

LM5164 100V Input, 1A Synchronous Buck DC/DC Converter With Ultra-low I_Q

1 Features

- Designed for reliable and rugged applications
 - Wide input voltage range of 6V to 100V
 - Junction temperature range: -40°C to $+150^{\circ}\text{C}$
 - Fixed 3ms internal soft-start timer
 - Peak and valley current-limit protection
 - Input UVLO and thermal shutdown protection
- Optimized for ultra-low EMI requirements
 - Meets [CISPR 25 class 5](#) standard
- Designed for scalable Industrial power supplies and battery packs
 - Low minimum on- and off-times of 50ns
 - Adjustable switching frequency up to 1MHz
 - Diode emulation for high light-load efficiency
 - 10.5 μA no-load input quiescent current
 - 3 μA shutdown quiescent current
- Integration reduces design size and cost
 - COT mode control architecture
 - Integrated 0.725 Ω NFET buck switch
 - Integrated 0.34 Ω NFET synchronous rectifier eliminates external Schottky diode
 - 1.2V internal voltage reference
 - No loop compensation components
 - Internal VCC bias regulator and boot diode
 - Open-drain power-good indicator
 - 8-pin SOIC package with PowerPAD™ integrated circuit package
- Create a custom regulator design using the LM5164 with [WEBENCH® Power Designer](#)

2 Applications

- [Industrial battery pack \(\$\geq 10\text{S}\$ \)](#)
- [Battery pack – e-bike, e-scooter, LEV](#)
- [Motor drives, drones, communications equipment](#)

3 Description

The LM5164 synchronous buck converter is designed to regulate over a wide input voltage range,

minimizing the need for external surge suppression components. A minimum controllable on-time of 50ns facilitates large step-down conversion ratios, enabling the direct step-down from a 48V nominal input to low-voltage rails for reduced system complexity and design cost. The LM5164 operates during input voltage dips as low as 6V, at nearly 100% duty cycle if needed, making the device an excellent choice for wide input supply range industrial and high cell count battery pack applications.

With integrated high-side and low-side power MOSFETs, the LM5164 delivers up to 1A of output current. A constant on-time (COT) control architecture provides nearly constant switching frequency with excellent load and line transient response. Additional features of the LM5164 include ultra-low I_Q and diode emulation mode operation for high light-load efficiency, remarkable peak and valley overcurrent protection, integrated VCC bias supply and bootstrap diode, precision enable and input UVLO, and thermal shutdown protection with automatic recovery. An open-drain PGOOD indicator provides sequencing, fault reporting, and output voltage monitoring. The LM5164 is available in a thermally-enhanced, 8-pin SO PowerPAD integrated circuit package. The 1.27mm pin pitch provides adequate spacing for high-voltage applications.

The LM5164 is available in a thermally-enhanced, 8-pin SO PowerPAD integrated circuit package. The device 1.27mm pin pitch provides adequate spacing for high-voltage applications.

Package Information

PART NUMBER	PACKAGE ⁽¹⁾	PACKAGE SIZE ⁽²⁾
LM5164	DDA (SO PowerPAD, 8)	4.9mm × 6mm

- For more information, see [Section 10](#).
- The package size (length × width) is a nominal value and includes pins, where applicable.

Typical Application

Typical Efficiency, $V_{OUT} = 12\text{V}$

4 Pin Configuration and Functions

Figure 4-1. DDA Package 8-Pin SO PowerPAD™ Integrated Circuit Package (Top View)

Table 4-1. Pin Functions

PIN		TYPE ⁽¹⁾	DESCRIPTION
NO.	NAME		
1	GND	G	Ground connection for internal circuits
2	VIN	P/I	Regulator supply input pin to high-side power MOSFET and internal bias regulator. Connect directly to the input supply of the buck converter with short, low impedance paths.
3	EN/UVLO	I	Precision enable and undervoltage lockout (UVLO) programming pin. If the EN/UVLO voltage is below 1.1V, the converter is in shutdown mode with all functions disabled. If the UVLO voltage is greater than 1.1V and below 1.5V, the converter is in standby mode with the internal VCC regulator operational and no switching. If the EN/UVLO voltage is above 1.5V, the start-up sequence begins.
4	RON	I	On-time programming pin. A resistor between this pin and GND sets the buck switch on-time.
5	FB	I	Feedback input of voltage regulation comparator
6	PGOOD	O	Power good indicator. This pin is an open-drain output pin. Connect to a source voltage through an external pullup resistor between 10kΩ to 100kΩ.
7	BST	P/I	Bootstrap gate-drive supply. Required to connect a high-quality 2.2nF 50V X7R ceramic capacitor between BST and SW to bias the internal high-side gate driver.
8	SW	P	Switching node that is internally connected to the source of the high-side NMOS buck switch and the drain of the low-side NMOS synchronous rectifier. Connect to the switching node of the power inductor.
—	EP	—	Exposed pad of the package. No internal electrical connection. Connect the EP to the GND pin and connect to a large copper plane to reduce thermal resistance.

5 Specifications

5.1 Absolute Maximum Ratings

Over the recommended operating junction temperature range of -40°C to $+150^{\circ}\text{C}$ (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Input voltage	VIN to GND	-0.3	100	V
	EN to GND	-0.3	100	
	FB to GND	-0.3	5.5	
	RON to GND	-0.3	5.5	
Bootstrap capacitor	External BST to SW capacitance	1.5	2.5	nF
Output voltage	BST to GND	-0.3	105.5	V
	BST to SW	-0.3	5.5	
	SW to GND	-1.5	100	
	SW to GND (20ns transient)	-3		
	PGOOD to GND	-0.3	14	
Operating junction temperature, T_J		-40	150	$^{\circ}\text{C}$
Storage temperature, T_{stg}		-65	150	$^{\circ}\text{C}$

- (1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

5.2 ESD Ratings

			VALUE	UNIT
$V_{\text{(ESD)}}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	± 2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	± 500	

- (1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.

- (2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

Over the recommended operating junction temperature range of -40°C to $+150^{\circ}\text{C}$ (unless otherwise noted)⁽¹⁾

		MIN	NOM	MAX	UNIT
V_{IN}	Input voltage	6		100	V
V_{SW}	Switch node voltage			100	V
$V_{\text{EN/UVLO}}$	Enable voltage			100	V
I_{LOAD}	Load current		1	1.25	A
F_{SW}	Switching frequency			1000	kHz
C_{BST}	External BST to SW capacitance		2.2		nF
t_{ON}	Programmable on-time	50		10000	ns

5.4 Thermal Information

THERMAL METRIC ⁽¹⁾		LM5164	UNIT
		DDA (SOIC)	
		8 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	43.4	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	59.5	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	16.1	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	4.0	°C/W
Ψ_{JB}	Junction-to-board characterization parameter	16.3	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	3.9	°C/W

(1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application note.

5.5 Electrical Characteristics

Typical values correspond to $T_J = 25^\circ\text{C}$. Minimum and maximum limits apply over the full -40°C to 150°C junction temperature range unless otherwise indicated. $V_{IN} = 24\text{V}$ and $V_{EN/UVLO} = 2\text{V}$ unless otherwise stated.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT

6 Detailed Description

6.1 Overview

The LM5164 is an easy-to-use, ultra-low I_Q constant on-time (COT) synchronous step-down buck regulator. With integrated high-side and low-side power MOSFETs, the LM5164 is a low-cost, highly efficient buck converter that operates from a wide input voltage of 6V to 100V, delivering up to 1A DC load current. The LM5164 is available in an 8-pin SO PowerPAD integrated circuit package with 1.27mm pin pitch for adequate spacing in high-voltage applications. This constant on-time (COT) converter is an excellent choice for low-noise, high-current, and fast load transient requirements, operating with a predictive on-time switching pulse. Over the input voltage range, input voltage feedforward is employed to achieve a quasi-fixed switching frequency. A controllable on-time as low as 50ns permits high step-down ratios and a minimum forced off-time of 50ns provides extremely high duty cycles, allowing V_{IN} to drop close to V_{OUT} before frequency foldback occurs. At light loads, the device transitions into an ultra-low I_Q mode to maintain high efficiency and prevent draining battery cells connected to the input when the system is in standby. The LM5164 implements a smart peak and valley current limit detection circuit to ensure robust protection during output short circuit conditions. Control loop compensation is not required for this regulator, reducing design time and external component count.

The LM5164 incorporates additional features for comprehensive system requirements, including an open-drain power good circuit for the following:

- Power-rail sequencing and fault reporting
- Internally-fixed soft start of 3ms
- Monotonic start-up into prebiased loads
- Precision enable for programmable line undervoltage lockout (UVLO)
- Smart cycle-by-cycle current limit for optimal inductor sizing
- Thermal shutdown with automatic recovery

These features enable a flexible and easy-to-use platform for a wide range of applications. The LM5164 supports a wide range of end-equipment systems requiring a regulated output from a high input supply where the transient voltage deviates from the DC level. The following are examples of such end-equipment systems:

- 48V automotive systems
- High cell-count battery-pack systems
- 24V industrial systems
- 48V telecom and PoE voltage ranges

The pin arrangement is designed for a simple PCB layout requiring only a few external components.

6.2 Functional Block Diagram

6.3 Feature Description

6.3.1 Control Architecture

The LM5164 buck switching converter employs a constant on-time (COT) control scheme. The COT control scheme sets a fixed on-time t_{ON} of the high-side FET using a timing resistor (R_{ON}). The t_{ON} is adjusted as input voltage changes and is inversely proportional to the input voltage to maintain a fixed frequency when in continuous conduction mode (CCM). After expiration of t_{ON} , the high-side FET remains off until the FB voltage is equal or below the reference voltage of 1.2V. To maintain stability, the feedback comparator requires a minimal ripple voltage that is in phase with the inductor current during the off-time. Furthermore, this change in FB voltage during the off-time must be large enough to dominate any noise present at the feedback node. The minimum recommended ripple voltage is 20mV. See Table 6-1 for ripple injection schemes that make sure of stability over the full input voltage range.

During a rapid start-up or a positive load step, the regulator operates with minimum off-times until regulation is achieved. This feature enables extremely fast load transient response with minimum output voltage undershoot. When regulating the output in steady-state operation, the off-time automatically adjusts itself to produce duty cycle required for output voltage regulation to maintain a fixed switching frequency. In CCM, the switching frequency F_{SW} is programmed by the R_{RON} resistor. Use Equation 1 to calculate the switching frequency.

$$F_{SW}(\text{kHz}) = \frac{V_{OUT}(\text{V}) \times 2500}{R_{RON}(\text{k}\Omega)} \quad (1)$$

Table 6-1. Ripple Generation Methods

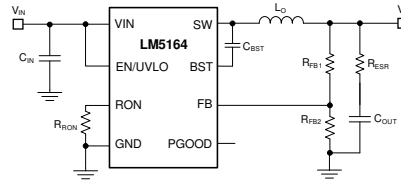

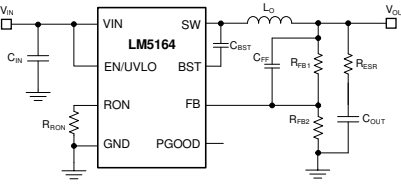

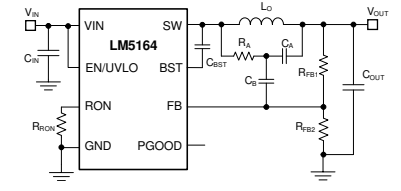

TYPE 1	TYPE 2	TYPE 3
Lowest Cost	Reduced Ripple	Minimum Ripple
		
$R_{ESR} \geq \frac{V_{OUT} \times 20mV}{V_{FB1} \times \Delta I_{L(nom)}} \quad (2)$ $R_{ESR} \geq \frac{V_{OUT}}{2 \times V_{IN} \times F_{SW} \times C_{out}} \quad (3)$	$R_{ESR} \geq \frac{20mV}{\Delta I_{L(nom)}} \quad (4)$ $R_{ESR} \geq \frac{V_{OUT}}{2 \times V_{IN} \times F_{SW} \times C_{out}} \quad (5)$ $C_{FF} \geq \frac{1}{2\pi \times F_{SW} \times (R_{FB1} R_{FB2})} \quad (6)$	$C_A \geq \frac{10}{F_{SW} \times (R_{FB1} R_{FB2})} \quad (7)$ $R_A C_A \leq \frac{t_{ON}(@V_{IN-nom}) \times (V_{IN-nom} - V_{OUT})}{20mV} \quad (8)$ $C_B \geq \frac{t_{TR-settling}}{3 \times R_{FB1}} \quad (9)$

Table 6-1 presents three different methods for generating appropriate voltage ripple at the feedback node. Type-1 ripple generation method uses a single resistor, R_{ESR} , in series with the output capacitor. The generated voltage ripple has two components: capacitive ripple caused by the inductor ripple current charging and discharging the output capacitor and resistive ripple caused by the inductor ripple current flowing into the output capacitor and through series resistance R_{ESR} . The capacitive ripple component is out of phase with the inductor current and does not decrease monotonically during the off-time. The resistive ripple component is in phase with the inductor current and decreases monotonically during the off-time. The resistive ripple must exceed the capacitive ripple at V_{OUT} for stable operation. If this condition is not satisfied, unstable switching behavior is observed in COT converters, with multiple on-time bursts in close succession followed by a long off-time. Equation 2 and Equation 3 define the value of the series resistance R_{ESR} to make sure of sufficient in-phase ripple at the feedback node.

Type-2 ripple generation uses a C_{FF} capacitor in addition to the series resistor. As the output voltage ripple is directly AC-coupled by C_{FF} to the feedback node, the R_{ESR} and ultimately the output voltage ripple are reduced by a factor of V_{OUT} / V_{FB} .

Type-3 ripple generation uses an RC network consisting of R_A and C_A , and the switch node voltage to generate a triangular ramp that is in-phase with the inductor current. This triangular wave is the AC-coupled into the feedback node with capacitor C_B . Because this circuit does not use output voltage ripple, this circuit is designed for applications where low output voltage ripple is critical. The [AN-1481 Controlling Output Ripple and Achieving ESR Independence in Constant On-time \(COT\) Regulator Designs](#) application note provides additional details on this topic.

Diode emulation mode (DEM) prevents negative inductor current, and pulse skipping maintains the highest efficiency at light load by decreasing the effective switching frequency. DEM operation occurs when the synchronous power MOSFET switches off as inductor valley current reaches zero. Here, the load current is less than half of the peak-to-peak inductor current ripple in CCM. Turning off the low-side MOSFET at zero current reduces switching loss, and preventing negative current reduces circulating energy loss. Power conversion efficiency is higher in a DEM converter than an equivalent forced-PWM CCM converter. With DEM operation, the duration that both power MOSFETs remain off progressively increases as load current decreases. When this idle duration exceeds 15μs, the converter transitions into an ultra-low I_Q mode, consuming only 10μA quiescent current from the input.

6.3.2 Internal VCC Regulator and Bootstrap Capacitor

The LM5164 contains an internal VCC bias supply subregulator that is powered from VIN with a nominal output of 5V, eliminating the need for an external capacitor for stability. The internal VCC subregulator supplies current

to internal circuit blocks including the MOSFET driver and logic circuits. The input pin (VIN) can be connected directly to line voltages up to 100V. As the high side power MOSFET has a low total gate charge, use a low bootstrap capacitor value to reduce the stress on the internal regulator. Selecting a high-quality 2.2nF 50V X7R ceramic bootstrap capacitor as specified in the [Absolute Maximum Ratings](#) section is required. Selecting a higher value capacitance stresses the internal VCC regulator and damages the device. A lower capacitance than required is not sufficient to drive the internal gate of the power MOSFET. An internal diode connects from the VCC regulator to the BST pin to replenish the charge in the high-side gate drive bootstrap capacitor when the SW voltage is low.

6.3.3 Regulation Comparator

The feedback voltage at FB is compared to an internal 1.2V Vref. The LM5164 voltage regulation loop regulates the output voltage by maintaining the FB voltage equal to VREF. A resistor divider programs the ratio from output voltage VOUT to FB.

For a target VOUT setpoint, use [Equation 10](#) to calculate RFB2 based on the selected RFB1.

$$R_{FB2} = \frac{1.2V}{V_{OUT} - 1.2V} \times R_{FB1} \quad (10)$$

TI recommends selecting RFB1 in the range of 100kΩ to 1MΩ for most applications. A larger RFB1 consumes less DC current, which is mandatory if light-load efficiency is critical. RFB1 larger than 1MΩ is not recommended as the feedback path becomes more susceptible to noise. Route the feedback trace away from the noisy area of the PCB and keep the feedback resistors close to the FB pin.

6.3.4 Internal Soft Start

The LM5164 employs an internal soft-start control ramp that allows the output voltage to gradually reach a steady-state operating point, thereby reducing start-up stresses and current surges. The soft-start feature produces a controlled, monotonic output voltage start-up. The soft-start time is internally set to 3ms.

6.3.5 On-Time Generator

The on-time of the LM5164 high-side MOSFET is determined by the RRON resistor and is inversely proportional to the input voltage, VIN. The inverse relationship with VIN results in a nearly constant frequency as VIN is varied. Use [Equation 11](#) to calculate the on-time.

$$t_{ON}(\mu s) = \frac{R_{ON}(k\Omega)}{V_{IN}(V) \times 2.5} \quad (11)$$

Use [Equation 12](#) to determine the RRON resistor to set a specific switching frequency in CCM.

$$R_{RON}(k\Omega) = \frac{V_{OUT}(V) \times 2500}{F_{SW}(kHz)} \quad (12)$$

Select RRON for a minimum on-time (at maximum VIN) greater than 50ns for proper operation. In addition to this minimum on-time, the maximum frequency for this device is limited to 1MHz.

6.3.6 Current Limit

The LM5164 manages overcurrent conditions with cycle-by-cycle current limiting of the peak inductor current. The current sensed in the high-side MOSFET is compared every switching cycle to the current limit threshold (1.5A). To protect the converter from potential current runaway conditions, the LM5164 includes a foldback valley current limit feature, set at 1.2A, that is enabled if a peak current limit is detected. As shown in [Figure 6-1](#), if the peak current in the high-side MOSFET exceeds 1.5A (typical), the present cycle is immediately terminated regardless of the programmed on-time (tON), the high-side MOSFET is turned off and the foldback valley current limit is activated. The low-side MOSFET remains on until the inductor current drops below this foldback valley current limit, after which the next on-pulse is initiated. This method folds back the switching frequency to prevent

overheating and limits the average output current to less than 1.5A to ensure proper short-circuit and heavy-load protection of the LM5164.

Figure 6-1. Current Limit Timing Diagram

Current is sensed after a leading-edge blanking time following the high-side MOSFET turn-on transition. The propagation delay of the current limit comparator is 100ns. During high step-down conditions when the on-time is less than 100ns, a back-up peak current limit comparator in the low-side FET also set at 1.5A enables the foldback valley current limit set at 1.2A. This remarkable current limit scheme enables ultra-low duty-cycle operation, permitting large step-down voltage conversions while ensuring robust protection of the converter.

6.3.7 N-Channel Buck Switch and Driver

The LM5164 integrates an N-channel buck switch and associated floating high-side gate driver. The gate-driver circuit works in conjunction with an external bootstrap capacitor and an internal high-voltage bootstrap diode. A high-quality 2.2nF, 50V X7R ceramic capacitor connected between the BST and SW pins provides the voltage to the high-side driver during the buck switch on-time. See the [Internal VCC Regulator and Bootstrap Capacitor](#) section for limitations. During the off-time, the SW pin is pulled down to approximately 0V, and the bootstrap capacitor charges from the internal VCC through the internal bootstrap diode. The minimum off-timer, set to 50ns (typical), ensures a minimum time each cycle to recharge the bootstrap capacitor. When the on-time is less than 300ns, the minimum off-timer is forced to 250ns to ensure that the BST capacitor is charged in a single cycle. This is vital during wake up from sleep mode when the BST capacitor is most likely discharged.

6.3.8 Synchronous Rectifier

The LM5164 provides an internal low-side synchronous rectifier N-channel MOSFET. This MOSFET provides a low-resistance path for the inductor current to flow when the high-side MOSFET is turned off.

The synchronous rectifier operates in a diode emulation mode. Diode emulation enables the regulator to operate in a pulse-skipping mode during light-load conditions. This mode leads to a reduction in the average switching frequency at light loads. MOSFET switching and gate driver losses, both of which are proportional to switching frequency, are significantly reduced at very light loads and efficiency is improved. This pulse-skipping mode also reduces the circulating inductor current and losses associated with conventional CCM at light loads.

6.3.9 Enable/Undervoltage Lockout (EN/UVLO)

The LM5164 contains a dual-level EN/UVLO circuit. When the EN/UVLO voltage is below 1.1V (typical), the converter is in a low-current shutdown mode and the input quiescent current (I_Q) is dropped down to 3μA. When the voltage is greater than 1.1V but less than 1.5V (typical), the converter is in standby mode. In standby mode, the internal bias regulator is active while the control circuit is disabled. When the voltage exceeds the rising threshold of 1.5V (typical), normal operation begins. Install a resistor divider from V_{IN} to GND to set the minimum operating voltage of the regulator. Use [Equation 13](#) and [Equation 14](#) to calculate the input UVLO turn-on and turn-off voltages, respectively.

$$V_{IN(on)} = 1.5V \times \left(1 + \frac{R_{UV1}}{R_{UV2}}\right) \quad (13)$$

$$V_{IN(off)} = 1.4V \times \left(1 + \frac{R_{UV1}}{R_{UV2}}\right) \quad (14)$$

TI recommends selecting R_{UV1} in the range of 1 M Ω for most applications. A larger R_{UV1} consumes less DC current, which is mandatory if light-load efficiency is critical. If input UVLO is not required, the power-supply designer can either drive EN/UVLO as an enable input driven by a logic signal or connect directly to VIN. If EN/UVLO is directly connected to VIN, the regulator begins switching as soon as the internal bias rails are active.

6.3.10 Power Good (PGOOD)

The LM5164 provides a PGOOD flag pin to indicate when the output voltage is within the regulation level. Use the PGOOD signal for start-up sequencing of downstream converters or for fault protection and output monitoring. PGOOD is an open-drain output that requires a pullup resistor to a DC supply not greater than 14V. The typical range of pullup resistance is 10k Ω to 100k Ω . If necessary, use a resistor divider to decrease the voltage from a higher voltage pullup rail. When the FB voltage exceeds 95% of the internal reference V_{REF} , the internal PGOOD switch turns off and PGOOD can be pulled high by the external pullup. If the FB voltage falls below 90% of V_{REF} , an internal 25 Ω PGOOD switch turns on and PGOOD is pulled low to indicate that the output voltage is out of regulation. The rising edge of PGOOD has a built-in deglitch delay of 5 μ s.

6.3.11 Thermal Protection

The LM5164 includes an internal junction temperature monitor to protect the device in the event of a higher than normal junction temperature. If the junction temperature exceeds 175°C (typical), thermal shutdown occurs to prevent further power dissipation and temperature rise. The LM5164 initiates a restart sequence when the junction temperature falls to 165°C, based on a typical thermal shutdown hysteresis of 10°C. This is a non-latching protection, so the device cycles into and out of thermal shutdown if the fault persists.

6.4 Device Functional Modes

6.4.1 Shutdown Mode

EN/UVLO provides ON and OFF control for the LM5164. When $V_{EN/UVLO}$ is below approximately 1.1V, the device is in shutdown mode. Both the internal linear regulator and the switching regulator are off. The quiescent current in shutdown mode drops to 3 μ A at $V_{IN} = 24$ V. The LM5164 also employs internal bias rail undervoltage protection. If the internal bias supply voltage is below the UV threshold, the regulator remains off.

6.4.2 Active Mode

The LM5164 is in active mode when $V_{EN/UVLO}$ is above the precision enable threshold and the internal bias rail is above the UV threshold. In COT active mode, the LM5164 is in one of three modes depending on the load current:

1. CCM with fixed switching frequency when load current is above half of the peak-to-peak inductor current ripple
2. Pulse skipping and diode emulation mode (DEM) when the load current is less than half of the peak-to-peak inductor current ripple in CCM operation
3. Current limit CCM with peak and valley current limit protection when an overcurrent condition is applied at the output

6.4.3 Sleep Mode

The [Control Architecture](#) section gives a brief introduction to the LM5164 diode emulation (DEM) feature. The converter enters DEM during light-load conditions when the inductor current decays to zero and the synchronous MOSFET is turned off to prevent negative current in the system. In the DEM state, the load current is lower than half of the peak-to-peak inductor current ripple and the switching frequency decreases when the load is further decreased as the device operates in a pulse skipping mode. A switching pulse is set when V_{FB} drops below 1.2V.

As the frequency of operation decreases and V_{FB} remains above 1.2V (V_{REF}) with the output capacitor sourcing the load current for greater than 15 μ s, the converter enters an ultra-low I_Q sleep mode to prevent draining the input power supply. The input quiescent current (I_Q) required by the LM5164 decreases to 10.5 μ A in sleep mode, improving the light-load efficiency of the regulator. In this mode, all internal controller circuits are turned off to ensure very low current consumption by the device. Such low I_Q renders the LM5164 as the best option to extend operating lifetime for off-battery applications. The FB comparator and internal bias rail are active to detect when the FB voltage drops below the internal reference V_{REF} and the converter transitions out of sleep mode into active mode. There is a 9 μ s wake-up delay from sleep to active states.

7 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

7.1 Application Information

The LM5164 requires only a few external components to step down from a wide range of supply voltages to a fixed output voltage. Several features are integrated to meet system design requirements, including the following:

- Precision enable
- Input voltage UVLO
- Internal soft start
- Programmable switching frequency
- A PGOOD indicator

To expedite and streamline the process of designing of a LM5164-based converter, a comprehensive LM5164 [quickstart calculator](#) is available for download to assist the designer with component selection for a given application. This tool is complemented by the availability of an [evaluation module \(EVM\)](#), numerous PSPICE models, as well as TI's [WEBENCH® Power Designer](#).

7.2 Typical Application

Figure 7-1 shows the schematic for a 12V, 1A COT converter.

Figure 7-1. Typical Application $V_{IN(nom)} = 48V$, $V_{OUT} = 12V$, $I_{OUT(max)} = 1A$, $F_{SW(nom)} = 300kHz$

Note

This and subsequent design examples are provided herein to showcase the LM5164 converter in several different applications. Depending on the source impedance of the input supply bus, an electrolytic capacitor can be required at the input to ensure stability, particularly at low input voltage and high output current operating conditions. See the [Power Supply Recommendations](#) section for more details.

7.2.1 Design Requirements

The target full-load efficiency is 92% based on a nominal input voltage of 48V and an output voltage of 12V. The required input voltage range is 15V to 100V. The LM5164 delivers a fixed 12V output voltage. The switching

frequency is set by resistor R_{RON} at 300kHz. The output voltage soft-start time is 3ms. [Table 7-1](#) lists the required components. See also the [LM5164-Q1 EVM User's Guide](#).

Table 7-1. List of Components

7.2.2 Detailed Design Procedure

7.2.2.1 Custom Design With WEBENCH® Tools

[Click here](#) to create a custom design using the LM5164 device with the WEBENCH® Power Designer.

1. Start by entering the input voltage (V_{IN}), output voltage (V_{OUT}), and output current (I_{OUT}) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:

- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WEBENCH.

7.2.2.2 Switching Frequency (R_{RON})

The switching frequency of the LM5164 is set by the on-time programming resistor placed at R_{ON} . As shown by [Equation 15](#), a standard 100k Ω , 1% resistor sets the switching frequency at 300kHz.

$$R_{RON}(k\Omega) = \frac{V_{OUT}(V) \times 2500}{F_{SW}(kHz)} \quad (15)$$

Note that at very low duty cycles, the 50ns minimum controllable on-time of the high-side MOSFET, $t_{ON(min)}$, limits the maximum switching frequency. In CCM, $t_{ON(min)}$ limits the voltage conversion step-down ratio for a given switching frequency. Use [Equation 16](#) to calculate the minimum controllable duty cycle.

$$D_{MIN} = t_{ON(min)} \times F_{SW} \quad (16)$$

Ultimately, the choice of switching frequency for a given output voltage affects the available input voltage range, design size, and efficiency. Use [Equation 17](#) to calculate the maximum supply voltage for a given $t_{ON(min)}$ before switching frequency reduction occurs.

$$V_{IN(max)} = \frac{V_{OUT}}{t_{ON(min)} \times F_{SW}} \quad (17)$$

7.2.2.3 Buck Inductor (L_O)

Use [Equation 18](#) and [Equation 19](#) to calculate the inductor ripple current (assuming CCM operation) and peak inductor current, respectively.

$$\Delta I_L = \frac{V_{OUT}}{F_{SW} \times L_O} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (18)$$

$$I_{L(peak)} = I_{OUT(max)} + \frac{\Delta I_L}{2} \quad (19)$$

For most applications, choose an inductance such that the inductor ripple current, ΔI_L , is between 30% and 50% of the rated load current at nominal input voltage. Use [Equation 20](#) to calculate the inductance.

$$L_O = \frac{V_{OUT}}{F_{SW} \times \Delta I_L} \times \left(1 - \frac{V_{OUT}}{V_{IN(nom)}}\right) \quad (20)$$

Choosing a 68 μ H inductor in this design results in 447 mA peak-to-peak ripple current at a nominal input voltage of 48 V, equivalent to 45% of the 1 A rated load current.

Check the inductor data sheet to make sure the saturation current of the inductor is well above the current limit setting of the LM5164. Ferrite-core inductors have relatively lower core losses and are preferred at high switching frequencies, but exhibit a hard saturation characteristic – the inductance collapses abruptly when the saturation current is exceeded. This results in an abrupt increase in inductor ripple current, higher output voltage ripple, and reduced efficiency, in turn compromising reliability. Note that inductor saturation current levels generally decrease as the core temperature increases. Meanwhile, powdered-iron inductors provide a soft saturation characteristic where inductance gradually decreases with current.

7.2.2.4 Output Capacitor (C_{OUT})

Select a ceramic output capacitor to limit the capacitive voltage ripple at the converter output. This is the sinusoidal ripple voltage that is generated from the triangular inductor current ripple flowing into and out of the capacitor. Select an output capacitance using [Equation 21](#) to limit the voltage ripple component to 0.5% of the output voltage.

$$C_{OUT} = \frac{\Delta I_L}{8 \times F_{SW} \times V_{OUT(ripple)}} \quad (21)$$

Substituting $\Delta I_{L(nom)}$ of 447mA gives C_{OUT} greater than 3 μ F. With voltage coefficients of ceramic capacitors taken in consideration, a 22 μ F, 25V rated capacitor with X7R dielectric is selected.

7.2.2.5 Input Capacitor (C_{IN})

An input capacitor is necessary to limit the input ripple voltage while providing AC current to the buck power stage at every switching cycle. To minimize the parasitic inductance in the switching loop, position the input capacitors as close as possible to the VIN and GND pins of the LM5164. The input capacitors conduct a square-wave current of peak-to-peak amplitude equal to the output current. Following, that the resultant capacitive component of AC ripple voltage is a triangular waveform.

Along with the ESR-related ripple component, use [Equation 22](#) to calculate the peak-to-peak ripple voltage amplitude.

$$V_{IN(ripple)} = \frac{I_{OUT} \times D \times (1 - D)}{C_{IN} \times F_{SW}} + I_{OUT} \times R_{ESR} \quad (22)$$

Use [Equation 23](#) to calculate the input capacitance required for a load current, based on an input voltage ripple specification (ΔV_{IN}).

$$C_{IN} \geq \frac{I_{OUT} \times D \times (1 - D)}{F_{SW} \times (V_{IN(ripple)} - (I_{OUT} \times R_{ESR}))} \quad (23)$$

The recommended high-frequency input capacitance is 2.2μF or higher. Make sure the input capacitor is a high-quality X7S or X7R ceramic capacitor with sufficient voltage rating for C_{IN}. Based on the voltage coefficient of ceramic capacitors, choose a voltage rating of twice the maximum input voltage. Additionally, some bulk capacitance is required if the LM5164 is not located within approximately 5cm from the input voltage source. This capacitor provides parallel damping to the resonance associated with parasitic inductance of the supply lines and high-Q ceramics. See also the [Power Supply Recommendations](#) section.

7.2.2.6 Type-3 Ripple Network

A Type-3 ripple generation network uses an RC filter consisting of R_A and C_A across SW and V_{OUT} to generate a triangular ramp that is in phase with the inductor current. This triangular ramp is then AC-coupled into the feedback node using capacitor C_B as shown in [Figure 7-1](#). Type-3 ripple injection is designed for applications where low output voltage ripple is crucial.

Use [Equation 24](#) and [Equation 25](#) to calculate R_A and C_A to provide the required ripple amplitude at the FB pin.

$$C_A \geq \frac{10}{f_{SW} \times (R_{FB1} || R_{FB2})} \quad (24)$$

For the feedback resistor values given in [Figure 7-1](#), [Equation 24](#) dictates a minimum C_A of 742pF. In this design, a 3300 pF capacitance is chosen. This is done to keep R_A within practical limits between 100kΩ and 1MΩ when using [Equation 25](#).

$$R_A C_A \leq \frac{t_{ON(nom)} \times (V_{IN - nom} - V_{OUT})}{20mV} \quad (25)$$

Based on C_A set at 3.3nF, R_A is calculated to be 453kΩ to provide a 20mV ripple voltage at FB. The general recommendation for a Type-3 network is to calculate R_A and C_A to get 20mV of ripple at typical operating conditions, while ensuring a 12mV minimum ripple voltage on FB at minimum V_{IN}.

While the amplitude of the generated ripple does not affect the output voltage ripple, the amplitude of the generated ripple impacts the output regulation as it reflects as a DC error of approximately half the amplitude of the generated ripple. For example, a converter circuit with Type-3 network that generates a 40mV ripple voltage at the feedback node has approximately 10mV worse load regulation scaled up through the FB divider to V_{OUT} than the same circuit that generates a 20mV ripple at FB. Use [Equation 26](#) to calculate the coupling capacitance C_B.

$$C_B \geq \frac{t_{TR - settling}}{3 \times R_{FB1}} \quad (26)$$

where

- t_{TR-settling} is the desired load transient response settling time

C_B calculates to 56pF based on a 75μs settling time. This value avoids excessive coupling capacitor discharge by the feedback resistors during sleep intervals when operating at light loads. To avoid capacitance fall-off with DC bias, use a C0G or NP0 dielectric capacitor for C_B.

7.3 Power Supply Recommendations

The LM5164 buck converter is designed to operate from a wide input voltage range between 6V and 100 V. The characteristics of the input supply must be compatible with the [Section 5.1](#) and [Section 5.3](#) tables. In addition, the input supply must be capable of delivering the required input current to the fully-loaded regulator. Use [Equation 27](#) to estimate the average input current.

$$I_{IN} = \frac{V_{OUT} \times I_{OUT}}{V_{IN} \times \eta} \quad (27)$$

where

- η is the efficiency

If the converter is connected to an input supply through long wires or PCB traces with a large impedance, take special care to achieve stable performance. The parasitic inductance and resistance of the input cables can have an adverse affect on converter operation. The parasitic inductance in combination with the low-ESR ceramic input capacitors form an underdamped resonant circuit. This circuit can cause overvoltage transients at VIN each time the input supply is cycled ON and OFF. The parasitic resistance causes the input voltage to dip during a load transient. If the converter is operating close to the minimum input voltage, this dip can cause false UVLO fault triggering and a system reset. The best way to solve such issues is to reduce the distance from the input supply to the regulator and use an aluminum electrolytic input capacitor in parallel with the ceramics. The moderate ESR of the electrolytic capacitor helps to damp the input resonant circuit and reduce any voltage overshoots. A 10µF electrolytic capacitor with a typical ESR of 0.5Ω provides enough damping for most input circuit configurations.

An EMI input filter is often used in front of the regulator that, unless carefully designed, can lead to instability as well as some of the effects mentioned above. The [Simple Success with Conducted EMI for DC-DC Converters application note](#) provides helpful suggestions when designing an input filter for any switching regulator.

7.4 Layout

7.4.1 Layout Guidelines

PCB layout is a critical portion of good power supply design. There are several paths that conduct high slew-rate currents or voltages that can interact with stray inductance or parasitic capacitance to generate noise and EMI or degrade the power supply performance.

1. To help eliminate these problems, bypass the VIN pin to GND with a low-ESR ceramic capacitor with a high-quality dielectric. Place C_{IN} as close as possible to the LM5164 VIN and GND pins. Grounding for both the input and output capacitors must consist of localized top-side planes that connect to the GND pin and GND PAD.
2. Minimize the loop area formed by the input capacitor connections to the VIN and GND pins.
3. Locate the inductor close to the SW pin. Minimize the area of the SW trace or plane to prevent excessive capacitive coupling.
4. Tie the GND pin directly to the power pad under the device and to a heat-sinking PCB ground plane.
5. Use a ground plane in layer 2 (below the power stage) one of the middle layers as a noise shielding and heat dissipation path.
6. Have a single-point ground connection to the plane. Route the ground connections for the feedback, R_{ON} , and enable components to the ground plane. This prevents any switched or load currents from flowing in analog ground traces. If not properly handled, poor grounding results in degraded load regulation or erratic output voltage ripple behavior.
7. Make V_{IN} , V_{OUT} and ground bus connections as wide as possible. This reduces any voltage drops on the input or output paths of the converter and maximizes efficiency.
8. Minimize trace length to the FB pin. Place both feedback resistors, R_{FB1} and R_{FB2} , close to the FB pin. Place C_{FF} (if needed) directly in parallel with R_{FB1} . If output setpoint accuracy at the load is important, connect the V_{OUT} sense at the load. Route the V_{OUT} sense path away from noisy nodes and preferably through a layer on the other side of a grounded shielding layer.

9. The RON pin is sensitive to noise. Thus, locate the R_{RON} resistor as close as possible to the device and route with minimal lengths of trace. The parasitic capacitance from RON to GND must not exceed 20 pF.
10. Provide adequate heat sinking for the LM5164 to keep the junction temperature below 150°C. For operation at full rated load, the top-side ground plane is an important heat-dissipating area. Use an array of heat-sinking vias to connect the exposed pad to the PCB ground plane. If the PCB has multiple copper layers, these thermal vias must also be connected to inner layer heat-spreading ground planes.

7.4.1.1 Compact PCB Layout for EMI Reduction

Radiated EMI generated by high di/dt components relates to pulsing currents in switching converters. The larger the area covered by the path of a pulsing current, the more electromagnetic emission is generated. The key to minimizing radiated EMI is to identify the pulsing current path and minimize the area of that path.

Figure 7-18 denotes the critical switching loop of the buck converter power stage in terms of EMI. The topological architecture of a buck converter means that a particularly high di/dt current path exists in the loop comprising the input capacitor and the integrated MOSFETs of the LM5164, and reducing the parasitic inductance of this loop by minimizing the effective loop area becomes mandatory.

Figure 7-18. DC/DC Buck Converter With Power Stage Circuit Switching Loop

The input capacitor provides the primary path for the high di/dt components of the current of the high-side MOSFET. Placing a ceramic capacitor as close as possible to the VIN and GND pins is the key to EMI reduction. Keep the trace connecting SW to the inductor as short as possible and just wide enough to carry the load current without excessive heating. Use short, thick traces or copper pours (shapes) for current conduction path to minimize parasitic resistance. Place the output capacitor close to the V_{OUT} side of the inductor, and connect the return terminal of the capacitor to the GND pin and exposed PAD of the LM5164.

7.4.1.2 Feedback Resistors

Reduce noise sensitivity of the output voltage feedback path by placing the resistor divider close to the FB pin, rather than close to the load. This reduces the trace length of FB signal and noise coupling. The FB pin is the input to the feedback comparator, and as such, is a high impedance node sensitive to noise. The output node is a low impedance node, so the trace from V_{OUT} to the resistor divider can be long if a short path is not available.

Route the voltage sense trace from the load to the feedback resistor divider, keeping away from the SW node, the inductor, and V_{IN} to avoid contaminating the feedback signal with switch noise, while also minimizing the

trace length. This is most important when high feedback resistances greater than 100k Ω are used to set the output voltage. Also, route the voltage sense trace on a different layer from the inductor, SW node, and V_{IN} so there is a ground plane that separates the feedback trace from the inductor and SW node copper polygon. This provides further shielding for the voltage feedback path from switching noise sources.

7.4.2 Layout Example

Figure 7-19 shows an example layout for the PCB top layer of a 2-layer board with essential components placed on the top side.

8.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature numbers SLMA002 (www.ti.com/lit/slma002) and SLMA004 (www.ti.com/lit/slma004).
9. Size of metal pad may vary due to creepage requirement.
10. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.

EXAMPLE STENCIL DESIGN**DDA0008B****PowerPAD™ SOIC - 1.7 mm max height**

PLASTIC SMALL OUTLINE

NOTES: (continued)

11. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
12. Board assembly site may have different recommendations for stencil design.

MECHANICAL DATA

PowerPAD™ PLASTIC SMALL-OUTLINE

- NOTES:
- All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5-1994.
 - This drawing is subject to change without notice.
 - Body dimensions do not include mold flash or protrusion not to exceed 0,15.
 - This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 for information regarding recommended board layout. This document is available at www.ti.com <<http://www.ti.com>>.
 - See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
 - This package complies to JEDEC MS-012 variation BA

THERMAL PAD MECHANICAL DATA

DDA (R-PDSO-G8)

PowerPAD™ PLASTIC SMALL OUTLINE

THERMAL INFORMATION

This PowerPAD™ package incorporates an exposed thermal pad that is designed to be attached to a printed circuit board (PCB). The thermal pad must be soldered directly to the PCB. After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

Exposed Thermal Pad Dimensions

PowerPAD™ PLASTIC SMALL OUTLINE

- NOTES:
- All linear dimensions are in millimeters.
 - This drawing is subject to change without notice.
 - Publication IPC-7351 is recommended for alternate designs.
 - This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SLMA002, SLMA004, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <<http://www.ti.com>>. Publication IPC-7351 is recommended for alternate designs.
 - Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
 - Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.
