If the RX\_FORCED\_TEARDOWN bit is set, a destructive teardown has been initiated. In this case, the UDMA will do the following:

1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
2. Completes any packets which may be pending in the ingress port buffers with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation) . Packets will be drained from the Rx FIFO either using 'null' write transfers or real transfers and the Packet Descriptors will be returned with an accurate accounting of actual bytes transferred.
3. Clears the channel enable in the Rx Channel N Realtime Control Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Rx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	1	Indicates that the teardown was not graceful. Data was potentially lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not. The normally intended method of issuing a teardown on a packet mode or single ended TR mode channel is to initiate the teardown at the remote PSI-L data source and allow it to flow into the UDMA. If that is not possible, the host may write the RX\_TEARDOWN bit directly to a 1.

The Host determines that a teardown is complete by periodically polling the teardown and enable bits for the channel or by waiting to receive the teardown record on the queue specified in the Tx Channel Completion Queue register for the channel.

#### 10.1.3.13 UDMA-P Receive Channel Pause

Setting the RX\_PAUSE bit in the Rx Channel N Realtime Control Register will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overflow conditions from a downstream data sink or upstream data source).

#### 10.1.3.14 UDMA-P Receive Free Descriptor/Buffer Queue Setup (Host Packets)

The Host is ultimately responsible for providing all of the free descriptors and buffers that the port uses as it receives packets. For Rx Free Descriptor/Buffer queues, descriptors are allocated in a large block by the Host and then initialized and linked with buffers before being given matched pairs where the Host initializes the descriptor to point to its corresponding buffer before being pushed onto a Receive Free Descriptor/Buffer queue. Once the host has allocated both a descriptor and a buffer, it adds them to an Rx Free Descriptor/Buffer Queue by writing the pointer to the descriptor to the Rx Free Descriptor/Buffer Queue register D for the desired queue.

Before the Host adds each Rx buffer descriptor to the queue, it must first initialize the Rx buffer descriptor values as follows:

- Write the Original Buffer Pointer with the byte aligned address of the buffer data
- Write the Original Buffer Size
- Write the Return Queue Number field in the descriptor to appropriate values (required if auto-recycling is intended)
- Write the On Chip/ Off Chip indicator in the descriptor

Depending on the software architecture, the Host may also desire to write the return policy bit in the descriptor at this point as well. The DMA will not overwrite any of these listed fields (including return policy) during reception.

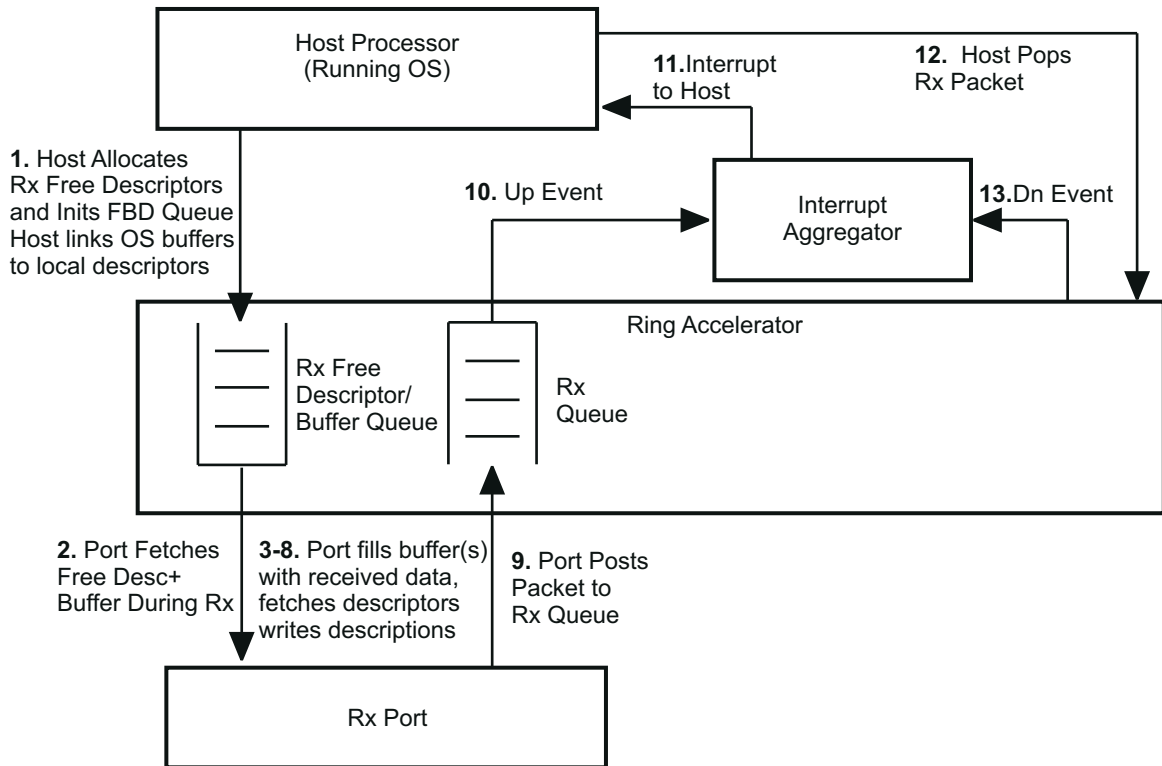

All other fields in the Descriptor do not need to be initialized as they will be overwritten by the Port on reception.

### 10.1.3.15 UDMA-P Receive FlowID Firewall Operation

Each incoming packet that enters the UDMA-P will either include an explicitly specified FlowID contained in the info words or it will have an implicitly specified default FlowID which is the same as the channel number. The Rx FlowID firewall checks the incoming FlowID on the received packet to verify that it is either the corresponding default FlowID for the channel or that the FlowID falls within the range specified in the Rx Channel Flow Range register. If the received flowID is not the channel number and it does not fall within the legal range as specified then the packet is dropped, the error is trapped in the Rx Flow ID Firewall Status register, and an optional output event is generated as specified in the Rx Flow ID Firewall Output Event Steering Register.

### 10.1.3.16 UDMA-P Receive Operation (Host Packet)

Figure 10-11 shows a diagram of the overall Receive operation for Host flow mode.

navss\_012

**Figure 10-11. Host Packet Receive Operation**

When packet reception begins on a given channel, the port will begin by fetching the first descriptor + buffer from the Ring Accelerator using the Free Descriptor/Buffer Queue 0 Index that was initialized in the Rx Flow Table for the flow which is being used by the channel. If the SOP Buffer Offset in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port will then continue filling that buffer and will fetch additional descriptors + buffers as needed using the Free Descriptor/Buffer Queue 1, 2, and 3 indexes for the 2<sup>nd</sup>, 3<sup>rd</sup>, and remaining buffers in the packet.

A detailed summary is as follows:

- Host allocates, populates, and places pointers to free descriptor/buffer structures onto Rx Free Descriptor/Buffer Queues
- UDMA-P fetches packet descriptor pointer from RA
- UDMA-P reads the packet descriptor to obtain the packet info, buffer pointer, and size
- UDMA-P fills the buffer with received data
- If packet is not complete, UDMA-P fetches next buffer descriptor pointer from RA
- UDMA-P fills the buffer with received data

If the RX\_DESC\_TYPE field in the Rx Flow Register A is set to 0 (Normal Rx Host Mode), Steps 5-7 continue until all packet data is received at which point the Rx engine proceeds to step 8. If the RX\_DESC\_TYPE is set to 1 (Single Buffer Packet Host Mode) the Rx engine will proceed to step 8 skipping step 7.

7. UDMA-P writes previous buffer descriptor to memory. This includes the following fields:

- a. Buffer information
- b. Buffer Pointer with the byte aligned address of the chunk of buffer data
- c. Buffer Length with the number of bytes in the chunk of buffer data
- d. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.

If the RX\_DESC\_TYPE field in the Rx Flow Register A is set to 0 (Normal Rx Host Mode), Steps 5-7 continue until all packet data is received at which point the Rx engine proceeds to step 8. If the RX\_DESC\_TYPE is set to 1 (Single Buffer Packet Host Mode) the Rx engine proceeds to step 8 as soon as the first buffer is full. Any remaining data in the packet from the line is then received into one or more additional packets each exactly one Host buffer long.

The UDMA-P performs the following operations when the entire packet has been received:

8. UDMA-P writes the packet descriptor to memory. This includes the following fields:
  - a. Descriptor Type (set to Host)
  - b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
  - c. Source Tag
  - d. Destination Tag (application specific)
  - e. Packet Type
  - f. Any protocol specific flags for the given packet type
  - g. SOP buffer information
    - i. Buffer Pointer with the byte aligned address of the chunk of buffer data
    - ii. Buffer Length with the number of bytes in the chunk of buffer data
  - h. Any protocol specific words that are required for the given packet type
  - i. Networking Stack Information (application specific and optional)
  - j. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.
9. UDMA-P writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the rx\_dest\_qnum field in the Rx Flow Table entry or will be a queue which was provided via the PSI-L destination queue number override field.
10. Once the packet pointer is written to the Ring Accelerator it will send an up event to the Interrupt Aggregator
11. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host
12. The Host will pop the packet pointer from the Rx Queue
13. If the pop causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

The Ring Accelerator is responsible for indicating the status of the Receive Queues to other ports/embedded processors using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

#### 10.1.3.17 UDMA-P Receive Operation (Monolithic Packet)

Figure 10-12 shows a diagram of the overall Receive operation for a monolithic descriptor type.

navss\_013

**Figure 10-12. Monolithic Packet Receive Operation**

The following sequence is a detailed summary of the Monolithic Packet Reception process:

1. The Host initializes free Descriptors and places them on an Rx Free Descriptor Queue
2. The UDMA-P fetches a single descriptor for the packet from the Ring Accelerator using the Monolithic Type Free Descriptor Queue Index that was initialized in the Rx Flow Table entry that is being used for the packet.
3. If the RX\_SOP\_OFFSET field in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the payload portion of the monolithic descriptor. The port will then continue filling the payload portion of the descriptor until the entire packet has been received.

The port performs the following operations when the entire packet has been received:

4. Writes the packet descriptor to memory. This includes the following fields:
  - a. Descriptor Type (set to Monolithic)
  - b. Packet Length indicating the total number of bytes in this packet.
  - c. Source Tag
  - d. Destination Tag (application specific)
  - e. Packet Type
  - f. Any protocol specific flags for the given packet type
  - g. Networking Stack Information (application specific and optional)
  - h. Any protocol specific words that are required for the given packet type
5. Writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the rx\_dest\_qnum fields in the Rx Flow Entry or can be overridden by the value in the PSI-L destination queue override field.
6. Once the packet pointer is written to the Ring Accelerator it will send an up event to the Interrupt Aggregator
7. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host
8. The Host will pop the packet pointer from the Rx Queue

9. If the pop causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

The Ring Accelerator is responsible for indicating the status of the Receive Queues to other ports/processors using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

#### 10.1.3.18 UDMA Receive Operation (TR Packet)

Packet reception in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
  - a. Descriptor Type (set to TR)
  - b. Reload Enable to 1 if looping is required, otherwise 0
  - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
  - d. Last Entry to TR count minus 1
  - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
  - f. Packet ID to a value that can be used to correlate the packet when it is placed back on the Tx completion queue
  - g. Source Tag
  - h. Destination Tag (application specific)
  - i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
  - j. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Rx TR Queues for the desired UDMA channel. Channels may provide more than one Rx TR Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the RA.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. These contents are then transmitted to an internal UTC.
8. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of writes (for single ended transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
9. The UDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the UDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the UDMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

#### 10.1.3.19 UDMA Receive Operation (Direct TR)

If the rings are configured in pass by value mode individual Transfer Request and Response records can be passed between software and hardware without any higher level data structures. This mode allows for

the UDMA to be prompted to do a transfer by just writing memory mapped locations with a source address, destination address and byte count (in the simplest case). Direct TR is accomplished as follows:

1. The Host writes a valid Transfer Request record to the Rx TR Queue of the desired UDMA channel.
2. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
3. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
4. The DMA controller reads the Transfer Request record from the ring via the RA in a single nominal TR sized block data move. These contents are then transmitted to an internal UTC (in the case of a UDMA-P).
5. All of the data transfers specified in a TR will be completed as a series of writes (for single ended transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
6. When a Transfer Response is returned for the Transfer Request record the UDMA will write the response into the next entry in the Transmit Completion Ring. Since the Transfer Responses come back from the UTC strongly ordered each response will be written into the ring strongly ordered as well.
7. After the Transfer Response has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

### 10.1.3.20 UDMA Receive Error/Exception Handling

Several types of errors/exceptions may be encountered during reception of data. The following table outlines the various errors and exceptions that can occur:

**Table 10-91. UDMA Rx Error/Exception Handling**

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Descriptor Starvation	All Packet	Exception	No	No	Option	Option	-	No
Protocol Errors	All Packet	Info	No	No	Normal	No	-	No
Drop	Host – normal	Exception	No	No	Partial <sup>(2)</sup>	Until EOP	-	No
	Host – single buffer	Error	Selectable <sup>(1)</sup>	Yes	Partial <sup>(2)</sup>	Until EOP <sup>(3)</sup>	-	No
	Mono	Exception	No	No	Partial <sup>(2)</sup>	Until EOP	-	No
	UTC–single ended	Exception	No	No	Partial <sup>(2)</sup>	Until EOP	Until EOP <sup>(4)</sup>	Yes
	UTC- block copy	Illegal	-	-	-	-	-	-
EOL Asserted Prematurely	All Packet	Error	Selectable <sup>(1)</sup>	Yes	No	Yes	-	No
	UTC – single ended	Exception	No	No	Normal	No	No	Yes
	UTC – block copy	Illegal	-	-	-	-	-	-
EOP Asserted Prematurely (Short Packet)	UTC – single ended	Exception	No	No	Normal	No	Until EOP <sup>(4)</sup>	Yes
EOP Asserted Late (Long Packet)	UTC – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All UTC	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No
Unsupported TR Type	All UTC	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No

(1) If PAUSE\_ON\_ERROR bit is set in channel configuration

(2) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.

(3) EOP will only occur when in single buffer mode when teardown is initiated. The data is a (never ending) stream. Drop is never supposed to be asserted during this mode of operation.

- (4) EOP on TR is true for all PBV TRs, the final TR in a PBR, or if the user specified EOP in the TR flags

#### **10.1.3.20.1 Error Conditions**

The following sections describe items which fall under an error severity when encountered by the UDMA on Rx:

##### **10.1.3.20.1.1 Bus Errors**

If a bus error is encountered during receive the DMA will log the error by asserting the RX\_ERROR bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

##### **10.1.3.20.1.2 Null Icnt0 Error**

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and it unproductive towards completion of any useful work. The Rx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

##### **10.1.3.20.1.3 Unsupported TR Type**

If a TR is provided to a channel which is of a type which is not supported by the channel, the Rx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

#### **10.1.3.20.2 Exception Conditions Exception Conditions**

There are a few cases which can occur when processing incoming packets which are not considered errors but which will require handling in order to avoid locking up the UDMA packet or TR mode write engines.

Packet mode channel exceptions include:

- Descriptor Starvation
- Protocol Errors
- Dropped Packets

Since the TR mode engine performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following sections outline these scenarios.

TR mode channel exceptions include:

- Reception of EOL delimiter
- Short Packets
- Long Packets

##### **10.1.3.20.2.1 Descriptor Starvation**

Descriptor starvation occurs when the Port attempts to fetch a free descriptor from an Rx Free Descriptor Queue or Rx Free Descriptor/Buffer Queue and none are available. When no descriptor is available, the Ring Accelerator will return a value of 0x0 for the descriptor pointer (Optionally, some ports may contain internal counters for the free queues which indicate how many elements are currently queued. In this case, no access to the RA is required and starvation is directly detected via a zero element count). When the port detects that descriptor starvation has occurred it will react based on the value of the RX\_ERROR\_HANDLING bit which was programmed into the Rx Flow N Configuration Register A.

- If the RX\_ERROR\_HANDLING bit is cleared:

The Port will assert a descriptor starvation indicator and will then return any descriptors that it has already used in the reception of the current packet back to the appropriate Free Descriptor or Free Descriptor/Buffer queue that they were fetched from. This is performed by writing the pointers for each descriptor to the Rx Free Descriptor Queue N Register in sequence using the queue indexes in the Rx DMA state. The port may choose to implement a counter that counts the number of packets that were dropped due to descriptor starvation and may

also desire to distinguish between whether the starvation occurred on the packet descriptor (SOP) or on a buffer starvation.

- If the RX\_ERROR\_HANDLING bit is set:

The Port will assert a descriptor starvation indicator (which may cause an interrupt to the Host) and will then behave as if it had not performed the current data block transfer which caused the starvation. The Port is required to pause its current processing saving the state of the transfer. The next time that the channel comes into context it will again try to allocate a descriptor with the intention being that if buffers/descriptors have been added that the operation will complete successfully on a subsequent retry.

#### **10.1.3.20.2.2 Protocol Errors**

Protocol errors occur when the port logic detects that the received packet did not pass protocol specific criteria that was checked during reception of the packet. Examples of protocol errors include packet length errors, CRC errors, or alignment errors.

When protocol errors are detected, the port may choose whether or not it will drop the packet. The mechanism that is used to determine which packets to drop and which to forward is application specific. If the port determines that it needs to forward the packet to the Host, it will set the Packet Error bit in the Descriptor indicating that this is a packet which experienced a protocol related error. The type of protocol related error is generally indicated in either the Protocol Specific bits in the Host or Monolithic descriptor or in the Protocol Specific bytes region. The packet length information and certain portions of the Protocol Specific region may not be correct for packets which encounter errors.

#### **10.1.3.20.2.3 Dropped Packets**

Packets can be dropped within an Rx Port for any number of reasons which with the exception of the starvation case which was covered above are application specific.

If a split TR mode channel receives instruction to drop a packet on the PSI-L interface, the UDMA/UTC will continue executing the TRs but without data transfer up until a TR is completed for which the EOP condition was set. Events will be generated as normal although data may not be actually transferred.

#### **10.1.3.20.2.4 Reception of EOL Delimiter**

If an end of line delimiter is received by the Rx (write) side of the UTC the EOL\_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

#### **10.1.3.20.2.5 EOP Asserted Prematurely (Short Packet)**

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and then to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

#### **10.1.3.20.2.6 EOP Asserted Late (Long Packets)**

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

### **10.1.3.21 UTC Operation**

A UTC accepts Transfer Request records from the UDMA-C and performs a sequence of transactions as specified in the TR record in accordance with the address generation algorithm that is specified in the Transfer Request format specification. The UTC will wait until an optional triggering event has occurred to load the

channel state into one of its read or write engines so that the data movement operations can be completed. The UTC will complete the specified transactions until it either has transferred a pre-set number of bytes or until it has reached a point in the sequence where the TR indicates that a trigger is required to continue execution. When either of these two conditions is met, the UTC will save off the current state of the channel and will wait until the channel is re-triggered at which point the TR execution will continue. Once the entire Transfer Request specified sequence of data transfers has completed, the UTC will wait to ensure that all outstanding writes have landed at their respective destination endpoints and will then return a Transfer Response message back to the UDMA-C indicating the success or failure of the Transfer Request. The UTC processes Transfer Request operations on a given channel with strong ordering such that all Transfer Response operations will be returned in an order corresponding to the exact order that Transfer Request operations were issued.

#### 10.1.3.22 UTC Receive Error/Exception Handling

Several types of errors/exceptions may be encountered during reception of data. The following table outlines the various errors and exceptions that can occur:

**Table 10-92. UTC Rx Error/Exception Handling**

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Drop	UTC–single ended	Exception	No	No	Partial <sup>(2)</sup>	Until EOP	Until EOP <sup>(3)</sup>	Yes
	UTC- block copy	Illegal	-	-	-	-	-	-
EOL Asserted Prematurely	UTC – single ended	Exception	No	No	Normal	No	No	Yes
	UTC – block copy	Illegal	-	-	-	-	-	-
EOP Asserted Prematurely (Short Packet)	UTC – single ended	Exception	No	No	Normal	No	Until EOP <sup>(3)</sup>	Yes
EOP Asserted Late (Long Packet)	UTC – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All UTC	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No
Unsupported TR Type	All UTC	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No

(1) If pause\_on\_error bit is set in channel configuration

(2) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.

(3) EOP on TR is true for all PBV TRs, the final TR in a PBR, or if the user specified EOP in the TR flags

##### 10.1.3.22.1 Error Handling

If an error occurs during the processing of a Transfer Request, the UTC will discontinue any further operations on the TR and will wait for all outstanding transactions to complete. At that point, the Transfer Response record will be returned to the UDMA-C with the appropriate codes indicating the type of failure as specified in the Transfer Response Format specification.

Depending on the value of the PAUSE\_ON\_ERROR bit in the UTC configuration register, the UTC will next do one of the following:

If the PAUSE\_ON\_ERROR bit is clear the channel will move on to the next Transfer Request record that it received from the UDMA-C.

If the PAUSE\_ON\_ERROR bit is set the channel will halt from processing any new Transfer Request records in order to allow the Host to examine the current channel state in order to determine the potential cause of the failure. The UTC is required to preserve as much of the channel state as possible as soon as a failure is determined. Note that the state will not necessarily provide exact details or a ‘smoking gun’ as the UTC implementation allows for large scale transaction pipelining and error status returns from the bus can occur well after the machine has moved on to other channel tasks.

#### **10.1.3.22.1.1 Null Icnt0 Error**

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and it unproductive towards completion of any useful work. The Rx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

#### **10.1.3.22.1.2 Unsupported TR Type**

If a TR is provided to a channel which is of a type which is not supported by the channel, the Rx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

#### **10.1.3.22.2 Exception Conditions**

There are a few cases which can occur when processing TRs which are not considered errors but which will require handling in order to avoid locking up the UTC read or write engines. Since the UTC performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following outline these scenarios.

##### **10.1.3.22.2.1 Reception of EOL Delimiter**

If an end of line delimiter is received by the Rx (write) side of the UTC the EOL\_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

##### **10.1.3.22.2.2 EOP Asserted Prematurely (Short Packet)**

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and the to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

##### **10.1.3.22.2.3 EOP Asserted Late (Long Packets)**

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

## 10.2 Navigator Subsystem (NAVSS)

This chapter describes the features and functions of the Navigator Subsystem (NAVSS) hardware modules in the device.

The SoC device contains two NAVSSes:

- Main NAVSS (NAVSS0) – See [Section 10.2.1](#), *Main Navigator Subsystem (NAVSS)*
- MCU NAVSS (MCU\_NAVSS0) – See [Section 10.2.2](#), *MCU Navigator Subsystem (MCU NAVSS)*.

## 10.2.1 Main Navigator Subsystem (NAVSS)

This section describes the top-level integration of the main Navigator Subsystem (NAVSS) in the device.

### 10.2.1.1 NAVSS Overview

Main SoC Navigator Subsystem (NAVSS0) consists of DMA/Queue Management components – UDMA and Ring Accelerator (UDMASS), Peripherals (Module subsystem [MODSS]), Virtualization translation (VirtSS), and a North Bridge (NBSS).

**UDMASS** – UDMASS is the essential part of the *TI Data Movement Architecture* (see [Section 10.1](#)). UDMASS consists of:

- Unified DMA Controller – [Section 10.2.3](#)
- Ring Accelerator – [Section 10.2.4](#)
- Packet Streaming Interface (PSI-L) – [Section 10.2.8](#)
- Block Copy DMA Controller

**MODSS** – Module subsystem is a collection of peripherals with different system-level functions, for example, interprocessor communication and time sync, among others. NAVSS0 contains the following modules:

- Mailbox
- Spinlock
- Two Timer Managers (Timer banks) – [Section 11.2](#)
- Time Stamp Module (CPTS)
- Infrastructure components such as:
  - CBASS – *System Interconnect*
  - Proxies – [Section 10.2.5](#), [Section 10.2.6](#)
  - Interrupt aggregators – [Section 10.2.7](#)
  - Interrupt router – *NAVSS Interrupt Router Configuration*

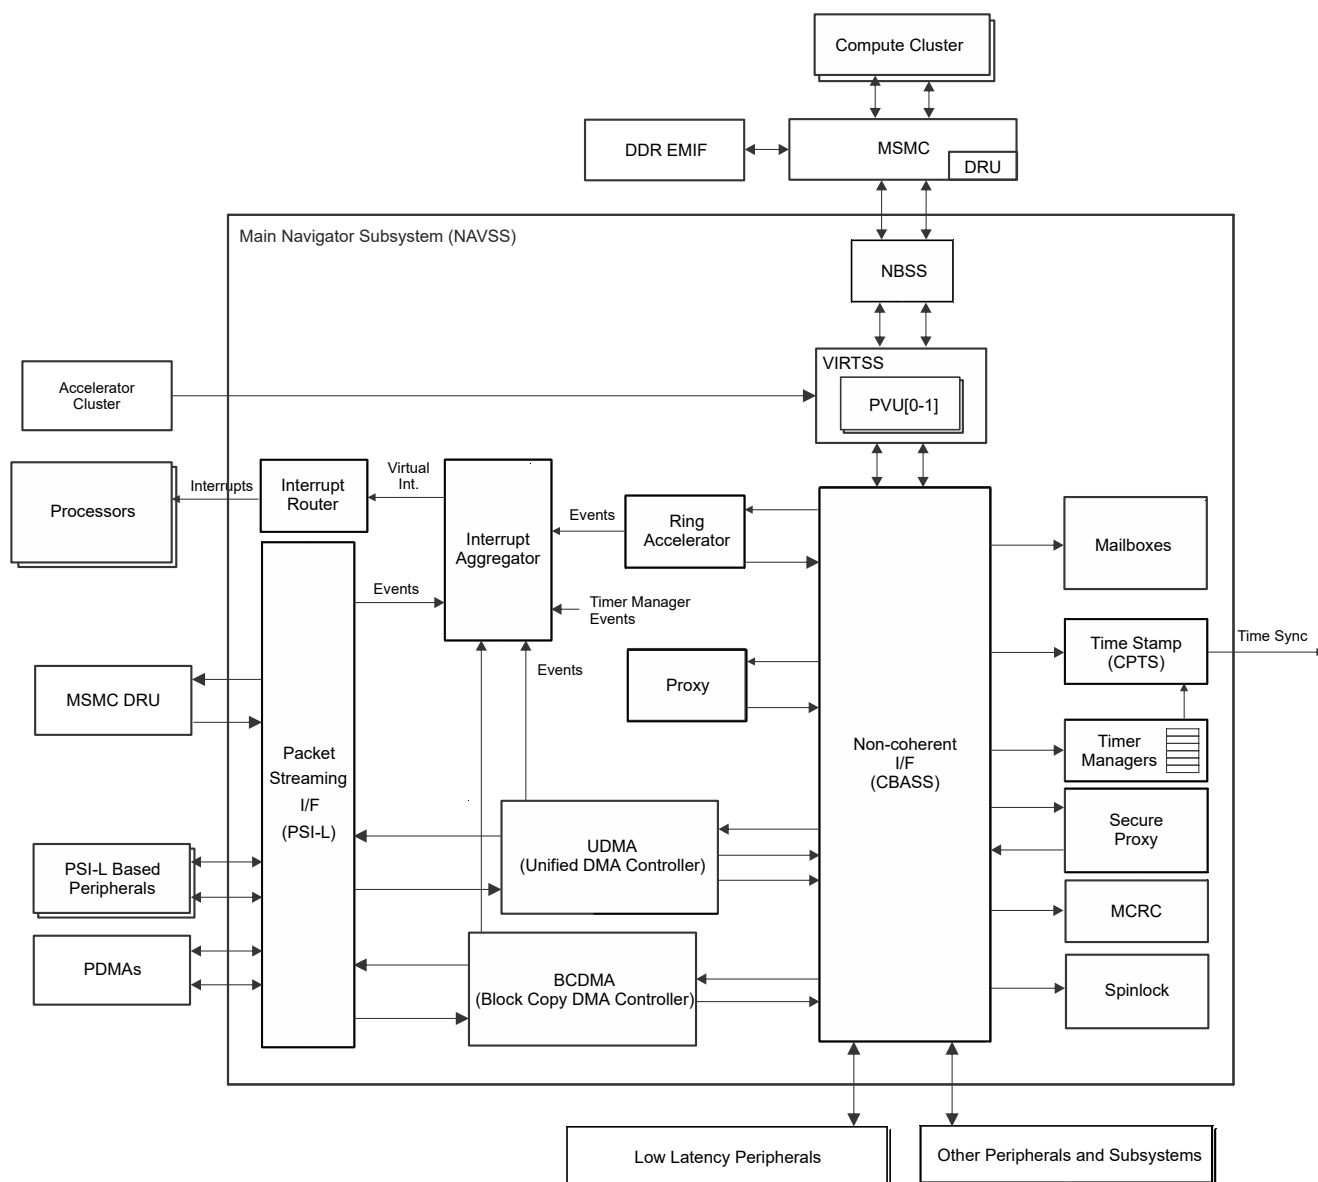

**NBSS** – North bridge – [Section 10.2.9](#)

**VirtSS** – Virtualization sub-system provides all the translation components supported in K3 for virtualization:

- Peripheral Virtualization Units (PVU)

### ECC aggregators

NAVSS0 hardware components and their integration are shown on [Figure 10-13](#).

**Figure 10-13. NAVSS0 Top-Level Block Diagram**

### Note

MCU NAVSS functionality is similar to that of main NAVSS, however it is composed of fewer peripherals and has reduced bandwidth.

#### 10.2.1.1.1 Main Navigator Subsystem (NAVSS) Ports

**Table 10-93. NAVSS Clocks and Resets**

Clocks	
Module Clock Input	Description
MODSS_VBUS_D2_CLK	MODSS config interface clock. This clock is used for most of the NAVSS modules (MODSS).
UDMASS_VBUS_D2_CLK	UDMASS config interface clock. This clock is used for UDMASS modules.
MSMC0_CLK	MSMC0 PSI-L interface clock
PDMA_MAIN_MISC_CLK	PDMA_MAIN_MISC PSI-L interface clock

**Table 10-93. NAVSS Clocks and Resets (continued)**

PDMA_MAIN_USART_CLK	PDMA_MAIN_USART PSI-L interface clock
PDMA_MAIN_AASRC_CLK	PDMA_MAIN_AASRC PSI-L interface clock
PDMA_MAIN_DEBUG_CLK	PDMA_MAIN_DEBUG PSI-L interface clock
PDMA_MAIN_MCASP_G1_CLK	PDMA_MAIN_MCASP_G1 PSI-L interface clock
ICSS_G0_CLK	ICSS_G0 PSI-L interface clock
ICSS_G1_CLK	ICSS_G1 PSI-L interface clock
NAVSS_MCU_CLK	MCU_NAVSS PSI-L interface clock
NBSS_VBUS_D2_CLK	NBSS config interface clock. This clock is used for NBSS modules (NB0-1, ECC_AGGR0).
NBSS_VBUS_CLK	NBSS VBUSM. This clock is used for NB0
VIRTSS_VBUS_D2_CLK	VIRTSS config interface clock.
EXT[0-3]_DTI_CLK	DTI clocks
Resets	
Module Reset Input	Description
MODSS_RST	MODSS hardware reset
UDMASS_RST	UDMASS hardware reset
NBSS_RST	NBSS hardware reset
VIRTSS_RST	VIRTSS hardware reset

**Table 10-94. NAVSS Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
INTR_ROUTER0_OUTL_INTR[63:0]	INTR_PEND[191:0] interrupts to GIC SPI	Level
INTR_ROUTER0_OUTL_INTR[127:64]		
INTR_ROUTER0_OUTL_INTR[191:128]		
INTR_ROUTER0_OUTL_INTR[223:192]	INTR_PEND[255:192] interrupts to main R5FSS0	Level
INTR_ROUTER0_OUTL_INTR[255:224]		
INTR_ROUTER0_OUTL_INTR[287:256]	INTR_PEND[319:256] interrupts to main R5FSS1	Level
INTR_ROUTER0_OUTL_INTR[319:288]		
INTR_ROUTER0_OUTL_INTR[351:344]	INTR_PEND[351:344] interrupts to C66SS0	Level
INTR_ROUTER0_OUTL_INTR[383:376]	INTR_PEND[383:376] interrupts to C66SS1	Level
INTR_ROUTER0_OUTL_INTR[391:348]	INTR_PEND[391:348] interrupts to PRU_ICSSG0 PR1	Level
INTR_ROUTER0_OUTL_INTR[399:392]	INTR_PEND[399:392] interrupts to PRU_ICSSG1 PR1	Level
INTR_ROUTER0_OUTL_INTR[407:400]	INTR_PEND[407:400] interrupts to MCU R5FSS0 CPU0 and CPU1	Level
MODSS_ECC_SEC_PEND	SEC interrupt from MODSS ECC_AGGR0	Level
MODSS_ECC_DED_PEND	DED interrupt from MODSS ECC_AGGR0	Level
UDMASS_ECC_SEC_PEND	SEC interrupt from UDMASS ECC_AGGR0	Level
UDMASS_ECC_DED_PEND	DED interrupt from UDMASS ECC_AGGR0	Level
NBSS_ECC_SEC_PEND	SEC interrupt from NBSS ECC_AGGR0	Level
NBSS_ECC_DED_PEND	DED interrupt from NBSS ECC_AGGR0	Level
VIRTSS_ECC_SEC_PEND	SEC interrupt from VIRTSS ECC_AGGR0	Level
VIRTSS_ECC_DED_PEND	DED interrupt from VIRTSS ECC_AGGR0	Level
L2G Interrupt Request Inputs		
Module Interrupt Signal	Description	Type
L2G_EVENT_PEND[7:0]	L2G interrupts from TIMESYNC_INTRTR0	Level
L2G_EVENT_PEND[15:8]	L2G interrupts from CMPEVT_INTRTR0	Level
L2G_EVENT_PEND[31:16]	L2G interrupts from GPIOMUX_INTRTR0	Level
DMA Events		

**Table 10-94. NAVSS Hardware Requests (continued)**

Module DMA Event	Description	Type
-	No PDMA channels to external DMA engines. See global event map.	-
<b>Time Sync Event Inputs</b>		
Module Sync Input	Description	Type
CPTS0_HW1_PUSH	CPTS Asynchronous hardware timestamp 1 push input	Pulse
CPTS0_HW2_PUSH	CPTS Asynchronous hardware timestamp 2 push input	Pulse
CPTS0_HW3_PUSH	CPTS Asynchronous hardware timestamp 3 push input	Pulse
CPTS0_HW4_PUSH	CPTS Asynchronous hardware timestamp 4 push input	Pulse
CPTS0_HW5_PUSH	CPTS Asynchronous hardware timestamp 5 push input	Pulse
CPTS0_HW6_PUSH	CPTS Asynchronous hardware timestamp 6 push input	Pulse
CPTS0_HW7_PUSH	CPTS Asynchronous hardware timestamp 7 push input	Pulse
CPTS0_HW8_PUSH	CPTS Asynchronous hardware timestamp 8 push input	Pulse
<b>Time Sync Event Outputs</b>		
Module Sync Output	Description	Type
CPTS0_TS_GENF0	CPTS Generation Function Output 0	Edge
CPTS0_TS_GENF1	CPTS Generation Function Output 1	Edge
CPTS0_TS_GENF2	CPTS Generation Function Output 2	Edge
CPTS0_TS_GENF3	CPTS Generation Function Output 3	Edge
CPTS0_TS_GENF4	CPTS Generation Function Output 4	Edge
CPTS0_TS_GENF5	CPTS Generation Function Output 5	Edge
CPTS0_TS_SYNC	CPTS Sync Output	Edge
<b>Compare Event Outputs</b>		
Module Compare Output	Description	Type
CPTS0_TS_COMP	CPTS Comparison Output	Edge

### 10.2.1.2 NAVSS Functional Description

See [Section 10.1](#), *DMA Architecture*, for the *TI K3 Data Movement (DMA) Architecture* specification.

See the following sections for the respective module description:

UDMASS:

- Unified DMA Controller – [Section 10.2.3](#)
- Ring Accelerator – [Section 10.2.4](#)
- Packet Streaming Interface (PSI-L) – [Section 10.2.8](#)
- Block Copy DMA Controller

MODSS:

- Mailbox
- Spinlock
- Two Timer Managers (Timer banks) – [Section 11.2](#)
- Time Stamp Module (CPTS)
- Infrastructure components:
  - CBASS – *System Interconnect*
  - Proxies – [Section 10.2.5](#)
  - Interrupt aggregators – [Section 10.2.7](#)
  - Interrupt router – *NAVSS Interrupt Router Configuration*

NBSS – North bridge – [Section 10.2.9](#)

ECC aggregators

**VirtSS** – Virtualization sub-system provides all the translation components supported in K3 for virtualization:

- Peripheral Virtualization Units (PVU)

### 10.2.1.3 NAVSS Interrupt Configuration

This section describes the actions needed to configure interrupts within the NAVSS. The information provided is applicable to either the NAVSS or MCU\_NAVSS subsystems.

Table 10-95 are module-specific hardcoded parameters required to properly configure the NAVSS interrupt support.

**Table 10-95. NAVSS Parameters**

Parameter	Value NAVSS0	Value MCU_NAVSS0	Description
RA_RING_CNT	1024	286	Number of total rings supported
IA_SEVI	4608	1536	UDMA Interrupt Aggregator Source Event Input (SEVI) count
IA_VINTR	256	256	UDMA Interrupt Aggregator Virtual Interrupt (VINTR) count
IR_IBASE	See NAVSS Interrupt Router Input Mapping	See Interrupt Router Input Mapping	Interrupt Router input interrupt base number for given module (hardcoded values in interrupt router)
EO	See Global Event Map	See Global Event Map	Event offset (hardcoded offsets in NAVSS)

Table 10-96 lists software-configurable variables used in the examples and descriptions.

**Table 10-96. NAVSS Software Variables**

Variable	Valid Range	Description
R#	0 – RA_RING_CNT-1	Ring number
E#	0 – (destination module specific)	Event number
GE#	= EO + E#	Global event number
SB#	0 – IA_SEVI-1	Interrupt aggregator status bit number
VI#	0 – IA_VINTR-1	Virtual interrupt number
OI#	0 – 407	Interrupt router output CPU interrupt number. See NAVSS Hardware Requests

#### 10.2.1.3.1 NAVSS Event and Interrupt Flow

Figure 10-14 illustrates the event and interrupt flow within the NAVSS and output interrupts to a CPU. Information that flows between NAVSS modules is also indicated (in this case, Global Event (GE) information flows between ring accelerator and the PSILSS).

**Figure 10-14. NAVSS Interrupt Flow**

#### 10.2.1.3.1.1 NAVSS Interrupts Description

This section describes the interrupt-related information that flows within NAVSS and how this information is configured or generated.

##### 1. Ring Number (R#)

- Data is read from and written to a specific Ring Accelerator ring using direct ring-mode, proxy, or secure proxy accesses
- The Ring Accelerator has specific ring number ranges for specific purposes. The R# must match the intended purpose of the ring (see *RINGACC Ring Mapping*)

##### 2. Global Event and Event Numbers (GE# and E#)

- $GE\# = EO + E\#$

- EO determines the destination module for the event. The PSILSS will route the GE# to the destination module per the NAVSS event mapping, removing EO in the process. The destination module sees only E#. See *Global event Map* for details. Examples:
  - GE# in the range 0x0000 – 0x1FFF (EO = 0x0000, E# = 0x0000 – 0x1FFF) would go to NAVSS0\_UDMASS\_INTR\_AGGR0. The INTR\_AGGR sees E#.
  - GE# in the range 0x4000 – 0x47FF (EO = 0x4000, E# = 0x0000 – 0x07FF) would go to MCU\_NAVSS0\_UDMASS\_INTR\_AGGR0. The INTR\_AGGR sees E#.
- For the INTR\_AGGR module, E# ranges from 0 to (IA\_SEVI - 1)

### 3. Virtual Interrupt (VI#)

- The INTR\_AGGR maps E# (via software configuration) to any SB#
- SB# ranges from 0 to (IA\_SEVI - 1)
- Each VI# (0 – (IA\_VINTR-1)) is driven by a group of 64 contiguous SB# numbers (VI# driven by SB#'s VI#×64 – (VI#×64)+63)

### 4. Output Interrupt (OI#)

- The Interrupt Router has a hardwired set of interrupt inputs from various modules (see *NAVSS Interrupt Router Input Mapping* ). Examples:
  - In the NAVSS, 256 interrupt inputs from the NAVSS0\_UDMASS\_INTR\_AGGR0 are hardwired to interrupt inputs 0 – 255. The VI# is zero-relative to this range.
  - In the MCU\_NAVSS, 4 event interrupt inputs from the MCRC0 are hardwired to interrupt inputs 256 – 259. The VI# is zero-relative to this range.
- Software configures an interrupt input (based on VI# + IR\_IBASE ) to an OI#

#### 10.2.1.3.1.2 Application Example

This section uses the following example to illustrate how to configure the NAVSS interrupt support for a specific use-case:

Using NAVSS0, use A72 MPU interrupt 7 for UDMA0 receive ring 16 (assumptions: use up/down event 10, NAVSS0\_UDMASS\_INTR\_AGGR0 for interrupt aggregation, and virtual interrupt 3).

Table 10-97 lists the modules' hardcoded parameters used for this example:

**Table 10-97. NAVSS Parameters for the Application Example**

Parameter	Value NAVSS0	From Table	Description
RA_UDMAP0_RX		<i>RINGACC Ring Mapping</i>	Starting ring number for UDMA0 receive channels
RA_RING_CNT	1024	<i>NAVSS0_RINGACC0 Configuration Parameters</i>	Number of total rings supported
IA_SEVI	4608	<i>Interrupt Aggregators Parameters</i>	NAVSS0_UDMASS_INTR_AGGR0 Steerable Event Input (SEVI) count
IA_VINTR	256	<i>Interrupt Aggregators Parameters</i>	NAVSS0_UDMASS_INTR_AGGR0 Virtual Interrupt (VINTR) count
IR_IBASE	0	<i>NAVSS Interrupt Router Input Mapping</i>	Interrupt-Router-input-interrupt base for NAVSS0_UDMASS_INTR_AGGR0
EO	0	<i>Global event Map</i>	Event offset. Destination is NAVSS0_UDMASS_INTR_AGGR0
CC_IBASE	0	<i>NAVSS0 Hardware Requests</i>	Interrupt-requests-to-CC base

Table 10-98 the variables and their respective calculations for this example.

**Table 10-98. NAVSS Software Variables for the Application Example**

Variable	Calculations/Value	Description
R#	= (RA_UDMAP0_RX + 16) + 16)	Receive ring 16 translates to ring number
E#	10	Zero-relative event number from PSILSS to NAVSS0_UDMASS_INTR_AGGR0
GE#	= (EO + E#) = (0 + 10) = 10	Global event number (event 10 to be sent to NAVSS0_UDMASS_INTR_AGGR0)

**Table 10-98. NAVSS Software Variables for the Application Example (continued)**

Variable	Calculations/Value	Description
VI#	= 3	VI# = 3 is per example assumptions. VI# could get any value 0 – IA_VINTR-1.
SB#	= 200	Must be in the range $(VI\# \times 64) - ((VI\# \times 64) + 63) = 192 - 255$ in order to drive VI# 3. We will use 200 for this example.
OI#	= (A72_IBASE + 7) = (0 + 7) = 7	OI# = 7 is per example assumptions. OI# could get any value 0 – 119 to drive an A72 interrupt.

Table 10-99 shows software register writes that will configure the NAVSS to produce the desired interrupt per the example description.

**Table 10-99. NAVSS Register Writes for the Application Example**

Module	Register	Value to Write	Description
RINGACC0	RING[R#]_EVT (EVENT_j)	RING[]_EVT = GE# = 10	Ring event number must be specified as a global event number
INTR_AGGR0	ENTRY[E#]_INTMAP (IMAP_j)	ENTRY[10]_INTMAP = $((SB\# / 64) \& 0x1FF) < 8$   $(SB\# \% 64)$ = $(3 < 8)   8$ = 0x308	regnum = SB# / 64 bitnum = SB# % 64
INTR_AGGR0	VINT[SB#/ 64]_ENABLE_SET (ENABLE_SET_j)	VINT[3]_ENABLE_SET = $1 < (SB\# \% 64)$ = $1 < 8$ = 0x100	Enable interrupt
INTR_ROUTER0	INTERRUPT_CONTR OL[OI#] (MUXCNTL_y)	INTERRUPT_CONTROL[7] = IR_IBASE + VI# = 0 + 3 = 3	Route interrupt

## 10.2.2 MCU Navigator Subsystem (MCU NAVSS)

This chapter describes the integration of the MCU Navigator Subsystem (MCU NAVSS) in the device and internal module parameters.

### 10.2.2.1 MCU NAVSS Overview

MCU Navigator Subsystem (MCU NAVSS) has a subset of the modules of the main NAVSS and is instantiated in the MCU domain.

MCU Navigator Subsystem consists of DMA/Queue Management components – UDMA and Ring Accelerator (UDMASS), and Peripherals (Module subsystem [MODSS]).

**UDMASS** – UDMASS is the essential part of the TI Data Movement Architecture. UDMASS consists of:

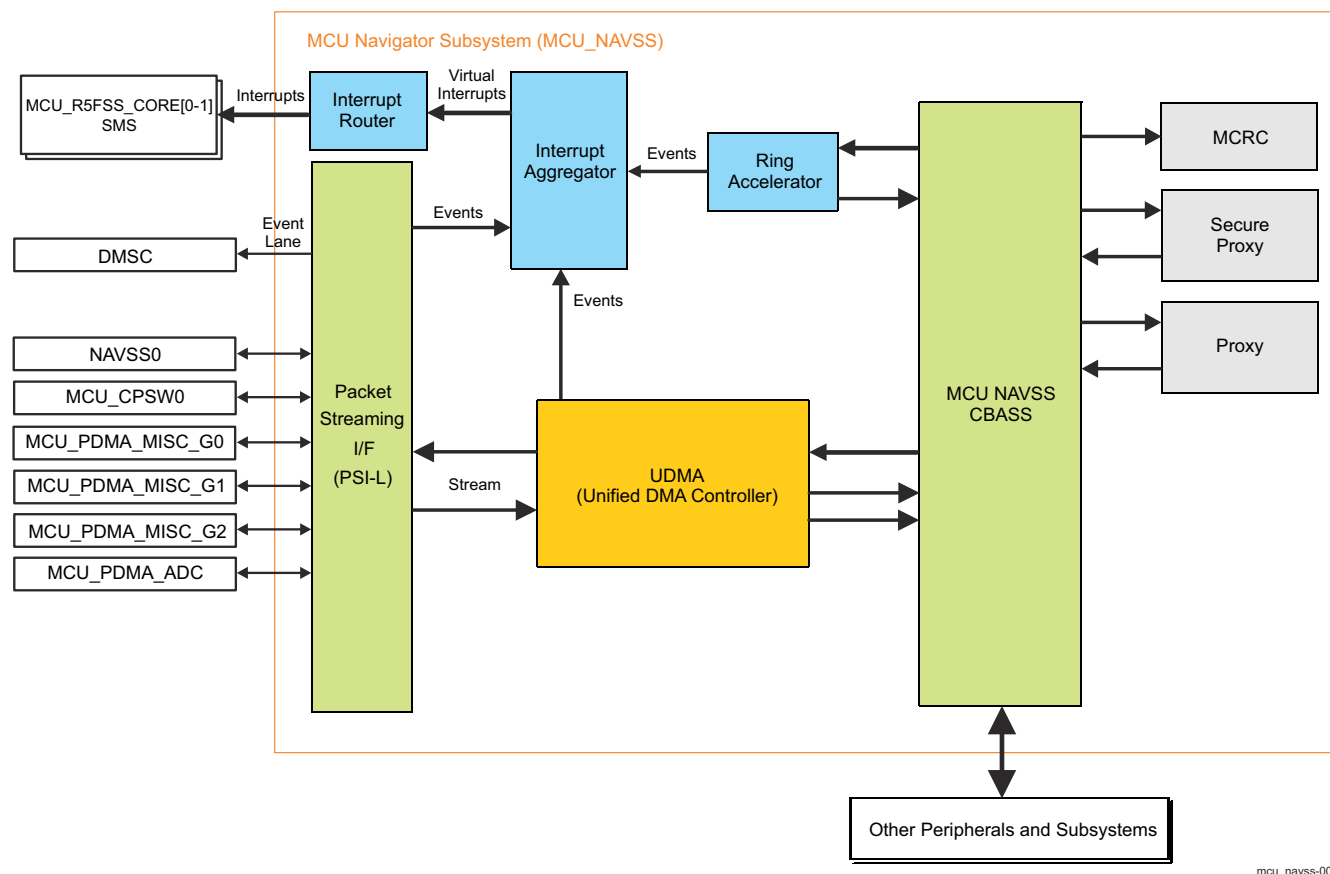

- Unified DMA Controller
- Ring Accelerator
- Packet Streaming Interface (PSILSS)

**MODSS** – MODSS is a collection of peripherals with different system-level functions. NAVSS0 contains the following modules:

- Memory CRC module
- Infrastructure components such as CBASS, proxies, interrupt aggregators, and an interrupt router

**ECC aggregators** – for SEC/DED memory protection.

Figure 10-15 shows the MCU\_NAVSS0 top-level block diagram.

**Figure 10-15. MCU NAVSS Top-Level Block Diagram**

### Note

MCU NAVSS functionality is similar to that of main NAVSS, however it is composed of fewer peripherals and has reduced bandwidth. This chapter describes the integration and parameters specific for MCU NAVSS.

#### 10.2.2.1.1 MCU NAVSS Ports

**Table 10-100. MCU NAVSS Clocks and Resets**

Clocks	
Module Clock Input	Description
MODSS_VBUS_D2_CLK	MODSS config interface clock. This clock is used for MCU_NAVSS modules (MODSS).
UDMASS_VBUS_D2_CLK	UDMASS config interface clock. This clock is used for UDMASS modules.
CPSW0_CLK	CPSW0 PSI-L interface clock
PDMA_MCU0_CLK	PDMA_MCU0 PSI-L interface clock
PDMA_MCU1_CLK	PDMA_MCU1 PSI-L interface clock
PDMA_MCU2_CLK	PDMA_MCU2 PSI-L interface clock
PDMA_ADC_CLK	PDMA_ADC PSI-L interface clock
Resets	
Module Reset Input	Description
MODSS_RST	MODSS hardware reset
UDMASS_RST	UDMASS hardware reset. Same as MODSS reset.

**Table 10-101. MCU NAVSS Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
INTR_ROUTER0_OUTL_INT[31:0]	Interrupts to MCU R5FSS Core 0	Level
INTR_ROUTER0_OUTL_INT[64:32]	Interrupts to MCU R5FSS Core 1	Level
MODSS_ECC_SEC_PEND	SEC interrupt from MODSS ECC_AGGR0	Level
MODSS_ECC_DED_PEND	DED interrupt from MODSS ECC_AGGR0	Level
UDMASS_ECC_SEC_PEND	SEC interrupt from UDMASS ECC_AGGR0	Level
UDMASS_ECC_DED_PEND	DED interrupt from UDMASS ECC_AGGR0	Level
Inbound Events		
DMA Event	Description	Type
WKUP_GPIOMUX_OUTP[19:12]	External L2G inputs into INTR_AGGR0. 4 MCRC events + 8 external.	Level
EVENT_PEND_INTR[3:0]		

### 10.2.2.2 MCU NAVSS Functional Description

See *DMA Architecture*, for the *TI K3 Data Movement (DMA) Architecture* specification.

See the following sections for the respective module description:

UDMASS:

- Unified DMA Controller – [Section 10.2.3](#)
- Ring Accelerator – [Section 10.2.4](#)
- Packet Streaming Interface (PSI-L) – [Section 10.2.8](#)

MODSS:

- Infrastructure components:
  - CBASS – *System Interconnect*
  - Proxies – [Section 10.2.5](#) and [Section 10.2.6](#)
  - Interrupt aggregator – [Section 10.2.7](#)

ECC aggregators

### 10.2.3 Unified DMA Controller (UDMA)

This chapter describes the UDMA controller module, part of NAVSS.

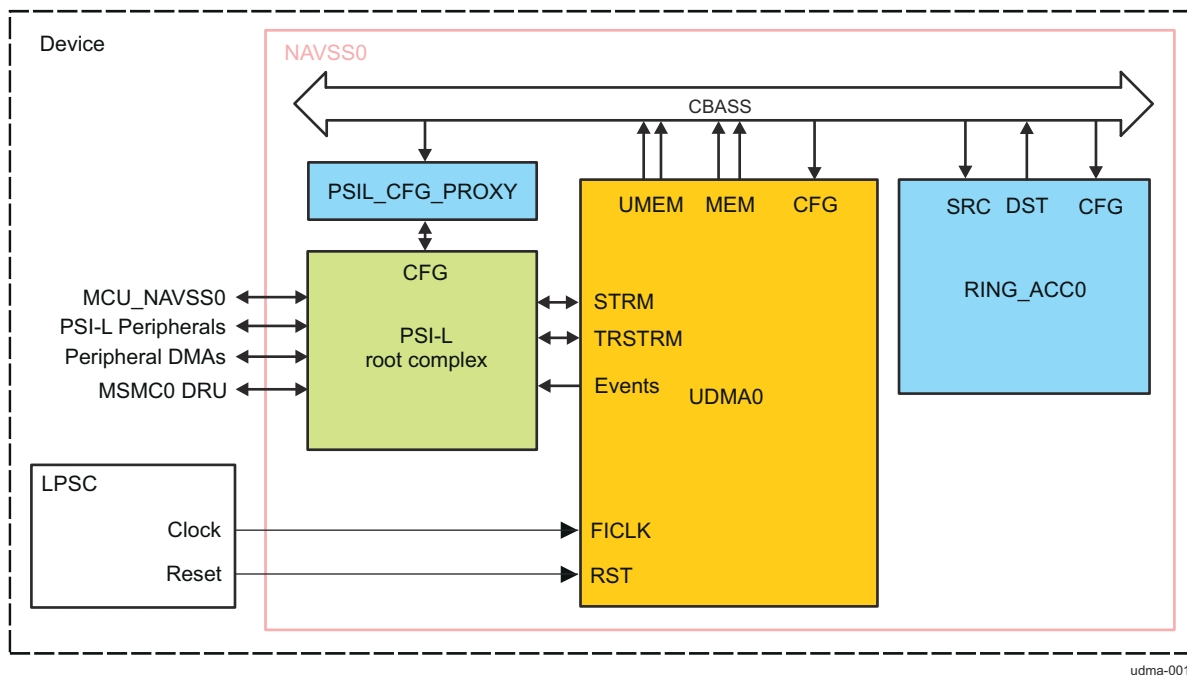

#### 10.2.3.1 UDMA Overview

The UDMA-P is intended to perform similar (but significantly upgraded) functions as the packet-oriented DMA used on previous SoC devices.

**Table 10-102. UDMA Allocation Across Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_UDMAP0	-	-	✓ (NAVSS)
MCU_NAVSS0_UDMAP0	-	✓ (MCU NAVSS)	-

Figure 10-16 shows a top-level overview of the UDMA module.

**Figure 10-16. UDMA Overview**

#### 10.2.3.1.1 UDMA Features

NAVSS0\_UDMAP0 controller module supports the following modes and features:

- *TI K3 DMA Architecture* compliant Tx/Rx port implementation (see [Section 10.1, DMA Architecture](#))
- Implements *TI DMA Architecture*-compliant Packet-Oriented DMA Functionality (UDMA-P)
  - Provides internal Tx Packet Oriented DMA processing unit
  - Provides internal Rx Packet Oriented DMA processing unit
  - Supports *rflow\_cnt* unique Rx flow table entries
  - Supports 1 transmit queue per data connection
  - Supports 1 receive queue per data connection
  - Supports physical separation of buffer control and payload information
  - Supports host and monolithic descriptor formats
  - Supports unlimited buffer scatter/gather for packets using host descriptor type
  - Supports data buffer sizes up to 4 Mbytes
  - Supports variable first valid byte offset within data buffers
  - Supports packet truncation on transmit
  - Provides per-channel buffering:

- Provides 16 word deep × 128-bit Packet FIFO for each Tx channel
- Provides 4 word deep Packet Info FIFO for each Rx channel
- Provides 8 word deep × 128-bit Packet Data FIFO for each Rx channel
- Supports up to 32 Protocol Specific words for Tx packets
- Supports up to 32 Protocol Specific words for Rx packets
- Implements *TI DMA Architecture* compliant Third Party Channel Controller
  - Channel controller is built as a prefetcher engine
  - Provides the same functionality as a discrete UDMA-C/UTC combination
    - Provides a fully integrated *TI DMA Architecture* Third Party DMA compliant solution
  - Can also fetch TRs and writeback TR responses for up to *echan\_cnt* external channels which are transported via the TR PSI-L interface
- Implements *TI DMA Architecture* compliant Unified Transfer Controller
  - Provides a memory read access unit
    - Supports read bursts up to 128 bytes (limited by Tx Per Channel FIFO depth for the channel)
  - Provides a memory write access unit
    - Supports write bursts up to 128 bytes (limited by Tx Per Channel FIFO depth for the channel)
  - Supports Type 0-4, and Type 15 Transfer Request types
- Provides a set of *TI DMA Architecture* compliant Unified DMA channels which all share the execution hardware using time division multiplexing
  - Supports *tchan\_cnt* concurrent Tx channels
    - Each Tx channel can be configured at runtime to be:
      - Packet oriented Tx data channel
      - Third party combination source control and data channel (Third Party channel mode)
  - Supports *rchan\_cnt* simultaneous Rx (destination) channels
    - Each Rx channel can be configured at runtime to be:
      - Packet oriented Rx data channel
      - Third party combination destination control and data channel (Third Party channel mode)
  - Provides support for three different groups of internal channels:
    - Ultra-high capacity (UHC) channels
      - Quantity specified by: *uchan\_cnt*
      - Provide deeper Tx Per Channel FIFOs
      - Provide 16 deep descriptor/TR prefetch buffers
      - UHC channels are the first *uchan\_cnt* channels within the Tx and Rx arrays (starting with channel 0 and extending up to channel *uchan\_cnt*-1)
      - Tx and Rx UHC channels are specified as a matched pair
        - Still usable as split channels but design must have same number of Tx/Rx UHC channels
    - High-capacity (HC) channels:
      - Quantity specified by: *hchan\_cnt* - *uchan\_cnt*
      - Provide deeper Tx Per Channel FIFOs
      - Provide 16 deep descriptor/TR prefetch buffers
      - HC channels are the next *hchan\_cnt* channels (after any UHC channels) within the Tx and Rx channel arrays (starting with channel *uchan\_cnt* and extending up to *uchan\_cnt* + *hchan\_cnt*-1).
    - Normal capacity (NC) channels:
      - Quantity on Tx specified by: *tchan\_cnt* - *uchan\_cnt* - *hchan\_cnt*
      - Quantity on Rx specified by: *rchan\_cnt* - *uchan\_cnt* - *hchan\_cnt*
      - Provide standard depth Tx/Rx per channel FIFOs
      - Provide 1 deep descriptor/TR prefetch buffers

#### Note

User can still use ultra-high capacity and high-capacity channels as general normal-capacity channels though may not be taking advantage of the potential DMA throughput advantages.

- Provides per-channel buffering:
  - Provides 16 word deep data FIFO for each NC Tx (source) channel
  - Provides 8 word deep data FIFO for each NC Rx (destination) channel

- Provides single 128-bit read/write VBUSM master interface for prefetcher accesses to RINGACC and memory.
  - Supports up to 16 outstanding reads.
  - Supports up to 16 outstanding writes.
- Provides single 128-bit read/write VBUSM master interface for packet DMA and coherency unit accesses to RINGACC and memory.
  - Supports up to 16 outstanding reads.
  - Supports up to 16 outstanding writes.
- Provides single 128-bit read only VBUSM master interface for payload transfers.
  - Supports up to 16 outstanding reads.
- Provides single 128-bit write only VBUSM master interface for payload transfers.
  - Supports up to 16 outstanding writes.
- Provides 128-bit wide PSI-L compliant source interface for sending data to remote UTCs and remote peripherals
  - Includes 1 outgoing event transport lane
- Provides 128-bit wide PSI-L compliant destination interface for receiving data from remote UTCs and remote peripherals
  - Includes 1 incoming event transport lane
- Provides PSI-L interface for sending Transfer Requests to remote UTC channels and receiving back Transfer Responses
  - Provides 32 entry deep unified Transfer Response FIFO for external channels
- Provides 0 local event input buses

### 10.2.3.1.2 UDMA Parameters

Table 10-103 shows the UDMA configuration parameters in this SoC.

**Table 10-103. UDMA Configuration Parameters**

Module Instance	Parameters <sup>(1)</sup>					
	tchan_cnt <sup>(2)</sup>	rchan_cnt <sup>(3)</sup>	echan_cnt <sup>(4)</sup>	hchan_cnt <sup>(6)</sup>	uchan_cnt <sup>(7)</sup>	rflow_cnt <sup>(5)</sup>
NAVSS0_UDMAP0	85	82	256	4	2	224
MCU_NAVSS0_UDMAP0	48	48	0	2	0	96

(1) Parameter values can be read from the capabilities registers. See UDMA\_CAP2 and UDMA\_CAP3 registers.

(2) Total internal Tx channel count (Normal- + High- + Ultra-high capacities)

(3) Total internal Rx channel count (Normal- + High- + Ultra-high capacities)

(4) External UTC channel count

(5) Rx flow table entry count

(6) High-capacity + Ultra-high capacity channel count

(7) Ultra-high capacity channel count

### 10.2.3.1.3 Unified DMA Controller (UDMA) Ports

**Table 10-104. UDMA Clocks and Resets**

Clocks	
Module Clock Input	Description
UDMAP0_FICLK	UDMA clock. This clock is used for all interface and functional operations.
Resets	
Module Reset Input	Description
UDMAP0_RST	UDMA hardware reset

**Table 10-105. UDMA Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
-	The module does not generate traditional (local) interrupts	-
Outbound Events		
Module Event	Description	Type
TX Complete	To other UDMA/UTC/PDMA instances on the device for synchronization and triggering purposes.	ETL Push
RX Complete	To other UDMA/UTC/PDMA instances on the device for synchronization and triggering purposes.	ETL Push
Error		ETL Push
Inbound Events		
Module Event	Description	Type
TXCH0_TRG0	Tx Channel 0 Trigger 0 in third party mode	ETL Push
TXCH0_TRG1	Tx Channel 0 Trigger 1 in third party mode	ETL Push
...	...	ETL Push
TXCH139_TRG0	Tx Channel 139 Trigger 0 in third party mode	ETL Push
TXCH139_TRG1	Tx Channel 139 Trigger 1 in third party mode	ETL Push
RXCH0_TRG0	Rx Channel 0 Trigger 0 in third party mode	ETL Push
RXCH0_TRG1	Rx Channel 0 Trigger 1 in third party mode	ETL Push
...	...	ETL Push
RXCH139_TRG0	Rx Channel 139 Trigger 0 in third party mode	ETL Push
RXCH139_TRG1	Rx Channel 139 Trigger 1 in third party mode	ETL Push

### 10.2.3.2 UDMA Functional Description

The UDMA module supports the transmission and reception of various packet types. The UDMA is architected to facilitate the segmentation and reassembly of K3 DMA data structure compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each connected peripheral. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be ongoing. The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware.

An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for Transmit operations. The ordering and rate of Receive operations is indirectly controlled by the order in which blocks are pushed into the DMA on the Rx PSI-L interface.

The UDMA also supports acting as a Unified Channel Controller (UDMA-C)/Unified Transfer Controller (UTC) combined unit which accepts Transfer Request packets from Ring Accelerator and then performs the transfers which the Transfer Request (TR) specifies.

Channels in the UDMA can be configured to be either Packet-based or TR-based Third Party channels on a channel by channel basis.

#### 10.2.3.2.1 Block Diagram

Figure 10-17 shows UDMA main internal components.

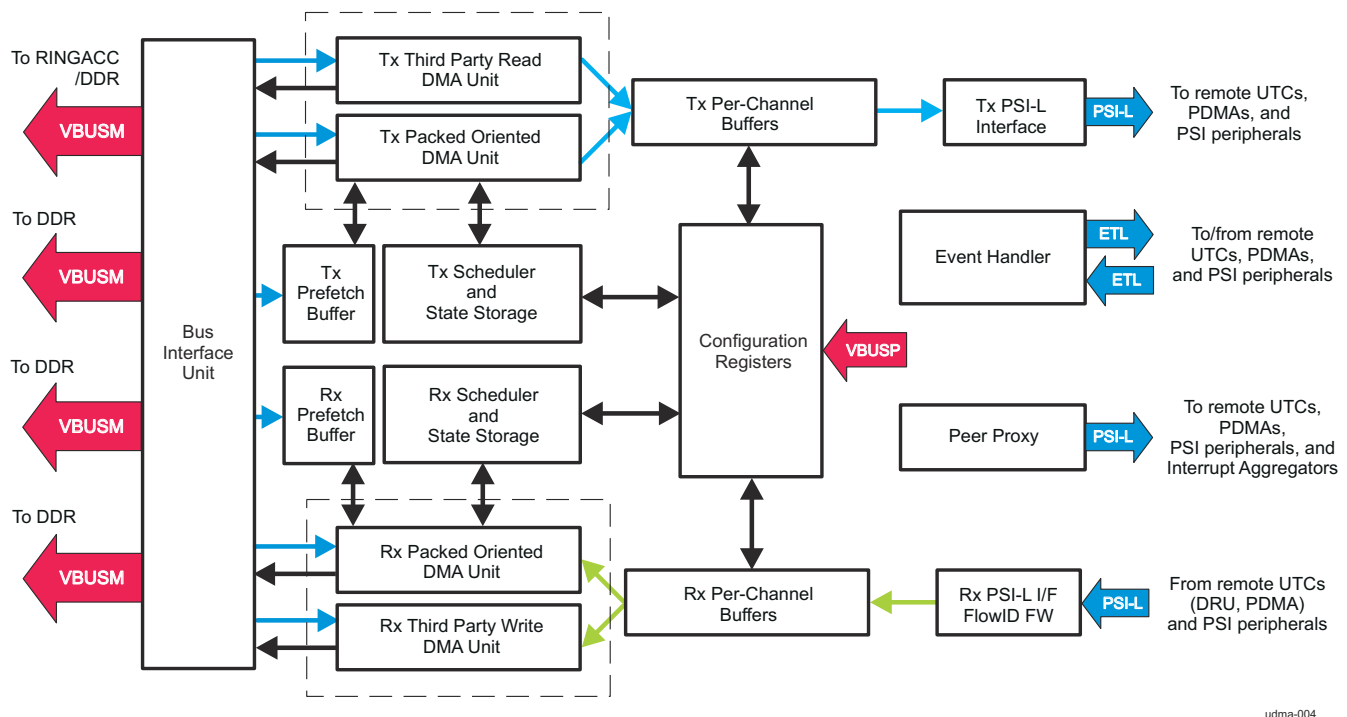

Figure 10-17. UDMA Block-Diagram

#### Bus Interface Unit

The Bus Interface Unit (BIU) is responsible for merging and buffering all of the transactions that originate from the various master blocks inside the DMA controller into the 4 separate VBUSM master interfaces. Arbitration between the blocks to a given VBUSM interface is round robin within a single priority level. A two word deep retiming buffer is provided on each sub interface of each provided VBUSM bus.

#### Tx Prefetcher Configuration Registers

The Tx Prefetcher Configuration Registers block is responsible for providing memory mapped registers for configuration of the Tx DMA function, monitoring the fullness level of the Tx prefetch buffers, maintaining Tx

prefetch state information, arbitrating which channel will be allowed to perform prefetch work next, issuing scheduler commands to the Tx Prefetch Units, and writing back the updated state returned from those same prefetch units.

### **Tx Prefetch Unit(s)**

The Tx Prefetch Unit block is responsible for performing a fetch of either a Packet Descriptor (packet mode) or a TR to feed the downstream Tx DMA/Tx Read Units.

### **Tx Configuration Registers**

The Tx Configuration Registers block (*UDMASS\_UDMAP0\_CFG\_TCHAN Registers*) is responsible for monitoring the fullness level of the Tx Per Channel FIFOs, monitoring data transfer work which is pending, maintaining data movement thread state information, arbitrating which channel will be allowed to perform work next, issuing scheduler commands to the Tx Packet and TR based DMA core blocks, and writing back the updated state returned from those same DMA core blocks.

### **Tx Packet DMA Unit**

The Tx Packet DMA Unit block implements all of the state machine functionality necessary to implement the K3 DMA Host and Monolithic Tx protocol. The Tx Packet DMA unit initiates VBUSM transactions in order to read and write descriptor pointers from the Ring Accelerator, read descriptors from memory, and read data from buffers in memory.

### **Tx Packet Coherency Unit**

The Tx Packet Coherency Unit is responsible for ensuring that all control structures and data have been read (and updated if applicable) by the Tx DMA unit(s) prior to returning the packet descriptor pointer to the appropriate return queue in the Ring Accelerator. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Tx queue. This unit is only used on channels which are in Pass-By-Reference mode

### **Tx TR Coherency Unit**

The Tx TR Coherency Unit is responsible for ensuring that all control structures and data have been read prior to allowing the TR response to be written to either the Packet Descriptor or a Pass by Value queue in the Ring Accelerator. This unit ensures that the ordering of TR response writes also directly matches the ordering of Transfer Requests that were processed by the channel. This unit is only used on channels which are in TR mode.

### **Tx External Channel TR Coherency Unit**

The Tx External Channel TR Coherency Unit is responsible for ensuring that TRs received back from remote UTCs are written in strong order to either the Packet Descriptor or a Pass-by-Value queue in the Ring Accelerator. This unit is only used on external UTC channels.

### **Tx Event Coherency Unit**

The Tx Event Coherency Unit is responsible for ensuring that all data transfers have completed before a completion event is issued through the outgoing Event Transport Lane (ETL). This unit is only used on channels which are in TR mode.

### **Tx Per Channel Buffers**

The Tx Per Channel Buffers implement a FIFO for each Tx DMA channel that is used for buffering packet control and payload data that has been fetched by the Tx Packet DMA units or Tx Third Party Read unit modules. The buffers are byte oriented on write so that the data from the DMA units which may not be full words can be packed properly. The buffers are block oriented on read in accordance with the transport mechanism outlined in the PSI-L Interface specification. Each Tx (source) channel in the UDMA controller maps directly onto a thread in the Tx PSI-L interface. The Tx Per Channel Buffer block outputs queue fullness information to the Tx Scheduler block which it then uses to determine when it must initiate DMA opportunities to backfill the buffers. The Tx Per Channel Buffer will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status

of all of the threads and will perform a round robin arbitration between the different threads for the use of the Transmit PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

### **Rx FlowID Firewall**

The Rx FlowID firewall checks the incoming flowID on the received packet from the Rx PSI-L interface to verify that it is either the corresponding flowID for the channel (that is, the default flow ID for the channel which is the same as the channel number) or that the flowID falls within a programmed range that is considered legal for the channel. If the received flowID does not fall within the legal range then the packet is dropped and the error is trapped.

### **Rx Per Channel Buffers**

The Rx Per Channel Buffers implement a FIFO for each Rx DMA channel that is used for buffering packet control and payload data that has been pushed into the DMA from the Rx PSI-L interface. The Rx Per Channel Buffers also includes an arbitration unit which determines which Rx DMA channel must be serviced next

### **Rx Configuration Registers**

The Rx Configuration Registers block (*UDMASS\_UDMAP0\_CFG\_RCHAN Registers*) is responsible for providing memory mapped registers for configuration of the Rx DMA functions including the default settings for the free descriptor and destination queues. For modularity and high speed pipelining reasons, the Rx traffic is looped through the Rx Configuration Registers block where the original stream information is merged with information from the configuration registers on its way to the Rx DMA unit module. This prevents the Rx DMA Core from having to spend cycles accessing the channel configuration information for the channel.

### **Rx Packet DMA Unit**

The Rx Packet DMA Unit block implements all of the state machine functionality necessary to implement the K3 DMA Rx protocol for Host and Monolithic descriptor types. The Rx Packet DMA Unit initiates VBUSM transactions in order to read descriptor pointers from the Ring Accelerator, read buffer descriptor information, write descriptors to memory, and write data to buffers in memory.

### **Rx Packet Coherency Unit**

The Rx Packet Coherency Unit is responsible for ensuring that all control structures and data have been written by the Rx DMA unit(s) prior to returning the packet descriptor pointer to the appropriate return queue in the Ring Accelerator. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Rx free queues. Writes are not considered complete by this unit until the entire write status has been returned for all outstanding transactions for a given packet ID. This unit is only used on channels which are in Pass By Reference mode

### **Rx TR Coherency Unit**

The Rx TR Coherency Unit is responsible for ensuring that all control structures have been read and all data has been written prior to allowing the TR response to be written to either the Packet Descriptor or a Pass by Value queue in the Ring Accelerator. This unit ensures that the ordering of TR response writes also directly matches the ordering of Transfer Requests that were processed by the channel. This unit is only used on channels which are in TR mode.

### **Rx Event Coherency Unit**

The Rx Event Coherency Unit is responsible for ensuring that all data transfers have completed before a completion event is issued through the outgoing ETL. This unit is only used on channels which are in TR mode.

### **Third Party Read Unit**

The Third Party Read Unit(s) are responsible for sequencing all of the Tx side channel control and data transfers. The Third Party Read Unit is responsible for performing the actual data read operations including sequential address generation and nested loop control. Like the Tx Packet DMA Unit, the Third Party Read Unit receives state information from the Tx Configuration Registers and returns that state when a transfer opportunity is complete. The Third Party Read Unit will perform as much data transfer as is specified in the Transfer Request

up until either a fixed number of bytes have been transferred, the transfer is completed, or the transfer has reached a point which requires an input trigger event to proceed.

### Third Party Write Unit

The Third Party Write Unit(s) are responsible for sequencing all of the Rx side channel data transfers. The Third Party Write Unit is responsible for performing the actual data write operations including sequential address generation and nested loop control. Like the Rx Packet DMA Unit, the Third Party Write Unit receives state information from the Rx Configuration Registers and returns that state when a transfer opportunity is complete. The Third Party Write Unit will perform as much data transfer as is specified in the Transfer Request up until either a fixed number of bytes have been transferred or the transfer is completed or the transfer has reached a point which requires an input trigger event to proceed.

### Event Handler

The Event Handler block is responsible for accepting and logging channel triggering events and for generating channel completion and error events.

### PSI-L Real Time Proxy

The PSI-L Real Time Proxy block is responsible for allowing tunneled VBUSP transactions to the Real Time Remote Peer registers to generate PSI-L configuration transactions to the paired remote peer for each Tx and Rx channel.

#### 10.2.3.2.2 General Functionality

This section is applicable to all UDMA modes.

##### 10.2.3.2.2.1 Operational States

At any given time the UDMA can be in one of three different states as described in [Table 10-106](#).

**Table 10-106. Operational States**

Operational State	Description
Init	This is the initial state of UDMA during and immediately after reset. During this state, all of the RAMs inside the UDMA will be initialized to known values including the ECC redundant parity bits. While in the Init state, the DMA will de-assert all ready signals on all applicable slave interfaces and will de-assert all request signals on all applicable master interfaces. The UDMA will automatically transition out of the Init state into the Idle state when all of the RAM initialization has been completed.
Idle	Once the UDMA leaves the Init state, it enters the Idle state whenever no outstanding transactions are pending on any of the UDMA interfaces (master or slave). The Idle state is generally a transient state and is used by the UDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. As channels have work queued on them and transactions begin flowing into the system, the UDMA transitions to the Active state. When no more work is pending, or when the host pauses/disables active channels, or when the SoC power management desires to shut down the UDMA, the UDMA will account for any outstanding transactions and will re-enter the Idle state. The UDMA leaves the Idle state anytime it generates or receives a transactions that requires a return response as those protocols dictate that the clock must remain running to avoid faulting the handshaking protocol.
Active	The UDMA enters the Active state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent) the UDMA transitions to the Idle state.

##### 10.2.3.2.2.2 Tx Channel Allocation

In NAVSS0, a total of 140 Packet Tx channels are provided within the DMA for concurrent data transfers between memory mapped space and the Tx Per Channel Buffers. Each of these channels can be configured to operate as a packet oriented channel (uses queues/rings/descriptors/buffer) or as a Third Party DMA source channel (uses Transfer Request packets to control read operations). Depending on which channel mode is selected, when a Tx channel comes into context the work for that channel will either be dispatched to a Tx Packet DMA Unit or a Third Party Read Unit respectively.

The Tx channels are allocated as shown in [Table 10-107](#).

**Table 10-107. Internal Tx Channel Allocation**

DMA Channel	Function	Tx Queue (Ring)
0	Tx Channel	0 (Starting queue number in RINGACC for Tx channel 0 )
...	...	...
139	Tx Channel	139

#### 10.2.3.2.2.3 Rx Channel Allocation

In NAVSS0, a total of 140 Rx channels are provided within the DMA for concurrent transfers between the Rx Per Channel Buffers and memory mapped space. Each of these channels can be configured to operate as a packet oriented channel (uses rings/descriptors/buffer) or as a Third Party DMA destination channel (uses rings/ Transfer Request packets or TR standalone records to control read operations). Depending on which channel mode is selected, when a Tx channel comes into context the work for that channel will either be dispatched to an Rx Packet DMA Unit or a Third Party Write Unit respectively. The Rx channels are allocated as shown in [Table 10-108](#).

**Table 10-108. Rx Channel Allocation**

DMA Channel	Function	Src Tag
0	Rx Channel	0
...	...	...
139	Rx Channel	139

#### 10.2.3.2.2.4 Tx Teardown

As is specified in the *TI DMA Architecture* specification, the host initiates a Tx DMA channel teardown operation by writing to the TDOWN bit in the TCHANRT UDMA\_TRT\_CTL\_j register. Once a channel teardown is requested, the appropriate Tx DMA unit will complete any packet/TRs that the channel has prefetched or is currently in the process of transferring and will then clear the EN bit, will send a Teardown packet out the outbound Payload Data PSI-L interface, and will push a Teardown Completion Record onto the Tx Default Queue for the channel. If the Tx DMA engine is not currently in a packet/TR for the channel, it will immediately clear the EN, send the Teardown packet, and push the Teardown Completion Record. Once the teardown is complete, no further packet processing will occur until the host software re-enables the channel.

#### 10.2.3.2.2.5 Rx Teardown

As is specified in the *TI DMA Architecture* specification, the host initiates an optimal Rx DMA channel teardown operation by shutting down the incoming payload stream at its source (a remote peer peripheral or the Tx side of a block copy channel). Once teardown is initiated at the source, data will eventually drain from the incoming PSI-L stream and when all data is complete, the remote peer entity will send a Teardown packet (either a standalone packet or tdown asserted with eop on the last data phase of the last packet). When the UDMA receives a teardown message, the TDOWN bit will be set in RCHANRT UDMA\_RRT\_CTL\_j. In the case where a remote peer cannot generate a teardown message, the host must ensure that all data has stopped flowing from the remote peer and will then directly set the TDOWN bit. Once the UDMA sees the TDOWN asserted it will wait for any existing packets which are currently held in the Rx Per Channel FIFO to be completed and will then de-assert the EN bit in RCHANRT UDMA\_RRT\_CTL\_j. If the back end application continues to allow new packets to be pushed into the Rx PC FIFO, the DMA will continue to delay marking the channel as torn down as long as the Rx PC FIFO never reaches an empty state

#### 10.2.3.2.2.6 Tx Clock Stop

The Tx clock stop interface allows the Tx portion of the UDMA to be gracefully commanded to shut down its operations and enter into an IDLE state so that the main clock (FICLK) can be stopped. When the tcs\_clkstop\_req input is asserted, the Tx portion of the UDMA will stop processing transmit packets/TRs for each channel at the next packet/TR boundary. Once all of the Tx channels have gracefully stopped transmission, the UDMA will assert the tcs\_clkstop\_ack output. Once the UDMA Tx engine has entered the IDLE state, it will remain there until the tx\_clockstop\_req is de-asserted.

### 10.2.3.2.2.7 Rx Clock Stop

The Rx clock stop interface allows the Rx portion of the UDMA to be gracefully commanded to shut down its operations and enter into an IDLE state so that the main clock (FICLK) can be stopped. When the rcs\_clkstop\_req input is asserted, the Rx portion of the UDMA will stop processing receive packets for each channel at the next packet boundary. Once all of the Rx channels have gracefully stopped reception, the UDMA will assert the rcs\_clkstop\_ack output. Once the UDMA Rx engine has entered the IDLE state, it will remain there until the rx\_clockstop\_req is de-asserted.

### 10.2.3.2.2.8 Rx Thread Enables

PSI-L threads must first be enabled in order to transfer commands or data. Threads are enabled or disabled by setting or clearing the enable bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

### 10.2.3.2.2.9 Events

Events are used in the *TI DMA Architecture* for triggering hardware or software (by being turned into interrupts) processes. Physical (or local) events in the *TI DMA Architecture* are implemented as active-high, single-cycle, long, synchronous pulses which are strobed to communicate that a particular condition has occurred. Virtual (or global) events are implemented as a value which is passed across a shared bus (ETL) - one value per cycle. Physical (local) events can be used by the UDMA to communicate with some local peripherals. Virtual (global) events are used by the UDMA to communicate with remote peripherals, the interrupt aggregator, and other DMA instances in the system.

#### 10.2.3.2.2.9.1 Local Event Inputs

There are no local events routed to the UDMA local event inputs in the current NAVSS implementation.

#### 10.2.3.2.2.9.2 Inbound Tx PSI-L Events

The Tx PSI-L interface includes a single inbound event transport lane (ETL) which allow events to be received from other UDMA/UTC/PDMA instances for synchronization and triggering purposes. Events passed in from this event transport lane will already have been decoded as destined for some event destination index for this particular UDMA. The appropriate LSBs of each event number are extracted and the specified event is asserted.

The event map for inbound events to the UDMA is shown in [Table 10-109](#).

**Table 10-109. Inbound Event Map**

Event Number	Target
0	Tx Channel 0 Global Trigger 0
1	Tx Channel 0 Global Trigger 1
2	Tx Channel 1 Global Trigger 0
3	Tx Channel 1 Global Trigger 1
...	...
279	Tx Channel 139 Global Trigger 1
280	Rx Channel 0 Global Trigger 0
281	Rx Channel 0 Global Trigger 1
282	Rx Channel 1 Global Trigger 0
283	Rx Channel 1 Global Trigger 1
...	...
559	Rx Channel 139 Global Trigger 1

#### 10.2.3.2.2.9.3 Outbound Rx PSI-L Events

The Rx PSI-L interface includes a single outbound event transport lane (ETL) which allows internal events to be sent to other UDMA/UTC/PDMA instances on the device for synchronization and triggering purposes. The destination event number is programmed for each event source within the UDMA. See registers:

- TCHAN\_UDMA\_TOES\_j
- TCHAN\_UDMA\_TEOES\_j

- RCHAN\_UDMA\_ROES\_j
- RCHAN\_UDMA\_REOES\_j

#### 10.2.3.2.2.10 Emulation Control

The emulation control input and register bits (SOFT and FREE in the UDMA\_EMU\_CTRL register) allow DMA operation to be suspended. When the emulation suspend state is entered, the DMA will stop processing receive and transmit packets for each channel at the next packet boundary. Any packet currently in reception or transmission will be completed normally without suspension. Emulation control is implemented for compatibility with other peripherals. Table 10-110 shows the operations of the emulation control input and register bits.

**Table 10-110. Emulation Behavior Control**

Emulation Control Input	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

#### 10.2.3.2.3 Packet Oriented Transmit Operation

Packet transmission is accomplished within the UDMA by moving data from structures that are located in memory via the VBUSM Memory Interfaces onto the Transmit Packet Data PSI-L Interface. This movement of data is performed in blocks whose size is specified by the Tx DMA scheduler.

##### 10.2.3.2.3.1 Packet Mode VBUSM Master Interface Command ID Selection

The UDMA keeps a transaction command scoreboard for each specific direction for the Packet Mode VBUSM Master interface. The scoreboard tracks which command indexes are currently outstanding from the DMA on that interface. When a read or write is requested by one of the internal master agents in the UDMA, the scoreboard corresponding to the specified interface and for the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*). The index values for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

##### 10.2.3.2.4 Packet Oriented Receive Operation

Packet reception is accomplished within the UDMA by moving data from the Receive PSI-L Interface to data structures that are located in memory accessible via the VBUSM Memory Interface(s).

##### 10.2.3.2.4.1 Rx Packet Drop

The Rx PSI-L Interface master may assert the *rstrmp\_drop* signal co-incident with the transfer of any data phase of a packet. When this signal is sampled asserted by the UDMA, the drop condition will be latched into a flag for that thread and the Rx Packet DMA unit will be notified that the packet is to be flushed and recycled rather than passed to the host. The drop signal is only required to be asserted with a single data phase and will only cause the current packet to be dropped from packet stream. The UDMA will drop all data given to it until the EOP is found on the thread and then the internal drop flag will be cleared. When the UDMA drops a packet on a channel configured for Packet mode there is no notification to the host.

##### 10.2.3.2.4.2 Rx Starvation and the Starvation Timer

As described in the *TI DMA Architecture* specification, whenever the Rx DMA engine needs to read a Free Descriptor Pointer from the Ring Accelerator, it is possible that the queue may be empty. When this occurs it is referred to as buffer starvation. The Ring Accelerator provides a message interface to the UDMA which provides increment and decrement information so that the UDMA can keep a local occupancy counter for each ring that it can access from the RINGACC. When the Rx engine requires a free descriptor it will first check to see if the local occupancy for that ring is non-zero. If the occupancy is zero, starvation has occurred. When starvation occurs the Rx DMA will respond in one of two ways depending on the value of the *rx\_error\_handling* bit in Rx Flow Table entry that is currently being used for that particular packet reception opportunity. If the *rx\_error\_handling* bit is 0, the Rx DMA will drop the packet and will return any descriptors which it may have previously allocated

for that packet to the respective queues from which they were allocated. If the rx\_error\_handling bit is set, the Rx DMA is required to retry checking to see if a Free Descriptor is available at a later time.

A timer is provided in order to control the rate at which the retry attempts will occur. All channels share the same timer and the period of the timer is set using the TIMEOUT\_CNT field in the UDMA\_PERF\_CTRL register. The TIMEOUT\_CNT field specifies in clock cycles the minimum delay between subsequent attempts to check if a Free Descriptor is available on each individual channel.

*Example:* If the TIMEOUT\_CNT is set to 256 and channel 1 finds its Free Descriptor queue empty on cycle 10, it will be required to wait until at least cycle 266 before it can make another attempt check the queue again. The actual number of cycles which will be waited by the DMA will typically be larger than the TIMEOUT\_CNT value and this is not intended to be a highly precise operation. The critical requirement is that the DMA will not attempt to bring a channel into context to check if a buffer is available at a more frequent rate than is allowed.

### 10.2.3.2.5 Third Party Mode Operation

#### 10.2.3.2.5.1 Events and Flow Control

The following sections describe the mechanisms that are provided for supporting flexible flow control between peripherals, the UDMA and other DMA instances.

##### 10.2.3.2.5.1.1 Channel Triggering

Channels which are configured in Third Party mode must be triggered in order for them to perform work. Triggering can be configured to be immediate, one-shot, or periodic at different levels of TR completion and is specified in the TR itself. Each channel in the UDMA is capable of being triggered by two separate events which are mapped at specific offsets in a global event target map (just like an address map for memory mapped slaves). The UDMA maps its channel triggers with Tx side channels first followed by Rx side channels as described in [Table 10-109, Inbound Event Map](#).

##### 10.2.3.2.5.1.2 Internal TR Completion Events

Each TR which is processed, provides the ability to assert 1 of 4 possible output events at specific completion levels for the TR. Since the output event is specified directly in the TR and the TRs are written by potentially untrusted software processes, channels are only able to assert *virtual events* when they complete various portions of the TR. These virtual events are then mapped to actual destination events in the global event map by the TCHAN UDMA\_TOES\_j or RCHAN UDMA\_ROES\_j event steering registers. These registers are programmed statically by a trusted software process that has determined the channels that should have access to the specified event destination slots.

### 10.2.3.2.5.2 Transmit Operation

#### 10.2.3.2.5.2.1 Transfer Request

After reset, all channels that are configured in Third Party transfer mode will be idle and waiting for work to be assigned to them. In order to initiate Third Party channel operation, the host software places work in the form of either a Transfer Request Descriptor or an individual Transfer Request record onto the Tx Queue of the channel. The exact mechanisms which are used and the contents of both the Transfer Request Descriptor and the Transfer Request record are given in the *TI DMA Architecture* specification.

##### 10.2.3.2.5.2.2 Transfer Response

At the completion of each set of operations which fulfill a Transfer Request record, the UDMA will return a Transfer Response record to either the original Transfer Request Descriptor or the Tx Completion Queue, depending on the mechanism which was used to provide the Transfer Request record. If the Transfer Request record originated in a Transfer Request Descriptor then a corresponding slot in the Transfer Request Descriptor will be overwritten with the response status. If the Transfer Request record originated in a pass by value Tx Ring, the Transfer Response record will be placed in a pass by value Tx Completion Ring. The Transfer Response record will only contain a completion code which indicates if the transfer was a success or if a particular type of failure occurred. The exact mechanisms which are used and the contents of the Transfer Response Record are given in the *TI DMA Architecture* specification.

#### 10.2.3.2.5.2.3 Data Transfer

Packet transmission is accomplished within the UDMA by moving data from structures that are located in memory via the VBUSM Memory Interface(s) onto the Transmit PSI-L Interface. On the Tx side of the UDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx Per Channel Buffer for that channel. At a later time, the data is moved from the Tx Per Channel FIFO to a remote peer DMA entity via the Tx PSI-L interface.

#### 10.2.3.2.5.2.4 Memory Interface Transactions

The sequence of control transactions that are performed by the UDMA on the Read/Write VBUSM interface during transmit is to read a Transfer Request record from a logical work queue and to then return a corresponding Transfer Response record to a separate logical work queue when all the transfers in the request have been completed. This sequence repeats for as long as Transfer Request records are provided on the work queue. The exact details of the operations that are involved are covered in the *TI DMA Architecture* specification (see [Section 10.1](#)).

The sequences of data transactions that are performed by the UDMA on the Read Only VBUSM interface during transmit can be described as a sequence of piecewise linear read transfers whose starting addresses are each sequentially calculated based on loops and offsets given in the Transfer Request record. A TR can have up to 4 levels of nested transfer sets where each set can have a different element count and stride between elements. TR record formats are described in detail in the Transfer Request format specification.

#### 10.2.3.2.5.2.5 Error Handling

In the case that an error occurs during any Tx operation, the UDMA will stop processing the TR at that point and will return an appropriate error code in the Transfer Response message as specified in the *TI DMA Architecture* specification. The PAUSE\_ON\_ERR bit in the TCHAN UDMA\_TCFG\_j registers controls whether or not the DMA will pause operation on that channel if an error or exception occurs. If the PAUSE\_ON\_ERR bit is set to 1 the channel will be paused so that the host can optionally read the channel state to determine where in the transfer the channel execution was. If the PAUSE\_ON\_ERR bit is 0 the DMA will flush the current Transfer Request record for channels in pass by value mode and will flush the current Transfer Request Descriptor for channels in pass by reference mode.

#### 10.2.3.2.5.3 Receive Operation

##### 10.2.3.2.5.3.1 Transfer Request

After reset, all channels that are configured in Third Party mode will be Idle and waiting for work to be assigned to them. In order to initiate Third Party channel operation, the Host places work in the form of either a Transfer Request Descriptor or an individual Transfer Request record onto the Rx TR Queue of the channel. The exact mechanisms which are used and the contents of both the Transfer Request Descriptor and the Transfer Request record are given in the *TI DMA Architecture* specification.

##### 10.2.3.2.5.3.2 Transfer Response

At the completion of each set of operations which fulfill a Transfer Request, the UDMA will send a Transfer Response message back to either the Packet Descriptor (pass by reference channel mode) or to the completion queue in the Ring Accelerator (pass by value channel mode). The contents of this message are described in detail in the *TI DMA Architecture*.

##### 10.2.3.2.5.3.3 Error Handling

In the case that an error occurs during any Rx operation, the UDMA will stop processing the TR at that point and will return an appropriate error code in the Transfer Response message as specified in the *TI DMA Architecture* specification. The PAUSE\_ON\_ERR bit in the RCHAN UDMA\_RCFG\_j registers controls whether or not the DMA will pause operation on that channel if an error or exception occurs. If the PAUSE\_ON\_ERR bit is set to 1 the channel will be paused so that the host can optionally read the channel state to determine where in the transfer the channel execution was. If the PAUSE\_ON\_ERR bit is 0 the DMA will flush the current Transfer Request record for channels in pass by value mode and will flush the current Transfer Request Descriptor for channels in pass by reference mode.

#### 10.2.3.2.5.4 Data Transfer

Third Party mode packet reception is accomplished within the UDMA by unpacking and moving data from the Rx Per Channel FIFOs which were filled via the Rx PSI-L Interface to specified memory mapped address ranges via the write only VBUSM master interface. On the Rx side of the UDMA, these transfers are always writes. Each write transfer which is performed by the Third Party Write Unit is to a destination address and of a size as calculated from parameters specified in the Transfer Request packet which was previously received to control the channel behavior.

##### 10.2.3.2.5.4.1 Memory Interface Transactions

The sequence of control transactions that are performed by the UDMA on the Read/Write VBUSM interface during transmit is to read a Transfer Request record from a logical work queue and to then return a corresponding Transfer Response record to a separate logical work queue when all the transfers in the request have been completed. This sequence repeats for as long as Transfer Request records are provided on the work queue. The exact details of the operations that are involved are covered in the *TI DMA Architecture* specification (see [Section 10.1](#)).

The sequences of data transactions that are performed by the UDMA on the Write Only Memory interface during receive can be described as a sequence of piecewise linear write transfers whose starting addresses are each sequentially calculated based on loops and offsets given in the Transfer Request record. A TR can have up to 4 levels of nested transfer sets where each set can have a different element count and stride between elements. TR record formats are described in detail in the Transfer Request format specification.

##### 10.2.3.2.5.4.2 Rx Packet Drop

The Rx PSI-L Interface master may assert the `rstrm_drop` signal co-incident with the transfer of any data phase of a packet. When this signal is sampled asserted by the UDMA, the drop condition will be latched into a flag for that thread and the Third Party write unit will be notified that the packet is to be flushed and no further writes are to be performed. The drop signal is only required to be asserted with a single data phase and will only cause the current packet to be dropped from packet stream. The UDMA will drop all data given to it until the EOP is found on the thread and then the internal drop flag will be cleared. When the UDMA drops the packet on a channel that is in Third Party mode, a 'dropped by source' error code will be placed in the Transfer Response packet which is returned to the Packet Descriptor or completion queue.

## 10.2.4 Ring Accelerator (RINGACC)

This chapter describes the RINGACC module, part of the NAVSS.

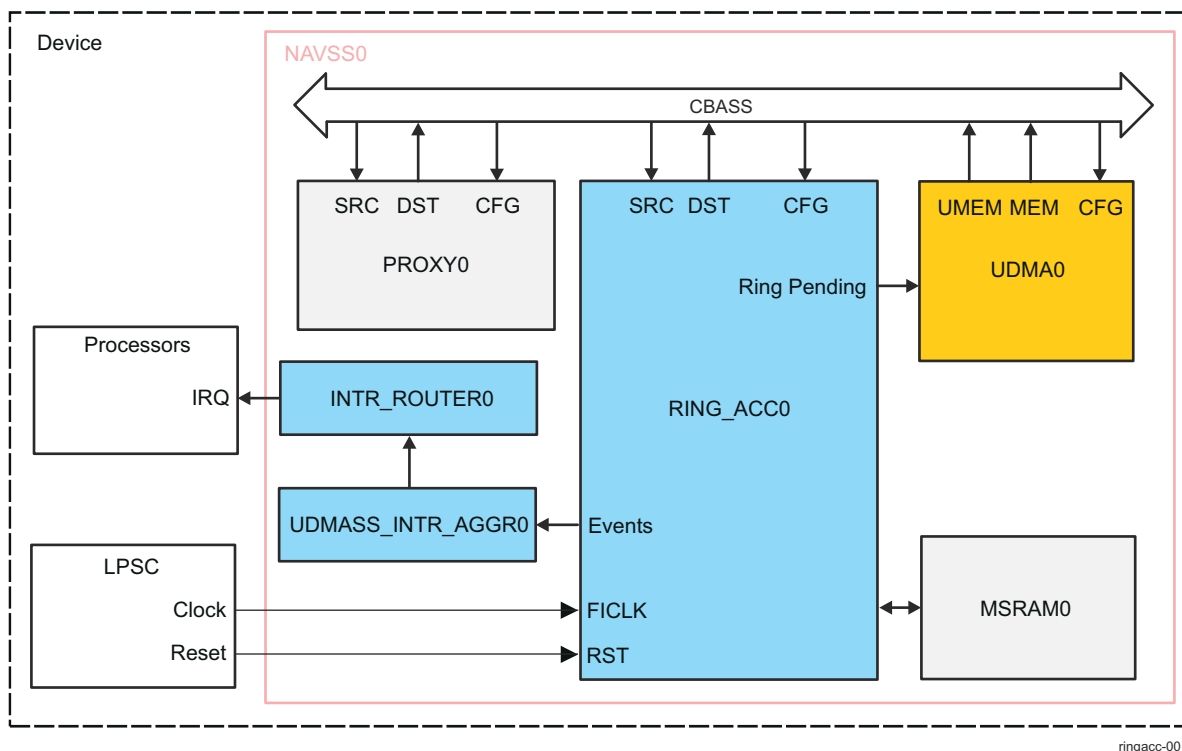

### 10.2.4.1 RINGACC Overview

The Ring Accelerator (RINGACC or RA) provides hardware acceleration to enable straightforward passing of work between a producer and a consumer. There is one RINGACC module per NAVSS.

**Table 10-111. RINGACC Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_RINGACC0	-	-	✓ (NAVSS)
MCU_NAVSS0_RINGACC0	-	✓ (MCU NAVSS)	-

Figure 10-18 shows a top-level overview of the RINGACC module.

**Figure 10-18. RINGACC Overview**

#### 10.2.4.1.1 RINGACC Features

NAVSS0\_RINGACC0 supports the following features:

- Supports independent memory-mapped ring structures. See ring count in [Table 10-112, RINGACC Configuration Parameters](#).
- Supports various modes for each ring based on usage and compatability
- Provides single-word deep shared incoming Transfer Response FIFO
- Provides bit-wide source VBUSM read/write slave interface for accesses from DMA controller entities.
  - Provides 2 word deep command FIFO
  - Provides 2 word deep write data FIFO
  - Provides 2 word deep read data FIFO
  - Provides 2 word deep write status FIFO
- Provides bit-wide destination VBUSM read/write master interface for accesses to ring structures in memory
- Supports up to 16 outstanding writes
- Supports up to 16 outstanding reads

- Source interface provides an array of 1024 × 512-byte long address windows (four for each ring) which are packed into a single contiguous address range
  - Read and write addresses which target a specific window are translated, in order to redirect the read or write transaction, to an effective address calculated from the base address for the ring plus current ring offset
  - Each read or write access presented on VBUSM slave interface is modified and bridged onto the VBUSM master interface

#### 10.2.4.1.2 RINGACC Not Supported Features

- Queue manager mode, which makes the queue act like a traditional queue-manager (QM) queue, is not supported.
- Peeks from tail

#### 10.2.4.1.3 RINGACC Parameters

Table 10-112 shows the RINGACC configuration parameters in this SoC.

**Table 10-112. RINGACC Configuration Parameters**

Module Instance	Parameters		
	Ring Count	Number of Monitors	Proxy Target Base
NAVSS0_RINGACC0	1024	32	0x000038000000
MCU_NAVSS0_UDMASS_RINGACC0	286	32	0x00002B000000

Table 10-113 shows the MSRAM configuration parameters set during SoC design. MSRAM0 is accessible only from the ring accelerator (DST port).

**Table 10-113. MSRAM Configuration Parameters**

Module Instance	Parameters		
	Depth	Width	Base Address
NAVSS0_MSRAM0	4096	128	0x000030000000
MCU_NAVSS0_UDMASS_MSRAM0	3594	64	0x000028000000
MCU_NAVSS0_UDMASS_MSRAM1	4096	64	0x000028010000

#### 10.2.4.1.4 Ring Accelerator (RINGACC) Ports

**Table 10-114. RINGACC Clocks and Resets**

Clocks	
Module Clock Input	Description
RINGACC_FICLK	RINGACC clock. This clock is used for all interface and functional operations.
Resets	
Module Reset Input	Description
RINGACC_RST	RINGACC hardware reset

**Table 10-115. RINGACC Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
-	The module does not generate traditional interrupts	-
Outbound Events		
Module Event	Description	Type
RING[0:1023]_EVT	Ring events. Can be used by an external host for statistics or interrupts.	ETL Push
MON[0:31]_EVT	Monitor events. Can be used by an external host for statistics or interrupts.	ETL Push
RINGACC_ERROR_EVT	Bus error event for host interrupts	ETL Push

#### 10.2.4.2 RINGACC Functional Description

The Ring Accelerator (RINGACC) converts constant-address read and write accesses to equivalent read or write accesses to a circular data structure in memory. The RINGACC eliminates the need for each DMA controller which needs to access ring elements from having to know the current state of the ring (base address, current offset). The DMA controller performs a read or write access to a specific address range (which maps to the source interface on the RINGACC) and the RINGACC replaces the address for the transaction with a new address which corresponds to the head or tail element of the ring (head for reads, tail for writes). Since the RINGACC maintains the state, multiple DMA controllers or channels are allowed to coherently share the same rings as applicable. The RINGACC serves a very similar function to the Queue Manager in the earlier SoCs. The RINGACC uses less memory and is able to place data which is destined towards software into cached memory directly.

##### 10.2.4.2.1 Block Diagram

Figure 10-19 shows ring accelerator's main internal components.

**Figure 10-19. Ring Accelerator Block-Diagram**

##### 10.2.4.2.1.1 Configuration Registers

The Configuration Registers block is responsible for providing memory mapped registers for configuration of the RINGACC functions. The configuration registers are divided into:

- Static configuration fields (NAVSS0\_UDMASS\_RINGACC0\_CFG Registers), which are typically initialized and then left at specified values for long time periods (or until a reset occurs)
- Real-time (RT) registers (NAVSS0\_UDMASS\_RINGACC0\_CFG\_RT Registers), which are modified frequently during runtime.

Configuration registers are listed and described in *RINGACC Register Manual*.

##### 10.2.4.2.1.2 Source Command FIFO

The Source Command FIFO buffers VBUSM command phases which are accepted from the VBUSM source interface.

##### 10.2.4.2.1.3 Source Write Data FIFO

The Source Write Data FIFO buffers VBUSM write data phases which are accepted from the VBUSM source interface.

#### 10.2.4.2.1.4 Source Read Data FIFO

The Source Read Data FIFO buffers VBUSM read data phases which have been returned from the VBUSM destination interface (via the main state machine) and which are to be output on the VBUSM source interface.

#### 10.2.4.2.1.5 Source Write Status FIFO

The Source Write Status FIFO buffers VBUSM write status data phases which have been returned from the VBUSM destination interface and which are to be output on the VBUSM source interface.

#### 10.2.4.2.1.6 Main State Machine

The Main State Machine (MSM) block implements all of the control logic which is necessary to accept a command from the source interface, perform a lookup into the ring state RAM, determine the effective address for the destination interface transaction, modify the address (and byte count for reads) for the transaction, and place that modified transaction into the outgoing destination FIFOs. The MSM block is also responsible for updating the ring index and occupancy values and for producing output status to indicate changes to the ring state. The MSM also modifies the ring state whenever the read data or write status for a previous ring transaction return and forwards those responses back to the originating master.

#### 10.2.4.2.1.7 Destination Command FIFO

The Destination Command FIFO stores VBUSM transaction commands which are output from the MSM as modified versions of transactions that were popped from the Source Command FIFO. The Destination command FIFO allocates a new command ID for each read or write command that is pushed to the FIFO. Read IDs are allocated from a scoreboard maintained in the Destination Read Data FIFO. Write IDs are allocated from a scoreboard maintained in the Destination Write Status FIFO. When a new command is allocated, the Destination Command FIFO also pushes the original *cid* and *crouteid* values from the source side transaction into a scoreboard in either the Destination Read Data or Destination Write Status FIFOs depending on the applicable transaction direction. The read interface of the Destination Command FIFO directly drives commands onto the destination VBUSM command interface.

#### 10.2.4.2.1.8 Destination Write Data FIFO

The Destination Write Data FIFO stores write data phases for write commands that are passing through the RINGACC towards memory. The write interface of the Destination Write Data FIFO is directly connected to the read interface of the Source Write Data FIFO and the read interface directly drives write data onto the destination VBUSM write data interface.

#### 10.2.4.2.1.9 Destination Read Data FIFO

The Destination Read Data FIFO provides a read command translation scoreboard and also stores read data phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Read Data FIFO is directly connected to the destination VBUSM read data interface. As read data passes through the Destination Read Data FIFO, the *rid* and *rrouteid* are changed back to their original values using information which was stored in read command translation scoreboard.

#### 10.2.4.2.1.10 Destination Write Status FIFO

The Destination Write Status FIFO provides a write command translation scoreboard and also stores write status phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Writes Status FIFO is directly connected to the destination VBUSM write status interface. As write status words pass through the Destination Write Status FIFO, the *sid* and *srouteid* are changed back to their original values using information which was stored in the write command translation scoreboard.

### 10.2.4.2.2 RINGACC Functional Operation

#### 10.2.4.2.2.1 Queue Modes

Each ring or queue can be in one of four modes that determines how it must be accessed and the compatibility it has with hardware and software.

##### 10.2.4.2.2.1.1 Ring Mode

Ring mode is used when software owns one side of the ring, and hardware or another software owns the other side. This mode allows the software that owns a side of the ring to control that side including accessing

the memory directly rather than going through hardware, and software updates the hardware on any changes through the Doorbell registers. These doorbell accesses indicate when software has pushed or popped entries, allowing the entity on the other side of the ring to know when there are elements ready. The ring mode has limitations that the exposed side of the ring is completely under software control, and any atomicity needed must also be performed by software, which is why the exposed side of a ring is usually owned by a single thread of software. This limitation also means that any hardware configuration that would normally access the same ring for both pushes and pops cannot use ring mode as hardware cannot access the exposed side of the ring, such as free queues that are normally read by hardware but could also be pushed by hardware on an error.

When software is popping from the ring, it must guarantee that it never pops more elements through the Doorbell register (RINGACC\_DB\_j) than what is valid in the Ring Occupancy (RINGACC\_OCC\_j) register, which holds how many elements are ready for software consumption. There could be some elements which have data written to memory but have not received status back from memory and those are not considered ready to pop yet as the ring status has not fully updated. Therefore, just reading from memory to determine the number of elements to pop is not sufficient. If software attempts to pop more than the RINGACC\_OCC\_j register value, then the occupancies could go negative resulting in missed down events and spurious interrupts. An optimization for software is to read the RINGACC\_OCC\_j register less frequently and keep a local copy which guarantees the maximum number of allowed pops. When the software copy of RINGACC\_OCC\_j reaches 0, or periodically, the software can read the register to refresh the value. This must reduce the frequency of register reads instead of reading the register for every software pop.

#### **10.2.4.2.2.1.2 Messaging Mode**

Messaging mode requires that all accesses to the queue must go through RINGACC so that all accesses to the memory are controlled and ordered. RINGACC then controls the entire state of the queue, and software has no direct control, such as through doorbells and cannot access the storage memory directly. This is particularly useful when more than one software or hardware entity can be the producer and/or consumer at the same time. Software must access the data through bus accesses to the RINGACC. As with the earlier example, if there are free queues that need the hardware to both push and pop, then they must be configured as at least messaging mode (or a later mode) and not ring mode.

#### **10.2.4.2.2.1.3 Credentials Mode**

Credentials mode adds per element credentials storage to messaging mode. This allows multiple producers with their own credentials to have those credentials stored with the element. This allows the consumer to inherit the credentials of each element rather than a single set for the entire queue, such as for DMA TR credential inheritance. This mode requires each operation to use two elements of storage since the credentials are stored in the second element, so the element count must be scaled appropriately. The credentials field is located in the same location as all modes, the word just before the first word of the message.

#### **10.2.4.2.2.1.4 Queue Manager Mode**

Queue manager mode makes the queue act like a traditional queue-manager (QM) queue in previous devices.

### **Note**

Queue Manager mode is no longer supported in this device. This section was left for completeness only.

#### **10.2.4.2.2.1.5 Peek Support**

All modes except ring mode allow the peek operations so that software can view the next element without actually popping it from the queue. This is done by reading from a different offset from the normal pop operation. All the same fields are read but the element is not actually popped off of the queue. This is useful for algorithms that need to know about the overall queue and head element to make decisions but have not yet decided to pop from the queue.

#### **10.2.4.2.2.1.6 Index Register Operation**

In ring mode, the Index (RINGACC\_INDX\_j) register follows the software control of the ring through the doorbell registers, while the hardware index (RINGACC\_HWINDX\_j) register follows the hardware access of

the ring through bus transactions. It works for a ring in either direction as the doorbell register update indicates whether elements were produced or consumed. But in the other queue modes, there is no simple manner to determine which index is for software or hardware since they both use bus transactions which the module cannot differentiate. So for these other queue modes, the index register is always the read index, and the hardware index register is the write index.

#### 10.2.4.2.2.2 VBUSM Slave Ring Operations

Each ring contains four memory spaces on the VBUSM slave bus for access, each of which is 512 bytes long, with a total of 4 kB per ring. Each ring space starts immediately after the preceding ring. The allocation per ring is as in [Table 10-116](#).

**Table 10-116. Ring Memory Partition**

Offset	Operation	Supported Ring Modes
0x0 - 0x1FF	Reads pop from head. Writes push to head.	Read supported in all modes, write supported in all modes except Ring mode
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.	Write supported in all modes, read supported in all modes except Ring mode
0x400 - 0x5FF	Reads peek from head. Writes ignored.	All modes except for Ring mode.
0x600 - 0x7FF	Reserved	Peeks from tail are not supported in this device
0x800 - 0xFFF	Reserved	Reserved

Within each 512-byte (0x200) space, the message data is right justified so that the last byte is always the 511-th byte. The element size of the ring defines which words are valid. The word just before the first valid message word is the credentials field. Access must not be made before the credentials register .

#### 10.2.4.2.2.3 VBUSM Master Interface Command ID Selection

The RINGACC keeps a transaction command scoreboard for reads and writes. Each scoreboard tracks which command indexes are currently outstanding from the RINGACC and which are free to use. When a read or write is requested by the Main State Machine, the scoreboard corresponding to the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*) for the outgoing transaction on the destination interface. 15 is the maximum index value for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

#### 10.2.4.2.2.4 Ring Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective write address using *ring base + ring\_index*
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments hardware index and hardware occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid*, *cid*, and *ring number* into scoreboard
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and *ring number* from scoreboard
2. RINGACC increments software index and occupancy for ring
3. RINGACC pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

#### 10.2.4.2.2.5 Ring Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective read address using ring base + ring\_index
4. RINGACC increments hardware index and decrements hardware occupancy for ring
5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC increments software index and decrements software occupancy for ring
3. RINGACC pushes restored *routeid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

#### 10.2.4.2.2.6 Host Doorbell Access

The following sequence will occur for each VBUSP write to the doorbell register (RINGACC\_DB\_j) for a ring:

1. RINGACC extracts ring number from config address
2. RINGACC looks up ring state using ring number
3. RINGACC adds doorbell ring value to both hardware and software occupancies for ring
4. RINGACC re-evaluates pending bit for ring

#### 10.2.4.2.2.7 Queue Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective write address using ring base + ring\_index
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments WR index and RD- and WR-occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid*, *cid*, and ring number into scoreboard
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

#### 10.2.4.2.2.8 Queue Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective read address using *ring base* + *ring\_index*
4. RINGACC increments RD index and decrements RD- and WR-occupancy for ring
5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC pushes restored *rrouteid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

#### 10.2.4.2.2.9 Mismatched Element Size Handling

When less data is written than defined by the element size for the ring for RING or MESSAGE modes, only the written data is stored in the memory and any remaining bytes maintain their old values. The index and *occ* are still incremented normally, and any special fields that are unwritten are assumed to be 0.

Writing less data for CREDENTIALS mode is illegal, as those types need the full data to append the additional words to the correct offsets in memory.

When more data is written than defined by the element size for the ring, it will be an error and the write will be ignored and no index or *occ* increments occur. The only exception is for writes to an 8-byte element size ring, where the additional fields up to another 8 bytes are allowed but not written (for old Queue Manager compatability).

When less data is read than defined by the element size for the ring, only the read data is fetched from memory, and any remaining bytes are lost. The index and *occ* are still incremented normally.

When more data is read than defined by the element size for the ring, it will be an error and the read will not affect the ring, the read data will be 0s, and no index or *occ* decrements occur. Access beyond the credentials word must not be attempted and can result in unpredictable behavior.

All accesses must be for multiples of 32-bit words, and partial bytes are not supported for all ring modes.

#### 10.2.4.2.3 Events

The module outputs events about queue levels that can be used by an external module for statistics or interrupts.

Each queue has

- an up event when the queue goes from 0 elements to 1 or more elements
- and a down event when the queue goes from 1 or more elements to 0 elements.

The event number is programmable per queue in the RINGACC\_EVENT\_j register. This event occurs when the state machine updates the final occupancy for the queue. In ring mode this is when the response from the memory access returns, while in other queue modes this is when the operation is processed.

An event number programmed to 0xFFFF indicates to not produce an event for that ring when an event is not necessary. The register event number fields reset to 0xFFFF, so they must be programmed to a valid value before events will be generated. This applies to the monitor event number fields as well.

#### 10.2.4.2.4 Bus Error Handling

If a bus error is detected on a response to a ring memory transaction, an error event is triggered to alert software. Since the ring contents may be corrupted as the push or pop was not completed correctly, software should consider resetting the ring and any software or hardware elements using the ring. A log register (RINGACC\_ERROR\_LOG) captures the ring that had the error and whether it was from a push or pop, and an error up event is sent to the programmed event number. After an error is logged, another will not be captured until the first is read out. When read, if an error is pending an error down event is sent to clear any interrupt, and then the next bus error log can be captured. A read of the RINGACC\_ERROR\_LOG register when there is no error log pending will not produce any down events. The event that is triggered is also programmable. Only legal push and pop operations will capture this error, and not for any peek, emudbg read, flush command, or any operations that is illegal and causes the resulting memory access to be flushed.

#### 10.2.4.2.5 Monitors

Monitors can be configured that allow various functions to be tracked of programmed queues. Each monitor is programmed to monitor a particular queue, the function to provide, and the data source to operate on. The supported functions are: to check the queue against programmed thresholds, to keep track of watermarks of the queue, to keep track of starvation occurrences (a read of an empty queue), or statistics capture. The supported

data sources are: the queue element count, the head element size value, or the accumulated size value. Each monitor can also be programmed to produce an event should it have a triggering condition.

#### 10.2.4.2.5.1 Threshold Monitor

A threshold monitor uses a programmed low threshold value and a programmed high threshold value to track the data source in the queue and cause an interrupt or status when a threshold is broken, either below the low value or above the high value. This is useful for software to replenish empty buffers when a queue has too few, or for a queue to accumulate enough elements so that software must start processing them, or for debug. The threshold being broken will cause the up or down event.

#### 10.2.4.2.5.2 Watermark Monitor

A watermark monitor tracks the low and high values of the data source since the last read of the monitor. After initial setup or clearing, the watermark values will load the current value of the data source as the low and high. Then for successive operations if the resulting data source of the queue is below the low watermark, or above the high watermark, the associated watermark will be updated. When the monitor value registers are read, the value is cleared and starts tracking again using the current data source value. This can be useful for tracking low and high values of queue element counts or sizes for data tracking, debug or future optimizations, such as allocating items to a queue or buffer sizes based on counts.

#### 10.2.4.2.5.3 Starvation Monitor

A starvation monitor tracks the number of starvation events (a read to an empty queue) that occurred on the queue. The data source is ignored, and the starvation count is always incremented whenever there is a read to the queue and the queue is empty. The count is cleared when the monitor value is read. This can be useful to trigger if any starvation event occurs, or to track how many of these events occur in a timeframe, and can be used for future optimizations or debug.

#### 10.2.4.2.5.4 Statistics Monitor

The statistics monitor can track some simple statistics on the queue operations. The data source is ignored. The first value is the count of the number of writes to the queue, and the second value is the count of the number of reads from the queue. The counts are cleared when the monitor values are read. This can be useful to track the activity on a queue, and can be used for future optimizations or debug.

#### 10.2.4.2.5.5 Overflow

RINGACC provides an overflow function where a push to a full ring will result in a push to a special overflow ring, rather than just losing the pushed data. The overflow ring is defined through the RINGACC\_OVRFLOW register, and that ring must be defined with a large enough element size to cover the element size of any other ring, as well as enough elements to hold enough overflow data (as an overflow to the overflow ring will be lost). When there is a push to a full ring, there will be two elements written to the overflow ring, first the push data, and then the ring number that was full. A supervisor entity can own the overflow ring and perform what actions are needed from the overflow data. The size of the overflow ring must be an even number since two elements will be pushed for each overflow event. The overflow ring must be configured in *ring* or *message* modes.

#### 10.2.4.2.5.6 Ring Update Port

To enhance performance for DMAs, the RINGACC provides a bus that indicates when ring updates occur, allowing the DMA to track their own rings and detect updates before the responses arrive. The bus will go valid whenever there is an update to the state of a ring, which can be from a push, pop, or doorbell write. It will not go valid for a peek, a emudbg pop, a push to a full ring, as those do not update the ring state. When the bus is valid, the other signals are valid and indicate whether the operation was a push or a pop, whether the resulting state of the ring is empty, the ring number, and the number of elements updated to the ring (the push determines whether it is subtracted or added to the current count). One special case is a pop from an empty ring, which indicates an update but the element count is 0 since no items were actually popped, but a DMA using the cnt to add or subtract must handle this correctly by default. The bus will go valid once the operation command has been completed, and not after the response has been received, even for ring mode rings, allowing the DMA to see the update as soon as it is known by the RINGACC even before it is known to software.

#### 10.2.4.2.5.7 Tracing

This module provides a trace output of all operations so that the traffic can be viewed at a later time. The trace uses a simple write-only 32-bit VBUSP bus, with a defined packet header. The *msgtype* field defines the type of operation, and the message data is simply the data involved in the operation. It is likely the trace output will be read slower than new operations could provide data, so there will be a trace buffer able to hold two complete messages plus trace headers. If a new operation starts while the trace buffer does not have enough space, then that trace message will not be sent. And RINGACC\_TRACE\_CTL register controls whether to enable the trace output, whether to trace a single queue or all queues, and whether to include the message data in the trace output.

Table 10-117 shows the trace message for a push.

**Table 10-117. Trace Message for a Push**

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x1	Msgtype for push
1	8:0	0x009	Standard Trace Header
2	31	push_to_head	Push to head flag, 0 = to tail, 1 = to head
2	30:16	0x0	Unused
2	15:0	queue	Queue for push
3-N	31:0	message data	Optional message data for push, length dependent on message size

Table 10-118 shows the trace message for a pop.

**Table 10-118. Trace Message for a Pop**

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x2	Msgtype for pop
1	8:0	0x009	Standard Trace Header
2	31	empty	empty pop, 0 = valid message, 1 = empty
2	30:16	0x0	unused
2	15:0	queue	queue for pop
3-N	31:0	message data	Optional message Data for pop, length dependent on message size

Table 10-119 shows the trace message for a peek.

**Table 10-119. Trace Message for a Peek**

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x3	Msgtype for peek
1	8:0	0x009	Standard Trace Header
2	31	empty	empty peek, 0 = valid message, 1 = empty
2	30:16	0x0	unused
2	15:0	queue	queue for peek
3-N	31:0	message data	Optional message Data for peek, length dependent on message size

## 10.2.5 Proxy

This chapter describes the Proxy module in a NAVSS.

### 10.2.5.1 Proxy Overview

The Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses.

Figure 10-20 shows a top-level overview of the Proxy module.

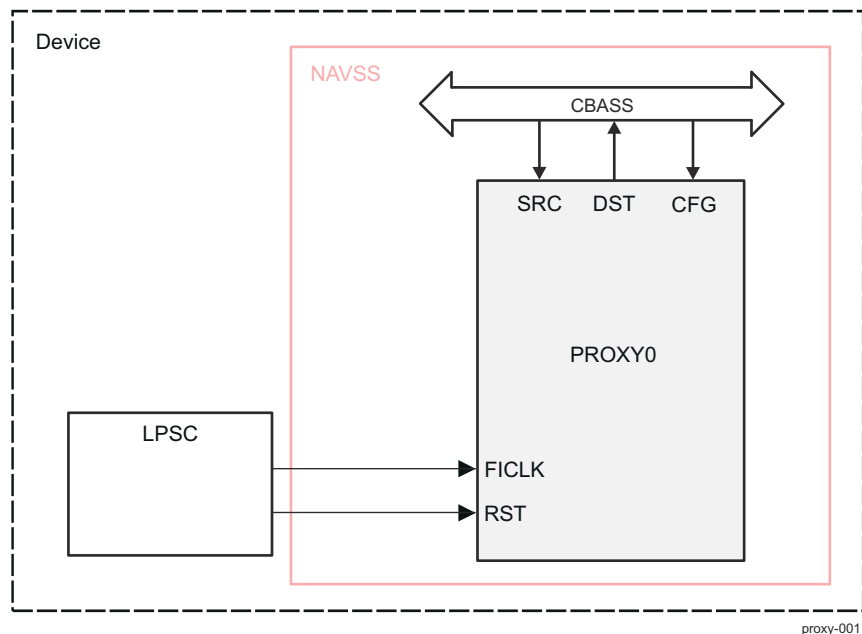

Figure 10-20. Proxy Overview

Table 10-120. Proxy Allocation Across Device Domains

#### 10.2.5.1.1 Proxy Features

Each Proxy supports the following features:

- Provides proxy buffers to store large data bursts that a host can only access in smaller amounts.
- Keeps the large data coherent until the complete data has been accessed.
- Allows for interleaved access between multiple hosts using multiple proxies.
- Each target has pre-configured number of channels, size of each channel, and address offset. See [Table 10-121](#).

#### 10.2.5.1.2 Proxy Parameters

[Table 10-121](#) shows the Proxy configuration parameters set during SoC design.

Table 10-121. Proxy Configuration Parameters

Module Instance	Parameters				
	Proxies <sup>(1)</sup>	Buffer Size <sup>(2)</sup>	Target	Channels <sup>(3)</sup>	Sizes <sup>(4)</sup>

- (2) Number of bytes per proxy buffer
- (3) Number of channels for the target
- (4) Number of bytes per channel supported for the target

#### 10.2.5.1.3 Proxy Not Supported Features

The following features are not supported by the module:

- Does not support proxy sharing. Each host must use its own proxy within the module.

#### 10.2.5.1.4 Proxy Ports

#### 10.2.5.2 Proxy Functional Description

This module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are for large Message Manager messages, Queue Manager data that is more than a pointer, or DMA Transfer Requests Messages. All of these require larger data sets, from 12 to 128 bytes, and the modules require the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as hardware registers, and the largest CPU access is typically 8 bytes. So the proxy provides the ability to access the module with a single burst, and at the same time allows the CPU to access the same data in smaller accesses. The proxy itself does not contain the resources, but it stays in front of other module (target module) that does contain the resources. The proxy will access the target module with the entire data in a single burst, once the host has completed the data.

##### 10.2.5.2.1 Targets

##### 10.2.5.2.1.1 Ring Accelerator

The RINGACC provides four distinct offsets to use per ring/queue shown in [Table 10-124](#), totaling 4 kB space per ring/queue. Each channel has access modes (enabled via PROXY\_CTL\_j[17-16] MODE field):

- head access
- tail access
- peeks from head

**Table 10-124. RINGACC Offsets per Ring/Queue**

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.

**Table 10-124. RINGACC Offsets per Ring/Queue (continued)**

Offset	Operation
0x400 - 0x5FF	Reads peek from head. Writes ignored.
0x600 - 0x7FF	Reads peek from tail. Writes ignored. This mode is not supported in this device.
0x800 - 0xFFFF	Reserved

#### 10.2.5.2.2 Proxy Sizes

The number of proxies in the module is configured during SoC design. See [Table 10-121](#). Each proxy has its own address space to the module and determining which proxy is being accessed is simply based on the address bits above the final size of each proxy space. The size of the proxy space is always 4 KB. This is enough to contain the data message, along with controls for which channel, access mode, and element size for the access.

#### 10.2.5.2.3 Proxy Interleaving

Each proxy must have a single owner, as each proxy only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy. Then they will have their own buffer and each can access a different resource at the same time. Each proxy is completely independent and kept coherent regardless of accesses to other proxies or regardless of the order of accesses. So the proxies support interleaving of multiple hosts' accesses.

#### 10.2.5.2.4 Proxy Host States

Each individual proxy per host uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy is in use or not, but also for error detection. The proxy always stays in idle state, when there is no activity. There is a write state for when the proxy has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy has read data from a resource and that entire data has not been fully read by the host. When a proxy access completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

#### 10.2.5.2.5 Proxy Host Channel Selection

The host must program the PROXY\_CTL\_j (where j = 0h to 3Fh) prior to accessing the PROXY\_DATA\_j\_y (where j = 0h to 3Fh, y = 0h to 7Fh) unless the previous values are to be reused. This sets the channel within the target, the access mode (head, tail, peek), and the element size. These values will be used when writing the full message to the target, or reading a new message from the target. The target address used will be based on the target base address, the programmed channel, the programmed access mode (for the offset within the 4 kB of the target channel), and the element size (for the offset within the 512 Bytes max size message).

$$\text{target address} = \text{target base} + (\text{channel} \times 4\text{KB}) + (\text{mode} \times 512\text{B}) + (512 - \text{element size in bytes})$$

, for element size in bytes length.

The proxy will detect an error if these fields are changed while in the middle of a message.

#### 10.2.5.2.6 Proxy Host Access

A proxy begins in an idle state, where there is no data in the buffer. In this state the proxy will accept any access to a new resource. If the proxy is in another state, representing a resource is in progress, and the host attempts to access another target or resource, or switches from read to write, then the proxy will detect that as an error and flush the buffer with no final target access and the data is lost and the proxy goes back to idle state.

##### 10.2.5.2.6.1 Proxy Host Writes

The first write to an idle proxy puts the proxy into write mode for the selected target and channel. Further legal writes are stored in the buffer for the enabled bytes and position within the buffer. A write to a previously written location will overwrite the previous data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host

to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy is then put back into idle state.

#### **10.2.5.2.6.2 Proxy Host Reads**

When in idle state, the first read to the proxy will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data is returned, and the proxy is put back into idle state.

#### **10.2.5.2.7 Permission Inheritance**

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target. This will copy the secure, debug, priv, privid, and virtid signals so that they can be firewalled during the target access for the resource.

#### **10.2.5.2.8 Buffer Size**

Buffer size is shown in [Table 10-121](#). An attempt to access a larger message will result in the proxy going into error mode. Software must only create messages up to the supported target size.

#### **10.2.5.2.9 Error Events**

Each proxy can produce an event when it has detected an error. This error occurs when the host changes the target, resource, or access direction before completing the previous data. An error can also occur for an access to an illegal target, illegal offset within a target, such as beyond the target size or buffer size, or if the access spans multiple channels. This error does not include accessing reserved register locations within the proxy thread, as that results in normal reserved register behavior of ignoring write data and reading 0s. There is a separate status bit per proxy for these errors. The event number is programmed via `PROXY_EVT_REG_j` (where `j = 0h to 3Fh`) for each proxy. The event will not be sent if the event is programmed to `0xFFFF`.

#### **10.2.5.2.10 Debug Reads**

Since debug reads with `emudbg=1` must not cause any side effects or bus errors, any debug read will just read the buffer and never cause a target read. It will also not return any bus errors.

## 10.2.6 Secure Proxy

This chapter describes the Secure Proxy module in NAVSS.

### 10.2.6.1 Secure Proxy Overview

The Secure Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses. Secure Proxy is a modified version of the Proxy module in NAVSS.

**Table 10-125. Secure Proxy Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_SEC_PROXY0	-	-	✓ (NAVSS)
MCU_NAVSS0_SEC_PROXY0	-	✓ (MCU NAVSS)	-

#### 10.2.6.1.1 Secure Proxy Features

Secure Proxy supports the following features:

- Provides proxy function to store large data bursts that a host can only access in smaller amounts
- Supports a number of threads, where each has their own independent proxy function
- Keeps the large data burst coherent until the complete data has been accessed
- Allows for interleaved access between multiple hosts or tasks using multiple proxy threads
- Supports a programmable fixed queue for each proxy thread
- Supports multiple producers all writing to the same queue
- Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
- Supports programmable thresholds for when to generate events.

#### 10.2.6.1.2 Secure Proxy Parameters

Table 10-126 shows the Secure Proxy configuration parameters set during SoC design.

**Table 10-126. Secure Proxy Configuration Parameters**

Module Instance	Parameters				
	Proxies <sup>(1)</sup>	Message Size <sup>(2)</sup>	Target	Channels <sup>(3)</sup>	Sizes <sup>(4)</sup>
NAVSS0_SEC_PROXY0	370	64	NAVSS0_RINGACC0	110	4096
MCU_NAVSS0_SEC_PROXY0	90	64	MCU_NAVSS0_RINGACC0	30	4096

(1) Number of proxy threads supported. Can be read off from the SEC\_PROXY\_CONFIG read-only register

(2) Number of bytes for message. Can be read off from the SEC\_PROXY\_CONFIG read-only register

(3) Number of channels for the target

(4) Number of bytes per channel supported for the target

#### 10.2.6.1.3 Secure Proxy Not Supported Features

The following features are not supported by the module:

- Does not support proxy thread sharing. Each host or task must use its own proxy thread within the module if they can access simultaneously or independently. This includes when the task can be interrupted by another task that also uses the proxy
- In the system, a proxy must be the only method to access messages that use the same set of queues (to keep credits local), which means all hosts using the same set of message queues must also use the same proxy for access and not local proxys
- Does not support multiple proxy threads reading from the same queue. For tracking purposes, there can be only 1 consumer proxy thread per queue.

#### 10.2.6.1.4 Secure Proxy Ports

-	No PDMA channels to external DMA engines	-

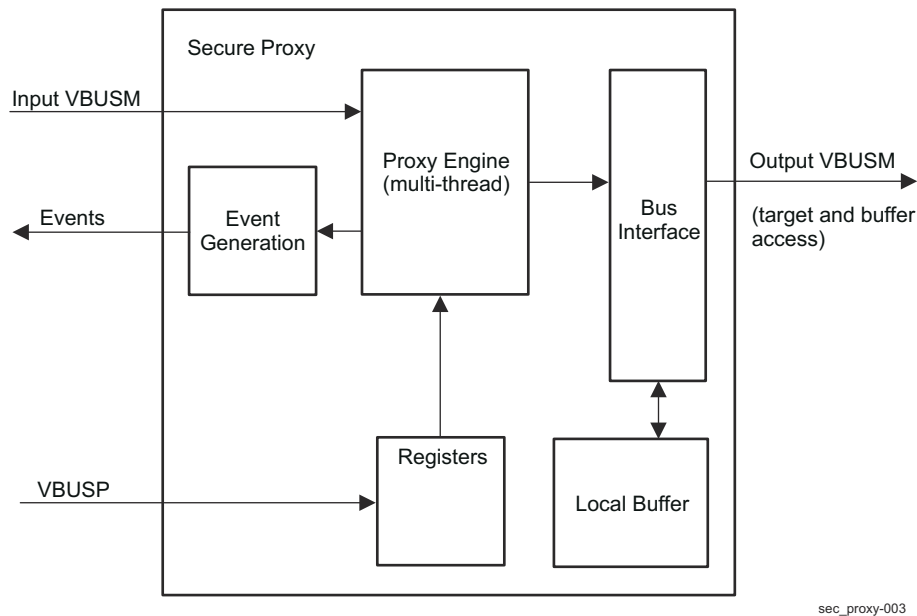

### 10.2.6.2 Secure Proxy Functional Description

This module provides proxy functions for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are:

- large messages (for power control, security control, or IPC)
- data descriptors that are more than a pointer
- DMA Transfer Requests (TR)

All of these require larger data sets, from 12 to 128 bytes, and the storage hardware requires the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as registers, and the largest CPU access is typically 8 bytes. Therefore the proxy provides the ability to access the hardware with a single burst, and at the same time allows the CPU to access the same data in smaller accesses.

Figure 10-21 describes Secure Proxy major building blocks.

sec\_proxy-003

**Figure 10-21. Secure Proxy Block Diagram**

#### 10.2.6.2.1 Targets

##### 10.2.6.2.1.1 Ring Accelerator

The RING\_ACC provides four distinct offsets to use per ring/queue shown in Table 10-129, totaling 4 KB space per ring/queue.

Secure Proxy always writes to tail, which is the offsets from 0x200 to 0x3FF. Secure Proxy always reads from the head, which is the offsets from 0x000 to 0x1FF. The latter two offsets in RING\_ACC are not used by this proxy. And if the proxy message size is less than 512 bytes, then it always access the upper bytes of those regions, so that the message always ends on the last byte of each region, byte 511.

**Table 10-129. RING\_ACC Offsets per Ring/Queue**

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.
0x400 - 0x5FF	Reads peek from head. Writes ignored. Not used by Secure Proxy
0x600 - 0x7FF	Reads peek from tail. Writes ignored. Not used by Secure Proxy
0x800 - 0xFFFF	Reserved

This means that target writes will use the following calculation:

$$\text{target base address} + (\text{queue} \times 4\text{KB}) + 0x400 - \text{msg\_size} \quad (17)$$

,and burst until offset 0x3FF.

And target reads will use the following calculation:

$$\text{target base address} + (\text{queue} \times 4\text{KB}) + 0x200 - \text{msg\_size} \quad (18)$$

,and burst until offset 0x1FF.

#### 10.2.6.2.2 Buffers

The proxy does not store all the buffers internally. It is programmed with a buffer base address (SEC\_PROXY\_BUFFER\_L, SEC\_PROXY\_BUFFER\_H), and all accesses to the buffer are made through the output VBUSM port using that base. The external buffer must be enough to store one *msg\_size* per proxy thread. The proxy only includes a small temporary buffer to save one entire message when accessing the target. Otherwise all host accesses are made to the external buffer. This buffer storage must be considered private for the proxy hardware, so any other access can cause unpredictable results.

##### 10.2.6.2.2.1 Proxy Credits

To support outbound proxy limits, the proxy will use internal credits for tracking resource usage. SEC\_PROXY\_CTL\_j register sets the max credits each outbound proxy thread contains. When a proxy thread sends a message, the current credit count (SEC\_PROXY\_STATUS\_j) decrements by 1. If the current credit count is 0, then the proxy thread is not allowed to send any more messages, and they just remain inside the proxy (so that the host can come back later when a credit has become available and quickly send the same message). When a message that was send by this proxy thread is read by an inbound proxy thread then the credit is returned to this proxy thread and the current credit count increments by 1.

For inbound proxy threads, the credits are used to track pending messages. When an outbound proxy thread sends a message that is read by this proxy thread, then the current credit count of this proxy thread is incremented by 1. A current credit count that is non zero indicates a message is pending and can be read. When the proxy thread completes the read of a message the current credit count is decremented by 1. If the current credit count is zero, then the proxy thread will read an empty message where all the data is 0s. The credit count saturates at 255, so if there can be more messages in the system for that proxy thread than 255 then multiple proxy threads should be used, or the count can become mismatched after a saturate.

##### 10.2.6.2.2.2 Proxy Private Word

To support tracking of credits from each proxy thread, the proxy will extract the first word from the total message size for private tracking usage. This will include saving the proxy thread ID used within the proxy. This is necessary so that when a proxy reads a new message from the target it can inspect this word and return the credit to the source proxy thread. This allows the outbound proxy threads to have a set number of message credits, which decrement when a new message is written, and increment when a message from that proxy

thread is read, thus keeping the credits in the system coherent. Any data written to this first word of the message will be ignored, so software should not write to the first word of messages through the proxy. Consumer software can use the first word to identify the source proxy thread of the message (SEC\_PROXY\_DATA\_j).

#### **10.2.6.2.2.3 Completion Byte**

The proxy completes a message when the completion byte is accessed. This completion byte is the final byte in the full size of the message. This byte can be written by any size access, whether byte, 32-bit, or 64-bit word. The write of a message is not complete until this final byte of the message is written, and only then will the message be sent to the target. The read of a message is not complete until this final byte of the message is read by the host, and only then will reading a new message be allowed. Even if the final byte of the message is not needed, it must be accessed to complete the message inside the proxy hardware.

#### **10.2.6.2.3 Proxy Thread Sizes**

There are a configurable number of proxy threads in the module. Each thread has its own address space to the module and determining which proxy thread is being accessed is simply based on the address bits above the final size of each proxy thread space. Since each proxy thread will be programmed to a single resource, the only space requirement is that for using 4 KB to match typically used MMU page sizes. Only the first N bytes, matching the target channel size, is usable.

#### **10.2.6.2.4 Proxy Thread Interleaving**

Each proxy thread must have a single owner, as each proxy thread only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy thread. Then they will have their own buffer and each can access a different resource at the same time. Each proxy thread is completely independent and kept coherent regardless of accesses to other proxy threads or regardless of the order of accesses. So the proxy support interleaving of multiple hosts' accesses.

#### **10.2.6.2.5 Proxy States**

Each proxy thread uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy thread is in use or not, but also for error detection. The proxy thread always starts in idle state, when there is no currently activity. There is a write state for when the proxy thread has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy thread has read data from a resource and that entire data has not been fully read by the host. When a proxy thread access completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

#### **10.2.6.2.6 Proxy Host Access**

A proxy thread begins in an idle state, where there is no data in the buffer. In this state the proxy thread will accept an access to the resource.

##### **10.2.6.2.6.1 Proxy Host Writes**

The first write to an idle proxy thread puts the proxy thread into write mode for the selected channel. Further legal writes are stored in the buffer for the enabled bytes and offset within the buffer. A write to a previously written location will overwrite the previous data. The buffer is not cleared initially, so if a byte is not written, the message will include previous buffer data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy thread is then put back into idle state. A write completion when there are no credits available results in the message not being written to the resource and the proxy thread remains in write mode (so that the message can be quickly completed when a credit becomes available).

##### **10.2.6.2.6.2 Proxy Host Reads**

When in idle state, the first read to the proxy thread will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data

is returned, and the proxy thread is put back into idle state. If an initial read is made and there are no pending messages, the proxy thread will return an empty message, where the data is all 0s.

#### **10.2.6.2.6.3 Buffer Accesses**

Each read or write will actually trigger a read or write to the external buffer space allocated for that proxy thread, where the real message data is stored. In addition, when a write message completes, the external buffer will be read for the entire message for that proxy thread so that it can then be written to the target. Similarly, after a read causes a read from the target to get a new message, the entire message is written to the external buffer to store the message to the buffer.

#### **10.2.6.2.6.4 Target Access**

After the write has completed and the external buffer read for the entire message, the entire message is then written to the target as a single burst. Similarly, for a read that needs a new message, the target is read for a full message as a single burst.

#### **10.2.6.2.6.5 Error State**

If an error is detected in a proxy thread, the proxy will put that proxy thread into error state, and the current buffer will be lost. A status bit will be set that indicates the proxy thread is in error. All accesses to that proxy thread will be ignored until the status bit is cleared. Once cleared the proxy thread is put back into idle state. Errors are: an access to an offset beyond the length of the message, or a mismatch in the direction of access against what was programmed such as reading an outbound thread or writing an inbound thread.

#### **10.2.6.2.6.7 Permission Inheritance**

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target.

#### **10.2.6.2.8 Resource Association**

Each proxy thread has a register (SEC\_PROXY\_CTL\_j) to define the resource within the target that the proxy thread is mapped to. The host has no ability to access any other resource in the target. This allows the setup of the proxy to determine the resources that all the hosts use.

#### **10.2.6.2.9 Direction**

Each proxy thread has a register (SEC\_PROXY\_CTL\_j) to define the direction for access. It can either be an outbound proxy thread for writing messages to resources. Or it can be an inbound proxy thread for reading messages from resources. The host must match the direction programmed or it will result in a proxy thread error.

#### **10.2.6.2.10 Threshold Events**

Each proxy thread can produce events based on the state of the resource it uses. For outbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to write. For inbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to read. These threshold values are programmed in SEC\_PROXY\_EVT\_MAP\_j, allowing the host to determine how often it gets events. Programming the count values while the threshold is set to 0 will not trigger events, but if the threshold is not 0 then programming the counts will trigger events based on whether the threshold is reached or not. No event is generated if the event is programmed to 0xFFFF.

#### **10.2.6.2.11 Error Events**

Each proxy thread can produce an event when it has detected an error. This error occurs when the host violates the programmed setup of the proxy thread or accesses beyond the message size. There is a separate status bit per proxy thread for these errors. No event is generated if the event is programmed to 0xFFFF.

#### **10.2.6.2.12 Bus Errors and Credits**

If a target read for a message returns a bus error, this indicates the read was bad and the data is corrupt and usually 0s. Because the private word is contained in the message, if the private word is corrupted then the source proxy thread is not valid and the credit return will not be correct. Since the data is usually 0, this means the credit would be returned to proxy thread 0 incorrectly most of the time. And the credit will be lost for the

actual source proxy thread of the message that was not read correctly. The hardware has no way to correct for this, as the message from the target is corrupt so it does not know the correct owner of the credit. If software detects that a read message is corrupt, it can attempt to correct the situation by resetting the affected proxy threads using that queue, to restore their credit counts back to the default. Software may also want to reset proxy thread 0 since it may be getting extra credits.

#### **10.2.6.2.13 Debug**

When the transaction has the *emudbg* set for a read, all side effects will not occur. This means that the read will not cause a target read since that would affect the target, and instead current buffer will be read even if the previous message has completed.

## 10.2.7 Interrupt Aggregator (INTR\_AGGR)

This chapter describes the INTR\_AGGR module, part of NAVSS.

### 10.2.7.1 INTR\_AGGR Overview

The Interrupt Aggregator (INTR\_AGGR or INTA) provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane (ETL) bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

**Table 10-130. INTR\_AGGR Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_INTR_AGGR0	-	-	✓ (NAVSS)
NAVSS0_INTR_AGGR1	-	-	✓ (NAVSS)
NAVSS0_UDMASS_INTR_AGGR0	-	-	✓ (NAVSS)
MCU_NAVSS0_UDMASS_INTR_AGGR0	-	✓ (MCU NAVSS)	-

#### 10.2.7.1.1 INTR\_AGGR Features

NAVSS0\_INTR\_AGGR0 supports the following features:

- 64-bit VBUSP slave using 64-bit registers
- Provides a set of *TI Interrupt Architecture* compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks.
  - Maps a collection of "DMA Messaged Events" which are input through an Event Transport Lane (ETL) into specific bit locations in one or more interrupt cause registers
  - Mapping is performed based on a programmable table which provides a single location for each ordinal input event number (0 through sevt\_cnt-1)
    - Table specifies a specific bit in a specific cause register that the event should set or clear depending on the type of event (up vs down)
    - Tracks a single 'event up'/'event down' condition. There is no event counting. (The 'cnt' field of the ETL is ignored)
  - Tracked status interrupts are presented to the user through a standard interrupt register interface
    - Provides separate 'enable set' and 'enable clear' registers
    - Provides both masked and unmasked interrupt status
    - Interrupt status bits can be manually cleared using 'write 1 to clear'
- Provides a set of Global Event Input (GEVI) counters which can count events which were delivered via an ingress Event Transport Lane (ETL)
  - Each counted event provides an register by which the count can be read and an register by which a specified amount can be decremented by the host
  - Each counted event generates a egress Global event on a zero to non-zero and non-zero to zero transition, controllable through a mapping register
- Provides a set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
  - Each ingress event index provides a configurable 'pulse' or 'rising edge' bit, plus the configurable index of the generated Global event
- Provides a set of Global Event Input (GEVI) 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces.

#### 10.2.7.1.2 INTR\_AGGR Parameters

[Table 10-131](#) shows the MODSS Interrupt Aggregators 0 and 1, and UDMASS Interrupt Aggregator 0 parameters set during design time. 4 local (LEVI) interrupts are from the MCRC0 module.

**Table 10-131. Interrupt Aggregators Parameters**

Module Instance	Parameters				
	VINTR <sup>(1)</sup>	SEVI <sup>(2)</sup>	GEVI <sup>(3)</sup>	LEVI <sup>(4)</sup>	MEVI <sup>(5)</sup>
NAVSS0_INTR_AGGR0	64	1024	0	0	0
NAVSS0_INTR_AGGR1	64	1024	0	0	0
NAVSS0_UDMASS_INTR_AGGR0	256	4608	512	132	512
MCU_NAVSS0_UDMASS_INTR_AGGR0	256	1536	256	12	128

- (1) VINTR – Number of Virtual Interrupt outputs. These are connected to the interrupt router inputs. Value can be read from INTA\_INTCAP/UDMA\_INTA\_INTCAP register.
- (2) SEVI – Number of Main (Steerable) Events. Value can be read from INTA\_INTCAP/UDMA\_INTA\_INTCAP register.
- (3) GEVI – Number of Countable Events. Value can be read from INTA\_AUXCAP/UDMA\_INTA\_AUXCAP register.
- (4) LEVI – Number of Local Event inputs. Value can be read from INTA\_AUXCAP/UDMA\_INTA\_AUXCAP register.
- (5) MEVI – Number of Multicast Events. Value can be read from INTA\_AUXCAP/UDMA\_INTA\_AUXCAP register.

#### 10.2.7.1.3 Interrupt Aggregator (INTR\_AGGR) Ports

**Table 10-132. INTR\_AGGR Clocks and Resets**

Clocks	
Module Clock Input	Description
INTR_AGGR_FICLK	INTR_AGGR clock. This clock is used for all interface and functional operations.
Resets	
Module Reset Input	Description
INTR_AGGR_RST	INTR_AGGR hardware reset

**Table 10-133. INTR\_AGGR Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
UDMASS_INTA0_VINTR_PEND[255:0]	Global/local events	Level
MODSS_INTA0_VINTR_PEND[63:0]	Global events from TIMER_MGR0	Level
MODSS_INTA1_VINTR_PEND[63:0]	Global events from TIMER_MGR1	Level
L2G Interrupt Request Inputs		
Module Interrupt Signal	Description	Type
L2G_EVENT_PEND[7:0]	Interrupts from TIMESYNC_INTRTR0	Level
L2G_EVENT_PEND[15:8]	Interrupts from CMPEVT_INTRTR0	Level
L2G_EVENT_PEND[31:16]	Interrupts from GPIOMUX_INTRTR0	Level
DMA Events		
Module DMA Event	Description	Type
-	No PDMA channels to external DMA engines	-

### 10.2.7.2 INTR\_AGGR Functional Description

The Interrupt Aggregator provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Both the signaling and content of K3 system events are incompatible with standard interrupt controllers. The INTR\_AGGR provides mechanisms which convert the TI proprietary system events to standard level sensitive pending bits which can be used by the Interrupt Router and all downstream interrupt infrastructure. Events can be presented to the INTR\_AGGR in two different forms:

- Events may be active high pulses, or clock synchronous rising edges, which are input on separate orthogonal pins. These are called 'Local Events'.
  - Local event signals that are used in pulse counting mode must be sourced by the same clock as the interrupt aggregator.
  - Local event signals that are used in edge counting mode must be sourced by pseudo-synchronous sources (and be a slower clock multiple) to the interrupt aggregator clock, and they must remain high for at least 1 'slow' clock cycle.
- Events may be messages which are input in time division multiplexed sequential order from an Event Transport Lane. These are called 'Global Events'.

In both cases, these events need to be conditioned to transition them from a transient indicator that something occurred to a persistent and reliable indication of the current state of the system. The INTR\_AGGR is architected to perform this conversion in an efficient and cost effective manner.

#### 10.2.7.2.1 Submodule Descriptions

##### 10.2.7.2.1.1 Status/Mask Registers

The Status and Mask Registers block is responsible for providing persistent storage for the interrupt status and mask bits and for formatting those in a way that is compliant to the *TI Interrupt Architecture* requirements. These requirements include the ability to set and clear bits orthogonally and to provide a masked version of the status register that corresponds to the supplied bit mask for each register.

##### 10.2.7.2.1.2 Interrupt Mapping Block

The Interrupt Mapping Block accepts ordinally numbered events (0-N) and converts those ordinal event numbers into a status register number and bit number pair that is then used to manipulate the specified bit in the Status Registers block.

##### 10.2.7.2.1.3 Global Event Input (GEVI) Counters

The GEVI Counters block is responsible for accepting an Event Transport Lane events and summing the total message counts for each received event index. The module creates global egress events for zero to non-zero count up' events and non-zero to zero 'count down' events. The egress global event index is configured via GEVI UDMA\_INTA\_MCMAP\_j register, so count status egress events can optionally be fed back into the INT\_AGGR, via the ETL switch fabric.

##### 10.2.7.2.1.4 Local Event Input (LEVI) to Global Event Conversion

The Local to Global event block is responsible for accepting an array of input pins and independently counting the number of cycles for which those pins are asserted high, or by counting individual clock synchronous rising edge events. The counting mode is configurable on a 'per pin' basis. The events are converted to egress Global events on an egress ETL. Global events can optionally be fed back into the INT\_AGGR, via the ETL switch fabric.

##### 10.2.7.2.1.5 Global Event Multicast

The Global event multicast block takes an ingress global event from an ingress ETL, and maps it into two egress Global events on two egress ETL interfaces. Global events can optionally be fed back into the INT\_AGGR, via the ETL switch fabric.

### 10.2.7.2.2 General Functionality

#### 10.2.7.2.2.1 Event to Interrupt Bit Steering

Each time an event message is received on the Main Event Transport Lane interface, the interrupt mapping block performs a direct lookup into an SRAM using the event number as the address. The SRAM stores a corresponding raw interrupt status register and bit number within that register which are to be manipulated anytime a message is received indicating something occurred on that specific event. When an *up* event is received, the specified bit in the *j* Status register will be set. When a *down* event is received, that same bit will be cleared. This block is what allows flexible aggregation of various system events into an array of bits in the interrupt status registers. It is intended that this mapping is essentially static - set up when a resource is allocated and left untouched until the resource is no longer needed. Note that the 'cnt' field of the ETL is ignored and no interrupt counting is performed here. When 'UpDn=1', the interrupt flag bit is set, and when 'UpDn=0', the flag bit is cleared.

#### 10.2.7.2.2.2 Interrupt Status

The event messages which are generated from the event to interrupt bit steering logic are input to the Interrupt Status registers. Each time an event is received, the interrupt status registers machine will assert or de-assert the specified bit in the specified register. The assertion and de-assertion in the interrupt status register is unaffected by the interrupt enable state. When an up event is received, the corresponding bit is set and when a down event is received, the corresponding bit is cleared. Some sources of input events will not include the ability to send a down event. In these cases, the interrupt router provides the ability to clear the status bits through the Interrupt Source Clear register. The host will write a one to the specific bit in the register which is to be cleared and the interrupt status machine will clear the bit internally. It is not intended that the Host directly clear bits which are automatically cleared via down events from the source itself.

#### 10.2.7.2.2.3 Interrupt Masked Status

Interrupt enable bits are used in conjunction with the interrupt status bits to create the interrupt masked status register values. The interrupt masked status register (INTA\_STATUSM\_j) contains the value of the interrupt status ANDed with the value of the interrupt enable register. Each time a new event message is received from the event to interrupt bit steering logic or the interrupt enable register is modified, the interrupt masked status register is re-evaluated.

#### 10.2.7.2.2.4 Enabling/Disabling Individual Interrupt Source Bits

Separate (INTA\_ENABLE\_SET\_j and INTA\_ENABLE\_CLEAR\_j) registers are provided to allow individual enable bits to be enabled or disabled without the need for a read-modify-write operation. When the INTA\_ENABLE\_SET\_j register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be set. When the INTA\_ENABLE\_CLEAR\_j register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be cleared.

#### 10.2.7.2.2.5 Interrupt Output Generation

Each interrupt masked status register (INTA\_STATUSM\_j) is accompanied by a single pending bit which indicates if any enabled interrupt source within the corresponding interrupt status register is currently asserted. These pending bits from the interrupt masked status registers are collectively output from the INTR\_AGGR as the VINTR\_PEND bus. The interrupt status outputs will always be updated to reflect the current values of the INTA\_STATUSM\_j register. This is accomplished by triggering output updates on write operations to the internal RAM that holds the current raw status and enable masks.

#### 10.2.7.2.2.6 Global Event Counting

When enabled, the INTR\_AGGR will provide a set of counters which will track how many outstanding messages have been observed for each ingress event index from the ingress Counted Global Event Transport Lane (ETL) interface. For each message received where the 'UpDn' flag is set, the corresponding counter will be incremented by value of the 'cnt' field of ingress message. Events where the 'UpDn' flag is cleared are ignored. The counter is made visible to software in the UDMA\_INTA\_COUNT\_j register. When software has read the count, it can acknowledge that count has been seen and processed by writing back an integer value specifying the amount by which the counter should be decremented, and the counter will subtract that value from the current count (which may have updated since it was read). The count will saturate at a value of 0xFFFFFFFF. Writing a count 'ack' value higher than the one read is not supported and will produce non-deterministic results.

When a count transitions from zero to a non-zero value, a Global Up 'UpDn=1' event is sent out an egress ETL interface. When a count transitions from a non-zero value to zero, a down 'UpDn=0' event will be sent. The index of the Global event is mappable on a 'per-counter' basis, using the UDMA\_INTA\_MAP\_j register. The event may be mapped such that it then re-enters INTR\_AGGR's 'Event to Interrupt Bit Steering Block' to generate an interrupt to the host. The event routing is handled by an external event switch fabric. Note that writing a new egress event index via the UDMA\_INTA\_MAP\_j register does not alter the stored event count for the ingress event register index.

#### **10.2.7.2.2.7 Local Event to Global Event Conversion**

When enabled, the INTR\_AGGR will provide a set of Local to Global event conversion registers. Local events may be discrete clock synchronous pulses or clock synchronous rising edges. The counting mode is configurable on a 'per pin' basis. In pulsed mode, the module will track how many outstanding clock cycle long pulses have been observed on each of the provided LEVI interface pins. For each cycle in which a LEVI input pending bit is asserted the corresponding counter will be incremented by 1. In 'rising edge' mode, the number of rising edge transitions on the pin is counted.

The module will generate egress Global events on its egress ETL, with a different global index configured for each ingress LEVI pin. The LEVI pins numbers (1-N) are converted to arbitrary global event indices via the global event mapping UDMA\_INTA\_MAP\_j registers. The egress Global events can themselves be mapped to re-enter the INTR\_AGGR's Global Event Counting block, so that the counts can then be made visible to software in the GEVI count registers as described in [Section 10.2.7.2.1.3](#). The event routing is handled by an external event switch fabric.

#### **10.2.7.2.2.8 Global Event Multicast**

In UDMASS\_INTR\_AGGR0, the INTR\_AGGR will provide a set of Global event multicast (UDMA\_INTA\_MCMAP\_j) registers. These registers allow an ingress Global event on its ingress ETL interface to be mapped into two egress Global events on two separate egress ETL interfaces. A set of registers map the ingress Global event index (1-N) into two arbitrary egress event indices.

### 10.2.8 Packet Streaming Interface Link (PSI-L)

This section describes the Packet Streaming Interface Link (PSI-L) for the device.

#### 10.2.8.1 PSI-L Overview

PSI-L is a packet based protocol used to transfer data between several device modules. Each transaction is routed based on thread ID value instead of physical address. All PSI-L interfaces are point to point direct connections to NAVSS0 or MCU\_NAVSS0. All switching functions among the PSI-L based interfaces are done inside NAVSS0 and MCU\_NAVSS0.

The PSI-L also has an event interface referred to as ETL, which is purely used to transfer event information. Only MCU\_NAVSS0 has such event interface. It is connected to WKUP\_ and allows MCU\_NAVSS0 to send event information to the interrupt aggregator inside WKUP\_.

[Figure 10-22](#) shows an overview of all PSI-L connections within the device.

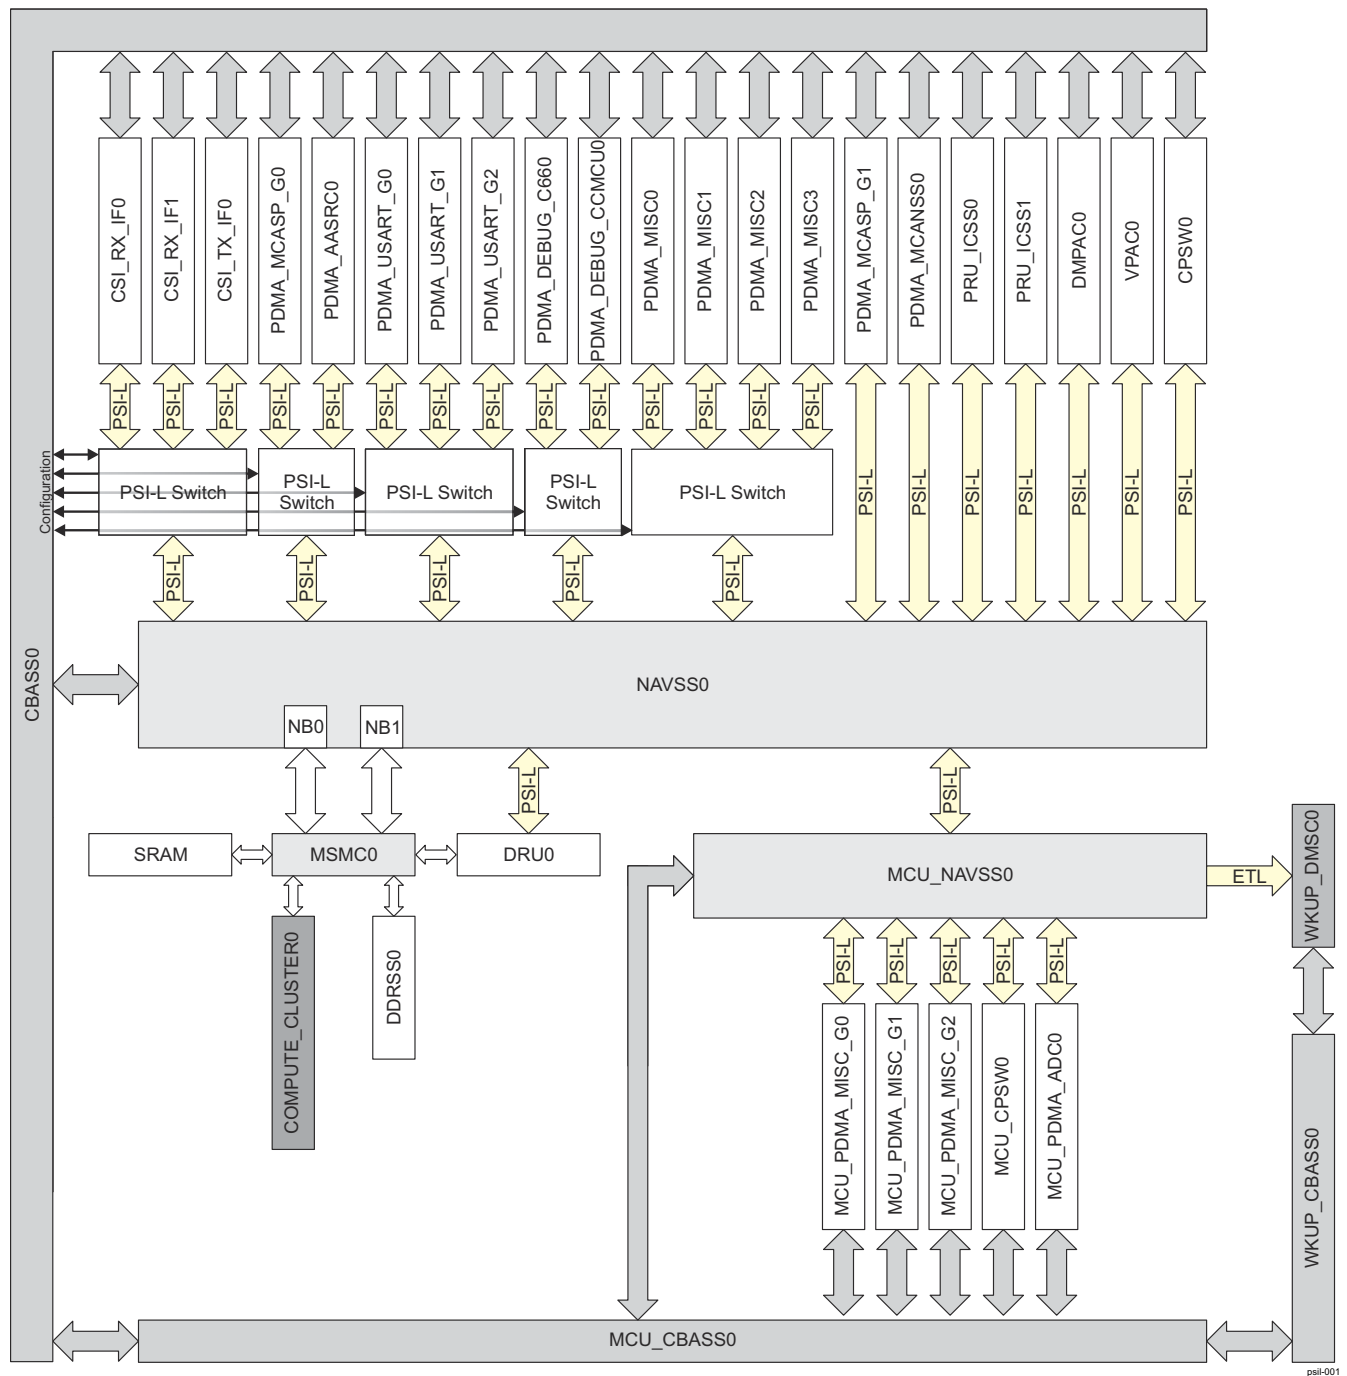

Figure 10-22. PSI-L Overview

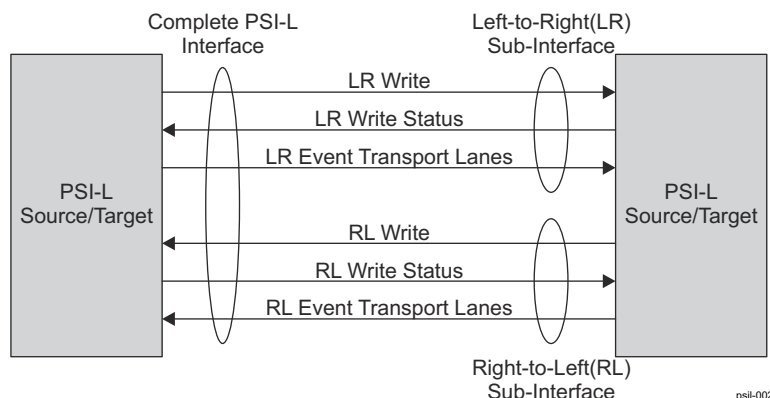

## 10.2.8.2 PSI-L Functional Description

### 10.2.8.2.1 PSI-L Introduction

The PSI-L is used to transfer words of packet data and control information between two peer entities via direct connection. There are credits used for flow control to guarantee that blocking does not occur between threads. Multiple packet transfers can be ongoing simultaneously across a PSI-L interface each on a separate logical thread but all sharing a single datapath through time division multiplexing. Each packet which is transferred is accompanied by a destination thread ID which indicates the logical destination thread to which the packet is being sent.

There is low level hardware handshake between PSI-L master and slave used for transferring data. As it is blocking by nature, a higher level protocol is also used in which credits are maintained for each thread connection. Moments of non-readiness are allowed on the interface but there is no possibility that one thread can block another for an indefinite time since a thread must have credit for the destination before it is allowed to use the interface.

Figure 10-23 illustrates the point to point PSI-L connection.

**Figure 10-23. PSI-L Connection**

PSI-L is intended to be a versatile interface which can carry various types of communications. Table 10-134 describes several types of threads which have been defined.

**Table 10-134. Types of PSI-L Threads**

Type	Description	Example Endpoints
Queue Management (QM) Messaging	Provides transport for queue push, pop, and divert messages to support distributed queue based work passing	Centralized queue manager or message manager and distributed DMA clients
Direct IO	Allows for tunneling CBASS compatible bus transactions through a PSI interconnect	Module which has no CBASS master to a remote proxy block
DMA Control Transport	Provides transport for DMA transfer descriptions from a source thread to a destination thread	DMA channel controller to DMA transfer controller
DMA Data Transport	Provides transport for packed data from a source thread to a destination thread	Packet oriented module like networking adapters to or from centralized DMA

Each thread on PSI-L is established between a single thread master and a single thread slave using a connection oriented transfer mechanism. A thread master and a thread slave are "paired" to create a logical connection between them referred to as a thread. Pairing is accomplished using a Pair Configuration Message which is valid in all thread types. Pairing can only occur between a thread master and a thread slave of the same type.

#### 10.2.8.2.2 PSI-L Operation

The PSI-L allows multiple independent streams of packet data (threads) to share a single interface using data phase granularity time division multiplexing. This time division multiplexing is accomplished by dividing each stream into single data transfers. In this way a stream is comprised of a sequence of strongly ordered data

transfers but packet transfers between different streams are allowed to be interleaved. Each data phase is qualified with a type identifier which indicates whether the data is packet info, direct IO write or read info, timestamp, software info, control data, payload data, or status.

#### 10.2.8.2.2.1 Event Transport

PSI-L provides a mechanism by which events can be transported within one or more optional sub-interfaces on a link. These sub-interfaces are referred to as event transport lanes (ETLs) and are independent of any PSI-L packet or message transfers which may be ongoing on the other interfaces within the PSI-L. A maximum of one event can be transferred on each event transport lane in each clock cycle. The event transport protocol is a simple request-ready type of hardware handshake.

#### 10.2.8.2.2.2 Threads

A thread is a complete flow-controlled stream of communication. The PSI-L thread space is divided into a 32K contiguous region representing all of the source threads (0x0000 - 0x7FFF) and a 32K contiguous region representing all of the destination threads (0x8000 - 0x8FFF).

Source threads are responsible for sending request transactions, accepting response transactions, and sending data transfer transactions. Destination threads are responsible for accepting request transactions, sending response transactions, and accepting data transfer transactions. A given thread generally performs only a single class of transactions (see [Table 10-134](#)). Both source and destination threads may act as masters for transfers on one of the PSI-L write sub-interfaces but in this case source threads are actually initiating data transfers while destination threads are only responding to a previous request issued by a source request. Source threads only transfer to destination threads and destination threads only transfer to source threads. Transfers between same thread types do not occur.

The following types of message transfers always originate from source threads and terminate in destination threads:

- Configuration write message
- Configuration read message
- QM push message
- QM pop message
- QM divert message
- Direct read operation message
- Direct write operation message
- DMA transfer request message
- DMA data message

The following types of message transfers always originate in destination threads and terminate in source threads:

- Configuration write response message
- Configuration read response message
- QM push response message
- QM pop response message
- QM divert response message
- DMA transfer response message

#### 10.2.8.2.2.3 Arbitration Protocol

On each cycle, an arbiter built into the master side of each interface decides on which thread to transfer data in the next clock cycle. Both forward (from source threads) and reverse (from destination threads) direction transfers can occur across the same physical interface so the arbiter must ensure that sustained blocking of any thread can occur.

The decision about which thread to allow using the interface is based on the following factors:

1. Whether data is ready at the source to be sent
2. Whether credit exists for the thread such that it is guaranteed there is a place for the data to land in the destination endpoint. For reverse direction transfers (response messages), it is assumed that credit always exists.

3. The relative priority of the traffic that the thread is carrying for the given packet duration
4. Whether the transfer is for a forward or reverse direction thread (requests versus responses).

No thread can be considered for inclusion in arbitration unless both data is available and credit exists in the destination endpoint. For each thread which can be considered in the current arbitration cycle, the arbiter should then pick the thread with the highest priority. Reverse transfers should be considered higher priority than forward transfers.

#### **10.2.8.2.2.4 Thread Configuration**

Each source thread has programmable registers for configuring the pairing with a corresponding destination thread and for enabling data flow. Each destination thread has programmable registers for reporting the buffering capability of the thread and for enabling data flow. These registers are accessed using configuration read and write messages from a configuration host.

Each configuration write message sent from a configuration host is acknowledged with a configuration write response message from the addressed endpoint. Each configuration read message sent from a configuration host is acknowledged with a configuration read response message from the addressed endpoint.

##### **10.2.8.2.2.4.1 Thread Pairing**

Depending on the type of traffic that each source thread carries it may or may not have a fixed pairing with a destination thread.

##### **10.2.8.2.2.4.1.1 Configuration Transaction Pairing**

Configuration write and read transactions are only initiated by a special module called configuration proxy (CFG\_PROXY). Each configuration proxy in the system uses a single source thread which can initiate configuration write and read transactions to the configuration registers of every other source and destination thread in the PSI-L system. The CFG\_PROXY registers are described in *PSI-L CFG\_PROXY Registers*.

Each source thread routes to a single target thread and this pairing is specified by programming a required pairing register set for each thread. A source has no ability to change what target thread it talks to. If a source must be able to talk to different targets (or target threads), then it can either have multiple threads or a streaming switch that can be programmed to route the transfers appropriately based on specific packet fields.

##### **10.2.8.2.2.4.2 Configuration Registers Region**

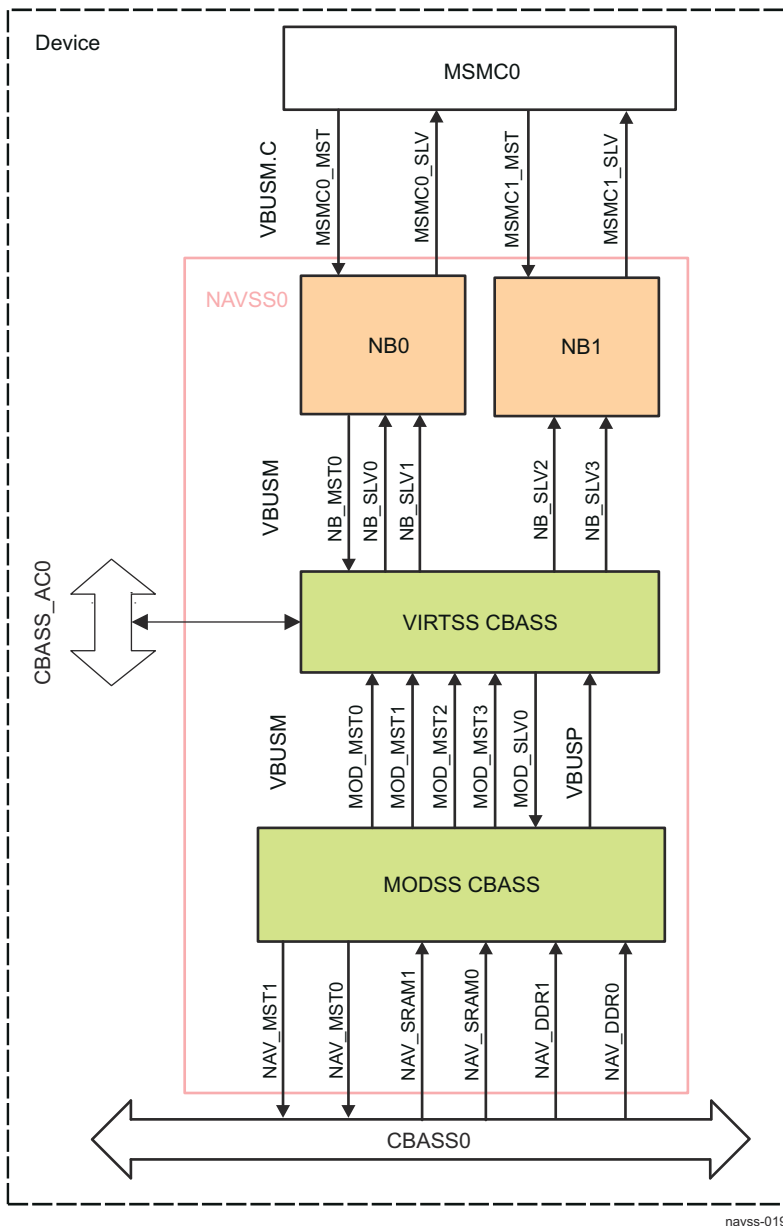

The configuration registers region contains static configuration information including the settings for linking a thread source to a thread destination. These registers are described in *PSI-L Configuration Registers*. The thread ID mapping is shown in *Navigator Subsystem (NAVSS)*.

## 10.2.9 NAVSS North Bridge (NB)

This section describes the North Bridge (NB) in the main Navigator Subsystem.

### 10.2.9.1 NB Overview

The North bridge bridges between CBA 4.0 compliant VBUSM interfaces and a three-threaded CBA 4.0 compliant VBUSM.C interface.

**Figure 10-24. NB Overview**

#### 10.2.9.1.1 Features Supported

- Implements a CBA 4.0 VBUSM to/from VBUSM.C compliant bridge
- Implements CBA 4.0 VBUSM compliant slave interface(s) to receive traffic from a VBUSM source
- Implements a CBA 4.0 VBUSM compliant master interface to create traffic to a VBUSM destination
- Implements a CBA 4.0 VBUSM.C compliant interface to receive and create traffic to and from a VBUSM.C endpoint using 3 threads
- Can optionally support fragmentation of VBUSM write commands into defined burst aligned sizes

- Can optionally support fragmentation and reassembly of VBUSM read commands into defined burst aligned sizes
- Can optionally support synchronous or asynchronous clock conversion
- Can optionally support data width conversion
- Can optionally support using the CBA 4.0 VBUSM credit interface for the VBUSM interfaces
- Allows for priority escalation through the bridge, either for higher priority pending commands inside the bridge or requesting into the bridge
- Supports the K3 clkstop idle signal
- Can optionally support a maximum outstanding read byte count to limit the total read data
- Can optionally insert memory attributes for commands
- Can optionally maintain VBUSM order based on orderid
- Allows programming the mapping of the VBUSM source interfaces to VBUSM.C threads

#### 10.2.9.1.2 NB Parameters

North Bridges are implemented in the SoC with the parameters shown in [Table 10-135](#) and [Table 10-136](#).

**Table 10-135. NB0 Configuration**

Parameter	Value	Description
Number of sources	2	The number of VBUSM source interfaces
Source 0	CBASS MSMC_SLV to MSMC0	Source 0
Source 1		Source 1
source_oidmap[0]	0-7	This defines the orderid mapping to the VBUSM sources. The index represents the source number. The values are integer.
source_oidmap[1]	8-15	
start64k	0x0060000000	This defines the starting address of the memory in VBUSM.C that uses the 64-KB table.
num64k	8192	This defines the number of entries in the 64-KB table.

**Table 10-136. NB1 Configuration**

Parameter	Value	Description
Number of sources	3	The number of VBUSM source interfaces
Source 0	CBASS MSMC_DDR_0 to MSMC1	Source 0
Source 1	CBASS MSMC_DDR_1 to MSMC1	Source 1
Source 2	CBASS MSMC_DDR_2 to MSMC1	Source 2
source_oidmap[0]	0-4	This defines the orderid mapping to the VBUSM sources. The index represents the source number. The values are integer.
source_oidmap[1]	5-9	
source_oidmap[2]	10-15	
start16m[0]	0x0080000000	This defines the starting address of the memory in VBUSM.C that uses the 16-MB table. The index is for each of the 16-MB regions.
start16m[1]	0x0800000000	
num16m[0]	128	This defines the number of entries in the 16-MB table. The index is for each 16-MB region.
num16m[1]	8192	

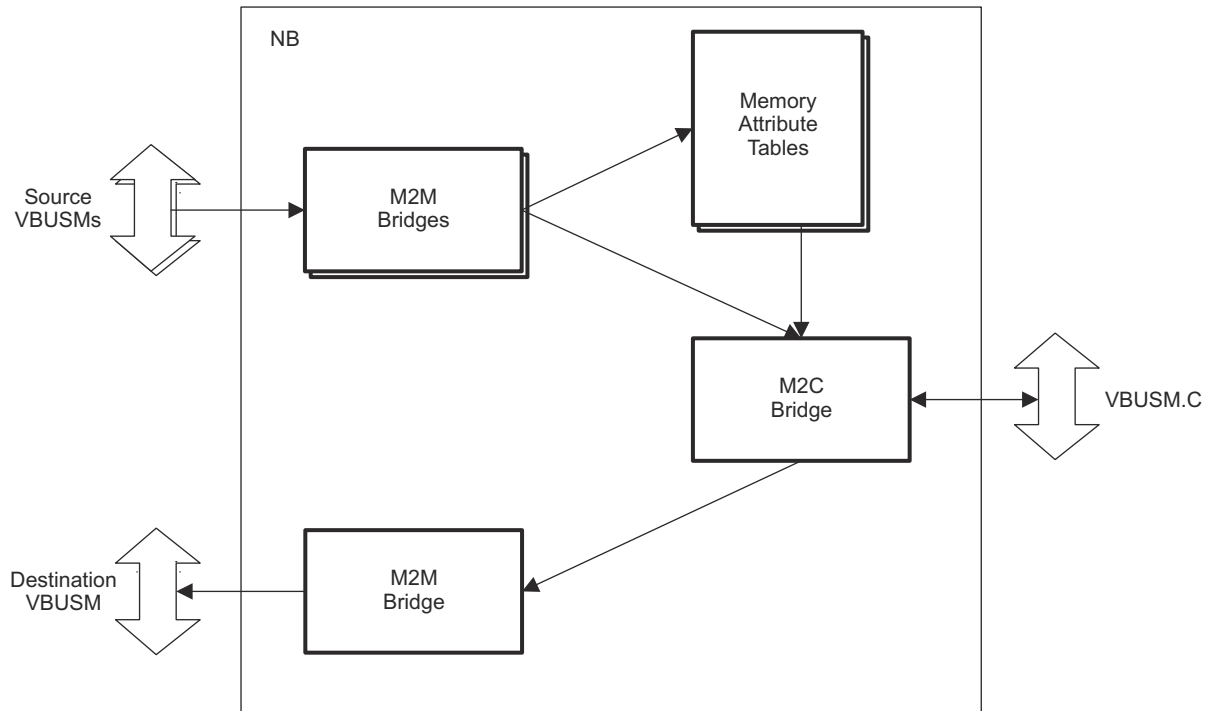

##### 10.2.9.1.2.1 Compliance to Standards

The module is compliant to the CBA 4.0 VBUSM specification and VBUSM.C annex.

##### 10.2.9.1.2.2 Features Not Supported

- Does not support fragmentation of VBUSM.C commands
- Does not support VBUSM.C coherence traffic

### 10.2.9.2 NB Functional Description

navss-020

**Figure 10-25. NB Block Diagram**

The CBA 4.0 North bridge, NB, bridges between CBA 4.0 compliant VBUSM interfaces and a three threaded CBA 4.0 compliant VBUSM.C interface. This is achieved by using M2M bridges to support all the M2M features and then an M2C bridge to convert the VBUSM interfaces to a VBUSM.C interface, which support duplex traffic. The M2M bridges allow for clock frequency conversion, data width conversion and fragmentation for the Source M2M bridge(s). This allows the M2C bridge to remain simple and operate at the VBUSM.C clock frequency and data width, as well as assume all required burst limitations have already been handled. Some additional features needed for the north bridge are implemented, including: adding memory attributes to source VBUSM transactions, and forcing a maximum outstanding read data limit.

#### 10.2.9.2.1 VBUSM Slave Interfaces

The slave interfaces on the bridge is the source VBUSM port to receive commands and return data and status. These ports have the defined prefix, smX (SoC Master, input to bridge), to identify them, where the X is the number to identify each port starting from zero. The number of these interfaces and bridges is shown in [Table 10-135](#) and [Table 10-136](#).

#### 10.2.9.2.2 VBUSM Master Interface

The master interface on the bridge is the destination VBUSM port to send commands and receive data and status. These ports have the defined prefix, ss (SoC Slave, output of bridge), to identify them.

It is important to note that any feature not supported in the optional signals for this bus that is supported on the VBUSM.C interface will not be corrected inside the bridge. Examples are excluding the emudbg pin on this bus but expecting VBUSM.C transactions with emudbg set to not create bus status errors on this VBUSM bus outside the bridge (as the bridge will just pass the returned status which could be an error if it does not support the emudbg pin).

#### 10.2.9.2.3 VBUSM.C Interfaces

The pair of interfaces on the bridge is the VBUSM.C port to send and receive commands and send and receive data and status. These ports will have the defined prefix, mm (Memory Master, output of bridge) and ms (Memory Slave, input to bridge), to identify them. These interfaces support three threads for sending and receiving traffic.

#### 10.2.9.2.3.1 Multi-Threading

The VBUSM.C interfaces use multi-threading to support both input and output traffic on the same data signals. The threads are used to separate that traffic. Thread 0 is used for commands to VBUSM.C, thread 1 is used for commands from VBUSM.C, and thread 2 is used for realtime commands to VBUSM.C. Any responses due to commands must use the same thread when returned.

#### 10.2.9.2.3.2 Write Command Crediting

VBUSM.C interfaces use credits for sending data phases. For writes and read responses to the MSMC (VBUSM.C consumer), there is a requirement that all credits for the write, including the command and all data phases, should be available before sending the command. Since the VBUSM.C data width is always half the max burst size on VBUSM.C, the write command must wait for a TAC credit available and 1 or 2 TDC credits available before the write can be sent.

#### 10.2.9.2.3.3 Early Credit Response

The VBUSM.C interfaces use the credit mechanism available. They do not check for full burst available credits before sending any piece of the burst (command or data). To prevent deadlocks, the connected VBUSM.C device must support sending early credit responses, before the entire burst is received.

#### 10.2.9.2.3.4 Priority Escalation

The VBUSM.C interface does not natively define a mechanism for priority escalation, since the cepriority signal is only valid when a command is sent, and can otherwise be ignored. To support this feature this bridge supports updating the cepriority output even if there is no valid command, so identify the highest priority of any pending commands when the bridge cannot sent a command, such as due to a lack of credits. The VBUSM.C consumer can assume the cepriority output from this bridge is always valid every cycle, and use the cepriority along with the priorities of all pending commands. When there are no pending commands, the cepriority output will be the lowest priority, 7.

#### 10.2.9.2.4 Source M2M Bridges

The source M2M bridges perform all the usual bridging functions from the source VBUSM interface to an internal VBUSM interface running at the same clock frequency and data width of the VBUSM.C interface. It also performs the fragmentation to sizes the VBUSM.C interface requires. It additionally performs full read data reassembly, orderid based ordering, and read data cacheline conversion.

#### 10.2.9.2.5 Destination M2M Bridge

The destination M2M bridge performs all the usual bridging functions to the destination VBUSM interface from an internal VBUSM interface running at the same clock frequency and data width of the VBUSM.C interface.

#### 10.2.9.2.6 M2C Bridge

The M2C bridge performs the protocol conversion and multi-threading of the VBUSM.C interface from the internal VBUSM interfaces. It also handles the cacheline conversion of the write data.

A VBUSM.C write with a dtype of 1 (CPU instruction) will be converted to a VBUSM write with a dtype of 0 (CPU data), as this condition is allowed in VBUSM.C but not in VBUSM.

#### 10.2.9.2.7 Memory Attribute Tables

The bridge can optionally include a memory attribute lookup table to add the coherence memory attributes required for VBUSM.C for VBUSM commands missing them. It is implemented using up to 4 tables, a table of 64-KB regions and 1 to 3 tables of 16-MB regions. The first table is meant to cover an internal memory with smaller granularity, while the second to fourth tables are meant to cover the external memory with a much larger size and larger granularity. The external memory has one to three regions as its address space might be fragmented in the SoC memory map. Starting address and number of table entries for each region are shown in [Table 10-135](#) and [Table 10-136](#).

When a command without memory attributes, an atype = 0, is input to the M2C bridge, this table performs the lookup in parallel and returns the memory attributes to the M2C bridge in the next cycle. If the atype is another value, it is assumed the memory attributes on the VBUSM interface are valid. The lookup is performed by matching the address against the starting addresses, assuming the successive regions always starts at later

address, including that the up to three 16-MB regions are given in increasing order. Then the offset from the starting address of the region and the region size, 64-KB or 16-MB, is used to calculate the entry of attributes for that address. Then a memory is read to retrieve the attributes and return them to the M2C bridge. An output FIFO is implemented to capture the attributes if they are not accepted immediately.

There is a memory attribute table module for each VBUSM slave interface. If the MAT is enabled, at least one of the 64-KB region and/or the first 16-MB region must be populated, or both. The second and third 16-MB regions are optional.

#### **10.2.9.2.8 Outstanding Read Data Limiter**

If a param defines a maximum outstanding read data byte count, then this function will track the requested read bytes against the limit. If a read command does not violate the total read bytes outstanding limit then the read is allowed to the VBUSM.C, otherwise it is stalled. When read data arrives from the VBUSM.C the outstanding count is reduced, allowing more read commands to be sent.

#### **10.2.9.2.9 Ordering**

Ordering becomes a concern due to the fact that the VBUSM commands are fragmented and not guaranteed to be returned in order by the VBUSM.C interface. This violates the CBA ordering rules for a single slave endpoint. So the bridge will force read data ordering based on the orderid signal across all masters, as a balance between cost and performance. This means that each read command received from the VBUSM interface with a particular orderid value will have their read data returned in exactly the same order. This means that even if the reads are from different masters, the data will still be returned in order, to reduce the amount of tracking the bridge has to perform. But, if the reads use different orderid values then that read data can be returned in any order, whichever is received first on the VBUSM.C interface.

#### **10.2.9.2.10 Quality of Service**

To support quality of service, QoS, the north bridge allows for configuring multiple VBUSM source interfaces. This not only allows defining particular sources to be realtime to achieve better qos, but also to load balance and effectively utilize any extra bandwidth provided by the VBUSM.C interface. There are registers (NB\_THREADMAP) allowing programming of which source interfaces map to which of the two VBUSM.C threads, normal or realtime traffic. All traffic on the source will always map to the defined thread.

Any sources mapped to the realtime thread will be arbitrated first, before any sources mapped to the normal thread, to provide the QoS. If there are multiple sources mapped to the same thread then they are arbitrated based on priority and if they are the same priority then by round robin.

To route return traffic from the VBUSM.C back to the correct VBUSM source, the orderid is used. As such, each source mapped to each thread must use a different orderid value in the SoC. This would mean that if there are 8 sources total, with 4 mapped to each thread, then each group of 4 should not share the same orderid for any traffic routed to it in the SoC to keep their pathid values unique. The bridge is configured to identify which VBUSM source uses which orderid value(s).

#### **10.2.9.2.11 IDLE Behavior**

The north bridge IDLE output is a combination of all the IDLE outputs from the components. These are combined and registered as the NB IDLE on the Destination VBUSM bus clock.

#### **10.2.9.2.12 Clock Power Management**

The north bridge provides internal clock power management for all major components: bridges and register modules. Each component will track its own activity and shut off the clock tree when there has been no activity for 12 cycles. There is a 1 cycle latency for starting up the clock once off, so bus transactions may be initially stalled. The bus early wakeup signals can be used to wakeup the clocks before the transactions arrives to remove some of the latency impact.

## 10.3 Peripheral DMA (PDMA)

This chapter describes the PDMA architecture in the device.

### 10.3.1 PDMA Controller

#### 10.3.1.1 PDMA Overview

The Peripheral DMA is a simple DMA which has been architected to specifically meet the data transfer needs of peripherals, which perform data transfers using memory mapped registers (MMRs) accessed via a standard non-coherent bus fabric. The PDMA module is located close to one or more peripherals which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only statically configured Transfer Request (TR) operations.

The PDMA is only responsible for performing the data movement transactions which interact with the peripherals themselves. Data which is read from a given peripheral is packed by a PDMA source channel into a PSI-L data stream which is then sent to a remote peer UDMA-P destination channel which then performs the movement of the data into memory. Likewise, a remote UDMA-P source channel fetches data from memory and transfers it to a peer PDMA destination channel over PSI-L which then performs the writes to the peripheral.

The PDMA architecture is intentionally heterogeneous (UDMA-P + PDMA) to right size the data transfer complexity at each point in the system to match the requirements of whatever is being transferred to or from. Peripherals are typically FIFO based and do not require multi-dimensional transfers beyond their FIFO dimensioning requirements, so the PDMA transfer engines are kept simple with only a few dimensions (typically for sample size and FIFO depth), hardcoded address maps, and simple triggering capabilities.

Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs round-robin scheduling between channels in order to share the underlying DMA hardware.

The PDMA is linked to the UDMA-P (NAVSS) either through a direct PSI-L connection, or through a PSI-L switch (PSILSS).

#### 10.3.1.1.1 PDMA Features

##### 10.3.1.1.1.1 MCU\_PDMA0 (MCU\_PDMA\_MISC\_G0) Features

The MCU\_PDMA0 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access units (write unit 0)
  - Provides a 32-bit wide VBUSP write only master interface for peripheral accesses
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0):
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 7 simultaneous destination (Tx) channels
- Supports up to 7 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

##### 10.3.1.1.1.2 MCU\_PDMA1 (MCU\_PDMA\_MISC\_G1) Features

The MCU\_PDMA1 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.

- Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 8 simultaneous destination (Tx) channels
- Supports up to 8 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### **10.3.1.1.1.3 MCU\_PDMA2 (MCU\_PDMA\_MISC\_G2) Features**

The MCU\_PDMA2 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 4 simultaneous destination (Tx) channels
- Supports up to 4 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### **10.3.1.1.1.4 MCU\_PDMA3 (MCU\_PDMA\_ADC) Features**

The MCU\_PDMA3 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 0 memory write access units
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 0 simultaneous destination (Tx) channels
- Supports up to 4 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.1.5 PDMA5 (PDMA\_MCAN) Features

The PDMA5 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 54 simultaneous destination (Tx) channels
- Supports up to 54 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports MCAN transfer mode only (does not support X-Y and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals
- Provides ECC support

#### 10.3.1.1.1.6 PDMA6 (PDMA\_MCASP\_G0) Features

The PDMA6 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to simultaneous destination (Tx) channels
- Supports up to simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.1.7 PDMA9 (PDMA\_SPI\_G0) Features

The PDMA9 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 16 simultaneous destination (Tx) channels
- Supports up to 16 simultaneous source (Rx) channels

- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals
- Provides ECC support

#### **10.3.1.1.1.8 PDMA10 (PDMA\_SPI\_G1) Features**

The PDMA10 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 16 simultaneous destination (Tx) channels
- Supports up to 16 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals
- Provides ECC support

#### **10.3.1.1.1.9 PDMA13 (PDMA\_USART\_G0) Features**

The PDMA13 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 2 simultaneous destination (Tx) channels
- Supports up to 2 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### **10.3.1.1.1.10 PDMA14 (PDMA\_USART\_G1) Features**

The PDMA14 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):

- Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
- Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 2 simultaneous destination (Tx) channels
- Supports up to 2 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.11 PDMA15 (PDMA\_USART\_G2) Features

The PDMA15 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 6 simultaneous destination (Tx) channels
- Supports up to 6 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

### 10.3.1.2 PDMA Functional Description

#### 10.3.1.2.1 PDMA Functional Blocks

Figure 10-26 shows the PDMA block diagram.

**Figure 10-26. PDMA Block Diagram**

#### Note

For detailed description of the PSI-L interface, see *Packet Streaming Interface Link (PSI-L)*.

#### 10.3.1.2.1.1 Scheduler

The scheduler block is responsible for monitoring the fullness level of the various FIFOs, monitoring input DMA triggering events, maintaining channel state information, and issuing credits to the Tx and Rx DMA units when it is time to perform each low-level read or write operation.

#### 10.3.1.2.1.2 Tx Per-Channel Buffers (TCP FIFO)

The Tx per-channel buffers implement channelized FIFOs for each DMA channel. A single logical data FIFO is provided for each destination DMA channel that is used for buffering payload data that has been pushed into the PDMA from the Tx PSI-L interface. The Tx per-channel buffers are always written with full Tx PSI-L wide words (except for EOL/EOP data phases) but are read on byte granularity from the Tx DMA units.

#### 10.3.1.2.1.3 Tx DMA Unit (Tx Engine)

The Tx DMA unit block implements all of the state machine functionality necessary to implement static TR type UTC destination channels. The Tx DMA unit waits until it is triggered by an incoming DMA event and then writes data from the Tx per-channel data FIFO associated with the channel to an external memory mapped target via a VBUSP controller interface. The number and width of the writes that are performed is in accordance with the parameters, which have been programmed via PSI-L into the static TR for the channel.

#### 10.3.1.2.1.4 Rx Per-Channel Buffers (RCP FIFO)

The Rx per-channel buffers implement a logical FIFO for each source DMA channel that is used for buffering payload data that has been fetched by the Rx DMA units. The buffers are byte-oriented on write so that the data from the Rx DMA units, which may not be full words, can be packed properly. The buffers are word-oriented on

read in accordance with the transport mechanism outlined in the PSI-L interface specification. Each channel in the Rx DMA controller maps directly onto a thread in the Rx PSI-L interface.

The Rx per-channel buffers block outputs queue fullness information to the scheduler block, which it then uses to determine when it should initiate DMA opportunities to backfill the buffers. The Rx per-channel buffers will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round-robin arbitration between the different threads for the use of the Rx PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

#### **10.3.1.2.1.5 Rx DMA Unit (Rx Engine)**

The Rx DMA unit block implements all of the state machine functionality necessary to implement static TR type UTC source channels. The Rx DMA unit waits until it is triggered by an incoming DMA event and then reads data from an external memory mapped source via a VBUSP controller read interface into the Rx per-channel data FIFO associated with the channel. The number and width of the writes that are performed is in accordance with the parameters, which have been programmed via PSI-L into the static TR for the channel.

#### **10.3.1.2.2 PDMA General Functionality**

##### **10.3.1.2.2.1 Operational States**

At any given time the PDMA can be in one of three different states as follows:

- **INIT:** This is the initial state of the machine during and immediately after reset. During this state, all of the RAMs inside the PDMA will be initialized to known values including the ECC redundant parity bits. While in the INIT state, the DMA will de-assert all 'ready' signals on all applicable target interfaces and will de-assert all 'request' signals on all applicable controller interfaces. The PDMA will automatically transition out of the INIT state into the IDLE state when all of the RAM initialization has been completed.
- **IDLE:** Once the PDMA leaves the INIT state, it enters the IDLE state whenever no outstanding transactions are pending on any of the PDMA interfaces (controller or target). The IDLE state is generally a transient state and is used by the PDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. As channels have work queued on them and transactions begin flowing into the system, the PDMA transitions to the ACTIVE state. When no more work is pending, or when the host pauses/disables active channels, or when the power management complex on the SoC desires to shut down the PDMA and asserts 'clock stop request', the PDMA will account for any outstanding transactions and will re-enter the IDLE state. The PDMA leaves the IDLE state anytime it generates or receives a transactions that requires a return response as those protocols dictate that the clock must remain running to avoid faulting the handshaking protocol.
- **ACTIVE:** The PDMA enters the ACTIVE state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent), the PDMA transitions to the IDLE state.

##### **10.3.1.2.2.2 Clock Stop**

The clock stop interface is a request/acknowledge interface used to coordinate the handshaking of properly stopping the main clock to the IP. Before attempting to perform a clock stop operation, software is required to teardown all active channels (via 'real time' registers in the BCDMA/PKTDMA, or PSIL register 0x408 in PSIL based peripherals), and after this is complete, also clear the global enable bit for all channels (via PSIL register 0x2 in BCDMA/PKTDMA and PSIL based peripherals). Attempting a clock stop on the IP without first performing the channel teardowns or clearing of global enable bits will result in IP specific behavior that may be UNDEFINED.

The PDMA will not drive clock stop IDLE or clock stop ACK while the global enable (PSIL register 0x2) is set for any channel.

##### **10.3.1.2.2.3 Emulation Control**

The emulation control input (EMUSUSP) and the per-channel emulation control FREE bit allow PDMA operation to be suspended on a per-channel basis. When the emulation suspend state is entered, the PDMA will stop

processing receive and transmit TRs for each channel at the next TR boundary. Any TR currently in reception or transmission will be halted at its next FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR.

Emulation control is implemented for compatibility with other peripherals. Each source and destination channel can be configured to either honor the suspend signal, or to 'free run' without regard to suspend. This is controlled via the PDMA\_PSILCFG\_TX\_RT\_ENABLE / PDMA\_PSILCFG\_RX\_RT\_ENABLE[0] FREE bit.

### 10.3.1.2.3 PDMA Events and Flow Control

The following sections describe the simplified mechanism that is provided on the PDMA for triggering and completion event generation.

#### 10.3.1.2.3.1 Channel Types

Each channel in the PDMA is configured at design time (and cannot be changed by software) to be either standard X-Y FIFO mode or MCAN channel or AASRC channel. Either of these two sections provide information about the channel type support in the device: *PDMA Features* and *PDMA Sources*.

When reading the sections below, ignore any information that concerns unsupported channel type.

##### 10.3.1.2.3.1.1 X-Y FIFO Mode

Most peripherals which are serviced by the PDMA follow the pattern of transferring 'X' bytes from a fixed, non-changing address in a burst 'Y' times for each triggering event that is received. The 'X' parameter is typically 1-16 bytes and the 'Y' parameter can be any integer up to 2048.

##### 10.3.1.2.3.1.2 MCAN Mode

The MCAN module is found to require a few minor differences than standard X-Y mode. First, buffer ownership on transmit is different in that the PDMA will start out owning the TX buffer space (instead of waiting for an initial DMA event from the MCAN). There is also a requirement to perform a write of a fixed value to a fixed address after each DMA event is serviced to pass ownership of a buffer back to the MCAN. Finally, there is an MCAN packet fragmentation requirement to place an 8-byte header on each 64-byte chunk that is transmitted and to remove the header from each 64-byte chunk (other than the first block) that is received.

##### 10.3.1.2.3.1.3 AASRC Mode

The AASRC mode of the PDMA is similar to the X-Y mode in that X specifies the sample width, any Y specifies the number of FIFO samples to transfer per DMA request, but in addition to this, a programmable FIFO list is supplied that allows a single PDMA channel to transfer data to multiple FIFOs. The FIFO list specifies which FIFOs to access, and in which order to access them. Both AASRC 'stream' and 'group' modes are supported in terms of DMA signalling and the FIFO memory map. When in AASRC mode, the entire PDMA operates exclusively in this mode. AASRC channels do not share the same PDMA as do XY and MCAN channels.

The following additional details apply to the PDMA in AASRC mode:

- Main features:
  - Up to 16 independent RX channels and 16 TX channels
    - Each channel represents a different data stream to either the paired-DMA or a McASP PDMA
  - Each channel can be configured to read or write any of the AASRC FIFOs in any order
  - Packing support for 1, 2, 3, and 4 byte samples
    - Can directly talk to a McASP using any McASP data format
    - Packing sample size is fixed for a given channel
  - Supports both 'group' and 'stream' AASRC signaling and FIFO memory maps
    - There is a single stream/group mode setting for each PDMA channel
- Additional details:
  - Each channel has a 'mask' of which DMA requests must fire to activate the channel
    - In stream mode, the mask specifies the all the FIFO DMA requests that must fire
    - In group mode, the mask specifies the one group DMA request that must fire
  - Each channel specifies an ordered list of how FIFOs should be accessed

- All channels use a common list, specifying a range of entry indices within that list
  - This allow each channel to use a varying number of list elements
- The order list can be processed multiple times per DMA request
  - The number of samples to be transferred per request must match the configured threshold for the DMA request in the AASRC
- All FIFOs are specified by index only
  - In the TX ordering table, the indices are assumed to be TX FIFOs
  - In the RX ordering table, the indices are assumed to be RX FIFOs
  - If a DMA channel is in group mode, the PDMA assumes the indices referenced by that channel represent group mode FIFOs; otherwise, it assumes stream mode FIFOs
- The PDMA has configured base addressed and inter-FIFO spans such that is can always convert from a FIFO index to the proper Stream or Group mode FIFO address

#### 10.3.1.2.3.2 Channel Triggering

Channels must be triggered in order for them to perform work. A local event input bus is provided on the PDMA and each bit in the input bus corresponds to the trigger for the channel with the same channel index as the bit index in the bus (bit 0 triggers channel 0, bit 1 triggers channel 1, etc.).

The PDMA provides a 2-bit counter per event input to accommodate startup latency in the channel.

#### 10.3.1.2.3.3 Completion Events

All transfers on PDMA are split TRs in that they have a paired-DMA half and a (static) PDMA half. Completion events are designed to be triggered from the paired-DMA half of the split TR.

#### 10.3.1.2.4 PDMA Transmit Operation

##### 10.3.1.2.4.1 Destination (Tx) Channel Allocation

A total of  $N$  destination channels are provided within the PDMA for concurrent transfers from Tx per-channel buffers to the various attached peripherals, where  $N$  is a design-time configurable paramater. Each Tx channel requires a single PSI-L thread. See *PDMA Sources* for Tx channel allocation for each PDMA.

##### 10.3.1.2.4.2 Destination (Tx) Channel Out-of-Band Signals

Table 10-140 shows how PSIL signals are handled for destination channels.

**Table 10-140. Tx Channel Out-of-Band Signals**

PSI-L Signal	XY/AASRC Mode	MCAN Mode
SOP	Ignored	Ignored
EOP	Ignored	Closes current MCAN packet
SOL	Ignored	Ignored
EOL	Ignored	Ignored
DROP	Ignored	Ignored
PKT_ERROR	Ignored	Ignored
PAUSE	Ignored	Ignored
TDOWN	Reflect in status; teardown when data marker reached	Reflect in status; teardown when data marker reached

##### 10.3.1.2.4.3 Destination Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will need to first pair the channel with a remote data source (normally a paired-DMA channel), setup the static TR for the channel, and enable the thread.

##### 10.3.1.2.4.3.1 PSI-L Destination Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The host will pair each destination PDMA channel with (typically) a corresponding source channel in the paired-DMA. The PDMA thread is configured to point to the paired-DMA thread and the paired DMA thread is configured to point to the PDMA thread. Once paired, the source channels in the paired-DMA will send all their data to the destination channel in the PDMA and

the destination channel in the PDMA will never see any data other than data from the source channel in the paired-DMA.

The following PSI-L registers are related to destination thread pairing:

- PDMA\_PSILCFG\_TX\_ENABLE
- PDMA\_PSILCFG\_TX\_CAPABILITIES
- PDMA\_PSILCFG\_TX\_BYTE\_COUNT
- PDMA\_PSILCFG\_TX\_RT\_ENABLE

Refer to their descriptions for further details.

#### **10.3.1.2.4.3.2 Static Transfer Request Setup**

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will send configuration transactions across PSI-L and will setup the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of 'X' and 'Y' parameters, but the field interpretation varies somewhat. The following PSI-L register bit fields are used to setup the static TR:

- PDMA\_PSILCFG\_TX\_STATIC\_TR[26-24] X
- PDMA\_PSILCFG\_TX\_STATIC\_TR[11-0] Y

Refer to their descriptions for further details.

#### **10.3.1.2.4.3.3 PSI-L Destination Thread Enables**

PSI-L destination threads must first be enabled in order to accept data. Threads are enabled or disabled by setting or clearing the ENABLE bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of write transactions.

#### **10.3.1.2.4.4 Data Transfer**

Packet transmission is accomplished within the PDMA by unpacking and moving data from the Tx per-channel FIFOs which were filled via the transmit PSI-L interface to specified memory mapped address ranges via the VBUSP controller interfaces. On the Tx side of the PDMA, these transfers are always writes. Each write transfer which is performed by the Tx DMA unit is to a destination address that is hardcoded in the channel at design time and of a size as specified in the static transfer request.

The sequences of logical transactions that are performed by the PDMA on the memory interface during transmit is dependent on the channel type. The following sections describe what will happen for the two different channel types.

##### **10.3.1.2.4.4.1 X-Y FIFO Mode Channel**

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter writes of 'X' parameter bytes to the data FIFO address specified for the channel. Each write that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the Tx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

##### **10.3.1.2.4.4.1.1 X-Y FIFO Burst Mode**

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. So for example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting the PDMA\_PSILCFG\_TX\_STATIC\_TR[31] BURST bit enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address will increment throughout the burst
- Bursts will be sub-divided to fit into a 64 byte transfer window
- One sample is transferred for every bus data phase
  - Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
  - Cannot burst 64-bit samples on a 32-bit bus (configure for 2×32-bit samples instead)
- PDMA will 'gap' the byte enables on writes as needed

#### **10.3.1.2.4.4.2 MCAN Mode Channel**

The PDMA channel will remain idle until data is received from the paired-DMA over the PSIL interface. At this time, the PDMA will immediately start copying packet bytes into the MCAN TX buffer corresponding the PDMA/MCAN channel. The number of bytes copied is smaller of the remaining bytes in the packet or the value of the 'Y' parameter. Once a TX buffer has been filled, the PDMA will transfer ownership of the buffer to MCAN by performing an MCAN register write. The PDMA will then wait to regain ownership of the TX buffer by waiting for the corresponding MCAN TX event. At this time, the PDMA will continue with refilling the TX buffer for the next packet fragment. On subsequent fills (until the end of packet is reached), the PDMA will skip over the 8-byte MCAN header, leaving the original contents from the initial fragment copy in place.

##### **10.3.1.2.4.4.2.1 MCAN Burst Mode**

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

#### **10.3.1.2.4.4.3 AASRC Mode Channel**

The AASRC channel is controlled primarily via the PDMA\_PSILCFG\_TX\_AASRC\_TX\_FIFO\_CONFIG register for the channel. This register holds three basic pieces of information:

- Whether the channel uses AASRC stream mode or group mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the PDMA\_PSILCFG\_TX\_AASRC\_TX\_FIFO\_CONFIG setting. The pulses for the individual events are latched and held by the PDMA until they all arrive. Once the channel activates, it will start reading FIFO index values from TX order table (PDMA\_PSILCFG\_TX\_AASRC\_TX\_ORDER\_TABLE0, PDMA\_PSILCFG\_TX\_AASRC\_TX\_ORDER\_TABLE1), starting at the configured FIRSTSLOT and ending with the LASTSLOT. The actual FIFO indices used are obtained from the ordering table. For example, say FIRSTSLOT=3 and LASTSLOT=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs written for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width written to the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel. Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

##### **10.3.1.2.4.5 Tx Pause**

The host initiates a channel pause by setting the PDMA\_PSILCFG\_TX\_RT\_ENABLE[9] PAUSE bit. The paused channel can be resumed by clearing the register bit.

##### **10.3.1.2.4.6 Tx Teardown**

The host initiates a channel teardown by setting the TDOWN bit in the paired-DMA (BCDMA/PKTDMA) channel that is paired with the PDMA. The paired-DMA communicates the teardown state through the PSI-L data channel, to ensure that the teardown is not seen by the PDMA until all the previous paired-

DMA data for the channel has been flushed. At this time, the teardown state will be reflected in the PDMA\_PSILCFG\_TX\_RT\_ENABLE[30] TDOWN bit. Note that a non-synchronized teardown can also be initiated by directly clearing the PDMA\_PSILCFG\_TX\_RT\_ENABLE[31] ENABLE.

Once all data has been flushed from the PDMA to the peripheral, the enable state of the PDMA channel will be cleared in the PDMA\_PSILCFG\_TX\_RT\_ENABLE register, but the teardown bit will remain high. Upon completion, no further packet processing will occur until the host re-configures the channel. If the channel fails to teardown because the peripheral has stopped responding, or if the paired-DMA transmission stops on a data boundary that is not compatible with the static TR configuration, the PDMA\_PSILCFG\_TX\_RT\_ENABLE[28] FLUSH bit can be set to guarantee that all data can be properly flushed from the internal pipe.

#### 10.3.1.2.4.7 Tx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully, even with flush enabled. If this occurs, the channel may be reset by clearing the PDMA\_PSILCFG\_TX\_ENABLE[31] ENABLE bit. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the paired-DMA peer. Resetting the paired-DMA peer is also required before re-initializing and re-pairing the channel.

#### 10.3.1.2.4.8 Tx Debug/State Registers

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. These registers appear on the PSI-L bus, near the static TR registers. For transmit, they are defined as follows:

- PDMA\_PSILCFG\_TX\_DEBUG\_1
- PDMA\_PSILCFG\_TX\_DEBUG\_2

Refer to their descriptions for further details.

#### 10.3.1.2.5 PDMA Receive Operation

##### 10.3.1.2.5.1 Source (Rx) Channel Allocation

A total of  $M$  destination channels are provided within the PDMA for concurrent transfers from the various attached peripherals into the Rx per-channel buffers and on to the PSI-L Rx Interface, where  $M$  is a design-time configurable parameter. Each Rx channel requires a single PSI-L thread. See *PDMA Sources* for Rx channel allocation for each PDMA.

##### 10.3.1.2.5.2 Source Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will need to first pair the channel with a remote data source (normally a paired-DMA channel), setup the static TR for the channel, and enable the thread.

##### 10.3.1.2.5.2.1 PSI-L Source Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The host will pair each source PDMA channel with (typically) a corresponding destination channel in the paired-DMA. The PDMA thread is configured to point to the paired-DMA thread and the paired-DMA thread is configured to point to the PDMA thread. Once paired, the source channels in the PDMA will send all their data to the source channel in the paired-DMA and the destination channel in the paired-DMA will never see any data other than data from the source channel in the PDMA.

Refer to their descriptions for further details.

##### 10.3.1.2.5.2.2 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will send configuration transactions across PSI-L and will set up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of 'X', 'Y', and 'Z' parameters, but the field interpretation varies somewhat. The following PSI-L register bit fields are used to setup the static TR:

- PDMA\_PSILCFG\_RX\_STATIC\_TR[26-24] X
- PDMA\_PSILCFG\_RX\_STATIC\_TR[11-0] Y

- PDMA\_PSILCFG\_RX\_STATIC\_TR\_Z[11-0] Z

Refer to their descriptions for further details.

#### 10.3.1.2.5.2.3 PSI-L Source Thread Enables

PSI-L source threads must be enabled in order to process peripheral DMA requests and send data. When disabled, DMA requests are ignored.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of read transactions.

#### 10.3.1.2.5.3 Data Transfer

Packet reception is accomplished within the PDMA by moving data from structures that are located in memory accessible via the VBUSP Memory Interface(s) onto the receive PSI-L interface. On the Rx side of the PDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx per-channel buffer for that channel. At a later time, the data is moved from the Rx per-channel FIFO to a remote peer DMA entity via the Rx PSI-L interface.

The sequences of logical transactions that are performed by the PDMA on the memory interface during receive is dependent on the channel type. The following sections describe what will happen for the two different channel types.

##### 10.3.1.2.5.3.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter reads of 'X' parameter bytes from the data FIFO address specified for the channel. Each read that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the Rx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same read unit.

##### 10.3.1.2.5.3.2 MCAN Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. The DMA event pins are mapped from the CAN filter event bits. The event bits determine the channel and one of two CAN buffers to use for the RX operation. This allows the RX buffers on the CAN to be configured in a ping/pong fashion, preventing the loss of CAN packet data. When an event is received, the PDMA will start copying bytes out of the corresponding CAN buffer. The number of bytes copied is equal to the value of the 'Y' parameter in the channel configuration. Once all data has been copied from the buffer, the PDMA transfers ownership of the buffer back to the CAN by writing a CAN register. It then waits for another RX DMA event. The PDMA can copy multiple CAN RX buffers to the same CPPI packet. It will not close out the CPPI packet until it has copied out a number of RX buffers equal to the 'Z' parameter in the channel configuration. On subsequent RX buffer copies, the MCAN will skip the first 8 bytes of the RX buffer, which is the MCAN packet header.

The mapping of MCAN filter events to MCAN channels and buffer is important for properly configuring the DMA. The mapping is defined as shown in [Table 10-141](#).

**Table 10-141. Mapping of MCAN Filter Events to MCAN Channels**

CAN FE2	CAN FE1	CAN FE0	Description
0	0	0	Not used
0	0	1	Not used
0	1	0	PDMA CAN channel offset 0, RX buffer 0
0	1	1	PDMA CAN channel offset 0, RX buffer 1
1	0	0	PDMA CAN channel offset 1, RX buffer 2
1	0	1	PDMA CAN channel offset 1, RX buffer 3
1	1	0	PDMA CAN channel offset 2, RX buffer 4
1	1	1	PDMA CAN channel offset 2, RX buffer 5

By using two filter entries in the CAN, software can setup a ping-pong buffer for a particular RX packet ID. For example, the following two filter entries will setup a ping-pong using RX buffers 0 and 1 for packet ID = 5 on CAN RX channel 0 (Table 10-142).

**Table 10-142. Ping-Pong Buffer Example in MCAN Mode**

Filter Entry	Packet Match ID	Filter Event Bits
0	5	0x2
1	5	0x3

#### 10.3.1.2.5.3.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

#### 10.3.1.2.5.3.3 AASRC Mode Channel

The AASRC channel is controlled primarily via the PDMA\_PSILCFG\_RX\_AASRC\_RX\_FIFO\_CONFIG register for the channel. This register holds three basic pieces of information:

- Whether the channel uses AASRC stream mode or group mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the PDMA\_PSILCFG\_RX\_AASRC\_RX\_FIFO\_CONFIG setting. The pulses for the individual events are latched and held by the PDMA until they all arrive. Once the channel activates, it will start reading FIFO index values from RX order table (PDMA\_PSILCFG\_RX\_AASRC\_RX\_ORDER\_TABLE0, PDMA\_PSILCFG\_RX\_AASRC\_RX\_ORDER\_TABLE1), starting at the configured FIRSTSLOT and ending with the LASTSLOT. The actual FIFO indices used are obtained from the ordering table. For example, say FIRSTSLOT=3 and LASTSLOT=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs read for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width read from the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel. Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

#### 10.3.1.2.5.4 Rx Pause

The host initiates a channel pause by setting the PDMA\_PSILCFG\_RX\_RT\_ENABLE[29] PAUSE bit. The paused channel can be resumed by clearing the register bit.

#### 10.3.1.2.5.5 Rx Teardown

The host initiates a RX channel teardown by setting the PDMA\_PSILCFG\_RX\_RT\_ENABLE[30] TDOWN bit for the target RX channel. The PDMA communicates the teardown state to the paired-DMA through the PSI-L data channel, to ensure that the teardown is not seen by the paired-DMA until all the previous PDMA data for the channel has been flushed.

The PDMA will not stop reading peripheral data until it reaches a FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR. It will always attempt to complete the 'Y' count for the current event being processed. Upon reaching a stopping point, the PDMA will then clear the ENABLE bit in the pairing register, however the TDOWN bit will remain set. No further packet processing will occur until the host re-configures the channel. The teardown process will propagate to the paired-DMA and its final status can be checked there.

#### 10.3.1.2.5.6 Rx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully. If this occurs, the channel may be reset by clearing the PDMA\_PSILCFG\_RX\_ENABLE[31] ENABLE bit. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the paired-DMA peer. Resetting the paired-DMA peer is also required before re-initializing and re-pairing the channel.

#### 10.3.1.2.5.7 Rx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. These registers appear on the PSI-L bus, near the static TR registers. For receive, they are defined as follows:

Refer to their descriptions for further details.

#### 10.3.1.2.6 PDMA ECC Support

The PDMA optionally integrates an ECC aggregator module that consolidates the ECC configuration and status bits for all the ECC-supported memories within the PDMA. The ECC aggregator provides a single end-of-interrupt (EOI) handshake based interrupt to the host (for both single and double error detections), and a standard 32-bit VBUSP interface for configuring and querying the various ECC wrappers via their respective register set.

In this device, only PDMA5, PDMA9 and PDMA10 include an ECC aggregator.

For detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of PDMA ECC aggregators, see *PDMA Registers*.

### 10.3.1.3 PDMA Registers

### 10.3.1.3.1 PDMA PSI-L TX Configuration Registers

Table 10-144 lists the PDMA PSI-L TX configuration registers (PDMA\_PSILCFG\_TX). These registers are not memory mapped and are accessed indirectly via CFG\_PROXY modules in NAVSS.

**Table 10-143. PDMA\_PSILCFG\_TX Instances**

Instance	Base Address
PDMA_PSILCFG_TX	N/A

**Table 10-144. PDMA\_PSILCFG\_TX Registers**

Offset	Acronym	Register Name	PDMA_PSILCFG_TX Physical Address
2h	<a href="#">PDMA_PSILCFG_TX_ENABLE</a>	TX enable register	N/A
40h	<a href="#">PDMA_PSILCFG_TX_CAPABILITIES</a>	TX local capabilities register	N/A
400h	<a href="#">PDMA_PSILCFG_TX_STATIC_TR</a>	TX static transfer request (X, Y) register	N/A
402h	<a href="#">PDMA_PSILCFG_TX_DEBUG_1</a>	TX debug/state register 1	N/A
403h	<a href="#">PDMA_PSILCFG_TX_DEBUG_2</a>	TX debug/state register 2	N/A

### 10.3.1.3.1.2 PDMA\_PSILCFG\_TX\_CAPABILITIES Register (Offset = 40h) [reset = Xh]

PDMA\_PSILCFG\_TX\_CAPABILITIES is shown in [Figure 10-28](#) and described in [Table 10-148](#).

Return to [Summary Table](#).

Local Capabilities Register. This register provides the width and count of the credits for which buffering is available in the local thread. This register can be read by the system configuration software to determine what values to place in the following registers of the source paired thread:

- PDMA\_PSILCFG\_RX\_PEER\_CREDIT and PDMA\_PSILCFG\_RX\_PEER\_THREAD\_ID

This register is only implemented for destination threads.

**Table 10-147. PDMA\_PSILCFG\_TX\_CAPABILITIES

### 10.3.1.3.1.3 PDMA\_PSILCFG\_TX\_STATIC\_TR Register (Offset = 400h) [reset = 0h]

PDMA\_PSILCFG\_TX\_STATIC\_TR is shown in [Figure 10-29](#) and described in [Table 10-150](#).

Return to [Summary Table](#).

Static Transfer Request (X, Y) Register. This register is used to define the 'X' and 'Y' parameters in a static TR.

**Table 10-149. PDMA\_PSILCFG\_TX\_STATIC\_TR Instances**

Bit	Field	Type	Reset	Description
31	BURST	R/W	0h	<b>X-Y FIFO mode static TR:</b> When set, enables VBUSP burst mode on this channel. See the XY burst description for more information.  <b>MCAN mode static TR:</b> When set, enables VBUSP burst mode on this channel. See the MCAN burst description for more information.  <b>AASRC mode static TR:</b> Not used.
30	ACC32	R/W	0h	<b>X-Y FIFO mode static TR:</b> When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.  <b>MCAN mode static TR:</b> Not used.  <b>AASRC mode static TR:</b> When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
29-27	RESERVED	R	0h	Reserved

**Table 10-150. PDMA\_PSILCFG\_TX\_STATIC\_TR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26-24	X	R/W	0h	<p><b>X-Y FIFO mode static TR:</b> Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0h = 8 bits; 1h = 16 bits; 2h = 24 bits; 3h = 32 bits; 4h = 64 bits; 5h-7h = RESERVED.</p> <p><b>MCAN mode static TR:</b> Not used.</p> <p><b>AASRC mode static TR:</b> Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0h = 8 bits; 1h = 16 bits; 2h = 24 bits; 3h = 32 bits; 4h = 64 bits; 5h-7h = RESERVED.</p>
23-12	RESERVED	R	0h	Reserved
11-0	Y	R/W	0h	<p><b>X-Y FIFO mode static TR:</b> Element count. This field specifies how many elements to transfer each time a trigger is received on the channel.</p> <p><b>MCAN mode static TR:</b> Buffer Size. This field specifies how many bytes should be written to an MCAN TX buffer. This field includes the 8-byte MCAN header on the initial packet fragment. The PDMA will break up the source packet into fragments of this buffer size, copying the 8-byte MCAN header for the initial fragment, and then skipping it for each additional fragment and thus reusing the header from the first fragment. A buffer size less than 16 is treated as 16, and a buffer size greater than 72 is treated as 72.</p> <p><b>AASRC mode static TR:</b> FIFO element count. In AASRC mode, a channel can service multiple FIFOs using a list supplied in its FIFO configuration. This field specifies how many times to service the FIFO list, hence how many elements to transfer from each FIFO, each time a trigger is received on the channel. Note for each loop specified by the value of Y, the entire list is processed. For example, if the FIFO list is 0, 1, 2, 3, and Y is set to 2 loops, the FIFOs are serviced in the order: 0, 1, 2, 3, 0, 1, 2, 3.</p>

#### 10.3.1.3.1.4 PDMA\_PSILCFG\_TX\_DEBUG\_1 Register (Offset = 402h) [reset = 0h]

PDMA\_PSILCFG\_TX\_DEBUG\_1 is shown in [Figure 10-30](#) and described in [Table 10-152](#).

Return to [Summary Table](#).

Debug/State Register 1. The debug/state registers give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations.

**Table 10-151. PDMA\_PSILCFG\_TX\_DEBUG\_1 Instances**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-0	Y	R/W	0h	This field holds the current Y count. In X-Y FIFO mode, this is the number of X sized samples yet to write to the peripheral for the DMA event being serviced. In MCAN mode, this field holds the next write offset to use when writing to the CAN TX buffer.

### 10.3.1.3.1.5 PDMA\_PSILCFG\_TX\_DEBUG\_2 Register (Offset = 403h) [reset = 0h]

PDMA\_PSILCFG\_TX\_DEBUG\_2 is shown in [Figure 10-31](#) and described in [Table 10-154](#).

Return to [Summary Table](#).

Debug/State Register 2. The debug/state registers give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations.

Bit	Field	Type	Reset	Description
31	INEVENT	R/W	0h	When set, the PDMA is in the middle of processing a FIFO event.
30	FLUSH	R/W	0h	When set, the PDMA is processing in a flushing state, where it runs without waiting for DMA requests and without writing data to the peripheral. It is only operating its internal state machine to allow internal data pipes to drain properly.
29	PAUSE	R/W	0h	When set, the PDMA waiting in a paused state. This bit will clear when data starts flowing again from the UDMA-P.
28	DATA	R/W	0h	When set, there is a non-zero amount of data still waiting to be written to the peripheral.
27	XDATA	R/W	0h	When set, there is enough data still waiting to be written to the peripheral to start servicing a peripheral DMA event.
26-24	RESERVED	R	0h	Reserved
23-20	STATE	R/W	0h	This code reflects the current state of the PDMA channel, and is specific to the current implementation.
19-16	EVENTCNT	R/W	0h	This field holds the number of backlogged DMA events yet to be serviced.
15-0	RESERVED	R	0h	Reserved

### 10.3.1.3.1.6 PDMA\_PSILCFG\_TX\_BYTE\_COUNT Register (Offset = 404h) [reset = 0h]

PDMA\_PSILCFG\_TX\_BYTE\_COUNT is shown in [Figure 10-32](#) and described in [Table 10-156](#).

Return to [Summary Table](#).

Byte Count Register. This register contains the number of bytes that have been written to the VBUSP mapped peripheral.

**Table 10-155. PDMA\_PSILCFG\_TX\_BYTE\_COUNT Instances**

Instance	Physical Address
PDMA_PSILCFG_TX	N/A

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

**Table 10-156. PDMA\_PSILCFG\_TX\_BYTE\_COUNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	BYTES	R/W	0h	This register contains the number of bytes that have been read from the VBUSP mapped peripheral. The register is write-to-decrement, so running counts can be tracked by reading register and then writing back the value that was read. It will wrap on overflow. It will reset to zero on a channel reset.

### 10.3.1.3.1.7 PDMA\_PSILCFG\_TX\_AASRC\_TX\_FIFO\_CONFIG Register (Offset = 405h) [reset = 0h]

PDMA\_PSILCFG\_TX\_AASRC\_TX\_FIFO\_CONFIG is shown in [Figure 10-33](#) and described in [Table 10-158](#).

Return to [Summary Table](#).

AASRC Tx FIFO configuration register.

**Table 10-157.**  
**PDMA\_PSILCFG\_TX\_AASRC\_TX\_FIFO\_CONFIG**  
**Instances**

Instance	Physical Address
PDMA_PSILCFG_TX	N/A

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

**Table 10-158. PDMA\_PSILCFG\_TX\_AASRC\_TX\_FIFO\_CONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	GROUPMODE	R/W	0h	When set, the channel is in 'group mode'. It will look for group mode DMA requests, and access the group mode FIFOs. When clear, the channel is 'stream mode'. It will look for stream FIFO DMA requests, and access the stream mode FIFOs.
30	DMAREQRESET	R/W	0h	When set, resets any latched DMA request using the DMAREQMASK. This bit is self-clearing. It should be used to synchronize the AASRC event status with the PDMA in the event that the AASRC has been previously used and it is not known if the PDMA may have latched, and is holding, previous DMA requests.
29-24	RESERVED	R	0h	Reserved
23-20	LASTSLOT	R/W	0h	This is the index (0-15) of the last slot in the TX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
19-16	FIRSTSLOT	R/W	0h	This is the index (0-15) of the first slot in the TX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.

**Table 10-158. PDMA\_PSILCFG\_TX\_AASRC\_TX\_FIFO\_CONFIG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
15-0	DMAREQMASK	R/W	0h	<p>This field holds a set of flags indicating which AASRC DMA requests must fire in order for this channel to activate.</p> <p>In stream mode, these 16 flags correspond to the 16 DMA requests for each TX FIFO. The flags corresponding to all TX FIFOs involved with the channel should be set to 1.</p> <p>In group mode, these flags indicate which group mode DMA requests must fire. In this case, only bits [3:0] are relevant and only one bit should be set to 1 as a DMA channel only services a single group.</p>

### 10.3.1.3.1.8 PDMA\_PSILCFG\_TX\_AASRC\_TX\_ORDER\_TABLE0 Register (Offset = 406h) [reset = 0h]

PDMA\_PSILCFG\_TX\_AASRC\_TX\_ORDER\_TABLE0 is shown in [Figure 10-34](#) and described in [Table 10-160](#).

Return to [Summary Table](#).

R-0h					R/W-0h	R-0h	R/W-0h

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

**Table 10-164. PDMA\_PSILCFG\_TX\_RT\_ENABLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	ENABLE	R/W	0h	When set, the TX channel is enabled. When cleared, the TX channel is disabled. When disabled, it discards all held data. It clears DMA event counts and ignores all future DMA events from the peripheral. It maintains data exchange with the UDMA-P so that credit handshake is not disrupted. A 'hard teardown' can be performed by directly clearing this bit. Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.
30	TDOWN	R/W	0h	When set, the channel will commence a TX channel teardown procedure. To perform a TX teardown, the teardown bit should be set in the UDMA-P and it will automatically propagate to this register bit with the normal flow of peripheral data. Once the channel is fully stopped and ready to be reused (including returning all credits), the ENABLE bit is cleared.
29	PAUSE	R/W	0h	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals but will not act on them. The PAUSE bit can be cleared and data will resume.

**Table 10-164. PDMA\_PSILCFG\_TX\_RT\_ENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
28	FLUSH	R/W	0h	When set, causes all TX channel data to be discarded instead of being written to the peripheral. It essentially allows the TX engine to 'free run' without DMA requests from the peripheral (it will also override 'pause'). This bit should be set only when a channel fails to complete its teardown procedure normally because a peripheral is no longer functioning or because data flow was halted on a boundary that is not compatible with the static TR configuration.
27-3	RESERVED	R	0h	Reserved
2	ERROR	R/W	0h	When set, the channel has encountered a PSI-L protocol violation. The ERROR bit can only be set by hardware and can only be cleared by software. Once this bit is set, the channel should be fully reset and re-initialized via the PSI-L pairing registers.
1	IDLE	R	0h	This is a read-only bit that signifies that the disabled thread is also idle. This bit is read only and can only become set if the ENABLE bit is cleared.
0	FREE	R/W	0h	When cleared, the channel honors the debug suspend signal. When set, the channel will 'free run', regardless of the value of debug suspend.

### 10.3.1.3.2 PDMA PSI-L RX Configuration Registers

Table 10-166 lists the PDMA PSI-L RX configuration registers (PDMA\_PSILCFG\_RX). These registers are not memory mapped and are accessed indirectly via CFG\_PROXY modules in NAVSS.

**Table 10-165. PDMA\_PSILCFG\_RX Instances**

Bit	Field	Type	Reset	Description
31	EOL	R/W	0h	EOL mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
30-12	RESERVED	R	0h	Reserved

**Table 10-176. PDMA\_PSILCFG\_RX\_STATIC\_TR\_Z Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11-0	Z	R/W	0h	<p><b>X-Y FIFO mode static TR:</b> FIFO count. This field specifies how many full FIFO operations comprise a complete packet. When the count has been reached, the PDMA will close the packet with an EOP indication. If this parameter is set to NULL, then no packet delineation is supplied by the PDMA and all framing is controlled via the UDMA-P TR.</p> <p><b>MCAN mode static TR:</b> Buffer Count. This field specifies how many MCAN RX buffers should be read before closing the CPPI packet with an EOP indication. When this count is greater than 1, multiple MCAN RX buffers will be read into a single CPPI packet buffer. The 8-byte MCAN header will be skipped on subsequent MCAN buffer reads. Setting this field to NULL will suppress all packet delineation, and should be avoided.</p> <p><b>AASRC mode static TR:</b> FIFO count. This field specifies how many full FIFO operations comprise a complete packet. When the count has been reached, the PDMA will close the packet with an EOP indication. If this parameter is set to NULL, then no packet delineation is supplied by the PDMA and all framing is controlled via the UDMA-P TR.</p>

### 10.3.1.3.2.6 PDMA\_PSILCFG\_RX\_DEBUG\_1 Register (Offset = 402h) [reset = 0h]

PDMA\_PSILCFG\_RX\_DEBUG\_1 is shown in [Figure 10-42](#) and described in [Table 10-178](#).

Return to [Summary Table](#).

Debug/State Register 1. The debug/state registers give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations.

**Table 10-177. PDMA\_PSILCFG\_RX\_DEBUG\_1  
Instances**

**Table 10-178. PDMA\_PSILCFG\_RX\_DEBUG\_1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	Z	R/W	0h	This field holds the current Z count. In X-Y FIFO mode, this field holds the 1 based FIFO count of the FIFO being currently read, or the number of FIFO completions when the current operation completes. In MCAN mode, this field holds the zero based buffer index of the buffer currently being read, or the number of previously completed buffers.
15-0	Y	R/W	0h	This field holds the current Y count. In X-Y FIFO mode, this is the number of X sized samples yet to be read from the peripheral for the DMA event being serviced. In MCAN mode, this field holds the next read offset to use when read to the CAN RX buffer.

### 10.3.1.3.2.7 PDMA\_PSILCFG\_RX\_DEBUG\_2 Register (Offset = 403h) [reset = 0h]

PDMA\_PSILCFG\_RX\_DEBUG\_2 is shown in [Figure 10-43](#) and described in [Table 10-180](#).

Return to [Summary Table](#).

Debug/State Register 2. The debug/state registers give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations.

**Table 10-179. PDMA\_PSILCFG\_RX\_DEBUG\_2 Instances**

**Table 10-180. PDMA\_PSILCFG\_RX\_DEBUG\_2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	INEVENT	R/W	0h	When set, the PDMA is in the middle of processing a FIFO event.
30	TDOWN	R/W	0h	When set, the PDMA is processing a teardown operation. This bit is set simultaneously with the teardown bit in the source (RX) RT enable register. This bit will clear when the teardown is complete, regardless as to if the teardown bit in the pairing register is cleared or not. The teardown will propagate to the UDMA-P and its full completion status can be checked there.
29	PAUSE	R/W	0h	When set, the PDMA is stopped in a paused state. This bit will clear if the channel is unpaused or disabled.
28	SPACE	R/W	0h	When set, there is a non-zero amount of internal FIFO space available to hold new read data.
27	XSPACE	R/W	0h	When set, there is enough internal FIFO space available to start servicing a peripheral DMA event.
26	BUFFER	R/W	0h	This is the current RX buffer (0/1) for the current MCAN receive operation.
25-24	RESERVED	R	0h	Reserved
23-20	STATE	R/W	0h	This code reflects the current state of the PDMA channel, and is specific to the current implementation.
19-16	EVENTCNT	R/W	0h	This field holds the number of backlogged DMA events yet to be serviced.

**Table 10-182. PDMA\_PSILCFG\_RX\_BYTE\_COUNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	BYTES	R/W	0h	This register contains the number of bytes that have been read from the VBUSP mapped peripheral. The register is write-to-decrement, so running counts can be tracked by reading register and then writing back the value that was read. It will wrap on overflow. It will reset to zero on a channel reset.

### 10.3.1.3.2.9 PDMA\_PSILCFG\_RX\_AASRC\_RX\_FIFO\_CONFIG Register (Offset = 405h) [reset = 0h]

PDMA\_PSILCFG\_RX\_AASRC\_RX\_FIFO\_CONFIG is shown in [Figure 10-45](#) and described in [Table 10-184](#).

Return to [Summary Table](#).

AASRC Rx FIFO configuration register.

**Table 10-184. PDMA\_PSILCFG\_RX\_AASRC\_RX\_FIFO\_CONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	GROUPMODE	R/W	0h	When set, the channel is in 'group mode'. It will look for group mode DMA requests, and access the group mode FIFOs. When clear, the channel is 'stream mode'. It will look for stream FIFO DMA requests, and access the stream mode FIFOs.
30	DMAREQRESET	R/W	0h	When set, resets any latched DMA request using the DMAREQMASK. This bit is self-clearing. It should be used to synchronize the AASRC event status with the PDMA in the event that the AASRC has been previously used and it is not known if the PDMA may have latched, and is holding, previous DMA requests.
29-24	RESERVED	R	0h	Reserved
23-20	LASTSLOT	R/W	0h	This is the index (0-15) of the last slot in the RX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
19-16	FIRSTSLOT	R/W	0h	This is the index (0-15) of the first slot in the RX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.

**Table 10-184. PDMA\_PSILCFG\_RX\_AASRC\_RX\_FIFO\_CONFIG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
15-0	DMAREQMASK	R/W	0h	<p>This field holds a set of flags indicating which AASRC DMA requests must fire in order for this channel to activate.</p> <p>In stream mode, these 16 flags correspond to the 16 DMA requests for each RX FIFO. The flags corresponding to all RX FIFOs involved with the channel should be set to 1.</p> <p>In group mode, these flags indicate which group mode DMA requests must fire. In this case, only bits [3:0] are relevant and only one bit should be set to 1 as a DMA channel only services a single group.</p>

### 10.3.1.3.2.10 PDMA\_PSILCFG\_RX\_AASRC\_RX\_ORDER\_TABLE0 Register (Offset = 406h) [reset = 0h]

PDMA\_PSILCFG\_RX\_AASRC\_RX\_ORDER\_TABLE0 is shown in [Figure 10-46](#) and described in [Table 10-186](#).

Return to [Summary Table](#).

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

**Table 10-190. PDMA\_PSILCFG\_RX\_RT\_ENABLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	ENABLE	R/W	0h	When set, the RX channel is enabled. When cleared, the RX channel is disabled. When disabled, the channel ignores all DMA events from the peripheral. It maintains proper data transfers with the UDMA-P such that the credit handshake is not disrupted. However, unlike teardown, it does not close out the current open packet. Thus the TDOWN bit should always be used to disable an RX channel instead of manually clearing this bit. Failing to use teardown may result in stale data remaining in the internal RX FIFO, which would also prevent the channel from going idle without a channel reset. Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.
30	TDOWN	R/W	0h	When set, the channel will commence a RX channel teardown procedure. It will stop on the next FIFO boundary. It then clears the DMA event count and ignores all future DMA events from the peripheral. After stopping peripheral reads, the PDMA sends a teardown message to the UDMA-P that also closes the current packet with an EOP. If no packet is open at the time of the teardown, the message also includes SOP. The EOP teardown message may or may not contain final packet data. Once the channel teardown is complete and ready to be reused, the ENABLE bit is cleared.

**Table 10-190. PDMA\_PSILCFG\_RX\_RT\_ENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
29	PAUSE	R/W	0h	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals but will not act on them. The PAUSE bit can be cleared and data will resume. Pause will not stop teardown from completing.
28-2	RESERVED	R	0h	Reserved
1	IDLE	R	0h	This is a read-only bit that signifies that the paused or disabled channel is also idle. It can only become set if PAUSE is set or ENABLE is cleared.
0	FREE	R/W	0h	When cleared, the channel honors the debug suspend signal. When set, the channel will 'free run', regardless of the value of debug suspend.

### 10.3.1.3.2.13 PDMA\_PSILCFG\_RX\_DEBUG\_3 Register (Offset = 40Fh) [reset = 0h]

PDMA\_PSILCFG\_RX\_DEBUG\_3 is shown in [Figure 10-49](#) and described in [Table 10-192](#).

Return to [Summary Table](#).

Debug/State Register 3. The debug/state registers give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations.

**Table 10-191. PDMA\_PSILCFG\_RX\_DEBUG\_3  
Instances**

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

**Table 10-192. PDMA\_PSILCFG\_RX\_DEBUG\_3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	Z	R/W	0h	This field holds the full width value of the current Z count. In X-Y FIFO mode, this field holds the 1 based FIFO count of the FIFO being currently read, or the number of FIFO completions when the current operation completes. In MCAN mode, this field holds the zero based buffer index of the buffer currently being read, or the number of previously completed buffers.

## 10.4 Data Routing Unit (DRU)

This section describes the SoC level Data Routing Units (DRUs) for the device.

### Note

There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as described in this section. For the differences between all DRUs, see [Section 10.4.3.8](#).

### 10.4.1 DRU Overview

The data routing unit (DRU) is a high bandwidth, flexible routing engine with programmable DMA transfer requests. It enables user to perform high speed data transfers between memory mapped slave endpoints, processor caches and shared caches. DRU behaves like a DMA transfer controller, moving data at CPU frequency.

The DRU supports the following features:

- Programmable configuration registers for direct transfer request submission
  - A dedicated atomic register set that requires entire TR sent in a single burst
  - Three nonatomic register sets that allow TR to be written in separate burst and a write to the SUBMIT\_WORD0 register triggers the TR
- Read and write command queues
  - Five different queues with a split arbitration between fixed priority and round robin arbitration
  - Each channel can be configured to go to one of these queues
- Programmable priority for each queue
  - Allows setting priority for commands relative to other masters in the system
- One dedicated read port and one dedicated write port to generate independent read and write commands
  - Generates one read command every cycle
  - Generates one write data phase every cycle
  - Moves the data at CPU frequency
  - Optimizes transfers up to 128 byte boundaries
- Support for triggers to gate levels of the DMA loop
  - Supports one dedicated local trigger
  - Supports two dedicated external global triggers from the PSI-L
  - All triggers can be overwritten and controlled by software instead of hardware based event
- Support for region based and channelized firewall
  - Region based firewall intended to protect DRU configuration registers within a programmatically specified range
  - Channelized firewall that protects:
    - The real time configuration registers for each channel
    - The TR submission registers for each channel
    - The data transfers for each channel
- Data formatting networks
  - Circular addressing support for one side of the transfer
- Independent 48-bit address fields for source and destinations
- Up to four dimensional data transfers
  - Has independent source and destination index for up to four dimensional transfers
- Error Handling
  - Debug support through memory mapped registers
  - Data transfer error reports
- Error detection and Correction
  - Full SEC/DED support for the incoming data
  - Full SEC/DED protection each entry in the TR queues
  - Single bit parity support for each 32-bit word in the data buffer

- Parity protection for the address
- PSI-L Interface
  - Receive requests for pre-warm of L2 or L3 Cache
  - Receive TR requests from the UDMA
  - Send response TRs
  - Receive data from a remote UTC
  - Send data to a remote UTC
  - Maintains 2D formatting across PSI-L if requested in TR
- Feature enhancements for DRU R30:
  - IO memory management unit and micro-TLB
    - Features integrated uTLB (Translation Look aside Buffer)
    - Supports virtual addresses and physical addresses in TR requests
    - A read and write uTLB with 2 entries per uTLB
    - Communicates through PSI-L to IOMMU
  - Compression and Decompression

Unsupported features:

- Transpose data between source and destination memory to memory transfers

#### 10.4.1.1 Data Routing Unit (DRU) Ports

## 10.4.2 DRU Integration

This section describes the SoC level DRUs integration in the device, including information about clocks, resets, and hardware requests.

---

### Note

There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as the SoC level DRUs. For the differences between all DRUs, see [Section 10.4.3.8](#). For integration details about the VPAC0 and DMPAC0 DRUs, see *Vision Pre-processing Accelerator (VPAC)* and *Depth and Motion Perception Accelerator (DMPAC)*.

---

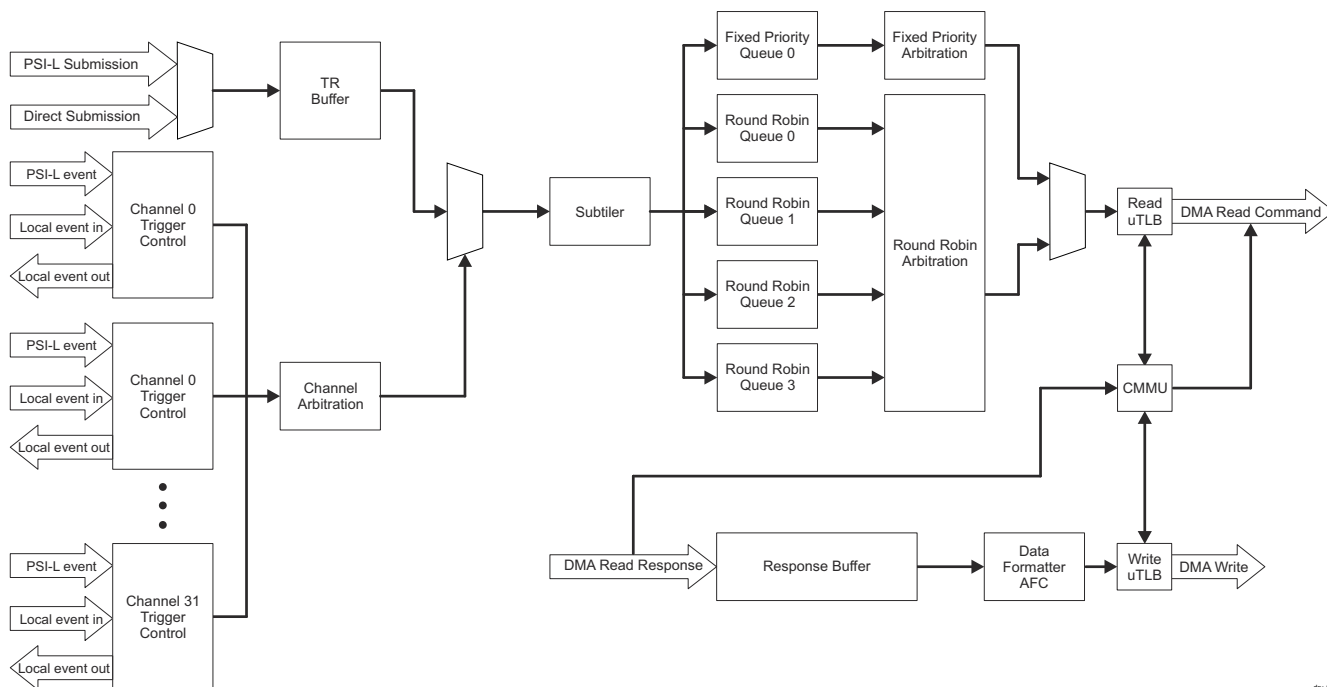

## 10.4.3 DRU Functional Description

### Note

This section describes the SoC level Data Routing Units (DRUs) for the device. There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as described in this section and its subsections. For the differences between all DRUs, see [Section 10.4.3.8](#).

### 10.4.3.1 DRU Basic Functionality

Figure 10-50 shows the DRU functional diagram.

**Figure 10-50. DRU Functional Diagram**

The DRU receives commands to transfer data from one location to another called Transfer Requests (TRs) or to send messages to CPUs or MMUs to pre-warm logic called Cache Requests (CRs). The DRU can receive these commands through the following mechanisms:

- A direct write to the DRU submission registers
- TR submission over PSI-L from external UDMA-C

The previously described mechanisms of receiving TRs and CRs are also referred to as TR submission (see, [Section 10.4.3.1.3](#)). In other words, the DRU memory-to-memory transfers work by receiving TR or CR through TR submission. Then the corresponding request (TR or CR) is placed in a queue to be processed.

Once the TR has been received the Channel Trigger Control block detects if the triggers specified in the TR have been received. If the trigger is not specified (value of 0x0 in the TRIGGER0 or TRIGGER1 fields of the TR FLAGS field), the treatment is as it is always received. Once received the channel is considered active. All active channels are involved in arbitration process for using the subtiler. The channel arbitration is based on the channel queue. There are queues using a fixed priority arbitration - the lowest channel has the highest priority. There are also round robin queues that use the same algorithm as in the fixed priority queue arbitration (lowest channel - highest priority) but on a round robin basis.

The subtiler takes the winning channel (that is, channel with highest priority) and generates the next 1D or 2D transfer (called also sub-TR) based on the trigger size, transfer type and event size specified in the TR. Then the subtiler places that sub-TR into the queue specified for the channel. Once the sub-TR is generated an event control is notified and any active triggers are cleared if the sub-TR crosses the boundary of one of the triggers.

For example, if a TR has a trigger size for a 3D block and the ICNT2 value is 16, then the active triggers are cleared after 16 sub-TRs are sent to the queue. ICNT2 can be specified through one of the following:

- DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD4\_5\_j[47-32] ICNT2 field
- DRU\_SUBMIT\_WORD4\_5\_j\_k[47-32] ICNT2 field
- ICNT2 field of the UDMA-C TR received over PSI-L

Upon reaching the top of the queue the TR is processed. Based on the information in the TR a read of the specified location and size is performed followed by writing the data to the specified destination. Upon sending the last write of the entire TR loop a completion event is generated. The completion event output also places a TR response in the PSI-L response FIFO in case of UDMA-C TR. For information about the TR response format, see *Transfer Response Record* in *DMA Architecture*.

---

#### Note

The channel is an independent data flow that can be given requests for data movement. Each channel operates independently of the others but they all share common resources.

The queue is a shared unit between several channels. It holds the order of the channel data movement requests until the shared data engine can perform the actual data move. A channel is assigned a queue where its data movement requests are placed.

---

---

#### Note

The CHRT\_SWTRIG register can only be accessed directly through the DRU configuration interface and is used if software wants to control the triggers for the TR.

---

[Figure 10-51](#) shows the interaction between software and hardware to setup DRU, submit TRs and then release the channel to be used by a different resource. [Section 10.4.3.1.1](#) through [Section 10.4.3.1.5](#) explain in more detail what occurs in each process or decision.

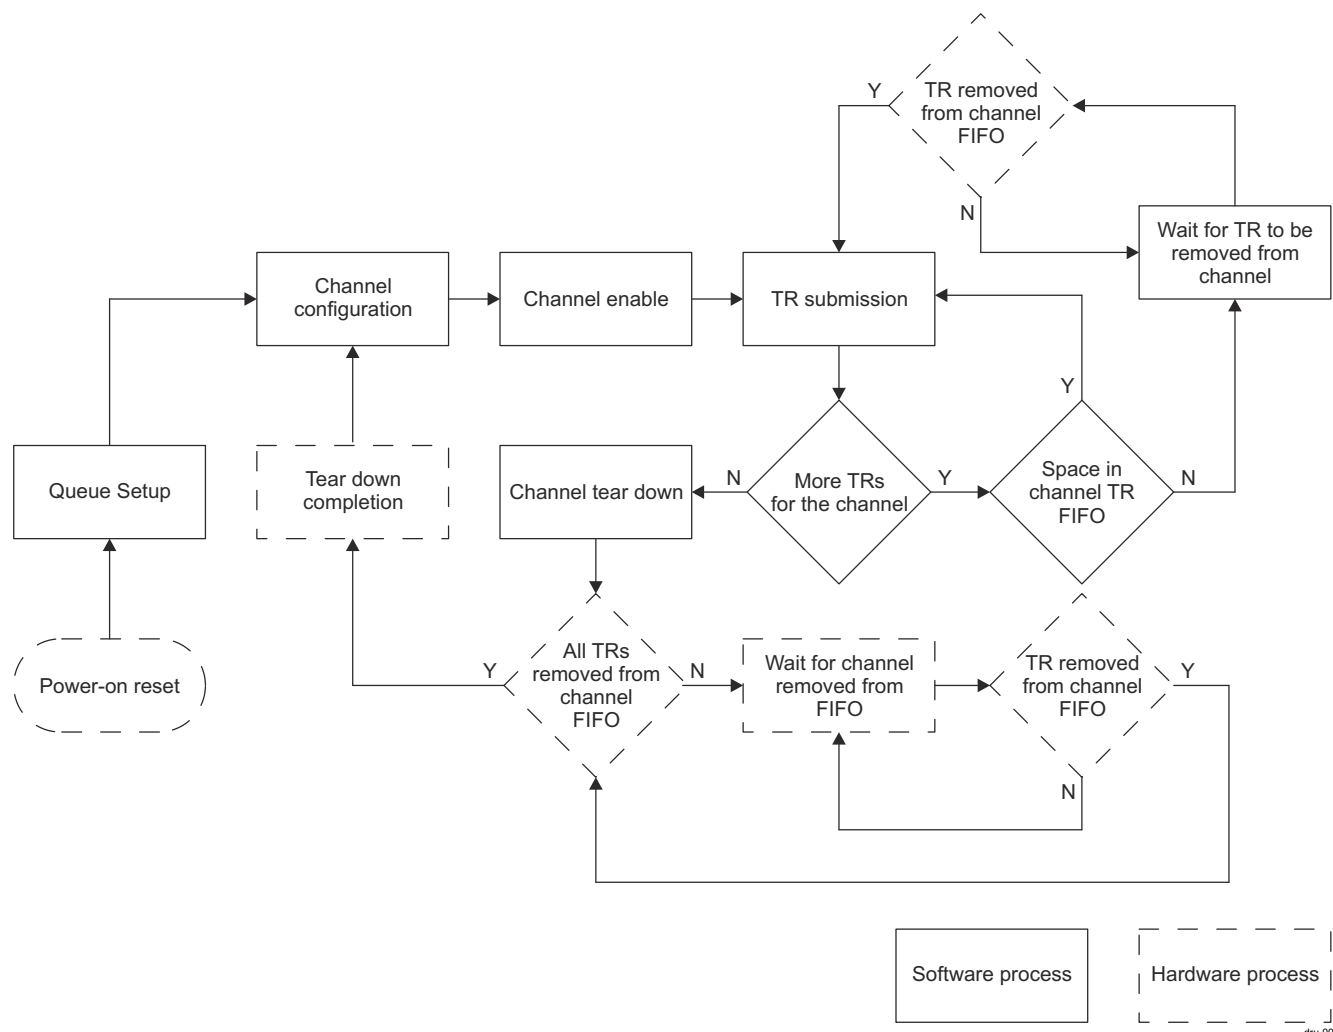

Figure 10-51. DRU Software Managed Flow Diagram

#### 10.4.3.1.1 Queues

Every TR that is active is placed in one of the DRU queues. Each queue operates independently of the others. In a given queue the TRs complete in the order they are placed by the subtiler. Only one read and one write queue may exist at a time. The queues use same resources and need arbitration which is performed based on fixed priority or round robin scheme. In both cases the highest priority queue is the one with the lowest number. The queue priority is specified through the DRU\_CFG\_y[2-0] PRI field.

Whenever arbitration occurs if there is a TR in a fixed priority queue that TR always goes and the round robin queues are held off. If the fixed priority queues are empty then the round robin queues are arbitrated on a round robin basis, that is, each queue sends its specified number of transactions and then arbitration starts again. On the write side an arbitration ends if the read response has not been received for the next command when the current one completes.

The arbitration happens the last phase of a transfer chunk. A transfer chunk is defined as sending the number of read transactions specified by the DRU\_CFG\_y[23-16] CONSECUTIVE\_TRANS field. After CONSECUTIVE\_TRANS number of commands elapse the queue releases the bus and waits for the number of commands specified by the DRU\_CFG\_y[31-24] REARB\_WAIT field before trying to request the bus and involve in arbitration again. Thus software can tune the data flow from each queue to prevent starvation.

If a queue is running and no other queues have a TR then the running one starts its next chunk without stopping. Each time arbitration is performed for round robin queues the queue with the next priority becomes the highest

priority and the current one the lowest priority queue. If a fixed priority queue is active then the current round robin queue remains the highest priority one until the CONSECUTIVE\_TRANS count expires or queue is empty.

The DMA bus QoS and order ID attributes for each queue can also be configured through the DRU\_CFG\_y[10-8] QOS and DRU\_CFG\_y[7-4] ORDERID fields.

---

#### Note

Queue configuration must be done before setting up any channel as queue changes while channels are active can cause unknown behavior.

---

#### 10.4.3.1.2 Channel Configuration

The DRU operates on having multiple channels that can run in parallel on the shared hardware but are independently triggered by events as needed. Each channel must be configured before it is used. The channel configuration has the following parts:

- Non-realtime configuration intended to be controlled by a single master in the system for all software processes and processors
- Real time configuration controlled by the software process that owns the channel

##### 10.4.3.1.2.1 Non-realtime Channel Configuration

The non-realtime configuration consists of the following:

- Assigning the channel to a submission mechanism via the DRU\_CFG\_j[19] CHAN\_TYPE\_OWNER bit
- Assigning the channel via the DRU\_CHST\_SCHED\_j[2-0] QUEUE field to a hardware queue to be used for channel transactions
- Assigning the channel via the DRU\_CHOES0\_j[15-0] EVT\_NUM field to an event to be used for channel notifications

The DRU\_CFG\_j[31] PAUSE\_ON\_ERR bit can be used to control the channel behavior in case of error or exception.

The DRU\_CFG\_j registers must be written to before the channel is enabled via the DRU\_CHRT\_CTL\_j[31] ENABLE bit as once a channel is enabled any write to the DRU\_CFG\_j, DRU\_CHST\_SCHED\_j and DRU\_CHOES0\_j registers will result in write failure and an address error. If a channel does not exist an address error is generated upon write too.

##### 10.4.3.1.2.2 Realtime Channel Configuration

Once the non-realtime channel configuration has been done the DRU\_CHRT\_CTL\_j[31] ENABLE bit should be written. It must be written before any TRs can be written. The mechanism to write this bit is based on the ownership of the channel as specified via the DRU\_CFG\_j[19] CHAN\_TYPE\_OWNER bit. If the owner is a CPU, than this bit must be written directly through the DRU configuration interface. If the owner is UDMA, than the PSI-L interface must be used to write the ENABLE bit through the PSI-L register configuration write process as described in *PSI-L*.

---

#### Note

Once a channel has been enabled the channel configuration registers cannot be modified. The channel can only be disabled through writing 0x1 to the DRU\_CHRT\_CTL\_j[30] TEARDOWN bit.

---

#### 10.4.3.1.3 TR Submission

The DRU supports the following TR methods:

- A direct write to the DRU submission registers
- TR submission over PSI-L from external UDMA-C

The TR submission checks the following:

- If a legal TR has been submitted
- If the correct submission method has been used
- If there is space in the channel TR FIFO for the new TR

#### 10.4.3.1.3.1 Direct TR Submission

The direct TR submission can be atomic or nonatomic. There is one atomic register set that allows for a TR to be submitted with a single burst write. There are also three nonatomic register sets for nonatomic direct TR submission. Each of these three sets allows direct TR submission without requiring submission in a single burst.

The direct atomic TR submission is handled through DRU register writes to the DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD0\_1\_j to DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD14\_15\_j registers which require write in a single 64-byte burst. Any write other than this size returns an address error. All burst values are checked if they are legal values and space in the channel FIFO is checked too. Then the TR is pushed into the FIFO and the write status is returned with success. If any of the legal TR format checks or FIFO space check fails or if the channel is not owned and enabled the result is an address error returned.

The direct nonatomic TR submission is handled through DRU register writes to the DRU\_SUBMIT\_WORD0\_1\_j\_k to DRU\_SUBMIT\_WORD14\_15\_j\_k registers which are intended to be used for cores not being able to perform a large burst write in a single cycle. There is a single set for each core regardless of the channel number. A write to the DRU\_SUBMIT\_WORD0\_1\_j\_k register triggers the TR.

#### Note

The following should be taken into account:

- If a channel is full any write to the DRU\_SUBMIT\_WORD0\_1\_j\_k register results in an address error.
- The DRU does not check anything to ensure that the same core writes to the same nonatomic register set. Software should perform the check procedure.

#### 10.4.3.1.3.2 PSI-L TR Submission

The DRU PSI-L TR submission is used for TR submissions from an external UDMA-C. The DRU has a single submission thread for each channel. The channel must be configured as UDMA-C type channel before PSI-L pairing.

The PSI-L pairing, TR submission and response follow the mechanisms as described in *PSI-L*. For every TR a TR response is sent. If the TR fails a legal check or channel ownership or FIFO fullness check, an immediate TR response is sent back with the cause of the submission error provided in the response.

#### 10.4.3.1.4 TR Removal from Channel

After all requested write responses are received from a TR the DRU sends completion event for the channel that completed the TR. Software can use this event to determine when a TR can be added to a channel FIFO. Each channel has a small FIFO allowing multiple TRs to be preloaded into a channel thus maximizing the channel throughput. The completion event signifies that an entry has become available in the FIFO.

#### 10.4.3.1.5 Channel Tear Down

A channel must be torn down through setting the DRU\_CHRT\_CTL\_j[30] TEARDOWN bit to 0x1. This allows for channel reconfiguration. Setting the TEARDOWN bit to 0x1 forces the channel to stop sending any new requests not already in the pipeline and when all outstanding requests have been received all other bits in the DRU\_CHRT\_CTL\_j register are cleared. If the DRU\_CFG\_j[31] PAUSE\_ON\_ERR bit is set and an error occurs the tear down mechanism can be used to restart the channel. The TEARDOWN bit being set to 0x1 also makes the TR STATIC field in any future reads from the TR memory to be set to 0x0 no matter the value when the TR was submitted. This is the mechanism used to stop a static TR.

#### 10.4.3.1.5.1 Tear Down Completion

The tear down completion process is when software has set the DRU\_CHRT\_CTL\_j[30] TEARDOWN bit to 0x1 so no new TRs can be added to the channel but when previous TRs that had been added to the channel are still running. Once the TR FIFO for the channel is empty hardware clears the DRU\_CHRT\_CTL\_j[30] TEARDOWN and DRU\_CHRT\_CTL\_j[31] ENABLE bits. The channel is now back at the channel configuration process as described in [Section 10.4.3.1.2.1](#) and can be reused as needed by the system.

### 10.4.3.2 DRU Virtualization

The DRU supports virtual addressing through integrated CMMU along with two uTLBs one for read commands and another for write commands. The CMMU is same as the one associated with C71SS.

The channel configuration adds a bit for ATYPE to choose if the addresses are virtual or physical. If a channel is configured to have virtual addresses the queue sends a request to the uTLB and waits for the status response before it sends the command. If the uTLB returns with a page fault then the TR will fail and all future commands for the TR will be flushed. If the pause on error option is set for the channel then no further TRs will be sent for the channel until it is torn down and setup again. All the attributes for the command are selected based on those returned from the uTLB.

### 10.4.3.3 DRU Compression and Decompression

The DRU supports compression and decompression of data in line by integrating the Accelerator Framework Compression (AFC) module inside the response buffer path.

The compression logic places the AFC module between the Read Response Buffer and a dedicated write engine for compression and a dedicated write engine of decompression. The read response buffer handles any out of order responses and then the data is pushed into FIFOs inside the AFC module. The AFC module pulls the data out of the FIFOs as 128-bit elements for compression or 128 CDBs for decompression.

Once the 128-bit entry is removed from the FIFO the symbol size specified for the compression is used to split the 128-bit element into the corresponding number of symbols. If the 128-bit does not divide into an even number of symbols then the remain bits are used with the next 128-bit element to create the first symbol. Once each symbol is determined then they are passed into the compression pipeline. The first stage of the compression pipeline is the difference phase. If it is a non-differential compression algorithm then a fixed bias value is subtracted from the symbol. If it is a differential compression algorithm then the symbol is subtracted from a symbol that is from a previous slot. If there was not data at the previous slot selected it will be zero until actual data is present.

The AFC module packs a byte stream into a set of 128-bit CDB that is defined as a super block. At the end of each super block the compression engine will generate a 8-byte write of the CDB information block. These CDB information blocks can then be read back in when decompressing the data to know the size location and decompression information to recreate the original data.

Table 10-216 through Table 10-220 show the templates used to setup the compression and decompression.

**Table 10-216. Compression Secondary Transfer Request Template 64 Byte Secondary TR**

word 15	word 14	word 13	word 12	
CDB3 Offset from ADDR	CDB3 Format	CDB2 Offset from ADDR	CDB2 Format	
word 11	word 10	word 9	word 8	
CDB1 Offset from ADDR	CDB1 Format	CDB0 Offset from ADDR	CDB0 Format	
word 7	word 6	word 5	word 4	
Max Offset/CDB Table Start Offset	DSTDIM0	SRCDIM0	SB ICNT1	SB ICNT0
word 3	word 2	word 1	word 0	
Compression Flags	SECONDARY TR FLAGS	ADDR of Compressed Data		

**Table 10-217. Compression Secondary TR Field Descriptions**

Word	Field	Description
0-1	ADDR of Compressed Data	The Location of where the compressed data starts.
2	Secondary TR FLAGS	The Secondary TR Flags that are common for all secondary TRs
3	Compression Flags	The Compression Flags used for the compression
4	SBICNT0 & SBICNT1	The size of the super block for the compression
5	DSTDIM0	The dimension to use for DICNT0 in the original TR after each super block
6	SRCDIM0	The dimension to use for ICNT0 in the original TR after each super block is complete

**Table 10-217. Compression Secondary TR Field Descriptions (continued)**

Word	Field	Description
7	Max Offset CDB Table Start Offset	For a compression TR this is the maximum offset value that can be written in the CDB table. This means that compressed data will not be written beyond ADDR + Max Offset. For a decompression TR this is the offset from the secondary TR that the first CDB entry should be read from in bytes. It is a signed value.
8	CDB0 Format	This is the format data for the first CDB table value written after the first super block. It will never be used in an initial fetch.
9	CDB0 Offset	This is where the CDB data for this entry begins relative to the ADDR of Compressed data and is always a positive number.

**Table 10-218. Multiple Buffer Interleave FLAGS Field Descriptions**

Bit	Field	Description
0-3	SEC_TR_TYPE	0: Multiple Buffer Interleave 1: CDB INFO Block and Decompression/Compression Configuration
4-31	SB_DIM0	The dimension to use between lines of the super block. Lower 4 bits are always 0 since minimum element size is 16 byte element.

**Table 10-219. Compression FLAGS Field for Non-Differential Algorithms Descriptions**

Bit	Field	Description
0-3	Compression Algorithm	0: Zero Based Algorithm 1: Unsigned Golumb 2: Signed Golumb 3-7: Reserved for Future Use 8-15: Differential Type see the Differential Compression Flags Definition
5-4	SB_AM0	The addressing mode to use for the super block during ICNT0 is decrementing. This is only used if the TR is using circular addressing for the direction of the compression engine.
6-7	SB_AM1	The addressing mode to use for the super block when SB_ICNT1 is decremented. This is only used if the TR is using circular addressing for the direction of the compression engine.
8-15	Bias	The constant value subtracted from the symbol before the compression algorithm is applied
16-31	RSVD	Reserved for future use

**Table 10-220. Compression FLAGS Field for Differential Algorithms Descriptions**

Bit	Field	Description
0-3	Compression Algorithm	0-7: Non-differential algorithms. See <a href="#">Table 10-219</a> 8: Signed Exponential Golumb with differential logic 9-15: Reserved for Future use
5-4	SB_AM0	The addressing mode to use for the super block during ICNT0 is decrementing. This is only used if the TR is using circular addressing for the direction of the compression engine.
6-7	SB_AM1	The addressing mode to use for the super block when SB_ICNT1 is decremented. This is only used if the TR is using circular addressing for the direction of the compression engine.

**Table 10-220. Compression FLAGS Field for Differential Algorithms Descriptions (continued)**

Bit	Field	Description
8-9	Initial k value	<p>The k value to be used for the initial super block. K value for later super blocks will be based upon the optimal k value calculation logic along with the Update K field. This is combined with the symbol size.</p> <p>8-bit symbol</p> <p>0: k = 0 1: k = 1 2: k = 2 3: k = 3</p> <p>12-bit symbol</p> <p>0: k = 4 1: k = 5 2: k = 6 3: k = 7</p> <p>16-bit symbol</p> <p>0: k = 8 1: k = 9 2: k = 10 3: k = 11</p>
11-10	RSVD	Reserved for future use
12-13	Update K Value	<p>Describes how the k value changes from one super block to the next.</p> <p>0: K is constant and uses the Initial K value specified in the Compression Flags Field</p> <p>1: K value moves by 1 towards the calculated optimal value.</p> <p>2: K value moves instantly to the calculated optimal value</p>
14-15	RSVD	Reserved for future use
16-18	Symbol Size	<p>The size of a signal symbol used for compression</p> <p>0: 8-bit symbol 1: 12-bit symbol 2: 16-bit symbol 3-7: Reserved for Future Use</p>
19	RSVD	Reserved for future use

30-31	SubSel3	Selection for the subtraction module 0: Current symbol uses the adjacent symbol 1: Current symbol uses the symbol 2 spaces away 2: Current symbol uses the symbol 3 spaces away 3: Current symbol uses the symbol 4 spaces away

#### 10.4.3.4 DRU Output Events

The DRU generates the following events:

- Local output events
- PSI-L global events
- Protocol violation event
- Completion events
- Error completion events

The EVENT\_SIZE field of each TR specifies how often a TR generates an output event. That event is provided on the local output event interface as shown in [Figure 10-50](#) and as global event on the PSI-L interface. There is one event per channel. The global event number used by a PSI-L event transport lane can be configured for each channel through the DRU\_CHOES0\_j[15-0] EVT\_NUM field.

As shown in [Table 10-221](#), if the EVENT\_SIZE value is in range from 1 to 3, then the output event is generated when the write command for the given loop level (ICNT1, ICNT2 or ICNT3 decremented) has been sent. If EVENT\_SIZE = 0, then the output event is generated when all responses have been received.

**Table 10-221. EVENT\_SIZE Encoding**

EVENT_SIZE Value	Event Encoding	Description
0	TR complete	The TR has completed and all responses have been received
1	ICNT1 loop is decremented	The last write command of a row has been sent
2	ICNT2 loop is decremented	The last write command of an array has been sent
3	ICNT3 loop is decremented	The last write command of an array of an array has been sent

For more information about PSI-L interface and its event transport lane, see *PSI-L*.

For more information about the TR EVENT\_SIZE field, see *Transfer Request Record* of *DMA Architecture*.

The protocol violation event is not channel associated.

The completion events are defined for each channel. The completion event fires whenever a channel completes a TR successfully. It is only generated when all responses are received from the write portion of the block copy. A single write completion event can occur in a given cycle since it is based on the write responses being received to generate the response.

The error completion events are defined for each channel. The error completion event fires whenever a channel completes a TR with an error and it has flushed out all data related to that TR in the response buffer. Upon determining that a TR is not able to complete successfully, the DRU enters a flush mode to remove all read data received after the error is determined as well as make sure all write responses are received. Once all of this criteria has been matched the write engine fires a completion event. If multiple error completions occur at the same time the DRU will still send them out one at a time using an arbitration scheme used for the original arbitration for the queue, either fixed priority or round robin based on the queue that has the error.

#### 10.4.3.5 DRU Address Fetch Algorithm, TR and CR Formats

The address fetch algorithm, TR and CR formats are defined in *Transfer Request Record* in *DMA Architecture*. It documents all features that can be supported by a Universal Transfer Controller (UTC) like the DRU but it may not support all of them. The DRU\_CAPABILITIES register must be read to check what features of the TR are supported by the DRU.

The TR format allows to perform some kinds of data reformatting or to alter from the standard addressing formats. The DRU supports the transpose data reformatting function and the circular buffering alternate addressing algorithm.

##### 10.4.3.5.1 Transpose

Linear streams work for large classes of algorithms, but not all. In some cases it is desired to transpose rows to columns and columns to rows in the data structure. To help in these cases the DRU supports a transpose function.

The transpose type works on element sizes of 32, 64 or 128 bits by sending sub-TRs in the size of 32 elements by 32 lines for 32-bit, 16 elements by 16 lines for 64-bit and 8 elements by 8 lines for 128-bit element. The sub-TR that is being sent always results in the maximum transfer size. For the write requests the data in the response buffer always looks as a buffer aligned to the zeroth offset in the address.

##### 10.4.3.5.2 Circular Buffering

Circular addressing modifies how the DRU performs address arithmetic so that addresses remain within a power-of-two sized window. Circular addressing works by holding upper address bits constant during an address update, while allowing the lower address bits to vary. This contrasts with the default linear addressing which allows all of the address bits to vary.

The TR provides address mode selection for each level of loop nest. Each level can select between linear addressing or circular addressing with one of two circular block sizes.

If circular addressing mode is selected in the AMODE field of the TR, the definition of the upper 16 bits of the FMTFLAGS field of the TR select the type of addressing for each entry in the loop and define two unique masks that can be used for the circular buffering. Additionally, the DIR field in the TR determines if the circular addressing flags apply for the source or the destination of the block move. The other direction always follows the standard linear addressing that is used if AMODE is not set.

For more information about circular buffering and the associated TR fields, see *Circular Address Mode Specific Flags* of *DMA Architecture*.

#### 10.4.3.6 DRU Firewalls

Unlike most of the device modules whose associated firewalls reside on system interconnect (CBASS) level the DRU has its own embedded firewalls. They are the following:

- Region based firewall intended to protect DRU configuration registers within a programmatically specified range.
- Channelized firewall that protects:
  - The real time configuration registers for each channel:
    - DRU\_CHRT\_CTL\_j
    - DRU\_CHRT\_SWTRIG\_j
  - The TR submission registers for each channel:
    - DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD0\_1\_j to DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD14\_15\_j
    - DRU\_SUBMIT\_WORD0\_1\_j\_k to DRU\_SUBMIT\_WORD14\_15\_j\_k
  - The data transfers for each channel

The region based firewall should be configured to cover the range from 0x6D00 4000 to 0x6D0C FFFF. This allows for a single master to control the memory attribute channels and channel ownership. If the region based firewall is configured to overlap the channelized firewall then both firewall checks have to pass for the register update to occur. If the firewall check fails the DRU returns protection error status to the requestor.

### Note

Protection error takes precedence over address error. If the address falls into the firewall protected range then a protection error is returned.

### Note

Each SoC DRU (DRU0 and DRU1) has both the region based and channelized firewall.

The DRU region based and channelized firewalls are same as the other device firewalls. For more information about their functionality, see *Interconnect Firewalls* in *System Interconnect*. The DRU firewall associated registers are described in the *DRU Registers* sections.

#### 10.4.3.7 DRU Errors

In all error cases the DRU reports the error to the system, ensures that all outstanding commands for the TR have completed and proceeds with the next TR in the queue as if the previous one has finished normally. In most error cases the read transaction completes as normal but the responses are flushed. This ensures that both the read and the write start fresh on the next TR. The error details are logged in the DRU\_CHRT\_STATUS\_DET\_j and DRU\_CHRT\_STATUS\_CNT\_j registers. The DRU\_CAUSE\_y registers can be read to check if an error for the corresponding channel has occurred.

#### 10.4.3.8 DRU Configurations

Table 10-222 shows the differences between the SoC level DRUs and the rest DRUs in the device. The rest of the features and functionality is same as described in Section 10.4.1 and Section 10.4.3.

**Table 10-222. Differences between DRU Configurations**

Feature	SoC Level DRUs	DMPAC.UTC_DRU	VPAC.UTC0_RT_DRU, VPAC.UTC1_NRT_DRU
Cache warm support	Y	Y	N
Atomic direct TR submission	Y	N	N
Nonatomic TR submission register sets	3	0	0
Data reformat functions	Transpose	None	None
Minimum transpose size	32 bits	N/A	N/A
Embedded firewall	Y	Y	N
Event generation	Encoded	Bit vector	Bit vector

## 11 Time Sync

This chapter describes the time sync modules in the device.

<b>11.1 Time Sync Module (CPTS)</b> .....	<b>1024</b>
<b>11.2 Timer Manager</b> .....	<b>1030</b>
<b>11.3 Time Sync and Compare Events</b> .....	<b>1036</b>

## 11.1 Time Sync Module (CPTS)

This chapter describes the Time Synchronization (CPTS) module.

### 11.1.1 CPTS Overview

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations.

#### 11.1.1.1 CPTS Features

Main features of CPTS module are:

- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling
- Supports 8 hardware timestamp push inputs
- Supports timestamp counter compare output
- Supports timestamp counter bit output
- Supports 6 timestamp Generator function outputs
- 32-bit and 64-bit timestamp modes.

#### 11.1.1.2 CPTS Not Supported Features

The following features are not supported by the module:

- Oscillator adjustment by module

### 11.1.2 CPTS Functional Description

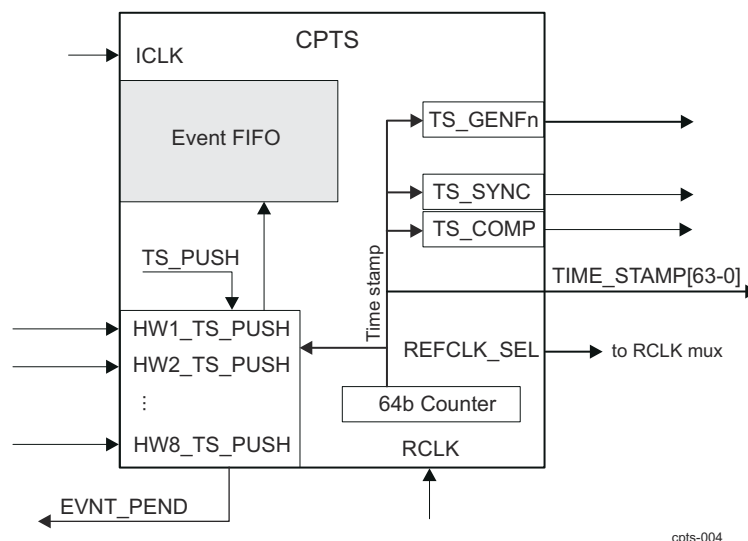

#### 11.1.2.1 CPTS Architecture

Figure 11-1 shows the architecture of the CPTS module.

The CPTS module is used to facilitate host control of time sync operations. The CPTS collects time sync events and then presents them to the host for processing. The types of time sync events are as follows:

- Host Transmit Event
- Ethernet receive event
- Ethernet transmit event
- Time stamp push event
- Time stamp counter rollover event (32-bit mode only)
- Time stamp counter half-rollover event (32-bit mode only)
- Hardware Time Stamp Push Event
- Time Stamp Compare Event

The reference clock used for the time stamp (RCLK) can be derived from several sources.

**Figure 11-1. CPTS Block Diagram**

### 11.1.2.2 CPTS Initialization

The CPTS module must be configured as follows:

1. Reset the CPTS module
2. Clear the CPTS\_EN bit in the CPTS\_CONTROL\_REG
3. Write the RFTCLK\_SEL value in the CPTS\_RFTCLK\_SEL\_REG with the desired reference clock selection
4. Set the CPTS\_EN bit in the CPTS\_CONTROL\_REG
5. If using interrupts and not polling, enable the interrupt by setting the TS\_PEND\_EN bit in the CPTS\_INT\_ENABLE\_REG

### 11.1.2.3 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each RCLK rising edge when CPTS\_EN is set to 1. When CPTS\_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS\_TS\_LOAD\_VAL\_REG and CPTS\_TS\_LOAD\_EN\_REG).

The TS\_INC\_VAL[2:0] value must be zero in 32-bit mode. Nudge and PPM adjustments are not supported in 32-bit mode.

### 11.1.2.4 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each RCLK rising edge when CPTS\_EN is set to 1. When CPTS\_EN is cleared to 0, the time stamp value is reset to 0.

64-bit mode is selected via CPTS\_CONTROL\_REG[5] MODE\_64BIT bit set to 1.

For test purposes, the time stamp can be written via the time stamp load function (CPTS\_TS\_LOAD\_VAL\_REG, CPTS\_TS\_LOAD\_HIGH\_VAL\_REG, and CPTS\_TS\_LOAD\_EN\_REG).

The TS\_ADD\_VAL feature is included to allow 1-ns timestamp operations with an RCLK rate less than 1 GHz. [Table 11-1](#) shows the RCLK and TS\_ADD\_VAL values for 1-ns operations. The highest RCLK frequency possible should be used as allowed by the silicon technology.

**Table 11-1. TS\_ADD\_VAL**

RCLK (MHz)	TS_ADD_VAL
1000	0
500	1
333.33	2
250	3
200	4
166.66	5
142.85714	6
125	7

#### 11.1.2.4.1 64-Bit Timestamp Nudge

The 64-bit TIME\_STAMP value can be adjusted by writing the CPTS\_TS\_NUDGE\_VAL\_REG[7:0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK clock from the next incremented TIME\_STAMP[63:0] value. A nudge value of 0x01 will add one RCLK clock to the next incremented TIME\_STAMP[63:0] value. For example, if the current TIME\_STAMP value is 0x0F06, and TS\_ADD\_VAL[2:0]=3, the next incremented timestamp value would be 0x0F0A without a nudge and 0x0F0A +/- TS\_NUDGE[7:0] with a nudge. The TS\_NUDGE value is cleared to zero when the nudge has occurred.

#### 11.1.2.4.2 64-bit Timestamp PPM

The 64-bit TIME\_STAMP can be adjusted by parts per million (PPM) or by parts per hour (PPH). Writing a non-zero value to the TS\_PPM[41:0] value enables PPM operations. The adjustment is up or down depending on the TS\_PPM\_DIR bit. The TIME\_STAMP value is increased by the PPM value when TS\_PPM\_DIR is cleared and decreased by the PPM value when TS\_PPM\_DIR is set.

- To adjust for 100 parts per million the configured value for TS\_PPM[41:0] is:  
 $1\ 000\ 000/100 = 10\ 000\ (DEC)$
- To adjust for 1 part per hour at 1 GHz RCLK, the configured value for TS\_PPM[41:0] is:  
 $(1\ 000\ 000\ 000Hz/1pph) \times (3600\ seconds/hour) = 346\ 30B8\ A000\ (HEX)$

#### 11.1.2.5 Event FIFO

All time sync events are push onto the Event FIFO. No overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

#### 11.1.2.6 Timestamp Compare Output

CPTS features one Time Stamp Compare (TS\_COMP) output.

---

#### Note

64-bit mode operation is identical to 32-bit mode except that all 64 bits of the TIME\_STAMP[63-0] are used instead of only the lower 32 bits.

---

##### 11.1.2.6.1 Non-Toggle Mode

The TS\_COMP output is asserted for CPTS\_TS\_COMP\_LEN\_REG[31-0] RCLK periods when the TIME\_STAMP[31-0] value compares with the CPTS\_TS\_COMP\_VAL\_REG[31-0] and the length value is non-zero. The TS\_COMP rising edge occurs three RCLK periods after the values compare. A timestamp compare event is pushed into the event FIFO when TS\_COMP is asserted. The polarity of the TS\_COMP output is determined by the CPTS\_CONTROL\_REG[2] TS\_POLARITY bit. The output is asserted low when the polarity bit is 0.

##### 11.1.2.6.2 Toggle Mode

The TS\_COMP output is asserted for CPTS\_TS\_COMP\_LEN\_REG RCLK periods when the TIME\_STAMP[31-0] value compares with the CPTS\_TS\_COMP\_VAL\_REG[31-0] and the length value is non-zero. The TS\_COMP toggles thereafter on CPTS\_TS\_COMP\_LEN\_REG[31-0] RCLK periods. The length high or low can be adjusted by writing the CPTS\_TS\_COMP\_NUDGE\_REG[7-0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK from the CPTS\_TS\_COMP\_LEN\_REG value. A value of 0x01 will add one RCLK to the CPTS\_TS\_COMP\_LEN\_REG value. Only a single high or low time is adjusted (nudged) and the CPTS\_TS\_COMP\_NUDGE\_REG value is cleared to zero when the nudge has occurred. The TS\_COMP output is asserted low when the CPTS\_CONTROL\_REG[2] TS\_COMP\_POLARITY bit is 0.

No compare events and no CPTS\_EVNT interrupts are generated in toggle mode.

The CPTS\_CONTROL\_REG[6] TS\_COMP\_TOG bit must be set for toggle mode, and must be set before writing a non-zero value to CPTS\_TS\_COMP\_LEN\_REG.

#### 11.1.2.7 Timestamp Sync Output

The TS\_SYNC output is a selected bit of the TIME\_STAMP counter value. One of the counter bits 17-31 can be selected in CPTS\_CONTROL\_REG[31-28] TS\_SYNC\_SEL. The TS\_SYNC output is disabled when CPTS\_CONTROL\_REG[31-28] TS\_SYNC\_SEL is zero.

If the selected counter bit is 1 at the time when TS\_SYNC\_SEL value is written then a rising edge will not occur on the TS\_SYNC output. A rising edge will occur on the TS\_SYNC output upon the next transition-to-1 of the selected counter bit. The TS\_SYNC\_SEL value must be written to zero before changing to a different non-zero value. No events are generated due to the TS\_SYNC operation. The TS\_SYNC output is two RCLK periods after the actual count value.

### 11.1.2.8 Timestamp GENF Output

There are six TS Generate Function (TS\_GENFn) outputs (n = 0 to 5). The TS\_GENFn outputs have a programmable cycle (frequency) with a PPM feature and a software nudge feature. The TS\_GENFn output cycle is CPTS\_LENGTH\_REG\_j[31:0] RCLK periods (which is different than TS\_COMP operation).

The TS\_GENFn output cycle is CPTS\_LENGTH\_REG\_j[31:0] RCLK periods beginning when the TIME\_STAMP[63:0] value compares with the CPTS\_COMP\_LOW\_REG\_j[63:0] and the length value is non-zero. The TS\_GENFn output cycle repeats thereafter every CPTS\_LENGTH\_REG\_j[31:0] RCLK periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the TS\_GENFn\_POLARITY bit is low. No compare events and no CPTS\_EVT interrupts are generated.

#### 11.1.2.8.1 GENFn Nudge

The cycle length can be adjusted by writing the CPTS\_NUDGE\_REG\_j[7:0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK clock from the CPTS\_LENGTH\_REG\_j[31:0] value. A value of 0x01 will add one RCLK clock to the CPTS\_LENGTH\_REG\_j value. The CPTS\_NUDGE\_REG\_j value is cleared to zero when the nudge has occurred.

#### 11.1.2.8.2 GENFn PPM

The TS\_GENFn output cycle can be adjusted by parts per million (PPM) or by parts per hour (PPH). Writing a non-zero CPTS\_PPM\_LOW\_REG\_j/CPTS\_PPM\_HIGH\_REG\_j value enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single RCLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPTS\_CONTROL\_REG\_j[0] PPM\_DIR bit. When PPM\_DIR is set a single RCLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM\_DIR is clear a single RCLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

- To adjust for 100 parts per million the configured value for TS\_GENFn\_PPM[41:0] is:  
 $1\,000\,000/100 = 10\,000$  (DEC)
- To adjust for 1 part per hour at 1 GHz RCLK the configured value for TS\_GENFn\_PPM[41:0] is:  
 $(1\,000\,000\,000\text{Hz}/1\text{pph}) \times (3600\text{ seconds/hour}) = 346\,30B8\,A000$  (HEX)

### 11.1.2.9 Time Sync Events

Time Sync events are 96-bit or 128-bit (for 32-bit and 64-bit time stamp respectively) values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPTS\_EVENT\_0\_REG through CPTS\_EVENT\_3\_REG hold the data of a time sync event.

#### 11.1.2.9.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS\_PUSH bit of the CPTS\_TS\_PUSH\_REG. The time stamp value is returned in the event, along with a time stamp push event code.

#### 11.1.2.9.2 Time Stamp Counter Rollover Event (32-bit mode only)

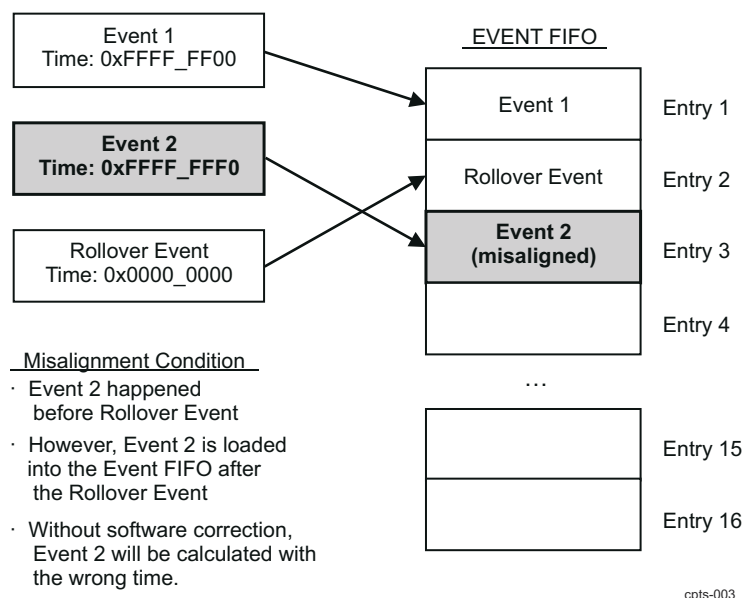

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented.

#### 11.1.2.9.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 11-2](#) shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

**Figure 11-2. Event FIFO Misalignment Condition**

#### 11.1.2.9.4 Hardware Time Stamp Push Event

There are eight hardware time stamp inputs (HW[1-8]\_TS\_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in *CPTS Integration*.

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT\_NUMBER field in the CPTS\_EVENT\_1\_REG register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS\_CONTROL\_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

#### 11.1.2.10 Timestamp Compare Event

##### Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode. The TS\_COMP output is also asserted when the event is generated. The event is generated when the TIME\_STAMP value compares with the CPTS\_TS\_COMP\_VAL\_REG/CPTS\_TS\_COMP\_HIGH\_VAL\_REG and the CPTS\_TS\_COMP\_LEN\_REG value is non-zero. The CPTS\_TS\_COMP\_LEN\_REG value should be written by software after the CPTS\_TS\_COMP\_VAL\_REG/CPTS\_TS\_COMP\_HIGH\_VAL\_REG is written and should be zero when the comparison value is written.

### 11.1.2.11 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPTS\_INT\_ENABLE\_REG.
2. Upon interrupt, read the CPTS\_EVENT\_0\_REG through CPTS\_EVENT\_3\_REG register values.
3. Set the CPTS\_EVENT\_POP\_REG[0] EVENT\_POP bit to 1 to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPTS\_INT\_ENABLE\_REG.
2. Upon interrupt, read the CPTS\_EVENT\_0\_REG through CPTS\_EVENT\_3\_REG register values.
3. Set the CPTS\_EVENT\_POP\_REG[0] bit to 1 to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four RCLK periods plus four ICLK periods.
5. Read the TS\_PEND\_RAW bit in the CPTS\_INTSTAT\_RAW\_REG register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, proceed to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS\_PEND\_RAW bit of the CPTS\_INTSTAT\_RAW\_REG to determine if a valid event is on the event FIFO.

## 11.2 Timer Manager

This chapter describes the Timer Manager module of the device.

### 11.2.1 Timer Manager Overview

The Timer Manager module provides timers for timing operations for the processes running on multiple processors in the device.

#### 11.2.1.1 Timer Manager Features

Timer Manager has the following features:

- 1024 × 32-bit RAM-based independent timers
- Host access to determine which timer(s) expired
- 32 registers with individual timeout status (one bit per timer)
- A pair of quick-read registers with the number of timers that have expired and the ids of the first timers to expire
- A bank timeout register with the banks that have expired timers – to avoid having to read all timeout status registers when only a few timers have expired
- Groups of 16 timers separated into pages of 4-K address space
- Timer bits within each page to read expiration status for each timer when software only has access to that page
- 10  $\mu$ s time to cycle through all of the timers
- Host access to reset individual timers
  - Reset values are preprogrammed for each timer
  - Timers may all be programmed before the timer manager is enabled, or programmed after enabled.

#### 11.2.1.2 Timer Manager Not Supported Features

The following features are not supported by the module:

- Tunable GENF CPTS output is an input to this module. The timer bank doesn't manage the divider or the rate/offset compensation. It takes the output of a tuner module as a single input EON\_TICK event.

### 11.2.2 Timer Manager Functional Description

#### 11.2.2.1 Timer Manager Function Overview

[Figure 11-3](#) shows the Timer Manager diagram.

timer\_mgr-004

**Figure 11-3. Timer Manager Block Diagram**

The 1024 timers in the timer manager are organized as the Timer RAM in Figure 11-3. When the timer manager is enabled, the timer counter will increment with the input timer tick, and the control module continuously loops over the Timer RAM, comparing the values against this timer count. When the timer count is greater than a timer value, the timer control module will generate a timer expiration event.

Based on software writes, the timer control module will update the values in the Timer RAM to setup or cancel active timers. Whenever a new value is written to a `TIMERMGR_SETUP_j_k` memory address, the corresponding timer is touched/setup with the current sum of the timer count and the written value; written values are relative to the current timer count. These values are stored in the Timer Reprogramming RAM, so the software may also write to the `TIMERMGR_CONTROL_j_k` registers to flag a timer for reprogramming, using the previously stored reprogramming value. The latter method is preferred when the timer setup value is not changing, as it does not interrupt the RAM state machine.

#### 11.2.2.2 Timer Counter

The Timer Manager takes an input timer tick to control the timer rate. All timers share a time base. On each rising edge of this tick event, the timer counter increments. The value of the timer counter may be read by software via the `TIMERMGR_COUNTER` register.

##### 11.2.2.2.1 Timer Counter Rollover

A rollover bit is maintained for each timer, such that when reprogrammed, it is the carry bit from the sum of the current time (counter) and the relative reprogramming value for that timer. This has the effect that any timer whose rollover bit is currently set to a 1 will not expire in the current epoch.

When the counter transitions from `0xFFFF FFFF` to `0x0000 0000`, the timer control module changes the rollover bit for all timers from a 1 to a 0. All timers that previously did not have the rollover bit set, will expire when they are next visited by the state machine, as their timeout value was for the previous epoch.

The overall effect is that the timers continue to expire as expected, regardless of when the counter rollover occurs relative to the state machine.

### 11.2.2.3 Timer Control Module (FSM)

The timer control module controls the RAM accesses for reading and writing. It controls the loops over the timer RAM, checks the values in the RAM to observe expiring timers, flagging timeouts so that events may be triggered and reported. It also takes as input any software-written updates to setup, clear, and touch the timers.

**Figure 11-4. Timer State Machine**

The timer states are sequential, that is, Timer 0 is checked, then Timer 1 is checked, then Timer 2, and so on. The Timer Control FSM will stall in a given state if the `cmd_accept` signal from the `ksdw_spram_ecc` module goes low, and will remain there until the ECC RAM will accept a command.

The timer state always transitions from N to N+1, unless N meets or exceeds the programmed `MAX_TIMER` value, in which case the system will start over at state 0.

### 11.2.2.4 Timer Reprogramming

There is a reprogramming module that runs in lock step with the FSM, always one state ahead – the FSM exports its `next_state` for use by the reprogramming RAM.

This RAM keeps track of the setup values for the timers as programmed by the `TIMERMGR_SETUP_j_k` memory mapped locations. There is a SET flag for each timer outside of the RAM – if this SET flag is true for the `next_state` timer, the VBUS ready signals are deasserted; if there is a pending timer setup, there cannot be a read or write to the memory, as this would interrupt the Timer FSM state machine and, with enough accesses, potentially cause the system to exceed the 10-μs window for timer accuracy.

### 11.2.2.5 Event FIFO

As the subsystem event aggregator requires more than one cycle to process events, there is an internal FIFO to store the generated events. Events may be generated by expiring timers or by activity on the CBA interface, as disabled timers or reset timers must send an event deactivation if the timer was previously expired.

This has an impact on performance, as if there are too many timer expirations in a given window, it potentially violates the 10-μs requirement (this is true without the event FIFO as well, given that the system cannot keep up with a timer expiring every cycle, in the worst case).

### 11.2.2.6 Output Event Lookup (OES RAM)

The expiring timers must be assigned corresponding event numbers for use in the instantiating system. These lookup values correspond to the 16-bit event number that is output on the event interface when a given timer expires.

The lookup table for timer to event number mapping defaults all timers to the invalid event number (0xFFFF), and any invalid event numbers observed upon lookup for an expiring timer will result in no events being generated by the timer manager – invalid (0xFFFF) events are suppressed and will not result in an event on the event interface.

It is expected that the output event assignments will be programmed once per module reset, and that they are static during operation of the timer manager.

### 11.2.3 Timer Manager Programming Guide

#### 11.2.3.1 Timer Manager Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

##### 11.2.3.1.1 Initialization Sequence

Initialization of the Timer Manager must include the following steps:

1. Set the number of timers to be used. `TIMERMGR_CNTL[10-1] MAX_TIMER`
  - This controls the loop over the timer RAM and is the highest ID timer that will be used in the operation of the Timer Manager (`MAX_TIMER + 1` is the total number of timers in use)
  - This number must not change during the course of operation; it can only be changed when `TIMERMGR_CNTL[0] ENABLE = 0`. It is assumed that the user will set the `MAX_TIMER` value as required.
  - This step can be skipped if using all timers. `MAX_TIMER` defaults to 1024 (that is, all timers in use).
2. Write output event mapping for all timers to the OES output event lookup table. This must be done before enabling timer manager and must not be done again once the timer manager has been enabled.
3. Write initial setup values to the `TIMERMGR_SETUP_j_k` registers. All timers that will be used initially must have a setup value before the Timer Manager is enabled.
4. Enable individual timers. There are two ways to do this.
  - To enable all timers, use the `TIMERMGR_CNTL[12] MASS_ENABLE` bit. This will enable all timers from 0 to `MAX_TIMER`.
    - Note that `MAX_TIMER` and `MASS_ENABLE` should be set in successive writes, or the previous value of `MAX_TIMER` will be used for `MASS_ENABLE`
    - `MASS_ENABLE` must only be used during initialization.
  - Alternately, individual timers can be enabled or disabled with `TIMERMGR_CONTROL_j_k`
    - It is therefore faster to set the individual `TIMERMGR_CONTROL_j_k` bits if more than half of the in-use timers are to be enabled initially. If more than half of the in-use timers are to be enabled initially, it is faster to use `MASS_ENABLE` and then disable specific timers with the `TIMERMGR_CONTROL_j_k` bits.
5. Enable the timer manager. Set `TIMERMGR_CNTL[0] ENABLE` to 1.

##### 11.2.3.1.2 Real-time Operating Requirements

While running, a CPU can take the following actions to enable, disable, or touch the timers:

###### 11.2.3.1.2.1 Timer Touch

When a timer needs to be updated – indicating that an interface or function is still alive and timeout should be delayed – there are two means of touching a timer:

- If the timer's respective `TIMERMGR_SETUP_j_k` has the appropriate value for its function, the timer can be set again by writing a 1 to the SET bit of the `TIMERMGR_CONTROL_j_k` register.
  - As the timer should remain enabled, this effectively means writing a 3 to the `TIMERMGR_CONTROL_j_k` register for the timer to be touched
- If the timer's respective `TIMERMGR_SETUP_j_k` needs a new value, writing this value has the side effect of also setting the timer – there is no need to also write to the SET bit of `TIMERMGR_CONTROL_j_k`. This should be relatively infrequent during operation, as the setup values for all timers must be written during initialization.

The preferred method for touching timers is using the SET bit of `TIMERMGR_CONTROL_j_k`. It is considerably more efficient. The reprogramming RAM is a single port RAM, and repeated writes to the `TIMERMGR_SETUP_j_k` registers will impact overall timer performance and may result in longer periods before a valid timeout is observed.

###### 11.2.3.1.2.2 Timer Disable

When a timer is no longer in use, the timer should be disabled with the respective `TIMERMGR_CONTROL_j_k` enable bit.

A disabled timer does not stop the time for that timer relative to the counter, and its current value is considered invalid once disabled. A timer should not be disabled and then subsequently re-enabled without reprogramming/re-setting, as it may timeout unexpectedly.

#### 11.2.3.1.2.3 Timer Enable

To enable a timer while the Timer Manager is running, the timer must first be setup again.

- If the current `TIMERMGR_SETUP_j_k` is appropriate for the timer's intended use, the timer can be re-enabled by writing a 3 to the `TIMERMGR_CONTROL_j_k` register. (ENABLE = 1, SET = 1)
- If the current `TIMERMGR_SETUP_j_k` needs to be changed, write to the `TIMERMGR_SETUP_j_k` before re-enabling the timer. After this value is changed, the timer can be re-enabled by writing 0x3 to the `TIMERMGR_CONTROL_j_k` register (ENABLE = 1, SET = 1)
  - While `TIMERMGR_SETUP_j_k` implies SET, it must still be set as the timer is enabled.

#### 11.2.3.1.3 Power Up/Power Down Sequence

The timer manager must be disabled (clear `TIMERMGR_CNTL[0] ENABLE` to 0) before the timer manager is powered down. The timer manager will only be idle if it is not enabled and the event FIFO is empty – an enabled Timer Manager means the state machine is running and the timer manager is waiting for expired timers.

To power up the Timer Manager if it has been powered down but not reset, the timer values in the timer RAM must be assumed to be invalid. Any timers must either be reprogrammed (`TIMER_SET`) before the timer is re-enabled. If this is not done, the Timer Manager may report timeouts as soon as it is enabled.

Additionally, all timers that have expired must be cleared before disabling the Timer Manager, otherwise there will be no Event Down generated on the event interface to clear the expired timers from the interrupt aggregator. This effectively means that software must disable all timers before writing a 0 to `TIMERMGR_CNTL[0] ENABLE`.

The event FIFO will continue to drive pending events even if the Timer Manager is disabled, so the remaining Event Down actions will still occur – software only needs to disable the timers to ensure that the Event Down commands are pushed into the event FIFO but does not need to wait for the event FIFO to flush before disabling the timer manager.

## 11.3 Time Sync and Compare Events

### 11.3.1 Time Sync Architecture

This section provides a high-level overview of the SoC time synchronization architecture.

#### 11.3.1.1 Time Sync Architecture Overview

[Table 11-2](#) shows the network time synchronization functions supported by the device.

**Table 11-2. Network Time Synchronization Functions in the SoC**

Interface	Time Sync Functions	Supported by
1×PCIE	Precision time measurement (PTM)	PCIe controller hardware
2×CPSW	IEEE 1588-2008 (2-step), 802.1AS	CPTS in CPSW
External input reference clock	External time/clock reference	CPTS

#### Note

These time sync functions are described in detail in their respective chapters.

Any of these functions can be a time sync master in the system. A sync router (TIMESYNC\_INTRTR0) provides flexibility for each time domain to choose its synch master independently. In addition, there is also a router (CMPEVT\_INTRTR0) that provides selection of active counter compare events for routing as CPU or DMA events.

## 11.3.2 Time Sync Routers

### 11.3.2.1 Time Sync Routers Overview

The timesync event router (TIMESYNC\_INTRTR0) and compare event router (CMPEVT\_INTRTR0) are instantiations of the generic interrupt router module in the device.

The TIMESYNC\_INTRTR0 implements a set of multiplexers to provide selection of active CPTS time sync events for routing to CPTS capable modules. There is one register per output that controls the selection (TIMESYNC\_INTRTR0\_MUXCNTL\_y).

The CMPEVT\_INTRTR0 implements a set of multiplexers to provide selection of active CPTS counter compare events for routing as CPU or DMA events. There is one register per output that controls the selection (CMPEVT\_INTRTR0\_MUXCNTL\_y).

Table 11-3 summarizes the configuration details for TIMESYNC\_INTRTR0 and CMPEVT\_INTRTR0.

**Table 11-3. TIMESYNC\_INTRTR0 and CMPEVT\_INTRTR0 Configuration**

Module	Input Interrupt Type
TIMESYNC_INTRTR0	Level
CMPEVT_INTRTR0	Pulse

Refer to *INTRTR Overview* for the general programming sequence that is recommended to be followed for all interrupt routers in the device.

### 11.3.3 Time Sync Event Sources

See *Interrupt Sources* for Time Sync event mapping.

## 12.1 General Connectivity Peripherals

This section describes the general connectivity peripherals in the device.

### 12.1.1 Analog-to-Digital Converter (ADC)

This chapter describes the Analog-to-Digital Converter (ADC) in the device.

#### 12.1.1.1 ADC Overview

The Analog-to-Digital Converter (ADC) module contains a single 12-bit ADC which can be multiplexed to any 1 of 8 analog inputs (channels).

Figure 12-1 presents an overview of the ADC modules.

adc-001

**Figure 12-1. ADC Modules Overview**

#### 12.1.1.1.1 ADC Features

Each ADC module has the following features:

- 4 MSPS rate with a 60 MHz SMPL\_CLK
- Single-ended or differential input options
- Programmable Finite State Machine (FSM) sequencer that supports the following:
  - Software initiated start of conversion
  - Optional hardware start of conversion (SOC), synchronized to external hardware event
  - Single conversion (one-shot mode)
  - Continuous conversions (continuous mode)
  - Sequence through all enabled steps based on a mask
  - Programmable open delay before executing each step
  - Programmable sampling delay for each step
  - Programmable averaging (16, 8, 4, 2, or 1) of input samples for each step
  - Store data in either of two FIFOs – 256-word × 16-bit
  - Option to encode input (channel) number with data

- Support for servicing FIFOs via DMA or processor
- Programmable DMA request event (for each FIFO)
- Support for the following interrupts and status, with masking:
  - Interrupt if AFE fails to return end of conversion (EOC)
  - Interrupt after a sequence of conversions (all non-masked steps)
  - Interrupt for FIFO threshold levels
  - Interrupt if sampled data is out of a programmable range
  - Interrupt for FIFO overflow and underflow conditions
  - Status bit to indicate if ADC is busy converting

**Unsupported Features:**

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

**12.1.1.1.2 ADC Not Supported Features**

- No packing of 16-bit FIFO data onto 32-bit DMA bus
- Big endian
- Support only 32-bit aligned read/write accesses on the MCU\_CBASS0/DMA ports

**12.1.1.1.3 ADC Ports**

**Table 12-1. MCU\_ADC[0-1] Clocks and Resets**

Clocks	
Module Clock Input	Description
MCU_ADC_VBUS_CLK	MCU_ADC interface clock
MCU_ADC_SYS_CLK	MCU_ADC system clock
MCU_ADC_CLK	MCU_ADC clock. Output of multiplexer, see <i>ADC Integration</i> . Multiplexer control is provided via CTRLMMR_MCU_ADC_CLKSEL[1-0] CLK_SEL bit field. Default state is HFOSC_CLKOUT.
Resets	
Module Reset Input	Description
MCU_ADC_RST	MCU_ADC reset

**Table 12-2. MCU\_ADC[0-1] Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCU_ADC_GEN_LEVEL_0	MCU_ADC interrupt request	Level
MCU_ADC_ECC_CORRECTED_ERR_LEVEL_0	MCU_ADC ECC corrected error interrupt request	Level
MCU_ADC_ECC_UNCORRECTED_ERR_LEVEL_0	MCU_ADC ECC uncorrected error interrupt request	Level
DMA Events		
Module DMA Event	Description	Type
MCU_ADC_FIFO0	MCU_ADC receive request line	Pulse
MCU_ADC_FIFO1	MCU_ADC receive request line	Pulse

**12.1.1.2 ADC Environment**

This section describes the ADC external connections (environment).

[Table 12-3](#) describes the ADC I/O signals.

**Table 12-3. ADC I/O Signals**

Module Pin	I/O <sup>(1)</sup>	Description
AIN0	A/I	Analog input 0
AIN1	A/I	Analog input 1
AIN2	A/I	Analog input 2
AIN3	A/I	Analog input 3

**Table 12-3. ADC I/O Signals (continued)**

Module Pin	I/O <sup>(1)</sup>	Description
AIN4	A/I	Analog input 4
AIN5	A/I	Analog input 5
AIN6	A/I	Analog input 6
AIN7	A/I	Analog input 7
REFN	A	ADC Reference (Negative)
REFP	A	ADC Reference (Positive)

(1) I = Input; A = Analog

### 12.1.1.3 ADC Functional Description

#### 12.1.1.3.1 ADC FSM Sequencer Functional Description

The FSM sequencer supports up to 16 steps that can be configured to perform analog-to-digital conversions. Each of the 16 steps can individually be enabled and configured to operate as software enabled steps or hardware enabled steps. Each step has its own programmable step configuration (ADC\_CONFIG\_j) and step delay (ADC\_DELAY\_j) registers that allow users to configure the ADC operation on a per-step basis.

The FSM sequencer enters Idle immediately after the ADC is enabled and remains in Idle while waiting for any of the 16 programmable steps to be enabled. When one or more step is enabled, the FSM sequencer will begin executing or skipping each step starting with the lowest and incrementing up through each step until the highest step has been executed or skipped. The FSM sequencer will execute enabled steps and skip disabled steps. Once all of the steps have been executed or skipped, the FSM sequencer will return to Idle or immediately begin repeating steps configured for continuous mode.

An ENDOSEQUENCE interrupt can be generated after the last enabled step has been executed. If any software enabled steps are configured for continuous operation and they are still enabled when the FSM sequencer has incremented through all the steps, the FSM sequencer will start the sequence again with the first enabled step. Hardware enabled steps are mapped to a hardware event and will need the hardware event to occur before being scheduled.

Figure 12-2 illustrates how the FSM sequencer works. Each shaded box represents a FSM state.

#### Note

Figure 12-2 does not represent the number of SMPL\_CLK cycles required by each state since some states implement user programmable delays that may require more than one SMPL\_CLK cycle to complete.

### 12.1.1.3.1.2 Step Configuration

#### 12.1.1.3.1.2.1 One-Shot (Single) or Continuous Mode

Each step can be configured to operate in one-shot or continuous mode via the least significant bit of the MODE bit-field of the respective ADC\_CONFIG\_j register. Steps configured for one-shot mode will perform a single conversion before being disabled by the FSM sequencer. Steps configured for continuous mode will automatically be re-enabled by the FSM sequencer after each conversion until disabled by software.

#### 12.1.1.3.1.2.2 Software- or Hardware-Enabled Steps

Each step can be configured to operate in SW Enabled mode or HW Enabled mode independently via the most significant bit of the MODE bit-field in the respective ADC\_CONFIG\_j register. However, the hardware event source is applied globally to all HW Enabled steps and configured via the ADC\_CONTROL register.

The user can configure each step to begin immediately after the step is enabled by software (SW Enabled), or wait for a hardware event to occur (HW Enabled).

The EXT\_TRIGGER input signal is used by HW Enabled steps. The trigger input has the option of being sourced from a device input pin or several on-device peripherals via a multiplexer controlled by TRIG\_SEL of the respective registers:

- ADCi\_CTRL where i represents a ADC instance see the device data sheet for available domains and ADC instances.
- MCU\_ADCi\_CTRL where i represents a ADC instance see the device data sheet for available domains and ADC instances.

When this option is selected, the hardware event will be triggered after the EXT\_TRIGGER input signal transitions from low to high and is held high for a period greater than two cycles of SYS\_CLK. This hardware event will only schedule one complete sequence, even for continuous mode. If HW Enabled steps need to be executed again, a new hardware event must be generated after the previously triggered sequence has completed.

SW Enabled steps can be preempted by HW Enabled steps when the HW\_PREEMPT bit in the ADC\_CONTROL register is set.

#### 12.1.1.3.1.2.3 Averaging of Samples

Each step can be configured, via the respective ADC\_CONFIG\_j register, to sample an input 1, 2, 4, 8, or 16 times and provide an average data value. If a step is configured to sample more than once, the additional samples are taken back-to-back immediately after the first sample. However, open delay is only applied to the first sample while sample delay is applied to all samples. Once the last sample has been taken the average data value will be stored in the FIFO.

#### 12.1.1.3.1.2.4 Analog Multiplexer Input Select

The AFE contains two 9-to-1 analog multiplexers which are used to select the source connected to the positive input (INP) and negative input (INM) of the ADC. Each step can be configured, via the respective ADC\_CONFIG\_j register, to select the appropriate input sources. For more information, refer to the functional block diagram and the ADC\_CONFIG\_j register field descriptions.

#### 12.1.1.3.1.2.5 Differential Control

The ADC supports differential inputs and each step can be configured, via the respective ADC\_CONFIG\_j register, to select single-ended input mode or differential input mode.

#### Note

The ADC INM input must be sourced from REFN for any steps configured to operate in single-ended mode.

#### 12.1.1.3.1.2.6 FIFO Select

The ADC contains two FIFOs and each step can be configured, via the respective ADC\_CONFIG\_j register, to store its ADC data into either FIFO.

#### 12.1.1.3.1.2.7 Range Check Interrupt Enable

Each step can be configured, via the respective ADC\_CONFIG\_j register, to compare the value of ADC data to high and low limits programmed in the ADC\_RANGE register. The out-of-range interrupt is generated if the value of ADC data is greater than the value of HIRANGE or less than the value of LOWRANGE. Refer to the ADC\_RANGE register field descriptions for information related to setting the high and low limits that trigger an out-of-range interrupt.

#### 12.1.1.3.1.3 Open Delay and Sample Delay

The FSM sequencer provides two programmable delays for each step. The value of OPENDELAY is used to control when the acquisition begins after the step starts and the value of SAMPLEDELAY is used to control the acquisition period. Delays for each of the 16 steps can be configured independently via the respective ADC\_DELAY\_j register.

##### 12.1.1.3.1.3.1 Open Delay

OPENDELAY defaults to a value of zero which causes the acquisition period to begin as soon as the step starts. The start of the acquisition period can be delayed one SMPL\_CLK clock period for each incremental value of OPENDELAY.

##### 12.1.1.3.1.3.2 Sample Delay

SAMPLEDELAY defaults to a value of zero which causes the acquisition period to be equal to two SMPL\_CLK clock periods. The acquisition period can be extended one SMPL\_CLK clock for each incremental value of SAMPLEDELAY.

The value of SAMPLEDELAY should be configured to provide enough time for the respective external voltage source to completely charge the AFE input capacitance during the acquisition period.

##### 12.1.1.3.1.4 Interrupts

The ADC has 9 internal events that can trigger an interrupt to the processor. These events are logically or'ed together to produce a single interrupt to the processor. The user can individually enable or disable each interrupt source via the ADC\_ENABLE\_SET and ADC\_ENABLE\_CLR registers. Once an interrupt is generated, the ADC\_STATUS register can be read to determine which interrupt source(s) interrupted the processor. The interrupt source(s) can be cleared by writing a '1' to the corresponding bit of the ADC\_STATUS register.

The following interrupts are supported by the device ADC:

- An ENDOSEQUENCE interrupt is generated after the FSM sequencer completes the last enabled step.
- FIFO0UNFL/FIFO1UNFL or FIFO0OVFL/FIFO1OVFL interrupts. Each FIFO also has the ability to generate overrun and underflow interrupts. The ADC does not recover from overrun or underflow conditions automatically. Therefore, software will need to disable and re-enable the ADC after this occurs. The FSM sequencer must be Idle before turning the ADC module back on. This can be confirmed by reading the ADC\_SEQUENCER\_STAT register, when FSM\_BUSY = 0x0 and STEP\_IDLE = 0x10000.
- FIFO0THRS and FIFO1THRS interrupts. Each FIFO has the ability to generate an interrupt when the FIFO word count has reached a programmable threshold value. The FIFO0THRS and FIFO1THRS interrupt is generated when the value of NUMWDS in the respective ADC\_FIFO0WC or ADC\_FIFO1WC register equals the word count threshold value programmed in THRESHOLD of the respective ADC\_FIFO0THRESHOLD or ADC\_FIFO1THRESHOLD register.
- OUTOFRANGE interrupt. This interrupt can be enabled or disabled on each step. If enabled, the ADC data value is compared to the low and high thresholds programmed in the global ADC\_RANGE register. The OUTOFRANGE interrupt is generated if the ADC data value is greater than the value programmed in HIRANGE or less than the value programmed in LOWRANGE.
- AFE\_EOC\_MISSING interrupt. This interrupt is generated when the FSM sequencer does not receive an expected EOC from the AFE.

##### 12.1.1.3.1.5 Power Management

The software also has the option to turn off the AFE power by writing to the ADC\_CONTROL[4] PD bit. By default, after the initial power on the AFE is powered down and software is responsible for turning it on. Software must wait minimum 4  $\mu$ s after a AFE power up and before starting a conversion (must be followed every time

the AFE is powered up). It is the software's responsibility to empty the FIFO before requesting the ADC to enter sleep state.

#### 12.1.1.3.1.6 DMA Requests

Each FIFO can be serviced by the processor or DMA. The user can individually enable or disable each FIFO DMA request via the ADC\_DMAENABLE\_SET and ADC\_DMAENABLE\_CLR registers.

#### 12.1.1.3.2 ADC AFE Functional Description

The AFE contains a single 12-bit successive approximation ADC which can be connected to one of eight user selectable analog inputs for each step executed by the FSM sequencer. There is also an option to configure the ADC to operate in differential mode where it samples the differential voltage applied to two of eight user selectable analog inputs.

The ADC sits idle until the FSM sequencer sends a Start of Conversion (SOC) pulse. Once the FSM sequencer sends a SOC pulse to the ADC, it begins sampling the analog input signal on the rising edge of SOC and continues sampling the analog input signal one cycle of SMPL\_CLK after the falling edge of SOC. The SOC pulse width will be the value of SAMPLEDELAY plus one SMPL\_CLK periods, so the total ADC acquisition time will be the value of SAMPLEDELAY plus two SMPL\_CLK periods. The ADC captures the analog input signal at the end of the acquisition period and starts conversion, which requires thirteen SMPL\_CLK periods to digitize the sampled input. An EOC signal is returned to the FSM sequencer to indicate the digital data is ready.

The ADC output is positive binary weighted data ranging from 0 to  $(2^{12} - 1)$ . When configured for single-ended mode, ADC output data values 0 to  $(2^{12} - 1)$  represents a corresponding input voltage that ranges from the ADC negative reference (REFN) voltage to the ADC positive reference (REFP) voltage. When configured for differential mode, ADC output data values 0 to  $((2^{12}/2) - 1)$  represents a corresponding negative differential input voltage that ranges from the REFP voltage to the REFN voltage and output data values  $(2^{12}/2)$  to  $(2^{12} - 1)$  represents a corresponding positive differential input voltage that ranges from the REFN voltage to the REFP voltage.

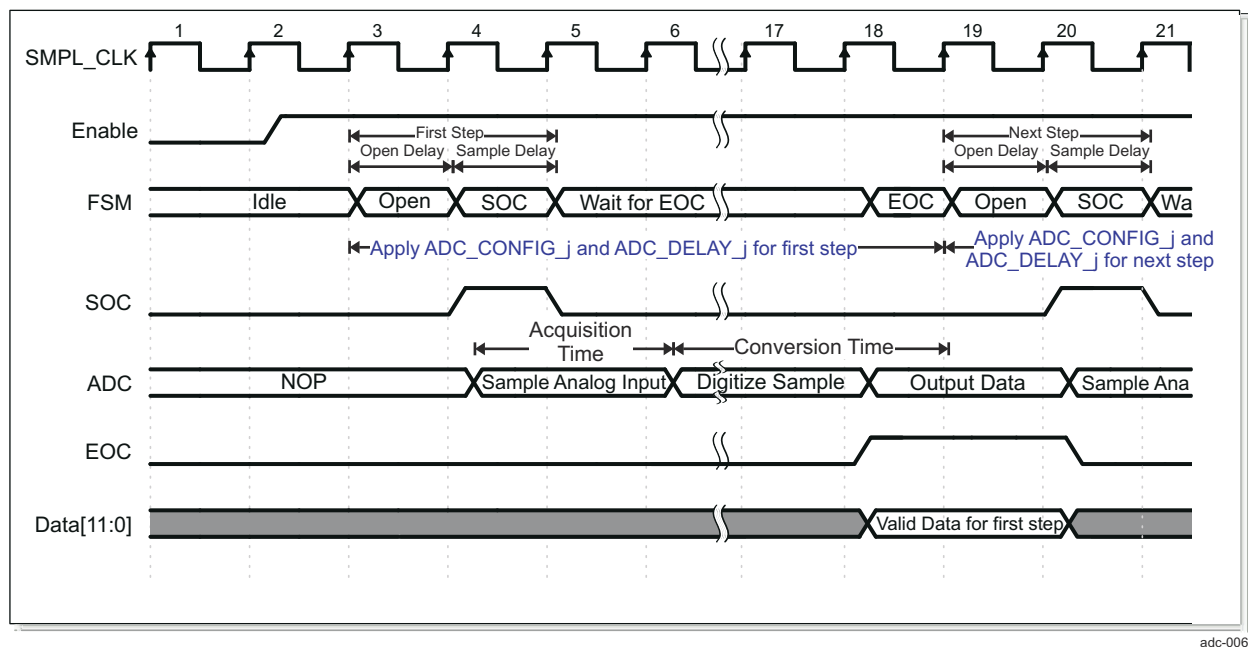

Using the minimum values of OPENDELAY and SAMPLEDELAY, the ADC can sample an analog input every 15 SMPL\_CLK periods.

Figure 12-3 illustrates the operation of the FSM sequencer and ADC AFE, with indicators showing when the hardware configuration defined by ADC\_CONFIG\_j and ADC\_DELAY\_j registers are applied.

#### Note

Figure 12-3 assumes both steps shown are software enabled with averaging turned off, an OPENDELAY value of 1, and SAMPLEDELAY value of 0. The analog input is sampled for the duration of the SOC pulse plus one cycle of the SMPL\_CLK. If the value of OPENDELAY were 0, it would appear as if the time associated with the Open portion of the FSM waveform would be removed from all the waveforms.

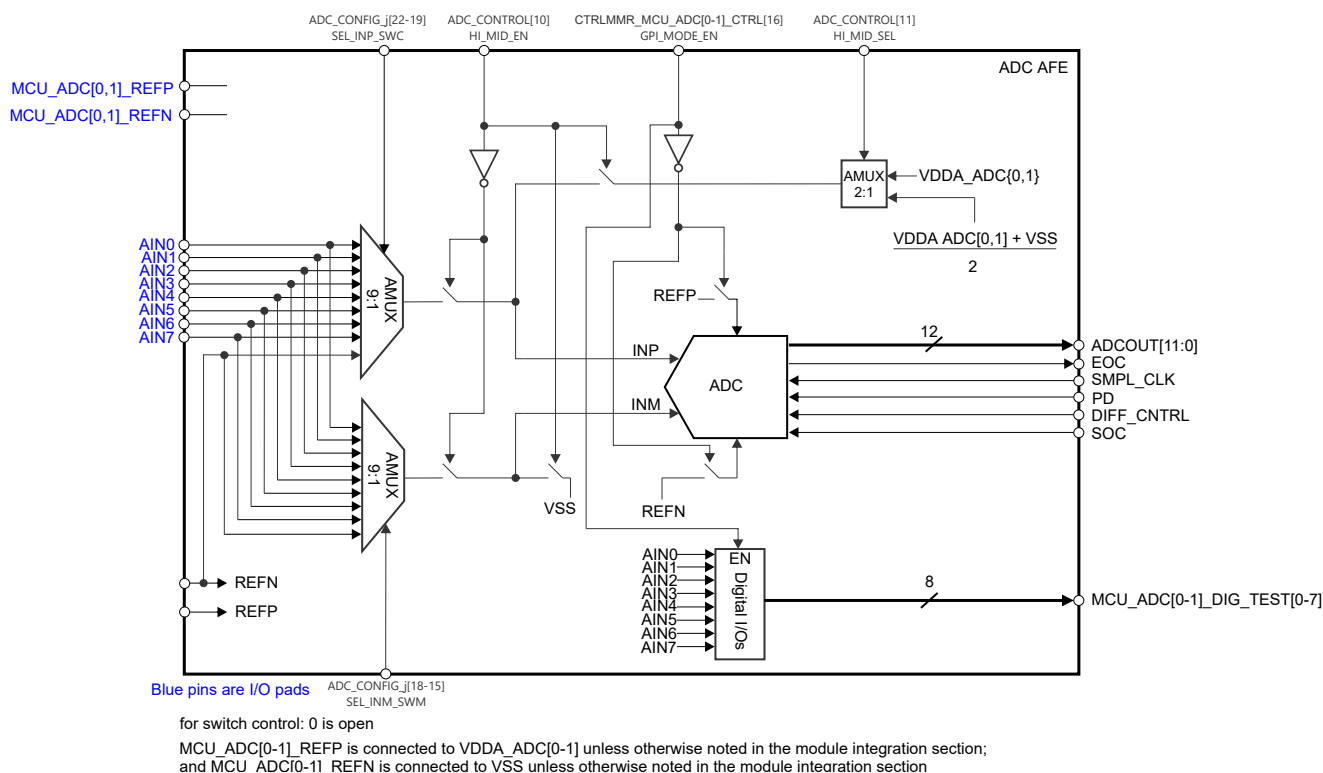

**Figure 12-3. Example Timing Diagram for Sequencer**

#### 12.1.1.3.2.1 AFE Functional Block Diagram

The AFE has 8 analog inputs which can be configured as either singled-ended or differential inputs to the ADC. The user may configure a step to use any 1 of the 8 inputs when operating in single-ended mode or any 2 of the 8 inputs when operating in differential mode. For more information, refer to [Figure 12-4](#) and the ADC\_CONFIG\_j register field descriptions.

**Figure 12-4. Functional Block Diagram**

### 12.1.1.3.3 ADC FIFOs and DMA

#### 12.1.1.3.3.1 FIFOs

There are two sample FIFOs (ADC\_FIFO0 and ADC\_FIFO1), which store sample data from the AFE. Can be configured, via the respective ADC\_CONFIG\_j register.

The processor can read ADC data directly from the FIFO by using the respective ADC\_FIFO0DATA or ADC\_FIFO1DATA register. The internal logic will pop the next data from the FIFO and increment the FIFO read pointers.

The FIFO data will no longer be accessible after the ADC is disabled because the FIFO pointers are reset. Therefore, it is important to read all FIFO data before disabling the ADC.

#### 12.1.1.3.3.2 DMA

The ADC has a dedicated slave port for the DMA which allows it to perform continuous burst reads when accessing the FIFOs.

Each FIFO has its own DMA request which can be enabled via the ADC\_DMAENABLE\_SET register and disabled via the ADC\_DMAENABLE\_CLR register.

The first DMA request is generated after the FIFO leaves the EMPTY state and fills to the level programmed in DMAREQLEVEL of the respective ADC\_FIFO0DMAREQ or ADC\_FIFO1DMAREQ register.

Subsequently, a new DMA request is automatically generated on the next clock cycle after the current DMA access completes if the previous DMA access did not empty the FIFO.

#### 12.1.1.3.4 ADC Error Correcting Code (ECC)

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC Aggregator provides a single EOI-handshake based interrupt to the host (for both single and double error detections).

The ECC Aggregator will write 0's to all of memory after reset is released. The ADC\_SEQUENCER\_STAT[6] MEM\_INIT\_DONE bit will be 0 during this period and will be set to 1 upon completion.

For more information about the ECC Aggregator, see *ECC Aggregator* and *ADC ECC Registers*.

See also *Testing ECC Error Injection* and *ADC ECC Registers*.

#### 12.1.1.3.4.1 Testing ECC Error Injection

The read enable (REN) input to the RAMs instantiated in this module are constantly tied to 1'b1. As a result, read is continuously in progress.

In order to test ECC single error injection on a particular RAM row, the following conditions have to be maintained before setting the ADC\_ECC\_CTRL[3] FORCE\_SEC bit:

- ADC\_ECC\_CTRL[5] FORCE\_N\_ROW bit has to be clear. This is required in order to configure required row in
- ADC\_ECC\_CTRL[6] ERROR\_ONCE bit has to be clear. If this bit is set, the ECC error occurs immediately after setting ADC\_ECC\_CTRL[3] FORCE\_SEC bit since REN is always set
- ADC\_ECC\_ERR\_CTRL1[31:0] ECC\_ROW bit field has to be point to the required row address

#### 12.1.1.3.5 ADC Functional Debug Mode

The ADC function can be validated by measuring known reference voltage sources. This feature provides register control that connects the AFE to known reference voltage sources. However, it does not automatically configure the FSM to perform conversions to measure these sources. Software will need to configure the FSM to perform a measurement after selecting this mode of operation.

ADC\_CONTROL[10] HI\_MID\_EN is used to disconnect the AFE from all analog inputs and connect it to one of two known reference voltage sources. ADC\_CONTROL[11] HI\_MID\_SEL is used to select REFP or VMID as the known reference voltage source.

The conversion results is expected to produce a full scale value when the AFE is connected to REFP and approximate half scale value when the AFE is connected to VMID.

The steps are:

- Disable the ADC if previously enabled and wait until the FSM is not busy.
- Put the AFE in a functional debug mode by setting the ADC\_CONTROL[10] HI\_MID\_EN bit to 1.
- Select one of the two reference voltage sources by setting the ADC\_CONTROL[11] HI\_MID\_SEL bit.
  - 0 selects VMID
  - 1 selects REFP
- Configure the FSM to measure the selected reference voltage source.
- Enable the ADC and evaluate the results.
- When debug is complete, disable the ADC and wait until the FSM is not busy, re-program the FSM for functional operation, then re-enable the ADC.

## 12.1.2 General-Purpose Interface (GPIO)

This chapter describes the General-Purpose Input/Output (GPIO) for the device.

### 12.1.2.1 GPIO Overview

The General-Purpose Input/Output (GPIO) peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs. When configured as an output, the user can write to an internal register to control the state driven on the output pin. When configured as an input, user can obtain the state of the input by reading the state of an internal register.

In addition, the GPIO peripheral can produce host CPU interrupts and DMA synchronization events in different interrupt/event generation modes.

#### 12.1.2.1.1 GPIO Features

Each channel in the GPIO modules has the following features:

- Supports 9 banks of 16 GPIO signals
- Supports up to 9 banks of interrupt capable GPIOs
- Interrupts:
  - Can enable interrupts for each bank of 16 GPIO signals
  - Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO signal
- Set/clear functionality:
  - Firmware writes 1 to corresponding bit position(s) to set or to clear GPIO signal(s). This allows multiple firmware processes to toggle GPIO output signals without critical section protection (disable interrupts, program GPIO, re-enable interrupts, to prevent context switching to another process during GPIO programming).
- Separate Input/Output registers:
  - If preferred by firmware, some GPIO output signals can be toggled by direct write to the output register(s) in addition to set/clear.
  - Output register, when read in, reflects output drive status. This, in addition to the input register reflecting pin status this allows wired logic to be implemented.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.1.2.1.2 GPIO Not Supported Features

- The following apply to WKUP\_GPIOu (u = 0, 1):
  - WKUP\_GPIOu[84:143] are not pinned out.
  - Interrupts [84:143] are not pinned out.
  - Bank Interrupts [8:6] are not pinned out.
  - From WKUP\_GPO[68] to WKUP\_GPO[83] buffer is output only.
- The following apply to GPIO<sub>n</sub> (n = 0, 2, 4, 6):
  - GPIO<sub>n</sub>[128:143] are not pinned out.
  - Interrupts [128:143] are not pinned out.
  - Bank Interrupt 8 is not pinned out.
- The following apply to GPIO<sub>m</sub> (m = 1, 3, 5, 7):
  - GPIO<sub>m</sub>[36:143] are not pinned out.
  - Interrupts [36:143] are not pinned out.
  - Bank Interrupts [8:2] are not pinned out.

#### 12.1.2.2 GPIO Environment

This section describes the GPIO external connections (environment).

[Table 12-8](#) describes the GPIO I/O signals.

**Table 12-8. GPIO I/O Signals**

Module Pin	I/O <sup>(1)</sup>	Description
GPIO_BANK[0-8]_[0-15]	I/O	General-purpose input/output. <sup>(2)</sup>

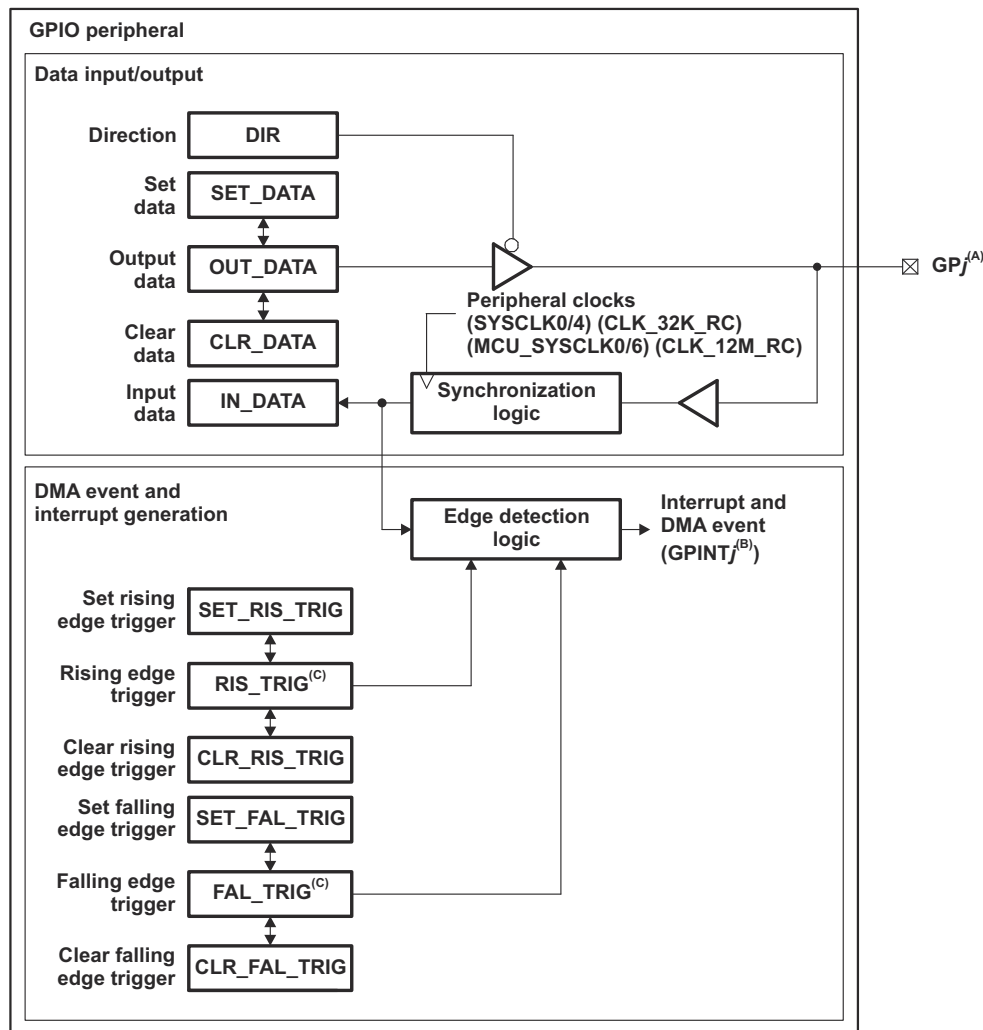

(1) I = Input; O = Output; I/O = Bidirectional

(2) Only GPIOs enabled through from the CTRLMMR\_WKUP\_PADCONFIG0 to CTRLMMR\_WKUP\_PADCONFIG93 or from the CTRLMMR\_PADCONFIG0 to CTRLMMR\_PADCONFIG172 registers for a particular instance can operate on I/O pins. For more information see *Pad Configuration Registers*.

### 12.1.2.3 GPIO Functional Description

#### 12.1.2.3.1 GPIO Block Diagram

Figure 12-5 shows the general-purpose interface block diagram.

gpio\_005

- A. Some of the GPj pins are muxed with other device signals. For details, see the device-specific Data sheet.
- B. All GPINTj can be used as host CPU interrupts and synchronization events to the DMA.
- C. The RIS\_TRIG and FAL\_TRIG registers are internal to the GPIO module and are not visible to the host CPU.

#### Note

The synchronization logic and tristate buffer are present in the SoC pinmux logic.

**Figure 12-5. GPIO Block Diagram**

#### 12.1.2.3.2 GPIO Function

Each GPIO pin (GPj) can be independently configured as either an input or an output using the GPIO direction registers. The GPIO direction register (DIR) specifies the direction of each GPIO signal. Logic 0 indicates the GPIO pin is configured as output, and logic 1 indicates input.

When configured as output, writing a 0x1 to a bit in the set data register drives the corresponding GPj to a logic-high state. Writing a 0x1 to a bit in the clear data register drives the corresponding GPj to a logic-low state. The output state of each GPj can also be directly controlled by writing to the output data register.

For example, to set GP8 to a logic-high state, the software can perform one of the following:

- Write 100h to the GPIO\_SET\_DATA01 register.
- Write 0h to the GPIO\_DIR01 register to configure as output pin.
- Read in GPIO\_OUT\_DATA01 register, change bit 8 to 0x1, and write the new value back to GPIO\_OUT\_DATA01.

To set GP8 to a logic-low state, the software can perform one of the following:

- Write 100h to the GPIO\_CLR\_DATA01 register.
- Write 0h to the GPIO\_DIR01 register to configure as output pin.
- Read in GPIO\_OUT\_DATA01 register, change bit 8 to 0x0, and write the new value back to GPIO\_OUT\_DATA01.

Note that writing a 0x0 to bits in the set data and clear data registers does not affect the GPIO pin state.

Also, for GPIO pins configured as input, writing to the set data, clear data, or output data registers does not affect the pin state.

For a GPIO pin configured as input, reading the input data register (IN\_DATA) will return the pin state. Reading the SET\_DATA register or the CLR\_DATA data register will return the value in OUT\_DATA, not the actual pin state. The pin state is available by reading the input data register. Note that when the direction is configured as input, the output state is determined by software's programming set/clear/output registers, and may not agree with the pin state, which is driven by an external device.

#### 12.1.2.3.3 GPIO Interrupt and Event Generation

Each GPIO pin (GPj) can be configured to generate a host CPU interrupt (GPINTj) or a synchronization event to the DMA (GPINTj). Configuration is on per-bank basis. Each bit of the BINTEN parameter dictates YES/NO option for each bank. Bit 0 controls bank 0, bit 1 controls bank 1, and so on.

The interrupt can be generated on the rising-edge, falling-edge, or on both edges of the GPIO signal. The edge detection logic is synchronized to the GPIO peripheral clock.

The direction of the GPIO pin does not need to be input when using the pin to generate the interrupt or DMA event. When the GPIO pin is configured as input, transitions on the pin trigger interrupts or DMA events. When the GPIO pin is configured as output, software can toggle the GPIO output register to change the pin state and in turn trigger the interrupt or DMA event.

Note that the direction of the pin need not be input for interrupt generation to work. When the GPIO pin is configured as input, transitions on the pin trigger interrupts. When the GPIO pin is configured as output, firmware can toggle the GPIO output register to change the pin state, and in turn trigger interrupts.

Each interrupt output of GPIO signal are available at the module boundary. Each group of 16 GPIO\_INTR\_INTj signals also has their masked interrupt outputs ORed together to generate a per bank interrupt, available at the module boundary. The idea is to either connect individual interrupts or per bank interrupts to the system interrupt controller.

##### 12.1.2.3.3.1 Interrupt Enable (per Bank)

The GPIO\_BINTEN register provides interrupt enable/disable feature for each bank of 16 GPINT signals.

##### 12.1.2.3.3.2 Trigger Configuration (per Bit)

Two internal registers, RIS\_TRIG and FAL\_TRIG, specify which edge of the GPj signal generates an interrupt or DMA event. Each bit in these two registers corresponds to a GPj pin. [Table 12-9](#) describes the host CPU interrupt and DMA event generation of GPj pin based on the bit settings of the RIS\_TRIG and FAL\_TRIG registers.

**Table 12-9. GPIO Interrupt and DMA Event Configuration Options**

RIS_TRIG Bit n	FAL_TRIG Bit n	Host CPU Interrupt and DMA Event Generation
0	0	GPINTj interrupt and DMA event is disabled
0	1	GPINTj interrupt and DMA event is triggered on falling edge of GPj signal

**Table 12-9. GPIO Interrupt and DMA Event Configuration Options (continued)**

RIS_TRIG Bit n	FAL_TRIG Bit n	Host CPU Interrupt and DMA Event Generation
1	0	GPINTj interrupt and DMA event is triggered on rising edge of GPj signal
1	1	GPINTj interrupt and DMA event is triggered on both rising and falling edge of GPj signal

The RIS\_TRIG and FAL\_TRIG registers are not directly accessible or visible to the host CPU. These registers are accessed indirectly through four registers: SET\_RIS\_TRIG, CLR\_RIS\_TRIG, SET\_FAL\_TRIG, and CLR\_FAL\_TRIG. Writing 1 to a bit on the SET\_RIS\_TRIG register sets the corresponding bit on the RIS\_TRIG register. Writing 1 to a bit of the CLR\_RIS\_TRIG register clears the corresponding bit on the RIS\_TRIG register. Writing to the SET\_FAL\_TRIG and CLR\_FAL\_TRIG registers works the same way on the FAL\_TRIG register.

Reading the SET\_RIS\_TRIG or CLR\_RIS\_TRIG register returns the value of the RIS\_TRIG register. Reading from the SET\_FAL\_TRIG or CLR\_FAL\_TRIG register returns the value of the FAL\_TRIG register.

To use the GPIO pins as sources for host CPU interrupts and DMA events, the associated bank interrupt enable register bit in GPIO\_BINTEN must also be set to 1. For example, to enable GPIO0\_19 (which is in bank 1), GPIO\_BINTEN[1] = 1 should be set to enable interrupts for bank 1.

#### 12.1.2.3.3.3 Interrupt Status and Clear (per Bit)

The INTSTAT registers provide interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding bit position(s). Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

#### Note

The GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

#### 12.1.2.3.4 GPIO Emulation Halt Operation

The GPIO peripheral is not affected by emulation halts.

## 12.1.2.4 GPIO Programming Guide

Step	Register/Bit Field/Programming Model	Value
Write 1h to clear desired bit(s) in CLR_DATA register.	CLR_DATA	-h

### 12.1.3 Inter-Integrated Circuit (I2C) Interface

This section describes the Inter-Integrated Circuit (I2C) module in the device.

#### 12.1.3.1 I2C Overview

The device contains Inter-Integrated Circuit (I2C) controllers each of which provides an interface between a local host (LH), such as an Arm or a Digital Signal Processor (DSP), and any I2C-bus-compatible device that connects via the I2C serial bus. External components attached to the I2C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I2C interface.

Each multimaster I2C module can be configured to act like a slave or master I2C-compatible device.

Some controllers have dedicated I2C compliant open drain buffers and support high speed mode (up to 3.4 Mbps in 1.8 V mode and up to 400 Kbps in 3.3 V mode). Other controllers are multiplexed with standard LVCMOS I/O, connected to emulate open drain, and support fast mode (up to 400 Kbps in 1.8 V/3.3 V mode). The I2C emulation is achieved by configuring the LVCMOS buffers to output Hi-Z instead of driving high when transmitting logic 1.

For the specific I/O buffer and timing characteristics of the different I2C instances, see the device-specific data sheet.

##### 12.1.3.1.1 I2C Features

Each multicontroller I2C module has the following features:

- Compliant with Philips I2C-bus specification version 2.1
- Supports a standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Supports HS mode (up to 3.4 Mbps) on some instances. See the the device-specific Data Manual for details.
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multicontroller transmitter/target receiver mode
- Multicontroller receiver/target transmitter mode
- Combined controller transmit/receive and receive/transmit mode
- Built-in FIFO for buffered read
- Module enable/disable capability
- Programmable multitarget channel (responds to four separate addresses)
- Programmable clock generation
- 8-bit-wide data access
- Low power consumption
- Support Auto Idle mechanism
- Support Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Wide interrupt capability

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

##### 12.1.3.1.2 I2C Not Supported Features

- Serial Camera Control Bus (SCCB) Protocol
- DMA Mode
- Full I2C electrical compliance (only for MAIN and MCU domain I2C modules)
- Local power management of clock activity
- Debug suspend mode
- Clockstop wakeup interrupt (only for MCU domain I2C modules)

### 12.1.3.1.3 I2C Ports

This section describes I2C ports related to clocks, resets, and hardware requests.

**Table 12-13. I2C[0-6] Clocks and Resets**

Interrupt Requests		
Module Interrupt Signal	Description	Type
I2C_POINTRPEND_0	I2C Interrupt request	Level

### 12.1.3.2 I2C Environment

This section describes the I2C external connections (environment).

#### 12.1.3.2.1 I2C Typical Application

Figure 12-6 shows the multicontroller I2C controller and their related connections with I2C-compliant devices.

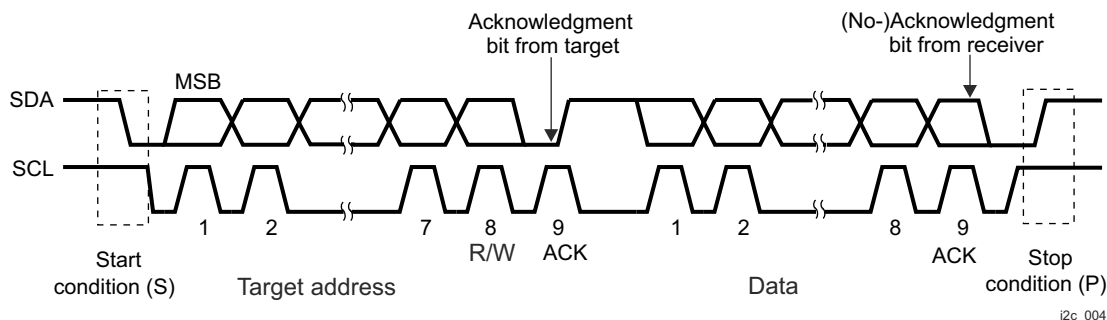

**Figure 12-6. I2C and Typical Connections to I2C Devices**

#### 12.1.3.2.2 I2C Typical Connection Protocol and Data Format

##### 12.1.3.2.2.1 I2C Serial Data Format

The I2C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I2C module.

Figure 12-7 shows a typical I2C communication format.

**Figure 12-7. I2C Data Transfer**

##### 12.1.3.2.2.2 I2C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

Figure 12-8 is an example of data validity requirements.

**Figure 12-8. I2C Bit Transfer on the I2C Bus**

#### 12.1.3.2.2.3 I2C Start and Stop Conditions

The I2C module generates start (S) and stop (P) conditions when it is configured as a controller.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2C\_IRQSTATUS\_RAW [12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2C\_IRQSTATUS\_RAW [12] BB bit is 0 to indicate that the bus is free).

Figure 12-9 shows the waveforms that occur during an S and a P condition.

**Figure 12-9. I2C S and P Condition Events**

#### Note

I2C controller does not support messages non-compliant with I<sup>2</sup>C standard. Void messages are non-standard I<sup>2</sup>C messages and will lockup the controller. A void message is a START condition followed by a STOP condition, in other words, while the bus is free the SDA line is pulled low (START) and then released (STOP). This would result in a timeout (software) of the next controller transfer which would never complete. A soft reset of the controller is recommended for recovery.

#### 12.1.3.2.2.4 I2C Addressing

The I2C module supports two data formats in fast/standard (F/S) mode:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

##### 12.1.3.2.2.4.1 Data Transfer Formats in F/S Mode

Figure 12-10 shows the I2C data transfer formats in F/S mode.

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) Addressing format with repeated start condition

i2c-007

**Figure 12-10. I2C Data Transfer Formats in F/S Mode**

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB target address bits and 1 least-significant bit (LSB) R/W\_ bit.

The LSB R/W\_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W\_ is 0, the controller writes data to the selected target; if it is 1, the controller reads data from the target.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W\_ bit. If the R/W\_ bit is 0, the next byte contains the last 8 bits of the target address. If the R/W\_ bit is 1, the next byte contains data transmitted from the target to the controller.

#### 12.1.3.2.2.4.2 Data Transfer Format in HS Mode

Figure 12-11 shows the I2C data transfer format in HS mode.

S = Start; Sr = repeated start; P = Stop; F/S = Fast/standard mode; HS = High-speed mode

i2c-008

**Figure 12-11. HS I2C Data Transfer in HS Mode**

Each multicontroller I2C controller can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the controller code address (0x00001XXX, where XXX is the variable portion of the controller code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the target address and the data, as shown in Figure 12-11.

#### 12.1.3.2.2.5 I2C Controller Transmitter

In controller transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock

pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

#### 12.1.3.2.2.6 I2C Controller Receiver

Controller receiver mode can be entered only from controller transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 12-10), if R/W\_ is high, the module enters controller receiver mode after the target address byte and bit R/W\_ are transmitted. Serial data bits received on bus line SDA are shifted in synchronization with the self-generated clock pulses on SCL.

#### 12.1.3.2.2.7 I2C Target Transmitter

Target transmitter mode can be entered only from target receiver mode. With any of the address formats (a), (b), or (c) (see Figure 12-10), the target transmitter is entered if the target address byte is the same as its own address and bit R/W\_ is transmitted, if R/W\_ is high. The target transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the controller device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

#### 12.1.3.2.2.8 I2C Target Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the controller device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

#### 12.1.3.2.2.9 I2C Bus Arbitration

If two or more controller transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the target receiver mode, sets the arbitration lost (I2C\_IRQSTATUS\_RAW[0] AL) flag, and generates the arbitration lost interrupt. Figure 12-12 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

**Figure 12-12. I2C Arbitration Between Controller Transmitters**

#### 12.1.3.2.2.10 I2C Clock Generation and Synchronization

Under normal conditions, only one controller device generates the clock signal - SCL. However, there are two or more controller devices during the arbitration procedure, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a target can slow down a fast controller and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (clock stretching).

### Note

In case the SCL or SDA lines are stuck low, a bus clearing operation is supported:

- If the clock line (SCL) is stuck low, the preferential procedure is to reset the bus using the hardware reset signal if the I<sup>2</sup>C devices have hardware reset inputs. If the I<sup>2</sup>C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.
- If the data line (SDA) is stuck low, the controller should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 12-13 shows clock synchronization.

**Figure 12-13. I2C Clock Generators Synchronization**

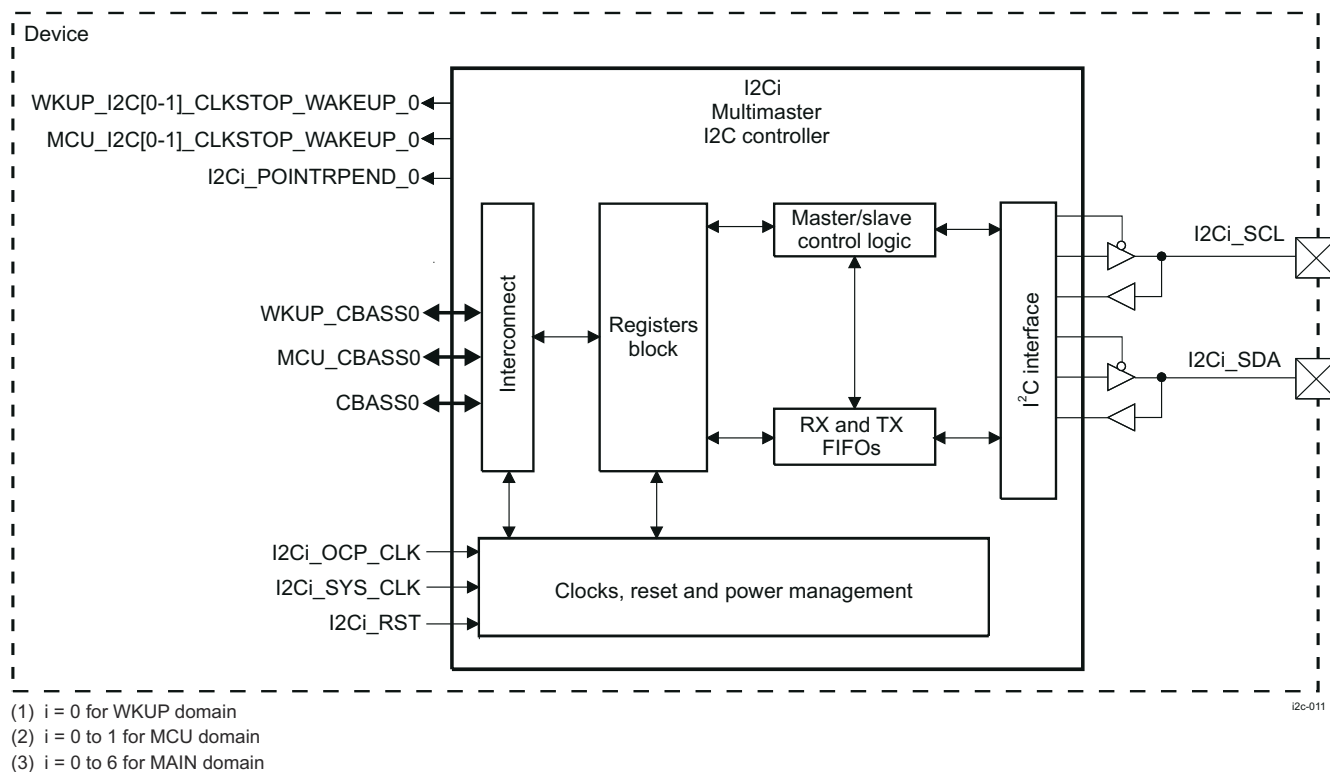

### 12.1.3.3 I2C Functional Description

#### 12.1.3.3.1 I2C Block Diagram

##### Note

DMA mode and SCCB Protocol are not supported on this family of devices.

Figure 12-14 presents the multimaster I2C controller block diagram.

**Figure 12-14. I2C Block Diagram**

The ten multimaster I2C controllers can be configured in F/S I2C mode or HS I2C mode. The operation mode is selected by configuring the I2C\_CON[13-12] OPMODE bit field.

Table 12-15 lists the available operation modes.

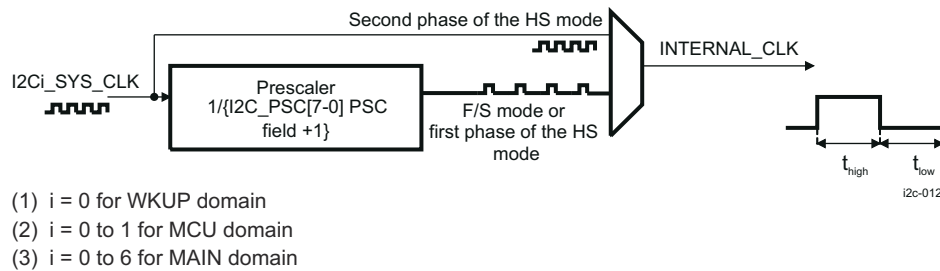

**Table 12-15. I2C Operation Mode Selection**

Operation Mode	Value of I2C_CON[13-12] OPMODE
F/S I2C	0x0
HS I2C	0x1
SCCB	0x2
Reserved (not used)	0x3

#### 12.1.3.3.2 I2C Clocks

##### 12.1.3.3.2.1 I2C Clocking

Figure 12-15 shows the I2C clock generation of the I2C controllers.

**Figure 12-15. I2C Clock Generation**

Each multimaster I2C controller uses the SYS\_CLK functional clock in the Device Configuration section. The internal sampling clock INTERNAL\_CLK is generated by dividing the functional clock by the I2C\_PSC[7-0] PSC bit field value + 1 in F/S mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the SCLL signal is determined by the I2C\_SCLL[7-0] SCLL bit field in F/S mode and in the first phase of HS mode; or by the I2C\_SCLL[15-8] HSSCLL bit field in the second phase of HS mode.

The high time of the SCLH signal is determined by the I2C\_SCLH[7-0] SCLH bit field in F/S mode and in the first phase of HS mode; or by the I2C\_SCLH[15-8] HSSCLH bit field in the second phase of HS mode.

Table 12-16 lists the  $t_{LOW}$  and  $t_{high}$  values in master mode only (in slave mode, the I2C controller does not generate the I2C clock).

**Table 12-16. I2C  $t_{LOW}$  and  $t_{high}$  Values of the I2C Clock**

Mode	Clock	$t_{Low}$	$t_{high}$
F/S or HS first phase	$INTERNAL\_CLK = SYS\_CLK / (I2C\_PSC[7-0] \text{ PSC bit field} + 1)$	$(I2C\_SCLL[7-0] \text{ SCLL bit field value} + 7) \times INTERNAL\_CLK \text{ period}$	$(I2C\_SCLH[7-0] \text{ SCLH bit field value} + 5) \times I2Ci\_INTERNAL\_CLK \text{ period}$
HS second phase	SYS_CLK	$(I2C\_SCLL[15-8] \text{ HSSCLL bit field value} + 7) \times SYS\_CLK \text{ period}$	$(I2C\_SCLH[15-8] \text{ HSSCLH bit field value} + 5) \times I2Ci\_SYS\_CLK \text{ period}$

**Note**

For HS mode, the I2C\_SCLL[15-8] HSSCLL and I2C\_SCLL[7-0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2C\_SCLH[15-8] HSSCLH and I2C\_SCLH[7-0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

**Note**

The equations in Table 12-16 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at I2C controller outputs. Actual  $t_{low}$  and  $t_{high}$  periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

**CAUTION**

During active mode (the I2C\_CON[15] I2C\_EN bit is set to 1), make no changes to the I2C\_SCLL and I2C\_SCLH registers. Changes may result in unpredictable behavior.

Table 12-17 lists the register values for obtaining the maximum I2C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

**Table 12-17. I2C Register Values for Maximum I2C Bit Rates in I2C F/S, I2C HS Modes**

	I <sup>2</sup> C Mode for			Description
	Standard Mode	Fast Mode	High-Speed Mode	
SYS_CLK frequency (MHz)	96			
OCP_CLK frequency (MHz)	133			
<b>I2C_PSC[7-0] PSC</b>	<b>23</b>	<b>9</b>	<b>1</b>	Prescaler value for F/S and HS modes
INTERNAL_CLK frequency (MHz)	4	9.6	96	
<b>I2C_SCLL[7-0] SCLL</b>	<b>13</b>	<b>7</b>	<b>115</b>	Value for F/S mode and first phase of HS mode
<b>I2C_SCLH[7-0] SCLH</b>	<b>15</b>	<b>5</b>	<b>113</b>	Value for F/S mode and first phase of HS mode
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate
Maximum filter period (ns)	250	104.2	10	
<b>I2C_SCLL[15-8] HSSCLL</b>			<b>12</b>	Values for second phase of HS mode
<b>I2C_SCLH[15-8] HSSCLH</b>			<b>5</b>	Values for second phase of HS mode
HS mode maximum bit rate (Mbps)			3.31	HS mode maximum bit rate
Maximum filter period (ns)			10	

#### Note

This table presents informative values only for the configuration parameters and the I<sup>2</sup>C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

#### Note

For WKUP\_I2C0

For MCU\_I2C[0-1]

For I2C[0-6]

$I2Ci\_INTERNAL\_CLK \text{ freq} = I2Ci\_SYS\_CLK / (PSC + 1)$

$F/S \text{ filter period} = 1 / I2Ci\_INTERNAL\_CLK$

$HS \text{ filter period} = 1 / I2Ci\_SYS\_CLK \text{ freq}$

$HS \text{ bit rate} = I2Ci\_SYS\_CLK \text{ freq} / (HSSCLL + 7 + HSSCLH + 5)$

$FS \text{ bit rate} = I2Ci\_INTERNAL\_CLK / (SCLL + 7 + SCLH + 5)$

#### 12.1.3.3.2.2 I2C Automatic Blocking of the I2C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I<sup>2</sup>C clock after the target addressing phase, when the I2C controller is addressed by an external controller device using a certain Own Address.

The release of the I<sup>2</sup>C clock can be performed independently for each Own Address (I2C\_OA, and I2C\_OAx registers, where x = 1, 2, 3) by deasserting the corresponding bit in the I2C\_SBLOCK register.

#### 12.1.3.3.3 I2C Software Reset

Each multicontroller I2C supports the software reset by accessing the I2C\_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2C\_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2C\_CON[15] I2C\_EN bit to 0).
2. Set the I2C\_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2C\_CON[15] I2C\_EN bit to 1.
4. Check the I2C\_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

#### Note

The I2C\_CON[15] I2C\_EN bit can hold the functional clock domain of the multicontroller I2C in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I2C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2C\_CON[15] I2C\_EN bit must be set to 1 to enable the functional part of the I2C controller.

The I2C\_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2C\_CON[15] I2C\_EN bit to 1.

#### 12.1.3.3.4 I2C Power Management

Table 12-18 describes power-management features available for the multimaster I2C controllers.

#### Note

For information about source clock gating, see *Power*, in the *Device Configuration*.

#### Note

Some of the I2C features described in this section may not be supported on this family of devices. For more information, see *I2C Not Supported Features*.

**Table 12-18. I2C Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2C_SYSC[4-3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2C_SYSC[9-8] CLOCKACTIVITY	For configuration details, see Table 12-19.
Global wake-up enable	I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

**Table 12-19. I2C Clock Activity Settings**

I2C_SYSC[9-8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	OCP_CLK	SYS_CLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; Functional clock is enabled
01	ON	OFF	Functional clock is disabled; Interface clock is enabled
11	ON	ON	Both clocks are enabled.

#### 12.1.3.3.5 I2C Interrupt Requests

The I2C controller must allocate a minimum of five registers for interrupts.

- Interrupt Raw Status (I2C\_IRQSTATUS\_RAW)
- Interrupt Enabled Status (I2C\_IRQSTATUS)
- Interrupt Enable Set (I2C\_IRQENABLE\_SET)
- Interrupt enable Clear (I2C\_IRQENABLE\_CLR)
- End of interrupt (I2C\_EOI)

End of Interrupt (I2C\_EOI) is used by software to trigger an interrupt service completion.

Table 12-20 lists the event flags, and their mask, that can cause module interrupts.

**Table 12-20. I2C Events**

Event Flag	Event Unmask	Event Mask	Description
I2C_IRQSTATUS[0] AL	I2C_IRQENABLE_SET[0] AL_IE	I2C_IRQENABLE_CLR[0] AL_IE	Arbitration lost. This bit is automatically set by the hardware when it loses the arbitration in controller transmit mode, an interrupt is signaled to the host.
I2C_IRQSTATUS[1] NACK	I2C_IRQENABLE_SET[1] NACK_IE	I2C_IRQENABLE_CLR[1] NACK_IE	No acknowledgement. Bit is set when No Acknowledge is received, an interrupt is signaled to the host.
I2C_IRQSTATUS[2] ARDY	I2C_IRQENABLE_SET[2] ARDY_IE	I2C_IRQENABLE_CLR[2] ARDY_IE	Register access ready. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the host.
I2C_IRQSTATUS[3] RRDY	I2C_IRQENABLE_SET[3] RRDY_IE	I2C_IRQENABLE_CLR[3] RRDY_IE	Receive data ready. Set to 1 by core when in receiver mode, a new data can be read. An interrupt is signaled to the host.
I2C_IRQSTATUS[4] XRDY	I2C_IRQENABLE_SET[4] XRDY_IE	I2C_IRQENABLE_CLR[4] XRDY_IE	Transmit data ready. Set to 1 by core when transmitter is ready for new data. An interrupt is signaled to the host.
I2C_IRQSTATUS[5] GC	I2C_IRQENABLE_SET[5] GC_IE	I2C_IRQENABLE_CLR[5] GC_IE	General call. Set to 1 by core when General Call address was detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[6] STC	I2C_IRQENABLE_SET[6] STC_IE	I2C_IRQENABLE_CLR[6] STC_IE	Start condition detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[7] AERR	I2C_IRQENABLE_SET[7] AERR_IE	I2C_IRQENABLE_CLR[7] AERR_IE	Bus Access Error. An interrupt is signaled to the host.
I2C_IRQSTATUS[8] BF	I2C_IRQENABLE_SET[8] BF_IE	I2C_IRQENABLE_CLR[8] BF_IE	Bus free. An interrupt is signaled to the host.
I2C_IRQSTATUS[9] AAS	I2C_IRQENABLE_SET[9] AAS_IE	I2C_IRQENABLE_CLR[9] AAS_IE	Address recognized as target. An interrupt is signaled to the host.
I2C_IRQSTATUS[10] XUDF	I2C_IRQENABLE_SET [10] XUDF_IE	I2C_IRQENABLE_CLR[10] XUDF_IE	Transmit underflow. An interrupt is signaled to the host.
I2C_IRQSTATUS[11] ROVR	I2C_IRQENABLE_SET [11] ROVR_IE	I2C_IRQENABLE_CLR[11] ROVR_IE	Receive overrun. An interrupt is signaled to the host.
I2C_IRQSTATUS[12] BB	N/A	N/A	Bus busy indicator
I2C_IRQSTATUS[13] RDR	I2C_IRQENABLE_SET [13] RDR_IE	I2C_IRQENABLE_CLR[13] RDR_IE	Receive draining. An interrupt is signaled to the host.
I2C_IRQSTATUS[14] XDR	I2C_IRQENABLE_SET [14] XDR_IE	I2C_IRQENABLE_CLR[14] XDR_IE	Transmit draining. An interrupt is signaled to the host.

#### 12.1.3.3.6 I2C Programmable Multitarget Channel Feature

This feature allows each multicontroller I2C to be addressed using four separate Own Addresses configured in the I2C\_OA and I2C\_OAx registers (where x = 1, 2, 3). An additional register (I2C\_ACTOA) is used to indicate to the LH which address is used by the external controller to communicate with the I2C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2C\_CON[7] XOA0, I2C\_CON[6] XOA1, I2C\_CON[5] XOA2, or I2C\_CON[4] XOA3).

#### 12.1.3.3.7 I2C FIFO Management

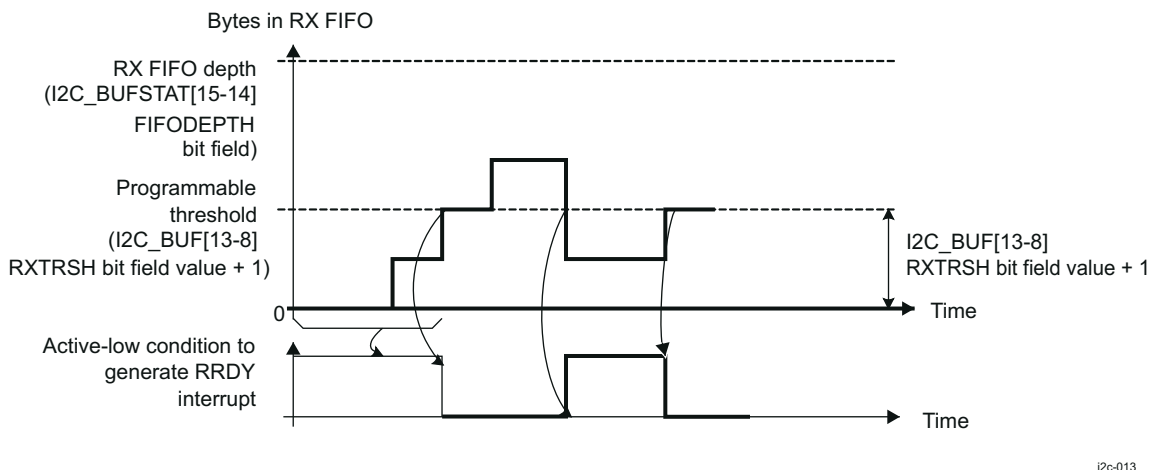

Each multicontroller I2C implements two internal 8-bit FIFOs, the RX and TX FIFOs.

The depth of the RX and TX FIFOs can be checked by reading the I2C\_BUFSTAT[15-14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

### 12.1.3.3.7.1 I2C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2C\_IRQENABLE\_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2C\_BUF[13-8] RXTRSH bit field value + 1 for the RX FIFO or the I2C\_BUF[5-0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I2C controller in receive mode and/or from any source to the I2C controller FIFO in transmit mode).

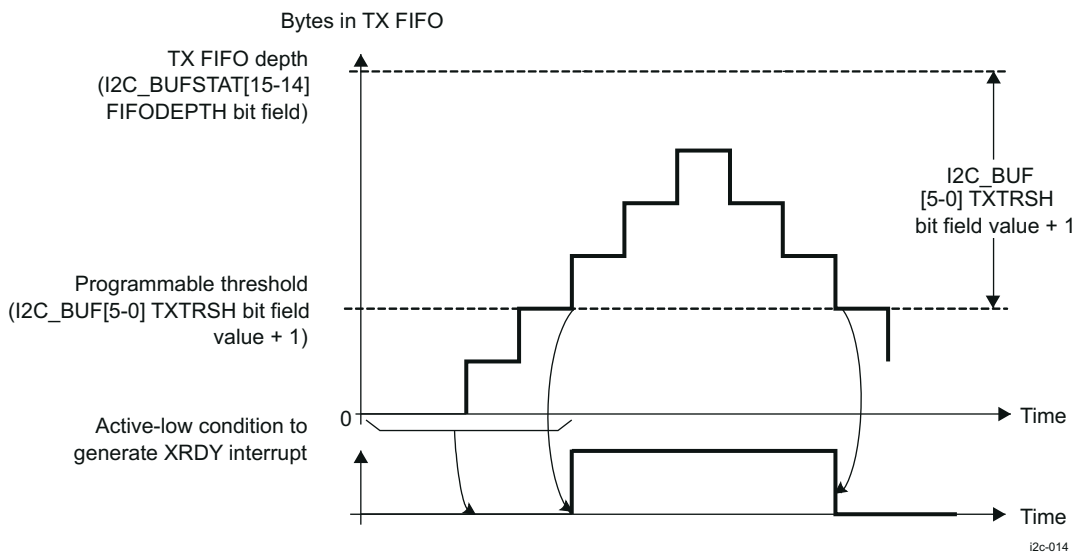

Figure 12-16 and Figure 12-17 show receive and transmit operations, respectively, from a FIFO management point of view.

**Figure 12-16. I2C Receive FIFO Interrupt Request Generation**

In Figure 12-16, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2C\_BUF[13-8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

**Figure 12-17. I2C Transmit FIFO Interrupt Request Generation**

In [Figure 12-17](#), the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2C\_IRQENABLE\_CLR [4] XRDY\_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C\_BUF[5-0] TXTRSH + 1 or I2C\_BUF[5-0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see [Section 12.1.3.3.7.3, Draining Feature \[I2C Mode Only\]](#)).

---

#### Note

In target transmit mode (the I2C\_CON[10] MST bit is cleared and the I2C\_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external controller can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in target transmit mode, data can remain in the TX FIFO without being transmitted over the I<sup>2</sup>C bus. In this case, the TX FIFO must be cleared by setting the I2C\_BUF[6] TXFIFO\_CLR bit.

---

##### 12.1.3.3.7.2 I2C FIFO Polling Mode

In FIFO polling mode (the I2C\_IRQENABLE\_SET[4] XRDY\_IE and I2C\_IRQENABLE\_SET[3] RRDY\_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2C\_IRQSTATUS\_RAW[4] XRDY and the I2C\_IRQSTATUS\_RAW[3] RRDY bits (the I2C\_IRQSTATUS\_RAW[13] RDR and I2C\_IRQSTATUS\_RAW[14] XDR bits can also be polled if the draining feature is enabled). The I2C\_IRQSTATUS\_RAW[4] XRDY and I2C\_IRQSTATUS\_RAW[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

##### 12.1.3.3.7.3 I2C Draining Feature

---

#### Note

DMA mode and SCCB Protocol are not supported on this family of devices.

---

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2C\_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold and the I2C\_BUF[5-0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2C\_IRQSTATUS\_RAW[7] AERR bit.

The draining mechanism generates an interrupt using the I2C\_IRQSTATUS\_RAW[13] RDR or I2C\_IRQSTATUS\_RAW[14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2C\_BUFSTAT[13-8] RXSTAT or I2C\_BUFSTAT[5-0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (controller or target), if the RX FIFO threshold (the I2C\_BUF[13-8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I<sup>2</sup>C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2C\_IRQSTATUS\_RAW[13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2C\_BUFSTAT[13-8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2C\_BUFSTAT[13-8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In controller transmit mode, if the TX FIFO threshold (the I2C\_BUF[5-0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2C\_IRQSTATUS\_RAW[14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2C\_BUFSTAT[5-0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2C\_BUFSTAT[5-0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In controller mode, the LH can alternately not check the values of the I2C\_BUFSTAT[5-0] TXSTAT and I2C\_BUFSTAT[13-8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2C\_CNT[15-0] DATACOUNT bit field value modulo I2C\_BUF[13-8] RXTRSH or I2C\_BUF[5-0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2C\_IRQENABLE\_SET[14] XDR\_IE or I2C\_IRQENABLE\_SET[13] RDR\_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2C\_BUF[5-0] TXTRSH bit field value + 1 for the TX threshold or the I2C\_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold).

#### 12.1.3.3.8 I2C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the INTERNAL\_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For standard mode (for example, the I2C\_PSC[7-0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2C\_I2C\_PSC[7-0] PSC bit field.

#### 12.1.3.3.9 I2C System Test Mode

A system test mode is available for multicontroller I2C module testing. This mode is enabled by setting the I2C\_SYSTEST[15] ST\_EN bit to 1. When this bit is cleared to 0, the I2C controller is configured in normal operation mode.

In system test mode, the I2C\_SYSTEST[13-12] TMODE bit field selects the type of test. [Table 12-21](#) lists the tests available for the multicontroller HS I2C controllers.

**Table 12-21. I2C List of Tests**

I2C_SYSTEST[13-12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of SCL serial clock line	The SCL line is driven with a permanent clock as if controlled with the parameters set in the I2C_PSC, I2C_SCLL, and I2C_SCLH registers.
11	Loop-back mode + SCL/SDA I/O	In controller transmit mode only, data transmitted out of the I2C_DATA register (write action) is received in the same I2C_DATA register through an internal path through the FIFO buffers. The interrupt request is normally generated if it is enabled. Moreover, the SCL and SDA are controlled with the I2C_SYSTEST[3-0] bits.

---

**Note**

When the I2C\_SYSTEST[13-12] TMODE bit field is set to 11, the I2C controller must be configured in I<sup>2</sup>C F/S (I2C\_CON[13-12] OPMODE set to 00) or I<sup>2</sup>C HS mode (I2C\_CON[13-12] OPMODE set to 01).

---

---

**Note**

In normal operation mode (the I2C\_SYSTEST[15] ST\_EN bit cleared to 0), the I2C\_SYSTEST[3-0] bits that control the SCL, SDA lines in system test mode are read-only bits.

---

In system test mode (the I2C\_SYSTEST[15] ST\_EN bit set to 1), the I2C\_IRQSTATUS\_RAW[4] XRDY, I2C\_IRQSTATUS\_RAW[3] RRDY, I2C\_IRQSTATUS\_RAW[10] XUDF, I2C\_IRQSTATUS\_RAW[11] ROVR, I2C\_IRQSTATUS\_RAW[2] ARDY and I2C\_IRQSTATUS\_RAW[1] NACK status bits can be set to 1 when the I2C\_SYSTEST[11] SSB bit is set to 1. Clearing the I2C\_SYSTEST[11] SSB bit to 0 does not clear the I2C\_IRQSTATUS\_RAW bits to 0. The I2C\_IRQSTATUS\_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

### 12.1.3.4 I2C Programming Guide

#### 12.1.3.4.1 I2C Low-Level Programming Models

##### 12.1.3.4.1.1 I2C Programming Model

This section describes the programming model of the multimaster I2C controllers configured in I<sup>2</sup>C mode.

##### 12.1.3.4.1.1.1 Main Program

###### 12.1.3.4.1.1.1.1 Configure the Module Before Enabling the I2C Controller

Before enabling the I2C controller, perform the following steps:

1. Enable the functional and interface clocks (see *WKUP I2C Clocks and Resets*, *MCU\_I2C Clocks and Resets*, and *I2C Clocks and Resets*).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2C\_PSC[7-0] PSC bit field. This value depends on the frequency of the functional clock (SYS\_CLK).
3. Program the I2C\_SCLL[7-0] SCLL and I2C\_SCLH[7-0] SCLH bit fields to obtain a bit rate of 100 Kbps or 400 Kbps. These values depend on the internal sampling clock frequency (see [Table 12-16](#)).
4. (Optional) Program the I2C\_SCLL[15-8] HSSCLL and I2C\_SCLH[15-8] HSSCLH bit fields to obtain a bit rate of 400 Kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 12-16](#)).
5. Configure the Own Address of the I2C controller by storing it in the I2C\_OA register. Up to four Own Addresses can be programmed in the I2C\_OA and I2C\_OAx registers (where x = 1, 2, 3) for each I2C controller.

#### Note

For a 10-bit address, set the corresponding expand Own Address bit in the I2C\_CON register.

6. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2C\_BUF[5-0] TXTRSH bit field to (TX threshold – 1) and the I2C\_BUF[13-8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
7. Take the I2C controller out of reset by setting the I2C\_CON[15] I2C\_EN bit to 1.

##### 12.1.3.4.1.1.1.2 Initialize the I2C Controller

To initialize the I2C controller, perform the following steps:

1. Configure the I2C\_CON register:
  - For controller or target mode, set the I2C\_CON[10] MST bit (0: target; 1: controller).
  - For transmitter or receiver mode, set the I2C\_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2C\_IRQENABLE\_SET register to 1 (the I2C\_IRQENABLE\_SET [4] XRDY\_IE bit for the transmit interrupt, the I2C\_IRQENABLE\_SET [3] RRDY bit for the receive interrupt).

##### 12.1.3.4.1.1.1.3 Configure Target Address and the Data Control Register

In controller mode, configure the target address register by programming the I2C\_SA[9-0] SA bit field and the number of data bytes (I<sup>2</sup>C data payload) associated with the transfer by programming the I2C\_CNT[15-0] DCOUNT bit field.

#### Note

For a 10-bit address, set the I2C\_CON[8] XSA bit to 1.

##### 12.1.3.4.1.1.1.4 Initiate a Transfer

Poll the I2C\_IRQSTATUS\_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2C\_CON[0] STT and I2C\_CON[1] STP bits. To initiate a transfer, the I2C\_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2C\_CON[1] STP bit to 1.

#### 12.1.3.4.1.1.5 Receive Data

Poll the I2C\_IRQSTATUS\_RAW [3] RRDY bit, or use the RRDY interrupt (the I2C\_IRQENABLE\_SET [3] RRDY\_IE bit must be set to 1) to read the receive data in the I2C\_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2C\_BUF[13-8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2C\_IRQENABLE\_SET [13] RDR\_IE bit to 1).

---

#### Note

In receive mode only, the I2C\_IRQSTATUS\_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I2C controller simply holds SCL to low to prevent other bytes from being received.

The I2C\_IRQSTATUS\_RAW[7] AERR bit is set to 1 when a read access is performed in the I2C\_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2C\_IRQENABLE\_SET [7] AERR\_IE bit to 1.

---

#### 12.1.3.4.1.1.6 Transmit Data

Poll the I2C\_IRQSTATUS\_RAW [4] XRDY bit, or use the XRDY interrupt (the I2C\_IRQENABLE\_SET [4] XRDY\_IE bit must be set to 1) to write data to the I2C\_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2C\_BUF[5-0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2C\_IRQENABLE\_SET [14] XDR\_IE bit to 1).

---

#### Note

In transmit mode only, the I2C\_IRQSTATUS\_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In controller transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2C\_CNT[15-0] DCOUNT bit field is not 0).

In target transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I2C controller device still requests data bytes to be read.

The I2C\_IRQSTATUS\_RAW [7] AERR bit is set to 1 when a write access is performed in the I2C\_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2C\_IRQENABLE\_SET [7] AERR\_IE bit to 1.

---

#### 12.1.3.4.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2C\_IRQSTATUS\_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2C\_IRQSTATUS\_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2C\_IRQSTATUS\_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2C\_IRQSTATUS\_RAW [3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2C\_IRQSTATUS\_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2C\_IRQSTATUS\_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2C\_IRQSTATUS\_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2C\_IRQSTATUS\_RAW [7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2C\_IRQSTATUS\_RAW [8] BF bit) and resolve accordingly.

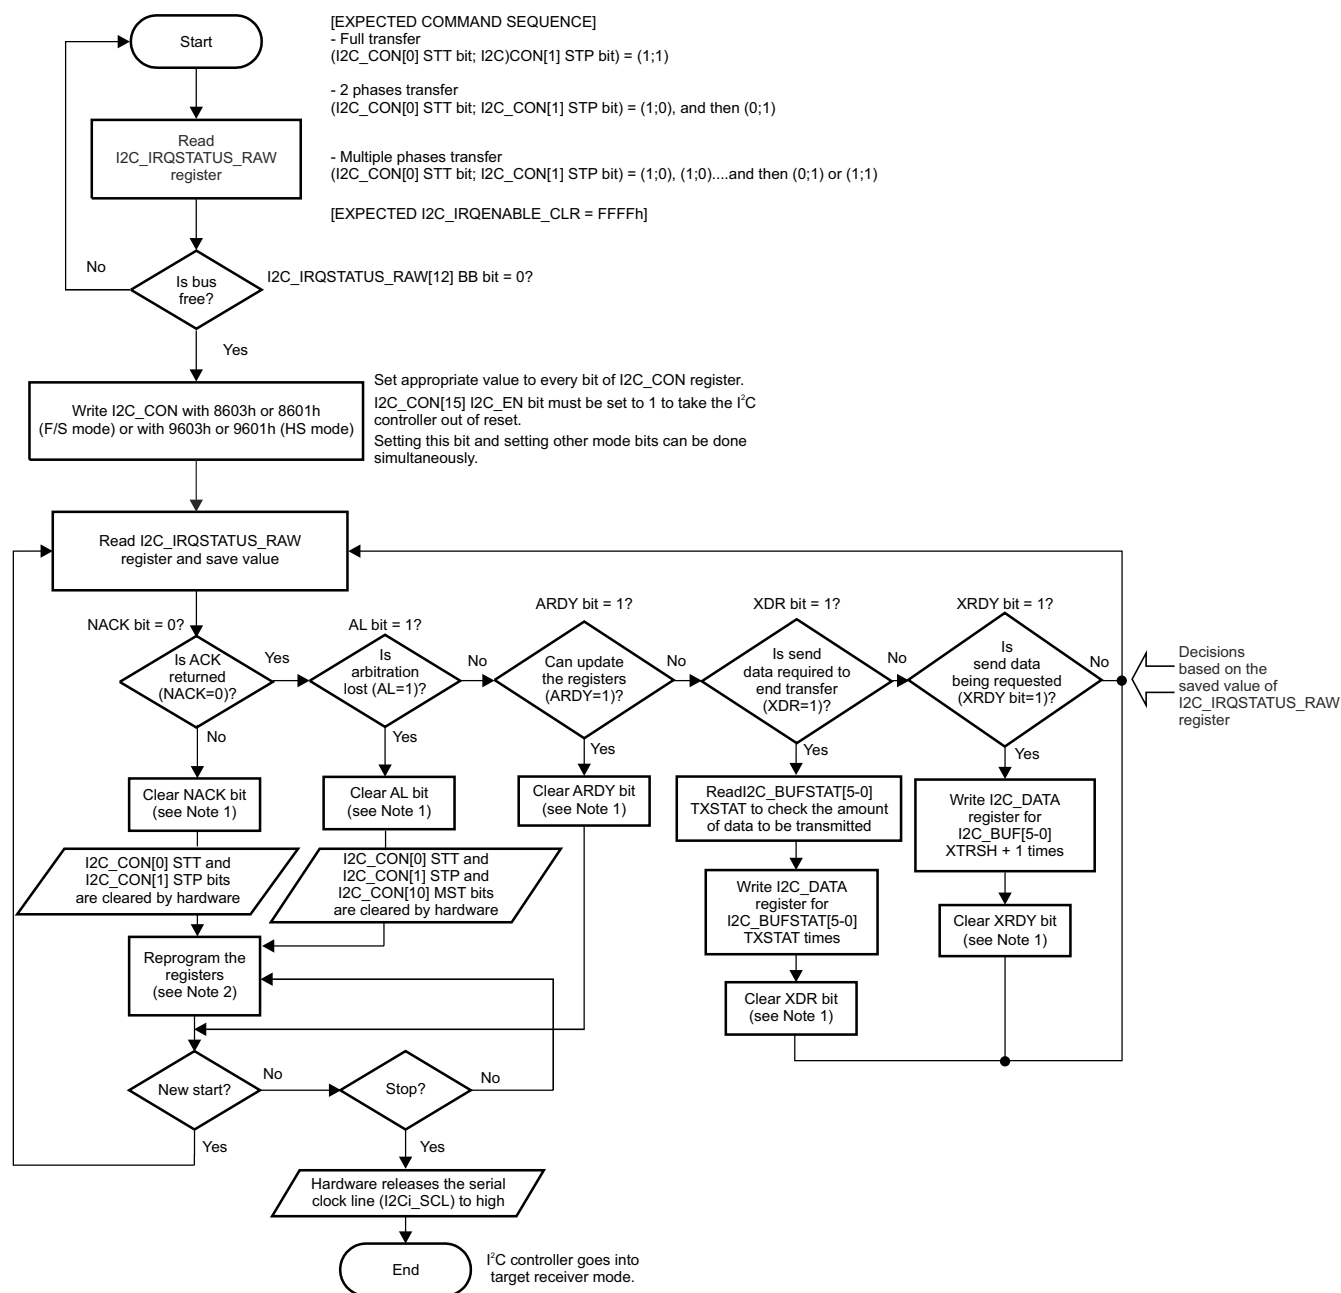

#### 12.1.3.4.1.1.3 Programming Flow-Diagrams

Figure 12-18 through Figure 12-24 are procedure flow charts for programming the F/S and HS I2C modes.

i2c-018

**Figure 12-18. I2C Setup Procedure**

- A. The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- B. Reprogram the registers means: I2C\_CON[11] STB and/or I2C\_CON[10] MST bit and/or I2C\_SA[9-0] SA register and/or I2C\_CNT[15-0] DCOUNT register and/or I2C\_CON[0] STT bit and/or I2C\_CON[1] STP bit.

**Figure 12-19. I2C Controller Transmitter Mode, Polling Method, in F/S and HS Modes**

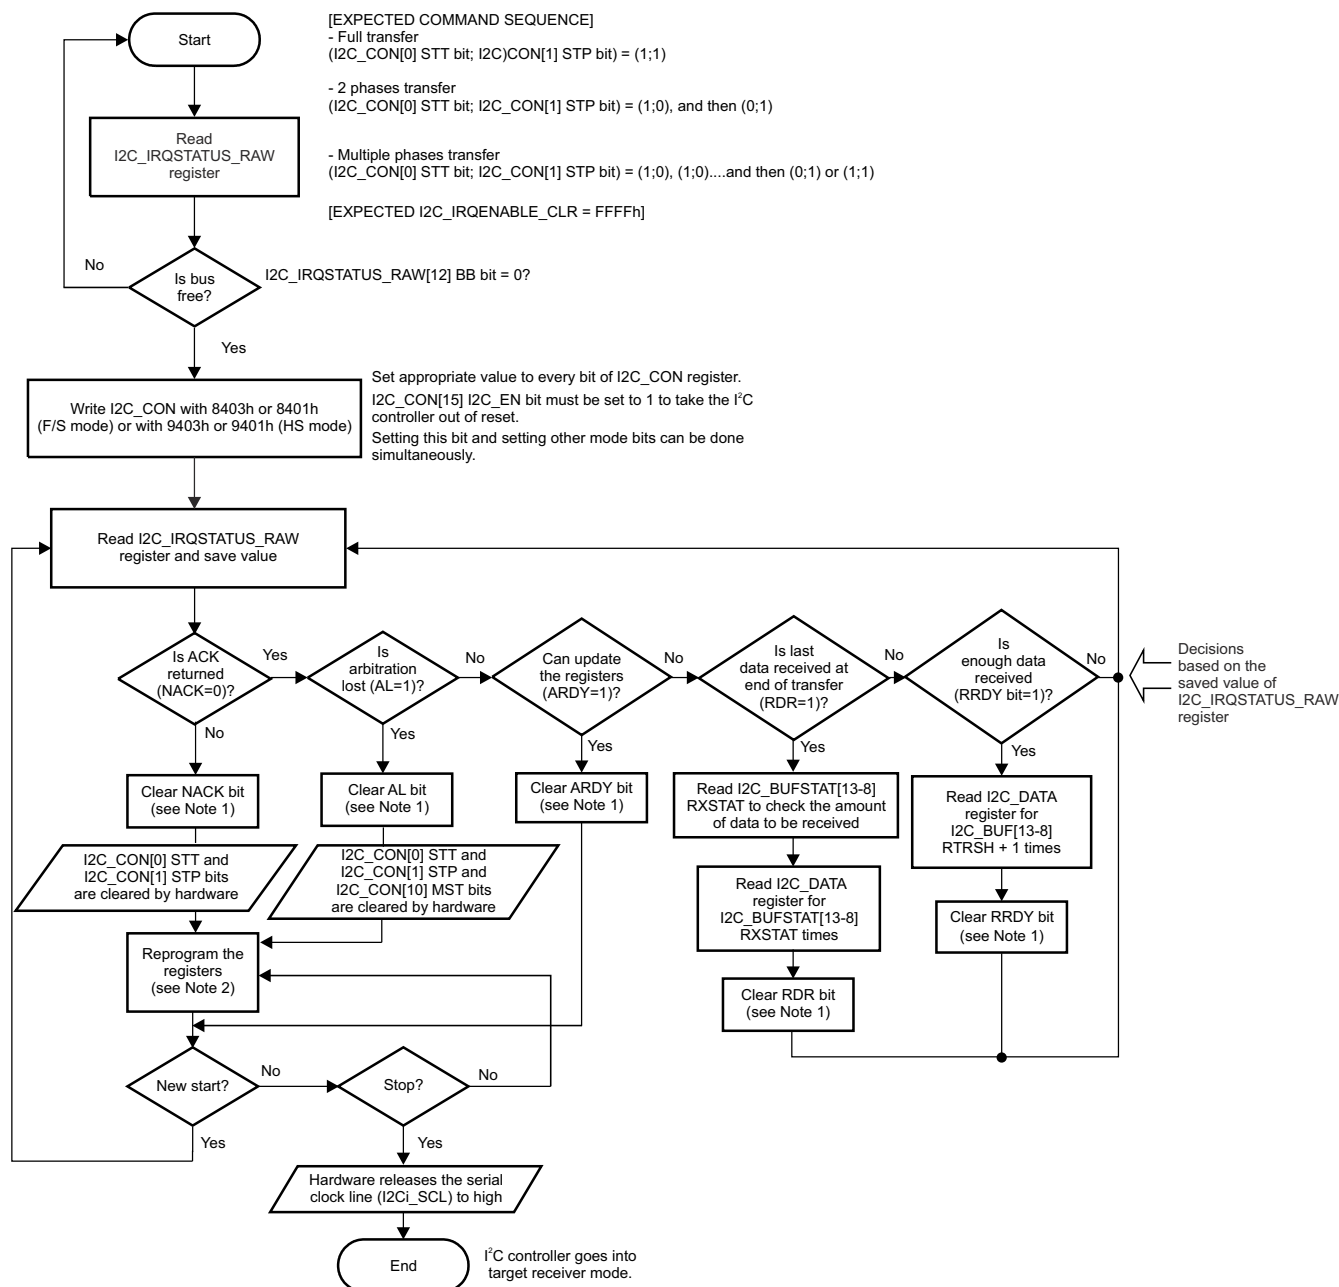

### Note

The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

## Note

In HS mode, the Sr condition and clock frequency switching are automatically generated by the multicontroller I2C.

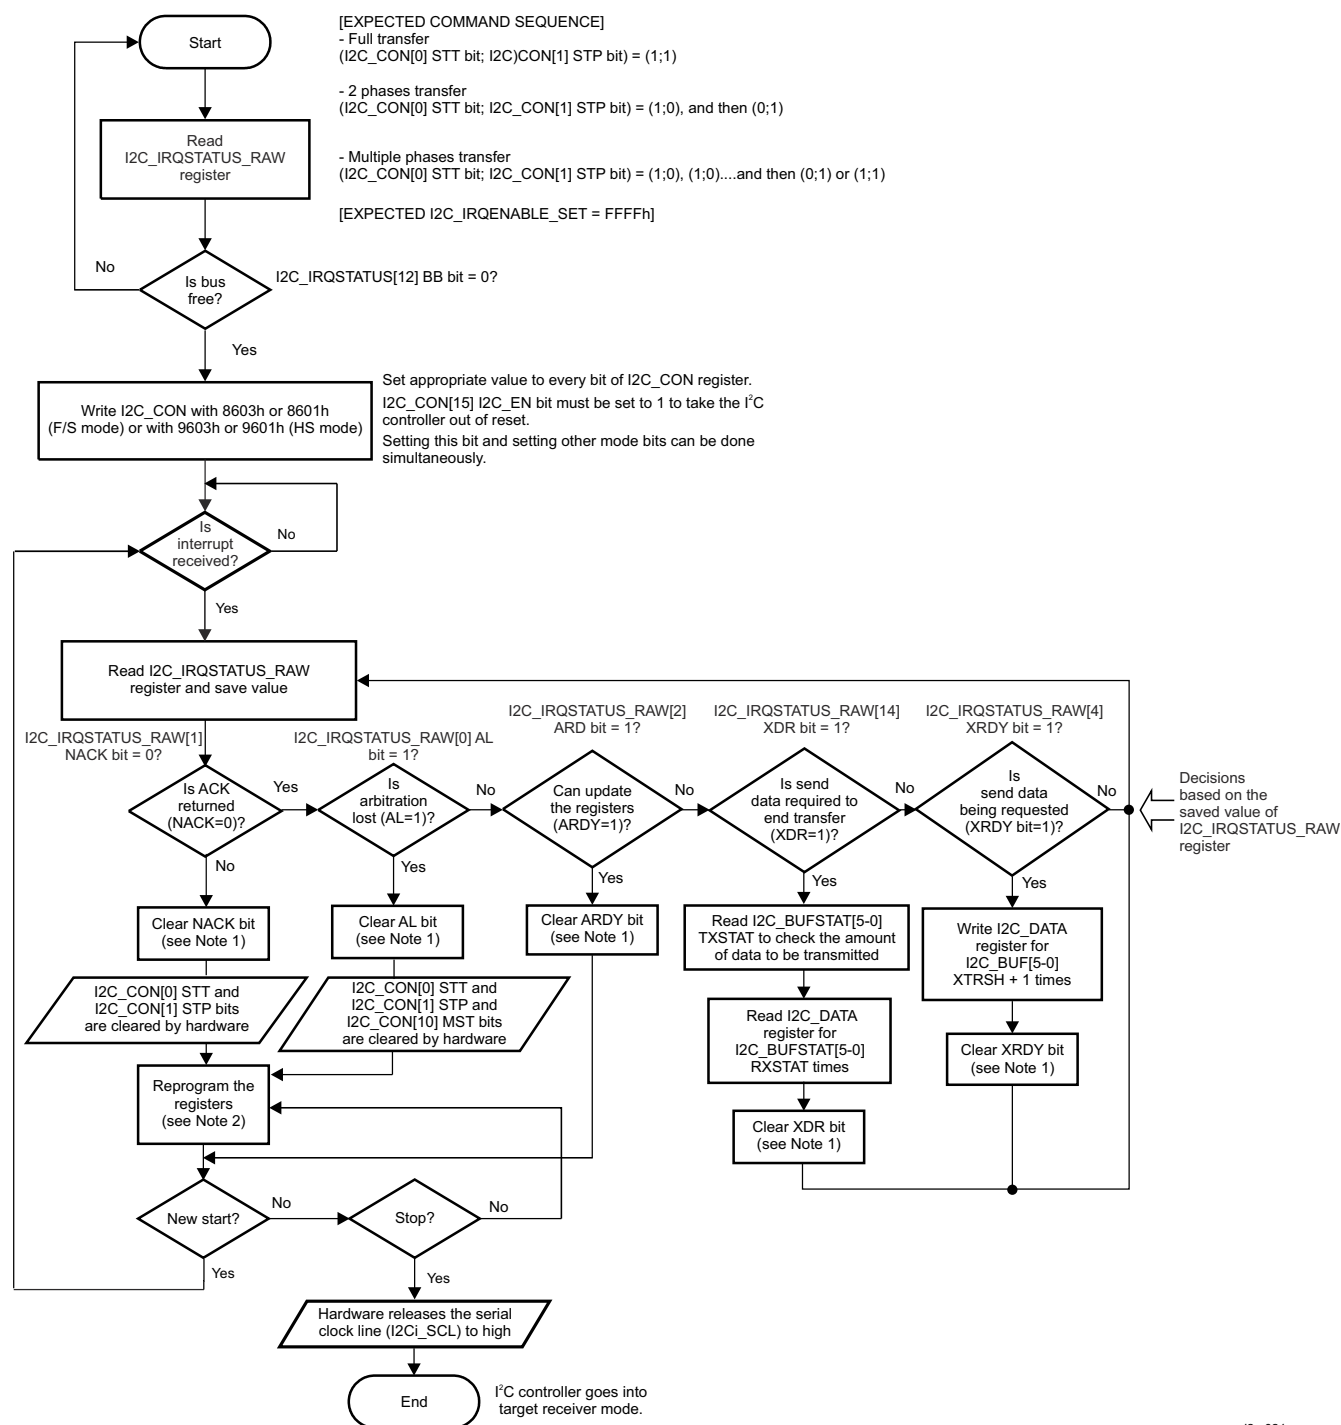

i2c-020

- The NACK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- Reprogram registers means: I2C\_CON[11] STB and/or I2C\_CON[10] MST bit and/or I2C\_SA[9-0] SA register and/or I2C\_CNT[15-0] DCOUNT register and/or I2C\_CON[0] STT bit and/or I2C\_CON[1] STP bit.

**Figure 12-20. I2C Controller Receiver Mode, Polling Method, in F/S and HS Modes**

i2c-021

- The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- Reprogram registers means: I2C\_CON[11] STB and/or I2C\_CON[10] MST bit and/or I2C\_SA[9-0] SA register and/or I2C\_CNT[15-0] DCOUNT register and/or I2C\_CON[0] STT bit and/or I2C\_CON[1] STP bit.

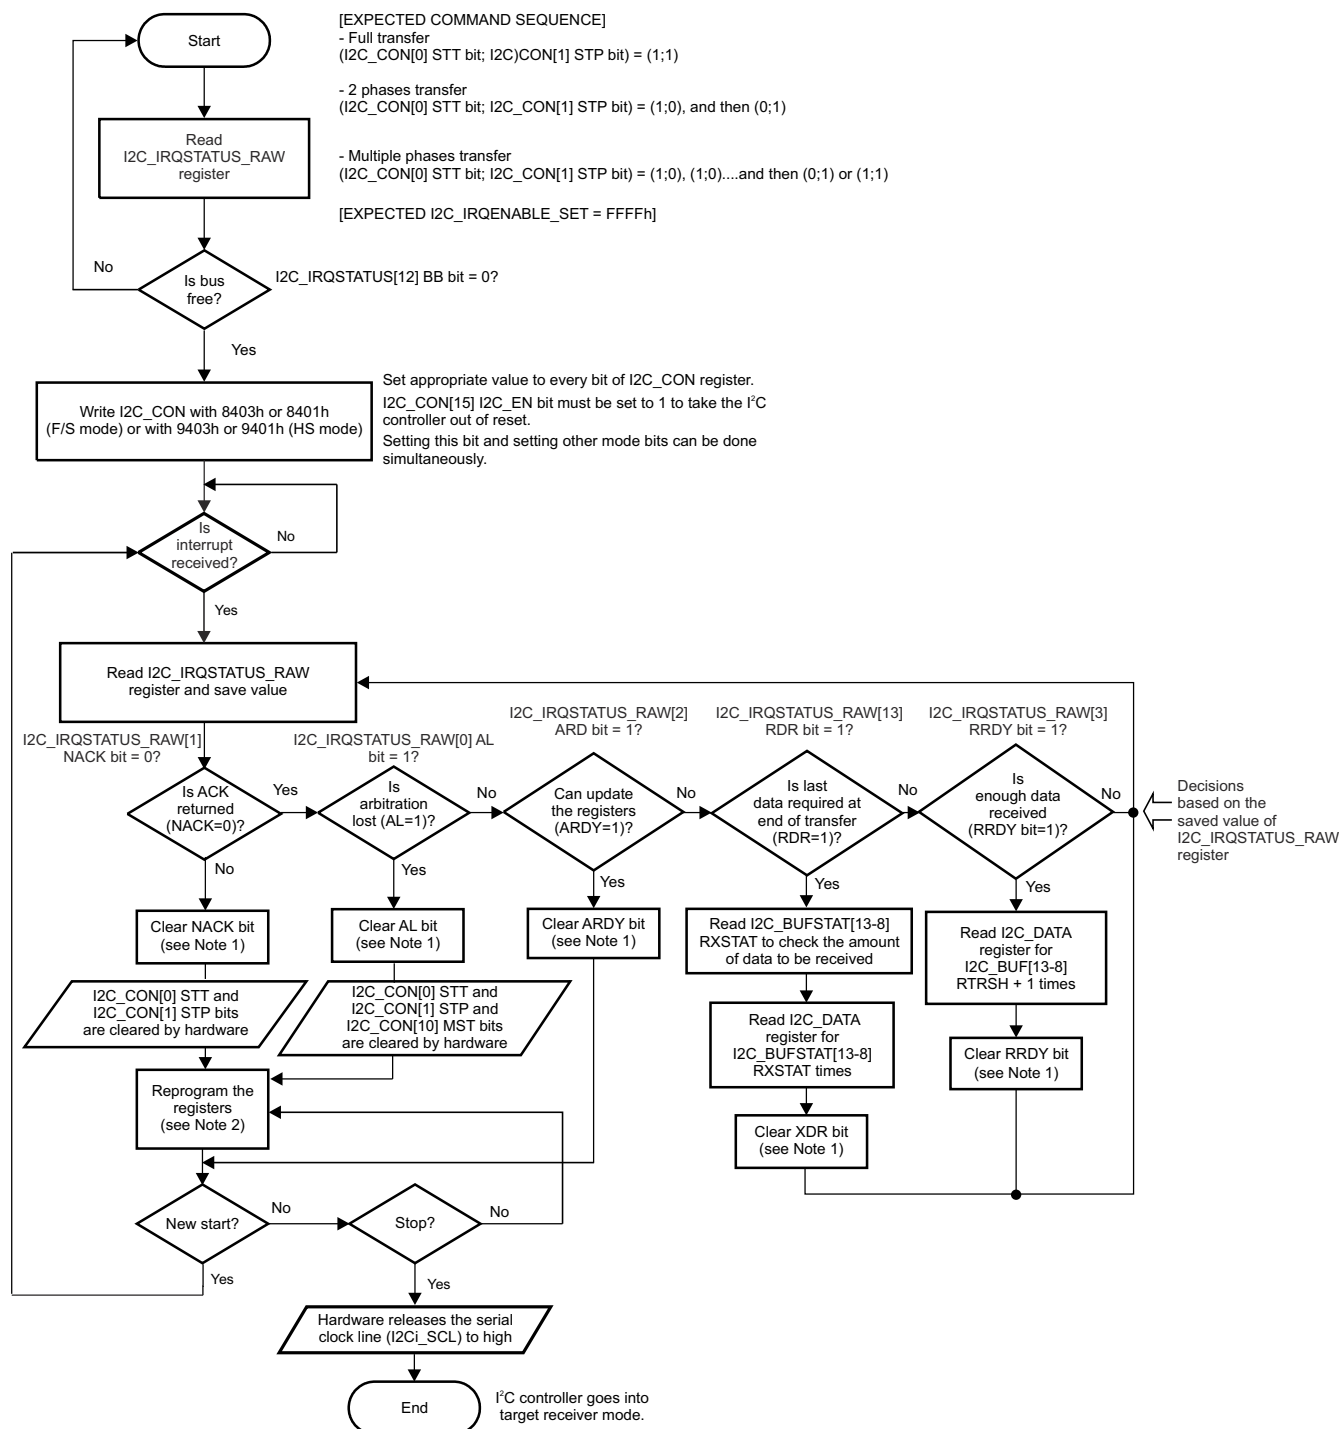

**Figure 12-21. I2C Controller Transmitter Mode, Interrupt Method, in F/S and HS Modes**

### Note

The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

## Note

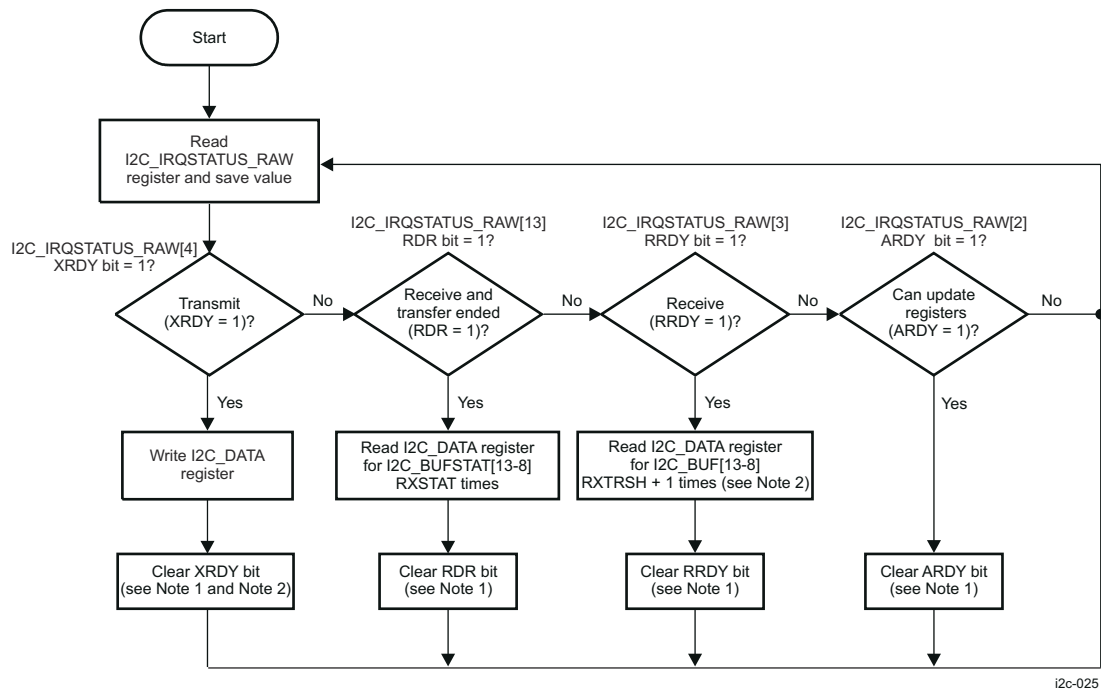

In HS mode, the Sr condition and clock frequency switching are automatically generated by the multicontroller I2C.

i2c-022

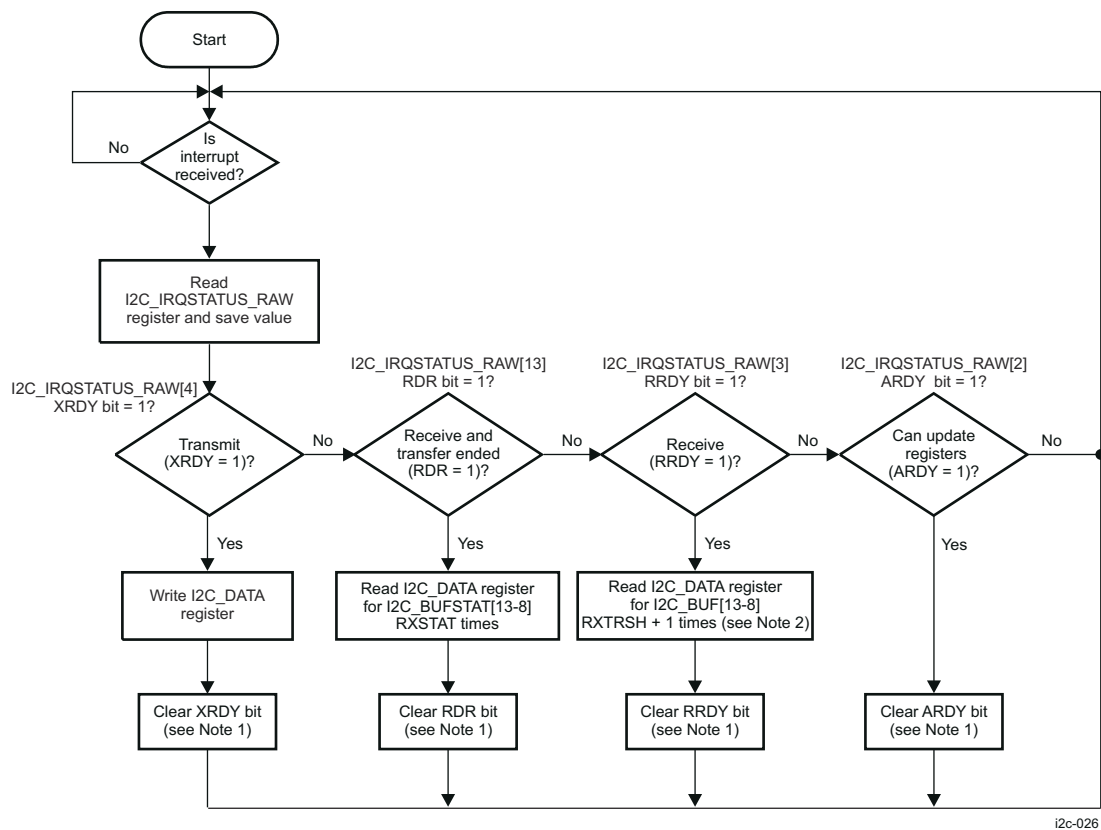

- The NACK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- Reprogram registers means: I2C\_CON[11] STB and/or I2C\_CON[10] MST bit and/or I2C\_SA[9-0] SA register and/or I2C\_CNT[15-0] DCOUNT register and/or I2C\_CON[0] STT bit and/or I2C\_CON[1] STP bit.

**Figure 12-22. I2C Controller Receiver Mode, Interrupt Method, in F/S and HS Modes**

- A. The XRDY, RDR, RRDY, and ARDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- B. In target transmitter mode, the amount of data requested by the external controller I<sup>2</sup>C device is unknown; thus, the I2C\_BUF[5-0] XTRSH bit field must be configured to 0x0 (TX threshold = 1).

**Figure 12-23. I2C Target Transmitter/Receiver Mode, Polling**

- A. The XRDY, RDR, RRDY, and ARDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.

- B. In target transmitter mode, the amount of data requested by the external controller I<sup>2</sup>C device is unknown; thus, the I2C\_BUF[5-0] XTRSH bit field must be configured to 0x0 (TX threshold = 1).

**Figure 12-24. I2C Target Transmitter/Receiver Mode, Interrupt**

### 12.1.4 Improved Inter-Integrated Circuit (I3C) Interface

This section describes the Improved Inter-Integrated Circuit (I3C) module in the device.

#### 12.1.4.1 I3C Overview

The device contains Improved Inter-Integrated Circuit (I3C) an interface between a local host (LH), such as an Arm, and any I3C-bus-compatible device that connects via the I3C serial bus.

For the specific I/O timing characteristics of the I3C , see the device-specific data sheet.

##### 12.1.4.1.1 I3C Features

I3C module has the following features:

- Communication Modes:
  - Single Data Rate (SDR) mode
  - High Data Rate – Dual Data Rate (HD-DDR) mode
- Bus Modes:
  - Pure Bus Mode (supports only I3C devices). Maximum supported frequency is 10.375 MHz
- Master and Multi-Master modes
- Common Command Codes (CCC)
- Bus Enumeration and Discovery:
  - Slaves implement standardized characteristics registers that can be queried by the master after power up to enumerate the devices attached to the bus.
- Hot-Join capability:
  - A slave device can be powered on and join the bus after initial enumeration.
- In Band Interrupts (IBI):
  - Slave devices request interrupts through the I3C bus rather than with separate side-band signals. This reduces the total IO count of the SoC as well as PCB routing.
- Dynamic Address Assignment (DAA):
  - The master can assign each slave device an address during configuration. This supports IBI because interrupt priority among slaves is arbitrated with the same address arbitration scheme that is used for all communication.
- Static Addressing (SA)
- FIFO Buffers:
  - CMD Queueing out going commands:
    - CMD0\_FIFO stores the least significant half-word of the command
    - CMD1\_FIFO stores the most significant half-word of the command
  - TXFIFO stores data transmitted with each command
  - RXFIFO stores data received as command response
  - IBI\_DATA\_FIFO stores data received as part of the in-band-interrupt transfer (IBI can transfer 0, 1, or N bytes of data payload depending on the slave)
- Immediate high priority command queue
- Registers to store the parameters for the response to an IBI interrupt from a number of slaves:
  - Each register holds the slave address and appropriate response type and payload length information for two different slaves, so that the controller can process in band interrupts without CPU intervention.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

##### 12.1.4.1.2 I3C Not Supported Features

- High Data Rate – Ternary Symbol Legacy (HDR-TSL) mode
- High Data Rate – Ternary Symbol Pure (HDR-TSP) mode
- Mixed Bus (I3C devices and Legacy I2C devices with open drain or emulated open drain I/O)
- Secondary master modes
- Slave mode
- Master takeovers
- Secondary Master Hot-Join

- DMA service of I3C FIFOs
- Stamping interface (for DMA FIFO levels)
- GPIO Interface
- Optional CCCs:
  - GETMXDS

#### 12.1.4.1.3 I3C Ports

**Table 12-22. I3C0 Clocks and Resets**

Clocks	
Module Clock Input	Description
I3C_PCLK	I3C configuration clock
I3C_SCLK	I3C system clock
Resets	
Module Reset Input	Description
I3C_RST	I3C reset

**Table 12-23. I3C0 Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
I3C_I3C_INT_0	I3C interrupt request	Level
I3C_PCLK_ECC_UNCORR_LVL_0	I3C PCLK ECC interrupt request	Level
I3C_SCLK_ECC_UNCORR_LVL_0	I3C SCLK ECC interrupt request	Level
I3C_I3C_NONFATAL_INT_0	I3C non fatal interrupt request	Level
I3C_I3C_FATAL_INT_0	I3C fatal interrupt request	Level

#### 12.1.4.2 I3C Environment

This section describes the I3C external connections (environment).

[Table 12-24](#) describes the I3C I/O signals.

**Table 12-24. I3C I/O Signals**

Module Pin	I/O <sup>(1)</sup>	Description
SCL	I/O	I <sup>3</sup> C serial clock line. Emulated open-drain output buffer.
SDA	I/O	I <sup>3</sup> C serial data line. Emulated open-drain output buffer.
SDAPULLEN	O	I <sup>3</sup> C data pull enable. <sup>(2)</sup>

(1) I = Input; O = Output; I/O = Bidirectional

(2) Enable buffer/switch for open drain class pull-up, enabled during open drain mode.

#### 12.1.4.3.1 I3C Block Diagram

Programming the prescalers must be performed prior to enabling I3C Master controller with I3C\_CTRL[31] DEV\_EN bit in the control register.

In all timing schemes, the base frequency resulting from prescalers corresponds directly to the duration of the high level of the SCL line which takes always 50% of the base period. Depending on various conditions, the duration of low level is extended beyond the base period as necessary.

There is a specific relationship between SCL frequency and system clock frequency, which requires system clock to have a multiple of four cycles per each SCL period. Thus the selection of system clock frequency must be done with caution, since only specific frequencies will allow configuring SCL to fit into desired bandwidth.

Table 12-26 presents achievable SCL frequencies for exemplary set of system clock frequency values.

**Table 12-26. Achievable SCL Frequencies**

frequency	I3C_PRESCAL_CTRL0[9-0] I3C	Actual frequencies
100 MHz	0x2	8.33 MHz
133 MHz	0x3	8.313 MHz
166 MHz	0x3	10.375 MHz
200 MHz	0x4	10 MHz

#### 12.1.4.3.2.2 Asymmetric Push-Pull SCL Timing

In case of I<sup>3</sup>C messaging, asymmetric generation pattern for driving SCL can be enabled. The main purpose for this feature is supporting I3C slaves that are not capable to use maximal SCL frequency during private read/write data transfers. Host can recognize limited speed device by examining value of I3C\_DEV\_IDn\_RR2[15-8] bit-field for n = 0 to 11. Maximum frequency supported by slave can be retrieved by GETMSCL command. The low period of SCL is extended by the value programmed in I3C\_PRESCAL\_CTRL1[15-8] PP\_LOW bit-field, which can be calculated using the following equation:

**Figure 12-27. SCL Asymmetric Push-Pull**

The I3C\_PRESCAL\_CTRL1[15-8] PP\_LOW resolution is set to ¼ of SCL period. The high period of the SCL remains unchanged and is equal to half period of I<sup>3</sup>C frequency.

The low period used in push-pull mode for slaves with limited SCL capability results from following equation:

$$SCL\_LOW = I3C\_PRESCAL\_CTRL1[15-8] PP\_LOW \times \frac{T}{4}$$

i3c\_014

Where:  
SCL\_LOW: SCL low period.  
T: base SCL period.

**Figure 12-28. SCL Asymmetric Push-Pull Actual Low Period**

#### 12.1.4.3.2.3 Open-Drain SCL Timing

In open-drain mode, due to protocol requirement, low period cannot be shorter than 160ns to support slowly rising SDA line. To fulfill this constrain in I<sup>3</sup>C SDR mode, the low period must be always extended beyond the value resulting from the base I<sup>3</sup>C frequency. The low period of SCL is extended by the value programmed in I3C\_PRESCAL\_CTRL1[7-0] OD\_LOW bit-field, which can be calculated using the following equation:

**Figure 12-29. SCL Open-Drain Low Period**

The I3C\_PRESCAL\_CTRL1[7-0] OD\_LOW bit-field resolution is set to ¼ of SCL period. The high period remains unchanged and is equal to half-period of I<sup>3</sup>C frequency.

The actual SCL low period used in open drain mode results from the following equation:

$$\text{SCL\_LOW} = \text{I3C\_PRESCL\_CTRL1}[7-0] \text{ OD\_LOW} \times \frac{T}{4}$$

i3c\_015

Where:

SCL\_LOW: SCL low period.

T: base SCL period.

**Figure 12-30. SCL Open-Drain Actual Low Period**

#### 12.1.4.3.2.4 Changing Programmed Frequencies

Since SCL clock is derived, in order to change the SCL timing for any mode or to keep current I<sup>3</sup>C bus timing, the following procedure should be used:

1. Disable the I3C controller by setting the I3C\_CTRL[31] DEV\_EN bit to 0.
2. Adjust to the new frequency if necessary, avoiding any glitches during change.
3. Reprogram the prescaler registers to achieve desired I<sup>3</sup>C timing.
4. Enable the core by setting the I3C\_CTRL[31] DEV\_EN bit to 1.

#### 12.1.4.3.3 I3C Interrupt Requests

The I3C controller has two sets of five interrupt registers:

- Interrupt Enable Register (I3C\_MST\_IER)
- Interrupt Disable Register (I3C\_MST\_IDR)
- Interrupt Mask Register (I3C\_MST\_IMR)
- Interrupt Clear Register (I3C\_MST\_ICR)
- Interrupt Status Register (I3C\_MST\_ISR)

After reset, status (I3C\_MST\_ISR) and mask (I3C\_MST\_IMR) registers both read zeroes, so all interrupts are disabled. CPU handles interrupts by several typical operations:

- To activate an interrupt, interrupt enable register (I3C\_MST\_IER) should be programmed with 0x1 on bit positions corresponding to interrupts sources which should be signaled to CPU. This interrupt mask is written to I3C\_MST\_IMR and defines which sources will be propagated.
- After receiving interrupt, I3C\_MST\_ISR should be read to identify the interrupt source. Since I3C\_MST\_ISR is always updated by all interrupt sources regardless of I3C\_MST\_IMR, the I3C\_MST\_ISR value should be compared to the programmed mask (stored in software or read from I3C\_MST\_IMR) as it can contain other flags which were not propagated. Interrupt handler should clear flag which triggered interrupt in I3C\_MST\_ISR by writing 0x1 to corresponding bits of I3C\_MST\_ICR. It is crucial for correct interrupt source identification to read status, apply mask and clear current interrupt flag before another (from the same or different source) interrupt can occur, so these actions should be executed at the beginning of the interrupt handler routine.
- If during operation additional interrupt sources need to be enabled, clearing their flags prior to enabling is necessary to avoid false signaling of events which occurred earlier.
- To disable interrupt source anytime during operation, corresponding bit in interrupt disable register (I3C\_MST\_IDR) should be programmed with 0x1, which in turn clears corresponding bit in I3C\_MST\_IMR, disabling interrupt source.

#### 12.1.4.3.4 I3C Power Configuration

Before I3C controller is put into operation, several settings need to be adjusted after cycling the power on. The general settings collected in I3C\_CTRL register. For most common usage scheme, two fields are the most important:

1. I3C\_CTRL[31] DEV\_EN bit allows enabling and disabling the I<sup>3</sup>C bus controller. It must be enabled before any I<sup>3</sup>C bus message is initiated, however following settings need to be programmed prior to enabling controller:
  - a. Bus Mode (Only Pure Bus Mode is supported)
  - b. SCL Divider prescalers (See *I3C Clock Configuration*)
  - c. Devices Retaining Registers (See *I3C Retaining Registers Space*)

During normal operation the controller should stay enabled. Before disabling, the I3C\_MST\_STATUS0[18] IDLE should be examined to confirm that no bus operation is pending.

2. I3C\_CTRL[1-0] BUS\_MODE bit-field is set to Pure Bus Mode by default. The I3C controller supports only I3C compatible devices on I3C bus and if changed bit-field has no effect. For more information see *I3C Not Supported Features*.

#### 12.1.4.3.5 I3C Dynamic Address Management

Enumeration of I3C devices involves Dynamic Address Assignment procedure. At power up of the I3C bus, the I3C Master should provide dynamic address for all I3C devices under the following conditions:

- If I3C Slave devices with Static Address are available (not supported for this device), firmware may choose to assign Dynamic Address using SETDASA CCC to shorten bus initialization time; such devices are called Static I3C Devices.
- For the devices that are enumerated using SETDASA CCC command the Provisional ID, BCR and DCR information should be manually acquired, using GETPID / GETBCR / GETDCR CCC commands. This step is not mandatory if the values are known prior to bus initialization and programmed into I3C Master by host application.
- Devices with no Static Address and these with Static Address not enumerated receive Dynamic Address using the DAA procedure initiated by issuing the ENTDAACCC command.
- For the devices that are enumerated using ENTDAACCC command the Provisional ID, BCR and DCR information are automatically received during DAA procedure.

During I3C bus operation, current master can disable one or all I3C devices by sending Direct or Broadcast RSTDAA CCC command. In such case, corresponding \*\_CLR bits in I3C\_DEVS\_CTRL should be set by firmware to clean retaining registers. In order to re-enable these devices, DAA procedure must be performed (initiated by master or by Hot-Join requests sent by slave devices).

Depending on I3C slave implementation, the slave that received RSTDAA CCC command may restore its static address. In order to perform private transfers to such slave or assign dynamic address using SETDASA CCC command rather than DAA procedure, the corresponding I3C\_DEV\_IDn\_RR0[7-0] DEV\_ADDR bit field (n = 0 to 11) should be updated with static address. Clearing Retaining Registers by setting corresponding I3C\_DEVS\_CTRL register is not mandatory in this scenario.

Current master can also assign new Dynamic Address to device which already has one by sending SETNEWDA command. After sending this command with new Dynamic Address in the data field, the I3C\_DEV\_IDn\_RR0[7-0] DEV\_ADDR bit field (n = 0 to 11) must be also updated with this address in order to perform subsequent transaction to this device.

#### 12.1.4.3.6 I3C Retaining Registers Space

The information on configuration, Provisional ID, BCR and DCR of each device connected to the I3C bus is stored by the I3C master in a set of retaining registers divided into Device ID sections associated with each device. Application host take any action to guarantee maintaining this information anytime the bus topology changes.

The retaining register space is divided to up to 12 sections (depending on selected configuration), from I3C\_DEV\_ID0 to I3C\_DEV\_ID11. Each containing three 32-bit registers to hold whole necessary information on I3C devices connected to the bus (e.g. hot-join device is attached, some of DA are reset to new value, etc.).

The AMBA APB interface address space for retaining registers starts at 0x080 and is divided into 12 quadruplets.

The map organization is presented in [Table 12-27](#) below.

**Table 12-27. Retaining Registers Map Organization**

Register	Address	Contents
I3C_DEV_ID0_RR0	0x080	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID0_RR1	0x084	Register stores MSB of Provisional ID <sup>(1)</sup>
I3C_DEV_ID0_RR2	0x088	Register stores LSB of Provisional ID, DCR, BCR <sup>(1)</sup>

**Table 12-27. Retaining Registers Map Organization (continued)**

Register	Address	Contents
I3C_DEV_ID1_RR0	0x090	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID1_RR1	0x094	Register stores MSB of Provisional ID <sup>(1)</sup>
I3C_DEV_ID1_RR2	0x098	Register stores LSB of Provisional ID, DCR, BCR <sup>(1)</sup>
I3C_DEV_ID2_RR0	0x0A0	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID2_RR1	0x0A4	Register stores MSB of Provisional ID <sup>(1)</sup>
I3C_DEV_ID2_RR2	0x0A8	Register stores LSB of Provisional ID, DCR, BCR <sup>(1)</sup>
...	...	...
I3C_DEV_ID11_RR0	0x130	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID11_RR1	0x134	Register stores MSB of Provisional ID <sup>(1)</sup>
I3C_DEV_ID11_RR2	0x138	Register stores LSB of Provisional ID, DCR, BCR <sup>(1)</sup>

(1) The information is relevant only for I<sup>3</sup>C devices and is automatically filled by hardware during DAA procedure. Application host needs to fill the information for all devices with Dynamic Addresses Assignment with SETDASA CCC command.

A special device control register (I3C\_DEVS\_CTRL) is provided to store information on devices currently connected to the bus. Each DeviceID section contains configuration register and two registers holding Provisional ID, BCR and DCR of the corresponding device. The active state bit is set automatically by hardware after Dynamic Address is assigned to given device. Firmware shall set it for devices enumerated with SETDASA CCC command after their Retaining Registers are configured and before any transaction to these devices is initiated.

The clearing bits need to be set by firmware every time RSTDAA CCC is send to corresponding devices (firmware should clear all of them for broadcast RSTDAA) or controller constantly receives NACK response and application recognizes device as no longer connected to the bus.

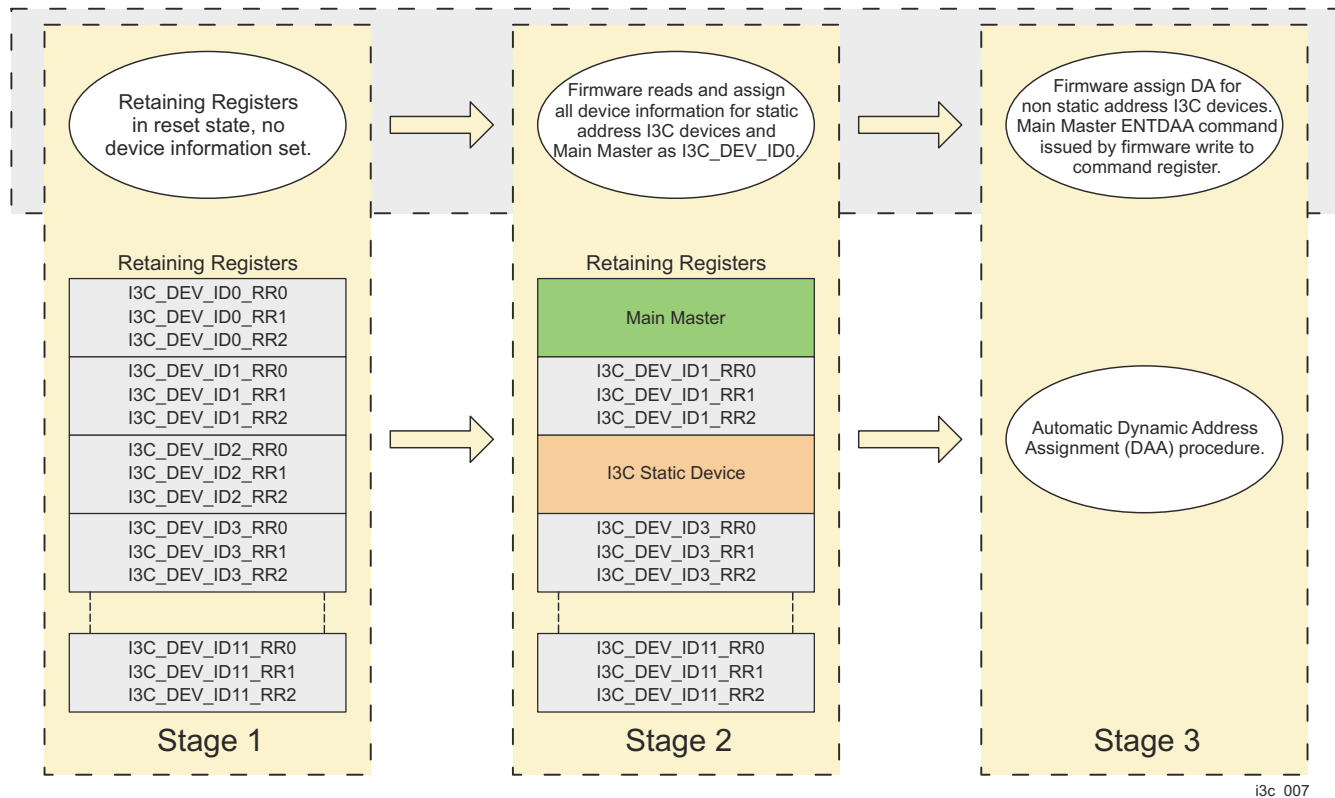

#### 12.1.4.3.7 I3C Dynamic Address Assignment Procedure

The I3C bus initialization procedure can be decomposed into three main stages, described below:

- **Stage 1:** On startup, the I3C master does not have any information about I<sup>3</sup>C slave devices and all Retaining Registers are set to the default reset vector table;
- **Stage 2:** Is fully maintained by application host. The first register section (Device ID0) is reserved for I3C master self-description. The following registers starting from Device ID1 will be filled by DAA procedure in Stage 3. This implies rules firmware should follow:
  - I<sup>3</sup>C devices with Static Address which firmware assume to enumerate with SETDASA CCC command shall be localized in Retaining Registers table (see [Figure 12-31](#)) after address space that reserved for I<sup>3</sup>C devices intended to be enumerated with ENTDA;A;
  - Corresponding I3C\_DEVS\_CTRL bits for active should be set;
- **Stage 3:** Before attempting DAA procedure, firmware should take following actions:
  - For Static I3C Devices intended to be enumerated with SETDASA CCC command:
    - Configuration registers should be programmed with Static Addresses and other settings relevant for I3C device;
    - Corresponding I3C\_DEVS\_CTRL bits for active should be set;
    - Dynamic Addresses should be assigned using SETDASA CCC command;
    - Configuration registers should be programmed with just assigned Dynamic Addresses;
    - Provisional ID / BCR / DCR Registers (I3C\_DEV\_IDn\_RR1 and I3C\_DEV\_IDn\_RR1, n = 0 to 11) should be programmed with data either predefined by application or obtained by reading PID / BCR / DCR with related CCC;
  - For I<sup>3</sup>C Devices intended to be enumerated with ENTDA;A CCC command:
    - Configuration registers should be programmed with Dynamic Addresses and other settings relevant for I3C Device;

Once all above conditions are satisfied the firmware can issue the ENTDAACCC command, which is considered as start condition for Stage 3.

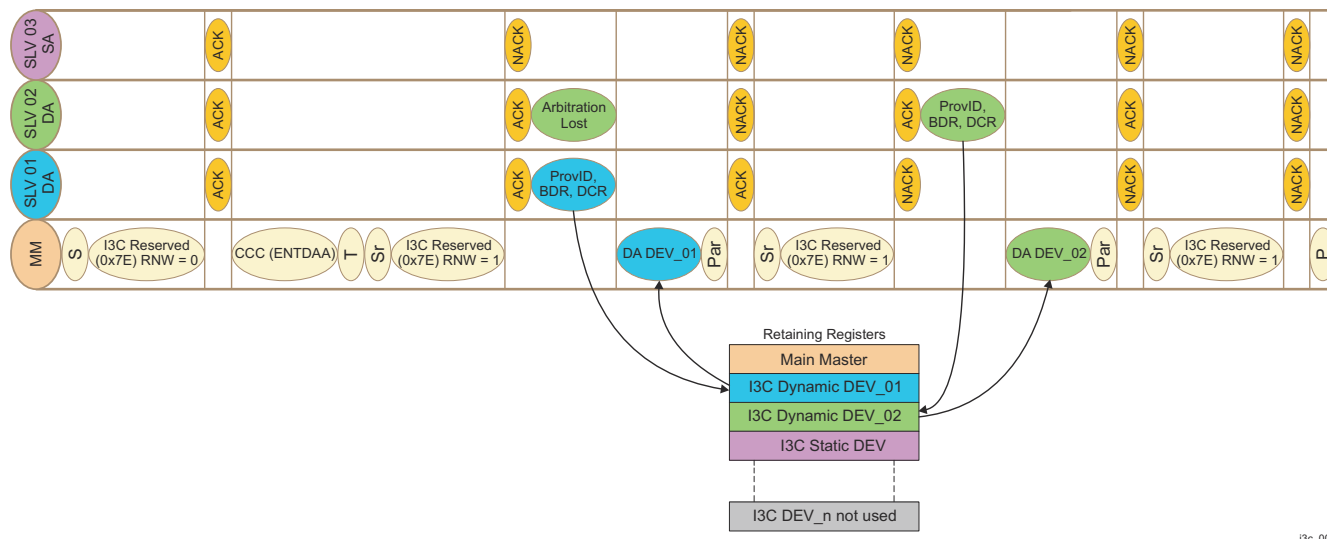

Figure 12-31 presents the I<sup>3</sup>C bus initialization for DAA procedure.

**Figure 12-31. Power-up I<sup>3</sup>C Bus Initialization**

During automatic Dynamic Address Assignment procedure, the I<sup>3</sup>C devices send their Provisional ID, BCR and DCR using open-drain class driver. The Device ID sections are assigned to the I3C Devices based on the Provisional ID arbitration. As a result, the lower value of the Provisional ID the device has, the lower position in retaining registers map it gets. Once device gets Dynamic Address and its Retaining Registers are filled, corresponding I3C\_DEVS\_CTRL bit for active is set automatically.

Figure 12-32 presents the I<sup>3</sup>C flow diagram for DAA procedure.

**Figure 12-32. Flow Diagram for DAA Procedure**

### Note

Static I<sup>3</sup>C devices have already assigned Dynamic Address with SETDASA CCC command and stay quiet during DAA procedure.

### Note

Although arbitration continues over BCR and DCR values, it is not guaranteed to be resolved in this phase, if not resolved during Provisional ID period.

i3c\_008

#### 12.1.4.3.8 I3C Sending CCC Messages

To send a CCC message, I3C controller uses Host Command Format.

Following are the only relevant Command Word fields for CCC message:

- I3C\_CMD0\_FIFO[30] IS\_CCC – should be set to 1;
- I3C\_CMD0\_FIFO[7-0] CCC – specifies the Common Command Code to be sent;
- I3C\_CMD0\_FIFO[23-12] PL\_LEN – specifies the length of the Data field for commands (the number of bytes to be sent for particular CCC);
- I3C\_CMD0\_FIFO[0] RNW – defines the direction of the Data field: 0 for writing data to slave(s) and 1 for reading data from slaves;
- I3C\_CMD0\_FIFO[29] BCH – when two sequential directed CCC messages of the same type are sent; this bit determines whether the broadcast address and message code should be issued before the second address and command code;
- I3C\_CMD0\_FIFO[25] RSBC – use in conjunction with BCH when issuing short CCC messages;

The payload for CCC commands writing data to the slaves needs to be written to the TX FIFO prior to sending the two Command Words. The payload received by reading CCC commands can be read after receiving the COMP interrupt corresponding to the command. Note that ENTDA command uses payload of 0, since the data it receives is not stored in RX FIFO; the amount of data depends on the number of slave responding to the command.

When sending a sequence of two identical directed CCC messages to different slaves, the I3C\_CMD0\_FIFO[29] BCH and I3C\_CMD0\_FIFO[25] RSBC Command Word fields can be used to send the second message as short CCC. I3C\_CMD0\_FIFO[29] BCH should be set to 0 for the second CCC message. Instead of sending the broadcast address, waiting for it to be acknowledged and then sending the message code, this will issue restart pattern and immediately transfer the address and payload afterwards. If I3C\_CMD0\_FIFO[29] BCH is set

to 1 the second CCC message is sent with broadcast address and command code in the beginning. In all other CCC message cases the I3C\_CMD0\_FIFO[29] BCH field is disregarded. Because the short CCC is preceded by restart pattern in order for this to work the I3C\_CMD0\_FIFO[25] RSBC field for the first command should also be set to 1.

Table 12-28 below summarizes available CCC set along with their payload layout in data FIFOs and Command Word settings.

**Table 12-28. CCC Commands**

CCC <sup>(1)</sup>	Description	Payload Layout <sup>(2)</sup>	PL	RNW
ENEC_BC (0x00) ENEC_DC (0x80)	Enables slave event driven interrupts	TX FIFO: {28'b0, 1'bHJ, 1'b0, 1'bMR, 1'bINT} (HJ – Hot-Join, MR – Mastership Request IBI, INT – regular IBI)	1	0
DISEC_BC (0x01) DISEC_DC (0x81)	Disables slave event driven interrupts	TX FIFO: {28'b0, 1'bHJ, 1'b0, 1'bMR, 1'bINT} (HJ – Hot-Join, MR – Mastership Request IBI, INT – regular IBI)	1	0
ENTAS0_BC (0x02) ENTAS0_DC (0x82)	Set activity to State 0 (normal operation)	No payload	0	0
RSTDAA_BC (0x06) RSTDAA_DC (0x86)	Forget current Dynamic Address and wait for new one	No payload	0	0
ENTDAA_BC (0x07)	Enter DAA procedure to assign Dynamic Addresses to unassigned devices	See <a href="#">Section 12.1.4.4.3, Initiate DAA Procedure</a>	0	0
SETMWL_BC (0x09) SETMWL_DC (0x89)	Set maximum write length of a single private transfer	TX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Write Length value)	2	0
SETMRL_BC (0x0A) SETMRL_DC (0x8A)	Set maximum read length of a single private transfer	TX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Write Length value)	2	0
DEFSLVS_BC (0x08)	Broadcast triples of DA, DCR and SA (or 0) for each slave	No payload	0	0
ENTHDR_BC (0x20)	Switch to HD-DDR mode	No payload	0	0
SETDASA_DC (0x87)	Set Dynamic Address to slave with Static Address	TX FIFO: {24'b0, 7'bDA, 1'bP} (DA – new Dynamic Address, P – XNOR of DA bits)	1	0
SETNEWDA_DC (0x88)	Assign new Dynamic Address	TX FIFO: {24'b0, 7'bDA, 1'bP} (DA – new Dynamic Address, P – XNOR of DA bits)	1	0
GETMWL_DC (0x8B)	Get maximum write length of a single private transfer	RX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Write Length value)	2	1
GETMRL_DC (0x8C)	Get maximum read length of a single private transfer	RX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Read Length value)	2	1
GETPID_DC (0x8D)	Get Slave's Provisional ID value	RX FIFO[n+1]: {16'b0, PID0, PID1} RX FIFO[n]: {PID2, PID3, PID4, PID5}	6	1
GETBCR_DC (0x8E)	Get Device's Bus Characteristic Register value	RX FIFO: {24'b0, BCR}	1	1
GETDCR_DC (0x8F)	Get Device's Characteristic Register value	RX FIFO: {24'b0, DCR}	1	1
GETSTATUS_DC (0x90)	Read Device's operating status	RX FIFO: {16'b0, 2'bAM, 1'bPE, 1'b0, 4'bINT, 8'b0} (AM – Activity Mode, PE – Protocol Error, INT – Pending Interrupt number)		
GETACCMST_DC (0x91)	Get accept mastership	RX FIFO: {24'b0, SlaveAddr}	1	1

**Table 12-28. CCC Commands (continued)**

CCC <sup>(1)</sup>	Description	Payload Layout <sup>(2)</sup>	PL	RNW
GETMXDS_DC (0x94)	Read Maximum SCL Frequency of the slave	RX FIFO: {16'b0, <b>MaxRd</b> , <b>MaxWr</b> }  ( <b>MaxRd</b> – Clock to Data Turnaround Time and Maximum Sustained Read Data Rate, <b>MaxWr</b> – Maximum Sustained Write Data Rate)	1	1
GETHDCAP (0x96)	Ask slave for HDR modes it supports (can be sent only if BCR identifies HDR support)	RX FIFO: {24'b0, <b>HDCAP</b> }  ( <b>HDCAP</b> – HDR capability modes)	1	1

(1) CCC column displays:

- The name of the Common Command Code, suffixed with \_BC for Broadcast CCC and \_DC for Direct CCC;
- In parentheses is value of CCC field to be used in Command Word 1;

(2) Payload Layout column displays:

- {<...>, <field1>, <field0>} - concatenation of 8-bit CCC data fields within 32-bit FIFO cell;
- <width>'b<field\_name> - field <field\_name> takes <width> bits (8 bits if not specified);
- The payload fields are denoted in bold;

#### 12.1.4.3.9 I3C In-Band Interrupt

In order to handle an incoming In-Band Interrupt from particular slave device, the address and configuration of IBI handling for this device needs to be stored in the I3C\_SIR\_MAP0 through I3C\_SIR\_MAP5 registers. This register map holds information on device address, length of payload, device role and response. The map organization is presented in the [Table 12-29](#) below.

**Table 12-29. SIR Map Organization**

Register	[31-16] bit fields	[15-0] bit fields
I3C_SIR_MAP0	Device 1	Device 0
I3C_SIR_MAP1	Device 3	Device 2
I3C_SIR_MAP2	Device 5	Device 4
I3C_SIR_MAP3	Device 7	Device 6
I3C_SIR_MAP4	Device 9	Device 8
I3C_SIR_MAP5	Reserved	Device 10

All devices requesting IBI, but not added to the SIR Map, will receive the NACK response from I3C master device.

Example for IBI Map configuration looks as follows:

- Write 0x80470445 which is translated to the following configurations for first two devices:
  - Regular slave with DA = 0x22 to be ACKed and receive 4 bytes of payload (Device 0)
  - Secondary master with DA = 0x23 to be ACKed and receive no payload (Device 1)
- Write 0x004A0749 which is translated to the following configurations for the third and fourth device:
  - Regular slave with DA = 0x24 to be ACKed and receive 7 bytes of payload (Device 2)
  - Regular slave with DA = 0x25 to be NACKed (Device 3)
- Write 0x0000034D which configures the last fifth device as follows:
  - Regular slave with DA = 0x26 to be ACKed and receive 3 bytes of payload (Device 4)

After receiving regular or mastership request IBI interrupt, firmware needs to read the I3C\_IBIR register to determine which device requested IBI. The ordering of bits in the I3C\_IBIR register corresponds to ordering of devices stored in I3C\_SIR\_MAP0 through I3C\_SIR\_MAP5 registers. Note that the IBI capable devices are enumerated and ordered independently from device ordering in the retaining registers used during DAA procedure.

#### 12.1.4.3.9.1 Regular I3C Slave In-Band Interrupt

When regular IBI request appears on the I<sup>3</sup>C bus, I<sup>3</sup>C master hardware automatically handles whole IBI procedure based on settings in I3C\_SIR\_MAP0 through I3C\_SIR\_MAP5 registers. As the IBI procedure acknowledged by I3C master finishes (including payload reception), host is informed by the IBI interrupt that such event occurred and was successfully processed. At this point, firmware should:

1. Read I3C\_IBIR register to determine requesting device
2. Read related payload from IBI RX FIFO
3. Execute related action (application/system dependent), if any designed for particular IBI/device.

#### 12.1.4.3.9.2 Current Master Takeover In-Band Interrupt

When mastership takeover IBI request appears on the I<sup>3</sup>C bus, I<sup>3</sup>C master hardware automatically sends the response based on settings in I3C\_SIR\_MAP0 through I3C\_SIR\_MAP5 registers. After this host is informed by the I3C\_MST\_ISR interrupt that handoff procedure should be executed. At this point, firmware should:

1. Read I3C\_IBIR register to determine requesting device (optionally, if such information is useful for application host)
2. Send the GETACCMST CCC to confirm mastership handover
3. Wait for the completion of pending I3C master command signaled by I3C\_MST\_ISR interrupt – at this moment I3C master switches to the slave mode
4. Write 0x001FXXXX to FLUSH\_CTRL register to flush the FIFOs as the slave mode reuses TX and RX FIFOs (bits marked X hold RX\_FIFO threshold so should be set/maintained as needed)
5. Depending on application/system, prepare for slave operation

Note that it is firmware and/or system responsibility to provide bus information to Secondary Masters before mastership handover is granted. It can be achieved in several ways:

- Secondary Masters listen to the bus during DAA and store necessary data
- Main Master sends DEFSLVS CCC after each ENTDA / RSTDA / SETNEWD / SETDASA sequence that modifies bus

#### 12.1.4.3.10 I3C Hot-Join Request

In order to accept any Hot-Join (HJ) request from slave device, application needs to set the I3C\_CTRL[6] HJ\_ACK and I3C\_CTRL[8] HJ\_DISEC control bits that define its response for Hot-Join request. Based on I3C\_CTRL[6] HJ\_ACK value the I3C master accepts or refuses the Hot-Join request by providing respectively ACK or NACK bit right after I3C\_CMD0\_FIFO[0] RNW bit. I3C\_CTRL[8] HJ\_DISEC bit controls whether master starts DAA procedure or sends broadcast DISEC command to disable HJ requests.

If Hot-Join request occurs, the application processor is notified by the I3C\_MST\_ISR interrupt. The application processor is aware how this particular Hot-Join request should be handled by checking current setting (can read the control bits or the stored previously used setting). In case of acknowledged request with subsequent DAA, the application processor is notified of automatically completed enumeration of hot-joined device by subsequent I3C\_MST\_ISR interrupt and simultaneously set I3C\_MST\_STATUS0 flag. In case of DISEC command, only I3C\_MST\_ISR interrupt will be set.

It is recommended to keep the I3C\_CTRL[6] HJ\_ACK bit disabled until the bus initialization procedure is completed in order to prevent slaves from indirect DAA enforcement.

#### 12.1.4.3.11 I3C Immediate Commands

Immediate Command Register is implemented in order to allow the application processor to issue immediate command which has a higher priority over the ordinary command. The immediate commands are supposed to be used in exceptional cases and only CCC commands are applicable. The I3C supports only one immediate command at a time and it is accessed by the host through two APB registers: I3C\_IMD\_CMD0 and I3C\_IMD\_CMD1. If a normal command is currently being executed and new immediate command is loaded, then controller waits to finish the current command and after that starts executing the higher priority command regardless of the content of the ordinary command FIFO. Immediate command can be used only for CCC commands and the corresponding payload must not exceed 4 bytes. As a result the GETPID and DEVSLSV CCC commands cannot be executed using immediate commands. The format for the immediate command

words is the same as for the ordinary commands, although some fields are reserved since not used or fixed for CCC commands (writing to these fields has no effect).

#### 12.1.4.3.12 I3C Host Commands

The normal operation of the controller allows the firmware to build a message and then issue the transaction to the I3C controller. The command queue is provided in order to allow the host to load a request for multiple messages. Single message consists of two 32-bit words (Command Word0 and Command Word1). In order to issue the transaction the following procedure should be followed:

- Write the payload to the TX FIFO (applicable for write transfers only);
- Write Command Word1;
- Write Command Word0;

If controller is enabled (I3C\_CTRL[31] DEV\_EN bit is set to 0x01), writing Command Word0 triggers the execution of the command, resulting in start condition on the I3C bus.

#### 12.1.4.3.13 I3C Sending Private Data in SDR Messages

The I3C controller supports private data transfers in Single Data Rate with SCL frequencies up to 10.375 MHz. It supports all types of SDR transfers and provides hardware built-in features for transfers to I3C slave devices with limited maximum SCL frequency. Before any private transfer to the slave devices occurs, bus mode and SCL prescalers shall be programmed properly. Controller also provides vendor extension to the basic transfers which simplifies addressing internal registers of slave devices. To take advantage of this extension, the I3C controller must communicate with the slave devices supporting such transmission scheme.

The extension, called XMIT modes, combines standard private write and read frames to pass the slave register sub-address in addition to the actual payload. Four transmit modes are designed for specific usage:

- XMIT00 – burst (byte-by-byte) transfer with static register sub-address. Sends static sub-address followed by data bytes only. Expecting slave will make self-increment of the address for each data byte or will have payload buffer implemented.
- XMIT01 – single transfer with incremented register sub-address. Each data byte followed by repeated start condition and the slave's internal register address are incremented explicitly.
- XMIT10 – single transfer with static register sub-address. Each data byte followed by repeated start condition, register sub-address remains intact.
- XMIT11 – burst (byte-by-byte) transfer without register sub-address (first data byte after the slave address is a payload byte).

In addition to the multiple transmit modes, I3C controller has an option to provide 16-bit address of the internal register in slave device to support slaves with more than 256 internal addresses.

For arbitration priorities management, private SDR commands may use Broadcast Command Header or not. This is controlled by BCH field of command descriptor.

##### 12.1.4.3.13.1 SDR Private Write Message

The Private Write message transmitted over I3C bus in all supported transmit modes is presented in [Figure 12-33, Master Write Transaction for Single and Multi Address Sequences](#). The provided transmit modes use additional I3C write frame that utilizes the data field to pass slave register address ahead of payload byte(s). As writing command word triggers start condition immediately, it shall be guaranteed by firmware that the data payload is written to the Tx FIFO in advance before it is going to be transmitted.

The completion of the message frame on the I3C bus is signaled by the I3C\_MST\_ISR[16] IMM\_COMP interrupt.

In case of transfers with data payload greater than the TX FIFO size, firmware can use I3C\_MST\_ISR[15] TX\_THR interrupt to fill the FIFO on time. The system design should prevent the TX FIFO from underflow. During the time elapsed between reading the last four bytes from almost empty TX FIFO and reading the subsequent one, firmware is required to refill the TX FIFO.

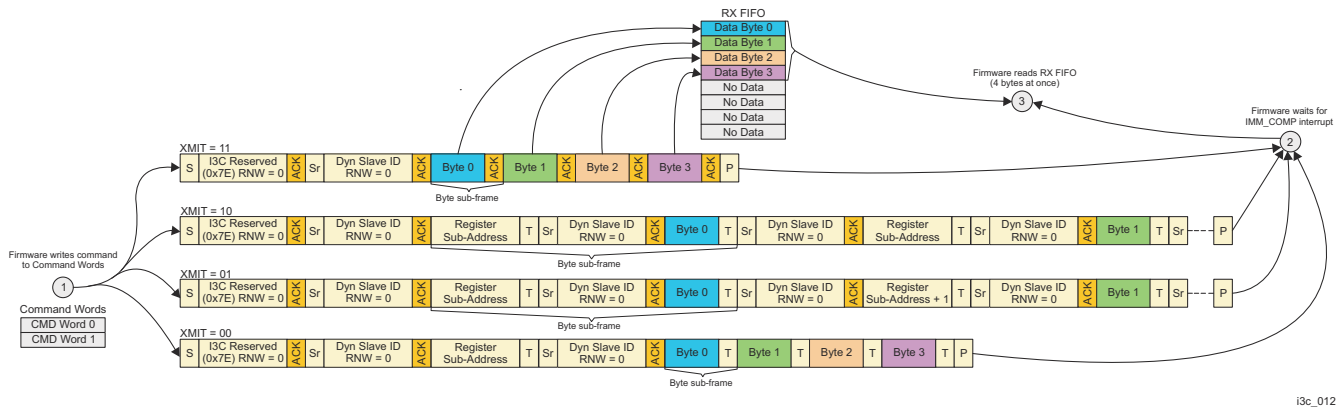

**Figure 12-33. Master Write Transaction for Single and Multi Address Sequences**

#### 12.1.4.3.13.2 SDR Private Read Message

The Private Read message transmitted over I3C bus in all supported transmit modes is presented in [Figure 12-34, Master Read Transaction for Single and Multi Address Sequences](#)

Similarly to Private Write message, each I3C read frame is preceded by I3C write frame which sends slave register address to be read. After sending the command, firmware should wait for I3C\_MST\_ISR[16] IMM\_COMP interrupt which signals the end of message and RX FIFO content ready to read.

In case of payload lengths exceeding RX FIFO size, firmware should utilize I3C\_MST\_ISR[7] TX\_THR interrupt to read RX FIFO before it gets filled and prevent from data corruption. For easier management of long FIFO and/or long host read intervals, the amount of data available in FIFO that triggers the interrupt can be programmed according to actual conditions in given system.

**Figure 12-34. Master Read Transaction for Single and Multi Address Sequences**

#### 12.1.4.3.13.3 SDR Payload Length Adjustment

In case of Private Write SDR commands, the payload length that needs to be specified is always equal to the number of data bytes sent to slave in Private Write transmission. If the payload specified is greater than slave's capability, the data are simply ignored by slave.

In case of Private Read SDR commands slave is the device which normally decides how many bytes it is able to send and when the read transfer is terminated. This can also result from hardware architecture or from SETMRL CCC command sent earlier to the slave.

For simplified handling I3C design triggers the read abort procedure after receiving specified number of payload bytes. This matters in these transfer modes which send data bytes after one another. If one of these modes is used, the I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field is interpreted as payload size that should not be reached during transfer rather than the actual number of bytes to be received. This applies only to read transfer from I3C devices.

**Table 12-30. Payload Setting in SDR Mode**

Transmission	I3C_CMD0_FIFO[28-27] XMIT_MODE	I3C_DEV_IDn_RR0[9] IS_I3C (n = 0 to 11)	I3C_CMD0_FIFO[23-12] PL_LEN
I3C, NCA	11	1	Abort limit <sup>(1)</sup>
I3C, Single	00	1	Abort limit <sup>(1)</sup>
I3C, Multi-Static	10	1	Number of bytes to receive
I3C, Multi-Incremental	01	1	Number of bytes to receive

- (1) If payload size is known, it can be set to one more than the known size; otherwise it should be set to MRL+1 where MRL is value programmed with SETMRL CCC in particular slave or its hardware payload size limit, if known.

#### 12.1.4.4 I3C Programming Guide

##### 12.1.4.4.1 I3C Power-On Programming Model

Typical power-on programming sequence is as follows:

1. Program bus description into Retaining Registers according [Section 12.1.4.3.6](#) and I3C\_DEVS\_CTRL.
2. If default values of SCL prescalers do not fit applied clock frequencies, program PRESCL\_CTRL0 and PRESCL\_CTRL1 according [Section 12.1.4.3.2](#).
3. If any of following applies:
  - a. Address Header Optimization is to be enabled.
  - b. Halt mechanism should be enabled.

then alter values of I3C\_CTRL[1-0] BUS\_MODE, I3C\_CTRL[3] AHDR\_OPT and I3C\_CTRL[30] HALT\_EN fields, respectively:

- a. Program I3C\_CTRL register with value 0x80000000 to enable the controller.

##### 12.1.4.4.2 I3C Static Devices Programming

I3C devices shipped with Static Address can be enumerated prior to DAA procedure using SETDASA CCC command. In order to enumerate I3C device firmware needs to follow procedure:

1. Prepare device's retaining register:
  - a. Write corresponding I3C\_DEV\_IDn\_RR0 (offset 0x080 + (n × 0x010)) for n = 0 to 11:
    - i. I3C\_DEV\_IDn\_RR0[9] IS\_I3C (n = 0 to 11): 0x01
    - ii. I3C\_DEV\_IDn\_RR0[7-0] DEV\_ADDR bit-field (n = 0 to 11): set to device's Static Address for [7-1] bits and set to Static Address parity for bit 0
2. Issue SETDASA CCC:
  - a. Make sure that controller is enabled.
  - b. Write new Dynamic Address to TX FIFO.
  - c. Write Command Word1 with SETDASA CCC value:
    - i. I3C\_IMD\_CMD1[7-0] CCC bit-field: 0x87
  - d. Write Command Word0 with following field values:
    - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x01
    - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: Static Address
    - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x00
3. Enable at least COMP, NACK and INVALID\_DA interrupts by writing 0h to IER register.
4. Wait for COMP interrupt (read I3C\_MST\_ISR).
5. If COMP and no other interrupt occurs, continue. Otherwise, handle the error situation.
6. Fill Dynamic Address into device configuration register:
  - a. Modify I3C\_DEV\_IDn\_RR0 (offset 0x080 + (n × 0x010)) for n = 0 to 11 register by writing Dynamic Address to DEV\_ADDR field and its parity to ADDR\_PAR field (keep values of other fields)
7. If not already known to application host, retrieve BCR with GETBCR CCC:
  - a. Write Command Word1 with GETBCR CCC value:
    - i. I3C\_IMD\_CMD1[7-0] CCC bit-field: 0x8E
  - b. Write Command Word0 with following field values:
    - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x01
    - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: Dynamic Address
    - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x01
  - c. Wait for COMP interrupt
  - d. Read RX FIFO register - BCR is stored in bits [7:0]

8. Optionally retrieve Provisional ID and DCR with corresponding CCCs:
  - a. Write Command Word1 with GETDCR CCC value:
    - i. I3C\_IMD\_CMD1[7-0] CCC bit-field: 0x8F
  - b. Write Command Word0 with following field values:
    - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x01
    - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: Dynamic Address
    - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x01
  - c. Wait for COMP interrupt
  - d. Read RX FIFO register - DCR is stored in bits [7:0]
  - e. Write Command Word1 with GETPID CCC value:
    - i. I3C\_IMD\_CMD1[7-0] CCC bit-field: 0x8D
  - f. Write Command Word0 with following field values:
    - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x06
    - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: Dynamic Address
    - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x01
  - g. Wait for COMP interrupt
  - h. Read RX FIFO register twice – PID bytes are stored in two FIFO locations. See [Table 12-28](#)
9. Write retrieved device configuration data to retaining registers:
  - a. Write four MSB of obtained PID value into I3C\_DEV\_IDn\_RR1 (offset 0x084 + (n × 0x010)) for n = 0 to 11:
  - b. Write two LSB of obtained PID value as well as BCR and DCR values into I3C\_DEV\_IDn\_RR2 (offset 0x088 + (n × 0x010)) for n = 0 to 11:

---

#### Note

SETDASA CCC command has advantage over DAA in shorter time spent on device configuration as retrieving PID and DCR (6 + 1 bytes transmitted over I3C bus) is optional and can be skipped if not used.

---

#### 12.1.4.4.3 I3C DAA Procedure Initiation

To initiate the DAA procedure I3C needs to issue ENTDAACCC command following the below procedure:

1. Enable at least COMP and NACK interrupts.
2. Issue ENTDAACCC command:
  - a. Make sure controller is enabled.
  - b. Write Command Word1 with ENTDAACCC command value:
    - i. I3C\_IMD\_CMD1[7-0] CCC bit-field: 0x07
  - c. Write Command Word0 with following field values:
    - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x00
    - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: 0x00
    - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x00
3. Wait for COMP interrupt (read I3C\_MST\_ISR)
4. If COMP and no other interrupt occurs, continue. Otherwise, handle the error situation. NACK interrupt indicates no slave devices available on bus.
5. Read I3C\_MST\_STATUS0[25] DAA\_COMP bit. It is asserted simultaneously with I3C\_MST\_ISR interrupt flag.

### Note

DAA procedure takes significant amount of time since there are always 9 bytes of data transmitted for each device (PID, BCR, DCR from device and DA to device), so for maximum bus size it will take 99 bytes.

#### 12.1.4.4.4 I3C SDR Write Message Programming Model

To accomplish the SDR write transfer, the host must perform the following steps:

1. Write all payload data bytes into TX FIFO buffer:
  - a. Write first four or less bytes to be sent, with first byte stored at LSB position.
  - b. Repeat writes until whole payload is written.
2. Write Private Write command to command queue:
  - a. Write the Command Word 1 (I3C\_CMD1\_FIFO) with slave CSR address:
    - i. CSR (bits [15:0] or [7:0]): Slave register address
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) with following data fields:
    - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x0
    - ii. I3C\_CMD0\_FIFO[30] IS\_CCC: 0x0
    - iii. I3C\_CMD0\_FIFO[28-27] XMIT\_MODE: Transmit Mode
    - iv. I3C\_CMD0\_FIFO[26] SB\_CA: 0x1 for 16-bit CSR address, 0x0 otherwise
    - v. I3C\_CMD0\_FIFO[23-12] PL\_LEN: Number of bytes to send
    - vi. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR: Slave Address
    - vii. I3C\_CMD0\_FIFO[0] RNW: 0x0
3. Wait for transfer completion notified by I3C\_MST\_ISR[16] IMM\_COMP bit, which indicates that all data of particular command are successfully transmitted to the slave.

#### 12.1.4.4.5 I3C SDR Read Message Programming Model

To accomplish the SDR read transfer, the host must perform the following steps:

1. Write Private Write command to command queue:
  - a. Write the Command Word1 (I3C\_CMD1\_FIFO) with slave CSR address:
    - i. CSR (bits [15:0] or [7:0]): Slave register address
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) with following data fields:
    - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x0
    - ii. I3C\_CMD0\_FIFO[30] IS\_CCC: 0x0
    - iii. I3C\_CMD0\_FIFO[28-27] XMIT\_MODE: Transmit Mode
    - iv. I3C\_CMD0\_FIFO[23-12] PL\_LEN: See [Section 12.1.4.3.13.3](#)
    - v. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR: Slave Address
    - vi. I3C\_CMD0\_FIFO[0] RNW: 0x1
2. Wait for transfer completion notified by I3C\_MST\_ISR[16] IMM\_COMP bit, which indicates that all data of particular command are successfully sent by the slave device and received data are ready to be read by the host.
3. Read all payload data bytes from RX FIFO buffer:
  - a. Read first four or less received bytes, with first received byte stored at LSB position.
  - b. Repeat reads until whole payload is read.

#### 12.1.4.4.6 I3C DDR Write Message Programming Model

To accomplish the DDR write transfer, the host must perform the following steps:

1. Prepare HDR-DDR message words (each 20-bit word is LSB aligned in TX FIFO cell; set bits unspecified below to 0):

- a. Write command word for write HDR-DDR command to TX FIFO using following field values:
    - i. Preamble (bits [19:18]): 0x01
    - ii. CMD (bits[17:10]): Write Command Code (from 0x00 to 0x7F)
    - iii. DA (bits[9:3]): Slave Dynamic Address
    - iv. Parity (bits[1:0]): Parity (XOR of odd and even bits of 16-bit payload)
  - b. Write first data word to TX FIFO using following field values:
    - i. Preamble (bits [19:18]): 0x10
    - ii. Data (bits[17:2]): 16-bit data
    - iii. Parity (bits[1:0]): Parity
  - c. Write zero or more subsequent data words to TX FIFO using following field values:
    - i. Preamble (bits [19:18]): 0x11
    - ii. Data (bits[17:2]): 16-bit data
    - iii. Parity (bits[1:0]): Parity
  - d. Write CRC word to TX FIFO:
    - i. Preamble (bits [19:18]): 0x01
    - ii. Token (bits[17:14]): Ch
    - iii. CRC (bits[13:9]): CRC5
  - e. Repeat steps 1(a) to 1(d) as many write commands are to be sent.
2. Write ENTHDR CCC command to command queue:
    - a. Write the Command Word1 (I3C\_CMD1\_FIFO) of ENTHDR CCC.
    - b. Write the Command Word0 (I3C\_CMD0\_FIFO) of ENTHDR CCC with following data fields:
      - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x0
      - ii. I3C\_CMD0\_FIFO[30] IS\_CCC: 0x1
      - iii. I3C\_CMD0\_FIFO[0] RNW: 0x0
  3. Write HDR-DDR command(s) to command queue:
    - a. Write the Command Word1 (I3C\_CMD1\_FIFO).
    - b. Write the Command Word0 (I3C\_CMD0\_FIFO) with following data fields:
      - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x1
      - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN: Number of TX FIFO words
    - c. Repeat steps 2(a) and 2(b) as many write commands are prepared in TX FIFO in step 1.
  4. Wait for transfer completion notified by I3C\_MST\_ISR[16] IMM\_COMP bit, which indicates that all data of particular command are successfully transmitted to the slave.

If I3C\_MST\_ISR[16] IMM\_COMP interrupt is utilized, the controller allows the application processor to perform other tasks or sleep while message is being sent.

In case of multiple command issued to command queue, I3C\_MST\_ISR[5] CMDD\_EMP interrupt may be utilized instead. It indicates completion of all commands in command queue and allows yet more efficient application processor resources management. It is issued simultaneously with the I3C\_MST\_ISR[5] CMDD\_EMP interrupt corresponding to the last command in the queue.

#### 12.1.4.4.7 I3C DDR Read Message Programming Model

To accomplish the DDR read transfer, the host must perform the following steps:

1. Prepare HDR-DDR message words (each 20-bit word is LSB-aligned in TX FIFO cell, set bits unspecified below to 0):
  - a. Write Command Word for Read HDR-DDR command to TX FIFO using following field values:
    - i. Preamble (bits [19:18]): 2'b01
    - ii. CMD (bits[17:10]): Read Command Code (0x80..0xBF)
    - iii. DA (bits[9:3]): Slave Dynamic Address

- iv. Parity (bits[1:0]): Parity (XOR of odd and even bits of 16-bit payload)
- b. Repeat step 1(a) as many read commands are to be sent.
2. Write ENTHDR CCC command to command queue:
  - a. Write the Command Word1 (I3C\_CMD1\_FIFO) of ENTHDR CCC.
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) of ENTHDR CCC with following data fields:
    - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x0
    - ii. I3C\_CMD0\_FIFO[30] IS\_CCC: 0x1
    - iii. I3C\_CMD0\_FIFO[0] RNW: 0x0
3. Write HDR-DDR command(s) to command queue:
  - a. Write the Command Word1 (I3C\_CMD1\_FIFO)
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) with following data fields:
    - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x1
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN: 0x1
  - c. Repeat steps 2(a) and 2(b) as many read commands are prepared in TX FIFO in step 1.
4. Wait for transfer completion notified by I3C\_MST\_ISR[16] IMM\_COMP bit in interrupt status register, which indicates that all data of particular command are successfully sent by the slave device and received data are ready to be read by the host.
5. Read received payload:
  - a. Read first data word from RX FIFO extracting field values:
    - i. Preamble (bits [19:18]): 0x10
    - ii. Data (bits[17:2]): 16-bit data
    - iii. Parity (bits[1:0]): Parity
  - b. Read zero or more subsequent data words from RX FIFO extracting field values as long as the read preamble matches following value:
    - i. Preamble (bits [19:18]): 0x11
    - ii. Data (bits[17:2]): 16-bit data
    - iii. Parity (bits[1:0]): Parity
  - c. As read preamble changes, read CRC Word:
    - i. Preamble (bits [19:18]): 0x01
    - ii. Token (bits[17:14]): Ch
    - iii. CRC (bits[13:9]): CRC5
  - d. Confirm (by firmware) that CRC5 value matches data payload received.

If I3C\_MST\_ISR[16] IMM\_COMP interrupt is utilized, the controller allows the application processor to perform other tasks or sleep while message is being sent.

In case of multiple command issued to command queue, I3C\_MST\_ISR[5] CMDD\_EMP interrupt may be utilized instead of I3C\_MST\_ISR[16] IMM\_COMP. It indicates completion of all commands in command queue and allows yet more efficient application processor resources management. It is issued simultaneously with the I3C\_MST\_ISR[16] IMM\_COMP interrupt corresponding to the last command in the queue.

### **12.1.5 Multichannel Serial Peripheral Interface (MCSPI)**

This section describes the Multichannel Serial Peripheral Interface (MCSPI) modules for the device.

#### **12.1.5.1 MCSPI Overview**

The MCSPI module is a multichannel transmit/receive, master/slave synchronous serial bus.

There are MCSPI modules in the device.

##### **12.1.5.1.1 SPI Features**

The SPI module includes the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to channels in controller mode, or single channel in receive mode
- Controller multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes
  - Flexible input/output (I/O) port controls per channel
  - Programmable clock granularity
  - Per channel configuration for clock definition, polarity enabling, and word width
- Single interrupt line for multiple interrupt source events
- Enable the addition of a programmable start-bit for MCSPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

##### **12.1.5.1.2 MCSPI Not Supported Features**

The following features are not supported on this family of devices:

- Slave mode wake-up
- Retention during power down
- MCU\_MCSPI2 and MCSPI4 are not pinned out
- MCSPI4 master mode is not supported
- In slave mode only channel 0 is used
- Local power management of clock activity.

### 12.1.5.1.3 MCSPI Ports

This section describes module ports related to clocks, resets, and hardware requests.

**Table 12-31. MCSPI Clocks and Resets**

Clocks	
Module Clock Input	Description
MCSPi_ICLK	MCSPi Interface Clock
MCSPi_FCLK	MCSPi Functional Clock
Resets	
Module Reset Input	Description
MCSPi_RST	MCSPi Asynchronous Reset
MCSPi_POR_RST	MCSPi Power-On Reset

**Table 12-32. MCSPI Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCSPI_INTR_SPI_0	MCSPI Interrupt Request	Level
DMA Events		
Module DMA Event	Description	Type
MCSPI_DMA_WRITE_EVENT0	MCSPI Channel 0 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT0	MCSPI Channel 0 Receive (Read) Request Line	Pulse
MCSPI_DMA_WRITE_EVENT1	MCSPI Channel 1 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT1	MCSPI Channel 1 Receive (Read) Request Line	Pulse
MCSPI_DMA_WRITE_EVENT2	MCSPI Channel 2 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT2	MCSPI Channel 2 Receive (Read) Request Line	Pulse
MCSPI_DMA_WRITE_EVENT3	MCSPI Channel 3 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT3	MCSPI Channel 3 Receive (Read) Request Line	Pulse

### 12.1.5.2 MCSPI Environment

This section describes the MCSPI external connections (environment).

Table 12-33 describes the MCSPI I/O signals in master mode.

**Table 12-33. MCSPI I/O Signals (Master Mode)**

Module Pin	I/O <sup>(1)</sup>	Description
SPICLK	O	MCSPI Serial clock output for master mode.
SPIDAT[0]	O <sup>(2)</sup>	MCSPI Data I/O for master mode.
SPIDAT[1]	I <sup>(3)</sup>	MCSPI Data I/O for master mode.
SPIEN[i]	O	MCSPI Chip-select i output for master mode

(1) I = Input; O = Output

(2) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHCONF\_0/1/2/3[18] IS and MCSPI\_CHCONF\_0/1/2/3[16] DPE0.

(3) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHCONF\_0/1/2/3[18] IS and MCSPI\_CHCONF\_0/1/2/3[17] DPE1.

Table 12-34 describes the MCSPI I/O signals in slave mode.

**Table 12-34. MCSPI I/O Signals (Slave Mode)**

Module Pin	I/O <sup>(1)</sup>	Description
SPICLK	I	MCSPI serial clock input for slave mode.
SPIDAT[0]	I <sup>(2)</sup>	MCSPI Data I/O for slave mode.
SPIDAT[1]	O <sup>(3)</sup>	MCSPI Data I/O for slave mode.
SPIEN[i]	I <sup>(4)</sup>	MCSPI chip-select i input for slave mode.

(1) I = Input; O = Output

(2) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHCONF\_0/1/2/3[18] IS and MCSPI\_CHCONF\_0/1/2/3[16] DPE0.

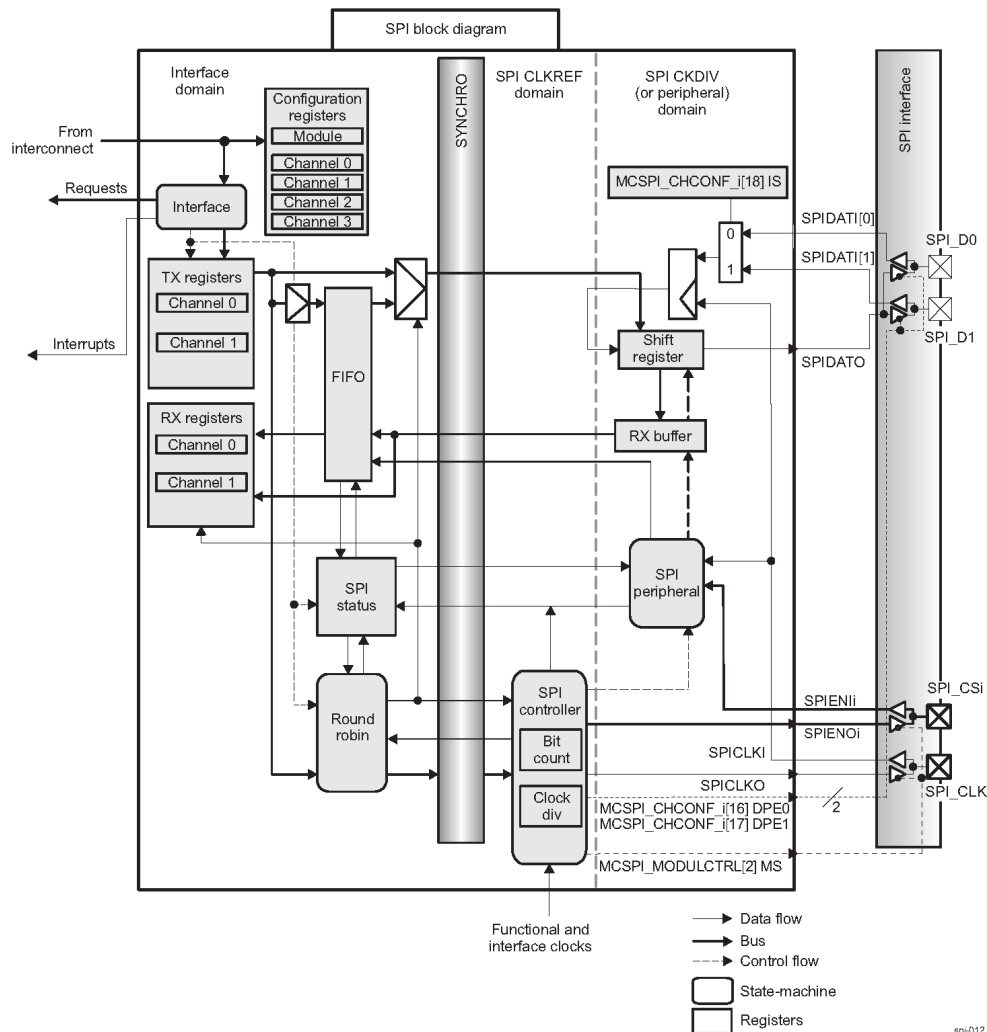

(3) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHCONF\_0/1/2/3[18] IS and MCSPI\_CHCONF\_0/1/2/3[17] DPE1.

(4) The chip-select input in slave mode can be selected through the MCSPI\_CHCONF\_0/1/2/3[22-21] SPIENSLV bit field.

### 12.1.5.3 MCSPI Functional Description

#### 12.1.5.3.1 SPI Block Diagram

Figure 12-35 shows the SPI module.

#### Note

For single channel operation ( $i=0$  or  $i=1$ ), MCSPI\_CHCONF[20]FORCE is asserted over the SPIENII and SPIENOI lines.

**Figure 12-35. SPI Block Diagram**

#### 12.1.5.3.2 MCSPI Reset

The MCSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPI\_RST). MCSPI can be reset by software through the MCSPI\_SYSCONFIG[1] SOFTRESET bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the MCSPI\_SYSCONFIG register is not affected by that software reset.

#### 12.1.5.3.3 MCSPI Controller Mode

##### 12.1.5.3.3.1 Controller Mode Features

The MCSPI controller mode supports multichannel communication with up to four independent MCSPI communication channel contexts. The MCSPI initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN[i]) signals.

Connected to multiple external devices, the MCSPI exchanges data with one MCSPI device at a time through two main modes (available in peripheral mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

---

#### Note

There is a fixed chip select line allocation in multichannel controller mode. Channel *i* is mapped to SPIEN[*i*].

---

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of MCSPI.

Three interrupt events can be used for data transmission and reception in controller mode (for more information about interrupts, see [Section 13.1.3.4.7.1, Interrupt Events in Controller Mode](#)).

#### 12.1.5.3.3.2 Controller Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The controller transmit-and-receive mode is programmable per channel (the MCSPI\_CHCONF\_0/1/2/3[13-12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPI\_TX\_0/1/2/3 transmitter register state, the MCSPI\_RX\_0/1/2/3 receiver register state, and round-robin arbitration.

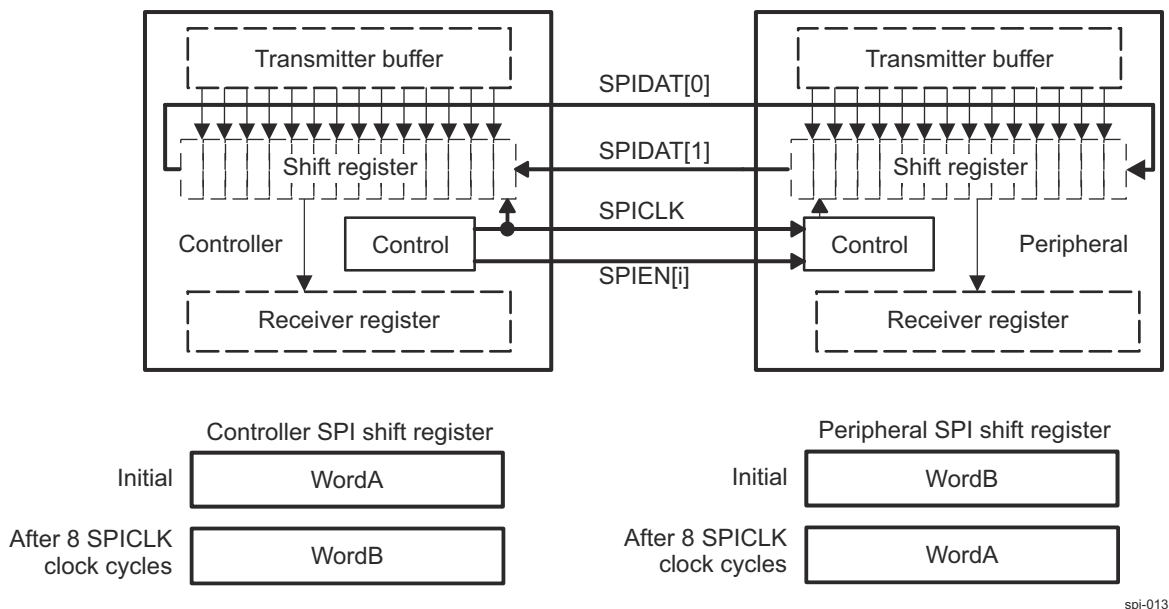

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- Rule 1: Only enabled channels (the MCSPI\_CHCTRL\_0/1/2/3[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPI\_TX\_0/1/2/3 transmitter register is not empty (the MCSPI\_CHSTAT\_0/1/2/3[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI\_TX\_0/1/2/3 register is empty when the shift register is assigned, the TXx\_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the MCSPI\_CHSTAT\_0/1/2/3[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPI\_RX\_0/1/2/3 register cannot be overwritten. The MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set to this mode.

When MCSPI word transfer completes (the MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit is set), the updated MCSPI\_TX\_0/1/2/3 register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral.

[Figure 12-36](#) shows an example of a full-duplex system with a controller device on the left and a peripheral device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral. At the same time, WordB transfers from the peripheral to the controller.

**Figure 12-36. MCSPI Full-Duplex Transmission (Example)**

#### 12.1.5.3.3.3 Controller Transmit-Only Mode (Half Duplex)

The controller transmit-only mode prevents the processor from reading the MCSPI\_RX\_0/1/2/3 register (minimizing data movement) when only transmission is meaningful.

The controller transmit-only mode is programmable per channel (the MCSPI\_CHCONF\_0/1/2/3[13-12] TRM bit field). Transmission starts only after data is loaded into the MCSPI\_TX\_0/1/2/3 register.

Rule 1 and Rule 2, defined in [Section 12.1.5.3.3.2](#), apply in this mode.

Rule 3, defined in [Section 12.1.5.3.3.2](#), does not apply.

In controller transmit-only mode, the MCSPI\_RX\_0/1/2/3 register state FULL does not prevent transmission and the MCSPI\_RX\_0/1/2/3 register is always overwritten with the new MCSPI word. This event is not significant when only transmission is meaningful. Thus, the RX0\_OVERFLOW bit in the MCSPI\_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX\_FULL interrupt and the DMA read requests.

The transfer status is given by the MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit.

#### 12.1.5.3.3.4 Controller Receive-Only Mode (Half Duplex)

The controller receive mode prevents the processor from refilling the MCSPI\_TX\_0/1/2/3 register (minimizing data movement) when only reception is meaningful.

The controller receive mode is programmable per channel (the MCSPI\_CHCONF\_0/1/2/3[13-12] TRM bit field).

The controller receive-only mode enables channel scheduling only on the empty state of the MCSPI\_RX\_0/1/2/3 register.

Rule 1 and Rule 3, defined in [Section 12.1.5.3.3.2](#), apply in this mode.

Rule 2, defined in [Section 12.1.5.3.3.2](#), does not apply.

In the controller receive-only mode, software must write dummy data to the MCSPI\_TX\_0/1/2/3 register. Only one dummy write is enough to receive any number of words from the peripheral. Software must ensure that the MCSPI\_TX\_0/1/2/3 register is always full (the TXx\_EMPTY bits of MCSPI\_IRQSTATUS) when receiving. The content of the MCSPI\_TX\_0/1/2/3 register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the MCSPI\_TX\_0/1/2/3 register, the TXx\_EMPTY and TXx\_UNDERFLOW bits in the MCSPI\_IRQSTATUS register are never set in receive-only mode.

The MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit gives the status of serialization. The RXx\_FULL bits of the MCSPI\_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI\_RX\_0/1/2/3 register. The MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set in this mode.

#### 12.1.5.3.3.5 Single-Channel Controller Mode

When the MCSPI is configured as a controller device with a single enabled channel (MCSPI\_MODULCTRL[2] MS = 0 and MCSPI\_MODULCTRL[0] SINGLE = 1), the assertion of the SPIEN[i] signal is optional depending on device connected to the controller. In 3-pin mode (MCSPI\_MODULCTRL[1] PIN34 = 1) the controller starts transmitting data when a write to the MCSPI\_TX\_0/1/2/3 register or the FIFO is performed. In 4-pin mode (MCSPI\_MODULCTRL[1] PIN34 = 0) the assertion and de-assertion of SPIEN[i] is controlled by software using the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit.

##### 12.1.5.3.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the MCSPI word transfer to complete (wait until the MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

##### 12.1.5.3.3.5.2 Force SPIEN[i] Mode

Continuous transfers are allowed manually by keeping the SPIEN[i] signal active for successive MCSPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIEN[i] line. This mode is supported by all channels and any controller sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIEN[i] active mode is supported when:

- A single channel is used (with the MCSPI\_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (MCSPI\_CHCONF\_0/1/2/3).

The state of the SPIEN[i] signal is programmable:

- Writing 1 to the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit drives the SPIEN[i] line high when the MCSPI\_CHCONF\_0/1/2/3[6] EPOL bit is set to 0. SPIEN[i] is driven low when the MCSPI\_CHCONF\_0/1/2/3[6] EPOL bit is set to 1.
- Writing 0 to the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit drives the SPIEN[i] line low when the MCSPI\_CHCONF\_0/1/2/3[6] EPOL bit is set to 0. SPIEN[i] is driven high when the MCSPI\_CHCONF\_0/1/2/3[6] EPOL bit is set to 1.
- A single channel is enabled (the MCSPI\_CHCTRL\_0/1/2/3[0] EN bit is set to 1). The first enabled channel activates the SPIEN[i] line.

When the channel is enabled, the SPIEN[i] signal activates with the programmed polarity. As in the multichannel controller mode, the transfer start depends on the status of the MCSPI\_TX\_0/1/2/3 register (the MCSPI\_CHSTAT\_0/1/2/3[1] TXS bit), the status of the MCSPI\_RX\_0/1/2/3 register (the MCSPI\_CHSTAT\_0/1/2/3[1] RXS bit), and the defined mode (the MCSPI\_CHCONF\_0/1/2/3[13-12] TRM bit field) of the channel enabled.

The MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit gives the transfer status of each MCSPI word. The RXx\_FULL bit in the MCSPI\_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI\_RX\_0/1/2/3 register.

A change in the configuration parameters is propagated directly on the MCSPI interface. If the SPIEN[i] signal is activated, ensure that the configuration is changed only between MCSPI words to avoid corrupting the current transfer.

#### Note

To avoid data corruption, SPIEN[i] polarity and SPICLK phase and SPICLK polarity must not be modified when the SPIEN[i] signal is activated.

A delay between MCSPI words that requires the connected MCSPI peripheral device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last MCSPI word, the channel must be deactivated (the MCSPI\_CHCTRL\_0/1/2/3[0] EN bit set to 0) and SPIEN[i] can be forced to its INACTIVE state using the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit.

Figure 12-37 and Figure 12-38 show successive transfers with SPIEN[i] maintained active low with a different configuration for each MCSPI word in single-data-pin and dual-data-pin interface modes, respectively.

**Figure 12-37. Continuous Transfers With SPIEN[i] Maintained Active (Single-Data-Pin Interface Mode)**

**Figure 12-38. Continuous Transfers With SPIEN[i] Maintained Active (Dual-Data-Pin Interface Mode)**

#### Note

The SPIEN[i] signal can be maintained active via software using the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit only when the MCSPI\_MODULCTRL[0] SINGLE bit is set to 0x1.

#### 12.1.5.3.3.5.3 Turbo Mode

Turbo mode improves the throughput of the MCSPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI\_RX\_0/1/2/3 register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the MCSPI\_CHCONF\_0/1/2/3[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 12.1.5.3.3.2, *Controller Transmit-and-Receive Mode (Full Duplex)*). An enabled channel can be scheduled if its receive register is full (the MCSPI\_CHSTAT\_0/1/2/3[0] RXS bit) when the shift-register is assigned until the shift register is full.

The MCSPI\_RX\_0/1/2/3 register cannot be overwritten in turbo mode. Consequently, the MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set in this mode.

#### 12.1.5.3.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the MCSPI word to indicate whether the next MCSPI word must be handled as a command or as data. This feature is available only in controller mode. Start-bit mode

cannot be used at the same time as turbo mode and/or force SPIEN[i] mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the MCSPI\_CHCONF\_0/1/2/3[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the MCSPI\_CHCONF\_0/1/2/3[24] SBPOL bit is set to 0, the MCSPI word must be handled as a command. When the MCSPI\_CHCONF\_0/1/2/3[24] SBPOL bit is set to 1, the MCSPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the MCSPI\_CHCONF\_0/1/2/3[24] SBPOL bit before writing the MCSPI word to be transmitted to the TX register.

#### 12.1.5.3.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in controller mode with automatic CS generation (the MCSPI\_MODULCTRL[0] SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when MCSPI\_MODULCTRL[1] PIN34 set to 0.

This mode is programmable per channel through the MCSPI\_CHCONF\_0/1/2/3[26-25] TCS0 bit field.

Figure 12-39 shows the CS SPIEN timing controls.

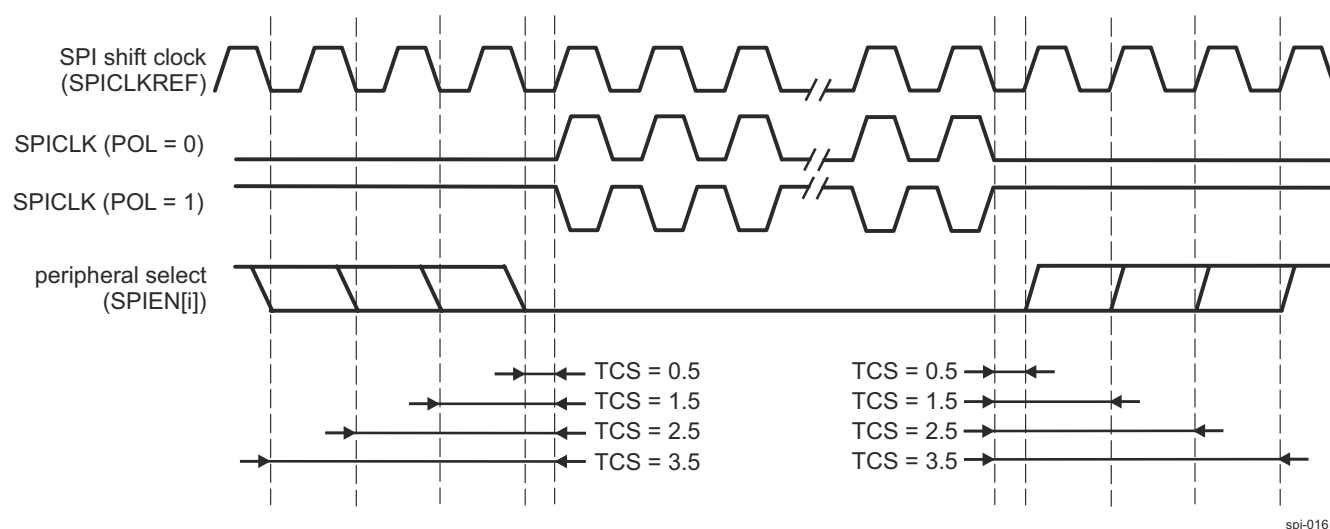

Figure 12-39. CS SPIEN Timing Controls

#### Note

Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

#### 12.1.5.3.3.8 Programmable MCSPI Clock (SPICLK)

In controller mode, the baud rate of the MCSPI serial clock is programmable.

An internal reference clock, SPICLKREF, is used as input of a programmable divider (the MCSPI\_CHCONF\_0/1/2/3[5-2] CLKD bit field) to generate the bit rate of the serial output clock SPICLK. Table 12-35 summarizes the supported divisor values.

Table 12-35. MCSPI Controller Clock Rates

Divider	Clock Rate
1	50 MHz <sup>(1)</sup>
2	25 MHz <sup>(1)</sup>
4	12.5 MHz
8	6.25 MHz

**Table 12-35. MCSPI Controller Clock Rates (continued)**

Divider	Clock Rate
16	3.125 MHz
32	1.5625 MHz
64	781.25 kHz
128	390 kHz <sup>(2)</sup>
256	195 kHz <sup>(2)</sup>
512	97.7 kHz <sup>(2)</sup>
1024	48.8 kHz <sup>(2)</sup>
2048	24.4 kHz <sup>(2)</sup>
4096	12.2 kHz <sup>(2)</sup>
8192 and higher: Division not supported	—

- (1) These frequencies are not necessarily supported by all MCSPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device-specific Data sheet.
- (2) Approximate Frequency

#### 12.1.5.3.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the MCSPI\_CHCONF\_0/1/2/3[5-2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the MCSPI\_CHCONF\_0/1/2/3[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the MCSPI\_CHCTRL\_0/1/2/3[15-8] EXTCLK bit field is concatenated with the MCSPI\_CHCONF\_0/1/2/3[5-2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the MCSPI\_CHCONF\_0/1/2/3[1] POL and MCSPI\_CHCONF\_0/1/2/3[0] PHA bits (see [Table 12-36](#)).

**Table 12-36. CLKSPPIO High/Low Time Computation**

Clock Ratio $F_{RATIO}$	CLKSPPIO High Time	CLKSPPIO Low Time
1	$T_{HIGH\_REF}$	$T_{LOW\_REF}$
Even $\geq 2$	$T_{ref} * (F_{RATIO}/2)$	$T_{ref} * (F_{RATIO}/2)$
Odd $\geq (POL = PHA)$	$T_{ref} * (F_{RATIO} - 1)/2$	$T_{ref} * (F_{RATIO} + 1)/2$
Odd $\geq (POL \neq PHA)$	$T_{ref} * (F_{RATIO} + 1)/2$	$T_{ref} * (F_{RATIO} - 1)/2$

#### Note

$F_{RATIO}$  = SPICLK frequency ( $F_{OUT}$ ) division ratio  
 $T_{HIGH}$  = SPICLK high time period  
 $T_{LOW}$  = SPICLK low time period  
 $T_{ref}$  = MCSPI\_FCLK period  
 $T_{HIGH\_REF}$  = MCSPI\_FCLK high time period  
 $T_{LOW\_REF}$  = MCSPI\_FCLK low time period

If the CLKG bit is set to 1;  $F_{RATIO}$  = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

$$\text{Duty\_cycle} = (1 - 1/F_{\text{RATIO}})/2$$

Table 12-37 shows examples of clock granularity with a clock source frequency of 50 MHz.

**Table 12-37. Clock Granularity Examples**

EXTCLK	CLKD	CLKG	F <sub>RATIO</sub>	PHA	POL	T <sub>HIGH</sub> (ns)	T <sub>LOW</sub> (ns)	T <sub>PERIOD</sub> (ns)	Duty Cycle	F <sub>OUT</sub> (MHz)
X	0	0	1	X	X	10.0	10.0	20.0	50–50	50
X	1	0	2	X	X	20.0	20.0	40.0	50–50	25
X	2	0	4	X	X	40.0	40.0	80.0	50–50	12.5
X	3	0	8	X	X	80.0	80.0	160.0	50–50	6.2
0	0	1	1	X	X	10.0	10.0	20.0	50–50	50
0	1	1	2	X	X	20.0	20.0	40.0	50–50	25
0	2	1	3	1	0	40.0	20.0	60.0	66–33	16.6
0	2	1	3	1	1	20.0	40.0	60.0	33–66	16.6
0	3	1	4	X	X	40.0	40.0	80.0	50–50	12.5
5	0	1	81	1	0	820.0	800.0	1620.0	50.6–49.4	0.617
5	7	1	88	X	X	880.0	880.0	1760.0	50–50	0.568

#### 12.1.5.3.4 MCSPI Peripheral Mode

To select the MCSPI peripheral mode, set the MCSPI\_MODULCTRL[2] MS bit.

A MCSPI peripheral device can be connected to up to four external MCSPI controller devices but handles transactions with one MCSPI controller device at a time.

In peripheral mode, the MCSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN[i]) and receives an MCSPI clock (SPICLK) from the external MCSPI controller device. Only channel 0 can be configured as a peripheral but through the MCSPI\_CHCONF\_0[22-21] SPIENSLV bit field any of the SPIEN[i] signals can be used to select the MCSPI module. In peripheral mode and when the MCSPI\_MODULCTRL[1] PIN34 is set to 0x0 (default behaviour), the MCSPI uses the edge of SPIEN[i] to detect word length. For this reason, SPIEN[i] must become inactive between each word.

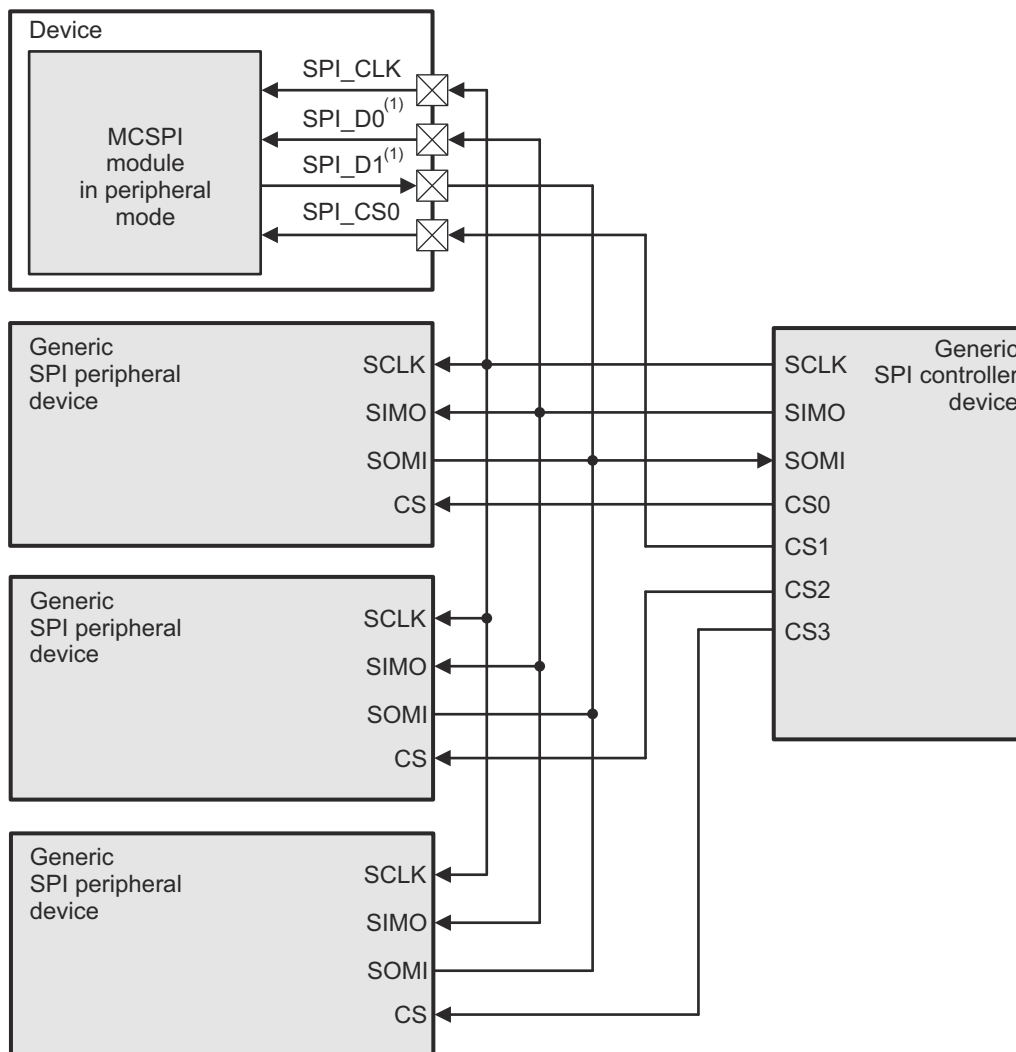

When the MCSPI\_MODULCTRL[1] PIN34 is set to 0x0, the MCSPI does not support SPIEN[i] active between MCSPI words. In this case, the MCSPI uses the edge to detect word length.

When the MCSPI\_MODULCTRL[1] PIN34 is set to 0x1, a multiword transfer can be performed without needing the external MCSPI controller to deactivate SPIEN[i] between each word as in this case the MCSPI module works in 3-pin peripheral mode and SPIEN[i] is not needed.

##### 12.1.5.3.4.1 Dedicated Resources

Only channel 0 can be enabled in peripheral mode.

Figure 12-40 shows an example of four peripherals wired on a single controller device.

spi-017

- A. Direction depends on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

**Figure 12-40. Example of MCSPI Peripheral With One Controller and Multiple Peripheral Devices on Channel 0**

Channel 0 in peripheral mode has the following resources:

- Its own channel enable, programmable with the MCSPI\_CHCTRL\_0[0] EN bit. This channel must be enabled before transmission and reception.
- For this mode, the peripheral-select signal can be detected on any of the SPIEN[i] ports. This is programmable with the MCSPI\_CHCONF\_0[22-21] SPIENSLV bit field.
- Its own transmitter register, MCSPI\_TX\_0, on top of the common transmit shift register. If the MCSPI\_TX\_0 register is empty, the MCSPI\_CHSTAT\_0[1] TXS bit is set. If MCSPI is selected by an external controller (the active signal on the SPIEN[i] port assigned to channel 0), the MCSPI\_TX\_0 register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI\_TX\_0 register must be loaded before MCSPI is selected by a controller.
- Its own receiver register, MCSPI\_RX\_0, on top of the common receive shift register. If the MCSPI\_RX\_0 register is full, the MCSPI\_CHSTAT\_0[0] RXS bit is set.

**Note**

The MCSPI\_TX\_1/2/3 and MCSPI\_RX\_1/2/3 registers are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the MCSPI\_CHCONF\_0:
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The MCSPI modules are in peripheral mode after reset and must be properly configured for the modules to act in controller mode.)
  - MCSPI word length, programmable with the WL bit
  - SPIEN[i] polarity, programmable with the EPOL bit
  - SPICLK polarity, programmable with the POL bit
  - SPICLK phase, programmable with the PHA bit

The SPICLK frequency of a transfer is controlled by the external MCSPI controller connected to the MCSPI peripheral device. The MCSPI\_CHCONF\_0[5-2] CLKD bit field is not used in peripheral mode.

**Note**

The configuration of the channel can be loaded in the MCSPI\_CHCONF\_0 only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of MCSPI. DMA requests are asserted using the MCSPI\_CHCONF\_0[15] DMAR bit for reading and the MCSPI\_CHCONF\_0[14] DMAW bit for writing.
- Four interrupt events (see [Section 12.1.5.3.7.2, Interrupt Events in Peripheral Mode](#)).

**12.1.5.3.4.2 Peripheral Transmit-and-Receive Mode**

The peripheral receive mode is programmable (set the MCSPI\_CHCONF\_0[13-12] TRM bit field to 0x0).

In peripheral transmit-and-receive mode, the MCSPI\_TX\_0 register must be loaded before MCSPI is selected by an external MCSPI controller device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI\_TX\_0 register content is always loaded in the shift register whether it is updated or not. The event TX0\_UNDERFLOW is activated accordingly and does not prevent transmission.

When the MCSPI word transfer completes (the MCSPI\_CHSTAT\_0[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use MCSPI as a peripheral transmit-only device, the RX0\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI\_RX\_0 register (see [Section 12.1.5.3.7.2, Interrupt Events in Peripheral Mode](#)).

**12.1.5.3.4.3 Peripheral Transmit-Only Mode**

The peripheral transmit-only mode is programmable (set the MCSPI\_CHCONF\_0[13-12] TRM bit field to 0x2) and avoids the requirement for the processor to read the MCSPI\_RX\_0 register (minimizing data movement) only when transmission is meaningful.

To use the MCSPI as a peripheral transmit-only device, the RX0\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI\_RX\_0 register.

When the MCSPI word transfer completes, the MCSPI\_CHSTAT\_0[2] EOT bit is set.

[Figure 12-41](#) shows a half-duplex system with a controller device on the left and a transmit-only peripheral device on the right. Each time a bit transfers out from the peripheral, 1 bit transfers in the controller. After eight cycles of the serial clock SPICLK, WordB transfers from the peripheral to the controller.

spi-018

k = 0 or 1 depending on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

**Figure 12-41. MCSPI Half-Duplex Transmission (Transmit-Only peripheral)**

#### 12.1.5.3.4.4 Peripheral Receive-Only Mode

The peripheral receive mode is programmable (set the MCSPI\_CHCONF\_0[13-12] TRM bit field to 0x1).

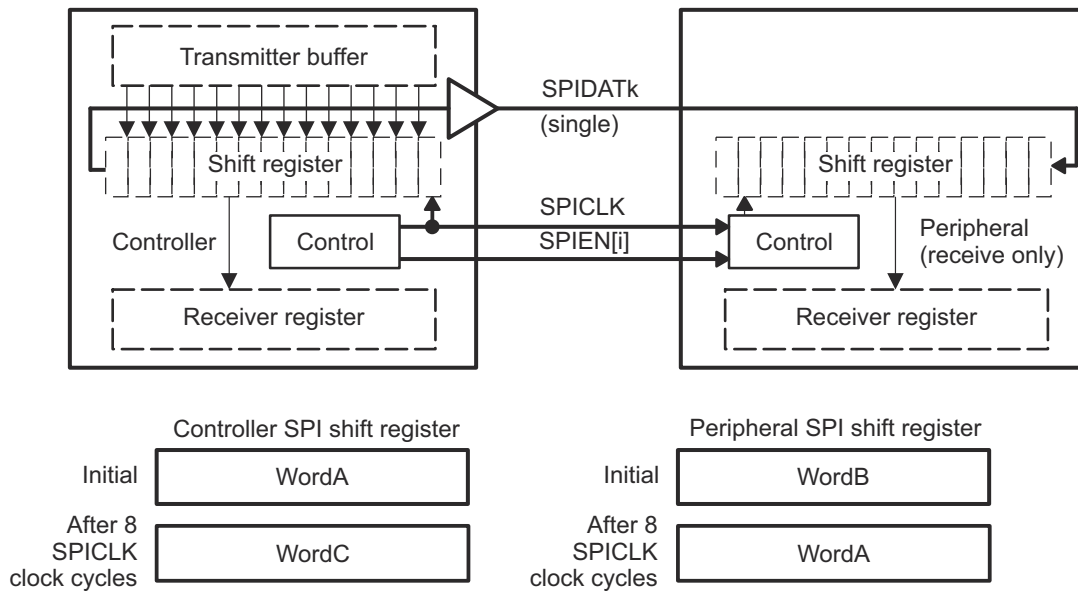

In receive-only mode, the MCSPI\_TX\_0 register must be loaded before the MCSPI is selected by an external MCSPI controller device. The MCSPI\_TX\_0 register content is always loaded into the shift register whether it is updated or not. The TX0\_UNDERFLOW event is activated accordingly and does not prevent transmission.

When the MCSPI word transfer completes (the MCSPI\_CHSTAT\_0[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use the MCSPI as a peripheral receive-only device, the TX0\_EMPTY and TX0\_UNDERFLOW interrupts and the DMA write requests must be disabled due to the state of the MCSPI\_TX\_0 register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 12-42 shows a half-duplex system with a controller device on the left and a receive-only peripheral device on the right. Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral.

spi-019

k = 0 or 1 depending on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

**Figure 12-42. MCSPI Half-Duplex Transmission (Receive-Only Peripheral)**

#### 12.1.5.3.5 MCSPI 3-Pin or 4-Pin Mode

Depending on targeted application the MCSPI interface can be configured to use 3 or 4 pins through the MCSPI\_MODULCTRL[1] PIN34 bit. If this bit is set to 0, MCSPI is in 4-pin mode using the SPICLK, SPIDAT[0], SPIDAT[1] and SPIEN[i] signals. If PIN34 is set to 1 the controller is in 3-pin mode and SPIEN[i] is not used. In this mode all options related to chip select management are useless (EPOL, FORCE and TCS0 bits of MCSPI\_CHCONF\_0/1/2/3). 3-pin and 4-pin operation applies to both controller and peripheral modes.

#### 12.1.5.3.6 MCSPI FIFO Buffer Management

The MCSPI controller has a built-in 64-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the MCSPI\_CHCONF\_0/1/2/3[28] FFER or MCSPI\_CHCONF\_0/1/2/3[27] FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Controller or peripheral mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (MCSPI\_CHCONF\_0/1/2/3[11-7] WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see [Figure 12-43](#)) or receive (see [Figure 12-44](#)) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see [Figure 12-45](#)).

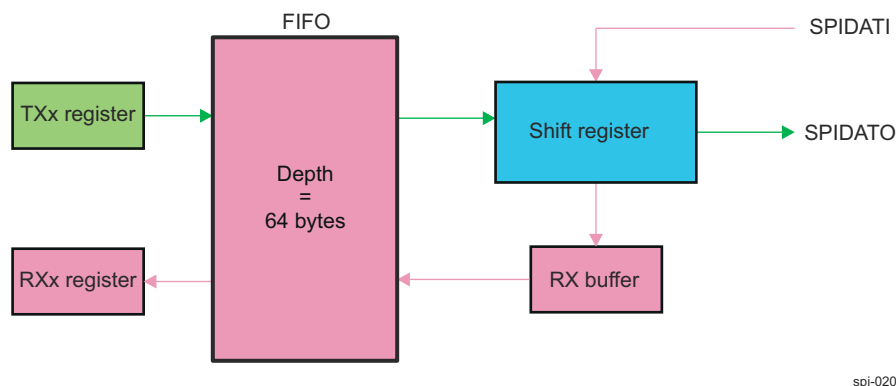

Figure 12-43. Buffer Used in Transmit Direction Only

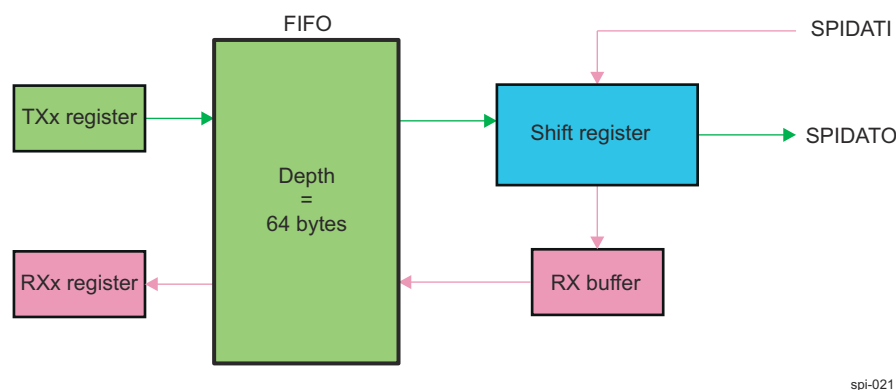

Figure 12-44. Buffer Used in Receive Direction Only

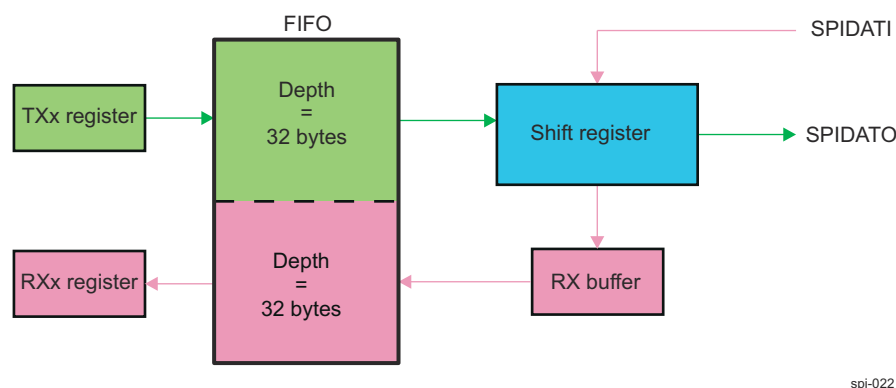

Figure 12-45. Buffer Used for Transmit and Receive Directions

Two levels (MCSPI\_XFERLEVEL[5-0] AEL and MCSPI\_XFERLEVEL[13-8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the MCSPI word length. The driver must set these values as a multiple of the MCSPI word length defined in WL. [Table 12-38](#) lists the number of bytes written in the FIFO, depending on the word length.

Table 12-38. FIFO Writes, Word Length Relationship

	MCSPI Word Length (WL)		
	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

#### 12.1.5.3.6.1 Buffer Almost Full

The MCSPI\_XFERLEVEL[15-8] AFL bit field is needed when the buffer is used to receive an MCSPI word from a peripheral (the MCSPI\_CHCONF\_0/1/2/3[28] FFER bit must be set to 1). It defines the almost-full buffer status. See [Figure 12-46](#).

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the processor to enable the system to read AFL + 1 bytes from the receive register.

#### Note

AFL + 1 must correspond to a multiple value of the MCSPI\_CHCONF\_0/1/2/3[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

**Figure 12-46. Buffer Almost Full Level (AFL)**

#### Note

The MCSPI\_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the request is asserted on the same conditions as the MCSPI\_IRQSTATUS RXx\_FULL flag.

#### 12.1.5.3.6.2 Buffer Almost Empty

The MCSPI\_XFERLEVEL[7-0] AEL bit field is needed when the buffer is used to transmit an MCSPI word to a peripheral (the MCSPI\_CHCONF\_0/1/2/3[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See [Figure 12-47](#).

When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the processor to enable the system to write AEL + 1 bytes to the transmit register.

#### Note

AEL + 1 must correspond to a multiple value of the MCSPI\_CHCONF\_0/1/2/3[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

**Figure 12-47. Buffer Almost Empty Level (AEL)**

**Note**

The MCSPI\_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the request is asserted on the same conditions as the MCSPI\_IRQSTATUS TXx\_EMPTY flag.

#### 12.1.5.3.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the MCSPI\_XFERLEVEL register the AEL and AFL levels and especially the MCSPI\_XFERLEVEL[31-16] WCNT bit field to define the number of MCSPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of MCSPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many MCSPI transfers have been done. For received words, software must poll the MCSPI\_CHSTAT\_i[5] RXFFE bit and read the MCSPI\_RX\_0/1/2/3 receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the MCSPI\_IRQSTATUS[17] EOW bit is set), the user can disable the channel and poll the MCSPI\_CHSTAT\_0/1/2/3[5] RXFFE bit to know the last MCSPI words in the FIFO buffer and read them.

#### 12.1.5.3.6.4 Multiple MCSPI Word Access

The processor has the ability to perform multiple MCSPI word access to the receive or transmit registers within a single 32-bit interface access by setting the MCSPI\_MODULCTRL[7] MOA to 1 under specific conditions:

- The channel selected has the FIFO enable.
- Only FIFO sense enabled support the kind of access.
- MCSPI\_MODULCTRL[7] MOA is set to 1.
- Only 32-bit interface access and data width can be performed to receive or transmit registers, for other kind of access the processor must de-assert MCSPI\_MODULCTRL[7] MOA bit.
- The level MCSPI\_XFERLEVEL[7-0] AEL and MCSPI\_XFERLEVEL[15-8] AFL must be 32-bit aligned, it means that AEL[0] = AEL[1] = 1 or AFL[0] = AFL[1] = 1.
- If MCSPI\_XFERLEVEL[31-16] WCNT is used it must be configured according to MCSPI word length.
- The word length of MCSPI words allows to perform multiple MCSPI access, that means that MCSPI\_CHCONF\_0/1/2/3[11-7] WL is <16.

The number of MCSPI word access depends on MCSPI word length:

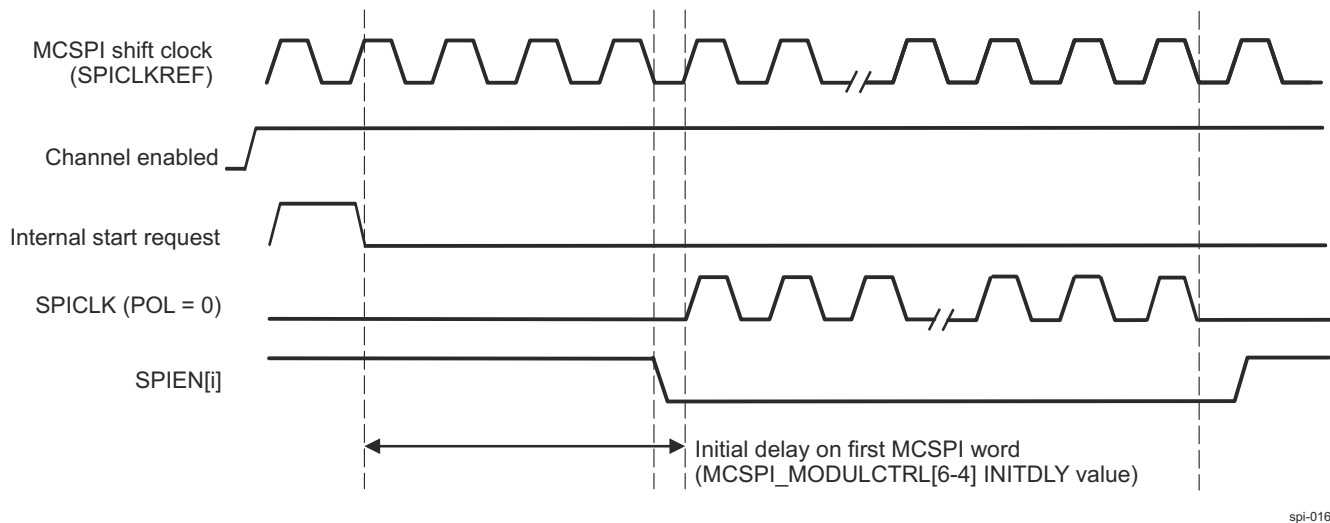

- $3 \leq WL \leq 7$ , MCSPI word length smaller or equal to byte length, 4 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI\_XFERLEVEL[31-16] WCNT), set the bit field to WCNT[0] = WCNT[1] = 0.
- $8 \leq WL \leq 15$ , MCSPI word length greater than byte or equal to 16-bit length, 2 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI\_XFERLEVEL[31-16] WCNT), set the bit field to WCNT[0] = 0.

- $16 \leq \text{WL}$  Multiple MCSPI word access is not applicable.

#### 12.1.5.3.6.5 First MCSPI Word Delay

Figure 12-48 shows the MCSPI controller ability to delay the first MCSPI word transfer to give time for system to complete some parallel processes or fill the FIFO in order to improve transfer bandwidth. This delay is applied only on first MCSPI word after MCSPI channel enabled and first write in transmit register. It is based on output clock frequency.

This option is meaningful in controller mode and single channel mode asserted through MCSPI\_MODULCTRL[0] SINGLE.

**Figure 12-48. Controller Single Channel Initial Delay**

Few delay values are available: No delay, 4/8/16/32 MCSPI cycles.

Its accuracy is half cycle in clock bypass mode and depends on clock polarity and phase.

#### 12.1.5.3.7 MCSPI Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the MCSPI\_IRQSTATUS register (RXx\_FULL, TXx\_UNDERFLOW, TXx\_EMPTY, etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the MCSPI\_IRQENABLE register (RXx\_FULL\_ENABLE, TXx\_UNDERFLOW\_ENABLE, TXx\_EMPTY\_ENABLE, etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The MCSPI supports interrupt-driven and polling operations.

##### 12.1.5.3.7.1 Interrupt Events in Controller Mode

In controller mode, the interrupt events related to the state of the MCSPI\_TX\_0/1/2/3 register are TXx\_EMPTY and TXx\_UNDERFLOW. The interrupt event related to the state of the MCSPI\_RX\_0/1/2/3 register is RXx\_FULL.

##### 12.1.5.3.7.1.1 TXx\_EMPTY

The TXx\_EMPTY event is activated when a channel is enabled and its MCSPI\_TX\_0/1/2/3 register is empty (transient event). Enabling a channel automatically triggers this event, except in controller receive-only mode (see [Section 12.1.5.3.3.4, Controller Receive-Only Mode](#)). When the FIFO buffer is enabled (the MCSPI\_CHCONF\_0/1/2/3[27] FFEW bit is set to 1), the MCSPI\_IRQSTATUS TXx\_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI\_XFERLEVEL[5-0] AEL bit field.

The MCSPI\_TX\_0/1/2/3 register must be loaded with data to remove the source of the interrupt; the MCSPI\_IRQSTATUS TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPI\_TX\_0/1/2/3 register defined by the MCSPI\_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

#### **12.1.5.3.7.1.2 TXx\_UNDERFLOW**

The event TXx\_UNDERFLOW is activated when the channel is enabled and if the MCSPI\_TX\_0/1/2/3 register or the FIFO is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPI (transmit and receive).

The TXx\_UNDERFLOW is a harmless warning in controller mode.

To avoid having a TXx\_UNDERFLOW event at the beginning of a transmission, the TXx\_UNDERFLOW event is not activated when no data has been loaded into the MCSPI\_TX\_0/1/2/3 register, because the channel is enabled. To avoid having a TXx\_UNDERFLOW event, the MCSPI\_TX\_0/1/2/3 register must seldom be loaded.

The MCSPI\_IRQSTATUS TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### **12.1.5.3.7.1.3 RXx\_FULL**

The RXx\_FULL event is activated when a channel is enabled and the MCSPI\_RX\_0/1/2/3 register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI\_CHCONF\_0/1/2/3[28] FFER bit is set to 1), RXx\_FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI\_XFERLEVEL[13-8] AFL threshold.

The MCSPI\_RX\_0/1/2/3 register must be read to remove the source of the interrupt; the MCSPI\_IRQSTATUS RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPI\_RX\_0/1/2/3. The processor must perform the correct number of reads.

#### **12.1.5.3.7.1.4 End Of Word Count**

The MCSPI\_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI\_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI\_XFERLEVEL[31-16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI\_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### **12.1.5.3.7.2 Interrupt Events in Peripheral Mode**

In peripheral mode, the interrupt events related to the state of the MCSPI\_TX\_0/1/2/3 register are TX0\_EMPTY and TX0\_UNDERFLOW. The interrupt events related to the state of the MCSPI\_RX\_0/1/2/3 are RX0\_FULL and RX0\_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI\_IRQSTATUS register.

##### **12.1.5.3.7.2.1 TXx\_EMPTY**

The TXx\_EMPTY event is activated when a channel is enabled and its MCSPI\_TX\_0/1/2/3 register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the MCSPI\_CHCONF\_0/1/2/3[27] FFEW bit is set to 1), the TXx\_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI\_XFERLEVEL[5-0] AEL bit field.

The MCSPI\_TX\_0/1/2/3 register must be loaded with data to remove the source of the interrupt; the MCSPI\_IRQSTATUS TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPI\_TX\_0/1/2/3 register defined by MCSPI\_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

#### **12.1.5.3.7.2.2 TXx\_UNDERFLOW**

The TXx\_UNDERFLOW event is activated when a channel is enabled and if the MCSPI\_TX\_0/1/2/3 register is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the old data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx\_UNDERFLOW indicates an error (data loss) in peripheral mode.

To avoid having a TXx\_UNDERFLOW event at the beginning of a transmission, the TXx\_UNDERFLOW event is not activated when no data has been loaded into the MCSPI\_TX\_0/1/2/3 register because the channel is enabled.

The MCSPI\_IRQSTATUS TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### **12.1.5.3.7.2.3 RXx\_FULL**

The RXx\_FULL event is activated when a channel is enabled and the MCSPI\_RX\_0/1/2/3 register is being filled (transient event). When the FIFO buffer is enabled (the MCSPI\_CHCONF\_0/1/2/3[28] FFER bit is set to 1), RXx\_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the MCSPI\_XFERLEVEL[13-8] AFL bit field.

The MCSPI\_RX\_0/1/2/3 register must be read to remove the source of the interrupt; the MCSPI\_IRQSTATUS RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPI\_RX\_0/1/2/3. The processor must perform the correct number of reads.

#### **12.1.5.3.7.2.4 RX0\_OVERFLOW**

The RX0\_OVERFLOW event is activated in peripheral mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the MCSPI\_RX\_0/1/2/3 register or FIFO is full when a new MCSPI word is received. The MCSPI\_RX\_0/1/2/3 register is always overwritten with the new MCSPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0\_OVERFLOW event should not appear in peripheral mode using the FIFO.

The RX0\_OVERFLOW event indicates an error (data loss) in peripheral mode.

The MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### **12.1.5.3.7.2.5 End Of Word Count**

The MCSPI\_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI\_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPI transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and the channel is not re-enabled.

The MCSPI\_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.5.3.7.3 Interrupt-Driven Operation

An interrupt enable bit in the MCSPI\_IRQENABLE register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the processor must:

1. Read the MCSPI\_IRQSTATUS register to identify which event occurred.
2. Read the MCSPI\_RX\_0/1/2/3 register that corresponds to the event to remove the source of an RXx\_FULL event or write into the MCSPI\_TX\_0/1/2/3 register that corresponds to the event to remove the source of a TXx\_EMPTY event. No action is required to remove the source of the TXx\_UNDERFLOW and RX0\_OVERFLOW events.
3. Set the corresponding bit of the MCSPI\_IRQSTATUS register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

#### 12.1.5.3.7.4 Polling

When the interrupt capability of an event is disabled in the MCSPI\_IRQENABLE register, the interrupt line is not asserted, but the status bits in the MCSPI\_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx\_FULL: To remove the source of the event, the processor must read the corresponding MCSPI\_RX\_0/1/2/3 register.
- TXx\_EMPTY: To remove the source of the event, the processor must write into the corresponding MCSPI\_TX\_0/1/2/3 register.
- TXx\_UNDERFLOW and RX0\_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the MCSPI\_IRQSTATUS register to 1. This does not affect the interrupt line state.

#### 12.1.5.3.8 MCSPI DMA Requests

Each MCSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per MCSPI channel (one for read and one for write).

The DMA read request line is asserted when the MCSPI channel is enabled and new data is available in the receive register of the MCSPI channel. A DMA read request can be individually masked with the MCSPI\_CHCONF\_0/1/2/3[15] DMAR bit. The DMA read request line is de-asserted when reading of the MCSPI\_RX\_0/1/2/3 register of the MCSPI channel completes.

The DMA write request line is asserted when the MCSPI channel is enabled and the MCSPI\_TX\_0/1/2/3 register of the MCSPI channel is empty. A DMA write request can be individually masked with the MCSPI\_CHCONF\_0/1/2/3[14] DMAW bit. The DMA write request line is de-asserted when loading of the MCSPI\_TX\_0/1/2/3 register of the channel completes.

#### 12.1.5.3.9 MCSPI Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity.

##### 12.1.5.3.9.1 Normal Mode

In normal mode, internal MCSPI module clocks are automatically switched off (autogated) when there is no activity in peripheral or controller mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The MCSPI\_SYSCONFIG[0] AUTOIDLE bit is set.
- In controller mode, there is no data to transmit or receive in all channels.
- In peripheral mode, the MCSPI is not selected by the external controller and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In controller mode, an internal access occurs.
- In peripheral mode, an internal access occurs or the MCSPI is selected by the external controller.

#### 12.1.5.3.9.2 Idle Mode

##### Note

Some of the MCSPI features described in this section may not be supported on this family of devices. For more information, see *MCSPI Not Supported Features*.

At the power management level, when all conditions to shut off the MCSPI\_FCLK or MCSPI\_ICLK clocks are met, the corresponding LPSC asserts a clock stop request to the MCSPI. Although this procedure is completely hardware-oriented and out of software control, the method in which the MCSPI module acknowledges the clock stop request can be configured through the MCSPI\_SYSCONFIG[4-3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgement modes are:

- Force-idle mode (the MCSPI\_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0): The MCSPI module acknowledges unconditionally the clock stop request, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The MCSPI never acknowledges the clock stop request and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow shut off of MCSPI\_FCLK and MCSPI\_ICLK.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The MCSPI acknowledges the clock stop request, depending on its internal activity. MCSPI acknowledges the shut off of MCSPI\_FCLK and MCSPI\_ICLK only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the MCSPI also offers an additional feature to control gating of MCSPI\_FCLK or MCSPI\_ICLK. The MCSPI\_SYSCONFIG[9-8] CLOCKACTIVITY bit field determines which clock shuts down (MCSPI\_FCLK, MCSPI\_ICLK, neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the MCSPI to determine on which part of the module the conditions to acknowledge the clock stop request are tested. For example, if MCSPI\_FCLK is not shut off on clock stop request, the MCSPI considers only MCSPI\_ICLK and the associated pending activities before acknowledging the request.

Some MCSPI features are associated with MCSPI\_ICLK and others with MCSPI\_FCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if MCSPI acknowledges the clock stop request.

##### 12.1.5.3.9.2.1 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the MCSPI\_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0.
  - In force-idle mode, the MCSPI responds unconditionally to the clock stop request by de-asserting unconditionally the interrupt and DMA request lines, if asserted.
  - The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI\_IRQSTATUS register.
  - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely de-asserted. The interface clock and MCSPI clock provided to the MCSPI can be switched off.
  - A clock stop request during an MCSPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.

#### 12.1.5.4 MCSPI Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the MCSPI module.

##### 12.1.5.4.1 MCSPI Operational Mode Configuration

###### 12.1.5.4.1.1 MCSPI Operational Modes

The selection of the working mode is done with the MCSPI\_CHCONF\_0/1/2/3 register.

**Table 12-39. MCSPI Receive Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set receive mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x1
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

**Table 12-40. MCSPI Transmit Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x2
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

**Table 12-41. MCSPI Transmit-and-Receive Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x0
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

###### 12.1.5.4.1.1.1 Common Transfer Sequence

MCSPI module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT-RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN[i] lines assertion/deassertion: automatic, manual

For all these sequences, the host process contains the main process and the interrupt routines.

The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

Table 12-42 represents the main sequence which is common to all transfers.

In multi-channel controller mode, the sequences of different channels can be run simultaneously.

**Table 12-42. Common Transfer Sequence (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	0x-
Write MCSPI_CHCONF_0/1/2/3 to configure the channel	MCSPI_CHCONF_0/1/2/3	0x-
Start the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	1
Wait for the first write request (TX empty or DMA write)		
Write the transmitter register with data	MCSPI_TX_0/1/2/3	0x-
Wait for the host event for end of transfer		

**Table 12-42. Common Transfer Sequence (Main Process) (continued)**

Step	Register/Bit Field/Programming Model	Value
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

#### 12.1.5.4.1.1.2 End of Transfer Sequences

The end of transfer depends on the transfer mode. [Table 12-43](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

**Table 12-43. End of Transfer Sequences**

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
<b>CONTROL LER Normal</b>	End of transfer sequence	See <a href="#">Section 12.1.5.4.1.1.3</a>		See <a href="#">Section 12.1.5.4.1.1.4.1</a>	See <a href="#">Section 12.1.5.4.1.1.4.2</a>	See <a href="#">Section 12.1.5.4.1.1.5.1</a>	See <a href="#">Section 12.1.5.4.1.1.5.2</a>
	Minimum number of word	1	1	1	1	1	2
	DMA transfer size		N		N		N-1
<b>CONTROL LER Turbo</b>	End of transfer sequence	See <a href="#">Section 12.1.5.4.1.1.3</a>		See <a href="#">Section 12.1.5.4.1.1.4.1</a>	See <a href="#">Section 12.1.5.4.1.1.4.2</a>	See <a href="#">Section 12.1.5.4.1.1.6.1</a>	See <a href="#">Section 12.1.5.4.1.1.6.2</a>
	Minimum number of word	1	1	1	1	2	3
	DMA transfer size		N		N		N-2
<b>PERIPHER AL</b>	End of transfer sequence	See <a href="#">Section 12.1.5.4.1.1.3</a>		See <a href="#">Section 12.1.5.4.1.1.4.1</a>	See <a href="#">Section 12.1.5.4.1.1.4.2</a>	See <a href="#">Section 12.1.5.4.1.1.7</a>	
	Minimum number of word	1	1	1	1	1	1
	DMA transfer size		N		N	N	N

The transfer to execute has a size of N words.

The different sequences can be merged in one process to manage transfers of several types. The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write\_count = 0
- read\_count = 0
- channel\_enable = FALSE
- last\_transfer = FALSE
- last\_request = FALSE

They are initialized before starting the channel.

#### 12.1.5.4.1.1.3 Transmit-and-Receive (Controller and Peripheral)

If the requests are configured in DMA, write\_count and read\_count are assigned with 'N' when the DMA handlers have completed their 'N' CBASS0 accesses.

**Table 12-44. Transmit-and-Receive (Controller and Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait for write_count = N AND read_count = N		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

**Table 12-45. Transmit-and-Receive (Controller and Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111

**Table 12-45. Transmit-and-Receive (Controller and Peripheral) (Interrupt Routine) (continued)**

Step	Register/Bit Field/Programming Model	Value
<b>IF: TXx_EMPTY</b>		
Write the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
Increment write_count +1		
<b>IF: RXx_FULL</b>		
Read the receiver register	MCSPi_RX_0/1/2/3	
Increment read_count +1		
<b>ENDIF</b>		

**12.1.5.4.1.1.4 Transmit-Only (Controller and Peripheral)****12.1.5.4.1.1.4.1 Based on Interrupt Requests****Table 12-46. Transmit-Only With Interrupts (Controller and Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

**Table 12-47. Transmit-Only With Interrupts (Controller and Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: TXx_EMPTY AND write_count &lt; N</b>		
Write the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
Increment write_count +1		
<b>ELSEIF: write_count ≥ N</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

**12.1.5.4.1.1.4.2 Based on DMA Write Requests**

When the DMA handler has completed its 'N' CBASS0 accesses, write\_count is assigned with 'N'.

**Table 12-48. Transmit-Only With DMA (Controller and Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until write_count = N		
Disable DMA write request	MCSPi_CHCONF_0/1/2/3[14] DMAW	0
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

**Table 12-49. Transmit-Only With DMA (Controller and Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: TXx_EMPTY AND write_count = N</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

### 12.1.5.4.1.1.5 Controller Normal Receive-Only

#### 12.1.5.4.1.1.5.1 Based on Interrupt Requests

**Table 12-50. Receive-Only With Interrupt (Controller Normal) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until last_request = TRUE		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		

**Table 12-51. Receive-Only With Interrupt (Controller Normal) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXx_FULL AND read_count = N - 1</b>		
last_request = TRUE		
<b>ELSEIF: read_count ≠ N - 1</b>		
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		
<b>ENDIF</b>		

#### 12.1.5.4.1.1.5.2 Based on DMA Read Requests

When the DMA handler has completed its 'N-1' CBASS0 accesses, read\_count is assigned with 'N-1'.

**Table 12-52. Receive-Only With DMA (Controller Normal) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until read_count = N - 1		
Disable DMA read request	MCSPi_CHCONF_0/1/2/3[15] DMAR	0
Wait until last_transfer = TRUE		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		

**Table 12-53. Receive-Only With DMA (Controller Normal) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXx_FULL AND read_count = N-1</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

### 12.1.5.4.1.1.6 Controller Turbo Receive-Only

#### 12.1.5.4.1.1.6.1 Based on Interrupt Requests

**Table 12-54. Receive-Only With Interrupt (Controller Turbo) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until channel_enable = TRUE		
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1

**Table 12-54. Receive-Only With Interrupt (Controller Turbo) (Main Process) (continued)**

Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXx_FULL</b>		
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		
<b>ENDIF</b>		

#### 12.1.5.4.1.1.8 Transfer Procedures With FIFO

These flows describe the transfer with FIFO.

The MCSPi module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT-RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see [Section 12.1.5.3.6, MCSPi FIFO Buffer Management](#).

**Table 12-60. FIFO Mode Common Sequence (Controller) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS	1
Write MCSPi_IRQENABLE to enable interrupts	MCSPi_IRQENABLE	1
Write MCSPi_CHCONF_0/1/2/3 to configure the channel	MCSPi_CHCONF_0/1/2/3	0x-
Write MCSPi_XFERLEVEL	MCSPi_XFERLEVEL	0x-
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
<b>IF: Receive only</b>		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
<b>ENDIF</b>		
Wait for the host event for end of transfer		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

#### 12.1.5.4.1.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in [Section 12.1.5.4.1.1.8, Transfer Procedures With FIFO](#).

In multi-channel, only one channel can use the FIFO.

Before enabling the FIFO for a channel (MCSPI\_CHCONF\_0/1/2/3[28] FFER and MCSPI\_CHCONF\_0/1/2/3[27] FFEW bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Peripheral mode, the channel 0 only can be activated. The correct SPIEN line is chosen in MCSPI\_CHCONF\_0[22-21] SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request has been released by writing the MCSPI\_TX\_0/1/2/3 register, even in receive-only mode (only one write request occurs in this case).

#### 12.1.5.4.1.1.8.2 End of Transfer Sequences in FIFO Mode

[Table 12-61](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

**Table 12-61. End of Transfer Sequences in FIFO Mode**

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See <a href="#">Figure 12-49</a>	See <a href="#">Figure 12-51</a>	See <a href="#">Figure 12-52</a>
No	See <a href="#">Figure 12-50</a>	See <a href="#">Figure 12-51</a>	See <a href="#">Figure 12-53</a>

The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write\_count = N
- read\_count = N
- last\_request = FALSE

They are initialized before starting the channel.

#### 12.1.5.4.1.1.8.3 Transmit-and-Receive With Word Count

[Figure 12-49](#) shows the flow of a transfer in transmit-and-receive mode, with word count.

mcspi\_025

**Figure 12-49. FIFO Mode Transmit-and-Receive With Word Count (Controller)**

#### 12.1.5.4.1.1.8.4 Transmit-and-Receive Without Word Count

Figure 12-50 shows the flow of a transfer in transmit-and-receive mode, without word count.

mcspi\_026

**Figure 12-50. FIFO Mode Transmit-and-Receive Without Word Count (Controller)**

#### 12.1.5.4.1.1.8.5 Transmit-Only

Figure 12-51 shows the flow of a transfer in transmit-only mode, with or without word count. The difference between word count enabled or not is just on the condition after starting the channel:

- word count enable: wait for EOW interrupt
- word count disable: wait for write\_count = 0

mcspi\_027

**Figure 12-51. FIFO Mode Transmit-Only (Controller)****12.1.5.4.1.1.8.6 Receive-Only With Word Count**

#### 12.1.5.4.1.1.9.2 Receive-Only Procedure – Interrupt Method

Table 12-63 lists the receive-only procedure using the interrupt method.

**Table 12-63. Receive-Only Procedure – Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-39.	
Start the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Enable the interrupt for the receiver register.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	1
Wait for interrupt.		
Read the status register.	MCSPi_IRQSTATUS[2] RX_FULL	1
Disable the interrupt if no more data is expected.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	0
Stop the channel if no more data is expected.	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Read the receiver register.	MCSPi_RX_0/1/2/3	0x-

#### 12.1.5.4.1.1.9.3 Transmit-Only Procedure – Polling Method

Table 12-64 lists the transmit-only procedure using the polling method.

**Table 12-64. Transmit-Only Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-40.	
Start the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Write the transmitter register with data.	MCSPi_TX_0/1/2/3	0x-
Wait until end of transfer?	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	0

#### 12.1.5.4.1.1.9.4 Transmit-and-Receive Procedure – Polling Method

Table 12-65 lists the transmit-and-receive procedure using the polling method.

**Table 12-65. Transmit-and-Receive Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-41.	
Start the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Write the transmitter register with data.	MCSPi_TX_0/1/2/3	0x-
Wait until transmit/receive word?	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Read the receiver register.	MCSPi_RX_0/1/2/3	0x-

### 12.1.6 Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the function, operation, and configuration of the Universal Asynchronous Receiver/Transmitter (UART)/RS-485/Infrared Data Association (IrDA)/Consumer Infrared (CIR)/ISO 7816 module in the device.

---

#### Note

UART and USART acronyms are used interchangeably in this section.

---

#### 12.1.6.1 UART Overview

The UART is a slave peripheral that utilizes the DMA for data transfer or interrupt polling via host CPU. There are UART modules in the device. All UART modules support IrDA and CIR modes when 48 MHz function clock is used. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

##### 12.1.6.1.1 UART Features

The UART includes the following features:

- 16C750-compatible
- RS-485 external transceiver auto flow control support
- 64-byte FIFO buffer for receiver and 64-byte FIFO buffer for transmitter
- Programmable interrupt trigger levels for FIFOs
- Programmable sleep mode
- The 48 MHz functional clock is default option and allows baud rates up to 3.6 Mbps
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Optional multi-drop transmission
- Configurable time-guard feature
- Configurable data format:
  - Parity bit: Even, Odd, None
  - Stop-bit: 1, 1.5, 2 bit
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- False start bit detection
- Line break generation and detection
- Fully prioritized interrupt system controls
- Internal test and loopback capabilities
- Modem control functions (CTS, RTS)
- Only module instance in MAIN domain has extended modem control signals (DCD, RI, DTR, DSR)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

##### 12.1.6.1.2 IrDA Features

The IrDA includes the following features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
  - Slow infrared (SIR 115.2 KBAUD), medium infrared (MIR 0.576 MBAUD) and fast infrared (FIR 4.0 MBAUD) operations (very fast infrared (VFIR) is not supported)
  - Frame formatting: addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  - 
  - Asynchronous transparency (automatic insertion of break character)
  - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection
- IrDA mode when 48 MHz function clock is used

### 12.1.6.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR includes the following features to provide CIR support for remote-control applications:

- Transmit and receive mode
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle
- CIR mode when 48 MHz function clock is used

### 12.1.6.1.4 UART Not Supported Features

- Synchronous mode
- ISO7816 mode
- DMA mode 2
- Full modem handshaking is not available on all instances - see device datasheet for details
- Multi-drop transmission
- 9-bit mode
- 12 Mbps operation

### 12.1.6.1.5 UART Ports

**Table 12-66. UART Clocks and Resets**

Clocks	
Module Clock Input	Description
UART_ICLK	UART interface clock
UART_FCLK	UART functional clock
Resets	
Module Reset Input	Description
UART_RST	UART reset

**Table 12-67. UART Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
USART_0_INT	UART interrupt request	Level
DMA Events		
Module DMA Event	Description	Type
USART_x_EVT0	UART transmit request line	Level
USART_x_EVT1	UART receive request line	Level

### 12.1.6.2 UART Environment

This section describes the UART/RS-485/IrDA/CIR external connections (environment).

[Table 12-68](#) lists the UART interface input/output (I/O) signals.

**Table 12-68. UART I/O Signals**

Module Pin Name	I/O <sup>(1)</sup>	Description
RX	I	Serial data input
TX	O	Serial data output <sup>(2)</sup>
CTS	I	Clear to send <sup>(3)</sup>
RTS	O	Request to send <sup>(4)</sup>
DCD	I	Data Carrier Detect <sup>(5)</sup>
DSR	I	Data Set Ready <sup>(6)</sup>

**Table 12-68. UART I/O Signals (continued)**

Module Pin Name	I/O <sup>(1)</sup>	Description
DTR	O	Data Terminal Ready <sup>(7)</sup>
RIN	I	Ring Indicator <sup>(8)</sup>

- (1) I = Input; O = Output
- (2) Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UART\_MDR1[2-0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UART\_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).
- (3) Active-low modem status signal. Reading the UART\_MSR[4] NCTS\_STS bit checks the condition of CTS. Reading the UART\_MSR[0] CTS\_STS bit checks a change of state of CTS since the last read of the modem status register. The auto-CTS mode uses CTS to control the transmitter.
- (4) When active (low), the module is ready to receive data. Setting the UART\_MCR[1] RTS bit activates RTS signal, which becomes inactive as the result of a module reset, loopback mode, or clearing the UART\_MCR[1] RTS bit. In auto-RTS mode, RTS signal becomes inactive as a result of the receiver threshold logic.
- (5) Active-low modem status signal. The condition of DCD can be checked by reading the UART\_MSR[7] NCD\_STS bit. Any change in its state can be detected by reading the UART\_MSR[3] DCD\_STS bit.
- (6) Active-low modem status signal. Reading the UART\_MSR[5] NDSR\_STS bit checks the condition of DSR. Reading the UART\_MSR[1] DSR\_STS bit checks a change of state of DSR since the last read of the UART\_MSR register.
- (7) When active (low), this signal informs the modem that the module is ready to communicate. It is activated by setting the UART\_MCR[0] DTR bit.
- (8) Active-low modem status signal. The condition of RIN can be checked by reading the UART\_MSR[6] NRI\_STS bit. Any change in its state can be detected by reading the UART\_MSR[2] RI\_STS bit.

Table 12-69 lists the RS-485 interface input/output (I/O) signals.

**Table 12-69. UART I/O Signals (RS-485 Mode)**

Module Pin	I/O <sup>(1)</sup>	Description
RX	I	Serial data input
TX	O	Serial data output
DIR	O	RS-485 Direction

- (1) I = Input; O = Output

Table 12-70 lists the IrDA interface I/O signals.

**Table 12-70. UART I/O Signals (IrDA Mode)**

Module Pin	I/O <sup>(1)</sup>	Description
RX	I	Serial data input
TX	O	Serial data output in CIR and IrDA modes (SIR, MIR, and FIR). <sup>(2)</sup>
SD	O	SD mode is used to configure the transceivers. <sup>(3)</sup>

- (1) I = Input; O = Output
- (2) In other modes, this pin is set to the reset value (inactive state).
- (3) The SD pinout (see UART\_ACREG[6] SD\_MOD bit).

### 12.1.6.3 UART Functional Description

#### 12.1.6.3.1 UART Block Diagram

The UART module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, RS-485, IrDA, or CIR) and enables the mechanism corresponding to the chosen function.
- Register mode: Enables conditional access to registers.

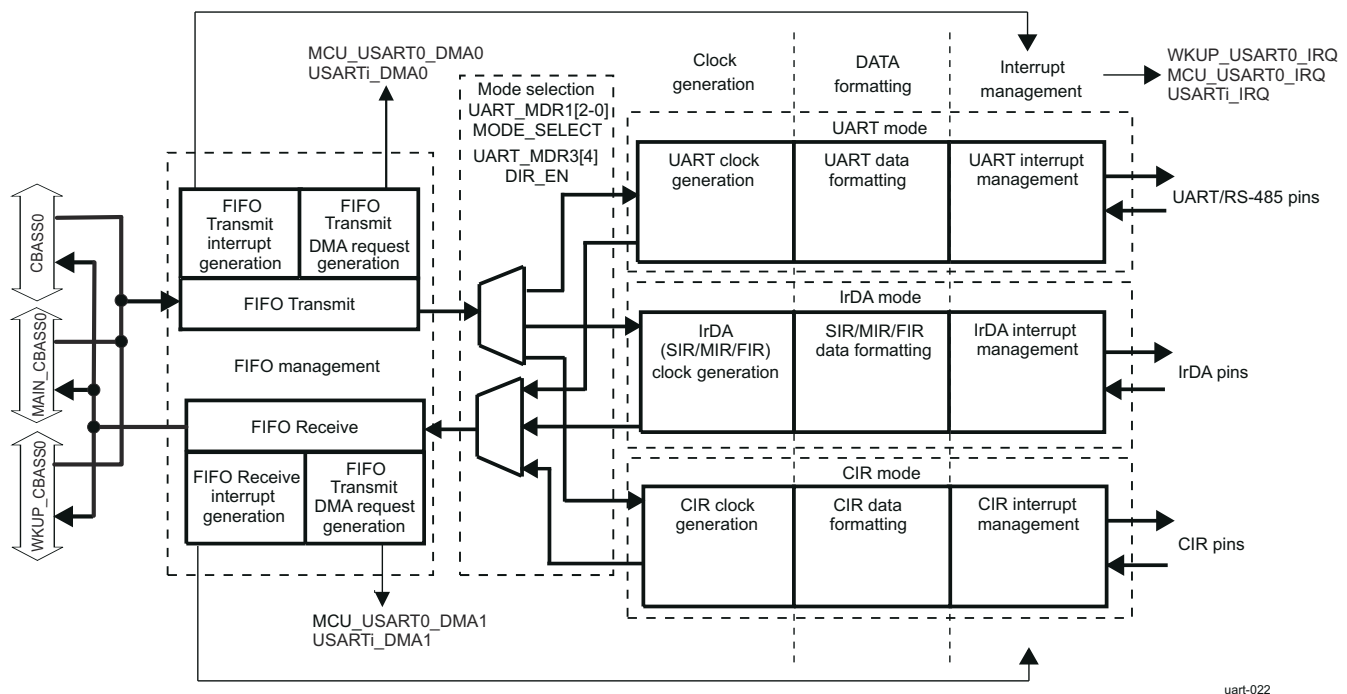

For more information about mode configuration, see *Mode Selection*.

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses a dedicated state-machine that is responsible for the transition between FIFO data and the associated frame data.
- Interrupt management: Different interrupt types are generated depending on the chosen function. In each mode, when an interrupt is generated, the UART\_IIR\_UART register indicates the interrupt type.
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

In parallel with these functional blocks, a power-saving strategy exists for each function.

The UART block diagram is shown below.

**Figure 12-54. UART Functional Block Diagram**

### 12.1.6.3.2 UART Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses.

#### 12.1.6.3.3 UART Software Reset

The UART\_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

##### 12.1.6.3.3.1 Independent TX/RX

The receiver and transmitter are enabled by default after reset. Software can choose to disable, re-enable or to reset either the RX or the TX side independently of the other through the UART\_ECR register.

#### 12.1.6.3.4 UART Power Management

##### 12.1.6.3.4.1 UART Mode Power Management

###### 12.1.6.3.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UART\_IER\_UART[4] SLEEP\_MODE bit to 1 (when the UART\_EFR[4] ENHANCED\_EN bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RX, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the RX line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UART\_SCR[4] RX\_CTS\_WU\_EN bit to 1. To understand how to manage the interrupt, see [Section 12.1.6.3.5.1.2, Wake-Up Interrupt](#).

---

#### Note

There must be no writing to the divisor latches, UART\_DLL and UART\_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UART\_IER\_UART[4] SLEEP\_MODE bit before writing to the UART\_DLL or UART\_DLH register.

---

##### 12.1.6.3.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

For more information, see *Power*, in the *Device Configuration*.

##### 12.1.6.3.4.2 IrDA Mode Power Management

###### 12.1.6.3.4.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART\_MDR1[3] IR\_SLEEP bit to 1.

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RXD, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the RXD line or when data is written to the TX FIFO.

#### 12.1.6.3.4.2.2 System Power Saving

System power saving for the IrDA mode has the same function as for the UART mode (see [Section 12.1.6.3.4.1.2, System Power Saving](#)).

#### 12.1.6.3.4.3 CIR Mode Power Management

##### 12.1.6.3.4.3.1 Module Power Saving

Module power saving for the CIR mode has the same function as for the IrDA mode (see [Section 12.1.6.3.4.2.1, Module Power Saving](#)).

##### 12.1.6.3.4.3.2 System Power Saving

System power saving for the CIR mode has the same function as for the UART mode (see [Section 12.1.6.3.4.1.2, System Power Saving](#)).

##### 12.1.6.3.4.4 Local Power Management

[Table 12-71](#) describes power-management features available for the UART.

#### Note

For information about source clock gating and the sleep/wake-up transitions description, see *Power*, in the *Device Configuration*.

**Table 12-71. UART Local Power-Management Features**

Feature	Registers	Description
Clock autogating		
Peripheral idle modes		
Clock activity	N/A	Feature not available
Controller standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

#### 12.1.6.3.5 UART Interrupt Requests

##### 12.1.6.3.5.1 UART Mode Interrupt Management

##### 12.1.6.3.5.1.1 UART Interrupts

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UART\_IIR\_UART) sets the UART\_IIR\_UART[0] IT\_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UART\_IIR\_UART[5-1] bit field. [Table 12-72](#) summarizes the interrupt control functions.

**Table 12-72. UART Mode Interrupts**

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	N/A	No Interrupt	N/A	N/A
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR_UART register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register if using the default timeout behavior: EFR2[6]=0 Cleared by reading its value (IIR) if using the periodic timeout behavior: EFR2[6]=1

**Table 12-72. UART Mode Interrupts (continued)**

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000100	2	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears
000010	3	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears
000000	4	Modem status	See the UART_MSR register.	Read the MSR register
010000	5	XOFF interrupt/ special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR_UART register, if special character interrupt
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high)	Read the UART_IIR_UART register

For the receiver-line status interrupt, the UART\_LSR\_UART[7] RX\_FIFO\_STS bit generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UART\_IIR\_UART register.

#### 12.1.6.3.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the RX\_CTS\_DSR\_WAKE\_UP\_ENABLE bit of the Supplementary Control Register (SCR[4]) is set to 1. The IIR register is not modified when it occurs, SSR[1] must be checked to detect a wake-up event. When a wake-up event occurs, the only way to clear it is to reset SCR[4] to 0. Wake-up can also occur if the WER[7] TX\_WAKEUP\_EN is set to 1 and one of the following events occurs:

1. THR interrupt is enabled and occurs (omitted if TX DMA request is enabled)
2. TX DMA request is enabled and occurs
3. TX\_STATUS\_IT is enabled and occurs (only IrDA and CIR modes). Cannot be used with THR Interrupt.

#### 12.1.6.3.5.2 IrDA Mode Interrupt Management

##### 12.1.6.3.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART\_IER\_IRDA). The interrupt status of the device can be checked by reading the interrupt identification register (UART\_IIR\_IRDA).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART\_IER\_IRDA and UART\_IIR\_IRDA mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see [Table 12-73](#)). The interrupt line is activated when any interrupt is generated (there is no priority).

**Table 12-73. IrDA Mode Interrupts**

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the UART_RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.

**Table 12-73. IrDA Mode Interrupts (continued)**

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
5	TX status	UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error OR Transmission of the last bit of the IrDA frame completed successfully.	Read the UART_RESUME register OR Read the UART_IIR_IRDA register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR_IRDA register.

#### 12.1.6.3.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see [Section 12.1.6.3.5.1.2, Wake-Up Interrupt](#)).

#### 12.1.6.3.5.3 CIR Mode Interrupt Management

##### 12.1.6.3.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART\_IER\_CIR). The interrupt status of the device can be checked by reading the interrupt identification register (UART\_IIR\_CIR).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART\_IER\_CIR and UART\_IIR\_CIR mappings, depending on the selected mode.

[Table 12-74](#) lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART\_IIR\_CIR[5] TX\_STATUS\_IT bit is to indicate that the last bit of infrared data was passed to the TX pin.

**Table 12-74. CIR Mode Interrupts**

IIR_CIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0			
1	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR register until the interrupt condition disappears
2			
3			
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is complete successfully	Read the UART_IIR_CIR register
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

#### 12.1.6.3.5.3.2 Wake-Up Interrupts

The wake-up interrupt for CIR mode has the same function as that for UART mode (see [Section 12.1.6.3.5.1.2, Wake-Up Interrupt](#)).

#### 12.1.6.3.6 UART FIFO Management

The FIFO is accessed by reading and writing the UART\_RHR and UART\_THR registers. Parameters are controlled using the FIFO control register (UART\_FCR) and supplementary control register (UART\_SCR). Reading the UART\_SSR[0] TX\_FIFO\_FULL bit at 1 means the FIFO is full.

The UART\_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. [Figure 12-55](#) shows the FIFO management registers.

#### Note

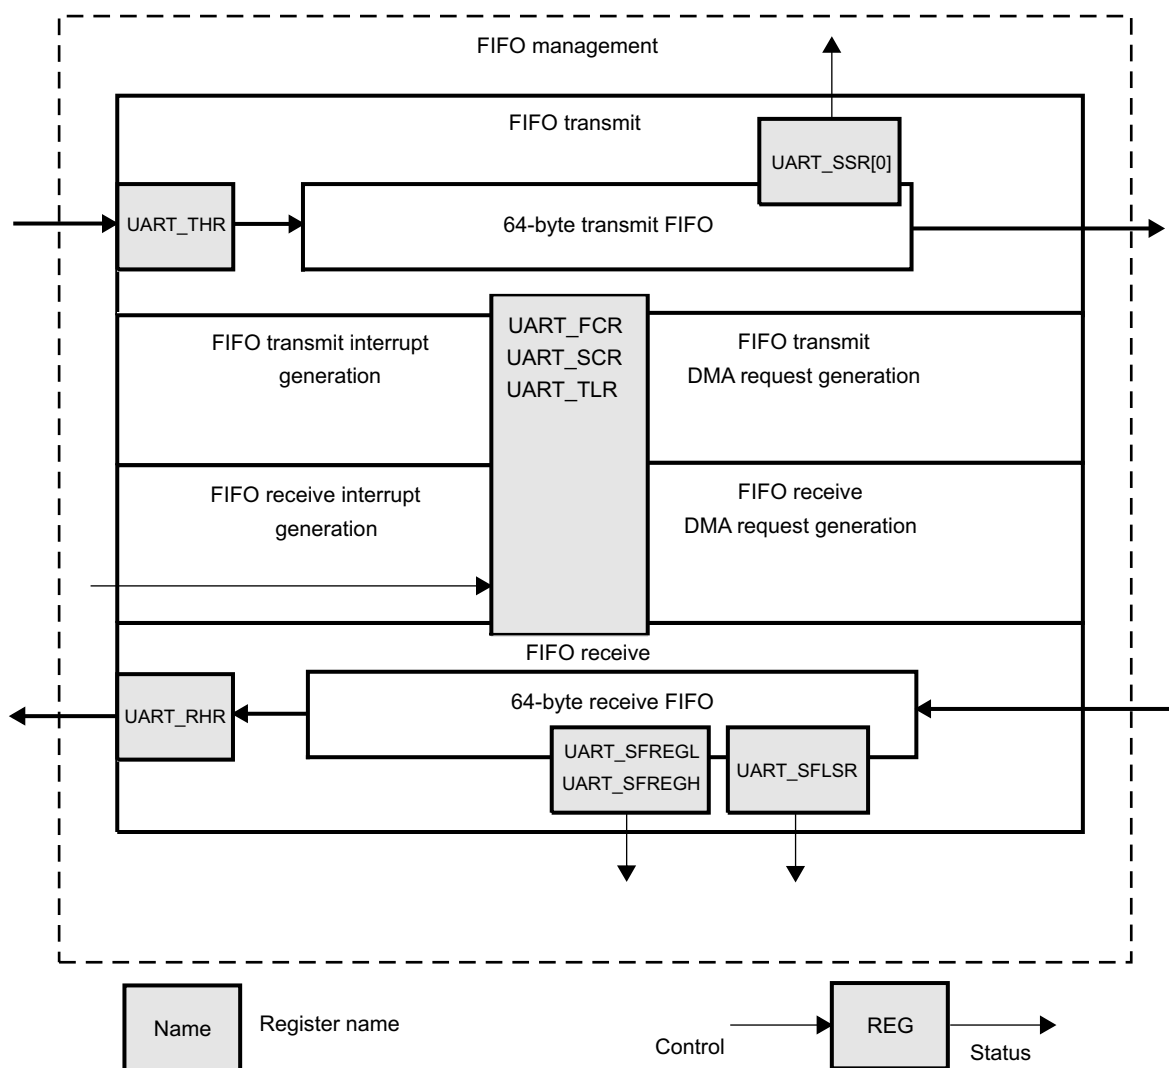

Data in the UART\_RHR register is not overwritten when an overflow occurs.

**Note**

The UART\_SFLSR, UART\_SFREGL, and UART\_SFREGH status registers are used in IrDA mode only. For information about their use, see [Section 12.1.6.3.8.3.3, IrDA Data Formatting](#).

**Note**

Bits UART\_FCR[2] TX\_FIFO\_CLEAR and UART\_FCR[1] RX\_FIFO\_CLEAR are automatically cleared by hardware after  $4 \times + 5 \times \text{UARTi\_FCLK}$  clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

uart-023

**Figure 12-55. UART FIFO Management Registers****12.1.6.3.6.1 FIFO Trigger****12.1.6.3.6.1.1 Transmit FIFO Trigger**

[Table 12-75](#) lists the TX FIFO trigger level settings.

**Table 12-75. UART TX FIFO Trigger Level Setting Summary**

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[5-4] TX_FIFO_TRIG bit field (8, 16, 32, or 56 spaces)

**Table 12-75. UART TX FIFO Trigger Level Setting Summary (continued)**

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	!= 0x0	Defined by the UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TLR[3:0] (higher bits) and FCR[5:4] (lower bits) from 1 to 63 spaces with a granularity of 1 space.  <b>Note:</b> The combination of TLR[3:0]=0000 and FCR[5:4]=00 (all zeros) is not supported (min 1 space required). All zeros will result in unsupported behavior.

#### 12.1.6.3.6.1.2 Receive FIFO Trigger

Table 12-76 lists the RX FIFO trigger-level settings.

**Table 12-76. UART RX FIFO Trigger-Level Setting Summary**

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[7-6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UART_TLR[7-4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of TLR[7:4] and FCR[7:6] from 1 to 63 characters with a granularity of one character.  <b>Note:</b> The combination of TLR[7:4]=0000 and FCR[7:6]=00 (all zeros) is not supported (min 1 character required). All zeros will result in unsupported behavior.

The receive threshold is programmed using the UART\_TCR[7-4] RX\_FIFO\_TRIG\_START and UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX\_FIFO\_TRIG\_HALT > RX\_FIFO\_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR\_LENGTH} + \text{Parity} + \text{Stop} - 0.5)] \times \text{Baud\_rate} + 4 \times \text{FCLK}$$

#### Note

The RTS signal is deasserted after the UART module receives the data over RX\_FIFO\_TRIG\_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX\_FIFO\_TRIG\_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UART\_TCR[7-4] RX\_FIFO\_TRIG\_START bit field or the UART\_FCR[7-6] RX\_FIFO\_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

#### 12.1.6.3.6.2 FIFO Interrupt Mode

In FIFO interrupt mode (the FIFO control register UART\_FCR[0] FIFO\_EN bit is set to 1 and relevant interrupts are enabled by the UART\_IER\_UART register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UART\_TLR[7-4] RX\_FIFO\_TRIG\_DMA and UART\_TLR[3-0] TX\_FIFO\_TRIG\_DMA bit fields or the UART\_FCR[7-6] RX\_FIFO\_TRIG and UART\_FCR[5-4] TX\_FIFO\_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the Host CPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT bit field) must be greater than or equal to the RX FIFO threshold.

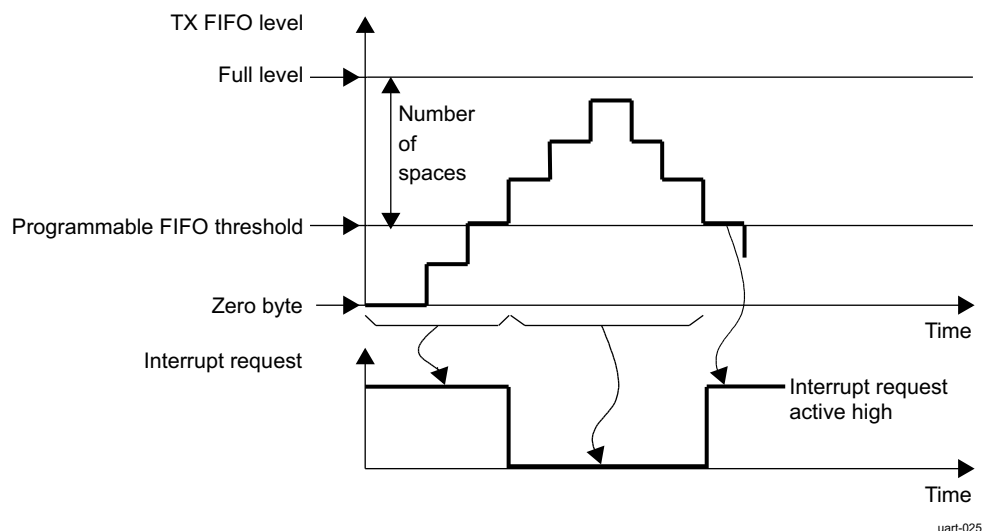

Figure 12-56 shows the generation of the RX FIFO interrupt request.

**Figure 12-56. UART RX FIFO Interrupt Request Generation**

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the Host CPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 12-57 shows the generation of the TX FIFO interrupt request.

**Figure 12-57. UART TX FIFO Interrupt Request Generation**

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

#### 12.1.6.3.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UART\_FCR[0] FIFO\_EN bit is set to 0 and the relevant interrupts are disabled by the UART\_IER\_UART register), the status of the receiver and transmitter can be checked by polling the line status register (UART\_LSR\_UART).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the Host CPU.

#### 12.1.6.3.6.4 FIFO DMA Mode Operation

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the signals (where  $i = 0$  to .

The DMA mode and signals usage can be selected as follows:

- When SCR[0]=0:
  - Setting FCR[3] to 0 enables DMA mode 0
  - Setting FCR[3] to 1 enables DMA mode 1
- When SCR[0]=1:
  - SCR[2:1] determines DMA mode 0 to 3 according to the Supplementary Control Register (SCR) description.

For example:

- If no DMA operation is desired: set SCR[0] to 1 and SCR[2:1] to 00 (FCR[3] is discarded)
- If DMA mode 1 is desired: either set SCR[0] to 0 and FCR[3] to 1 or set SCR[0] to 1 and SCR[2:1] to 01 (FCR[3] is discarded)

If the FIFOs are disabled (FCR[0]=0), DMA operations occur in single character transfers.

Note that when DMA Mode 0 has been programmed, the signals associated with DMA operation are not active.

Depending on UART\_MDR3[2] SET\_DMA\_TX\_THRESHOLD, the threshold can be programmed different ways:

- SET\_TX\_DMA\_THRESHOLD = 1:  
The threshold value will be the value of the UART\_TX\_DMA\_THRESHOLD register. If SET\_TX\_DMA\_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET\_TX\_DMA\_THRESHOLD = 0:  
The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

#### 12.1.6.3.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers UART\_SCR[0] DMA\_MODE\_CTL = 0 and UART\_FCR[3] DMA\_MODE = 1:
  - a. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit fields to 01 (DMA mode 1)
  - b. Set the UART\_SCR[0] DMA\_MODE\_CTL bit to 1 (this setting of UART\_SCR[0] DMA\_MODE-CTL will ignores UART\_FCR[3] DMA\_MODE\_CTL bit)

#### Note

It is strongly suggested to do steps 'a' and 'b' in two separate write in order to avoid malfunction of the device.

- c. Set the UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART\_ACREG[5] DIS\_IR\_RX bit

#### Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- d. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- e. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).

- f. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
  - g. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
2. DMA mode 1 is set (both TX/RX DMA) by registers UART\_FCR[3] DMA\_MODE = 0 and UART\_SCR[0] DMA\_MODE\_CTL = 1, UART\_SCR[2-1] DMA\_MODE\_2 = 01. It is almost the same as above, but steps 'a', and 'b' can be skipped:
    - a. Set the UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART\_ACREG[5] DIS\_IR\_RX bit

---

#### Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- b. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
  - c. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
  - d. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
  - e. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
3. DMA mode 3 is set (TX DMA only) by registers UART\_FCR[3] DMA\_MODE = 0 and UART\_SCR[0] DMA\_MODE\_CTL = 1, UART\_SCR[2-1] DMA\_MODE\_2 = 11. It is the same as above:
    - a. Set the UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART\_ACREG[5] DIS\_IR\_RX bit

---

#### Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- b. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- c. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
- d. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- e. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

#### 12.1.6.3.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 12-58 through Figure 12-61 show the supported DMA operations.

**Figure 12-58. UART Receive FIFO DMA Request Generation (32 Characters)**

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UART\_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UART\_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

**Figure 12-59. UART Transmit FIFO DMA Request Generation (56 Spaces)**

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UART\_TLR register.

The threshold can be programmed in a number of ways. [Figure 12-59](#) shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UART\_FCR[5-4] TX\_FIFO\_TRIG bit field or the UART\_TLR[3-0] TX\_FIFO\_TRIG\_DMA bit field concatenated with the TX\_FIFO\_TRIG bit field.

The setting of 56 spaces in the UART module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART module).

[Figure 12-60](#) shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART module.

**Figure 12-60. UART Transmit FIFO DMA Request Generation (8 Spaces)**

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see [Figure 12-61](#)). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UART\_DLL and UART\_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

**Figure 12-61. UART Transmit FIFO DMA Request Generation (1 Space)**

The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting UART\_MDR3[1] NONDEFAULT\_FREQ bit and UART\_TX\_DMA\_THRESHOLD register (see [Figure 12-62](#)). In the example, the UART\_TX\_DMA\_THRESHOLD[5-0] TX\_DMA\_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the UART\_DLL and UART\_DLH registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the UART\_MDR3[1] NONDEFAULT\_FREQ value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

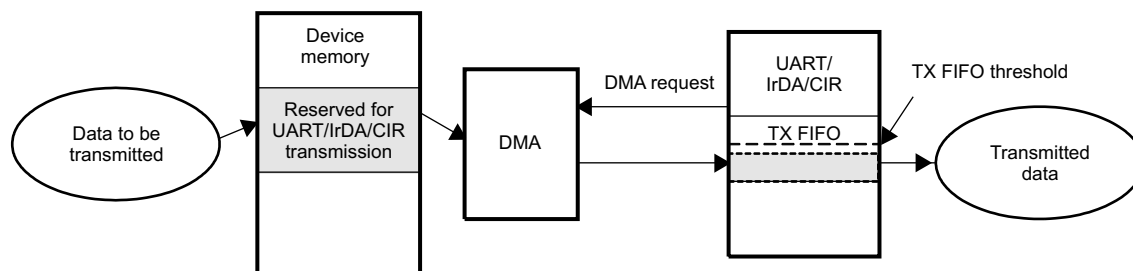

uart-036

**Figure 12-62. UART Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)**

#### 12.1.6.3.6.4.3 DMA Transmission

Figure 12-63 shows DMA transmission.

uart-030

**Figure 12-63. DMA Transmission**

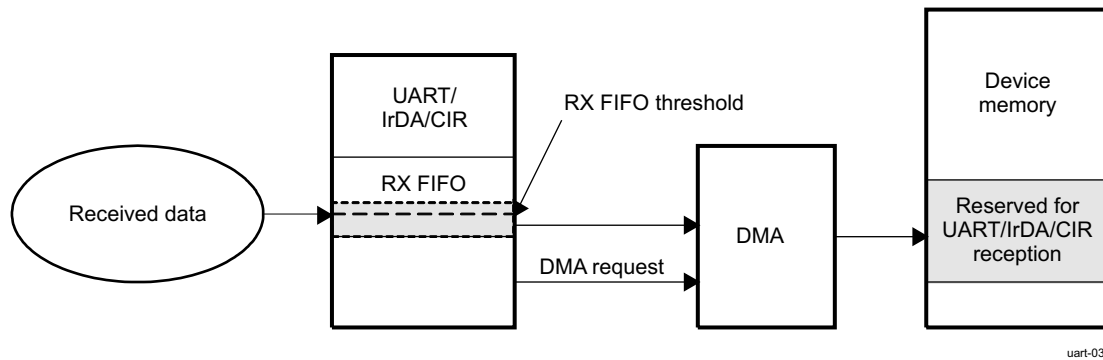

1. Data to be transmitted are put in the device memory reserved for UART transmission by the DMA:
  - a. Until the TX FIFO trigger level is not reached, a DMA request is generated
  - b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UART\_THR empty (TX FIFO empty).

#### Note

In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UART\_THR register empties.

#### 12.1.6.3.6.4.4 DMA Reception

Figure 12-64 shows DMA reception.

**Figure 12-64. DMA Reception**

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
  - a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
  - b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

#### 12.1.6.3.7 UART Mode Selection

##### 12.1.6.3.7.1 Register Access Modes

###### 12.1.6.3.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UART\_LCR register determines the register access mode (see [Table 12-77](#)).

**Table 12-77. UART Register Access Mode Programming (Using UART\_LCR)**

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7-0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7-0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

###### 12.1.6.3.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR\_SPR, TCR\_TLR, and XOFF). These registers are identified in [Table 12-99](#), *UART Load FIFO Triggers Defined by the Concatenated Value*.

[Table 12-78](#) through [Table 12-80](#) summarize the register access submodes.

**Table 12-78. UART Subconfiguration Mode A Summary**

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

**Table 12-79. UART Subconfiguration Mode B Summary**

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

**Table 12-80. UART Suboperational Mode Summary**

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

### 12.1.6.3.7.1.3 Registers Available for the Register Access Modes

Table 12-81 lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

**Table 12-81. UART Register Access Mode Overview**

#### 12.1.6.3.7.2 UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UART\_MDR1[2:0] MODE\_SELECT bit field (see [Table 12-82](#)).

**Table 12-82. UART Mode Selection**

Value	Mode
0x0:	UART 16× mode
0x1:	SIR mode
0x2:	UART 16× auto-baud
0x3:	UART 13× mode
0x4:	MIR mode
0x5:	FIR mode
0x6:	CIR mode
0x7:	Disable (default state)

MODE\_SELECT is effective when the module is in operational mode (see [Section 12.1.6.3.7.1, Register Access Modes](#)).

To select a RS-485 mode, set the UART\_MDR3[4] DIR\_EN bit field to 0x1.

#### 12.1.6.3.7.2.1 Registers Available for the UART Function

Only the registers listed in [Table 12-83](#) are used for the UART function.

**Table 12-83. UART Mode Register Overview**

Address Offset	Registers <sup>(1) (2)</sup>					
	Configuration Mode A		Configuration Mode B		Operational Mode	
	Read	Write	Read	Write	Read	Write
0x000	UART_DLL	UART_DLL	UART_DLL	UART_DLL	UART_RHR	UART_THR
0x004	UART_DLH	UART_DLH	UART_DLH	UART_DLH	UART_IER_UART (UART)	UART_IER_UART (UART)

(1) REGISTER\_NAME(CIR) notation indicates that the register exists for other functions (IrDA or UART), but fields have different meanings for other functions (described separately in *UART Registers*).

(2) REGISTER\_NAME[m:n] notation indicates that only register bits numbered m to n apply to the CIR function.

### 12.1.6.3.8 UART Protocol Formatting

#### 12.1.6.3.8.1 UART Mode

##### 12.1.6.3.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-65 shows the baud rate generator and associated controls.

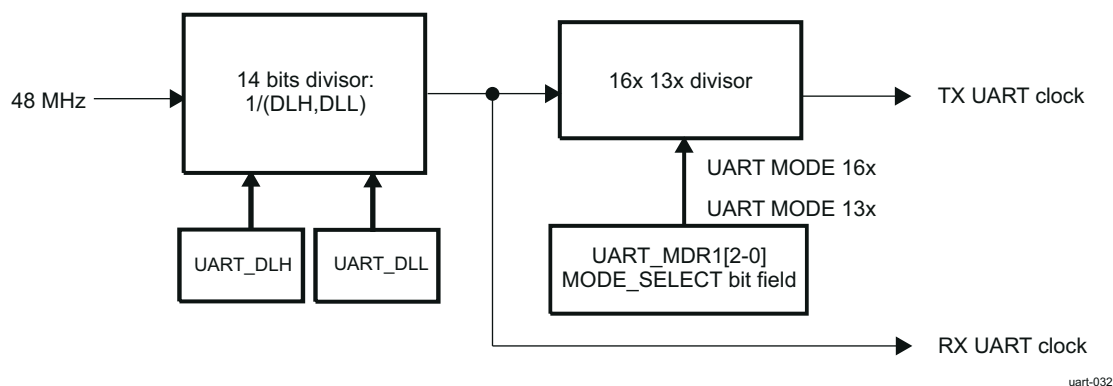

Figure 12-65. UART Baud Rate Generation

**CAUTION**

Before initializing or modifying clock parameter controls (UART\_DLH, UART\_DLL), UART\_MDR1[2-0] MODE\_SELECT = DISABLE must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

**12.1.6.3.8.1.2 Choosing the Appropriate Divisor Value**

Two divisor values are:

- UART 16× mode: Divisor value = Operating frequency / (16× baud rate)
- UART 13× mode: Divisor value = Operating frequency / (13× baud rate)

**Table 12-86. UART Baud Rate Settings (48-MHz Clock)**

Baud Rate	Baud Multiple	DLH, DLL (Decimal)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)

### 12.1.6.3.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

#### 12.1.6.3.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UART\_LCR register.

Character length is specified using the UART\_LCR[1-0] CHAR\_LENGTH bit field.

The number of stop-bits is specified using the UART\_LCR[2] NB\_STOP bit.

The parity bit is programmed using the UART\_LCR[5-3] PARITY\_EN, UART\_LCR[5-3] PARITY\_TYPE\_1, and UART\_LCR[5-3] PARITY\_TYPE\_2 bit fields (see [Table 12-87](#)).

**Table 12-87. UART Parity Bit Encoding**

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

#### 12.1.6.3.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UART\_EFR[7] AUTO\_CTS\_EN and UART\_EFR[6] AUTO\_RTS\_EN bit fields, respectively.

With auto-CTS, CTS signal must be active before the module can transmit data.

Auto-RTS activates the RTS output only when there is enough room in the RX FIFO to receive data. It deactivates the RTS output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UART\_TCR register determine the levels at which RTS is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UART\_TCR register. RTS is active if the RX FIFO level is below the HALT trigger level in the UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT bit field. When the RX FIFO HALT trigger level is reached, RTS is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

RTS is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UART\_TCR[7-4] RX\_FIFO\_TRIG\_START bit field. This reassertion requests the sending device to resume transmission.

In this case, RTS is an active-low signal.

- Auto-CTS:

The transmitter circuitry checks CTS before sending the next data byte. When CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, CTS must be deasserted before the middle of the last stop-bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the CTS state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, CTS is an active-low signal.

#### 12.1.6.3.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UART\_EFR) and the modem control register (UART\_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UART\_EFR[3-0] bit field (see [Table 12-88](#)).

Two other enhanced features relate to software flow control:

- XON-any function (UART\_MCR[5] XON\_EN): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

#### Note

The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UART\_EFR[5] SPECIAL\_CHAR\_DETECT): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UART\_IIR\_UART) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UART\_IIR\_UART. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

**Table 12-88. UART\_EFR[3:0] Software Flow Control Options**

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>

- (1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.  
XON1 is defined in the UART\_XON1\_ADDR1[7-0] XON\_WORD1 bit field. XON2 is defined in the UART\_XON2\_ADDR2[7-0] XON\_WORD2 bit field.  
XOFF1 is defined in the UART\_XOFF1[7-0] XOFF\_WORD1 bit field. XOFF2 is defined in the UART\_XOFF2[7-0] XOFF\_WORD2 bit field.

#### 12.1.6.3.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UART\_IIR\_UART[4] bit (if enabled by UART\_IER\_UART[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UART\_IIR\_UART[4] bit is cleared and the XOFF interrupt disappears.

#### Note

When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UART\_EFR[1-0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UART\_EFR[1-0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

#### 12.1.6.3.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT. As soon as the RX FIFO reaches the trigger level programmed by UART\_TCR[7-4] RX\_FIFO\_TRIG\_START, two XON1 characters are sent, so the data transfer recovers.

#### Note

If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

#### 12.1.6.3.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UART\_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud

- 14.4K baud
- 9.6K baud
- 4.8K baud
- 2.4K baud
- 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

---

#### Note

The combination of 7-bit character plus space parity is not supported.

---

Autobauding mode is selected when the UART\_MDR1[2-0] MODE\_SELECT bit field is set to 0x2. In UART autobauding mode, UART\_DLL, UART\_DLH, and UART\_LCR[5-0] bit field settings are not used; instead, the UART\_UASR register is updated with the configuration detected by the autobauding logic.

#### UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UART\_LCR, UART\_DLL, and UART\_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UART\_MDR1[2-0] MODE\_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115.2 bps (10 possibilities)

##### 12.1.6.3.8.1.3.5 Error Detection

When the UART\_LSR\_UART register is read, the UART\_LSR\_UART[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UART\_LSR\_UART register and then reading the UART\_RHR register identifies errors in a character.

Reading the UART\_RHR register updates the BI, FE, and PE bits (see [Table 12-72](#) for the UART mode interrupts).

The UART\_LSR\_UART[7] RX\_FIFO\_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

---

#### Note

Reading the UART\_LSR\_UART register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UART\_RHR register.

---

Reading the UART\_LSR\_UART register clears the OE bit if it is set (see [Table 12-72](#) for the UART mode interrupts).

##### 12.1.6.3.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the Host CPU with the UART\_IIR\_UART[5-1] IT\_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the Host CPU must:

- Reset the RX FIFO.
- Read the UART\_RESUME register, which clears the internal flag.

### **12.1.6.3.8.1.3.7 Time-Out and Break Conditions**

#### **12.1.6.3.8.1.3.7.1 Time-Out Counter**

An RX idle condition is detected when the receiver line (RX) is high for a time that equals 4x the programmed word length + 12 bits or manually configured amount of baud clocks, if a value other zero is set in the timeout register. RX is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on RX.

There are two modes of operation:

- In default operation on the UART\_EFR2[6] TIMEOUT\_BEHAVE is set to 0. For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on RX or when the UART\_RHR register is read.
- Optionally, for choose to enable the timeout counter even if no character has been received by setting UART\_EFR2[6] TIMEOUT\_BEHAVE bit. This will generate periodic interrupts if the RX line remains idle. In this mode the counter will auto-reset when a timeout has been reached. Reading the UART\_IIR\_UART will clear the interrupt, but not the counter.

#### **12.1.6.3.8.1.3.7.2 Break Condition**

When a break condition occurs, TX is pulled low. A break condition is activated by setting the UART\_LCR[6] BREAK\_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UART\_LSR\_UART[6] TX\_SR\_E bit is set to 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK\_EN bit to 1.

The break condition is asserted while the BREAK\_EN bit is set to 1.

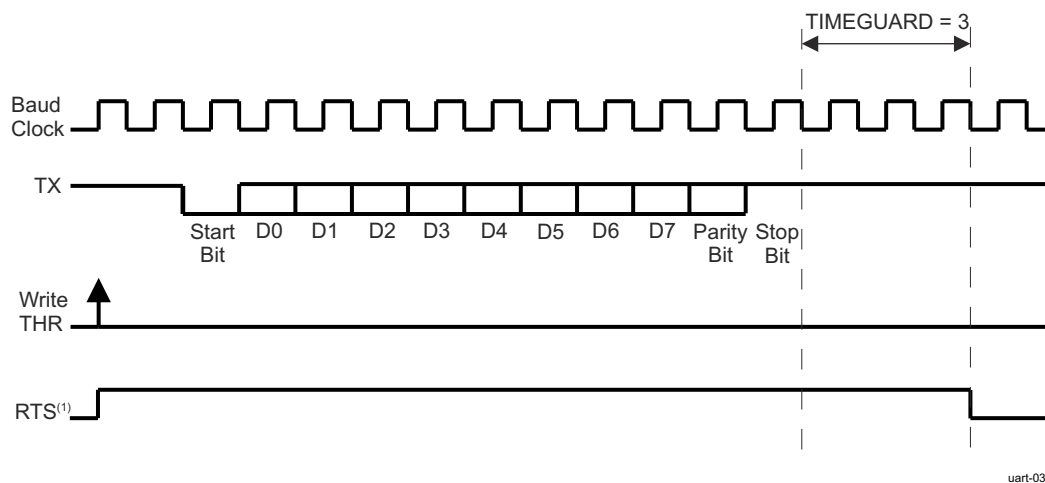

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

### **12.1.6.3.8.2 RS-485 Mode**

#### **12.1.6.3.8.2.1 RS-485 External Transceiver Direction Control**

The UART\_MDR3[4] DIR\_EN bit enables hardware control over an external transceiver to support RS-485. The direction signal comes across the DIR port. The direction polarity is controlled by the UART\_MDR3[3] DIR\_POL bit. The direction is determined by the hardware monitoring the TX FIFO and the TX shift register. When both are empty the transceiver is set to RX. There is a guard band delay counter of 3 bit clock cycles after the TX shift register is going empty to allow time for the stop bit to transition through the transceiver before a direction change to receive might be applied.

[Figure 12-66](#) shows the direction control.

(1) Assumes DIR\_POL = 1

**Figure 12-66. RS-485 External Transceiver Direction Control**

#### 12.1.6.3.8.3 IrDA Mode

##### 12.1.6.3.8.3.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-67 shows the baud rate generator and associated controls.

**Figure 12-67. IrDA Baud Rate Generator**

### CAUTION

Before initializing or modifying clock parameter controls (UART\_DLH, UART\_DLL), MODE\_SELECT=DISABLE (UART\_MDR1[2-0] MODE\_SELECT) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

#### 12.1.6.3.8.3.2 Choosing the Appropriate Divisor Value

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16× baud rate)
- MIR mode: Divisor value = Operating frequency/(41×/42× baud rate)
- FIR mode: Divisor value = None

Table 12-89 lists the IrDA baud rate settings.

**Table 12-89. IrDA Baud Rate Settings**

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 μs
9.6 kbps	SIR	16x	3/16	312	9.6153 kbps	+0.16	0	19.5 μs
19.2 kbps	SIR	16x	3/16	156	19.231 kbps	+0.16	0	9.75 μs
38.4 kbps	SIR	16x	3/16	78	38.462 kbps	+0.16	0	4.87 μs
57.6 kbps	SIR	16x	3/16	52	57.692 kbps	+0.16	0	3.25 μs
115.2 kbps	SIR	16x	3/16	26	115.38 kbps	+0.16	0	1.62 μs
0.576 Mbps	MIR	41×/42×	1/4	2	0.5756 Mbps <sup>(1)</sup>	0	+1.63/-0.80	416 ns
1.152 Mbps	MIR	41×/42×	1/4	1	1.1511 Mbps <sup>(1)</sup>	0	+1.63/-0.80	208 ns
4 Mbps	FIR	6×	4 PPM	–	4 Mbps	0	0	125 ns

(1) Average value

### Note

Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

#### 12.1.6.3.8.3.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

##### 12.1.6.3.8.3.3.1 IR RX Polarity Control

The UART\_MDR2[6] IRRXINVERT bit provides the flexibility to invert the RX pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.

##### 12.1.6.3.8.3.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the RX input can be disabled by the UART\_ACREG[5] DIS\_IR\_RX bit.

##### 12.1.6.3.8.3.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART\_XON1\_ADDR1[7-0] XON\_WORD1 and UART\_XON2\_ADDR2[7-0] XON\_WORD2 bit fields.

Setting the UART\_EFR[0] bit to 1 selects address1 checking. Setting the UART\_EFR[1] bit to 1 selects address2 checking. Setting the UART\_EFR[1-0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

#### 12.1.6.3.8.3.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART\_MDR1[7] FRAME\_END\_MODE bit to 0. The Host CPU writes the value of the frame length to the UART\_TXFLH and UART\_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the UART\_MDR1[7] FRAME\_END\_MODE bit to 1. The Host CPU writes 1 to the UART\_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the Host CPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

#### 12.1.6.3.8.3.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the Host CPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the Host CPU writes 1 to the UART\_ACREG[2] SCTX\_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART\_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

#### 12.1.6.3.8.3.3.6 Error Detection

When the UART\_LSR\_UART register is read, the UART\_LSR\_UART[4-2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see [Table 12-73](#)). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

#### 12.1.6.3.8.3.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the Host CPU must:

- Reset the TX FIFO.
- Read the UART\_RESUME register, which clears the internal flag.

This function can be disabled by the UART\_ACREG[4] DIS\_TX\_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

#### 12.1.6.3.8.3.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see [Section 12.1.6.3.8.1.3.6, Overrun During Receive](#)).

#### 12.1.6.3.8.3.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART\_SFREGH[3-0] MSB and UART\_SFREGL[3-0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART\_SFLSR register. Reading the UART\_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The Host CPU uses the frame-length information to locate the frame boundary in the received frame data. The Host CPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the Host CPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

#### 12.1.6.3.8.3.3.10 Multi-drop Parity Mode with Address Match

Multi-drop mode is enabled in the UART\_EFR2 register.

Address matching mode is only available with 8 bit character length setting. UART\_LCR[1-0] CHAR\_LENGTH bit fields should always be set to 0x11 (8 bits) prior to enabling the feature.

This mode allows the transmitter to send data on a line where multiple receivers are connected, when supported. In this mode, a set parity bit is used to mark an address, and a parity of 0 denotes data.

This setting affects how the parity is generated. Writing a 0x1 into the UART\_ECR[0] A\_MULTIDROP bit will set the parity bit for the next byte to be sent, which will then be considered an address, for sending a data frame, the UART\_ECR[0] A\_MULTIDROP bit has to be cleared.

On reception if the feature is enabled by setting the UART\_EFR2[2] MULTIDROP bit to 0x1 incoming frames with parity set to 0x1 are treated as address frames and with parity set to 0x0 as data frames. The receiver will drop all data frames until a matching address frame was found.

The matching address is determined by the values set in UART\_MAR, UART\_MMR and UART\_MBR registers and the value set in UART\_EFR2[7] BROADCAST bit.

Table 12-90 summarizes the operation of address matching based on the mentioned values.

**Table 12-90. Details of address matching**

Received frame	Received parity	Frame type	UART_MAR	UART_MMR	UART_MBR	UART_EFR2[7] BROADCAST	Operation of receiver	Address matching
0xXX <sup>(2)</sup>	0	DATA	X <sup>(1)</sup>	X <sup>(1)</sup>	0xXX <sup>(2)</sup>	X <sup>(1)</sup>	Drops data until matching address found	N/A
0xXX <sup>(2)</sup>	1	ADDRESS	0xXX <sup>(2)</sup>	0x00	0xXX <sup>(2)</sup>	0	Matches any address	Yes
0xEF	1	ADDRESS	0xXX <sup>(2)</sup>	0xXX <sup>(2)</sup>	0xEF	1	Matches broadcast address	Yes
0x1A	1	ADDRESS	0x1A	0xFF	0xXX <sup>(2)</sup>	0	Single address match	Yes
0xF5	1	ADDRESS	0xF3	0xF9	0xXX <sup>(2)</sup>	0	Group address match	Yes

(1) X indicates a do not care bit value

(2) 0xXX indicates a do not care 8 bit hexadecimal value

The possible values for matching address can be calculated in the following way:

- Single and Group addresses can be formed by masking the UART\_MAR registers value with the value set in the UART\_MMR register, bits set to 0x0 in the UART\_MMR register result in do not care values.
- Broadcast addresses can be set in the UART\_MBR register if broadcast address is enabled in the UART\_EFR2[7] BROADCAST bit, the module will match on received address frames containing the broadcast address.
- For more details, see example below:
  - UART\_MAR: 0xF3, UART\_MMR: 0xF9, UART\_MBR: 0xFF
  - Single and Group addresses: 0xF1, 0xF3, 0xF5, 0xF7
  - Broadcast addresses: 0xFF

If an address match occurred the matching address value can be obtained from the UART\_RHR register in the following way:

- If the FIFO is disabled or the threshold is set to 0x1, the matching address can be directly read from UART\_RHR as the FIFO will not be overwritten.
- If the FIFO is enabled or the threshold is greater than 0x1, the matching address will be the latest frame in the FIFO with a parity error bit set.

For received data, the parity error bit in the UART\_LSR\_UART register is set when a bit with a parity of 0x1 is received indicating an address frame and the received address matches based on the values of UART\_MAR, UART\_MMR, UART\_MBR and UART\_EFR2[2] MULTIDROP bit.

In Multi-drop mode no parity is used, as the parity bit is used to differentiate address and data frames. The parity error bit is used for indicating an address match.

For enabling the interrupt generation for address matching UART\_IER\_UART[2] LINE\_STS\_IT bit has to be set to 0x1.

An interrupt for the matching address can be identified by reading the UART\_IIR\_UART[5-1] IT\_TYPE bit fields, a value of 0x00011 indicates a receiver line status error. After the UART\_LSR\_UART[2] RX\_PE bit has to be read, a value of 0x1 indicates that an address match occurred. The reception of a frame is indicated with a value of 0x1 in the UART\_LSR\_UART[0] RX\_FIFO\_E bit as the matching value is written into the FIFO regardless of the frame type (data or address). UART\_LSR\_UART[7] RX\_FIFO\_STS bit will also be set to 0x1 as the parity error bit is used to indicate a matching address.

Note that the operation of the UART\_LSR\_UART[2] RX\_PE bit depends on the value set in UART\_EFR2[2] MULTIDROP bit. If UART\_EFR2[2] MULTIDROP bit is set to 0x0, UART\_LSR\_UART[2] RX\_PE bit is used to indicate a received parity error. If UART\_EFR2[2] MULTIDROP bit is set to 0x1, the receiver is in Multi-drop Address Match mode, thus the value in UART\_LSR\_UART[2] RX\_PE bit is used to indicate an address match.

The interrupt is cleared the same way in both operation modes: reading the UART\_LSR\_UART register updates the values.

This feature is available in UART and synchronous modes. The ISO7816 has not defined Multidrop Parity Mode, so the feature should be left off.

#### **12.1.6.3.8.3.3.11 Time-guard**

The time-guard feature enables the UART interface to operate with slow remote devices.

When set, it will insert a number of idle states between transmitting two characters, the length of which can be set in the UART\_TIMEGUARD register. The value in the register defines the number of baud clocks of idle period to insert.

This idle state essentially acts like a long stop bit. In UART and synchronous modes, a Timeguard is added in addition to the stop bit. In ISO7816 there is a waiting period rather than an actual stop bit. Software should set 1-2 or more Timeguard cycles according to the protocol used and the card requirements.

#### **12.1.6.3.8.3.4 SIR Mode Data Formatting**

This section provides specific instructions for SIR mode programming.

##### **12.1.6.3.8.3.4.1 Abort Sequence**

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART\_ACREG[1] ABORT\_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

### CAUTION

When the TX FIFO is not empty and the UART\_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

#### 12.1.6.3.8.3.4.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6- $\mu$ s pulse duration methods. The UART\_ACREG[7] PULSE\_TYPE bit selects the pulse width method in the transmit mode.

#### 12.1.6.3.8.3.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART\_MDR1[2-0] MODE\_SELECT = 0x0) and the UART\_MDR2[3] PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART\_LCR[1-0] CHAR\_LENGTH bit field = 0x3 (8 data bits)
- UART\_LCR[2] NB\_STOP bit = 0x0 (1 stop-bit)
- UART\_LCR[3] PARITY\_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

#### 12.1.6.3.8.3.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the CPU reads the line status register (UART\_LSR\_UART) to detect errors in the received frame.

When the UART\_MDR1[6] SIP\_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP\_MODE bit is set to 0, SIP transmission depends on the UART\_ACREG[3] SEND\_SIP bit.

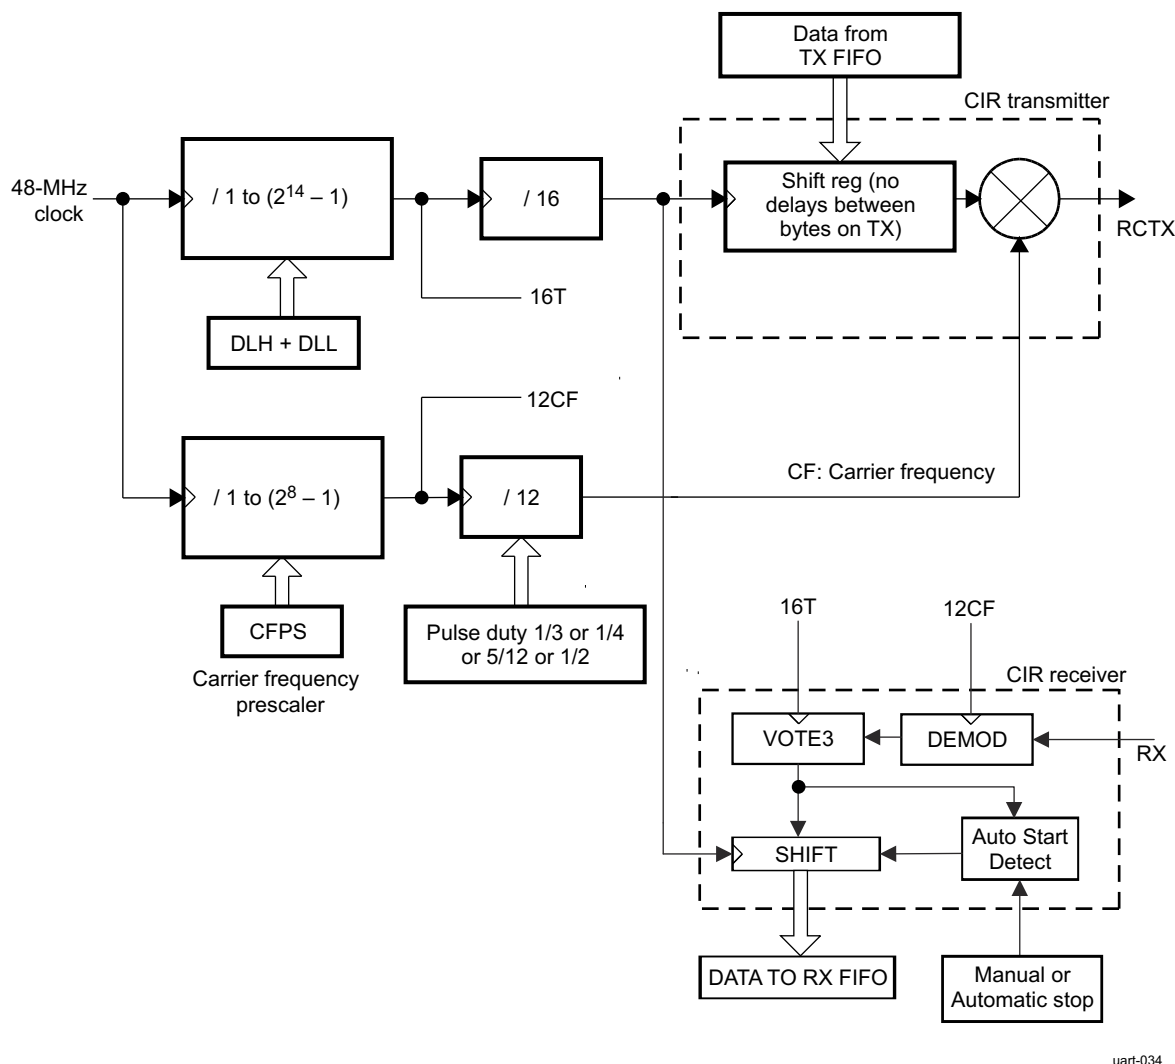

The CPU can set the SEND\_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

#### 12.1.6.3.8.4 CIR Mode

##### 12.1.6.3.8.4.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the Host CPU must develop a data structure that combines 1 and 0 with a  $t$  period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in [Figure 12-68](#).

**Figure 12-68. CIR Mode Block Components**

Based on the requested modulation frequency, the UART\_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK} / 12) / \text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

#### Note

The UART\_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART\_MDR2 register. [Table 12-91](#) shows the duty cycle.

**Table 12-91. CIR Duty Cycle**

UART_MDR2[5-4] CIR_PULSE_MODE	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

#### 12.1.6.3.8.4.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

##### 12.1.6.3.8.4.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see [Section 12.1.6.3.8.3.3.1, IR RX Polarity Control](#)).

##### 12.1.6.3.8.4.2.2 CIR Transmission

In transmission, the Host CPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a  $t$  period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART\_MDR1[5] SCT bit and the UART\_ACREG[2] SCTX\_EN bit, depending on the timer status
  - Using the UART\_IIR\_UART[5] TX\_STATUS\_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

##### 12.1.6.3.8.4.2.3 CIR Reception

There are 2 ways to stop a CIR reception:

- The Host CPU can disable the reception by setting the UART\_ACREG[5] DIS\_IR\_RX bit to 1. When it considers that the reception is finished because a large number of 0 has been received. To receive a new frame, the UART\_ACREG[5] DIS\_IR\_RX bit must be set to 0.
- An automatic stop mechanism can be configured by setting a value in the BOF length register (UART\_EBLR). If the value set in the UART\_EBLR register is different than 0, this features is enabled and the number of bits received will begin counting from 0. When the counter reaches the value defined in the UART\_EBLR register, reception is automatically disabled and UART\_IIR\_CIR[2] RX\_STOP\_IT bit is set. When a 1 is detected on the RX pin, reception is automatically re-enabled.

There is a limitation when receiving data in UART CIR mode. Certain IrDA transceivers on the market have a characteristic that causes shrinking of the received modulation pulse hold-time. The UART receive filtering schema is based on the same encoding mechanism used for transmission.

For the following scenario:

- Shift register period: 0.9 $\mu$ s
- Modulation frequency: 36kHz
- Duty cycle: 1/4 of a modulation frequency period

Data sent with these conditions would contains 7 $\mu$ s pulses within a 28 $\mu$ s period. The UART expects to receive similar incoming data on receive, but various transceiver timing characteristics typically only send 2 $\mu$ s modulated pulses. These 2 $\mu$ s pulses will be filtered out and RX FIFO will not receive data. This does not affect UART CIR mode in transmission.

CIR RX demodulation can be bypassed by setting the UART\_MDR3[0] DISABLE\_CIR\_RX\_DEMOD bit.

### 12.1.6.4 UART Programming Guide

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

#### Note

Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 12.1.6.3.7.1, Register Access Modes](#).

#### 12.1.6.4.1 UART Mode selection

[Table 12-92](#) describes how to set different register access mode.

**Table 12-92. UART Configure Register Access Mode**

Step	Register/Bit Field/Programming Model	Value
Set the register access mode A	UART_LCR[7] DIV_EN	1
	UART_LCR[7-0]	≠0xBF
Set the register access mode B	UART_LCR[7-0]	0xBF
Set the operational mode	UART_LCR[7] DIV_EN	0

#### 12.1.6.4.2 UART Submode selection

This section describes how to set different register access submode.

**Table 12-93. UART Configure Register Access Submode TCR\_TLR**

Step	Register/Bit Field/Programming Model	Value
Configure the submode TCR_TLR		
Configure mode B	see <a href="#">Table 12-92</a>	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1
Configure mode A	see <a href="#">Table 12-92</a>	0x1
Set the submode TCR_TLR	UART_MCR[6] TCR_TLR	1

**Table 12-94. UART Configure Register Access Submode MSR\_SPR**

Step	Register/Bit Field/Programming Model	Value
First option: configure the submode MSR_SPR		
Configure mode B	see <a href="#">Table 12-92</a>	
Set the submode MSR_SPR	UART_EFR[4] ENHANCED_EN	0
Second option: configure the submode MSR_SPR		
Configure mode B	see <a href="#">Table 12-92</a>	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1
Set the submode MSR_SPR	UART_MCR[6] TCR_TLR	0

**Table 12-95. UART Configure Register Access Submode XOFF**

Step	Register/Bit Field/Programming Model	Value
Configure of the XOFF		
Configure B	see <a href="#">Table 12-92</a>	

**Table 12-95. UART Configure Register Access Submode XOFF (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0

#### 12.1.6.4.3 UART Load FIFO trigger and DMA mode settings

##### 12.1.6.4.3.1 DMA mode Settings

To enable and configure program the DMA mode, perform the following steps:

**Table 12-96. DMA Mode Settings**

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration	UART_SCR[0] DMA_MODE_CTL	-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	=0
Select the DMA mode, for more information see <a href="#">Section 12.1.6.3.6.4</a>	UART_FCR[3] DMA_MODE	-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	=1
Select the DMA mode, for more information see <a href="#">Section 12.1.6.3.6.4</a>	UART_SCR[2-1] DMA_MODE_2	-

##### 12.1.6.4.3.2 FIFO Trigger Settings

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

**Table 12-97. Load FIFO Triggers Defined by the FCR**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-93</a>	0x-
Set the desire RX FIFO trigger level	UART_FCR[5-4] TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7-6] RX_FIFO_TRIG	0x-

**Table 12-98. Load FIFO Triggers Defined by the TLR**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-93</a>	0x-
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA	0x-

**Table 12-99. Load FIFO Triggers Defined by the Concatenated Value**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-93</a>	0x-
Set the register bit	UART_SCR[7] RX_TRIG_GRANU1	1
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA UART_FCR[7-6] RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6] TX_TRIG_GRANU1	1
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA UART_FCR[5-4] TX_FIFO_TRIG	0x-

#### 12.1.6.4.4 UART Protocol, Baud rate and interrupt settings

##### 12.1.6.4.4.1 Baud rate settings

**Table 12-100. UART Baud Rate Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Switch to register configuration mode B	see <a href="#">Table 12-92</a>	
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see <a href="#">Table 12-92</a>	

**Table 12-100. UART Baud Rate Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Disable sleep mode	UART_IER_UART[4] SLEEP_MODE	0
Switch to register configuration mode A or B	see <a href="#">Table 12-92</a>	
Set the appropriate divisor value	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x-

#### 12.1.6.4.4.2 Interrupt settings

**Table 12-101. UART Interrupt Settings**

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see <a href="#">Table 12-92</a>	0x7
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see <a href="#">Table 12-92</a>	
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER_UART[7] CTS_IT UART_IER_UART[6] RTS_IT UART_IER_UART[5] XOFF_IT UART_IER_UART[4] SLEEP_MODE UART_IER_UART[3] MODEM_STS_IT UART_IER_UART[2] LINE_STS_IT UART_IER_UART[1] THR_IT UART_IER_UART[0] RHR_IT	0x-

#### 12.1.6.4.4.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

**Table 12-102. UART Protocol Settings**

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see <a href="#">Section 12.1.6.3.8.1.3.1</a> , <i>Frame Formatting</i>	UART_LCR[5] PARITY_TYPE_2 UART_LCR[4] PARITY_TYPE_1 UART_LCR[3] PARITY_EN UART_LCR[2] NB_STOP UART_LCR[1-0] PARITY_LENGTH	0x-
Switch to register operational mode	UART_LCR[7] DIV_EN UART_LCR[6] BREAK_EN	0

#### 12.1.6.4.4.4 UART/RS-485/IrDA(SIR/MIR/FIR)/CIR

**Table 12-103. UART Mode Selection**

Step	Register/Bit Field/Programming Model	Value
Load the desired UART/IrDA (SIR, MIR, FIR)/CIR modes, see <a href="#">Section 12.1.6.3.7.2</a> , <i>UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection</i>	UART_MDR1[2-0] MODE_SELECT	0x-
Load the desired RS-485 mode, see <a href="#">Section 12.1.6.3.7.2</a> , <i>UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection</i>	UART_MDR3[4] DIR_EN	0x1

#### 12.1.6.4.4.5 UART Multi-drop Parity Address Match Mode Configuration

**Table 12-104. UART Multi-drop Parity Address Match Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Disable receive mode	UART_ECR[3] RX_EN	0
Enable Multi-drop parity Address match mode	UART_EFR2[2] MULTIDROP	1
Set the matching device address	UART_MAR[7-0] ADDRESS	0x-
Set the address match masking	UART_MMR[7-0] MASK	0x-

**Table 12-104. UART Multi-drop Parity Address Match Mode Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the broadcast address match	UART_MBR[7-0] BROADCAST_ADDRESS	0x-
Enable broadcast address matching if needed	UART_EFR2[7] BROADCAST	1
Enable receive mode	UART_ECR[3] RX_EN	1

#### 12.1.6.4.5 UART Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

##### 12.1.6.4.5.1 Hardware Flow Control Configuration

**Table 12-105. UART Hardware Flow Control Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-93</a>	0x7
Load the start and halt trigger value.	UART_TCR[7-4] AUTO_RTS_START UART_TCR[3-0] AUTO_RTS_HALT	0x-
Enable or disable receive and transmit hardware flow control mode.	UART_EFR[7] AUTO_CTS_EN UART_EFR[6] AUTO_RTS_EN	0x-

##### 12.1.6.4.5.2 Software Flow Control Configuration

**Table 12-106. UART Software Flow Control Configuration**

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see <a href="#">Table 12-95</a>	
Load the software control characters	UART_XON1_ADDR1[7-0] XON_WORD1 UART_XON2_ADDR2[7-0] XON_WORD2 UART_XOFF1[7-0] XOFF_WORD1 UART_XOFF2[7-0] XOFF_WORD2	0x-
Set the register access submode TCR_TLR	see <a href="#">Table 12-93</a>	
Enable or disable XON any function (0: Disable; 1: Enable).	UART_MCR[5] XON_EN	--
Load start and halt trigger value for software flow control	UART_TCR[7-4] AUTO_RTS_START UART_TCR[3-0] AUTO_RTS_HALT	0x-
Enable or disable special character function (0: Disable; 1: Enable)	UART_EFR[5] SPEC_CHAR	0x-
Set the software flow control mode	UART_EFR[3-0] SW_FLOW_CONTROL	0x-

#### 12.1.6.4.6 IrDA Programming Model

##### 12.1.6.4.6.1 SIR mode

##### 12.1.6.4.6.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 115.2 kbps, FIFOs disabled, 2 stop-bits, and 8-bit word length:

**Table 12-107. SIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate(115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x1A 0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00

**Table 12-107. SIR Mode Receive Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

#### 12.1.6.4.6.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 115.2 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

**Table 12-108. SIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB	0x1A
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 6 bytes	UART_TXFLL[7-0] TXFLL	0x06
Set the seven starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
Set SIR pulse width to be 1.6 $\mu$ s	UART_ACREG[7] PULSE_TYPE	1

#### 12.1.6.4.6.2 MIR mode

##### 12.1.6.4.6.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

**Table 12-109. MIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (1.152 bps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set MIR mode	UART_MDR1[2-0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force outputs DTR and RTS to active	UART_MCR[1-0]	0x3
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

##### 12.1.6.4.6.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

**Table 12-110. MIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 kbps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x4

**Table 12-110. MIR Mode Transmit Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 60 bytes	UART_TXFLL[7-0] TXFLL	0x3C
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

**12.1.6.4.6.3 FIR mode****12.1.6.4.6.3.1 Receive**

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

**Table 12-111. FIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB UART_DLH[7-0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see <a href="#">Section 12.1.6.4.3, Load FIFO trigger and DMA mode settings</a>	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x5
Set frame length	UART_RXFLL[7-0] RXFLL	0xA
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

**12.1.6.4.6.3.2 Transmit**

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

**Table 12-112. FIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see <a href="#">Section 12.1.6.4.3, Load FIFO trigger and DMA mode settings</a>	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Set FIR mode and enable auto-SIP mode	UART_MDR1[7-0]	0x45
Set frame length	UART_TXFLL[7-0] TXFLL UART_TXFLH[7-0] TXFLH	0x4 0x0
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	1
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08

**Table 12-112. FIR Mode Transmit Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

## 12.2 High-speed Serial Interfaces

This section describes the high-speed serial interfaces in the device.

## 12.2.1 Gigabit Ethernet MAC (CPSW)

This chapter describes the Gigabit Ethernet MAC (Media Access Controller). For conceptual purposes the below documentation refers to this MAC as being a two port CPSW with port 0 being the CPPI DMA host port and port 1 being the Ethernet port.

### 12.2.1.1 CPSW Programming Guide

#### 12.2.1.1.1 Initialization and Configuration of CPSW Subsystem

To configure the CPSW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (RMII, or RGMII ) Mode. See the CTRLMMR\_MCU\_ENET\_CTRL[1-0] MODE\_SEL register.
2. Configure pads (pin muxing), as per the interface selected. Refer to *Pad Configuration Registers* and the device-specific Datasheet.
3. Enable the CPSW Ethernet Subsystem clocks. See *CPSW Integration*
4. Ensure that at least 2000 CPPI\_ICLK periods are run after reset is de-asserted.
5. Configure the CPSW\_CONTROL\_REG register
6. Configure the Ethernet Port Source Address registers (CPSW\_PN\_SA\_L\_REG and CPSW\_PN\_SA\_H\_REG)
7. Configure the CPSW statistic port enable register CPSW\_STAT\_PORT\_EN\_REG
8. Configure the ALE (*Address Lookup Engine*)
9. Configure the MDIO (*Initializing the MDIO Module*)
10. Configure Ethernet port, as per the desired mode of operations

#### 12.2.1.1.2 CPSW Reset

To reset the Ethernet port, the host must perform the following:

1. Set CMD\_IDLE bit to 1h in the Ethernet port control register: CPSW\_PN\_MAC\_CONTROL\_REG.
2. Wait for IDLE bit to be set to 1h, which is indicated in the Ethernet port status register: CPSW\_PN\_MAC\_STATUS\_REG.
3. Set SOFT\_RESET bit to 1h in the Ethernet port software reset register: CPSW\_PN\_MAC\_SOFT\_RESET\_REG.
4. Wait for SOFT\_RESET bit in the CPSW\_PN\_MAC\_SOFT\_RESET\_REG registers to be cleared to confirm reset completion.
5. Configure the Ethernet ports.
6. Re-configure registers reset to default value by CPSW\_PN\_MAC\_SOFT\_RESET\_REG.

#### 12.2.1.1.3 MDIO Software Interface

##### 12.2.1.1.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CPSW\_MDIO\_CONTROL\_REG).
2. Enable the MDIO module by setting the ENABLE bit in CPSW\_MDIO\_CONTROL\_REG.
3. The MDIO PHY alive status register (MDIO CPSW\_MDIO\_ALIVE\_REG) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO CPSW\_MDIO\_LINK\_REG) can determine whether this PHY already has a link.
4. Set the appropriate PHY addresses in the MDIO user PHY select register (CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k, where k = 0 or 1), and set the LINKINT\_ENABLE bit to enable a link change event interrupt if desirable.
5. Set the appropriate LINKSEL bit in the CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k register (where k = 0 or 1).
6. Set the appropriate USERINTMASKSET bit field in the CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG register.
7. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG) to use the MDIO user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1).

#### 12.2.1.1.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k corresponding to the PHY and PHY register SW wants to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_RAW\_REG) corresponding to MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_MASKED\_REG) and an interrupt is triggered on the host processor.

#### 12.2.1.1.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in the CPSW\_MDIO\_USER\_ACCESS\_REG\_k register corresponding to the PHY and PHY register SW wants to read.
3. The read data value is available in the DATA bit field in MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k register after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in CPSW\_MDIO\_USER\_ACCESS\_REG\_k register. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_RAW\_REG) corresponding to MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_MASKED\_REG) and an interrupt is triggered on the host processor.

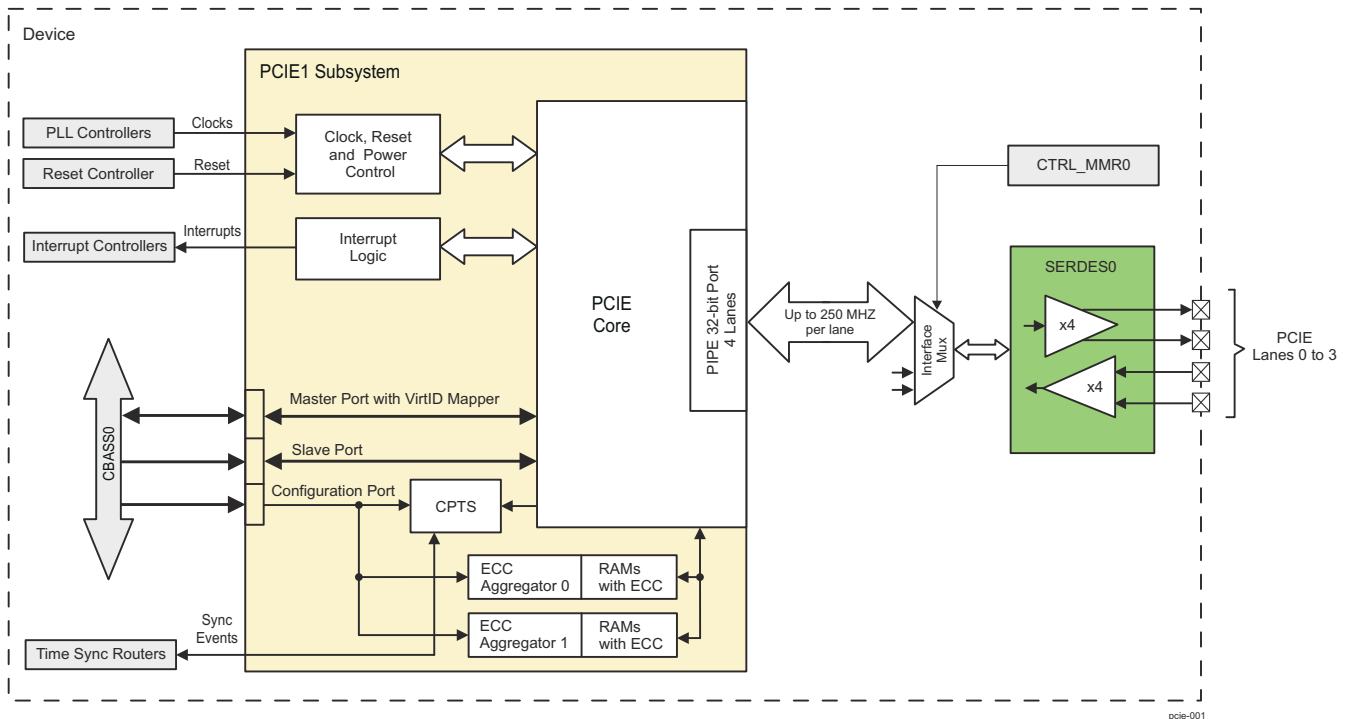

## 12.2.2 Peripheral Component Interconnect Express (PCIe) Subsystem

This chapter describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) subsystem.

### 12.2.2.1 PCIe Subsystem Overview

The Peripheral Component Interconnect Express (PCIe) subsystem is built around a multi-lane dual-mode PCIe controller that provides low pin-count, high reliability, and high-speed data transfers at rates of up to 8.0 Gbps per lane for serial links on backplanes and printed wiring boards.

Figure 12-69 provides PCIe subsystem overview.

**Figure 12-69. PCIe Subsystem Overview**

#### 12.2.2.1.1 PCIe Subsystem Features

Each PCIe subsystem supports the following main features:

- Compliance to PCIe® Base Specification, Revision 4.0 (Version 0.7)
- 4-lane configuration with up to 8.0 Gbps/lane (Gen3). Can be used in 1x4, 1x2, 1x1 modes.
- Gen3 (8 Gbps 128/130-bit encoding), Gen2 (5 Gbps 8/10-bit encoding), and Gen1 (2.5 Gbps 8/10-bit encoding) with auto-negotiation
- 62.5/125/250MHz operation on PIPE interface for Gen1/Gen2/Gen3, respectively
- Constant 32-bit PIPE width for Gen1/2/3 modes
- Dynamic PIPE width change when switching between Gen1/2/3 modes
- Dual mode: Root Port (RP) or End Point (EP) operation modes
- Maximum payload size of 256 bytes
- Maximum remote read request size of 4K bytes
- Four virtual channels (VC)
- Four traffic classes (TC)
- PCI Power Management states are:
  - L1 Active State Power Management
  - L1 Power Management substates support
  - D1 Device Power Management state
- Maximum number of non-posted outstanding transactions: 32
- Resizable BAR capability

- Separate Reference Clock with Independent Spread (SRIS)
- Legacy, MSI and MSI-X Interrupt Support
- 32 outbound address translation regions
- Precision time measurement (PTM)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### **12.2.2.1.2 PCIe Subsystem Not Supported Features**

The PCIe subsystem does not support the following features:

- Gen4 (16GT/s) operation
- Breaking the x4 link into multiple x1 or x2 links
- PCIe beacon for in-band wake
- Vendor Messaging
- I/O access in inbound direction in RP or EP mode
- Addressing modes other than incremental for burst transactions. As a result, the PCIe addresses cannot be in cacheable memory space.
- Address Translation Services (ATS)
- Quality of Service (QoS)
- L2 power state
- Hot-plug
- PHY loopback
- Reduced Swing Signaling
- Separate Reference Clock with Independent Spread (SRIS)

### 12.2.2.1.3 PCIe Subsystem Ports

This section describes PCIe subsystem ports related to clocks, resets, and hardware requests.

**Table 12-113. PCIe Subsystem Clocks and Resets**

Clocks	
Module Clock Input	Description
PCIE_FICLK	PCIe interface bus clock (CBA_CLK).
PCIE_PM_CLK	PCIe core free-running clock used for low power state transitions and clock control generation.
PCIE_CPTS_RCLK	PCIe CPTS reference clock (RCLK). The CPTS RCLK clock frequency should be greater than or equal to the PCIe CBA_CLK clock frequency. Otherwise, the software will have to add some wait cycles before a correct event is generated by the CPTS module. Additionally, the CPTS RCLK should be set to same frequency as the PCIe core clock.
PCIE_LANE0_TXMCLK	PCIe core clock (CORE_CLK) driven by SERDES via lane 0. In multi-lane modes, only PCIE1_LANE0_TXMCLK is used as the core clock input for all lanes. The TXMCLKs for the rest of the lanes are left unconnected
PCIE_LANE0_RXCLK	PCIe PIPE interface clock driven by SERDES via lane 0. In multi-lane modes, only PCIE1_LANE0_RXCLK is used as the PIPE interface clock for all lanes. The RXCLKs for the rest of the lanes are left unconnected.
SERDES0_IP2_LN0_TXCLK	PCIe lane 0 PIPE/RAW TX return clock.
SERDES0_IP2_LN1_TXCLK	PCIe lane 1 PIPE/RAW TX return clock.
SERDES0_IP2_LN2_TXCLK	PCIe lane 2 PIPE/RAW TX return clock.
SERDES0_IP2_LN3_TXCLK	PCIe lane 3 PIPE/RAW TX return clock.
Resets	
Module Reset Input	Description
PCIE_RST	PCIe reset

**Table 12-114. PCIe Subsystem Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
PCIE_DOWNSTREAM_PULSE_0	PCIe downstream interrupt	Pulse
PCIE_ERROR_PULSE_0	PCIe error interrupt	Pulse
PCIE_FLR_PULSE_0	PCIe function level interrupt	Pulse
PCIE_HOT_RESET_PULSE_0	PCIe hot reset interrupt	Pulse
PCIE_LEGACY_PULSE_0	PCIe legacy interrupt	Pulse
PCIE_LINK_STATE_PULSE_0	PCIe link state interrupt	Pulse
PCIE_LOCAL_LEVEL_0	PCIe local interrupt	Level
PCIE_PWR_STATE_PULSE_0	PCIe power state interrupt	Pulse
PCIE_PHY_LEVEL_0	PCIe PHY interrupt	Level
PCIE_PTM_VALID_PULSE_0	PCIe PTM valid interrupt	Pulse
PCIE_ECC0_CORR_LEVEL_0	PCIe ECC AGGR 0 correctable error interrupt	Level
PCIE_ECC0_UNCORR_LEVEL_0	PCIe ECC AGGR 0 uncorrectable error interrupt	Level
PCIE_ECC1_UNCORR_LEVEL_0	PCIe ECC AGGR 1 uncorrectable error interrupt	Level
PCIE_ASF_NONFATAL_LEVEL_0	PCIe active internal diagnostics interrupt	Level
PCIE_ASF_FATAL_LEVEL_0	PCIe active internal diagnostics interrupt	Level
PCIE_CPTS_PEND_0	PCIe timesync interrupt	Level
PCIE_DPA_PULSE_0	PCIe dynamic power allocation interrupt	Pulse
DMA Events		
Module DMA Event	Description	Type
-	The PCIe subsystem does not provide built-in DMA capabilities	-

**Table 12-114. PCIe Subsystem Hardware Requests (continued)**

Time Sync and Compare Events (Output)		
Module Event	Description	Type
PCIE_CPTS_HW1_PUSH_0	PCIE CPTS hardware push event (HW1_TS_PUSH)	Edge
PCIE_CPTS_COMP_0	PCIE CPTS compare output interrupt	Edge
PCIE_CPTS_SYNC_0	PCIE CPTS sync output interrupt	Edge
PCIE_CPTS_GENF_0	PCIE CPTS GENF0 output interrupt	Edge
Time Sync Events (Input)		
Module Event	Description	Type
PCIE_CPTS_HW2_PUSH_0	PCIE CPTS hardware time stamp push event (HW2_TS_PUSH)	Edge

### 12.2.2.2 PCIe Environment

This section describes the PCIe subsystem application fields from an environment point of view (external connections).

[Table 12-115](#) describes the SERDES signal names at device level related to PCIe subsystem and specifies their functions.

**Table 12-115. PCIe Subsystem I/O Signals**

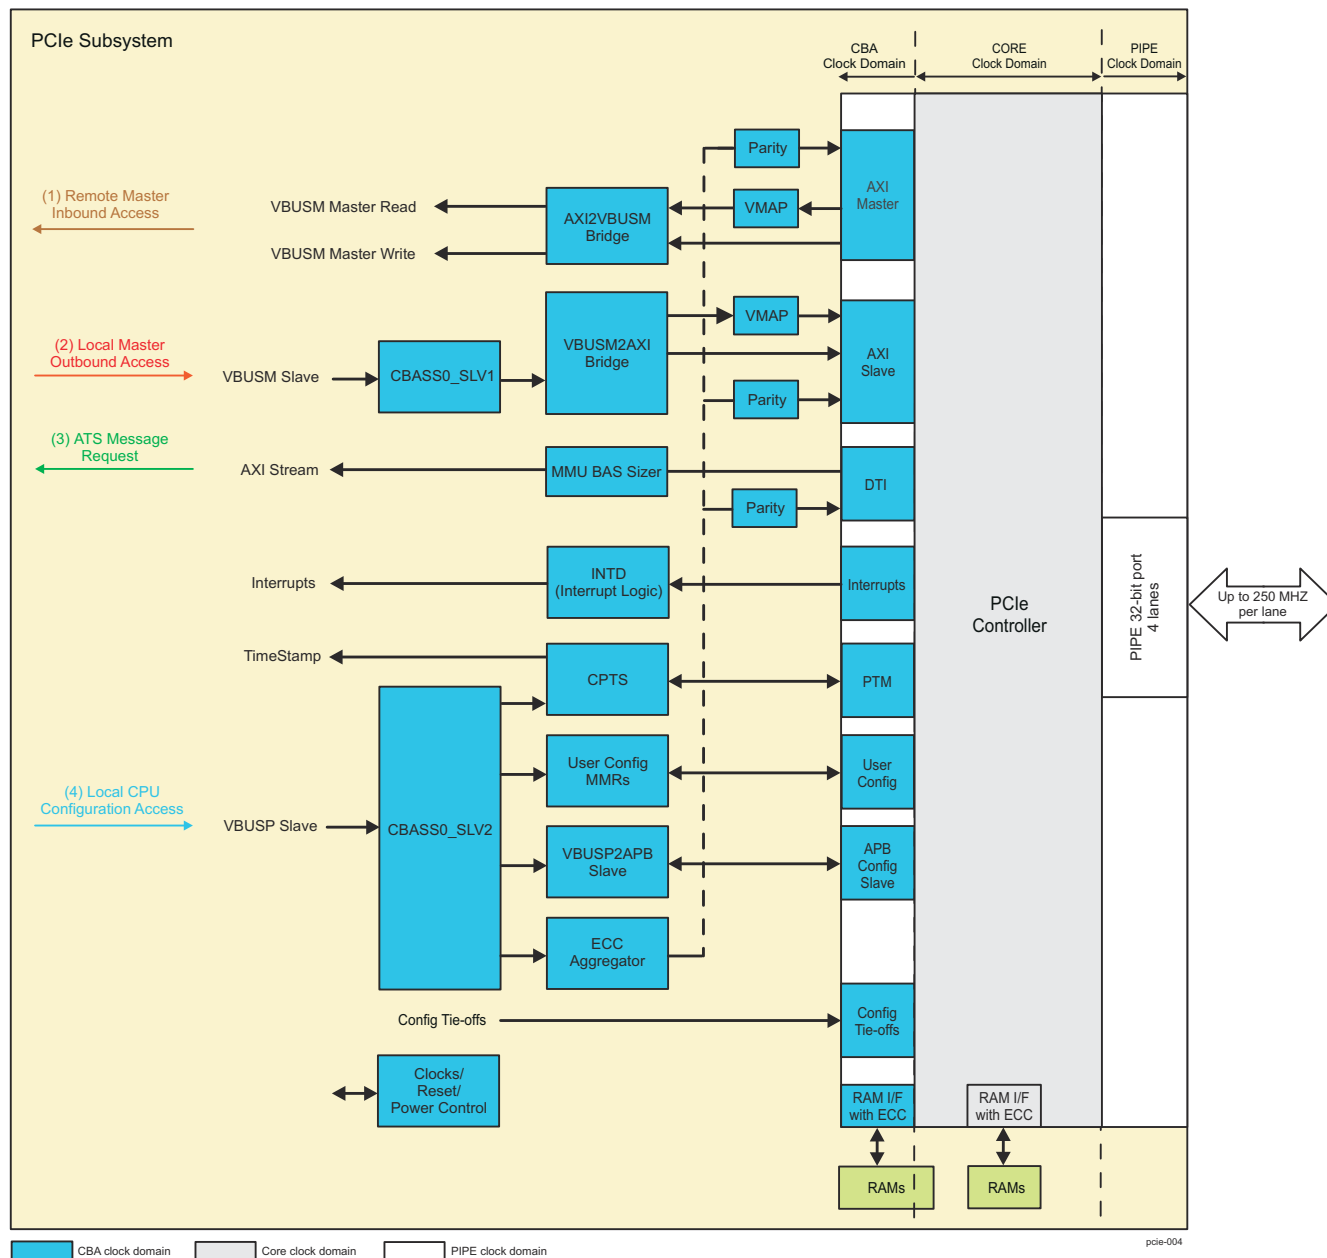

Device Level Signal	I/O <sup>(1)</sup>	Description
RXN0	I	PCIe Lane 0 Receive Differential Data (-)
RXP0	I	PCIe Lane 0 Receive Differential Data (+)
TXN0	O	PCIe Lane 0 Transmit Differential Data (-)
TXP0	O	PCIe Lane 0 Transmit Differential Data (+)
RXN1	I	PCIe Lane 1 Receive Differential Data (-)
RXP1	I	PCIe Lane 1 Receive Differential Data (+)
TXN1	O	PCIe Lane 1 Transmit Differential Data (-)
TXP1	O	PCIe Lane 1 Transmit Differential Data (+)
RXN2	I	PCIe Lane 2 Receive Differential Data (-)
RXP2	I	PCIe Lane 2 Receive Differential Data (+)
TXN2	O	PCIe Lane 2 Transmit Differential Data (-)
TXP2	O	PCIe Lane 2 Transmit Differential Data (+)
RXN3	I	PCIe Lane 3 Receive Differential Data (-)
RXP3	I	PCIe Lane 3 Receive Differential Data (+)
TXN3	O	PCIe Lane 3 Transmit Differential Data (-)
TXP3	O	PCIe Lane 3 Transmit Differential Data (+)
CLKREQn	I/O	PCIe sideband signal for negotiation of L1 Substate entry/exit. The PCIE1_CLKREQn pin operates as an active low open-drain bidirection reference clock request pin. 1 = no request for clock; 0 = request for clock

(1) I = Input; O = Output.

## 12.2.2.3 PCIe Subsystem Functional Description

### 12.2.2.3.1 PCIe Subsystem Block Diagram

The block diagram of PCIe subsystem is shown in [Figure 12-70](#). The subsystem comprises of these major components – the PCIe Core with AXI interfaces, bridges to connect to the system CBASS0 interconnect master and slave interfaces, bridges to connect the system CBASS0 configuration interfaces, additional logic to implement the Precision Time Measurement (PTM), user configuration and interrupt, and RAMs to support the controller FIFOs.

**Figure 12-70. PCIe Subsystem Block Diagram**

[Figure 12-70](#) also shows some example data flows in the PCIe subsystem, such as:

1. A remote master issues a read or write access over PCIe to the local device. This will create a command to be issued on the PCIe VBUSM master read or write interface.
2. A master in the local device issues a read or write access over PCIe to the remote device. This will create a command to be issued on the PCIe VBUSM slave read or write interface.

3. A remote endpoint issues an Address Translation Request (ATS). This will create an inbound transaction on the AXI DTI interface.
4. A master in the local device wants to access the local PCIe configuration registers, the ECC aggregator registers or the CPTS registers. This will create a transaction over the PCIe VBUSP slave interface.

#### 12.2.2.3.1.1 PCIe Core Module

The PCIe Core module supports dual mode of operation - it can be configured as an End Point (EP) and also as a Root Port (RP). The operational mode is selected with the CTRLMMR\_PCIE1\_CTRL[7] MODE\_SEL register bit within the device Control Module (CTRL\_MMR0). It is expected that the MODE\_SEL bit is programmed during initial power up based on settings in the SoC boot configuration or a non-volatile storage such as eFuse or Flash memory.

It is not expected that the MODE\_SEL setting would have to change during a full power cycle of the device. It is more likely that the operational mode of a SoC will stay as EP or RP for a particular end product's life cycle. It is not expected to switch back and forth during operation without a reset cycle.

The PCIe core module supports four virtual channels (VC) and four transfer classes (TC). The VCs can be used to implement Quality-of-Service (QoS) mechanism by enabling priority or round-robin arbitration. Typically, the highest numbered enabled VC is assigned the highest priority.

The PCIe core module is configured to support Single Root I/O virtualization (SR-IOV). It supports 6 Physical Functions (PF) and 16 Virtual Functions (VF).

There is one AXI master port and one AXI slave port in the PCIe core. All ingress data traffic regardless of the VC assigned will be delivered on the AXI master port. Similarly, all egress data that is presented on AXI slave port of the PCIe core will be assigned VCs through the outbound address translation registers.

#### 12.2.2.3.1.2 PCIe PHY Interface

The PCIe subsystem incorporates a 4-lane PCIe compliant PHY (PIPE) interface to connect to a SERDES-based PHY. The PCIe PHY module consist of a SERDES module and a PCIe PCS (Physical Coding Sub-block) module. The SERDES module converts parallel data into PCIe serial signals and the PCIe PCS module provides an industry standard PIPE Interface to PCIe MAC. The frequency of the PIPE interface can be 62.5MHz, 125MHz or 250MHz depending on whether the system is operating in Gen1, Gen2 or Gen3 mode. The width of the PIPE interface remains constant at 32-bits for all modes of operation. The PCIe controller Lane 0 will always be the master lane for any lane width. For more information on the SERDES module, see *Serializer/Deserializer (SerDes)*.

#### 12.2.2.3.1.3 CBA Infrastructure

The PCIe subsystem includes two CBASS modules (CBASS\_SLV1 and CBASS\_SLV2) to provide access to the various sub-components.

The CBASS\_SLV1 is used to access the PCIe egress data region through the VBUSM2AXI bridge and the AXI slave port of the PCIe controller. There are three data regions implemented in the CBASS\_SLV1. The PCIE\_DAT0 region provides a region with 27 bits of address and PCIE\_DAT1 region provides a region with 32 bits of address. These regions are provided to ensure separate memory spaces for 32-bit and 64-bit maps at the SoC level. The PCIE\_DAT2 region provides a region with 48 bits of address. This is used to route all requests with *case/* not equal to zero to the PCIe controller slave port. The destination for all these three regions is the AXI slave port of the PCIe controller.

The CBASS\_SLV2 provides multiple regions to access the VBUSP configuration ports of the sub-components of the PCIe sub-system like the PCIe controller configuration port, USER\_CFG, VMAP, CPTS and the ECC aggregators. Having multiple regions on the VBUSP configuration port enables the SoC infrastructure to have hardware firewalls that can provide secure access to configuration registers.

The SERDES PLL should be initialized prior to accessing the PCIe core and ECC\_AGGR1 configuration registers. Any accesses to these two regions prior to initializing the SERDES PLL will complete with a read/write status error in CBASS\_SLV2.

#### 12.2.2.3.1.4 VBUSM to AXI Bridges

A VBUSM2AXI protocol conversion bridge is attached to the each AXI slave port. This bridge translates all incoming data requests and sends them to the AXI slave port of the PCIe controller core. Wherever required, it also generates side band signals that the AXI bridge needs based upon the address and the address space of the transaction on the device's native bus.

#### 12.2.2.3.1.5 AXI to VBUSM Bridges

The AXI master port of the PCIe core has an AXI2VBUSM bridge that is used for high speed data transfer during data read/write transactions originated by remote devices over the PCIe link. This bridge provides the protocol translation between the AXI master interface of the PCIe controller core and the VBUSM interface used in the device.

#### 12.2.2.3.1.6 VBUSP to APB Bridge

A VBUSP2APB bridge is used to convert the device VBUSP configuration access to the APB protocol supported by the PCIe controller core.

#### 12.2.2.3.1.7 Custom Logic

The PCIe subsystem includes custom logic to implement Precision Time Management (PTM), interrupts and user configuration registers.

#### 12.2.2.3.2 PCIe Subsystem Reset Schemes

This section describes the reset schemes supported by PCIe Base Specification and the way these resets are supported by the PCIe Subsystem. PCIe Base Specification specifies two mechanisms for performing reset – Conventional Reset mechanism and Functional Level Reset mechanism.

##### 12.2.2.3.2.1 PCIe Conventional Reset

There are three distinct types of Conventional Reset and each of these causes the hardware state machines, hardware logic, port states and configuration registers to be initialized to their default values.

1. Cold Reset – The reset occurring at power-up of the device is referred to as Cold Reset. Cold Reset is triggered by the PERSTn signal being asserted. PERSTn signal is an auxiliary signal in PCIe Specification and can be used at power on reset for the device that has PCIe as its primary bus interface to rest of the system. The device is allowed to generate its own power-on reset as long as the PCIe requirements for PERSTn are met. See PCIe Base Specifications for details.
2. Warm Reset – A reset can be triggered by the hardware without the removal of power from the device. This reset is referred to as Warm Reset. The hardware implementation is not specified by the PCIe Specification.
3. Hot Reset – The PCIe Specifications provides an in-band mechanism to propagate a Conventional Reset across a Link. This reset, called the Hot Reset, propagates via the transmission of TS1 Ordered Sets. In general, Hot Reset is software controlled procedure and can only be issued by Root Port in a PCIe network as the propagation is downstream only. PCIe subsystem translates the received in-band hot reset into an interrupt that can then be used by software to reset the PCIe subsystem.

After a conventional reset, the software must wait at least 100 ms before attempting any PCIe transaction on the device that has been reset. If the downstream device does not respond to transaction packets, it must not give up until 1 second plus an additional 50% (0.5 second) time is lapsed.

##### 12.2.2.3.2.2 PCIe Function Level Reset

The Function Level Reset (FLR) is an optional in-band reset mechanism that is used to reset one particular function in a PCIe device. The PCIe core will initiate the appropriate function level reset process when it receives the FLR message. The PCIe subsystem will raise an interrupt to the SoC, based on the FLR\_IN\_PROGRESS[5:0] and VF\_FLR\_IN\_PROGRESS[15:0] status outputs from the PCIe core. Software can update the PCIE\_USER\_FLR\_DONE[5-0] FLR\_DONE and/or PCIE\_USER\_VF\_FLR\_DONE[15-0] VF\_FLR\_DONE register bits to signal to the PCIe core that the application layer FLR processing is complete.

##### 12.2.2.3.2.3 PCIe Reset Isolation

It can be important to isolate reset of PCIe subsystem from reset of the rest of the device. The procedure to implement this depends upon what functionality the PCIe subsystem is providing – Root Port or End Point.

### 12.2.2.3.2.3.1 Root Port Reset with Device Not Reset

When PCIe subsystem is operating as a Root Port, it is the master controller on the PCIe subsystem. When PCIe subsystem is to be reset in this operating mode, the link to the downstream device will get disconnected. To accomplish this reset, the PCIe subsystem RP should issue a hot reset to End Point or Switch downstream. It should also stop any ongoing transactions. Then, a PCIe subsystem reset can be issued. The sequence of events is outlined below:

1. Stop transactions at system and application level. This is recommended for graceful suspension of activity at system level. It is not required by PCIe subsystem though. Not choosing to gracefully stop transaction would cause some of the outstanding transactions to complete in error and it may be harmful from software stability standpoint.
2. Disable “Bus Master Enable” for End Points (see [Section 12.2.2.3.6.2, PCIe Transaction Limitations](#)). Note that a hand shake with EP Software may be required as not all End Point application software will automatically become aware of this disable action from RP.
3. Optionally, issue Hot Reset to End Point devices via PCIE\_USER\_RSTCMD[0] INIT\_HOT\_RESET bit . Note that the link will be getting disconnected. So, a reset may be happening regardless of the Hot Reset command from RP. It depends on the architecture of the other (external) device. In devices with PCIe subsystem, link disconnection automatically results in a reset request interrupt. A PCIe subsystem reset is required to get the memory buffers out of internal flush modes.
4. Initiate Clock Stop sequence and wait for Acknowledgement. For more information, see [Section 12.2.2.3.3.1, CBA Power Management](#).
5. Issue reset to PCIe subsystem (local reset).
6. Reinitialize PCIe subsystem and downstream devices. PCIe bus enumeration must be performed again.

Note that it is possible for Root Port to occasionally see the downstream device going down for some reason and disconnecting. Such events typically occur due to an internal error condition in the End Point. When such an event occurs, the sequence of events for the Root Port will be as follows:

1. The PCIe subsystem in RP mode will issue the “Reset Request” interrupt when it detects link getting disconnected unexpectedly.
2. The PCIe subsystem will flush all master transactions and any completion data from pending transactions. It will also start completing slave transactions with error completions.
3. After servicing the interrupt and disabling further interrupts, the system software must reset PCIe subsystem Root Port (see steps #4 and later specified previously in this section).

### 12.2.2.3.2.3.2 Device Reset with Root Port Not Reset

As a Root Port, PCIe core is the master of PCIe subsystem. If the device hardware and the software is reset and re-initialized, the system does not get additional benefit of keeping the PCIe subsystem alive as all context information is lost. So, this mode is not supported.

### 12.2.2.3.2.3.3 End Point Device Reset with Root Port Not Reset

It may be desirable to isolate the reset only to PCIe subsystem when it is operating as an End Point. Such resets may be implemented when a Hot Reset command is received from upstream device (Root Port or Switch). The sequence to be followed is as outlined below.

1. Hot Reset is received. The “Request Reset” interrupt is triggered.
2. The PCIe subsystem will automatically enter Flush Mode. The PCIe Link Training and Status State Machine (LTSSM) will be disabled automatically.
3. PCIe subsystem will complete all master transactions and any completion data from pending transactions will be accepted and discarded. It will also start issuing error response for new slave transactions.
4. Upon receipt of the reset interrupt from PCIe subsystem, the system software must immediately start preparing for shut down of PCIe subsystem. The DMA or software process accessing PCIe subsystem should gracefully suspend operations. Otherwise, step #3 may continue for unduly long time and Root Port may assume that the EP is non-responsive to its link re-training attempts.
5. Read the Reset Command register (PCIE\_USER\_RSTCMD) to check if the bridge activity flush bit is zero. This indicates that it is safe to issue warm reset to PCIe subsystem.
6. Initiate Clock Stop sequence. This will ensure no outstanding transactions exist.

7. Issue a PCIe subsystem Reset.
8. Resume initialization sequence.

#### **12.2.2.3.2.3.4 Device Reset with End Point Device Not Reset**

As an End Point, the PCIe subsystem does not need to stay operational when the device reset is happening. Upon detecting the link disconnection, the upstream port will re-train the link when Root Port issues a link retrain command to itself or to a switch port next to the EP.

If it is required that the PCIe subsystem be operational (without any transactions though), the End Point must negotiate with the other devices (primarily Root Port) to stop activity. Otherwise, if the End Point goes into force idle/standby or clock stop modes without properly managing the process, there will be timeouts or errors on incoming read transactions and writes will be completely lost. In such situation, the Root Port will encounter excessive errors and may issue a hot reset to the End Point anyway.

#### **12.2.2.3.2.4 PCIe Reset Limitations**

Once a reset situation occurs, the PCIe subsystem prepares for reset assertion from the device level reset controller. In this mode, all outbound write transactions are discarded and all outbound reads are returned with error. Similarly, all inbound reads/writes are discarded and any pending reads are completed but data is discarded. Additionally, any register reads on local or remote registers regions are returned in error even through data may be correct. Register writes on local registers are executed correctly.

Whenever the reset interrupt is asserted by PCIe subsystem, the host controller should clear the interrupt, perform a clock stop request/ack sequence and issue a local reset to PCIe subsystem.

#### **12.2.2.3.2.5 PCIe Reset Requirements**

Whenever link goes from connected to disconnected state, the PCIe subsystem requires re-initialization based on the events occurring in PCIe core. A request for reset is typically going to be issued and will manifest as a link down interrupt. Since loopback requires transitions through link connect and disconnect, it will generate a link down interrupts. Typically, issuing the warm reset (module reset for CBA) would be sufficient.

#### **12.2.2.3.3 PCIe Subsystem Power Management**

PCIe has multiple power management protocols. Some of them are invoked by the hardware, such as Active State Power Management (ASPM), while others are activated at higher levels via software.

The PCIe core supports D0, D1 and D3-Hot power states.

Link power states L0, L0s, L1, L1s are supported.

L0s entry and exit is managed by the PCIe core if ASPM L0s is enabled.

L1 entry and exit is also managed by the PCIe core if ASPM L1 is enabled. Software can force the exit from L1 by writing to the PCIE\_USER\_PMCMD[0] CLIENT\_REQ\_EXIT\_L1 bit in the PCIe subsystem. Entry into L1 can also be blocked by setting the PCIE\_USER\_PMCMD[0] CLIENT\_REQ\_EXIT\_L1 bit.

L1s support requires that the CLKREQ pin be connected to the remote peer. L1s power state is entered when the link is in L1 and CLKREQ pin is de-asserted. Software can force the exit from L1s by writing to either the PCIE\_USER\_PMCMD[0] CLIENT\_REQ\_EXIT\_L1 or PCIE\_USER\_PMCMD[1] CLIENT\_REQ\_EXIT\_L1\_SUBSTATE bits in the PCIe subsystem.

#### **12.2.2.3.3.1 CBA Power Management**

The power management for PCIe subsystem with CBA interface is primarily accomplished through the clock stop protocol. Any time the clock stop protocol is initiated, the PCIe subsystem will acknowledge after making sure that there are no outstanding transactions. If there are any pending transactions in the subsystem, then the clock stop acknowledgement procedure cannot be completed. Therefore, it is necessary that the system software first suspend activity on the serial link as well as on the CBA interface. To do so, it is expected that the devices communicating with the device on which clock stop procedure is to be performed agree to stop transactions targeted to the device in question. Similarly, it is required that the outgoing transactions also be stopped to successfully complete the clock stop sequence. The PCIe subsystem will guarantee that in the event

there are pending transactions that are still in process of draining will prevent the clock-stop acknowledgement to be issued to CBA subsystem power management logic.

### Note

The PCIe subsystem does not have ability to terminate the clock stop state. Therefore, any wakeup sequence can only be initiated through other means such as software driven timers or software detected events occurring outside of PCIe subsystem.

#### 12.2.2.3.4 PCIe Subsystem Interrupts

The PCIe subsystem provides a mix of interrupts from the PCIe controller interrupt, CPTS interrupts, and interrupts generated in the subsystem using the internal Interrupt Distributor (CP\_INTD) module.

The CP\_INTD module is used to generate and aggregate interrupts from various status signals of the PCIe core. Interrupts from the PCIe core and CPTS module are ported out directly to the PCIe subsystem boundary without any aggregation. [Table 12-116](#) shows the details on the PCIe subsystem interrupt outputs.

**Table 12-116. PCIe Subsystem Interrupt Events**

Interrupt Name	Clock Dependency	Description
PCIE_LEGACY_PULSE	CBA_CLK	PCIe legacy interrupt. INTA_OUT, INTB_OUT, INTC_OUT and INTD_OUT status outputs from the PCIe core are aggregated. Note: Valid in RP mode only.
PCIE_ERROR_PULSE	CBA_CLK	PCIe error interrupt. FATAL_ERROR_OUT, NON_FATAL_ERROR_OUT and CORRECTABLE_ERROR_OUT status outputs from the PCIe core are aggregated. Note: Valid in both RP and EP modes.
PCIE_ASF_FATAL_LEVEL	CBA_CLK	PCIe internal diagnostics fatal interrupt. The ASF_INT_FATAL from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_ASF_NONFATAL_LEVEL	CBA_CLK	PCIe internal diagnostics nonfatal interrupt. The ASF_INT_NONFATAL from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_FLR_PULSE	CBA_CLK	PCIe Function Level interrupt. FLR_IN_PROGRESS[5:0] and VF_FLR_IN_PROGRESS[15:0] status outputs from the PCIe core are aggregated. Note: Valid in EP mode only.
PCIE_DOWNSTREAM_PULSE	CBA_CLK	PCIe downstream interrupt. <ul style="list-style-type: none"> <li>F0_VSEC_INTERRUPT_OUT,</li> <li>F1_VSEC_INTERRUPT_OUT,</li> <li>F2_VSEC_INTERRUPT_OUT,</li> <li>F3_VSEC_INTERRUPT_OUT,</li> <li>F4_VSEC_INTERRUPT_OUT and</li> <li>F5_VSEC_INTERRUPT_OUT</li> </ul> status outputs from the PCIe controller are aggregated. Note: Valid in EP mode only
PCIE_HOT_RESET_PULSE	CBA_CLK	PCIe hot reset interrupt. HOT_RESET_OUT status output from the PCIe controller is aggregated. Note: Valid in EP mode only.
PCIE_LINK_STATE_PULSE	CBA_CLK	PCIe link state interrupt. LINK_DOWN_RESET_OUT status from the PCIe core is aggregated. Note: Valid in both RP and EP modes.
PCIE_PWR_STATE_PULSE	CBA_CLK	PCIe power state interrupt. POWER_STATE_CHANGE status output from the PCIe core are aggregated. Note: Valid in both EP and RP modes.

**Table 12-116. PCIe Subsystem Interrupt Events (continued)**

Interrupt Name	Clock Dependency	Description
PCIE_DPA_PULSE	CBA_CLK	PCIe dynamic power allocation interrupt. DPA_INTERRUPT[5:0] status output from the PCIe core are aggregated. Note: Valid in both EP and RP modes.
PCIE_LOCAL_LEVEL	CBA_CLK	PCIe local interrupt. The LOCAL_INTERRUPT from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_PHY_LEVEL	CBA_CLK	PCIe PHY interrupt. The PHY_INTERRUPT_OUT from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_PTM_VALID_PULSE	CBA_CLK	PCIe PTM valid interrupt. PTM_LOCAL_TIMER_OUT_VALID status output from the PCIe controller is aggregated. Note: Valid only in EP mode.
PCIE_ECC0_UNCORR_PULSE	CBA_CLK	PCIe ECC Aggregator0 uncorrected pulse interrupt.
PCIE_ECC0_UNCORR_LEVEL	CBA_CLK	PCIe ECC Aggregator0 uncorrected level interrupt.
PCIE_ECC0_CORR_PULSE	CBA_CLK	PCIe ECC Aggregator0 corrected pulse interrupt.
PCIE_ECC0_CORR_LEVEL	CBA_CLK	PCIe ECC Aggregator0 corrected level interrupt.
PCIE_ECC1_UNCORR_PULSE	LANE0_TXMCLK	PCIe ECC Aggregator1 uncorrected pulse interrupt.
PCIE_ECC1_UNCORR_LEVEL	LANE0_TXMCLK	PCIe ECC Aggregator1 uncorrected level interrupt.
PCIE_CPTS_PEND_INTR	CBA_CLK	PCIe CPTS level interrupt.

### 12.2.2.3.4.1 Interrupts Aggregation

The PCIe subsystem includes the CP\_INTD module to aggregate some of the PCIe controller signals into the subsystem interrupts indicated in [Table 12-116](#). The interrupt aggregator takes both level and pulse signals from the PCIe core and produces the aggregated pulse interrupt outputs.

The aggregator also supports the End of Interrupt (EOI) feature. EOI can be used to re-trigger a pulse interrupt output, if a PCIe controller level signal is still asserted at the end of interrupt processing. The re-triggering of the the pulse interrupt can be achieved by writing the specified EOI vector value to the PCIE\_USER\_EOI\_VECTOR register.

**Table 12-117. PCIe Controller Interrupts Aggregation - 1**

Aggregated Interrupt	CP_INTD Registers and Bits Mapping		EOI_VECTOR	PCIe Controller Signal	Description
	PCIE_INTD_ENABLE_REG_SYS_0 PCIE_INTD_ENABLE_CLR_REG_SYS_0 PCIE_INTD_STATUS_REG_SYS_0 <sup>(1)</sup>				
PCIE_DOWNSTREAM_PULSE	0	pcie_downstream_0	0	down_pf0_intr	Downstream PF0 interrupt (EP mode only)
	1	pcie_downstream_1		down_pf1_intr	Downstream PF1 interrupt (EP mode only)
	2	pcie_downstream_2		down_pf2_intr	Downstream PF2 interrupt (EP mode only)
	3	pcie_downstream_3		down_pf3_intr	Downstream PF3 interrupt (EP mode only)
	4	pcie_downstream_4		down_pf4_intr	Downstream PF4 interrupt (EP mode only)
	5	pcie_downstream_5		down_pf5_intr	Downstream PF5 interrupt (EP mode only)
-	31-6	Reserved	-	-	-

(1) Register is not used since all PCIe controller signals being aggregated are of type 'level'.

**Table 12-118. PCIe Controller Interrupts Aggregation - 2**

Aggregated Interrupt	CP_INTD Registers and Bits Mapping		EOI_VECTOR	PCIe Controller Signal	Description
	PCIE_INTD_ENABLE_REG_SYS_1 PCIE_INTD_ENABLE_CLR_REG_SYS_1 PCIE_INTD_STATUS_REG_SYS_1				
PCIE_FLR_PULSE	0	pcie_flr_0	1	flr0_in_progress	PF0 function-level reset (EP mode only)
	1	pcie_flr_1		flr1_in_progress	PF1 function-level reset (EP mode only)
	2	pcie_flr_2		flr2_in_progress	PF2 function-level reset (EP mode only)
	3	pcie_flr_3		flr3_in_progress	PF3 function-level reset (EP mode only)
	4	pcie_flr_4		flr4_in_progress	PF4 function-level reset (EP mode only)
	5	pcie_flr_5		flr5_in_progress	PF5 function-level reset (EP mode only)
	6	pcie_flr_6		vf0_flr_in_progress	VF0 function-level reset (EP mode only)
	7	pcie_flr_7		vf1_flr_in_progress	VF1 function-level reset (EP mode only)
	8	pcie_flr_8		vf2_flr_in_progress	VF2 function-level reset (EP mode only)
	9	pcie_flr_9		vf3_flr_in_progress	VF3 function-level reset (EP mode only)

**Table 12-118. PCIe Controller Interrupts Aggregation - 2 (continued)**

Aggregated Interrupt	CP_INTD Registers and Bits Mapping		EOI_VECTOR	PCIe Controller Signal	Description
	PCIE_INTD_ENABLE_REG_SYS_1 PCIE_INTD_ENABLE_CLR_REG_SYS_1 PCIE_INTD_STATUS_REG_SYS_1				
	15	pcie_flr_15		vf9_flr_in_progress	VF9 function-level reset (EP mode only)
	16	pcie_flr_16		vf10_flr_in_progress	VF10 function-level reset (EP mode only)
	17	pcie_flr_17		vf11_flr_in_progress	VF11 function-level reset (EP mode only)
	18	pcie_flr_18		vf12_flr_in_progress	VF12 function-level reset (EP mode only)
	19	pcie_flr_19		vf13_flr_in_progress	VF13 function-level reset (EP mode only)
	20	pcie_flr_20		vf14_flr_in_progress	VF14 function-level reset (EP mode only)
	21	pcie_flr_21		vf15_flr_in_progress	VF15 function-level reset (EP mode only)
PCIE_LEGACY_PULSE	22	pcie_legacy_0	2	int0	Legacy interrupt A (RP mode only)
	23	pcie_legacy_1		int1	Legacy interrupt B (RP mode only)
	24	pcie_legacy_2		int2	Legacy interrupt C (RP mode only)
	25	pcie_legacy_3		int3	Legacy interrupt D (RP mode only)
PCIE_PWR_STATE_PULSE	26	pcie_pwr_state	3	power_state_change_interrupt	Power state change to D1 or D3
-	31-27	Reserved	-	-	-

**Table 12-119. PCIe Controller Interrupts Aggregation - 3**

Aggregated Interrupt	CP_INTD Registers and Bits Mapping		EOI_VECTOR	PCIe Controller Signal	Description
	PCIE_INTD_ENABLE_REG_SYS_2 PCIE_INTD_ENABLE_CLR_REG_SYS_2 PCIE_INTD_STATUS_REG_SYS_2 PCIE_INTD_STATUS_CLR_REG_SYS_2				
PCIE_DPA_PULSE	0	pcie_dpa_0	N/A <sup>(1)</sup>	dpa_intr0	PF0 DPA power state change (EP mode only)
	1	pcie_dpa_1		dpa_intr1	PF1 DPA power state change (EP mode only)
	2	pcie_dpa_2		dpa_intr2	PF2 DPA power state change (EP mode only)
	3	pcie_dpa_3		dpa_intr3	PF3 DPA power state change (EP mode only)
	4	pcie_dpa_4		dpa_intr4	PF4 DPA power state change (EP mode only)
	5	pcie_dpa_5		dpa_intr5	PF5 DPA power state change (EP mode only)
PCIE_ERROR_PULSE	6	pcie_error_0	N/A <sup>(1)</sup>	correctable_error	Correctable error
	7	pcie_error_1		non_fatal_error	Non-Fatal error
	8	pcie_error_2		fatal_error	Fatal error
PCIE_HOT_RESET_PULSE	9	pcie_hot_reset	N/A <sup>(1)</sup>	hot_reset	Hot reset (EP mode only)
PCIE_LINK_STATE_PULSE	10	pcie_link_state	N/A <sup>(1)</sup>	link_state	Link down reset
PCIE_PTM_VALID_PULSE	11	pcie_ptm	N/A <sup>(1)</sup>	ptm_local_timer_val id	PTM local timer valid (EP mode only)
-	31-12	Reserved	-	-	-

(1) EOI is not used since the input signal is of type 'pulse'.

#### 12.2.2.3.4.2 Interrupt Generation in EP Mode

When PCIe subsystem is operating as an End Point (EP), either the legacy interrupts, MSI or MSI-X interrupts can be triggered to the upstream ports (eventually leading to an interrupt in RP device). As per PCIe Specifications, each PCIe function may generate only one of the Legacy or MSI interrupt types as decided during configuration period.

##### 12.2.2.3.4.2.1 Legacy Interrupt Generation in EP Mode

The End Point (EP) can trigger generation of a PCI Legacy Interrupt at the Root Port via an in-band Assert\_INTx / Deassert\_INTx messages (where x = A, B, C, or D). Software can write to the PCIE\_USER\_LEGACY\_INTR\_SET register to trigger the required INTx (where x = A, B, C, or D) assert and de-assert message from the PCIe core. Once an assert message has been generated, it cannot be generated again until a deassert message is generated. Thus, only one interrupt can be pending at a time.

There is no hardware input port provided that will allow generation of legacy interrupts on the EP port.

#### Note

The interrupt messaging mechanism makes it unfeasible to guarantee a time of delivery of the interrupt unlike in conventional designs where the interrupt line is often electrically connected to the final destination.

##### 12.2.2.3.4.2.2 MSI and MSI-X Interrupt Generation

In the case of MSI interrupts signaling, the interrupt conditions are communicated from the EP to the RP via messages. Thus, upon the occurrence of an interrupt condition, a message is sent by the EP with information that identifies the origin of the interrupt. Each message is in the form of a memory write request, containing an address and a data value to be written. Each PCI function supported by a device can be assigned a separate memory address, thus providing separate virtual channels for signaling interrupts generated by each function. In addition, the MSI mechanism allows a maximum of 32 distinct data patterns in the messages generated by each PCI function, and each pattern can be assigned to an interrupt condition within the function.

In the case of MSI-X interrupts signaling, the operation is similar to the MSI mode, except that the mechanism allows a much larger number of distinct interrupt conditions as many as 2048 per function to be communicated, and enables a distinct address to be defined for each of these conditions. This mechanism requires two tables to be stored in the EP memory. The MSI-X table contains the address/data patterns to be used for each interrupt condition (as many as 2048 per function) as well as individual enable/mask bits, and the Pending Bit Array (PBA) stores the status of each interrupt condition. Interrupt conditions are communicated from the EP to the RP via messages (write requests), as in the case of the MSI mode.

##### 12.2.2.3.4.3 Interrupt Reception in EP Mode

The PCIe specification does not have provision for End Points to receive legacy interrupts. As a result, only events other than these are used to map to interrupts.

##### 12.2.2.3.4.3.1 PCIe Core Downstream Interrupts

The Vendor Specific Capability signals of the PCIe core - F0\_VSEC\_INTERRUPT\_OUT, F1\_VSEC\_INTERRUPT\_OUT, F2\_VSEC\_INTERRUPT\_OUT, F3\_VSEC\_INTERRUPT\_OUT, F4\_VSEC\_INTERRUPT\_OUT and F5\_VSEC\_INTERRUPT\_OUT, are used to generate interrupts to the EP from the RP. The F0\_VSEC\_INTERRUPT\_OUT represents the interrupt for the EP Physical Function 0, the F1\_VSEC\_INTERRUPT\_OUT is the interrupt output for EP Physical Function 1 and so on. These signals are aggregated into the PCIE\_DOWNSTREAM\_PULSE interrupt to the local host.

The RP can write to the Vendor Specific Control registers (PCIE\_CORE\_PFn\_I\_VENDOR\_SPECIFIC\_CONTROL\_REG) to assert these signals at the EP and this will trigger the PCIE\_DOWNSTREAM\_PULSE interrupt to the EP host.

##### 12.2.2.3.4.3.2 PCIe Core Function Level Reset Interrupts

The PCIE\_FLR\_PULSE interrupt is asserted to indicate to the host that the PCIe controller has received a function-level reset request from the remote side. The PCIE\_FLR\_PULSE interrupt is an

aggregation of the FLR\_IN\_PROGRESS[5:0] and VF\_FLR\_IN\_PROGRESS[15:0] signals from the PCIe core. Each bit of FLR\_IN\_PROGRESS[5:0] represents Physical Function0 through 5 and each bit of the VF\_FLR\_IN\_PROGRESS[15:0] represents Virtual Function0 through 15.

Upon assertion of the function level reset interrupt, software will need to write to the PCIE\_USER\_FLR\_DONE[5:0] FLR\_DONE bit field within 100ms to acknowledge to the PCIe core that all the application level processing related to the function level reset is complete. Similarly, software will need to acknowledge virtual function level reset completion by writing to the PCIE\_USER\_VF\_FLR\_DONE[15:0] VF\_FLR\_DONE bit field within 100ms of the virtual function level reset being asserted.

#### **12.2.2.3.4.3.3 PCIe Core Power Management Event Interrupts**

The PCIE\_PWR\_STATE\_PULSE interrupt is generated to let the software know of the power management events. The PCIE\_PWR\_STATE\_PULSE interrupt is generated by the POWER\_STATE\_CHANGE\_INTERRUPT output of the PCIe core. This interrupt is asserted when the power state of a physical or virtual function is being changed to D1 or D3 state by writing into their Power Management Control register (PCIE\_CORE\_PFn\_I\_PWR\_MGMT\_CTRL\_STAT\_REP or PCIE\_CORE\_VFm\_I\_PWR\_MGMT\_CTRL\_STAT\_REP, respectively).

Software can check the PCIE\_USER\_LINKSTATUS[23:16] POWER\_STATE\_CHANGE\_FUNCTION\_NUM register field to determine the physical function for which power state change occurred. The PCIE\_USER\_PMCMD[2] POWER\_STATE\_CHANGE\_ACK register bit can be used to acknowledge the POWER\_STATE\_CHANGE\_INTERRUPT.

The PCIE\_DPA\_PULSE interrupt is generated by aggregating the PCIe controller DPA\_INTRs interrupt status outputs. This interrupt is asserted in EP mode when there is a configuration write to the dynamic power allocation control register (PCIE\_CORE\_PFn\_I\_DPA\_CTRL\_STATUS\_REG) to modify the DPA power state of the device. The DPA\_INTR0 is asserted for such an event for PF0, the DPA\_INTR1 for PF1 and so on.

#### **12.2.2.3.4.3.4 PCIe Core Hot Reset Request Interrupt**

When the link is down, the Root Port may request reset of the End Point. This request is terminated as an PCIE\_HOT\_RESET\_PULSE interrupt to the End Point host software. All outstanding transactions are completed in error on slave port and further transactions are not generated on the master port. Once the transactions are completely stopped, the software should issue a local reset to PCIe subsystem. The re-initialization process may then be started.

The PCIE\_HOT\_RESET\_PULSE interrupt is generated from the HOT\_RESET\_OUT output of the PCIe core.

#### **12.2.2.3.4.3.5 PTM Valid Interrupt**

In EP mode, the PCIe subsystem will generate the PCIE\_PTM\_VALID\_PULSE interrupt to the local CPU after a PTM dialog between the PTM requester (EP) and the PTM responder (RP). The PTM valid interrupt indicates to the CPU in the EP that the local timers have been updated with the timestamp data obtained from the RP. The CPU can read the timer registers inside the EP to determine the current timebase.

The PCIE\_PTM\_VALID\_PULSE interrupt is generated from the PTM\_LOCAL\_TIMER\_OUT\_VALID signal from the PCIe core.

#### **12.2.2.3.4.4 Interrupt Generation in RP Mode**

As per PCIe Base Specifications, Root Port ports only receive interrupts. There is no mechanism to generate interrupts from RP port to EP mode as per PCIe specification.

However, PCIe subsystem does support generation of interrupts from RP to EP. The downstream interrupts described in [Section 12.2.2.3.4.3.1, PCIe Core Downstream Interrupts](#) provides a mechanism for the RP to generate software triggered interrupts to the EP.

#### **12.2.2.3.4.5 Interrupt Reception in RP Mode**

##### **12.2.2.3.4.5.1 PCIe Legacy Interrupt Reception in RP Mode**

The RP can receive any of the four legacy INTx interrupts from the EP. These will trigger the PCIE\_LEGACY\_PULSE interrupt to the host CPU.

The PCIE\_LEGACY\_PULSE interrupt is an aggregation INTA\_OUT, INTB\_OUT, INTC\_OUT and INTD\_OUT signals from the PCIe core.

#### **12.2.2.3.4.5.2 MSI/MSI-X Interrupt Reception in RP Mode**

The PCIe core decodes all MSI and MSI-X messages received from the link and forwards them on the low-priority AXI master interface. These messages must then be routed to the system interrupt controller by the SoC interconnect (CBASS0).

#### **12.2.2.3.4.5.3 Advanced Error Reporting Interrupt**

If enabled by software at the time of enumeration, PCIe subsystem will generate this interrupt to indicate occurrence of errors of various levels of severity. The software can choose not to enable Advanced Error Reporting but if it enables, it must process the interrupt as per PCIe Specifications.

The advanced error reporting interrupt is signaled by the PCIE\_ERROR\_PULSE interrupt. The PCIE\_ERROR\_PULSE is an aggregation of the FATAL\_ERROR\_OUT, NON\_FATAL\_ERROR\_OUT and CORRECTABLE\_ERROR\_OUT from the PCIe core.

#### **12.2.2.3.4.6 Common Interrupt Reception in RP and EP Modes**

These interrupts are common to both RP and EP modes of operation.

##### **12.2.2.3.4.6.1 PCIe Local Interrupt**

The LOCAL\_INTERRUPT from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

##### **12.2.2.3.4.6.2 PHY Interrupt**

The PHY\_INTERRUPT\_OUT from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

##### **12.2.2.3.4.6.3 Link down Interrupt**

If the PHY link is disconnected, the PCIE\_LINK\_STATE\_PULSE interrupt will be generated. The expected course of action is to reset the entire PCIe subsystem and restart. All application states must also be initialized so that the operations can resume following the reset and renegotiation of the link.

The PCIE\_LINK\_STATE\_PULSE interrupt is generated from the LINK\_DOWN\_RESET\_OUT output of the PCIe core.

##### **12.2.2.3.4.6.4 Transaction Error Interrupts**

If there is a timeout on PCIe or an abort, PCIE\_PHY\_LOCAL\_LEVEL interrupt will be issued. The PCIE\_PHY\_LOCAL\_LEVEL interrupt is generated by the aggregation of the LOCAL\_INTERRUPT and PHY\_INTERRUPT\_OUT signals from the PCIe core. For more details, see the PCIe specification.

##### **12.2.2.3.4.6.5 Power Management Event Interrupt**

This PCIE\_PWR\_STATE\_PULSE interrupt is generated to let the software know of the power management events. The PCIE\_PWR\_STATE\_PULSE interrupt is generated by aggregating the POWER\_STATE\_CHANGE\_INTERRUPT and DPA\_INTERRUPT outputs of the PCIe core.

In EP mode, software can check the PCIE\_USER\_LINKSTATUS[23-16] POWER\_STATE\_CHANGE\_FUNCTION\_NUM bit field to determine the physical function for which power state change occurred.

The PCIE\_USER\_PMCMD[2] POWER\_STATE\_CHANGE\_ACK bit can be used to acknowledge the POWER\_STATE\_CHANGE\_INTERRUPT.

##### **12.2.2.3.4.6.6 Active Internal Diagnostics Interrupts**

The active internal diagnostics interrupt is signaled by the PCIE\_ASF\_PULSE interrupt. This is an aggregation of the ASF\_CSR\_ERR, ASF\_DAP\_ERR, ASF\_INTEGRITY\_ERR, ASF\_INT\_FATAL, ASF\_INT\_NONFATAL, ASF\_PROTOCOL\_ERR, ASF\_SRAM\_CORR\_ERR, ASF\_SRAM\_UNCORR\_ERR, and ASF\_TRANS\_TO\_ERR signals from the PCIe core.

#### **12.2.2.3.4.7 ECC Aggregator Interrupts**

The PCIE\_ECC0\_UNCORR\_PULSE/PCIE\_ECC0\_UNCORR\_LEVEL and PCIE\_ECC0\_CORR\_PULSE/PCIE\_ECC0\_CORR\_LEVEL interrupts are asserted by the CBA clock domain ECC Aggregator. The PCIE\_ECC1\_UNCORR\_PULSE/PCIE\_ECC1\_UNCORR\_LEVEL interrupts are asserted by the Core clock domain ECC Aggregator. The Core clock domain ECC Aggregator correctable interrupts are not exported since this aggregator is only connected to the parity injection logic and the correctable interrupts for this module will never fire.

#### **12.2.2.3.4.8 CPTS Interrupt**

The PCIE CPTS\_PEND\_INT interrupt is asserted by the CPTS module in the PCIe subsystem to signal a TimeStamp event.

#### **12.2.2.3.5 PCIe Subsystem DMA Support**

The PCIe Subsystem has different requirements based upon whether it is operated in Root Port (RP) or End Point (EP) mode. The PCIe subsystem does not have DMA capabilities built into it. It has internal slave and master ports connected to the device-level interconnect.

An external DMA engine can make burst data read/writes on the slave port and the master port on PCIe subsystem can initiate reads/writes to memory on behalf of a remote PCIe device.

The PCIe subsystem does not specify the DMA protocol that is used for data transfers. The software implementations on the two ends of the PCIe link implement a data transfer protocol that is compatible with each other.

As a result, there will be several software drivers required – one driver that will manage the PCIe subsystem in RP mode and another set of drivers that will run on the RP side and will manage each of the End Points connected to the PCIe subsystem RP.

Similarly, when PCIe subsystem is operating as an End Point, there are two drivers – one to manage the PCIe subsystem from the device side and another driver that will run on the device operating as the Root Port.

##### **12.2.2.3.5.1 PCIe DMA Support in RP Mode**

When operating in Root Port mode, a DMA controller internal to the device (outside PCIe subsystem) can perform DMA to and from any remote device located on the PCIe subsystem. The memory address of such devices is available to the software via the PCIe bus enumeration procedure. In addition, the PCIe subsystem has a provision to perform memory address translation on outbound requests. Thus, the software is able to map different memory regions in its memory map to correspond to different addresses (and different access types) on the PCIe side.

##### **12.2.2.3.5.2 PCIe DMA Support in EP Mode**

When operating as a PCIe End Point, the device will be located in PCIe memory map at location programmed in the Base Address Registers by the PCIe Root device. Any PCIe transactions destined for the device from the upstream ports will get transferred to the master port on the PCIe subsystem. Similarly, any transactions originating from the software will be sent over to PCIe link.

In End Point mode, the PCIe subsystem provides address translation functionality. It is possible to map memory accesses originating on PCIe side to memory accesses with different address on the CBA bus side. These address ranges are configurable through application registers.

#### **12.2.2.3.6 PCIe Subsystem Transactions**

##### **12.2.2.3.6.1 PCIe Supported Transactions**

PCIe subsystem supports the following transactions:

1. Memory Read/Write in inbound/outbound direction in Root Port (RP) and End Point (EP) modes.
2. I/O Read/Write in outbound direction in RP mode.
3. Configuration Read/Write in outbound direction in RP mode.
4. Configuration Read/Write in inbound direction in EP mode.
5. Message Transactions for interrupts and power management in RP and EP modes.

The following transactions are not supported:

1. Locked Read transactions and associated messages.
2. Inbound I/O Transaction Layer Packets (TLPs).
3. User defined messages.

#### 12.2.2.3.6.2 PCIe Transaction Limitations

Added

There are some limitations that must be adhered to while issuing transactions to PCIe subsystem internal bus interface.

- System Initialization

#### CAUTION

The PCIe subsystem operation is completely dependent upon the availability of the SERDES module for PCIe transactions. The SERDES module must be configured and corresponding PLLs must be locked before the PCIe subsystem is able to process any data transactions. Any data accesses to the PCIe subsystem prior to this initialization may result in an internal bus hang condition.

- Remote Configuration and I/O Requests

Since the remote configuration and I/O transaction windows are directly mapped to internal bus space, the software must care to not access these spaces when there is no operational PCIe link. No response may be generated for such transactions. It is recommended that checks be built into software to avoid remote accesses in the absence of an operational link.

- Byte Strobe Limitations

For any type of write transactions, the byte enables can only have a single unbroken string of 1s. In other words, in a transaction, if a byte's write strobe is set, then all following bytes must have write strobe set until the last byte with write enabled. "Holes" or "Zeros" in between the byte enables are not allowed.

Since the internal bus width is greater than 32-bit, the TLP (Transaction Layer Packets) size will not be 1 (PCIe counts in 32-bit units) and therefore, it is through the FBE/LBE (First/Last Byte Enable) that the actual data transfer size is controlled.

- Burst Type Limitations

The PCIe core and respectively the PCIe subsystem does not support 'fixed' or 'wrap' burst types on its Slave or Master port. Transactions that require any burst type other than incremental burst type will result in unspecified behavior, possibly bus lock up.

- Transaction Address Alignment

The PCIe subsystem imposes a limitation of a maximum of 128-byte outbound read/write command. However, if the starting address is not aligned to an 8-byte boundary, then the maximum transaction size is reduced to 120 bytes. This limitation is placed to avoid arithmetic overflow in computing transaction length from CBA to AXI. Unspecified behavior will occur, if misaligned transactions in outbound direction are not limited to a maximum of 120 bytes.

- Read Interleaving

Read interleaving refers to the process of returning split read responses from multiple transactions. This implies that read data is not guaranteed to be sent in sequential order (data for one transaction to be sent completely before the next). The PCIe core will not interleave read responses, if the outbound read command/transaction size does not exceed the maximum transaction size configured in the PCIe core.

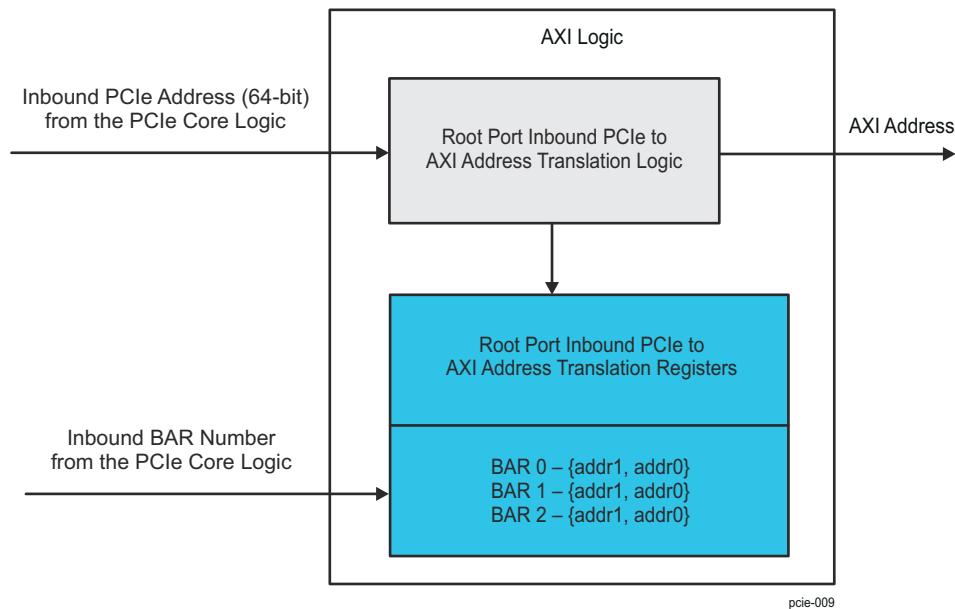

#### 12.2.2.3.7 PCIe Subsystem Address Translation

The PCIe subsystem uses the address translation registers in the PCIe core to translate outbound system addresses to PCIe space and inbound PCIe address to a valid system address. Note that internal address translation is different from the Address Translation Services (ATS).

### 12.2.2.3.7.1 PCIe Inbound Address Translation

#### 12.2.2.3.7.1.1 Root Port Inbound PCIe to AXI Address Translation

The Root Port inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the BAR match of the incoming TLP. In Root Port mode there are 2 bars, so BAR 0 and BAR1 registers are implemented. There is a BAR7 register which is used as a no match BAR address translation register. In Root Port mode there are 2 bars but a BAR value of 7 will be indicated by HAL2AXI when BAR matching is disabled. Any address that does not match the Root Port BARs will be sent out as a BAR7 TLP. Each BAR register is implemented as two 32-bit registers which are named addr0 and addr1. The "Root Port Inbound PCIe to AXI Address Translation Logic" takes the upper bits from the "Root Port Inbound PCIe to AXI Address Translation Registers" and the lower bits are taken from the inbound PCIe address to form the AXI address. An addr0 [5:0] + 1 number of lower bits are passed from the inbound PCIe address to AXI address. In other words, the number of bits taken from inbound PCIe address is given by the addr0[5:0] + 1 value.

**Figure 12-71. PCIe Root Port Inbound PCIe to AXI Address Translation**

A set of registers corresponding to one Root Port BAR is shown in [Table 12-120](#).

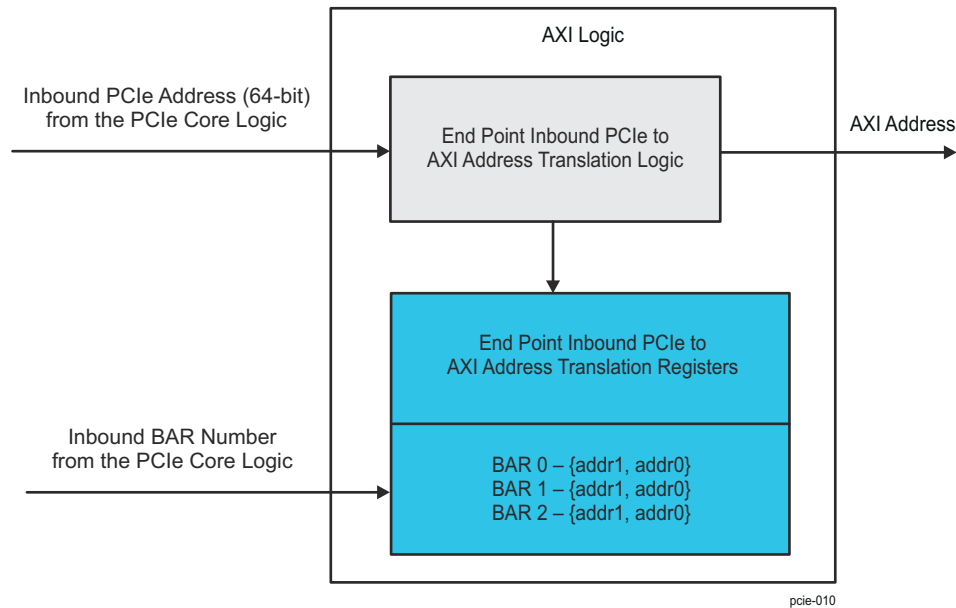

**Table 12-120. PCIe Root Port Inbound PCIe to AXI Address Translation Registers for one BAR**

Register Name	Bits	Description	Default Value
addr1 (where BAR can be bar0, bar1 or bar7)	31:0	Upper [63:32] bits of the AXI address.	32'd0
addr0 (where BAR can be bar0, bar1 or bar7)	31:8	Lower [31:8] bits of the AXI address.	24'd0
	7:6	Reserved	2'd0
	5:0	Number of address bits passed through from PCIe to AXI. The PCIe controller passes the programmed value + 1 bits from PCIe to AXI. Minimum value to be programmed into this field is 7 as the lower 8 bits of the base address programmed in these registers (AXI) are replaced by zeros by the Root Port Inbound PCIe to AXI Address Translation Logic.	6'd0

#### 12.2.2.3.7.1.2 End Point Inbound PCIe to AXI Address Translation

The End Point Inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the function number and BAR match of the incoming TLP. In End Point mode there are 7 bars per function, so 7 sets of registers are

implemented per function, each BAR having two 32-bit registers (addr0 and addr1). The "End Point Inbound PCIe to AXI Address Translation Logic" takes the upper bits from the "End Point Inbound PCIe to AXI Address Translation Registers" and the lower bits are taken from the Inbound PCIe Address to form the AXI address. The number of bits to pass from Inbound PCIe Address to AXI is decided by the Inbound BAR aperture.

**Figure 12-72. PCIe End Point Inbound PCIe to AXI Address Translation**

A set of registers corresponding to one End Point BAR is shown in [Table 12-121](#).

**Table 12-121. PCIe End Point Inbound PCIe to AXI Address Translation Registers for one BAR**

Register Name	Bits	Description	Default Value
addr1 (where BAR can be bar0, bar1, bar2,...bar7, and PF can be pf0, pf1, pf2,... pf21)	31:0	Upper [63:32] bits of the AXI address.	32'd0
addr0 (where BAR can be bar0, bar1, bar2,...bar7, and PF can be pf0, pf1, pf2,... pf21)	31:0	Lower [31:0] bits of the AXI address.	32'd0

#### 12.2.2.3.7.2 PCIe Outbound Address Translation

The PCIe Subsystem allows mapping of PCIe addresses to/from the internal bus addresses of the device. This is accomplished by using internal address translation unit (iATU) in the PCIe core. For each outbound read/write request, the address translation module within PCIe subsystem can convert a VBUSM address to a PCIe address of memory Read/Write type.

If a transaction is large enough that it goes past the address translation region, unspecified behavior may occur. The address translation only works at the time a command is issued. So, a memory write, for example, will not automatically go to next translation region, if it starts in the previous one and is bigger than the remaining size in the starting translation region.

The "Dynamic Method: Sideband Descriptor Based" outbound address translation mechanism is used to bypass the outbound address translation unit under certain conditions. For more details on the bypass operation, see [Section 12.2.2.3.7.2.1, PCIe Outbound Address Translation Bypass](#).

##### 12.2.2.3.7.2.1 PCIe Outbound Address Translation Bypass

The PCIe subsystem supports bypassing the outbound address translation in the PCIe controller when the *case/* value on the VBUSM slave interface is non-zero.

The device UDMA has the ability to send transactions to alternate address maps which are external to the local device. This is achieved by using casel identifier in the DMA descriptors. There are three requirements that need to be met in the PCIe subsystem when using this mode in the DMA, namely:

- Block transactions based on initiator credentials to support FFI (Freedom from Interference)
- Bypass the Address Translation Unit (ATU) inside the PCIe controller since the transaction address is external to the local device
- Assign the correct Bus, Device, Function (BDF) and Traffic Class (TC) values to the transaction

To meet these requirements, the PCIe subsystem uses the *cvirtid* values on the VBUSM slave interface to filter transactions based on initiator credentials. The VMAP block in the PCIe subsystem has a *virtid* match register (PCIE\_VMAP\_OB\_VIRTID\_MATCH) and a set of 32 registers that can be used to program the descriptor fields when the ATU logic in the PCIe controller is bypassed.

The PCIe subsystem will filter outbound VBUSM slave transactions that have a non-zero casel value. If the *cvirtid*[11:5] attribute of the VBUSM slave transaction matches the value programmed in the PCIE\_VMAP\_OB\_VIRTID\_MATCH register, the credentials of the transaction initiator are verified. The *cvirtid*[11:5] value should also be non-zero for a successful match.

When the credentials match, the ATU of the PCIe controller is bypassed. The *cvirtid*[4:0] is used to select one of the 32 PCIE\_VMAP\_DESC\_j descriptor registers. These registers can be programmed to assign the BDF and TC values to the outbound PCIe transaction. If the PCIE\_VMAP\_DESC\_j[16] BD\_EN0 register bit is set, then the bus, device and function numbers are all set from the external descriptor registers. If the BD\_EN bit is not set, then the bus and device numbers are assigned by the PCIe controller using the values captured during enumeration. If ARI mode is enabled (in the PCIE\_CORE\_PFN\_I\_SRIOV\_CTRL\_STATUS\_REG register), the function number uses the PCIE\_VMAP\_DESC\_j[7:0] DEV\_FUNC\_NUM register field. If ARI mode is not enabled, the device number uses PCIE\_VMAP\_DESC\_j[7:4] DEV\_FUNC\_NUM field and the function number uses the [3:0] DEV\_FUNC\_NUM field. The ARI mode is a PCIe controller hardware configuration option that is enabled for PCIe endpoints that support SR-IOV.

If the credentials of the initiator fail to match the programmed value in the PCIE\_VMAP\_OB\_VIRTID\_MATCH register, the VBUSM slave transaction is then flushed by the bridge and is not submitted to the PCIe controller. The VBUSM2AXI2 bridge will return a protection error status for both read and write transactions. In addition, the write data is discarded and the correct number of read data phases with data value of zero are returned.

#### 12.2.2.3.8 PCIe Subsystem Virtualization Support

The PCIe subsystem supports Address Translation Request (ATS) messages in Root Port mode. All PCIe ATS requests are forwarded to the SMMU. The ATS response sent back by the SMMU is forwarded to the remote PCIe requestor.

In End Point mode, the PCIe subsystem supports SR-IOV with 6 physical functions (PF), and 4 virtual functions (VF) per physical function for PF0-PF3 only (6PF/16VF).

##### 12.2.2.3.8.1 End Point SR-IOV Support

In End Point (EP) mode, the PCIe subsystem supports Single Root I/O Virtualization (SR-IOV) with four physical functions (PF) and four virtual functions (VF) per physical function for PF0-PF3 only.

##### 12.2.2.3.8.2 Root Port ATS Support

In Root Port (RP) mode, the PCIe subsystem has an AXI streaming interface (DTI) to connect to the system level SMMU. The Address Translation Messages (ATS) from the End Point is routed to the SMMU over the DTI interface. The translated address and any invalidation requests from the SMMU, sent to the PCIe over the DTI interface, is converted to ATS messages and sent to the End Point.

##### 12.2.2.3.8.3 VirtID Mapping

The PCIe subsystem includes the VMAP module that can be programmed to map (convert) the incoming 16-bit PCIe requestID + 2-bit PCIe AT bits to the 16-bit CBA virtID + 2-bit CBA atype attributes.

Figure 12-73 shows the block diagram of the VMAP module. The blocks shown in the diagram are replicated for the read and write AXI channels. However, there is only one set of configuration registers in the VMAP module and these are shared by both the read and write channel logic.

**Figure 12-73. PCIe Subsystem VirtID Mapper**

The RequestID Clamp block is used to clamp the incoming requestID to a maximum value. This block compares the incoming PCIe requestID[15:12] masked with the virtid\_mask[3:0] to an expected value. Bit [19] BDF\_MODE in PCIE\_VMAP\_DEFMAP is used to set the value to virtid\_force[3:0] or 4'h0. The clamped\_requestid is set to the maximum value of FFFFh if the comparison is false. The clamped\_requestid value is later used downstream by the PVU or SMMU in the SoC.

Each of the VMAP modules includes a set of 32 match and mask registers. Software can enable the registers to be used for the mapping by setting the [0] EN bit in PCIE\_VMAP\_CTRL\_j registers. Software can also program the [15-0] RID and [31-16] MASK bit fields in PCIE\_VMAP\_REQID\_j registers to indicate the incoming PCIe requestid that needs to be matched. The [11-0] VID and [17-16] ATYPE bit fields in PCIE\_VMAP\_VIRTID\_j registers are used to program the required CBA virtID and Atype fields in case of a match. In order to prevent a spurious match, the [15-0] RID and [31-16] MASK bit fields in PCIE\_VMAP\_REQID\_j registers should be set up before the [0] EN bit in PCIE\_VMAP\_CTRL\_j registers is set. The same sets of registers are used for both read and write transactions.

The Match logic with Priority Encoding block compares the incoming PCIe requestID with the values programmed in the VMAP control registers and sets the value of the virtid\_int and atype\_int variables. For every incoming PCIe transaction, the incoming PCIe requestID[11:0] bits are masked with the PCIE\_VMAP\_REQID\_j[31-16] MASK bit field and compared against each of the thirty two values indicated by PCIE\_VMAP\_REQID\_j[15-0] RID that are enabled. The location of the first match of this comparison operation is used to select the [11-0] VID and [17-16] ATYPE bit fields in PCIE\_VMAP\_VIRTID\_j registers. This is used as the virtid\_int and atype\_int values for the downstream logic. In case none of the enabled [15-0] RID and [31-16] MASK bit fields in PCIE\_VMAP\_REQID\_j registers pairs match the incoming requestID, the value in [11-0] DEF\_VID and [17-16] DEF\_ATYPE bit fields in PCIE\_VMAP\_DEFMAP registers is used.

The VirtID and Atype Fix block uses the incoming PCIe AT\_bits along with the matched and clamped values of the requestID from the downstream blocks to set the final values of the virtID, catype and cflush attributes for the particular CBA transaction. The values of the virtID, catype and cflush are determined based on the following criteria:

1. If the incoming PCIe TLP has a translated address, as indicated by the PCIe AT\_bits equal to 2 and if the match operation results in an expected atype value of 2 and Address Translation Services (ATS) is enabled

in the system, as indicated by the PCIE\_VMAP\_DEFMAP[20] ATS\_DIS register bit, the virtID is set to the *clamped\_requestid* and the *catype* value is set to 2. This enables the PCIe subsystem to pass along the full incoming requestID[15:0] to the upstream SMMU/PVU. The incoming transaction is flushed if it fails this criteria by setting the cflush attribute to 1. The PCIe EP initiating this transaction will be sent a Completion Abort (CA) response for a read request, if the transaction is flushed.

2. If the incoming PCIe TLP does not have a translated address, as indicated by the PCIe AT\_bits equal to 0, the virtID can be set to the output of the mask/match registers or the *clamped\_requestid*. The *catype* attribute for this transaction can be set to the value from the mask/match registers.

---

#### Note

The PCIe implementation in the device uses the *direct\_mode* workaround. This forces the *cvirtID* and *catype* to 0 when the incoming transaction matches the criteria outlined in (1) above.

The system Interconnect only supports 12-bits of *virtid*. As a result, only *virtid*[11:0] from the PCIe VMAP module will be used in the system and *virtid*[15:12] is not connected.

---

The pseudo-code for the virtID mapping algorithm implemented is described below.

```
// Requestid Clamp
// Note: only the low 4 bits of virtid_force & virtid_mask are used in the current PCIe wrapper
// virtid_mask[7:4] should always be 1
// virtid_mask[n] of 1 means use the virtid_force value for this bit
// virtid_mask[n] of 0 means use the requestID value for this bit, virtid_force[n] should be 0
// Bit [19] BDF_MODE in PCIE_VMAP_DEFMAP specifies if we are using
// 0 based bus numbers (0) or offset bus numbers (1)
expected_value[3:0] = PCIE_VMAP_DEFMAP[19] BDF_MODE ? virtid_force[3:0] : 4'h0;
if (requestID[15:12] & virtid_mask[3:0] == expected_value[3:0] )
{

virtid[15:12] = 4'h0;
}
}
}

```

### 12.2.2.3.9 PCIe Subsystem Quality-of-Service (QoS)

The Virtual Channel/Transfer Class (VC/TC) feature in the PCIe core, in conjunction with the device system CBASS Quality-of-Service (QOS) capabilities, provide a mechanism for supporting differentiated QOS within the PCIe subsystem. The policy for traffic differentiation is determined by the Transfer Class (TC) and Virtual Channel (VC) mapping and VC-based arbitration mechanism.

A Virtual Channel is established when one or more TCs are associated with a physical resource designated by a VC ID. Every Traffic Class that is supported on a given path within the subsystem must be mapped to one of the enabled Virtual Channels. Every Port must support the default TC0/VC0 pair – this is “hardwired.” Any additional TC mapping or additional VC resource enablement is optional. The number of VC resources provisioned within a component or enabled within a given subsystem may vary due to implementation and usage model requirements.

The PCIe core in the PCIe subsystem is configured to support four virtual channels (4VC/4TC). For both ingress and egress traffic, VC3, the highest numbered virtual channel, has the highest priority.

For ingress traffic, the TC information from each transaction on the AXI master information is mapped to the CCHANID signal of the VBUSM master interface. The system level interconnect can use the CCHANID along with the ORDERID for QoS purposes. [Table 12-122](#) shows the TC mapping to the 12-bit CCHANID of each VBUSM master interface.

**Table 12-122. PCIe Subsystem QoS Ingress CCHANID Mapping**

TC Value	CCHANID[11:0]
0	{9'd0, 3'b000}
1	{9'd0, 3'b001}
2	{9'd0, 3'b010}
3	{9'd0, 3'b011}
4	{9'd0, 3'b110}
5	{9'd0, 3'b101}
6	{9'd0, 3'b110}
7	{9'd0, 3'b111}

For egress traffic requiring the highest priority it should be mapped to VC=3 in the PCIe controller. The VC mapping is done using the AXI outbound descriptor registers in the PCIe controller.

### 12.2.2.3.10 PCIe Subsystem Precision Time Measurement (PTM)

The Precision Time Measurement (PTM) enables precise coordination of events across multiple components with independent local time clocks. Ordinarily, such precise coordination would be difficult given that individual time clocks have differing notions of the value and rate of change of time. To work around this limitation, PTM enables components to calculate the relationship between their local times and a shared PTM Master Time: an independent time domain associated with a PTM Root.

The PTM defines the following components:

- PTM Requester - A Function capable of using PTM as a consumer associated with an Endpoint.
- PTM Responder - A Function capable of using PTM to supply PTM Master Time associated with a RP.
- Time Source - A local clock associated with a PTM Responder.
- PTM Root – The source of PTM Master Time for a PTM hierarchy. A PTM Root must also be a Time Source and is typically also a PTM Responder.

When using PTM between two components on a Link, the EP sends PTM requests to the RP on the same link. During each dialog, the RP populates the PTM Response message based on timestamps stored during previous PTM dialogs. Once each component has historical timestamps from the preceding dialog, the EP can combine its timestamps with those passed in the PTM Response message to calculate the PTM Master Time.

The PCIe core implements all of the features required to handle the PTM conversation between the requestor and responder in hardware. In addition, an internal TimeStamp module (CPTS) is connected to the timestamp interface of the PCIe core so that events can be logged.

The Precision Time Measurement (PTM) support in the PCIe subsystem is handled by the combination of the PCIe core and the CPTS module.

The PCIe core controller handles the PCIe conversation to exchange timestamps between the RP and EP. It also includes logic to calculate the timestamp differences as specified in the PCIe standard. A 64-bit timer that is the master clock is included in the PCIe core. The PCIe controller can be programmed to initiate the PTM conversation automatically by setting the [0] PTMRQM bit in the PCIE\_CORE\_LM\_I\_PTMR\_LOCAL\_CONTROL\_REG register.

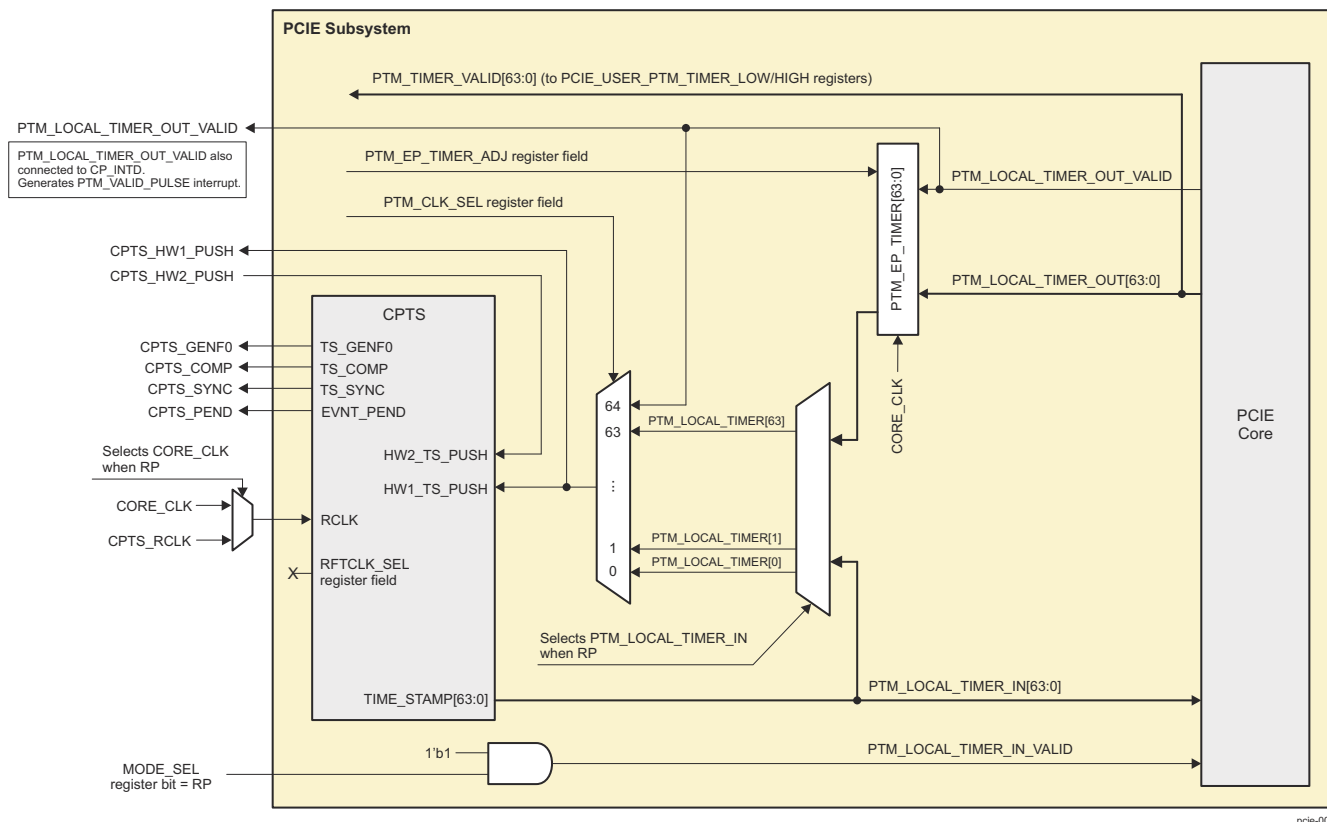

In EP mode, there are two methods to register a CPTS HW1 push timestamp that is needed to transfer the PCIe PTM timebase to the local system time base.

1. The first method involves the PTM\_LOCAL\_TIMER\_OUT\_VALID and PTM\_EP\_TIMER. The PTM\_LOCAL\_TIMER\_OUT\_VALID output from the PCIe controller will be asserted when the PTM conversation is complete and the EP local timer has been updated. The adjusted value of the EP 64-bit timer is available in the PTM\_LOCAL\_TIMER\_OUT output of the controller. A second 64-bit free running timer, PTM\_EP\_TIMER, is used to shadow the value of the EP timebase. The PTM\_EP\_TIMER is loaded with the value of the PTM\_LOCAL\_TIMER\_OUT[63:0] when PTM\_LOCAL\_TIMER\_OUT\_VALID is high. When PTM\_LOCAL\_TIMER\_OUT\_VALID is low, PTM\_EP\_TIMER will be free running based on the same PCIE\_CORE\_CLK that drives the PTM\_LOCAL\_TIMER\_OUT. The increment value of PTM\_EP\_TIMER can be adjusted by writing to the PCIE\_USER\_PTM\_CFG[10-8] PTM\_EP\_TIMER\_ADJ register field. The increment value is one by default. The value of the PTM\_EP\_TIMER will not be updated to the RP timebase until the first PTM dialog has occurred. Software can set the PCIE\_USER\_PTM\_CFG[6-0] PTM\_CLK\_SEL register field value between 0 and 63 to choose a particular bit of the PTM\_EP\_TIMER as the source for the CPTS HW1 time stamp push event.
2. The second method to register the CPTS HW1 push timestamp involves only the PTM\_LOCAL\_TIMER\_OUT\_VALID output from the PCIe controller. Software can set the PCIE\_USER\_PTM\_CFG[6-0] PTM\_CLK\_SEL register field value to 64 to select the PTM\_LOCAL\_TIMER\_OUT\_VALID as the source of the CPTS HW1 time stamp push event. This will create a CPTS HW1 timestamp when there is a PTM dialog between the PCIe End Point and Root Port. The actual value of the EP PTM local timer can be read from the PCIE\_USER\_PTM\_TIMER\_LOW and PCIE\_USER\_PTM\_TIMER\_HIGH registers.

In RP mode, the CPTS can take control of the PTM master time. The 64-bit CPTS timer is continuously loaded into the PCIe PTM master clock by tying high the PTM\_TIMER\_IN\_VALID input of the PCIe controller. This allows for software to adjust the PCIe PTM master clock as necessary using the CPTS module and maintain the PTM master time by monotonically increasing it as required by the PCIe standard. The CPTS HW1\_PUSH timestamp input is driven by the particular bit of the PTM\_LOCAL\_TIMER\_IN counter, as selected by the value in the PCIE\_USER\_PTM\_CFG[6-0] PTM\_CLK\_SEL register field.

The reference clock (RCLK) for the CPTS can be controlled via the CTRLMMR\_PCIE1\_CLKSEL[3-0] CPTS\_CLKSEL register field in the device Control Module. This enables the SoC flexibility in choosing the CPTS reference clock input. In RP mode, the RCLK needs to be connected to the SERDES PIPE clock since the CPTS will be driving the PTM master clock. For more information on the RCLK source clock selection, see *PCIe Subsystem Integration*.

Figure 12-74 shows the PTM support logic in the PCIe subsystem.

**Figure 12-74. PCIe Subsystem PTM Implementation**

### 12.2.2.3.11 PCIe Subsystem Loopback

The PCIe subsystem provides loopback support through PIPE interface (Link Layer).

#### 12.2.2.3.11.1 PCIe PIPE Loopback

The procedure depends upon whether the device is operating in RP or EP Mode. In either case, the PCIe subsystem can be loopback master or loopback slave as outlined in PCIe specifications. A loopback master is the component requesting loopback and transmitting the data. A loopback slave is the component looping back the data.

#### Note

The PIPE loopback mode cannot be used for looping back transactions.

#### 12.2.2.3.11.1.1 PIPE Loopback Master Mode

The loopback path when PCIe subsystem is loopback master is:

PCIe subsystem (loopback master) -> PIPE (TX) -> PCIe Link -> Loopback -> PCIe Link -> PIPE (RX) -> PCIe subsystem

#### 12.2.2.3.11.1.2 PIPE Loopback Slave Mode

The loopback path when PCIe subsystem is loopback slave is:

Remote device -> PCIe Link -> PIPE (RX) -> Loopback -> PIPE (TX) -> PCIe Link -> Remote device

If the PCIe subsystem is a loopback slave, then the incoming serial data is routed back to the originating device from the PIPE interface as per PCIe loopback requirements. Typically, PCIe test equipment will be used as loopback master and it will transition PCIe subsystem into loopback slave state following which the inbound transactions will be loopback to the test equipment. There is no programming required on PCIe subsystem to enter loopback in slave mode. PHY support is not required to use this loopback mode.

### 12.2.2.3.12 PCIe Subsystem Error Handling

As an End Point, PCIe subsystem reports errors to root complex so that corrective action may be taken. These messages become error interrupts on the Root Port side. In addition, the errors that are detected by the PCIe subsystem locally are also reported to software via interrupts.

Note that for several errors of the same type that are detected in close succession, the PCIe subsystem will not necessarily send as many error messages to Root Port. It is guaranteed to send at least one such error message.

### 12.2.2.3.12.1 PCIe AXI to/from VBUSM Bus Error Mapping

[Table 12-123](#) and [Table 12-124](#) show the bus error mapping to/from the AXI interface on the PCIe controller to the system VBUSM interfaces.

The AXI2VBUSM bridge maps the bus errors on the ingress AXI interface to the VBUSM master interface as shown in the table below.

**Table 12-123. AXI to VBUSM Bus Error Mapping**

VBUSM		AXI	
Code	Error	Code	Error
0 (decimal)	Success	0h	OKAY
1 (decimal)	N/A	3h	N/A
2-3 (decimal) 7 (decimal)	All Others	2h	SLVERR

The VBUSM2AXI bridge maps the bus errors on the egress VBUSM slave interface to the AXI interface as shown in the table below.

**Table 12-124. VBUSM to AXI Bus Error Mapping**

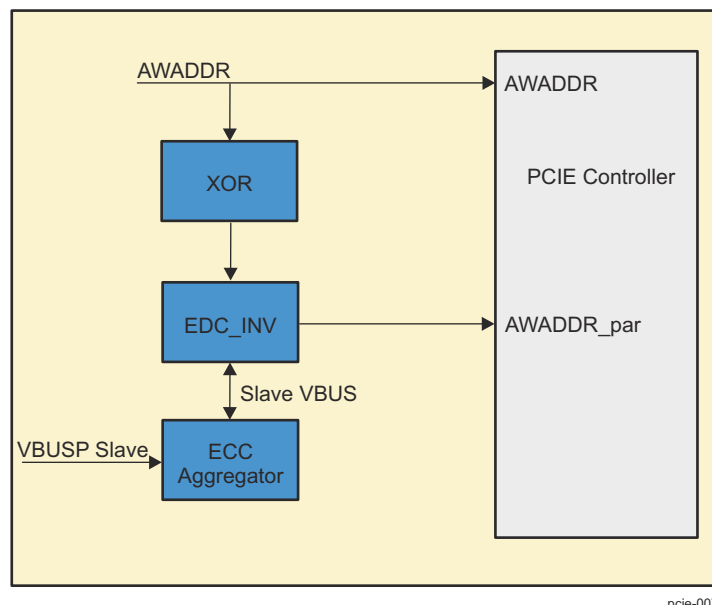

AXI		VBUSM	
Code	Error	Code	Error
N/A	N/A	2 (decimal)	Protection Error
0h	OKAY	0 (decimal)	Success
3h	DECERR	1 (decimal)	Addressing Error
2h	SLVERR	1 (decimal)	Addressing Error

### 12.2.2.3.13 PCIe Subsystem Internal Diagnostics Features

#### 12.2.2.3.13.1 PCIe Parity

All the parity inputs on the PCIe controller core are driven by the EDC\_INV module. This allows the parity input to the PCIe controller to be inverted and thus inject an error. [Figure 12-75](#) shows the parity logic on the AXI AWADDR port as an example. The parity of the AWADDR inputs to the PCIe controller are calculated as an XOR and this is fed into the PCIe controller using the EDC\_INV block. The input AWADDR\_par can be inverted using commands from the ECC Aggregator to enable error injection. Similar logic is present on all other parity inputs to the PCIe controller.

Checking input parity and output parity are handled inside the PCIe controller. Any errors in parity are signaled using the PCIe active internal diagnostics interrupt (PCIE\_ASF\_PEND).

**Figure 12-75. Parity Logic on AXI AWADDR Input**

#### 12.2.2.3.13.2 ECC Aggregators

The PCIe subsystem instantiates two ECC Aggregators: AXI\_ECC\_AGGR and CORE\_ECC\_AGGR.

AXI\_ECC\_AGGR is connected to the RAMs in PCIe CBA Clock Domain and CORE\_ECC\_AGGR is connected to the RAMs in the PIPE Clock Domain.

The ECC Aggregator modules integrated within the PCIe subsystem provide a mechanism to control and monitor the ECC RAMs via Single Error Correction (SEC) and Double Error Detection (DED) functions. Each ECC Aggregator module gathers level pending status from the ECC RAMs into two interrupts to system level. One interrupt is for correctable errors (SEC) and the other one for uncorrectable errors (DED). The ECC Aggregator supports software readable status of ECC single/double-bit errors and associated information such as RAM address and data bit(s) that are in error. Write back correction for async read RAMs is not supported.

For more information on the ECC Aggregator operation, see [Section 12.10.6, ECC Aggregator](#).

#### 12.2.2.3.13.3 RAM ECC Inversion

The RAM ECC logic inside the PCIe controller can be tested using the ECC inversion logic.

#### 12.2.2.3.14 LTSSM State Encoding

[Table 12-125](#) is used when the PCIe/M-PCIe core is configured to be operating in PCIe mode.

[Table 12-125](#) provides the encoding of the LTSSM states on the LTSSM\_STATE output of the core, as well the state read from the Physical Layer Configuration Register 0.

**Table 12-125. LTSSM State Encoding**

LTSSM State Name	Value (hex)
Detect.Quiet	00
Detect.Active	01
Polling.Active	02
Polling.Compliance	03

### 12.2.3 Universal Serial Bus (USB) Subsystem

This section describes the USB 3.0 Dual-Role-Device (DRD) interface subsystem of the device.

#### Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

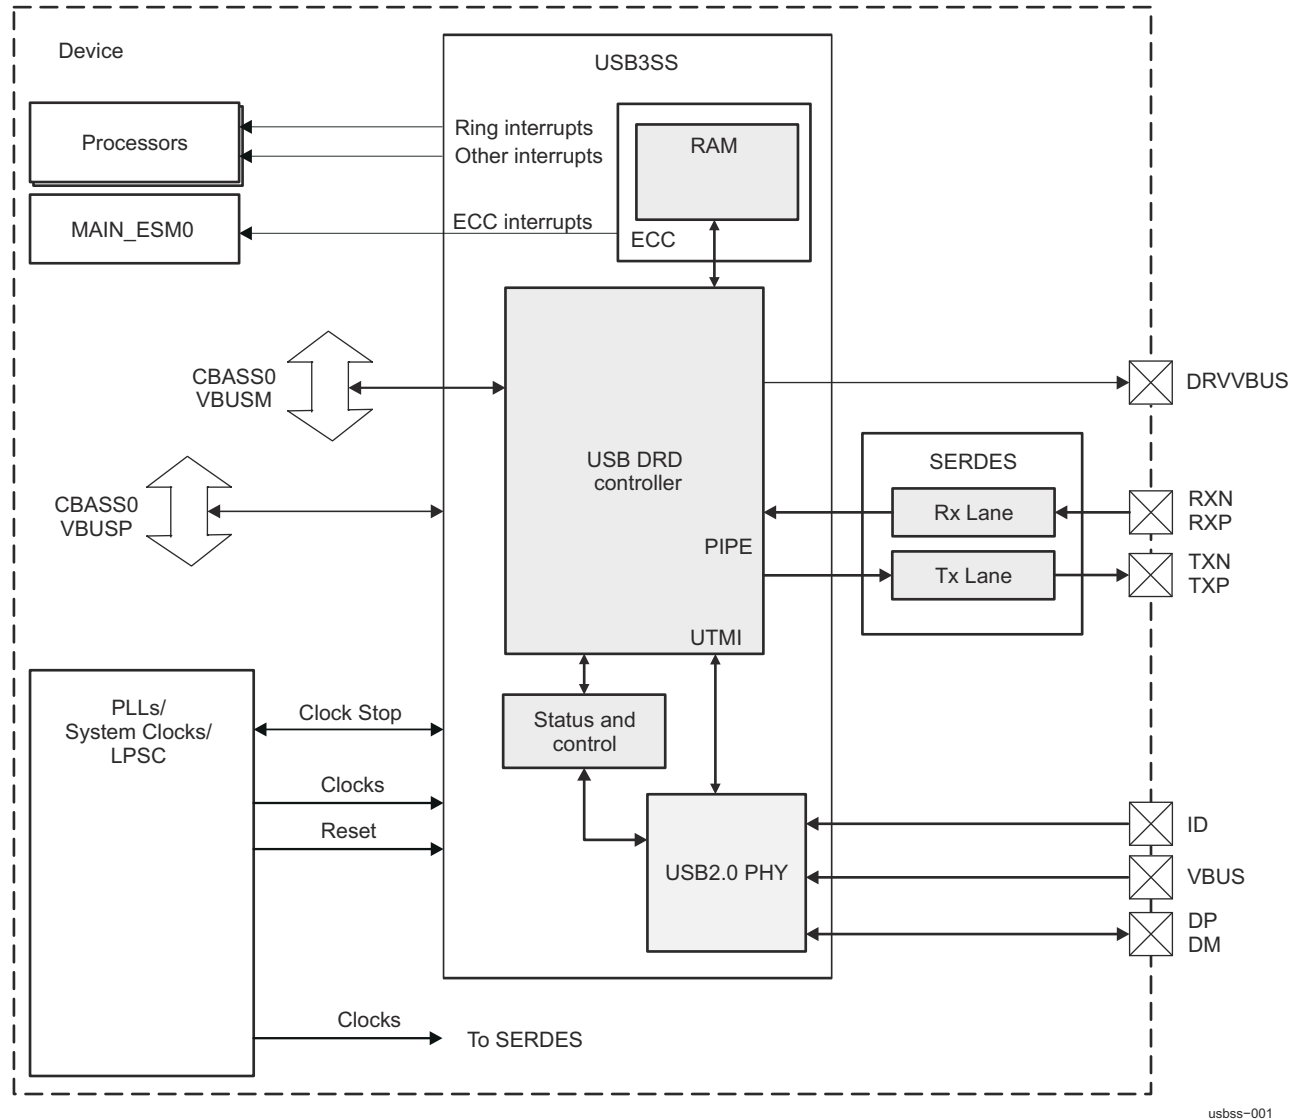

#### 12.2.3.1 USB Overview

Similar to earlier versions of USB bus, USB 3.0 is a general-purpose cable bus, supporting data exchange between a host device and a wide range of simultaneously accessible peripherals.

The device supports these USB subsystems:

- USB3SS0 is SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem with on-chip SS (USB3.0) PHY and HS/FS/LS <sup>1</sup>(USB2.0) PHY

Figure 12-76 shows the USB subsystem highlights.

**Figure 12-76. USB Subsystem Overview**

#### 12.2.3.1.1 USB Features

The USB Dual-Role-Device (DRD) subsystem, supports the following USB features:

- General features:
  - Supports Peripheral (aka Device) mode at Superspeed (5 Gbps), Highspeed (480 Mbps), and Fullspeed (12 Mbps)
  - Supports Host mode at Superspeed (5 Gbps), Highspeed (480 Mbps), Fullspeed (12 Mbps), and Lowspeed (1.5 Mbps)
  - Static peripheral operation
  - Static host operation
  - Compliant with USB 3.1 Gen1 Specification
  - Limited OTG 2.0 functionality
  - Supports VBUS and ID detection
  - Host Negotiation Protocol (HNP) support

<sup>1</sup> LowSpeed (LS) is supported only in host mode.

- Charger Downstream Port (CDP) as per Battery Charging Specification, Revision 1.2
- Each controller instance contains single xHCI with the following features:
  - Compatible to the xHCI specification (revision 1.0)
  - Supports 15 Transmit (TX), 15 Receive (RX) endpoints (EPs), and one EP0 endpoint which is bidirectional
  - Internal scatter-gather DMA controller
  - Dynamic data buffering
  - USB3 power saving states (U1, U2, and U3) and USB2 L1/L2
  - 64 slots supported with 32 endpoints per slot, for host operation
- Operation flexibility:
  - Uniform programming model for SS, HS, FS, and LS operation
  - Multiple interrupt lines:
    - 8 interrupts associated with 8 programmable Event Rings for multi-core support
    - Interrupt for OTG events
- Functional safety:
  - Internal RAM with ECC
  - Hardware transaction timeout monitor
- Supports VBUS and ID detection in the USB2.0 PHY
- External requirements and I/O features:
  - Requires an external charge pump or power switch for VBUS 5-V generation
  - Requires an external circuitry or PMIC to start the battery charging upon Battery Charger (BC) detected event
  - Requires external high-precision resistors for USB2.0 PHY and SERDES termination calibration
  - Supports internal data lane swapping for Type C connector. All other Type C features, like cable detection and CC configuration, have to be implemented using external circuitry
  - Supports short circuit protection to GND and short-term short circuit protection to VBUS on data pins

**Unsupported Features:**

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

**12.2.3.1.2 USB Not Supported Features**

The following are USB features which are not supported in the current device:

- OTG 3.0 functionality
- HSIC (High Speed Inter-Chip) and SSIC interface
- ULPI Interface for external PHY
- SRP and ADP protocols
- Hibernation
- Cache-line wrap addressing mode on both bus interfaces
- Debug trace interface
- xHCI IO virtualization
- MSI support

**12.2.3.1.3 USB Ports**

This section describes USB module ports related to clocks, resets, and hardware requests.

**Table 12-126. USB Clocks and Resets**

Clocks	
Module Clock Input	Description
ACLK	VBUSM interface clock
PCLK	VBUSP interface clock
BUFCLK	VBUSM bridge clock
CLK_LPM	Low power clock (24 MHz). This clock has to be free running when USB is enabled.
USB2_REFCLK	USB2PHY reference clock. HFOSC selected via CTRLMMR_USB0_CLKSEL. Frequency value must be indicated to PHY via USB3P0SS_STATIC_CONFIG.

**Table 12-126. USB Clocks and Resets (continued)**

USB2\_APB\_PCLK USB2PHY VBUSP interface clock

Resets	
Module Reset Input	Description
USB_RST	USB3SS0 hardware reset

**Table 12-127. USB Hardware Requests**

Interrupt Requests		
Module Interrupt	Description	Type
IRQ_[0:7]	8 event ring interrupts in host mode. In device mode, IRQ[6] is device USB interrupt and IRQ[7] is device wakeup request.	Level
HOST_SYSTEM_ERROR	USB host system error	Level
OTGIRQ	USB OTG events	Level
ASF_INT_NONFATAL	USB safety features nonfatal interrupt	Level
ASF_INT_FATAL	USB safety features fatal interrupt	Level
A_ECC_AGGR_CORRECTED_ERR_LEVEL	ECC aggregator interrupt	Level
A_ECC_AGGR_UNCORRECTED_ERR_LEVEL	ECC aggregator interrupt	Level
DMA Events		
Module DMA Event	Description	Type
-	No PDMA channels to external DMA engines. USB has an internal DMA controller.	-

**12.2.3.1.4 USB Terminology**

The following acronyms and abbreviations are related to USB.

Term	Definition
<b>ADP</b>	Attach Detection Protocol: detects USB OTG attach/detach events.
<b>DRD</b>	Dual Role Device: USB Host and Peripheral capable.
<b>DS</b>	Down Stream (A USB port facing from a Host or Hub to a Device/Peripheral).
<b>EP</b>	Endpoint: USB communication channel between the USB link partners carrying a single transfer type (BULK, ISOCH, INT, or CONTROL) and bus sharing arbitration scheme.
<b>FS</b>	Full-Speed USB data rate (12 Mbps).
<b>HNP</b>	Host Negotiation Protocol, OTG extension to swap USB host and peripheral roles.
<b>HS</b>	High-Speed USB data rate (480 Mbps).
<b>ITP</b>	Isochronous Timestamp Packet: USB SS micro-frame boundary packets.
<b>LMP</b>	Link Management Packet.
<b>LS</b>	Low-Speed USB data rate (1.5 Mbps).
<b>OTG</b>	On-The-Go extension to USB protocol.
<b>PHY</b>	Physical Layer Device.
<b>SS</b>	Super-Speed USB data rate. 5 Gbps (USB3.0 or USB3.1 Gen1)
<b>US</b>	Upstream facing from a device (or hub) to the host (or a hub).
<b>USB IF</b>	USB Implementers Forum. The governing organization that develops and maintains the USB specifications and compliance standard. <a href="http://www.usb.org">http://www.usb.org</a>
<b>xHC</b>	Host Controller, designates the USB hardware that implements the xHCI specification.
<b>xHCI</b>	eXtensible Host Controller Interface. The specification that defines the register level interface for host controller.

**12.2.3.2 USB Environment**

This chapter details the USB subsystem environment.

[Table 12-128](#) describes the external signals of the USB3SS0 subsystem.

**Table 12-128. USB3SS Input/Output Description**

Device Pin	I/O <sup>(1)</sup>	Description
DP	I/O	USB2.0 data pins. These are HS/FS/LS bidirectional differential data lane (D+/D-)
DM	I/O	
SSRX1P (SSRX2P)	I	USB3.0 differential data receive lane (RX+ pin)
SSRX1N (SSRX2N)	I	USB3.0 differential data receive lane (RX- pin)
SSTX1P (SSTX2P)	O	USB3.0 differential data transmit lane (TX+ pin)
SSTX1N (SSTX2N)	O	USB3.0 differential data transmit lane (TX- pin)
REXT	A/I	USB3.0 SerDes external calibration resistor. Requires a 3.01 kOhm $\pm 1\%$ accurate off-chip resistor connected from this pin to ground.
ID	A/I	USB cable identifier (A/B-device). Analog ID pin sense with internal pull-up
VBUS	A/I	An 3.3-V analog input for monitoring the voltage on VBUS (VBUS sense). 5-V VBUS must be applied via an external resistive divider /3. For example, R1 = 20 kOhm and R2 = 10 kOhm
DRVVBUS	O	A digital output signal for VBUS Power Supply Enabling. Used to enable an external charge pump or power switch to supply +5V power to the VBUS port, when appropriate
RCALIB	A/I	External resistor for USB2.0 PHY calibration. Requires a 500 Ohm $\pm 1\%$ off-chip resistor connected from this pin to ground

(1) I = Input; O = Output; A = Analog

### 12.2.3.3 USB Functional Description

#### Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

The USB3SS subsystem contains the USB3.0 Dual Role Device (DRD) controller module and a USB2.0 PHY module. A wrapper module is controlling some top-level functions like Host and Device role switch and reset release.

The USB controller uses USB2PHY for USB2.0 operation and one of the device SERDESes for USB3.0 speeds. The SERDES also contains lane swap feature for USB Type-C plug flipping support.

#### 12.2.3.3.1 USB Type-C Connector Support

Lane swapping for Type-C connector support is performed within the SERDES wrapper module. Type-C CC detection and configuration has to be performed by external ICs. Type-C device attachment/detachment and cable orientation have to be communicated using I2C, GPIO, or a similar method.

For USB Type-C support, the SERDES wrapper and SERDES must be programmed for USB protocol on lane 0, lane 1, and/or lane2, and lane 3. Software must hold PHY in reset and then write to the LN10\_SWAP and/or LN23\_SWAP bit of the to mux the PIPE interface to the other lane. Also the SuperSpeed port in the controller has to be in disabled state when programming LN10\_SWAP or LN23\_SWAP.

#### 12.2.3.3.2 USB Controller Reset

USB controller has three resets going in, called preset\_n, pwrup\_rst\_n, and aresetn.

- preset\_n comes from the mod\_g\_rst\_n input coming from LPSC
- pwrup\_rst\_n is PWRUP\_RST\_N register bit in the USB wrapper module (USB3P0SS\_W1). This reset has to be deasserted before accessing controller registers. The default value for pwrup\_rst\_n is 0 (reset asserted). This reset goes to the default asserted state when mod\_g\_rst\_n reset is asserted.
- areset\_n comes from PWRUP\_RST\_N register bit, but the deassertion is synchronized to ACLK.

#### 12.2.3.3.3 Overcurrent Detection

The overcurrent detection circuit is external to the device. Software must specify an overcurrent condition to the controller whenever the overcurrent signal is received from the detection circuit. Software must set the OVERCURRENT\_N bit to 0 in the USB3P0SS\_W1 register when overcurrent was detected.

#### 12.2.3.3.4 Top-Level Initialization Sequence

The following initialization sequence has to be followed before configuring the controller for USB operation:

1. Software must select and configure the SERDES for USB operation. Some of the registers are shown in . Refer to *Serializer/Deserializer (SerDes)* for more details. USB2.0 PHY contains default configuration that normally does not need change.
2. Software must configure the pseudo-static settings in USB3P0SS\_W1 register
3. Software must set PWRUP\_RST\_N to 1 in order to deassert controller reset

After the above sequence, software can access controller registers.

## 12.2.4 Serializer/Deserializer (SerDes)

This section describes the Serializer/Deserializer (SerDes) in the device.

### 12.2.4.1 SerDes Overview

SerDes' goal is to convert device (SoC) parallel data into serialized data that can be output over a high-speed electrical interface. In the opposite direction, SerDes converts high-speed serial data into parallel data that can be processed by the device. To this end, the SerDes contains a variety of functional blocks to handle both the external analog interface as well as the internal digital logic.

Most important building blocks of SerDes are:

- Physical Media Attachment (PMA):
  - Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer, and Clock and Data Recovery (CDR) unit.
  - Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes, and muxes SerDes to peripherals.

#### 12.2.4.1.1 SerDes Features

The SERDES module features include:

- Quad lane PHY containing:
  - Transmit and Receive I/Os
  - Serializer
  - Deserializer
  - Clock and data recovery (CDR) unit
- Common Module (CMN)
  - PLLs
  - Master bias
  - Automatic calibration of pin termination resistors
  - Reference clock input buffers
  - Reset and startup management
- Physical Coding Sub-block (PCS)
  - USB3.1 Gen 1 (5 Gbps)
  - PCIe Gen 1 (2.5 Gbps), Gen 2 (5 Gbps), Gen 3 (8 Gbps)
  - Hyperlink (10 Gbps)
  - Display Port / Embedded Display port v1.4
  - Symbol alignment
  - Selectable serial pin polarity reversal for both transmit and receive paths
  - Bit stream reordering
- Physical Media Attachment (PMA) layer
  - Transmit equalization
  - Receive equalization
  - Data path BIST with programmable pattern generation and error detection
  - Serial bit stream and parallel word loopback for both line and parallel side
  - 8-bit ADC provides digitized ATB measurement results
  - Supports DC and AC JTAG (boundary scan) per IEEE 1149.6

The SERDES mux (WIZ) module supports the following features:

- Multiplexes device interfaces onto a single SERDES lane (Tx and Rx)
- Provides registers to implement SERDES control and status functions and alignment delays
- Clock generator block for providing MAC transmit clock
- Rx comma align block
  - Performs de-stuffing the Rx data stream in the event that the Rx rate is different from the Tx rate

- Supports comma detection that is not sensitive to false commas using all 8B/10B character combinations

#### **12.2.4.1.2 Not Supported Features**

All features described in this chapter are supported.

### 12.2.4.1.3 SerDes Ports

This section describes SerDes module ports related to clocks, resets, and hardware requests.

**Table 12-129. SerDes Clocks and Resets**

Clocks	
Module Clock Input	Description
SERDES_ICLK	VBUS interface clock
CMN_REFCLK_INT	Internal reference clock from device sources. Software selectable.
Resets	
Module Reset Input	Description
SERDES_RST	Serdes LPSC reset

**Table 12-130. SerDes Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
PHY_PWR_TIMEOUT_LVL_0	Lane power timeout interrupt	Level
DMA Events		
Module DMA Event	Description	Type
-	No PDMA channels to external DMA engines	-

### 12.2.4.1.4 Industry Standards Compatibility

All SerDes interfaces are configured as point-to-point connections. It is assumed that the connection is made between the SoC and another device that is compliant to the appropriate industry standard. The list of supported standards is given below.

This chapter deals with the physical layer and, therefore, it is the electrical specifications in these standards that are relevant. For more information regarding protocol compliance <sup>2</sup>, see the device-specific Datasheet.

- PCIe: This is electrically compliant with Base specification revision 4.0.
- USB: This is electrically compliant with USB 3.1.
- Hyperlink: Electrically compliant to OIF-CEI-11G-SR.
- Display Port/ Embedded Display Port VESA Standard v1.4

**Table 12-131. SerDes Supported Standards**

Standard	Bit Rate (Gbps)	Reference Clock Frequency (MHz)	Bus Width (bits)
PCI Express 4.0 Gen1	2.5	19.2, 24, 25, 26, 100	32
PCI Express 4.0 Gen2	5.0	19.2, 24, 25, 26, 100	32
PCI Express 4.0 Gen3	8.0	19.2, 24, 25, 26, 100	32
Hyperlink	10.0	19.2, 24, 25, 26, 100, 125	20
DP/eDP	1.62-8.1	19.2, 24, 25, 26	10
USB 3.1 Gen1 SuperSpeed	5.0	19.2, 24, 25, 26, 100	32

<sup>2</sup> Electrical compatibility does not guarantee interoperability with devices

## 12.2.4.2 SerDes Environment

### 12.2.4.2.1 SerDes I/Os

[Figure 12-77](#) shows the I/O interface signals of SERDES.

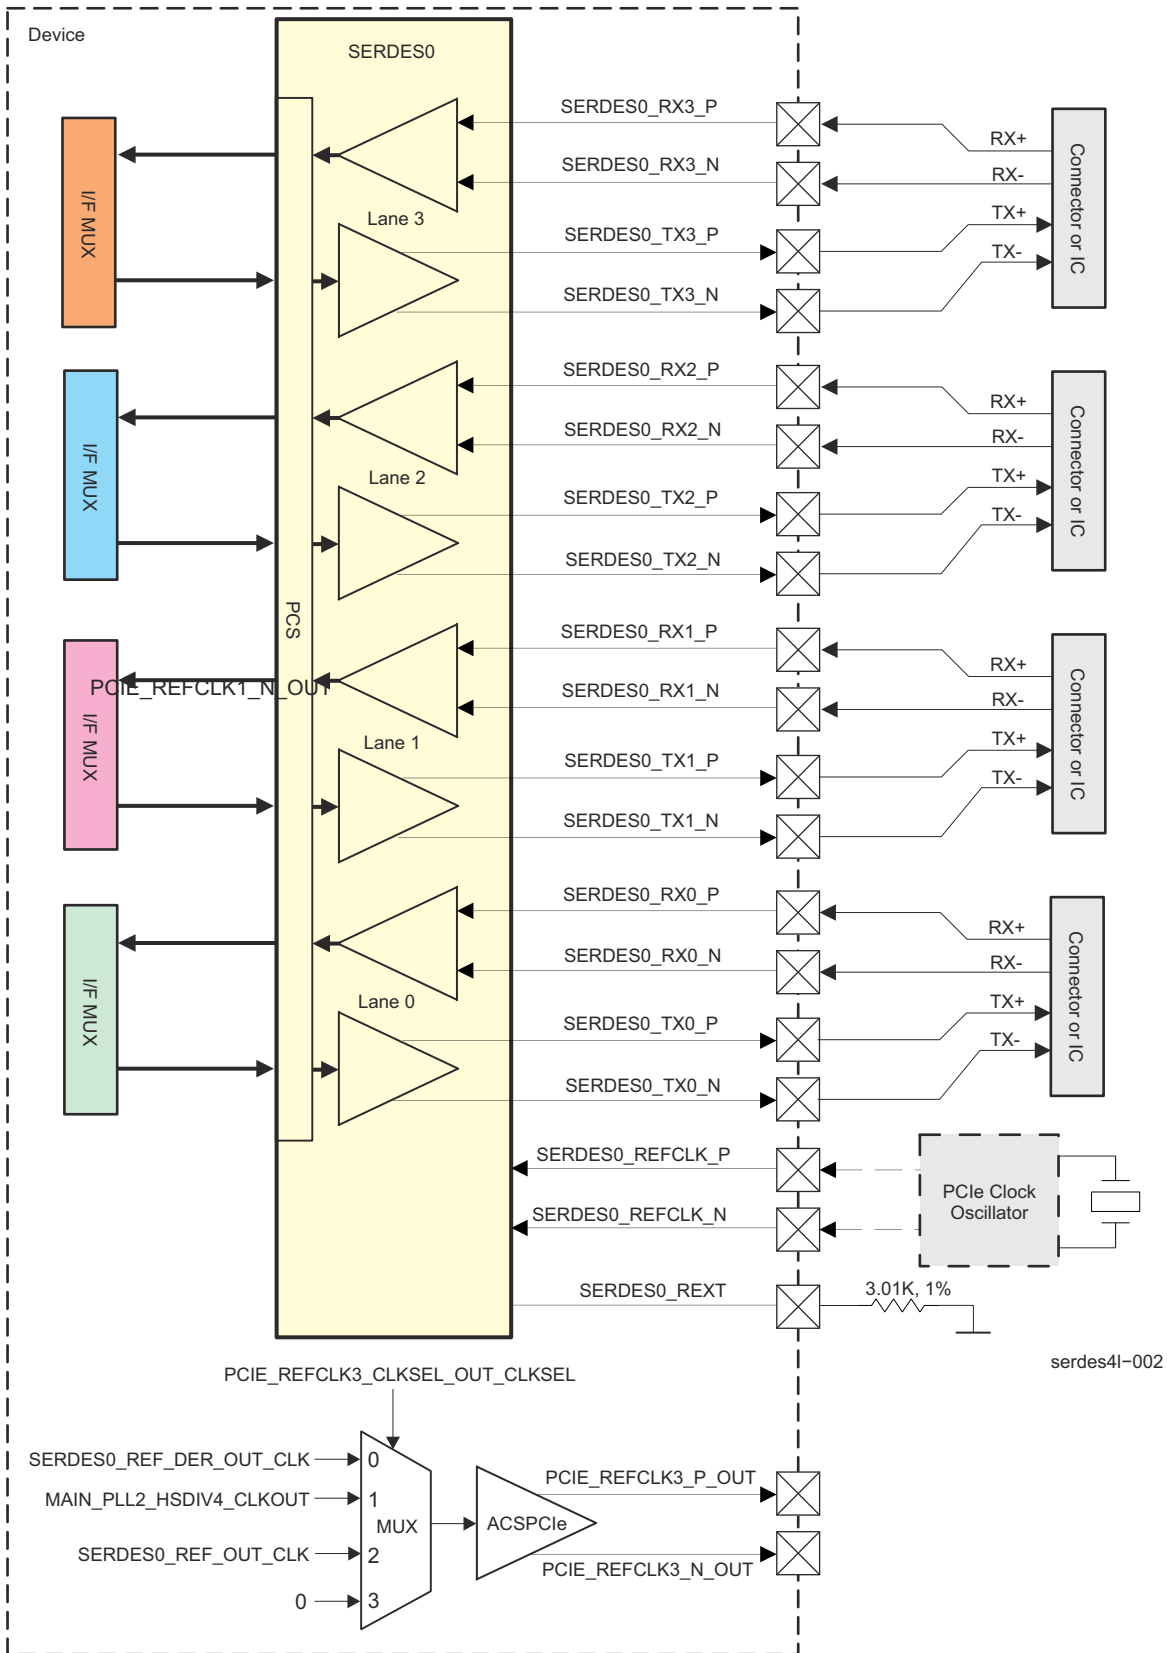

Figure 12-77. SerDes Environment

### Note

Although containing some of the basic external components, [Figure 12-77](#) must not be considered as an exhaustive guide for the PCB designer. TI provides additional documents for those who are willing to design PCBs and/or fine tune the SerDes.

[Table 12-132](#) describes the external signals of SERDES0 module.

**Table 12-132. SerDes Input/Output Description**

Device Pin	I/O <sup>(1)</sup>	Description
SERDES0_RX0_P	I	SerDes differential data receive pins. Lane 0
SERDES0_RX0_N	I	
SERDES0_TX0_P	O	SerDes differential data transmit pins. Lane 0
SERDES0_TX0_N	O	
SERDES0_RX1_P	I	SerDes differential data receive pins. Lane 1
SERDES0_RX1_N	I	
SERDES0_TX1_P	O	SerDes differential data transmit pins. Lane 1
SERDES0_TX1_N	O	
SERDES0_RX2_P	I	SerDes differential data receive pins. Lane 2
SERDES0_RX2_N	I	
SERDES0_TX2_P	O	SerDes differential data transmit pins. Lane 2
SERDES0_TX2_N	O	
SERDES0_RX3_P	I	SerDes differential data receive pins. Lane 3
SERDES0_RX3_N	I	
SERDES0_TX3_P	O	SerDes differential data transmit pins. Lane 3
SERDES0_TX3_N	O	
PCIE_REFCLK1_P_OUT	O	Serdes Internal reference clock Output
PCIE_REFCLK1_N_OUT	O	
SERDES0_REFCLK_P	I	SerDes external system reference clock
SERDES0_REFCLK_N	I	
SERDES0_REXT	A/I	PMA external calibration resistor. Requires a 3.01 kOhm $\pm 1\%$ accurate off-chip resistor connected from this pin to ground.

(1) I = Input; O = Output; A = Analog

### 12.2.4.3 SerDes Integration

This section describes SerDes module integration in the device, including information about clocks, resets, and hardware requests.

[Table 12-133](#) summarize the integration of SerDes in device MAIN domain.

**Table 12-133. SerDes Hardware Requests**

Interrupt Requests			
Module Instance	Module Interrupt Signal	Description	Type
SERDES0	PHY_PWR_TIMEOUT_LVL_0	Lane power timeout interrupt	Level
DMA Events			
Module Instance	Module DMA Event	Description	Type
SERDES0	-	No PDMA channels to external DMA engines	-

#### Note

For more information on the interconnects, see *System Interconnect*.

For more information on the power, reset and clock management, see the corresponding sections within *Device Configuration*.

### 12.2.4.3.1 WIZ Settings

This section describes the quasi-static settings that software must perform after global resets. These settings are made via registers in the CTRL\_MMR0 module. For CTRL\_MMR0 description, please refer to *Control Module (CTRL\_MMR)*.

#### 12.2.4.3.1.1 Interface Selection

SerDeses provide PHY functions for the following high-speed interfaces:

- DP/eDP
- PCIe1 (one- to four-lane)
- Hyperlink
- USB3.0 on lane 1 or 3. Lane 0 or 2 used for Type-C plug reversal feature.

Table 12-134 describes the interface combinations supported by SERDES0.

**Table 12-134. SERDES0 Supported Configurations**

Interface Alias	CTRLMMR_SERDES0_LN0_C TRL [1:0]	Interface on Lane 0	CTRLMMR_SERDES0_LN1_C TRL [1:0]	Interface on Lane 1	CTRLMMR_SERDES0_LN2_C TRL [1:0]	Interface on Lane 2	CTRLMMR_SERDES0_LN3_C TRL [1:0]	Interface on Lane 3
	LANE_FUNC_ SEL		LANE_FUNC_ SEL		LANE_FUNC_ SEL		LANE_FUNC_ SEL	
IP1	0x0	eDP0 Lane0	0x0	eDP0 Lane 1	0x0	eDP0 Lane 2/0	0x0	eDP0 Lane3/1
IP2	0x1	PCIe Lane0	0x1	PCIe Lane 1	0x1	PCIe Lane 2	0x1	PCIe Lane 3
IP3	0x2	.(1)	0x2	USB3_0	0x2	.(1)	0x2	USB3_0
IP4	0x3	Hyperlink Lane0	0x3	Hyperlink Lane 1	0x3	Hyperlink Lane 2	0x3	Hyperlink Lane 3

(1) Reserved for USB0 for type-C connector lane swap. That is, select this function if Type C was implemented in the design. See [Section 12.2.3, USB](#).

As seen in [Table 12-134](#), USB0 can be routed to two different lanes. To avoid routing to two lanes at the same time, an additional muxing exists.

[Table 12-135](#) describes the additional muxing for USB0 to lane 1 or to lane 3.

#### Note

Settings in [Table 12-135](#) must be aligned with the settings made in [Table 12-134](#).

**Table 12-135. USB0 Muxing to Serdes Lanes**

CTRLMMR_USB0_CTRL	
[27] SERDES_SEL	Lane Selected
0	Lane 1 (Lane 0 for Type-C)
1	Lane 3 (Lane 2 for Type-C)

#### 12.2.4.3.1.2 ACSPCIE Reference Clock Selection

[Table 12-136](#) describes the SERDES ACSPCIE reference clock selection. ACSPCIE buffer clk selection: Needs PCIE\_REFCLK1\_CLKSEL\_OUT\_CLK\_EN to be enabled for driving the clk out onto the ref clk pins.

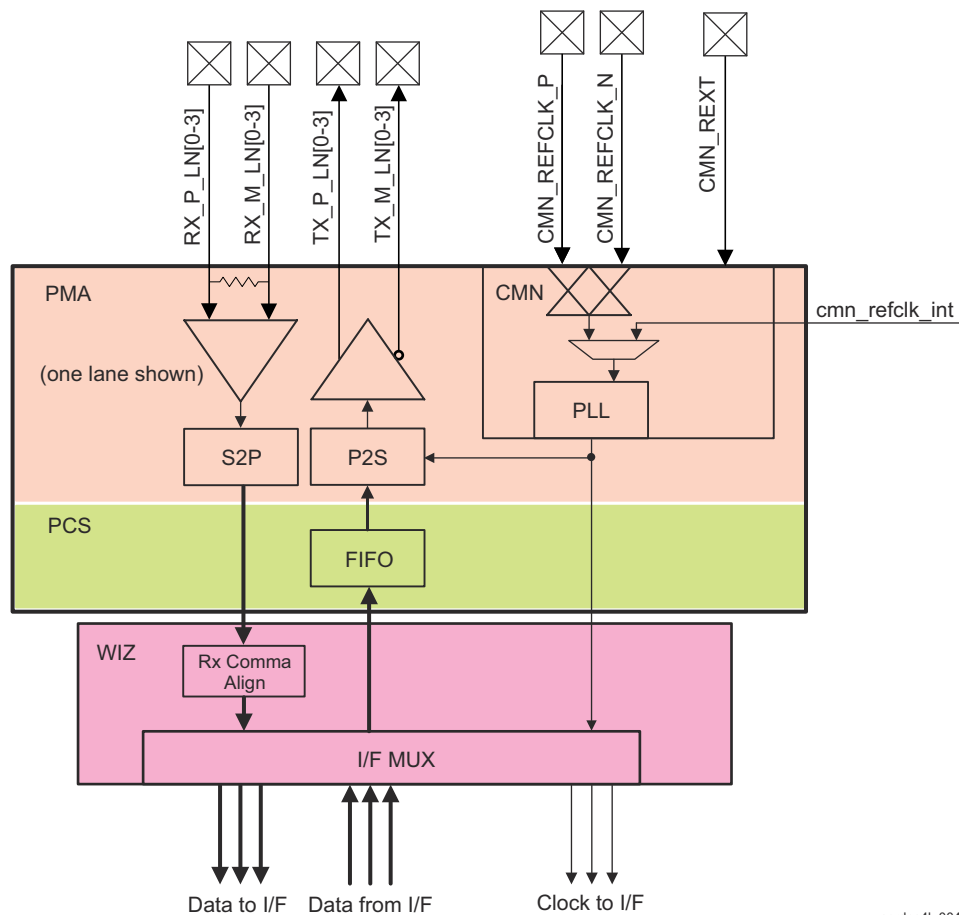

**Table 12-136. SerDes ACSPCIE Reference Clock Selection**

[1:0] CLK_SEL	ACSPCIE Clk Source
0x0	SERDES_REF_DER_OUT_CLK
0x1	MAIN_PLL2_HSDIV4_CLKOUT
0x2	SERDES0_REF_OUT_CLK
0x3	0

## 12.2.4.4 SerDes Functional Description

### 12.2.4.4.1 SerDes Block Diagram

Figure 12-78 is a top-level, non-exhaustive diagram of SerDes and WIZ wrapper. Note that only one (Tx + Rx) lane is shown.

**Figure 12-78. SerDes and WIZ Block Diagram**

Building blocks of SerDes include:

- Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer (P2S/S2P), and Clock and Data Recovery (CDR) unit. Each SerDes contains one Tx and Rx lane.
- Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Lanes and CMN are parts of the Physical Media Attachment (PMA) layer.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes (register interface), and muxes SerDes to peripherals (USB, PCIe, and others).

## 12.3 Memory Interfaces

This section describes the memory interfaces in the device.

### 12.3.1 Flash Subsystem (FSS)

This section describes the Flash Subsystem (FSS) in the device.

#### 12.3.1.1 FSS Overview

The Flash Subsystem (FSS) provides access to external flash devices via Octal SPI (OSPI) and HyperBus™ interface along with encryption/decryption, authentication, and in-line ECC protection.

The FSS includes two OSPI and one HyperBus interface. For more information, see *Octal Serial Peripheral Interface (OSPI)* and *HyperBus Interface*.

**Table 12-137. FSS Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MCU_FSS0	-	✓	-

The first FSS path (FSS0) has access to either OSPI0 or HyperBus interface and can be configured for ECC, authentication, or both. The second FSS path (FSS1) has access only to OSPI1 and can be configured with or without ECC.

**Figure 12-79. FSS Overview**

#### 12.3.1.1.1 FSS Features

The FSS has the following features:

- Two simultaneous flash interfaces:
  - Two OSPIs (OSPI0 and OSPI1) OR
  - One HyperBus interface and one OSPI (OSPI1)
- Primary OSPI0/HyperBus interface supports:
  - Execute in place (XIP) operation
  - 32-byte block copy (BC) operation
  - Prefetch for two XIP flows to improve performance from external flash device
- Secondary OSPI1 interface supports:
  - 32-byte block copy (BC) operation
  - ECC
- OSPIs support single, dual, quad, or octal SPI devices
- OSPIs support up to 4 devices
- HyperBus interface supports up to 2 devices
- The OSPIs and HyperBus interface have independent power management for low power operations

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.3.1.1.2 FSS Not Supported Features

- DMA for INDAC is not supported for OSPI0

#### 12.3.1.1.3 Flash Ports

**Table 12-138. MCU\_FSS0 Clocks and Resets**

Clocks	
Module Clock Input	Description
MCU_FSS_ICLK	MCU_FSS Interface Clock
Resets	
Module Reset Input	Description
MCU_FSS_RST	MCU_FSS System Reset

**Table 12-139. MCU\_FSS0 Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCU_FSS_ECC_ERR_INT	MCU_FSS ECC Error Interrupt	Level

**12.3.1.2 FSS Environment**

[Table 12-140](#) describes the MCU\_FSS0 I/O signals.

**Table 12-140. MCU\_FSS0 I/O Signals**

FSS Interface	I/O Signals
OSPIs (OSPI0 and OSPI1)	For more information about OSPIs I/O signals, see <i>OSPI Environment</i> .
HyperBus interface	For more information about HyperBus interface I/O signals, see <i>HyperBus Environment</i> .

### 12.3.1.3 FSS Functional Description

#### 12.3.1.3.1 FSS Block Diagram

The FSS provides access to external Flash and RAM devices. It supports XIP (Execute-in-Place) and BC (Block Copy) operations.

The FSS consists of two OSPIs and one HyperBus interface. There are two FSS paths - FSS0 and FSS1 (see ). The first path (FSS0) includes OSPI0 and HyperBus interface. The second path (FSS1) includes OSPI1. These two FSS paths can be used simultaneously (see *FSS Typical Application*).

Table 12-141 shows the FSS allowed interface combinations.

**Table 12-141. FSS Allowed Interface Combinations**

Combination	Primary Interface (FSS0)	Secondary Interface (FSS1)
1.	OSPI0 (MCU_FSS0_OSPI0)	Not Used
2.	HyperBus Interface (MCU_FSS0_HPB0)	Not Used
3.	OSPI0 (MCU_FSS0_OSPI0)	OSPI1 (MCU_FSS0_OSPI1)
4.	HyperBus Interface (MCU_FSS0_HPB0)	OSPI1 (MCU_FSS0_OSPI1)
5.	Not Used	OSPI1 (MCU_FSS0_OSPI1)

Figure 12-80 shows the FSS block diagram.

fss\_004

**Figure 12-80. FSS Block Diagram**

FSS Blocks:

- **MCU\_CBASS0:** The MCU\_CBASS0 interconnect allows FSS to communicate with the device modules and subsystems.
- **Data Interface (FSS0):** It is 64-bit data/32-bit address multi issue data interface with coherent in-band bypass. It provides accessibility to either the OSPI0 or HyperBus interface.
- **Data Interface (FSS1):** It is 64-bit data/32-bit address multi issue data interface with coherent in-band bypass. It provides accessibility to the OSPI1.
- **Config Interface:** It is used for configuration of the memory mapped registers within the FSS.
- **Interface Clock and Reset:**
  - For more information, see *MCU\_FSS0 Clocks and Resets*.
  - For more information, see *MCU\_FSS0\_OSPI Clocks and Resets*.
  - For more information, see *MCU\_FSS0\_HPB0 Clocks and Resets*.

- **Memory Mapped Registers:** This block conditionally includes registers from the following blocks: FSS, ECC, MUX, and DF. The configuration of these registers defines which combination of FSS interfaces is selected (see [Table 12-141](#)) and also which FSS features and operation modes are used. For more information, see `MCU_FSS0_SYSCONFIG`.
- **MUX:** The Muxing (MUX) block is used as a software controlled switch in the primary FSS (FSS0) interface. It defines which interface to be used (OSPI0 or HyperBus interface). The MUX block can switch only when the traffic is idle. The software has responsibility to cause the traffic to be stopped.
- **DF:** The Dynamic Fragmenter (DF) module is responsible for fragmenting write data to the flash region so that all writes to the flash region are done in 16-bits chunks (a requirement for HyperFlash). It passes all other transaction through unaffected.
- **FSS Interfaces:**
  - `MCU_FSS0_OSPI0`: The OSPI0 is part of the primary FSS interface (FSS0). It can be configured to use ECC and/or OTFE module.
  - `MCU_FSS0_OSPI1`: The OSPI1 is part of the secondary FSS interface (FSS1). It can be configured with or without ECC.
  - `MCU_FSS0_HPB0`: The HyperBus interface is part of the primary FSS interface (FSS0). It can be configured to use ECC and/or OTFE module.
- **FSS I/O Pins:**
  - **OSPI1 I/O Pins:** All used `MCU_FSS0_OSPI1` interface pins (for more information, see *OSPI I/O Signals*).
  - **HyperBus I/O Pins:** All used `MCU_FSS0_HPB0` interface pins (for more information, see *HyperBus I/O Signals*).

#### 12.3.1.3.2 FSS ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

For more information about ECC, refer to *ECC Aggregator*.

For FSS1 path when the stand-alone ECC module is used:

- The input for the ECC module is 32-byte data block.
- The ECC module generates ECC codes for the 32-byte data block.
- The ECC module packs data + ECC, reformats the address and sends this to the flash controller (OSPI1 flash controller).

For more information, see *ECC Calculation*.

#### 12.3.1.3.3 FSS Modes of Operation

[Table 12-141](#) presents the possible combinations of FSS interfaces.

Both paths (FSS0 and FSS1) support XIP and BC modes.

#### 12.3.1.3.4 FSS Memory Regions

[Table 12-142](#) shows the FSS memory regions.

**Table 12-142. FSS Memory Regions**

Address Range		Size	Description
FSS0 (HyperBus interface or OSPI0)	FSS1 (OSPI1)		
0x04 0000 0000 to 0x04 FFFF FFFF	0x06 0000 0000 to 0x06 FFFF FFFF	4 GB	External Memory Space (Region 0)
0x00 5000 0000 to 0x00 57FF FFFF	0x00 5800 0000 to 0x00 5FFF FFFF	128 MB	Boot Space (Region 1)
0x05 0000 0000 to 0x05 FFFF FFFF	0x07 0000 0000 to 0x07 FFFF FFFF	4 GB	External Memory Space (Region 3)

#### 12.3.1.4 FSS Programming Guide

##### 12.3.1.4.1 FSS Initialization Sequence

Initialization steps:

- Configure the main boot parameters for FSS0 or FSS1):

- Select the boot block to be used.
- Select the size of the boot block to be used.
- Enable FSS in PSC.
- Configure the FSS interface which will be used:
  - For FSS0 - OSPI0 or HyperBus interface.
  - For FSS1 - OSPI1.
- Enable the selected FSS interface in PSC.
- Configure the FSS interface:
  - For more information about OSPI configuration, please see *Octal Serial Peripheral Interface (OSPI)*.
  - For more information about HyperBus interface configuration, please see *HyperBus Interface*.
- Configure the ECC region start address and size:
  - MCU\_FSS0\_ECC\_RGSTRT\_j
  - MCU\_FSS0\_ECC\_RGSIZ\_j
- Enable the ECC option if the target flash device has ECC encoded within.
- If the target device is HyperFlash/SRAM configure fragmentation address boundary:
  - Flash device requires fragmentation.
  - SRAM device does not require fragmentation.
- Enable error interrupts (see MCU\_FSS0\_ENABLE\_SET).

#### 12.3.1.4.2 FSS Real-Time Operation

In the event of an ECC single error detect, the 32-byte block address and associated error bits are stored and an interrupt is generated (if enabled). The CPU can then service the interrupt and determine the error type. If a single error occurs, the CPU can scrub the flash block to determine if the error is permanent and requires reprogramming.

In the event of an ECC double error detect, the 32-byte block address and associated error bits are stored and an interrupt is generated (if enabled). The CPU can then service the interrupt and determine the error type. If the double error detect is within the flash, the region is corrupt and have to be treated as unused.

#### 12.3.1.4.3 FSS Power Up/Down Sequence

There are four PSC controls for the FSS: the FSS itself, OSPI0, HyperBus interface, and OSPI1. The CPU enables the appropriate interfaces before using FSS0 or FSS1 of the FSS.

The FSS0 can be used for HyperBus interface or OSPI0 and only the interface in use has to be enabled. Software should ensure the selected interface is enabled prior to FSS0 transactions.

The FSS1 can only be used to access OSPI1. The FSS1 transaction may be blocked depending on the power state of the OSPI1.

Normal Power Down Sequence:

- Block any new transaction to the particular interface - FSS0 or FSS1.
- Power down the target FSS interface.
- In the event when all targets are powered down, the FSS can then be powered down.

### 12.3.2 Octal Serial Peripheral Interface (OSPI)

This section describes the Octal Serial Peripheral Interface (OSPI) module for the device.

#### 12.3.2.1 OSPI Overview

The Octal Serial Peripheral Interface (OSPI) module is a kind of Serial Peripheral Interface (SPI) module which allows single, dual, quad or octal read and write access to external flash devices.

The OSPI module is used to transfer data, either in a memory mapped direct mode (for example a processor wishing to execute code directly from external flash memory), or in an indirect mode where the module is set-up to silently perform some requested operation, signaling its completion via interrupts or status registers. For indirect operations, data is transferred between system memory and external flash memory via an internal SRAM which is loaded for writes and unloaded for reads by a device master at low latency system speeds. Interrupts or status registers are used to identify the specific times at which this SRAM should be accessed using user programmable configuration registers.

##### 12.3.2.1.1 OSPI Features

The OSPI modules have the following features:

- Support for single, dual, quad (QSPI mode) or octal (on MCU\_FSS0\_OSPI0 only) I/O instructions.
- Support dual Quad-SPI mode for fast boot applications.
- Memory mapped 'direct' mode of operation for performing flash data transfers and executing code from flash memory.
- Software triggered 'indirect' mode of operation for performing low latency and non-processor intensive flash data transfers.
- Local SRAM of configurable size to reduce advanced high-performance bus overhead and buffer flash data during indirect transfers.
- Set of software advanced peripheral bus accessible flash control registers to perform any flash command, including data transfers up to 8-bytes at a time.
- Additional addressable memory bank to accommodate more than 8-bytes at a time.
- Support for XIP, sometimes referred to as continuous mode.
- Support for DDR Mode and DTR protocol (including Octal DDR protocol with DQS for Octal-SPI devices)
- Programmable device sizes.
- Programmable write protected regions to block system writes from taking effect.
- Programmable delays between transactions.
- Legacy mode allowing software direct access to low level transmit and receive FIFOs, bypassing the higher layer processes.
- An independent reference clock to decouple bus clock from SPI clock – allows slow system clocks.
- Programmable baud rate generator to generate OSPI clocks.
- Features included to improve high speed read data capture mechanism.
- Option to use adapted clocks or DQS to further improve read data capturing.
- Programmable interrupt generation.
- Up to four external device selects - OSPI and QSPI devices can be mixed:
  - MCU\_FSS0\_OSPI0 has four chip-selects
  - MCU\_FSS0\_OSPI1 has two chip-selects.
- Programmable data decoder, enables continuous addressing mode for each of the connected devices and auto-detection of boundaries between devices.
- Support BOOT mode.
- Bidirectional CRC on Multiple-SPI interface.
- Handling ECC errors for flash devices with embedded correction engine.
- Full integration with PHY module dedicated to more flexible and power efficient transfers.
- MCU\_FSS0\_OSPI0 supports RESET\_OUT[1-0] and ECC\_FAIL pins for external flash devices where ECC is checked on the flash.
- Automatic Flash device status polling for programming operation (Auto HW Polling)

##### 12.3.2.1.2 OSPI Not Supported Features

The following features are not supported on this family of devices:

- OSPI1\_D[7-4] are not pinned out.
- OSPI1\_SCn[3-2] are not pinned out.
- Pulse events not used.
- In Octal-SPI and Quad-SPI mode, Mode 1, 2, and 3 are not supported.
- Flash device status polling for programming operation using STIG

#### 12.3.2.1.3 OSPI Ports

**Table 12-143. MCU\_FSS0\_OSPI Clocks and Resets**

Clocks	
Module Clock Input	Description
OSPI_HCLK	MCU_FSS0_OSPI data transfer clock
OSPI_PCLK	MCU_FSS0_OSPI configuration clock
OSPI_RCLK	MCU_FSS0_OSPI Reference clock. Mux controlled by CTRLMMR_MCU_OSPI0_CLKSEL[0] CLK_SEL in <i>Control Module (CTRL_MMR)</i>
Resets	
Module Reset Input	Description
MCU_FSS0_OSPI_RST	MCU_FSS0_OSPI reset

**Table 12-144. MCU\_FSS0\_OSPI Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCU_FSS0_OSPI_LVL_INTR_0	MCU_FSS0_OSPI interrupt	Level
MCU_FSS0_OSPI_0_OSPI_ECC_CORR_LVL_INTR_0	MCU_FSS0_OSPI ECC correctable error interrupt	Level
MCU_FSS0_OSPI_0_OSPI_ECC_UNCORR_LVL_INTR_0	MCU_FSS0_OSPI ECC uncorrectable error interrupt	Level

#### 12.3.2.2 OSPI Environment

This section describes the OSPI external connections (environment).

[Table 12-145](#) lists and describes the MCU\_FSS0\_OSPI I/O signals.

**Table 12-145. OSPI I/O Signals**

Module Pin	I/O <sup>(1)</sup>	Description
DQ0	IO	MCU_FSS0_OSPI0 data input/output 0
DQ1	IO	MCU_FSS0_OSPI0 data input/output 1
DQ2	IO	MCU_FSS0_OSPI0 data input/output 2
DQ3	IO	MCU_FSS0_OSPI0 data input/output 3
DQ4	IO	MCU_FSS0_OSPI0 data input/output 4
DQ5	IO	MCU_FSS0_OSPI0 data input/output 5
DQ6	IO	MCU_FSS0_OSPI0 data input/output 6
DQ7	IO	MCU_FSS0_OSPI0 data input/output 7
N_SS_OUT0	O	MCU_FSS0_OSPI0 external flash device chip select 0
N_SS_OUT1	O	MCU_FSS0_OSPI0 external flash device chip select 1
N_SS_OUT2	O	MCU_FSS0_OSPI0 external flash device chip select 2
N_SS_OUT3	O	MCU_FSS0_OSPI0 external flash device chip select 3
OCLK	O	MCU_FSS0_OSPI0 clock output for the external flash device
	O	MCU_FSS0_OSPI0 external loopback output
DQS	I <sup>(2)</sup>	MCU_FSS0_OSPI0 data strobe / external loopback input
RESET_OUT0	O	MCU_FSS0_OSPI0 reset output 0 for the external flash device
RESET_OUT1	O	MCU_FSS0_OSPI0 reset output 1 for the external flash device
ECC_FAIL	I	MCU_FSS0_OSPI0 ECC status from the external flash device

**Table 12-145. OSPI I/O Signals (continued)**

Module Pin	I/O <sup>(1)</sup>	Description
DQ0	IO	MCU_FSS0_OSPI1 data input/output 0
DQ1	IO	MCU_FSS0_OSPI1 data input/output 1
DQ2	IO	MCU_FSS0_OSPI1 data input/output 2
DQ3	IO	MCU_FSS0_OSPI1 data input/output 3
N_SS_OUT0	O	MCU_FSS0_OSPI1 external flash device chip select 0
N_SS_OUT1	O	MCU_FSS0_OSPI1 external flash device chip select 1
OCLK	O	MCU_FSS0_OSPI1 clock output for the external flash device
	O	MCU_FSS0_OSPI1 external loopback output
DQS	I <sup>(2)</sup>	MCU_FSS0_OSPI1 data strobe / external loopback input

(1) I = Input; O = Output

(2) When used as an external loopback input, the DQS signal can alternatively be referred to as LBCLKI. The LBCLKI clock input signal is a looped back version of the LBCLKO clock output signal and facilitates easier timing closure at higher speeds. The loopback has to be at board level in order to support higher OSPI speeds. The source of the loopback clock is defined by CTRLMMR\_MCU\_OSPIn\_CLKSEL[4] LOOPCLK\_SEL bit in *Control Module (CTRL\_MMR)*.

### 12.3.2.3 OSPI Functional Description

#### 12.3.2.3.1 OSPI Block Diagram

Figure 12-81 shows the OSPI module block diagram.

**Figure 12-81. OSPI Block Diagram**

The OSPI module is composed of three main blocks. The first one is the OSPI controller, the second one is the low level SPI protocol controller, and the third one is the integrated PHY.

The OSPI module has the following two slave interfaces:

- Data slave interface intended for data transfer.
- Configuration slave interface intended for accessing the programmable set of registers.

##### 12.3.2.3.1.1 Data Slave Interface

The data interface is used for data transfer to external flash devices in direct and indirect mode of operation. The data slave controller validates incoming data accesses, responds to invalid requests, performs any required byte and halfword reordering, blocks writes that violate the programmed write protection rules (only for direct access) and forwards the transfer request to either the direct access controller (DAC) or the indirect access controller (INDAC).

The data interface bus is 32-bits wide. Therefore only byte, halfword and word accesses are permitted. When the controller is configured to work in SPI Octal DDR Mode or Octal DDR Protocol (where 2 bytes are collected within single SPI clock cycle what exceeds the size of 1 byte transfer request), 8 bit transfer size is not allowed.

**Note**

Cache line wrap accesses over the data slave port should be word aligned.

Data slave port doesn't support cache line wrap bursts of 128 bytes.

**12.3.2.3.1.2 Configuration Slave Interface**

The configuration interface is used to configure the OSPI module and perform software controlled flash accesses using the OSPI\_FLASH\_CMD\_CTRL\_REG register (for more information refer to [Section 12.3.2.3.11, Software Triggered Instruction Generator \(STIG\)](#)). Depending on the address it routes the incoming interconnect transfer to the Low level SPI protocol controller or to the ECC aggregator. The configuration port is also used to interact with the OSPI configuration and SRAM ECC registers.

**Note**

The configuration interface supports only 32-bit accesses. For single byte or halfword manipulations software should perform read-modify-write operations.

**12.3.2.3.1.3 OSPI Clock Domains**

The OSPI module has two main clock sources for the Octal-SPI controller.

- For interface clocks
- For reference clock

The source for the interface clocks corresponds to the configuration and data buses. The data bus clock (OSPI\_HCLK) is the main system clock used to transfer data over the data bus between a master on the system interconnect and the OSPI module. The data bus clock also drives the internal OSPI SRAM. The configuration bus clock (OSPI\_PCLK) is used to access the OSPI configuration register and perform basic configuration and for interrupt handling. The OSPI reference clock (OSPI\_RCLK) drives the SPI transmit and receive logic in the OSPI module. It is also used to generate the output SPI protocol clock (OSPI\_OCLK) and for oversampling of the input data. Using the reference clock (OSPI\_RCLK) allows the OSPI module to decouple the frequency of the SPI flash device from the device system clocks, thereby providing more flexible clocking solution.

**Note**

There is no particular clock ratio requirement between configuration (OSPI\_PCLK) and data bus (OSPI\_HCLK) clocks.

**12.3.2.3.2 OSPI Modes****Note**

Some of the OSPI features described in this section may not be supported on this family of devices. For more information, see *OSPI Not Supported Features*.

The OSPI module supports four SPI modes. These modes are defined through the OSPI\_CONFIG\_REG[1] SEL\_CLK\_POL\_FLD and OSPI\_CONFIG\_REG[2] SEL\_CLK\_PHASE\_FLD bits. The SEL\_CLK\_POL\_FLD bit defines the clock polarity and the SEL\_CLK\_PHASE\_FLD bit defines the data launch and data capture relation to the OSPI clock edges. [Table 12-146](#) gives a brief description of these modes.

**Table 12-146. OSPI Modes**

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
0	0	0	Clock inactive state: low Data launch edge: clock falling edge Data capture edge: clock rising edge
1	0	1	Clock inactive state: low Data launch edge: clock rising edge Data capture edge: clock falling edge

Table 12-146. OSPI Modes (continued)

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
2	1	0	Clock inactive state: high Data launch edge: clock rising edge Data capture edge: clock falling edge
3	1	1	Clock inactive state: high Data launch edge: clock falling edge Data capture edge: clock rising edge

Octal flash devices provide DQS signal which allows source synchronous capture, but for Quad flash devices the OSPI module has a loopback mode. In this loopback mode the clock, looped back at board level, is used for registering the input data, and the edge used is same as the launch edge, thus giving a full cycle path (for more information, see *Read Data Capture*).

#### 12.3.2.3.2.1 Read Data Capture

Figure 12-82 shows the Read Data Capture Logic in the OSPI module.

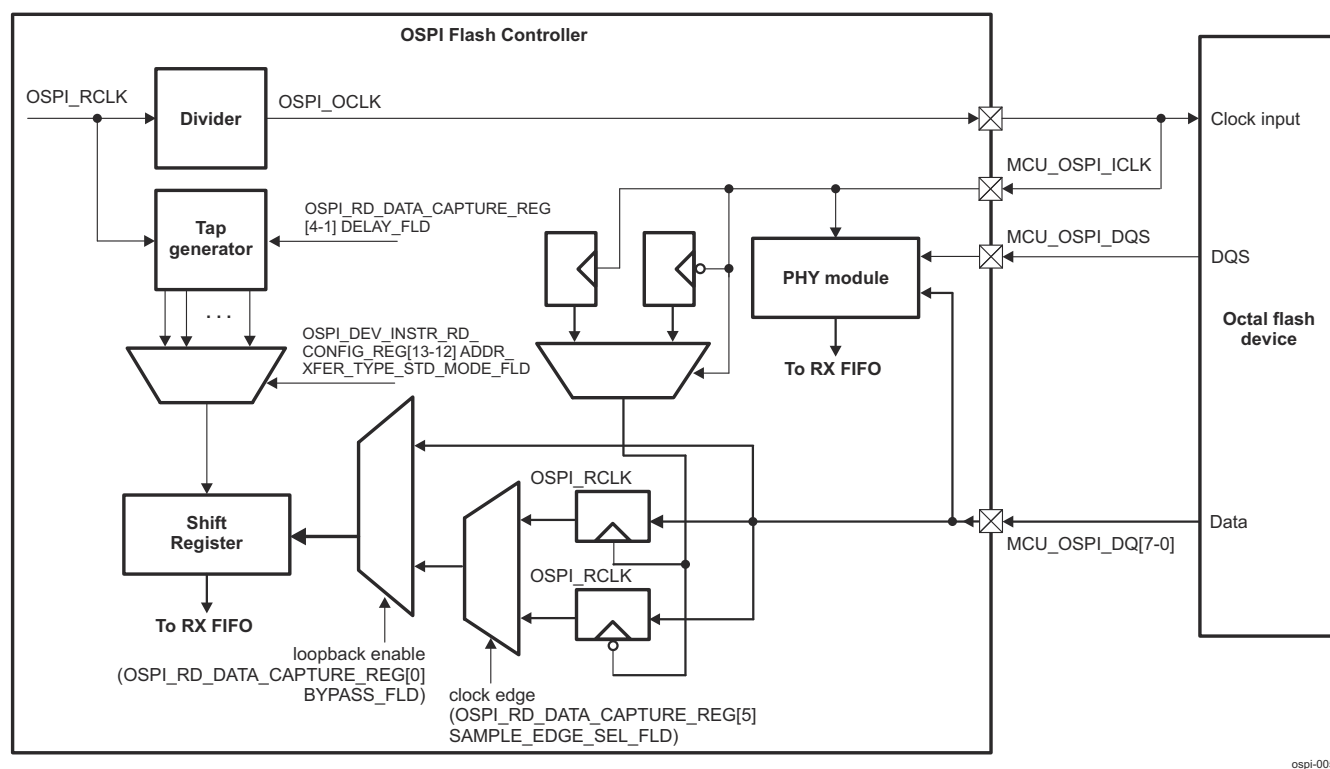

Figure 12-82. Read Data Capture Logic

The PHY module includes a DLL which allows adjustment of the sampling edge with respect to the incoming data to achieve maximum frequency. There are three sources for the sampling signal:

- The reference clock
- Output SPI clock external loopback
- The DQS (only available in Octal Flash devices)

The loopback mode (only for Quad flash devices) can work in two cases. The first one is when OSPI\_CONFIG\_REG[2] SEL\_CLK\_PHASE\_FLD=0. When SEL\_CLK\_PHASE\_FLD=1 there aren't enough clock falling edges for the register pipeline to catch the last data driven, thus causing a functional failure. Additionally, since the capture edge is falling edge, it gives a full cycle input path only in SPI mode 0, that is when SEL\_CLK\_POL\_FLD=0 and SEL\_CLK\_PHASE\_FLD=0. Thus SPI mode 0 is the first of two modes that support high MHz operation (greater than 50 MHz). The second mode is when SEL\_CLK\_PHASE\_FLD=1 and

SEL\_CLK\_PHASE\_FLD=1 (SPI mode 3). In this case the missing clock falling edge is compensated inside the OSPI controller when using the incorporated PHY module by inverting the loopback clock.

The loopback mode is enabled by writing 0x0 to OSPI\_RD\_DATA\_CAPTURE\_REG[0] BYPASS\_FLD. The taps are selected by programming OSPI\_RD\_DATA\_CAPTURE\_REG[4-1] DELAY\_FLD field. The taps delay the read data capturing logic by the programmed number of OSPI\_RCLK cycles.

#### 12.3.2.3.2.1.1 Mechanisms of Data Capturing

There are two mechanisms of data capturing in the OSPI module. They can be combined in some parts to ensure reliable sampling solution independent on the system requirements and the controller configuration. The mechanisms are as follows:

- Data capturing mechanism using taps
- Data capturing mechanism using PHY module.

#### 12.3.2.3.2.1.2 Data Capturing Mechanism Using Taps

This section describes the data capturing mechanism where sampling point is adjusted for one of the reference clock edges inside divided OSPI clock.

After POR, the adapted loopback clock circuit and the OSPI\_RCLK delay register line both wake in a disabled state. The OSPI\_RD\_DATA\_CAPTURE\_REG register provides the control for the mechanism using taps.

OSPI\_RD\_DATA\_CAPTURE\_REG[5] SAMPLE\_EDGE\_SEL\_FLD bit selects the edge of the reference clock, on which data outputs from flash memory are sampled.

OSPI\_RD\_DATA\_CAPTURE\_REG[4-1] DELAY\_FLD bit field controls the additional number of read data capture cycles (this is the fast reference clock, running at least x4 of the device clock) that should be applied to the internal read data capture circuit. The large clock-to-out delay of the flash memory together with trace delays as well as other device delays may impose a maximum flash clock frequency which is less than the flash memory device itself can operate at. To compensate, software shall set this register to a value that guarantees robust data captures.

#### 12.3.2.3.2.1.3 Data Capturing Mechanism Using PHY Module

PHY module is responsible for data capturing. More detailed description of all internal PHY sampling mechanisms is included in [Section 12.3.2.3.16.2, Read Data Capturing by the PHY Module](#).

#### 12.3.2.3.2.2 External Pull Down on DQS

Per the OSPI protocol, the FLASH device drives DQS while CS is asserted. When CS is not asserted the FLASH device presents HiZ on DQS. When configured to use DQS, the controller uses the DQS as a clock, which samples the incoming data into a FIFO. Noise on the DQS when it is HiZ can cause spurious false triggering of the FIFO and filling it with invalid data. There is no way to clear this data except to reset the OSPI module.

To avoid this issue, it is recommended to add a pull down on the DQS line.

During device wakeup, before the IO ring is configured properly, the CS to the FLASH device is HiZ. Depending on the actual level of the CS line the FLASH device might drive the DQS High, Low or HiZ. A pull down on DQS forces the DQS input to Low, but the DQS might still be High or in the presence of noise there might be transitions between Low and High. This again can cause the same issue of capturing garbage data in the Controller FIFO.

To avoid this issue it is recommended to release the OSPI from reset only after the IO ring is configured properly.

#### 12.3.2.3.3 OSPI Power Management

##### Note

The OSPI module does not provide any hardware signal for busy or idle status. Software need to ensure that the OSPI module is idle before clocks can be shut off by reading the OSPI\_CONFIG\_REG[31] IDLE\_FLD bit.

OSPI\_PCLK and OSPI\_HCLK share the same clock stop request/acknowledge and clock enable/acknowledge interface.

#### 12.3.2.3.4 Auto HW Polling

The OSPI controller is capable of automatically testing the Flash device busy bit to guarantee no reads or writes are ignored by the flash when it is busy burning in programmed data.

At the end of a programming transaction, the Flash device goes into a burn-in state and becomes busy.

When Auto HW Polling is enabled, the OSPI controller keeps track of programming transactions and will initiate a Flash status read polling transactions automatically, until Flash indicates it is not busy, before any additional data read or programming operations are sent to the flash device. See OSPI\_WRITE\_COMPLETION\_CTRL\_REG register and the associated registers.

The OSPI controller requires that the OSPI\_WRITE\_COMPLETION\_CTRL\_REG[23-16] POLL\_COUNT\_FLD field should always be set with values greater or equal to 3 ( $\geq 3$ ).

#### 12.3.2.3.5 Flash Reset

OSPI provides Flash reset out ports. These ports are active low and controlled thru OSPI\_CONFIG\_REG register.

#### 12.3.2.3.6 OSPI Memory Regions

[Table 12-147](#) shows the OSPI memory map in MCU domain.

**Table 12-147. OSPI Memory Map**

Address Range		Size	Description
MCU_FSS0_OSPI0	MCU_FSS0_OSPI1		
0x00 4704 0000 to 0x00 4704 0100	0x00 4705 0000 to 0x00 4705 0100	256 B	Configuration registers space
0x00 4704 4000 to 0x00 4704 4200	0x00 4705 4000 to 0x00 4705 4200	512 B	Global control registers space
0x00 4706 8000 to 0x00 4706 8400	0x00 4706 4000 to 0x00 4706 4400	1 KB	OSPI_ECC_AGGR registers space

#### Note

For more information about the memory space, see [Section 12.3.1.3.4, FSS Memory Regions](#).

#### 12.3.2.3.7 OSPI Interrupt Requests

The OSPI module generates three interrupts per instance. The ECC interrupts (MCU\_FSS0\_OSPI\_0\_OSPI\_ECC\_CORR\_LVL\_INTR\_0 and MCU\_FSS0\_OSPI\_0\_OSPI\_ECC\_UNCORR\_LVL\_INTR\_0 for MCU\_FSS0\_OSPI0; MCU\_FSS0\_OSPI\_1\_OSPI\_ECC\_CORR\_LVL\_INTR\_0 and MCU\_FSS0\_OSPI\_1\_OSPI\_ECC\_UNCORR\_LVL\_INTR\_0 for MCU\_FSS0\_OSPI1) are generated by the ECC aggregator.

The other interrupts (MCU\_FSS0\_OSPI0\_LVL\_INTR\_0 for MCU\_FSS0\_OSPI0 and MCU\_FSS0\_OSPI1\_LVL\_INTR\_0 for MCU\_FSS0\_OSPI1) are generated by the OSPI module.

[Table 12-148](#) lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

**Table 12-148. OSPI Events**

Event Flag	Event Mask	Description
OSPI_IRQ_STATUS_REG[0] MODE_M_FAIL_FLD	OSPI_IRQ_MASK_REG[0] MODE_M_FAIL_MASK_FLD	Event Flag and Event Mask for the OSPI Interrupts.

OSPI_ECC_AGGR_STATUS_CLR[3-2] TIMEOUT	OSPI_ECC_AGGR_ENABLE_CLR[1] TIMEOUT	

### 12.3.2.3.8 OSPI Data Interface

#### 12.3.2.3.8.1 Data Interface Address Remapping

The incoming data interface address, by default, maps directly to the address sent serially to the FLASH device. If the FLASH device has a 24-bit address, then the 24 LSB's of the data address is forwarded. A remap feature is available to remap all incoming data addresses to ADDRESS + N, where N is the value stored in the OSPI\_REMAP\_ADDR\_REG[31-0] VALUE\_FLD bit field. It is enabled via the OSPI\_CONFIG\_REG[16] ENB\_AHB\_ADDR\_REMAP\_FLD bit. This feature could be used when software needs to move boot code to another FLASH region.

#### 12.3.2.3.8.2 Write Protection

In order to protect the FLASH device, a software controlled write protection feature is supported. Any data write detected (by using DAC), pointing to an area of the FLASH that is protected, is not permitted.

A programmable region of the FLASH device, defined as a number of FLASH 'blocks' starting from a particular block number can be protected. Three programmable registers are provided. The first OSPI\_LOWER\_WR\_PROT\_REG register defines the FLASH block that is located at the bottom of the region to be protected. The second OSPI\_UPPER\_WR\_PROT\_REG register defines the FLASH block that is located at the top of the region to be protected. The third OSPI\_WR\_PROT\_CTRL\_REG register is a control register consisting of 2 bits. The OSPI\_WR\_PROT\_CTRL\_REG[0] INV\_FLD bit allows software to invert the region that is being protected, causing the programmed region to become the only areas of FLASH memory that is not protected from writes. The OSPI\_WR\_PROT\_CTRL\_REG[1] ENB\_FLD bit is the write protection enable bit. When this bit is set to 0, the FLASH device is unprotected.

For implementation, the data interface must map the incoming address into its associated FLASH block. A block can be between 1 and 65 KB, programmed via the OSPI\_DEV\_SIZE\_CONFIG\_REG register.

#### 12.3.2.3.8.3 Access Forwarding

For legal accesses, the data interface will forward all accesses to one of two access controllers - the direct access and the indirect access controllers. Assuming DAC has been enabled via the OSPI\_CONFIG\_REG[7] ENB\_DIR\_ACC\_CTRL\_FLD bit, then by default all accesses will be forwarded to this controller. Before any accesses can be forwarded to INDAC, it must first be configured by software. This process is fully explained in [Section 12.3.2.3.10, Indirect Controller \(INDAC\)](#). If DAC is disabled, any incoming access that cannot be forwarded to INDAC will be completed immediately with an error. If DAC is enabled, the same access will be forwarded and serviced by DAC.

### 12.3.2.3.9 OSPI Direct Access Controller (DAC)

Direct access refers to the operation where data interface accesses directly trigger a read or write to FLASH memory. It is memory mapped and can be used to both access and directly execute code from external FLASH memory. Any incoming access that is not recognized as being within the programmable indirect trigger region is assumed to be a direct access and will be serviced by the DAC. Note that accesses that use DAC do not use the embedded SRAM. The data transfer stops when read or write burst is carried out. The amount of wait states applied will be dependent on the latency through the controller. Latency is kept to a minimum when the use of XIP read instructions are enabled (see OSPI\_CONFIG\_REG[18] ENTER\_XIP\_MODE\_IMM\_FLD and OSPI\_CONFIG\_REG[17] ENTER\_XIP\_MODE\_FLD bits).

### 12.3.2.3.10 OSPI Indirect Access Controller (INDAC)

#### 12.3.2.3.10.1 Indirect Read Controller

The aim of the indirect mode of operation is to read significant numbers of bytes from FLASH memory without requiring a data interface access to trigger it. Instead indirect operations are controlled and triggered by software via specific control/configuration Indirect Read Transfer registers (OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG, OSPI\_INDIRECT\_READ\_XFER\_WATERMARK\_REG, OSPI\_INDIRECT\_READ\_XFER\_START\_REG, and OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG). This block will communicate with an embedded low level SPI protocol state machine module to perform an efficient and optimized FLASH read burst, placing the read data into the local SRAM module ready for fast and low latency delivery to any external master.

By default, the Indirect Read controller is disabled. Before enabling it, software must configure how much data is required and the start address. The start address and total number of bytes to be fetched is defined in OSPI\_INDIRECT\_READ\_XFER\_START\_REG and OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. For more information refer to [Section 12.3.2.3.10.3, Indirect Access Queuing](#).

The total number of bytes to read in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the size of requests. In the case of SRAM overrun, the controller will back pressure FLASH reads until space becomes available in the SRAM. Back pressuring the reads on the SPI interface is handled by completing any current read burst, waiting until space in the SRAM becomes available and then issuing a new read burst at the address where the previous terminated burst ended.

An external master will be able to fetch the data that the controller has read from external FLASH memory by issuing data interface reads to the OSPI module. The address of the incoming read access must be in the range of indirect trigger address programmed via the OSPI\_IND\_AHB\_ADDR\_TRIGGER\_REG register to indirect trigger address +  $2^{**}(\text{indirect trigger address range}) - 1$ . Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the indirect range to grant SRAM as source. Each valid Indirect Read will cause the internal SRAM to be popped, thereby decoupling the incoming read access address from the FLASH address – that is not direct mapped. Therefore the indirect trigger address does not have any relationship with the FLASH address. It is just to indicate that data should take the SRAM as source instead of the FLASH memory array after triggering of any valid Indirect Read. The FLASH address for Indirect Read is taken from the OSPI\_INDIRECT\_READ\_XFER\_START\_REG register. Assuming the requested data is present in the SRAM at the point the data interface access is received by the OSPI module, then the data will be fetched from the SRAM and the response to the read burst will be achieved with minimum latency. Once the data has been read from the SRAM, the OSPI module will free up the associated resource in the SRAM.

If a read access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a read access is received whose address is within the range described above but the requested data is not immediately present in the SRAM then wait states will be applied until the data has been read from FLASH and pushed to the SRAM.

If a read burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external master is only permitted to issue 32-bit data interface reads until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final read, the external master may issue a 16-bit (Halfword) or byte access to complete the transfer. It is also permitted for the external master to always issue a 32-bit Word read on the last indirect access. The controller will pad the upper bits of the response with zero. The current expectation is that the SRAM will be kept fairly full while the read operation is carried out. The fill level of the SRAM is directly readable by software reading the OSPI\_SRAM\_FILL\_REG register.

An indirect operation may be cancelled at any time by setting 1 to OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[1] CANCEL\_FLD bit.

Any bus master should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via configuration registers and then decide for itself when the data should be fetched from the local SRAM. The fill level watermark register (see OSPI\_INDIRECT\_READ\_XFER\_WATERMARK\_REG register) is provided. When the SRAM fill level passes this watermark, an interrupt is generated. If the watermark value is > 0, the watermark interrupt is also generated when the final byte of data has been read by the OSPI module and placed in the SRAM, even if the actual SRAM fill level has not risen above the watermark. This last feature is useful to avoid software tracking how much data has been read and resetting the watermark value for the last few bytes of an indirect read transfer.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an Indirect Read operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[0] START\_FLD bit starts an indirect read operation. OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[2] RD\_STATUS\_FLD bit is available to check the status.

#### **12.3.2.3.10.1 Indirect Read Transfer Process**

The following sequence can be followed:

1. Setup OSPI\_CONFIG\_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI\_INDIRECT\_READ\_XFER\_START\_REG register.
3. Setup the number of bytes to be transferred in the OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG register.
4. Setup the indirect transfer's trigger address in the OSPI\_IND\_AHB\_ADDR\_TRIGGER\_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI\_INDIRECT\_TRIGGER\_ADDR\_RANGE\_REG register.
6. If the watermark interrupt feature is to be used, set the OSPI\_INDIRECT\_READ\_XFER\_WATERMARK\_REG register which will cause an interrupt to be generated when the fill level increases beyond the watermark level. Setting the watermark can be useful indication to software when to read the next part of the indirect read transfer. Note that if the watermark is set to a value other than zero, the watermark interrupt will always trigger once the final byte of indirect transfer has been fetched and placed in the embedded SRAM, even if the watermark value is higher than the actual completed fill level.
7. Trigger Indirect Read access by setting the OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[0] START\_FLD bit to 1.
8. If the watermark interrupt feature is to be used, wait for watermark interrupt. Else poll the SRAM fill level via the OSPI\_SRAM\_FILL\_REG register to decide when sufficient data is in the SRAM to trigger data fetches.
9. Read the expected amount of data from SRAM. If there is still more data to fetch in order to complete the indirect read transfer, then loop back to step 8. Otherwise continue to step 10.
10. The completion status of the Indirect Read operation can be polled via the OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[5] IND\_OPS\_DONE\_STATUS\_FLD bit.
11. An Indirect Complete interrupt will be generated when the Indirect read operation has completed.

### 12.3.2.3.10.2 Indirect Write Controller

The aim of the indirect mode of operation is to perform bulk transfer of data from the processor into a FLASH memory in the most efficient manner. The fewest possible write cycles inside the FLASH device will be carried out for the indirect transfer, thus maximizing the life of the device. Indirect write operation can be thought of from a software perspective as the inverse of the indirect read. It is controlled and triggered by software via specific control/configuration Indirect Write Transfer registers (for more information see the following registers: OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG, OSPI\_INDIRECT\_WRITE\_XFER\_WATERMARK\_REG, OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG, and OSPI\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG). This block will await delivery of the write data via the external data interface master, placing it in the local SRAM before communicating with the existing legacy SPI core to perform an efficient and optimized FLASH write burst.

By default, the indirect write controller is disabled. Before enabling it, the software must configure how much data is required and the start address. The start address and total number of bytes to be written is defined in OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG and OSPI\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. The Indirect write queuing is very similar to indirect read queuing. For more information refer to [Section 12.3.2.3.10.3, Indirect Access Queuing](#).

The total number of bytes to write in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the amount of data that can be accepted from the external master. In the case of an SRAM overrun, the controller will back pressure the data interface with wait states. Note the fill level of the SRAM is readable via programmable OSPI\_SRAM\_FILL\_REG register and this can be used to avoid this situation.

An external master will provide the write data and will transfer this to the OSPI module by issuing data interface writes. The address of the incoming write access must be in the range of Indirect trigger address programmed via the OSPI\_IND\_AHB\_ADDR\_TRIGGER\_REG register to Indirect trigger address +  $2^{**}(\text{Indirect trigger address range}) - 1$ . Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the Indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the Indirect Range to grant SRAM as source. Each write will cause the internal SRAM to be pushed, thereby decoupling the incoming write access address from the FLASH address – that is not direct mapped. Therefore Indirect trigger address does not have any relationship with FLASH address. It is just to indicate that data should take SRAM as source instead of FLASH Memory array after triggering of any valid Indirect Write. The FLASH address for Indirect Write is taken from the OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG register. Assuming the SRAM is not full at the point the data interface access is received by the OSPI module, then the data will be pushed to the SRAM with minimum latency.

If a write access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a write access is received whose address is within the range described above but the SRAM is full then wait states will be applied until some or all of the data has been pushed from the SRAM to the FLASH.

If a write burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller, and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external master is only permitted to issue 32-bit data interface writes until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final write, the external master may issue a 32-bit word, 16-bit (halfword) or a byte access to complete the transfer. If the number of bytes to write is less than 4 on the last transfer, the master is still permitted to issue a 32-bit transfer. In these cases, the extra bytes are discarded by the controller.

When the SRAM holds a number of bytes equal to or greater than the size of a FLASH page (which itself is programmed into the OSPI module, with a default of 256 bytes) or when the SRAM holds all remaining bytes of the currently executing indirect transfer, the OSPI module will initiate a write burst to the flash command generator.

An indirect operation may be cancelled at any time by setting 1 to the OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[1] CANCEL\_FLD bit.

Any bus master should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via the configuration registers and then decide for itself when the data should be written to the local SRAM. The fill level watermark register (see OSPI\_INDIRECT\_WRITE\_XFER\_WATERMARK\_REG register) is provided. When the SRAM fill level falls below this watermark, an interrupt is generated.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an indirect write operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[0] START\_FLD bit starts an indirect write operation. The OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[2] WR\_STATUS\_FLD bit is available to check the status.

#### 12.3.2.3.10.2.1 Indirect Write Transfer Process

The following sequence can be followed:

1. Setup OSPI\_CONFIG\_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG register.
3. Setup the number of bytes to be transferred in the OSPI\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG register.
4. Setup the indirect transfer's trigger address in the OSPI\_IND\_AHB\_ADDR\_TRIGGER\_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI\_INDIRECT\_TRIGGER\_ADDR\_RANGE\_REG register.
6. It is functionally valid for software to simply write all the data to the SRAM in one block transfer. However, if the total number of bytes to write is greater than the size of the partitioned SRAM, then it is quite likely the SRAM will become full causing the OSPI to back-pressure the system data bus for a considerable time. This time is based on the FLASH data-rate and the page-write time of the device. To avoid sending all the write data in one block transfer, software can make use of the watermark interrupt to identify a convenient time to send data a page at a time to the SRAM module. Alternatively, software can poll the SRAM fill level register directly to identify how empty the SRAM is at any one time in order to make a judgment as to when the most practical time to send the next part of the transfer.
7. If the watermark interrupt feature is to be used, set the OSPI\_INDIRECT\_WRITE\_XFER\_WATERMARK\_REG register which will cause an interrupt to be generated when the fill level falls below the watermark. The watermark should be set to a number between zero and a page size. That is if the page size is 256 bytes, then setting the watermark to a value between 10 and 250 is reasonable and will cause the interrupt to trigger when the fill level drops below the programmed number. Setting the watermark can be useful to provide an indication to software when to write the next page of data to the SRAM.
8. Trigger Indirect Write access by setting OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[0] START\_FLD bit.
9. If the remaining number of bytes still to be transferred into the SRAM for the current indirect transfer is greater than a FLASH page, then write 1 FLASH page worth of data to the SRAM. Otherwise send the remaining data from the indirect transfer to SRAM.
10. If all the data in the indirect transfer has now been sent to the SRAM, then go to 12 and await indirect complete status. Otherwise if there is more data still to be transferred then either:
  - If the watermark interrupt feature is being used, then wait for watermark interrupt.
  - Alternatively the SRAM fill level can be interrogated to identify a convenient time to send more data.
11. Loop back to 9.
12. Optional: The completion status of the Indirect write operation can be polled via OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[5] IND\_OPS\_DONE\_STATUS\_FLD.
13. An Indirect Complete interrupt will be generated when the Indirect write operation has completed.

### 12.3.2.3.10.3 Indirect Access Queuing

Software is permitted to queue up to two indirect transfers for both the indirect write controller and the indirect read controller. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. Any attempt to queue more than two operations will cause an interrupt to be generated. To take advantage of this feature, software should attempt to keep both indirect programming slots full at all times.

From the software perspective, indirect access queuing is achieved by triggering bit 0 of the indirect transfer control register (OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[0] START\_FLD bit or OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[0] START\_FLD bit) twice in short succession. The indirect number of bytes register (OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG or OSPI\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG register) and the indirect FLASH start address register (OSPI\_INDIRECT\_READ\_XFER\_START\_REG or OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG register) must be setup with the relevant transfer data before START\_FLD bit can be triggered for each transfer. Since these registers will change regularly, the hardware must keep sampled versions of these registers for the duration of the indirect transfer.

The internal register block will only issue an indirect start trigger to the key underlying datapath blocks one at a time. There are 2 independent datapath blocks in the indirect access controller that will receive and independently sample this information. The first is the datapath block on the data bus side of the SRAM. For indirect reads, this is a read interface, for indirect writes, it is a write interface. The second is the datapath block on the FLASH side of the SRAM. For indirect reads, this is a write interface, for indirect writes, it is a read interface. Both blocks will process the indirect transfers at different times. For example, for an indirect read operation, the datapath block on the FLASH side of the SRAM will be able to start processing the second queued transfer as soon as the last byte of the first transfer has been written to the SRAM. Before commencing the second transfer, this block must resample the OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG and OSPI\_INDIRECT\_READ\_XFER\_START\_REG registers. Similarly, the datapath block on the bus side will resample the same registers locally when it has forwarded all the FLASH data associated with the first indirect transfer from the SRAM onto the data bus.

### 12.3.2.3.10.4 Consecutive Writes and Reads Using Indirect Transfers

It is permitted for software to trigger an indirect read operation while an indirect write operation is in progress. Similarly it is permitted to trigger an indirect write while an indirect read operation is in progress. Indirect write operations will take overall precedence.

### 12.3.2.3.10.5 Accessing the SRAM

The SRAM depth is separated in two segments. The lower segment is reserved for indirect read use. The upper segment is for indirect write use only. The size of each segment is programmable via the OSPI\_SRAM\_PARTITION\_CFG\_REG register. This feature allows to allocate how many bits of the SRAM address bus are allocated to indirect read. By default, this is set so that exactly half of the SRAM is portioned for use by the indirect read controller. To ensure the read data bus is not directly fed by the SRAM read data through combinatorial logic, an extra bank of holding registers is included in the indirect read data path. These registers act as an extra location to be added to the allocated number of SRAM locations for indirect read.

To illustrate how the SRAM (and the extra bank of holding registers) can be allocated between indirect read and write, the following example is provided. The depth of the SRAM in this example is configured to be 8 bits. This is equal to 256 locations.

- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0x00, then 256 locations are allocated to indirect writes and 1 location to indirect reads.
- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0x01, then 255 locations are allocated to indirect writes and 2 locations to indirect reads.
- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0x02, then 254 locations are allocated to indirect writes and 3 locations to indirect reads.
- And so on until.
- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0xFD, then 3 locations are allocated to indirect writes and 254 locations to indirect reads.

- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0xFE, then 2 locations are allocated to indirect writes and 255 locations to indirect reads.
- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0xFF, then 1 location is allocated to indirect writes and 256 locations to indirect reads.

#### Note

A value of 0xFF or 0x00 in the OSPI\_SRAM\_PARTITION\_CFG\_REG register should be avoided by software, as only the bottom 8 bits of the SRAM fill level are accessible through software (up to 255 limit) via the OSPI\_SRAM\_FILL\_REG register. If the fill level reaches 256 on either the indirect read or write side, it will appear when reading the Fill Level to be 0.

There are four SRAM sources that are arbitrated and muxed onto the single SRAM port. Up to three sources can access this port at any one time. The sources are described as follows:

- Indirect Write, Write source. This is located on the data bus side of the SRAM.
- Indirect Write, Read source. This is located on the FLASH side of the SRAM.
- Indirect Read, Write source. This is located on the FLASH side of the SRAM.
- Indirect Read, Read source. This is located on the data bus side of the SRAM.

A fixed priority arbitration scheme is implemented. [Table 12-149](#) shows priority allocated to these sources.

**Table 12-149. SRAM Access Priority**

SRAM Access Priority		
Indirect Write	Write to SRAM (from System Data Bus)	3rd (exclusive with Data Bus Read Request)
	Read from SRAM (from OSPI Module)	2nd
Indirect Read	Write to SRAM (from OSPI Module)	1st
	Read from SRAM (from System Data Bus)	3rd (exclusive with Data Bus Write Request)

#### Note

With the exception of the write port during an Indirect Read operation (on the FLASH side of the SRAM), the logic driving all four sources must not assume single cycle completion. Writes to the SRAM during an indirect read must be allowed to complete immediately to avoid data loss. Therefore this port is given maximum priority.

#### 12.3.2.3.11 OSPI Software-Triggered Instruction Generator (STIG)

The DAC and INDAC are used to transfer data. In order to access the volatile and non-volatile configuration registers, the legacy SPI Status register, other status/protection registers as well as to perform ERASE functions, a separate software controller is required. The software triggered instruction generator (STIG) is controlled using the OSPI\_FLASH\_CMD\_CTRL\_REG register by setting up the command to issue to the FLASH device. This is a generic controller and can be used to perform any instruction that the FLASH device supports from the extended SPI protocol. Configuring of instructions which are not compliant with the specification of the FLASH devices could cause unpredicted behavior of the controller. OSPI\_FLASH\_CMD\_CTRL\_REG[31-24] CMD\_OPCODE\_FLD bits should be set different than OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[7-0] RD\_OPCODE\_NON\_XIP\_FLD and OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG[7-0] WR\_OPCODE\_FLD. The OSPI\_FLASH\_CMD\_CTRL\_REG[0] CMD\_EXEC\_FLD bit is used to trigger the command. The OSPI\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit is used by software to poll the status of the command execution. For reads, when the command has been serviced (OSPI\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit toggles from '1' to '0'), up to 8 bytes of read data will be placed in the OSPI\_FLASH\_RD\_DATA\_LOWER\_REG and OSPI\_FLASH\_RD\_DATA\_UPPER\_REG registers. For writes, the write data should be placed in the OSPI\_FLASH\_WR\_DATA\_LOWER\_REG and OSPI\_FLASH\_WR\_DATA\_UPPER\_REG registers.

The completion of the STIG request could be also checked by the corresponding interrupt. The occurrence of the interrupt indicates that the controller is ready for accepting a new STIG request. It is important to notice that completion of the STIG request is not equivalent to completion it on SPI side. For example, if STIG is configured

to the command composed of data to transmit only, the data is taken from the corresponding STIG register fields and put into TX FIFO. Since all bytes to write are known, another STIG can be queued before serialization of the current one is completed.

There are some commands which require more data to read than 8 bytes (for example READ ID command). The additional STIG Memory Bank is implemented in order to accommodate these data if needed. The STIG Memory Bank (internal component of the controller) is controlled by the OSPI\_FLASH\_CMD\_CTRL\_REG[2] STIG\_MEM\_BANK\_EN\_FLD bit. If enabled, the number of bytes to read in the STIG is extended to the value ranging from 16 to 512 as defined in OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[18-16] NB\_OF\_STIG\_READ\_BYTES\_FLD bit field. It should be noticed that there are very few commands (excluding Read Array ones which are not intended to handle effectively in STIG Mode but in Direct/Indirect Modes) which return more than 8 bytes to the controller. If the maximum number of bytes to Read using STIG in target application is less than 512, the depth of the STIG Memory Bank can be set smaller what will result in saving noticeable part of the area.

If number of bytes to Read in the STIG as defined in OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[18-16] NB\_OF\_STIG\_READ\_BYTES\_FLD bit field exceeds the Memory Bank Depth, remaining data will overwrite the STIG Memory Bank locations starting from its first address. OSPI\_FLASH\_RD\_DATA\_LOWER\_REG and OSPI\_FLASH\_RD\_DATA\_UPPER\_REG keep the last 8 bytes read from the Flash Device by STIG when Memory Bank is enabled. Therefore, for example if the user wants to get just a single byte from the last eight bytes from long continuous read SPI data chain, there is no need to access the STIG Memory Bank since data can be taken from suitable Flash Command Read Data register. In order to access more data, STIG Memory Bank data request should be triggered. It is controlled by the OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG and works analogously for triggering STIG from the functional standpoint.

OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[0] TRIGGER\_MEM\_BANK\_REQ\_FLD bit is used to trigger the command, bit OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[1] MEM\_BANK\_REQ\_IN\_PROGRESS\_FLD is used by software to poll the status of the command execution. When MEM\_BANK\_REQ\_IN\_PROGRESS\_FLD bit toggles from "1" to "0", the byte of data (OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[15-8] MEM\_BANK\_READ\_DATA\_FLD) from corresponding address (OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[28-20] MEM\_BANK\_ADDR\_FLD bit field) is valid. The address should be set before triggering the STIG Memory Bank access. Each consecutive STIG access overwrites the previous one so that the data in the Bank always fit into byte index fetched by the last STIG access configured to use the Memory Bank (first incoming byte equals first address of the Memory Bank, second one equals the second address and so on).

#### 12.3.2.3.11.1 Servicing a STIG Request

A STIG request will cause the OSPI Flash controller to interrogate the OSPI\_FLASH\_CMD\_CTRL\_REG register to determine what and how many bytes it should send to the FLASH device. The OSPI\_FLASH\_CMD\_CTRL\_REG[31-24] CMD\_OPCODE\_FLD field of this register indicate the instruction to be sent and is always pushed first. If there is an address to send, then the address (the size of which is also programmed in the same register) is sent next. The address itself is stored in the OSPI\_FLASH\_CMD\_ADDR\_REG register. If Mode bits are enabled by OSPI\_FLASH\_CMD\_CTRL\_REG[18] ENB\_MODE\_BIT\_FLD bit. OSPI\_MODE\_BIT\_CONFIG\_REG[7-0] MODE\_FLD bit field are being sent right after address. If OSPI\_FLASH\_CMD\_CTRL\_REG[18] ENB\_MODE\_BIT\_FLD and OSPI\_CONFIG\_REG[29] CRC\_ENABLE\_FLD are both enabled, STIG will replace XIP Mode bits (not applicable for CRC aware SPI interface) for automatically calculated address CRC byte. Therefore, to execute CRC aware STIGs (meaning the commands requiring sending address CRC byte), ENB\_MODE\_BIT\_FLD bit should always be set. If there are any dummy cycles to send (the size of which is also programmed in OSPI\_FLASH\_CMD\_CTRL\_REG register) then those are sent next. If there is data to write or read (the size of which is also programmed in OSPI\_FLASH\_CMD\_CTRL\_REG register) then for the case of writes, up to 8 bytes can be sent (as stored in the Flash Command Write Data registers, OSPI\_FLASH\_WR\_DATA\_LOWER\_REG and OSPI\_FLASH\_WR\_DATA\_UPPER\_REG registers) next. In the read case, when the read data has been collected from the FLASH device, the OSPI Flash Controller stores that in the Flash Command Read Data Registers (OSPI\_FLASH\_RD\_DATA\_LOWER\_REG and OSPI\_FLASH\_RD\_DATA\_UPPER\_REG registers). Up to 8 bytes can be get if OSPI\_FLASH\_CMD\_CTRL\_REG[2] STIG\_MEM\_BANK\_EN\_FLD bit is disabled or up to 512 when enabled. When the OSPI Flash controller starts to service a STIG request, it sets the

OSPI\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit to indicate a command execution is in progress. When the OSPI Flash controller is in the auto-polling state, servicing a STIG request is slightly different. Most of devices are largely inaccessible after a program operation until the device has completed that write. Some group of them has a possibility to suspend programming page. It can be controlled by the OSPI\_POLLING\_FLASH\_STATUS\_REG[8] DEVICE\_STATUS\_VALID\_FLD bit, which indicate active auto-polling phase. After requesting a STIG, the OSPI Flash Controller immediately issues appropriate OPCODE to Memory. During servicing a STIG (in auto-polling phase) the status bit of command execution remains steady and other parts of transfer such as ADDRESS or DUMMY BITS, and so forth, are disabled (to issued Program Suspend Command is needed OPCODE only). There is a programmable option to add delay between every repetitive poll operation (delay is defined by OSPI\_WRITE\_COMPLETION\_CTRL\_REG[31-24] POLL\_REP\_DELAY\_FLD bit field). This feature is implemented to free up SPI bandwidth if needed.

---

**Note**

The OSPI data is sent LSB first, while address is sent MSB first.

---

---

**Note**

The STIG complete status bit gets cleared before the actual flash access completes. Software should wait for about 700 ns if there is any dependency on actual access completion.

---

#### 12.3.2.3.11.2

---

**Note**

The OSPI data is sent LSB first, while address is sent MSB first.

---

---

**Note**

The STIG complete status bit gets cleared before the actual flash access completes. Software should wait for about 700 ns if there is any dependency on actual access completion.

---

#### 12.3.2.3.12 OSPI Arbitration Between Direct / Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a simple fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

- The Indirect Access Write
- The Direct Access Write
- The STIG
- The Direct Access Read
- The Indirect Access Read

#### 12.3.2.3.13 OSPI Command Translation

Requests issued by the direct access controller, the indirect access controller or the STIG will be translated into a sequence of byte transfers to send downstream (before serialization to the FLASH device). These sequences depend on the requested transfer but an example of a typical 1-byte non sequential READ is shown below:

INSTRUCTION OPCODE -> ADDRESS -> Mode Byte -> Dummy Bytes -> 1 byte of don't care

For sequential accesses, an extra byte of data per read is pushed to the FLASH device on the back of the above sequence assuming it can be done so with no gap between each transferred byte.

When PHY mode is enabled and consequently no clock divider is configured, latency caused by multi domain synchronization may make an extra byte insufficient to avoid the transfer gap. To ensure the sequential access non-interrupted and keep the maximum performance of the controller, PHY Pipeline Mode is implemented. When enabled, number of don't care bytes is calculated based on the configuration.

The actual sequence sent to the FLASH device depends on the requested transfers, whether the transfer is non-sequential or sequential, whether the device has been configured in XIP mode and the state of the main Device Instruction Type programmable registers (OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG and OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG).

For writes, the write enable latch (or WEL) within the FLASH device itself must be high before a write sequence can be issued. The OSPI Flash Controller will automatically issue the write enable latch command before triggering a write command via the direct or indirect access controllers (DAC/INDAC) – that is the user does not need to perform this operation. For increasing flexibility and performance user can turn off this feature by setting the OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG[8] WEL\_DIS\_FLD bit. The opcode for WREN is typically 0x06 and is common between devices.

When write requests from the direct or indirect access controllers are no longer being received and all outstanding requests have been sent, the FLASH device will automatically start the page program write cycle. Any incoming request at this time will be held in wait states until the cycle has completed. The OSPI Flash Controller will automatically poll the FLASH device legacy SPI status register to identify when the write cycle has completed. This is achieved by sending the RDSR opcode to the FLASH device and waiting until the device itself has indicated the write cycle has completed (until the Write in Progress bit has cleared to zero and the write enable latch bit has also cleared to zero or device is ready bit has set to one). The WREN and the RDSR device instructions are the only ones that are sent by the controller under the hood. For any other specific instruction that the user determines should be sent to the device (for example if the device needs to be unprotected before a write command is issued), these should be handled separately by issuing FLASH commands via the STIG.

There is an option to trigger HOLD or RESET feature on I/Os of the Flash Device. The HOLD one is generally common across the devices and takes an alternative function of DQ3 pin (applicable when device operates neither in Quad SPI mode nor DDR). The transfer can be hold and then resumed by dedicated software trigger field (OSPI\_CONFIG\_REG[4] HOLD\_PIN\_FLD). The devices which have the HOLD feature on DQ3 usually need another dedicated pin for hardware reset and ones without HOLD feature usually have alternative reset on DQ3 what makes the additional reset pin being redundant. The controller supports both variants and reset selection register field (OSPI\_CONFIG\_REG[6] RESET\_CFG\_FLD) allows the user to configure which hardware reset solution is implemented in the device under usage.

After configuration is done, it is possible to trigger HOLD or RESET features using I/Os (OSPI\_CONFIG\_REG[4] HOLD\_PIN\_FLD or OSPI\_CONFIG\_REG[5] RESET\_PIN\_FLD bits). After HOLD activation the controller is introduced into waiting state and any other operations should not be requested before de-asserting of HOLD configuration bit. The HOLD feature is useful when any SPI transaction needs to be prolonged in order to adjust it into specific point in time. Note that any HOLD trigger issued during active SPI transaction may be synchronized into reference clock domain at the time the SPI transfer turns to be finished. In this case, there is nothing to hold so the low level SPI logic will not activate HOLD on DQ3. To check if HOLD request suspended the transfer OSPI\_CONFIG\_REG[31] IDLE\_FLD bit can be polled for. If SPI is not in the IDLE state, the transfer was successfully suspended. It is important for the software to take care of resetting OSPI\_CONFIG\_REG[4] HOLD\_PIN\_FLD bit before newly triggered SPI transaction. In case HOLD request is set before the beginning of the transfer it will be HOLD right after it starts what may not always be a goal. The hardware RESET needs to be activated when CS is high (no valid transaction is present on SPI bus). It can be checked by polling of OSPI\_CONFIG\_REG[31]. If the controller is in the IDLE state and no other transfer requests are queued to perform, the hardware RESET can be triggered. The RESET feature is useful when any write, program or erase operation needs to be cancelled. No transfer request is permitted before driving the reset back to being inactive. Triggering HOLD or RESET on DQ3 at the time the device is configured to work in Quad SPI mode or DDR will overwrite transfer data on DQ3 with '0'. This behavior is considered as a software error so it is advisable for the system to make sure that the flash device was introduced to suitable SPI mode (that is by polling its configuration register) before triggering alternative DQ3 function. There are four independent reset outputs implemented to separate between multiple devices connected to the controller (up to 4 are supported). The decision which reset output is to be activated after triggering OSPI\_CONFIG\_REG[5] RESET\_PIN\_FLD bit is made based on OSPI\_CONFIG\_REG[9] PERIPH\_SEL\_DEC\_FLD and OSPI\_CONFIG\_REG[13-10] PERIPH\_CS\_LINES\_FLD bits. Reset output OSPI\_ECC\_VECTOR is to be directly driven into corresponding dedicated RESET pins of the devices with separated RESET pin and alternatively, Reset output OSPI\_ECC\_VECTOR is to be

control OSPI\_ECC\_VECTOR of the DQ3 RESET devices enabling separating of DQ3 Master Outputs on SoC integration level.

The controller supports all combinations of CPHA and CPOL for Serial Clock. It allows the controller to support any SPI slave devices not limited to Flash Memories. Multiple-SPI flash devices use just a subset of these combinations depending on the Transfer Mode as defined in [Table 12-150](#).

**Table 12-150. Flash SPI Modes**

(SEL_CLK_POL_FLD, SEL_CLK_PHASE_FLD)	Edge Mode	Support
0x00 (SPI MODE 0)	SDR	Yes
0x01 (SPI MODE 1)	SDR	No
0x10 (SPI MODE 2)	SDR	No
0x11 (SPI MODE 3)	SDR	No
0x00 (SPI MODE 0)	DDR	Yes
0x01 (SPI MODE 1)	DDR	No
0x10 (SPI MODE 2)	DDR	No
0x11 (SPI MODE 3)	DDR	No

#### 12.3.2.3.14 Selecting the Flash Instruction Type

In order to send the correct READ and WRITE opcodes, software should initialize the OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG and the OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG registers. These registers include fields to setup the required instruction opcodes that is intended to be used to access the FLASH (default is basic READ and basic page program) as well as the instruction type, edge mode (DDR or SDR) and whether the instruction uses single, dual, quad or octal pins for address and data transfer. Providing this level of control to the user provides a future proofed generic solution. To ensure the controller can operate from a reset state, the registers will be reset to an opcode compatible with SIO devices what can be modified using BOOT feature.

Despite being applicable for both READs and WRITES, the OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[9-8] INSTR\_TYPE\_FLD field only appears once – it is not included in the OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG register. If software sets this to anything other than '0', then the address transfer type and the data transfer type bits of both OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG and OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG registers become don't care. It is made available to allow software to support the less common FLASH instructions where the opcode, address and data are sent on 2 or 4 lanes (the opcode from most instructions are sent serially to the FLASH device, even for dual/quad instructions).

There are devices capable to handling Read Operations in Dual Data Rate Mode (DDR) (it is also called Dual Transfer Rate Mode (DTR)). That means they can issue and capture the data on both rising and falling edges during working with dedicated command type. This enables the controller to maintain throughput at twice lower frequency of OSPI clock. The Device Read Instruction Register has DDR enable bit which informs Octal-SPI Flash Controller that opcode written into Read Opcode field is capable with DDR command type. The other field defined in OSPI\_RD\_DATA\_CAPTURE\_REG[19-16] DDR\_READ\_DELAY\_FLD which enables the controller to shift the transmitted data in DDR mode. By default, data are shifted by 1 clock cycle to ensure hold timing greater than 0 during DDR transactions. It may not be sufficient for high reference clock frequency in accordance with the high dividers.

[Table 12-151](#) shows how software should configure the OSPI module for selected specific READ and WRITE instruction supported by the abovementioned device.

**Table 12-151. READ and WRITE Instruction Configuration**

**Note**

This data are applicable for both 3-byte or 4-byte address variants of the commands if did not indicate otherwise.

**Note**

In DTR protocol all transfer phases (including opcode) take DDR edge mode independently on the command under execution. DTR protocol is to be enabled by OSPI\_CONFIG\_REG[24] ENABLE\_DTR\_PROTOCOL\_FLD bit. It has higher priority than DDR Mode enable bit from OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[10] DDR\_EN\_FLD.

**12.3.2.3.15 OSPI Data Integrity**

The CRC aware SPI transfer can be performed when both controller and device are configured to work in the Octal DDR Protocol.

For write transactions (the controller transmits data throughout all transfer), the controller is responsible for sending address CRC byte (XOR of all address bytes) following address bytes and TX data CRC byte (XOR of all data bytes to write) following data chunk with size as defined in OSPI\_MODE\_BIT\_CONFIG\_REG[10-8] CHUNK\_SIZE\_FLD bit field. All CRC data are being calculated and sent automatically by the controller and the external device is responsible for reacting accordingly on any possible interpolation on the Flash interface. For read transactions, the controller is also responsible for sending address CRC byte (like

for write) and for getting and progressing RX data CRC byte returning by the Flash Device after each chunk with size as defined in OSPI\_MODE\_BIT\_CONFIG\_REG[10-8] CHUNK\_SIZE\_FLD bit field. At the time when the Flash Device is returning data back to the controller, the controller dynamically calculates checksum byte by byte. Once the chunk is completed, CRC returned from Flash Device should fit to dynamically calculated CRC by the controller. In case of any deviation, controller reports CRC error to the system by corresponding interrupt (CRC error interrupt). The controller also provides the last captured CRC data in RX data chunk (defined in OSPI\_MODE\_BIT\_CONFIG\_REG[31-24] RX\_CRC\_DATA\_LOW\_FLD and OSPI\_MODE\_BIT\_CONFIG\_REG[23-16] RX\_CRC\_DATA\_UP\_FLD bit fields) to give the software driver the opportunity to further detecting any data corruption on system interfaces. The CRC data valid interrupt informs the system about the accessibility of the new RX CRC data in the registers. Once the system gets the full data word, it can calculate CRC by itself. At the time it collects all data words in chunk and then gets the CRC data valid interrupt, it can compare these data and react accordingly.

Some devices also have embedded ECC mechanism allowing them to report data abnormal conditions on their ECC Correction Signal output. At the time this output turns low, the device expect the OSPI controller to read status register of the device in order to get more details about the source of detected abnormal situation. The OSPI controller investigates ECC status on its ECC\_FAIL input and generates an interrupt when detecting this signal being low.

### 12.3.2.3.16 OSPI PHY Module

OSPI module fully integrates PHY module dedicated to more flexible and power efficient transfers.

The PHY module communicates with the OSPI Flash controller via the aforementioned PHY Interface and handles data transfer on low-level stage of design hierarchy. However, when the OSPI\_RCLK is configured to be equal to the SPI clock instead of alternative approach using clock divider, there is just one OSPI\_RCLK cycle (not 4 or more) within single SPI period or half period for DDR Mode (SPI Control Module works on reference clock). Given that OSPI\_RCLK is the input clock for RX FIFO and the output one for TX FIFO, the PHY solution incurs more restrictive requirement for value of system clock in order to synchronize data without SPI transfer interruption. For example, when the controller operates in DDR 1× octal Mode, 2 bytes of data (equivalent to one RX FIFO location) is gathered within just single OSPI\_RCLK cycle. The controller cannot predict next data access while operating in the Direct Mode (meaning its size or whether it is sequential to the previous one or not). As a result, if the OSPI\_HCLK is not significantly greater than OSPI\_RCLK, the SPI transfer has to be suspended until the Flash Command Generator forwards new data to TX FIFO.

An optional PHY Pipeline Mode is implemented to avoid the necessity of stable clocking of the system clock for the Direct Mode when the PHY mode is enabled and to keep maximum performance while ensuring correct operation of the OSPI controller with the PHY using low frequencies from all its domains. This mode is a trade-off between large software overhead when operating in the Indirect Mode and the described limitations present in the Direct Mode. For more information about PHY Pipeline Mode, see [Section 12.3.2.3.16.1, PHY Pipeline Mode](#).

When DDR 2× Mode is granted based on configuration – SPI transfer is automatically performed using the PHY module even if the OSPI\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD is de-asserted. SDR 2× commands are handled with PHY module paths being bypassed. Nevertheless, dividers of 2, 4 or 6 for DDR and divider of 2 for SDR should not be configured based on controller requirements and these configurations are perceived as a software error.

The following steps are an example of software algorithm of adapting the OSPI controller with the PHY module incorporated to work in octal 1× clock DDR Protocol. Note that all necessary configuration steps described in [Section 12.3.2.4.2, Configuring the OSPI Controller for Optimal Use](#) shall be completed before the algorithm.

1. Set PHY mode enable (OSPI\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD bit) and DDR protocol (OSPI\_CONFIG\_REG[24] ENABLE\_DTR\_PROTOCOL\_FLD bit). It is assumed that device is configured to work in DDR Protocol.
2. Before setting the DLL parameters, software calibration could be needed. OSPI\_PHY\_MASTER\_CONTROL\_REG[23] PHY\_MASTER\_BYPASS\_MODE\_FLD bit controls the bypass mode of the master and slave DLLs. If this bit is set, the DLL bypass mode is enabled. This mode is

intended to be used only for debug. When set to 0, a Master operational mode is selected, when set to 1 the Bypass mode is selected.

DLL works in normal mode of operation where the slave delay line settings are used as fractional delay of the master delay line encoder reading of the number of delays in one cycle.

Master DLL is disabled with only 1 delay element in its delay line. The slave delay lines decode delays in absolute delay elements rather than as fractional delays.

- DLL Bypass Mode (follow only if operating in this mode):
  - Depending on frequency of reference clock, calculate how many delay elements should be used to shift this clock by 25% of its period (best case for DDR transfers from setup/hold timings standpoint). Note that delay could be slightly different in a real design. TX Delay is configured in OSPI\_PHY\_CONFIGURATION\_REG[22-16] PHY\_CONFIG\_TX\_DLL\_DELAY\_FLD bit field.
  - Re-synchronize DLLs by asserting OSPI\_PHY\_CONFIGURATION\_REG[31] PHY\_CONFIG\_RESYNC\_FLD bit (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set PHY bypass mode enable through OSPI\_PHY\_MASTER\_CONTROL\_REG[23] PHY\_MASTER\_BYPASS\_MODE\_FLD bit.
- DLL Master Mode (follow only if operating in this mode):
  - Drive DLL reset bit OSPI\_PHY\_CONFIGURATION\_REG[30] PHY\_CONFIG\_RESET\_FLD into low.
  - Calculate initial delay value for the Master DLL according to the OSPI\_PHY\_MASTER\_CONTROL\_REG[6-0] PHY\_MASTER\_INITIAL\_DELAY\_FLD bit field.
  - Depending on frequency of reference clock, calculate how many delay elements should be used to shift this clock by 25% of its period (best case for DDR transfers from setup/hold timings standpoint). Note that delay could be slightly different in a real design. TX Delay is configured in OSPI\_PHY\_CONFIGURATION\_REG[22-16] PHY\_CONFIG\_TX\_DLL\_DELAY\_FLD bit field.
  - Re-synchronize DLLs by asserting OSPI\_PHY\_CONFIGURATION\_REG[31] PHY\_CONFIG\_RESYNC\_FLD (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set DLL reset bit back to high (since both bits are within the same register, it is acceptable to set both bits simultaneously).
  - Poll OSPI\_DLL\_OBSERVABLE\_LOWER\_REG[15] DLL\_OBSERVABLE\_LOWER\_LOOPBACK\_LOCK\_FLD bit. When set – lock is done.
  - Re-synchronize Slave DLLs by asserting OSPI\_PHY\_CONFIGURATION\_REG[31] PHY\_CONFIG\_RESYNC\_FLD bit (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set TX DLL Delay (OSPI\_PHY\_CONFIGURATION\_REG[22-16] PHY\_CONFIG\_TX\_DLL\_DELAY\_FLD) and RX DLL Delay (OSPI\_PHY\_CONFIGURATION\_REG[6-0] PHY\_CONFIG\_RX\_DLL\_DELAY\_FLD) fields which are equivalent to percentage clock offsets now. It is recommended to wait for the new configuration being propagated by 20 reference clock cycles before triggering the next SPI transfer.
- Consider Read Data from location where its value is predictable. This step can be performed in different ways, depending on the device. Parameter Page, ID, Status, Data from OTP region or Data from location of Flash Array the value of which is known can act as the pattern.
- Trigger Read request chosen from above options.
- Check correctness of data and store that information:
  - Increment value of RX clock delay – it is configurable in the OSPI\_PHY\_CONFIGURATION\_REG[6-0] PHY\_CONFIG\_RX\_DLL\_DELAY\_FLD bit field.
  - Re-synchronize DLLs.
  - Trigger valid Read request.
  - Check correctness of data and store information.
  - If range boundary of RX clock delay is achieved, go to step 3. Otherwise go back to step "Increment value of RX clock delay".
- 3. Set RX clock delay value for one from the middle of valid range based on information in storage.
- 4. Re-synchronize DLLs.
- 5. Set OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG for Octal Read DDR Configuration (each transfer phase should be configured to work in Octal mode, Number of Dummy cycles should be set as specified in the

documentation of the device or more when because of additional read paths delays of actual systems data is predicted to be flopped by PHY module with delay excesses actual cycle of SPI clock generated by the controller).

6. Enable Pipeline mode in the OSPI\_CONFIG\_REG[25] PIPELINE\_PHY\_FLD bit.
7. Perform Sequential Read of Data consistent with conditions indicated within [Section 12.3.2.3.16.1, PHY Pipeline Mode](#).
8. After de-asserting the data slave select signal by software – poll OSPI\_CONFIG\_REG[31] IDLE\_FLD bit.
9. When it is asserted to high – next transfer request can be triggered.

#### 12.3.2.3.16.1 PHY Pipeline Mode

This mode is used for Direct Read Mode of operation. If any other operations are intended to be executed, it is recommended to disable PHY Pipeline Mode and re-enable for subsequent Direct Reads in PHY mode. Since there is comprehensive software mechanism controlling Read data transfers in Indirect Mode, pipeline of data interface accesses is not effective for this mode. Enable PHY Pipeline feature when at least four 4-byte-sized data words are predicted to be read in sequentially. The Flash Command Generator pipelines and puts them into TX FIFO which causes CS to remain active because low level SPI protocol controller controls TX FIFO fill level. In order to correctly trigger Direct Read in Pipeline Mode TX FIFO must be empty. Therefore first polling of OSPI\_CONFIG\_REG[31] IDLE\_FLD bit needs to be done. The sequential data transfer will be interrupted when the data slave select signal of the data interface is asserted to low. This information is also detected by Data Slave Module which informs the Flash Command Generator that the next access is invalid and a TX FIFO locations can be flushed transparently for the system.

In PHY Pipeline Mode it is recommended for Data Master not to introduce wait states in between consecutive occurrences of the data interface signal that indicates transfer has finished. It will ensure regular transfer rate on data side. Introducing wait states gradually slows data transfer rate down and may finally cause SPI transfer interruption because of TX FIFO data starvation. The system, however, may need to introduce some number of wait states after completion of sequential transfer (composed of 4-byte sized data words) for progressing the data. The dedicated buffer is implemented in Data Slave Controller which collects all incoming data during wait states injection. In order to keep SPI transfer uninterrupted, number of wait states should be as little as possible. The higher the OSPI\_HCLK/ OSPI\_RCLK ratio the more wait states can be introduced without SPI transfer interruption. In case the system is able to launch a new transfer before wait states overflow, buffered data transfer to the host will continue. It compensates slowed down transfer by introducing wait states. In case the system is not able to launch a new transfer before wait states overflow, next incoming transfer is considered non-sequential and is executed after all pipelined data is flushed.

This mode can be enabled when following conditions are met:

- OSPI\_HCLK > OSPI\_RCLK (Comparing the slow data clock with the fast reference one makes Pipeline Mode ineffective – Suspend of SPI Transfer would be possible. Consequently, this condition has to be met to operate in this mode.)
- Only 4-byte sized Data Words are permitted (This ensures more data clock cycles for synchronization of FIFOs between consecutive pulses of the signal indicating transfer has finished.)
- The transfer with introduced wait states or non-sequential transfers can only be triggered in between at least four 4-byte sized Data Bursts sequential accesses (16 Bytes) to be sure that Data Master can trust buffered incoming data during wait states injection.
- Do not use Pipeline Mode along with Continuous Mode (XIP). Benefit of XIP is limited for bulk data transfers intended to execute in Pipeline Mode.

#### 12.3.2.3.16.2 Read Data Capturing by the PHY Module

Read Data Capturing by the PHY module is useful, as the user is not responsible for the design dedicated DLL being compatible with the Octal-SPI Flash Controller. Another benefit is an option to adjust both SPI clock and sampling clock in a very wide range to fit them into individual requirements of any system. If loopback clock (OSPI\_RD\_DATA\_CAPTURE\_REG[0] BYPASS\_FLD) and PHY mode (OSPI\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD) are both enabled, the loopback clock is driven into RX DLL instead of gated reference clock. Because of the architecture of DLL, loopback clock needs to be provided in SPI Mode 0. If DQS (OSPI\_RD\_DATA\_CAPTURE\_REG[8] DQS\_ENABLE\_FLD) and PHY mode (OSPI\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD) are both enabled, the DQS is driven into RX DLL instead of gated reference clock.

### 12.3.2.4 OSPI Programming Guide

#### 12.3.2.4.1 Configuring the OSPI Controller for Use After Reset

The OSPI controller has been designed to wake up in a state that is suitable for performing basic reads and writes using the direct access controller. The BASIC read (opcode 0x03) and BASIC write (opcode 0x02) instructions are operations supported by all target devices. The controller also wakes up with a baud rate divider setting of divide-by-32. Assuming the reference clock is operating at 400 MHz after reset, then this means the effective SPI clock is just 12.5 MHz. This should be slow enough to meet all timing requirements of all target devices without any further device programming.

If the target device does not use 3 address bytes, the device size configuration register must be modified to the appropriate size.

If software plans to write to the device, and the number of bytes per device page is not equal to 256, then the device size configuration register must also be modified.

While not a requirement, it is prudent for software to enable the write protect feature prior to enabling the OSPI controller. This will block any data writes from taking effect. To do so, the protection registers (OSPI\_LOWER\_WR\_PROT\_REG, OSPI\_UPPER\_WR\_PROT\_REG and OSPI\_WR\_PROT\_CTRL\_REG) should be setup and the number of bytes per device block in the device size configuration register should also be setup.

After Power-on Reset (POR), software can read from and write to the FLASH device (albeit slowly). Enabling/Disabling the controller and DAC is achieved with just one write to corresponding fields of the OSPI\_CONFIG\_REG register. User shall take note to maintain the default values of the baud rate divisor and the default state of SEL\_CLK\_POL\_FLD/ SEL\_CLK\_PHASE\_FLD bits of this register. A write data value of 0x00780081 is recommended.

#### 12.3.2.4.2 Configuring the OSPI Controller for Optimal Use

##### Note

When using the OSPI Controller, the opcodes in OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[7-0] RD\_OPCODE\_NON\_XIP\_FLD, OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG[7-0] WR\_OPCODE\_FLD and OSPI\_WRITE\_COMPLETION\_CTRL\_REG[7-0] OPCODE\_FLD bit fields shall not match the opcode in the OSPI\_FLASH\_CMD\_CTRL\_REG[31-24] CMD\_OPCODE\_FLD bit field.

For high speed transfers PHY mode can be enabled and for optimal configuration PHY Pipeline mode is recommended. For more information, see [Section 12.3.2.3.16.1, PHY Pipeline Mode](#).

To access the flash optimally, software must configure the controller accurately:

1. Wait until any pending STIG or INDAC operation has completed or poll OSPI\_CONFIG\_REG[31] IDLE\_FLD bit.
2. Disable the DAC through OSPI\_CONFIG\_REG[7] ENB\_DIR\_ACC\_CTLR\_FLD bit. It is permitted, but not necessary to also disable the OSPI controller completely via OSPI\_CONFIG\_REG[0] ENB\_SPI\_FLD bit.
3. Update the OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG and OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG registers for the instruction type you wish to use for indirect and direct writes and reads.
4. Update the OSPI\_MODE\_BIT\_CONFIG\_REG[7-0] MODE\_FLD bit field if mode bits have been enabled in the OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[20] MODE\_BIT\_ENABLE\_FLD bit.
5. Update the OSPI\_DEV\_SIZE\_CONFIG\_REG if the contents are incorrect. Note parts or all of this register may have been updated after initialization. The number of address bytes is a key configuration setting required for performing reads and writes. The number of bytes per page is required for performing any write. The number of bytes per device block is only required if the write protect feature is used. If the default values are correct for the target device, or if some of the values (not including the number address bytes) were incorrect but device writes were not permitted.
6. Update the OSPI\_DEV\_DELAY\_REG. This register allows the user to tweak how the chip select is driven after each FLASH access. This is required as each device may have different timing requirements. As the serial clock frequency is increased, these timing requirements become more important. Note the numbers programmed in this register are based on the period of reference clock. Example: A device

needs 50ns minimum time before CS can be re-asserted after it has been de-asserted. By default, the controller will only provide a minimum of 1 SCLK period. When the device is operating at 100 MHz, the SCLK period is only 10ns, so 40ns extra is required. Since the register defines the number of reference clock cycles to add, and reference clock is running at 400 MHz (2.5ns period), then the user should program a value of at least 16 to the OSPI\_DEV\_DELAY\_REG[31-24] D\_NSS\_FLD. This delay can be extended during auto-polling phase. There is possibility to define the polling repetition delay in the OSPI\_WRITE\_COMPLETION\_CTRL\_REG[31-24] POLL\_REP\_DELAY\_FLD bit field.

7. Update the OSPI\_REMAP\_ADDR\_REG register, if required. Affects DAC path only.
8. Setup and enable write protection registers (OSPI\_LOWER\_WR\_PROT\_REG, OSPI\_UPPER\_WR\_PROT\_REG and OSPI\_WR\_PROT\_CTRL\_REG) if they are required and if they have not already been setup from post initialization.
9. Enable required interrupts via the OSPI\_IRQ\_MASK\_REG register.
10. Setup the baud rate divisor in the OSPI\_CONFIG\_REG[22-19] MSTR\_BAUD\_DIV\_FLD to define the required clock frequency of the target device.
11. Update the OSPI\_RD\_DATA\_CAPTURE\_REG register. This register will delay when the read data is captured and can help when the read data path from the device to the controller is long and the device clock frequency is high. An update to this register may not be necessary.
12. Enable the OSPI controller and the DAC via the OSPI\_CONFIG\_REG.

#### 12.3.2.4.3 Using the Flash Command Control Register (STIG Operation)

The OSPI\_FLASH\_CMD\_CTRL\_REG register provides software means to access the FLASH device in a flexible and programmable manner. This is known as a STIG operation (Software Triggered Instruction Generator). The instruction opcode, number of address bytes (if any), the address itself, number of dummy cycles (if any), number of write data bytes (if any), the write data itself and the number of read data bytes (if any) can be programmed. Once these have been programmed, software can trigger the command via OSPI\_FLASH\_CMD\_CTRL\_REG[0] CMD\_EXEC\_FLD bit and wait for its acceptance by polling OSPI\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit. When CMD\_EXEC\_STATUS\_FLD bit turns de-asserted, another STIG can be triggered. This method of accessing the FLASH is the typical mechanism that software would use to access the FLASH device's registers, as well as for performing ERASE operations. It can also be used to access the FLASH array itself, although the maximum of 8 data bytes may be read or written at any one time, defined in the Flash Command Write and Read Data registers (OSPI\_FLASH\_RD\_DATA\_LOWER\_REG, OSPI\_FLASH\_RD\_DATA\_UPPER\_REG, OSPI\_FLASH\_WR\_DATA\_LOWER\_REG and OSPI\_FLASH\_WR\_DATA\_UPPER\_REG). This number of bytes can be extended for Read Data commands using additional STIG Memory Bank controlled by OSPI\_FLASH\_CMD\_CTRL\_REG[2] STIG\_MEM\_BANK\_EN\_FLD and OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG.

Commands issued using this interface have a higher priority than all other READ accesses coming from data interface, and will therefore interrupt any READ commands being requested by the indirect or direct controllers.

#### 12.3.2.4.4 Using SPI Legacy Mode

SPI legacy mode allows software to access the internal TX-FIFO and RX-FIFO directly, thus bypassing the direct, indirect and STIG controllers.

Legacy mode allows the user to issue any FLASH instruction to the device, but does place a heavy software overhead in order to manage the fill levels of the FIFO's effectively. This is because the legacy SPI core is bi-directional in nature, with data continuously being transferred in either direction while the chip select is enabled. Even if the driver only wishes to read data from the FLASH device, dummy data must be written out to ensure the chip select stays active, and vice versa for write transactions.

Since the TX-FIFO and RX-FIFO are of limited depth, software has a responsibility to maintain the FIFO levels to ensure the TX-FIFO does not become exhausted during the instruction execution and the RX-FIFO doesn't overflow. This can place a lot of overhead on software. Interrupts are provided to indicate when the fill levels pass programmable watermarks, which are themselves programmable registers OSPI\_TX\_THRESH\_REG and OSPI\_RX\_THRESH\_REG.

The limited depth may impose the limitation over execution of some specific SPI commands in legacy mode. Note that the controller interprets all transmitted bytes as valid. For example, if the Flash Device was configured to return valid data after many dummy cycles, the TX FIFO could become full before the controller sends all of dummy data.

#### **12.3.2.4.5 Entering XIP Mode from POR**

XIP is a mode that can be entered in a non-volatile way if the device has XIP enabled as a non-volatile configuration setting. Software will not be able to discover the state of XIP from POR via FLASH status register reads as the only operation a FLASH device will recognize when XIP mode is enabled is an XIP read operation.

If it is already known that the device will enter XIP from POR, then the OSPI\_MODE\_BIT\_CONFIG\_REG[7-0] MODE\_FLD and OSPI\_CONFIG\_REG[18] ENTER\_XIP\_MODE\_IMM\_FLD bits should be set in initial boot.

If it is not already known that the device will enter XIP from POR, and XIP from POR may be supported by the attached FLASH device, then software can attempt to exit XIP mode by issuing an XIP exit command using a STIG command (via the OSPI\_FLASH\_CMD\_CTRL\_REG register). To do this, software must be aware of the mode bit requirements of that device, as XIP entry and exit changes per device.

#### **12.3.2.4.6 Entering XIP Mode Otherwise**

XIP mode is supported in most FLASH devices. Some of them use signature bits that are sent to the device immediately following the address bytes, other use signature bits and also require a FLASH device configuration register write to enable XIP. For the FLASH devices that must be compliant to the OSPI controller, the following steps can be taken by software to enter XIP mode:

1. Disable the DAC and INDAC (OSPI\_CONFIG\_REG[7] ENB\_DIR\_ACC\_CTRL\_FLD) to ensure no new data read accesses will be sent to the FLASH device.
2. (Optional) Configure the OSPI\_FLASH\_CMD\_CTRL\_REG to issue a VCR write to FLASH memory, because XIP mode must first be enabled for some devices.
3. Configure the XIP mode bits in the OSPI\_MODE\_BIT\_CONFIG\_REG[7-0] MODE\_FLD bit field.
4. Enable the local controllers XIP mode by setting OSPI\_CONFIG\_REG[17] ENTER\_XIP\_MODE\_FLD bit.
5. Re-enable the DAC and, if required, the INDAC.

#### **12.3.2.4.7 Exiting XIP Mode**

To exit XIP mode, software should first disable the DAC and INDAC to ensure no new data read accesses will be sent to the FLASH device. It should then set mode bits to other than the established in the corresponding Flash Device specifications. These are dependent on the FLASH device and manufacturer. Software should then reset OSPI\_CONFIG\_REG[17] ENTER\_XIP\_MODE\_FLD.

Note the FLASH device must see a READ instruction before it can disable its internal XIP mode state, so this means XIP mode will internally stay active until the next READ instruction is serviced. User must take care to ensure that XIP mode is disabled before the end of any READ sequence.

### 12.3.3 HyperBus Interface

This section describes the HyperBus module in the device.

#### 12.3.3.1 HyperBus Overview

The HyperBus module is a part of the device Flash Subsystem (FSS). For more information about FSS, see *Flash Subsystem (FSS)*.

The HyperBus module is a low pin count memory interface that provides high read/write performance. The HyperBus module connects to HyperBus memory (HyperFlash or HyperRAM) and uses simple HyperBus protocol for read and write transactions.

There is one HyperBus™ module inside the device. The HyperBus module includes one HyperBus Memory Controller (HBMC).

##### 12.3.3.1.1 HyperBus Features

- Support for Cypress® HyperFlash and HyperRAM
- Up to 166 MHz maximum memory bus operation for reads
  - Supports up to 166 MHz dual data rate (333 MBps) flash devices for system requiring rapid boot or instant-on displays
  - Supports up to 333 MBps external pseudo-RAM (HyperRAM) for systems

**Note:** For more information, see section Timing and Switching Characteristics in the device-specific Datasheet.

- Low pin count interface with LVCMOS I/O pins (can be muxed with other FSS interfaces (OSPIs))
- Two memory chip selects
- Linear incrementing mode for reads and writes
- Up to 16 outstanding read transactions (see [Section 12.3.3.3.5, HyperBus True Continuous Read \(TCR\) Mode](#))
- Asynchronous bus clock

##### 12.3.3.1.2 HyperBus Not Supported Features

- Cache-line wrap and fixed address modes for reads or writes
- General Purpose Output register (MCU\_FSS0\_HPBO\_MC\_GPOR) of the HBMC is not used

##### 12.3.3.1.3 Hyperbus Ports

**Table 12-152. MCU\_FSS0\_HPBO Clocks and Resets**

Clocks	
Module Clock Input	Description
MCU_FSS0_HPBO_ICLK	Interface Clock
MCU_FSS0_HPBO_CLKX1	Functional Clock 1 (main functional clock)
MCU_FSS0_HPBO_CLKX1_INV	Functional Clock 2 (inverted Functional Clock 1 to create 180 degree phase shift)
MCU_FSS0_HPBO_CLKX2	Functional Clock 3 (2 × Functional Clock 1 for DDR data and command)
MCU_FSS0_HPBO_CLKX2_INV	Functional Clock 4 (inverted Functional Clock 3 to create 180 degree phase shift)
Resets	
Module Reset Input	Description
MCU_FSS0_HPBO_RST	HyperBus Reset

**Table 12-153. MCU\_FSS0\_HPBO Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCU_HYPFLSH_INT	HyperBus Interrupt Request	Level
MCU_HYPFLSH_SEC_INT	HyperBus ECC SEC Error Interrupt Request	Level
MCU_HYPFLSH_DED_INT	HyperBus ECC DED Error Interrupt Request	Level

### 12.3.3.2 HyperBus Environment

This section describes the HyperBus external connections (environment).

[Table 12-154](#) describes the HyperBus I/O signals.

**Table 12-154. HyperBus I/O Signals**

Module Pin	I/O <sup>(1)</sup>	Description
CK	O	HyperBus Clock Output (differential)
CKn	O	HyperBus Inverted Clock Output (differential)
RWDS	I/O/HiZ	HyperBus Read/Write Data Strobe
DQ[7:0]	I/O/HiZ	HyperBus Data
CSn0	O	HyperBus Chip Select 0
CSn1	O	HyperBus Chip Select 1
RESETn	O	HyperBus Reset Output
RESETOn	I	Reset State Indicator (output from HyperBus memory)
INTn	I	Memory Interrupt (output from HyperBus memory)
WPn <sup>(2)</sup>	O	HyperBus Write Protect (output to HyperBus memory)

(1) I = Input; O = Output; HiZ = High Impedance

(2) WPn pin is not used on Cypress flash devices.

### 12.3.3.3 HyperBus Functional Description

The HyperBus module is a high throughput memory interface. It is a part of the device FSS and provides execute in place (XIP) operation and block copy access to HyperBus memory devices (HyperRAM and HyperFlash). The FSS enables in-line ECC protection and authentication features for the HyperBus module.

For more information about FSS, see *Flash Subsystem (FSS)*.

The HyperBus module is compliant to the *Cypress HyperBus™ Specification v1.2*.

Figure 12-83 shows the HyperBus module block diagram.

**Figure 12-83. HyperBus Module Block Diagram**

Basic Blocks:

- **HBMC:** The HyperBus Memory Controller (HBMC) is the main part (the core) of the HyperBus Subsystem and provides accessibility to external HyperBus memory (HyperFlash or HyperRAM) using simple HyperBus protocol for data read and write transfers.

- The Data Port on the HBMC is used for CBASS data slave interface to access the external HyperBus memory.
- The CFG Port on the HBMC is used for configuration of the HBMC registers.
- HyperBus I/O Interface: The HyperBus I/O Interface includes all used interface pins (for more information, see *HyperBus I/O Signals*).
- Memory IF: The Memory IF block implements the following functionality:
  - Convert single-rate command and data output from the HBMC to double-rate (DDR)
  - Use DLL to delay the incoming read data strobe from the memory
- FIFO Memories with ECC: There are internal HyperBus FIFOs implemented with memories that are used during read and write transactions. These FIFO memories are ECC protected (for more information about the FIFOs, see [Section 12.3.3.3.3, HyperBus Internal FIFOs](#)).
- ECC Aggregator: The ECC Aggregator facilitates aggregating and reporting internal HyperBus FIFO memory errors (for more information, see [Section 12.3.3.3.2, HyperBus ECC Support](#)).
- HBMC Registers: This block includes set of all used HBMC registers.
- HyperBus Subsystem Registers: This block implements memory-mapped registers at the HyperBus Subsystem level.
- ECC Aggregator Registers: This block includes all used ECC Aggregator registers.

For more information about all HyperBus registers, see *HyperBus Registers*.

- MCU\_CBASS0: The MCU\_CBASS0 interconnect implements the clock domain crossing bridges needed to separate the two main clock domains: MCU\_CBASS0 clock domain and Memory clock domain.
- Data Slave IF: The Data Slave IF on the interconnect is a 32-bit wide interface and is used to access an external HyperBus memory via the Data Port on the HBMC. The data interface supports linear incrementing addresses only. Cache-line wrap and fixed addressing modes are not supported.
- Config Slave IF: The Config Slave IF on the interconnect is a 32-bit wide interface and is used to access the HBMC registers (via the CFG Port on the HBMC), HyperBus Subsystem registers, and ECC Aggregator registers. The config interface also supports linear incrementing address mode only.

For more information about supported and not supported HyperBus features, see *HyperBus Overview*.

- Clocks: For more information about HyperBus Clocks, see *MCU\_FSS0\_HBP0 Clocks and Resets*.
- Subsystem Reset: The reset signal to the Subsystem Reset block provides reset to the all HyperBus Subsystem parts (for more information about HyperBus Resets, see *MCU\_FSS0\_HBP0 Clocks and Resets*).
- Interrupts: For more information, see *MCU\_FSS0\_HBP0 Clocks and Resets* and *HyperBus Interrupts*.

#### 12.3.3.3.1 HyperBus Interrupts

The HyperBus module sources one active high level HyperBus interrupt and two active high level ECC Aggregator interrupts (see *MCU\_FSS0\_HBP0 Hardware Requests*).

The HyperBus interrupt is generated based on the HyperBus memory's active low level interrupt. In the HyperBus Subsystem this active low level interrupt is converted to active high level HyperBus interrupt (see RESETOn pin in *Hyperbus I/O Signals*).

The ECC Aggregator interrupts are generated based on the ECC errors (single (correctable) and double (uncorrectable) bit errors) in the embedded HyperBus memories (for more information, see *HyperBus ECC Support*).

#### 12.3.3.3.2 HyperBus ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

The SEC logic detects and corrects a single bit error (single bit error per ECC word or per ECC data segment). The DED logic only detects (does not correct) double errors (double bit errors per ECC word or per ECC data segment).

The embedded HyperBus memories are ECC protected.

### 12.3.3.3.2.1 ECC Aggregator

#### Note

For more information about ECC Aggregator, refer to [Section 12.10.6, ECC Aggregator](#).

For more information about ECC Aggregator Registers, refer to *HyperBus Registers*.

### 12.3.3.3.3 HyperBus Internal FIFOs

There are 10 FIFO buffers in the module that help improve performance. [Table 12-155](#) shows the HyperBus FIFOs details.

**Table 12-155. HyperBus FIFOs**

Buffer Name	Size (Width x Depth)
Address (ADR) FIFO	Two port RAM – 16 x 46-bit
Write data (WDAT) FIFO	Two port RAM – 256 x 40-bit
Write status (BDAT) FIFO	Two port RAM – 16 x 2-bit
Read data (RDAT) FIFO	Two port RAM – 128 x 40-bit
Receive (RX) FIFO	Two port RAM – 256 x 20-bit
Address write (AW) FIFO	Two port RAM – 16 x 44-bit
Write ID (WID) FIFO	Two port RAM – 16 x 2-bit
Address write ID (AWID) FIFO	Two port RAM – 16 x 14-bit
Address read (AR) FIFO	Two port RAM – 16 x 44-bit
Address read ID (ARID) FIFO	Two port RAM – 16 x 18-bit

### 12.3.3.3.4 HyperBus Data Regions

For more information about HyperBus data regions, refer to [Section 12.3.1.3.4, FSS Memory Regions](#).

### 12.3.3.3.5 HyperBus True Continuous Read (TCR) Mode

The HBMC supports True Continuous Read (TCR) operation for HyperFlash. This feature is able to improve HyperFlash read performance.

When this feature is enabled, the HBMC can merge multiple up to 16 max burst read commands that are present in its command FIFO into a single memory read transaction to the HyperFlash memory. As a result, the command input and initial latency for the latter burst read commands are saved, which leads to improved throughput.

### 12.3.3.4 HyperBus Programming Guide

#### 12.3.3.4.1 HyperBus Initialization Sequence

The HBMC provides two sets of Memory Base Address, Memory Configuration and Memory Timing registers to access devices connected to the two external chip selects. The following programming guidelines need to use the correct set of registers depending on which chip select is accessed.

The HBMC compares the input address bits [31-24] to the value programmed in the MCU\_FSS0\_HPBO\_MC\_MBAR\_y registers to determine the external chip select that is accessed.

##### 12.3.3.4.1.1 HyperFlash Access

**Table 12-156. HyperFlash Access Sequence**

Step	Description
1.	Ensure that the FIFO RAM auto-initialization is complete by reading the MCU_FSS0_HPBO_SS_RAM_STAT_REG[0] INIT_DONE bit .
2.	<p>Lock MDLL:</p> <ul style="list-style-type: none"> <li>- To ensure that the MDLL in the HyperBus is locked, the reset to the HyperBus module should be de-asserted only after all the clock inputs are stable at the desired operating frequency (see <i>MCU_FSS0_HPBO Clocks and Resets</i>). The MDLL can lose the lock if the frequencies of the clock inputs to the HyperBus module are changed during operation.</li> <li>- To ensure that the MDLL is stabilized, the following sequence is required. Boot code should attempt to read 64 bytes of Flash data, for 16 iterations, and if the data is the same in 4 successive iterations, the DLL can be considered to be stabilized and the software proceed with normal Flash access .</li> <li>- The MCU_FSS0_HPBO_SS_DLL_STAT_REG[0] MDLL_LOCK and MCU_FSS0_HPBO_SS_DLL_STAT_REG[1] SDL_LOCK bits can be used to determine if the master delay line and slave delay line have locked, respectively .</li> </ul>
3.	<p>Initialize Memory Configuration register (MCU_FSS0_HPBO_MC_MCR_y):</p> <ul style="list-style-type: none"> <li>- MCU_FSS0_HPBO_MC_MCR_y[31] MAXEN bit and MCU_FSS0_HPBO_MC_MCR_y[26-18] MAXLEN bit field based on burst transaction length to memory.</li> <li>- MCU_FSS0_HPBO_MC_MCR_y[17] TCMO = 1h, to enable HBMC to merge multiple accesses with sequential addresses into a single memory access. This will improve memory throughput.</li> <li>- MCU_FSS0_HPBO_MC_MCR_y[16] ACS = 0h, to set 'No asymmetry cache system support'.</li> <li>- MCU_FSS0_HPBO_MC_MCR_y[5] CRT = 0h, to set 'Memory space' instead 'CR space'.</li> <li>- MCU_FSS0_HPBO_MC_MCR_y[4] DEVTYPE = 0h, to set 'HyperFlash' instead 'HyperRAM'.</li> <li>- MCU_FSS0_HPBO_MC_MCR_y[1-0] WRAPSIZE = 00h, since the HBMC does not support wrap bursts.</li> </ul>
4.	Initialize Memory Timing register (MCU_FSS0_HPBO_MC_MTR_y) based on timing of the memory device being used.
5.	<p>Initialize Memory Base Address register (MCU_FSS0_HPBO_MC_MBAR_y):</p> <ul style="list-style-type: none"> <li>- MCU_FSS0_HPBO_MC_MBAR_y[31-24] A_MSB = 8 MSB bits of memory address space. This will define the start of the 16 MB address region in the system memory where the HyperFlash can be accessed. The HBMC will initiate HyperFlash access to any memory mapped access in this range.</li> </ul>
6.	Check the MCU_FSS0_HPBO_MC_CSR[10] RRSTOERR bit in Controller Status register to ensure that the HyperFlash is out of reset.
7.	Normal HyperFlash access can be performed after this.
8.	The HyperFlash device registers and CFI (Common Flash Interface) region can be accessed by read/write transactions to the offset from the base address as specified in the device command summary table.
9.	The HyperFlash memory data array can be read as memory mapped access.
10.	The HyperFlash write sequence needs to be followed to update contents of the memory array.

### 12.3.3.4.1.2 HyperRAM Access

**Table 12-157. HyperRAM Access Sequence**

Step	Description
1.	Wait 150 $\mu$ s for RAM to power up after reset. The HyperRAM does not provide any feedback on reset/ready state to the HBMC.
2.	Ensure that the FIFO RAM auto-initialization is complete by reading the MCU_FSS0_HPB0_SS_RAM_STAT_REG[0] INIT_DONE bit.
3.	Lock MDLL: <ul style="list-style-type: none"> <li>- To ensure that the MDLL in the HyperBus is locked, the reset to the HyperBus module should be de-asserted only after all the clock inputs are stable at the desired operating frequency (see <i>MCU_FSS0_HPB0 Clocks and Resets</i>). The MDLL can lose the lock if the frequencies of the clock inputs to the HyperBus module are changed during operation.</li> <li>- To ensure that the MDLL is stabilized, the following sequence is required. Boot code should attempt to read 64 bytes of RAM data, for 16 iterations, and if the data is the same in 4 successive iterations, the DLL can be considered to be stabilized and the software proceed with normal RAM access.</li> <li>- The MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK and MCU_FSS0_HPB0_SS_DLL_STAT_REG[1] SDL_LOCK bits can be used to determine if the master delay line and slave delay line have locked, respectively.</li> </ul>
4.	Initialize Memory Configuration register (MCU_FSS0_HPB0_MC_MCR_y): <ul style="list-style-type: none"> <li>- MCU_FSS0_HPB0_MC_MCR_y[31] MAXEN bit and MCU_FSS0_HPB0_MC_MCR_y[26-18] MAXLEN bit field based on burst transaction length to memory.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[17] TCMO = 0h, since HBMC does not support command merging for HyperRAM accesses.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[16] ACS = 0h, to set 'No asymmetry cache system support'.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[5] CRT = 0h or 1h, depending on what needs to be accessed (memory or register space).</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[4] DEVTYPE = 1h, to set 'HyperRAM' instead 'HyperFlash'.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[1-0] WRAPSIZE = 00h, since the HBMC does not support wrap bursts.</li> </ul>
5.	Initialize MCU_FSS0_HPB0_MC_MTR_y register based on timing of the memory device being used.
6.	Initialize MCU_FSS0_HPB0_MC_MCR_y register: <ul style="list-style-type: none"> <li>- MCU_FSS0_HPB0_MC_MCR_y[31-24] A_MSB = 8 MSB bits of memory address space. This will define the start of the 16 MB address region in the system memory where the HyperRAM can be accessed. The controller will initiate HyperRAM access to any memory mapped access in this range.</li> </ul>
7.	Check the MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK bit to ensure the Master DLL is locked.
8.	Normal HyperRAM access can be performed after this.
9.	The HyperRAM device registers can be accessed by read/write transactions to the offset from the base address as specified in the device command summary table with MCU_FSS0_HPB0_MC_MCR_y[5] CRT bit set to register space.
10.	The HyperRAM memory data array can be read/written to as memory mapped access with MCU_FSS0_HPB0_MC_MCR_y[5] CRT bit set to memory space.

#### Note

HyperRAM devices have a 150  $\mu$ s startup time. Software needs to wait this duration after reset to initiate transactions to a HyperRAM device.

### 12.3.3.4.2 HyperBus Real-time Operating Requirements

The HBMC may assert the memory interrupt based on the status of the memory transaction. Software needs to handle this interrupt using the MCU\_FSS0\_HPB0\_MC\_ISR register. The MCU\_FSS0\_HPB0\_MC\_ISR register can provide the status information to determine the cause of the interrupt.

### 12.3.3.4.3 HyperBus Power Up/Down Sequence

Software needs to ensure that there are no pending transactions before stopping clock and/or power to the HBMC.

### 12.3.4 General-Purpose Memory Controller (GPMC)

This section describes the General-Purpose Memory Controller (GPMC) for the device.

#### 12.3.4.1 GPMC Overview

The General-Purpose Memory Controller is a unified memory controller dedicated for interfacing with external memory devices like:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in non-multiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

##### 12.3.4.1.1 GPMC Features

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to 4 chip select regions of programmable size and programmable base addresses in a total address space of 1GB
- Supports on-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) ( $t = 4, 8, \text{ or } 16$ ) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth usage
- The clock to the external memory is provided from GPMC\_FCLK divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters with a timing granularity of one GPMC\_FCLK clock cycle.
- Flexible internal access time control (wait state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write-posting engine associated with DMA controller at system level to achieve full performance from the NAND device with minimum effect on NOR/SRAM concurrent access
- 32-bit interconnect slave interface which supports non-wrapping and wrapping burst of up to 16x32 bits.

The GPMC supports the following various access types:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8 and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8 and 16 Word16)
- Address-data-multiplexed (AD) access
- Address-address-data (AAD) multiplexed access
- Little-endian access only

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit non-multiplexed NOR flash device
- External 16-bit address and data multiplexed NOR Flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

---

#### Note

Page mode is available only in non-multiplexed mode.

---

#### Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

##### 12.3.4.1.2 GPMC Not Supported Features

The following features are not supported on this family of devices:

- DMA mode is not supported.
- Asynchronous page write mode is not supported.
- Multiple write access in asynchronous mode is not supported.
- Multiple read access in asynchronous mode is not supported in address/data-multiplexed and AAD-multiplexed modes.

##### 12.3.4.1.3 GPMC Ports

**Table 12-158. GPMC0 Clocks and Resets**

Clocks	
Module Clock Input	Description
GPMC_FCLK	GPMC Functional Clock. For more information about clock multiplexing, see CTRLMMR_GPMC_CLKSEL[1-0] CLK_SEL in <i>Control Module (CTRL_MMR)</i> .
GPMC_ICLK	GPMC Interface Clock
Resets	
Module Reset Input	Description
GPMC_RST	GPMC Asynchronous Reset

**Table 12-159. GPMC0 Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
GPMC_GPMC_SINTERRUPT_0	GPMC Interrupt Request	Level

##### 12.3.4.2 GPMC Environment

This section describes the GPMC0 external connections (environment).

[Table 12-160](#) lists the GPMC subsystem input/output (I/O) pins.

**Table 12-160. GPMC I/O Signals (Master Mode)**

Module Pin	I/O <sup>(1)</sup>	Description
A[27-0]	O	28-bit output address bus
A[16-1]/D[15-0]	I/O	Multiplexed address/data
nCS[3-0]	O	Chip-selects (active low)
CLK	O	Clock generated for the external memory or device. For more information, see <i>GPMC Integration</i> .
RET_CLK		
N/A	O	Free running clock. GPMC functional clock (GPMC0_FCLK) propagated on a device pad. For more information on the GPMC0_FCLK_MUX integration, see <i>GPMC Integration</i> .
nADV/ALE	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	O	Write enable (active low)
nBE0/CLE	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	O	Upper-byte enable (active low)
WAIT[3-0]	I	External wait signal for NOR and NAND protocol memories. Can be mapped on any of the chip-selects.
nWP	O	Write protect (active low)

**Table 12-160. GPMC I/O Signals (Master Mode) (continued)**

Module Pin	I/O <sup>(1)</sup>	Description
DIR	O	This signal can be used to control an external buffer direction. Also controls the signal direction of D[15-0]. Low during transmit (for write access: data OUT from GPMC0 to memory). High during receive (for read access: data IN from memory to GPMC0).

(1) I = Input; O = Output; I/O - Bidirectional

### 12.3.4.3 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the four configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external WAIT pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

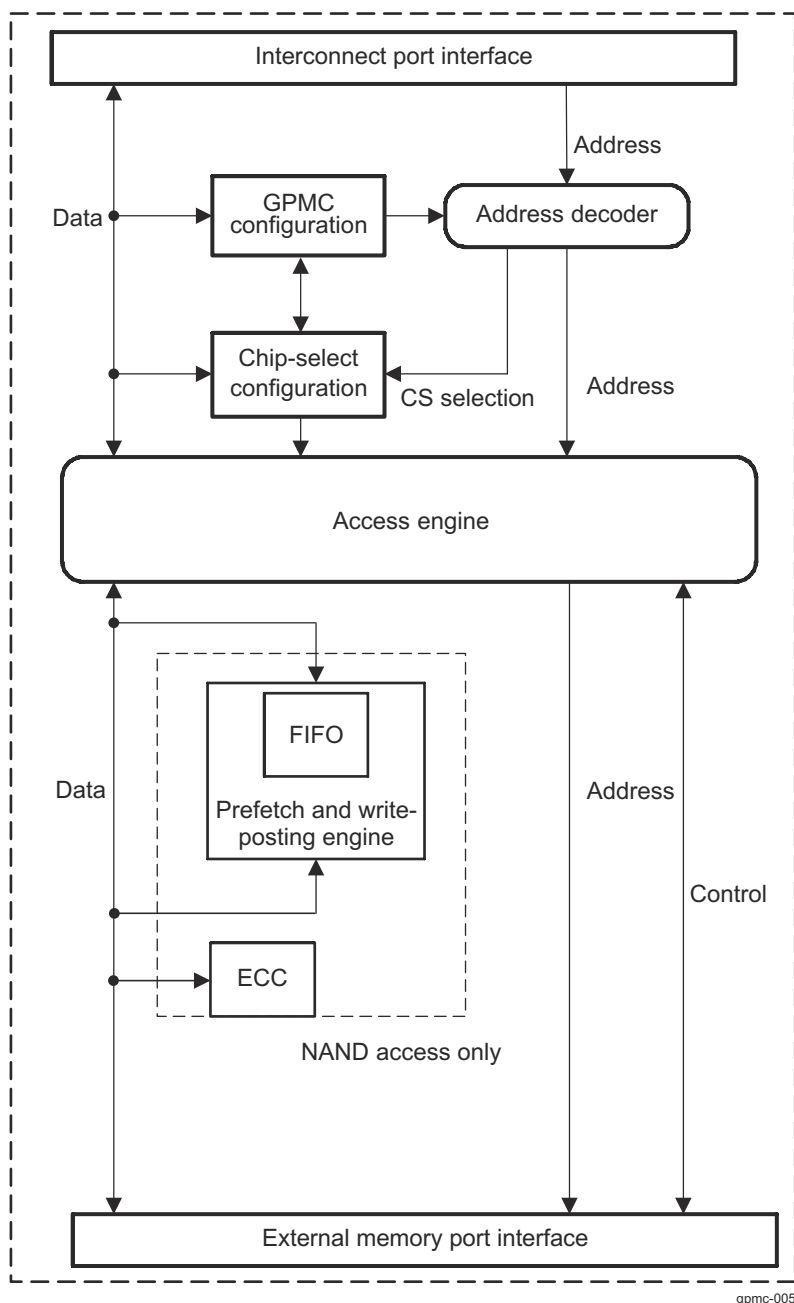

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC\_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

#### 12.3.4.3.1 GPMC Block Diagram

Figure 12-84 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

**Figure 12-84. GPMC Block Diagram**

The GPMC can access various external devices. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

#### 12.3.4.3.2 GPMC Clock Configuration

Table 12-161 describes the GPMC clocks.

**Table 12-161. GPMC Clocks**

Signal	I/O <sup>(1)</sup>	Description
GPMC_FCLK	I	Functional clock

**Table 12-161. GPMC Clocks (continued)**

Signal	I/O <sup>(1)</sup>	Description
GPMC_ICLK	I	Interface clock
CLK (GPMC_CLKOUT pin)	O	External clock provided to synchronous external memory devices.

(1) I = Input; O = Output; I/O - Bidirectional

The GPMC output clock (CLK) is generated by the GPMC from the internal GPMC\_FCLK clock. The source of the GPMC\_FCLK is described in *GPMC0 Clocks and Resets*. The GPMC output clock is configured using the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), as shown in [Table 12-162](#).

**Table 12-162. GPMC Output Clock Configuration**

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC Output Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

When using synchronous interface protocols, the GPMC output clock (CLK), toggles only during the read or write access cycle. In some applications, it may be desirable to have a continuous clock running at the GPMC interface clock frequency for clocking attached devices. This option is enabled by an optional clock path from the GPMC functional clock input (GPMC\_FCLK) to the GPMC\_FCLK\_MUX pin. This output clock, to GPMC\_FCLK\_MUX pin, can be selected through the standard MUXMODE selection of the GPMC\_FCLK\_MUX pin PADCONFIG control register.

Note that when using such synchronous interface protocols with the continuous clock option, user should ensure that the GPMC outputs are timed to the same frequency (GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0).

#### 12.3.4.3.3 GPMC Power Management

[Table 12-163](#) describes the local power-management features available for the GPMC module.

**Table 12-163. GPMC Local Power-Management Features**

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_ICLK clock upon the internal activity.
Slave idle modes	GPMC_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle and smart-idle modes are available.

#### 12.3.4.3.4 GPMC Interrupt Requests

The GPMC generates one interrupt request (see *GPMC0 Hardware Requests*).

[Table 12-164](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 12-164. GPMC Interrupt Events**

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[11] WAIT3EDGE DETECTIONSTATUS	GPMC_IRQENABLE[11] WAIT3EDGE DETECTIONENABLE	Edge	Wait3 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT3 signal. The rising or falling edge detection of Wait3 is selected through the GPMC_CONFIG[11] WAIT3PINPOLARITY bit.
GPMC_IRQSTATUS[10] WAIT2EDGE DETECTIONSTATUS	GPMC_IRQENABLE[10] WAIT2EDGE DETECTIONENABLE	Edge	Wait2 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT2 signal. The rising or falling edge detection of Wait2 is selected through the GPMC_CONFIG[10] WAIT2PINPOLARITY bit.

**Table 12-164. GPMC Interrupt Events (continued)**

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

#### 12.3.4.3.5 GPMC Interconnect Port Interface

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The GPMC interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the GPMC\_CONFIG1\_i[31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

#### 12.3.4.3.6 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-non-multiplexed memories or devices is supported with an address range of 256MB.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit-wide NOR devices do not use GPMC I/O: GPMC\_AD[15-8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: .
- 8-bit-wide NAND devices do not use GPMC I/O: and GPMC I/O: GPMC\_AD[15-8].

#### 12.3.4.3.6.1 GPMC I/O Configuration Setting

---

##### Note

In this section and the following sections, the *i* in GPMC\_CONFIGx\_*i* stands for the GPMC chip-select *i*, where *i* = 0 to 3.

---

To select a NAND device, program the following register fields:

- GPMC\_CONFIG1\_*i*[11-10] DEVICETYPE = 0b10
- GPMC\_CONFIG1\_*i*[9-8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_*i*[11-10] DEVICETYPE = 0b00
- GPMC\_CONFIG1\_*i*[9-8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_*i*[11-10] DEVICETYPE = 0b00
- GPMC\_CONFIG1\_*i*[9-8] MUXADDDATA = 0b01

To select an address/data-non-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_*i*[11-10] DEVICETYPE = 0b00
- GPMC\_CONFIG1\_*i*[9-8] MUXADDDATA = 0b00

#### 12.3.4.3.7 GPMC Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and four sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

##### 12.3.4.3.7.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 128MB address space. For more information, see *Memory Map*.

---

##### Note

Even though GPMC supports total address space of 1GB, only 128MB are physically available in this device.

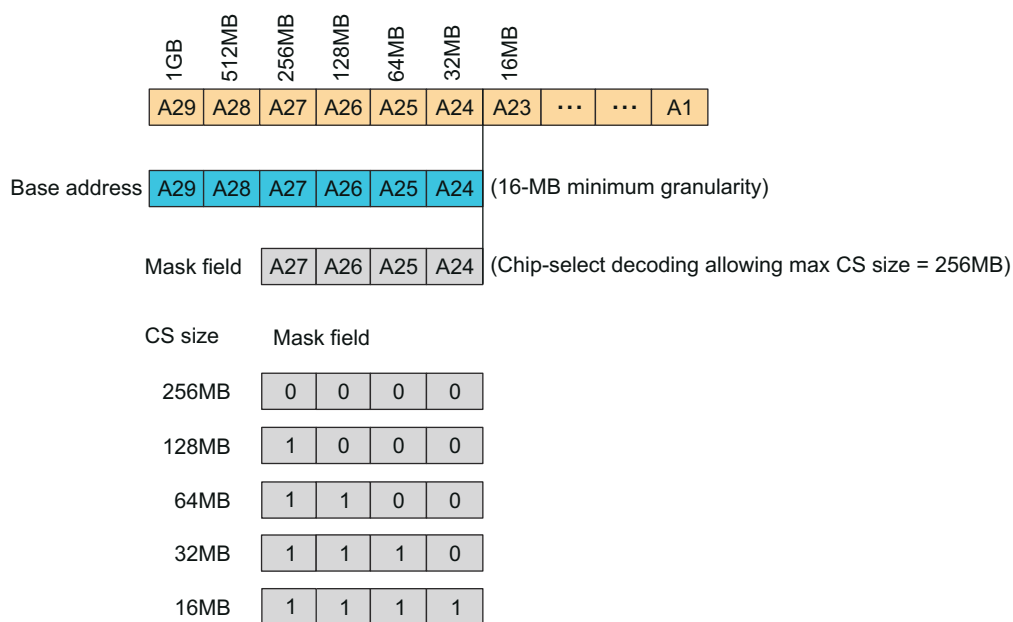

---

The GPMC 128MB address space can be divided into a maximum of four chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16MB to 256MB

(must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in [Figure 12-85](#) (with A0 as the device system byte-address line). The base address is programmed through the GPMC\_CONFIG7\_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC\_CONFIG7\_i[11-8] MASKADDRESS bit field.

gpmc-006

**Figure 12-85. Chip-Select Address Mapping and Decoding Mask**

For example, to map the 128MB address space (from 2000 0000h to 27FF FFFFh), the GPMC\_CONFIG7\_i[5-0] BASEADDRESS bit field should be set to 20h.

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC\_CONFIG7\_i[6] CSVALID bit (where i stands for the GPMC chip-select i, where i = 0 to 3). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

**CAUTION**

Although the GPMC interface can drive up to four chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines at the value specified in the device-specific Datasheet.

**12.3.4.3.7.2 Access Protocol****12.3.4.3.7.2.1 Supported Devices**

The access protocol of each chip-select can be independently specified through the GPMC\_CONFIG1\_i[11-10] DEVICETYPE parameter (where i = 0 to 3) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM
- NAND flash asynchronous devices

**Note**

For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 12.3.4.3.11, GPMC NAND Device Basic Programming Model](#), and [Section 12.3.4.3.11.1, NAND Memory Device in Byte or Word16 Stream Mode](#).

**12.3.4.3.7.2.2 Access Size Adaptation and Device Width**

Each chip-select can be independently configured through the GPMC\_CONFIG1\_i[13-12] DEVICESIZE bit field (where i = 0 to 3) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

**12.3.4.3.7.2.3 Address/Data-Multiplexing Interface**

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit field (where i = 0 to 3). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See *GPMC Integration*.

**Note**

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See [Section 12.3.4.3.11, NAND Device Basic Programming Model](#).

**12.3.4.3.7.3 External Signals****12.3.4.3.7.3.1 WAIT Pin Monitoring Control**

GPMC access time can be dynamically controlled using an external GPMC\_WAIT pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features four input WAIT pins: GPMC\_WAIT0 through GPMC\_WAIT3. These pins allow control of external devices with different WAIT pin polarity. They also allow the overlap of WAIT pin assertion from different devices without affecting access to devices for which the WAIT pin is not asserted.

- The GPMC\_CONFIG1\_i[17-16] WAITPINSELECT bit field (where i = 0 to 3) selects which input GPMC\_WAIT pin is used for the device attached to the corresponding chip-select.
- The polarity of the WAIT pin is defined through the WAITxPINPOLARITY bit of the GPMC\_CONFIG register. A WAIT pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a WAIT pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the WAIT pin of the external memory device, based on the access type: read or write.

- The GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit defines whether or not the WAIT pin must be monitored during read accesses.
- The GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit defines whether or not the WAIT pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the WAIT pin of the external memory device asynchronously or synchronously with the GPMC output clock, depending on the access type: synchronous or asynchronous (the GPMC\_CONFIG1\_i[29] READTYPE and GPMC\_CONFIG1\_i[27] WRITETYPE bits).

#### 12.3.4.3.7.3.1.1 Wait Monitoring During Asynchronous Read Access

When WAIT pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with WAIT pin monitoring enabled, the WAIT pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through WAIT pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the WAIT pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

#### Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and no GPMC output clock is provided to the external device. Still, because GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 12-86 shows wait behavior during an asynchronous single read access.

**Figure 12-86. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)**

### Note

The WAIT signal is active low. GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME = 0b00, or 0b01.

#### 12.3.4.3.7.3.1.2 Wait Monitoring During Asynchronous Write Access

When WAIT pin monitoring is enabled for write accesses (GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the WAIT pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

### Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

#### 12.3.4.3.7.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with WAIT pin monitoring enabled, the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC output clock cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3), and is expressed as a number of GPMC output clock cycles.

In synchronous mode, when WAIT pin monitoring is enabled (the GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the WAIT pin must be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC\_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access

time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.

- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 12-87 shows wait behavior during a synchronous read burst access.

**Figure 12-87. Wait Behavior During a Synchronous Read Burst Access**

---

**Note**

The WAIT signal is active low. WAITMONITORINGTIME = 0b00, 0b01.

---

#### 12.3.4.3.7.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with WAIT pin monitoring enabled (the GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit), the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

If enabled, external WAIT pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC output clock capture edge of the effective memory device.

WAIT-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC\_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

---

**Note**

WAIT monitoring is supported for all configurations except GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME = 0x0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 (the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field is equal to 0x0 or 0x1, respectively).

---

#### 12.3.4.3.7.3.1.5 Wait With NAND Device

For information about the use of the WAIT pin for communication with a NAND flash external device, see [Section 12.3.4.3.11.2, NAND Device-Ready Pin](#).

#### 12.3.4.3.7.3.1.6 Idle Cycle Control Between Successive Accesses

##### 12.3.4.3.7.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC\_CONFIG6\_i[3-0] BUSTURNAROUND bit field (where i = 0 to 3).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

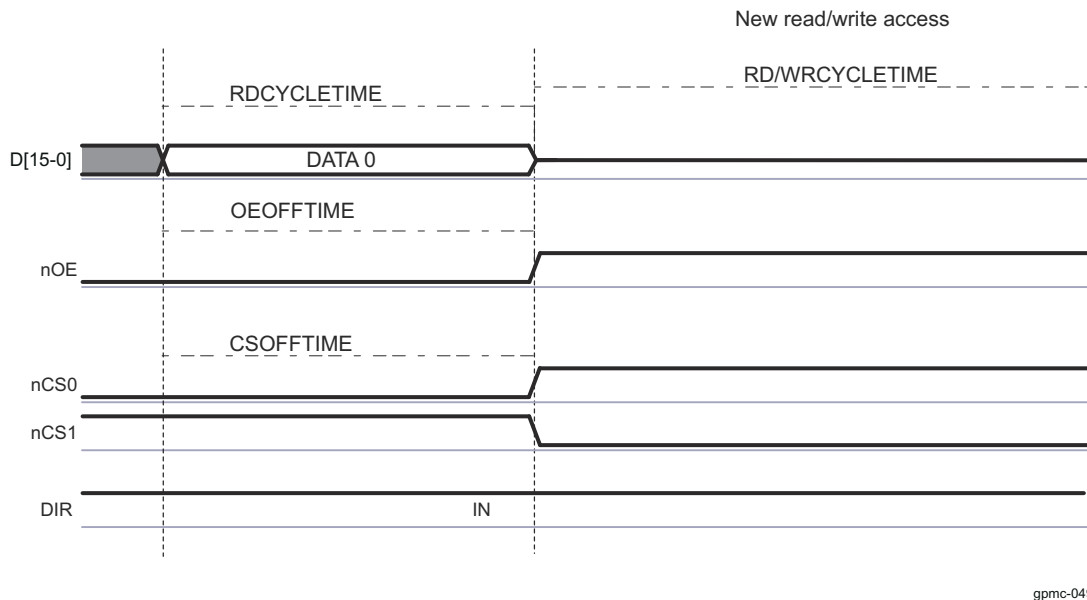

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

#### Note

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC\_CONFIG6\_i[3-0] CYCLE2CYCLEDELAY bit field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see the following figures).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

**Figure 12-88. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)**

#### 12.3.4.3.7.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMECSSEN bit (where i = 0 to 3) enables insertion of a minimum number of GPMC\_FCLK cycles, defined by the GPMC\_CONFIG6\_i[11-8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSROFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC\_CONFIG1\_i[30] READMULTIPLE = 0 or GPMC\_CONFIG1\_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC output clock (CLK)) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC output clock at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC\_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

#### 12.3.4.3.7.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the GPMC\_CONFIG6\_i[6] CYCLE2CYCLEDIFFCSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC\_FCLK cycles.

#### Note

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the GPMC\_CONFIG6\_i registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see [Section 3.4.3.7.3.1.6.1, Bus Turnaround \(BUSTURNAROUND\)](#).

Table 12-165 describes the configuration required for idle cycle insertion.

**Table 12-165. Idle Cycle Insertion Configuration**

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.

**Table 12-165. Idle Cycle Insertion Configuration (continued)**

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

#### 12.3.4.3.7.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select i, where i = 0 to 3). Increasing all access timing parameters allows support of slow devices.

#### 12.3.4.3.7.3.2 DIR Pin

The DIR pin is used to control I/O direction on the GPMC data bus GPMC\_D[15-0]. Depending on pad multiplexing, this signal can be output and used externally to the device, if required. The DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the DIR pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled
  - The DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
  - After an asynchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 1 GPMC\_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 2 GPMC\_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the DIR pin is OUT (see [Section 12.3.4.3.8.10, Bus Keeping Support](#)). In non-multiplexed devices, the DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

#### 12.3.4.3.7.3.3 Reset

No reset signal is sent to the external memory device by the GPMC.

GPMC\_RST is the reset signal for the GPMC module. It is connected and controlled by LPSC8 in VD\_CORE. That reset signal initializes the internal state-machine and the internal configuration registers.

#### 12.3.4.3.7.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The nWP output pin value is controlled through the GPMC\_CONFIG[4] WRITEPROTECT bit which is common for all chip selects.

#### 12.3.4.3.7.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

#### 12.3.4.3.7.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC\_ERR\_TYPE register and the address of the illegal access is stored in the GPMC\_ERR\_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC\_ERR\_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC\_ERR\_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC\_TIMEOUT\_CONTROL register and enabled with the GPMC\_TIMEOUT\_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. An interrupt generation is handled at interconnect level.

#### 12.3.4.3.8 GPMC Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about GPMC\_CLKOUT and GPMC\_FCLK, see *GPMC\_CLKOUT*.

#### Note

In the following sections, the start access time refers to the time at which the access begins.

#### 12.3.4.3.8.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC\_CONFIG5\_i[4-0] RDCYCLETIME and GPMC\_CONFIG5\_i[12-8] WRCYCLETIME bit fields (where  $i = 0$  to 3) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC output clock between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC\_FCLK cycles and must be multiples of the GPMC output clock cycle. The RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit.

When RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

#### Note

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC output clock) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC output clock at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC\_FCLK cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMECSSEN = 0 or GPMC\_CONFIG6\_i[6] CYCLE2CYCLEDIFFCSSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, CYCLE2CYCLESAMECSSEN = 1 or CYCLE2CYCLEDIFFCSSEN = 1), the control signals are forced to their respective default reset values for the number of GPMC\_FCLK cycles defined in CYCLE2CYCLEDELAY.

#### 12.3.4.3.8.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC\_CONFIG2\_i[3-0] CSONTIME bit field (where i = 0 to 3) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC\_CONFIG2\_i[12-8] CSRDOFFTIME (read access) and GPMC\_CONFIG2\_i[20-16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG2\_i[7] CSEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. CSEXTRADELAY is especially useful in configurations where GPMC output clock and GPMC\_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### 12.3.4.3.8.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC\_CONFIG3\_i[3-0] ADVONTIME field (where i = 0 to 3) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME (read access) and GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG3\_i[7] ADVEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC output clock and GPMC\_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME, GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME, and GPMC\_CONFIG3\_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see [Section 12.3.4.3.11](#), *GPMC NAND Access Description*.

#### **12.3.4.3.8.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)**

The GPMC\_CONFIG4\_i[3-0] OEONTIME bit field (where i = 0 to 3) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user must ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG4\_i[7] OEEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### **Note**

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

#### 12.3.4.3.8.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC\_CONFIG4\_i[19-16] WEONTIME bit field (where i = 0 to 3) defines the nWE signal-assertion time relative to start access time. The GPMC\_CONFIG4\_i[28-24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG4\_i[23] WEEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### 12.3.4.3.8.6 GPMC\_CLKOUT

The GPMC output clock generated for external synchronous memory or device is GPMC\_CLKOUT.

- The GPMC\_CLKOUT clock frequency is the GPMC\_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device-specific Datasheet.
- The GPMC\_CLKOUT clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) defines the number of GPMC\_FCLK cycles from start access time to GPMC\_CLKOUT activation.
- The GPMC\_CLKOUT clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC\_CLKOUT clock is kept low when access is defined as asynchronous.

#### CAUTION

When the cycle time completes, the GPMC\_CLKOUT may be high because of the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC\_CLKOUT clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

#### Note

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

#### 12.3.4.3.8.7 GPMC Output Clock and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC output clock edge can be controlled in the following ways:

- For the GPMC output clock signal, the GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC output clock allows setup and hold control of the control-signal assertion and deassertion times.
- When the GPMC output clock runs at the GPMC\_FCLK frequency so that GPMC output clock edge and control-signal transitions refer to the same GPMC\_FCLK edge, the control-signal transitions can be delayed by a half-GPMC\_FCLK period to provide minimum setup and hold times. This half-GPMC\_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEXTRADELAY, or WEEXTRADELAY parameter.

This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC\_FCLK cycle.

#### **12.3.4.3.8.8 Access Time (RDACCESSTIME / WRACCESSTIME)**

The read/write access time durations can be programmed independently through the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME and GPMC\_CONFIG6\_i[28-24] WRACCESSTIME bit fields (where i = 0 to 3). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit.

##### **12.3.4.3.8.8.1 Access Time on Read Access**

In asynchronous read mode, for single and paged accesses, the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field (where i = 0 to 3) defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC\_FCLK cycles from the start access time to the GPMC\_FCLK rising edge corresponding to the GPMC output clock rising edge used for the first data capture.

GPMC output clock, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC\_CONFIG5\_i[4-0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC output clock.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

##### **12.3.4.3.8.8.2 Access Time on Write Access**

In asynchronous write mode, the GPMC\_CONFIG6\_i[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the GPMC\_WAIT pin is at a valid state two GPMC output clock cycles before WRACCESSTIME completes. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC\_FCLK cycles from the start access time to the GPMC output clock rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC output clock edge for a synchronous write access. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

#### **12.3.4.3.8.9 Page Burst Access Time (PAGEBURSTACCESSTIME)**

The GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME bit field (where i = 0 to 3) can be set with a granularity of 1 or 2 through the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit.

##### **12.3.4.3.8.9.1 Page Burst Access Time on Read Access**

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

#### 12.3.4.3.8.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC output clock edge in synchronous write mode. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

#### 12.3.4.3.8.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

#### 12.3.4.3.9 GPMC NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC\_CONFIG1\_i[29] READTYPE bit (where i = 0 to 3). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC\_CONFIG1\_i[27] WRITETYPE bit where (i = 0 to 3).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC\_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC output clock (CLK), RdAccessTime, WrAccessTime, and WAIT pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

#### Note

The address bus and nBE[1-0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

#### 12.3.4.3.9.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC output clock is not provided outside the GPMC and is kept low.

##### 12.3.4.3.9.1.1 Access on Address/Data Multiplexed Devices

##### 12.3.4.3.9.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-205](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.4.3.7.2.3, Address/Data-Multiplexing Interface](#).

Address bits (A[16-1] from a GPMC perspective, A[15-0] from an external device perspective) are placed on the address/data bus, and the remaining address bits are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CSONTIME bit field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC\_CONFIG2\_i[12-8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see [Section 12.3.4.3.9.5, System Burst Versus External Device Burst Support](#).

Between two successive accesses, if an nCS pulse is needed:

- The GPMC\_CONFIG6\_i[11-8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMECSSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

#### **12.3.4.3.9.1.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-205](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see [Section 12.3.4.3.7.2.3, Address/Data-Multiplexing Interface](#).

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC\_CONFIG4\_i[19-16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC\_CONFIG4\_i[28-24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC\_CONFIG5\_i[12-8] WRCYCLETIME parameter.

Address bits A[16-1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits are placed on the address bus.

Data is driven on the address/data bus at a GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS time.

#### **Note**

Multiple write access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 12.3.4.3.8.10, Bus Keeping Support](#).

#### **12.3.4.3.9.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device**

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC\_CONFIG1\_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC\_CONFIG1\_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 12.3.4.3.9.3, Asynchronous and Synchronous Accesses in non-multiplexed Mode](#).

#### **12.3.4.3.9.1.2 Access on Address/Address/Data-Multiplexed Devices**

##### **12.3.4.3.9.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-205](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVAADMUXRD OFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRD OFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUX OFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OE OFFTIME bit field.

##### **12.3.4.3.9.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-205](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See [Table 12-196, NAND Memory Type](#).

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[30-28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUX OFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS parameter.

#### 12.3.4.3.9.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the GPMC\_CONFIG1\_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC\_CONFIG1\_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 12.3.4.3.9.3, Asynchronous and Synchronous Accessed in non-multiplexed Mode](#).

#### 12.3.4.3.9.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (non-multiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on non-multiplexed devices, see [Section 12.3.4.3.9.3, Asynchronous and Synchronous Accessed in non-multiplexed Mode](#).

In synchronous operations:

- The GPMC\_CLKOUT clock is provided outside the GPMC when accessing the memory device.
- The GPMC\_CLKOUT clock is derived from the GPMC\_FCLK clock using the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field. In the following section *i* stands for the chip-select number, *i* = 0 to 3.
- The GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME bit field specifies that the GPMC\_CLKOUT is provided outside the GPMC for 0 to 2 GPMC\_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

##### 12.3.4.3.9.2.1 Synchronous Single Read

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-205](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.4.3.7.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CSONTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC\_CONFIG2\_i[12-8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.

- nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVADMUXRDOffTIME bit field.
- nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
- nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOffTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 12.3.4.3.8.10, Bus Keeping Support](#).

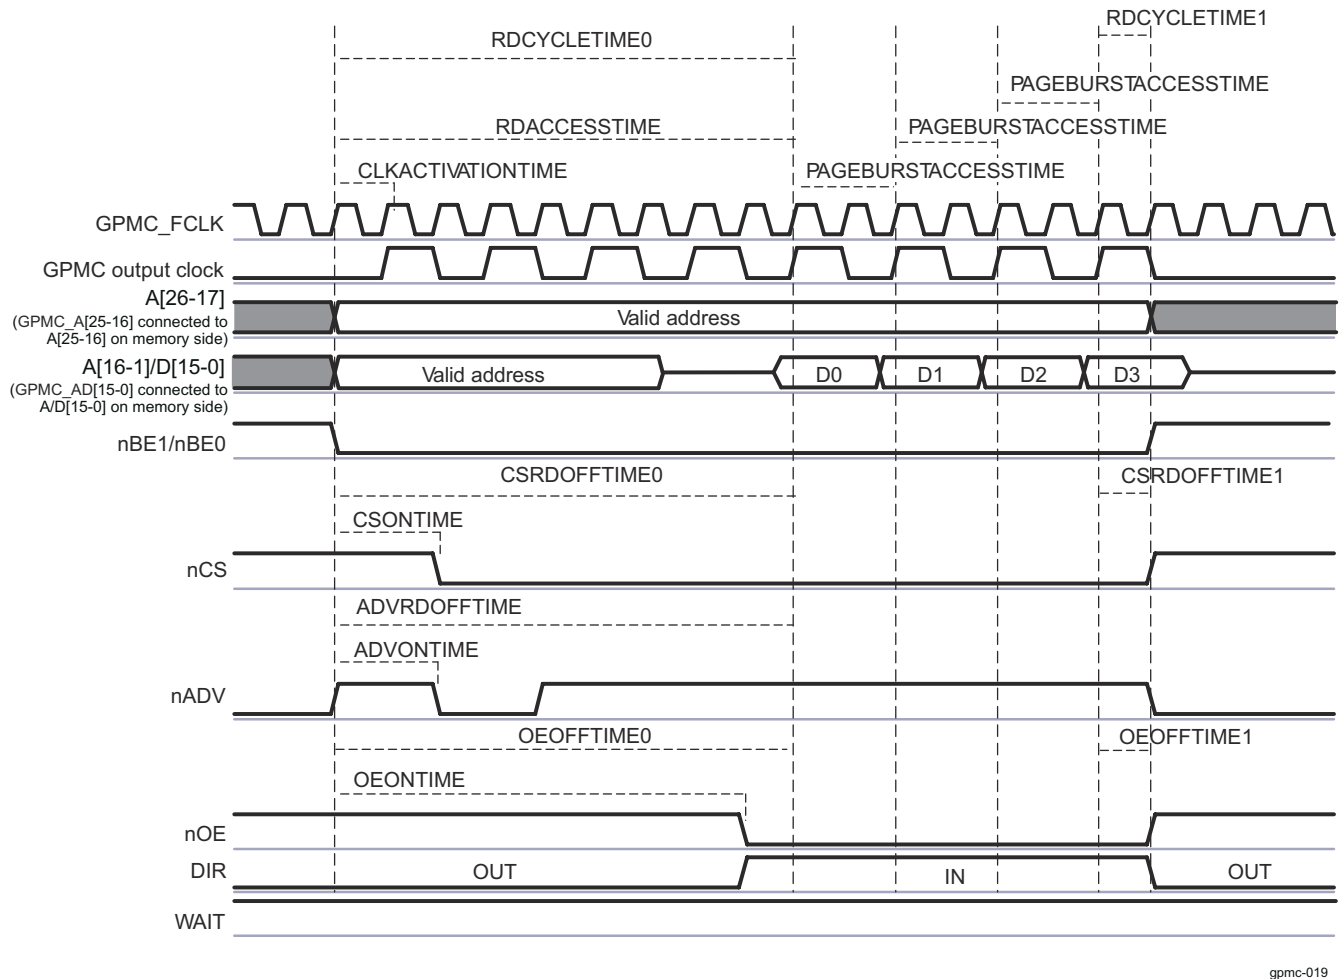

#### 12.3.4.3.9.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

[Figure 12-89](#) and [Figure 12-90](#) show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

gpmc-018

**Figure 12-89. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)**

gpmc-019

**Figure 12-90. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)**

When the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See [Table 12-191](#), *NOR Memory Type*.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC\_CLKOUT cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC\_CONFIG5\_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In [Figure 12-90](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 12.3.4.3.8.10](#), *Bus Keeping Support*.

Burst wraparound is enabled through the GPMC\_CONFIG1\_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field.

### 12.3.4.3.9.2.3 Synchronous Single Write

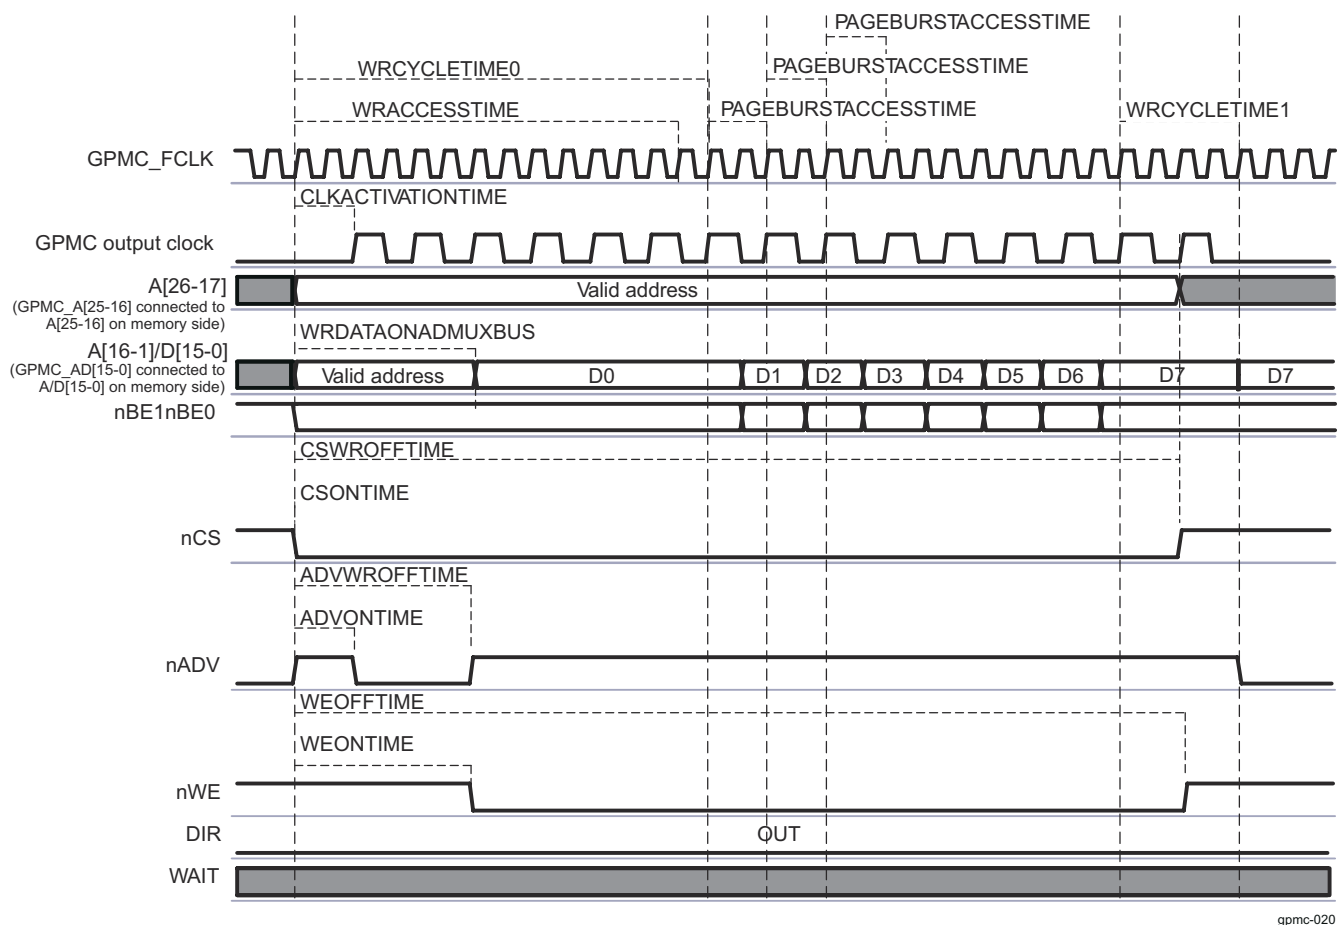

Burst write mode is used for synchronous single or burst accesses.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16-1]) until the GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

### 12.3.4.3.9.2.4 Synchronous Multiple (Burst) Write

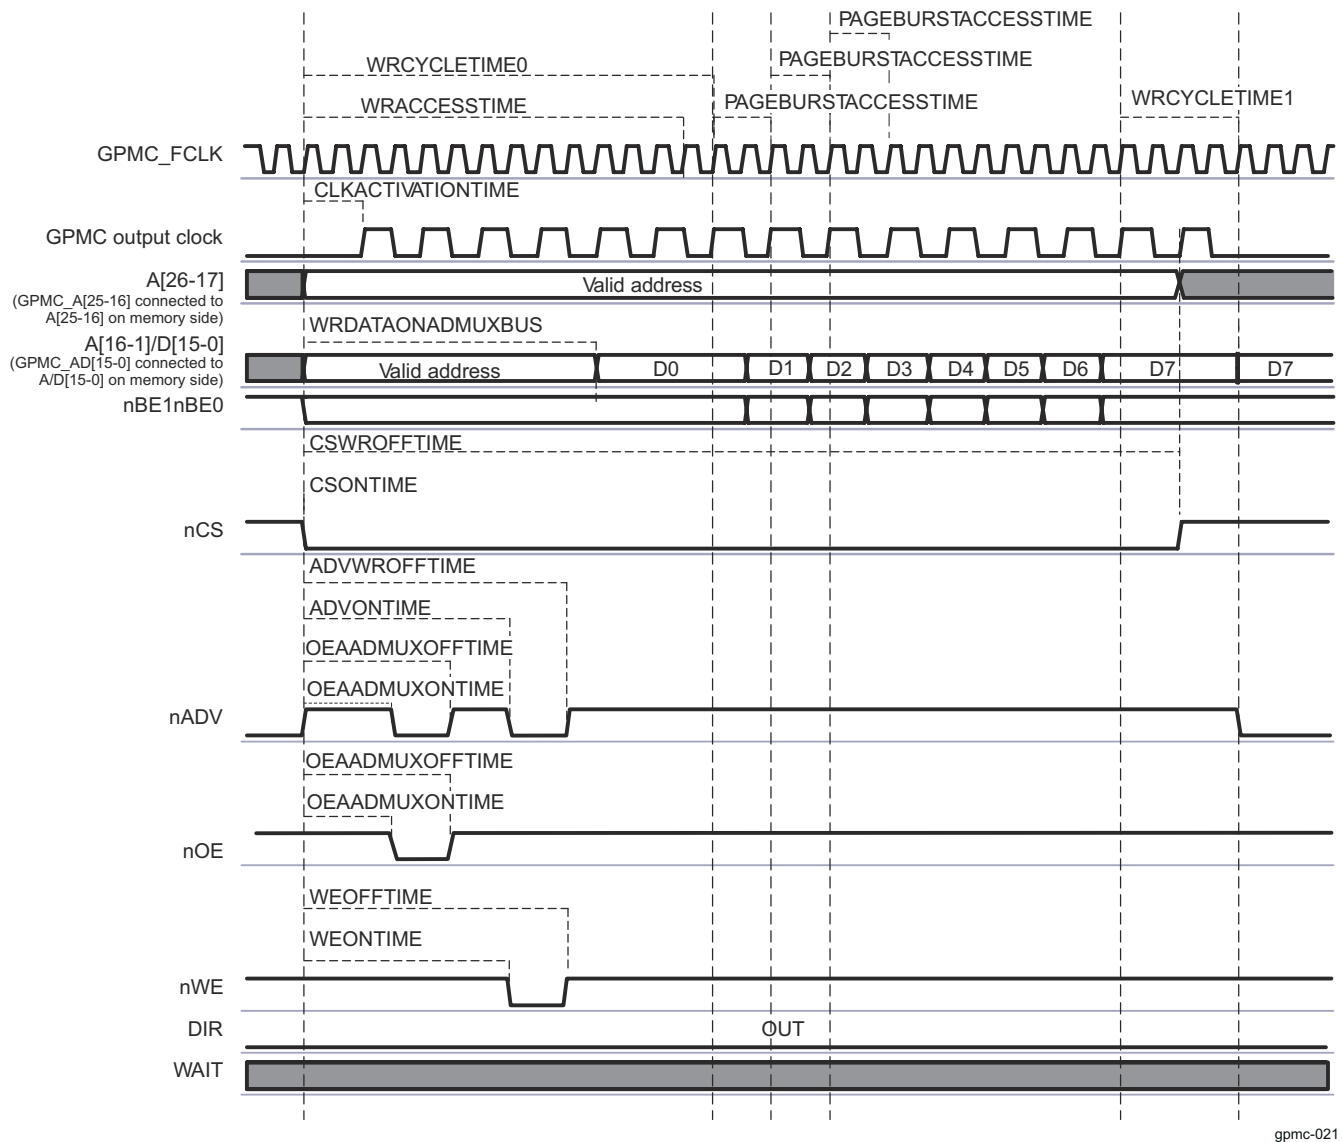

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 12-91 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

**Figure 12-91. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode**

Figure 12-92 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

**Figure 12-92. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode**

The first data of the burst is driven on the A/D bus at the GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS bit field.

When WRACCESTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.4.3.7.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CSONTIME bit field (where i = 0 to 3) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC\_CONFIG2\_i[20-16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME bit field.
- Write enable signal nWE:

- nWE assertion indicates a read cycle.
- nWE assertion time is controlled by the GPMC\_CONFIG4\_i[19-16] WEONTIME bit field.
- nWE deassertion time is controlled by the GPMC\_CONFIG4\_i[28-24] WEOFFTIME bit field.

#### Note

The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC\_CONFIG4\_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME GPMC\_FCLK cycles. The last data of the synchronous burst write is driven until GPMC\_CONFIG5\_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC\_CONFIG6\_i[28-24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC\_CONFIG5\_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In [Figure 12-91](#), the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 12.3.4.3.8.10, Bus Keeping Support](#).

#### 12.3.4.3.9.3 Asynchronous and Synchronous Accesses in non-multiplexed Mode

Page mode is available only in non-multiplexed mode.

- Asynchronous single-read operation on a non-multiplexed device
- Asynchronous single-write operation on a non-multiplexed device
- Asynchronous multiple- (page mode) read operation on a non-multiplexed device
- Synchronous operations on a non-multiplexed device

##### 12.3.4.3.9.3.1 Asynchronous Single-Read Operation on non-multiplexed Device

The address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus and the 16-bit data is driven onto the data bus D[15-0].

Read data is latched at GPMC\_CONFIG1\_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC\_CONFIG1\_5[4-0] RDCYCLETIME parameter.

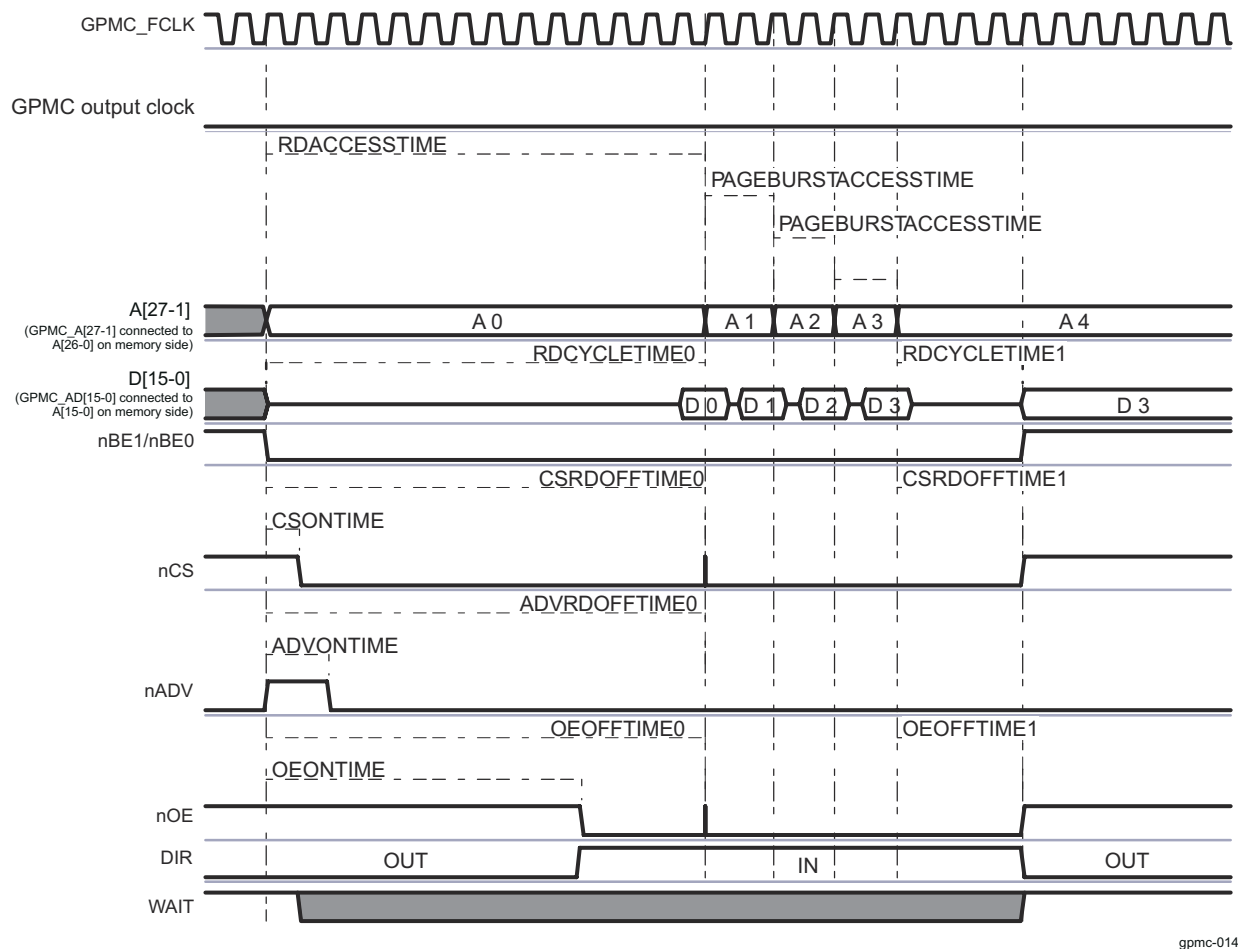

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 12-196, *NAND Memory Type*).

#### 12.3.4.3.9.3.2 Asynchronous Single-Write Operation on non-multiplexed Device

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 12-196).

#### 12.3.4.3.9.3.3 Asynchronous Multiple (Page Mode) Read Operation on non-multiplexed Device

Figure 12-93 shows an asynchronous multiple-read operation on a non-multiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

gpmc-014

**Figure 12-93. Asynchronous Multiple (Page Mode) Read**

#### Note

The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 12-196).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC\_CONFIG5\_i[20-16] RDACCESSTIME completion time (where i = 0 to 3). The end of the access is defined by the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME bit field.
- In [Figure 12-93](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

#### 12.3.4.3.9.3.4 Synchronous Operations on a non-multiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 12.3.4.4.3, GPMC Configuration in NOR Mode](#).

#### 12.3.4.3.9.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC\_CONFIG1\_i[30] READMULTIPLE and GPMC\_CONFIG1\_i[28] WRITEMULTIPLE bits (where i = 0 to 3) are associated with the READTYPE and WRITETYPE parameters.

#### Note

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

#### 12.3.4.3.9.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 3). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC\_CONFIG1\_i[31] WRAPBURST bit (where i = 0 to 3) must be set to 1. Similarly

DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), WAIT pin monitoring must be enabled to dynamically control data access completion within the burst.

#### Note

When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

#### 12.3.4.3.10 GPMC pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC\_CONFIG1\_i[11-10] DEVICETYPE bit field (where i = 0 to 3) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

#### 12.3.4.3.11 GPMC NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

#### 12.3.4.3.11.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model depends on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

#### 12.3.4.3.11.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC\_CONFIG7\_i register (where i = 0 to 3) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

### CAUTION

To allow correct command, address, and data-access controls, the GPMC\_CONFIG1\_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in [Table 12-166](#). Failure to comply with these settings corrupts the NAND interface protocol.

**Table 12-166. Chip-Select Configuration for NAND Interfacing**

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] <sup>(1)</sup>	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26-25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24-23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19-18]	Don't care	Wait not monitored by GPMC access engine

**Table 12-166. Chip-Select Configuration for NAND Interfacing (continued)**

Bit Field	Register	Value	Comments
WAITPINSELECT	GPMC_CONFIG1_i[17-16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13-12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11-10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9-8]	0b00	non-multiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1-0]	Don't care	Asynchronous mode

(1)  $i = 0$  to 3

The GPMC\_CONFIG1\_i to GPMC\_CONFIG4\_i registers (where  $i = 0$  to 3) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

#### 12.3.4.3.11.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i register locations (where  $i = 0$  to 3) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i register locations must be posted for faster operations (where  $i = 0$  to 3). The GPMC\_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC\_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i registers (where  $i = 0$  to 3) are 32-bit word locations, which means any 32- or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i registers can be used, and any of the four byte locations of the registers is valid.

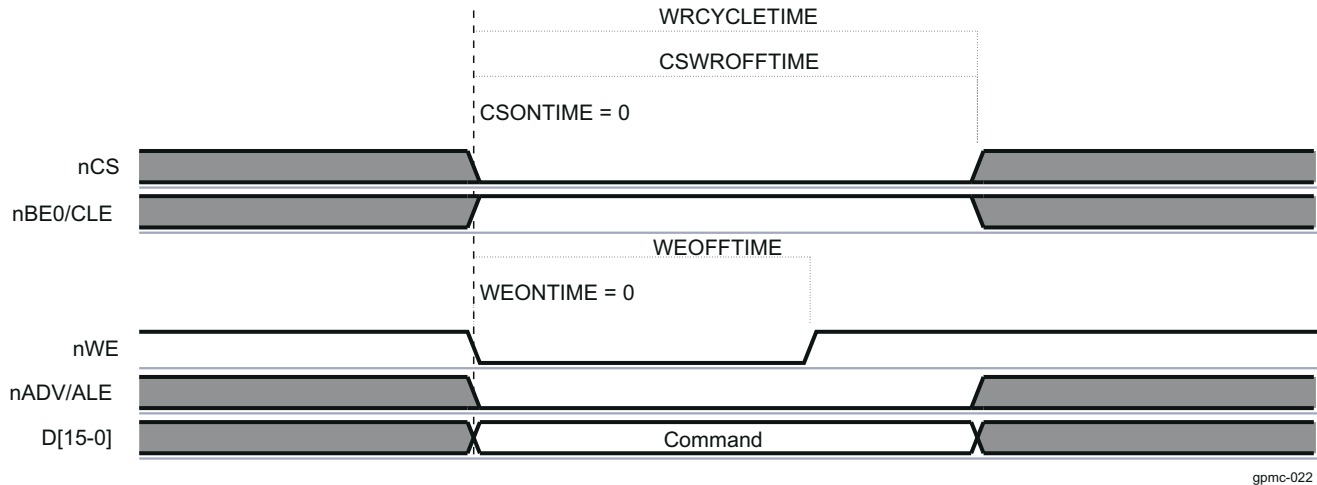

The same applies to a GPMC\_NAND\_COMMAND\_i and a GPMC\_NAND\_ADDRESS\_i (where  $i = 0$  to 3) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

### 12.3.4.3.11.1.3 Command Latch Cycle

Writing data at the GPMC\_NAND\_COMMAND\_i location (where i = 0 to 3) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 12-94 shows the NAND command latch cycle.

**Figure 12-94. NAND Command Latch Cycle**

#### Note

CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

### 12.3.4.3.11.1.4 Address Latch Cycle

Writing data at the GPMC\_NAND\_ADDRESS\_i location (where i = 0 to 3) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 12-95 shows the NAND address latch cycle.

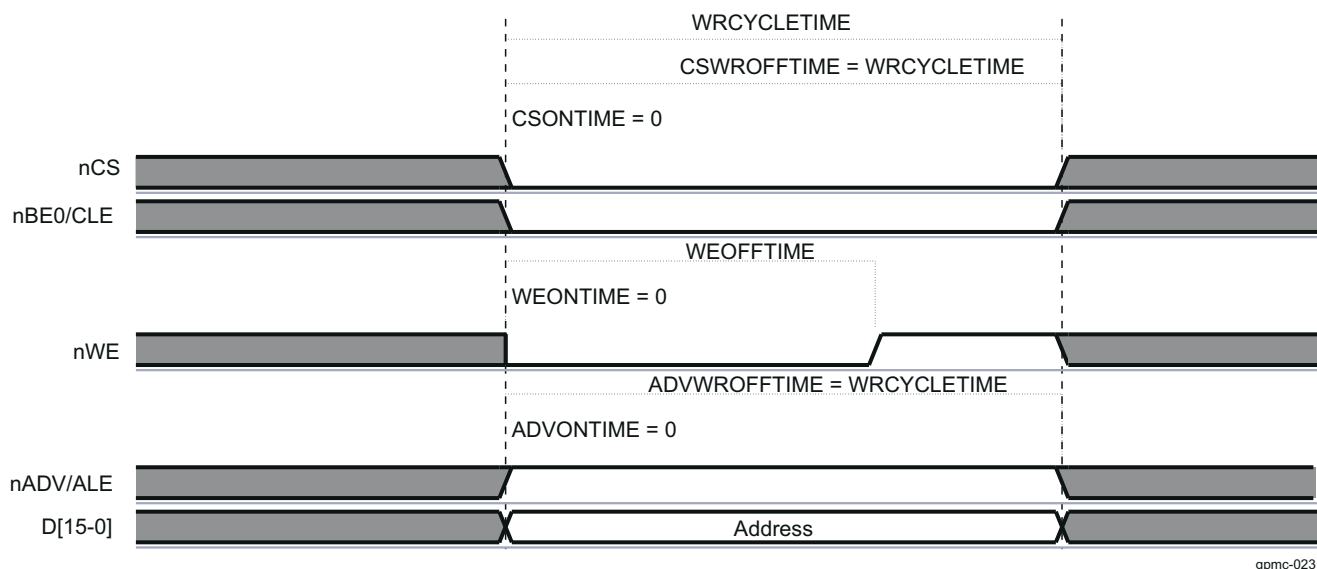

Figure 12-95. NAND Address Latch Cycle

#### Note

ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

#### 12.3.4.3.11.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC\_NAND\_DATA\_i location (where i = 0 to 3) mapped in the chip-select-associated control register region. GPMC\_NAND\_DATA\_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC\_NAND\_DATA\_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 12-96 shows the NAND data read cycle.

gpmc-024

**Figure 12-96. NAND Data Read Cycle**

Writing data to the GPMC\_NAND\_DATA\_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CS ONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WE ONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 12-97 shows the NAND data write cycle.

gpmc-025

**Figure 12-97. NAND Data Write Cycle**

#### 12.3.4.3.11.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see [Section 12.3.4.3.11.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMEECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

#### **12.3.4.3.11.1.7 Read and Write Access Size Adaptation**

##### **12.3.4.3.11.1.7.1 8-Bit-Wide NAND Device**

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

##### **12.3.4.3.11.1.7.2 16-Bit-Wide NAND Device**

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

### 12.3.4.3.11.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

#### Note

If a read access to a NAND flash is done using WAIT monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the WAIT pin monitoring for read and write accesses (that is, set the GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING and GPMC\_CONFIG1\_i[22] WAITREADMONITORING bits to 0, where i = 0 to 3), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 3) of the GPMC\_STATUS.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC\_IRQENABLE register bits[11-8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC\_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

#### 12.3.4.3.11.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC\_STATUS WAITxSTATUS bit (where x = 0 to 3). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

#### 12.3.4.3.11.2.2 Ready Pin Monitored by Hardware Interrupt

Each GPMC\_WAIT input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC\_CONFIG WAITxPINPOLARITY bits (where x = 0 to 3) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 3) of the GPMC\_IRQSTATUS register according to the GPMC\_WAIT pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC\_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC\_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC\_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC\_IRQSTATUS register according to the GPMC\_WAIT pin used for NAND device ready signal monitoring.

#### 12.3.4.3.11.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC\_ECC\_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhuri-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC\_ECC\_CONFIG[3-1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

#### **12.3.4.3.11.3.1 Hamming Code**

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

##### **12.3.4.3.11.3.1.1 ECC Result Register and ECC Computation Accumulation Size**

The GPMC includes up to nine ECC result registers (GPMC\_ECCj\_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC\_ECCj\_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC\_ECC\_CONTROL[3-0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC\_ECCj\_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC\_ECCj\_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC\_ECC\_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC\_ECCj\_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZe bits (where j = 1 to 9) in the GPMC\_ECC\_SIZE\_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC\_ECCj\_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC\_ECCj\_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZe bits are set to 0, and the ECC9RESULTSIZe bit is set to 1.

#### 12.3.4.3.11.3.1.2 ECC Enabling

The GPMC\_ECC\_CONFIG[3-1] ECCCS bit field selects the allocated chip-select. The GPMC\_ECC\_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZe (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 12-167 describes the ECC enable settings.

**Table 12-167. ECC Enable Settings**

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZe (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

### 12.3.4.3.11.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 12-98 and Figure 12-99. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

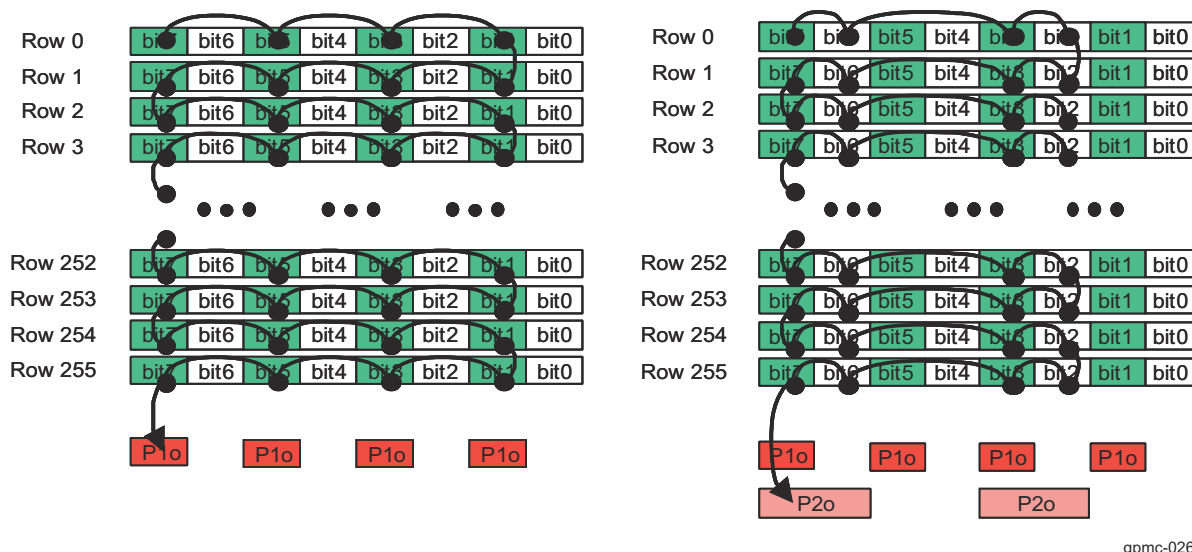

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

gpmc-026

**Figure 12-98. Hamming Code Accumulation Algorithm (1/2)**

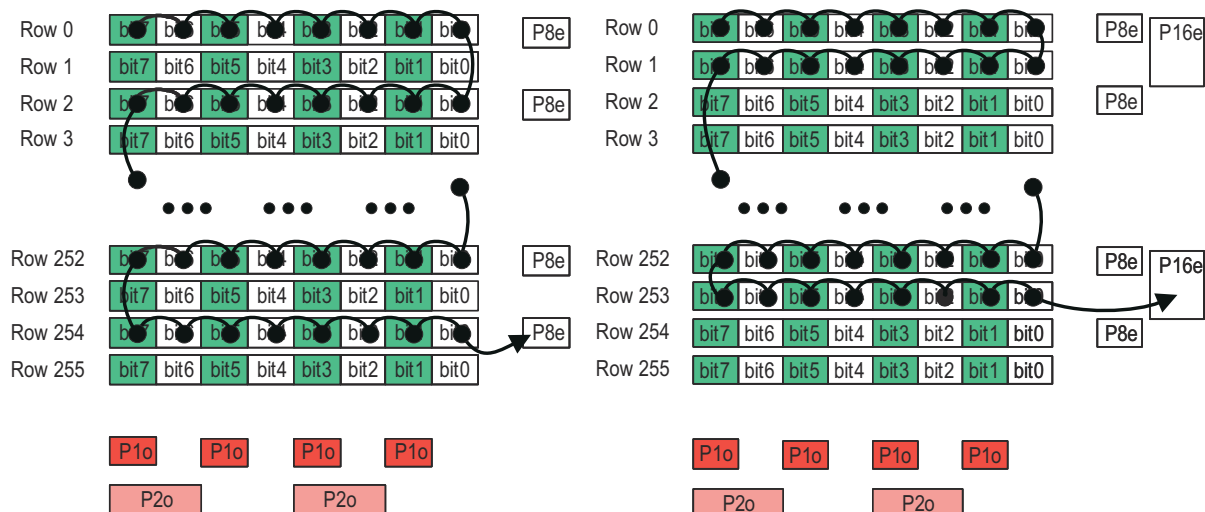

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

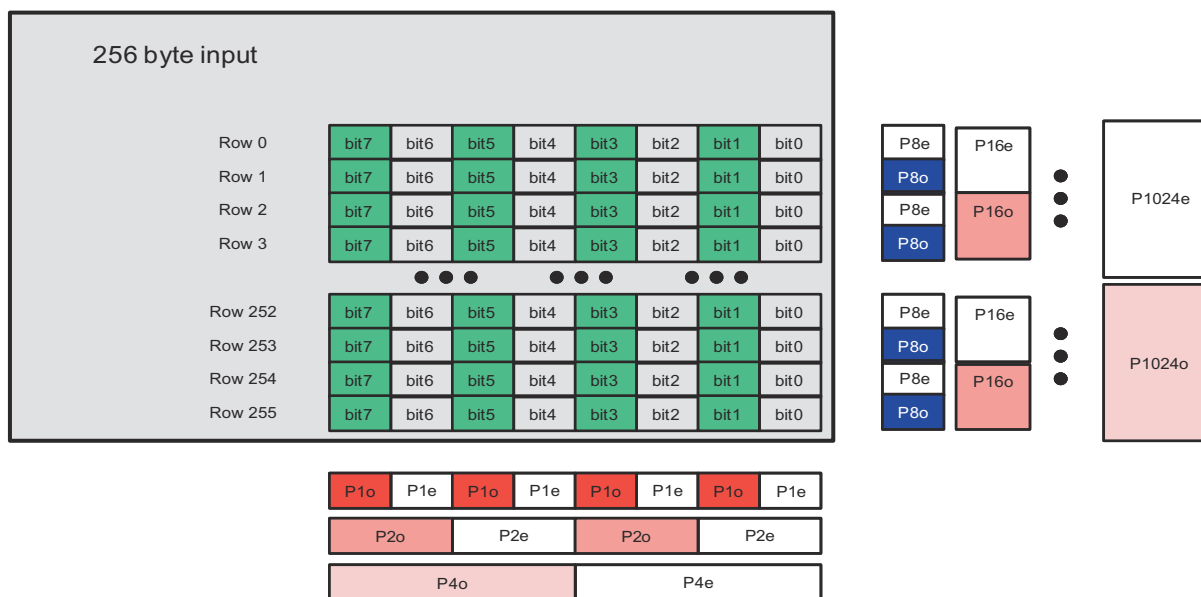

gpmc-027

**Figure 12-99. Hamming Code Accumulation Algorithm (2/2)**

Unused parity bits in the result registers are set to 0.

Figure 12-100 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

gpmc-028

**Figure 12-100. ECC Computation for a 256-Byte Data Stream (Read or Write)**

Figure 12-101 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

**Figure 12-101. ECC Computation for a 512-Byte Data Stream (Read or Write)**

For a 2-KB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC\_ECCj\_RESULT registers (where j = 1 to 9).

#### 12.3.4.3.11.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

#### 12.3.4.3.11.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

#### 12.3.4.3.11.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC\_ECC\_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. Figure 12-102 and Figure 12-103 show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

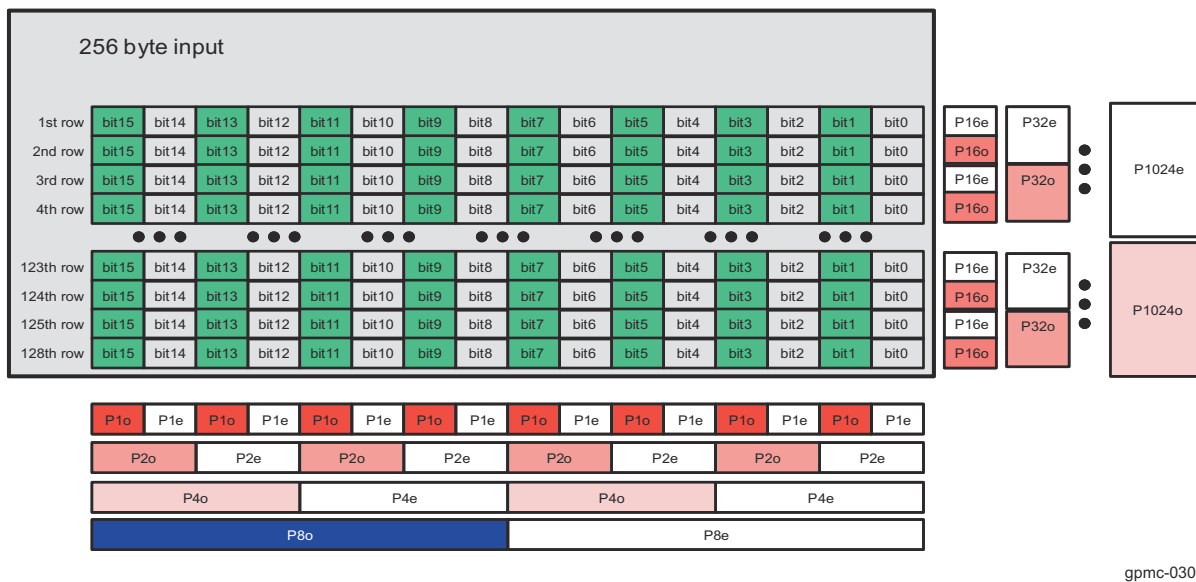

Figure 12-102. 128 Word16 ECC Computation

Figure 12-103. 256 Word16 ECC Computation

### 12.3.4.3.11.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

#### 12.3.4.3.11.3.2.1 Requirements

- Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
  - Typical page write sequence:
    - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy accesses.
    - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
    - NAND writes its cache line (page) to the array.

- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.
- 2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
- 3. Each page can hold up to 4KB of data, spare bytes not included. This means up to  $8 \times 512$ -byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- 4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
- 5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

#### 12.3.4.3.11.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message  $M(x)$ . In a standard case, 512 bytes of data (that is,  $2^{12}$  bits = 4096 bits) are seen as a polynomial of degree  $2^{12} - 1 = 4095$ , with parameters ranging from  $M_0$  to  $M_{4095}$ . For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial  $R(x)$  of degree 103 (or 51, depending on the selected mode). The complete codeword  $C(x)$  is the concatenation of  $M(x)$  and  $R(x)$ , as described in [Table 12-168](#).

**Table 12-168. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)**

Bit Number	Message $M(x)$			ECC $R(x)$		
	M4095	...	$M_0$	R103	...	$R_0$

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message  $M(x)$  of degree  $((512 + 3) \times 8) - 1 = 4119$ , for a total of  $3 + 13 = 16$  spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where  $i = 0$  to 3):

- GPMC\_BCH\_RESULT0\_i
- GPMC\_BCH\_RESULT1\_i
- GPMC\_BCH\_RESULT2\_i
- GPMC\_BCH\_RESULT3\_i

#### 12.3.4.3.11.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte  $b_7$ - $b_0$  (with  $b_0$  the LSB) represents a segment of polynomial  $b_7 * x^{(7+i)} + b_6 * x^{(6+i)} + \dots + b_0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

**Note**

The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

[Table 12-169](#) and [Table 12-170](#) describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset module 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2<sup>12</sup>–1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

**Table 12-169. Aligned Message Byte Mapping in 8-Bit NAND**

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

**Table 12-170. Aligned Message Byte Mapping in 16-Bit NAND**

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

[Table 12-171](#) through [Table 12-176](#) list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

**Table 12-171. Aligned Nibble Mapping of Message in 8-Bit NAND**

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 – 2	Nibble 3	Nibble 2
S/2 – 1	Nibble 1	Nibble 0 (LSB)

**Table 12-172. Misaligned Nibble Mapping of Message in 8-Bit NAND**

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
$(S + 1) / 2 - 2$	Nibble 2	Nibble 1
$(S + 1) / 2 - 1$	Nibble 0 (LSB)	

**Table 12-173. Aligned Nibble Mapping of Message in 16-Bit NAND**

Byte Offset		16-Bit Word

0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6

**Table 12-173. Aligned Nibble Mapping of Message in 16-Bit NAND (continued)**

Byte Offset	16-Bit Word			
...	...	...	...	...
S/2 – 4	Nibble 5	Nibble 4	Nibble 7	Nibble 6
S/2 – 2	Nibble 1	Nibble 0 (LSB)	Nibble 3	Nibble 2

**Table 12-174. Misaligned Nibble Mapping of Message in 16-Bit NAND (1 Unused Nibble)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
(S + 1) / 2 – 4	Nibble 4	Nibble 3	Nibble 6	Nibble 5
(S + 1) / 2 – 2	Nibble 0 (LSB)		Nibble 2	Nibble 1

**Table 12-175. Misaligned Nibble Mapping of Message in 16-Bit NAND (2 Unused Nibbles)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
(S + 2) / 2 – 4	Nibble 3	Nibble 2	Nibble 5	Nibble 4
(S + 2) / 2 – 2			Nibble 1	Nibble 0 (LSB)

**Table 12-176. Misaligned Nibble Mapping of Message in 16-Bit NAND (3 Unused Nibbles)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
(S + 3) / 2 – 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S + 3) / 2 – 2			Nibble 0 (LSB)	

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

#### 12.3.4.3.11.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.

- The completed line buffer is then written to the NAND array.

### 12.3.4.3.11.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see [Section 12.3.4.3.11.3.2.3, Supported NAND Page Mappings and ECC Schemes](#).

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for  $t = 4$  ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

### 12.3.4.3.11.3.2.2.3.1 Manual Mode (0x0)

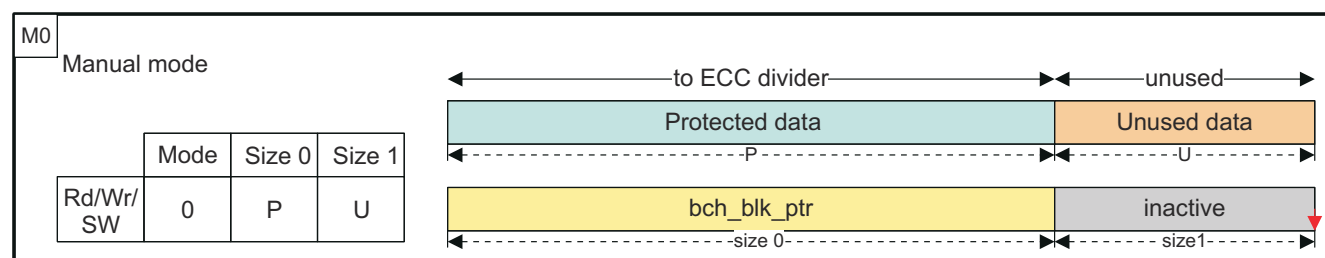

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC\_ECC\_SIZE\_CONFIG[31-22] ECCSIZE1. In the same example, 5 nibbles to process + 3 to discard = 8 nibbles =  $2 \times 16$ -bit accesses. Software must set:

- GPMC\_ECC\_SIZE\_CONFIG[21-12] ECCSIZE0 = 0x5
- GPMC\_ECC\_SIZE\_CONFIG[31-22] ECCSIZE1 = 0x3

#### Note

In the following figures, size and size0 are the same parameter.

gpmc-032

Figure 12-104. Manual Mode Sequence and Mapping

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

#### 12.3.4.3.11.3.2.2.3.2 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) =  $S - (\text{size0} + \text{size1})$

#### 12.3.4.3.11.3.2.2.3.3 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) =  $S - (\text{size0} + 1 + \text{size1})$

#### 12.3.4.3.11.3.2.2.3.4 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) =  $S - (\text{size0} + \text{size1})$

#### 12.3.4.3.11.3.2.2.3.5 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) =  $\text{size0} + (S - \text{size1})$

#### 12.3.4.3.11.3.2.2.3.6 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) =  $\text{size0} + (S - \text{size1})$

#### 12.3.4.3.11.3.2.2.3.7 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

#### 12.3.4.3.11.3.2.2.3.8 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

#### 12.3.4.3.11.3.2.2.3.9 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

#### 12.3.4.3.11.3.2.2.3.10 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

#### 12.3.4.3.11.3.2.2.3.11 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF

- size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) =  $S - (\text{size0} + 1 + \text{size1})$

#### 12.3.4.3.11.3.2.2.3.12 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) =  $S - (\text{size0} + \text{size1})$

#### 12.3.4.3.11.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 3.4.3.11.3.2.2.1, Memory Mapping of Data Message](#).

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 12-105](#) through [Figure 12-107](#), the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KB + spares; that is,  $S = 2$  sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of  $n = 2^{13} - 1 = 8191$  bits; that codeword (higher-order bits) is all-zero and implicit during computations.

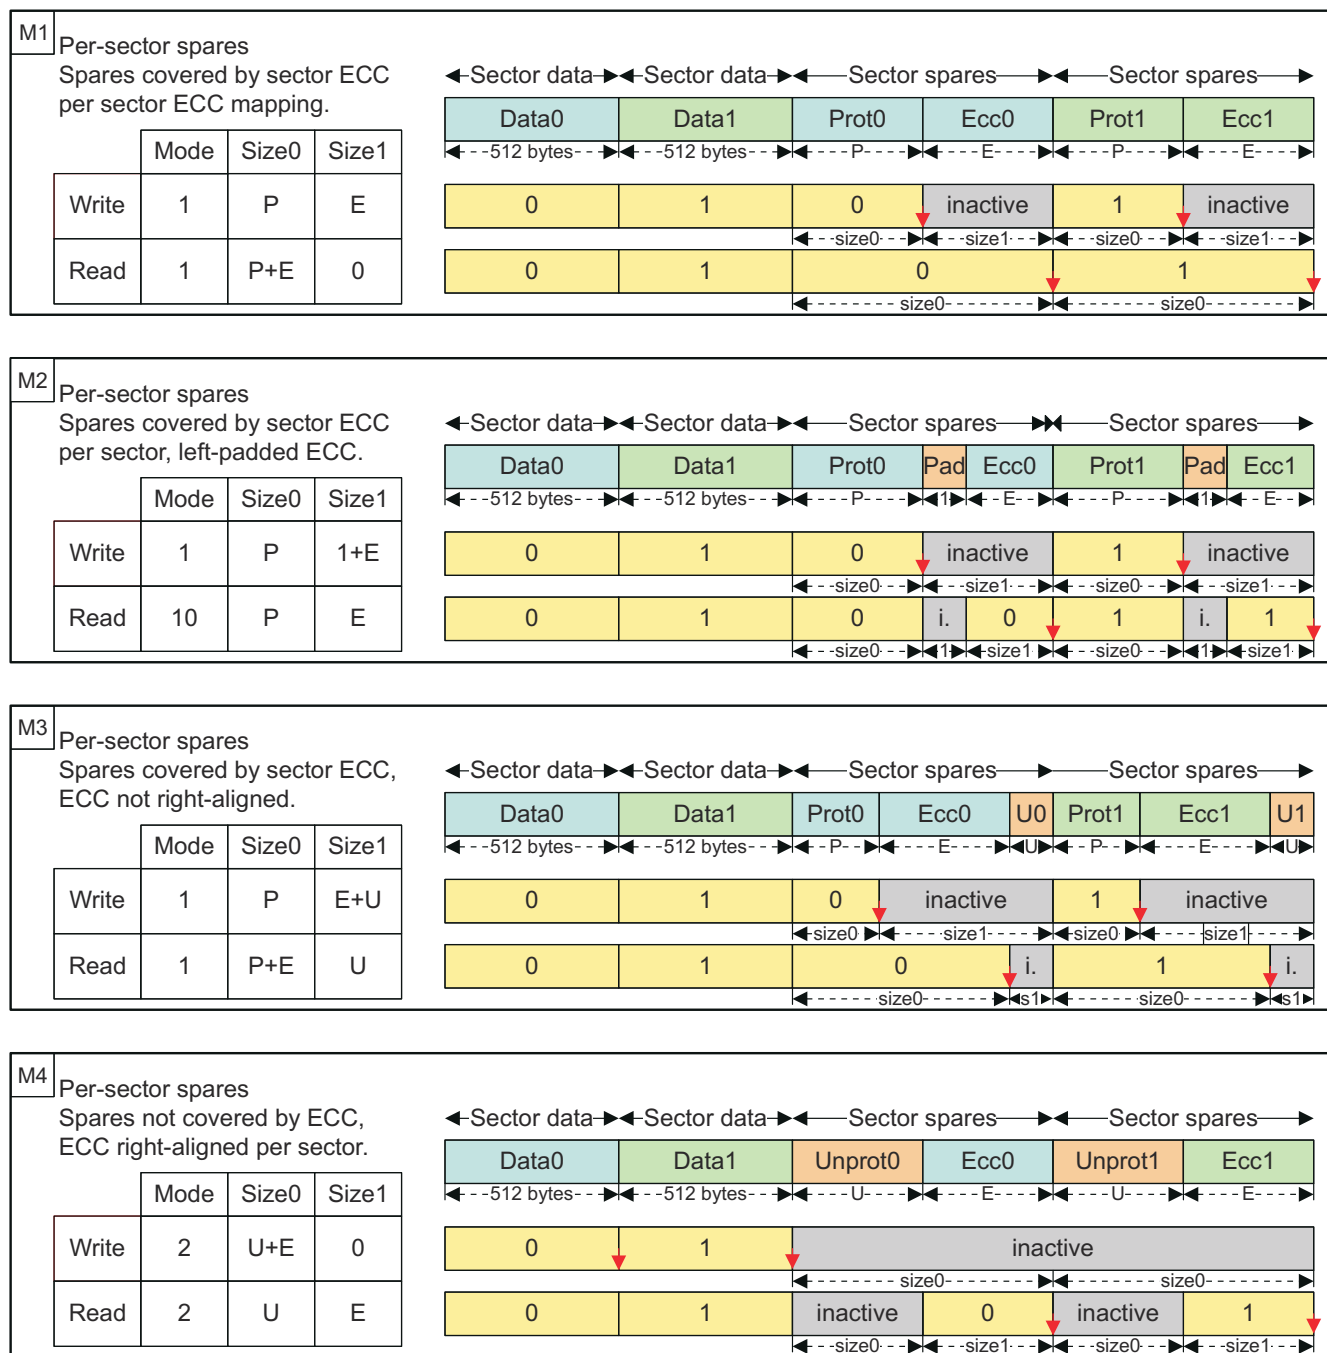

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors:  $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword:  $(512) + P + E$
  - Other sectors:  $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords  $(512) + E$

### 12.3.4.3.11.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

gpmc-033

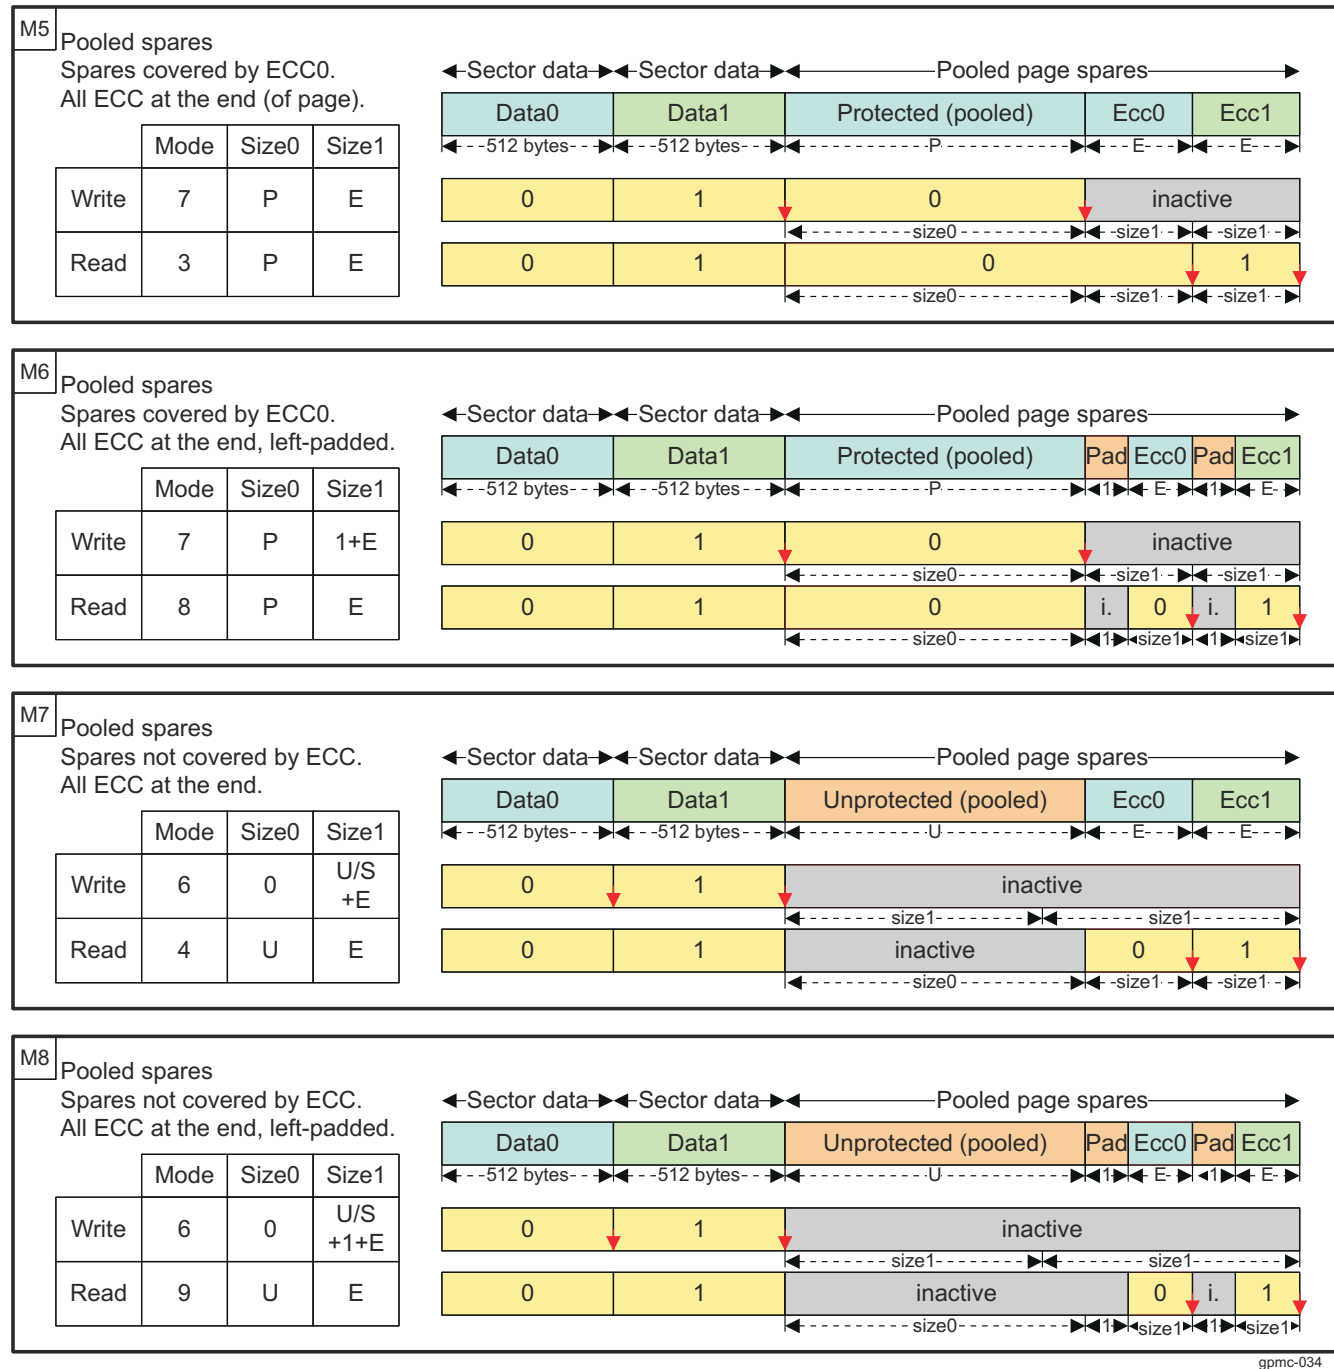

**Figure 12-105. NAND Page Mapping and ECC: Per-Sector Schemes**

### 12.3.4.3.11.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.

- The non-ECC spare data may or may not be covered by the ECC of sector 0.

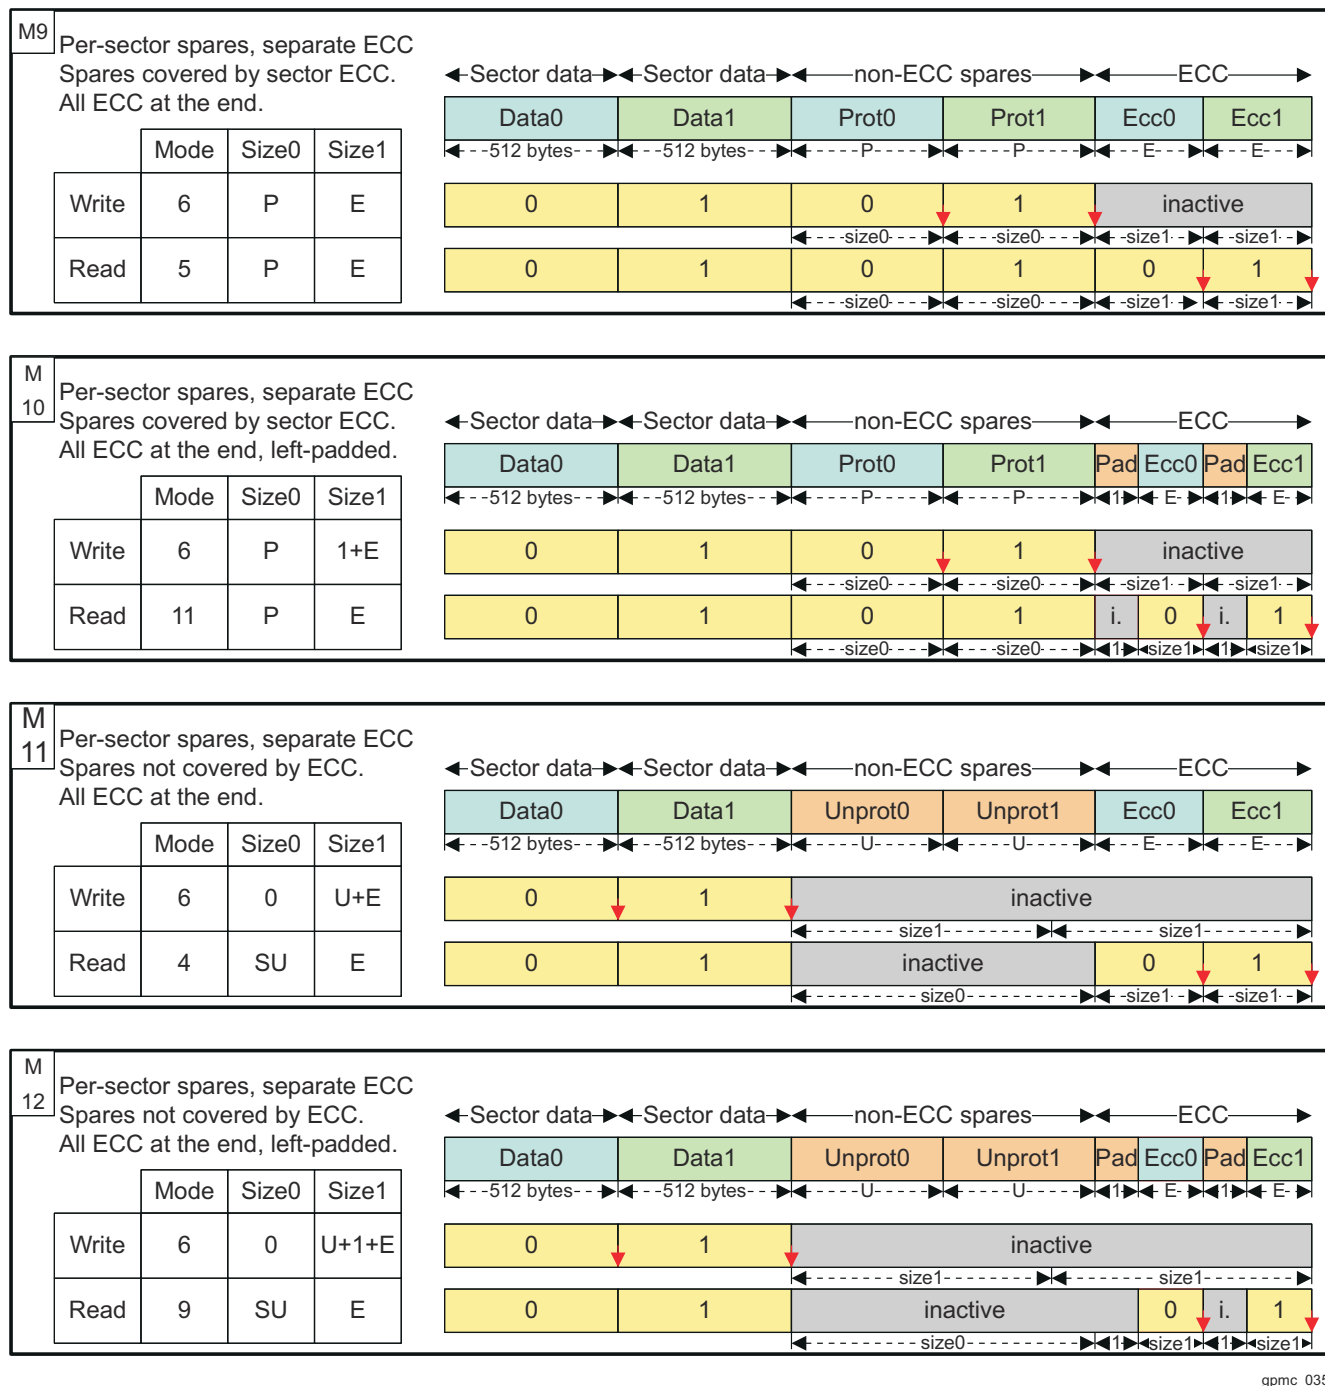

gpmc-034

**Figure 12-106. NAND Page Mapping and ECC: Pooled Spare Schemes**

#### 12.3.4.3.11.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

**Figure 12-107. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC**

#### 12.3.4.3.11.4 Prefetch and Write-Posting Engine

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

NAND device data access cycles are usually much slower than the CPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system

performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the interconnect interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine depends on the NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write-posting engine access to the GPMC bus for a number of requests programmed in the GPMC\_PREFETCH\_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

#### Note

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

#### 12.3.4.3.11.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC\_PREFETCH\_CONFIG1[26-24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

When the GPMC\_PREFETCH\_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 3):

- GPMC\_NAND\_COMMAND\_i
- GPMC\_NAND\_ADDRESS\_i
- GPMC\_NAND\_DATA\_i

The FIFO entry on the interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC\_PREFETCH\_STATUS[30-24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC\_PREFETCH\_STATUS[13-0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

#### 12.3.4.3.11.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is cleared.

The NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see [Section 12.3.4.3.11.2.2, Ready Pin Monitored by Hardware Interrupt](#)). The GPMC\_PREFETCH\_CONFIG1[5-4] WAITPINSELECTOR bit field selects which GPMC\_WAIT pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC\_PREFETCH\_CONFIG2[13-0] TRANSFERCOUNT bit field.

[Table 12-177](#) describes the prefetch mode configuration.

**Table 12-177. Prefetch Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17-16]	0 to 1	Selects WAIT pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See <a href="#">Section 12.3.4.3.11.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine.</a>
CYCLOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 12.3.4.3.11.4.3 FIFO Control in Prefetch Mode

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be drained directly by a device host processor or a DMA module channel.

In draining mode, the FIFO status can be monitored through the GPMC\_PREFETCH\_STATUS[30-24] FIFOPointer bit field or through the GPMC\_PREFETCH\_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPointer indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC\_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC\_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, all the available bytes must be read, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC\_PREFETCH\_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC\_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC\_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

### Note

The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

#### 12.3.4.3.11.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is set.

The NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC\_PREFETCH\_CONFIG2[13-0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

[Table 12-178](#) describes the write-posting configuration.

**Table 12-178. Write-Posting Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See <a href="#">Section 12.3.4.3.11.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine</a> .
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 12.3.4.3.11.4.5 FIFO Control in Write-Posting Mode

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be filled directly by a device host processor or a DMA module channel.

In filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC\_PREFETCH\_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC\_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC\_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, enough bytes must be written to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC\_PREFETCH\_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC\_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC\_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

##### Note

The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, DMA or CPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

#### **12.3.4.3.11.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine**

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMEECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC\_NAND\_DATA\_i location, where i = 0 to 3) are never optimized.

The GPMC\_PREFETCH\_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC\_PREFETCH\_CONFIG1[30-28] CYCLEOPTIMIZATION bit field defines the number of GPMC\_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 12-108 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMEECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC\_PREFETCH\_CONFIG1[30-28] CYCLEOPTIMIZATION bit field.

**Figure 12-108. NAND Read Cycle Optimization Timing Description**

#### 12.3.4.3.11.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC\_PREFETCH\_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

#### 12.3.4.3.12 GPMC Use Cases and Tips

##### 12.3.4.3.12.1 How to Set GPMC Timing Parameters for Typical Accesses

###### 12.3.4.3.12.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or non-multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

#### 12.3.4.3.12.1.2 Typical GPMC Setup

Table 12-179 lists some of the I/Os of the GPMC module.

**Table 12-179. Typical GPMC Setup Signals**

Module Pin	I/O <sup>(1)</sup>	Description
GPMC0_FCLK	Internal	Functional clock. Acts as the time reference.
GPMC0_ICLK	Internal	Interface clock. Acts as the time reference.
GPMC0_CLKOUT	O	External clock provided to the external device for synchronous operations
	O	Address
GPMC0_AD[15-0]	I/O	Data-multiplexed with addresses A[16-1] on memory side
GPMC0_CSn[3-0]	O	Chip-selects
GPMC0_ADVn_ALE	O	Address valid enable
GPMC0_OEn_REn	O	Output enable (read access only)
GPMC0_WEn	O	Write enable (write access only)
GPMC0_WAIT[3-0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

(1) I = Input; O = Output

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

#### 12.3.4.3.12.1.2.1 GPMC Configuration for Synchronous Burst Read Access

##### Note

The examples in [Section 12.3.4.3.12.1.2.1](#) through [Section 12.3.4.3.12.1.2.3](#) are based on a clock rate of 104 MHz. See the device-specific Datasheet for the maximum frequency appropriate for this device and the memory datasheet for the maximum frequency for the particular memory device.

The clock runs at 104 MHz ( $f = 104 \text{ MHz}$ ;  $T = 9.615 \text{ ns}$ ).

Table 12-180 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 12-181 shows how to calculate timings for the GPMC using the memory parameters.

Figure 12-109 shows the synchronous burst read access.

**Table 12-180. Useful Timing Parameters on the Memory Side**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3

**Table 12-180. Useful Timing Parameters on the Memory Side (continued)**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5.2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ( $T = 9.615$  ns). The read access time between two bursts of data is  $tBACC = 5.2$  ns. Therefore, data setup time is a clock period –  $tBACC = 4.415$  ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

**Table 12-181. Calculating GPMC Timing Parameters**

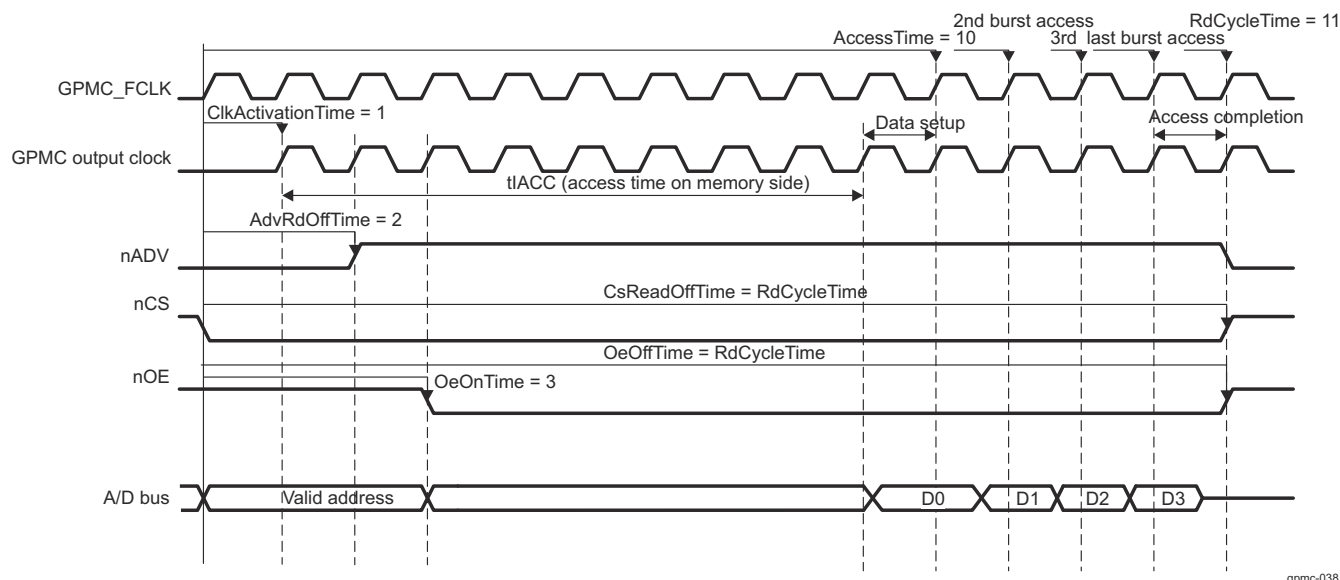

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	$\min(tCES, tACS)$	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	$\text{roundmax}(\text{ClkActivationTime} + tIACC + \text{DataSetupTime})$	94.03: (9.615 + 80 + 4.415)	10: $\text{roundmax}(94.03 / 9.615)$	RDACCESSTIME = 0xA
PageBurst RdAccessTime	$\text{roundmax}(tBACC)$	$\text{roundmax}(5.2)$	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	$\text{RdAccess time} + \max(tCEZ, tOEZ)$	101.03: (94.03 + 7)	11	RDCYCLETIME = 0xB
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	–	11	CSRDOFFTIME = 0xB
AdvOnTime	tAVC <sup>(1)</sup>	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC <sup>(2)</sup>	12	2	ADVRDOFFTIME = 0x2
OeOnTime <sup>(3)</sup>	$(\text{ClkActivationTime} + tACH) < \text{OeOnTime}(\text{ClkActivationTime} + tIACC)$	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0xB

(1) The external clock provided to the NOR flash is not yet available.

(2)  $\text{AdvRdOffTime} - \text{AdvOnTime} = tAVD$ ; thus,  $\text{AdvRdOffTime} = tAVD + \text{AdvOnTime} = tAVD + tAVC$ .

(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

**Figure 12-109. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)**

#### 12.3.4.3.12.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz ( $f = 104 \text{ MHz}$ ;  $T = 9.615 \text{ ns}$ ).

Table 12-182 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 12-183 shows how to calculate timings for the GPMC using the memory parameters.

Figure 12-110 shows the asynchronous read access.

**Table 12-182. AC Characteristics for Asynchronous Read Access**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

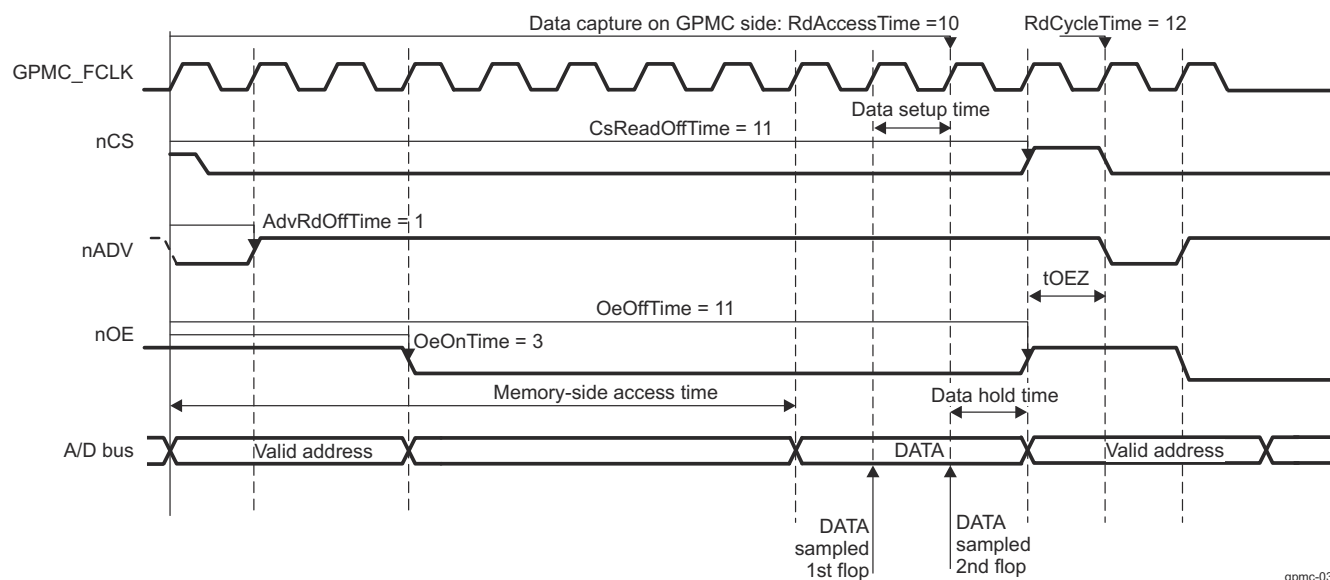

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 12-182: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).
4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.
5. Addresses can now be relatched and a new read cycle begun.

**Table 12-183. GPMC Timing Parameters for Asynchronous Read Access**

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = 0xA
PageBurstAccessTime	N/A (single access)			
RdCycleTime	RdAccessTime + 1cycle + tOEZ	96.615	12	RDCYCLETIME = 0xC
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	RdAccessTime + 1 cycle	89.615	11	CSRDOFFTIME = 0xB
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x1
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	RdAccessTime + 1cycle	89.615	11	OEOFFTIME = 0xB

**Figure 12-110. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)**

#### 12.3.4.3.12.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9.615 ns).

Table 12-185 shows how to calculate timings for the GPMC using the memory parameters.

Table 12-184 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 12-111 shows the synchronous burst write access.

**Table 12-184. AC Characteristics for Asynchronous Single Write (Memory Side)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0

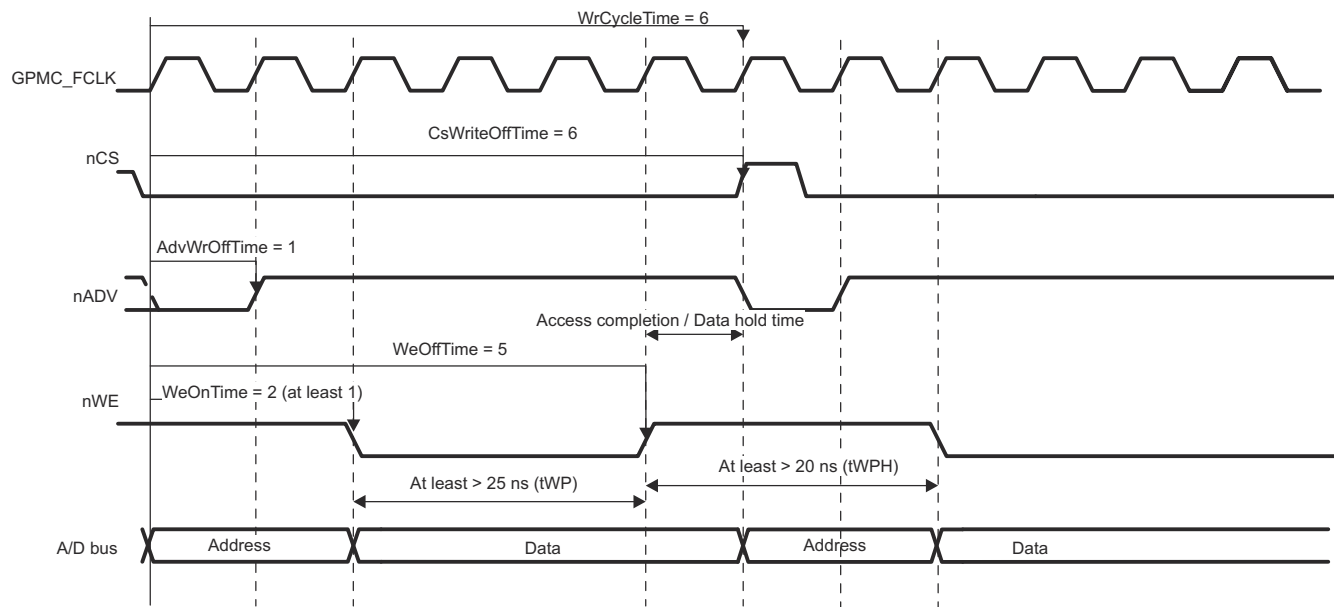

**Table 12-184. AC Characteristics for Asynchronous Single Write (Memory Side) (continued)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is  $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$ . For the AccessCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device-specific Datasheet.

**Table 12-185. GPMC Timing Parameters for Asynchronous Single Write**

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		N/A (asynchronous mode)		
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		N/A (single access)		
WrCycleTime	WeOffTime + AccessCompletion	57.615	6	WRCYCLETIME = 0x6
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57.615	6	CSWROFFTIME = 0x6
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x1
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x5

#### 12.3.4.3.12.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

##### 12.3.4.3.12.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, and so on)
- 8- and 16-bit NAND flash devices

### 12.3.4.3.12.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

**Table 12-186. Supported Memory Interfaces**

Function	16-Bit Address/ Data-Multiplexed pSRAM or NOR Flash <sup>(1)</sup>	16-Bit NAND	8-Bit NAND

GPMC_WAIT3	WAIT3	R/nB3	
GPMC_WPn	nWP (Write Protect)	nWP (Write Protect)	

(1) Addresses seen from the device side. When interfacing to the external device, A1 is connected to the memory A0, A2 to the memory A1, and so on.

#### 12.3.4.3.12.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 12-187 summarizes the NAND interface signals level applied to external device or memories.

**Table 12-187. NAND Interface Bus Operations Summary**

Bus Operation	CLE	ALE	nCE	nWE <sup>(1)</sup>	nRE <sup>(1)</sup>	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H <sup>(2)</sup>	H <sup>(2)</sup>	H <sup>(2)</sup>	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Standby	x	x	H	x	x	H/L

(1) RE stands for rising edge; FE stands for falling edge

(2) Can be nCE high, or WE and nRE high.

#### 12.3.4.3.12.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited

to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

[Table 12-188](#) summarizes the level of the NOR interface signals applied to external devices or memories.

**Table 12-188. NOR Interface Bus Operations Summary**

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15-0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

#### 12.3.4.3.12.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

FPGA (Field-Programmable Gate Array) is a low-power integrated circuit based on an array of programmable logic blocks.

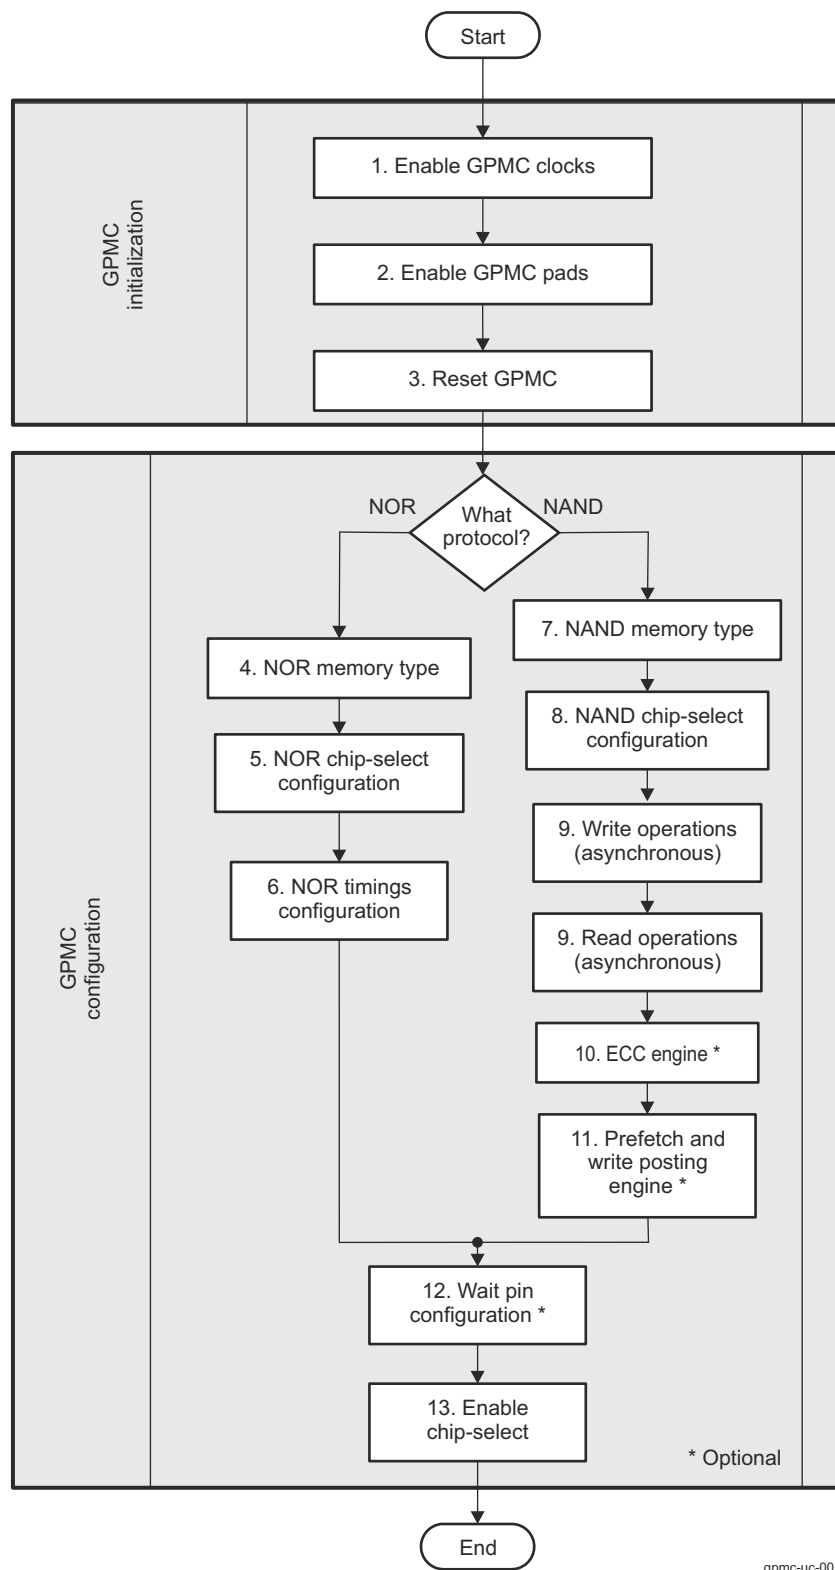

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It has synchronous write capability.

#### 12.3.4.4 GPMC Basic Programming Model

##### 12.3.4.4.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

[Figure 12-112](#) and [Table 12-189](#) through [Table 12-190](#) show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

**Figure 12-112. Programming Model Top-Level Diagram**

**Table 12-189. GPMC Configuration in NOR Mode**

Step	Description
NOR Memory Type	See <a href="#">Table 12-191</a> .
NOR Chip-Select Configuration	See <a href="#">Table 12-192</a> .

**Table 12-189. GPMC Configuration in NOR Mode (continued)**

Step	Description
NOR Timings Configuration	See <a href="#">Table 12-193</a> .
WAIT Pin Configuration	See <a href="#">Table 12-201</a> .
Enable Chip-Select	See <a href="#">Table 12-202</a> .

**Table 12-190. GPMC Configuration in NAND Mode**

Step	Description
NAND Memory Type	See <a href="#">Table 12-196</a> .
NAND Chip-Select Configuration	See <a href="#">Table 12-197</a> .
Write Operations (Asynchronous)	See <a href="#">Table 12-198</a> .
Read Operations (Asynchronous)	See <a href="#">Table 12-198</a> .
ECC Engine	See <a href="#">Table 12-199</a> .
Prefetch and Write-Posting Engine	See <a href="#">Table 12-200</a> .
WAIT Pin Configuration	See <a href="#">Table 12-201</a> .
Enable Chip-Select	See <a href="#">Table 12-202</a> .

**12.3.4.4.2 GPMC Initialization**

GPMC can be reset via software bit in LPSC. For more information, see [Section 5.3, Reset](#).

**12.3.4.4.3 GPMC Configuration in NOR Mode**

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

**Table 12-191. NOR Memory Type**

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency <sup>(1)</sup> .	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	x
Choose an output clock activation time <sup>(1)</sup> .	GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations <sup>(1)</sup> .	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

(1) Applies only to synchronous configurations (or non-multiplexed asynchronous for multiple access one)

**Table 12-192. NOR Chip-Select Configuration**

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

**Table 12-193. NOR Timings Configuration**

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See <a href="#">Section 12.3.4.4.6, GPMC Timing Parameters</a>	

**Table 12-194. WAIT Pin Configuration**

Subprocess Name	Register/Bit Field	Value
Enable or disable WAIT pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable WAIT pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a WAIT pin monitoring time.	GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME	x
Choose the input WAIT pin for the chip-select.	GPMC_CONFIG1_i[17-16] WAITPINSELECT	x

**Table 12-195. Enable Chip-Select**

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

#### 12.3.4.4.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

#### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

**Table 12-196. NAND Memory Type**

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See <a href="#">Section 12.3.4.4.5</a> , <i>Set Memory Access</i> .	x

**Table 12-197. NAND Chip-Select Configuration**

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select minimum granularity (16MB).	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

**Table 12-198. Asynchronous Read and Write Operations**

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See <a href="#">Section 12.3.4.4.6</a> , <i>GPMC Timing Parameters</i> .	

**Table 12-199. ECC Engine**

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3-0] ECCPOINTER	x <sup>(2)</sup>
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[21-12] ECCSIZE0 and [31-22] ECCSIZE1	x <sup>(1)</sup>
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZ where j = 1 to 9	x
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3-1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13-12] ECCBCHTSEL and GPMC_ECC_CONFIG[6-4] ECCTOPSECTOR	x

**Table 12-199. ECC Engine (continued)**

Subprocess Name	Register/Bit Field	Value
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

- (1) Depends on the size of each sector in the NAND page  
(2) This parameter depends on the numbers of sectors in a page.

**Table 12-200. Prefetch and Write-Posting Engine**

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue an interrupt request.	GPMC_PREFETCH_CONFIG1[14-8] FIFOTHRESHOLD	x
Select interrupt synchronization mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

**Table 12-201. WAIT Pin Configuration**

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x

**Table 12-202. Enable Chip-Select**

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

#### 12.3.4.4.5 Set Memory Access

#### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

This section describes the bit field to configure to set the GPMC in various memory modes. [Table 12-203](#) and [Table 12-204](#) provide check lists for mode parameters and access type parameters, respectively.

**Table 12-203. Mode Parameters Check List**

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	Don't care	0x1 <sup>(1)</sup>	Not Supported	0x0	Don't care	0x1	Don't care
GPMC_CONFIG1_i	29	READTYPE	0x0	Don't care	0x0 <sup>(1)</sup>	Not Supported	0x1	Don't care	0x1	Don't care

**Table 12-203. Mode Parameters Check List (continued)**

Register	Bit	Name	Asynchronous				Synchronous			
GPMC_CONFIG1_i	28	WRITEMULTIPLE	Don't care	0x0	- (1)	Not Supported	Don't care	0x0	Don't care	0x1
GPMC_CONFIG1_i	27	WRITETYPE	Don't care	0x0	- (1)	Not Supported	Don't care	0x1	Don't care	0x1

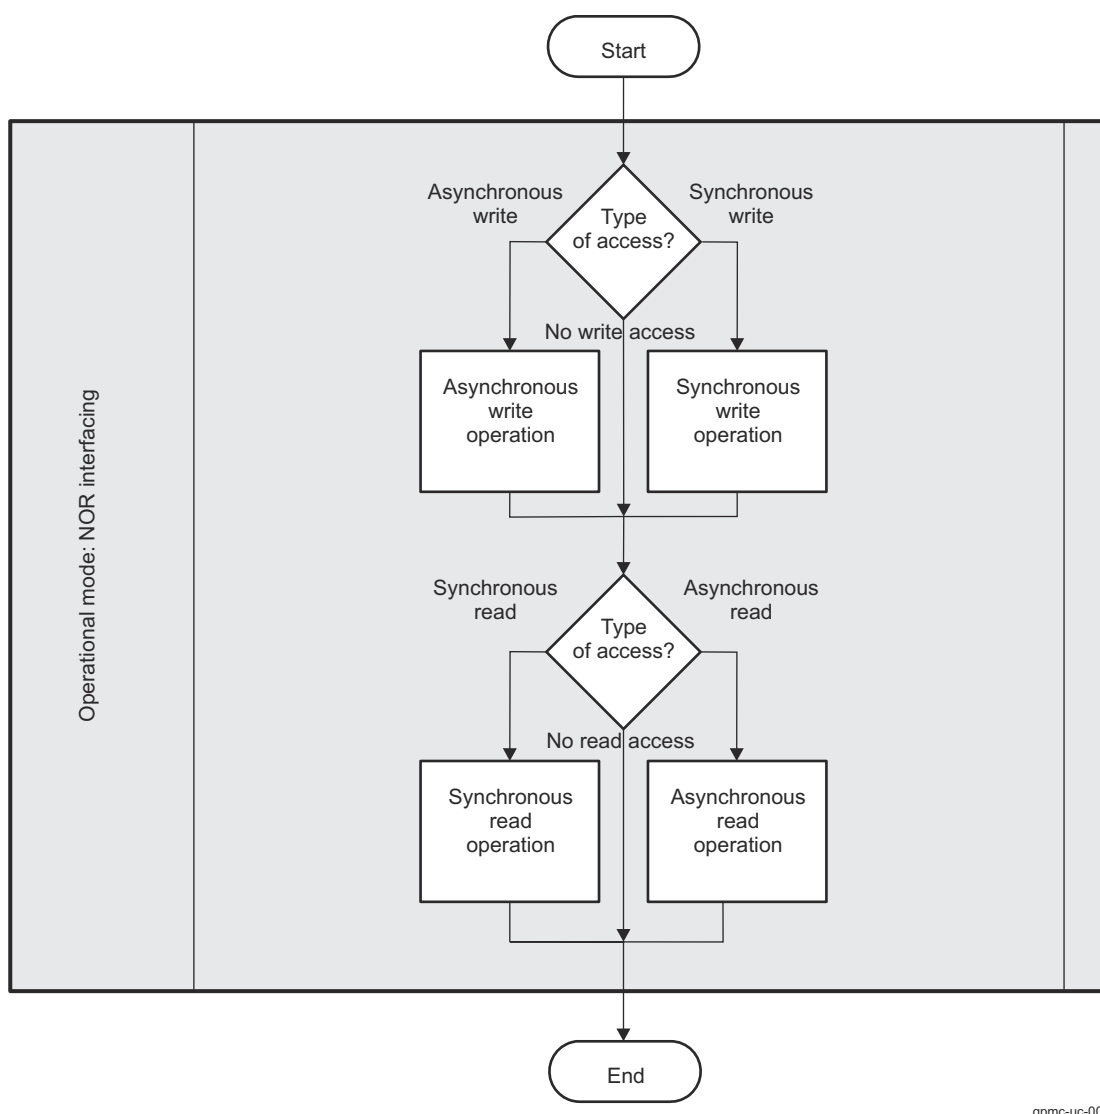

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in non-multiplexed mode.

**Table 12-204. Access Type Parameters Check List**

Register	Bit	Name	Access Type		
			non-multiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9-8	MUXADDDATA	0x0	0x2	0x1

#### 12.3.4.4.6 GPMC Timing Parameters

Figure 12-113 shows a programming model diagram for the NOR interfacing timing parameters.

**Figure 12-113. NOR Interfacing Timing Parameters Diagram**

Table 12-205 lists the bit fields to configure adequate timing parameters in various memory modes.

**Table 12-205. Timing Parameters**

Register	Bit	Name	Asynchronous			Synchronous				Access Type		
			Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiplexed	Address/Data-Multiplexed	AAD Multiplexed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y

#### 12.3.4.4.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device-specific Datasheet.

##### 12.3.4.4.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0x2. [Table 12-206](#) describes the NAND timing parameters.

**Table 12-206. NAND Formulas Description**

Configuration Parameter	Unit	Description
A	ns	Pulse duration – GPMC_WEn valid time
B	ns	Delay time – GPMC_CS valid to GPMC_WEn valid
C	ns	Delay time – GPMC_BE0n_CLE/GPMC_ADVn_ALE high to GPMC_WEn valid
D	ns	Delay time – GPMC_AD[15-0] valid to GPMC_WEn valid
E	ns	Delay time – GPMC_WEn invalid to GPMC_AD[15-0] invalid
F	ns	Delay time – GPMC_WEn invalid to GPMC_BE0n_CLE/GPMC_ADVn_ALE invalid
G	ns	Delay time – GPMC_WEn invalid to GPMC_CS invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – GPMC_CS valid to GPMC_OEn_REn valid
J	ns	Setup time – GPMC_AD[15-0] valid to GPMC_OEn_REn invalid
K	ns	Pulse duration – GPMC_OEn_REn valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – GPMC_OEn_REn invalid to GPMC_CS invalid

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

$$A = (WEOffTime - WEOnTime) * (TimeParaGranularity + 1) * GPMC\_FCLK \text{ period}$$

$$B = ((WEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - CSEExtraDelay)) * GPMC\_FCLK \text{ period}$$

$$C = ((WEOnTime - ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - ADVExtraDelay)) * GPMC\_FCLK \text{ period}$$

$$D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEEExtraDelay) * GPMC\_FCLK \text{ period}$$

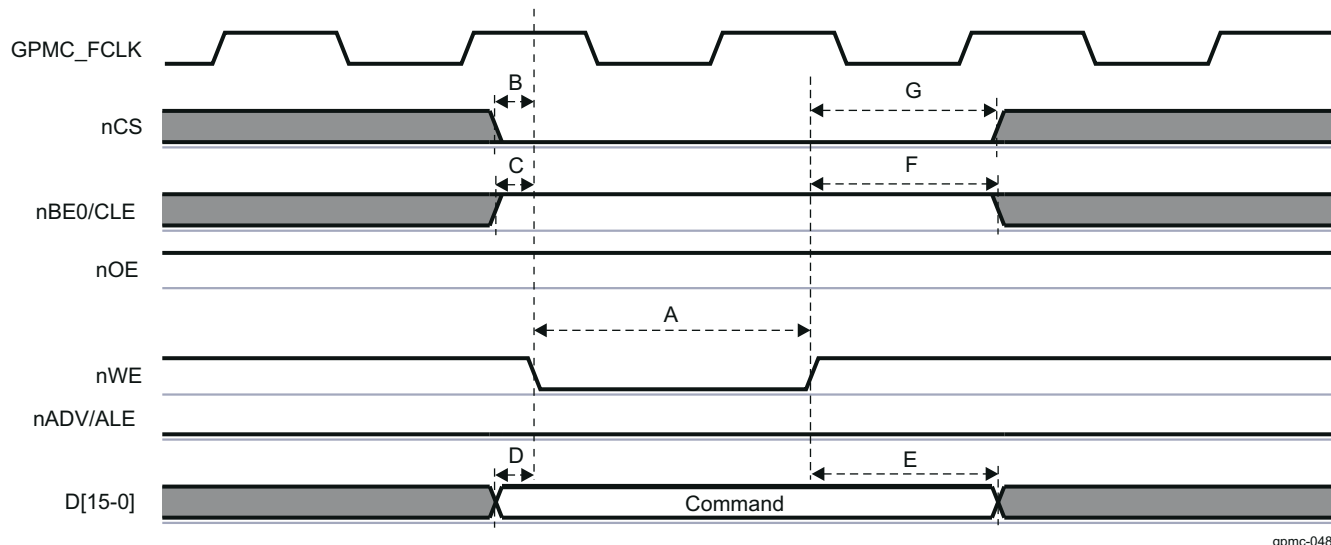

$$E = (WrCycleTime - WEOffTime * (TimeParaGranularity + 1) - 0.5 * WEEExtraDelay) * GPMC\_FCLK \text{ period}$$

$$F = (ADVWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay - WEEExtraDelay)) * GPMC\_FCLK \text{ period}$$

$$G = (CSWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSEExtraDelay - WEEExtraDelay)) * GPMC\_FCLK \text{ period}$$

$H = \text{WrCycleTime} * (1 + \text{TimeParaGranularity}) * \text{GPMC\_FCLK period}$   
 $I = ((\text{OEOnTime} - \text{CSONTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{OEExtraDelay} - \text{CSEExtraDelay})) * \text{GPMC\_FCLK period}$   
 $J = ((\text{RdAccessTime} - \text{OEOffTime}) * (\text{TimeParaGranularity} + 1) - 0.5 * \text{OEExtraDelay}) * \text{GPMC\_FCLK period}$   
 $K = (\text{OEOffTime} - \text{OEOnTime}) * (1 + \text{TimeParaGranularity}) * \text{GPMC\_FCLK period}$   
 $L = \text{RdCycleTime} * (1 + \text{TimeParaGranularity}) * \text{GPMC\_FCLK period}$   
 $M = (\text{CSRdOffTime} - \text{OEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{CSEExtraDelay} - \text{OEExtraDelay})) * \text{GPMC\_FCLK period}$

Figure 12-114 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

**Figure 12-114. NAND Command Latch Cycle Timing Simplified Example**

#### 12.3.4.4.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode. Table 12-207 describes the synchronous NOR formulas.

**Table 12-207. Synchronous NOR Formulas Description**

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low
B	ns	Delay time – address bus valid to CLK first edge
C	ns	Pulse duration – nBE0 / nBE1 low
D	ns	Delay time – CLK rising edge to nBE0 / nBE1 invalid
E	ns	Delay time – CLK rising edge to nADV/ALE invalid
F	ns	Delay time – CLK rising edge to nCS transition
G	ns	Delay time – CLK rising edge to nADV/ALE transition
H	ns	Delay time – CLK rising edge to nOE/nRE transition
I	ns	Delay time – CLK rising edge to nWE transition
J	ns	Delay time – CLK rising edge to A[16-1]/D[15-0] data bus transition
K	ns	Pulse duration – nADV/ALE low
L	ns	Delay time – WAIT invalid to first data latching CLK edge

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

1. For single read accesses:  
 $A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
 $C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
 $D = (RDCYCLETIME - RDACCESSTIME) * GPMC\_FCLK \text{ period}$   
 $E = (CSRDOFFTIME - RDACCESSTIME) * GPMC\_FCLK \text{ period}$
2. For burst read accesses (where n is the page burst access number):  
 $A = (CSRDOFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
 $C = (RDCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
 $D = (RDCYCLETIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC\_FCLK \text{ period}$   
 $E = (CSRDOFFTIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC\_FCLK \text{ period}$
3. For burst write accesses (where n is the page burst access number):  
 $A = (CSWROFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
 $C = (WRCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
 $D = (WRCYCLETIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC\_FCLK \text{ period}$   
 $E = (CSWROFFTIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC\_FCLK \text{ period}$
4. For all accesses:  
For nCS falling edge (chip-select activated):
  - Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:  
 $F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$
  - Case where GPMCFCLKDIVIDER = 0x1:  
 $F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)  
 $F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$  otherwise.
  - Case where GPMCFCLKDIVIDER = 0x2:  
 $F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3  
 $F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3  
 $F = (2 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3
For nCS rising edge (chip-select deactivated) in reading mode:
  - Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:  
 $F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$
  - Case where GPMCFCLKDIVIDER = 0x1:  
 $F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)  
 $F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$  otherwise.
  - Case where GPMCFCLKDIVIDER = 0x2:  
 $F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3  
 $F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3  
 $F = (2 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (CSRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3
For nCS rising edge (chip-select deactivated) in writing mode:
  - Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:  
 $F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$
  - Case where GPMCFCLKDIVIDER = 0x1:

$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK$  period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)

$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK$  period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:

$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK$  period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3

$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK$  period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3

$F = (2 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK$  period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV falling edge (nADV activated):

- Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:

$G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period

- Case where GPMCFCLKDIVIDER = 0x1:

$G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)

$G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:

$G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 3

$G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3

$G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:

$G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period

- Case where GPMCFCLKDIVIDER = 0x1:

$G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)

$G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:

$G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

$G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

$G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:

$G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period

- Case where GPMCFCLKDIVIDER = 0x1:

$G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)

$G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:

$G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (ADVVROFFTIME – CLKACTIVATIONTIME) is a multiple of 3

$G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVVROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3

$G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVVROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE falling edge (nOE activated):

- Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:

- $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)  
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period}$  otherwise.
  - Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 3  
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3  
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE rising edge (nOE deactivated):

- Case where  $GPMC\_CONFIG1\_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)  
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period}$  otherwise.
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3  
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3  
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE falling edge (nWE activated):

- Case where  $GPMC\_CONFIG1\_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)  
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period}$  otherwise.
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 3  
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3  
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE rising edge (nWE deactivated):

- Case where  $GPMC\_CONFIG1\_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)  
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period}$  otherwise.
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$ , when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3  
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3  
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period}$ , when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV low pulse duration:

- Read operation:  

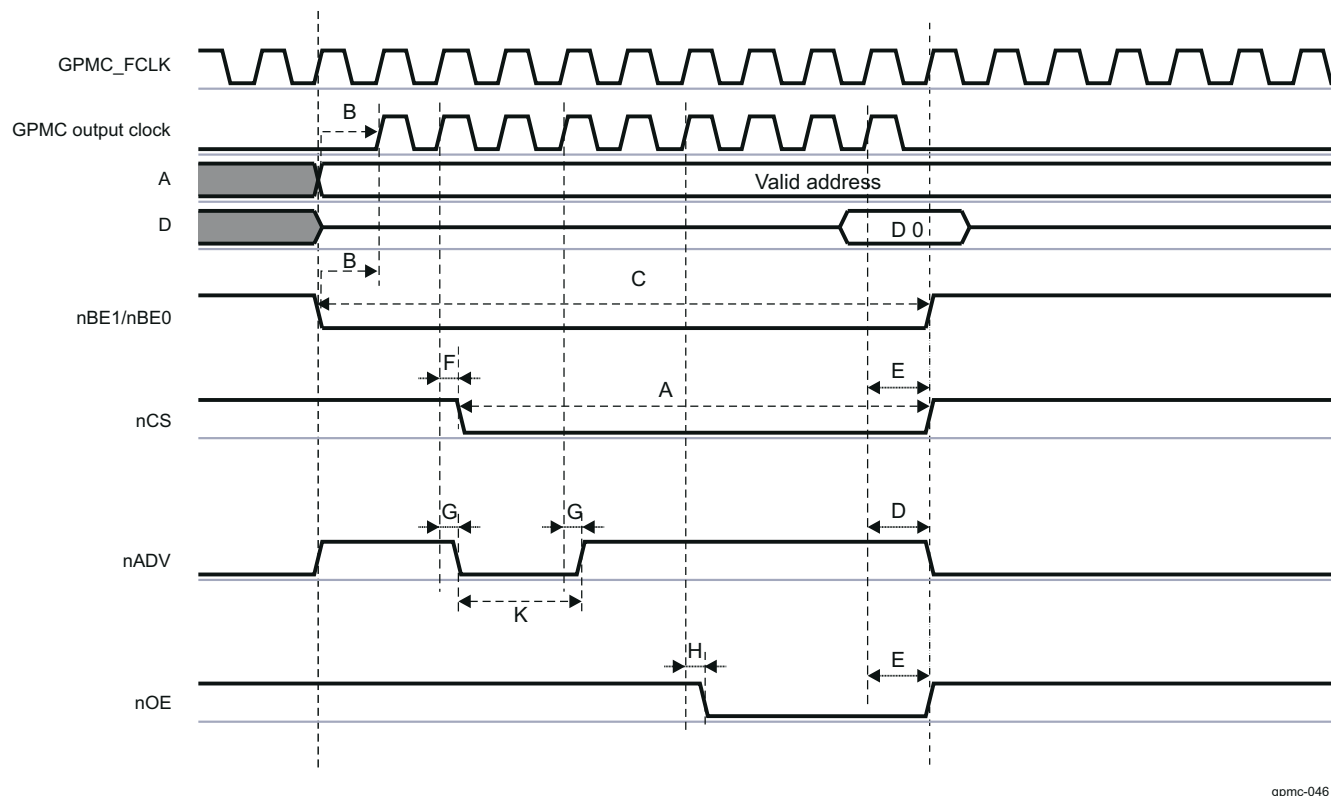

$$K = (\text{ADVRDOFFTIME} - \text{ADVONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$
- Write operation:  

$$K = (\text{ADVWROFFTIME} - \text{ADVONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$

For WAIT invalid to first data latching GPMC output clock edge:

- $$L = \text{WAITMONITORINGTIME} * (\text{GPMCFCLKDIVIDER} + 1) * \text{GPMC\_FCLK period} + \text{GPMC output clock period}$$

Figure 12-115 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

gpmc-046

**Figure 12-115. Synchronous NOR Single Read Simplified Example**

#### 12.3.4.4.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 12-208 describes the asynchronous NOR formulas.

**Table 12-208. Asynchronous NOR Formulas Description**

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low
B	ns	Delay time – nCS valid to nADV/ALE invalid
C	ns	Delay time – nCS valid to nOE/nRE invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – nCS valid to nWE valid
F	ns	Delay time – nCS valid to nWE invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before nOE/nRE high

**Table 12-208. Asynchronous NOR Formulas Description (continued)**

Configuration Parameter	Unit	Description
I	ns	Delay time – nCS valid to nOE/nRE invalid (burst read)
J	ns	Delay time – address bus valid to nCS valid
		Delay time – data bus valid to nCS valid
		Delay time – nBE0 / nBE1 valid to nCS valid
K	ns	Delay time – nCS valid to nADV/ALE valid
L	ns	Delay time – nCS valid to nOE/nRE valid
M	ns	Delay time – nCS valid to first data latching edge
N	ns	Pulse duration – nBE0 / nBE1 valid time
O	ns	Delay time – nCS valid to nADV/ALE valid

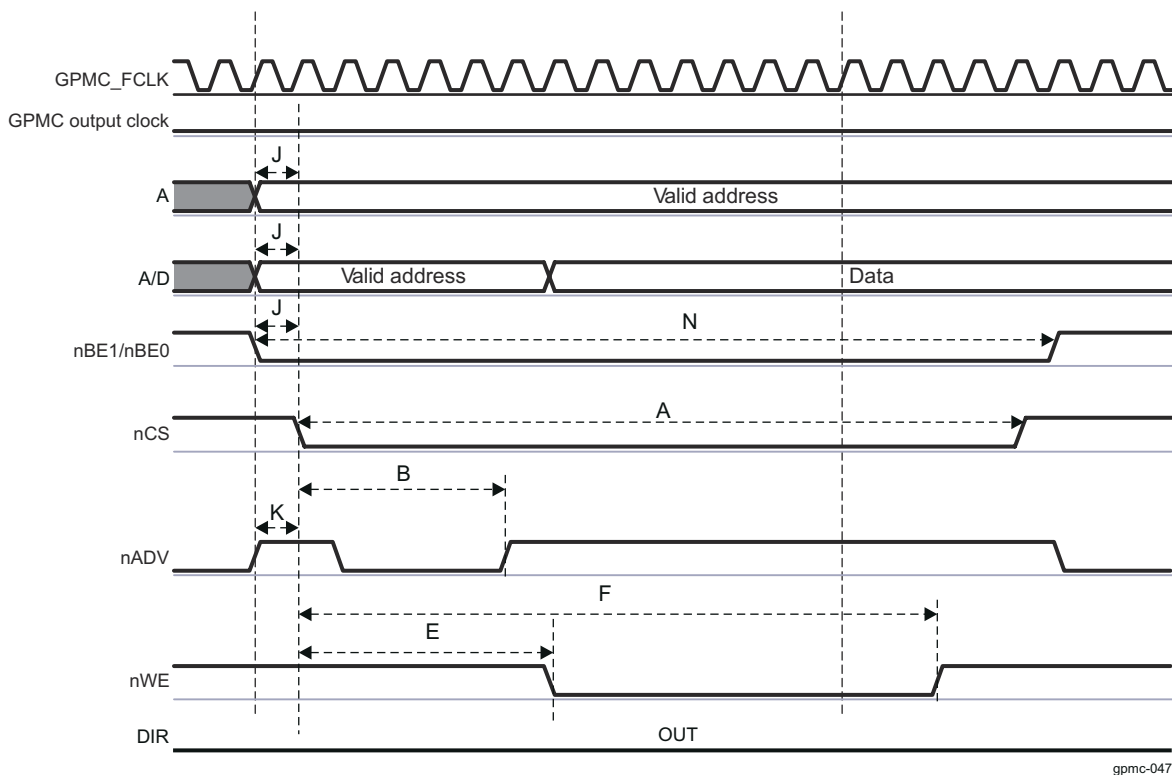

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device-specific Datasheet.

- nCS low pulse:  
For single read:  $A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
For burst read:  $A = (CSRDOFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where N = page burst access number  
For single write:  $A = (CSWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
For burst write:  $A = (CSWROFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where N = page burst access number
- nCS valid to nADV/ALE invalid delay:  
For reading:  $B = ((ADVRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$   
For writing:  $B = ((ADVWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $C = ((OE OFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$
- $E = ((WEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $F = ((WE OFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $G = CYCLE2CYCLEDELAY * GPMC\_FCLK \text{ period}$
- $H = ((OE OFFTIME - RDACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period}$
- $I = ((OE OFFTIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$ , where N = page burst access number
- $J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$
- $K = ((ADVONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $L = ((OEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $M = ((RDACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) - 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$
- nBE0 / nBE1 pulse:  
For single read:  $N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
For burst read:  $N = (RDCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where N = page burst access number

For burst write:  $N = (WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where N = page burst access number

- $O = ((WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$

Figure 12-116 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

**Figure 12-116. Asynchronous NOR Single Write Simplified Example**

#### Note

Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

### 12.3.5 Error Location Module (ELM)

This section describes the Error Location Module (ELM) for the device.

#### 12.3.5.1 ELM Overview

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. A host processor can then correct the data block by flipping the bits to which the ELM error-location outputs point.

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller. ELM can be also used to support parallel NOR flash or NAND flash.

The General-Purpose Memory Controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The ELM extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM depends on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

##### 12.3.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode.

##### 12.3.5.1.2 ELM Not Supported Features

The following features are not supported on this family of devices:

- Local power management of clock activity

##### 12.3.5.1.3 ELM Ports

**Table 12-209. ELM0 Clocks and Resets**

Clocks	
Module Clock Input	Description
ELM_FICLK	ELM functional and interface clock
Resets	

**Table 12-209. ELM0 Clocks and Resets (continued)**

Module Reset Input	Description
ELM_RST	ELM hardware reset

**Table 12-210. ELM0 Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
ELM_ELM_POROCPSINTERRUPT_LVL_0	Error-location process complete interrupt	Level

### 12.3.5.2 ELM Functional Description

The ELM0 module is hereinafter referred to as ELM.

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

#### 12.3.5.2.1 ELM Software Reset

To perform a software reset, set the ELM\_SYSCONFIG[1] SOFTRESET bit to 1. The ELM\_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM\_SYSCONFIG[1] SOFTRESET bit is automatically reset.

#### 12.3.5.2.2 ELM Power Management

##### Note

Some of the ELM features described in this section may not be supported on this family of devices. For more information, see *ELM Not Supported Features*.

Table 12-211 describes the power-management features available to the ELM.

**Table 12-211. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FICLK clock upon the interface activity.
Idle modes	ELM_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained.

#### 12.3.5.2.3 ELM Interrupt Requests

Table 12-212 lists the event flags, and their masks, that can cause module interrupts asserting the signal.

**Table 12-212. ELM Events**

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

#### 12.3.5.2.4 ELM Processing Initialization

ELM\_LOCATION\_CONFIG global setting parameters must be set before using the error-location engine. The ELM\_LOCATION\_CONFIG[1-0] ECC\_BCH\_LEVEL bit field defines the error-correction level used

(4-, 8-, or 16-bit error correction). The ELM\_LOCATION\_CONFIG[26-16] ECC\_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM\_PAGE\_CTRL[i] SECTOR\_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM\_IRQENABLE[i] LOCATION\_MASK\_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM\_IRQENABLE[8] PAGE\_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM\_SYNDROME\_FRAGMENT\_0\_i to ELM\_SYNDROME\_FRAGMENT\_6\_i. The first six registers can be written in any order, but ELM\_SYNDROME\_FRAGMENT\_6\_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit).

As soon as one validity bit is asserted (ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM\_LOCATION\_STATUS\_i and ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM\_IRQSTATUS[i] LOC\_VALID\_i bit is set.

#### 12.3.5.2.5 ELM Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM\_LOCATION\_STATUS\_i[8] ECC\_CORRECTABLE bit is set to 1 and the ELM\_LOCATION\_STATUS\_i[4-0] ECC\_NB\_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM\_LOCATION\_STATUS\_i[8] ECC\_CORRECTABLE bit is set to 0 while the ELM\_LOCATION\_STATUS\_i[4-0] ECC\_NB\_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC\_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC\_ERROR\_LOCATION bit field. The first error detected is logged in the ELM\_ERROR\_LOCATION\_0\_i[12-0] ECC\_ERROR\_LOCATION bit field; the second is logged in the ELM\_ERROR\_LOCATION\_1\_i[12-0] ECC\_ERROR\_LOCATION bit field, and so on.

Table 12-213 describes the ELM\_LOCATION\_STATUS\_i value decoding.

**Table 12-213. ELM\_LOCATION\_STATUS\_i Value Decoding**

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

#### 12.3.5.2.6 ELM Processing Completion

When the processing for a given syndrome polynomial completes, its ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit is reset. It must not be set again until the exit status registers, ELM\_LOCATION\_STATUS\_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM\_IRQSTATUS[i] LOC\_VALID\_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM\_LOCATION\_STATUS\_i register, and error locations are stored in order in the ECC\_ERROR\_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM\_PAGE\_CTRL are reset), an interrupt is triggered whenever a ELM\_IRQSTATUS[i] LOC\_VALID\_i bit is asserted. Software must read the ELM\_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM\_LOCATION\_STATUS\_i and ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i). When done, software must clear the corresponding ELM\_IRQSTATUS[i] LOC\_VALID\_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM\_IRQSTATUS[8] PAGE\_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM\_IRQENABLE[i] LOCATION\_MASK\_i bits are cleared. A page is defined using the ELM\_PAGE\_CTRL register. Each SECTOR\_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM\_IRQSTATUS[i] LOC\_VALID\_i bits. The module triggers an ELM\_IRQSTATUS[8] PAGE\_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM\_IRQSTATUS register must be cleared by using a single atomic-write access.

---

#### Note

Do not modify page setting parameters in the ELM\_PAGE\_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

---

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM\_PAGE\_CTRL[i] SECTOR\_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM\_IRQSTATUS bits to check for their status.

### 12.3.5.3 ELM Basic Programming Model

#### 12.3.5.3.1 ELM Low-Level Programming Model

##### 12.3.5.3.1.1 Processing Initialization

**Table 12-214. ELM Processing Initialization**

Step	Register/Bit Field/Programming Model	Value
Resets the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management.	ELM_SYSCONFIG[4-3] SIDLEMODE	Set value
Defines the error-correction level used.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length.	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode.	ELM_PAGE_CTRL	Set value
<b>IF</b> continuous mode is used:	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x0
Enable interrupt for syndrome polynomial i.	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
<b>ELSE</b> (page mode is used):	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value
<b>ENDIF</b>		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

##### 12.3.5.3.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 12-215](#) and [Table 12-216](#) describe the processing completion for continuous and page modes, respectively.

**Table 12-215. ELM Processing Completion for Continuous Mode**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
<b>IF</b> the process fails (too many errors):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
<b>ELSE</b> (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
<b>ENDIF</b>		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID = 0x0) and after the exit status register check (ELM\_LOCATION\_STATUS\_i).

**Table 12-216. ELM Processing Completion for Page Mode**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
<b>Repeat</b> the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
<b>IF</b> the process fails (too many errors):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependent.		
<b>ELSE</b> (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
<b>ENDIF</b>		
<b>End Repeat</b>		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM\_IRQSTATUS[i] LOC\_VALID\_i = 0x1 for all syndrome polynomials i used in the page).

#### 12.3.5.3.1.3

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM\_IRQSTATUS[i] LOC\_VALID\_i = 0x1 for all syndrome polynomials i used in the page).

#### 12.3.5.3.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see [Table 12-217](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980.

**Table 12-217. Use Case: Continuous Mode**

Step	Register/Bit Field/Programming Model	Value
Reset the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	0x2
Define the error-correction level used: 8 bits.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	0x1
Define the maximum buffer length: 528 bytes (2 × 528 = 1056).	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	0x420
Set the ELM in continuous mode.	ELM_PAGE_CTRL	0
Enable interrupt for syndrome polynomial 0.	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0x0000000A
Initiate the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1

**Table 12-217. Use Case: Continuous Mode (continued)**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial 0: is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 12-218](#) are given in decimal format.

**Table 12-218. 16-Bit NAND Sector Buffer Address Map**

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176
...

49	3431	3430	3429	3428	3427	3426	3425	3424	3439	3438	3437	3436	3435	3434	3433	3432
50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

### 12.3.5.3.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for a 16-bit error-correction capability in page mode (see [Table 12-219](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

**Table 12-219. Use Case: Page Mode**

Step	Register/Bit Field/Programming Model	Value
Reset the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	0x2
Define the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	0x2
Define the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	0x420
Set the ELM in page mode (four blocks in a page)	ELM_PAGE_CTRL[0] SECTOR_0	0x1
	ELM_PAGE_CTRL[1] SECTOR_1	0x1
	ELM_PAGE_CTRL[2] SECTOR_2	0x1
	ELM_PAGE_CTRL[3] SECTOR_3	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	ELM_IRQENABLE	0x100
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xE0B718EF
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xA329AA05
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x8330B5CC
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0xB0693DB2
	ELM_SYNDROME_FRAGMENT_4_i (where i = 0)	0x318E05BE
	ELM_SYNDROME_FRAGMENT_5_i (where i = 0)	0x12ADDB5A
	ELM_SYNDROME_FRAGMENT_6_i (where i = 0)	0xE8B0
Set the input syndrome polynomial 1.	ELM_SYNDROME_FRAGMENT_0_i (where i = 1)	0xE5F935EB
	ELM_SYNDROME_FRAGMENT_1_i (where i = 1)	0x79C6BA10
	ELM_SYNDROME_FRAGMENT_2_i (where i = 1)	0xBE093336
	ELM_SYNDROME_FRAGMENT_3_i (where i = 1)	0x0948DF08
	ELM_SYNDROME_FRAGMENT_4_i (where i = 1)	0xC22E6669
	ELM_SYNDROME_FRAGMENT_5_i (where i = 1)	0x49A0D932
	ELM_SYNDROME_FRAGMENT_6_i (where i = 1)	0xBAD0
Set the input syndrome polynomial 2.	ELM_SYNDROME_FRAGMENT_0_i (where i = 2)	0x60BA3189
	ELM_SYNDROME_FRAGMENT_1_i (where i = 2)	0x1579EF7D
	ELM_SYNDROME_FRAGMENT_2_i (where i = 2)	0x54556EA0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 2)	0xA6498FEE

	ELM_SYNDROME_FRAGMENT_6_i (where i = 2)	0x69D9

**Table 12-219. Use Case: Page Mode (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the input syndrome polynomial 3.	ELM_SYNDROME_FRAGMENT_0_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_1_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_2_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_4_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_5_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_6_i (where i = 3)	0x0
Initiate the computation process for syndrome polynomial 0	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Initiate the computation process for syndrome polynomial 1	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 1)	0x1
Initiate the computation process for syndrome polynomial 2	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 2)	0x1
Initiate the computation process for syndrome polynomial 3	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 3)	0x1
Wait until process is complete for syndrome polynomial 0, 1, 2, and 3: Wait until the interrupt is generated or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Read the process exit status for syndrome polynomial 0: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the process exit status for syndrome polynomial 1: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 1)	0x1
Read the process exit status for syndrome polynomial 2: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 2)	0x1
Read the process exit status for syndrome polynomial 3: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 3)	0x1
Read the number of errors for syndrome polynomial 0: four errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 0)	0x4
Read the number of errors for syndrome polynomial 1: two errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 1)	0x2
Read the number of errors for syndrome polynomial 2: one error detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 2)	0x1
Read the number of errors for syndrome polynomial 3: no errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 3)	0x0
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers:	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1FE
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x617
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x650
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the first two registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x4
	ELM_ERROR_LOCATION_1_i (where i = 1)	0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x3E8
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

### 12.3.6 Multi-Media Card Secure Digital (MMCSD) Interface

This section describes the MMCSD modules in the device.

#### 12.3.6.1 MMCSD Overview

There are two MMCSD modules inside the device - MMCSD0 and MMCSD1. Each MMCSD module includes one MMCSD Host Controller.

Each controller has the following data bus width:

- MMCSD0 - 8-bit wide data bus
- MMCSD1 - 4-bit wide data bus

The MMCSD Host Controller provides an interface to eMMC 5.1 (embedded Multi-Media Card), SD 4.10 (Secure Digital), and SDIO 4.0 (Secure Digital IO) devices. The MMCSD Host Controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit insertion, and checking for syntactical correctness.

The MMCSD Host Controller provides accessibility to external MMC/SD/SDIO devices using a Programmed IO method or DMA data transfer method. In programmed IO method, the device CPU transfers data using the Buffer Data Port register (MMCSD0\_DATA\_PORT / MMCSD1\_DATA\_PORT). In DMA data transfer method, the MMCSD Host Controller can read or write memory without device CPU intervention.

### 12.3.6.1.1 MMCSD Features

Each MMCSD Host Controller supports:

- Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3 (for more information about ADMA support, see [Section 12.3.6.3.5, Advanced DMA](#))
- System Bus Interface:
  - 64-bit data width (master interface)
  - 64-bit address
  - Clock asynchronous to MMCSD clock (MMCi\_CLK)
  - Little endian only
- Configuration Bus Interface:
  - 32-bit data width (slave interface)
  - Linear incrementing addressing mode
  - 32-bit aligned accesses only
  - Little endian only
- Muxing of other LVCMOS interfaces onto the MMCSD interface at the SoC level (MMCSD1 only)

MMCSD0 Host Controller (eMMC interface):

- MultiMedia Card Support:
  - eMMC Electrical Standard 5.1 (JESD84-B51)
  - Backward compatible with earlier eMMC standards
  - Legacy MMC SDR:
    - 1.8 V, 8-bit bus width, 0-25 MHz, 25 MBps
    - 1.8 V, 4-bit bus width, 0-25 MHz, 12.5 MBps
    - 1.8 V, 1-bit bus width, 0-25 MHz, 3.125 MBps
  - High Speed SDR:
    - 1.8 V, 8-bit bus width, 0-50 MHz, 50 MBps
    - 1.8 V, 4-bit bus width, 0-50 MHz, 25 MBps
    - 1.8 V, 1-bit bus width, 0-50 MHz, 6.25 MBps
  - High Speed DDR:
    - 1.8 V, 8-bit bus width, 0-50 MHz, 100 MBps
    - 1.8 V, 4-bit bus width, 0-50 MHz, 50 MBps
  - HS200 SDR:
    - 1.8 V, 0-200 MHz, 8-bit bus width, 200 MBps
    - 1.8 V, 0-200 MHz, 4-bit bus width, 100 MBps
  - HS400 DDR:
    - 1.8 V, 0-200 MHz, 8-bit bus width, 400 MBps

MMCSD1 Host Controller (SD/SDIO interface):

- 
- Secure Digital Card Support:
  - Backward compatible with earlier SD card specifications
  - SD Host Controller Standard Specification 4.10 and SD Physical Layer Specification v3.01
  - SDIO Specification v3.00
  - Default Speed mode: 3.3 V signaling, frequency up to 25 MHz, up to 12.5 MBps
  - High Speed mode: 3.3 V signaling, frequency up to 50 MHz, up to 25 MBps
  - SDR12: UHS-I 1.8 V signaling, frequency up to 25 MHz, up to 12.5 MBps
  - SDR25: UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 25 MBps
  - SDR50: UHS-I 1.8 V signaling, frequency up to 100 MHz, up to 50 MBps
  - DDR50: UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 50 MBps
  - SDR104: UHS-I 1.8 V signaling, frequency up to 200 MHz, up to 100 MBps

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

### 12.3.6.1.2 MMCSD Not Supported Features

MMCSD0 Host Controller:

- MultiMedia Card:
  - 3.3 V, 3.0 V and 1.2 V
  - Secure Digital Card and SDIO
  - Muxing of other LVCMOS interfaces onto the MMCSD interface at the SoC level

MMCSD1 Host Controller:

- MultiMedia Card
- Secure Digital Card:
  - UHS-II

### 12.3.6.1.3 MMCSD Ports

**Table 12-220. MMCSD Clocks and Resets**

Clocks	
Module Clock Input	Description
MMCSD_ICLK	MMCSD Interface Clock
MMCSD_FCLK	MMCSD Functional Clock
Resets	
Module Reset Input	Description
MMCSD_RST	MMCSD Asynchronous Reset

**Table 12-221. MMCSD Hardware Requests**

Interrupt Requests			
Module Interrupt Signal	Description	Type	
MMCSD_EMMCSS_INTR_0	MMCSD Interrupt Request	Level	
MMCSD_EMMCSS_RXMEM_CORR_ERR_LVL_0	MMCSD Receive ECC Correctable Error Interrupt Request	Level	
MMCSD_EMMCSS_RXMEM_UNCORR_ERR_LVL_0	MMCSD Receive ECC Uncorrectable Error Interrupt Request	Level	
MMCSD_EMMCSS_TXMEM_CORR_ERR_LVL_0	MMCSD Transmit ECC Correctable Error Interrupt Request	Level	
MMCSD_EMMCSS_TXMEM_UNCORR_ERR_LVL_0	MMCSD Transmit ECC Uncorrectable Error Interrupt Request	Level	

### 12.3.6.2 MMCSD Environment

This section describes the MMCSDi external connections (environment).

Table 12-222 describes the MMCSDi I/O signals.

**Table 12-222. MMCSDi I/O Signals**

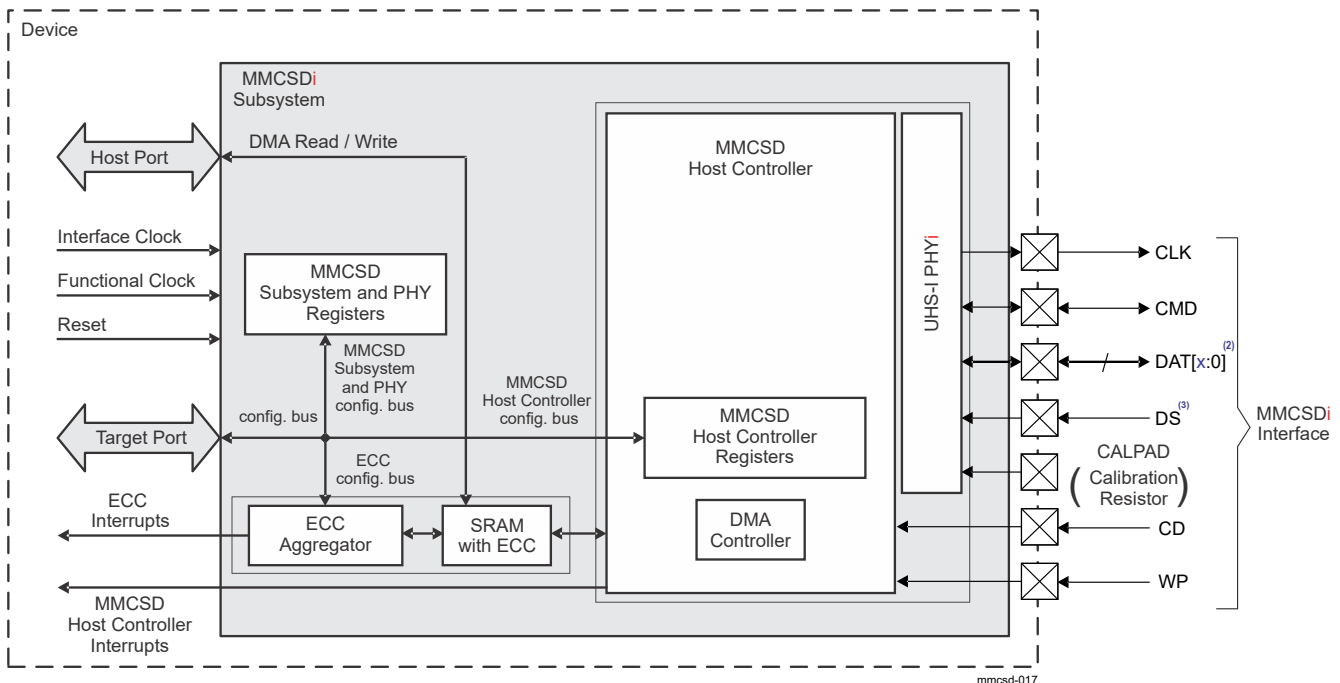

Module Pin	I/O <sup>(1)</sup>	Description
DAT[7:0]	I/O	Data Signals
DS	I	Data Strobe
CALPAD	A	PHY Calibration Resistor
CLK	O	External Clock
CMD	I/O	Command Line
DAT[3:0]	I/O	Data Signals
WP	I	SD Card Write Protect
CD	I	SD Card Detect

(1) I = Input; O = Output; HiZ = High Impedance; A = Analog

### 12.3.6.3 MMCSD Functional Description

#### 12.3.6.3.1 Block Diagram

Figure 12-117 shows the MMCSDi module block diagram (where i = 0 to 1).

**Figure 12-117. MMCSDi Module Block Diagram**

#### Basic Blocks:

- **MMCSD Host Controller:** The MMCSD Host Controller is situated in the MMCSD Subsystem and provides accessibility to external MMC/SD/SDIO devices using a Programmed IO method or DMA data transfer method.
- **UHS-I PHY:** The integrated UHS-I PHY provides an interface between the MMCSD Host Controller and external MMC/SD/SDIO devices.
- **MMCSDi Interface:** The MMCSDi Interface includes all used interface pins (for more information, see *MMCSDi I/O Signals*).
- **Host Port:** Provides a 64-bit wide read/write interface between the device and the MMCSD Subsystem internal SRAM.
- **Target Port:** Provides a 32-bit wide interface between the device and the MMCSD Subsystem and MMCSD Host Controller parts.
- **MMCSD Host Controller Registers:** This block includes set of all MMCSD Host Controller registers.
- **MMCSD Subsystem and PHY Registers:** This block implements memory-mapped registers at the MMCSD Subsystem level and memory-mapped registers to control and program the MMCSD PHY.
- **ECC Aggregator:** The ECC Aggregator block facilitates aggregating and reporting internal SRAM ECC errors (for more information, see [Section 12.3.6.3.4, ECC Support](#)).
- **Internal SRAM with ECC:** The internal SRAM block is used for data storage during read/write transactions.
- **DMA Controller:** Manages the data transfer between the device memory and the MMCSD Subsystem internal SRAM.
- **System Clocks:** There are asynchronous relationship between the interface (system) clock and functional clock (for more information, see *MMCSD Clocks*).
- **System Reset:** The reset to the MMCSD Subsystem provides reset to the all MMCSD Subsystem parts (for more information, see *MMCSD Clocks*).
- **Interrupts:** The MMCSD Subsystem sources one MMCSD Host Controller interrupt and four ECC Aggregator interrupts (for more information, see *MMCSD Hardware Requests and Interrupt Requests*).

For more information about all MMCSD registers, see *MMCSD Registers*.

The MMCSD Host Controller can use a Programmed IO method (PIO) or DMA data transfer method to access external MMC/SD/SDIO devices.

The target port is used for device CPU access to the MMCSD Host Controller register set. The MMCSD Host Controller register set provides the communication between the device CPU and the MMCSD Host Controller. In PIO method the device CPU transfers data using the MMCSD0\_DATA\_PORT / MMCSD1\_DATA\_PORT register. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the target port, the MMCSD0\_DATA\_PORT / MMCSD1\_DATA\_PORT register in the MMCSD Host Controller, and the PHY.

The host port is used for connection to the DMA controller (for more information about ADMA support, see [Section 12.3.6.3.5, Advanced DMA](#) and MMCSD0\_CAPABILITIES / MMCSD1\_CAPABILITIES register). In DMA data transfer method the DMA controller uses the host port to transfer data between the device memory and the MMCSD Subsystem internal SRAM. The other side of the internal SRAM is connected to the MMCSD Host Controller. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the host port, internal SRAM, MMCSD Host Controller, and the PHY. The DMA controller manages the read/write operations from/to the internal SRAM without device CPU intervention.

#### 12.3.6.3.2 Memory Regions

shows MMCSDi module memory map.

#### 12.3.6.3.3 Interrupt Requests

Each MMCSD instance sources one active high level MMCSD Host Controller interrupt and four active high level ECC Aggregator interrupts (see *MMCSD Hardware Requests*). The MMCSD Host Controller interrupt is generated based on the bit values in the MMCSD0\_NORMAL\_INTR\_STS / MMCSD1\_NORMAL\_INTR\_STS and MMCSD0\_NORMAL\_INTR\_STS\_ENA / MMCSD1\_NORMAL\_INTR\_STS\_ENA registers. The ECC Aggregator interrupts are generated based on the ECC errors - single and double bit errors (for more information about ECC Aggregator interrupts, see [Section 12.3.6.3.4, ECC Support](#)).

#### 12.3.6.3.4 ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

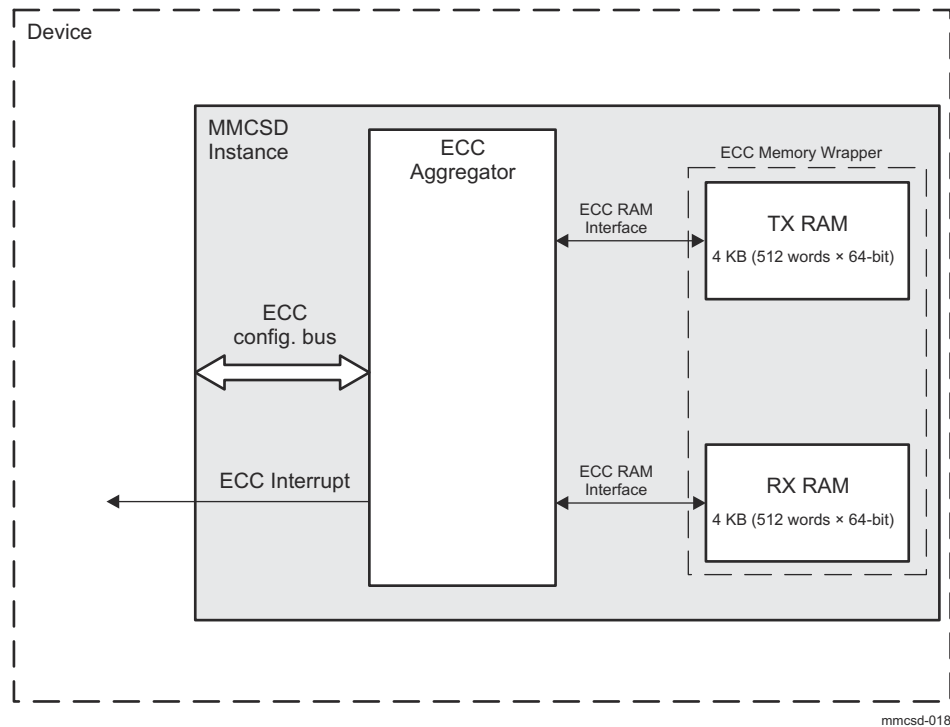

There are two SRAM memories (transmit SRAM and receive SRAM) within each MMCSD instance. These two memories are ECC protected.

The SEC logic detects and corrects a single bit error (single bit error per ECC word or per ECC data segment). The DED logic only detects (does not correct) double errors (double bit errors per ECC word or per ECC data segment).

##### 12.3.6.3.4.1 ECC Aggregator

There are two SRAMs (each with size 4 KB - 512 words × 64-bit) in each MMCSD Subsystem. One SRAM dedicated for transmit and one SRAM dedicated for receive operations.

[Figure 12-118](#) shows the ECC Aggregator block diagram.

**Figure 12-118. ECC Aggregator Block Diagram**

**Note**

For more information about ECC Aggregator Registers, refer to *MMCSd Registers*.

#### 12.3.6.3.5 Advanced DMA

The MMCSd modules support SD Advanced DMA – ADMA2 and ADMA3.

**Note**

For more information, refer to the SD Association specification titled "*SD Host Controller Simplified Specification, Part A2, Version 4.10*".

#### 12.3.6.3.6 eMMC PHY BIST

##### 12.3.6.3.6.1 BIST Overview

To verify the eMMC5.1 PHY functionality, the BIST function is built on top of the eMMC5.1 PHY that can either be controlled from SOC registers or from special Vendor Registers defined in the TI's eMMC5.1 Host Controller. The functionality of the BIST is to be able to test various functions of the PHY (without using the eMMC protocol/software stack) and provide the results of the testing to the diagnostic software.

The BIST logic drives a known pattern on the transmit path (into DFE) and is received on the receive path (as the IOs are bidirectional in nature). The received data is captured in the BIST logic (after the DFE) and are compared. The result of the pattern comparison is reported into status register for software to read out.

The fixed pattern is the well-known tuning pattern used in HS200 mode as defined by the JEDEC. This pattern is 128-bytes in length, is preceded by eMMC START Condition on all lanes, and is terminated with END Condition on all lanes. Unlike the normal Tuning command, there is no CRC appended to this pattern.

The 128-byte Test Pattern is as follows:

F	F	0	F	F	F	0	0	F	F	C	C	C	3	C	C	C	3	3	C	C	C	F	F	F	E	F	F	F	E	E	F

**Figure 12-119. 128-byte Test Pattern**

In non-HS200 Modes, the testing is performed for one time with programmed Tx Phase and Rx Phase values. In HS200 Mode, the testing is performed 32-times and it is expected that some of the iterations will have data mismatch because of the RxPhase Timing. The BIST engine iterates through all 32-phases of Rx Clock and provides the result of data/cmd line compare for each of the phases in a 32-bit status vector.

#### 12.3.6.3.6.2 BIST Modes

The following are the various modes supported by the eMMC5.1 PHY BIST Logic. These modes test both the CMD line and all DATA Lines.

##### 12.3.6.3.6.2.1 DS Mode

This is the Default Speed (DS) mode where the eMMC CLK is set to 25 MHz and the timing of the interface is from negative edge launch to positive edge capture. The DLL and the DLY lines are disabled in this phase.

##### 12.3.6.3.6.2.2 HS Mode with TXDLY using DLL

This is the High Speed (HS) mode where the eMMC CLK is set to 50 MHz. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the TX Clock Phase shift is being performed by using one of the first 16-taps of the DLL TXCLK Phases. The Phase shifting on the RX path is disabled in this mode.

##### 12.3.6.3.6.2.3 HS Mode with TXDLY using Delay Chain

This is the High Speed (HS) mode where the eMMC CLK is set to 50 MHz. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the TX Clock Phase shift is being performed by using one of the first 16-taps of the TX Delay Chain Phases. The Phase shifting on the RX path is disabled in this mode.

The DLL is disabled in this mode.

##### 12.3.6.3.6.2.4 DDR50 Mode with TXDLY using DLL

This is the DDR50 mode where the eMMC CLK is set to 50 MHz. The data is driven on both the edges of the clock. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted TX Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the TX Clock Phase shift is being

performed by using one of the first 16-taps of the DLL TXCLK Phases. The Phase shifting on the RX path is disabled in this mode.

#### **12.3.6.3.6.2.5 DDR50 Mode with TXDLY using Delay Chain**

This is the DDR50 mode where the eMMC CLK is set to 50 MHz. The data is driven on both the edges of the clock. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the Tx Clock Phase shift is being performed by using one of the first 16-taps of the Tx Delay Chain Phases. The Phase shifting on the RX path is disabled in this mode. The DLL is disabled in this mode.

#### **12.3.6.3.6.2.6 HS200 Mode with TX/RXDLY using DLL**

This is the HS200 mode where the eMMC CLK is set to 200 MHz. To emulate the Interface timing, a small Hold time is inserted on Transmit data lines by using the Phase shifted TX Clock. The amount of phase shift can be from 1 to 16 Taps. The RxClock Phase is adjusted from 1 to 32 Phases to check the data at different phases. In this mode, the TX Phase shift is being performed by using one of the first 16-taps of the DLL TXCLK Phases and the RX Phase shift is being performed by using one of the 32 taps of the DLL RXCLK Phases.

#### **12.3.6.3.6.2.7 HS200 Mode with TX/RXDLY using Delay Chain**

This is the HS200 mode where the eMMC CLK is set to 200 MHz. To emulate the Interface timing, a small Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. The Rx Clock Phase is adjusted from 1 to 32 Phases to check the data at different phases. In this mode, the TX Phase shift is being performed by using one of the first 16-taps of the Delay Chain Phases and the RX Phase shift is being performed by using one of the 32 taps of the Delay Chain Phases.

The DLL is disabled in this mode.

#### **12.3.6.3.6.2.8 HS400 Mode**

In this mode, the Receive data is captured using the STRB line. To support this mode, the AFE is configured such that the STRB is toggled during the time when the fixed pattern transmission (including the START/END). The Receive STRB line is phase shifted by 90 and 180 degrees by the DLL. As the data is captured using the STRB, there is no need to enable the RX Clock Phases, and these can be disabled. To maintain the timing, the TX Phase can be adjusted accordingly.

#### **12.3.6.3.6.3 BIST Functionality**

The BIST engine inside the eMMC PHY leverages the Tuning Pattern to verify the functionality of the PHY (including the IOs and the DLL). The BIST engine is controlled from SOC and the eMMC Host Controller should be disabled during the BIST Mode. The BIST can be run at different modes (Clock Speeds) and the result of the BIST operation is presented to the SOC.

In normal mode, the PHY Transmit Data path operates on the MMCS0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL. This clock is provided by the eMMC Host Controller and the frequency of this clock is varied based on the operating mode. The following are the various frequencies used in various modes.

- Default Speed: 25 MHz
- High Speed: 25 MHz
- DDR52: 50 MHz
- HS200: 200 MHz
- HS400: 200 MHz

This clock is generated by the eMMC Host Controller and under direct control of the software through the Clock Control Register @0x2C of the Host Controller Register Set. The eMMC Host Controller uses the XIN\_CLK (the reference clock to the Host Controller, which is usually 200 MHz) and uses the Clock Divider Value and the Clock Enable Control.

The BIST Engine runs on the same MMCS0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL. Though the Host Controller is disabled during the BIST operation, the software should program the Clock Control Register so that the MMCS0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL is generated for the BIST engine.

#### 12.3.6.3.6.4 Signal Interface

The BIST logic is controlled by a set of signals which can be from a set of registers that are software accessible. The following are the signals for BIST Functions.

**Table 12-223. BIST Logic Signals**

Signal	Direction	Description
MMCSDB0_SS_PHY_CTRL_6_REG[31].BISTENABLE	Input	<b>BIST Enable</b> When set the BIST Controller controls the DFE and overwrites the data path signals from the Host Controller Interface. When this is cleared, the Host Controller signals are connected to the DFE and BIST is disabled.
MMCSDB0_SS_PHY_CTRL_6_REG[27:24].BISTMODE	Input	<b>BIST Mode</b> This selects one of the specified BIST Modes for running the BIST sequence. The following are the encoding for the mode: 4'b0000: HS200 Mode with DLL 4'b0001: HS200 Mode with DLY_CHAIN 4'b0010: HS400 Mode (STROBE Mode) 4'b0011: DDR52 Mode with DLL 4'b0100: DDR52 Mode with DLY_CHAIN 4'b0101: HS Mode with DLL 4'b0110: HS Mode with DLY_CHAIN 4'b0111: DS Mode (with DLY_CHAIN)
MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART	Input	<b>BIST Start</b> The rising edge of this signal is used to start the BIST function on the specified BIST Mode. When the BIST is complete the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE output is asserted. Before setting this signal, the SOC must make sure that the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE is low (deasserted).
MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS	Output	<b>BIST Status</b> This is the status of the BIST Testing. In non HS200 Mode, the Bit[0] indicates whether the BIST Passed or not. In HS200 modes, the 32-bit indicates the Pattern Match at each of the 32-taps on RxClk Path.
MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE	Output	<b>BIST Done</b> This is asserted when the BIST completes its sequence. The result of the test is presented in the MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS output. This is asserted until the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART is deasserted at which point the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE is also cleared.

#### 12.3.6.3.6.5 Programming Flow

For the BIST operation, the OD\_EN/REN/PU/OD controls to the CMD/STRB/DAT lines should be programmed as follows:

- OD\_EN: 1'b0
- REN: 1'b0
- PU: 1'b1
- OD: 1'b0

### 12.3.6.3.6.5.1 DS Mode

The following are the various settings required for performing the BIST in Default Speed timing.

#### 12.3.6.3.6.5.1.1 Configuration

- MMCSDB0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 25 MHz.
- PHY's DLL should be disabled.
- MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0111.
- MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b0.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to 4'b0000.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA to 1'b0
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL to 5'b00000
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0

#### 12.3.6.3.6.5.1.2 BIST Programming

1. Set the MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSDB0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSDB0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSDB0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

4. Clear the MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

### 12.3.6.3.6.5.2 HS Mode with DLY\_CHAIN

The following are the various settings required for performing the BIST in HS Mode with DLY Chain.

#### 12.3.6.3.6.5.2.1 Configuration

- MMCSDB0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 50 MHz.
- PHY's DLL should be disabled.
- MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0110.
- MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to on of the tap Value based on Timing Closure.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0

\* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

#### 12.3.6.3.6.5.2.2 BIST Programming

1. Set the MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSDB0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSDB0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSDB0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

4. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.3.6.5.3 HS Mode with DLL

The following are the various settings required for performing the BIST in HS Mode with DLL.

##### 12.3.6.3.6.5.3.1 Configuration

- MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 50 MHz.
- PHY's DLL should be Enabled.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0101.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to on of the tap Value based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0
- MMCSD0\_SS\_PHY\_CTRL\_5\_REG[10:8].FRQSEL should be set for 50 MHz Mode.

\* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

##### 12.3.6.3.6.5.3.2 BIST Programming

1. Wait for MMCSD0\_SS\_PHY\_STAT\_1\_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

5. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.3.6.5.4 DDR52 Mode with DLY\_CHAIN

The following are the various settings required for performing the BIST in DDR52 Mode with DLY Chain.

##### 12.3.6.3.6.5.4.1 Configuration

- MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 50 MHz.
- PHY's DLL should be disabled.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0100.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to on of the tap Value based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0

If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

##### 12.3.6.3.6.5.4.2 BIST Programming

1. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

```
BIST PASS
```

```
else
```

```
BIST FAIL;
```

```
endif
```

4. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.3.6.5.5 DDR52 Mode with DLL

The following are the various settings required for performing the BIST in DDR52 Mode with DLL.

##### 12.3.6.3.6.5.5.1 Configuration

- MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 50 MHz
- PHY's DLL should be Enabled.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0011.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0
- MMCSD0\_SS\_PHY\_CTRL\_5\_REG[10:8].FRQSEL should be set for 50MHz Mode.

If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

##### 12.3.6.3.6.5.5.2 BIST Programming

1. Wait for MMCSD0\_SS\_PHY\_STAT\_1\_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

```
BIST PASS
```

```
else
```

```
BIST FAIL;
```

```
endif
```

5. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.3.6.5.6 HS200 Mode with DLY\_CHAIN

The following are the various settings required for performing the BIST in HS200 Mode with DLY Chain.

##### 12.3.6.3.6.5.6.1 Configuration

- MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 200 MHz.
- PHY's DLL should be disabled.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0001.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA to 1'b0
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0

\*In this mode, the BIST Engine cycles thru all the 32 taps, so there is no need of controlling the Input Tap Delay.

##### 12.3.6.3.6.5.6.2 BIST Programming

1. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*31:0+ Bit and run the "HS200 Bist Result Check Procedure"
4. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.3.6.5.7 HS200 Mode with DLL

The following are the various settings required for performing the BIST in HS200 Mode with DLL.

##### 12.3.6.3.6.5.7.1 Configuration

- MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 200 MHz.
- PHY's DLL should be disabled.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0000.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0
- MMCSD0\_SS\_PHY\_CTRL\_5\_REG[10:8].FRQSEL should be set for 200 MHz Mode.

\* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

##### 12.3.6.3.6.5.7.2 BIST Programming

1. Wait for MMCSD0\_SS\_PHY\_STAT\_1\_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*31:0+ Bit and run the "HS200 Bist Result Check Procedure".
5. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.3.6.5.8 HS400 Mode with DLL

The following are the various settings required for performing the BIST in HS400 Mode with DLL.

##### 12.3.6.3.6.5.8.1 Configuration

- MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 200 MHz.
- PHY's DLL should be enabled.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0010.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA to 1'b0
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0
- MMCSD0\_SS\_PHY\_CTRL\_5\_REG[10:8].FRQSEL should be set for 200 MHz Mode.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[31:24].STRBSEL should be set to appropriate values based on based on STRB timing closure.

\* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

##### 12.3.6.3.6.5.8.2 BIST Programming

1. Wait for MMCSD0\_SS\_PHY\_STAT\_1\_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

```
If (MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS*0+==1'b1) then
```

```
    BIST PASS
```

```
else
```

```
    BIST FAIL;
```

```
endif
```

5. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### **12.3.6.3.6.6 HS200 BIST Result Check Procedure**

In HS200 Mode, the BIST engine in the PHY runs Tuning Pattern test 32 times, with different TAP values selected, for each iteration. The result from the 32 iterations is presented on the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS output. It is expected that some of the TAP values will have timing issues and results in pattern mismatch when compared with the received pattern for those taps. The PASS/FAIL for the HS200 Mode is based on the following theory.

Of the 32 taps, the Data Capture EYE for certain taps will result in mismatches, but these will be sequential tap values. Thus, in a full 32 iterations, a sequence of taps results in data mismatches. Also, based on the timing closure, the number of taps with pattern mismatch should be approximately 1/4th of the number of taps with pattern match. This 1/4th count is not absolute, as this involves various factors such as the timing closure, PVT variation, and so forth. Anywhere from 4 to 16 invalid sequential taps is normal.

For example, if 8 of the 32 sequential taps have the data mismatches, the following would be the resulting MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS output based which of the 8 sequential taps the mismatches are. The following is the notation used:

- 1: Pattern matched at this tap
- 0: Pattern match failed at this tap

[illegible]

### 12.3.6.4 MMCSD Programming Guide

#### 12.3.6.4.1 Sequences

This section defines basic sequence flow chart divided into several sub sequences.

#### Note

This section is applicable for MMCSD0 and MMCSD1 but MMCSD0 registers are used in the content.

#### Note

UHSII is not supported. For more information, see *Not Supported Features*.

"Wait for interrupts" is used in the flow chart. This means the Host Driver waits until specified interrupts are asserted. If already asserted, then fall through that step in the flow chart. Timeout checking shall be always required to detect no interrupt generated but this is not described in the flow chart.

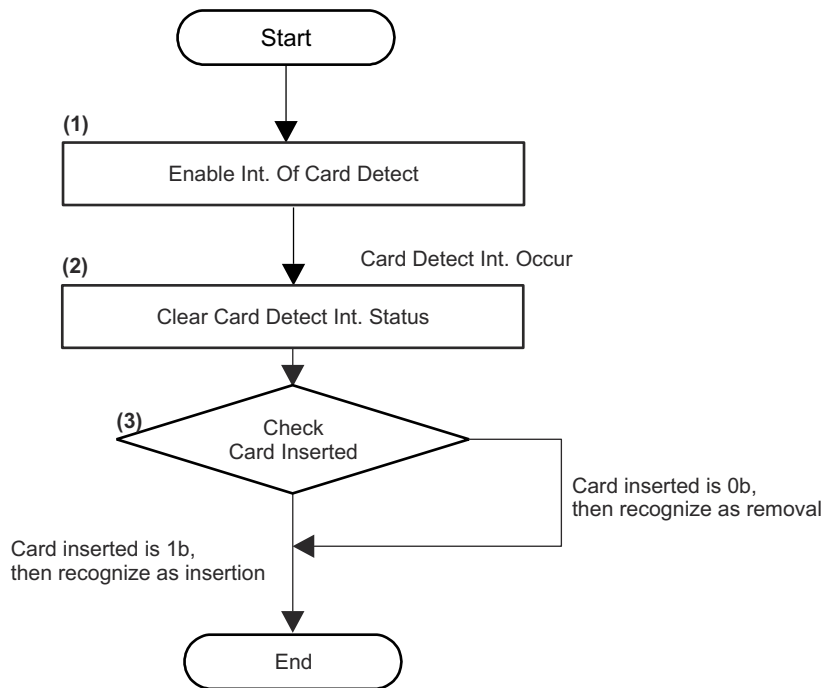

This specification uses the double box like [Figure 12-120](#), (the step (1) in [Figure 12-124](#)), it means that the other flows, which already are shown, shall be performed. Therefore, the interrupt may be included in the other flows.

mmcsd-019

**Figure 12-120. Double Box Notation**

#### 12.3.6.4.1.1 SD Card Detection

mmcsd-020

**Figure 12-121. SD Card Detect Sequence**

The flow chart for detecting a SD card is shown in [Figure 12-121](#).

Each step is executed as follows:

To enable interrupt for card detection, write 1 to the following bits:

- MMCSD0\_NORMAL\_INTR\_STS\_ENA[6] CARD\_INSERTION
- MMCSD0\_NORMAL\_INTR\_SIG\_ENA[6] CARD\_INSERTION
- MMCSD0\_NORMAL\_INTR\_STS\_ENA[7] CARD\_REMOVAL
- MMCSD0\_NORMAL\_INTR\_SIG\_ENA[7] CARD\_REMOVAL

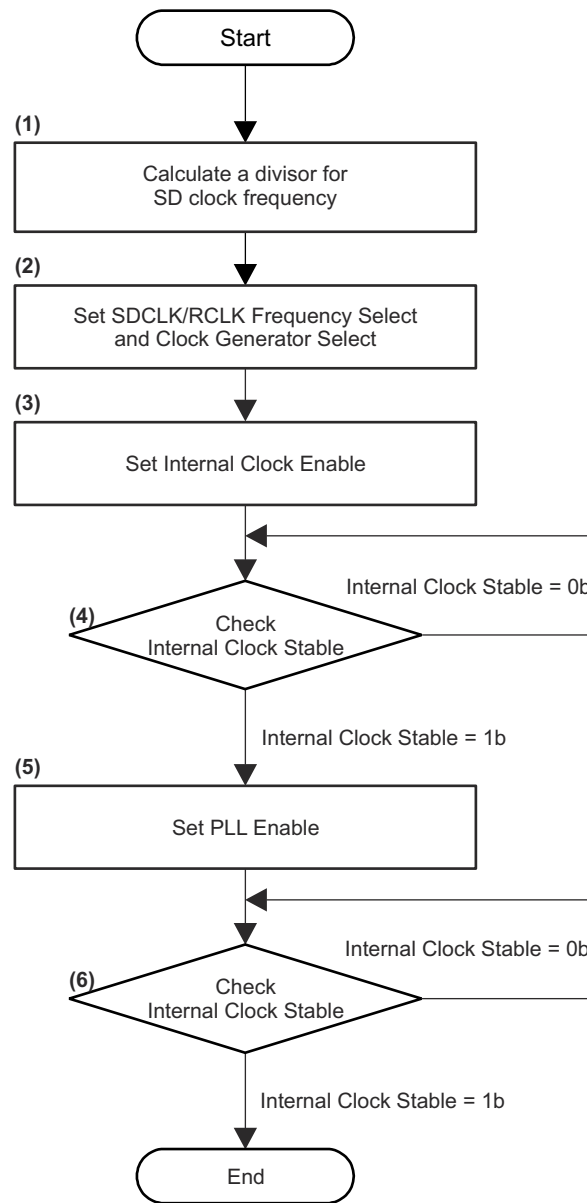

(1) When the Host Driver detects the card insertion or removal, clear its interrupt statuses. If Card Insertion interrupt is generated, write 1 to MMCSD0\_NORMAL\_INTR\_STS\_ENA[6] CARD\_INSERTION bit. If Card Removal interrupt is generated, write 1 to MMCSD0\_NORMAL\_INTR\_STS\_ENA[7] CARD\_REMOVAL bit.

(2) Check MMCSD0\_PRESENTSTATE[16] CARD\_INSERTED bit. In the case where MMCSD0\_PRESENTSTATE[16] CARD\_INSERTED bit is 1, the Host Driver can supply the power and the clock to the SD card. In the case where MMCSD0\_PRESENTSTATE[16] CARD\_INSERTED bit is 0, the other executing processes of the Host Driver shall be immediately closed.

If miniSD adaptor is used for standard SD slot and miniSD card is inserted or extracted from the adaptor, card detect interrupt may not be generated. When host does not receive response to any commands, miniSD card is extracted or in idle state, the host should try to re-initialize the card. In this case, all card information shall be re-loaded.

### 12.3.6.4.1.2 SD Clock Control

#### 12.3.6.4.1.2.1 Internal Clock Setup Sequence

mmcsd-021

**Figure 12-122. Internal Clock Setup Sequence**

The sequence for supplying SD Clock to a SD card is described in [Figure 12-122](#). From Version 4.10, MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is added. This sequence is also applicable to prior versions which do not support MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit.

(1) Calculate a divisor to determine SD Clock frequency for legacy IF or RCLK frequency for UHS-II IF by reading MMCSD0\_CAPABILITIES[15-8] BASE\_CLK\_FREQ and MMCSD0\_CAPABILITIES[55-48] CLOCK\_MULTIPLIER bit fields. If non-zero value is set to MMCSD0\_CAPABILITIES[55-48] CLOCK\_MULTIPLIER bit field, Programmable Clock Mode can be used (for more information, see MMCSD0\_CLOCK\_CONTROL[5] CLKGEN\_SEL bit). If MMCSD0\_CAPABILITIES[15-8] BASE\_CLK\_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

(2) Set MMCSD0\_CLOCK\_CONTROL[15-8] SDCLK\_FRQSEL bit field and MMCSD0\_CLOCK\_CONTROL[5] CLKGEN\_SEL bit in accordance with the calculated result of step (1).

If MMCSD0\_HOST\_CONTROL2[15] PRESET\_VALUE\_ENA bit is set, these bits are set by Host Controller automatically as specified in the Preset Value register (MMCSD0\_PRESET\_VALUE0 - MMCSD0\_PRESET\_VALUE10).

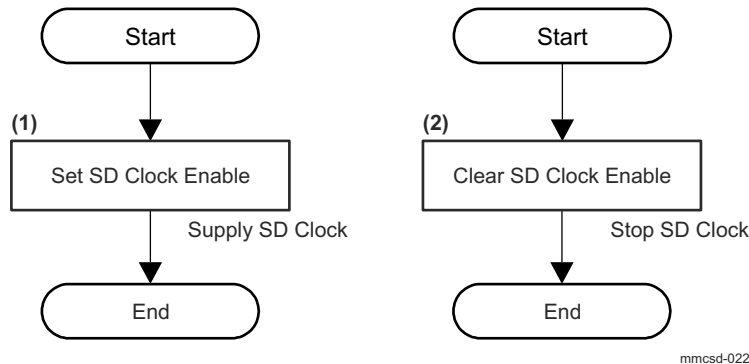

(3) Set MMCSD0\_CLOCK\_CONTROL[0] INT\_CLK\_ENA bit.

(4) Check MMCSD0\_CLOCK\_CONTROL[1] INT\_CLK\_STABLE bit. Repeat this step until this status is 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

(5) Set MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit. This step does not affect Host Controllers which do not support MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit.

(6) If MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is supported, PLL locked may be checked by this status (if MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is not supported, this status is supposed to indicate 1 by step (3)). Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

#### 12.3.6.4.1.2.2 SD Clock Supply and Stop Sequence

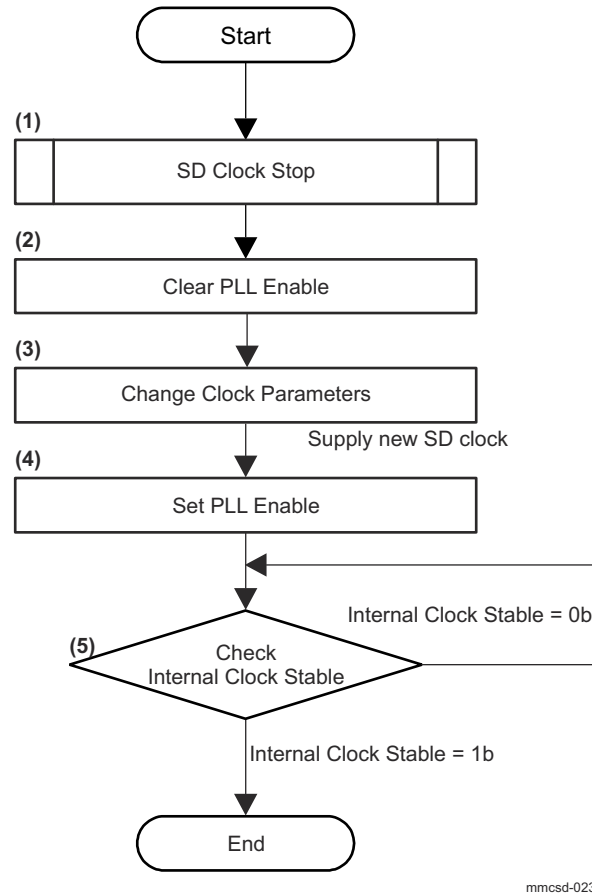

**Figure 12-123. SD Clock Supply and Stop Sequence**

The flow chart for stopping the SD Clock is shown in [Figure 12-123](#). The Host Driver shall not stop the SD Clock when a SD transaction is occurring on the SD Bus -- namely, when either MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT or MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is set to 1.

(1) Setup Internal Clock (see [Figure 12-122](#)). Then set MMCSD0\_CLOCK\_CONTROL[2] SD\_CLK\_ENA bit to 1. Then, the Host Controller starts supplying the SD Clock.

(2) Set MMCSD0\_CLOCK\_CONTROL[2] SD\_CLK\_ENA bit to 0. Then, the Host Controller stops supplying the SD Clock. Internal Clock is still oscillating.

### 12.3.6.4.1.2.3 SD Clock Frequency Change Sequence

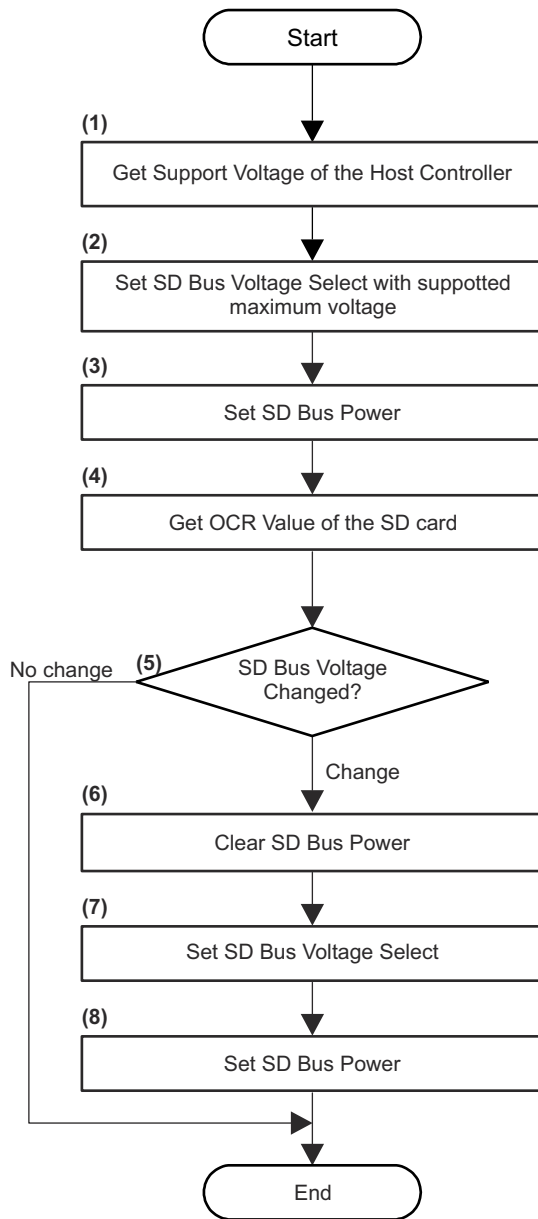

**Figure 12-124. SD Clock Change Sequence**

The sequence for changing SD Clock frequency is shown in [Figure 12-124](#).

- (1) Execute the SD Clock Stop Sequence (see [Figure 12-123](#)). If SD Clock supply to card is already stopped, skip this step.
- (2) Clear MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit to 0. If MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is not supported, this step has no effect and may be skipped.
- (3) When MMCSD0\_HOST\_CONTROL2[15] PRESET\_VALUE\_ENA bit is set to 0, change clock parameters in the MMCSD0\_CLOCK\_CONTROL register. When MMCSD0\_HOST\_CONTROL2[15] PRESET\_VALUE\_ENA bit is set to 1, select Bus Speed Mode as described.
- (4) Set MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit to 1. If MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is not supported, this step has no effect and may be skipped.
- (5) Wait until MMCSD0\_CLOCK\_CONTROL[1] INT\_CLK\_STABLE bit is set to 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms. SD Clock Supply Sequence is required to provide clock to device (see [Figure 12-123](#)).

### 12.3.6.4.1.3 SD Bus Power Control

The sequence for controlling the SD Bus Power is described in [Figure 12-125](#).

mmcsd-024

**Figure 12-125. SD Bus Power Control Sequence**

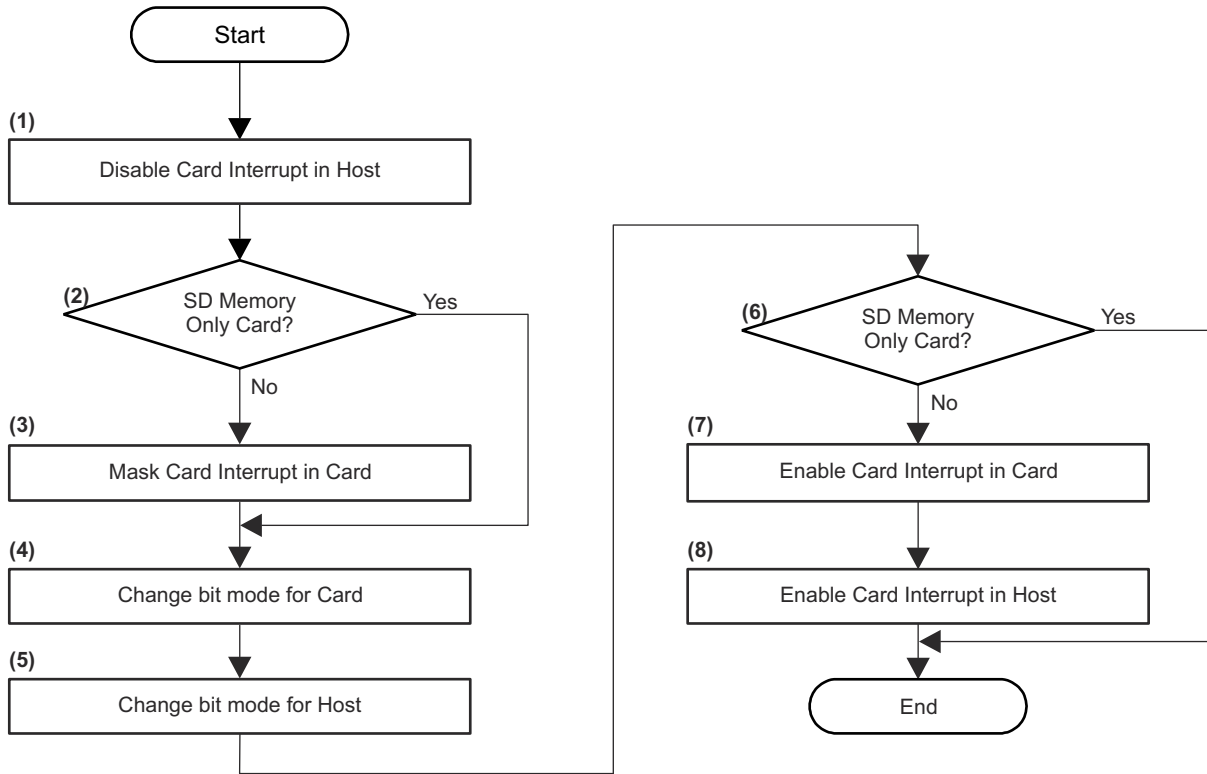

- (1) By reading the MMCSD0\_CAPABILITIES register, get the support voltage of the Host Controller.
- (2) Set MMCSD0\_POWER\_CONTROL[3-1] SD\_BUS\_VOLTAGE bit field with maximum voltage that the Host Controller supports.
- (3) Set MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER bit to 1.
- (4) Get the OCR value of all function internal of SD card.
- (5) Judge whether SD Bus voltage needs to be changed or not. In case where SD Bus voltage needs to be changed, go to step (6). In case where SD Bus voltage does not need to be changed, go to "End".
- (6) Set MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER bit to 0 for clearing this bit. The card requires voltage rising from 0 volt to detect it correctly. The Host Driver shall clear MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER bit before changing voltage by setting MMCSD0\_POWER\_CONTROL[3-1] SD\_BUS\_VOLTAGE bit field.

(7) Set MMCSD0\_POWER\_CONTROL[3-1] SD\_BUS\_VOLTAGE bit field.

(8) Set MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER to 1.

**Note:** Step (2) and step (3) can be executed at same time. And also, step (7) and step (8) can be executed at same time.

#### 12.3.6.4.1.4 Changing Bus Width

mmcsd-025

**Figure 12-126. Change Bus Width Sequence**

The sequence for changing bit mode on SD Bus is shown in [Figure 12-126](#).

(1) Set MMCSD0\_NORMAL\_INTR\_STS\_ENA[8] CARD\_INTERRUPT bit to 0 for masking incorrect interrupts that may occur while changing the bus width.

(2) In case of SD memory only card, go to step (4). In case of other card, go to step (3).

(3) Set "IENM" of the CCCR in a SDIO or SD combo card to 0 by CMD52.

(4) Change the bus width mode for a SD card. SD Memory Card bus width is changed by ACMD6 and SDIO card bus width is changed by setting Bus Width of Bus Interface Control register in CCCR.

(5) In case of changing to 4-bit mode, set MMCSD0\_HOST\_CONTROL1[1] DATA\_WIDTH bit to 1. In another case (1-bit mode), set this bit to 0.

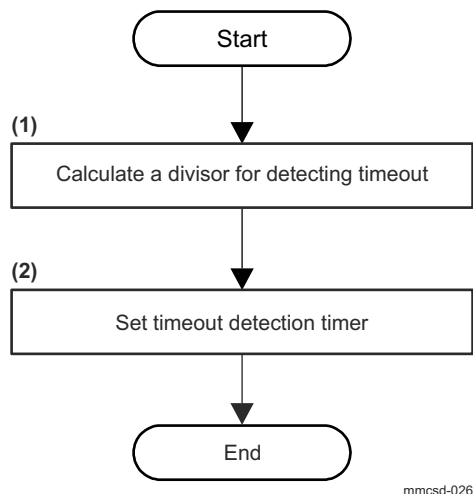

(6) In case of SD memory only card, go to the "End". In case of other card, go to step (7).

(7) Set "IENM" of the CCCR in a SDIO or SD combo card to 1 by CMD52.

(8) Set MMCSD0\_NORMAL\_INTR\_STS\_ENA[8] CARD\_INTERRUPT bit to 1.

Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

#### 12.3.6.4.1.5 Timeout Setting on DAT Line

**Figure 12-127. Timeout Setting Sequence**

In order to detect timeout errors on DAT line, the Host Driver shall execute the following two steps before any SD transaction. For more information regarding SD transactions:

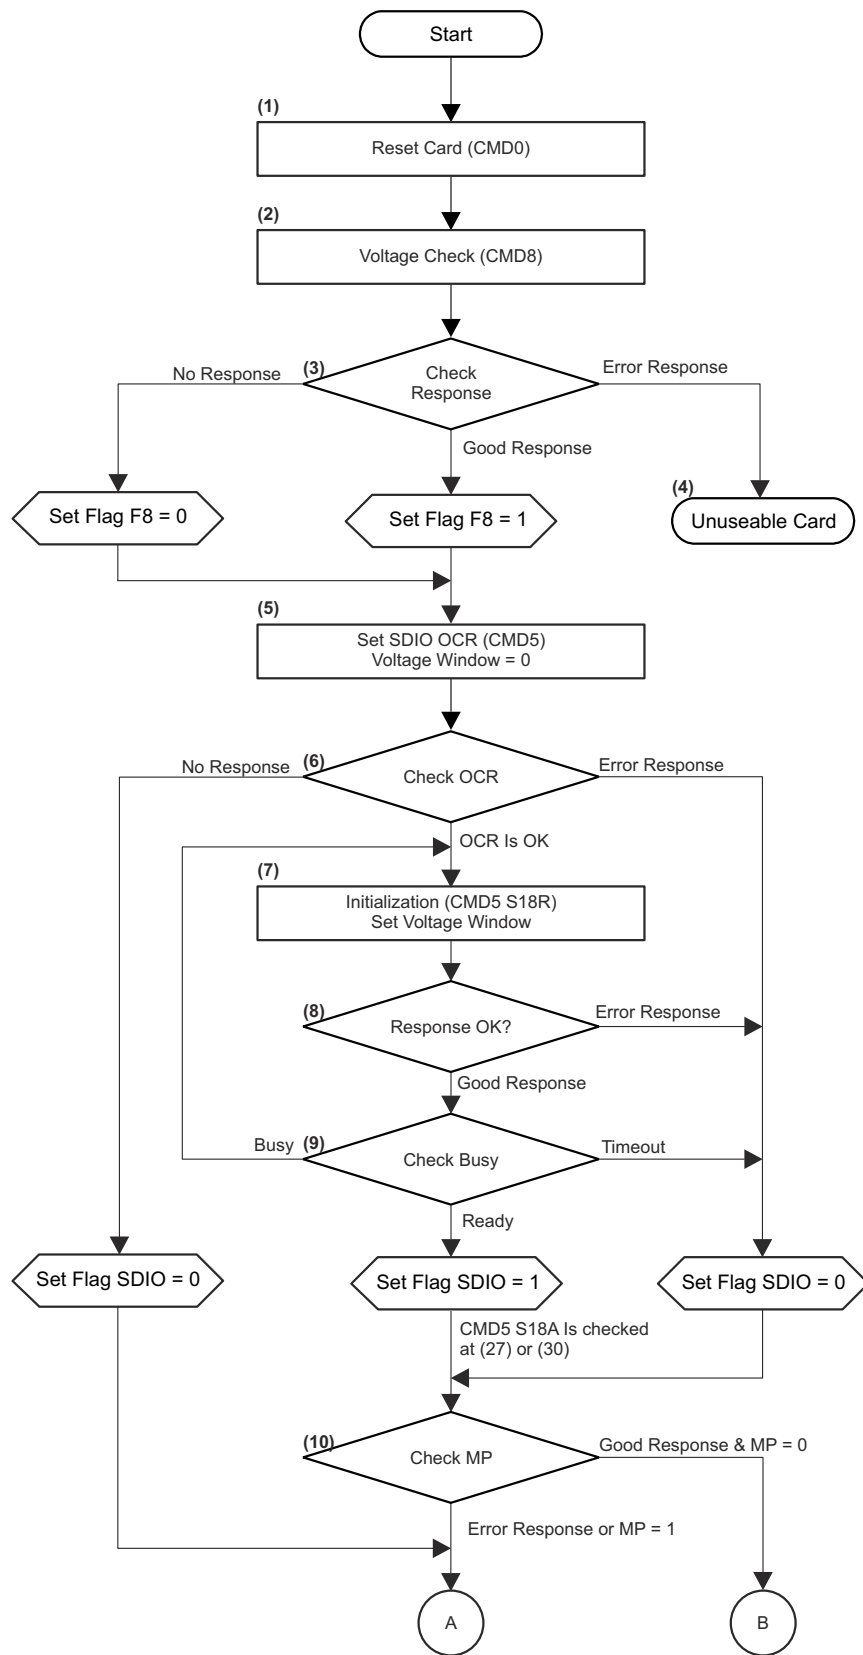

(1) Calculate a divisor to detect timeout errors by reading MMCSD0\_CAPABILITIES[5-0] TIMEOUT\_CLK\_FREQ bit field and MMCSD0\_CAPABILITIES[7] TIMEOUT\_CLK\_UNIT bit. If MMCSD0\_CAPABILITIES[5-0] TIMEOUT\_CLK\_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

(2) Set MMCSD0\_TIMEOUT\_CONTROL[3-0] COUNTER\_VALUE bit field in accordance with the value from step (1) above.

#### 12.3.6.4.1.6 Card Initialization and Identification (for SD I/F)

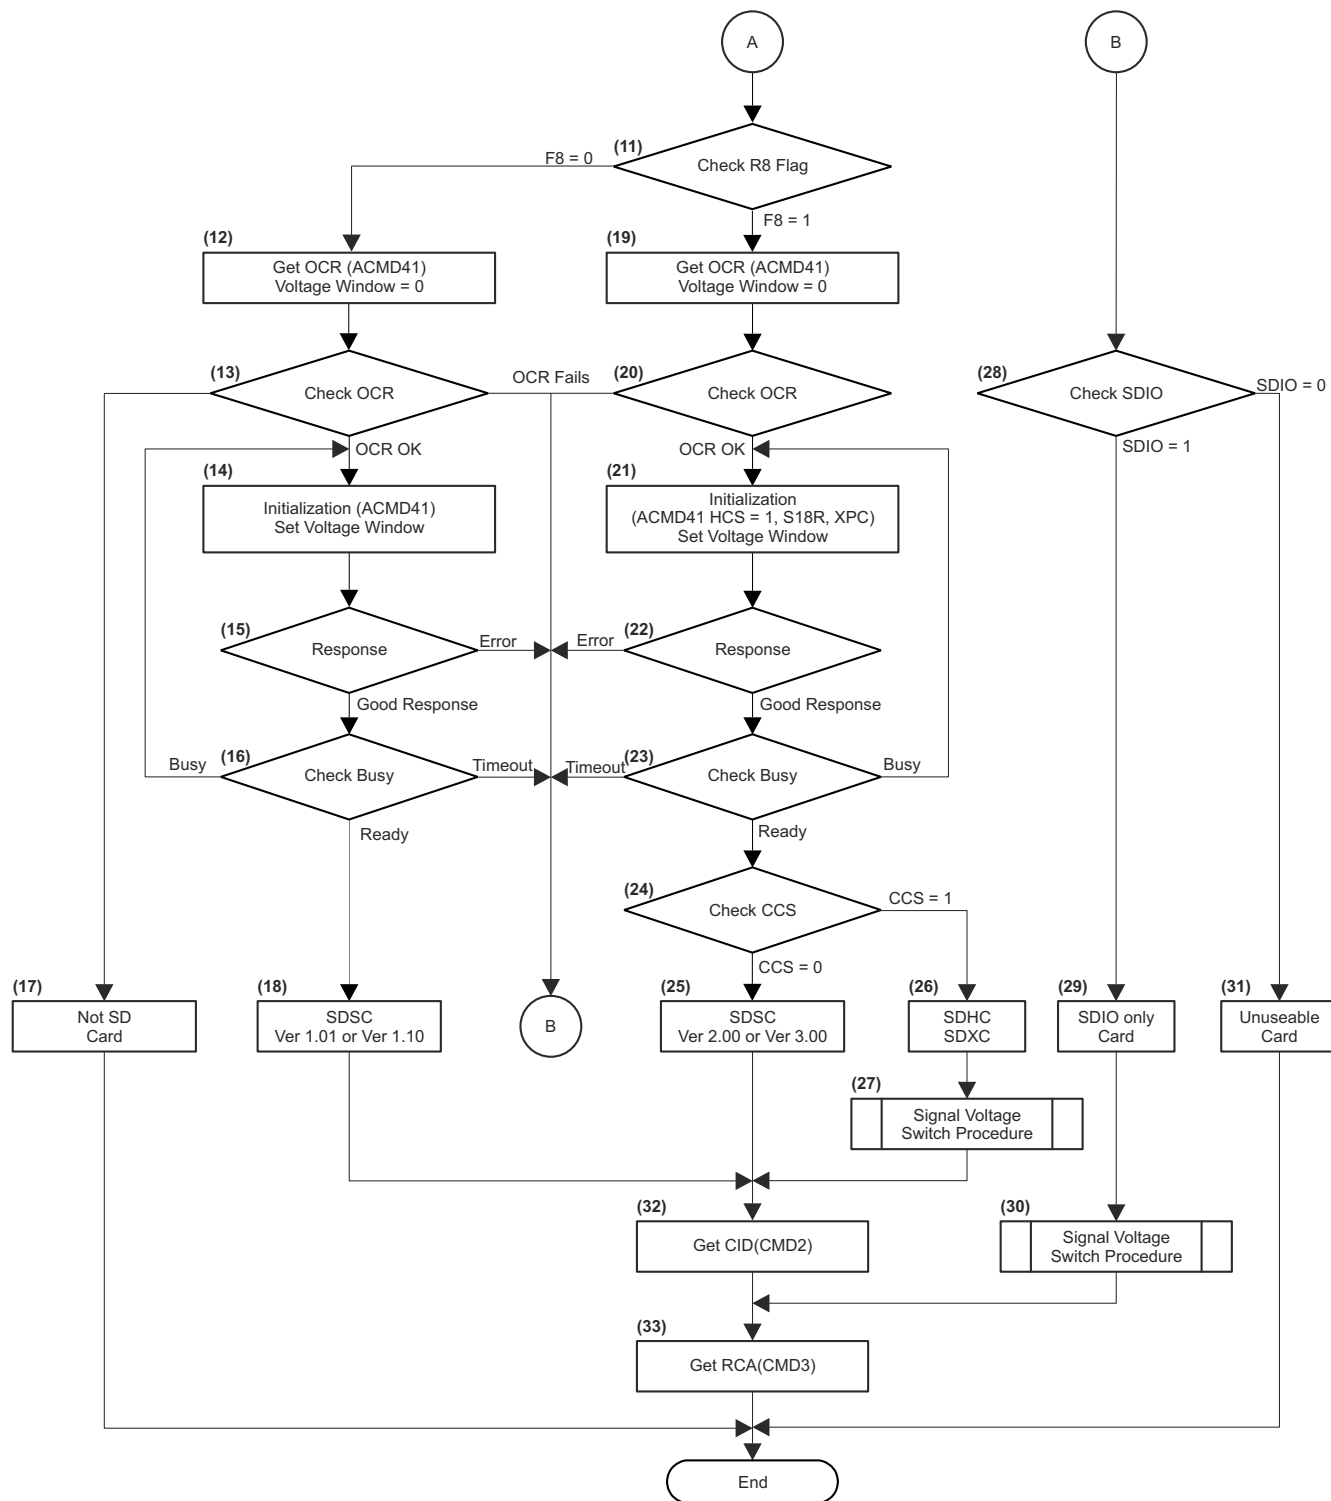

Figure 12-128 and Figure 12-129 shows initialization and card identification sequence for the Standard Capacity SD Memory Card (SDSC), the High Capacity SD Memory Card (SDHC) and the Extended Capacity SD Memory Card (SDXC) that was based on the Physical Layer Version 3.01. Refer to the latest sequence.

mmcsd-027

**Figure 12-128. Card Initialization and Identification (1)**

mmcsd-028

**Figure 12-129. Card Initialization and Identification (2)**

- (1) SD Bus mode is selected by CMD0 (Keep Pin 1 to high during CMD0 execution).
- (2) New CMD8 shall be issued after CMD0 to support High Capacity SD Memory Card.
- (3) Voltage check command enables the Hosts to support future low voltage specification. However, at this time, only one voltage is defined. Legacy cards and Not SD cards do not respond to CMD8. In this case, set F8 to 0 (F8 is CMD8 valid flag used in step (11)) and go to Step (5). Only Version 2.00 or higher cards can respond to

CMD8. The host needs to check whether CRC of the response is valid and whether VHS and check pattern in the argument are equal to VCA and check pattern in the response. Passing all these checks results in CMD8 response OK. In this case, set F8 to 1 and go to step (5). If one of the checks is failed, go to step (4).

(4) Initialization is stopped by CMD8 fails. The Host Driver should retry step (1) to (3) one more time (this is not described in the figure).

(5) SDIO OCR is available by issuing CMD5 with setting voltage window (bit 23 to 0) in the argument to 0. SDIO initialization is not started.

(6) No response means the card does not have SDIO function. Set SDIO flag to 0 and go to step (11). If the card responds to CMD5 and the response is OK, go to step (7). If the response is error, set SDIO flag to 0 and go to step (10). SDIO flag indicates whether SDIO functions are initialized or not.

(7) The SDIO portion starts initialization by CMD5 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to 1. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.

(8) If no response or error response is received, set SDIO flag to 0 and go to step (10). If good response is received, go to step (9).

(9) Check busy status in the response. If busy is released, set SDIO flag to 1 and go to step (10). Repeat from step (7) while busy is indicated. Detecting timeout of 1 second exits the loop. In this case, set SDIO flag to 0 and go to step (10).

(10) Good response in this step means that all responses received at (6) and (8) are valid. When response is good, MP (memory present) flag in the response can be checked. If the response valid and MP = 0, go to step (28). Otherwise, go to step (11).

(11) Check F8 flag set in step (3). If CMD8 is executed correctly (F8 = 1), go to step (19). Otherwise, go to step (12).

(12) OCR is available by issuing ACMD41 with the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. The response of CMD55 (ACMD41) may indicate illegal command error due to some SD cards do not recognize CMD8. The Host Driver should ignore this error or issue CMD0 before ACMD41 to clear this error status.

(13) If response of CMD55 is not received, the card is not SD cards and goes to (17). If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (14). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.

(14) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.

(15) If no response or error response is received, go to step (28). If good response is received, go to step (16).

(16) Check busy status in the response. If busy is released, go to step (18). Repeat from step (14) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).

(17) The host recognizes that the card is not SD memory card and quits SD card initialization.

(18) The host recognizes that the card is Version 1.xx Standard Capacity SD Memory Card. Go to Step (30).

(19) OCR is available by issuing ACMD41 with setting the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. Setting of HCS does not affect this operation.

(20) If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (21). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.

(21) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to 1. If the host can supply more than 150mA, XPC is set to 1. HCS in

the argument is set to 1, which indicates supporting High Capacity Memory Card. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.

(22) If no response or error response is received, go to step (28). If good response is received, go to step (23).

(23) Check busy status in the response. If busy is released, go to step (24). Repeat from step (21) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).

(24) CCS in the response is valid after busy is released. If CCS = 0, it indicates the Standard Capacity SD Memory Card and go to step (25). If CCS = 1, it indicates the High Capacity SD Memory Card or Extended Capacity Memory Card and go to Step (26).

(25) The host recognizes that the card is Ver2.00 or Ver3.00 Standard Capacity SD Memory Card. Optimal functions defined in Version 2.00 or higher are available. Go to Step (32).

(26) The host recognizes that the card is the High Capacity SD Memory Card or Extended Capacity Memory Card.

(27) Perform the signal voltage switch procedure and go to step (32).

(28) Check SDIO flag. If SDIO = 1, go to step (28). Otherwise, go to step (31).

(29) The host recognizes that the card is SDIO only card and go to step (30).

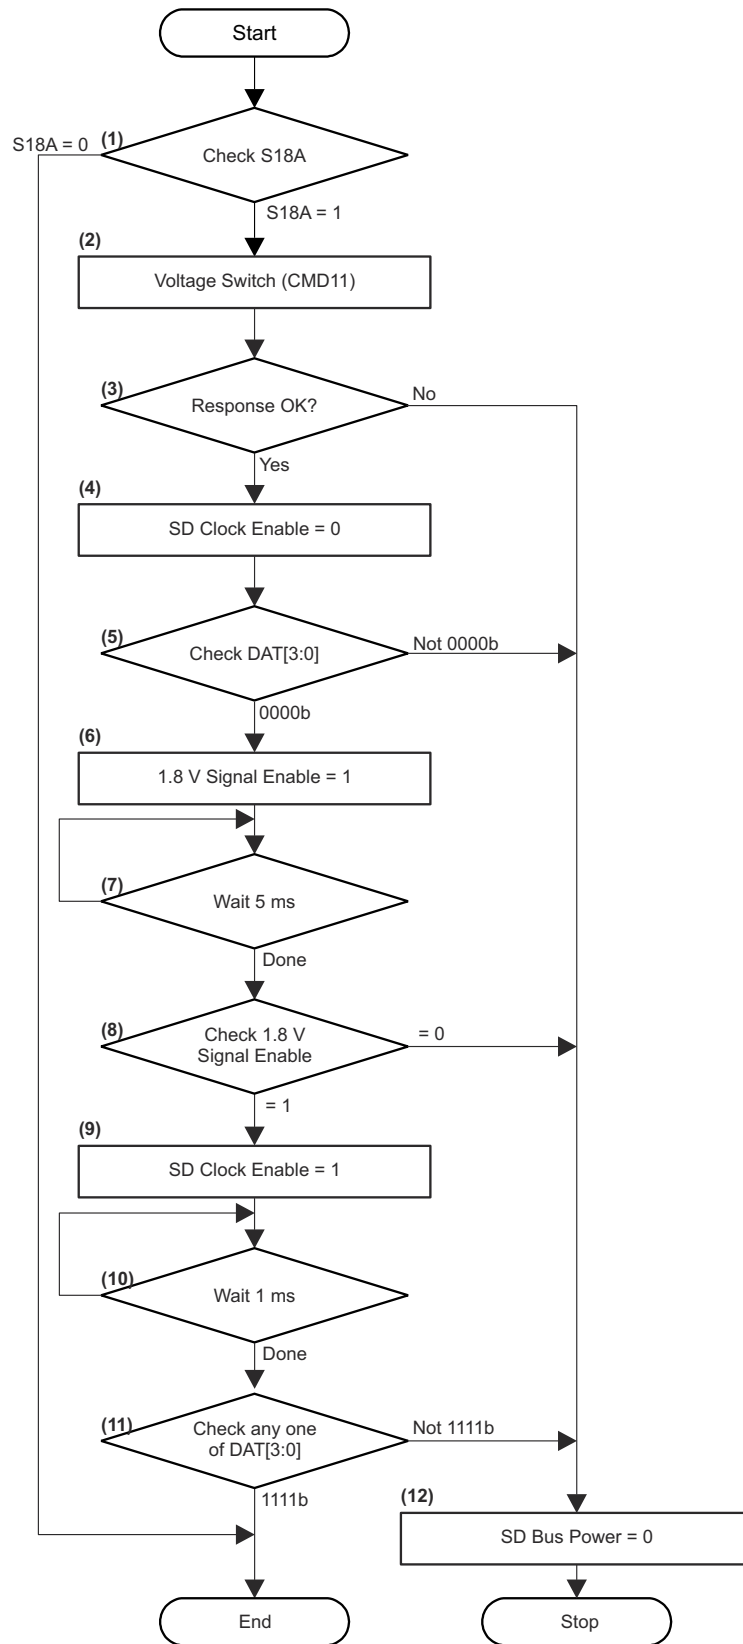

(30) Perform the signal voltage switch procedure and go to step (33).

(31) The host recognizes that the card is unusable.

(32) In case of memory card, CMD2 is issued to get CID and Go to Step (31).

(33) CMD3 is issued to get RCA. If the RCA number is 0, the Host should issue CMD3 again.

### 12.3.6.4.1.6.1 Signal Voltage Switch Procedure (for UHS-I)

mmcsd-029

**Figure 12-130. Signal Voltage Switch Procedure**

- (1) If S18A of CMD5 or S18A of ACMD41 is set to 1, signal voltage switch is performed according to the following steps. Otherwise, exits from this procedure.
- (2) Issue CMD11.
- (3) Check response and if an error is detected, go to step (12).
- (4) Stop providing SD clock to the card.
- (5) Check DAT[3:0] level. If the level is 0000b, the card is ready to start voltage switch sequence. Otherwise, go to (12) to quit the sequence.
- (6) Set MMCSD0\_HOST\_CONTROL2[3] V1P8\_SIGNAL\_ENA bit.
- (7) Wait 5 ms. 1.8 V voltage regulator shall be stable within this period.
- (8) If MMCSD0\_HOST\_CONTROL2[3] V1P8\_SIGNAL\_ENA bit is cleared by Host Controller, go to step (12).
- (9) Provide SD Clock to the card again.
- (10) Wait 1 ms.
- (11) Check DAT[3:0] level. If the level is 1111b, switch to 1.8 V signal level is completed successfully. Otherwise, go to (12).
- (12) If an error occurs during voltage switch procedure, stop providing the power to the card. In this case, Host Driver should retry initialization procedure by setting S18R to 0 at step (7) and (21) in [Figure 12-128](#) and [Figure 12-129](#).

#### **12.3.6.4.1.7 SD Transaction Generation**

This section describes the sequences how to generate and control various kinds of SD transactions. SD transactions are classified into three cases:

- (1) Transactions that do not use the DAT line.
- (2) Transactions that use the DAT line only for the busy signal.
- (3) Transactions that use the DAT line for transferring data.

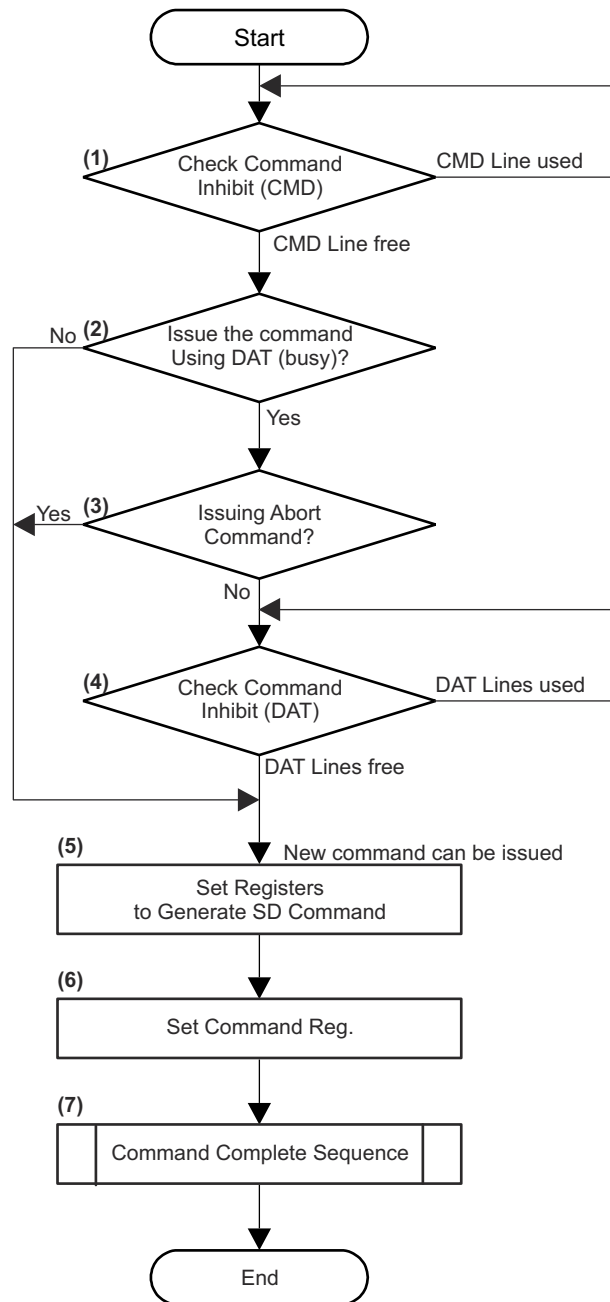

In this specification the first and the second case's transactions are classified as "Transaction Control without Data Transfer using DAT Line", the third case's transaction is classified as "Transaction Control with Data Transfer using DAT Line". Refer to the latest SD Physical Layer Specification and SDIO Specification for more detail about SD commands specification.

##### **12.3.6.4.1.7.1 Transaction Control without Data Transfer Using DAT Line**

In this section, the sequence for how to issue SD Command and how to complete SD Command is explained. [Figure 12-131](#) shows the sequence to issue a SD Command and [Figure 12-132](#) shows the sequence to finalize a SD Command.

###### **12.3.6.4.1.7.1.1 The Sequence to Issue a SD Command**

The sequence to issue the SD Command is detailed in [Figure 12-131](#).

mmcsd-030

**Figure 12-131. SD Command Issue Sequence**

(1) Check MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit. Repeat this step until MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is 0. That is, when MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is 1, the Host Driver shall not issue a SD Command.

(2) If the Host Driver issues a SD Command using DAT lines including busy signal, go to step (3). If without using DAT lines including busy signal, go to step (5).

(3) If the Host Driver is issuing an abort command, go to step (5). In the case of nonabort command, go to step (4).

(4) Check MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit. Repeat this step until MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit is set to 0.

(5) Set registers except the MMCSD0\_COMMAND register.

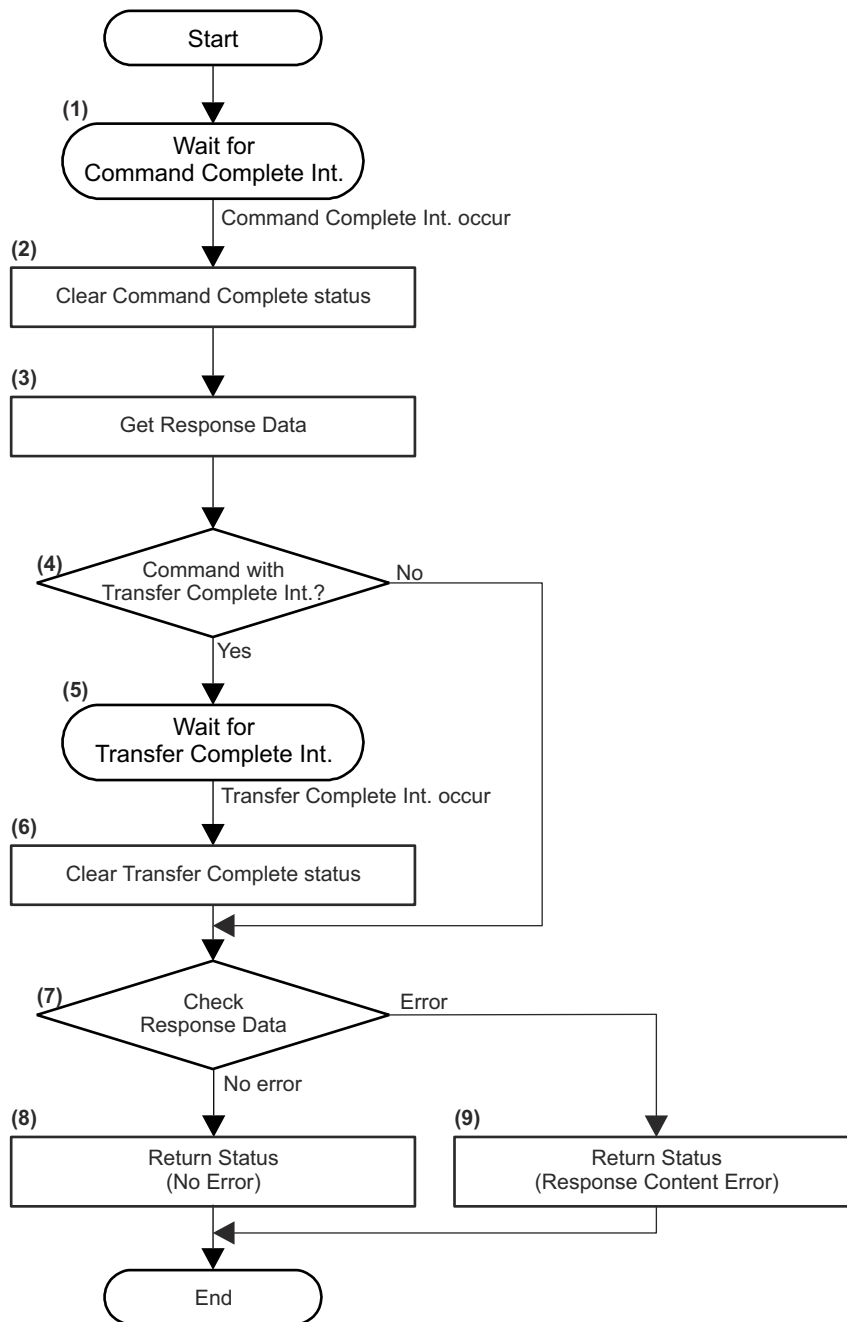

(6) Set the MMCSD0\_COMMAND register.

**Note:** Writing the upper byte [3] in the MMCSD0\_COMMAND register causes the Host Controller to issue a SD command to the SD card.

(7) Perform Command Completion Sequence in accordance.

#### 12.3.6.4.1.7.1.2 The Sequence to Finalize a Command

Figure 12-132 shows the sequence to finalize a SD Command when response check is disabled. There is a possibility that some errors (Command Index/End bit/CRC/Timeout Error) occur during this sequence. If response check is enabled, error is indicated by Response Error Interrupt.

mmcsd-031

**Figure 12-132. Command Complete Sequence**

- (1) If MMCSD0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit is set to 1 (response check is enabled), go to step (4) else wait for the Command Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE). If the Command Complete Interrupt has occurred, go to step (2).
- (2) Write 1 to MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit to clear this bit.
- (3) Read the Response register (see MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7) and get necessary information of the issued command.
- (4) Judge whether the command uses the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE) or not. If it uses Transfer Complete, go to step (5). If not, go to step (7).
- (5) Wait for the Transfer Complete Interrupt. If the Transfer Complete Interrupt has occurred, go to step (6).
- (6) Write 1 to MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit to clear this bit.
- (7) Check for errors in Response Data (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7). If there is no error, go to step (8). If there is an error, go to step (9).
- (8) Return Status of "No Error".
- (9) Return Status of "Response Contents Error".

**Note1:** While waiting for the Transfer Complete interrupt, the Host Driver shall only issue commands that do not use the busy signal.

**Note2:** The Host Driver shall judge the Auto CMD12 complete by monitoring Transfer Complete.

**Note3:** When the last block of un-protected area is read using memory multiple block read command (CMD18), OUT\_OF\_RANGE error may occur even if the sequence is correct. The Host Driver should ignore it. This error will appear in the response of Auto CMD12 or in the response of the next memory command.

#### **12.3.6.4.1.7.2 Transaction Control with Data Transfer Using DAT Line**

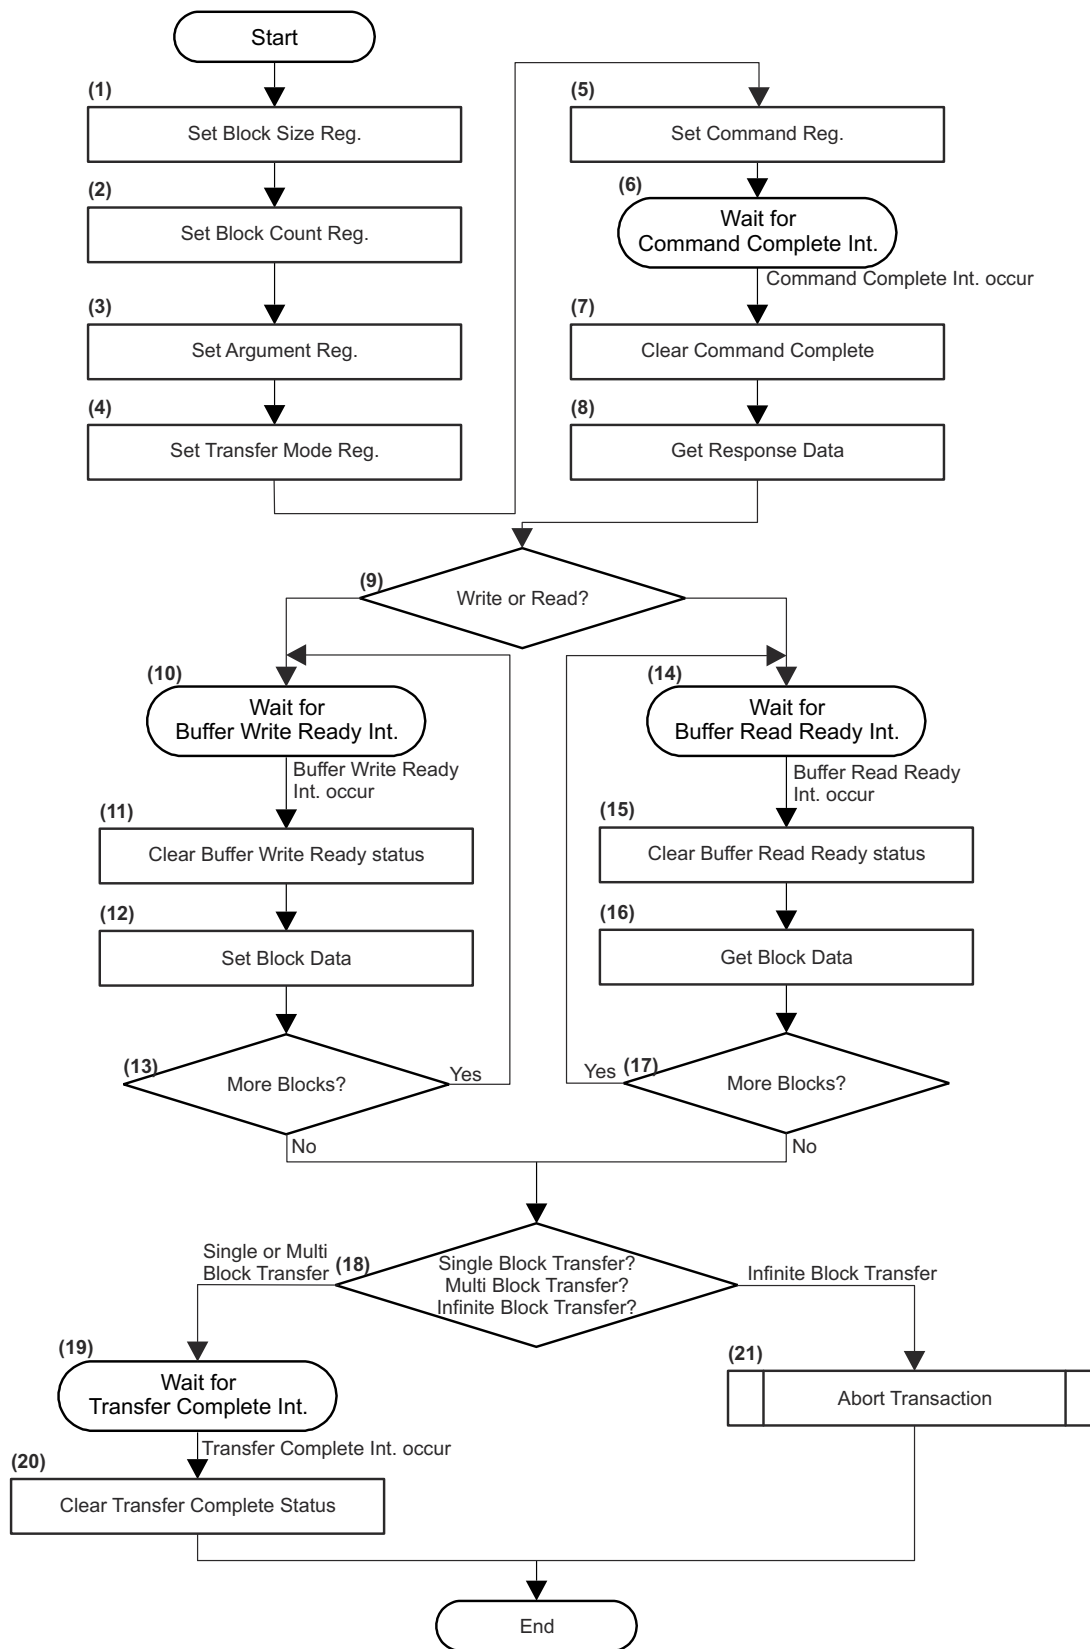

Depending on whether DMA (optional) is used or not, there are two execution methods.

In addition, the sequences for SD transfers are classified into following three kinds according to how the number of blocks is specified:

- (1) Single Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified is always one.
- (2) Multiple Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified shall be one or more.
- (3) Infinite Block Transfer: The number of blocks is not specified to the Host Controller before the transfer. This transfer is continued until an abort transaction is executed. This abort transaction is performed by CMD12 in the case of a SD memory card and by CMD52 in the case of a SDIO card.

##### **12.3.6.4.1.7.2.1 Not using DMA**

The sequence for not using DMA is shown in [Figure 12-133](#).

mmscd-032

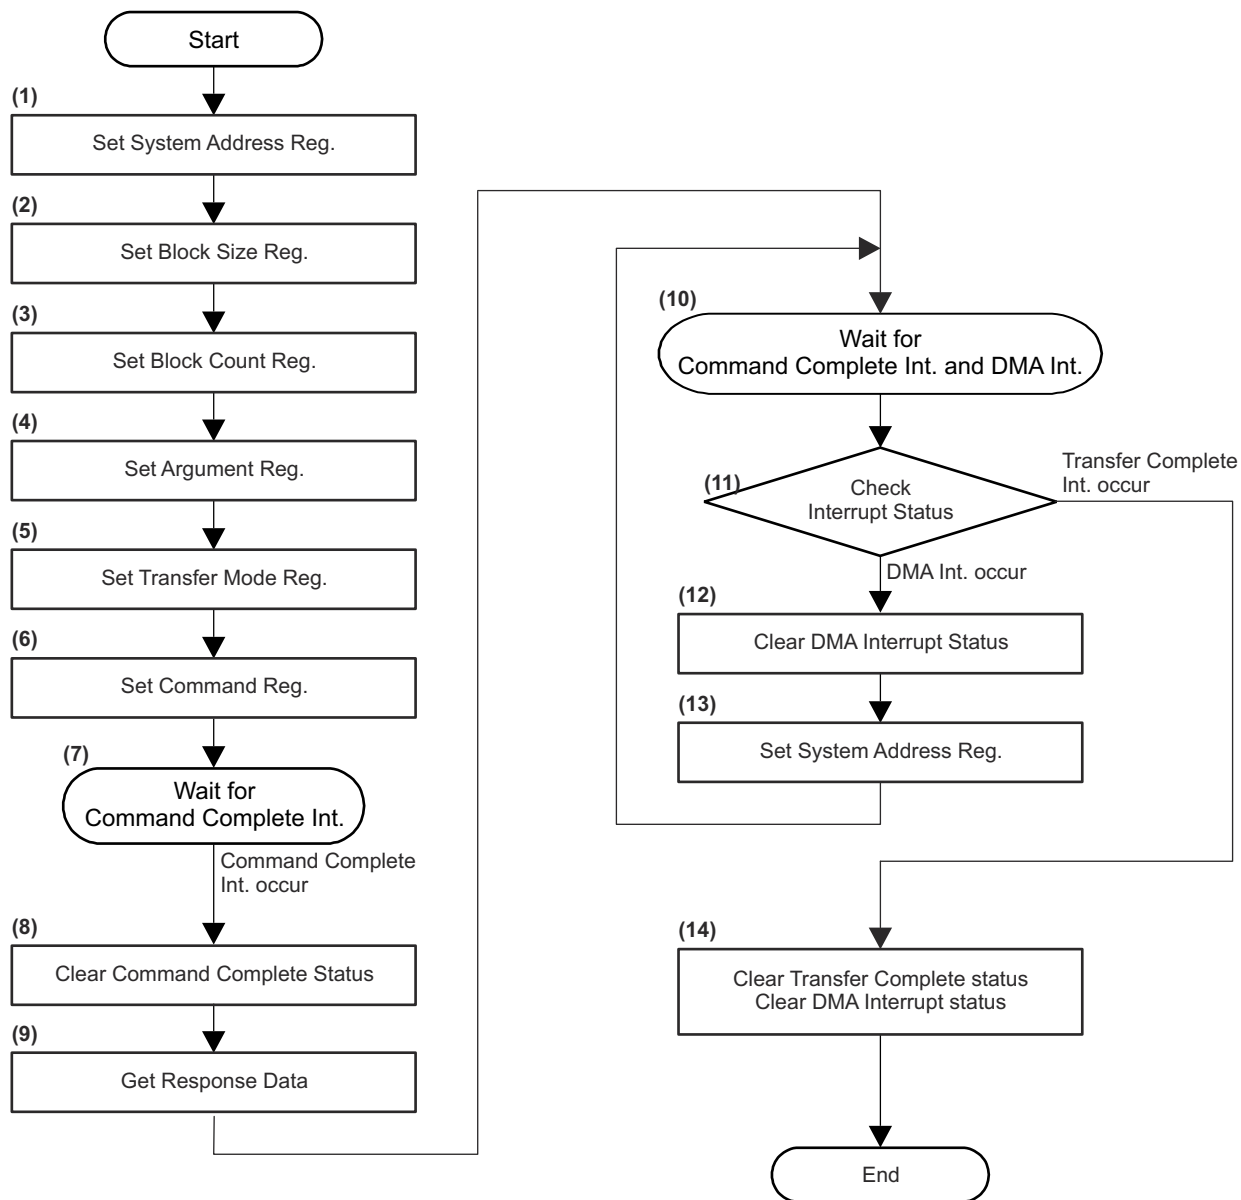

**Figure 12-133. Transaction Control with Data Transfer Using DAT Line Sequence (Not using DMA)**

- (1) Set the value corresponding to the executed data byte length of one block to the MMCSD0\_BLOCK\_SIZE register.
  - (2) Set the value corresponding to the executed data block count to the MMCSD0\_BLOCK\_COUNT register in accordance with *Determination of Transfer Type*.
  - (3) Set the argument value to Argument register (MMCSD0\_ARGUMENT1\_LO and MMCSD0\_ARGUMENT1\_HI).
  - (4) Set the value to the MMCSD0\_TRANSFER\_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSD0\_TRANSFER\_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*.
- If response check is enabled (MMCSD0\_TRANSFER\_MODE[7] RESP\_ERR\_CHK\_ENA = 1), set MMCSD0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit to 1 and select Response Type R1/R5 (MMCSD0\_TRANSFER\_MODE[6] RESP\_TYPE).
- (5) Set the value to MMCSD0\_COMMAND register.
- Note:** When writing the upper byte [3] of MMCSD0\_COMMAND register, SD command is issued.
- (6) If response check is enabled, go to stop (9) else wait for the Command Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit).
  - (7) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit for clearing this bit.
  - (8) Read Response register (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7) and get necessary information of the issued command.
  - (9) In the case where this sequence is for write to a card, go to step (10). In case of read from a card, go to step (14).
  - (10) Then wait for Buffer Write Ready Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[4] BUF\_WR\_READY).
  - (11) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[4] BUF\_WR\_READY bit for clearing this bit.
  - (12) Write block data (in according to the number of bytes specified at the step (1)) to MMCSD0\_DATA\_PORT register.
  - (13) Repeat until all blocks are sent and then go to step (18).
  - (14) Then wait for the Buffer Read Ready Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[5] BUF\_RD\_READY).
  - (15) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[5] BUF\_RD\_READY bit for clearing this bit.
  - (16) Read block data (in according to the number of bytes specified at the step (1)) from the MMCSD0\_DATA\_PORT register.
  - (17) Repeat until all blocks are received and then go to step (18).
  - (18) If this sequence is for Single or Multiple Block Transfer, go to step (19). In case of Infinite Block Transfer, go to step (21).
  - (19) Wait for Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE).
  - (20) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit for clearing this bit.
  - (21) Perform the sequence for Abort Transaction in accordance with [Section 12.3.6.4.1.8, Abort Transaction](#).

**Note:** Step (1) and Step (2) can be executed at same time. Step (4) and Step (5) can be executed at same time.

#### 12.3.6.4.1.7.2.2 Using SDMA

The sequence for using SDMA is shown in [Figure 12-134](#).

mmcsd-033

**Figure 12-134. Transaction Control with Data Transfer Using DAT Line Sequence (Using SDMA)**

(1) Data location of system memory is set to the SDMA System Address register if MMCS0\_HOST\_CONTROL2[12] HOST\_VER40\_ENA = 0 or set to the MMCS0\_ADMA\_SYS\_ADDRESS register if MMCS0\_HOST\_CONTROL2[12] HOST\_VER40\_ENA = 1.

(2) Set the value corresponding to the executed data byte length of one block in the MMCS0\_BLOCK\_SIZE register.

(3) Set the value corresponding to the executed data block count in the MMCS0\_BLOCK\_COUNT register in accordance with *Determination of Transfer Type*.

(4) Set the argument value to the Argument register (MMCS0\_ARGUMENT1\_LO and MMCS0\_ARGUMENT1\_HI).

(5) Set the value to the MMCS0\_TRANSFER\_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCS0\_TRANSFER\_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*. If response check is enabled (MMCS0\_TRANSFER\_MODE[7]

RESP\_ERR\_CHK\_ENA = 1), set MMCSD0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit to 1 and select Response Type R1/R5.

(6) Set the value to the MMCSD0\_COMMAND register.

**Note:** When writing to the upper byte [3] of the MMCSD0\_COMMAND register, the SD command is issued and SDMA is started.

(7) If response check is enabled, go to stop (10) else wait for the Command Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit).

(8) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit to clear this bit.

(9) Read Response register (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7) and get necessary information of the issued command.

(10) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE) and DMA Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT).

(11) If MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit is set to 1, go to Step (14) else if MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit is set to 1, go to Step (12). The MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit is higher priority than the MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit.

(12) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit to clear this bit.

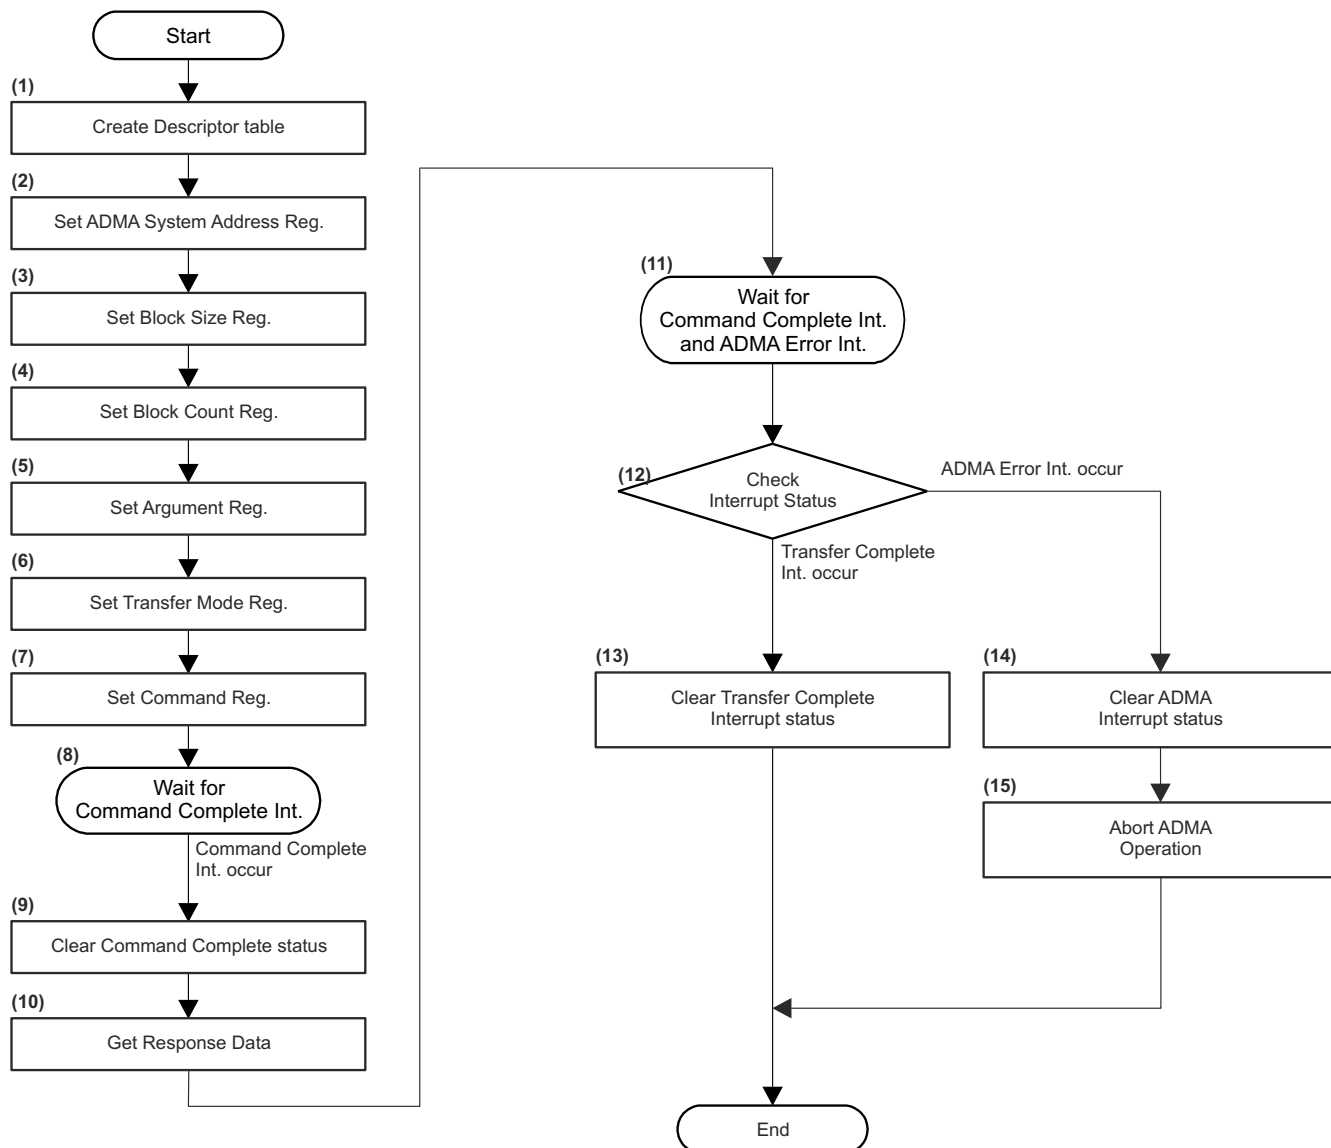

(13) Set the next system address of the next data position to the System Address register (MMCSD0\_ADMA\_SYS\_ADDRESS) and go to Step (10).

(14) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit and MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit to clear this bit.

**Note:** Step (2) and Step (3) can be executed simultaneously. Step (5) and Step (6) can also be executed simultaneously.

#### 12.3.6.4.1.7.2.3 Using ADMA

The sequence for using ADMA is shown in [Figure 12-135](#).

mmcsd-034

**Figure 12-135. Transaction Control with Data Transfer Using DAT Line Sequence (Using ADMA)**

- (1) Create Descriptor table for ADMA in the system memory.
- (2) Set the Descriptor address for ADMA in the MMCS0\_ADMA\_SYS\_ADDRESS register.
- (3) Set the value corresponding to the executed data byte length of one block in the MMCS0\_BLOCK\_SIZE register.
- (4) Set the value corresponding to the executed data block count in the MMCS0\_BLOCK\_COUNT register in accordance with *Determination of Transfer Type*.
- (5) Set the argument value to the Argument register (MMCS0\_ARGUMENT1\_LO and MMCS0\_ARGUMENT1\_HI).
- (6) Set the value to the MMCS0\_TRANSFER\_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCS0\_TRANSFER\_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*. If response check is enabled (MMCS0\_TRANSFER\_MODE[7] RESP\_ERR\_CHK\_ENA = 1), set MMCS0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit to 1 and select Response Type R1/R5 (MMCS0\_TRANSFER\_MODE[6] RESP\_TYPE).

(7) Set the value to the MMCSD0\_COMMAND register.

**Note:** When writing to the upper byte [3] of the MMCSD0\_COMMAND register, the SD command is issued and DMA is started.

(8) If response check is enabled, go to stop (11) else wait for the Command Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit).

(9) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit to clear this bit.

(10) Read Response register (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7) and get necessary information of the issued command.

(11) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE) and ADMA Error Interrupt (MMCSD0\_ADMA\_ERR\_STATUS[1-0] ADMA\_ERR\_STATE).

(12) If MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit is set to 1, go to Step (13) else if MMCSD0\_ADMA\_ERR\_STATUS[1-0] ADMA\_ERR\_STATE bit field is set to 1, go to Step (14).

(13) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit to clear this bit.

(14) Write 1 to the MMCSD0\_ADMA\_ERR\_STATUS[1-0] ADMA\_ERR\_STATE bit field to clear this bit.

(15) Abort ADMA operation. SD card operation should be stopped by issuing abort command. If necessary, the Host Driver checks MMCSD0\_ADMA\_ERR\_STATUS register to detect why ADMA error is generated.

**Note:** Step (3) and Step (4) can be executed simultaneously. Step (6) and Step (7) can also be executed simultaneously.

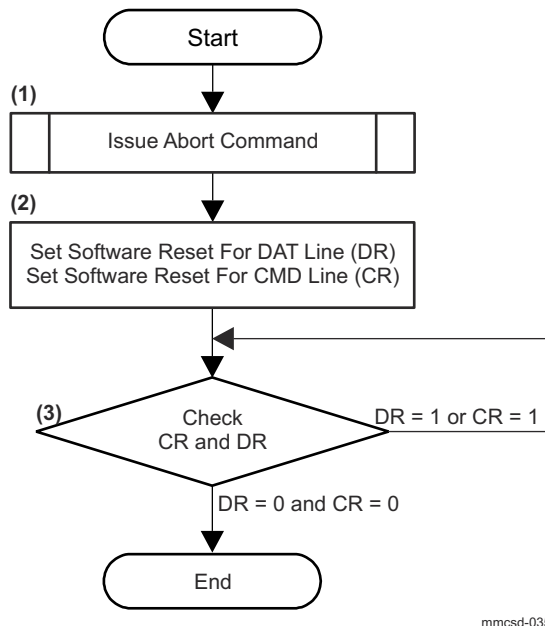

#### 12.3.6.4.1.8 Abort Transaction

An abort transaction is performed by issuing CMD12 for a SD memory card and by issuing CMD52 for a SDIO card. There are two cases where the Host Driver needs to do an Abort Transaction. The first case is when the Host Driver stops Infinite Block Transfers. The second case is when the Host Driver stops transfers while a Multiple Block Transfer is executing.

There are two ways to issue an Abort Command. The first is an asynchronous abort. The second is a synchronous abort. In an asynchronous abort sequence, the Host Driver can issue an Abort Command at any time unless MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is set to 1. In a synchronous abort, the Host Driver shall issue an Abort Command after the data transfer stopped by using MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

##### 12.3.6.4.1.8.1 Asynchronous Abort

The sequence for Asynchronous Abort is shown in [Figure 12-136](#).

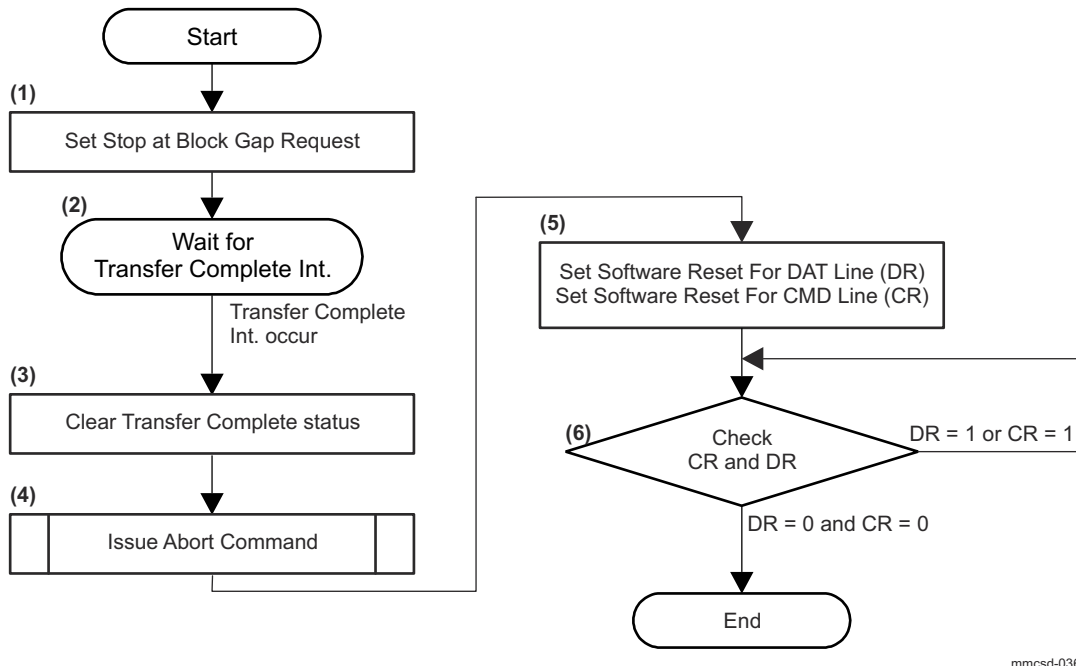

**Figure 12-136. Asynchronous Abort Sequence**

(1) Issue Abort Command in accordance.

(2) Set both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1 to do software reset.

(3) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit are 0, go to "End". If either MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit or MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 1, go to step (3).

#### 12.3.6.4.1.8.2 Synchronous Abort

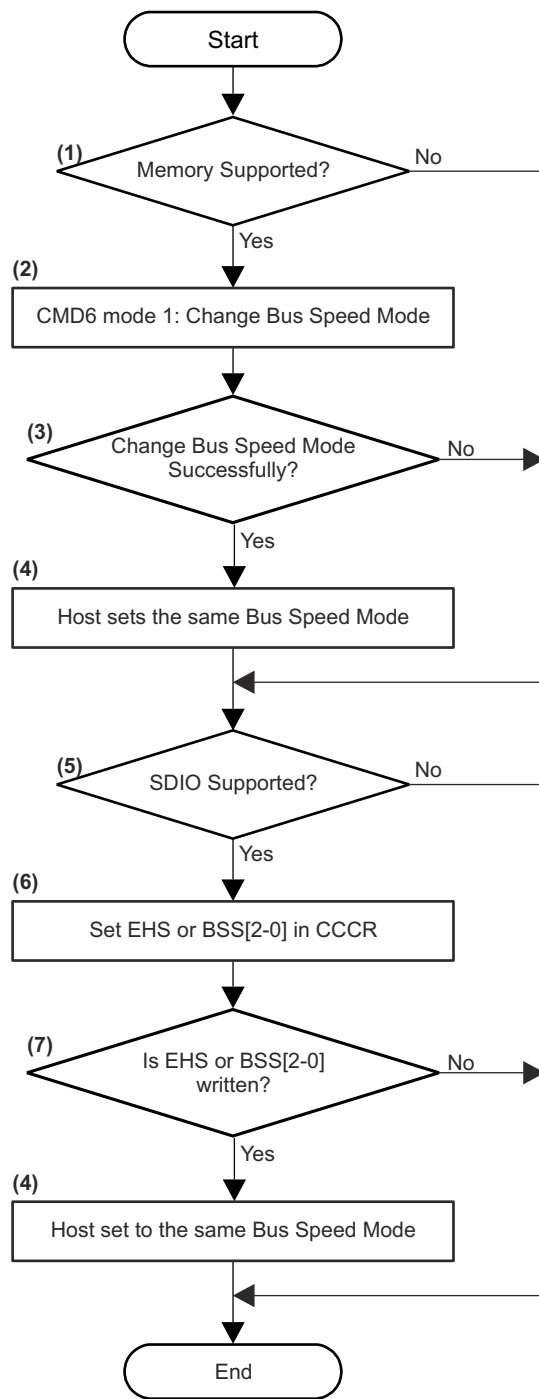

**Figure 12-137. Synchronous Abort Sequence**

- (1) Set the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to 1 to stop SD transactions.
- (2) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE).
- (3) Set the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit to 1 to clear this bit.
- (4) Issue the Abort Command
- (5) Set both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1 to do software reset.
- (6) Check both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit are 0, go to "End". If either MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit or MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 1, go to step (6).

#### **12.3.6.4.1.9 Changing Bus Speed Mode**

This section describes the sequence for switching the bus speed mode: Default Speed, High Speed mode and UHS-I mode. The switch command (CMD6) is used to change memory card bus speed mode. The EHS bit (SDIO Version 2.00) or BSS[2-0] bits (SDIO Version 3.00) in the CCCR register is used to change the bus speed mode for SDIO card. In case of Combo card, either of the switch method changes both memory and IO bus speed mode. This means the first switch is effective. Refer to the Physical Layer Specification Version 3.0x and the SDIO Specification Version 3.00 for more information about switching bus speed. [Figure 12-138](#) shows the sequence for switching bus speed mode for Combo Card. Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

mmcsd-037

**Figure 12-138. Changing Bus Speed Mode**

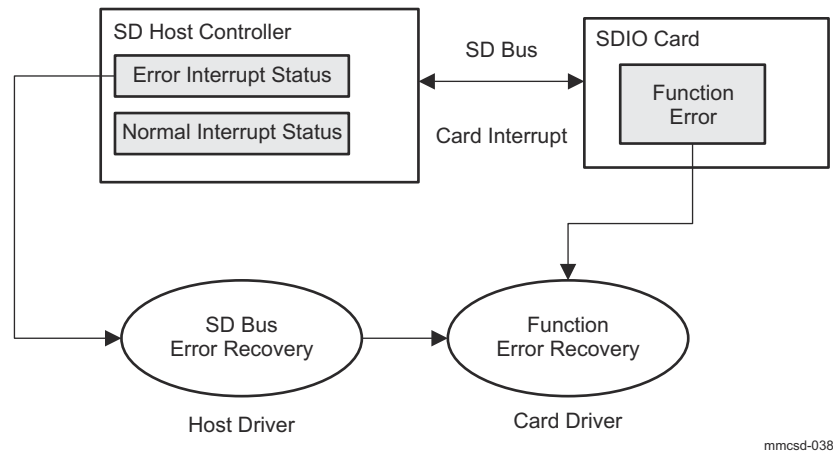

- (1) The Host Driver checks if the card supports memory. If not supported, go to (5).
- (2) Issue CMD6 with mode 1 to change bus speed mode (Default, High Speed mode or UHS-I mode).
- (3) Check the response of CMD6. If the card does not supports CMD6 (no response) or bus speed is not changed successfully, go to step (5). In this case, the card is in Default Speed mode.
- (4) The Host Driver changes the Host Controller bus speed mode to the same mode.
- (5) The Host Driver checks if the card supports SDIO. If not supported, go to the end.

(6) Issue CMD52 to write EHS bit or BSS[2-0] bits in CCCR to change bus speed mode (the same bus speed mode of (2) shall be set).

(7) If EHS or BSS[2-0] are not changed successfully, go to the end.

(8) The Host Driver changes the Host Controller bus speed to the same mode. In case of Combo card, bus speed is already changed at step (4) and this step does not affect changing bus speed.

#### 12.3.6.4.1.10 Error Recovery

**Figure 12-139. Error Report and Recovery**

Figure 12-139 shows concept of error report and its recovery. The Host Controller has 2 interrupt status registers. If an error occurs in the SD Bus transaction, one of the bits is set in the MMCSD0\_ERROR\_INTR\_STS register. If the function errors occur in the SDIO card, the card interrupt informs these function errors and the Card interrupt is set in the MMCSD0\_NORMAL\_INTR\_STS\_ENA register (the Card Interrupt is used to inform not only error statuses but also normal information. For example, to inform function ready). The Card Driver shall do function error recovery because the Host Driver does not know how to control the function. In the case that function error occurs due to SD Bus error, SD Bus error recovery is required before function error recovery. Abort command is used to recover SD Bus, and then the Host Driver should save error statuses related to SD Bus errors before issuing abort command and transfer these statuses to the Card Driver. These statuses may be used to recover function error. Following explanations are related to SD Bus error recovery. This specification does not specify the function error recovery.

When an error occurs during data transfer in 2L-HD UHS-II mode, there will be the case that Host Controller cannot drive D0 lane in input mode due to DIR LSS for retrieving lane direction is not detected. In this case, Host Driver cannot issue abort command for recovery. Then if DIR LSS is not detected, Host Controller sets MMCSD0\_UHS2\_ERR\_INTR\_STS[17] DEADLOCK\_TIMEOUT bit. Host Driver should execute power cycle if MMCSD0\_UHS2\_ERR\_INTR\_STS[17] DEADLOCK\_TIMEOUT bit is detected to recover from this error. Furthermore, if this type of error is detected several times in 2L-HD, Host Driver should use FD mode rather than using 2L-HD.

#### Implementation Note:

If the Card Driver cannot recover the function errors, the Host Driver should try following methods.

(9) Using IOEx for SDIO card

IOEx may be used as the reset per function basis. Sequence is as follows:

Clear IOEx = 0 and wait until IORx = 0 and then set IOEx = 1 again. SDIO may be recovered when IORx = 1.

(10) Using reset command for memory and SDIO card Re-initialization sequence is required.

(11) Off and on power supply for the SD Bus.

The card may be recovered by the power on reset. Re-initialization sequence is required.

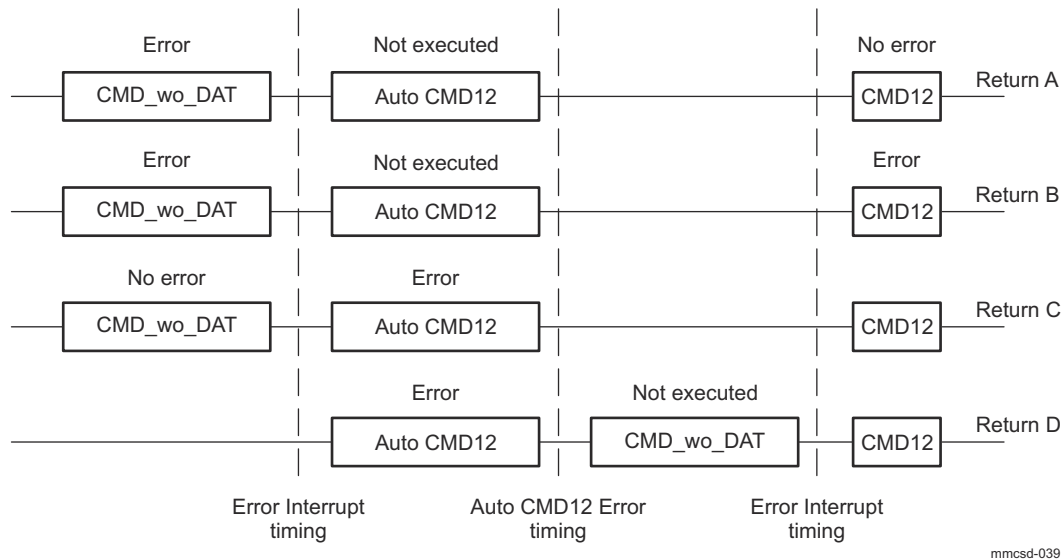

The two cases where the Host Driver needs the "Error Recovery" sequence are classified as follows:

(1) Error Interrupt Recovery:

If error interrupt is indicated by the MMCSD0\_ERROR\_INTR\_STS register, the Host Driver shall apply this sequence.

(2) Auto CMD12 Error Recovery:

If there are errors in Auto CMD12, the Host Driver shall apply this sequence. In terms of Return Status, Auto CMD12 Error Recovery is classified into 4 cases. It is shown in [Figure 12-140](#). If error occurs during memory write transfer, strongly recommend using ACMD22 and then in the following recovery sequence, retry to send remaining blocks not written.

**Figure 12-140. Return Status of Auto CMD12 Error Recovery**

Implementation Note:

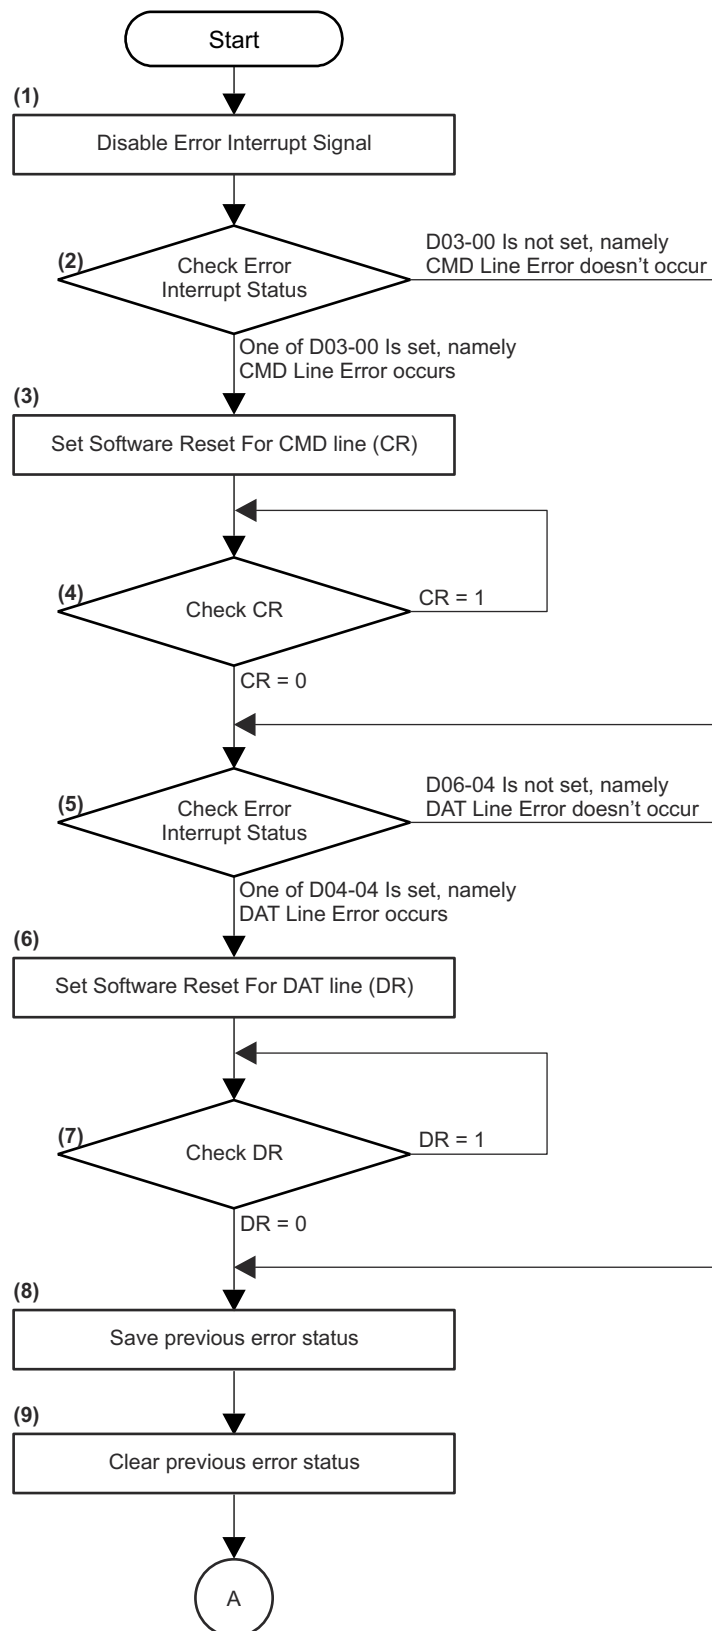

Abort command is used to recover from SD Bus error. SDIO transaction abort using CMD52 returns response but in the case of memory transaction abort using CMD12, response returns depending on the memory card state. If no response returns after issue CMD12, the Host Driver should check card state using CMD13. If the state is "tran" in the CURRENT\_STATE, consider CMD12 is successful.

Implementation Note:

The following sequence is one possible error recovery flow. There may be another methods, sometimes using interrupts or polling. It can be possible to use another flows, based on Host System requirements.

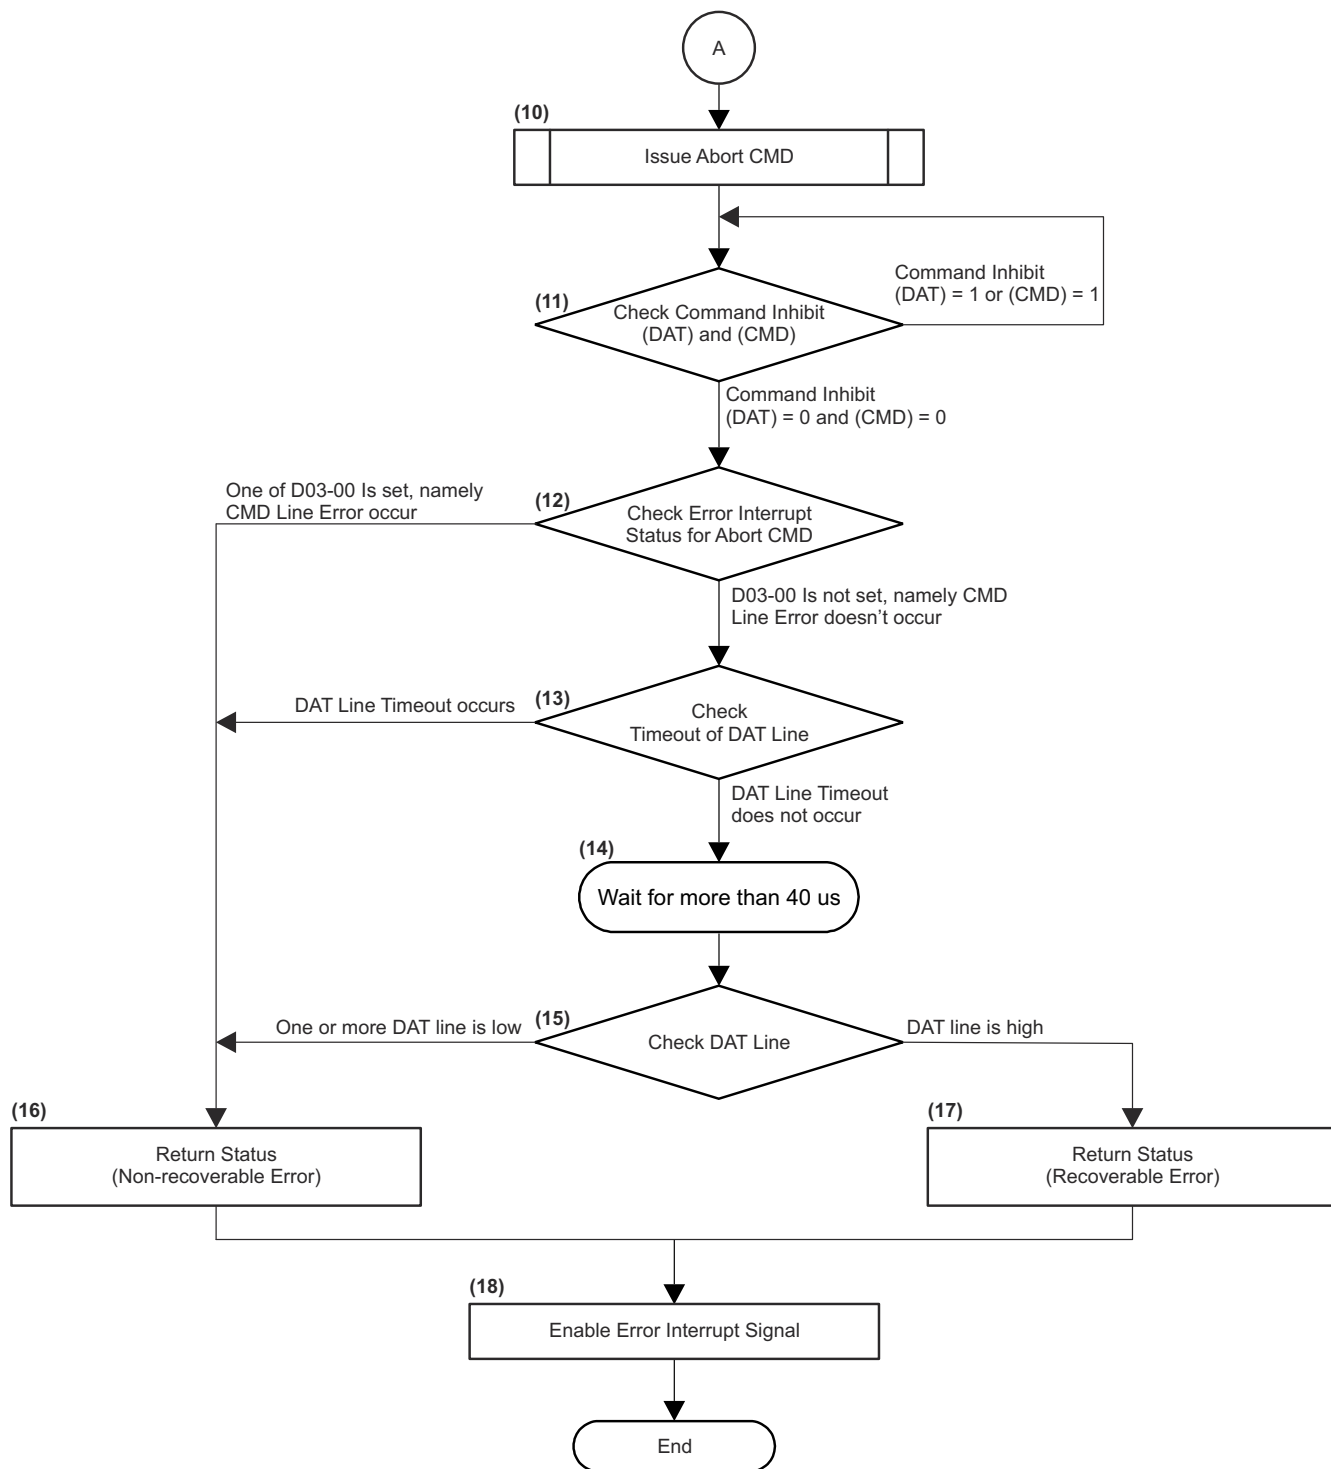

In these error recovery sequences, return statuses for the next sequence. When the Host Controller cannot issue the next command due to SD Bus error, the error recovery sequences return "Non-recoverable" status. In this case, the Host System may cut off power to the SD Bus and then power on SD Bus and initialize both the Host Controller and the SD card again.

### 12.3.6.4.1.10.1 Error Interrupt Recovery

mmcsd-040

**Figure 12-141. Error Interrupt Recovery Sequence (1)**

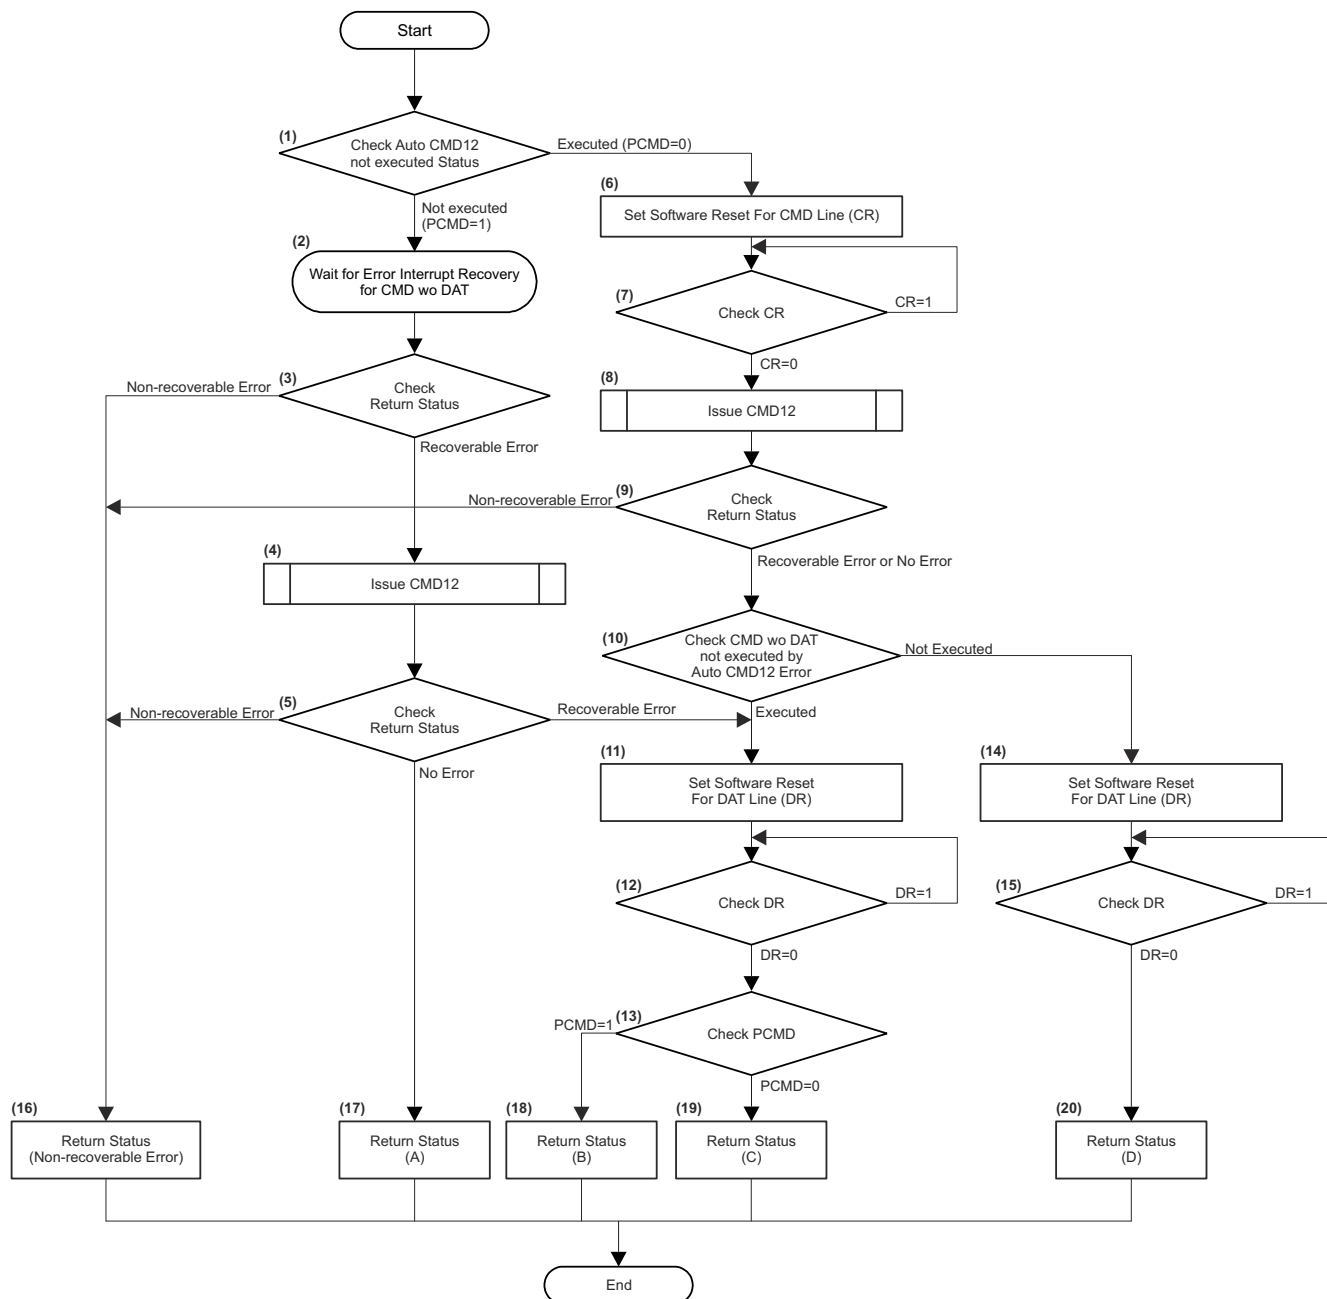

mmcsd-041

**Figure 12-142. Error Interrupt Recovery Sequence (2)**

- (1) Disable the Error Interrupt Signal (MMCSD0\_ERROR\_INTR\_SIG\_ENA).
- (2) Check bits D03-00 in the MMCSD0\_ERROR\_INTR\_STS register. If one of these bits (D03-00) is set to 1, go to step (3). If none are set to 1 (all are 0), go to step (5).
- (3) Set MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1.

- (4) Check MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 0, go to step (5). If it is 1, go to step (4).
- (5) Check bits D06-04 in the MMCSD0\_ERROR\_INTR\_STS register. If one of these bits (D06-04) is set to 1, go to step (6). If none are set to 1 (all are 0), go to step (8).
- (6) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (7) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to step (8). If it is 1, go to step (7).
- (8) Save previous error status.
- (9) Clear previous error status with setting them to 1.
- (10) Issue Abort Command.
- (11) MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit and MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit. Repeat this step until both MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit and MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit are set to 0.
- (12) Check bits D03-00 in the MMCSD0\_ERROR\_INTR\_STS register for Abort Command. If one of these bits is set to 1, go to step (16). If none of these bits are set to 1 (all are 0), go to step (13).
- (13) Check MMCSD0\_ERROR\_INTR\_STS[4] DATA\_TIMEOUT bit. If this bit is set to 1, go to step (16). If it is 0, go to step (14).
- (14) Wait for more than 40 us.
- (15) By monitoring the DAT [3:0] Line Signal Level in the MMCSD0\_PRESENTSTATE register, judge whether the level of the DAT line is low or not. If one or more DAT lines are low, go to step (16). If the DAT lines are high, go to step (17).
- (16) Return Status of "Non-recoverable Error".
- (17) Return Status of "Recoverable Error".
- (18) Enable the Error Interrupt Signal (MMCSD0\_ERROR\_INTR\_SIG\_ENA).

### 12.3.6.4.1.10.2 Auto CMD12 Error Recovery

**Figure 12-143. Auto CMD12 Error Recovery**

The sequence for Auto CMD12 Error Recovery is shown in [Figure 12-143](#). Following four cases A-D shall be covered.

- A: An error occurred in CMD\_wo\_DAT, but not in the SD memory transfer.
- B: An error occurred in CMD\_wo\_DAT, and also occurred in the SD memory transfer.
- C: An error did not occur in CMD\_wo\_DAT, but an error occurred in the SD memory transfer.
- D: CMD\_wo\_DAT was not issued, and an error occurred in the SD memory transfer.

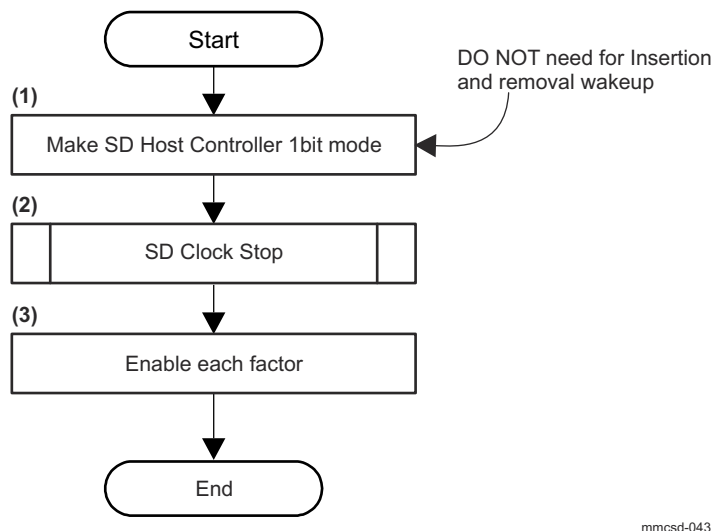

- (1) Check MMCSD0\_AUTOCMD\_ERR\_STS[0] ACMD12\_NOT\_EXEC bit. If this bit is set to 1, go to step (2). If this bit is set to 0, go to step (6). In addition, the Host Driver shall define PCMD flag, which changes to 1 if MMCSD0\_AUTOCMD\_ERR\_STS[0] ACMD12\_NOT\_EXEC bit is set to 1.
- (2) Wait for Error Interrupt Recovery for CMD\_wo\_DAT.
- (3) Check "Return Status". In the case of "Non-recoverable Error", go to step (16). In the case of "Recoverable Error", go to step (4).
- (4) Issue CMD12 .
- (5) If the CMD line errors occur for the CMD12 (one of D03-00 is set in the MMCSD0\_ERROR\_INTR\_STS register), "Return Status" is "Non-recoverable Error" and go to step (16). If not CMD line error and busy timeout error occur (D04 is set in the MMCSD0\_ERROR\_INTR\_STS register), "Return Status" is "Recoverable Error" and go to step (11). Otherwise, "Return Status" is "No error" and go to step (17).
- (6) Set MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1 for software reset of the CMD line.
- (7) Check MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 0, go to step (8). If it is 1, go to step (7).
- (8) Issue CMD12 . Acceptance of CMD12 depends on the state of the card. CMD12 may make the card to return to tran state. If the card is already in tran state, the card does not response to CMD12.
- (9) Check "Return Status" for CMD12. If "Return Status" returns "Non-recoverable Error", go to step (16). In the case of "Recoverable Error" or "No error", go to step (10).
- (10) Check the MMCSD0\_AUTOCMD\_ERR\_STS[0] ACMD12\_NOT\_EXEC bit. If this bit is 0, go to step (11). If it is 1, go to step (14).
- (11) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (12) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to step (13). If it is 1, go to step (12).
- (13) Check the PCMD flag. If PCMD is 1, go to step (18). If it is 0, go to step (19).
- (14) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (15) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to step (20). If it is 1, go to step (15).
- (16) Return Status of "Non-recoverable Error".
- (17) Return Status that an error has occurred in CMD\_wo\_DAT, but not in the SD memory transfer.
- (18) Return Status that an error has occurred in both CMD\_wo\_DAT, and the SD memory transfer.
- (19) Return Status that an error has not occurred in CMD\_wo\_DAT, but has occurred in the SD memory transfer.
- (20) Return Status that CMD\_wo\_DAT has not been issued, and an error has occurred in the SD memory transfer.

#### 12.3.6.4.1.11 Wakeup Control (Optional)

After the Host System goes into standby mode, the Host System can resume from standby via a wakeup event initiated by one of the following three events:

- (1) Interrupt from a SD card: If an SD card interrupt occurs, the Host System can resume from standby mode. If the Host System uses this wakeup factor, SD Bus power shall be kept on.
- (2) Insertion of SD card: If a SD card is inserted, the Host System can resume from standby mode.
- (3) Removal of SD card: If a SD card is removed, the Host System can resume from standby mode.

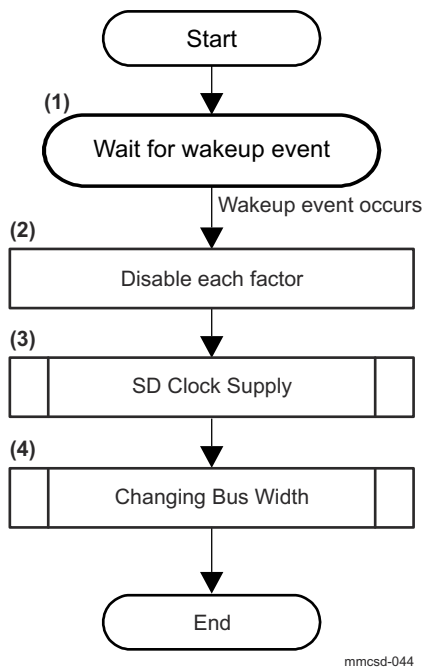

The sequence for preparing wakeup before the Host System goes into standby mode is shown in [Figure 12-144](#).

**Figure 12-144. Wakeup Control before Standby Mode**

- (1) Set MMCSD0\_HOST\_CONTROL1[1] DATA\_WIDTH bit to 0.
- (2) Execute SD Clock Stop Sequence as described in [Section 12.3.6.4.1.2.2, SD Clock Supply and Stop Sequence](#).
- (3) Clear the MMCSD0\_NORMAL\_INTR\_STS register and the MMCSD0\_NORMAL\_INTR\_SIG\_ENA register, and then set the enable bits of each wakeup event factor to 1 in the MMCSD0\_WAKEUP\_CONTROL register and set the bits of MMCSD0\_ERROR\_INTR\_STS\_ENA register to use wakeup.

The sequence for wakeup once in standby mode is shown in [Figure 12-145](#).

**Figure 12-145. Wakeup from Standby**

- (1) Wait for wakeup event.
- (2) Set the enable bits of each wakeup event factor to 0 in the MMCSD0\_WAKEUP\_CONTROL register and then clear event statuses in the MMCSD0\_NORMAL\_INTR\_STS register. If necessary, set the MMCSD0\_NORMAL\_INTR\_SIG\_ENA register.

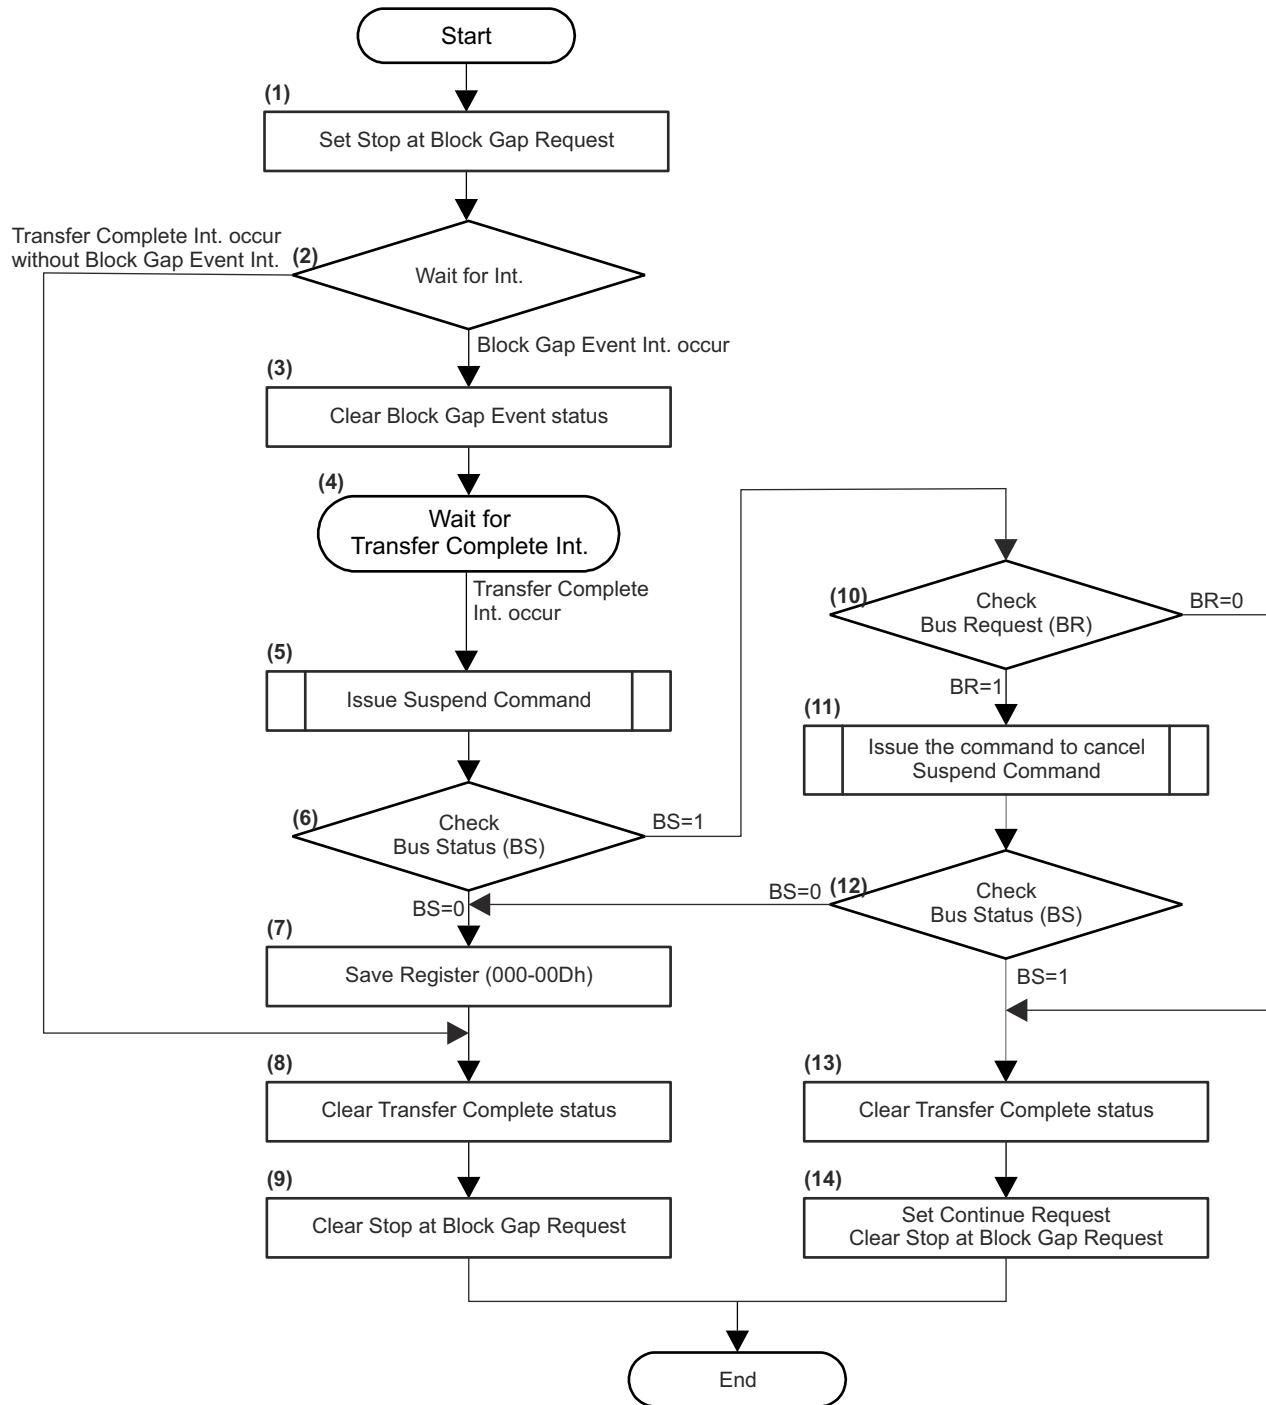

(3) Execute SD Clock Supply Sequence (see [Section 12.3.6.4.1.2.2](#), *SD Clock Supply and Stop Sequence*).

(4) Set the SD Bus width (see [Section 12.3.6.4.1.4](#), *Changing Bus Width*).

#### 12.3.6.4.1.12 Suspend/Resume (Optional, Not Supported from Version 4.00)

If a SD card supports suspend and resume functionality, then the Host Controller can initiate suspend and resume. It is necessary for both the Host Controller and the SD card to support the function of "Read Wait". ADMA operation does not support this function.

##### 12.3.6.4.1.12.1 Suspend Sequence

mmcsd-045

**Figure 12-146. The Sequence for Suspend**

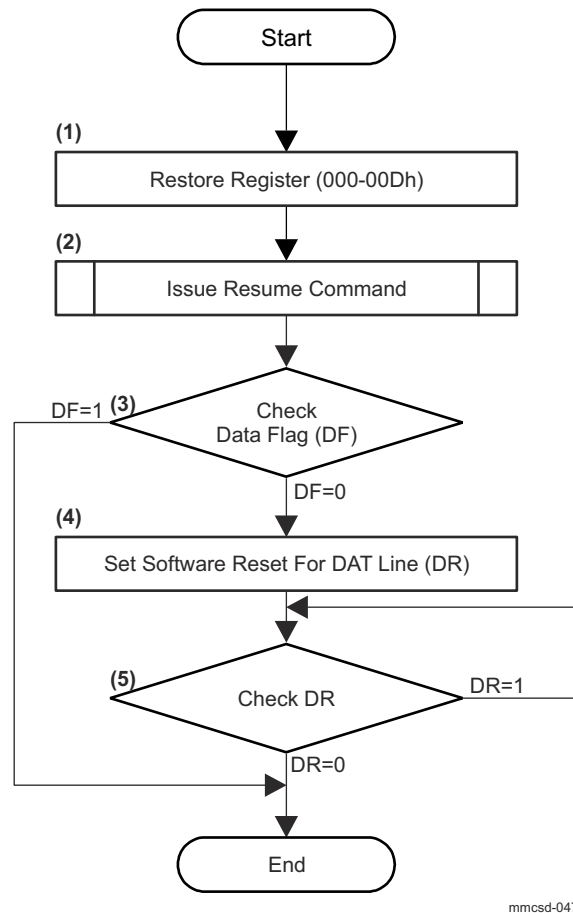

- (1) Set MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to 1 to stop the SD transaction.
- (2) Wait for an Interrupt. If MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit is set to 0 and MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit is set to 1, go to step (8). If MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit is set to 1, go to step (3).
- (3) Set MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit to 1 to clear this bit.
- (4) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE).
- (5) Issue the Suspend Command in accordance with [Section 12.3.6.4.1.7.1](#), *Transaction Control without Data Transfer Using DAT Line*.
- (6) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (10).
- (7) Save the register .
- (8) Set MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit to 1 to clear this bit.
- (9) Set MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to 0 to clear this bit.
- (10) Check the BR value of the response data. If BR is 1, go to step (11). If BR is 0, go to step (13).
- (11) Issues the command to cancel the previous suspend command in accordance with [Section 12.3.6.4.1.7.1](#), *Transaction Control without Data Transfer Using DAT Line*.
- (12) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (13).
- (13) Set MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit to 1 to clear this bit.
- (14) Set MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit to 1 to continue the transaction. At the same time, write 0 to MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to clear this bit.

Conditions			Suspend/Resume Function	
Host Suspend/Resume Support	Card Suspend/Resume Support	Card Read Wait Support	Write Suspend/Resume	Read Suspend/Resume
Not supported	Don't care	Don't care	Cannot be used	Cannot be used
Supported	Not supported	Don't care	Cannot be used	Cannot be used
Supported	Supported	Not supported	Can be used	Cannot be used
Supported	Supported	Supported	Can be used	Can be used

mmcsd-046

**Figure 12-147. Suspend/Resume Condition**

### 12.3.6.4.1.12.2 Resume Sequence

mmcsd-047

**Figure 12-148. The Sequence for Resume**

- (1) Restore the register .
- (2) Issue the Resume Command .
- (3) Check the DF value of the response data. If DF is 0, go to step (4). If DF is 1, go to "End".
- (4) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (5) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to "End". If it is 1, go to step (5).

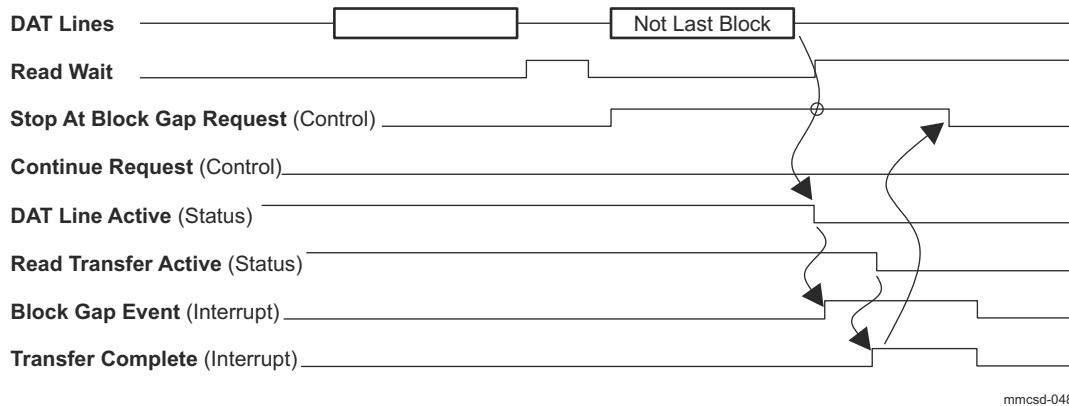

### 12.3.6.4.1.12.3 Stop At Block Gap/Continue Timing for Read Transaction

The timing of Stop At Block Gap Request and Continue Request. The Transfer Complete interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE) is always generated by setting MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit where data transfer is stopped. However, generation of the Block Gap Event interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT) is dependent on whether the last data block is sent or not. Block Gap Event is not generated If all data blocks are transferred (the last block is transferred). It is not necessary to enable Block Gap Event interrupt. The status can be checked when transfer complete interrupt is detected. It is not necessary to use Continue Request (MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE) if Block Gap Event status is not set because there is no further data to be transferred. If Read Wait is not supported, Host Controller stops SD Clock at the block gap.

Implementation Note:

The MMCSD0\_BLOCK\_GAP\_CONTROL[2] RDWAIT\_CTRL, MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE, MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bits shall be set and cleared by the Host Controller.

The MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit shall be set and cleared by the Host Driver. The MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit shall be set by the Host Driver and be cleared by the Host Controller. The MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit and MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit shall be set by the Host Controller and be cleared by the Host Driver.

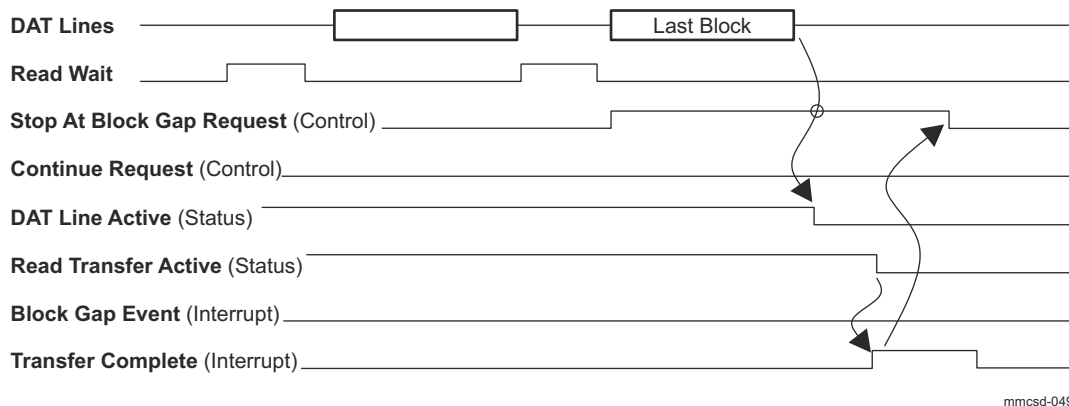

**Figure 12-149. Wait Read Transfer by Stop At Block Gap Request**

The Host Controller can accept a Stop At Block Gap Request (MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP) when all the following conditions are met.

- (1) It is at the block gap.
- (2) The Host Controller can assert read wait or it is already asserted.
- (3) The MMCSD0\_BLOCK\_GAP\_CONTROL[2] RDWAIT\_CTRL bit is set to 1.

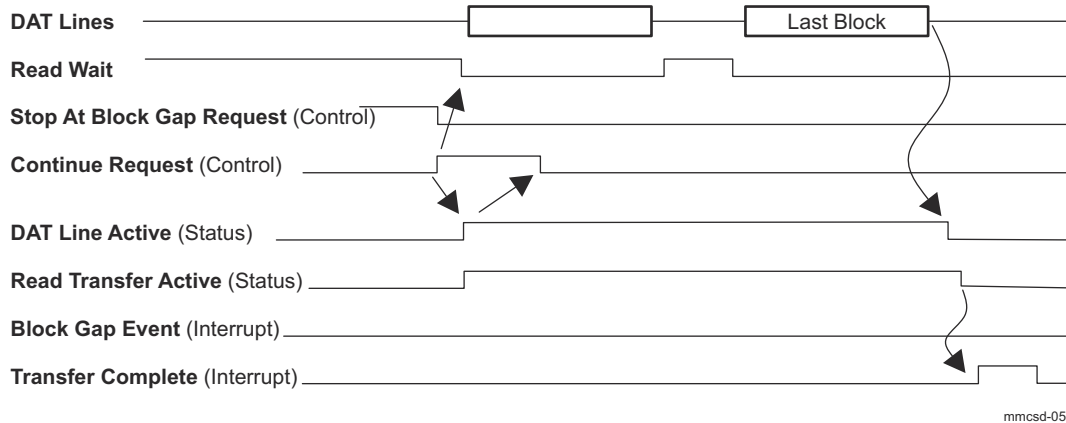

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit:

- (1) Clear MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and generate the Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT).
- (2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE).
- (3) After accepting MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit, clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-150. Stop At Block Gap Request is Not Accepted at the Last Block of the Read Transfer**

If the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit and stops the transaction normally. The Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT) is not generated. When the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE) is generated, and if the MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit status is not set to 1, the driver shall clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-151. Continue Read Transfer by Continue Request**

To restart a stopped data transfer, set the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit to 1 (the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit shall be set to 0).

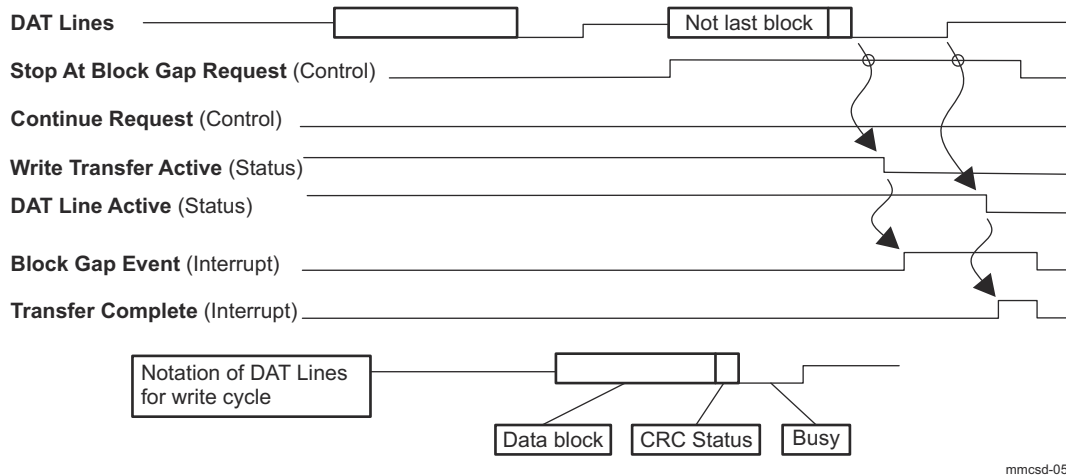

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit:

- (1) Release MMCSD0\_BLOCK\_GAP\_CONTROL[2] RDWAIT\_CTRL bit (if the data block can accept the next data).
- (2) Set the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and the MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bit.
- (3) The MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit is automatically cleared by (2).

The end of the read transfer is specified by data length.

- (1) Clear the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and do not generate the Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit).
- (2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit).

#### 12.3.6.4.1.12.4 Stop At Block Gap/Continue Timing for Write Transaction

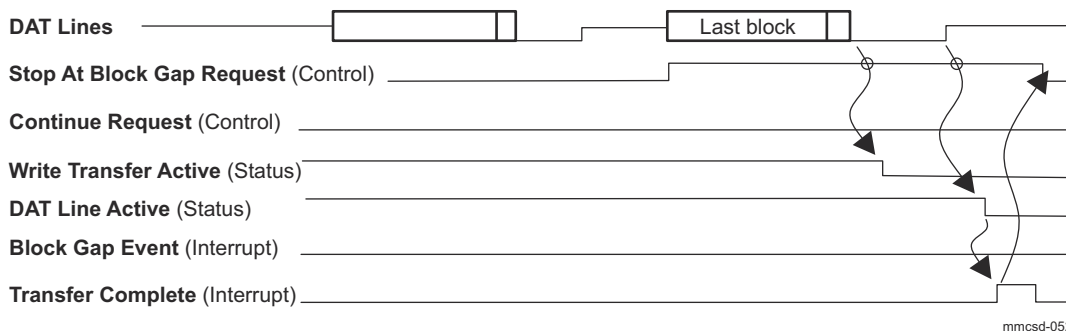

**Figure 12-152. Wait Write Transfer by Stop At Block Gap Request**

The Host Controller can accept the MMCS0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit when matches all following conditions:

- (1) It is at the block gap.
- (2) No valid write data remains in the Host Controller.

After accepting the MMCS0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

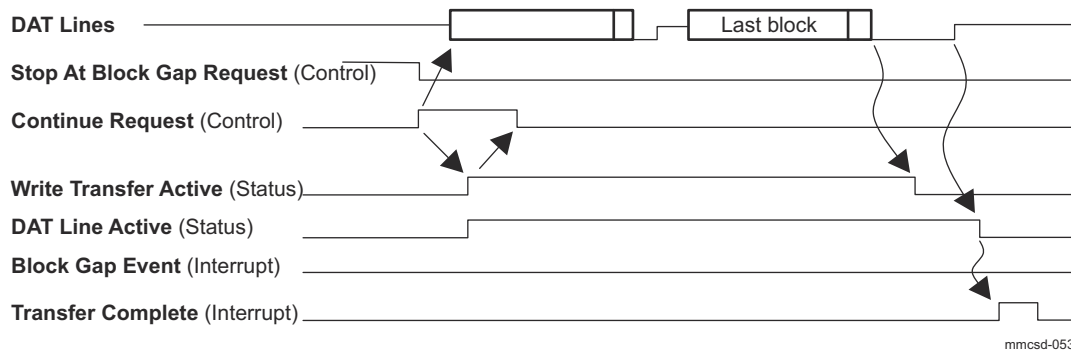

- (1) Clear the MMCS0\_PRESENTSTATE[8] WR\_XFER\_ACTIVE bit and generate the Block Gap Event Interrupt (MMCS0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit).
- (2) After the busy signal is released, clear the MMCS0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and generate the Transfer Complete Interrupt (MMCS0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit).
- (3) After accepting the Transfer Complete Interrupt (MMCS0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit), clear the MMCS0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-153. Stop At Block Gap Request is Not Accepted at the Last Block of the Write Transfer**

If the MMCS0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCS0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit and terminates the transaction normally. The Block Gap Event Interrupt (MMCS0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT) is not generated. When the Transfer Complete Interrupt (MMCS0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE) is generated, and if the MMCS0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit is not set to 1, the driver shall clear the MMCS0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-154. Continue Write Transfer by Continue Request**

To restart a stopped data transfer, set the MMCSDD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit to 1 (the MMCSDD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit shall be set to 0).

After accepting the MMCSDD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit:

(1) Set the MMCSDD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and MMCSDD0\_PRESENTSTATE[8] WR\_XFER\_ACTIVE bit.

(2) The MMCSDD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit is automatically cleared by (1).

The end of transfer is specified by data length.

(1) Clear the MMCSDD0\_PRESENTSTATE[8] WR\_XFER\_ACTIVE bit, and do not generate the (MMCSDD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVEN).

(2) After the busy signal is released, clear the MMCSDD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and generates the Transfer Complete Interrupt (MMCSDD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit).

### 12.3.6.4.2 Driver Flow Sequence

#### Note

This section is applicable for MMCSD0 and MMCSD1 but MMCSD0 registers are used in the content.

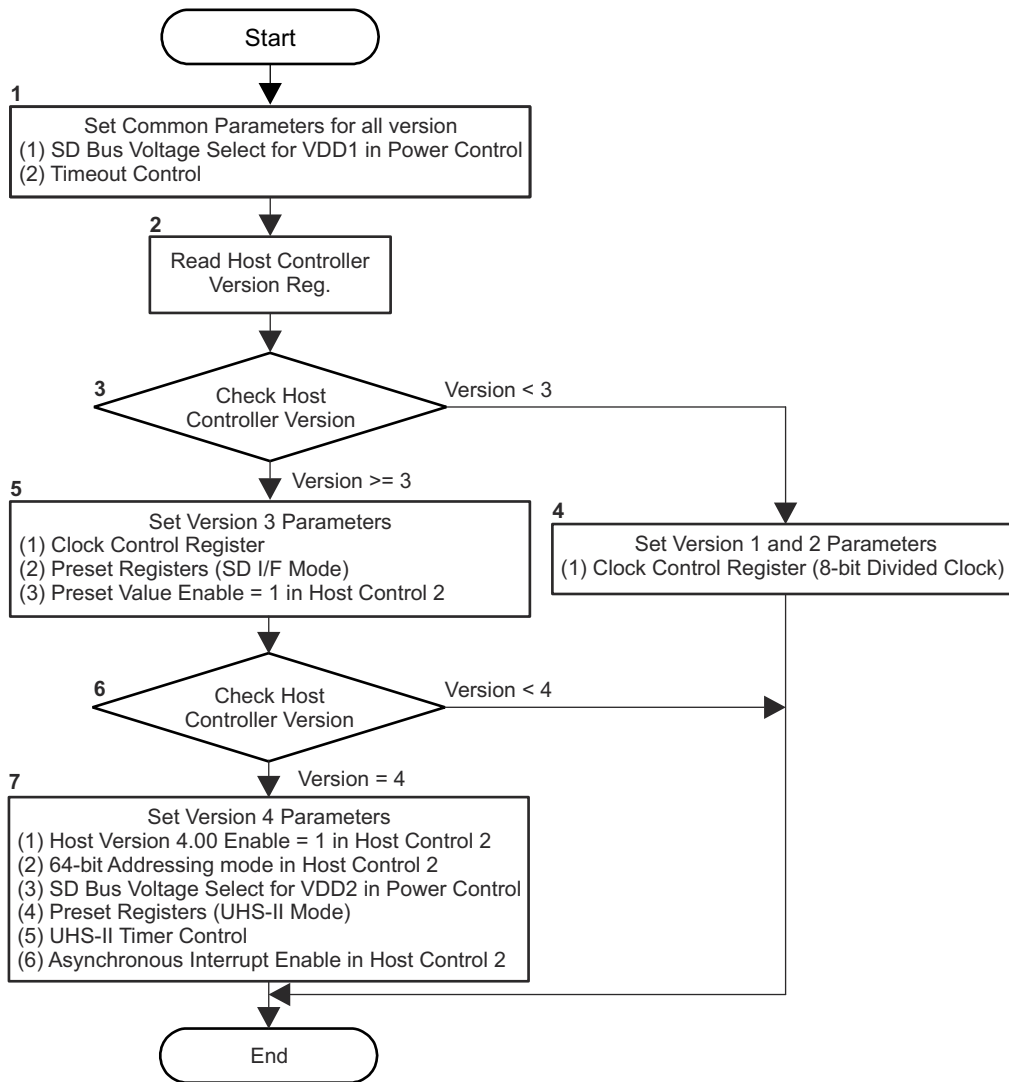

#### Note

UHSII is not supported. For more information, see *MMCSD Not Supported Features*.

#### 12.3.6.4.2.1 Host Controller Setup and Card Detection

##### 12.3.6.4.2.1.1 Host Controller Setup Sequence

Figure 12-155 and Table 12-224 show a Host Controller setup sequence.

mmcsd-054

**Figure 12-155. Host Controller Setup Sequence**

**Table 12-224. Host Controller Setup Sequence**

Step	Description
1	Set parameters for all Host Controller version. Set the MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE and MMCSD0_TIMEOUT_CONTROL[3-0] COUNTER_VALUE bit fields.
2	Read the MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM bit field.

**Table 12-224. Host Controller Setup Sequence (continued)**

Step	Description
3	If Specification Version number (MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM) is less than version 3, go to step (4), if it is version 3 or later go to step (5).
4	Set the MMCSD0_CLOCK_CONTROL register using 8-bit Divided Clock mode.
5	Set Version 3 parameters. The MMCSD0_CLOCK_CONTROL register is sets in 10-bit Divided Clock Mode or Programmable Clock Mode. If Clock Multiplier in the MMCSD0_CAPABILITIES register is not zero, Programmable Clock Mode should be used. If Preset Value is used, set Preset Values of SD I/F Modes in the Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set the MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit to 1.
6	If Specification Version number (MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM) is version 4, go to step (7), if it is less than version 4, exits.
7	Set Version 4 parameters. Set the MMCSD0_HOST_CONTROL2[12] HOST_VER40_ENA bit to 1. If the MMCSD0_CAPABILITIES[27] ADDR_64BIT_SUPPORT_V4 bit is set to 1, set the MMCSD0_HOST_CONTROL2[13] BIT64_ADDRESSING bit to 1. If UHS-II Support is set to 1 and 1.8 V VDD2 Support is set to 1 in the MMCSD0_CAPABILITIES register, set SD Bus Voltage Select for VDD2 to 1.8 V mode in the MMCSD0_POWER_CONTROL register, set preset value for UHS-II Mode to Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set Timeout Counter Value for CMD_RES and Timeout Counter Value for Deadlock in the MMCSD0_UHS2_TIMER_CONTROL register based on Timeout Clock Frequency and Timeout Clock Unit in the MMCSD0_CAPABILITIES register. If Asynchronous Interrupt Support in the MMCSD0_CAPABILITIES register is set to 1, set Asynchronous Interrupt Enable to 1 in the MMCSD0_HOST_CONTROL2 register.

**12.3.6.4.2.1.2 Card Interface Detection Sequence**

This procedure is invoked by the Card Insertion interrupt. [Figure 12-156](#) and [Table 12-225](#) show a card interface detection sequence.

mmcsd-055

**Figure 12-156. Card Interface Detection Sequence**

**Table 12-225. Card Interface Detection Sequence**

Step	Description
1	Set Internal Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
2	Wait until Internal Clock Stable is set to 1 in the MMCSD0_CLOCK_CONTROL register.
3	If Host Supports UHS-II, go to step (4) else go to step (12).
4	Try to initialize a card to UHS-II mode. Set UHS-II Interface Enable to 1 in the MMCSD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 and SD Bus Power for VDD2 to 1 in the MMCSD0_POWER_CONTROL register, and set UHS Mode Select to 111b in the MMCSD0_HOST_CONTROL2 register.
5	Wait power ramp up time. It is dependent on a Host System.

**Table 12-225. Card Interface Detection Sequence (continued)**

Step	Description
6	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
7	Wait 200 $\mu$ s to check a card supports UHS-II mode.
8	Check STB.L Detection in the MMCSD0_PRESENTSTATE register. If UHS-II IF is detected, go to step (9). If UHS-II IF is not detected, go to step (11).
9	Wait until Lane Synchronization in the MMCSD0_PRESENTSTATE register is set to 1 (PHY Initialization is completed).
10	Perform UHS-II initialization.
11	Perform card power cycle.
12	Try to initialize a card to SD 4-bit mode. Set UHS-II Interface Enable to 0 in the MMCSD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 to 1 in the MMCSD0_POWER_CONTROL register, and set UHS Mode Select to 000b in the MMCSD0_HOST_CONTROL2 register.
13	Wait power ramp up time. It is dependent on a Host System.
14	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
15	Perform SD 4-bit mode initialization. Refer to <a href="#">Section 12.3.6.4.1.6, Card Initialization and Identification (for SD I/F)</a> .

**12.3.6.4.2.2 Boot Operation**

The boot operation sequence is shown in [Figure 12-157](#).

mmcsd-056

**Figure 12-157. Boot Operation Sequence**

#### 12.3.6.4.2.2.1 Normal Boot Operation: (For Legacy eMMC 5.0)

The Host driver writes the boot timeout value into MMCSDD0\_BOOT\_TIMEOUT\_CONTROL register as per the eMMC4.3+ spec.

When the Host driver sets the "BOOT\_ENABLE" to 1 in MMCSDD0\_BLOCK\_GAP\_CONTROL register and "DATA\_XFER\_DIR" bit to "1" in MMCSDD0\_TRANSFER\_MODE register, the Host controller drives the CMD line to "0" for boot operation.

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV\_BOOT\_ACK" interrupt to the driver (MMCSDD0\_NORMAL\_INTR\_STS[13] RCV\_BOOT\_ACK). If the Host controller doesn't receive the boot

acknowledgement from the device within the timeout value, the Host controller will assert the data timeout error interrupt (MMCSD0\_ERROR\_INTR\_STS[4] DATA\_TIMEOUT).

After servicing the boot acknowledge interrupt or data timeout error interrupt, the driver programs the MMCSD0\_BOOT\_TIMEOUT\_CONTROL register with boot data timeout value.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The Host controller terminates the boot operation when the programmed number of blocks is transferred to the System. The Driver can write "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register.

The boot operation can also be terminated in between the boot transfer (the Driver can set the "BOOT\_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, the Host controller asserts soft reset for CMD line and DATA line internally once the driver clears the BOOT\_COMPLETE interrupt (MMCSD0\_NORMAL\_INTR\_STS[14] BOOT\_COMPLETE), to reset all the state machines to idle state.

There is no need to perform error recovery sequence in case data timeout interrupt occurs during boot operation (ignore sending abort command, soft reset and just clear the timeout interrupt and proceed with the boot flow).

If the device sends wrong acknowledgement to the Host, the Host controller will assert Data CRC Error interrupt (MMCSD0\_ERROR\_INTR\_STS[5] DATA\_CRC) on the Driver. In this case, the Host driver has to stop the boot mode operation by setting "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller will assert Data End Bit Error interrupt (MMCSD0\_ERROR\_INTR\_STS[6] DATA\_ENDBIT) on the Driver.

The Host driver stops the boot mode operation by setting "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

**Note:** Enable the MMCSD0\_BLOCK\_GAP\_CONTROL[7] BOOT\_ACK\_ENA bit during boot operation. If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

#### 12.3.6.4.2.2 Alternate Boot Operation (For Legacy eMMC 5.0):

The Host driver writes the boot timeout value as per the eMMC4.3+ spec into MMCSD0\_BOOT\_TIMEOUT\_CONTROL register.

If the "ALT\_BOOT\_MODE" and "BOOT\_ENABLE" is set to 1 in MMCSD0\_BLOCK\_GAP\_CONTROL register and "DATA\_XFER\_DIR" bit is set to 1 in MMCSD0\_TRANSFER\_MODE register, the host controller drives the CMD0 (0xFFFFFFFF) on the CMD line.

The system shall wait for command complete interrupt before "RCV\_BOOT\_ACK" interrupt (MMCSD0\_NORMAL\_INTR\_STS[13] RCV\_BOOT\_ACK).

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV\_BOOT\_ACK" interrupt to the driver.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The System needs to send CMD0 to inform the device about the boot operation complete. The system shall program MMCSD0\_COMMAND register with argument "00000000h" for the CMD0 and waits for command complete.

The Host controller terminates the boot operation when the programmed number of blocks are transferred to the System and the Driver shall send CMD0 to eMMC card and then program "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register.

The boot operation can be terminated at any time (the Driver can send CMD0 and set the "BOOT\_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, all state machines in the Host controller need to move to IDLE state. The Host controller asserts the soft reset for CMD and data line internally when the driver clears the BOOT\_COMPLETE interrupt (MMCSD0\_NORMAL\_INTR\_STS[14] BOOT\_COMPLETE) and all the state machine goes to the idle state.

If the Host controller doesn't receive the acknowledgement from the device with in timeout value the Host controller will assert the data timeout error interrupt (MCSD0\_ERROR\_INTR\_STS[4] DATA\_TIMEOUT).

The driver programs the MMCSD0\_BOOT\_TIMEOUT\_CONTROL register with boot data timeout value.

There is no need to perform error recovery sequence in case of data timeout interrupt as mentioned above. If the device sends wrong acknowledgement to the Host, then Host controller will assert Data CRC Error interrupt to the Driver (MCSD0\_ERROR\_INTR\_STS[5] DATA\_CRC). The Host driver has to stop the boot mode operation by setting "ALT\_BOOT\_MODE" and "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

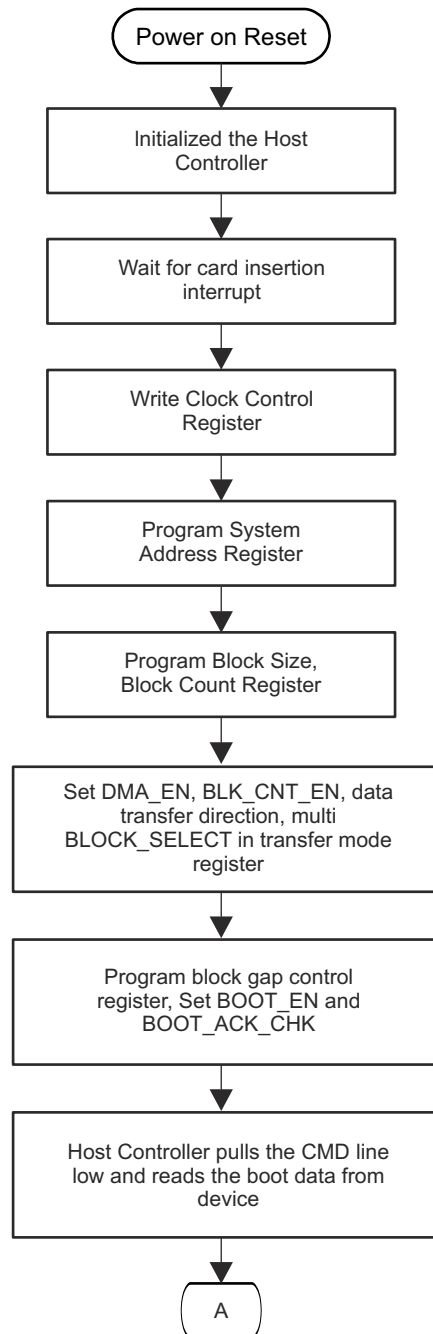

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller asserts Data End Bit Error interrupt (MCSD0\_ERROR\_INTR\_STS[6] DATA\_ENDBIT) on the Driver. The Host driver stops the boot mode operation by setting "ALT\_BOOT\_MODE" and "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

**Note:** Enable the MMCSD0\_BLOCK\_GAP\_CONTROL[7] BOOT\_ACK\_ENA bit during boot operation . If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

#### **12.3.6.4.2.2.3 Boot Code Chunk Read Operation (For Legacy eMMC 5.0):**

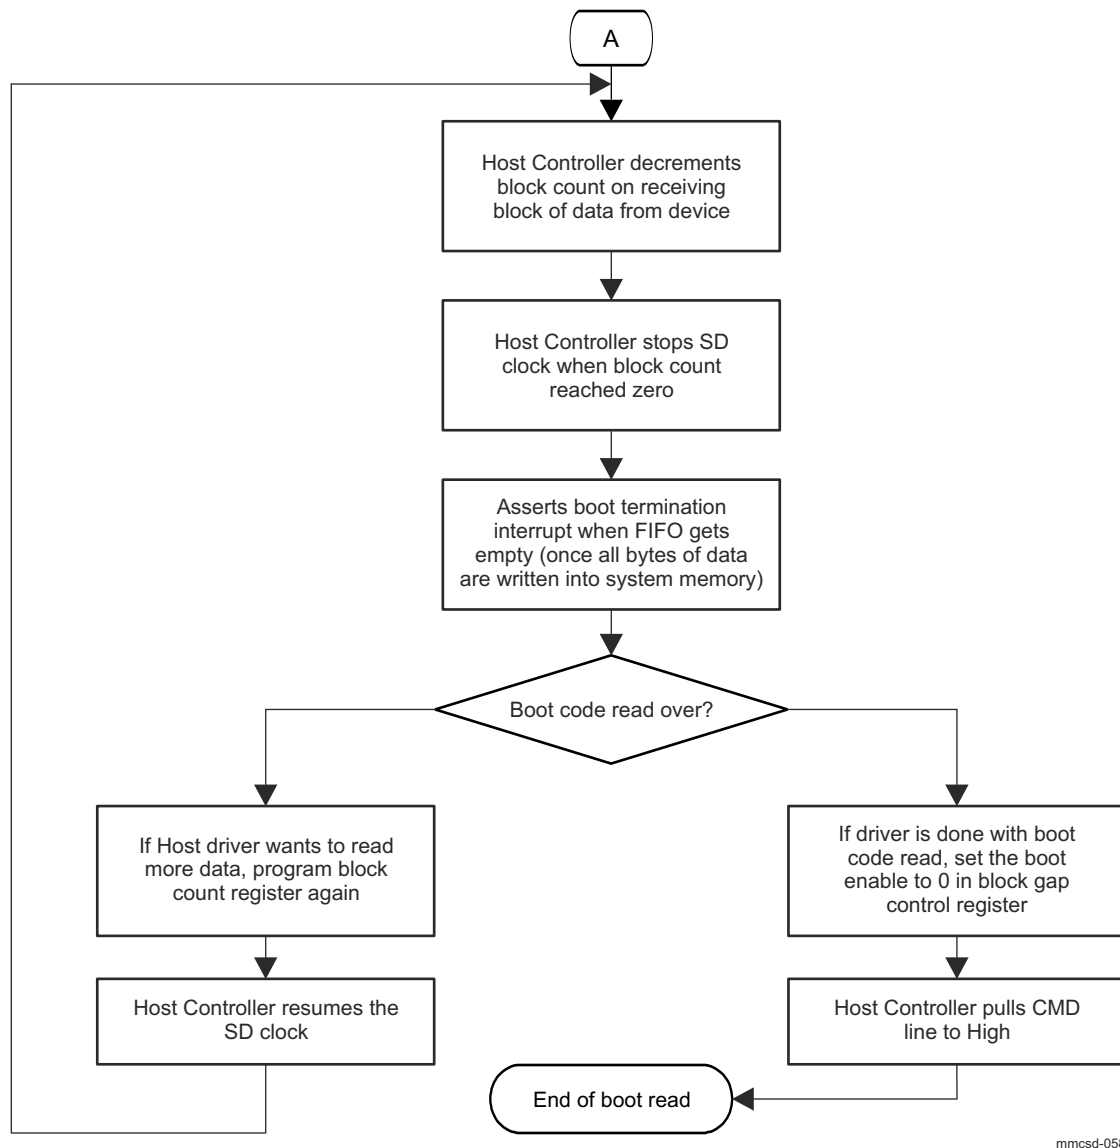

The following figure explains the boot code read done as chunks of data (the Driver can read the boot data as 2K, 4K, 1K and 8K etc. instead of 128K at a time

mmcsd-057

**Figure 12-158. Boot Code Access Flow Diagram (1)**

**Figure 12-159. Boot Code Access Flow Diagram (2)**

#### 12.3.6.4.2.3 Retuning procedure (For Legacy Interface)

##### 12.3.6.4.2.3.1 Sampling Clock Tuning

The SD bus can be operating in high clock frequency mode and then the data window from the card on CMD and DAT[3:0] lines gets smaller. The position of the data window will vary depending on the card and host system implementation. Therefore, the Host Controller shall support a tuning circuit when SDR104 or SDR50.

The Host Controller shall support a tuning circuit when SDR104 or SDR50 (if Use Tuning for SDR50 is set to 1 in the MMCSD0\_CAPABILITIES register) is supported by executing the tuning procedure and adjusting the sampling clock. Execute Tuning and Sampling Clock Select in the MMCSD0\_HOST\_CONTROL2 register are used to control the tuning circuit.

##### 12.3.6.4.2.3.2 Tuning Modes

The re-tuning timing is specified by two methods: Re-Tuning Request generated by Host Controller and expiration of a re-tuning timer prepared by Host Driver.

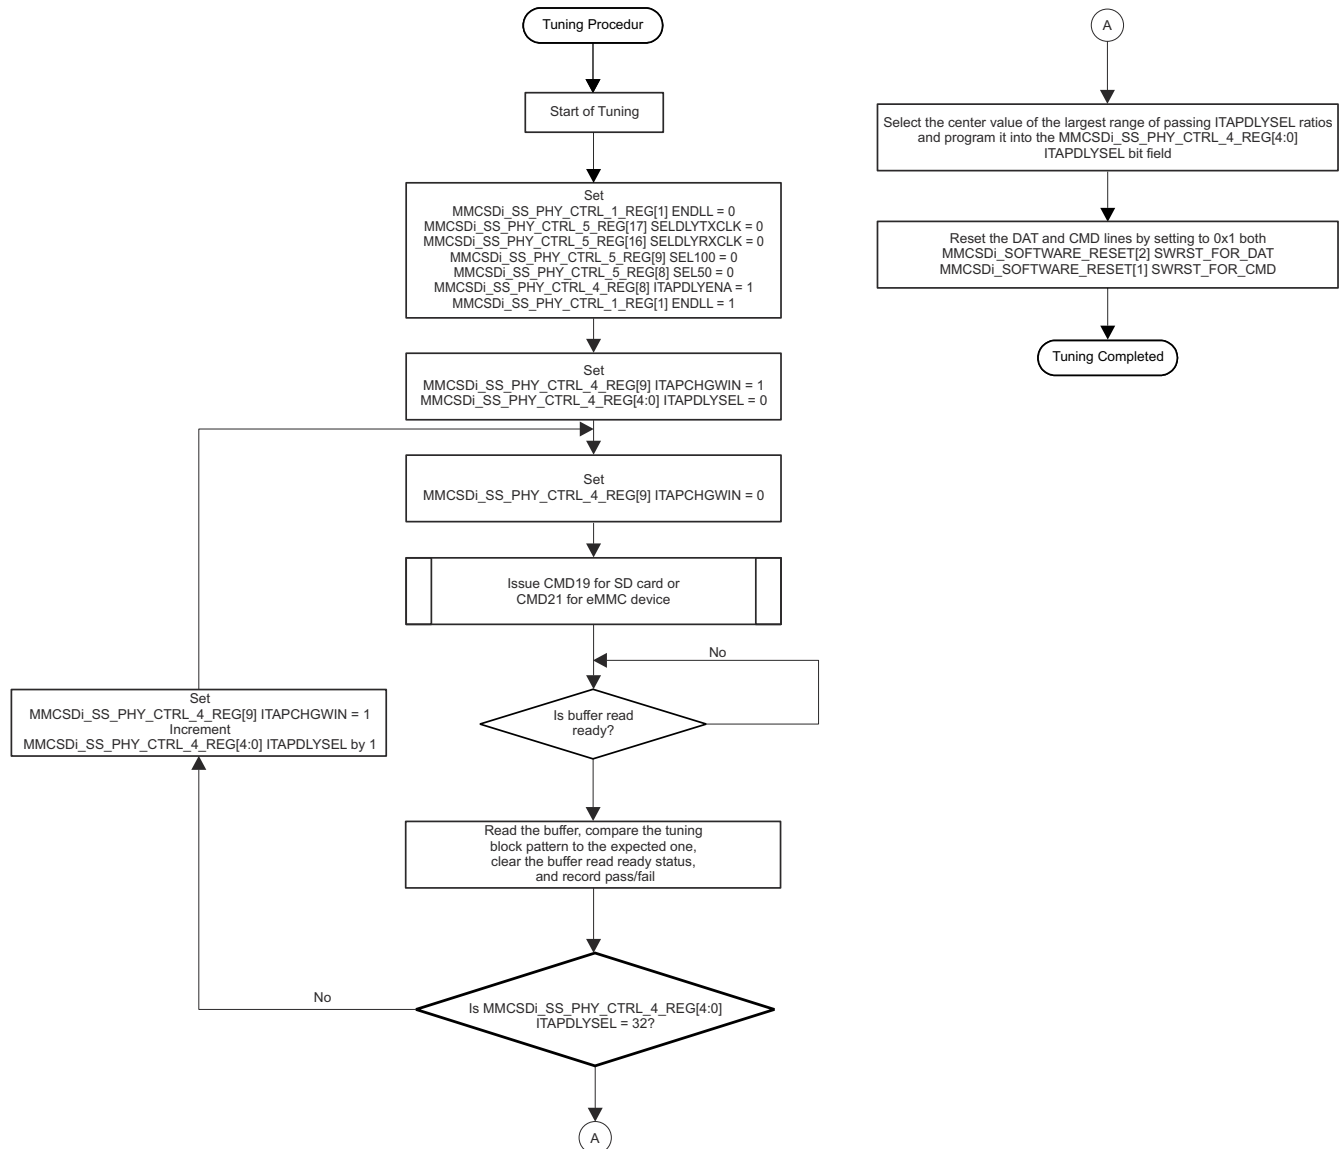

(1) Re-Tuning Mode 1 The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To

enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MB.

(2) Re-Tuning Mode 2 The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled.

#### 12.3.6.4.2.3.3 Re-Tuning Mode 2

The [Figure 12-160](#) defines sampling clock tuning procedure supported by Host Controller. In default, for lower frequency operation, fixed sampling clock is used to receive signals on CMD and DAT[3:0]. Before using SDR104, sampling clock tuning is required. Start of sampling clock tuning is requested by setting Execute Tuning to 1 and Sampling Clock Select to 0.

**Figure 12-160. MMCSD Clock Tuning**

Host driver issue CMD19 repeatedly until the host controller resets Execute Tuning to 0. Host Controller resets Execute Tuning to 0 when tuning is completed or tuning is not completed within 40 times. Host Driver can abort this loop by 40 times CMD19 issue or 150 ms time-out.

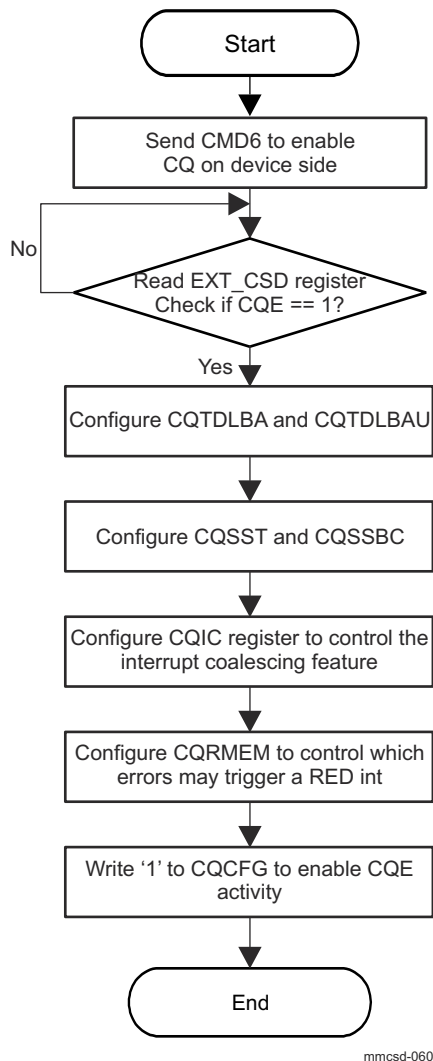

If tuning is completed successfully, Host Controller set Sampling Clock Select to 1 and this means the Host Controller start to use tuned sampling clock. If tuning is failed, Host Controller keeps Sampling Clock Select to 0. By writing Sampling Clock Select to 0, sampling clock is switched from tuned sampling clock to fixed sampling clock. Re-tuning time would be smaller than the first tuning time. CMD19 response errors are not indicated while tuning is performed.

The clock tuning tap delay values are selected using Variable sampling point detection. Fixed tap delay value is used for fixed tuning clock method.

#### 12.3.6.4.2.4 Command Queuing Driver Flow Sequence

##### 12.3.6.4.2.4.1 Command Queuing Initialization Sequence

Figure 12-161 and Table 12-226 show a Command Queuing initialization sequence.

**Figure 12-161. Command Queuing Initialization Sequence**

**Table 12-226. Command Queuing Initialization Sequence**

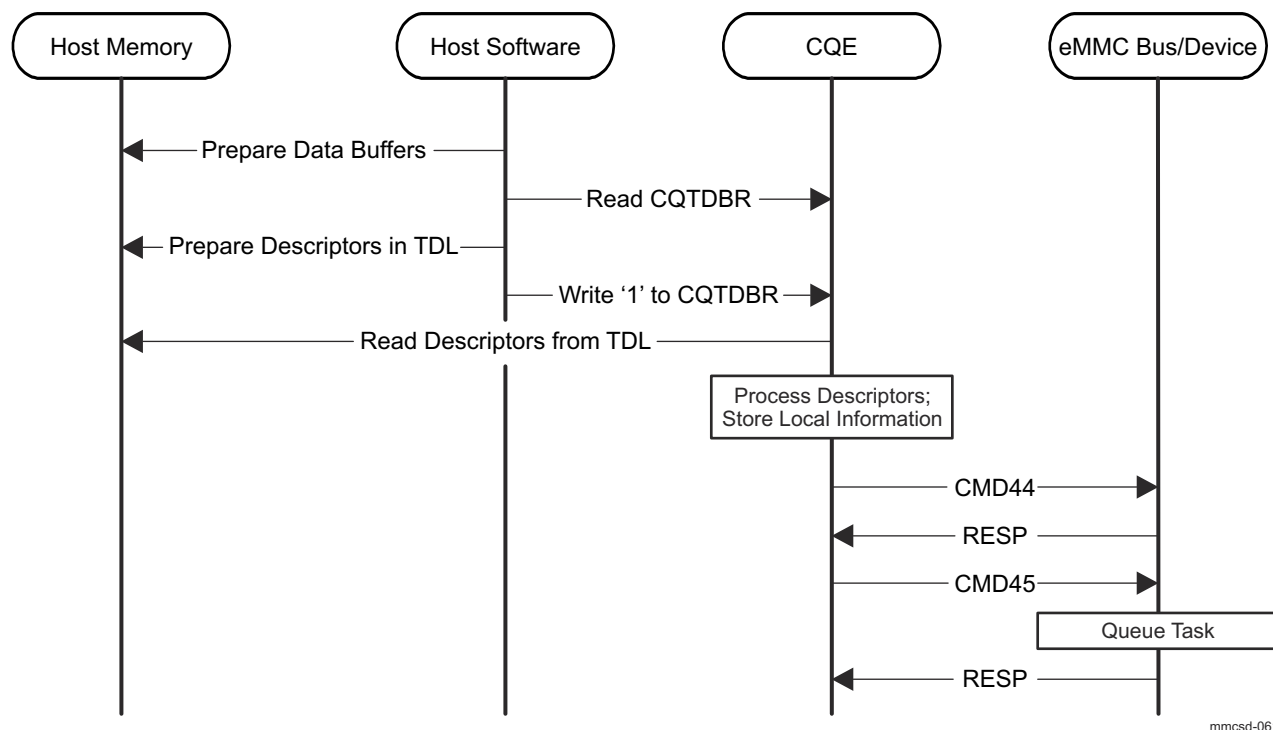

Step	Description
1	Initialize and enable Command Queueing in the device.
2	Configure Task Descriptor size in MMCSD0_CQ_CONFIG register.
3	Configure MMCSD0_CQ_TDL_BASE_ADDR and MMCSD0_CQ_TDL_BASE_ADDR_UPBITS registers to point to the memory location allocated to the TDL in host memory.
4	Configure CQSST and CQSSBC to control when SEND_QUEUE_STATUS commands are sent to the device by CQE.

**Table 12-226. Command Queuing Initialization Sequence (continued)**

Step	Description
5	Configure MMCSD0_CQ_INTR_COALESCING register to control the interrupt coalescing feature: enable/disable, set interrupt count and timer protection.
6	Configure MMCSD0_CQ_RESP_ERR_MASK register to control which errors may trigger a RED interrupt (if different from reset values).
7	Write '1' to MMCSD0_CQ_CONFIG register to enable CQE activity.

**12.3.6.4.2.4.2 Task Issuance Sequence**

Figure 12-162 and Table 12-227 show a task issuance sequence.

mmcsd-061

**Figure 12-162. Task Issuance Sequence****Table 12-227. Task Issuance Sequence**

Step	Description
1	Find an empty transfer request slot by reading the MMCSD0_CQ_TASK_DOOR_BELL register. An empty transfer request slot has its respective bit cleared to '0' in the MMCSD0_CQ_TASK_DOOR_BELL register.
2	Build a Task Descriptor at the 1st entry of the empty slot. Task Descriptor field values: <ul style="list-style-type: none"> <li>1. Valid = 1, to indicate the descriptor is effective.</li> <li>2. End = 1, as required for Task Descriptors.</li> <li>3. Int = 1, if an interrupt on completion is required. Otherwise, Int = 0.</li> <li>4. Act = b101, to indicate a Task Descriptor.</li> <li>5. Data Direction = 1 for read commands, and 0 for write commands.</li> <li>6. Priority = 1 for high priority, and 0 for simple requests.</li> <li>7. QBR = 1 if Queue Barrier functionality is required. 0 otherwise.</li> <li>8. Forced Programming, Context ID, Tag Request, Reliable Write, Block Count, and Block Address programmed according to application requirements.</li> </ul>

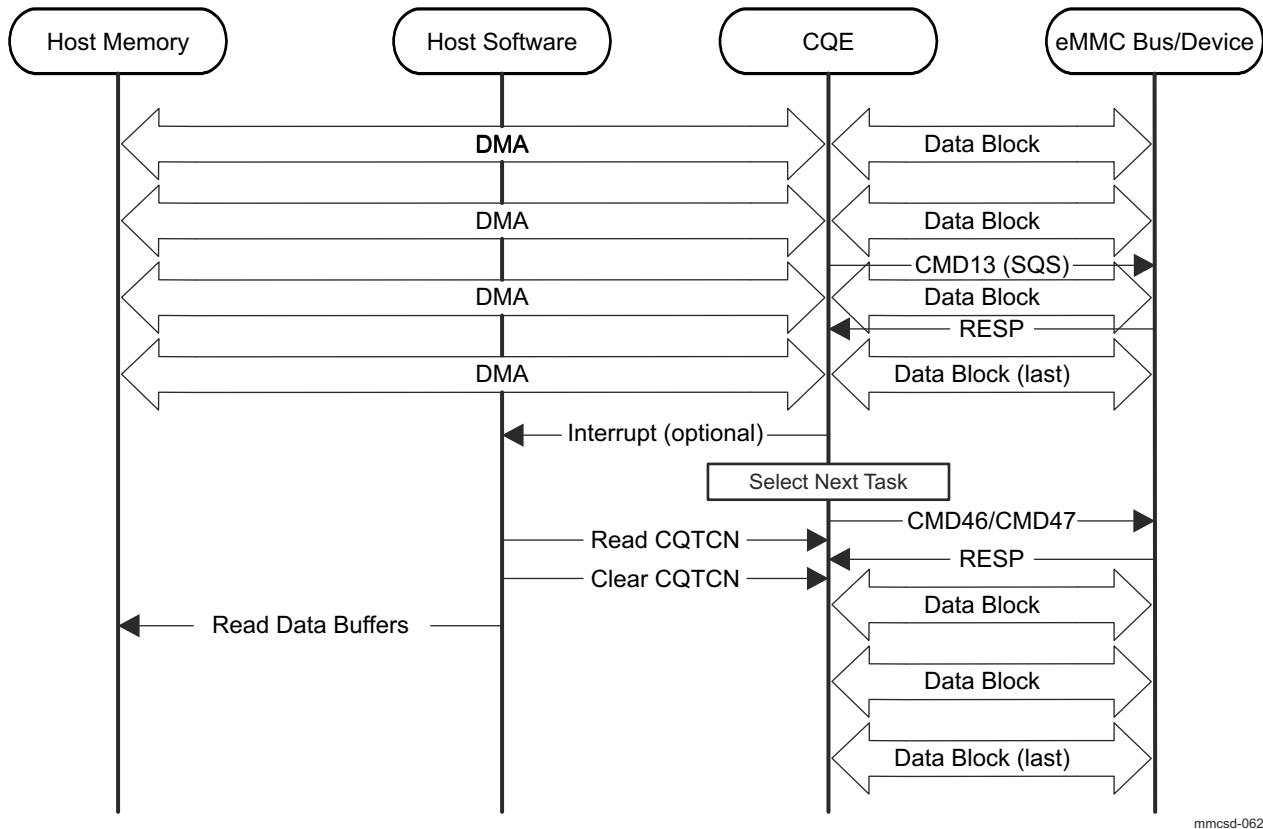

**Table 12-227. Task Issuance Sequence (continued)**

Step	Description
3	Build a Transfer Descriptor at the 2nd entry of the empty slot. Transfer Descriptor field values: <ul style="list-style-type: none"> <li>1. Valid = 1, to indicate the descriptor is effective.</li> <li>2. End = 1, if a TRAN descriptor is used, to indicate the task only has one data buffer. End = 0 if LINK descriptor is used.</li> <li>3. Int = 0. Ignore in Command queueing.</li> <li>4. Act = b100, for TRAN descriptors, pointing directly to the task's single data buffer. Act = 401 b110, for LINK descriptors, point to a scatter/gather list (indirect).</li> <li>5. Address and Length programmed according to the data buffer supplied by the application.</li> </ul>
4	If more than one transfer is requested, repeat step 1-3 for all needed transfers.
5	Set MMCSD0_CQ_TASK_DOOR_BELL register to indicate to the CQE that one or more transfer requests are ready to be sent to the attached device. Host software shall only write a '1' to the bit position that corresponds to new tasks; all other bit positions within MMCSD0_CQ_TASK_DOOR_BELL register should be written with a '0', which indicates no change to their current values.

#### 12.3.6.4.2.4.3 Task Execution and Completion Sequence

The CQE is responsible for task execution, communication with the device and moving the data to the buffers in the host memory.

Figure 12-163 and Table 12-228 show a task execution and completion sequence.

mmscd-062

**Figure 12-163. Task Execution and Completion Sequence**

**Table 12-228. Task Execution and Completion Sequence**

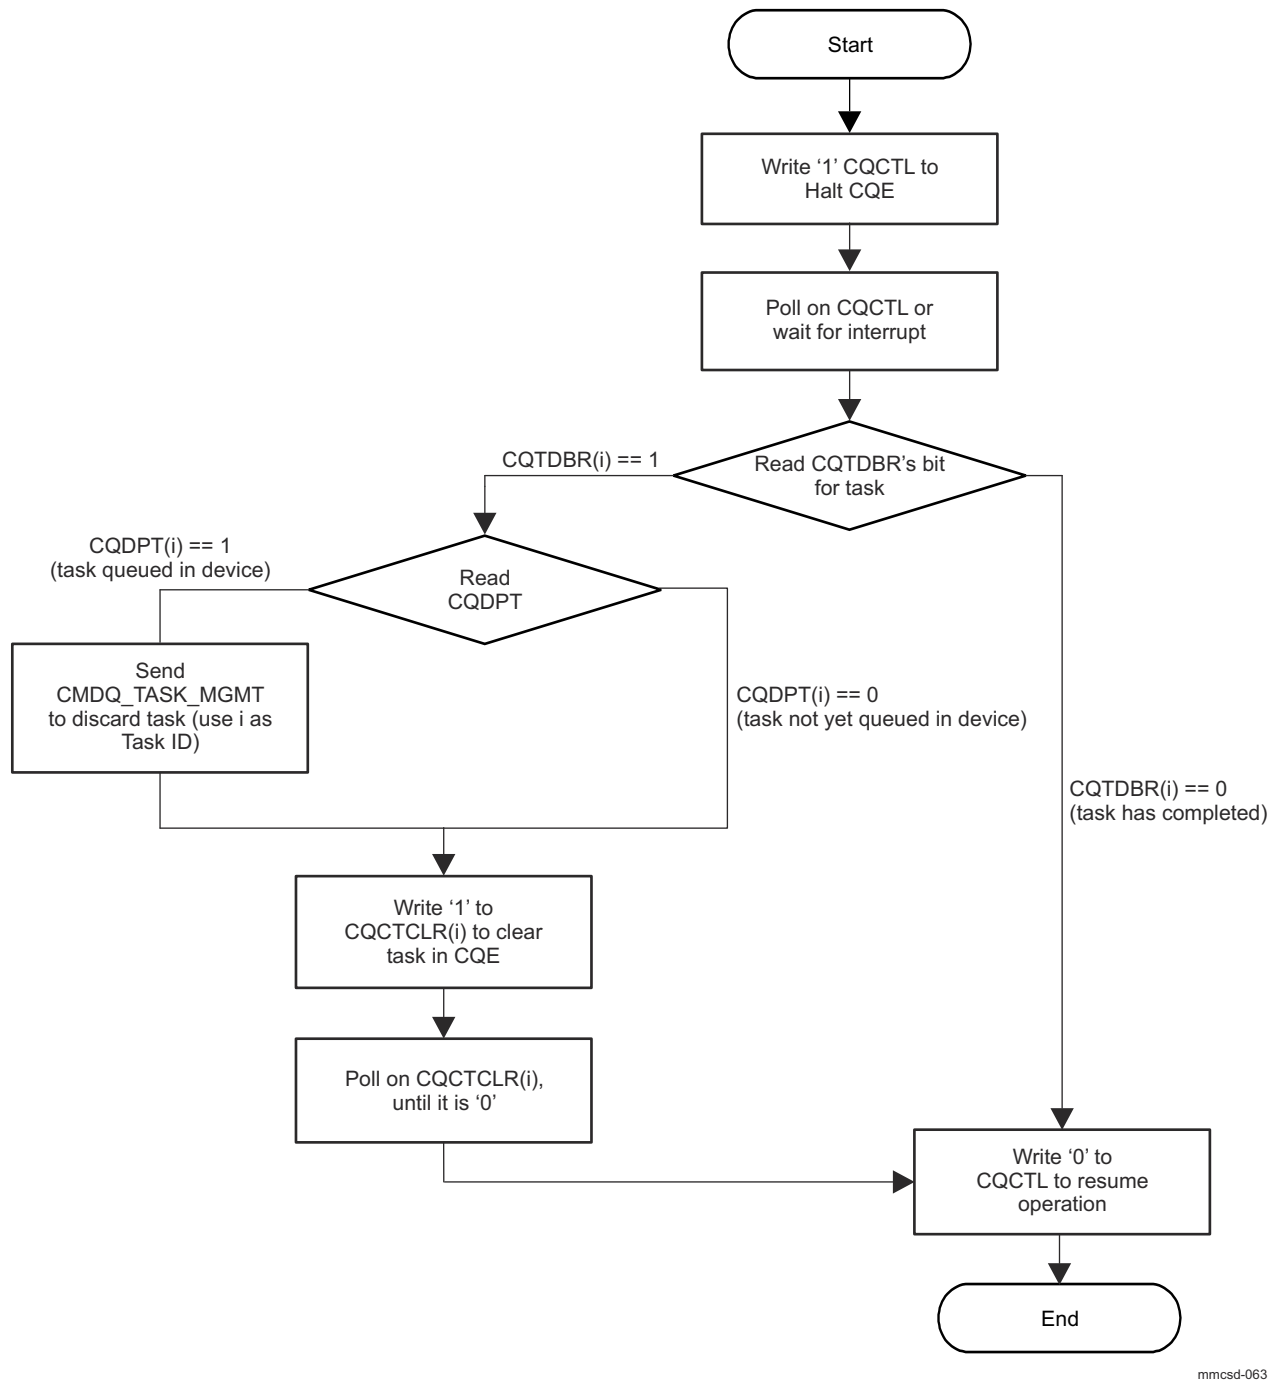

Step	Description
1	Once the tasks are queued on the device side CQE sends CMD13 to determine the queue status. The queue status lets the CQE know which tasks are ready for execution.
2	The response to CMD13 may indicate no task is ready in which case the CQE is required to send CMD13 again at a later time as controlled CQSST register.

**Table 12-228. Task Execution and Completion Sequence (continued)**

Step	Description
3	If a task is ready for execution then the host sends EXECUTE_READ_TASK (CMD46) or EXECUTE_WRITE_TASK (CMD47) to the device with the task id ordering it to execute a task.
4	When the task execution is completed, an interrupt may be generated, if requested, or as determined by Interrupt Coalescing mechanism.
5	The host software reads MMCSD0_CQ_TASK_COMP_NOTIF register to determine which task(s) has(have) been completed. Each bit set in MMCSD0_CQ_TASK_COMP_NOTIF register represents by index which task has completed but hasn't yet been served by software.
6	For every task completed clear the appropriate MMCSD0_CQ_TASK_COMP_NOTIF register bit.
7	Repeat steps 1-6 for the pending tasks.

**12.3.6.4.2.4.4 Task Discard and Clear Sequence**

[Figure 12-164](#) and [Table 12-229](#) show a task discard and clear sequence.

mmcsd-063

**Figure 12-164. Task Discard and Clear Sequence**

**Table 12-229. Task Discard and Clear Sequence**

Step	Description
1	While CQE is enabled write '1' to MMCSD0_CQ_CONTROL[0] HALT_BIT bit to halt CQE.
2	Poll on MMCSD0_CQ_INTR_STS[0] HALT_COMPLETE bit.
3	Read MMCSD0_CQ_TASK_DOOR_BELL register to determine if the task to be discarded is set to 1.
4	Read MMCSD0_CQ_DEV_PENDING_TASKS register to check if the task is queued in the device.
5	Send CMDQ_TASK_MGMT(CMD48) to discard task using the task id as the argument.
6	Write '1' to CQCTCLR[i] to clear task in CQE.
7	Poll on CQCTCLR[i] until it is '0'.

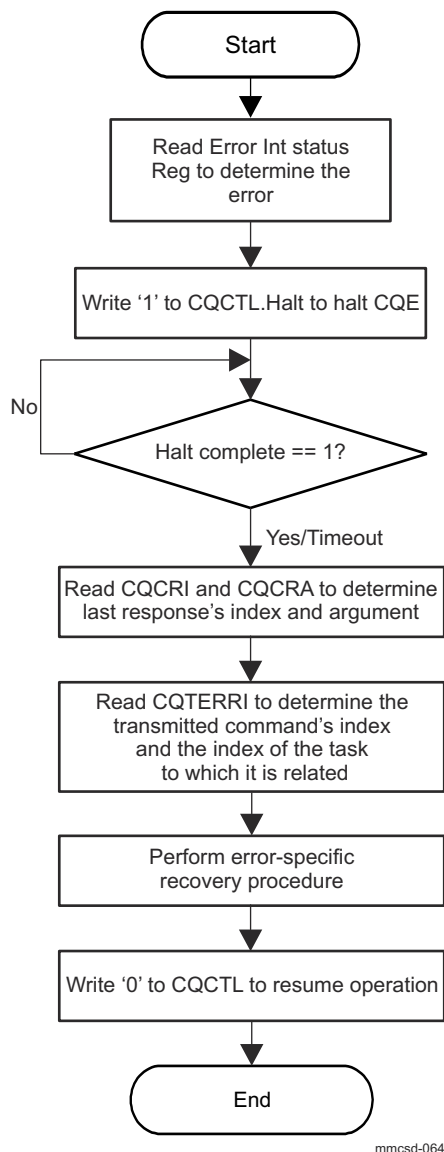

**Table 12-229. Task Discard and Clear Sequence (continued)**

Step	Description
8	Write '0' to MMCSD0_CQ_CONTROL register to resume CQE.

**12.3.6.4.2.4.5 Error Detect and Recovery when CQ is enabled**

Figure 12-165 and Table 12-230 show an error detect and recovery sequence.

**Figure 12-165. Error Detect and Recovery Sequence****Table 12-230. Error Detect and Recovery Sequence**

Step	Description
1	Read eMMC host controller MMCSD0_ERROR_INTR_STS register and determine error is related to CQE.
2	Write '1' to MMCSD0_CQ_CONTROL[0] HALT_BIT bit to halt CQE.
3	Wait for MMCSD0_CQ_CONTROL[0] HALT_BIT bit to read '1'. In some error cases, this may not happen, so software should proceed to the next step after a sufficient time-out.
4	Read MMCSD0_CQ_CMD_RESP_INDEX and MMCSD0_CQ_CMD_RESP_ARG registers to determine last response's index and argument.
5	Read MMCSD0_CQ_TASK_ERR_INFO register to determine the transmitted command's index and the index of the task to which it is related.

**Table 12-230. Error Detect and Recovery Sequence (continued)**

Step	Description
6	Perform error-specific recovery procedure.
7	Write '0' to MMCSD0_CQ_CONTROL register to resume operation.

## 12.4 Industrial and Control Interfaces

This section describes the industrial and control Interfaces in the device.

### 12.4.1 Enhanced Capture (ECAP) Module

This section describes the Enhanced Capture (ECAP) module in the device.

#### 12.4.1.1 ECAP Overview

The Enhanced Capture (ECAP) module can be used for:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The device has three instances of the ECAP module.

#### 12.4.1.1.1 ECAP Features

The ECAP module includes the following features:

- 32-bit time base counter
- 4 × 32 bits event time-stamp capture registers (ECAP\_CAP1 through ECAP\_CAP4)
- 4-stage sequencer (Mod4 counter), synchronized to external events (ECAPx pin edges)
- Independent edge polarity (rising / falling edge) selection for all 4 sequenced time-stamp capture events
- Input capture signal pre-scaling (from 1 to 16)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Interrupt capabilities on any of the 4 capture events
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.4.1.1.2 ECAP Ports

**Table 12-231. ECAP Clocks and Resets**

Clocks	
Module Clock Input	Description
ECAP_FICLK	ECAP functional and interface clock
Resets	
Module Reset Input	Description
ECAP_RST	Module Reset

**Table 12-232. ECAP Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
ECAP_ECAPH_INT_0	ECAP interrupt	Pulse

#### 12.4.1.2 ECAP Environment

This section describes the ECAP external connections (environment).

[Table 12-233](#) describes the ECAP I/O signals.

**Table 12-233. ECAP I/O Signals**

Module Pin	I/O <sup>(1)</sup>	Description
ECAP0_CAPIN_APWMOUT	I/O	ECAP0 Capture input / PWM output
ECAP1_CAPIN_APWMOUT	I/O	ECAP1 Capture input / PWM output
ECAP2_CAPIN_APWMOUT	I/O	ECAP2 Capture input / PWM output

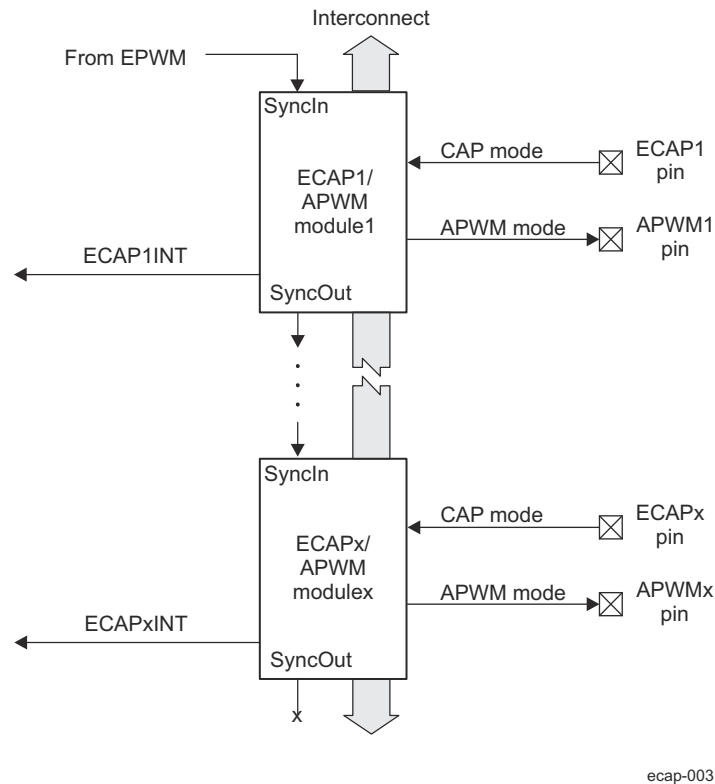

(1) I = Input; O = Output

### 12.4.1.3 ECAP Functional Description

The ECAP module represents one complete capture channel, which has the following independent key resources:

- Dedicated input capture pin
- 32 events selection mapping capability to the input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers (ECAP\_CAP1 through ECAP\_CAP4)
- 4-stage sequencer (Mod4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (ECAP\_CAP1 through ECAP\_CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

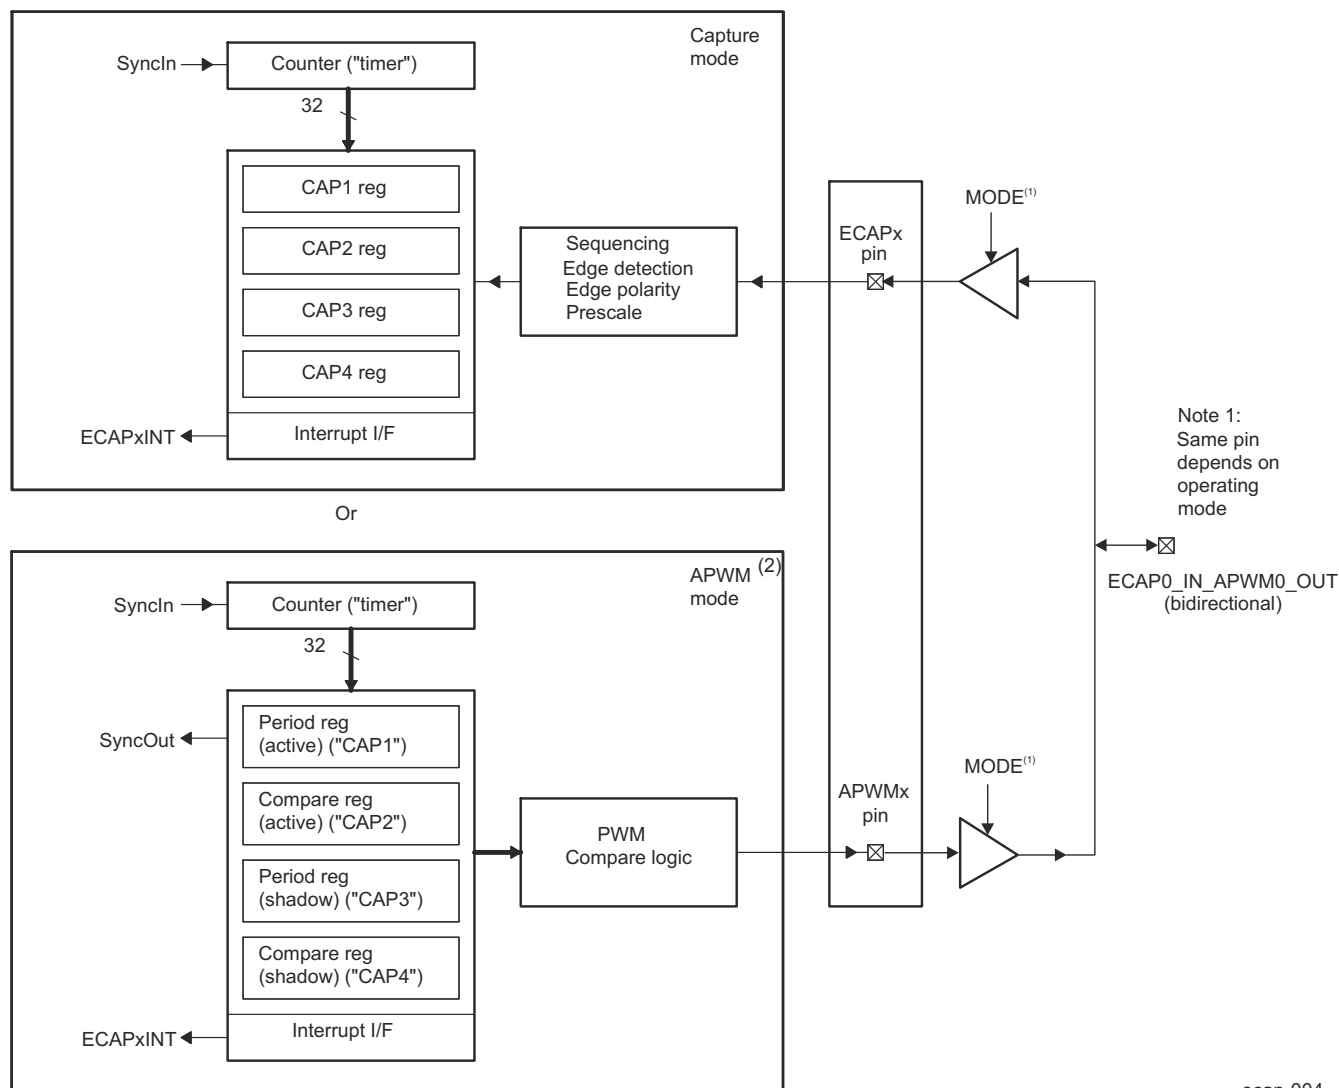

Multiple identical ECAP modules can be contained in a system as shown in [Figure 12-166](#). For actual number of the ECAP modules integrated in the device, refer to the *ECAP Integration*. The letter x within a signal or module name is used to indicate a generic ECAP instance on a device. For example, output interrupt request, ECAP1INT belongs to ECAP1, ECAP2INT belongs to ECAP2, and so forth.

**Figure 12-166. Multiple ECAP Modules**

#### 12.4.1.3.1 Capture and APWM Operating Modes

The ECAP module resources can be used to implement a single-channel PWM generator (with 32-bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The ECAP\_CAP1 and ECAP\_CAP2 registers become the active period and compare registers, respectively, while the ECAP\_CAP3 and ECAP\_CAP4 registers become the period and capture shadow registers, respectively. [Figure 12-167](#) is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

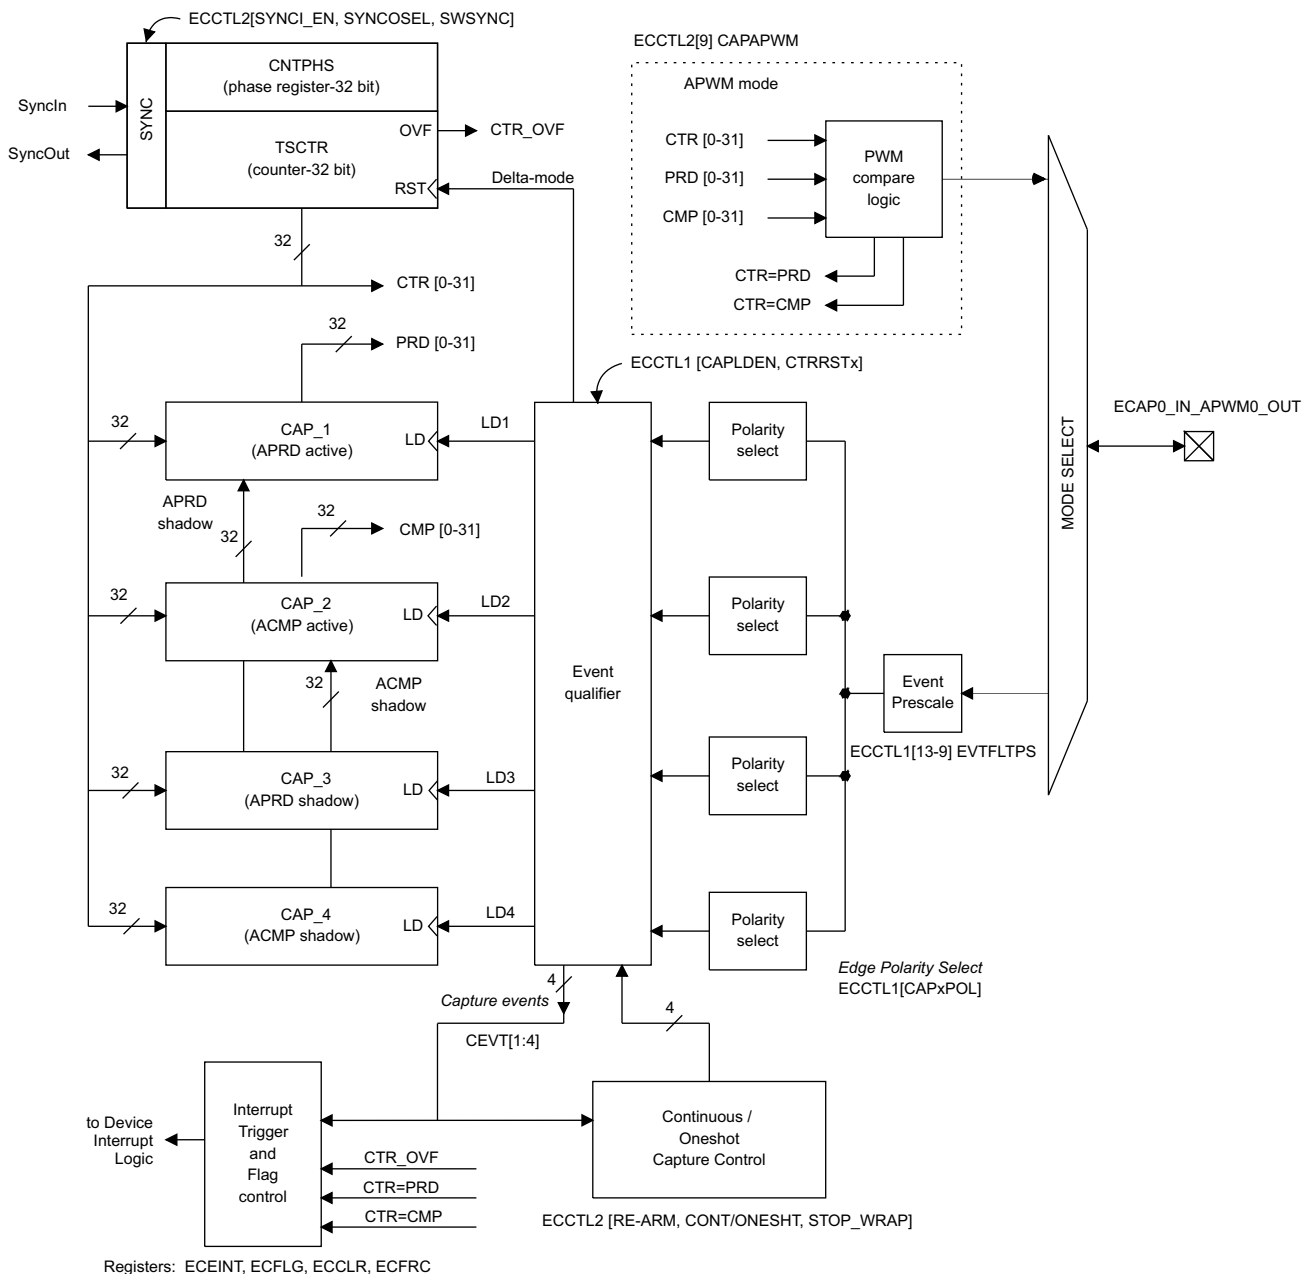

- A single pin is shared between CAP and APWM functions. In capture mode, it is an input. In APWM mode, it is an output.
- In APWM mode, writing any value to the ECAP\_CAP1/ECAP\_CAP2 active registers also writes the same value to the corresponding shadow registers (ECAP\_CAP3/ECAP\_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP\_CAP3/ECAP\_CAP4) invokes the shadow mode.

**Figure 12-167. Capture and APWM Modes of Operation**

#### 12.4.1.3.1.1 ECAP Capture Mode Description

Figure 12-168 shows the various components that implement the capture function.

**Figure 12-168. Capture Function Diagram**

#### 12.4.1.3.1.1.1 ECAP Event Prescaler

An input capture signal (pulse train) can be prescaled by  $N = 2-62$  (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. [Figure 12-169](#) shows a functional diagram and [Figure 12-170](#) shows the operation of the prescale function.

- A. When a prescale value of 1 is chosen (ECAP\_ECCTL[13-9] EVTFLTPS = 0b0000) the input capture signal by-passes the prescale logic completely.

**Figure 12-169. Event Prescale Control**

**Figure 12-170. Prescale Function Waveforms**

#### 12.4.1.3.1.1.2 ECAP Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Mod4 sequencer.
- The edge event is gated to its respective CAP $n$  register by the Mod4 counter. The CAP $n$  register is loaded on the falling edge.

#### 12.4.1.3.1.1.3 ECAP Continuous/One-Shot Control

- The Mod4 (2-bit) counter is incremented via edge qualified events CEVT1 through CEVT4 (see the ECAP\_ECINT\_EN\_FLG register).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output; when equal the Mod4 counter stops and inhibits further loads of the ECAP\_CAP1 through ECAP\_CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block (Figure 12-171) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the ECAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of the ECAP\_CAP1 through ECAP\_CAP4 registers (time-stamps).

Re-arming prepares the ECAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of the ECAP\_CAP1 through ECAP\_CAP4 registers again, providing the ECAP\_ECCTL[8] CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0), the one-shot action is ignored, and capture values continue to be written to the ECAP\_CAP1 through ECAP\_CAP4 registers in a circular buffer sequence.

ecap-008

**Figure 12-171. ECAP Continuous/One-shot Block Diagram**

#### 12.4.1.3.1.1.4 ECAP 32-Bit Counter and Phase Control

This counter (Figure 12-172) provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1 through LD4 signals.

**Figure 12-172. ECAP Counter and Synchronization Block Diagram**

#### 12.4.1.3.1.1.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via the control ECAP\_ECCTL[8] CAPLDEN bit. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

The ECAP\_CAP1 and ECAP\_CAP2 registers become the active period and compare registers, respectively, in APWM mode.

The ECAP\_CAP3 and ECAP\_CAP4 registers become the respective shadow registers (APRD and ACMP) for the ECAP\_CAP1 and ECAP\_CAP2 registers during APWM operation.

#### 12.4.1.3.1.1.6 ECAP Interrupt Control

An interrupt can be generated on capture events CEVT1 through CEVT4, CINTOVF (see the ECAP\_ECINT\_EN\_FLG[21] CINTOVF\_FLG bit) or APWM events (TSCNT = PRD, TSCNT = CMP). See [Figure 12-173](#).

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CINTOVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the ECAP<sub>n</sub> module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CINTOVF, TSCNT = PRD, TSCNT = CMP) can be generated. The interrupt enable register (ECAP\_ECINT\_EN\_FLG) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECAP\_ECINT\_EN\_FLG) indicates if any interrupt event has been latched and contains the global interrupt flag ECAP\_ECINT\_EN\_FLG[16] INT\_FLG bit. An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1h, and the INT\_FLG flag bit is 0h. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECAP\_ECINT\_CLR\_FRC) before any other interrupt pulses are generated. The interrupt force register (ECAP\_ECINT\_CLR\_FRC) can force an interrupt event. This is useful for test purposes.

#### 12.4.1.3.1.1.7 ECAP Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of the ECAP\_CAP1 or ECAP\_CAP2 registers from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to the ECAP\_CAP1 or ECAP\_CAP2 register immediately upon writing a new value.
- On period equal, CTR[31-0] = PRD[31-0]

#### Note

The CEVT1\_FLG, CEVT2\_FLG, CEVT3\_FLG, CEVT4\_FLG flags are only active in capture mode (ECAP\_ECCTL[25] CAP\_APWM == 0h). The TSCNT = PRD, TSCNT = CMP flags are only valid in APWM mode (ECAP\_ECCTL[25] CAP\_APWM == 1h). CINTOVF\_FLG flag is valid in both modes.

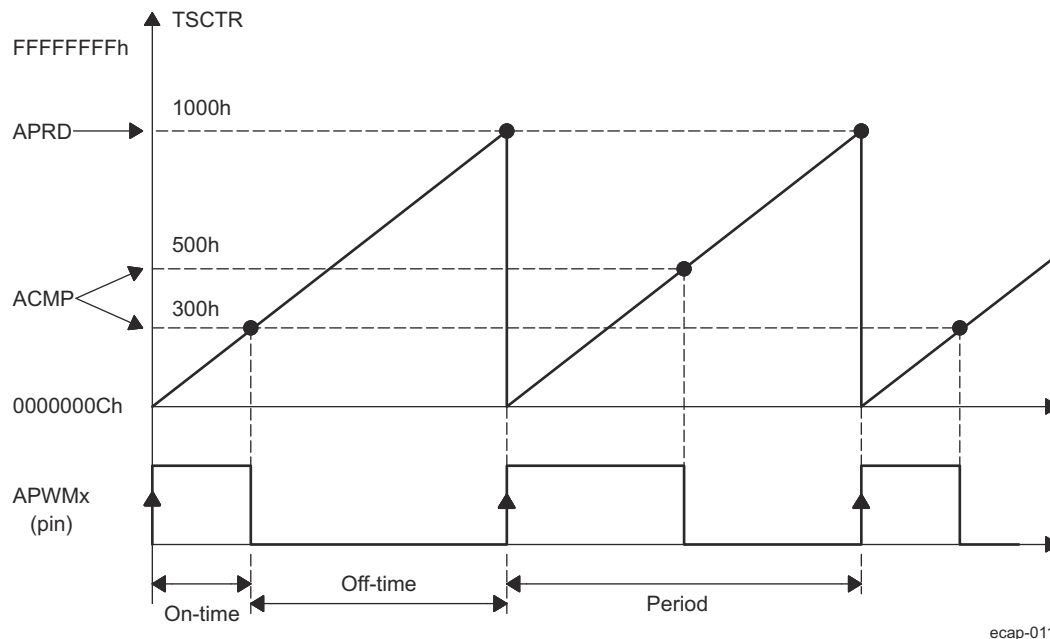

ecap-010

**Figure 12-173. Interrupts in ECAP Module**

#### 12.4.1.3.1.2 ECAP APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When the ECAP\_CAP1/ECAP\_CAP2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via the shadow registers - APRD and ACMP (ECAP\_CAP3/ECAP\_CAP4). The shadow register contents are transferred over to ECAP\_CAP1/ECAP\_CAP2 registers either immediately upon a write, or on a TSCNT = PRD trigger.
- In APWM mode, writing to the ECAP\_CAP1/ECAP\_CAP2 active registers will also write the same value to the corresponding shadow registers (ECAP\_CAP3/ECAP\_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP\_CAP3/ECAP\_CAP4) will invoke the shadow mode.
- During initialization, software must write the PRD and CMP values to the active registers. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, software should use only shadow registers.

**Figure 12-174. PWM Waveform Details of ECAP APWM Mode Operation**

The behavior of APWM active-high mode (APWMPOL == 0) is:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active-low mode (APWMPOL == 1) is:

CMP = 0x00000000, output high for duration of period (0% duty)

CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

#### 12.4.1.3.2 Summary of ECAP Functional Registers

Table 12-234 shows the ECAP module control and status register set. All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode.

#### Note

In APWM mode, writing to the ECAP\_CAP1/ECAP\_CAP2 active registers also writes the same value to the corresponding shadow registers (ECAP\_CAP3/ECAP\_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP\_CAP3/ECAP\_CAP4) invokes the shadow mode.

**Table 12-234. ECAP Control and Status Functional Registers**

Offset	Register Name	Description	Size (×16)
0h	ECAP_TSCNT	Time-Stamp Counter Register	2
4h	ECAP_CNTPHS	Counter Phase Offset Value Register	2
8h	ECAP_CAP1	Capture 1 Register	2
Ch	ECAP_CAP2	Capture 2 Register	2
10h	ECAP_CAP3	Capture 3 Register	2
14h	ECAP_CAP4	Capture 4 Register	2
28h	ECAP_ECCTL	Capture Control Register	2
2Ch	ECAP_ECINT_EN_FLG	Capture Interrupt Enable and Flag Register	2
30h	ECAP_ECINT_CLR_FRC	Capture Interrupt Clear and Forcing Register	2
5Ch	ECAP_PID	Revision ID Register	2

#### Note

For more information on the ECAP registers, see *ECAP Registers*.

### 12.4.1.4 ECAP Use Cases

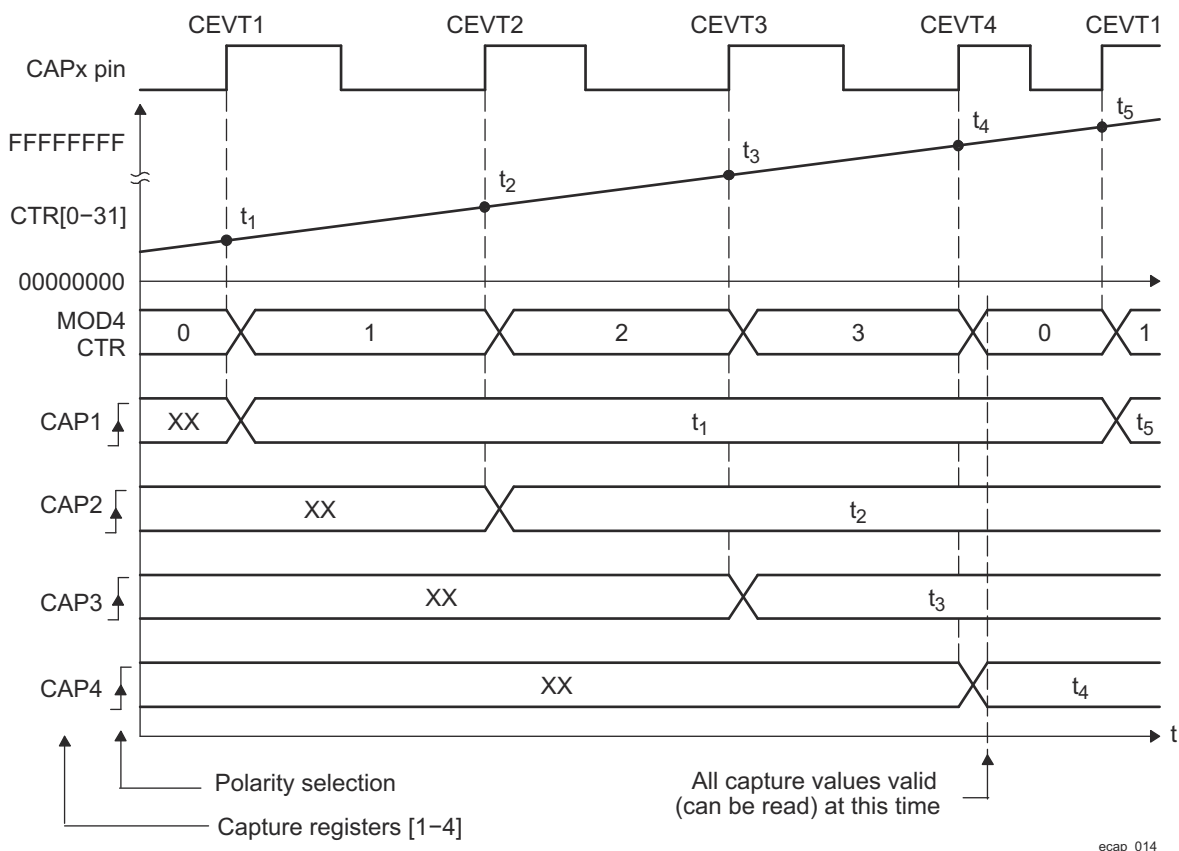

The following sections will provide applications examples and code snippets to show how to configure and operate the ECAP module. For clarity and ease of use, below are useful #defines which will help in the understanding of the examples.

```
// ECCTL1 ( ECAP Control Reg 1)
//=====
// CAPxPOL bits
#define EC_RISING          0x0
#define EC_FALLING        0x1
// CTRRSTx bits
#define EC_ABS_MODE        0x0
#define EC_DELTA_MODE      0x1
// PRESCALE bits
#define EC_BYPASS          0x0
#define EC_DIV1            0x0
#define EC_DIV2            0x1
#define EC_DIV4            0x2
#define EC_DIV6            0x3
#define EC_DIV8            0x4
#define EC_DIV10           0x5
// ECCTL2 ( ECAP Control Reg 2)
//=====
// CONT/ONESHOT bit
#define EC_CONTINUOUS      0x0
#define EC_ONESHOT         0x1
// STOPVALUE bit
#define EC_EVENT1          0x0
#define EC_EVENT2          0x1
#define EC_EVENT3          0x2
#define EC_EVENT4          0x3
// RE-ARM bit
#define EC_ARM             0x1
// TSCTRSTOP bit
#define EC_FREEZE          0x0
#define EC_RUN             0x1
// SYNCO_SEL bit
#define EC_SYNCIN          0x0
#define EC_CTR_PRD         0x1
#define EC_SYNCO_DIS       0x2
// CAP/APWM mode bit
#define EC_CAP_MODE        0x0
#define EC_APWM_MODE       0x1
// APWMPOL bit
#define EC_ACTV_HI         0x0
#define EC_ACTV_LO         0x1
// Generic
#define EC_DISABLE         0x0
#define EC_ENABLE          0x1
#define EC_FORCE           0x1
```

#### 12.4.1.4.1 Absolute Time-Stamp Operation Rising Edge Trigger Example

Figure 12-175 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (maximum value), it wraps around to 0000 0000h (not shown in Figure 12-175), if this occurs, the CNTOVF\_FLG (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured time-stamps are valid at the point indicated by the diagram, after the 4-th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPn registers.

**Figure 12-175. Capture Sequence for Absolute Time-Stamp, Rising Edge Detect**

**Table 12-235. ECAP Initialization for CAP Mode Absolute Time, Rising Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_ABS_MODE
ECCTL1	CTRRST2	EC_ABS_MODE
ECCTL1	CTRRST3	EC_ABS_MODE
ECCTL1	CTRRST4	EC_ABS_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-1. Code Snippet for CAP Mode Absolute Time, Rising Edge Trigger**

```
// Code snippet for CAP mode Absolute Time, Rising edge trigger
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;      // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;      // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;      // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;      // Fetch Time-Stamp captured at t4
Period1 = TSt2-TSt1;         // Calculate 1st period
Period2 = TSt3-TSt2;         // Calculate 2nd period
Period3 = TSt4-TSt3;         // Calculate 3rd period
```

#### 12.4.1.4.2 Absolute Time-Stamp Operation Rising and Falling Edge Trigger Example

In Figure 12-176 the ECAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information: Period1 =  $t_3 - t_1$ , Period2 =  $t_5 - t_3$ , ...etc. Duty Cycle1 (on-time %) =  $(t_2 - t_1) / \text{Period1} \times 100\%$ , etc. Duty Cycle1 (off-time %) =  $(t_3 - t_2) / \text{Period1} \times 100\%$ , etc.

ecap\_015

**Table 12-236. ECAP Initialization for CAP Mode Absolute Time, Rising and Falling Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_FALLING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_FALLING
ECCTL1	CTRRST1	EC_ABS_MODE
ECCTL1	CTRRST2	EC_ABS_MODE
ECCTL1	CTRRST3	EC_ABS_MODE
ECCTL1	CTRRST4	EC_ABS_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-2. Code Snippet for CAP Mode Absolute Time, Rising and Falling Edge Trigger**

```
// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;      // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;      // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;      // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;      // Fetch Time-Stamp captured at t4
Period1 = TSt3-TSt1;        // Calculate 1st period
DutyOnTime1 = TSt2-TSt1;     // Calculate On time
DutyOffTime1 = TSt3-TSt2;    // Calculate Off time
```

#### 12.4.1.4.3 Time Difference (Delta) Operation Rising Edge Trigger Example

Figure 12-177 shows how the ECAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (maximum value), before the next event, it wraps around to 0000 0000h and continues, a CNTOVF\_FLG (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAP $n$  contents directly give timing data without the need for CPU calculations: Period1 =  $T_1$ , Period2 =  $T_2$ ,...etc. As shown in Figure 12-177, the CEVT1 event is a good trigger point to read the timing data,  $T_1$ ,  $T_2$ ,  $T_3$ ,  $T_4$  are all valid here.

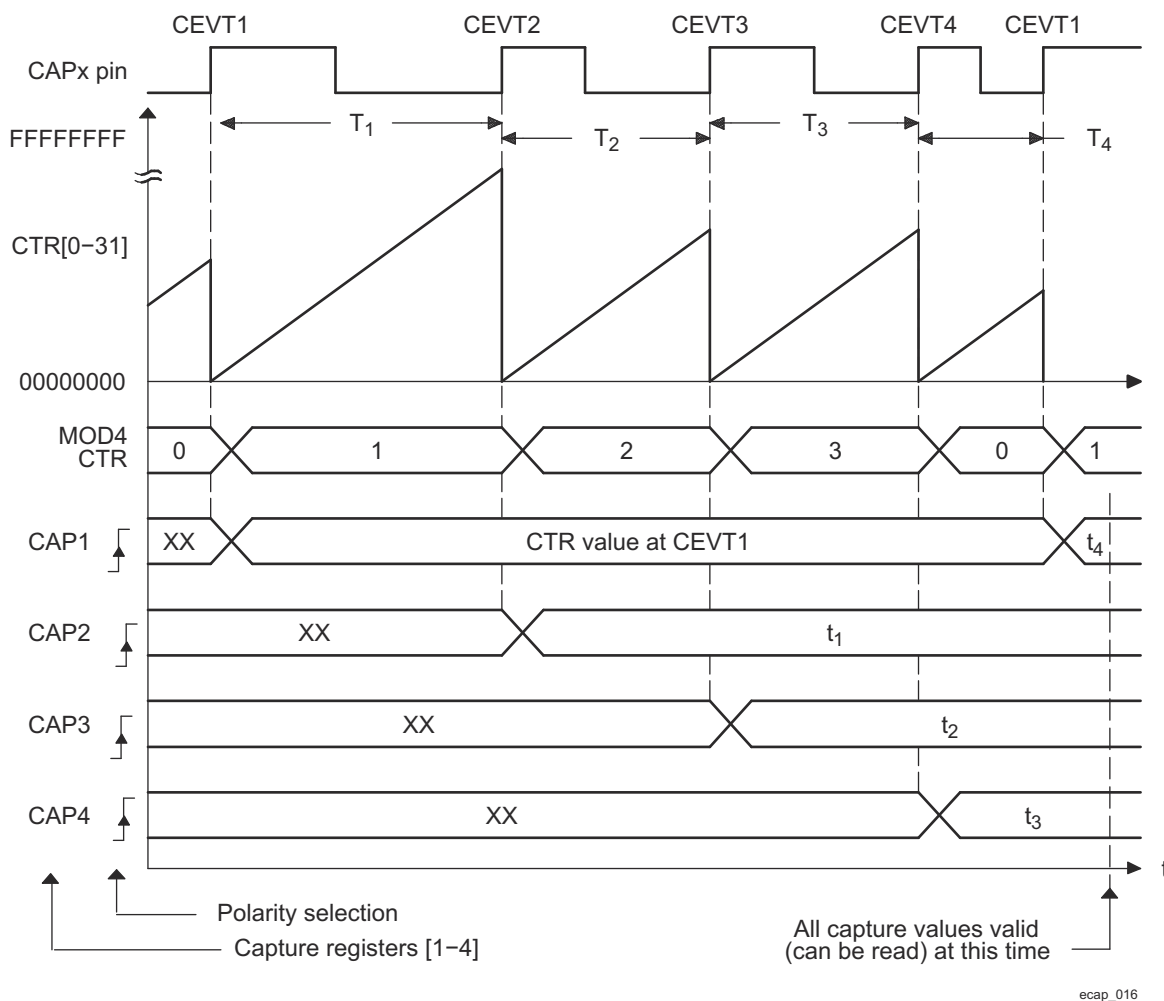

Figure 12-177. Capture Sequence for Delta Mode Time-Stamp, Rising Edge Detect

**Table 12-237. ECAP Initialization for CAP Mode Delta Time, Rising Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_DELTA_MODE
ECCTL1	CTRRST2	EC_DELTA_MODE
ECCTL1	CTRRST3	EC_DELTA_MODE
ECCTL1	CTRRST4	EC_DELTA_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

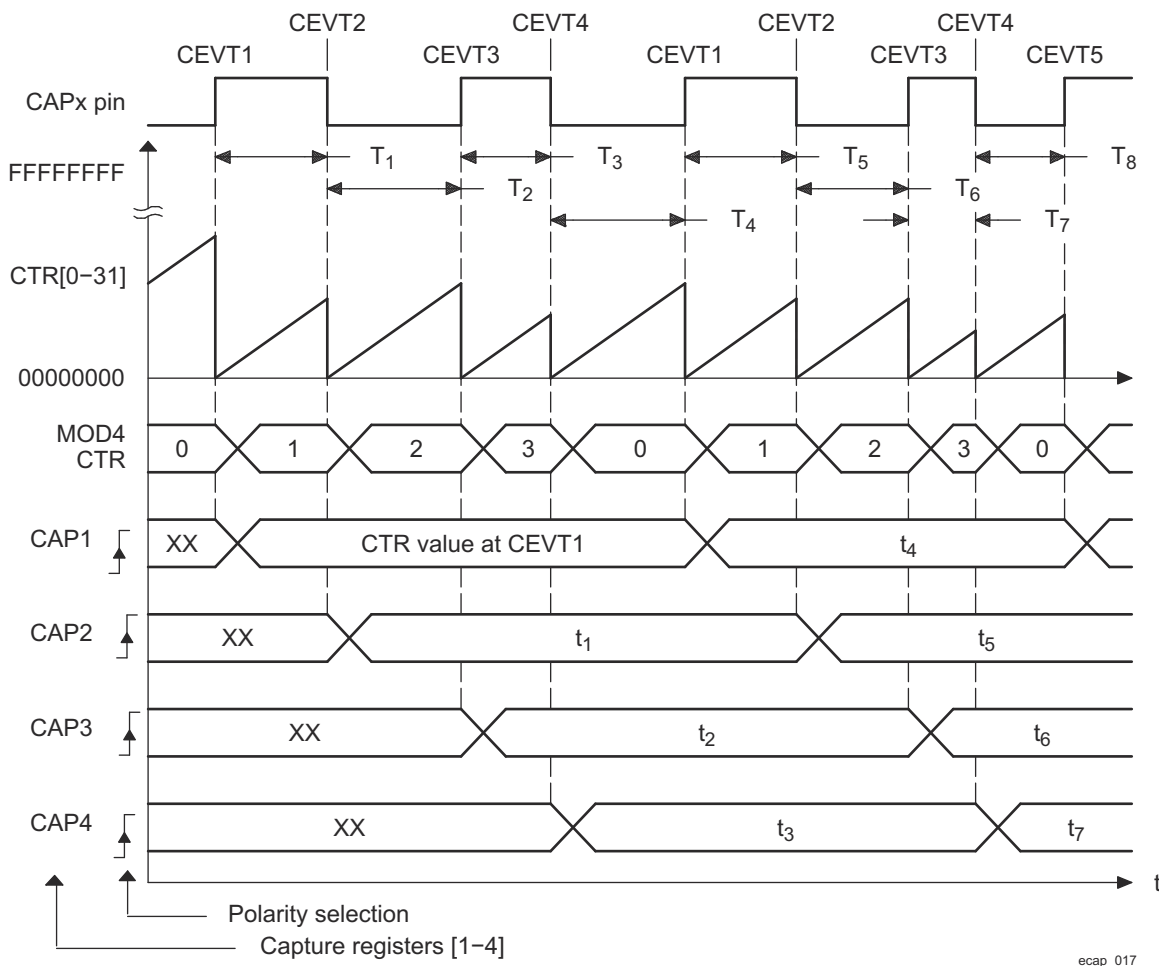

**Example 12-3. Code Snippet for CAP Mode Delta Time, Rising Edge Trigger**

```
// Code snippet for CAP mode Delta Time, Rising edge trigger
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Period value.
Period4 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1
Period1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
Period2 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
Period3 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
```

#### 12.4.1.4.4 Time Difference (Delta) Operation Rising and Falling Edge Trigger Example

In Figure 12-178 the ECAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information: Period1 =  $T_1 + T_2$ , Period2 =  $T_3 + T_4$ , ...etc Duty Cycle1 (on-time %) =  $T_1 / \text{Period1} \times 100\%$ , etc Duty Cycle1 (off-time %) =  $T_2 / \text{Period1} \times 100\%$ , etc.

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, that is, during run-time, only the shadow registers must be used.

**Figure 12-178. Capture Sequence for Delta Mode Time-Stamp, Rising and Falling Edge Detect**

**Table 12-238. ECAP Initialization for CAP Mode Delta Time, Rising and Falling Edge Triggers**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_FALLING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_FALLING
ECCTL1	CTRRST1	EC_DELTA_MODE
ECCTL1	CTRRST2	EC_DELTA_MODE
ECCTL1	CTRRST3	EC_DELTA_MODE
ECCTL1	CTRRST4	EC_DELTA_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-4. Code Snippet for CAP Mode Delta Time, Rising and Falling Edge Triggers**

```
// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Duty cycle values.
DutyOnTime1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
DutyOffTime1 = ECAPxRegs.CAP3;   // Fetch Time-Stamp captured at T3
DutyOnTime2 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
DutyOffTime2 = ECAPxRegs.CAP1;   // Fetch Time-Stamp captured at T1
Period1 = DutyOnTime1 + DutyOffTime1;
Period2 = DutyOnTime2 + DutyOffTime2;
```

#### 12.4.1.4.5 Application of the APWM Mode

##### 12.4.1.4.5.1 Simple PWM Generation (Independent Channel/s) Example

In this example, the ECAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWM $n$ . The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

**Figure 12-179. PWM Waveform Details of APWM Mode Operation**

**Table 12-239. ECAP Initialization for APWM Mode**

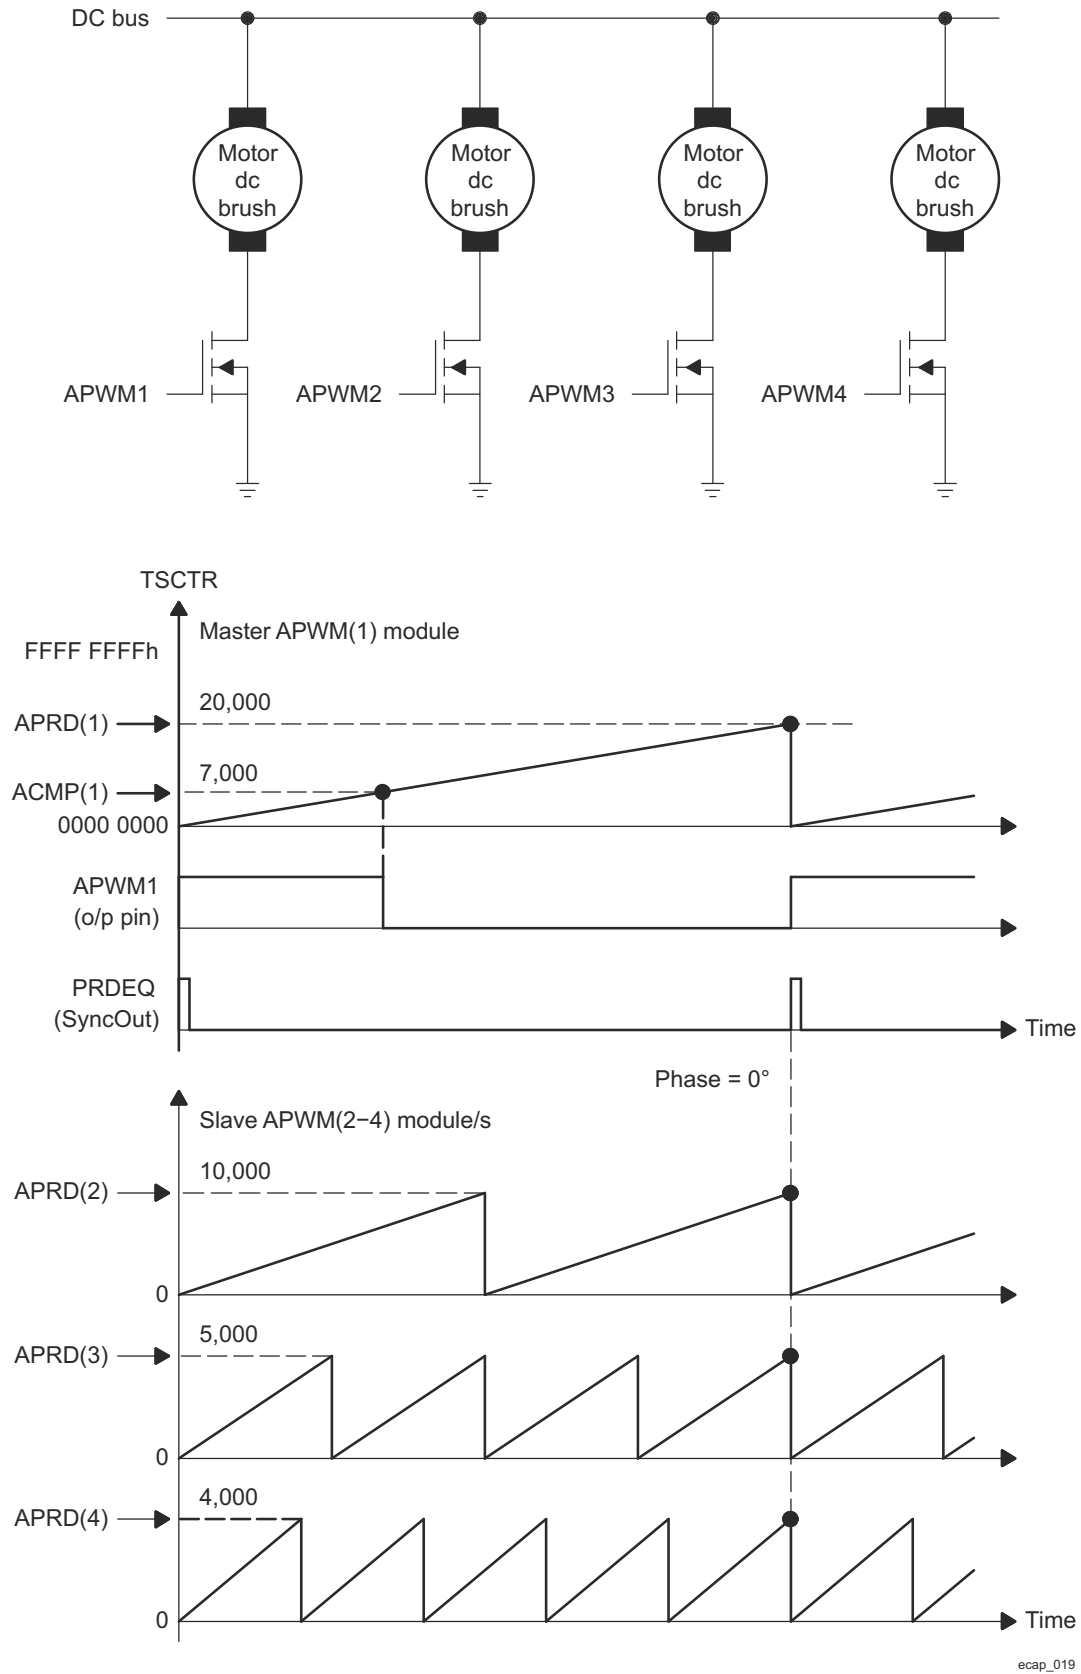

Register	Bit	Value
CAP1	CAP1	0x1000
CTRPHS	CTRPHS	0x0
ECCTL2	CAP_APWM	EC_APWM_MODE
ECCTL2	APWMPOL	EC_ACTV_HI
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-5. Code Snippet for APWM Mode**

```
// Code snippet for APWM mode Example 1
// Run Time (Instant 1, e.g. ISR call)
//=====
ECAPxRegs.CAP2 = 0x300;      // Set Duty cycle i.e. compare value
// Run Time (Instant 2, e.g. another ISR call)
//=====
ECAPxRegs.CAP2 = 0x500;      // Set Duty cycle i.e. compare value
```

**12.4.1.4.5.2 Multichannel PWM Generation with Synchronization Example**

Figure 12-180 takes advantage of the synchronization feature between the ECAP modules. Here 4 independent PWM channels are required with different frequencies, but at integer multiples of each other to avoid "beat" frequencies. Hence one ECAP module is configured as the Master and the remaining 3 are Slaves all receiving their synch pulse (CTR = PRD) from the master. Note the Master is chosen to have the lower frequency ( $F_1 = 1/20,000$ ) requirement. Here Slave2 Freq =  $2 \times F_1$ , Slave3 Freq =  $4 \times F_1$  and Slave4 Freq =  $5 \times F_1$ . Note here values are in decimal notation. Also, only the APWM1 output waveform is shown.

**Figure 12-180. Multichannel PWM Example Using 4 ECAP Modules**

**Example 12-6. Code Snippet for Multichannel PWM Generation with Synchronization**

```
// Code snippet for APWM mode Example 2
// Run Time (Note: Example execution of one run-time instant)
//=====
ECAP1Regs.CAP2 = 7000;    // Set Duty cycle i.e., compare value = 7000
ECAP2Regs.CAP2 = 2000;    // Set Duty cycle i.e., compare value = 2000
ECAP3Regs.CAP2 = 550;     // Set Duty cycle i.e., compare value = 550
ECAP4Regs.CAP2 = 6500;    // Set Duty cycle i.e., compare value = 6500
```

#### 12.4.1.4.5.3 Multichannel PWM Generation with Phase Control Example

In [Figure 12-181](#), the Phase control feature of the APWM mode is used to control a 3 phase Interleaved DC/DC converter topology. This topology requires each phase to be off-set by  $120^\circ$  from each other. Hence if "Leg" 1 (controlled by APWM1) is the reference Leg (or phase), that is,  $0^\circ$ , then Leg 2 need  $120^\circ$  off-set and Leg 3 needs  $240^\circ$  off-set. The waveforms in [Figure 12-181](#) show the timing relationship between each of the phases (Legs). Note ECAP1 module is the Master and issues a SyncOut pulse to the slaves (modules 2, 3) whenever TSCTR = Period value.

**Figure 12-181. Multiphase (channel) Interleaved PWM Example Using 3 ECAP Modules**

**Example 12-7. Code Snippet for Multichannel PWM Generation with Phase Control**

```
// Code snippet for APWM mode Example 3
// Run Time (Note: Example execution of one run-time instant)
//=====
// All phases are set to the same duty cycle
ECAP1Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP2Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP3Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
```

## 12.4.2 Enhanced Pulse Width Modulation (EPWM) Module

This chapter describes the Enhanced PWM (EPWM) module in the device.

### 12.4.2.1 EPWM Overview

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The EPWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the EPWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In the further description the letter x within a signal or module name is used to indicate a generic EPWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the EPWMx

instance. Thus, EPWM1A and EPWM1B belong to EPWM1, EPWM2A and EPWM2B belong to EPWM2, and so forth.

The EPWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. A given EPWM module functionality can be extended with the so called **High-Resolution Pulse Width Modulator**. Refer to the *EPWM Integration*, to determine which EPWM instances include the HRPWM feature. The HRPWM functionalities are described in [Section 12.4.2.3.9](#).

As also described in *Daisy-Chain Connectivity between EPWM Modules*, the EPWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, the EPWM integration allows this synchronization scheme to be extended to the capture peripheral modules (ECAP). The number of modules is device-dependent and based on target application needs. Modules can also operate stand-alone.

The device has six instances of the EPWM modules.

#### 12.4.2.1.1 EPWM Features

Each EPWM module supports the following features:

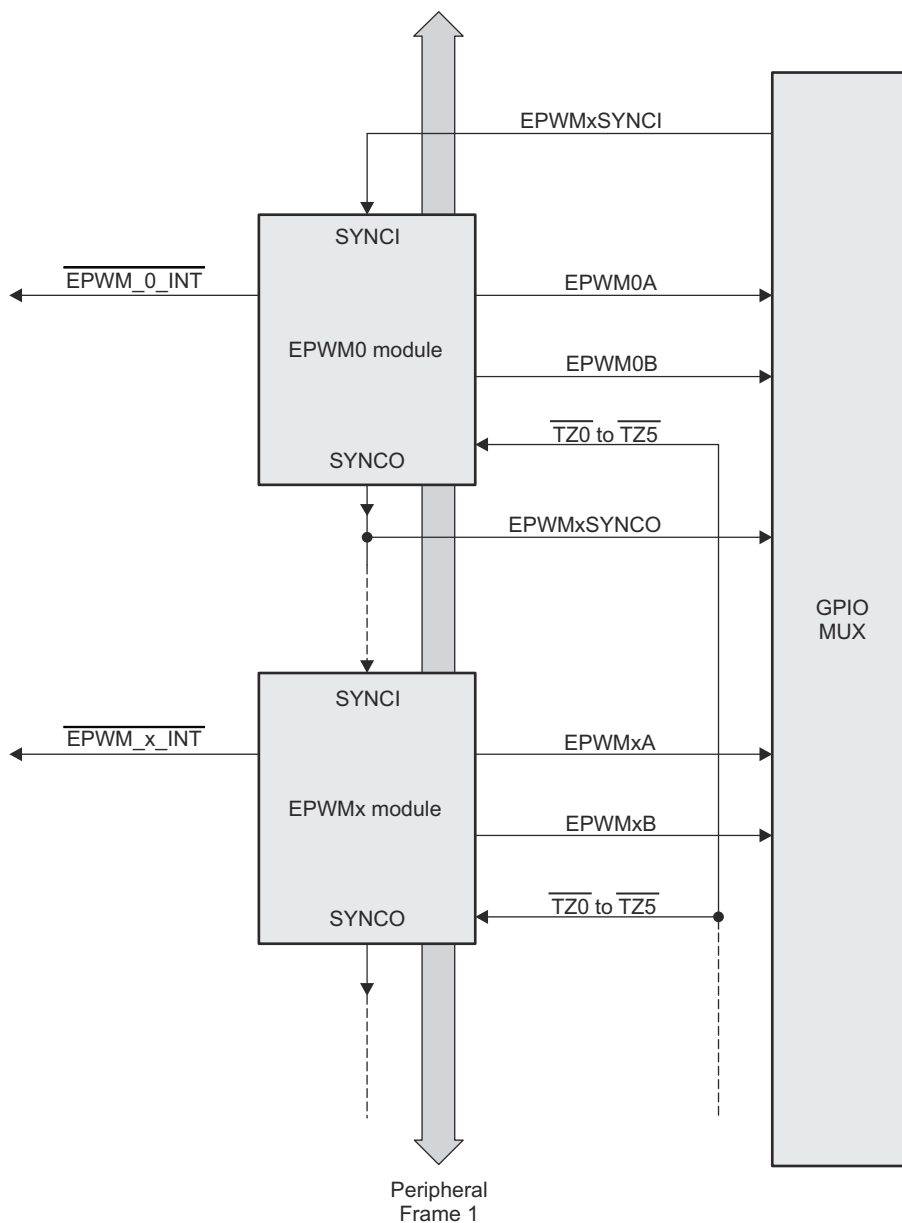

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software
- Programmable phase-control support for lag or lead operation relative to other EPWM modules
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs
- Allows events to trigger both CPU interrupts and ADC start of conversions
- Programmable event prescaling minimizes CPU overhead on interrupts
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives
- High-resolution module with programmable delay line:
  - Programmable on a per PWM period basis
  - Can be inserted either on the rising edge or falling edge of the PWM pulse or both or not at all.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

Each EPWM module is connected to the input/output signals shown in [Figure 12-182](#). The signals are described in detail in subsequent sections.

The order in which the EPWM modules are connected may differ from what is shown in [Figure 12-182](#). See *Daisy-Chain Connectivity between EPWM Modules* for the actual synchronization scheme implemented in the device. Each EPWM module consists of eight submodules and is connected within a system via the signals shown in [Figure 12-183](#).

epwm-001

**Figure 12-182. Multiple EPWM Modules**

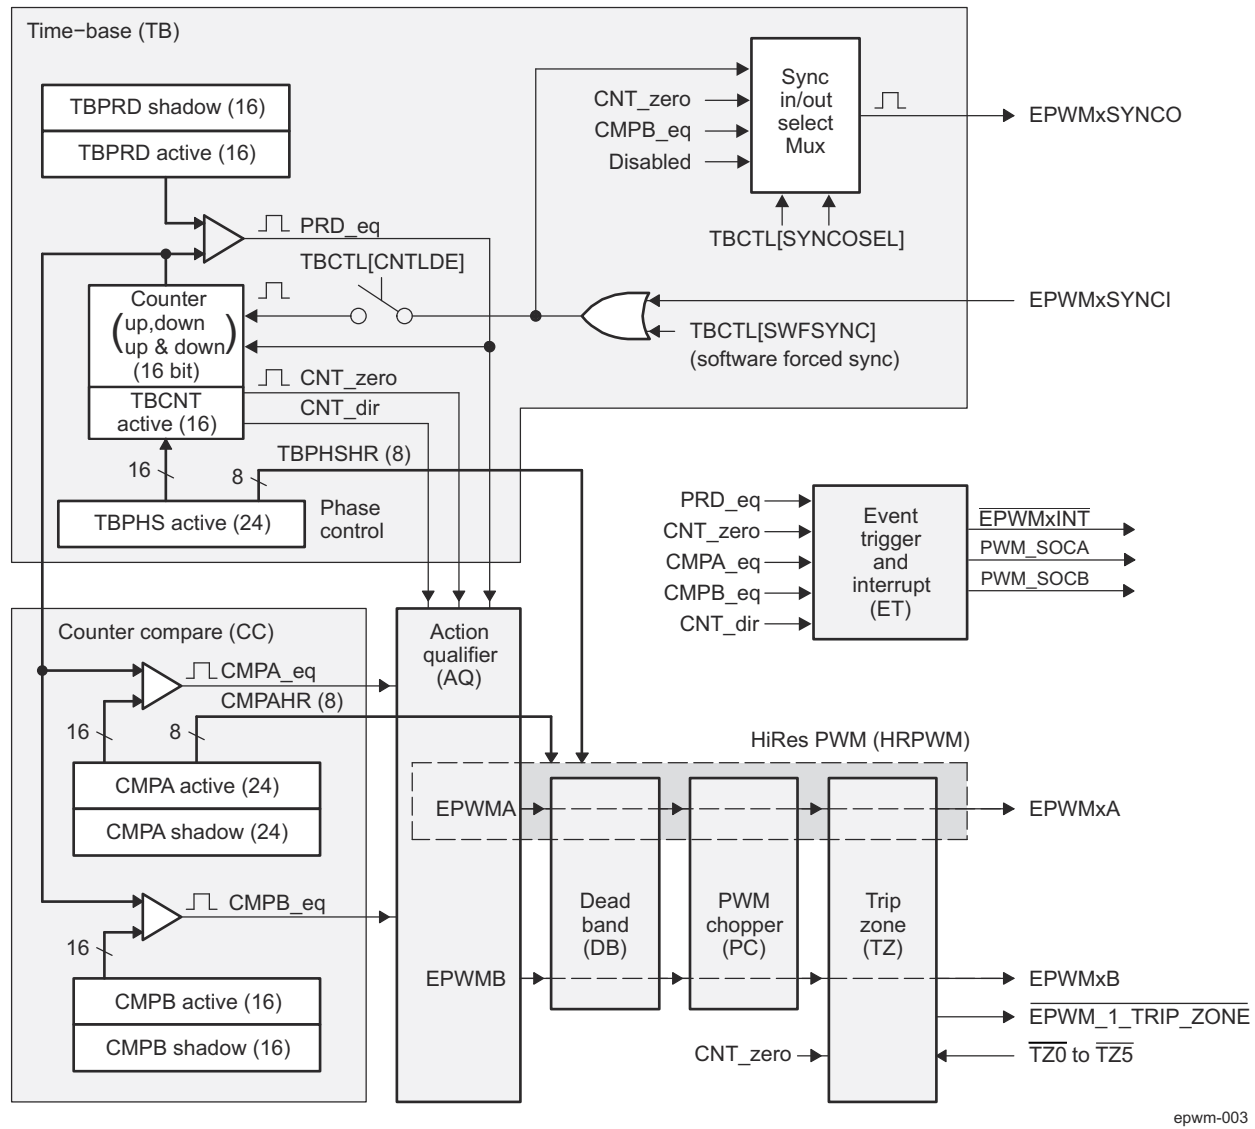

epwm-002

**Figure 12-183. Submodules and Signal Connections for an EPWM Module**

Figure 12-184 shows more internal details of a single EPWM module. The main signals used by the EPWM module are:

- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for the device.
- **Trip-zone signals (TZ0 to TZ5).** These input signals alert the EPWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral.
- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the EPWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins for EPWM0 (EPWM module 0) and EPWM3. The EPWM5 synchronization output (EPWM5SYNCO) is also connected to the input SYNCIN of the Enhanced Capture Module (ECAP0).
- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).** Each EPWM module has two ADC start of conversion signals (one for each sequencer). Any EPWM module can trigger a start of conversion for either sequencer. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the EPWM.
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the EPWM register file.

Figure 12-184 also shows the key internal submodule interconnect signals. Each submodule is described in Section 12.4.2.3.

### 12.4.2.3 EPWM Functional Description

8 submodules are included in each EPWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

#### 12.4.2.3.1 EPWM Submodule Features

Table 12-250 lists the eight key submodules together with a list of their main configuration parameters.

**Table 12-250. Submodule Configuration Parameters**

Submodule	Configuration Parameter or Option
Time-base (TB)	<ul style="list-style-type: none"> <li>Scale the time-base clock (TBCLK) relative to the system clock (FICLK).</li> <li>Configure the PWM time-base counter (TBCNT) frequency or period.</li> <li>Time-base counter mode selection: <ul style="list-style-type: none"> <li>count-up mode: used for asymmetric PWM</li> <li>count-down mode: used for asymmetric PWM</li> <li>count-up-and-down mode: used for symmetric PWM</li> </ul> </li> <li>Configure the time-base phase relative to another EPWM module.</li> <li>Synchronize the time-base counter between modules through hardware or software.</li> <li>Configure the direction (up or down) of the time-base counter after a synchronization event.</li> <li>Configure how the time-base counter will behave when the device is halted by an emulator.</li> <li>Specify the source for the synchronization output of the EPWM module: <ul style="list-style-type: none"> <li>Synchronization input signal</li> <li>Time-base counter equal to zero</li> <li>Time-base counter equal to counter-compare B (CMPB)</li> <li>No output synchronization signal generated</li> </ul> </li> </ul>
Counter-compare (CC)	<ul style="list-style-type: none"> <li>Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB</li> <li>Specify the time at which switching events occur on the EPWMxA or EPWMxB output</li> </ul>
Action-qualifier (AQ)	<ul style="list-style-type: none"> <li>Specify the type of action taken when a time-base or counter-compare submodule event occurs: <ul style="list-style-type: none"> <li>No action taken</li> <li>Output EPWMxA and/or EPWMxB switched high</li> <li>Output EPWMxA and/or EPWMxB switched low</li> <li>Output EPWMxA and/or EPWMxB toggled</li> </ul> </li> <li>Force the PWM output state through software control</li> <li>Configure and control the PWM dead-band through software</li> </ul>
Dead-band (DB)	<ul style="list-style-type: none"> <li>Control of traditional complementary dead-band relationship between upper and lower switches</li> <li>Specify the output rising-edge-delay value</li> <li>Specify the output falling-edge delay value</li> <li>Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification</li> </ul>
PWM-chopper (PC)	<ul style="list-style-type: none"> <li>Create a chopping (carrier) frequency</li> <li>Pulse width of the first pulse in the chopped pulse train</li> <li>Duty cycle of the second and subsequent pulses</li> <li>Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.</li> </ul>

**Table 12-250. Submodule Configuration Parameters (continued)**

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	<ul style="list-style-type: none"> <li>Configure the EPWM module to react to one, all, or none of the trip-zone pins</li> <li>Specify the tripping action taken when a fault occurs: <ul style="list-style-type: none"> <li>Force EPWMxA and/or EPWMxB high</li> <li>Force EPWMxA and/or EPWMxB low</li> <li>Force EPWMxA and/or EPWMxB to a high-impedance state</li> <li>Configure EPWMxA and/or EPWMxB to ignore any trip condition</li> </ul> </li> <li>Configure how often the EPWM will react to the trip-zone pin: <ul style="list-style-type: none"> <li>One-shot</li> <li>Cycle-by-cycle</li> </ul> </li> <li>Enable the trip-zone to initiate an interrupt</li> <li>Bypass the trip-zone module entirely</li> </ul>
Event-trigger (ET)	<ul style="list-style-type: none"> <li>Enable the EPWM events that will trigger an interrupt.</li> <li>Specify the rate at which events cause triggers (every occurrence or every second or third occurrence)</li> <li>Poll, set, or clear event flags</li> </ul>
High-Resolution PWM (HRPWM)	<ul style="list-style-type: none"> <li>Enable extended time resolution capabilities</li> <li>Configure finer time granularity control or edge positioning</li> </ul>

Some examples on various EPWM module configurations are shown below. These examples use the constant definitions shown in [Example 12-8](#).

## Constant Definitions Used in the EPWM Code Examples

```
// TBCTL (Time-Base Control)

```

### 12.4.2.3.2 EPWM Time-Base (TB) Submodule

This section describes the Time-Base (TB) submodule in the PWM module.

#### 12.4.2.3.2.1 Overview

Each EPWM module has its own time-base submodule that determines all of the timing events. Built-in synchronization logic allows the time-base of multiple EPWM modules (EPWMx) to work together as a single system. [Figure 12-185](#) illustrates the time-base module's place within the EPWM.

**Figure 12-185. EPWM Time-Base Submodule**

The TB module generates the period (or frequency) of the PWM output waveforms and consists of a 16-bit counter that can be configured for up, down or up and down counting. The time base for the counter is a pre-scaled version of the system clock (FICLK/n) which can be programmed for a pre-scale of 1, that is same as system clock.

TB module features:

- Specify the EPWMx time-base counter (TBCNT) frequency or period in the EPWM\_TBCNT register to control how often events occur.
- Manage time-base synchronization with other EPWMx modules.
- Maintain a phase relationship with other EPWMx modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - PRD\_eq (Time-base counter (EPWM\_TBCNT register) equal to the specified period in EPWM\_TBPRD register (that is TBCNT = TBPRD)).
  - CNT\_zero (Time-base counter equal to zero (TBCNT = 0000h)).
- Configure the rate of the time-base clock; a prescaled version of the CPU m clock (FICLK). This allows the time-base counter to increment/decrement at a slower rate.

#### 12.4.2.3.2.2 Controlling and Monitoring the EPWM Time-Base Submodule

[Table 12-251](#) lists the registers used to control and monitor the time-base submodule.

**Table 12-251. EPWM Time-Base Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCTL	Time-Base Control Register	0h	No
EPWM_TBSTS	Time-Base Status Register	2h	No
HRPWM_TBPHSHR	HRPWM extension Phase Register <sup>(1)</sup>	4h	No
EPWM_TBPHS	Time-Base Phase Register	6h	No

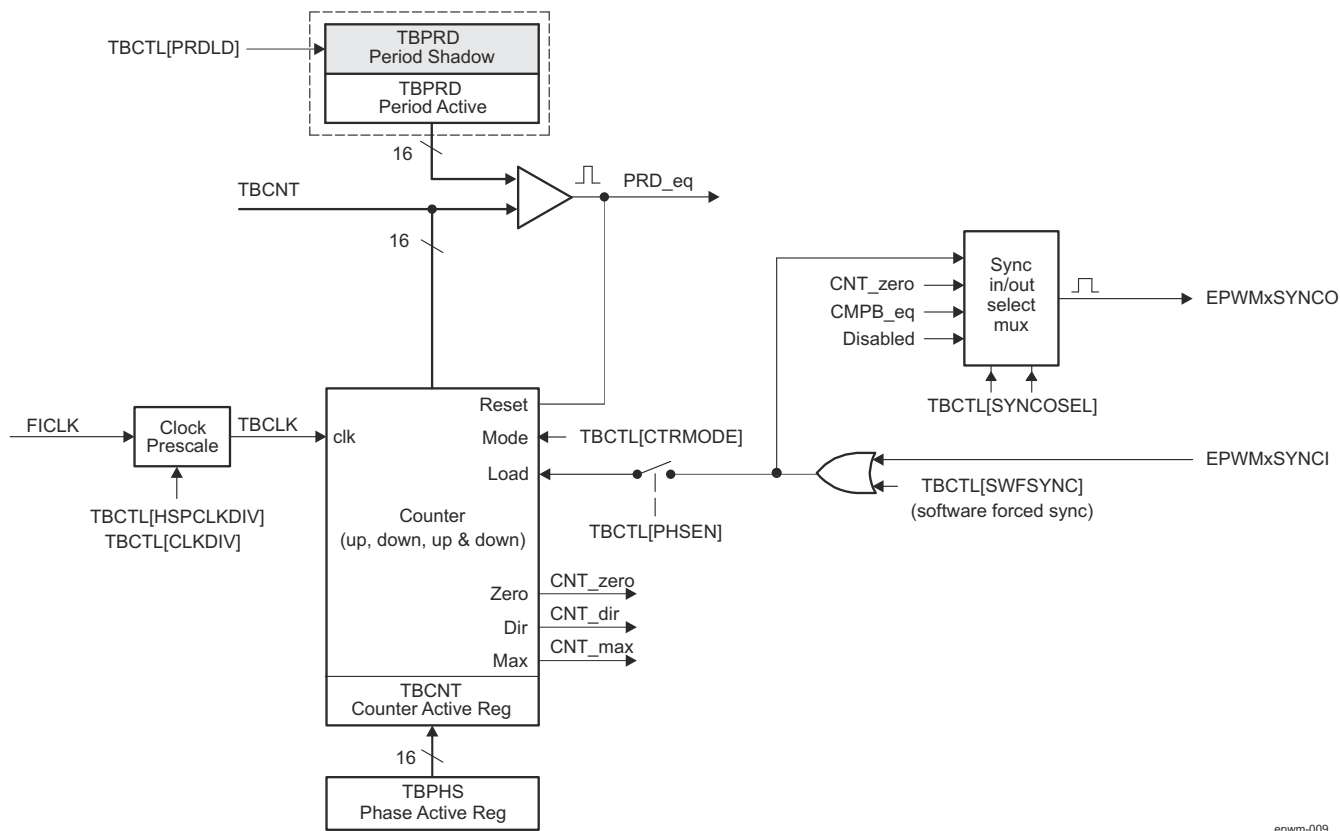

**Table 12-251. EPWM Time-Base Submodule Registers (continued)**

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCNT	Time-Base Counter Register	8h	No
EPWM_TBPRD	Time-Base Period Register	Ah	Yes

- (1) This register is available only on EPWM instances that include the high-resolution extension (HRPWM). On EPWM modules that do not include the HRPWM, this location is reserved. See *EPWM Integration* to determine which EPWM instances include this feature.

Figure 12-186 shows the critical signals and registers of the time-base submodule. Table 12-252 provides descriptions of the key signals associated with the time-base submodule.

### Figure 12-186. EPWM Time-Base Submodule Signals and Registers

### Table 12-252. EPWM Time-Base Submodule Key Signals

Signal	Description
EPWMxSYNCl	<p>Time-base synchronization input.</p> <p>Input pulse used to synchronize the time-base counter with the counter of another EPWM module earlier in the synchronization chain. An EPWM peripheral can be configured to use or ignore this signal. For the first EPWM module (EPWM0) this signal comes from a device pin. For subsequent EPWM modules this signal is passed from another EPWM peripheral. For example, EPWM2SYNCl is generated by the EPWM1 peripheral and the EPWM3SYNCl is generated (optional through internal multiplexer) by EPWM2 or from a device pin. See <a href="#">Section 12.4.2.3.2.3.2</a> for information on the synchronization order of a particular device.</p>
EPWMxSYNCO	<p>Time-base synchronization output.</p> <p>This output pulse is used to synchronize the counter of an EPWM module later in the synchronization chain. The EPWM module generates this signal from one of three event sources:</p> <ol style="list-style-type: none"> <li>1. EPWMxSYNCl (Synchronization input pulse)</li> <li>2. TBCNT = 0: The time-base counter (EPWM_TBCNT register) equal to zero (TBCNT = 0000h).</li> <li>3. TBCNT = CMPB: The time-base counter (EPWM_TBCNT register) equal to the counter-compare B register — EPWM_CMPB (that is bitfield TBCNT = bitfield CMPB).</li> </ol>

**Table 12-252. EPWM Time-Base Submodule Key Signals (continued)**

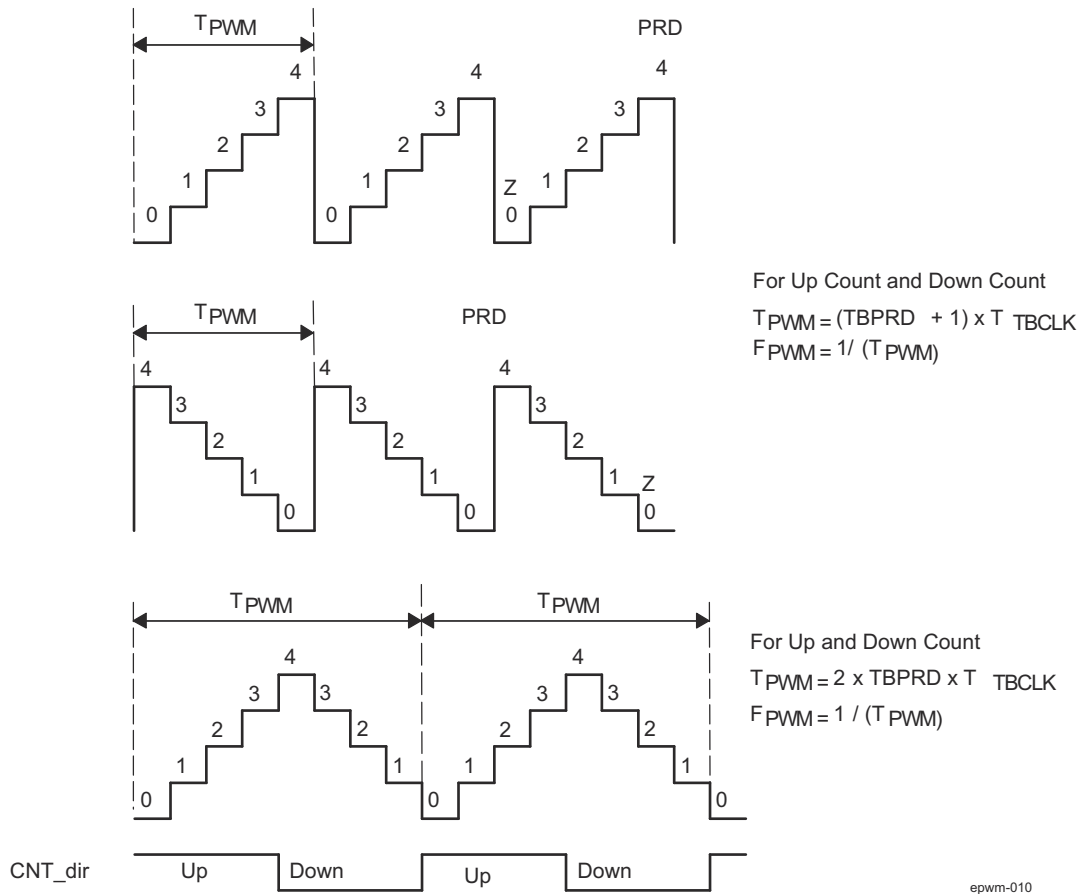

Signal	Description
PRD_eq	Time-base counter equal to the specified period.  This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.
CNT_zero	Time-base counter equal to zero.  This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.
CMPB_eq	Time-base counter equal to active counter-compare B register (TBCNT = CMPB).  This event is generated by the counter-compare submodule and used by the synchronization out logic.
CNT_dir	Time-base counter direction.  Indicates the current direction of the EPWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CNT_max	Time-base counter equal max value (TBCNT = FFFFh).  Generated event when the EPWM_TBCNT register value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock.  This is a prescaled version of the system clock — FICLK and is used by all submodules within the EPWMn. This clock determines the rate at which time-base counter increments or decrements.

#### 12.4.2.3.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period register (EPWM\_TBPRD) and the mode of the time-base counter. [Figure 12-187](#) shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (EPWM\_TBPRD[15-0] TBPRD = 0x4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (FICLK).

The time-base counter has three modes of operation selected by the time-base control register (EPWM\_TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset back to the period value and it repeats this pattern.

**Figure 12-187. EPWM Time-Base Frequency and Period**

#### 12.4.2.3.2.3.1 EPWM Time-Base Period Shadow Register

The time-base period register (EPWM\_TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the EPWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the EPWM\_TBCTL[3] PRDL D bit. This bit enables and disables the EPWM\_TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The EPWM\_TBPRD shadow register is enabled when EPWM\_TBCTL[3] PRDL D = 0h. Reads from and writes to the EPWM\_TBPRD register memory address go to the shadow register. The shadow register contents are transferred to the active register (EPWM\_TBPRD (Active) ← EPWM\_TBPRD (shadow)) when the time-base counter register (EPWM\_TBCNT) equals zero (TBCNT = 0000h). By default the EPWM\_TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (EPWM\_TBCTL[3] PRDL D = 1h), then a read from or a write to the TBPRD memory address goes directly to the active register.

#### 12.4.2.3.2.3.2 EPWM Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the EPWM modules on a device. Each EPWM module has a synchronization input (EPWMxSYNCl) and a synchronization output (EPWMxSYNCO). The input

synchronization for the first instance (EPWM0) comes from an external pin. For the device EPWM environment sync pin details refer to *EPWM Environment*. The possible synchronization connections for the remaining EPWM modules is shown in Figure 12-188.

epwm-011

**Figure 12-188. EPWM Time-Base Counter Synchronization Scheme 1**

Each EPWM module can be configured to use or ignore the synchronization input. If the EPWM\_TBCTL[2] PHSEN bit is set, then the time-base counter (TBCNT) of the EPWM module (EPWM\_TBCNT register) will be automatically loaded with the phase register (EPWM\_TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (EPWM\_TBPHS → EPWM\_TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1h to the EPWM\_TBCTL[6] SWFSYNC control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

This feature enables the EPWM module to be automatically synchronized to the time base of another EPWM module. Lead or lag phase control can be added to the waveforms generated by different EPWM modules to synchronize them. In up-down-count mode, the EPWM\_TBCTL[13] PHSDIR bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See Figure 12-189 through Figure 12-192 for examples.

Clearing the EPWM\_TBCTL[2] PHSEN bit configures the EPWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other EPWM modules. In this way, a controller time-base (for example, EPWM1) and downstream modules (EPWM2–EPWMx) can be set and they may select to run in synchronization with the controller.

#### 12.4.2.3.2.4 Phase Locking the Time-Base Clocks of Multiple EPWM Modules

As already described in *EPWM Modules Time-Base Clock Gating*, TB\_CLKEN bit in the EPWMn\_CTRL (where n = 0 to 5) register of the device CTRL\_MMR0 can be used to individually control or globally synchronize the time-base clocks of all enabled EPWM modules on a device. When all TB\_CLKEN bits are set to 0b0, the time-base clocks of all EPWMx (where x = 0 to 5) modules are stopped (default). When all TB\_CLKEN bits are simultaneously set in software to 0b1, all EPWMx modules time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the EPWM\_TBCTL register of each EPWM module must be set identically. The proper procedure for enabling the EPWM clocks is as follows:

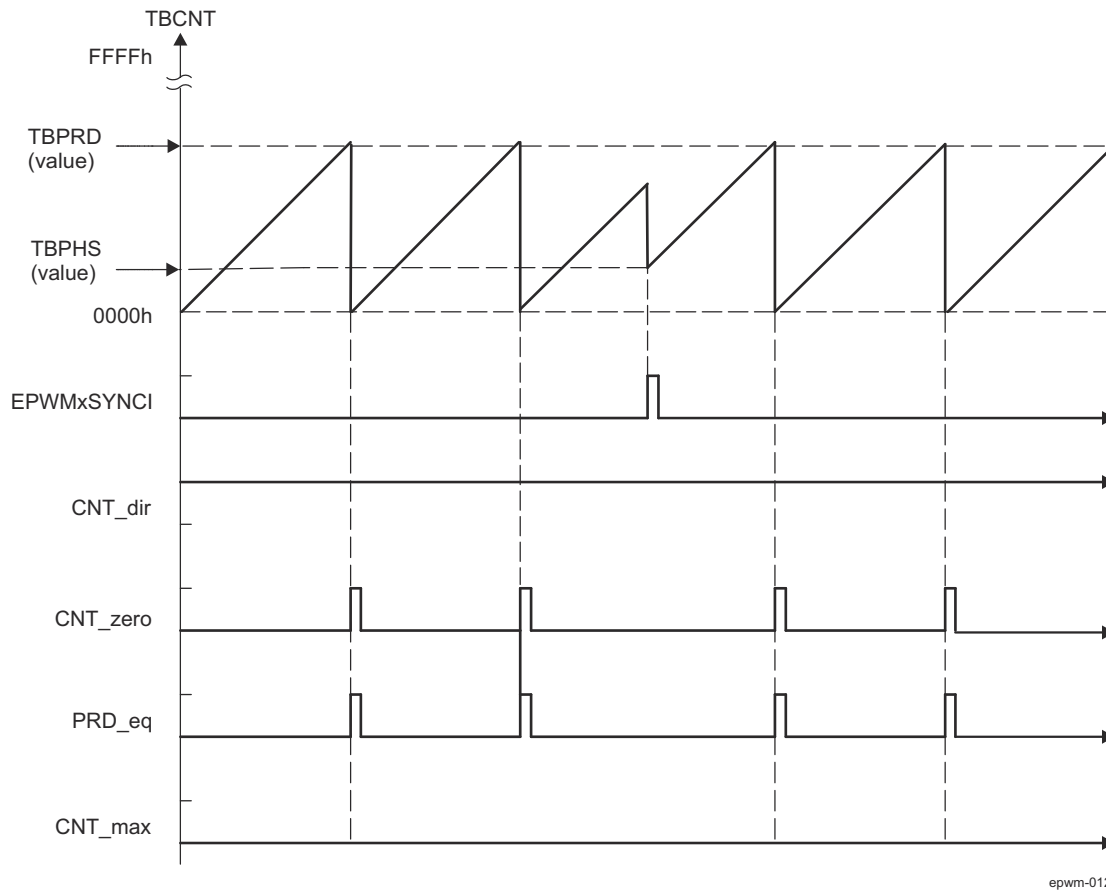

1. Enable the EPWM module clocks.
2. Set TB\_CLKEN = 0. This will stop the time-base clock within any enabled EPWMx module.
3. Configure the prescaler values and desired EPWM modes per each involved EPWMx.
4. Simultaneously set TB\_CLKEN bits to 0b1.

#### 12.4.2.3.2.5 EPWM Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, [Figure 12-189](#) to [Figure 12-192](#) show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

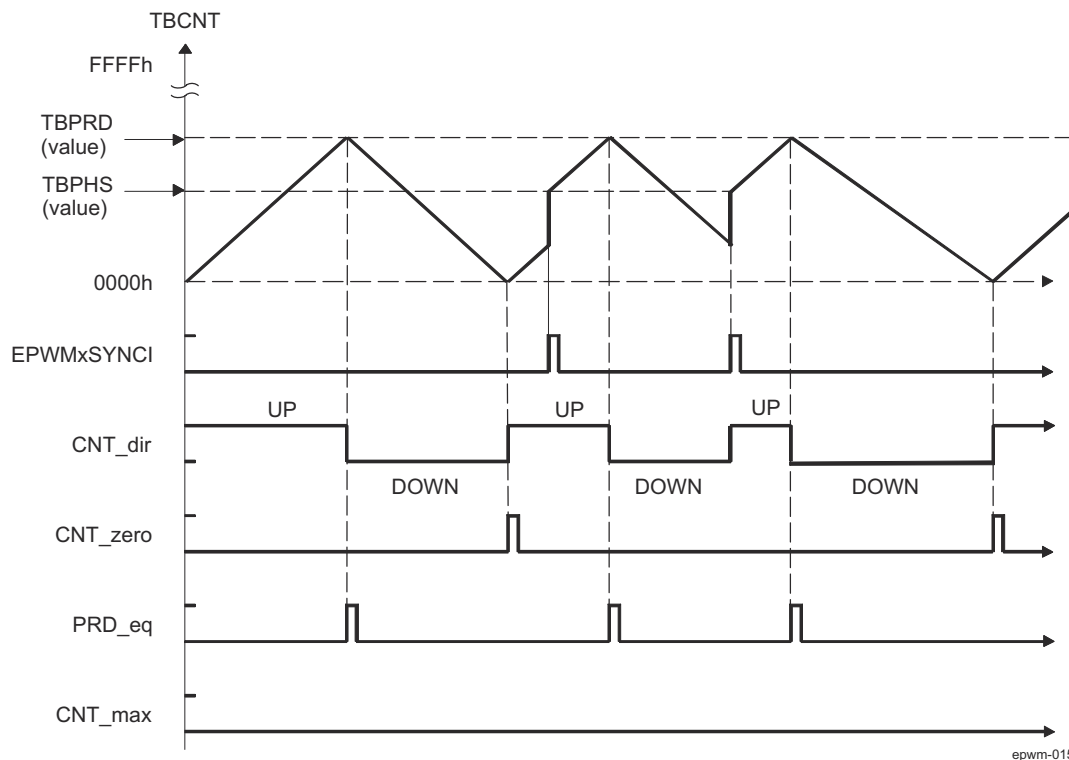

**Figure 12-189. EPWM Time-Base Up-Count Mode Waveforms**

**Figure 12-190. EPWM Time-Base Down-Count Mode Waveforms**

**Figure 12-191. EPWM Time-Base Up-Down-Count Waveforms, EPWM\_TBCTL[13] PHSDIR = 0 Count Down on Synchronization Event**

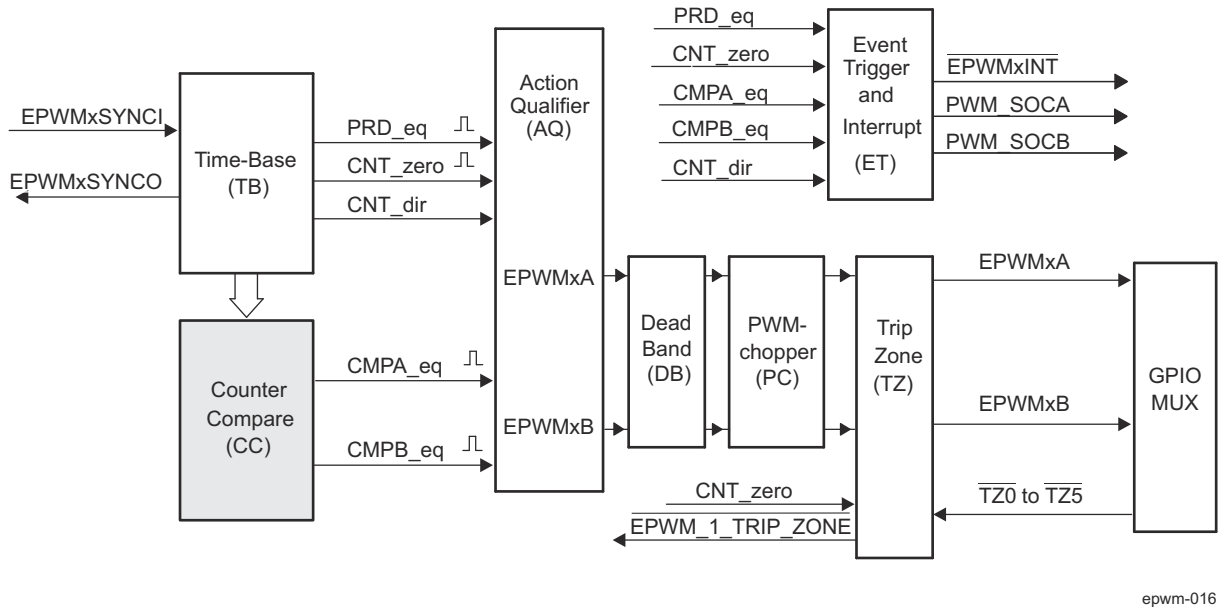

**Figure 12-192. EPWM Time-Base Up-Down Count Waveforms, EPWM\_TBCTL[13] PHSDIR = 1 Count Up on Synchronization Event**

### 12.4.2.3.3 EPWM Counter-Compare (CC) Submodule

This section describes the Counter-Compare (CC) submodule in the PWM module.

#### 12.4.2.3.3.1 Overview

Figure 12-193 illustrates the counter-compare submodule within the EPWM. Figure 12-194 shows the basic structure of the counter-compare submodule.

**Figure 12-193. EPWM Counter-Compare Submodule**

CC module features:

- Generates events based on programmable time stamps using the EPWM\_CMPA and EPWM\_CMPB registers
  - CMPA\_eq (Time-base counter equals counter-compare A register (TBCNT = CMPA)).
  - CMPB\_eq (Time-base counter equals counter-compare B register (TBCNT = CMPB)).
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle.

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (EPWM\_CMPA) and counter-compare B (EPWM\_CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

#### 12.4.2.3.3.2 Controlling and Monitoring the EPWM Counter-Compare Submodule

Table 12-253 lists the registers used to control and monitor the counter-compare submodule. Table 12-254 lists the key signals associated with the counter-compare submodule.

**Table 12-253. EPWM Counter-Compare Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_CMPCTL	Counter-Compare Control Register.	Eh	No
HRPWM_CMPAHR	HRPWM Counter-Compare A Extension Register <sup>(1)</sup>	10h	Yes
EPWM_CMPA	Counter-Compare A Register	12h	Yes
EPWM_CMPB	Counter-Compare B Register	14h	Yes

(1) This register is available only on the EPWM modules with the high-resolution extension (HRPWM). On the EPWM modules that do not include the HRPWM, this location is reserved. See *EPWM Integration* to determine which EPWM instances include this feature.

epwm-017

**Figure 12-194. EPWM Counter-Compare Submodule Signals and Registers**

**Table 12-254. EPWM Counter-Compare Submodule Key Signals**

Signal	Description of Event	Register Bitfields Compared
CMPA_eq	Time-base counter equal to the active counter-compare A value	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the active counter-compare B value	TBCNT = CMPB
PRD_eq	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCNT = 0000h

#### 12.4.2.3.3.3 Operational Highlights for the EPWM Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CMPA: Time-base counter equal to counter-compare A register (EPWM\_TBCNT = EPWM\_CMPA).
2. CMPB: Time-base counter equal to counter-compare B register (EPWM\_TBCNT = EPWM\_CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 12.4.2.3.4](#) for more details.

The counter-compare EPWM\_CMPA and EPWM\_CMPB registers each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the EPWM\_CMPCTL[4] SHDWAMODE and EPWM\_CMPCTL[6] SHDWBMODE bits. These bits enable and disable the EPWM\_CMPA shadow register and EPWM\_CMPB shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Load Mode:**

The shadow mode for the EPWM\_CMPA register is enabled by clearing the EPWM\_CMPCTL[4] SHDWAMODE bit and the shadow register for EPWM\_CMPB register is enabled by clearing the EPWM\_CMPCTL[6] SHDWBMODE bit. Shadow mode is enabled by default for both EPWM\_CMPA and EPWM\_CMPB register.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:

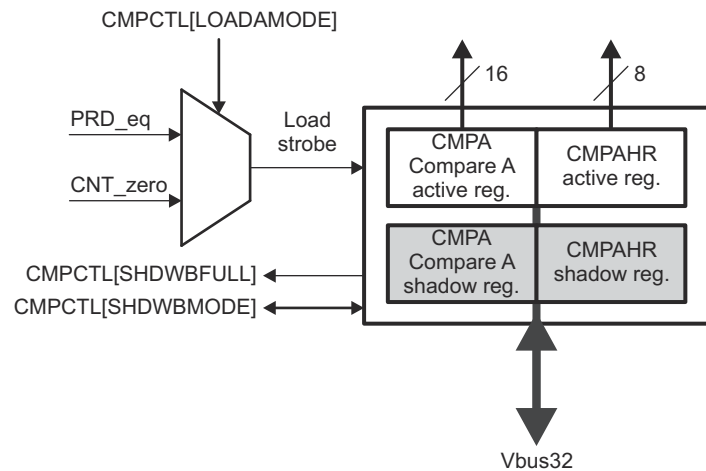

- PRD\_eq: Time-base counter equal to the period (TBCNT = TBPRD).
- CNT\_zero: Time-base counter equal to zero (TBCNT = 0000h)
- Both PRD\_eq and CNT\_zero events occurrence

Which of these three events will drive the counter compare module is specified by the EPWM\_CMPCTL[1-0] LOADAMODE and EPWM\_CMPCTL[3-2] LOADBMODE register bit fields. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

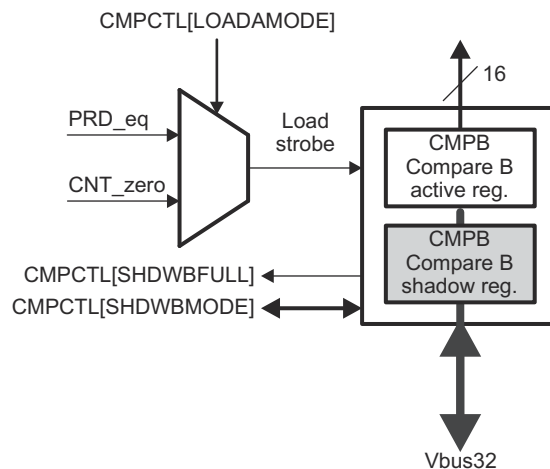

- **Immediate Load Mode:**

If immediate load mode is selected (EPWM\_CMPCTL[4] SHDWAMODE = 1h or EPWM\_CMPCTL[6] SHDWBMODE = 1h), then a read from or a write to the register will go directly to the active register.

[Figure 12-195](#) and [Figure 12-196](#) show Compare A and B Dual Shadow registers.

epwm-050

**Figure 12-195. Compare A Dual Shadow register**

epwm-051

**Figure 12-196. Compare B Dual Shadow register****Note**

In HRPWM mode the user must perform a single 32-bit write access to both the HRPWM\_CMPAHR and EPWM\_CMPA registers. Two 16-bit accesses are not allowed.

**12.4.2.3.3.4 EPWM Counter-Compare Submodule Timing Waveforms**

As described in [Section 12.4.2.3.2](#), the Time Base (TB) module can be configured to operate in 3 distinct count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

The timing diagrams in [Figure 12-197](#) to [Figure 12-200](#) show how CMPA and CMPB events are generated in each of the 3 count modes and how the EPWMxSYNCI signal interacts.

An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 12-197. EPWM Counter-Compare Event Waveforms in Up-Count Mode**

**Figure 12-198. EPWM Counter-Compare Events in Down-Count Mode**

**Figure 12-199. EPWM Counter-Compare Events in Up-Down-Count Mode,  $EPWM\_TBCTL[13] \text{ PHSDIR} = 0$  Count Down on Synchronization Event**

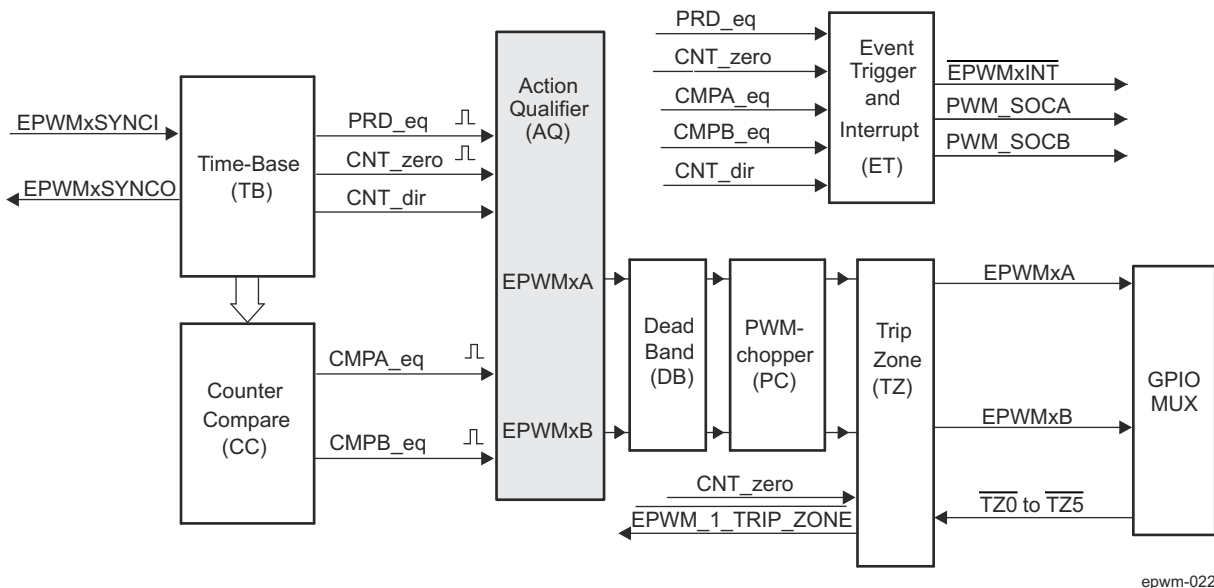

**Figure 12-200. EPWM Counter-Compare Events in Up-Down-Count Mode,  $EPWM\_TBCTL[13] \text{ PHSDIR} = 1$  Count Up on Synchronization Event**

#### 12.4.2.3.4 EPWM Action-Qualifier (AQ) Submodule

This section describes the Action-Qualifier (AQ) submodule in the PWM module.

##### 12.4.2.3.4.1 Overview

Figure 12-201 shows the action-qualifier (AQ) submodule in the EPWM system. This submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

**Figure 12-201. EPWM Action-Qualifier Submodule**

AQ module features:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - PRD\_eq: Time-base counter equal to the period (TBCNT = TBPRD)
  - CNT\_zero: Time-base counter equal to zero (TBCNT = 0000h)
  - CMPA\_eq: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
  - CMPB\_eq: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

##### 12.4.2.3.4.2 Controlling and Monitoring the EPWM Action-Qualifier Submodule

Table 12-255 lists the registers used to control and monitor the action-qualifier submodule.

**Table 12-255. EPWM Action-Qualifier Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_AQCTLA	Action-Qualifier Control Register For Output A (EPWMxA)	16h	No
EPWM_AQCTLB	Action-Qualifier Control Register For Output B (EPWMxB)	18h	No
EPWM_AQSFRC	Action-Qualifier Software Force Register	1Ah	No
EPWM_AQCSFRC	Action-Qualifier Continuous Software Force	1Ch	Yes

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers as shown in Figure 12-202. The possible input events are summarized again in Table 12-256.

**Figure 12-202. EPWM Action-Qualifier Submodule Inputs and Outputs**

**Table 12-256. EPWM Action-Qualifier Submodule Possible Input Events**

Signal	Description	Register Bitfield Compared
PRD_eq	Time-base counter equal to the period value	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero	TBCNT = 0000h
CMPA_eq	Time-base counter equal to the counter-compare A	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the counter-compare B	TBCNT = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by EPWM\_AQSFRC and EPWM\_AQCSFRC registers.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts. See the Event\_Trigger (ET) submodule description in [Section 12.4.2.3.8](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 12-203](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
<div>SW</div> <div>×</div>	<div>Z</div> <div>×</div>	<div>CA</div> <div>×</div>	<div>CB</div> <div>×</div>	<div>P</div> <div>×</div>	Do Nothing
<div>SW</div> <div>↓</div>	<div>Z</div> <div>↓</div>	<div>CA</div> <div>↓</div>	<div>CB</div> <div>↓</div>	<div>P</div> <div>↓</div>	Clear Low
<div>SW</div> <div>↑</div>	<div>Z</div> <div>↑</div>	<div>CA</div> <div>↑</div>	<div>CB</div> <div>↑</div>	<div>P</div> <div>↑</div>	Set High
<div>SW</div> <div>T</div>	<div>Z</div> <div>T</div>	<div>CA</div> <div>T</div>	<div>CB</div> <div>T</div>	<div>P</div> <div>T</div>	Toggle

epwm-024

**Figure 12-203. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

#### 12.4.2.3.4.3 EPWM Action-Qualifier Event Priority

It is possible for the EPWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is: events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 12-257](#). A priority level 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

**Table 12-257. EPWM Action-Qualifier Event Priority for Up-Down-Count Mode**

Priority Level	Event if TBCNT is Incrementing TBCNT = 0 up to TBCNT = TBPRD	Event if TBCNT is Decrementing TBCNT = TBPRD down to TBCNT = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD in EPWM_TBPRD active register)
5	Counter equals CMPB on down-count (CBD) <sup>(1)</sup>	Counter equals CMPB on up-count (CBU) <sup>(1)</sup>
6 (Lowest)	Counter equals CMPA on down-count (CAD) <sup>(1)</sup>	Counter equals CMPA on up-count (CBU) <sup>(1)</sup>

- (1) To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

[Table 12-258](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

**Table 12-258. EPWM Action-Qualifier Event Priority for Up-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

[Table 12-259](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

**Table 12-259. EPWM Action-Qualifier Event Priority for Down-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 12-260](#).

**Table 12-260. Behavior if CMPA/CMPB is Greater than the Period**

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAU/CBU
Up-Count Mode	If CMPA/CMPB $\leq$ TBPRD period, then the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB > TBPRD, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If CMPA/CMPB < TBPRD, the event will occur on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $\geq$ TBPRD, the event will occur on a period match (TBCNT = TBPRD).
Up-Down-Count Mode	If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB is $\geq$ TBPRD, the event will occur on a period match (TBCNT = TBPRD).	If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $\geq$ TBPRD, the event occurs on a period match (TBCNT = TBPRD).

#### 12.4.2.3.4.4 Waveforms for Common EPWM Configurations

##### Note

The waveforms in this chapter show the EPWMs behavior for a static compare register value. In a running system, the active compare registers (EPWM\_CMPA and EPWM\_CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place — either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

##### Use up-down-count mode to generate a symmetric PWM:

- If EPWM\_CMPA / EPWM\_CMPB is loaded on zero, then use EPWM\_CMPA / EPWM\_CMPB values greater than or equal to 1.
- If EPWM\_CMPA / EPWM\_CMPB is loaded on period, then use EPWM\_CMPA / EPWM\_CMPB values less than or equal to TBPRD - 1.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

##### Use up-down-count mode to generate an asymmetric PWM:

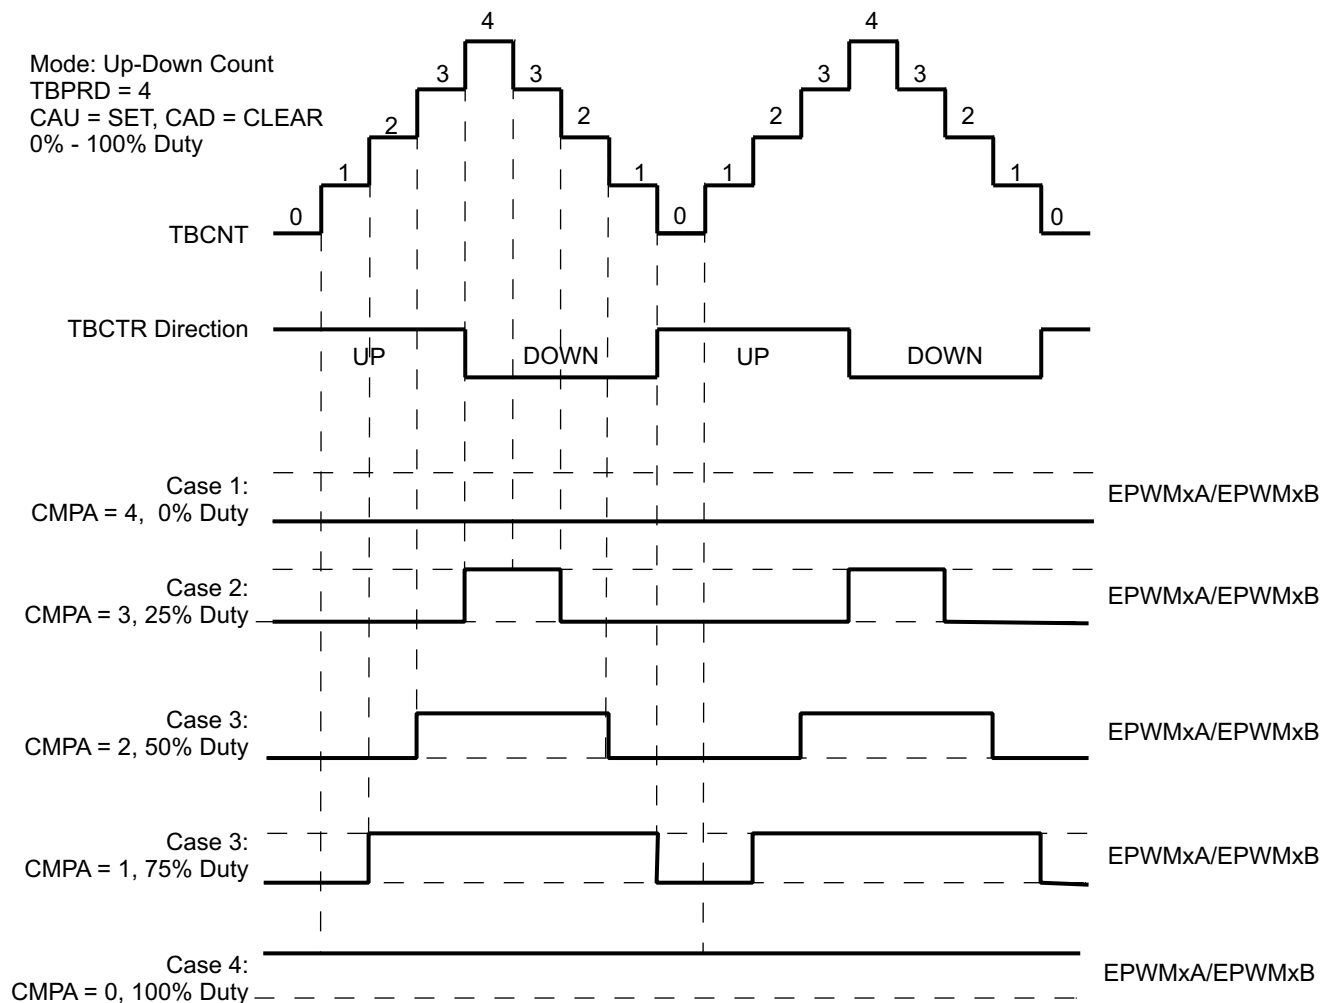

- To achieve 50-0% asymmetric PWM use the following configuration: Load EPWM\_CMPA / EPWM\_CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50-0% PWM duty.

##### When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load EPWM\_CMPA / EPWM\_CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

Figure 12-204 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When  $CMPA = 0$ , the PWM signal is low for the entire period giving the 0% duty waveform. When  $EPWM\_CMPA = EPWM\_TBPRD$ , the PWM signal is high achieving 100% duty.

When using this configuration in practice, if  $CMPA/CMPB$  is loaded on zero, then use  $CMPA/CMPB$  values greater than or equal to 1. If  $CMPA/CMPB$  is loaded on period, then use  $CMPA/CMPB$  values less than or equal to  $TBPRD - 1$ . This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

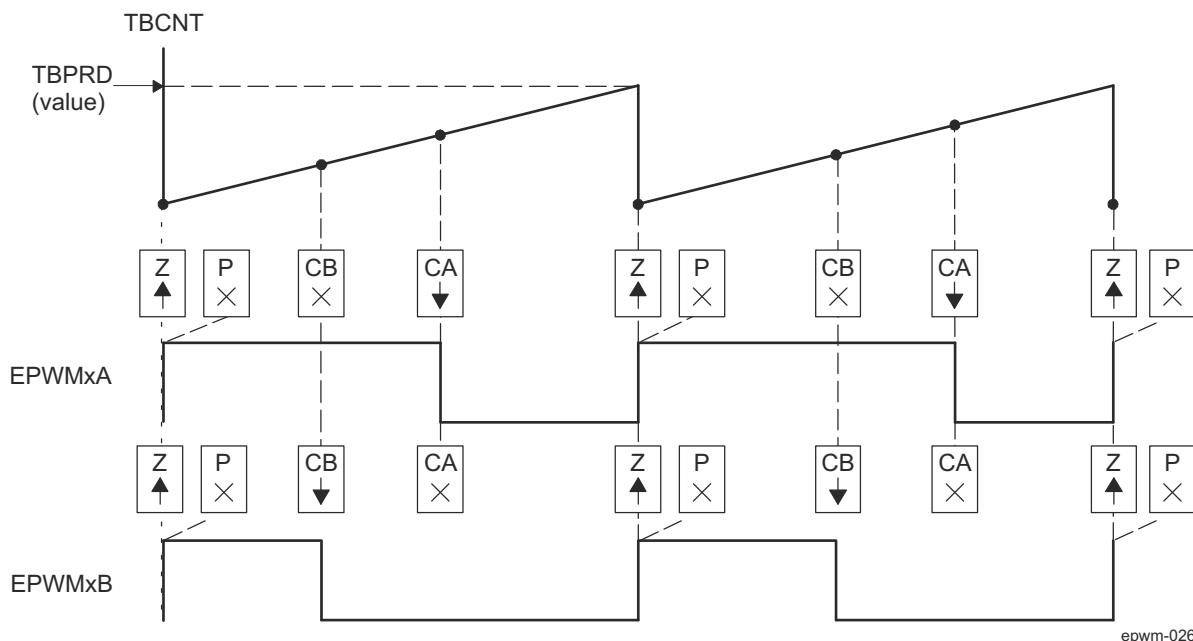

epwm-025

**Figure 12-204. EPWM Up-Down-Count Mode Symmetrical Waveform**

The PWM waveforms in [Figure 12-205](#) through [Figure 12-210](#) show some common action-qualifier configurations. Some conventions used in the figures are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers (EPWM\_TBPRD, EPWM\_CMPA, and EPWM\_CMPB). The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from EPWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

[Table 12-261](#) and [Table 12-262](#) contains initialization and runtime register configurations for the waveforms in [Figure 12-205](#).

- PWM period =  $(TBPRD + 1) \times T_{TBCLK}$
- Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- The "Do Nothing" actions ( X ) are shown for completeness, but will not be shown on subsequent diagrams.
- Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

**Figure 12-205. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active High**

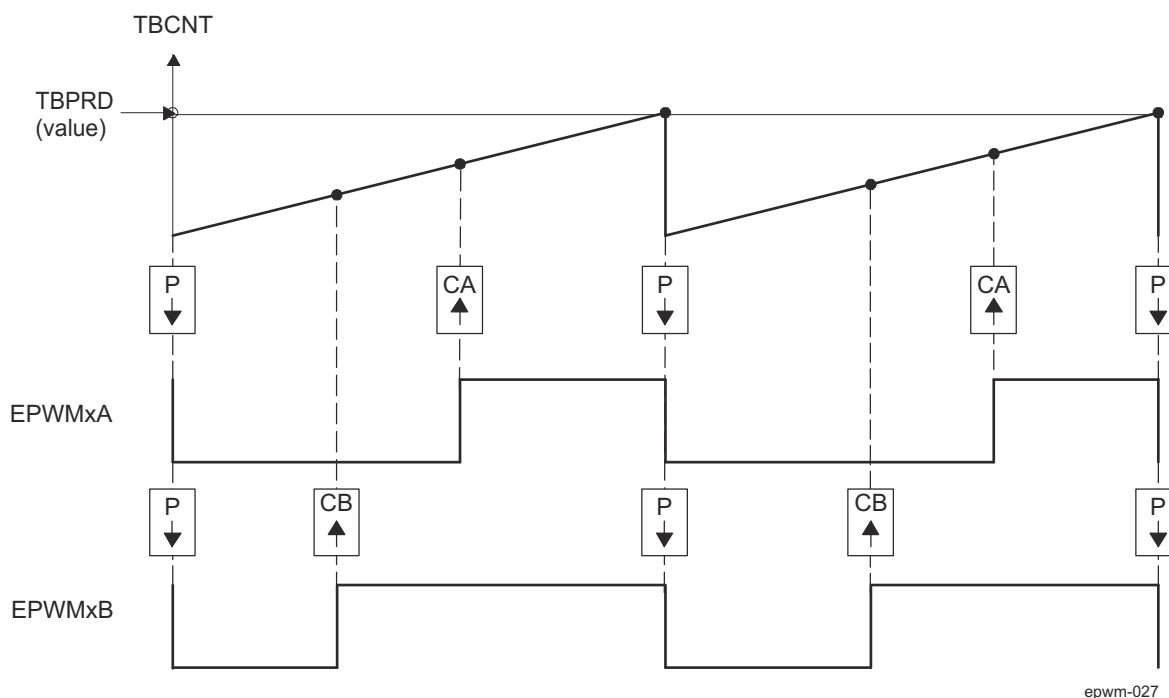

**Table 12-261. EPWMx Initialization for Figure 12-205**

Register	Bitfield	Value	Comments

EPWM_CMPB	CMPB	Duty1B	Adjust duty for output EPWM1B

Table 12-263 and Table 12-264 contains initialization and runtime register configurations for the waveforms in Figure 12-206.

- A.  $\text{PWM period} = (\text{TBPRD} + 1) \times T_{\text{TBCLK}}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D. The Do Nothing actions ( X ) are shown for completeness here, but will not be shown on subsequent diagrams.
- E. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

epwm-031

- A. PWM period =  $2 \times \text{TBPRD} \times \text{TBCLK}$
- B. Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
- C. Duty modulation for EPWMxA is set by CMPA and CMPB.
- D. Low time duty for EPWMxA is proportional to (CMPA + CMPB).
- E. To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Set ! Clear and Clear Set).
- F. Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB).

#### 12.4.2.3.5 EPWM Dead-Band Generator (DB) Submodule

This section describes the Dead-Band Generator (DB) submodule in the PWM module.

##### 12.4.2.3.5.1 Overview

Figure 12-211 illustrates the dead-band generator submodule within the EPWM module.

**Figure 12-211. Dead-Band Generator Submodule**

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the EPWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in Figure 12-211)

##### 12.4.2.3.5.2 Controlling and Monitoring the EPWM Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

**Table 12-273. Dead-Band Generator Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_DBCTL	Dead-Band Control Register	1Eh	No
EPWM_DBRED	Dead-Band Rising Edge Delay Count Register	20h	No
EPWM_DBFED	Dead-Band Falling Edge Delay Count Register	22h	No

##### 12.4.2.3.5.3 Operational Highlights for the EPWM Dead-Band Generator Submodule

The dead-band submodule has two groups of independent selection options as shown in Figure 12-212.

- **Input Source Selection:** The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the EPWM\_DBCTL[5-4] IN\_MODE control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
  - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  - EPWMxB In is the source for both falling-edge and rising-edge delay.
- **Output Mode Control:** The output mode is configured by way of the EPWM\_DBCTL[1-0] OUT\_MODE bit fields. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- **Polarity Control:** The polarity control (EPWM\_DBCTL[3-2] POLSEL) allows to be specified whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

**Figure 12-212. Configuration Options for the EPWM Dead-Band Generator Submodule**

Although all combinations are supported, not all are typical usage modes. [Table 12-274](#) lists some classical dead-band configurations. These modes assume that the EPWM\_DBCTL[5-4] IN\_MODE is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 12-274](#) fall into the following categories:

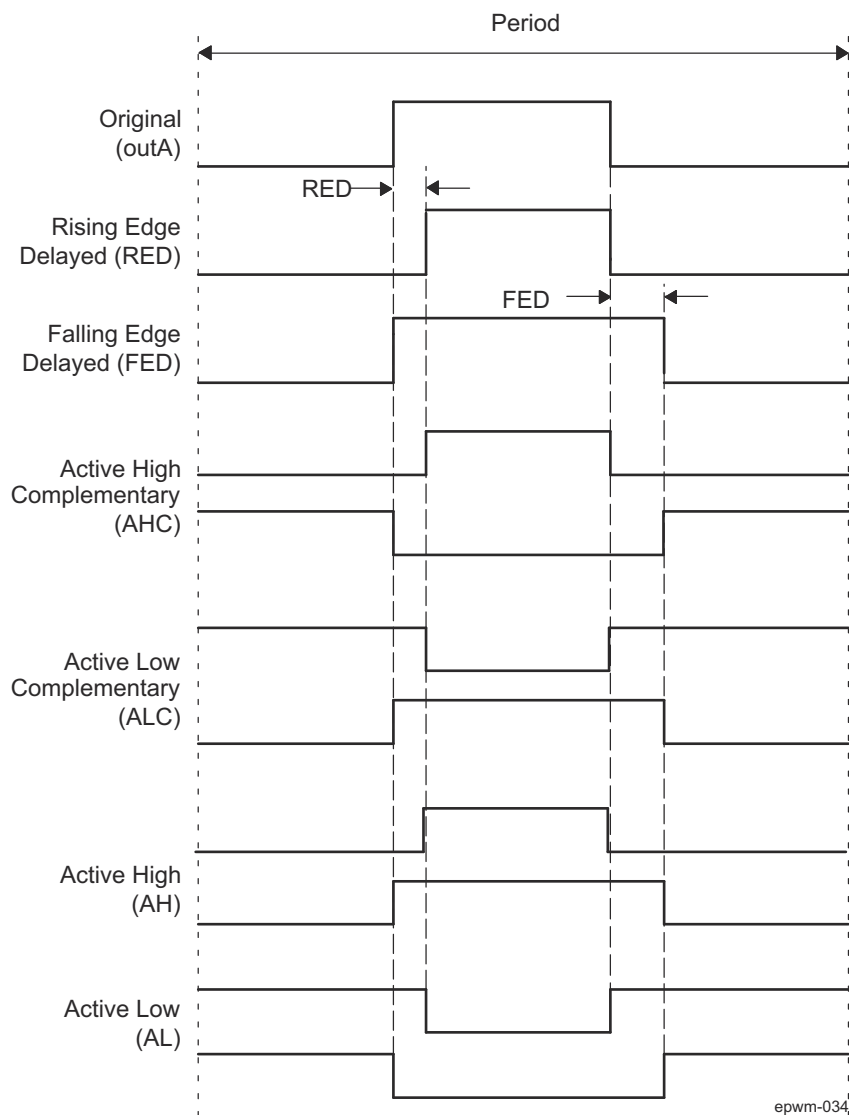

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows to be fully disabled the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 12-213](#). Note that to generate equivalent waveforms to [Figure 12-213](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in [Table 12-274](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

**Table 12-274. Classical Dead-Band Operating Modes**

Mode	Mode Description <sup>(1)</sup>	EPWM_DBCTL[3-2] POLSEL		EPWM_DBCTL[1-0] OUT_MODE	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	x	x	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

(1) These are classical dead-band modes and assume that EPWM\_DBCTL[5-4] IN\_MODE = 0b00. That is, EPWMxA in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the IN\_MODE configuration.

[Figure 12-213](#) shows waveforms for typical cases where 0% < duty < 100%.

**Figure 12-213. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)**

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the EPWM\_DBRED and EPWM\_DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formulas to calculate falling-edge-delay and rising-edge-delay are:

$$\text{FED} = \text{EPWM\_DBFED} \times T_{\text{TBCLK}}$$

$$\text{RED} = \text{EPWM\_DBRED} \times T_{\text{TBCLK}}$$

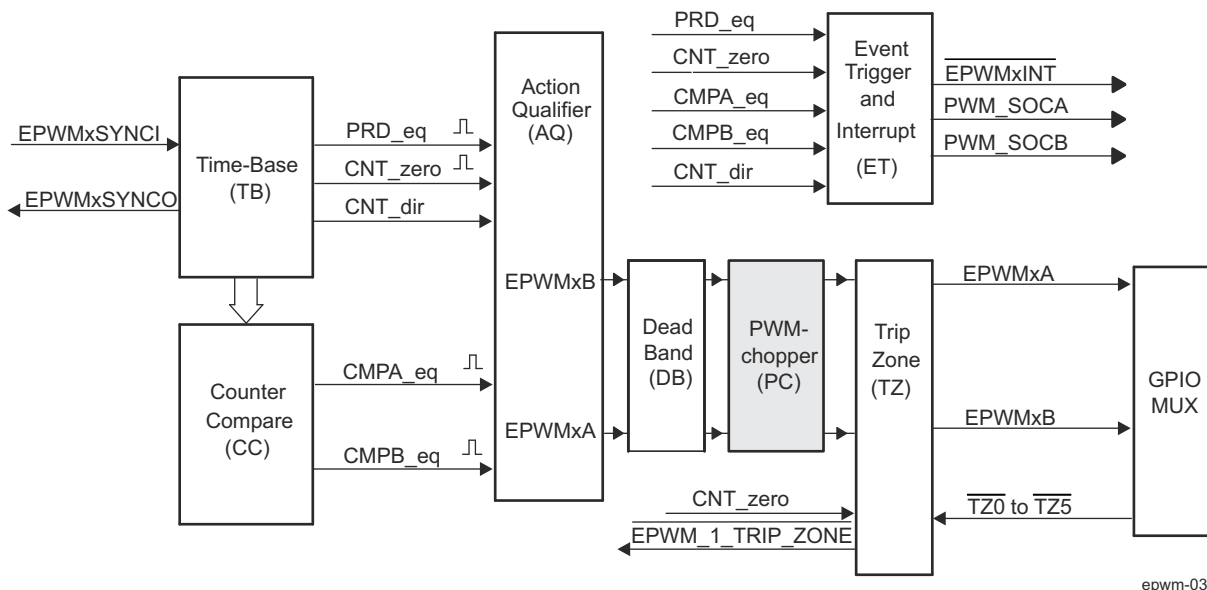

Where  $T_{\text{TBCLK}}$  is the period of TBCLK, the prescaled version of FICLK.

### 12.4.2.3.6 EPWM-Chopper (PC) Submodule

This section describes the PWM-Chopper (PC) submodule in the PWM module.

#### 12.4.2.3.6.1 Overview

Figure 12-214 illustrates the PWM-chopper (PC) submodule within the EPWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if a pulse transformer-based gate drivers to control the power switching elements is needed.

**Figure 12-214. PWM-Chopper Submodule**

PC module key features:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

#### 12.4.2.3.6.2

PC module key features:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

#### 12.4.2.3.6.3 Controlling the EPWM-Chopper Submodule

The EPWM-chopper submodule operation is controlled via the register in [Table 12-275](#).

**Table 12-275. EPWM-Chopper Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_PCCTL	PWM-chopper Control Register	3Ch	No

#### 12.4.2.3.6.4 Operational Highlights for the EPWM-Chopper Submodule

Figure 12-215 shows the operational details of the EPWM-chopper submodule. The carrier clock is derived from FICLK. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the EPWM\_PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

**Figure 12-215. PWM-Chopper Submodule Signals and Registers**

#### 12.4.2.3.6.5 EPWM-Chopper Waveforms

Figure 12-216 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

**Figure 12-216. Simple EPWM-Chopper Submodule Waveforms Showing Chopping Action Only**

##### 12.4.2.3.6.5.1 EPWM-Chopper One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{FICLK} \times 8 \times OSHTWTH$$

Where  $T_{FICLK}$  is the period of the system clock (FICLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 12-217 shows the first and subsequent sustaining pulses.

**Figure 12-217. EPWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

#### 12.4.2.3.6.5.2 EPWM-Chopper Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 12-218 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5 to 87.5%.

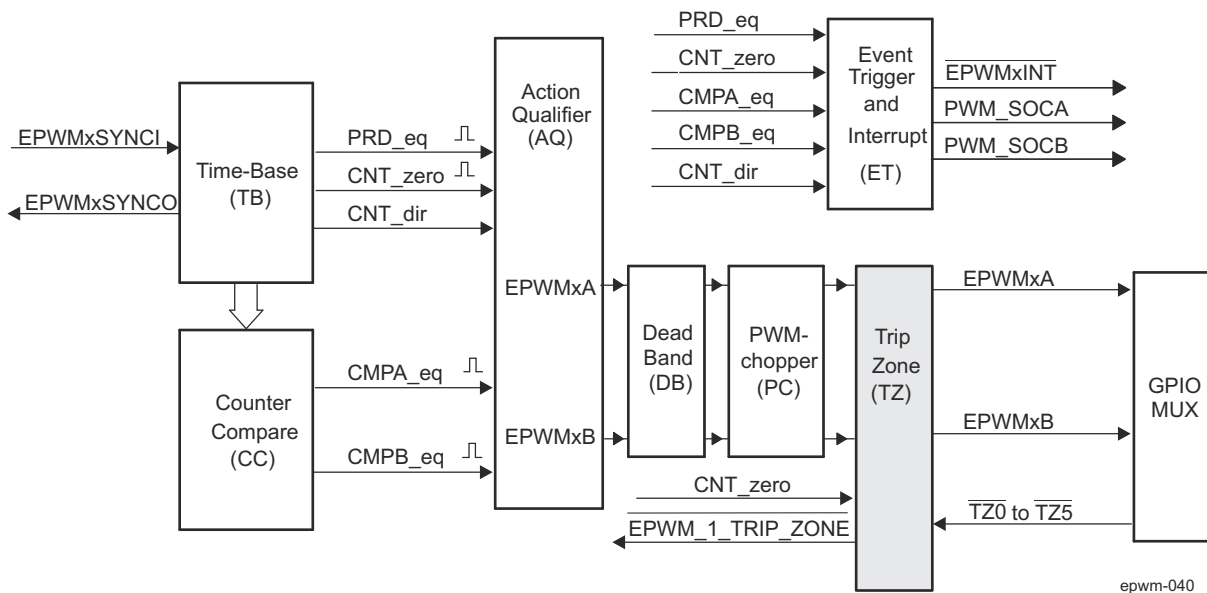

**Figure 12-218. EPWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

#### 12.4.2.3.7 EPWM Trip-Zone (TZ) Submodule

This section describes the Trip-Zone (TZ) submodule in the PWM module.

### 12.4.2.3.7.1 Overview

Figure 12-219 shows how the trip-zone (TZ) submodule fits within the EPWM module. Each EPWM module is connected to six TZ signals (TZ0 to TZ5) that are sourced from the GPIO MUX. These signals indicate external fault or trip conditions, and the EPWM outputs can be programmed to respond accordingly when faults occur. See *EPWM Integration* to determine the number of trip-zone pins available for the device.

**Figure 12-219. EPWM Trip-Zone Submodule**

The key functions of the trip-zone submodule are:

- Trip inputs TZ0 to TZ5 can be flexibly mapped to any EPWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

#### Note

For each EPWMx module, 6 tripzone input events are supported (EPWMx\_TRIP\_TZ[5:0]). Each tripzone input for all EPWMx modules (where x = 0 to 5) are tied to a common tripzone input pin, so that any EPWMx can be triggered by any of the six tripzone inputs.

#### 12.4.2.3.7.2 Controlling and Monitoring the EPWM Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

**Table 12-276. EPWM Trip-Zone Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_TZSEL	Trip-Zone Select Register <sup>(1)</sup>	24h	No
EPWM_TZCTL	Trip-Zone Control Register <sup>(1)</sup>	28h	No
EPWM_TZEINT	Trip-Zone Enable Interrupt Register <sup>(1)</sup>	2Ah	No
EPWM_TZFLG	Trip-Zone Flag Register <sup>(1)</sup>	2Ch	No
EPWM_TZCLR	Trip-Zone Clear Register <sup>(1)</sup>	2Eh	No
EPWM_TZFRC	Trip-Zone Force Register <sup>(1)</sup>	30h	No

(1) All trip-zone registers are EALLOW protected and can be modified only after executing the EALLOW instruction.

#### 12.4.2.3.7.3 Operational Highlights for the EPWM Trip-Zone Submodule

The trip-zone signals at pin  $\overline{TZ0}$  to  $\overline{TZ5}$  is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. Each EPWM module can be individually configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used by a particular EPWM module is determined by the EPWM\_TZSEL register for that specific EPWM module. The trip-zone signal may or may not be synchronized to the system clock (FICLK). A minimum of 1 FICLK low pulse on the  $\overline{TZ0}$  to  $\overline{TZ5}$  inputs is sufficient to trigger a fault condition in the EPWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the  $\overline{TZ0}$  to  $\overline{TZ5}$  inputs.

The  $\overline{TZ0}$  to  $\overline{TZ5}$  inputs can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a EPWM module. The configuration is determined by the EPWM\_TZSEL[5-0] CBCk and EPWM\_TZSEL[13-8] OSHTk bit field (where k = 0 to 5 corresponds to the trip pin), respectively.

- **Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the EPWM\_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 12-277](#) lists the possible actions. In addition, the cycle-by-cycle trip event flag (EPWM\_TZFLG[1] CBC) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM\_TZEINT register.

The specified condition on the pins is automatically cleared when the EPWM time-base counter reaches zero (EPWM\_TBCNT[15-0] TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The EPWM\_TZFLG[1] CBC flag bit will remain set until it is manually cleared by writing to the EPWM\_TZCLR[1] CBC bit. If the cycle-by-cycle trip event is still present when the EPWM\_TZFLG[1] CBC bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the EPWM\_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 12-277](#) lists the possible actions. In addition, the one-shot trip event flag (EPWM\_TZFLG[2] OST) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM\_TZEINT register. The one-shot trip condition must be cleared manually by writing to the EPWM\_TZCLR[2] OST bit.

The action taken when a trip event occurs can be configured individually for each of the EPWM output pins by way of the EPWM\_TZCTL[1-0] TZA and EPWM\_TZCTL[3-2] TZB register bit field. One of four possible actions, shown in [Table 12-277](#), can be taken on a trip event.

**Table 12-277. Possible Actions On an EPWM Trip Event**

EPWM_TZCTL[1-0] TZA and/or EPWM_TZCTL[3-2] TZB	EPWMxA and/or EPWMxB	Comment
0	High-Impedance	Tripped
1h	Force to High State	Tripped
2h	Force to Low State	Tripped
3h	No Change	Do Nothing. No change is made to the output.

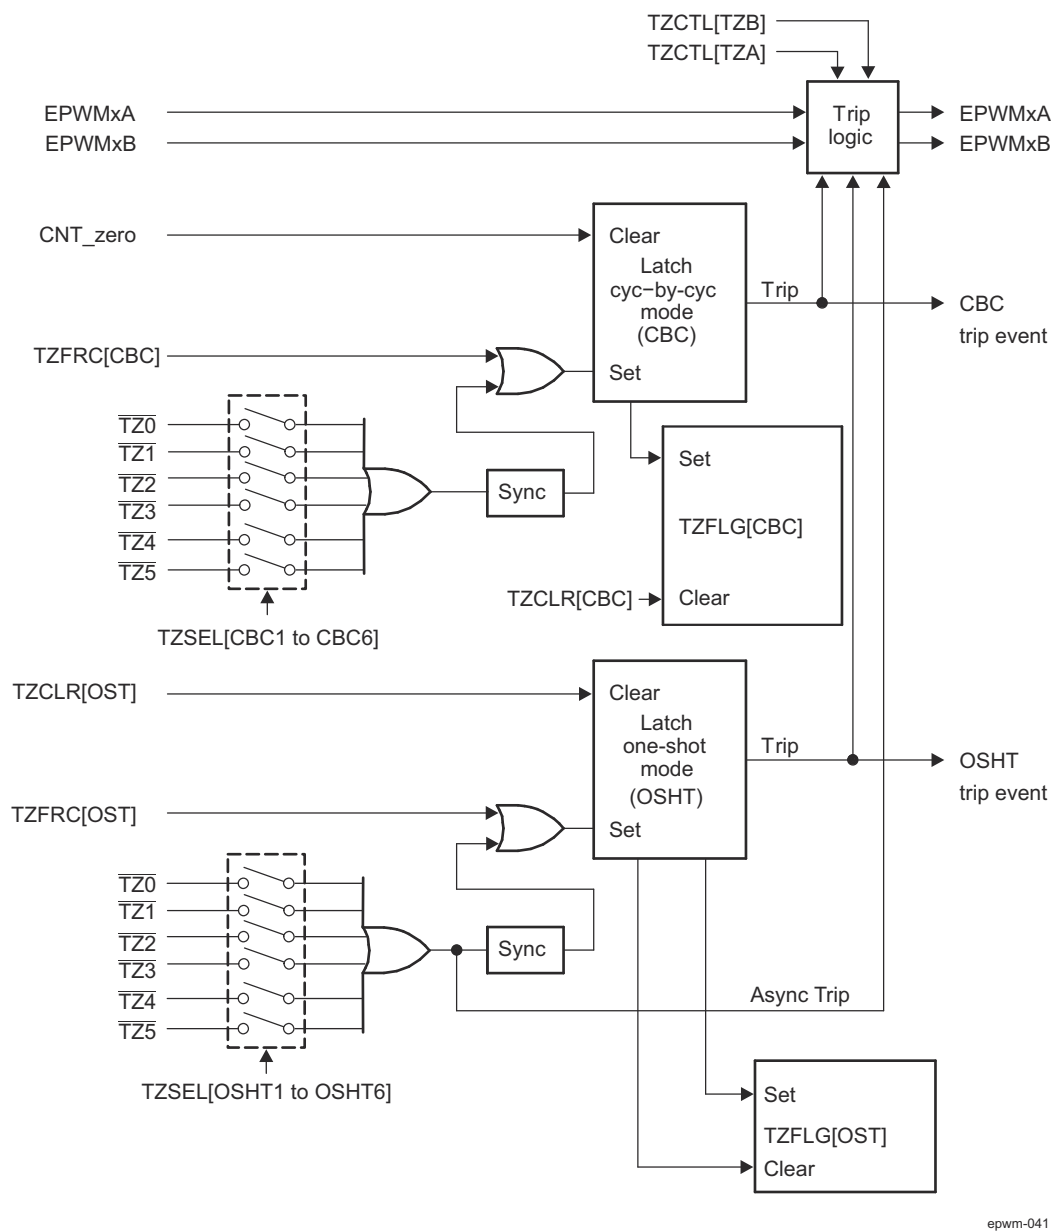

### **Example of EPWM Trip-Zone Configurations**

A one-shot trip event on  $\overline{TZ0}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the EPWM1 registers as follows:
  - EPWM\_TZSEL[8] OSHT1 = 1: enables  $\overline{TZ}$  as a one-shot event source for EPWM1
  - EPWM\_TZCTL[1-0] TZA = 2: EPWM1A will be forced low on a trip event
  - EPWM\_TZCTL[3-2] TZB = 2: EPWM1B will be forced low on a trip event
- Configure the EPWM2 registers as follows:
  - EPWM\_TZSEL[8] OSHT1 = 1: enables  $\overline{TZ}$  as a one-shot event source for EPWM2
  - EPWM\_TZCTL[1-0] TZA = 1: EPWM2A will be forced high on a trip event
  - EPWM\_TZCTL[3-2] TZB = 1: EPWM2B will be forced high on a trip event

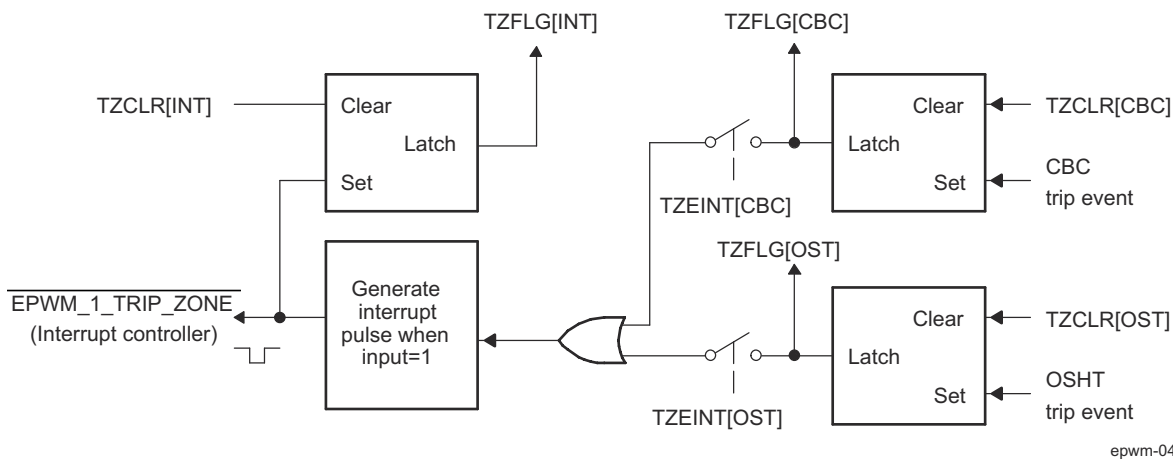

#### **12.4.2.3.7.4 Generating EPWM Trip-Event Interrupts**

Figure 12-220 and Figure 12-221 illustrate the trip-zone submodule control and interrupt logic, respectively.

epwm-041

epwm-042

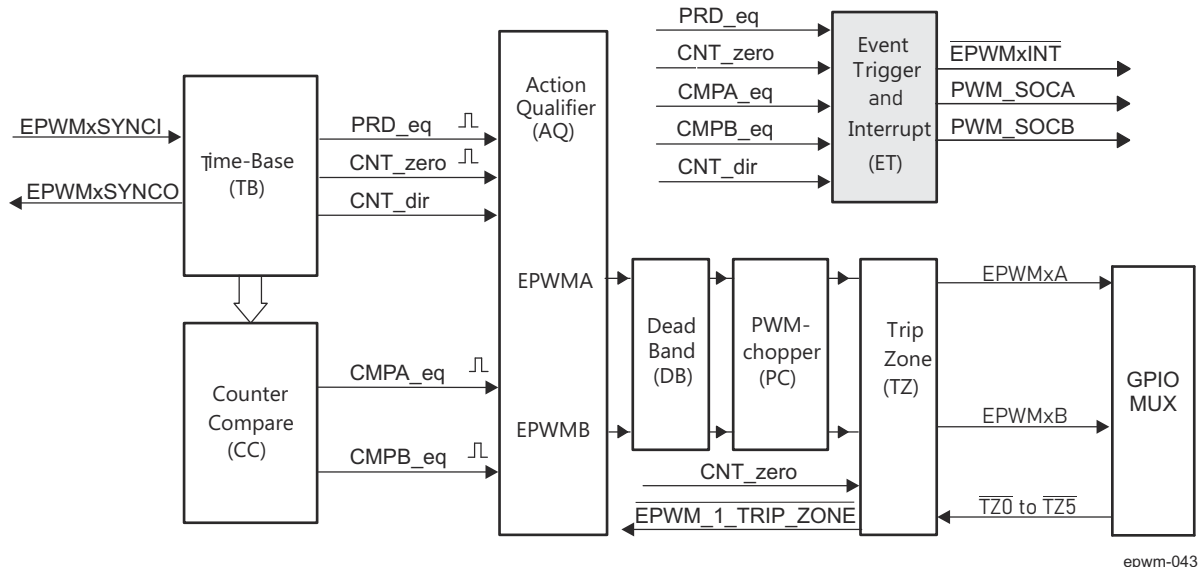

**Figure 12-221. EPWM Trip-Zone Submodule Interrupt Logic**

#### 12.4.2.3.8 EPWM Event-Trigger (ET) Submodule

This section describes the Event-Trigger (ET) submodule in the PWM module.

##### 12.4.2.3.8.1 Overview

Figure 12-222 shows the event-trigger (ET) submodule in the EPWM system. The event-trigger submodule manages the events generated by the time-base submodule and the counter-compare submodule to generate an aggregated interrupt request.

**Figure 12-222. EPWM Event-Trigger Submodule**

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base and counter-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests at:
  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags

##### 12.4.2.3.8.2 Controlling and Monitoring the EPWM Event-Trigger Submodule

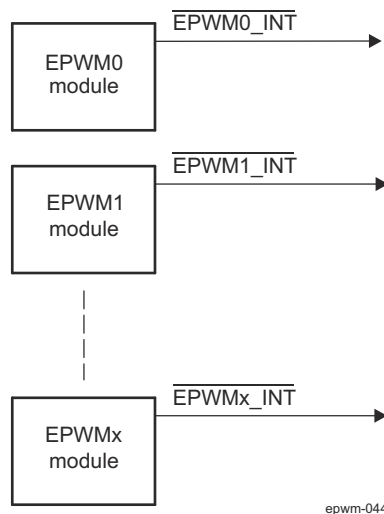

The key registers used to configure the event-trigger submodule are shown in Table 12-278:

**Table 12-278. EPWM Event-Trigger Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_ETSEL	Event-Trigger Selection Register	32h	No
EPWM_ETPS	Event-Trigger Prescale Register	34h	No
EPWM_ETFLG	Event-Trigger Flag Register	36h	No
EPWM_ETCLR	Event-Trigger Clear Register	38h	No
EPWM_ETFRC	Event-Trigger Force Register	3Ah	No

##### 12.4.2.3.8.3 Operational Overview of the EPWM Event-Trigger Submodule

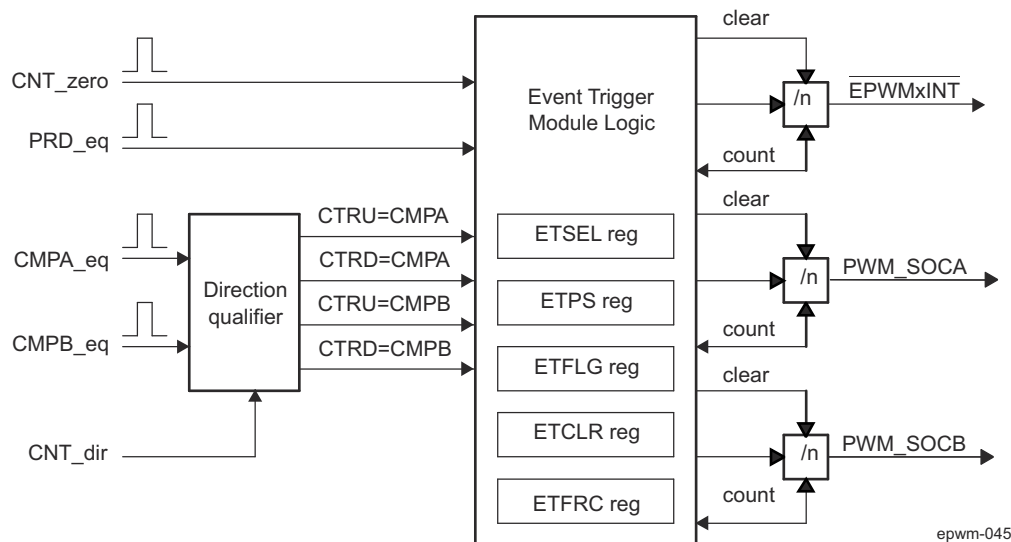

Each EPWM module has one interrupt request line as shown in Figure 12-223. Mapping interrupt lines to device host interrupt controllers is device specific and is covered in *EPWM Integration*.

**Figure 12-223. EPWM Event-Trigger Submodule Inter-Connectivity to Interrupt Controller**

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 12-224) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

**Figure 12-224. EPWM Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

- ETSEL — This selects which of the possible events will trigger an interrupt.
- ETPS — This programs the event prescaling options previously mentioned.
- ETFLG — These are flag bits indicating status of the selected and prescaled events.
- ETCLR — These bits allow to clear the flag bits in the EPWM\_ETFLG register via software.
- ETFRC — These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in [Figure 12-225](#).

[Figure 12-225](#) shows the event-trigger's interrupt generation logic. The interrupt-period (EPWM\_ETPS[1-0] INTPRD) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (EPWM\_ETSEL[2-0] INTSEL) bits. The event can be one of the following:

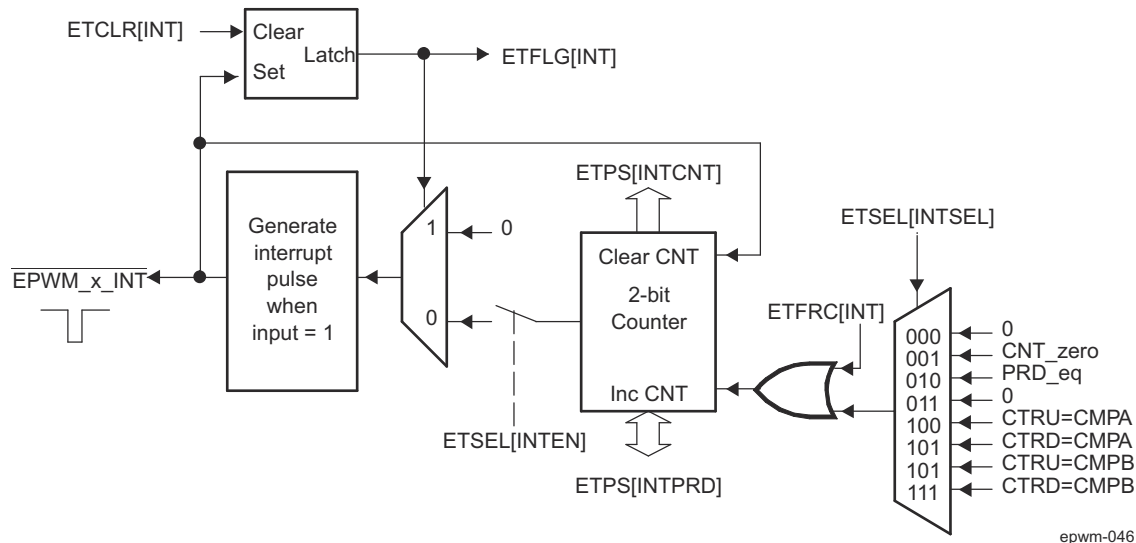

- Time-base counter equal to zero (EPWM\_TBCNT[15-0] TBCNT = 0000h).
- Time-base counter equal to period (EPWM\_TBCNT[15-0] TBCNT = EPWM\_TBPRD[15-0] TBPRD).
- Time-base counter equal to the compare A register (EPWM\_CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (EPWM\_CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (EPWM\_CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (EPWM\_CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (EPWM\_ETPS[3-2] INTCNT) register bits. That is, when the specified event occurs the EPWM\_ETPS[3-2] INTCNT bits are incremented until they reach the value specified by the EPWM\_ETPS[1-0] INTPRD bit field. When EPWM\_ETPS[3-2] INTCNT = EPWM\_ETPS[1-0] INTPRD the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When EPWM\_ETPS[3-2] INTCNT reaches EPWM\_ETPS[1-0] INTPRD, one of the following behaviors will occur:

- If interrupts are enabled, EPWM\_ETSEL[3] INTEN = 1h and the interrupt flag is clear, EPWM\_ETFLG[0] INT = 0h, then an interrupt pulse is generated and the interrupt flag is set, EPWM\_ETFLG[0] INT = 1h, and the event counter is cleared EPWM\_ETPS[3-2] INTCNT = 0h. The counter will begin counting events again.
- If interrupts are disabled, EPWM\_ETSEL[3] INTEN = 0, or the interrupt flag is set, EPWM\_ETFLG[0] INT = 1h, the counter stops counting events when it reaches the period value EPWM\_ETPS[3-2] INTCNT = EPWM\_ETPS[1-0] INTPRD.
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[0] INT flag is cleared. This allows for one interrupt to be pending while one is serviced.

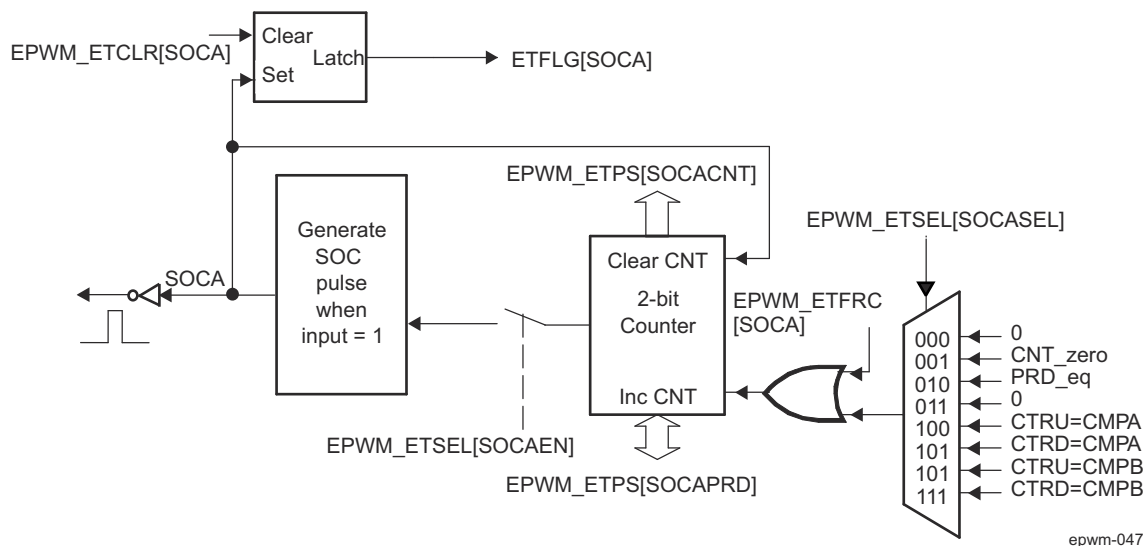

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1h to the EPWM ETFRC[0] INT bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0h, the counter is disabled and hence no events will be detected and the EPWM ETFRC[0] INT bit is also ignored.

**Figure 12-225. EPWM Event-Trigger Interrupt Generator**

#### 12.4.2.3.8.4

**Figure 12-226** shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The EPWM\_ETPS[11-10] SOCACNT counter and EPWM\_ETPS[9-8] SOCAPRD period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag EPWM\_ETFLG[2] SOCA is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable EPWM\_ETSEL[11] SOCAEN bit stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the EPWM\_ETSEL[10-8] SOCASEL and EPWM\_ETSEL[14-12] SOCBSEL bit field. The possible events are the same events that can be specified for the interrupt generation logic.

**Figure 12-226. EPWM Event-Trigger SOCA Pulse Generator**

Figure 12-227 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

**Figure 12-227. EPWM Event-Trigger SOCB Pulse Generator**

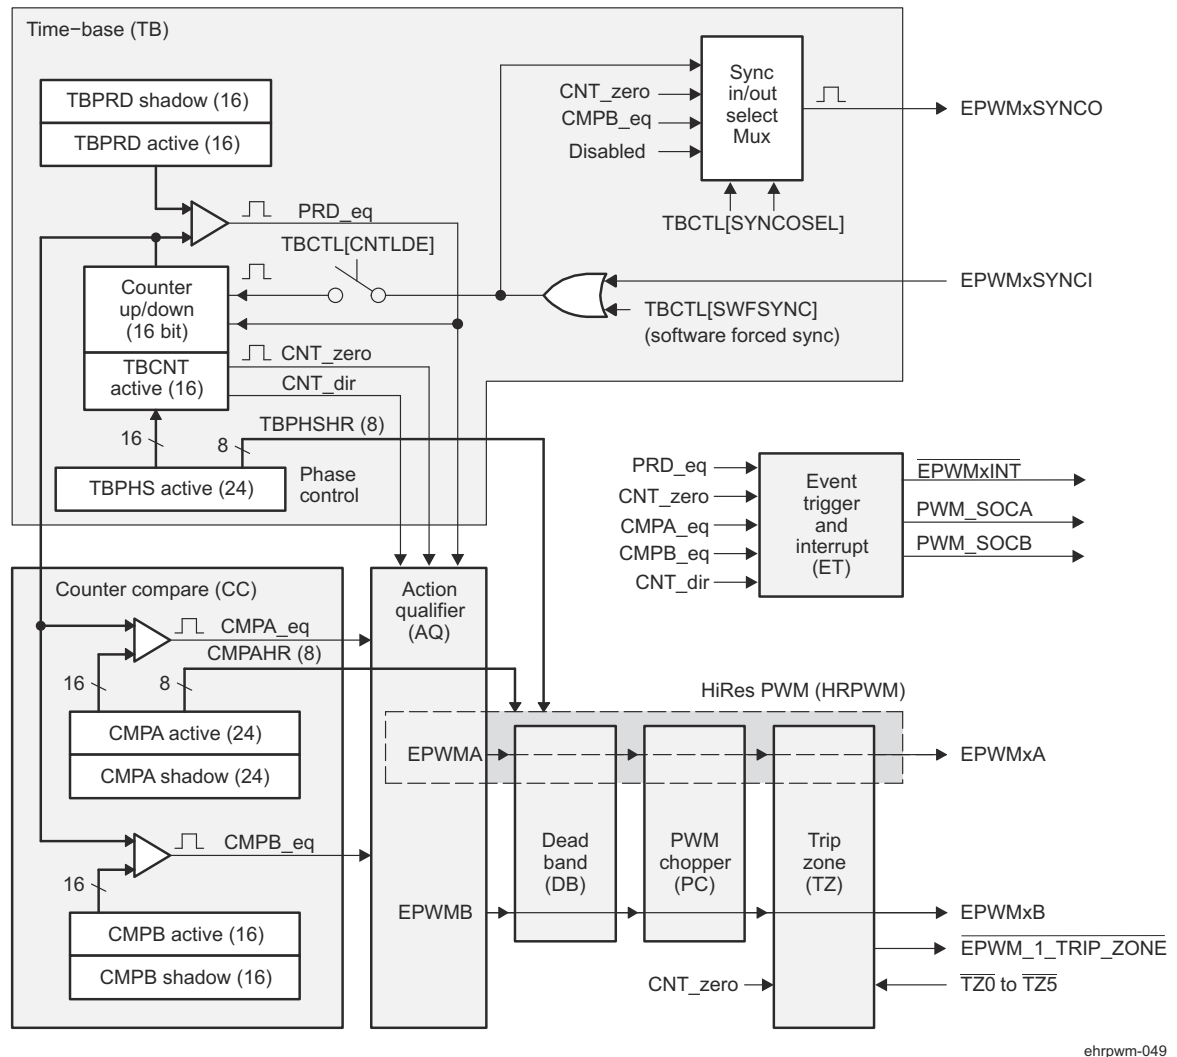

### 12.4.2.3.9 EPWM High Resolution (HRPWM) Submodule

This section describes the High-Resolution PWM (HRPWM) submodule in the PWM module.

#### 12.4.2.3.9.1 Overview

Figure 12-228 shows the high-resolution PWM (HRPWM) submodule in the EPWM system. Some devices include the high-resolution PWM submodule, see *EPWM Integration* to determine which EPWM instances include this feature.

**Figure 12-228. HRPWM System Interface**

The high-resolution pulse-width modulator (HRPWM) extends the time resolution capabilities of the conventionally derived digital pulse-width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~9-10 bits.

The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
- Implemented using the A signal path of PWM, that is, on the EPWMxA output. **EPWMxB output has conventional PWM capabilities**

The EPWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 12-229, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

**Figure 12-229. Resolution Calculations for Conventionally Generated PWM**

Use HRPWM when the required PWM operating frequency does not offer sufficient resolution in PWM mode. As an example of improved performance offered by HRPWM, Table 12-279 shows resolution in bits for various PWM frequencies. Table 12-279 values assume a MEP step size of 180 ps. See the device-specific Datasheet for typical and maximum performance specifications for the MEP.

**Table 12-279. Resolution for PWM and HRPWM**

PWM Frequency (kHz)	Regular Resolution (PWM)		High Resolution (HRPWM)	
	Bits	%	Bits	%
20	12.3	0.0	18.1	0.000
50	11.0	0.0	16.8	0.001
100	10.0	0.1	15.8	0.002
150	9.4	0.2	15.2	0.003
200	9.0	0.2	14.8	0.004
250	8.6	0.3	14.4	0.005
500	7.6	0.5	13.8	0.007
1000	6.6	1.0	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2.0	11.4	0.036

Although each application may differ, typical low-frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

#### 12.4.2.3.9.2 Architecture of the High-Resolution PWM Submodule

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions.

Figure 12-230 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (HRPWM\_CMPAHR).

ehrpwm-051

A. For MEP range and rounding adjustment.

**Figure 12-230. Operating Logic Using MEP**

To generate an HRPWM waveform of a given frequency and polarity, the user needs to configure the TBM (Time-Base Module), CCM (Counter-Compare Module), and AQM (Action-Qualifier Module) registers. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical.

#### 12.4.2.3.9.3 Controlling and Monitoring the High-Resolution PWM Submodule

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit EPWM\_TBPHS and EPWM\_CMPA registers used to control PWM operation.

- HRPWM\_TBPHSHR — Time-Base Phase High-Resolution Register
- HRPWM\_CMPAHR — Counter-Compare A High-Resolution Register.

Table 12-280 lists the registers used to control and monitor the high-resolution PWM submodule.

**Table 12-280. HRPWM Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
HRPWM_TBPHSHR	Extension Register for HRPWM Phase	4h	No
HRPWM_CMPAHR	Extension Register for HRPWM Duty	10h	Yes
HRPWM_HRCTL	HRPWM Configuration Register	40h	No

#### 12.4.2.3.9.4 Configuring the High-Resolution PWM Submodule

Once the EPWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRPWM\_HRCTL register located at offset address 40h. This register provides configuration options for the following key operating modes:

- **Edge Mode:** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE), or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge.
- **Control Mode:** The MEP is programmed to be controlled either from the HRPWM\_CMPAHR register (duty cycle control) or the HRPWM\_TBPHSHR register (phase control). RE or FE control mode should be used with the HRPWM\_CMPAHR register. BE control mode should be used with the HRPWM\_TBPHSHR register.
- **Shadow Mode:** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the HRPWM\_CMPAHR register and should be chosen to be the same as the regular load option for the CMPA register. If the HRPWM\_TBPHSHR register is used, then this option has no effect.

#### 12.4.2.3.9.5 Operational Highlights for the High-Resolution PWM Submodule

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps, each of which has a time resolution on the order of 150 ps. The MEP works with the TBM (Time-Base Module) and CCM (Counter-Compare Module) registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. [Table 12-281](#) shows the typical range of operating frequencies supported by the HRPWM.

**Table 12-281. Relationship Between MEP Steps, PWM Frequency and Resolution**

System (MHz)	MEP Steps Per FICLK <sup>(1)</sup> (2) (3)	PWM Minimum (Hz) <sup>(4)</sup>	PWM Maximum (MHz)	Resolution at Maximum (Bits) <sup>(5)</sup>
50.0	111	763	2.50	11.1
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

- (1) System frequency = FICLK, that is, CPU clock. TBCLK = FICLK.
- (2) Table data based on a MEP time resolution of 180 ps (this is an example value).
- (3) MEP steps applied =  $T_{FICLK}/180$  ps in this example.
- (4) PWM minimum frequency is based on a maximum period value, TBPRD = 65 535. PWM mode is asymmetrical up-count.
- (5) Resolution in bits is given for the maximum PWM frequency stated.

### 12.4.2.3.9.5.1 HRPWM Edge Positioning

In a typical power control loop (switch modes, digital motor control (DMC), uninterruptible power supply (UPS)), a digital controller (PID, 2pole/2zero, lag/lead, and so forth) issues a duty command, usually expressed in a per unit or percentage terms.

In the following example, assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on-time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. [Figure 12-231](#) shows that duty cycle of 40% (a compare value of 32 counts) is the closest to 40.5%. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in [Table 12-282](#).

Utilizing MEP allows to achieve an edge position much closer to the desired point of 324 ns. [Table 12-282](#) shows that in addition to the CMPA value, 22 steps of the MEP (HRPWM\_CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ns.

**Figure 12-231. Required PWM Waveform for a Requested Duty = 40.5%**

**Table 12-282. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)**

CMPA (count) <sup>(1) (2) (3)</sup>	DUTY (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

- (1) System clock, FICLK and TBCLK = 100 MHz, 10 ns
- (2) For a PWM Period register value of 80 counts, PWM Period = 80 × 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz
- (3) Assumed MEP step size for the above example = 180 ps

#### 12.4.2.3.9.5.2 HRPWM Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard (EPWM\_CMPA) and MEP (HRPWM\_CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

System clock, FICLK	=	10 ns (100 MHz)
PWM frequency	=	1.25 MHz (1/800 ns)
Required PWM duty cycle, <b>PWMDuty</b>	=	0.405 (40.5%)
PWM period in terms of coarse steps, <b>PWMperiod</b> (800 ns/10 ns)	=	80
Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), <b>MEP_SF</b>	=	55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	=	180h

#### Step 1: Percentage Integer Duty value conversion for EPWM\_CMPA register

EPWM_CMPA register value	=	$\text{int}(\text{PWMDuty} \times \text{PWMperiod})$ ; int means integer part
	=	$\text{int}(0.405 \times 80)$
	=	$\text{int}(32.4)$
EPWM_CMPA register value	=	32 (20h)

#### Step 2: Fractional value conversion for HRPWM\_CMPAHR register

HRPWM_CMPAHR register value	=	$(\text{frac}(\text{PWMDuty} \times \text{PWMperiod}) \times \text{MEP\_SF}) \ll 8 + 180\text{h}$ ; frac means fractional part
	=	$(\text{frac}(32.4) \times 55 \ll 8) + 180\text{h}$ ; Shift is to move the value as CMPAHR high byte
	=	$((0.4 \times 55) \ll 8) + 180\text{h}$
	=	$(22 \ll 8) + 180\text{h}$
	=	$22 \times 256 + 180\text{h}$ ; Shifting left by 8 is the same multiplying by 256.
	=	$5632 + 180\text{h}$
	=	$1600\text{h} + 180\text{h}$
HRPWM_CMPAHR value	=	1780h; HRPWM_CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.

### 12.4.2.3.9.5.3 HRPWM Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational 3 FICLK cycles after the period starts.

Duty cycle range limitations are illustrated in [Figure 12-232](#). This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle.

**Figure 12-232. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz**

If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in [Figure 12-233](#). In this case low percent duty limitation is no longer an issue.

**Figure 12-233. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz**

### 12.4.2.3.10 EPWM / HRPWM Functional Register Groups

The [Table 12-283](#) lists the groups of EPWM and the high-resolution PWM module registers according to their functionalities.

**Table 12-283. EPWM / HRPWM Module Control and Status Registers Grouped by Submodule**

Register Name	Offset	Size (×16)	Shadow	Register Description
<b>Time-Base (TB) Submodule Registers</b>				
EPWM_TBCTL	0h	1	No	Time-Base Control Register
EPWM_TBSTS	2h	1	No	Time-Base Status Register
EPWM_TBPHS	6h	1	No	Time-Base Phase Register

**Table 12-283. EPWM / HRPWM Module Control and Status Registers Grouped by Submodule (continued)**

Register Name	Offset	Size (×16)	Shadow	Register Description
EPWM_TBCNT	8h	1	No	Time-Base Counter Register
EPWM_TBPRD	Ah	1	Yes	Time-Base Period Register
<b>Counter-Compare (CC) Submodule Registers</b>				
EPWM_CMPCTL	Eh	1	No	Counter-Compare Control Register
EPWM_CMPA	12h	1	Yes	Counter-Compare A Register
EPWM_CMPB	14h	1	Yes	Counter-Compare B Register
<b>Action-Qualifier (AQ) Submodule Registers</b>				
EPWM_AQCTLA	16h	1	No	Action-Qualifier Control Register for Output A (EPWMxA)
EPWM_AQCTLB	18h	1	No	Action-Qualifier Control Register for Output B (EPWMxB)
EPWM_AQSFRC	1Ah	1	No	Action-Qualifier Software Force Register
EPWM_AQCSFRC	1Ch	1	Yes	Action-Qualifier Continuous S/W Force Register Set
<b>Dead-Band (DB) Generator Submodule Registers</b>				
EPWM_DBCTL	1Eh	1	No	Dead-Band Generator Control Register
EPWM_DBRED	20h	1	No	Dead-Band Generator Rising Edge Delay Count Register
EPWM_DBFED	22h	1	No	Dead-Band Generator Falling Edge Delay Count Register
<b>Trip-Zone (TZ) Submodule Registers</b>				
EPWM_TZSEL	24h	1	No	Trip-Zone Select Register
EPWM_TZCTL	28h	1	No	Trip-Zone Control Register <sup>(1)</sup>
EPWM_TZEINT	2Ah	1	No	Trip-Zone Enable Interrupt Register <sup>(1)</sup>
EPWM_TZFLG	2Ch	1	No	Trip-Zone Flag Register <sup>(1)</sup>
EPWM_TZCLR	2Eh	1	No	Trip-Zone Clear Register <sup>(1)</sup>
EPWM_TZFRC	30h	1	No	Trip-Zone Force Register <sup>(1)</sup>
<b>Event-Trigger (ET) Submodule Registers</b>				
EPWM_ETSEL	32h	1	No	Event-Trigger Selection Register
EPWM_ETPS	34h	1	No	Event-Trigger Pre-Scale Register
EPWM_ETFLG	36h	1	No	Event-Trigger Flag Register
EPWM_ETCLR	38h	1	No	Event-Trigger Clear Register
EPWM_ETFRC	3Ah	1	No	Event-Trigger Force Register
<b>PWM-Chopper Submodule Registers</b>				
EPWM_PCCTL	3Ch	1	No	PWM-Chopper Control Register
<b>High-Resolution PWM (HRPWM) Submodule Registers</b>				
HRPWM_TBPHSHR	4h	1	No	Extension for HRPWM Phase Register
HRPWM_CMPAHR	10h	1	No	Extension for HRPWM Counter-Compare A Register
HRPWM_HRCTL	40h	1	No	HRPWM Control Register

(1) EALLOW protected registers.

**12.4.2.3.11 Proper EPWM Interrupt Initialization Procedure**

When the EPWM peripheral clock is enabled it is possible that interrupt flags may be set due to spurious events as the EPWM registers not being properly initialized. The proper procedure for initializing the EPWM peripheral is:

1. Disable global interrupts (CPU INTM flag)
2. Disable EPWM interrupts
3. Initialize peripheral registers
4. Clear any spurious EPWM flags
5. Enable EPWM interrupts

## 6. Enable global interrupts

### 12.4.3 Enhanced Quadrature Encoder Pulse (EQEP) Module

This section describes the Enhanced Quadrature Encoder Pulse (EQEP) module in the device.

#### 12.4.3.1 EQEP Overview

The Enhanced Quadrature Encoder Pulse (EQEP) peripheral is used for direct interface with a linear or rotary incremental encoder to get position, direction and speed information from a rotating machine for use in high performance motion and position control system. The disk of an incremental encoder is patterned with a single track of slots patterns, as shown in [Figure 12-234](#). These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position and zero reference.

**Figure 12-234. Optical Encoder Disk**

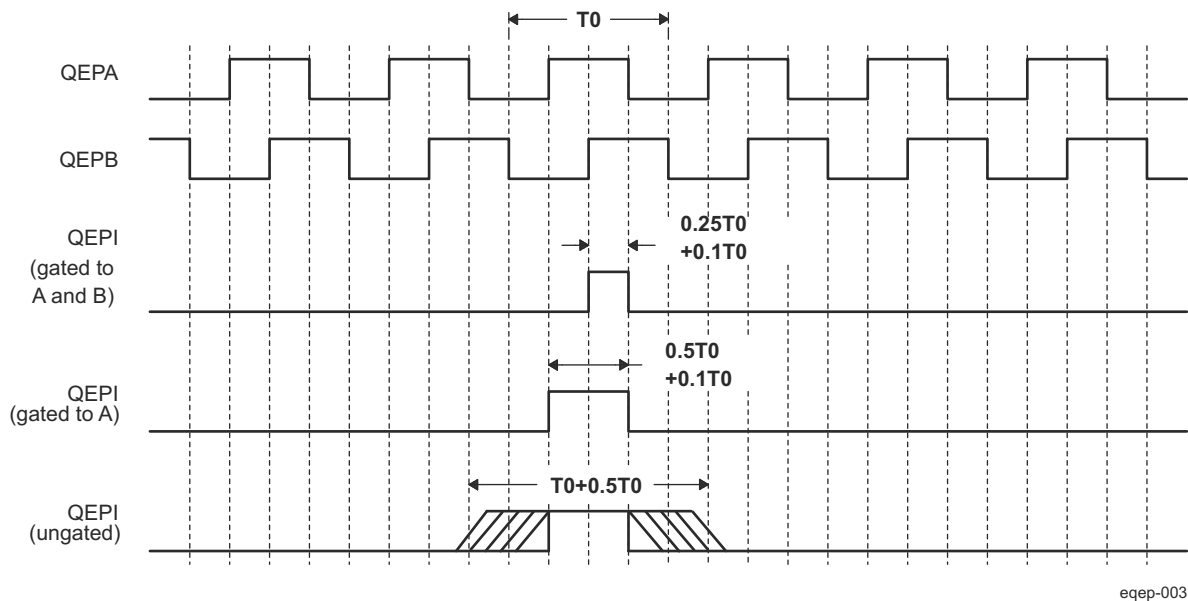

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90 degrees out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vice versa as shown in [Figure 12-235](#).

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 kHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

**Figure 12-235. QEP Encoder Output Signal for Forward/Reverse Movement**

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 12-236. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

**Figure 12-236. Index Pulse Example**

Some typical applications for rotary encoders range from fax machines to motor controllers, and even robot localization. Rotary sensors are fundamental to the robotics and motion control systems found today. The optical shaft encoder can be used to improve a robot in various ways. The encoder can measure rotational distance traveled and speed, which can be used to monitor, for example, the angular position of a robot gripper arm or the speed of a robot.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$V(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad \text{eqep-004} \quad (19)$$

$$V(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad \text{eqep-005} \quad (20)$$

where

$v(k)$ : Velocity at time instant  $k$

$x(k)$ : Position at time instant  $k$

$x(k-1)$ : Position at time instant  $k - 1$

$T$ : Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

$t(k)$ : Time instant " $k$ "

$t(k-1)$ : Time instant " $k - 1$ "

$X$ : Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement.

[Equation 19](#) is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity  $[x(k) - x(k-1)]$  is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant  $1/T$  (where  $T$  is the constant time between unit time events and is known in advance).

Estimation based on [Equation 19](#) has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period  $T$ . For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, [Equation 20](#) provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. [Equation 20](#) can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation of [Equation 19](#). A combination of relatively large motor speeds and high sensor resolution makes the time interval  $\Delta T$  small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use [Equation 20](#) at low speed and have the software switch over to [Equation 19](#) when the motor speed rises above some specified threshold.

The device has three instances of the EQEP modules.

#### 12.4.3.1.1 EQEP Features

The EQEP module includes the following features:

- Input synchronization
- Three stage/six stage digital noise filter
- Quadrature decoder unit

- Position counter and control unit for position measurement
- Quadrature edge capture unit for low-speed measurement
- Unit time base for speed and frequency measurement
- Watchdog timer for detecting stalls
- EQEP inputs (A/B/INDEX and STROBE) are available at chip level
- EQEP phase error output is also available. The status of the phase error can be observed by software through the CTRLMMR\_EQEP\_STAT register in the CTRL\_MMR0 module.

#### 12.4.3.1.2 EQEP Not Supported Features

The following EQEP features are not supported:

- EQEP quadrature outputs (A and B) are not pinned out

For more information about EQEP module restrictions in functionality, see *Device Specific EQEP Features*.

#### 12.4.3.1.3 EQEP Ports

**Table 12-284. EQEP Clocks and Resets**

Clocks	
Module Clock Input	Description
EQEP_FICLK	EQEP functional and interface clock
Resets	
Module Reset Input	Description
EQEP_RST	Module Reset

#### 12.4.3.2 EQEP Environment

This section describes the EQEP external connections (environment).

[Table 12-286](#) describes the EQEP I/O signals.

**Table 12-286. EQEP I/O Signals**

Module Pin	I/O Type <sup>(1)</sup>	Description
EQEP0_A	I	EQEP0 Quadrature input A
EQEP0_B	I	EQEP0 Quadrature input B
EQEP0_INDEX	I/O <sup>(2)</sup>	EQEP0 Index input/output
EQEP0_STROBE	I/O <sup>(2)</sup>	EQEP0 Strobe input/output
EQEP1_A	I	EQEP1 Quadrature input A
EQEP1_B	I	EQEP1 Quadrature input B
EQEP1_INDEX	I/O <sup>(2)</sup>	EQEP1 Index input/output
EQEP1_STROBE	I/O <sup>(2)</sup>	EQEP1 Strobe input/output
EQEP2_A	I	EQEP2 Quadrature input A
EQEP2_B	I	EQEP2 Quadrature input B
EQEP2_INDEX	I/O <sup>(2)</sup>	EQEP2 Index input/output
EQEP2_STROBE	I/O <sup>(2)</sup>	EQEP2 Strobe input/output

(1) I = Input; O = Output

(2) Output functionality is not supported. Only inputs are pinned out. For more information see *Device Specific EQEP Features*.

### 12.4.3.3 EQEP Functional Description

This section provides the EQEP functional description and corresponding functional details about EQEPx inputs.

#### Note

Multiple identical EQEP modules can be contained in a system. For actual number of EQEP modules integrated in the device, refer to *EQEP Integration*. The letter x within a signal or module name is used to indicate a generic EQEP instance on a device. For example, output interrupt request, EQEP0\_EQEP\_INT\_0 belongs to EQEP0, EQEP1\_EQEP\_INT\_0 belongs to EQEP1, and so forth.

The EQEP peripheral contains the following major functional units (as shown in Figure 12-237):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Three stage/six stage digital noise filter
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG).

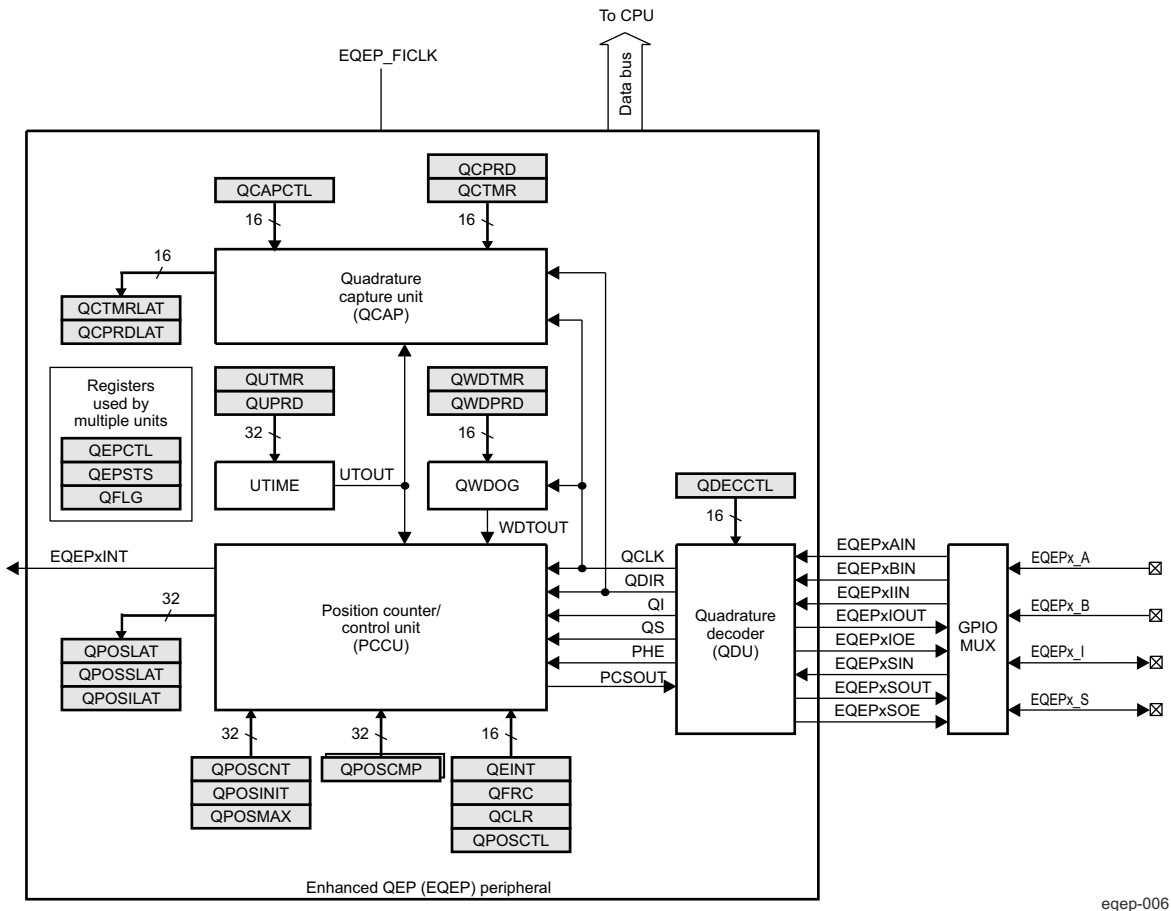

Figure 12-237. Functional Block Diagram of the EQEP Peripheral

#### 12.4.3.3.1 EQEP Inputs

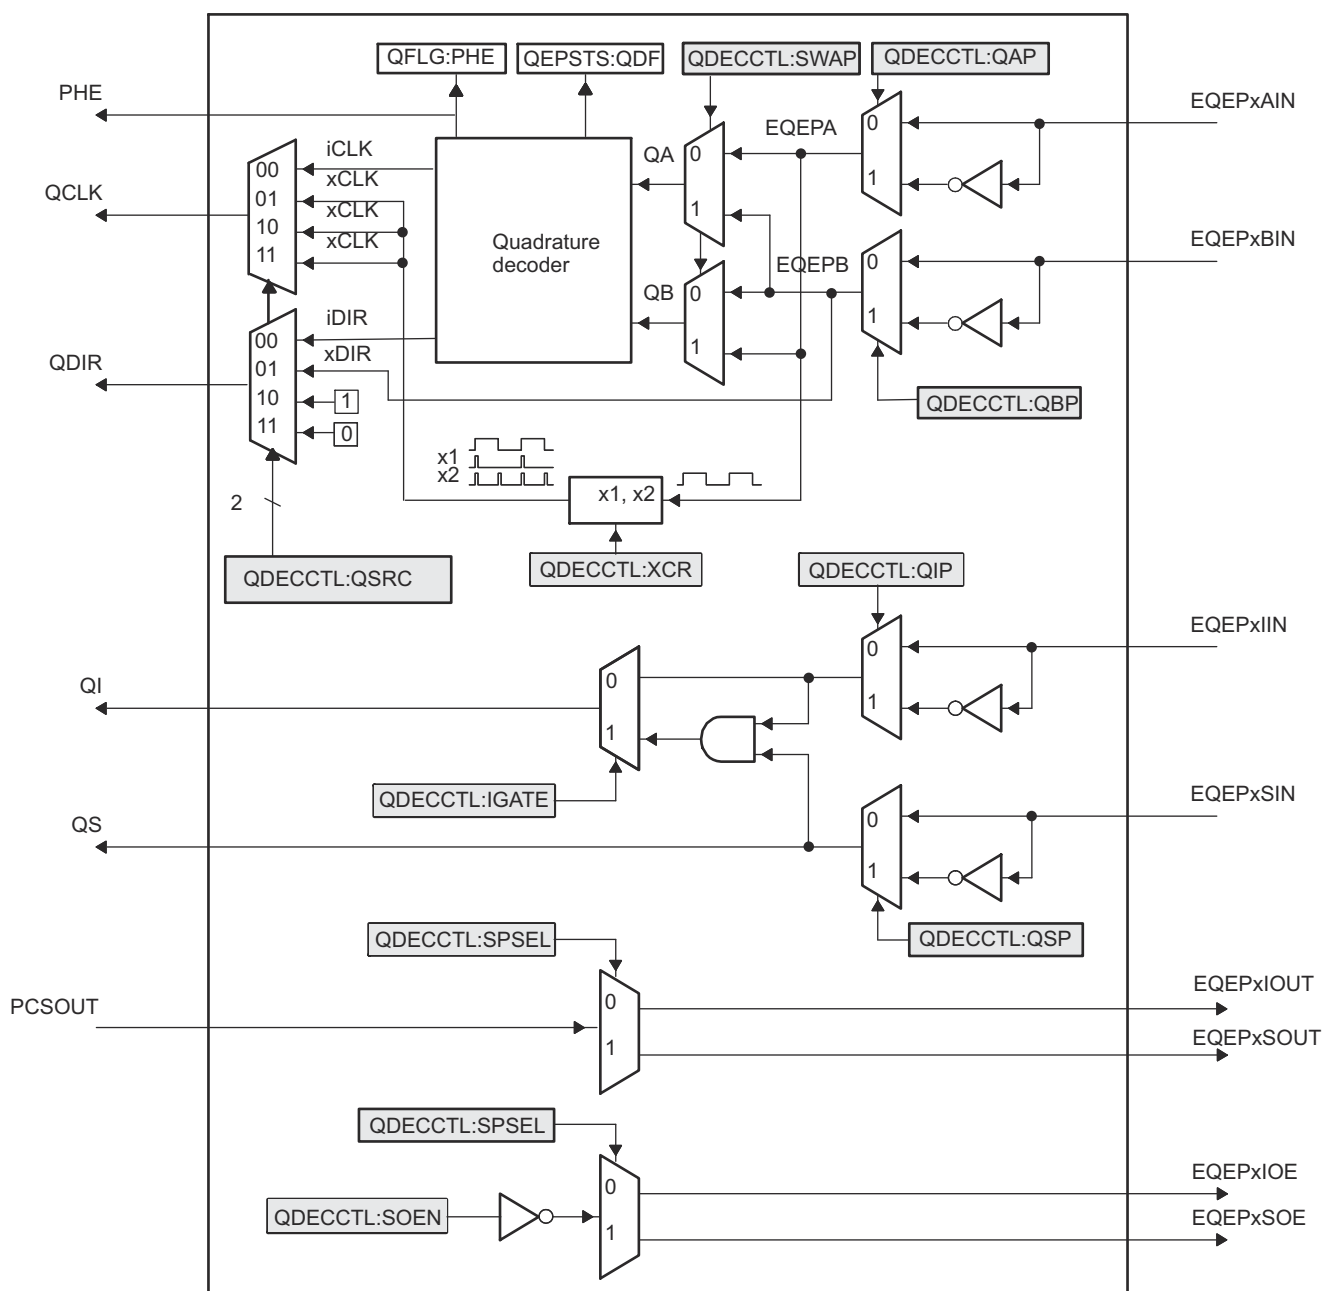

The EQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- EQEPx\_A and EQEPx\_B: These two pins can be used in quadrature-clock mode or direction-count mode.

- Quadrature-clock mode: The EQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of EQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
- Direction-count mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The EQEPx\_A pin provides the clock input and the EQEPx\_B pin provides the direction input.
- EQEPx\_I: Index or Zero Marker: The EQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the EQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- EQEPx\_S: Strobe Input: This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

### 12.4.3.3.2 EQEP Quadrature Decoder Unit (QDU)

Figure 12-238 shows a functional block diagram of the QDU.

eqep-007

**Figure 12-238. Functional Block Diagram of Decoder Unit**

### 12.4.3.3.2.1 EQEP Position Counter Input Modes

Clock and direction input to position counter is selected using the QSRC bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL), based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode.

#### 12.4.3.3.2.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

#### Direction Decoding

The direction decoding logic of the EQEP circuit determines which one of the sequences (EQEPA, EQEPB) is the leading sequence and accordingly updates the direction information in the QDF bit in the EQEP status register (EQEP\_QEP\_STS\_CT). [Table 12-287](#) and [Figure 12-239](#) show the direction decoding logic in truth table and state machine form. Both edges of the EQEPA and EQEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the EQEP logic is four times that of each input sequence. [Figure 12-240](#) shows the direction decoding and clock generation from the EQEP input signals.

#### Phase Error Flag

In normal operating conditions, quadrature inputs EQEPA and EQEPB will be 90 degrees out of phase. The phase error flag (QPEI\_FLG) is set in the EQEP\_QINT\_EN\_FLG register when edge transition is detected simultaneously on the EQEPA and  $\overline{\text{EQEPB}}$  signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 12-239](#) are invalid transitions that generate a phase error.

#### Count Multiplication

The EQEP position counter provides 4× times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both EQEP input clocks (EQEPA and EQEPB) as shown in [Figure 12-240](#).

#### Reverse Count

In normal quadrature count operation, EQEPA input is fed to the QA input of the quadrature decoder and the EQEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL). This will swap the input to the quadrature decoder thereby reversing the counting direction.

**Table 12-287. Quadrature Decoder Truth Table**

Previous Edge	Present Edge	QDIR	QPOSCNT
QA↑	QB↑	UP	Increment
	QB↓	DOWN	Decrement
	QA↓	TOGGLE	Increment or Decrement
QA↓	QB↓	UP	Increment
	QB↑	DOWN	Decrement
	QA↑	TOGGLE	Increment or Decrement

	QA↓	UP	Decrement
	QB↓	TOGGLE	Increment or Decrement
QB↓	QA↓	DOWN	Increment
	QA↑	UP	Decrement
	QB↑	TOGGLE	Increment or Decrement

**Figure 12-239. Quadrature Decoder State Machine**

**Figure 12-240. Quadrature-clock and Direction Decoding**

#### 12.4.3.3.2.1.2 EQEP Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. EQEPA input will provide the clock for position counter and the EQEPB input will have the direction information. The position counter is incremented on every rising edge of a EQEPA input when the direction input is high and decremented when the direction input is low.

#### 12.4.3.3.2.1.3 EQEP Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL) enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2× factor.

#### 12.4.3.3.2.1.4 EQEP Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL) enables clock generation to the position counter on both edges of a EQEPA input, thereby increasing the measurement resolution by 2× factor.

#### 12.4.3.3.2.2 EQEP Input Polarity Selection

Each EQEP input can be inverted using the in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL[8-5]) control bits. As an example, setting of the QIP bit in EQEP\_QDEC\_QEP\_CTL inverts the index input.

#### 12.4.3.3.2.3 EQEP Position-Compare Sync Output

The EQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (EQEP\_QPOSCNT) and the position-compare register (EQEP\_QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the SOEN bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL) enables the position-compare sync output and the SPSEL bit in EQEP\_QDEC\_QEP\_CTL selects either an EQEP index pin or an EQEP strobe pin.

#### 12.4.3.3.3 EQEP Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (EQEP\_QDEC\_QEP\_CTL and EQEP\_QCAP\_QPOS\_CTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

##### 12.4.3.3.3.1 EQEP Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement).

In all the above operating modes, position counter is reset to 0 on overflow and to QPOSMAX bifold value in EQEP\_QPOSMAX register on underflow. Overflow occurs when the position counter counts up after QPOSMAX

value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in EQEP\_QINT\_EN\_FLG register.

#### 12.4.3.3.3.1.1 EQEP Position Counter Reset on Index Event (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM] = 0b00)

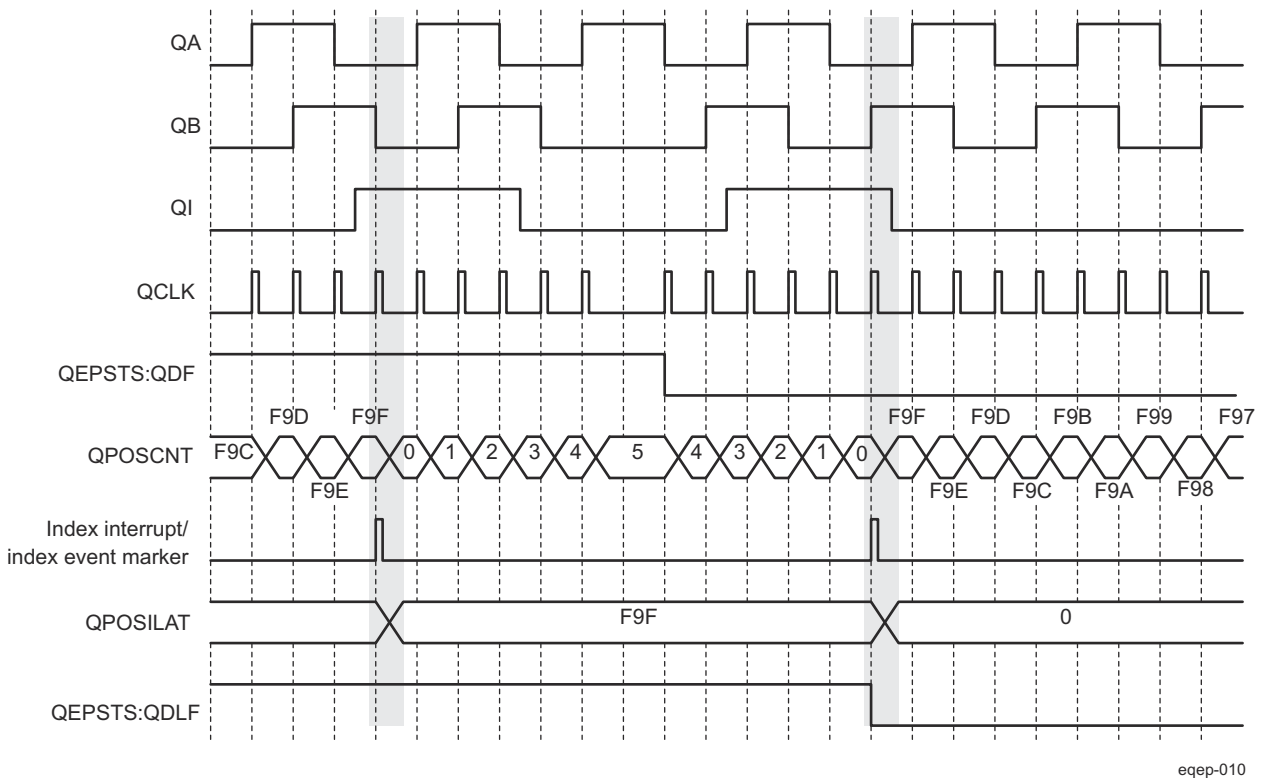

If the index event occurs during the forward movement, then position counter is reset to 0 on the next EQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP\_QPOSMAX register on the next EQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF) in EQEP\_QEP\_STS\_CT registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of EQEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of EQEPB for the forward rotation and on the rising edge of EQEPB for the reverse rotation as shown in Figure 12-241.

The position-counter value is latched to the EQEP\_QPOSILAT register and direction information is recorded in the EQEP\_QEP\_STS\_CT[4] QDLF bit on every index event marker. The position-counter error flag (EQEP\_QEP\_STS\_CT[0] PCEF) and error interrupt flag (EQEP\_QINT\_EN\_FLG[17] PCEI\_FLG) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (EQEP\_QEP\_STS\_CT[0] PCEF) is updated on every index event marker and an interrupt flag (EQEP\_QINT\_EN\_FLG[17] PCEI\_FLG) will be set on error that can be cleared only through software.

The index event latch configuration EQEP\_QDEC\_QEP\_CTL[21-20] IEL bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

eqep-010

**Figure 12-241. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or F9Fh)**

#### 12.4.3.3.3.1.2 EQEP Position Counter Reset on Maximum Position (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM=0b01)

If the position counter is equal to QPOS MAX (in EQEP\_QPOS MAX register), then the position counter is reset to 0 on the next EQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to 0, then the position counter is reset to QPOS MAX on the next QEP clock for reverse movement and position counter underflow flag is set. [Figure 12-242](#) shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF); it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (EQEP\_QDEC\_QEP\_CTL[21-20] IEL= 0b11).

**Figure 12-242. Position Counter Underflow/Overflow (QPOS MAX = 4)**

eqep-011

#### 12.4.3.3.3.1.3 Position Counter Reset on the First Index Event (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next EQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP\_QPOSMAX register on the next EQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in [Section 12.4.3.3.3.1.2](#).

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF) in EQEP\_QEP\_STS\_CT registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b11).

#### 12.4.3.3.3.1.4 Position Counter Reset on Unit Time out Event (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b11)

In this mode, the QPOSCNT value is latched to the EQEP\_QPOSILAT register and then the QPOSCNT field is reset (to 0 or the QPOSMAX value in the EQEP\_QPOSMAX register, depending on the direction mode selected by EQEP\_QDEC\_QEP\_CTL[15-14] QSRC bits on a unit time event). This is useful for frequency measurement.

#### 12.4.3.3.3.2 EQEP Position Counter Latch

The EQEP index and strobe input can be configured to latch the position counter QPOSCNT (EQEP\_QPOSCNT) into QPOSILAT (EQEP\_QPOSILAT register) and QPOSSLAT (EQEP\_QPOSSLAT register) bitfields, respectively, on occurrence of a definite event on these pins.

##### 12.4.3.3.3.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b01 and EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b10 modes).

In such cases, the EQEP position counter can be configured to latch on the following events and direction information is recorded in the EQEP\_QEP\_STS\_CT[4] QDLF bit on every index event marker.

- Latch on Rising edge (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b01)
- Latch on Falling edge (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b10)
- Latch on Index Event Marker (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (EQEP\_QINT\_EN\_FLG[26] IELI\_FLG) is set when the position counter is latched to the EQEP\_QPOSILAT register. The index event latch configuration bits are ignored when EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b00.

When Position counter reset on an index event mode is selected through EQEP\_QDEC\_QEP\_CTL[29-28] PCRM bit field (value: 0h), EQEP\_QDEC\_QEP\_CTL[21-20] IEL bit field must be configured to 0h and position counter value is latched into the EQEP\_QPOSILAT[31-0] QPOSILAT register for every index marker.

##### Latch on Rising Edge

(EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b01)

The position counter value (QPOSCNT) is latched to the EQEP\_QPOSILAT register on every rising edge of an index input.

##### Latch on Falling Edge

(EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b10)

The position counter value (QPOSCNT) is latched to the EQEP\_QPOSILAT register on every falling edge of index input.

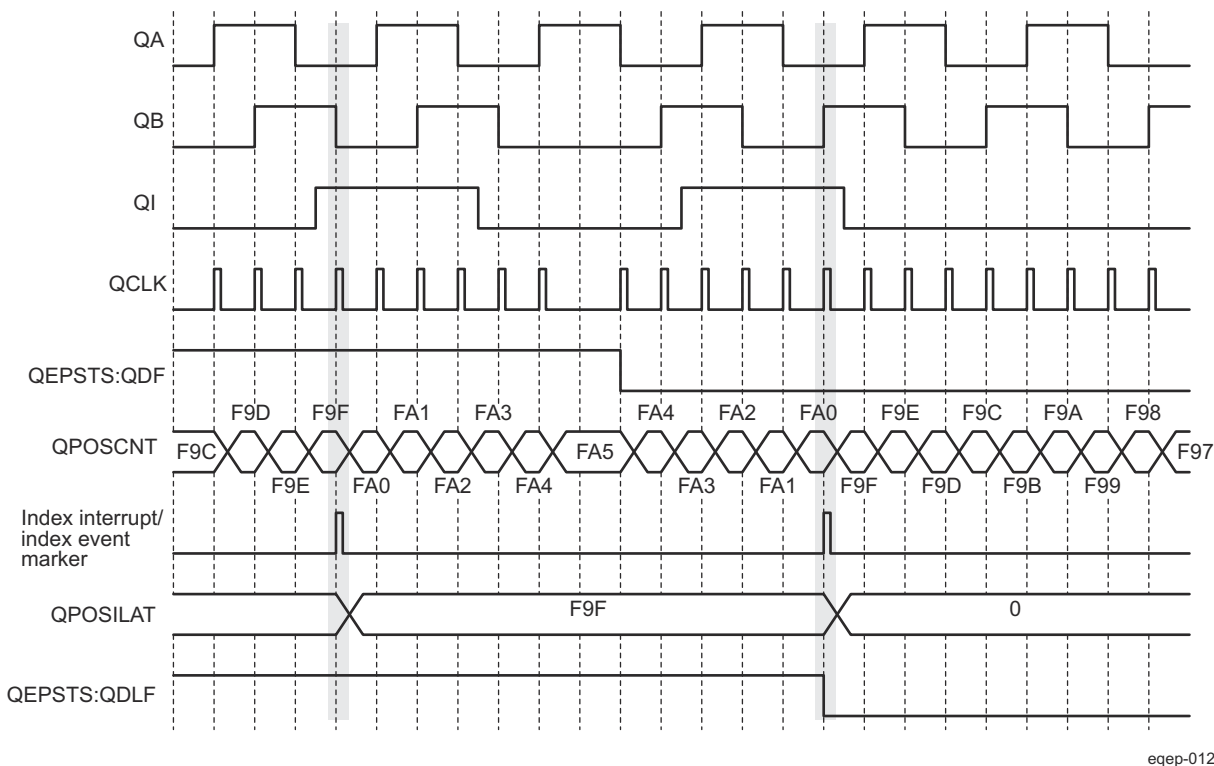

##### Latch on Index Event

Marker/Software Index Marker  
(EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b11)

The first index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF) in the EQEP\_QEP\_STS\_CT registers. It also remembers the

quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (EQEP\_QDEC\_QEP\_CTL[21:20] IEL = 0b11).

Figure 12-243 shows the position counter latch using an index event marker.

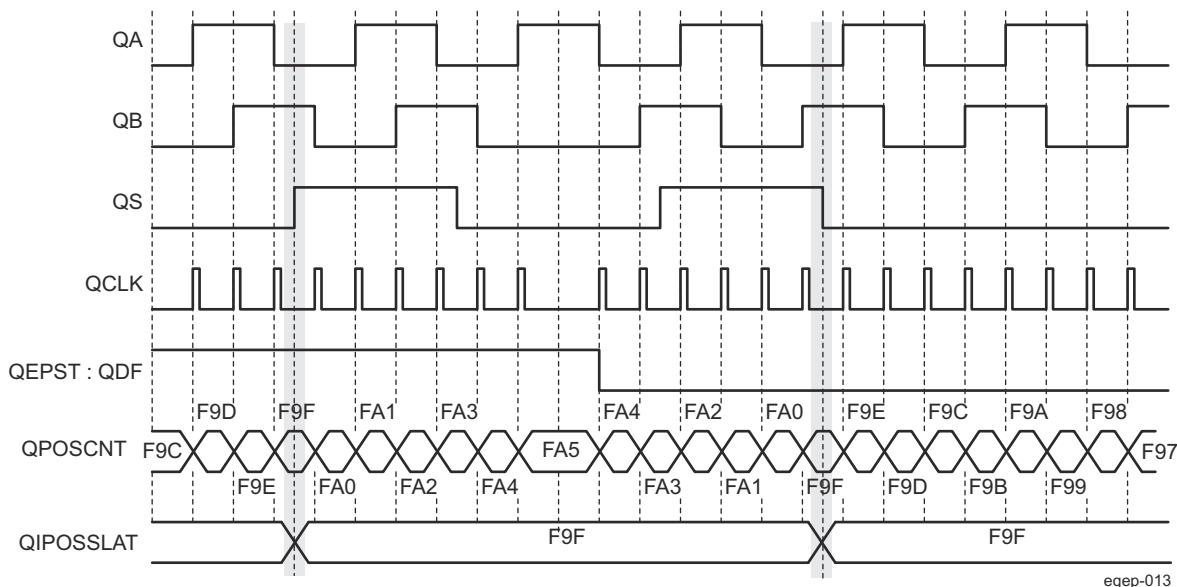

**Figure 12-243. Software Index Marker for 1000-line Encoder (EQEP\_QDEC\_QEP\_CTL[21:20] IEL = 0b01)**

#### 12.4.3.3.2.2 EQEP Strobe Event Latch

The position-counter value is latched to the EQEP\_QPOSSLAT register on the rising edge of the strobe input (QCLK) by clearing the EQEP\_QDEC\_QEP\_CTL[22] SEL bit. Latching on the falling edge of the strobe input (QCLK) can be done by inverting the strobe input using the EQEP\_QDEC\_QEP\_CTL[5] QSP bit.

If the EQEP\_QDEC\_QEP\_CTL[22] SEL bit is set, then the position counter value is latched to the EQEP\_QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in [Figure 12-244](#).

The strobe event latch interrupt flag (EQEP\_QINT\_EN\_FLG[25] SELI\_FLG) is set when the position counter is latched to the EQEP\_QPOSSLAT register.

**Figure 12-244. EQEP Strobe Event Latch (EQEP\_QDEC\_QEP\_CTL[22] SEL = 0b1)**

#### 12.4.3.3.3 EQEP Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization.

---

#### Note

When all of the above events occur simultaneously, the sequence of priority is as follows: 1) Software Initialization, 2) strobe event initialization, 3) Index Event Initialization.

---

#### Index Event Initialization (IEI)

The EQEPx\_I index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input.

If the EQEP\_QDEC\_QEP\_CTL[25-24] IEI bits are 2h, then the position counter (EQEP\_QPOSCNT) is initialized with a value in the EQEP\_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The index event initialization interrupt flag (EQEP\_QDEC\_QEP\_CTL[25-24] IEI) is set when the position counter is initialized with a value in the EQEP\_QPOSINIT register.

If EQEP\_QDEC\_QEP\_CTL[25-24] IEI bit field is configured with value 0h (default) or 1h, the index event initialization of position counter is disabled.

If EQEP\_QDEC\_QEP\_CTL[25-24] IEI bit field is configured with value 3h, then the the position counter (EQEP\_QPOSCNT) is initialized with a value in the EQEP\_QPOSINIT register on the falling edge of strobe input signal.

#### Strobe Event Initialization (SEI)

If the EQEP\_QDEC\_QEP\_CTL[27-26] SEI bits are 2h, then the position counter is initialized with a value in the EQEP\_QPOSINIT register on the rising edge of strobe input.

If the EQEP\_QDEC\_QEP\_CTL[27-26] SEI bits are 3h, then the position counter (EQEP\_QPOSCNT) is initialized with a value in the EQEP\_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The strobe event initialization interrupt flag (EQEP\_QDEC\_QEP\_CTL[27-26] SEI) is set when the position counter is initialized with a value in the EQEP\_QPOSINIT register.

If EQEP\_QDEC\_QEP\_CTL[27-26] SEI bit field is configured with value 0h (default) or 1h, the strobe event initialization of position counter is disabled.

#### Software Initialization (SWI)

The position counter can be initialized in software by writing a 1h to the EQEP\_QDEC\_QEP\_CTL[23] SWI bit, which will automatically be cleared after initialization.

#### 12.4.3.3.4 EQEP Position-Compare Unit

The EQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. [Figure 12-245](#) shows a diagram. The position-compare (EQEP\_QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the EQEP\_QCAP\_QPOS\_CTL[31] PCSHDW bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

**Figure 12-245. EQEP Position-compare Unit**

In shadow mode, SW can configure the position-compare unit (EQEP\_QCAP\_QPOS\_CTL[30] PCLOAD) to load the shadow register value into the active register on the following events and to generate the position-compare ready (EQEP\_QINT\_EN\_FLG[23] PCRI\_FLG) interrupt after loading.

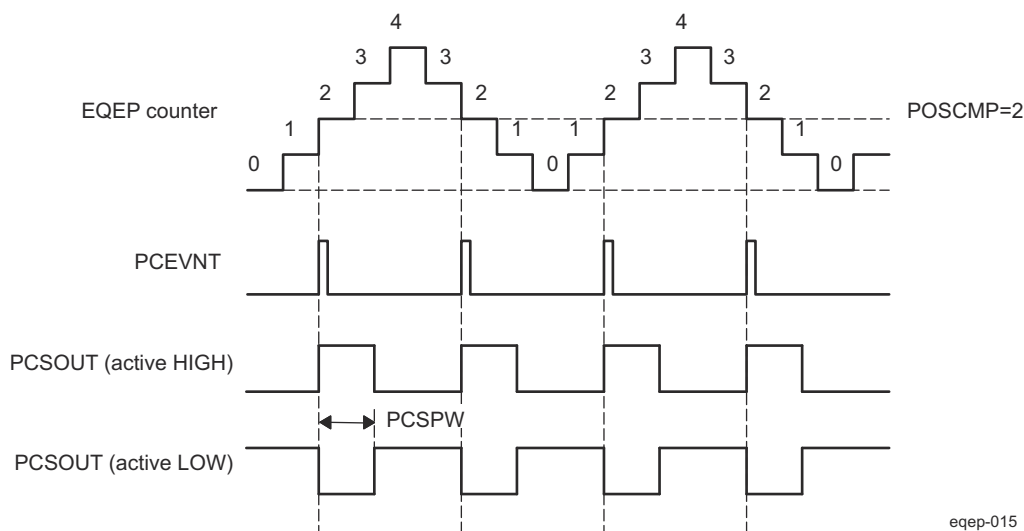

- Load on compare match
- Load on position-counter zero event.

The position-compare match (EQEP\_QINT\_EN\_FLG[24] PCMI\_FLG) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (EQEP\_QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if EQEP\_QPOSCMP bitfield POSCMP = 0x2, the position-compare unit generates a position-compare event on the transition from 1 to 2 of the EQEP position counter for forward counting direction and on the transition from 3 to 2 of the EQEP position counter for reverse counting direction (see [Figure 12-246](#)).

#### Note

When EQEP\_QCAP\_QPOS\_CTL[30] PCLOAD=0h, the shadow register is loaded into the active register as soon as POSCNT becomes zero, and it should not generate another shadow load if the POSCNT continues to stay at zero

**Figure 12-246. EQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in [Figure 12-247](#).

**Figure 12-247. EQEP Position-compare Sync Output Pulse Stretcher**

#### 12.4.3.3.4 EQEP Edge Capture Unit

The EQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 12-248](#). This feature is typically used for low speed measurement using the following equation:

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (21)$$

eqep-017

where,

- X - Unit position is defined by integer multiple of quadrature edges (see [Figure 12-249](#))
- $\Delta T$  - Elapsed time between unit position events
- $v(k)$  - Velocity at time instant "k"

The EQEP capture timer (QCTMR bitfield in EQEP\_QCTMR register) runs from prescaled SYSCLKOUT and the prescaler is programmed by the EQEP\_QCAP\_QPOS\_CTL[6-4] CCPS bits. The capture timer QCTMR value is latched into the capture period register (EQEP\_QC\_PRD\_TLAT) on every unit position event and then the capture timer is reset.

Time measurement ( $\Delta T$ ) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the EQEP overflow error flag (EQEP\_QEP\_STS\_CT[3] COEF) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (EQEP\_QEP\_STS\_CT[2] CDEF).

Capture Timer (EQEP\_QCTMR register) and Capture period register (EQEP\_QC\_PRD\_TLAT) can be configured to latch on following events.

- CPU read of EQEP\_QPOSCNT register
- Unit time-out event

If the EQEP\_QDEC\_QEP\_CTL[18] QCLM bit is cleared, then the capture timer and capture period values are latched into the EQEP\_QC\_PRD\_TLAT and EQEP\_QCPRDLAT registers, respectively, when the CPU reads the position counter in EQEP\_QPOSCNT.

#### Note

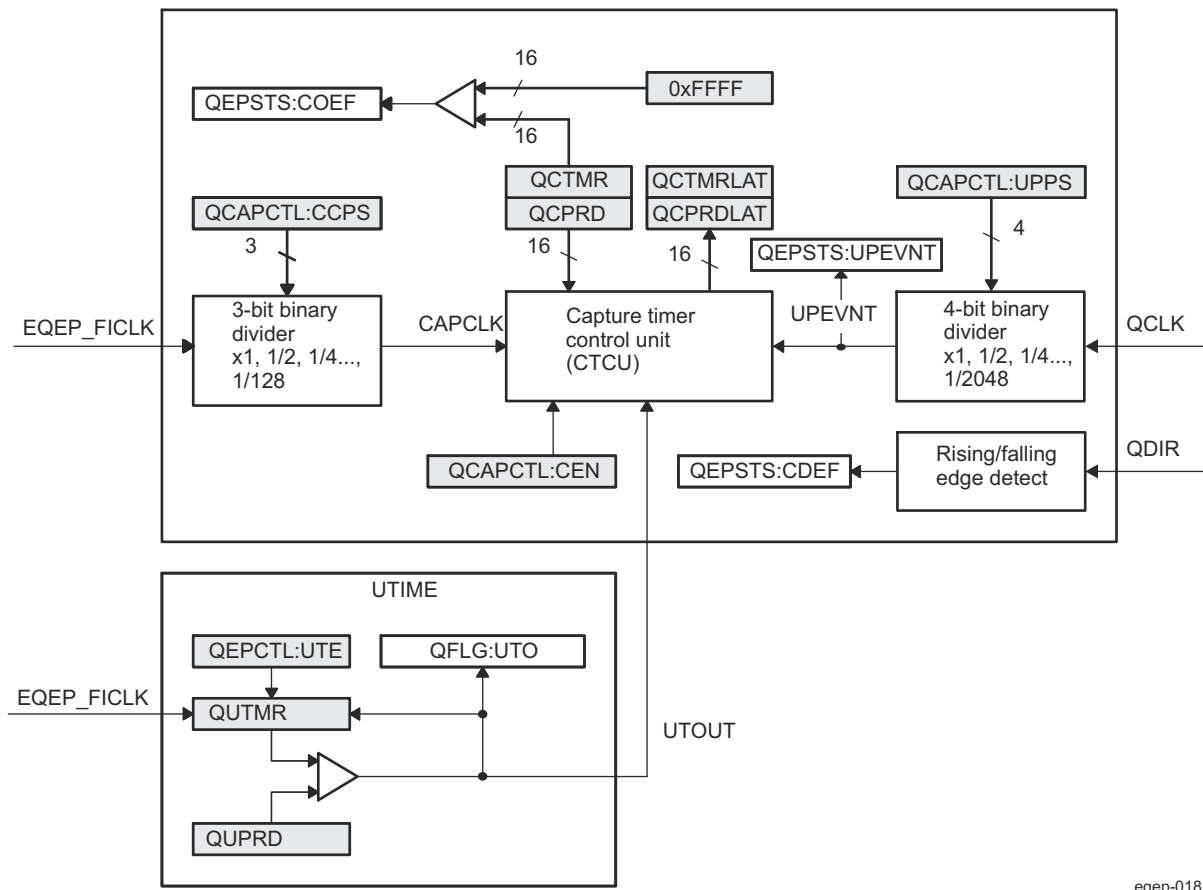

Capture timer and capture period values are not latched for an emulation read.

If the EQEP\_QDEC\_QEP\_CTL[18] QCLM bit is set, then the position counter, capture timer, and capture period values are latched into the EQEP\_QPOSLAT, EQEP\_QC\_PRD\_TLAT and EQEP\_QCPRDLAT registers, respectively, on unit time out.

Figure 12-250 shows the capture unit operation along with the position counter.

#### Note

The EQEP\_QCAP\_QPOS\_CTL register should not be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLKOUT/4 to SYSCLKOUT/8, where SYSCLKOUT is equivalent to EQEPx\_FICLK). The capture unit must be disabled before changing the prescaler.

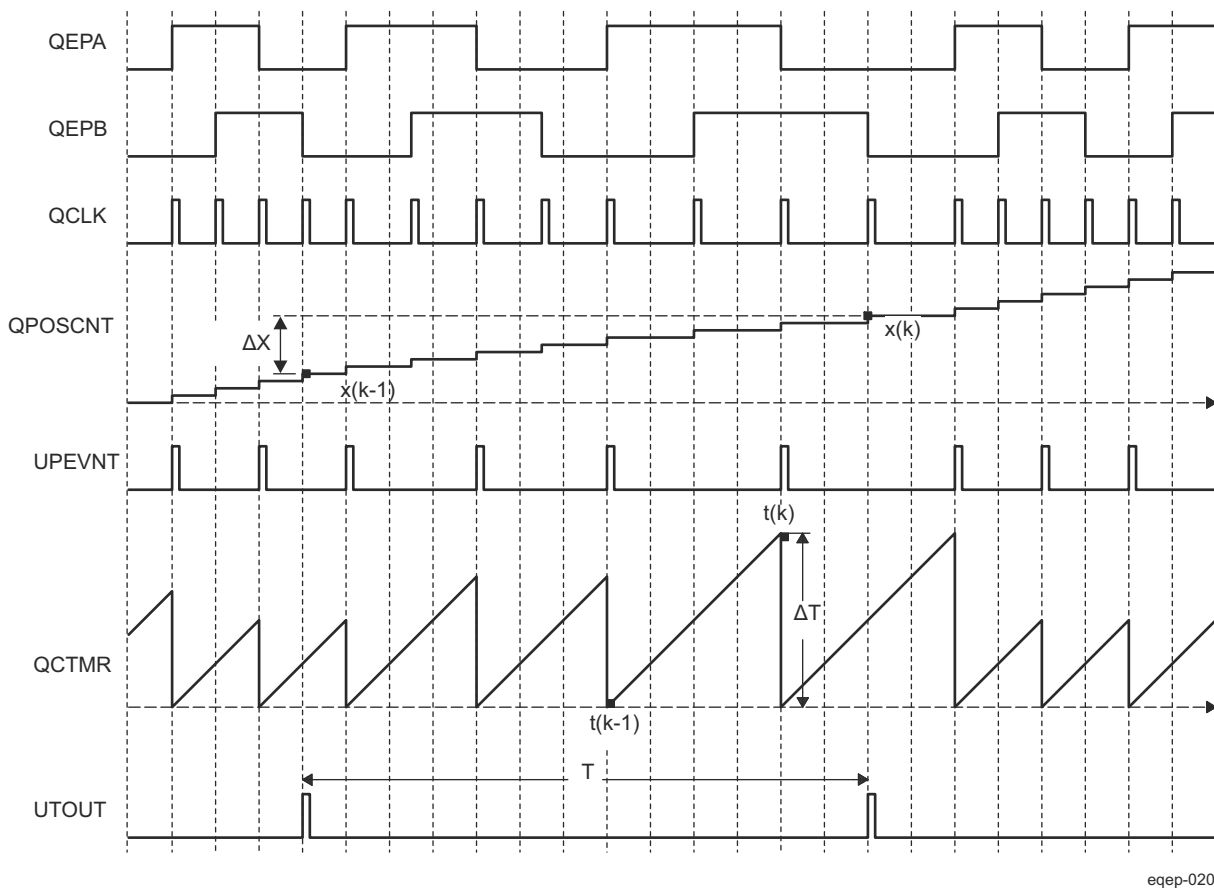

**Figure 12-248. EQEP Edge Capture Unit**

N - Number of quadrature periods selected using EQEP\_QCAP\_QPOS\_CTL[3-0] UPPS bits

**Figure 12-249. Unit Position Event for Low Speed Measurement (EQEP\_QCAP\_QPOS\_CTL[UPPS] = 0010)**

**Figure 12-250. EQEP Edge Capture Unit - Timing Details**

Velocity Calculation Equations:

$$V(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad \text{or} \quad V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T}$$

(22)

eqep\_021

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement

t(k): Time instant "k"

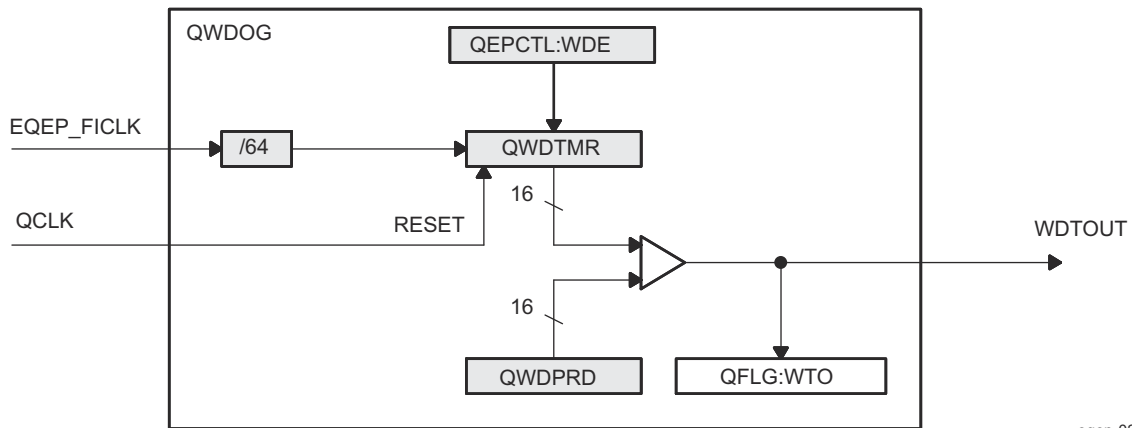

t(k-1): Time instant "k - 1"

Unit time (T) and unit period (X) are configured using the EQEP\_QUPRD and EQEP\_QCAP\_QPOS\_CTL[3-0] UPPS registers. Incremental position output and incremental time output is available in the EQEP\_QOSLAT and EQEP\_QCPRLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (EQEP_QUPRD)
ΔX	Incremental Position = QOSLAT(k) - QOSLAT(k - 1)
X	Fixed unit position defined by sensor resolution and QCAPCTL[3-0] UPPS bits
ΔT	Capture Period Latch (QCPRLAT)

#### 12.4.3.3.5 EQEP Watchdog

The EQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The EQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer will time out and the watchdog interrupt flag will be set (EQEP\_QINT\_EN\_FLG[20] WTOI\_FLG). The time-out value is programmable through the watchdog period bit field (EQEP\_QWD\_TMR\_PRD[31-16] QWDPRD).

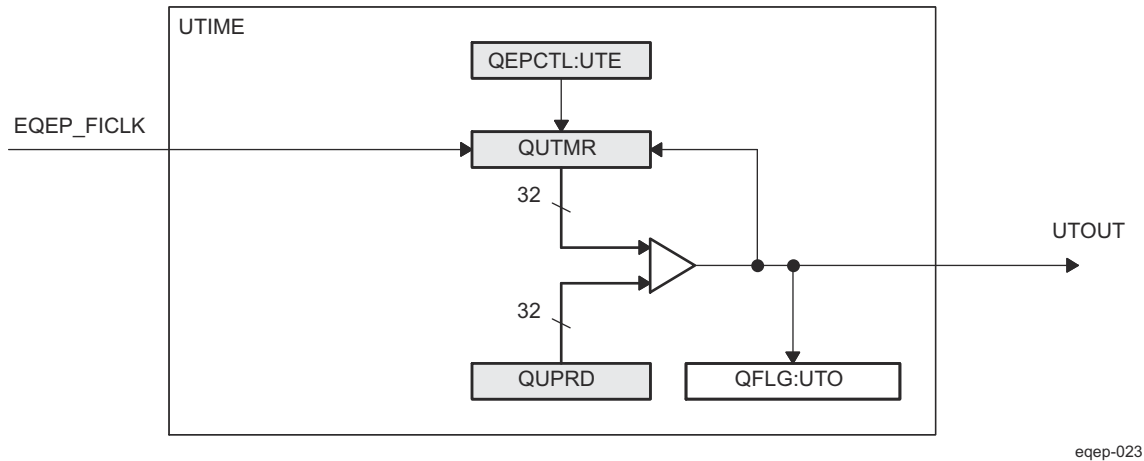

eqep-022

**Figure 12-251. EQEP Watchdog Timer**

#### 12.4.3.3.6 Unit Timer Base

The EQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (EQEP\_QINT\_EN\_FLG[27] UTOI\_FLG) when the unit timer (QUTMR) matches the unit period register (EQEP\_QUPRD).

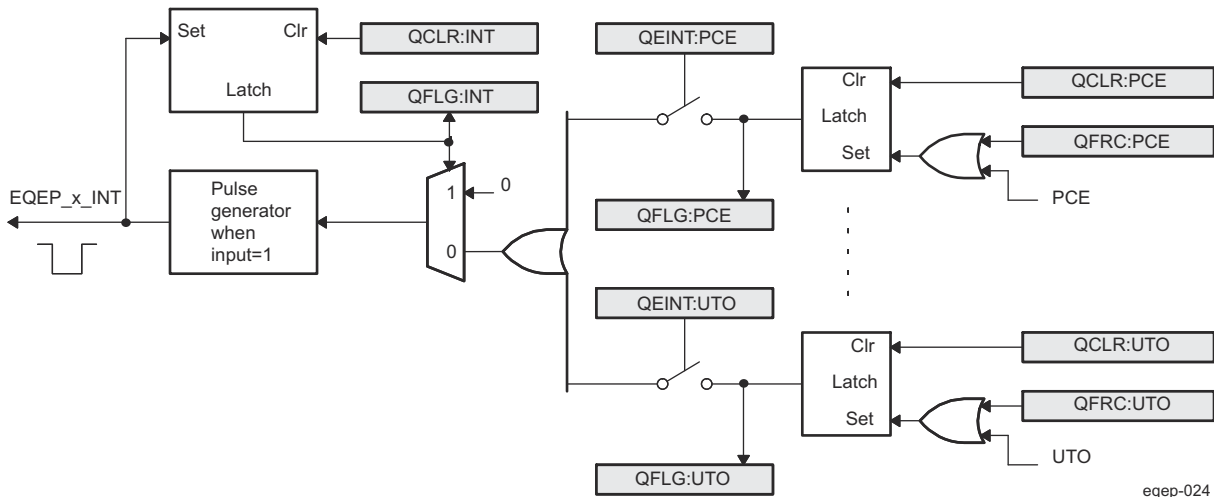

The EQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event. The latched values are used for velocity calculation as described in Section [Section 12.4.3.3.4](#).

**Figure 12-252. EQEP Unit Time Base**

#### 12.4.3.3.7 EQEP Interrupt Structure

Figure 12-253 shows how the interrupt mechanism works in the EQEP module.

**Figure 12-253. EQEP Interrupt Generation**

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL, and UTO) can be generated. The interrupt control register (EQEP\_QINT\_EN\_FLG) is used to enable/disable individual interrupt event sources. The interrupt flag register (EQEP\_QINT\_EN\_FLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is only generated to the interrupt controller if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (EQEP\_QINT\_CLR\_FRC), before any other interrupt pulses are generated. SW can force an interrupt event by way of the interrupt force register (EQEP\_QINT\_CLR\_FRC), which is useful for test purposes.

#### 12.4.3.3.8 Summary of EQEP Functional Registers

Table 12-288 lists the registers with their memory locations, sizes, and reset values.

**Table 12-288. EQEP Control and Status Functional Registers**

Offset	Acronym	Register Description	Size (×16)/ #shadow
0h	EQEP_QPOSCNT	EQEP Position Counter Register	2/0
4h	EQEP_QPOSINIT	EQEP Position Counter Initialization Register	2/0
8h	EQEP_QPOSMAX	EQEP Maximum Position Count Register	2/0
Ch	EQEP_QPOSCMP	EQEP Position-Compare Register	2/1
10h	EQEP_QPOSILAT	EQEP Index Position Latch Register	2/0
14h	EQEP_QPOSSLAT	EQEP Strobe Position Latch Register	2/0
18h	EQEP_QPOSLAT	EQEP Position Counter Latch Register	2/0
1Ch	EQEP_QUTMR	EQEP Unit Timer Register	2/0
20h	EQEP_QUPRD	EQEP Unit Period Register	2/0
24h	EQEP_QWD_TMR_PRD	EQEP Watchdog Timer and Period Register	2/0
28h	EQEP_QDEC_QEP_CTL	EQEP Decoder and EQEP Control Register	2/0
2Ch	EQEP_QCAP_QPOS_CTL	EQEP Capture and Position Compare Control Register	2/0
30h	EQEP_QINT_EN_FLG	EQEP Interrupt Enable and Flag Register	2/0
34h	EQEP_QINT_CLR_FRC	EQEP Interrupt Clear and Forcing Register	2/0
38h	EQEP_QEP_STS_CT	EQEP Status and Capture Timer Register	2/0
3Ch	EQEP_QC_PRD_TLAT	EQEP Capture Period and Timer Latch Register	2/0
40h	EQEP_QCPRDLAT	EQEP Capture Period Latch Register	1/0
5Ch	EQEP_PID	EQEP Revision ID Register	2/0

## 12.4.4 Controller Area Network (MCAN)

This section describes the Controller Area Network (MCAN) modules in the device.

### 12.4.4.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control. CAN has high immunity to electrical interference. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

They connect to the physical layer of the CAN network through external (for the device) transceivers. Each MCAN module supports flexible bit rates greater than 1 Mbps and is compliant to ISO 11898-1:2015.

#### 12.4.4.1.1 MCAN Features

Each MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- SAE J1939 support
- AUTOSAR support
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements
- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock/Host clock)
- Parity/ECC support - Message RAM single error correction and double error detection (SECDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.4.4.1.2 MCAN Not Supported Features

- Host bus firewall
- GPIO mode
- Clock calibration
- External (IO) Loopback mode
- Debug DMA (see [Section 12.4.4.3.7.4](#))
- TX DMA channels [31:3]

#### 12.4.4.1.3 MCAN Ports

**Table 12-289. MCAN Clocks and Resets**

Clocks	
Module Clock Input	Description
MCAN_ICLK	Interface Clock
MCAN_FCLK	Functional Clock
Resets	
Module Reset Input	Description

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCAN_MCANSS_MCAN_LVL_INT_0	MCAN Line 0 Interrupt Request	Level
MCAN_MCANSS_MCAN_LVL_INT_1	MCAN Line 1 Interrupt Request	Level
MCAN_MCANSS_EXT_TS_ROLLOVER_LVL_INT_0	MCAN External TimeStamp Counter Rollover Interrupt	Level
MCAN_MCANSS_ECC_CORR_LVL_INT_0	MCAN ECC Correctable Error Interrupt Request	Level
MCAN_MCANSS_ECC_UNCORR_LVL_INT_0	MCAN ECC Uncorrectable Error Interrupt Request	Level

#### 12.4.4.2 MCAN Environment

This section describes the MCAN external connections (environment).

[Table 12-291](#) describes the MCAN I/O signals.

**Table 12-291. MCAN I/O Signals**

Module Pin	I/O <sup>(1)</sup>	Description
RX	I	Serial data input from external CAN transceiver
TX	O	Serial data output to external CAN transceiver

(1) I = Input; O = Output; HiZ = High Impedance

### 12.4.4.3 MCAN Functional Description

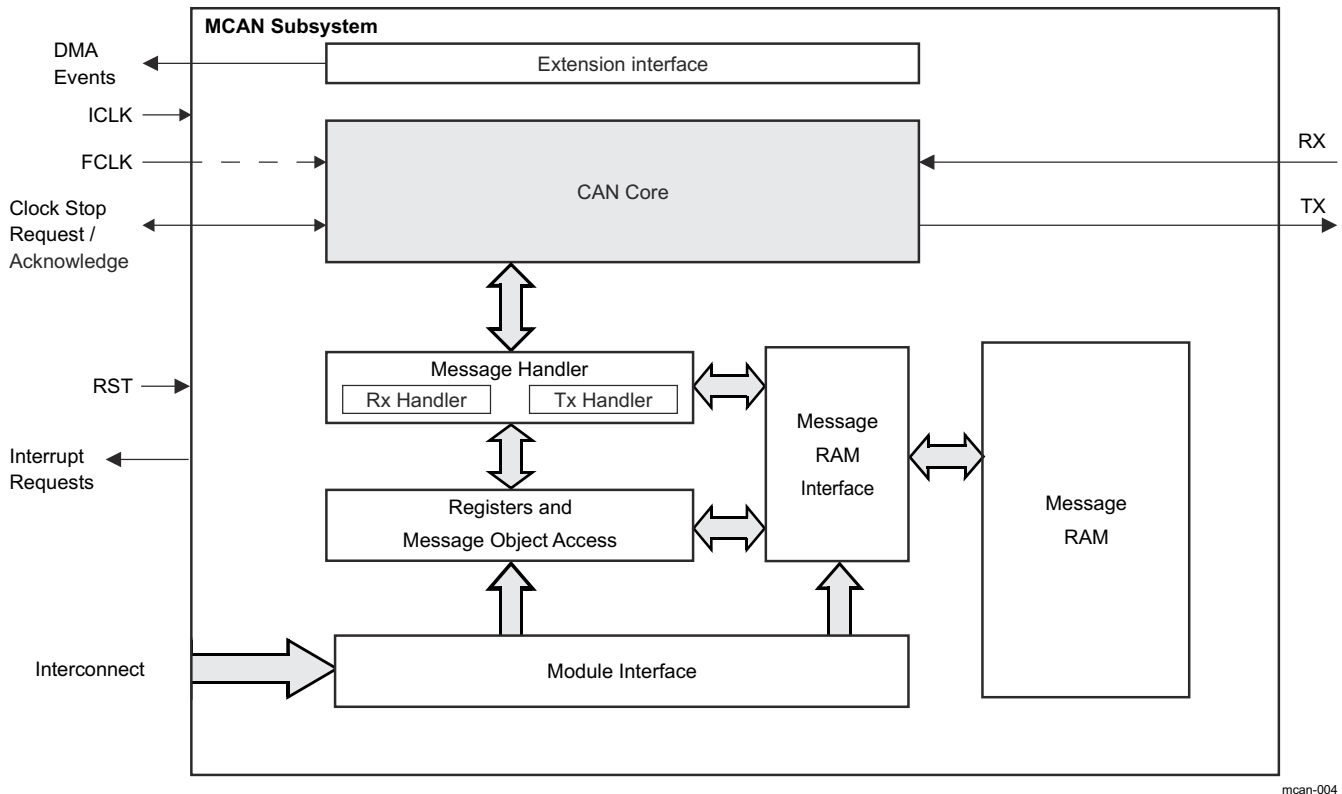

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values greater than 1 Mbps. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 12-254 shows the MCAN module block diagram.

**Figure 12-254. MCAN Block Diagram**

The MCAN module blocks description:

- **CAN Core:** the CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler:** the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and the Interrupt/DMA request generation as programmed in the control registers.
- **Message RAM:** the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see *Message RAM*).
- **Message RAM Interface:** enables connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access:** data consistency is ensured by indirect accesses to the message objects. The interface registers have the same word-length as the Message RAM.
- **Module Interface:** provides connection to the Registers and Message Object Access block and Message RAM Interface block

- **Clocking:** two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock ICLK) and the peripheral asynchronous clock (functional clock - FCLK). For more information, see *MCU\_MCAN Clocks and Resets* and *MCAN Clocks and Resets*.
- **Extension Interface:** this interface is used for DMA requests signaling (see *DMA Requests*).

#### 12.4.4.3.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There is synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal to the Host clock domain and to the CAN clock domain.

#### Note

ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated ICLK has to be considered:

$$f_{0,ICLK} \pm \Delta f_{FM,ICLK} \geq f_{FCLK}$$

For more information on how to configure the relevant clock source registers, see *Clocking* and the device-specific Datasheet.

#### 12.4.4.3.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode is requesting or forcing (based on MCANSS\_CTRL[3] DBG\_SUSP\_FREE bit) the MCAN module to go into initialization mode (see MCAN\_CCCR[0] INIT bit) in which new interrupts and DMA requests will not be issued, that is to prevent the interrupt and DMA requests from propagating to the Host CPU (for more information, see [Section 12.4.4.3.3.8.2, Suspend Mode](#)).

##### 12.4.4.3.2.1 Interrupt Requests

The MCAN module has two interrupt lines. There are 30 internal interrupt sources. Each source can be configured to drive one of the two interrupt lines. The interrupts are 'level high' interrupts.

The MCAN core provides two interrupt requests (for Line 0 and Line 1).

For more information, see the following registers:

- Interrupt Register (MCAN\_IR)
- Interrupt Enable (MCAN\_IE)
- Interrupt Line Select (MCAN\_ILS)
- Interrupt Line Enable (MCAN\_ILE)

The MCAN module is capable of issuing ECC interrupts. After clearing the ECC interrupt source, the application software must also write 1 to EOI register (MCANSS\_ECC\_SEC\_EOI\_REG/MCANSS\_ECC\_DED\_EOI\_REG). For more information, see *ECC Aggregator*.

The MCAN module supports External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see *External Timestamp Counter*).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS\_ICS)
- Interrupt Raw Status Register (MCANSS\_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS\_IECS)
- Interrupt Enable Register (MCANSS\_IE)
- Interrupt Enable Status Register (MCANSS\_IES)
- End Of Interrupt Register (MCANSS\_EOI)
- External Timestamp Prescaler Register (MCANSS\_EXT\_TS\_PRESCALER)

- External Timestamp Unserviced Interrupts Counter Register (MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR)

For more information about available Interrupt Requests, see *MCU\_MCAN Hardware Requests* and *MCAN Hardware Requests*.

#### 12.4.4.3.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extension Interface. The DMA signaling uses a simple DMA request active high pulse.

The active high pulse indicates a pending message is transmitted (see MCAN\_TXBRP). This pulse can be used to transfer another message to the Tx Buffer, which would need to be followed by writing 1 to the corresponding MCAN\_TXBAR[0] AR bit to mark a new Tx message pending transmission.

The Parity on Tx DMA Events is available using an EDC Controller which can be accessed through the ECC Aggregator.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle pulses (ICLK).

#### 12.4.4.3.3 Operating Modes

##### 12.4.4.3.3.1 Software Initialization

Setting the MCAN\_CCCR[0] INIT bit to 1 starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus\_Off state. While the MCAN\_CCCR[0] INIT bit is set, the message transfer is stopped and the status of the output TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN\_CCCR[0] INIT bit does not change any configuration register. Resetting the MCAN\_CCCR[0] INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus\_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN\_CCCR[0] INIT and MCAN\_CCCR[1] CCE bits are set (write protection).

The MCAN\_CCCR[1] CCE bit can only be set/reset while the MCAN\_CCCR[0] INIT = 1. The MCAN\_CCCR[1] CCE bit is automatically reset when the MCAN\_CCCR[0] INIT bit is reset.

The following registers are reset when the MCAN\_CCCR[1] CCE bit is set:

- MCAN\_HPMS - High Priority Message Status
- MCAN\_RXF0S - Rx FIFO 0 Status
- MCAN\_RXF1S - Rx FIFO 1 Status
- MCAN\_TXFQS - Tx FIFO/Queue Status
- MCAN\_TXBRP - Tx Buffer Request Pending
- MCAN\_TXBTO - Tx Buffer Transmission Occurred
- MCAN\_TXBCF - Tx Buffer Cancellation Finished
- MCAN\_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN\_TOCV[15-0] TOC field is preset to the value configured by the MCAN\_TOCC[31-16] TOP field when the MCAN\_CCCR[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while MCAN\_CCCR[1] CCE = 1.

The following registers are only writeable while MCAN\_CCCR[1] CCE = 0

- MCAN\_TXBAR - Tx Buffer Add Request
- MCAN\_TXBCR - Tx Buffer Cancellation Request

MCAN\_CCCR[7] TEST and MCAN\_CCCR[5] MON bits can only be set by the Host CPU while MCAN\_CCCR[0] INIT = 1 and MCAN\_CCCR[1] CCE = 1. Both bits may be reset at any time. The MCAN\_CCCR[6] DAR bit can only be set/reset while MCAN\_CCCR[0] INIT = 1 and MCAN\_CCCR[1] CCE = 1.

Table 12-292 shows the steps to configure the MCAN module.

**Table 12-292. Steps to Configure MCAN Module**

Step	Operation	Description	Pseudo Code
1	Initialize MCAN_CCCR	Set MCAN_CCCR[0] INIT bit and check that it has been set	INIT = 1; If INIT ≠ 1, wait until it is
2	Unlock protected registers	Set MCAN_CCCR[1] CCE bit	CCE = 1;
3	Configure CAN mode	Set MCAN_CCCR[8] FDOE bit to CAN FD	FDOE = 1 for CAN FD FDOE = 0 for CAN
4	Configure Bit Rate Switching	Set MCAN_CCCR[9] BRSE bit	BRSE = 1 with bit rate switching BRSE = 0 without bit rate switching
5	Set bit timing	Set MCAN_NBTP register	
6	Lock protected registers	Clear MCAN_CCCR[1] CCE bit	CCE = 0;
7	Return MCAN module to normal operation	Clear MCAN_CCCR[0] INIT bit and check it has been cleared	INIT = 0; If INIT ≠ 0, wait until it is

#### 12.4.4.3.3.2 Normal Operation

Once the MCAN module is initialized and the MCAN\_CCCR[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

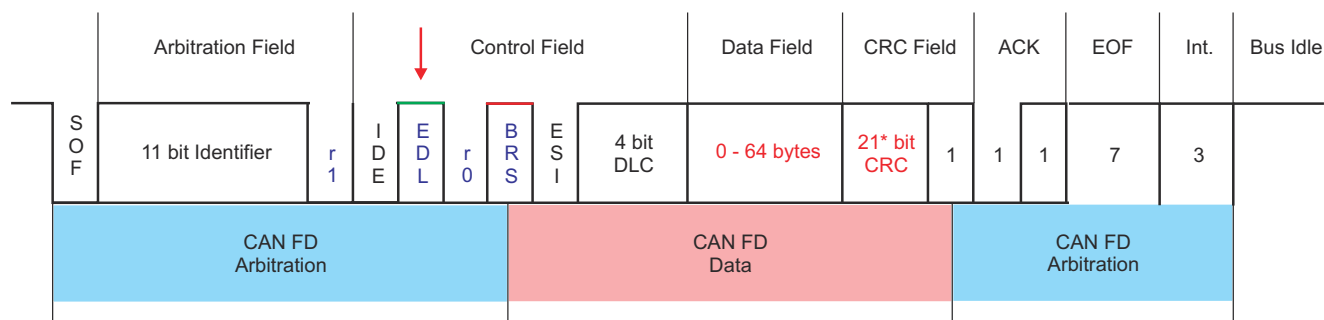

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

#### Note

Automated transmission on reception of remote frames is not supported.

#### 12.4.4.3.3.3 CAN FD Operation

The CAN FD standard allows extended frames to be sent, up to 64 data bytes in a single frame at a higher bit rate for the data phase of a frame, up to 8 Mbps. The CAN FD standard introduces the ability to switch from one bit rate to another. Extended Data Length (EDL), as shown in Figure 12-255, sets a data length of up to 8 or up to 64 data bytes. Bit Rate Switching (BRS) indicates whether two bit rates (the data phase is transmitted at a different bit rate to the arbitration phase) are enabled.

\* 17 bit CRC for data fields with up to 16 bytes

mcan-004a

**Figure 12-255. CAN FD Frame**

**Note**

Figure 12-255 presents CAN FD frame according to the Non-ISO CAN FD (legacy) protocol. In the new ISO CAN FD protocol the CRC Field includes additional 5 bits (three stuff bit counter (SBC) bits and two parity bits). With these additional bits, a weakness identified in the error detection scheme chosen by the original protocol is removed. By setting MCAN\_CCCR[15] NISO bit, the ISO or Non-ISO CAN FD format can be chosen. In CAN network ISO CAN FD and non-ISO CAN FD devices should never mix.

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN\_PSR[14] EXE bit. When Protocol Exception Handling is enabled (MCAN\_CCCR[12] PXHD = 0), this causes the operation state to change from Receiver (MCAN\_PSR[4-3] ACT = 10) to Integrating (MCAN\_PSR[4-3] ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN\_CCCR[12] PXHD = 1), the MCAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN\_CCCR[8] FDOE bit. In case MCAN\_CCCR[8] FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN\_CCCR[8] FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN\_CCCR[8] FDOE and MCAN\_CCCR[9] BRSE bits can only be changed while the MCAN\_CCCR[0] INIT and MCAN\_CCCR[1] CCE bits are both set. With MCAN\_CCCR[8] FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN\_CCCR[8] FDOE = 1 and MCAN\_CCCR[9] BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN\_CCCR[8] FDOE = 1 and MCAN\_CCCR[9] BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wakeup messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

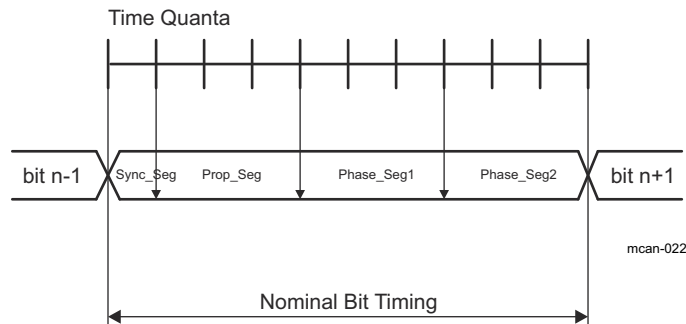

In the CAN FD format, the DLC coding differs from the standard CAN format (see Table 12-293).

**Table 12-293. DLC Coding**

DLC	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Number of Data Bytes in Standard CAN	0	1	2	3	4	5	6	7	8	8	8	8	8	8	8	8
Number of Data Bytes in CAN FD	0	1	2	3	4	5	6	7	8	12	16	20	24	32	48	64

For CAN FD frames, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see [Figure 12-256](#)) is used as configured by the Nominal Bit Timing and Prescaler Register MCAN\_NBTP. In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register MCAN\_DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

**Figure 12-256. CAN Bit Timing**

The maximum configurable data phase bit timing depends on the CAN clock frequency (FCLK). Example: with FCLK = 20 MHz and the shortest configurable bit time of 4  $t_q$  (time quanta), the bit rate in the data phase is 5 Mbps.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see MCAN\_PSR[11] RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

#### **12.4.4.3.3.4 Transmitter Delay Compensation**

##### **12.4.4.3.3.4.1 Description**

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the TX pin the MCAN module receives the transmitted data from its local CAN transceiver via the RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

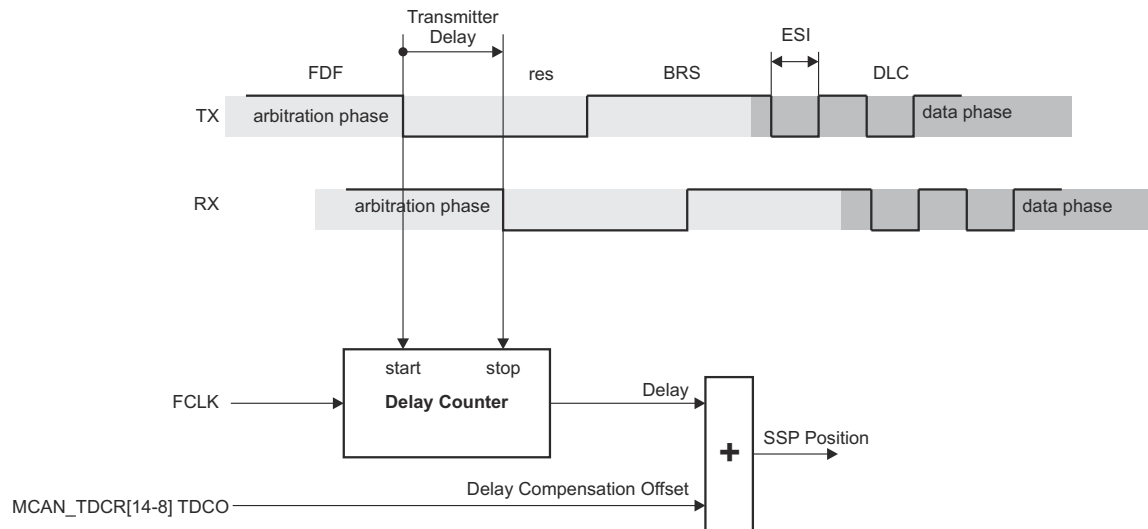

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN\_DBTP[23] TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output TX pin through the transceiver to the receive input RX pin plus the transmitter delay compensation offset configured by the MCAN\_TDCR[14-8] TDCO field (see [Figure 12-257](#)). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of  $mtq$ .

The actual transmitter delay compensation value can be checked by reading the MCAN\_PSR[22-16] TDCV field. This field is cleared when the MCAN\_CCCR[0] INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN\_DBTP[23] TDC bit is set.

mcan-005

**Figure 12-257. Transmitter Delay Measurement**

#### 12.4.4.3.3.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN\_DBTP[23] TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input RX pin of the transmitter. The resolution of this measurement is one mtq (see Figure 12-257). The mtq (minimum time quantum) dimension is equal to the CAN clock period (FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming MCAN\_TDCR[6-0] TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the RX pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN\_TDCR[6-0] TDCF field and the RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN\_TDCR[14-8] TDCO field) has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN\_TDCR[14-8] TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

#### 12.4.4.3.3.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The receive and transmit error counters (MCAN\_ECR[14-8] REC and MCAN\_ECR[7-0] TEC) are frozen while CAN error logging (MCAN\_ECR[23-16] CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting MCAN\_CCCR[2] ASM bit. The bit can only be set by the Host CPU at any time when both MCAN\_CCCR[2] CCE and MCAN\_CCCR[0] INIT bits are set to 1.

The Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset MCAN\_CCCR[2] ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

#### Note

The Restricted Operation Mode must not be combined with the Internal Loopback Mode .

#### 12.4.4.3.3.6 Bus Monitoring Mode

Entering Bus Monitoring Mode is done by setting the MCAN\_CCCR[5] MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode the MCAN\_TXBRP register is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. Figure 12-258 shows the connection of the TX and RX signals to the MCAN module in Bus Monitoring Mode.

Figure 12-258. Connection of Signals in Bus Monitoring Mode

#### 12.4.4.3.3.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN\_CCCR[6] DAR bit).

##### 12.4.4.3.3.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending MCAN\_TXBRP[xx] TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred MCAN\_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN\_TXBCF[xx] CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred MCAN\_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN\_TXBCF[xx] CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred MCAN\_TXBTO[xx] TOx bit is not set

- Corresponding Tx Buffer Cancellation Finished MCAN\_TXBCF[xx] CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

#### 12.4.4.3.3.8 Power Down (Sleep Mode)

The entering in Power Down mode is controlled via two sources:

- PSC (via clock stop request signal)
- Software (by writing to the MCAN\_CCCR[4] CSR bit)

As long as the clock stop request signal is active, the MCAN\_CCCR[4] CSR bit is read as 1.

When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN\_CCCR[0] INIT bit to 1 to prevent any further CAN transfers.

The MCAN module acknowledges that it is ready for power down:

- By asserting clock stop acknowledge signal to the PSC (in case of PSC source).
- By setting the MCAN\_CCCR[3] CSA flag bit to 1 (in case of Software source).

In this state, before the clocks are switched off, further register accesses can be made. Now the module clock inputs ICLK and FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN\_CCCR[4] CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN\_CCCR[3] CSA flag bit. Afterwards, the application can restart CAN communication by resetting the MCAN\_CCCR[0] INIT bit.

Restoring the clocks from clock stop mode, needs to be done according to how the clock stop was initiated:

- If Software asserts the MCAN\_CCCR[3] CSA flag bit, once the MCAN module goes idle, the MCAN\_CCCR[0] INIT bit is set. To get it started again, Software needs to write 0 to the MCAN\_CCCR[0] INIT bit.
- If PSC is issuing a clock stop request, than there are two options for waking up:
  - After removing clock stop request signal, Software would need to write 0 to the MCAN\_CCCR[0] INIT bit, or
  - If the MCANSS\_CTRL[5] AUTOWAKEUP bit is set, than after removing clock stop request signal, an FSM inside the MCAN module will reset the MCAN\_CCCR[0] INIT bit (without Software).

#### 12.4.4.3.3.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN\_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL[5] AUTOWAKEUP and MCANSS\_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 12.4.4.3.3.8.3, Wakeup request](#)). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN\_CCCR[0] INIT bit is performed to clear it.

#### 12.4.4.3.3.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS\_CTRL[3] DBGSUSP\_FREE bit), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that

point the MCAN\_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading MCAN\_CCCR[0] INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL[5] AUTOWAKEUP and MCANSS\_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 12.4.4.3.3.8.3, Wakeup request](#)). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN\_CCCR[0] INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN\_ECR[23-16] CEL
- MCAN\_PSR[2-0] LEC
- MCAN\_PSR[10-8] DLEC
- MCAN\_PSR[11] RESI
- MCAN\_PSR[12] RBRS
- MCAN\_PSR[13] RFDF
- MCAN\_PSR[14] PXE

#### **12.4.4.3.3.8.3 Wakeup request**

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS\_CTRL[5] AUTOWAKEUP and MCANSS\_CTRL[4] WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN\_CCCR[0] INIT bit and the MCAN core will resume operation.

If the MCANSS\_CTRL[4] WAKEUPREQEN bit is set, the MCAN module provides a wakeup request on the following wakeup event:

- The receive RX pin is dominant (logical 0)

The wakeup request is de-asserted when any of the following conditions occur:

- Clock stop request is removed and clock stop acknowledge is de-asserted
- A reset is applied to the MCAN module

#### **12.4.4.3.3.9 Test Modes**

The MCAN\_TEST register write access is enabled by setting the test mode enable MCAN\_CCCR[7] TEST bit to 1. The MCAN\_TEST register allows the configuration of the test modes and test functions.

The CAN transmit TX pin has four output functions. One of those functions can be selected by programming the MCAN\_TEST[6-5] TX field. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

The actual value of the CAN receive RX pin can be monitored from MCAN\_TEST[7] RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (FCLK) and Host clock (ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN\_TEST[6-5] TX field until the new configuration is visible at the output TX pin. This applies also when reading input RX pin via the MCAN\_TEST[7] RX bit.

#### **Note**

Test modes should be used for self test only. The software control for TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

#### **12.4.4.3.3.9.1 Internal Loopback Mode**

The MCAN module can be set into Internal Loopback Mode by programming MCAN\_TEST[4] LBCK and MCAN\_CCCR[5] MON bits to 1. The Internal Loopback Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the TX and RX pins. In this mode RX pin is disconnected from the MCAN module and TX pin is held recessive. [Figure 12-259](#) shows the connection of the TX and RX pins to the MCAN module in case of Internal Loopback Mode.

**Figure 12-259. Internal Loopback Mode**

#### 12.4.4.3.4 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN\_TSCC[19-16] TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the MCAN\_TSCV[15-0] TSC field. A write access to the MCAN\_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN\_IR[16] TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15-0]) or Tx Event FIFO (TXTS[15-0]) element. For more information, see [Section 12.4.4.3.10, Message RAM](#).

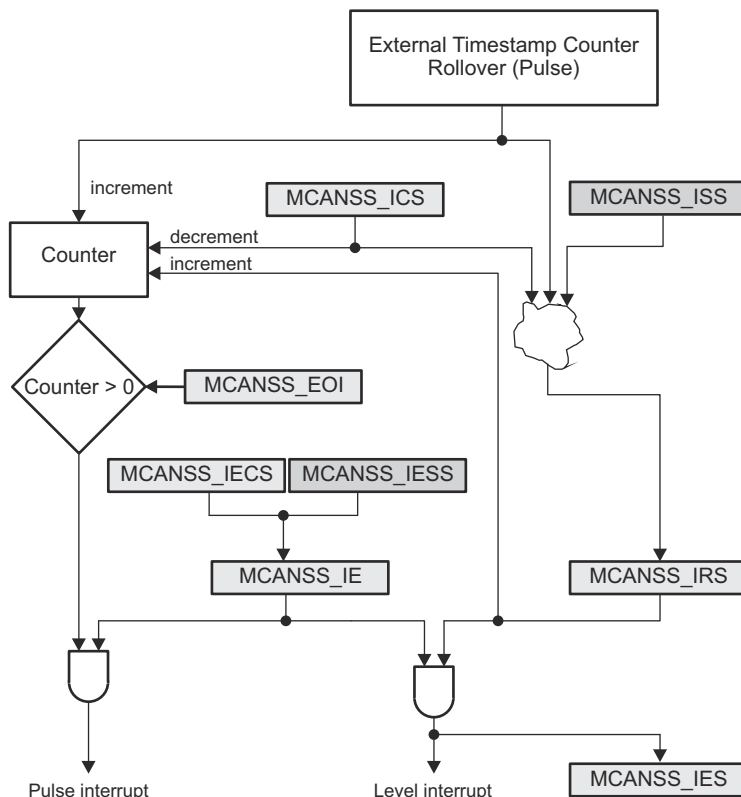

##### 12.4.4.3.4.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN\_TSCC[1-0] TSS field.

The External Timestamp Counter uses the interface clock (ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS\_EXT\_TS\_PRESCALER[23-0] PRESCALER bit field). The External Timestamp Counter can be enabled or disabled through the MCANSS\_CTRL[6] EXT\_TS\_CNTR\_EN bit. When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the MCAN timestamp interrupt is generated.

When the timestamp rolls over the MCANSS\_IRS register is set (see [Figure 12-260](#)). The MCANSS\_IE register can be affected by writing to the MCANSS\_IESS register to set or to the MCANSS\_IECS register to clear. The MCANSS\_IESS register is a shadow register mapped to the same address as the MCANSS\_IE register. The level interrupt is a reflection of both MCANSS\_IRS and MCANSS\_IE being set. The MCANSS\_IES register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the MCANSS\_ICS register to clear the MCANSS\_IRS register will also decrement the interrupt counter. Writing to the MCANSS\_EOI register will issue another pulse if the interrupt counter is not zero.

The rollover event can be artificially simulated by software through writing to the Interrupt Set Shadow register (MCANSS\_ISS). The MCANSS\_ISS register is a shadow register mapped to the same address as the MCANSS\_IRS register.

mcan-021

**Figure 12-260. External Timestamp Counter Interrupt**

#### 12.4.4.3.5 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the MCAN\_TOCC register. It is enabled via the MCAN\_TOCC[0] ETOC bit. The Timeout Counter operates as down-counter and uses the same prescaler programmed by the MCAN\_TSCC[19-16] TCP field as the Timestamp Counter. The actual counter value can be monitored from the MCAN\_TOCV[15-0] TOC field. The Timeout Counter can be started only when MCAN\_CCCR[0] INIT = 0 and stopped when MCAN\_CCCR[0] INIT = 1 (example: when the MCAN enters Bus\_Off state). The operation mode is selected by the MCAN\_TOCC[2-1] TOS field. When Continuous Mode is selected, the counter starts when MCAN\_CCCR[0] INIT = 0, a write to the MCAN\_TOCV register presets the counter to the value configured by the MCAN\_TOCC[31-16] TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN\_TOCC[31-16] TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN\_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN\_IR[18] TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the MCAN\_TOCC[31-16] TOP field.

#### 12.4.4.3.6 ECC Support

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC Aggregator.

##### 12.4.4.3.6.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

#### 12.4.4.3.6.2 ECC Aggregator

---

#### Note

For more information about ECC Aggregator, refer to [Section 12.10.6, ECC Aggregator](#).

---

#### 12.4.4.3.7 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

##### 12.4.4.3.7.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range Filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic Bit Mask Filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register
- Extended ID AND Mask (MCAN\_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in [Section 12.4.4.3.10, Message RAM](#)) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single ICLK pulse. For more information, see [Section 12.4.4.3.2.1, DMA Requests](#).
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN\_IR[8] HPM
- Set High Priority Message interrupt flag MCAN\_IR[8] HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:

New Data flag (MCAN\_NDAT1/MCAN\_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see MCAN\_PSR[2-0] LEC respectively MCAN\_PSR[10-8] DLEC fields).

- Rx FIFO:  
Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see MCAN\_PSR[2-0] LEC respectively MCAN\_PSR[10-8] DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in [Section 12.4.4.3.7.2.2](#) have to be considered.

#### **12.4.4.3.7.1.1 Range Filter**

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see [Section 12.4.4.3.10.5, Standard Message ID Filter Element](#) and [Section 12.4.4.3.10.6, Extended Message ID Filter Element](#).

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN\_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN\_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN\_XIDAM) is not used for Range Filtering.

#### **12.4.4.3.7.1.2 Filter for specific IDs**

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT = 01/Extended Filter Type EFT = 01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see [Section 12.4.4.3.10.5, Standard Message ID Filter Element](#) and [Section 12.4.4.3.10.6, Extended Message ID Filter Element](#).

#### **12.4.4.3.7.1.3 Classic Bit Mask Filter**

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT = 10/Extended Filter Type EFT = 10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

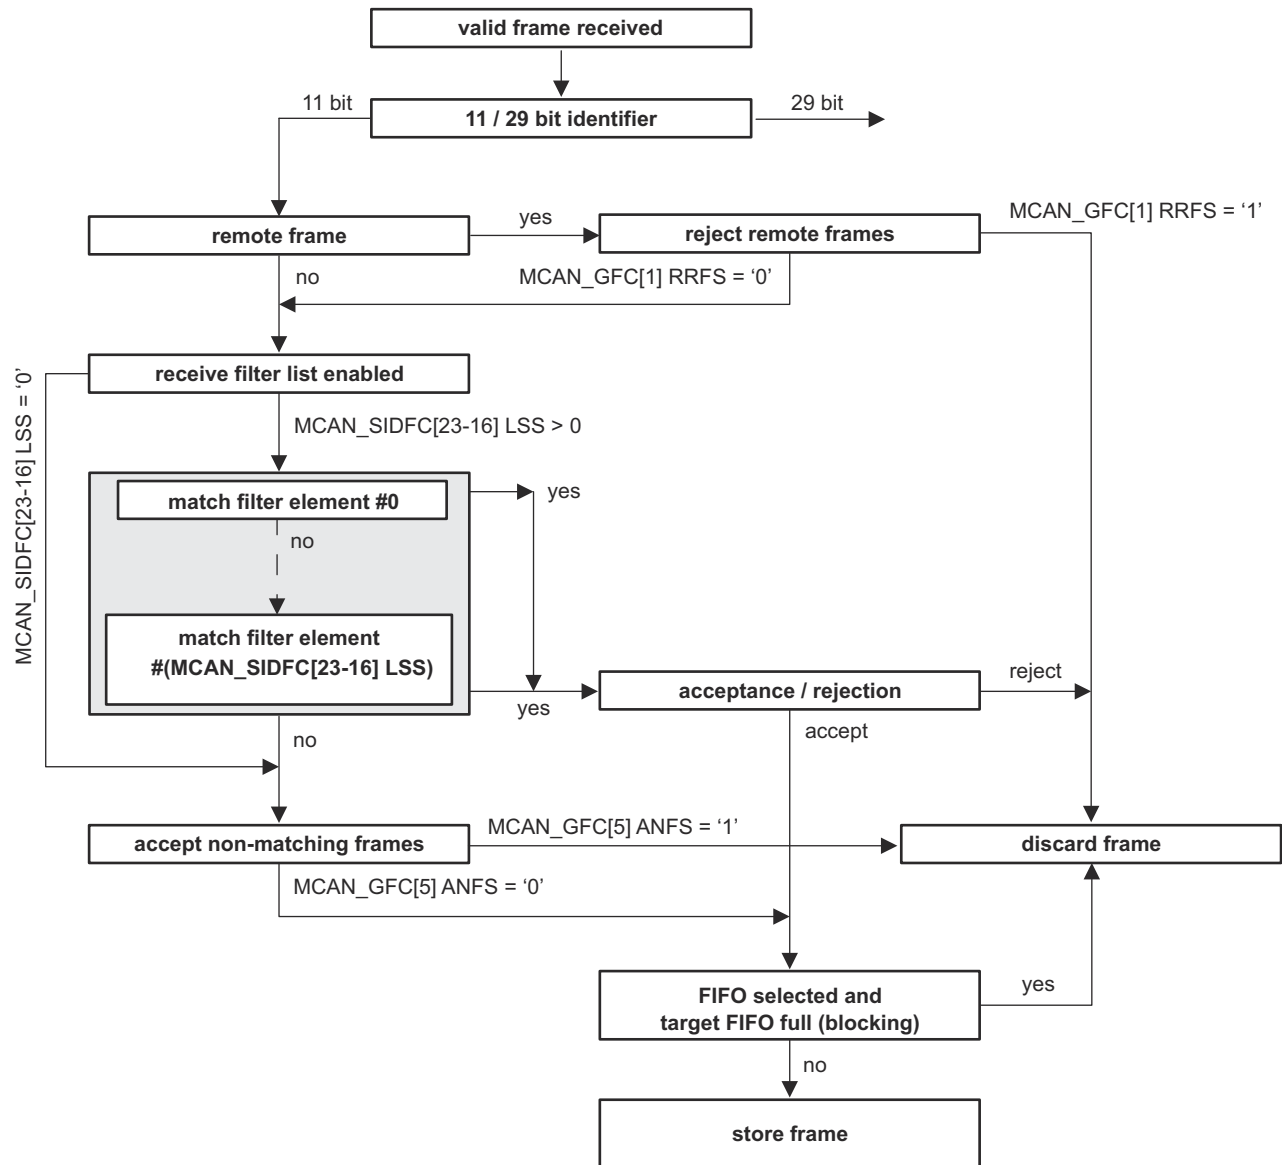

#### **12.4.4.3.7.1.4 Standard Message ID Filtering**

The standard Message ID (11-bit ID) filtering flow is shown in [Figure 12-261](#). [Section 12.4.4.3.10.5, Standard Message ID Filter Element](#) describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register

mcan-009

**Figure 12-261. Standard Message ID Filter Path****12.4.4.3.7.1.5 Extended Message ID Filtering**

The extended Message ID (29-bit ID) filtering flow is shown in [Figure 12-262](#). [Section 12.4.4.3.10.6, Extended Message ID Filter Element](#) describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask (MCAN\_XIDAM).

mcan-010

Figure 12-262. Extended Message ID Filter Path

#### 12.4.4.3.7.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the MCAN\_RXF0C and MCAN\_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in [Section 12.4.4.3.7.1, Acceptance Filtering](#). [Section 12.4.4.3.10.2, Rx Buffer and FIFO Element](#) describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN\_RXFnC[30-24] FnWM field (where: n = 0 or 1) an interrupt flag MCAN\_IR[1] RF0W/MCAN\_IR[5] RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN\_RXFnS[21-16] FnPI = MCAN\_RXFnS[13-8] FnGI) an Rx FIFO Full condition is signalled by the MCAN\_RXFnS[24] FnF status bit and interrupt flag MCAN\_IR[2] RF0F/MCAN\_IR[6] RF1F is set. [Figure 12-263](#) shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN\_RXFnS[6-0] FnFL field (the number of elements stored in Rx FIFO).

**Figure 12-263. Rx FIFO Status**

Rx FIFOs start address in the Message RAM (MCAN\_RXFnC[15-2] FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN\_RXFnS[13-8] FnGI). Table 12-294 presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer/Rx FIFO Data Field Size which is configured via the MCAN\_RXESC register.

**Table 12-294. Rx Buffer/Rx FIFO Element Size**

MCAN_RXESC[10-8] RBDS MCAN_RXESC[2-0] F0DS/ MCAN_RXESC[6-4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

#### 12.4.4.3.7.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN\_RXFnC[31] FnOM = 0.

If an Rx FIFO full condition is reached (MCAN\_RXFnS[21-16] FnPI = MCAN\_RXFnS[13-8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN\_RXFnS[24] FnF = 1 and interrupt flag MCAN\_IR[2] RF0F/MCAN\_IR[6] RF1F is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN\_RXFnS[25] RFnL = 1 and interrupt flag MCAN\_IR[3] RFnL/MCAN\_IR[25] RFnL is set.

#### 12.4.4.3.7.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN\_RXFnC[31] FnOM = 1. When an Rx FIFO full condition is reached (MCAN\_RXFnS[21-16] FnPI = MCAN\_RXFnS[13-8] FnGI) signalled by MCAN\_RXFnS[24] FnF = 1,

the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. [Figure 12-264](#) shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

**Figure 12-264. Rx FIFO Overflow Handling**

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index `MCAN_RXFnA[5-0] FnAI`. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (`MCAN_RXFnS[24] FnF = 0`).

#### 12.4.4.3.7.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via `MCAN_RXBC[15-2] RBSA` field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with `SFEC/EFEC = 111` and `SFID2/EFID2[10-9] = 00` has to be configured (see [Section 12.4.4.3.10.5, Standard Message ID Filter Element](#) and [Section 12.4.4.3.10.6, Extended Message ID Filter Element](#)).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag `MCAN_IR[19] DRX` (Message stored in Dedicated Rx Buffer) is set.

[Table 12-295](#) shows Example Filter Configuration for Rx Buffers.

**Table 12-295. Example Filter Configuration for Rx Buffers**

Filter Element	SFID1[10-0] EFID1[28-0]	SFID2[10-9] EFID2[10-9]	SFID2[5-0] EFID2[5-0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register `MCAN_NDAT1/MCAN_NDAT2` is set. As long as the New Data flag is set, the respective

Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

#### 12.4.4.3.7.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN\_IR[19] DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

#### 12.4.4.3.7.4 Debug on CAN Support

Debug DMA is not supported feature. Debug messages can be traced through the RX FIFO (see [Section 12.4.4.3.7.2](#)).

#### 12.4.4.3.8 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers/Tx FIFO or dedicated Tx Buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. [Section 12.4.4.3.10.3](#) describes the Tx Buffer Element. [Table 12-296](#) shows the possible configurations for message transmission.

**Table 12-296. Possible Configurations for Message Transmission**

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending MCAN\_TXBRP register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

#### Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

#### 12.4.4.3.8.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN\_CCCR[14] TXP bit. By default this bit is disabled (MCAN\_CCCR[14] TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times

occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

#### 12.4.4.3.8.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the MCAN\_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 12-297 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN\_TXFQS[20-16] TFQPI) × Element Size to the Tx Buffer Start Address MCAN\_TXBC[15-2] TBSA field.

**Table 12-297. Tx Buffer/Tx FIFO/Tx Queue Element Size**

MCAN_TXESC[2-0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

#### 12.4.4.3.8.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN\_TXBC[30] TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN\_TXFQS[12-8] TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN\_TXFQS[5-0] TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS[20-16] TFQPI field. After each Add Request (MCAN\_TXBAR[x] ARn = 1) the Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN\_TXFQS[20-16] TFQPI = MCAN\_TXFQS[12-8] TFGI), Tx FIFO Full condition is signalled by bit MCAN\_TXFQS[21] TFQF = 1. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level MCAN\_TXFQS[5-0] TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN\_TXFQS[5-0] TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see Table 12-297). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index

MCAN\_TXFQS[20-16] TFQPI (from 0 to 31)  $\times$  Element Size to the Tx Buffer Start Address MCAN\_TXBC[15-2] TBSA field.

#### 12.4.4.3.8.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN\_TXBC[30] TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS[20-16] TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN\_TXFQS[21] TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the MCAN\_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see Table 12-297). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS[20-16] TFQPI (from 0 to 31)  $\times$  Element Size to the Tx Buffer Start Address MCAN\_TXBC[15-2] TBSA field.

#### 12.4.4.3.8.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN\_TXBC[21-16] NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the MCAN\_TXBC[29-24] TFQS field

If the MCAN\_TXBC[29-24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN\_TXFQS[12-8] TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 12-265 shows Mixed Dedicated Tx Buffers/Tx FIFO example.

**Figure 12-265. Mixed Dedicated Tx Buffers/Tx FIFO (example)**

#### 12.4.4.3.8.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN\_TXBC[21-16] NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the MCAN\_TXBC[29-24] TFQS field

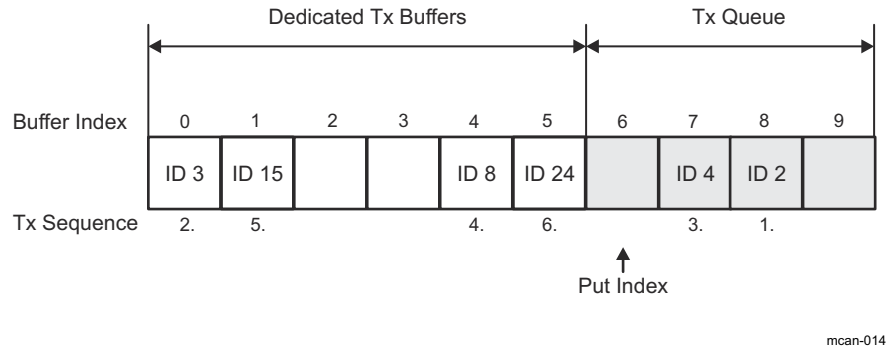

If MCAN\_TXBC[29-24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 12-266 shows Mixed Dedicated Tx Buffers/Tx Queue example.

**Figure 12-266. Mixed Dedicated Tx Buffers/Tx Queue (example)**

#### 12.4.4.3.8.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN\_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the MCAN\_TXBCF register (MCAN\_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN\_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN\_TXBTO[n] TOn and MCAN\_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN\_TXBCF[n] CFn = 1.

#### Note

If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

#### 12.4.4.3.8.8 Tx Event Handling

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. Section 12.4.4.3.10.4 describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the MCAN\_IR[14] TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN\_TXEFS[12-8] EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN\_IR[15] TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN\_TXEFC[29-24] EFWM field, interrupt flag MCAN\_IR[13] TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index

MCAN\_TXEFS[12-8] EFGI field has to be added to the Tx Event FIFO start address MCAN\_TXEFC[15-2] EFSA field.

#### **12.4.4.3.9 FIFO Acknowledge Handling**

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN\_RXF0A, MCAN\_RXF1A, and MCAN\_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

---

#### **Note**

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

---

#### 12.4.4.3.10 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

##### 12.4.4.3.10.1 Message RAM Configuration

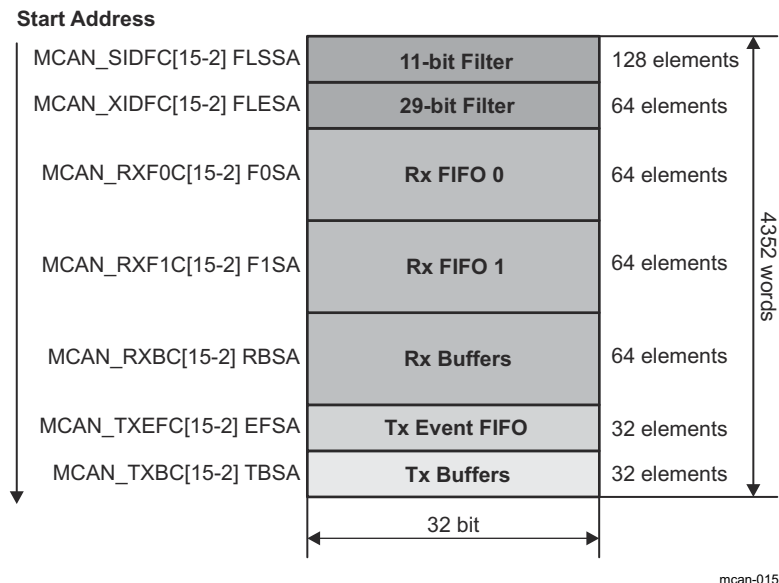

The MCAN module is configured to allocate 4352 words in the Message RAM. The Message RAM has a width of 32 bits.

The Message RAM is capable to include each of the sections listed in [Figure 12-267](#). It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the MCAN\_RXESC[2-0] F0DS field
- Rx FIFO 1 via the MCAN\_RXESC[6-4] F1DS field
- Rx Buffers via the MCAN\_RXESC[10-8] RBDS field
- Tx Buffers via the MCAN\_TXESC[2-0] TBDS field

**Figure 12-267. Message RAM Configuration**

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

#### Note

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

### 12.4.4.3.10.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN\_RXESC register.

Figure 12-268 shows Rx Buffer/Rx FIFO element structure.

**Figure 12-268. Rx Buffer/Rx FIFO Element Structure**

Table 12-298 shows Rx Buffer/Rx FIFO element field descriptions.

**Table 12-298. Rx Buffer/Rx FIFO Element Field Descriptions**

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator <ul style="list-style-type: none"> <li>0h = Transmitting node is error active</li> <li>1h = Transmitting node is error passive</li> </ul>
	30	XTD	Extended Identifier <p>Signals to the Host CPU whether the received frame has a standard or extended identifier.</p> <ul style="list-style-type: none"> <li>0h = 11-bit standard identifier</li> <li>1h = 29-bit extended identifier</li> </ul>
	29	RTR	Remote Transmission Request <p>Signals to the Host CPU whether the received frame is a data frame or a remote frame.</p> <ul style="list-style-type: none"> <li>0h = Received frame is a data frame</li> <li>1h = Received frame is a remote frame</li> </ul> <p><b>Note:</b> There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = 1), RTR bit reflects the state of the reserved r1 bit (RES[23]).</p>
	28-0	ID[28-0]	Identifier <p>Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28-18].</p>

**Table 12-298. Rx Buffer/Rx FIFO Element Field Descriptions (continued)**

Word	Bits	Field Name	Description
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames may be enabled via the MCAN_GFC[5-4] ANFS and MCAN_GFC[3-2] ANFE fields. <ul style="list-style-type: none"> <li>0h = Received frame matching filter index FIDX field</li> <li>1h = Received frame did not match any Rx filter element</li> </ul>
	30-24	FIDX[6-0]	Filter Index 0h-7Fh (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to MCAN_SIDFC[23-16] LSS - 1 respectively MCAN_XIDFC[22-16] LSE - 1.
	23-22	RES	Reserved
	21	FDF	FD Format <ul style="list-style-type: none"> <li>0h = Standard frame format</li> <li>1h = CAN FD frame format (new DLC-coding and CRC)</li> </ul>

	...	...	...
	31-24	DBm[7-0]	Data Byte m
	23-16	DBm-1[7-0]	Data Byte m-1
Rn	15-8	DBm-2[7-0]	Data Byte m-2
	7-0	DBm-3[7-0]	Data Byte m-3

**Note:** Depending on the configuration of the element size (MCAN\_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

### 12.4.4.3.10.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO/Tx Queue via the MCAN\_TXBC[29-24] TFQS and MCAN\_TXBC[21-16] NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN\_TXESC register.

Figure 12-269 shows Tx Buffer element structure.

**Figure 12-269. Tx Buffer Element Structure**

Table 12-299 shows Tx Buffer element field descriptions.

**Table 12-299. Tx Buffer Element Field Descriptions**

Word	Bits	Field Name	Description
T0	31	ESI	<p>Error State Indicator</p> <ul style="list-style-type: none"> <li>0h = ESI bit in CAN FD format depends only on error passive flag</li> <li>1h = ESI bit in CAN FD format transmitted recessive</li> </ul> <p><b>Note:</b> The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted CAN FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive.</p>
	30	XTD	<p>Extended Identifier</p> <ul style="list-style-type: none"> <li>0h = 11-bit standard identifier</li> <li>1h = 29-bit extended identifier</li> </ul>
	29	RTR	<p>Remote Transmission Request</p> <ul style="list-style-type: none"> <li>0h = Transmit data frame</li> <li>1h = Transmit remote frame</li> </ul> <p><b>Note:</b> When RTR = 1, the MCAN module transmits a remote frame according to ISO11898-1:2015, even if the MCAN_CCCR[8] FDOE bit enables the transmission in CAN FD format.</p>
	28-0	ID[28-0]	<p>Identifier</p> <p>Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28-18].</p>

**Table 12-299. Tx Buffer Element Field Descriptions (continued)**

	15-8	DBm-2[7-0]	Data Byte m-2
	7-0	DBm-3[7-0]	Data Byte m-3

**Note:** Depending on the configuration of the element size (MCAN\_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

#### 12.4.4.3.10.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN\_TXEFS register.

Figure 12-270 shows Tx Event FIFO element structure.

**Figure 12-270. Tx Event FIFO Element Structure**

Table 12-300 shows Tx Event FIFO element field descriptions.

**Table 12-300. Tx Event FIFO Element Field Descriptions**

Word	Bits	Field Name	Description
E0	31	ESI	Error State Indicator <ul style="list-style-type: none"> <li>0h = Transmitting node is error active</li> <li>1h = Transmitting node is error passive</li> </ul>
	30	XTD	Extended Identifier <ul style="list-style-type: none"> <li>0h = 11-bit standard identifier</li> <li>1h = 29-bit extended identifier</li> </ul>
	29	RTR	Remote Transmission Request <ul style="list-style-type: none"> <li>0h = Data frame transmitted</li> <li>1h = Remote frame transmitted</li> </ul>
	28-0	ID[28-0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28-18].

**Table 12-300. Tx Event FIFO Element Field Descriptions (continued)**

Word	Bits	Field Name	Description

	21	FDF	FD Format <ul style="list-style-type: none"> <li>0h = Standard frame format</li> <li>1h = CAN FD frame format (new DLC-coding and CRC)</li> </ul>
	20	BRS	Bit Rate Switch <ul style="list-style-type: none"> <li>0h = Frame transmitted without bit rate switching</li> <li>1h = Frame transmitted with bit rate switching</li> </ul>
	19-16	DLC[3-0]	Data Length Code <ul style="list-style-type: none"> <li>0h-8h (0-8) = CAN + CAN FD: frame with 0-8 data bytes transmitted</li> <li>9h-Fh (9-15) = CAN: frame with 8 data bytes transmitted</li> <li>9h-Fh (9-15) = CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted</li> </ul>
	15-0	TXTS[15-0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19-16] TCP field.

#### 12.4.4.3.10.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address MCAN\_SIDFC[15-2] FLSSA field plus the index of the filter element (0-127).

[Figure 12-271](#) shows Standard Message ID Filter element structure.

**Figure 12-271. Standard Message ID Filter Element Structure**

[Table 12-301](#) shows Standard Message ID Filter element field descriptions.

**Table 12-301. Standard Message ID Filter Element Field Descriptions**

Word	Bits	Field Name	Description
S0	31-30	SFT[1-0]	<p>Standard Filter Type</p> <ul style="list-style-type: none"> <li>0h = Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1)</li> <li>1h = Dual ID filter for SFID1 or SFID2</li> <li>2h = Classic filter: SFID1 = filter; SFID2 = mask</li> <li>3h = Filter element disabled</li> </ul> <p><b>Note:</b> With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behaviour as with SFEC = 000)</p>
	29-27	SFEC[2-0]	<p>Standard Filter Element Configuration</p> <p>All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match.</p> <ul style="list-style-type: none"> <li>0h = Disable filter element</li> <li>1h = Store in Rx FIFO 0 if filter matches</li> <li>2h = Store in Rx FIFO 1 if filter matches</li> <li>3h = Reject ID if filter matches</li> <li>4h = Set priority if filter matches</li> <li>5h = Set priority and store in FIFO 0 if filter matches</li> <li>6h = Set priority and store in FIFO 1 if filter matches</li> <li>7h = Store into Rx Buffer , configuration of SFT[1-0] ignored</li> </ul>
	26-16	SFID1[10-0]	<p>Standard Filter ID 1</p> <p>When filtering for Rx Buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.</p>
	15-11	RES	Reserved
		SFID2[10-0]	<p>Standard Filter ID 2</p> <p>This bit field has a different meaning depending on the configuration of SFEC:</p> <ul style="list-style-type: none"> <li>1) SFEC = 001 - 110 Second ID of standard ID filter element</li> <li>2) SFEC = 111 Filter for Rx Buffers</li> </ul>
	10-0	SFID2[10-9]	<p>This field is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence.</p> <ul style="list-style-type: none"> <li>0h = Store message into an Rx Buffer</li> <li>1h = Debug Message A</li> <li>2h = Debug Message B</li> <li>3h = Debug Message C</li> </ul> <p><b>Note:</b> Debug feature is not supported.</p>
		SFID2[8-6]	<p>This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches.</p> <p><b>Note:</b> Only three filter event pins are supported.</p>
		SFID2[5-0]	<p>This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15-2] RBSA field for storage of a matching message.</p>

### 12.4.4.3.10.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address MCAN\_XIDFC[15-2] FLESA field plus two times the index of the filter element (0-63).

Figure 12-272 shows Extended Message ID Filter element structure.

**Figure 12-272. Extended Message ID Filter Element Structure**

Table 12-302 shows Extended Message ID Filter element field descriptions.

**Table 12-302. Extended Message ID Filter Element Field Descriptions**

Word	Bits	Field Name	Description
F0	31-29	EFEC[2-0]	<p>Extended Filter Element Configuration</p> <p>All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match.</p> <ul style="list-style-type: none"> <li>0h = Disable filter element</li> <li>1h = Store in Rx FIFO 0 if filter matches</li> <li>2h = Store in Rx FIFO 1 if filter matches</li> <li>3h = Reject ID if filter matches</li> <li>4h = Set priority if filter matches</li> <li>5h = Set priority and store in FIFO 0 if filter matches</li> <li>6h = Set priority and store in FIFO 1 if filter matches</li> <li>7h = Store into Rx Buffer or as debug message, configuration of EFT[1-0] ignored</li> </ul>
	28-0	EFID1[28-0]	<p>Extended Filter ID 1</p> <p>First ID of extended ID filter element.</p> <p>When filtering for Rx Buffers this field defines the ID of an extended message to be stored. 	29	RES	Reserved
		EFID2[28-0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: <ul style="list-style-type: none"> <li>1) EFEC = 001 - 110 Second ID of extended ID filter element</li> <li>2) EFEC = 111 Filter for Rx Buffers</li> </ul>
	28-0	EFID2[10-9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. <ul style="list-style-type: none"> <li>0h = Store message into an Rx Buffer</li> <li>1h = Debug Message A</li> <li>2h = Debug Message B</li> <li>3h = Debug Message C</li> </ul> <p><b>Note:</b> Debug feature is not supported.</p>
		EFID2[8-6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. <p><b>Note:</b> Only three filter event pins are supported.</p>
		EFID2[5-0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15-2] RBSA field for storage of a matching message.

## 12.5 Audio Interfaces

## 12.5.1 Audio Tracking Logic (ATL)

This chapter describes the integration of the Audio Tracking Logic (ATL) subsystem in the device.

### 12.5.1.1 ATL Overview

The Audio Tracking Logic (ATL) is used by HD Radio™ applications to synchronize the digital audio output to the baseband clock. This same IP can also be used generically to track errors between two reference signals (such as frame syncs) and generate a modulated clock output (using software-controlled cycle stealing) which averages to some desired frequency. This process can be used as a hardware assist for asynchronous sample rate conversion algorithms.

#### 12.5.1.1.1 ATL Features Overview

The ATL module supports the following features:

- One ATL module, containing four ATL instances, for HD Radio support and asynchronous sample rate conversion assistance
- Each instance tracks the time error between two syncs (local audio word select [AWS] and baseband word select [BWS])
- Each instance generates modulated ATCLK clock signals with software-initiated pulse stealing. The intention is to use these clocks to derive audio output bit clock on MCASP
- Selection between ATL\_VCLK clock or functional ATL\_PCLK to run error counting timers and to derive modulated ATCLK clock outputs.
- Clock and reset management: Receives clock and reset signals from the device PSC module. The ATL module receives hardware reset.
- Power management: The ATL belongs to the PD0 power domain.
- Local software reset

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.5.1.1.2 ATL Not Supported Features

The ATL module not supports the following features:

- Smart ATL\_CLK\_STOP
- ATL\_MOD\_OUT[3-0] clock outputs

#### 12.5.1.1.3 ATL Ports

**Table 12-303. ATL Clocks and Resets**

Clocks	
Module Clock Input	Description
ATL_VCLK	ATL interface clock
ATL_PCLK	ATL functional clock.

## 12.5.2 Multichannel Audio Serial Port (MCASP)

This section describes the Multichannel Audio Serial Port (MCASP).

### 12.5.2.1 MCASP Overview

This section introduces the Multichannel Audio Serial Port (MCASP) module and describes its main functions and connections in the device.

The MCASP functions as a general-purpose audio serial port are optimized to the requirements of various audio applications. The MCASP module can operate in both transmit and receive modes. The MCASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an inter-component digital audio interface transmission (DIT). The MCASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

Although inter-component digital audio interface reception (DIR) mode (this is, S/PDIF stream receiving) is not natively supported by the MCASP module, a specific TDM mode implementation for the MCASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

#### 12.5.2.1.1 MCASP Features

Each MCASP module includes the following main features:

- Independent serializer for each AXRx channel of each MCASP module
- Clock stop request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- Interconnect interface port for CBASS0
- Two independent clock generator modules for transmit and receive (clocking flexibility allows the MCASP to receive and transmit at different rates. For example, the MCASP can receive data at 48 kHz, but output up-sampled data at 96 kHz or 192 kHz)
- Each MCASP module functional clock can be generated:
  - Internally (master mode)
  - Supplied over MCASP serial interface (slave mode)
  - Has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator
  - TDM streams from 2 to 32, and 384 time slots
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits
  - Data formatter for bit manipulation
- Glueless connection to audio Analog-to-Digital Converters (ADC), Digital-to-Analog Converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components
- Wide variety of I2S and similar bit-stream format
- Integrated digital audio interface transmitter (DIT):
  - S/PDIF, IEC60958-1, AES-3 formats
  - Enhanced channel status/user data RAM
- 384-slot TDM with external digital audio interface receiver (DIR) device
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the MCASP receive section
- Support for 2 × DMA requests (one per direction):
  - 1 level-sensitive transmit direct memory access (DMA) request common for all of the MCASP serializers
  - 1 level-sensitive receive direct memory access (DMA) request common for all of the MCASP serializers
  - All transmit DMA requests are mapped to the device DMA controllers
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupts

**Note**

Because a serializer receive and transmit channels data is shared on the same MCASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

**12.5.2.1.2 MCASP Not Supported Features**

Each MCASP module does not support the following features:

- Muting output (AMUTE)
- Muting input (AMUTEIN)

**12.5.2.1.3 MCASP Ports****Table 12-304. MCASP Clocks and Resets**

Clocks	
Module Clock Input	Description
MCASP_ICLK	MCASP interface clock
MCASP_AUX_CLK	MCASP functional clock (Master Mode).

(1) I = Input; O = Output; I/O = Bidirectional

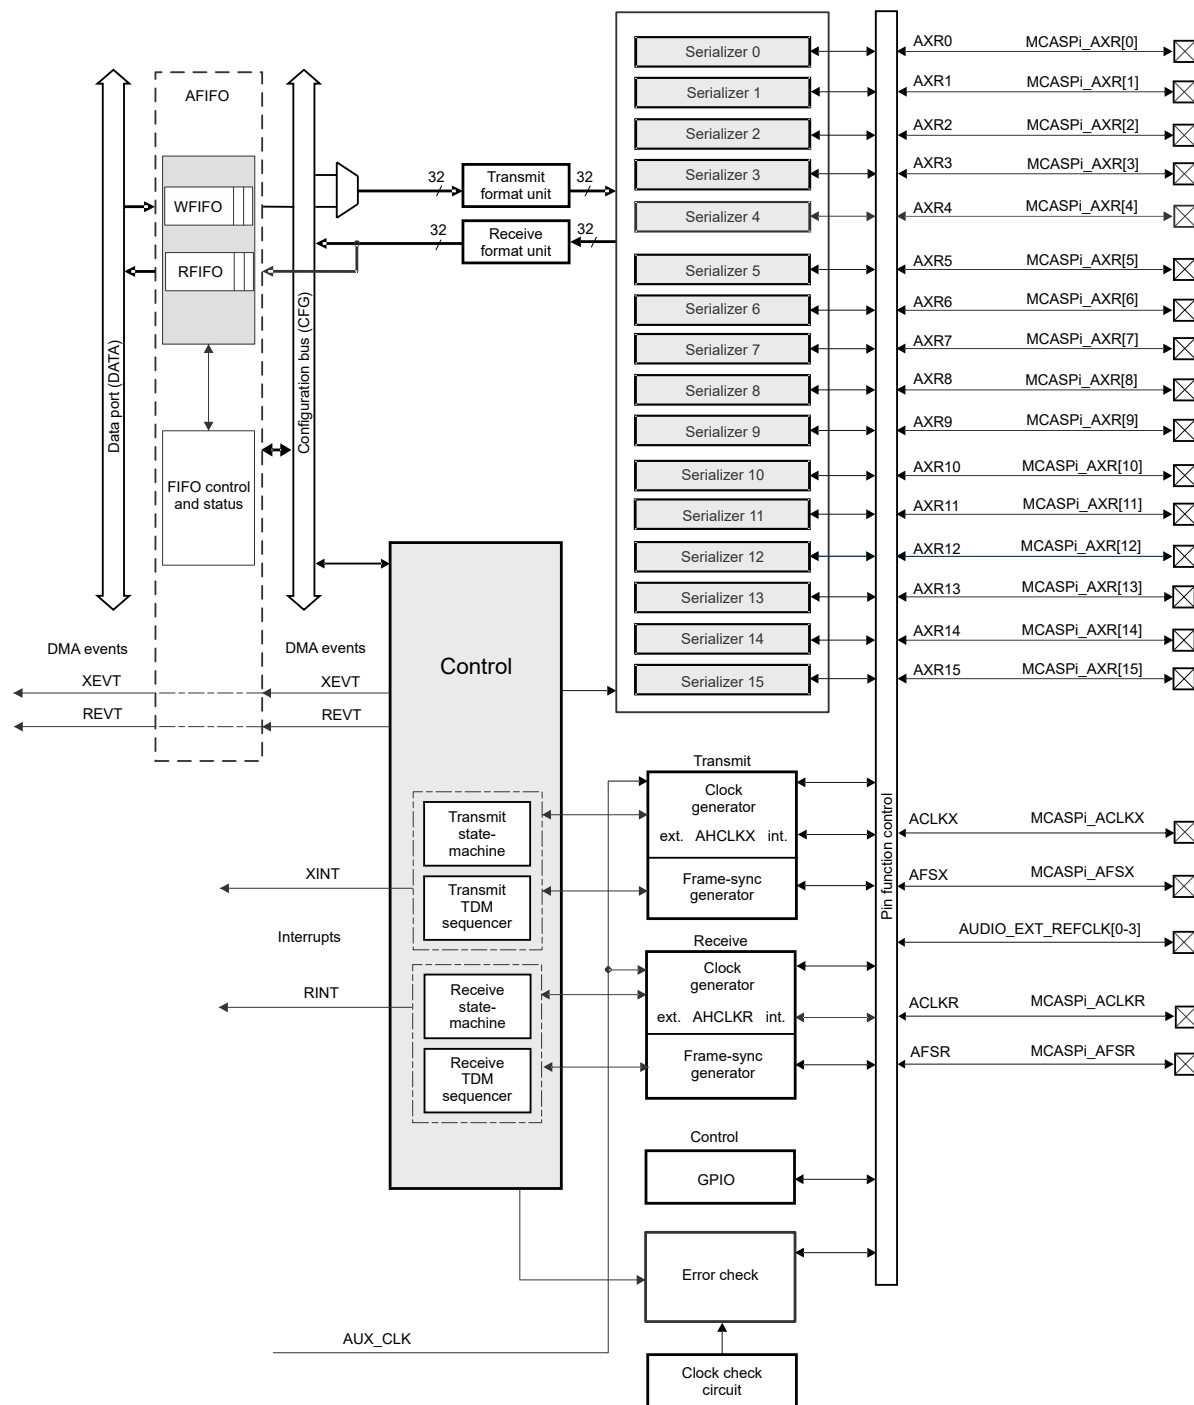

### 12.5.2.3 MCASP Functional Description

In the text throughout this section a single instance of MCASP is described assuming that all modules are functionally identical. For module availability and integration differences, see *MCASP Environment* and *MCASP Integration*.

#### 12.5.2.3.1 MCASP Block Diagram

Figure 12-273 shows the major blocks of the MCASP module.

mcasp-012

- A. i represents a valid instance of MCASP in a domain. See the device datasheet for valid instances.
- B. All signals might not be valid for an instance. See the device datasheet for specifics.

**Figure 12-273. MCASP Module Block Diagram**

## Note

The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

### 12.5.2.3.2 MCASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the MCASP serializers. The first three scenarios are identical between the Tx and Rx part of the MCASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for MCASP receivers - RCLK is derived from the bit rate clock of the MCASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the MCASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

#### 12.5.2.3.2.1 MCASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- MCASP\_ACLKXCTL
- MCASP\_AHCLKXCTL

In case, the transmit bit clock, ACLKX, is generated internally, the MCASP\_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP\_ACLKXCTL[4-0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in [Section 12.5.2.3.2](#), the MCASP\_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP\_AHCLKXCTL[11-0] HCLKXDIV bit field) from the MCASP internal clock source AUXCLK.

Internally, the MCASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see [Figure 12-274](#)). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If MCASP\_ACLKXCTL[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the MCASP shifts transmit data at the rising edge of ACLKX. If MCASP\_ACLKXCTL[7] CLKXP = 1, the CLKXP mux passes the inverted version of ACLKX to XCLK. As a result, the MCASP shifts transmit data at the falling edge of ACLKX.

It can be seen in [Figure 12-274](#) that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between MCASP transmitters and receivers. This is used for example in the MCASP loopback mode.

#### Note

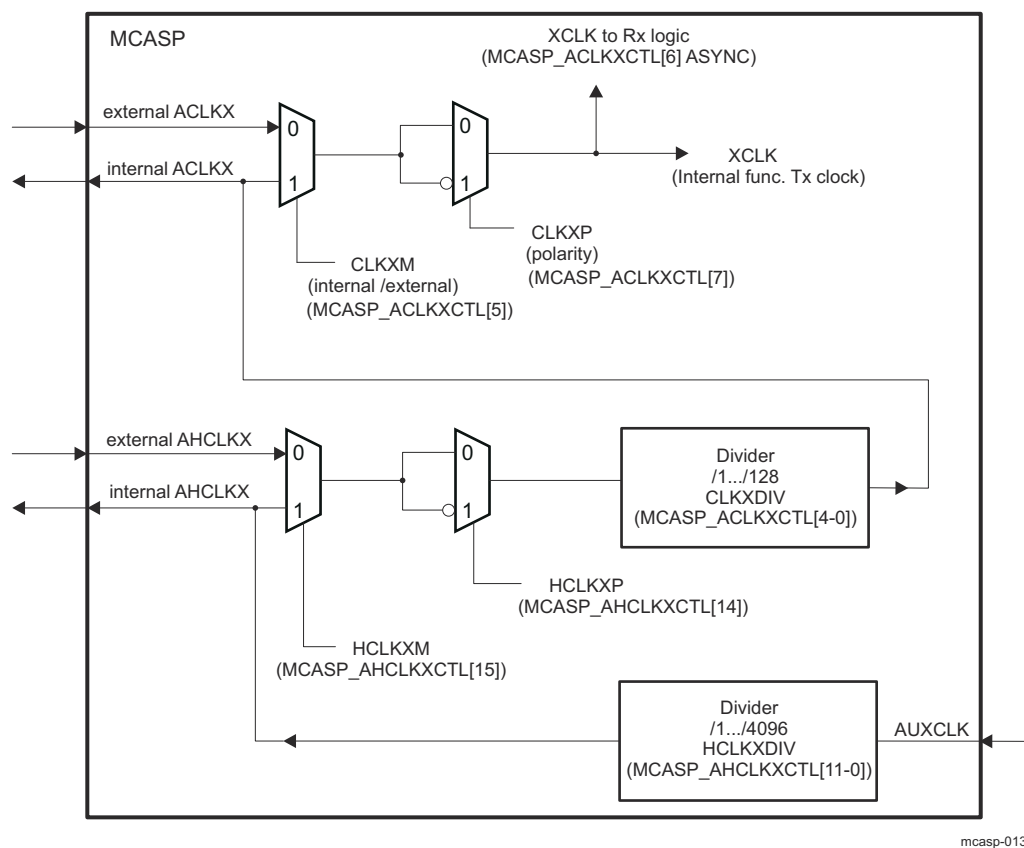

The polarity of ACLKX can be controlled in the MCASP\_ACLKXCTL[7] CLKXP bit, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the MCASP\_AHCLKXCTL[14] HCLKXP bit.

#### Note

In a similar way, the polarity of AHCLKX clock can be controlled in the MCASP\_AHCLKXCTL[14] HCLKXP bit, regardless of the AHCLKX signal being internally or externally sourced.

[Figure 12-274](#) presents the block diagram of the transmit clock generator.

**Figure 12-274. Transmit Clock Generator Block Diagram**

#### Note

In this device:

- ACLKX is mapped on the device ball ACLKX
- internal AHCLKX is mapped on the device balls AUDIO\_EXT\_REFCLK[0-1]
- external AHCLKX is mapped on MCASPi\_AHCLKX clock from the Device Configuration

For more information about MCASP integration, see *MCASP Environment* and *MCASP Integration*.

#### 12.5.2.3.2.2 MCASP Receive Clock

The MCASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- MCASP\_ACLKRCTL
- MCASP\_AHCLKRCTL

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the MCASP\_ACLKRCTL[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP\_ACLKRCTL[4-0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in [Section 12.5.2.3.2](#)) and the MCASP\_AHCLKRCTL[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP\_AHCLKRCTL[11-0] HCLKRDIV bit field) from the MCASP internal clock source AUXCLK.

---

#### Note

The polarity of ACLKR can be controlled in the MCASP\_ACLKRCTL[7] CLKRP bit, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in the MCASP\_AHCLKRCTL[14] HCLKRP bit, regardless of the AHCLKR signal being internally or externally sourced.

---

There is an option for the MCASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see [Figure 12-274](#) and [Figure 12-275](#)) becomes source of the receive clock (RCLK output), when the MCASP\_ACLKXCTL[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to [Section 12.5.2.3.2.4](#).

[Figure 12-275](#) presents the block diagram of the receive clock generator.

**Figure 12-275. Receive Clock Generator Block Diagram**

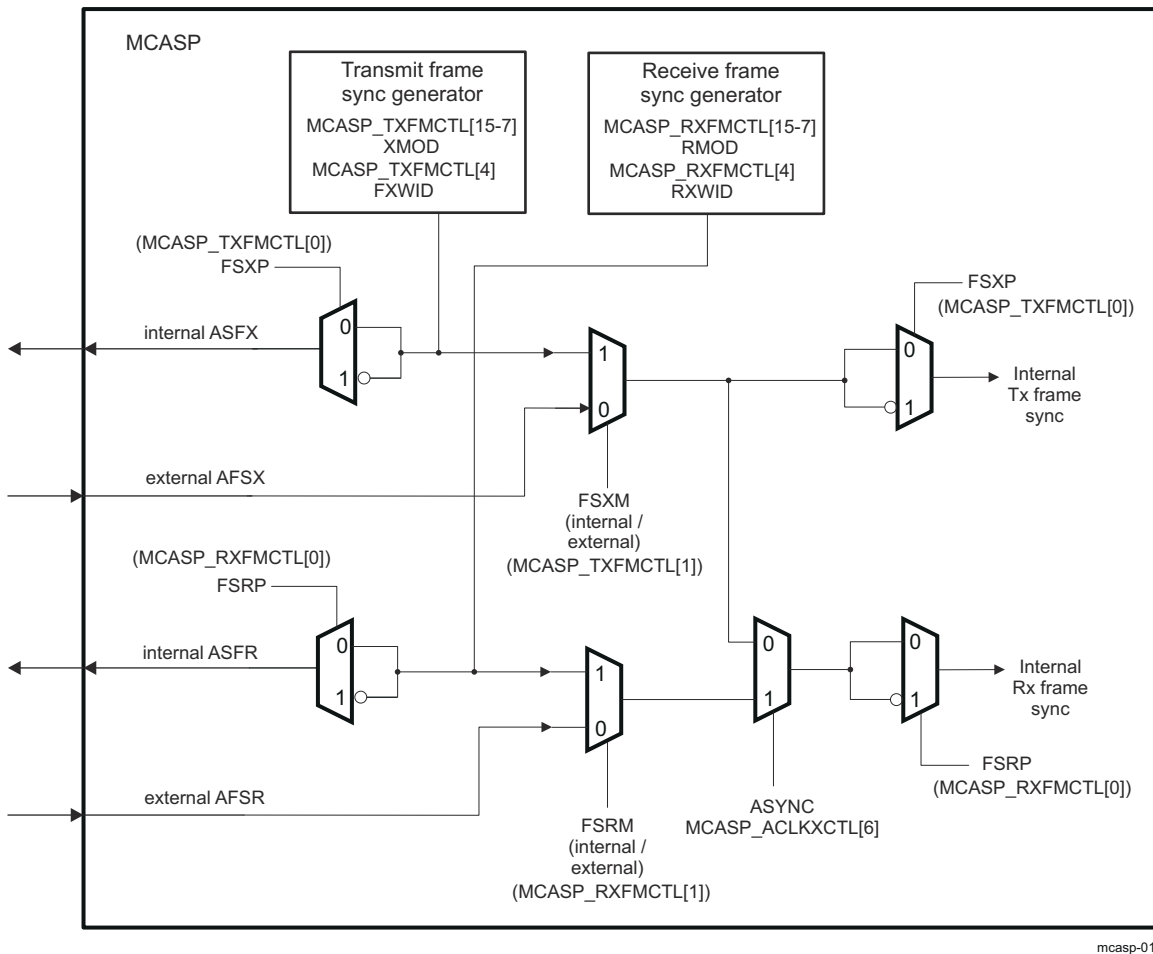

#### Note

In this device:

- ACLK is mapped on the device ball ACLK
- internal AHCLKX is mapped on the device balls AUDIO\_EXT\_REFCLK[0-1]
- external AHCLKR is mapped on Device Configuration MCASPi\_AHCLKR from Device Configuration

#### 12.5.2.3.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The MCASP frame sync generator logic is illustrated in [Figure 12-276](#). The I/O buffers are not part of the MCASP module, and are not shown in the figure.

**Figure 12-276. Frame Sync Generator Block Diagram**

**For the transmit logic**, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring MCASP\_AFSXCTL[1] FSXM bit
- Frame-sync polarity: Rising edge or falling edge via configuring MCASP\_AFSXCTL[0] FSXP bit
- Frame-sync width: "single bit" or "single word" via configuring MCASP\_AFSXCTL[4] FXWID bit
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the MCASP\_AFSXCTL[15-7] XMOD bit field, as follows:
  - For DIT mode (384 slots) - MCASP\_AFSXCTL[15-7] XMOD = 0x180
  - For I2S mode (2 TDM slots) - MCASP\_AFSXCTL[15-7] XMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP\_AFSXCTL[15-7] XMOD bit field set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP\_XFMT[17-16] XDATDLY bit field

**For the receive logic**, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring MCASP\_AFSRCTL[1] FSRM bit
- Frame-sync polarity: Rising edge or falling edge via configuring MCASP\_AFSRCTL[0] FSRP bit
- Frame-sync width: "single bit" or "single word" via configuring MCASP\_AFSRCTL[4] FRWID bit
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the MCASP\_AFSRCTL[15-7] RMOD bit field, as follows:
  - For I2S mode (2 TDM slots) - MCASP\_AFSRCTL[15-7] RMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP\_AFSRCTL[15-7] RMOD set in range 0x3 - 0x20
  - For the special 384-slot TDM mode - MCASP\_AFSRCTL[15-7] RMOD = 0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in the MCASP\_RFMT[17-16] RDATDLY bit field

- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP\_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to [Section 12.5.2.3.2.4, Synchronous and Asynchronous Transmit and Receive Operations](#).

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

---

#### Note

Certain restrictions apply to the receive and transmit logic settings, when the MCASP\_ACLKXCTL[6] ASYNC bit is set to 0b0. They are described in [Section 12.5.2.3.2.4](#).

---

#### 12.5.2.3.2.4 Synchronous and Asynchronous Transmit and Receive Operations

##### Synchronous Transmit and Receive Operations -

When the MCASP\_ACLKXCTL[6] ASYNC bit is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the [Figure 12-275](#), with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When the MCASP\_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP\_DITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ \* RMOD product value must equal XSSZ \* XMOD product value)
- The settings in the MCASP\_ACLKRCTL register are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

##### Asynchronous Transmit and Receive Operations -

When the MCASP\_ACLKXCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

---

#### Note

Synchronous transmit and receive operations are allowed only in the MCASP TDM (I2S) mode (this is, when MCASP\_DITCTL[0] DITEN = 0b0).

---

#### 12.5.2.3.3 MCASP Frame Sync Feedback for Cross Synchronization

The device level requirement is to align frame syncs across McASP that may be feeding DACs with different formats but the same frequency.

The intent of is to provide a mechanism to check for the alignment of frame syncs. This works by feeding the frame sync of McASP into the a receive data pin of McASP. If this serializer is enabled as a receiver, then the frame sync of McASP will appear as receive data for McASP.

To adjust the McASP transmit bit clock, the MCASP\_ACLKXCTL[17-16] CLKXADJ register bit field can be used to lengthen (write 0x2) or reduce (write 0x1) the McASP bit clock period in a one-shot fashion. After each adjustment the frame sync should be checked again and the process repeated until the two frame syncs are aligned.

This process is expected to be carried out once, before any audio transfers occur. It is not intended to be used for sample rate conversion but rather initial phase alignment of transmit data across McASP.

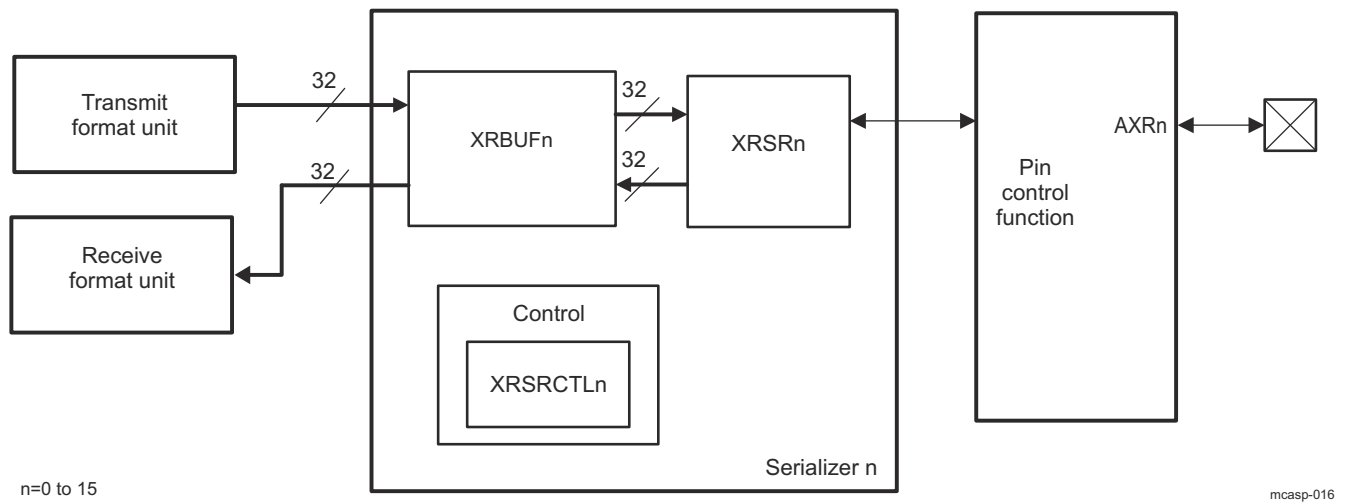

#### 12.5.2.3.4 MCASP Serializers

The MCASP serializers shift serial data in (Rx) and out (Tx) of the MCASP. A given serializer  $n$  consists of a shift register (XRSRn) with a single-entry data buffer XRBUF $n$  used either for transmitting (write accessible in the MCASP\_XBUF $n$  register) or for receiving (read accessible in the MCASP\_RBUF $n$  register) data. In addition, each serializer has a dedicated control register (MCASP\_SRCTL $n$ ) and a serial bidirectional data pin - AXR $n$ . The register MCASP\_SRCTL $n$  allows  $n$ -th serializer to be configured as a transmitter, receiver, or as inactive. There are transmit and receive data formatting units to support data alignment options of the MCASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSR $n$  shifter configured as a receiver in the MCASP\_SRCTL $n$  register, shifts in data through MCASP corresponding device level bidirectional data pad AXR $n$ . A given serializer XRSR $n$  shifter configured as a transmitter in the MCASP\_SRCTL $n$  register, shifts out data on MCASP corresponding device level bidirectional data pad AXR $n$  ( $n = 0$  to 15).

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for MCASP there are at most a couple of zones, one for transmit and one for receive.

Figure 12-277 shows the serializer block diagram.

**Figure 12-277. Individual Serializer and Connections Within MCASP**

#### Transmission on the $n$ -th serializer is performed as follows:

The MCASP is serviced by writing data into the MCASP\_XBUF $n$  register, which is an alias of the serializer data buffer - XRBUF $n$  for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUF $n$  register in the serializer. The data is then copied from the XRBUF $n$  to XRSR $n$  and shifted out from AXR $n$  synchronously to the serial clock.

#### Reception from the $n$ -th serializer is performed as follows:

The data is shifted into the MCASP XRSR $n$  serializer register through the AXR $n$  pin, bit by bit. Once the entire slot becomes available within the XRSR $n$  shift register, the data is copied into the serializer data buffer - XRBUF $n$ , and can be accessed in the MCASP\_RBUF $n$  register, which is an alias of the serializer data buffer - XRBUF $n$  for receive function. When software reads the data from this register, the MCASP passes the data through the receive format unit, hence it returns the formatted data.

#### Serializer controls:

A serializer  $n$  is configured as inactive via setting MCASP\_SRCTL $n$ [1-0] SRMOD bit field to 0x0.

For a transmitting serializer, the MCASP\_SRCTL $n$ [3-2] DISMOD bitfield, defines the AXR $n$  pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting MCASP\_SRCTLn[1-0] SRMOD bit field to 0x1.

Receive function for the n-th serializer is selected via setting MCASP\_SRCTLn[1-0] SRMOD bit field to 0x2 (n = 0 to 15).

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see *S/PDIF Coding Format*.

#### 12.5.2.3.5 MCASP Format Units

The MCASP has one transmit data formatting unit and one receive data formatting unit, shared between the device MCASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the MCASP only supports one transmit format at a time. For example, the MCASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the MCASP only supports one data format at a time, and this format applies to all receiving serializers.

#### Note

The MCASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP\_RFMT/MCASP\_XFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the MCASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the MCASP\_RFMT/MCASP\_XFMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in the MCASP\_RFMT/MCASP\_XFMT register means that the MCASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

##### 12.5.2.3.5.1 Transmit Format Unit

The MCASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

Figure 12-278 shows the transmit formatting unit.

The MCASP transmitter supports serial formats of:

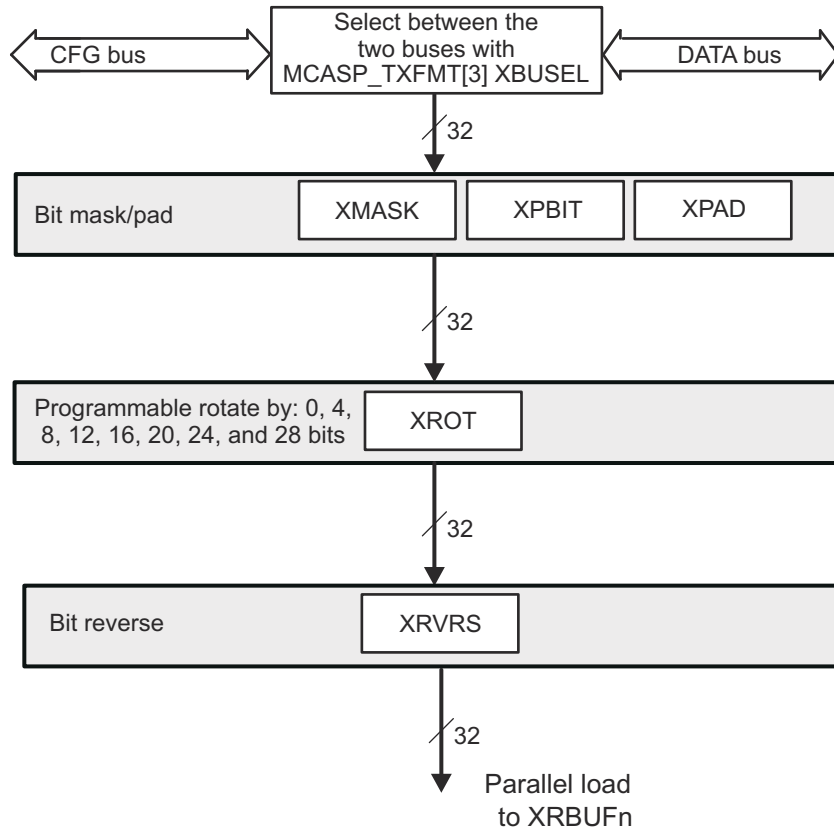

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB

- LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register

- MCASP\_XFMT:

- XRVRs: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

mcasp-017

**Figure 12-278. Transmit Format Unit**

As shown in [Figure 12-278](#), the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP\_XFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 12.5.2.3.11.1.3, Transfers Through the DATA Port](#), and [Section 12.5.2.3.11.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP\_XMASK[31-0] XMASK contents. The masked data is then right-rotated to the MCASP\_XFMT[2-0] XROT bit field positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

#### 12.5.2.3.5.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots.

XSSZ should always be programmed to match the slot size of the serial stream.

### Note

Note that, TDM word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the XROT field.

The [Table 12-307](#) show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The [Table 12-307](#) assumes that all slot size (SLOT in [Table 12-307](#)) and word size (WORD in [Table 12-307](#)) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter (typically Q31 or integer).

**Table 12-307. MCASP TFU TDM Mode Settings**

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_XFMT bits	
			XROT <sup>(1)</sup>	XRVRS
MSB first <sup>(2)</sup>	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first <sup>(2)</sup>	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

#### 12.5.2.3.5.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP\_XFMT[17-16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP\_XFMT[2-0] XROT =
  - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
  - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
  - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- MCASP\_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.
- MCASP\_XMASK[32] XMASK = 0xFFFFFFFF00 – 0xFFFF0000
- MCASP\_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP\_XFMT[2-0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP\_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.

- MCASP\_XMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF
- MCASP\_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in [Table 12-308](#) should be applied to MCASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the MCASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

**Table 12-308. MCASP TFU DIT-Mode Example Settings**

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFFF000	0x3
LEFT	24	8	0xFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated on the MCASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the [Table 12-308](#), the user must set XMASK = 0xFFFFF000, and to select a right-rotation to 12 positions (XROT = 0x3).

- After applying 0-s (XPAD = 0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF. Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVR = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the MCASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table MCASP TFU Example Settings, user is supposed to set XMASK = 0x0000FFFF, and to select right-rotation to 0 positions (XROT = 0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

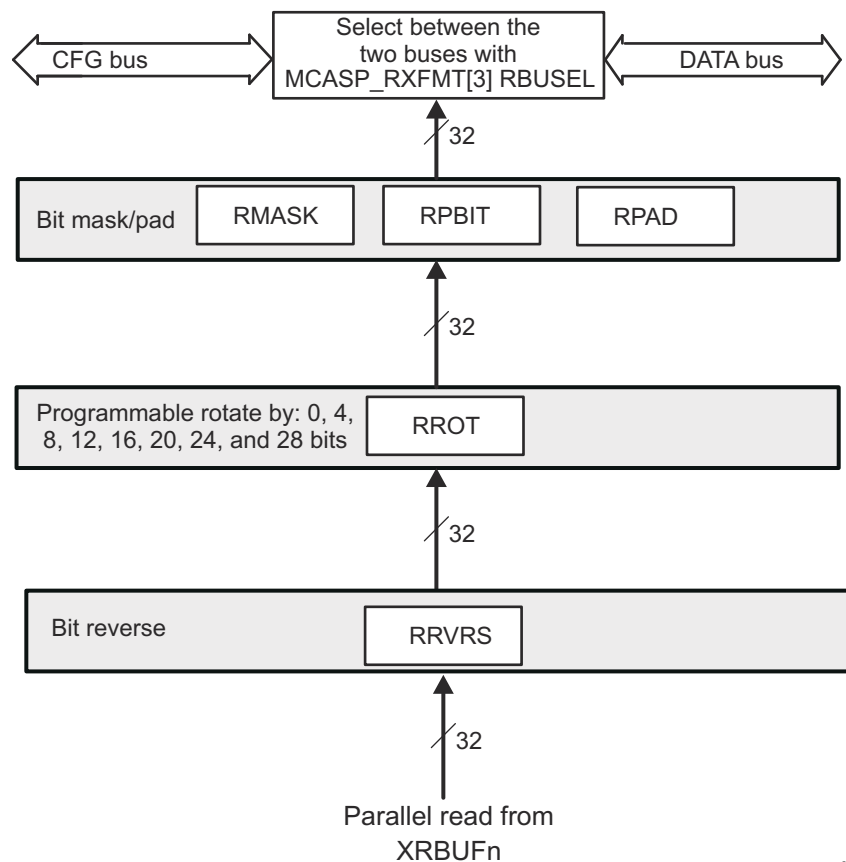

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

#### 12.5.2.3.5.2 Receive Format Unit

The MCASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

[Figure 12-279](#) shows the receive format unit (RFU).

mcasp-018

**Figure 12-279. Receive Format Unit**

The MCASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - MCASP\_RFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on [Figure 12-279](#), the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP\_RFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 12.5.2.3.11.1.3, Transfers Through the DATA Port](#), and [Section 12.5.2.3.11.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

#### 12.5.2.3.5.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

### Note

Note that the word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the RROT field.

Table 12-309 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

**Table 12-309. MCASP RFU Settings**

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RFMT bits	
			RROT <sup>(1)</sup>	RRVRS
MSB first <sup>(2)</sup>	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	$(32 - (\text{SLOT} - \text{WORD})) \% 32$	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first <sup>(2)</sup>	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 12-309 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 12-279), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer).

#### 12.5.2.3.6 MCASP State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the MCASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP\_XFMT) and it reports the MCASP status and error conditions in the transmitter status register (MCASP\_XSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP\_RFMT) and it reports the MCASP status and error conditions in the receiver status register (MCASP\_RSTAT).

#### 12.5.2.3.7 MCASP TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of the MCASP\_RTDM/ MCASP\_XTDM register and determines if the MCASP should receive/transmit in that time slot.

There are two possibilities for a slot: The MCASP either performs Rx/Tx operations during the time slot (transmit/receive bit is active), or the MCASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUFF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRN in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each

serializer control MCASP\_SRCTLn[3-2] DISMOD register. Refer also to [Section 12.5.2.3.10.2.1, TDM Time Slots Generation and Processing](#), for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

**In case of a DIT-transmission (S/PDIF transfers):** the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP\_XBUF<sub>n</sub> register during the current time slot (slot 1) is actually shifted out on the next time slot ( $n = 0$  to 15).

The transmit TDM sequencer is controlled by the MCASP\_XTDM register and reports the current transmit slot to the MCASP\_XTDM\_SLOT[9-0] XSLOT\_CNT bit field.

#### 12.5.2.3.8 MCASP Software Reset

The MCASP can be put into reset through the global transmit and receive control register (MCASP\_GBLCTL). A valid serial clock must be supplied to the MCASP to assert the software reset bits in the MCASP\_GBLCTL register.

#### 12.5.2.3.9 MCASP Power Management

[Table 12-310](#) describes power-management features available to the MCASP.

**Table 12-310. Local Power-Management Features**

Feature	Registers	Description
Slave clock stop modes	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	Force-clock stop, no-clock stop, and smart-clock stop modes are available.

#### CAUTION

No wakeup schema is supported for the MCASP. To ensure a correct behavior after enabling MCASP at device Device Configuration level, the user software is strongly recommended to choose *No Idle* mode, setting MCASP\_PWRIDLESYSCONFIG[1-0] IDLE\_MODE bit field to 0x1. Before disabling MCASP at device Device Configuration level, user software is strongly recommended to choose a *Smart-Idle* mode, setting MCASP\_PWRIDLESYSCONFIG[1-0] IDLE\_MODE bit field to 0x2.

#### 12.5.2.3.10 MCASP Transfer Modes

##### 12.5.2.3.10.1 Burst Transfer Mode

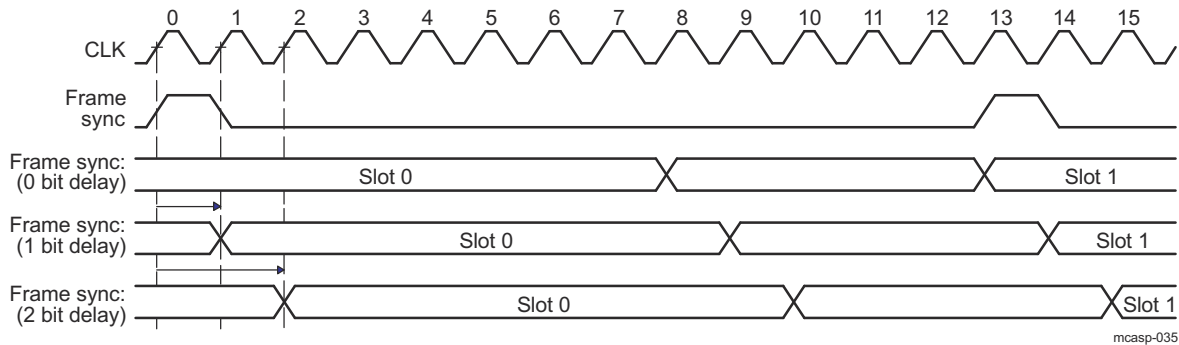

The MCASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

When operating in burst frame sync mode (see [Figure 12-280](#)), as specified for transmit (MCASP\_AFSXCTL[15-7] = 0) and receive (MCASP\_AFSRCTL[15-7] RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (MCASP\_AFSRCTL[4] FRWID = 0, MCASP\_AFSXCTL[4] FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF<sub>n</sub> (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF<sub>n</sub> (for every serializer set to operate as a receiver) has been read.

**Figure 12-280. Burst Frame Sync Mode**

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- MCASP\_PFUNC: The clock, frame, data pins must be configured for MCASP function.
- MCASP\_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP\_PDOUT, MCASP\_PDIN, MCASP\_PDCLR: Not applicable. Leave at default.
- MCASP\_GBLCTL: Follow the initialization sequence in *MCASP Global Initialization*, to configure this register.
- MCASP\_AMUTE: Not applicable. Leave at default.
- MCASP\_DLBCTL: If loopback mode is desired, configure this register according to [Section 12.5.2.3.15, MCASP Loopback Modes](#), otherwise leave this register at default.
- MCASP\_DITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- MCASP\_RMASK/MCASP\_XMASK: Mask desired bits according to [Section 12.5.2.3.5, MCASP Format Units](#).
- MCASP\_RFMT/MCASP\_XFMT: Program all fields according to data format desired. See [Section 12.5.2.3.5, MCASP Format Units](#).
- MCASP\_RFMT/MCASP\_XFMT: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- MCASP\_ACLKRCTL/MCASP\_ACLKXCTL: Program all fields according to bit clock desired. See [Section 12.5.2.3.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP\_AHCLKRCTL/MCASP\_AHCLKXCTL: Program all fields according to high-frequency clock desired. See [Section 12.5.2.3.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP\_RTDM/MCASP\_XTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- MCASP\_RINTCTL/MCASP\_XINTCTL: Program all fields according to interrupts desired.
- MCASP\_RCLKCHK/MCASP\_XCLKCHK: Not applicable. Leave at default.
- MCASP\_SRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default (n = 0 to 15).
- MCASP\_DITCSRAi, MCASP\_DITCSRBi, MCASP\_DITUDRAi, MCASP\_DITUDRBi: Not applicable. Leave at default (i = 0 to 5).

#### 12.5.2.3.10.2 Time-Division Multiplexed (TDM) Transfer Mode

The MCASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in *TDM Format*.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to transmit

For more details on MCASP transmitting serializers clock and frame sync options, refer to the [Section 12.5.2.3.2.1, Transmit Clock](#), and [Section 12.5.2.3.2.3, Frame-Sync Generator](#).

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on MCASP receiving serializers clock and frame sync options, refer to [Section 12.5.2.3.2.2, Receive Clock](#), and [Section 12.5.2.3.2.3, Frame-Sync Generator](#).

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- MCASP\_PFUNC: The clock, frame, data pins must be configured for MCASP function.
- MCASP\_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP\_PDOUT, MCASP\_PDIN, MCASP\_PDCLR: Not applicable. Leave at default.
- MCASP\_GBLCTL: Follow the initialization sequence is described in the [Section 12.5.2.4.1, MCASP Operational Modes Configuration](#).
- MCASP\_AMUTE: Leave this register at default state.
- MCASP\_DLBCTL: If loopback mode is desired, configure this register according to [Section 12.5.2.3.15](#), otherwise leave this register at default.
- MCASP\_DITCTL: DITEN must be left at default 0 to select TDM mode (transmitters only).
- MCASP\_RMASK/MCASP\_XMASK: Mask desired bits according to [Section 12.5.2.3.5, MCASP Format Units](#).
- MCASP\_RFMT/MCASP\_XFMT: Program all fields according to data format desired. See the [Section 12.5.2.3.5, MCASP Format Units](#).
- MCASP\_AFSRCTL/MCASP\_AFSXCTL: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by MCASP. Configure other fields as desired.
- MCASP\_ACLKRCTL/MCASP\_ACLKXCTL: Program all fields according to bit clock desired. For more information, refer to [Section 12.5.2.3.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP\_AHCLKRCTL/MCASP\_AHCLKXCTL: Program all fields according to high-frequency clock desired. For more details, refer to [Section 12.5.2.3.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP\_RTDM/MCASP\_XTDM: Program all fields according to the time slot characteristics desired.
- MCASP\_XINTCTL: Program all fields according to transmit interrupts desired.
- MCASP\_RCLKCHK/MCASP\_XCLKCHK: Program all fields according to clock checking desired.
- MCASP\_SRCTLn: Program all fields according to serializer operation desired (n = 0 to 15).

---

#### Note

The MCASP\_DITCSRAi, MCASP\_DITCSRBi, MCASP\_DITUDRAi, MCASP\_DITUDRBi (i = 0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

---

#### 12.5.2.3.10.2.1 TDM Time Slots Generation and Processing

TDM mode on the MCASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the MCASP may be configured to participate or to be inactive by configuring MCASP\_XTDM and/or MCASP\_RTDM registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either MCASP\_XTDM or MCASP\_RTDM register to determine if the MCASP transmits/receives in that time slot.

---

#### Note

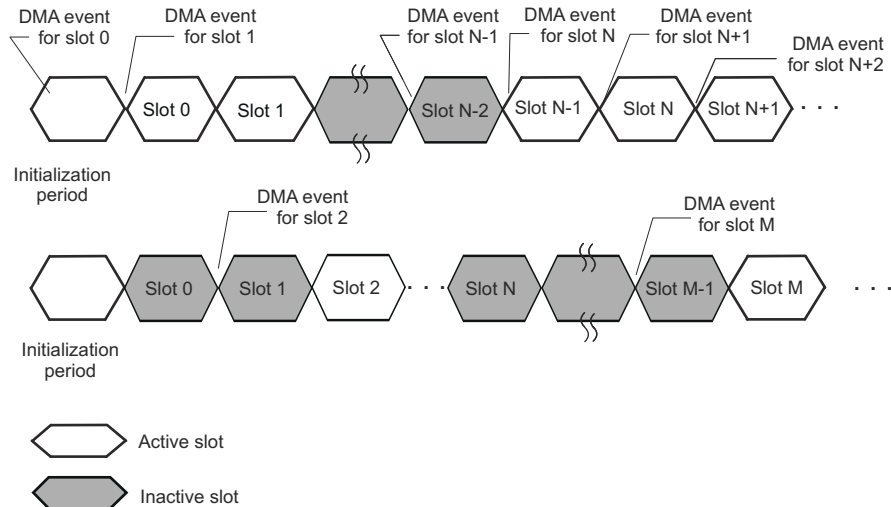

If a MCASP\_XTDM/MCASP\_RTDM bit defines an active slot (number of slot matches the bit position), the MCASP functions normally during that time slot; otherwise, the MCASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. MCASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP\_SRCTLn[3-2] DISMOD (n = 0 to 15).

---

[Figure 12-281](#) shows when the transmit DMA event - XINT is generated. See [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#) for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUFFn to XRSRn generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

mcasp-019

**Figure 12-281. Transmit DMA Event (XINT) Generation in TDM Time Slots**

#### 12.5.2.3.10.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The MCASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to MCASP frame) size is 384 samples. The receive TDM time slot register (MCASP\_RTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXRn, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set MCASP\_AFSRCTL[15-7] RMOD bit field to 384 (0x180) to receive 384 time slots

#### 12.5.2.3.10.3 DIT Transfer Mode

The DIT transfer mode of the MCASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see *S/PDIF Coding Format*.

##### 12.5.2.3.10.3.1 Transmit DIT Encoding

When the MCASP operates in DIT mode, the data transmitted is output as a biphasemark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the MCASP. The MCASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

### Note

The transmit TDM time slot register (MCASP\_XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see [Section 12.5.2.3.5.1.2, DIT Mode Transmission Data Alignment Settings](#).

If the MCASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

#### 12.5.2.3.10.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP\_AFSXCTL):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP\_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP\_XFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- MCASP\_PFUNC: The data pin - AXRn must be configured for MCASP function. If AHCLKX is used, it must also be configured for MCASP function. Other pins can be configured to function as GPIOs, if desired.
- MCASP\_PDIR: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- MCASP\_GBLCTL: Global initialization
- MCASP\_AMUTE: Leave this register at default state.
- MCASP\_DITCTL: The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as desired.
- MCASP\_XMASK: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- MCASP\_XFMT: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the [Section 12.5.2.3.5.1.2](#).
- MCASP\_AFSXCTL: Configure the bits according to former discussions.
- MCASP\_ACLKXCTL: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- MCASP\_AHCLKXCTL: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- MCASP\_XTDM: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP\_XINTCTL: Program all fields according to the interrupts desired.
- MCASP\_XCLKCHK: Program all fields according to the clock checking desired.
- MCASP\_SRCTLn: Set SRMOD = 1 (transmitter) for the DIT pins (n = 0 to 15).
- MCASP\_DITCSRAi and MCASP\_DITCSRBi: Program the channel status bits as desired (i = 0 to 5).
- MCASP\_DITUDRAi and MCASP\_DITUDRBi: Program the user data bits as desired (i = 0 to 5).

### Note

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphasic Mark Encoded Data - see *Biphase-Mark Code*).

#### 12.5.2.3.10.3.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP\_DITCSRAi and MCASP\_DITCSRBi) and user data registers (MCASP\_DITUDRAi and MCASP\_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used (i = 0 to 5).

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP\_DITCSRA0 to MCASP\_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP\_DITCSRB0 to MCASP\_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP\_DITUDRA0 to MCASP\_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP\_DITUDRB0 to MCASP\_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in *S/PDIF Frame Format*. There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 12-311](#).

**Table 12-311. Channel Status and User Data for Each DIT Block**

**12.5.2.3.11 MCASP Data Transmission and Reception**

The MCASP is serviced by writing data to the MCASP\_XBUF<sub>n</sub> registers for transmit operations, and by reading data from the MCASP\_RBUF<sub>n</sub> registers for receive operations. The MCASP sets status flags and notifies the software whenever data is ready to be serviced. The [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#), discusses data-ready status in details (n = 0 to 15).

The MCASP transmit/receive XRBUF<sub>n</sub> buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA initiated data transfers on the device for MCASP transmit (Tx) purposes.
- Configuration bus (CFG): The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

[Section 12.5.2.3.11.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 12.5.2.3.11.1.4, Transfers Through the Configuration Bus \(CFG\)](#), discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in [Section 12.5.2.3.11.1.5, Using the device CPUs for MCASP Servicing](#), and [Section 12.5.2.3.11.1.6, Using the DMA for MCASP Servicing](#), respectively.

MCASP DATA port allows DMAs to access the MCASP transmit buffer more efficiently on the CBASS0, using burst transfers. The physical addresses to access these registers are listed in *DMA Registers*.

**12.5.2.3.11.1 Data Ready Status and Event/Interrupt Generation****12.5.2.3.11.1.1 Transmit Data Ready**

The transmit data ready flag - XDATA in the MCASP\_XSTAT register reflects the data ready status of XRBUF<sub>n</sub> buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUF<sub>n</sub> to its corresponding XRSR<sub>n</sub> shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUF<sub>n</sub> is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in

its corresponding control register MCASP\_SRCTLn[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP\_XBUF<sub>n</sub> is written to by the host, the MCASP\_SRCTLn[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the MCASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP\_XBUF<sub>n</sub> register has to be currently written. Once all requested MCASP\_XBUF<sub>n</sub> are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP\_XSTAT[5] XDATA bit is written to 0b1, or once MCASP\_XBUF<sub>n</sub> registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the XINT event is automatically generated on MCASP[0-2]\_XMIT\_DMA\_EVT line (if enabled in the MCASP\_XEVTCTL register) to notify the DMA of the MCASP\_XBUF<sub>n</sub> empty status. An interrupt - MCASP[0-2]\_XMIT\_INTR\_PEND can be also generated if the XDATA interrupt is enabled in the MCASP\_XINTCTL register (for details, see [Section 12.5.2.3.13.1, Transmit Data Ready Interrupt](#)).

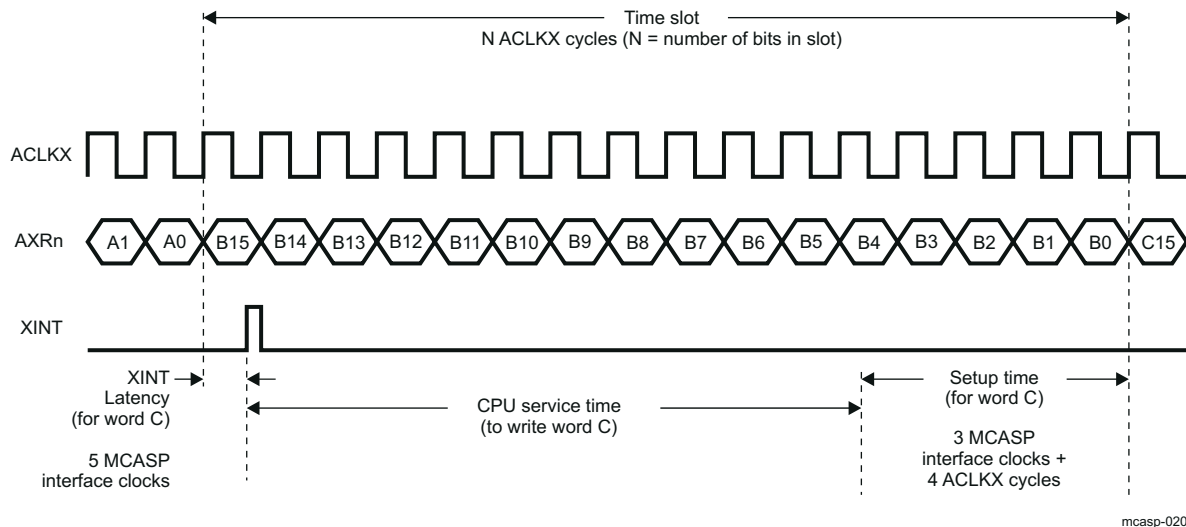

For DMA requests, the MCASP does not require that MCASP\_XSTAT register be read between DMA events. This means that, even if MCASP\_XSTAT register already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

[Figure 12-282](#) shows the timing details of when XINT is generated at the MCASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the MCASP sets the XDATA flag and generates an XINT event. However, it takes up to five MCASP interface clocks (XINT latency) before XINT is active at the MCASP boundary. Upon XINT, the CPU can begin servicing the MCASP by writing word C into the MCASP\_XBUF<sub>n</sub> (service time). The CPU must write word C into the MCASP\_XBUF<sub>n</sub> within the setup time required by the MCASP (setup time) ( $n = 0$  to 15).

The maximum service time (see [Figure 12-282](#)) can be calculated as:

**Service Time = Time Slot – XINT Latency – Setup Time**

**Figure 12-282. Service Time Upon Transmit DMA Event (XINT)**

#### 12.5.2.3.11.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the MCASP\_RSTAT register reflects the data ready status of XRBUF<sub>n</sub> buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSR<sub>n</sub> to its corresponding XRBUF<sub>n</sub> data buffer. Thus, the RDATA bit

indicates the global event that some of the receivers data buffer - RXBUF<sub>n</sub> already contains received data (this is, a buffer is full) and is ready to transfer it to the host. The receive data ready event is individually indicated per serializer in its corresponding control register MCASP\_SRCTL<sub>n</sub> [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP\_RBUF<sub>n</sub> register is read from the host, the MCASP\_SRCTL<sub>n</sub> [5] RRDY bit is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the MCASP host (RDATA = 0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP\_RBUF<sub>n</sub> register has to be currently read. Once all requested MCASP\_RBUF<sub>n</sub> registers are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

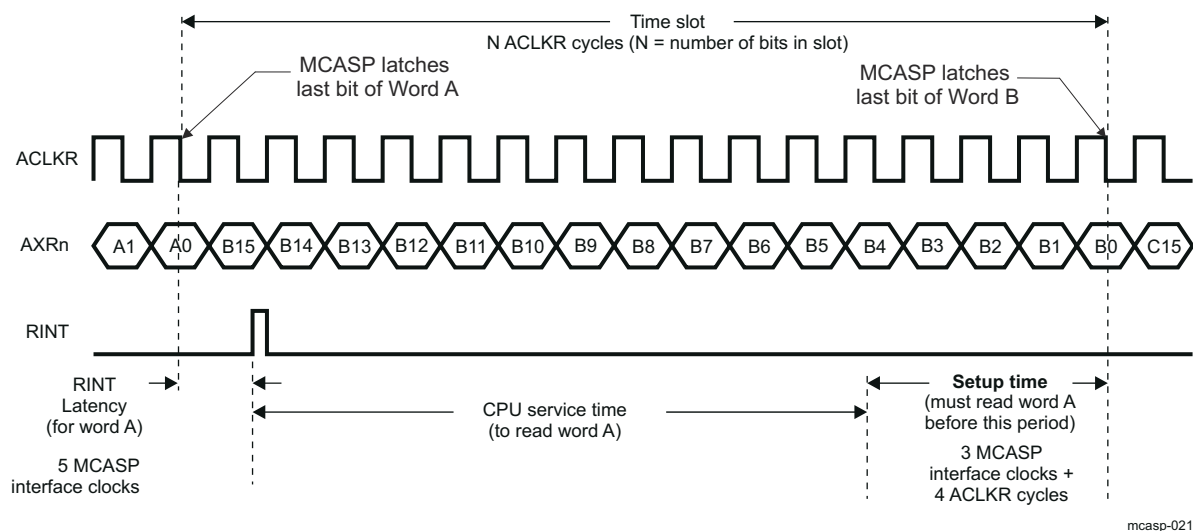

The global RDATA flag can be cleared when the MCASP\_RSTAT[5] RDATA bit is written to 0b1, or once MCASP\_RBUF<sub>n</sub> registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA flag is set, the RINT event is automatically generated on MCASP[0-2]\_REC\_DMA\_EVT line (if enabled in the MCASP\_PIDTCTL register) to notify the DMA of the MCASP\_RBUF<sub>n</sub> full status. An interrupt - MCASP[0-2]\_REC\_INTR\_PEND can be also generated if the RDATA interrupt is enabled in the MCASP\_RINTCTL register (for details, see [Section 12.5.2.3.13.1, Receive Data Ready Interrupt](#)).

[Figure 12-283](#) shows the timing details of when RINT event is generated at the MCASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the MCASP sets the RDATA flag and generates an RINT event. However, it takes up to five MCASP interface clocks (RINT Latency) before RINT is active at the MCASP boundary. Upon RINT, the CPU can begin servicing the MCASP by reading Word A from the MCASP\_RBUF<sub>n</sub> (service time). The CPU must read Word A from the MCASP\_RBUF<sub>n</sub> register no later than the setup time required by the MCASP (Setup Time) ( $n = 0$  to 15).

The maximum service time (see [Figure 12-283](#)) can be calculated as:

**Service Time = Time Slot - RINT Latency - Setup Time**

**Figure 12-283. CPU Service Time Upon Receive Event (RINT)**

#### 12.5.2.3.11.1.3 Transfers Through the Data Port (DATA)

##### CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the MCASP\_XFMT/MCASP\_RFMT register, respectively. Failure to do so may result in software malfunction.

In a typical MCASP transfer scenario, the DMA Controller write accesses the XRBUF<sub>n</sub> transmit buffer through the MCASP data port (DATA) on CBASS0 Interconnect. CPU hosts can access both XRBUF<sub>n</sub> transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the MCASP Tx buffer through Interconnect DATA port location. Refer to *DMA Registers*. Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in [Section 12.5.2.3.12](#).

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in *DMA Registers*, the same physical DATA port address is used regardless of a read or write access is performed. The MCASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

---

#### Note

DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the MCASP configuration registers addressing their corresponding MCASP DATA port.

---

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port address) to service all of the active slot transmitting serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See *DMA Registers*).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

---

#### Note

For write transfers through MCASP DATA port it is preferable to use DMA on corresponding Interconnect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

---

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port address) to service all of the active slot receiving serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See *DMA Registers*).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the CPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0, 1 and 3 in this exact order, upon each receive data ready event.

---

#### Note

To service a serializer for a transmit or receive operation through the MCASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to *DMA Registers*), respectively.

---

**Note**

When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in MCASP\_XTDM) and *transmit* (Tx enabled in MCASP\_SRCTLn) within each time slot. Failure to do so results in a buffer underrun condition (see [Section 12.5.2.3.16.1, Buffer Underrun Error - Transmitter](#)). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in MCASP\_RTDM) and *receive* (Rx enabled in MCASP\_SRCTLn) within each time slot. Failure to do so results in a buffer overrun condition (see [Section 12.5.2.3.16.2, Buffer Overrun Error - Receiver](#)) (n = 0 to 15).

**12.5.2.3.11.4 Transfers Through the Configuration Bus (CFG)****CAUTION**

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the MCASP\_XFMT/MCASP\_RFMT registers, respectively. Failure to do so may result in software malfunction.

**Note**

MCASP[0-2] whose data ports are accessible directly via CBASS0 do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In this method, the CPU accesses the XRBUF<sub>n</sub> transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUF<sub>n</sub> transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of MCASP CFG port actual for CBASS0 accesses. The XRBUF<sub>n</sub> buffer of the n-th serializer configured as a transmitter is aliased - MCASP\_XBUF<sub>n</sub> in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the MCASP\_XBUF2 register. Similarly, the XRBUF<sub>n</sub> buffer of the n-th serializer configured as a receiver is aliased - MCASP\_RBUF<sub>n</sub> in the CFG port address space. For example, the XRBUF3 receive buffer is mapped as the MCASP\_RBUF3 register.

Accessing the XRBUF through the DATA port (see [Section 12.5.2.3.11.1.3](#)) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index, while accessing through the peripheral configuration port - CFG, the CPU must provide the exact MCASP\_XBUF<sub>n</sub> or MCASP\_RBUF<sub>n</sub> address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP\_XBUF<sub>n</sub> and MCASP\_RBUF<sub>n</sub> addresses corresponding to MCASP CFG port, see *CFG Registers* (n = 0 to 15).

**12.5.2.3.11.1.5 Using a Device CPU for MCASP Servicing**

The device CPUs can be used to service the MCASP transmit channels through interrupts (upon MCASP[0-2]\_XMIT\_INTR\_PEND and MCASP[0-2]\_REC\_INTR\_PEND interrupts). Because these interrupt events are connected to device COMPUTE\_CLUSTER0, PRU\_ICSSG0/1, MAIN2MCU\_LVL\_INTRTR0, R5FSS0/1\_INTRTR0, C66SS0/1\_INTRTR0, R5FSS0/1 modules, they could be software mapped to input interrupt lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP\_XSTAT register and RDATA bit in the MCASP\_RSTAT register can be performed by device CPUs, respectively. As discussed in [Section 12.5.2.3.11.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 12.5.2.3.11.1.4, Transfers Through the Configuration Bus \(CFG\)](#), the device CPUs can access MCASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the MCASP through interrupts, the XDATA/RDATA bit must be enabled in the respective MCASP\_XINTCTL/MCASP\_RINTCTL registers, to generate interrupts MCASP[0-2]\_XMIT\_INTR\_PEND/MCASP[0-2]\_REC\_INTR\_PEND to the device CPUs upon data ready

### 12.5.2.3.11.1.6 Using the DMA for MCASP Servicing

#### Note

The associated static Transfer Request (TR) operations of PDMA0, located in front of MCASP, must be configured to match the MCASP configuration. For more information, refer to *DMA Controllers*.

The typical scenario is to use the DMA to service the MCASP transmit and receive logic through the DATA port. The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see [Figure 12-273](#)). The data transfer is managed by the AFIFO according to generated transmit and receive events in the MCASP and data is fed to transmit buffers and fetched from receive buffers as described in [Section 12.5.2.3.12, MCASP Audio FIFO \(AFIFO\)](#). The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from MCASP module, these events are collected in AFIFO and on specific AFIFO conditions described in [Section 12.5.2.3.12, MCASP Audio FIFO \(AFIFO\)](#) the requests (transmit or receive) are forwarded to a DMA controller via MCASP[0-2]\_XMIT\_DMA\_EVT and MCASP[0-2]\_REC\_DMA\_EVT outputs. If the AFIFO is disabled (default state) it is transparent for the MCASP module and all request are directly sent to the DMA controller.

**Figure 12-284. DMA Transmit and Receive Event in an Audio Example – One Event**

In transmit mode, the DMA event - XINT (MCASP[0-2]\_XMIT\_DMA\_EVT output), which is triggered upon each XDATA transition from 0 to 1, is used to service the MCASP TXBUF<sub>n</sub> transmit buffers. In receive mode, the DMA event RINT (MCASP[0-2]\_REC\_DMA\_EVT output) which is triggered upon each RDATA transition from 0 to 1, is used to service the MCASP RXBUF<sub>n</sub> receive buffers.

[Figure 12-284](#) is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the MCASP signals - AXR0, AXR1 and AXR2. It shows the points at which events XINT/RINT are triggered.

In [Figure 12-284](#), a Tx DMA event XINT is triggered on each time slot. In the example, XINT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP\_XEVTCTL register. Similarly, Rx DMA event RINT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP\_PIDTCTL register.

### 12.5.2.3.12 MCASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See [Figure 12-285](#) for a high-level block diagram of the AFIFO.

The AFIFO may be enabled/disabled and configured via the MCASP\_WFIFOCTL and MCASP\_RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the MCASP.

mcasp-034

**Figure 12-285. MCASP Audio FIFO (AFIFO) Block Diagram**

#### 12.5.2.3.12.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the MCASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the MCASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the MCASP. When the Write FIFO is enabled, transmit DMA requests from the MCASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the MCASP, the WFIFO writes WNUMDMA 32-bit words to the MCASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the MCASP (see description for the MCASP\_WFIFOCTL[7-0] WNUMDMA). If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

### 12.5.2.3.12.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, MCASP\_WFIFOCTL[15-8] WNUMEVT bit field should be set to a non-zero integer multiple of the value in MCASP\_WFIFOCTL[7-0] WNUMDMA bit field. If transmit DMA event pacing is not desired, then the value in MCASP\_WFIFOCTL[15-8] WNUMEVT bit field should be set equal to the value in MCASP\_WFIFOCTL[7-0] WNUMDMA bit field.

### 12.5.2.3.12.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from MCASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the MCASP generates receive DMA requests as needed; the AFIFO is “invisible” to the MCASP. When the Read FIFO is enabled, receive DMA requests from the MCASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the MCASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the MCASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the MCASP (see description for the MCASP\_RFIFOCTL[7-0] RNUMDMA). If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than RNUMEVT words, those words will be read correctly, emptying the FIFO.

### 12.5.2.3.12.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least RNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once RNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another RNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, MCASP\_RFIFOCTL[15-8] RNUMEVT bit field should be set to a non-zero integer multiple of the value in MCASP\_RFIFOCTL[7-0] RNUMDMA bit field. If receive DMA event pacing is not desired, then the value in MCASP\_RFIFOCTL[15-8] RNUMEVT bit field should be set equal to the value in MCASP\_RFIFOCTL[7-0] RNUMDMA bit field.

### 12.5.2.3.12.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

### 12.5.2.3.13 MCASP Events and Interrupt Requests

[Table 12-312](#) lists all the transmit event flags. [Table 12-313](#) lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any MCASP serializer configured as transmitter or receiver respectively.

**Table 12-312. TX Events**

Event Mask <sup>(1)</sup>	Event Flag	Map to <sup>(1)</sup>	Description
MCASP_XINTCTL[0] XUNDRN	MCASP_XSTAT[0] XUNDRN	MCASP[0-2]_XMIT_INTR_PEND	Transmit buffer underrun
MCASP_XINTCTL[1] XSYNCERR	MCASP_XSTAT[1] XSYNCERR	MCASP[0-2]_XMIT_INTR_PEND	Unexpected transmit frame sync

**Table 12-312. TX Events (continued)**

Event Mask <sup>(1)</sup>	Event Flag	Map to <sup>(1)</sup>	Description
MCASP_XINTCTL[2] XCKFAIL	MCASP_XSTAT[2] XCKFAIL	MCASP[0-2]_XMIT_INTR_PEND	Transmit clock failure
MCASP_XINTCTL[3] XDMAERR	MCASP_XSTAT[7] XDMAERR	MCASP[0-2]_XMIT_INTR_PEND	DATA port transmit error
MCASP_XINTCTL[4] XLAST	MCASP_XSTAT[4] XLAST	MCASP[0-2]_XMIT_INTR_PEND	Transmit last slot interrupt
MCASP_XINTCTL[5] XDATA	MCASP_XSTAT[5] XDATA	MCASP[0-2]_XMIT_INTR_PEND	Transmit data-ready interrupt
MCASP_XINTCTL[7] XSTAFRM	MCASP_XSTAT[6] XSTAFRM	MCASP[0-2]_XMIT_INTR_PEND	Transmit start of frame interrupt
n.a.	MCASP_XSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR   XCKFAIL   XUNDRN   XSYNCERR ). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_XSTAT[3] XTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every MCASP module generates separate interrupt event.

**Table 12-313. RX Events**

Event Mask <sup>(1)</sup>	Event Flag	Map to <sup>(1)</sup>	Description
MCASP_RINTCTL[0] ROVRN	MCASP_RSTAT[0] ROVRN	MCASP[0-2]_REC_INTR_PEND	Receive buffer overrun
MCASP_RINTCTL[1] RSYNCERR	MCASP_RSTAT[1] RSYNCERR	MCASP[0-2]_REC_INTR_PEND	Unexpected receive frame sync
MCASP_RINTCTL[2] RCKFAIL	MCASP_RSTAT[2] RCKFAIL	MCASP[0-2]_REC_INTR_PEND	Receive clock failure
MCASP_RINTCTL[3] RDMAERR	MCASP_RSTAT[7] RDMAERR	MCASP[0-2]_REC_INTR_PEND	DATA port receive error
MCASP_RINTCTL[4] RLAST	MCASP_RSTAT[4] RLAST	MCASP[0-2]_REC_INTR_PEND	Receive last slot
MCASP_RINTCTL[5] RDATA	MCASP_RSTAT[5] RDATA	MCASP[0-2]_REC_INTR_PEND	Receive data-ready
MCASP_RINTCTL[7] RSTAFRM	MCASP_RSTAT[6] RSTAFRM	MCASP[0-2]_REC_INTR_PEND	Receive start of frame
n.a.	MCASP_RSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR   RCKFAIL   ROVRN   RSYNCERR ). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RSTAT[3] RTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every MCASP module generates separate interrupt event.

Software has to read the MCASP\_XSTAT/MCASP\_RSTAT register to determine which event occurs at a global level for MCASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the MCASP\_SRCTLn registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASP[0-2]\_XMIT\_INTR\_PEND) is asserted (active high) when one of the MCASP\_XSTAT notified events occurs, provided that it is enabled in its corresponding MCASP\_XINTCTL bit. Similarly, a Rx interrupt line (MCASP[0-2]\_REC\_INTR\_PEND) is asserted (active high) when one of MCASP\_RSTAT notified events occurs, provided that it is enabled in its corresponding MCASP\_RINTCTL bit. See also [Section 12.5.2.3.13.4, Multiple Interrupts](#) and the [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#) (n = 0 to 15).

#### 12.5.2.3.13.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if the MCASP\_XSTAT[5] XDATA bit is 1 and MCASP\_XINTCTL[5] XDATA bit is enabled. The [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when XDATA is set in the MCASP\_XSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

#### 12.5.2.3.13.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if the MCASP\_RSTAT[5] RDATA bit is 1 and MCASP\_RINTCTL[5] RDATA bit is enabled. The [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when the MCASP\_RSTAT[5] RDATA bit is set.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

#### 12.5.2.3.13.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP\_XSTAT):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP\_XINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP\_XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP\_RSTAT) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (MCASP\_RINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP\_RSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

#### 12.5.2.3.13.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in MCASP\_XSTAT is set and the interrupt is enabled in MCASP\_XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the MCASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP\_XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in MCASP\_XSTAT/MCASP\_RSTAT and the interrupt enabled in MCASP\_XINTCTL/MCASP\_RINTCTL generates a request on the MCASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the MCASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the MCASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to MCASP\_XSTAT/MCASP\_RSTAT. If any interrupt requests are active after the write, a new request is generated on the MCASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

#### **12.5.2.3.14 MCASP DMA Requests**

The MCASP can generate one DMA request to the DMA controller to transmit (MCASP[0-2]\_XMIT\_DMA\_EVT) or receive (MCASP[0-2]\_REC\_DMA\_EVT) data. A DMA request to transmit data is generated if the MCASP\_XEVTCTL[0] XDATDMA bit is cleared. A DMA request to receive data is generated if the MCASP\_PIDTCTL[0] RDATDMA bit is cleared.

#### **12.5.2.3.15 MCASP Loopback Modes**

The MCASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between MCASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the MCASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

[Figure 12-286](#) shows the basic logical connection of the serializers in loopback mode.

mcasp-023

**Figure 12-286. MCASP Serializers Operation in Loopback Mode**

Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - MCASP\_DLBCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (the MCASP\_DLBCTL[4] IOLBEN bit) between a MCASP module internal loopback and a device I/O level loopback.

When a **MCASP internal loopback** is selected (MCASP\_DLBCTL[4] IOLBEN = 0b0 ), it is NOT necessary to configure MCASP\_PFUNC and MCASP\_PDIR registers for MCASP pin settings. Nevertheless, data can be

optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a MCASP output pin by setting the corresponding MCASP\_PFUNC bit to 0 (this is, to function as MCASP, not GPIO) and MCASP\_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP\_DLBCTL[4] IOLBEN = 0b1 ), the MCASP\_PFUNC and MCASP\_PDIR registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (this is, reaching device I/O buffers ).

When in loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the MCASP. The transmit and receive sections operate synchronously. This is achieved by setting the MCASP\_DLBCTL[3-2] MODE bit field to 0x1 and the MCASP\_ACLKXCTL[6] ASYNC bit to 0b0.

#### 12.5.2.3.15.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The MCASP\_DLBCTL[0] DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal MCASP operation.
- The MCASP\_DLBCTL[4] IOLBEN bit must be set to select between internal (MCASP local) loopback mode or device I/O level loopback mode.
- The MCASP\_DLBCTL[3-2] MODE bit field must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP\_DLBCTL[1] ORD bit must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The MCASP\_ACLKXCTL[6] ASYNC bit must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The MCASP\_AFSRCTL[15-7] RMOD bit field and MCASP\_AFSXCTL[15-7] XMOD bit field must be set within range (0x2 - 0x20) to indicate TDM mode.

#### Note

Loopback mode does not apply to DIT or burst mode, because MCASP receivers do NOT natively support DIR - reception.

#### 12.5.2.3.16 MCASP Error Reporting

The MCASP includes error-checking capability for the serial protocol and data underrun. In addition, the MCASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

##### 12.5.2.3.16.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUFn buffer to XRSRn shift register, but the corresponding (MCASP\_XBUFn ) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP\_XSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it (n = 0 to 15).

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the MCASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the MCASP and start again with the proper initialization.

#### **12.5.2.3.16.2 Buffer Overrun Error-Receiver**

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding MCASP\_RBUn register has not yet been read since the last time the transfer occurred. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting (n = 0 to 15).

An overrun is checked only once per time slot. The MCASP\_RSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

#### **12.5.2.3.16.3 DATA Port Error - Transmitter**

A transmit DATA port error, as indicated by the MCASP\_XSTAT[7] XDMAERR bit, occurs when the DMA or device CPU writes more words to the DATA port of the MCASP than it should.

The MCASP\_XSTAT[7] XDMAERR = 0b1 indicates that the DMA or device CPU wrote too many words to the MCASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting the MCASP\_XSTAT[0] XUNDRN bit.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the DMA or device CPU. The MCASP transmitter and the DMA must be reinitialized to resynchronize them.

#### **12.5.2.3.16.4 DATA Port Error - Receiver**

A receive DATA port error, as indicated by the MCASP\_RSTAT[7] RDMAERR bit, occurs when the DMA or device CPU reads more words from the DATA port of the MCASP than it should.

The MCASP\_RSTAT[7] RDMAERR bit indicates that the DMA or device CPU read too many words from the MCASP DATA port for a given receive RINT event. Reading too few words results in a receiver overrun error setting the MCASP\_RSTAT[0] ROVRN bit.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the DMA or device CPU. The MCASP receiver and the DMA must be reinitialized to resynchronize them.

#### **12.5.2.3.16.5 Unexpected Frame Sync Error**

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the MCASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
  - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
  - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):

- Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
- Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

#### **12.5.2.3.16.6 Clock Failure Detection**

##### **12.5.2.3.16.6.1 Clock Failure Check Startup**

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP\_XCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP\_XSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
  - a. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP\_XINTCTL)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP\_RCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP\_RSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
  - a. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register (MCASP\_RINTCTL)

##### **12.5.2.3.16.6.2 Transmit Clock Failure Check and Recovery**

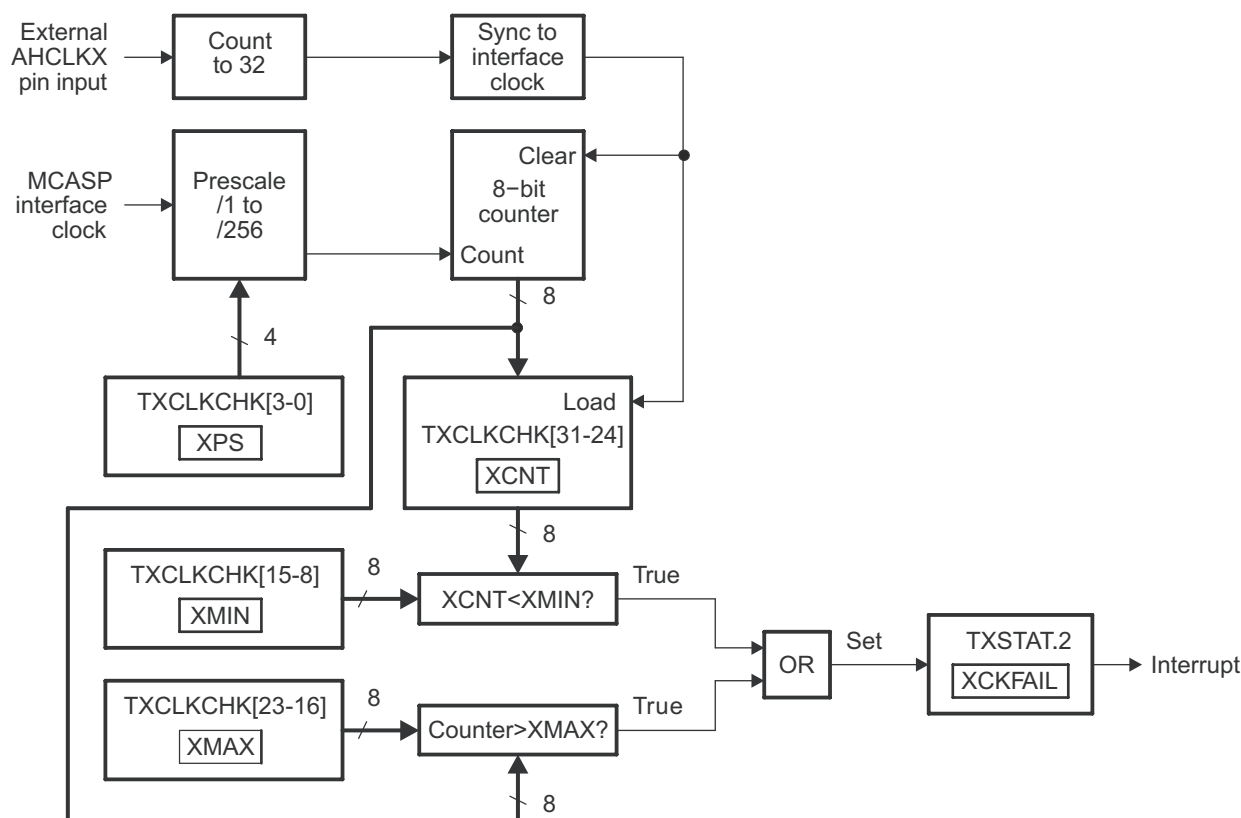

The transmit clock failure check circuit (see [Figure 12-287](#)) works off the internal MCASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (MCASP\_XCLKCHK) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (the MCASP\_XSTAT[2] XCKFAIL bit) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the MCASP\_XSTAT[2] XCKFAIL transmit clock failure flag is set. This causes an interrupt if the MCASP\_XINTCTL[2] XCKFAIL transmit clock failure interrupt enable bit is set.

mcasps-024

**Figure 12-287. Transmit Clock Failure Detection Circuit Block Diagram**

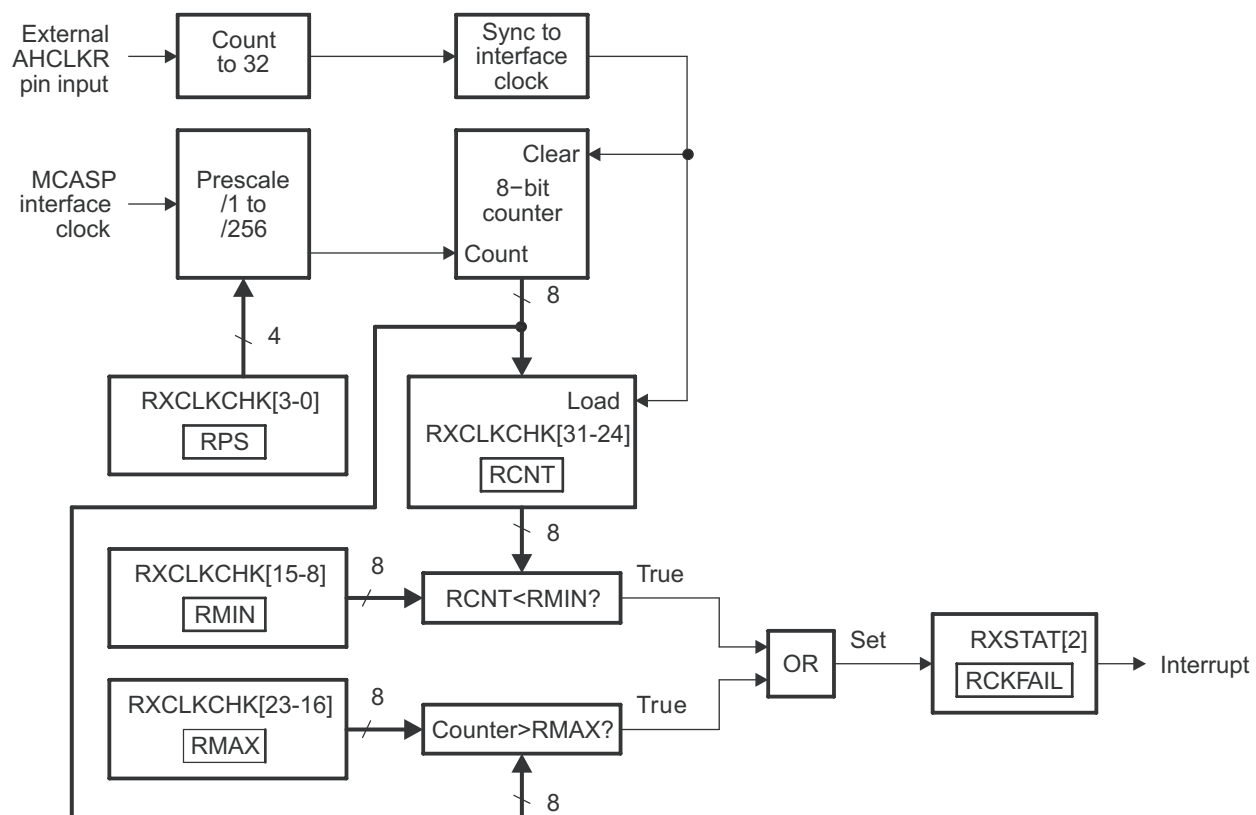

#### 12.5.2.3.16.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (see [Figure 12-288](#)) works off both the internal MCASP interface clock and the external high-frequency serial clock (AHCLKR). It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP\_RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (the MCASP\_RSTAT[2] RCKFAIL bit) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

## 12.5.2.4 MCASP Programming Guide

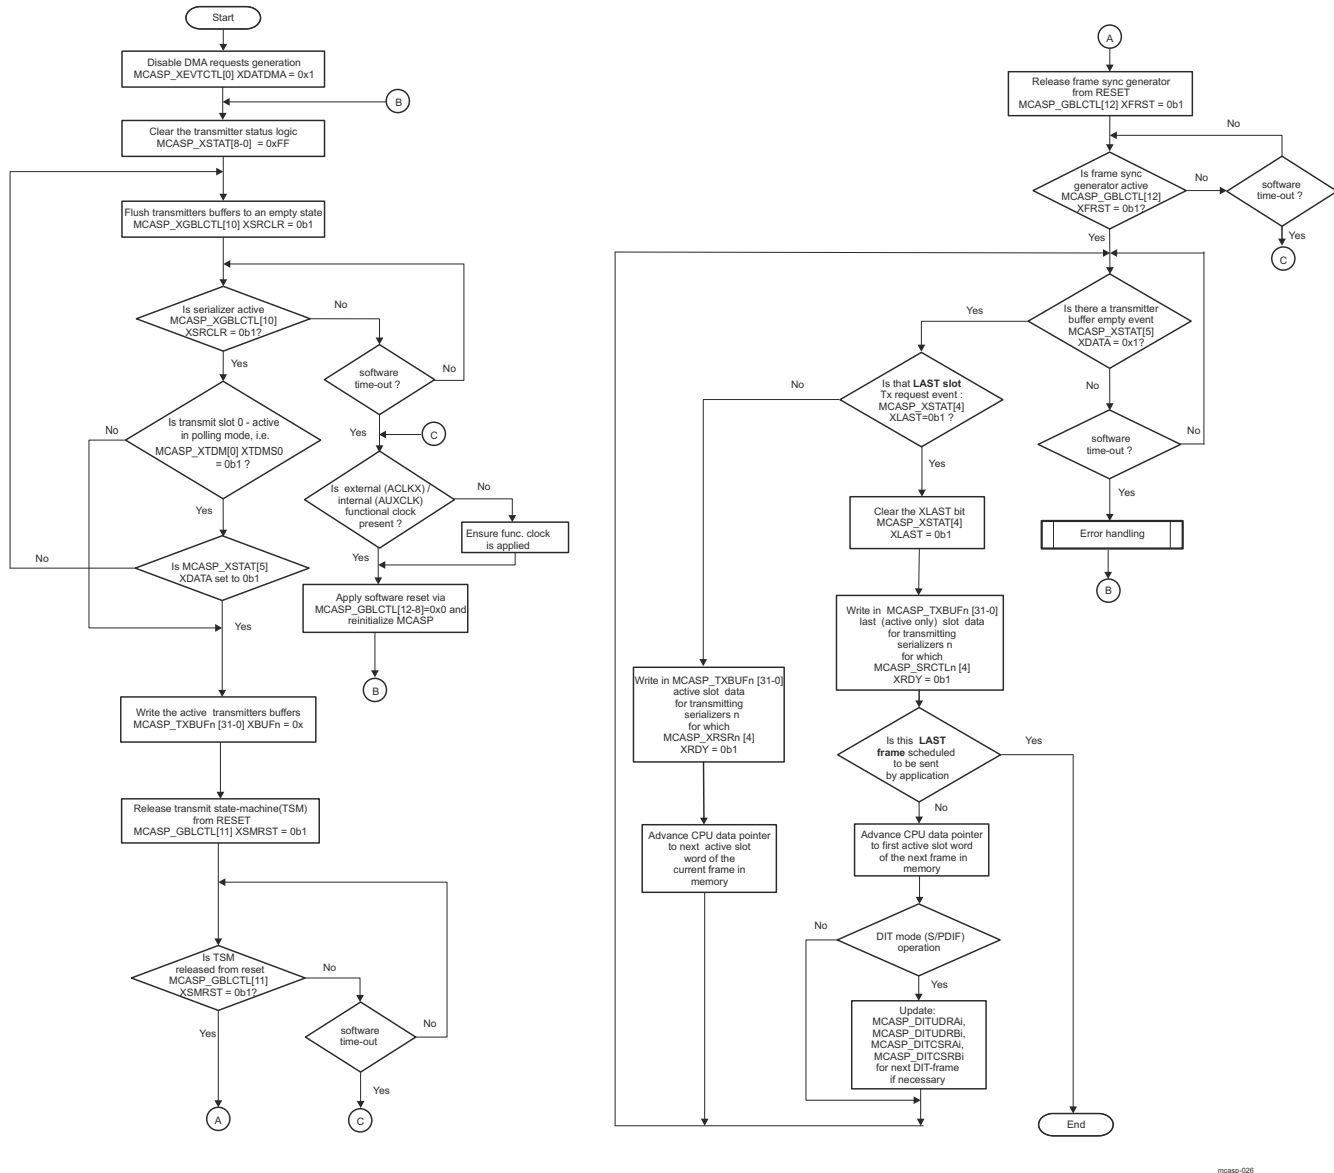

This section describes the low-level hardware programming sequences for the configuration and use of the MCASP module.

### 12.5.2.4.1 MCASP Operational Modes Configuration

#### 12.5.2.4.1.1 MCASP Transmission Modes

##### 12.5.2.4.1.1.1 Main Sequence – MCASP DIT- /TDM- Polling Transmission Method

Figure 12-289 shows the MCASP DIT-/TDM- polling method.

**Figure 12-289. MCASP DIT- /TDM- Transmission Polling Method**

These registers are for MCASP DIT-/TDM- transmission polling method: MCASP\_XEVTCTL, MCASP\_XSTAT, MCASP\_GBLCTL, MCASP\_XTDM, MCASP\_XBUFn, MCASP\_SRCTLn, MCASP\_DITUDRAi, MCASP\_DITUDRBi, MCASP\_DITCSRAi, MCASP\_DITCSRBi (n = 0 to 15 and i = 0 to 5).

Table 12-314 summarizes the subprocess call for the DIT-/TDM- transmission polling mode.

**Table 12-314. Subprocess Call Summary for Main Sequence – MCASP DIT-/TDM- Transmission Polling Method**

Subprocess Name	Cross-Reference
Error handling	<a href="#">Figure 12-295</a>

#### **12.5.2.4.1.1.2 Main Sequence – MCASP DIT- /TDM - Interrupt Transmission Method**

[Figure 12-290](#) shows the initial setup for interrupt-based transmission.

mcasp-027

**Figure 12-290. Subsequence – DIT-/TDM- Transmission Startup Procedure**

Table 12-315 shows the configuration of the MCASP using an interrupt method for DIT-/TDM- transmission.

**Table 12-315. MCASP DIT-/TDM- Interrupt Transmission Model**

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_XINTCTL[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_XINTCTL[2] XCKFAIL	0x1
	MCASP_XINTCTL[1] XSYNCERR	0x1
	MCASP_XINTCTL[0] XUNDRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_XINTCTL[7] XSTAFRM	0x1
Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update).	MCASP_XINTCTL[4] XLAST	0x1
<b>IF</b> write transfer is through the MCASP DATA port (MCASP_XFMT[3] XBUSEL is set to 0b0).		
Software test condition (setting is done in step4 of the <i>MCASP Transmitters Global Initialization</i> - see <i>MCASP Transmitters Global Initialization for DIT-Mode Operation</i> )		
Enable the DATA port error based interrupt.	MCASP_XINTCTL[3] XDMAERR	0x1
<b>ELSE</b>		
Disable the DATA port error based interrupt.	MCASP_XINTCTL[3] XDMAERR	0x0
<b>ENDIF</b>		
DIT/TDM - Transmission Startup Procedure	See <a href="#">Figure 12-290</a> .	

These registers are for MCASP DIT-/TDM- transmission startup procedure: MCASP\_GBLCTL, MCASP\_XSTAT.

#### 12.5.2.4.1.1.3 Main Sequence –MCASP DIT- /TDM - Mode DMA Transmission Method

[Table 12-316](#) shows the configuration of the ↓ using the DMA method for transmission. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

#### Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the MCASP DATA port.

**Table 12-316. MCASP DMA Transmission Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
<b>Recommended:</b> Select DATA port to access the transmit buffers.	MCASP_XFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of MCASP DATA port usage.	MCASP_XINTCTL[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_XINTCTL[2] XCKFAIL	0x1
	MCASP_XINTCTL[1] XSYNCERR	0x1
	MCASP_XINTCTL[0] XUNDRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_XINTCTL[7] XSTAFRM	0x1
Optional: Enable the last slot data interrupt.	MCASP_XINTCTL[4] XLAST	0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_XINTCTL[5] XDATA	0x0
DMA startup transmission procedure. This procedure is identical than the one shown in <a href="#">Figure 12-290</a> . The only difference is that DMA automatically services all the XINT events raised by the MCASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in <a href="#">Figure 12-293</a> .	See <a href="#">Figure 12-290</a> .	

#### 12.5.2.4.1.2 MCASP Reception Modes

##### 12.5.2.4.1.2.1 Main Sequence – MCASP Polling Reception Method

[Figure 12-291](#) shows the MCASP polling reception method.

The MCASP polling reception model considers the device CPUs as the accessor of audio data from the MCASP receive buffers.

These registers are for MCASP reception polling method: MCASP\_RSTAT, MCASP\_XGBLCTL, MCASP\_RBUF<sub>n</sub>, MCASP\_SRCTL<sub>n</sub> (n = 0 to 15).

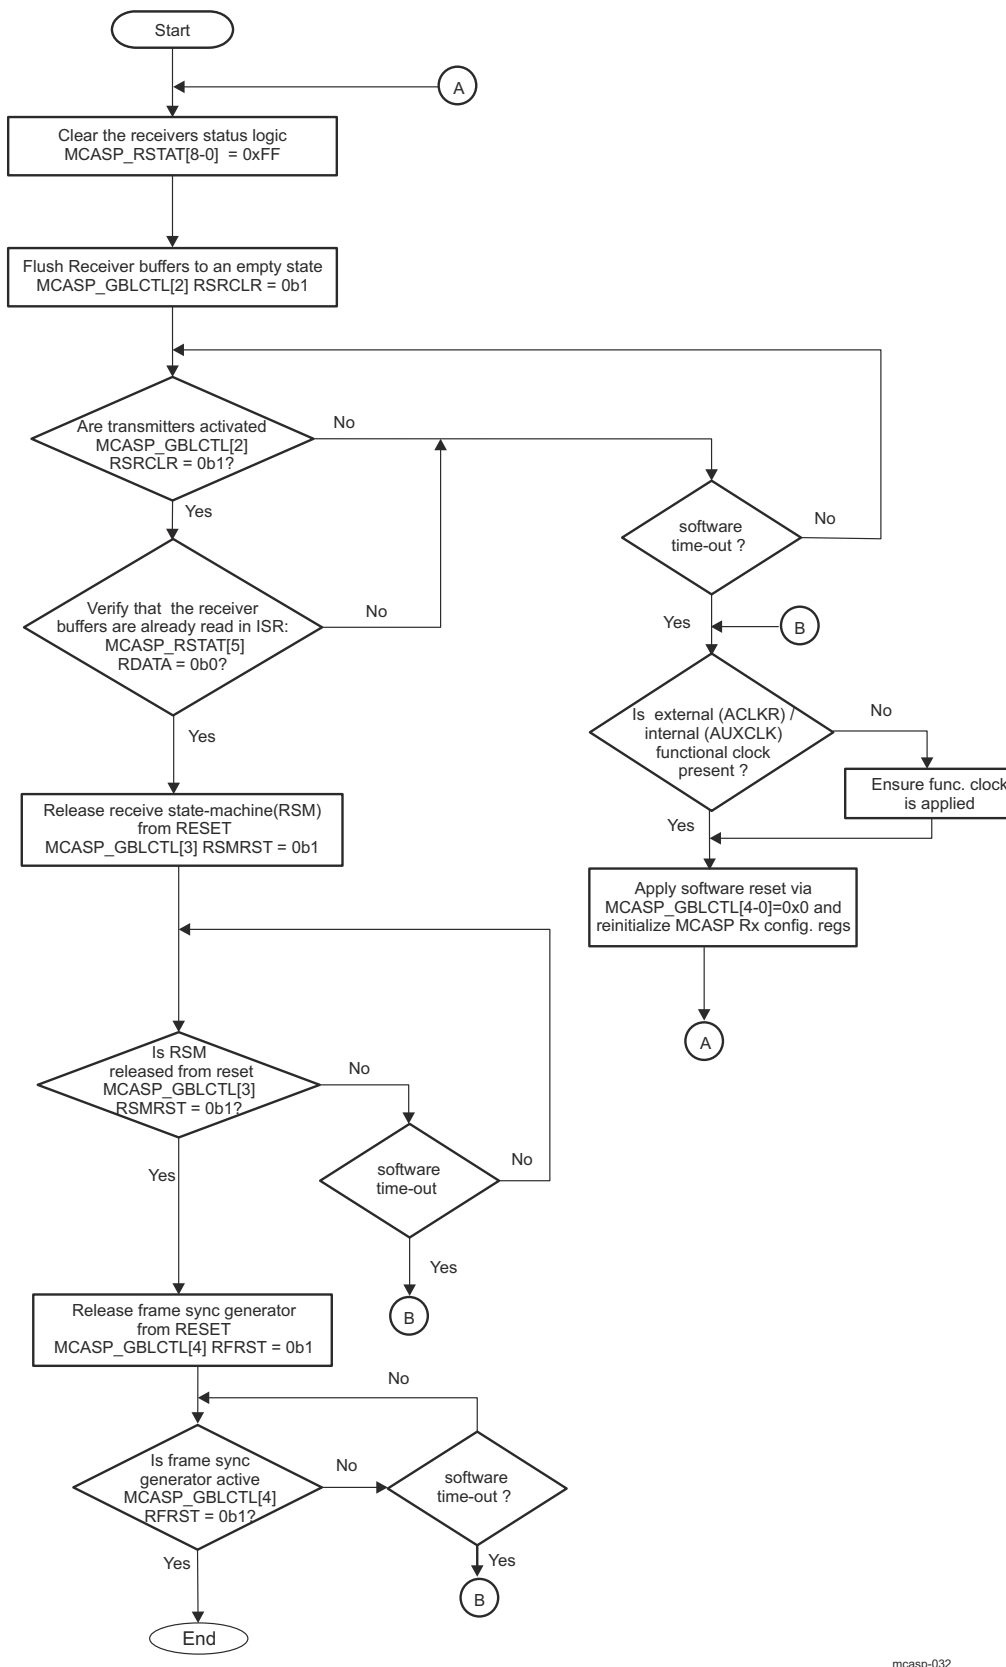

[Table 12-317](#) summarizes the subprocess call for the polling mode.

**Table 12-317. Subprocess Call Summary for Main Sequence – MCASP Reception Polling Method**

Subprocess Name	Cross-Reference
Error handling	<a href="#">Figure 12-296</a>

#### **12.5.2.4.1.2.2 Main Sequence – MCASP TDM - Interrupt Reception Method**

[Figure 12-292](#) shows the initial setup for interrupt-based reception.

mcasp-032

**Figure 12-292. Subsequence – TDM - Reception Startup Procedure**

Table 12-318 shows the configuration of the MCASP using an interrupt method for TDM- reception.

**Table 12-318. MCASP TDM- Interrupt Reception Model**

Step	Register/Bit Field/Programming Model	Value
Disable Rx DMA requests generation.	MCASP_PIDTCTL[0] RDATDMA	0x1
Enable the data ready event receive interrupt.	MCASP_RINTCTL[5] RDATA	0x1
Optional: Enable the receive error event interrupts.	MCASP_RINTCTL[2] RCKFAIL	0x1
	MCASP_RINTCTL[1] RSYNCERR	0x1
	MCASP_RINTCTL[0] ROVRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_RINTCTL[7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt	MCASP_RINTCTL[4] RLAST	0x1
<b>IF</b> read transfer is through the MCASP DATA port (MCASP_RFMT[3] RBUSEL is set to 0b0).		
Software test condition (setting is done in step4 of the <i>MCASP Receivers Global Initialization for TDM-Mode Operation</i> - see <i>MCASP Receivers Global Initialization for TDM-Mode Operation</i> )		
Enable the DATA port error based interrupt.	MCASP_RINTCTL[3] RDMAERR	0x1
<b>ELSE</b>		
Disable the DATA port error based interrupt.	MCASP_RINTCTL[3] RDMAERR	0x0
<b>ENDIF</b>		
TDM - Transmission Startup Procedure	See <a href="#">Figure 12-292</a> .	

These registers are for MCASP TDM- interrupt reception model: MCASP\_XGBLCTL, MCASP\_RSTAT.

#### 12.5.2.4.1.2.3 Main Sequence – MCASP TDM - Mode DMA Reception Method

[Table 12-319](#) shows the configuration of the MCASP using the DMA method for reception. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

#### Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the MCASP DATA port.

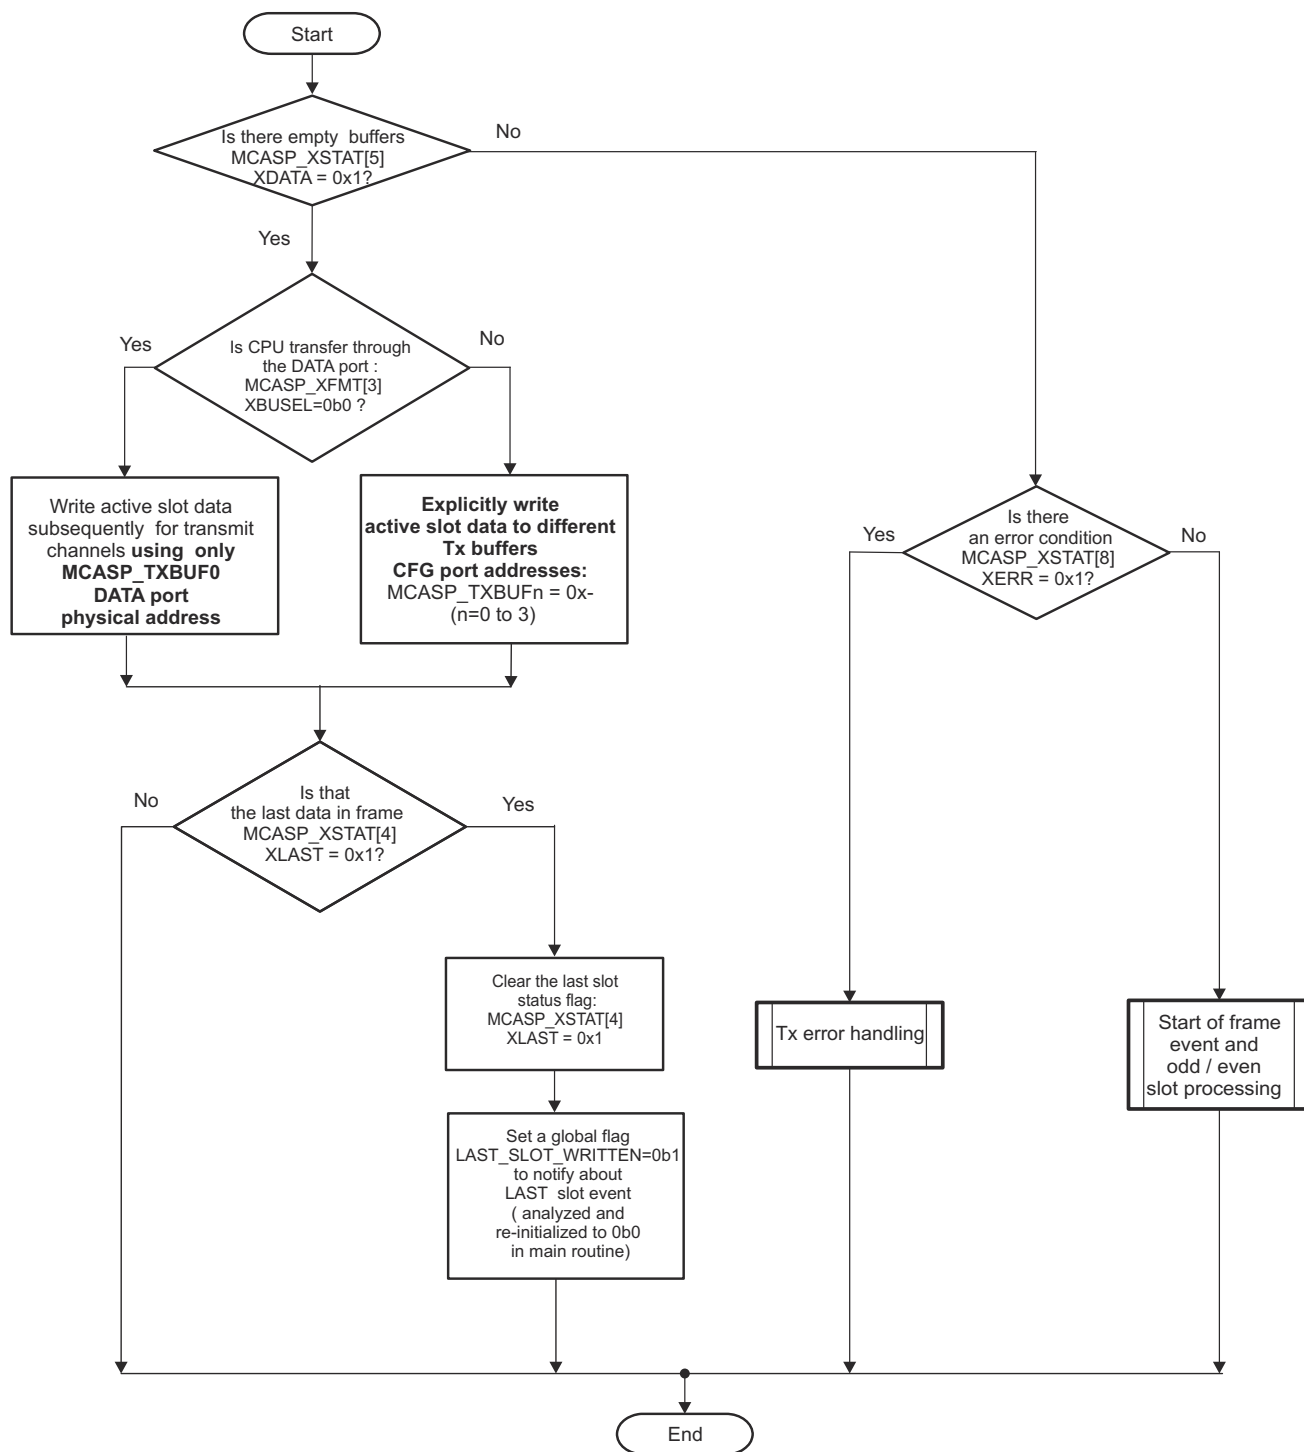

**Table 12-319. MCASP DMA Reception Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
<b>Recommended:</b> Select DATA port to access the transmit buffers.	MCASP_RFMT[3] RBUSEL	0x0
Enable the Rx DMA requests generation.	MCASP_PIDTCTL[0] RDATDMA	0x0
Enable the Rx DMA error event, because of MCASP DATA port usage.	MCASP_RINTCTL[3] RDMAERR	0x1
Optional: Enable the receive error event interrupts.	MCASP_RINTCTL[2] RCKFAIL	0x1
	MCASP_RINTCTL[1] RSYNCERR	0x1
	MCASP_RINTCTL[0] ROVRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_RINTCTL[7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt.	MCASP_RINTCTL[4] RLAST	0x1
Disable the data ready event receive interrupt, as DMA is used to service this request.	MCASP_RINTCTL[5] RDATA	0x0
DMA startup reception procedure. This procedure is identical than the one shown in <a href="#">Figure 12-292</a> . The only difference is that DMA automatically services all the RINT events raised by the MCASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in <a href="#">Figure 12-294</a> .	See <a href="#">Figure 12-292</a> .	

#### 12.5.2.4.1.3 MCASP Event Servicing

##### 12.5.2.4.1.3.1 MCASP DIT-/TDM- Transmit Interrupt Events Servicing

[Figure 12-293](#) shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the MCASP module.

mcasp-029

Figure 12-293. MCASP Transmit Interrupt Events Servicing

#### 12.5.2.4.1.3.2 MCASP TDM- Receive Interrupt Events Servicing

Figure 12-294 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the MCASP module.

mcasp-033

**Figure 12-294. MCASP Receive Interrupt Events Servicing**

These registers are for MCASP receive interrupt events servicing: MCASP\_RSTAT, MCASP\_RBUF<sub>n</sub>, MCASP\_RFMT (n = 0 to 15).

Table 12-320 lists the subprocess call summary for receive interrupt events servicing.

**Table 12-320. Subprocess Call Summary for Receive Interrupt Events Servicing**

Subprocess Name	Cross-Reference
MCASP receive error handling	Figure 12-296

**Table 12-320. Subprocess Call Summary for Receive Interrupt Events Servicing (continued)**

Subprocess Name	Cross-Reference
Start of frame handling	<a href="#">Section 12.5.2.3.13.2, Receive Data Ready Event and Interrupt</a>

#### 12.5.2.4.1.3.3 Subsequence – MCASP DIT-/TDM -Modes Transmit Error Handling

Figure 12-295 shows the transmit error handling schema for the MCASP, which can be implemented as part of the Tx interrupt service routine or as part of the Tx polling sequence.

mcasp-030

**Figure 12-295. MCASP Transmit Error Handling**

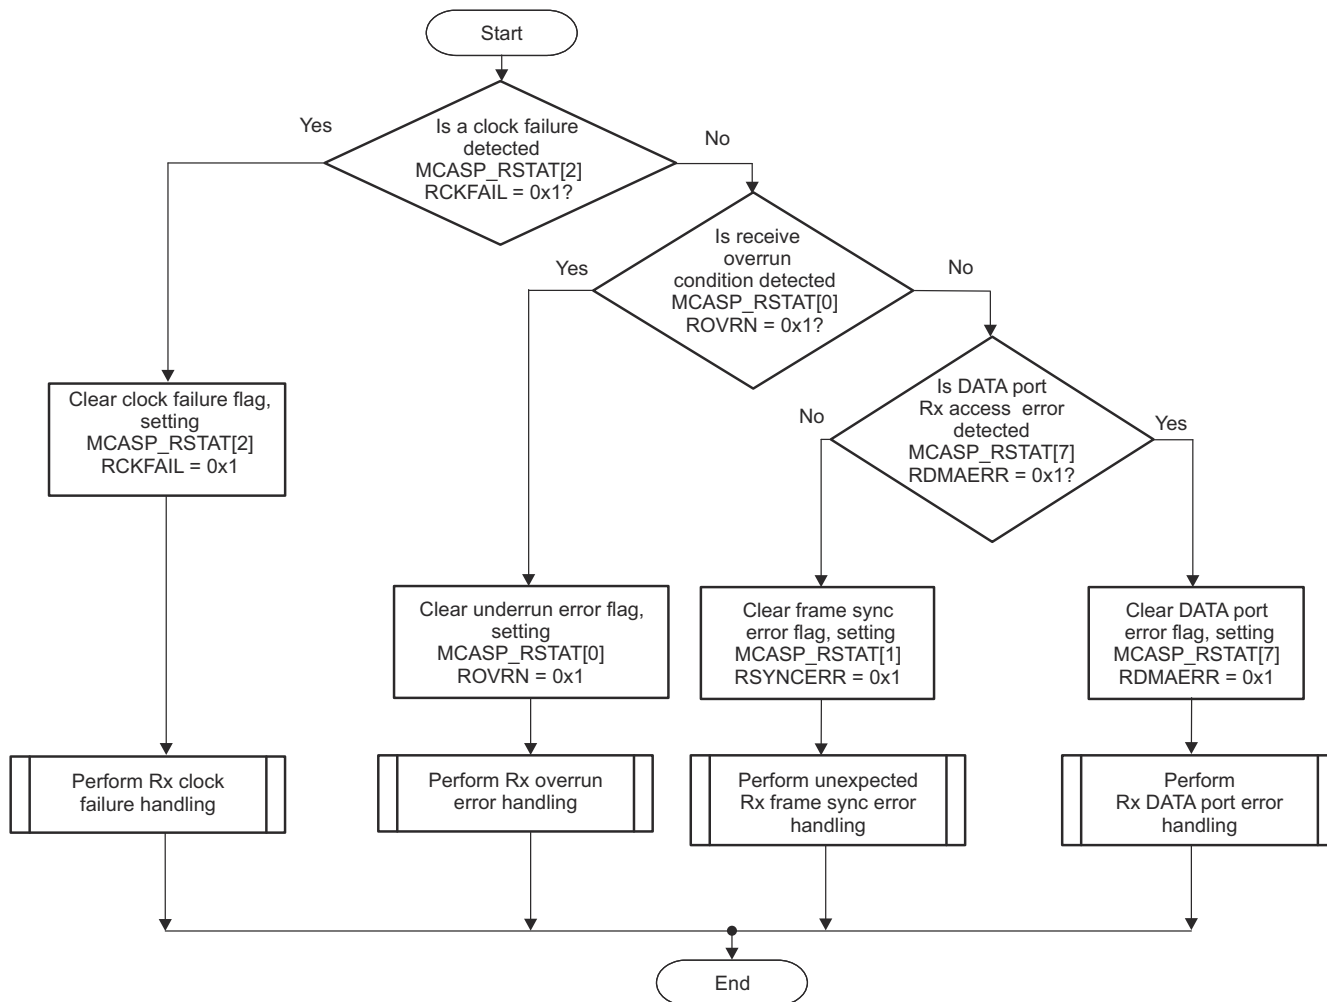

#### Note

- For more information about transmit clock failure handling, see [Section 12.5.2.3.16.6.2, Transmit Clock Failure Check and Recovery](#).
- For more information about transmit buffer underrun handling, see [Section 12.5.2.3.16.1, Buffer Underrun Error - Transmitter](#).
- For more information about DATA port Tx error handling, see [Section 12.5.2.3.16.3, DATA Port Error - Transmitter](#).
- For more information about unexpected Tx frame sync error handling, see [Section 12.5.2.3.16.5, Unexpected Frame Sync Error](#).

#### 12.5.2.4.1.3.4 Subsequence – MCASP Receive Error Handling

Figure 12-296 shows the receive error handling schema for the MCASP, which can ONLY be implemented as part of the Rx polling sequence.

mcasp-031

**Figure 12-296. MCASP Receive Error Handling**

This register is for MCASP receive error handling: MCASP\_RSTAT.

#### Note

- For more information about receive clock failure handling, see [Section 12.5.2.3.16.6.3, Receive Clock Failure Check and Recovery](#).
- For more information about receive buffer overrun handling, see [Section 12.5.2.3.16.2, Buffer Overrun Error - Receiver](#).
- For more information about DATA port Rx error handling, see [Section 12.5.2.3.16.4, DATA Port Error - Receiver](#).
- For more information about unexpected Rx frame sync error handling, see [Section 12.5.2.3.16.5, Unexpected Frame Sync Error](#).

## 12.6 Display Subsystem (DSS) and Peripherals

This section describes the Display Subsystem (DSS) in the device, integrated together with display peripherals, such as the MIPI Display Serial Interface (DSI) transmitter host controller with associated MIPI DSI (Physical Layer) D-PHY module (DPHY\_TX), and the Embedded Display Port (eDP) transmitter with associated SerDes and auxiliary complex I/O (eDP AUXPHY) modules.

### 12.6.1 DSS Overview

The DSS is a flexible composition-enabled display subsystem, that supports multiple high resolution display outputs. It consists of a Display Controller (DISPC) and a Frame Buffer Decompression Core (FBDC). The DISPC supports a multi-layer blending and transparency for each of its display outputs. The DISPC also supports a write-back pipeline with scaling to enable memory-to-memory composition and/or to capture a display output for Ethernet video encoding. The DISPC supports gamma correction and programmable color control in both source and destination pipelines for enhanced color space control and video output quality. The DISPC video outputs connect to various display interface controllers, integrated at the SoC level, to drive specific displays in the end application. The DSS also includes freeze frame detection and data signature check capabilities for each display output path.

The MIPI DSI v1.3.1 Controller (DSITX) implements the stream arbitration and low-level protocol layer functionalities required by MIPI DSI 1.3 standard. It supports up to 4 x 2.5 Gbps D-PHY data lanes in a single-link configuration and handles the byte lane mapping per use case (1, 2, 3, or 4-lanes). The accompanying DSI (Physical Layer) D-PHY module (DPHY\_TX) provides the video output interfacing by implementing a four-lane MIPI D-PHY transmitter.

The VESA DP1.4/eDP1.4 Compliant Transmitter Host Controller (EDP) can output up to 4 video streams (through Multiple Stream Transport / MST) and one audio stream through the 4-lane accompanying SerDes module. It provides up to 25.92 Gbps of application bandwidth. An additional auxiliary PHY (AUXPHY) module implements a doubly-terminated differential pair required for 1 Mbps data rates over a long (15m) cable. This is a half duplex, Manchester II encoded connection, used by the EDP to configure the link. The AUX channel is used to access the Display Port Configuration Data (DPCD) memory area in the sink device and to implement VESA Enhanced Extended Display Identification Data (EDID) function.

#### 12.6.1.1 DSS Features

The Display Controller (DISPC) supports:

- An embedded DMA Controller with the following features:
  - Support for 1D-only DMA transfers
  - Support for 48b addressable memory space
  - Support for memory fragmentation through external PAT (Page Address Translation) table at SoC level
  - Integrated shared buffer management for pipelines within the same DMA controller group
    - Support for up to 8K-pixels wide frame buffer for 8/16/32/64 bits per pixel (total buffer space requirement not exceeding the total DMA buffer size of the DISPC)
  - Programmable DMA request management
    - Programmable buffer thresholds for request priority
    - Bandwidth limiter on write requests (insertion on idle cycles between requests)
    - Self-refresh using the DMA buffers
    - Arbitration between normal/low priority pipelines
  - Support for source image flip along X and Y-axis
  - Support for secure access to firewall protected frame buffer in DDR memory
- Two input display processing Video Pipelines, each supporting:
  - Input RGB source pixel formats:
    - Bitmap-1, Bitmap-2, Bitmap-4, Bitmap-8
    - ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555
    - RGB16-565/BGR16-565 with a separate A8 plane
    - RGB24-888, BGR24-888

- ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, ARGB32-2101010, ABGR32-2101010
- ARGB64-16161616, RGBA64-16161616
- Additionally, equivalent RGBx, xRGB, xBGR, and BGRx pixel formats defined, considering that A component of RGBA, ARGB, ABGR, BGRA pixel formats is ignored by HW (for example, ARGB → xRGB); ("A" can be ignored by not selecting Alpha pixel)
- Pre-multiplied ARGB/RGBA formats
- Input YUV source pixel formats:
  - Packed: YUV422-UYVY, YUV422-YUV2
  - 2-plane: YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21
  - 8-bit per component support for all YUV formats
  - 10-bit IMG pack-format and 12-bit TI fully packed format support for 420/422 (internally processed as 10-bit component data)
  - 16-bit unpacked source format (internally processed as 10-bit component data)
- Programmable poly-phase filter (scaler):
  - Independent horizontal and vertical re-sampling: up-sampling (up to x16) and down-sampling (down to x0.25)
  - Maximum input width of 2048 pixels using ARGB pixels and 5-tap, 4096 pixels using YUV pixels and 5-tap, and 4096 pixels using ARGB pixels and 3-tap. No limitation on the input height.
  - Alpha blending factor is re-scaled like the R, G and B color components
  - Implementation with 16 phases with symmetrical coefficients
- Programmable color space conversion from YUV422/YUV420 (chroma upsampled to YUV444 using the scaler) into ARGB48-12121212
- Programmable VC1 range mapping
- Programmable Brightness/Contrast/Hue/Saturation
- Programmable Gamma Correction LUT
- Luma Key generation
- 10-bit processing pipeline
- Two input display processing Video Lite Pipelines, each supporting:
  - Input RGB source pixel formats:
    - Bitmap-1, Bitmap-2, Bitmap-4, Bitmap-8
    - ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555
    - RGB16-565/BGR16-565 with a separate A8 plane
    - RGB24-888, BGR24-888
    - ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, ARGB32-2101010, ABGR32-2101010
    - ARGB64-16161616, RGBA64-16161616
    - Additionally, equivalent RGBx, xRGB, xBGR, and BGRx pixel formats defined, considering that A component of RGBA, ARGB, ABGR, BGRA pixel formats is ignored by HW (for example, ARGB → xRGB); ("A" can be ignored by not selecting Alpha pixel)
    - Pre-multiplied ARGB/RGBA formats
  - Input YUV source pixel formats:
    - Packed: YUV422-UYVY, YUV422-YUV2
    - 2-plane: YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21
    - 8-bit per component support for all YUV formats
    - 10-bit IMG pack-format and 12-bit TI fully packed format support for 420/422 (internally processed as 10-bit component data)
    - 16-bit unpacked source format (internally processed as 10-bit component data)
  - YUV420 to YUV422 chroma upsampling using an average filter
  - YUV422 to YUV444 chroma upsampling using a 4-tap filter based on Catmull-Rom algorithm
  - Programmable color space conversion from YUV422/YUV420 into ARGB48-12121212
  - Programmable VC1 range mapping
  - Programmable Brightness/Contrast/Hue/Saturation
  - Programmable Gamma Correction LUT
  - Luma Key generation

- 10-bit processing pipeline
- One Write-back (WB) pipeline, supporting:
  - Destination RGB pixel formats:
    - ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555
    - RGB24-888 (no support for BGR24-888)
    - RGB16-565/BGR16-565 with a separate A8 plane
    - ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, ARGB32-2101010, ABGR32-2101010
    - ARGB64-16161616, RGBA64-16161616
  - Destination YUV pixel formats:
    - Packed: YUV422-UYYV, YUV422-YUV2
    - 2-plane: YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21
    - Only 8-bit output support for YUV formats
  - Programmable poly-phase filter (scaler):
    - Independent horizontal and vertical re-sampling: up-sampling (up to x16) and down-sampling (down to x0.25). When the output format of the WB pipeline includes a format change RGB/YUV422 → YUV420, the maximum downscaling provided by the WB scaler is x0.5.
    - Maximum input width of 2048 pixels using ARGB pixels and 5-tap, 4096 pixels using YUV pixels and 5-tap, and 4096 pixels using ARGB pixels and 3-tap. No limitation on the input height.
    - Alpha blending factor is re-scaled like the R, G and B color components
    - Implementation with 16 phases with symmetrical coefficients
  - Operation modes:
    - Output capture mode (to save one of the display outputs)
    - Memory-to-memory (M2M) mode (to save a M2M composition/conversion operation result)
- Four Overlay Managers (OVR), each supporting:
  - Input pixel format: ARGB48-12121212
  - Output pixel format: ARGB48-12121212 ("A" component data is only used for the Write-back path)
  - Overlay of the input pipelines (fully mapped to all input pipelines)
  - Up to 4 input layers blending, plus background layer
  - Transparency color key (source and destination)
  - Alpha blending support: Embedded pixel alpha (ARGB and RGBA), global pixel, and combination of global pixel and pixel alpha
  - Z-order programmable (full flexibility)
  - Color bar test pattern insertion
  - Any overlay output can be selected to drive the Write-back pipeline
- Four Video Port (VP) display outputs, each supporting:
  - 36-bit per pixel on the RGB output interface (12-bits per component)
  - Independent programmable timing generator, supporting up to 600 MHz pixel clock video formats (actual support limited by the maximum pixel clock provided to DSS at SoC level)
  - Independent programmable 10-bit gamma correction
  - Independent programmable multiple cycles output format on 8/9/12/16-bit interface (TDM)
  - Selection between RGB and YUV422 output pixel format (YUV422 only available when BT.656/BT.1120 output is enabled)
  - Configurable VP output mode: progressive mode only on RGB output, or progressive/interlaced mode on BT.656/BT.1120 output
- Internal data check diagnostic features:
  - Supports up to 4 programmable (position/size) check regions on the DISPC video port display outputs
  - Support for 1 check region on each input video pipeline output
  - MISR (Multiple Input Signature Register) used on each check region to perform data correctness check and/or freeze frame detection
- Local power management features:
  - Low power saving modes
  - Capability to associate all buffers with a single pipeline for a display self-refresh
- System interconnect ports:

- Two 128-bit VBUSM master interfaces for data read/write
- One 32-bit VBUSP slave interfaces for configuration

MIPI Display Serial Interface (DSI) transmitter host controller supports:

- Compliance with MIPI DSI v1.3.1 protocol specification and previous specifications
- Compliance with MIPI Stereoscopic Display Formats (MIPI SDF v1.0) specification
- Video and command operational modes
- Both burst and non-burst modes for video mode data transmission (with either sync pulses or sync events)
- Up to 4 virtual channels via command mode
  - Supports data interleaving support for one synchronous stream (video mode) from the display controller, and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
  - Supports data interleaving for up to four interleaved asynchronous streams (virtual channels in command mode) from the interconnect
- Bi-directional communication and escape mode (only on Lane-0)
- Pixel clock rate range 25-330 MHz (10-bit/component, 4MPix @60fps performance). Actual performance is limited by the maximum pixel clock provided to the DSI controller at SoC level.
- Programmable display resolutions with maximum clock rate not exceeding the total available bandwidth over 4MPix @60fps (10-bit/component RGB)
- 16/18/24/30/36-bit RGB input data formats for video mode
- RGB16, RGB18 packed, and RGB24 input data formats for command mode
- All generic data types defined by MIPI
- Display Command Set (DCS): transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral
- ECC on the APB interface
- Data splitter for 2-, 3-, or 4-data lane configuration
- Connection to a single MIPI D-PHY complex I/O through an 8-bit Protocol Peripheral Interface (PPI)
- Bus contention recovery
- Video mode pattern generator: color bar pattern image and D-PHY BET testing pattern
- APB slave interface with 32-bit data and address for configuration

MIPI DSI (Physical Layer) D-PHY module supports:

- Compliance with MIPI D-PHY 1.2 physical layer interface specification and features
- 1, 2 or 4 data lanes, in addition to clock signaling
- Maximum data rate up to 2.5 Gbps per data lane
- Protocol Peripheral Interface (PPI)
- HS continuous and burst mode
- LP (Low-Power), ULPM (Ultra-Lower Power Mode), and Shutdown modes
- Forward direction and reverse direction escape modes (only on Lane-0)
- Automatic termination control in both high-speed and low-power modes
- DSI D-PHY IO pad signals work at/with electrical specification specified by requested standards
- Single 32-bit VBUSP slave interface

The Embedded Display Port (eDP) transmitter host controller supports:

- Compliance with VESA Display Port (DP) 1.3 (with 1.4 DSC/FEC support) specification
- Compliance with VESA embedded Display Port (eDP) 1.4 specification
- Static configuration of either DP or eDP mode
- Link rates up to HBR3 (maximum application bandwidth up to 25.92Gbps)
- Pixel clock rate range 25-600 MHz (10-bit/component, 8MPix@60fps performance).
- Transceiver AUX CH (1 MHz Manchester II coding mode) for access of DPCD and EDID
- 8, 10, and 12 bpc (bits per component), in RGB/YCbCr444 colorimetry formats (CEA-861 compliant) and YCbCr422 (via simple decimation)
- Data splitter for 1-, 2-, or 4-data lane configuration
- SST (Single Stream Transport)
- MST (Multiple Stream Transport):
  - Up to 4 video and up to 1 audio sources

- Support for up to 25 Gbps throughput (equivalent to approximately 4K + 2xFHD streams) use case
- HDCP support on one video source
- DSC (Display Stream Compression) support on one 4K or 2x2.5K streams
- HDCP 1.4 and HDCP 2.2 with True Random Number Generator (TRNG with 8 FRO)
- DSC (Display Stream Compression) encoded stream data transport via an embedded DSC core:
  - Supports VESA DSC 1.1 compliant video compression at 2x~3x compression ratios
  - Supports all DSC 1.1 mandatory encoding mechanisms (MMAP, BP, MPP and ICH)
  - Supports configurable maximum display resolution up to 8Mpix @60fps including (but not limited to) 4K@60 (4096x2160), and up to 8K wide-aspect-ratio resolution displays
  - Supports two hard encoder slices (peak pixel ratio <= 340MP/s on each slice)
  - Supports 8 and 10 bits per video component
  - Supports RGB/YCbCr4:4:4 video input format (Native Encoding) only
  - Supports Dual pixel streams or Split panel input streams
  - Supports dual or single transport link
- Forward Error Correction (FEC) encoder with/without DSC enabled in DP mode
- Various eDP specific features:
  - eDP DPCD registers
  - Full and Fast Link Training
  - (Regional) backlights and multi-touch command over AUX channel
  - Alternate Scrambler Reset
- Audio transport features:
  - I2S (LPCM/IEC60948/619376) audio input stream
  - Audio transport of uncompressed multichannel (up to eight channels) via SDP (Secondary-data Packet)
- Metadata transport via MSA (Main Stream Attribute) packet or via SDP
- Display Port transmitter functionalities:
  - Scrambler
  - 8/10-bit Encoder (in the DPTX core)
  - Inter Lane Skew Insertion
  - Training Pattern Generation – TPS1,2,3,4 PRBS7 and 80-bit custom training pattern generation (bypassing the scrambler and encoder)
- PAPB Interface:
  - The primary APB slave port controls the HD Display controller from the host processor
  - During the boot, the primary APB slave port enables access to the I-MEM and D-MEM, and to the full address space for debugging purposes
  - After the boot, the primary APB slave port enables direct register access to designated HW modules and enables communication with uCPU through a mailbox channel
- SAPB Interface
  - For configuring the embedded HDCP, this bus is considered as a secured APB to carry secured commands over the mailbox channel
- Internal diagnostic features:
  - ECC on the critical memories
  - Parity check on the configuration interface
  - Encoder self-check diagnostics support in the DSC core
  - Corrected/Uncorrected error interrupt generation
  - Injection of ECC and parity errors

The DP (Physical Layer) SERDES and Aux PHY modules support:

- DP1.3 HBR3 and eDP1.4a HBR3 throughput
- 1, 2, or 4 lanes at 1.62 Gbps, 2.7 Gbps, 5.4 Gbps, and 8.1 Gbps per lane
- Additional link rates (2.16, 2.43, 3.24, 4.32 Gbps) per lane in eDP mode
- Reduced differential voltage swing (0.2/0.25/0.30/0.35/0.40/0.45) in eDP mode
- Hot Plug Detect (HPD) for connection detection and interrupt from sink
- Integrated Low Jitter, Fixed Bandwidth PLL
- 1 Mbps AUX PHY for link training, DPCD register access, HDCP authentication and EDID access.

### 12.6.1.2 DSS Not Supported Features

The DISPC does not support the following features:

- 2D tiled buffer access
- On the fly rotation (90/270-degree)
- Sending ancillary data on the video port outputs during VBLANK period
- YUV422 planar formats (8-bit and 10-bit) for video pipelines and write-back (encoder/decoder compatibility)

The DSI controller does not support the following features:

- Audio data transmission
- Optional sub-link
- VESA DSC (Display Stream Compression)
- 12-bit wide input component width
- SDI video mode

The eDP transmitter does not support the following features:

- Multi-SST Operation (MSO) for segmented display panel support in eDP mode
- Type-C DP Alt Mode
- FAUX (Fast AUX)(720MBps AUX)
- SPDIF Audio Interface
- Advanced Low Power Management (ALPM)(Pending proposal in VESA to remove the requirement of ALPM in eDP)
- MCCS Support (other mode available to access needed registers in Sink device)
- PSR-1 mode (Full Panel Refresh Mode)
- Specific DP 1.4 standard features:
  - SDP splitting and chaining (DP 1.4 specification, chapter 2.2.5.12)
  - New SDP formats introduced in DP 1.4 specification
  - Video Stream Configuration Extension (VESA SDP), (DP 1.4 specification, chapter 2.2.5.10)
  - CEA SDP (DP 1.4 specification, chapter 2.2.5.11)
  - New DP 1.4 audio formats:
    - 3D LPCM audio (up to 32 audio channels) (DP 1.4 specification, chapter A.4.5, A.4.6)
    - 1-bit audio (DP 1.4 specification, chapter A.4.3)
    - Direct Stream Transfer (DST) audio (DP 1.4 specification, chapter A.4.7)
    - HBR 8-channel audio up to 1536 kHz
    - Changes to the Audio\_Stream SDP header (DP 1.4 specification, chapter 2.2.5.3.2)
  - New 3DChannelCount, OneBit\_DST\_Double\_Rate fields
  - New supported values for the Coding Type field
  - 16-bit data format
- Specific DSC core features:
  - VESA DSC 1.2 updated requirements (no support for YCbCr 422 or 420 native coding)
  - De-rasterization buffer
  - 12-bit wide input component width

### 12.6.1.3 DSS Ports

**Table 12-321. DISPC Clocks and Resets**

Clocks	
Module Clock Input	Description
DSS_FUNC_CLK	DISPC functional clock.
DSS_DPI_0_PCLK	DISPC peripheral pixel clocks for VP1.
DSS_DPI_0_DIV_PCLK	
DSS_DPI_1_PCLK	DISPC peripheral pixel clock for VP2.
DSS_DPI_2_PCLK	DISPC peripheral pixel clocks for VP3.
DSS_DPI_2_DIV_PCLK	
DSS_DPI_3_PCLK	DISPC peripheral pixel clock for VP4.

**Table 12-321. DISPC Clocks and Resets (continued)**

DSS_DPI_0_OUT_PCLK_2X	DISPC output pixel clocks to display peripherals.

### 12.6.2 DSS Environment

This section describes the interfaces handled by the Display Subsystem.

The DSS is capable of driving multiple displays in parallel, through a combination of interfaces:

- Two DPI parallel interfaces, directly delivered on SoC pads from DISPC Video Port (VP) outputs
- One MIPI Display Serial Interface (DSI)
- One Embedded DisplayPort (DP/eDP) interface

The pixel format mapping between the DISPC VP outputs and DPI, eDP, and DSI display peripherals varies depending on the interface used. The pixel bit color mapping for the DISPC VP outputs is as shown in [Figure 12-297](#).

Color Format	Pixel Width	Pixel Interface Mapping																																			
		35	34	33	32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RGB565	16-bit																																				
RGB666	18-bit																																				
RGB888	24-bit																																				
RGB101010	30-bit																																				
RGB121212	36-bit																																				

dss-007

**Figure 12-297. DSS Pixel Mapping on the DISPC Video Port Outputs**

The pixel format support at a DISPC VP output when connected to each of the DPI, eDP, and DSI peripherals is as listed in [Table 12-327](#).

**Table 12-327. DSS Pixel Format Interoperability between DISPC VP Output and DPI, eDP, and DSI**

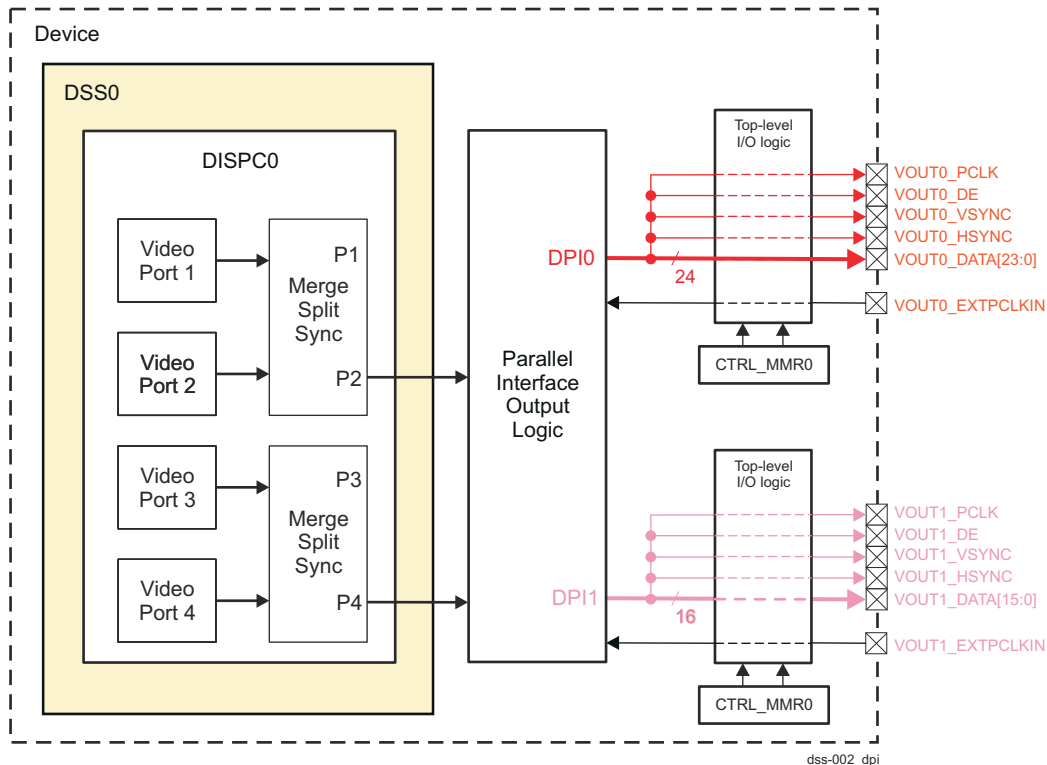

Pixel Format	DISPC VP Output Pixel Format	DPI Parallel Out	DSI		eDP
	DSS0_VP_CONTROL [10-8] DATALINES Register Field Value		DSI-DPI Interface	DSI-SDI Interface	
RGB565	0x1	Supported	Supported	Supported	Not supported
RGB666	0x2	Supported	Supported	Supported	Not supported
RGB888	0x3	Supported	Supported	Supported	Not supported
RGB101010	0x4	Not supported	Supported	Not supported	Supported
RGB121212	0x5	Not supported	Supported	Not supported	Supported

### Note

The DISPC VP outputs are connected to the display peripherals through the Merge-Split-Sync (MSS) block. For more details, see *DISPC VP Merge-Split-Sync (MSS) Module*.

#### 12.6.2.1 DISPC Environment

Figure 12-298 shows the DSS DPI parallel interface signals. The output data bus of the DISPC video ports is 36 bits wide. The DSS DPI parallel interface uses up to the 24 LSB bits [23:0] of the data bus.

**Figure 12-298. DSS DPI Parallel Interface Signals**

Each DISPC video port in Figure 12-298 can be connected to any DPI output via the parallel interface output logic.

The [3-0] DPI\_0\_CONN and [7-4] DPI\_1\_CONN fields in the DSS0\_COMMON\_DISPC\_CONNECTIONS register define the DISPC VP connections to DPI0 and DPI1 outputs, respectively.

The DISPC video ports output the required data and control signals to device pads to support one of the following display interface modes:

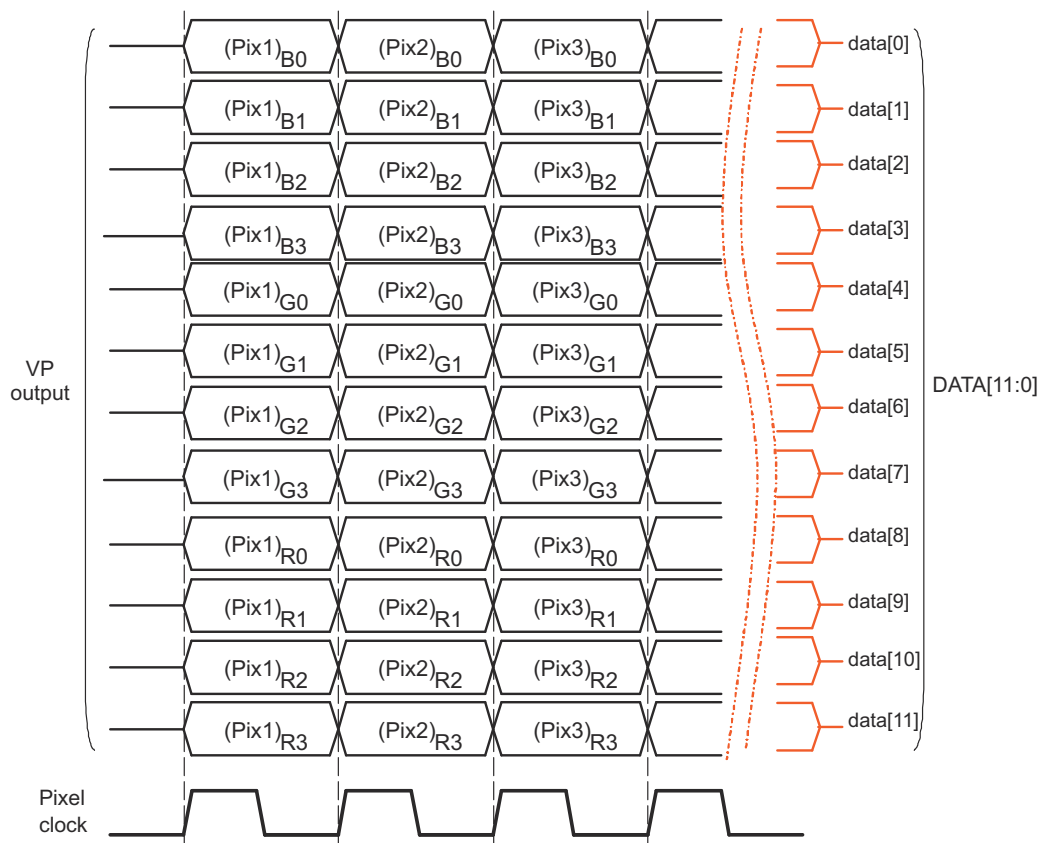

- Parallel MIPI DPI 2.0 (Digital Pixel Interface): RGB 16/18/24-bit output with separate sync signals.
- BT.656/BT.1120 interface: YUV422 output (8/10-bit modes) with embedded syncs.
- BT.601 interface: YUV422 output with discrete syncs. For more details, see *VSYNC/HSYNC/DE Signal Export to SoC Boundary*.

##### 12.6.2.1.1 RGB Data Output

This section describes the pixel data bus for RGB formats and shows timing diagrams of transactions and synchronizations.

For the active matrix display type, one pixel per pixel clock is displayed. The diagrams represent the configuration of assertion of the data on the rising edge of the pixel clock. It is possible to program the interface timings to output the data on the falling edge of the pixel clock.

Figure 12-299 through Figure 12-302 show the interface to 12-, 16-, 18-, and 24-bit RGB active matrix displays. Each vertical line represents one output pixel. The width of the data bus can be configured through DSS0\_VP\_CONTROL[10-8] DATALINES register bitfield.

**Figure 12-302. DISPC Video Port Pixel Data - 24-bit RGB Active Matrix**

#### 12.6.2.1.2 YUV Data Output (BT.656/BT.1120)

Figure 12-303 shows the signal mapping on the DATA[23:0] output data bus for the BT.656 mode. Bits [9-0] are dedicated for BT.656 mode (10-bit). In BT.656 mode however, for compatibility with existing 8-bit interfaces, the two LSBs are ignored and only bits [9-2] are effectively used.

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused														BT.656									

**Figure 12-303. DISPC Video Port Data Mapping for BT.656 Mode**

Figure 12-304 shows the signal mapping on a DATA[23:0] output data bus for the BT.1120 mode. Bits [19-10] (CbCr) and [9-0] (Y) are used in 20-bit mode. Bits [19-12] (CbCr) and [9-2] (Y) are used in 16-bit mode (YCbCr422).

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused														BT.1120 (CbCr, 16-bit mode)									
Unused														BT.1120 (CbCr, 20-bit mode)									
Unused														BT.1120 (Y, 16-bit mode)									
Unused														BT.1120 (Y, 20-bit mode)									

dispc-049x

**Figure 12-304. DISPC Video Port Data Mapping for BT.1120 Mode**

The DISPC VP outputs support both interlace and progressive content in BT.656/BT.1120 modes. For more information on timings configuration, see [Section 12.6.3.11.8, DISPC VP Timing Generator and Display Panel Settings](#).

#### Note

In progressive BT.656/BT.1120 mode the maximum output resolution will be limited, as it requires two pixel clock cycles to send out one pixel.

#### 12.6.2.1.3 Display Timing Diagrams

Figure 12-305 through Figure 12-308 show examples with timing diagrams of synchronization signals and pixel clocks for active matrix panels. The DISPC video ports directly drive these signals, which are related to the

programmable fields listed in [Table 12-328](#). For more information, see also [Section 12.6.3.11.8](#), *DISPC VP Timing Generator and Display Panel Settings*.

**Table 12-328. DISPC Video Port Register Fields for Active Matrix Display**

Name	Register	Description
PPL	DSS0_VP_SIZE_SCREEN[13-0] PPL value + 1	Pixels per line
LPP	DSS0_VP_SIZE_SCREEN[29-16] LPP value + 1	Lines per panel
HBP	DSS0_VP_TIMING_H[31-20] HBP value + 1	Horizontal back porch
HFP	DSS0_VP_TIMING_H[19-8] HFP value + 1	Horizontal front porch
HSW	DSS0_VP_TIMING_H[7-0] HSW value + 1	Horizontal synchronization pulse width
VBP	DSS0_VP_TIMING_V[31-20] VBP value	Vertical back porch
VFP	DSS0_VP_TIMING_V[19-8] VFP value	Vertical front porch
VSW	DSS0_VP_TIMING_V[7-0] VSW value + 1	Vertical synchronization pulse width
ALIGN	DSS0_VP_POL_FREQ[18] ALIGN	Alignment between HSYNC and VSYNC assertion
ONOFF	DSS0_VP_POL_FREQ[17] ONOFF	HSYNC and VSYNC pixel clock control
RF	DSS0_VP_POL_FREQ[16] RF	HSYNC and VSYNC pixel clock edge control
IEO	DSS0_VP_POL_FREQ[15] IEO	Invert output enable
IPC	DSS0_VP_POL_FREQ[14] IPC	Invert PCLK
IHS	DSS0_VP_POL_FREQ[13] IHS	Invert HSYNC
IVS	DSS0_VP_POL_FREQ[12] IVS	Invert VSYNC

- Active matrix timing configuration 1:
  - DSS0\_VP\_POL\_FREQ[17] ONOFF = 0
  - DSS0\_VP\_POL\_FREQ[16] RF = 0

The HSYNC and VSYNC signals are driven on the opposite edge of PCLK from the pixel data.

- DSS0\_VP\_POL\_FREQ[15] IEO = 0

The DE signal is active high.

- DSS0\_VP\_POL\_FREQ[14] IPC = 0

The pixel data are driven on the rising edge of PCLK.

- DSS0\_VP\_POL\_FREQ[13] IHS = 0

The HSYNC signal is active high.

- DSS0\_VP\_POL\_FREQ[12] IVS = 0

The VSYNC signal is active high.

- DSS0\_VP\_POL\_FREQ[18] ALIGN = 0

The VSYNC and HSYNC assertion is not aligned.

**Figure 12-305. DISPC Display Timing Diagram of Configuration 1 (Start of Frame)**

**Figure 12-306. DISPC Display Timing Diagram of Configuration 1 (Between Lines)**

**Figure 12-307. DISPC Display Timing Diagram of Configuration 1 (Between Frames)**

**Figure 12-308. DISPC Display Timing Diagram of Configuration 1 (End of Frame)**

- Active matrix timing configuration 2:

- DSS0\_VP\_POL\_FREQ[17] ONOFF = 1
- DSS0\_VP\_POL\_FREQ[16] RF = 1

The HSYNC and VSYNC signals are driven on the rising edge of PCLK.

- DSS0\_VP\_POL\_FREQ[15] IEO = 1

The DE signal is active low.

- DSS0\_VP\_POL\_FREQ[14] IPC = 1

The pixel data is driven on the falling edge of PCLK.

- DSS0\_VP\_POL\_FREQ[13] IHS = 1

The HSYNC signal is active low.

- DSS0\_VP\_POL\_FREQ[12] IVS = 1

The VSYNC signal is active low.

- DSS0\_VP\_POL\_FREQ[18] ALIGN = 0

The VSYNC and HSYNC assertion is not aligned.

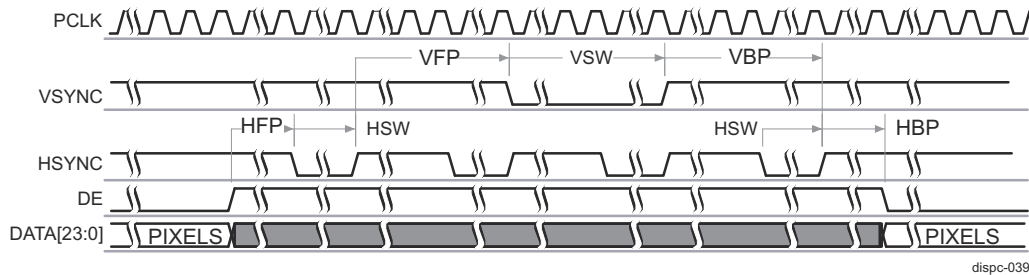

**Figure 12-309. DISPC Display Timing Diagram of Configuration 2 (Start of Frame)**

**Figure 12-310. DISPC Display Timing Diagram of Configuration 2 (Between Lines)**

**Figure 12-311. DISPC Display Timing Diagram of Configuration 2 (Between Frames)**

**Figure 12-312. DISPC Display Timing Diagram of Configuration 2 (End of Frame)**

- Active matrix timing configuration 3:
  - DSS0\_VP\_POL\_FREQ[17] ONOFF = 1
  - DSS0\_VP\_POL\_FREQ[16] RF = 1

The HSYNC and VSYNC signals are driven on the rising edge of PCLK.

- DSS0\_VP\_POL\_FREQ[15] IEO = 0

The DE signal is active high.

- DSS0\_VP\_POL\_FREQ[14] IPC = 0

The pixel data are driven on the rising edge of PCLK.

- DSS0\_VP\_POL\_FREQ[13] IHS = 0

The HSYNC signal is active high.

- DSS0\_VP\_POL\_FREQ[12] IVS = 0

The VSYNC signal is active high.

- DSS0\_VP\_POL\_FREQ[18] ALIGN = 0

The VSYNC and HSYNC assertion is not aligned.

**Figure 12-313. DISPC Display Timing Diagram of Configuration 3 (Start of Frame)**

**Figure 12-314. DISPC Display Timing Diagram of Configuration 3 (Between Lines)**

**Figure 12-315. DISPC Display Timing Diagram of Configuration 3 (Between Frames)**

**Figure 12-316. DISPC Display Timing Diagram of Configuration 3 (End of Frame)**

#### 12.6.2.1.4 VSYNC/HSYNC/DE Signal Export to SoC Boundary

The DSS exports the VSYNC, HSYNC and DE signals of all DISPC video port outputs to the SoC boundary. This feature is supplementary to the signals already exported out on the parallel DPI interfaces (DPI0/DPI1). This allows the support of the following use cases:

- BT.601 interface (YUV output with discrete syncs)
- FSYNC support for external camera sensor

The necessary signal muxing is achieved at SoC level (via I/O pin multiplexing).

#### BT.601 Standard Support

The DSS only supports YUV output with embedded syncs (BT.656 and BT.1120 standards). YUV output with discrete sync (BT.601 standard) is not supported natively on the DISPC VP outputs.

At SoC level, it is possible to achieve BT.601 operation on a DPI parallel out (DPI0/DPI1) by combining two DISPC VP outputs as follows:

- Enable one DISPC VP to output YUV422 data in BT.656 mode on either DPI0 or DPI1 output.
- Use an alternative DISPC VP, that is synchronized and programmed (in RGB TDM mode), to output the discrete sync signals on the same DPI output. This can be achieved by configuring the I/O pin multiplexing at SoC level.
- The following restrictions apply:
  - If DPI0 is used to output YUV422 data, then the VSYNC/HSYNC/DE signals of either VP1 or VP3 can be output on DPI0.
  - If DPI1 is used to output YUV422 data, then the VSYNC/HSYNC/DE signals of only VP1 can be output on DPI1.

#### FSYNC Support for External Camera Sensor

An external camera sensors can use the VSYNC output from DSS as a synchronization input (FSYNC input). To make this connection, the VSYNC signals of all DISPC video ports are made available at SoC boundary.

Generally, in the cases where the DISPC VP is connected to DSI or eDP, the VSYNC information is "lost" as a separate signal at SoC boundary, although this VSYNC is still available at DISPC module boundary. For such cases, the VSYNCs are exported to SoC level in parallel to the DSI/eDP connection.

#### 12.6.2.2 DSI Environment

[Figure 12-317](#) shows the DSI interface signals.

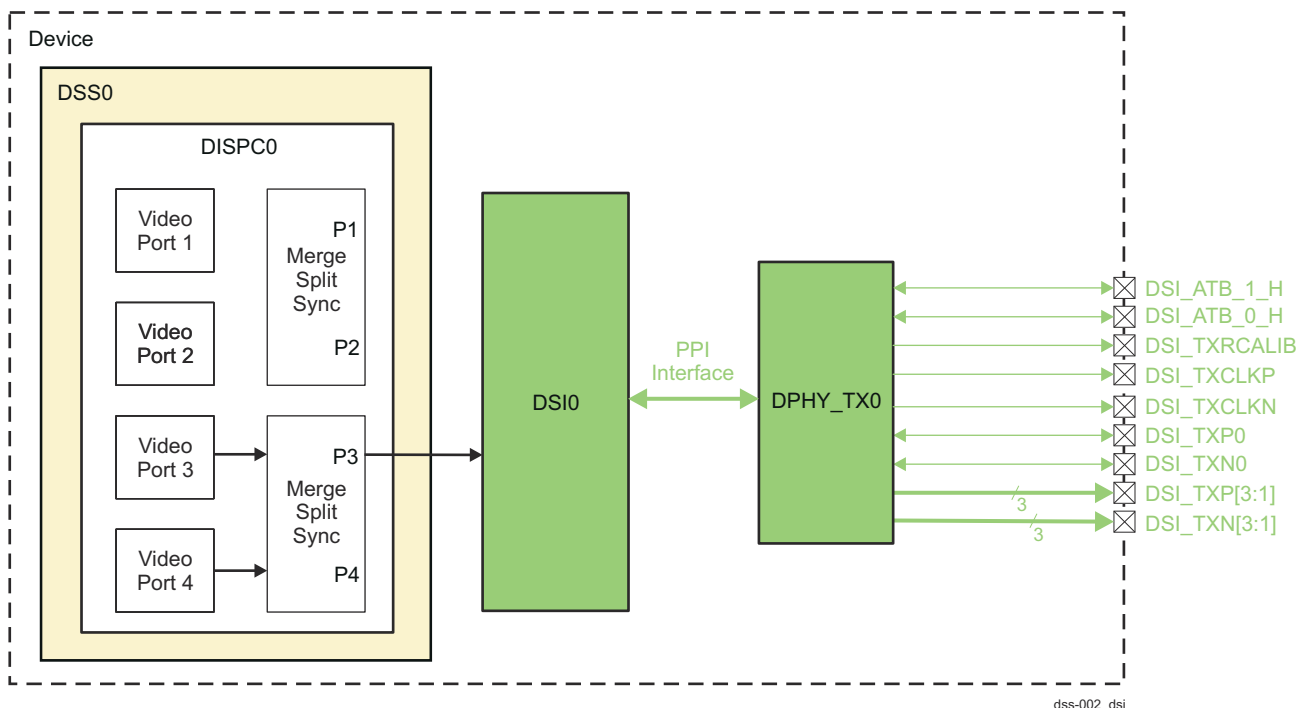

Figure 12-317. DSI Interface Signals

### 12.6.2.3 EDP Environment

Figure 12-318 shows the EDP interface signals.

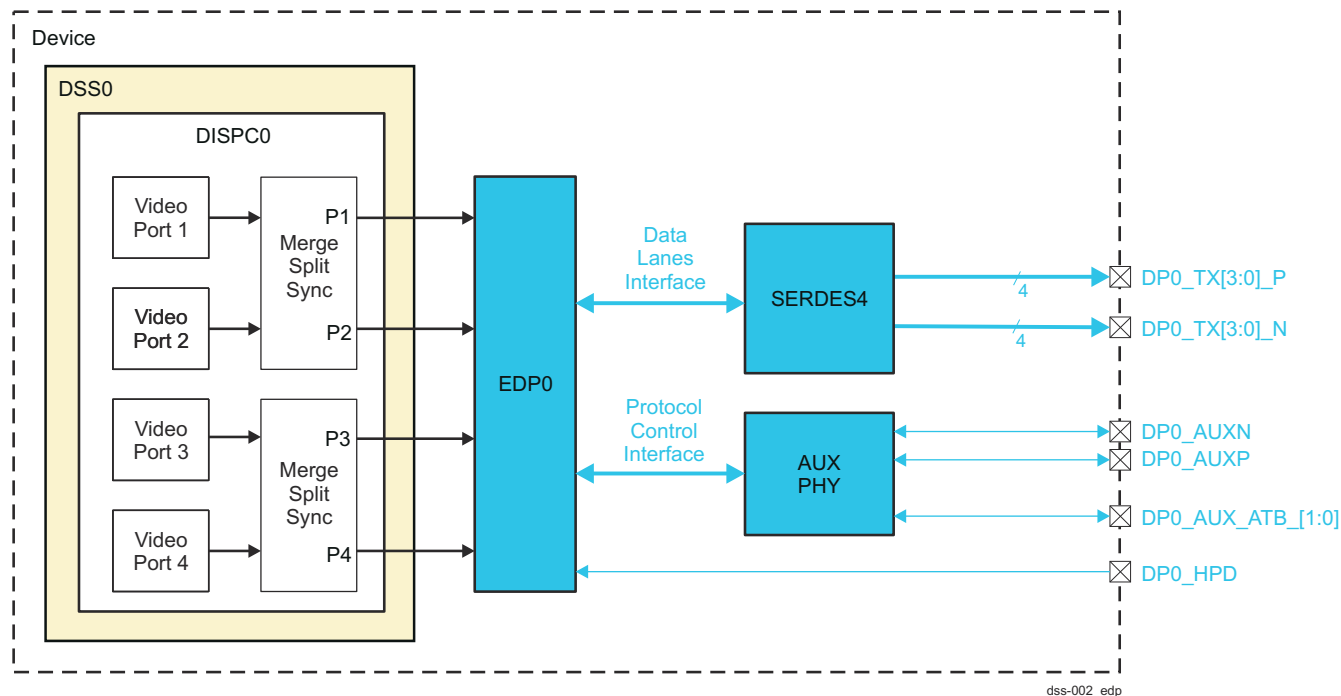

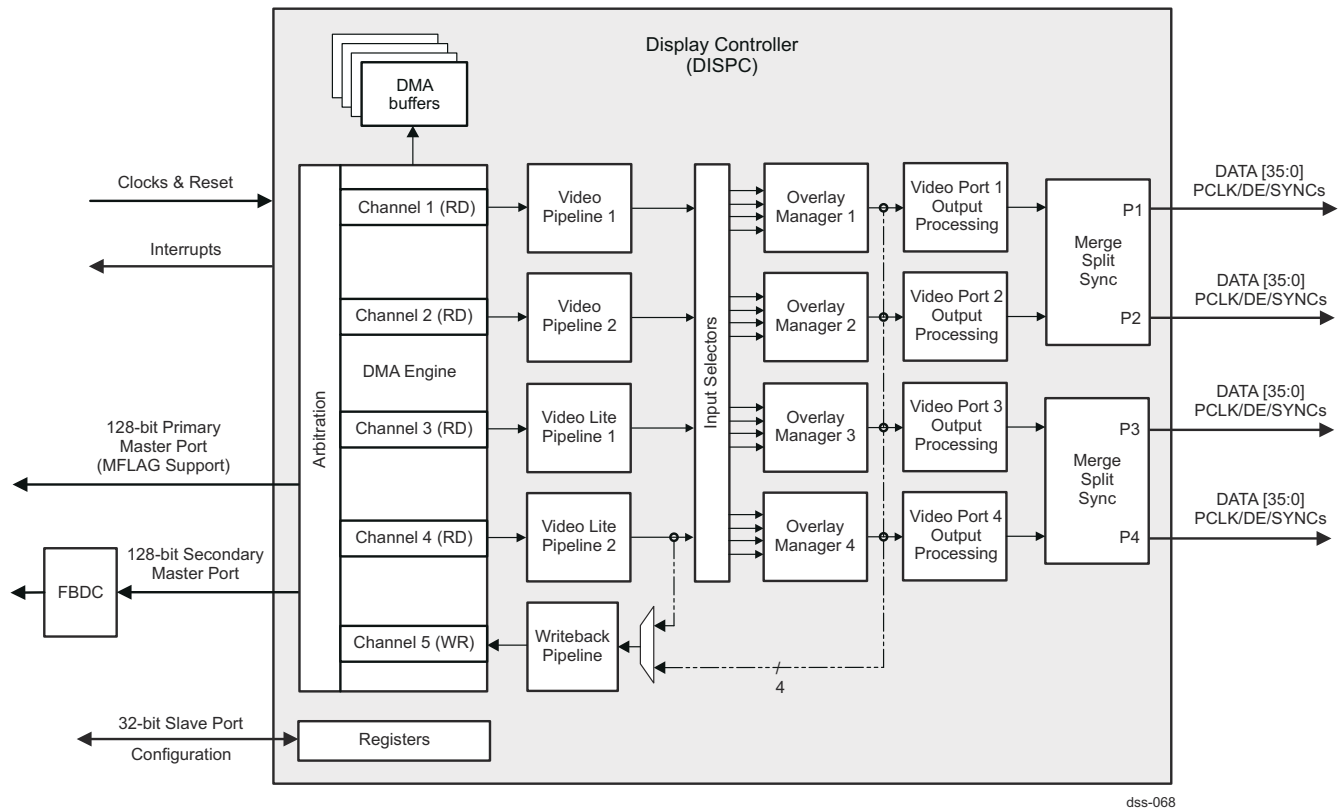

Figure 12-318. DP/eDP Interface Signals

### 12.6.3 Display Subsystem Controller (DISPC) with Frame Buffer Decompression Core (FBDC)

#### 12.6.3.1 DISPC Overview

Figure 12-319 is a simplified block diagram of DISPC.

**Figure 12-319. DISPC Architecture Overview**

The DISPC integrated within DSS is capable of fetching pixel data from the device system memory through its dual master ports, performing various pixel processing, and then providing the processed pixels to an external display panel. The internal DMA engine tightly coupled to the DISPC is used for the pixel data transfer from system memory (frame buffer). The DISPC DMA engine is in charge of scheduling the memory requests. Several processes are configurable in order to manage the video pipeline features (color space conversion, up-sampling, down-sampling) and overlay features. The internal timing generator logic generates the video port output signals based on VESA DMT and CEA-861 standards. The DISPC video port outputs can be connected to display panels either directly (for MIPI DPI 2.0 or BT.656/BT.1120 support), or through either MIPI DSI or DisplayPort (DP/eDP) interfaces.

#### Note

The DISPC does not support any tiled frame buffer. The DISPC has no internal capability to support rotation of the frame buffer. The support for a compressed frame buffer is provided via the Frame Buffer Decompression (FBDC) module connected to the DISPC secondary master port.

#### Note

The display resolution is programmable and can be any width in the range [1:4096] pixels. The following limitations apply, related to the type of display or the processing done:

- Active Matrix screen + dithering forces a width multiple of 2 pixels
- Active Matrix + TDM may force a width multiple of 2 pixels

The display buffers in the system memory must consist of contiguous pixels.

### 12.6.3.2 DISPC Clocks

The DISPC has one clock domain for its internal logic and separate domains for each video port output.

The DISPC functional clock (DSS\_FUNC\_CLK) serves as the internal logic clock and also acts as the interface clock for the DISPC master and slave ports to system interconnect. There is no internal divider on this clock.

The DISPC pixel clocks (DSS\_DPI\_p\_PCLK and DSS\_DPI\_p\_DIV\_PCLK, where  $p = 0$  to  $3$ ) serve as the clocks for the output display interface. The DSS\_DPI\_p\_PCLK clock is the 2x version of the DSS\_DPI\_p\_DIV\_PCLK clock. There are no internal dividers on the pixel clocks.

The relationship between the outgoing pixel clock and the input pixel clocks is as shown in [Section 12.6.3.11.9.1, MSS Clocking Scheme](#).

The frequency of the display controller logic clock (DSS\_FUNC\_CLK) has to be greater than the frequency of the DSS\_DPI\_p\_PCLK clocks, in order to get the DISPC internal logic to function properly. The frequency of the DSS\_DPI\_p\_PCLK and DSS\_DPI\_p\_DIV\_PCLK clocks depend on the required output display resolution and frame rate. For information on the maximum supported frequency ratings, see the device-specific Datasheet.

The DSS\_FUNC\_CLK is asynchronous to DSS\_DPI\_p\_PCLK and DSS\_DPI\_p\_DIV\_PCLK clocks. They can be generated by different sources.

The DSS\_DPI\_p\_PCLK and DSS\_DPI\_p\_DIV\_PCLK clocks are synchronous to one another (for the same value of  $p$ ).

The DSS0\_COMMON\_DSS\_SYSCONFIG[0] AUTOCLKGATING register bit is set by default to allow the auto-gating of the interface and functional clocks. The AUTOCLKGATING bit can be reset to disable the auto-gating of the clocks, if required.

The DISPC provides also a clock-gating control on sub-module level, via configuration of the appropriate DSS0\_COMMON\_DISPC\_CLKGATING\_DISABLE register fields.

#### 12.6.3.3 DISPC Resets

DISPC receives a single hardware reset signal. For more information, see *DSS Integration*.

To perform a software reset on the DISPC, set the DSS0\_COMMON\_DSS\_SYSCONFIG[1] SOFTRESET bit to 0x1. The DSS0\_COMMON\_DSS\_SYSSTATUS[0] DISPC\_FUNC\_RESETDONE bit indicates that the software reset is complete (for the DISPC internal logic) when its value is 0x1. When the software reset completes, the DSS0\_COMMON\_DSS\_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing DISPC operations.

The completion of the software reset for the video ports logic is indicated in the DSS0\_COMMON\_DSS\_SYSSTATUS[3-1] DISPC\_VP\_RESETDONE register bit-field.

#### 12.6.3.4 DISPC Power Management

DISPC supports a power management protocol with the device Power Sleep Controller (PSC).

The (software) sequence, while performing a *clkstop\_req* to DISPC, is as follows:

1. Disable DISPC by programming the [0] ENABLE bit of DSS0\_VP\_CONTROL register to 0.
2. DISPC hardware completes the output of the current frame. Then hardware sets the DSS0\_COMMON\_DSS\_SYSSTATUS[9] DISPC\_IDLE\_STATUS register bit to 1.
3. Poll the DSS\_IDLE\_STATUS bit to ensure that DISPC is in idle mode.
4. PSC initiates *clkstop\_req* to DISPC.
5. DISPC hardware acknowledges with *clkstop\_ack* immediately.

### 12.6.3.5 DISPC Interrupt Requests

The DISPC supports twelve interrupt output lines. The DISPC interrupt events are classified into functional, internal diagnostic error, and secure interrupt sub-categories, and then mapped to the respective sub-category interrupt line. Multiple sets of IRQ aggregation registers and IRQ generators enable fully independent monitoring and control of the interrupt events by up to 4 processor hosts at SoC level, as shown in [Figure 12-320](#). For more details on the mapping of the interrupt lines to SoC-level resources, see *DISPC Integration*.

- The 4 functional interrupt (FUNC\_IRQ) lines are DISPC\_FUNC\_IRQ\_PROC0\_0 through DISPC\_FUNC\_IRQ\_PROC3\_0.
- The 4 internal diagnostic error interrupt (SAFETY\_ERROR\_IRQ) lines are DISPC\_SAFETY\_ERROR\_IRQ\_PROC0\_0 through DISPC\_SAFETY\_ERROR\_IRQ\_PROC3\_0.
- The 4 secure interrupt (SECURE\_IRQ) lines are DISPC\_SECURE\_IRQ\_PROC0\_0 through DISPC\_SECURE\_IRQ\_PROC3\_0.

**Figure 12-320. DISPC Interrupts Generation**

Each of the interrupt signals indicates that one or more interrupt events are detected by the hardware. Each event is independently maskable for each interrupt output.

There are two level of interrupt events, as shown in [Figure 12-320](#). The first level is used to indicate common events and is also source for the second level of interrupts. The second level of interrupt events consists of status and enable interrupt registers for each video pipeline and each video port.

[Table 12-329](#) describes the first level of interrupt events with associated mask and status register fields. Each interrupt event is captured in an interrupt status register. Equivalent DSS0\_COMMON\_DISPC\_IRQSTATUS\_RAW register exist, which is updated even if interrupts are not enabled. This allows software to get access to updated status for all interrupt events.

**Table 12-329. DISPC Interrupts - First Level**

Interrupt Name	Set Interrupt Enable Register DSS0_COMMON_DISPC_IRQENABLE_SET	Clear Interrupt Enable Register DSS0_COMMON_DISPC_IRQENABLE_CLR	Interrupt Status Register DSS0_COMMON_DISPC_IRQSTATUS	Description
VID1_IRQ	[4] SET_VID_IRQ	[4] CLR_VID_IRQ	[4] VID_IRQ	At least one event of the VID1 pipeline interrupt events has occurred. See <a href="#">Table 12-330</a> for more details.

**Table 12-329. DISPC Interrupts - First Level (continued)**

Interrupt Name	Set Interrupt Enable Register DSS0_COMMON_DISPC_IRQENA BLE_SET	Clear Interrupt Enable Register DSS0_COMMON_DISPC_IRQENA BLE_CLR	Interrupt Status Register DSS0_COMMON_DISPC_IRQSTAT US	Description
VIDL1_IRQ	[5] SET_VID_IRQ	[5] CLR_VID_IRQ	[5] VID_IRQ	At least one event of the VIDL1 pipeline interrupt events has occurred. See <a href="#">Table 12-331</a> for more details.

The MISR signature generated does not match the expected signature, or the VP output frame freeze detection has triggered.

### 12.6.3.6 DISPC DMA Controller

The DISPC DMA controller is based on a 5-channel DMA engine that:

- Requests and supplies data from system memory to the VID and VIDL pipelines (up to 4 input layers) through the SoC system interconnect, based on the configuration of the pipeline settings.
- Stores the composed frames back into system memory by using the WB pipeline.
- Is fully programmable and fetches pixel data via 128-bit requests using 1D burst.

The DISPC DMA engine has an additional (secondary) 128-bit master port. By default, all transactions from every channel go through the primary 128-bit master port. If compression is enabled for a particular channel (by using the FBDC module), then all the transactions of that channel go through the secondary master port. It is also possible to force transactions from a particular channel to the secondary master port (even without compression) by setting the DSS0\_VID\_ATTRIBUTES2[25] MPORTSEL register bit to 0x1. This is possible only when compression through the FBDC is completely disabled (that is, none of the read channels are fetching compressed data).

Each pipeline has a dedicated DMA buffer and channel with independent settings. If a pipeline is disabled (that is, not used), then its DMA buffer can be assigned to another pipeline by configuring the DSS0\_COMMON\_DISPC\_GLOBAL\_BUFFER register. For example, unused buffers for a VIDL pipeline can be used by a VID pipeline.

Each DMA channel supports a total of 8 line buffers, each of which can store 2048 32-bit pixels.

- The size of each DMA buffer associated to the VID, VIDL and WB pipelines is 8x512x128-bit.

The DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration has been programmed for the video layer), that is, when the video window is present and the video pipeline is active.

#### 12.6.3.6.1 DISPC DMA Addressing and Bursts

For each line to be fetched, the DMA engine address generator:

- Calculates the pixel address
- Aligns the address
- Determines byte enable pattern
- Determines 1D burst length

The meaning of the address bits is as follows:

- Bits [31-0]: system (DDR) memory address (pixel address)
- Bits [47-32]: 32 bits + address extension

The address extension bits are defined by the programmable parameter DSS0\_VID\_BA\_EXT\_0/DSS0\_VID\_BA\_EXT\_1 and DSS0\_VID\_BA\_UV\_EXT\_0/DSS0\_VID\_BA\_UV\_EXT\_1 registers, optionally used to extend the BA memory addressing to 48-bit addressed external memory space (that is, to extend DISPC address space into 4GB+ space).

The DDR scan pixel addresses are generated by the DMA engine in order to read data from the system memory. The base address defines the start address of the first pixel, and then the address is incremented based on the number of pixels per line, offset between two consecutive lines and number of lines. The DSS0\_VID\_ROW\_INC register allow the access to a frame using 1D bursts (but as a two-dimensional block) by adding a fixed address offset at the end of a line. The ROW\_INC can also be used to skip lines from the input frame.

The byte address of each pixel in the frame buffer located in the system memory is determined by:

Pixel address = base\_address + x × (bpp/8) + y × (width × (bpp/8) + increment), where:

- "base\_address" corresponds to the base address defined by:
  - DSS0\_VID\_BA\_0/DSS0\_VID\_BA\_1[31-0] BA register bit-fields for all formats, and Y frame buffer in case of YUV-NV12 format. Optional extension bits in DSS0\_VID\_BA\_EXT\_0/DSS0\_VID\_BA\_EXT\_1 registers.
  - DSS0\_VID\_BA\_UV\_0/DSS0\_VID\_BA\_UV\_1[31-0] BA register bit-fields for UV frame buffer in case of YUV-NV12 format. Optional extension bits in DSS0\_VID\_BA\_UV\_EXT\_0/DSS0\_VID\_BA\_UV\_EXT\_1 registers.

- "bpp" corresponds to the number of bits per pixel defined by the DSS0\_VID\_ATTRIBUTES[6-1] FORMAT register bit-field.
- "width" corresponds to the number of pixels per line defined by the DSS0\_VID\_PICTURE\_SIZE[11-0] MEMSIZEX + 1 register bit-field.
- "increment" corresponds to the number of bytes to skip between two contiguous lines defined by the DSS0\_VID\_ROW\_INC [31-0] ROWINC – 1 register bit-field.
- "x" corresponds to the pixel position on the x-axis.
- "y" corresponds to the pixel position on the y-axis.

In cases where the DMA controller is doing a flip/mirror (see [Section 12.6.3.6.4, DISPC Flip/Mirror Support](#)) or fetching a compressed frame buffer (see [DISPC Compressed Data Format Support](#)), the above equation for pixel byte address needs to be modified according to those features.

#### Note

Since the base address is aligned on pixel size boundary the horizontal resolution is one pixel. In case of YUV422 formats, the resolution is 4 bytes (2 pixels). In case of RGB24 packed format the resolution is 4 pixels. In case of Y frame buffer (YUV-NV12 format) the resolution is one byte. The vertical resolution is one line.

In case of YUV422 non-planar format, the number of pixels per line shall be a multiple of 2 pixels and the size of a pixel shall be considered as 2 bytes. In case of YUV planar format (YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21), the Y buffer shall be considered as an 8-bit frame buffer, and the CbCr shall be considered as a 16-bit frame buffer. The pixel size is 1 byte and 2 bytes respectively for Y and CbCr.

For two-plane pixel formats (YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21, RGB565-A8), the pixel values are defined in two separate buffers (Y and UV buffers). The first buffer consists of Y values (8 bits for each Y sample) or 16-bit RGB value. The second buffer consists of CbCr values (16 bits for each pair of CbCr samples) or 8-bit Alpha value. The base address, the number of bytes to skip between pixels and between lines of each buffer are defined by separate registers:

- The DSS0\_VID\_BA\_0/DSS0\_VID\_BA\_1, DSS0\_VID\_PIXEL\_INC and DSS0\_VID\_ROW\_INC registers define the values to use for the first buffer
- The DSS0\_VID\_BA\_UV\_0/DSS0\_VID\_BA\_UV\_1 and DSS0\_VID\_ROW\_INC\_UV define the values to use for the second buffer
- Internal to the DMA controller, the two planes use the same shared memory space, which is allocated to the relevant pipeline which has the two-plane pixel format set

In case of interlaced mode, DSS0\_VID\_BA\_0 and DSS0\_VID\_BA\_UV\_0 registers define the base address of the even field, and DSS0\_VID\_BA\_1 and DSS0\_VID\_BA\_UV\_1 registers define the base address of the odd field.

[Table 12-335](#) summarizes the register settings for a simple access of a picture in the system memory.

**Table 12-335. DISPC Register Settings for Accessing Image in Internal Memory**

Pipeline Registers	Value
DSS0_VID_BA_0 <sup>(1)</sup> and DSS0_VID_BA_1 <sup>(2)</sup> / DSS0_WB_BA_0 and DSS0_WB_BA_1	The physical base address (PBA) of image in the memory for all formats and Y buffer.
DSS0_VID_BA_EXT_0 and DSS0_VID_BA_EXT_1 / DSS0_WB_BA_EXT_0 and DSS0_WB_BA_EXT_1	Address extension bits of PBA for all formats and Y buffer.
DSS0_VID_BA_UV_0 <sup>(1)</sup> and DSS0_VID_BA_UV_1 <sup>(2)</sup> / DSS0_WB_BA_UV_0 and DSS0_WB_BA_UV_1	The physical base address (PBA) of UV buffers image in the memory.
DSS0_VID_BA_UV_EXT_0 and DSS0_VID_BA_UV_EXT_1 / DSS0_WB_BA_UV_EXT_0 and DSS0_WB_BA_UV_EXT_1	Address extension bits of PBA for UV buffers.
DSS0_VID_PIXEL_INC / DSS0_WB_PIXEL_INC	1 or other in pixel incremental value.
DSS0_VID_ROW_INC / DSS0_WB_ROW_INC	1 or other in row incremental value. Used for Y buffer.

**Table 12-335. DISPC Register Settings for Accessing Image in Internal Memory (continued)**

Pipeline Registers	Value
DSS0_VID_ROW_INC_UV / DSS0_WB_ROW_INC_UV	1 or other in row incremental value. Used for UV buffer.

- (1) The BA\_0 and BA\_UV\_0 registers define the base address of even field, in case of interlaced mode.  
 (2) The BA\_1 and BA\_UV\_1 registers define the base address of odd field, in case of interlaced mode.

An interconnect request (128 bits) corresponds to one or several pixels, depending on the bits per pixel. Therefore, the DMA engine determines the appropriate burst sequence to optimize the fetching of each new line. The DMA engine must prevent a single burst from crossing two lines. The DMA engine supports only 1D burst. 1D burst is used, if the fetch data is linear in memory. The size of the burst can be one of the following values:

- 1x128-bit, 2x128-bit, 4x128-bit: Only during start of the row and end of the row, if there is a misaligned address
- 8x128-bit: Steady state burst size
- 16x128-bit: Only while accessing a compressed frame buffer

The DMA controller supports the start address of a row of pixels to be aligned to any arbitrary boundary in memory (with the restriction that a 32-bit format is aligned to 32-bit boundary, a 16-bit format is aligned to a 16-bit boundary, a 8-bit format is aligned to a 8-bit boundary, etc.). However, it operates most efficiently when the start address of a row is aligned to the max burst boundary of 8x128-bit. For all other cases of unaligned rows the DMA will need to go through non-optimal transactions at the start and end of each row, till it can issue a max burst of 8x128.

While accessing a compressed frame buffer (through the FBDC module), the base-address needs to be aligned to 256 bytes. In this case, the DMA will always issue a burst of 16x128-bit.

#### 12.6.3.6.2 DISPC Read DMA Buffers

The read DMA buffers are used by the VID and VIDL pipelines.

When the vertical front porch (VFP) period starts after the last horizontal front porch (HFP) of the last line, the DMA buffers are flushed according to the video port output associated with the particular video pipeline. The DMA engine restarts fetching new frame data from the memory through the DISPC master port. Enabling or disabling the DISPC also flushes the DMA buffers.

Programmable high and low thresholds, independent for each DMA buffer, are used by the DMA engine to start and stop requesting data through the master port.

- When low threshold (set in the DSS0\_VID\_BUF\_THRESHOLD [15-0] BUFLOWTHRESHOLD register bit-field) is reached, the DMA engine starts a request on the device interconnect to fill the DMA buffer.
- When high threshold (set in the DSS0\_VID\_BUF\_THRESHOLD [31-16] BUFHIGHTHRESHOLD register bit-field) is reached, the DMA engine stops requesting encoded pixels.

#### Note

The configuration of thresholds for optimal performance can be defined using the DSS0\_VID\_BUF\_SIZE\_STATUS[15-0] BUFSIZE register field value, as follows:

- For high threshold: BUFSIZE (in number of 128-bit words) – 1
- For low threshold: BUFSIZE (in number of 128-bit words) – burst size (in number of 128-bit words)

The following limitations for BUFLOWTHRESHOLD values must be also considered:

- If the scaler in VID pipeline is disabled, BUFLOWTHRESHOLD can be programmed as low as interconnect latency and pixel output rate allow it.
- If the scaler in VID pipeline is enabled, BUFLOWTHRESHOLD must be programmed to guarantee that at least four full lines can be stored.

To avoid underflow at the beginning of a frame and have sufficient encoded pixel data to start some processing, a preloading of the DMA buffer is configurable between a fixed value of bytes and the high threshold value. When the preload value is reached, the associated channel will start pulling pixels out of the DMA buffer. To

enable the preload based on the value entered in the DSS0\_VID\_PRELOAD[11-0] PRELOAD register bit-field, the DSS0\_VID\_ATTRIBUTES[19] BUFPRELOAD register bit must be set to 0x0.

The vertical blanking between two frames must be long enough to allow fetching the number of pixels defined by the DSS0\_VID\_PRELOAD register and preloading the whole video pipeline. If the value set in the preload register is greater than some overflow conditions detected by the hardware, then data will start to be read from the video DMA buffer before the preload value is reached. If SYNCLOST\_IRQ event occurs the video buffer needs to be increased (buffer merge). Preload value must be greater or equal to low threshold, and smaller or equal to high threshold value.

#### Note

When self-refresh mode is selected (which means that the data in the DMA buffer are used for multiple frames) the DMA buffers are not flushed at the end of each frame. Each DMA buffer has an independent control for selecting the self-refresh mode. For more information, see [Section 12.6.3.6.10, DISPC DMA Ultra-Low Power Mode](#).

#### 12.6.3.6.3 DISPC Write DMA Buffer

The write DMA buffer is used by the WB pipeline.

Two modes for filling the DMA buffer are supported by the WB channel, selectable through the DSS0\_WB\_ATTRIBUTES[19] WRITEBACKMODE bit:

- Capture mode, WRITEBACKMODE bit set to 0: One of the overlay outputs connected to an external interface is captured at the same time the data are sent on the output. The WB timings are controlled by the VP timings.
- Memory-to-memory mode, WRITEBACKMODE bit set to 1: One of the overlay outputs or one of the pipelines is captured to perform a memory-to-memory transfer, with some processing by the DISPC (rescaling, overlaying, color space conversion, etc.).

**In capture mode:** Transfer is synchronous (that is, tightly coupled) to one of the display outputs. In this mode, the write back buffer starts receiving data after DSS0\_WB\_ATTRIBUTES[0] ENABLE register bit has been set and the associated output vertical sync has triggered the start of the transfer (VFP). In addition, the WB ENABLE bit shall be set prior to the enable of the captured channel output in order to capture the first frame.

**In memory-to-memory mode:** The data transfer is not synchronous to any of the display outputs. In this mode, the write back buffer starts receiving data after the DSS0\_WB\_ATTRIBUTES[0] ENABLE has been set. The WB ENABLE bit also is triggering the update of the shadow register in the WB pipeline.

Programmable high and low thresholds are used by the DMA engine to start and stop sending data to the system interconnect.

- When high threshold (set in the DSS0\_WB\_BUF\_THRESHOLD[31:16] BUFHIGHTHRESHOLD bit field) is reached, and there are enough data for at least one burst of pixels in the DMA buffer ready for transfer, the DMA engine generates a request to the arbitration logic. The size of the burst is defined by the user.
- When low threshold (set in the DSS0\_WB\_BUF\_THRESHOLD[15:0] BUFLOWTHRESHOLD bit field) is reached, the DMA engine stops sending encoded pixels.

At the end of the frame, to completely drain the DMA buffer, some smaller bursts (even single requests) may have to be issued. To limit the number of interconnect requests from the DISPC (that is, to limit the throughput of the write-back channel to the memory), a number of IDLE cycles between requests can be inserted. IDLE cycles can be inserted only when WB is used in memory-to-memory mode. It is ignored when WB is in capture mode.

The number of IDLE cycles between requests can be activated and determined by:

- Setting the DSS0\_WB\_ATTRIBUTES[27] IDLESIZE bit to 0x0 (default value) and entering the number of idles between requests in the DSS0\_WB\_ATTRIBUTES[31:28] IDLENUMBER bit field. Idle numbers vary from 0 to 15.
- Setting the DSS0\_WB\_ATTRIBUTES[27] IDLESIZE bit to 0x1, which considers the size of the burst (the DSS0\_WB\_ATTRIBUTES[15:14] BURSTSIZE bit field) to determine the number of IDLE cycles.
  - If BURSTSIZE = 0x0, then the number of IDLE cycles equals IDLENUMBER (0 to 15).

- If BURSTSIZE = 0x1, then the number of IDLE cycles equals IDLENUMBER × 4 (0 to 60).
- If BURSTSIZE = 0x2, then the number of IDLE cycles equals IDLENUMBER × 8 (0 to 120).

#### 12.6.3.6.4 DISPC Flip/Mirror Support

The DISPC supports on-the-fly source image flip along the x/y-axis for 8-bit/component formats (ARGB or YUV) to create a mirror effect on the source data. The DMA engine reads the source frame from right to left by requesting burst transfers for each line in negative address increments while performing each burst transfer as a linear incremental burst. The read data is repacked and stored in the line buffer incrementally - effectively storing the frame as a flipped image for the processing pipeline. The configuration of the flip/mirror operation is explained in [Table 12-336](#).

**Table 12-336. DISPC Flip/Mirror Configuration**

Flip Direction	FLIP Bit	Base Address	Byte Increment
Along Y-axis (vertical mirror)	1	Start of window	1
Along X-axis (horizontal mirror)	0	Start of last line of the window	-(2*(width of the line in bytes))
Along both X-axis and Y-axis (horizontal and vertical mirror)	1	Start of last line of the window	-(2*(width of the line in bytes))

In [Table 12-336](#):

- The FLIP bit is located in DSS0\_VID\_ATTRIBUTES register.
- The base address of the video buffer must be configured as explained in [Section 12.6.3.6.1, DISPC DMA Addressing and Bursts](#).
- The the number of bytes to increment at the end of the row in the video buffer can be configured through DSS0\_VID\_ROW\_INC and DSS0\_VID\_ROW\_INC\_UV registers. For more information, see [Section 12.6.3.6.1, DISPC DMA Addressing and Bursts](#), and [Section 12.6.3.6.5, DISPC DMA Predecimation](#).

The flip/mirror feature is not supported for compressed data formats (when the DMA engine receives daat dream the FBDC module).

#### 12.6.3.6.5 DISPC DMA Predecimation

The predecimation process consists of downscaling an image by fetching only the necessary pixels out of the memory. Vertical and horizontal predecimation are possible:

- Vertical predecimation: The picture stored in memory can be predecimated vertically by skipping lines. Burst mode is used to fetch the data when skipping lines. Only the lines that will be used by the DISPC are fetched from memory; the other lines are skipped. The DMA engine sends requests only for the useful lines using 1D burst. The base address indicates the first valid pixel to fetch from memory. The number of lines to skip is set in the ROW\_INC and ROW\_INC\_UV registers (see [Section 12.6.3.6.1, DISPC DMA Addressing and Bursts](#)).
- Horizontal predecimation: When fetching data from memory, it is possible to skip 1 out of 2 pixels, up to 1 of ouf 2047 pixels, by setting the PIXEL\_INC register (see [Section 12.6.3.6.1, DISPC DMA Addressing and Bursts](#)) to the number of pixels to skip (n), multiplied by the size of a pixel (in bytes), +1. The condition to generate a burst is that there is at least one useful pixel per 128-bit OCP request. Therefore, when the pixels are 16/32-bit, the maximum number of pixels that can be skipped is 8/4. If *PixelWidthInBytes + BytesToSkip* is greater than 16, then the programmed burst is changed into single request.

No decimation is supported when the input format is 1, 2, 4, or 8-bit BITMAP.

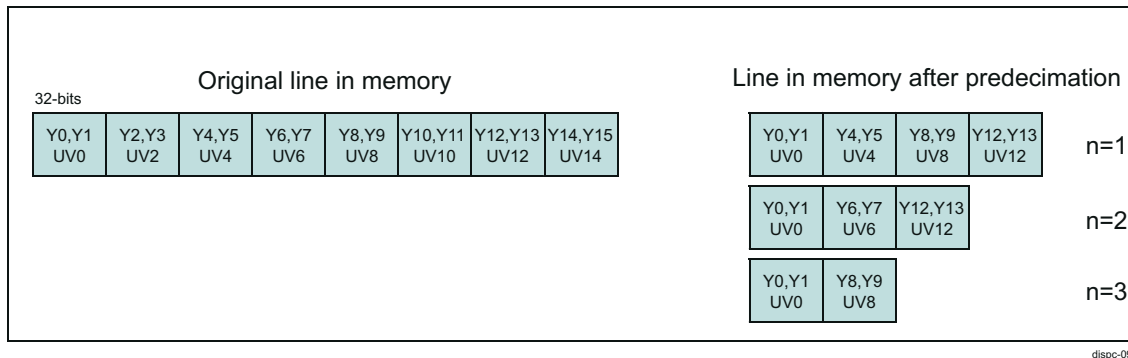

For RGB and YUV420 data formats, each pixel data container in memory holds 1 pixel. Thus, when configuring the PIXEL\_INC register, the value of n equals the number of pixels to skip:

- For RGB format, one pixel data container = 32 bits = 1 pixel
- For YUV format:
  - One Y pixel data container = 8 bits = 1 pixel
  - One UV pixel data container = 16 bits = 1 pixel

For YUV422 format, each 32-bit pixel data container holds the Luma components for 2 pixels, and the Chrominance component of 1 pixel (see [Figure 12-321](#)). Therefore, for the valid values of the PIXELINC bit field in the case of the following YUV422 format, caution must be taken because n equals the number of pixel data containers to skip, and not the number of pixels:

- For n = 1, PIXELINC = 5
- For n = 2, PIXELINC = 9
- For n = 3, PIXELINC = 13
- For n = 4, PIXELINC = 17, etc.

**Figure 12-321. DISPC YUV422 Predecimation**

#### 12.6.3.6.6 DISPC DMA Buffer Sharing

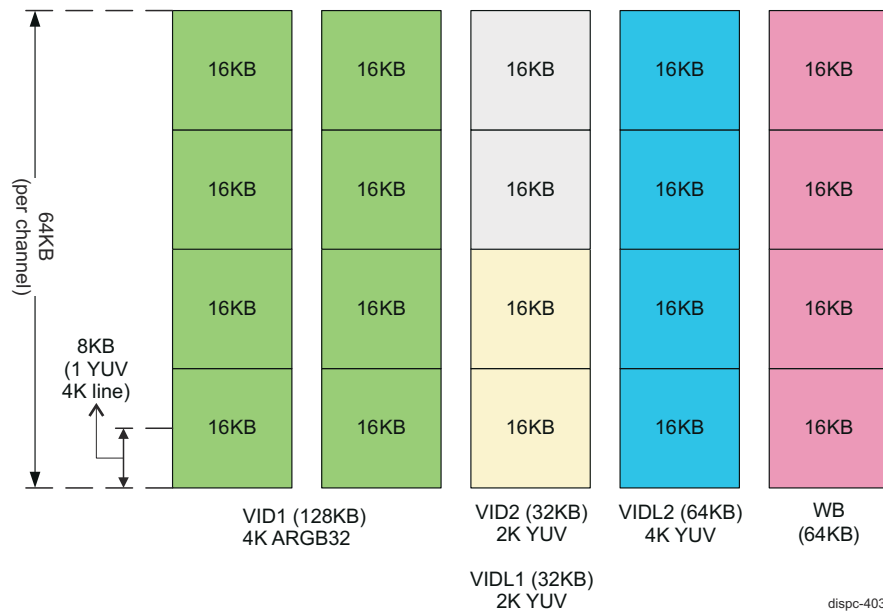

The DISPC DMA controller supports dynamic re-partition of the memory among the different channels.

At reset, each channel in DMA is allocated a uniform buffer size of 64KB. This 64KB is further partitioned into four 16KB blocks as shown in [Figure 12-322](#). A 64KB buffer is enough to support ping-pong mode for resolutions up to 4K for YUV420/YUV422 formats and up to 2K for ARGB32 formats.

**Figure 12-322. DISPC DMA Channel Memory Allocation at Reset**

To support resolutions larger than 4K YUV or 2K ARGB (with ping-pong configuration), the default buffer size of 64KB per read channel is not sufficient. In such cases, the DISPC allows dynamic repartition of the allocated buffers across the different read channels. In this way each read channel can have a variable buffer size allocated to it, starting from a minimum of 16KB to a maximum of 256KB, in 16KB increments. The WB channel buffers cannot be re-allocated and remain fixed. This is the case even when WB channel is disabled. A particular configuration (for a specific example use-case) is as shown in [Figure 12-323](#).

**Figure 12-323. DISPC Dynamic Buffer Repartition between DMA Read Channels**

When the size of the buffer is changed, the thresholds shall be re-programmed by the user to reflect the new DMA buffer configuration.

The activity on a read channel is controlled by the timing of the Overlay/VP to which the channel is connected (or to the WB, if the channel is connected to WB in M2M mode). Due to this, the DISPC HW ensures that any change in a channel buffer setting is synchronized with regard to the Overlay/VP or WB (M2M mode) to which the channel is connected. In addition, the software also must follow the following programming sequences:

- Initialization sequence (before enabling any pipe or VP or WB):
  1. Allocate the total available memory among the different threads (configurable through the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZE[19-0] VP#nTHREADSIZESIZE and [24-20] WBTHREADSIZESIZE register bit-fields).
  2. Wait for the DISPC HW to sync to the programmed THREADSIZE (read the value from DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESIZESTATUS[19-0] VP#nTHREADSIZESIZE and [24-20] WBTHREADSIZESIZE register bit-fields).
  3. Allocate a buffer for each of the (active) read channels (configurable through the DSS0\_VID\_DMA\_BUFSIZE[4-0] BUFSIZE register field). Software needs to ensure that the total size allocated to all the channels in a thread does not surpass the total size allocated to the thread.
  4. Enable the read channels as well as the VP output.
- Intra thread re-allocation sequence. Within the thread the re-allocation always happens at the next VSYNC. There is no handshake needed on the part of software.
  1. Allocate the new buffer size (configurable through the DSS0\_VID\_DMA\_BUFSIZE[4-0] BUFSIZE register field).
- Inter thread re-allocation sequence. The synchronization events (VSYNC) between two threads will be different. Therefore, any re-allocation between two threads needs to go through a software managed handshake sequence as follows:
  1. Free the required amount of memory from Thread-#n (configurable through the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZE register).
  2. Wait till the synchronization event of Thread-#n (achieved by looking at the status reflected in the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESIZESTATUS register).
  3. Allocate the freed buffer space to a different thread, Thread-#m (configurable through the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZE register).

4. Further allocate this space to the different read channels of Thread-#m (configurable through the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESTATUS register).
5. Further allocate the new buffer size to the read channels in Thread-#m (configurable through DSS0\_VID\_DMA\_BUFSIZE register).

#### Note

In a case where a channel is connected to multiple Overlay/VP (multi-cast use-case), then the channel belongs to the thread corresponding to the first (lowest numbered) Overlay/VP to which it is connected.

#### 12.6.3.6.7 DISPC DMA MFLAG Mechanism

The MFLAG mechanism allows a dynamic increase of the priority of DISPC real-time traffic, when required, based on the fullness of the DISPC DMA read buffers.

The MFLAG mechanism is used when fullness of the DMA buffers is critical (close to underflow). The mechanism is implemented for all DMA buffers of the video pipelines.

Programmable buffer thresholds (forming hysteresis) are used to configure when a local MFLAG signal is generated. The 1-bit MFLAG signal is generated on DISPC master port in order to inform the system that the outstanding requests from DISPC shall be considered with higher priority in order to get faster interconnect responses. The MFLAG signal is asynchronous to any ongoing interconnect transaction.

Each pipeline maintains its own MFLAG bit. The MFLAG bit is asserted depending on the fullness of the DMA buffers associated with the pipeline and depending on the thresholds programmed by software. All MFLAG signals are OR-ed together to generate the single 1-bit MFLAG for the master port connected to the DISPC DMA engine.

The threshold for video pipelines corresponds to the fullness of the associated DMA buffer, and is defined by two threshold parameters:

- HT\_MFLAG: High threshold.
  - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
  - This threshold can be programmed in the DSS0\_VID\_MFLAG\_THRESHOLD [31-16] HT\_MFLAG register field.
- LT\_MFLAG: Low threshold.
  - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
  - This threshold can be programmed in the DSS0\_VID\_MFLAG\_THRESHOLD [15-0] LT\_MFLAG register field.

Summary of the MFLAG value, based on DMA read buffer fullness:

- If DMA read buffer fullness < LT\_MFLAG, then MFLAG signal = 1
- If LT\_MFLAG < DMA read buffer fullness < HT\_MFLAG, then MFLAG signal = 1
- If DMA read buffer fullness > HT\_MFLAG, then MFLAG signal = 0

Similarly, the MFLAG is set based on fullness and the transition history on the out bound writeback pipeline. There is no pre-fetch state for out bound DMA controller. The MFLAG is set when the buffer fullness rises above the HT\_MFLAG bit-field value. The MFLAG is cleared only when the buffer fullness falls back below the LT\_MFLAG bit-field value. In between these two fullness states, the MFLAG bit keeps the previous value.

By default, the MFLAG mechanism is disabled (DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[1-0] MFLAG\_CTRL register field = 0x0), and the MFLAG signal is low (de-asserted). The arbitration scheme for the pipelines is the same as described in [Section 12.6.3.6.9, DISPC DMA Arbitration](#). That is, round-robin either between high-priority pipelines, or between normal-priority pipelines (if all pipelines are of normal priority).

When the MFLAG\_CTRL register field is set to 0x2, the MFLAG mechanism is enabled, and the MFLAG signal is dynamically set to 0 or 1, depending on DMA buffer fullness and programmed threshold levels, as explained

previously in this section. In this case, the arbitration scheme for the pipelines is round-robin between those high-priority pipelines, which have asserted their local MFLAG signals. If there are no high-priority pipelines with their local MFLAG signals asserted, then the arbitration scheme is the same as described in [Section 12.6.3.6.9, DISPC DMA Arbitration](#).

The DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[6] MFLAG\_START bit defines the following additional rules for the MFLAG mechanism:

- If the MFLAG\_START bit is set to 0x0 (default value), then when the DMA buffer is empty at the beginning of the frame, the MFLAG signal of each pipeline is kept at 0 until PRELOAD is reached (for more information on preloading, see [Section 12.6.3.6.2, DISPC Read DMA Buffers](#)). Then, based on the setting of the DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[1-0] MFLAG\_CTRL register field, the MFLAG signal is generated and DISPC internal logic is arbitrating between pipeline requests.
- If the MFLAG\_START bit is set to 0x1, then even in the beginning of the frame when the DMA buffer is empty, the configuration of DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[1-0] MFLAG\_CTRL register field determines the generation of the MFLAG signal.

#### 12.6.3.6.8 DISPC DMA Priority Requests Control

The DSS0\_COMMON\_DSS\_CBA\_CFG register controls the priority level for DMA requests going out to the memory through the system interconnect.

As explained in [Section 12.6.3.6.7, DISPC DMA MFLAG Mechanism](#), the DISPC master port generates a 1-bit MFLAG output signal to raise the priority of all requests made on that port, if any of its DMA buffers runs critically low (determined by a set of user programmable threshold values for each buffer).

DSS uses the MFLAG signal from DISPC to set a 3-bit priority level output (*Mpriority*) for the master port to either a low or high value (configurable in DSS0\_COMMON\_DSS\_CBA\_CFG[2-0] PRI\_LO and [5-3] PRI\_HI register fields with optional values of 0~7) as follows:

- When MFLAG = 0, the PRI\_LO register field determines the value of the Mpriority output for the normal transactions.
- When MFLAG = 1, the PRI\_HI register field determines the value of the Mpriority output for the high-priority transactions.

This Mpriority output directly drives the respective input of the system interconnect port, which corresponds to the DISPC DMA master port.

#### CAUTION

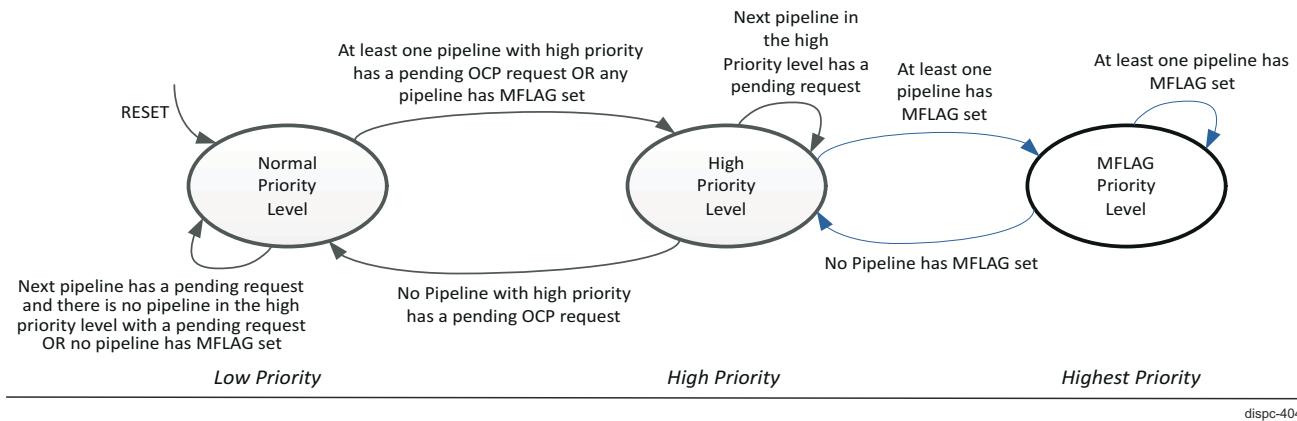

Upon a hardware reset, DSS0\_COMMON\_DSS\_CBA\_CFG[2-0] PRI\_LO and [5-3] PRI\_HI register fields are set by default to 4 and 1, respectively. Afterwards, these priority level register fields can only be modified by a secure host.

#### 12.6.3.6.9 DISPC DMA Arbitration

The read requests sent to the system interconnect are pipelined and arbitrated in a round-robin scheme. The default arbitration scheme can be modified by setting the priority attribute of each pipeline as defined in the DSS0\_VID\_ATTRIBUTES[23] ARBITRATION register bit.

By default, all pipelines have the same priority (normal priority), which means all pipeline requests are treated in a round-robin order manner. If one or more pipelines require a higher number of requests going to the system interconnect, its priority can be moved up to high priority. In this case, the high-priority pipeline is granted access before any pipeline in normal priority. If more than one active pipeline is in high priority, then the behavior is the same as all active pipelines in normal priority. Normal active pipelines are not treated until all high active pipelines are finished. The ARBITRATION bit cannot be modified during the entire frame.

In addition to the priority bit-field, the MFLAG mechanism can also result in a higher priority for a pipeline. An MFLAG priority level is set, for all pipelines for which MFLAG bit is set, which is defined as the highest priority level for arbitration. For more details on MFLAG mechanism, see [Section 12.6.3.6.7, DISPC DMA MFLAG Mechanism](#). [Figure 12-324](#) shows the transition between the different priority levels.

**Figure 12-324. DISPC DMA High/Low Priority Arbitration**

#### 12.6.3.6.10 DISPC DMA Ultra-Low Power Mode

In ultra-low power mode, the system interconnect is used to fill up the DMA buffers to store all the data required to display a full frame. Then, the system interconnect is not used anymore to fetch new pixels for the consequent frames. The data are fetched once into the DMA buffer and then the following frames re-use the DMA buffer to display on the screen.

The programming of the ultra-low power mode is independent for each pipeline and is achieved via the DSS0\_VID\_ATTRIBUTES[24] SELFREFRESH register bit. One pipeline may have all frame pixels into the DMA buffer and other pipeline may have to refill the DMA buffers along the display scan, because the frame buffer is too big to be stored in the DMA buffer.

The DMA buffers can be merged in order to optimize the system interconnect OFF time. Each DMA buffer dedicated to one pipeline can be split into two buffers. The merge of the DMA buffers into a single one can be used at the same time to improve the Ultra-Low Power mode.

Two ultra-low power modes can be entered, manual or automatic mode:

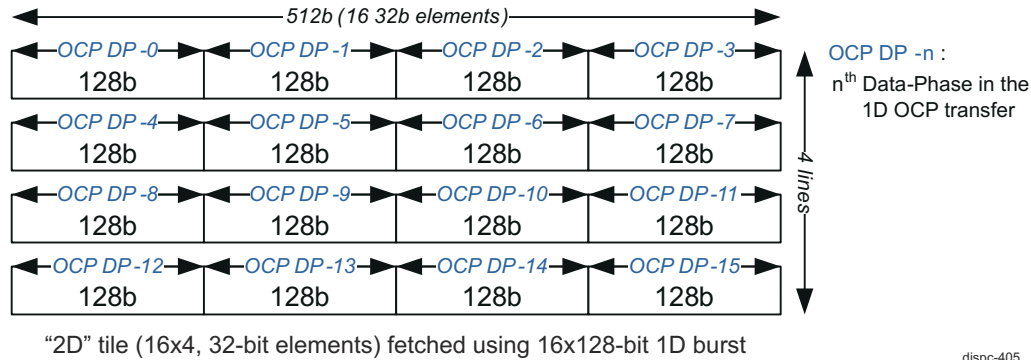

- **Manual self-refresh mode:** Starting self-refresh mode is done manually by setting the SELFREFRESH bit to 0x1 after capturing a frame in the DMA buffers. Self-refresh mode is stopped by setting the SELFREFRESH bit to 0x0. Software must first disable the SELFREFRESH bit during at least one frame in order to capture the data (by setting the GOBIT register bit of the video port the pipeline is associated with). Once the DSS0\_VP\_CONTROL[5] GOBIT bit has been set, the software must read the GOBIT bit to ensure that the frame has been loaded into the buffer, then it can set the SELFREFRESH bit to 1. Once SELFREFRESH is enabled, the fetch of data from the system memory is stopped for the following frames. The software needs to reset the SELFREFRESH bit in order to restart fetching data from system memory.
- **Automatic self-refresh mode:** By setting the DSS0\_VID\_ATTRIBUTES[17] SELFREFRESHAUTO bit to 0x1, the transition from disabled to enabled for self-refresh mode is controlled by hardware. This allows the software to reset the SELFREFRESH bit to "disabled", and then automatically after the fetch of the first frame the hardware switches back SELFREFRESH bit to "enabled". The SELFREFRESH must be disabled during at least one frame in order to capture the data, so software must reset the bit to 0 every time the data in the DMA buffer needs to be updated. The hardware reads the data inside the DMA buffer without accessing the interconnect and system memory during the frame, then modifies the SELFREFRESH bit to reflect the current state of the self-refresh mode by setting the bit to 0x1.

#### 12.6.3.6.11 DISPC Compressed Data Format Support

The DISPC is capable of reading a compressed frame buffer through the FBDC block. The FBDC is a Frame Buffer Decompression module that is compatible with the lossless compression module (FBC) in the GPU in the SoC. The FBDC performs the lossless decompression of the compressed images on a tile-by-tile basis. The size of the tiles is 16 pixels by 4 lines or 32 pixels by 2 lines. The FBDC is enabled by setting the DSS0\_VID\_FBDC\_ATTRIBUTES[0] ENABLE register bit.

### 12.6.3.6.11.1 FBDC Tile Request

Since the compression/decompression is tile based, the DMA engine generates a 256-byte (16x128-bit) 1D burst request for each tile (a tile is a 16x4 or 32x2 2D structure of 32-bit elements) to FBDC which handles the DMA transfer and decompression of the requested tile. The de-compression phases are transparent to the DISPC hardware. Only ordering of the pixels from a returned tile is taken care by the DISPC DMA engine using 1D burst. The data returned from the FBDC, for a single tile over different OCP data-phases (DP), is as shown in Figure 12-325.

**Figure 12-325. DISPC FBDC Tile Request (16x4 Tile)**

#### Note

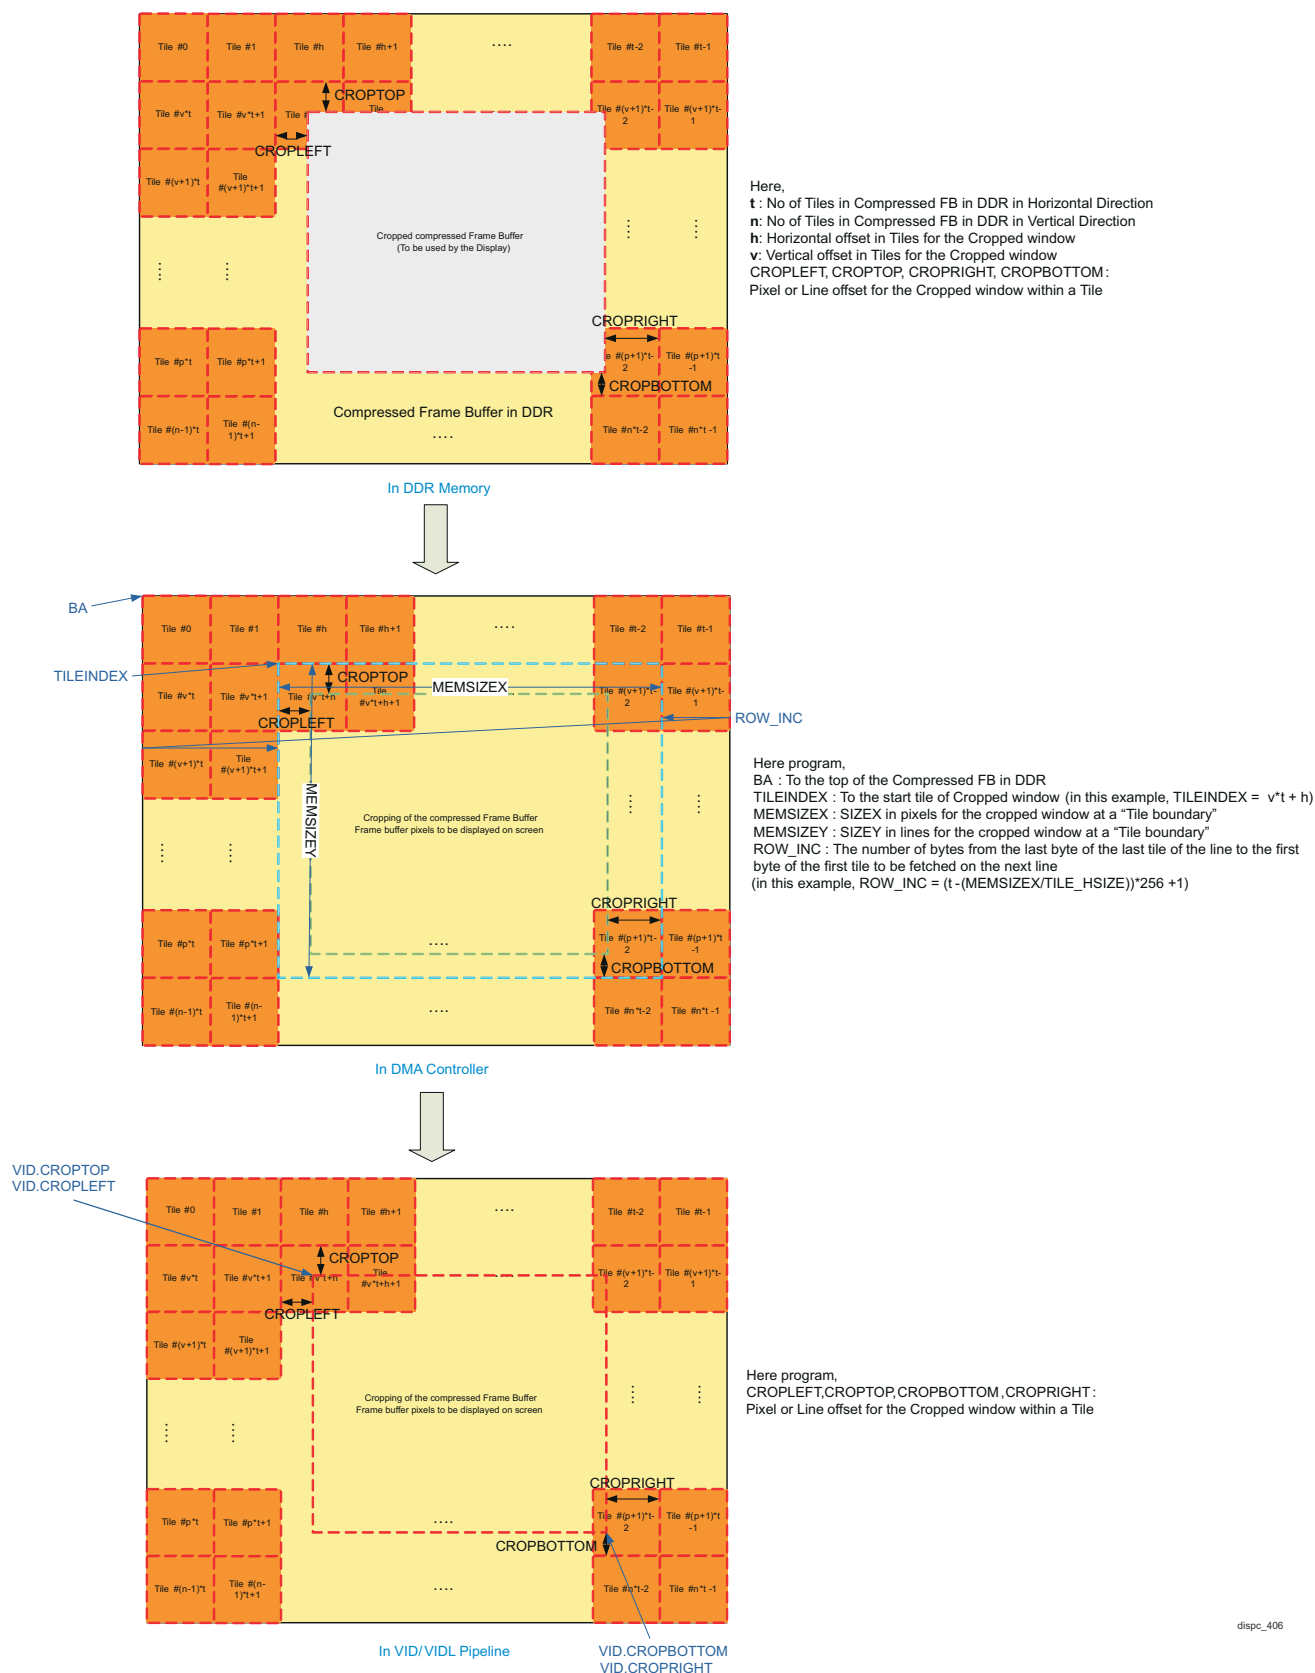

Due to the tile nature of the data, the following DMA features are not available with compressed data formats:

- Flip/Mirror support
- ROW\_INC on a line basis (that is, ROW\_INC cannot be used to skip lines). It can only be specified in such a way as to skip entire tile rows.

### 12.6.3.6.11.2 FBDC Source Cropping

The FBDC supports a source cropping of the compressed frame buffer. The source cropping is achieved as a two-step process.

- Cropping at a tile boundary is achieved by the DMA controller.
- Cropping within a tile (to a pixel or a line) is achieved by the VID/VIDL pipeline. That is a regular crop feature in the VID/VIDL pipeline which is useful for non-compressed frames as well.

dispc\_406

**Figure 12-326. DISPC FBDC Example of a Frame Buffer Source Cropping (Decompression)**

The necessary programming for cropping at a tile boundary within the DMA Controller (based on [Figure 12-326](#)) is as follows:

- BA must be programmed to the top of the compressed frame buffer in DDR.
- TILEINDEX must be programmed to the start tile of the cropped window in the DSS0\_VID\_TILE[22-0] TILEINDEX register field. In this example,  $TILEINDEX = v * t + h$ .
- MEMSIZE\_X is the SIZE\_X in pixels for the cropped window at a "Tile boundary".
- MEMSIZE\_Y is the SIZE\_Y in lines for the cropped window at a "Tile boundary".
- ROW\_INC is the number of bytes from the last byte of the last tile of the line to the first byte of the first tile to be fetched on the next line. In this example,  $ROW\_INC = (t - (MEMSIZE\_X / TILE\_H\_SIZE)) * 256 + 1$ , where  $TILE\_H\_SIZE = 16$  or  $32$  depending on whether 16x4 tile-type is used or a 32x2 tile-type is used. The tile type must be programmed in the DSS0\_VID\_FBDC\_ATTRIBUTES[9-8] TILETYPE register field.

For details on the register programming for the crop feature in the VID/VIDL pipeline, see [Section 12.6.3.8.9, DISPC VID Cropping Support](#).

### 12.6.3.7 DISPC Pixel Data Formats

The DISPC pipelines support various types of memory formats, as listed in [Table 12-337](#).

For BITMAP formats the nibble mode (pixels in each byte are packed in reverse order) can be enabled by setting the DSS0\_VID\_ATTRIBUTES[10] NIBBLEMODE register bit to 0x1. The nibble mode is supported only for the VID/VIDL pipelines, but not for the WB pipeline.

The pixel data format can be selected by loading the corresponding value from [Table 12-337](#) in the DSS0\_VID\_ATTRIBUTES/DSS0\_WB\_ATTRIBUTES[6-1] FORMAT register bit-field.

**Table 12-337. DISPC Supported Pixel Data Formats**

NA	See <sup>(2)</sup>	YUV420-NV21 YUV422-NV21	YUV420-NV21 YUV422-NV21	8/10/12

- (1) The video and writeback pipelines support an optional 8-bit Alpha plane (separate buffer), if the pixel format of the source/destination buffer is either RGB16-565 or BGR16-565.
- (2) NV21 formats for YUV420/YUV422 are indirectly supported through chroma swapping during the color space conversion.
- (3) The 10-bit/12-bit versions of these YUV formats are also supported in both packed and unpacked (in 16-bit container) formats. For unpacked formats, both LSB or MSB alignments are supported. These configurations are set using a separate configuration registers: DSS0\_VID\_ATTRIBUTES2 and DSS0\_WB\_ATTRIBUTES2. The default is an 8-bit packed format support.
- (4) All RGB formats with alpha component include both pre/non-pre-multiplied data support. Also, alpha can be disabled to work as X (can be replaced with global alpha value).
- (5) The writeback path supports only 8-bit and 10-bit YUV data formats.

Figure 12-327 shows the pixel data memory organization for the bitmap pixel formats.

### 12.6.3.8 DISPC Video Pipeline

The DISPC includes two types of input video pipelines:

- Video pipeline (VID1 and VID2)
- Video lite pipeline (VIDL1 and VIDL2)

The video pipeline (VID) consists of:

- VC-1 range mapping unit for YUV422/YUV420 input formats;
- Replication logic for ARGB input formats;
- One 256 x 24-bit entries Color Look-up Table (CLUT);
- Polyphase-filter based resizer unit (scaler) supporting chroma upsampling;
- Luma-key support;
- Color Space Conversion (CSC) unit (YUV to RGB), which can be used also for programmable BCHS (Brightness/Contrast/Hue/Saturation) control;

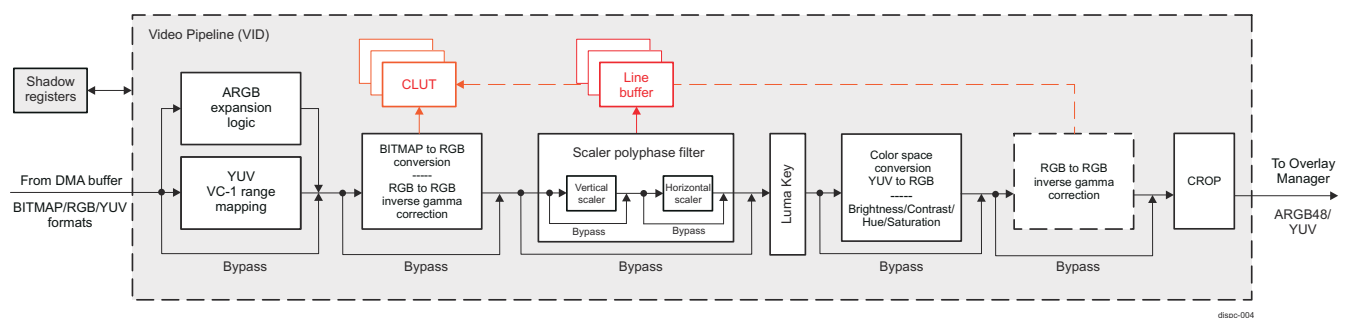

The video lite pipeline (VIDL) is identical to the video pipeline (VID), except for:

- Polyphase-filter based resizer (scaler) is not included;
- Chroma upsampling is done using dedicated YUV420-to-422 and YUV422-to-444 upsamplers (instead of using the scaler);

Each pipeline processing block can be independently bypassed.

#### Note

The DISPC input video pipelines, VID and VID1L, will be commonly referred to as *video pipeline (VID)* in the following sections. Any differences in their functionality will be highlighted.

**Figure 12-342. DISPC Video Pipeline Configuration**

**Figure 12-343. DISPC Video Lite Pipeline Configuration**

The input of the VID pipeline is connected to the video DMA buffer controller. The pixel output of the VID pipeline is connected to the overlay managers. The VID pipeline configuration supports various BITMAP, RGB (ARGB and RGBA), and YUV formats, as listed in [Table 12-337](#), *DISPC Pixel Data Formats*.

The 256-entry CLUT is either used to convert BITMAP (1, 2, 4, or 8-bit indexed formats) into RGB format, or for RGB to RGB inverse gamma correction. For a BITMAP format data, scaling is not supported. Scaling and

color look-up table features are mutually exclusive. If the color look-up feature is enabled, then the video pipeline scaler has to be disabled.

For chroma sub-sampled YUV formats (YUV422 and YUV420-NV12/NV21):

- VID pipeline: the scaler unit upsamples the chrominance data using both vertical and horizontal polyphase filters;
- VIDL pipeline: dedicated YUV420 to YUV422 and YUV422 to YUV444 chroma upsamplers are used;

For ARGB source data with less than/equal to 10-bit component data size the replication logic (ARGB expansion) converts the data to ARGB48 by replicating the MSBs into the LSBs:

- When scaling is disabled (or no scaler supported), the resulting ARGB48 data is directly provided to the pipeline output;
- When vertical scaling is engaged, the resulting ARGB48 data is first truncated to ARGB8888, and then converted to ARGB10101010 (by MSBs replication into LSBs), before being fed to the vertical scaler input;
- When vertical scaling is disabled, but horizontal scaling is engaged, the resulting ARGB48 data is directly provided to the horizontal scaler input;

### Note

There are limitations on using the inverse gamma (InvGamma) operation along with scaling. If the scaler is enabled, the InvGamma operation must always take place after the scaler in the data-path (as shown in [Figure 12-342](#)). This position of the InvGamma operation is controllable through the DSS0\_VID\_ATTRIBUTES2[29] GAMMAINVERSIONPOS register field.

All the memories (line buffers attached to the scaler, LUT and chroma upsamplers) are sized to support 10-bit per color component. This allows full 10-bit support inside the video pipeline.

The VID pipeline can be enabled by setting the DSS0\_VID\_ATTRIBUTES[0] ENABLE register bit. If the video pipeline is disabled, the video window does not exist on the screen and the whole video pipeline and its DMA are inactive. Prior to enabling the video layer a valid configuration has to be set by the user.

#### 12.6.3.8.1 DISPC VID Replication Logic

The replication logic (ARGB expansion) converts ARGB pixel formats into ARGB48 format by replicating the MSBs into the LSBs. The logic is always enabled.

[Table 12-338](#) shows how some of the ARGB formats supported by VID are remapped into ARGB48 by default.

**Table 12-338. DISPC VID Replication: ARGB Pixel Formats Remapping into ARGB48-12121212**

Formats	A[11:0]	R[11:0]	G[11:0]	B[11:0]

RGBA16-4444	A[3:0]A[3:0]A[3:0]	R[3:0]R[3:0]R[3:0]	G[3:0]G[3:0]G[3:0]	B[3:0]B[3:0]B[3:0]
ARGB32-8888	A[7:0]A[7:4]	R[7:0]R[7:4]	G[7:0]G[7:4]	B[7:0]B[7:4]

#### 12.6.3.8.2 DISPC VID VC-1 Range Mapping Unit

The VC-1 range mapping unit is used when the video frame picture is decoded using a VC-1 codec by the video accelerator. It remaps the Y, Cb, and Cr components to the full range (from the reduced data range) before displaying. The unit is used primarily for YUV420-NV12 (NV21) pixel format, but also can be applied to YUV422 pixel formats (YUV2 and UYVY).

The VC-1 range mapping unit is enabled by setting the DSS0\_VID\_ATTRIBUTES2[0] VC1ENABLE bit to 0x1. The VC-1 range mapping must be enabled only for 8 bits/component YUV input data.

The DSS0\_VID\_ATTRIBUTES2[3:1] VC1\_RANGE\_Y and [6:4]VC1\_RANGE\_CBCR register bitfields are two 3-bit values programmed by the user.

The equations for the mapping process are:

$$Y_{out} = \text{CLIP}((((Y_{int} - 128) \times (VC1\_RANGE\_Y + 9) + 4) / 8) + 128)$$

$$C_b = \text{CLIP}((((C_b - 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$$

$$C_r = \text{CLIP}((((C_r - 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$$

#### Note

The input and output pixel values are unsigned (Y, Cr, and Cb).

The function CLIP() clips to 0 or 255 when minimum or maximum, respectively, is reached. Otherwise, the resulting output remains identical.

#### 12.6.3.8.3 DISPC VID Color Look-Up Table (CLUT)

The video pipeline supports a look up table to perform either of the following operations:

- Conversions of BITMAP formats (1, 2, 4, or 8-bit indexed) into RGB format (CLUT mode), or
- Inverse gamma correction on non-linear RGB source data (gamma mode)

The look-up table consists of 3 separate 1024 x 10-bit memories and is indexed either by the source BITMAP data or by R/G/B component data. The table is loaded through direct register access by writing to the CLUT registers.

The sequence to load the table is:

1. SW writes (only writes are supported) 32-bit values for both color and monochrome mode using single access, or burst access in linear increment burst mode, into the DSS0\_VID\_CLUT\_0 through DSS0\_VID\_CLUT\_15 registers. The LSB 30 bits [29:0] are used for the value and the MSB 1 bit [31] is used to reset the index of the table for the color mode, while the LSB 8 bits are used for the value and the MSB 1 bit to reset the index of the table for monochrome mode. [Figure 12-344](#) describes the format of one of the palette value in the memory.
2. Loop to Step 1, if there is a new access to the CLUT registers. Software can access other registers between two accesses to the CLUT registers.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the look-up table in CLUT mode is activated when a BITMAP format is selected in the DSS0\_VID\_ATTRIBUTES[6:1] FORMAT register bit-field.

The usage of the look-up table for RGB inverse gamma correction can be enabled by setting DSS0\_VID\_ATTRIBUTES[30] GAMMAINVERSION register bit.

**Figure 12-344. DISPC VID CLUT/Gamma Data Memory Organization**

#### Note

Scaling and color look-up table features are mutually exclusive. If color look-up feature is enabled, then video pipeline scaler has to be disabled.

### 12.6.3.8.4 DISPC VID Chrominance Resampling

#### 12.6.3.8.4.1 Chrominance Resampling for VID Pipeline

The chrominance resampling from 8-bpc or 10-bpc to 12-bit color components is always performed using filtering (the scaler unit filter). Chrominance resampling and rescaling can be combined to support native rescaling of YUV formats.

The usage of the scaler unit for resampling the chrominance of YUV420 and YUV422 is shown in [Figure 12-345](#) and [Figure 12-346](#), respectively. The settings of the scaler unit to perform chrominance resampling are described in [Section 12.6.3.8.5, DISPC VID Scaler Unit](#).

**Figure 12-345. DISPC VID YUV420 to ARGB48 Using Scaler Unit for Resampling Chrominance**

**Figure 12-346. DISPC VID YUV422 to ARGB48 Using Scaler Unit for Resampling Chrominance**

The vertical scaler is not a mandatory block for resampling the chrominance of YUV422 data, as shown in [Figure 12-346](#).

Using the filter it is possible to re-sample the chrominance from either MPEG1 or MPEG2 sub-sampled chroma source.

#### 12.6.3.8.4.2 Chrominance Resampling for VIDL Pipeline

The VIDL pipeline does not include a scaler unit. Chroma upsampling is done using dedicated YUV420 to YUV422, and YUV422 to YUV444 chroma upsamplers.

The VIDL pipeline converts YUV420 (Chroma) data to YUV422 (Chroma) using a simple vertical average filter (average of two adjacent chroma lines to generate a missing line except for the very bottom line which is generated by repeating the previous chroma line). If the video image is a sub-image of a larger video frame data, then the vertical Luma line offset from the top should be an even number.

The VIDL pipeline converts YUV422 data to YUV444 format using a 4-tap filter (implementing the Catmull-Rom algorithm) to generate missing chroma data as follows:

$$\text{Cout}[2*i] = \text{Cin}[i]$$

$$\text{Cout}[2*i+1] = \text{CLIP} (-1/16*\text{Cin}[i-1] + 9/16*\text{Cin}[i] + 9/16*\text{Cin}[i+1] - 1/16*\text{Cin}[i+2])$$

The missing chroma data is generated as a simple weighted average of the surrounding 4 chroma values, which is equivalent to a 4x1 filter kernel with values: [-1/16, 9/16, 9/16, -1/16]. In this algorithm, edge effects are treated by repeating the first and last pixel.

### 12.6.3.8.5 DISPC VID Scaler Unit

#### Note

Only VID pipeline includes a resizer unit (scaler). The VIDL pipeline does not include a scaler.

The programmable scaler filter works with all supported video formats, including formats with alpha channel. The alpha channel is scaled with the same parameters as the RGB color components. For the YUV formats,

Y and Cb/Cr are processed independently. A RGB 64-bit source (16 bits per component) is truncated to 8-bit/component, if the scaler is enabled. Otherwise, it will be truncated to ARGB48 format in the scaler bypass mode. A 10-bit/12-bit YUV source is also truncated to 8-bit, since the scaler is enabled to either upsample the chroma component and/or resize the YUV frame data directly (for memory-to-memory operation with YUV format as the memory destination type).

The filter is based on a finite impulse response (FIR) filter with 16 phases. The filter is a 5-tap for horizontal filtering, and can be configured for 3 or 5 taps for vertical filtering. The filtering can be used for various processing:

- Up-sampling of the picture
- Down-sampling of the picture
- Anti-aliasing reduction
- Chrominance resampling in case of YUV data formats

The following limitations must be considered:

- The up-sampling ratio is up to x16.
- The down-sampling ratio using 3-tap configuration is down to x0.5 for RGB format.
- The down-sampling ratio using 5-tap configuration is down to x0.25 for RGB format.

#### Note

The user must set the correct size and position of the original video before resize in order for the up-sampled/down-sampled video to be displayed inside the screen boundaries.

Figure 12-347 shows an example of video up-sampling, with corresponding video window attributes.

**Figure 12-347. DISPC Video Window Attributes**

The video window attributes can be configured in the following register bit-fields:

- Source data format (input to the scaler unit) in DSS0\_VID\_ATTRIBUTES[6-1] FORMAT bit-field
- Video picture width in system memory (frame buffer) in DSS0\_VID\_PICTURE\_SIZE[13-0] MEMSIZEX bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed except for YUV422 formats. In case of YUV2422 and UYVY422 formats the width has to be a multiple of 2 pixels.
- Video picture height in system memory (frame buffer) in DSS0\_VID\_PICTURE\_SIZE[29-16] MEMSIZEY bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed.

- Video window width at pipeline output (after resizing) in DSS0\_VID\_SIZE[13-0] SIZE\_X bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen width minus the horizontal start location of the window on the screen.
- Video window height at pipeline output (after resizing) in DSS0\_VID\_SIZE[29-16] SIZE\_Y bit-field. The window height is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen height minus the vertical start location of the window on the screen.
- Video window overlay X-position in DSS0\_OVR\_ATTRIBUTES2\_0 through DSS0\_OVR\_ATTRIBUTES2\_4[13-0] POS\_X bit-field. See [Section 12.6.3.10, DISPC Overlay Managers](#).
- Video window overlay Y-position in DSS0\_OVR\_ATTRIBUTES2\_0 through DSS0\_OVR\_ATTRIBUTES2\_4[29-16] POS\_Y bit-field. See [Section 12.6.3.10, DISPC Overlay Managers](#).
- For configuration of LPP and PPL video port output display parameters, see [Section 12.6.3.11.8, DISPC VP Timing Generator and Display Panel Settings](#).

For vertical up-sampling and down-sampling in a 3-tap configuration, the equations are:

For RGB formats	For YUV formats
$Aout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Ain(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Rout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Gout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Gin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Bout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Bin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$	$Yout(n) = \left( \sum_{i=-1}^{i=1} Cyi(\Phi_y) \times Yin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cbout(n) = \left( \sum_{i=-1}^{i=1} Cci(\Phi_c) \times Cbin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Crout(n) = \left( \sum_{i=-1}^{i=1} Cci(\Phi_c) \times Crin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-012

(23)

For vertical and horizontal up-sampling and down-sampling in a 5-tap configuration, the equations are:

For RGB formats	For YUV formats
$Aout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Ain(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Rout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Gout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Gin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Bout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Bin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$	$Yout(n) = \left( \sum_{i=-2}^{i=2} Cyi(\Phi_y) \times Yin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cbout(n) = \left( \sum_{i=-2}^{i=2} Cci(\Phi_c) \times Cbin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Crout(n) = \left( \sum_{i=-2}^{i=2} Cci(\Phi_c) \times Crin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-012

(24)

### Note

The pixel (n + 1) is the previous pixel with respect to pixel (n). The line (n + 1) is the previous line with respect to line (n).

The coefficients Ci() depend on the phase between input and output pixels.

The coefficients are different for Y and Cr/Cb filtering because the calculations are independent due to the chrominance resampling for YUV422 and YUV420.

First, the vertical filter is applied to the encoded input pixel data, and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. The vertical input of the filter consists of:

- Six lines of 2048 × 32 bits for 5-tap configuration
- Three lines of 4096 × 32 bits for 3-tap configuration

Table 12-339 lists some of the scaler supported configurations.

**Table 12-339. DISPC VID Line Buffer Width for Scaler Unit**

Pixel Format	Maximum Input Width (Pixels) for 5-tap	Maximum Input Width (Pixels) for 3-tap
32 bits per pixel (ARGB32-8888, ARGB-2101010, etc.)	2048 pixels wide <sup>(1)</sup>	4096 pixels wide
YUV420, YUV422	4096 pixels wide	4096 pixels wide

- (1) For the 5-tap configuration, the 6th video line is used on the output of the horizontal scaler in order to start the next output line generation while the video pipeline output is being stalled by the overlay manager (either due to display in blanking period and/or in background pixel period). The 6th line buffer is actually 48-bit wide to allow storage of ARGB48 format pixel data.

At the beginning of frame scaling processing, the first line may be duplicated multiple times depending on the initial vertical phase programmed for the poly-phase filter.

At the end of frame scaling processing the last line is duplicated, if the scaling logic requires loading more lines and the last line has been reached.

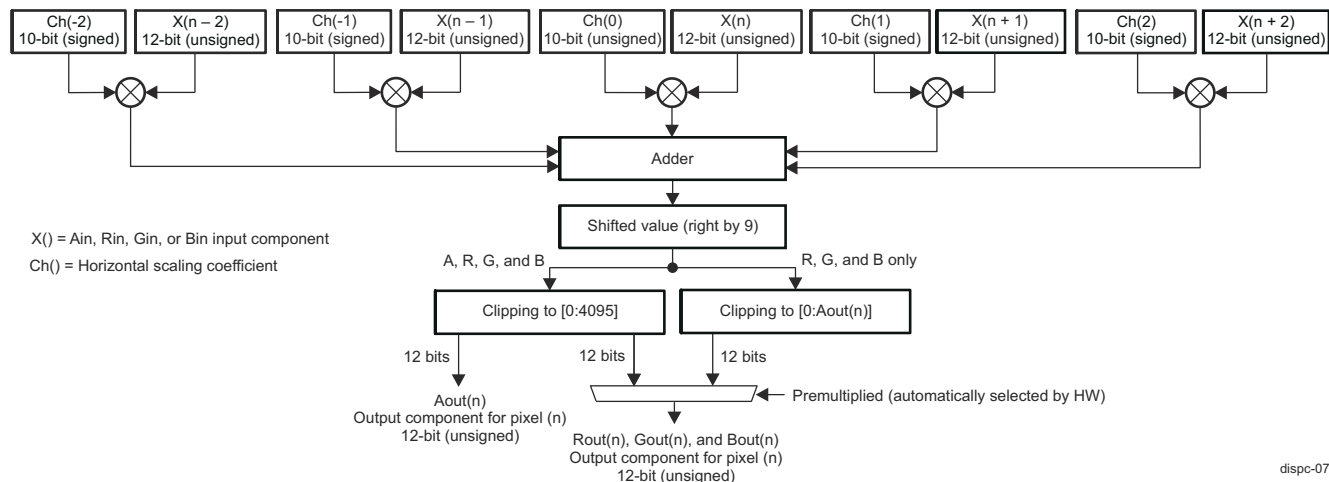

Similarly, the first pixel may be duplicated multiple times depending on the initial horizontal phase programmed for the poly-phase filter. The last pixel is duplicated, if the scaling logic requires loading more pixels and the last pixel has been reached.

The programmable coefficients of the polyphase filters are signed 10-bit values (except for the central coefficient, which is unsigned). The vertical video scaler has an 10-bit input and a 12-bit output. The horizontal scaling stage takes the resulting 12-bit input and produces 12-bit output.

Figure 12-348 and Figure 12-349 show the scaler macro-architecture for components A, R, G, and B. Figure 12-350 and Figure 12-351 show the scaler macro-architecture for components Y, Cr, and Cb.

#### Note

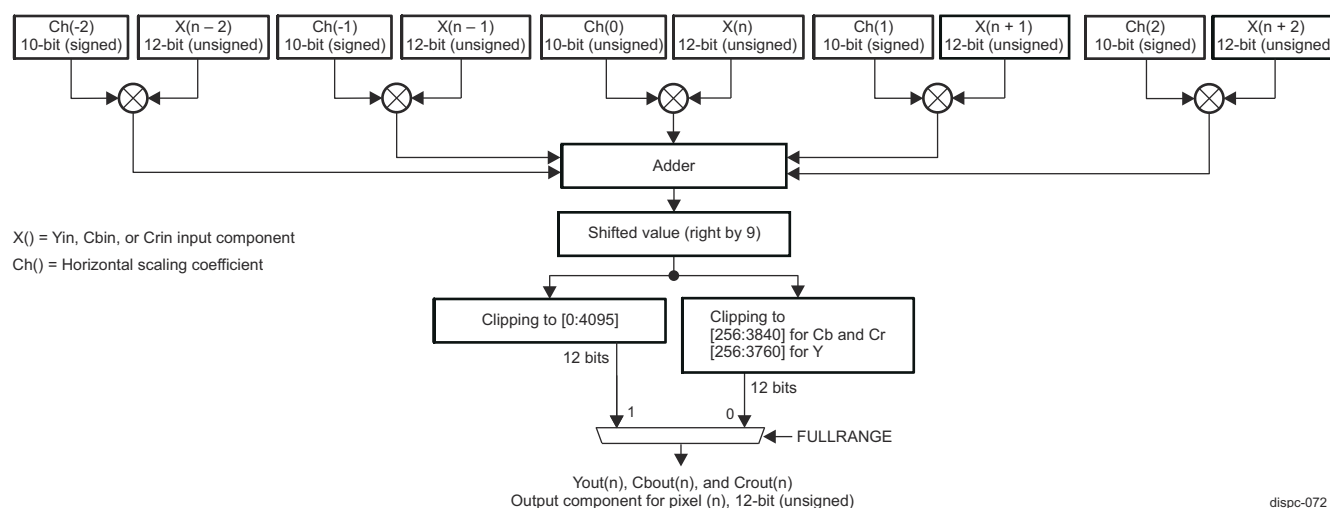

The scaling and CSC clipping is set by the same bit, DSS0\_VID\_ATTRIBUTES[11] FULLRANGE.

**Figure 12-348. DISPC VID Macro-Architecture of the Horizontal Scaling for A, R, G, and B Components (5-tap Restriction)**

**Figure 12-349. DISPC VID Macro-Architecture of the Vertical Scaling for A, R, G, and B Components (5 and 3 taps)**

**Figure 12-350. DISPC VID Macro-Architecture of the Horizontal Scaling for Y, Cr, and Cb Components (5-tap Restriction)**

**Figure 12-351. DISPC VID Macro-Architecture of the Vertical Scaling for Y, Cr, and Cb Components (5 and 3 taps)**

Table 12-340 list the register fields in the function of the coefficients for the VID horizontal scaler in the DSS0\_VID\_FIR\_COEF\_H0\_0 to DSS0\_VID\_FIR\_COEF\_H0\_8, and DSS0\_VID\_FIR\_COEF\_H12\_0 to DSS0\_VID\_FIR\_COEF\_H12\_15 registers.

**Note**

In Table 12-340, the cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DSS0\_VID\_FIR\_COEF\_V0\_0 to DSS0\_VID\_FIR\_COEF\_V0\_8, and DSS0\_VID\_FIR\_COEF\_V12\_0 to DSS0\_VID\_FIR\_COEF\_V12\_15 are used).

Similar table approach applies to the coefficients for Cb/Cr filtering in case of YUV format (registers DSS0\_VID\_FIR\_COEF\_H0\_C\_0 to DSS0\_VID\_FIR\_COEF\_H0\_C\_8, and DSS0\_VID\_FIR\_COEF\_H12\_C\_0 to DSS0\_VID\_FIR\_COEF\_H12\_C\_15, and DSS0\_VID\_FIR\_COEF\_V0\_C\_0 to DSS0\_VID\_FIR\_COEF\_V0\_C\_8 and DSS0\_VID\_FIR\_COEF\_V12\_C\_0 to DSS0\_VID\_FIR\_COEF\_V12\_C\_15 are used).

The VID scaler unit vertical and/or horizontal sampling is selected by configuring the DSS0\_VID\_ATTRIBUTES[8-7] RESIZEENABLE bit field.

Prior to enabling the video up/down-sampling block a valid configuration has to be set by the user. After configuring the required VID registers change the DSS0\_VP\_CONTROL[5] GOBIT register bit of the video port the video pipeline is associated with. The software has to wait before setting the GO bit that the hardware has reset the bit. The software reset is not recommended since the application cannot guarantee to be able to reset it before the HW.

The following fields define the configuration of the video up-sampling/down-sampling block in the VID pipeline for ARGB and YUV formats:

- Vertical upsampling and downsampling increment value in the [23-0] FIRVINC bit field of DSS0\_VID\_FIRV (for ARGB and Y) and DSS0\_VID\_FIRV2 (for CbCr) registers. The unsigned integer value range is  $2^{23}$ . Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left( \frac{MEMSIZEY+1}{SIZEY+1} \right)$$

dispc-066

- Horizontal upsampling and downsampling increment value in the [23-0] FIRHINC bit field of the DSS0\_VID\_FIRH (for ARGB and Y) and DSS0\_VID\_FIRH2 (for CbCr) registers. The unsigned integer value range is [1:16384]. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left( \frac{MEMSIZEH+1}{SIZEH+1} \right)$$

dispc-067

- Vertical up/downsampling accumulator value in the [23-0] VERTICALACCU bit field of the DSS0\_VID\_ACCUV\_0 and DSS0\_VID\_ACCUV\_1 (for ARGB and Y), and DSS0\_VID\_ACCUV2\_0 and DSS0\_VID\_ACCUV2\_1 (for CbCr) registers. The accumulator value indicates on which phase the vertical filtering starts. The DSS0\_VID\_ACCUV\_0 register is used for progressive output, while for interlace output both DSS0\_VID\_ACCUV\_0 and DSS0\_VID\_ACCUV\_1 registers are used. The DSS0\_VID\_ACCUV2\_0 and DSS0\_VID\_ACCUV2\_1 registers are used in the same manner for progressive or interlace output.
- Vertical upsampling and downsampling line buffer configuration via the DSS0\_VID\_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value in the [23-0] HORIZONTALACCU bit field of the DSS0\_VID\_ACCUH\_0 and DSS0\_VID\_ACCUH\_1 (for ARGB and Y), and DSS0\_VID\_ACCUH2\_0 and DSS0\_VID\_ACCUH2\_1 (for CbCr) registers. The accumulator value indicates on which phase the horizontal filtering starts. The register DSS0\_VID\_ACCUH\_0 is used for progressive output, while for interlace output both DSS0\_VID\_ACCUH\_0 and DSS0\_VID\_ACCUH\_1 registers are used. The DSS0\_VID\_ACCUH2\_0 and DSS0\_VID\_ACCUH2\_1 are used in the same manner for progressive or interlace output.

Table 12-341 lists the scaler vertical and horizontal accumulator values and phases.

**Table 12-341. DISPC VID Scaler Vertical and Horizontal Accumulator Phases**

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8

**Table 12-341. DISPC VID Scaler Vertical and Horizontal Accumulator Phases (continued)**

Accumulator Value (MSB bits)	Phases f
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling central coefficients are defined in the DSS0\_VID\_FIR\_COEF\_V0\_0 to DSS0\_VID\_FIR\_COEF\_V0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four CbCr, the vertical upsampling and downsampling central coefficients are set in DSS0\_VID\_FIR\_COEF\_V0\_C\_0 to DSS0\_VID\_FIR\_COEF\_V0\_C\_8 registers.
- Vertical upsampling and downsampling coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling coefficients are defined in the DSS0\_VID\_FIR\_COEF\_V12\_0 to DSS0\_VID\_FIR\_COEF\_V12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the vertical upsampling and downsampling coefficients are set in DSS0\_VID\_FIR\_COEF\_V12\_C\_0 to DSS0\_VID\_FIR\_COEF\_V12\_C\_15 registers.
- Horizontal upsampling and downsampling central coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling central coefficients are defined in the DSS0\_VID\_FIR\_COEF\_H0\_0 to DSS0\_VID\_FIR\_COEF\_H0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four CbCr, the horizontal upsampling and downsampling central coefficients are set in DSS0\_VID\_FIR\_COEF\_H0\_C\_0 to DSS0\_VID\_FIR\_COEF\_H0\_C\_8 registers.
- Horizontal upsampling and downsampling coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling coefficients are defined in the DSS0\_VID\_FIR\_COEF\_H12\_0 to DSS0\_VID\_FIR\_COEF\_H12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the horizontal upsampling and downsampling coefficients are set in DSS0\_VID\_FIR\_COEF\_H12\_C\_0 to DSS0\_VID\_FIR\_COEF\_H12\_C\_15 registers.

The YUV filtering is based on the equations of the ARGB filtering. In addition to the registers used for ARGB filtering configuration, a second set of registers for filtering is used. The first set of registers is used for Y configuration (instead of ARGB configuration) and the second set of registers is used for CbCr filtering configuration. The two sets of registers can be the same when the YUV format is not converted to RGB after filtering. When the RGB conversion is required after filtering, then the chrominance needs to be re-sampled with a different filtering configuration because:

- Chrominance samples are offset to the luminance samples. That is, DSS0\_VID\_FIRH2 and DSS0\_VID\_FIRV2, and DSS0\_VID\_ACCUV2\_0/DSS0\_VID\_ACCUV2\_1 and DSS0\_VID\_ACCUH2\_0/DSS0\_VID\_ACCUH2\_1 registers need to be configured differently than DSS0\_VID\_FIRH and DSS0\_VID\_FIRV, and DSS0\_VID\_ACCUH\_0/DSS0\_VID\_ACCUH\_1 and DSS0\_VID\_ACCUV\_0/DSS0\_VID\_ACCUV\_1 registers used for the luminance filtering.
- Chrominance is sub-sampled by two horizontally only in case of YUV422, and horizontally and vertically in case of YUV420. The coefficients for the vertical chrominance re-sampling are identical to the coefficients for

vertical luminance filtering in case of YUV422. The coefficients for the horizontal and vertical chrominance re-sampling are different than the ones for luminance filtering in case of YUV420.

#### 12.6.3.8.6 DISPC VID Color Space Conversion YUV to RGB

The Color Space Conversion (CSC) unit converts the video-encoded pixel values from YUV444 format into ARGB48 format (12-bit value per component A, R, G, and B, with A fixed at 0xFFFF).

In case of YUV420 or YUV422 formats, a chrominance resampling to YUV444 is performed before converting the YUV into RGB values (see [Section 12.6.3.8.4, DISPC VID Chrominance Resampling](#)). The YUV422/YUV420 to YUV444 chrominance resampling is a pre-processing to the color space conversion.

[Figure 12-352](#) and [Figure 12-353](#) show the  $3 \times 3$  11-bit coefficients used to convert from YUV444 into ARGB48. The value of A component is fixed at 0xFFFF in the output. The coefficients are set according to the standard used to encode the pixel data in YUV color space. [Table 12-342](#) summarizes the coefficients with their respective register bit fields.

**Table 12-342. DISPC VID CSC - YUV to RGB Register Settings**

Coefficients	Register Fields
$R_Y$	DSS0_VID_CSC_COEF0[10-0] C00
$R_{Cr}$	DSS0_VID_CSC_COEF0[26-16] C01
$R_{Cb}$	DSS0_VID_CSC_COEF1[10-0] C02
$G_Y$	DSS0_VID_CSC_COEF1[26-16] C10
$G_{Cr}$	DSS0_VID_CSC_COEF2[10-0] C11
$G_{Cb}$	DSS0_VID_CSC_COEF2[26-16] C12
$B_Y$	DSS0_VID_CSC_COEF3[10-0] C20
$B_{Cr}$	DSS0_VID_CSC_COEF3[26-16] C21
$B_{Cb}$	DSS0_VID_CSC_COEF4[10-0] C22
Y offset	DSS0_VID_CSC_COEF5[15-3] PREOFFSET1
Cr offset	DSS0_VID_CSC_COEF5[31-19] PREOFFSET2
Cb offset	DSS0_VID_CSC_COEF6[15-3] PREOFFSET3

- Limited data range conversion (video data range)

If the active range for the luminance samples (Y) is [256:3760] and for the chrominance samples (Cb and Cr) is [256:3840], the following equation in [Figure 12-352](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the DSS0\_VID\_ATTRIBUTES[11] FULLRANGE bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{Cr} & R_{Cb} \\ G_Y & G_{Cr} & G_{Cb} \\ B_Y & B_{Cr} & B_{Cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 256 \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-005

**Figure 12-352. DISPC VID CSC YCbCr to RGB Equation (Limited Data Range), 12-Bit Outputs**

In [Figure 12-352](#), the offset values (-256, -2048, -2048) are also programmed via corresponding register bit-fields shown in [Table 12-342, DISPC VID CSC - YUV to RGB Register Settings](#).

- Full data range conversion (graphics data range)

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], the following equation in [Figure 12-353](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the DSS0\_VID\_ATTRIBUTES[11] FULLRANGE bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{Cr} & R_{Cb} \\ G_Y & G_{Cr} & G_{Cb} \\ B_Y & B_{Cr} & B_{Cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-006

**Figure 12-353. DISPC VID CSC YCbCr to RGB Equation (Full Data Range), 12-Bit Outputs**

In [Figure 12-352](#) and [Figure 12-353](#), the offset values (0, -256, -2048) can be programmed via the corresponding register bit-fields shown in [Table 12-342](#), *DISPC VID CSC - YUV to RGB Register Settings*.

#### Note

In case of YUV420/YUV422-NV21 data, the coefficients for Cr and Cb must be swapped in order to correctly support YUV420/YUV422-NV21 format.

The scaling and CSC clipping is set by the same bit, DSS0\_VID\_ATTRIBUTES[11] FULLRANGE.

### Output Clipping

It is possible for the output results to be larger (overflow) than the maximum or smaller (underflow) than the minimum value the output representation supports. The Color Space Conversion module clips the overflow/underflow result to the maximum/minimum value as follows:

- FULLRANGE = 1 (Graphics range)
  - Maximum: 4095
  - Minimum : 0
- FULLRANGE = 0 (Video range)
  - Maximum: 3760 for Luma, 3840 for Chroma
  - Minimum: 256 for both Luma and Chroma

The FULLRANGE = 0 setting should only be used when the CSC logic is used to convert RGB to YCrCb and the output needs to be in the video data range.

For YCrCb to RGB conversion and other RGB to RGB processing, the FULLRANGE bit should be set to 1 to enable full data range in the output.

#### 12.6.3.8.7 DISPC VID Brightness/Contrast/Saturation/Hue Control

The brightness/contrast/saturation controls are implemented in the same Color Space Conversion (CSC) block by making adjustments to the conversion coefficients and input/output offset values as shown in [Figure 12-354](#):

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * B0 & m * k * C0 \\ m * A1 & m * k * B1 & m * k * C1 \\ m * A2 & m * k * B2 & m * k * C2 \end{bmatrix} \begin{bmatrix} Y + Y\_offset\_adj \\ Cr + Cr\_offset \\ Cb + Cb\_offset \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

dispc-101

**Figure 12-354. DISPC VID Brightness/Contrast/Saturation Equation for YUV to RGB**

In [Figure 12-354](#) the following terminology is used:

- A/B/C coefficients and the offset parameters are for YUV to RGB conversion. See [Table 12-343](#) below for coefficients and offsets mapping to register fields.
- The gain term (m) is used for contrast control. The allowed range is: 0 < m ≤ 2.0 (where m=1 means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is: 0 < k ≤ 2.0 (where k=1 means saturation bypass).
- The brightness offset (b) is added to Y\_offset\_adj. The allowed range (for 8-bit example) is: -128 ≤ b ≤ +127 (where b=0 means brightness bypass).

The hue adjustment can also be built into the above equation ([Figure 12-354](#)) to comprehend the following Cb/Cr hue angle adjustments:

$$Cb\_hue\_adj = (Cb * \cos \emptyset + Cr * \sin \emptyset)$$

$Cr\_hue\_adj = (Cr * \cos \emptyset - Cb * \sin \emptyset)$ , where  $\emptyset$  is the desired hue angle (with  $\emptyset=0$  meaning hue adjustment bypass)

The final combined matrix equation for controlling brightness/contrast/saturation/hue (BCSH) during YUV to RGB conversion is shown in [Figure 12-355](#)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * [B0 * \cos(Hue) + C0 * \sin(Hue)] & m * k * [C0 * \cos(Hue) - B0 * \sin(Hue)] \\ m * A1 & m * k * [B1 * \cos(Hue) + C1 * \sin(Hue)] & m * k * [C1 * \cos(Hue) - B1 * \sin(Hue)] \\ m * A2 & m * k * [B2 * \cos(Hue) + C2 * \sin(Hue)] & m * k * [C2 * \cos(Hue) - B2 * \sin(Hue)] \end{bmatrix} \begin{bmatrix} Y + Y\_offset\_adj \\ Cr + Cr\_offset \\ Cb + Cb\_offset \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

dispc-102

**Figure 12-355. DISPC VID Brightness/Contrast/Saturation/Hue Equation for YUV to RGB**

Gain and offset terms in the above equation ([Figure 12-355](#)) are programmed in the hardware registers as adjusted CSC coefficients (11-bit signed) and offset values (13-bit signed) to control the brightness, contrast, saturation and hue. Mapping of the coefficients and offsets to register fields is provided in [Table 12-343](#). Outputs are clipped to keep the output values in the proper range.

**Table 12-343. DISPC VID BCSH Register Settings for YUV to RGB**

Coefficients	Register Fields
A0	DSS0_VID_CSC_COEF0[10-0] C00
B0	DSS0_VID_CSC_COEF0[26-16] C01
C0	DSS0_VID_CSC_COEF1[10-0] C02
A1	DSS0_VID_CSC_COEF1[26-16] C10
B1	DSS0_VID_CSC_COEF2[10-0] C11
C1	DSS0_VID_CSC_COEF2[26-16] C12
A2	DSS0_VID_CSC_COEF3[10-0] C20
B2	DSS0_VID_CSC_COEF3[26-16] C21
C2	DSS0_VID_CSC_COEF4[10-0] C22
Y offset	DSS0_VID_CSC_COEF5[15-3] PREOFFSET1
Cr offset	DSS0_VID_CSC_COEF5[31-19] PREOFFSET2
Cb offset	DSS0_VID_CSC_COEF6[15-3] PREOFFSET3
R offset	DSS0_VID_CSC_COEF6[31-19] POSTOFFSET1
G offset	DSS0_VID_CSC_COEF7[15-3] POSTOFFSET2
B offset	DSS0_VID_CSC_COEF7[31-19] POSTOFFSET3

For RGB input formats, the same CSC block can be used to adjust contrast, brightness, saturation, and hue using the matrix equation from [Figure 12-356](#).

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * [B0 * \cos(Hue) + C0 * \sin(Hue)] & m * k * [C0 * \cos(Hue) - B0 * \sin(Hue)] \\ m * A1 & m * k * [B1 * \cos(Hue) + C1 * \sin(Hue)] & m * k * [C1 * \cos(Hue) - B1 * \sin(Hue)] \\ m * A2 & m * k * [B2 * \cos(Hue) + C2 * \sin(Hue)] & m * k * [C2 * \cos(Hue) - B2 * \sin(Hue)] \end{bmatrix} \begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

Coefficients a/b/c are related to A/B/C (for RGB to YUV and YUV to RGB conversions) as follows:

$$\begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} = \begin{bmatrix} A0 & B0 & C0 \\ A1 & B1 & C1 \\ A2 & B2 & C2 \end{bmatrix}^{-1}$$

dispc-103

**Figure 12-356. DISPC VID Brightness/Contrast/Saturation/Hue Equation for RGB Input**

In [Figure 12-356](#) the following specifics apply:

- A/B/C coefficients and the RGB offset parameters mapping to register fields is provided in [Table 12-343](#).

- The gain term (m) is used for contrast control. The allowed range is:  $0 < m \leq 2.0$  (where  $m=1$  means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is:  $0 < k \leq 2.0$  (where  $k=1$  means saturation bypass).
- The brightness is controlled by the RGB offset values.
- The Hue angle is used to adjust hue. Hue  $\emptyset=0$  means hue adjustment bypass.

Outputs are clipped to keep the output values in the proper range.

#### 12.6.3.8.8 DISPC VID Luma Key Support

The video pipeline supports Luma key transparency for Blue-ray video layer composition. When enabled, Y value of each pixel will be checked against luma key range values. The range values are defined in DSS0\_VID\_LUMAKEY register fields, as follows:  $[11-0] \text{ LUMAKEYMIN} < Y < [27-16] \text{ LUMAKEYMAX}$ . If this condition is true, then the pixel alpha value will be forced to zero (transparent) to make the pixel transparent during the blending process in the overlay manager.

#### 12.6.3.8.9 DISPC VID Cropping Support

At the output of the video pipeline a final crop stage is added which allows further cropping of the video window to the required dimensions. The crop feature is enabled by DSS0\_VID\_ATTRIBUTES[13] CROP register field and the cropping dimensions are further set by DSS0\_VID\_CROP[...] CROPLEFT/CROPTOP/CROPBOTTOM/CROPRIGHT register fields. Cropping of up to 31 pixels/lines is supported in every direction.

The crop feature is especially useful while dealing with the compressed frame buffer using the FBDC module, as explained in [Section 12.6.3.6.11, DISPC Compressed Data Format Support](#).

#### 12.6.3.9 DISPC Write-Back Pipeline

The write-back (WB) pipeline is used to store in the system memory the capture of the overlay output or the output of one of the pipelines. The WB pipeline consists of a CSC unit, a scaler unit, and an RGB truncation logic. The format from the overlay managers is always ARGB48. The format from the output of the VID pipeline can be YUV422, YUV420 or ARGB48. Because the overlay works on ARGB48 format and the video accelerator works on YUV format, the color space conversion from RGB to YUV is used to directly output to memory the format that can be encoded with no extra processing.

The write-back pipeline can be connected either to the VID pipeline output or to the output of one of the overlay managers, either in M2M (memory-to-memory) or Capture mode (see [Section 12.6.3.6.3, DISPC Write DMA Buffer](#)), by configuring the DSS0\_COMMON\_DISPC\_CONNECTIONS[20-16] WB\_CONN register field.

- In M2M mode, the pipeline or overlay manager connected to WB must not be connected to any VP.
- In Capture mode, the pipeline or overlay manager connected to WB must be connected to at least one VP.

The capture frame rate can be set in the DSS0\_WB\_ATTRIBUTES[26:24] CAPTUREMODE bit field.

The write-back pipeline also supports input source cropping to allow a sub-frame capture.

The ARGB48 format is truncated (LSB drop) or expanded to match the output color depth formats. No dithering on the output is supported. When there is no alpha field mentioned by x in the pixel format description, 0's shall be used. For example, for RGB12 pixel format the upper 4 bits are 0's since RGB value is only 12 bits inside a 16-bit container.

The WB pipeline is enabled by setting the DSS0\_WB\_ATTRIBUTES[0] ENABLE bit to 0x1.

[Figure 12-357](#) shows the WB pipeline.

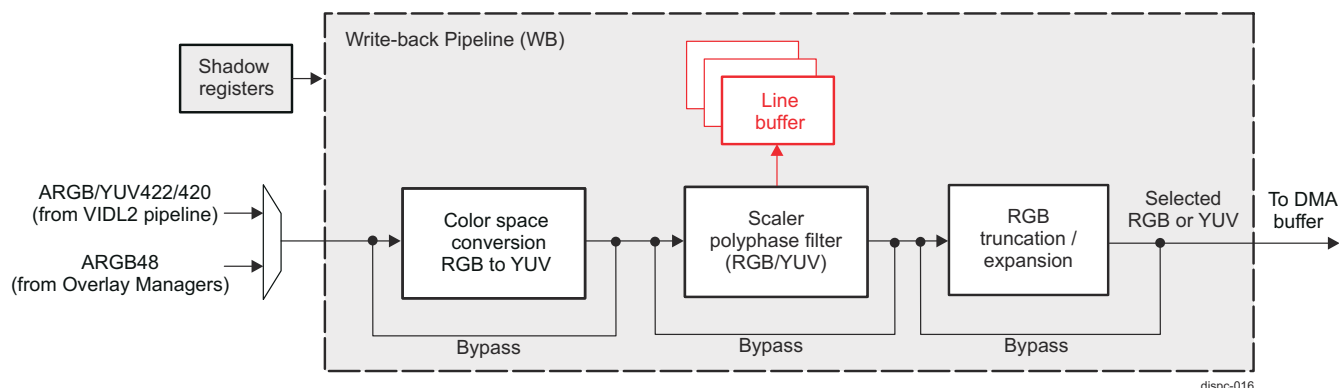

Figure 12-357. DISPC Write-Back Pipeline

#### 12.6.3.9.1 DISPC WB Color Space Conversion RGB to YUV

The WB CSC unit converts the encoded pixel values from RGB48 into YUV444 format. For YUV420 or YUV422 as output formats, a chrominance subsampling (YUV444 to YUV422, and YUV422 to YUV420) is performed in the WB scaler block after the CSC operation.

Figure 12-358 and Figure 12-359 show the  $3 \times 3$  11-bit coefficients used for the CSC operation. The user sets the coefficients according to the standard used to encode the pixel data in YUV color space. Table 12-344 lists the coefficients with their respective bit fields, together with the post offsets (that are 13-bit signed integer numbers).

Table 12-344. DISPC WB CSC - RGB to YUV Register Settings

Coefficients	Register Bit Fields
$Y_R$	DSS0_WB_CSC_COEF0[10:0] C00
$Y_G$	DSS0_WB_CSC_COEF0[26:16] C01
$Y_B$	DSS0_WB_CSC_COEF1[10:0] C02
$Cr_R$	DSS0_WB_CSC_COEF1[26:16] C10
$Cr_G$	DSS0_WB_CSC_COEF2[10:0] C11
$Cr_B$	DSS0_WB_CSC_COEF2[26:16] C12
$Cb_R$	DSS0_WB_CSC_COEF3[10:0] C20
$Cb_G$	DSS0_WB_CSC_COEF3[26:16] C21
$Cb_B$	DSS0_WB_CSC_COEF4[10:0] C22
$R_{POSTOFFSET}$	DSS0_WB_CSC_COEF6[31-19] POSTOFFSET1
$G_{POSTOFFSET}$	DSS0_WB_CSC_COEF7[15-3] POSTOFFSET2
$B_{POSTOFFSET}$	DSS0_WB_CSC_COEF7[31-19] POSTOFFSET3

#### Limited data range conversion (video data range)

If the active range for the 12-bit output luminance samples (Y) is to be [256:3760] and for the output chrominance samples (Cb and Cr) is to be [256:3840], then Figure 12-358 gives the equation (based on 11-bit coefficients) to convert the RGB to YUV. The range selection is done by setting the DSS0\_WB\_ATTRIBUTES[11] FULLRANGE bit to 0x0. The [256, 2048, 2048] offset values are programmable through the registers from Table 12-344.

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 256 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-017

Figure 12-358. DISPC WB CSC RGB to YCbCr Equation (Limited Data Range), 12-bit Outputs

## Full data range conversion (graphics data range)

If the active range for the output luminance samples (Y) and or the chrominance samples (Cb and Cr) is [0:4095], then [Figure 12-359](#) gives the equation (based on 11-bit coefficients) to convert the RGB to YUV. The [0, 2048, 2048] offset values are programmable through the registers from [Table 12-344](#).

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-018

**Figure 12-359. DISPC WB CSC RGB to YCbCr Equation (Full Data Range), 12-bit Outputs**

### 12.6.3.9.2 DISPC WB Scaler Unit

The functional aspect of the WB pipeline scaler unit is identical to the VID pipeline scaler unit (see [Section 12.6.3.8.5, DISPC VID Scaler Unit](#)), except that the WB scaler is 8-bit only and takes only the 8 most significant bits of the data fed through. The WB scaler, similarly to the one in the video pipeline, can perform scaling in the native ARGB, YUV422, or YUV420 formats. The support for scaling in YUV formats allows a YUV source to be scaled through video and write-back scalers without chroma up and downsampling, if the output is to remain in the same format. In addition, the scaling capability of VID and WB pipelines can be combined to double the maximum rescaling factor (applicable for memory-to-memory operations only).

The downscaling capability is further reduced, if the pipeline is doing a format conversion where downsampling is inherent. When doing RGB/YUV422-to-YUV420 conversion in WB pipeline, the downsampling capability of WB scaler is reduced to:

- If 5 taps is selected, then the downsampling is limited to 0.5 in RGB
- If 3 taps is selected, then no down-scaling is available

The write-back window attributes of the WB pipeline can be configured in the following register bit-fields:

- Source data format for write-back (input to the scaler unit) in DSS0\_WB\_ATTRIBUTES[6-1] FORMAT bit-field
- Start position (offset) of the window on the overlay which WB will capture in DSS0\_WB\_POSITION[29-16] POSY and [13-0] POSX register field. Only applicable when the WB pipeline is operating in capture\_mode.
- Write-back picture width in system memory (frame buffer) in DSS0\_WB\_PICTURE\_SIZE[13-0] MEMSIZEX bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed in the case of RGB16 and RGB24 video data. In the case of YUV2422 and UYVY422 formats the width has to be a multiple of 2 pixels.
- Write-back picture height in system memory (frame buffer) in DSS0\_WB\_PICTURE\_SIZE[29-16] MEMSIZEY bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed. In the case of YUV420 the height has to be a multiple of 2 lines.
- Write-back window width at pipeline input (before resizing) in DSS0\_WB\_SIZE[13-0] SIZEX bit-field. The window width is from 1 up to 4096 pixels. The width of the image sent to the write back pipe has to be a multiple of 2 pixels, if its format (input) is YUV420/YUV422.
- Write-back window height at pipeline input (before resizing) in DSS0\_WB\_SIZE[29-16] SIZEY bit-field. The window height is from 1 up to 4096 pixels. The width of the image sent to the write back pipe has to be a multiple of 2 lines, if its format (input) is YUV420.

### Note

The WB pipeline supports input source cropping to allow a sub-frame capture by specifying the offset position and the size of the sub-frame. With the offset position parameters (POSY, POSX) set to (0,0) and the size parameters (SIZEY, SIZEX) set to the full size, no clipping should be applied. The software must make sure that the clipping parameters are set up correctly to avoid going over the WB input frame boundaries. Otherwise, the pipeline may lock up.

[Table 12-345](#) list the register fields in the function of the coefficients for the VID horizontal scaler in the DSS0\_WB\_FIR\_COEF\_H0\_0 to DSS0\_WB\_FIR\_COEF\_H0\_8, and DSS0\_WB\_FIR\_COEF\_H12\_0 to DSS0\_WB\_FIR\_COEF\_H12\_15 registers.

**Table 12-345. DISPC Register Fields Associated to Coefficients for ARGB and Y Configuration in WB Horizontal Scaler**

Phases	Ch(2)	Ch(1)	Ch(0)	Ch(-1)	Ch(-2)
	Signed coefficient [29-20] FIRHC2 bitfield	Signed coefficient [19-10] FIRHC1 bitfield	Unsigned central coefficient [9-0] FIRHC0 bitfield	Signed coefficient [19-10] FIRHC1 bitfield	Signed coefficient [29-20] FIRHC2 bitfield

15	DSS0_WB_FIR_COEF_F_H12_15	DSS0_WB_FIR_COEF_F_H12_15	DSS0_WB_FIR_COEF_F_H0_1	DSS0_WB_FIR_COEF_F_H12_1	DSS0_WB_FIR_COEF_F_H12_1

### Note

In [Table 12-345](#), the cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DSS0\_WB\_FIR\_COEF\_V0\_0 to DSS0\_WB\_FIR\_COEF\_V0\_8, and DSS0\_WB\_FIR\_COEF\_V12\_0 to DSS0\_WB\_FIR\_COEF\_V12\_15 are used).

Similar table approach applies to the coefficients for Cb/Cr filtering in case of YUV format (registers DSS0\_WB\_FIR\_COEF\_H0\_C\_0 to DSS0\_WB\_FIR\_COEF\_H0\_C\_8, and DSS0\_WB\_FIR\_COEF\_H12\_C\_0 to DSS0\_WB\_FIR\_COEF\_H12\_C\_15, and DSS0\_WB\_FIR\_COEF\_V0\_C\_0 to DSS0\_WB\_FIR\_COEF\_V0\_C\_8 and DSS0\_WB\_FIR\_COEF\_V12\_C\_0 to DSS0\_WB\_FIR\_COEF\_V12\_C\_15 are used).

The WB scaler unit vertical and/or horizontal sampling is selected by configuring the DSS0\_WB\_ATTRIBUTES[8-7] RESIZEENABLE register bit field.

Prior to enabling the WB scaler a valid configuration has to be set by the user.

In case of capturing data of one of the output channels, the corresponding DSS0\_VP\_CONTROL[5] GOBIT bit has to be set to update the configuration depending to which VP output the write-back pipeline is associated with. Refers also to [Section 12.6.3.15, DISPC Shadow Mechanism for Registers](#) when write back channel is active. The SW has to wait before setting the GOBIT bit that the HW has reset the same bit. The DSS0\_WB\_ATTRIBUTES[0] ENABLE bit can be set to update those registers, if it has been previously disabled.

The following register fields define the configuration of the video up/downsampling block in the WB pipeline:

- Vertical up/downsampling increment value in the[23-0] FIRVINC bit field of DSS0\_WB\_FIRV (for ARGB and Y) and DSS0\_WB\_FIRV2 (for CbCr) registers. Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left( \frac{SIZEY+1}{MEMSIZEY+1} \right)$$

dispc-066

(25)

- Horizontal up/downsampling increment value in the [23-0] FIRHINC bit field of the DSS0\_WB\_FIRH (for ARGB and Y) and DSS0\_WB\_FIRH2 (for CbCr) registers. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left( \frac{SIZEX+1}{MEMSIZEX+1} \right)$$

dispc-067

(26)

- Vertical up/downsampling accumulator value in the [23-0] VERTICALACCU bit field of the DSS0\_WB\_ACCUV\_0 and DSS0\_WB\_ACCUV\_1 (for ARGB and Y), and DSS0\_WB\_ACCUV2\_0 and DSS0\_WB\_ACCUV2\_1 (for CbCr) registers. The accumulator value indicates on which phase the vertical filtering starts.
- Vertical upsampling and downsampling line buffer configuration via the DSS0\_WB\_ATTRIBUTES[21] VERTICALTAPS bit. The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value in the [23-0] HORIZONTALACCU bit field of the DSS0\_WB\_ACCUH\_0 and DSS0\_WB\_ACCUH\_1 (for ARGB and Y), and DSS0\_WB\_ACCUH2\_0 and DSS0\_WB\_ACCUH2\_1 (for CbCr) registers. The accumulator value indicates on which phase the horizontal filtering starts.

[Table 12-346](#) lists the DISPC vertical and horizontal accumulator values and phases. Other accumulator values are also supported. The HW determines the nearest phase value in order to load the corresponding one.

**Table 12-346. DISPC WB Scaler Vertical and Horizontal Accumulator Phases**

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3

Accumulator Value (MSB bits)	Phases f
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling central coefficients are defined in the DSS0\_WB\_FIR\_COEF\_V0\_0 to DSS0\_WB\_FIR\_COEF\_V0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four CbCr, the vertical upsampling and downsampling central coefficients are set in DSS0\_WB\_FIR\_COEF\_V0\_C\_0 to DSS0\_WB\_FIR\_COEF\_V0\_C\_8 registers.
- Vertical upsampling and downsampling coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling coefficients are defined in the DSS0\_WB\_FIR\_COEF\_V12\_0 to DSS0\_WB\_FIR\_COEF\_V12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the vertical upsampling and downsampling coefficients are set in DSS0\_WB\_FIR\_COEF\_V12\_C\_0 to DSS0\_WB\_FIR\_COEF\_V12\_C\_15 registers.
- Horizontal upsampling and downsampling central coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling central coefficients are defined in the DSS0\_WB\_FIR\_COEF\_H0\_0 to DSS0\_WB\_FIR\_COEF\_H0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four CbCr, the horizontal upsampling and downsampling central coefficients are set in DSS0\_WB\_FIR\_COEF\_H0\_C\_0 to DSS0\_WB\_FIR\_COEF\_H0\_C\_8 registers.
- Horizontal upsampling and downsampling coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling coefficients are defined in the DSS0\_WB\_FIR\_COEF\_H12\_0 to DSS0\_WB\_FIR\_COEF\_H12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the horizontal upsampling and downsampling coefficients are set in DSS0\_WB\_FIR\_COEF\_H12\_C\_0 to DSS0\_WB\_FIR\_COEF\_H12\_C\_15 registers.

The YUV filtering is based on the equations of the ARGB filtering. In addition to the registers used for ARGB filtering configuration, a second set of registers for filtering is used. The first set of registers is used for Y configuration (instead of ARGB configuration) and the second set of registers is used for CbCr filtering configuration. The two sets of registers can be the same when the YUV format is not converted to RGB after filtering. When the RGB conversion is required after filtering, then the chrominance needs to be re-sampled with a different filtering configuration because:

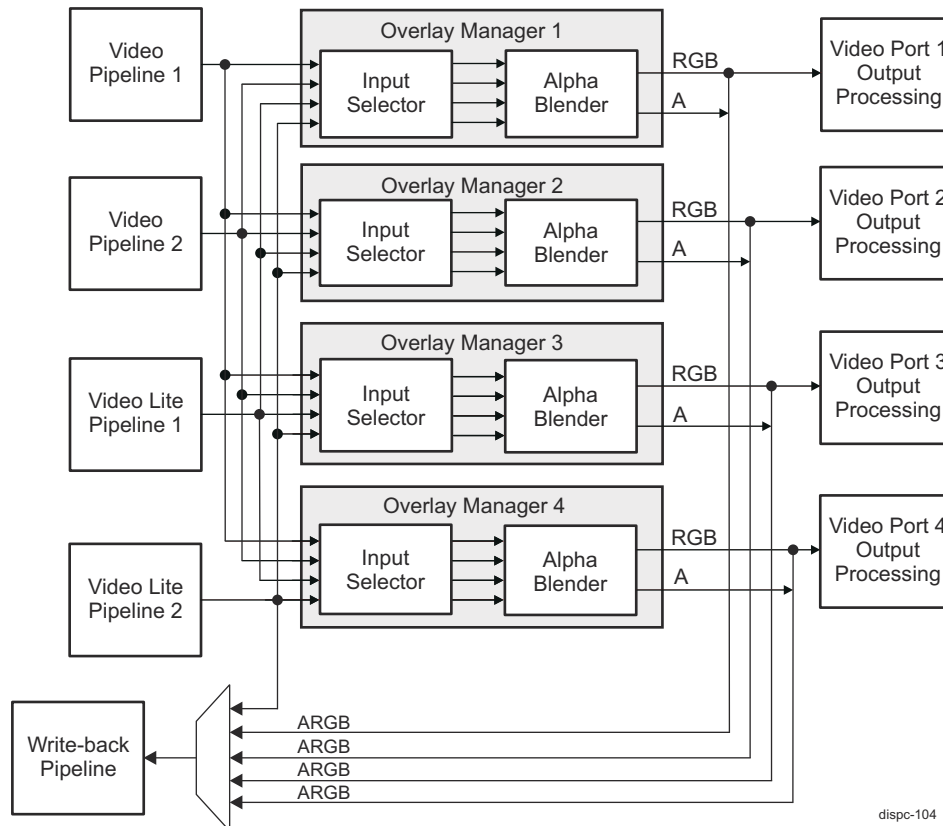

- Chrominance samples are offset to the luminance samples. That is, DSS0\_WB\_FIRH2 and DSS0\_WB\_FIRV2, and DSS0\_WB\_ACCUV2\_0/DSS0\_WB\_ACCUV2\_1 and DSS0\_WB\_ACCUH2\_0/DSS0\_WB\_ACCUH2\_1 registers need to be configured differently than DSS0\_WB\_FIRH and DSS0\_WB\_FIRV, and DSS0\_WB\_ACCUH\_0/DSS0\_WB\_ACCUH\_1 and DSS0\_WB\_ACCUV\_0/DSS0\_WB\_ACCUV\_1 registers used for the luminance filtering.
- Chrominance is sub-sampled by two horizontally only in case of YUV422, and horizontally and vertically in case of YUV420. The coefficients for the vertical chrominance re-sampling are identical to the coefficients for vertical luminance filtering in case of YUV422. The coefficients for the horizontal and vertical chrominance re-sampling are different than the ones for luminance filtering in case of YUV420.

#### 12.6.3.10 DISPC Overlay Manager

The overlay manager (OVR) is responsible for compositing selected input layers together to generate the final display output frame. The DISPC implements four identical overlay managers, one for each display output (see [Figure 12-319, DISPC Architecture Overview](#)). Any of these overlay managers can be used to source also the Write-back pipeline.

- OVR1 is connected to Video Port 1 (VP1).
- OVR2 is connected to Video Port 2 (VP2).
- OVR3 is connected to Video Port 3 (VP3).
- OVR4 is connected to Video Port 4 (VP4).

Each OVR is preceded by a programmable input pipeline selector which re-maps the output of the selected input pipelines according to the overlay manager Z-order configuration.

**Figure 12-360. DISPC Overlay Manager and Input Selector**

#### Note

The DISPC overlay managers, OVR1 through OVR4, will be commonly referred to as *overlay manager* (OVR) in the following sections.

##### 12.6.3.10.1 DISPC Overlay Input Selector

The overlay input selector before the overlay manager is a n-input to n-output crossbar switch. As such, any input can be connected to any output in the selector. The selection is based on the Z-order layer selection in the overlay configuration through the following register fields:

- DSS0\_OVR\_ATTRIBUTES\_0[4-1] CHANNELIN field for layer 0, Z-order 0
- DSS0\_OVR\_ATTRIBUTES\_1[4-1] CHANNELIN field for layer 1, Z-order 1
- DSS0\_OVR\_ATTRIBUTES\_2[4-1] CHANNELIN field for layer 2, Z-order 2
- DSS0\_OVR\_ATTRIBUTES\_3[4-1] CHANNELIN field for layer 3, Z-order 3
- DSS0\_OVR\_ATTRIBUTES\_4[4-1] CHANNELIN field for layer 4, Z-order 4

The z-order determines the order in which the selected layers are blended together to generate the final output by the overlay manager:

- The lowest enabled order input is the bottom-most layer, just above the background color
- The highest enabled order input is the top-most layer

The OVR input selector also passes the following attributes from the selected input pipeline to the corresponding selector output port (*zsel*):

- Source pipeline size attributes:
  - Number of pixels per line (from DSS0\_VID\_SIZE[13-0] SIZEX register field)
  - Number of lines (from DSS0\_VID\_SIZE[29-16] SIZEY register field)
- Source pipeline global blending level (from DSS0\_VID\_GLOBAL\_ALPHA register)

Then, the overlay manager uses the above listed attributes as input layer attributes along with POSX and POSY overlay manager configuration parameters. The POSX and POSY can be configured in the [13-0] POSX and [29-16] POSY fields of the following registers:

- For layer 0, Z-order 0, in DSS0\_OVR\_ATTRIBUTES2\_0 register
- For layer 1, Z-order 1, in DSS0\_OVR\_ATTRIBUTES2\_1 register
- For layer 2, Z-order 2, in DSS0\_OVR\_ATTRIBUTES2\_2 register
- For layer 3, Z-order 3, in DSS0\_OVR\_ATTRIBUTES2\_3 register
- For layer 4, Z-order 4, in DSS0\_OVR\_ATTRIBUTES2\_4 register

---

#### Note

The output of an input pipeline can be mapped to more than one overlay manager simultaneously, if and only if the following conditions are true:

- All video port timing generators controlling the overlay managers are identically programmed (same frame width/height with same blanking parameters running at same frame rate) and clocked by the same pixel clock source, AND ...
- The pipeline output is positioned on each display output at the same frame position, OR ...
- One of the overlay managers is connected to the write-back path only.

The software is responsible for managing the pipeline assignment and setting up the video port timing generators properly in order to avoid any resource conflicts that may cause the DISPC to lock up (sync loss).

---

#### 12.6.3.10.2 DISPC Overlay Mechanism

The overlay mechanism consists of displaying more than one input layer (graphics and/or video layers) using:

- A priority rule based on the display Z-order (selected by configuring the overlay input selector, as described in [Section 12.6.3.10.1](#))
- Transparency color keys configuration (destination and source transparency)
- Alpha blending values (using the alpha component of each pixel or a global alpha value set by the user)
- Size and position attributes of the source window data, as described in [Section 12.6.3.10.1](#)

The overlay manager is configured by using the Z-order parameter. The Z-order value defined for each pipeline indicates the visibility order of the window on the screen. If the Z-order value of window A is lower than the Z-order of layer B, then layer A is displayed below layer B. The transparency color keys and the alpha blending factors are then used to blend the layers together (see [Section 12.6.3.10.2.1, Overlay Alpha Blender](#), and [Section 12.6.3.10.2.2, Overlay Transparency Color Keys](#)).

[Figure 12-361](#) gives an simplified example of how two input pipeline frame outputs are merged together to generate the final display output.

**Figure 12-361. DISPC Overlay Example and Display Attributes**

As shown in [Figure 12-361](#), each input pipeline generates one rectangular sub-frame output in ARGB48 format. The overlay is responsible for positioning the sub-frame in the display output frame (specified by DSS0\_VP\_SIZE\_SCREEN[13-0] PPL and [29-16] LPP video port register fields), using the overlay window position parameters (specified by the [13-0] POSX and [29-16] POSY overlay fields in the DSS0\_OVR\_ATTRIBUTES2\_0 through DSS0\_OVR\_ATTRIBUTES2\_4 registers), and the window size parameters (specified by the [13-0] SIZEX and [29-16] SIZEY input pipeline fields in the DSS0\_VID\_SIZE registers). When the overlay manager does not require the input pipeline data (either because it is currently outputting the background color pixel or it is being stalled by the VP output module), the overlay manager stalls the input pipeline.

When there are no video-encoded pixels at a specific position, the programmable solid background color appears. The solid background color can be set in the DSS0\_OVR\_DEFAULT\_COLOR and DSS0\_OVR\_DEFAULT\_COLOR2 registers.

The entire pixels of the video window have to be inside the display screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width must be adjusted by software to limit the right edge of the window inside the display screen. The same is also true for the video layer height in the input pipe line configuration.

#### 12.6.3.10.2.1 Overlay Alpha Blender

The overlay manager can blend as many as four input pipelines using three cascaded stages of basically the same alpha-blending logic. Alpha output generation is supported only for the write-back path.

The alpha blending value is defined by:

- The component value A when using an ARGB or RGBA pixel format (alpha in the source pixel data is converted to 8-bit alpha value in the input pipeline logic):
  - For ARGB-1555, the alpha blending is defined using a 1-bit value. It is converted into an 8-bit value by duplicating the 1-bit value (see [Table 12-347](#)).
  - For ARGB-4444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value (see [Table 12-347](#)).
  - If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF, and if alpha is equal to 0xFF, there is no multiplication.
  - For BITMAP or YUV formats, there is no alpha blending factor associated with each pixel value. Only the global alpha blending factor associated with the window displaying the BITMAP or YUV format is used.
- The global alpha blending value can be set in the DSS0\_VID\_GLOBAL\_ALPHA register of the input pipeline, and is updated in synch with the selected output channel.
- The modulated alpha blending value (that is, a total alpha blending value, when a combination of the pixel alpha blending value A and a global alpha blending ia present) is determined as:  $\text{Alpha} = (\text{Pixel\_Alpha} \times \text{Global\_Alpha}) / 256$ .

[Table 12-347](#) shows the remapping and the percentage of alpha blending achieved.

**Table 12-347. DISPC Overlay Alpha Blending – ARGB**

Alpha Blending 1-Bit Value (ARGB16-1555)	Alpha Blending 4-Bit Value (ARGB16-4444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x0	0x00	100% (transparent)
N/A	0x1	0x11	93.33%
N/A	0x2	0x22	86.6%
N/A	...	...	...
N/A	0xE	0xEE	6.6%
0x1	0xF	0xFF	0% (opaque)

## Premultiplied Alpha and Alpha Output Generation

The source image in ARGB format may have its RGB component already premultiplied with the alpha (AR'G'B') where:

- $R' = A * R$
- $G' = A * G$
- $B' = A * B$

In that case, the processing is as follows:

- Color components of premultiplied layers are multiplied with the global alpha, if Global\_Alpha is not equal to 0.
- Color components of the composed underlying layer are multiplied with  $(1 - A * \text{Global\_Alpha})$ .

The premultiplied alpha option is accessible through the DSS0\_VID\_ATTRIBUTES[28] PREMULIPLYALPHA register bit of the input pipeline. The following settings are available:

- PREMULIPLYALPHA bit = 0: Source is not premultiplied with alpha. Full blending is done in the overlay manager.
- PREMULIPLYALPHA bit = 1: Source is premultiplied with alpha. Partial blending is done.

When the write-back channel copies back to memory the premultiplied color component, the the alpha value is computed as follows:

$$A(\text{dst}) = A(\text{src}) + (1 - A(\text{src}))A(\text{dst})$$

When the DSS0\_WB\_ATTRIBUTES[9] ALPHAENABLE register bit is cleared or when the overlay channel is not selected for write-back, the computation of the A(dst) is disabled.

### Note

There is no alpha blending between the background and the next layer (layer-0) above it.

Layer-0 cannot be pre-multiplied, if the overlay output is driving the display, since that layer (or the background color) defines the bottom most layer. In this case, layer-0 alpha is 1 always.

Layer-0 can have an alpha value other than 1 when the overlay output is only used to generate an intermediate layer composition result in a memory-to-memory operation (through the WB pipeline). But, if alpha is not 1, the resulting data will be "pre-multiplied". If a non-premultiplied data is required, the resulting overlay output must be fed through a Porter-Duff compositing engine to have the result divided by the overlay alpha output.

#### 12.6.3.10.2.2 Overlay Transparency Color Keys

The overlay manager supports two color transparency modes - source and destination. These modes cannot be active at the same time.

The source transparency is tied to the top most layer, so the layer to have this transparency applied to has to be mapped to the highest Z-ordered input (layer-4) of the overlay manager. The destination transparency is tied to the bottom most layer, so the layer to have this transparency applied to has to be mapped to the lowest Z-ordered input (layer-0) of the overlay manager.

The source and destination transparencies are defined as following:

- Source color transparency: Top layer pixel that meets the source transparency color check is made transparent.
- Destination color transparency: Top layer pixel is made transparent, only if the bottom layer pixel does not meet the destination transparency color check.

The transparency color key is enabled via the DSS0\_OVR\_CONFIG[10] TCKLCDENABLE register bit.

The minimum transparency color values are specified in the TRANSCOLORKEY field of the DSS0\_OVR\_TRANS\_COLOR\_MIN and DSS0\_OVR\_TRANS\_COLOR\_MIN2 registers.

The maximum transparency color values are specified in the TRANSCOLORKEY field of the DSS0\_OVR\_TRANS\_COLOR\_MAX and DSS0\_OVR\_TRANS\_COLOR\_MAX2 registers.

The transparency color key values defined in the registers are compared with the pixel values. If each color component (R, G, and B) is in the range defined by MIN and MAX, then there is a match. If at least one of the color component is not in the range, then there is no match.

#### • Source transparency color key

The values of the source transparency color key define the range of encoded pixel data considered as a transparent pixel. The encoded pixel values with the source color key value inside the valid range are not visible, and the encoded pixel values of the under layers or solid background color are visible.

The source transparency color key can be used with YUV and RGB formats (ARGB, RGB, RGBA, xRGB, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care, since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison, in case the original format is YUV.

The scaler can be enabled as a preprocessor in the video pipelines. The pixel scaling processing can be considered in order to define the color key value to be used after the rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the DSS0\_OVR\_CONFIG[11] TCKLCDSELECTION register bit to 0x1.

Figure 12-362 shows an example of source transparency color key usage. The pixels with the transparency color key are not displayed. Instead, pixels of the resulting layer underneath are shown.

**Figure 12-362. DISPC Overlay Source Transparency Color Key Example**

- **Destination transparency color key**

The destination transparency color key values define the range of the encoded pixels in layer-0 (bottom layer), which are not going to be displayed. That is, the encoded pixel values matching the destination color key value range are pixels not visible on the screen. Pixels at the same position in the layers above layer-0 are visible. The destination transparency color key is applicable in the layer in background position only when there is an overlap between the layer in background position and the layer just above it, otherwise, the destination transparency color key is ignored. See [Section 12.6.3.10.2, DISPC Overlay Mechanism](#), for details on layer position depending on the Z-order parameter.

The destination transparency color key can be used only with RGB formats (ARGB, RGB, xRGB, RGBA, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison in case the original format is YUV.

The scaler can be enabled as a preprocessor in the pipelines. The pixel scaling processing must be considered in order to define the color key value to be used after rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the DSS0\_OVR\_CONFIG[11] TCKLCDSELECTION register bit to 0x0.

[Figure 12-363](#) shows an example of the destination color key usage. The pixels from layer-0 (bottom layer) equal to the transparency color key are not displayed and are replaced by the pixels from layer-1 (top layer). All other layer-0 pixels, different from the transparency color key, are displayed over layer-1.

**Figure 12-363. DISPC Overlay Destination Transparency Color Key Example**

#### 12.6.3.10.3 Overlay 3D Support

In order to support S3D (Stereoscopic 3D) by combining in hardware left and right frames into the same output frame, the following configurations (defined by HDMI 1.4b standard specification) can be used:

- Separate pipeline mode: Left/Right or Top/Bottom. One layer is used for left/top and another layer is used for right/bottom.

#### 12.6.3.10.4 Overlay Color Bar Insertion

Each overlay manager supports a simple internal color bar insertion in each display output path to enable testing of display output interface without using the frame buffer data from the memory.

The colors are: White, Yellow, Cyan, Green, Magenta, Red, Blue, Black, as shown in below. These make three primary colors, three secondary colors, white, and black.

**Figure 12-364. DISPC Overlay Internal Color Bar**

When the DSS0\_OVR\_CONFIG[1] COLORBAREN register bit is set to 1, the overlay output data is replaced by the predefined ARGB48 color bar data.

When color bar mode is used, the color space conversion matrix should be appropriately programmed, so that it can convert the full-range RGB to the desired color format.

**Table 12-348. DISPC Overlay Color Bar Table**

Color	G	B	R
White	0xFFF	0xFFF	0xFFF
Yellow	0xFFF	0	0xFFF
Cyan	0xFFF	0xFFF	0
Green	0xFFF	0	0
Magenta	0	0xFFF	0xFFF
Red	0	0	0xFFF
Blue	0	0xFFF	0
Black	0	0	0

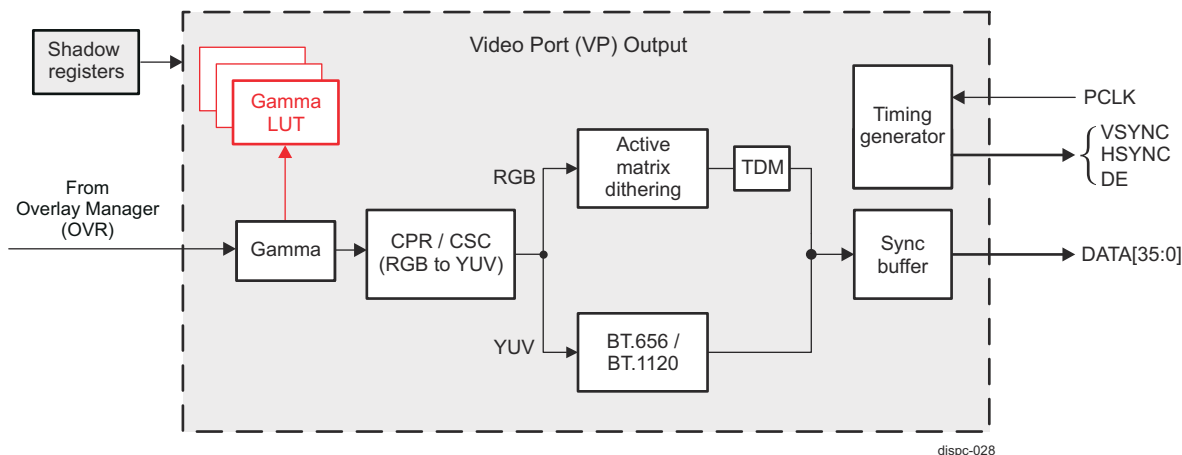

**12.6.3.11 DISPC Video Port Output**

The DISPC implements four identical Video Port (VP) outputs:

- VP1 processes data received from Overlay Manager 1 (OVR1)
- VP2 processes data received from Overlay Manager 2 (OVR2)
- VP3 processes data received from Overlay Manager 3 (OVR3)
- VP4 processes data received from Overlay Manager 4 (OVR4)

The VP output path consists of several processing blocks (see [Figure 12-365](#)):

- Gamma correction unit
- Color phase rotation (CPR) unit, also used for RGB to YUV color space conversion (CSC)
- Active matrix dithering with TDM (multiple cycle output format)
- BT.656/BT.1120 block
- Timing generator
- Async buffer

**Figure 12-365. DISPC VP Output Architecture**

The CSC processing can be configured to occur either before or after the gamma correction in the VP output module via the DSS0\_VP\_CONFIG[26] COLORCONVPOS register bit. For RGB to YUV color space conversion, the conversion must be done after the gamma correction. For other RGB output applications, the conversion must be done before the final gamma correction.

**Note**

The DISPC video port (VP) outputs, VP1 through VP4, will be commonly referred to as *video port (VP)* in the following sections.

### 12.6.3.11.1 DISPC VP Gamma Correction Unit

The VP supports a look up table to perform the gamma correction on the display output. The look up table consists of 3 separate 1024x10-bit memories, which are indexed by the R/G/B component data.

When performing gamma correction, the selected encoded pixel values from the video pipeline path are sent by the overlay manager to the gamma curve table. Each R/G/B component of the encoded pixel value is used as a pointer to index 1 out of 1024x30-bit gamma curve entries in the table. Each 10-bit component is replaced with the 10-bit table value corresponding to R, G, or B component. The table is loaded by software via the DSS0\_VP\_GAMMA\_TABLE\_0 through DSS0\_VP\_GAMMA\_TABLE\_15 registers. It is possible to load only part of the table.

The sequence to load the gamma table is:

1. SW writes (only writes are supported) 32-bit gamma correction values using single access, or burst access in linear increment burst mode, into the 64-byte region strating at DSS0\_VP\_GAMMA\_TABLE\_0 register address. The LSB 30 bits [29:0] are used for the value, and the MSB 1 bit [31] is used for resetting the index into the table at the end.
2. Loop to step #1, if there is a new access to the gamma table register. The software can access other registers between two accesses to the gamma table register.

Software needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the gamma table is activated by setting DSS0\_VP\_CONFIG[2] GAMMAENABLE register bit.

Figure 12-366 describes the format of one of the gamma curve values in the memory.

**Figure 12-366. DISPC VP Output Gamma Table Write Data Format**

### 12.6.3.11.2 DISPC VP Color Phase Rotation Unit

If required, a color phase rotation (CPR) processing can be applied on the "gamma" data before the spatial/temporal dithering.

The CPR can be selected to correct the non-pure white backlight of the display panel by using a programmable matrix to convert the 36-bit RGB pixel value into a new 36-bit RGB pixel value. The matrix is programmed through a set of nine 11-bit signed coefficients. The output of the calculation is clipped to [0:4095]. The CPR is enabled by setting the DSS0\_VP\_CONFIG[15] CPR bit to 0x1.

The CPR processing is expressed by the equation shown in Figure 12-367. Table 12-349 lists all coefficients with their respective register bitfields for configuration.

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_r & R_g & R_b \\ G_r & G_g & G_b \\ B_r & B_g & B_b \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dispc-023

**Figure 12-367. DISPC VP CPR Matrix**

**Table 12-349. DISPC VP CPR and CSC Coefficients with Associated Register Fields**

Register Field	Color Phase Rotation	Color Space Conversion RGB to YUV
DSS0_VP_CSC_COEF0[10-0] C00	RR	YR
DSS0_VP_CSC_COEF0[26-16] C01	RG	YG
DSS0_VP_CSC_COEF1[10-0] C02	RB	YB

**Table 12-349. DISPC VP CPR and CSC Coefficients with Associated Register Fields (continued)**

Register Field	Color Phase Rotation	Color Space Conversion RGB to YUV
DSS0_VP_CSC_COEF1[26-16] C10	GR	CrR
DSS0_VP_CSC_COEF2[10-0] C11	GG	CrG
DSS0_VP_CSC_COEF2[26-16] C12	GB	CrB
DSS0_VP_CSC_COEF3[10-0] C20	BR	CbR
DSS0_VP_CSC_COEF3[26-16] C21	BG	CbG
DSS0_VP_CSC_COEF4[10-0] C22	BB	CbB
DSS0_VP_CSC_COEF6[31-19] POSTOFFSET1	-	R offset
DSS0_VP_CSC_COEF7[15-3] POSTOFFSET2	-	G offset
DSS0_VP_CSC_COEF7[31-19] POSTOFFSET3	-	B offset

### 12.6.3.11.3 DISPC VP Color Space Conversion - RGB to YUV

The RGB to YUV color space conversion (CSC) in the video port is done by using the same programmable logic used for CPR. If CPR is also required, then the process can be combined with the CSC processing by adjusting matrix coefficients. Table 12-349 lists the associated coefficients with their respective register bit-fields. The CSC processing is enabled by setting the DSS0\_VP\_CONFIG[24] COLORCONVENABLE register bit.

The color space conversion can be selected in order to convert from 36-bit RGB to YUV444. The conversion matrix is programmed through a set of nine 11-bit signed coefficients. The result is clipped to [256:3760] for the luminance and [256:3840] for the chrominance, when a full-range YUV output is not desired (equivalent to clipping to [16..235] and [16..240] in 8-bit video). In this case the DSS0\_VP\_CONFIG[25] FULLRANGE register bit must be set to 0x0.

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 256 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-098

**Figure 12-368. DISPC VP CSC RGB to YUV Equation (FULLRANGE=0)**

If the programmed active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], then the values Y, Cb, and Cr are clipped to the range [0:4095]. The following equation gives the 11-bit coefficients of the RGB to YUV color space conversion, for full range (when DSS0\_VP\_CONFIG[25] FULLRANGE = 0x1).

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-099

**Figure 12-369. DISPC VP CSC RGB to YUV Equation (FULLRANGE=1)**

In order to provide YUV422 data to the BT.656 / BT.1120 block, the YUV444 format is further converted to YUV422 by sub-sampling the chrominance values. The hardware does this by averaging two-by-two the chrominance samples. The conversion from YUV444 to YUV422 is performed when the color space conversion in the VP is enabled.

#### 12.6.3.11.4 DISPC VP BT.656 and BT.1120 Modes

Each VP output can be configured in BT.656 or BT.1120 mode. The following standards are not supported in BT.656 mode:

- BT.470 (Support for conventional Analog TV Systems)
- BT.803 (The avoidance of interference generated by digital television studio equipment)
- BT.1364 (Format of ancillary data signals carried in digital component studio interfaces)
- BT.601 (Studio encoding parameters for digital TV standards for standard 4:3 and wide 16:9 aspect ratios)

Unsupported formats when BT.1120 mode is used:

- BT.1364 (Support for Ancillary Data during blanking period)
- BT.709 (Square pixel support)

BT.656/BT.1120 modes use embedded EAV/SAV syncs.

Enabling BT.656 or BT.1120 format for a VP output is done by setting DSS0\_VP\_CONFIG[20] BT656ENABLE or [21] BT1120ENABLE register bit, respectively

#### Note

It is not possible to enable BT.656 and BT.1120 modes simultaneously on the same VP output.

##### 12.6.3.11.4.1 DISPC BT Mode Blanking

During the transmission of the video signal, the portion of the stream in-between active video data segments is known as the horizontal blanking interval.

Strictly speaking this entire region is the blanking interval, but this interval also includes the EAV and SAV codes. The remaining bytes of information in a digital blanking interval are filled with values corresponding to the blanking levels of the Cb, Y and Cr signals respectively, and in accordance with the standard multiplex sequence for the stream (CbYCrY..). The blanking levels are as follows:

- Cb = 80h
- Y = 10h
- Cr = 80h.

The sequence in the BLANKING region of the data stream is therefore: 80h, 10h, 80h, 10h.....80h, 10h

For more details on setting the blanking timing values for BT.1120 and/or BT.656 mode, see [Section 12.6.3.11.8, DISPC VP Timing Generator and Display Panel Settings](#).

##### 12.6.3.11.4.2 DISPC BT Mode EAV and SAV

The End of Active Video (EAV) and Start of Active Video (SAV) parts of the stream are timing codes. Their function can be summarized as follows:

- EAV – marks the end of the active video data within the current line and therefore also the start of the subsequent line.
- SAV – heralds the start of the active video data within the current line.

These codes are embedded within the BT.656 video data stream, thereby eliminating the need for additional timing signals (HSYNC, VSYNC) to be included as part of the interface.

Both EAV and SAV codes are comprised of a sequence of four bytes ( FFh – 00h – 00h - XY). The first three bytes in the sequence constitute a fixed preamble. The fourth byte, contains information about the field being transmitted (Field 1 or Field 2 in an interlaced video signal), the state of field blanking (Vertical) and the state of line blanking (Horizontal). The bit assignment for this byte of the code is shown in [Figure 12-370](#), with the function of each bit described in [Table 12-350](#).

MSB							LSB
1	F	V	H	P3	P2	P1	P0

**Figure 12-370. DISPC BT Mode Bit-Assignment for the Fourth Byte of EAV/SAV Codes**

**Table 12-350. DISPC BT Mode Bit Function**

Bit	Symbol	Function
7	1	Always set to '1'.
6	F	Field bit. 0 – Field 1 1 – Field 2
5	V	Vertical Blanking Status bit. This bit goes High during a vertical field blanking interval, otherwise it remains Low.
4	H	Horizontal Blanking Status bit. 0 – byte is part of SAV code (i.e. stream is entering an active video data region for the current line) 1 – byte is part of EAV code (i.e. stream has entered a horizontal blanking interval - start of a new line)
3	P3	Protection bit 3
2	P2	Protection bit 2
1	P1	Protection bit 1
0	P0	Protection bit 0

The protection bits allow for detection and correction of 1-bit errors and the detection of 2-bit errors. The status of P3, P2, P1 and P0 depend on the states of bits F, V, and H. This dependency is shown in [Table 12-351](#).

**Table 12-351. DISPC BT Mode Status of Protection Bits in Function of F, V, and H**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

#### 12.6.3.11.5 DISPC VP Spatial/Temporal Dithering

The active spatial/temporal dithering logic can be enabled to minimize the color banding when displaying the data on a LCD panel with color depth lower than 24-bit. The dithering logic is integrated after the color/gamma conversion blocks and before the TDM (Time Division Multiplexing) block. The spatial/temporal dithering algorithm is based on the (x,y) pixel position and frame rate control (the value of removed bits and the frame number). The dithering logic can process the pixels over one frame, two frames, or four frames. The number of frames is selected by setting the DSS0\_VP\_CONTROL[31-30] SPATIALTEMPORALDITHERINGFRAMES register field. In the case of a single frame, only spatial processing is applied. In case of multiple frames, both spatial and temporal processing are applied to the pixels. The number of frame is initialized before enabling the spatial/temporal dithering logic. It must be never changed by the software while the spatial/temporal logic is enabled. The spatial/temporal dithering logic is enabled by setting the DSS0\_VP\_CONTROL[7] STDITHERENABLE bit to 0x1.

#### Note

- If the interface data bus is smaller than the pixel format size and the spatial/temporal dithering is not enabled, the MSBs of the pixel color components are output on the interface data bus.
- If the interface data bus is larger than the pixel format size, then by programming the pixel components replication active/inactive the MSB is replicated to the LSB of the interface data bus.

#### 12.6.3.11.6 DISPC VP Multiple Cycle Output Format (TDM)

The pixels (only RGB components) after the active matrix dithering unit are formatted on one or multiple cycles (from 1 to 3 cycles). On three cycles, two pixels can concatenate and send to the panel. The cycle format is

selected through the DSS0\_VP\_CONTROL[24-23] TDMCYCLEFORMAT bit field. The number of bits for each cycle is set in the DSS0\_VP\_DATA\_CYCLE\_0 register for the first cycle, the DSS0\_VP\_DATA\_CYCLE1 register for the second cycle, and the DSS0\_VP\_DATA\_CYCLE2 register for the third cycle. The output interface data bus width, when TDM mode is enabled (DSS0\_VP\_CONTROL[20] TDMENABLE register bit = 1), can be 8, 9, 12, or 16 bits, configurable through the DSS0\_VP\_CONTROL[22-21] TDMPARALLELMODE register field.

When the TDM is disabled (DSS0\_VP\_CONTROL[20] TDMENABLE = 0), the video port output interface data bus width is configured through the DSS0\_VP\_CONTROL[10-8] DATALINES register field.

When using TDM mode, only up to 24 bits per pixel can be output on the interface. For higher color depth, only the upper bits are kept before converting each pixel into TDM output.

Figure 12-371 through Figure 12-374 show various examples of TDM settings in the function of pixel data formats and the interface data bus width.

**Figure 12-374. DISPC VP TDM 16-Bit Interface Settings**

### 12.6.3.11.7 DISPC VP Stall Mode

The VP output can be programmed to operate in Stall Mode, where there is a stall handshake mechanism (back-pressure) with the display peripheral to which the VP is connected. No sync signals (HS, VS) are generated in Stall Mode of operation. Data and Enable (DE) signals are provided only when the stall signal is de-asserted (1'b0) by the peripheral. The Stall Mode can be enabled via the DSS0\_VP\_CONTROL[11] STALLMODE register bit.

### Note

In this SoC, the Stall Mode of operation is supported only on the VP outputs connected to the DSI peripheral module.

There are two types of data transfer, if Stall Mode is enabled, that can be selected by the DSS0\_VP\_CONTROL[12] STALLMODETYPE register bit:

- In DSI Video Mode, multiple frames are sent out on VP until the VP is disabled. A FRAMEDONE\_IRQ interrupt is generated at the end of each frame. No VSYNC\_IRQ interrupt is generated.
- In DSI Command Mode, a single frame is sent out on VP and the VP is auto disabled. A FRAMEDONE\_IRQ interrupt is generated at the end of frame. To transfer another frame in Command Mode, the user needs to re-enable the VP. No VSYNC\_IRQ interrupt is generated.

#### 12.6.3.11.8 DISPC VP Timing Generator and Display Panel Settings

Each video port output has a dedicated timing generator supporting progressive and interlaced modes. It is clocked using the pixel clock and is configured to generate the video data and sync signals to match the desired video display standard timings.

Two-level configuration for enabling the video ports exists:

- Via the individual DSS0\_VP\_CONTROL[0] ENABLE register bit for each VP. It allows each VP to be independently controlled by two different hosts.
- Via the common DSS0\_COMMON\_DISPC\_GLOBAL\_OUTPUT\_ENABLE[2-0] VP\_ENABLE register field. It allows two or more VP timing generators to be in sync by enabling them simultaneously with a single register write.

Both ENABLE and VP\_ENABLE register fields must be set in order for a VP (timing generator) to start.

Figure 12-375 shows the timing generator display parameters.

**Figure 12-375. DISPC VP Display Timing Parameters**

The width of VP output data bus is configured in the DSS0\_VP\_CONTROL[10-8] DATALINES register field, when TDM feature is disabled. When TDM is enabled, the width of the output data bus is defined according to [Section 12.6.3.11.6, DISPC VP Multiple Cycle Output Format \(TDM\)](#).

The size of the display panel is defined by:

- Number of lines per frame, DSS0\_VP\_SIZE\_SCREEN[29-16] LPP bit field
- Number of pixels per line, DSS0\_VP\_SIZE\_SCREEN[13-0] PPL bit field

Standard HSYNC/VSYNC timing generation is programmable as follows:

- Horizontal front porch is set in the DSS0\_VP\_TIMING\_H[19-8] HFP bit field.
- Horizontal back porch is set in the DSS0\_VP\_TIMING\_H[31-20] HBP bit field.
- Horizontal synchronization pulse width is set in the DSS0\_VP\_TIMING\_H[7-0] HSW bit field.
- Vertical front porch is set in the DSS0\_VP\_TIMING\_V[19-8] VFP bit field.
- Vertical back porch is set in the DSS0\_VP\_TIMING\_V[31-20] VBP bit field.
- Vertical synchronization pulse width is set in the DSS0\_VP\_TIMING\_V[7-0] VSW bit field.

When the output is in BT.1120 or BT.656 mode, the following timing constants are mapped onto the DSS0\_VP\_TIMING\_H and DSS0\_VP\_TIMING\_V registers:

- Progressive mode:
  - Horizontal blanking (12 bits) is set in the {DSS0\_VP\_TIMING\_V[3-0] VSW, DSS0\_VP\_TIMING\_H[7-0] HSW} register fields (up to 2048 bytes of horizontal blanking supported).
  - Vertical frame blanking No 1 is set in the DSS0\_VP\_TIMING\_V[19-8] VFP bit field.
  - Vertical frame blanking No 2 is set in the DSS0\_VP\_TIMING\_V[31-20] VBP bit field.
  - Number of lines per frame is set in the DSS0\_VP\_SIZE\_SCREEN[29-16] LPP bit field.
  - Number of pixels per line is set in the DSS0\_VP\_SIZE\_SCREEN[13-0] PPL bit field.
- Interlaced mode:
  - Horizontal blanking (12 bits) is set in the {DSS0\_VP\_TIMING\_V[3-0] VSW, DSS0\_VP\_TIMING\_H[7-0] HSW} register fields (up to 2048 bytes of horizontal blanking supported).
  - Vertical field blanking No.1 for Even Field is set in the DSS0\_VP\_TIMING\_H[19-8] HFP bit field.
  - Vertical field blanking No.2 for Even Field is set in the DSS0\_VP\_TIMING\_H[31-20] HBP bit field.
  - Vertical field blanking No.1 for Odd Field is set in the DSS0\_VP\_TIMING\_V[19-8] VFP bit field.
  - Vertical field blanking No.2 for Odd Field is set in the DSS0\_VP\_TIMING\_V[31-20] VBP bit field.
  - Number of lines per field (even) is set in the DSS0\_VP\_SIZE\_SCREEN[29-16] LPP bit field.
  - Delta number of odd field compared to even field (in a single line) is set in the DSS0\_VP\_SIZE\_SCREEN[15-14] DELTA\_LPP bit field. The DELTA\_LPP field only controls the output channel and not the size of the field fetched from the frame buffer in memory. This field must be set to zero for YUV420 format.
  - Number of pixels per line is set in the DSS0\_VP\_SIZE\_SCREEN[13-0] PPL bit field.

Horizontal/vertical synchronization and output enable signals polarity are programmable by setting the DSS0\_VP\_POL\_FREQ[12] IVS, [13] IHS, and [15] IEO register bits. These signals can be gated by setting the DSS0\_VP\_CONFIG[7] VSYNCGATED and [6] HSYNCGATED register bits. In addition, the alignment between VSYNC and HSYNC signals can be programmed via the DSS0\_VP\_POL\_FREQ[18] ALIGN register bit.

The latch of data can be driven on the rising or falling edge of the pixel clock by setting the DSS0\_VP\_POL\_FREQ[14] IPC register bit. The drive of the SYNC and VSYNC signals in the function of the pixel clock is done by setting the DSS0\_VP\_POL\_FREQ[16] RF bit.

Each VP output can be configured in progressive output mode or interlaced output mode. The selection is done by writing into the bit-field DSS0\_VP\_CONFIG[22] OUTPUTMODEENABLE register bit. The default setting is for progressive mode. The selection can be changed only when the corresponding VP output is disabled. The configuration is independent for each VP output. It is possible to change the configuration of one of the VP outputs while the other VP is enabled.

The pixel clock for each VP output can be gated by setting the DSS0\_VP\_CONFIG[5] PIXELCLOCKGATED register bit.

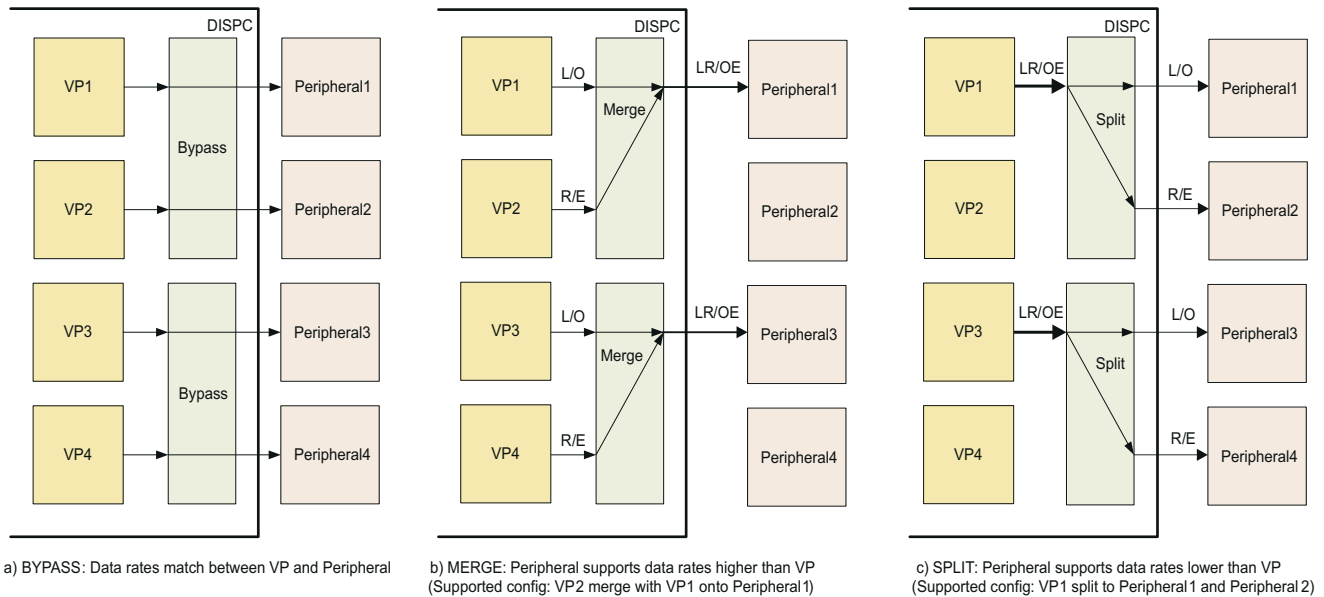

The hold time of the pixels on the data bus is determined in clock cycles by the DSS0\_VP\_CONTROL[16-14] HT register field.

#### 12.6.3.11.9 DISPC VP Merge-Split-Sync (MSS) Module

In order to interface with peripherals which can support a different data rate than the VP output, a Merge-Split-Sync (MSS) module is introduced between the VP outputs and DISPC final output. When interfacing with a peripheral which can support a higher data rate than the VP, two VP outputs can be merged to generate one

high data rate stream on the DISPC output (MERGE mode). When interfacing with a peripheral which requires dual physical links to support a high resolution video, one VP output can be split into two half data rate pixel streams on two separate DISPC outputs (SPLIT mode).

Both left/right (L/R) or odd/even (O/E) pixel selection types are supported.

**Figure 12-376. DISPC VP Merge-Split Scheme**

Additionally, the MSS module can also operate in a SYNC mode where two VP outputs get the same source pixel clock. The SYNC mode only affects the clock muxing and does not manipulate the data going out of each VP output.

Only the following configurations, as shown in [Figure 12-376](#), are supported:

- MERGE Mode
  - VP2 (Right/Even stream) merged with VP1 (Left/Odd stream) output onto Peripheral #1 (P1)
  - VP4 (Right/Even stream) merged with VP3 (Left/Odd stream) output onto Peripheral #3 (P3)
- SPLIT Mode
  - VP1 split into Peripheral #1 (P1)(Left/Odd stream) and Peripheral #2 (P2)(Right/Even stream)
  - VP3 split into Peripheral #3 (P3)(Left/Odd stream) and Peripheral #4 (P4)(Right/Even stream)
- SYNC Mode
  - VP1 and VP2 in sync and get the same pixel clock
  - VP3 and VP4 in sync and get the same pixel clock

The DSS0\_COMMON\_DISPC\_MSS\_VP1 and DSS0\_COMMON\_DISPC\_MSS\_VP3 registers control the MSS operation.

The MSS line buffers are sized to support up to 6K RGB30 video data. Therefore, in MERGE use-case, two 3K VP outputs can be merged to create a 6K output at DISPC. In SPLIT use-case, one 6K output can be split into two 3K outputs.

In both, MERGE and SPLIT use-cases, all the control signals (VS, HS, DE) are re-generated so as to match with the timing of the new merged frame or split frames.

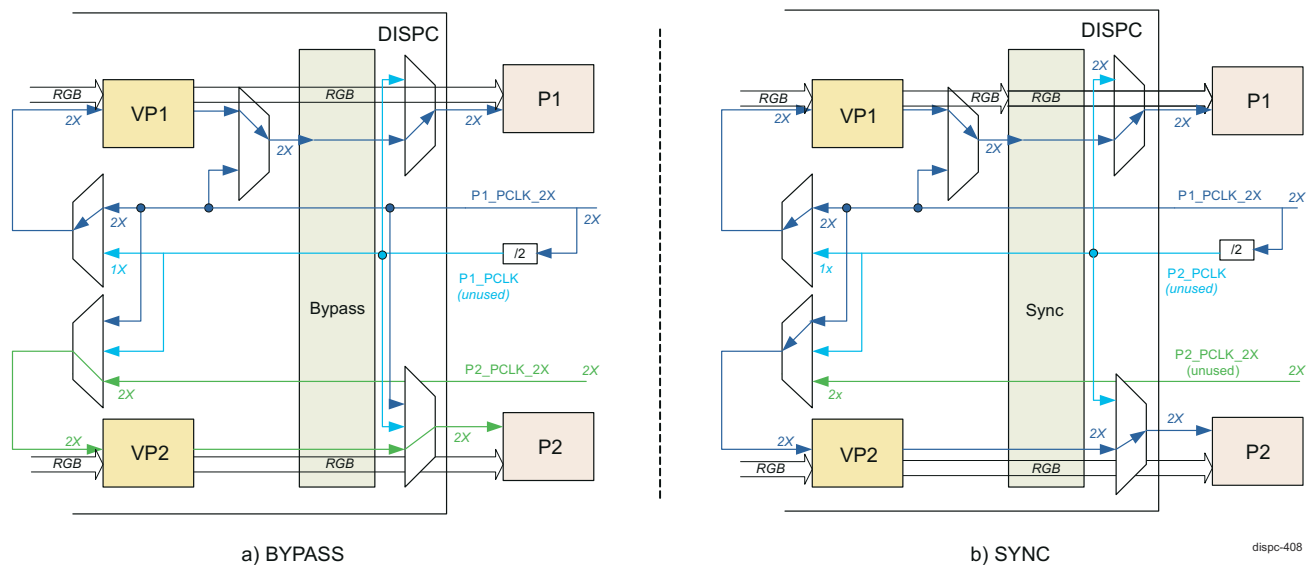

### Note

For Merge-Split-Sync mode of operation, the VP outputs need to be programmed to be active-high for the different signals (DE, VS, HS). For SPLIT mode of operation, it is required that the total number of pixels in a line is a multiple of 2. For both SPLIT mode and SYNC mode of operation, both the VP blocks need to be enabled at the same cycle. This is achieved by making a single write to the global enable register (DSS0\_COMMON\_DISPC\_GLOBAL\_OUTPUT\_ENABLE[3-0] VP\_ENABLE field).

When the DISPC is interfaced with the DP/eDP peripheral, the SPLIT mode corresponds to the Split (single stream transport) mode of operation of the DSC (Digital Stream Compression) sub-module within the EDP module. In this case, the two streams at half the pixel clock rate are first provided to DSC\_ENC0 and DSC\_ENC1 within the EDP. Then, the combined encoded stream is provided to the EDP MHDPTX Controller VIF0 port. The SYNC mode corresponds to the Dual (multi stream transport) mode of operation of the EDP module. In this case, the two streams at full pixel clock rate are provided to the EDP VIF0 and VIF1 ports (the EDP DSC has to be bypassed in this mode). For more details, see the EDP [Section 12.6.5.2.1](#), *Video Stream Clock/Data Muxing*.

#### 12.6.3.11.9.1 MSS Clocking Scheme

The pixel clocks going to the VPn as well as the pixel clocks going to the peripherals (Pn) will be different under different cases, depending on whether the output is in BYPASS, SYNC, MERGE or SPLIT mode. The different combinations of the clocks are as shown in [Figure 12-377](#) and [Figure 12-378](#).

**Figure 12-377. DISPC VP Clocking Scheme for MSS BYPASS and SYNC Modes**

**Figure 12-378. DISPC VP Clocking Scheme for MSS MERGE and SPLIT Modes**

Figure 12-378 show VP1 and VP2. Same clock scheme is applicable to VP3 and VP4.

For all cases in Figure 12-377 and Figure 12-378 there is no async interaction between P1\_PCLKs and P2\_PCLKs.

#### 12.6.3.11.9.2 MSS Merge with Scaling

Merge operation with scaling enabled in the VID pipelines can result in visual artifacts at the merged boundary. The artifacts can be avoided by scaling each half to a larger window size and then using the crop feature of the VID pipelines to get to the required size for each half.

#### 12.6.3.12 DISPC Internal Diagnostic Features

The DSS supports the following internal diagnostic features in DISPC hardware:

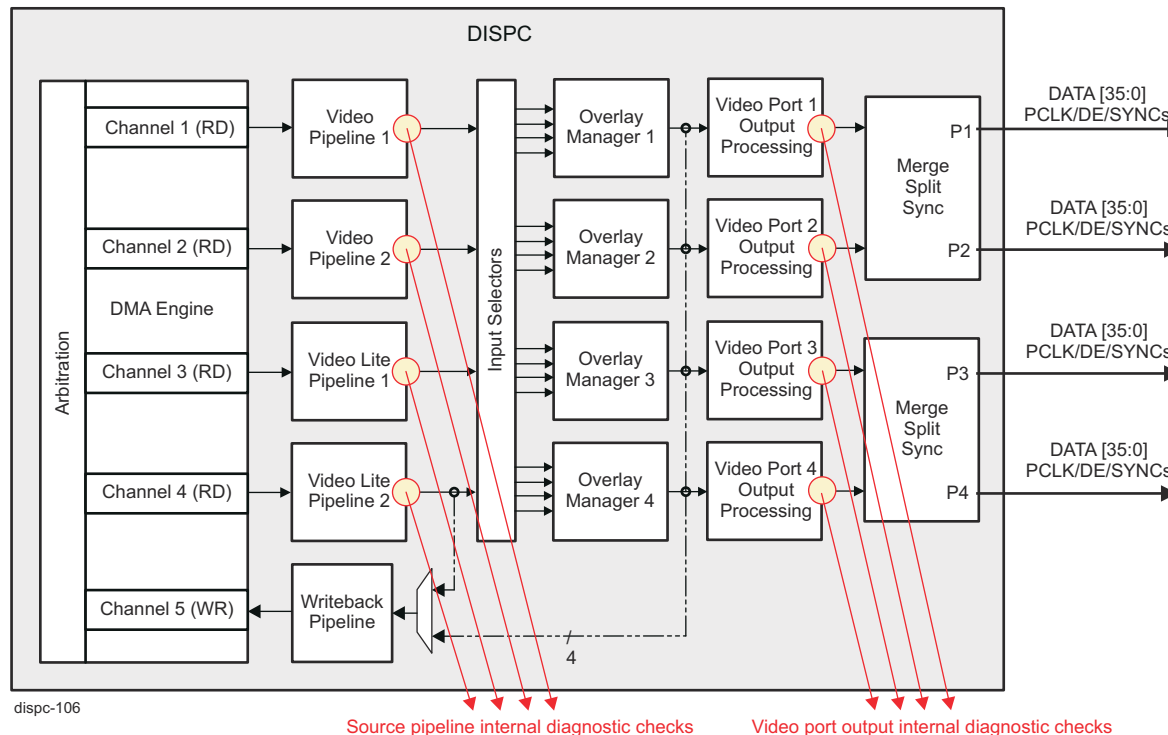

- Data correctness check: To verify intended data is shown correctly on the display.
- Freeze frame detection: To notify a possible frame freeze, when there is no change in the display frame over a multiple frame periods.

These features are implemented by collecting signatures from user-defined regions within each pipeline output frame and the final display output frame, and comparing them to reference signatures provided by the user (software) and/or to previously saved signatures. The signature from each region is generated by using a MISR (Multiple Input Signature Register) module.

### 12.6.3.12.1 Internal Diagnostic Check Regions

The DSS supports the following internal diagnostic check regions:

- Video pipelines: One internal diagnostic check region at the output of each video pipeline.
- Video port outputs: Up to eight internal diagnostic sub-regions within the active video output area of the final display output of each video port.

**Figure 12-379. DISPC Internal Diagnostic Check Regions**

Table 12-352 lists the parameters supported by each of the internal diagnostic check regions, together with the associated register control fields.

**Table 12-352. DISPC Internal Diagnostic Check Regions Parameters**

Internal Diagnostic Region Parameter	Video Pipeline Control Register	Video Port Sub-region m (m = 0 to 7) Control Register
X position	DSS0_VID_SAFETY_POSITION[11-0] POSX	DSS0_VP_SAFETY_POSITION_m[11-0] POSX
Y position	DSS0_VID_SAFETY_POSITION[27-16] POSY	DSS0_VP_SAFETY_POSITION_m[27-16] POSY
Width	DSS0_VID_SAFETY_SIZE[11-0] SIZEX	DSS0_VP_SAFETY_SIZE_m[11-0] SIZEX
Height	DSS0_VID_SAFETY_SIZE[27-16] SIZEY	DSS0_VP_SAFETY_SIZE_m[27-16] SIZEY

**Table 12-352. DISPC Internal Diagnostic Check Regions Parameters (continued)**

Internal Diagnostic Region Parameter	Video Pipeline Control Register	Video Port Sub-region m (m = 0 to 7) Control Register
Data Correctness Check Mode Enable	DSS0_VID_SAFETY_ATTRIBUTES[1] CAPTUREMODE	DSS0_VP_SAFETY_ATTRIBUTES_m[1] CAPTUREMODE
Freeze Frame Detection Mode Enable	DSS0_VID_SAFETY_ATTRIBUTES[1] CAPTUREMODE	DSS0_VP_SAFETY_ATTRIBUTES_m[1] CAPTUREMODE
Region Internal Diagnostic Check Enable	DSS0_VID_SAFETY_ATTRIBUTES[0] ENABLE	DSS0_VP_SAFETY_ATTRIBUTES_m[0] ENABLE
Freeze Frame Detection Threshold	DSS0_VID_SAFETY_ATTRIBUTES[10-3] THRESHOLD	DSS0_VP_SAFETY_ATTRIBUTES_m[10-3] THRESHOLD
Frames to Skip	DSS0_VID_SAFETY_ATTRIBUTES[12-11] FRAMESKIP	DSS0_VP_SAFETY_ATTRIBUTES_m[12-11] FRAMESKIP
Reference Signature	DSS0_VID_SAFETY_REF_SIGNATURE[31-0] SIGNATURE	DSS0_VP_SAFETY_REF_SIGNATURE_m[31-0] SIGNATURE
MISR Seed	DSS0_VID_SAFETY_LFSR_SEED[31-0] SEED	DSS0_VP_SAFETY_LFSR_SEED[31-0] SEED
MISR Seed Selection	DSS0_VID_SAFETY_ATTRIBUTES[2] SEEDSELECT	DSS0_VP_SAFETY_ATTRIBUTES_m[2] SEEDSELECT
MISR Captured Signature	DSS0_VID_SAFETY_CAPT_SIGNATURE[31-0] SIGNATURE	DSS0_VP_SAFETY_CAPT_SIGNATURE_m[31-0] SIGNATURE

Figure 12-380 shows examples of one internal diagnostic region in the video pipeline output stage and up to 8 possible regions in the final video port output stage.

**Figure 12-380. DISPC Internal Diagnostic Check Region Examples**

The internal diagnostic region in the video pipeline captures data, only if the embedded alpha data is not equal to 0 (that is, non-transparent pixels). The internal diagnostic regions in the display video port output captures all active video pixels within the region boundary. The regions (up to eight) in the display output should be typically non-overlapping areas of the screen, but the hardware does not restrict them to be non-overlapping.

Figure 12-381 shows the locations within DISPC data path where the data is analyzed.

**Figure 12-381. DISPC Internal Diagnostic Check Locations**

### 12.6.3.12.2 Internal Diagnostic Signature Generator Using MISR

A 32-bit multiple input signature register (MISR) with 32-bit Galois LFSR polynomial,  $P(x)=X^{32}+X^{22}+X^2+X+1$ , is used to capture a signature of active video pixel data (the 10 MSB bits of each color component) for each internal diagnostic region, as shown in Figure 12-382 and the algorithm below it.

**Figure 12-382. DISPC Internal Diagnostic 32-bit MISR Implementation**

The MISR (32-bit Galois LFSR based) signature generation algorithm is as follows:

Tap\_polynomial = 32'hE000\_0200

lfsr\_q = seed // initial LFSR value - any non-zero value should work

For each (pixel data in the internal diagnostic region) {

data\_in[31:0] = { 2'b0, r,g,b } // 10 MSB bits of R,G,B components

lfsr\_d = (data\_in << lfsr\_q >> 1)

If (lfsr\_q[0]) lfsr\_d = lfsr\_d ^ Tap\_polynomial

lfsr\_q = lfsr\_d

}

signature = lfsr\_q

All MISRs are initialized at the beginning of each frame with a non-zero "seed" value either with the default constant value (0xFFFF\_FFFF) or with the programmable seed configuration value in SAFETY\_LFSR\_SEED register for each group of regions (refer to Table 12-352, *DISPC Internal Diagnostic Check Regions Parameters*). Note that a same seed must be used to compare signatures between two frames. If different than the default seed value is desired, then a SEEDSELECT parameter must be set before the corresponding SAFETY\_LFSR\_SEED register is configured with the customer seed value.

All captured signatures from the internal diagnostic regions are memory mapped to read-only SAFETY\_CAPT\_SIGNATURE registers for each video port (refer to Table 12-352, *DISPC Internal Diagnostic Check Regions Parameters*). A SAFETY\_CAPT\_SIGNATURE register is updated with the signature from each sub-region at the end of every frame. This register returns the signature of the last frame data when the MISR is enabled. When MISR is disabled, this register is cleared.

The MISR aliasing (faulty signature matches fault-free signature) probability is:

$$(2^{(L-n)} - 1) / (2^L - 1) \approx 2^{(L-n)} / 2^L = 2^{-n} \text{ for large } L, \text{ where}$$

n = length of signature register

L = length of input sequence

Using the above approximation, the result is:

n=4, aliasing probability = 6.25%

n=16, aliasing probability = 0.0015%

...

n=32 (as in DISPC MISR), aliasing probability is  $\sim 2^{-32}$  (negligible)

#### 12.6.3.12.3 Internal Diagnostic Checks

If the data correctness check is enabled (see [Table 12-352](#), *DISPC Internal Diagnostic Check Regions Parameters*):

- When a new signature is generated, it is compared against the reference signature provided by the software. A SAFETY\_REF\_SIGNATURE register must be configured with a reference signature data, see [Table 12-352](#), *DISPC Internal Diagnostic Check Regions Parameters*.
- If signatures do not match, an interrupt event is generated to indicate data mismatch.

If the freeze frame detection is enabled (see [Table 12-352](#), *DISPC Internal Diagnostic Check Regions Parameters*):

- When a new signature is generated, it is first compared against the saved signature (from previous frame).
  - There exists a capability within the frame freeze detection logic to skip alternate frames during comparison. This feature is useful while handling ping-pong buffers or interlaced input video. This feature is controlled via the [12-11] FRAMESKIP field within a SAFETY\_ATTRIBUTES register.
- If signatures match, an internal counter used to keep track of the number of frames with no data change (for the region) is incremented.
- If signatures do not match, the counter is cleared.
- If the counter value is greater than the user programmed freeze frame detection threshold value (see [Table 12-352](#), *DISPC Internal Diagnostic Check Regions Parameters*), an interrupt event (VIDSAFETYREGION\_IRQ or VPSAFETYREGION\_IRQ, see [Section 12.6.3.5](#), *DISPC Interrupt Requests*) is generated to indicate a possible freeze frame detection. The threshold value must be configured with the maximum number of identical successive frames allowed before an interrupt is generated.
- After the comparison, the signature is saved as the previous signature.
- The counter is cleared when the interrupt event is generated or when freeze frame detection check is disabled.

This frame freeze is different from the display getting frozen due to pipeline lock up. In that case, the DISPC will generate an SYNCLOST\_IRQ and/or DMA VIDBUFFERUNDERFLOW\_IRQ interrupt. The freeze frame detection is for source data getting frozen while the DSS is working normally.

The two internal diagnostic checks are continuously performed over multiple frames as long as their mode enable register bits are set.

#### 12.6.3.12.4 Internal Diagnostic Check Limitations

The internal diagnostic check is only be available when the DISPC is outputting RGB/YUV component data with separate sync signals. The internal diagnostic functions are not available for the following output modes:

- YUV422 embedded sync modes (BT.656 and BT.1120)
- RGB TDM (Time Division Multiplex) mode

#### 12.6.3.13 DISPC Security Management

##### 12.6.3.13.1 Security Implementation

DSS supports the following security features:

- Secure mode configuration
- Illegal connection prevention

#### Secure Mode

The DISPC supports secure mode configuration registers (DSS0\_VID\_SECURE, DSS0\_WB\_SECURE, DSS0\_OVR\_SECURE and DSS0\_VP\_SECURE) which defines the "secure mode" attribute of each pipeline, overlay manager, and video port instance in DISPC. These registers can only be modified by a host with an appropriate secure privilege (MReqSecure=1). When the SECURE bit corresponding to an instance is set by a secure host, the instance is deemed to be in "secure mode" and the DISPC hardware prevents the output of the

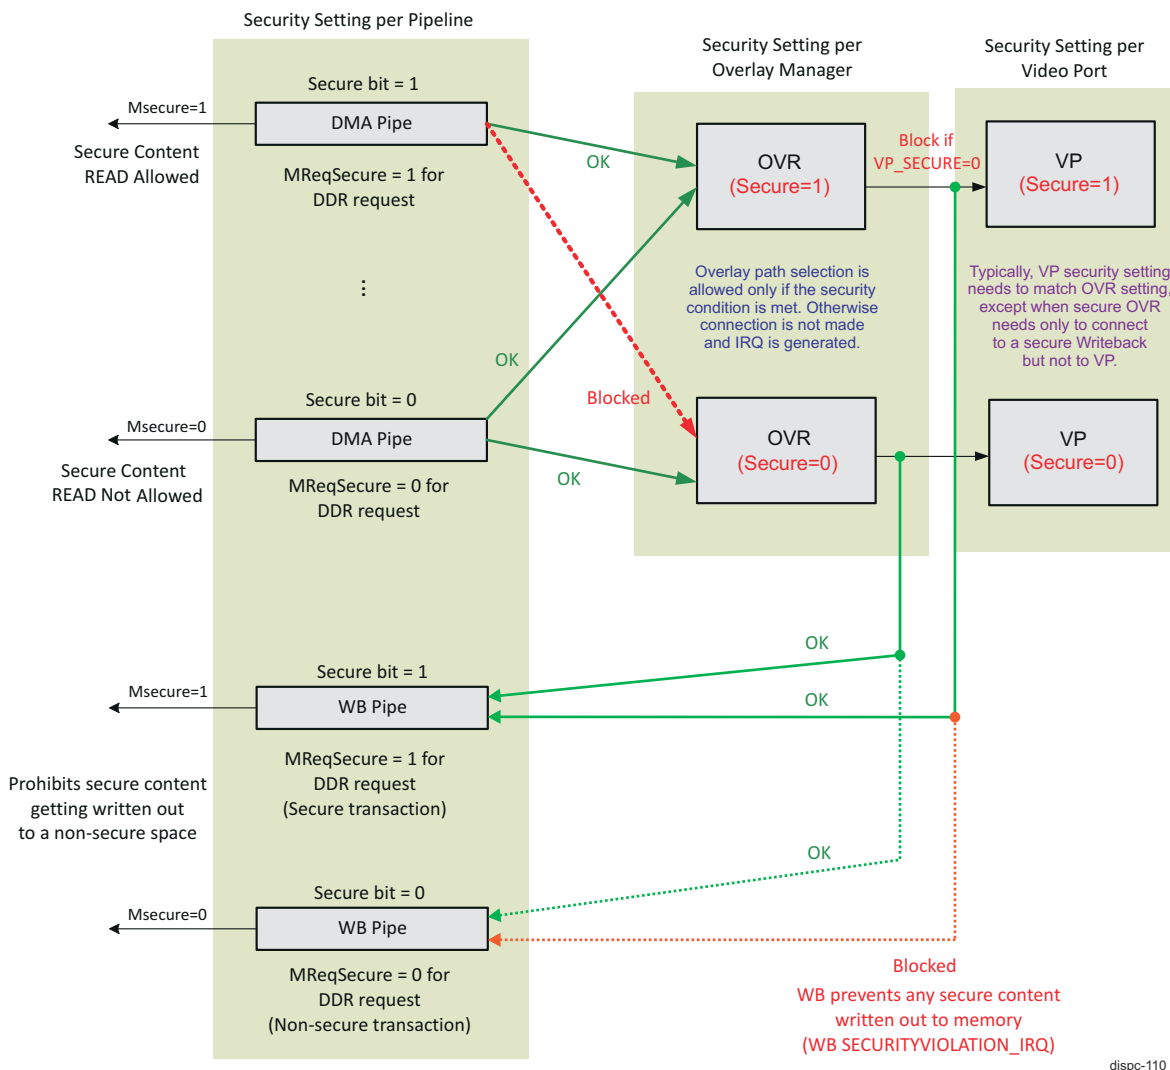

instance getting connected to a non-secure downstream module. Also, any DMA transfer initiated by a secure pipeline will have its OCP in-band signal MReqSecure set to HIGH to indicate that is a secure mode transaction request.

By default, all pipelines, overlay managers, and video ports are in a "non-secure mode". The corresponding SECURE bits in the DSS0\_VID\_SECURE, DSS0\_WB\_SECURE, DSS0\_OVR\_SECURE and DSS0\_VP\_SECURE registers are active, only when the DSS0\_COMMON\_DISPC\_SECURE\_DISABLE[0] SECURE\_DISABLE register bit is configured properly to 0x0. When the SECURE\_DISABLE bit is set to 0x1, the SECURE register bits are non-active and DISPC will behave as non-secure module.

### Illegal Connection Prevention

The DISPC hardware enforces the following rules to prevent an illegal connection:

- Secure input pipeline can only connect to a secure overlay manager: If any host (secure or non-secure) configures an overlay manager input selection to connect a secure input pipeline to a non-secure overlay manager, then the DISPC hardware will block the connection and issue a "security violation" interrupt (SECURITYVIOLATION\_IRQ) to alert the host.
- Non-Secure WB pipeline can take its input only from a non-secure input pipeline or a non-secure overlay manager output. Otherwise, the DISPC hardware will block the data transfer through WB and issue a "security violation" interrupt to alert the host.
- Non-Secure video port can only display data from a non-secure overlay manager output. Otherwise, the DISPC hardware will block the data display on the video port and issue a "security violation" interrupt to alert the host.

dispc-110

**Figure 12-383. DISPC Secure Bit Setting and Illegal Connection Block**

#### 12.6.3.13.2 Secure Mode Configuration

The SECURE bit in DSS0\_VID\_SECURE, DSS0\_WB\_SECURE, DSS0\_OVR\_SECURE and DSS0\_VP\_SECURE registers is set/reset by a secure transaction. When the SECURE bit has been set, the software in "secure mode" is responsible for checking the DISPC configuration. The SECURE bit is propagated by DISPC to the system Interconnect in order to qualify all DISPC requests as secure or non-secure requests, based on the secure bits defined in the control register.

When DISPC accesses the frame buffer, in the case the SECURE bit has been reset and the frame buffer has been set secure, the DISPC will receive an "error" in response of non-secure requests.

#### 12.6.3.14 DISPC Resources Sharing

For resource sharing of sub-components across different hosts processors or virtual machines, the DISPC implements the following features:

- Register region in memory per sub-component
- Interrupt duplication
- Independent context update for pipelines
- CHANNELID support

### 12.6.3.14.1 Register Region per Sub-component

The DISPC register regions in memory are partitioned such that each DISPC sub-component has its own region as shown in [Table 12-353](#). This allows the SoC infrastructure to firewall the register memory regions in such a way that a particular processor host or virtual machine can only access the sub-component(s) allocated to it.

**Table 12-353. DISPC Register Memory Region Partitioning**

Region Name	Description	Byte Offset
DISPC_0_COMMON_M	COMMON Region for Master Host (Control Processor)	0x0
DISPC_0_COMMON_S0	COMMON Region for Slave Host-0	0x10000
VIDL1	Video Lite 1 Pipeline	0x20000
VIDL2	Video Lite 2 Pipeline	0x30000
VID1	Video 1 Pipeline	0x50000
VID2	Video 2 Pipeline	0x60000
OVR1	Overlay 1	0x70000
VP1	Video Port 1	0x80000
OVR2	Overlay 2	0x90000
VP2	Video Port 2	0xA0000
OVR3	Overlay 3	0xB0000
VP3	Video Port 3	0xC0000
OVR4	Overlay 4	0xD0000
VP4	Video Port 4	0xE0000
WB	Write-Back Pipeline	0xF0000
DISPC_0_COMMON_S1	COMMON Region for Slave Host-1	0x100000
DISPC_0_COMMON_S2	COMMON Region for Slave Host-2	0x110000

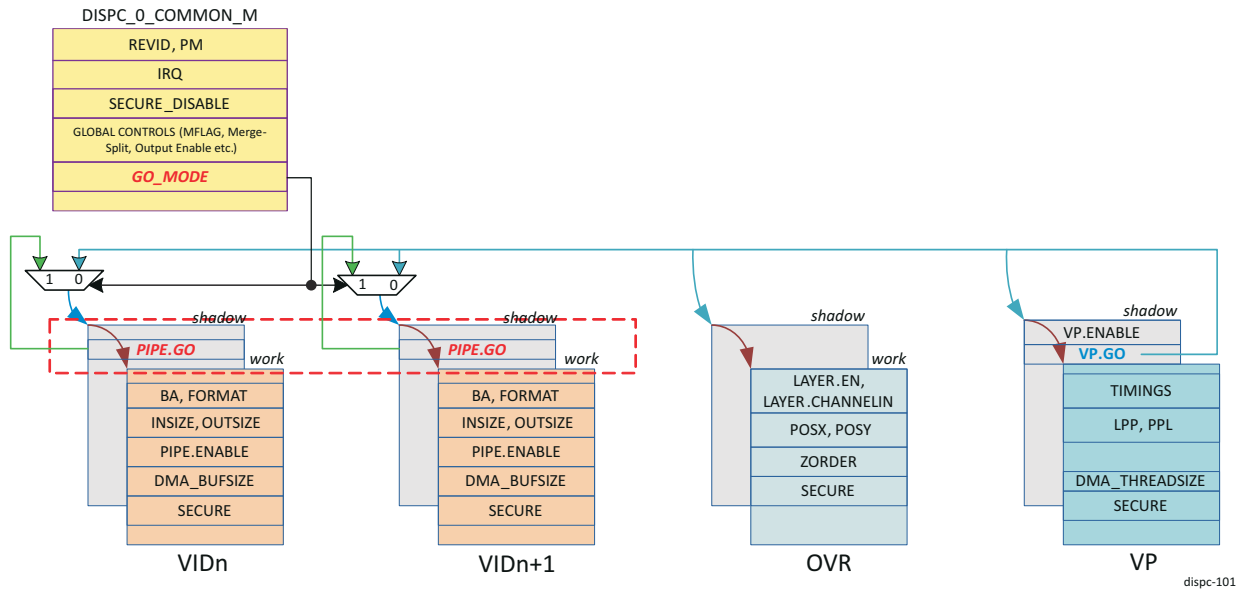

### 12.6.3.14.2 Interrupt Duplication

The DISPC supports multiple interrupt outputs, each of which can be set up independently of the other. There are also separate interrupt lines for different category of events such as functional, internal diagnostic error, and secure. This allows fully independent monitoring/control of the interrupt events by multiple hosts (up to 4). For more details on interrupts, see [Section 12.6.3.5, DISPC Interrupt Requests](#).

### 12.6.3.14.3 Independent Context Update for Pipelines

The DISPC supports use-cases where portions of a single display (driven out of single OVR and VP) are controlled by multiple host processors (or virtual machines). In such a case, having a single GO bit per VP (display output) would result in partial updates of a particular pipeline register configuration on a frame boundary. The DISPC provides the additional capability to sync register configurations of each pipeline independently to a chosen frame boundary. This is achieved by setting the <PIPE> GO bit.

When the DSS0\_COMMON\_GLOBAL\_GOBITMODE[0] MODE register bit is set, the individual pipeline register configurations are synced (shadow to work copy) only on frame boundaries where the DSS0\_VID\_PIPE\_GO[0] GOBIT register bit of each used pipeline is set. The scheme is as shown in [Figure 12-384](#).

**Figure 12-384. DISPC PIPE GO Bit Implementation**

#### 12.6.3.14.4 CHANNELID Support

In order to support IO virtualization that allows control of different DISPC pipes by different hosts, the DISPC pipelines must be identifiable on the SoC system interconnect with different channel IDs. To achieve this, every read and write transaction out of the DISPC DMA is tagged with a CHANNELID. The SoC infrastructure then uses the CHANNELID to set the various parameters (address translation, priority, security, etc.) on a per-channel basis.

The LSB bit of the CHANNELID (that is, CHANNELID[0]) is always used to differentiate between the two planes when a pipe is fetching a 2-plane pixel format (for example, YUV420-NV12). When the pipeline is fetching a 1-plane pixel format, the LSB bit is always '0'. The mapping of the MSB bits of the CHANNELID is as shown in Table 12-354.

**Table 12-354. DISPC CHANNELID Mapping**

CHANNELID[m:1]	Pipeline Mapping
0	VID1
1	VIDL1
2	VID2
3	VIDL2
4	WB

#### 12.6.3.15 DISPC Shadow Mechanism for Registers

Some DISPC registers are termed *shadow registers*. The shadow registers allow the software to modify them at any time, without direct effect on the DISPC hardware configuration. When all the values for a given configuration are written into the shadow registers, software must set only one register bit to validate the configuration. When the hardware reaches the end of the current frame and sees that the bit has been set by software, the new configuration is now the configuration used by the hardware.

The DSS0\_VP\_CONTROL[5] GOBIT bit enables the hardware to use the new configuration, for all shadow registers associated with each VP output.

The registers are statically associated to a particular output (for example, timing registers) or dynamically associated to one output at a time (for example, video registers).

## 12.6.4 MIPI Display Serial Interface (DSI) Controller

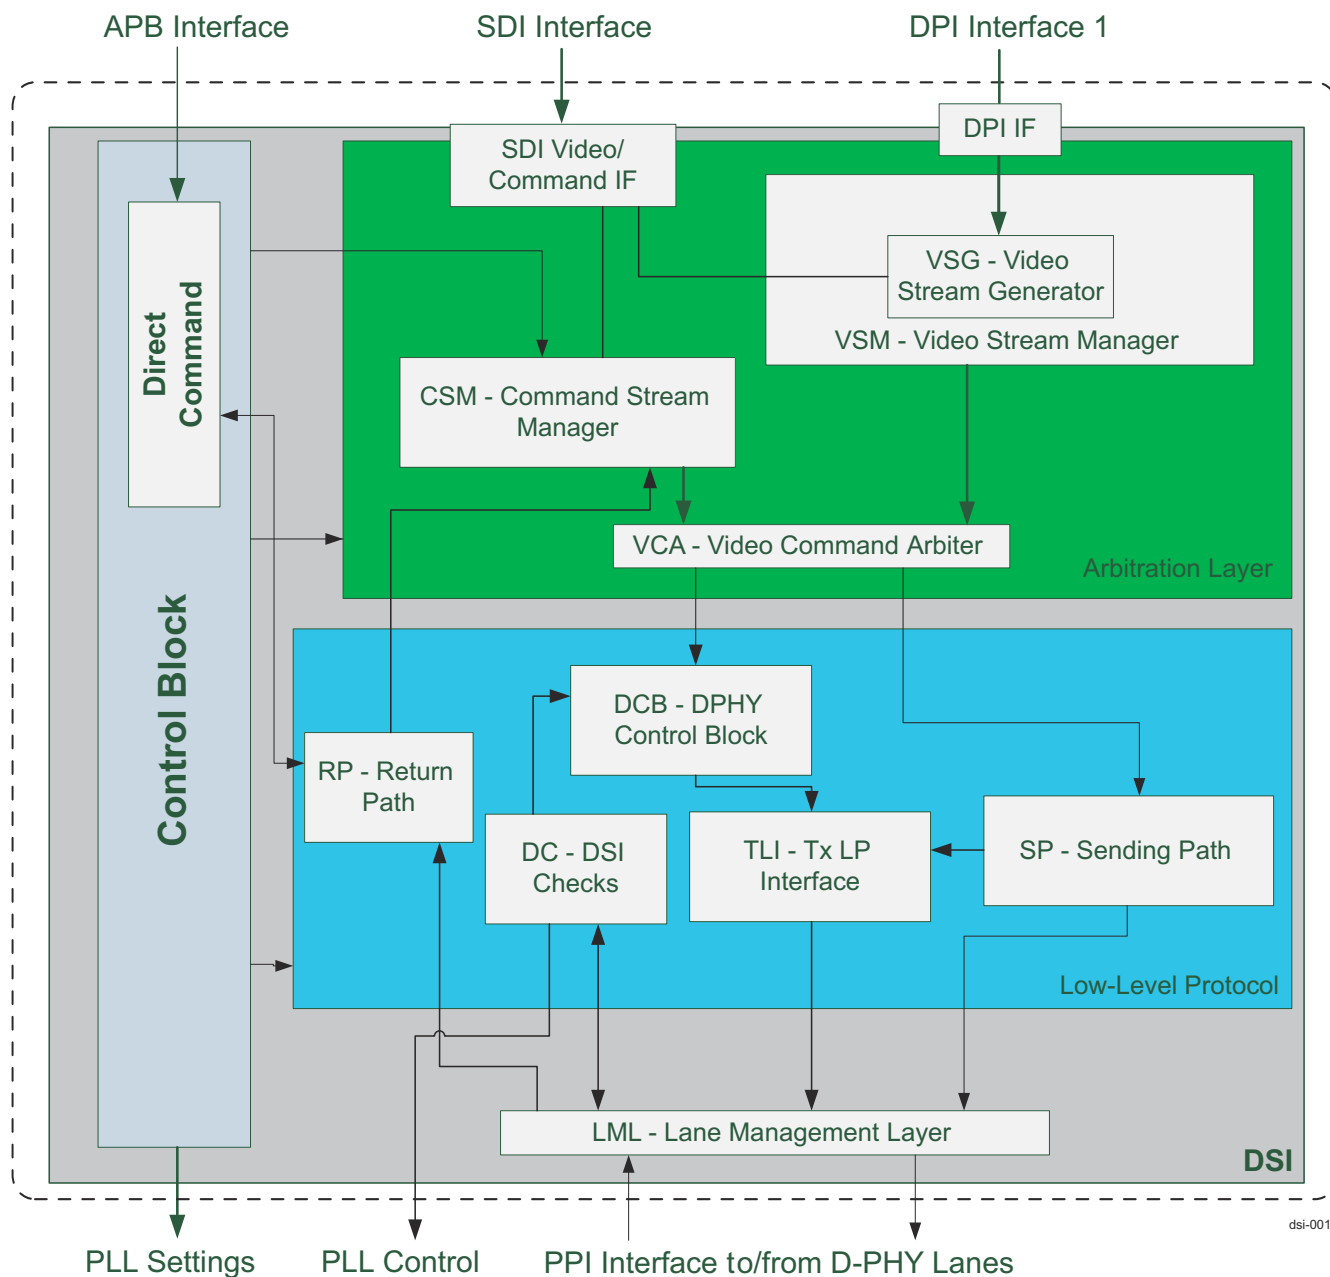

### 12.6.4.1 DSI Block Diagram

The MIPI DSI v1.3.1 Transmitter Controller (DSITX) provides an interface that receives data and control from the host processor display system using either the DPI or SDI input bus interfaces. The DSITX will translate the incoming pixel information and control signals into an internal packed byte format, in the case of DPI, or pass in the prepacked SDI byte format, before the internal byte format data is packetized and sent to the MIPI DSI Compatible display via the MIPI D-PHY physical interface. It supports video and command mode displays and can work in multi-display mode using virtual channel identification on the packets.

The DSITX controller provides two interfaces for connection to a display panel. Normal operation for a panel supporting DCS commands can be done using either SDI interface, or using the APB (Advanced Peripheral Bus) access to DIRECT\_CMD registers. Video streaming applications can only use the SDI or DPI interface. The DSI controller supports flow control using the SDI video interface.

The DSITX implements the stream arbitration and low-level protocol layer functionalities required by MIPI DSI specification v1.3. It supports up to 4 x 2.5 Gbps D-PHY data lanes in a single-link configuration and handles the byte lane mapping per use case (1, 2, 3, or 4-lanes).

The DSITX controller block diagram is illustrated in [Figure 12-385](#).

**Figure 12-385. DSITX Controller Block Architecture**

#### 12.6.4.2 DSI Clocking

The DSI receives all the clocks from DISPC or DPHY\_TX modules. There are no other dedicated PLLs. For more details on DSI clocks mapping at DSS and SoC level, see *DSI Integration*.

The DSI requires multiple clocks running asynchronously, that are shown in [Table 12-355](#).

**Table 12-355. DSI Clocking**

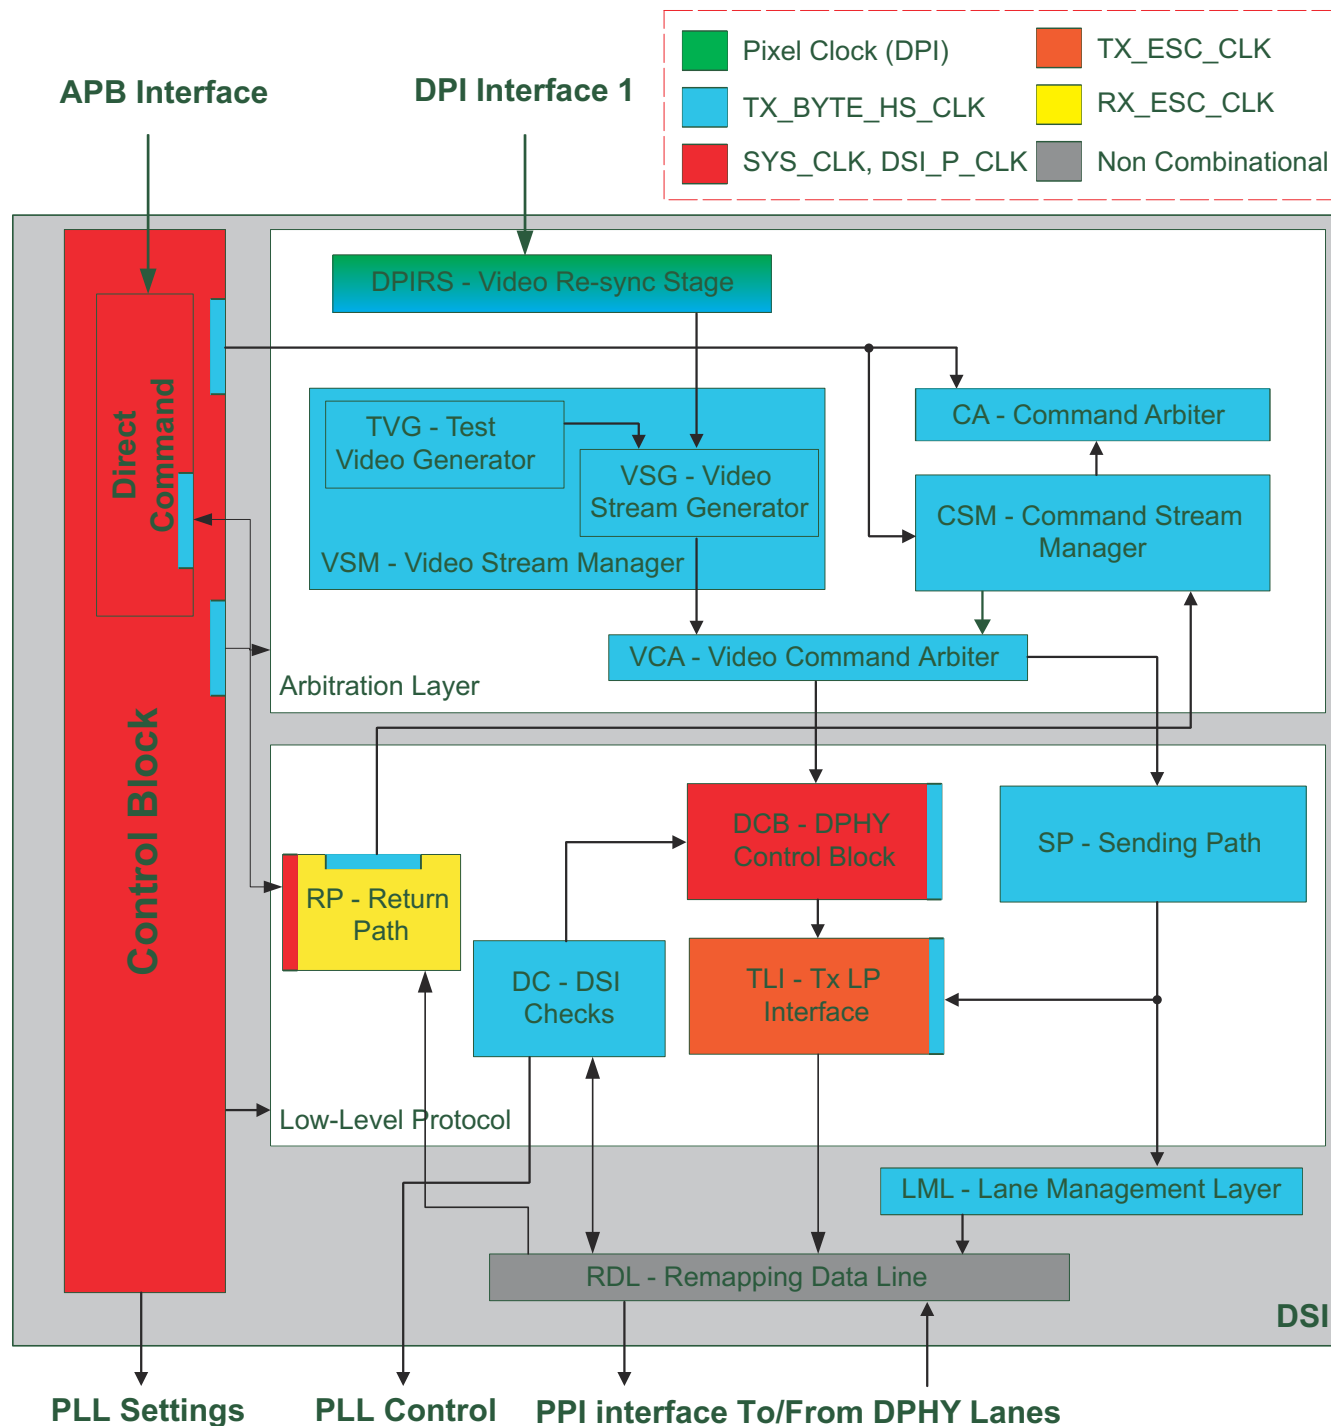

Clock	Direction	Min	Max	Constraints	Description
dpi_0_clk (Async to all other clocks)	Input	7 MHz	425 MHz	$F_{\text{pixel\_clk}} = F_{\text{tx\_byte\_hs\_clk}} \times \text{active\_lanes} \times 8 / (\text{bits\_per\_pixel})$	Used for DPI interface only. Frequency range depends on expected data rate with respect of number of data lanes, data lane frequency and frame rate

**Table 12-355. DSI Clocking (continued)**

Clock	Direction	Min	Max	Constraints	Description
sys_clk (Async to all other clocks)	Input	7 MHz	250 MHz	1. Cannot be slower than tx_byte_hs_clk x datapath_size/ if_datasize (risk of underrun) in SDI mode. 2. Must be greater than: rx_esc_clk x 8. 3. Speed should be sufficient to provide enough data in SDI operation. 4. Must be faster than the tx_byte_hs_clk for Direct command operation.	Main functional clock Also used for the VBUS/APB interface
dphy_0_tx_byte_hs_clk (Async to all other clocks)	Input	10 MHz	312.5 MHz	The max value in SDI interface operation depends on sys_clk: can't exceed sys_clk freq x if_datasize datapath_size Otherwise 312.5 MHz to match the 2.5Gbps limit on DPHY v1.3 specification	DPHY PPI Byte Clock Frequency set by the DPHY and its High Speed input clock (tx_byte_hs_clk = dphy bit rate /8) Maximum limit due to risk of underrun
dphy_0_tx_esc_clk (Async to all other clocks)	Input	1 MHz	20 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 20 MHz	TX Escape Clock
dphy_0_rx_esc_clk (Async to all other clocks)	Input	1 MHz	10 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 10 MHz	RX Escape Clock

Figure 12-386 describes the clock scheme and domains of the DSI\_TX.

dsi\_spruij7-057

Figure 12-386. DSITX Clock Scheme and Domains

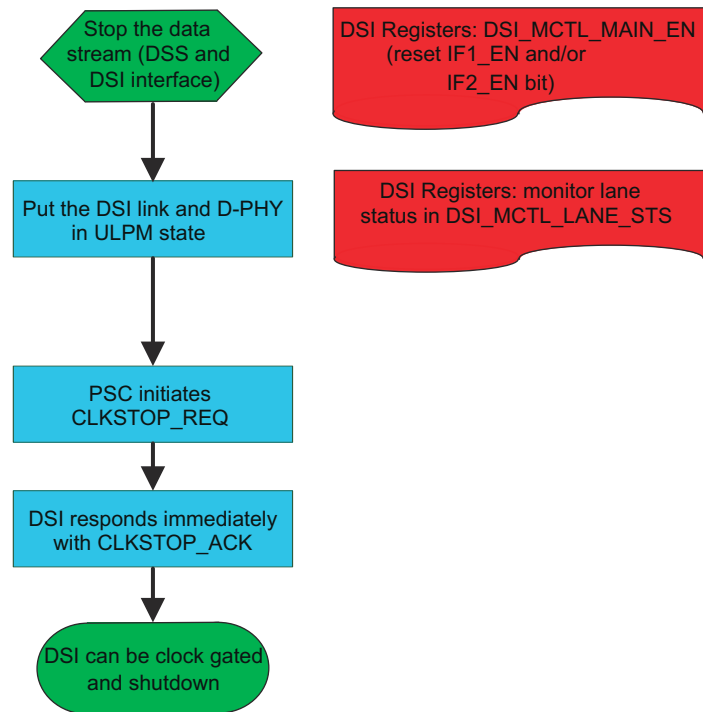

#### 12.6.4.3 DSI Reset

The DSI has one active low reset input. The entire internal logic is reset by this reset. Internal resets (synchronous and asynchronous) for different clock domains are generated internally (synchronized to the respective clock domain).

#### 12.6.4.4 DSI Power Management

The DSI implements a power management protocol to interface to a PSC (Power and Sleep Controller) module SoC level.

Figure 12-387 shows the expected sequence from SW while performing a *clkstop\_req* to the DSI.

dsi\_spruij7-058

**Figure 12-387. DSI Clock Gate / Power Off Procedure**

#### 12.6.4.5 DSI Interrupts

Table 12-356 shows the interrupts that are generated by the DSI module.

**Table 12-356. DSI Interrupts**

Interrupt (n = 0)	Description	Source Module	Source Signal Name
dsi_#n_func_intr	DSI-#n Func Interrupt	DSI Controller	dsi_irq_n
dsi_#n_safety_error_fatal_intr	DSI #n Internal Diagnostic Fatal interrupt	DSI Controller	asf_int_fatal
dsi_#n_safety_error_nonfatal_intr	DSI #n Internal Diagnostic Non-fatal interrupt	DSI Controller	asf_int_nonfatal
ecc_intr_uncorr_level_sys_intr	ECC aggr uncorrectable error	-	-

#### 12.6.4.6 DSI Internal Interfaces

##### 12.6.4.6.1 Video Input Interfaces

DSITX supports following video streaming interfaces:

- DPI (Uncompressed video stream)
- SDI (Serial Display Interface)

The DSI does not require DSI sub-link support. Therefore, only one video mode source is supported.

##### 12.6.4.6.1.1 Pixel Mapping

The pixel bit color mapping for the DSITX input interfaces are as shown in Figure 12-388. This matches with the pixel bit mapping on the output of DISPC for the supported formats.

[illegible]

**Figure 12-388. DSI Pixel Mapping On The DSI-DPI Interface**

**Table 12-357. DSI Pixel Format Interoperability between DISPC and DSITX**

DSITX DPI Pixel Format	DISPC VPOUT Pixel Format <sup>(1)</sup> DSS0_VP_CONTROL[10-8] DATALINES Register Field Setting	DPI Interface Support	SDI Interface Support
RGB565	16-bit (DATALINES = 0x1)	Supported	Supported
RGB666	18-bit (DATALINES = 0x2)	Supported	Supported
RGB666lp	N/A	Not Supported	Not Supported
RGB888	24-bit (DATALINES = 0x3)	Supported	Supported
RGB10	30-bit (DATALINES = 0x4)	Supported	Not Supported
RGB12	36-bit (DATALINES = 0x5)	Supported	Not Supported
YcbCr422 8-bit	N/A	Not Supported	Not Supported
YCbCr420 12-bit	N/A	Not Supported	Not Supported

(1) Output aligned on the LSB of the pixel data interface.

#### 12.6.4.6.2 DPI (Pixel Stream Interface)

- One uncompressed video stream input
- CEA-861 signaling/timing compatible interface
- Pixel clock rate range from 7 MHz - 425 MHz
- Frame Resolution – 4MPix@60fps equivalent frame size – supporting various frame resolutions and aspect ratios (with pixel clock freq < MAX\_dsi\_pixel rate = 425 MHz)
- Progressive video timing only
- Maximum Width - 8K (should only be constrained by the throughput)
- RGB format only –color space conversion or chroma up-sampling NOT supported

#### 12.6.4.6.2.1 Signals

DPI interface supports the following set of DPI standard signals:

- VSYNC – Video Vertical Blanking indication signal as defined in the above standards
- HSYNC - Video Horizontal Blanking indication signal as defined in the above standards
- DATA ENABLE – Video data enable indication signal as defined in the above standards
- DATA - 36 bits of data for supporting up to 12bpp
- Clock – As defined for each format from 7 MHz - 425 MHz

#### 12.6.4.6.3 SDI (Serial Data Interface)

DSITX uses a SDI interface (32-bit) to receive active video data from an internal frame memory using a DMA or other data pull mechanism. The interface uses req/ready handshake signaling to control the data flow.

The DSITX SDI Interface supports one of the following modes:

- Command-only

SDI-DSI Interface requires following signals:

- dsi\_if\_valid
- dsi\_if\_stall
- dsi\_if\_start (Line Start)
- dsi\_if\_frame\_sync (frame\_sync)
- dsi\_if\_data

The SDI interface of DSI\_TX receives data directly from DSS VP output and is functional when the user configures the DSS to operate in COMMAND\_STALLMODE (DSS0\_VP\_CONTROL[11] STALLMODE = '1' and DSS0\_VP\_CONTROL[12] STALLMODETYPE = '0').

#### 12.6.4.6.3.1 Secure Display Support

Only secure peripherals can be connected to a secure DPI (VP) output of DSS. In order to support this requirement, the DSS exports a secure qualifier to the DSI\_TX. Inside the DSI a SECURE register is implemented (DSI\_WRAP\_DPI\_SECURE), which contains SECURE bits, [0] DPI\_0\_SECURE and [1] DPI\_0\_SECURE\_VIOLATION, corresponding to the DPI port. These SECURE bits can only be set or reset by a secure host (vbusp transactions with secure qualifier set).

The behavior of DSI module for different settings of SECURE register bit and SECURE qualifier from DSS is as shown below:

**Table 12-358. Secure Display Support**

SECURE Register Bit (DSI)	SECURE mqualifier (DSS)	Security Violation Status	Comments
0	0	0	Data is passed (non-secure DSS data through non-secure DSI)
1	0	0	Data is passed (non-secure DSS data through secure DSI)
1	1	0	Data is passed (secure DSS data through secure DSI)
0	1	1	<b>Security Violation.</b> Data is blocked (secure DSS data through non-secure DSI)

Once a security violation is detected, it is captured in the DSI\_WRAP\_DPI\_SECURE[1] DPI\_0\_SECURE\_VIOLATION register status bit.

#### 12.6.4.7 DSI Programming Guide

This section describes the programming guidelines for the DSI Controller and D-PHY.

The goal of this section is to present more in detail how the DSI link should be used at application level plus some scenarios of use of the DSI link (start-up, display switch on/off, dual-display).

##### 12.6.4.7.1 Application Guidelines

The purpose of this section is to provide guidelines on how to drive the DSI host controller, provide general sequence of operations and some typical application notes.

##### 12.6.4.7.1.1 Overview of a Display Subsystem

Figure 12-389 shows an overview of a display subsystem. It covers the point to point interfaces between the DPI/SDI and DSI blocks. Other blocks and interfaces are included to give a better understanding of the environment for this interface.

A DSI interface is made up from one DSI controller and one D-PHY block. D-PHY is the physical layer of the DSI interface. The DSI block handles protocol. The DSI interfaces support displays that comply with the MIPI DSI standard.

The displays can be of either command mode type or video mode type. Command mode displays have a frame memory that can hold the entire image. The display is refreshed from this memory and only changes of the display content are sent over the display interface. Video mode displays do not have this memory and thus all data for every refresh must be transferred in real time.

The SDI block can support one display in command mode. By using command mode displays and rerouting of connections, between display updates, more than two displays can be connected and active.

**Figure 12-389. Example Display Subsystem Showing Controller and PHY Blocks**

#### 12.6.4.7.1.2 D-PHY And DSI Configuration

The DPHY and DSI controller must be configured before any panel video display can be used. All accesses to the DPHY to configure it for use with the DSI Controller should be performed through the DPHY own APB interface .

#### 12.6.4.7.1.3 DSI Controller Initialization

The DSI controller will always require the DPHY and data path configuration to be set after power up and any hard reset. The minimum sequence should define the data path lane configuration; mappings, available lanes, DPHY power, resets and lane swap. All these register values should be set before the DSI controller is enabled for functional operation.

The DSI registers are accessed through the APB interface. The programming sequence for command, video and controller configuration must follow a sequence of accesses to ensure the clock gate control updates the internal nodes before the link is enabled.

All DSI\_VID\_xxx registers must be programmed, if required, before the write to the DSI\_VID\_MAIN\_CTL register.

All DSI\_MCTL\_DPHY\_xxx registers must be programmed, if required, before the write to the DSI\_MCTL\_MAIN\_DATA\_CTL register to set the [0] LINK\_EN bit.

#### 12.6.4.7.1.4 Panel Configuration Using Command Mode

The DSI controller can provide DCS command access using either the SDI interface or through the APB interface control of the DIRECT COMMAND registers (see [Table 12-359](#)). The panel registers will be programmed using the LP mode before the high-speed video is enabled. Commands can either be sent using the command interface or though the Command FIFO using the APB registers.

The command FIFO access is done though the APB Command mode registers by forming packets of DCS commands. The DCS commands can be found in the MIPI DCS specification or the display panel data sheet.

DCS commands are essentially register write or read transfers to panel registers. The initialization of a panel will require APB register writes to fill the FIFO with the DCS commands. The commands can be grouped into a long packet by sending the packet split into 4 bytes to fill the FIFO using a write to the DSI\_DIRECT\_CMD\_WRDAT register.

**Table 12-359. DSI Direct Command Mode Registers**

DSI Register	Description
DSI_DIRECT_CMD_SEND	Direct Command - trigger the direct command sending - write only
DSI_DIRECT_CMD_MAIN_SETTINGS	Direct Command - main settings
DSI_DIRECT_CMD_STS	Direct Command - status - read only
DSI_DIRECT_CMD_RD_INIT	Direct Command - stop read operation
DSI_DIRECT_CMD_WRDAT	Direct Command - data to write byte 0 to 3
DSI_DIRECT_CMD_FIFO_RST	Direct Command- reset the write FIFO pointer

Each DCS command packet to be sent can be built by first selecting the packet configuration using the DSI\_DIRECT\_CMD\_MAIN\_SETTINGS. The DCS Command data types are defined in the DSI specification based on the number of parameters that are expected to be sent. Configuration of a panel display will normally use DCS write data types.

Table 12-360 shows the DSI\_DIRECT\_CMD\_MAIN\_SETTINGS register bit description.

**Table 12-360. DSI Main Settings Register Description**

DSI_DIRECT_CMD_MAIN_SETTINGS Register Bit	Description			
[24] CMD_LP_EN	Enables LP sending for the command request.			
[23:16] CMD_SIZE	Size of the command in case of write command - when written value is bigger than 0x10, the value is rounded to 0x10 for write - when size is bigger to 0x2 for read it is rounded to 0x2.			
[15:14] CMD_ID	In case of read/write command, Virtual Channel of the command.			
[13:8] CMD_HEAD	In case of read/write command, data type of the command:			
	0x05	DCS Write	0 parameters	Short Packet
	0x15	DCS Write	1 parameter	Short packet
	0x39	DCS Long Write	N parameters	Long Packet
[3] CMD_LONGNOTSHORT	This bit must be tied to one.			
[2:0] CMD_NAT	Nature of the direct command: 000: write command.			

Once the packet is loaded, issue a DIRECT\_CMD\_SEND (via the DSI\_DIRECT\_CMD\_SEND register) and the data will be sent in LP mode.

#### 12.6.4.7.1.5 VIDEO Interface Configuration

The DSI video operation requires the configuration of the VSG and TVG registers to match the panel configuration. The two video interface options will also require careful selection of the clock and registers to achieve error free video streaming.

The DSITX controller supports the mechanism for initial skew calibration for D-PHY data rates greater than 1.5 Gbps.

#### DPI Video Interface Operation

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. If this is the case, then the blanking and active data periods must be matched up. The DSI controller will slave its frame timing to the incoming DPI **VSNC**, if it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered.

The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So, programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

Program the DSI vertical size registers as follows:

- $VSA = DPI\_VSI$  (lines, minimum of 2)
- $VBP = DPI\_VBP$  (lines, minimum of 0)
- $VACT = DPI\_VACT$  (lines)
- $VFP < DPI\_VFP$  (minimum of 1)

The timing should also be matched per line, therefore the blanking and active periods should match. DPI horizontal timing is measured in pixels, whereas the DSI controller uses bytes. If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync\_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure the FIFO depth and vsync\_delay is suitable.

The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. Additionally, the PPI short packets and packet headers that are inserted by the controller must be accounted for. HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and footer (4 + 2 bytes) and the HSE short packet (4 bytes). HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (6 bytes). HFP should be reduced by 6 bytes to account for the long packet header and footer. Finally, for lines with no active data, the BLKLINE\_PULSE\_PCK is the total size minus 20 bytes (14 for HSA, 6 for the remaining blanking which is all combined into a single packet).

Program the DSI horizontal size registers as follows:

- $HSA = (DPI\_HSA \times \text{bpp}/8) - 14$
- $HBP = (DPI\_HBP \times \text{bpp}/8) - 12$
- $HACT = (DPI\_HACT \times \text{bpp}/8)$  NOTE:  $(DPI\_HACT \times \text{bpp}/32)$  must be an integer.
- $HFP = (DPI\_HFP \times \text{bpp}/8) - 6$
- $BLKLINE\_PULSE\_PCK = ((DPI\_HSA + DPI\_HBP + DPI\_HACT + DPI\_HFP) \times \text{bpp}/8) - 20;$

### TVG Generator

The TVG oversees generating dummy data (to display something even if there is no video stream running). It is also able to ease verification or validation of the DSI without having a complete environment (application or verification test bench). The controller has a Test Video Generator that can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

[Figure 12-390](#) presents TVG MODE patterns.

dsi\_spruij7-003

**Figure 12-390. TVG MODE Patterns**

The TVG generates a data stream in the same format than the one specified for the normal functional video stream (as set in VSG register). The content of that flow is specified by registers. Those registers specify the following information: Image size: Number of bytes per line (see TVG\_LINE\_SIZE[14:0] register) and number of lines per frame (TVG\_NBLINE[12:0]).

Image kind: Single color, vertical stripes or horizontal stripes (see TVG\_MODE[1:0] register). Stripe width: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128 (see TVG\_STRIPE\_SIZE[2:0] register).

Pixel kind: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB (see VID\_PIXEL\_MODE[3:0] register).

Color one: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered (see COL1\_GREEN[11:0], COL1\_RED[11:0], COL1\_BLUE[11:0] registers).

Color two: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered. (see COL2\_GREEN[11:0], COL2\_RED[11:0], COL2\_BLUE[11:0] registers). Start pulse and stop handshake (+ stop mode) (see TVG\_CTL register).

An example of the sequence is as follows:

- Select TVG for video stream generation instead of SDI 1 interface:
  - IF1\_EN bit to 0 (stall signal at 1) in MCTL\_MAIN\_EN.
- Select video mode for interface 1 in MCTL\_MAIN\_DATA\_CTL:
  - TVG\_SEL bit to 1 in MCTL\_MAIN\_DATA\_CTL register to select stream from TVG.
- Select generated frame format in TVG\_CTL register:
  - Image format (single color, H stripes, V stripes) in TVG\_MODE field.
  - Image color selection in TVG\_COLOR1, TVG\_COLOR1\_BIS, TVG\_COLOR2, VG\_COLOR2\_BIS.
  - Stripes size in TVG\_STRIPE\_SIZE field.

- Image size in TVG\_IMG\_SIZE register.

**Note:** The number of lines per frame and number of bytes per line. It is required that TVG settings on active area match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG\_STOPMODE field of TVG\_CTL:
  - TVG video stream generation start/stop controlled by the TVG\_RUN bit in TVG\_CTL register. Polling TVG run status from the TVG\_RUNNING bit in TVG\_STS register is useful when setting TVG\_RUN to 0. TVG video stream generation does not stop instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

#### 12.6.4.7.2 Application Considerations

The following sections outline the normal operation of the DSITX controller and the programming and sequences require to operate the DSITX controller for normal video and command operation.

##### 12.6.4.7.2.1 D-PHY Timings Control

Several DPHY timing constraints must be respected by the system, which are described in this section. When a switch in ULP is requested, the application should be aware that the D-PHY needs 1 ms to leave this state (this timing is guaranteed by the DSI itself). It makes no sense to start an ULP request if the expected time in ULP is short.

When PLL power down is asserted, the system should continue to assert for a specific minimum period of time (PLL internal requirement – please refer to DPHY documentation). Please note that shutting down the PLL implies that no clock is present on tx\_byte\_hs\_clk input and thus the DSI link is stopped; even if the system-side interface clocks remain active, no more HS transfers can be done.

Force\_stop, ppi\_c\_force\_tx\_stop (clock lane) and ppi\_d\_force\_tx\_stop (1 per data lane), can be useful to resolve certain deadlock situations, for example: DSI slave does not give back control to master, or critical DPHY error. When a 'force stop mode' is issued by the application, the system should maintain this state on the bus to ensure the request is correctly considered by the D-PHY cells and the **stop\_state** is asserted and direction signal is deasserted.

reg\_wait\_burst\_time (for the LML) must be programmed to ensure that two HS bursts are separated by at least 100 ns. The value will be based on the period of the tx\_byte\_clk cycle.

VCA: When trying to interleave commands to video stream, it is assumed that only write/read commands and BTA request are sent (no TE). The reason is that such transfers are slow and difficult to predict in term of duration. They could take longer than the slots available for video. The read commands are unpredictable and may cause some break in the video stream, however, they can still be used, if an appropriate response time can be guaranteed. It is the responsibility of the system integrator and the application to plan and implement recovery procedures when the video stream is stalled due to a read that takes too long.

##### 12.6.4.7.2.2 Control Block

Most of the register contents must be resynchronized against a DSI internal clock (tx\_hs\_byte\_clk). This means there is a certain time to pass data from one clock domain to the other. If two writes in the same register are too close, the register itself is updated but the synchronization may fail.

The formula to calculate the number of system clock periods between two writes is:.

$$\text{nb\_cycle}(\text{dsi\_p\_clk}) = 6 * (\text{f}_{\text{dsi\_p\_clk}} / \text{f}_{\text{tx\_byte\_hs\_clk}} + 1)$$

The application must respect a period of TX ns between two write accesses to the same register (there is no issue writing different registers back-to-back).

Table 12-361 shows an example of required time between two write accesses.

**Table 12-361. Example of Required Time between Two Write Accesses**

$\text{f}_{\text{dsi\_p\_clk}}$	$\text{f}_{\text{tx\_byte\_hs\_clk}}$	TX minimum time between 2 writes accesses
200 MHz	106 MHz	~ 90 ns
160 MHz	10 MHz	~ 650 ns

**Table 12-361. Example of Required Time between Two Write Accesses (continued)**

$f_{dsi\_p\_clk}$	$f_{tx\_byte\_hs\_clk}$	TX minimum time between 2 writes accesses
200 MHz	10 MHz	~ 650 ns

Another place where asynchronous behaviour may interfere with programming in the CB is the direct command status register `DIRECT_CMD_STS`. Some of the bits of this register are set when a pulse (that lasts one clock period) coming from `tx_hs_byte_clk` domain is observed (after resynchronization on `dsi_p_clk`) and is reset when the clear bit is written. In use case where `tx_byte_hs_clk` is slow (10 MHz range), the bit can be read and a clear attempted before the end of the source pulse. This can result in the re-assertion of the bit immediately after it is cleared. For that reason, it is recommended to wait for a while between reading the bits of the `DIRECT_CMD_STS` register and clearing them.

### Application Issues

Some register fields cannot take all the possible values but are restricted to a certain number of combinations (mode control). The DSI controller does not check that all the fields match a valid setup so it is the responsibility of the system integrator and the application to check that the written values are amongst the permitted combinations. Amongst the register fields that fall in to this category are most of the mode settings (stop mode, recovery mode, direct command type, image sizes, etc.)

### Programming Coherency

The application level must ensure that the register configurations are valid for the system to operate correctly. There are several possible combinations are possible in the CB registers however should be avoided. A few examples:

- No HS transfer should be enabled when PLL is shut-off.
- TVG should not be run when the video interface is running.
- No access (from interface or from register) should be attempted while TBG is active.
- Prior to shut-down of the DPHY PLL, application should verify that the DSI link is in proper state. If the bit that enables BTA is not set and that any operation implying a BTA is sent, the system is stalled. Then the bit that enables BTA must be aligned with application needs. Moreover, read enable or TE enable cannot be set if `bta_en` is not set (these operations cannot be enabled when BTA is not enabled).
- TE feature must not be enabled in SDI interface.

#### 12.6.4.7.2.3 Video Coherency

In video mode, there are a lot of sizes defined for the video stream generation. This data corresponds to the payload of the various generated packets and not to their duration. However, they are closely linked. It is the responsibility of the system integrator and the application to use correct sizes to ensure the correct video timing and behaviour, because the system may use 1 to 4 active data lanes with a fixed number of bytes for the header/checksum overhead. In the same way, when programming D-PHY time (to switch from LP to HS), the application must consider D-PHY time plus overhead due to LLP and LML crossing time (see [Section 12.6.4.7.7.2, Video stream settings \(VSG\)](#)).

### VSG Control

Start and stop sequences can take a long time to be performed. If the requests are not maintained up to the time the status bit are indicating effective start or stop, they can be ignored and the VSG may not have started or stopped as expected by application. It is then up to the application to carefully manage the request and to verify that requests are being processed before changing the state of the VSG.

### Test Generator:

The DSITX provides test generator to provide a video data stream. When using TVG, all sources can be used (provided VCA permits it) however the SDI interface must not be programmed to send video data and must be restricted to command mode.

The pixel modes supported are: RGB 16-, 18-, 24-, 30- and 36-bit; YCbCr422 16-bit; and YCbCr420 12-bit (note that additional YCbCr422 20-bit and YCbCr420 24-bit may be supported using SDI interface, but are restricted to command mode only).

The supported display sizes are listed below:

- QQVGA (160 x 120) - 15/20/30/60 fps - RGB 16-18-24 (-30 and 36) bits per pixels
- QCIF (176x144), QCIF + (176x208 and 176x220) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QVGA (320x240) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- CIF (352x288), CIF + (352x416 or 352x440) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- 1/2 VGA (320x480) and 2/3 VGA (640x320) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- VGA (640x480) - 15/20/30/60 fps - RGB 16-18-24(-30 and 36) bits per pixels
- WVGA (800x480 - 848x480 - 854x480 - 852x480) - RGB 15/20/30/60 fps - 16-18 and 24 bits per pixels
- SVGA (800x600) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QHD (960x540) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- XVGA (1024x768) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- Full HD (1920x1080) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- WUXGA(1920x1200) - 15/20/30/60/(120 fps – 16 bpp only) 16, 18 and 24 bits per pixels
- 4Kx4K(4096x4096) - 15/20/30 fps - 16-18 and 24 bits per pixels

#### 12.6.4.7.3 Start-up Procedure

The start-up sequence described in [Figure 12-391](#) assumes that the rest of the chip is ready (all clocks are present except tx\_byte\_hs\_clk, application it is ready...) and that the DSI is ready (reset de-asserted).

The following is the most common start up sequence:

Firstly, application layer programs and enables the PLL, then waits for a period for the PLL to lock (minimum time will be defined by the PHY documentation). At the end of the minimum wait period, the application layer should poll the PLL lock status register periodically to confirm lock status, repeating until confirmed. At the end of this step, it is assumed that a clock is present on the tx\_byte\_hs\_clk input (this step may be replaced by an interrupt-based alternative if available from the selected DPHY or provided in the system integration logic).

During the time taken by the PLL to lock, the application can program the configuration registers and prepare the DSI link. This can also be done after the PLL is locked. It should at least configure enough to be able to use LP mode to send direct commands.

Enable clock and data lane(s) per the needs. This action is only concerned with programming registers that control the D-PHY lane enable signal. The active lane configuration with the DSI\_MCTL\_MAIN\_PHY\_CTL and DSI\_MCTL\_MAIN\_EN registers must be programmed to match, i.e. for two data lanes (0 and 1).

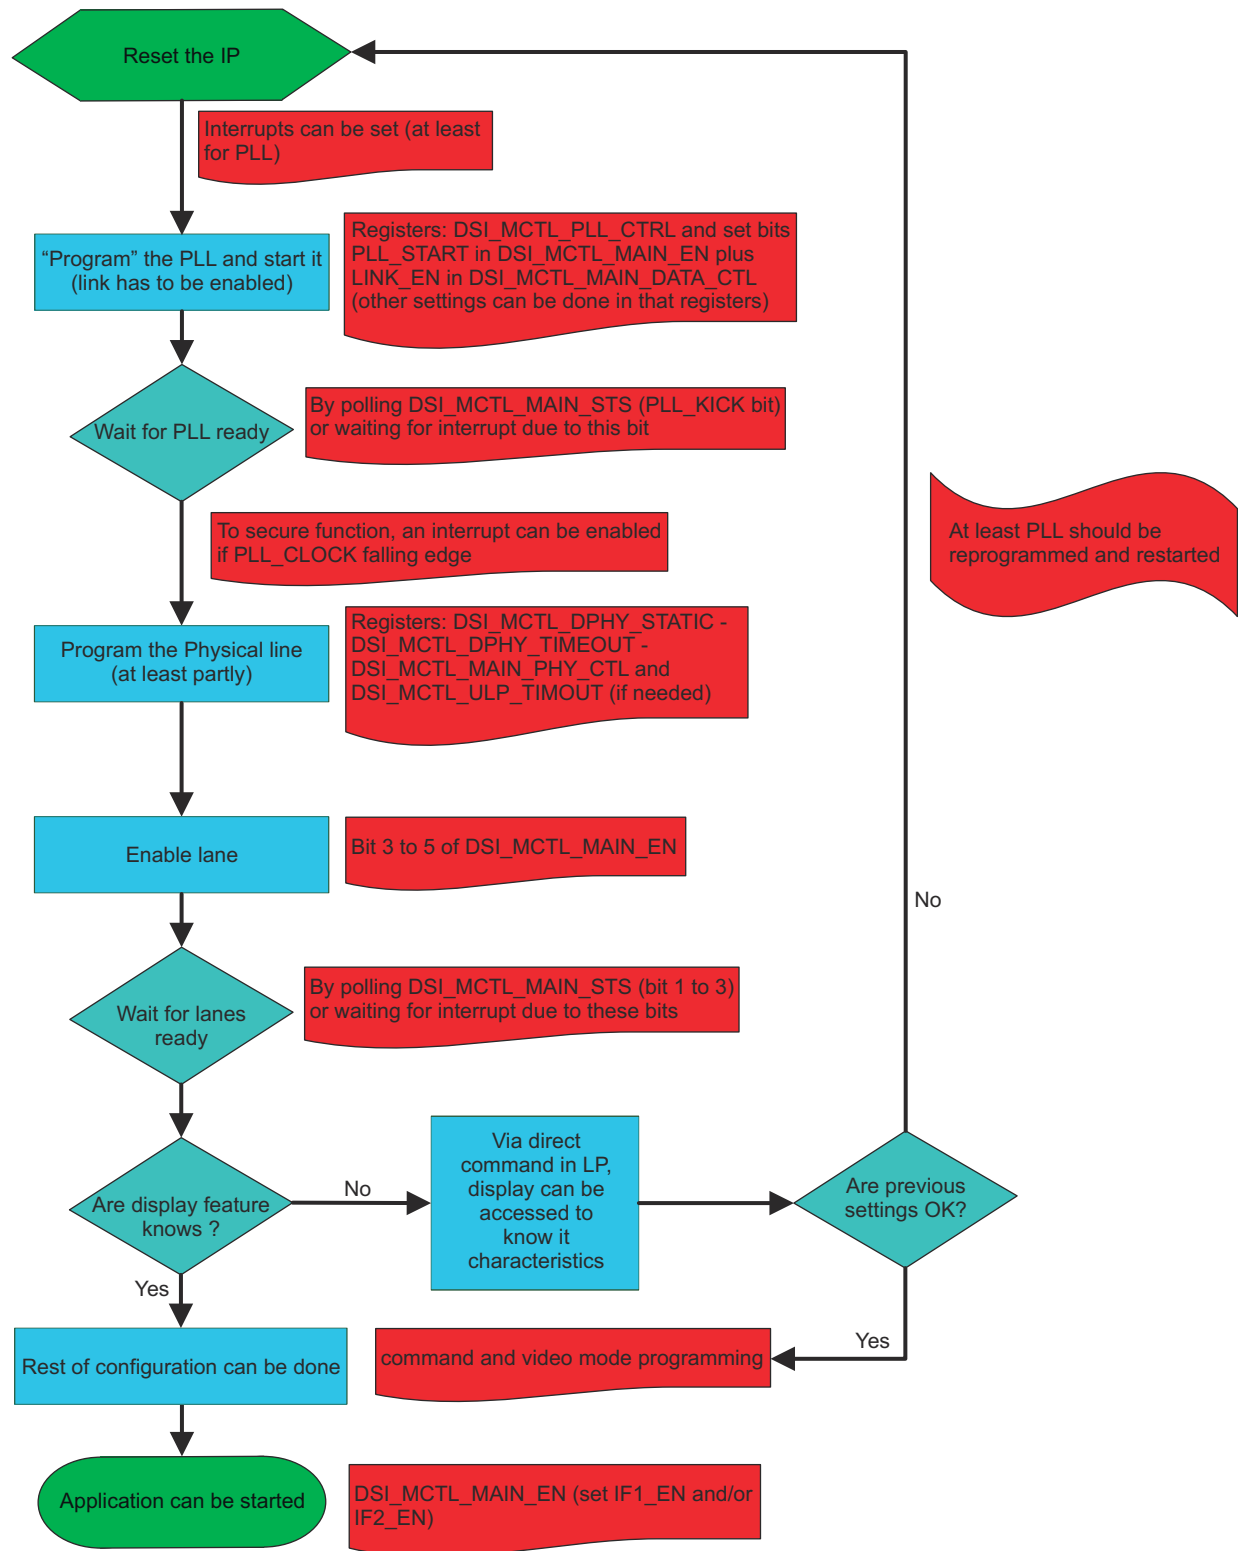

- DSI\_MCTL\_MAIN\_PHY\_CTL (0x08) register – LANE3/4\_EN - bits[2:1] set to zero to disable lanes 2/3.
- DSI\_MCTL\_MAIN\_EN (0x24) register – DAT3/4\_EN fields - bits[6:5] set to zero to disable lanes 2/3.

Start the lane in the DCB. The DCB state machine puts the lanes in the correct state to be ready.

At this step, the DSI link should be able to access to display - at least in LP mode. If the system (DSI link and display) is fully programmed, code to display image can be started. If display characteristics must be read from the display and the system is programmed in LP mode, this is time to read the displays parameters to allow correct programming of the DSI. A new round of programming can then take place to set-up the system, based on the parameters which have been read from the display.

The DSI internal setting is now completed and it is ready to accept data. The application can now enable the interface so that the stall signal is removed and that DSI link can accept data.

When the procedure described above is terminated, it does not imply that display itself is ready. At this stage, the D-PHY and DSI link are ready to send/receive data to/from display and thus application may still need to initialize the display itself.

ds\_i\_spruij7-005

**Figure 12-391. Start-up Procedure Summary****12.6.4.7.4 Interrupt Management**

There are numerous error and status conditions that can be monitored via the interrupt mechanism. The edge on which these conditions are generated is programmable.

Each interrupt source has four associated registers:

1. The status register itself "<sts\_reg>"
2. a control register "<sts\_reg>\_ctl" to control corresponding interrupt behaviour
3. a flag register "<sts\_reg>\_flag" to observe when interrupt/event has been triggered
4. A clear register "<sts\_reg>\_clr" to clear the event flag register.

The decision of which status bits (<sts\_bit>) can generate interrupt is taken when the corresponding enable bit "<sts\_bit>\_en" is set in the status control register. In the same register the status bit edge "<sts\_bit>\_edge" states on which edge of the status bit the interrupt is triggered. When the selected edge is observed, the flag bit "<sts\_bit>\_flag" is set. The interrupt signal is an OR of all flag bits that are enabled. When the register "<sts\_reg>\_clr" is written with the bit "<sts\_bit>\_clr", the "<sts\_bit>\_flag" is cleared.

#### 12.6.4.7.4.1 Error and Status Registers

The error register bank handles storing all error flags that are identified. It also stores some status bits that must be observable and detectable by the application. These status and error registers can generate an interrupt on the rising or falling edge if this generation is enabled.

This mechanism is different depending on the nature of the status or error bits. For those that are generated in the DSI block (basically all status and error bits except direct command), the status bits cannot be easily controlled and toggle according to the internal status meaning only the current value is observed in the status/error register itself.

If the interrupt generation is enabled with the associated enable bit, a rising edge (associated edge bit set to 0) or a falling edge (associated edge bit set to 1) of that status bit toggles the corresponding flag bit. At the end, all the flag bits are put together with an OR to generate the interrupt signal. The flag register can be reset by writing in the clear register.

The described behavior can be summarized by the following pseudo-HDL. The signal named signal\_sts\_bit is the bit that is observable by reading status bit.

- reg\_sts\_q is the status register (accessible via APB)
- reg\_flag\_sts\_q is the flag register
- clear\_the\_flag is set when the register clear is written
- edge\_sts\_ctl is the edge bit
- enable\_sts\_ctl is the enable bit

```
reg_sts_d <= signal_sts_bit;
```

```
reg_flag_sts_d <= '0' WHEN clear_the_flag = '1' ELSE
```

- '1' WHEN (reg\_sts\_q = '0' AND reg\_sts\_d = '1' AND edge\_sts\_ctl = '0') ELSE – detect rising
- '1' WHEN (reg\_sts\_q = '1' AND reg\_sts\_d = '0' AND edge\_sts\_ctl = '1') ELSE – detect falling
- reg\_flag\_sts\_q;

```
irq_n <= NOT (OR_OF_ALL(reg_flag_sts_q AND enable_sts_ctl));
```

The code is slightly different in cases where the observed bit is a generated condition (in the control block), as is the case for the direct command status and error flags. The status/error information is automatically generated but is cleared only when writing in the corresponding clear bit. The interrupt generation behaves similarly to the error condition cases, however, as the status falling edge is observed only when the bit is cleared, it is not possible to use the falling edge detection on flag (however the code is kept as-is to provide a standard implementation method). This leads to the following code:

- reg\_sts\_d <= '0' WHEN clear\_the\_flag = '1' ELSE
  - '1' WHEN the\_sts\_bit (Note 1) = '1' AND reg\_sts\_q = '0' ELSE -- (see Note)
  - reg\_sts\_q;
- reg\_flag\_sts\_d <= '0' WHEN clear\_the\_flag = '1' ELSE
  - '1' WHEN (reg\_sts\_q = '0' AND reg\_sts\_d = '1' AND edge\_sts\_ctl = '0') ELSE – detect rising
  - '1' WHEN (reg\_sts\_q = '1' AND reg\_sts\_d = '0' AND edge\_sts\_ctl = '1') ELSE – detect falling
  - reg\_flag\_sts\_q;
- int <= NOT(OR\_OF\_ALL(reg\_flag\_sts\_q AND enable\_sts\_ctl));

**Note:** In some case (pulse generated), the rising edge detection is not done and the code becomes simply '1' WHEN signal\_sts\_bit = '1' ELSE...

#### 12.6.4.7.4.2 Interrupt Management for Direct Command Registers

The following direct command status bits/registers are only set when error is generated and only cleared when the clear bit is written:

- all the status bits of the register DSI\_DIRECT\_CMD\_RD\_STS
- all the status bits of the register DSI\_DIRECT\_CMD\_STS
- all the status bits except bit 0 (cmd\_transmission) of the register DSI\_DIRECT\_CMD\_STS

As these registers are reset only when the clear register is written, it is not possible to detect the falling edge on them to generate interrupts. Only the rising edges can generate the interrupt.

**Note:** There can be issues with detection when using the bits for all the signals that are a pulse generated in the tx\_byte\_hs\_clk domain. When the speed of that clock is slower in relation to dsi\_p\_clk, it is possible to have the interrupt set, the bit read and the clear attempted before the end of the tx\_byte\_hs\_clk pulse, after the clear, the bit is set again.

#### 12.6.4.7.5 Direct Command Usage

The direct command mechanism is a way to send commands (with a maximum size of direct\_cmd\_fifodepth bytes) by writing and reading registers. It allows commands to be sent that are not allowed through the SDI-DSI interface (DSI commands, triggers), to perform read operations or to send DCS / generic write / generic read operations when the DSI link is not fully programmed and cannot use the SDI interface for commands.

Figure 12-392 shows direct command management sequence.

Basically, the procedure to do so is as follows:

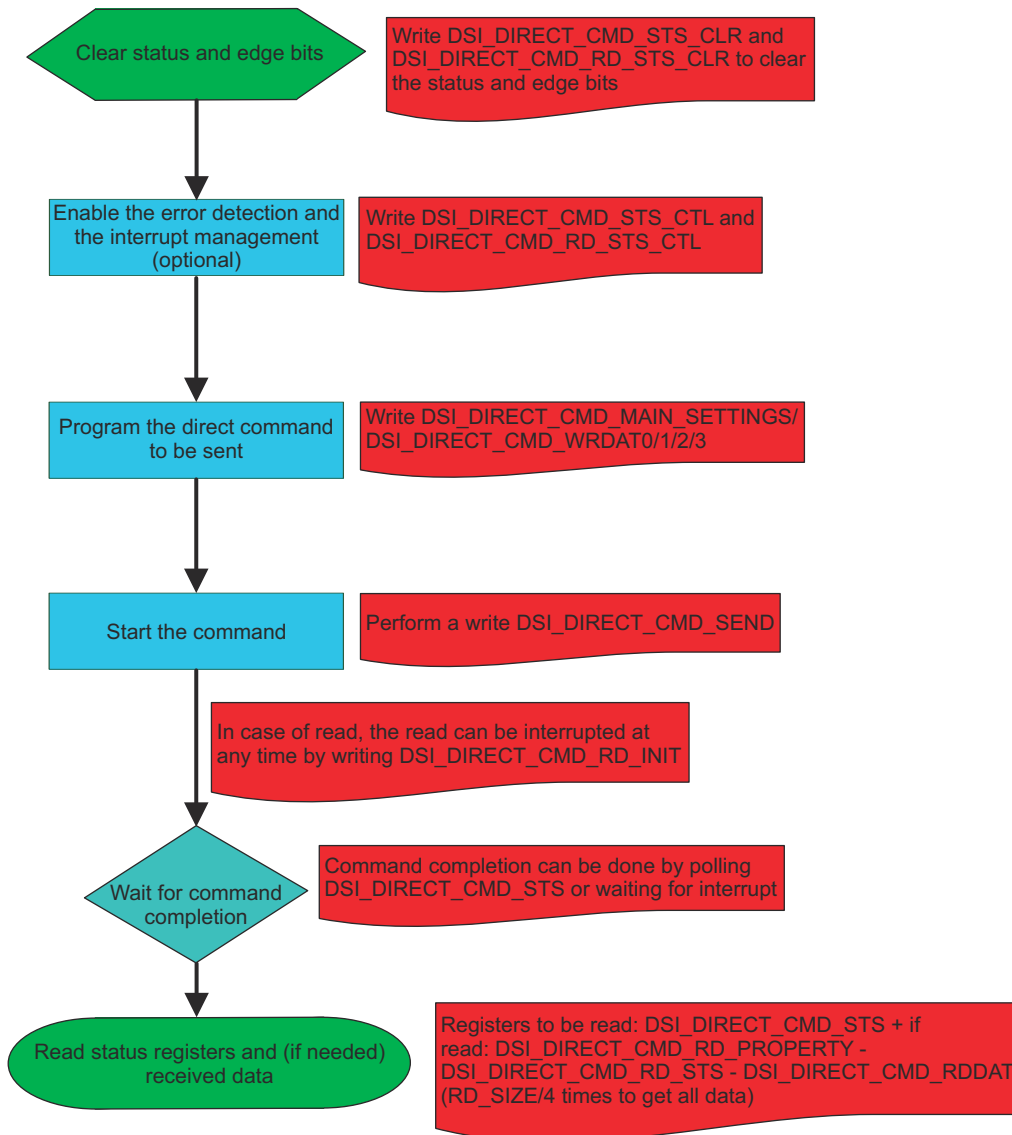

- Clear the status bits (when reading the status bits, only the DSI reads the current access status).
- Program the various registers that define the command to send.
- Write the direct\_cmd\_send register. Writing in that register (any value) triggers the command sending mechanism.

The command should be started only if the command request is amongst the defined ones for DCS or Generic Write or Read with 0, 1, or more parameters:

- DCS Write codes 0x05, 0x15, 0x39
- DCS Read codes 0x06
- Generic Write codes 0x03, 0x13, 0x23, 0x29
- Generic Read codes 0x04, 0x14, 0x24

**Note:** The direct\_cmd\_main\_settings register can use other data type values for cmd\_head to support future types and no check is performed for invalid types.

- Wait for the assertion of the command\_completed bit in the direct\_cmd\_sts register (or any of the relevant bits that indicate a specific command termination). Instead of polling the registers, it is possible to enable the corresponding interrupts and wait for its detection.
- Read the received data and (if any) the different status bits.

dsi\_spruij7-006

**Figure 12-392. Direct Command Management**

There are several checks performed when sending a direct command to verify that requested command sizes are supported and to check that the requested command exists (otherwise the request to send the command is ignored).

- For Short packets commands the DCS and Generic Read and Write the data size is rounded to maximum of 2.
- For Long packet DCS and Generic Read and Write the data size is rounded to the maximum size of the FIFO.
- No checks are made for the write FIFO having the expected number of bytes programmed into the CMD\_SIZE in the dir\_cmd\_main register. In this case the data written out will loop back through the value in the FIFO.

At completion of a read command, registers can be read (they contain read data and/or errors detected during the communication) and trigger events are sent to the application to announce the request completion (using the status and error register bank).

When a read request is performed, the read data is put in the RP FIFO. If more bytes are sent, they are ignored and errors are set accordingly. The received read can then be accessed by reading several times the register that gives an access to the FIFO.

For every new command, several status bits are present: one signals that a command is being transmitted (cmd\_transmission). When the command is complete, several bits can be toggled to signal it (write\_completed, trigger\_completed, te\_received, read\_completed and read\_completed\_with\_err).

Some complex commands provide intermediate information. For BTA requests, there is a bit that signals when the BTA request has been sent (BTA\_completed) and another one that signals when the DSI is master of the D-PHY interface again (BTA\_finished). For commands that imply a BTA, some other bits specify whether specific data has been received (such as trigger, acknowledge with or without error).

#### 12.6.4.7.5.1 Trigger Mapping Information

Triggers are one of the groups of direct commands that can be sent and received using the DPHY in Low Power escape mode. The trigger\_val[3:0] bits (in the registers DIRECT\_CMD\_MAIN\_SETTINGS and DIRECT\_CMD\_STS) are used to define which of the four possible trigger entry codes has to be sent or has been received. The register fields described above are copied in signal ppi\_d1\_tx\_trigger\_esc[3:0] (for trigger\_val[3:0] of DIRECT\_CMD\_MAIN\_SETTINGS) or are a copy of ppi\_d1\_rx\_trigger\_esc[3:0] (for trigger\_val[3:0] of DIRECT\_CMD\_STS). Only one bit out of the four should be set else the D-PHY behavior is not very precisely defined. Table 12-362 gives the trigger mapping in the system.

**Table 12-362. Trigger Mapping**

Trigger name	Trigger entry code	trigger_val	meaning in TX direction	meaning in RX direction
trigger 0 - reset	01100010	1b0001	Reset	Not affected by DSI spec
trigger 1 - unknown 3	01011101	1b0010	Not affected by DSI spec	TE response <sup>(1)</sup>
trigger 2- unknown 4	00100001	1b0100	Not affected by DSI spec	Acknowledge with no error <sup>(1)</sup>
trigger 3 - unknown 5	10100000	1b1000	Not affected by DSI spec	Not affected by DSI spec

(1) These triggers are not observed in the trigger\_val field of the direct\_cmd\_sts register because they are used by the DSI link for a specific purpose.

**Trigger Reset** – This will request from the display and expects an immediate reset of the DSI command/video mode with all pending requests in TX sending path FIFO for transfer to be discarded.

**Acknowledge** – This is a response to DSITX controller. The host processor may request a command acknowledge and error information related to any transmission by asserting Bus Turnaround with the transmission. The peripheral shall respond with ACK Trigger Message if there are no errors and with Acknowledge and Error Report packet if any errors were detected in previous transmissions. Appropriate flags shall be set to indicate what errors were detected on the preceding transmissions.

If the transmission was a Read request, the peripheral shall return READ data without issuing additional ACK Trigger Message or an Acknowledge and Error Report packet if no errors were detected. If there was an error in the Read request, the peripheral shall return the appropriate Acknowledge and Error Report unless the error was a single-bit correctable error. In that case, the peripheral shall return the requested READ data packet followed by Acknowledge and Error Report packet with appropriate error bits set.

**Tearing Effect** - The Tearing effect on the display is avoided by having synchronization information from the display. It is used only in command mode. Users are responsible for selecting the command mode for the VC using the TE feature and selecting the polling or automatic mechanism.

The user is responsible for ensuring that there is a delay after a trigger is issued by the host to the panel, before any other action, message or trigger is performed. When the host issues a reset trigger, the system will expect the controller to stop and re initialise the clock and data links. All other triggers issued by the host will be application specific and are outside the scope of this document.

#### 12.6.4.7.5.2 Command Mode Settings

The command mode is enabled on the SDI interface. This is controlled using the register mctl\_main\_en. Other settings can be set using the registers: mctl\_main\_data\_ctrl (to decide about TE usage, read enable...); and cmd\_mode\_ctl (Virtual Channel of the command packets, arbitration between requests of the two interfaces, possibility to use LPDT, TE timer programming and padding value in case of an error).

When programming Direct READ commands, a BTA request is sent automatically following the read transmission, for the peripheral to respond – it is therefore not necessary to explicitly send a BTA request at that time. The system must allow the BTA request to be completed and the bus returned to the host before issuing any new read or write command. The system must either: poll the read\_completed (and read\_completed\_with\_err) status bits; or, wait for an interrupt caused by these bits before issuing any new command.

When programming Direct WRITE commands, it is advisable to ensure that each transaction can complete successfully before moving on to a subsequent command. There are two recommended methods to achieve this, either: explicitly request a BTA between write transactions while checking for the associated interrupt or polling the appropriate status flag (this method also provides the added security of an ACK response from the peripheral); or allowing a gap between commands sufficient to allow completion of the first before commencing with the second. The recommended approximate gap time required to ensure that all commands complete successfully is equivalent to 100 TX ESC byte periods. If required (for instance, to minimize the start-up time), it is also possible to calculate the minimum delay time required for each transaction, based on the TX escape clock frequency used in the application and the length of each command (no active video transmission should be enabled at the time – a typical use case would be peripheral parameter configuration). As with read operations, any write operation followed by an explicit BTA request must allow the BTA to be completed and the bus returned to the host before issuing any new read or write command.

For single parameter commands, the upper bytes of the 32-bit value written to the Direct Command write data register (direct\_cmd\_wrdat) should be masked to zero to comply with the DSI specification requirement that unused parameter locations are set to zero. For zero parameter writes, assuming there have been previous write commands sent, it is necessary to clear the sending path FIFO by writing to the direct\_cmd\_fifo\_rst register to clear the data path, then write a zero value to the direct\_cmd\_wrdat register to send the zero parameter write command.

**Note:** Failure to follow these procedures may result in non-zero data in the unused parameter locations; this may or may not affect the peripheral, however it is recommended to use the process described to ensure compliance with the DSI specification in this regard.

If STOP mode is forced during a command mode read or write transaction, all outstanding transactions should be considered lost and all status and error flags should be disregarded and cleared. Similarly, if an LPDT read data operation is stopped by writing to the STOP\_READ\_OPERATION field of the DIRECT\_CMD\_RD\_INIT register, the status for the aborted read operation should be disregarded and cleared before resuming normal operation.

#### 12.6.4.7.5.3 Bus Turnaround Sequence

The command operation can request a read or an acknowledge response from the panel after a long sequence of packets is sent. The Bus turnaround is also used to control the Tearing Effect control.

When a Bus Turnaround is requested from the command stream manager, the DPHY will be given a turn request. The request will make the DPHY interface perform a sequence of LP states (LP11-10-00-10-00) to indicate that it is releasing control of the DP/DN signals. The DPHY Direction signal will change once it detects the Panel side driving the LP00-10-11 states. The panel will then be able to send any response packets (see section 0) and release the bus by issuing a bus turnaround sequence to the controller DPHY. The DSITX controller DPHY will detect the sequence and change the direction signal once the pattern is sent and LP00 state is valid for 2-3 TX\_ESC\_CLK cycles.

Figure 12-393 shows Bus turnaround timing sequence from controller to panel and panel to controller.

**Figure 12-393. Bus Turnaround Timing Sequence from Controller to Panel and Panel to Controller**

#### 12.6.4.7.5.4 Tearing Effect Control

The DSI command control for a tearing effect request can be performed using the polling method or automatically. The enable bits for BTA and TE must be enabled for the mechanism to be performed with either the SDI or DIRCMD interface. For automatic operation, the DSI will send a first BTA, and then waits for BTA reception and if no TE has been received during the first BTA <sup>(1)</sup>, it sends another BTA and then waits for TE. There are three possible error conditions that can happen (but only the two first are detected by the DSITX controller and passed to registers):

- If the display answers to the second BTA with another BTA and thus does not send the TE - this means that the display does not support TE generation OR that TE generation mechanism has not been enabled (reg\_err\_no\_te).
- If the TE has not arrived within a given programmable period – this means that the TE request arrived too late and that the Display Application Processor is not synchronized with the display. The error reported is reg\_err\_te\_miss but the system continues to wait until the TE is received. <sup>(2)</sup>
- If a time-out has been detected by the DSI showing that a problem happened during the BTA and that the system is forced back to idle without BTA – in this case, a BTA without TE is seen and the CSM generates a reg\_err\_no\_te (as for first case).

For the polling method to request a tearing effect (TE polling mode is enabled with te\_hw\_polling\_en = 1) the DSI sends a first BTA, waits for peripheral TE + BTA, if only BTA has been received after the first BTA, it keeps sending BTAs until peripheral responds to the BTA by a TE + BTA instead of BTA only; in this specific mode reg\_err\_no\_te will never be asserted. To stop sending BTA and waiting for TE a force stop <sup>(3)</sup> is needed.

**Note 1:** TE received is checked on the first BTA in case a BTA was the last command issued by the DSI link (BTA or read command sent via direct command interface).

**Note 2:** Again to support the cases where a BTA was emitted just before the TE request, the TE windows is counted on the first BTA (in case the display understands this BTA as the TE request and thus may emit too late the TE), and is restarted after the second BTA.

**Note 3:** The time to wait before forcing a stop should be around the duration of a frame. The reason is that if you miss the TE time at the end of the current frame, you've to wait till the end of the next frame before new TE can be sent by display.

The following table describes the TE timeout counter operation, Programming of the IP. The counter value should be calculated based on the tx\_byte\_clk period.

**Table 12-363. TE Timeout Programming**

te_timeout(11)	te_timeout(10)	timeout value
0	0	$256 \times \text{te\_timeout}<9:0>$
0	1	$512 \times \text{te\_timeout}<9:0>$
1	0	$1024 \times \text{te\_timeout}<9:0>$
1	1	$2048 \times \text{te\_timeout}<9:0>$

#### 12.6.4.7.5.5 Tearing Effect Control on Panels with Frame Buffer

Display panels will use command mode sequencing when an on-board frame buffer is used to store the video image rather than using the video streaming and synchronisation packets to control the update of the image information. This means that the host display driver must know when the panel is processing the image and avoid changing pixel information before it is updated. The mechanism is known as the tearing effect. The DSITX controller can support two schemes as outlined in the MIPI DSI specification.

#### TE control using the Polling Method

For polling to the display module, the host processor shall detect the current scan line information with a DCS command such as **get\_scan\_line** to avoid Tearing Effects. DSITX controller will issue a READ using this command until it gets to the expected value for the last line.

#### DCS Command - get\_scanline (45h)

##### Command

Direction H->D

Hex Code 0 1 0 0 0 1 0 1 45h

##### Parameter 1

Direction D->H

Hex Code N15 N14 N13 N12 N11 N10 N9 N8 XXh

##### Parameter 2

Direction D->H

Hex Code N7 N6 N5 N4 N3 N2 N1 N0 XXh

**Figure 12-394. get\_scan\_line Command**

#### Description

The display module returns the current scanline, N, used to update the display device. The total number of scanlines on a display device is defined as VSYNC + VBP + VACT + VFP. The first scanline is defined as the first line of V Sync and is denoted as Line 0.

In Sleep Mode, the value returned by **get\_scanline** is undefined. See [MIPI-DPI] for definitions of VSYNC, VBP, VACT, and VFP.

- In 2D mode, the scanline value of the display memory and the display panel is the same.
- In 3D Mode, the scanline value of the display memory and the display panel can be different; **get\_scanline** shall return the current scanline of the display panel.

#### Restrictions

None

#### TE control using the Automatic Method

For TE-reporting from the display module, the TE-reporting function is enabled and disabled by three DCS commands to the display module controller: `set_tear_on`, `set_tear_scanline`, and `set_tear_off`. See [MIPI-DCS] for details.

`set_tear_on` and `set_tear_scanline` are sent to the display module as DSI Data Type 0x15 (DCS Short Write, one parameter) and DSI Data Type 0x39 (DCS Long Write/write\_LUT), respectively. The host processor ends the transmission with Bus Turn-Around asserted, giving bus possession to the display module.

Since the display module DSI Protocol layer does not interpret DCS commands, but only passes them through to the display controller, it responds with a normal Acknowledge and returns bus possession to the host processor. In this state, the display module cannot report TE events to the host processor since it does not have bus possession.

To enable TE-reporting, the host processor shall give bus possession to the display module without an accompanying DSI command transmission after TE reporting has been enabled. This is accomplished by the host processor protocol logic asserting (internal) Bus Turn-Around signal to its D-PHY functional block. The PHY layer will then initiate a Bus Turn-Around sequence in LP mode, which gives bus possession to the display module.

Since the timing of a TE event is unknown to the host processor, the host processor shall give bus possession to the display module and then wait for up to one video frame period for the TE response. During this time, the host processor cannot send new commands, or requests to the display module, because it does not have bus possession.

#### DCS Command - `set_tear_on` (35h)

##### Command

Direction H->D

Hex Code 35h

##### Parameter

Direction H->D

Hex Code X X X X X X M XXh

**Figure 12-395. `set_tear_on` Command - 1**

##### Description

This command turns on the display module Tearing Effect output signal on the TE signal line. The TE signal is not affected by changing `set_address_mode` bit B4. `set_tear_on` has one parameter that describes the Tearing Effect Output Line mode.

If M = 0 (Mode 0):

The Tearing Effect Output line consists of V-Blanking information only.

**Figure 12-396. set\_tear\_on Command - 2**

If M = 1 (Mode 1):

The Tearing Effect Output Line consists of both V-Blanking and H-Blanking information.

**Figure 12-397. set\_tear\_on Command - 3**

The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI- DPI] for definitions of tvdl, tvdh, thdl and thdh.

### Restrictions

This command takes effect on the frame following the current frame. Therefore, if the Tearing Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous set\_tear\_on, or set\_tear\_scanline, command until the end of the frame.

### DCS Command - set\_tear\_scanline (44h)

#### Command

Direction H->D

Hex Code 0 1 0 0 0 1 0 0 44h

#### Parameter 1

Direction H->D

Hex Code N15 N14 N13 N12 N11 N10 N9 N8 XXh

#### Parameter 2

Direction H->D

Hex Code N7 N6 N5 N4 N3 N2 N1 N0 XXh

dsi\_spruij7-012

**Figure 12-398. set\_tear\_scanline Command - 1****Description**

This command turns on the display module Tearing Effect output signal on the TE signal line when the display module reaches line N. The TE signal is not affected by changing `set_address_mode` bit B4.

The Tearing Effect Line On has one parameter that describes the Tearing Effect Output Line mode.

After issuing a `set_tear_scanline` command to the display module, the Tearing Effect output signal, e.g. as in DBI- 2 systems, shall be a delayed version of V-Blanking information as illustrated in [Figure 12-399](#).

dsi\_spruij7-013

**Figure 12-399. set\_tear\_scanline Command - 2**

Note that `set_tear_scanline` with  $N = 0$  is equivalent to `set_tear_on` with  $M = 0$ . The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI-DBI] for definitions of  $t_{vdl}$  and  $t_{vhd}$  and [MIPI-DSI] for definition of display module line numbers. In 2D mode, the scanline value of the display memory and the display panel is the same.

**Restrictions**

This command takes effect on the frame following the current frame. Therefore, if the Tear Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous `set_tear_on`, or `set_tear_scanline`, command until the end of the frame.

**DCS Command - set\_tear\_off (34h)****Command**

**Direction** H->D

**Hex Code** 0 0 1 1 0 1 0 0 34h

**Parameters** None

**Description**

This command turns off the display module Tearing Effect output signal on the TE signal line.

dsi\_spruij7-014

**Figure 12-400. set\_tear\_off Command**

## Restrictions

This command has no effect when the Tearing Effect output is already off.

### 12.6.4.7.5.6 Return Path Operation

The DSI Return Path behaves like a slave, by collecting data from the DPHY receive interface when the DPHY is configured to accept a transmission from the peripheral. The RP receives 6 signals from the DPHY (see [Table 12-364](#)).

The data (and trigger) reception is inactive if the DPHY PPI direction signal is at low level. When it is active, data is received using the RX ESC\_CLK clock (the clock is transmitted with the data itself - see D-PHY protocol description from MIPI) and may stop if there is a pause in the data transmission but data is generated on clock falling edge. New data is available on rx\_data\_esc on a rising edge of the clock, if both rx\_lpd\_t\_esc and rx\_valid\_esc are asserted.

**Table 12-364. Interface Between Return Path and DPHY**

Signal Name	I/O	From/To	Description
rx_lpd_t_esc	I	DPHY	Escape Low Power data receive mode This active high signal is asserted to indicate that the lane module is in low-power data receive mode. While in this mode, received data bytes are driven onto the rx_data_esc output when rx_valid_esc is active. The lane module remains in this mode with rx_lpd_t_esc asserted until a stop state is detected on the lane interconnect.
rx_trigger_esc(3:0)	I	DPHY	Escape trigger received These signals indicate that an escape trigger command has been received. Only one of these signals will be asserted at any time and the signal will remain asserted until the lane module returns to stop state.
rx_data_esc(7:0)	I	DPHY	Escape receive data For Low Power data receptions, this eight-bit value is driven by the D-PHY and is valid on rising edges of rx_clk_esc with rx_valid_esc asserted. The bit connected to rx_data_esc[0] was received first.
rx_valid_esc	I	DPHY	Escape receive data valid This signal indicates that the lane module is driving data on rx_data_esc and expects the protocol layers to take the data at the current rising edge of rx_clk_esc. There is no "ready" signal to throttle the receive data.
stop_state_dl1	I	DPHY	Lane is in stop state This signal indicates that the lane module is in STOP state. Note that this signal is asynchronous to any clock in the protocol interface.
direction	I	DPHY	Lane direction. When this signal is high, the lane module is in receive mode. When direction is low, the lane module is in transmit mode. (Mnemonic: 1 = Input, 0 = Output.)

The received data messages are identified as one of two possible types:

- Trigger
- Read packet

**Trigger** messages are passed almost directly to the register (reg\_req = reg\_trigger = 1 and reg\_rd\_data<3:0> equals to trigger value during one clock cycle). However, triggers are decoded to see if they are a TE trigger or an acknowledge with no error.

- The TE data is passed separately to the CSM using csm\_te\_received pin. It needs to be resynchronized with tx\_byte\_clk byte clock because of the CSM working clock domain.
- The acknowledge is only passed to register using reg\_req and reg\_ack pins. All other trigger values are passed undecoded to the registers without any processing. It is the responsibility of the application to decode and decide what to do with them.

**Read Packet:** When data is received, the system waits for the 4 bytes of the **HEADER**, and performs an ECC correction (if it is enabled) and then decodes the packets.

The following cases are considered when the system performs the ECC check:

- If the received command is not in the list of legal display opcodes, (i.e. errors in the packet header), it discards that packet and all further incoming bytes, even if they are legal packets (until the next BTA - i.e. direction change). It sends errors to the register bank (err\_undecodable and uncorrectable\_err). This may also result in an EOT error being reported as no further bytes have been decoded. But even if ECC correction shows an uncorrected error, decoding is attempted (if the errors are in the ECC byte or in the payload bytes, the opcode can be understood and data correctly recovered). In this case only err\_uncorrectable error bit is sent to register and it falls in the situation of regular commands (acknowledge with error or read).
- If "an acknowledge with error", the two status bytes are sent to the registers (reg\_req = 1 and reg\_ack\_err = 1 and reg\_rd\_data<15:0> contains the correct value).
- If the message type is a short read (either DCS or generic), data is passed to the registers (2 bytes without any specific decoding). Interface signals must be set accordingly and the two bytes are sent to registers (reg\_req = reg\_start = reg\_end = reg\_read = 1 with data and dscnotgen set accordingly). Size information is decoded in the first byte of the received packet depending on the data type information and then sent to register using reg\_size port.
- If a long read, the size is sent to the register using reg\_size. The system goes to **LONG state**. All data received are sent to register using reg\_data and are used for checksum detection. If during receive, return packet fifo (in control block) becomes full (rd\_data\_fifo\_full), the error flag err\_oversize must be set. All remaining data is used for checksum calculation but are not transferred to registers. When the number of received bytes is equal to the packet size, the system will check the **CHECKSUM**. The two checksum bytes are never transferred to register. They are used to make checksum detection and indicate err\_checksum status.
- If the transfer is shorter than the size specified in the header, the error err\_wrong\_length is issued along with any subsequent errors such as err\_missing\_eot (if needed). The case where it is longer drives to a tentative checksum decoding that generates an error and by a tentative to decode a new header (that is in fact a part of the previous packet) that drives to an error err\_undecodable and the throwing of the rest of the received bytes (with corresponding errors such as err\_missing\_eot).
- If it is an EoT packet, it is not passed to the control block. The following data is ignored (if any). If the system is waiting for **EoT**, this is the only action. If system is not waiting for EoT packet, the err\_eot\_with\_err is sent.
- If after an "acknowledge with error", the system waits for EoT packet and counts 4 bytes but is not able to decode them, it emits an err\_eot\_with\_err and err\_undecodable.
- If direction is removed at a "wrong" time (i.e before the fourth byte of a small packet, the system stops to works but emit errors to the register: err\_receive with eventually err\_missing\_eot.

The DSI is designed to support multi-peripheral integration, the virtual channel of the received packet is also stored in register using reg\_vc port.

The application FW layer is responsible of all read actions, it is assumed that once a read is requested, application reads return packets before requesting other read actions. Based on this assumption, the receive FIFO implemented in the register block is cleared each time a read action is started. All data not read before the new read command are lost.

A re-initialization of the return path is also performed using register access on reg\_init\_rp.

All errors related to short or long received data packets should be captured in the register when the direction changes (to capture all errors at the same time and not generate several errors and possibly several interrupts on the same reverse transaction). As soon as an error is detected on a packet, the error must be recorded and maintained up to the end of the packet transfer.

The maximum packet size supported by the DSI return path is 16 bytes. If a longer packet is received, only the first 16 bytes are available (by register way) for application.

#### 12.6.4.7.5.7 EoT Packet Management

The DSI protocol states that, in the sending path, only the HS transmission requires use of EoT packet. For transfer from display to host, it is not recommended to use EoT but it is possible. The host needs to be able to detect the EoT packet and then behaves accordingly.

In case the display makes use of the EoT packet, the bit disp\_eot\_gen must be set to one. In that case, if after the ECC correction, the packet header is 0x08, we've detected an EoT packet and all bytes that may arrive between this packet and the direction change must be ignored.

If additional data is received between the EOT packet and the next BTA (end of read process), or if an unwanted EOT packet is detected, the unwanted bytes must be rejected and err\_receive is asserted.

If the EoT packet is not detected although it should be present, the error err\_missing\_eot is set. If after an "acknowledge with error", 4 bytes are received before BTA but are not identified as EoT (because of errors), it is assumed these 4 bytes are the EoT. In that case, the error err\_eot\_with\_err has to be set with err\_undecodable.

#### 12.6.4.7.5.8 ECC Correction

The DSITX controller uses the packet header ECC information to detect and correct one error, and can detect two or more errors without correction.

#### 12.6.4.7.5.9 LP Transmission and BTA

The DSI host may send a command sequence and then request an acknowledge message from the panel. The host will send the command and release the bus by performing a BTA sequence. The panel will then respond with an acknowledge message (or error response) followed by a BTA to return the bus to the host. This sequence is illustrated in Overview of a Display Subsystem.

Overview of a Display Subsystem.

Figure 12-401 shows LP transmission timing diagram.

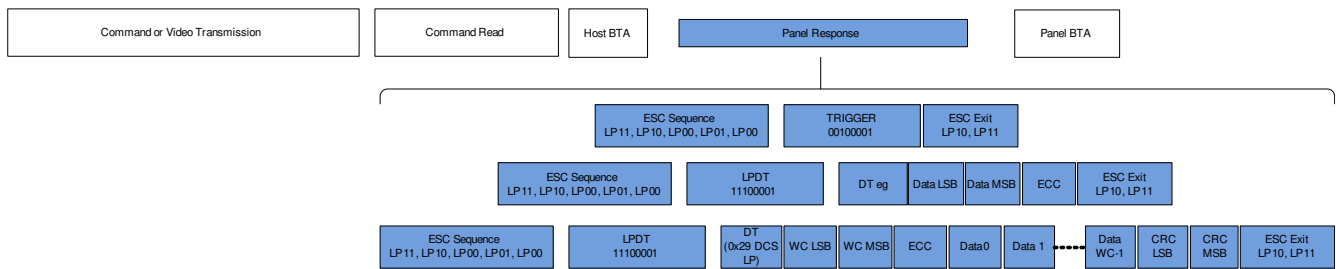

ds1\_spruij7-015

**Figure 12-401. LP Transmission Timing Diagram for Host Read and Trigger ACK**

The Host will not be able to transmit any other packets once the BTA is sent to the panel and will expect either an ACK trigger or response LPDT message with a payload. The system must ensure there is sufficient time to send any command and issue the BTA, receive the response (Trigger, Short or long packet) and accept the BTA from the panel, if this request is made in the line blanking intervals.

Figure 12-402 presents panel read response sequences.

**Figure 12-402. Panel Read Response Sequences**

The panel response time will be based on the tx\_esc\_clk used inside the panel and the expected number of bytes for the payload. The expected responses are illustrated in the blocks in the MIPI DSI standard.

#### 12.6.4.7.6 Low-power Management

There are several low-power scenarios which consist of switching off various parts of the design:

1. Switch D-PHY cells in ULP mode when there is no data to be sent (bits clk\_lane\_ulpm\_en, dat1\_ulpm\_en, dat2\_ulpm\_en, dat3\_ulpm\_en and dat4\_ulpm\_en in register mctl\_main\_en set to one with ULP mode enabled in register mctl\_main\_phy\_ctl). Please, note that the time to leave ULP state is 1 ms and needs to be set in clock cycles in the register mctl\_ulpout\_time.
2. Switch the DPHY byte/bit clock PLL off (refer to DPHY documentation for control sequence). In this case, the D-PHY cell can only transmit data in LPDT thus maximum bandwidth is 10 Mbits/s).
3. More drastic methods are to shut-down some parts of the design. The D-PHY and the DSI themselves can be shut down.

When D-PHY and DSI are both shut-down and the display is powered down, the restart is a normal start procedure as described in [Section 12.6.4.7.3, Start-up procedure](#).

When only the D-PHY is stopped, it is placed in either the stop or ULP state. Restarting the D-PHY is similar to the regular start-up procedure, however, after the lanes are enabled by the DSI Controller (clk\_lane\_en, dat1\_en, dat2\_en, dat3\_en and dat4\_en in register mctl\_main\_en are set), the D-PHY generates a rising edge on the stopstate signal to indicate to the DSI Controller that the enable request has been effective within the D-PHY. After that the start-up procedure may continue up to the point that the DSI link is ready to begin transmission.

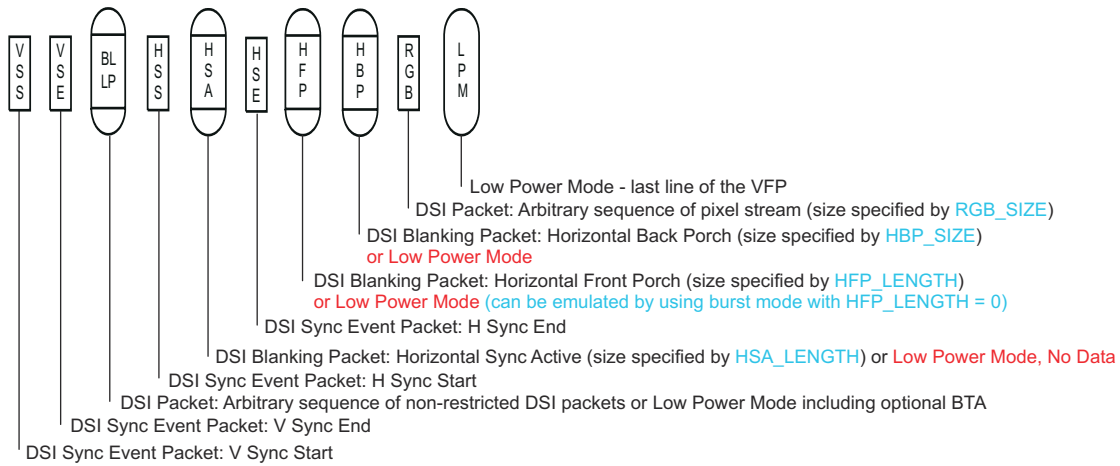

Note that when setting the D-PHY into the ULP state, the application needs to wait enough time between the time it sets the ULP request in register and the time the D-PHY is disabled – this ensures that the ULP request is detected on the D-PHY interface.

#### 12.6.4.7.7 Video Mode Settings

All values contained in the Control Block (CB) registers must be set with meaningful values and are expressed with a range of different units: clock cycles, bytes, number of lines.

##### 12.6.4.7.7.1 Video Stream Presentation

In [Figure 12-403](#), it shows the list of packets that can be part of a video stream and the associated register fields. In the four following figures ([Figure 12-404](#), [Figure 12-405](#), [Figure 12-406](#), [Figure 12-407](#)), different video streams that can be generated are presented.

dsi-017

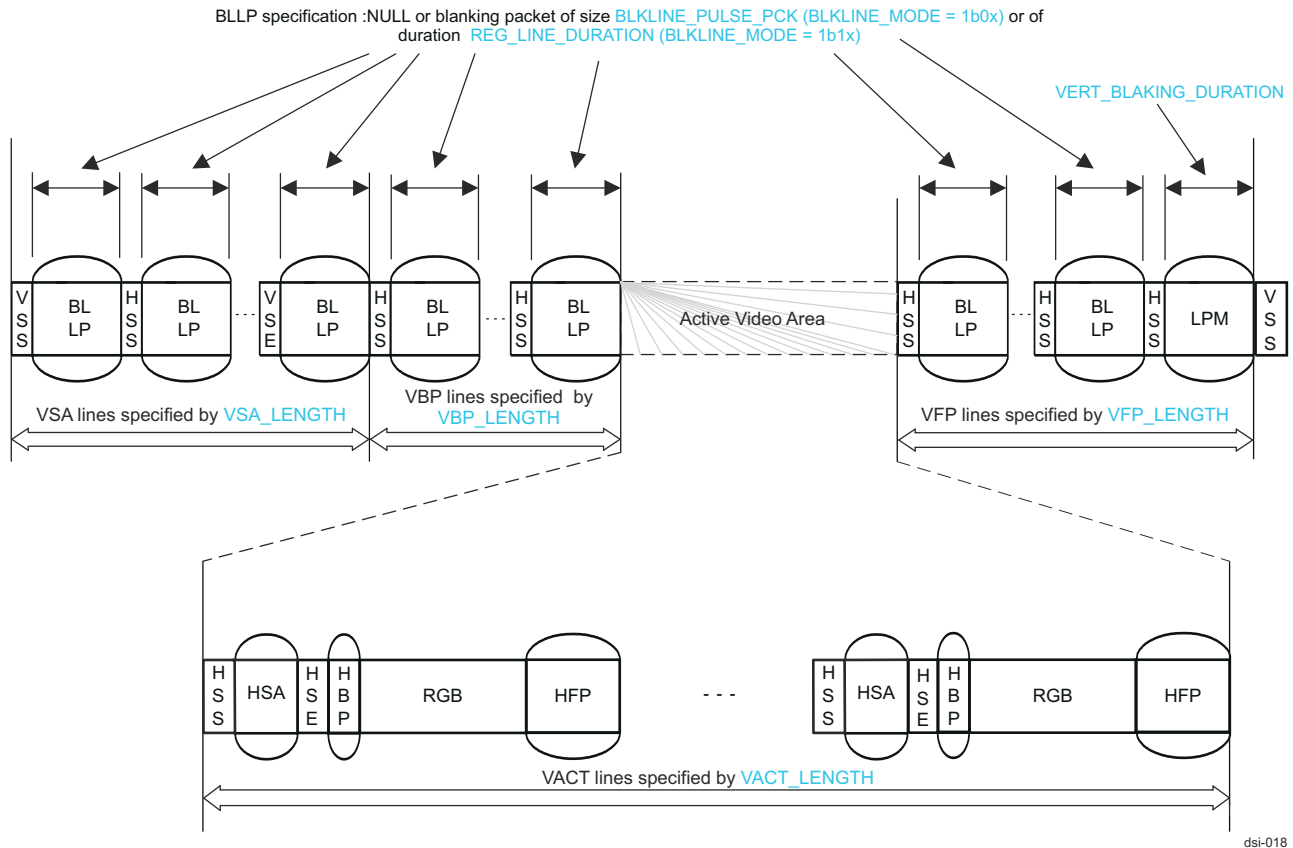

**Figure 12-403. DSI Packet Terminology**

Red text - behaviour not possible.

Blue text - register fields used to specify the packet size.

The BLLP (Blanking – Low Power) periods allow the DPHY link to perform the following sequences:

- Host Transmit blanking packets in HS.
- Host Transmit command packets in HS or LP (Escape mode).
- Host Transmit packets using interleaving to a different virtual Channel in HS or LP (Escape mode).
- Host performs BTA and waits for response packets from the panel using Escape Mode followed by a panel BTA.

dsi-018

**Figure 12-404. Video Pulse Mode (Non-Burst) Timing Diagram**

**Note**

This sequence is no longer specified in the MIPI spec Version 1.02.00 28-Jun-2010 but supported by the DSI-controller.

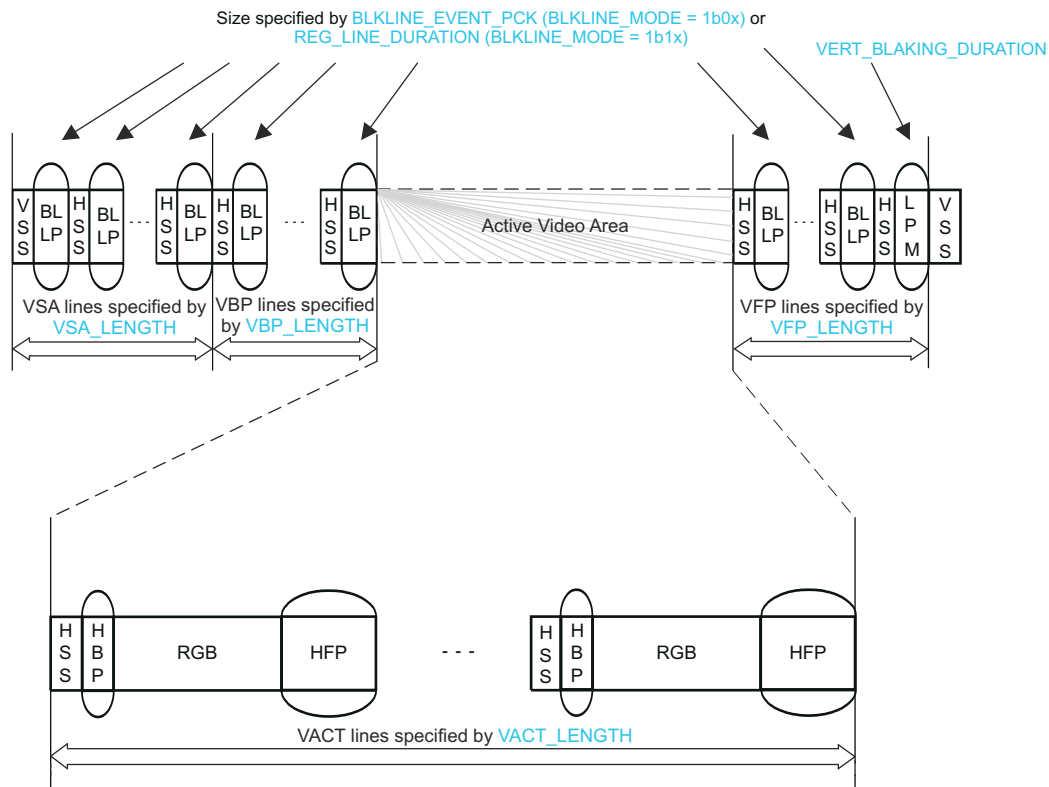

dsi-019

**Figure 12-405. Video Pulse Mode (Non-Burst)**

**Note**

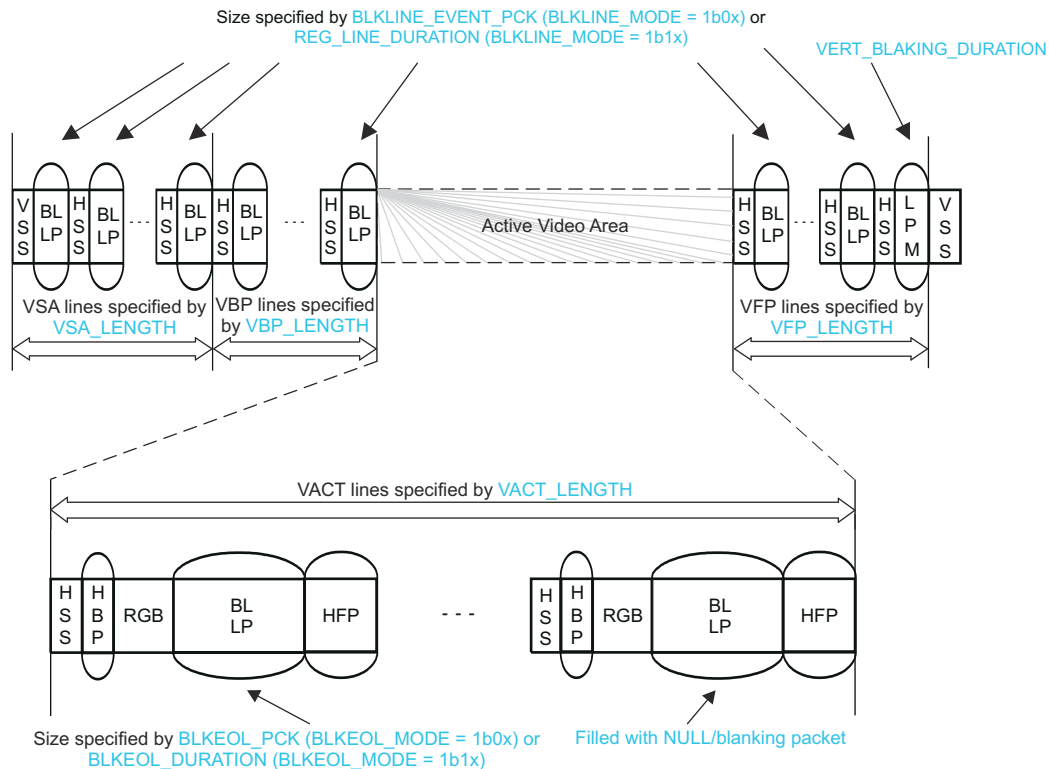

In the MIPI spec 1.02.00 June 2010, the line (VSE/HSA/HSE/BLLP) has been moved from VSA lines part to the VBP lines part. The sequence is the same but in the design the VSA lines has one more line and the VBP lines has one line less. This must be considered during the VSA and VBP register programming if the DSI MIPI spec 1.02.00 is used as reference.

dsi-020

**Figure 12-406. Video Event Mode (Non-Burst)**

burst\_mode = sync\_pulse\_active = sync\_pulse\_horizontal = 0 - all spec versions.

dsi-021

**Figure 12-407. Video Sync Event in Burst Mode**

burst\_mode = 1 and sync\_pulse\_active = sync\_pulse\_horizontal = 0 - all spec versions.

Burst Mode operation requires the tx\_byte\_clk to be set to double the bit rate compared to the non-burst case. The calculations for the video parameters must then be increased to match the higher rate. The DPI FIFO must also be large enough to store at least half of the active line bytes before the output transmission begins otherwise it will underrun.

#### 12.6.4.7.7.2 Video Stream Settings (VSG)

The following is all the registers that need to be set before using the video in SDI or DPI interface operation.

- vid\_vsize1, 2
- vid\_hsize1, 2
- vid\_blksize1, 2
- vid\_pck\_time
- vid\_dphy\_time
- vid\_error\_color1, 2
- vid\_vca\_setting1, 2
- vid\_main\_ctl – programmed last in sequence of vid registers to apply to DSI registers

This section addresses the dependencies between all video registers, and details how the TVG and VCA registers must be set per VSG registers.

##### vid\_main\_ctl

- header information must correspond with the vid\_pixel\_mode used to control the generation of the recovery streams. The header information is used to be enable management of future cases where the DSI link could be used to pass streams with formats that differ from those currently supported directly.
- sync\_pulse\_horizontal can only be asserted if sync\_pulse\_active = 1.

When sync\_pulse\_active is set to one, the HSYNC pulses are emulated only during the active part of the frame. When both sync\_pulse\_horizontal and sync\_pulse\_active are set, the HSYNC pulses are present on all lines of the frame.

**vid\_vsize** - the variables are expressed in line numbers in this register.

- vsa\_length should be at least one (in order VSG can insert at least the vertical synchronization start VSS line) and greater or equal to 2 when pulse mode (sync\_pulse\_active = 1).
- vbp\_length 0 to 63.
- vfp\_length must be greater than 0.
- vact\_length must be greater than 0.
- vid\_hsize1: - the numbers are expressed in number of bytes (the fields are specifying the payload).

**vid\_hsize1** - the numbers are expressed in number of bytes (the fields are specifying the payload of the corresponding packet).

- hsa\_length need to be at least set to one if pulse mode is enabled. The expected normal operating range is 1 to 255, large values for the HAS length will impact on the size of the DPI FIFO required.
- hbp\_length can have any value. However, when set to 0, a HBP packet is generated with 0 payload.

**vid\_hsize2** - again the fields are specifying the payload of the corresponding packet (in byte).

- hfp\_length can have any value. However, when set to 0, no HFP blanking packet is generated.
- rgb\_size must match the number of pixel per line of the display multiplied by the number of byte per pixel.

**vid\_blksize1** - still specifying size of the payload in byte.

- blkline\_event\_pck defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when reg\_blkline\_mode = 0b01 or 0b00 and when sync\_pulse\_active = 0. It is also needed by the VSG when reg\_blkline\_mode = 0b1x. Its value depends on the hbp, rgb, blkcol, and hfp packet length.
- blkline\_event\_pck defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when reg\_blkline\_mode = 0b01 or 0b00 and when sync\_pulse\_active = 0. It is also needed by the VSG when reg\_blkline\_mode = 0b1x. Its value depends on the hbp, rgb, blkcol, and hfp packet length.

-- 32767 = 0x7FFF = max value on 15 bits and -100 to take

margin blkeol\_pck < 32767 - hfp\_length - hbp\_length - hsa\_length - rgb\_size - 100;

The blkeol\_pck (and blkeol\_duration) must be adapted to the reg\_wakeup\_time in case VCA is authorized to go back in LP.

**vid\_blksize2** - still specifying size of the payload in byte.

- blkline\_pulse\_pck has almost the same definition than blk\_event\_pck but it concerns blanking lines with sync pulse.

**vid\_pck\_time** - specifies duration in clock cycles.

- blkeol\_duration:  $\text{blkeol\_duration} = \text{div\_round\_up}^{(1)}((\text{blkeol\_pck} + 6), \text{lane\_nb})$ ;
- vert\_blanking\_duration is no longer used and can always be set to 0. It remains present in the design for legacy reason.

**Note 1:** The function div\_round\_up is a function that performs a division then round the result to the first entire number superior or equal to the division result.

**vid\_dphy\_time:** specifies duration in clock cycles. These are values that have external dependencies and thus need to be calculated first (and rest of VSG programming is calculated from these values).

**reg\_line\_duration:** depends on display type and size and of its programming (in some display, the blanking sizes can be adapted to provide a given number of frame per second with one of the D-PHY possible clock frequency (as PLL can only generate a given number of discrete frequencies)).

**if (pulse mode) {**

**line\_length = (blkline\_pulse\_pck + 6);**

**}**

**else (event mode) {**

**line\_length = (blkline\_event\_pck + 6);**

**if (burst\_mode and burst\_lp and lane\_nb == 2 and**

**hsa\_length[0:0] == 1 and hfp\_length[0:0] == 1)**

**line\_length = line\_length - 1;**

**}**

**result = div\_round\_up(line\_length, lane\_nb);**

**Note 1:** The function div\_round\_up is a function that performs a division then round the result to the first entire number superior or equal to the division result.

Additional Notes about the line duration:

- If line length (in bytes) is a multiple of the number of lanes enabled, DSI will never face any timing jitter except due to the resynchronization in SP/DCB.
- If line length (in bytes) is NOT a multiple of the number of lanes enabled For Non LP operation, there should not have any problem since the line is once longer, once shorter than the "normal" value. For example: if line length is 491 bytes, it will be 245 then 246 in clock cycles with 2 lanes for an average value of 245.5.

For LP enabled operation, the controller cannot allow underflow of the line and frame timing. With the previous example, the LP line length in clock cycles will be 246 since we cannot start the HS transmission in the middle of a clock cycle. And there is no mechanism to have one line in 245 and the next one in 246 cycles. For LP see section 0.

**reg\_wakeup\_time** must be shorter than line duration and depends on the D-PHY cell plus some pipelines delays inserted by the DSI link. This value strongly depends on the DPHY PLL programming and configuration, and is a mix of both internal and external analog and digital timing factors, therefore it is very difficult to provide an exact formula. The recommended approach to selecting a suitable value for this parameter is to characterize

behaviour in at the system level environment using simulation, emulation (e.g. Palladium) or validation (e.g. FPGA).

The DPHY needs 100 ns + time for THXS-EXIT to go to Low Power mode.

The timing for the clock lane TXRequestHS going active to the TXReadyHS will be determined by the DPHY DDR bit rate clock frequency. The timing will be the total number of DDR bit clk cycles for the TXRequestHS to be detected and the clock lane to transition to High Speed, so TLPX + TCLK-PREPARE + TCLK\_ZERO. Additional time is required between the clock lane driving HS clocks and the Data Lanes being activate, TCLK-PRE. All of these parameters can be calculated from the DPHY datasheet.

Figure 12-408 shows timing diagram for clock lane activation/deactivation.

**Figure 12-408. Timing Diagram for Clock Lane Activation/Deactivation**

The data lane request follows a similar timing sequence from the TX\_Request\_HS to TX\_Ready\_HS, TLPX + THS-PREPARE + THS\_ZERO. The data lane requests will be activated once the clock lane is ready, i.e TX\_Ready\_HSCLK is high.

Figure 12-409 shows timing diagram for data lane activation/deactivation.

**Figure 12-409. Timing Diagram for Data Lane Activation/Deactivation**

**Table 12-365. Timing Parameters**

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
TLPX	Transmitted length of any Low- Power state period.	50 ns		50 ns

**Table 12-365. Timing Parameters (continued)**

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
TCLK-PREPARE	Time that the transmitter drives the Clock Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	38 ns	95 ns	38-95 ns
TCLK-PREPARE + TCLK-ZERO	TCLK-PREPARE + time that the transmitter drives the HS-0 state prior to starting the Clock.	300 ns		300 ns
Wakeup Time CL				388-445 ns
TCLK-PRE	Time that the HS clock shall be driven by the transmitter prior to any associated Data Lane beginning the transition from LP to HS mode.	8 UI		12.3 ns
THS-PREPARE	Time that the transmitter drives the Data Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	40 ns + 4 × UI	85 ns + 6 × UI	~ 46-95 ns
THS-PREPARE + THS-ZERO	THS-PREPARE + time that the transmitter drives the HS-0 state prior to transmitting the Sync sequence.	145 ns + 10 × UI		160 ns
Wakeup Time DL				~ 270 ns

So the wakeup time values expressed as tx\_byte\_clk (12.3ns) cycles, CL = 36 and CLKPRE + DL = 22.

Figure 12-410 shows wakeup time timing diagram.

**Figure 12-410. Wakeup Time Timing Diagram**

Here is the example of the calculation done for the system running at **650 MHz**.

```

if (clk_continuous == TRUE) {
wakeup_time_cl = 0x1;
} else {
wakeup_time_cl = 0x24;
};

wakeup_time_dsi = 0xA; -- from request on VSG to request HS on DL1 (+ 1 for VSG internal cycle)
wakeup_time_dl = 0x14; -- from stop state falling edge to tx_ready rising edge
reg_wakeup_time = wakeup_time_dsi + wakeup_time_cl + wakeup_time_dl + (hs_host_eot × 4 / lane_nb)

```

**Note:** It is not necessary to program all the register values every time because some of them are used only in some modes. For instance, blkline\_event\_pck and blkline\_pulse\_pck are used depending on the way SYNC is generated, and then in pulse mode, there is no need to program blkline\_event\_pck and vice-versa.

### 12.6.4.7.7.3 VCA Configuration

The VCA setting done in two registers: vid\_vca\_setting\_1 and vid\_vca\_setting\_2. Their programming must respect the following rules:

- vid\_vca\_setting\_1:
  - max\_burst\_limit specifies the size of the bigger packet that generates the following sequence RGB + packet + NULL packet + BLK packet; it must be linked with blkeol\_pck (same size minus the smaller NULL packet). It is equal to blkeol\_pck - 6.
    - burst\_lp can be set to 1'b1 if blkeol\_pck > 2 × reg\_wakeup\_time × lane\_number (reg\_wakeup\_time is only specifying the time to go from LP to HS thus need to consider the time to go from HS to LP too).
- vid\_vca\_setting\_2:
  - exact\_burst\_limit: as it specifies (in byte) the payload of the packet that generates a sequence RGB + packet + HFP, it must have the same value as of blkeol\_pck when the DSI link is in burst mode.
  - max\_line\_limit specifies the maximum size of a packet that generates HSS + (HSA + HSE) + packet + NULL packet. It then depends on line\_duration, hsa\_length regardless if the system is using pulse or event synchronizing. Its size is linked to vert\_blanking\_duration.

```
if (sync_pulse_active == 0) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = (blkline_event_pck-6);
};
if (sync_pulse_active == 1) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = gen_blkline_pulse_pck-6;
```

Another constraint to respect when using VCA is to ensure that only supported operations are sent from command side when video is active. For instance, no TE should be attempted, because it could break the video stream (TE completion time can be long). Command messages can be inserted into the LP states provided there is sufficient space for the message bytes and any associate bytes for the header and CRC, if a long packet type.

### 12.6.4.7.7.4 TVG Configuration

The TVG has a single register: tvg\_img\_size that should complies with the following rules against VSG settings:

tvg\_line\_size: must be equal to rgb\_size set for VSG

tvg\_nblne: must be equal to vact\_length set for VSG

The TVG generates a data stream in the same format than the one specified at the output of the VRS. The content of that flow is specified by the following registers:

- Image size - TVG\_LINE\_SIZE[14:0] and TVG\_NBLINE[12:0] registers: Number of bytes per line and number of lines per frame.
- Image kind - TVG\_MODE[1:0] register: Single color, vertical stripes or horizontal stripes.
- Stripe width - TVG\_STRIPE\_SIZE[2:0] register: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128.
- Pixel kind VID\_PIXEL\_MODE[3:0] register: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB.
- Color one - COL1\_GREEN[11:0], COL1\_RED[11:0], COL1\_BLUE[11:0] registers: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered.
- Color two - COL2\_GREEN[11:0], COL2\_RED[11:0], COL2\_BLUE[11:0] registers: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered.
- Start pulse and stop handshake (+ stop mode) (see TVG\_CTL register).

The Test Video Generator can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

Figure 12-411 presents TVG MODE patterns.

**Figure 12-411. TVG MODE Patterns**

An example of the sequence is as follows:

- Select TVG for video stream generation instead of DPI/SDI 1 interface.
  - IF1\_EN bit to 0 (SDI stall signal at 1) in MCTL\_MAIN\_EN.
- Select video mode for interface 1 in MCTL\_MAIN\_DATA\_CTL.
  - TVG\_SEL bit to 1 in MCTL\_MAIN\_DATA\_CTL register to select stream from TVG.
- Select generated frame format in TVG\_CTL register.
  - Image format (single color, H stripes, V stripes) in TVG\_MODE field.
  - Image color selection in TVG\_COLOR1, TVG\_COLOR1\_BIS, TVG\_COLOR2, VG\_COLOR2\_BIS.
  - Stripes size in TVG\_STRIPE\_SIZE field.
  - Image size in TVG\_IMG\_SIZE register.

**Note:** The TVG settings on active area for the number of lines per frame and number of bytes per line must match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG\_STOPMODE field of TVG\_CTL.
  - TVG video stream generation start/stop controlled by the TVG\_RUN bit in TVG\_CTL register.
  - Polling TVG run status from the TVG\_RUNNING bit in TVG\_STS register is useful when setting TVG\_RUN to 0. TVG video stream generation does not stop the instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

#### 12.6.4.7.8 DPI To DSI Programming

The DPI interface will normally be driven from a graphics driver that will be configured to match a frame geometry and refresh rate for a panel display. The DPI driver will use the expected refresh rate and geometry for the active and blanking parts of a frame to determine the pixel rate clock. The DSITX controller will then translate this to match the incoming byte information to send across the DSI DPHY link.

A system will always expect the bandwidth of the incoming pixels × BPP to match the transmission of bytes from the DSI DPHY based on the number of active lanes. The relationship of DPI clock to TX byte clock must ideally hold with the following formula:

$$F_{\text{pixel\_clk}} = F_{\text{tx\_byte\_clk}} \times \text{active\_lanes} \times 8 \div \text{bits\_per\_pixel};$$

The DSI will supply packets to the DPHY interface using the internal sequencing and counters clocked from the tx\_byte clock. The normal system operation will mean that the DSI must always have the correct number of tx\_byte clock cycles to match the number of pixel clock cycles. This means that all the events used for the packet generation will be directly impacted by the delay that exists in the DPHY High Speed request to ready.

The DSITX controller relies upon the DPHY PLL being programmed and locked before starting the DPI video. The DSITX controller can then be configured and enabled (clock lane and data lanes) before starting the video transmission.

The DSITX controller will begin data transmission with a High Speed request after it receives the falling edge of the VSYNC on the DPI interface. The controller will then begin to build the bytes for the VSYNC packets (VSS, HSA, Blanking packets) during the delay period before the ready is returned from the DPHY. This delay will add an interval effect on all the packets that follow.

The DPI FIFO size must be sufficient to buffer all the incoming pixel data during the active line stage while the DSITX controller continues to send the previous lines packet information due to this interval effect.

**Figure 12-412. Timing Diagram**

The DPI and DSI system may not be able to guarantee the exact frequency on the pixel clock input or tx\_byte clock from the DPHY. The DSI configuration can be adjusted to support a small deviation in frequencies using the size of the HFP packet so that it changes the alignment of packets on the active lanes to absorb the different pixel clock cycles during the line. More details are given in section0.

#### 12.6.4.7.8.1 DSI and DPHY Operation

The DPI FIFO is used to buffer all the active pixel data from the DPI interface during the active line. The depth of the FIFO must be selected to allow the pixel to be stored after the DPHY request to ready delay is introduced at the start of every frame. The FIFO will fill to a depth based on the tx\_byte clock cycles used from the point where VSYNC is identified to the response from the DPHY link after it has exited Low Power and entered the zeroes state on the active data lanes.

Figure 12-413 presents DPI interface to DSI DPHY timing diagram.

**Figure 12-413. DPI Interface to DSI DPHY Timing Diagram**

The timing diagram above illustrates how the packets are generated for a DPHY with two and with four lanes activated. The diagram shows that the tx\_byte clock changes based on the number of lanes, and that the configuration register values for the number of bytes used for HSA, HBP and HFP will remain the same.

The register values calculated for each of the line synchronization stages needs to take the number of bytes used to form the packet into account so that the timing for each stage aligns to the timing of the DPI input and most importantly that the total number of bytes exactly matches the number of byte clock cycles. The values used for the Horizontal Front porch must be larger than the combined horizontal sync and back porch to allow the DPI FIFO to empty.

The basic rule is that the values used for the DSI will be based on the  $\text{DPI} \times \text{BPP}/8$ .

The DPI graphics driver must be configured with horizontal values that can be directly translated to DSI packet payloads.

- The minimum values for the DPI HSA must convert to be greater than:
  - Non-Burst Sync Pulses – 15 bytes
  - Non-Burst Sync Events – 11 bytes
- The minimum values for the DPI HBP must convert to be greater than:
  - Non-Burst Sync Pulses – 7 bytes
  - Non-Burst Sync Events – 7 bytes

These values will then form the number of tx\_byte\_clk cycles used to send the bytes over the number of active lanes. So, for an RGB888, DSI configuration the minimum values will be:

- $\text{HSA} = \text{roundup}(15/3) = 5$
- $\text{HBP} = \text{roundup}(11/3) = 4$

The diagram below, D-PHY Timings Control (see [Figure 12-414](#)), illustrates the byte mapping for a four lane DPHY link. In this example, the calculation for the horizontal sync stage aligns exactly across the four byte lanes.

- HSS – Four Bytes
- HSA – Blank Packet with Header (4) + HSA\_Count + CRC(2)
- HSE – Four Bytes

The next stage is the horizontal back porch:

- HBP – Blank Packet with Header (4) + HBP\_Count + CRC(2)

The value used in the HBP count can be used to account for the Header bytes used in the active data packet in next stage, although it is best to add this to the HFP stage calculation and allow time to empty the FIFO.

**Figure 12-414. Horizontal Line Packet Timing Diagram**

The Active part of the line will be a fixed size based on the line size and BPP, and include the six bytes for the packet header and CRC. The final stage is the horizontal front porch.

- HFP – Blank Packet with Header (4) + HFP\_Count + CRC(2)

The HFP value should be adjusted to ensure that the number of tx\_byte clock cycles for the horizontal line exactly matches the pixel clock cycles for the line times the BPP.

The timing diagram below, Control Block, illustrates the byte alignment changing when the HBP calculated is two bytes shorter than the previous case. This leads to the active and front porch packet headers beginning two bytes earlier, however the HFP count is adjusted to keep the end of the line on exactly the same tx\_byte\_clk cycle count.

**Figure 12-415. Horizontal Line Packet - Shorter HBP - Longer HFP Timing Diagram**

The recommendation is to ensure that the total bytes for each horizontal line results in an exact integer tx\_byte clock cycles (Total\_bytes MOD num\_of\_lanes = zero), except for the case where the clocks are not exactly matched.

#### 12.6.4.7.8.2 Pixel Clock to TX\_BYTE\_CLK Variation

The selection of the Pixel clock rate and DPHY Bit clock rate should ideally match based on the ratio of bpp on the pixel side compared to the tx\_byte\_clk. The timing for the horizontal sync, back and front porch will also be configured to allow the pixel data to be transferred without any over or underflow of the DPI FIFO.

The DPI FIFO fill level register (DPI\_CFG) can be used to track that the parameters are sufficient and that any clock variation can still be handled by the FIFO depth. This register will show the pixel data held in the buffer, so during the HSA and HBP packet generation stages DPI pixel data will be stored and this value will increment. Once the data packet is being generated, the DPI\_CFG level will remain constant, as the buffer is emptied at the same bandwidth as it is filled. Finally, the value will reduce to zero during the HFP stage.

The packet length of the HFP can be adjusted to help absorb small differences in the pixel\_clk to tx\_byte\_clk relationship. The DSITX controller will concatenate all of the packets during High Speed transmission, so for example adding to the byte value of the HFP will make the bytes at the end of the packet move to align on another lane.

The packets that follow will then be concatenated and aligned to the next available lane, so if the tx\_byte\_clk is faster than the expected pixel clock times bpp the extra byte will delay the start of the new line tx\_byte\_clk × extra\_byte/lanes.

Figure 12-416, Video coherency, illustrates the impact of increasing the HFP by one byte so that the next line begins ¼ tx\_byte clock later. This allows averaging out across the line length of small differences in the pixel to tx\_byte clocks when the tx\_byte clock is not ideally matched to the expected pixel clock multiplied by bpp.

dsi\_spruij7-030

**Figure 12-416. Packet Alignment Control Using HFP Byte Increase - tx\_byte\_clk Faster than Ideal Rate**

The DPI\_CFG register will show any clock misalignment as an increasing/decreasing value for the FIFO fill level on each line of pixels (must be read mid-line for an accurate reading of the level). When the byte count adjustment is made, the DPI\_CFG register will return to the original fill level value every four lines.

#### 12.6.4.7.8.3 LP Operation

The DSITX controller can be configured to perform a transition between LP state and HS state during the horizontal lines which have long periods of blanking. The registers controlling the timing for the DPHY wakeup time and the reg\_line\_duration must be programmed to exactly match the DPI cycles of the horizontal line to the tx\_byte\_clk cycles required for the number of active lanes selected.

dsi\_spruij7-031

**Figure 12-417. Low Power Operation with Four and Two Active Lanes**

The LP operation for each vertical blanking line will require the `reg_line_duration` to be configured to match the following:

- `Max_line_length` (in `tx_byte_clk` cycles see 2.2.4) minus `Eot` (if enabled), also minus further 10 if `CLOCK` lane is non-continuous.

Note `REG_WAKEUP_TIME` is used internally to adjust the cycles for each vertical LP line.

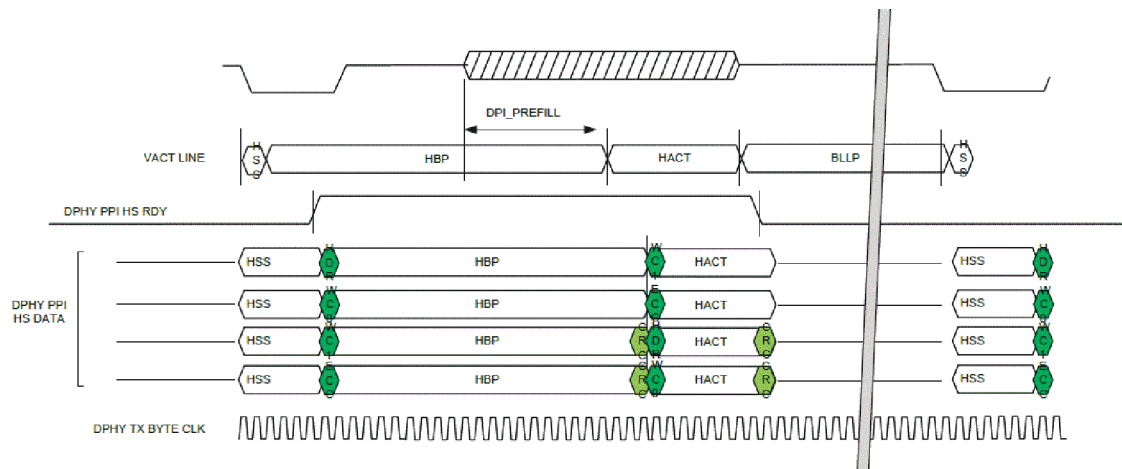

**Figure 12-418. REG\_LINE\_DURATION Timing Example for LP Operation**

#### 12.6.4.7.8.4 DPI Interface Burst Operation

The DSITX controller can support burst operation on the DPI interface provided the DPI FIFO size is large enough to store the line pixel data with enough data to not underflow. The burst operation will use a `tx_byte_clk` that is faster than normal event based operation, so the DPI FIFO size will be impacted by the ratio of the `pixel_clk` and BPP input to the `tx_byte_clk` and number of lanes on the output.

The recommended operation is to set the DSI HSA and DSI HFP registers to zero, and adjust the DSI HBP size to control the number of bytes prefilled in the DPI FIFO before the burst is sent.

Figure 12-419 shows DPI operation with event burst mode.

dsi\_spruij7-033

**Figure 12-419. DPI Operation with Event Burst Mode**

#### 12.6.4.7.9 Programming the DSITX Controller to Match the Incoming DPI Stream

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. Assuming that is the case, then the blanking and active data periods must be matched up.

For each frame of video the time will be:

$$(V_{\text{total}} * H_{\text{total}})_{\text{@pixel\_clk}} = (V_{\text{total}} * H_{\text{total}})_{\text{@tx\_byte\_clk}} \times \text{bits\_per\_pixel}/8;$$

So for example, the time for a full HD frame 1920x1080 with reduced blanking in RGB565 will be:

$$2200 \times 1200 \text{ pixels} = 2200 \times 1200 \text{ tx\_bytes} \times 16/8;$$

The DSITX controller will slave its frame timing to the incoming DPI vsync, as long as it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered. The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

##### 12.6.4.7.9.1 Vertical Timing

The DSITX controller will generate vertical packets for each part of the frame beginning with the VSS and VSE combined with blanking packets to fill the VSA. The blanking packets for the pulse mode program the DSI vertical size registers as follows:

- VSA = DPI\_VSI (lines, minimum of 2 → VSS and VSE)
- VBP = DPI\_VBP (lines, minimum of 0)
- VACT = DPI\_VACT (lines)
- VFP < DPI\_VFP (minimum of 1)

DPI horizontal timing is measured in pixel clocks, whereas the DSITX controller uses byte clocks. The horizontal timing should also be matched per line; therefore the blanking and active periods of each line should match. The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. The timing for a horizontal line for the DPI driver side will be the number of pixel cycles for the **HLINE** = (HSA + HBP + HACT + HFP) and this will form **HLINE** × bpp/8 bytes for the controller. These bytes will then be sent using 1, 2, 3 or 4 data lanes, so the DSITX controller will required 1, ½, 1/3, ¼ this number of tx\_byte\_clk cycles respectively.

e.g a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line.

This gives the DSI horizontal lines 3936 bytes to transmit and would use 984 tx\_byte\_clks on a four lane system, or 1312 on a three lane system etc..

The horizontal configuration uses different registers depending on the Mode (Pulse or Event) and the control of the BLKLINE\_MODE register bit.

- Non-Burst Mode with Sync Pulses – enables the peripheral to accurately reconstruct original video timing, including sync pulse widths.

Note that for accurate reconstruction of timing, packet overhead including Data ID, ECC, and Checksum bytes should be taken into consideration.

- Non-Burst Mode with Sync Events – similar to above, but accurate reconstruction of sync pulse widths is not required, so a single Sync Event is substituted.
- Burst mode – RGB pixel packets (active video) portion are time-compressed, leaving more time during a scan line for LP mode (saving power) or for multiplexing other transmissions onto the DSI link.

dsi-034

**Figure 12-420. Vertical Timing**

#### 12.6.4.7.9.2 Horizontal Timing for Non-Burst Mode with Sync Pulses

Sync Pulse Mode uses the Short packet and Long packet structures to accurately track the DPI interface timing. Figure 12-421 illustrates the packet sequence for a single frame.

dsi-035

**Figure 12-421. Vertical Timing**

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal line based on the DPI line configuration and the BPP for the colour pixel data.

The packet structure for each type of line during the frame is shown below, Trigger Mapping Information. The calculation of the total number of bytes in any horizontal line must always be  $HLINE \times bpp/8$  bytes.

**Figure 12-422. Non-Burst Mode With Sync Pulse Line Structures**

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and CRC footer (4 + 2 bytes) and the HSE short packet (4 bytes).
- HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes).
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.

Finally for lines with no active data, the controller will use either:

- BLKLINE\_PULSE\_PCK: Total line size ( $HLINE \times bpp/8$ ) in bytes minus the HSA 20 bytes (14 for HSA header and CRC, 6 for the remaining blanking which is all combined into a single packet).
- REG\_LINE\_DURATION: Total line size ( $HLINE \times bpp/8$ ) in tx\_byte\_clk cycles minus the calculated HSA in tx\_byte\_clk cycles ( $HSA \times bpp/8$  minus 14 bytes (14 for HSA header and CRC) minus the EOT packet (4 bytes) if required, divided by number of lanes). This should be aligned to the number of active lane so rounding the value so that  $REG\_LINE\_DURATION \bmod \text{Lanes}$  equals zero.
- VERT\_BLANKING\_DURATION: Total line size ( $HLINE \times bpp/8$ ) in tx\_byte\_clk cycles minus the calculated HSA in tx\_byte\_clk cycles ( $HSA \times bpp/8$  minus 14 bytes (14 for HSA header and CRC) divided by number of lanes).

Program the DSI horizontal size registers as follows:

$\text{burst\_mode} = 0$  and  $\text{sync\_pulse\_active} = \text{sync\_pulse\_horizontal} = 1$ ;

$HSA = (DPI\_HSA \times bpp/8) - 14 - DPI$  HSA min value 5 for RGB888

$HBP = (DPI\_HBP \times bpp/8) - 12 - DPI$  HBP min value 5 for RGB888

$HACT = (DPI\_HACT \times bpp/8)$

$HFP = (DPI\_HFP \times bpp/8) - 6 - DPI$  HFP min value 10 for RGB888

**Note:**  $(DPI\_HACT \times bpp/32)$  must be an integer. Total Line Length =  $\text{div\_roundup}((HLINE \times bpp/8), \text{num of lanes})$ ;

$(BLKLINE\_PULSE\_PCK) \text{ bytes} = (HLINE \times bpp/8) - 20 - HSA$ ;

$(\text{REG\_LINE\_DURATION})_{\text{tx\_byte\_clks}} = \text{Total Line Length} - \text{div\_roundup}((\text{HSA} \times \text{bpp}/8) - 14, \text{number of lanes});$

$(\text{VERT\_BLANKING\_DURATION})_{\text{tx\_byte\_clks}} = \text{Total Line Length} - \text{div\_roundup}((\text{HSA} \times \text{bpp}/8) - 14, \text{number of lanes});$

For example; a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI HLINE of 3936 bytes. So for 4 lanes, 984 tx\_byte\_clk cycles;

$$\text{HSA} = (12 \times 16/8) - 14 = 10$$

$$\text{HBP} = (12 \times 16/8) - 12 = 12$$

$$\text{HACT} = (1920 \times 16/8) = 3840$$

$$\text{HFP} = (24 \times 16/8) - 6 = 42$$

$$\text{Total Line} = \text{div\_roundup}((12 + 12 + 1920 + 24) \times 16/8, 4) = 984 \text{ tx\_byte\_clk cycles} = 3936 \text{ bytes};$$

$$\text{BLKLINE\_PULSE\_PCK} = (3936) - 20 - 10 = 3906$$

$$\text{REG\_LINE\_DURATION} = 984 - \text{div\_roundup}(12 \times 2, 4) = 978$$

$$\text{VERT\_BLANKING\_DURATION} = 984 - \text{div\_roundup}(12 \times 2, 4) = 978$$

Confirming the calculation for each line with BLKLINE\_MODE = 0;

$$\text{VSS} = \text{VSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{BLK\_LINE\_PULSE\_PCKPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$$

$$\text{VSALine} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{BLK\_LINE\_PULSE\_PCKPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$$

$$\text{VSE} = \text{VSEPKT} + \text{HSAPkt} + \text{HSEPkt} + \text{BLK\_LINE\_PULSE\_PCKPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$$

$$\text{VACT} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{HBPPkt} + \text{HACTPkt} + \text{HFPPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 12 + 2) + (4 + 3840 + 2) + (4 + 42 + 2) = 3936;$$

$$\text{VFP} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{BLK\_LINE\_PULSE\_PCKPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$$

$$\text{VFPLast} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{VERT\_BLANKING\_DURATION} = 4 + (4 + 10 + 2) + 4 + (978 \times 4) = 3936;$$

Confirming the calculation for each line with BLKLINE\_MODE = 1 matches the tx\_byte cycles;

$$\text{VSS} = \text{VSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{REG\_LINE\_DURATION} = \text{div\_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$$

$$\text{VSALine} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{REG\_LINE\_DURATION} = \text{div\_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$$

$$\text{VSE} = \text{VSEPKT} + \text{HSAPkt} + \text{HSEPkt} + \text{REG\_LINE\_DURATION} = \text{div\_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$$

$$\text{VACT} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{HBPPkt} + \text{HACTPkt} + \text{HFPPkt} = \text{div\_roundup}((4 + (4 + 10 + 2) + 4 + (4 + 12 + 2) + (4 + 3840 + 2) + (4 + 42 + 2)), 4) = 984;$$

$$\text{VFP} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{REG\_LINE\_DURATION} = \text{div\_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$$

$$\text{VFPLast} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{VERT\_BLANKING\_DURATION} = \text{div\_roundup}((4 + (4 + 10 + 2) + 4 + (3912)), 4) = 984;$$

#### 12.6.4.7.9.3 Event Mode Horizontal Timing

Non Burst Event Mode uses the Short packet and Long packet structures to track the DPI interface timing without accurate reconstruction of sync pulse widths, so a single Sync Event is substituted. [Figure 12-423](#) illustrates the packet sequence for a single frame.

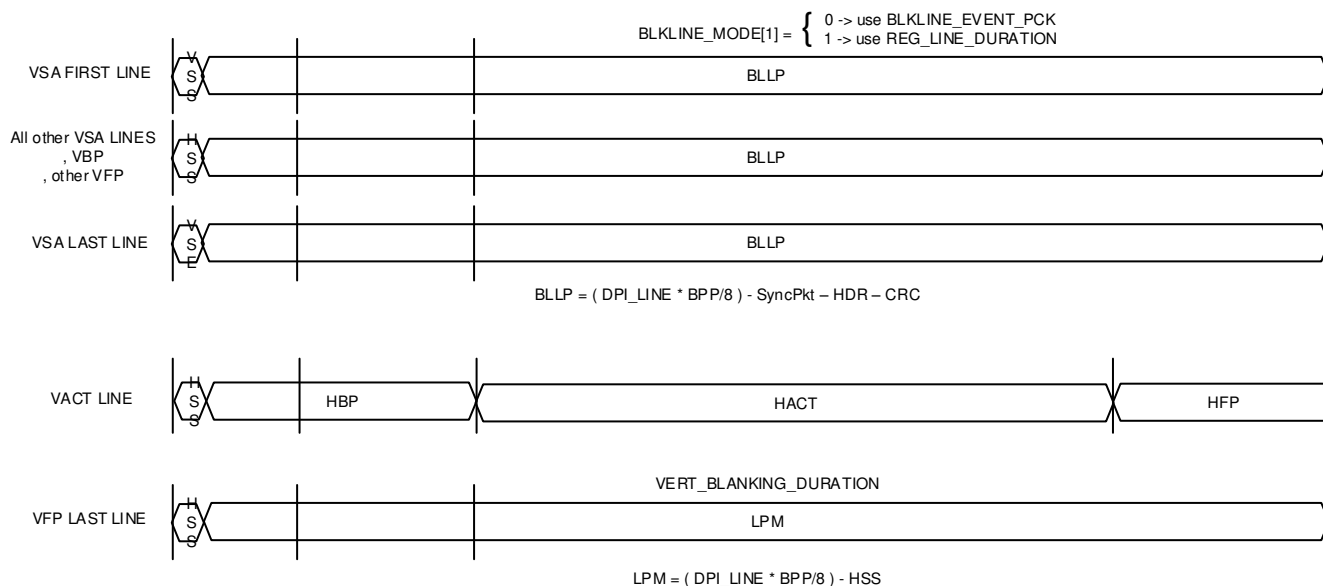

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal.

dsi-037

**Figure 12-423. Horizontal Timing - 1**

line based on the DPI line configuration and the BPP for the colour pixel data. The packet structure for each type of line during the frame is shown in [Figure 12-424](#):

**Figure 12-424. Horizontal Timing - 1**

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).
- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (2 bytes). This will match the DPI\_HSA + DPI\_HBP minus the Sync Short packet.
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer and footer of the active data.

Finally, for lines with no active data, the controller will use either:

- **BLKLINE\_EVENT\_PCK**: Total line size (HLINE × bpp/8) in bytes minus 10 bytes (4 for VSS/VSE/HSS, 6 for the remaining blanking header/footer which is all combined into a single packet).
- **REG\_LINE\_DURATION**: Total line size div\_roundup(HLINE × bpp/8, num\_of\_lanes) in tx\_byte\_clk cycles minus tx\_byte cycles for the 8 bytes (4 for VSS/VSE/HSS, and 4 for EOT). This should be aligned to the number of active lane so round the value so that REG\_LINE\_DURATION MOD Lanes equals zero.
- **VERT\_BLANKING\_DURATION**: Total line size div\_roundup(HLINE × bpp/8, num\_of\_lanes) in tx\_byte\_clk cycles minus tx\_byte cycles for the 4 bytes (4 for HSS).

Program the DSI horizontal size registers as follows:

burst\_mode = 0 and sync\_pulse\_active = sync\_pulse\_horizontal = 0;

- HSA = 0
- HBP = ((DPI\_HSA + DPI\_HBP) × bpp/8) - 12 – DPI HSA + HBP min value 5 for RGB888
- HACT = (DPI\_HACT × bpp/8)
- HFP = (DPI\_HFP × bpp/8) - 6 – DPI HFP min value 10 for RGB888

**Note:** (DPI\_HACT × bpp/32) must be an integer. Total Line Length = div\_roundup((HLINE × bpp/8), num of lanes).

(BLKLINE\_EVENT\_PCK) bytes} = (HLINE × bpp/8) - 10

(REG\_LINE\_DURATION) tx\_byteclks} = Total Line Length - div\_roundup(8, number of lanes)

(VERT\_BLANKING\_DURATION) tx\_byteclks} = Total Line Length - div\_roundup(4, number of lanes)

For example: a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI HLINE of 3936 bytes.

HSA = 0

HBP = ((12 + 12) × 16/8) - 12 = 24

HACT = (1920 × 16/8) = 3840

HFP = (24 × 16/8) - 6 = 42

Total Line = div\_roundup((12 + 12 + 1920 + 24) × 16/8, 4) = 984

BLKLINE\_EVENT\_PCK = (HLINE × bpp/8) – 10 = 981

REG\_LINE\_DURATION = 984 – div\_roundup(8, 4) = 982

VERT\_BLANKING\_DURATION = 984 – div\_roundup(4, 4) = 983

Confirming the calculation for each line:

VSS = VSSPkt + BLK\_LINE\_EVENT\_PCKPkt = 4 + (4 + 3926 + 2) = 3936

VSALine = HSSPkt + BLK\_LINE\_EVENT\_PCKPkt = 4 + (4 + 3926 + 2) = 3936

VSE = VSEPKT + BLK\_LINE\_EVENT\_PCKPkt = 4 + (4 + 3926 + 2) = 3936

VACT = HSSPkt + HBPPkt + HACTPkt + HFPPkt = 4 + (4 + 24 + 2) + (4 + 3840 + 2) + (4 + 42 + 2) = 3936

VFP = HSSPkt + BLK\_LINE\_EVENT\_PCKPkt = 4 + (4 + 3926 + 2) = 3936

VFPLast = HSSPkt + VERT\_BLANKING\_DURATION = 4 + (983 × 4) = 3936

#### 12.6.4.7.9.4 Burst Event Mode Horizontal Timing

Burst Event Mode uses the Short packet and Long packet structures to transmit the video information in short bursts and allow the system to use the Low Power states to save active power. This can only be supported with DSITX controllers able to store a horizontal line in the DPI FIFO. The burst mode will expect the tx\_byte\_clk to be twice the rate of the non burst event mode, and the register calculation will expect the total bytes for each line to double. [Figure 12-425](#) illustrates the packet sequence for a single frame.

dsi-039

**Figure 12-425. Burst Event Mode Horizontal Timing - 1**

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal line based on the DPI line configuration and the BPP for the colour pixel data.

The packet structure for each type of line during the frame is shown below, with the DSI HFP = 0 to select BLLP operation.

dsi\_spruij7-040

**Figure 12-426. Burst Event Mode Horizontal Timing - 2**

The DSI short packets and packet headers that are inserted by the controller for active lines must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).

- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes). This will match the DPI\_HSA + DPI\_HBP minus the Sync Short packet. In this case the DPI must also reduce the HSA and HFP timing.
- BLLP uses BLKEOL\_PCK or BLKEOL\_DURATION and will change depending on the HFP use case:
  - HFP can be zero to extend the BLKEOL\_x values (recommended).
  - or a non-zero value to transmit a Blanking Packet instead of LP state. The Blanking Packet HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.
  - The host\_eot state will cause the BLLP to either add an EOT cycle or not. The BLKEOL\_PCK or BLKEOL\_DURATION value will need to be adjusted to include this extra cycle if host\_eot is disabled.

Finally for lines with no active data, the controller will use either:

- BLKLINE\_EVENT\_PCK in bytes, excluding the header and crc.
- REG\_LINE\_DURATION or VERT\_BLANKING\_DURATION.
- Both are the total expected tx\_byte\_clk cycle for the line minus the number of cycles required to send the header packet bytes (4 for VSS/VSE/HSS) over the active lanes.

Program the DSI horizontal size registers as follows:

burst\_mode = 1 and sync\_pulse\_active = sync\_pulse\_horizontal = 0;

- HSA = 0
- HBP =  $(2 \times (\text{DPI\_HSA} + \text{DPI\_HBP}) \times \text{bpp}/8) - 12 + \text{DPI FIFO Prefill}$
- HACT =  $(\text{DPI\_HACT} \times \text{bpp}/8)$  NOTE:  $(\text{DPI\_HACT} \times \text{bpp}/32)$  must be an integer.
- HFP = Zero

Total Line Length =  $\text{div\_roundup}((\text{HLINE} \times \text{bpp}/8), \text{num of lanes})$ ;

$(\text{BLKLINE\_EVENT\_PCK}) = (\text{HLINE} \times \text{bpp}/8) \times 2 - 4$

$(\text{REG\_LINE\_DURATION}) = \text{Total Line Length} \times 2 - \text{div\_roundup}(4, \text{number of lanes})$

$(\text{VERT\_BLANKING\_DURATION}) = \text{Total Line Length} \times 2 - \text{div\_roundup}(4, \text{number of lanes})$

$(\text{BLKEOL\_DURATION}) = \text{Total Line Length} \times 2 - \text{TX\_BYTE\_CYCLES}$

$(\text{BLKEOL\_PCK}) \text{ bytes} = \text{Total Line Length} \times 2 - (\text{HACT} + \text{HBP} + \text{HSS})$

**Note:** TX\_BYTE\_CYCLES = TX Byte clock cycles to send Active Line bytes on the number of active lanes =  $\text{div\_roundup}(\text{HBP} + \text{HACT}, \text{number of lanes})$ .

### Burst Operation Frame Configuration

Burst mode operation can be used to save power provided the system configuration can support the higher tx\_byte clock rate. The user should consider if the power saving during LP states is more than reducing the number of active lanes and running in non-burst mode.

The burst mode can only be used if the controller configuration can support it; either using SDI video interface, or DPI interface with a buffer size large enough to prefill the data. The video driver timing from the DPI side will also need to be changed.

dsi\_spruij7-041

**Figure 12-427. DSITX Controller Video Frames for Burst Mode Compared with DPI Driver Side**

For example:

The VESA configuration for a 1920x1200 frame at 60-frames per second with normal blanking would have a pixel clock at 193.25 MHz, HSA 200 pixels, HBP 336 pixels, HFP 136 pixels and total line 2592 pixels. This would need to be reconfigured to move the active area earlier in the horizontal line for the DSITX controller, so could be changed to; HSA 20 pixels, HBP 30 pixels, HFP 622 pixels. This would allow the HFP LP state to be almost  $\frac{1}{4}$  of the line (622/2592).

#### 12.6.4.7.9.5 Burst Mode Operation

The DSI IP offers different options for behavior in the BLLP areas:

- Insertion of blanking or null packets.
- Switch to LP (power saving).
- Insertion of commands (if any) + blanking or null packet.

Figure 12-428 shows burst mode operation.

**Figure 12-428. Burst Mode Operation**

The user should balance the increase in the clock frequencies for transmission of the active display, against the power saving by using BLLP(Null) or LP state.

For Burst with the LP state the register fields must be programmed for `burst_lp = 1` and `reg_blkeol_mode = 2'b2`.

### Command Insertion Operation

The DSITX can use the burst operation to allow the blanking/LP stages to be used for DCS/GEN command insertion by programming the size of the space available after the sync of each line.

Only one command packet can be passed within each video line. The decision to insert a command in a video line is done at the beginning of the slot just after the previous video packet. If a command arrives in the middle of the slot, it is not processed in that line, the decision to accept the command will be taken in the next line.

If the packet does not fit in a short slot (size bigger than `reg_max_burst_limit` and not equal to `reg_exact_burst_limit`), it is delayed up to next long slot. The signal `reg_err_burstwrite` is flagged (it is only an information that can help application software control). If its length is longer than `reg_max_line_limit`, it is discarded and the error `reg_err_linewrite` is generated.

Read commands and BTA requests are only passed during long slots, as there is no way to calculate their duration exactly. In the case where their duration takes longer time than the vertical blanking period, the error `reg_err_longread` is flagged.

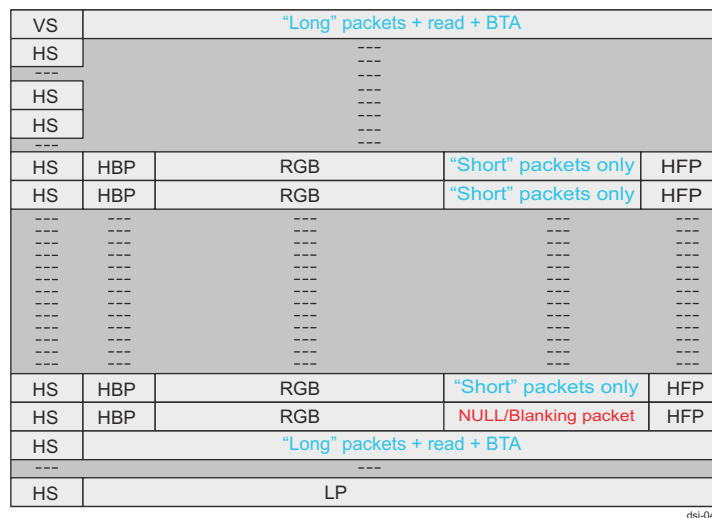

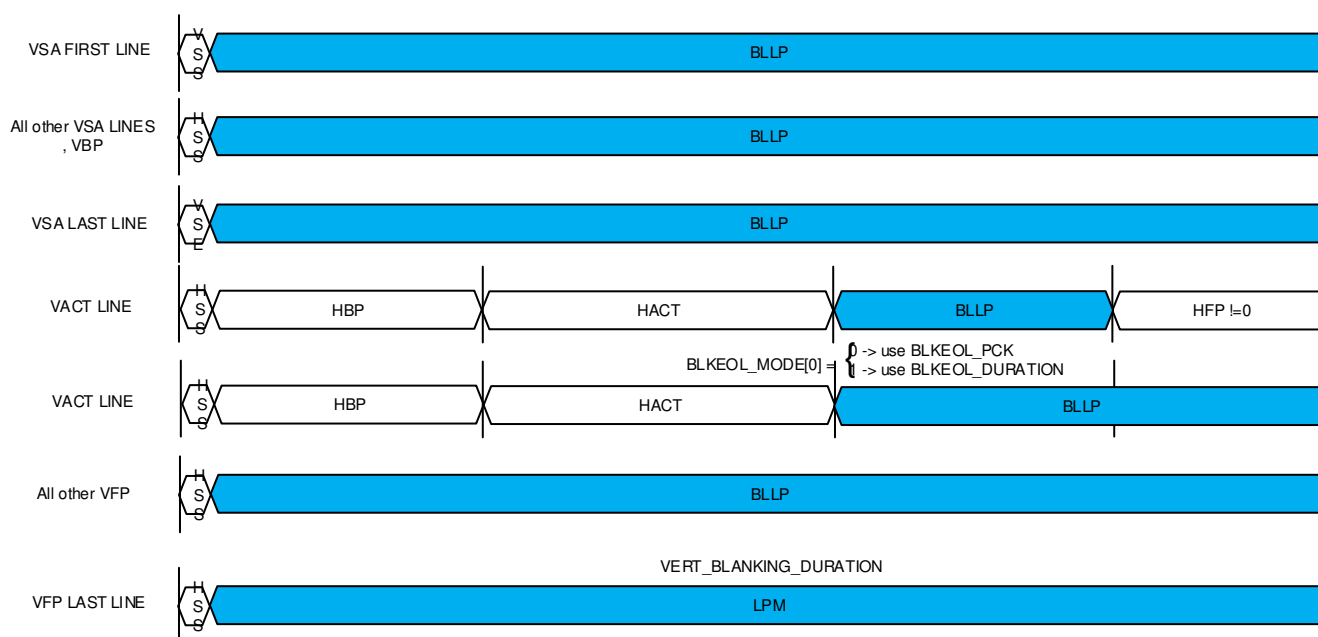

Figure 12-429. Burst Mode Command Locations During Video Frame

### Command Insertion Registers in Burst Operation

The burst operation requires the configuration of the registers to control the size of the packets that will fit in the space available on each type of horizontal line.

In VSA, VBP or VFP: Insertion of short and long command packets, read or BTA are allowed.

ds1-045

- In VACT: Only short packets can be inserted.
- Command, if inserted, is inserted right after the HSA or HSE or the video packet.
- Only one command can be inserted by line.
- When a command is inserted on a video line, no switch to LP but Null packet insertion.
- Trigger and TE insertion not supported.

VID\_VCA\_SETTING1 register:

[16] BURST\_LP: After an active line, in burst mode, the system can switch in LP (1) or should complete the line with NULL packet (0).

VID\_VCA\_SETTING1 register:

[15:0] MAX\_BURST\_LIMIT: Maximum length of a packet (number of bytes) that can be passed during the blanking period at the end of an active line (in burst mode) followed by a NULL packet with no data (6 bytes).

VID\_VCA\_SETTING2 register:

[15:0] EXACT\_BURST\_LIMIT: Exact maximum size of the burst packet (packet that fits after pixel data in burst mode), that is with no Null packet insertion afterwards.

VID\_VCA\_SETTING2 register:

[31:16] MAX\_LINE\_LIMIT: The "maximum" packet (number of bytes) that can be passed during the vertical blanking period.

If the packet does not fit in a short slot (size bigger than MAX\_BURST\_LIMIT and not equal to EXACT\_BURST\_LIMIT), it is delayed up to next long slot.

- If the packet length is longer than MAX\_LINE\_LIMIT, it is thrown away (an error is asserted).

Table 12-366 outlines the expected behaviour of each packet type during the video frame.

**Table 12-366. Behavior of the DSITX Transmission when Both Video and Command are Running**

Packet type	Packet Size	Behavior	Error Flagged
VACT Active Line - Read and BTA do not pass			
No packet	-	LP mode null packet sent	
Short packet		Packet passed followed by a null packet	
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	
Long packet	size = reg_exact_burst_limit	Packet passed	
Long packet	reg_max_burst_limit < size < reg_exact_burst_limit	Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite

**Table 12-366. Behavior of the DSITX Transmission when Both Video and Command are Running (continued)**

Packet type	Packet Size	Behavior	Error Flagged
Long packet	reg_exact_burst_limit < size <= reg_max_line_limit	packet is delayed to non-active part of frame: Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite
Packet type	Packet Size	Behavior	Error Flagged
Long packet	size > reg_max_line_limit	Packet thrown, LP mode packet thrown, null packet sent	Linewrite Linewrite
Read packet	-	Packet delayed, LP mode Packet delayed, null packet sent	-
BTA request	-	Packet delayed, LP mode Packet delayed, null packet sent	-
VSA, VBP, VFP - Long packet, read and BTA can be passed			
No packet	-	LP mode	-
Short packet	-	Packet passed followed by a null packet	-
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	
Long packet	size > reg_exact_burst_limit	packet thrown, LP mode	Linewrite
Read packet	read completed (direction) before end of slot	Packet passed	
Read packet	read not completed (direction) before end of slot	Packet passed	Longread If operation lasts too long
BTA request	-	Packet passed	Longread If operation lasts too long

Note that for burst operation with Low Power, the command will be sent as a high-speed packet even if the request is made to send as Low Power. Also, the next active line will return to using LP during the HFP phase if no other commands are requested.

#### 12.6.4.7.9.6 Example Configurations

1. Here is an example for a VGA frame with 24bpp @60fps using non burst pulse sync mode: With blanking, total size 500 lines, each line is 800 pixels.

400000 DPI cycles/frame @ 24 MHz pixel clock <-> 300000 DSI cycles/frame @ 18 MHz byte clock;

800 DPI cycles/line @ 24 MHz <-> 600 DSI cycles/line @ 18 MHz;

**Table 12-367. DPI and DSI Parameters - 1**

Parameter	DPI	DSI
VSA	5	5
VBP	5	5
VACT	480	480
VFP	10	5
HSA	40	106 (120-14)
HBP	40	108 (120-12)
HACT	640	1920
HFP	80	234 (240-6)

**Table 12-367. DPI and DSI Parameters - 1 (continued)**

Parameter	DPI	DSI
HTOTAL	800 pixel cycles	2400 bytes

burst\_mode = 0

sync\_pulse\_active = 1

sync\_pulse\_horizontal = 1

BLKLINE\_PULSE\_PCK = 2380 (2400-20)

REG\_LINE\_DURATION = 2380

VERT\_BLANKING\_DURATION = 2384

**Note:** The controller will send 4 VFP lines then transition to LP for the duration equivalent to 6 lines.

2. Here are some example values for a 24fps UHD frame size with 24bpp using non-burst event mode: With blanking, total size 2250 lines, each line is 4000 pixels.

9000000 DPI cycles/frame @ 216 MHz pixel clock <-> 6750000 DSI cycles/frame @ 162 MHz byte clock

4000 DPI cycles/line @ 216 MHz <-> 3000 DSI cycles/line @ 162 MHz

**Table 12-368. DPI and DSI Parameters - 2**

Parameter	DPI	DSI
VSA	2	2
VBP	0	0
VACT	2160	2160
VFP	40	1
HSA	40	0
HBP	40	228 (120 + 120 - 12)
HACT	3840	11520
HFP	80	234 (240 - 6)
HTOTAL	4000	12000

burst\_mode = 0

sync\_pulse\_active = 0

sync\_pulse\_horizontal = 0

BLKLINE\_EVENT\_PCK = 11990 (12000-10)

REG\_LINE\_DURATION = 11990

VERT\_BLANKING\_DURATION = 11996

**Note:** After the active data the controller will transition immediately to LP for the duration equivalent to 88 lines, giving the maximum power saving between lines.

If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync\_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure.

#### 12.6.4.7.9.7 Stereoscopic Video Support

The DSI controller can support stereoscopic display format (SDF) using both command and video modes.

- Command Mode
  - APB Direct Command 3D Commands – Use get\_3D\_control with Read
  - SDI Command Mode – DCS Writes

- Video Mode – Single Link Operation
  - VSYNC Parameter1 Definition (L/R, Mode, Format)
  - SDI Video Mode
  - DPI Video Mode – Video stream will expect to follow expected format; frame, line, pixel
    - 3DVSYNC = 0 not currently supported.

The DSI must be configured to enable the 3D operation and identify the format that is being used using the register control to enable the 3D features and the configuration that matches the video stream from the system.

The SDF format requires the system to provide frame and synchronisation information using the two parameter fields within the vertical sync short packet (VSS).

Configured the DSI mctl\_3dvideo\_ctl register to match format – L/R Pixel, L/R Line, L/R Frame Drive video stream based on orientation and format.

**Note:** DSI Controller will not perform any on-the-fly pixel manipulation for L-R ordering.

### Example Video Operation

For a 3D video stream where the DSI video is given the combined images as one continuous large frame, the VSYNC packet would identify that the left image is sent first, it is a line based format and in landscape mode (see [Table 12-369](#)).

**Table 12-369. Example Video Operation**

Position	D7	D6	D5	D4	D3	D2	D1	D0
Value	0	0	0	0	0	0	1	0
Description	Rsvd	Rsvd	Left First	No Sync	Line-based		Landscape	

mctl\_3dvideo\_ctl (0x20)

**Table 12-370. VSYNC Parameter 1**

[7]	vid_vsync_3d_en	1
[5]	vid_vsync_3d_lr	0
[4]	vid_vsync_3d_second_en	1
[3:2]	vid_vsync_3dformat	00
[1:0]	vid_vsync_3dmode	10

The video stream would then be configured in the DSI to be twice the line length of the normal image.

dsi\_spruij7-050

**Figure 12-430. Example DPI Image Format for SDF Combining Left And Right Pixels**

**Note:** The vertical operation DSI controller will expect the system to provide the left and right as two individual frames with SYNC to allow the blanking to be generated. The DSI does not insert the vertical blanking area when VSYNC = 0.

dsi-051

**Figure 12-431. 3D Image format for 3DVSYNC splitting first and second images**

#### 12.6.4.7.10 DSITX Video Stream Variable Refresh

The DSITX Controller can be programmed to allow the video stream sequence from a video source to halt between frames and enter Low Power state. The DPI video stream can halt before the new VSYNC is sent and remain in this state until the host video system wants to begin transmitting the new frame.

The DSITX will not perform the normal frame recovery mechanism when this is enabled, however it will continue to recover from line errors until the end of the frame.

**Table 12-371. DSITX Video Stream Variable Refresh**

Variable refresh rate operation enable control	Configures how the video generation timing is controlled.0, 1 DPI mode operation supports = 1 (enabled). For SDI operation, this parameter can optionally be set to FALSE (= 0) when the system clock and tx_byte_clk are generated from the same reference clock source, or TRUE to allow variable refresh rate control.
------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## 12.6.5 Embedded DisplayPort (eDP) Transmitter

### 12.6.5.1 EDP Block Diagram

Figure 12-432 shows the high level architecture of EDP and system integration.

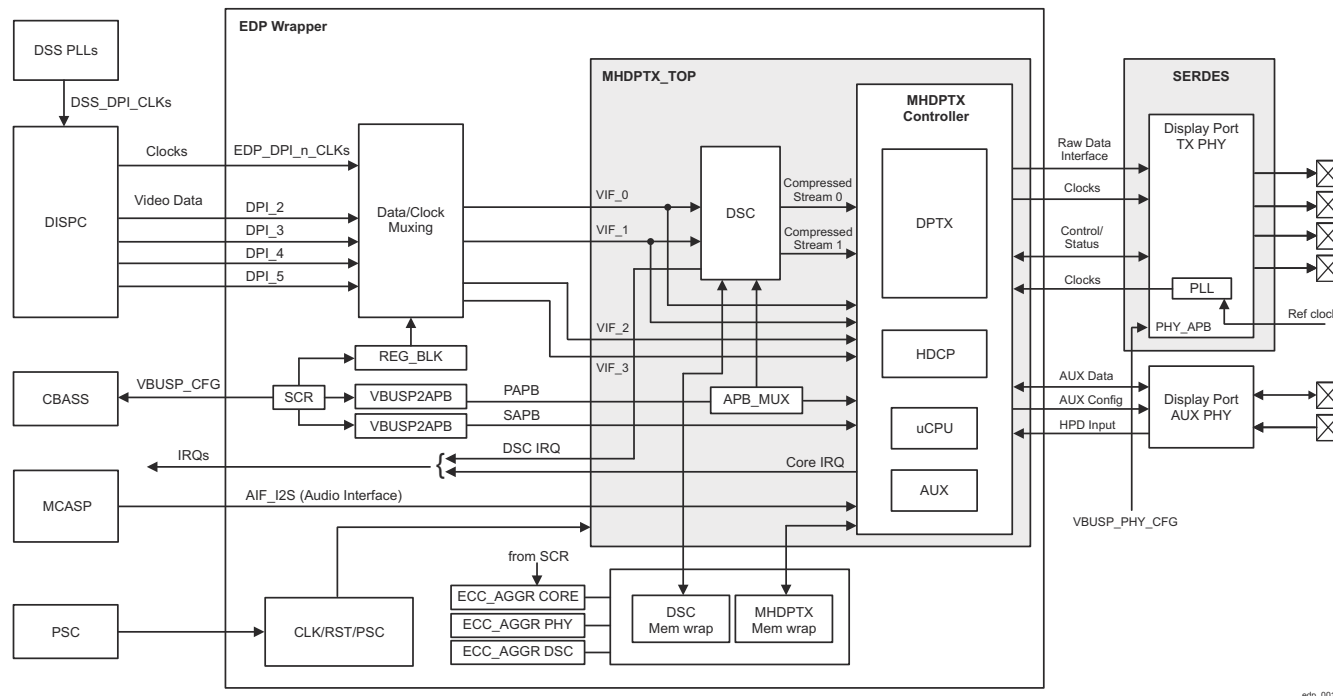

Figure 12-432. EDP System Integration Block Diagram

### 12.6.5.2 EDP Wrapper Functions

The EDP Wrapper provides logics for following interfaces:

- Interface Bridges - Map VBUS\_CFG bus to APB interfaces via CBASS switch and VBUSP2APB bridges
- Video Stream Clock/Data Muxing - Muxes the DPI (from DSS) streams and maps the selected streams to MHDPTX\_TOP video interface (VIF) inputs
- SERDES PHY Interface Mapping
- Clock/Reset/Power Management
- Configurations – Provides a register bank to configure/control the top level EDP wrapper functions

#### 12.6.5.2.1 Video Stream Clock/Data Muxing

The EDP wrapper supports up to 6 DPI inputs and internally maps 4 of them to the MHDPTX module, which can support up to 4-stream transmission in Multiple Stream Transport (MST) mode.

Each DPI interface supports the following:

- CEA-861 signaling/timing compatible interface
- Pixel clock rate range from 25MHz to 600MHz
- Frame Resolution - 4K@60Hz equivalent frame size – supporting various frame resolutions and aspect ratios that are equivalent to 4Kx2K@60Hz UHD (Ultra High Definition – 4096x2160 pixels)
- Progressive video timing only
- Maximum Width - 8x1024 pixels wide
- RGB (or YUV444) format only

Table 12-372 describes the DPI interface signals at EDP Wrapper boundary.

Table 12-372. EDP Wrapper DPI Interface Signals

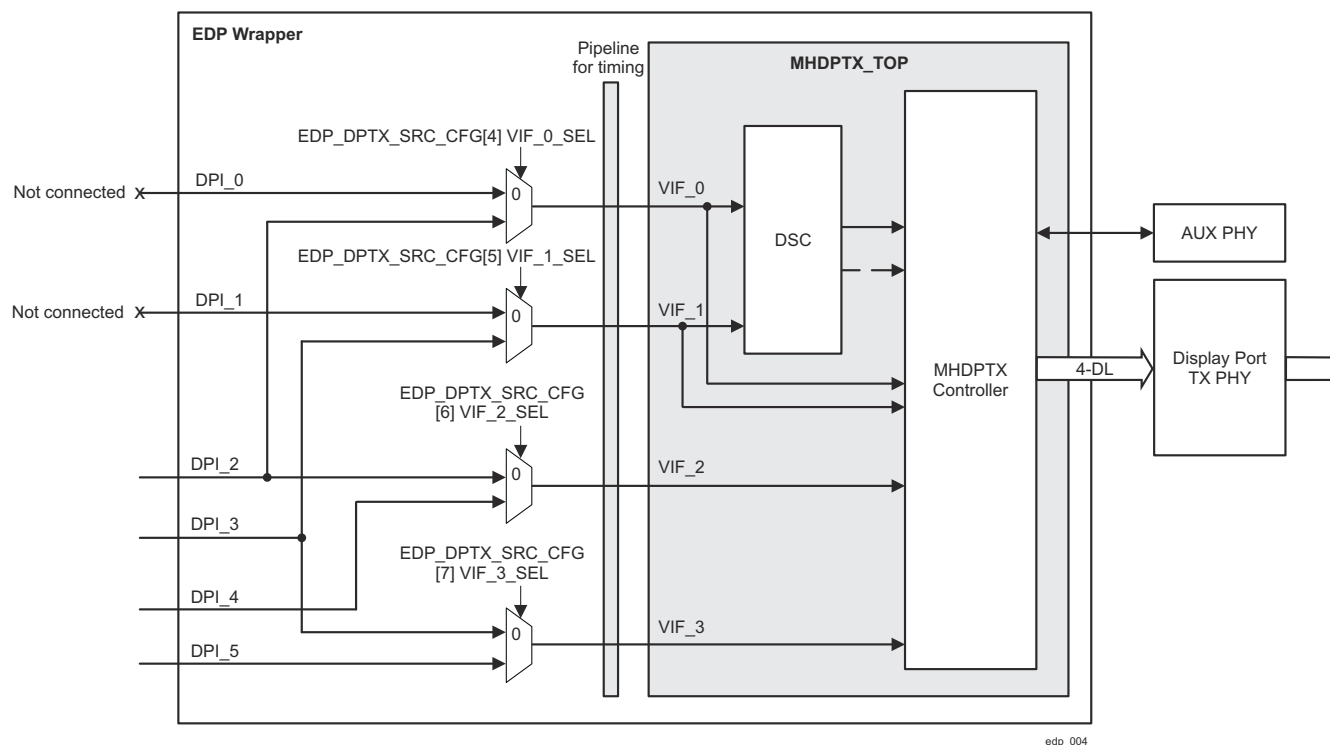

Signal Name <sup>(1)</sup>	Direction	Default Value	Description
dpi_n_data[47:0]	Input	48'd0	Pixel Data

**Table 12-372. EDP Wrapper DPI Interface Signals (continued)**

Signal Name <sup>(1)</sup>	Direction	Default Value	Description
dpi_n_m_mdata[47:0]	Input	48'd0	Master Meta Data Only bit [10] secure mode bit is used
dpi_n_de	Input	1'd0	Data Enable (active high)
dpi_n_vs	Input	1'd0	Start of frame or Vsync (active low)
dpi_n_hs	Input	1'd0	Start of line or Hsync (active low)

(1) n = 0 to 5

Figure 12-433 shows the DPI data mapping to VIF ports via muxing in the EDP wrapper.

**Figure 12-433. DP Wrapper DPI Data Muxing and VIF Mapping**

The following data stream transport modes are supported by the DPI data mapping to VIF ports:

**SST Mode (Single Stream Transport) – VIF0 used**

- DPI\_2 - Single Panel Input (optional DSC compression) mapped to VIF0
- DPI\_2/DPI\_3 - Split Panel Dual Inputs (for DSC compression only) mapped to VIF0 (via DSC) (see Note 1)

**MST Mode (Multi-Stream Transport) – All VIFs used**

- DPI\_2 - Single Panel Input (optional DSC compression) mapped to VIF0
- DPI\_3 - Single Panel Input (optional DSC compression in dual panel mode) mapped to VIF1 (see Note 2 and Note 3)
- DPI\_2/DPI\_3 - Split Panel Dual Inputs (for DSC compression only - two L/R streams compressed separately but outputs combined as one stream) with compressed output mapped to VIF0 (via DSC)
- DPI\_2 or DPI\_4 - Single Panel Input (no DSC compression) mapped to VIF2
- DPI\_3 or DPI\_5 - Single Panel Input (no DSC compression) mapped to VIF3

Notes:

1. DSC can be enabled to perform compression on a single input stream as Left and Right panel data for high resolution video (pixel clock > ~400 MHz) that cannot be compressed with a single DSC encoder. In this

- mode, two input streams share the same video timing (vs/hs/de) and identical input pixel clocks. This mode is referred to as **"split panel mode"**.
2. DSC can also be enabled to perform compression of two unrelated input streams of the same resolution. These streams must share the same pixel input clock since the DSC encoders require two encoder clocks to be synchronous. But, in this case, two streams can be asynchronous in terms of video timing (vs/hs/de). This mode is also referred to as **"dual panel mode"**.
  3. When DSC is using only one encoder, then it is required to be on Enc0 input (meaning the stream to be compressed must be on DPI\_2). In MST mode (where this constraint is applicable), the single stream that is to be compressed must be placed on DPI\_2 and therefore the DP sink device (that receives the compressed stream) will be assigned to receive the STREAM\_0.

When DSC is in split or dual panel mode, the DSS uses a common clock to send two streams. In the EDP, two DSC input clocks are sourced from the same DPI\_2 source clock to keep these clocks to be the same (per DSC requirement) in order to minimize the skew between two DSC encoder clocks.

For detailed description of the clock diagrams, including the clock muxes per data selection, refer to [Section 12.6.5.5.1, Clock Diagram](#).

### 12.6.5.2.2 Secure Video Content Protection

Each DPI\_n input port includes a 48-bit DPI\_n\_M\_MDATA bus from DSS (DISPC) which carries attribute sideband signals associated with the DPI interface. The EDP sets the security status (DPISECURE) of the incoming DPI interface using the DPI\_n\_M\_MDATA[10] bit as shown in [Table 12-373](#).

**Table 12-373. EDP Secure Video Content Protection**

Sideband bit(s)	Name	Description
DPI_n_M_MDATA[10]	DPISECURE	DPI-np secure bit 1: DPI-np is secure 0: DPI-np is not secure

The EDP performs a simple security check on the selected DPI connection by comparing the value of the selected DPISECURE bit (per EDP\_DPTX\_SRC\_CFG[7-4] VIF\_n\_SEL bits (where n = 0 to 3)) to the EDP\_DPTX\_VIF\_SECURE\_MODE\_CFG[3-0] VIF\_n bits.

If the selected DPISECURE bit is set to 1, the video content is considered to be secure and the connection (transmission via DPTX) is only made if the EDP\_DPTX\_VIF\_SECURE\_MODE\_CFG[3-0] VIF\_n bits are also set to 1 (indicating the display is also secure). Otherwise, the EDP forces the DSS\_DPI\_DATA to be 0h while leaving the sync signals alone – in effect, causing the video to go black. If the DPISECURE bit is set to 0, then the connection is also enabled.

### 12.6.5.2.3 DPI\_DATA Input Pixel Format Supported

[Figure 12-434](#) shows the supported by the EDP pixel packing formats in the DSS\_DPI\_DATA.

Default: **RGB121212** - 36-bit pixel data (12 bpc) LSB aligned in 48-bit data bus

Optional: **RGB101010** - 30-bit pixel data (10 bpc) LSB aligned in 48-bit data bus

EDP\_005

**Figure 12-434. EDP Wrapper Supported Input DSS\_DPI\_DATA Pixel Formats**

The selection between these two formats is made per VIF\_n source by configuration EDP\_DPTX\_SRC\_CFG[11-8] VIF\_n\_IN30B parameters. The default is 36-bit format (RGB121212). Optionally, the 30-bit format (which is the pixel format when the DPI\_data is generated from the DSS's merge/split module) can be selected to match the DSS configuration.

Internally, the EDP wrapper performs following pixel data/component realignments to match the input pixel data alignment required by the MHDPTX core (MSB alignment) and DSC (native LSB alignment).

Figure 12-435 shows the internal mapping from the LSB packed pixel bus to MSB-aligned container packed bus: the 30 or 36-bit pixel data remapped to 48-bit (16 bpc (bits per component) MSB aligned within color component). The MHDPTX core extracts MSB 8/10/12-bits from each 16-bit color component to include in the display port video transport packet (see Table 12-374, *EDP Video Interface Pixel Mapping (MSB Mapping)*).

**Figure 12-435. EDP Wrapper Internal Pixel Bus Remapping (First Stage)**

DSC Input Data Re-alignment (Optional for DSC enabled VIF\_0 and VIF\_1) – From the 48-bit aligned data bus, the EDP wrapper performs additional re-alignment (LSB aligned component data per DSC requirement) and pixel data alignment per DSC input processing bit size configuration.

For this LSB alignment, EDP\_DPTX\_DSC\_CFG[6-5] DSC\_1/0\_10BPC bits must be configured to extract significant 8 or 10-bit component data from the input pixel bus, as shown on Figure 12-436.

The parameters in these bits must match the parameters in the EDP\_CORE\_ENC0\_MAIN\_CONF\_P/EDP\_CORE\_ENC1\_MAIN\_CONF\_P[1-0] IPUT\_BPC bitfields.

**Figure 12-436. EDP Wrapper Internal Pixel Remapping (Additional for DSC Bound Pixel Data Bus)**

Pixel data alignment within the MHDPTX\_TOP should be set to be MSB always to enable the pixel mapping, as shown in Table 12-374. DSC bound pixel data bus is to be LSB aligned and requires no other MHDPTX\_TOP configuration.

**Table 12-374. EDP Wrapper Video Interface Pixel Mapping (MSB Mapping)**

Video Bus	Source RGB/YCbCr444 (C of YCbCr422 <sup>(2)</sup> )				
	Bit Width	8-bit	10-bit	12-bit	16-bit <sup>(1)</sup>
Channel 2	[47:40]	R/Cr[15:8] / C[15:8]	R/Cr[15:6] / C[15:6]	R/Cr[15:4] / C[15:4]	R/Cr[15:0] / C[15:0]
	[39:38]				
	[37:36]				
	[35:32]				
Channel 1	[31:24]	G/Y[15:8]	G/Y[15:6]	G/Y[15:4]	G/Y[15:0]
	[23:22]				
	[21:20]				
	[19:16]				
Channel 0	[15:8]	B/Cb[15:8]	B/Cb[15:6]	B/Cb[15:4]	B/Cb[15:0]
	[7:6]				
	[5:4]				
	[3:0]				

(1) 16-bit source format is not supported. When selected, lower 4 bits are set to 0x0.

(2) YCbCr422 format is locally generated from YCbCr444 input from DSS (by a simple chroma decimation).

#### 12.6.5.2.4 Audio Input Interface

The audio input interface provides the following features:

- One I2S interface configured to support multiple physical audio channels (up to 8-channels)
- Frame Format – TDM mode
  - Multiple Physical Channels N = 1, 2, or 4
  - Variable TDM time slots M = 2 or 8
  - Time slot size: 32, 24, or 16
  - Variable word length (28, 24, 20, 16) configured as left or right justified
- I2S\_DATA - 4-bits wide
- Supports data rate up to 8-channel L-PCM @192 kHz (Buffer dependent)
- SPDIF mode is not supported

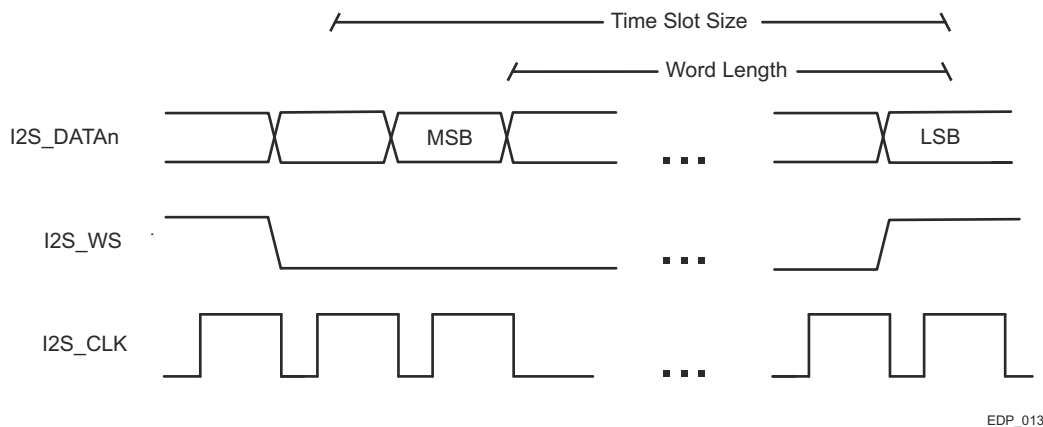

##### 12.6.5.2.4.1 Audio I2S Signals/Timing

Table 12-375 shows the I2S signals and timing.

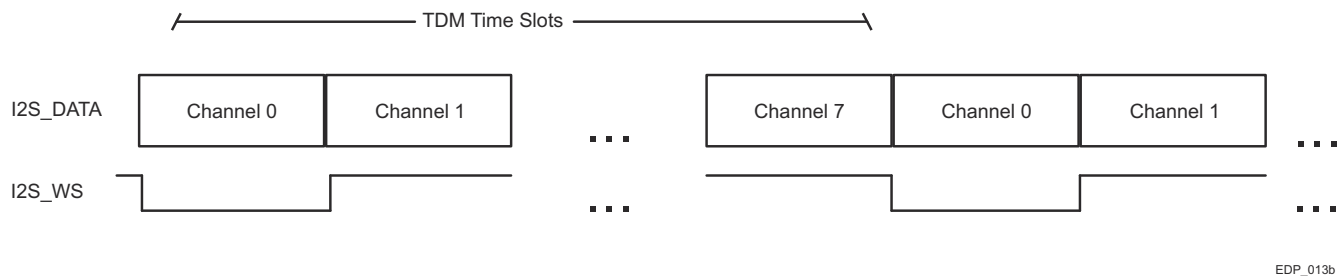

**Table 12-375. EDP Audio I2S Signals/Timing**

Signal Name	Direction	Default Value	Description
AIF_I2S_CLK	Input	1'd0	I2S clock
AIF_I2S_DATA[3:0]	Input	4'd0	I2S data for up to 4*M logical channels. Number of physical channels: 1, 2, or 4 M – number of time slots: 2 or 8
AIF_I2S_WS	Input	1'd0	I2S word-select indication. In TDM mode, WS = 0 indicates channel 0.

Figure 12-437 and Figure 12-438 show the I2S timing.

**Figure 12-437. EDP Audio I2S Timing - Bit Allocation (Right Justification)**

**Figure 12-438. EDP Audio I2S Timing - TDM Time Slot Allocation (M = 8)**

#### 12.6.5.2.4.2 Audio I2S Clock Frequency

The bit clock frequency is defined as below:

- Bit clk freq = Sampling\_rate \* Number\_of\_bits\_per\_channel \* Number\_of\_channels

For 16-bit/44.1 kHz stereo channels:

- I2S\_CLK (freq) = 44.1 kHz x 16 x 2 = 1.4112 MHz

For 24-bit/192 kHz stereo channels:

- I2S\_CLK (freq) = 192 kHz x 24 x 2 = 9.216 MHz

#### 12.6.5.3 EDP Transmitter Controller Subsystem (MHDPTX\_TOP)

The EDP Transmitter Controller Subsystem (MHDPTX\_TOP) integrates the following major components:

- Display Stream Compression (DSC) v1.1 Encoder – VESA Compression Engine
- Display Port TX Controller (MHDPTX Controller) - EDP/DP Transmitter Controller

##### 12.6.5.3.1 Display Stream Compression Encoder (DSC)

This module performs the VESA Digital Stream Compression encoding for the Display Port TX interface. The DSC contains two parallel Hard Slice Encoders, which support compression for VESA Display Port transmitter.

##### 12.6.5.3.1.1 DSC Encoder Features

The DSC Encoder supports the following main features:

- Maximum image width and height per encoder slice can be configured with up to 8K
  - Programmable slice width and height
  - All slices must be the same height, including the final slice of the picture
- 8 bits/component (24 bits/pixel)
- 10 bits/component (30 bits/pixel)
  - An encoder built for 10 bits/component will be able to run in either 8 or 10 bits/component mode based on a register value

- RGB/YCbCr with 4:4:4 sampling support only on the input streams
- Single or Dual Pixel input(s)
  - Single pixel input (one encoder slice processing only)
  - Dual pixel inputs
    - Split Panel (Left/Right) streams – requires low skew between streams
- Support for all DSC 1.1 encoding mechanisms
  - MMAP, BP, MPP predictions and ICH
  - Flatness detection and signaling
- Supports CBR (Constant Bit Rate) mode only - Configurable target bpp (bits per pixel), non-integer values supported. The following modes are available:
  - 8 bpp and 12 bpp compressed bit rates for 8 bits/component - Corresponds to 3:1 and 2:1 compression
  - 10 bpp and 15 bpp compressed bit rates for 10 bits/component - Corresponds to 3:1 and 2:1 compression
  - 12 bpp and 18 bpp compressed bit rates for 12 bits/component
- Each Hard Slice encoder instance can be configured (with the parameter NB\_SS\_ENC) to support the following number of slices per line
  - Supports 1 or 2 slices (soft slices) per line
    - When configured with support for 2 slices per line, the encoder support dynamically the configuration of both 1 and 2 slices per line.
  - Thus a total of up to 4 slices per line can be supported with two Hard Slice Encoders
- Encoder data flow supported:
  - Synchronous Streaming mode – no back pressure support
- Implements the following active internal diagnostic mechanisms:
  - Self-Checking during VBLANK
  - Control output diagnostics
  - SRAM Protection
  - Configuration and Status Register (CSR) Protection
  - Fault avoidance mechanism

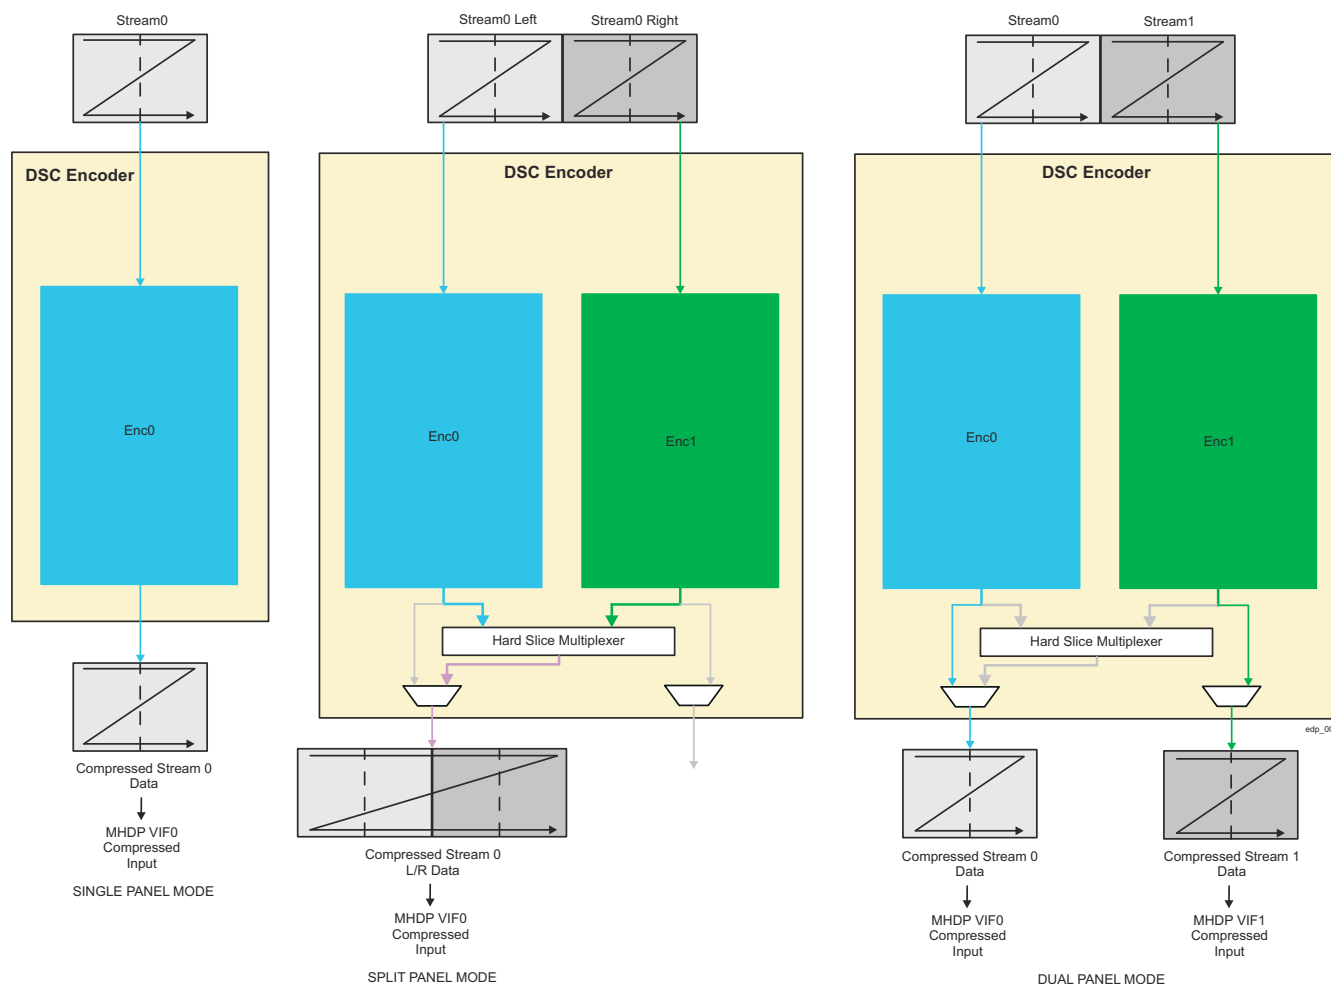

#### 12.6.5.3.1.2 Usage Models for EDP

Table 12-376 summarizes the usage models supported by DSC instantiated in the MHDPTX\_TOP subsystem.

**Table 12-376. EDP DSC Usage Models**

Usage Models			
	Single Panel Mode (SST/MST)	Split Panel Mode (SST/MST)	Dual Panel Mode (Only in MST)
ENC0	Stream 0 Full Frame	Stream 0 Left Frame	Stream 0
ENC1	Not Used	Stream 0 Right Frame	Stream 1

The shaded boxes in Table 12-376 indicate the encoder slice enabled for EDP usage. The active paths for these two modes are shown on Figure 12-439.

**Figure 12-439. EDP DSC Single Input/1-Transport Link Mode and Split Panel/Dual Panel Mode**

#### 12.6.5.3.2 Display Port Transmitter Controller (MHDPTX Controller)

Figure 12-440 shows a simplified block diagram of the EDP Display Port Transmitter Controller (MHDPTX) that is included in the EDP subsystem.

**Figure 12-440. EDP Display Port Transmitter Controller Functional Block Diagram**

n = 0 to 3

#### 12.6.5.3.2.1 EDP Transmitter Controller Mode Configurations

This section describes the configuration mode input signals of the MHDPTX\_TOP module.

##### **SOURCE\_SECURE\_MODE**

This mode configuration signal sets the "source\_secure\_mode" of the MHDPTX's APB interface to provide additional security control on the host interface. The main APB interface in "debug" mode can be used to access almost all internal registers as well as IRAM/DRAM of the internal uCPU. This signal must be set to 0 to load FW during boot time. By setting SOURCE\_SECURE\_MODE to 1, this functionality can be disabled to only allow mailbox and basic control register accesses.

In EDP, this signal is mapped to a wrapper level configuration register within the EDP\_CFG region: EDP\_DPTX\_IPCFG[0] APB\_SECURE\_REG\_BLOCK\_EN. If tempering of this register should be blocked, the EDP\_CFG region should be firewalled to grant access only to a secure host only.

If the DP firmware regions are needed to be protected (to prevent either corruption or altering of the firmware), a secure host can change this setting to 1 after initializing the firmware memories. Then, a non-secure host can come and take the CPU out of reset and enable the DP function without an ability to alter the firmware.

##### **SOURCE\_CRYPTO\_DIS**

This mode configuration signal is used to completely disable HDCP functionality by disabling Crypto module (module responsible for keys encryption during authentication). Refer to *EDP eFuse Tie-Off*, for eFuse tie-off information.

#### 12.6.5.4 EDP AUX\_PHY Interface

The AUX PHY module is required for each Display Port interface. The AUX\_PHY module is integrated with the EDP controller as shown on [Figure 12-441](#). The AUX PHY has no configuration interface. All configuration and control signals are supplied from EDP\_CORE\_APB memory-mapped registers.

**Figure 12-441. EDP Interface to AUX PHY**

The configurations and controls in [Figure 12-441](#) are specified through EDP\_CORE\_AUX\_CONFIG\_P and EDP\_CORE\_AUX\_CTRL\_P registers.

#### 12.6.5.5 EDP Clocks

##### 12.6.5.5.1 Clock Diagram

[Figure 12-442](#) shows the input clocks of eDP and muxing on the DPI input clocks to match the pixel data selection.

**Figure 12-442. EDP Clock Diagram**

#### 12.6.5.5.1.1 DPI Interface Clock Sourcing

In default (non-DSC enabled) modes, the EDP performs the matching pixel data clock selection (MuxA - MuxE) based only on the VIF input source selection (EDP\_DTPX\_SRC\_CFG[7-4] VIF\_n\_SEL register fields) settings.

For VIF0\_CLK, the source selection in non-DSC enabled mode comes from the output of MuxA (EDP\_DPI\_0\_2x\_CLK or EDP\_DPI\_2\_2x\_CLK). These clocks are full pixel data frequency clocks.

When DSC is enabled, the DSC\_ENC0\_CLK and DSC\_ENC1\_CLK clocks are sourced (MuxF) from:

- Full pixel data frequency clock (MuxA selected clock) - when DSC is configured in a non-split panel mode (EDP\_DPTX\_DSC\_CFG[1-0] MODE\_SEL != 0h AND EDP\_DPTX\_DSC\_CFG[2] SPLIT\_PANEL\_EN = 0h)
- Half pixel data frequency clock (MuxB selected clock) – when DSC is configured in the split panel mode (EDP\_DPTX\_DSC\_CFG[1-0] MODE\_SEL = 2h AND eDP\_DPTX\_DSC\_CFG[2] SPLIT\_PANEL\_EN = 1h)

VIF0\_CLK and VIF1\_CLK selection goes through additional muxing (MuxG/MuxH) to match the DSC encoder clocks.

#### 12.6.5.5.1.2 Memory Clock Gating

Memory clock gating is handled at the wrapper based on the scheme described below.

Functional mode clock enable (functional clock gating – for memory):

- DPTX firmware memory (I/D mem) clocks are enabled when EDP\_DPTX\_IPCFG[1] FW\_MEM\_CLK\_EN = 1.
- Memory clocks for all DPTX data memories in the normal functional mode are only enabled when the corresponding source (video/audio/pif) is enabled per DPTX\_SRC\_CFG.
  - Clocks for the video stream memories (vif\_mem) are enabled whenever the stream is enabled (EDP\_DPTX\_SRC\_CFG[3-0] VIF\_n\_EN).
  - Clocks for the packet memories (pkt\_mem) are enabled whenever the packet stream interface is enabled (EDP\_DPTX\_SRC\_CFG[3-0] VIF\_n\_EN).
  - Similarly clock for the audio buffer (aif\_mem) is enabled whenever the audio stream is enabled (EDP\_DPTX\_SRC\_CFG[16] AIF\_EN).
- Clocks for the DSC memories (DSC\_ENC0 and DSC\_ENC1 mem) are enabled based on the ENC0/ENC1 usage (EDP\_DPTX\_DSC\_CFG[1-0] MODE\_SEL). When EDP\_DPTX\_DSC\_CFG[1-0] MODE\_SEL is not 0 (that is, at least one DSC encoder is enabled), the wrapper enables VIF\_n\_MEM clock based on the DSC usage

Functional mode clock enable override:

- Clocks for all ECC memories can be forced to turn on (that is, functional clock gating bypassed) during ECC diagnostic access mode by setting EDP\_ECC\_MEM\_CFG[0] CLK\_EN = 1.

#### 12.6.5.5.1.3 PHY Clock Connections

There are multiple clocks from/to the physical interface. Figure 12-443 shows clocks used for the PHY clock domain logic (TXMCLK/TXFCLK) and for the return data clock (TXCLK). Not shown in the diagram are RX mode input clocks unused by EDP (TX only mode) – PHY\_INn\_RXCLK/RXFCLK/REFCLK.

**Figure 12-443. EDP PHY Clock Connections**

#### 12.6.5.5.2 Clock Groups

Following are the major groups of clocks in the EDP subsystem:

- System clock – This is the VBUSP configuration clock. It is used to source the clock for all internal configuration interfaces (VBUSP and PAB) and the core logic of the MHDPTX controller.
- DPI clocks - These are video stream source clocks. These can be sourced either directly from PLL or DSS (that is, DPI\_CLK outputs, DSS sourced mode).

- PHY I/O clocks - These are clocks used to transmit display port raw data to the SERDES or the clock used to receive audio data from MCASP.

Table 12-377 describes clocks at the EDP boundary.

**Table 12-377. EDP Clocks**

Clock	Freq Min	Freq Max	Source	Description
EDP_DPTX_CLK	125 MHz	125 MHz	System PLL	Functional clock (all VBUSP/APB/DPTX_core logics are clocked by this clock) Valid Freq: 100 – 200 MHz (125 MHz chosen to be 1/4x of CBASS 500 MHz clock)
EDP_DPI_2_2x_CLK	25 MHz	600 MHz	Video PLL or DSS EDP_DPI_2x_CLK	DPI Streaming Clock – Typically 1x of the corresponding EDP_DPI_2_CLK. But, in DSC split-panel mode, 2x of the EDP_DPI_2_CLK
EDP_DPI_2/3/4/5_CLK	25 MHz	600 MHz	Video PLL or DSS EDP_DPI_CLK	DPI Clock – pixel clock of the EDP_DPI_DATA bus. In DSS-sourced mode, EDP_DPI_n_CLK is the pixel clock of the EDP_DPI_n_DATA bus. In PLL-sourced mode, the pixel clock needs to be internally muxed between EDP_DPI_2_2x_CLK and EDP_DPI_2_CLK depending on the EDP_DPI_DATA type (split panel data or not).
EDP_AIF_I2S_CLK	1 MHz	125 MHz	MCASP	Audio I2S Clock (192 kHz clock)
PHY_LN0_TXMCLK (SOURCE_PHY_DATA_CLK)	81 MHz	405 MHz	DP-SERDES (PHY) PLL	PHY Data clock (1/2 Char Clock)
PHY_LN0_TXFCLK (SOURCE_PHY_CHAR_CLK)	162 MHz	810 MHz	DP-SERDES (PHY) PLL	PHY Char Clock

#### 12.6.5.6 EDP Resets

The EDP subsystem has one synchronous active low reset input. The entire subsystem is reset by this reset. All resets for different clock domains (both synchronous and asynchronous) are generated internally using this reset.

All resets within the MHDPTX\_TOP are asynchronous. Each clock's sub-domain resets are synchronized with respective software reset.

#### 12.6.5.7 EDP Interrupt Requests

The interrupt signals generated by the EDP subsystem and propagated to SoC level are shown in Table 12-378.

**Table 12-378. EDP Subsystem Interrupts**

Interrupt	Description
EDP_INTR[3:0]	EDP Controller Interrupt Event (Functional)
EDP_INTR_ASF[6:0]	EDP Controller ASF Error Interrupt

##### 12.6.5.7.1 EDP\_INTR Interrupt Description

Table 12-379 provides details on the EDP\_INTR[3:0] interrupt lines. Each of the interrupts listed in Table 12-379 has a corresponding set of memory-mapped interrupt registers (status/mask/clear).

**Table 12-379. EDP\_INTR Interrupts**

Interrupt Bit	Source	Description	Status Register	Mask Register	Clear Register
[3]	DSC	DSC Enc1 interrupt event detected	EDP_CORE_ENC1_IN_T_STAT_P	EDP_CORE_ENC1_IN_T_MASK_P	EDP_CORE_ENC1_IN_T_CLR_P
[2]		DSC Enc0 interrupt event detected	EDP_CORE_ENC0_IN_T_STAT_P	EDP_CORE_ENC0_IN_T_MASK_P	EDP_CORE_ENC0_IN_T_CLR_P

**Table 12-379. EDP\_INTR Interrupts (continued)**

Interrupt Bit	Source	Description	Status Register	Mask Register	Clear Register
[1]	MHDPTX Controller	DPTX SIRQ - Secure APB domain interrupt event. Set when an interrupt in the status register is reported.	EDP_CORE_APB_STA_TUS_S	EDP_CORE_APB_INT_MASK_S	-
[0]		DPTX PIRQ - General DPTX interrupt event. Set when an interrupt in the status register is reported.	EDP_CORE_APB_INT_STATUS_P	EDP_CORE_APB_INT_MASK_P	-

#### 12.6.5.7.2 EDP\_INTR\_ASF Interrupt Description

Table 12-380 provides details on the EDP\_INTR\_ASF[6:0] interrupts lines. Each of the interrupts listed in Table 12-380 has corresponding set of memory-mapped interrupt registers (status/mask/clear).

**Table 12-380. EDP\_INTR\_ASF Interrupts**

Interrupt Bit	Source	Description	Status Register	Mask Register	Clear Register
[6]	ECC_AGGR_DSC	ECC Aggregator Uncorrected Error Interrupt	EDP_ECC_DSC_DED_STATUS_REG0	EDP_ECC_DSC_DED_ENABLE_SET_REG0	EDP_ECC_DSC_DED_ENABLE_CLR_REG0
[5]	ECC_AGGR_PHY	ECC Aggregator Uncorrected Error Interrupt	EDP_ECC_PHY_DED_STATUS_REG0	EDP_ECC_PHY_DED_ENABLE_SET_REG0	EDP_ECC_PHY_DED_ENABLE_CLR_REG0
[4]	ECC_AGGR_CORE	ECC Aggregator Uncorrected Error Interrupt	EDP_ECC_CORE_DED_STATUS_REG0	EDP_ECC_CORE_DED_ENABLE_SET_REG0	EDP_ECC_CORE_DED_ENABLE_CLR_REG0
[3]	DSC	ASF Corrected interrupt detected in DSC	EDP_CORE_ENC_ASF_INT_STAT_P	EDP_CORE_ENC_ASF_INT_MASK_P	EDP_CORE_ENC_ASF_INT_CLR_P
[2]		ASF Un-Corrected interrupt detected in DSC			
[1]	MHDPTX Controller	ASF Corrected (NonFatal) event detected in MHDPTX Controller. Set if non-fatal error occurs.	EDP_CORE_ASF_INT_STATUS <sup>(1)</sup>	EDP_CORE_ASF_INT_MASK <sup>(1)</sup>	-
[0]		ASF Un-corrected (Fatal) event detected in MHDPTX Controller. Set when fatal error occurs.			

(1) Each interrupt can be individually defined as fatal or non-fatal in the EDP\_CORE\_ASF\_FATAL\_NONFATAL\_SELECT register.

#### 12.6.5.8 EDP Embedded Memories

##### 12.6.5.8.1 MHDPTX Controller Memories

**Table 12-381. EDP MHDPTX Controller Memories**

Name	ECC	Description
IRAM	Yes	uCPU Instruction Memory. Contains uCPU FW, loaded by host during boot time.
DRAM	Yes	uCPU DATA Memory. Contains uCPU data-memory, mailbox for communication between uCPU and host processor and EDID segment. In DisplayPort mode, it contains DPCD registers and AUX mailbox. In HDMI mode, it contains SCDC standard registers. When HDCP is supported, it contains keys and protected information.
PKT_MEM_n (n = 0 to 3)	Yes	Source Packet Memory. Contains up to 16 info-frames. Accessed by host processor (over APB) for write and by HD Display TX Controller for read.

**Table 12-381. EDP MHDPTX Controller Memories (continued)**

Name	ECC	Description
VIF_MEM_n (n = 0 to 3)	No (No ECC for the video buffer)	Video Memory. Elastic buffer, compensating the difference between the pixel clock and the line clock.
AIF_MEM	Yes	Audio Memory. Buffer audio samples during H active period.

**12.6.5.8.2 DSC Memories****Table 12-382. EDP DSC Memories**

Name	ECC	Description
ENC0/1_LB	Yes	Line Buffer RAM. Stores the reconstructed pixels that will be re-used for next line processing.
ENC0/1_OB0	Yes	Output Buffer RAM. Holds (as FIFO) results of encoder slices.
ENC0/1_SSM_S	Yes	Sub-stream Mux Size RAM. Holds context information required to generate the proper order of the mux words.
ENC0/1_SSM_D	Yes	Sub-stream mux balance FIFO RAM. Holds stream data for re-ordering.

**12.6.5.8.3 ECC Aggregation**

The tasks of ECC detection/correction of 'ECC enabled' memories are handled within the MHDPTX Controller. The EDP wrapper provides 'ECC error injection' using a combination of ECC\_Wrapper (to access the memory) and ECC\_Aggregator (to allow system to access the ECC injection logic). An ECC\_Aggregator can access multiple ECC\_Wrappers of the same clock group. [Table 12-383](#) shows how the ECC memories (and the EDC\_CTRL for Parity Inv) in the EDP are grouped to three ECC aggregators.

**Table 12-383. EDP ECC\_Aggregator (Based on Clock Group)**

Memory / Logic	ECC Vector_ID	ECC_Aggregator
IRAM	0	ECC_AGGR_CORE
DRAM	1	
EDC_CTRL (Parity)	2	
PKT_MEM_0	0	ECC_AGGR_PHY
PKT_MEM_1	1	
PKT_MEM_2	2	
PKT_MEM_3	3	
AIF_MEM	4	
VIF_MEM_0	-	N/A (No ECC for the video buffer)
VIF_MEM_1	-	
VIF_MEM_2	-	
VIF_MEM_3	-	
ENC0_LB	0	ECC_AGGR_DSC
ENC0_SSM_S	1	
ENC0_SSM_D	2	
ENC0_OB0	3	
ENC1_LB	4	
ENC1_SSM_S	5	
ENC1_SSM_D	6	
ENC1_OB0	7	

Furthermore, each ECC\_Aggregator is connected to the VBUSP\_CFG via the main CBASS SCR (with asynchronous bridge). All ECC aggregator bound VBUSP\_CFG transactions are mapped to a separate RSEL (in EDP case, RSEL=3), see [Figure 12-444](#).

Each ECC\_Aggregator and the asynchronous VBUSP interface of the aggregator are clocked using the read clocks used to read the memory, as follows:

- ECC\_AGGR\_CORE: EDP\_DPTX\_CLK
- ECC\_AGGR\_PHY: SOURCE\_PHY\_DATA\_CLK (PHY\_LN0\_TXMCLK)
- ECC\_AGGR\_DSC: EDP\_DPI\_0\_CLK or EDP\_DPI\_2\_CLK (selected by mux)

The clocks to some ECC memories may be disabled when the associated video or audio channel is not enabled. If none of the memories for an ECC aggregator is enabled (for example, DSC memory clocks are disabled, if the DSC is not enabled), then the clock for the aggregator is also disabled and the aggregator is disconnected from the CBASS (resulting in null return for any VBUSP access to the aggregator)

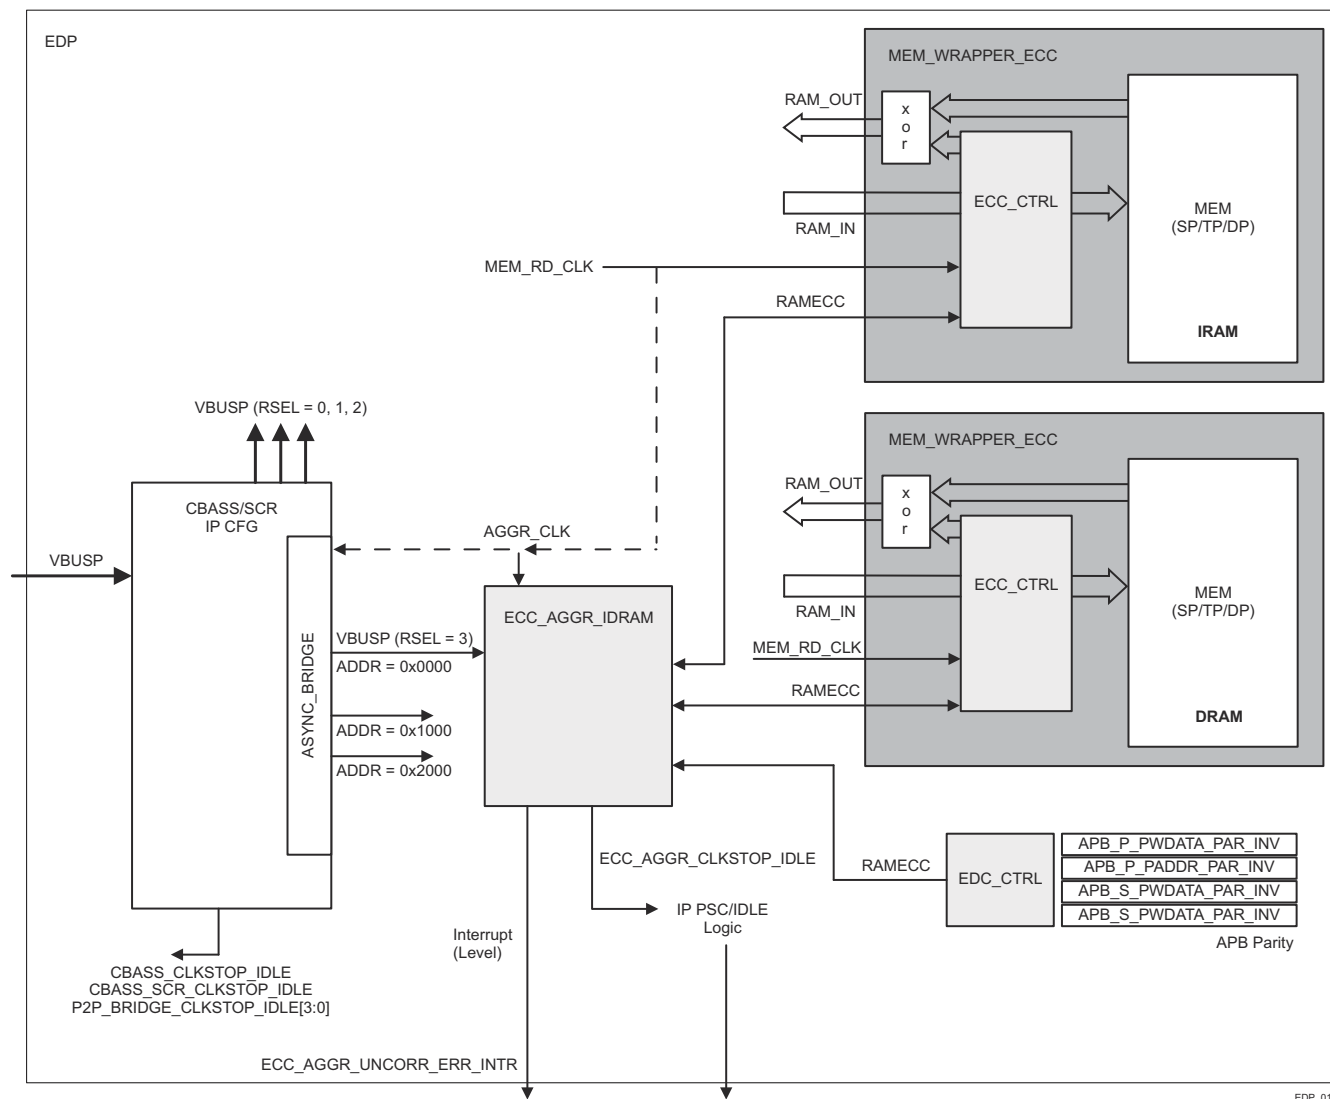

But, if any of the ECC memories connected to an ECC aggregator is enabled, the clock for the ECC aggregator must also be enabled. Any access to the ECC\_CTRL of the disabled memory will result in TIMEOUT error (interrupt generated) since the memory clock is not running.

If ECC diagnostics/access are needed for all ECC memories whether the memories are enabled or not, the ECC software can set the clock enable override configuration register - EDP\_ECC\_MEM\_CFG[0] CLK\_EN to bypass the clock gating.

Even with this bit set, the ECC\_CTRL connected to the ECC\_AGGR\_PHY aggregator may not get any clock if the PHY is not enabled and properly configured. The EDP\_PHY\_CLK\_STATUS[0] VALID status register tells whether the PHY data clock is running or not.

The DSC clock is sourced from the system video PLL and therefore it should be running. Therefore, the ECC software just need to ensure the clock gating is not active and/or set the ECC CLK\_EN override bit to get the clock to the memory.

The ECC\_CORE Aggregator clock should be running whenever the EDP is enabled. There is no clock gating to the IRAM/DRAM memories.

**Figure 12-444. EDP ECC WRAP/ECC AGGR and PARITY INV Logic Connection**

#### 12.6.5.9 EDP Programmer's Guide

This chapter describes the programming guidelines for the MDPTX Controller and EDP PHY.

#### 12.6.5.9.1 EDP Controller Programming

#### 12.6.5.9.1.1 MHDPTX Register/Memory Regions

Table 12-384 provides a summary of the bus interfaces and the MMR regions mapped to each interface in this module.

### Table 12-384. EDP Memory Map Region - Firewall Secure Mode Settings

Region Name	Firewall Secure Mode Settings <sup>(1) (2)</sup>
INTG_CFG_VP	Should be Secure
V2A_CORE_VP_REGS_APB	Secure (for Secure display) / Non-secure
V2A_S_CORE_VP_REGS_SAPB	Must be Secure always (HDCP configuration)
MHDPTX_WRAPPER_ECC_AGGR_CORE_CFG	Secure (for Secure display) / Non-secure
MHDPTX_WRAPPER_ECC_AGGR_PHY_CFG	Secure (for Secure display) / Non-secure
MHDPTX_WRAPPER_ECC_AGGR_DSC_CFG	Secure (for Secure display) / Non-secure

(1) Firewall secure mode settings:

- The V2A\_S\_CORE\_VP\_REGS\_SAPB (secure APB) region must be restricted to secure host access only (for HDCP key protection)
  - The INTG\_CFG\_VP region should be set to secure host access only since this region controls the security of the DPI ports and controls the clock enables.
  - Other regions should be set to secure, if the display connected is to be secure.
- (2) Word-access only for RSEL (1 and 2) – accessing APB and SAPB regions of MHDPTX core. Any non-word access request will result in either rstatus=1 or sstatus=1.

Table 12-385 shows the MHDPTX Controller register/memory regions that are accessible during various operational modes:

**Table 12-385. EDP MHDPTX Controller APB/SAPB Memory Map and Access Modes**

Description	Address Base [19:0]	Register Bank	Direct access (x= APB (x= APB /SAPB)	Mailbox access (x= APB (x= APB /SAPB)	FW (uCPU) access	APB debug (Bootmode) access
Main configuration and Mailbox control registers. Each APB interface has its own set of these registers.	0x00000	APB_CFG	x			x

Fault reporting module	0x30B00	ASF	APB			x

**Table 12-385. EDP MHDPTX Controller APB/SAPB Memory Map and Access Modes (continued)**

Description	Address Base [19:0]	Register Bank	Direct access (x= APB (x= APB /SAPB)	Mailbox access (x= APB (x= APB /SAPB)	FW (uCPU) access	APB debug (Bootmode) access
DSC encoder	0x30C00 - 0x30F00	DSC	APB			x

**Access Modes:**

- APB Debug (Boot Mode) Access - After a hardware reset, MHDPTX comes up in this mode – allowing APB access to all regions including IMEM/DMEM (for FW download)
- Direct Access - Once the boot mode initialization is complete, APB\_CTRL register is cleared. This takes it out of the Boot mode and into the direct access mode in which only the mailbox control (APB\_CFG space) and regions marked as APB in the direct access column.
- Mailbox Access - While in Direct Access mode, all configurations of the DPTX for DP operation are done through the APB mailbox accesses. Secure transactions (secure refers to transactions to protect "secure" content) are done through the secure mailbox access via SAPB interface. The SAPB access is made through the secure EDP vbusp region (must be configured as such in the cfg Firewall)
- FW (uCPU) Access – This column indicates register/memory bank accessible by FW access.

**12.6.5.9.1.2 Boot Sequence**

After reset, the uCPU is disabled. The full MHDPTX Controller address space is accessible for the host processor for debugging purposes, and the I-MEM and D-MEM.

The host processor must perform the following:

- Load the FW into the memories.
- Enable the uCPU.
- Verify that FW is running as expected.

**Figure 12-445. EDP MHDPTX Controller Boot Sequence**

#### 12.6.5.9.1.3 Setting Core Clock Frequency

The FW relies on a known core\_clock frequency for configuring time HW dividers and timeout counters.

Therefore, core\_clock frequency (SW\_CLK\_H, SW\_CLK\_I) must be configured by the host processor, prior to booting the FW.

#### 12.6.5.9.1.4 Loading Firmware

The FW binaries are provided in the hexadecimal format that is composed from two files IRAM0.DATA and DRAM0.DATA.

The IRAM0.DATA contains the instruction memory and the DRAM0.DATA contains the variables initialization.

The external host processor should load the FW into the I-MEM and D-MEM, and enable the uCPU. Accessing the I-MEM, D-MEM is enabled only after reset (after reset, the system is going into debug mode, after loading FW and set EDP\_CORE\_APB\_CTRL\_P register to 0 system is going out from debug mode, and only reset can bring the system back to debug mode).

After loading the memories, the host processor should select the uCPU to be the master of the I-MEM and D-MEM memories, and enable the uCPU by writing 0x00 to the EDP\_CORE\_APB\_CTRL\_P register.

#### 12.6.5.9.1.5 FW Running indication

After loading the FW, the embedded FW takes approximately 2ms to complete the INIT phase and start running. The EDP\_CORE\_KEEP\_ALIVE\_P register specifies whether the FW is running.

**KEEP\_ALIVE** – The EDP\_CORE\_KEEP\_ALIVE\_P register is a counter initialized to 0 after reset and incremented by the FW on any scheduler loop.

When a valid FW is running, this register will be changed on every FW Scheduler loop (< 2ms). The host processor may use the mailbox channel immediately after reset, FW will response after the completion of INIT phase.

### Operational mode

After completion of boot sequence, the FW set the MHDPTX Controller in a standby mode. In the standby mode, it is ensured that no transaction is executed over the external interfaces (that is, AUX, PHY, Video).

Switching into active mode is done by executing the GENERAL\_MAIN\_CONTROL command.

#### 12.6.5.9.1.6 Software Events Handling

Software events are captured by the MHDPTX Controller FW, where the Event Value is stored in a designated area (in the D-MEM) and a bit is set by the FW in EDP\_CORE\_SW\_EVENTS0\_P register, see [Table 12-386](#).

The host processor should poll the EDP\_CORE\_SW\_EVENTS0\_P register (cleared after read) and following a detection of event(s) the host processor should call the relevant command which returns the Event Value.

The Event Value holds the latest value associated with the event.

The EDP\_CORE\_SW\_EVENTS0\_P register is not cleared by the FW. Therefore, it is recommended to read this register (dummy read) to initialize the events to zero.

While any bit in EDP\_CORE\_SW\_EVENTS0\_P register is set, the MHDPTX Controller raises a hardware interrupt.

**Table 12-386. EDP MHDPTX Controller Software Events**

Bit	Event	Description
31:8	RESERVED	-
7	HDCP_TX_IS_RECEIVER_ID_VALID	IP has an ID to check if it is valid, HDCP_TX_IS_RECEIVER_ID_VALID_REQ needs to be called.
6	HDCP2_TX_STORE_KM	IP has Km to store, HDCP2_TX_STORE_KM_REQ needs to be called.
5	HDCP2_TX_IS_KM_STORED	IP need to check if Km is stored, HDCP2_TX_IS_KM_STORED_REQ needs to be called.
4	HDCP_TX_STATUS	HDCP TX was changed, HDCP_TX_STATUS_REQ needs to be called.
3:1	RESERVED	-
0	DPTX_HPDP	HPDP was changed, DPTX_READ_EVENT_REQUEST needs to be called.

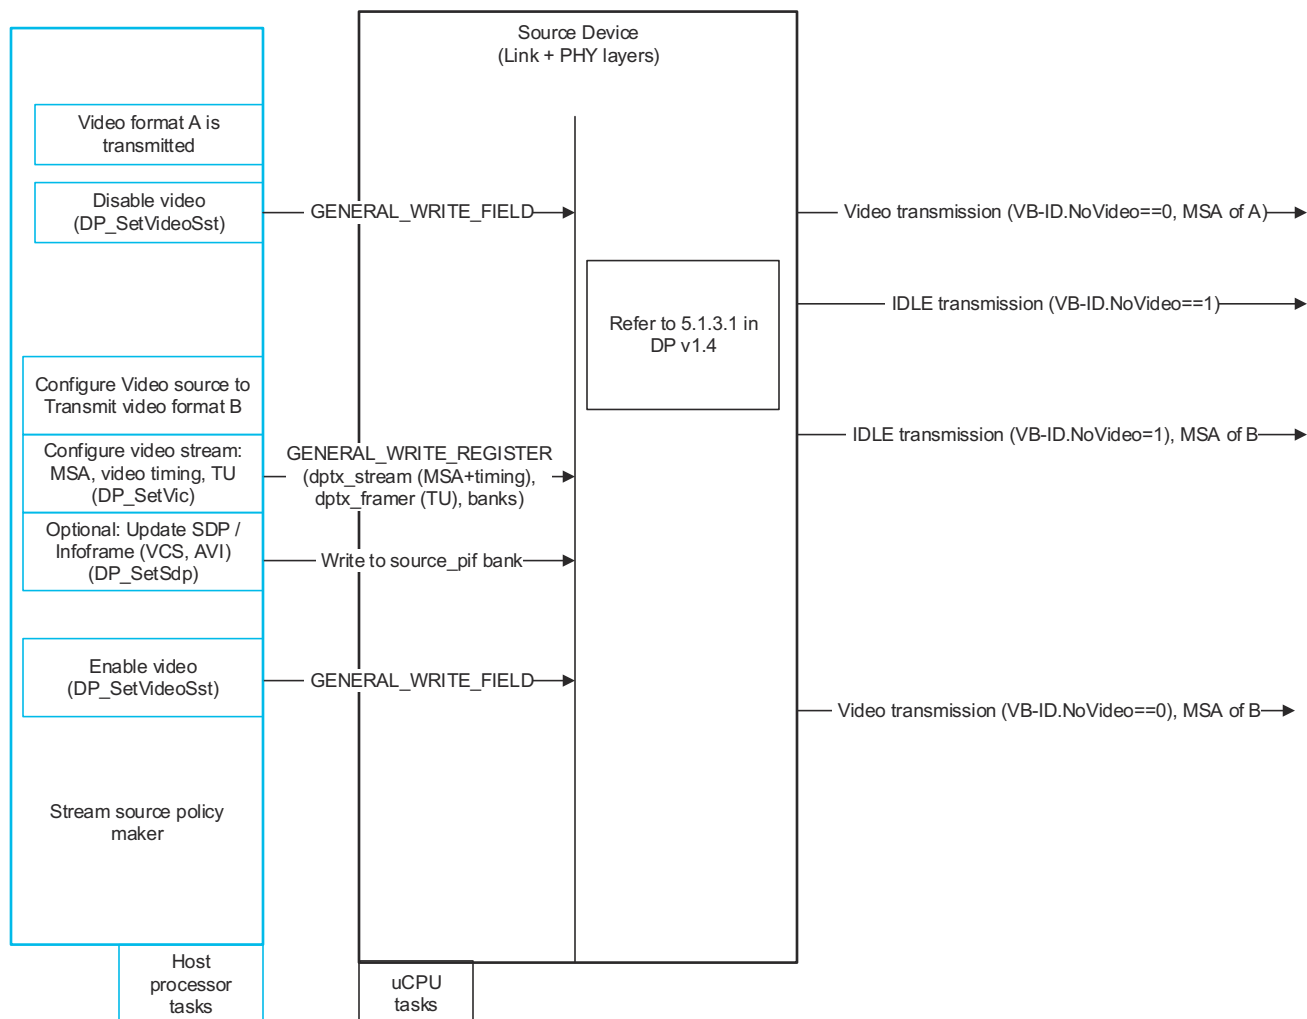

#### 12.6.5.9.1.7 DisplayPort Source (TX) Sequence

[Figure 12-446](#) shows the expected host processor and uCPU tasks executed to start a video/audio transmission.

SPRUJ28F – NOVEMBER 2021 – REVISED AUGUST 2025  
[Submit Document Feedback](#)

**Figure 12-447. EDP Operation Sequence – DisplayPort Video Format Change**

**Figure 12-448. EDP Operation Sequence – DisplayPort Audio Format Change**

#### 12.6.5.9.1.8 HDCP

The FW supports embedded HDCP crypto, with optional Km-key encryption.

##### 12.6.5.9.1.8.1 Embedded HDCP Crypto

In this mode, the HDCP functionality is fully supported by the MHDPTX Controller. The AKE phase and the corresponding cryptographic operations are handled by the FW.

Following the AKE phase, the FW initializes the stream cipher with the session key.

The host processor communicates with the MHDPTX Controller for:

- Configuring the capabilities
- Loading the HDCP keys (or certificate)
- Monitoring authentication status.

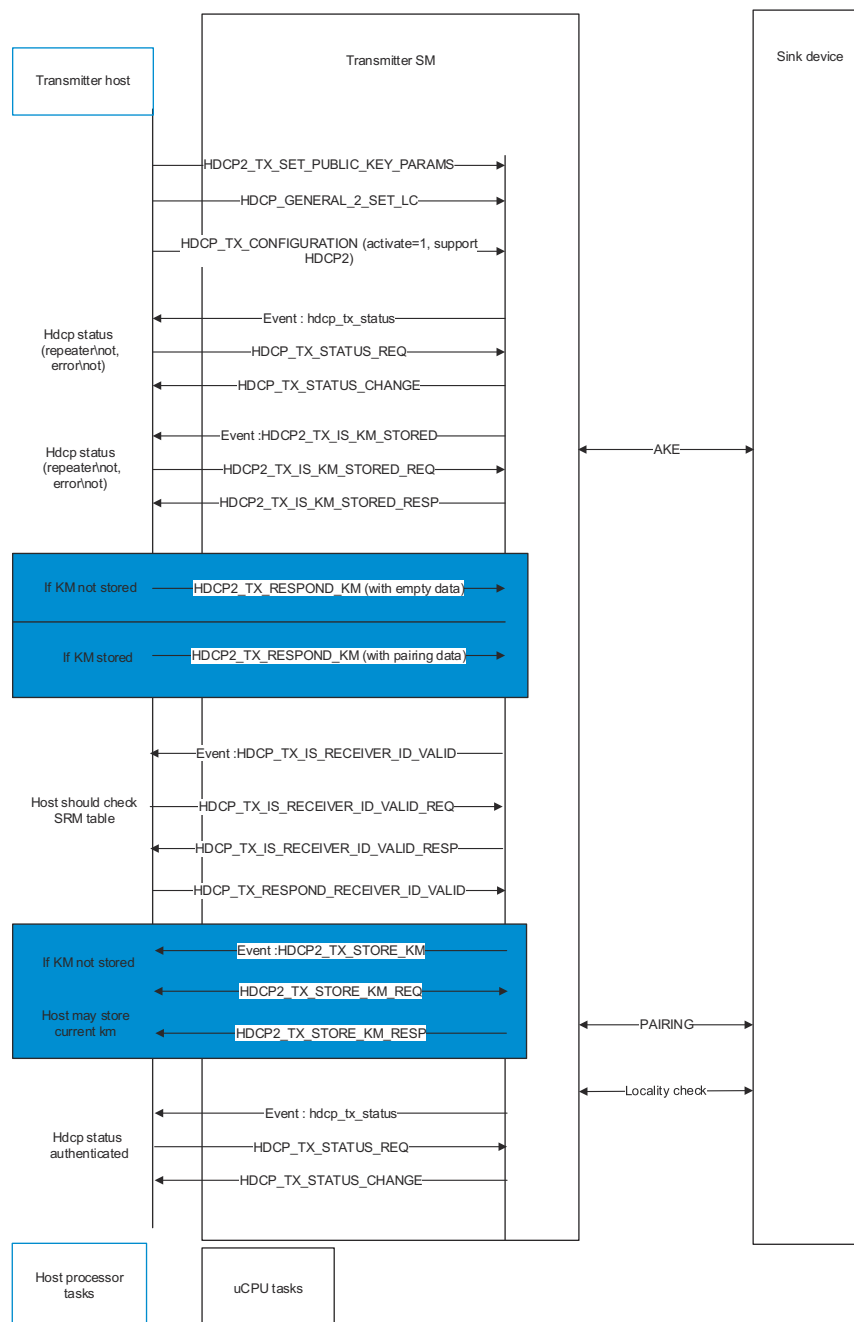

#### Note

Commands that carry secret information must be protected from tampering. Therefore, SAPB must be used to carry secured commands over mailbox.

**Table 12-387. EDP HDCP Commands With Secret Information**

HDCP command	Description
HDCP_GENERAL_2_SET_LC	Refer to HDCP 2.2 Appendix A
HDCP_GENERAL_SET_SEED	External TRNG must be used for generating a true random seed number. Therefore, it is expected that the seed number will meet the high entropy level.
HDCP2_TX_RESPOND_KM	Refer to HDCP 2.2 Appendix A
HDCP1_TX_SEND_KEYS	Refer to HDCP 1.4 Appendix B
HDCP2_TX_STORE_KM	Refer to HDCP 2.2 Appendix A

Figure 12-449 and Figure 12-450 show the operation sequences for an embedded HDCP 2.2 and HDCP 1.4

**Figure 12-449. EDP Operation Sequence – Embedded HDCP 2.2**

**Figure 12-450. EDP Operation Sequence – Embedded HDCP 1.4**

#### 12.6.5.9.1.8.2 Additional Security Features

##### 12.6.5.9.1.8.2.1 KM-Key Encryption

In order to provide higher security level an optional Km-key encryption is provided. If Km-key encryption is enabled while sending `HDCP1_TX_CONFIGURATION` command, then HDCP controller will expect Master Key, 1.4 Device Keys and Global Constant. These keys will be decrypted using Km-key (loaded using `HDCP2_TX_SET_KM_KEY_PARAMS` command) by the controller's internal Firmware and used during Authentication and Key Exchange procedure. The Km-key encryption will also assure that when host reads Master Key it will receive it in encrypted form.

Enabling Km-key encryption affects the following commands or their parameters:

- `HDCP2_TX_RESPOND_KM/Km`
- `HDCP1_TX_SEND_KEYS/Transmitter Device Key`
- `HDCP2_TX_STORE_KM_RESP/Km`
- `HDCP_GENERAL_2_SET_LC`

### 12.6.5.9.1.8.2.2 Cyphertext Stealing

In order to use Km-key encryption for the 1.4 Device Keys and avoid changes in the API a Cyphertext Stealing technique is used. This technique allows to apply AES-ECB in Km-key encryption while 1.4 Device Key does not have size equal to multiple of 16.

### 12.6.5.9.1.9 HD Display TX Controller

#### 12.6.5.9.1.9.1 Info-Frame Handling

Info-frames, which include meta-data (that is, auto type or video format), are initialized by the host processor.

The host processor directly initializes the PKT-MEM (which stores the info-frames). Initialization includes loading info-frame into PKT-MEM and updating the PKT LUT. Refer to DP\_SetSdp, DP\_RemoveSdp.

#### 12.6.5.9.1.9.1.1 EDID Handling

The MHDPTX Controller issues command for reading EDID data from the remote side (sink). The EDID is sent to the host processor in a single block, that is, each block in one message. The MHDPTX Controller does not parse the EDID blocks. Refer to DP\_ReadEdid.

#### 12.6.5.9.1.9.1.2 Audio Control

When changing an audio stream format, the host processor must follow a specific programming sequence by configuring the I2S decoder and audio info frame packet. Refer to DP\_AudioAutoConfig.

#### 12.6.5.9.1.9.1.3 Video Control

The host processor need to configure the video timing before enabling the video stream over the VIF interface.

### 12.6.5.9.1.10 DPTX TX Controller

#### 12.6.5.9.1.10.1 Protocol over Auxiliary

The firmware provides an interface for the AUX and I2C-over-AUX data transactions. The host processor may use it for direct DPCD (including the HDCP address range) or EDID access.

#### 12.6.5.9.1.10.2 PHY (Physical layer) Handling

Separate PHY driver is used to initialize PHY.

DPTX PHY is handled by Core Driver, during link training (that is, Lane count, Link Rate, Pre-emphasis and Voltage Swing control).

### 12.6.5.9.2 EDP PHY Wrapper Initialization

EDP connects to the SERDES PHY wrapper (WIZ) using the RAW data mode. To enable this connection, the WIZ configuration registers in the SERDES PHY must be configured. For details on the SERDES PHY wrapper configuration, see Section 10-G *SerDes Programming Guide*.

The following is an example configuration for enabling 4-data lane RAW data mode for Display Port connection.

// SERDES\_TOP\_CTRL register bit-field settings:

// PMA\_CMN\_REF\_CLK\_MODE = 2'b10, PMA\_CMN\_REF\_CLK\_INT\_MODE = 2'b10,  
PMA\_CMN\_REFCLK\_DIG\_DIV = 0, PMA\_SUSPEND\_OVERRIDE = 0

SERDES\_TOP\_CTRL register value = 32'h30000000

// SERDES\_RST register bit-field settings:

// PHY\_RESET\_N = 0 (PHY in reset)

// PHY\_EN\_REFCLK = 0 (PHY reference clock output disabled)

// PLL1/0\_REFCLK\_SEL = 0 (for cmn\_refclk\_<p/m> select), 1 (for pma\_cmn\_refclk\_int select)

// REFCLK\_TERM\_DIS = 1 (termination disabled)

// REFCLK\_DIG\_SEL = 1 (PMA common reference clock select: 0 for cmn\_refclk\_<p/m>, 1 –  
pma\_cmn\_refclk\_int)

```
// If the reference clock is sourced from internal digital input:
// PLL1_REFCLK_SEL = 1, PLL0_REFCLK_SEL = 1, REFCLK_TERM_DIS = 1, REFCLK_DIG_SEL = 1
SERDES_RST register value = 32'h39000000

// Alternatively, if the reference clock is sourced from <p/m> inputs:
// PLL1_REFCLK_SEL = 0, PLL0_REFCLK_SEL = 0, REFCLK_TERM_DIS = 0, REFCLK_DIG_SEL = 0
SERDES_RST alternative register value = 32'h00000000

// LANECTLx register bit-field settings:
// P0_ENABLE = 0, P0_FORCE_ENABLE = 1, P0_ALIGN = 1, P0_RAW_AUTO_START = 1,
P0_STANDARD_MODE = 0, P0_FULLRT_DIV = 0
LANECTL0 register value = 32'h70000000 // for lane 0
// P0_ENABLE = 1, P0_FORCE_ENABLE = 0, P0_ALIGN = 0, P0_RAW_AUTO_START = 0,
P0_STANDARD_MODE = 0, P0_FULLRT_DIV = 0
LANECTL1 register value = 32'h80000000 // for lane 1
LANECTL2 register value = 32'h80000000 // for lane 2
LANECTL3 register value = 32'h80000000 // for lane 3

// LANEDIVx register bit-field settings:
// P0_MAC_DIV_SEL0 = 7'b1, P0_MAC_DIV_SEL1 = 9'b1
LANEDIV0 register value = 32'h00010001 // for lane 0
LANEDIV1 register value = 32'h00010001 // for lane 1
LANEDIV2 register value = 32'h00010001 // for lane 2
LANEDIV3 register value = 32'h00010001 // for lane 3

// Set DIAG_REG register to 0
DIAG_TEST register value = 32'h0
```

#### Note

The SERDES PHY reset is not driven by the EDP controller (that is, by writing to the EDP\_CORE\_PHY\_RESET\_P[8] PHY\_RESET register bit. Instead, the SERDES PHY reset is mapped to the SERDES\_RST[31] PHY\_RESET\_N register bit in the SERDES PHY wrapper. But, the EDP\_CORE\_PHY\_RESET[8] PHY\_RESET bit is still used in the EDP controller to disable the controller's output to the SERDES. Therefore, after reset, the EDP\_CORE\_PHY\_RESET[8] PHY\_RESET bit must be set to 1 (reset off). After this, the SERDES reset can be controlled strictly with the SERDES\_RST[31] PHY\_RESET\_N bit.

#### 12.6.5.9.3 EDP PHY Programming

Table 12-388 shows information on how to program the EDP PHY (SERDES).

**Table 12-388. EDP PHY (SERDES) Programming Details**

General Information	
Standards / links / lanes supported	Display port and embedded display port / 2 links / 1, 2, or 4 lanes per link
Reference clock information and setup	
External / internal reference clock selection	Set up external or internal reference clock.
Reference clock frequency selection	Set up the reference clock programming for the selected reference clock frequency
PLL and high speed clocking information and setup	

**Table 12-388. EDP PHY (SERDES) Programming Details (continued)**

<b>General Information</b>	
PLL 0, Mode 0	Display port link 0. Note, if only link 1 is used, PLL 0 must be programmed in the same way as PLL 1.
PLL 0, Mode 1	Unused
PLL 1, Mode 0	Display port link 1. Note, if only link 0 is used, PLL 1 must be programmed in the same way as PLL 0.
PMA common full rate and data rate clocks	Unused
PMA transceiver full rate and data rate clocks	Full rate and data rate clocks are used as specified in the PMA spec table Clock rates for supported standards.
<b>Top level pins</b>	
PMA: cmn_pll0_mode_sel (Driven by PHY internal logic)	1'b0
PMA: cmn_pll1_mode_sel (Driven by PHY internal logic)	1'b0
PHY: phy_{nn:00}_mode[1:0]	2'b11
PHY: phy_link_cfg_ln_{n:1}	1'b0 for slave lanes of each link 1'b1 for the master lane of each link
<b>PHY configuration specific registers</b>	
SERDES register PHY_AUTO_CFG_SPDUP, bit-fields [1] PHY_PLL_CFG_1 and [0] PHY_PLL_CFG_0	16'h0000 for single DP link configuration 16'h0002 for 2 DP link configuration
<b>Set PLL analog clock divider values</b>	
SERDES register CMN_PDIAG_PLL0_CLK_SEL_M0__CMN_PDIAG_PLL0_CTL_M0	Link 0: Program it as described
SERDES register CMN_PDIAG_PLL1_CLK_SEL_M0__CMN_PDIAG_PLL1_CTL_M0	Link 1: Program it as described
<b>Select analog high speed clock, and transceiver clock divider values</b>	
SERDES register XCVR_DIAG_HSCLK_DIV__XCVR_DIAG_HSCLK_SEL_j, bits [15:0] Link 0 Link 1	16'h0000 16'h0001
SERDES register XCVR_DIAG_HSCLK_DIV__XCVR_DIAG_HSCLK_SEL_j, bits [31:16]	Program it as described
<b>Select digital PLL clock and data rate divider values</b>	
SERDES register XCVR_DIAG_PLLDRC_CTRL__XCVR_DIAG_XDP_PWRI_S TAT_j Link 0 Link 1	16'h0001 16'h0009
<b>Protocol specific setup</b>	
Display port and embedded display	Program it as described

## 12.7 Camera Subsystem

This section describes the Camera Subsystem in the device.

### 12.7.1 Camera Streaming Interface Receiver (CSI\_RX\_IF)

The following sections describe the camera streaming receiver interface (CSI\_RX\_IF) modules in the device.

#### 12.7.1.1 CSI\_RX\_IF Overview

The integration of the CSI\_RX\_IF module allows the device to stream video inputs from multiple cameras to the image processing accelerator (VPAC) or to internal memory. The video input may also be retransmitted via the transmitter CSI (CSI\_TX\_IF) for debug and test purposes.

##### 12.7.1.1.1 CSI\_RX\_IF Features

The CSI\_RX\_IF module supports the following features:

- Compliant to MIPI CSI v1.3
- Supports up to 16 virtual channels per input (partial MIPI CSI v2.0 feature)
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to DPHY\_RX
- Programmable formats including YUV420, YUV422, RGB, Raw, and User Defined (over 25 different formats supported)
- Four independent (simultaneous) output streams:
  - Two VP 32-bit streams to VISS inputs of VPAC image processing accelerator:
    - 2x 16-bit pixels per clock cycle
    - One virtual channel and data type per port
    - Raw format only (8-16 bits)
    - 32bit, 2 pixels wide, elastic buffer mode
      - Data[15:0]: Pixel n (MSB zero padding)
      - Data[31:0]: Pixel n+1 (MSB zero padding)
      - Internal full flag (FF) based FIFO (2048x32)
      - VP clock asynchronous to CSI\_RX\_IF main clock. Crossing done internally.
  - One (up to 4 channels) PPI 16-bit pixel retransmission interface to CSI\_TX\_IF:
    - 2x 16-bit pixels per clock cycle
    - 32bit retransmission width
    - No external buffer
    - Raw format only (8-20 bits, partial MIPI CSI v2.0 feature)
    - CSI\_RX\_IF and CSI\_TX\_IF main clocks must be running at the same frequency and synchronous.
  - One (up to 32 Channels) DMA interface through a 128-bit PSI\_L connection to NAVSS for transfers to memory:
    - Byte packed (32x4) format, elastic buffer mode
    - Max rate 1 data cycle every 4 main clocks
    - ByteValid per byte in Last Data Phase (LDP)
    - 32 thread ID's supported (virtual channel & data type combinations); Flexible number of threads (32 Max)
    - Virtual channels and data types mapped via mmr to PSI\_L thread ID's
    - Internal FF based FIFO; RAM based buffer (2kx128)
- Functional and data path error interrupts
- ECC support

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

##### 12.7.1.1.2 CSI\_RX\_IF Not Supported Features

The CSI\_RX\_IF does not support the following features:

- MIPI CSI2 v2.0 scrambling
- MIPI CSI2 v2.0 optional no LP (low power state) between packets
- Cropping
- Pixel processing

- Virtualization
- YUV420-8 legacy not supported
- YUV420 interleave limitation. The entire frame must be sent.
- Full line buffer mode is not supported

### 12.7.1.1.3 CSI\_RX\_IF Ports

This section describes the CSI\_RX\_IF ports related to clocks, resets, and hardware requests.

**Table 12-389. CSI\_RX\_IF Clocks and Resets**

Clocks	
Module Clock Input	Description
CSI_RX_MAIN_CLK	Main functional clock.
CSI_RX_VBUS_CLK	The VBUS clock runs at always half the speed of the CSI_RX_MAIN_CLK.
CSI_RX_VP_CLK	Video port interface clock. It must run at the same speed or higher than the CSI_RX_MAIN_CLK. It can be async to the CSI_RX_MAIN_CLK clock. However, it must be sync to VPAC video clock.
CSI_RX_BYTE_CLK	The byte clock is the clock supplied by the DPHY_RX.
Resets	
Module Reset Input	Description
CSI_RX_RST	Asynchronous module global reset, driving all collater asynchronous resets of the 4 clock domains to the low state.

**Table 12-390. CSI\_RX\_IF Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
CSI_RX_IF_CSI_ERR_IRQ_0	Stream error detected. The CSI_RX_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI_RX_CSI_ERR_IRQ.	Level
CSI_RX_IF_CSI_IRQ_0	Global interrupt that various resynchronized sources converge into interrupt generation.	Level
CSI_RX_IF_CSI_LEVEL_0	PSI_L fifo overflow or VP0/VP1 frame/line mismatch	Level
CSI_RX_IF_CORR_LEVEL_0	This interrupt is for checking the interface signals of the CSI_RX_IF controller for parity.	Level
CSI_RX_IF_CSI_FATAL_0	ASF port fatal interrupt. Level sensitive.	Level
CSI_RX_IF_CSI_NONFATAL_0	ASF port non-fatal interrupt. Level sensitive.	Level
CSI_RX_IF_UNCORR_LEVEL_0	This interrupt is for checking the interface signals of the CSI_RX_IF controller for parity.	Level

### 12.7.1.2 CSI\_RX\_IF Environment

The CSI\_RX\_IF has no dedicated pins. At the device level, video inputs come from the DPHY\_RX; see [Section 12.8.2](#).

#### 12.7.1.3.1 CSI RX IF Block Diagram

[illegible]

2. The CSI\_RX\_VBUS\_CLK is the interface configuration clock that runs at half the speed of the CSI\_RX\_MAIN\_CLK.
3. The CSI\_RX\_VP\_CLK is the video port interface clock. It must run at the same speed or higher than CSI\_RX\_MAIN\_CLK. It can be async to CSI\_RX\_MAIN\_CLK clock. It also must be sync to VPAC video clock. Up to 720MHz max rate
4. The CSI\_RX\_BYTE\_CLK is the clock supplied by the DPHY\_RX PLL and is divided down to byte clock. The DPHY\_RX is designed for max of 10gbps. This translates to a max byte clock of 312.5MHz. The clock is inactive when DPHY\_RX is not in HS operation.

Table 12-391 shows the CSI\_RX\_IF and DPHY\_RX inter-clock dependencies.

**Table 12-391. CSI\_RX\_IF Inter-clock Dependencies**

	CSI_RX_MAIN_CLK	CSI_RX_VBUS_CLK	CSI_RX_VP_CLK	CSI_RX_BYTE_CLK
<b>Min freq</b>	CSI_RX_BYTE_CLK freq	CSI_RX_MAIN_CLK / 2 freq	CSI_RX_BYTE_CLK freq	N/A
<b>Max freq</b>	500MHz	CSI_RX_MAIN_CLK / 2 freq	720MHz	312.5MHz

#### 12.7.1.3.4 CSI\_RX\_IF Interrupt Events

This section describes the register configuration of the interrupt events that can trigger the several CSI\_RX\_IF interrupt signals. For detailed description and mapping of the interrupt of the device interrupt processors see *CSI\_RX\_IF Integration*.

The interrupts are generally handled within the INTD module of the CSI\_RX\_IF, although there are several interrupt registers in the ECC\_AGGR for ECC errors and in the VBUS2APB for stream monitoring errors/flags.

Table 12-392 lists the event generation and corresponding registers of the CSI\_RX\_IF controller.

**Table 12-392. CSI\_RX\_IF Interrupt Events Cross Table**

Event	Mask Register	Status Register	Description
CSI_RX_CSI_ERR_IRQ	CSI_RX_IF_VBUS2APB_ERROR_IRQS_MASK_CFG	CSI_RX_IF_VBUS2APB_ERROR_IRQS	Stream error detected. The CSI_RX_IF0 will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI_RX_CSI_ERR_IRQ. Read the status register bitfields to trace the source of the event.
CSI_RX_CSI_IRQ	CSI_RX_IF_CP_INTD_ENABLE_REG_LEVEL_0 CSI_RX_IF_VBUS2APB_ERROR_IRQS_MASK_CFG	CSI_RX_IF_CP_INTD_STATUS_REG_LEVEL_0 CSI_RX_IF_VBUS2APB_ERROR_IRQS	Global functional interrupt that various resynchronized sources converge into interrupt generation.
CSI_RX_CSI_LEVEL	CSI_RX_IF_VBUS2APB_MONITOR_IRQS_MASK_CFG	CSI_RX_IF_VBUS2APB_STREAM_M0_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM_M1_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM_M2_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM_M3_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM_M0_FIFO_FILL_LVL	PSI_L fifo overflow or VP0/VP1 frame/line mismatch (at the minimum an error interrupt will occur at the end of frame but may be issued within the frame as well). Read the status register bitfields to trace the source of the event.
CSI_RX_CORR_LEVEL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	This interrupt is for checking the interface signals of the CSI_RX_IF0 controller for parity.
CSI_RX_UNCORR_LEVEL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	This interrupt is for checking the interface signals of the CSI_RX_IF0 controller for parity.

**Table 12-392. CSI\_RX\_IF Interrupt Events Cross Table (continued)**

Event	Mask Register	Status Register	Description
CSI_RX_CSI_FATAL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_RX_IF_VBUS2APB_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_RX_IF_VBUS2APB_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.
CSI_RX_CSI_NONFATAL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	ASF port non-fatal interrupt. Level sensitive. Set CSI_RX_IF_VBUS2APB_ASF_FATAL_NONFATAL_SELECT to whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_RX_IF_VBUS2APB_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.

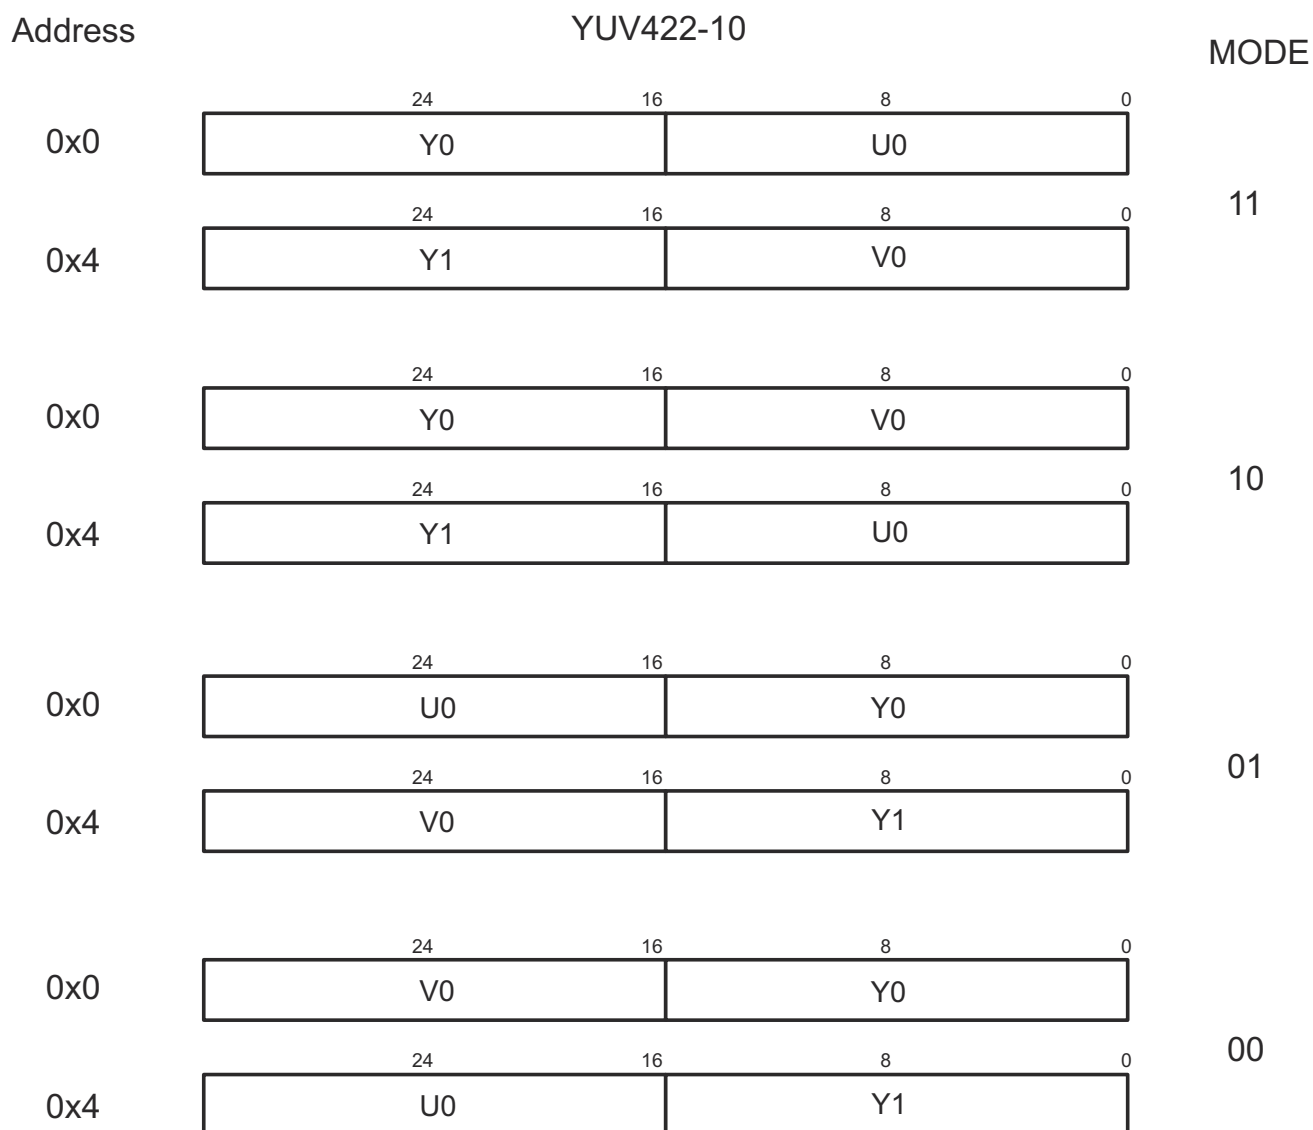

#### 12.7.1.3.5 CSI\_RX\_IF Data Memory Organization Details

Figure 12-452 shows the YUV422-8 data organization in memory.

**Figure 12-452. CSI\_RX\_IF YUV422-8 Memory Data Organization**

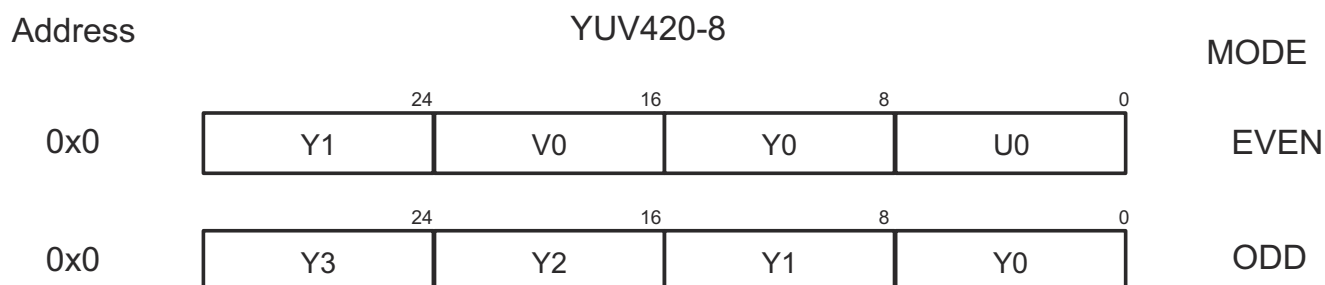

Figure 12-453 shows the YUV422-10 data organization in memory.

#### 12.7.1.3.6 CSI\_RX\_IF PSI\_L (DMA) Interface

##### Note

This section describes CSI\_RX\_IF PSI\_L specific functionality related to the camera interface. The general PSI\_L functional description and registers are described in the PSI\_L specific chapter (see *PSIL Subsystem (PSILSS)*).

##### 12.7.1.3.6.1 PSI\_L DMA framing

The CSI\_RX\_IF stream interface provides the usual VSYNC/HSYNC signals. The signals are per virtual channel where the transition from 1-to-0 or 0-to-1 represents SOF/EOF or SOL/EOL. VSYNC/HSYNC transition is usually not coincident with a valid data phase, though there are use cases where it can be. Because of the nature of CSI protocol, the VSYNC and HSYNC transactions require at least a single clock cycle and can only transition sequentially (important fact in handling of VSYNC events).

There is a rarely used mode of CSI where an entire frame is passed in a single packets without line breaks. In this mode, there are no HSYNC transitions at line starts/ends.

Lastly, there is redundant information provided with each CSI packet where the packet length is supplied in bytes.

To overcome these framing restrictions, the CSI\_RX\_IF PSILSS0 passes metadata through the DMA FIFO. Anytime metadata is inserted into the FIFO, the CSI\_RX\_IF stream is stalled for a clock cycle. The forms of supported meta tags are:

- SOF for a given virtChan
- EOF for a given virtChan
- Packet length in bytes for a given dmaCntx

The PSILSS0 will disregard the HSYNC signal entirely. The long packet beginning is used as SOL and the EOL will be "counted" using the packet length provided. In the special case where packets are of FRAME length, the SOL/EOL handling is identical.

The PSILSS0 solution for VSYNC handling is to create the concept of metadata FIFO entry which is indicated by a metadata bit. The SOF or EOF VSYNC information plus the virtualChan index is fed into the FIFO. On the output of the FIFO, the SOF is saved for each context of that virtualChan type. The very next data phase of that channel context will be marked as SOF. Additionally a state bit per context is maintained indicating the channel is MOP (middle of packet). Once the EOF arrives at the FIFO output, all contexts of that type virtual channel (and currently in MOP state) will receive a PSI\_EOP with zero active bytes of data.

**CAUTION**

The line and frame size is not known outside the CSI core (i.e. not passed to the DMA interface). Therefore any mismatches at system level programming will be unknown. If the DMA line/frame size does not match the CSI\_RX\_IF line/frame size, it is assumed the DMA will not result in any adverse side effects as a result of not enough data or too much data.

**12.7.1.3.6.2 PSI\_L DMA error handling due to FIFO overflow**

The DMA error handling is also called a PSI\_L protocol enforcer. It is intended to prevent hang of the PSILSS0. Unnatural packet size should not cause hang so only SOP/SOL/EOL/EOP framing is enforced. The following list highlights the error handling mechanism:

- For context cleanup the protocol enforcer:
  - cycle through each context index checking if context is in MOL or MOP
  - close out MOP with EOP and MOL&MOP with EOL&EOP
- dropOnFloor SOP if currently in MOPstate
- dropOnFloor EOP if not currently in MOPstate
- dropOnFloor FIFO data
- EOL context if EOP and MOLstate
- After closing out all open contexts the PSILSS0 logic will then wait till end of frame per virtual channel. Once a new frame starts it will then start sending out data from that new frame

**12.7.1.3.7 CSI\_RX\_IF ECC Protection Support**

ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC protection on the CSI\_RX\_IF RAM provides Single Error Correction and Double Error Detection (SEC/DED). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC protection also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

The ECC aggregator in the CSI\_RX\_IF subsystem level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. It provides a single EOI-handshake based interrupt to the interrupt processors (for both single and double error detections) and a standard 32-bit VBUSP interface for configuring and querying the ECC register set, see *CSI\_\_RX\_IF\_ECC Registers*. For complete details on the features and functions of the ECC aggregator, see chapter *ECC Aggregator*.

**12.7.1.3.8 CSI\_RX\_IF Programming Guide****12.7.1.3.8.1 Overview**

This section details specific steps on how to program the CSI\_RX\_IF controller.

**12.7.1.3.8.2 Controller Configuration**

The CSI\_RX\_IF streams will default to accept all virtual channels and all data types after reset, so the user must program the stream configuration and pixel interface to match the system use case.

**Note**

The CSI\_RX\_IF controller can be configured so that the reset values can adopt the users Power\_On state. This can reduce the programming steps required by the system.

The CSI\_RX\_IF controller is designed to operate all the defined streams with all virtual channels and all data types passed to the pixel interface. Also, the connection to the front interface adopts reset values that will allow the connection of the lanes to expect no remapping.

The basic system configuration steps are then programming the number of enabled data lanes and starting the streams.

The system can also decrease the virtual channel and data type processed by the stream by configuring the data config (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_DATA\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_DATA\_CFG) registers.

The user must perform a read from the stream config register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CFG) at power up to identify the number of streams and pixel interface mode. The stream FIFO depth must be determined from the system configuration information defined at build time to ensure that any programmed [31-16] FIFO\_FILL level is valid for the available FIFO depth.

#### 12.7.1.3.8.3 Power on Configuration

The CSI\_RX\_IF requires the system to perform the configuration of the DPHY\_RX interface before starting the streams of the controller. The default configuration of the controller and each stream can be identified by reading the device ID CSI\_RX\_IF\_VBUS2APB\_DEVICE\_CONFIG register.

The FW must read the CSI\_RX\_IF\_VBUS2APB\_DEVICE\_CONFIG register at power up. This will provide the FW the number of streams that will need to be configured, and all the default system information for the FIFO structures in the available streams.

**Table 12-393. CSI\_RX\_IF\_VBUS2APB\_DEVICE\_CONFIG bitfield details**

STREAMx_NUM_PIXELS	The width of the pixel interface and the bits per pixel for the selected datatype will determine how many pixels can be output in a single cycle. Default will be 1 pixel per clock. 00 -> 1 pixel per clock 01 -> 2 pixels per clock 10 -> 4 pixels per clock
DATAPATH_SIZE	Internal Datapath width 00 - 32 bit, all other values are reserved.
NUM_STREAMS	Number of Stream interfaces (1-4) = (value+1)
MAX_LANE_NB	Max Number of Lanes (1-4) = (value+1)

Figure 12-459 shows the minimal sequence of registers that will configure the DPHY\_RX and then start the stream; this will output all the pixel information for all virtual channels and all data types detected in the link data stream.

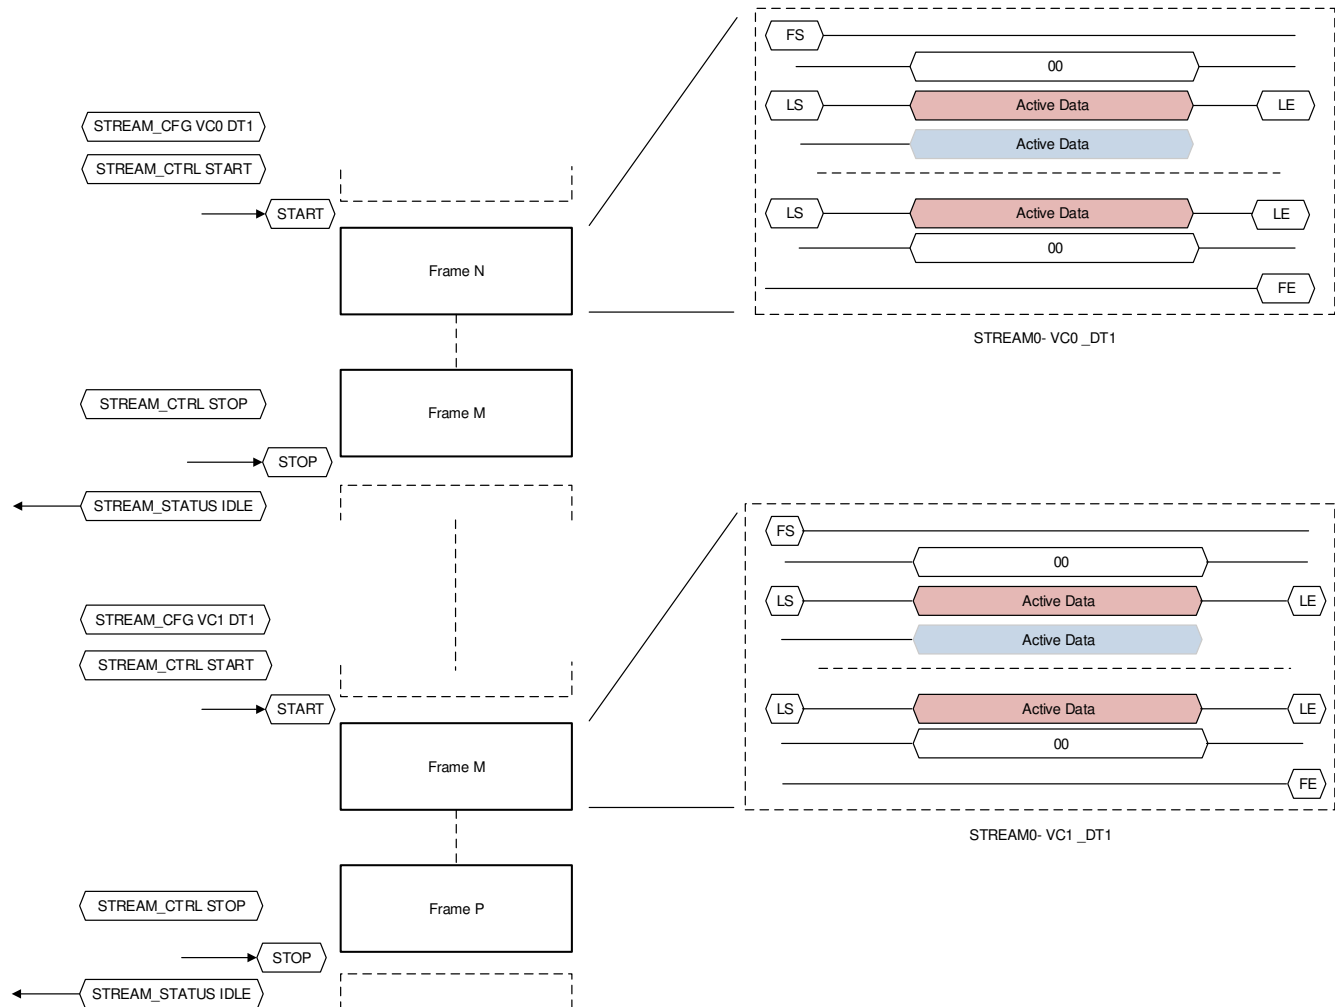

**Figure 12-459. Minimal Stream Control - Start and Stop**

#### 12.7.1.3.8.4 Stream Start and Stop

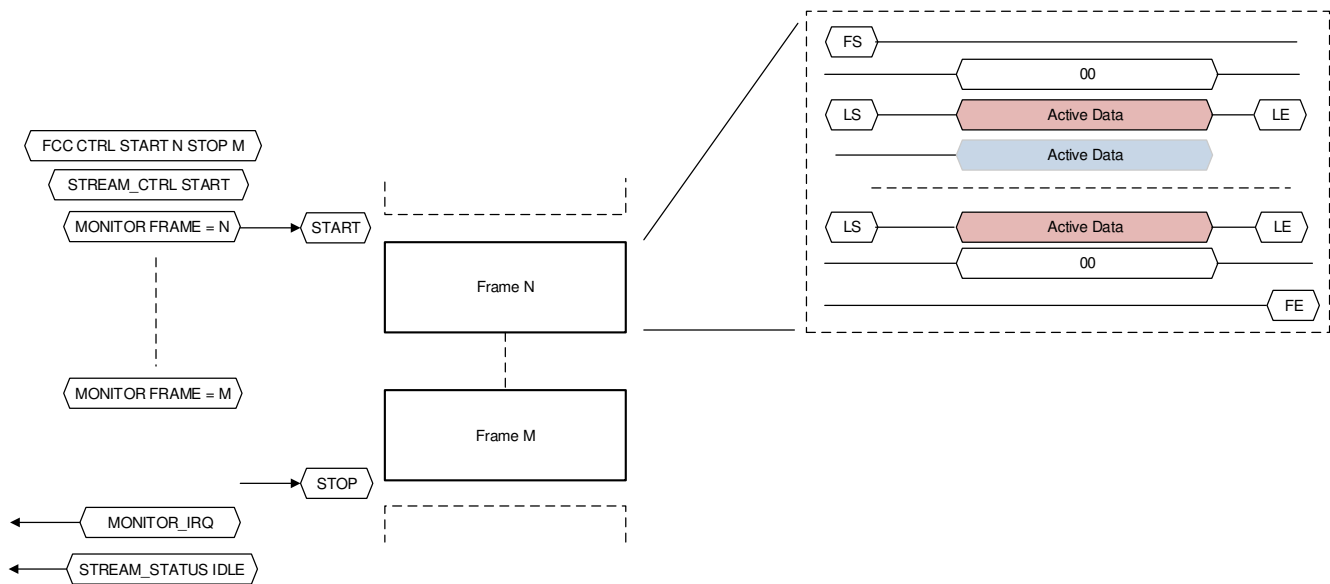

The CSI\_RX\_IF will perform management of the stop and halt control to the pixel stream during functional operation to allow any stream to change the virtual channel or data type information that the stream will process.

- The FW will use the stream control register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CTRL) to perform a stop (set bit 1) and wait for the end of any current frame, and wait for the stream to return its state to IDLE, which can be read from stream status register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_STATUS - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_STATUS)[31] RUNNING = 1.
- The FW will use the stream control register to perform an abort and wait for the end of any current line, and wait for the stream to return its state to IDLE, which can be read from register STREAM\_STATUS[31] RUNNING = 1.

**Figure 12-460. Stream Reconfiguration Using Start Stop Start Flow**

The CSI\_RX\_IF will use the monitor control or STOP mechanism to stop the stream processing at the end of the active frame. The stream monitor, configuration and interrupt registers can be redefined and then the stream restarted. The pixel interface will begin processing at the next frame start.

**Figure 12-461. Stream Start and Stop Using Monitor Control**

#### 12.7.1.3.8.5 Error Control With Soft Resets

The CSI\_RX\_IF will perform control of the soft reset either for error event recovery or to clear a stream FIFO or internal state machine.

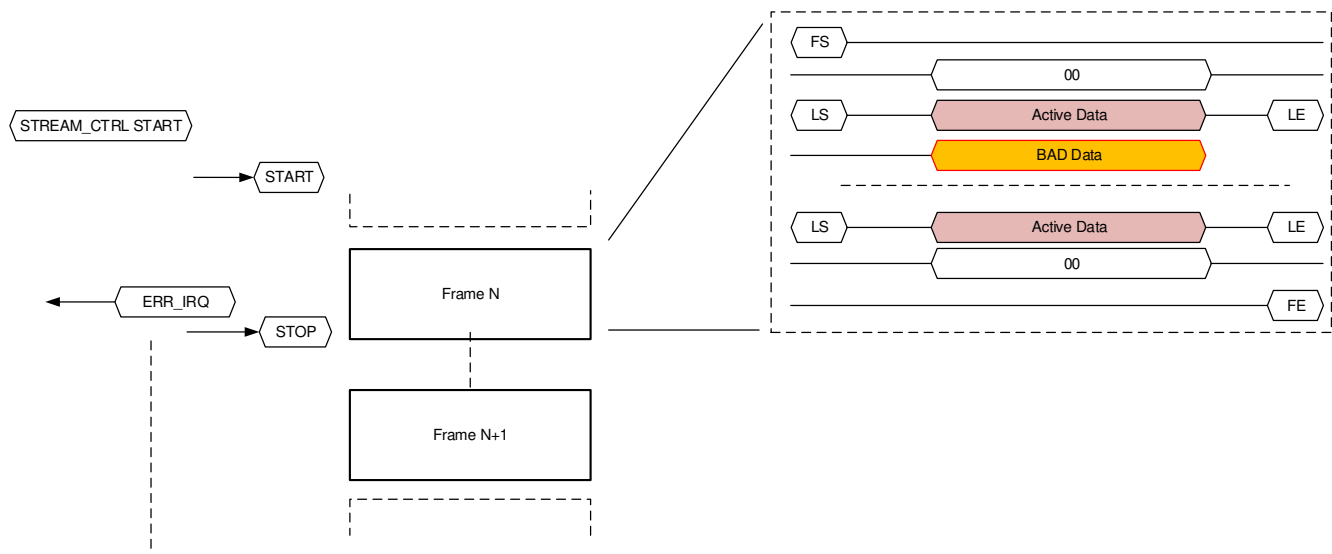

- The FRONT block can be soft reset if the DPHY\_RX becomes unresponsive and the controller wishes to maintain its configuration. In this case the DPHY\_RX resets can be applied and the DPHY\_RX enabled to begin the transfer again.
- The Protocol block can be soft reset if the FRONT soft reset is required, and the protocol is not in the IDLE state.
- The stream soft resets (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CTRL)[4] SOFT\_RST can be used to clear the stream to the stop state and reset all the stream state machines and FIFO. If the system has a failure and wishes to clear the stream FIFO and return to a safe state on the pixel interface, the stream soft reset should be asserted.

#### 12.7.1.3.8.6 Stream Error Detected – No Error Bypass Mode

The CSI\_RX\_IF will default to stop processing the frame whenever a header Reserved DT or ECC error is detected, or when a long packet payload CRC is identified.

The CSI\_RX\_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI\_RX\_IF\_VBUS2APB\_ERROR\_IRQS.

The CSI\_RX\_IF will stop processing the current frame and stop the stream.

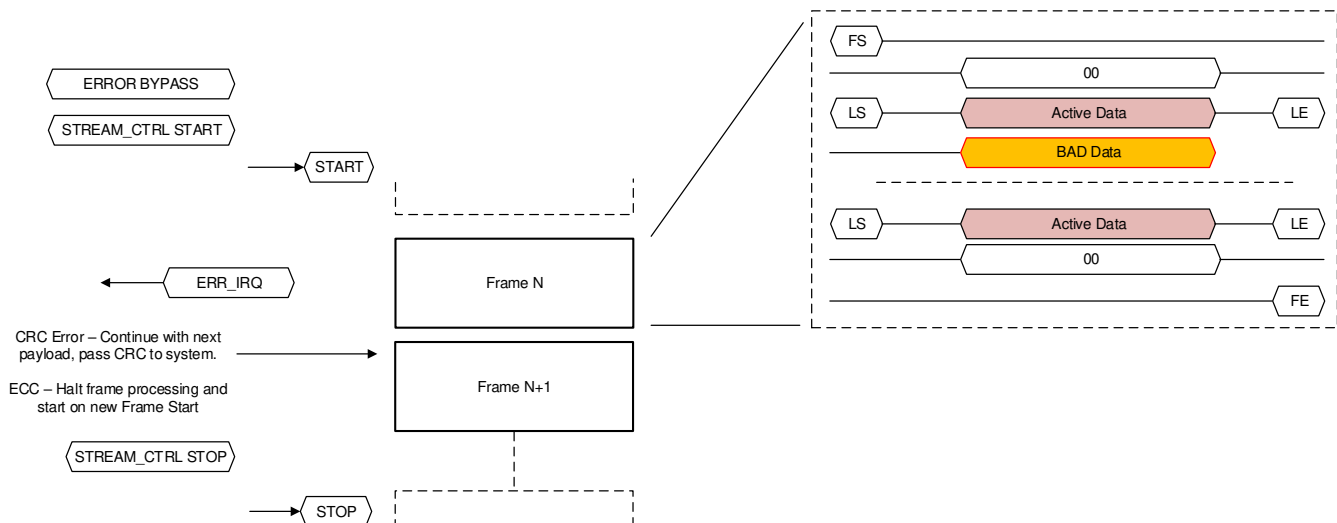

**Figure 12-462. Stream Error Detection Causing Stop**

#### 12.7.1.3.8.7 Stream Error Detected – Error Bypass Mode

The CSI\_RX\_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI\_RX\_IF\_VBUS2APB\_ERROR\_IRQS.

The CSI\_RX\_IF will continue processing the current frame and continue the stream when a header Reserved DT or a long packet payload CRC error is detected.

The CSI\_RX\_IF will stop processing the current frame and continue the stream when a packet header ECC error is detected, as the current frame synchronisation cannot be maintained.

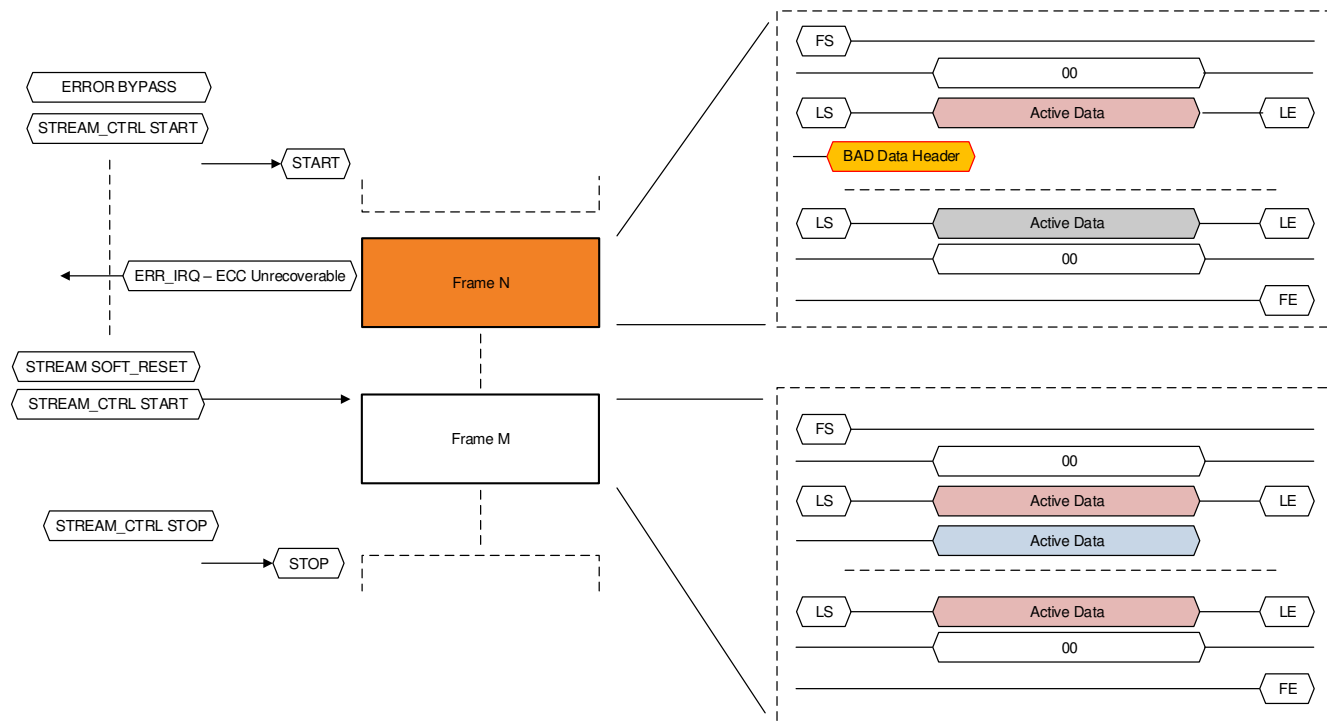

**Figure 12-463. Stream Error Bypass - CRC Error During Payload**

#### 12.7.1.3.8.8 Stream Error Detected – Soft Reset Recovery

The CSI\_RX\_IF will stop processing the current frame and continue the stream when a packet header ECC error is detected, as the current frame synchronisation cannot be maintained.

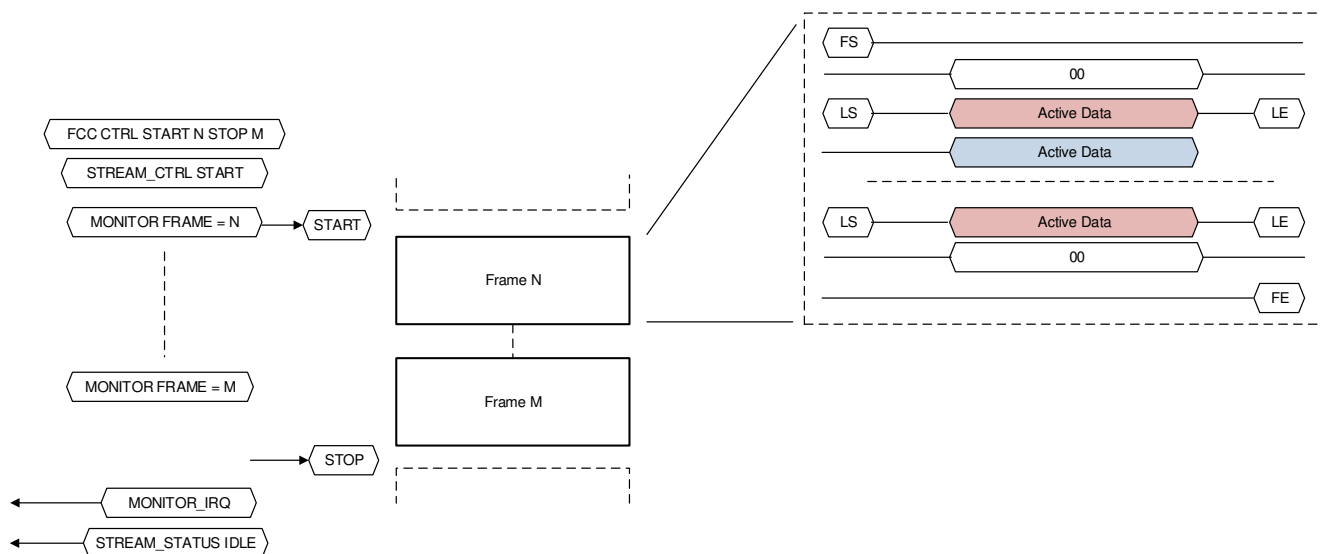

The system can perform a soft reset on the individual stream to clear the pixel interface and payload FIFO and allow the system to restart the stream from the next frame start.

**Figure 12-464. Stream Soft Reset After ECC Non-Recoverable Error**

#### 12.7.1.3.8.9 Stream Monitor Configuration

The CSI\_RX\_IF will use the monitor control (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_MONITOR\_CTRL) or STOP mechanism to stop the stream processing at the end of the active frame. The stream monitor, configuration and interrupt registers can be redefined and then the stream restarted. The pixel interface will begin processing at the next frame start.

**Figure 12-465. Stream Start and Stop Using Monitor Control**

The FW will use the FCC config control register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CFG) to perform a start and stop as soon as a frame count is detected. The FCC config control register will define the start and stop frame count and the stream will identify when these values are matched. The stream output will begin when start frame is detected and then stop once the stop frame is reached. The virtual channel can be defined

in CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL[4-1] FCC\_VC, and must match the virtual channels that are available to the stream in the CSI\_RX\_IF\_VBUS2APB\_STREAM0\_DATA\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_DATA\_CFG register.

The frame capture is enabled when CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL[0] FCC\_EN is set '1'

The FW can check the current frame counter value from the CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL[31:16] FRAME\_COUNTER

#### 12.7.1.3.8.10 Stream Monitor Frame Capture Control

To use Monitor Frame Capture Control Start and Stop operations:

1. Set Stop and Start values in config register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CFG). Set to '0' for free-running.
  - a. [31:16] FRAME\_COUNT\_STOP -> define desired value
  - b. [15:0] FRAME\_COUNT\_START -> define desired value
2. Set the Virtual Channel to the one that is enabled and the enable in register CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL.
  - a. [4:1] FCC\_VC -> define VC used
  - b. [0] FCC\_EN -> set to '1'

This will allow visual checking, by setting the Start/Stop as the following examples, this is the behaviour to be observed:

- Stop = 1 / Start = 1: Output (i.e. display) will show a Frame of the Input (i.e. camera)
- Stop = F / Start = 1: Output will show live image from the input during 14 frames and then will freeze in the last one.

Optionally software can read back the frame count value from register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL).

In order to do that, software will first need to enable the monitor control register.

1. Define the same Virtual Channel as above and enable the monitor control register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_MONITOR\_CTRL).
  - a. [15] FRAME\_MON\_EN -> set to '1'
  - b. [14:11] FRAME\_MON\_VC -> define VC used
2. Read frame\_counter containing the current frame number being processed from CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL (only when frame numbers are coming from the protocol, not when internal counter)
  - a. [31:16] FRAME\_COUNTER -> read frame number value

The easiest way to check that the frame number matches the Start and/or Stop values defined, is to use the interrupts in CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS register. To be able to do that you will need to allow those interrupts through the mask register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG.

1. By default, the CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0's, meaning all interrupts are disabled.
  - a. [4] STREAM0\_FCC\_STOP\_IRQM -> set to '1'
  - b. [3] STREAM0\_FCC\_START\_IRQM -> set to '1'
2. Create an interrupt handler to read from CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS.
  - a. [4] STREAM0\_FCC\_STOP\_IRQ -> read, if '1', Stop interrupt triggered
  - b. [3] STREAM0\_FCC\_START\_IRQ -> read, if '1', Start interrupt triggered

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled if software is using Frame Counter Control features.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

**Figure 12-466. Stream Frame Capture Control Flow Diagram**

#### 12.7.1.3.8.11 Stream Monitor Timer interrupt

To use the Stream Monitor Timer operations:

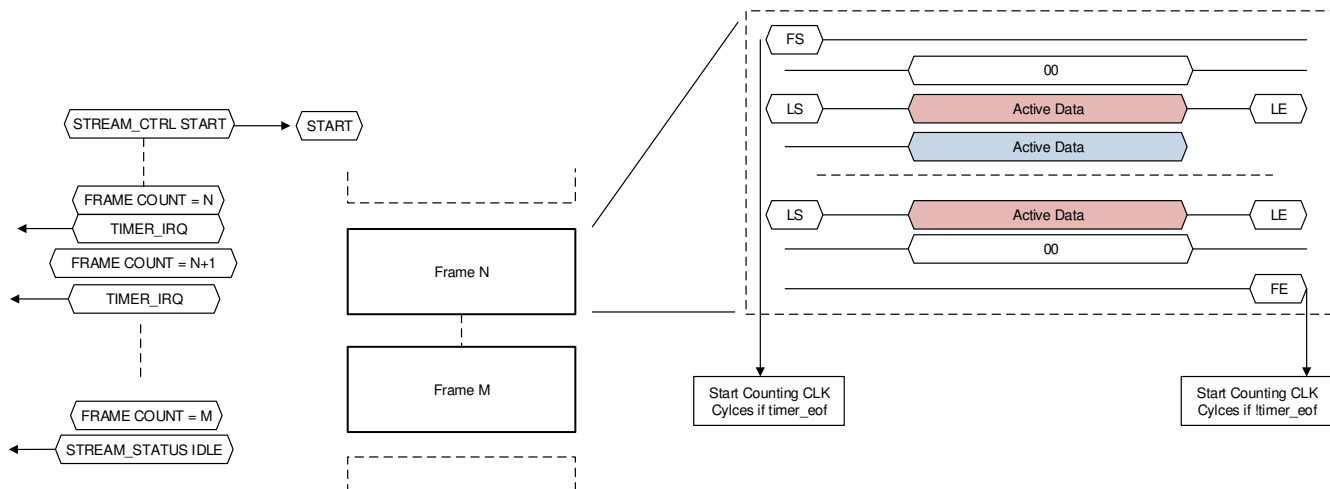

- Set Count value in timer register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_TIMER - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_TIMER). If set to 0 won't count but interrupt will still trigger every EOF or SOF.
  - [24:0] COUNT -> define desired value
- Set the Virtual Channel to the one that is enabled, define timer\_eof and set enable in the monitor controll register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_MONITOR\_CTRL).
  - [15] FRAME\_MON\_EN -> set to '1'
  - [14:11] FRAME\_MON\_VC -> define VC used
  - [10] TIMER\_EOF -> set to '1' to count from EOF, set to '0' to count from SOF
  - [9] TIMER\_EN -> set to '1'
  - [8:5] TIMER\_VC -> define VC used

Software should now use the interrupts in register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS. To be able to do that you will need to allow those interrupts through the mask register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG.

- By default, the CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0', meaning all interrupts are disabled.
  - [0] STREAM0\_TIMER\_IRQM -> set to '1'
- Create an interrupt handler to read from monitor\_irqs.
  - [0] STREAM0\_TIMER\_IRQ -> read, if '1', timer interrupt is triggered

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

**Figure 12-467. Timer Interrupt Flow Diagram**

#### 12.7.1.3.8.12 Stream Monitor Line/Byte Counters Interrupt

To use the stream Monitor Line and Byte counters operations:

1. Set LineCount and ByteCount values in register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_LB - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_MONITOR\_LB).
  - a. [31:16] LINE\_COUNT -> define desired value
  - b. [15:0] BYTE\_COUNT -> define desired value
2. Set the Virtual Channel to the one that is enabled, and set enable in register SI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_CTRL.
  - a. [15] FRAME\_MON\_EN -> set to '1'
  - b. [14:11] FRAME\_MON\_VC -> define VC used
  - c. [4] LB\_EN -> set to '1'
  - d. [3:0] LB\_VC -> set to VC used

Software should now use the interrupts in register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS. To be able to do that you will need to allow those interrupts through the mask register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG.

1. By default, the CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0', meaning all interrupts are disabled.
  - a. [7] STREAM0\_LINE\_CNT\_E RROR\_IRQM -> set to '1'
  - b. STREAM0\_LB\_IRQM [1] -> set to '1'
2. Create an interrupt handler to read from CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS.
  - a. [7] STREAM0\_LINE\_CNT\_E RROR\_IRQ -> read, if '1', line count error interrupt is triggered
  - b. [1] STREAM0\_LB\_IRQ -> read, if '1', line/byte counter interrupt is triggered

Note that the interrupt will trigger on each frame when it reaches byte number BYTE\_COUNT in line number LINE\_COUNT.

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

Figure 12-468. Line/Byte Counters Interrupt Flow Diagram

### 12.7.1.3.8.13 Example Controller Programming Sequence (Single Stream Operation)

The single stream operation will provide the smallest multi-lane IP configuration with the reduced registers configuration removing some control and status registers. The stream will not require a large FIFO configuration and the clock rates will be matched to simplify the implementation to single pixel transfers using all the available interface bits, (i.e. up to 32).

Figure 12-469. Basic Single Stream Use Case Illustration

For single pixel stream configuration, elastic buffer, RAW8 Data type on VC2, one pixel per cycle:

1. Configure the number of DPHY\_RX lanes:
  - a. See CSI\_RX\_IF\_VBUS2APB\_STATIC\_CFG register
2. Set Error Interrupt mask:
  - a. See CSI\_RX\_IF\_VBUS2APB\_ERROR\_IRQS\_MASK\_CFG register
3. Set the Pixel Interface and FIFO configuration. See CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CFG.
  - a. Set [9-8] FIFO\_MODE to select the elastic buffer configuration -> '1'

- b. Set the FIFO fill level that will determines the FIFO depth that must be reached before data is output -> 0x0000
  - c. Select the number of pixels to be output on each cycle -> '0'.
  - d. Set the type of stream interface to "pixel" mode -> '0'
4. Select the virtual channel and data types to be processed. See CSI\_RX\_IF\_VBUS2APB\_STREAM0\_DATA\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_DATA\_CFG register.
  - a. Set [31-16] VC\_SELECT and virtual channel bits if not supporting all virtual channels -> 1h, 2h
  - b. Set [7] ENABLE\_DT0 and [5-0] DATATYPE\_SELECT0 values for one or both data types (default all DT) -> 0h, 1h, 2Ah
5. Enable the stream to begin processing the incoming data from the DPHY\_RX. See CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CTRL.
  - a. Set [0] START bit -> '1'

The stream will begin to pass pixel data matching the configuration on the next frame start.

#### 12.7.1.3.8.14 CSI\_RX\_IF Programming Restrictions

The following CSI\_RX\_IF programming restrictions apply:

- Full line buffer mode is not supported.
- LS/LE detection has a restriction to be disabled
- Only use Pixel transmit mode can be used, never packet mode
  - In pixel mode only single, dual, or quad mode can be used. It is not allowed to mix these based on data format or virtual channels.
- LSB alignment only
- In CSI\_RX\_IF to CSI\_TX\_IF loop back, the stream needs to have the same mode on both controllers(single, dual, quad). Can not mix dual on CSI\_RX\_IF and single on CSI\_TX\_IF.
- Video port(VP) stream interfaces must be programmed in the CSI\_RX\_IF to meet the following restrictions:
  - Raw 8-16 formats only
  - Dual pixel mode
  - Filtering for single virtual channel and single data type

#### Note

CSI\_RX\_IF has a limitation that any line must fully be exported on its stream interface before a new line or even end of frame is sent on the D-PHY interface. To meet this requirement, software will need to take into account export rates on stream interface(single, dual, quad modes) at 500MHz versus D-PHY 32-bits @ byte clock frequency to know when a new line or end of frame can be sent in after last line was sent over D-PHY interface.

Table 12-394 shows the CSI\_RX\_IF programming requirements for pixel modes and data sizes.

**Table 12-394. CSI\_RX\_IF Programming requirements for pixel modes and data sizes**

Format	Pixel transmit mode used	Size	Details
RAW(6-8), user defined 8-bit	Single	0	
RAW(6-8), user defined 8-bit	Dual	1	
RAW(6-8), user defined 8-bit	Quad	2	
RAW(10-16), user defined 16-bit	Single	1	
RAW(10-16), user defined 16-bit	Dual	2	
RAW20	Single	2	
YUV422-8	Single	0	must set dual mode=0
YUV422-8	Dual	0	must set dual mode=1
YUV422-10	Single	1	
YUV420-8	Single	0	must set dual mode=0

**Table 12-394. CSI\_RX\_IF Programming requirements for pixel modes and data sizes (continued)**

Format	Pixel transmit mode used	Size	Details
YUV420-8	Dual	0	must set dual mode=1
YUV420-10	Single	1	

#### 12.7.1.3.8.15 CSI\_RX\_IF Real-time operating requirements

Care must be taken on blanking requirements for next line, end of frame, or start of frame. The previous packets(long or short) must be fully consumed before any new line, end of frame, or start frame can be sent over the CSI interface. Software will get various error conditions if these are not met. Below are some sample equations to determine this blanking time. Note that this is not blanking data. High level details are that the internal FIFO must be completely empty prior to sending any thing new into it. below are some sample equations to determine how much time is needed to empty the FIFO and blanking time needed. Byte clock rates, pixel data type, and export modes play into the calculation as well.

$$\text{Byte\_clock\_rate} \times 8 \times \#\text{lanes} \times \text{Tcsi} = \text{pixel\_clock\_rate} \times \text{BPP} \times \text{Tpix} = \text{total bits} \quad (27)$$

BPP = Bits Per Pixel. This number is how many bits are sent per pixel clock cycle is based on single, dual, quad modes and data type.

Tcsi = Time for csi interface to complete 1 line

Tpix = Time for pixel interface to complete 1 line

Tpix16 = Tpix+16/pixel\_clock\_rate

(Tpix16-Tcsi) = required blanking time on CSI interface

Tpix16-Tcsi <= 0 implies 0

## 12.7.2 MIPI D-PHY Receiver (DPHY\_RX)

The following sections describe the MIPI D-PHY receiver (DPHY\_RX) modules in the device.

### 12.7.2.1 DPHY\_RX Overview

The integration of the DPHY\_RX camera physical port module allows the device to grab video streams from external sensor cameras and other CSI2 compliant sources.

#### 12.7.2.1.1 DPHY\_RX Features

The DPHY\_RX module supports the following features:

- Compliant to MIPI D-PHY standard v1.2
- Supports up to 4 data and 1 clock lanes
- Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
- Clock lane control / interface logic type is CIL-SCNN for HS and low power receiving:
  1. **S**lave
  2. **C**lock
  3. **N/A** forward, **N/A** reverse escape mode features
- Data lane control / interface logic type is CIL-SFAN for HS and low power receiving:
  1. **S**lave
  2. **F**orward direction only for high speed mode
  3. **A**ll forward direction escape mode features are supported
  4. **N**o reverse direction escape mode features are supported
- Data lanes can be independently operated in HS or ULP mode
- Swapping of DP/DN signals within each clock/data pair (Facilitated by CSI\_RX\_IF controller)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.7.2.1.2 DPHY\_RX Not Supported Features

The DPHY\_RX does not support the following features:

- Swapping of clock & data lanes to ease PCB routing

### 12.7.2.1.3 DPHY\_RX Ports

This section describes the DPHY\_RX ports related to clocks, resets, and hardware requests.

**Table 12-395. DPHY\_RX Clocks and Resets**

Clocks	
Module Clock Input	Description
DPHY_RX_MAIN_CLK	Main functional clock.
CSI_RX_BYTE_CLK	The byte clock is the clock supplied by the DPHY_RX.
Resets	
Module Reset Input	Description
DPHY_RX_RST	Asynchronous module global reset.

### 12.7.2.2 DPHY\_RX Environment

This section describes the DPHY\_RX application fields from an environment point of view (external connections).

Table 12-396 describes the external signals of the DPHY\_RX.

**Table 12-396. DPHY\_RX I/O Signals**

Device Level Signal	I/O	Description
CSI0_RXN0	I	Lane 0 Receive Differential Data (Negative)
CSI0_RXP0	I	Lane 0 Receive Differential Data (Positive)
CSI0_RXN1	I	Lane 1 Receive Differential Data (Negative)
CSI0_RXP1	I	Lane 1 Receive Differential Data (Positive)
CSI0_RXN2	I	Lane 2 Receive Differential Data (Negative)
CSI0_RXP2	I	Lane 2 Receive Differential Data (Positive)
CSI0_RXN3	I	Lane 3 Receive Differential Data (Negative)
CSI0_RXP3	I	Lane 3 Receive Differential Data (Positive)
CSI0_RXCLKN	I	Lane 3 Receive Differential Clock (Negative)
CSI0_RXCLKP	I	Lane 3 Receive Differential Clock (Positive)
CSI0_RXRCALIB	A	Pin for external calibration resistor. An external resistor must be connected between this pin and package ground. Refer to the device-specific Datasheet for a recommended resistor value.
CSI1_RXN0	I	Lane 0 Receive Differential Data (Negative)
CSI1_RXP0	I	Lane 0 Receive Differential Data (Positive)
CSI1_RXN1	I	Lane 1 Receive Differential Data (Negative)
CSI1_RXP1	I	Lane 1 Receive Differential Data (Positive)
CSI1_RXN2	I	Lane 2 Receive Differential Data (Negative)
CSI1_RXP2	I	Lane 2 Receive Differential Data (Positive)
CSI1_RXN3	I	Lane 3 Receive Differential Data (Negative)
CSI1_RXP3	I	Lane 3 Receive Differential Data (Positive)
CSI1_RXCLKN	I	Lane 3 Receive Differential Clock (Negative)
CSI1_RXCLKP	I	Lane 3 Receive Differential Clock (Positive)
CSI1_RXRCALIB	A	Pin for external calibration resistor. An external resistor must be connected between this pin and package ground. Refer to the device-specific Datasheet for a recommended resistor value.

### 12.7.2.3 DPHY\_RX Functional Description

#### 12.7.2.3.1 DPHY\_RX Programming Guide

##### 12.7.2.3.1.1 Overview

This section details specific steps on how to program the DPHY\_RX

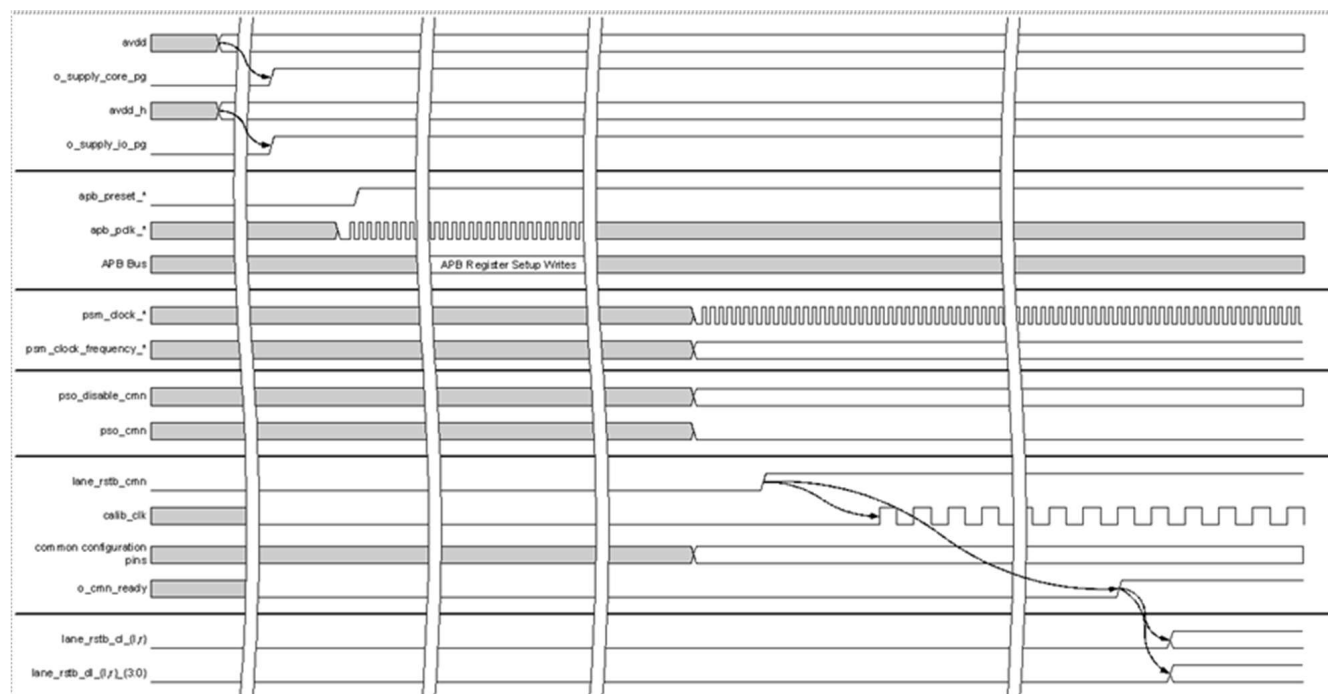

##### 12.7.2.3.1.2 Initial Configuration Programming

The DPHY\_RX operation shows the registers that are written during the startup sequence.

This section provides description and timing diagrams for DPHY\_RX operation. Unless otherwise described in this subsection, the DPHY\_RX PPI interface is compliant with the timing diagrams described in the MIPI D-PHY v1.2 specification.

##### 12.7.2.3.1.2.1 Start-up Sequence Timing Diagram

The common configuration pins noted in [Figure 12-470](#) are ipconfig\_cmnn, pll\_ipdiv, pll\_fbdiv, pll\_opdiv, psm\_clock\_freq\_cmnn. Drive these pins as per the pin description given in PHY pin list.

**Figure 12-470. Common Power Up and Initialization Timing Diagram**

**Figure 12-471. Lane Power Up and Initialization Timing Diagram**

**Figure 12-472. PHY Disable Timing Diagram**

For initial set up, the DPHY\_RX must be configured/set (registers and configuration input pins) for the common module prior to releasing it from reset, and the lane modules prior to releasing them from reset. Registers shall be configured (as required) between releasing the APB from reset and releasing the common / lanes from reset.

Note that in some cases, the option exists to configure a function using either a pin or a register. In such cases, both options will be specified and the you can select the preferred option.

### 12.7.2.3.1.3 Common Configuration

**Table 12-397. Common Configuration-Related Setup**

Configuration Register / Pin	Configuration Requirement
PHY Pin: psm_clock_freq PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 1	Set the PMA state machine clock frequency divider. Set either the pin or the register, as specified in the respective description, for the required PMA state machine clock.
PHY Pin: ipconfig_cmh PHY Register: DPHY_RX_MMR_SLV_LANE[11-9] IPCONFIG_CMN	Set the clock lane configuration. Set as specified in the description for the required clock lane configuration.
PMA Register: DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT2[0] O_CMN_SSM_EN, DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT2[10] O_CMN_RX_MODE_EN	Enable the startup state machines for TX mode of operation. Set both register bits to 1'b1.
PMA Register: DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT35	Set the RX oscillator calibration feedback clock counter start values. Set the register fields, as specified in the description for the required PMA state machine clock and oscillator clock.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 2	Set the required power island phase 2 time. Set the register to 32'hAAAAAAAA.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[7:4] POWER_SW_2_TIME_CL_R, DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[3:0] POWER_SW_2_TIME_CL_L	Set the required power island phase 2 time. Set the register to 8'hAA

### 12.7.2.3.1.4 Lane Configuration

**Table 12-398. Lane Configuration-Related Setup**

Configuration Register / Pin	Configuration Requirement
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 0	Set the lane band control value. Set the register fields, as specified in the register description for the required data rate.
PMA Register (clock lanes): DPHY_RX_VBUS2APB_CLK0_RX_DIG_TBIT2[18:15] RXDA_FREQ_BAND_SEL1 PMA Register (clock lanes): DPHY_RX_VBUS2APB_CLK0_RX_DIG_TBIT2[13:10] RXDA_FREQ_BAND_SEL2	Set the analog frequency band selects, as specified in the register description for the required data rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 0 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 0[21] TM_1P5TO2P5G_MODE_EN	Set the analog data rate select, as specified in the register description for the required data rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 0 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 0[16] TM_SETTLE_COUNT_SEL and [15-9] TM_SETTLE_COUNT	Set the HS-settle counter, as specified in the register description for the required data rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 3 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 3	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 5 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 5	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.

**Table 12-398. Lane Configuration-Related Setup (continued)**

Configuration Register / Pin	Configuration Requirement
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 7 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 7	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 9 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 9	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 12 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 12	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.

### 12.7.2.3.1.5 Procedure: Clock Lane Low Power Analog Receiver Functions Test

#### 12.7.2.3.1.5.1 Description of Procedure

This procedure describes how the low power analog receiver functions (LPRX, and ULPRX) can be tested. The process used in this test is to enable test MUXes for the low power receiver functions, then write registers in common to drive LP signaling states to the lanes, and read registers in the lanes to detect the current state of the analog functions in the lane.

#### 12.7.2.3.1.5.2 Details of the Procedure

- Follow the procedure described in section [Section 12.7.2.3.1.2](#), but do not release the common or lanes from reset.
- Write the following registers.
  - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT21[0] O\_RX\_DIG\_BIST\_EN = 1'b1, to enable the analog BIST power island in common.
  - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT28[23:20] = 4'b1111, to enable the clock lane diagnostic low power override functions, and drive LP11 from common to the clock lanes.
  - PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT2[24] = 1'b1, to enable the diagnostic low power override MUXes in the analog.
  - PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT2[1:0] = 2'b11, to force the analog ULPS receiver to be enabled.
- Release the common from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[5] O\_CMN\_READY to be driven to 1'b1.
- Release the clock and data lanes from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[8] LANE\_READY\_CMN to be driven to 1'b1.
- Poll PMA Register (CMN): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT56[20-11] I\_CMN\_RX\_SSM\_STATE until it is set to 9'b100000000.
- Repeat the following for each of the following values, to drive LP values from common and test the analog functions in the clock lanes: 2'b01, 2'b00, 2'b10, 2'b11.
  - Write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT28[22,20] = value.
  - Read and confirm the PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_CLK0\_RX\_DIG\_TBIT4[13:12] = value.
  - Read and confirm the PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_CLK0\_RX\_DIG\_TBIT4[9:8] = value.

### 12.7.2.3.1.6 Procedure: Data Lane Low Power Analog Receiver Functions Test

#### 12.7.2.3.1.6.1 Description of Procedure

This procedure describes how the low power analog receiver functions (LPRX, and ULPRX) can be tested. The process used in this test is to enable test MUXes for the low power receiver functions, then write registers in

common to drive LP signaling states to the lanes, and read registers in the lanes to detect the current state of the analog functions in the lane.

#### 12.7.2.3.1.6.2 Details of the Procedure

1. Follow the procedure described in section [Section 12.7.2.3.1.2](#), but do not release the common or lanes from reset.
2. Write the following registers.
  - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT21[0] O\_RX\_DIG\_BIST\_EN = 1'b1, to enable the analog BIST power island in common.
  - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT28[19:16] = 4'b1111, to enable the data lane diagnostic low power override functions, and drive LP11 from common to the data lanes.
  - PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT30[1] TM\_LPRX\_BIST\_EN = 1'b1, to enable the diagnostic low power override MUXes in the analog.
  - PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT1[9:8] = 2'b11, to force the analog ULPS receiver to be enabled.
3. Release the common from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[5] O\_CMN\_READY to be driven to 1'b1.
4. Release the clock and data lanes from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[8] LANE\_READY\_CMN to be driven to 1'b1.
5. Poll PMA Register (CMN): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT56[20-11] I\_CMN\_RX\_SSM\_STATE until it is set to 9'b100000000.
6. Repeat the following for each of the following values, to drive LP values from common and test the analog functions in the data lanes: 2'b01, 2'b00, 2'b10, 2'b11.
  - a. Write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT28[18,16] = value.
  - b. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT34[13:12] = value.
  - c. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT34[9:8] = value.

#### 12.7.2.3.1.7 Procedure: Clock and Data Lane High Speed Receiver BIST Functions Test

##### 12.7.2.3.1.7.1 Description of Procedure

This procedure describes how to use the high speed data BIST generation and checking functions to test the high speed data receiver functions. The process used in this test is to enable test MUXes for the low power and high speed data receiver functions, then write registers to setup, run and check the results of the BIST functions.

##### 12.7.2.3.1.7.2 Details of the Procedure

1. Set up IP for BIST operations.
  - a. Follow the procedure described in section [Section 12.7.2.3.1.2](#), but do not release the common or lanes from reset.
  - b. Write the following registers.
    - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT21[0] O\_RX\_DIG\_BIST\_EN = 1'b1, to enable the analog BIST power island in common.
    - PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT2 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT2 [24] = 1'b1, to enable the diagnostic low power override MUXes in the analog.
    - PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT2 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT2 [21:20] = 2'b11, to enable the diagnostic high speed override MUXes in the analog.
    - PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT30 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT30[1:0] = 2'b11, to enable the diagnostic low power and high speed override MUXes in the analog.
  - c. Release the common from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[5] O\_CMN\_READY to be driven to 1'b1.
  - d. Release the clock and data lanes from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[8] LANE\_READY\_CMN to be driven to 1'b1.

- e. Poll PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT56[20-11] I\_CMN\_RX\_SSM\_STATE until it is set to 9'b100000000.
  - f. When running BIST at 1.5 Gbps, do the following, otherwise skip this if running BIST at 2.5 Gbps.
    - i. Write PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT36[1] O\_RX\_TM\_SEL\_1P5G\_M\_ODE = 1'b1.
    - ii. Wait 5 uSec.
2. Run BIST operations.
    - a. At this point, the BIST generator and checker registers can be written to the values required to generate the desired data patterns. One should see the BIST register descriptions for information about programming the various fields for creating different data patterns. If no registers are written, the BIST default pattern will be generated and checked.
    - b. If running infinite BIST mode is desired, write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT24[15] BIST\_INF\_MODE = 1'b1, to enable infinite BIST mode.
  3. Write PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT27[0] = 1'b1, to enable the pattern checkers in the data lanes.
  4. Write PMA Register (cmn): CMN\_DIG\_TBIT22[0] TM\_BIST\_EN = 1'b1, to enable the pattern generator in the common.
  5. If infinite BIST mode was enabled, do the following.
    - a. Allow the BIST to run as long as required.
    - b. Write the PMA Register (cmn lanes): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT24[15] BIST\_INF\_MODE = 1'b0, to disable infinite BIST mode.
  6. Wait for a minimum of 100 nSec.
  7. Poll PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT50[1] BIST\_COMPLETE until it is set to 1'b1, indicating that the BIST pattern generation process is complete.
  8. Wait 1 uSec.
  9. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT48 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT48[0] W\_DRX\_BIST\_PASS = 1'b1, indicating the BIST checker has indicated a pass condition.
  10. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT48 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT48[1] R\_PAT\_CHE\_SYNC = 1'b1, indicating the BIST checker has observed a marker symbol.
  11. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT48 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT48[2] W\_BIST\_ERROR = 1'b0, indicating the BIST checker has not detected any errors.
  12. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT47 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT47[15:0] W\_PAT\_CHE\_PKT\_COUNT = the generated number of packets (15 by default).
  13. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT47 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT47[31:16] W\_PAT\_CHE\_ERROR\_COUNT = 16'h0000, indicating the BIST checker error count is 0.
  14. Clear the internal state of the BIST pattern checkers by doing the following:
    - a. Read PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT29 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT29[28] TM\_CLEAR\_BIST.
    - b. Write PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT29 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT29[28] TM\_CLEAR\_BIST = inverted value of what was read from this bit in the previous step.
  15. Write PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT27 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT27[0] TM\_BIST\_EN = 1'b0, to disable the pattern checkers in the data lanes.
  16. Clear the internal state of the BIST pattern generator by doing the following:
    - a. Write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT24[6] = 1'b1,
    - b. Write the PMA Register (cmn): CMN\_DIG\_TBIT24[6] BIST\_CLEAR = 1'b0.

17. Write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT22[0]  
BIST\_CONTROLLER\_EN = 1'b0, to disable the BIST pattern generator.
18. If desired, the run BIST operations can be repeated without needing to run set up the IP for BIST operations again.

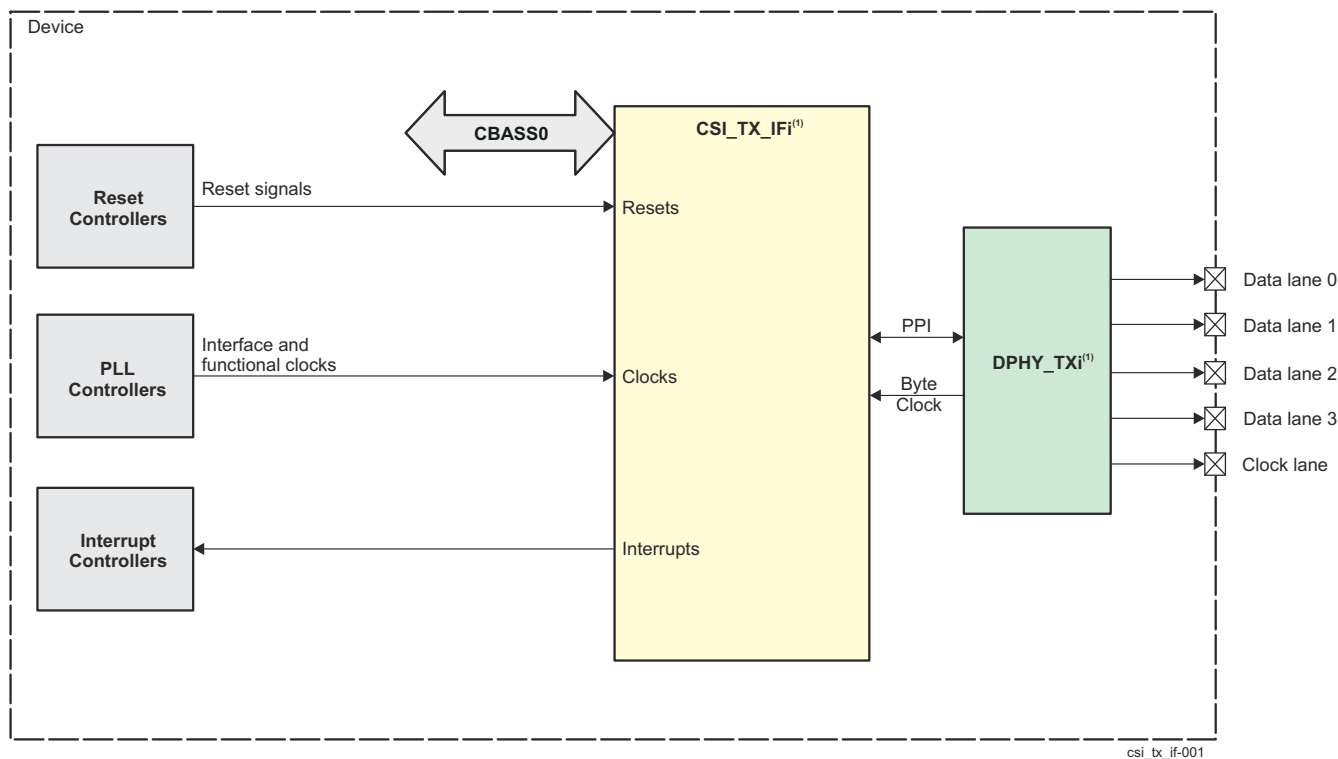

## 12.7.3 Camera Streaming Interface Transmitter (CSI\_TX\_IF)

The following sections describe the camera streaming transmitter interface (CSI\_TX\_IF) module in the device.

### 12.7.3.1 CSI\_TX\_IF Overview

The integration of the CSI\_TX\_IF module allows the device to stream out video data from memory, or retransmit from the CSI receivers as an optional loopback output for diagnostics, debug, and test purposes.

Figure 12-473 shows the CSI\_TX\_IF module overview.

A.  $i = 0$  to 1

**Figure 12-473. CSI\_TX\_IF Module Overview**

#### 12.7.3.1.1 CSI\_TX\_IF Ports

This section describes the CSI\_TX\_IF ports related to clocks, resets, and hardware requests.

**Table 12-399. CSI\_TX\_IF Clocks and Resets**

Clocks	
Module Clock Input	Description
CSI_TX_MAIN_CLK	Main functional(sometimes referred to as pixel clock) clock.
CSI_TX_VBUS_CLK	The VBUS clock runs at always half the speed of the CSI_TX_MAIN_CLK.
CSI_TX_ESC_CLK	20 MHz max clock input for low speed data transmission and some control signals.
DPHY_TXBYTECLKHS	The byte clock is the clock supplied by the DPHY_TX.
Resets	
Module Reset Input	Description
CSI_TX_RST	Asynchronous module global reset, driving all collateral asynchronous resets of the 4 clock domains to the low state.

**Table 12-400. CSI\_TX\_IF Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type

**Table 12-400. CSI\_TX\_IF Hardware Requests (continued)**

CSI_TX_IF_CSI_INTERRUPT_0	Global interrupt that various re-synchronized sources converge into interrupt generation.	Level
CSI_TX_IF_CSI_LEVEL_0	Error interrupt that is generated under the following conditions: <ul style="list-style-type: none"> <li>Retransmit error on Stream2 (packet error on the stream interface)</li> <li>Retransmit error on Stream3 (packet error on the stream interface)</li> </ul>	Level
CSI_TX_IF_CSI_FATAL_0	ASF port fatal interrupt. Level sensitive.	Level
CSI_TX_IF_CSI_NONFATAL_0	ASF port non-fatal interrupt. Level sensitive.	Level
CSI_TX_IF_CDNS_RAM_CORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_CDNS_RAM_UNCORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_CORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_UNCORR_LEVEL_0	Interrupt on internal FIFO RAM	Level

### 12.7.3.2 CSI\_TX\_IF Features

The CSI\_TX\_IF module supports the following features:

- Compliant to MIPI CSI v1.3, MIPI CSI v2.1, and MIPI D-PHY v2.1
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to DPHY\_TX
- Programmable formats including YUV422, RGB, Raw, and User Defined (over 25 different formats supported); Limitations apply depending on the stream used
- 16 virtual channel support
- Configurable input streams supported:
  - Stream0:** DMA interface through a 128-bit PSI\_L connection for transfers from memory **OR** CSI\_RX retransmit:
    - 128bit wide pixel data with bursting
    - ByteValid per byte in Last Data Phase (LDP)
    - 32 thread IDs supported (virtual channel & data type combinations); Flexible number of threads (32 Max).
    - Unpacking PSI\_L data and converting to CSI video format
    - Internal FF based FIFO and external RAM based buffer
  - Stream1:** Color bar video data generator
    - 2 pixel wide
    - YUV422 8-bit format support only
    - Configurable frame/line size via registers
    - 1 programmable virtual channel
    - Internal FF based FIFO; No external buffer.
- Functional and data path error interrupts
- ECC support on external RAMs

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.7.3.2.1 CSI\_TX\_IF Legacy Compatibility

The following lists changes that must be considered compared to previous generation CSI\_TX\_IF:

- YUV420 is not supported, YUV420 configuration registers/bitfields are not used
- Word count must be programmed in the CSI\_TX\_IF, not in the TX Core.
- CSI\_TX\_IF compatibility mode must be used in Stream0 when retransmitting from CSI\_RX\_IF

**Figure 12-475. CSI\_TX\_IF PSI\_L thread mapping**

Software must take the following notes in consideration

- Interleaved data formats on single virtual channel and frame are supported.
- All PSI\_L threads that open a frame must be closed before a new PSI\_L thread can start a new frame. Until all channels close the frame other threads will be stalled.
- DATA is assumed in a specific organization for CSI\_TX\_IF to export data correctly. See memory organization details in *CSI\_TX\_IF Data Memory Organization Details*.
- Threads can only switch after full lines are received. PSI\_L pushback will occur on all other threads.
- Thread priority is 0 - 31 and after a line is received will be re-arbitrated in that order for the next thread to send.

Registers CSI\_TX\_IF\_L2L\_DELAY\_j control the line start to next line start. Also register CSI\_TX\_IF\_L2L\_DELAY\_j control the last line of frame to next start of frame first line start of next frame. Buffering of PSI\_L data is 2kx128 RAM.

**Stream0 (from CSI\_RX\_IF)** is a loopback stream from the CSI receiver muxed with PSI\_L data stream.

**Stream1** streams data from the Color Bar generator. It supports YUV422 8bit format only.

CSI\_TX\_IF\_COLOR\_PARAM register is used to control height and width information. Width is divided by 8 for each color section. Colors are defined below. Transfers are done on the Stream1 interface in 32-bit packed 8-bit pixel format(required programming in CSI\_TX\_IF core). Virtual channel and data type is configurable in CSI\_TX\_IF\_COLOR\_CNTL register. Data selection inside CSI\_TX\_IF controller maps data type information. CSI\_TX\_IF\_COLOR\_START\_DELAY register can configure delays from enabled to start. CSI\_TX\_IF\_COLOR\_LINE\_DELAY, and CSI\_TX\_IF\_COLOR\_FRAME\_DELAY register can delay last line to first line of new frame. Once enabled, it will continuously send out frames until disabled. Once disabled, it will stop at end of current frame. [Table 12-401](#) shows the Color Bar format.

**Table 12-401. CSI\_TX\_IF Color Bar format details**

Color	Y	CB	CR
White	235	128	128
Yellow	162	44	142
Cyan	131	156	44
Green	112	72	58
Magenta	84	184	198
Red	65	100	212
Blue	35	212	114
Black	16	128	128

**Figure 12-476. CSI\_TX\_IF PSI\_L Color Bar sample output**

#### Note

It is a requirement that only PSI\_L/DMA, color bar, or CSI\_RX\_IF loopback streams are not active at the same point in time. The intended use model is not to have multiple combinations active at any given time. The main issue with this is that RAMs are not sized for concurrent operation and will likely overflow resulting in data loss.

#### 12.7.3.4.2 CSI\_TX\_IF Hardware and Software Reset

An active low asynchronous hardware reset is provided to CSI\_TX\_IF by device LPSC. It is internally re-synchronized to the functional clock domain.

A software reset is triggered by configuring the CSI\_TX\_IF\_TX\_CONF[1] SOFT\_RESET\_REQUEST bit-field for protocol reset and/or module reset.

#### 12.7.3.4.3 CSI\_TX\_IF Clock Configuration

There are four clock domain in the CSI\_TX\_IF.

1. The CSI\_TX\_MAIN\_CLK (or also referred to as pixel clock) runs most of the logic. It needs to be same frequency as CSI\_RX\_MAIN\_CLK main clock (500MHz). When CSI\_TX\_MAIN\_CLK is operating lower than 312.5MHz, then the clock is essentially limiting the clock rate of the DPHY\_TX. Said another way, CSI\_TX\_MAIN\_CLK must be at least the DPHY\_TXBYTECLKHS rate else FIFOs will overflow, crashing the module.
2. The CSI\_TX\_VBUS\_CLK is the interface configuration clock that runs at half the speed of the CSI\_TX\_MAIN\_CLK (250MHz).
3. The DPHY\_TXBYTECLKHS is the clock supplied by the DPHY\_TX PLL and is divided down to byte clock. The DPHY\_TX is designed for max of 10gbps. This translates to a max byte clock of 312.5MHz. The clock is inactive when DPHY\_TX is not in HS operation.
4. The CSI\_TX\_ESC\_CLK escape clock runs at 20MHz. CSI\_TX\_ESC\_CLK is rarely used by the CSI\_TX\_IF, usually is only to clock in some low speed control signals from DPHY\_TX. The ESC interface is a low speed DPHY common link to the camera/sensor.

Table 12-402 shows the CSI\_TX\_IF and DPHY\_TX inter-clock dependencies.

**Table 12-402. CSI\_TX\_IF Inter-clock Dependencies**

	CSI_TX_MAIN_CLK	CSI_TX_VBUS_CLK	DPHY_TXBYTECLKHS	CSI_TX_ESC_CLK
<b>Min freq</b>	DPHY_TXBYTECLKHS freq	CSI_TX_MAIN_CLK / 2 freq	N/A	N/A
<b>Max freq</b>	500MHz	CSI_TX_MAIN_CLK / 2 freq	312.5MHz	20MHz

### 12.7.3.4.4 CSI\_TX\_IF Interrupt Events

#### 12.7.3.4.4.1 CSI\_TX\_IF Interrupt Events

This section describes the register configuration of the interrupt events that can trigger the several CSI\_TX\_IF interrupt signals. For detailed description and mapping of the interrupt to the device interrupt processors see *CSI\_TX\_IF Integration*.

The interrupts are generally handled within the INTD module of the CSI\_TX\_IF, although there are several interrupt registers in the ECC\_AGGR for ECC errors and in the VBUS2APB for stream monitoring errors/flags.

Table 12-403 lists the event generation and corresponding registers of the CSI\_TX\_IF controller.

**Table 12-403. CSI\_TX\_IF Interrupt Events Cross Table**

Event	Mask Register	Status Register	Description
CSI_TX_IF_MAIN_0_CSI_INTERRUPT	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Global interrupt that various re-synchronized sources converge into interrupt generation. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_LEVEL	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Error interrupt that is generated under the following conditions: <ul style="list-style-type: none"> <li>Retransmit error</li> <li>Unselected stream error. An unselected DMA path or CSI_RX_IF loopback path is sending data when not selected</li> </ul> Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_CORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_UNCORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_UNCORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_FATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.
CSI_RX_CSI_NONFATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.

#### 12.7.3.4.5 CSI\_TX\_IF Data Memory Organization Details

Figure 12-477 shows the YUV422-8 data organization in memory.

csi\_tx\_if-007

**Figure 12-477. CSI\_TX\_IF YUV422-8 Memory Data Organization**

Figure 12-478 shows the YUV422-10 data organization in memory.

csi\_tx\_if-008

**Figure 12-478. CSI\_TX\_IF YUV422-10 memory data organization**

Figure 12-479 shows the RAW data organization in memory. User defined data types behave the same as RAW data types.

#### 12.7.3.4.6 CSI\_TX\_IF PSI\_L (DMA) Interface

The PSI\_L (DMA) interfaces is common for both CSI\_RX\_IF and CSI\_TX\_IF, see chapter *Camera Streaming Interface Receiver (CSI\_RX\_IF) and MIPI DPHY Receiver (DPHY\_RX)*, subsection *CSI\_RX\_IF PSI\_L (DMA) Interface*.

#### 12.7.3.4.7 CSI\_TX\_IF ECC Protection Support

The CSI\_TX\_IF has two ECC aggregators, one for byte clock (DPHY\_TXBYTECLKHS) and the other one for all other clocks. The ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC protection on the CSI\_TX\_IF RAM provides Single Error Correction and Double Error Detection (SEC/DED). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC protection also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

The ECC aggregators on the CSI\_TX\_IF subsystem level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. They provide a single EOI-handshake based interrupt to the interrupt processors (for both single and double error detections) and a standard 32-bit VBUS interface for configuring and querying the ECC register set, see *CSI\_RX\_IF\_ECC Registers*. For complete details on the features and functions of the ECC aggregator, see *ECC Aggregator*.

#### 12.7.3.5 CSI\_TX\_IF Programming Guide

##### Note

Software must keep the CSI\_TX\_IF\_CONTROL1[0] PIXEL\_RESET register in the asserted state in the control register until all CSI\_TX\_IF controller registers are programmed. Only after all CSI\_TX\_IF controller programming can software de-assert CSI\_TX\_IF\_CONTROL1 register. If software has to reprogram any CSI\_TX\_IF controller registers it MUST have the control CSI\_TX\_IF\_CONTROL1 register reset asserted.

It is a restriction that LS/LE detection is disabled.

##### 12.7.3.5.1 CSI\_TX\_IF Programming (Configuration Mode)

Although it is always possible to read/write all control registers, it strongly recommended writing to the control registers only while configuration mode is active. To enter configuration mode, the CSI\_TX\_IF\_TX\_CONF[2]

CONFIGURATION\_REQUEST bit must be set. CSI\_TX\_IF enters configuration mode when transmission of any ongoing frame has ended and the configuration request bit is set. Configuration mode is the default state after reset. While configuration mode is active, the CSI\_TX\_IF\_STATUS[2] CONFIGURATION\_ACTIVE bit is set. Traffic at the pixel interface is ignored during configuration mode, and it is safe to write to control registers and change configuration.

To exit configuration mode, the CONFIGURATION\_REQUEST bit in the CSI\_TX\_IF\_TX\_CONF register must be cleared. The CSI\_TX\_IF then starts normal operation, with first new frame incoming after configuration mode exit.

During configuration mode, all interrupts are disabled.

---

#### Note

A mandatory assertion of soft reset occurs following the de-assertion of CONFIGURATION\_REQUEST. This ensures the controller is in a known state and all the parameters set in the configuration registers have been loaded correctly into the internal state. The DPHY\_TXBYTECLKHS must be active before the configuration request is completed.

---

#### 12.7.3.5.2 CSI\_TX\_IF System Initialization Programming

The power up/reset release of the system will clear all the register values to their reset conditions. Software must perform programming of the virtual channel and data type registers to match the system operation if the reset conditions do not match the required values. Software must ensure that all the data type select registers are programmed with valid values for the pixel\_dt\_sel\_if parameter used.

The CSI\_TX\_IF registers for all the DPHY\_TX related control and delays must be set before starting the system. The DPHY\_TX delays must be calculated using the system clock periods associated with CSI\_TX\_ESC\_CLK and DPHY\_TXBYTECLKHS. The wait burst time must be calculated using the relevant DPHY\_TX data sheet to ensure that all the lanes begin new requests at the same point.

Software must configure the FIFO fill level control registers, if required to suit clock ratios used and the desired payload control configurations. When all registers are programmed the configuration can be made active. The pixel streams can then start requests.

---

#### Note

The CSI\_TX\_IF is configured at design time, such that the reset values adopt a generic preferred Power\_On state. This reduces the programming steps required by the system for the general use case scenario.

---

#### 12.7.3.5.3 CSI\_TX\_IF Lane Control Programming

The CSI\_TX\_IF links to the DPHY\_TX clock and data lanes. After power up, software must identify that the DPHY\_TX is powered on and the DPHY\_TX PLL has locked. The DPHY\_TX controls for swapping the DP/DN control can be modified using the CSI\_TX\_IF\_DPHY\_CFG1 register if required.

Software must then program the enable for the clock lane and each data lane that is required. The DPHY\_TX lane signals can be checked using the CSI\_TX\_IF\_DPHY\_STATUS register to identify that the lane is in STOPSTATE and is ready for High Speed transmission. This register can also be used to identify when ULPS is active.

#### 12.7.3.5.4 CSI\_TX\_IF Virtual Channel and Data Type Management

The following section provides information on how the configuration of virtual channels and data types may be used in conjunction with one or more stream inputs to meet the system requirements.

##### 12.7.3.5.4.1 CSI\_TX\_IF Data Type Interleaving

The CSI\_TX\_IF can support interleaving of data types by configuring the pixel\_dt\_sel\_if inputs at the pixel interface to select the required data type and pixel count values.

#### 12.7.3.5.4.2 CSI\_TX\_IF Data Type Interleaving with Multiple Interfaces

The CSI\_TX\_IF will perform data type interleaving with one, two, or more pixel interfaces. In this scenario, Stream0 will be the master and one or more streams may be ganged together as slaves to the master stream. Therefore, for all the ganged streams, the virtual channel signals must be configured to the same value and the pixel streams must have the same active frame valid cycle (that is the virtual\_channel\_if\* and frame\_valid\_if\* must be wired in parallel). The STREAM\_IF\_\*\_SLAVE\_MODE bit in the STREAM\_IF\_\*\_CFG registers must also be set for all slaved streams. This ensures that only one frame start and frame end are generated for all the ganged streams. Note that the pixel 0 interface is always the master and slave bits exist for the other streams, in the control registers, to determine if they are to operate in master or slave mode.

In the case where streams are ganged together as master and slave(s), all ganged interfaces must have the same virtual channel value, but the pixel\_dt\_sel\_if inputs must be set to different values. Again, each of the interfaces can have the pixel\_dt\_sel\_if input change on a line by line basis, so that interleaving is done with all the ganged streams.

---

#### Note

Each stream must have exclusive use of the data types allocated to it.

---

Data type interleaving is only done when the frame is valid (CSI\_TX\_IF\_DEBUG\_PROT\*\_FSM[11] FRAME\_VALID\_IF\* bitfield input is asserted). The virtual channel will be sampled on the first cycle after the rising edge of the FRAME\_VALID\_IF input and this virtual channel will be used for all the packets originating from that stream during that frame. The FRAME\_VALID\_IF input must be the same on all ganged stream interfaces.

#### 12.7.3.5.4.3 CSI\_TX\_IF Virtual Channel Interleaving

The CSI\_TX\_IF can support interleaving of virtual channels by using two or more pixel interfaces and configuring the value of the virtual channels signal differently on each interface. The data streams can then be controlled using the pixel\_dt\_sel\_if inputs to select the data type for the lines. In this scenario, each pixel interface must have exclusive use of the virtual channel. Each stream will generate its own frame start and frame end synchronisation packets. In this case, all the stream protocol modules employing virtual channel interleaving must be configured as masters by clearing the STREAM\_IF\_\*\_SLAVE\_MODE bit in the STREAM\_IF\_\*\_CFG registers.

Note that the virtual channel control input is sampled at the rising edge of the frame\_valid\_if input, and thereafter remains fixed for that frame, therefore the virtual channel cannot be switched on a line-by-line basis for any single pixel interface. While it is possible to switch the Virtual Channel control input from frame to frame, the timing-critical switching required here would indicate a requirement for hardware rather than software control.

#### 12.7.3.5.4.4 CSI\_TX\_IF Virtual Channel and Data Type Interleaving

The CSI\_TX\_IF may be configured to perform a combination of the scenarios outlined in the previous sections if sufficient streams are available. One or more streams may be ganged with Stream0 to perform data type interleaving on the same virtual channel, whilst the remaining streams may be left autonomous to perform virtual channel interleaving.

In this case, the same rules governing the use of the virtual channels and data types must be observed. In this scenario, the virtual channel signals will be configured to the single value required for the ganged group (as they need to be controlled within the same frame valid active signal) and different values for those left to be autonomous (as they may generate their own frame start and frame end events). The slave stream for each virtual channel can have a different data type selected, and this may change on a line-by-line (or packet-by-packet) basis.

#### 12.7.3.5.5 CSI\_TX\_IF Line Control

The line control block uses the DPHY\_TXBYTECLKHS from the DPHY\_TX PPI interface to take the line data from the packet interface FIFO and transfer the bytes to the active lanes of the DPHY\_TX. The block detects when the DPHY\_TX is ready to transmit high speed data and the pixel stream has packets available.

The line control block performs pixel stream arbitration using the line control arbitration block when more than one pixel stream is generated in the configuration. The block performs all the clock and data lane control required to activate the high-speed transmission and return the lane to ULPS state as required.

#### 12.7.3.5.5.1 CSI\_TX\_IF Line Control Arbitration

The CSI\_TX\_IF controller uses a simple arbitration scheme for configurations with more than one pixel interface.

The arbitration has 2 levels; the first is a round-robin scheme and if no streams are granted by this a priority based scheme is used. The arbitration will select the first stream making a request if there is only one stream waiting or the first in the round robin after a stream has completed transmission. This means that there may be one cycle where the round-robin selector moves across a stream position that is not requesting to transmit.

The re-arbitration boundary is between packets except where line sync is used. In this case the line start packet, long packet and line end are grouped together.

The selected stream will pass the line data from the stream FIFO to the line control block for distribution to the active PPI lanes of the DPHY\_TX.

#### 12.7.3.5.6 CSI\_TX\_IF Lane Manager FSM

Data distribution to the available lanes is controlled via the lane manager FSM.

The state descriptions can be found in [Table 12-404](#).

**Table 12-404. CSI\_TX\_IF Lane Manager FSM State Description**

State (line_fsm_st_r)	Description
LINE_FSM_IDLE	Wait for new transmission to be ready. When start_hs_transmission_c is asserted then go to the transmission state per enabled lanes (lanes_enable_r)
LINE_FSM_BURST_1L	Transmit burst data over lane 0 until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_BURST_2L	Transmit burst data over lanes 0 and 1 until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_BURST_4L	Transmit burst data over all lanes until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_LRTE_EPD_SPACER	Insert spacer packets across each active lane. When finished, if EPD Option 1 then go to the LINE_FSM_LRTE_EPD_PDQ state, otherwise go to the LINE_FSM_IDLE state.
LINE_FSM_LRTE_EPD_PDQ	Tell D-PHY to initiate HS-IDLE state and insert PDQ.
LINE_FSM_BURST_END	Wait for being ready for new burst transmission. In this state counter counts until WAIT_BURST_TIME value in the register is reached.

#### 12.7.3.5.7 CSI\_TX\_IF Data Lane Control FSM

Data lanes control uses a simple FSM to sequence entry and exit of Ultra Low Power mode. This FSM observes inputs from the control registers and based on these inputs it generates PPI outputs for ULP mode.

[Table 12-405](#) shows the state descriptions.

**Table 12-405. CSI\_TX\_IF Data Lanes Control FSM State Description**

State (ulps_data_fsm_st_r)	Description
DATA_LN_IDLE	Idle state. In this state HS transmission can be issued if the Clock Lane is in HS mode.
DATA_LN_ULPS_REQ	Request to enter ULP state. Waiting for activation ULP confirmed by the ppi_ulps_active_not_dl input.
DATA_LN_ULPS_ACTIVE	ULPS for Data Lanes is active. Waiting for the ulps_req_sync signal being low to exit ULPS.
DATA_LN_ULPS_EXIT	ULPS exiting, waiting for the time defined in the CSI_TX_IF_DPHY_ULPS_WAKEUP register.

### 12.7.3.5.8 CSI\_TX\_IF Application Examples

This section details specific steps on how to program the CSI\_TX\_IF.

#### 12.7.3.5.8.1 CSI\_TX\_IF D-PHY Control and Configuration

The DPHY\_TX will use a PLL to provide the bit clock for transmission. The CSI\_TX\_IF controller uses the associated byte clock as a primary clock source and this must be active and stable before the CSI\_TX\_IF is ready to transmit high speed data.

Software must perform the programming of the PLL dividers and monitor the lock status. Software must also ensure the correct sequence of programming the PLL, DPHY\_TX and CSI\_TX\_IF to guarantee the clocks are active and resets are released, following the start-up sequence described in DPHY\_TX chapter (See chapter *Shared MIPI D-PHY Transmitter (DPHY\_TX)*).

#### 12.7.3.5.8.2 CSI\_TX\_IF Clock and Data Lane Enable

The DPHY\_TX lanes are controlled using the CSI\_TX\_IF\_DPHY\_CFG register. The clock enable will be asserted once the DPHY\_TX is configured, PLL is programmed and locked and the lanes are enabled. Enabling the clock lane will then make the TX clock module stay in stop state with the DP/DN pads in LP11. The TX clock high speed ready state will be detected once the TX clock lane has completed the preamble and begun to drive the high speed clock.

The configured number of data lanes will be enabled at the same time as enabling the TX clock. The data lane will remain in LP until the high-speed clock is stable and the CSI\_TX\_IF makes the request for the data lane transitions from stop state to active (LP11-LP01-LP00).

#### 12.7.3.5.8.3 CSI\_TX\_IF DP/DN Signal Swap

The DPHY\_TX may have the capability to swap the data pin polarity or invert the clock lane polarity - the CSI\_TX\_IF\_DPHY\_CFG1 register is available within the controller for driving these pad level controls (using the DPHY\_DIFF\_INVERT\_\* fields). The DPHY\_TX will identify any contention issues with the transmitter and flag this using the contention signals and error interrupt - this may be used by software to determine if the data pin or clock lane polarity switching is required or not (by optimizing to the minimum, preferably zero, rate of occurrence of contention issues).

In the DPHY\_TX, the IO pads for the clock and data lanes support swapping of the polarity of the signals DP-DN. All dphy\_differential\_invert\_\* outputs should be treated as asynchronous. Note that, if these signals need to be asserted, they should be asserted before releasing the DPHY\_TX reset.

Each lane can be controlled independently with the CSI\_TX\_IF\_DPHY\_CFG and CSI\_TX\_IF\_DPHY\_CFG1 registers.

#### 12.7.3.5.9 CSI\_TX\_IF DPHY\_TX Status

The status of clock and data lanes is available in the read only CSI\_TX\_IF\_DPHY\_STATUS register. The clock lane fields show the condition of the ppi\_tx\_ulps\_active\_not\_cl and ppi\_stopstate\_cl PPI inputs. The data lane fields show the ppi\_ulps\_active\_not\_dl\* and ppi\_stopstate\_dl\* PPI inputs.

All the status signals are based on the active enabled lane configuration.

The DPHY\_TX can signal error conditions for each lane for contention in low power transitions and signal errors at the start of high speed transitions, using the CSI\_TX\_IF\_DPHY\_IRQ register. The signals can be used to generate an error interrupt event if the relevant bits are set in the CSI\_TX\_IF\_DPHY\_IRQ\_MASK register. The flag can be cleared by writing to the CSI\_TX\_IF\_DPHY\_IRQ register.

#### 12.7.3.5.10 CSI\_TX\_IF ULPS Operation

Each lane can be put in ultra-low power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane must be in stop state.
- For data lanes, no data must be pending in the CSI\_TX\_IF module.

#### 12.7.3.5.11 CSI\_TX\_IF System Frame Rate Measurement

The CSI\_TX\_IF provides an interrupt event to signal when the frame start (FS) and frame end (FE) packets are sent to the DPHY\_TX. These events are generated on a stream basis for each virtual channel and allow a system configured to perform virtual channel interleaving to capture the events, and to derive the frame rate achieved based on the flow control and clock configuration.

The system performance will be impacted by the FIFO sizing and any flow control mechanism used by the pixel streams, so this provides a mechanism for checking that the system is scaled correctly.

#### 12.7.3.5.12 CSI\_TX\_IF Configuration for PSI\_L

Table 12-406 lists the settings that must be programmed before enabling CSI\_TX\_IF controller and sending PSI\_L data.

**Table 12-406. CSI\_TX\_IF Configuration table for PSI\_L**

Format	Pixel transmit mode used	Size	Details
YUV420-8	single	0	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV420-10	single	1	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	single	0	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-10	single	1	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	packed	2	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
RGB888, RGB666	single	2	
RGB565, RGB555, RGB444	single	1	
RAW6-7 <sup>(1)</sup>	single	0	
RAW8 <sup>(1)</sup>	dual	1	
RAW8 <sup>(1)</sup>	quad	2	
RAW10 <sup>(1)</sup>	single	1	
RAW10 <sup>(1)</sup>	dual	2	
RAW12 <sup>(1)</sup>	single	1	No packing
RAW12 <sup>(1)</sup>	dual	2	No packing
RAW12(packed) <sup>(1)</sup>	single	0	Must set CSI_TX_IF_DMACNTX_j[23] PACK12_CFG = 1
RAW12(packed) <sup>(1)</sup>	dual	1	Must set CSI_TX_IF_DMACNTX_j[23] PACK12_CFG = 1
RAW14 <sup>(1)</sup>	single	1	
RAW14 <sup>(1)</sup>	dual	2	
RAW16 <sup>(1)</sup>	single	1	
RAW20 <sup>(1)</sup>	single	2	

(1) User defined/blanking/generic data types are programmed the same way as RAW data types.

#### 12.7.3.5.13 CSI\_TX\_IF Configuration for Color Bar

The following lists the Color Bar configuration requirements:

- Color bar must be set to packed YUV422-8 format, this is an extended datatype in CSI\_TX\_IF controller.
- Software must program CSI\_TX\_IF controller before enabling the color bar from the CSI\_TX\_IF\_COLOR\_CNTL[0] EN bit-field.
- Program CSI\_TX\_IF\_COLOR\_LINE\_DELAY, CSI\_TX\_IF\_COLOR\_FRAME\_DELAY, CSI\_TX\_IF\_COLOR\_START\_DELAY, and CSI\_TX\_IF\_COLOR\_PARAM registers with appropriate configurations. Update CSI\_TX\_IF\_COLOR\_CNTL with virtual channel and data type desired and enable it.

#### **12.7.3.5.14 CSI\_TX\_IF Error Recovery**

When an underflow error occurs, software must reset the entire CSI\_TX\_IF by SoC PSC reset and restart over.

#### **12.7.3.5.15 CSI\_TX\_IF Power up/down Sequence**

The following lists the power up/down sequence requirements:

1. Software must ensure no more PSI\_L traffic is directed toward the CSI\_TX\_IF module.
2. Software must then go through a tear down process on PSI\_L gasket inside CSI\_TX\_IF wrapper. Refer to chapter *PSI\_L* for tear down process.
3. Software must then check the stream idle values so that they are idle in the CSI\_TX\_IF\_CONTROL1 register.
4. Software must then stop all traffic inside the CSI\_TX\_IF controller and wait till it is idle.
5. After that software can then proceed to do PSC power down routine.

## 12.8 Shared MIPI D-PHY Transmitter (DPHY\_TX)

This section describes the features and functions of the shared MIPI D-PHY Transmitter (DPHY\_TX).

### 12.8.1 DPHY\_TX Subsystem Overview

The DPHY\_TX module provides one option for video output interfacing by implementing a four-lane MIPI D-PHY Transmitter.

The device includes of DPHY\_TX module.

#### 12.8.1.1 DPHY\_TX Features

The DPHY\_TX module supports the following main features:

- Compliance with MIPI D-PHY 1.2 physical layer interface specification and features
- 1, 2 or 4 data lanes, in addition to clock signaling
- Maximum data rate up to 2.5 Gbps per data lane (with deskew) and 1.5 Gbps (without deskew)
- Protocol Peripheral Interface (PPI)
- HS (High-Speed) continuous and burst modes
- LP (Low-Power), ULPM (Ultra-Lower Power), and Shutdown modes
- Data lanes can be independently operated in HS or ULP mode.
- Forward direction and reverse direction escape modes (only on Lane-0)
- Automatic termination control in both high-speed and low-power modes
- Fault detection:
  - Contention detection
  - Sequence error detection (corruption on lanes)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

### 12.8.1.2 DPHY\_TX Ports

This section describes the DPHY\_TX ports related to clocks and resets.

**Table 12-407. DPHY\_TX Clocks and Resets**

Clocks	
Module Clock Input	Description
DPHY_TX_CLK	DPHY_TX interface clock
PSM_CLK	DPHY_TX reference clock
IP1_PPI_K_M_TXCLKESC	DPHY_TX escape mode clock
IP1_PPI_K_LN0_M_TXCLKESC	DPHY_TX escape mode clock for lane 0 for IP1_PPI
IP1_PPI_K_LN1_M_TXCLKESC	DPHY_TX escape mode clock for lane 1 for IP1_PPI
IP1_PPI_K_LN2_M_TXCLKESC	DPHY_TX escape mode clock for lane 2 for IP1_PPI
IP1_PPI_K_LN3_M_TXCLKESC	DPHY_TX escape mode clock for lane 3 for IP1_PPI
DPHY_REF_CLK	DPHY_TX reference clock.
PPI_0_TXBYTECLKHS	DPHY_TX byte clock for IP1_PPI
DPHY_0_RXCLKESC	DPHY_TX reverse escape mode recovered clock from lane 0
DPHY_TXBYTECLKHS	DPHY_TX byte clock for IP2_PPI
Resets	
Module Reset Input	Description
DPHY_TX_RST	DPHY_TX reset

### 12.8.2 DPHY\_TX Environment

This section describes the DPHY\_TX application fields from an environment point of view (external connections).

[Table 12-408](#) describes the DPHY\_TX signals when transmitting data from a DSI module, and [Table 12-409](#) describes the DPHY\_TX signals when transmitting data from a CSI\_TX\_IF module.

**Table 12-408. DPHY\_TX I/O Signals in DSI Mode**

Device Level Signal	I/O <sup>(1)</sup>	Description
DSI_TXN0	I/O	DPHY_TX0 Lane 0 Transmit Differential Data (Negative)
DSI_TXP0	I/O	DPHY_TX0 Lane 0 Transmit Differential Data (Positive)
DSI_TXN1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Negative)
DSI_TXP1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Positive)
DSI_TXN2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Negative)
DSI_TXP2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Positive)
DSI_TXN3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Negative)
DSI_TXP3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Positive)
DSI_TXCLKN	O	DPHY_TX0 Transmit Differential Clock Lane (Negative)
DSI_TXCLKP	O	DPHY_TX0 Transmit Differential Clock Lane (Positive)
DSI_TXRCALIB	A	DPHY_TX0 pin for external calibration resistor. Refer to the device-specific Datasheet for a recommended resistor value.
DSI_ATB_0_H	I/O	DPHY_TX0 Analog Test Bus 0
DSI_ATB_1_H	I/O	DPHY_TX0 Analog Test Bus 1

(1) I = Input; O = Output.

**Table 12-409. DPHY\_TX I/O Signals in CSI Mode**

Device Level Signal	I/O	Description
CSI0_TXN0	O	DPHY_TX0 Lane 0 Transmit Differential Data (Negative)
CSI0_TXP0	O	DPHY_TX0 Lane 0 Transmit Differential Data (Positive)
CSI0_TXN1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Negative)
CSI0_TXP1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Positive)

**Table 12-409. DPHY\_TX I/O Signals in CSI Mode (continued)**

Device Level Signal	I/O	Description
CSI0_TXN2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Negative)
CSI0_TXP2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Positive)
CSI0_TXN3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Negative)
CSI0_TXP3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Positive)
CSI0_TXCLKN	O	DPHY_TX0 Transmit Differential Clock Lane (Negative)
CSI0_TXCLKP	O	DPHY_TX0 Transmit Differential Clock Lane (Positive)

## 12.9 Timer Modules

This section describes the timer modules in the device.

### 12.9.1 Global Timebase Counter (GTC)

This section describes the global timebase counter (GTC) in the device.

#### 12.9.1.1 GTC Overview

The GTC module provides a continuous running counter that can be used for time synchronization and debug trace time stamping.

The device includes one GTC instance.

##### 12.9.1.1.1 GTC Features

The GTC supports the following features:

- 64-bit up counter
- No rollover during the lifetime of the device
- Compatible with ARMv8 system counter requirements:
  - Disabled at power-up
  - Register definition and memory map aligned to ARMv8 definition
  - Implements memory-mapped counter control and status frames
- Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
- Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols

##### 12.9.1.1.2 GTC Not Supported Features

The GTC module does *not* support:

- System counter frequency change for reduced power operation
- ARMv8 memory-mapped timer
- Register write locks (MMR kick protection)

##### 12.9.1.1.3 GTC Ports

**Table 12-410. GTC Clocks and Resets**

Clocks	
Module Clock Input	Description
GTC_CLK	Module functional (counter) clock.
GTC_VBUSP_CLK	Module interface clock.
Resets	
Module Reset Input	Description
GTC_POR_RST	Module reset. Affects counter and MMR logic.
GTC_SYS_RST	POR that is unstretched and not delayed by any sequential logic. Used for boot config to sample device pins.

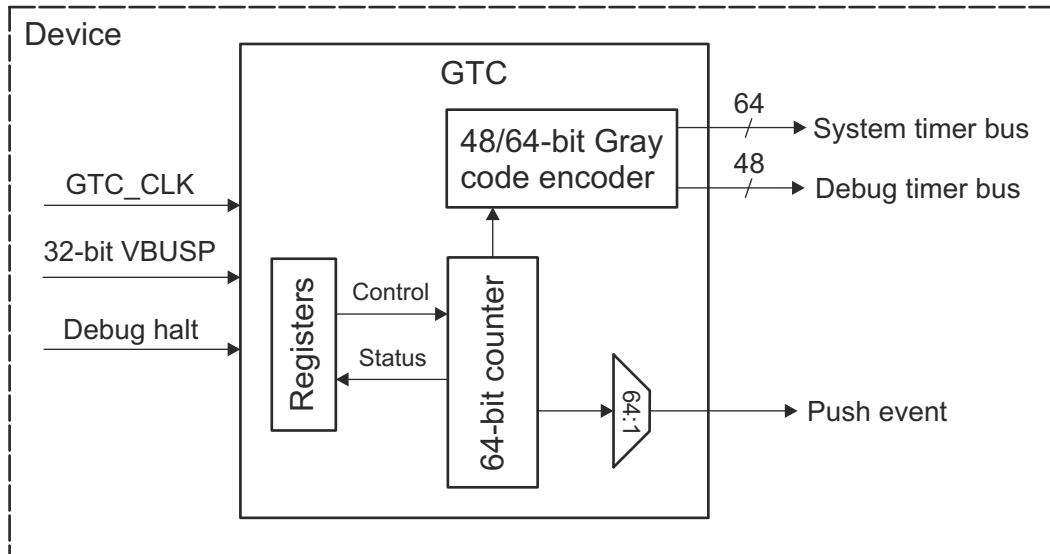

**Table 12-411. GTC Hardware Requests**

Time Sync Events		
Module Sync Output	Description	Type
GTC_GTC_PUSH_EVENT_0	GTC hardware push event	Pulse

### 12.9.1.2 GTC Functional Description

#### 12.9.1.2.1 GTC Block Diagram

The GTC is essentially comprised of a 64-bit up counter, a Gray encoder, a 64-bit multiplexer, and memory-mapped control registers. [Figure 12-482](#) shows a high-level block diagram of the GTC.

**Figure 12-482. GTC Block Diagram**

#### 12.9.1.2.2 GTC Counter

The counter is a 64-bit binary up counter that increments on every GTC\_CLK rising edge. The source for GTC\_CLK is selected through a mux which is controlled via the CTRLMMR\_GTC\_CLKSEL[2-0] CLK\_SEL register bit field.

The counter is disabled by default (at power-on-reset) and increments only when enabled by setting the GTC\_CNTCR[0] EN bit to '1'. The current counter value is readable via the combined COUNTVALUE bit field of both GTC\_CNTCV\_HI (upper 32 bits) and GTC\_CNTCV\_LO (lower 32 bits) registers.

When counting is disabled, a new counter value can be loaded via a software write to the combined COUNTVALUE bit field. In this case, when the counter gets re-enabled, it will start counting from the last value written to this field.

The counter can be optionally configured to stop incrementing when a debug halt signal is issued, by writing a '1' to the GTC\_CNTCR[1] HDBG bit. This condition is indicated through the GTC\_CNTCR[1] DBGH status bit.

#### 12.9.1.2.3 GTC Gray Encoder

The Gray encoder performs a realtime conversion of the binary counter value into a 64-bit Gray code. This value is exported as the system timer bus for distributing the counter value to:

- (2x) A72SS global timestamp input bus
- (1x) GPU timestamp input bus

A second realtime conversion of the 48 LSBs of the binary counter value into a 48-bit Gray code value is also performed and exported to:

- (2x) A72SS debug timestamp input bus
- (1x) DMPAC timestamp input bus
- (2x) VPAC timestamp input bus
- (1x) DMSC timestamp input bus

#### 12.9.1.2.4 GTC Push Event Generation

The GTC can generate periodic push events for global time synchronization at up to half the GTC\_CLK frequency. The frequency of the events is determined by selecting one of the counter bits through the internal [64:1] mux, which is controlled through the GTC\_PUSHEVT[5-0] EXPBIT\_SEL bit field.

#### 12.9.1.2.5 GTC Register Partitioning

The ARMv8 architecture spec requires specific system-level components, each with one or two register frames. To accommodate this, the GTC memory-mapped registers (MMRs) are divided into four separate regions (4KB each):

- Peripheral MMRs (GTC0\_GTC\_CFG0): This region includes standard peripheral identification registers and any other control registers not associated with the ARMv8 system timer functions.
- Counter control MMRs (GTC0\_GTC\_CFG1): This region includes registers that provide control over the operation of the system timer.
- Counter status MMRs (GTC0\_GTC\_CFG2): This region includes registers that provide a mechanism for reading the status of the system timer.
- Timer control MMRs (GTC0\_GTC\_CFG3): This region includes registers that identify and provide a control mechanism for memory-mapped timer implementations. For this device, no memory-mapped timers are implemented and only the minimum registers required to indicate the presence of no timers are necessary.

## 12.9.2 Windowed Watchdog Timer (WWDT)

This section describes the Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWDT) function of the Real Time Interrupt (RTI) module in the device.

### CAUTION

The RTI module shall be used to serve only as a Digital Windowed Watchdog (DWWDT).

The Real Time Interrupt module provides timer functionality for operating systems and for benchmarking code. The module incorporates several counters, which define the timebases needed for scheduling in the operating system.

This module is specifically designed to fulfill the requirements for OSEK (“Offene Systeme und deren Schnittstellen für die Elektronik im Kraftfahrzeug”; “Open Systems and the Corresponding Interfaces for Automotive Electronics”) as well as OSEK/Time compliant operating systems.

The timers also provide the ability to benchmark certain areas of code by reading the counter contents at the beginning and the end of the desired code range and calculating the difference between the values.

### 12.9.2.1 RTI Overview

#### 12.9.2.1.1 RTI Features

The RTI modules include the following main features:

- Windowed Watchdog Timer (WWDT) feature.
- Two independent 64 bit counter blocks (counter block0 or counter block1). Each block consists of
  - One 32 bit up counter
  - One 32 bit free running counter
  - Two capture registers for capturing the prescale and free running counter on a special event.
- Free running counter 0 can be incremented by either the internal prescale counter or by an external event.
- Four configurable compare registers for generating operating system ticks . Each event can be driven by either counter block0 or counter block1.
- Fast enabling/disabling of events.
- RTI clock input derived from any of the available clock sources, selectable in the System Module
- Optional capability to drive a pulse-width modulated signal out on an interrupt line.

#### 12.9.2.1.2 RTI Not Supported Features

See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.9.2.1.3 RTI Ports

**Table 12-412. RTI Clocks and Resets**

Clocks	
Module Clock Input	Description
RTI_ICLK	RTI Interface Clock
RTI_FCLK	RTI Functional Clock.
Resets	
Module Reset Input	Description
RTI_RST	RTI Asynchronous Reset
RTI_POR_RST	RTI Power-On Reset

**Table 12-413. RTI Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
RTI_INTR_WWD_0	RTI window watchdog violation interrupt	Pulse

### 12.9.2.2 RTI Functional Description

The MCU\_RTII[1-0] and RTII (where i = ) modules are hereinafter referred to as RTI module.

#### 12.9.2.2.1 RTI Counter Operation

##### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Figure 12-483 shows the RTI module counter blocks. The RTI module supports two counter blocks.

rti-004

**Figure 12-483. RTI Counters Block Diagram**

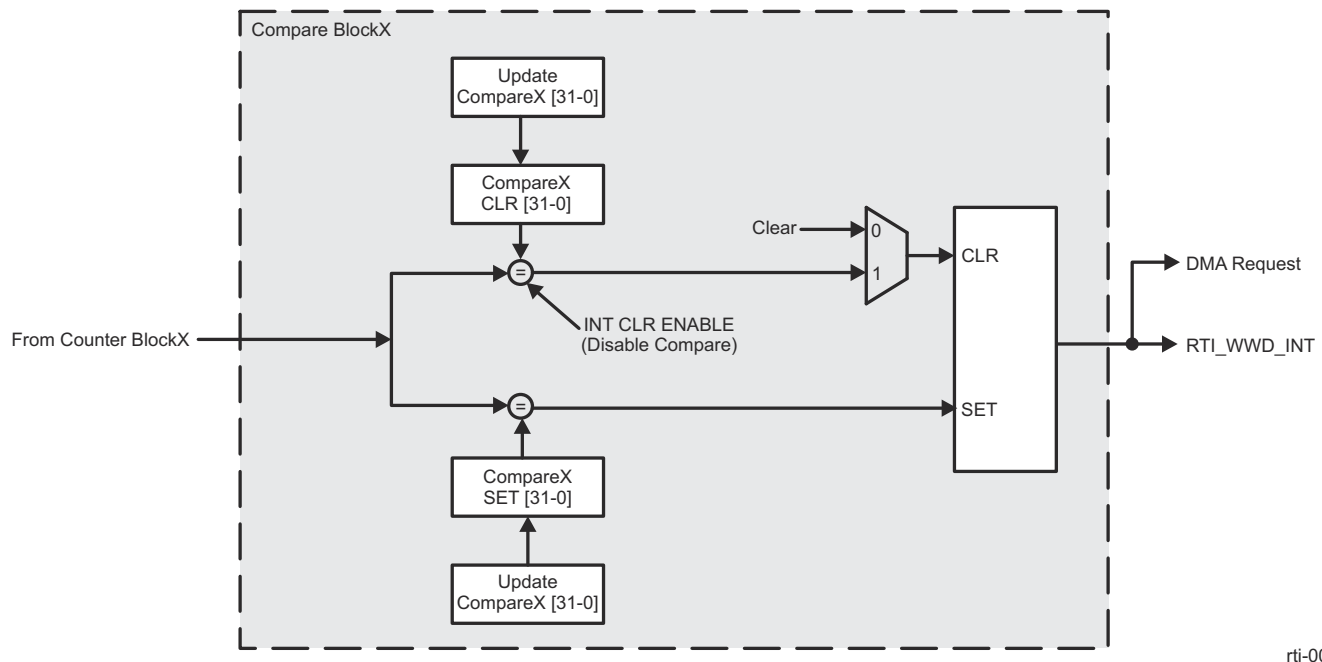

Each block consists of two 32 bit up counters - Up Counter (UC) and Free Running Counter (FRC). The Up Counter (RTI\_UC0 or RTI\_UC1 register) is driven by the RTI\_FCLK and counts up until the compare value in the Compare Up Counter register (RTI\_CPUC0 or RTI\_CPUC1) is reached. When the compare matches, the second counter (RTI\_FRC0 or RTI\_FRC1 register), which is a free running counter, is incremented. At the same time UCx is reset to zero.

To ensure the consistency of the counters, when both counter value have to be determined, the Free Running Counter has to be read first. This will ensure that at the CPU read cycle, the Up Counter value is stored in the

counter register. The second read is done on the Up Counter register, which holds then the value of the counter cycle of the previous read on the Free Running Counter register.

Both blocks provide also a capture feature on external events. Two capture sources can trigger the capture event. Which event triggers block 0 or block 1 is configurable from the RTI\_CAPCTRL register. The sources are coming from the interrupt manager, in order to be able to generate a capture event when one of the peripheral modules has generated an interrupt. The peripheral, which can generate an event is configured in the interrupt manager. When the event is detected, UCx and FRCx are stored in Capture Up Counter (RTI\_CAUC0 or RTI\_CAUC1) and Capture Free Running Counter (RTI\_CAFRC0 or RTI\_CAFRC1) registers. The read order of the captured values has to be like the order of the actual counters. So the CAFRCx has to be read first and the CAUCx registers has to be read after the CAFRCx value was determined. While the CAFRCx is read the CAUCx value is loaded into a shadow register to ensure data consistency, if during the two reads of the captured data another capture event happens. If the application fails to read the two registers before a second capture event happens, the previous data will be overwritten.

Figure 12-484 shows the block diagram for one compare block. The RTI module supports four compare blocks.

**Figure 12-484. RTI Compare Block Diagram**

In order to generate interrupt requests to the interrupt manager, there are four compare registers (RTI\_COMP0, RTI\_COMP1, RTI\_COMP2, and RTI\_COMP3). Each of the compare registers can be configured to work either on FRC0 (Counter block0) or FRC1 (Counter block1). When the counter value matches the compare value, an interrupt is generated. This sets an interrupt request line to the interrupt manager. The compare value gets updated automatically with the value stored in Update Compare (RTI\_UDCP0, RTI\_UDCP1, RTI\_UDCP2, and RTI\_UDCP3) registers when the compare matches. This gives the ability to generate periodic interrupts/DMA requests without having to update the compare value by software.

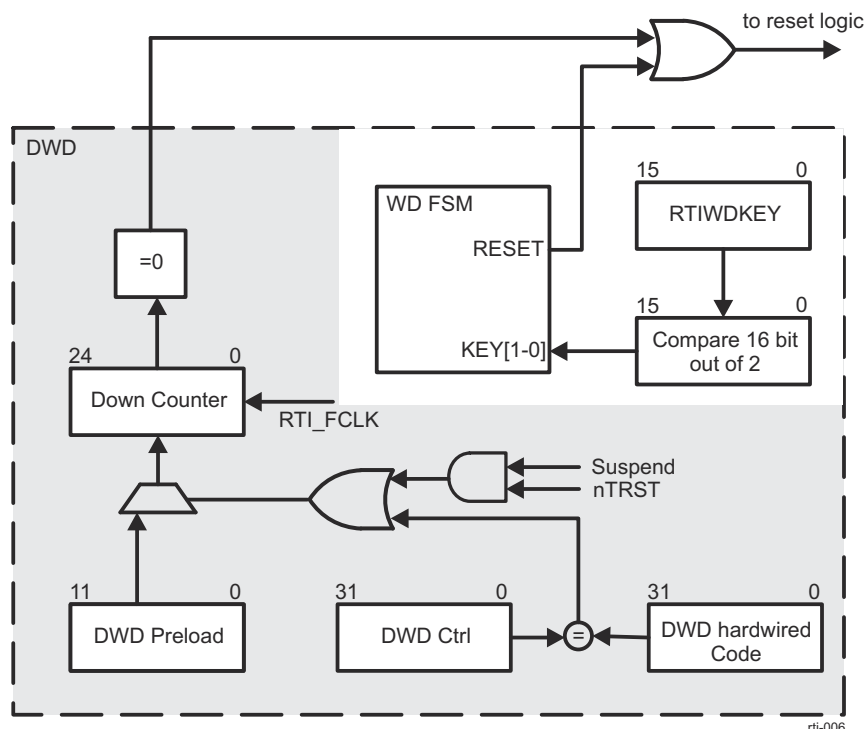

An optional feature allows an application to program another compare value which is then used to clear the interrupt request line. This feature is supported by four compare clear registers (RTI\_COMP0CLR, RTI\_COMP1CLR, RTI\_COMP2CLR, and RTI\_COMP3CLR). When the counter value matches the compare clear value, the interrupt line is cleared. This clears the interrupt request line to the interrupt manager. The compare clear value gets updated automatically with the value stored in Update Compare (RTI\_UDCPx) registers when the compare matches.

### 12.9.2.2.2 RTI Digital Watchdog

#### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Some applications might use a digital watchdog (DWD) integrated in the RTI module. The digital watchdog generates resets after a programmable period, if no correct key sequence is written to the RTI\_WDKEY register. Figure 12-485 shows the digital watchdog functional block.

**Figure 12-485. RTI Digital Watchdog Functional Block Diagram**

The digital watchdog functionality is implemented such that it can be enabled by software.

The DWD starts counting down from the reset value of the RTI\_DWDCNTR (DWD Counter Register). The DWD preload register can be configured at any time by the application according to the desired time-out period.

When enabled by software, the digital watchdog is disabled after system reset. If it should be used, it has to be enabled by writing A98559DAh to the RTI\_DWDCTRL register. The DWD timeout period must be configured using the DWD preload register before the DWD is enabled. The DWD cannot be disabled by the application once it is enabled.

#### Note

When the DWD is enabled by software, any system reset will disable the DWD. This reset could have been generated by the watchdog itself.

If the correct key sequence is written to the RTI\_WDKEY register (E51Ah followed by A35Ch), the 25-bit DWD Down Counter is reloaded with the 12-bit preload value stored in RTI\_DWDPRLD register. If any incorrect value is written to the RTI\_WDKEY register, a watchdog reset will occur immediately. A reset will also be generated, when the DWD Down Counter is decremented to 0.

The user has to take into account that the write to the RTI\_WDKEY register takes 3 RTI\_ICLK cycles. This needs to be considered for the DWD expiration calculation.

The DWD Down Counter will be decremented with RTI\_FCLK frequency. If the RTI\_FCLK is switched off via the disable registers of the Clock management, the DWD counter stops decrementing. The DWD module cannot generate a reset under this condition.

**Figure 12-486. RTI Digital Watchdog Operation**

The expiration time of the DWD Down Counter can be determined with following equation:

$$t_{exp} = (RTI\_DWDPRLD + 1) \times 2^{13} / RTI\_FCLK \quad (28)$$

where RTI\_DWDPRLD = 0...4095

#### 12.9.2.2.3 RTI Digital Windowed Watchdog

##### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

##### Note

Digital windowed watchdog (DWWD) timer is implemented using the digital windowed watchdog function of the RTI modules. Real time interrupt functionality is not supported. In this mode, the timer should default to disabled and user can adjust the period as desired before enabling the watchdog.

In addition to the time-out boundary configurable via the digital watchdog (DWD), some applications may also want to configure the start-time boundary of the watchdog. This is enabled by the digital windowed watchdog (DWWD) feature.

#### Functional Behavior

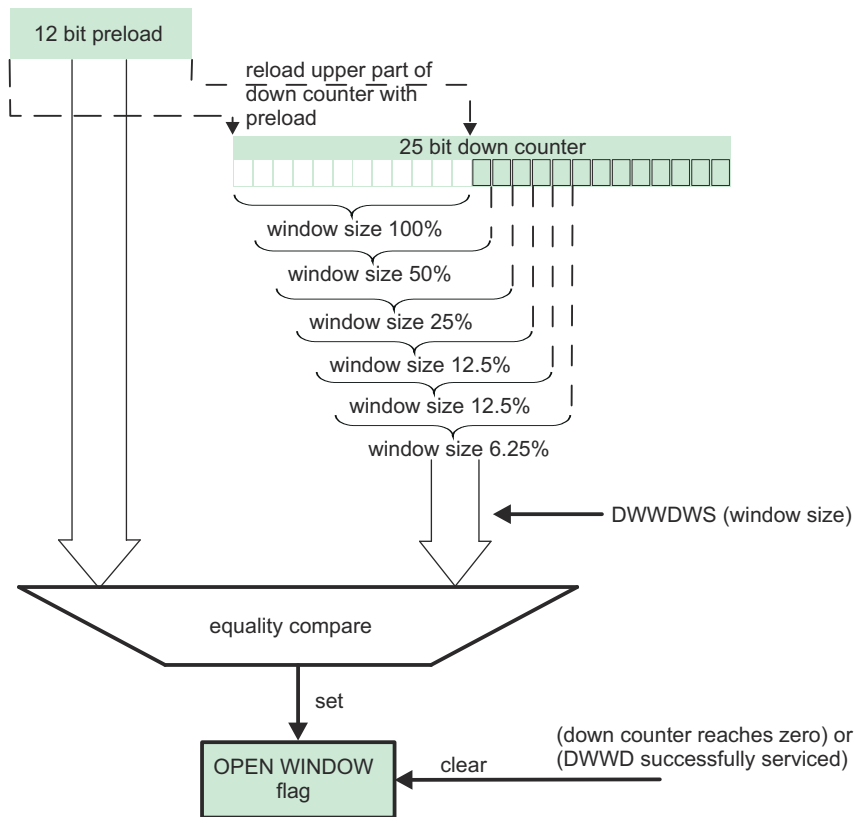

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a non-maskable interrupt to the CPU. This is controlled by configuring the RTI\_WWDRXNCTRL register. As stated earlier, when the watchdog needs to be enabled by software, the watchdog counter is disabled on a system reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The RTI\_INTR\_WWD interrupt handler needs to clear the watchdog violation status flag(s) and then service the watchdog by writing the correct sequence in the watchdog key RTI\_WDKEY register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the RTI\_INTR\_WWD handler does not service the watchdog in time, it could count down all the way to zero and wrap around. No second exception for a time out is generated in this case.

#### Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD.

**Figure 12-487. RTI Digital Windowed Watchdog Timing Example**

**Figure 12-488. RTI Digital Windowed Watchdog Operation Block Diagram**

#### 12.9.2.2.4 RTI Low Power Mode Operation

The operation of the RTI module is guaranteed in run, doze and snooze mode. In sleep or hibernate mode all clocks will be switched off and the RTI module will not work.

In doze and snooze modes all parts of the RTI are active, since it has to be able to wake up the device with compare and timebases interrupts. Capturing events generated by the interrupt module is also possible since in

both modes the peripheral modules are able to generate interrupts, which can trigger capture events. The RTI module will generate compare and timebases interrupts. The compare interrupts will periodically wake up the device.

---

**Note**

In the special case of doze mode with DPLL off, RTI\_FCLK might have a different period than with DPLL enabled, since RTI\_FCLK will be derived from the oscillator output. It has to be ensured that the RTI\_ICLK to RTI\_FCLK ratio is at least 3:1.

---

The DWD/DWWD remains active when the device enters low power mode as long as the RTI\_FCLK is kept active.

Whenever the LPSC that controls an RTI is in any state other than Enable (see *Module States*), the RTI cannot count or generate interrupts. For more information, see *Power Control Modules*.

During standard SoC warm reset the RTI and the rest of the SoC are reset. In this case, the RTI counters are stopped and interrupts are not issued. During reset-isolated warm reset, if an R5FSS is put in reset-isolation, then the associated RTI also becomes reset isolated. As such, the R5FSS and the RTI are not reset, but RTI stops counting and cannot generate interrupts until R5FSS is taken out of CLKSTOP (brought to Enable state).

#### **12.9.2.2.5 RTI Debug Mode Behavior**

---

**Note**

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

---

Once the system enters debug mode, the behavior of the RTI depends on the RTI\_GCTRL[15] COS bit. If the bit is cleared and debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode.

The DWD counter will not decrement in debug mode and will hold its current value, regardless of the RTI\_GCTRL[15] COS bit.

---

**Note**

The user must not service the watchdog while in debug mode.

---

## 12.9.3 Timers

This section describes the Timer modules for the device.

### 12.9.3.1 Timers Overview

There are thirty timer modules in the device.

All timers include specific functions to generate accurate tick interrupts to the operating system.

Each timer can be clocked from several different independent clocks. The selection of clock source is made from registers in the MCU\_CTRL\_MMR0/CTRL\_MMR0.

In the MCU domain the device provides 10 timer pins to be used as MCU Timer Capture inputs or as MCU Timer PWM outputs. In order to provide maximum flexibility, these 10 pins may be used with any of MCU\_TIMER0 through MCU\_TIMER9 instances. System level muxes are used to control the capture source pin for each MCU\_TIMER[9-0] and the MCU\_TIMER[9-0] source for each MCU\_TIMER\_IO[9-0] PWM output.

In the MAIN domain the device provides 8 timer pins to be used as Timer Capture inputs or as Timer PWM outputs. For maximum flexibility, these 8 pins may be used with any of TIMER0 through TIMER19 instances. System level muxes are used to control the capture source pin for each TIMER[19-0] and the TIMER[19-0] source for each TIMER\_IO[7-0] PWM output.

Each odd numbered timer instance from each of the domains may be optionally cascaded with the previous even numbered timer instance from the same domain to form up to a 64-bit timer. For example, TIMER1 may be cascaded to TIMER0, MCU\_TIMER1 may be cascaded to MCU\_TIMER0, etc.

When cascaded, TIMER<sub>i</sub> acts as a 32-bit prescaler to TIMER<sub>i+1</sub>, as well as MCU\_TIMER<sub>n</sub> acts as a 32-bit prescaler to MCU\_TIMER<sub>n+1</sub>. TIMER<sub>i</sub> / MCU\_TIMER<sub>n</sub> must be configured to generate a PWM output edge at the desired rate to increment the TIMER<sub>i+1</sub> / MCU\_TIMER<sub>n+1</sub> counter.

#### 12.9.3.1.1 Timers Features

The following are the main features of the timer controllers:

- Slave interface supports:
  - 32-bit data bus width
  - 32-bit access supported
  - 10-bit address bus width
  - Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source ( $2^n$ , where  $n = [0-8]$ )
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- On-the-fly read/write register (while counting)
- Generates a 1-ms tick clock when functional clock is 32.768 kHz

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.9.3.1.2 Timers Not Supported Features

The following features are not supported on this family of devices:

- Atomic 64-bit timer value read of cascaded timers is not supported.
- Smart-idle with wake-up mode is not supported.

#### 12.9.3.1.3 Timers Ports

TIMER_INTR_PEND_0	TIMER Interrupt Request	Level
TIMER_TIMER_PWM_0	TIMER Timesync Event	Level

### 12.9.3.2 Timers Environment

This section describes the timers external connections (environment).

**Table 12-416. Timer I/O Signals**

Module Pin	I/O <sup>(1)</sup>	Description
TIMER_IO[9-0]	I/O	TIMER[9-0] trigger input or TIMER[9-0] output

(1) When configured for that function; I = Input, O = Output

### 12.9.3.3 Timers Functional Description

Each timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the `TIMER_IRQSTATUS_SET` and `TIMER_IRQSTATUS_CLR` register for the interrupt features, and a dedicated bit of the `TIMER_IRQWAKEEN` register for a wake-up. In addition, timers have a mechanism implemented to generate an accurate tick interrupt.

For each timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

For more information of the selection of the input clock source, see *Clocking*.

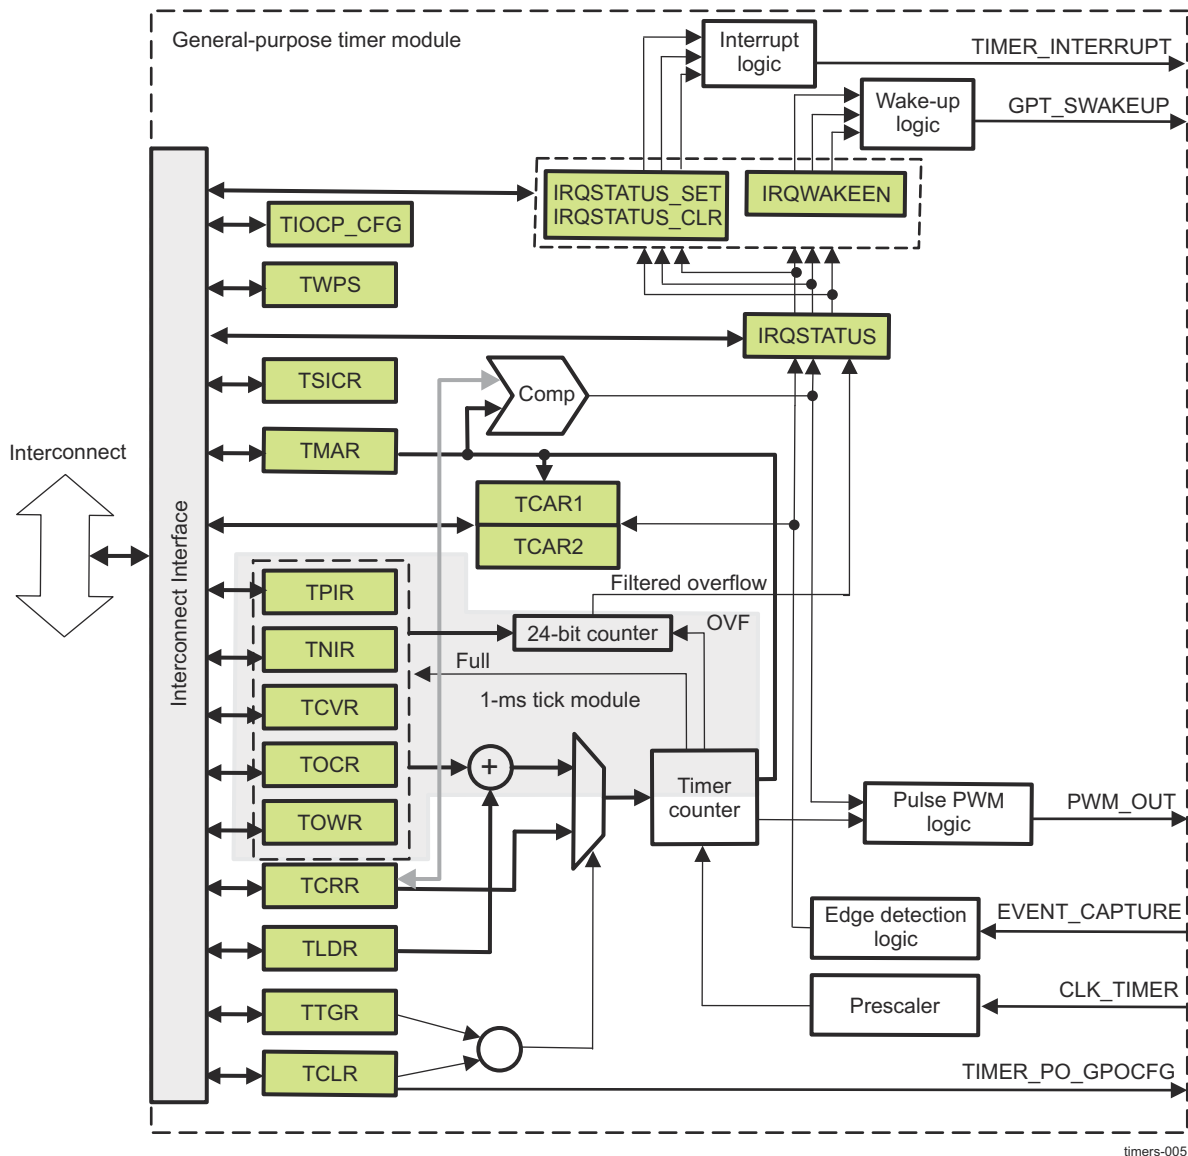

Each timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

#### 12.9.3.3.1 Timer Block Diagram

[Figure 12-489](#) is a block diagram of the timers.

### Figure 12-489. Timer Block Diagram

#### 12.9.3.3.2 Timer Power Management

### Note

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Timers Not Supported Features*.

The way the timer acknowledges the LPSC clock stop request is configurable through the `TIMER_TIOCP_CFG[3-2] IDLEMODE` bit field.

Table 12-417 lists the IDLEMODE settings and the related acknowledgment modes.

### Table 12-417. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The clock stop request is unconditionally acknowledged from the timer, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The clock stop request is never acknowledged from the timer. This mode is safe from a module point of view but is not efficient from a power-saving perspective because the clocks remain active.

**Table 12-417. IDLEMODE Settings (continued)**

IDLEMODE Value	Selected Mode	Description
10	Smart-idle	The timer acknowledges the clock stop request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and interrupt requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

**12.9.3.3.2.1 Wake-Up Capability****Note**

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Timers Not Supported Features*.

If the TIMER\_TIOCP\_CFG[3-2] IDLEMODE bit field sets the smart-idle mode or smart-idle with wake-up mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the clock stop acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if configured in smart-idle with wake-up mode.

Figure 12-490 shows the wake-up request generation.

**Figure 12-490. Wake-Up Request Generation**

The timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the Clock management sends a clock stop request. The expected source of the wake-up event is an overflow (TIMER\_TCR), a timer match (the compare result of TIMER\_TCR and TIMER\_TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER\_PIEVENTCAP).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (TIMER\_IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

**Note**

The status bit must be reset to re-enter idle mode.

### 12.9.3.3.3 Timer Software Reset

TIMER\_TIOCP\_CFG[0] SOFTRESET bit can initiate a software reset of the timer. This bit is autocleared to 0 when the reset is complete.

Before accessing or using the timer, the local host must ensure that internal reset is released by reading the TIMER\_TIOCP\_CFG[0] SOFTRESET bit. This bit monitors the internal reset status.

### 12.9.3.3.4 Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (TIMER\_IRQSTATUS\_SET) and disabled in the interrupt-disable register (TIMER\_IRQSTATUS\_CLR). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (TIMER\_IRQSTATUS).

### 12.9.3.3.5 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the TIMER\_TCLR[0] ST bit). The timer counter register (TIMER\_TCRR) can be loaded when stopped or on-the-fly (while counting). TIMER\_TCRR can be loaded directly by a TIMER\_TCRR write access with a new timer value. TIMER\_TCRR can also be loaded with the value held in the timer load register (TIMER\_TLDR) by a trigger register (TIMER\_TTGR) write access. The loading of TIMER\_TCRR is done regardless of the written value of TIMER\_TTGR. The value of TIMER\_TCRR can be read when stopped or captured on-the-fly by a TIMER\_TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the TIMER\_TCLR[1] AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the TIMER\_TCLR[1] AR bit is set to 1), TIMER\_TCRR is reloaded with the value of TIMER\_TLDR after a counting overflow occurs.

#### CAUTION

Do not put the overflow value (0xFFFF FFFF) in the TIMER\_TLDR register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the TIMER\_IRQSTATUS\_SET[1] OVF\_EN\_FLAG bit is set to 1). A dedicated output pin (POTIMERPWM) can be programmed in the TIMER\_TCLR[12] PT bit through the TIMER\_TCLR[11-10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The TIMER\_TCLR[12] PT bit selects pulse/toggle modulation (the TIMER\_TCLR[11-10] TRG bit field selects trigger mode).

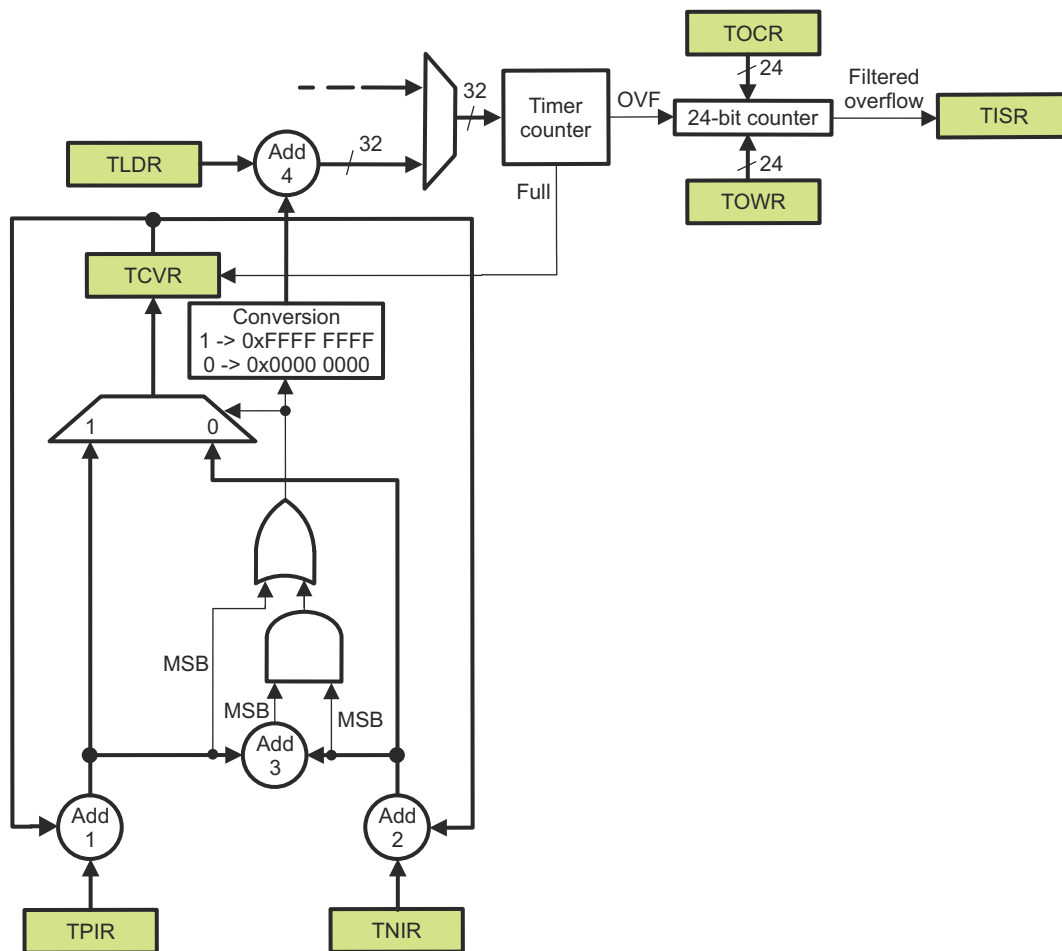

Figure 12-491 shows the TIMER\_TCRR timing value.

**Figure 12-491. TIMER\_TCRR Timing Value**

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 kHz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the `TIMER_TPIR[31-0]` `POSITIVE_INC_VALUE` bit field) and the timer negative increment register (the `TIMER_TNIR[31-0]` `NEGATIVE_INC_VALUE` bit field). An automatic adaptation mechanism is used to simplify the programming model.

timers-009

Table 12-418 lists the value loaded in the `TIMER_TCR` according to the sign of the result of `Add1`, `Add2`, and `Add3`.

---

1924 J721S2/TDA4VE/TDA4AL/TDA4VL/AM68 Processors  
Silicon Revision 1.0 Texas Instruments Families of Products

**Table 12-418. Value Loaded in TIMER\_TCCR to Generate 1-ms Tick**

Add1 MSB	Add2 MSB	Add3 MSB	Value of TIMER_TCCR Register
0	0	0	TIMER_TLDR[31-0] LOAD_VALUE bit field
0	0	1	TIMER_TLDR[31-0] LOAD_VALUE bit field
0	1	0	TIMER_TLDR[31-0] LOAD_VALUE bit field
0	1	1	TIMER_TLDR[31-0] LOAD_VALUE –1
1	0	0	N/A
1	0	1	N/A
1	1	0	TIMER_TLDR[31-0] LOAD_VALUE –1
1	1	1	TIMER_TLDR[31-0] LOAD_VALUE –1

The values of the TIMER\_TPIR and TIMER\_TNIR registers are calculated using the following formulas:

- Positive increment value =  $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] + 1) \times 1\text{e}6 - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$
- Negative increment value =  $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$

**Note**

$F_{\text{clk}}$  clock frequency (kHz)

$T_{\text{tick}}$  tick period (ms)

The timer overflow counter register (TIMER\_TOCR) and the timer overflow wrapping register (TIMER\_TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TIMER\_TOCR. When the values in the 24-bit TIMER\_TOCR match the values in the 24-bit TIMER\_TOWR and the timer overflow is asserted, the TIMER\_TOCR is reset and an interrupt is generated to the TIMER\_IRQSTATUS register.

**Note**

TIMER\_TOWR has to be set to requested value. For example, if no interrupt needs to be masked TIMER\_TOWR must be set to 0, if one interrupt needs to be masked TIMER\_TOWR must be set to 1, if two interrupts need to be masked TIMER\_TOWR must be set to 2 and so on.

It is important to have in mind that the case when FFFFFFF interrupts need to be masked is not possible.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of timers remain unchanged.

For 1-ms tick with a 32.768-kHz clock:

- TIMER\_TPIR[31-0] POSITIVE\_INC\_VALUE = 232,000
- TIMER\_TNIR[31-0] NEGATIVE\_INC\_VALUE = –768,000
- TIMER\_TLDR[31-0] LOAD\_VALUE = 0xFFFF FFE0

**Note**

Any value of the tick period can be generated with the appropriate value of the TIMER\_TPIR, TIMER\_TNIR, and TIMER\_TLDR.

By default, the TIMER\_TPIR, TIMER\_TNIR, TIMER\_TCVR, TIMER\_TOCR, and TIMER\_TOWR and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

### 12.9.3.3.6 Timer Capture Mode Functionality

When a transition is detected on the module input pin (PIEVENTCAPT), the timer value in the TIMER\_TCCR can be captured and saved in the TIMER\_TCAR1 or TIMER\_TCAR2 register function of the mode selected in the TIMER\_TCLR[13] CAPT\_MODE bit. The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

The rising edge, falling edge, or both, can be selected in the `TIMER_TCLR[9-8]` TCM bit field to trigger the timer counter capture. The module sets the `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` bit when an active edge is detected, and at the same time, the counter value `TIMER_TCR` is stored in timer capture register `TIMER_TCAR1` or `TIMER_TCAR2`, as follows:

- If the `TIMER_TCLR[13] CAPT_MODE` bit is 0, on the first enabled capture event, the value of the counter register is saved in the `TIMER_TCAR1` register, and the next events are ignored (no update on the `TIMER_TCAR1` register and no interrupt triggering) until the detection logic is reset or the `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` is cleared by writing 1 to it.
- If the `TIMER_TCLR[13] CAPT_MODE` bit is 1, on the first enabled capture event, the value of the counter register is saved in the `TIMER_TCAR1` register, and on the second enabled capture event, the value of the counter register is saved in the `TIMER_TCAR2` register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on `TIMER_TCAR1/TIMER_TCAR2` and no interrupt triggering) until the detection logic is reset or the `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the `PIEVENTCAPT` input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` bit is cleared by writing 1 to it or when the edge detection mode bits (the `TIMER_TCLR[9-8]` TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (`PIEVENTCAPT`). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the `TIMER_IRQSTATUS_SET[2] TCAR_EN_FLAG` bit. See the examples in [Figure 12-493](#) and [Figure 12-494](#).

In [Figure 12-493](#), the value of the `TIMER_TCLR[9-8]` TCM bit field is 1h, and the `TIMER_TCLR[13] CAPT_MODE` bit is 0. Only the rising edge of `PIEVENTCAPT` triggers a capture in the `TIMER_TCAR1` and `TIMER_TCAR2` registers, and only the `TIMER_TCAR1` register updates.

**Figure 12-493. Capture Wave Example for `TIMER_TCLR[13] CAPT_MODE = 0`**

In [Figure 12-494](#), the value of the `TIMER_TCLR[9-8]` TCM bit field is 1h, and the `TIMER_TCLR[13] CAPT_MODE` bit is 1. Only the rising edge of `PIEVENTCAPT` triggers a capture in the `TIMER_TCAR1` register on the first enabled event, and the `TIMER_TCAR2` register updates on the second enabled event.

**Figure 12-494. Capture Wave Example for TIMER\_TCLR[13] CAPT\_MODE = 1**

#### 12.9.3.3.7 Timer Compare Mode Functionality

When the compare-enable register `TIMER_TCLR[6]` CE bit is set to 1, the timer value (the `TIMER_TCCR[31-0]` `TIMER_COUNTER` bit field) is continuously compared to the value held in the timer match register (`TIMER_TMAR`). The value of the `TIMER_TMAR[31-0]` `COMPARE_VALUE` bit field can be loaded at any time (timer counting or stopped). When the `TIMER_TCCR` and the `TIMER_TMAR` values match, an interrupt is issued, if the `TIMER_IRQSTATUS_SET[0]` `MAT_EN_FLAG` bit is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the `TIMER_TMAR` before setting the `TIMER_TCLR[6]` CE bit.

The dedicated output pin (`POTIMERPWM`) can be programmed in the `TIMER_TCLR[12]` PT bit through the `TIMER_TCLR[11-10]` TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

#### 12.9.3.3.8 Timer Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the `TIMER_TCLR[5]` PRE bit is set. The `TIMER_TCLR[4-2]` PTV bit field sets the  $2^n$  division ratio (prescaler value is  $2^{(PTV + 1)}$ ). The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 12-419 lists the prescaler/timer reload values versus contexts.

**Table 12-419. Prescaler/Timer Reload Values Versus Contexts**

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	<code>TIMER_TLDR[31-0]</code>
<code>TIMER_TCCR</code> write	Reset	<code>TIMER_TCCR[31-0]</code>
<code>TIMER_TTGR</code> write	Reset	<code>TIMER_TLDR[31-0]</code>
Stop	Reset	Frozen

#### 12.9.3.3.9 Timer Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM (`POTIMERPWM`) output pin can be configured to toggle on an event. The `TIMER_TCLR[11-10]` TRG bit field determines on which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

### Note

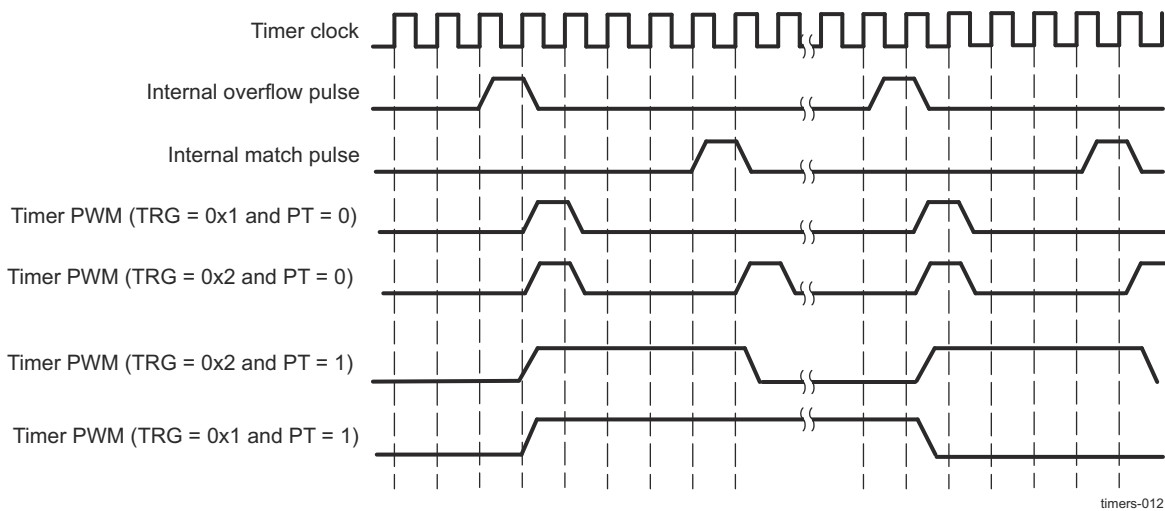

In toggle mode, when `TIMER_TCLR[11-10] TRG = 0x2` (overflow and match), the first event that toggles the PWM line is an overflow event.

The `TIMER_TCLR[7] SCPWM` bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the `TIMER_TCLR[11-10] TRG` bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

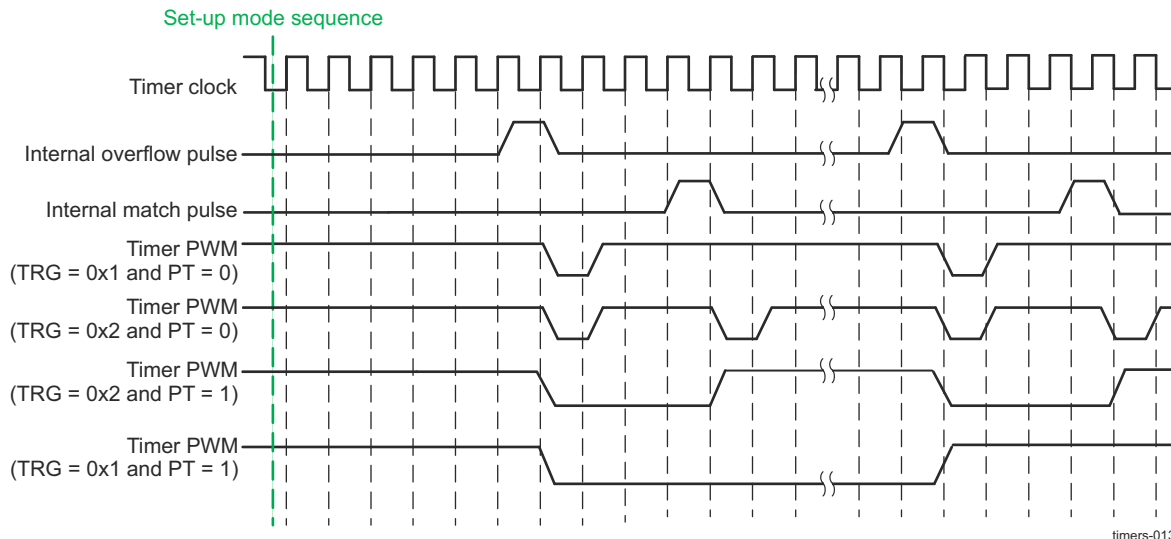

In [Figure 12-495](#), the internal overflow pulse is set each time the  $(0xFFFF\ FFFF - \text{TIMER\_TLDR}[31-0] \text{ LOAD\_VALUE} + 1)$  value is reached, and the internal match pulse is set when the counter reaches the value of `TIMER_TMAR`. Depending on the value of the `TIMER_TCLR[12] PT` bit and `TIMER_TCLR[11-10] TRG` bit field, the timer provides pulse or PWM event on the output pin (`POTIMERPWM`).

The `TIMER_TLDR` and `TIMER_TMAR` must keep values below the overflow value (`0xFFFF FFFF`) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the `TIMER_TMAR` and the value in the `TIMER_TLDR` must be at least two units. When match event is used, the compare mode `TIMER_TCLR[6] CE` bit must be set.

In [Figure 12-495](#), the `TIMER_TCLR[7] SCPWM` bit is set to 0. In [Figure 12-496](#), the `TIMER_TCLR[7] SCPWM` bit is set to 1. To obtain the desired wave form, start the counter at `0xFFFF FFFE` value (to ensure an overflow first) or adjust the line polarity (`TIMER_TCLR[7] SCPWM` bit).

**Figure 12-495. Timing Diagram of PWM With `TIMER_TCLR[7] SCPWM` Bit = 0**

**Figure 12-496. Timing Diagram of PWM With TIMER\_TCLR[7] SCPWM Bit = 1**

#### 12.9.3.3.10 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the TIMER\_TCLR[5] PRE bit and TIMER\_TCLR[4-2] PTV bit field)
- Value loaded into the TIMER\_TLDR

Table 12-420 lists the prescaler clock ratio values.

**Table 12-420. Prescaler Clock Ratio Values**

TIMER_TCLR[5] PRE	TIMER_TCLR[4-2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

$$\text{OVF\_Rate} = (\text{0xFFFF FFFF} - \text{TIMER\_TLDR} + 1) \times (\text{timer-functional clock period}) \times \text{PS}$$

With (timer-functional clock period) =  $1/(\text{timer-functional clock frequency})$  and  $\text{PS} = 2^{(\text{PTV} + 1)}$  if prescaler is enabled, or  $\text{PS} = 1$  if prescaler is disabled.

#### CAUTION

Internal resynchronization causes any write to the TIMER\_TCLR[1] ST bit to have some latency before the register is updated:

$2.5 \times \text{functional clock cycles}$  write\_TIMER\_TCLR\_latency  $3.5 \times \text{functional clock cycles}$

Remember to consider this latency whenever the timer must be started or stopped by a software change to the TIMER\_TCLR[1] ST bit.

**CAUTION**

- In non-PWM mode, TIMER\_TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, TIMER\_TLDR must be maintained at less than or equal to 0xFFFF FFDD.

For example, with a timer clock input of 32 kHz and the TIMER\_TCLR[5] PRE bit set to 0, the timer output period is as listed in [Table 12-421](#).

**Table 12-421. Value and Corresponding Interrupt Period**

TIMER_TLDR[31-0] LOAD_VALUE	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 $\mu$ s
0xFFFF FFFE	62.5 $\mu$ s

**12.9.3.3.11 Timer Under Emulation**

During emulation mode, the timer continues to run according to the value of the TIMER\_TIOCP\_CFG[1] EMUFREE bit.

If the TIMER\_TIOCP\_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the TIMER\_TIOCP\_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (MCU\_TIMER\_IO[9-0] or TIMER\_IO[7-0]) is internally synchronized on two timer-clock rising edges.

**12.9.3.3.12 Accessing Timer Registers**

All accesses are posted mode, under the assumption that  $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$ , until software reconfiguration. In addition, it is not recommended to access the timer registers prior to the PLLs generating the timer and interface clocks have been configured and the clocks have stabilized. All registers are 32 bits wide, accessible through the configuration interface with 32-bit access (read/write).

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- TIMER\_TCLR
- TIMER\_TCRR
- TIMER\_TLDR
- TIMER\_TTGR
- TIMER\_TMAR
- TIMER\_TPIR
- TIMER\_TNIR
- TIMER\_TCVR
- TIMER\_TOCR
- TIMER\_TOWR

The following registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one interface clock cycle from command assertion:

- TIMER\_TIDR
- TIMER\_TIOCP\_CFG
- TIMER\_IRQSTATUS
- TIMER\_IRQSTATUS\_RAW
- TIMER\_IRQSTATUS\_SET
- TIMER\_IRQSTATUS\_CLR
- TIMER\_IRQWAKEEN
- TIMER\_TWPS
- TIMER\_TSICR

### 12.9.3.3.12.1 Writing to Timer Registers

The host uses the configuration interface to write to the following registers synchronously with the timer interface clock:

- TIMER\_TLDR
- TIMER\_TCRR
- TIMER\_TCLR
- TIMER\_TIOCP\_CFG
- TIMER\_IRQSTATUS
- TIMER\_IRQSTATUS\_SET
- TIMER\_IRQSTATUS\_CLR
- TIMER\_IRQWAKEEN
- TIMER\_TTGR
- TIMER\_TSICR
- TIMER\_TMAR
- TIMER\_TPIR
- TIMER\_TNIR
- TIMER\_TCVR
- TIMER\_TOCR
- TIMER\_TOWR

#### 12.9.3.3.12.1.1 Write Posting Synchronization Mode

This mode is used if the TIMER\_TSICR[2] POSTED bit is set to 1 (default value).

This mode uses a posted write scheme to update any internal register (TIMER\_TCLR, TIMER\_TCRR, TIMER\_TLDR, TIMER\_TTGR, TIMER\_TMAR, TIMER\_TPIR, TIMER\_TNIR, TIMER\_TCVR, TIMER\_TOCR, and TIMER\_TOWR). Therefore, the write transaction is immediately acknowledged on the configuration interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect, nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status (TIMER\_TWPS) register. In this mode, it is mandatory that software check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the interface clock. Consequently, any read access to TIMER\_TCRR does not add any resynchronization latency; the current value is always available.

---

#### Note

Because the overflow IRQ is generated when the value of TIMER\_TCRR reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of ( $1 \times PS \times$  timer functional clock period) before any read access to TIMER\_TCRR to ensure a correct reading of its content.

---

---

#### Note

If TIMER\_TTGR register is written during a posted write to TIMER\_TCRR, the value to be written to TIMER\_TCRR will be discarded.

If a posted write to TIMER\_TCVR is started, the user must not write to TIMER\_TPIR or TIMER\_TNIR before the TIMER\_TCVR write is finished, because the value of TIMER\_TCVR is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

---

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range:  $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$ .

### 12.9.3.3.12.1.2 Write Nonposting Synchronization Mode

This mode is used if the `TIMER_TSICR[2] POSTED` bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the configuration interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the configuration interface frequency and the timer clock frequency.

### 12.9.3.3.12.2 Reading From Timer Counter Registers

#### Note

LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

The `TIMER_TCRR` is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. This capture scheme is also performed for the `TIMER_TCAR1` and `TIMER_TCAR2` registers as they can be changed due to internal processes too.

#### 12.9.3.3.12.2.1 Read Posted

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. The recommended functional frequency range is  $\text{freq}(\text{timer}) < \text{freq}(\text{interface clock})/4$ .

Read posted mode is used if `TIMER_TSICR[2] POSTED = 0x1` or `TIMER_TSICR[3] READ_MODE` is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the configuration interface, prior to the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to `TIMER_TCRR`, `TIMER_TCAR1`, `TIMER_TCAR2`, `TIMER_TCVR`, and `TIMER_TOWR`, which needs resynchronization from functional to interface clock domains.

Note that in Posted mode, if the `TIMER_TCRR` is read immediately after wake-up and the interface clock is off during idle state, then it is possible to get an old value from just before going to idle state due to the fact the interface clock is needed for synchronization.

In order to avoid this situation, another synchronization mechanism is used for the first read operation after idle state. The `TIMER_TSICR[4] READ_AFTER_IDLE` bit is used to enable/disable the mechanism.

When the synchronization mechanism is disabled (`READ_AFTER_IDLE` bit is set to 1), first read transaction takes only 2 interface clock cycles, but the read value of `TIMER_TCRR` could be wrong.

When the synchronization mechanism is enabled (`READ_AFTER_IDLE` bit is set to 0), first read value of `TIMER_TCRR` is correct, but the read transaction takes more than 2 interface clock cycles.

#### 12.9.3.3.12.2.2 Read Non-Posted

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. Recommended functional frequency range is  $\text{freq}(\text{timer}) \geq \text{freq}(\text{interface clock})/4$ .

Read non-posted mode is used if `TIMER_TSICR[2] POSTED = 0x0` and `TIMER_TSICR[3] READ_MODE = 0x1`. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the configuration interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to `TIMER_TCRR`, `TIMER_TCAR1`, `TIMER_TCAR2`, `TIMER_TCVR`, and `TIMER_TOWR`, which need resynchronization from functional to interface clock domains.

### 12.9.3.3.13 Timer Posted Mode Selection

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are `TIMER_TCLR`, `TIMER_TLDR`, `TIMER_TCR`, `TIMER_TTGR`, `TIMER_TMAR`, `TIMER_TPIR`, `TIMER_TNIR`, `TIMER_TCV`, `TIMER_TOCR`, and `TIMER_TOWR`. For read operation, the registers affected by this selection are: `TIMER_TCR`, `TIMER_TCAR1`, `TIMER_TCAR2`, `TIMER_TCV`, and `TIMER_TOWR`.

The interface clock domain synchronous registers `TIMER_TIDR`, `TIMER_TIOCP_CFG`, `TIMER_IRQSTATUS`, `TIMER_IRQSTATUS_SET`, `TIMER_IRQWAKEEN`, `TIMER_TWPS`, and `TIMER_TSICR` are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one interface clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in `TIMER_TSICR[2]` `POSTED` bit. The `TIMER_TSICR[3]` `READ_MODE` defines how the read operation is performed when the module is configured in non-posted mode (see `TIMER_TSICR`). The following cases are possible:

- `TIMER_TSICR[2]` `POSTED` = 0x1 and `TIMER_TSICR[3]` `READ_MODE` = x (don't care): read and write operations are expected in posted mode.
- `TIMER_TSICR[2]` `POSTED` = 0x0 and `TIMER_TSICR[3]` `READ_MODE` = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.
- `TIMER_TSICR[2]` `POSTED` = 0x0 and `TIMER_TSICR[3]` `READ_MODE` = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

### 12.9.3.4 Timers Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

#### 12.9.3.4.1 Timer Operational Mode Configuration

##### 12.9.3.4.1.1 Timer Mode

##### 12.9.3.4.1.1.1 Main Sequence – Timer Mode Configuration

[Table 12-422](#) lists the steps in the timer mode configuration.

**Table 12-422. Timer Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Enable overflow interrupt.	TIMER_IRQSTATUS_SET[1] OVF_EN_FLAG	0x1
Load timer counter value.	TIMER_TCRR	0x-
Load timer load value.	TIMER_TLDR	0x-
Start the timer.	TIMER_TCLR[0] ST	0x1

##### 12.9.3.4.1.2 Timer Compare Mode

##### 12.9.3.4.1.2.1 Main Sequence – Timer Compare Mode Configuration

[Table 12-423](#) lists the steps in the timer compare mode configuration.

**Table 12-423. Timer Compare Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Enable match interrupt.	TIMER_IRQSTATUS_SET[0] MAT_EN_FLAG	0x1
Load timer counter value.	TIMER_TCRR	0x-
Load timer compare value.	TIMER_TMAR	0x-
Enable compare mode.	TIMER_TCLR[6] CE	0x1
Start the timer.	TIMER_TCLR[0] ST	0x1

##### 12.9.3.4.1.3 Timer Capture Mode

##### 12.9.3.4.1.3.1 Main Sequence – Timer Capture Mode Configuration

[Table 12-424](#) lists the steps in the timer capture mode configuration.

**Table 12-424. Timer Capture Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See <a href="#">Section 12.9.3.4.1.3.2</a> .	
Enable capture interrupt.	TIMER_IRQSTATUS_SET[2] TCAR_EN_FLAG	0x1
Start the timer.	TIMER_TCLR[0] ST	0x1
Detect event.	See <a href="#">Section 12.9.3.4.1.3.3</a> .	

##### 12.9.3.4.1.3.2 Subsequence – Initialize Capture Mode

[Table 12-425](#) lists the steps to initialize capture mode.

**Table 12-425. Initialize Capture Mode**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-

**Table 12-425. Initialize Capture Mode (continued)**

Step	Register/Bit Field/Programming Model	Value
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Select TIMER[19-0] or MCU_TIMER[9-0] Capture input at device pins TIMER_IO[7-0] for TIMER[19-0] or at pins MCU_TIMER_IO[9-0] for MCU_TIMER[9-0].	TIMER_TCLR[14] GPO_CFG	0x1
Select single or second event capture.	TIMER_TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	TIMER_TCLR[9-8] TCM	0x-

#### 12.9.3.4.1.3.3 Subsequence – Detect Event

Table 12-426 lists the steps in detecting an event.

**Table 12-426. Detect Event**

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	TIMER_IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	TIMER_TCAR1 and/or TIMER_TCAR2	
Clear capture interrupt request.	TIMER_IRQSTATUS[2] TCAR_IT_FLAG	0x1

#### 12.9.3.4.1.4 Timer PWM Mode

##### 12.9.3.4.1.4.1 Main Sequence – Timer PWM Mode Configuration

Table 12-427 lists the steps in the timer PWM mode configuration.

**Table 12-427. Timer PWM Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Select trigger output mode.	TIMER_TCLR[11-10] TRG	0x-
Select pulse or toggle modulation PWM mode.	TIMER_TCLR[12] PT	0x-
Select TIMER[19-0] or MCU_TIMER[9-0] PWM output at device pins TIMER_IO[7-0] for TIMER[19-0] or at pins MCU_TIMER_IO[9-0] for MCU_TIMER[9-0].	TIMER_TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	TIMER_TCLR[7] SCPWM	0x-
Load timer load value.	TIMER_TLDR	0x-
Load timer compare value.	TIMER_TMAR	0x-
Enable compare.	TIMER_TCLR[6] CE	0x1
Start the timer.	TIMER_TCLR[0] ST	0x1

## 12.10 Internal Diagnostics Modules

This section describes the internal diagnostics modules in the device.

### 12.10.1 Dual Clock Comparator (DCC)

This section describes the Dual Clock Comparator (DCC) modules in the device.

#### 12.10.1.1 DCC Overview

The Dual Clock Comparator (DCC) is used to determine the accuracy of a clock signal during the time execution of an application. Specifically, the DCC is designed to detect drifts from the expected clock frequency. The desired accuracy can be programmed based on calculation for each application. The DCC measures the frequency of a selectable clock source using another input clock as a reference.

##### 12.10.1.1.1 DCC Features

The DCC uses two independent clock sources to detect when one is out of specification. Each DCC module implements the following features:

- Two independent counter blocks count clock pulses from each clock source
- Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
- Configurable timebase for error signal
- Error signal generation when one of the clocks is out of specification
- Clock frequency measurement

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

##### 12.10.1.1.2 DCC Not Supported Features

The DCC does not support the following features:

- Debug suspend functionality deprecated. Software will have to disable DCCs if it starts messing with clocks during debug.

##### 12.10.1.1.3 DCC Ports

**Table 12-428. DCC Clocks and Resets**

Clocks	
Module Clock Input	Description
DCC_FICLK	DCC interface and functional clock
Resets	
Module Reset Input	Description
DCC_RST	DCC asynchronous module reset

**Table 12-429. DCC Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
DCC_INTR_DONE_LEVEL_0	DCC one-shot mode complete interrupt	Level
DCC_INTR_ERR_LEVEL_0	DCC error interrupt	Level

### 12.10.1.2 DCC Functional Description

The DCC module supports two selectable clock sources for Counter0 and Counter1. Figure 12-497 shows the DCC functional block diagram.

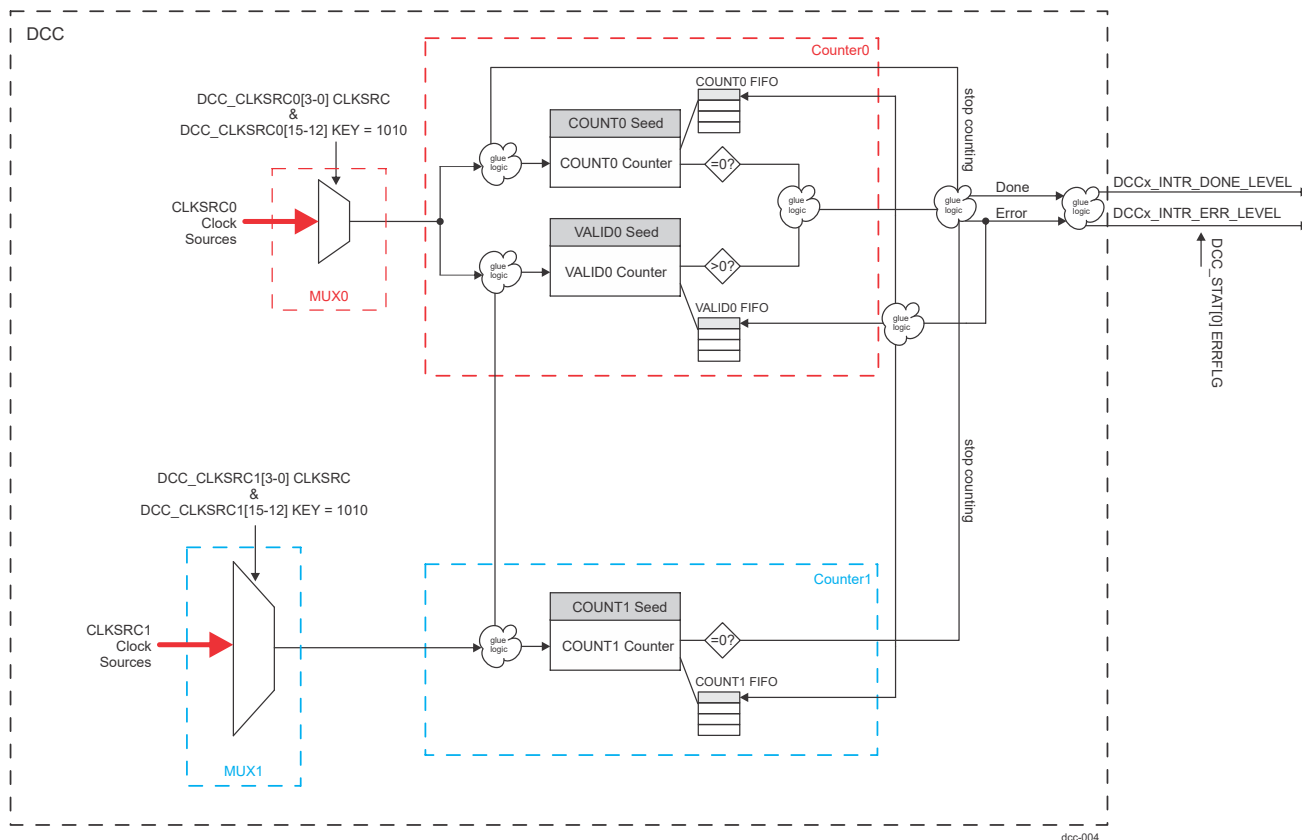

Figure 12-497. DCC Functional Block Diagram

#### 12.10.1.2.1 DCC Counter Operation

##### Note

For detailed DCC compute calculations, refer to [Continuous Monitor of the PLL Frequency With the DCC App Note](#).

The DCC has two parallel counters that count clock pulses for two independent clock sources:

- Counter0 generates a fixed-width counting window (VALID0) after a pre-programmed number of pulses (COUNT0). The values for VALID0 and COUNT0 can be programmed in DCC\_VALIDSEED0 and DCC\_CNTSEED0 registers respectively.
- Counter1 generates a fixed-width pulse (1 cycle) after a pre-programmed number of pulses (COUNT1). This pulse sets an error signal if Counter1 does not reach 0 during the time when VALID0 is running. The seed value for COUNT1 can be programmed in DCC\_CNTSEED1 register.

The error signal is generated by any one of the following conditions:

- Clock1 expires before the COUNT0 reaches 0.
- Clock1 expires after both COUNT0 and VALID0 reach 0.
- Clock1 not present.
- Clock0 not present.

Any of these errors causes the counters to stop counting. An application must then read out the counter values to determine what caused the error. Once the error is detected, the counters are stopped after 3 FICLK and 2 source clock cycles due to the cross clock domain synchronisation.

Reloads or restarts occur under two conditions:

- The module is reset or restarted through software (that is, software starts the module after reset, or software checks an error condition and decides to restart the module).
- COUNT0, COUNT1, and VALID0 all reach 0 without error.

### CAUTION

The DCC module does not check jitter for Clock0 or Clock1.

As the counter preset signal is synchronized to either of the source clock domains, the counters begin downcounting after two corresponding source clock cycles.

The error signal is captured to the FICLK domain. There is 1 FICLK period uncertainty on either side of the fixed width counting window (VALID0) in generating the error signal since the counters work in different clock domains. This should be accounted for when setting the count value for VALID0.

Figure 12-498 through Figure 12-502 shows examples of counters relationship and error generation.

**Figure 12-498. DCC Clock0 and Clock1 With no Error**

**Figure 12-499. DCC Clock1 slower than Clock0 results in an error and stops counting**

**Figure 12-500. DCC Clock1 faster than Clock0 results in an error and stops counting**

**Figure 12-501. DCC Clock1 not present results in an error and stops counting**

**Figure 12-502. DCC Clock0 not present results in an error and stops counting**

#### 12.10.1.2.2 DCC Low Power Mode Operation

The DCC module does not function in Low Power Mode. It is the responsibility of software to stop the module before entering low power mode and to restart the module after exiting low power mode.

### 12.10.1.2.3 DCC Suspend Mode Behavior

The DCC module will continue running regardless of the state of emulation. All registers are readable via emulation reads.

### 12.10.1.2.4 DCC Single-Shot Mode

The DCC can be programmed to count down one time using single-shot mode. In this mode, the DCC stops operation when both COUNT0 and VALID0 reach 0.

At the end of one sequence in single-shot mode the DCC\_GCTRL[3-0] DCCENA bitfield is set to disabled, which stops further counting. Single-shot mode is enabled from the DCC\_GCTRL[11-8] SINGLESOT bitfield.

At the end of one sequence in single-shot mode, if there is no error which stops counting, then the done status bit is set in the DCC\_STAT[1] DONEFLG bitfield and a done interrupt DCCx\_INTR\_DONE\_LEVEL is generated. Software must clear the done bit before restarting the counting.

### 12.10.1.2.5 DCC Continuous mode

When DCC runs in continuous mode both the counts shall get reloaded with seed value upon completion of counts without error. If the counts end in error DCC stops the operation and counts are not reloaded.

#### 12.10.1.2.5.1 DCC Continue on Error

During debug, if there are events which are causing clocks to be anomalous over short period covering more than one evaluation window then it would be important to capture trajectory of error event and period around such event. To allow capturing the successive error events DCC can be programmed to continue after error. DCC\_GCTRL2 [3-0] CONT\_ON\_ERR shall be set to value other than "0101" to enable this mode. It is recommended to write "1010" to avoid single soft errors.

#### 12.10.1.2.5.2 DCC Error Count

DCC also counts the number of error pulses generated since reset or since last time the error count is cleared. This is read/write register for CPU to clear when new trace of number of errors is required to be maintained.

### 12.10.1.2.6 DCC Control and count hand-off across clock domains

As the counters run in two different selectable clock domains and the register interface runs on the fixed bus clock domain, control signals and counter value hand-off have synchronizers implemented. These add to the margins of error while comparing the counts.

1. With all three counts synchronized to FICLK domain for comparison error detection there is delay in terms of FICLK domain.
2. Based on the error signal, the enable for the counters is synchronized back to the respective clock domains of the counters, which adds latency in terms of clock periods which are different, this would create a skew between start of count. Depending upon frequency ratios of the clocks used, the difference between two could vary.

Application needs to consider the worst case delay differences while measuring the clocks.

### 12.10.1.2.7 DCC Error Trajectory record

Once the clock errors out, the host can read the counter values to determine the extent of error to analyze type of failure. For short window comparisons this would become difficult, specially if there are back to back errors due to some transient event. Secondly, for random events which can cause an interrupt during the critical phase of application running, then event if not recorded may get overwritten and also not provide meaningful trace of error.

#### 12.10.1.2.7.1 DCC FIFO capturing for Errors

DCC provides the FIFO for capturing COUNT0, VALID0, and COUNT1 information which captures all three counts upon "Error" event. For "Done" event no results are captured by default.

#### 12.10.1.2.7.2 DCC FIFO in continuous capture mode

To track the VALID0 counter values regardless of "Error" or not, FIFOs can be configured to capture the count for each compare window. This is useful in validation and characterization exercise. DCC\_GCTRL2[11-7]

FIFO\_NONERR control when set to value other than "0101" this mode is set; it is recommended to write "1010" to avoid single soft errors. Note, this capture is applicable only in continuous mode and not in single shot mode.

#### **12.10.1.2.7.3 DCC FIFO Details**

The FIFO is 4 deep for each count and updates new count information for all the non-full FIFOs. Information is updated on every configured trigger of error or cycle completion. If full, the next values are not written till at-least one entry is read. Application owns responsibility to read the FIFOs uniformly to keep synchronisation between three entries of the FIFO. Both empty and full indications for individual FIFOs is provided through the DCC\_STATUS2.

#### **12.10.1.2.7.4 DCC FIFO Debug mode behavior**

Upon debug access, the FIFO pointers should not advance hence not impacting the functional behavior. This requirement is same as other functional blocks in the device.

#### **12.10.1.2.8 DCC Count read registers**

DCC has provision to read the counts during operation. This is performed using DCC\_CNT0, DCC\_VALID0, and DCC\_CNT1 registers. Read from these registers in default mode allows reading the present value of count. This is useful when in single shot mode or mode where DCC stops upon error.

These registers can be used to read the FIFO through the DCC\_GCTRL2[7-4] FIFO\_READ configuration. Reads on the empty FIFO shall provide the contents of last pointed location. Application shall track the empty/full conditions of the FIFOs to track the count records consistently.

Regardless of FIFO\_READ configuration, the FIFO internally keeps updating records based on configured triggers till full.

## 12.10.2 Error Signaling Module (ESM)

This section describes the Error Signaling Module (ESM) in the device.

### 12.10.2.1 ESM Overview

The Error Signaling Module (ESM) aggregates events and/or errors from throughout the device into one location. It can signal both low and high priority interrupts to a processor to deal with an event and/or manipulate an I/O error pin to signal an external hardware that an error has occurred. Therefore an external controller is able to reset the device or keep the system in a safe, known state.

#### 12.10.2.1.1 ESM Features

Each ESM module implements the following features:

- Up to 1024 error event inputs
  - Implemented in groups of 32 events
  - Level or Pulse inputs (Pulse inputs are triple redundant)
- Selectable low and high priority interrupt error pin prioritization of each error event
- Error pin to signal severe device failure
  - Support of level or PWM modes
- Configurable timebase for error signal
- Error forcing capability
- Internal redundant flops on critical fields

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

#### 12.10.2.1.2 ESM Ports

**Table 12-430. ESM Clocks and Resets**

Clocks	
Module Clock Input	Description
ESM_FICLK	ESM Interface and Functional clock
Resets	
Module Reset Input	Description
ESM_RST	ESM Asynchronous module reset
ESM_POR_RST	ESM Power-on module reset

**Table 12-431. ESM Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
ESM_ESM_INT_CFG_LVL_0	ESM configuration error interrupt	Level
ESM_ESM_INT_LOW_LVL_0	ESM low priority interrupt	Level
ESM_ESM_INT_HI_LVL_0	ESM high priority interrupt	Level

### 12.10.2.2 ESM Environment

This section describes the ESM external connections (environment).

[Table 12-432](#) describes the ESM I/O signals.

**Table 12-432. ESM I/O Signals**

Module Pin	I/O <sup>(1)</sup>	Description
ERR_O	O	Active low error output signal.

(1) O = Output;

### 12.10.2.3 ESM Functional Description

The Error Signaling Module (ESM) centralizes fault reports. It provides mechanisms to classify errors by severity and to provide programmable error response. The error classification in the ESM is determined by programmed configuration for each individual error input. For each individual error input the configuration can be set to assert an output error pin, or generate an interrupt to a CPU, or both. When an individual error input is configured to generate an interrupt, the configuration will also select whether the interrupt that is generated will be one of high priority or low priority.

By reporting the faults in a central location, the system may determine what caused the fault and what action can be taken. In general, the faults can be split into two categories:

- Corrected faults
- Non-corrected faults

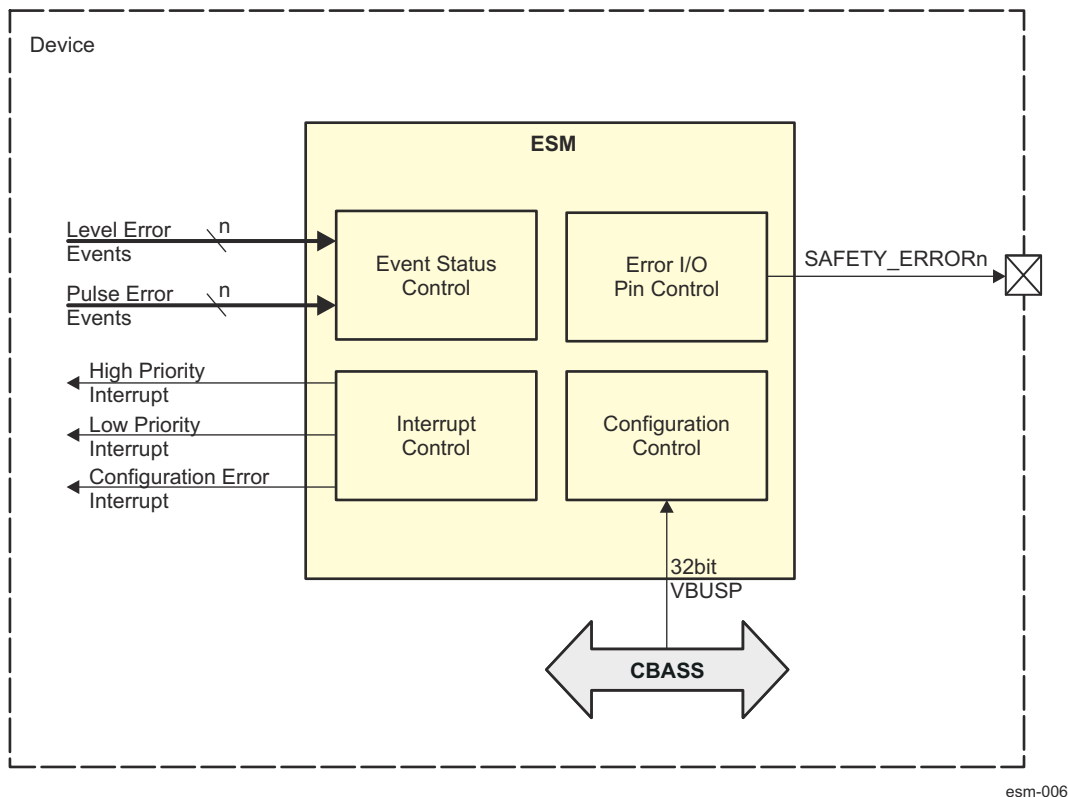

The ESM reports errors in two ways:

- An interrupt to a processor in the device. This allows the device to analyze and try to recover from an error.
- An external ERROR pin. This allows the system outside of the SoC to monitor for potentially fatal errors(errors that the device cannot self-recover from). Moreover, the external I/O (ERROR pin) can operate in level or PWM modes. In level mode, the output will remain asserted (active low) for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin will go inactive (high). If it does not go inactive in that time, then an external agent should intervene, as there may be an unrecoverable error. In PWM mode, the error will cause the output pin to maintain its value for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin will continue the PWM pattern. If it does not go inactive in that time, then an external agent should intervene, as there may be an unrecoverable error.

Both mechanisms can be used at the same time for the same fault, signaling both an interrupt and the external ERROR pin. This allows the device to attempt to recover, but if it fails, then the external system is still alerted. If it succeeds, then it can remove the ERROR pin assertion so that the external system knows that a potentially unsafe condition was avoided.

Lastly, the ESM does not specify any methods of intervention, only the process of alerting internal CPUs and external monitor(s) of an existing error event.

[Figure 12-503](#) shows the ESM module block diagram. Note that not all instances may be pinned out in the device. For more information, see *ESM Environment*.

**Figure 12-503. ESM Block Diagram**

#### 12.10.2.3.1 ESM Interrupt Requests

The ESM module generates three output interrupts to the device interrupt controllers:

- Configuration error interrupt (see [Section 12.10.2.3.1.1](#))
- High priority error interrupt (see [Section 12.10.2.3.1.2](#))
- Low priority error interrupt (see [Section 12.10.2.3.1.3](#))

The error interrupt outputs are provided so that a processor in the device can be signaled to intervene when an error event occurs. Each error event input can be enabled, via software, to cause an error interrupt to occur (via the ESM\_INTR\_EN\_SET $j$  register). Additionally, each error event input can be programmed to influence either the low priority (default) interrupt or the high priority interrupt (via the ESM\_INT\_PRIO $j$ ). The low priority interrupt is intended for events that are of interest, but do not require immediate intervention. For example, an indication that there was a single bit error that was corrected may signal a low priority interrupt, so that information can be collected for statistical purposes. A high priority interrupt is intended for events that need immediate attention. For example, an indication that there was an uncorrected two-bit error may be signaled as a high priority interrupt.

##### 12.10.2.3.1.1 ESM Configuration Error Interrupt

The configuration error interrupt (ESM\_INT\_CFG\_LVL\_0) indicates that there is an inconsistency in the configuration of one (or more) error group  $j$  registers (MMRs).

In such inconsistency in the internal copies of any of the MMRs caused by fault associated with error group  $j$ , the corresponding raw status will be set in the ESM\_ERR\_RAW register. If the corresponding bit is enabled in the ESM\_ERR\_EN\_SET register, a configuration error interrupt will be triggered.

When a configuration error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_ERR\_STS register to determine which group has a configuration error
2. Write the correct values to the following group registers:

---

**Note**

If there has been a configuration error, the values in the below registers cannot be guaranteed to be correct anymore. Therefore, software should maintain a copy of the correct values prior to an error to ensure that they can be re-programmed with the correct configuration.

---

- a. ESM\_INTR\_EN\_SET\_j
- b. ESM\_INTR\_EN\_CLR\_j
- c. ESM\_INT\_PRIO\_j
- d. ESM\_PIN\_EN\_SET\_j
- e. ESM\_PIN\_EN\_CLR\_j

3. Service any pending interrupts in steps 4, 5, and 6 below
- 

**Note**

The raw status of any pending interrupts may be inconsistent. Servicing the interrupt will return it to consistency via the error group ESM\_RAW\_j register.

---

4. Write 0x1 to the appropriate bits in the ESM\_ERR\_STS register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no additional errors, the level interrupt will go low
5. Write the end of interrupt vector to the ESM\_EOI register
  - a. If there are additional configuration error interrupts pending, then a new pulse will be generated. The level interrupt will remain asserted and is unaffected by EOI.
  - b. If there are no additional low priority error interrupts pending, there will be no new pulse.

#### 12.10.2.3.1.2 ESM Low Priority Error Interrupt

Events mapped to the low priority error interrupt (ESM\_INT\_LOW\_LVL\_0) are intended to be events of interest that should be addressed eventually, not events that require immediate attention. An example would be an event indicating a corrected error. The system may want to track this for statistical purposes, but it does not require immediate attention.

Any error event can be mapped to the low priority error interrupt. A low priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM\_INTR\_EN\_SET\_j register) and mapped to the low priority error interrupt (via ESM\_INT\_PRIO\_j register) and the raw status is set (via the ESM\_RAW\_j register).

When a low priority error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_LOW\_PRI register
    - a. If both [31-16]PLS and [15-0]LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
    - b. If either [31-16]PLS or [15-0]LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
      - i. First option: Record the value in [31-16]PLS and [15-0]LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority low priority error event
- 

**Note**

The global event map is neither defined by nor maintained in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

---

- ii. Second option:
  1. Read the ESM\_LOW register to determine which event group(s) have pending low priority error interrupts

2. Read the desired error group  $j$  ESM\_STS\_j register
  3. Identify which low priority interrupt to service
2. Determine, based on the global event map for the device, where the error event came from
  3. Service the error event based on the IP's specification:
    - a. The system may take several actions including (but not limited to):
      - i. Fixing the error
      - ii. Resetting the errored IP peripheral
      - iii. Resetting the device
      - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.10.2.3.1.2.1](#)) or pulse (see [Section 12.10.2.3.1.2.2](#)) event.

#### **12.10.2.3.1.2.1 ESM Low Priority Error Level Event**

When a low priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the low priority error level event at the source
2. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_j register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no error events, the level will de-assert

---

#### **Note**

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

---

3. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are low priority error level events enabled and pending, then a new pulse will be generated
  - b. If there are no additional low priority error level events enabled and pending, there will be no new pulse
  - c. The level interrupt output is unaffected by EOI
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_j register), but may be done regardless as an extra CLEAR is not harmful.

#### **12.10.2.3.1.2.2 ESM Low Priority Error Pulse Event**

When a low priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_j register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are additional low priority error pulse events enabled and pending, then a new pulse will be generated. The level interrupt will remain asserted and is unaffected by EOI.
  - b. If there are no additional low priority error pulse events enabled and pending, there will be no new pulse
  - c. Note – a pulse error event input that stays asserted will be treated as a “new” pulse event when it is cleared in the ESM.
  - d. The level interrupt will remain asserted and is unaffected by EOI.
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM

4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group *j* ESM\_PIN\_EN\_SET\_*j* register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.10.2.3.1.3 ESM High Priority Error Interrupt

Events mapped to the high priority error interrupt are intended to be events that require immediate intervention from the system because a potentially dangerous error has occurred. An example would be an event indicating an uncorrected error. The system will want to diagnose the issue and intervene to ensure there are no violations.

Any error event can be mapped to the high priority error interrupt. A high priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM\_INTR\_EN\_SET\_*j*) register and mapped to the high priority interrupt (via the ESM\_INT\_PRIO\_*j*) register and the raw status is set (via the ESM\_RAW\_*j*).

When a high priority error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_HI\_PRI register
  - a. If both [31-16] PLS and [15-0] LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
  - b. If either [31-16] PLS or [15-0] LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
    - i. First option: Record the value in [31-16] PLS and [15-0] LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority high priority error event.

#### Note

The global event map is neither defined by nor maintain in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

- ii. Second option:
    1. Read the ESM\_HI register to determine which event group(s) have pending high priority error interrupts
    2. Read the desired error group *j* ESM\_STS\_*j* register
    3. Identify which high priority error interrupt to service
2. Determine, based on the global event map for the device, where the error event came from
3. Service the error event based on the IP's specification:
  - a. The system may take several actions including (but not limited to):
    - i. Fixing the error
    - ii. Resetting the errored IP peripheral
    - iii. Resetting the device
    - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.10.2.3.1.3.1](#)) or pulse (see [Section 12.10.2.3.1.3.2](#)) event.

#### 12.10.2.3.1.3.1 ESM High Priority Error Level Event

When a high priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the error event at the source
2. Write 0x1 to the appropriate bit in the error group *j* of the ESM\_STS\_*j* register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no error events, the level will de-assert

### Note

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

3. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are high priority error level events enabled and pending, then a new pulse will be generated
  - b. If there are no additional high priority error level events enabled and pending, there will be no new pulse
  - c. The level interrupt output is unaffected by EOI.
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group *j* ESM\_PIN\_EN\_SET\_ *j* register, but may be done regardless as an extra CLEAR is not harmful.

#### 12.10.2.3.1.3.2 ESM High Priority Error Pulse Event

When a high priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group *j* of the ESM\_STS\_ *j* register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are high priority error pulse events enabled and pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional high priority error pulse events enabled and pending, there will be no new pulse
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group *j* ESM\_PIN\_EN\_SET\_ *j* register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.10.2.3.2 ESM Error Event Inputs

The ESM can have up to 1024 error event inputs, configurable by groups of 32. For the mapping of system interrupt error events to ESM interrupt inputs, see *Interrupt Sources*.

Level error events (active high) are synchronized to the ESM clock. This synchronized value is captured in to a flop.

Pulse error events use rising edge detection. Each pulse error event has 3 redundant inputs. Each input has its own edge detection logic. Multiple transmission protects against Single Event Upsets (SEUs, transient errors) causing a pulse to be lost during transmission and against failure of the edge detection logic. Once an edge has been detected on any of the three inputs, the ESM\_RAW\_ *j* status is set. Subsequent pulses are likely to come concurrently or quickly enough that software will not have reacted yet. This logic is intentionally biased against false negatives and towards false positives. An SEU that causes an event where none actually occurred will cause software to be called in to action. Software must observe that there is no real error and clear the false status.

#### 12.10.2.3.3 ESM Error Pin Output

The error pin output (ERR\_O) is used to signal an external agent that it needs to (or may need to) intervene because of an error. Each error event input can be programmed, via software, to influence the error pin output (via the ESM\_PIN\_EN\_SET\_ *j* register). The error pin output is active low or PWM based on the ESM\_EN[7-4] PWM\_EN field. This bit field should only be modified when the ESM is disabled, based on the ESM\_EN register.

During Power-On Reset (POR), the error pin is active (asserted low) and the device drives this via a weak internal pull-down. The I/O is under the control of the device. When POR is removed from the ESM, it will be driving the error pin so the device can hand over control to the ESM. The user may also add an external pull-down that is only active when the device is in reset.

During a warm reset the state of the error pin is unchanged, that is the error pin logic is only reset by a POR. The device leaves the I/O active during a warm reset.

The ESM has also a software error forcing capability on the error pin. That is, a force error can be set via the ESM\_EN[3-0] KEY bit field.

### CAUTION

The isolation value for the ERR\_O output of ESM is active (0). This is intended and supposed to protect against an accidental transition to a low power state. If the actual low power mode transition is intended, the PMIC should be made aware by software to ignore the ESM error signal. Otherwise device resets will be asserted from companion chip.

Figure 12-504 describes the behavior of the error pin. Not shown is that a reset (Power-On-Reset only) will immediately transition the error pin to the ESM\_RESET state and a Global Soft Reset will immediately transition the error pin to the ESM\_IDLE state. A pending error interrupt event is any error event with the raw state set and the error pin Influence enabled. There are two types of "clear" events associated with servicing the error pin. The first is to clear the status of the pending event (see Section 12.10.2.3.1 for how to clear level and pulse pending events). The second is the CLEAR event meant to de-assert the error pin.

**Figure 12-504. ESM Error Pin State Flowchart**

If an error event happens that has been programmed to influence the error pin, the error pin will assert (active low) for a minimum time (as programmed by the ESM\_PIN\_CNTR\_PRE register). In order for the error pin to de-assert, the following 3 things must happen:

1. The minimum time interval must expire

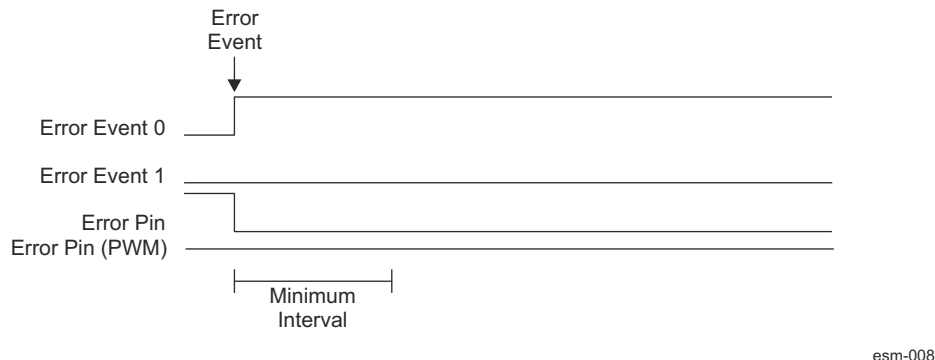

2. The event that caused the error pin to assert must be cleared (see [Section 12.10.2.3.1](#))
3. A CLEAR (0x5) must be written to the ESM\_PIN\_CTRL register.

### Note

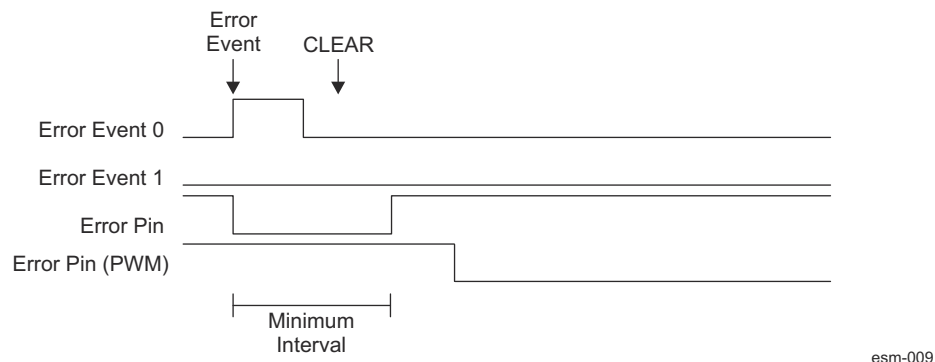

Step 3 should happen after step 2, but either (or both) of these steps may happen before or after step 1.

Figure 12-505 shows a typical error pin assertion.

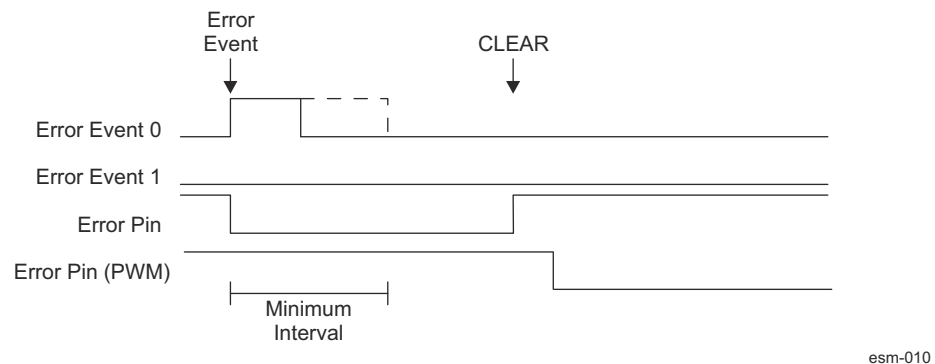

**Figure 12-505. ESM Error Pin Assertion**

If, during the minimum time, CLEAR is written to the error key, then the error pin will de-assert after the minimum time interval, as shown in Figure 12-506.

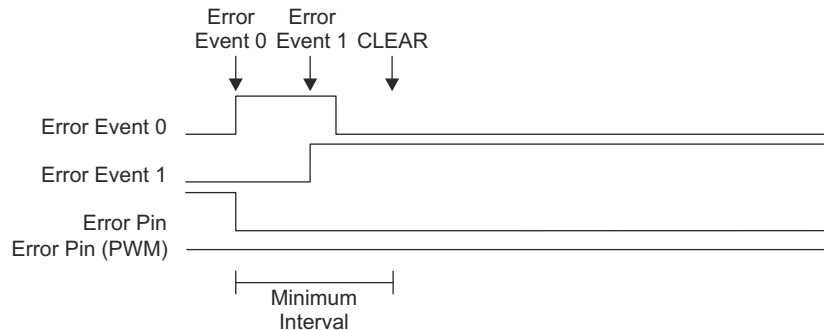

**Figure 12-506. ESM Error Pin Assertion with CLEAR during Minimum Interval**

If CLEAR is not written till after the minimum time interval, the error pin will de-assert when CLEAR is written. This is regardless of whether the error interrupt event itself is removed before or after the minimum time interval, as shown by the dotted line in Figure 12-507.

**Figure 12-507. ESM Error Pin Asserting with CLEAR after Minimum Interval**

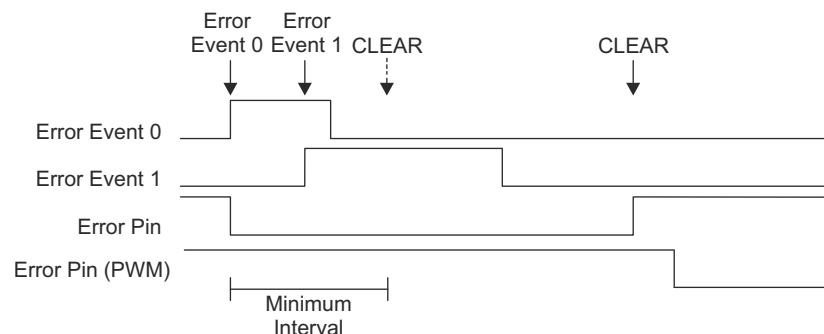

When in the ESM\_ERROR state and a CLEAR event happen, if there are still pending error events, the ESM stays in the ESM\_ERROR state with the error pin asserted. Multiple error events when in the ESM\_ERROR state do not reset the minimum time interval counter as shown in [Figure 12-508](#).

esm-011

**Figure 12-508. ESM Error Pin Asserting with Interval Reset by Additional Error Event(s)**

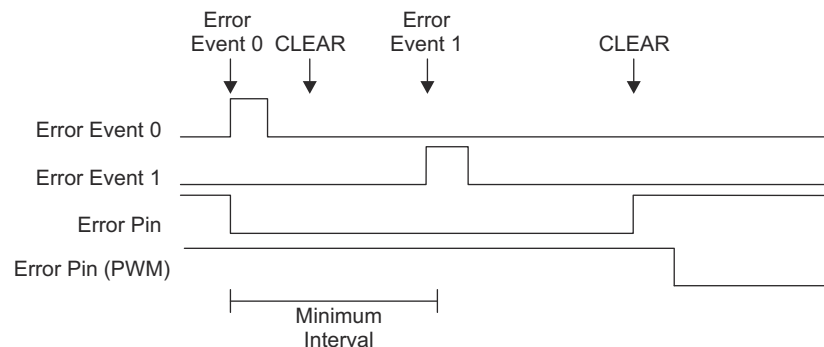

A CLEAR event causes a re-evaluation of whether there are any pending error events. As such, a single CLEAR can be used to clear the error pin after multiple error events. Multiple CLEAR events can occur (such as the one with the dotted arrow shown in [Figure 12-509](#)), but are not necessary. No matter how many error events occur nor when (or how many) CLEAR events occur, the error pin will always be asserted for at least the minimum time interval

esm-012

**Figure 12-509. ESM Error Pin Asserting with Single CLEAR for Multiple Events**

If all error events are cleared and the ESM is in the ESM\_WAIT state, waiting for the minimum time interval to expire, and a new error interrupt event occurs, the ESM will go back to the ESM\_ERROR state. The minimum time interval will not reset, but a new CLEAR event will be required as shown in [Figure 12-510](#).

esm-013

**Figure 12-510. ESM Error Pin Asserting with New Error During Minimum Time Interval**

[Table 12-433](#) shows some common scenarios of how the error pin as well as the two associated registers (ESM\_PIN\_CTRL and ESM\_PIN\_STS) will be set.

**Table 12-433. ESM Error Pin Scenarios**

Scenario	Error Pin State Value	ESM_PIN_CTRL[3-0] KEY	ESM_PIN_STS[0] VAL status value	Additional Notes
POR Asserted	0	N/A	N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
After de-assertion of POR	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was not asserted when reset asserted)	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was asserted when reset asserted)	0	0x0 (Normal Mode)	0x1	-
Force error pin	0	0xA (Force Error Mode)	0x0	Forcing error on the pin via software.

#### 12.10.2.3.4 PWM Mode

If the error output pin is in PWM mode then when no error is detected it will toggle according to programmable MMR widths for high and low periods. When an error occurs, the error pin stops toggling and remains constant until the error is cleared. An external PMIC that is detecting the PWM toggles can identify the error if the pin stops toggling. The periods should be programmed such that they fit within the expectation of the external PMIC.

#### 12.10.2.3.5 ESM Minimum Time Interval

The minimum time interval is the minimum amount of time that the error pin will be asserted (active low) when an enabled error interrupt event happens. This value is system dependent, but should be enough time so that the external monitoring agent can always see the error pin asserted, but short enough so that if all of the error events are cleared, then the error pin can be de-asserted before the external agent decides to intervene. This is highly dependent on the application and the Fault Tolerant Time Interval.

The Minimum Time Interval counter is clock cycle based, therefore the time of the interval is a combination of the value in the ESM\_PIN\_CNTR\_PRE register and the clock frequency of the ESM. Software must calculate the value accordingly. The Minimum Time Interval should be set according to the needs of the application.

#### 12.10.2.3.6 ESM Protection for Registers

The configuration for each error group *j* of registers are backed up by 3 flops in order to protect against single or double-bit errors. When written, all 3 bits are set to the same value. When read (and for functioning of the internal state machines) the value is the OR of all 3 bits. Whenever any of the bits disagree, the Configuration Error interrupt is asserted (if enabled). The registers covered by this mechanism are:

- ESM\_ERR\_RAW
- ESM\_ERR\_STS
- ESM\_ERR\_EN\_SET
- ESM\_ERR\_EN\_CLR
- ESM\_RAW<sub>j</sub>
- ESM\_STS<sub>j</sub>
- ESM\_INTR\_EN\_SET<sub>j</sub>
- ESM\_INTR\_EN\_CLR<sub>j</sub>
- ESM\_INT\_PRIO<sub>j</sub>
- ESM\_PIN\_EN\_SET<sub>j</sub>
- ESM\_PIN\_EN\_CLR<sub>j</sub>

The error pin control register ESM\_PIN\_CTRL contains a multi-bit field KEY. The key value ensures normal operation on the error pin and that an error even will be generated if one occurs. Software should periodically read check the KEY bit field value and make sure it is 0x0. If the value is not 0x0, software must re-write it to this key value (unless in test mode forcing an error on the pin) to ensure the normal operation. [Table 12-434](#) lists the KEY values and their respective meaning.

**Table 12-434. ESM Error Pin Control Values**

ESM_PIN_CTRL[3-0] KEY	Description
N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
0x0 (Normal)	Normal operation mode - Error pin will activate when an enabled error event occurs.
0xA (Force Error)	Force error mode - Forces the error pin active. To clear the error pin (return to the ESM_IDLE state) write this field back to normal mode (writing a CLEAR event will also work). Force error mode must be set only while in IDLE. Attempting force error while in another state will have no effect.
0x5 (CLEAR)	CLEAR Event - generates a CLEAR event to the ESM state machine. KEY will return to normal mode (0x0) on the next cycle.
Other Values	All other values - Normal mode. Writing any of these values will have no effect. When reading any of these values indicates that one or more bits have experienced a single event upset, software should write the field back to 0x0. The ESM will continue to operate in normal mode.

The error pin counter pre-load register ESM\_PIN\_CNTR\_PRE should also be read and checked periodically by software.

#### **12.10.2.3.7 ESM Clock Stop**

The ESM can only be put in to clock stop if all of the internal state machines are idle and the [3-0] KEY bit field for the global enable command is cleared in the ESM\_EN register.

### 12.10.3 Memory Cyclic Redundancy Check (MCRC) Controller

This chapter describes the Memory Cyclic Redundancy Check (MCRC) controller in the device.

#### 12.10.3.1 MCRC Overview

VBUSM CRC controller is a module which is used to perform CRC (Cyclic Redundancy Check) to verify the integrity of a memory system. A signature representing the contents of the memory is obtained when the contents of the memory are read into MCRC Controller. The responsibility of MCRC controller is to calculate the signature for a set of data and then compare the calculated signature value against a pre-determined good signature value. MCRC controller provides four channels to perform CRC calculation on multiple memories in parallel and can be used on any memory system.

##### 12.10.3.1.1 MCRC Features

MCRC has the following features:

- Four channels to perform background signature verification on any memory subsystem
- Data compression on 8-, 16-, 32-, and 64-bit data size
- Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64-bit primitive polynomial
- Each channel has a CRC Value Register which contains the pre-determined CRC value
- Use timed base event trigger from timer to initiate DMA data transfer
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression
- Three modes of operation:
  - Auto
  - Semi-CPU
  - Full-CPU
- For each channel, CRC can be performed either by MCRC Controller or by CPU
- Automatically performs signature verification without CPU intervention in AUTO mode
- Generates interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification itself
- Generates CRC fail interrupt in AUTO mode if signature verification fails
- Generates Timeout interrupt if CRC is not performed within the time limit
- Generates DMA request per channel to initiate CRC value transfer
- An 128-byte block burst address for the PSA register to DMA without constant mode bus attribute

##### 12.10.3.1.2 MCRC Not Supported Features

The following features are not supported by the module:

- Data trace capability on VBUSM, ITCM and DTCM data buses.

##### 12.10.3.1.3 MCRC Ports

**Table 12-435. MCRC Clocks and Resets**

Clocks	
Module Clock Input	Description
MCRC_FICLK	MCRC clock. This clock is used for all interface and functional operations.
Resets	
Module Reset Input	Description
MCRC_RST	MCRC hardware reset

**Table 12-436. MCRC Hardware Requests**

Interrupt Requests		
Module Interrupt Signal	Description	Type
INT_MCRC_INTR	MCRC Interrupt signal	Level
DMA Events		
Module DMA Event	Description	Type
DMA_EVENT_INTR0	MCRC DMA event for channel 1	Pulse
DMA_EVENT_INTR1	MCRC DMA event for channel 2	Pulse
DMA_EVENT_INTR2	MCRC DMA event for channel 3	Pulse

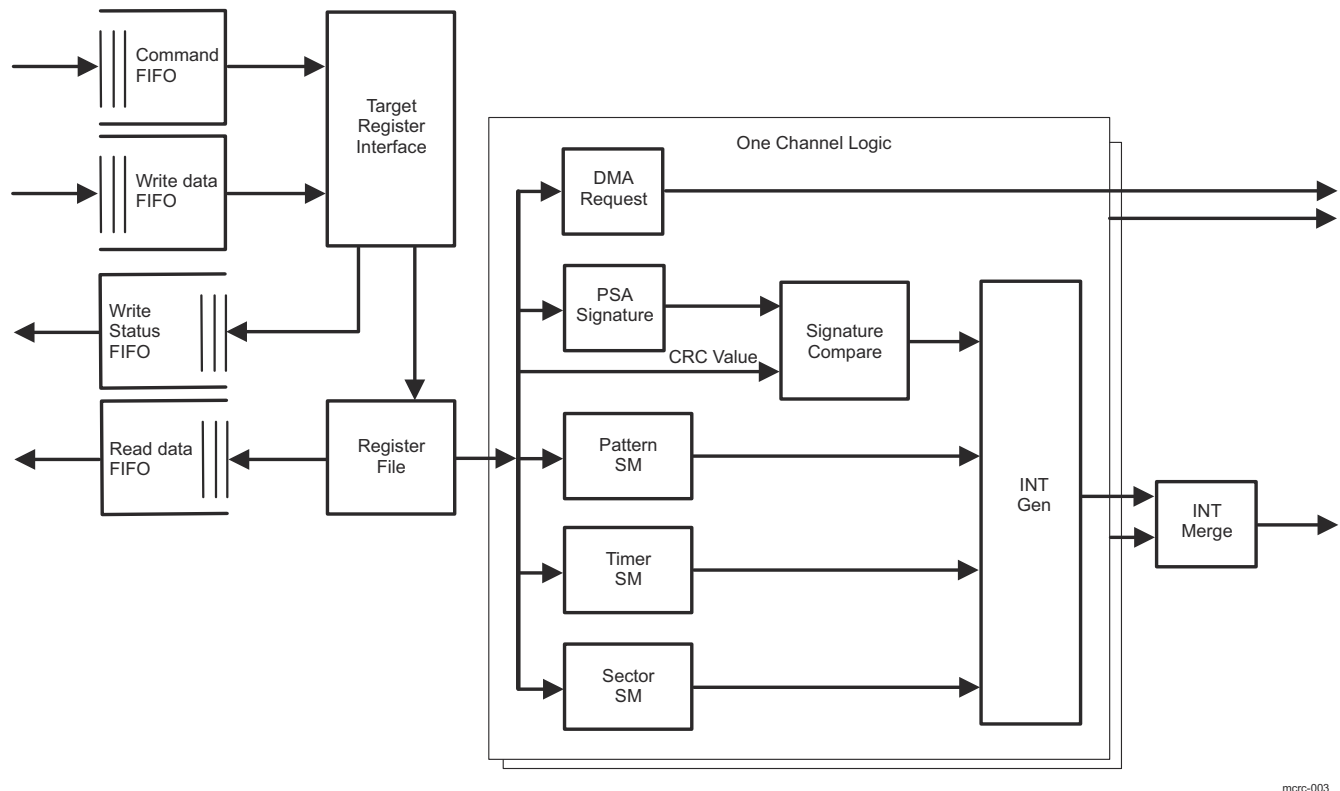

**Table 12-436. MCRC Hardware Requests (continued)**

### 12.10.3.2 MCRC Functional Description

#### 12.10.3.2.1 MCRC Block Diagram

Figure 12-511 shows the MCRC internal blocks.

**Figure 12-511. MCRC Block Diagram**

- **Command FIFO:** The Command FIFO pipelines the commands to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 4 elements deep.
- **Write FIFO:** The Write FIFO pipelines the write data to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 2 elements deep.
- **Write Status FIFO:** The Write Status FIFO pipelines the write status back to the VBUSM. A write status will be issued on the final data phase of a write command. This FIFO is 2 elements deep.
- **Read Data FIFO:** The Read Data FIFO pipelines the read data back to the VBUSM. This FIFO is 3 elements deep.
- **Target Register Interface:** The Target Register Interface directs the written data to the register file.
- **PSA Signature:** The PSA Signature creates the signature of the data written. This data will then be compared to the CRC Value or read by software to determine goodness.
- **Pattern State Machine:** The Pattern State Machine determines when a block of data has been serviced.
- **Timer State Machine:** The Timer State Machine determines when overrun and under-run events are detected.
- **Sector State Machine:** The Sector State Machine determines when a sector error should be captured so the software can determine the errant block of data.
- **Signature Compare:** The Signature Compare block compares the current signature to the CRC Value register and sends the result to the Interrupt Generation block.

### 12.10.3.2.2 MCRC General Operation

There are four channels in MCRC controller and for each channel there is a PSA (Parallel Signature Analysis) Signature Register (MCRC\_PSA\_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC\_CRC\_REGL1-4).

A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be a 8-, 16-, 32-, or 64-bit data. MCRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory of which the contents to be verified to the memory mapped PSA Signature Register. When DMA transfers data to the memory mapped PSA Signature Register, a signature is generated.

A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed automatically by MCRC controller in AUTO mode or by CPU itself in Semi-CPU or Full-CPU mode. In AUTO mode, a self-sustained CRC signature calculation can be achieved without any CPU intervention.

### 12.10.3.2.3 MCRC Modes of Operation

MCRC Controller can operate in AUTO, Semi-CPU, and Full-CPU modes.

#### 12.10.3.2.3.1 AUTO Mode

In AUTO mode, MCRC Controller in conjunction with DMA controller can perform CRC without CPU intervention. A sustained transfer of data to both the PSA Signature Register (MCRC\_PSA\_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC\_CRC\_REGL1-4) are performed in the background of CPU. When a mismatch is detected, an interrupt is generated to the CPU. A 16-bit, current sector ID register (MCRC\_CRC\_CURSEC\_REG1-4) is provided to identify which sector causes a CRC failure.

#### 12.10.3.2.3.2 Semi-CPU Mode

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register (MCRC\_PSA\_SIGREGL1-4). Instead of performing signature verification automatically, the CRC controller generates an compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register (MCRC\_PSA\_SECSIGREGL1-4) and compare it to a pre-determined CRC value.

#### 12.10.3.2.3.3 Full-CPU Mode

In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register (MCRC\_PSA\_SIGREGL1). After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

### 12.10.3.2.4 PSA Signature Register

The 64-bit PSA Signature Register (MCRC\_PSA\_SIGREGL1-4 and MCRC\_PSA\_SIGREGLH1-4) is based on one of the selected CRC polynomials to produce the maximum length LFSR (Linear Feedback Shift Register).

$$\text{CRC64: } f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (29)$$

- A. More details of the 64-bit primitive polynomial can be found at W. Stahnke, Primitive binary polynomials, Math. Comp. 27 (1973), 977–980.

There is one PSA Signature Register per CRC channel. PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHi\_MODE

bits (where  $i = 1$  to 4). If `CHI_MODE=0x0` (Data Capture), a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature.

MCRC Controller should be used in conjunction with the on-chip DMA controller to produce optimal system performance. The incoming data pattern to PSA Signature Register is typically initiated by the DMA controller. When DMA is properly setup, it would read data from the pre-determined memory system and write them to the memory mapped PSA Signature Register. Each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

After a system reset and when AUTO mode is enabled, MCRC Controller automatically generates a DMA request to request the pre-determined CRC value corresponding to the first sector of memory to be checked.

In AUTO mode, when one sector of data patterns is compressed, the signature stored at the PSA Signature Register is first copied to the PSA Sector Signature Register (`MCRC_PSA_SECSIGREGL1-4`) and PSA Signature Register is then cleared out to all zeros. An automatic signature verification is then performed by comparing the signature stored at the PSA Sector Signature Register to the CRC Value Register (`MCRC_CRC_REGL1-4`). After the comparison the MCRC Controller can generate a DMA request. Upon receiving the DMA request the DMA controller will update the CRC Value Register by transferring the next pre-determined signature value associated with the next sector of memory system. If the signature verification fails then MCRC Controller can generate a CRC fail interrupt.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. Software can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

MCRC Controller supports double word, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zeros before compression. Note that comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bits because a compressed value is always expressed in 64 bits.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros.

PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns is compressed

#### **12.10.3.2.5 PSA Sector Signature Register**

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the 64-bit PSA Sector Signature Register (`MCRC_PSA_SECSIGREGL1-4` and `MCRC_PSA_SECSIGREGH1-4`). PSA Signature Register is a read-only register. During Semi-CPU mode, the host CPU must read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the compression complete interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enabled to generate when overrun condition occurs.

#### 12.10.3.2.6 CRC Value Register

Associated with each channel there is a 64-bit CRC Value Register (MCRC\_CRC\_REGL1-4 and MCRC\_CRC\_REGH1-4).

The CRC Value Register stores the pre-determined CRC value. After one sector of data patterns is compressed by PSA Signature Register, MCRC Controller can automatically compare the resulting signature stored at the PSA Sector Signature Register with the pre-determined value stored at the CRC Value Register if AUTO mode is enabled. If the signature verification fails, MCRC Controller can be enabled to generate an CRC fail interrupt. When the channel is set up for Semi-CPU mode, CRC controller first generates a compression complete interrupt to CPU. Upon servicing the interrupt, CPU will then read the PSA Sector Signature Register and then read the corresponding CRC value stored at another location and compare them. CPU must not read from the CRC Value Register during Semi-CPU or Full-CPU mode because the CRC Value Register is not updated during these two modes.

In AUTO mode, for first sector's signature, DMA request is generated when mode is programmed to AUTO. For subsequent sectors, DMA request is generated after each sector is compressed. Responding to the DMA request, DMA controller reloads the CRC Value Register for the next sector of memory system to be checked. The user software needs to configure the DMA to ensure that the DMA first writes to the MCRC\_CRC\_REGL1 followed by the MCRC\_CRC\_REGH1 register in during the AUTO Mode.

When CRC Value Register is updated with a new CRC value, an internal flag is set to indicate that CRC Value Register contains the most current value. This flag is cleared when CRC comparison is performed. Each time at the end of the final data pattern compression of a sector, MCRC Controller first checks to see if the corresponding CRC Value Register has the most current CRC value stored in it by polling the flag. If the flag is set then the CRC comparison can be performed. If the flag is not set then it means the CRC Value Register contains stale information. A CRC underrun interrupt is generated. When an underrun condition is detected, signature verification is not performed.

MCRC Controller supports double word, word, half word and byte access to the CRC Value Register. As noted before comparison between PSA Sector Signature Register and CRC Value Register during AUTO mode is carried out in 64 bits.

#### 12.10.3.2.7 Raw Data Register

The raw or un-compressed data written to the PSA Signature Register is also saved in the 64-bit Raw Data Register (MCRC\_RAW\_DATAAREGL1-4 and MCRC\_RAW\_DATAAREGH1-4). This register is read only.

#### 12.10.3.2.8 Example DMA Controller Setup

DMA controller needs to be setup properly in either AUTO or Semi-CPU mode as DMA controller is used to transfer data patterns. Hardware or a combination of hardware and software DMA triggering are supported.

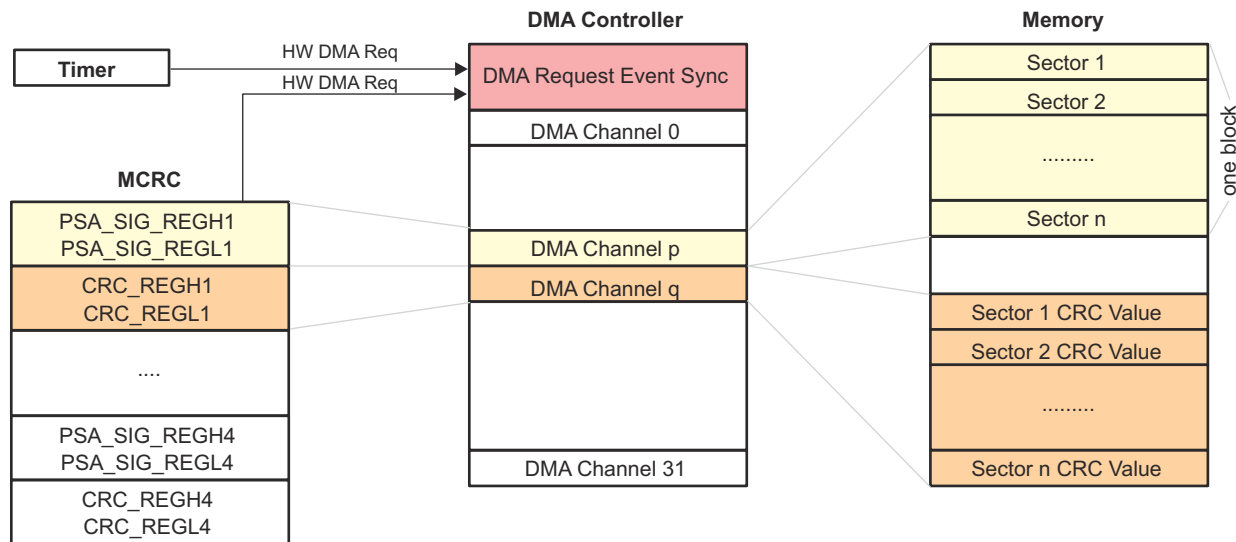

##### 12.10.3.2.8.1 AUTO Mode Using Hardware Timer Trigger

There are two DMA channels associated with each CRC channel when in AUTO mode. One DMA channel is setup to transfer data patterns from the source memory to the PSA Signature Register (MCRC\_PSA\_SIGREGL1-4). The second DMA channel is setup to transfer the pre-determined signature to the CRC Value Register (MCRC\_CRC\_REGL1-4). The trigger source for the first DMA channel can be either by hardware or by software. As illustrated in [Figure 12-512](#), a timer can be used to trigger a DMA request to initiate transfer from the source memory system to PSA Signature Register. In AUTO mode, MCRC Controller also generates DMA request after one sector of data patterns is compressed to initiate transfer of the next CRC value corresponding to the next sector of memory. Thus a new CRC value is always updated in the CRC Value Register (MCRC\_CRC\_REGL1-4) by DMA synchronized to each sector of memory.

A block of memory system is usually divided into many sectors. All sectors are the same size. The sector size is programmed in the MCRC\_CRC\_PCOUNT\_REG1-4 and the number of sectors in one block is programmed in the MCRC\_CRC\_SCOUNT\_REG1-4 of the respective channel. MCRC\_CRC\_PCOUNT\_REG1-4 multiplies MCRC\_CRC\_SCOUNT\_REG1-4 and multiplies transfer size of each data pattern should give the total block size in number of bytes.

The total size of the memory system to be examined is also programmed in the respective transfer count register inside DMA module. The DMA transfer count register is divided into two parts. They are element count and

frame count. Note that a hardware DMA request can be programmed to trigger either one frame or one entire block transfer. In [Figure 12-512](#), a hardware DMA request from a timer is used as a trigger source to initiate DMA transfer. If all four CRC channels are active in AUTO mode then a total of four DMA requests would be generated by MCRC Controller.

mrcr-004

**Figure 12-512. AUTO Mode Using Hardware Timer Trigger**

#### 12.10.3.2.8.2 AUTO Mode Using Software Trigger

The data patterns transfer can also be initiated by software. CPU can generate a software DMA request to activate the DMA channel to transfer data patterns from source memory system to the PSA Signature Register. To generate a software DMA request CPU needs to set the corresponding DMA channel in the DMA software trigger register. Note that just one software DMA request from CPU is enough to complete the entire data patterns transfer for all sectors. Please see [AUTO Mode With Software CPU Trigger](#) for illustration.

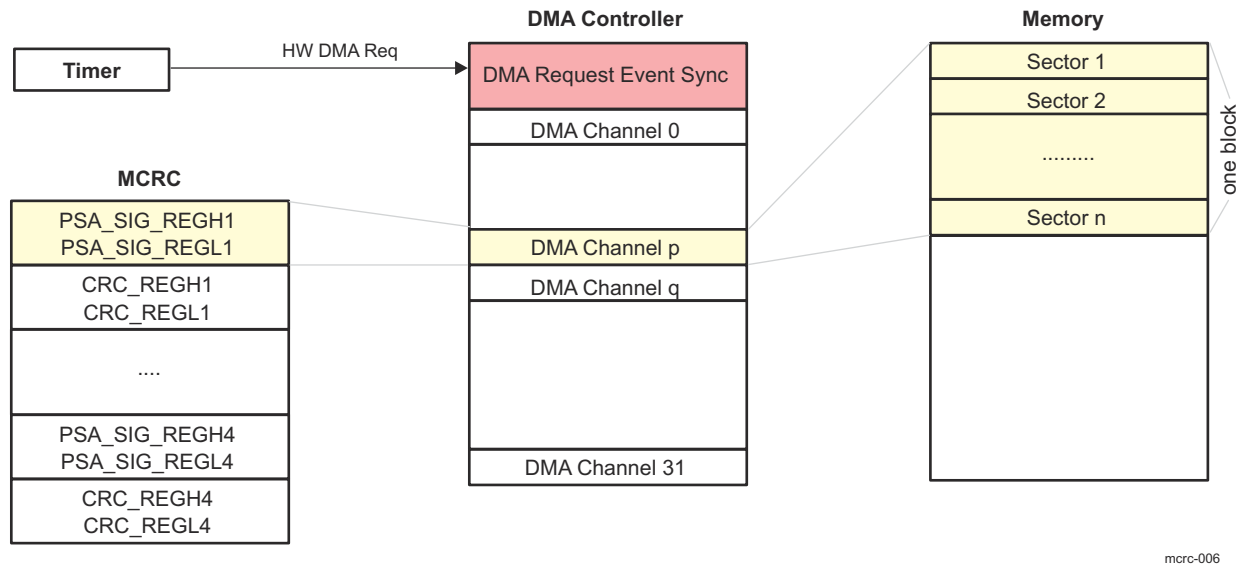

mrcr-005

**Figure 12-513. AUTO Mode With Software CPU Trigger**

#### 12.10.3.2.8.3 Semi-CPU Mode Using Hardware Timer Trigger

During Semi-CPU mode, no DMA request is generated by CRC controller. Therefore, no DMA channel is allocated to update CRC Value Register. CPU should not read from CRC Value Register in semi-CPU mode as it contains stale value. Note that no signature verification is performed at all during this mode. Similar to AUTO

mode, either by hardware or by software DMA request can be used as a trigger for data patterns transfer. [Figure 12-514](#) illustrates the DMA setup using semi-CPU mode with hardware timer trigger.

**Figure 12-514. Semi-CPU Mode With Hardware Timer Trigger**

**Table 12-437. DMA Request and Counter Logic Operation According to CRC Mode**

CRC Mode	DMA Request	Pattern Counter	Sector Counter	Timeout Counter
AUTO	Active	Active	Active	Active
Semi-CPU	Inactive	Active	Active	Active
Full CPU	Inactive	Inactive	Inactive	Inactive

#### 12.10.3.2.9 Pattern Count Register

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register (MCRC\_CRC\_PCOUNT\_REG1-4). When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode and an automatic signature verification is performed in AUTO mode. In AUTO only, DMA request is generated to trigger the DMA controller to update the CRC Value Register.

#### Note

The data pattern count must be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

#### 12.10.3.2.10 Sector Count Register/Current Sector Register

Each channel contains a 16-bit sector counter. The sector count register stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register (MCRC\_CRC\_CURSEC\_REG1-4). If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure it is advisable to use the following equation during CRC and DMA setup.

$$\text{CRC Pattern Count} \times \text{CRC Sector Count} = \text{DMA Element Count} \times \text{DMA Frame Count} \quad (30)$$

The current sector register is frozen from being updated until both the current sector register is read and CRC fail (CHi\_CRC\_FAIL) status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen

with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

Current sector register is reset when the PSA software reset is enabled.

#### Note

Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

#### 12.10.3.2.11 Interrupts

CRC generate several types of interrupts per channel. Associated with each interrupt there is a interrupt enable bit (see MCRC\_CRC\_INTS). No interrupt is generated in Full-CPU mode.

- Compression complete interrupt
- CRC fail interrupt
- Overrun interrupt
- Underrun interrupt
- Timeout interrupt

**Table 12-438. Interrupt Conditions Per CRC Mode**

CRC Mode	Compression Complete	CRC Fail	Overrun	Underrun	Timeout
AUTO	No	Yes	Yes	Yes	Yes
Semi-CPU	Yes	No	Yes	No	Yes
Full-CPU	No	No	No	No	No

##### 12.10.3.2.11.1 Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated

##### 12.10.3.2.11.2 CRC Fail Interrupt

CRC fail interrupt is generated in AUTO mode only. When the signature verification fails, the CRC fail flag is set, and CPU must take action to address the fail condition and clear the CRC fail flag after it resolves the CRC mismatch.

##### 12.10.3.2.11.3 Overrun Interrupt

Overrun Interrupt is generated in either AUTO or Semi-CPU mode. During AUTO mode, if a CRC fail is detected then the current sector number is recorded in the current sector register (MCRC\_CRC\_CURSEC\_REG1-4). If CRC fail status bit is not cleared and current sector register is not read by the host CPU before another CRC fail is detected for another sector then an overrun interrupt is generated. During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt. At the same time the signature is copied into the PSA Sector Signature Register (MCRC\_PSA\_SECSIGREGL1-4). If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value then an overrun interrupt is generated.

##### 12.10.3.2.11.4 Underrun Interrupt

Underrun interrupt only occurs in AUTO mode. The interrupt is generated when the CRC Value Register is not updated with the corresponding signature when the data pattern counter finishes counting. During AUTO mode, MCRC Controller generates DMA request to update CRC Value Register in synchronization to the corresponding sector of the memory. Signature verification is also performed if underrun condition is detected. And CRC fail interrupt is generated at the same time as the underrun interrupt.

### 12.10.3.2.11.5 Timeout Interrupt

To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24-bit timeout counter per CRC channel. The timeout counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (MCRC\_CRC\_WDTPLD1-4) and block complete timeout pre-load value (MCRC\_CRC\_BCTOPLD1-4). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of FICLK clock.

Watchdog timeout pre-load register (MCRC\_CRC\_WDTPLD1-4) is used to check if DMA does supply a block of data responding to a request in a given time frame. Block complete timeout pre-load register (MCRC\_CRC\_BCTOPLD1-4) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with MCRC\_CRC\_WDTPLD1-4 after either AUTO or Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with MCRC\_CRC\_BCTOPLD1-4 the block complete timeout pre-load value.

Block complete timeout pre-load value is used to check if one block of data patterns are compressed within a given time limit. If the timeout counter pre-loaded with MCRC\_CRC\_BCTOPLD1-4 value expires before one block of data patterns are compressed a timeout interrupt is generated. When one block (pattern count × sector count) of data patterns are compressed before the counter has expired, the counter is pre-loaded with MCRC\_CRC\_WDTPLD1-4 value again. If the timeout counter is pre-loaded with zero then the counter is disable and no timeout interrupt is generated.

### 12.10.3.2.11.6 Interrupt Offset Register

MCRC Controller only generates one interrupt request to interrupt manager. An interrupt offset register (MCRC\_CRC\_INT\_OFFSET\_REG) is provided to indicate the source of the pending interrupt with highest priority. [Table 12-439](#) shows the offset interrupt vector address of each interrupt in an ascending order of priority.

**Table 12-439. Interrupt Offset Mapping**

Interrupt Condition	Offset Value
Phantom	0x0
Ch1 CRC Fail	0x1
Ch2 CRC Fail	0x2
Ch3 CRC Fail	0x3
Ch4 CRC Fail	0x4
reserved	0x5-0x8
Ch1 Compression Complete	0x9
Ch2 Compression Complete	0xA
Ch3 Compression Complete	0xB
Ch4 Compression Complete	0xC
reserved	0xD-0x10
Ch1 Overrun	0x11
Ch2 Overrun	0x12
Ch3 Overrun	0x13
Ch4 Overrun	0x14
reserved	0x15-0x18
Ch1 Underrun	0x19
Ch2 Underrun	0x1A
Ch3 Underrun	0x1B
Ch4 Underrun	0x1C
reserved	0x1D-0x20
Ch1 Timeout	0x21
Ch2 Timeout	0x22

**Table 12-439. Interrupt Offset Mapping (continued)**

Interrupt Condition	Offset Value
Ch3 Timeout	0x23
Ch4 Timeout	0x24

**12.10.3.2.11.7 Error Handling**

When an interrupt is generated, host CPU must take appropriate actions to identify the source of error and restart the respective channel in DMA and MCRC module. To restart a CRC channel user must perform the following steps in the ISR:

1. Write to software reset bit in MCRC\_CRC\_CTRL0 register to reset the respective PSA Signature Register
2. Reset the CHi\_MODE bits to 0 in MCRC\_CRC\_CTRL2 register as Data capture mode
3. Set the CHi\_MODE bits in MCRC\_CRC\_CTRL2 register to desired new mode again
4. Release software reset

The host CPU must use byte write to restart each individual channel.

**12.10.3.2.12 Power Down Mode**

MCRC module can be put into power down mode when the power down control bit MCRC\_CRC\_CTRL1[0] PWDN is set. The module wakes up when the PWDN bit is cleared.

**12.10.3.2.13 Emulation**

A read access from a register in functional mode can sometimes trigger a certain internal event to follow. For example, reading interrupt offset register triggers an event to clear the corresponding interrupt status flag. During emulation when SUSPEND signal is high, a read access from any register should only return the register contents to the bus and should not trigger or mask any event as it would have in functional mode. This is to prevent debugger from reading the interrupt offset register, that is, during refreshing screen and cause the corresponding interrupt status flag to get cleared. Timeout counters are stopped to generate timeout interrupts in emulation mode. No VBUSM bus error will be generated if reading from the unimplemented locations. .

CEMUDBG is the VBUSM suspend signal which need not explicitly indicate that whether CPU is in suspend mode or not. In data trace mode, a separate suspend signal CPU\_EMUSP, is used to indicate MCRC controller that the CPU is in suspend mode or not.

### 12.10.3.3 MCRC Programming Examples

#### 12.10.3.3.1 Example: Auto Mode Using Time Based Event Triggering

A large memory area with 2 Mbyte (256 k × 32-bit [doubleword]) is to be checked in the background of CPU. CRC is to be performed every 1 Kbyte (128 doubleword). Therefore there will be 2048 pre-recorded CRC values. For illustration purpose, we map MCRC\_CRC\_REGL1 register to DMA channel 1 and MCRC\_PSA\_SIGREGL1 register to DMA channel 2. Let's assume all DMA transfers are carried out in 64-bit transfer size.

##### 12.10.3.3.1.1 DMA Setup

- Setup DMA channel 1 with the starting address from which the pre-determined CRC values are stored. Setup the destination address to the MCRC\_CRC\_REGL1. Put the source address at post increment addressing mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1 to trigger a frame transfer.
- Setup DMA channel 2 with the source address from which the contents of memory to be verified. Setup the destination address to the MCRC\_PSA\_SIGREGL1. Program the element transfer count to 128 and the frame transfer count to 2048. Program the read and write element size to 64 bits. Put the source address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request for channel 2 to trigger an entire block transfer.

##### 12.10.3.3.1.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 2. For example, software can setup the timer to generate a DMA request every 10 ms.

##### 12.10.3.3.1.3 CRC Setup

- Program the pattern count MCRC\_CRC\_PCOUNT\_REG1 to 128
- Program the sector count MCRC\_CRC\_SCOUNT\_REG1 to 2048
- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load (MCRC\_CRC\_BCTOPLD1-4) value to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected MCRC Controller automatically generates a DMA request on channel 1. Around the same time the timer module also generates a DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the MCRC\_CRC\_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC\_PSA\_SECSIGREGL1/H1 does not match the MCRC\_CRC\_REGL1/H1 Register. MCRC Controller generates a DMA request on DMA channel 1 when one sector of data patterns are compressed. This routine will continue until the entire 2 Mbytes are consumed. If the timeout counter reached zero before the entire 2 Mbytes are compressed, a timeout interrupt is generated. After 2Mbytes are transferred, the DMA can generate an interrupt to CPU. The entire operation will continue again when DMA responds to the DMA request from both the timer and MCRC Controller. The CRC is performed totally without any CPU intervention.

#### 12.10.3.3.2 Example: Auto Mode Without Using Time Based Triggering

A small but highly secured memory area with 1 Kbytes is to be checked in the background of CPU. CRC is to be performed every 1 Kbytes. Therefore, there is only one pre-recorded CRC value. For illustration purpose, we map channel 1 MCRC\_CRC\_REGL1/H1 to DMA channel 1 and channel 1 MCRC\_PSA\_SIGREGL1/H1 to DMA channel 2. Assume all transfers carried out by DMA are in 64-bit transfer size.

##### 12.10.3.3.2.1 DMA Setup

- Setup DMA channel 1 with the source address from which the pre-determined CRC value is stored. Setup the destination address to the MCRC\_CRC\_REGL1 Register. Put the source address at constant addressing mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1.

- Setup DMA channel 2 with the source address from which the memory area to be verified. Setup the destination address to the MCRC\_PSA\_SIGREGL1/H1. Program the element transfer count to 128 and the frame transfer count to 1. Put the source address at post increment addressing mode and put the destination address at constant address mode. Generate a software DMA request on channel 2 after CRC has completed its setup. Enable autoinitiation for DMA channel 2.

#### 12.10.3.3.2.2 CRC Setup

- Program the MCRC\_CRC\_PCOUNT\_REG1 to 128
- Program the MCRC\_CRC\_SCOUNT\_REG1 to 1
- Leaving the timeout count MCRC\_CRC\_BCTOPLD1 register with the reset value of zero means no timeout interrupt is generated
- Enable AUTO mode and all interrupts

After AUTO mode is selected the MCRC Controller automatically generates a DMA request on channel 1. At the same time the CPU generates a software DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the MCRC\_CRC\_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC\_PSA\_SECSIGREGL1/H1 does not match the MCRC\_CRC\_REGL1/H1. MCRC Controller generate a DMA request on DMA channel 1 again after one sector is compressed. After 1 Kbytes are transferred, the DMA can generate an interrupt to CPU. Responding to the DMA interrupt CPU can restart the CRC routine by generating a software DMA request onto channel 2 again.

#### 12.10.3.3.3 Example: Semi-CPU Mode

If DMA controller is available in a system the CRC module can also operate in semi-CPU mode. This means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. The difference between semi-CPU mode and AUTO mode is that CRC controller does not automatically perform the signature verification. CRC controllers generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

A memory area with 2 Mbytes is to be verified with the help of the CPU. CRC operation is to be performed every 1 Kbyte. Since there are 2 Mbytes (256 K doublewords) of memory to be check and we want to perform a CRC every 1 Kbytes (128 doublewords) and therefore there must be 2048 pre-recorded CRC values. In Semi-CPU mode, the MCRC\_CRC\_REGL1/H1 is not updated and contains indeterminate data.

#### 12.10.3.3.3.1 DMA Setup

- Setup DMA channel 1 with the source address from which the memory area to be verified are mapped. Setup the destination address to the MCRC\_PSA\_SIGREGL1/H1. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

#### 12.10.3.3.3.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time-based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 1. For example, software can setup the timer to generate a DMA request every 10 ms.

#### 12.10.3.3.3.3 CRC Setup

- Program the MCRC\_CRC\_PCOUNT\_REG1 to 128
- Program the MCRC\_CRC\_SCOUNT\_REG1 to 2048
- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load value MCRC\_CRC\_BCTOPLD1 to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz
- Enable AUTO mode and all interrupts.

The timer module first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the MCRC\_PSA\_SIGREGL1/H1, the CRC controller will compress it. After one sector of

data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the MCRC\_PSA\_SECSIGREGL1/H1. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2 Mbytes are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from MCRC\_PSA\_SECSIGREGL1 before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller.

#### 12.10.3.3.4 Example: Full-CPU Mode

In a system without the availability of DMA controller, the CRC routine can be operated by CPU provided the CPU has enough throughput. CPU needs to read from the memory area from which CRC is to be performed.

A memory area with 2 Mbytes is to be checked with the help of the CPU. CRC operation is to be performed every 1 Kbyte. In CPU mode, the MCRC\_CRC\_REGL1/H1 is not updated and contains indeterminate data.

##### 12.10.3.3.4.1 CRC Setup

- All control registers can be left in their reset state. Only enable Full-CPU mode.

CPU itself reads from the memory and write the data to the MCRC\_PSA\_SIGREGL1/MCRC\_PSA\_SIGREGH1 inside MCRC Controller. When the first incoming data pattern arrives at the MCRC\_PSA\_SIGREGL1/MCRC\_PSA\_SIGREGH1, the MCRC Controller will compress it. After n data patterns are compressed, CPU can read from the MCRC\_PSA\_SIGREGL1/MCRC\_PSA\_SIGREGH1. It is up to the CPU on how to deal with the PSA signature value just read. It can compare it to a known signature value stored at another memory location.

### 12.10.4 Logical Built-In Self-Test (LBIST)

#### 12.10.4.1 LBIST Overview

Built-in Self-test (BIST) is a feature that allows self-testing of the memory areas and logic circuitry in an Integrated Circuit (IC) without any external test equipment. In an embedded system, these tests are typically used during boot time or shutdown of the system to check the health of an SoC.

LBIST is used to test the logic circuitry in an SoC associated with the CPU cores. There are multiple LBIST instances in the SoC, and each has a different processor core associated with it. There are LBIST tests that can be software-initiated, as well as LBIST status of HW Power on self-tests (POST).

- LBIST is expected to be run at startup
- LBIST must be initiated from a different core than is being tested. The reason for this is that the LBIST test will impact the S/W running on the core, upon which the LBIST test is being run.
- BIST is executed by hardware for MCU and SMS automatically at boot up as part of HW POST

For a list of LBIST modules, see *Device Configuration -> Module Integration -> LBIST*.

#### 12.10.4.2 LBIST Functional Description

The Logic BIST Controller contains a Pseudo Random Pattern Generator (PRPG) and a Multiple Input Signature Register (MISR). The PRPG creates pseudo-random scan in data to drive the block's scan chains, and the MISR captures the scan out data and creates a signature based on this data. At the end of the test, the signature is compared with the expected signature value to determine if the test has passed or failed.

Each H/W module with Logic BIST has a standard Logic BIST Interface that is connected to the central Logic BIST MMR block. Control signals from the central MMR block fan out to all of the sub-chips, and status signals from the sub-chips back to the central MMR block connect to dedicated ports on the MMR block.

Logic BIST execution can be controlled by writing and reading registers in the MMR block. In a secure device, this MMR access will be limited by the SMS. An interrupt (generated by the MMR block) is sent back to the system when the LBIST execution is complete. The system processor can then use the MMRs to read the LBIST MISR signature and verify that the LBIST execution passed

Figure 12-515 shows the details of submodules with LBIST.

**Figure 12-515. LBIST Submodules**

#### 12.10.4.2.1 Sub-Chip Isolation

During LBIST run-time execution, the block under test by LBIST must be isolated from the remainder of the design so as not to negatively impact the operation of other areas of the SoC. This is accomplished by logically isolating the block under test. LBIST requires that the block inputs be isolated for LBIST macro operation (i.e. the inputs need to be in a deterministic state to obtain coverage). The block outputs need to be isolated so that the LBIST operation does not corrupt other logic in the SoC dependent on the outputs of the block being LBISTed.

#### 12.10.4.2.2 HW Power-On Self-Test (POST)

HW Power-On Self-Test (POST) tests are hardware tests performed every time the device is powered up, and are executed by hardware prior to ROM code being run. Software can check the HW POST MISR status in CTRL\_MMR\_WKUP registers. See *Device Configuration -> Module Integration -> LBIST* for details on modules which are tested by HW POST, and location of status results. Reference *Initialization Overview* for further details on device boot flow.

#### 12.10.4.2.3 Software Initiated Self-Test

The self-test operation for each IP can only be performed during periods where the IP is idle, as such recommendation is to run these tests at during device startup. Run time logic BIST will corrupt the state of every flip-flop in the IP, but it will not corrupt the state of the RAMs. The software that runs the self-test is responsible for:

- Informing the system that the IP is temporarily offline
- Saving the state of any critical registers in the IP before starting the self-test
- Triggering the self-test
- Restoring critical register values and/or reinitializing the IP after the self-test has completed

#### 12.10.4.2.4 Programming Sequence Software Initiated Self-Test

Execution of the LBIST tests requires preparation of the IPs under test by bringing them to a certain power and reset state before executing the test. It will be required that the application bring the cores/IPs to the proper state before executing the LBIST. Additionally, there is an "exit sequence" that is required to bring the cores/IPs back to the system control after the LBIST test is executed.

- For IP cores that are paired (ie A72, R5 etc), the entry sequence and exit sequence steps should be followed for both of cores, when either of the cores is the IP under test. Paired Cores are noted in *Device Configuration -> Module Integration -> LBIST*.
- For IP cores that have auxiliary cores defined, the entry sequence exist sequence steps should be followed for these auxiliary cores as well.

##### 12.10.4.2.4.1 Entry Sequence

1. Software decides to execute Self-Test.
2. Software must take appropriate steps to bring the target IP off-line.
  - a. This may include disabling interfaces, disabling interrupts, and storing any state information for re-start after Self-Test execution, but the required actions are to be determined by software.
3. Software places target IP in PSC\_SOFTWARE\_RESET\_DISABLE State.
4. Program Self-Test MMRs to enable to:
  - a. Switch clocks and override resets to the IP.

##### 12.10.4.2.4.2 LBIST Execution

To initiate the Logic Self-Test Operation (LBIST), follow below sequence, using values available in *Device Configuration -> Module Integration -> LBIST*.

1. Program MMRs to configure LBIST, using values available in *Device Configuration -> Module Integration->LBIST*.
  - a. Set LBIST\_CTRL register, divide\_ratio, dc\_def, values appropriate for block under test
  - b. Clear and set LBIST\_CTRL[7] load\_div.
  - c. Set LBIST\_PATCOUNT scan\_pc\_def, reset\_pc\_def, set\_pc\_def and static\_pc\_def to desired value
  - d. Set LBIST\_SEEDn, prpg\_def value
2. Enable self-test isolation of the IP
  - a. Set LBIST\_SPARE[0] to 1.
3. Program MMRs to run LBIST.
  - a. Set LBIST\_CTRL[31] bist\_reset to 1'b0
  - b. Set LBIST\_CTRL[15:12] runbist\_mode to 1'b1111
  - c. Set LBIST\_CTRL[31] bist\_reset to 1'b1
  - d. Set LBIST\_CTRL[27:24] bist\_run to 4'b1111
4. Optional check status by reading LBIST\_STAT[15] bist\_running.
5. Wait for LBIST\_STAT[31] bist\_done interrupt
6. Check the MISR signature and compare to expected value.
  - a. Set LBIST\_STAT[9:8] lbist\_out\_mux\_ctrl to 2'b1x

- b. Set LBIST\_STAT[7:0] lbist\_misr\_mux\_ctrl to 32'd0 (selects compact MISR signature)
- c. Read LBIST\_STAT[31:0] to trigger updating of LBIST\_MISR
- d. Read LBIST\_MISR[31:0]

#### 12.10.4.2.4.3 Exit Sequence

There are two options after Self-Test operation has completed. If the IP module is not needed by the system, the software may leave the IP in the PSC disable state with no further action. If software desires to begin using the IP after Self-Test, the following operations must be performed: Software must restore system control of the block by:

1. Programming Self-Test MMRs to switch back clock and reset control to the system
  - a. Set LBIST\_CTRL[27:24] bist\_run to 0
  - b. Set LBIST\_CTRL[31] bist\_reset to 0
2. Power off the LBISTed IP
3. Remove the BIST isolation set in the Self-Test Entry Sequence, by setting LBIST\_SPARE[0] to 1.
4. Power-on the LBISTed IP (software reset disable state)
5. Power-off and on the LBISTed IP

### 12.10.5 Programmable Built-In Self Test (PBIST)

#### 12.10.5.1 PBIST Overview

The PBIST (Programmable Built-In Self Test) architecture provides a memory BIST engine for varying levels of coverage across many embedded memory instances.

Built-in Self-test (BIST) is a feature that allows self testing of the memory areas and logic circuitry in an Integrated Circuit (IC) without any external test equipment. In an embedded system, these tests are typically used during boot time or shutdown of the system to check the health of an SoC. PBIST is used to test the memory regions in the SoC and provides detection for permanent faults. The primary use case for PBIST is when it is invoked at start-up providing valuable information on any stuck-at bits in the memory.

There can be multiple instances of PBIST in the SoC, and each has a number of memory regions associated with it. For further details on PBIST instances see *Device Configuration -> Module Integration -> PBIST*.

PBIST is expected to be run at power-up, but can be run at anytime between power-up and power-down of the device with following conditions:

- PBIST must be run from a different core than is being tested. This is because the PBIST test will impact any S/W which is running on core, upon which the PBIST test is being run.
- When PBIST test is being run, the memories under test must be isolated from the rest of the system, as any memory accesses to the H/W module memory during the PBIST test could cause it to fail.

#### 12.10.5.2 PBIST Functional Description

The PBIST architecture consists of a small CPU with an instruction set targeted specifically towards testing memories. This CPU includes both the control and the instruction registers necessary to execute the individual memory algorithms. Once an algorithm is loaded into the instruction registers, it can be run on multiple memories of different sizes or types by changing the control register. The following figure shows the basic block diagram for PBIST.

**Figure 12-516. PBIST Block Diagram**

### 12.10.5.3 PBIST Configuration Registers

PBIST uses internal configuration registers. All the configuration registers are memory mapped for access through the CPU or another programmable interface.

Details on the configuration registers are available in the register description spreadsheet.

### 12.10.5.4 PBIST Status Registers

#### Fail Status Data Registers

The FSRDL0[31:0], FSRDL1[31:0], FSRDU0[31:0] and FSRDU1[31:0] are read only internal registers that capture the failure data in case of failures.

- FSRDL0 corresponds to Port 0
- FSRDL1 corresponds to Port 1
- FSRDU0 and FSRDU1 registers are not used

#### Note

PBIST MISR is currently supported by H/W only for PBIST test of ROM.

#### Fail Status Address Register

Not used in TDA4VH device

#### Fail Status Count Register

Not used in TDA4VH device

#### Fail Status Fail Register

The FSRF0[31:0] and FSRF1[31:0] read only registers indicate whether a failure occurred or not.

- FSRF0 indicates Port 0 failures and FSRF1 indicates Port 1 failures.

### 12.10.5.5 Programming Sequence

#### 12.10.5.5.1 PBIST Entry Sequence

1. Ensure IPs modules under test are isolated such that the rest of the device does not send transactions to the IPs under test
2. Put IPs modules under test in enable state and reset state
3. Assert reset for the IP modules if available

4. Assert PBIST\_EN MMRs for the IPs if available
5. Put IP modules under test in enable state, but not reset state

#### 12.10.5.5.2 PBIST Programming

##### 12.10.5.5.2.1 PBIST Positive Test

To initiate the PBIST test of the H/W IP modules, follow the below programming sequence.

1. PBIST\_PACT – Set PACT[1:0] to turn on internal PBIST clocks. While this bit is 0, any access to PBIST will not go through.
2. PBIST\_CMS – PBIST Clock Mux Select Register, program to select between clock inputs.
  - Set PBIST\_CMS[1:0] to 1 to enable internal PBIST controller clock. When this bit is 0, any access to PBIST will not go through.
3. PBIST\_MARGIN\_MODE - Safety enable and algorithm subset select register. This register is repurposed on the TDA4VH device.
  - PBIST\_MARGIN\_MODE [2:0] are safety enable bits, set all bits 1.
  - PBIST\_MARGIN\_MODE [3] selects algorithm subset #0 or #1
    - MARGIN\_MODE[3] should be programmed to 0 for software based PBIST.
4. PBIST\_L0 - Variable loop count register
  - Initialize to 0.
5. PBIST\_ALGO - Algorithm mask register
  - The default value of this register is all 1s.
  - To meet the safety coverage requirements, TI will run a subset of all of the available algorithms.
  - Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> Positive Test Data to program this register.
6. PBIST\_RINFOL - RAM info mask register (lower)
  - The default value of this register is all 1s.
  - To meet the safety coverage requirements, TI will run a subset of all of the available algorithms.
  - Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> Positive Test Data to program this register.
7. PBIST\_RINFOU - Ram info mask register (upper)
  - See PBIST\_RINFOL above.
8. PBIST\_OVER - Override register
  - PBIST\_OVERRIDE [3] is the PBIST\_ALGO override bit.
    - To meet the safety coverage requirements, TI will run a subset of all available algorithms. To run this subset, set this bit to 0.
  - PBIST\_OVERRIDE[0] is PBIST\_RINFO override bit
    - To meet the safety coverage requirements, TI will run a subset of all available algorithms. To run this subset, set this bit to 0.
9. PBIST\_SCR0 - Address scrambling register (lower)
  - The PBIST\_SCR0 programmed value is not used on TDA4VH device.
10. PBIST\_SCR4 - Address scrambling register (upper)
  - Upper bits for address scrambling programmability.
  - The PBIST\_SCR4 programmed value is not used on TDA4VH device.
11. PBIST\_DLR - Datalogger register
  - Put PBIST controller into the appropriate modes and start the test.
  - Use rom-based config mode: set bit [2], DLR0\_ROM to 1 for PBIST test for ROM mode and set bit [4], DLR\_CAM0 to 1 for config mode.
12. Wait for PBIST Module StatusWait for PBIST controller interrupt.
  - Upon completion of the test, an interrupt will be generated and the system interrupt handler will read the pbist\_fail register to confirm pass/fail status of the test.
13. If the NUM\_TEST\_VECTORS entry, in *Device Configuration->Module Integration 0 -> PBIST Positive Test Data* is greater than one, run the test again, with the next set of PBIST\_AGLO and PBIST\_INFO values.

#### 12.10.5.5.2.2 PBIST Negative Test

To initiate a negative PBIST test of the H/W IP modules, follow the below programming sequence.

1. PBIST\_PACT – Set PACT[1:0] While this bit is 0, any access to PBIST will not go through.
  - Set to 1 to turn on internal PBIST clocks.
2. PBIST\_MARGIN\_MODE - Safety enable and algorithm subset select register. This register is repurposed on the TDA4VH device.
  - PBIST\_MARGIN\_MODE[2:0] are safety bits, set all bits 1.
  - PBIST\_MARGIN\_MODE [3] selects algorithm subset #0 or #1
    - ROM0 is for system-test and basic production test.
    - MARGIN\_MODE[3] is not used in PBIST Negative test.
3. PBIST\_L0 - Variable loop count register
  - Initialize to 0.
4. PBIST\_DLR - Datalogger register
  - Put PBIST controller into the appropriate modes and start the test.
  - Set bit [4] for config mode by programming 0x10
5. Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> Negative Test Data, to program the following registers.
  - PBIST\_RF0L, PBIST\_RF0U
  - PBIST\_RF1L, PBIST\_RF1U
  - PBIST\_RF2L, PBIST\_RF2U
  - PBIST\_RF3L, PBIST\_RF3U
  - PBIST\_RF4L, PBIST\_RF4U
  - PBIST\_D
  - PBIST\_E
6. Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> Negative Test Data, to program below registers.
  - PBIST\_DLR
  - PBIST\_CA2
  - PBIST\_CL0
  - PBIST\_CA3
  - PBIST\_IO0
  - PBIST\_CL1
  - PBIST\_I3
  - PBIST\_I2
  - PBIST\_CL2
  - PBIST\_CA1
  - PBIST\_CA0
  - PBIST\_CL3
  - PBIST\_I1
  - PBIST\_RAMT
  - PBIST\_CSR
  - PBIST\_CMS
7. Set PBIST\_STR to 0x1, to start.
8. Wait for PBIST controller interrupt. Upon completion of the test, an interrupt will be generated and the system interrupt handler will read the pbist\_fail registers below to confirm pass/fail status of the test.
  - Read registers FSRF0,1 for port0,1 pbist fail.
    - Expected value for both: 0x1
  - Read registers FSRA0,1
    - Expected value for both: 0x0
  - Read registers FSRDL0,1
    - Expected value for both: 0xFFFFFFFF

#### 12.10.5.5.2.3 PBIST Tests for ROM

1. PBIST\_PACT – Set PACT[1:0] to 0x1, to turn on internal PBIST clocks. While this bit is 0, any access to PBIST will not go through.
2. PBIST\_MARGIN\_MODE - Safety enable and algorithm subset select register. This register is repurposed on the TDA4VH device.
  - PBIST\_MARGIN\_MODE[2:0] are safety enable bits, set all bits 1.
  - PBIST\_MARGIN\_MODE[3] select algorithm subset, set to 0
    - PBIST\_MARGIN\_MODE[3] is not used in the PBIST tests for ROM
3. PBIST\_L0 - Variable loop count register
  - Initialize to 0.
4. PBIST\_DLR - Datalogger register
  - Put PBIST controller into the appropriate modes and start the test.
  - Set bit [4] for config mode, bit [8] for MISR mode, and bit [9] for go-nogo test. Expected MISR value is programmed into PBIST\_D and PBIST\_E.
5. Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> ROM Test Data, to program below registers.
  - PBIST\_RF0L, PBIST\_RF0U
  - PBIST\_RF1L, PBIST\_RF1U
  - PBIST\_RF2L, PBIST\_RF2U
  - PBIST\_RF3L, PBIST\_RF3U
  - PBIST\_RF4L, PBIST\_RF4U
  - PBIST\_RF5L, PBIST\_RF5U
  - PBIST\_RF6L, PBIST\_RF6U
  - PBIST\_RF7L, PBIST\_RF7U
  - PBIST\_RF8L, PBIST\_RF8U
  - PBIST\_RF9L, PBIST\_RF9U
  - PBIST\_RF10L, PBIST\_RF10U
  - PBIST\_D
  - PBIST\_E
6. Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST-> ROM Test Data, to program below registers.
  - PBIST\_CA2
  - PBIST\_CL0
  - PBIST\_CA3
  - PBIST\_IO0
  - PBIST\_CL1
  - PBIST\_I3
  - PBIST\_I2
  - PBIST\_CL2
  - PBIST\_CA1
  - PBIST\_CA0
  - PBIST\_CL3
  - PBIST\_I1
  - PBIST\_RAMT
  - PBIST\_CSR
  - PBIST\_CMS
7. Set PBIST\_STR[0] to 0x1 to start
8. Wait for PBIST Module StatusWait for PBIST controller interrupt.
  - Upon completion of the test, an interrupt will be generated and the system interrupt handler will read the pbist fail register to confirm pass/fail status of the test.
  - Optionally the MISR value, in FSRDL0 can be read back and compared to the value entered into registers PBIST\_D / PBIST\_E in Step 5. If values are equal, this is indicative of a pass, if values are different, this indicates a fail. This MISR comparison has been done by H/W in the preceding sub bullet.
9. For modules in *Device Configuration -> Module Integration -> PBIST -> PBIST tests for ROM Data*, that have more than one vector, run the test again for each vector. The Exit Sequence Reset should be followed before running next test.

#### **12.10.5.5.3 PBIST Exit Sequence Reset**

##### **PBIST soft reset (bring PBIST back to the state for next PBIST execution)**

1. Set register, PBIST\_PACT = 0x1
2. Set register, PBIST\_L0 = 0
3. Set register, PBIST\_PID = 0
4. Set register, PBIST\_OVER = 0xF
5. Set register, PBIST\_DLR = 0
6. Set register, PBIST\_CMS = 0

##### **Bring PBIST back to default state (state for when PBIST is not being used)**

1. Set register PBIST\_MARGIN\_MODE = 0
2. Set register PBIST\_RAMT = 0
3. Set register PBIST\_PACT = 0

## 12.10.6 ECC Aggregator

This section describes the common ECC aggregator functionality.

### 12.10.6.1 ECC Aggregator Overview

To increase functional and system reliability the memories (for example, FIFOs, queues, SRAMs and others) in many device modules and subsystems are protected by error correcting code (ECC). This is accomplished through an ECC aggregator and ECC wrapper. The ECC aggregator is connected to these memories (hereinafter ECC RAMs) and involved in the ECC process. Each memory is surrounded by an ECC wrapper which performs the ECC detection and correction. The wrapper communicates via serial interface with the aggregator which has memory mapped configuration interface.

The ECC aggregator is also connected to interconnect ECC components that protect the command, address and data buses of the system interconnect. ECC is calculated for the data bus and parity and redundancy for the command and address buses. Each interconnect ECC component has the same serial interface for communication with the aggregator as the ECC wrapper. An ECC aggregator may be connected to both endpoints - the ECC wrapper and interconnect ECC component.

The ECC aggregator, ECC wrapper and interconnect ECC component are considered as single entity and are hereinafter referred to as ECC aggregator unless otherwise explicitly specified.

Table 12-440 lists the device modules and subsystems which have ECC aggregator.

**Table 12-440. Device Modules and Subsystems with ECC Aggregator**

### 12.10.6.1.1 ECC Aggregator Features

The ECC aggregator has the following features:

- Reduces memory software errors via single error correction (SEC) and double error detection (DED)
- Provides a mechanism to control and monitor the ECC protected memories in a module or subsystem
- SEC and DED over the system interconnect data bus and parity and redundancy for the system interconnect command and address buses
- Generates an interrupt for correctable error
- Generates an interrupt for non-correctable error
- Supports inject only mode for diagnostic purposes
- Supports software readable status for single and double-bit ECC errors and associated information such as row address where error has occurred and data bits that have been flipped
- Supports up to 256 ECC endpoints. An ECC endpoint can be either ECC RAM or interconnect ECC component.
- Detects single bit error via parity checking on:
  - Memory mapped configuration interface FIFO
  - Serial interface FIFO
  - Serial interface transaction
- Single bit error detection via parity checking results in a non-correctable error interrupt
- Supports timeout mechanism on transactions over the ECC serial interface. Timeout occurrence results in a non-correctable error interrupt.
- Certain control bits have redundancy and if a bit flips an interrupt is generated

### 12.10.6.2 ECC Aggregator Functional Description

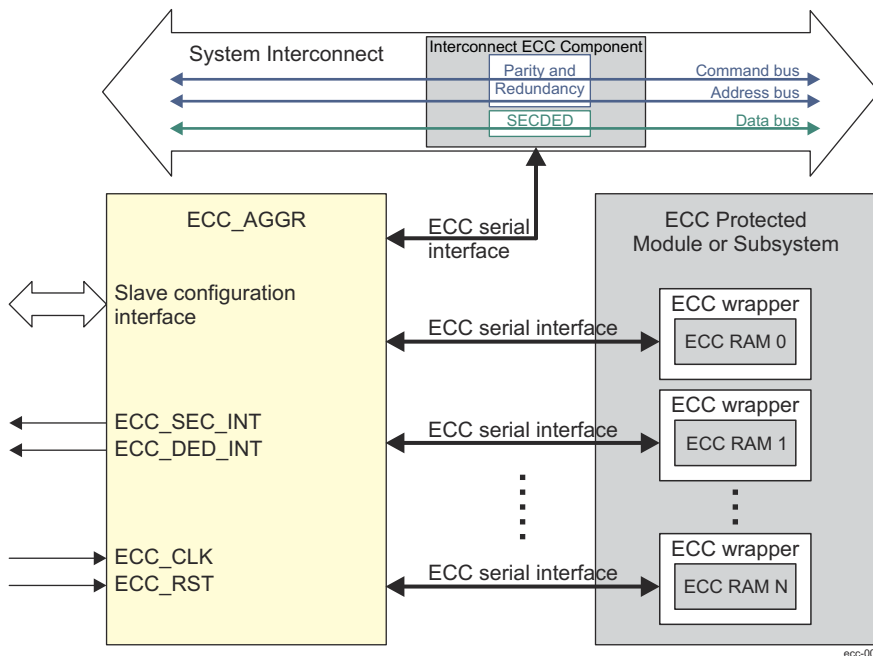

This section describes the architecture and functional details of the ECC aggregator.

#### Note

See Appendix Spreadsheet for ECC Aggregators Interconnect details.

#### 12.10.6.2.1 ECC Aggregator Block Diagram

Figure 12-517 shows the ECC aggregator block diagram.

**Figure 12-517. ECC Aggregator Block Diagram**

The ECC aggregator is connected to one or more ECC endpoints each of which has assigned a unique ID used when the endpoint is accessed for status information or configuration. The ECC aggregator provides software access to all ECC related registers through its memory mapped slave configuration interface while the serial interface is used to communicate with the ECC endpoints. Upon detection of single or double-bit error the corresponding interrupt line is asserted.

#### 12.10.6.2.2 ECC Aggregator Register Groups

The ECC aggregator has ECC control, status and interrupt registers for each ECC endpoint in a module or subsystem. These registers are memory mapped and occupy 1 KB address space although part of it may contain reserved locations. The registers are split in the following types:

- **Global registers.** They are common to all ECC endpoints associated with the ECC aggregator and include the ECC\_VECTOR and ECC\_REV registers. Each ECC endpoint has assigned a unique ID. When this ID is written to the ECC\_VECTOR[10-0] ECC\_VECTOR field the corresponding endpoint is selected either for control or for status reading.
- **ECC control and status registers.** These registers are specific to each ECC endpoint and reside in the range from address offset 0x10 to 0x28, if the endpoint is ECC RAM or from 0x10 to 0x24, if the endpoint is interconnect ECC component. They are memory mapped but are accessed through the ECC serial interface. They are also selected by the ECC endpoint ID written to the ECC\_VECTOR[10-0] ECC\_VECTOR field. Because of latency on the serial interface the ECC control and status registers are read by performing special sequence as described in [Section 12.10.6.2.3](#). These registers have also different functionality for both types of endpoints - ECC RAM and interconnect ECC component.
- **Interrupt registers.** They include interrupt status, interrupt enable, interrupt disable, and EOI registers. For more information, see *Interrupts*.

### 12.10.6.2.3 Read Access to the ECC Control and Status Registers

Read accesses to the ECC control and status registers for each ECC endpoint represent read operations over the ECC serial interface and are triggered by performing the following sequence:

- Software writes the following in the ECC\_VECTOR register:
  - The ECC endpoint ID in the ECC\_VECTOR[10-0] ECC\_VECTOR field to select particular ECC endpoint.
  - The register read address in the ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field to select which register has to be read through the ECC serial interface.
  - A value of 0x1 in the ECC\_VECTOR[15] RD\_SVBUS bit to trigger read operation through the ECC serial interface.
- Software polls the ECC\_VECTOR[24] RD\_SVBUS\_DONE bit to check if it is 0x1. This indicates that the read operation on the ECC serial interface has completed.
- Software reads the data from the register previously selected by the ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field.

The following is an example for serial read operation:

- Write 0x0010 8005 to the ECC\_VECTOR register. This sends read request to the ECC\_WRAP\_REV or ECC\_CBASS\_REV register (address = 0x10) associated with ECC endpoint with ID = 5.
- Poll the ECC\_VECTOR[24] RD\_SVBUS\_DONE bit until value of 0x1 is read.
- Read the ECC\_WRAP\_REV or ECC\_CBASS\_REV register to get its value.

### 12.10.6.2.4 Serial Write Operation

Write operations over the ECC serial interface are performed as follows:

- Software specifies the ECC endpoint ID in the ECC\_VECTOR[10-0] ECC\_VECTOR field. The ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field is a don't care but the ECC\_VECTOR[15] RD\_SVBUS bit must be set to 0x0.
- Software performs regular write operation to the desired address. If the ECC endpoint ID has already been specified, step 1 can be skipped. Unlike serial read operations it is not necessary to always specify the endpoint ID before performing serial write operation.

The following is an example for serial write operation:

- Write 0x0000 0008 to the ECC\_VECTOR register.
- Write 0x0000 000F to the ECC\_CTRL register. This sends write request with data 0x0000 000F to the ECC\_CTRL register associated with ECC RAM with ID = 8.

### 12.10.6.2.5 Interrupts

The ECC aggregator generates the following interrupts:

- Correctable interrupt (ECC\_SEC\_INT) where hardware can correct the error but notifies the system in case of SEC.
- Non-correctable interrupt (ECC\_DED\_INT) where hardware cannot correct the error in cases of DED, parity check, redundancy check or timeout occurrence.

The following is the sequence for servicing interrupts:

- Software enables the interrupts for an ECC endpoint by writing 0x1 to the corresponding bit of the following interrupt enable registers:
  - ECC\_SEC\_ENABLE\_SET\_REG0 through ECC\_SEC\_ENABLE\_SET\_REG7 for the correctable interrupt
  - ECC\_DED\_ENABLE\_SET\_REG0 through ECC\_DED\_ENABLE\_SET\_REG7 for the non-correctable interrupt
- On receiving an interrupt, software checks which ECC endpoint has caused the error by reading the following interrupt status registers:
  - ECC\_SEC\_STATUS\_REG0 through ECC\_SEC\_STATUS\_REG7 for the correctable interrupt
  - ECC\_DED\_STATUS\_REG0 through ECC\_DED\_STATUS\_REG7 for the non-correctable interrupt
- Software performs serial read operations as described in [Section 12.10.6.2.3](#) to read the following status registers that contain details about the error:

- If the endpoint is ECC RAM:
  - ECC\_ERR\_STAT1
  - ECC\_ERR\_STAT2
  - ECC\_ERR\_STAT3
- If the endpoint is interconnect ECC component:
  - ECC\_CBASS\_ERR\_STAT1
  - ECC\_CBASS\_ERR\_STAT2
- After the interrupt has been serviced, depending on the error type, software should clear the corresponding status bits in the ECC\_ERR\_STAT1 and ECC\_ERR\_STAT3 registers or in the ECC\_CBASS\_ERR\_STAT1 register. Software has to poll these registers to guarantee that status bits are cleared as there is no other indication for write completion over the ECC serial interface.  
The value of the \*\_PEND\_CLR fields in the ECC\_CBASS\_ERR\_STAT1 register must be read and then written back to decrement the count of each field back to 0x0. A further error capture into the ECC\_CBASS\_ERR\_STAT1 register does not occur unless all its fields are 0x0. The decrement value should not be larger than the read value. If a field in the ECC\_CBASS\_ERR\_STAT1 register should not be modified, write a value of 0x0 to that field.
- Software writes 0x1 to the corresponding end of interrupt register to clear the interrupt:
  - ECC\_SEC\_EOI\_REG for the correctable interrupt
  - ECC\_DED\_EOI\_REG for the non-correctable interrupt

#### 12.10.6.2.6 Inject Only Mode

There are modules that already perform the ECC generation and checking as part of their data path. In this case, the ECC wrapper may be configured in inject only mode, if needed. In this mode the ECC wrapper does not perform ECC detection and correction. The inject only mode allows users to inject single or double-bit errors so that the module logic can be tested for diagnostic purposes.

#### Note

There is no software control to enable inject only mode. It is configured via tie-off value. Inject only and ECC modes are mutually exclusive.

The interconnect ECC component also supports error injection mode. There is error injection logic for testing of the error checking logic (checkers). The injection logic can be configured to inject either single or double bit error and what data pattern to be used for injection (ECC\_CBASS\_CTRL[11-8] ECC\_PATTERN). The ECC\_CBASS\_ERR\_CTRL1 and ECC\_CBASS\_ERR\_CTRL2 registers should be written first to setup the injection. Then, either the ECC\_CBASS\_CTRL[3] FORCE\_SE or the ECC\_CBASS\_CTRL[4] FORCE\_DE bit must be set to 0x1 to start the injection. Both bits must not be set at the same time. If the injection should continue in incrementing mode, then the ECC\_CBASS\_CTRL[5] FORCE\_N\_BIT bit should be set to 0x1. Once the FORCE\_N\_BIT is set, then each successive injection can simply write the ECC\_CBASS\_CTRL register to set the FORCE\_SE or FORCE\_DE again. Reading 0x0 from either the FORCE\_SE or the FORCE\_DE bit indicates that the injection has completed, as these bits automatically clear when the checker indicates that it has performed the injection. The time for an injection to complete is not guaranteed, so some delay is needed between successive injections.

#### 12.10.6.2.7 ECC Error Injection Sequence

The ECC aggregator is a critical component for enhancing system reliability by protecting memories in various device modules and subsystems. The ECC Aggregator is connected to these memory and interconnect components which have the ECC, to provide access to control and monitor the ECC protected memories in a module or subsystem.

The ECC aggregator supports error injection to aid in diagnostic purposes and to evaluate robustness. The Error Injection feature supported by the ECC aggregator allows users to deliberately introduce errors into their system to test the resilience and effectiveness of error correction mechanisms. This feature helps in evaluating the robustness of the ECC aggregator by simulating real-world error scenarios, enabling users to identify potential vulnerabilities and improve their error handling strategies.

This feature includes configurable parameters such as ECC aggregator type, subtype, error type, and injection location, allowing users to customize their testing scenarios based on their specific requirements.

#### **12.10.6.2.7.1 Types of Error Injection**

ECC is a mechanism for providing increased protection against soft errors by allowing single bit errors to be detected and corrected and double bit errors to be detected. The ECC Control Register can be used to inject single bit or double bit errors. For more information on this register, refer to [Section 12.10.6.2.2](#). These errors are then reported through the Error Signal Module (ESM).

- **Single Error Correction (SEC):** In the event of single bit errors, the ECC aggregator has the ability to both detect and correct these errors, ensuring the integrity of the data. Single bit error injection is supported for all endpoints and checkers. Single bit error correction is not supported for parity and redundancy type of checkers.
- **Double Error Detection (DED):** For double bit errors, the ECC aggregator can detect these errors. However, it does not have the capability to correct them. Instead, it signals the presence of these errors to the Central Processing Unit (CPU) via ESM interrupts. This is supported for all RAM wrapper types and interconnect EDC checker type of endpoints. Parity and Redundant checker types do not support double bit ECC error injection.

The ECC aggregator plays a crucial role in maintaining data accuracy by correcting single bit errors and detecting double bit errors, although it cannot correct the latter. This process helps in enhancing the overall system reliability. Each ECC aggregator connects to two kinds of ESM events – Correctable error events (for SEC events) and Un-correctable error events (for DED events and parity and redundancy checker types). ESM is used for notification of events from endpoints which are not Inject-Only. Inject-Only endpoints notify errors through IP-specific mechanisms. Sometimes a separate ESM event (not via ECC aggregator) is available. Please refer to the individual IP sections for more details on the ESM events generated.

The ECC aggregator provides support for injecting single and double bit errors. In the case of RAM wrapper type endpoints, errors can be injected to a specific row or can be requested to be injected on the next row access (`n_row`). Errors can be requested to be injected once or on repeated reads. For Interconnect endpoint types, single and double bit errors (depending on the checker type) can be injected.

##### **12.10.6.2.7.1.1 ECC Wrapper Type Endpoints**

Each memory is surrounded by an ECC wrapper which performs the ECC detection and correction. The wrapper communicates via serial interface with the aggregator which has memory a mapped configuration interface. For RAM wrapper types, after injecting the error, the RAM location where the error was injected needs to be accessed in order to trigger the error interrupt. If the “`force_n_row`” option is selected during error injection, then any RAM access will trigger the interrupt and the specific row is not needed.

##### **12.10.6.2.7.1.2 EDC Interconnect Type Endpoints**

The ECC aggregator is also connected to interconnect ECC components that protect the command, address and data buses of the system interconnect. ECC is calculated for the data bus and parity and redundancy for the command and address buses. For the interconnect types, the type of checker must be verified to determine if they are parity or redundant types.

##### **12.10.6.2.7.1.3 Inject Only ECC Endpoints**

Some modules may already do the generation of and checking of ECC as part of their data path. In this case, the ECC wrapper does not have to perform ECC detection and correction and is configured in inject only mode. The wrapper will not add extra bits to the ram, generate, nor check ECC. It will, however, allow the user to inject single or double-bit errors so that the IP's logic can be tested for diagnostic purposes. Detection and correction occurs in the IP itself. In some cases, the error may also be routed to ESM, but not to the same ESM event as the ECC aggregator. For more information on these memories, refer to [Section 12.10.6.2.6](#).

##### **12.10.6.2.7.1.4 Full Functionality Error Capture ECC Endpoints**

These ECC aggregators possess the ability to perform Error Injection alongside Error Capture. The wrapper can be utilized to introduce either single or double-bit errors, while also having the capability to detect and correct errors.

For more information regarding the ECC endpoint types, refer to the Appendix spreadsheet.

#### **12.10.6.2.7.2 Types of ECC Checkers**

There are various checkers for bus signals, MMRs, or internal registers in the interconnect.

##### **12.10.6.2.7.2.1 Parity Type Checkers**

The most common checker type is parity. The parity type refers to checkers where a parity bit is added to cover the entire signal. The parity bit is the  $\sim^{\wedge}\text{signal}$ , where the signal width can be any number of bits.

##### **12.10.6.2.7.2.2 Redundant Type Checkers**

The redundant type refers to checkers for critical signals (like request). The redundant signal is the opposite of the signal it is protecting.

##### **12.10.6.2.7.2.3 Error Detect and Correct (EDC) Type Checkers**

The EDC type refers to SECDED error-correcting code that can correct single bit error, and detect a two bit error.

For more information regarding the ECC checker type for each aggregator, refer to the Appendix spreadsheet.

#### **12.10.6.2.7.3 Recommendations for Testing Error Injection**

The following are the general recommendations on when the error injection on ECC aggregators must be performed:

- The ECC error injection and monitoring of the error response should be run at 'startup' where possible.
- An alternative recommended approach is to run ECC error injection at 'shutdown'.

When running of ECC error injection during 'runtime', the system integrator must be aware of the below:

##### **For interconnect endpoints:**

- The ECC SEC error injection runs during idle cycles, so can be run during 'runtime' for checkers of all types.
  - Parity and redundant bit error injections are non-destructive and can be done at runtime.
- The ECC DED error injection runs during idle cycles, so can be run during 'runtime'.
  - Only single bit error injections are to be done on parity/redundant checker types. This is because these protect odd number of injections. A 2 bit injection on parity will not cause a failure.

##### **For RAM memories:**

- ECC self-test for SEC on RAM memories, can be run at runtime:
  - The ECC self-test for SEC injects a single-bit error that is corrected in-line.
- ECC DED error injection during 'runtime' for RAM memories, should only be done for memories with direct read access
  - Two examples of direct read access memories are MSMC SRAM and MCU SRAM
  - Double-bit error injection on all other embedded SRAMS could possibly result in the downstream IP reading bad data if run during 'runtime'
- CC error injection on inject-only memories, should be run at 'startup', they are not recommended to be run during 'runtime'. For more information on these memories, refer to [Section 12.10.6.2.6](#).

#### **12.10.6.2.7.4 Error Injection Programming Sequence**

##### **12.10.6.2.7.4.1 ESM Initialization**

The ESM instance must be initialized with the following sequence. This initialization will allow the application to specify for each event whether the interrupt is enabled or disabled, the priority of the event, and whether the nErrorPin assertion is enabled or disabled for the event. This needs to be done only once. All the required ESM events can be initialized at the same time.

For more information on the ESM, refer to [Section 12.10.2](#).

To initialize the ESM module for a specified instance:

1. Clear all raw status and enable bits by setting ESM\_SFT\_RST Register bits [3:0] to 0Fh, to reset the ESM
2. Write 0x1 to the appropriate bits in the ESM\_ERR\_STS register. This step will clear the configuration interrupt raw status

3. Write 0x1 to the appropriate bits in the ESM\_ERR\_EN\_SET register, to enable the configuration error interrupt as described in [Section 12.10.2.3.1.1](#).
4. Write 0x1 to the appropriate bits in the error group j of the ESM\_STS\_j register. This step will clear the level interrupt raw status.
5. Write 0x1 to the appropriate bits in the error group j of the ESM\_INTR\_EN\_SET\_j register, to enable the level error interrupt.
6. Write 0x1 to the appropriate bits in the error group j of the ESM\_INT\_PRIO\_j register, to indicate which interrupt the corresponding event influences (if enabled) for event group j.
7. If required, write 0x1 to the appropriate bits in the error group j of the ESM\_PIN\_EN\_SET\_j register, to set error output corresponding to the desired events.
8. Enable the global interrupts by setting ESM\_EN Register bits [3:0] to 0Fh

#### 12.10.6.2.7.4.2 ECC Initialization

1. Setting the timeout bit is required to enable notification for ECC serial interface timeout errors. The parity bit must be set to enable notification for parity errors. To enable the timeout (bit 1) and parity (bit 0) bits, write 0x1 to the ECC\_AGGR\_ENABLE\_SET register.
2. Write 0x1 to the ECC\_SEC\_ENABLE\_SET\_REGx (to enable correctable SEC error interrupts) and ECC\_DED\_ENABLE\_SET\_REGx (to enable uncorrectable DED error interrupts) registers for required endpoints.

The following register configurations are per endpoint and done through the SVBUS programming interface. Refer to [Section 12.10.6.2.4](#) for more information.

1. Write 0x1 to the ECC\_CHECK field of the ECC\_CBASS\_CTRL register to enable ECC check for interconnect endpoints.
2. Write 0x1 to the ENABLE\_RMW, ECC\_CHECK and ECC\_ENABLE bit fields of the ECC\_CTRL register to enable ECC check for wrapper type endpoints.

#### 12.10.6.2.7.4.3 Error Injection

For ECC Wrapper Type Endpoints:

1. Write to the ECC\_ERR\_CTRL1 Register to set the row address where FORCE\_SEC or FORCE\_DED needs to be applied. This is ignored if FORCE\_N\_ROW is set.
2. Configure the ECC\_RAM\_CTRL bits[6:3] register based on the type of error injection.
3. Perform a read back of the ECC\_RAM\_CTRL register to confirm error injection. The read value may not be same as what is written as some fields in the register are not writable or can self-clear.
4. For RAM wrapper types, after injecting the error, the RAM needs to be accessed in the row where the error was injected (if FORCE\_N\_ROW is used, any row can be accessed) in order to trigger the error interrupt.
5. For Inject-only Wrapper endpoints, only error injection is possible via the ECC aggregator, the detection and correction is be done by the IP itself.

Field	Name	Type	Reset	Description
0	ecc_enable	r/w	1	Enable ECC generation. <b>Reset to 1 with inject only configuration, but any write to this register byte clears this bit to 0. Resets to 1 in all other configurations.</b>
1	ecc_check	r/w	1/0	Enable ECC check. ECC is completely bypassed if both ecc_enable and ecc_check are '0'. <b>Reset to 0 with inject only configuration, and not writable. Reset to 1 in all other configurations.</b>
2	enable_rmw	r/w	1/0	Enable read-modify-write on partial word writes. <b>If disabled ecc detection and correction will no longer work and if re-enabled the ram contents must all be rewritten to correct ecc codes. Reset to 0 with inject only configuration, and not writable. Reset to 1 in all other configurations.</b>

Field	Name	Type	Reset	Description
3	force_sec	r/w	0	Force single-bit error. Cleared the cycle following the error if error_once is asserted. for write through mode this applies to writes as well as reads.
4	force_ded	r/w	0	Force double-bit error. Cleared the cycle following the error if error_once is asserted. for write through mode this applies to writes as well as reads.
5	force_n_row	r/w	0	Force single/double-bit error on the next RAM access. for write through mode this applies to writes as well as reads.
6	error_once	r/w	0	If this bit is set, the force_sec/force_ded will inject an error to the specified row only once. The force_sec bit will be cleared the cycle after the error is generated. For double-bit errors, the force_ded bit will be cleared the cycle following the double-bit error. In either case force_n_row will be cleared as well. Any subsequent reads will not force an error.
7	check_parity	r/w	1	Enables parity checking on internal data
8	Check svbus timeout	r/w	1	Enable svbus timeout mechanism
9-31	Reserved			

For ECC Interconnect Type Endpoints:

1. Clear any pending error injection by writing 0x0 to the bit fields of the ECC\_CBASS\_CTRL register
2. Configure the ECC\_CBASS\_ERR\_CTRL1 and ECC\_CBASS\_ERR\_CTRL2 registers based on the error group and type of error injection.
3. Write to the ECC\_CBASS\_CTRL register to inject the error.
4. For interconnect types, the error injection happens on idle cycles, so no additional access of the memory is required.

#### 12.10.6.2.7.4.4 Error Handling

1. When an error event occurs, the user can query and collect the information about the endpoint and offset information for the location relative to the start of the associated RAM.
2. To clear the ECC error event, clear the pending status of the ECC error events by configuring the ECC\_RAM\_ERR\_STAT1 (for Wrapper type endpoints) and SDL\_EDC\_CTL\_ERR\_STATUS1(for Interconnect type endpoints) register.
3. The ECC\_SEC\_EOI\_REG register is used to re-trigger the pulse interrupt signal to ensure that any nested interrupt events are serviced. The software interrupt handler must write to the ECC\_SEC\_EOI\_REG register at the end of the current interrupt processing routine, so that new events can re-trigger the pulse interrupt signal again. For level interrupt signals the ECC\_SEC\_EOI\_REG register is not functional and must not be used.
4. Clear the ESM error interrupt using the ESM registers.

### 12.10.6.3 ECC Aggregator Registers

Table 12-443 lists the memory-mapped registers for an ECC Aggregator (ECC\_AGGR).

**Table 12-443. ECC\_AGGR Registers**

Offset	Acronym	Register Name
ECC Wrapper Registers		
10h	<a href="#">Section 12.10.6.3.1</a>	ECC Wrapper Revision Register
14h	<a href="#">Section 12.10.6.3.2</a>	ECC RAM Control Register
18h	<a href="#">Section 12.10.6.3.3</a>	ECC RAM Error Control 1 Register

Bit	Field	Type	Reset	Description
31-16	ECC_BIT2	R/W	0h	Data bit that needs to be flipped if double-bit error has to be forced. The ECC_CTRL[4] FORCE_DED bit must be set to 1h for these values to take affect.
15-0	ECC_BIT1	R/W	0h	Data bit that needs to be flipped if single-bit error has to be forced. The ECC_CTRL[3] FORCE_SEC bit must be set to 1h for these values to take affect.

### 12.10.6.3.5 ECC\_ERR\_STAT1 Register (Offset = 20h) [reset = X]

ECC\_ERR\_STAT1 is shown in [Figure 12-522](#) and described in [Table 12-448](#).

Return to [Summary Table](#).

ECC RAM Error Status 1 Register

LEGEND: R = Read Only; R/W = Read/Write; R/W1C = Read/Write 1 to Clear Bit; R/W1S = Read/Write 1 to Set Bit; -n = value after reset

**Table 12-448. ECC\_ERR\_STAT1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	ECC_BIT1	R	0h	Indicates the bit position in the RAM data that is in error. For example, a value of 1h indicates that bit [1] in the RAM data is in error. This is valid only for single-bit errors.  <b>Note</b> <b>NOTE:</b> Not used in inject only mode. Always read as 0h.
15	CLR_CTRL_REG_ERR	R/W1C	0h	Clear the CTR_REG_ERR bit. A write of 1h clears this bit and the CTR_REG_ERR bit, but if the redundancy protected bits in the ECC_CTRL register have not been written to a known state to correct the error, this flag is immediately set again.
14-13	CLR_PARITY_ERR	R/W	0h	A write of a non-zero value to this field decrements the CLR_ECC_DED and ECC_DED fields by that value. If the value written is less than the current one, the non-correctable interrupt (ECC_DED_INT) stays asserted. If the value to decrement is more than the current value, the result is 0. 0h - No parity errors have occurred 1h - 1 parity error has occurred 2h - 2 parity errors have occurred 3h - 3 or more parity errors have occurred
12	CLR_ECC_OTHER	R/W1C	0h	Clear other error status. 1h indicates a successive single-bit error. Writing 1h clears the status bit.

**Table 12-448. ECC\_ERR\_STAT1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11-10	CLR_ECC_DED	R/W	0h	<p>A write of a non-zero value to this field decrements it and the ECC_DED field by that value. If the value written is less than the current one, the non-correctable interrupt (ECC_DED_INT) stays asserted. If the value to decrement is more than the current value, the result is 0.</p> <p>0h - No double-bit errors have occurred  1h - 1 double-bit has error occurred  2h - 2 double-bit have errors occurred  3h - 3 or more double-bit errors have occurred</p> <hr/> <p style="text-align: center;"><b>Note</b></p> <p><b>NOTE:</b> Not used in inject only mode. Always read as 0h.</p> <hr/>
9-8	CLR_ECC_SEC	R/W	0h	<p>A write of a non-zero value to this field decrements it and the ECC_SEC field by that value. If the value written is less than the current one, the correctable interrupt (ECC_SEC_INT) stays asserted. If the value to decrement is more than the current value, the result is 0.</p> <p>0h - No single-bit errors have occurred  1h - 1 single-bit has occurred  2h - 2 single-bit have occurred  3h - 3 or more single-bit have occurred</p> <hr/> <p style="text-align: center;"><b>Note</b></p> <p><b>NOTE:</b> Not used in inject only mode. Always read as 0h.</p> <hr/>
7	CTR_REG_ERR	R/W1S	0h	<p>Indicates that a redundancy protected bit in the ECC_CTRL register has been flipped. This means that the redundancy logic have detected a state where not all values are the same and has defaulted to the reset state. Software needs to re-write these registers to a known state. A write of 1h sets this bit.</p> <p>0h - Bit not flipped  1h - Bit flipped</p>
6-5	PARITY_ERR	R/W1S	0h	<p>2-bit saturating counter for the number of parity errors that have occurred since last cleared. This is also a status set register and a non-zero value sets the level interrupt. Software can also write a value to the CLR_PARITY_ERR field to decrement this counter.</p> <p>0h - No parity errors have occurred  1h - 1 parity error has occurred  2h - 2 parity errors have occurred  3h - 3 or more parity errors have occurred</p>
4	ECC_OTHER	R/W1S	0h	<p>1h - Indicates that successive single-bit errors have occurred while a write-back is still pending. Software can also write 1h to set the pending status and write 1h to the corresponding clear bit to clear the status.</p> <hr/> <p style="text-align: center;"><b>Note</b></p> <p><b>NOTE:</b> Not used in inject only mode. Always read as 0h.</p> <hr/>

**Table 12-448. ECC\_ERR\_STAT1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3-2	ECC_DED	R/W	0h	<p>2-bit saturating counter for the number of double-bit errors that have occurred since last cleared. This is also a status set register and a non-zero value sets the level interrupt. Software can also write a value to the CLR_ECC_SEC field to decrement this counter.</p> <p>0h - No double-bit errors have occurred            1h - 1 double-bit has error occurred            2h - 2 double-bit have errors occurred            3h - 3 or more double-bit errors have occurred</p> <hr/> <p style="text-align: center;"><b>Note</b></p> <p><b>NOTE:</b> Not used in inject only mode. Always read as 0h.</p> <hr/>
1-0	ECC_SEC	R/W	0h	<p>2-bit saturating counter for the number of single-bit errors that have occurred since last cleared. This is also a status set register and a non-zero value sets the level interrupt. Software can also write a value to the CLR_ECC_SEC field to decrement this counter.</p> <p>0h - No single-bit errors have occurred            1h - 1 single-bit has occurred            2h - 2 single-bit have occurred            3h - 3 or more single-bit have occurred</p> <hr/> <p style="text-align: center;"><b>Note</b></p> <p><b>NOTE:</b> Not used in inject only mode. Always read as 0h.</p> <hr/>

### 12.10.6.3.6 ECC\_ERR\_STAT2 Register (Offset = 24h) [reset = X]

ECC\_ERR\_STAT2 is shown in [Figure 12-523](#) and described in [Table 12-449](#).

Return to [Summary Table](#).

ECC RAM Error Status 2 Register

**Figure 12-523. ECC\_ERR\_STAT2 Register**

LEGEND: R = Read Only; R/WD = Read/Write to Decrement Field; R/WI = Read/Write to Increment Field; -n = value after reset

**Table 12-455. ECC\_CBASS\_ERR\_STAT1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	ERR_GRP	R	0h	Specific checker that reported the error.
15-14	INJ_UNC_PEND_CLR	R/WD	0h	Number of injected uncorrected pending interrupts (same value as UNC_PEND). Writing decrements INJ_UNC_PEND by that value.
13-12	INJ_COR_PEND_CLR	R/WD	0h	Number of injected corrected pending interrupts (same value as COR_PEND). Writing decrements INJ_COR_PEND by that value.
11-10	UNC_PEND_CLR	R/WD	0h	Number of uncorrected pending interrupts (same value as UNC_PEND). Writing decrements UNC_PEND by that value.
9-8	COR_PEND_CLR	R/WD	0h	Number of corrected pending interrupts (same value as COR_PEND). Writing decrements COR_PEND by that value.
7-6	INJ_UNC_PEND	R/WI	0h	Number of injected uncorrected pending interrupts. Writing increments by that value.
5-4	INJ_COR_PEND	R/WI	0h	Number of injected corrected pending interrupts. Writing increments by that value.
3-2	UNC_PEND	R/WI	0h	Number of uncorrected pending interrupts. Writing increments by that value.
1-0	COR_PEND	R/WI	0h	Number of corrected pending interrupts. Writing increments by that value.

### 12.10.6.3.13 ECC\_CBASS\_ERR\_STAT2 Register (Offset = 24h) [reset = X]

ECC\_CBASS\_ERR\_STAT2 is shown in [Figure 12-530](#) and described in [Table 12-456](#).

Return to [Summary Table](#).

Interconnect ECC Component Error Status 2 Register.

This register allows reading the captured error data.

**Figure 12-530. ECC\_CBASS\_ERR\_STAT2 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ERR_TYPE																ERR_BIT															
R-0h																R-0h															

LEGEND: R = Read Only; -n = value after reset

**Table 12-456. ECC\_CBASS\_ERR\_STAT2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	ERR_TYPE	R	0h	This field is not supported and can read any value and be ignored.
15-0	ERR_BIT	R	0h	Bit that caused the error. Always valid for EDC single bit corrected errors or redundant errors. Identifies parity segment number (but not the exact bit) with a parity error. This field is not valid for EDC double bit errors.

## 13 On-Chip Debug

This chapter describes the on-chip debug support.

### Note

This chapter is under development and is included as a placeholder for future updates.

## 14 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

### Changes from September 30, 2024 to August 31, 2025 (from Revision E (September 2024) to Revision F (August 2025))

Page

• Updated Common Platform Time Sync Module value in Modules Allocation and Instances within Device Domains table.....	8
• Added TOG Timeout Gasket chapter.....	165
• Added Footnote to POST Selection table.....	179
• Updated Serial NAND Boot Parameter Table.....	212
• Updated Clock Mapping table.....	282
• Added Resets, Interrupts, and Clocks sections.....	359
• Added LBIST Integration section.....	384
• Added PVU Parameters section.....	398
• Added PBIST Integration section.....	400
• Added Timeout Gasket (TOG) section.....	426
• MTOG Instances and Registers table and STOG Self-Test Target Addresses and Self-Test Timeout Values table moved into Timeout Gasket (TOG) Integration Details section.....	426
• Added Safety Event Mapping for Compute Cluster (ESM Events) section.....	433
• Added R5FSS Not Supported Features section.....	448
• Added Note to R5FSS ECC Support section.....	467
• Updated Unsupported Features section.....	526
• Added VPAC Not Supported Features section.....	537

• Added LDC Not Supported Features section.....	651
• Added MSC Not Supported Features section.....	677
• Added DMPAC Not Supported Features section.....	718
• Added Mailbox Not Supported Features section.....	719
• Added Spinlock Not Supported Features section.....	731
• Added DDRSS Not Supported Features section.....	759
• Updated DDRSS Not Supported Features section.....	759
• Added PVU Integration section.....	803
• Added PVU Not Supported Features section.....	803
• Updated Interrupt Architecture section.....	809
• Updated INTRTR Overview section.....	821
• Added RINGACC Not Supported Features section.....	912
• Added Proxy Not Supported Features section.....	922
• Added Secure Proxy Not Supported Features section.....	925
• Added CPTS Not Supported Features section.....	1024
• Added Timer Manager Not Supported Features section.....	1030
• Added ADC Not Supported Features section.....	1039
• ADC: Replaced registers with more generic names .....	1043
• Updated AFE Functional Block Diagram.....	1046
• Added GPIO Not Supported Features section.....	1050
• [Trigger Configuration (per Bit)] updated method to return the value of the FAL_TRIG register. User can read SET_FAL_TRIG or CLR_FAL_TRIG registers to obtain FAL_TRIG value (rather than SET_FAL_TRIG and CLR_FAL_TRIG). .....	1054
• Added I2C Not Supported Features section.....	1057
• Added I3C Not Supported Features section.....	1082
• Added MCSPI Not Supported Features section.....	1102
• [Peripheral Receive-Only Mode] Added clarification to definition of full-duplex mode (requires 2 serial data lines).....	1115
• Added UART Not Supported Features section.....	1139
• Deleted the first paragraph for AM26x Devices as there is no reference to the UART hardware requests that is mentioned in the first paragraph.....	1148
• Added PCIe Not Supported Features section.....	1187
• Added USB Not Supported Features section.....	1221
• Added SerDes Not Supported Features section.....	1226
• Added FSS Not Supported Features section.....	1235
• Added OSPI Not Supported Features section.....	1242
• Added HyperBus Not Supported Features section.....	1270
• Added GPMC Not Supported Features section.....	1278
• Added ELM Not Supported Features section.....	1364
• Added MMCSD Not Supported Features section.....	1376
• Added EPWM Not Supported Features section.....	1479
• Added EQEP Not Supported Features section.....	1546
• Added MCAN Not Supported Features section.....	1566
• Added ATL Not Supported Features section.....	1602
• Added MCASP Not Supported Features section.....	1604
• Updated MCASP Module Block Diagram.....	1606
• Added DSS Not Supported Features section.....	1660
• Added CSI_RX_IF Not Supported Features section.....	1854
• Added DPHY_RX Not Supported Features section.....	1876
• Added GTC Not Supported Features section.....	1906
• Added RTI Not Supported Features section.....	1909
• Added Timers Not Supported Features section.....	1917
• Added DCC Not Supported Features section.....	1936
• Added MCRC Not Supported Features section.....	1954
• Added Logical Built-In Self-Test (LBIST) chapter.....	1967

- 
- Added Programmable Built-In Self Test (PBIST) section..... 1970
