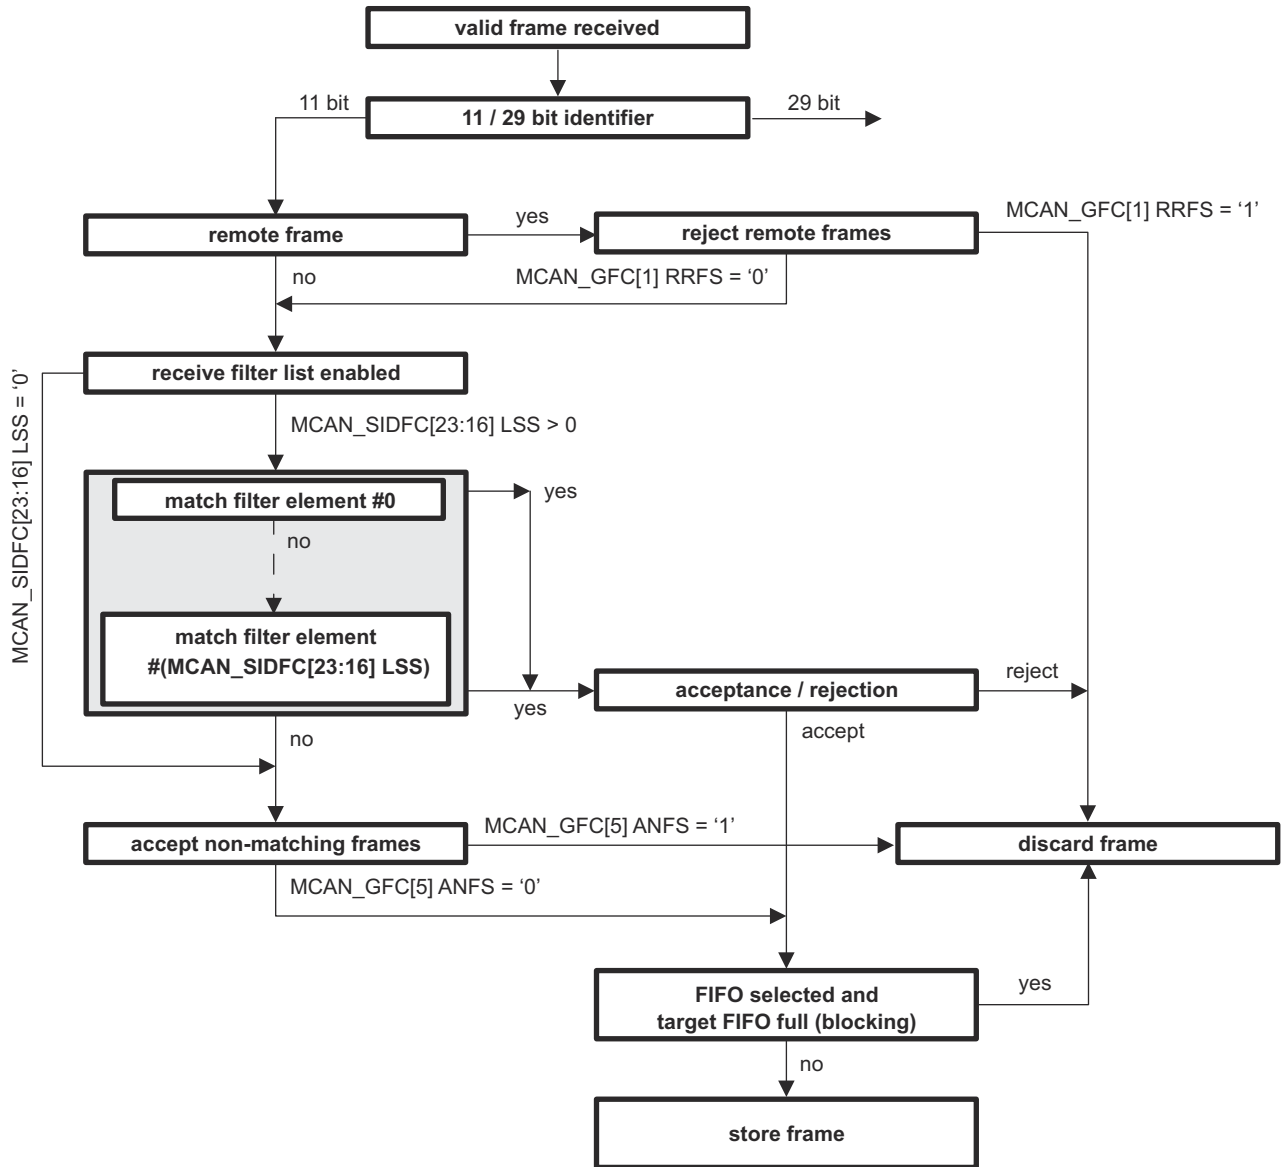

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

31.4.16.1.4 Standard Message ID Filtering

Figure 31-16 shows the standard Message ID (11-bit ID) filtering flow. Section 31.4.19.5 describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register

mcan-009

Figure 31-16. Standard Message ID Filter Path

Note

In MCAN\_GFC[1]RRFS and MCAN\_GFC[5]ANFS; the [1] and [5] denotes the bit position for the RRFs and ANFS bits respectively in the MCAN\_GFC register

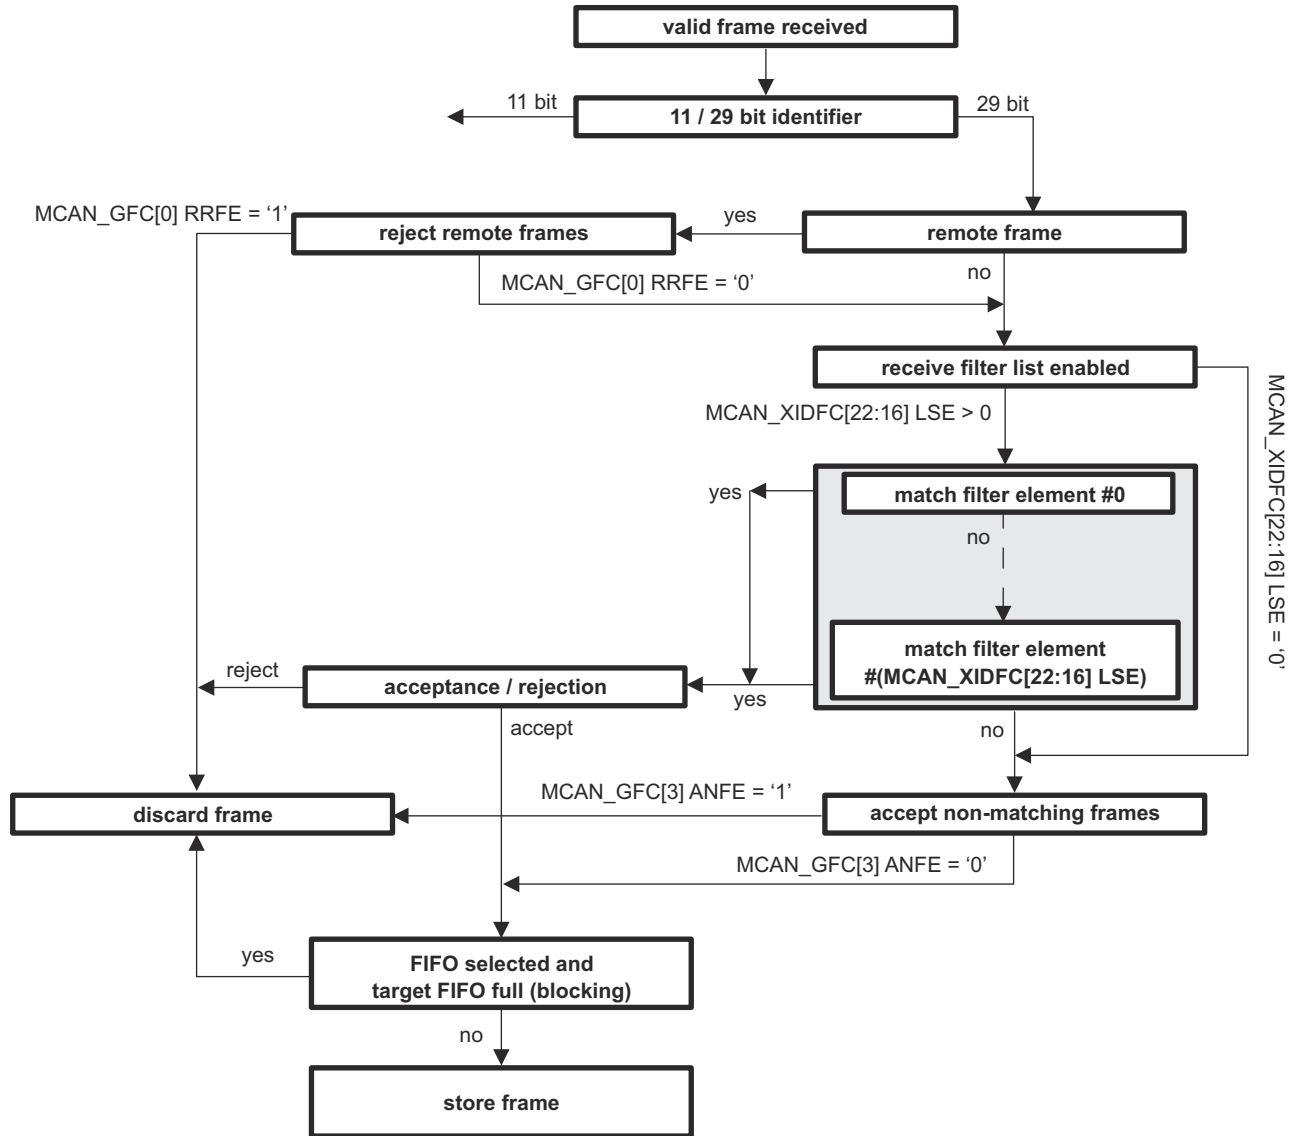

31.4.16.1.5 Extended Message ID Filtering

Figure 31-17 shows the extended Message ID (29-bit ID) filtering flow. Section 31.4.19.6 describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register

Note that before the filter list is executed, the received identifier is ANDed with the Extended ID AND Mask (MCAN\_XIDAM).

mcan-010

Figure 31-17. Extended Message ID Filter Path

In MCAN\_GFC[0]RRFS and MCAN\_GFC[3]ANFS; the [0] and [3] denotes the bit position for the RRFS and ANFS bits respectively in the MCAN\_GFC register

### 31.4.17 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done by way of the MCAN\_RXF0C and MCAN\_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 are described in [Section 31.4.16.1](#). The Rx FIFO element is described in [Section 31.4.19.2](#).

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN\_RXFnC[30:24] FnWM filed (where: n = 0 or 1), an interrupt flag MCAN\_IR.RF0W/MCAN\_IR.RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN\_RXFnS[21:16] FnPI = MCAN\_RXFnS[13:8] FnGI), an Rx FIFO Full condition is signaled by the MCAN\_RXFnS[24] FnF status bit and interrupt flag MCAN\_IR.RF0F/MCAN\_IR.RF1F is set. [Figure 31-18](#) shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN\_RXFnS[6:0] FnFL field (the number of elements stored in Rx FIFO).

**Figure 31-18. Rx FIFO Status**

Rx FIFOs start address in the Message RAM (MCAN\_RXFnC[15:2]FnSA field) has to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN\_RXFnS[13:8] FnGI). [Table 31-7](#) presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer / Rx FIFO Data Field Size which is configured by way of the MCAN\_RXESC register.

**Table 31-7. Rx Buffer/Rx FIFO Element Size**

MCAN_RXESC Register RBDS/F0DS/F1DS Bits	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5

### 31.4.17.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs and is configured by  $MCAN\_RXFnC[31] FnOM = 0$ .

If an Rx FIFO full condition is reached ( $MCAN\_RXFnS[21:16] FnPI = MCAN\_RXFnS[13:8] FnGI$ ), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signaled by the  $MCAN\_RXFnS[24] FnF = 1$  and interrupt flag  $MCAN\_IR.RF0F/MCAN\_IR.RF1F$  is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signaled by  $MCAN\_RXFnS[25] RFnL = 1$  and interrupt flag  $MCAN\_IR.RF0L/MCAN\_IR.RF1L$  is set.

### 31.4.17.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by  $MCAN\_RXFnC[31] FnOM = 1$ . When an Rx FIFO full condition is reached ( $MCAN\_RXFnS[21:16] FnPI = MCAN\_RXFnS[13:8] FnGI$ ) signaled by  $MCAN\_RXFnS[24] FnF = 1$ , the next accepted message for the FIFO overwrites the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signaled, reading of the Rx FIFO elements starts at least at get index + 1. The reason for this is a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case, inconsistent data can be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 31-19 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case, the two messages stored in element 1 and 2 are lost.

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index  $MCAN\_RXFnA[5:0] FnAI$ . This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset ( $MCAN\_RXFnS[24] FnF = 0$ ).

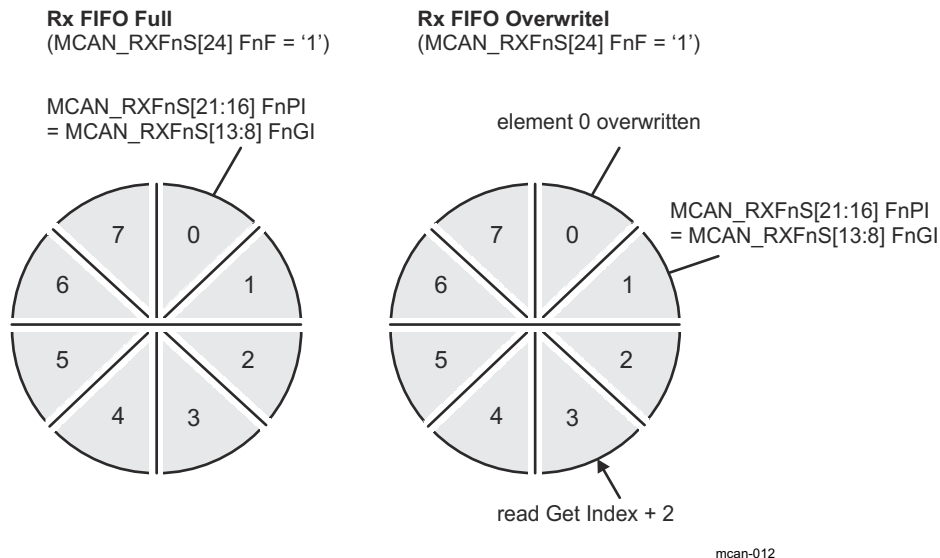

Figure 31-19. Rx FIFO Overflow Handling

### 31.4.18 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx buffers. The start address of the Rx buffers section in the Message RAM is configured by way of the MCAN\_RXBC.RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10:9] = 00 has to be configured (see [Section 31.4.19.5](#) and [Section 31.4.19.6](#)).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition, the flag MCAN\_IR.DRX (message stored in Dedicated Rx Buffer) is set.

[Table 31-8](#) shows Example Filter Configuration for Rx buffers.

**Table 31-8. Example Filter Configuration for Rx Buffers**

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN\_NDAT1/MCAN\_NDAT2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements can cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message can be rejected, depending on filter configuration.

#### 31.4.18.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN\_IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

### 31.4.19 Message RAM

The MCAN module has a Message RAM. The main purpose of the Message RAM is to store:

- Received Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

### 31.4.19.1 Message RAM Configuration

The MCAN module can have different Message RAM sizes. The maximum size of the message RAM is 1kB and is offset 0x3FF from the base address. An example of the MCAN module being configured for 1kB size with a width of 32 bits is described here.

The Message RAM can include each of the sections listed in [Message RAM Configuration](#). It is not necessary to configure each of the sections (a section in the Message RAM can be 0) and there is no restriction with respect to the sequence of the sections. For parity checking or ECC, a respective number of bits has to be added to each word. When the MCAN module addresses the Message RAM, it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0, by way of the MCAN\_RXESC.F0DS field
- Rx FIFO, 1 by way of the MCAN\_RXESC.F1DS field
- Rx buffers, by way of the MCAN\_RXESC.RBDS field
- Tx buffers, by way of the MCAN\_TXESC.TBDS field

**Figure 31-20. Message RAM Configuration**

The host CPU configures the following information in the message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

**Note**

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This prevents falsification or loss of data.

An example of the max elements that can be accommodated for each section based on a RAM size of 1kB for the Rx FIFO is provided in [Message Transmission configurations](#) table

**Table 31-9. Message Transmission configurations**

Frame Size, DLC Code (Bytes)	Element Size (Words)	Maximum Elements
8	4	64
12	5	51
16	6	43
20	7	37
24	8	32
32	10	26
48	14	18

**Table 31-9. Message Transmission configurations (continued)**

Frame Size, DLC Code (Bytes)	Element Size (Words)	Maximum Elements
64	18	14

### 31.4.19.2 Rx Buffer and FIFO Element

Up to 64 Rx buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN\_RXESC register.

Figure 31-21 shows the Rx Buffer/Rx FIFO element structure. Table 31-10 shows the Rx Buffer/Rx FIFO element field descriptions.

Figure 31-21. Rx Buffer/Rx FIFO Element Structure

	7:0	DB4[7:0]	Data Byte 4
	...	...	...
Rn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

**Note:** Depending on the configuration of the element size (MCAN\_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

### 31.4.19.3 Tx Buffer Element

The Tx buffers section can be configured to hold dedicated Tx buffers as well as a Tx FIFO/Tx Queue. In case that the Tx buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx buffers start at the beginning of the Tx buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx buffers and Tx FIFO/Tx Queue by way of the MCAN\_TXBC.TFQS and MCAN\_TXBC.NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN\_TXESC register.

Figure 31-22 shows the Tx Buffer element structure. Table 31-11 shows the Tx Buffer element field descriptions.

	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
Tn	7:0	DBm-3[7:0]	Data Byte m-3

**Note**

Depending on the configuration of the element size (MCAN\_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

### 31.4.19.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN\_TXEFS register.

Figure 31-23 shows the Tx Event FIFO element structure. Table 31-12 shows the Tx Event FIFO element field descriptions.

mcan-018

**Figure 31-23. Tx Event FIFO Element Structure**

		EFID2[5:0]	<p>This field defines the offset to the Rx Buffer Start Address MCAN_RXBC.RBSA field for storage of a matching message.</p>

### 31.5 MCAN Integration

Figure 31-26 shows the integration of the MCAN module in the device.

**Figure 31-26. MCAN Integration**

Table 31-15 summarizes the integration of the MCAN module in the device.

**Table 31-15. MCAN Clocks and Resets**

Destination Signal Name	Source Signal Name	Description
<b>Clocks</b>		
MCAN_ICLK	MCLK	Interface clock for the MCAN module
MCAN_FCLK	CANCLK	Bit timing clock for MCAN
<b>Resets</b>		
MCAN_RST	Peripheral Reset	Asynchronous reset signal to the MCAN module

### 31.6 Interrupt and Event Support

The MCAN module contains one [event publisher](#) (CPU\_INT) that manages MCAN interrupt requests (IRQs) to the CPU subsystem via a [static event route](#).

The MCAN events are summarized in [Table 31-16](#).

**Table 31-16. MCAN Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU interrupt</a>	Publisher	MCAN	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from MCAN to CPU

#### 31.6.1 CPU Interrupt Event Publisher (CPU\_INT)

The MCAN module provides different interrupt sources which can be configured to source a CPU interrupt event. In order of decreasing interrupt priority, the CPU interrupt events from the MCAN are shown in [Table 31-17](#).

**Table 31-17. MCAN Interrupt Event Conditions (CPU\_INT)**

Index (IIDX)	Name	Description
0x1	MCAN_IRQ_INT0	MCAN interrupt 0
0x2	MCAN_IRQ_INT1	MCAN interrupt 1
0x3	MCAN_IRQ_ECC	MCAN ECC SEC (single error correct) interrupt
0x4	MCAN_IRQ_ECC_UNCORR	MCAN ECC uncorrectable / DED (double error detect) interrupt
0x5	MCANSS_IRQ_TS_CNTR_OVFL	MCAN timestamp counter overflow interrupt
0x6	MCANSS_IRQ_TS_WAKE	MCAN clock stop wakeup interrupt

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. Interrupt (RIS) flags are cleared upon software reading the IIDX register or writing to the respective ICLR register bits.

See *Using Event Registers* for guidance on configuring the event registers for CPU interrupts.

## 31.7 MCAN Registers

Table 31-18 lists the memory-mapped registers for the MCAN registers. All register offset addresses not listed in Table 31-18 should be considered as reserved locations and the register contents should not be modified.

**Table 31-18. MCAN Registers**

Offset	Acronym	Register Name	Group	Section
6004h	CANRX	CAN RX IO		<a href="#">Go</a>
6008h	CANTX	CAN TX IO		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 31-19](#) shows the codes that are used for access types in this section.

**Table 31-19. MCAN Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
RC	R C	Read to Clear
RS	R S	Read to Set
Write Type		

**Table 31-19. MCAN Access Type Codes (continued)**

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
W1SQ	W 1S Q	Write 1 to set Qualified. A condition must be met for this operation to occur.
WD	W D	Write Decrement. Decrements the specified bit field by the amount written.
WI	W I	Write Increment. Increments the specified bit field by the amount written.
WK	W K	Write Write protected by a key
WQ	W Q	Write Qualified. A condition must be met for this operation to occur.
Reset or Default Value		
-n		Value after reset or the default value

## 11 MCAN\_DBTP (Offset = 700Ch) [Reset = 0000A33h]

MCAN\_DBTP is shown in [Figure 31-37](#) and described in [Table 31-30](#).

Return to the [Summary Table](#).

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32  $m\_can\_clk$  periods.  $tq = (DBRP + 1) mtq$ .

DTSEG1 is the sum of Prop\_Seg and Phase\_Seg1. DTSEG2 is Phase\_Seg2.

Therefore the length of the bit time is (programmed values) (DTSEG1 + DTSEG2 + 3) tq or (functional values) (Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2) tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

6	DAR	R/WQ	0h	Disable Automatic Retransmission 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'.
5	MON	R/W1SQ	0h	Bus Monitoring Mode. Bit MON can only be set by SW when both CCE and INIT are set to '1'. The bit can be reset by SW at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled Qualified Write 1 to Set is possible only with CCCR.CCE='1' and CCCR.INIT='1'.
4	CSR	R/W	0h	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
3	CSA	R	0h	Clock Stop Acknowledge 0 No clock stop acknowledged 1 MCAN may be set in power down by stopping the Host and CAN clocks
2	ASM	R/W1SQ	0h	Restricted Operation Mode. Bit ASM can only be set by SW when both CCE and INIT are set to '1'. The bit can be reset by SW at any time. 0 Normal CAN operation 1 Restricted Operation Mode active Qualified Write 1 to Set is possible only with CCCR.CCE='1' and CCCR.INIT='1'.
1	CCE	R/WQ	0h	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1') Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'.
0	INIT	R/W	1h	Initialization 0 Normal Operation 1 Initialization is started Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

### 15 MCAN\_NBTP (Offset = 701Ch) [Reset = 06000A03h]

MCAN\_NBTP is shown in [Figure 31-41](#) and described in [Table 31-34](#).

Return to the [Summary Table](#).

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512  $m\_can\_clk$  periods.  $tq = (NBRP + 1) mtq$ .

NTSEG1 is the sum of Prop\_Seg and Phase\_Seg1. NTSEG2 is Phase\_Seg2.

Therefore the length of the bit time is (programmed values) (NTSEG1 + NTSEG2 + 3)  $tq$  or (functional values) (Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2)  $tq$ .

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Note: With a CAN clock of 8MHz, the reset value of 0x06000A03 configures the MCAN for a bit rate of 500 kbit/s.

BO	EW	EP	ACT		LEC			
R-0h	R-0h	R-0h	R-0h		RS-7h			

**Table 31-61. MCAN\_PSR Field Descriptions**

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	
22-16	TDCV	R	0h	Transmitter Delay Compensation Value. Position of the secondary sample point, defined by the sum of the measured delay from the internal CAN TX signal to the internal CAN RX signal and TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.
15	RESERVED	R	0h	
14	PXE	RC	0h	Protocol Exception Event 0 No protocol exception event occurred since last read access 1 Protocol exception event occurred
13	RFDF	RC	0h	Received a CAN FD Message. This bit is set independent of acceptance filtering. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with FDF flag set has been received
12	RBRS	RC	0h	BRS Flag of Last Received CAN FD Message. This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its BRS flag set 1 Last received CAN FD message had its BRS flag set
11	RESI	RC	0h	ESI Flag of Last Received CAN FD Message. This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set 1 Last received CAN FD message had its ESI flag set
10-8	DLEC	RS	7h	Data Phase Last Error Code. Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.
7	BO	R	0h	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state

**Table 31-61. MCAN\_PSR Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	EW	R	0h	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
5	EP	R	0h	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state
4-3	ACT	R	0h	Node Activity. Monitors the module's CAN communication state. 00 Synchronizing - node is synchronizing on CAN communication 01 Idle - node is neither receiver nor transmitter 10 Receiver - node is operating as receiver 11 Transmitter - node is operating as transmitter Note: ACT is set to '00' by a Protocol Exception Event.
2-0	LEC	RS	7h	Last Error Code. The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0 No Error: No error occurred since LEC has been reset by successful reception or transmission. 1 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 2 Form Error: A fixed format part of a received frame has the wrong format. 3 AckError: The message transmitted by the MCAN was not acknowledged by another node. 4 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 5 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 6 CRCErrror: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 7 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register. Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error. Note: The Bus_Off recovery sequence (see ISO 11898-1:2015) cannot be shortened by setting or resetting CCCR.INIT. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR.REC is used to count these sequences.

## 22 MCAN\_TDCR (Offset = 7048h) [Reset = 0000000h]

MCAN\_TDCR is shown in [Figure 31-48](#) and described in [Table 31-41](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
31-15	RESERVED	R	0h	
14-8	TDCO	R/WQ	0h	Transmitter Delay Compensation Offset. Offset value defining the distance between the measured delay from the internal CAN TX signal to the internal CAN RX signal and the secondary sample point. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'.
7	RESERVED	R	0h	
6-0	TDCF	R/WQ	0h	Transmitter Delay Compensation Filter Window Length. Defines the minimum value for the SSP position, dominant edges on the internal CAN RX signal that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'.

### 23 MCAN\_IR (Offset = 7050h) [Reset = 8000000h]

MCAN\_IR is shown in [Figure 31-49](#) and described in [Table 31-42](#).

Return to the [Summary Table](#).

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

**Table 31-65. MCAN\_IR Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
21	BEU	R/W1C	0h	Bit Error Uncorrected. Message RAM bit error detected, uncorrected. This bit is set when a double bit error is detected by the ECC aggregator attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR.INIT to '1'. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (parity logic)
20	RESERVED	R	0h	
19	DRX	R/W1C	0h	Message Stored to Dedicated Rx Buffer. The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into an Rx Buffer
18	TOO	R/W1C	0h	Timeout Occurred 0 No timeout 1 Timeout reached
17	MRAF	R/W1C	0h	Message RAM Access Failure. The flag is set, when the Rx Handler: - has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. - was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the MCAN is switched into Restricted Operation Mode. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred
16	TSW	R/W1C	0h	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around

## 25 MCAN\_ILS (Offset = 7058h) [Reset = 0000000h]

MCAN\_ILS is shown in [Figure 31-51](#) and described in [Table 31-44](#).

Return to the [Summary Table](#).

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE.EINT0 and ILE.EINT1.

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	
5-0	F0AI	R/W	0h	Rx FIFO 0 Acknowledge Index. After the Host has read a message or a sequence of messages from Rx FIFO 0 it has to write the buffer index of the last element read from Rx FIFO 0 to F0AI. This will set the Rx FIFO 0 Get Index RXF0S.F0GI to F0AI + 1 and update the FIFO 0 Fill Level RXF0S.F0FL.

**37 MCAN\_RXBC (Offset = 70ACh) [Reset = 0000000h]**

MCAN\_RXBC is shown in [Figure 31-63](#) and described in [Table 31-56](#).

Return to the [Summary Table](#).

## 67 MCANERR\_VECTOR (Offset = 7408h) [Reset = 0000000h]

MCANERR\_VECTOR is shown in [Figure 31-93](#) and described in [Table 31-86](#).

Return to the [Summary Table](#).

Each error detection and correction (EDC) controller has a bank of error registers (offsets 0x10 - 0x3B) associated with it. These registers are accessed via an internal serial bus (SVBUS). To access them through the ECC aggregator the controller ID desired must be written to the ECC\_VECTOR field, together with the RD\_SVBUS trigger and RD\_SVBUS\_ADDRESS bit field. This initiates the serial read which consummates by setting the RD\_SVBUS\_DONE bit. At this point the addressed register may be read by a normal CPU read of the appropriate offset address.

31-25	RESERVED	R	0h	
24	RD_SVBUS_DONE	R	0h	Read Completion Flag
23-16	RD_SVBUS_ADDRESS	R/W	0h	Read Address Offset
15	RD_SVBUS	R-0/W1S	0h	Read Trigger
14-11	RESERVED	R	0h	
10-0	ECC_VECTOR	R/W	0h	ECC RAM ID. Each error detection and correction (EDC) controller has a bank of error registers (offsets 0x10 - 0x3B) associated with it. These registers are accessed via an internal serial bus (SVBUS). To access them through the ECC aggregator the controller ID desired must be written to the ECC_VECTOR field, together with the RD_SVBUS trigger and RD_SVBUS_ADDRESS bit field. This initiates the serial read which consummates by setting the RD_SVBUS_DONE bit. At this point the addressed register may be read by a normal CPU read of the appropriate offset address. 0x000 Message RAM ECC controller is selected Others Reserved (do not use) Subsequent writes through the SVBUS (offsets 0x10 - 0x3B) have a delayed completion. To avoid conflicts, perform a read back of a register within this range after writing.

**68 MCANERR\_STAT (Offset = 740Ch) [Reset = 0000002h]**

MCANERR\_STAT is shown in [Figure 31-94](#) and described in [Table 31-87](#).

Return to the [Summary Table](#).

**Table 31-159. MCANERR\_CTRL Field Descriptions**

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8	CHECK_SVBUS_TIMEOUT	R/W	1h	Enables Serial VBUS timeout mechanism
7	RESERVED	R	0h	
6	ERROR_ONCE	R/W	0h	If this bit is set, the FORCE_SEC/FORCE_DED will inject an error to the specified row only once. The FORCE_SEC bit will be cleared once a writeback happens. If writeback is not enabled, this error will be cleared the cycle following the read when the data is corrected. For double-bit errors, the FORCE_DED bit will be cleared the cycle following the double-bit error. Any subsequent reads will not force an error.
5	FORCE_N_ROW	R/W	0h	Enable single/double-bit error on the next RAM read, regardless of the MCANERR_ERR_CTRL1.ECC_ROW setting. For write through mode, this applies to writes as well as reads.
4	FORCE_DED	R/W	0h	Force double-bit error. Cleared the cycle following the error if ERROR_ONCE is asserted. For write through mode, this applies to writes as well as reads. MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2 should be configured prior to setting this bit.
3	FORCE_SEC	R/W	0h	Force single-bit error. Cleared on a writeback or the cycle following the error if ERROR_ONCE is asserted. For write through mode, this applies to writes as well as reads. MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2 should be configured prior to setting this bit.
2	ENABLE_RMW	R/W	1h	Enable read-modify-write on partial word writes
1	ECC_CHECK	R/W	1h	Enable ECC Check. ECC is completely bypassed if both ECC_ENABLE and ECC_CHECK are '0'.
0	ECC_ENABLE	R/W	1h	Enable ECC Generation

**71 MCANERR\_ERR\_CTRL1 (Offset = 7418h) [Reset = 0000000h]**

MCANERR\_ERR\_CTRL1 is shown in [Figure 31-97](#) and described in [Table 31-90](#).

Return to the [Summary Table](#).

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

**Table 31-165. MCANERR\_ERR\_STAT1 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	ECC_BIT1	R	0h	ECC Error Bit Position. Indicates the bit position in the RAM data that is in error on an SEC error. Only valid on an SEC error. 0 Bit 0 is in error 1 Bit 1 is in error 2 Bit 2 is in error 3 Bit 3 is in error ... 31 Bit 31 is in error >32 Invalid
15	CLR_CTRL_REG_ERROR	R/W1S	0h	Writing a '1' clears the CTRL_REG_ERROR bit
14-13	RESERVED	R	0h	
12	CLR_ECC_OTHER	R/W1C	0h	Writing a '1' clears the ECC_OTHER bit.
11-10	CLR_ECC_DED	R/WD	0h	Clear ECC_DED. A write of a non-zero value to this bit field decrements the ECC_DED bit field by the value provided.
9-8	CLR_ECC_SEC	R/WD	0h	Clear ECC_SEC. A write of a non-zero value to this bit field decrements the ECC_SEC bit field by the value provided.
7	CTRL_REG_ERROR	R/W1S	0h	Control Register Error. A bit field in the control register is in an ambiguous state. This means that the redundancy registers have detected a state where not all values are the same and has defaulted to the reset state. S/W needs to re-write these registers to a known state. A write of 1 will set this interrupt flag.
6-5	RESERVED	R	0h	
4	ECC_OTHER	R/W1S	0h	SEC While Writeback Error Status 0 No SEC error while writeback pending 1 Indicates that successive single-bit errors have occurred while a writeback is still pending

**Table 31-165. MCANERR\_ERR\_STAT1 Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3-2	ECC_DED	R/WI	0h	Double Bit Error Detected Status. A 2-bit saturating counter of the number of DED errors that have occurred since last cleared. 0 No double-bit error detected 1 One double-bit error was detected 2 Two double-bit errors were detected 3 Three double-bit errors were detected A write of a non-zero value to this bit field increments it by the value provided.
1-0	ECC_SEC	R/WI	0h	Single Bit Error Corrected Status. A 2-bit saturating counter of the number of SEC errors that have occurred since last cleared. 0 No single-bit error detected 1 One single-bit error was detected and corrected 2 Two single-bit errors were detected and corrected 3 Three single-bit errors were detected and corrected A write of a non-zero value to this bit field increments it by the value provided.

**74 MCANERR\_ERR\_STAT2 (Offset = 7424h) [Reset = 0000000h]**

MCANERR\_ERR\_STAT2 is shown in [Figure 31-100](#) and described in [Table 31-93](#).

Return to the [Summary Table](#).

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

### 88 IIDX (Offset = 7820h) [Reset = 0000000h]

IIDX is shown in [Figure 31-114](#) and described in [Table 31-107](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS](#) and [MIS](#) are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 31-114. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 32.1 USB Overview

The USB controller operates as a full-speed function controller during point-to-point communications with the USB host. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. The USB controller has sixteen endpoints, one-half of them being for IN transactions and one-half of them being for OUT transactions. One IN and one OUT endpoint are fixed-function endpoints used for control transfers; the others are defined by firmware. A dynamically sizeable FIFO supports queuing multiple packets. Software-controlled connect and disconnect allow flexibility during USB device startup.

### 32.1.1 Features

The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) operation in host and device modes as well as low-speed (1.5 Mbps) operation in host mode
- Integrated PHY
- Four transfer types: Control, Interrupt, Bulk, and Isochronous
- Sixteen endpoints
  - One dedicated control IN endpoint and one dedicated control OUT endpoint
  - Seven configurable IN endpoints and seven configurable OUT endpoints
- Two kB dedicated endpoint memory
- Dedicated hardware triggers for DMA support
- Support for USB-based device firmware update (DFU) through bootstrap loader (BSL)

### 32.1.2 USB Related Collateral

### 32.1.3 Block Diagram

The USB block diagram is shown in [Figure 32-1](#).

Figure 32-1. USB Block Diagram

### 32.1.3.1 Signal Description

The USB controller requires a total of three signals (D+, D-, and  $V_{BUS}$ ) to operate in device mode and two signals (D+, D-) to operate in embedded host mode. Because of the differential signaling needed for USB, the pins D+ and D- have special buffers to support USB. As such, their position on the chip is not user-selectable. These pins at reset are, by default, GPIOs. They must be configured before being used as USB function pins. The PHYMODE bit in the USBMODE register should be set to choose the USB function.

### 32.1.4 VBus Recommendations

Most applications do not need to monitor  $V_{BUS}$ . Because of this, a dedicated  $V_{BUS}$  monitoring pin was not included on this microcontroller. If you are designing a bus-powered device application or an embedded host application, you do not need to monitor  $V_{BUS}$ . If you are designing a self-powered device, you need to actively monitor the state of the  $V_{BUS}$  pin to make sure compliance with the USB specification. In Section 7.1.5 and Section 7.2.1 of the USB Specification Revision 2.0™:

- "The voltage source on the [speed identification] pull-up resistor must be derived from or controlled by the power supplied on the USB cable such that when  $V_{BUS}$  is removed, the pull-up resistor does not supply current on the data line to which it is attached.
- When  $V_{BUS}$  is removed, the device must remove power from the D+/D- pull-up resistor within 10 seconds.
- Later in the timing tables (Section 7.3.2) of the USB Specification 2.0 it is also stated that the D+/D- pull-up resistor should be applied within 100ms of  $V_{BUS}$  reaching a valid level."

Meeting the above specification is easy because of the slow timing requirements. The hardware part of the  $V_{BUS}$  monitoring is discussed in this chapter. The corresponding software is discussed briefly, but for examples and an explanation, consult the USB software guide

#### 32.1.4.1 VBUS Status via COMP

The pins of this microcontroller are not 5-V tolerant, and because of this, the  $V_{BUS}$  signal cannot be directly connected to a GPIO pin. Directly connecting 5 V to a pin of the microcontroller destroys the I/O buffer of the pin and possibly more of the chip.

To detect the a sufficient voltage level of 4.01V on the  $V_{BUS}$  signal after a USB cable connect, a resistive divider in combination with the COMP module needs to be used. A schematic of this connection is shown in [USB VBUS Detection](#). The  $V_{BUS}$  signal feeds into a 3:1 resistive divider. The divided output reflects 1/4 of the  $V_{BUS}$  signal voltage and will always stay in the maximum operating range of the powered microcontroller. The divided output is then connected to the positive input of the COMP. The negative input of the COMP is connected to the internal DAC of the COMP. By adjusting the DAC voltage on the negative input to the COMP, the trip voltage can be adjusted. The COMP allows an interrupt event notification to the software, when a USB cable is connected or disconnected to the device. Please refer to the COMP chapter of the TRM for details on how to configer the COMP module and the reference DAC.

---

#### Note

This method to detect the USB cable connect or disconnect can also be done in STOP and STANDBY mode, since the COMP is operational in these low power modes.

---

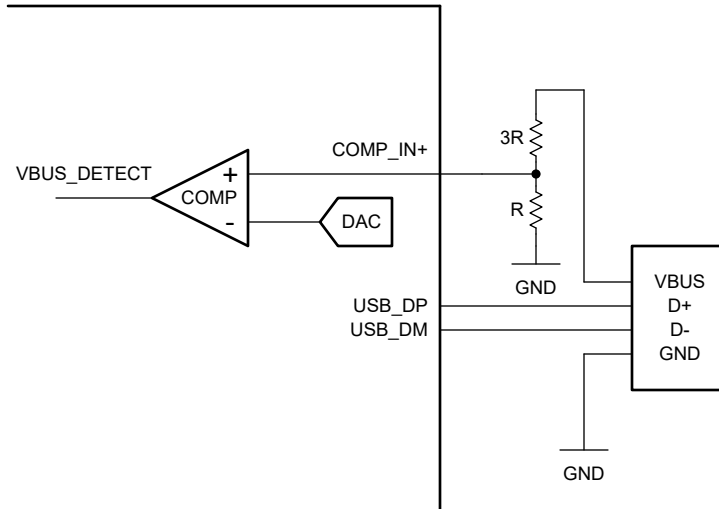

Figure 32-2. USB VBUS Detection

### 32.1.4.2 VUSB33 Status via ADC

Alternatively the connect or disconnect of a USB cable can be achieved, by monitoring the supply voltage on the VUSB33 supply pin. This requires, that the VUSB33 supply pin is connected to the output of a 3.3V LDO, which is directly powered by the V<sub>Bus</sub> signal off the USB connector. The voltage on the microcontroller VUSB33 supply pin can be monitored by the internal ADC. The assumption is, that the 3.3V LDO will only operate when the USB cable provides a sufficient supply voltage on the V<sub>Bus</sub> signal (USB cable connected). Otherwise if the VUSB33 is below 3.0V, this will indicate that the USB cable is not connected. Please refer to the ADC chapter in the TRM for detail regarding the configuration of the ADC, and the device specific datasheet for the ADC input channel mapping.

A schematic of this method to detect the cable connect or disconnect status is shown in [USB VUSB33 Detection](#).

This method of the USB cable connect or disconnect does not require any additional pin, but the ADC operation does limit the use of the STOP and STANDBY low power modes.

Figure 32-3. USB VUSB33 Detection

### 32.1.4.3 VUSB33 Status via PMU-Monitor

The VUSB33 supply pin is also monitored by the power management unit (PMU) to control the PHY function in case the VUSB33 supply is unpowered (less than 1.35V). The status of this supply monitor is available as a register bit VUSB in the USB.DEVCTL register. The PMU monitor of the VUSB33 is completely internal to the microcontroller and always available. It does not require the ADC or any other configuration to operate, but it only tells whether VUSB33 is below or above 1.35V.

With the VUSB33 pin connected to the output of a 3.3V LDO, which is directly powered by the  $V_{BUS}$  signal off the USB connector like shown in [USB VUSB33 Detect](#), the USB cable connection status can be implied by the VUSB status of the USB.DEVCTL register.

The power loss event on the VUSB33 pin (disconnect of the USB cable) is a noteworthy system event and therefore indicated as a VUSBPWRDN event (interrupt) in the USB.RIS/USB.MIS event register. Software can utilize this event to disable the pull-up on the USB\_DP/USB\_DM pin, without the need to constantly sample the VUSB33 pin via the ADC.

## 32.2 Functional Description

The USB controller can be configured to act as either a dedicated host or device. However, when the USB controller is acting as a self-powered device, a GPIO input or analog comparator input must be connected to  $V_{BUS}$  and configured to generate an interrupt when the  $V_{BUS}$  level drops. This interrupt is used to disable the pullup resistor on the USB\_DP or USB\_DM signal.

---

### Note

When USB is used in the system, the minimum system frequency is 30MHz.

---

### 32.2.1 Operation as a Device

This section describes how the USB controller performs when it is being used as a USB device. IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of start of frame (SOF) are all described.

When in device mode, IN transactions are controlled by the endpoint transmit interface and uses the transmit endpoint registers for the given endpoint. OUT transactions are handled with the endpoints receive interface and use the receive endpoint registers for the given endpoint. When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint. Note the following:

- Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint for a USB device. However, in most cases the USB device should use the dedicated control endpoint on the USB controller's endpoint 0.

### 32.2.1.1 Control and Configurable Endpoints

When operating as a device, the USB controller provides two dedicated control endpoints (IN and OUT). The remaining available configurable endpoints (one-half IN and one-half OUT) can be used for communications with a host controller. The endpoint number and direction associated with an endpoint is directly related to its register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface. Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions. The remaining six endpoints can be configured as control, bulk, or interrupt endpoints. They should be treated as three configurable IN and three configurable OUT endpoints. The endpoint pairs are not required to have the same type for their IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair could be a bulk endpoint, while the IN portion of that endpoint pair could be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

#### 32.2.1.1.1 IN Transactions as a Device

When operating as a USB device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the configurable IN endpoints are determined by the USB Transmit FIFO Start Address (USB.TXFIFOADD) register. The maximum size of a data packet that may be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the USB Maximum Transmit Data Endpoint n (USB.TXMAXPn) register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

**Note:** The maximum packet size set for any endpoint must not exceed the FIFO size. The USBTXMAXPn register should not be written to while data is in the FIFO as unexpected results may occur.

#### Single-Packet Buffering

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the USB Transmit Dynamic FIFO Sizing (USB.TXFIFOSZ) register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the USB Transmit Control and Status Endpoint n Low (USB.TXCSRLn) register must be set. If the AUTOSET bit in the USB Transmit Control and Status Endpoint n High (USB.TXCSRHn) register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

#### Double-Packet Buffering

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the USB.TXCSRLn register must be set. If the AUTOSET bit in the USBTXCSRHn register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the USB.TXCSRLn register at this point indicates how many packets may be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Transmit Double Packet Buffer Disable (USB.TXDPKTBUFDIS) register. This bit is set by default, so it must be cleared to enable double-packet buffering.

#### 32.2.1.1.2 Out Transactions as a Device

When in device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the configurable OUT endpoints are determined by the USB Receive FIFO Start Address (USB.RXFIFOADD) register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the USB Maximum Receive Data Endpoint n (USB.RXMAXPn) register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

**Note:** In all cases, the maximum packet size must not exceed the FIFO size.

#### Single-Packet Buffering

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the USB Receive Control and Status Endpoint n Low (USB.RXCSRL[n]) register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the RXRDY bit must be cleared in order to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the USB Receive Control and Status Endpoint n High (USB.RXCSRH[n]) register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

#### Double-Packet Buffering

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the USB.RXCSRL[n] register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

**Note:** The FULL bit in USB.RXCSRL[n] is not set when the first packet is received. It is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the USB.RXCSRH[n] register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Receive Double Packet Buffer Disable (USB.RXDPKTBUFDIS) register. This bit is set by default, so it must be cleared to enable double-packet buffering.

### 32.2.1.1.3 Scheduling

The device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

### 32.2.1.1.4 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

#### Stalled Control Transfer

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the USB Control and Status Endpoint 0 Low (USB.CSRL0) register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what should have been the last packet.
3. The Host sends more than USB.RXMAXPn bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

#### Zero Length OUT Data Packets

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets should only be received after the entire length of the device request has been transferred. However, if the Host sends a zero-length OUT data packet before the entire length of device request has been transferred, it is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the USB.CSRL0 register.

#### Setting the Device Address

When a Host is attempting to enumerate the USB device, it requests that the device change its address from zero to some other value. The address is changed by writing the value that the Host requested to the USB Device Functional Address (USB.FADDR) register. However, care should be taken when writing to USB.FADDR to avoid changing the address before the transaction is complete. This register should only be set after the SET\_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the device has left the STATUS phase. In the case of a SET\_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the device has responded to the IN request, the USB.FADDR register should be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

**Note:** If the USB.FADDR register is set to the new value as soon as the device receives the OUT transaction with the SET\_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the device.

### 32.2.1.1.5 Device Mode Suspend

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the USB Interrupt Enable (USBIE) register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the USB Power (USBPOWER) register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling. To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state.

### 32.2.1.1.6 Start of Frame

When the USB controller is operating in device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the USB Frame Value (USB.FRAME) register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the USB.FRAME register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

### 32.2.1.1.7 USB Reset

When the USB controller is in device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the USBFADDR register
- Clears the USB Endpoint Index (USB.EPINDEX) register
- Flushes all endpoint FIFOs
- Clears all control/status registers
- Enables all endpoint interrupts
- Generates a RESET interrupt

### 32.2.1.1.8 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the SOFT\_CONN bit of the USB.POWER register. When the SOFT\_CONN bit is set, the PHY is placed in its normal mode, and the USB\_DP/USB\_DM lines of the USB bus are enabled. At the same time, the USB controller is placed into a state, in which it does not respond to any USB signaling except a USB RESET. When the SOFTCONN bit is cleared, the PHY is put into non-driving mode, USB\_DP and USB\_DM are tristated, and the USB controller appears to other devices on the USB bus as if it has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the SOFT\_CONN bit has been set. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the SOFT\_CONN bit has been set, the USB controller can be disconnected by clearing this bit.

---

#### Note

The USB controller does not generate an interrupt when the device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

---

## 32.2.2 Operation as a Host

When the USB controller is operating in Host mode, it can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed

or full-speed device to be used with a USB 2.0 hub. Control, bulk, and interrupt transactions are supported. This section describes the USB controller's actions when it is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in device mode, the FIFOs for endpoints should take into account the maximum packet size for an endpoint.

- Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint to communicate with a device. However, in most cases the USB controller should use the dedicated control endpoint to communicate with a device's endpoint 0.

### 32.2.2.1 Endpoint Registers

The endpoint registers are used to control the USB endpoint interfaces which communicate with devices that are connected. The endpoints consist of a dedicated control IN endpoint and a dedicated control OUT endpoint. The remaining available endpoints are configurable, with one-half of them being OUT endpoints, and one-half of them being IN endpoints. See [Section 32.1.1](#) for the number of available endpoints on this device.

The dedicated control interface can only be used for control transactions to endpoint 0 of devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, or interrupt endpoints.

These USB interfaces can be used to simultaneously schedule as many as seven independent OUT and seven independent IN transactions to any endpoints on any device. The IN and OUT controls are paired together in the same set of registers for the respective endpoints. However, the IN and OUT controls can be configured to communicate with different types of endpoints and different endpoints on devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a device's bulk OUT endpoint 1, while the IN portion is communicating with a device's interrupt IN endpoint 2.

Before accessing any device, whether for point-to-point communications or for communications via a hub, the relevant USB Receive Functional Address Endpoint *n* (USB.RXFUNCADDR<sub>*n*</sub>) or USB Transmit Functional Address Endpoint *n* (USB.TXFUNCADDR<sub>*n*</sub>) registers must be set for each receive or transmit endpoint to record the address of the device being accessed.

The USB controller also supports connections to devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

### 32.2.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in device mode except that the transaction first must be initiated by setting the REQPKT bit in the USB.CSRL0 register, indicating to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the USB.CSRL0 register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the USB.RXCSRH<sub>*n*</sub> register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in USB.RXCSRH<sub>*n*</sub> causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. When the RXRDY bit is cleared, the controller sends an acknowledge to the device. When there

is a known number of packets to be transferred, the USB Request Packet Count in Block Transfer Endpoint  $n$  (USB.RQPKTCOUNT $n$ ) register associated with the endpoint should be configured to the number of packets to be transferred. The USB controller decrements the value in the USB.RQPKTCOUNT $n$  register following each request. When the USB.RQPKTCOUNT $n$  value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, USB.RQPKTCOUNT $n$  should be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the USB.RXMAXP $n$  register) such as may occur at the end of a bulk transfer.

If the device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the USB.CSRL0 register. If the target device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the USB.CSRL0 register.

### 32.2.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in device mode. The TXRDY bit in the USB.TXCSSL $n$  register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the USB.TXCSRH $n$  register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO.

If the target device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the USB.TXCSSL $n$  register. If the target device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the USB.TXCSSL $n$  register.

### 32.2.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every 255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a device is not responding.

The USB controller maintains a frame counter. If the target device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target device is a low-speed device, a K state is transmitted on the bus to act as a keep-alive to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt transaction occurs per endpoint every  $n$  frames, where  $n$  is the interval set via the USB Host Transmit Interval Endpoint  $n$  (USB.TXINTERVAL[ $n$ ]) or USB Host Receive Interval Endpoint  $n$  (USB.RXINTERVAL[ $n$ ]) register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process ensures that an endpoint

that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target device before the endpoint times out.

#### **32.2.2.5 USB Hubs**

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed device is connected to the USB controller via a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding USB Receive Hub Address Endpoint  $n$  (USB.RXHUBADDR $n$ ) and USB Receive Hub Port Endpoint  $n$  (USB.RXHUBPORT $n$ ) or the USB Transmit Hub Address Endpoint  $n$  (USB.TXHUBADDR $n$ ) and USB Transmit Hub Port Endpoint  $n$  (USB.TXHUBPORT $n$ ) registers. In addition, the speed at which the device operates (full or low) must be recorded in the USB Type Endpoint 0 (USBTYPE0) (endpoint 0), USB Host Configure Transmit Type Endpoint  $n$  (USB.TXTYPE $n$ ), or USB Host Configure Receive Type Endpoint  $n$  (USB.RXTYPE $n$ ) registers for each endpoint that is accessed by the device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB devices. To maximize the number of devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to device functions must be made following the completion of any on-going transactions on the endpoints affected.

#### **32.2.2.6 Babble**

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

#### **32.2.2.7 Host SUSPEND**

If the SUSPEND bit in the USBPOWER register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20 ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

#### **32.2.2.8 USB RESET**

If the RESET bit in the USB.POWER register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20 ms to ensure correct resetting of the target device. After the CPU has cleared the bit, the USB Host controller starts its frame counter and transaction scheduler.

#### **32.2.2.9 Connect/Disconnect**

A session is started by setting the SESSION bit in the USB device Control (USB.DEVCTL) register, enabling the USB controller to wait for a device to be connected. When a device is detected, a connect interrupt is generated. The speed of the device that has been connected can be determined by reading the USB.DEVCTL register where the FSDEV bit is set for a full-speed device, and the LSDEV bit is set for a low-speed device. The USB controller must generate a RESET to the device, and then the USB Host controller can begin device enumeration. If the device is disconnected while a session is in progress, a disconnect interrupt is generated.

### 32.2.3 DMA Operation

The USB module supports four RX and four TX triggers (TRIG[A-D]RX and TRIG[A-D]TX) to the DMA. Each trigger can be assigned to a specific Endpoint (EPx)

The DMA controller may be used to read and write the USB FIFOs via software or hardware triggering. See the Direct Memory Access (DMA) chapter for more details about programming the DMA controller.

## 32.3 Initialization and Configuration

To use the USB Controller, the clock for the USB controller must first be configured. USBCLK is a 60-MHz clock to the USB module. This fixed frequency is required for all USB operations.

The USBCLK can either be sourced by the USBFLL or the SYSPLL. When the SYSPLL is used, a crystal needs to be used as clock reference for the SYSPLL. The USBCLK can be asynchronous to the system clock. For USB operation the system clock needs to be at least 30MHz.

If the USB Controller is operated in device mode, the clock can come from the USBFLL or the SYSPLL.

If the USB Controller is operated in host mode, the clock needs to come from the SYSPLL with an external crystal as clock reference.

### 32.3.1 Pin Configuration

Before the USB controller can be used, the USB PHY needs to be switched into USB mode by setting the PHYMODE bit in the USB.USBMODE register.

If the USB controller operates in host mode, the HOST bit in the USB.USBMODE register needs to be set.

If the USB controller operates in device mode, the DEVICEONLY bit in the USB.USBMODE register needs to be set.

### 32.3.2 Endpoint Configuration

To start communication in Host or device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a device. In device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because it is a fixed-function, fixed-FIFO-size endpoint. In device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, or interrupt mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. The maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 2 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a device, the USB device controller's soft connect must be enabled when the device is ready to start communications, indicating to the host controller that the device is ready to start the enumeration process. If operating as a Host controller, the device soft connect must be disabled and power must be provided to V<sub>BUS</sub>.

## 32.4 Interrupt and Event Support

The USB controller contains one event publisher (CPU\_INT) which manages USB interrupt requests (IRQs) to the CPU subsystem through a static event rout.

The CPU\_INT event register is a overarching event status, which combines the different event sources in the USB module. The INTRTX, INTRRX and INTRUSB interrupt status in the USB.RIS are set, when a corresponding interrupt in the USB.TXIS, USB.RXIS and USB.USBIS are set.

The VUSBPWRDN is set when the external supply voltage on the VUSB33 pin drops below 1.35V.

The DMADONExRX/DMADONExTX are set when the corresponding DMA channel has completed the transfer.

## 32.5 USB Registers

Table 32-1 lists the memory-mapped registers for the USB registers. All register offset addresses not listed in Table 32-1 should be considered as reserved locations and the register contents should not be modified.

**Table 32-1. USB Registers**

Offset	Acronym	Register Name	Group	Section
800h	PWREN	Power enable		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 32-2](#) shows the codes that are used for access types in this section.

**Table 32-2. USB Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
WK	W K	Write Write protected by a key
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

## 5 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 32-8](#) and described in [Table 32-7](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. 0x0 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 32-8. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 9 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 32-12](#) and described in [Table 32-11](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

### 38 FIFO[y] (Offset = 2020h + formula) [Reset = 00000000h]

FIFO[y] is shown in [Figure 32-41](#) and described in [Table 32-40](#).

Return to the [Summary Table](#).

FIFO for Endpoint [y].

This address range provides 16 addresses for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the TxFIFO for the corresponding endpoint. Reading from these addresses unloads data from the RxFIFO for the corresponding endpoint.

Note: Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of access is allowed provided the data accessed is contiguous. However, all the transfers associated with one packet must be of the same width so that the data is consistently byte-, word- or double-word-aligned. The last transfer may however contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer. Note: Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering. However, burst writing of multiple packets is not supported as flags need to be set after each packet is written.

Note: Following a STALL response or a TX Strike Out error on Endpoint 1 – 15, the associated FIFO is completely flushed.

Offset = 2020h + (y \* 4h); where y = 0h to Fh

**Figure 32-41. FIFO[y]**

**Table 32-78. FIFO[y] Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	EPDATA	R/W	0h	Endpoint Data. Writing to this register loads the data into the Transmit FIFO and reading unloads data from the Receive FIFO.

### 39 DEVCTL (Offset = 2060h) [Reset = 80h]

DEVCTL is shown in [Figure 32-42](#) and described in [Table 32-41](#).

Return to the [Summary Table](#).

USB Device Control.

DEVCTL is an 8-bit register that is used to select whether the USB controller is operating in Peripheral mode or in Host mode.

Note: If the PHY is suspended no PHY clock is received.

**Figure 32-42. DEVCTL**

7	6	5	4	3	2	1	0
DEV	FSDEV	LSDEV	VUSB		HOST	HOSTREQ	SESSION
R-1h	R-0h	R-0h	R-0h		R-0h	R/W-0h	R/W-0h

**Table 32-80. DEVCTL Field Descriptions**

Bit	Field	Type	Reset	Description
7	DEV	R	1h	Device Mode. This Read-only bit indicates whether the USB controller is operating as the host mode or device mode. Note: Only valid while a session is in progress. 0h (R/W) = The USB controller is operating in host mode. 1h (R/W) = The USB controller is operating in device mode.
6	FSDEV	R	0h	Full Speed Device Detected. This Read-only bit is set when a full-speed device has been detected being connected to the port. Note: Only valid in Host mode. 0h (R/W) = A full-speed Device has not been detected on the port. 1h (R/W) = A full-speed Device has been detected on the port.
5	LSDEV	R	0h	Low Speed Device Detected. This Read-only bit is set when a low-speed device has been detected being connected to the port. Note: Only valid in Host mode. 0h (R/W) = A low-speed Device has not been detected on the port. 1h (R/W) = A low-speed Device has been detected on the port.
4-3	VUSB	R	0h	VUSB / USB-PHY is powered. 0h (R/W) = VUSB / USB-PHY supply is detected as under 1.35V. 3h (R/W) = VUSB / USB-PHY supply is detected as above 1.35V.
2	HOST	R	0h	Host Mode. This Read-only bit is set when the USB controller is acting as a Host. Note: Only valid while a session is in progress. 0h (R/W) = The USB controller is acting as a Device. 1h (R/W) = The USB controller is acting as a Host.
1	HOSTREQ	R/W	0h	When set, the USB controller will initiate the Host Negotiation when Suspend mode is entered. It is cleared when Host Negotiation is completed. 0h (R/W) = No effect 1h (R/W) = Initiates the Host Negotiation when SUSPENDmode is entered.

**Table 32-80. DEVCTL Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	SESSION	R/W	0h	<p>Session Start/End.</p> <p>Host mode: This bit is set or cleared by the CPU to start or end a session.</p> <p>Device mode: This bit is set/cleared by the USB controller when a session starts/ends. It is also set by the CPU to initiate the Session Request Protocol. When the USB controller is in Suspend mode, the bit may be cleared by the CPU to perform a software disconnect.</p> <p>Note: Clearing this bit when the core is not suspended will result in undefined behavior.</p> <p>0h (R/W) = When operating as a Host: When cleared by software, this bit ends a session.</p> <p>When operating as a Device: The USB controller has ended a session. When the USB controller is in SUSPEND mode, this bit may be cleared by software to perform a software disconnect.</p> <p>1h (R/W) = When operating as a Host: When set by software, this bit starts a session.</p> <p>When operating as a Device: The USB controller has started a session. When set by software, the Session Request Protocol is initiated.</p> <p>Clearing this bit when the USB controller is not suspended results in undefined behavior.</p>

**40 MISC (Offset = 2061h) [Reset = 00h]**

MISC is shown in [Figure 32-43](#) and described in [Table 32-42](#).

Return to the [Summary Table](#).

USB Miscellaneous registers

The MISC Register is an 8-bit register that contain various common configuration bits. These bits include the Rx/TX Early DMA enable bits.

**Figure 32-43. MISC**

7	6	5	4	3	2	1	0
RESERVED						TX_EDMA	RX_EDMA

Bit	Field	Type	Reset	Description
7-2	RESERVED	R	0h	
1	TX_EDMA	R/W	0h	Transmit early DMA mode. 0h (R/W) = Late mode: DMA_REQ signal for all IN Endpoints will be de-asserted when MAXP bytes have been written to an endpoint. This is late mode. 1h (R/W) = Early mode: DMA_REQ signal for all IN Endpoints will be de-asserted when MAXP-8 bytes have been written to an endpoint. This is early mode.
0	RX_EDMA	R/W	0h	Receive early DMA mode. 0h (R/W) = Late mode: DMA_REQ signal for all OUT Endpoints will be de-asserted when MAXP bytes have been read to an endpoint. 1h (R/W) = Early Mode: DMA_REQ signal for all OUT Endpoints will be de-asserted when MAXP-8 bytes have been read to an endpoint.

#### 41 IDTXFIFOSZ (Offset = 2062h) [Reset = 00h]

IDTXFIFOSZ is shown in [Figure 32-44](#) and described in [Table 32-43](#).

Return to the [Summary Table](#).

Indexed Transmit Dynamic FIFO Sizing.

IDTXFIFOSZ is a 5-bit register which controls the size of the selected TX endpoint FIFO. There is one set of register per End Point Excluding End Point 0.

Note: These are indexed registers therefore to access them the EPINDEX register must be set to the appropriate end point.

**Figure 32-44. IDTXFIFOSZ**

#### 44 IDRXFIFOADD (Offset = 2066h) [Reset = 0000h]

IDRXFIFOADD is shown in [Figure 32-47](#) and described in [Table 32-46](#).

Return to the [Summary Table](#).

Indexed Receive FIFO Start Address.

IDRXFIFOADD is a 14-bit register which controls the start address of the selected Rx endpoint FIFO. There is one set of register per End Point Excluding End Point 0.

Note: These are indexed registers therefore to access them the EPINDEX register must be set to the appropriate end point.

Bit	Field	Type	Reset	Description
7-0	FSEOFG	R/W	77h	The full-speed end-of-frame gap field is used during full-speed transactions to configure the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. Note: The default corresponds to 63.46 us.

### 49 LSEOF (Offset = 207Eh) [Reset = 72h]

LSEOF is shown in [Figure 32-52](#) and described in [Table 32-51](#).

Return to the [Summary Table](#).

USB-Low-Speed Last Transaction to End of Frame Timing.

This 8-bit register sets the minimum time gap that is to be allowed between the start of the last transaction and the EOF for Low-speed transactions.

**Figure 32-52. LSEOF**

7	6	5	4	3	2	1	0
LSEOFG							
R-72h							

**Table 32-100. LSEOF Field Descriptions**

Bit	Field	Type	Reset	Description
7-0	LSEOFG	R	72h	The low-speed end-of-frame gap field is used during low-speed transactions to set the gap between the last transaction and the End-of-Frame (EOF), in units of 1.067 us. Note: The default corresponds to 121.6 us.

### 50 TXFUNCADDR[j] (Offset = 2080h + formula) [Reset = 00h]

TXFUNCADDR[j] is shown in [Figure 32-53](#) and described in [Table 32-52](#).

Return to the [Summary Table](#).

Transmit Functional Address Endpoint [j]

TXFUNCADDR is a 7-bit read/write registers that record the address of the target function that is to be accessed through the associated endpoint (EPn). TXFUNCADDR needs to be defined for each TX endpoint that is used.

Note: TXFUNCADDR must be defined for Endpoint 0.

Note: Relevant in host mode only

Offset = 2080h + (j \* 8h); where j = 0h to Fh

**Figure 32-53. TXFUNCADDR[j]**

7	6	5	4	3	2	1	0
RESERVED							ADDR
R-0h							R/W-0h

**Table 32-102. TXFUNCADDR[j] Field Descriptions**

Bit	Field	Type	Reset	Description
7	RESERVED	R	0h	
6-0	ADDR	R/W	0h	Device Address specifies the USB bus address for the target Device.

### 51 TXHUBADDR[j] (Offset = 2082h + formula) [Reset = 00h]

TXHUBADDR[j] is shown in [Figure 32-54](#) and described in [Table 32-53](#).

Return to the [Summary Table](#).

#### USB Transmit Hub Address Endpoint [j]

TXHUBADDR is an 8-bit read/write registers which, like TXHUBPORT, only need to be written where a full- or low-speed device is connected to TX/RX Endpoint EPn via a high-speed USB 2.0 hub which carries out the necessary transaction translation to convert between high-speed transmission and full-/low-speed transmission. In such circumstances:

- the lower 7 bits should record the address of this USB 2.0 hub
- the top bit should record whether the hub has multiple transaction translators (set to '0' if single transaction translator; set to '1' if multiple transaction translators).

Note: If Endpoint 0 is connected to a hub, then TXHUBADDR must be defined for EP0.

Note: Relevant in host mode only

Offset = 2082h + (j \* 8h); where j = 0h to Fh

**Figure 32-54. TXHUBADDR[j]**

7	6	5	4	3	2	1	0
MULTTRAN							
R/W-0h	ADDR						
				R/W-0h			

**Table 32-104. TXHUBADDR[j] Field Descriptions**

Bit	Field	Type	Reset	Description
7	MULTTRAN	R/W	0h	Record whether the hub has multiple transaction translators. 0h (R/W) = Clear to indicate that the hub has a single transaction translator. 1h (R/W) = Set to indicate that the hub has multiple transaction translators.
6-0	ADDR	R/W	0h	Device Address specifies the USB bus address for the target Device.

## 52 TXHUBPORT[j] (Offset = 2083h + formula) [Reset = 00h]

TXHUBPORT[j] is shown in [Figure 32-55](#) and described in [Table 32-54](#).

Return to the [Summary Table](#).

Transmit Hub Port Endpoint [j]

TXHUBPORT only need to be written where a full- or low-speed device is connected to TX/RX Endpoint EPn via a high-speed USB 2.0 hub which carries out the necessary transaction translation. In such circumstances, these 7-bit read/write registers need to be used to record the port of that USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: If Endpoint 0 is connected to a hub, then TXHUBPORT must be defined.

Note: Relevant in host mode only

Offset = 2083h + (j \* 8h); where j = 0h to Fh

**Figure 32-55. TXHUBPORT[j]**

6-0	ADDR	R/W	0h	Device Address specifies the USB bus address for the target Device.

### 54 RXHUBADDR[jj] (Offset = 2086h + formula) [Reset = 00h]

RXHUBADDR[jj] is shown in [Figure 32-57](#) and described in [Table 32-56](#).

Return to the [Summary Table](#).

#### Receive Hub Address Endpoint [jj]

RXHUBADDR is an 8-bit read/write registers which, like RXHUBPORT, only need to be written where a full- or low-speed device is connected to TX/RX Endpoint EPn via a high-speed USB 2.0 hub which carries out the necessary transaction translation to convert between high-speed transmission and full-/low-speed transmission. In such circumstances:

- the lower 7 bits should record the address of this USB 2.0 hub
- the top bit should record whether the hub has multiple transaction translators (set to '0' if single transaction translator; set to '1' if multiple transaction translators).

Note: The RXHUBADDR register does not exist on EP0.

Note: Relevant in host mode only

Offset = 2086h + (j \* 8h); where j = 0h to Fh

## 56 CSR0L (Offset = 2102h) [Reset = 00h]

CSR0L is shown in [Figure 32-59](#) and described in [Table 32-58](#).

Return to the [Summary Table](#).

Control and Status Endpoint 0 Low.

CSR0L is an 8-bit register that provides control and status bits for Endpoint 0.

Note: The interpretation of the register depends on whether the USB controller is acting as a peripheral or as a host.

Note: Users should also be aware that the value returned when the register is read reflects the status attained e.g. as a result of writing to the register.

**Figure 32-59. CSR0L**

7	6	5	4	3	2	1	0
SETENDC_NAKTO	RXRDYC_STATUS	STALL_RQPKT	SETEND_ERROR	DATAEND_SETUP	STALLED	TXRDY	RXRDY
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-114. CSR0L Field Descriptions**

Bit	Field	Type	Reset	Description
7	SETENDC_NAKTO	R/W	0h	Setup End Clear / NAK Timeout Device mode: The CPU writes a 1 to this bit to clear the SETEND_ERROR bit. It is cleared automatically. Host mode: This bit will be set when Endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the USBNAKLMT register. The CPU should clear this bit to allow the endpoint to continue. 0h (R/W) = No effect 1h (R/W) = Clear SETEND_ERROR or SETENDC_NAKTO
6	RXRDYC_STATUS	R/W	0h	Receive ready clear / Status packet Device mode: Receive ready clear. The CPU writes a 1 to this bit to clear the RXRDY bit. It is cleared automatically Host mode: Status Packet. The CPU sets this bit at the same time as the TXRDY or STALL_RQPKT bit is set, to perform a status stage transaction. Setting this bit ensures that the DT bit is set in the USBCSRH0 register, so that a DATA1 packet is used for the Status Stage transaction. Setting this bit ensures that the DT bit is set in the USBCSRH0 register so that a DATA1 packet is used for the STATUS stage transaction. 0h (R/W) = No transaction 1h (R/W) = Clear RXRDY or sent status packet.
5	STALL_RQPKT	R/W	0h	Send Stall / Request Packet. Device mode: The CPU writes a 1 to this bit to terminate the current transaction. The STALL handshake will be transmitted and then this bit will be cleared automatically. Host mode: The CPU sets this bit to request an IN transaction. It is cleared when RXRDY bit is set. 0h (R/W) = No effect 1h (R/W) = Send stall request or request packet is in effect.
4	SETEND_ERROR	R/W	0h	Setup end / Error. Device mode: Setup end. This bit will be set when a control transaction ends before the DATAEND_SETUP bit has been set. An interrupt will be generated and the FIFO flushed at this time. The bit is cleared by the CPU writing a 1 to the SETENDC_NAKTO bit. Host mode: Error indication. This bit will be set when three attempts have been made to perform a transaction with no response from the peripheral. The CPU should clear this bit. An interrupt is generated when this bit is set. 0h (R/W) = Clear Error. Note: Only effective in host mode. 1h (R/W) = Setup end / Error indication.

**Table 32-114. CSR0L Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	DATAEND_SETUP	R/W	0h	<p>Data end / Setup Packet.</p> <p>Device mode: Data end bit. The CPU sets this bit:</p> <ol style="list-style-type: none"> <li>1. When setting TXRDY for the last data packet.</li> <li>2. When clearing RXRDY after unloading the last data packet.</li> <li>3. When setting TXRDY for a zero length data packet.</li> </ol> <p>Host mode: Setup packet. The CPU sets this bit, at the same time as the TXRDY bit is set, to send a SETUP token instead of an OUT token for the transaction.</p> <p>Note: Setting this bit always clears the DT bit in the USBCSRH0 register.</p> <p>0h (R/W) = EFFECT : No effect 1h (R/W) = Indicates data end or sends setup token.</p>
2	STALLED	R/W	0h	<p>Sent Stall / Receive Stall</p> <p>Device mode: This bit is set when a STALL handshake is transmitted. The CPU should clear this bit.</p> <p>Host mode: This bit is set when a STALL handshake is received. The CPU should clear this bit.</p> <p>0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received or transmitted</p>
1	TXRDY	R/W	0h	<p>Transmit Packet Ready.</p> <p>Device &amp; Host mode: The CPU sets this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is also generated at this point (if enabled).</p> <p>Host mode: If both the TXRDY and DATAEND_SETUP bits are set, a setup packet is sent. If just TXRDY is set, an OUT packet is sent.</p> <p>0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.</p>
0	RXRDY	R/W	0h	<p>Receive Packet Ready.</p> <p>Device mode: This bit is set when a data packet has been received. An interrupt is generated when this bit is set. The CPU clears this bit by setting the RXRDYC_STATUS bit.</p> <p>Host mode: Software must clear this bit after the packet has been read from the FIFO to acknowledge that the data has been read from the FIFO.</p> <p>0h (R/W) = No receive packet has been received. 1h (R/W) = Indicates that a data packet has been received in the RX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.</p>

### 57 CSR0H (Offset = 2103h) [Reset = 00h]

CSR0H is shown in [Figure 32-60](#) and described in [Table 32-59](#).

Return to the [Summary Table](#).

Control and Status Endpoint 0 High.

CSR0H is an 8-bit register that provides control and status bits for Endpoint 0.

Note: The interpretation of the register depends on whether the USB controller is acting as a peripheral or as a host.

Note: Users should also be aware that the value returned when the register is read reflects the status attained e.g. as a result of writing to the register.

**Figure 32-60. CSR0H**

7	6	5	4	3	2	1	0
RESERVED				DISPING	DTWE	DT	FLUSH

Bit	Field	Type	Reset	Description
7-4	RESERVED	R	0h	
3	DISPING	R/W	0h	Disable PING tokens in data and status phases of a high-speed Control transfer. 0h (R/W) = Ping is allowed. 1h (R/W) = Ping is not allowed.
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Note: This bit is only effective in host mode. 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the endpoint 0 data toggle to be written (see DT bit).
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the endpoint 0 data toggle. If DTWE is set, this bit may be written with the required setting of the data toggle. If DTWE is Low, this bit cannot be written. Care should be taken when writing to this bit as it should only be changed to RESET USB endpoint 0. Note: This bit is only effective in host mode. 0h = Data toggle is low 1h = Data toggle is high
0	FLUSH	R/W	0h	Flush FIFO. The CPU writes a 1 to this bit to flush the next packet to be transmitted/read from the Endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit in the USBCSRL0 register is cleared. Note: FLUSH should only be used when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted. 0h (R/W) = No effect 1h (R/W) = Flush the FIFO

**58 COUNT0 (Offset = 2108h) [Reset = 00h]**

COUNT0 is shown in [Figure 32-61](#) and described in [Table 32-60](#).

Return to the [Summary Table](#).

Receive Byte Count Endpoint 0

COUNT0 is a 7-bit read-only register that indicates the number of received data bytes in the Endpoint 0 FIFO.

Note: The value returned changes as the contents of the FIFO change and is only valid while RXRDY (CSR0L.RXRDY) is set.

**Figure 32-61. COUNT0**

4	STALLSETUP	R/W	0h	<p>Send stall / Setup packet request.</p> <p>Device mode: The CPU writes a 1 to this bit to issue a STALL handshake to an IN token. The CPU clears this bit to terminate the stall condition. Note: This bit has no effect where the endpoint is being used for Isochronous transfers.</p> <p>Host mode: The CPU sets this bit, at the same time as the TXRDY bit is set, to send a SETUP token instead of an OUT token for the transaction. Note: Setting this bit also clears the USBTXCSRH.DT register.</p> <p>0h (R/W) = No effect 1h (R/W) = Send stall or setup packet request.</p>
3	FLUSH	R/W	0h	<p>Flush FIFO.</p> <p>The CPU writes a 1 to this bit to flush the latest packet from the endpoint TX FIFO. The FIFO pointer is reset, the TXRDY bit is cleared and an interrupt is generated. May be set simultaneously with TXRDY to abort the packet that is currently being loaded into the FIFO.</p> <p>Note: FLUSH should only be used when TXRDY is set. At other times, it may cause data to be corrupted. Also note that, if the FIFO is double-buffered, FLUSH may need to be set twice to completely clear the FIFO.</p> <p>Note: Host and device mode.</p> <p>0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO.</p>
2	UNDRNERROR	R/W	0h	<p>Underrun / Error condition.</p> <p>Device mode: The USB controller sets this bit if an IN token is received when TXRDY is not set. The CPU should clear this bit.</p> <p>Host mode: The USB controller sets this bit when 3 attempts have been made to send a packet and no handshake packet has been received. When the bit is set, an interrupt is generated, TXRDY is cleared and the FIFO is completely flushed. The CPU should clear this bit. Valid only when the endpoint is operating in Bulk or Interrupt mode.</p> <p>0h (R/W) = No underrun or error condition 1h (R/W) = Underrun or error condition exist.</p>
1	FIFONE	R/W	0h	<p>FIFO Not Empty.</p> <p>The USB controller sets this bit when there is at least 1 packet in the TX FIFO.</p> <p>Note: Host and device mode.</p> <p>0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.</p>
0	TXRDY	R/W	0h	<p>Transmit Packet Ready.</p> <p>The CPU sets this bit after loading a data packet into the FIFO. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO.</p> <p>Note: Host and device mode</p> <p>0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.</p>

## 64 TXCSRH[j] (Offset = 2113h + formula) [Reset = 00h]

TXCSRH[j] is shown in [Figure 32-67](#) and described in [Table 32-66](#).

Return to the [Summary Table](#).

Transmit Control and Status Endpoint [j] High.

TXCSRH is an 8-bit register that provides additional control for transfers through the currently-selected TX endpoint. There is a TXCSRH register for each configured TX endpoint (not including Endpoint 0).

Note: The interpretation of the register depends on whether the USB controller is acting as a peripheral or as a host. Users should also be aware that the value returned when the register is read reflects the status attained e.g. as a result of writing to the register.

Offset = 2113h + (j \* 10h); where j = 0h to Eh

**Figure 32-67. TXCSRH[j]**

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-130. TXCSRH[j] Field Descriptions**

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set. If the CPU sets this bit, the TXRDY bit will be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually. Note: Should not be set for either high-bandwidth Isochronous endpoints or high-bandwidth Interrupt endpoints. Note: Device and host mode. 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = The TXRDY bit is automatically set when maximum packet size is loaded into the TX FIFO.
6	ISO	R/W	0h	Isochronous Transfers. The CPU sets this bit to enable the TX endpoint for Isochronous transfers, and clears it to enable the TX endpoint for Bulk or Interrupt transfers. Note: This bit only has any effect in device mode. In host mode, it always returns zero. 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode The CPU sets this bit to enable the endpoint direction as TX, and clears the bit to enable it as Rx. Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Note: Host and device mode. 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable The CPU sets this bit to enable the DMA request for the TX endpoint. Note: Four TX and four RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the TRIGATX, TRIGBTX, TRIGCTX, or TRIGDCTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly. Note: Device and host mode. 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.

**Table 32-130. TXCSRH[j] Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	FDT	R/W	0h	<p>Force Data Toggle.</p> <p>The CPU sets this bit to force the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This can be used by Interrupt TX endpoints that are used to communicate rate feedback for Isochronous endpoints.</p> <p>Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.</p> <p>Note: Device and host mode.</p> <p>0h (R/W) = No effect 1h (R/W) = Forces data toggle</p>
2	DMAMOD	R/W	0h	<p>DMA Request Mode.</p> <p>The CPU sets this bit to select DMA Request Mode 1 and clears it to select DMA Request Mode 0.</p> <p>Note: This bit must not be cleared either before or in the same cycle as the DMAEN bit is cleared.</p> <p>Note: Device and host mode.</p> <p>0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete.</p>
1	DTWE	R/W	0h	<p>Data Toggle Write Enable.</p> <p>The CPU writes a 1 to this bit to enable the current state of the TX Endpoint data toggle to be written. This bit is automatically cleared once the new value is written.</p> <p>Note: Host mode only.</p> <p>0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).</p>
0	DT	R/W	0h	<p>Data Toggle.</p> <p>When read, this bit indicates the current state of the transmit endpoint data toggle.</p> <p>If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint.</p> <p>Note: Host mode only</p> <p>0h = Data toggle is low 1h = Data toggle is high</p>

**65 RXMAXP[j] (Offset = 2114h + formula) [Reset = 0000h]**

RXMAXP[j] is shown in [Figure 32-68](#) and described in [Table 32-67](#).

Return to the [Summary Table](#).

Maximum Receive Data Endpoint [j].

The RXMAXP register defines the maximum amount of data that can be transferred through the selected Rx endpoint in a single operation. There is a RXMAXP register for each RX endpoint (except Endpoint 0).

Offset = 2114h + (j \* 10h); where j = 0h to Eh

**Table 32-134. RXCSRL[j] Field Descriptions**

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. The CPU writes a 1 to this bit to reset the endpoint data toggle to 0. Note: Device and host mode. 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Sent Stall / RX Stall Device mode: This bit is set when a STALL handshake is transmitted. The CPU should clear this bit. Host mode: When a STALL handshake is received, this bit is set and an interrupt is generated. The CPU should clear this bit. 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Send Stall / Request Packet. Device mode: The CPU writes a 1 to this bit to issue a STALL handshake. The CPU clears this bit to terminate the stall condition. - Note: This bit has no effect where the endpoint is being used for Isochronous transfers. Host mode: The CPU writes a 1 to this bit to request an IN transaction. It is cleared when RXRDY is set. 0h (R/W) = No effect 1h (R/W) = Send stall or packet request.
4	FLUSH	R/W	0h	Flush FIFO. The CPU writes a 1 to this bit to flush the next packet to be read from the endpoint RX FIFO. The FIFO pointer is reset and the RXRDY bit is cleared. Note: This bit should only be set when RXRDY is set. At other times, it may cause data to be corrupted. Note: If the FIFO is double-buffered, FLUSH may need to be set twice to completely clear the FIFO. Note: Device and host mode. 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared

**Table 32-134. RXCSRL[j] Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	DATAERRNAKTO	R/W	0h	<p>Data Error / NAK Timeout</p> <p>Device mode: Data Error - This bit is set when RXRDY is set, if the data packet has a CRC or bit-stuff error. It is cleared when RXRDY is cleared. - Note: This bit is only valid when the endpoint is operating in ISO mode. In Bulk mode, it always returns zero.</p> <p>Host mode: NAK Timeout - When operating in ISO mode, this bit is set when RXRDY is set, if the data packet has a CRC or bit-stuff error and cleared when RXRDY is cleared. In Bulk mode, this bit will be set when the Rx endpoint is halted following the receipt of NAK responses for longer than the time set as the NAK Limit by the USBRXINTERVAL register. The CPU should clear this bit to allow the endpoint to continue.</p> <p>0h (R/W) = Normal operation 1h (R/W) = Data error or NAK Timeout condition exist.</p>
2	OVERERROR	R/W	0h	<p>Over run / Error.</p> <p>Device mode: Over run - This bit is set if an OUT packet cannot be loaded into the receive FIFO. The CPU should clear this bit. - Note: This bit is only valid when the endpoint is operating in ISO mode. In Bulk mode, it always returns zero.</p> <p>Host mode: The USB sets this bit when 3 attempts have been made to receive a packet and no data packet has been received. The CPU should clear this bit. An interrupt is generated when the bit is set. - Note: This bit is only valid when the RX endpoint is operating in Bulk or Interrupt mode. In ISO mode, it always returns zero.</p> <p>0h (R/W) = No over run or error condition. 1h (R/W) = Under run or error condition exist.</p>
1	FULL	R	0h	<p>FIFO Full.</p> <p>This bit is set when no more packets can be loaded into the RX FIFO.</p> <p>Note: Device and host mode.</p> <p>0h (R/W) = The receive FIFO is not full. 1h (R/W) = The receive FIFO is full. No more packets can be loaded into the receive FIFO.</p>
0	RXRDY	R/W	0h	<p>Receive Packet Ready.</p> <p>This bit is set when a data packet has been received. The CPU should clear this bit when the packet has been unloaded from the Rx FIFO. An interrupt is generated when the bit is set.</p> <p>If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO.</p> <p>Note: Device and host mode.</p> <p>0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EP[j] bit in the USBTXIS register is also set in this situation</p>

### 67 RXCSRH[j] (Offset = 2117h + formula) [Reset = 00h]

RXCSRH[j] is shown in [Figure 32-70](#) and described in [Table 32-69](#).

Return to the [Summary Table](#).

Receive Control and Status Endpoint [j] High.

RXCSRH is an 8-bit register that provides additional control and status bits for transfers. There is a RXCSRH register for each configured Rx endpoint (not including Endpoint 0).

Note: The interpretation of the register depends on whether the USB controller is acting as a peripheral or as a host. Users should also be aware that the

value returned when the register is read reflects the status attained e.g. as a result of writing to the register.

Offset = 2117h + (j \* 10h); where j = 0h to Eh

**Figure 32-70. RXCSRH[j]**

7	6	5	4	3	2	1	0
AUTOCLR	ISOAUTORQ	DMAEN	PIDERR	DMAMOD	DTWE	DT	INCOMPRX
R/W-0h	R/W-0h	R/W-0h	R-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-136. RXCSRH[j] Field Descriptions**

Bit	Field	Type	Reset	Description
7	AUTOCLR	R/W	0h	Auto Clear. If the CPU sets this bit then the RXRDY bit will be automatically cleared when a packet of USBRXMAXP bytes has been unloaded from the RX FIFO. When packets of less than the maximum packet size are unloaded, RXRDY will have to be cleared manually. When using a DMA to unload the RX-FIFO, data is read from the RX-FIFO in 4 byte chunks regardless of the USBRXMAXP setting. Note: Device and host mode. 0h (R/W) = No effect 1h (R/W) = Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO.
6	ISOAUTORQ	R/W	0h	Isochronous transfer mode / Auto request. Device mode: The CPU sets this bit to enable the Rx endpoint for Isochronous transfers, and clears it to enable the Rx endpoint for Bulk/Interrupt transfers. Host mode: If the CPU sets this bit, the STALLREQPKT bit will be automatically set when the RXRDY bit is cleared. - Note: This bit is automatically cleared when a short packet is received. 0h (R/W) = No effect 1h (R/W) = Sets ISO transfer mode or enables the REQPKT bit to be automatically set when the RXRDY bit is cleared.
5	DMAEN	R/W	0h	DMA Request Enable The CPU sets this bit to enable the DMA request for the Rx endpoint. Note: Four TX and four RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the TRIGARX, TRIGBRX, TRIGCRX, or TRIGDRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly 0h (R/W) = Disables the DMA request for the receive endpoint. 1h (R/W) = Enables the DMA request for the receive endpoint.
4	PIDERR	R	0h	PID error ISO Transactions: The USB controller sets this bit to indicate a PID error in the received packet. Bulk/Interrupt Transactions: The setting of this bit is ignored. Note: Device and host mode. 0h (R/W) = No error 1h (R/W) = Indicates a PID error in the received packet of an isochronous transaction.

**Table 32-136. RXCSRH[j] Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	DMAMOD	R/W	0h	<p>DMA request mode</p> <p>The CPU sets this bit to select DMA Request Mode 1 and clears it to select DMA Request Mode 0.</p> <p>Note: This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared.</p> <p>Note: Device and host mode.</p> <p>0h (R/W) = An interrupt is generated after every DMA packet transfer.</p> <p>1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete.</p>
2	DTWE	R/W	0h	<p>Data Toggle Write Enable.</p> <p>The CPU writes a 1 to this bit to enable the current state of the Endpoint 0 data toggle to be written. This bit is automatically cleared once the new value is written.</p> <p>Note: Host mode only.</p> <p>0h (R/W) = The DT bit cannot be written.</p> <p>1h (R/W) = Enables the current state of the receive endpoint data to be written (see DT bit).</p>
1	DT	R/W	0h	<p>Data Toggle.</p> <p>When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint.</p> <p>Note: Host mode only.</p> <p>0h = Data toggle is low</p> <p>1h = Data toggle is high</p>
0	INCOMPRX	R/W	0h	<p>This bit will be set in a high-bandwidth Isochronous or Interrupt transfer if the packet received is incomplete, because parts of the data were not received. It is cleared when RXRDY is cleared.</p> <p>Note: In anything other than Isochronous transfer, this bit will always return 0.</p> <p>Note: Device and host mode.</p>

### 68 RXCOUNT[j] (Offset = 2118h + formula) [Reset = 0000h]

RXCOUNT[j] is shown in [Figure 32-71](#) and described in [Table 32-70](#).

Return to the [Summary Table](#).

USB Receive Byte Count Endpoint [j].

USB RXCOUNT is a 13-bit read-only register that holds the number of data bytes in the packet currently in line to be read from the RX

FIFO. If the packet was transmitted as multiple bulk packets, the number given will be for the combined packet.

Note: The value returned changes as the FIFO is unloaded and is only valid while RXRDY is set.

Offset = 2118h + (j \* 10h); where j = 0h to Eh

### 73 FIFOSZ[j] (Offset = 211Fh + formula) [Reset = 00h]

FIFOSZ[j] is shown in [Figure 32-76](#) and described in [Table 32-75](#).

Return to the [Summary Table](#).

FIFO Size Endpoint [j].

FIFOSZ is an 8-bit Read-Only register that returns the sizes of the FIFOs associated with the selected additional TX/Rx endpoints. The lower nibble encodes the size of the selected TX endpoint FIFO; the upper nibble encodes the size of the selected Rx endpoint FIFO. Values of 3 – 13 correspond to a FIFO size of 2<sup>n</sup> bytes (8 – 8192 bytes). If an endpoint has not been configured, a value of 0 will be displayed. Where the TX and Rx endpoints share the same FIFO, the Rx FIFO size will be encoded as 0xF.

Note: The register only has this interpretation when the Index register is set to select one of Endpoints 1 – 15 and Dynamic Sizing is not selected. It has a special interpretation when the Index register is set to select Endpoint 0, while the result returned is not valid where Dynamic FIFO sizing is used.

Offset = 211Fh + (j \* 10h); where j = 0h to Eh

15-0	COUNT	R/W	0h	Block Transfer Packet Count sets the number of packets of the size defined by the MAXLOAD bit field that are to be transferred in a block transfer. Note: This is only used in Host mode when AUTORQ is set. The bit has no effect in Device mode or when AUTORQ is not set.

## 75 RXDPKTBUFDIS (Offset = 2340h) [Reset = 0000h]

RXDPKTBUFDIS is shown in [Figure 32-78](#) and described in [Table 32-77](#).

Return to the [Summary Table](#).

USB Receive Double Packet Buffer Disable.

For each Rx Endpoint 1 – 15, the USB controller provides a RXDPKTBUFDIS bit. These read/write bits are used to control the use of double packet buffering on a per endpoint basis. When asserted (RXDPKTBUFDIS equals 1'b1), the bit will disable double packet buffering for the corresponding endpoint regardless of the End Point FIFO Size and the INMAXP size relationship. When de-asserted (RXDPKTBUFDIS equals 1'b0), this bit does NOT necessarily enable double packet buffering but rather allows double packet buffering to be determined based upon the End Point FIFO Size and INMAXP size relationship.

## 76 TXDPKTBUFDIS (Offset = 2342h) [Reset = 0000h]

TXDPKTBUFDIS is shown in [Figure 32-79](#) and described in [Table 32-78](#).

Return to the [Summary Table](#).

Transmit Double Packet Buffer Disable.

For each Tx Endpoint 1 – 15, the USB controller provides a TXDPKTBUFDIS bit. These read/write bits are used to control the use of double packet buffering on a per endpoint basis. When asserted (TXPKTBUFDIS equals 1'b1), the bit will disable double packet buffering for the corresponding endpoint regardless of the End Point FIFO Size and the INMAXP size relationship. When de-asserted (TXDPKTBUFDIS equals 1'b0), this bit does NOT necessarily enable double packet buffering but rather allows double packet buffering to be determined based upon the End Point FIFO Size and INMAXP size relationship.

**Figure 32-79. TXDPKTBUFDIS**

The I2S/TDM module provides a standardized serial interface to transfer audio data. This chapter describes the operation of the I2S/TDM module.

<b>33.1 I2S/TDM Introduction</b> .....	<b>2151</b>
<b>33.2 I2S/TDM Operation</b> .....	<b>2151</b>
<b>33.3 I2S Registers</b> .....	<b>2165</b>

### 33.1 I2S/TDM Introduction

The I2S/TDM module provides a standardized serial interface to transfer audio data. The module can be configured in different modes including I2S standards, LSB or MSB-justified, PCM/DSP and TDM for example. It can be used in conjunction with the DMA controller.

#### 33.1.1 I2S/TDM features

- Configurable and independent transmitter and receiver functions on data lines
- Configurable controller or target function
- Integrated transmitter and receiver FIFO with packing feature
- Clock generator to target specific audio frequency generation
- Independent channel/slot length and audio word length of 8, 16, 24 or 32-bits
- Audio protocol: I2S, Left- or Right-justified, PCM/DSP, TDM
- Up to 16 slots available in TDM format
- Empty slot configuration for sending 0's, 1's or Hi-Z
- Configurable bit clock sampling edge
- Frame synchronization configurable for offset and bit length
- Independent DMA request for transmitter and receiver functions

### 33.2 I2S/TDM Operation

#### 33.2.1 Functional Block Diagram

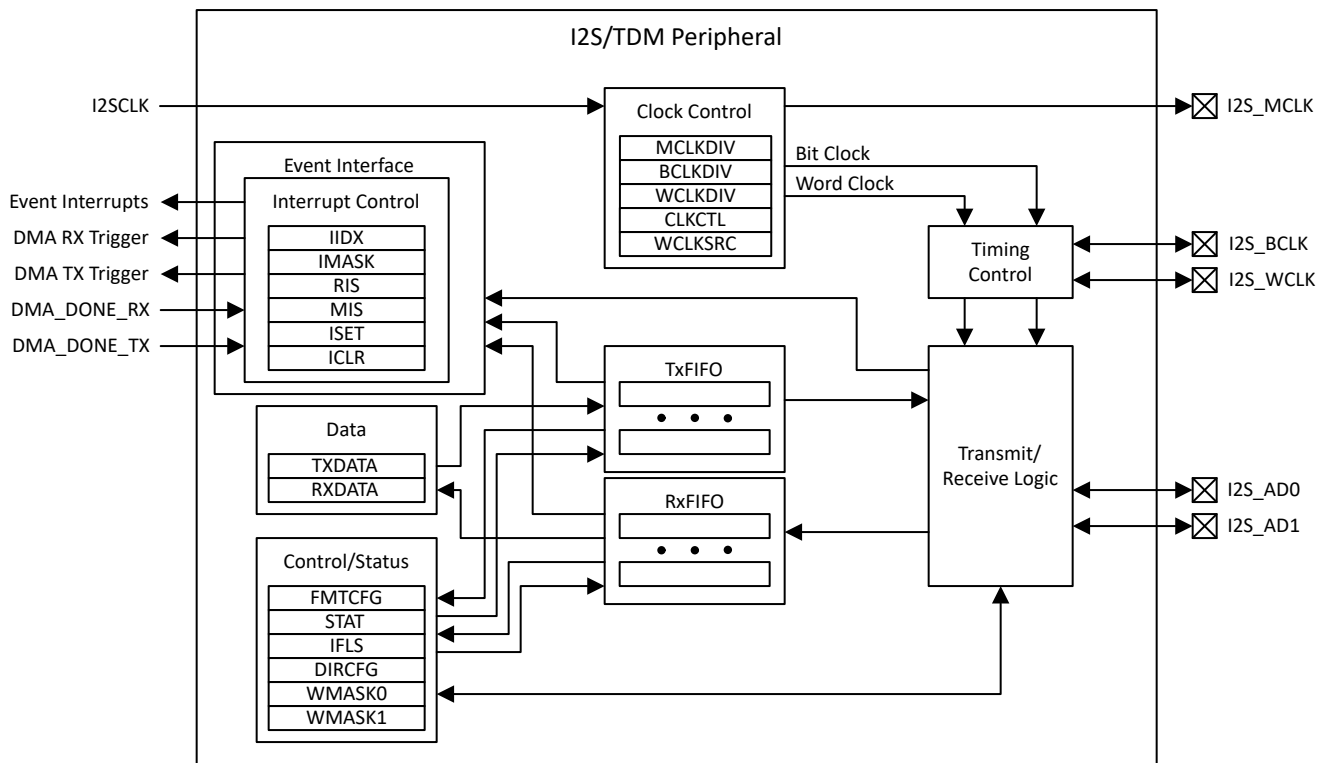

Figure 33-1. I2S/TDM Functional Block Diagram

#### Note

Refer to TxFIFO and RxFIFO depth in device specific data sheet.

#### 33.2.2 Modes of Operation

The I2S module can be configured as a controller or target function.

### 33.2.2.1 Controller Mode

In controller mode the I2S module generates the bit clock (I2S\_BCLK) and word clock (I2S\_WCLK). The I2S controller supports a highly configurable data pins I2S\_ADx which can be independently configured in transmitter or receiver functions. This allows the controller to support dual transmitter, dual receiver or standard transmit-receive function.

When the module is configured as a controller

- The source clock selection is through registers in system control and can be sourced from multiple sources.
- The controller generates the I2S\_BCLK using the I2S.BCLKDIV register.
- The controller generates the I2S\_WCLK using the I2S.WCLKDIV register.
- The module can generate an optional master clock (I2S\_MCLK) using I2S.MCLKDIV register.

### 33.2.2.2 Target Mode

In target mode the I2S module receives the bit clock (I2S\_BCLK) and word clock (I2S\_WCLK). The I2S target also supports a highly configurable data pins I2S\_ADx which can be independently configured in transmitter or receiver functions. This allows the controller to support dual transmitter, dual receiver or standard transmit-receive function.

When the module is configured as a target

- The I2S\_BCLK and I2S\_WCLK must be sourced through the pad.

### 33.2.3 Clock and Timing Control

The I2S/TDM internal functional clock is selected from either one of the device clocks (when the module is a controller) or from the pad (when the module is a target).

- Use the I2S.WCLKSRC register to select the source of clock as internal or external.
- If internal clock source is selected, use the SYSCTL.I2S.CLKCFG register to select the source of clock. Refer to the device data sheet for the options available for internal clock sources.
  - SYSOSC
  - HFXT
  - PLL
  - EXTCLK

The clock generator is a highly programmable block in the module which is used to derive the BCLK, WCLK and MCLK. The BCLK and MCLK generation is straightforward and [Equation 30](#) and [Equation 31](#) can be used to derive the clock frequency respectively.

$$BCLK \text{ Frequency} = \frac{\text{Module Clock Frequency}}{BCLKDIV} \quad (30)$$

$$MCLK \text{ Frequency} = \frac{\text{Module Clock Frequency}}{MCLKDIV} \quad (31)$$

The WCLK generation is calculated differently depending on the configuration of CLKCTL.WCLKPHASE register bit.

For frame format where the WCLK is high for one clock (single-phase) the CLKCTL.WCLKPHASE is configured as 0, the [Equation 32](#) defines the equation for calculating the WCLK frequency or frame rate.

$$WCLK \text{ Frequency (Frame Rate)} = \frac{\text{Module Clock Frequency}}{(BCLKDIV \times (WCLKDIV[9:0] + 1))} \quad (32)$$

For frame format where the WCLK is high with a 50% duty cycle (dual-phase) the CLKCTL.WCLKPHASE is configured as 1, [Equation 33](#) defines the equation for calculating the WCLK frequency or frame rate.

$$WCLK \text{ Frequency (Frame Rate)} = \frac{\text{Module Clock Frequency}}{(BCLKDIV \times (2 \times WCLKDIV[9:0]))} \quad (33)$$

For user defined frame format where WCLK can be arbitrarily high for CLKCTL.WCLKDIV[7:0] and low for CLKCTL.WCLKDIV[15:8], the WCLKPHASE is configured as 2. [Equation 34](#) defines the equation for calculating the WCLK frequency or frame rate.

$$WCLK \text{ Frequency (Frame Rate)} = \frac{\text{Module Clock Frequency}}{(BCLKDIV \times (WCLKDIV[7:0] + WCLKDIV[15:8]))} \quad (34)$$

---

#### Note

When in controller mode, the bit clock may have stringent requirements for precise clock frequency and jitter specifications. It is preferred that the application configure the internal clock source as HFXT, EXTCLK or PLL (if the clock source for the PLL is HFXT).

---

### 33.2.4 Frame Synchronization

The I2S\_WCLK signal acts as the frame synchronization signal in the audio frame to denote the start of frame. The signal is completely configurable in order to target the different audio formats. The configurability of the WCLK is managed using CLKCTL, WCLKSRC and WCLKDIV registers.

The I2S\_WCLK can be configured based on the serial format. This is configured using the CLKCTL.WCLKPHASE and correspondingly the appropriate WCLKDIV.WDIV values

- CLKCTL.WCLKPHASE = 0: Start of frame for data formats such as PCM, DSP and TDM, where I2S\_WCLK is high for one and low for WCLKDIV.WDIV[9:0] I2S\_BCLK.
- CLKCTL.WCLKPHASE = 1: Start of frame and channel identification for data formats such as I2S, Left-justified and Right-justified, where I2S\_WCLK is high or low for number of bit clocks configured in WCLKDIV.WDIV[9:0].
- CLKCTL.WCLKPHASE = 2: Start of frame for custom formats such as PCM long frame, where I2S\_WCLK is high for WCLKDIV.WDIV[7:0] and low for WCLKDIV.WDIV[15:8] I2S\_BCLK

#### 33.2.4.1 Frame and Word Length

The frame length is calculated as the number I2S\_BCLK from a rising or falling I2S\_WCLK to the corresponding edge on the next frame. In a frame, the word length or number of data bits per slot/channel is configured through FMTCFG.WORDLEN which has a minimum value of 8 bits and maximum value of 32 bits. The I2S\_WCLK is used in target mode to automatically detect the number of I2S\_BCLK used for a channel for dual-phase formats:

- If the I2S\_WCLK edge occurs before the word length count is over, then the sample word is truncated
- If the I2S\_WCLK edge occurs after the word length count is over, then the sample word is zero padded in the least significant bit position.

The data that is transmitted or received on the I2S\_ADx comes from the FIFO which can be configured using the FMTCFG.MEMLEN32 as 16-bit or 32-bit data per entry in the FIFO.

#### FMTCFG.MEMLEN32 = 0

When configured as 0, each FIFO entry holds data in the lower 16-bit and the upper 16-bit is unused. This setting must only be used when FMTCFG.WORDLEN ≤ 16-bits. If word length programmed is less than 16-bits then sample words are truncated when transmitting and zero-padded when receiving in the least significant bit position as shown in [Figure 33-2](#).

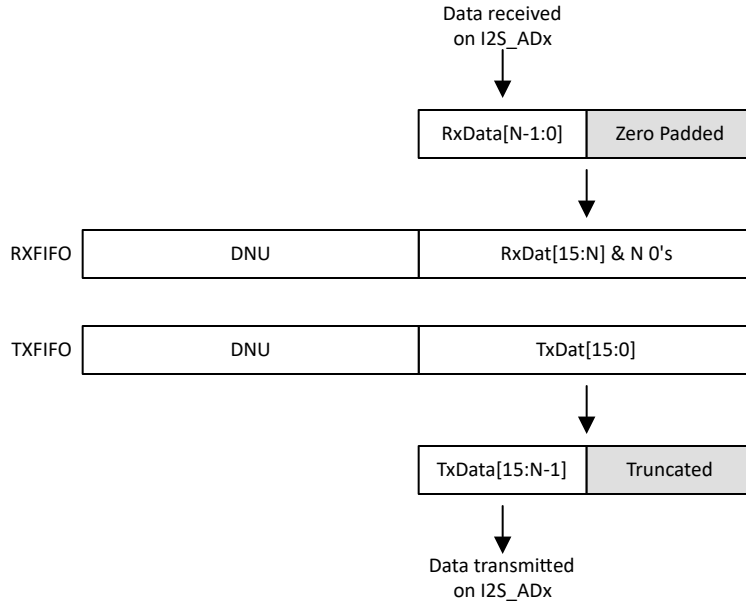

Figure 33-2. Data Mapping for MEMLEN32=0

**FMTCFG.MEMLEN32 = 1**

When configured as 1, each FIFO entry holds two samples when FMTCFG.WORDLEN ≤ 16-bits or a single entry when FMTCFG.WORDLEN > 16-bits. If the word length programmed results in truncation on transmit or zero-padding on receive, the operation happens in the least significant bit position as shown in Figure 33-3.

Figure 33-3. Data Mapping for MEMLEN32=1

**33.2.4.2 Polarity**

The I2S\_WCLK first active edge is configured using WCLKSRC.WCLKINV field. When the field is programmed as "0", the first I2S\_WCLK starts with a rising edge on the first I2S\_BCLK. When the field is programmed as "1", the first I2S\_WCLK starts with a falling edge on the first I2S\_BCLK. Data transmission and receive on I2S\_ADx also follows the same phase as the I2S\_WCLK for transmit and receive.

It is important to note that when I2S module is disabled, the I2S\_WCLK may be either be "0" or "1" and requires a peripheral reset to ensure that it starts in the correct state.

### 33.2.4.3 Data Delay (Offset)

Based on the audio frame format, the I2S\_ADx can be delayed or not delayed with respect to the I2S\_WCLK edge. This configuration is enabled using the FMTCFG.DATADLY field. The valid values that can be programmed are from 0 to 255 I2S\_BCLK.

When programmed as non-zero value, the I2S\_ADx is transmitted or sampled after FMTCFG.DATADLY number of I2S\_BCLK after the I2S\_WCLK edge is transmitted.

### 33.2.5 Slot Mapping and Configuration

The I2S module supports up to 16 slots or channels for different audio formats which can be configured through the DIRCFG and WMASKx register. Each I2S\_ADx has a corresponding WMASKx register which is used to configure the channel or slot count. In single-phase format up to 16-bits are available depending on the device capabilities on number of slots supported.

- WMASKx.MASK[n] = 0: The corresponding slot is not used. No data will be transmitted nor will it be received
- WMASKx.MASK[n] = 1: The corresponding slot is used. Data will be transmitted if I2S\_ADx is configured in output mode or data will be received if I2S\_ADx is configured in input mode.

The slots are configured with least significant bit for the lowest channel. In single-phase formats, channel-0 corresponds to bit-0 in WCMASKx.MASK register, channel-1 to bit-1 and so on. In dual-phase formats only lower 2-bits of the registers are considered for the left and right channels.

Moreover, when a output slot is disabled the behavior of the empty slot can be decided using FMTCFG.EMPTY\_SLOT\_OUTPUT

- FMTCFG.EMPTY\_SLOT\_OUTPUT = 0: All zeroes are sent during the empty slot
- FMTCFG.EMPTY\_SLOT\_OUTPUT = 1: All ones are sent during the empty slot
- FMTCFG.EMPTY\_SLOT\_OUTPUT = 2: The output line is tri-stated
- FMTCFG.EMPTY\_SLOT\_OUTPUT = 3: Reserved and must not be used

### Data Direction Configuration

For each I2S\_ADx, the direction of data flow (data transmit or receive) is controlled using the DIRCFG.ADx pins.

- DIRCFG.ADx = 0: The corresponding I2S\_ADx pin is disabled.
- DIRCFG.ADx = 1: The corresponding I2S\_ADx pin is set as input. Data is received on the pin and stored in the RXFIFO.
- DIRCFG.ADx = 2: The corresponding I2S\_ADx pin is set as output. Data is transmitted from the TXFIFO to the pin.
- DIRCFG.ADx = 3: Reserved and must not be used.

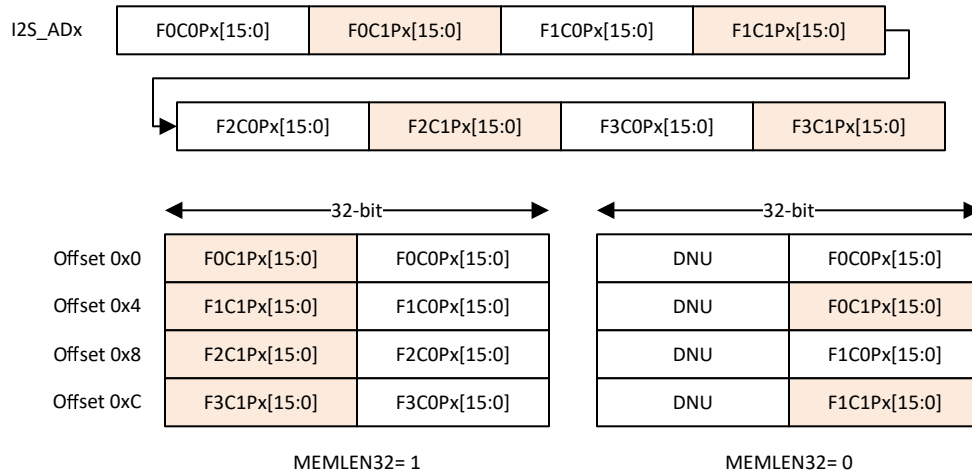

### 33.2.5.1 Channel Mapping in Memory

Based on the slot mapping and channel configuration, data is read from the RXFIFO or written to the TXFIFO. For the MCU application, the mapping of the channel in the FIFO is important to understand how data will be received or transmitted to external devices and to maintain appropriate data structure management.

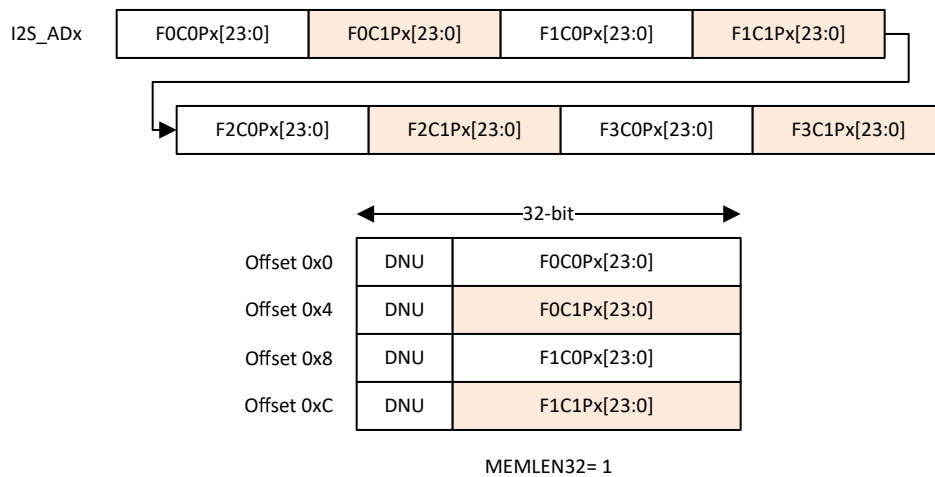

Audio data is always stored in little-endian format in the FIFO. When multiple I2S\_ADx pins are used, data is read or stored with I2S\_AD0 stored first and I2S\_AD1 stored next. For cases where FMTCFG.MEMLEN32 = 1 and data is packed, I2S\_AD0 is stored in the lower bytes and I2S\_AD1 stored in the upper bytes. However, there are caveats based on configured multi-channels/slots in TDM mode, where individual channel/slot(s) may be disabled. [Figure 33-4](#) to [Figure 33-9](#) show some examples of mapping channel data to memory. Any channel which is grayed out is inactive and no data shall be read or written in memory.

**Figure 33-4. 16-bit Mono Single I2S\_ADx to Memory Mapping**

**Figure 33-5. 16-bit Stereo Single I2S\_ADx to Memory Mapping**

**Note**

MEMLEN32=0 is not supported

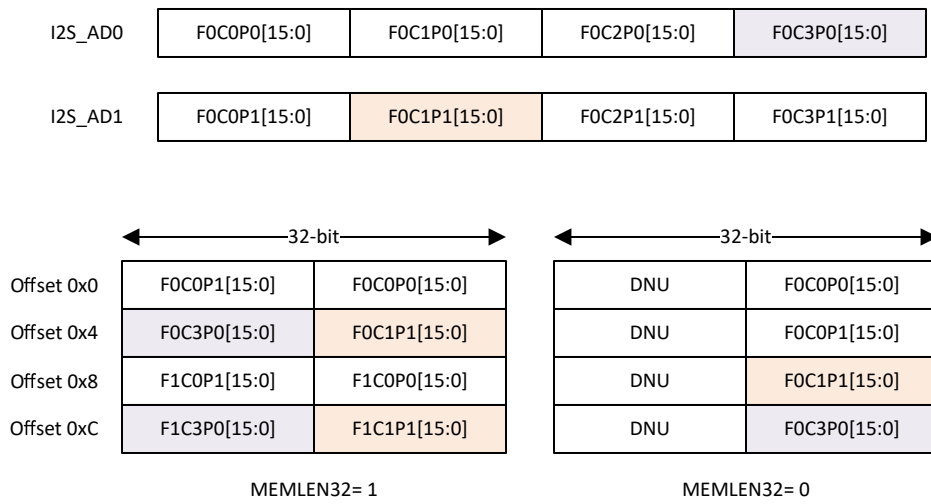

Figure 33-8. 16-bit TDM Dual I2S\_ADx Slots Disabled to Memory Mapping

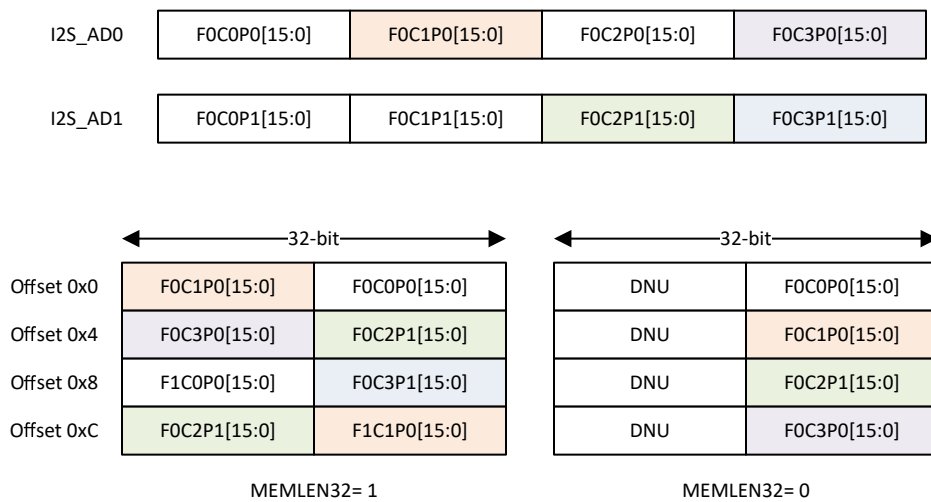

Figure 33-9. 16-bit TDM Dual I2S\_ADx Slots Disabled to Memory Mapping

### 33.2.6 Serial Frame Format Examples

The module supports the dual-phase formats I2S, Left-Justified Format (LJF) and Right-Justified Format (RJF), which supports one or two audio channels per I2S\_ADx pin. The module also supports the single-phase format, DSP, PCM and TDM, which supports up to 16 slots.

The I2S\_WCLK and I2S\_ADx signals are updated on one edge of the I2S\_BCLK and sampled on the opposite (trailing edge). All of the serial formats are comprised of frames. Each frame starts with the first (rising or falling) I2S\_WCLK edge of an audio sample (one or more slots) to the next corresponding (rising or falling) I2S\_WCLK edge. The audio sample words transferred on the I2S\_ADx are aligned with the I2S\_WCLK.

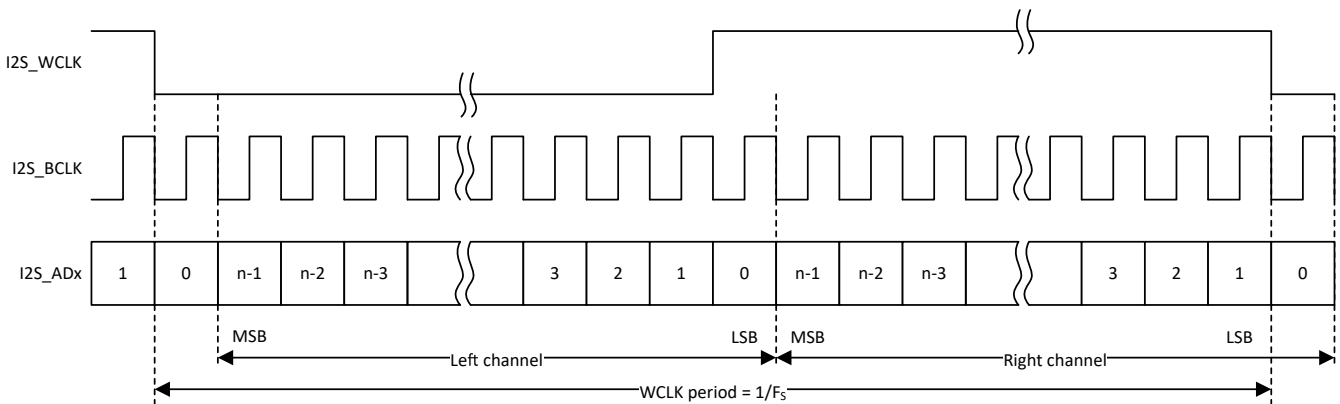

The different serial formats supported by the module require the application to setup the module configuration accordingly as shown in Table 33-1. Subsequent sub-sections illustrate how the application can generate some of the most common audio formats. This is intended to be informational-only.

**Table 33-1. Serial Format Configuration**

PARAMETER NAME	PARAMETER FIELD	DESCRIPTION
Data Delay	FMTCFG.DATADLY	I2S_BCLK period between first I2S_WCLK edge and MSB of first audio channel data transferred
Word length	FMTCFG.WORDLEN	Number of bits per sample
Sample Edge	FMTCFG.SMPLEDGE	The edge at which input data is sampled and output data is clocked out
Phase Format	FMTCFG.DUALPHASE	Single phase is used for TDM formats and dual phase is used for I2S formats
Word Clock Inversion	WCLKSRC.WCLKINV	Mostly applicable in dual phase format to indicate the left or right channel
Word Clock Division Ratio	CLKCTL.WCLKPHASE	Controls how WCLKDIV is used for generating I2S_WCLK
Word Clock High Time	WCLKDIV.WDIV	I2S_WCLK high and low time based on CLKCTL.WCLKPHASE settings
Word Clock Low Time	WCLKDIV.WDIV	

#### 33.2.6.1 I2S Format

I2S is a dual-phase format with a 50% I2S\_WCLK duty cycle with two channels as shown in Figure 33-10 with the configuration example shown in Table 33-2. The left channel is transferred when I2S\_WCLK phase is low followed by the right channel when I2S\_WCLK phase is high. The data is delayed by one I2S\_BCLK period, I2S\_ADx is sampled on the rising edge and launched on the falling edge of the I2S\_BCLK.

**Figure 33-10. I2S Frame Format**

**Table 33-2. I2S Format Configuration**

PARAMETER FIELD	VALUE
FMTCFG.DATADLY	1
FMTCFG.WORDLEN	Number of bits per sample in the left or right channel

**Table 33-2. I2S Format Configuration (continued)**

PARAMETER FIELD	VALUE
FMTCFG.SMPLEDGE	1
FMTCFG.DUALPHASE	1
WCLKSRC.WCLKINV	1
CLKCTL.WCLKPHASE	1
WCLKDIV.WDIV[15:10]	Do not program
WCLKDIV.WDIV[9:0]	≥ Number of bits per sample x 2 channels

**33.2.6.2 Right Justified Format**

The right-justified format (RJF) is a dual-phase format with a 50% I2S\_WCLK duty cycle and two channels as shown in Figure 33-11 with the configuration example shown in Table 33-3. The left channel is transferred when I2S\_WCLK phase is high followed by the right channel when I2S\_WCLK phase is low.

The data delay (FMTCFG.DATADLY) must be equal to the number of I2S\_BCLK periods per I2S\_WCLK phase minus the word length. This allows the data to be transmitted or received with the LSB aligned to the end of the phase.

**Figure 33-11. Right Justified Format**

**Table 33-3. Right Justified Format Configuration**

PARAMETER FIELD	VALUE
FMTCFG.DATADLY	WCLKDIV.WDIV[9:0] - FMTCFG.WORDLEN
FMTCFG.WORDLEN	Number of bits per sample in the left or right channel
FMTCFG.SMPLEDGE	1
FMTCFG.DUALPHASE	1
WCLKSRC.WCLKINV	0
CLKCTL.WCLKPHASE	1
WCLKDIV.WDIV[15:10]	Do not program
WCLKDIV.WDIV[9:0]	≥ Number of bits per sample x 2 channels

**33.2.6.3 Left Justified Format**

The left-justified format (LJF) is a dual-phase format with a 50% I2S\_WCLK duty cycle and two channels as shown in Figure 33-12 with the configuration example shown in Table 33-4. The left channel is transferred when I2S\_WCLK phase is high followed by the right channel when I2S\_WCLK phase is low.

Figure 33-12. Left Justified Format

Table 33-4. Left Justified Format Configuration

PARAMETER FIELD	VALUE
FMTCFG.DATADLY	0
FMTCFG.WORDLEN	Number of bits per sample in the left or right channel
FMTCFG.SMPLEDGE	1
FMTCFG.DUALPHASE	1
WCLKSRC.WCLKINV	0
CLKCTL.WCLKPHASE	1
WCLKDIV.WDIV[15:10]	Do not program
WCLKDIV.WDIV[9:0]	≥ Number of bits per sample x 2 channels

### 33.2.6.4 DSP Format

The DSP format is a single-phase format with I2S\_WCLK high for one I2S\_BCLK period as shown in Figure 33-13. Sample words may be transferred one after the other and the MSB is aligned to I2S\_WCLK or the subsequent I2S\_BCLK, which is programmable as shown in the configuration example in Table 33-5.

Figure 33-13. DSP Format

Table 33-5. DSP Format Configuration

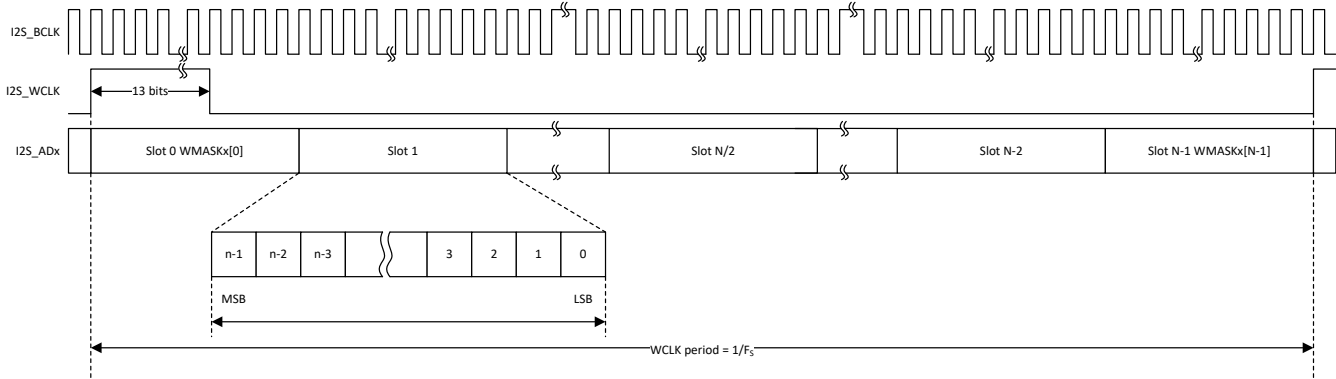

PARAMETER FIELD	VALUE
FMTCFG.DATADLY	0 or 1
FMTCFG.WORDLEN	Number of bits per sample
FMTCFG.SMPLEDGE	0
FMTCFG.DUALPHASE	0
WCLKSRC.WCLKINV	0

**Table 33-5. DSP Format Configuration (continued)**

PARAMETER FIELD	VALUE
CLKCTL.WCLKPHASE	0
WCLKDIV.WDIV[15:10]	Do not program
WCLKDIV.WDIV[9:0]	$\geq$ Number of bits per sample x Number of slots

### 33.2.6.5 PCM Long Frame Format

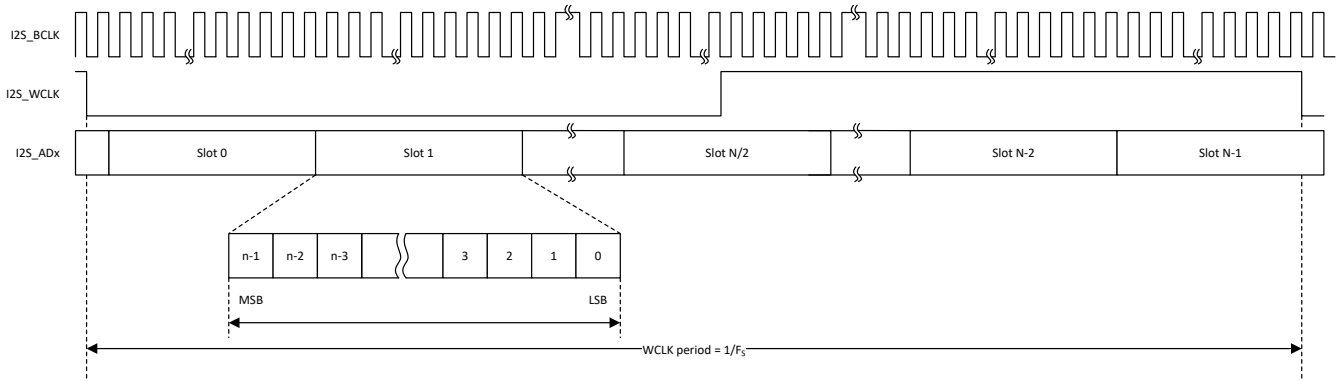

PCM long frame is a single-phase format with I2S\_WCLK high for 13 I2S\_BCLK period as shown in [Figure 33-14](#). In this frame format, the I2S\_WCLK is a pattern which requires setting the CLKCTL.WCLKPHASE for a custom I2S\_WCLK creation by programming the WCLKDIV.WDIV accordingly as given in [Table 33-6](#).

**Figure 33-14. PCM Long Frame Format**
**Table 33-6. PCM Long Frame Format Configuration**

PARAMETER FIELD	VALUE
FMTCFG.DATADLY	0
FMTCFG.WORDLEN	Number of bits per sample
FMTCFG.SMPLEDGE	0
FMTCFG.DUALPHASE	0
WCLKSRC.WCLKINV	0
CLKCTL.WCLKPHASE	2
WCLKDIV.WDIV[15:8]	13
WCLKDIV.WDIV[7:0]	$13 - (\text{Number of bits per samples} \times \text{Number of slots})$

### 33.2.6.6 TDM Classic Format

TDM frame format is a single-phase format and has multiple variations with I2S\_WCLK high and low. One of the format is shown in [Figure 33-15](#), where the I2S\_WCLK is a 50% duty cycle over the entire frame rate. This can be achieved by setting the CLKCTL.WCLKPHASE for a custom I2S\_WCLK creation and programming the WCLKDIV.WDIV accordingly as given in [Table 33-7](#).

**Figure 33-15. TDM Classic Format**

**Table 33-7. TDM Classic Format Configuration**

PARAMETER FIELD	VALUE
FMTCFG.DATADLY	1
FMTCFG.WORDLEN	Number of bits per sample
FMTCFG.SMPLEDGE	1
FMTCFG.DUALPHASE	0
WCLKSRC.WCLKINV	1
CLKCTL.WCLKPHASE	2
WCLKDIV.WDIV[15:8]	(Number of bits per sample x Number of slots) ÷ 2
WCLKDIV.WDIV[7:0]	(Number of bits per sample x Number of slots) ÷ 2

### 33.2.7 Initialization

Before the I2S module is setup or configuration changes, the FMTCFG.ENABLE bit must be cleared to avoid unpredictable behavior during the updates or for first data receive or transmitted afterward.

The following steps are common to both controller and target configuration:

1. Configure the I2S pins in the pin's IOMUX register for the I2S\_BCLK, I2S\_WCLK, I2S\_MCLK (optional), I2S\_AD0 and I2S\_AD1 pin functions.
2. Reset the peripheral using I2Sx.RSTCTL register.
3. Enable the power to I2S peripheral using the I2Sx.PWREN register.

#### Controller mode configuration

1. Select the I2S functional clock source as internal clock by writing I2Sx.WCLKSRC as "2h"
2. Select the I2S\_MCLK (optional), I2S\_BCLK and I2S\_WCLK dividers using the I2Sx.MCLKDIV (optional), I2Sx.BCLKDIV and I2Sx.WCLKDIV, respectively.
3. Setup the configuration for frame format. Example configurations can be found in [Section 33.2.6](#).
4. Setup the configuration for the channel configuration. Example channel configurations can be found in [Section 33.2.5](#).
5. Setup the FIFO thresholds for interrupt or DMA triggers in the I2S\_IFLS register.
6. When in the controller mode, enable the frame clock generation by setting I2Sx.CLKCTL.WBEN and I2Sx.CLKCTL.MEN (optional) bit
7. Enable the peripheral operation by setting I2Sx.FMTCFG.ENABLE as '1'.

#### Target mode configuration

1. Select the I2S functional clock source as pad by writing I2Sx.WCLKSRC as "1h"
2. Setup the configuration for frame format. Example configurations can be found in [Section 33.2.6](#).

3. Setup the configuration for the channel configuration. Example channel configurations can be found in [Section 33.2.5](#).
4. Setup the FIFO thresholds for interrupt or DMA triggers in the I2S\_IFLS register.
5. Enable the peripheral operation by setting I2Sx.FMTCFG.ENABLE as '1'.

### 33.2.8 Disabling I2S

I2S is a continuously streaming protocol, and it may be necessary when going into a low power mode like STOP, STANDBY or SHUTDOWN, that the peripheral is disabled. Since there is no IDLE status bit, because there is no such condition on the bus, the host application must ensure the TXFIFO and RXFIFO are flushed when disabling the peripheral.

Additionally, as the I2S module may be in between frames, it is recommended that the peripheral be reset and an initialization be done when restarting the peripheral to ensure external devices can recognize valid I2S\_WCLK frame synchronization boundary.

---

#### Note

When disabling the I2S\_BCLK and I2S\_WCLK the host must wait for 4 I2S\_BCLK period before enabling it again during a transition.

Remember to write to the PWREN bit to enable writing to the peripherals registers.

---

### 33.2.9 Interrupts and Events Support

The I2S module contains three event publishers and no event subscribers. One event publisher (CPU\_INT) manages I2S interrupt requests (IRQs) to the CPU subsystem through a static event route. The second and third event publishers (DMA\_TRIG\_RX, DMA\_TRIG\_TX) are used to setup the trigger signaling for the DMA through DMA event route.

The I2S events are summarized in [Table 33-8](#).

**Table 33-8. I2S Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
CPU interrupt	Publisher	I2S	CPU Subsystem	Static route	CPU_INT registers	Fixed interrupt route from I2S to CPU
DMA trigger	Publisher	I2S	DMA	DMA event route	DMA_TRIG_RX registers	Fixed interrupt route from I2S to DMA
DMA trigger	Publisher	I2S	DMA	DMA event route	DMA_TRIG_TX registers	Fixed interrupt route from I2S to DMA

#### 33.2.9.1 CPU Interrupt Event Publisher (CPU\_INT)

The I2S module provides 8 interrupt sources which can be configured to source a CPU interrupt event. In order of decreasing interrupt priority, the CPU interrupt events from the I2S are:

**Table 33-9. I2S CPU Interrupt Event Conditions (CPU\_INT)**

IIDX STAT	Name	Description
0x01	WCLKERR	Error interrupt when an unexpected I2Sx_WCLK edge occurs during the data delay period of a phase
0x02	RXIFG	I2S receive interrupt flag.
0x03	TXIFG	I2S transmit interrupt flag.
0x04	RXFIFO_OFV_EVT	RXFIFO overflow interrupt
0x05	TXFIFO_UNF_EVT	TXFIFO underflow interrupt
0x10	DMA_DONE_RX	This interrupt is set if the RX DMA channel sends the DONE signal.

**Table 33-9. I2S CPU Interrupt Event Conditions (CPU\_INT) (continued)**

IIDX STAT	Name	Description
0x11	DMA_DONE_TX	This interrupt is set if the TX DMA channel sends the DONE signal.

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers for CPU interrupts.

The receive interrupt (RXIFG, 0x02) changes state when one of the following events occurs:

- Receive interrupt is set when receive FIFO is greater than or equal to the programmed trigger level.
- Receive interrupt is cleared by reading data from the receive FIFO until it falls below the trigger threshold, by reading interrupt index (IIDX read) or by writing a 1 to the receive interrupt bit in ICLR.

Receive FIFO should be read till the number of entries in the receive FIFO falls below the programmed threshold in IFLS, to ensure that further interrupts are generated correctly.

The transmit interrupt (TXIFG, 0x03) changes state when one of the following events occurs:

- Transmit interrupt is set when transmit FIFO is less than or equal to programmed trigger level.
- Transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger threshold, by reading the interrupt index (IIDX read) or by writing a 1 to the transmit interrupt bit in ICLR.

Transmit FIFO should be filled till the number of entries in the FIFO crosses the programmed threshold in IFLS, to ensure that further interrupts are generated correctly.

### 33.2.9.2 DMA Trigger Publisher (DMA\_TRIG\_RX, DMA\_TRIG\_TX)

DMA\_TRIG\_RX and DMA\_TRIG\_TX registers are used to setup the trigger signaling for the DMA. This can be setup in a flexible way to trigger the DMA for receive or transmit events with the trigger conditions.

DMA\_TRIG\_RX is used for triggering the DMA to do a receive data transfer and DMA\_TRIG\_TX is used for triggering the DMA to do a transmit data transfer. The DMA trigger event configuration is managed with the DMA\_TRIG\_RX and DMA\_TRIG\_TX event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers and [Section 7.1.3.2](#) for on how the DMA trigger event works.

### 33.2.10 Emulation Modes

The module behavior while the device is in debug mode is controlled by the FREE and SOFT bits in PDBGCTL register. When the device is in debug mode and set into halt mode below behavior can be configured.

**Table 33-10. Debug Mode Peripheral Behavior**

PDBGCTL.FREE	PDBGCTL.SOFT	Function
1	X	Module continues operation
0	0	Reserved. Behavior is unpredictable
0	1	Module stops after the next transfer has finished

### 33.3 I2S Registers

Table 33-11 lists the memory-mapped registers for the I2S registers. All register offset addresses not listed in Table 33-11 should be considered as reserved locations and the register contents should not be modified.

**Table 33-11. I2S Registers**

Offset	Acronym	Register Name	Group	Section
800h	PWREN	Power enable		<a href="#">Go</a>
804h	RSTCTL	Reset Control		<a href="#">Go</a>
808h	CLKCFG	Peripheral Clock Configuration Register		<a href="#">Go</a>
814h	STAT	Status Register		<a href="#">Go</a>
1008h	PDBGCTL	Peripheral Debug Control		<a href="#">Go</a>
1020h	IIDX	Interrupt index		<a href="#">Go</a>
1028h	IMASK	Interrupt Mask Register Selects mask states of the flags in [IRQFLAGS.*] that contribute to the I2S_IRQ event.		<a href="#">Go</a>
1030h	RIS	This registers gives the raw interrupt status		<a href="#">Go</a>
1038h	MIS	This registers gives the raw interrupt status		<a href="#">Go</a>
1040h	ISSET	Interrupt Set Register. This register can be used by software for diagnostics and safety checking purposes.		<a href="#">Go</a>
1048h	ICLR	Interrupt clear register. This register allows software to clear interrupts.		<a href="#">Go</a>
1058h	IMASK	Interrupt mask	DMA_TRIG_RX	<a href="#">Go</a>
1060h	RIS	Raw interrupt status	DMA_TRIG_RX	<a href="#">Go</a>
1068h	MIS	Masked interrupt status	DMA_TRIG_RX	<a href="#">Go</a>
1070h	ISSET	Interrupt set	DMA_TRIG_RX	<a href="#">Go</a>
1088h	IMASK	Interrupt mask	DMA_TRIG_TX	<a href="#">Go</a>
1090h	RIS	Raw interrupt status	DMA_TRIG_TX	<a href="#">Go</a>
1098h	MIS	Masked interrupt status	DMA_TRIG_TX	<a href="#">Go</a>
10A0h	ISSET	Interrupt set	DMA_TRIG_TX	<a href="#">Go</a>
10E4h	INTCTL	Interrupt control register		<a href="#">Go</a>
1100h	FMTCFG	This register configures the serial interface format		<a href="#">Go</a>
1104h	CLKCTL	This register controls internal audio clock		<a href="#">Go</a>
1108h	STAT	Status Register		<a href="#">Go</a>
110Ch	IFLS	Interrupt FIFO Level Select Register		<a href="#">Go</a>
1110h	WCLKSRC	This register configures the WCLK Source		<a href="#">Go</a>
1118h	DIRCFG	This register configures the direction of data pins(AD0/AD1)		<a href="#">Go</a>
1120h	TXDATA	Transmit Data Register		<a href="#">Go</a>

**Table 33-11. I2S Registers (continued)**

Offset	Acronym	Register Name	Group	Section
1124h	RXDATA	Receive Data Register		<a href="#">Go</a>
1148h	WMASK0	This register configures the word selection mask for data pin 0(AD0)		<a href="#">Go</a>
114Ch	WMASK1	This register configures the word selection mask for data pin 1(AD1)		<a href="#">Go</a>
1160h	MCLKDIV	This field configures MCLK division ratio		<a href="#">Go</a>
1164h	WCLKDIV	Configures WCLK division ratio		<a href="#">Go</a>
1168h	BCLKDIV	This field configures BCLK division ratio		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 33-12](#) shows the codes that are used for access types in this section.

**Table 33-12. I2S Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WK	W K	Write Write protected by a key
Reset or Default Value		
-n		Value after reset or the default value

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1	SOFT	R/W	1h	Soft halt boundary control. This function is only available, if <a href="#">FREE</a> is set to 'STOP' 0h = The peripheral will halt immediately, even if the resultant state will result in corruption if the system is restarted 1h = The peripheral blocks the debug freeze until it has reached a boundary where it can resume without corruption
0	FREE	R/W	1h	Free run control 0h = The peripheral freezes functionality while the Core Halted input is asserted and resumes when it is de-asserted. 1h = The peripheral ignores the state of the Core Halted input

## 6 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 33-21](#) and described in [Table 33-18](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 33-21. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1-0	RESERVED	R	0h	

## 24 IFLS (Offset = 110Ch) [Reset = 0000022h]

IFLS is shown in [Figure 33-39](#) and described in [Table 33-36](#).

Return to the [Summary Table](#).

The IFLS register is the interrupt FIFO level select register. You can use this register to define the levels at which the TX, RX and timeout interrupt flags are triggered. The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered when the receive FIFO is filled with two or more characters. Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**29 WMASK0 (Offset = 1148h) [Reset = 0000000h]**

WMASK0 is shown in [Figure 33-44](#) and described in [Table 33-41](#).

Return to the [Summary Table](#).

This register configures the word selection mask for data pin 0(AD0)

**Figure 33-44. WMASK0**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MASK															
R-0h																R/W-0h															

**Table 33-70. WMASK0 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	MASK	R/W	3h	Bit-mask indicating valid channels in a frame on AD0. In single-phase mode, each bit represents one channel, starting with LSB for the first word in the frame. A frame can contain up to 8/16 channels based on SoC configuration. Channels that are not included in the mask will not be sampled nor stored in memory; data clocked out in these slots is as per configured EMPTY_SLOT_OUTPUT. In dual-phase mode, only the two LSBs are considered. For a stereo configuration, set both bits. For a mono configuration, set bit 0 only. In mono mode, only channel 0 will be sampled and stored to memory, and channel 0 will be repeated when clocked out. In mono mode, only channel 0 will be sampled and stored to memory, and channel 0 will be repeated in the second phase when clocked out. If all bits are zero, no input words will be stored to memory, and the output data lines will be constant '0'. This can be utilized when PWM debug output is desired without any actively used output pins.

### 30 WMASK1 (Offset = 114Ch) [Reset = 0000000h]

WMASK1 is shown in [Figure 33-45](#) and described in [Table 33-42](#).

Return to the [Summary Table](#).

This register configures the word selection mask for data pin 1(AD1)

**Figure 33-45. WMASK1**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Table 33-72. WMASK1 Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	MASK	R/W	3h	Bit-mask indicating valid channels in a frame on AD1. In single-phase mode, each bit represents one channel, starting with LSB for the first word in the frame. A frame can contain up to 8/16 channels based on SoC configuration. Channels that are not included in the mask will not be sampled nor stored in memory; data clocked out in these slots is as per configured EMPTY_SLOT_OUTPUT. In dual-phase mode, only the two LSBs are considered. For a stereo configuration, set both bits. For a mono configuration, set bit 0 only. In mono mode, only channel 0 will be sampled and stored to memory, and channel 0 will be repeated when clocked out. In mono mode, only channel 0 will be sampled and stored to memory, and channel 0 will be repeated in the second phase when clocked out. If all bits are zero, no input words will be stored to memory, and the output data lines will be constant '0'. This can be utilized when PWM debug output is desired without any actively used output pins.

**31 MCLKDIV (Offset = 1160h) [Reset = 0000000h]**

If BDIV is odd and <b>SMPLEDGE</b> = 0, the low phase of the clock is one MCUCLK period longer than the high phase. If BDIV is odd and <b>SMPLEDGE</b> = 1, the high phase of the clock is one MCUCLK period longer than the low phase.

The timer module (TIMx) is a timer counting module with multiple compare/capture blocks. Based on the device, two types of timers are available: general-purpose timers (TIMG) and advanced control timers (TIMA). Both timers include many common features that can be used for a variety of functions such as measuring the input signal edge and period (capture mode) or generating output waveforms like PWMs (compare mode output). See the device-specific data sheet to determine which timers and timer instances are available.

<b>34.1 TIMx Overview</b> .....	<b>2204</b>
<b>34.2 TIMx Operation</b> .....	<b>2207</b>
<b>34.3 TIMx Registers</b> .....	<b>2255</b>

## 34.1 TIMx Overview

The timer module (TIMx) is a timer counting module with multiple compare/capture blocks. Based on the device, two types of timers are available: general-purpose timers (TIMG) and advanced control timers (TIMA). Both timers use a common timer architecture, which allows for easy migration between timer instances with common functions. This minimizes the need to write extra software for timer-based applications and allows for easy porting and maintenance between TIMx instances.

---

### Note

See [Section 34.1.3](#) to determine the common features available between TIMG and TIMA instances.

---

In this section:

- "TIMx" indicates a common feature available on TIMG and TIMA.
- "TIMA" indicates a feature available only on TIMA.
- "TIMG" indicates a feature available only on TIMG.

### 34.1.1 TIMG Overview

The TIMG module consists of 16-bit and 32-bit auto reload counters driven by a programmable prescaler with up to 4 capture/compare (CC) blocks for multiple capture/compares, PWM outputs, and interval timing. TIMG also has extensive event generation capabilities, including counter overflow, reload, and capture/compare actions for a variety of use cases.

#### 34.1.1.1 TIMG Features

Specific features for TIMG include:

- 16-bit or 32-bit up, down, or up-down counter, with repeat-reload mode
- 8-bit programmable prescaler to divide the counter clock frequency
- Up to four independent channels for
  - Output compare
  - Input capture
  - PWM output (Edge-Aligned and Center-Aligned)
  - One-shot mode
- Selectable and configurable clock source
- Shadow register mode for load and compare values (see [Section 34.2.4](#) )
- Support for quadrature encoder interface (QEI) (see [Section 34.2.3.1.3](#) )
- 3-input Hall sensor mode for position sensing and speed computation (see [Section 34.2.3.1.4](#) )
- Support synchronization and cross trigger among different TIMx instances in the same power domain (see [Section 34.2.7](#) )
- Support CPU interrupt generation and cross peripherals (such as ADC, DAC, etc.) using the Event (see [Section 34.2.9](#) )

#### 34.1.1.2 Functional Block Diagram

[Figure 34-1](#) shows the TIMG block diagram.

(1) TIMG0-3 and TIMG8-12 do not have shadow load and compare registers  
 (2) Devices with comparator only  
 (3) TIMG8-TIMG11 support QE1 and Hall input mode  
 (4) Not supported on TIMG12 and TIMG13  
 (5) Generic event (GEN\_EVENTx) subscribers can be used to trigger any TIMx instance from any generic event publisher (GPIO, COMP, ADC, etc.)

Figure 34-1. TIMx Functional Block Diagram

### 34.1.2 TIMA Overview

The TIMA module consists of a 16-bit auto reload counter driven by a programmable prescaler with up to four capture/compare (CC) blocks for multiple capture/compares, PWM outputs with deadband insertion, and interval timing. TIMA has extensive event generation capabilities from different counter events such as overflow, reload, and each of the capture/compare events. It also has the hardware design to handle the fault signal generated by internal or external circuitry to indicate a fault in the system.

#### 34.1.2.1 TIMA Features

- 16-bit up, down, or up-down counter, with repeat-reload mode
- Selectable and configurable clock source
- 8-bit programmable prescaler to divide the counter clock frequency
- Repeat counter to generate an interrupt or event only after a given number of cycles of the counter (see [Section 34.2.1.2](#) )
- Up to four independent channels for:
  - Output compare
  - Input capture
  - PWM output (Edge-Aligned and Center-Aligned)
  - One-shot mode
- Two additional capture/compare channels for internal events (CC4/CC5)
- Shadow register for load and compare values (see [Section 34.2.4](#) )
- Complementary PWM output with programmable deadband insertion (see [Section 34.2.5.2.4](#) )
- Asymmetric PWM output (see [Section 34.2.2.5](#) )

- Fault handling mechanisms to ensure the output signals are in a safe user-defined state when a fault condition is encountered (see Section 34.2.6 )
- Support synchronization and cross trigger among different TIMx instances in the same power domain (see Section 34.2.7 )
- Support CPU interrupt generation and cross peripherals (such as ADC, DAC, etc.) using the Event (see Section 34.2.9 )

34.1.2.2 Functional Block Diagram

Figure 34-2 shows the TIMA block diagram.

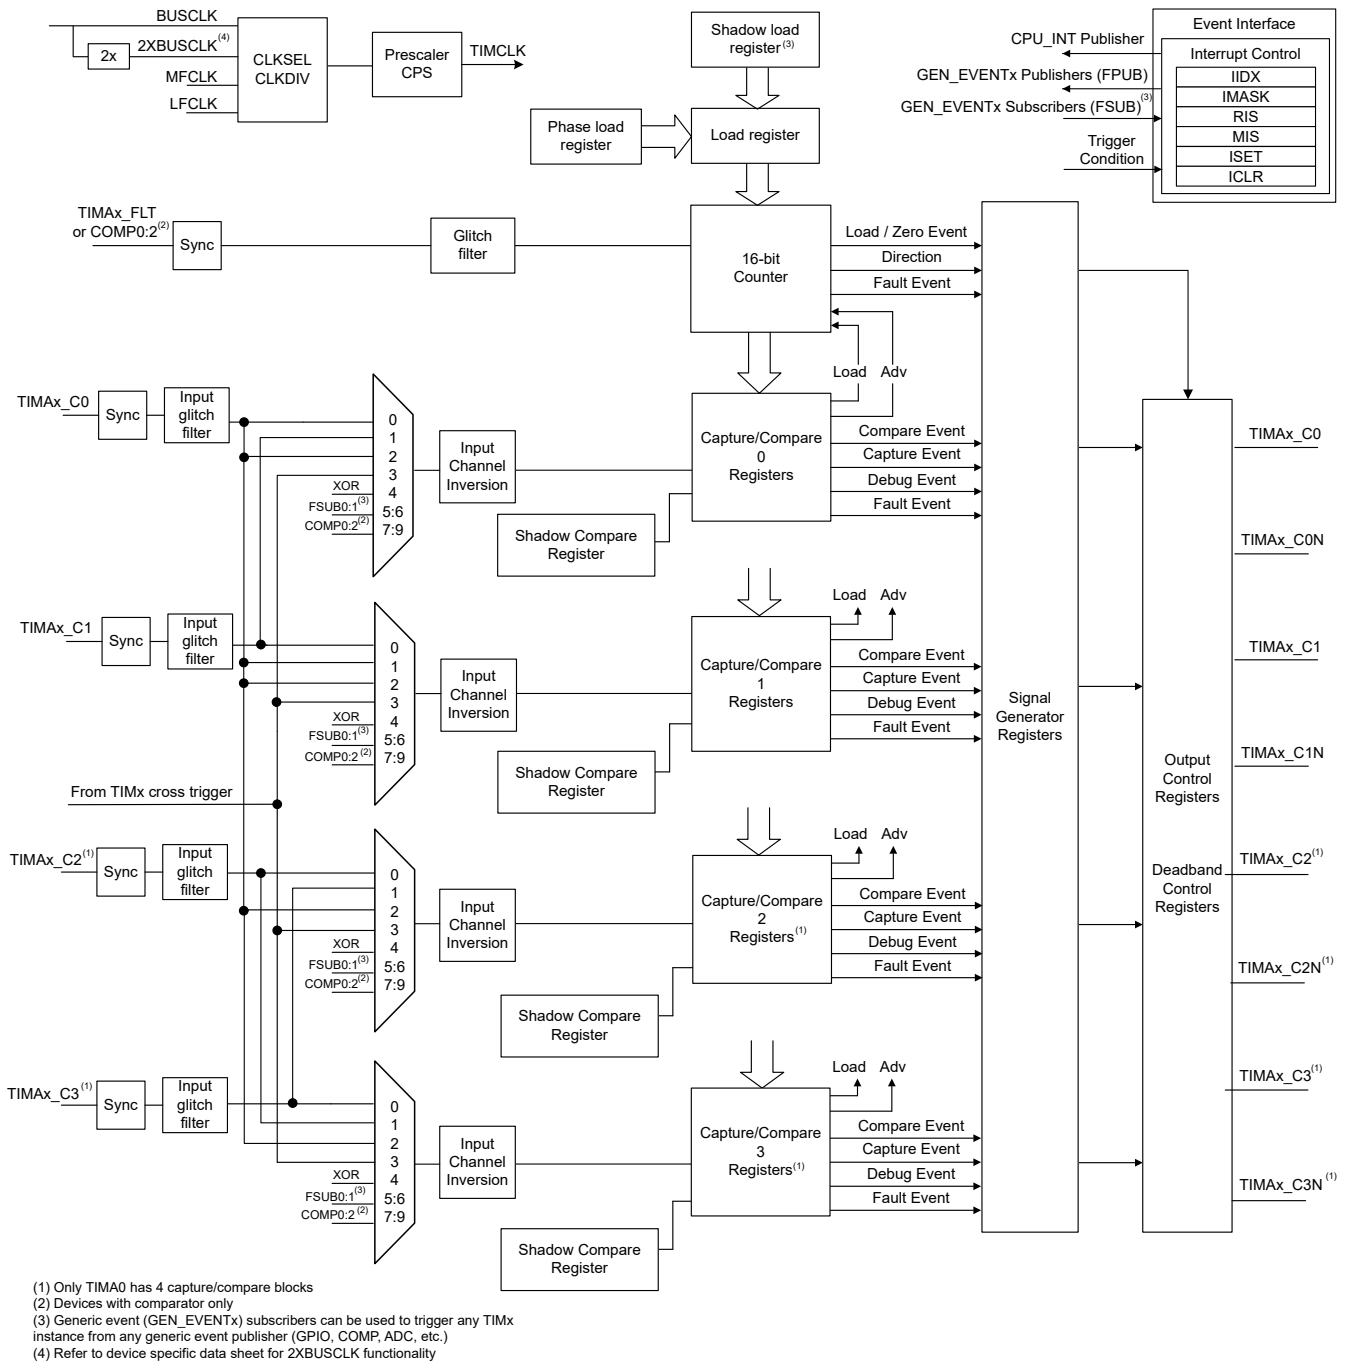

Figure 34-2. TIMA Block Diagram

### 34.1.3 TIMx Instance Configuration

Table 34-1 shows the TIMx instance configuration for TIMA and TIMG instances.

**Table 34-1. TIMx Instance Configuration**

Instance	Counter Resolution	Prescaler	Repeat Counter	CCP Channels (External/Internal)	External PWM Channels	Phase Load	Shadow Load	Shadow CCs	Deadband	Fault Handler	QEI / Hall Input Mode
TIMG0	16-bit	8-bit	-	2	2	-	-	-	-	-	-
TIMG1	16-bit	8-bit	-	2	2	-	-	-	-	-	-
TIMG2	16-bit	8-bit	-	2	2	-	-	-	-	-	-
TIMG3	16-bit	8-bit	-	2	2	-	-	-	-	-	-
TIMG4	16-bit	8-bit	-	2	2	-	Yes	Yes	-	-	-
TIMG5	16-bit	8-bit	-	2	2	-	Yes	Yes	-	-	-
TIMG6	16-bit	8-bit	-	2	2	-	Yes	Yes	-	-	-
TIMG7	16-bit	8-bit	-	2	2	-	Yes	Yes	-	-	-
TIMG8	16-bit	8-bit	-	2	2	-	-	-	-	-	Yes
TIMG9	16-bit	8-bit	-	2	2	-	-	-	-	-	Yes
TIMG10	16-bit	8-bit	-	2	2	-	-	-	-	-	Yes
TIMG11	16-bit	8-bit	-	2	2	-	-	-	-	-	Yes
TIMG12	32-bit	-	-	2	2	-	-	Yes	-	-	-
TIMG13	32-bit	-	-	2	2	-	-	Yes	-	-	-
TIMG14	16-bit	8-bit	-	4	4	-	-	-	-	-	-
TIMA0	16-bit	8-bit	Yes	4/2	8	Yes	Yes	Yes	Yes	Yes	-
TIMA1	16-bit	8-bit	Yes	2/2	4	Yes	Yes	Yes	Yes	Yes	-

---

#### Note

On TIMA instances, external PWM channels are pairs of complementary PWM output signals with deadband generation with respect to the CC block instance, such as TIMA0\_C0 and TIMA0\_C0N. For independent PWM output generation, separate noninverting channels must be used, such as TIMA0\_C0 and TIMA0\_C1.

---

---

#### Note

Internal CC channels 4 and 5 (CC\_45) can be used for internal compare events and are available in TIMA only.

---

---

#### Note

Look at the device-specific data sheet to check which TIMx instances are available on the device and their respective power domains

---

## 34.2 TIMx Operation

The TIMx module is configured with user software. The setup and operation of TIMx is discussed in the following sections.

---

#### Note

There are register arrays in the timer module to group registers with same bit fields for different capture/compare ports. For example, TIMx.CC\_01[0/1] is a register array that contains the capture/compare registers for both CCP0 and CCP1. Access TIMx.CC\_01[0] to read the CC0 capture/compare value, and access TIMx.CC\_01[1] to read the CC1 capture/compare value.

---

---

### Note

TIMx supports event subscribers and event publishers through event register arrays. For more information, please see the Events chapter.

---

#### 34.2.1 Timer Counter

All TIMx instances have 16-bit counter blocks except for TIMG12 and TIMG13, which have 32-bit counter blocks. The timer counter register (TIMx.CTR) can count down, up-and-down, or up depending on the operation mode. It can also be read or written with software. Each count occurs with each rising edge of the TIMCLK signal or with both edges of external signals.

#### Enabling the TIMx Counter

The counter is clocked by the prescaler output TIMCLK. The counter enable bit TIMx.CTRCTL.EN can be enabled in two ways:

- Set in software manually
- After a load condition (LCOND) or zero condition (ZCOND) is met, and the counter value after enable (CVAE) is changed to the load value or zero value, respectively.

---

### Note

The ability to write the counter register while TIMx is running is possible but should be avoided because the user write can collide with a load, zero, or advance event. Depending on the prescaler ratio, the application cannot predict the timing of the write, which can affect the correct timer period.

---

#### 34.2.1.1 Clock Source Select and Prescaler

The TIMx clock (TIMCLK) can be sourced from an internal clock or an external signal trigger to advance the clock.

##### 34.2.1.1.1 Internal Clock and Prescaler

The TIMx clock (TIMCLK) can be sourced from BUSCLK, MFCLK and LFCLK by setting the TIMx.CLKSEL register. It can also be divided by a ratio by setting the TIMx.CLKDIV register and a prescaler (if present). The selected source clock is always available and the frequency depends on the power mode. For more information, see the *Clock Module (CKM)* section.

The TIMCLK can come from the following sources and refer to the datasheet for the clock availability as per the power domain:

- BUSCLK: the current bus clock is selected as the source for TIMx. The current bus clock depends on power domain.
  - If the TIMx instance is in Power Domain 1 (PD1), refer to MCLK.
  - If the TIMx instance is in Power Domain 0 (PD0), refer to ULPCCLK.
- MFCLK: MFCLK is selected as the source for TIMx, refer to MFCLK.
- LFCLK: LFCLK is selected as the source for TIMx, refer to LFCLK.

The selected clock source can be passed directly to TIMx or divided by the 8-bit prescaler. The prescaler setting can be configured with register TIMx.CPS.PCNT bit. The selected TIMCLK source is divided by a value of (PCNT+1). A PCNT value of 0 divides TIMCLK by 1, effectively bypassing the divider. A PCNT value of greater than 0 divides the TIMCLK source to generate a slower clock.

TIMx also has a software mechanism for disabling the timer clock. Set TIMx.CCLKCTL.CLKEN to 0 to put the timer in an IDLE state.

#### TIMCLK Configuration

To configure the clock source, divider, and prescaler:

1. Select the TIMCLK clock source (BUSCLK, MFCLK, or LFCLK) using the CLKSEL register.

2. Optionally divide the TIMCLK using CLKDIV.RATIO.
3. In TIMx instances with prescalers, optionally set a prescaler using CPS.PCNT.
4. Enable the TIMCLK by setting CCLKCTL.CLKEN = 1.

The frequency of TIMCLK is determined using [Equation 35](#).

$$f_{TIMCLK} = \frac{f_{CLK\_SOURCE}}{((CLKDIV.RATIO + 1) * (CPS.PCNT + 1))} \quad (35)$$

#### 34.2.1.1.2 External Signal Trigger

The counter can also advance (increment or decrement) by using an external signal on the timer input pin or by triggering from an event from other peripherals in the system. This can be configured by using the advance condition setting (TIMx.CCCTL\_xy[0/1].ACOND) to specify what creates the advance event. To specify what event advances the counter, use the TIMx.CTRCTL.CAC setting.

The counter can advance using the internal clock TIMCLK, a different edge of a timer external input, or an internal trigger event from other peripherals.

#### 34.2.1.2 Repeat Counter (TIMA only)

In TIMA only, the repeat counter (RC) is an 8-bit counter that provides the mechanism to suppress unnecessary events and generate real events for interrupt generation. Specifically, the repeat counter can suppress Load, Compare, and Zero events in the case where the timer is generating events that repeat for a known number of cycles, such a periodic PWM output waveform. This prevents generating excessive and unnecessary interrupts every timer period.

When the timer counter (TIMA.CTR) is advancing, the repeat counter (TIMA.RC) advances when the counter reloads (TIMA.CTR = 0). Software can set the how many timer counter reloads occur until generating the interrupts and events by setting the TIMA.RCLD register. When TIMA.RC = TIMA.RCLD, the repeat counter is reset back to zero and a Repeat Counter Zero event occurs (REPC) in the Interrupt and Event Status registers.

#### Note

If software configures the counter to stop counting in a debug or fault condition, also stop the repeat counter. See [Section 34.2.6](#) and [Section 34.2.10](#) for more details.

Additionally, the repeat counter provides the ability to suppress generation of Zero, Load, and Compare events when TIMA.RC does not equal zero.

- Zero and Load events are suppressed by setting TIMA.CTRCTL.SLZERCNEZ register bit
- Compare events (see [Table 34-15](#)) are suppressed by setting the TIMA.CCCTL\_xy[0/1].SCERCNEZ bit

[Table 34-2](#) shows the repeat counter behavior with respect to the timer counter and repeat counter load value.

**Table 34-2. Repeat Counter Behavior**

TIMA.CTR is Advancing (+1)	Counter value	TIMA.RC = TIMA.RCLD	Repeat Counter Behavior	Suppress Load and Zero Events (SLZERCNEZ = 1)	Suppress Compare Events (SCERCNEZ = 1)
No	-	-	Does not advance	Yes	Yes
Yes	TIMA.CTR ≠ 0	-	Does not advance	Yes	Yes
Yes	TIMA.CTR = 0	No	Advance (+1)	Yes	Yes
Yes	TIMA.CTR = 0	Yes	TIMA.RC = 0	No	No

#### Repeat counter example

As shown in [Figure 34-3](#), the TIMA.CTR is configured for down-counting mode and zero events are generated once TIMA.CTR = 0. To suppress interrupt generation until 4 timer reloads occur, set TIMA.RCLD = 4 and TIMA.CTRCTL.SLZERCNEZ = 1 to suppress zero and load events until RC = 0 (which occurs once TIMA.RC = TIMA.RCLD).

**Note**

The use of the repeat counter does not affect the output signal generation. All events are generated regardless of the repeat counter value sent to the signal generator unit.

**Figure 34-3. Event Suppressed by Repeat Counter with TIMx.RCLD = 4 in Down Counting Mode**

**34.2.2 Counting Mode Control**

When the device is out of reset, TIMx is disabled. Writing 1 to the TIMx.CTRCTL.EN bit enables the counter. This bit is automatically cleared if TIMx.CTRCTL.REPEAT=0 (do not automatically reload), and the counter value equals zero.

TIMx has three counting modes when enabled: down, up/down, and up. The operating mode is selected by TIMx.CTRCTL.CM bit (shown in Table 34-3). After the counter is enabled, the timer will start counting from the TIMx.CTRCTL.CVAE setting.

**Table 34-3. TIMx Counting Modes (CM)**

TIMx.CTRCTL.CM	Counting Mode
0	Down
1	Up/Down
2	Up

**Table 34-4. TIMx Counter Value after Enable (CVAE)**

Count Value After Enable (CVAE)	Description	Supported Counting Modes
0	LOAD value	Up, up/down, down
1	Unchanged from current value	Up/down
2	Zero value	Up, up/down, down

### 34.2.2.1 One-shot and Periodic Modes

Figure 34-4 shows TIMx working in both one-shot mode and periodic mode.

#### One-shot Mode

When TIMx.CTRCTL.REPEAT bit is set to 0, TIMx does not advance when:

- TIMx.CTR value reaches 0 in either down- or up/down-counting mode
- TIMx.CTR value reaches TIMx.LOAD in up-counting mode

#### Periodic Mode (Counter Reload)

When TIMx.CTRCTL.REPEAT is set to 1h, TIMx automatically repeats once a zero event occurs. This happens when:

- TIMx.CTR reaches 0 in either down- or up/down-counting mode
  - In down-counting mode, a zero event is followed by a load event at the next advance condition
  - In up/down-counting mode, a zero event is followed by an advance event (+1)
- TIMx.CTR reaches TIMx.LOAD in up-counting mode
  - A load event is followed by a zero at the next advance condition

TIMx.CTRCTL.REPEAT can also be set to 3h for TIMx to repeat only when not in a debug condition. If there is a debug condition, TIMx will count to the zero event and repeat only once the debug condition is removed.

Figure 34-4. One-shot and Periodic Mode Behavior

### 34.2.2.2 Down Counting Mode

In down counting mode (CM = 0), TIMx counts from the value defined in TIMx.LOAD (CVAE = 0) down to zero. When the TIMx.CTR value equals zero and TIMx.CTRCTL.REPEAT is set to 1, the TIMx.LOAD value is loaded into TIMx.CTR and the timer repeats the down counting pattern as shown in [Figure 34-5](#).

A Zero event is generated when TIMx counts to zero. A Load event is generated when TIMx counts from zero to the TIMx.LOAD value. Figure 34-6 shows the event generating cycle.

Figure 34-5. Down Counting Mode, CVAE = 0

Figure 34-6. Down Counting Mode Event Generation

### 34.2.2.3 Up/Down Counting Mode

The Up/Down counting mode can count in an down-up direction or an up-down direction depending on TIMx.CTRCTL.CVAE value. The TIMx.CTRCTL.CVAE bits specify the initialization condition of the counter.

Table 34-5. Counter Value after Enable Initialization Conditions

TIMx.CTRCTL.CVAE Value	Counter Value After Enable
0x0	Load Value
0x1	No Change
0x2	Zero

### Counting in down-up direction

When TIMx.CTRCTL.CVAE = 0, TIMx.CTR is set to TIMx.LOAD register value and TIMx counts in the down direction. When it reaches zero, a Zero event is generated and TIMx counts back up to TIMx.LOAD value. A Load event is generated when it reaches TIMx.LOAD value.

Figure 34-7 shows TIMx counting in the down-up direction when TIMx.CTRCTL.CVAE = 0.

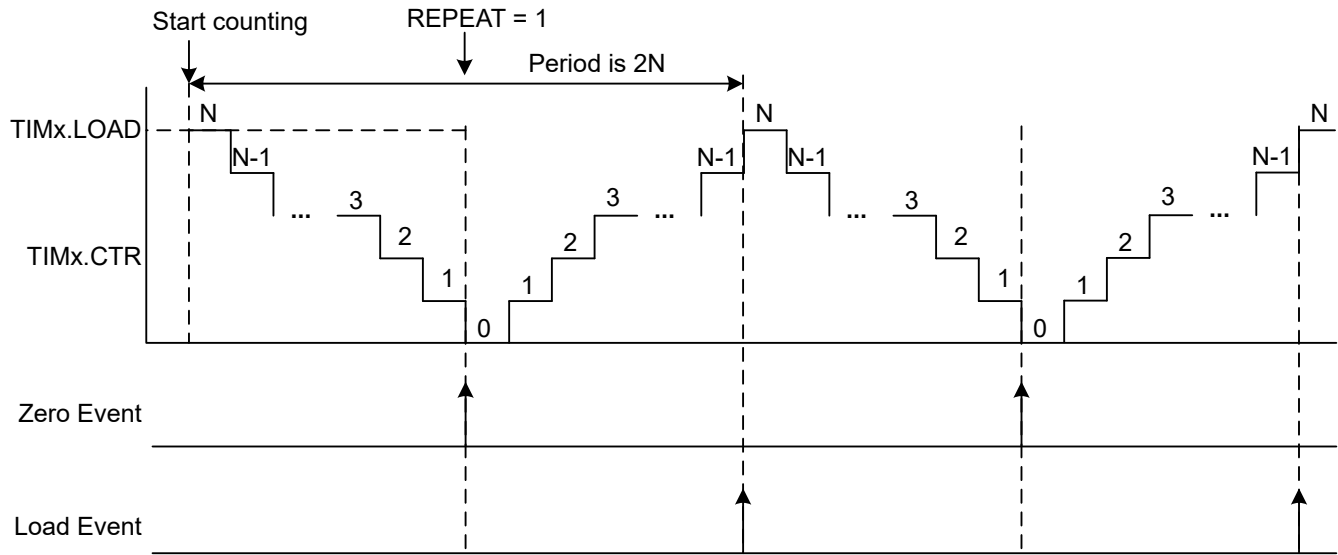

Figure 34-7. Down-up Counting Mode and Event Generation, CVAE = 0

### Counting in up-down direction

When  $TIMx.CTRCTL.CVAE = 2$ ,  $TIMx.CTR$  is set to zero and  $TIMx$  counts in the up direction. When it reaches  $TIMx.LOAD$ , a Load event is generated and  $TIMx$  counts back down to zero. A Zero event is generated when it reaches zero.

Figure 34-8 shows  $TIMx$  counting in up-down direction when  $TIMx.CTRCTL.CVAE = 2$ .

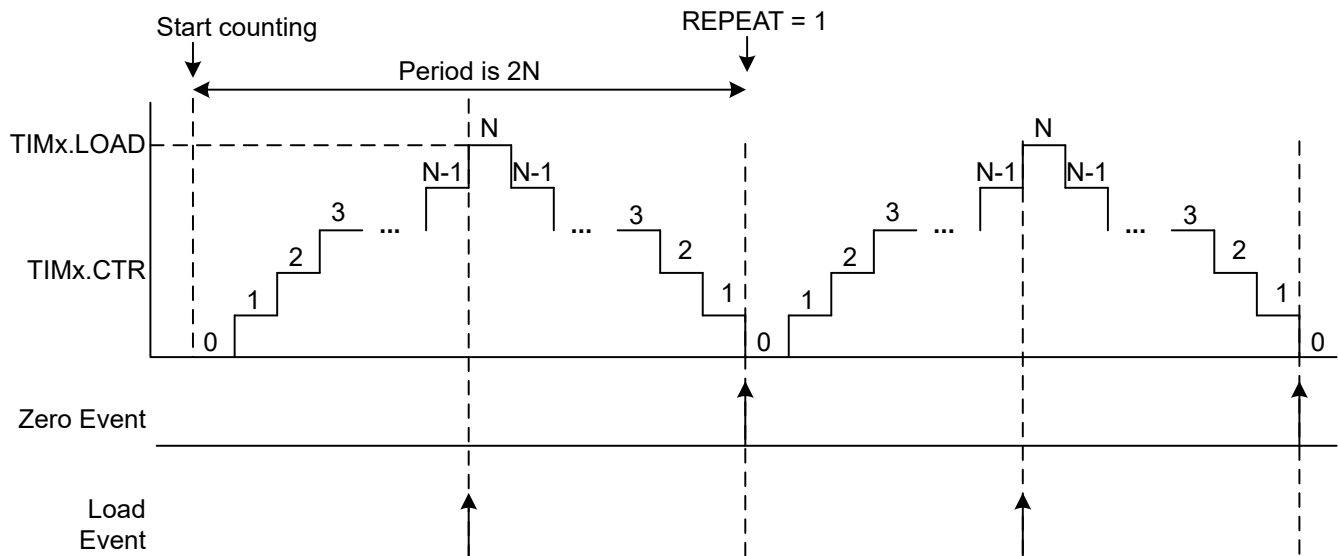

Figure 34-8. Up-down Counting Mode and Event Generation, CVAE = 2

#### 34.2.2.4 Up Counting Mode

In up counting mode,  $TIMx$  counts from zero up to the value defined in  $TIMx.LOAD$ . When the  $TIMx.CTR$  value equals  $TIMx.LOAD$  and  $TIMx.CTRCTL.REPEAT$  is not equal to 0, the zero is loaded into  $TIMx.CTR$  and the timer repeats the up counting pattern as shown in Figure 34-5.

A Load event is generated when  $TIMx$  counts to  $TIMx.LOAD$ . A Zero event is generated when  $TIMx$  counts from  $TIMx.LOAD$  to the zero value. Figure 34-6 shows the event generating cycle.

Figure 34-9. Up Counting Mode, CVAE = 2

Figure 34-10. Up Counting Mode Event Generation

### 34.2.2.5 Phase Load (TIMA only)

In TIMA only, the phase load register TIMA.PL provides the capability for TIMA.CTR to count from a value other than zero or TIMA.LOAD in Up/Down counting mode. Phase load is used to generate asymmetric center-aligned PWM output signals with a controlled phase shift between different timer instances.

When TIMA.PL is nonzero, phase load is enabled by setting TIMA.CTRCTL.PLEN = 1 and triggered when TIMA.CTTRIG.TRIG = 1. When phase load is triggered while TIMA.CTRCTL.CVAE = 0, the timer counts from the TIMA.PL value in the down direction. When phase load is triggered while TIMA.CTRCTL.CVAE = 1, the TIMx counts from the TIMA.PL value in the up direction.

TIMA.PL is latched when the timer starts, and TIMA.PL is synchronized every time when the counter reaches the previously latched TIMA.PL value. [Figure 34-11](#) shows how the phase load register works when the timer is counting in the up-down direction and the phase load value changes to a new value.

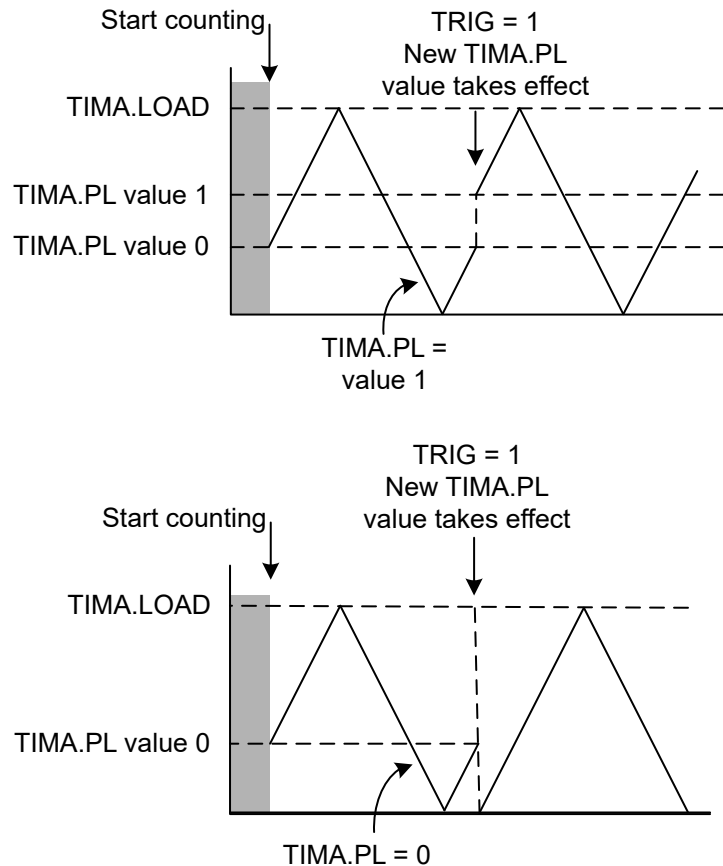

Figure 34-11. Phase Load Register Synchronization in Up-Down Mode

### 34.2.3 Capture/Compare Module

The capture/compare (CC) block is used for capture events or compare events. TIMG has up to 2 identical capture/compare blocks and TIMA has up to 4 identical capture/compare blocks present to support external or internal signals. Additionally, TIMA provides 2 additional CC blocks (CC4 and CC5) for compare events only from internal signals. Any of the TIMx capture/compare blocks may be used to capture timings of an input signal or to generate time intervals.

#### 34.2.3.1 Capture Mode

Capture mode is selected when the TIMx.CCCTL\_xy[0/1].COC bit is set to 1. Capture mode is used to generate capture events and record time intervals, which is useful for speed computation or time measurements.

Key registers for configuring capture mode:

- **TIMx.LOAD**: the contents of this register are copied to counter (TIMx.CTR) on any operation designated to do a "load". This value is also used to compare with the counter value for generating a "Load Event" which can be used for interrupt, trigger, or signal generation actions.
- **TIMx.CC\_xy[0/1]**: this is a register that can be used as either a capture register to acquire or record the next counter value on an event, or a compare register to the current counter to create an event.
- **TIMx.CCCTL\_xy[0/1]**: this register controls the operations of the respective CC (capture/compare) blocks. In capture mode, it can configure whether a rising edge or falling edge generates a load, zero, advance, or capture condition. In compare mode, it controls which sources generate different types of compare events.
- **TIMx.CTRCTL**: this register provides control over the counter operation in different conditions.
- **TIMx.IFCTL\_xy[0/1]**: this register controls the input filtering (FE, FP, CPV), selection (ISEL), and inversion (INV) for the associated CC block.

### 34.2.3.1.1 Input Selection, Counter Conditions, and Inversion

The TIMx.IFCTL register is used for selecting input source, filtering, and final inversion options for the capture/compare block.

Figure 34-12 shows the block diagram for the TIMx capture block with two CC channels.

Figure 34-12. TIMx Capture Block Diagram

#### 34.2.3.1.1.1 CCP Input Edge Synchronization

When using a capture/compare pin (CCP) as an input, configure the pin control management register (PINCMx) for the TIMx CCP input. Refer to the device data sheet for TIMx CCP pinmux input options, such as TIMG0\_C0.

The CCP input signal is always passed through a synchronizer, and the input state (high or low) must be greater than one TIMCLK clock period for the synchronizer to detect the edge. CCP input edge detection requires at least one TIMCLK cycle to synchronize the edge input. Timing in the first TIMCLK cycle is uncertain because the edge detection cannot be predicted in the first TIMCLK period.

When the capture condition occurs, an additional TIMCLK cycle is required to generate the capture event.

#### 34.2.3.1.1.2 CCP Input Pulse Conditions

The TIMx.CCCTL\_xy[0/1] register can control whether each timer instance generates a zero, load, capture, or advance pulse based on the edge or polarity of the CCP input signal or trigger edge. The conditions that can be generated are:

- Advance condition (ACOND)
- Load condition (LCOND)
- Zero condition (ZCOND)
- Capture condition (CCOND)

#### Advance conditions

By default, the timer advances based on each TIMCLK. (ACOND = 0h). However, the timer can also advance based off the specified TIMx.CCCTL\_xy[0/1].ACOND settings below.

**Table 34-6. Advance pulse condition settings (ACOND)**

ACOND	Condition
0h	Each TIMCLK
1h	Rising edge of CCP or trigger assertion edge
2h	Falling edge of CCP or trigger de-assertion edge
3h	Either edge of CCP or trigger
5h	CCP high or trigger assertion

### Load, zero, and capture conditions

Load, zero, and capture pulses can be generated the LCOND, ZCOND, and CCOND condition settings below in the TIMx.CCCTL\_xy[0/1] register.

**Table 34-7. Load, zero, and capture condition settings (LCOND, ZCOND, CCOND)**

LCOND	ZCOND	CCOND	Condition
N/A	N/A	0h	None
1h	1h	1h	Rising edge of CCP or trigger assertion edge
2h	2h	2h	Falling edge of CCP or trigger de-assertion edge
3h	3h	3h	Either edge of CCP or trigger

#### 34.2.3.1.1.3 Counter Control Operation

To specify what CC instance controls the load, zero, or advance event, the CZC, CAC, and CLC fields are used for configuration in the TIMx.CTRCTL register.

See [Table 34-8](#) for counter zero control settings. For example, if a timer triggers a ZCOND event in Channel 1, then CZC should be set to 1h to register that a ZCOND event in channel 1 triggers the zero event.

**Table 34-8. Counter Zero Control (CZC) settings**

TIMx.CTRCTL.CZC	Setting
0h	Channel 0 ZCOND event zeroes the TIMx instance
1h	Channel 1 ZCOND event zeroes the TIMx instance
2h	Channel 2 ZCOND event zeroes the TIMx instance (4 CC timer only)
3h	Channel 3 ZCOND event zeroes the TIMx instance (4 CC timer only)
4h	2-input QEI mode. See <a href="#">Section 34.2.3.1.3</a>
5h	3-input QEI mode. See <a href="#">Section 34.2.3.1.3</a>

See [Table 34-9](#) for counter load control settings. For example, if a timer triggers a LCOND event in Channel 2, then CLC should be set to 2h to register that a LCOND event in channel 2 triggers the load event.

**Table 34-9. Counter Load Control (CLC) settings**

TIMx.CTRCTL.CLC	Setting
0h	Channel 0 LCOND event loads the TIMx instance
1h	Channel 1 LCOND event loads the TIMx instance
2h	Channel 2 LCOND event loads the TIMx instance (4 CC timer only)
3h	Channel 3 LCOND event loads the TIMx instance (4 CC timer only)
4h	2-input QEI mode. See <a href="#">Section 34.2.3.1.3</a>
5h	3-input QEI mode. See <a href="#">Section 34.2.3.1.3</a>

See [Table 34-10](#) for counter advance control settings. For example, if a timer triggers a ACOND event in Channel 3, then CAC should be set to 3h to register that a ACOND event in channel 3 triggers the advance event.

**Table 34-10. Counter Advance Control (CAC) settings**

TIMx.CTRCTL.CAC	Setting
0h	Channel 0 ACOND event advances the TIMx instance
1h	Channel 1 ACOND event advances the TIMx instance
2h	Channel 2 ACOND event advances the TIMx instance (4 CC timer only)
3h	Channel 3 ACOND event advances the TIMx instance (4 CC timer only)
4h	2-input QEI mode. See <a href="#">Section 34.2.3.1.3</a>
5h	3-input QEI mode. See <a href="#">Section 34.2.3.1.3</a>

**34.2.3.1.1.4 CCP Input Filtering**

The input glitch filter can be enabled by setting the TIMx. IFCTL\_01[0/1].FE bit. The filter period is configured by setting the TIMx. IFCTL\_01[0/1].FP bit.

A consecutive period or majority voting format selected by the TIMx.IFCTL\_xy[0/1].CPV bit is used to select the criteria for a CCP input signal.

- **Consecutive period** - The CCP input signal must be at the specified level for the defined number of FP timer clocks for the CCP input to be processed.
- **Majority voting** - The filter ignores one clock of opposite logic over the filter period. For example, over the number of FP samples of the input, up to 1 sample can be of an opposite logic value (glitch) without affecting the output.

The example shown in [Figure 34-13](#) shows the difference between consecutive period and majority voting formats with a digital filter implemented to capture a CCP input signal of 3 TIMCLK periods.

**Figure 34-13. Consecutive Period and Majority Voting for Input Glitch Filtering using FP = 0 (3 TIMCLK cycles)**

### 34.2.3.1.1.5 Input Selection

The input select bits TIMx.IFCTL\_xy[0/1].ISEL select the input source to the filter input as the corresponding CCP input, CCP0 for cross-triggering across CC blocks, an external trigger, XOR (used in Hall input mode), event subscribers, or comparator inputs.

**Table 34-11. Input Selection Options for TIMx CC Instances**

Input selection (TIMx.IFCTL_xy[0/1].ISEL)	Source
0h	TIMx CCP of the corresponding capture compare unit
1h	Input pair CCPx of the capture compare unit. [CCP0/CCP1, CCP2/CCP3]
2h	TIMx CCP0
3h	Cross trigger signal
4h	XOR of CCP inputs. Used in Hall input mode. See <a href="#">Section 34.2.3.1.4</a>
5h	Subscriber event 0 (FSUB0). See <a href="#">Section 34.2.9.2</a>
6h	Subscriber event 1 (FSUB1). See <a href="#">Section 34.2.9.2</a>
7h	COMP0_OUT (devices with comparator only)
8h	COMP1_OUT (devices with comparator only)
9h	COMP2_OUT (devices with comparator only)

### 34.2.3.1.2 Use Cases

Several different use cases can be achieved in capture mode and are discussed in the following sections.

#### 34.2.3.1.2.1 Edge Time Capture

Edge time capture measures the time (in TIMCLK cycles) from the start of the capture operation to the signal edge. The counter is loaded when TIMx is enabled and counts with each TIMCLK period until the CCP edge is detected, which triggers the capture of the timer value and generates a capture event. The capture edge time is equivalent to the difference between the starting value of the counter and the capture value in TIMx.CC\_xy[0/1] register.

#### Edge Time Capture Configuration

- Set the TIMx.LOAD value.
- In the CTRCTL register, set the desired counter control settings for:
  - Counting mode (CM) and counter value after enable (CVAE) (see as described in [Section 34.2.2](#))
  - Zero (CZC), advance (CAC), and load control (CLC) to specify what condition controls zeroing, advancing, or loading the counter
  - Repeat or one-shot mode (REPEAT)
- Set TIMx.CCCTL\_xy[0/1].COC = 1 for capture mode.
- Configure CCP as an input for the CC block by setting respective bit in the CCPD registers. For instance, if TIMx Channel 0 is an input, set CCPD.C0CCP0 = 0.
- For the corresponding CC block control register (CCCTL\_01[0/1]), set CCOND to the corresponding setting to capture events based off the input signal condition (rising and/or falling edge). Additionally, set ZCOND or LCOND depending on the counting mode used.
- Configure input capture settings in the TIMx.IFCTL\_xy[0/1] register as described in [Section 34.2.3.1.1](#).
- Enable the counter by setting EN = 1 or waiting for a capture event to occur from the input edge.

#### Example using up-counting mode for rising edge capture

In up-counting mode starting from zero (CM = 2, CVAE = 2), TIMx can be configured to generate a zero pulse and start the counter from the configured capture event (CCOND) by setting ZCOND to 1.

The expected internal timing for a rising or positive edge time capture in up-counting mode is shown in [Figure 34-14](#).

Figure 34-14. Edge Time Capture Mode in Up-Counting Mode, CVAE = 2

#### 34.2.3.1.2.2 Period Capture

Period capture measures the period of a signal on an input CCP in TIMCLK cycles. On each positive (or negative) edge of the CCP input, the TIMx.CTR value is both captured into the TIMx.CC register to generate a capture event. The period capture time is equivalent to the difference between the starting value of the counter generated to the capture event, or time between reoccurring capture events for a periodic input signal.

#### Period Capture Configuration

1. Set the TIMx.LOAD value.
2. In the CTRCTL register, set the desired counter control settings for:
  - a. Counting mode (CM) and counter value after enable (CVAE) (see as described in [Section 34.2.2](#))
  - b. Advance (CAC) to specify what condition controls advancing the counter
  - c. Repeat or one-shot mode (REPEAT)
3. Set TIMx.CCCTL\_xy[0/1].COC = 1 for capture mode.
4. Configure CCP as an input for the CC block by setting respective bit in the CCPD registers. For instance, if TIMx Channel 0 is an input, set CCPD.C0CCP0 = 0.
5. For the corresponding CC block control register (CCCTL\_01[0/1]),
  - a. Set CCOND to the corresponding setting to capture events based off the input signal condition (rising and/or falling edge)
  - b. Set ZCOND or LCOND depending on the counting mode used
6. Configure input capture settings in the TIMx.IFCTL\_xy[0/1] register as described in [Section 34.2.3.1.1](#).
7. Enable the counter by setting EN = 1 or waiting for a capture event to occur from the input edge.

#### Example using up-counting mode for rising-edge period capture

In up-counting mode starting from zero ( $CM = 2$ ,  $CVAE = 2$ ), TIMx channel 0 can be configured to generate a capture event from a rising edge input by setting  $CCOND = 1h$ . After enabling the counter, when a rising edge input is detected, the counter will capture the counter value in  $TIMx.CC$ . After the capture event, set the  $TIMx.LOAD$  value back to 0 to reset the timer counter for the periodic CCP input signal.

The expected internal timing for a period capture in up-counting mode using two rising edges is shown in [Figure 34-14](#).

**Figure 34-15. Period Capture Mode in Up-Counting Mode,  $CVAE = 2$**

#### 34.2.3.1.2.3 Pulse Width Capture

Pulse width capture measures the high-time of a signal on CCP. The high time is the number of TIMCLK periods from rising edge to falling edge of the CCP input, and is useful for applications such as measuring the duty cycle of an PWM input signal. The counter is loaded at the positive edge and captured at the negative edge (capture event is generated).

#### Pulse-Width Capture Configuration

1. Set the  $TIMx.LOAD$  value.
2. In the  $CTRCTL$  register, set the desired counter control settings for:
  - a. Counting mode ( $CM$ ) and counter value after enable ( $CVAE$ ) (see as described in [Section 34.2.2](#))
  - b. Zero ( $CZC$ ), advance ( $CAC$ ), and load control ( $CLC$ ) to specify what condition controls zeroing, advancing, or loading the counter
  - c. Repeat or one-shot mode ( $REPEAT$ )
3. Set  $TIMx.CCCTL_{xy}[0/1].COC = 1$  for capture mode.
4. Configure CCP as an input for the CC block by setting respective bit in the  $CCPD$  registers. For instance, if TIMx Channel 0 is an input, set  $CCPD.C0CCP0 = 0$ .
5. For the corresponding CC block control register ( $CCCTL_{01}[0/1]$ ), set  $CCOND$  to the corresponding setting to capture events based off the input signal condition (rising and/or falling edge). Additionally, set  $ZCOND$  or  $LCOND$  depending on the counting mode used.
6. Configure input capture settings in the  $TIMx.IFCTL_{xy}[0/1]$  register as described in [Section 34.2.3.1.1](#).

7. Enable the counter by setting EN = 1 or waiting for a capture event to occur from the input edge.

### Example using up-counting mode for pulse width capture

In up-counting mode starting from zero (CM = 2, CVAE = 2), TIMx channel 0 can be configured to generate a zero pulse and start the counter from the configured capture event (CCOND) by setting ZCOND to 1. To start the counter, a load condition can be triggered from the CCP rising edge input by setting LCOND = 1.

The expected internal timing for a pulse width capture in up-counting mode using a rising and falling edge is shown in Figure 34-14.

**Figure 34-16. Pulse-Width Capture Mode**

#### 34.2.3.1.2.4 Combined Pulse Width and Period Time

Using two capture registers can combine pulse-width and period capture of a single input waveform. The input signal can be externally connected to CCP channel 0, and the IFCTL\_01[1] register can be configured to have the input connected to CCP channel 1 internally so capture register 0 (TIMx.CC0) captures pulse width and capture register 1 (TIMx.CC1) captures period. The expected internal timing for combined pulse-width and period capture is shown in Figure 34-17.

### Pulse-Width and Period Capture Configuration

1. Set the TIMx.LOAD value.
2. In the CTRCTL register, set the desired counter control settings for:
  - a. Counting mode (CM) and counter value after enable (CVAE) (see as described in Section 34.2.2)
  - b. Zero (CZC), advance (CAC), and load control (CLC) to specify what condition controls zeroing, advancing, or loading the counter
  - c. Repeat or one-shot mode (REPEAT)
3. Set TIMx.CCCTL\_xy[0/1].COC = 1 for capture mode for each CC channel.
4. Configure CCP as an input for each CC block by setting respective bits in the CCPD register. For instance, if TIMx Channel 0 is an input, set CCPD.C0CCP0 = 0.
5. For the corresponding CC block control register (CCCTL\_01[0/1]),

- a. Set CCOND to the corresponding setting to capture events based off the input signal condition (rising and/or falling edge)
  - b. Set ZCOND or LCOND depending on the counting mode used.
6. Configure input capture settings in the TIMx.IFCTL\_xy[0/1] register as described in [Section 34.2.3.1.1](#).
  7. Enable the counter by setting EN = 1 or waiting for a capture event to occur from the input edge.

### Example using pulse-width and period time capture

In up counting mode, TIMx can be configured to generate a zero pulse and start the counter from the configured capture event (CCOND) by setting ZCOND to 1.

The expected internal timing for a pulse-width and period capture in up-counting mode using two CC blocks is shown in [Figure 34-14](#).

**Figure 34-17. Combined Pulse-Width and Period Capture**

#### 34.2.3.1.3 QEI Mode (TIMG with QEI support only)

In TIMGx instances with QEI support, Quadrature Encoder Interface (QEI) mode provides an interface to the output of a quadrature encoder. It decodes the quadrature encoded data to provide the information on the relative positioning and movement of a linear or rotary motion.

The QEI consists of two Gray coded quadrature input signals PHA and PHB, and an index input signal IDX. All input signals go to CCP inputs of a single counter, such that PHA and PHB are mapped to CCP0 and CCP1, and IDX is brought in as a separate input. An error detection mechanism can report erroneous transitions to avoid improper signal decodings.

#### Note

See [Section 34.1.3](#) and the device-specific data sheet for TIMG instances that support QEI / Hall Input Mode.

34.2.3.1.3.1 QEI With 2-Signal

QEI is used to decode signals from optical position encoders. Optical position encoders typically output 2 signals (PHA/PHB) which are often used to measure rotary or linear movement of physical items with rotating shafts, such as 3-phase motors. The measurement provided by the interface is incremental, which means as movement occurs, the interface provides the ability to capture the relative change from the previous position.

When operating in QEI mode, a counter accumulates the incremental updates, deriving current position from initial position and the accumulated change. The initial position can be determined by the signal of the IDX input (3-signal QEI mode) or by other software means (software directly setting the initial position). The capture and compare register can be used to store the position value by defining a capture condition.

When a direction change (DC) occurs, a DC interrupt is generated in the RIS register.

Figure 34-18 shows the state machine in the QEI interface to detect the directional rotation from the two CCP input signals, PHA and PHB.

Figure 34-18. State Machine for 2-signal and 3-signal QEI mode

QEI 2-Signal Mode Configuration

1. Configure PINCMx for TIMGx\_C0 (PHA) and TIMGx\_C1 (PHB).
2. Set TIMG.CCCTL\_01[0].COC = 1 and TIMG.CCCTL\_01[1].COC = 1 for capture mode for both CCP channels 0 and 1 (PHA and PHB).
3. Configure CCP as an input for each CC block by setting respective bits in the CCPD register. For instance, if TIMx Channel 0 is an input, set CCPD.C0CCP0 = 0.
4. Set the TIMx.LOAD to the encoder resolution, such as 4000.
5. In the CTRCTL register, set the CAC, CZC, and CLC bits to 4h.
6. Configure input capture settings as described in Section 34.2.3.1.1, if desired.
7. Enable the counter to start counting by setting EN = 1.

Example using QEI mode with 2 input signals

The behavior of PHA/PHB follows Table 34-12 and Figure 34-19.

Table 34-12. PHA/PHB State Table and Counter Actions

Current State (PHA, PHB)	Next State (PHA, PHB)	Direction (DIR)	Counter Action
00	10	1 (Up)	+1 (If TIMx.CTR = LOAD, then CTR = 0)
10	11		
11	01		
01	00		
00	01	0 (Down)	-1 (If TIMx.CTR = 0, then CTR = TIMx.LOAD)
01	11		
11	10		
10	00		

Figure 34-19. 2-Signal QEI Operation

34.2.3.1.3.2 QEI With Index Input

3-signal QEI mode is similar to the 2-signal mode with additional index input signal IDX. Generally, IDX input pulses once per rotation which can be used to reset the counter. It is used in one of two applications:

- One IDX pulse is generated each movement cycle. In this case, the accumulated position represents the fraction of the movement cycle.
- An IDX pulse is generated at a specific position in a noncyclic movement.

QEI 3-Signal Mode Configuration

1. Configure PINCMx for TIMGx\_C0 (PHA), TIMGx\_C1 (PHB), and TIMGx\_IDX (IDX).
2. Set TIMG.CCCTL\_01[0].COC = 1 and TIMG.CCCTL\_01[1].COC = 1 for capture mode for both CCP channels 0 and 1 (PHA and PHB).
3. Configure CCP as an input for each CC block by setting respective bits in the CCPD register. For instance, if TIMx Channel 0 is an input, set CCPD.C0CCP0 = 0.
4. Set the TIMx.LOAD value to the encoder resolution, such as 4000.
5. In the CTRCTL register, set the CAC, CZC, and CLC bits to 5h.
6. Configure input capture settings as described in Section 34.2.3.1.1, if desired.
7. Enable the counter to start counting by setting EN = 1.

The IDX input is sampled when a rising edge is detected. The IDX signal affects the counter value depending on the direction as shown in Table 34-13 and

Table 34-13. Relation of IDX Input and Counter Value

Direction (DIR)	IDX	Counter Action
1	Rising	Zero (TIMx.CTR is set to zero)
0	Rising	Load (TIMx.CTR is set to TIMx.LOAD)

Figure 34-20. 2-Signal QEI with Index Input Operation

34.2.3.1.3.3 QEI Error Detection

The QEI module can detect erroneous transactions or state errors as shown in Figure 34-18. A QEIERR interrupt is generated and the counter or direction signal does not change in the error state.

Note

QEIERR can occur if the TIMCLK period is slower than the period of the PHA or PHB signals.

34.2.3.1.4 Hall Input Mode (TIMG with QEI support only)

In TIMGx instances with QEI support, three digital Hall signals can be input into CCP channel 0 (CCP0), CCP channel input 1 (CCP1), and IDX for position control of 3-phase Hall-sensored motor applications. Hall signals are used to detect real-time motor position in motor control applications and can be used for speed computation measurements, position control, or motor stall status.

Note

See Section 34.1.3 and the device-specific data sheet for TIMG instances that support QEI / Hall Input Mode.

Table 34-14 shows the signal mapping for Hall signals A (U), B (V), and C (W) to TIMG capture/compare input signals.

Table 34-14. Hall Input and TIMx Input Signal Mapping

Hall input signal	TIMx input
HALL A / HALL U	CCP0
HALL B / HALL V	CCP1
HALL C / HALL W	IDX

Note

Hall input signals should be digital inputs from Hall sensor ICs with a pullup to VCC.

As shown in Figure 34-21, the input capture module provides a 3-input XOR of synced CCP0, CCP1, and IDX signals to create a frequency generator (FG) signal. The XOR output signal is selected when IFCTL\_xy[0/1].ISEL is set to 4h. See Figure 34-21 for XOR option in the input capture block diagram.

**Figure 34-21. Hall 3-input XOR for Frequency Generator (FG) Signal to CC input block**

The XOR'ed output signal is propagated to the CC block and a period or pulse-width capture can be used to compute the linear motor speed in relation to the calculated period or pulse width in the TIMx.CC register. See Section 34.2.3.1.2.2 and Section 34.2.3.1.2.3 on how to calculate period and pulse-width captures based on the XOR'ed input signal.

Figure 34-22 shows the input signal to the CC block which can be used for speed calculations.

**Figure 34-22. Hall 3-Input XOR Signal used with Pulse Width or Period Capture for Speed Computation**

### Hall Input Mode Configuration

1. Configure PINCMx for TIMGx\_C0 (HALLA), TIMGx\_C1 (HALLB), and TIMGx\_IDX (HALLC).
2. Set TIMG.CCCTL\_01[0].COC = 1 and TIMG.CCCTL\_01[1].COC = 1 for capture mode for both CCP channels 0 and 1 (HALLA and HALLB).
3. Configure CCP as an input for each CC block by setting respective bits in the CCPD register. For instance, if TIMx Channel 0 is an input, set CCPD.C0CCP0 = 0.
4. Set the TIMx.LOAD value.
5. Set TIMG.IFCTL\_xy[0/1].ISEL = 4h to select the XOR option for Hall signals.
6. Enable the counter to start counting by setting EN = 1.

### 34.2.3.2 Compare Mode

Compare mode is selected when TIMx.CCCTL\_xy[0/1].COC = 0. Compare mode is used to generate a compare event to output PWM output signals at specific time intervals. Compare events can be used to generate a timing base internally or generate a PWM output with specific profiles using active, inactive, or toggle action behaviors, and optional deadband insertion.

Many types of compare mode events can be generated based on the configuration of the CC action register CCACT\_xy[0/1]:

- Compare events: occurs for a CC channel when TIMx.CTR counts up (CCU) or down (CCD) to the value in TIMx.CC\_xy[0/1]
- Secondary compare events: occurs when a secondary CCx block compare up (CC2U) or down (CC2D) is configured for another CCx block's CCU event or CCD event, respectively. This enables more flexible output generation from other external events such as comparator outputs or fault signals. It can be useful for real-time control applications, like digital power or motor control.

In TIMA only, an additional internal 5th and 6th CC block (TIMA.CC\_45[0/1]) can be used for internal secondary compare events while continuing to use CC channels with dedicated output pins for external PWM signal generation.

Table 34-15 shows the types of compare mode events that can be generated and conditions to generate the events.

**Table 34-15. Compare Mode Events**

Event	Name	Event Condition
CCDn (n = CC channel)	Capture/compare down event	When timer is counting down, TIMx.CTR = TIMx.CC_xy[0/1]
CCUn (n = CC channel)	Capture/compare up event	When timer is counting up, TIMx.CTR = TIMx.CC_xy[0/1]
CC2Dn (n = CC channel)	Secondary capture/compare down event	Occurs when CC2SELD is configured for the source of the CCDn event
CC2Un (n = CC channel)	Secondary capture/compare up event	Occurs when CC2SELU is configured for the source of the CCUn event

#### Note

Look at the device specific data sheet to check how many CC channels are available in each TIMx instance on the device.

#### 34.2.3.2.1 Edge Count

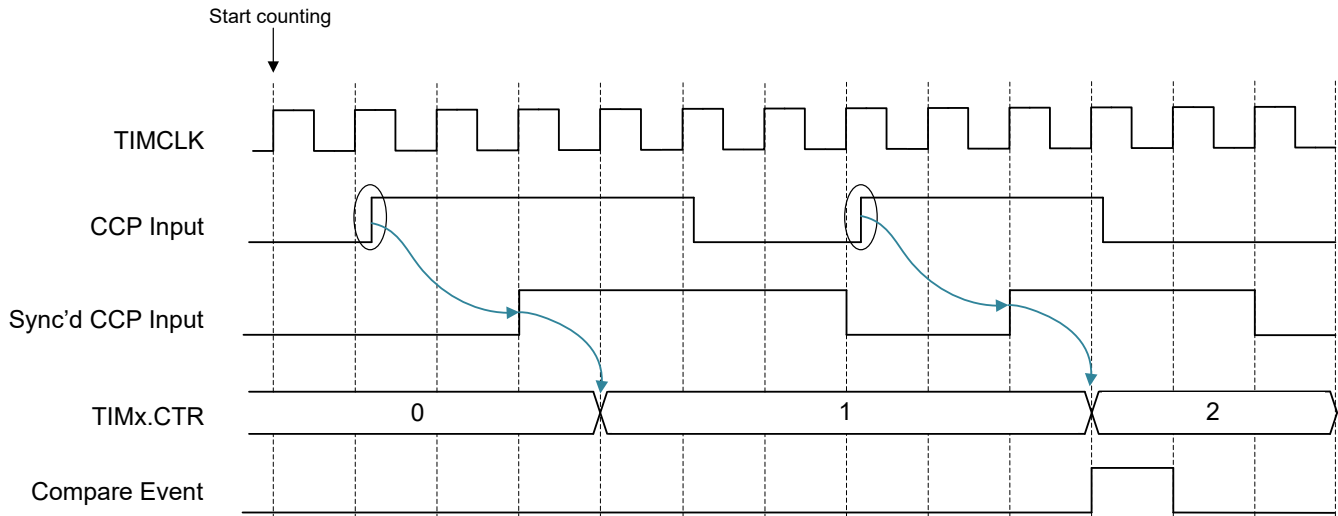

In addition to event or PWM output generation, compare mode can also be used for input signal edge counting to determine when a number of edges has been detected. In edge count operation, a CCP input edge can advance the counter based on the ACOND condition. The counter register is initialized with the starting value, and the number of detected CCP input edges at any time can increment or decrement depending on the counting mode configuration. The user can count rising edges, falling edges, or both edges by configuring the CCOND value.

#### Edge Count Configuration

1. Set TIMx.CCCTL\_xy[0/1].COC = 0 for compare mode.
2. Optionally set the corresponding TIMx.CC\_xy[0/1] to a compare value to generate a compare interrupt when the counter reaches this value.
3. In the CTRCTL register, set the desired counter control settings for:
  - a. Counting mode (CM) and counter value after enable (CVAE) (see as described in [Section 34.2.2](#))
  - b. Zero (CZC), advance (CAC), and load control (CLC) to specify what condition controls zeroing, advancing, or loading the counter
  - c. Repeat or one-shot mode (REPEAT)
4. Set ACOND to a setting to advance the counter based on the input edge polarity.
5. Configure input capture settings as described in [Section 34.2.3.1.1](#), if desired.
6. Enable the counter by setting EN = 1.

#### Example using edge count operation using up-counting mode

In up-counting mode starting from zero (CM = 2, CVAE = 2), the expected internal timing for rising edge count operation to increment the counter is shown in [Figure 34-23](#).

**Figure 34-23. Edge Count Operation to Generate Compare Event (TIMx.CC = 2)**

#### 34.2.4 Shadow Load and Shadow Compare

Some timer modules have a shadow load and shadow compare register feature which gives the user the flexibility of holding the update of load and CC values until a certain event occurs. This is useful in timing-critical applications where PWM control signals need to be updated with correct timings, such as duty cycle updates. Refer to the timer features for specific configurations of the TIMx modules.

##### Note

See [Section 34.1.3](#) and the device-specific data sheet for TIMx instances that support Shadow Load and Shadow Compare.

##### 34.2.4.1 Shadow Load (TIMG4-7, TIMA only)

On shadow-load capable timers, the shadow load feature allows holding the update of load values until a zero event occurs. To enable shadow loading, set the TIMx.GCTL.SHDWLDEN bit while the timer is enabled (EN = 1).

If the TIMx module has a shadow load feature, there is an internal shadow register for the load value (TIMx.LOAD). The shadow register will update the load value at a zero event as shown in [Figure 34-24](#).

##### Note

On shadow-load capable timers, SHDWLDEN must be set or else the load value will not update.

If the timer instance does not have shadow load capability (standard timer), the load value will update immediately when TIMx.LOAD is written to.

Shadow-load capable timers update the load value from the internal shadow register when:

- TIMx.CTRCTL.EN = 1
- GCTL.SHDWLDEN = 1
- Available for TIMG4-7, TIMAx

Standard timers update the load value from TIMx.LOAD immediately when:

- TIMx.CTRCTL.EN = 1
- Available for TIMG0-3, TIMG8-14

**Figure 34-24. Load value updates for TIMx instances when EN=1**

**Note**

To update the load value for shadow load capable timers, the timer must be disabled before changing the TIMx.LOAD value.

When TIMx.GCTL.SHDWLDEN = 1, load values update at zero events for all counting modes. Consult the counting mode operations below to determine if a shadow load is needed:

- In down-counting modes, since TIMx.LOAD value is updated when a zero event occurs, a shadow load is not needed in these modes.
- In up/down counting mode, TIMx.LOAD is compared with the counter value to determine if the peak is reached and when to start to counting down. A shadow load is necessary to ensure that TIMx counts up to the load value before the zero event, or else the load value can update immediately and cause incorrect timings.
- In up-counting mode, the timer counts to TIMx.LOAD. A shadow load is necessary to ensure that TIMx counts up to the load value before the zero event, or else the load value can update immediately and cause incorrect timings.

Figure 34-25 shows an example of how shadow load and shadow compare takes effect at the zero event for both the TIMx.LOAD and TIMx.CC value in up/down counting mode.

**34.2.4.2 Shadow Compare (TIMG4-7, TIMG12-13, TIMA only)**

When shadow compare is enabled for updating the capture/compare register (TIMx.CC), the value written to the respective compare register is first stored into a shadow compare register and then transferred to the compare register at different events configured by setting the TIMx.CCCTL\_xy[0/1].CCUPD bits.

Additionally, the capture/compare action register (TIMx.CCACT) has the ability to update the action at different events configured by setting the TIMx.CCCTL\_xy[0/1].CCACTION bits.

Table 34-16 shows the settings for configuring when shadow compare and actions occur at different events.

**Table 34-16. Shadow Compare and Action Update Behavior**

Bit Field	Value	Description/Comment
CCUPD / CCACTUPD	0	The value written to TIMx.CC register take effect immediately.
	1	The value written to the TIMx.CC register is stored in a shadow compare register and gets transferred to the TIMx.CC register in the TIMCLK cycle following a zero event (TIMx.CTR value equals 0).
	2	The value written to the TIMx.CC register is stored in a shadow compare register and gets transferred to the TIMx.CC register in the TIMCLK cycle following a compare (down) event (TIMx.CTR value equals TIMx.CC)
	3	The value written to the TIMx.CC register is stored in a shadow compare register and gets transferred to the TIMx.CC register in the TIMCLK cycle following a compare (up) event (TIMx.CTR value equals TIMx.CC)
	4	The value written to the TIMx.CC register is stored in a shadow compare register and gets transferred to the TIMx.CC register in the TIMCLK cycle following a zero or load event (TIMx.CTR value equals 0 or TIMx.CTR equals TIMx.LOAD). <b>Note: this update mechanism is defined for use only in up/down counting mode.</b>
	5	The value written to the TIMx.CC register is stored in a shadow compare register and gets transferred to the TIMx.CC register in the TIMCLK cycle following a zero event and the repeat count equaling zero (TIMx.CTR value equals 0 and TIMx.RC equals 0)
	6	The value written to the TIMx.CC register is stored in a shadow compare register, and gets transferred to the TIMx.CC register in the TIMCLK cycle following a trigger pulse. See <a href="#">Section 34.2.7</a> .

Figure 34-25 shows an example of how shadow load and shadow compare takes effect at the zero event for both the TIMx.LOAD and TIMx.CC value in up/down counting mode.

TIMx.GCTL.SHDWLDEN = 1

TIMx.CCCTL\_xy[0/1].CCUPD = 1h (update CC register after zero event)

**Figure 34-25. Shadow Load and Shadow Compare Taking Effect at Zero Event in Up/Down Mode**

### 34.2.5 Output Generator

The output signal generation unit can be used with the counter and capture/compare modules to generate desired pulse-width modulation (PWM) output waveforms, event signals, synchronized capture inputs, or the counter direction. Many output waveforms are generated from counter events (load, zero, counter direction) and the capture/compare block (compare match).

TIMA and TIMG have many common features in the output generation signal unit. Additionally, TIMA has advanced output generation features such as complimentary output signals, deadband insertion, and fault generation.

Figure 34-27 shows the TIMG output block diagram.

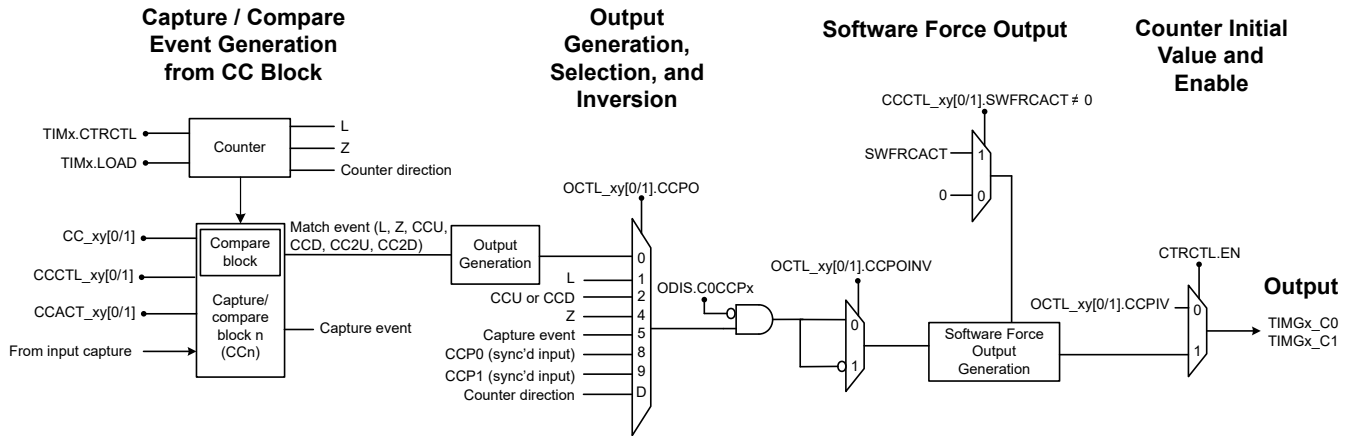

Figure 34-26. Output Connection for TIMG

Figure 34-27 shows the TIMA output block diagram.

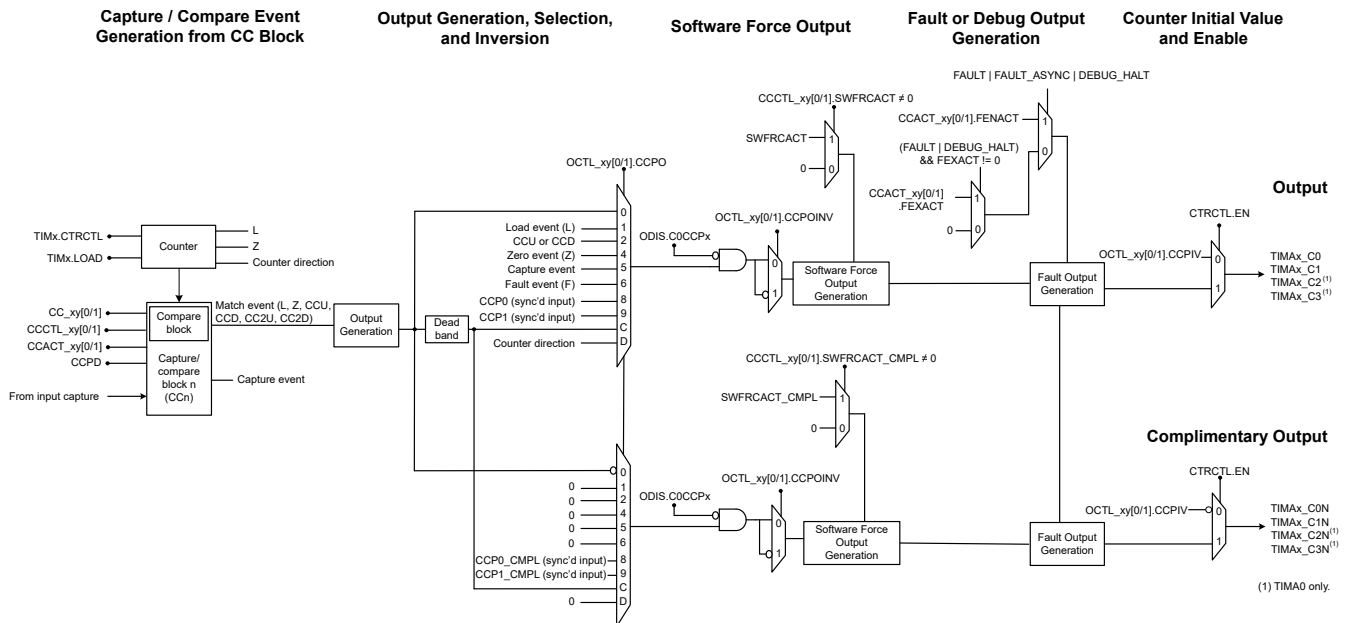

Figure 34-27. Output Connection for TIMA

### Signal Generator Actions

Table 34-17 shows the types of signal generator actions capable by the output generator. Signal generator actions are configured in the CCACT\_xy[0/1] register for zero, load, and compare events. For types of compare events, see Table 34-15.

**Table 34-17. Signal Generator Actions from Compare Event**

Value	Action
0h	Event is disabled and a lower priority event is selected if asserting
1h	CCP output value is set high
2h	CCP output value is set low
3h	CCP output value is toggled

The key registers for generation of output signals are:

- **LOAD**: the contents of this register are copied to the counter (TIMx.CTR) on any operation designated to do a "load". This value is also used to compare with the counter value for generating a "Load Event" that can be used for interrupt, trigger, or signal generator actions.
- **CCPD**: this register configures the direction of the CCP pins as inputs or outputs.
- **CC\_xy[0/1]**: this is a register used as a compare value to the current counter to create a match event.
- **CTRCTL**: this register provides control over the counter operation in different conditions.
- **CCCTL\_xy[0/1]**: this register controls the operations of the respective CC registers and the counter
- **OCTL\_xy[0/1]**: this register controls the output of the capture-compare portion of the counter. This includes the ability to select the source of what is driven out along with initial condition values and final inversion options.
- **CCACT\_xy[0/1]**: this register controls the actions of the signal generator of the capture-compare portion based on the events created in the counter block, the capture and compare block, and debug events.
- **ODIS**: this register disables the output signal selected by OCTL.CCPO (before conditional inversion) to allow software the ability to hold the CCP output low during configuration or shutdown.

These are key registers for configuring the compare mode to generate PWM signals:

#### 34.2.5.1 Configuration

There are five stages to configuring output signal generation in TIMx devices:

- Counter and CC Block Event Generation
- Output Generation, Selection and Inversion
- Software Force Output
- Fault Output Generation (TIMA only)
- Counter Initial Value and Enable

#### Counter and CC Block Event Generation

The counter block contains the counter and produces a load event (L), zero event (Z), and direction of counting based on the counting mode used.

The CC blocks contain the CC register and can generate two types of output signals: compare match events and capture events. Please see Table 34-15 for the compare events that can be generated.

#### Output Generation, Selection and Inversion

The TIMx.CCACT register specifies the waveform generation of a CCP output depending on the counting mode and counter compare actions.

TIMx.OCTL\_xy[0/1].CCPO controls the CCP output selection from the output generation unit, output generation unit with deadband (TIMA only), counter events, compare events, capture events, fault events, or signal inputs.

The output disable register (ODIS) can optionally disable the CCP output to optionally hold the CCP output low during configuration or shutdown. TIMx.OCTL\_xy[0/1].INV controls final inversion options.

---

#### Note

Mux selections for synchronized inputs are tied to 0 for TIMAx CC2 and CC3 instances. Do not use TIMAx.OCTL\_23[0/1].CCPO = 8 or 9.

---

On TIMA devices only, CCP complimentary output channels can be generated from the output generation unit (denoted by "N" in the signal name). For instance, TIMA0 channel 2 (TIMA0\_C2) can also produce a complimentary output (TIMA0\_C2N). The CCPO and INV bits also controls the selection and inversion options for the complementary output.

Complimentary outputs with deadband insertion are a common use case for inverter-based applications with half-bridge topologies. For more information, please see [Section 34.2.5.2.4](#).

### Software Force Output

The output of the signal generator can be overwritten in software by setting CCCTL\_xy[0/1].SWFRCACT to a nonzero setting. For TIMA devices only, the complementary output of the signal generator can be overwritten by setting CCCTL\_xy[0/1].SWFRCACT\_CMPL to a nonzero setting.

For more information, see [Section 34.2.5.3](#).

### Fault / Debug Output Generation (TIMA only)

On TIMA devices, the CCP output can be overwritten after the software force output block if there is a system fault (FAULT), fault condition upon exit (FEXACT), fault condition upon entry (FENACT), an asynchronous fault (FAULT\_ASYNC), or the debugger is halted (DEBUG\_HALT).

For more information, see [Section 34.2.6](#) and [Section 34.2.10](#).

### Counter Compare Initial Value and Enable

To specify an initial value for the CCP output while the counter is disabled, set OCTL\_xy[0/1].CCPIV to 0 for a low value or 1 for a high value. This is useful for applications where CCP outputs need to be in a default state before enabling the counter.

To enable the counter, set TIMx.CTRCTL.EN to 1.

#### 34.2.5.2 Use Cases

Several different use cases can be achieved with the output generator and are discussed in the following sections.

##### 34.2.5.2.1 Edge-Aligned PWM

To generate edge-aligned PWMs, TIMx can be configured for up- or down-counting mode and the PWM period in TIMCLK cycles is TIMx.LOAD + 1. The waveform uses load, zero, and compare events to drive the CCPx output high or low depending on the configuration settings of the compare/capture block and counter.

### Edge-Aligned PWM Configuration

To generate edge-aligned PWMs using compare match events from the counter:

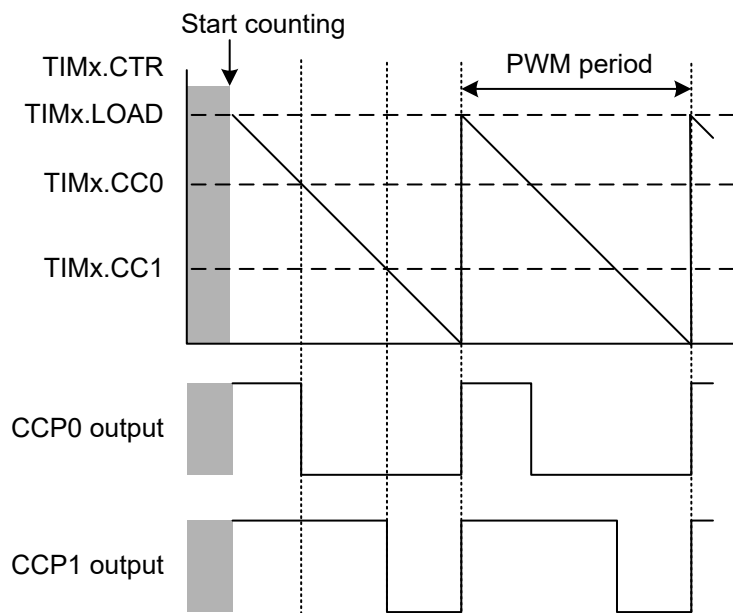

- In the TIMx.CTRCTL register, set the desired counter control settings for:
  - Up-counting (CM = 2) or down-counting mode (CM = 0) and counter value after enable (CVAE) (see as described in [Section 34.2.2](#))
  - Zero (CZC), advance (CAC), and load control (CLC) to specify what condition controls zeroing, advancing, or loading the counter
  - Repeat or one-shot mode (REPEAT)
- Set the TIMx.LOAD value to configure the PWM period.
- Set the TIMx.CC\_xy[0/1] value to configure the duty cycle.

4. Set `TIMx.CCCTL_xy[0/1].COC = 1` for compare mode.
5. Configure CCP as an output for the CC block by setting respective bit in the CCPD registers. For instance, if TIMx Channel 0 is an output, set `CCPD.C0CCP0 = 1`.
6. In `TIMx.CCACT_xy[0/1]`, set the CCP output action settings for compare events, zero events, load events, software force action, or fault events (TIMA only).
7. In `TIMx.OCTL_xy[0/1]`, set `CCPO = 0` to select the signal generator output.
8. Enable the corresponding CCP output by setting `ODIS.C0CCPn` to 1 for the corresponding counter n.
9. Configure polarity of the signal using the `CCPOINV` bit, and configure `CCPIV` to specify the CCP output state while disabled.
10. Enable the counter by setting `TIMx.CTRCTL.EN = 1`.

### Example using edge-aligned PWM in down-counting mode

A typical 2-channel edge-aligned PWM generation for down-counting mode is shown in Figure 34-28 with the following edge-aligned PWM output waveforms:

- CCP0 output generates:
  - High pulse-width from `TIMx.LOAD` to `TIMx.CC0` value ( $LACT = 1h$ )
  - Low pulse-width from `TIMx.CC0` value to zero ( $CDACT = 2h$ )
- CCP1 output generates:
  - High pulse-width from `TIMx.LOAD` to `TIMx.CC1` value ( $LACT = 1h$ )
  - Low pulse-width from `TIMx.CC1` value to zero ( $CDACT = 2h$ )

**Figure 34-28. Edge-Aligned PWM Signals in Down-Counting Mode**

### Example using edge-aligned PWM in up-counting mode

A typical 2-channel edge-aligned PWM generation for up-counting mode is shown in Figure 34-28 with the following edge-aligned PWM output waveforms:

- CCP0 output generates:
  - High pulse-width from zero to `TIMx.CC0` value ( $ZACT = 1h$ )
  - Low pulse-width from `TIMx.CC0` value to `TIMx.LOAD` ( $CUACT = 2h$ )
- CCP1 output generates:
  - High pulse-width from zero to `TIMx.CC1` value ( $ZACT = 1h$ )
  - Low pulse-width from `TIMx.CC1` value to `TIMx.LOAD` ( $CUACT = 2h$ )

**Figure 34-29. Edge-Aligned PWM Signals in Up-Counting Mode**

#### 34.2.5.2.2 Center-Aligned PWM

To generate center-aligned PWMs, TIMx is configured for up/down counting mode and the TIMx.LOAD value contains the half-period. The waveform uses up compare events and down compare events to drive the CCPx output high or low depending on the configuration settings of the compare/capture block and counter.

In TIMCLK cycles, the PWM period is  $(2 * \text{TIMx.LOAD})$  and the duty cycle is  $1 - (\text{TIMx.CC\_xy}[0/1] / \text{TIMx.LOAD})$ .

#### Center-Aligned PWM Configuration

To generate center-aligned PWMs using compare match events from the counter:

1. In the TIMx.CTRCTL register, set the desired counter control settings for:
  - a. Up/down counting mode ( $\text{CM} = 1$ ) and counter value after enable (CVAE) (see as described in [Section 34.2.2](#))
  - b. Zero (CZC), advance (CAC), and load control (CLC) to specify what condition controls zeroing, advancing, or loading the counter
  - c. Repeat or one-shot mode (REPEAT)
2. Set the TIMx.LOAD value to configure the PWM period.
3. Set the TIMx.CC\_xy[0/1] value to configure the duty cycle.
4. Set TIMx.CCCTL\_xy[0/1].COC = 1 for compare mode.
5. Configure CCP as an output for the CC block by setting respective bit in the CCPD registers. For instance, if TIMx Channel 0 is an output, set CCPD.C0CCP0 = 1.
6. In TIMx.CCACT\_xy[0/1], set the CCP output action settings for compare events, zero events, load events, software force action, or fault events (TIMA only).
7. In TIMx.OCTL\_xy[0/1], set CCPO = 0 to select the signal generator output.
8. Enable the corresponding CCP output by setting ODIS.C0CCPn to 1 for the corresponding counter n.
9. Configure polarity of the signal using the CCPOINV bit, and configure CCPIV to specify the CCP output state while disabled.
10. Enable the counter by setting TIMx.CTRCTL.EN = 1.

#### Example using center-aligned PWM in up/down counting mode

A typical 2-channel center-aligned PWM generation using up/down counting mode is shown in [Figure 34-30](#) with the following center-aligned PWM output waveforms:

- CCP0 output generates:
  - High pulse-width from TIMx.CC0 compare up event to TIMx.CC0 compare down event (CUACT = 1h)
  - Low pulse-width from TIMx.CC0 compare down event to TIMx.CC0 compare up event (CDACT = 2h)
- CCP1 output generates:
  - High pulse-width from TIMx.CC0 compare up event to TIMx.CC0 compare down event (CUACT = 1h)
  - Low pulse-width from TIMx.CC0 compare down event to TIMx.CC0 compare up event (CDACT = 2h)

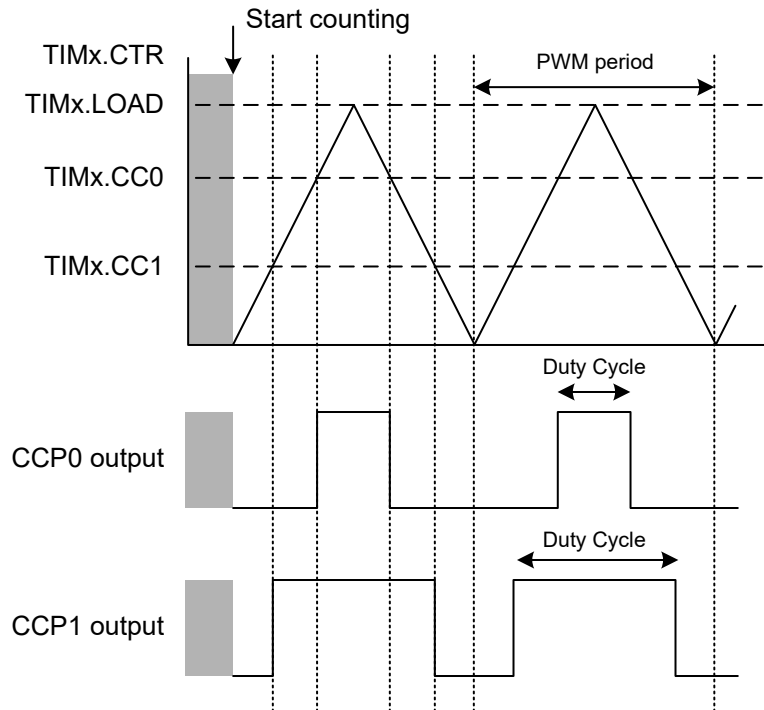

Figure 34-30. Center-Aligned PWM

#### 34.2.5.2.3 Asymmetric PWM (TIMA only)

In TIMA only, asymmetric PWMs can be generated by generating two synchronized center-aligned PWM signals with a controlled phase shift. To generate the asymmetric PWM signals, the phase load feature is used as described in [Section 34.2.2.5](#).

#### Asymmetric PWM Configuration

To generate asymmetric PWMs using compare match events from the counter:

1. Synchronize TIMA0 and TIMA1 using a cross trigger as described in [Section 34.2.7](#).
2. Configure two center-aligned PWMs as described in [Section 34.2.5.2.2](#) using TIMA0 and TIMA1. TIMA0 and TIMA1 should have the same load value (TIMA.LOAD) and compare value (TIMA.CC\_xy[0/1]) to generate the same PWM frequency and duty cycle.
3. Add a phase shift value for TIMA0 or TIMA1 by configuring the phase load value TIMA.PL as described in [Section 34.2.2.5](#).
4. Enable the counter by setting TIMA.CTRCTL.EN = 1.

[Figure 34-31](#) shows an example of asymmetric PWM configuration using CCP channel 0 of TIMA0 and TIMA1.

**Figure 34-31. Asymmetric PWM Configuration with Phase Load for CCP channel 0 of TIMA0 and TIMA1**

**34.2.5.2.4 Complementary PWM With Deadband Insertion (TIMA only)**

TIMA provides the option of generating complimentary PWM outputs with deadband insertion (nonoverlapping transitions in complimentary PWM signals) from a signal PWM reference signal. Deadband is useful for applications with half-bridge control to avoid shoot-through conditions, such as motor driver or inverter-based applications.

The reference signal is generated on the TIMAx\_Cy signal, and the complimentary signal is generated on TIMAx\_CyN, where x is the timer instance and y is the CCP output channel. For instances, a reference PWM signal generated on TIMA0 CCP output channel 2 will produce complimentary output signals on TIMA0\_C2 and TIMA0\_C2N.

The deadband control register (TIMAx.DBCTL) is programmed with the deadband mode and timing information. The deadband mode is selected using the M1\_ENABLE bit, and the timing information to control the deadband width in TIMCLK cycles is selected by the RISEDELAY and FALLDELAY bit fields. RISEDELAY and FALLDELAY are a function of the rising or falling edge delay to or from the reference PWM.

See [Table 34-18](#) for the configuration and relationship between deadband mode and deadband width settings.

**Table 34-18. Deadband Modes and Delay Timing Configuration in DBCTL register**

Deadband Mode	Bitfield	Description	Counting Mode
Mode 0	M1_ENABLE = 0	RISEDELAY is applied from <b>rising edge of reference PWM</b> to rising edge of TIMAx_Cy signal.  FALLDELAY is applied from <b>falling edge of reference PWM</b> to rising edge of CxN signal.	Any

**Table 34-18. Deadband Modes and Delay Timing Configuration in DBCTL register (continued)**

Deadband Mode	Bitfield	Description	Counting Mode
Mode 1	M1_ENABLE = 1	RISEDELAY is applied from falling edge of TIMAx_CyN signal to <b>rising edge of reference PWM</b> . FALLDELAY is applied to <b>falling edge of reference PWM</b> to rising edge of TIMAx_CyN signal.	Up/down counting mode only

### Deadband timing equation and example

The equations for configuring RISEDELAY and FALLDELAY from TIMCLK frequency and deadband timing is shown in [Equation 36](#) and [Equation 37](#).

$$RISEDELAY = f_{TIMCLK} \times t_{dead\_rise} \quad (36)$$

$$FALLDELAY = f_{TIMCLK} \times t_{dead\_fall} \quad (37)$$

For example, if 400ns of deadband is required when using a TIMCLK frequency of 80MHz, and Mode 1 is used with center-aligned PWMs to generate equal deadband every PWM period, then RISEDELAY = FALLDELAY = (80MHz) \* (400ns) = 32.

### Complimentary PWM with Deadband Configuration

1. Configure a PWM output for an edge-aligned PWM ([Section 34.2.5.2.1](#)) or center-aligned PWM ([Section 34.2.5.2.2](#)) for any CCP output channel in TIMA.
2. Configure TIMA.DBCTL with the specified deadband mode (M1\_ENABLE) and deadband width RISEDELAY and FALLDELAY, depending on the deadband mode.
3. In TIMx.OCTL\_xy[0/1], set CCPO = 0xC to select the signal generator with deadband output.
4. Enable the counter by setting TIMx.CTRCTL.EN = 1.

### Example 1 - Complimentary PWM outputs with deadband using edge-aligned PWM in down-counting mode

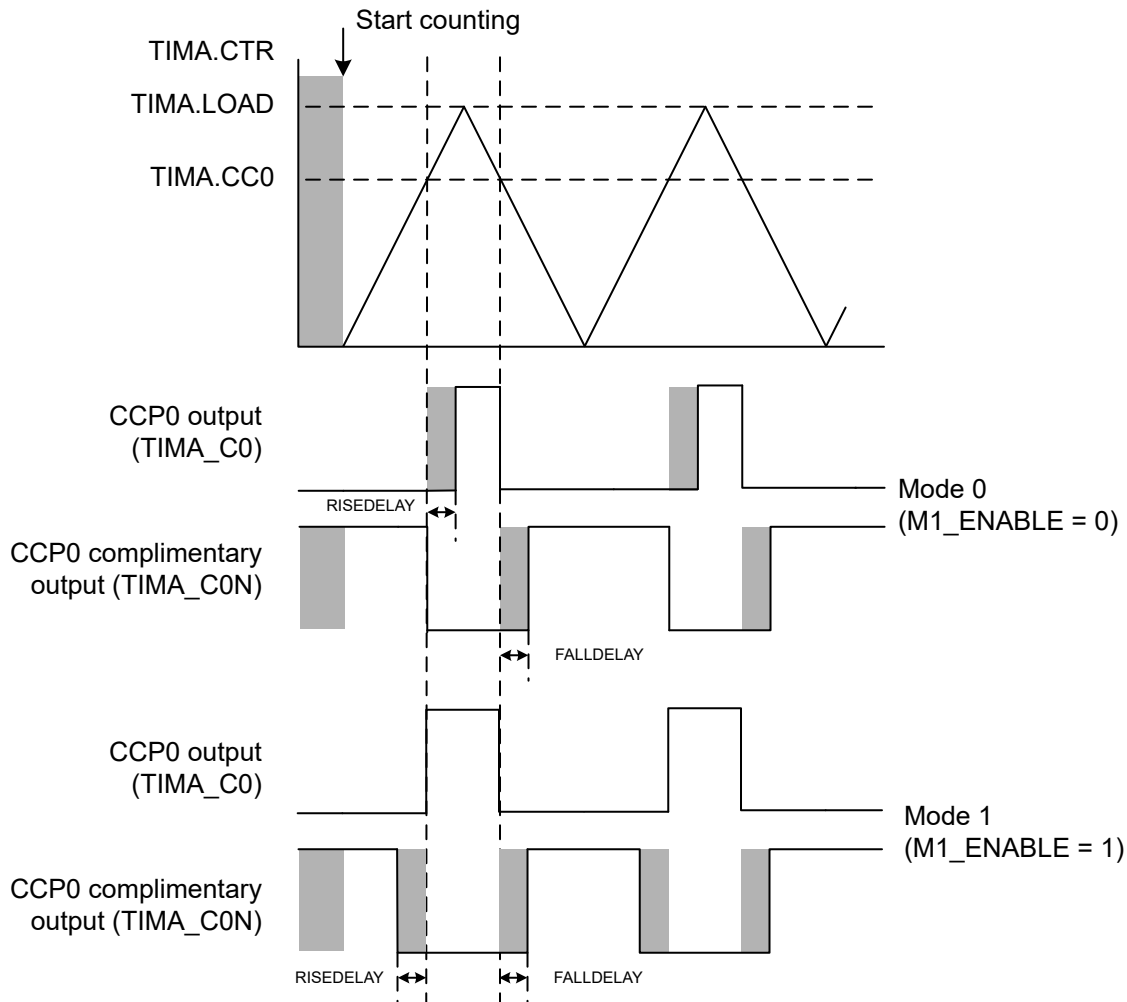

For edge-aligned PWM, Mode 0 can only be used for deadband insertion mode. See [Figure 34-32](#) for inserting configurable deadband using down counting mode, TIMA output channel 0, and edge-aligned PWM.

**Figure 34-32. Deadband Insertion (Mode 0) for PWM in Down-Counting Mode**

**Example 2- Complimentary PWM outputs with deadband using center-aligned PWM**

For center-aligned PWM, Mode 0 or Mode 1 can be used for deadband insertion mode. See [Figure 34-33](#) for inserting configurable deadband using up/down counting mode, TIMA output channel 0, and center-aligned PWMs with deadband.

**Figure 34-33. Dead Band Insertion for Center-Aligned PWM (Mode 0 and Mode 1)**

### 34.2.5.3 Forced Output

Each output channel signal can be forced to a high or low level directly by software, independently of any comparison between the compare register and the counter. A shadow register exists to ensure the forced output action occurs at the end of the timer period.

The output of the CCP channel can be forced to high or low by setting the SWFRCACT bit in the TIMx.CCACT\_xy[0/1] register.

In TIMA only, the complimentary output channel can also be forced to high or low by setting the SWFRCACT\_CMPL bit in the TIMx.CCACT\_xy[0/1] register.

Table 34-19 shows the software force output action configuration options.

**Table 34-19. Force Output Action Configuration**

Bit Field	Value	Description/Comment
SWFRCACT / SWFRCACT_CMPL	0	No forced output. Output is directly from the signal generation block.
	1	Force output high
	2	Force output low

### 34.2.6 Fault Handler (TIMA only)

In TIMA only, there are internal and external fault inputs which can be used to control the generation of PWM signals. The intended use of these inputs is as a mechanism for internal or external circuitry to indicate a fault in the system. This allows the hardware to react quickly to the external fault while optionally signaling an interrupt for software correction and leaving the output signals in a safe state.

It is important to consider the following basic properties of faults in a system, such as:

- Fault input selection (fault signal from external IC, internal signal, etc.)
- How long a fault condition lasts, or the fault condition duration
- How the counter reacts to the entry and exit of a fault condition
- How the output signal reacts to the entry and exit of a fault condition

Fault conditions are synchronously detected using TIMCLK or asynchronously detected. Synchronous faults have a configurable glitch filter and can generate a latched fault event. Asynchronous faults cannot be latched and do not generate a fault event, with a latency of 1-2 TIMCLK cycles to detect the fault and perform a configured action. The CCP output can be configured for either type of fault upon entry and exit conditions.

The fault handler logic diagrams are split into three parts: asynchronous faults, synchronous faults, and fault output generation.

Figure 34-34 shows the asynchronous fault handler logic connections.

Figure 34-34. Asynchronous Fault Handler Connections

Figure 34-35 shows the synchronous fault handler logic connections.

Figure 34-35. Synchronous Fault Handler Connections

Figure 34-36 shows the fault output generation logic connections.

Figure 34-36. Fault Output Generation Connections

Key registers for configuring the fault handler are:

- **TIMA.FCTL**: this register controls the fault inputs, fault detection, and error handling behavior.
- **TIMA.FSCTL**: this register controls the fault source selection and enable.
- **TIMA.FIFCTL**: this register controls the input filtering (FILTEN, FP, CPV) for the fault input.
- **TIMA.CCACT\_xy[0/1]**: this register controls the actions of the signal generator of the capture-compare portion based on fault events.

### 34.2.6.1 Fault Input Conditioning

The comparator and external fault pin fault source input passes through a two TIMCLK synchronization stage and the fault input can be filtered through the glitch filter using the fault input filter (TIMA.FIFCTL) register.

The fault input glitch filter can be enabled by setting the TIMA.FIFCTL.FILTEN bit. The filter period is configured by setting the TIMA.FIFCTL.FP bit.

A consecutive period or majority voting format selected by the TIMA.FIFCTL.CPV bit is used to select the criteria for a CCP input signal.

- **Consecutive period** - The fault input signal must be at the specified level for the defined number of FP timer clocks for the fault input to be processed.
- **Majority voting** - The filter ignores one clock of opposite logic over the filter period. For example, over the number of FP samples of the fault input, up to 1 sample may be of an opposite logic value (glitch) without affecting the output.

The example shown in [Figure 34-13](#) shows the difference between consecutive period and majority voting formats with a digital filter implemented to capture a fault input of 3 TIMCLK periods.

### 34.2.6.2 Fault Input Sources

The fault control (FCTL) and fault source control (FSCTL) registers are used to select the polarity and enable various fault input sources as shown in [Table 34-20](#).

To enable the final input for fault detection, set TIMA.FTCL.FIEN = 1.

There are four types of fault input sources that are available for synchronous or asynchronous fault detection:

#### Comparator (COMP) output

The comparator output is useful for fault detection when COMPs are used for detecting overcurrent or overvoltage events. To enable the comparator output for fault detection, set the TIMA.FSCTL.FACxEN bit, and configure the polarity to detect the fault using TIMA.FCTL.FSENACx bit (x = 0, 1, or 2 for COMP instance).

#### External Fault Pin

Many IC devices include a fault detection pin (i.e. nFAULT) that an MCU can detect when there is a fault condition in the system. There are 3 fault external signal pins (TIMA\_FLTx) connected to every TIMA module, where x = 0, 1, or 2. Each signal pin can be enabled by setting the TIMA.FSCTL.FEXxEN bit, and the polarity of this signal to trigger a fault condition can be configured by using TIMA.FCTL.FSENEXTx bit (where x = 0, 1, or 2 for each TIMA\_FLTx pin).

#### System Clock Fault

Any system clock fault can be used to trigger the PWM output(s) to a Hi-Z state. This can be enabled by setting the TIMA.FSCTL.FCEN bit.

---

#### Note

When a SYSCLK fault occurs, a device reset is generated. Various TIMA fault entry and exit options are invalid while the device is in reset.

---

#### Trigger

A trigger can be configured to generate a fault condition is detected. This is useful for performing diagnostics or creating fault dependencies from other peripherals in the event fabric. For trigger configuration, please see [Section 34.2.7](#) . The fault input mask can be enabled by setting the TIMA.FSCTL.TFIM bit.

**Table 34-20. Fault Input Sources and Configuration**

Signal name	Input source	Fault type	Polarity Bit	Enable Bit
COMP0_OUT	COMP0 output	Synchronous or Asynchronous	FSENAC0	FAC0EN
COMP1_OUT	COMP1 output		FSENAC1	FAC1EN

**Table 34-20. Fault Input Sources and Configuration (continued)**

Signal name	Input source	Fault type	Polarity Bit	Enable Bit
COMP2_OUT	COMP2 output		FSENAC2	FAC2EN
TIMA_FLT0	External Fault 0		FSENEXT0	FSENEXT0
TIMA_FLT1	External Fault 1		FSENEXT1	FSENEXT1
TIMA_FLT2	External Fault 2		FSENEXT2	FSENEXT2
SYCLK	System Clock	Synchronous	-	FCEN
TRIG	Trigger Output		-	TFIM

### 34.2.6.3 Counter Behavior With Fault Conditions

There are two settings for specifying the counter behavior in fault conditions: TIMA.CTRCTL.FB (during fault behavior) and TIMA.CTRCTL.FRB (fault resume behavior). The counter should continue to be enabled (TIMA.CTRCTL.EN = 1) during the fault handler behavior.

The counter behavior of the fault condition is described in [Table 34-21](#) and [Figure 34-37](#).

**Table 34-21. Counter Behavior in Fault Condition With TIMA.CTRCTL Register**

Bit Fields				Counter Behavior
FB	FRB	CVAE	REPEAT	
0	X	X	0	Ignores fault mode. Counter continues to count during fault and stops when reaches zero.
			1/3	Ignores fault mode. Counter continues to count during fault and repeat.
1	0	X	0/1/3	Reacts immediately to fault mode. The counter stops counting immediately and throughout the fault mode. Upon exit of fault mode, the counter continues counting from where it left off.
			X	0
	1	1		Reacts immediately to fault mode. The counter stops counting immediately and throughout the debug mode. Upon exit of debug mode, the counter restarts from where it paused at fault entry.
		2	Reacts immediately to fault mode. The counter stops counting immediately and throughout the fault mode. Upon exit of fault mode, it restarts from 0 value (restarts an up/down count).	

Figure 34-37. Counter Behavior in Fault Condition with TIMx.CTRCTL Register

#### 34.2.6.4 Output Behavior With Fault Conditions

There are two settings for the CCP output channel behavior in a fault condition, TIMA.CCACT\_01[0/1].FEXACT (fault exit behavior) and TIMA.CCACT\_01[0/1].FENACT (fault entry behavior). The output behavior of fault condition is described in [Table 34-22](#).

**Table 34-22. CCP Output Behavior in Fault Condition With TIMA.CCACT Register**

Bit Fields		Output Behavior
FEXACT	FENACT	
0		The CCP output value is unaffected by the fault event
1		CCP output value is set high
2		CCP output value is set low
3		CCP output value toggles
4		CCP output is tristated (Hi-Z)

---

#### Note

Fault entry and exit behavior is not dependent on the counter being enabled. They will always update the output when in fault mode. Enabling the counter through a software write when in fault mode will generate a load event that will be captured in RIS but the counter will not proceed. Load events will not affect the output when in fault mode. Fault events takes the absolute priority and no events can update the output until you are out of fault mode.

---

#### Note

If using the TIMA\_FALx pin with the CCP capture channel inputs (such as adding deadband to complimentary PWMs) for low latency actions, an external connection should be in hardware between the TIMA\_FALx pin and TIMAx\_Cy pin (x = timer instance, y = CC channel).

---

#### 34.2.7 Synchronization With Cross Trigger

When using a main-secondary timer configuration by connecting multiple timers together, the cross-trigger feature can instruct multiple timer modules in the same power domain or across different power domains using the event fabric to start counting simultaneously.

Cross-triggers can be enabled using software, compare events from other timer instances, zero or load events, or generic subscriber events. Some applications may require more than one counter block that can be simultaneously started across the same power domain (such as TIMA0 and TIMA1) or different power domains (such as TIMA0 and TIMG0).

This configuration uses cross triggers from a main timer module as the input trigger condition for the secondary timers. The timer cross trigger is essentially the combined logic of the hardware and software conditions that control the EN bit in the TIMx.CTRCTL register.

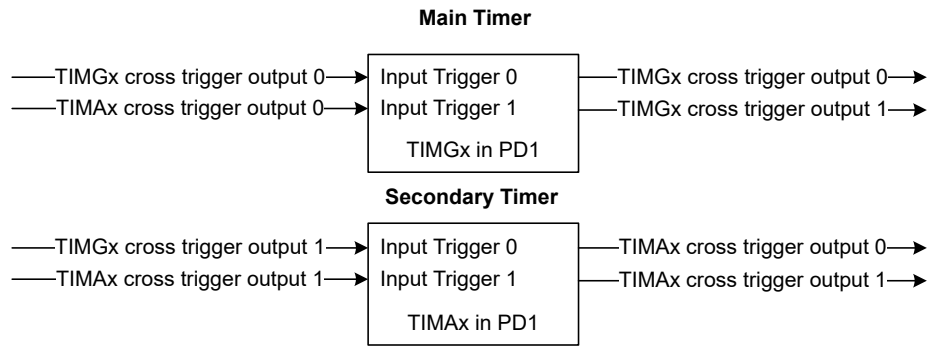

The cross triggers that are outputted from the main timer are connected to the external trigger input of other secondary timer modules. As shown in [Figure 34-38](#), TIMGx is the main timer and TIMAx is the secondary timer that will be cross triggered in the configuration example.

---

#### Note

For power domains and cross trigger selection sources enabled for timer instances, refer to the device-specific data sheet.

---

**Figure 34-38. Cross Trigger Connections for Main Timer (TIMGx) and Secondary Timer (TIMAx) in Power Domain 1**

### 34.2.7.1 Main Timer Cross Trigger Configuration

The following steps are used to configure the main timer cross trigger (which is TIMGx in this example):

1. Configure the main timer (which triggers other secondary timers) for the desired function, such as PWM output generation or using compare mode, to trigger other peripherals. See [Section 34.2.5](#) for how to configure for PWM generation.
2. Select which cross trigger output needs to be generated. For example, in [Figure 34-38](#), TIMGx cross trigger 1 can be used to trigger TIMAx and TIMGx cross trigger 0 can be used to trigger itself.
3. Enable the cross trigger output function by setting TIMx.CTTRIGCTL.CTEN bit to 1.
4. Choose how to trigger the start of these connected timers, which can be a software trigger or hardware trigger from a subscriber port, zero, load, or compare event.
  - a. For a software event trigger, set the TIMx.CTTRIG.TRIG bit.
  - b. For a hardware trigger event, select the source for the trigger using TIMx.CTTRIGCTL.EVTCTTRIGSEL and enable the hardware trigger by setting TIMx.CTTRIGCTL.EVTCTEN.

[Figure 34-39](#) shows the connection logic and registers.

**Figure 34-39. Main Timer Cross Trigger Output Configuration**

### 34.2.7.2 Secondary Timer Cross Trigger Configuration

The following steps are used to configure the secondary timer cross trigger (which is TIMAx in this example):

1. Configure the secondary timer (triggered by the main timer) for the desired function for this timer, such as PWM output generation or using compare mode, to trigger other peripherals. See [Section 34.2.5](#) for how to configure for PWM generation.
2. Select which input trigger to use according to the device-specific data sheet. Using the example connection in [Figure 34-38](#), TIMAx must be triggered by TIMGx and the cross trigger output 1 of TIMGx is connected to input trigger 0 of TIMAx. Therefore, select input trigger 0 of TIMAx by setting TIMA.TSEL.ETSEL bit to 0.
3. Enable the input trigger function by setting the TIMA.TSEL.TE bit to 1.
4. Set TIMAx.IFCTL\_01[0].ISEL = 3 and TIMAx.IFCTL\_01[1].ISEL = 3 to select the trigger as the input source.
  - a. For a center-aligned PWM, set the TIMA.CCCTL\_01[0].ZCOND and TIMA.CCCTL\_01[1].ZCOND bits to 1 to use a trigger assertion edge for a zero event.
  - b. For an edge-aligned PWM, set the TIMA.CCCTL\_01[0].LCOND and TIMA.CCCTL\_01[1].LCOND bits to 1 to use the trigger assertion edge for a load event.
5. The TIMx.CTRCTL.EN bit is set as the result of an LCOND or ZCOND condition being met, and the counter value changes to the load value or zero value, respectively.

As the main timer TIMGx must also trigger itself, complete the previous configuration steps for TIMAx to trigger TIMGx itself.

[Figure 34-40](#) shows the logic connection.

**Figure 34-40. Secondary Timer Cross Trigger Input Configuration**

#### Note

Refer to "TIMx Cross Trigger Map" in the device-specific data sheet for enabled cross trigger mapping using the ETSEL bit. For instance, if the timer instances of a device all use trigger input 0 (TRIG0) to cross trigger other timers, then only TRIG0 can be used to cross trigger other instances.

### 34.2.8 Low Power Operation

For detailed information on the low power modes in terms of available clock source and behaviors, refer to *Power Domains*.

Timer modules in power domain PD0 can be active and configured to continue counting in all power modes except SHUTDOWN mode. See *Power Domains* for the available clock sources in each low-power mode. The user needs to configure the proper clock to source the timer in low-power mode.

Timer modules in power domain PD1 can only be active in RUN and SLEEP modes. When the system goes to STOP or STANDBY mode, the timer modules will be forced to a disabled state and resume when the systems moves back to RUN or SLEEP modes.

### 34.2.9 Interrupt and Event Support

TIMx interrupts and events can be configured to any peripheral of the device using the Event Manager. The timer can generate interrupts or events as an **event publisher**, and be triggered from other peripheral events (such as GPIO, comparator, ADC, etc.) as an **event subscriber**. See [Section 7.2.5](#) for guidance on configuring the event registers for CPU interrupts or generic events.

The TIMx module contains three [event publishers](#) and two [event subscribers](#).

- One event publisher (CPU\_INT) manages TIMx interrupt requests (IRQs) to the CPU subsystem through a [static event route](#).
- The second and third event (GEN\_EVENT0 and GEN\_EVENT1) are used to setup the generic event publishers and subscribers through [Generic route](#).

TIMx events are summarized in [Table 34-23](#).

**Table 34-23. TIMx Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU interrupt</a>	Publisher	TIMx	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from TIMx to CPU
<a href="#">Generic publisher event</a>	Publisher	TIMx	Other peripherals	<a href="#">Generic route</a>	GEN_EVENT0 and FPUB_0 registers	Configurable interrupt route from TIMx to other peripherals
<a href="#">Generic publisher event</a>	Publisher	TIMx	Other peripherals	<a href="#">Generic route</a>	GEN_EVENT 1 and FPUB_1 registers	Configurable interrupt route from TIMx to other peripherals
<a href="#">Generic subscriber event</a>	Subscriber	Other peripherals	TIMx	<a href="#">Generic route</a>	FSUB_0	Configurable interrupt route from other peripherals to TIMx
<a href="#">Generic subscriber event</a>	Subscriber	Other peripherals	TIMx	<a href="#">Generic route</a>	FSUB_1	Configurable interrupt route from other peripherals to TIMx

#### 34.2.9.1 CPU Interrupt Event Publisher (CPU\_INT)

The TIMx module provides 18 interrupt sources (depending on the specific TIMx module features) which can be configured to source a [CPU interrupt event](#). The CPU interrupt event configuration is managed with the CPU\_INT event management registers. [Table 34-24](#) lists the CPU interrupt events from the TIMx in order of decreasing interrupt priority.

**Table 34-24. TIMx CPU Interrupt Event Conditions (CPU\_INT)**

IIDX STAT	Name	Description	Timer Module
0x01	Z	Zero event interrupt. This interrupt is set when there is a zero event.	TIMx
0x02	L	Load event interrupt. This interrupt is set when there is a load event.	TIMx
0x05	CCD0	Capture or compare 0 down event. This interrupt is set when there is a down compare match event at CC0.	TIMx
0x06	CCD1	Capture or compare 1 down event. This interrupt is set when there is a down compare match event at CC1.	TIMx
0x07	CCD2	Capture or compare 2 down event. This interrupt is set when there is a down compare match event at CC2. This interrupt is only available for TIMA0.	TIMx
0x08	CCD3	Capture or compare 3 down event. This interrupt is set when there is a down compare match event at CC3. This interrupt is only available for TIMA0.	TIMx
0x09	CCU0	Capture or compare 0 up event. This interrupt is set when there is a up compare match event at CC0.	TIMx
0x0A	CCU1	Capture or compare 1 up event. This interrupt is set when there is a up compare match event at CC1.	TIMx
0x0B	CCU2	Capture or compare 2 up event. This interrupt is set when there is a up compare match event at CC2.	TIMx

**Table 34-24. TIMx CPU Interrupt Event Conditions (CPU\_INT) (continued)**

IIDX STAT	Name	Description	Timer Module
0x0C	CCU3	Capture or compare 3 up event. This interrupt is set when there is a up compare match event at CC3.	TIMx
0x0D	CCD4	Capture or compare 4 down event. This interrupt is set when there is a down compare match event at CC4. This interrupt is only available for TIMA modules.	TIMA
0x0E	CCD5	Capture or compare 5 down event. This interrupt is set when there is a down compare match event at CC5. This interrupt is only available for TIMA modules.	TIMA
0x0F	CCU4	Capture or compare 4 up event. This interrupt is set when there is a up compare match event at CC4. This interrupt is only available for TIMA modules.	TIMA
0x10	CCU5	Capture or compare 5 up event. This interrupt is set when there is a up compare match event at CC5. This interrupt is only available for TIMA modules.	TIMA
0x19	F	Fault event interrupt. This interrupt is set when there is a fault condition event. See <a href="#">Section 34.2.6</a> . This interrupt is only available for TIMA modules with fault handler features.	TIMA
0x1A	TOV	Trigger overflow interrupt. This interrupt is set if a trigger event is generated while the associated trigger channel is active.	TIMx
0x1B	REPC	Repeat counter zero interrupt. This bit controls the generation of an interrupt if the repeat counter value transitions from a nonzero value to zero. This interrupt is only available for TIMA modules with a repeat counter feature.	TIMA
0x1C	DC	Direction change interrupt, used in QEI mode. This interrupt is only available for TIMG modules with QEI features.	TIMG
0x1D	QEIERR	Direction change interrupt, used in QEI mode. This interrupt is only available for TIMG modules with QEI features.	TIMG

See [Section 7.2.5](#) for guidance on configuring the event registers for CPU interrupts.

#### 34.2.9.2 Generic Event Publisher and Subscriber (GEN\_EVENT0 and GEN\_EVENT1)

A generic route is a route in which the comparator peripheral publishing the event is configured to use one of several available generic route channels to publish its event to another entity (or entities, in the case of a splitter route), where an entity can be another peripheral, a generic DMA trigger event, or a generic CPU event.

The GEN\_EVENT0 and GEN\_EVENT1 registers are used to select a peripheral condition ([Table 34-25](#)) to use for publishing or subscribing an event. FPUB\_0 and FPUB\_1 are the publisher port registers and are used to configure which generic route channel to use to broadcast the event. FSUB\_0 and FSUB\_1 are the subscriber port registers and are used to configure which generic route channel to use to subscribe the event. Other peripherals, the DMA, or the CPU can subscribe to this event by configuring its subscriber port to listen on the same generic route channel which the publishing peripheral is connected to.

For example, through the use of a generic event channel, it is possible to directly start an ADC conversion from a TIMx event by connecting a TIMx FPUB\_x and ADC FSUB\_0 to the same generic event channel. Refer to [Section 7.1.3.3](#) and [Section 7.2.3](#) for how generic event route works.

**Table 34-25. TIMx Generic Event Conditions (GEN\_EVENT0 and GEN\_EVENT1)**

IIDX STAT	Name	Description	Timer Module
0x01	Z	Zero event interrupt. This interrupt is set when there is a zero event.	TIMx
0x02	L	Load event interrupt. This interrupt is set when there is a load event.	TIMx
0x05	CCD0	Capture or compare 0 down event. This interrupt is set when there is a down compare match event at CC0.	TIMx
0x06	CCD1	Capture or compare 1 down event. This interrupt is set when there is a down compare match event at CC1.	TIMx
0x07	CCD2	Capture or compare 2 down event. This interrupt is set when there is a down compare match event at CC2. This interrupt is only available for TIMA0.	TIMx
0x08	CCD3	Capture or compare 3 down event. This interrupt is set when there is a down compare match event at CC3. This interrupt is only available for TIMA0.	TIMx

**Table 34-25. TIMx Generic Event Conditions (GEN\_EVENT0 and GEN\_EVENT1) (continued)**

IIDX STAT	Name	Description	Timer Module
0x09	CCU0	Capture or compare 0 up event. This interrupt is set when there is a up compare match event at CC0.	TIMx
0x0A	CCU1	Capture or compare 1 up event. This interrupt is set when there is a up compare match event at CC1.	TIMx
0x0B	CCU2	Capture or compare 2 up event. This interrupt is set when there is a up compare match event at CC2.	TIMx
0x0C	CCU3	Capture or compare 3 up event. This interrupt is set when there is a up compare match event at CC3.	TIMx
0x0D	CCD4	Capture or compare 4 down event. This interrupt is set when there is a down compare match event at CC4. This interrupt is only available for TIMA modules.	TIMA
0x0E	CCD5	Capture or compare 5 down event. This interrupt is set when there is a down compare match event at CC5. This interrupt is only available for TIMA modules.	TIMA
0x0F	CCU4	Capture or compare 4 up event. This interrupt is set when there is a up compare match event at CC4. This interrupt is only available for TIMA modules.	TIMA
0x10	CCU5	Capture or compare 5 up event. This interrupt is set when there is a up compare match event at CC5. This interrupt is only available for TIMA modules.	TIMA
0x19	F	Fault event interrupt. This interrupt is set when there is a fault condition event. See <a href="#">Section 34.2.6</a> . This interrupt is only available for TIMA modules with fault handler features.	TIMA
0x1A	TOV	Trigger overflow interrupt. This interrupt is set if a trigger event is generated while the associated trigger channel is active.	TIMx
0x1B	REPC	Repeat counter zero interrupt. This bit controls the generation of an interrupt if the repeat counter value transitions from a nonzero value to zero. This interrupt is only available for TIMA modules with a repeat counter feature.	TIMA
0x1C	DC	Direction change interrupt, used in QEI mode. This interrupt is only available for TIMG modules with QEI features.	TIMG
0x1D	QEIERR	Direction change interrupt, used in QEI mode. This interrupt is only available for TIMG modules with QEI features.	TIMG

See [Section 7.2.5](#) for guidance on configuring the event registers.

### 34.2.9.3 Generic Subscriber Event Example (COMP to TIMx)

A common use case is to directly trigger a timer action (reset, PWM output, etc.) from the comparator output. The Event Manager can be used to set up the comparator as a generic event publisher (FPUB\_1) and the timer as a generic event subscriber (FSUB\_0 or FSUB\_1) listening for an event from the publisher.

#### Comparator configuration (Publisher):

1. Set COMPIFG bit in GEN\_EVENT0 IMASK register to mask the comparator output interrupt. For more info, see the COMP chapter.
2. Configure FPUB\_1 register in comparator module to connect to event channel y.
3. Configure and enable the comparator.

#### TIMx configuration (Subscriber):

1. Configure FSUB\_0 or FSUB\_1 register in the TIMx module to connect to event channel y. Channel y must not be in use by another peripheral.
2. Set TIMx.IFCTL\_xy[0/1].ISEL = 5 or 6 to select the CC input source as FSUB0 or FSUB1 for the TIMx module. See [Figure 34-12](#) and [Section 34.2.3.1.1.5](#) .
3. Configure and enable the timer.

---

**Note**

The comparator output (COMP0:2) has two more options for cross-peripherals:

- Input to the TIMx CC block directly using TIMx.IFCTL\_xy[0/1].ISEL = 7h, 8h, or 9h.
    - This is a lower latency path and is useful for applications such as cycle-by-cycle overcurrent limiting. See [Figure 34-12](#).
  - Using the timer's cross trigger path to configure the event subscriber port as a trigger source by configuring the TIMx.TSEL.ETSEL = 0x10 for FSUB0 or to 0x11 for FSUB1.
    - Enable the input trigger function by setting the TIMx.TSEL.TE bit to 1.
    - Set TIMx.IFCTL\_xy[0/1].ISEL bit to 3 to select the cross trigger as input source for the TIMx module.
    - This is useful for using an event subscriber to trigger multiple timer instances in the same power domain, such as COMP to multiple TIMG instances.
- 

**34.2.10 Debug Handler (TIMA Only)**

In TIMA only, the counter behavior in CPU halt debug mode and debug resume can also be configured by software using the PDBGCTL and CTRCTL registers.

TIMA can be configured to stop counting or continue counting when the CPU is halted for debug by the debug subsystem. By default, TIMA stops counting when the CPU is halted for debug and the device is in a debug state. To allow TIMA to continue to free run when the CPU is stopped for debug, set the FREE bit in the PDBGCTL register. See [Section 40.2.1.2](#) for more information.

The CTRCTL register lets the device to resume counting or perform the action specified by the CVAE field following the exit of debug mode using the DRB bit.

### 34.3 TIMx Registers

Table 34-26 lists the memory-mapped registers for the TIMx registers. All register offset addresses not listed in Table 34-26 should be considered as reserved locations and the register contents should not be modified.

**Table 34-26. TIMX Registers**

Offset	Acronym	Register Name	Group	Section
400h	FSUB_0	Subscriber Port 0		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 34-27](#) shows the codes that are used for access types in this section.

**Table 34-27. TIMx Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WK	W K	Write Write protected by a key
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

**Table 34-27. TIMx Access Type Codes (continued)**

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1	SOFT	R/W	0h	Soft halt boundary control. This function is only available, if <a href="#">FREE</a> is set to 'STOP' 0h = The peripheral will halt immediately, even if the resultant state will result in corruption if the system is restarted 1h = The peripheral blocks the debug freeze until it has reached a boundary where it can resume without corruption
0	FREE	R/W	0h	Free run control 0h = The peripheral freezes functionality while the Core Halted input is asserted and resumes when it is deasserted. 1h = The peripheral ignores the state of the Core Halted input

### 11 IIDX (Offset = 1020h) [Reset = 0000000h]

IIDX is shown in [Figure 34-51](#) and described in [Table 34-38](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 34-51. IIDX**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 17 IIDX (Offset = 1050h) [Reset = 0000000h]

IIDX is shown in [Figure 34-57](#) and described in [Table 34-44](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

### 23 IIDX (Offset = 1080h) [Reset = 0000000h]

IIDX is shown in [Figure 34-63](#) and described in [Table 34-50](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 34-63. IIDX**

## 27 ISET (Offset = 10A0h) [Reset = 0000000h]

ISET is shown in [Figure 34-67](#) and described in [Table 34-54](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

### 33 CCLKCTL (Offset = 1108h) [Reset = 0000000h]

CCLKCTL is shown in [Figure 34-73](#) and described in [Table 34-60](#).

Return to the [Summary Table](#).

The CCLKCTL register provides a SW mechanism for gating the TIMER clock if the module is expected not to be used but the power domain is alive.

This effectively puts the IP in an IDLE state

**Figure 34-73. CCLKCTL**

6	RESERVED	R	0h	

**Table 34-109. CTRCTL Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5-4	CM	R/W	0h	Count Mode 0h = Down 1h = Up/Down 2h = Counter counts up.
3-1	REPEAT	R/W	0h	Repeat. The repeat bit controls whether the counter continues to advance following a zero event, or the exiting of a debug or fault condition. If counting down, a zero event is followed by a load at the next advance condition. If counting up-down, a zero event is followed by an advance event (+1). The intent of encoding 3 is that if the debug condition is in effect, the generation of the load pulse is deferred until the debug condition is over. This allows the counter to reach zero before counting is suspended. 0h = Does not automatically advance following a zero event. 1h = Continues to advance following a zero event. 2h = Reserved 3h = Continues to advance following a zero event if the debug mode is not in effect, or following the release of the debug mode. 4h = Reserved
0	EN	R/W	0h	Counter Enable. This bit allows the timer to advance This bit is automatically cleared if REPEAT=0 (do not automatically reload) and the counter value equals zero. CPU Write: A register write that sets the EN bit, the counter value is set per the CVAE value. Hardware: This bit may also be set as the result of an LCOND or ZCOND condition being met and the counter value changed to the load value or zero value, respectively. 0h = Disabled 1h = Enabled

## 42 LOAD (Offset = 1808h) [Reset = 00000000h]

LOAD is shown in [Figure 34-82](#) and described in [Table 34-69](#).

Return to the [Summary Table](#).

The contents of LOAD register are copied to CTR on any operation designated to do a "LOAD". The LOAD is used to compare with the CTR for generating a "Load Event" that can be used for interrupt, trigger, or signal generator actions.

**Figure 34-82. LOAD**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 43 CC\_01[y] (Offset = 1810h + formula) [Reset = 0000000h]

CC\_01[y] is shown in [Figure 34-83](#) and described in [Table 34-70](#).

Return to the [Summary Table](#).

The CC\_01 register is a register that can be used as either a capture register, to capture the next CTR value on an event, or a compare to the current CTR to create an event. It cannot operate concurrently as both. There are two Capture-Compare slices of hardware for each counter, hence there are two CC\_01 registers per timer. On a capture event, the next value of the CTR is loaded so that CTR and CC\_01 (which captured) will be equal on the cycle that an interrupt or trigger is created from the capture action.

Offset = 1810h + (y \* 4h); where y = 0h to 1h

The Basic Timer (TIMB) delivers fundamental timing functionality through configurable counters that support periodic interrupts for various timing applications.

<b>35.1 TIMB Overview</b> .....	<b>2350</b>
<b>35.2 TIMB Operation</b> .....	<b>2351</b>
<b>35.3 TIMB Example Applications</b> .....	<b>2356</b>
<b>35.4 TIMB Registers</b> .....	<b>2362</b>

## 35.1 TIMB Overview

The Basic Timer (TIMB) is designed to provide fundamental timing functionality for system operations and event management. TIMB offers configurable periodic interrupt generation through an array of simple counters. The module can be used in various timing applications, from basic periodic interrupts to more complex event timing measurements. Each counter in the array operates independently or can be chained together to create longer time bases. The event management system allows the timer to measure timing properties of external events, including duration measurement and event counting.

### 35.1.1 Features

TIMB features include:

- Configurable array of 2-8 counters
  - 16-bit resolution
  - Bus clock source with prescaler
  - Up counting mode
  - Chaining 16-bit counters for longer time base
  - One-shot or continuous operation
  - Event-based control (start/stop/reset)
- Event generation capabilities
  - Counter overflow events
  - Start/stop events
  - Capture events
- Event Measurement features
  - Event counting
  - Duration measurement
  - Event sequence detection
- Interrupt / event generation support
- Hardware register locking during operation

### 35.1.2 TIMB Block Diagram

[Figure 35-1](#) depicts the top level functionality of a TIMB instance. TIMB consists of an array of counters (CNTR0 to CNTRN). Each counter generates three events, counter overflow (OVF), counter start (START), and counter stop (STOP). The events from each counter can be enabled selectively to generate the timer interrupt (BTIMINT). A generic publisher event is also available for triggering other IPs based on timer events.

Each counter can START, STOP, or RESET from external events such as an OVF, ADC, timer, GPIO or another peripheral. All counters are clocked from the Bus Clock.

---

#### Note

Refer to the device-specific data sheet to determine the number of counters and the external event which are supported.

---

Figure 35-1. TIMB Block Diagram

## 35.2 TIMB Operation

### 35.2.1 Counter Block Operation

The functions of the counter block are outlined in the [TIMB Counter Block](#). The counter operation can be controlled from hardware events (clock, reset, and enable) or through software configuration. Once enabled (TIMB.CTL0[j].EN = 1), the counter (TIMB.CNT[j]) increments by one on each positive edge of the counter clock. The counter continues incrementing until reaching the value stored in the respective load register (TIMB.LD[j]) generating an overflow (OVF). On the next positive clock edge the counter is reset to zero. The counter enable and reset behavior is summarized in [Table 35-1](#).

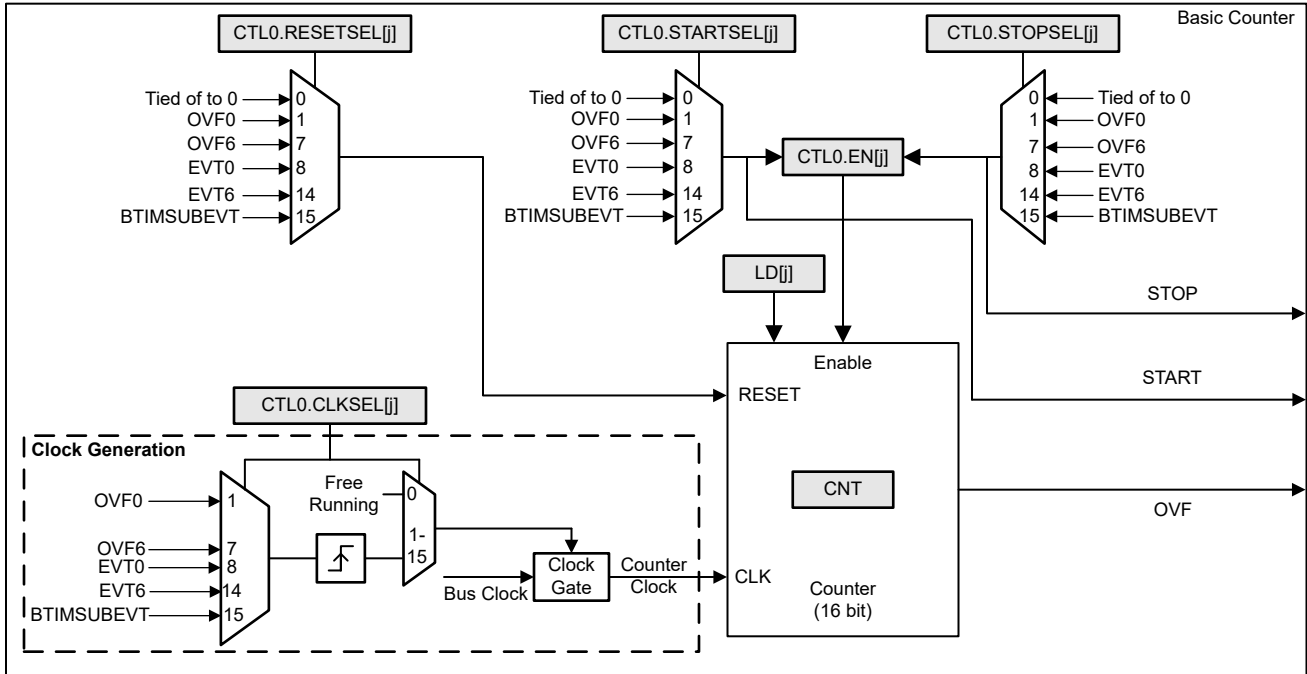

Figure 35-2. TIMB Counter Block

Table 35-1. Counter Operation

CTL0.EN[j]	Counter reset	Effect on counter
0	x	Counter remains in the current state
1	0	If the current value of the counter equals the LD value then, the counter overflows to 0, else counter = counter + 1
1	1	Counter is cleared to 0

### 35.2.1.1 Clock Source Selection

The Basic Timer provides flexible clock source selection for each counter through the TIMB.CTL0[j].CLKSEL field. Each counter is driven by the BUSCLK which can be gated by external event edges or overflow events from other counters. By default the BUSCLK is the clock source to the counter.

#### Note

Counter n can only use the OVF from counters with indices less than (n-1) as a clock source selection.

The clock path includes:

1. Event source multiplexer controlled by TIMB.CTL0[j].CLKSEL
2. Edge detection logic for event-based clocking
3. BUSCLK clock gating

The [Counter Clock Source Generation](#) figure indicates the relationship between BUSCLK, TIMB.CTL0[j].CLKSEL, and the counter clock. In this example, EVT1 is selected to gate the BUSCLK using the TIMB.CTL0[j].CLKSEL field. The counter clock is pulsed on the next positive edge of EVT1.

Figure 35-3. Counter Clock Source Generation

### 35.2.1.2 Counter Reset Generation

The counter can be reset to zero based on the selected reset sources configured by TIMB.CTL0[j].RESETSEL. When the reset source is pulsed high the counter is cleared to zero.

**Note**

Counter n can only use the OVF from counters with indices less than (n-1) as a reset source selection.

Figure 35-4 shows the counters reset generation functionality. EVT2 is selected as the reset source for the counter. On the next positive edge of EVT2 the counter is cleared to zero.

Figure 35-4. Counter Reset Example

### 35.2.1.3 Event Based Enable and Disable

The TIMB.CTL0[j].EN field enables the counter based on software or hardware events. The start event can be configured to be one of the events using TIMB.CTL0[j].STARTSEL field. In this case, TIMB.CTL0[j].EN is set based on the selected start event, provided the TIMB.MIS.CNTxSTOP bit is 0. Similarly, the source of stop event can be configured by using the TIMB.CTL0[j].STOPSEL field. If a stop event occurs, TIMB.CTL0[j].EN is cleared.

**Note**

In cases where the same event is chosen as both the start and stop sources, clearing TIMB.CTL0[j].EN has a higher priority than setting TIMB.CTL0[j].EN.

Effect of START and STOP events on CTL0[j].EN demonstrates the effect of start and stop events on TIMB.CTL0[j].EN. TIMB.CTL0[j].EN is set on the next positive clock edge after the EVT1\_ED and is cleared on the next positive edge after EVT2\_ED.

- TIMB.CTL0[j].EN is not enabled in software
- TIMB.CTL0[j].STARTSEL is configured to EVT1
- TIMB.CTL0[j].STOPSEL is configured to EVT2

Figure 35-5. Effect of START and STOP events on CTL0[j].EN

### 35.2.1.4 Event Generation

Each counter generates 3 events, OVF, START and STOP. Figure 35-6 depicts example waveforms to illustrate the generation of the OVF event. OVF is pulsed for 1 bus clock cycle when the counter value equals the TIMB.LD[j] value.

START and STOP event generation is shown in START & STOP Event Generation. In this scenario the counter generates a START event on EVT1 and a STOP event on EVT2.

Figure 35-6. OVF Generation

Figure 35-7. START & STOP Event Generation

35.2.1.5 Interrupt Generation

One interrupt is generated for all of the counters with the TIMB array. The sources to the interrupt are the OVF, START, & STOP events from each timer. Refer to Table 35-2 for a summary of the interrupt sources.

The TIMB.IIDX register is a priority enabled interrupt index. The interrupts are set from the Raw Interrupt Status (TIMB.RIS) and Interrupt Mask (TIMB.IMASK) registers. Setting an IMASK bit un-masks the corresponding interrupt source and exposes the interrupt in the TIMB.IIDX register. On each read of TIMB.IIDX the highest priority interrupt is indicated. After it's read, the pending interrupt is cleared.

Table 35-2. TIMB Interrupt Sources

Counter	Name	Description
CNTRx	CNTxOVF	CNTRx.OVF event occurred.
	CNTxSTRT	CNTRx.START event occurred.
	CNTxSTOP	CNTRx.STOP event occurred.

35.2.1.6 Counter Behavior on a Debug Halt

The behavior of the counters on a CPU halting execution due to a debug halt event, can be controlled by the TIMB.PDBGCTL.FREE and TIMB.PDBGCTL.SOFT bits. Table 35-3 describes the effect of debug halt on the counter behavior.

Table 35-3. Effects of Debug Halt on Counter

TIMB.PDBGCTL.FREE	TIMB.PDBGCTL.SOFT	Effect of debug halt on the counter.
1	x	No effect
0	0	Counter stops immediately. When the debug halt condition is removed, the counter starts from the current value.
0	1	Counter stops on reaching 0. When the debug halt condition is removed, the counter starts from the current value.

**Figure 35-8. Effects of Debug Halt on Counter Timing Diagram**

### 35.2.1.7 Hardware Locking of Configuration Registers

When TIMB.CTL0[j].EN = 1, writes to the following register fields are ignored in hardware. This prevents unintentional writes to the configuration registers when the counter is operational.

- TIMB.CTL0[j].STARTSEL
- TIMB.CTL0[j].STOPSEL
- TIMB.CTL0[j].RESETSEL
- TIMB.CTL0[j].CLOCKSEL
- TIMB.LD[j].VAL
- TIMB.CNT[j].VALUE

## 35.3 TIMB Example Applications

### 35.3.1 Periodic Interrupt Generation

This is a basic use case, wherein a periodic interrupt is generated with one counter. The register configuration for the example waveform shown is tabulated in [Table 35-4](#). In this example, an interrupt is generated when CNTR0 equals a value of 3.

**Table 35-4. Periodic Interrupt Configuration**

Register	Value	Description
TIMB.CTL0[0].STARTSEL	0	N/A
TIMB.CTL0[0].STOPSEL	0	N/A
TIMB.CTL0[0].RESETSEL	0	N/A
TIMB.CTL0[0].CLKSEL	0	Bus clock clocks the counter
TIMB[0].LD	3	LD value
TIMB.IMASK	0x001	OVF0 interrupt is enabled
TIMB.CTL0[0].EN	1	Enabled by software

Figure 35-9. Periodic Interrupt Generation Example

### 35.3.2 Counter Chaining

In the Figure 35-10, two counters are cascaded to create a larger time duration. CNTR0 OVFO is used as the clock source of CNTR1. The interrupt is generated when the CNTR1 OVFO occurs. This results in interrupt being generated every 12 bus clock cycles.

Table 35-5. Counter Chaining Register Configuration

Register	Value	Description
<b>CNTR0</b>		
TIMB.CTL0[0].STARTSEL	0	N/A
TIMB.CTL0[0].STOPSEL	0	N/A
TIMB.CTL0[0].RESETSEL	0	N/A
TIMB.CTL0[0].CLKSEL	0	N/A
TIMB.LD[0]	2	LD value
TIMB.CTL0[0].EN	1	Enabled by software
<b>CNTR1</b>		
TIMB.CTL0[1].STARTSEL	0	N/A
TIMB.CTL0[1].STOPSEL	0	N/A
TIMB.CTL0[1].RESETSEL	0	N/A
TIMB.CTL0[1].CLKSEL	1	OVFO is the CLK source
TIMB.LD[1]	3	LD Value
TIMB.CTL0[1].EN	1	Enabled by software
IMASK	0x008	OVF interrpr of CNTR1 enabled

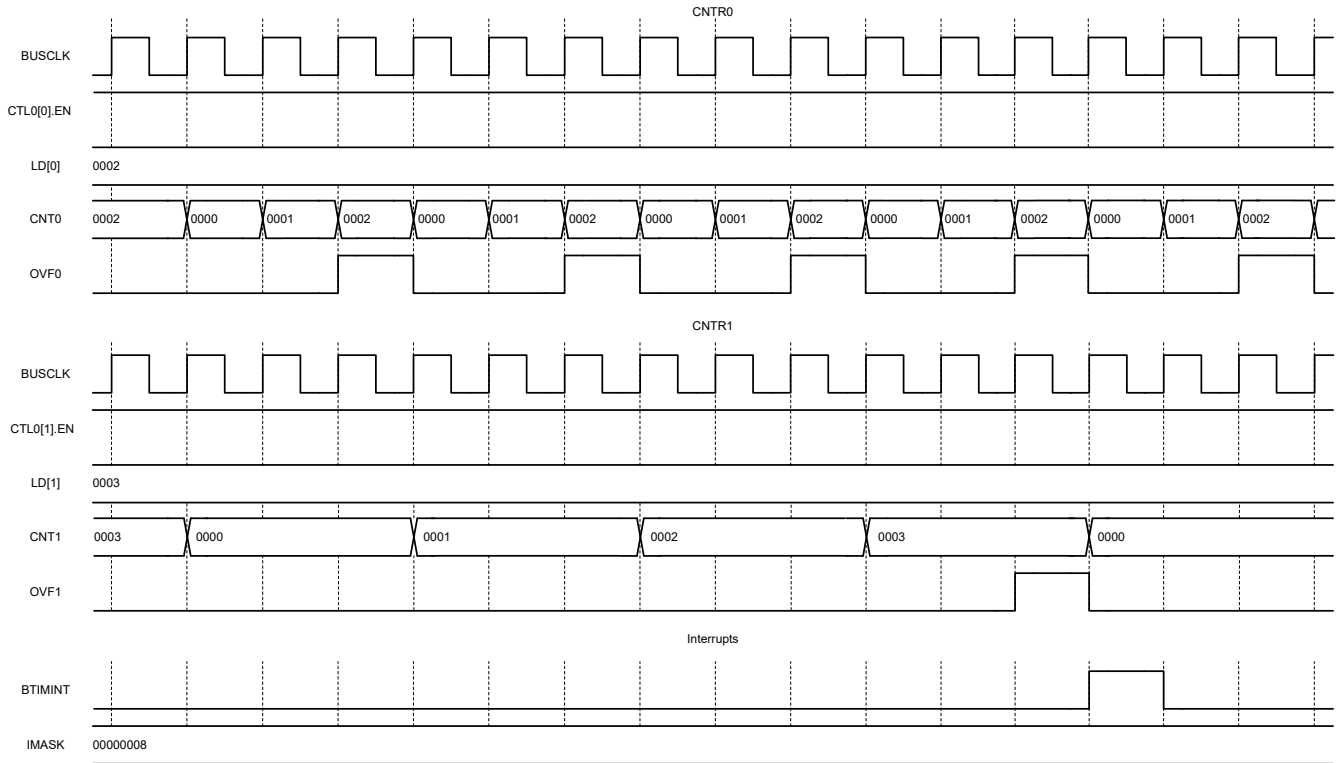

Figure 35-10. Counter Chaining Example

### 35.3.3 Event Counting

The Figure 35-11 implements a counter to generate an interrupt after counting a certain number of events. In this specific example, as the LD value is 2, an interrupt is generated after 3 events on EVT2.

Table 35-6. Event Counting Register Configuration

Register	Value	Description
TIMB.CTL0[j].STARTSEL	9	Enabled by EVT2
TIMB.CTL0.STOPSEL	0	N/A
TIMB.CTL0[j].RESETSEL	0	N/A
TIMB.CTL0[j].CLKSEL	9	EVT2 is selected
TIMB.LD[j]	2	LD Value
TIMB.IMASK	0x001	OVF interrupt enabled
TIMB.CTL0[j].EN	0	Enabled by hardware event

**Figure 35-11. Event Counting Example**

### 35.3.4 Event Duration Measurement

In the [Figure 35-12](#), the average period of EVT2 is being measured. The following configuration is used to achieve this function.

- EVT2 is used as the start source for CNTR0 and CNTR1
- EVT2 is also used as the clock source of CNTR1
- CNTR0 operates off the BUSCLK
- CNTR1's OVF is the stop source for both counters
- The LD value of CNTR0 needs to be large enough so that CNTR0 does not overflow before the STOP event
- The LD value of CNTR1 is set to 2

Both the counters start on the first EVT2 event. After 2 more EVT2 events, CNTR1 will assert OVF1. This will stop both the counters. Using the value of CNTR0, we can compute the average duration of EVT2.

$$\text{EVT2-duration} = (\text{CNTR0 value when it stopped}) / (\text{CNTR1 LD value} + 1) = 36 (0x24) / 3 = 12 \text{ cycles.}$$

**Table 35-7. Event Duration Example Configuration**

Register	Value	Description
<b>CNTR0</b>		
TIMB.CTL0[0].EN	0	Enabled by hardware event
TIMB.CTL0[0].STARTSEL	9	EVT2 is used as the start source
TIMB.CTL0[0].STOPSEL	2	CNTR1 OVF is selected
TIMB.CTL0[0].RESETSEL	0	N/A
TIMB.CTL0[0].CLKSEL	0	Bus clock is the clock source
TIMB.LD[0]	Large value	CNTR0 should not overflow before the stop event
TIMB.CTL0[0].EN	0	Enabled by hardware event
<b>CNTR1</b>		
TIMB.CTL0[1].STARTSEL	9	EVT2 is used as the start source
TIMB.CTL0[1].STOPSEL	2	CNTR1 OVF is selected
TIMB.CTL0[1].RESETSEL	0	N/A
TIMB.CTL0[1].CLKSEL	9	EVT2 is used as the clock source
TIMB[1].LD	2	LD value
TIMB[1].IMASK	0x008	OVF1 is enabled
TIMB.CTL0[1].EN	0	Enabled by hardware event

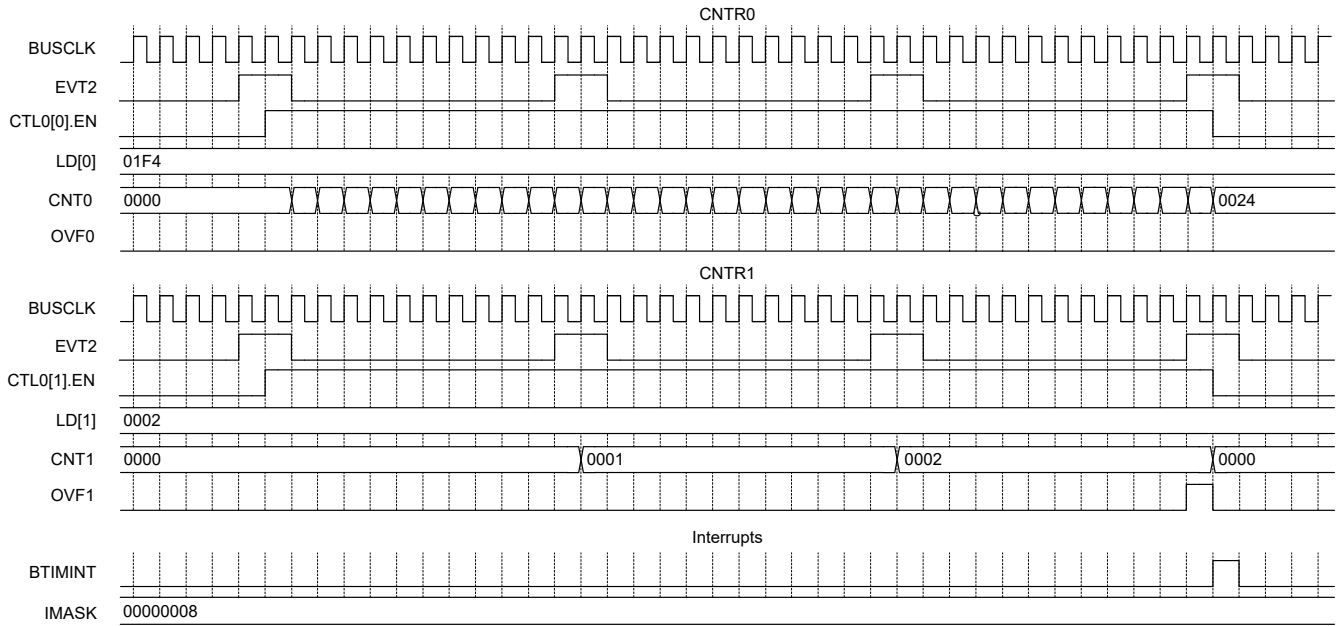

Figure 35-12. Event Duration Measurement Example

### 35.3.5 Event Sequence Checking

The Figure 35-13 implements a single counter to detect the occurrence of EVT3 after EVT2. If EVT3 occurs within a specified window after EVT2 then the counter is stopped and reset. The window interval is determined by the LD[j] value. If EVT3 does not occur in this window, the counter overflows and generates an interrupt.

Table 35-8. Event Sequence Configuration

Register	Value	Description
TIMB.CTL0.STARTSEL[1]	9	EVT2 is used as the start source
TIMB.CTL0.STOPSEL[1]	10	EVT3 is used as the stop source
TIMB.CTL0.RESETSEL[1]	10	EVT3 is used as the reset source
TIMB.CTL0.CLKSEL[1]	0	BUSCLK is used as the counter clock
TIMB.LD[1]	0x06	LD defines the window
TIMB.IMASK	0x08	OVF1 is enabled
TIMB.CTL0.EN[1]	0	Enabled by hardware

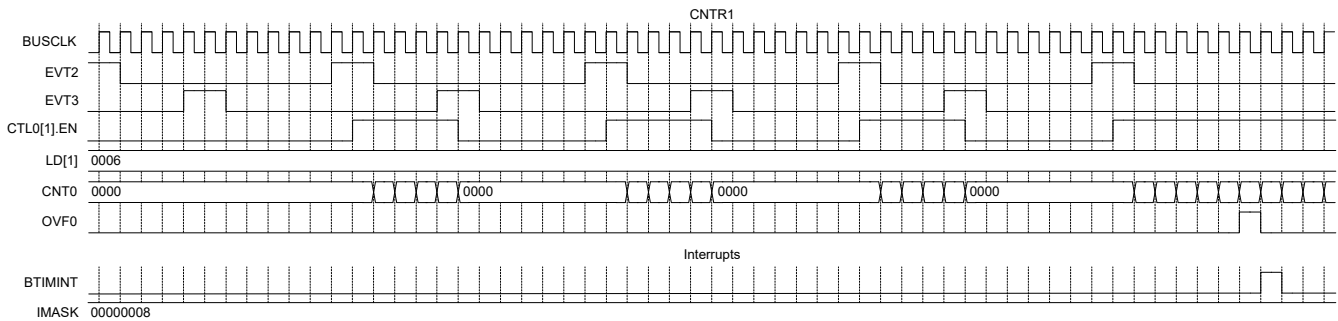

Figure 35-13. Event Sequence Checker Example

### 35.3.6 PWM Generation

This example generates a pulse width modulated (PWM) signal using GPIO and two TIMB counters. One counter defines the period of the PWM signal and the other counter defines the pulse width of the PWM signal.

The register configuration of the counters, IMASK configuration of timer publisher are described in the table below.

- CNTR0 is setup to be a free running counter.
- CNTR1 is started on CNTR0 overflow.
- CNTR1 is stopped and reset on OVF1. This ensures that CNTR1 runs once on every CNTR0 overflow.
- A publisher event is generated on OVF0 and OVF1
- GPIO pin is programmed to toggle on the publisher event of the timer

Table 35-9 illustrates an example PWM generation method. The relative position of OVF1 with respect to OVF0 varies as the LD value of CNTR1 is varied. This modulates the pulse width of the GPIO pin as seen in the Figure 35-14.

**Table 35-9. PWM Register Configuration**

Register	Value	Description
<b>CNTR0</b>		
TIMB.CNT[0]	LD -1	EVT2 is used as the start source.
TIMB.CTL0[0].CLKSEL	0	Bus clock is used to clock the counter
TIMB.LD[0]	8	LD value defines PWM signal period. Set to 8 in this example
TIMB.CTL[0].EN	1	Enable counter 0 after configuring all the registers.
<b>CNTR1</b>		
TIMB.CTL0[1].STARTSEL	1	Use CNTR0's OVF as the start condition.
TIMB.CTL0[1].STOPSEL	2	Use CNTR1's OVF as the stop condition.
TIMB.CTL0[1].RESETSEL	2	Use CNTR1's OVF as the reset condition.
TIMB.LD[1]	Vary between 2 and CNTR0.LD -2	LD value defines the high pulse width of the PWM.
TIMB.CNT0[1].CTL0.EN	1	Enable counter 1 after configuring all the registers.
<b>Publisher configuration</b>		
TIMB.PUB0.IMASK	0x9	Generate a publisher event on CNTR0.OVF and CNTR1.OVF

**Figure 35-14. PWM Example**

## 35.4 TIMB Registers

Table 35-10 lists the memory-mapped registers for the TIMB registers. All register offset addresses not listed in Table 35-10 should be considered as reserved locations and the register contents should not be modified.

**Table 35-10. TIMB Registers**

Offset	Acronym	Register Name	Section
400h	FSUB_0	Subscriber Configuration Register.	<a href="#">Section 1</a>
444h	FPUB_0	Publisher Port 0	<a href="#">Section 2</a>
800h	PWREN	Power enable	<a href="#">Section 3</a>
804h	RSTCTL	Reset Control	<a href="#">Section 4</a>
814h	STAT	Status Register	<a href="#">Section 5</a>
1018h	PDBGCTL	Peripheral Debug Control	<a href="#">Section 6</a>
1020h	IIDX	Interrupt index	<a href="#">Section 7</a>
1028h	IMASK	Interrupt Mask. If a bit is set, then corresponding interrupt is un-masked. Un-masking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.	<a href="#">Section 8</a>
1030h	RIS	Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.	<a href="#">Section 9</a>
1038h	MIS	Masked interrupt status. This is an AND of the IMASK and RIS registers.	<a href="#">Section 10</a>
1040h	ISET	Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.	<a href="#">Section 11</a>
1048h	ICLR	Interrupt clear. Write a 1 to clear corresponding Interrupt.	<a href="#">Section 12</a>
1050h	IIDX	Interrupt index	<a href="#">Section 13</a>
1058h	IMASK	Interrupt Mask. If a bit is set, then corresponding interrupt is un-masked. Un-masking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.	<a href="#">Section 14</a>
1060h	RIS	Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.	<a href="#">Section 15</a>
1068h	MIS	Masked interrupt status. This is an AND of the IMASK and RIS registers.	<a href="#">Section 16</a>
1070h	ISET	Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.	<a href="#">Section 17</a>
1078h	ICLR	Interrupt clear. Write a 1 to clear corresponding Interrupt.	<a href="#">Section 18</a>

**Table 35-10. TIMB Registers (continued)**

Offset	Acronym	Register Name	Section
10E0h	EVT_MODE	Event Mode	<a href="#">Section 19</a>
1100h + formula	CTL0_j	CTL0 register	<a href="#">Section 20</a>
1104h + formula	LD_j	Counter period register.	<a href="#">Section 21</a>
1108h + formula	CNT_j	Counter register.	<a href="#">Section 22</a>

Complex bit access types are encoded to fit into small table cells. [Table 35-11](#) shows the codes that are used for access types in this section.

**Table 35-11. TIMB Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
RH	R H	Read Set or cleared by hardware
Write Type		
W	W	Write
WK	W K	Write Write protected by a key
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

**1 FSUB\_0 Register (Offset = 400h) [Reset = 0000000h]**

 FSUB\_0 is shown in [Table 35-12](#).

 Return to the [Summary Table](#).

Subscriber port

**Table 35-12. FSUB\_0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-4	RESERVED	R/W	0h	
3-0	CHANID	R/W	0h	0 = disconnected. 1-15 = connected to channelID = CHANID. 0h = A value of 0 specifies that the event is not connected Fh = Consult your device datasheet as the actual allowed maximum may be less than 255.

## 2 FPUB\_0 Register (Offset = 444h) [Reset = 0000000h]

FPUB\_0 is shown in [Table 35-13](#).

Return to the [Summary Table](#).

Publisher port

### 3 PWREN Register (Offset = 800h) [Reset = 00000000h]

PWREN is shown in [Table 35-14](#).

Return to the [Summary Table](#).

Register to control the power state

**Table 35-14. PWREN Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	KEY	W	0h	KEY to allow Power State Change 26h = KEY to allow write access to this register
23-1	RESERVED	R/W	0h	
0	ENABLE	R/WK	0h	Enable the power <a href="#">KEY</a> must be set to 26h to write to this bit. 0h = Disable Power 1h = Enable Power

#### 4 RSTCTL Register (Offset = 804h) [Reset = 0000000h]

RSTCTL is shown in [Table 35-15](#).

Return to the [Summary Table](#).

Register to control reset assertion and de-assertion

**Table 35-15. RSTCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	KEY	W	0h	Unlock key B1h = KEY to allow write access to this register
23-2	RESERVED	W	0h	
1	RESETSTKYCLR	WK	0h	Clear the RESETSTKY bit in the STAT register <b>KEY</b> must be set to B1h to write to this bit. 0h = Writing 0 has no effect 1h = Clear reset sticky bit
0	RESETASSERT	WK	0h	Assert reset to the peripheral <b>KEY</b> must be set to B1h to write to this bit. 0h = Writing 0 has no effect 1h = Assert reset

**5 STAT Register (Offset = 814h) [Reset = 00000000h]**

STAT is shown in [Table 35-16](#).

Return to the [Summary Table](#).

peripheral enable and reset status

**Table 35-16. STAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-17	RESERVED	R	0h	
16	RESETSTKY	R	0h	This bit indicates, if the peripheral was reset, since this bit was cleared by RESETSTKYCLR in the RSTCTL register 0h = The peripheral has not been reset since this bit was last cleared by RESETSTKYCLR in the RSTCTL register 1h = The peripheral was reset since the last bit clear
15-0	RESERVED	R	0h	

## 6 PDBGCTL Register (Offset = 1018h) [Reset = 0000000h]

PDBGCTL is shown in [Table 35-17](#).

Return to the [Summary Table](#).

This register can be used by the software developer to control the behavior of the peripheral relative to the 'Core Halted' input

**Table 35-17. PDBGCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	R/W	0h	
1	SOFT	R/W	0h	Soft halt boundary control. This function is only available, if <b>FREE</b> is set to 'STOP' 0h = The peripheral will halt immediately, even if the resultant state will result in corruption if the system is restarted 1h = The peripheral blocks the debug freeze until it has reached a boundary where it can resume without corruption
0	FREE	R/W	0h	Free run control 0h = The peripheral freezes functionality while the Core Halted input is asserted and resumes when it is deasserted. 1h = The peripheral ignores the state of the Core Halted input

## 7 IIDX Register (Offset = 1020h) [Reset = 0000000h]

IIDX is shown in [Table 35-18](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. 0x0 means no event pending. Interrupt 1 is the highest priority, 2 next highest priority etc. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Table 35-18. IIDX Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	
9-0	STAT	R	0h	Interrupt index status 00h = No bit is set means there is no pending interrupt request 01h = Counter0 period match interrupt 02h = Counter 0 start 03h = Counter0 stop 04h = Counter1 period match interrupt 05h = Counter 1 start 06h = Counter1 stop 07h = Counter2 period match interrupt 08h = Counter 2 start 09h = Counter2 stop 0Ah = Counter3 period match interrupt 0Bh = Counter 3 start 0Ch = Counter3 stop Dh = Counter4 period match interrupt Eh = Counter 4 start Fh = Counter4 stop 10h = Counter5 period match interrupt 11h = Counter 5 start 12h = Counter5 stop 13h = Counter6 period match interrupt 14h = Counter 6 start 15h = Counter6 stop 16h = Counter7 period match interrupt 17h = Counter 7 start 18h = Counter7 stop

## 8 IMASK Register (Offset = 1028h) [Reset = 0000000h]

IMASK is shown in [Table 35-19](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is un-masked. Un-masking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

**Table 35-19. IMASK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	R/W	0h	
23	CNT7STOP	R/W	0h	CNT7STOP Interrupt enable bit 0h = Interrupt is not pending. 1h = Interrupt is pending.
22	CNT7STRT	R/W	0h	CNT7STRT Interrupt enable bit 0h = Interrupt is not pending. 1h = Interrupt is pending.
21	CNT7OVF	R/W	0h	CNT7OVF Interrupt enable bit 0h = Interrupt is not pending. 1h = Interrupt is pending.
20	CNT6STOP	R/W	0h	CNT6STOP Interrupt enable bit 0h = Interrupt is not pending. 1h = Interrupt is pending.

## 11 ISET Register (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Table 35-22](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Table 35-22. ISET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	W	0h	
23	CNT7STOP	W	0h	Set Counter 7 stop event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.

0	CNT0OVF	W	0h	Clear Counter 0 period match flag. 0h = Interrupt is not pending. 1h = Interrupt is pending.

### 13 IIDX Register (Offset = 1050h) [Reset = 0000000h]

IIDX is shown in [Table 35-24](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. 0x0 means no event pending. Interrupt 1 is the highest priority, 2 next highest priority etc. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Table 35-24. IIDX Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	
9-0	STAT	R	0h	Interrupt index status 00h = No bit is set means there is no pending interrupt request 01h = Counter0 period match interrupt 02h = Counter 0 start 03h = Counter0 stop 04h = Counter1 period match interrupt 05h = Counter 1 start 06h = Counter1 stop 07h = Counter2 period match interrupt 08h = Counter 2 start 09h = Counter2 stop 0Ah = Counter3 period match interrupt 0Bh = Counter 3 start 0Ch = Counter3 stop Dh = Counter4 period match interrupt Eh = Counter 4 start Fh = Counter4 stop 10h = Counter5 period match interrupt 11h = Counter 5 start 12h = Counter5 stop 13h = Counter6 period match interrupt 14h = Counter 6 start 15h = Counter6 stop 16h = Counter7 period match interrupt 17h = Counter 7 start 18h = Counter7 stop

## 14 IMASK Register (Offset = 1058h) [Reset = 0000000h]

IMASK is shown in [Table 35-25](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is un-masked. Un-masking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

**Table 35-25. IMASK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	R/W	0h

## 17 ISET Register (Offset = 1070h) [Reset = 0000000h]

ISET is shown in [Table 35-28](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Table 35-28. ISET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	W	0h	
23	CNT7STOP	W	0h	Set Counter 7 stop event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
22	CNT7STRT	W	0h	Set Counter 7 start event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
21	CNT7OVF	W	0h	Set Counter 7 period match flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
20	CNT6STOP	W	0h	Set Counter 6 stop event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
19	CNT6STRT	W	0h	Set Counter 6 start event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
18	CNT6OVF	W	0h	Set Counter 6 period match flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
17	CNT5STOP	W	0h	Set Counter 5 stop event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
16	CNT5STRT	W	0h	Set Counter 5 start event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
15	CNT5OVF	W	0h	Set Counter 5 period match flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
14	CNT4STOP	W	0h	Set Counter 4 stop event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
13	CNT4STRT	W	0h	Set Counter 4 start event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
12	CNT4OVF	W	0h	Set Counter 4 period match flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
11	CNT3STOP	W	0h	Set Counter 3 stop event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
10	CNT3STRT	W	0h	Set Counter 3 start event flag 0h = Interrupt is not pending. 1h = Interrupt is pending.
9	CNT3OVF	W	0h	Set Counter 3 period match flag 0h = Interrupt is not pending. 1h = Interrupt is pending.

### 36.1 Overview

The Low-Frequency Subsystem (LFSS) combines several functional peripherals under one shared subsystem. These peripherals are clocked by the low-frequency clock (LFCLK) or need to be active during low-power modes. The low-frequency clock has a typical frequency of 32kHz and is mainly intended for long-term timekeeping. In some devices, the LFSS is powered by a separate battery backup power domain called PDB, and the device will have a physical VBAT power pin present.

**Note**

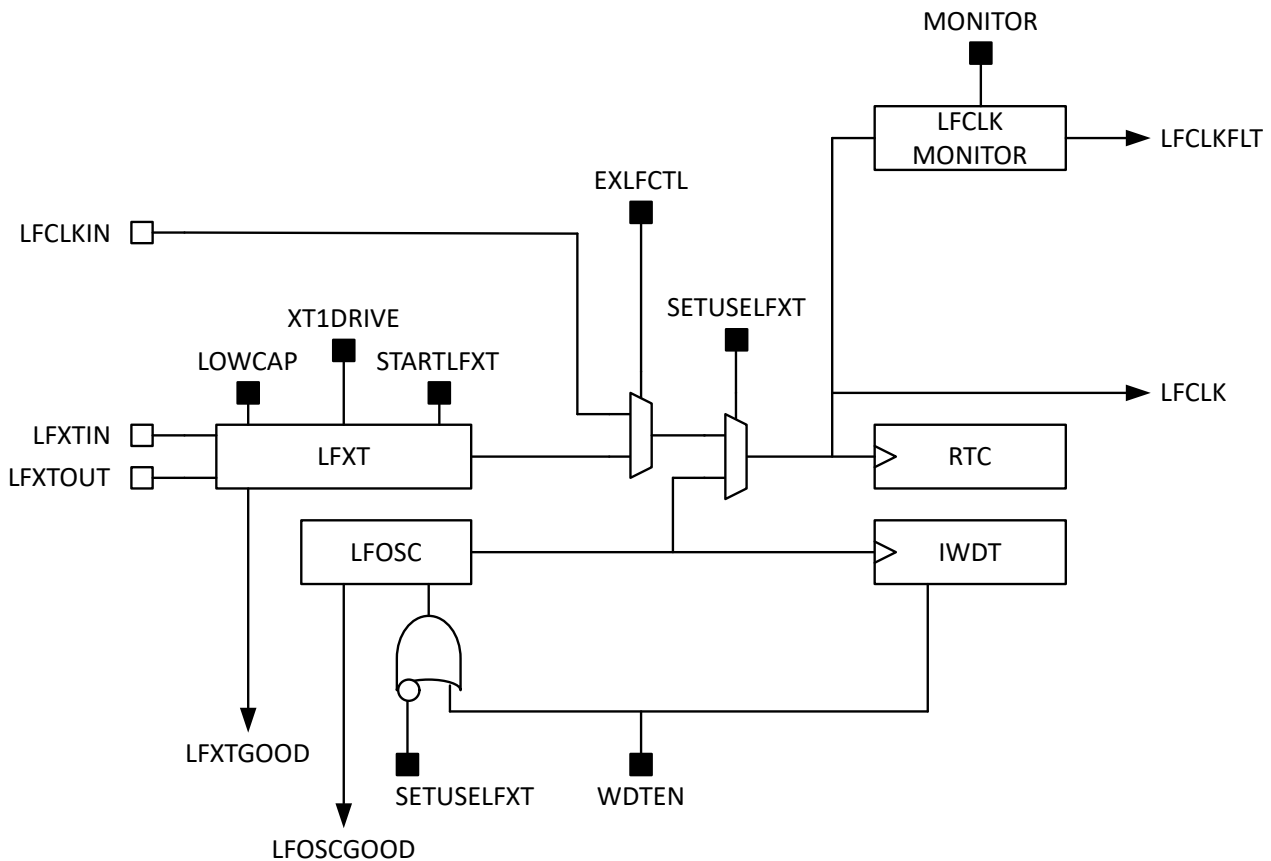

Not all the features described in this chapter are present in all devices. Refer to the device-specific data sheet to know which features of LFSS are present in the specific device.

The superset version of the LFSS contains following components:

- A dedicated battery backup power domain and a dedicated supply pin (VBAT)
- Real time clock (RTC) with additional prescaler extension and timestamp captures
- An independent watchdog timer (IWDT)
- Tamper detection input/output (TIO) module
- A small scratchpad memory storage (SPM)

### 36.2 Clock System

The low-frequency clock system is part of LFSS, but the control bits are located in the SYSCCTL module. [Figure 36-1](#) illustrates the components of the clock system.

**Figure 36-1. LFSS Low-Frequency Clock System**

The control bits for LFCLK control is located inside the SYSCCTL registers. In case of a power loss of the VDD / VCORE domain, the contents of the registers are lost.

In devices with a dedicated backup power domain (PDB) which remains powered by VBAT:

- The shadow latches will keep the LFCLK configuration active until the power returns
- The shadow latches are not reset on return of power and keep the last configuration status until the device clock configuration is restored by software

In devices without a dedicated backup power domain:

- The LFSS will not be operational without VDD / VCORE present

In both scenarios, the user must reconfigure the LFCLK registers after restoring power on VDD / VCORE to the device.

### 36.3 LFSS Reset

In devices with a dedicated battery backup power domain (PDB) with supply pin (VBAT), the LFSS has its VBAT power management unit (VBAT PMU) and its own reset generation circuit related to the VBAT supply pin.

---

#### Note

For devices without the PDB and VBAT supply pin, refer to the respective TRM chapters on the supported peripherals (RTC, IWDT)

---

Two subcircuits are related to the reset of the LFSS.

- The VBAT power-on-reset (POR) circuit is a  $V_{th}$  based supply voltage monitor. The POR circuit is used to reset the VBAT PMU and initiate the startup of the cold boot sequence.
- The VBAT brown-out-reset (BOR) circuit is a bandgap reference-based voltage monitor and enables the VBAT PMU LDO when the VBAT supply is large enough to operate the LDO safely. The battery backup power domain (PDB) becomes available after this sequence, and will reset all logic in the PDB.

The battery backup power domain (PDB) does not experience a reset unless the power supply on the VBAT pin drops below the VBAT BOR level. The VDD BOR reset from the Main PMU does not reset the PDB domain while VBAT remains sufficiently powered.

In addition, the LFSS supports an VBAT PMU POR level software-reset request. This reset supports software development and from the LFSS point of view it looks like the VBAT supply was temporary disconnected and reconnected. This also means the PDB domain is brought down and back up and all flops have a full reset.

---

#### Note

The software POR request is mainly for the software-development to emulate the removal of the external battery from VBAT. After this POR request event, the software needs to re-enable the LFXTAL, switch the LFCLK to the LFXTAL, and finally re-initialize the peripherals within LFSS (RTC, IWDT, TIO, SPM).

---

After the LFXT and LFSS peripherals are configured and initialized by software, a persistent status bit in the LFSS domain indicates the “running / RTC active” status to the software. On device power-up, the software reads the reset cause table and initializes the device accordingly (for example, initial power up or wake from SHUTDOWN mode). Before initializing the RTC, the software should check the LFXT and RTC good/active status and skip the initialization when already running and active.

### 36.4 Real Time Counter (RTC\_x)

The low-frequency subsystem (LFSS) contains a real-time counter (RTC).

In devices for which the LFSS is powered by an independent VBAT supply pin to support the backup-battery power domain (PDB), the RTC variant has extended features and is referred to as RTC\_A.

In devices for which the LFSS is powered internally by the main power supply pin VDD, the RTC variant is referred as RTC\_B.

The design of the RTC\_x instances are intended to be backward compatible with RTC.

For more information on the LFSS real-time counter and various RTC instances, see the RTC chapter.

### 36.5 Independent Watchdog Timer (IWDT)

The low-frequency subsystem (LFSS) contains an independent watchdog timer (IWDT).

- In devices for which the LFSS is powered by an independent VBAT supply pin to support the backup-battery power domain (PDB), the IWDT variant is independent in the sense of having both an independent power supply and an independent, fail-safe clock source.
- In devices for which the LFSS is powered internally by the main power supply pin VDD, the IWDT variant is only independent in the sense of having an independent, fail-safe clock source.

The independent watchdog timer (IWDT) is a device-independent supervisor which monitors code execution and overall hang up scenarios of the device. If the application software does not successfully reset the watchdog within the programmed time, the watchdog generates a POR reset to the device.

For more information on the LFSS independent watchdog timer, see the IWDT chapter.

### 36.6 Lock Function of RTC and IWDT

Safety or secure applications must make sure that the RTC value and IWDT configurations cannot be changed after initial configuration on accident by software or during an address transient error during an intentional write access. Therefore, the RTC counter, LFXT clock configuration, and IWDT configuration registers are protected by a lock bit.

When the lock bit is set, the protected registers cannot be changed even if the correct key is applied. The lock bit is writable and can be unset in case the RTC time needs to be updated or some other configuration needs to be changed. The RTC alarm, RTC timestamp, and IWDT restart function are not affected by the lock bit.

## 36.7 LFSS Registers

Table 36-1 lists the memory-mapped registers for the LFSS registers. All register offset addresses not listed in Table 36-1 should be considered as reserved locations and the register contents should not be modified.

**Table 36-1. LFSS Registers**

#### 4 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 36-5](#) and described in [Table 36-6](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

**Figure 36-5. IIDX**

## 6 RIS (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 36-7](#) and described in [Table 36-8](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Figure 36-7. RIS**

## 8 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 36-9](#) and described in [Table 36-10](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Figure 36-9. ISET**

## 10 IIDX (Offset = 1050h) [Reset = 0000000h]

IIDX is shown in [Figure 36-11](#) and described in [Table 36-12](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

## 11 IMASK (Offset = 1058h) [Reset = 0000000h]

IMASK is shown in [Figure 36-12](#) and described in [Table 36-13](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is unmasked. Unmasking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

## 12 RIS (Offset = 1060h) [Reset = 0000000h]

RIS is shown in [Figure 36-13](#) and described in [Table 36-14](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

#### 14 ISET (Offset = 1070h) [Reset = 0000000h]

ISET is shown in [Figure 36-15](#) and described in [Table 36-16](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Figure 36-15. ISET**

The real-time clock (RTC) module provides clock counters with calendar mode, a flexible programmable alarm, offset calibration, and a provision for temperature compensation.

<b>37.1 Overview</b> .....	<a href="#">2523</a>
<b>37.2 Basic Operation</b> .....	<a href="#">2524</a>
<b>37.3 Configuration</b> .....	<a href="#">2526</a>
<b>37.4 RTC Registers</b> .....	<a href="#">2537</a>

### 37.1 Overview

The real-time clock module provides time-keeping for the application, with counters for seconds, minutes, hours, day of the week, day of the month, and year, in selectable binary or binary-coded decimal (BCD) format. A variety of programmable interrupt alarms are provided. There are RTC instances (**RTC**, **RTC\_x**) that provide common key features, and additional instances (**RTC\_x**) that provide specific key features.

Common key features of across all instances of the real-time clock (**RTC**, **RTC\_x**) include:

- Real-time clock and calendar mode providing seconds, minutes, hours, day of week, day of month, and year
- Selectable binary or binary-coded decimal (BCD) format
- Leap-year correction (valid for year 1901 through 2099)
- Two customizable calendar alarm interrupts based on minute, hour, day of the week, and day of the month
- Interval alarm interrupt to wake every minute, every hour, at midnight, or at noon
- Periodic interrupt to wake at 4096, 2048, 1024, 512, 256, or 128Hz
- Periodic interrupt to wake at 64, 32, 16, 8, 4, 2, 1, and 0.5Hz
- Interrupt capability down to STANDBY mode with STOPCLKSTBY
- Calibration for crystal offset error and crystal temperature drift (up to  $\pm 240$  ppm total)
- RTC clock output to pin for calibration

**RTC\_x** instances include features such as:

- Three bit prescaler for heartbeat function with interrupt generation
- RTC external clock selection of untrimmed 32kHz, trimmed 512Hz, 256Hz or 1Hz
- RTC time stamp capture upon detection of a timer stamp event, including tamper (TIO) event and VDD fail event
- RTC counter lock function

#### 37.1.1 RTC Instances

Table 37-1 shows a comparison table of RTC instances and supported features.

**Table 37-1. RTC Instances and Key Features**

RTC Feature	RTC	RTC_A	RTC_B
Power enable register	Yes	–	–
Real-time clock and calendar mode providing seconds, minutes, hours, day of week, day of month, and year	Yes	Yes	Yes
Selectable binary or binary-coded decimal (BCD) format	Yes	Yes	Yes
Leap-year correction (valid for year 1901 through 2099)	Yes	Yes	Yes
Two customizable calendar alarm interrupts based on minute, hour, day of the week, and day of the month	Yes	Yes	Yes
Interval alarm interrupt to wake every minute, every hour, at midnight, or at noon	Yes	Yes	Yes
Periodic interrupt to wake at 4096, 2048, 1024, 512, 256, or 128Hz	Yes	Yes	Yes
Periodic interrupt to wake at 64, 32, 16, 8, 4, 2, 1, and 0.5Hz	Yes	Yes	Yes
Periodic interrupt to wake at 16, 8, 4 seconds	–	–	Yes
Interrupt capability down to STANDBY mode with STOPCLKSTBY	Yes	Yes	Yes
Calibration for crystal offset error and crystal temperature drift (up to $\pm 240$ ppm total)	Yes	Yes	Yes
RTC clock output to pin for calibration (GPIO)	Yes	Yes	Yes
RTC clock output to pin for calibration (TIO)	–	Yes	–
Three bit prescaler for heartbeat function with interrupt generation	–	Yes	–
RTC external clock selection of untrimmed 32kHz, trimmed 512Hz, 256Hz, or 1Hz	–	Yes	–

**Table 37-1. RTC Instances and Key Features (continued)**

RTC Feature	RTC	RTC_A	RTC_B
RTC time stamp capture upon detection of a timer stamp event, including: <ul style="list-style-type: none"> <li>TIO event</li> <li>VDD fail event</li> </ul>	–	Yes	–
RTC counter lock function	–	Yes	–

**Note**

To see which RTC instances and features are supported in a device, please see the device-specific data sheet.

**37.2 Basic Operation**

The RTC utilizes two prescaler blocks (RT0PS, RT1PS) to generate a 128Hz and 1Hz clock, respectively, from the source 32.768kHz RTCCLK. The prescaler blocks each support generating a periodic interrupt alarm at a variety of rates from 4096Hz down to 0.5Hz. The 1Hz clock output from RT1PS ticks the counter block, which tracks seconds, minutes, hours, and day of the week. The counter block also sources an interval alarm interrupt once per minute, per hour, at midnight, or at noon. The counter midnight output sources the calendar block, which provides day of the month, month, and year, with leap year correction. Two independent calendar alarm interrupts are provided to wake the application at specific times.

Figure 37-1. RTC Block Diagram

### 37.3 Configuration

The RTC is configured with the RTC peripheral registers.

The RTC state can be reset at any time by asserting the VBATPOR bit in the LFSSRST register.

Application software may reset the RTC state at any time by setting the RESETASSERT bit in the RSTCTL register of the RTC together with the matching RSTCTL KEY value. The RESETSTKY bit in the STAT register of the RTC will be set following a reset of the RTC. This flag may be cleared by setting the RESETSTKYCLR bit in the RSTCTL register of the RTC. As such, software may determine if the RTC has been reset since the sticky reset bit (RESETSTKY) was last cleared. Many RTC registers have no initial conditions. These registers must be configured by application software before use.

To start the RTC counters, the MODCLKEN bit in the CLKCTL register must be set by application software. The MODCLKEN bit is initially cleared following a reset of the RTC.

When enabled and configured, the RTC runs in all power modes except SHUTDOWN. The RTC is not reset by a CPURST, SYSRST, or NRST pin triggered BOOTRST (see the [reset control](#) section for a detailed overview of device reset levels). As such, the RTC continues to operate even through software invocation of the bootstrap loader (BSL) or a hold of <1s on the external NRST pin.

#### 37.3.1 Clocking

The RTC is clocked directly from [RTCCLK](#), which is sourced either from the internal [LFOSC](#) or the external low frequency crystal oscillator ([LFXT](#)). The LFOSC and LFXT both require startup time. Ensure that the oscillator sourcing LFCLK in the application is configured and that LFCLK is operational before enabling power to the RTC module.

Two prescale dividers, RT0PS and RT1PS, are automatically configured to provide a 1-second clock interval for the RTC. The LFCLK must be running at 32kHz clock frequency for proper RTC operation. The RT0PS divider is sourced directly from LFCLK at 32kHz. The output of the RT0PS divider block is 32kHz/256, or 128Hz, and is used to source the input of the RT1PS divider block. The RT1PS output is 128Hz/128, or 1Hz, and is used to source the real-time clock counter registers with the required 1-second time interval.

Clearing the MODCLKEN bit in the CLKCTL register of the RTC halts the propagation of LFCLK to the real-time counters and the prescale counters (RT0PS and RT1PS) in the RTC. It does not have any effect on the LFCLK itself.

#### 37.3.2 Reading and Writing to RTC Peripheral Registers

The peripheral bus clock (ULPCLK) is asynchronous to the RTC clock source (RTCCLK). As a result, special care must be taken when reading and writing certain RTC peripheral registers.

#### Counter/Calendar Registers

The RTC counter/calendar registers are updated once per second. To prevent reading any counter/calendar register at the time of an update (which could result in an invalid time being read), a keep-out window is provided. The keep-out window is approximately 128/32768 seconds before the counters update. The read-only RTCRDY bit in the STA register is reset during the keep-out window, and set outside the keep-out window period. Any read of the counter/calendar registers while RTCRDY bit in the STA register is reset can potentially be invalid, and the time read should be ignored.

The RTCRDY interrupt mechanism can also be used to safely read the RTC counter/calendar registers. When the RTCRDY interrupt is enabled, an interrupt is generated based on the rising edge of the RTCRDY bit, causing the RTCRDY interrupt flag to be set. At this point, the application has nearly a complete second to safely read any or all of the RTC registers. To ensure a safe read, the RTCRDY bit in the STA register can be read again in the interrupt service routine and other interrupts can be disabled. This synchronization process prevents reading the time value during a counter/calendar transition. The RTCRDY interrupt flag is reset automatically when the interrupt is serviced, or can be reset by software.

The RTC counter/calendar registers can be written to at any time. Writes to the calendar registers take 2 to 3 RTCCLK cycles to take effect. If a back-to-back write is done on counter/calendar registers, then it is possible that for 2-3 RTCCLK cycles, the register is set to an undefined value. Therefore, back-to-back writes to calendar registers need to be avoided. Note that due to the synchronization, if a read immediately follows a write to the calendar registers, the read back value is always the actual counter value, which can be different than the written value due to the 2-3 RTCCLK cycles required to synchronize the newly written value.

The following registers are subject to the restrictions above: SEC, MIN, HOUR, DAY, MON, YEAR.

### Control Register

The RTC control register (CTL) can be read at any time. Writes to the CTL register should only be done when the TEV (interval timer) interrupt is disabled and after the RTCRDY interrupt is set.

The following register is subject to the restrictions above: CTL.

### Alarm Registers

The RTC alarm configuration registers can be read at any time. Writes to the alarm registers must be done when the corresponding alarm interrupt is disabled, and after the RTCRDY interrupt is set.

The following registers are subject to the restrictions above: A1MIN, A1HOUR, A1DAY, A2MIN, A2HOUR, A2DAY.

### Offset Correction and Temperature Compensation Registers

The offset correction register (CAL) and temperature compensation register (TCMP) must only be written when the RTCTCRDY bit in the STA register is set. RTCTCRDY is a read-only bit which is set when the hardware is ready to take in new correction or compensation values. Writes applied when RTCTCRDY is cleared have no effect. The RTCTCOK status bit is provided in the STA register. If a write to CAL or TCMP was successful, RTCTCOK will be set, else it will be reset. RTCTCOK will hold its status until the next write attempt. If a write is unsuccessful, software needs to re-attempt the write when RTCTCRDY is set.

The following registers are subject to the restrictions above: TCMP, CAL.

### Prescaler Control Registers

The prescaler interval control registers can be read at any time. Writes to the prescaler control registers should only be done when the PS0 and PS1 interrupts are disabled.

The following registers are subject to the restrictions above: PSCTL.

#### 37.3.3 Binary vs. BCD

The RTC provides seconds, minutes, hours, day of week, day of month, month, and year in selectable binary or binary-coded decimal (BCD) format. When the RTCBCD bit in the CTL register of the RTC is set, BCD format is selected. When BCD format is selected, only the BCD bits are valid in the calendar registers. The format must be selected before the time is set.

#### 37.3.4 Leap Year Handling

The calendar includes a leap-year algorithm which considers all years evenly divisible by four as leap years. This algorithm is accurate from the year 1901 through 2099.

#### 37.3.5 Calendar Alarm Configuration

The RTC provides a flexible alarm system. There are two user-programmable alarms (A0 and A1) which can be programmed based on the settings contained in the alarm registers for minutes, hours, day of week, and day of month.

Each alarm register contains an alarm enable (AE) bit that can be used to enable the respective alarm register. By setting the AE bits of the various alarm registers, a variety of alarm events can be generated.

- **Example 1:** A user wants to set an alarm every hour at 15 minutes past the hour (for example, at 00:15:00, 01:15:00, 02:15:00, and so on). This is possible by setting AxMIN to 15. By setting the AE bit of the AxMIN and clearing all other AE bits of the alarm registers, the alarm is enabled. When enabled, the RTCAX interrupt flag is set when the count transitions from 00:14:59 to 00:15:00, 01:14:59 to 01:15:00, 02:14:59 to 02:15:00, and so on.
- **Example 2:** A user wants to set an alarm every day at 04:00:00. This is possible by setting AxHOUR to 4. By setting the AE bit of the AxHOUR and clearing all other AE bits of the alarm registers, the alarm is enabled. When enabled, the RTCAX interrupt flag is set when the count transitions from 03:59:59 to 04:00:00.
- **Example 3:** A user wants to set an alarm for 06:30:00. AxHOUR would be set to 6 and AxMIN would be set to 30. By setting the AE bits of AxHOUR and AxMIN, the alarm is enabled. When enabled, the RTCAX interrupt flag is set when the time count transitions from 06:29:59 to 06:30:00. In this case, the alarm event occurs every day at 06:30:00.
- **Example 4:** A user wants to set an alarm every Tuesday at 06:30:00. AxDOW in the AxDAY register would be set to 2, AxHOUR would be set to 6 and AxMIN would be set to 30. By setting the AE bits of AxDOW, AxHOUR and AxMIN, the alarm is enabled. When enabled, the RTCAX interrupt flag is set when the time count transitions from 06:29:59 to 06:30:00 and the DOW transitions from 1 to 2.
- **Example 5:** A user wants to set an alarm the fifth day of each month at 06:30:00. AxDAY would be set to 5, AxHOUR would be set to 6 and AxMIN would be set to 30. By setting the AE bits of AxDAY, AxHOUR and AxMIN, the alarm is enabled. When enabled, the RTCAX interrupt flag is set when the time count transitions from 06:29:59 to 06:30:00 and the RTCDAY equals 5.

---

#### Note

##### Invalid alarm settings

Invalid alarm settings are not checked through hardware. It is the user's responsibility that valid alarm settings are entered.

---

#### Note

##### Invalid time and date values

Writing of invalid date and/or time information or data values outside the legal ranges specified in the calendar and alarm registers can result in unpredictable behavior.

---

#### Note

##### Setting the alarm

Before setting an initial alarm, all alarm registers including the AE bits should be cleared.

To prevent potential erroneous alarm conditions from occurring, the alarms should be disabled by clearing the RTCAX interrupt enable, RTCAX interrupt flag, and AE bits before writing initial or new time values to the RTC time registers.

---

### 37.3.6 Interval Alarm Configuration

The interval alarm is provided in addition to the two calendar alarms, and can be configured to generate an interval alarm event when the following events occur:

- MIN changes
- HOUR changes
- Every day at midnight

- Every day at noon

The interval is selected by programming the RTCTEVTX field in the CTL register of the RTC. The interval alarm sources the RTCTEV interrupt.

### 37.3.7 Periodic Alarm Configuration

Two periodic alarms are provided, and can be configured to generate two periodic time bases for the application.

The RT0PS periodic alarm can be configured to generate a periodic interrupt at one of the following rates: 4096Hz, 2048Hz, 1024Hz, 512Hz, 256Hz, or 128Hz. The RT0PS period is set by the RT0IP bits in the PSCTL register. The RT0PS event sources the RT0PS interrupt.

The RT1PS periodic alarm can be configured to generate a periodic interrupt at one of the following rates: 64Hz, 32Hz, 16Hz, 8Hz, 4Hz, 2Hz, 1Hz, or 0.5Hz. The RT1PS period is set by the RT1IP bits in the PSCTL register. The RT1PS event sources the RT1PS interrupt.

---

#### Note

Changing the settings of the periodic alarm configuration (RT0IP, RT1IP) while the corresponding prescaler is running can result in setting the corresponding interrupt flags. To avoid this, the RT0PS and RT1PS interrupts should be masked when changing RT0IP or RT1IP while the prescaler is running.

---

### 37.3.8 Calibration

The RTC module provides calibration mechanisms for reducing timekeeping error due to crystal offset error and crystal temperature drift. [Crystal offset error](#) can be corrected by measuring the crystal frequency through the RTC\_OUT output and adjusting calibration registers in the RTC. [Crystal temperature drift](#) can be corrected by measuring the system temperature with software, computing a correction factor in ppm based on the measured temperature, and applying the correction factor to the RTC.

Up to  $\pm 240$  ppm of offset correction or up to  $\pm 240$  ppm of temperature compensation correction can be applied individually, but the total correction allowed when both offset correction and temperature compensation are used together is  $\pm 240$  ppm. This means that the signed addition of offset error and temperature compensation should not exceed the maximum of  $\pm 240$  ppm, else the values in excess of  $\pm 240$  ppm will be ignored by hardware.

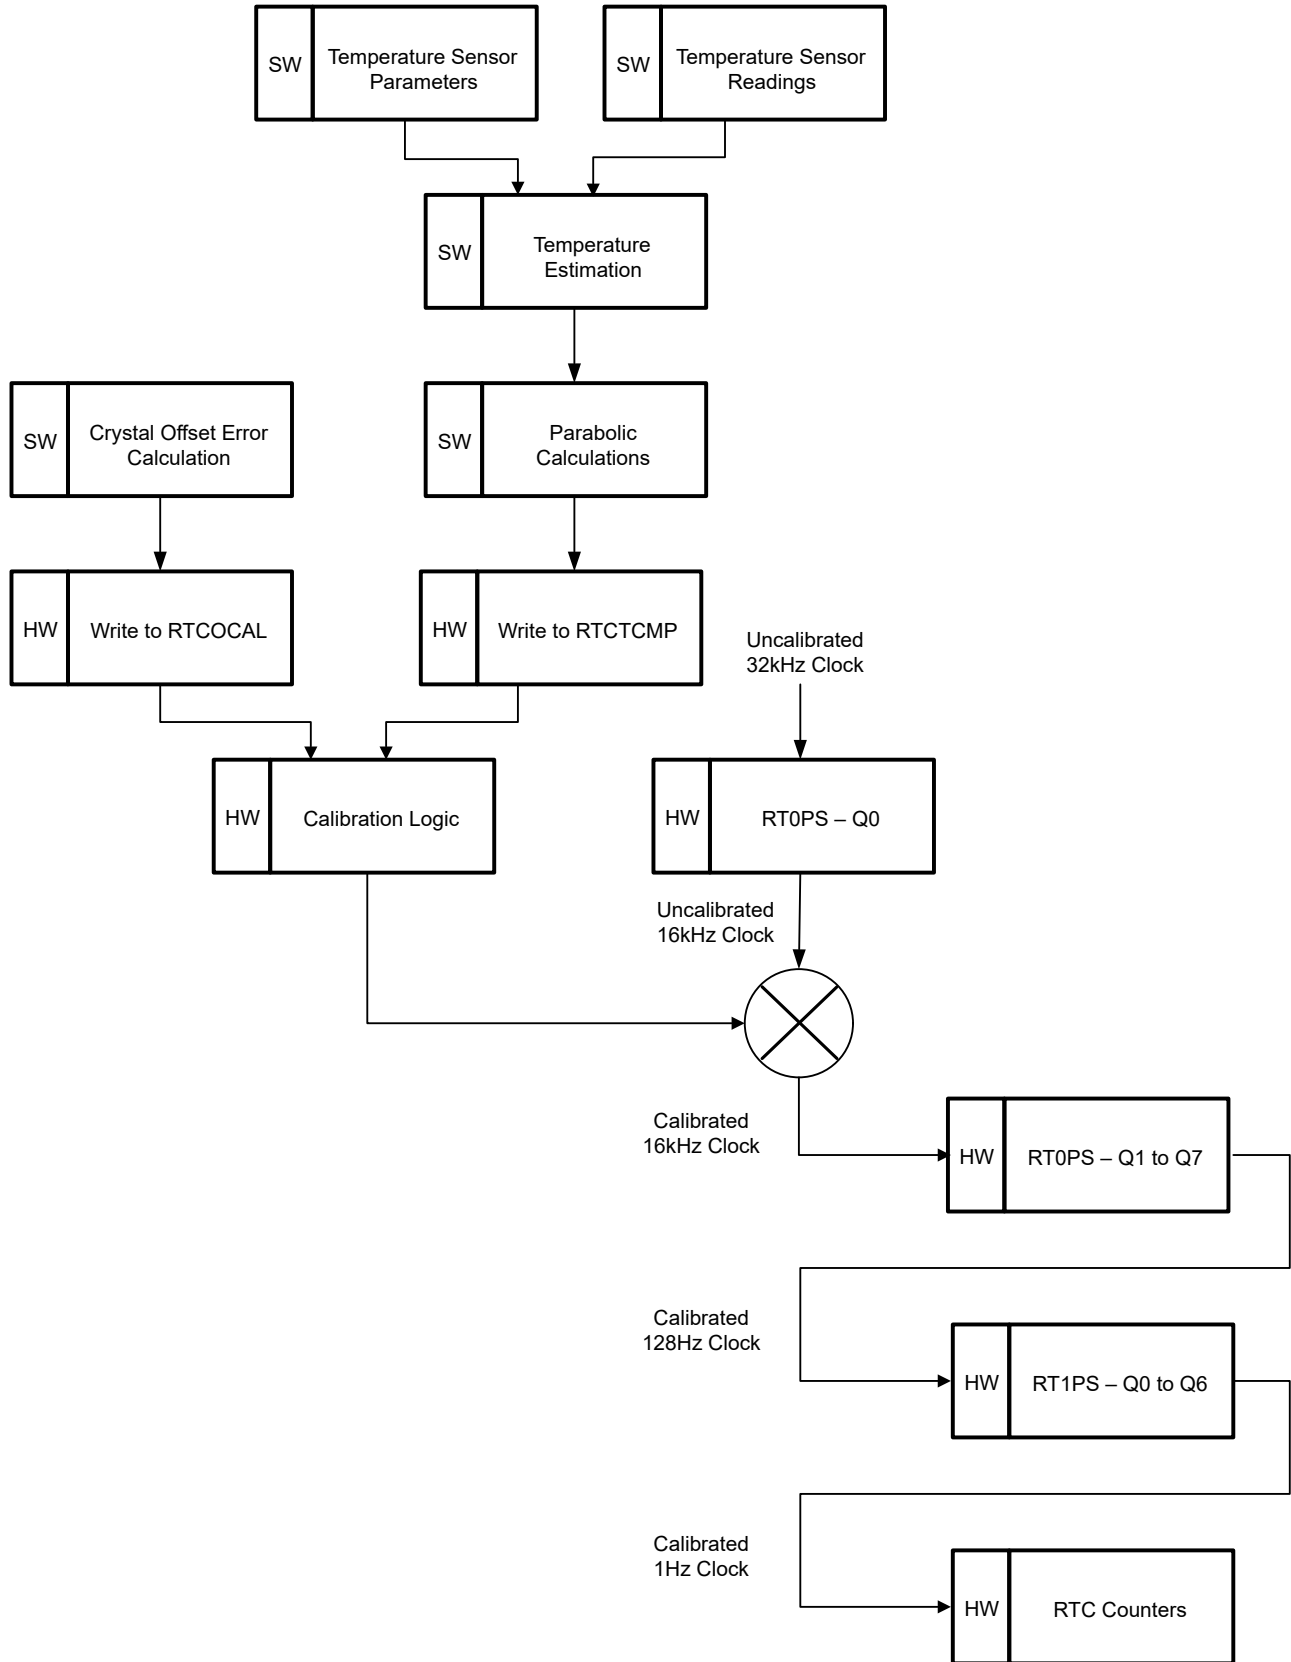

Figure 37-2. RTC Calibration

### 37.3.8.1 Crystal Offset Error

The RTC module can be calibrated for crystal manufacturing tolerance or offset error for higher timekeeping accuracy. A crystal frequency error of up to  $\pm 240$  ppm can be calibrated smoothly over a period of 60 seconds.

The CAL register is used to adjust the frequency. The calibration value is written into the RTCOCALX field in the CAL register, and each LSB in this field represents approximately  $\pm 1$  ppm correction (the sign is based on the RTCOCALS bit in the CAL register). When RTCOCALS is set, up calibration is selected and each LSB in RTCOCALX represents +1 ppm adjustment. When RTCOCALS is cleared, down calibration is selected and each LSB in RTCOCALX represents -1 ppm adjustment. The RTCOCALX field is 8 bits. Software can write a value of up to 256ppm into this register, but the maximum frequency error that can be corrected is only 240ppm. Software is responsible for writing legal values into RTCOCALX. Offset error calibration is inactive when the RTC is not enabled (MODCLKEN is cleared) or when RTCOCALX is zero. Writing to the RTCOCAL register resets the temperature compensation to zero.

---

#### Note

The CAL register must only be accessed via half-word (16-bit) or word (32-bit) wide operations to ensure that the sign bit is set together with the calibration value.

---

To calibrate the RTC frequency, the RTC\_OUT output signal is available on a pin. The RTCCALFX field in the CAL register can be used to select the frequency rate of the output signal to the pin. When RTCCALFX = 0x0, no signal is output on the RTC\_OUT pin. The other settings of the RTCCALFX select one of the three frequency options to output: 512Hz, 256Hz, or 1Hz. RTC\_OUT output can be measured, and the result of this measurement can be applied to the RTCOCALS and RTCOCALX bits to effectively reduce the initial offset of the RTCCLK.

#### 37.3.8.1.1 Offset Error Correction Mechanism

In the RTC, offset error calibration takes place over a period of 60 seconds. To achieve approximately  $\pm 1$ ppm correction, the 16kHz clock (Q0 output of RT0PS) is adjusted to add or subtract 1 clock pulse. This correction happens once every quarter second until the programmed ppm error is compensated.

All three possible output frequencies 512Hz, 256Hz, and 1Hz at the RTC\_OUT pin are affected by calibration settings. RT0PS interrupt triggered by RT0PS – Q2 to Q7 is based on calibrated clock. RT1PS interrupt (RT1PS) and RTC clock time event interrupt (RTCDEV) are also based on the calibrated clock.

The following can be used as a guide for setting RTCOCALS and RTCOCALX, given  $f_{\text{RTCCLK}} = f_{\text{RTCCLK, meas}} \times$  divider factor (set by RTCCALFX):

#### Slow Crystal ( $f_{\text{RTCCLK}} < 32768\text{Hz}$ )

- Set RTCOCALS = 1
- Set RTCOCALX to Round ( $60 \times 16384 \times (1 - f_{\text{RTCCLK}}/32768)$ )

As an example for up calibration, when the measured frequency is 511.9658Hz against the reference frequency of 512Hz, the frequency error is approximately 67ppm low. In order to increase the frequency by 67ppm, RTCOCALS should be set, and RTCOCALX should be set to Round ( $60 \times 16384 \times (1 - 511.9658 \times 64 / 32768)$ ) = 66.

#### Fast Crystal ( $f_{\text{ACLK}} \geq 32768\text{Hz}$ )

- Set RTCOCALS = 0
- Set RTCOCALX to Round ( $60 \times 16384 \times (1 - f_{\text{RTCCLK}}/32768)$ )

As an example for down calibration, when the measured frequency is 512.0241Hz against the reference frequency of 512Hz, the frequency error is approximately 47ppm high. In order to decrease the frequency by 47ppm, RTCOCALS should be cleared, and RTCOCALX should be set to Round ( $60 \times 16384 \times (1 - 512.0241 \times 64 / 32768)$ ) = 46.

### 37.3.8.2 Crystal Temperature Error

The output frequency of a crystal can vary significantly due to drift in temperature. A hybrid software and hardware approach can be applied to achieve temperature compensation for the RTC. The RTC supports temperature compensation up to  $\pm 240$  ppm.

Application software can make use of the on-chip temperature sensor to measure the device temperature at desired intervals (for example, every few seconds or minutes) to approximate the ambient temperature of the circuit. Then, software can be used to do parabolic calculations to determine the corresponding frequency error in ppm. This frequency error can then be written into the TCMP register for temperature compensation.

The RTCTCMPX field contains 8 bits which provide frequency correction up to  $\pm 240$  ppm. The LSB represents  $\pm 1$  ppm based on the RTCTCMPS bit in the TCMP register. When RTCTCMPS is set, each step in RTCTCMPX represents a +1ppm adjustment (up calibration). When the RTCTCMPS bit is cleared, each step in RTCTCMPX represents a -1ppm adjustment (down calibration).

#### 37.3.8.2.1 Temperature Drift Correction Mechanism

When the temperature compensation value is written into RTCTCMPX, it is added together with the offset error calibration value and the resulting value is taken into account from the next calibration cycle onwards. The ongoing calibration cycle will not be affected by writes into the TCMP register.

Reading the TCMPX at any time returns the cumulative correction value (offset + temperature) which is the signed addition of RTCOCALX and RTCTCMPX, and the updated sign bit (RTCTCMPS) of the addition result. Note that writing to the RTCOCAL register will reset the temperature compensation value to zero.

For example, when RTCOCALX is +150 ppm, and RTCTCMP is written with +200 ppm, the effective value taken in for the next calibration cycle is +240 ppm (saturated). If the RTCOCALX is +150 ppm, and RTCTCMP is written with +50 ppm, the effective value taken for the next calibration cycle is +200 ppm (40 ppm of compensation headroom remains).

To achieve effective temperature compensation, software is responsible to:

1. Measure the temperature as often as required by the operating conditions, crystal performance, and targeted accuracy
2. Calculate the frequency error due to temperature
3. Write the temperature compensation value into RTCTCMPX while not exceeding the maximum combined correction limit of  $\pm 240$  ppm

Writing to the TCMP register for temperature compensation requires 60 seconds (one minute) to take effect as a part of the next calibration cycle. Therefore, if temperature must be measured more frequently than once per minute (for example, once every 5 seconds) then it needs to average the error over one minute and update the TCMP register once per minute.

---

#### Note

The TCMP register must only be accessed via half-word (16-bit) or word (32-bit) wide operations to ensure that the sign bit is set together with the calibration value.

---

### 37.3.9 RTC Prescaler Extension

In RTC\_x instances only, a three-bit prescaler extension is included to support a longer interval time for a heartbeat function. The RT2PS prescaler allows interrupt generation with a 4s, 8s, or 16s interval.

The RTCCLK is used to provide RTC clock to the outside (512Hz, 256Hz, or 1Hz). The clock source is after the calibration circuit and allows to trim the LFXT offset and temperature compensation register.

For some applications, the raw uncalibrated 32kHz clock can be used as source for other components in the system. For LFSS, LFCLK is a mux option of RTCCLK.

See [Figure 37-3](#) for configuration of the prescalers, internal timer events, and RTC output options.

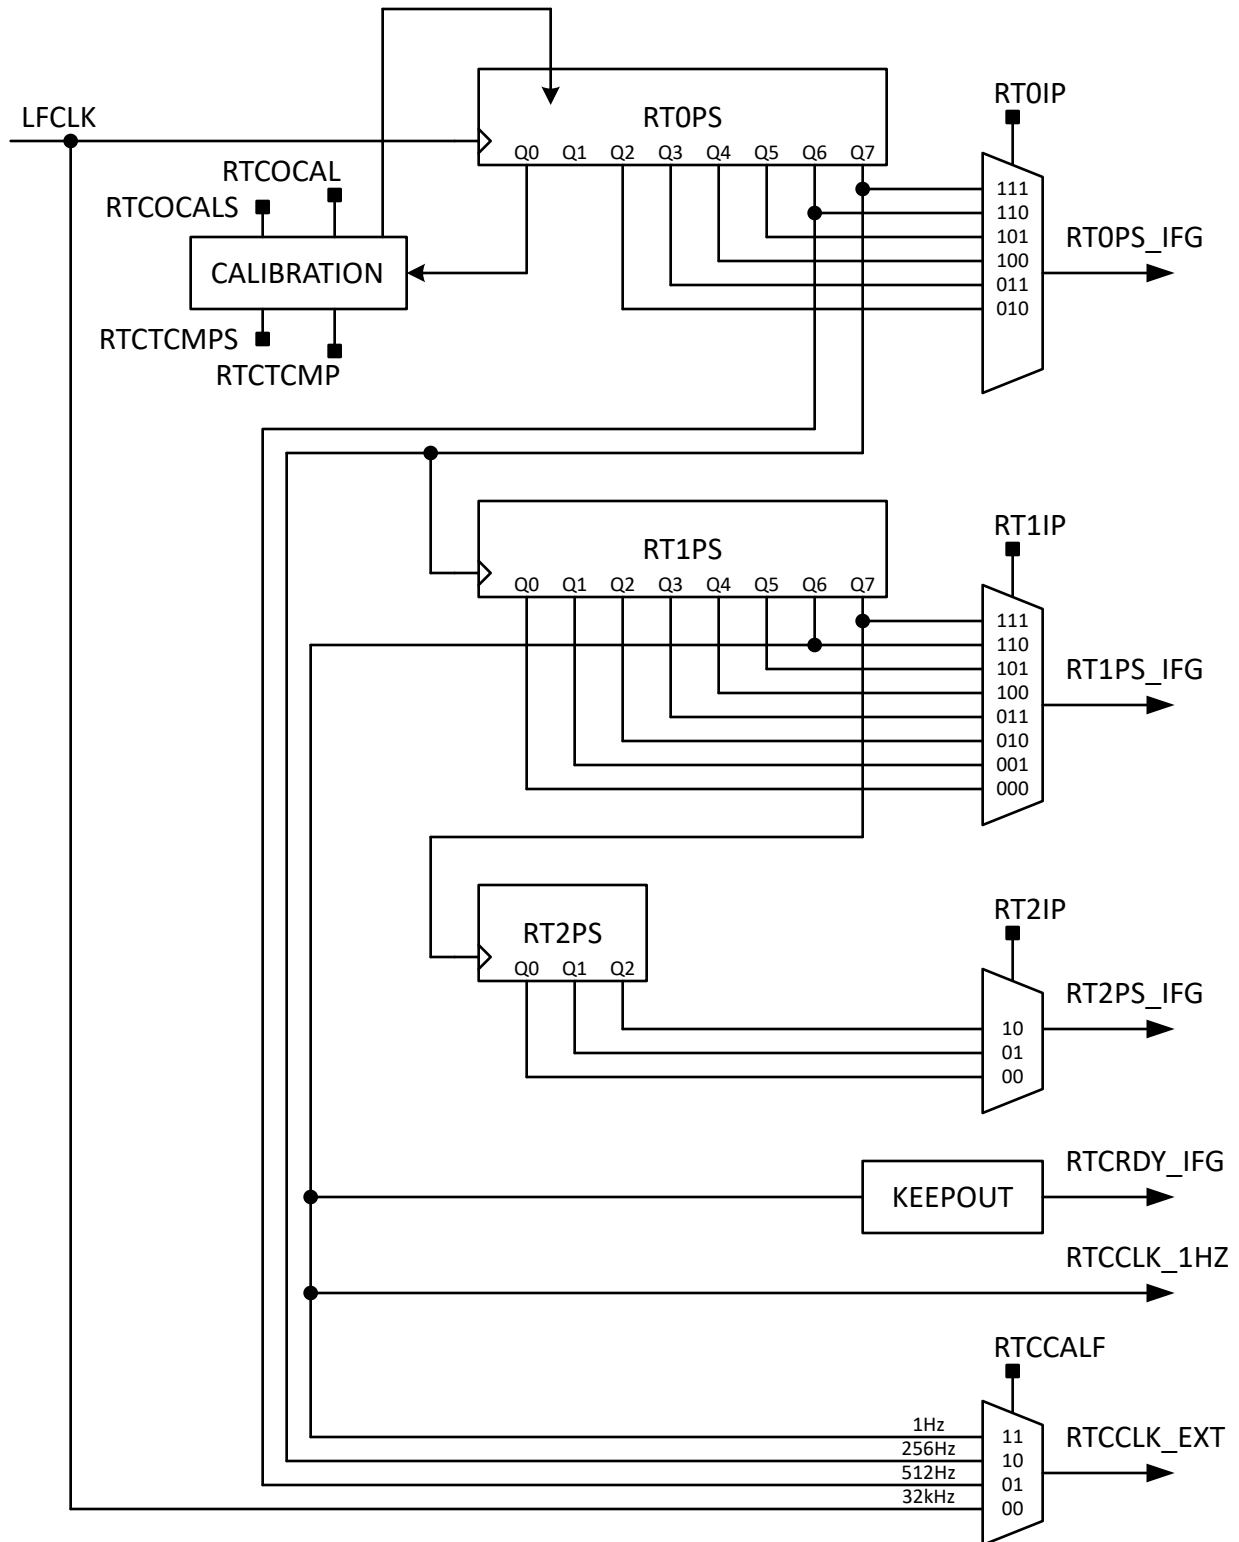

Figure 37-3. RTC Prescaler and Interval Timer Event

### 37.3.10 RTC Timestamp Capture

In RTC\_x instances only, an RTC timestamp feature allows the capture of an RTC status on the detection of a timestamp event. When a timestamp event happens, the whole RTC register from seconds to years is copied

to the timestamp capture registers. In case of multiple timestamp events, the TSCAPTURE register defines whether only the first or every (last) RTC status should be captured. The timestamp event status is sticky and needs to be cleared by software with the TSCLR register bit.

See [Figure 37-4](#) for the RTC block diagram and timestamping.

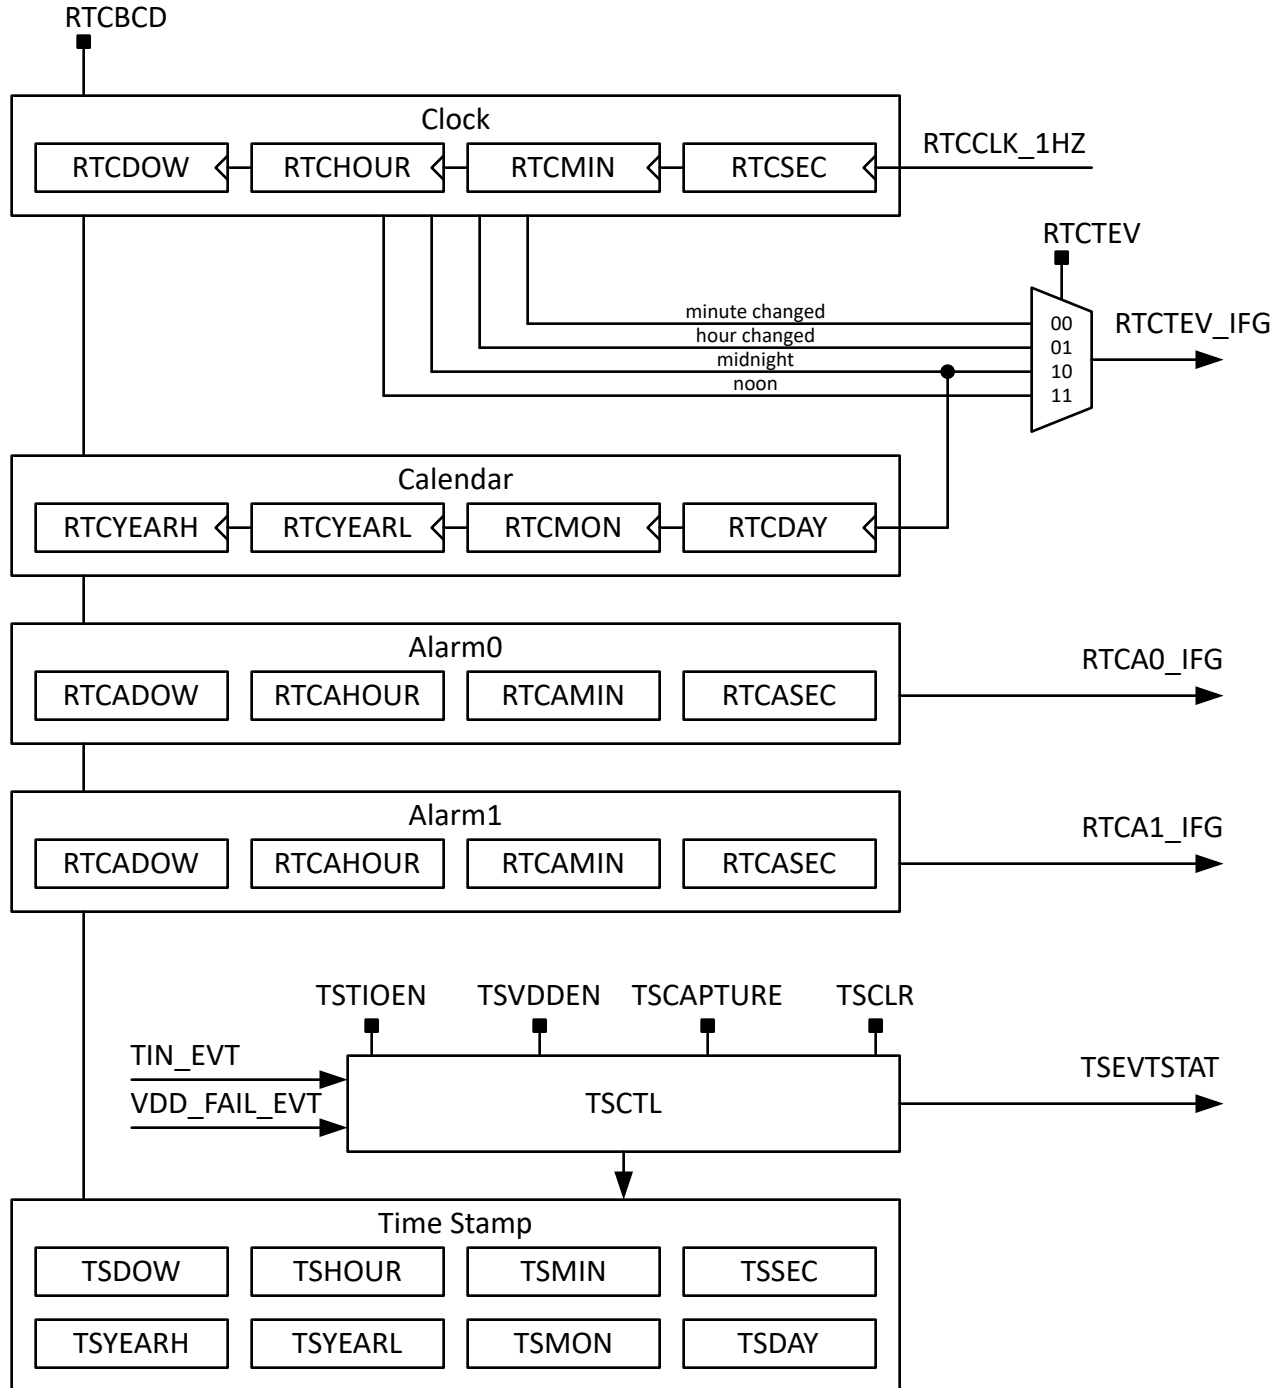

Figure 37-4. RTC Block Diagram and Timestamping

The following timestamp events are supported:

- **Tamper I/O input event after filtering and edge detection**

- Depending on the configuration of the polarity (rising, falling or both edges), the tamper I/O input will trigger a timestamp event capture when the TIO changes its state.
- This feature is used in a typical tamper detect application when the TIO input is connected to a switch which detects the opening of an enclosure.
- **VDD fail event**
  - The VDD fail event allows the capture of a timestamp when the main supply (VDD) is lost. Once the device's main supply regains power, the timestamp status information indicates that a power low timestamp event happened.
  - This feature is used in applications where it is important to know how long the main power was lost.

### 37.3.11 RTC Events

The RTC module contains two [event publishers](#) and no [event subscribers](#). One event publisher (CPU\_INT) manages RTC interrupt requests (IRQs) to the CPU subsystem through a [static event route](#). The second event publisher (GEN\_EVENT) can be used to publish RTC events to a subscriber through a [generic event route channel](#).

The RTC events are summarized in [Table 37-2](#).

**Table 37-2. RTC Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU interrupt event</a>	Publisher	RTC	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from RTC to CPU
<a href="#">Generic event</a>	Publisher	RTC	Generic event channel	<a href="#">Generic route (FPUB_0)</a>	GEN_EVENT registers, FPUB_0 register	Trigger generic event channel from RTC

#### 37.3.11.1 CPU Interrupt Event Publisher (CPU\_INT)

The RTC module provides six interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the RTC are given in [Table 37-3](#).

**Table 37-3. RTC CPU Interrupt Event Conditions (CPU\_INT)**

Index (IIDX)	Name	Description
0	RTCRDY	Indicates that the RTC counter/calendar registers are safe to be read for approximately one second
1	RTCDEV	Interval interrupt, configurable as once per minute, per hour, at midnight, or at noon
2	RTCA1	Calendar alarm 1 interrupt
3	RTCA2	Calendar alarm 2 interrupt
4	RTC0PS	Prescaler 0 periodic alarm interrupt
5	RTC1PS	Prescaler 1 periodic alarm interrupt

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring the event registers for CPU interrupts.

#### 37.3.11.2 Generic Event Publisher (GEN\_EVENT)

The RTC module provides six interrupt sources, of which one can be configured to publish an event to a generic event route channel are given in [Table 37-4](#).

**Table 37-4. RTC Generic Event Publisher Conditions (GEN\_EVENT)**

Index	Name	Description
0	RTCRDY	Indicates that the RTC counter/calendar registers are safe to be read for approximately one second

**Table 37-4. RTC Generic Event Publisher Conditions (GEN\_EVENT) (continued)**

Index	Name	Description
1	RTCTEV	Interval interrupt, configurable as once per minute, per hour, at midnight, or at noon
2	RTCA1	Calendar alarm 1 interrupt
3	RTCA2	Calendar alarm 2 interrupt
4	RTC0PS	Prescaler 0 periodic alarm interrupt
5	RTC1PS	Prescaler 1 periodic alarm interrupt

The generic event publisher configuration is managed with the GEN\_EVENT event management registers. See [Section 7.2.5](#) for guidance on configuring the event registers for generic event publishers.

The generic event channel which generic event is to publish to must be selected by writing the target generic channel ID to the **FPUB\_0** register in the RTC. See [Section 7.1.3.3](#) for guidance on configuring generic event routes.

If this publisher is not used in an application, the FPUB\_0 register can be left in a disconnected state (set equal to zero) and no events should be unmasked through the MIS register in the RTC GEN\_EVENT register set.

### 37.4 RTC Registers

Table 37-5 lists the memory-mapped registers for the RTC registers. All register offset addresses not listed in Table 37-5 should be considered as reserved locations and the register contents should not be modified.

**Table 37-5. RTC Registers**

## 7 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 37-11](#) and described in [Table 37-13](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

## 8 IMASK (Offset = 1028h) [Reset = 00000000h]

IMASK is shown in [Figure 37-12](#) and described in [Table 37-14](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is unmasked. Unmasking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

## 9 RIS (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 37-13](#) and described in [Table 37-15](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

### 11 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 37-15](#) and described in [Table 37-17](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Figure 37-15. ISET**

### 13 IIDX (Offset = 1050h) [Reset = 0000000h]

IIDX is shown in [Figure 37-17](#) and described in [Table 37-19](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. Value 0x00 means no event pending. Interrupt 1 is the highest priority, IIDX next highest, 4, 8, ... IIDX^31 is the least priority. That is, the least bit position that is set to 1 denotes the highest priority pending interrupt. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred. On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in [RIS] and [MIS] are cleared as well. After a read from the CPU (not from the debug interface), the register is updated with the next highest priority interrupt, if none are pending, then it should display 0x0.

#### 14 IMASK (Offset = 1054h) [Reset = 0000000h]

IMASK is shown in [Figure 37-18](#) and described in [Table 37-20](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is unmasked. Unmasking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

**Figure 37-18. IMASK**

### 15 RIS (Offset = 1058h) [Reset = 0000000h]

RIS is shown in [Figure 37-19](#) and described in [Table 37-21](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

**Figure 37-19. RIS**

### 17 ISET (Offset = 1060h) [Reset = 0000000h]

ISET is shown in [Figure 37-21](#) and described in [Table 37-23](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Figure 37-21. ISET**

**Table 37-46. DESC Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	MODULEID	R	911h	Module identifier. This ID is unique for each module. 0x0911 = Module ID of the RTC Module 0000h = Minimum value FFFFh = Maximum value
15-12	FEATUREVER	R	8h	Feature set of this module. Differentiates the complexity of the actually instantiated module if there are differences. 0h = Minimum value Fh = Maximum value
11-8	INSTNUM	R	0h	Instantiated version. Describes which instance of the module accessed. 0h = This is the default, if there is only one instance - like for SSIM
7-4	MAJREV	R	1h	Major revision. This number holds the module revision and is incremented by the module developers. n = Major version (see device-specific data sheet) 0h = Minimum value Fh = Maximum value
3-0	MINREV	R	0h	Minor revision. This number holds the module revision and is incremented by the module developers. n = Minor module revision (see device-specific data sheet) 0h = Minimum value Fh = Maximum value

The independent watchdog timer (IWDT) is a device-independent supervisor which monitors code execution and overall hang up scenarios of the device. This IWDT has its own system independent clock source. If the application software does not successfully reset the watchdog within the programmed time, the watchdog generates a POR reset to the device.

Key features of the IWDT include:

- A 25-bit counter
- Counter driven from LFOSC (fixed 32kHz clock path) with a programmable clock divider
- Eight selectable watchdog timer periods

Figure 38-1 shows the block diagram of the IWDT.

**Figure 38-1. Independent Watchdog Timer (IWDT) Block Diagram**

The typical use case of the IWDT is the replacement of an external watchdog timer in the system. Some safety applications require the monitoring of a device by an independent watchdog timer. This means the IWDT requires a system independent clock source, which is achieved through LFOSC.

The primary function of the IWDT is to initiate a full power on reset (POR) of the device when correct operation of the device has failed due to an unexpected software or system delay. The IWDT can be programmed with a predefined time within the application software.

The application software must restart the timer, indicating that application execution is proceeding normally. If application software fails to restart the timer within the specified time, the IWDT will issue a POR reset request to PMU of the device to generate a POR, restarting the device in a cold boot process.

<b>38.3 IWDT Period Selection</b> .....	<b>2607</b>
<b>38.4 Debug Behavior of the IWDT</b> .....	<b>2607</b>
<b>38.5 IWDT Registers</b> .....	<b>2607</b>

## 38.1

### 38.2 IWDT Clock Configuration

The IWDT runs from the 32kHz low-frequency oscillator (LFOSC). A clock divider supports dividing the input clock from /1 (no divide) to /8 (divide-by-8) using the CLKDIV field in the WDTCTL register. The default CLKDIV setting is 0x03 (32kHz divided by 4, or 8kHz).

### 38.3 IWDT Period Selection

The IWDT has a 25-bit counter which is initially stopped after a power up of the VBAT power domain. The IWDT period (total time interval) is set by the PER field in the WDTCTL register. The total IWDT period is calculated as follows:

$$TWDT = (CLKDIV + 1) * PERCOUNT / 32768Hz$$

The total timer count PERCOUNT is selected to be one of 8 possible period count values, with the encoding given in [Table 38-1](#).

**Table 38-1. IWDT Period and Period Count Settings**

Period (PER)	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7
Period Count (PERCOUNT)	225	221	218	215	212	210	28	26

The combination of the period selection (PER) and clock divider (CLKDIV) enable a wide range of IWDT periods, from as short as 1.95ms to as long as 136.53 minutes.

[Table 38-2](#) gives all possible IWDT periods for a given combination of PER and CLKDIV.

**Table 38-2. IWDT Period Timing Options**

CLKDIV	PER							
	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7
	min	min	s	s	s	ms	ms	ms

0x5 (/6)	102.40	6.40	48.00	6.00	0.75	187.50	46.88	11.72
0x6 (/7)	119.47	7.47	56.00	7.00	0.88	218.75	54.69	14.67
0x7 (/8)	136.53	8.53	64.00	8.00	1.00	250.00	62.50	15.63

### 38.4 Debug Behavior of the IWDT

The IWDT can be configured to stop counting or continue counting when the CPU is halted for debug by the debug subsystem. By default, the IWDT stops counting when the CPU is halted for debug and the device is in a debug state. To allow the IWDT to continue to free run when the CPU is stopped for debug, set the FREE bit in the WDTDBGCTL register.

### 38.5 IWDT Registers

For IWDT registers, refer to the [Section 36.7](#) related to the watchdog timer.

Chapter 39

# Window Watchdog Timer (WWDT)

---

The window watchdog timer (WWDT) supervises code execution. If the application software does not successfully reset the window watchdog within the programmed open time window, the window watchdog generates a reset.

<b>39.1 WWDT Overview</b> .....	<b>2609</b>
<b>39.2 WWDT Operation</b> .....	<b>2610</b>
<b>39.3 WWDT Registers</b> .....	<b>2614</b>

### 39.1 WWDT Overview

The primary function of the window watchdog timer (WWDT) is to initiate a reset when correct operation of the device has failed due to an unexpected software or system delay. The WWDT can be programmed with a predefined time window within which the application software must restart the timer, indicating that application execution is proceeding normally. If application software fails to restart the timer within the specified window, the WWDT will issue a WWDT violation signal to SYSCCTL to generate a reset.

If watchdog functionality is not required in an application, the WWDT can also be configured as a basic system interval timer which is capable of generating periodic maskable interrupts to the CPU.

Key features of the WWDT include:

- A 25-bit counter with closed and open window
- Counter driven from LFCLK (fixed 32kHz clock path) with a programmable clock divider
- Eight selectable watchdog timer periods
- Optional automatic suspension of counter when operating in low power modes
- Support for standard window watchdog mode or interval timer (nonwatchdog) mode

Devices may have 1 or 2 WWDT instances. A WWDT0 violation generates a BOOTRST, which resets the peripheral and CPU state and also causes the boot configuration routine (BCR) to run. A WWDT1 violation generates a SYSRST, which resets the peripheral and CPU state but does not trigger execution of the BCR. As such, WWDT1 is well suited for recovering from execution stalls that result from software execution, while WWDT0 is well suited for catching larger issues such as a corrupted trim value, at the expense of a longer reset time.

#### 39.1.1 Watchdog Mode

In watchdog mode, the WWDT is configured to count up to the specified WWDT period. The WWDT counter must be restarted with the configured open window of the WWDT period, or the WWDT will assert a WWDT violation to SYSCCTL and a reset will be generated.

The window watchdog timer supports detecting both a "too late" response as well as a "too early" response through the use of an optional closed window, as shown in [Figure 39-1](#). The WWDT period consists of a closed window period and an open window period. The closed window period begins first, followed by the open window period. The WWDT can only be restarted during the open window period. An attempt to restart the WWDT during the closed window period results in a violation. Following the closed window, if the WWDT is not restarted before the end of the open window, the WWDT period expires and a violation is also generated.

**Figure 39-1. WWDT Functionality**

If the closed window functionality is not desired, it can be disabled (set to 0%), giving traditional watchdog timer functionality where the WWDT can be reset any time before the WWDT period expires.

### 39.1.2 Interval Timer Mode

The WWDT can be used in interval timer mode to generate periodic interrupts to the CPU when not using the watchdog functionality. When used in interval timer mode, a WWDT interrupt is generated when the WWDT period expires, or when an incorrect password is applied to the WWDT control registers.

## 39.2 WWDT Operation

The WWDT must be enabled before being configured for use through the PWREN register (see peripheral power enable).

The WWDT is configured through the WWDTCTL0 and WWDTCTL1 registers. The registers are password protected. Any register access (read or write) must be a 32-bit access. Write access must also include the corresponding password in the most significant byte (0xC9 for WWDTCTL0, and 0xBE for WWDTCTL1). Attempting a register write without the correct password, or attempting a write with an access other than a 32-bit access generates a WWDT violation to SYSCTL. The password byte always reads as 0x00.

The WWDT is disabled and cleared after a SYSRST. The WWDTCTL0 register sets the static configuration of the WWDT, including: the clock divider, the timer period, the two closed window percentages, the timer mode (WWDT or interval), and the stop-in-sleep status. The first write (with a key match) to the WWDTCTL0 register enables the WWDT. Once the WWDT is enabled, the WWDTCTL0 register becomes write protected. Any attempt to write to the WWDTCTL0 register after the WWDT is enabled generates a WWDT violation to SYSCTL. The RUN bit in the WWDTSTAT register indicates that the WWDT is running.

Figure 39-2 shows the WWDT functional block diagram.

Figure 39-2. WWDT Diagram

### 39.2.1 Mode Selection

The WWDT operating mode (watchdog mode or interval timer mode) is selected by the MODE bit in the WWDTCTL0 register. Watchdog mode is the default mode (MODE cleared). Setting the MODE bit configures the WWDT for interval mode.

When the WWDT is in watchdog mode, the WWDT counter must be restarted within the open window period by writing the RESTART value (0x000000A7) to the WWDTCNTRST register. After a reset or restart, the WWDT counter will restart from zero. A failure to restart the WWDT within the open window or an attempt to restart the WWDT counter during the closed window will generate a WWDT violation to SYSCTL. Writing any value other than the RESTART value to the WWDTCNTRST register also generates a WWDT violation.

When the WWDT is in interval mode, the timer acts as an interval timer, generating WWDT interrupts to the CPU as specified by the WWDT period. As soon as the WWDT is enabled in interval mode, the WWDT interval timer interrupt will be asserted after the expiration of the timer. It is not necessary to restart the WWDT in interval timer mode.

### 39.2.2 Clock Configuration

The WWDT runs from the 32kHz low-frequency clock (LFCLK). A clock divider supports dividing the input clock from /1 (no divide) to /8 (divide-by-8) using the CLKDIV field in the WWDTCTL0 register. The default CLKDIV setting is 0x03 (32kHz divided by 4, or 8kHz).

By running from the LFCLK, the WWDT time base is independent of the main clock (MCLK) and CPU clock (CPUCLK) time base, provided that these clocks are not also configured to be running from the LFCLK. While the time base may be considered as independent and derived from a separate oscillator source, LFCLK edges are synchronized to the MCLK before sourcing the WWDT to enable simple access to the memory-mapped registers from application software. A simplified view of the clock scheme is given in Figure 39-3. In Figure 39-3, the internal LFOSC is configured to set the LFCLK rate, and the internal SYSOSC sets the MCLK/CPUCLK rate. Clock selection muxes and dividers are excluded from the figure to simplify the view; the complete clock tree is provided in *Clock Tree*.

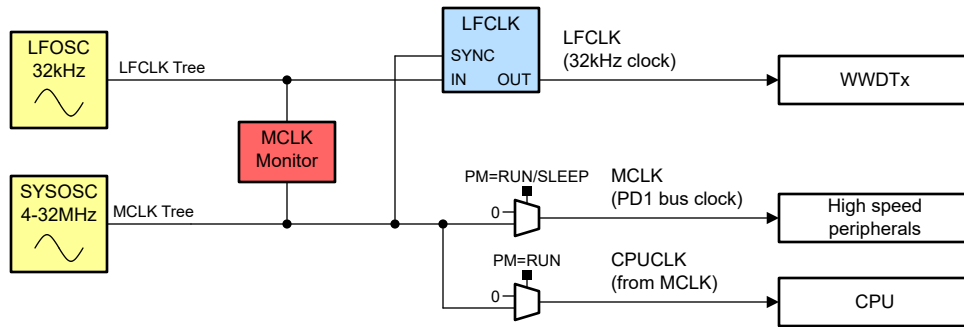

Figure 39-3. WWDT Simplified Clock Source Tree

In the event that the MCLK fails and synchronization of the LFCLK to the MCLK is lost, this failure may be detected by enabling the continuous MCLK monitor. When the MCLK monitor is enabled, a loss of MCLK is always a catastrophic failure which generates a BOOTRST within 12 LFCLK cycles. As a result, a loss of the MCLK tree, and corresponding loss of synchronization, does not prevent a BOOTRST from being generated.

#### Period Selection

The WWDT has a 25-bit counter which is initially stopped after a SYSRST. The WWDT period (total time interval) is set by the PER field in the WWDTCTL0 register. The total WWDT period is calculated as follows:

$$T_{WWDT} = (CLKDIV + 1) * PER_{COUNT} / 32768Hz \quad (38)$$

The total timer count  $PER_{COUNT}$  is selected to be one of 8 possible period count values, with the encoding given in Table 39-1.

Table 39-1. WWDT Period Total Timer Count

PER	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7
$PER_{COUNT}$	$2^{25}$	$2^{21}$	$2^{18}$	$2^{15}$	$2^{12}$	$2^{10}$	$2^8$	$2^6$

The combination of the period selection (PER) and clock divider (CLKDIV) enable a wide range of WWDT periods, from as short as 1.95ms to as long as 136.53 minutes. Table 39-2 gives all possible WWDT periods for a given combination of PER and CLKDIV.

Table 39-2. WWDT Period Timing Options

CLKDIV	PER							
	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7
	min	min	s	s	s	ms	ms	ms
0x0 (/1)	17.07	1.07	8.00	1.00	0.13	31.25	7.81	1.95

**Table 39-2. WWDT Period Timing Options (continued)**

CLKDIV	PER							
	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7
	<i>min</i>	<i>min</i>	<i>s</i>	<i>s</i>	<i>s</i>	<i>ms</i>	<i>ms</i>	<i>ms</i>
0x1 (/2)	34.13	2.13	16.00	2.00	0.25	62.50	15.63	3.91
0x2 (/3)	51.20	3.20	24.00	3.00	0.38	93.75	23.44	5.86
0x3 (/4)	68.27	4.27	32.00	4.00	0.50	125.00	32.25	7.81
0x4 (/5)	85.33	5.33	40.00	5.00	0.63	156.25	39.06	9.77
0x5 (/6)	102.40	6.40	48.00	6.00	0.75	187.50	46.88	11.72
0x6 (/7)	119.47	7.47	56.00	7.00	0.88	218.75	54.69	13.67
0x7 (/8)	136.53	8.53	64.00	8.00	1.00	250.00	62.50	15.63

### Synchronization Delay

When starting or re-starting the WWDT counter, a maximum synchronization delay of one 32kHz clock cycle (30.5μs) can occur before the WWDT counter begins counting from zero. The periods given in [Table 39-2](#) do not include this synchronization delay.

### Closed Window Selection

Configuration of two closed window periods is supported by setting the WINDOW0 and WINDOW1 fields in the WWDTCTL0 register. The WINSEL bit in the WWDTCTL1 register determines the active window (either WINDOW0 or WINDOW1). Either window can be set to one of 8 possible window settings.

**Table 39-3. WWDT Window Options**

WINDOW	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7
Closed window	0%	12.5%	18.75%	25%	50%	75%	81.25%	87.5%

Setting a WINDOWx value to 0x0 (0% closed, 100% open) is equivalent to disabling the window function of the WWDT. In this configuration, the WWDT can be restarted at any point during the WWDT period.

The active window selection can be changed after the WWDT has been enabled. When the WWDT is restarted by writing to the WWDTCNTRST register, the closed window selection (WINSEL) must not be changed for at least four 32kHz clock cycles ( $\approx 122\mu\text{s}$ ).

#### 39.2.3 Low-Power Mode Behavior

The WWDT counter can be configured to continue counting when the device is in a low-power mode (CPU is disabled) or to continue to run when the device is in a low-power mode.

The STISM bit in the WWDTCTL0 register controls if the WWDT counter stops counting in sleep mode. By default, the STISM bit is cleared, indicating that the WWDT continues to count in low-power modes. To stop the WWDT from counting in low-power modes, set the STISM bit when loading the WWDTCTL0 configuration to start the WWDT. In this case, when the low-power mode is exited and the CPU returns to operation, the WWDT counter resumes counting from the same value it held before entering the low-power mode.

#### 39.2.4 Debug Behavior

The WWDT can be configured to stop counting or continue counting when the CPU is halted for debug by the debug subsystem. By default, the WWDT stops counting when the CPU is halted for debug and the device is in a debug state. To allow the WWDT to continue to free run when the CPU is stopped for debug, set the FREE bit in the PDBGCTL register.

### 39.2.5 WWDT Events

The WWDT module contains one [event publisher](#) and no [event subscribers](#). One event publisher (CPU\_INT) manages WWDT interrupt requests (IRQs) to the CPU subsystem through a [static event route](#).

[Table 39-4](#) lists the WWDT events.

**Table 39-4. WWDT Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU Interrupt Event</a>	Publisher	WWDT	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from WWDT to CPU

#### 39.2.5.1 CPU Interrupt Event Publisher (CPU\_INT)

The WWDT module provides one interrupt source which can be configured to source a [CPU interrupt event](#). The WWDT interrupt conditions are given in [Table 39-5](#).

**Table 39-5. WWDT CPU Interrupt Conditions (CPU\_INT)**

Index (IIDX)	Name	Description
0	INTTIM	Indicates that the WWDT interval timer period has expired

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers for CPU interrupts.

### 39.3 WWDT Registers

Table 39-6 lists the memory-mapped registers for the WWDT registers. All register offset addresses not listed in Table 39-6 should be considered as reserved locations and the register contents should not be modified.

**Table 39-6. WWDT Registers**

Offset	Acronym	Register Name	Section
800h	PWREN	Power enable	<a href="#">Section 1</a>
804h	RSTCTL	Reset Control	<a href="#">Section 2</a>
814h	STAT	Status Register	<a href="#">Section 3</a>
1018h	PDBGCTL	Peripheral Debug Control	<a href="#">Section 4</a>
1020h	IIDX	Interrupt index	<a href="#">Section 5</a>
1028h	IMASK	Interrupt mask	<a href="#">Section 6</a>
1030h	RIS	Raw interrupt status	<a href="#">Section 7</a>
1038h	MIS	Masked interrupt status	<a href="#">Section 8</a>
1040h	ISSET	Interrupt set	<a href="#">Section 9</a>
1048h	ICLR	Interrupt clear	<a href="#">Section 10</a>
10E0h	EVT_MODE	Event Mode	<a href="#">Section 11</a>
10FCh	DESC	Module Description	<a href="#">Section 12</a>
1100h	WWDTCNTL0	Window Watchdog Timer Control Register 0	<a href="#">Section 13</a>
1104h	WWDTCNTL1	Window Watchdog Timer Control Register 0	<a href="#">Section 14</a>
1108h	WWDTCNTRST	Window Watchdog Timer Counter Reset Register	<a href="#">Section 15</a>
110Ch	WWDTSTAT	Window Watchdog Timer Status Register	<a href="#">Section 16</a>

Complex bit access types are encoded to fit into small table cells. Table 39-7 shows the codes that are used for access types in this section.

**Table 39-7. WWDT Access Type Codes**

Access Type	Code	Description
<b>Read Type</b>		
R	R	Read
<b>Write Type</b>		
K	K	Write protected by a key
W	W	Write
WK	W K	Write Write protected by a key
<b>Reset or Default Value</b>		
-n		Value after reset or the default value

### 1 PWREN Register (Offset = 800h) [Reset = 0000000h]

PWREN is shown in [Figure 39-4](#) and described in [Table 39-8](#).

Return to the [Summary Table](#).

Register to control the power state

The debug subsystem (DEBUGSS) is implemented in all MSP devices. The DEBUGSS enables comprehensive debug of application software running on the processor during development by interfacing an external debug probe to the device systems through a serial wire debug (SWD) interface.

<b>40.1 DEBUGSS Overview</b> .....	<b>2633</b>
<b>40.2 DEBUGSS Operation</b> .....	<b>2636</b>
<b>40.3 DEBUGSS Registers</b> .....	<b>2644</b>

## 40.1 DEBUGSS Overview

The debug subsystem (DEBUGSS) interfaces the ARM Serial Wire Debug (SWD) two-wire physical interface to multiple debug functions within the device. MSP devices support debugging of processor execution, the device state, and the power state (through EnergyTrace technology). The DEBUGSS also provides a mailbox system for communicating with software through SWD.

Key features provided by the debug subsystem include:

- The ARM Serial Wire Debug (SWD) two-wire (SWDIO, SWCLK) debug interface, compatible with both TI and 3<sup>rd</sup> party debug probes
  - On-chip pullup and pulldown resistors for SWDIO and SWCLK, respectively, enabled by default
  - Support for disabling SWD functions to use SWD pins as general-purpose input/output pins
  - Support for debug on all low power modes
- Debug of the processor
  - Run, halt, and step debug support
  - Up to 4 hardware breakpoints (BPU)
  - Up to 2 hardware watchpoints (DWT)
  - Instruction trace of up to 4 branches through the ARM micro trace buffer (MTB)
  - Supporting software breakpoints
- Software-configurable peripheral behavior during processor debug
  - Ability to free run select peripherals through debug halt
  - Ability to halt select peripherals on a debug halt
  - Ability to request reset and mode changes to the PMCU
- Monitoring of CPU state through EnergyTrace technology
- Mailbox (DSSM) for passing data and control signals between the SWD interface and boot ROM (as well as application software)
- Support for various security features, including SWD lockout and password authenticated debugging

---

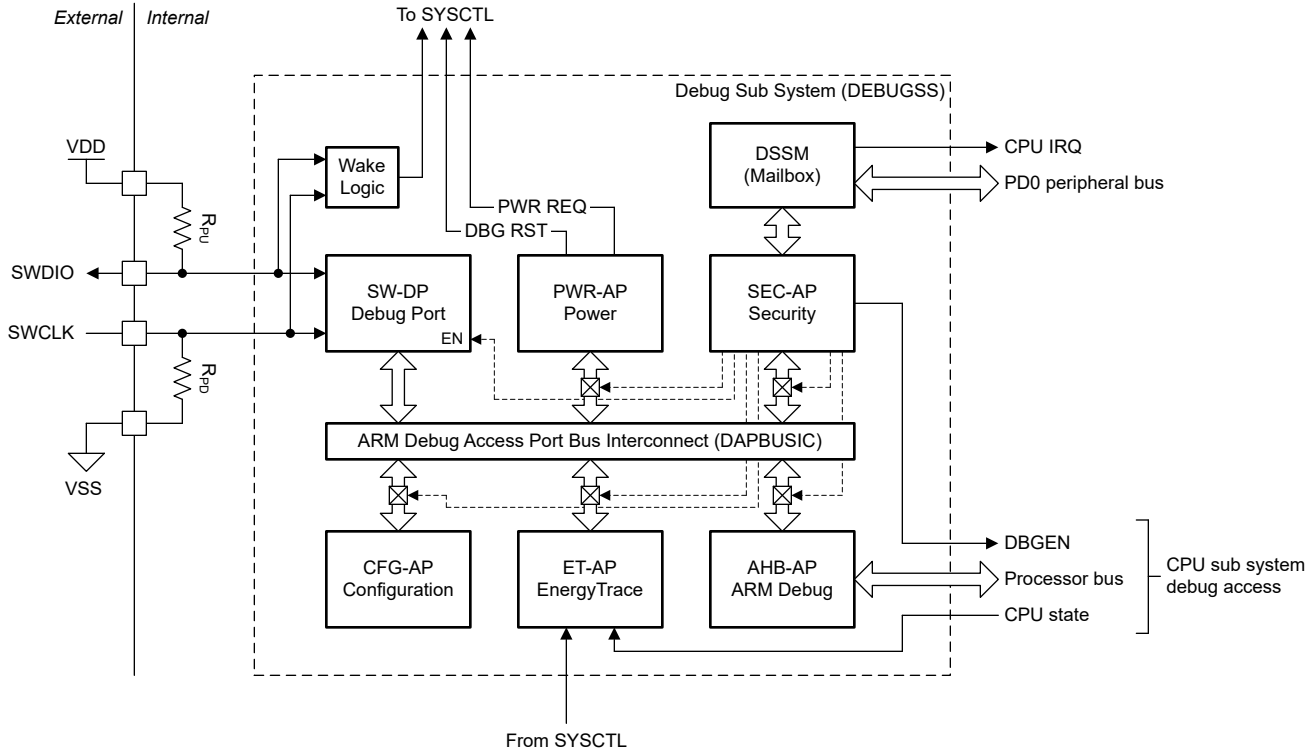

### Note

Refer to the datasheet for device-specific features

---

### 40.1.1 Debug Interconnect

The DEBUGSS architecture is given in [Figure 40-1](#).

**Figure 40-1. Debug Sub System Block Diagram**

The SWD physical interface interacts with the Arm serial wire debug port (SW-DP) to gain access to the debug access port bus interconnect (DAPBUSIC) when the SW-DP is enabled. From TI, devices ship with the SW-DP enabled to allow SWD access to the device for development and production programming, but the SW-DP can be configured to be permanently disabled through the boot configuration policy (see [Section 40.2.3](#)).

The DAPBUSIC enables a debug probe to access one or more debug access ports. For a debug probe to be able to communicate with an access port, the SW-DP debug port must not be disabled by the device boot configuration policy, and the target access port must also not be disabled by the boot configuration policy. The available access ports are given in [Section 40.1.3](#).

The SWD and SW-DP also contain signaling to the PMCU module to support debug-generated resets and operating mode changes (see [Section 40.2.2](#)).

#### 40.1.2 Physical Interface

Debug connections to the device are supported through an Arm serial wire debug (SWD) compliant interface. The SWD interface requires two connections:

- A bidirectional data line (SWDIO) used to send data to, and receive data from, the device
- A unidirectional clock line (SWCLK) driven by the debug probe connecting to the device

The SWD interface uses the standard logic levels of the device for SWD communication. See the device-specific data sheet for input and output logic levels for a given supply voltage (VDD). A SWCLK frequency of up to 10MHz is supported by the DEBUGSS.

During SWD operation, the SWDIO line can be driven high or driven low by either the target device or the debug probe. As either device can drive the line, when ownership of the shared SWDIO line is switched between the device and the debug probe, undriven time slots are inserted as a part of the SWD protocol. The primary purpose of the pullup resistor on the SWDIO line, and the pulldown resistor on the SWCLK line, is to place the SWD pins into a known state when no debug probe is attached. A minimum resistance of 100kΩ is recommended by Arm. The internal pullup/pulldown resistors fulfill this requirement and external resistors are not required for correct operation of the SWD interface.

After a power-on reset (POR), MSP devices configure the SWD pins in SWD mode with an internal pullup resistor enabled on the SWDIO line and an internal pulldown resistor enabled on the SWCLK line. If the device configuration has not permanently disabled all SWD access, then the SWD interface is enabled during the boot process and a debug probe can be connected to the DEBUGSS.

In the event that a device was configured by software to enter SHUTDOWN mode, and a debug probe is then connected to the SWD pins with SWCLK active, wakeup logic will trigger an exit from SHUTDOWN mode and cause a BOR. A debug connection can then be established to the DEBUGSS after the BOR completes.

Upon physical connection of a debug probe, a valid JTAG-to-SWD sequence must be sent from the debug probe to the target device to initiate a SWD connection with the SW-DP. Any other sequence will not wake the device from SHUTDOWN mode. Once the sequence is applied and the SWD connection is established, communication with enabled debug access points is possible.

For secure applications the software can be made aware of a connect by utilizing the DEBUGSS PWRUPIFG interrupt. When the debug probe is disconnected and the SWD connection is lost, the PWRDWNIFG interrupt is asserted.

It is possible for application software to disable the SWD interface in SYSCTL, freeing the IO to be used for general purpose IO functionality. Review *SWD Pins* in SYSCTL for using the SWD pins for functionality other than SWD. Once software disables SWD functionality, it is not possible to re-enable it other than by triggering a POR. A POR will automatically re-enable the SWD functionality and put the SWD pins into SWD mode with pullup/pulldown resistors enabled. To re-gain debug access to a device which contains software that disables the SWD pins at startup, it is necessary to hold the device in a reset state with the NRST pin during a POR. This will prevent the application software from starting and will allow the debug probe to gain access to the device, at which point a mass erase DSSM command can be sent from the integrated development environment to the device via the debug probe to remove the application software which is disabling the SWD pins.

#### Note

BOR, BOOTRST, and SYSRST levels do reset the IOMUX logic, which will re-enable the pullup/pulldown resistors on the SWDIO/SWCLK pin. However, the SWD functionality remains disabled until the next POR. Because the device always powers up with the SWDIO pullup and SWCLK pulldown resistors enabled, the hardware design must accommodate this when using the SWD pins for functions other than SWD after startup. After reset, application software may disable the pullup/pulldown resistors in the IOMUX to free the SWD pins for other purposes.

### 40.1.3 Debug Access Ports

The debug access ports in the DEBUGSS are given in [Table 40-1](#).

**Table 40-1. DEBUGSS Access Port Listing**

APSEL	AP	Port Description	Purpose
0x0	AHB-AP	MCPUSS debug access port	Debug of the processor and peripherals
0x1	CFG-AP	Configuration access port	Access device type information
0x2	SEC-AP	Security access port	Access the debug mailbox (DSSM)
0x3	ET-AP	EnergyTrace™ technology access port	Read the power state data from EnergyTrace technology for power aware debug
0x4	PWR-AP	Power access port	Configure the device power states (interfaces with PMCU/SYSCTL)

The AHB-AP, PWR-AP, and ET-AP provide the complete device debug functionality (processor debug, peripheral and memory bus access, power state control, and processor state). See [Section 40.2.1](#) for more information.

The CFG-AP provides device information to the debug probe so that the debug probe can identify device characteristics, including the device part number and the device revision.

The SEC-AP provides access to the mailbox for communicating with software running on the device through SWD. See [Section 40.2.4](#) for more information.

## 40.2 DEBUGSS Operation

The features and behaviors of the DEBUGSS module is discussed in the following sections.

### 40.2.1 Debug Features

The DEBUGSS supports processor debug, processor trace, peripheral debug, and energy state debug.

#### 40.2.1.1 Processor Debug

The Arm Cortex-M0+ processor supports a wide range of features to simplify debugging of application software during development. Key features supported by MSP MCUs include:

- Ability to halt the processor through a assertion of a halt signal, a configured debug event (such as a hard fault entry or reset), or a BKPT instruction (for software breakpoints)
- Ability to step through instructions (with or without peripheral interrupts enabled)
- Ability to run through instructions (with or without peripheral interrupts enabled)
- Ability to read and write CPU registers when halted
- Ability to read exception information through the Cortex-M0+ system control space (SCS)
- Support for up to 4 hardware breakpoints
- Support for up to 2 hardware watchpoints
- Support for accessing the device memory map
- Support for Microtrace Buffer (MTB) up to 4 jump locations

##### 40.2.1.1.1 Breakpoint Unit (BPU)

The breakpoint unit (BPU) provides up to 4 comparators which can be used to generate a debug event when the address of an instruction fetch matches the address programmed into the respective BPU comparator.

The BPU does not generate a debug event upon an address match for a data read or data write access.

Address matching is possible for half-word (16-bit) instructions and word (32-bit) instructions fetched from the CODE region (0x0000.0000 to 0x1FFF.FFFF).

If a debug scenario requires more than the supported hardware breakpoints, software breakpoints can be used together with hardware breakpoints using the BKPT instruction. If debugging of code in the SRAM region is desired, hardware breakpoints are not available and software breakpoints must be inserted by the debug probe instead.

```
// Example of a breakpoint function in C (TI Arm CLANG compiler)
__BKPT(0);
```

##### 40.2.1.1.2 Data Watchpoint and Trace Unit (DWT)

The data watchpoint and trace unit (DWT) provides up to 2 comparators which both support generating an event upon a data address match (watchpoint event) or an instruction address match (PC watchpoint event).

The DWT comparators support masking of the address, enabling an event to be generated when the processor attempts to access an address within a specified address range.

##### 40.2.1.1.3 Processor Trace (MTB)

Some devices support basic instruction execution trace to obtain context of the sequence of execution which led to a certain state of the processor. The processor trace engine is based on the Arm CoreSight MTB-M0+ micro trace buffer.

The MTB captures the processor's program counter (PC) state when the PC changes in a nonsequential way due to a branch instruction or an exception. Load and store activity is not captured by the MTB. When nonsequential execution is detected by the MTB, the change is captured and stored into a small buffer memory (described in [Table 40-2](#)) which can be read out later by application software or the debug probe.

**Table 40-2. MTB Buffer Memory**

Start Address	End Address	Length
0x4040.3000	0x4040.3020	32B (4 trace packets)

#### 40.2.1.2 Peripheral Debug

In addition to processor debug, the DEBUGSS can be used to access the device memory map from the perspective of the processor. Thus, a connected debug probe can be used to read and write memory-mapped peripheral registers, the system SRAM, and the flash memory.

Certain peripherals support advanced debug configuration options. These options are configured by application software (or optionally, the debug probe) by setting/clearing various debug control bits in the memory map of a given peripheral. In general, the debug behavior of a particular peripheral is specified in the PDBGCTL register of each peripheral. Many peripherals offer the option of halting the functional clock to the peripheral when the processor is halted for debug, thus pausing the peripheral together with the processor (default configuration), or letting the peripheral run even when the processor is halted for debug.

For example, the WWDT peripheral supports the FREE bit in the PDBGCTL register. Setting the FREE bit in PDBGCTL for a WWDT causes the WWDT counter to run even if the processor is halted for debug. Which will result in the watchdog not being serviced (causing an interrupt or reset).

#### 40.2.1.3 EnergyTrace Technology

The DEBUGSS in MSPM0 devices supports [EnergyTrace](#) technology. EnergyTrace technology enables power profiling of MCU devices running application code. This is very useful when developing an application which must be optimized for low-power operation.

Development tools from Texas Instruments, including the MSPM0 LaunchPad development tools, support hardware energy measurement of the target MSPM0 over time through EnergyTrace charge counting. This mechanism enables a developer to obtain an energy usage profile for an application, based on real current measurements with a wide dynamic range.

To give context to the energy measurements made by the hardware development tools supporting EnergyTrace technology, MSPM0 MCUs also enable EnergyTrace+. EnergyTrace+ is a component of the DEBUGSS that lets the debug probe log the state of the processor (RUN, SLEEP) and the current program counter value while the device is running. This state information can be then overlaid with energy measurements to determine if the cause of high current is the processor running or some other activity on the device.

TI's [Code Composer Studio](#) integrated development environment provides out-of-the-box support for EnergyTrace energy measurement and EnergyTrace+ processor state logging with MSPM0 devices.

---

#### Note

EnergyTrace+ state logging is not supported in SHUTDOWN mode, however the energy profiling function of EnergyTrace is still functional

---

#### 40.2.2 Behavior in Low Power Modes

The DEBUGSS supports maintaining a debug connection through SWD in all operating modes except SHUTDOWN. While in SHUTDOWN mode the DEBUGSS supports wakeup of the device to regain full access over the SWD connection.

By default access to device memory and peripherals is possible in RUN mode and SLEEP mode, in which a debug probe can be actively connected to the AHB-AP access port to interface with the processor. In STOP and STANDBY modes, a debug connection can be established and/or maintained with the DEBUGSS, but not with the CPU debug access port. The PWR-AP of the DEBUGSS allows an overwrite of the default behavior to keep access to the processor interface established while being in STOP or STANDBY mode.

In SHUTDOWN mode, any active debug connection is terminated as the debug logic is powered down with the device VCORE. While a debug connection to the DEBUGSS is not possible while the device is in SHUTDOWN mode, a debug probe can cause the device to exit SHUTDOWN mode by attempting to communicate with the

SWD pins. The device will detect attempted SWD communication even when the device is in SHUTDOWN. If activity is detected, a SHUTDOWN exit is initiated and the device will transition through a BOR state, after which a debug connection can be made to the DEBUGSS through SWD.

For more details regarding the access points of the DEBUGSS please refer to the following application note [Hardware Programming and Debugger Guide for MSP](#).

The DEBUGSS functionality by operating mode is given in [Table 40-3](#).

**Table 40-3. DEBUGSS Functionality by Operating Mode**

Capability	RUN	SLEEP	STOP	STANDBY	SHUTDOWN	NRST HOLD
Processor debug	Y	Y	N	N	N	N
Memory map access	Y	Y	N	N	N	N
Debug status through SW-DP	Y	Y	Y	Y	N	Y
Debug state maintained	Y	Y	Y	Y	N	N
Wake from SWD	-	-	-	-	Y	-

### 40.2.3 Restricting Debug Access

The debug subsystem supports several methods for restricting access to the device through the SWD interface. The debug access policy is determined by the user configuration specified in the NONMAIN flash region.

There are 4 levels of access control, given in [Table 40-4](#). By default, products shipped from TI arrive in a "debug enabled" state where the device is fully open. This state is not recommended for production. For production, TI recommends changing the debug configuration to password protected, debug disabled, or SWD disabled.

**Table 40-4. Debug Access Control**

DEBUGSS Function	Debug Configuration			
	Debug Enabled (default)	Debug Enabled with Password	Debug Disabled	SWD Disabled
SW-DP (debug port)	EN	EN	EN	DIS
CFG-AP	EN	EN	EN	DIS
SEC-AP	EN	EN	EN	DIS
ET-AP	EN	EN w/ PW	DIS	DIS
AHB-AP (CPU Debug)	EN	EN w/ PW	DIS	DIS

The debug access control can be configured by writing predefined values into the NONMAIN BOOTCFG0.

**Table 40-5. Debug Access Control Settings for BOOTCFG0**

Debug Configuration	SWDP_MODE	DEBUGACCESS
Debug Enabled (default)	AABBh	AABBh
Debug Enabled with Password	AABBh	CCDDh
Debug Disabled	AABBh	5566h
SWD Disabled	5566h	5566h

When debug is set to enabled with password, the debug access command together with the user-specified debug access password must be provided to the DEBUGSS [mailbox](#), and a BOOTRST must be issued. The password for access control is stored in NONMAIN utilizing the PWDDEBUGLOCK registers. Depending on the SOC implementation the password is either 128-bit plain text or 256-bit SHA-256 hash value. Refer to the data sheet for device-specific features.

When debug is disabled, the SW-DP is disabled during the boot process and any commands previously sent to the mailbox are ignored during boot. Following boot, any attempt to connect to the SW-DP is ignored.

Permanently lock debug access to the device by configuring the NONMAIN flash region to disable debug access while also configuring the NONMAIN flash region as statically write protected (locked). Locking the NONMAIN configuration has the added security of preventing the bootstrap loader (BSL) and application code from changing the debug security policy.

**Table 40-6. Debug related password registers**

Debug Function	Debug Access Control	Factory Reset	Mass Erase
Register Name	PWDDEBUGLOCK	PWDFACTORYRESET	PWDMASSERASE

### 128-bit plain text password

To enable a password on a debug function write a 128-bit hex value split into four 32-bit words into the respective password register.

Example: Factory Reset Password Configuration

- Create 128-bit hex value
  - 0xCAFECAFE12345678A5A5C3C30000FFFF
- Split the 128-bit value into four 32-bit words and write the value into the respective registers
  - PWDFACTORYRESET[0]←0x0000FFFF
  - PWDFACTORYRESET[1]←0xA5A5C3C3
  - PWDFACTORYRESET[2]←0x12345678
  - PWDFACTORYRESET[3]←0xCAFECAFE
- Repeat the same steps for any function that needs password protection

### 256-bit SHA-256 hash value

To enable a password on a debug function write the SHA-256 digest of the 128-bit plain text password into the respective registers.

Example: Factory Reset Password Configuration

- Determine the desired 128-bit plain text password  
0xCAFECAFE12345678A5A5C3C30000FFFF
- Split into four 32-bit words, reverse the password endianness, and then combine into one value
  - 0xFECAFECA
  - 0x78563412
  - 0xC3C3A5A5
  - 0xFFFF0000
  - 0xFECAFECA78563412C3C3A5A5FFFF0000
- Calculate the SHA of the value and break up the output into eight 32-bit words
  - 0x20E5F739C8D245C0E34A9C1301C12037DA29224D9B2C0738949C8ADC49AD34CA
  - 0x2738a568
  - 0x2ad52550
  - 0x17722746
  - 0x8dd2b55f
  - 0x552c34bd
  - 0x25560b90
  - 0x67b0a3f3
  - 0xd5c648f9
- Reverse the output of the eight 32-bit words

- a. 0x20E5F739 → 0x39F7E520
  - b. 0xC8D245C0 → 0xC045D2C8
  - c. 0xE34A9C13 → 0x139C4AE3
  - d. 0x01C12037 → 0x3720C101
  - e. 0xDA29224D → 0x4D2229DA
  - f. 0x9B2C0738 → 0x38072C9B
  - g. 0x949C8ADC → 0xDC8A9C94
  - h. 0x49AD34CA → 0xCA34AD49
5. Split the 128-bit value into four 32-bit words and write the value into the respective registers
    - a. PWDFACTORYRESET[0] ← 0x39F7E520
    - b. PWDFACTORYRESET[1] ← 0xC045D2C8
    - c. PWDFACTORYRESET[2] ← 0x139C4AE3
    - d. PWDFACTORYRESET[3] ← 0x3720C101
    - e. PWDFACTORYRESET[4] ← 0x4D2229DA
    - f. PWDFACTORYRESET[5] ← 0x38072C9B
    - g. PWDFACTORYRESET[6] ← 0xDC8A9C94
    - h. PWDFACTORYRESET[7] ← 0xCA34AD49
  6. Repeat the same steps for any function that needs password protection

#### 40.2.4 Mailbox (DSSM)

The debug subsystem mailbox (DSSM) enables a debug probe to pass messages to the target device through the SWD interface, as well as making it possible for the target device to return data to the debug probe.

The DSSM supports the following functions:

- Transmission of commands to the device during boot, including authenticating the debug probe for password-protected debug, mass erase, and factory reset operations
- Communicating with application software running on the target device when no other communication interface is present

Two 32-bit word data buffers are provided for TX data (debug probe to target device) and RX data (target device to debug probe). These data buffers are implemented as 32-bit memory-mapped registers in the DEBUGSS. In addition, TXCTL and RXCTL registers are provided for enabling flow control and indicating status of the mailbox.

**Table 40-7. DSSM Register Functions**

DSSM Register	Description	Debug Probe	Target Device	Actions
TX_DATA	Data buffer	RW	R	TXCTL.TRANSMIT is set on write by the debug probe, and cleared on a read by the target device; TXIFG is also set on a write by the debug probe
TXCTL	Flow control and status	RW	R	None
RX_DATA	Data buffer	R	RW	RXCTL.RECEIVE is set on write by the target device, and cleared on a read by the debug probe; RXIFG is also set on a write by the target device
RXCTL	Flow control and status	R	RW	None

The TXCTL and RXCTL registers provide generic transmit and receive flags. BIT0 of the TXCTL and RXCTL registers provide a specific TRANSMIT and RECEIVE flag which indicate the status of the TX\_DATA and RX\_DATA. The TRANSMIT bit is set in the TXCTL register when a debug probe writes data to the TX\_DATA buffer register. The TRANSMIT flag will then remain set until the CPU in the target device reads TX\_DATA or a POR occurs. The RECEIVE flag is set in the RXCTL register when the CPU in the target device writes data to

the RX\_DATA buffer register. The RECEIVE flag will then remain set until the debug probe reads the data from RX\_DATA.

It is not possible for software running on the target device to write to TX\_DATA, and it is also not possible for target software to clear the TRANSMIT flag other than by reading TX\_DATA.

The upper 31 bits of the TXCTL register, TRANSMIT\_FLAGS, contain generic flag bits which can be set or cleared by the debug probe to implement a protocol if desired. Only the debug probe can write to the TRANSMIT\_FLAGS field in TXCTL. The [DSSM Commands](#) is an example of a protocol to communicate with the target device. Also refer to *Boot Configuration* for security level control related to the DSSM commands.

In a similar way, only the target device software can write to RX\_DATA and RXCTL. The debug probe cannot write to RX\_DATA and it can only clear the RECEIVE flag in RXCTL by reading RX\_DATA. BIT1 through BIT7 (0xFE) of RXCTL contains the RECEIVE\_FLAGS field. Software on the target device can set or clear bits in the RECEIVE\_FLAGS field to implement a protocol if desired. These flags can be read by the debug probe but can not be modified by the debug probe.

**Table 40-8. DEBUGSS SEC-AP Register Definition**

AP SEL	ADDR	BANK	INDEX	REGISTER NAME	BIT 31 - 8	BIT 7 - 1	BIT 0
2	0x00	0	0	TXDATA	TX DATA		
	0x04	0	1	TXCTL	TRANSMIT_FLAGS		TRANSMIT
	0x08	0	2	RXDATA	RX Data		
	0x0C	0	3	RXCTL	Reserved	RECEIVE_FLAGS	RECEIVE
	0x0FC	15	3	IDR	Access point ID		

#### 40.2.4.1 DSSM Events

The DSSM contains one [event publisher](#) and no [event subscribers](#). One event publisher (CPU\_INT) manages DSSM interrupt requests (IRQs) to the CPU subsystem through a [static event route](#).

The DSSM events are summarized in [Table 40-9](#).

**Table 40-9. DSSM Events**

Event	Type	Source	Destination	Route	Configuration	Functionality
<a href="#">CPU Interrupt Event</a>	Publisher	DEBUGSS	CPU Subsystem	<a href="#">Static route</a>	CPU_INT registers	Fixed interrupt route from DEBUGSS to CPU

##### 40.2.4.1.1 CPU Interrupt Event (CPU\_INT)

The DSSM provides 4 interrupt sources which can be configured to source a [CPU interrupt event](#). In order of decreasing interrupt priority, the CPU interrupt events from the DSSM are given in [Table 40-10](#).

**Table 40-10. DSSM CPU Interrupt Event Conditions (CPU\_INT)**

Index (IIDX)	Name	Description
0	TXIFG	Indicates that the TX_DATA buffer in the DSSM has received data.
1	RXIFG	Indicates that the data in RX_DATA buffer in the DSSM was read.
2	PWRUPIFG	Indicates that the DEBUGSS was started due to a debug probe attaching to the device.
3	PWRDWNIFG	Indicates that the DEBUGSS was stopped due to a debug probe disconnecting from the device.

The CPU interrupt event configuration is managed with the CPU\_INT event management registers. See [Section 7.2.5](#) for guidance on configuring the Event registers for CPU interrupts.

#### 40.2.4.2 Reference

DSSM commands are serviced by the bootcode upon a BOOTRST. If passwords are enabled for DSSM commands, the commands do not execute until the correct password sequence is entered. Refer to [Table 40-11](#) for possible DSSM commands and values.

**Table 40-11. DSSM Commands**

DSSM Command	DSSM Value
Factory Reset	0x020Ah
Mass Erase	0x020Ch
Password Authentication	0x030Eh
Data Exchange	0x00EEh
Wait for debug	0x0206h

#### Factory Reset

The "Factory Reset" command erases all contents within main and nonmain memory, then nonmain is repopulated with default contents. This command is useful in the cases of:

- Nonmain misconfiguration
- Disabled debug access
- Peripheral/device misconfiguration

The factory reset has its own configuration and password refer to for security level details.

---

#### Note

The factory reset restores the NONMAIN configuration memory and therefore all previous security level settings are lost.

---

#### Mass Erase

The "Mass Erase" command erases all contents within the main memory but nonmain remains untouched. This command is useful in the case of:

- Peripheral/device misconfiguration

#### Password Authentication

The "Password Authentication" command unlocks debug access after the correct password has been processed.

#### Data Exchange

Data exchange is the only DSSM command that does not require a BOOTRST to process the command. This command is used in combination with factory reset, mass erase, or password authentication which do require a password. After sending the initial command to the mailbox and performing a reset, the user must begin sending the password to the TXDATA register. After each word 0x00EEh must be written to the TXCTL register.

#### Wait for Debug

The "Wait for Debug" command resets the peripherals defined by the reset level and then forces the device into the reset handler.

## **Custom DSSM Command**

The user can also create a custom DSSM command and perform actions defined by the user. This is done by having the debugger communicate to the CPU core through the TXDATA and TXCTL registers. The core can then receive messages from the debugger and send responses back by using the RXDATA and RXCTL registers for the debugger to read. CPU interrupt events can be configured for activity seen in the TX\_DATA buffer, RX\_DATA buffer, and DAP connection.

### 40.3 DEBUGSS Registers

Table 40-12 lists the memory-mapped registers for the DEBUGSS registers. All register offset addresses not listed in Table 40-12 should be considered as reserved locations and the register contents should not be modified.

**Table 40-12. DEBUGSS Registers**

Offset	Acronym	Register Name	Group	Section
1020h	IIDX	Interrupt index	CPU_INT	<a href="#">Go</a>
1028h	IMASK	Interrupt mask	CPU_INT	<a href="#">Go</a>
1030h	RIS	Raw interrupt status	CPU_INT	<a href="#">Go</a>
1038h	MIS	Masked interrupt status	CPU_INT	<a href="#">Go</a>
1040h	ISSET	Interrupt set	CPU_INT	<a href="#">Go</a>
1048h	ICLR	Interrupt clear	CPU_INT	<a href="#">Go</a>
10E0h	EVT_MODE	Event Mode		<a href="#">Go</a>
10FCh	DESC	Module Description		<a href="#">Go</a>
1100h	TXD	Transmit data register		<a href="#">Go</a>
1104h	TXCTL	Transmit control register		<a href="#">Go</a>
1108h	RXD	Receive data register		<a href="#">Go</a>
110Ch	RXCTL	Receive control register		<a href="#">Go</a>
1200h	SPECIAL_AUTH	Special enable authorization register		<a href="#">Go</a>
1210h	APP_AUTH	Application CPU0 authorization register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 40-13 shows the codes that are used for access types in this section.

**Table 40-13. DEBUGSS Access Type Codes**

Access Type	Code	Description
<b>Read Type</b>		
R	R	Read
R-0	R -0	Read Returns 0s
<b>Write Type</b>		
W	W	Write
WK	W K	Write Write protected by a key
<b>Reset or Default Value</b>		
-n		Value after reset or the default value

## 1 IIDX (Offset = 1020h) [Reset = 00000000h]

IIDX is shown in [Figure 40-2](#) and described in [Table 40-14](#).

Return to the [Summary Table](#).

This register provides the highest priority enabled interrupt index. 0xFF means no event pending. Interrupt 0x0 is the highest priority, 0x1 next highest, and 0xFE is the least priority. The priority order is fixed. However, users can implement their own prioritization schemes using other registers that expose the full set of interrupts that have occurred.

On each read, only one interrupt is indicated. On a read, the current interrupt (highest priority) is automatically cleared by the hardware and the corresponding interrupt flag in the RIS and MIS are cleared as well. After a read from the CPU (not from the debug interface), the register must be updated with the next highest priority interrupt, if none are pending, then it displays 0xFF.

**Figure 40-2. IIDX**

## 2 IMASK (Offset = 1028h) [Reset = 0000000h]

IMASK is shown in [Figure 40-3](#) and described in [Table 40-15](#).

Return to the [Summary Table](#).

Interrupt Mask. If a bit is set, then corresponding interrupt is unmasked. Unmasking the interrupt causes the raw interrupt to be visible in IIDX, as well as MIS.

### 3 RIS (Offset = 1030h) [Reset = 0000000h]

RIS is shown in [Figure 40-4](#) and described in [Table 40-16](#).

Return to the [Summary Table](#).

Raw interrupt status. Reflects all pending interrupts, regardless of masking. The RIS register allows the user to implement a poll scheme. A flag set in this register can be cleared by writing 1 to the ICLR register bit even if the corresponding IMASK bit is not enabled.

## 5 ISET (Offset = 1040h) [Reset = 0000000h]

ISET is shown in [Figure 40-6](#) and described in [Table 40-18](#).

Return to the [Summary Table](#).

Interrupt set. Allows interrupts to be set by software (useful in diagnostics and safety checks). Writing a 1 to a bit in ISET will set the event and therefore the related RIS bit also gets set. If the interrupt is enabled through the mask, then the corresponding MIS bit is also set.

**Figure 40-6. ISET**

0	TXIFG	W	0h	Clears TXIFG in RIS register 0h = Writing a 0 has no effect 1h = RIS bit corresponding to TXIFG is cleared

## 7 EVT\_MODE (Offset = 10E0h) [Reset = 0000001h]

EVT\_MODE is shown in [Figure 40-8](#) and described in [Table 40-20](#).

Return to the [Summary Table](#).

Event mode register. It is used to select whether each line is disabled, in software mode (software clears the RIS) or in hardware mode (hardware clears the RIS)

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1-0	INT0_CFG	R	1h	Event line mode select for peripheral events 0h = The interrupt or event line is disabled. 1h = The interrupt or event line is in software mode. Software must clear the RIS. 2h = The interrupt or event line is in hardware mode. The hardware (another module) clears automatically the associated RIS flag.

### 8 DESC (Offset = 10FCh) [Reset = 03400000h]

DESC is shown in [Figure 40-9](#) and described in [Table 40-21](#).

Return to the [Summary Table](#).

This register identifies the peripheral and its exact version.

**Figure 40-9. DESC**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FEATUREVER				INSTNUM				MAJREV				MINREV			
R-0h				R-0h				R-0h				R-0h			

**Table 40-29. DESC Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	MODULEID	R	340h	Module identification contains a unique peripheral identification number. The assignments are maintained in a central database for all of the platform modules to ensure uniqueness.
15-12	FEATUREVER	R	0h	Feature Set for the module *instance*
11-8	INSTNUM	R	0h	Instance Number within the device. This will be a parameter to the RTL for modules that can have multiple instances
7-4	MAJREV	R	0h	Major rev of the IP
3-0	MINREV	R	0h	Minor rev of the IP

### 9 TXD (Offset = 1100h) [Reset = 00000000h]

TXD is shown in [Figure 40-10](#) and described in [Table 40-22](#).

Return to the [Summary Table](#).

This register is used for data transfers from external debug tools to the DSSM module. The register is written by the debug tool and read by the CPU.

**Figure 40-10. TXD**

**Table 40-31. TXD Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_DATA	R	0h	Contains data written by an external debug tool to the SEC-AP TXDATA register

**10 TXCTL (Offset = 1104h) [Reset = 0000000h]**

TXCTL is shown in [Figure 40-11](#) and described in [Table 40-23](#).

Return to the [Summary Table](#).

Transmit control register

**Figure 40-11. TXCTL**

31	30	29	28	27	26	25	24

**Table 40-33. TXCTL Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	TRANSMIT_FLAGS	R	0h	Generic TX flags that can be set by external debug tool. Functionality is defined by SW.
0	TRANSMIT	R	0h	Indicates data request in DSSM.TXD, set on write via Debug AP to DSSM.TXD. A read of the DSSM.TXD register by SW will clear the TX field. The tool can check that TXD is empty by reading this field. 0h = TXD is empty 1h = TXD is full

### 11 RXD (Offset = 1108h) [Reset = 0000000h]

RXD is shown in [Figure 40-12](#) and described in [Table 40-24](#).

Return to the [Summary Table](#).

Receive data register. This register contains the data written by the CPU. This data is read by external debug tool.

**Figure 40-12. RXD**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-8	RESERVED	R/W	0h	
7-1	RECEIVE_FLAGS	R/W	0h	Generic RX flags that can be set by SW and read by external debug tool. Functionality is defined by SW.
0	RECEIVE	R	0h	Indicates SW write to the DSSM.RXD register. A read of the DSSM.RXD register by SWD Access Port will clear the RX field. 0h = RXD empty 1h = RXD full

### 13 SPECIAL\_AUTH (Offset = 1200h) [Reset = 0000013h]

SPECIAL\_AUTH is shown in [Figure 40-14](#) and described in [Table 40-26](#).

Return to the [Summary Table](#).

This register is used to control ET-AP, DFT-TAP, SWD, CFG-AP and SEC-AP.

**Figure 40-14. SPECIAL\_AUTH**

**Table 40-39. SPECIAL\_AUTH Field Descriptions**

Bit	Field	Type	Reset	Description
31-7	RESERVED	R	0h	
6	PWRAPEN	R	0h	An active high input. When asserted (and SWD access is also permitted), the debug tools can then access the PWR-AP to power and reset state of the CPU. When deasserted, a DAPBUS firewall will isolate the AP and prevent access. 0h = Disable PWR-AP 1h = Enable PWR-AP
5	AHBAPEN	R	0h	Disabling / enabling debug access to the M0+ Core via the AHB-AP DAP bus isolation. 0h = Disable AHB-AP 1h = Enable AHB-AP
4	CFGAPEN	R	1h	An active high input. When asserted (and SWD access is also permitted), the debug tools can use the Config-AP to read device configuration information. When deasserted, a DAPBUS firewall will isolate the AP and prevent access to the Config-AP. 0h = Disable CFG-AP 1h = Enable CFG-AP
3	ETAPEN	R	0h	An active high input. When asserted (and SWD access is also permitted), the debug tools can then access an ET-AP external to the DebugSS lite. When deasserted, a DAPBUS firewall will isolate the AP and prevent access. 0h = Disable ET+ -AP 1h = Enable ET+ -AP
2	DFTAPEN	R	0h	An active high input. When asserted (and SWD access is also permitted), the debug tools can then access the DFT-AP external to the DebugSS lite. When deasserted, a DAPBUS firewall will isolate the AP and prevent access. 0h = Disable DFT-TAP 1h = Enable DFT-TAP
1	SWDPORTEN	R	1h	When asserted, the SW-DP functions normally. When deasserted, the SW-DP effectively disables all external debug access. 0h = Disable SWD port 1h = Enable SWD port

**Table 40-39. SPECIAL\_AUTH Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	SECAPEN	R	1h	An active high input. When asserted (and SWD access is also permitted), the debug tools can use the Security-AP to communicate with security control logic. When deasserted, a DAPBUS firewall will isolate the AP and prevent access to the Security-AP. 0h = Disable SEC-AP 1h = Enable SEC-AP

#### 14 APP\_AUTH (Offset = 1210h) [Reset = 0000000h]

APP\_AUTH is shown in [Figure 40-15](#) and described in [Table 40-27](#).

Return to the [Summary Table](#).

This register is used to control DBGEN, NIDEN, SPIDEN, and SPNIDEN of Application CPU0. DBGEN, NIDEN are further processed by DSW based on Active and Debug IPF ID.
