Complex bit access types are encoded to fit into small table cells. Table 19-66 shows the codes that are used for access types in this section.

Table 19-107. MDL_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

19.5.7 ICL_XBAR_REGS Registers

Table 19-72 lists the memory-mapped registers for the ICL_XBAR_REGS registers. All register offset addresses not listed in Table 19-72 should be considered as reserved locations and the register contents should not be modified.

Table 19-118. ICL_XBAR_REGS Registers

Offset	Acronym	Register Name	Protection
30h	ICLXBAROutInvert	Output Signal Invert Select	
80h	ICLXBARLock	Configuration Lock register	
100h + formula	ICLXBARG0SEL_j	ICLXBAR G0 Input Select	
104h + formula	ICLXBARG1SEL_j	ICLXBAR G1 Input Select	
108h + formula	ICLXBARG2SEL_j	ICLXBAR G2 Input Select	

Complex bit access types are encoded to fit into small table cells. Table 19-73 shows the codes that are used for access types in this section.

Table 19-119. ICL_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

19.5.8 OUTPUTXBAR_FLAG_REGS Registers

Table 19-79 lists the memory-mapped registers for the OUTPUTXBAR_FLAG_REGS registers. All register offset addresses not listed in Table 19-79 should be considered as reserved locations and the register contents should not be modified.

Table 19-130. OUTPUTXBAR_FLAG_REGS Registers

Offset	Acronym	Register Name	Protection
10h	OUTPUTXBARStatus	Output Signal Status register	
18h	OUTPUTXBARFlag	Output latched flag register	
1Ch	OUTPUTXBARFlagClear	Output latched flag clear register	
20h	OUTPUTXBARFlagForce	Output latched flag Force register	

Complex bit access types are encoded to fit into small table cells. Table 19-80 shows the codes that are used for access types in this section.

Table 19-131. OUTPUTXBAR_FLAG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

19.5.9 XBAR_REGS Registers

Table 19-85 lists the memory-mapped registers for the XBAR_REGS registers. All register offset addresses not listed in Table 19-85 should be considered as reserved locations and the register contents should not be modified.

Table 19-140. XBAR_REGS Registers

Offset	Acronym	Register Name	Protection
0h	XBARFLG1	X-Bar Input Flag Register 1	
4h	XBARFLG2	X-Bar Input Flag Register 2	
8h	XBARFLG3	X-Bar Input Flag Register 3	
Ch	XBARFLG4	X-Bar Input Flag Register 4	
10h	XBARFLG5	X-Bar Input Flag Register 5

Table 19-141. XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

1 XBARFLG1 Register (Offset = 0h) [Reset = 00000000h]

XBARFLG1 is shown in Figure 19-63 and described in Table 19-87.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

4 XBARFLG4 Register (Offset = Ch) [Reset = 00000000h]

XBARFLG4 is shown in Figure 19-66 and described in Table 19-90.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

5 XBARFLG5 Register (Offset = 10h) [Reset = 00000000h]

XBARFLG5 is shown in Figure 19-67 and described in Table 19-91.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

Table 19-151. XBARFLG5 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	CPU3_ADCCHECKEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU3_ADCCHECKEVT1 input was triggered 0: CPU3_ADCCHECKEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
27	CPU2_ADCCHECKEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU2_ADCCHECKEVT4 input was triggered 0: CPU2_ADCCHECKEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
26	CPU2_ADCCHECKEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU2_ADCCHECKEVT3 input was triggered 0: CPU2_ADCCHECKEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
25	CPU2_ADCCHECKEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU2_ADCCHECKEVT2 input was triggered 0: CPU2_ADCCHECKEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
24	CPU2_ADCCHECKEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU2_ADCCHECKEVT1 input was triggered 0: CPU2_ADCCHECKEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
23	CPU1_ADCCHECKEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU1_ADCCHECKEVT4 input was triggered 0: CPU1_ADCCHECKEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
22	CPU1_ADCCHECKEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU1_ADCCHECKEVT3 input was triggered 0: CPU1_ADCCHECKEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

6 XBARFLG6 Register (Offset = 14h) [Reset = 00000000h]

XBARFLG6 is shown in Figure 19-68 and described in Table 19-92.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

Bit	Field	Type	Reset	Description
9	EPWM10_DEL_ACTIVE	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM10_DEL_ACTIVE input was triggered 0: EPWM10_DEL_ACTIVE Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
8	EPWM9_DEL_ACTIVE	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM9_DEL_ACTIVE input was triggered 0: EPWM9_DEL_ACTIVE Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
7	EPWM8_DEL_ACTIVE	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM8_DEL_ACTIVE input was triggered 0: EPWM8_DEL_ACTIVE Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
6	EPWM7_DEL_ACTIVE	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM7_DEL_ACTIVE input was triggered 0: EPWM7_DEL_ACTIVE Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
5	EPWM6_DEL_ACTIVE	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM6_DEL_ACTIVE input was triggered 0: EPWM6_DEL_ACTIVE Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
4	EPWM5_DEL_ACTIVE	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM5_DEL_ACTIVE input was triggered 0: EPWM5_DEL_ACTIVE Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
3	EPWM4_DEL_ACTIVE	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM4_DEL_ACTIVE input was triggered 0: EPWM4_DEL_ACTIVE Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

20 XBARCLR2 Register (Offset = 104h) [Reset = 00000000h]

XBARCLR2 is shown in Figure 19-82 and described in Table 19-106.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG register.
1: Clears the corresponding bit in the XBARFLG register.
0: Writing 0 has no effect

XBARCLR4 is shown in Figure 19-84 and described in Table 19-108.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG register.
1: Clears the corresponding bit in the XBARFLG register.
0: Writing 0 has no effect

25 XBARCLR7 Register (Offset = 118h) [Reset = 00000000h]

XBARCLR7 is shown in Figure 19-87 and described in Table 19-111.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG register.
1: Clears the corresponding bit in the XBARFLG register.
0: Writing 0 has no effect

29 XBARCLR11 Register (Offset = 128h) [Reset = 00000000h]

XBARCLR11 is shown in Figure 19-91 and described in Table 19-115.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG register.
1: Clears the corresponding bit in the XBARFLG register.
0: Writing 0 has no effect

20.1 Introduction

The Embedded Pattern Generator (EPG) module is a customizable pattern and clock generator that can serve many test and application scenarios that require a simple pattern generator or a periodic clock generator. The EPG module can also be used to capture an incoming serial stream of data.

20.1.1 Features

Features of the EPG module are:

- Clock generation:
  - Independent clock generation and clock division
  - Synchronous clock generation with programmable offsets
  - Can generate clocks to act as source for external modulator and internal demodulator for the SDFM
- Pattern generation:
  - Independent serial data stream generation
  - Serial data stream and the associated clock generation
  - Ability to skew clock with respect to serial data
  - Synchronous data stream with programmable offset with respect to one another
  - Can generate waveforms for loopback test of communication peripherals
  - Useful as diagnostics test if not already built-in

The EPG output signals are connected to GPIOs or other peripherals inside the device. The EPG inputs act as shift register inputs to capture incoming serial data streams. This allows the EPG to be configured as a custom serial module. The EPG is also capable of generating interrupts that are used to supply the pattern generators with new data or signal the completion of a generated pattern.

20.1.2 EPG Block Diagram

Figure 20-1 shows the EPG overview block diagram.

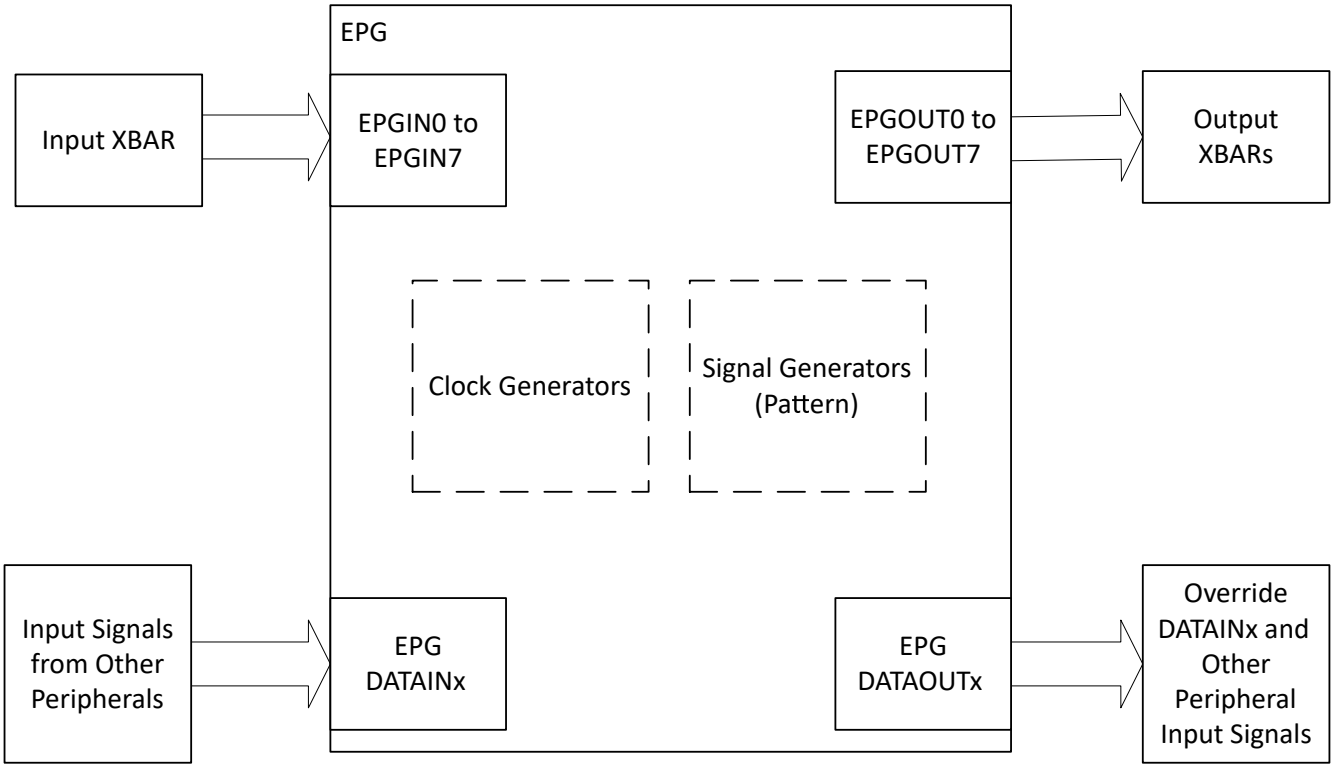

Figure 20-1. EPG Overview Block Diagram

Figure 20-2 shows the EPG block diagram.

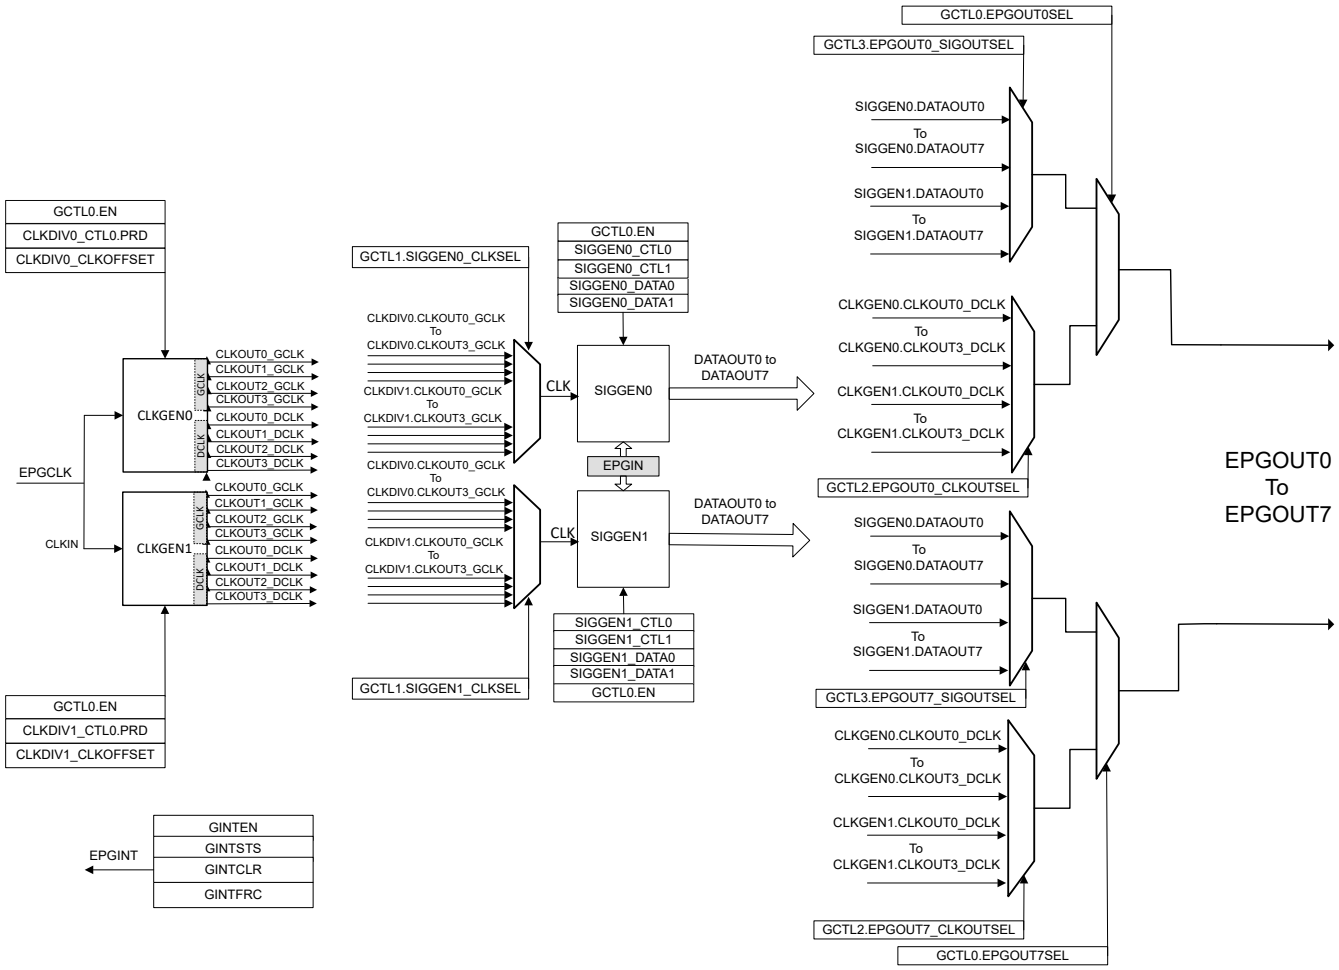

Figure 20-2. EPG Detailed Block Diagram

Note

The number of available EPGx SIGGEN modules for each device can be different. This diagram shows an EPG with 2 SIGGEN modules (SIGGEN0 and SIGGEN1). Refer to the EPG_REGS register description to see how many SIGGEN modules are available for a specific device.

The EPG input clock (EPGCLK) is sourced from PERx.SYSCLK.

20.2 Clock Generator Modules

The clock generator modules use the EPG input clock and generate four output clocks, see Figure 20-3. Each of the four output clocks (CLKOUT0 to CLKOUT3) has a DCLK and a GCLK version. The EPG clock division results in a gated, GCLK, version of the EPG input clock which are named CLKOUT0_GCLK to CLKOUT3_GCLK. The other version, DCLK (CLKOUT0_DCLK to CLKOUT3_DCLK), have the same period but with an approximately 50% duty cycle. The clock generation takes place using the divider settings CLKDIVx_CTL0.PRD, and clock offset settings CLKDIVx_CLK.CLKyOFFSET. The RUNCLOCK signal generated by the clock stop logic determines when the clock generation is started and stopped.

The clock divider counter is a simple up counter, which has a period determined by CLKDIVx_CTL0.PRD. This divider counter begins counting when RUNCLOCK is set. The CLKOUT0 to CLKOUT4 GCLKs are gated versions of the CLKIN (EPG input clock). The clock gates are enabled when the counter value matches the corresponding clock offsets. In the case where RUNCLOCK is cleared, the clock gates are disabled and the counter is set to zero.

Note

The CLKDIVx_CTL0.PRD register can only be written when GCTL0.EN is 0.

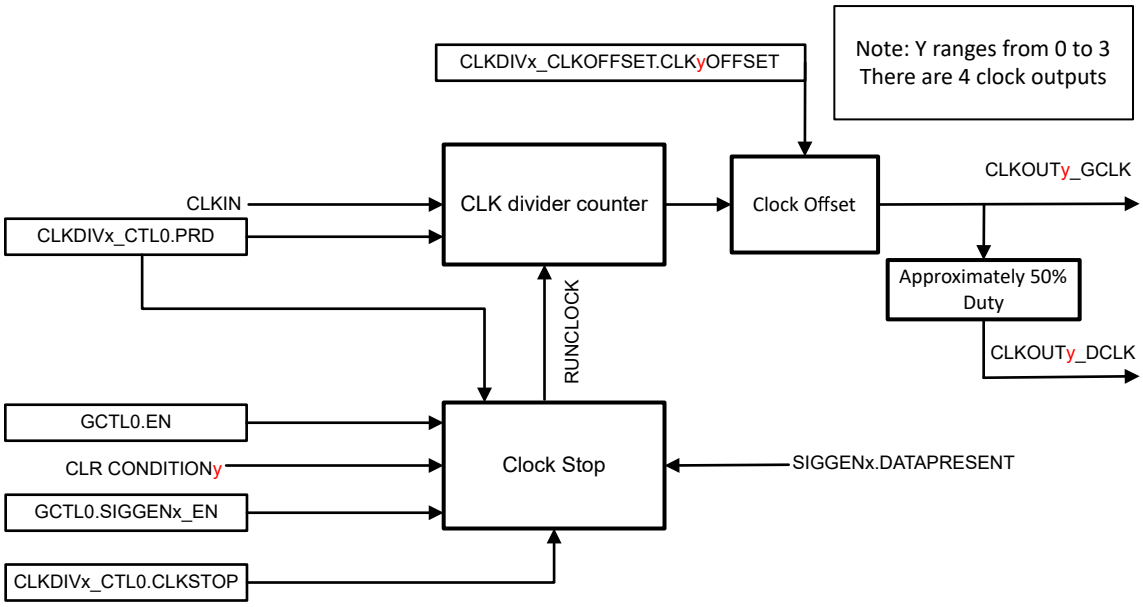

Figure 20-3. EPG Clock Generator

20.2.1 DCLK (50% duty cycle clock)

The CLKOUTy_DCLK is generated by setting the clock output for half the clock divider period. When CLKDIVx_CTL0.PRD is set to zero, CLKOUTy_DCLK is the same as the input clock.

Copyright © 2025Texas Instruments

20.2.2 Clock Stop

Figure 20-4 shows how the Clock Stop module sets and clears the RUNCLOCK signal.

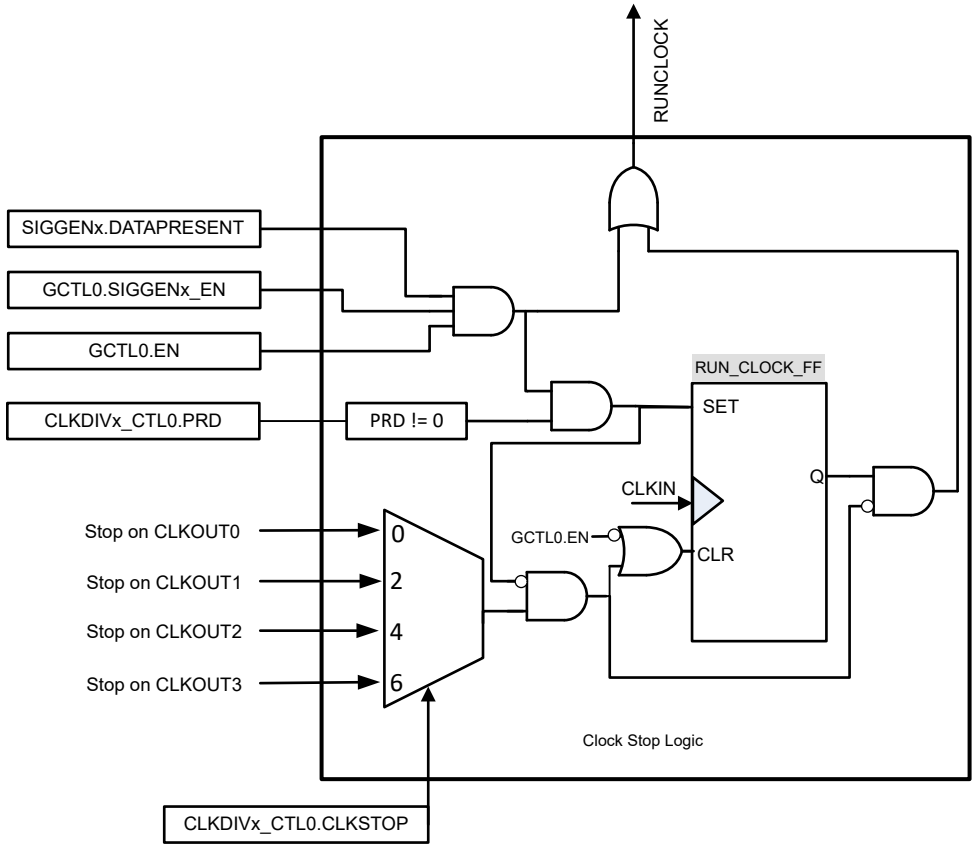

Figure 20-4. EPG Clock Stop

In signal generator modes, GCTL0.SIGGENx_EN bit is cleared when BIT_LENGTH shifts (or rotates) is completed. This makes sure that data is not shifted out. In addition, clock generation (generation of CLKOUT0 to CLKOUT3) also is stopped to make sure that sampling of input data does not continue after BIT_LENGTH shifts when GCTL0.SIGGENx_EN is cleared to 0.

The RUNCLOCK signal has to be high for the clock generation circuitry to be active. When GCTL0.SIGGENx_EN is cleared, the clock generation can be selected to stop on the falling edge of CLKOUT0 to CLKOUT3.

The clock stop module operates as follow:

- RUNCLOCK is asserted as soon as both GCTL0.SIGGENx_EN and GCTL0.EN are set.
- RUN_CLOCK_FF is set when both GCTL0.SIGGENx_EN and GCTL0.EN are set and CLKDIVx_CTL0.PRD is not zero.
- When GCTL0.SIGGENx_EN is cleared, RUN_CLOCK_FF is not cleared immediately. This makes sure that RUNCLOCK remains set and the clock generation circuitry remains enabled.
- When SIGGENx.DATA0 and SIGGENx.DATA1 are not filled with data before the next shift sequence (repeat shift modes) and signal generator is waiting for data to be written, clocks are stopped.
- The RUN_CLOCK_FF can be cleared on the falling edge of CLKOUT0 to CLKOUT3 based on the configuration of CLKSTOP field.
- Clearing GCTL0.EN clears RUN_CLOCK_FF unconditionally.

20.3 Signal Generator Module

The signal generator module is the main component of the EPG and generates the data stream that follows custom patterns. Figure 20-5 shows the main components. This module has 8 output ports DATAOUT0 to DATAOUT7. The two registers SIGGENx_DATA1 and SIGGENx_DATA0 constitute a 64-bit bus named DATA[63:0]. DATAIN[63:0], which is used for all the data transform operations, can be DATA[63:0] or bit reversed DATA (when SIGGENx_CTL0.BRIN bit is set). The DATAOUT0 to DATAOUT7 are connected to DATAIN0 to DATAIN7 when the signal generator is not in BIT_BANG mode. In BIT_BANG mode, DATAOUT0 to DATAOUT7 are connected to DATAIN[0,8,16,24,32,40,48,56].

In addition to generating data outputs, one of the 8 EPGIN inputs can act as data input to SIGGENx_DATAy registers. In Figure 20-5, the EPGIN_MUX block illustrates the mechanism used to capture the input data stream. This enables one to capture a data input stream using EPG module.

Data transformation is done on the DATAIN bus, and is determined by the configured mode (SIGGENx_CTL0.MODE), provided GCTL0.EN and GCTL0.SIGGENx_EN are both set. If either of these enable bits are 0, then the data output of the transform block is the same as the input. The transformed output is bit reversed when SIGGENx_CTL0.BROUT bit is set. Conditions under which the DATA active register (SIGGENx_DATA0_ACTIVE and SIGGENx_DATA1_ACTIVE) are:

- Loaded from SIGGENx_DATA1 and SIGGENx_DATA0
- Directly updated on a memory mapped write to SIGGENx_DATA1 and SIGGENx_DATA0
- Holds the current data

Table 20-1. SIGGENx Active Register Loading

Condition	SIGGENx_DATA1_ACTIVE DATA ACTIVE Register [63:32]	SIGGENx_DATA0_ACTIVE DATA ACTIVE Register [31:0]
Memory mapped write to SIGGENx_DATA0 register and GCTL0.SIGGENx_EN is 0	No updates	Updated with the value written to SIGGENx_DATA0 register
Memory mapped write to SIGGENx_DATA1 register and GCTL0.SIGGENx_EN is 0.	Updated with the value written to SIGGENx_DATA1 register	No updates
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Either SIGGENx_DATA0 or SIGGENx_DATA1 has been updated	Copy SIGGENx_DATA1 register content	Copy SIGGENx_DATA0 register content
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Both SIGGENx_DATA0 and SIGGENx_DATA1 have been updated	Copy SIGGENx_DATA1 register contents	Copy SIGGENx_DATA0 register contents
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has been updated	Hold the current value, no shifts	Hold the current value, no shifts
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has not been updated	Hold the current value, no shifts	Hold the current value, no shifts
All other conditions	Updates based on current mode of operation	Updates based on current mode of operation

Following are the possible data transformations:

Bit-bang mode: In this mode, DATATRAN[63:0] is the same as DATATRANIN[63:0].

Shift right once mode: In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx_CTL0.BITLENGTH shifts, SIGENx_CTL0.EN is cleared.

Shift right repeat mode: In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx_CTL0.BITLENGTH shifts, load the data as per Table 20-1.

Rotate right once mode: In this mode, DATATRAN[63:0] = {DATATRANIN[0],DATATRANIN[63:1]}. After SIGENx_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx_CTL0.EN is cleared.

Rotate right repeat: This mode is same as rotate right once, except that SIGENx_CTL0.EN is not cleared upon SIGENx_CTL0.BITLENGTH rotates.

Shift left once mode: In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx_CTL0.BITLENGTH shifts, SIGENx_CTL0.EN is cleared.

Shift left repeat mode: In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx_CTL0.BITLENGTH shifts, load the data as per Table 20-1.

Rotate left once mode: In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],DATATRANIN[63]}. After SIGENx_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx_CTL0.EN is cleared.

Rotate left repeat: This mode is same as rotate left once, except that SIGENx_CTL0.EN is not cleared upon SIGENx_CTL0.BITLENGTH rotates.

Note

SIGGENx_CTL0.MODE and SIGGENx_CTL.BITWIDTH must only be updated when GCTL0.SIGGENx_EN is 0.

EPGOUT0 to EPGOUT7 can override peripheral input signals connected to DATAINx. For example, the peripheral CAN RX input signal can be overwritten by EPGOUTx. DATAINx can be passed to DATAOUTx untouched, if EPG is not required, or the DATAINx can be replaced with EPGOUTy (y = x%8). The EPGMXSEL0 and EPGMXSEL1 registers must be configured to select the source of the DATAOUTx signals. Also, EPGOUTx signals can be connected to GPIOs through the Output XBARs and CLB Output XBARs, while EPGINx signals can be connected to the Input XBARs.

20.5 Application Software Notes

The following points are important considerations when utilizing the EPG:

- SIGGENx_CTL0.MODE and SIGGENx_CTL0.BITLENGTH can only be written to when SIGGENx_CTL0.EN is 0
- CLKDIVx_CTL0.PRD register can be written, when GCTL0.EN is 0
- GCTL0.EN can be enabled before GCTL0.SIGGENx_EN

20.6 EPG Example Use Cases

This section provides example register configurations for different EPG use cases.

Note

Some examples can require more than one SIGGEN module. Check the device registers or data sheet for the number of available SIGGEN modules.

20.6.1 EPG Example: Synchronous Clocks with Offset

Section 20.6.1.1 register configuration generates 4 clocks, all synchronous to one another with edges offset by 2 clock cycles. In Section 20.6.1.1 , a clock divide value of 12 is used.

Synchronous Clocks with Offset Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
EPGMXSEL0.SEL2	0x1	Select EPGOUT2 to drive DATAOUT[2]
EPGMXSEL0.SEL3	0x1	Select EPGOUT3 to drive DATAOUT[3]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL0.EPGOUT2SEL	0x0	Selects signal mux output on EPGOUT2
GCTL0.EPGOUT3SEL	0x0	Selects signal mux output on EPGOUT3
GCTL3.EPGOUT0_SIGOUTSEL	0x0	Select SIGGEN0.OUT[0] on EPGOUT0
GCTL3.EPGOUT1_SIGOUTSEL	0x1	Select SIGGEN0.OUT[1] on EPGOUT1
GCTL3.EPGOUT2_SIGOUTSEL	0x2	Select SIGGEN0.OUT[2] on EPGOUT2
GCTL3.EPGOUT3_SIGOUTSEL	0x3	Select SIGGEN0.OUT[3] on EPGOUT3
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x0	Divide by 1
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0xC	Configure bit length to 12 to get a divide-by-12 clock.
SIGGEN0_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode to generate a periodic waveform.
SIGGEN0_DATA0[11:0]	0000 0111 1110	Initialize the 12 bits to 6 ones and 6 zeroes, which makes sure of a 50% duty cycle clock.
SIGGEN0_DATA0[27:16]	0001 1111 1000	Create a 2-cycle offset with respect to first clock.
SIGGEN0_DATA1[11:0]	0111 1110 0000	Create a 4-cycle offset with respect to first clock.
SIGGEN0_DATA1[27:16]	1111 1000 0001	Create a 6-cycle offset with respect to first clock.

Copyright © 2025Texas Instruments

20.6.2 EPG Example: Serial Data Bit Stream (LSB first)

Section 20.6.2.1 register configuration shifts out a data word, the data rate is set to divide by 8 and the LSB is shifted out first. After 32 shifts are completed, an interrupt is generated for further sequencing.

Serial Data Bit Stream (LSB first) Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
Epg1Regs		
Global Settings		
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out

Copyright © 2025Texas Instruments

20.6.3 EPG Example: Serial Data Bit Stream (MSB first)

Section 20.6.3.1 register configuration shifts out a data word, the data rate is set to divide by 8 and MSB is shifted out first. After 32 shifts are complete, an interrupt is generated for further sequencing.

Serial Data Bit Stream (MSB first) Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out

Copyright © 2025Texas Instruments

20.6.4 EPG Example: Clock and Data Pair

Section 20.6.4.1 register configuration shifts out a data word, also an associated clock is generated to latch the data (EPGOUT1), the data rate is set to divide by 8 and MSB is shifted out first. After 32 shifts are complete, an interrupt is generated for further sequencing.

Clock and Data Pair Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL3.EPGOUT1_SIGOUTSEL	0x8	Select SIGGEN1.OUT[0] on EPGOUT1.
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
GCTL1.SIGGEN1_CLKSEL	0x4	Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
CLKDIV1_CTL0.PRD	0x3	Divide by 4
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out
SIGGEN1 Mode and Bit Length Configuration		
SIGGEN1_CTL0.BITLENGTH	0x2	Set bit length to 2 to generate a 50% duty clock.
SIGGEN1_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode. Generates a 50% duty cycle clock.
SIGGEN1_DATA0[15:0]	0x2	Data to be shifted out

Copyright © 2025Texas Instruments

20.6.5 EPG Example: Clock and Skewed Data Pair

Section 20.6.5.1 register configuration shows the data shifted out is skewed by few a EPG input clock cycles.

Clock and Skewed Data Pair Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL3.EPGOUT1_SIGOUTSEL	0x8	Select SIGGEN1.OUT[0] on EPGOUT1.
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
GCTL1.SIGGEN1_CLKSEL	0x4	Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x2	Offset of 2 cycles.
CLKDIV1_CTL0.PRD	0x3	Divide by 4
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out
SIGGEN1 Mode and Bit Length Configuration		
SIGGEN1_DATA0[15:0]	0x2	Data to be shifted out
SIGGEN1_CTL0.BITLENGTH	0x2	Set bit length to 2 to generate a 50% duty clock.
SIGGEN1_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode. Generates a 50% duty cycle clock.

20.6.6 EPG Example: Capturing Serial Data with a Known Baud Rate

Section 20.6.6.1 register configuration captures a 32-bit data stream. The data is generated from SIGGEN0 and captured in SIGGEN1 (EPGOUT0 looped back as EPGIN0). The clock to SIGEN1 is offset by a few cycles to reliably capture the data.

Capturing Serial Data with a Known Baud Rate Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL3.EPGOUT1_SIGOUTSEL	0x8	Select SIGGEN1.OUT[0] on EPGOUT1.
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
GCTL1.SIGGEN1_CLKSEL	0x4	Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
CLKDIV1_CTL0.PRD	0x7	Divide by 8
CLKDIV1_CLKOFFSET.CLK0OFFSET	0x2	Offset the capture clock by a few cycles to capture the data reliably.
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts, data out looped back to EPGIN[0] to demonstrate the data capture function.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x0	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x0	Reverse the data back and store in the register
SIGGEN_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN_DATA1[31:16]	0x55AA	Data to be shifted out
SIGGEN1 Mode and Bit Length Configuration		
SIGGEN1_CTL0.BITLENGTH	0x32	Set bit length to 2 to generate a 50% duty clock.
SIGGEN1_CTL0.MODE	0x4	Configure the mode to shift left once mode. To capture the data pattern on EPGIN[0].
SIGGEN1_CTL1.DATA0_INSEL	0x1	Select EPGIN[0] as the data input of bit 0.
SIGGEN1_DATA0	0x0	Clear the data contents. Holds 0xAA55 3333 at the end of 32 shifts.

20.7 EPG Interrupt

EPG interrupt can be generated on “BIT_LENGTH" shifts or rotates, or “BIT_LENGTH/2” shifts or rotates. Interrupts can be generated in any of the signal generator modes.

The GINTSTS, GINTEN, GINTCLR, and GINTFRC registers are used to configure the EPG interrupt, as shown in Figure 20-7.

20.8.2 EPG Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location: f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/epg

Cloud access to these examples is available at the following link: dev.ti.com F29x SDK Examples.

20.8.2.1 EPG Generating Synchronous Clocks - SINGLE_CORE

FILE: epg_ex1_generate_clocks.c

Copyright © 2025Texas Instruments

This example shows how to generate 2 synchronous clocks with edges being offset by 2 clock cycles. It configures Signal Generator to shift a periodic data. Generated Clock has period EPG CLOCK/6.

External Connections

- None. Signal is generated on GPIO 2, 3. Can be visualized through oscilloscope.

Watch Variables

- sigGenActiveData - Active Data of signal generator transform output

20.8.2.2 EPG Generating Two Offset Clocks - SINGLE_CORE

FILE: epg_ex2_generate_two_offset_clocks.c

This example generates two offset clocks using the CLKGEN (CLKDIV) modules. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 2, 3. Can be visualized through oscilloscope.

20.8.2.3 EPG Generating Two Offset Clocks With SIGGEN - SINGLE_CORE

FILE: epg_ex3_generate_two_offset_clocks_with_siggen.c

This example generates two offset clocks using the SIGGEN module. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 2, 3. Can be visualized through oscilloscope.

20.8.2.4 EPG Generate Serial Data - SINGLE_CORE

FILE: epg_ex4_generate_serial_data.c

This example generates SPICLK and SPI DATA signals using the SIGGEN module. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 2, 3. Can be visualized through oscilloscope.

20.8.2.5 EPG Generate Serial Data Shift Mode - SINGLE_CORE

FILE: epg_ex5_generate_serial_data_shift_mode.c

This example generates SPICLK and SPI DATA signals using the SIGGEN module in SHIFT mode. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 2, 3. Can be visualized through oscilloscope.

20.9 EPG Registers

This Section describes the EPG Registers.

20.9.1 EPG Base Address Table

Table 20-6. EPG Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
EPG_REGS	EPG_BASE	0x701C_0000	YES	YES	YES	YES	YES	YES	-	YES

Table 20-8. EPG_REGS Access Type Codes (continued)

Access Type	Code	Description
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.9.3 EPG_MUX_REGS Registers

Table 20-36 lists the memory-mapped registers for the EPG_MUX_REGS registers. All register offset addresses not listed in Table 20-36 should be considered as reserved locations and the register contents should not be modified.

Table 20-63. EPG_MUX_REGS Registers

Offset	Acronym	Register Name	Protection
0h	EPGMXSEL0	EPG Mux select register 0	
4h	EPGMXSEL1	EPG Mux select register 1	
18h	EPGMXSELLOCK	EPG Mux select register lock	
1Ch	EPGMXSELCOMMIT	EPG Mux select register commit	

Complex bit access types are encoded to fit into small table cells. Table 20-37 shows the codes that are used for access types in this section.

Table 20-64. EPG_MUX_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

The following chapters describe the analog peripherals.

Technical Reference Manual Overview

The block diagram is shown in Block Diagram. This Technical Reference Manual is organized into five major sections:

- C29x SYSTEM RESOURCES

  These chapters describe the C29x CPU subsystem, C29x Boot ROM, device configuration, and other system peripherals.

- ANALOG PERIPHERALS

  These chapters describe the general analog subsystem configuration, Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

- CONTROL PERIPHERALS

  These chapters describe the Enhanced Capture (eCAP), High-Resolution Capture (HRCAP), Enhanced Pulse-Width Modulator (ePWM) with High-Resolution Pulse-Width Modulator (HRPWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- COMMUNICATION PERIPHERALS

  These chapters describe the communication peripherals available to the C29x subsystem such as the EtherCAT, FSI, I2C, PMBUS, UART, LIN, SPI, and SENT.

- SECURITY PERIPHERALS

  This chapter describes the safety peripherals available to the C29x subsystem such as the Hardware Security Module (HSM) and Cryptographic Accelerator.

21.1 Introduction

21.1.1 Features

The analog subsystem has the following features:

- Flexible voltage references:
  - The ADCs are referenced to VREFHIx and VREFLOx pins.
    - VREFHIAB and VREFHICDE pin voltages can be driven in externally or can be generated by an internal bandgap voltage reference.
    - The internal voltage reference range can be selected to be 0V to 2.5V for ADC A and ADC B when operated in 16-bit mode; however, the internal voltage reference range can be selected to be 0V to 3.3V or 0V to 2.5V for ADC A and ADC B when operated in 12-bit mode.
    - The internal voltage reference range can be selected to be 0V to 3.3V or 0V to 2.5V for ADC C, ADC D, and ADC E.
  - The buffered DACs are referenced to VREFHIx and VSSA
    - Alternately, these DACs can be referenced to the VDAC pin and VSSA
  - The comparator DACs are referenced to VDDA and VSSA
    - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- Flexible pin usage
  - Buffered DAC outputs, comparator subsystem inputs, and digital inputs (AIOs)/outputs (AGPIOs) are multiplexed with ADC inputs
  - Internal connection to V_{REFLO} for offset self-calibration

21.1.2 Block Diagram

The following analog subsystem block diagrams show the connections between the different integrated analog modules to the device pins. These pins fall into two categories: analog module inputs/outputs and reference pins.

There are two reference pair pins, VREFHIAB /VREFLOAB and VREFHICDE/VREFLOCDE. VREFHIAB and VREFLOAB supply the reference for ADC A and ADC B modules which support both 16-bit and 12-bit mode. VREFHICDE and VREFLOCDE supply ADC C, ADC D and ADC E modules which only support 12-bit mode. VREFHIAB can also be used to supply DAC A, and VREFHICDE can also be used to supply DAC B

The VDAC reference pin can be used to set an alternate range for DAC A and DAC B, and for the DACs inside the CMPSS modules (the CMPSS DACs are referenced to VDDA and VSSA by default). Using this pin as a reference prevents the channel from being used as an ADC input (but the ADC can be used to sample the VDAC voltage, if desired). The choice of reference is configurable per module for each CMPSS or buffered DAC; the selection is made using the module's configuration registers.

Some analog pins support digital functionality through muxed AIOs and AGPIOs. AIOs only support digital input functionality, while AGPIOs support full digital input and output functionality.

The following notes apply to all packages:

- Not all analog pins are available on all devices. See the device data sheet to determine which pins are available.
- See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
- An external capacitor is required on the VREFHI pins. See the device data sheet for the specific value required.
- For buffered DAC modules, VSSA is the low reference whether VREFHIx or VDAC is selected as the high reference.
- For CMPSS modules, VSSA is the low reference whether VDAC or VDDA is selected as the high reference.

The following figures show how each analog group is structured. Table 21-3 lists the analog pins and internal connections.

Input connections to the CMPSS modules are selectable through a programmable input mux. Figure 21-3 shows the CMPSS input connections. Table 21-1 shows the mapping of ADC input signals to CMPSS mux inputs.

- To configure the CMPH_POSIN input mux for CMPSSx, write to the CMPxHPMXSEL field in the CMPHPMXSEL or CMPHPMXSEL1 analog subsystem register.
- To configure the CMPH_NEGIN input mux for CMPSSx, write to the CMPxHNMXSEL field in the CMPHNMXSEL analog subsystem register.
- To configure the CMPL_POSIN input mux for CMPSSx, write to the CMPxLPMXSEL field in the CMPLPMXSEL or CMPLPMXSEL1 analog subsystem register.
- To configure the CMPL_NEGIN input mux for CMPSSx, write to the CMPxLNMXSEL field in the CMPLNMXSEL analog subsystem register.

21.2 Optimizing Power-Up Time

The analog-to-digital converters (ADC) and buffered digital-to-analog converters (DAC) share a common reference circuit. If needed, an application using one or more of these modules can optimize power-up time by taking advantage of the shared reference. Once one of the modules using the shared reference has been initialized in internal reference mode, the power-up time for subsequent modules can be optimized by subtracting the reference power-up time from the minimum power-up time requirement.

For instance, if ADCA requires $t_{ADCPUINT}$ to power up in internal reference mode, and $t_{ADCPUEXT}$ to power up in external reference mode, the application does not need to wait $t_{ADCPUINT}$ to power up a second ADC instance such as ADCC in internal reference mode. In this case, the application can simply wait for $t_{ADCPUEXT}$ after powering up ADCC, even though both ADCs are used in internal reference mode. In the same scenario, if the application wished to use DACA in internal reference mode, the required wait time after power-up is $t_{DACPUEXT}$, not the longer $t_{DACPUINT}$.

There is also a wait time associated with power-up in internal reference mode when switching between 2.5V and 3.3V range. See the device data sheet for wait time values.

21.3 Digital Inputs on ADC Pins (AIOs)

Some GPIOs are multiplexed with analog pins and only have digital input functionality. These are also referred to as AIOs. Pins with only an AIO option on this port can only function in input mode. See the device data sheet for list of AIO signals. By default, these pins function as analog pins and the GPIOs are in a high-impedance state. The GPyAMSEL register is used to configure these pins for digital or analog operation.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

Copyright © 2025Texas Instruments

21.4 Digital Inputs and Outputs on ADC Pins (AGPIOs)

Some GPIOs are multiplexed with analog pins and have digital input and output functionality. These are also referred to as AGPIOs. Unlike AIOs, AGPIOs have full input and output capability. By default, the AGPIOs are not connected and must be configured. Table 21-2 shows how to configure the AGPIOs. To enable the analog functionality, set the register AGPIOCTRLx from analog subsystem. To enable the digital functionality, set the register GPxAMSEL from the *General-Purpose Input/Output (GPIO)* chapter.

Table 21-2. AGPIO Configuration

AGPIOCTRLx.GPIOy (Default = 0)	GPxAMSEL.GPIOy (Default = 1)	Pin Connected To:	
		ADC	GPIOy
0	0	-	Yes
0	**1**	-(1)	-(1)
1	0	-	Yes
1	1	Yes	-

(1) By default there are no signals connected to AGPIO pins. One of the other rows in the table must be chosen for pin functionality.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AGPIOs, cross-talk can occur with adjacent analog signals. The user must therefore limit the edge rate of signals connected to AGPIOs, if adjacent channels are being used for analog functions.

Table 21-4. Analog Signal Descriptions

Signal Name	Description
ADCINAx, Ax	ADC A Input
ADCINBx, Bx	ADC B Input
ADCINCx, Cx	ADC C Input
ADCINDx, Dx	ADC D Input
ADCINEx, Ex	ADC E Input
CMPx_HNy	Comparator subsystem high comparator negative input
CMPx_HPy	Comparator subsystem high comparator positive input
CMPx_LNy	Comparator subsystem low comparator negative input
CMPx_LPy	Comparator subsystem low comparator positive input
DACOUTx	Buffered DAC Output
TEMP SENSOR, TS	Internal temperature sensor
VDAC	Optional external reference voltage for on-chip DACs. There is a 100pF capacitor to VSSA on this pin whether used for ADC input or DAC reference that cannot be disabled. If this pin is being used as a reference for the on-chip DACs, place at least a 1µF capacitor on this pin.

21.7 Lock Registers

Setting one of the bits in the lock registers prevents further writes to the associated analog subsystem configuration register. This lock can only be cleared by a device reset.

21.8 ASBSYS Registers

This Section describes the ASBSYS Registers.

21.8.1 ASBSYS Base Address Table

Table 21-7. ASBSYS Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
ANALOG_SUBSYS_REGS[1]	ANALOGSUBSYS_BASE	0x3018_2000	-	YES	YES	YES	-	-	YES	YES

(1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

Copyright © 2025Texas Instruments

21.8.2 ANALOG_SUBSYS_REGS Registers

Table 21-8 lists the memory-mapped registers for the ANALOG_SUBSYS_REGS registers. All register offset addresses not listed in Table 21-8 should be considered as reserved locations and the register contents should not be modified.

Table 21-8. ANALOG_SUBSYS_REGS Registers

Offset	Acronym	Register Name	Protection
44h	PMMVREGTRIM	Power Management Module VREG Trim Register	PARITY
70h	CTLTRIMSTS	HWCTL TRIM Error Status register	
154h	REFBUFCONFIGCDE	Config register for analog reference CDE	PARITY
1A8h	INTERNALTESTCTL	INTERNALTEST Node Control Register	PARITY
1E8h	CONFIGLOCK	Lock Register for all the config registers.	PARITY
1ECh	TSNSCTL	Temperature Sensor Control Register	PARITY
20Ch	ANAREFCTL	Analog Reference Control Register.	PARITY
214h	VREGCTL	Voltage Regulator Control Register	PARITY
22Ch	VMONCTL	Voltage Monitor Control Register	PARITY
26Ch	CMPHPMXSEL	Bits to select one of the many sources on CopmHP inputs. Refer to Pimux diagram for details.	PARITY
270h	CMPHPMXSEL1	Bits to select one of the many sources on CopmHP inputs. Refer to Pimux diagram for details.	PARITY
274h	CMPLPMXSEL	Bits to select one of the many sources on CopmLP inputs. Refer to Pimux diagram for details.	PARITY
278h	CMPLPMXSEL1	Bits to select one of the many sources on CopmLP inputs. Refer to Pimux diagram for details.	PARITY
27Ch	CMPHNMXSEL	Bits to select one of the many sources on CopmHN inputs. Refer to Pimux diagram for details.	PARITY
280h	CMPLNMXSEL	Bits to select one of the many sources on CopmLN inputs. Refer to Pimux diagram for details.	PARITY
294h	LOCK	Lock Register	PARITY
45Ch	IOMODESEL	PMBUS IO Mode select register	PARITY
464h	AGPIOFILTER	AGPIO Filter Control Register	PARITY
48Ch	AGPIOCTRLH	AGPIO Control Register	PARITY
4B4h	PARITY_TEST	Enables parity test	

Complex bit access types are encoded to fit into small table cells. Table 21-9 shows the codes that are used for access types in this section.

Table 21-9. ANALOG_SUBSYS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
WSonce	W Sonce	Write Set once

Table 21-9. ANALOG_SUBSYS_REGS Access Type Codes (continued)

Access Type	Code	Description
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

15	ENMASK	R/W	0h	Enable VMON function mask on a TRIM load. This bit, when set, masks the generation of POR/BOR for a fixed duration whenever TRIM bits are changed. If this bit is cleared, then POR/BOR generation is not masked on a TRIM load. Reset type: XRSn
14-1	RESERVED	R-0	0h	Reserved
0	PWRDNVREG	R/W	0h	Power down internal voltage regulator. This bit, when cleared, enables the internal voltage regulator, when set powers down the internal voltage regulator. Note: On devices, in which VREGENZ is not bonded out, this bit should be used to disable internal VREG. Reset type: XRSn

Table 21-49. PARITY_TEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: SYSRSn

Chapter 22

Analog-to-Digital Converter (ADC)

The analog-to-digital converter (ADC) module described in this chapter is a Type 4 for 16-bit ADC and Type 5 for 12-bit ADC. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

22.1 Introduction

The ADC module is a 12-bit successive approximation (SAR) style ADC . The ADC module in this device has five instances of SAR ADC, two of which are designed with selectable resolution of either 16 bits or 12 bits, and three of which have a fixed resolution of 12 bits.The ADC is composed of a core and a wrapper. The core is composed of the analog circuits which include the channel select MUX, the sample-and-hold (S/H) circuit, the successive approximation circuits, voltage reference circuits, and other analog support circuits. The wrapper is composed of the digital circuits that configure and control the ADC. These circuits include the logic for programmable conversions, result registers, interfaces to analog circuits, interfaces to the peripheral buses, post-processing circuits, and interfaces to other on-chip modules.

Each ADC module consists of a single sample-and-hold (S/H) circuit. The ADC module is designed to be duplicated multiple times on the same chip, allowing simultaneous sampling or independent operation of multiple ADCs. The ADC wrapper is start-of-conversion (SOC) based (see Section 22.3).

22.1.1 Features

Each ADC supports the following features:

- Selectable resolution of 12 bits or 16 bits (ADC-A, ADC-B); 12-bit resolution (ADC-C, ADC-D, ADC-E)
- Ratiometric external reference set by VREFHI and VREFLO pins
- Selectable internal reference of 2.5V or 3.3V
- Differential signal conversions on ADC-A and ADC-B
- Single-ended (SE) signal conversions
- Input multiplexer with up to 80 channels (single-ended) or 40 channels (differential)
- External channel mux option to expand available ADC channels
- 32 configurable SOCs
- 32 individually addressable result registers
- Two trigger repeater modules , enabling customizable hardware oversamplingand undersampling modes with little or no CPU overhead
- Multiple trigger sources:
  - S/W (with available global synchronization for multiple ADCs) - software immediate start
  - All ePWMs- ADCSOC A or B
  - GPIO XINT2
  - CPU Timers 0/1/2 (from each C29x core present)
  - ADCINT1/2
  - ECAP events in capture mode (CEVT1, CEVT2, CEVT3, and CEVT4) and APWM mode (period match, compare match, or both)
- Four flexible PIPE interrupts triggers
- Configurable interrupt placement
- Burst mode
- Four post-processing blocks, each with:
  - Saturating offset calibration
  - Error from set-point calculation
  - High, low, and zero-crossing compare, with interrupt and ePWM trip capability
  - Trigger-to-sample delay capture
  - Aggregation functions: max, min, sum and average (binary shift)
  - Configurable digital filter for high/low/zero-crossing compare
  - Absolute value function
- Result safety checkers to compare SOC results on same ADC or multiple ADC instances

Note

Not every channel is pinned out from all ADCs. Check the device data sheet to determine which channels are available.

22.1.3 Block Diagram

Figure 22-1 shows the block diagram for the ADC core and ADC wrapper.

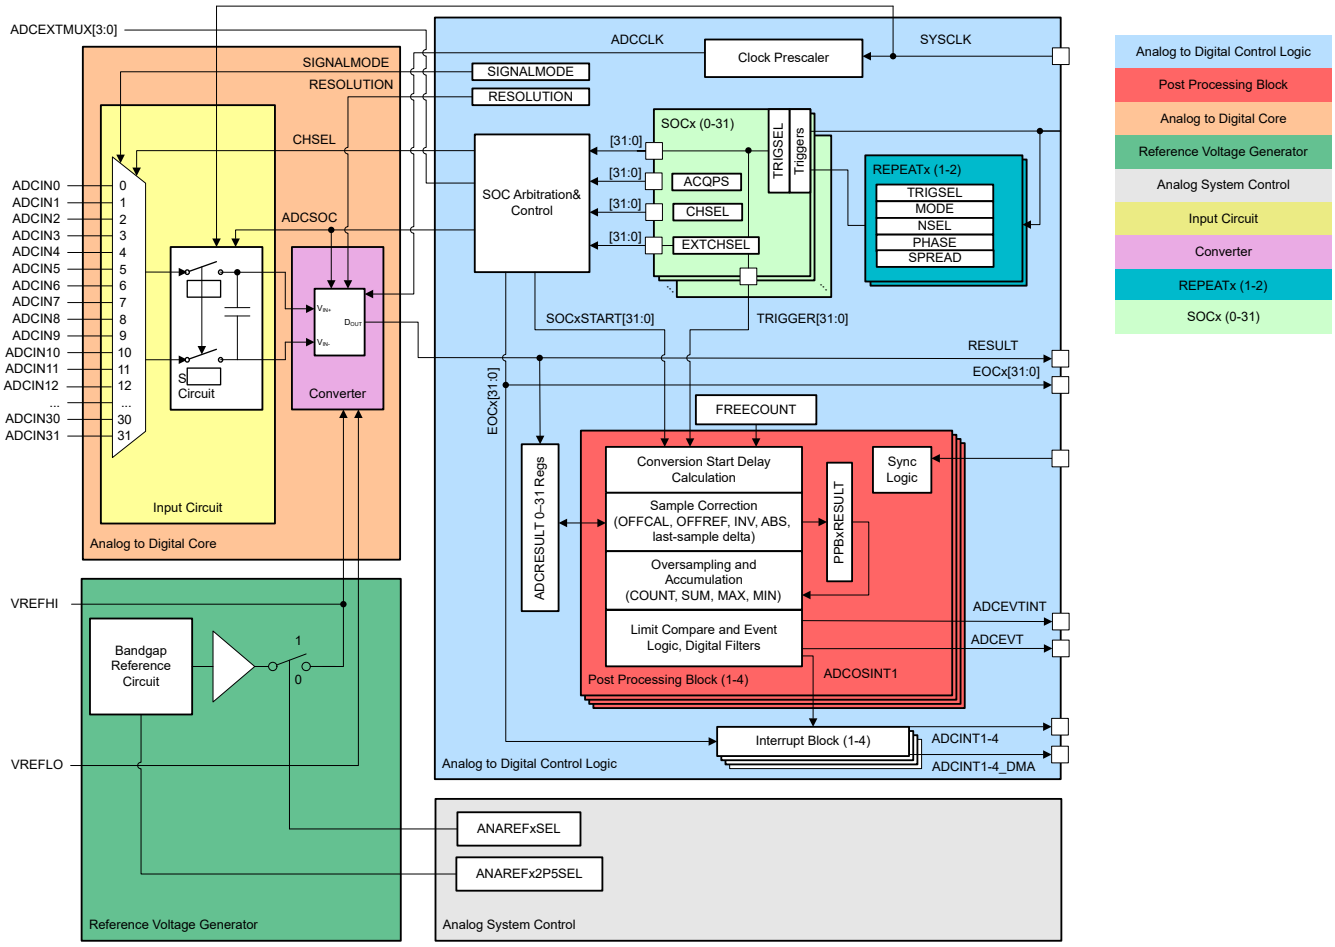

Figure 22-1. ADC Module Block Diagram

Note

- The ADC block diagram reflects the number of ADC channels internally configurable on the device. The actual number of available external ADC inputs varies depending on device part number and package type.

Copyright © 2025Texas Instruments

22.2 ADC Configurability

Some ADC configurations are individually controlled by the SOCs, while others are globally controlled per ADC module. Table 22-1 summarizes the basic ADC options and the level of configurability. The subsequent sections discuss these configurations.

Table 22-1. ADC Options and Configuration Levels

Options	Configurability
Clock	Per module(1)
Resolution	Per module (ADC-A and ADC-B only)(1)
Signal Mode	Per module (ADC-A and ADC-B only)
Reference Voltage Source	Per module (external or internal)(2)
Trigger Source	Per SOC(1)
Converted Channel	Per SOC
Acquisition Window Duration	Per SOC(1)
EOC Location	Per module
Burst Mode	Per module(1)

(1) Writing these values differently to different ADC modules can cause the ADCs to operate asynchronously. See *Ensuring Synchronous Operation* for guidance on when the ADCs are operating synchronously or asynchronously.

(2) On this device, VREFHI pins are shared among multiple ADCs. In this case, the ADCs that share a reference pin must have the reference modes configured identically

22.2.1 ADC Clock Configuration

The base ADC clock is provided directly by the system clock. SYSCLK is used to generate the ADC acquisition window. The register ADCCTL2 has a PRESCALE field that determines the ADCCLK. ADCCLK is used to clock the converter, and is only active during the conversion phase. At all other times, including during the sample-and-hold window, the ADCCLK signal is gated off.

In 16-bit mode, the core requires approximately 29.5 ADCCLK cycles to process a voltage into a conversion result, while in 12-bit mode, this process requires approximately 10.5 ADCCLK cycles. The choice of resolution also determines the necessary duration of the acquisition window, see *Choosing an Acquisition Window Duration*.

Note

To determine an appropriate value for ADCCTL2.PRESCALE, see the device data sheet for the maximum allowable ADCCLK frequencies.

22.2.2 Resolution

The resolution of the ADC determines how finely the analog range is quantized into digital values. Each ADC module supports 12-bit resolution, with configurable 16-bit resolution available on ADC-A and ADC-B. Refer to the device data sheet for a description of available ADC modules and supported resolutions.

The resolution can be configured by using either the AdcSetMode() or ADC_setMode() functions, depending on the header files used, provided in the F29x Software Development Kit (F29-SDK). These functions make sure that the correct trim is loaded into the ADC trim registers, and must be called at least once after a device reset. Do not configure the resolution by directly writing to the ADCCTL2 register.

The resolution can be changed at any time when the ADC is idle (no active or pending SOCs). No wait time is necessary after changing the resolution before conversions can be initiated. If SOCs are active or pending when the resolution is changed, those SOCs can produce incorrect conversion results.

Copyright © 2025Texas Instruments

22.2.3 Voltage Reference

22.2.3.1 External Reference Mode

There are two groups of ADCs. The 16-bit ADCs (ADC-A and ADC-B) form the first group, and the 12-bit ADCs (ADC-C, ADC-D and ADC-E) form the second group. Each group of ADCs shares VREFHI and VREFLO inputs. In external reference mode, these pins are used as a ratiometric reference to determine the ADC conversion input range.

See Section 22.14.6 for information on how to supply the reference voltage.

Note

- On devices with no external VREFLO pin, VREFLO is internally connected to the device analog ground, VSSA.
- See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
- The external reference mode requires an external capacitor on the VREFHI pin. See the device data sheet for the specific value required.

22.2.3.2 Internal Reference Mode

In internal reference mode, the device drives a voltage out onto the VREFHI pin. The VREFHI and VREFLO pins then set the ADC conversion range.

The internal reference voltage can be configured to be either 2.5V or 1.65V. When the 1.65V internal reference voltage is selected, the ADC input signal is internally divided by 2 before conversion, which effectively makes the ADC conversion range from VREFLO to 3.3V.

The 1.65V internal reference mode is not supported when the ADC is configured for 16-bit resolution.

Note

The internal reference mode also requires an external capacitor on the VREFHI pin. See the device data sheet for the specific value required.

22.2.3.3 Ganged References

On some packages, the voltage reference pins for multiple ADCs can be combined. In this case, configure the ganged references identically when selecting external versus internal reference mode and for selecting an internal reference voltage range of 3.3V or 2.5V.

For example, if ADC A and ADC B reference pins are combined and the desired reference mode is 2.5V internal reference mode, the following reference configuration code can be run:

```
//ADCA VREFHI and ADCB VREFHI share a pin
//ADCA VREFLO and ADCB VREFLO share a pin
//Both references must be explicitly configured
//Both references must be configured identically
SetVREF(ADC_ADCA, ADC_INTERNAL, ADC_VREF2P5);
SetVREF(ADC_ADCB, ADC_INTERNAL, ADC_VREF2P5);
```

Internal device hardware makes sure multiple references do not drive conflicting voltages onto the same pin. Because of this, references can be configured in any order or over any amount of time.

22.2.3.4 Selecting Reference Mode

The voltage reference mode must be configured by using the ADC_setVREF() function, depending on the header files used, provided in the F29x Software Development Kit (F29-SDK) Device SDK. Using either of these functions makes sure that the correct trim is loaded in the ADC trim registers. This function must be called at least once after a device reset. Do not configure the voltage reference mode by directly writing to the ANAREFCTL register.

Copyright © 2025Texas Instruments

22.2.4 Signal Mode

ADC-A and ADC-B support two signal modes: single-ended and differential. For the other ADCs, only single-ended signal mode is supported.

In single-ended mode, the input voltage to the converter is sampled through a single pin (ADCINx), referenced to VREFLO.

In differential signaling mode, the input voltage to the converter is sampled through a pair of input pins, one of which is the positive input (ADCINxP) and the other is the negative input (ADCINxN). The actual input voltage is the difference between the two (ADCINxP – ADCINxN).

Note

- In differential signal mode, VREFLO must be connected to VSSA.
- In differential signal mode, the common mode voltage is V_{CM} = (ADCINxP + ADCINxN)/2.

  The data sheet for a particular device places some requirements on how close this voltage needs to be to: (VREFHI + VREFLO)/2

  The above condition is not met by connecting the negative input to VSSA or VREFLO.
- Differential signaling mode is advantageous because noise encountered on both inputs is largely canceled. The effect can be maximized by routing the positive and negative traces for the same differential input as close together as possible and keeping them symmetrical with respect to the signal reference.

The signal mode must be configured by using either the ADC_setMode() or AdcSetMode() functions, depending on the header files used, provided in the F29x Software Development Kit (F29-SDK). These functions make sure that the correct trim is loaded into the ADC trim registers. These functions must be called at least once after a device reset. The signal mode must not be configured by writing to the ADCCTL2 register directly.

22.2.4.1 Expected Conversion Results

Based on a given analog input voltage, the expected digital conversion is given in Table 22-2 and Table 22-3. Fractional values are truncated.

Table 22-2. Analog to 12-bit Digital Formulas

	Analog Input	Digital Result
Single-Ended	when ADCINy ≤ VREFLO	ADCRESULTx = 0
	when VREFLO < ADCINy < VREFHI	$ADCRESULTx = 4096\left(\frac{ADCINy - VREFLO}{VREFHI - VREFLO}\right)$
	when ADCINy ≥ VREFHI	ADCRESULTx = 4095
Differential	when ADCINyP - ADCINyN ≤ -(VREFHI-VREFLO)	ADCRESULTx = 0
	when -(VREFHI-VREFLO) < ADCINyP - ADCINyN ≤ (VREFHI-VREFLO)	$ADCRESULTx = 4096\left(\frac{ADCINyP - ADCINyN + VREFHI - VREFLO}{2(VREFHI - VREFLO)}\right)$
	when ADCINyP - ADCINyN ≥ (VREFHI-VREFLO)	ADCRESULTx = 4095

Table 22-3. Analog to 16-bit Digital Formulas

	Analog Input	Digital Result
Single-Ended	when ADCINy ≤ VREFLO	ADCRESULTx=0
	when VREFLO < ADCINy < VREFHI	$ADCRESULTx = 65536\left(\frac{ADCINy - VREFLO}{VREFHI - VREFLO}\right)$
	when ADCINy ≥VREFHI	ADCRESULTx=65535
Differential	when ADCINyP - ADCINyN ≤ -(VREFHI-VREFLO)	ADCRESULTx = 0
	when -(VREFHI-VREFLO) < ADCINyP - ADCINyN ≤ (VREFHI-VREFLO)	$ADCRESULTx = 65536\left(\frac{ADCINyP - ADCINyN + VREFHI - VREFLO}{2(VREFHI - VREFLO)}\right)$

Copyright © 2025Texas Instruments

Table 22-3. Analog to 16-bit Digital Formulas (continued)

	Analog Input	Digital Result
	when ADCINyP - ADCINyN ≥ (VREFHI-VREFLO)	ADCRESULTx = 65535

22.2.4.2 Interpreting Conversion Results

Based on a given ADC conversion result, the corresponding analog input is given in Table 22-4 and Table 22-5. This corresponds to the center of the possible range of analog voltages that can produce this conversion result.

Table 22-4. 12-Bit Digital-to-Analog Formulas

	Digital Value	Analog Equivalent	
Single-Ended	when ADCRESULTy = 0	$\text{ADCINx} \leq \text{VREFLO}$	(2)
	when 0 < ADCRESULTy < 4095	$\text{ADCINx} = (\text{VREFHI} - \text{VREFLO})\left(\frac{\text{ADCRESULTy}}{4096}\right) + \text{VREFLO}$	(3)
	when ADCRESULTy = 4095	$\text{ADCINx} \geq \text{VREFHI}$	(4)
Differential	when ADCRESULTy = 0	$ADCINxP - ADCINxN \leq (VREFHI - VREFLO)$	(5)

22.3 SOC Principle of Operation

The ADC triggering and conversion sequencing is accomplished through configurable start-of-conversions (SOCs). Each SOC is a configuration set defining the single conversion of a single channel. In that set, there are three configurations: the trigger source that starts the conversion, the channel to convert, and the acquisition (sample) window duration. Upon receiving the trigger configured for a SOC, the wrapper makes sure that the specified channel is captured using the specified acquisition window duration.

Multiple SOCs can be configured for the same trigger, channel, and acquisition window as desired. Configuring multiple SOCs to use the same trigger allows the trigger to generate a sequence of conversions. Configuring multiple SOCs to use the same trigger and channel allows for oversampling. Oversampling can also be achieved using a single trigger source by configuring the trigger repeater module. See *Trigger Repeaters* for more information.

22.3.1 ADC Sequencer

Sequencer Overview

WIP

22.3.2 SOC Configuration

Each SOC has a configuration register, ADCSOCxCTL. Within this register, SOCx can be configured for a specific trigger source, channel to convert, optional external channel mux selection, and acquisition (sample) window duration.

22.3.3 Trigger Operation

Each SOC can be configured to start on one of many input triggers. The primary trigger select for SOCx is in the ADCSOCxCTL.TRIGSEL register, which can select between:

- Disabled (Software only)
- CPU Timers 0/1/2 (from each C29x core present)
- GPIO: INPUTXBAR.OUT[5]
- ADCSOCA or ADCSOCB from each ePWM module
- eCAP events
- Either of the two trigger repeater blocks. This can be used to achieve oversampling, undersampling, or to apply a trigger delay.
- A global synchronous software trigger. This is achieved by configuring the ADCSOCFRCGBSEL and ADCSOCFRCGB registers.

In addition, each SOC can also be triggered when the ADCINT1 flag or ADCINT2 flag is set. This is achieved by configuring the ADCINTSOCSEL1 register (for SOC0 to SOC15) or the ADCINTSOCSEL2 register (for SOC16 and higher where applicable). This can be useful for creating continuous conversions.

22.3.3.1 Global Software Trigger

This ADC supports synchronous global software triggers. Synchronous global triggers allow the application to trigger SOCs on multiple ADC instances that are exactly simultaneous in time. To generate a global software trigger, configure the analog subsystem register ADCSOCFRCGBSEL to select the ADC instances to be triggered, then write to ADCSOCFRCGB to trigger the desired SOCs simultaneously on each ADC.

For example, to trigger SOC0, SOC1, and SOC2 on ADCA and ADCC:

1. Set ADCSOCFRCGBSEL.ADCA = 1 and ADCSOCFRCGBSEL.ADCC = 1 by writing 0x5 to the ADCSOCFRCGBSEL register.
2. Trigger SOCs 0, 1, and 2 by writing 0x7 to the ADCSOCFRCGB register.

Note

The CONTROLSS_CTRL.ADCSOCFRCGBSEL (ADC SOC SW Force Global Select Bit) must be configured to select which ADC instances use the global software trigger.

Copyright © 2025Texas Instruments

22.3.3.2 Trigger Repeaters

Each ADC instance contains two trigger repeater modules. These modules can select any of the regular ADC triggers that are selectable by the ADCSOCxCTL.TRIGGER register, and generate a number of repeat pulses as configured in the REPxN.NSEL register. Figure 22-3 shows a functional block diagram of the ADC trigger repeater module.

Each repeater module can apply four types of trigger modifications:

- Oversampling mode
- Undersampling mode
- Phase delay
- Re-trigger spread

Each of these trigger modification features is explained in detail in the following sections.

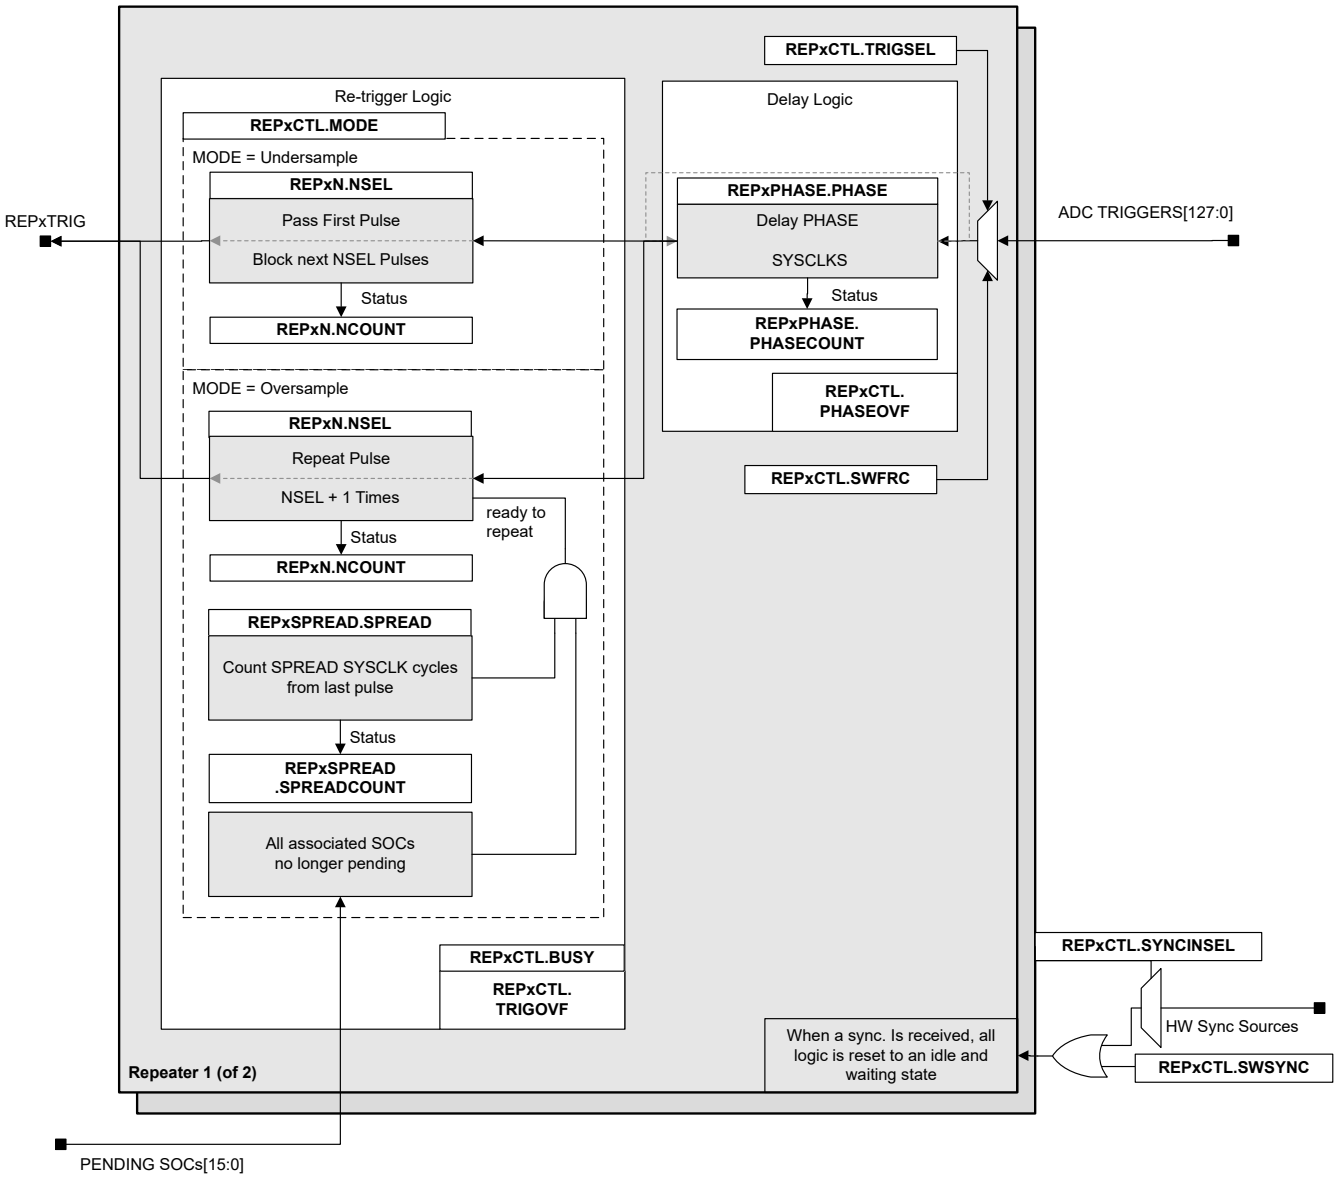

Figure 22-3. ADC Trigger Repeater Block Diagram

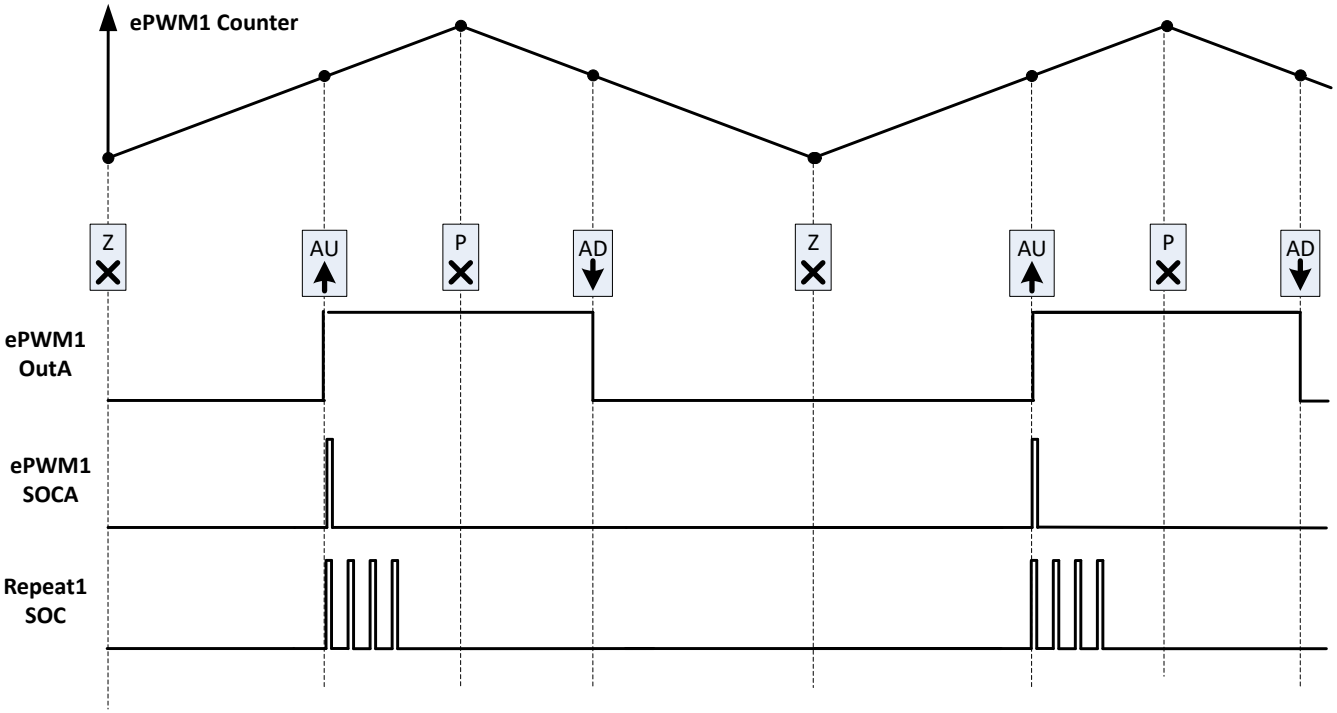
Copyright © 2025Texas Instruments

22.3.3.2.1 Oversampling Mode

In this mode, the repeater module passes the initial trigger through to the output. As soon as all SOCs configured to receive the trigger are in progress or completed, the repeater issues the trigger again. The process repeats until the configured number of trigger pulses (NSEL + 1) have been issued.

This mode allows the application to easily perform multiple back-to-back samples from a single trigger pulse. When used in conjunction with the aggregation options in the post-processing block, this mode enables oversampling, averaging, or peak detection. Figure 22-4 shows an example of oversampling SOCs generated from a single ePWM trigger.



TRIGGER = ePWM SOCA, NSEL = 3, PHASE = 0, MODE = Oversampling, SPREAD = 0

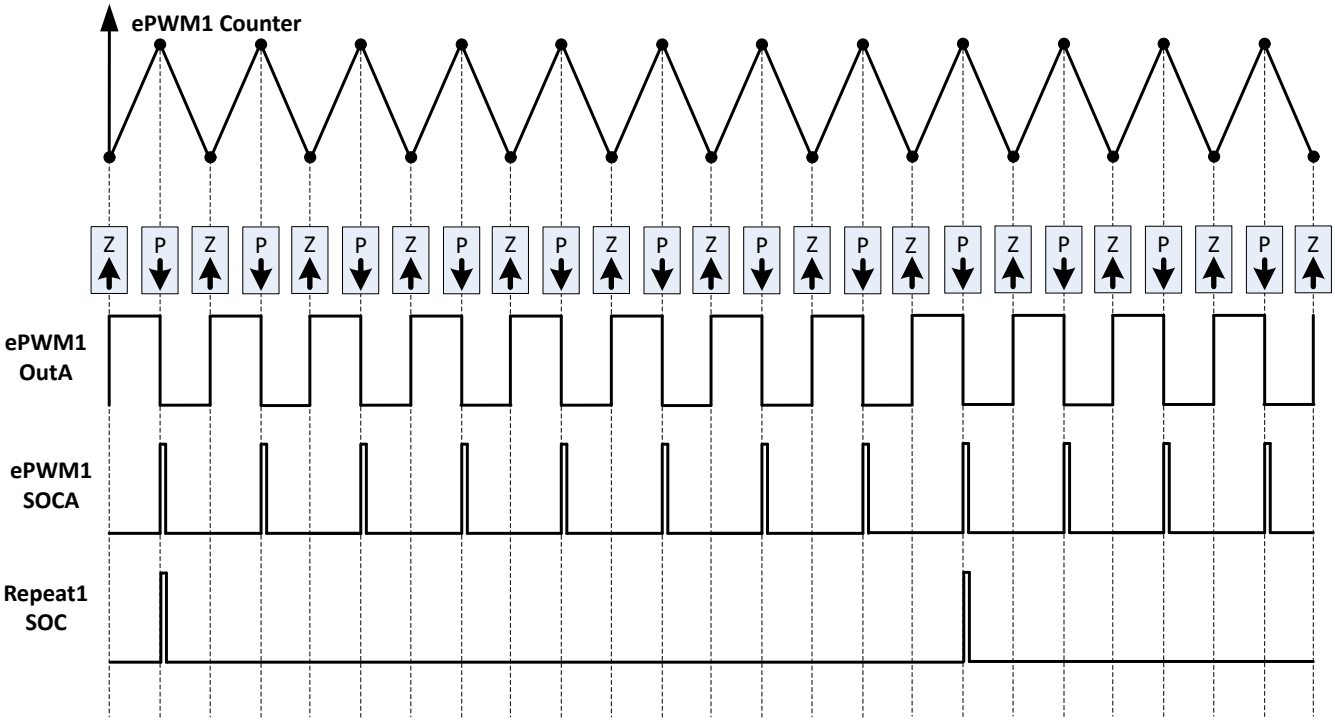
Figure 22-4. Oversampled ADC Trigger Example

Copyright © 2025Texas Instruments

22.3.3.2.2 Undersampling Mode

In this mode, the repeater module passes the initial trigger through to the output, and then blocks subsequent triggers until the configured number of trigger pulses (NSEL + 1) arrive. The result is that only 1 in every (NSEL + 1) pulses passes through to the output. Figure 22-5 shows an example of undersampled SOCs from multiple ePWM triggers.

This mode enables the application to scale down the trigger frequency for one or more SOCs. This is useful for charge-sharing input drivers which have increased error with higher sampling frequencies.



TRIGGER = ePWM SOCA, NSEL = 7, PHASE = 0, MODE = Undersampling, SPREAD = (don't care)

Figure 22-5. Undersampled ADC Trigger Example

Note

Oversampling and undersampling modes are mutually exclusive for each repeater module. However, multiple repeater modules can (and are intended to) be used in different modes concurrently.

22.3.3.2.3 Trigger Phase Delay

The repeater module can delay the initial trigger by a specified number of SYSCLK cycles. This feature can be used in combination with oversampling or undersampling modes, or as a standalone delay by setting NSEL = 0. The phase delay does not affect the timing between subsequent repeated oversampled triggers—the phase delay only delays the initial trigger. When PHASE = 0, the initial trigger arrives at the same time as an unmodified trigger. Figure 22-6 shows an example of phase delay combined with oversampling. Figure 22-7 shows an example of a standalone phase delay with a single SOC trigger.

Phase delay enables the application to tie the trigger start point to an ePWM event while allowing for a necessary sampling delay (for example, settling time). In addition, when phase delay is combined with oversampling functionality, a single trigger can generate an interleaved burst of conversions across multiple ADCs. To achieve this, set PHASE in increments of (t_{sample}/n_interleaved_ADCs). Figure 22-8 shows an example of interleaving 12 samples across 3 ADCs.

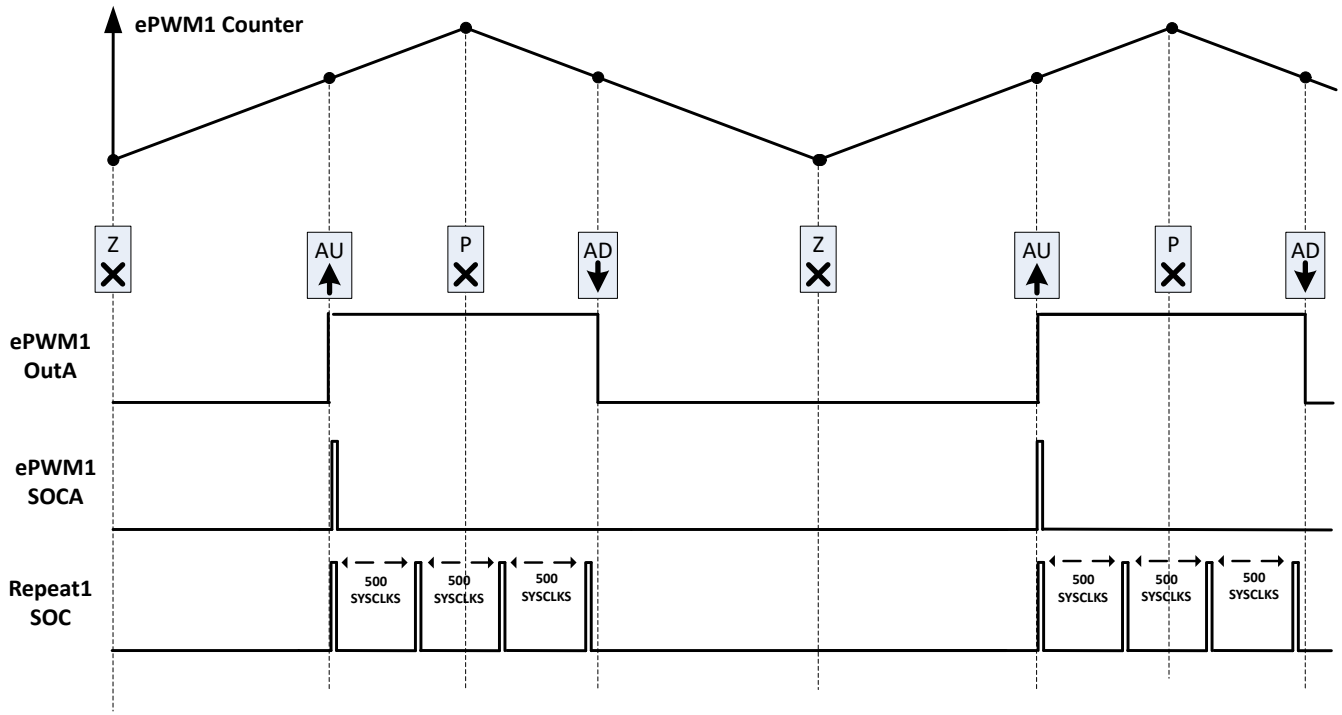
22.3.3.2.4 Re-trigger Spread

If additional time between samples is desired, the application can configure SPREAD equal to the number of SYSCLK cycles desired between samples. Figure 22-9 shows an example of oversampling from an ePWM trigger with a 500-cycle spread between samples.

- By default, SPREAD = 0, and samples are re-triggered as soon as all associated SOCs are no longer pending.
- If SPREAD is set to a value smaller than the time needed for the associated SOCs to complete, then the ADC performs the triggered conversions back-to-back, and SPREAD is effectively 0.
- SPREAD has no effect in undersampling mode, or when NSEL = 0.



TRIGGER = ePWM SOCA, NSEL = 3, MODE = Oversampling, PHASE=0, SPREAD = 500

Figure 22-9. ADC Repeated Trigger Example with Sample Spread

22.3.3.2.5 Trigger Repeater Configuration

To configure ADC oversampling or undersampling using the trigger repeater module, follow this procedure:

1. Set up the SOC by writing to ADCSOCxCTL. Specify one of the two repeater modules (REP1TRIG or REP2TRIG) as the trigger source.
2. Configure the repeater module by writing to the REPxCTL register:
   a. Configure oversampling or undersampling mode using the MODE bit.
   b. Specify the desired SOC trigger source in the TRIGGER field.
   c. If desired, configure a sync source for the repeater module in the SYNCINSEL field. A sync event resets all repeater registers to a ready and waiting state, while preserving NSEL, PHASE and MODE. A software-initiated sync is also possible by writing 1 to the SWSYNC bit.
   d. If desired, clear any previously set phase and trigger overflow flags by writing to the PHASEOVF and TRIGGEROVF bits.
3. Configure the trigger repeat count by writing to the REPxN.NSEL register. The repeater module supports up to 128 repeats for each trigger.
4. Configure the repeater phase delay by writing to the REPxPHASE.PHASE register.
5. To configure a re-trigger spread delay in oversampling mode, write the desired delay value in SYSCLK cycles to the REPxSPREAD.SPREAD register.
6. Configure the PPBxLIMIT register. This register defines how many samples the post-processing block accumulates before loading the partial sum value in ADCPPBxPSUM into ADCPPBxSUM.
7. The post-processing block (PPB) and trigger repeater module have independent sync source configurations. To configure the PPB sync source, write to the ADCPPBxCONFIG2 register. For more information on how to configure the ADC post-processing block, see Section 22.8 .

Note

When NSEL = 0, the repeater module essentially acts as a pass-through for SOC triggers, but is still useful for applying phase delay. SOC triggers are passed through in both oversampling and undersampling mode, even if there are still pending SOCs. In this scenario, the ADC sets a trigger overflow flag for the individual SOC (ADCSOCOVF1.SOCx), not the repeater module. When oversampling with NSEL > 0, the ADC sets the oversampled trigger overflow flag (REPxCTL.TRIGGEROVF) if a trigger arrives while there are pending SOCs.

When NSEL = 0, the repeater module does not set the REPxCTL.MODULEBUSY indicator. In this scenario, the application must make sure that all associated SOC flags have completed before enabling oversampling or undersamplingmode by setting NSEL > 0.

22.3.3.2.5.1 Register Shadow Updates

To avoid latency or processing delays between triggers, the application can write updated values to the NSEL, PHASE and SPREAD registers while the repeater module is still actively working. When a new SOC trigger is received, these values are loaded into the NCOUNT, PHASECOUNT and SPREADCOUNT registers, which then count down to zero as each SOC is triggered by the repeater module.

In addition, the application can change the repeater module's oversampling or undersampling mode by writing to the REPxCTL.MODE register while the repeater is actively working, without affecting the current operation. The repeater module loads the value of REPxCTL.MODE into REPxCTL.ACTIVEMODE when a new SOC trigger is received.

Copyright © 2025Texas Instruments

22.3.3.2.6 Re-Trigger Logic

The repeater module determines when to re-trigger based on the values of ADCSOCxCTL.TRIGSEL and the SOC flags in ADCSOCFLG1. A repeat trigger is issued when all SOCs configured to be triggered by the repeater module instance are no longer pending. Figure 22-10 describes the trigger repeat logic. Because the SOC pending flag goes low at the end of the sample and hold phase, the module has plenty of time to re-trigger conversions without introducing any latency between repeat conversions.

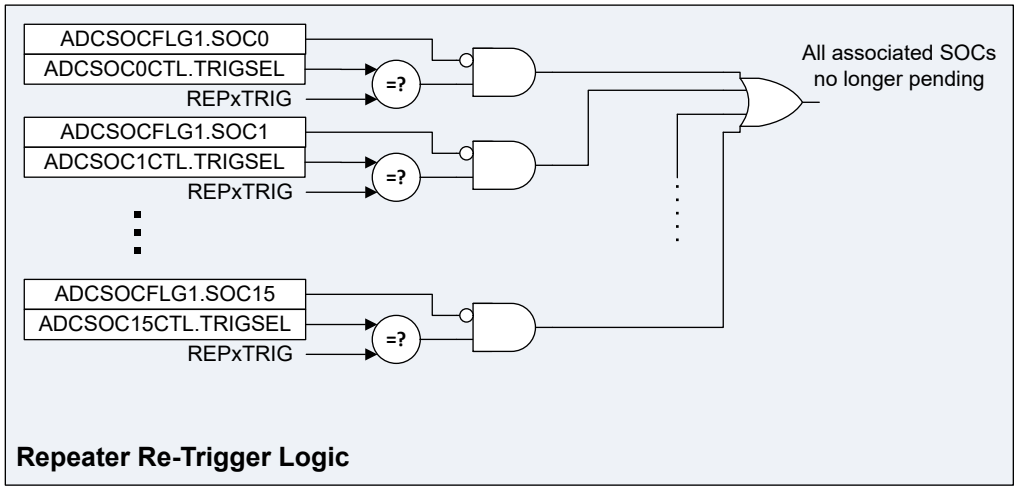

Figure 22-10. Trigger Repeater Repeat Logic

Re-triggering in Burst Mode

If the ADC is in burst mode, and the repeater is selected as the BURSTTRIG source, then the repeater fires a re-trigger pulse whenever there are no high-priority associated SOCs pending, and there are no round-robin SOCs pending.

22.3.3.2.7 Multi-Path Triggering Behavior

With the trigger repeater modules, to have one trigger source take multiple paths to set SOCs in various ways is possible. For example, ePWM1 can directly trigger SOC3 and SOC4, while one repeater block uses ePWM1 to generate oversampling triggers on SOCs 0-2, and the second repeater block generates undersampled triggers to SOC5. Assuming all SOCs are configured for round-robin priority and the various triggers all arrive in the same cycle, the conversion order is SOC0 to SOC5 in increasing order; this is then followed by the oversampled conversions on SOC0-SOC2.

22.3.4 ADC Acquisition (Sample and Hold) Window

External signal sources vary in the ability to drive an analog signal quickly and effectively. To achieve rated resolution, the signal source needs to charge the sampling capacitor in the ADC core to within 0.5 LSBs of the signal voltage. The acquisition window is the amount of time the sampling capacitor is allowed to charge and is configurable per SOCx by the ADCSOCxCTL.ACQPSADCSEQxCTONFIG.ACQPS register.

ACQPS is a 9-bit register field that can be set to a value between 0 and 511, resulting in an acquisition window duration of:

Acquisition Window = (ACQPS + 1) × (System Clock (SYSCLK) cycle time)

- The acquisition window duration is based on the System Clock (SYSCLK), not the ADC clock (ADCCLK).
- The selected acquisition window duration must be at least as long as one ADCCLK cycle.
- The data sheet specifies a minimum acquisition window duration (in nanoseconds). The user is responsible for selecting an acquisition window duration that meets this requirement.

Copyright © 2025Texas Instruments

22.3.5 ADC Input Models

For single-ended operation, the ADC input characteristics for values in the single-ended input model (see Figure 22-11) can be found in the device data sheet.

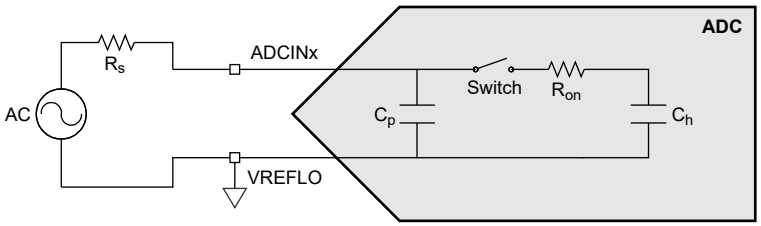

Figure 22-11. Single-Ended Input Model

For differential operation, the ADC input characteristics for values in the differential input model (see Figure 22-12) can be found in the device data sheet.

These input models must be used along with actual signal source impedance to determine the acquisition window duration. See *Choosing an Acquisition Window Duration* for more information.

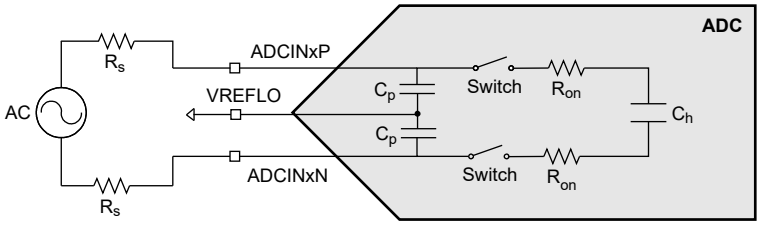

Figure 22-12. Differential Input Model

Copyright © 2025Texas Instruments

22.3.6 Channel Selection

Each SOC can be configured to convert any of the ADC channels. This behavior is selected for SOCx by the ADCSOCxCTL.CHSEL register. Depending on the signal mode, the selection is different. For single-ended signal mode, the value in CHSEL selects a single pin as the input. For differential signal mode, the value in CHSEL selects an even-odd pin pair to be the positive and negative inputs. This is summarized in Table 22-7. For pin location of ADC inputs, refer to the device specific datasheet.

Table 22-7. Channel Selection of Input Pins

22.3.6.1 External Channel Selection

The ADCSOCxCTRL.EXTCHSEL field for each SOC can be used to automatically control an external mux with digital output pins ADCxEXTMUX[3:0]. This functionality enables the application to add additional ADC channels using an external mux, with minimal software overhead. The ADCxEXTMUXy outputs can be mapped to GPIO pins by configuring the GPIO output crossbar, or configuring the GPIO mux accordingly. The EXTCHSEL field supports up to 4-bit muxes, but fewer mux selection output pins can be configured if desired.

To select a specific channel on the external mux, configure ADCSOCxCTRL.CHSEL to select the ADC pin that is connected to the mux output, and configure ADCSOCxCTRL.EXTCHSEL to select the desired mux input channel. There are a variety of potential mux topologies possible. A basic example can be a single external mux connected to a single ADC input channel.

- To select ADCxIN0.2, the user configures the SOC with CHSEL = 0 and EXTCHSEL = 2.
- To select ADCxIN3, the user configures the SOC with CHSEL = 3. The value of EXTCHSEL does not effect the conversion channel selection.

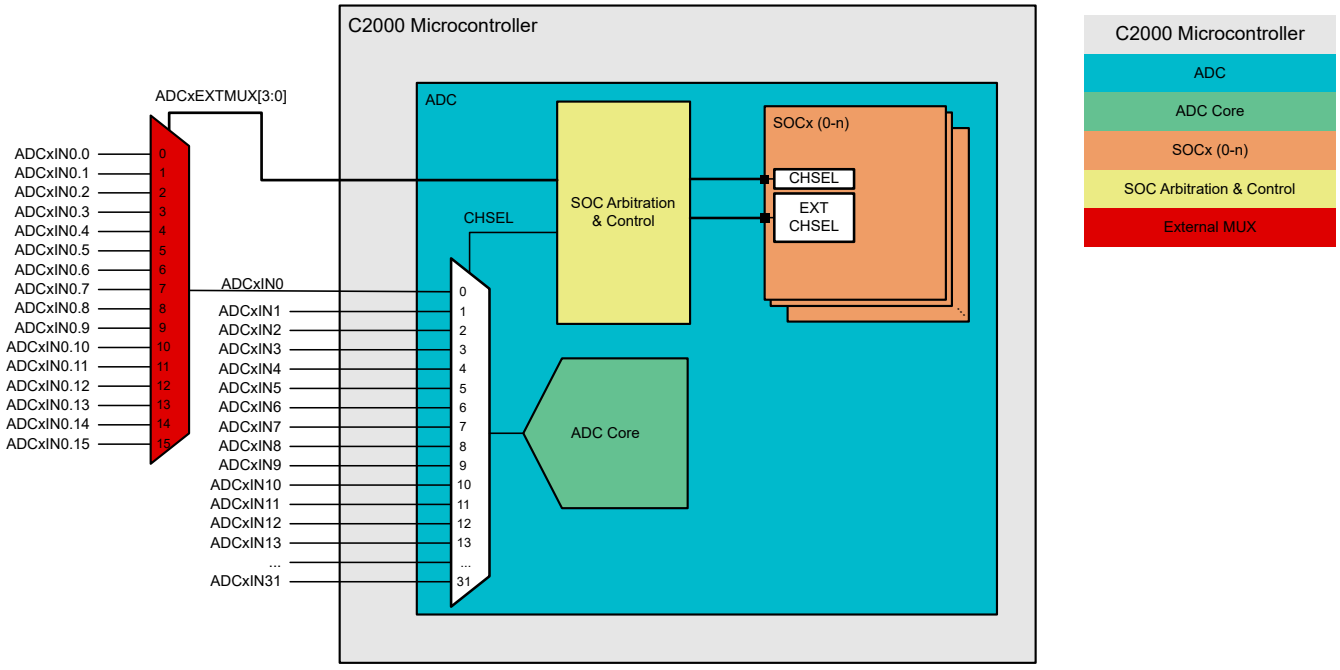

Figure 22-13. ADC with External Input Mux

Another example can be to use multiple external muxes connected to different ADC inputs.

- To select ADCxIN0.4, the user configures the SOC with CHSEL = 0 and EXTCHSEL = 4.
- To select ADCxIN3.2, the user configures the SOC with CHSEL = 3 and EXTCHSEL = 2.
- To select ADCxIN5, the user configures the SOC with CHSEL = 5. The value of EXTCHSEL does not affect the conversion.

This scheme saves one digital mux pin, at the expense of using two small muxes instead of a single large mux, and a second ADC input pin.

Copyright © 2025Texas Instruments

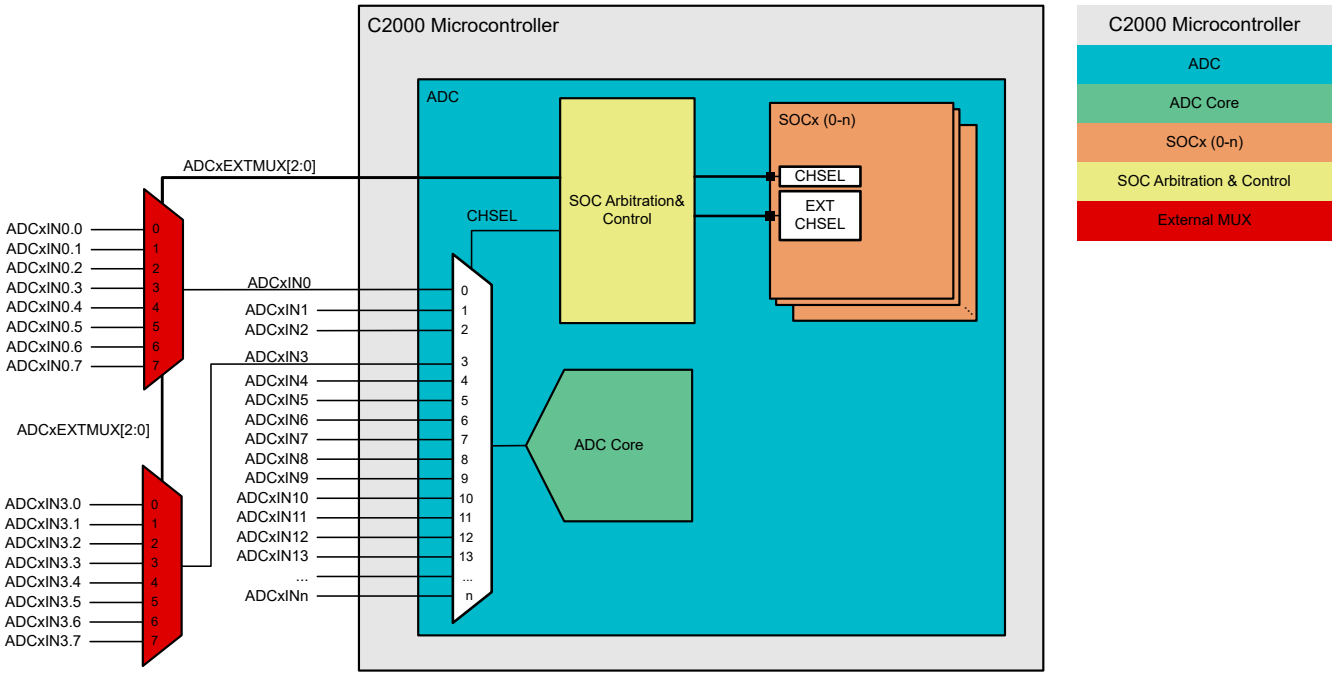

Figure 22-14. ADC with Multiple External Input Muxes and Shared Selection

When using an external channel mux, make sure to comprehend the mux selection and switching delay in the sample/hold time requirement for the SOC. This requirement includes the propagation delay for the output X-BAR (if this is used to configure the mux selection pin), any mux switching delays, and the total resistance and capacitance added to the ADC input network by the external mux device. For more information on calculating the acquisition window size, see Section 22.14.2 .

Note

While the external channel selection can technically be used to select up to 16 times the number of total ADC pins (by placing a 16-input mux on each external ADC channel), the system incurs significant added overhead if the total number of channels (internal and external) exceeds 32 – the total number of available SOCs available on the ADC instance. A sensible option is to map the ADCxEXTMUX outputs to ADC pins (AGPIOs). For instance, using one ADC input to sample an external mux output, and 4 inputs for external channel selection, the application effectively gains an additional 11 ADC inputs (from 5 to 16 pins), without using up any additional device pins.

Externally multiplexed ADC channels lose the ability to practically use the analog comparators in the comparator subsystem. However, the digital limit compares in the post-processing block can still be used to generate interrupts and/or PWM trips. For more information, see Section 22.8

Copyright © 2025Texas Instruments

22.3.6.1.1 External Channel Selection Timing

The ADCxEXTMUX output follows two possible timing schemes, depending on the setting of the EXTMUXPRESELECTEN bit in the ADCCTL1 register:

- When EXTMUXPRESELECTEN is set to 0, the ADCxEXTMUX output changes at the beginning of the associated SOC's sample and hold period. The applied external mux setting is maintained until the start of the next SOC sample-and-hold period. This is the default configuration at reset. Examples of SOC timings in this mode are shown in Figure 22-15 and Figure 22-17. When external mux preselect is disabled, make sure to configure the SOC acquisition window duration to account for both external mux settling time and internal channel settling time.
- When EXTMUXPRESELECTEN is set to 1, the ADCxEXTMUX output changes at least one SYSCLK cycle after the end of the sample and hold period. At this point, the ADC sets the external mux selection based on the next highest priority SOC that is pending. If no SOC is pending, then the mux selection is based on the next highest priority SOC, based on the current SOC priority scheme (see Section 22.5 for more information on SOC priority schemes). Examples of SOC timings in this mode are shown in Figure 22-16 and Figure 22-18. Enabling preselect mode enables the application to avoid increasing the acquisition window duration due to external mux switching and settling delays.

Note

When EXTMUXPRESELECTEN is enabled, setting SOC0 as high priority without actually triggering SOC0 conversions is a good way to define an idle value for ADCxEXTMUX. SOC0 always has the highest priority when no SOCs are pending, so the value of ADCSOC0CTL.EXTCHSEL is always pushed onto the mux select pins by default.

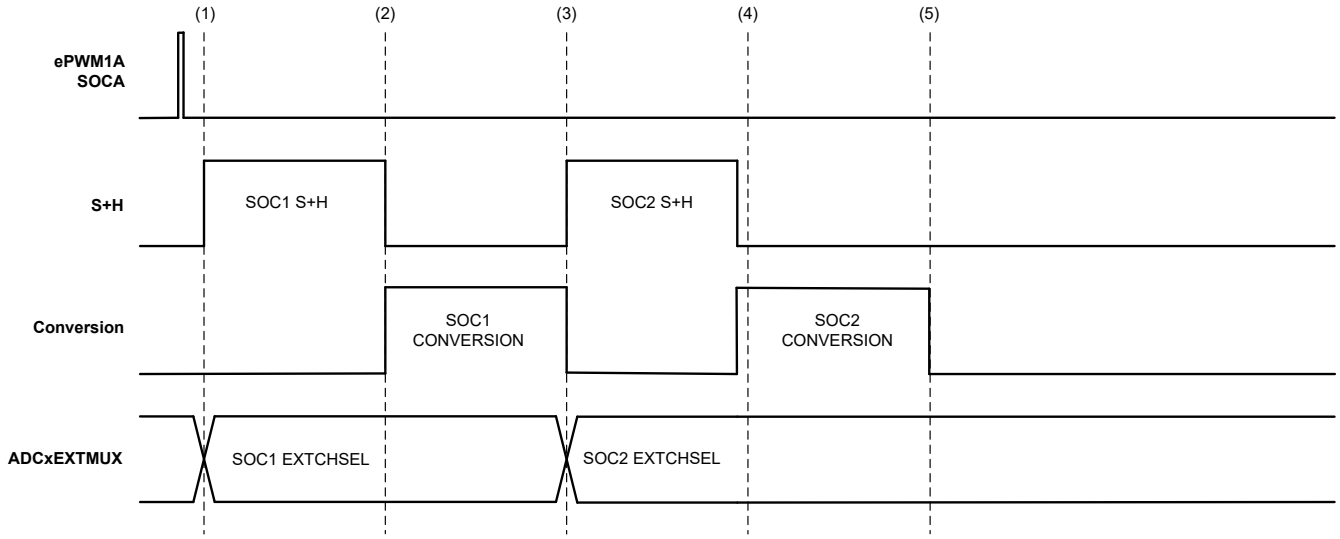

Figure 22-15. ADC External Channel Select Timing Example

In Figure 22-15, the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- No high priority SOCs are defined.

The ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 to pending. SOC1 gains priority, and the sample-and-hold period for SOC1 begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the conversion begins. ADCxEXTMUX remains unchanged until the start of the next SOC sample-and-hold period.

Copyright © 2025Texas Instruments

3. In this example case, there are no asynchronous high priority triggers defined, so SOC2 sample-and-hold starts as soon as SOC1 conversion ends. The ADC pushes ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins.
4. At the end of the sample-and-hold for SOC2, there are no more pending SOCs. SOC2 begins conversion, and ADCxEXTMUX is unchanged.
5. The SOC2 conversion ends. There are no pending SOCs or triggers, so ADCxEXTMUX remains unchanged.

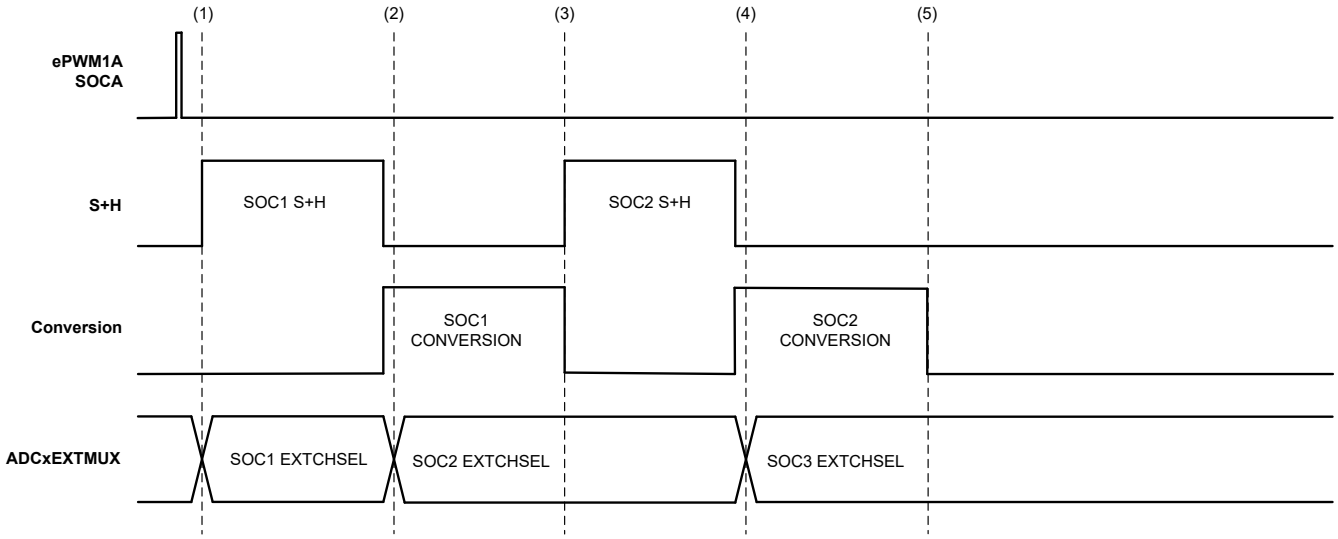

Figure 22-16. ADC External Channel Timing Example in Preselect Mode

In Figure 22-16, the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- No high priority SOCs are defined.

The ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 to pending. SOC1 gains priority, and the sample-and-hold period for SOC1 begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the highest priority SOC that is pending is SOC2, so the ADC pushes the value of ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins.
3. In this example case, there are no asynchronous high priority triggers defined, so SOC2 sample-and-hold starts as soon as SOC1 conversion ends. The ADC pushes ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins again, but this is already the current value so there is no change.
4. At the end of the sample-and-hold for SOC2, there are no more pending SOCs. SOC3 has the next highest priority by way of the round-robin pointer, so the ADC pushes the value of ADCSOC3CTL.EXTCHSEL onto ADCxEXTMUX. In this case, the application can set ADCSOC3CTL.EXTCHSEL = ADCSOC1CTL.EXTCHSEL. Although SOC3 is not actually used, this makes sure that the external mux channel is already preselected when the next ePWM1 SOC arrives.
5. The SOC2 conversion ends. There are no pending SOCs or triggers, so ADCxEXTMUX remains unchanged.

Copyright © 2025Texas Instruments

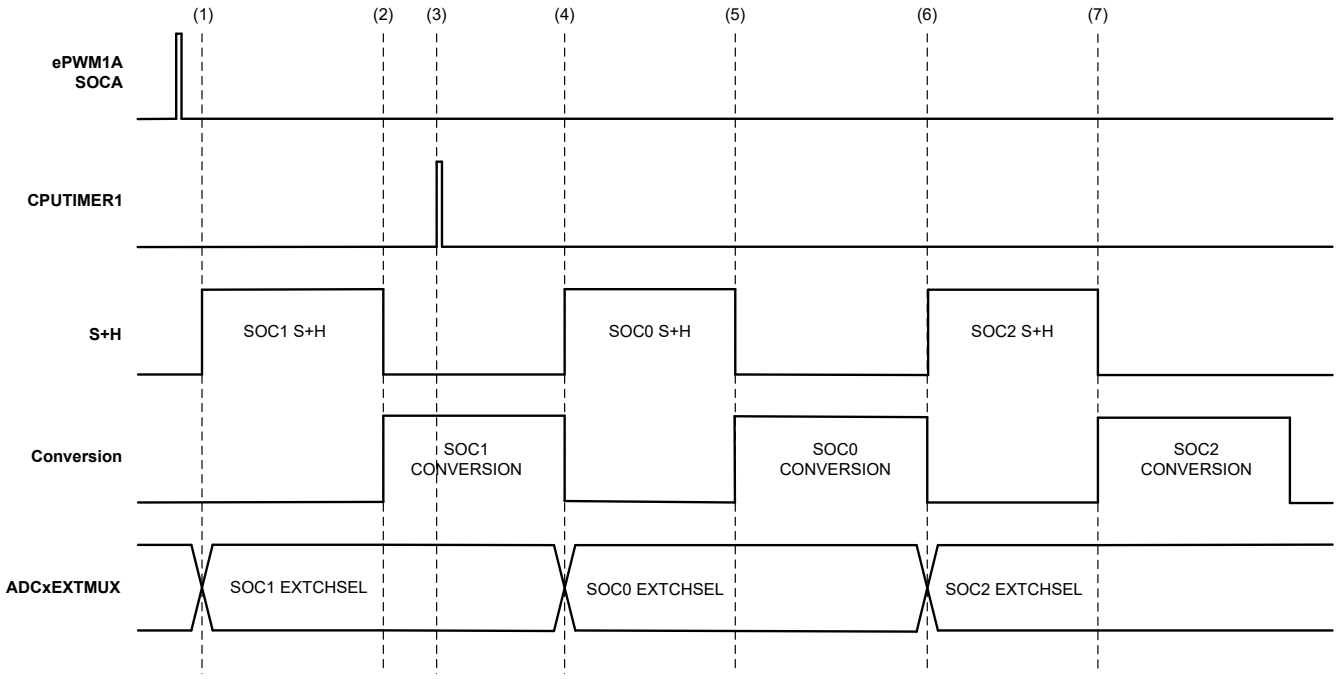

Figure 22-17. ADC External Channel Select Timing Example with Asynchronous Trigger

In Figure 22-17, the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- SOC0 is triggered from CPUTIMER1, and has a high priority.

With this configuration, the ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 flags to pending. SOC1 gains priority, and the SOC1 sample-and-hold period begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the SOC1 conversion begins. ADCxEXTMUX remains unchanged until the start of the next SOC sample-and-hold period.
3. CPUTIMER1 issues a trigger asynchronously, setting the SOC0 flag to pending.
4. Since SOC0 has high priority, SOC0 converts next instead of SOC2. The ADC pushes ADCSOC0CTL.EXTCHSEL onto ADCxEXTMUX when the sample-and-hold period for SOC0 starts.
5. At the end of the sample-and-hold period for SOC0, the conversion for SOC0 begins. ADCxEXTMUX remains unchanged until the start of the next SOC sample-and-hold period.
6. At the end of the conversion for SOC0, SOC2 is the next pending SOC. SOC2's sample-and-hold period begins, and ADCSOC2CTL.EXTCHSEL is pushed onto the ADCxEXTMUX pins.
7. The SOC2 conversion begins, and there are no pending SOCs left. ADCxEXTMUX remains unchanged until a new SOC trigger arrives.

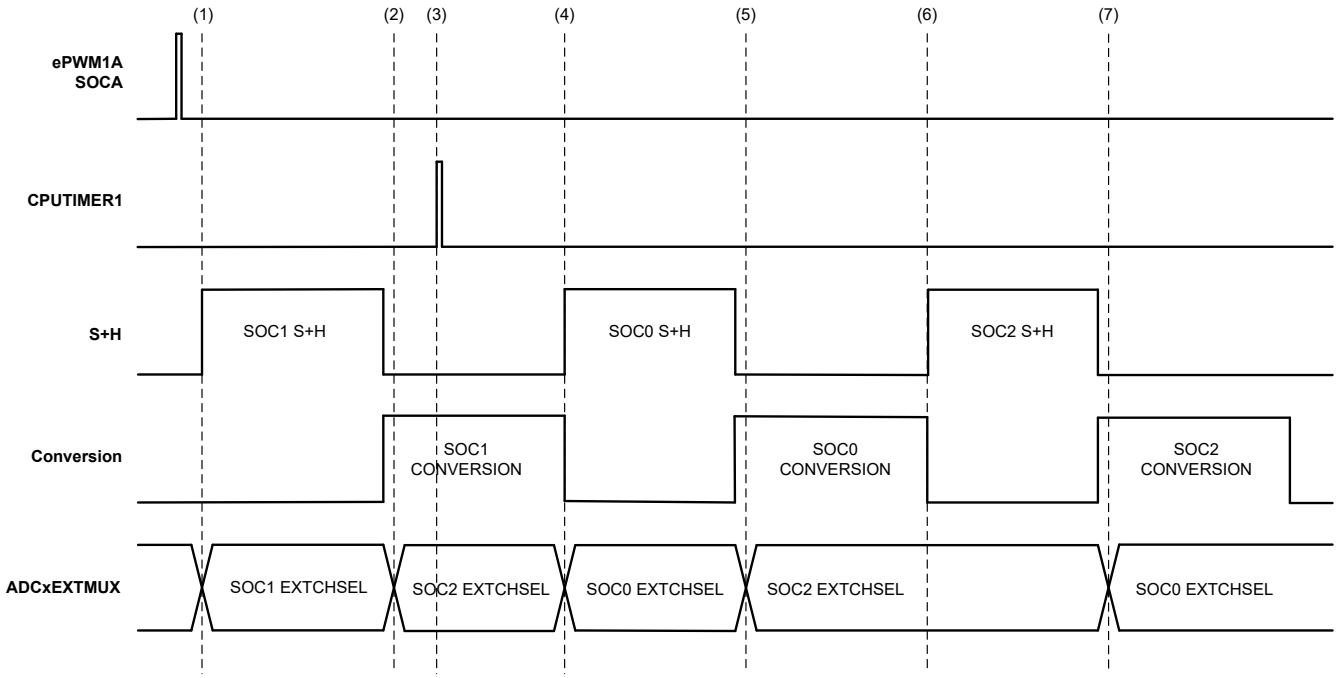

Figure 22-18. ADC External Channel Timing Example in Preselect Mode with Asynchronous Trigger

In Figure 22-18, the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- SOC0 is triggered from CPUTIMER1, and has a high priority.

With this configuration, the ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 flags to pending. SOC1 gains priority, and the SOC1 sample-and-hold period begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the highest priority SOC that is pending is SOC2, so the ADC pushes the value of ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins.
3. CPUTIMER1 issues a trigger asynchronously, setting the SOC0 flag to pending.
4. Since SOC0 has high priority, SOC0 converts next instead of SOC2. The ADC overwrites the previous speculative external mux selection (ADCSOC2CTL.EXTCHSEL) with ADCSOC0.EXTCHSEL when the sample-and-hold period for SOC0 starts. In situations like this where asynchronous triggers are possible, make sure to set the acquisition window size of the priority SOC large enough to allow for both external mux settling and internal channel settling.
5. At the end of the sample-and-hold period for SOC0, the highest priority SOC that is pending is SOC2, so the ADC pushes EXTCHSEL value for SOC2 onto the ADCxEXTMUX pins. SOC0 begins converting.
6. At the end of the SOC0 conversion, SOC2 is the next highest-priority pending SOC, and so SOC2's sample-and-hold period begins. The ADC again pushes ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins, but since this is already the current value, the mux pins are unchanged.
7. At the end of the sample-and-hold period for SOC2, there are no SOCs pending. SOC0 has the next highest priority, since the ADC has been configured to give SOC0 high priority. The ADC pushes ADCSOC0CTL.EXTCHSEL onto the ADCxEXTMUX pins.

22.4 SOC Configuration Examples

The following sections provide some specific examples of how to configure the SOCs to produce some conversions.

22.4.1 Single Conversion from ePWM Trigger

To configure ADCA to perform a single conversion on channel ADCIN1 when the ePWM timer reaches the period match, a few things are necessary. First, ePWM3 must be configured to generate an SOCA or SOCB signal (in this statement, SOC refers to a signal in the ePWM module). See the *Enhanced Pulse Width Modulator Module (ePWM)* chapter on how to do this. Assume that SOCB was chosen.

SOC5 is chosen arbitrarily. Any of the 32 SOCs can be used.

Assuming a 100ns sample window is desired with a SYSCLK frequency of 200MHz, then the acquisition window duration must be 100ns/5ns = 20 SYSCLK cycles. The ACQPS field must be set to 20 - 1 = 19.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 converts ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 19;     //SOC5 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;   //SOC5 begins conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches the period and generates the SOCB signal, the ADC begins sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 begins sampling when SOC5 gains priority (see Section 22.5). The ADC control logic samples ADCINA1 with the specified acquisition window width of 100ns. Immediately after the acquisition is complete, the ADC begins converting the sampled voltage to a digital value. When the ADC conversion is complete, the results are available in the ADCRESULT5 register (see Section 22.13 for exact sample, conversion, and result latch timings).

22.4.2 Oversampled Conversion from ePWM Trigger

To configure the ADC to oversample ADCINA1 four times, we use the same configurations as the previous example, but apply them to SOC5, SOC6, SOC7, and SOC8.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;        //SOC5 converts ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 19;       //SOC5 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;     //SOC5 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC6CTL.bit.CHSEL = 1;        //SOC6 converts ADCINA1
AdcaRegs.ADCSOC6CTL.bit.ACQPS = 19;       //SOC6 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC6CTL.bit.TRIGSEL = 10;     //SOC6 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC7CTL.bit.CHSEL = 1;        //SOC7 converts ADCINA1
AdcaRegs.ADCSOC7CTL.bit.ACQPS = 19;       //SOC7 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC7CTL.bit.TRIGSEL = 10;     //SOC7 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC8CTL.bit.CHSEL = 1;        //SOC8 converts ADCINA1
AdcaRegs.ADCSOC8CTL.bit.ACQPS = 19;       //SOC8 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC8CTL.bit.TRIGSEL = 10;     //SOC8 begins conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches the period and generates the SOCB signal, the ADC begins sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 begins sampling when SOC5 gains priority (see Section 22.5). Once the conversion is complete for SOC5, SOC6 begins converting ADCINA1 and the results for SOC5 are placed in the ADCRESULT5 register. All four conversions eventually are completed sequentially, with the results in ADCRESULT5, ADCRESULT6, ADCRESULT7, and ADCRESULT8 for SOC5, SOC6, SOC7, and SOC8, respectively.

Note

Possible, but unlikely, that the ADC can begin converting SOC6, SOC7, or SOC8 before SOC5 depending on the position of the round-robin pointer when the ePWM trigger is received. See Section 22.5 to understand how the next SOC to be converted is chosen.

Copyright © 2025Texas Instruments

22.4.3 Multiple Conversions from CPU Timer Trigger

This example shows how to sample multiple signals with different acquisition window requirements. CPU1 Timer 2 is used to generate the trigger. To see how to configure the CPU timer, see the *System Control and Interrupts* chapter.

A good first step when designing a sampling scheme with many signals is to list out the signals and the required acquisition window. From this, calculate the necessary number of SYSCLK cycles for each signal, then the ACQPS register setting. This is shown in Table 22-8, where a SYSCLK of 200MHz is assumed (5ns cycle time).

Table 22-8. Example Requirements for Multiple Signal Sampling

Signal Name	Acquisition Window Requirement	Acquisition Window (SYSCLK Cycles)	ACQPS Register Value
Signal 1	>120ns	120ns/5ns = 24	24 – 1 = 23
Signal 2	>444ns	444ns/5ns = 89 (round up)	89 – 1 = 88
Signal 3	>110ns	110ns/5ns = 22	22 – 1 = 21
Signal 4	>291ns	291ns/5ns = 59 (round up)	59 – 1 = 58

Next decide which ADC pins to connect to each signal. This is highly dependent on the application board layout. Once the pins are selected, determining the value of CHSEL is straightforward (see Table 22-9).

Table 22-9. Example Connections for Multiple Signal Sampling

Signal Name	ADC Pin	CHSEL Register Value
Signal 1	ADCINA5	5
Signal 2	ADCINA0	0
Signal 3	ADCINA3	3
Signal 4	ADCINA2	2

With the information tabulated, generate the SOC configurations:

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 5;        //SOC0 converts ADCINA5
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 23;       //SOC0 uses a sample duration of 24 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 3;      //SOC0 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC1CTL.bit.CHSEL = 0;        //SOC1 converts ADCINA0
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 88;       //SOC1 uses a sample duration of 89 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 3;      //SOC1 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC2CTL.bit.CHSEL = 3;        //SOC2 converts ADCINA3
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 21;       //SOC2 uses a sample duration of 22 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 3;      //SOC2 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC3CTL.bit.CHSEL = 2;        //SOC3 converts ADCINA2
AdcaRegs.ADCSOC3CTL.bit.ACQPS = 58;       //SOC3 uses a sample duration of 59 SYSCLK cycles
AdcaRegs.ADCSOC3CTL.bit.TRIGSEL = 3;      //SOC3 begins conversion on CPU1 Timer 2
```

As configured, when CPU1 Timer 2 generates an event, SOC0, SOC1, SOC2, and SOC3 eventually is sampled and converted, in that order. The conversion results for ACINA5 (Signal 1) are in ADCRESULT0. Similarly, The results for ADCINA0 (Signal 2), ADCINA3 (Signal 3), and ADCINA2 (Signal 4) are in ADCRESULT1, ADCRESULT2, and ADCRESULT3, respectively.

Note

There is a possibility, but unlikely, that the ADC can begin converting SOC1, SOC2, or SOC3 before SOC0 depending on the position of the round-robin pointer when the CPU Timer trigger is received. See Section 22.5 to understand how the next SOC to be converted is chosen.

Copyright © 2025Texas Instruments

22.4.4 Software Triggering of SOCs

At any point, whether or not the SOCs have been configured to accept a specific trigger, a software trigger can set the SOCs to be converted. This is accomplished by writing bits in the ADCSOCFRC1 register.

Software triggering of the previous example without waiting for the CPU1 Timer 2 to generate the trigger can be accomplished by the statement:

```
AdcaRegs.ADCSOCFRC1.all = 0x000F;        //set SOC flags for SOC0 to SOC3
```

22.5 ADC Conversion Priority

When multiple SOC flags are set at the same time, one of two forms of priority determines the converted order. The default priority method is round-robin. In this scheme, no SOC has an inherent higher priority than another. Priority depends on the round-robin pointer (RRPOINTER). The RRPOINTER reflected in the ADCSOCPRIORITYCTL register points to the last SOC converted. The highest priority SOC is given to the next value greater than the RRPOINTER value, wrapping around back to SOC0 after SOC15. At reset the value is 16 since 0 indicates a conversion has already occurred. When RRPOINTER equals 16 the highest priority is given to SOC0. The RRPOINTER is reset when the ADC module is reset or when the reset value is written to the SOCPRICTL register. The ADC module is reset by writing and clearing the SOFTPRES bit corresponding to the ADC instance.

An example of the round-robin priority method is given in Figure 22-19.

The SOCPRIORITY field in the ADCSOCPRIORITYCTL register can be used to assign high priority from a single to all of the SOCs. When configured as high priority, an SOC interrupts the round-robin wheel after any current conversion completes and inserts in as the next conversion. After the conversion completes, the round-robin wheel continues where the conversion was interrupted. If two high priority SOCs are triggered at the same time, the SOC with the lower number takes precedence.

High priority mode is assigned first to SOC0, then in increasing numerical order. The value written in the SOCPRIORITY field defines the first SOC that is not high priority. In other words, if a value of 4 is written into SOCPRIORITY, then SOC0, SOC1, SOC2, and SOC3 are defined as high priority, with SOC0 the highest.

An example using high priority SOC's is given in Figure 22-20.

Copyright © 2025Texas Instruments

A After reset, SOC0 is highest priority SOC; SOC7 receives trigger; SOC7 configured channel is converted immediately.

B RRPOINTER changes to point to SOC 7; SOC8 is now highest priority SOC.

C SOC2 & SOC12 triggers rcvd. simultaneously; SOC12 is first on round robin wheel; SOC12 configured channel is converted while SOC2 stays pending.

D RRPOINTER changes to point to SOC 12; SOC2 configured channel is now converted.

E RRPOINTER changes to point to SOC 2; SOC3 is now highest priority SOC.

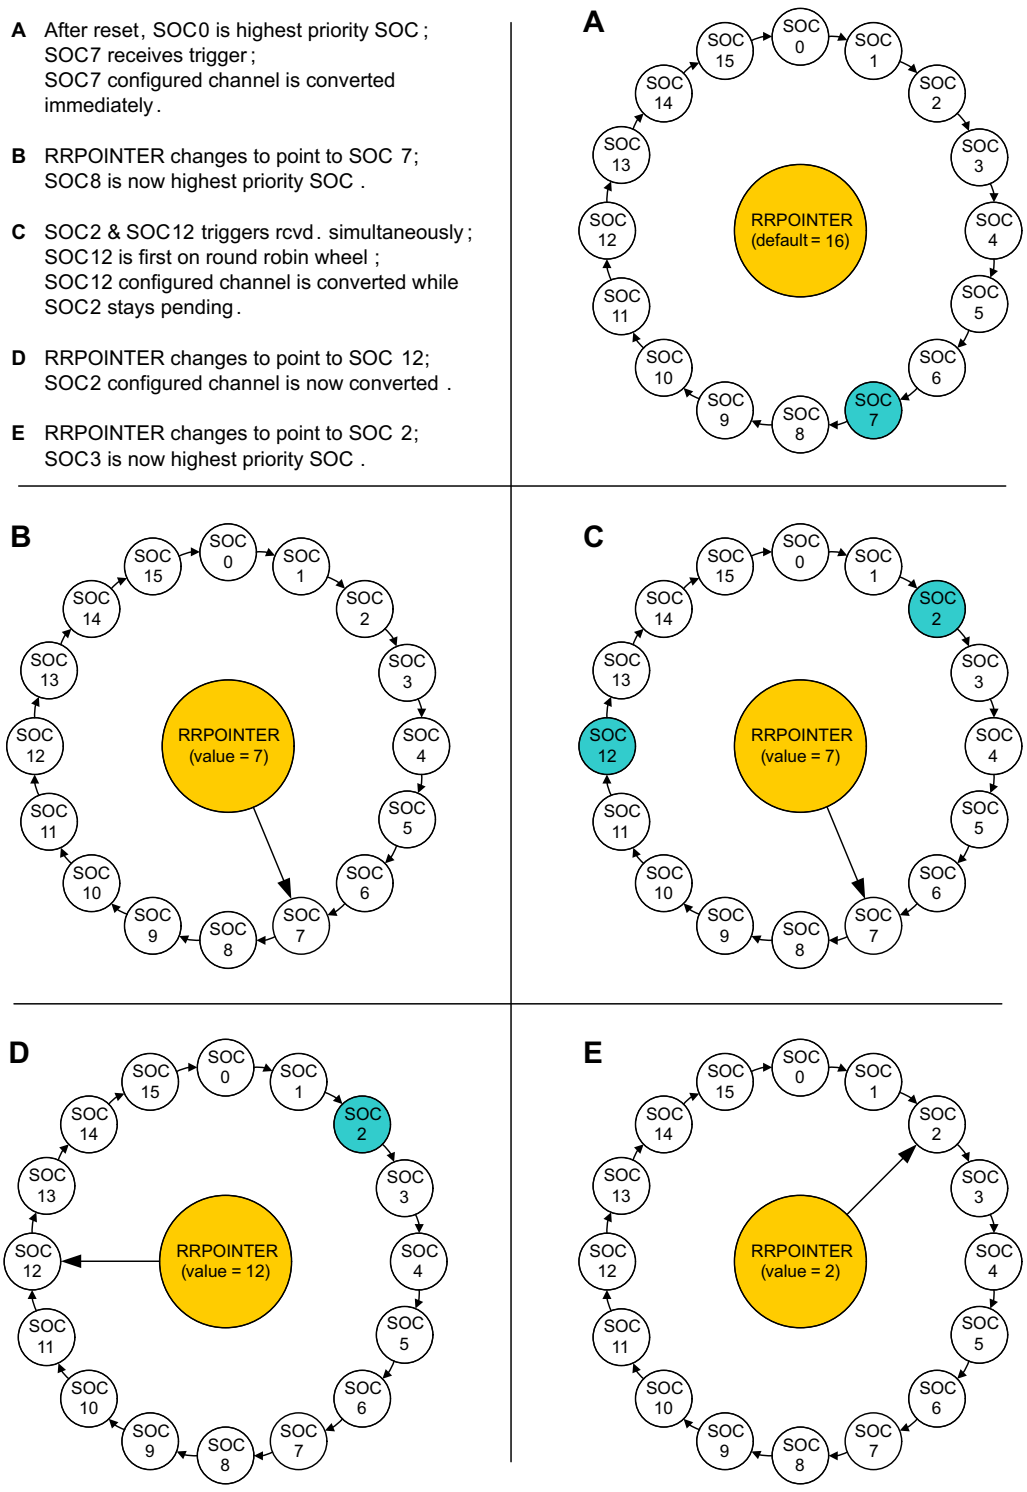

Figure 22-19. Round Robin Priority Example

Copyright © 2025Texas Instruments

Example when SOCPRIORITY = 4

A After reset, SOC4 is 1st on round robin wheel ;
SOC7 receives trigger ;
SOC7 configured channel is converted immediately .

B RRPOINTER changes to point to SOC 7;
SOC8 is now 1st on round robin wheel .

C SOC2 & SOC12 triggers rcvd . simultaneously ;
SOC2 interrupts round robin wheel and SOC 2 configured channel is converted while SOC 12 stays pending .

D RRPOINTER stays pointing to 7;
SOC12 configured channel is now converted .

E RRPOINTER changes to point to SOC 12;
SOC13 is now 1st on round robin wheel .

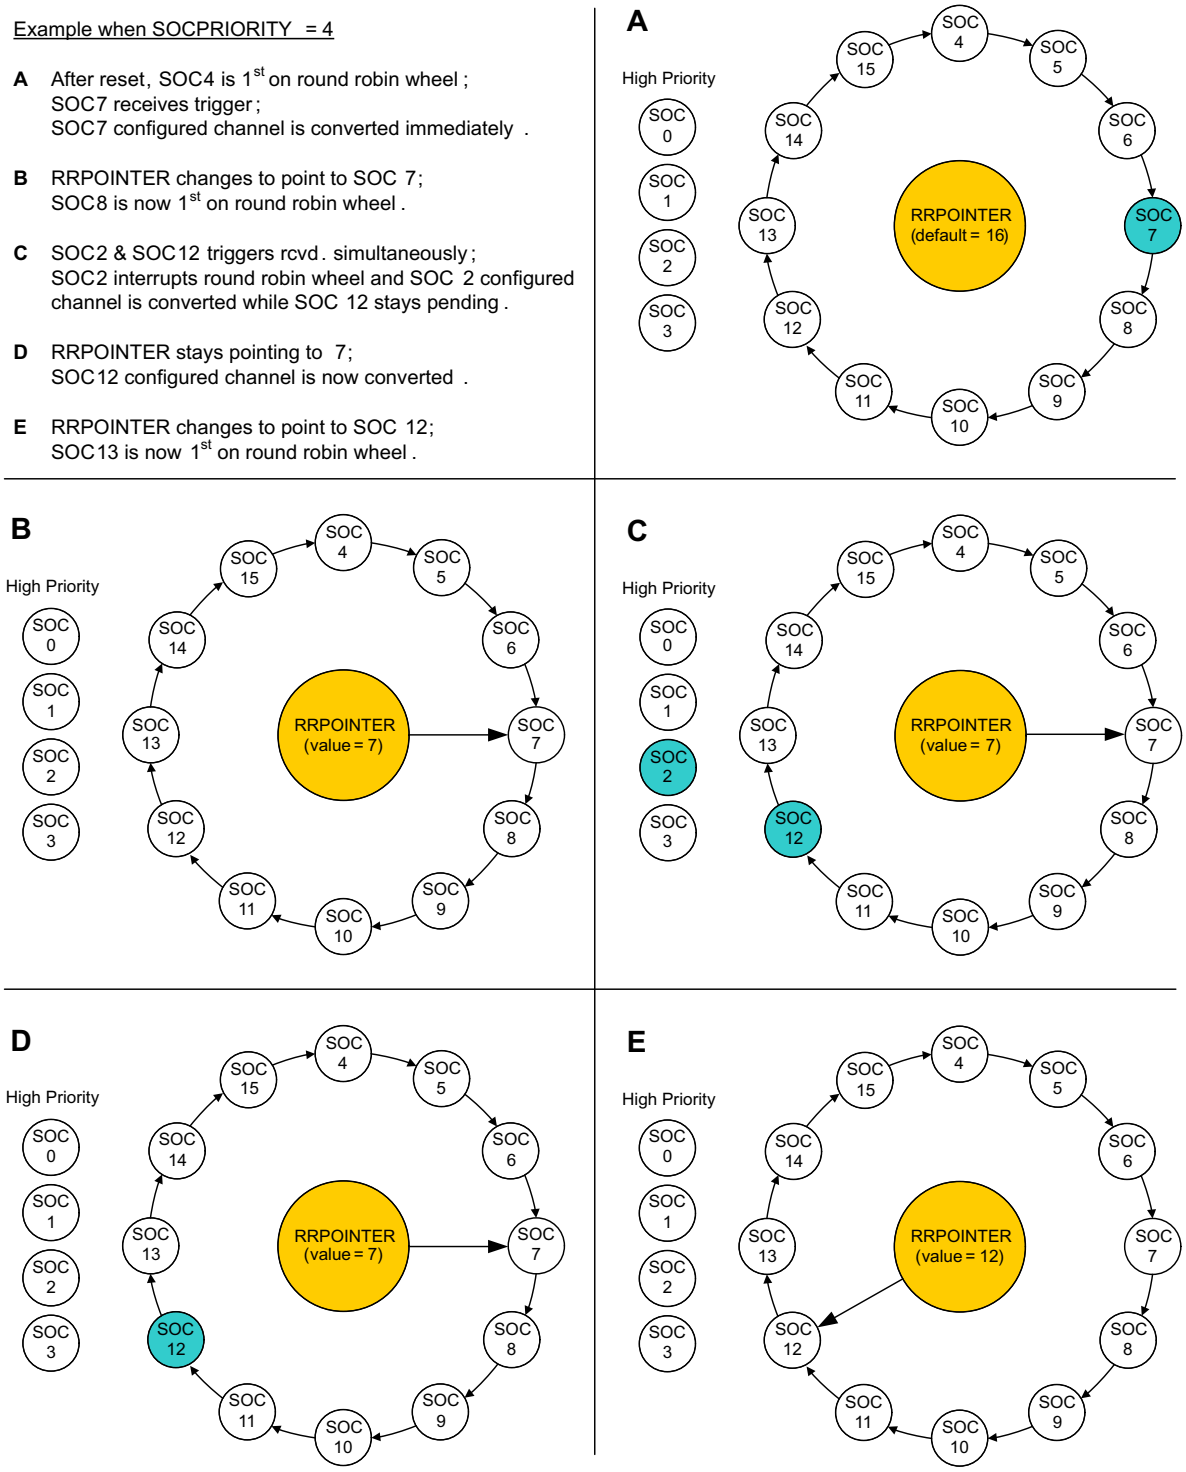

Figure 22-20. High Priority Example

22.6 Burst Mode

Burst mode allows a single trigger to walk through the round-robin SOCs one or more at a time. Setting the bit BURSTEN in the ADCBURSTCTL register configures the ADC wrapper for burst mode. This causes the TRIGSEL field to be ignored, but only for SOCs that are configured for round-robin operation (not high priority). Instead of the TRIGSEL field, all round-robin SOCs are triggered based on the BURSTTRIG field in the ADCBURSTCTL register. Upon reception of the burst trigger, the ADC wrapper does not set all round-robin SOCs to be converted, but only (ADCBURSTCTL.BURSTSIZE + 1) SOCs. The first SOC to be set is the SOC with the highest priority based on the round-robin pointer, and subsequent SOCs are set until BURSTSIZE SOCs have been set.

Note

When configuring the ADC for burst mode, the user is responsible for ensuring that each burst of conversions is allowed to complete before the next burst trigger is received. The value of (ADCBURSTCTL.BURSTSIZE + 1) must be less than or equal to the number of SOCs configured for round-robin priority. If the previous burst is not complete at the time when a new burst trigger arrives, for each SOC that was already pending and receives a new trigger, the corresponding overflow flag in ADCSOCOVF1 is set.

For example, if SOCPRIORITY = 12, that is, SOC12, SOC13, SOC14, and SOC15 are in round-robin, ADCBURSTCTL.BURSTSIZE setting must be ≤3 for burst mode to operate correctly.

22.6.1 Burst Mode Example

Burst mode can be used to sample a different set of signals on every other trigger. In the following example, ADCIN7 and ADCIN5 are converted on the first trigger from CPU1 Timer 2 and every other trigger thereafter. ADCIN2 and ACIN3 are converted on the second trigger from CPU1 Timer 2 and every other trigger thereafter. All signals are converted with 20 SYSCLK cycle wide acquisition windows, but different durations can be configured for each SOC as desired.

```
AdcaRegs.BURSTCTL.BURSTEN = 1;              //Enable ADC burst mode
AdcaRegs.BURSTCTL.BURSTTRIG = 3;            //CPU1 Timer 2 triggers burst of conversions
AdcaRegs.BURSTCTL.BURSTSIZE = 1;            //conversion bursts are 1 + 1 = 2 conversions long
AdcaRegs.SOCPRICTL.bit.SOCPRIORITY = 12;    //SOC0 to SOC11 are high priority
AdcaRegs.ADCSOC12CTL.bit.CHSEL = 7;         //SOC12 converts ADCINA7
AdcaRegs.ADCSOC12CTL.bit.ACQPS = 19;        //SOC12 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC13CTL.bit.CHSEL = 5;         //SOC13 converts ADCINA5
AdcaRegs.ADCSOC13CTL.bit.ACQPS = 19;        //SOC13 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC14CTL.bit.CHSEL = 2;         //SOC14 converts ADCINA2
AdcaRegs.ADCSOC14CTL.bit.ACQPS = 19;        //SOC14 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC15CTL.bit.CHSEL = 3;         //SOC15 converts ADCINA3
AdcaRegs.ADCSOC15CTL.bit.ACQPS = 19;        //SOC15 uses sample duration of 20 SYSCLK cycles
```

When the first CPU1 Timer 2 trigger is received, SOC12 and SOC13 are converted immediately if the ADC is idle. If the ADC is busy, SOC12 and SOC13 are converted once the SOCs gain priority. The results for SOC12 and SOC13 are in ADCRESULT12 and ADCRESULT13, respectively. After SOC13 completes, the round-robin pointer gives the highest priority to SOC14. Because of this, when the next CPU1 Timer 2 trigger is received, SOC14 and SOC15 is set as pending and eventually converted. The results for SOC14 and SOC15 are in ADCRESULT14 and ADCRESULT15, respectively. Subsequent triggers continue to toggle between converting SOC12 and SOC13, and converting SOC14 and SOC15.

While the above example toggles between two sets of conversions, three or more different sets of conversions can be achieved using a similar approach.

22.7 EOC and Interrupt Operation

Each SOC has a corresponding end-of-conversion (EOC) signal. This EOC signal can be used to trigger an ADC interrupt. The ADC can be configured to generate the EOC pulse at either the end of the acquisition window or at the end of the voltage conversion. This is configured using the bit INTPULSEPOS in the ADCCTL1 register. See Section 22.13 for exact EOC pulse location.

Each ADC module has 4 configurable ADC interrupts. These interrupts can be triggered by any of the 32 EOC signals. The flag bit for each ADCINT can be read directly to determine if the associated SOC is complete or the interrupt can be passed on to the Interrupt Controller. Each ADCINT flag also has a corresponding ADCINTxRESULT flag. The ADCINTxRESULT flag is only set when results corresponding to the EOC are latched. This is useful for interrupt service routines or CLA tasks with early interrupt timing configured, allowing the application code to perform some pre-processing or setup work, and then acting on the ADC conversion result as soon as the result is latched.

It is also possible to generate an ADC interrupt based on a PPB oversampling logic event, such as when the sample count matches the configured limit. There are four oversampling interrupt (OSINT) flags available in each module for this purpose. Any of the ADCINT flags can be configured for an OSINT by configuring the INTxSEL field the corresponding ADCINTSELxNy register.

Note

The ADCCTL1.ADCBSY bit being clear does not indicate that all conversions in a set of SOCs have completed, only that the ADC is ready to process the next conversion. To determine if a sequence of SOCs is complete, link an ADCINT flag to the last SOC in the sequence and monitor that ADCINT flag.

Figure 22-22 shows a block diagram of the ADC interrupt structure.

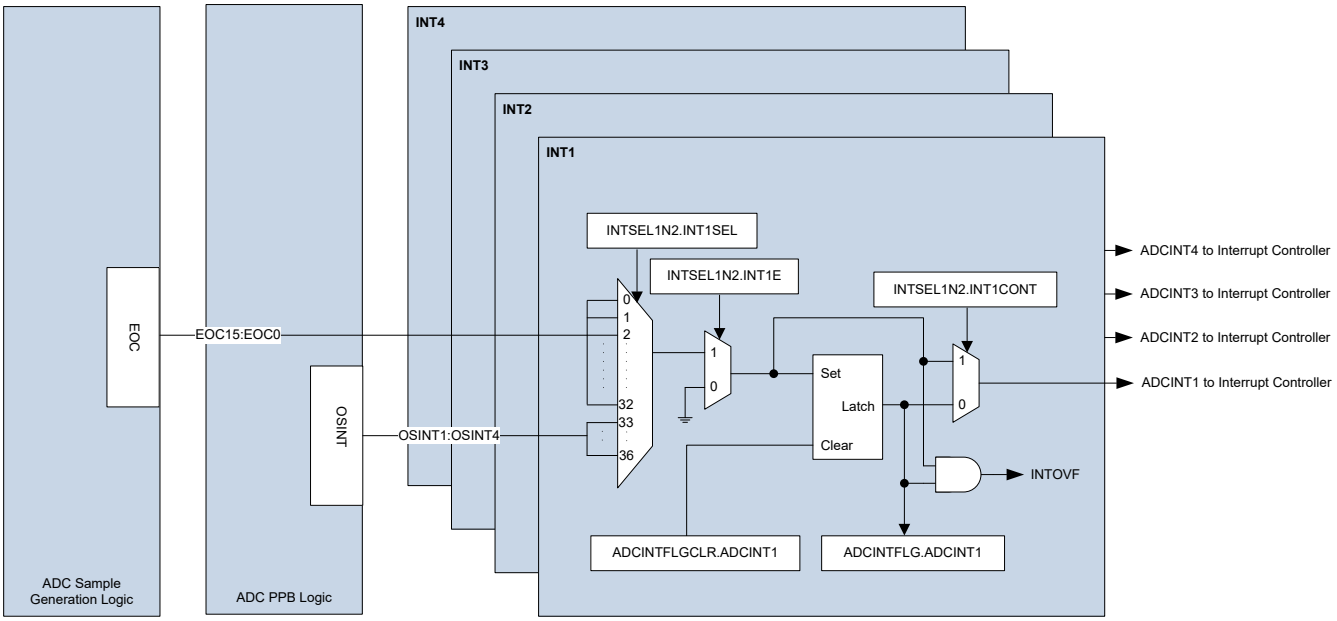

Figure 22-22. ADC End-of-Conversion (EOC) Signal Interrupts

Copyright © 2025Texas Instruments

22.7.1 Interrupt Overflow

If the EOC signal sets a flag in the ADCINTFLG register, but that flag is already set, an interrupt overflow occurs. By default, overflow interrupts are not passed on to the Interrupt Controller module. When an overflow occurs on a given flag in the ADCINTFLG register, the corresponding flag in the ADCINOVF register is set. This overflow flag is only used to detect that an overflow has occurred; the flag does not block further interrupts from propagating to the Interrupt Controller module.

When an ADC interrupt overflow occurs, the application must check the appropriate ADCINTOVF flag inside the ISR or in the background loop and take appropriate action when an overflow is detected. The following code snippets demonstrate how to check the ADCINTOVF flag inside the ISR after attempting to clear the ADCINT flag.

```
// Clear the interrupt flag
AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1;      //clear INT1 flag for ADC-A

// Check if an overflow has occurred
if(1 == AdcaRegs.ADCINTOVF.bit.ADCINT1)     //ADCINT overflow occurred
{
    AdcaRegs.ADCINTOVFCLR.bit.ADCINT1 = 1   //Clear overflow flag
    AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1   //Re-clear ADCINT flag
}
```

```
//
// Clear the interrupt flag
//
ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);

//
// Check if an overflow has occurred
//
if(true == ADC_getInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1))
{
    ADC_clearInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1);
    ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);
}
```

22.7.2 Continue to Interrupt Mode

The INTxCONT bits in the ADCINTSEL1N2 and ADCINTSEL3N4 registers configure how interrupts are handled when an ADCINTFLG has not yet been cleared from a prior interrupt. This mode is disabled by default and additional overlapping interrupts are not issued to the Interrupt Controller. By activating this mode, ADC interrupts always reach the Interrupt Controller. If interrupts occur while ADCINTFLG is set, the ADCINTOVF register remains set regardless of the configuration of the INTxCONT bits.

Copyright © 2025Texas Instruments

22.7.3 Early Interrupt Configuration Mode

Enabling early interrupt mode can allow the application to enter the ADC interrupt service routine before the ADC results are ready. This allows the application to do any necessary pre-work so that the application can act on the ADC results immediately when the ADC results become available. If the timing of the early interrupt is too early, then the application needs to waste time until the updated ADC results become available. To prevent this situation, the time the ADC interrupt is entered in early interrupt mode is configurable by way of the DELAY field in the ADCINTCYCLE register.

- To use the configurable interrupt time, the ADC must be in early interrupt mode. To achieve this, clear the bit INTPULSEPOS to 0 in ADCCTL1.
- The DELAY value in the ADCINTCYCLE register sets the number of additional SYSCLK cycles after the falling edge of the SOC pulse before the ADCINT flag is set.
- If the value of DELAY goes beyond EOC, the ADC interrupt is generated along with EOC.
- Writing values to DELAY when INTPULSEPOS is set to 1 does not have any effect on the interrupt generation.

To determine exactly when the ADC result has been latched into the ADCRESULT register, poll the ADCINTxRESULT flag bit in the ADCINTFLG register.

Copyright © 2025Texas Instruments

22.8 Post-Processing Blocks

Each ADC module contains four post-processing blocks (PPB). These blocks can be associated with any of the 32 RESULT registers using the ADCPPBxCONFIG.CONFIG bit field. The post-processing blocks have the ability to:

- Remove an offset associated with the ADCIN channel
- Subtract out a reference value
- Compute the delta between the current conversion result and the previous conversion.
- Aggregate successive samples using sum , max, and min calculations
- Automatically calculate average of oversampled conversions without CPU overhead, when sample count is a power of 2
- Transform the conversion result into an absolute value
- Flag a zero-crossing point, with the option to trip a PWM and generate an interrupt
- Flag a high or low compare limit, with the option to trip a PWM and generate an interrupt
- Digitally filter high or low compare results, to help prevent unwanted threshold trips
- Record the delay between the associated SOC trigger and when sampling actually begins

Figure 22-23 presents the structure of each PPB. Subsequent sections explain the use of each submodule.

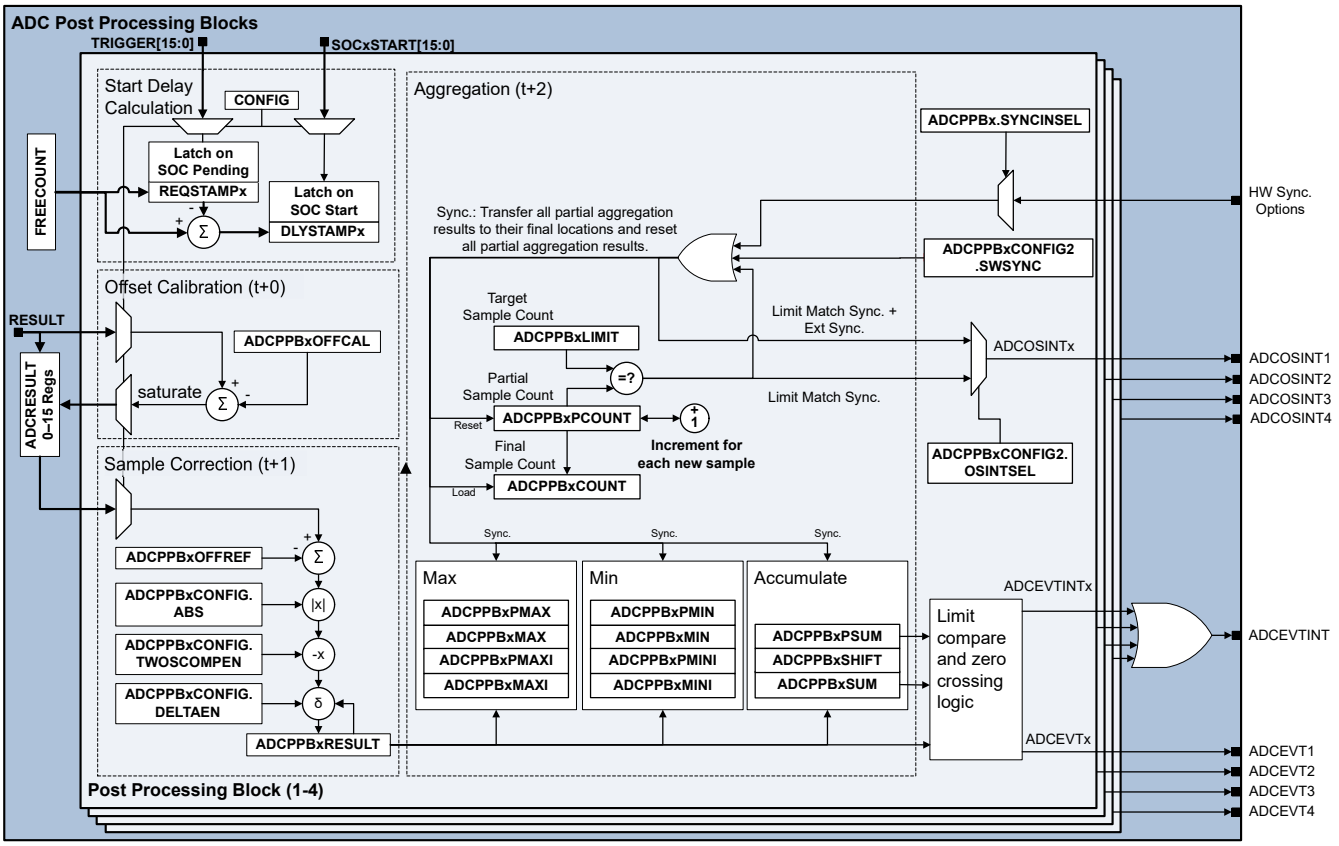

Figure 22-23. ADC Post-Processing Blocks (PPB) Block Diagram

Copyright © 2025Texas Instruments

22.8.1 PPB Offset Correction

In many applications, external sensors and signal sources produce an offset. A global trimming of the ADC offset is not enough to compensate for these offsets, which vary from channel to channel. The post-processing block can remove these offsets with zero overhead, saving numerous cycles in tight control loops.

Offset correction is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing an offset correction value to the ADCPPBxOFFCAL.OFFCAL register. The post-processing block automatically adds or subtracts the value in the OFFCAL register from the raw conversion result and stores the value in the ADCRESULT register. This addition/subtraction saturates at 0 on the low end and either 4095 or 65535 on the high end for 12-bit or 16-bit mode, respectively.

Note

- Writing a 0 to the OFFCAL register effectively disables the offset correction feature, passing the raw result unchanged to the ADCRESULT register.
- To point multiple PPBs to the same SOC is possible. In this case, the OFFCAL value that is actually applied comes from the PPB with the lowest number.

22.8.2 PPB Error Calculation

In many applications, an error from a set point or expected value must be computed from the digital output of an ADC conversion. In other cases, a bipolar signal is necessary or convenient for control calculations. The PPB can perform these functions automatically, reducing the sample to output latency and reducing software overhead.

Error calculation is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing a value to the ADCPPBxOFFCAL.OFFREF register. The post-processing block automatically subtracts the value in the OFFREF register from the ADCRESULT value and stores the value in the ADCPPBxRESULT register. This subtraction produces a sign-extended 32-bit result. It is also possible to selectively invert the calculated value before storing in the ADCPPBxRESULT register by setting the TWOSCOMPEN bit in the ADCPPBxCONFIG register.

If desired, the absolute value of the ADC result after the offset reference calculation can be obtained by setting the ADDCPPBxCONFIG.ABSEN bit. The absolute value is computed before evaluating the TWOSCOMPEN logic, so setting both TWOSCOMPEN and ABSEN always results in a negative value stored in ADCPPBxRESULT.

Note

- In 12-bit mode, do not write a value larger than 12 bits to the ADCPPBxOFFREF register.
- Since the ADCPPBxRESULT register is unique for each PPB, to point multiple PPBs to the same SOC and get different results for each PPB is possible.
- Writing a 0 to the ADCPPBxOFFREF register effectively disables the error calculation feature, passing the ADCRESULT value unchanged to the ADCPPBxRESULT register.

22.8.3 PPB Result Delta Calculation

The ADC's post-processing block has the capability to calculate the delta from the previous conversion sample. When enabled, the ADCPPBxRESULT register contains the difference between the current conversion result and the previous conversion. This delta is computed on the actual conversion result, not the result of the a prior delta calculation. The delta calculation occurs after OFFREF, TWOSCOMPEN and ABSEN calculations have been applied.

To enable result delta computation, write 1 to the DELTAEN bit in the ADCPPBxCONFIG register.

Copyright © 2025Texas Instruments

22.8.4 PPB Limit Detection and Zero-Crossing Detection

Many applications perform a limit check against the ADC conversion results. The PPB can automatically perform a check against a high limit, a low limit, or whenever ADCPPBxRESULT changes sign. Based on these comparisons, the PPB can generate a trip to the PWM and an interrupt automatically, lowering the sample to ePWM latency and reducing software overhead. This functionality also enables safety-conscious applications to trip the ePWM based on an out-of-range ADC conversion without any CPU intervention.

To enable this functionality, first point the ADCPPBxCONFIG.CONFIG to the desired SOC, then write a value to one or both of the registers ADCPPBxTRIPHI.LIMITHI and ADCPPBxTRIPLO.LIMITLO (zero-crossing detection does not require further configuration). Whenever these limits are exceeded, the PPBxTRIPHI bit or PPBxTRIPLO bit is set in the ADCEVTSTAT register. Note that the PPBxZERO bit in the ADCEVTSTAT register is gated by end-of-conversion (EOC), not by the sign change in the ADCPPBxRESULT register. The ADCEVTCLR register has corresponding bits to clear these event flags. The ADCEVTSEL register has corresponding bits that allow the events to propagate through to the PWM. The ADCEVTINTSEL register has corresponding bits that allow the events to propagate through to the Interrupt Controller.

One Interrupt Controller interrupt is shared between all the PPBs for a given ADC module as shown in the following figure.

Figure 22-25 illustrates the ADC limit compare and zero-crossing logic.

Note

- If different actions need to be taken for different PPB events from the same ADC module, then the ADCEVTINT ISR has to read the PPB event flags in the ADCEVTSTAT register to determine which event caused the interrupt.
- If different ePWM trips need to be generated separately for high compare, low compare, and zero-crossing, this can be achieved by pointing multiple PPBs to the same SOC.
- The zero-crossing detect circuit considers a result of zero to be positive.

22.8.4.1 PPB Digital Trip Filter

The ADC provides digital filters on the TRIPHI and TRIPLO signals to help prevent unwanted threshold trips. Each digital filter works on a window of FIFO samples (SAMPWIN) taken from the threshold comparator output. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged. Figure 22-26 shows a block diagram of the PPB digital trip filter.

For proper operation, the value of THRESH must be greater than SAMPWIN / 2, and less than or equal to SAMPWIN.

A prescale function (CLKPRESCALE) determines the filter sampling rate. The filter FIFO captures one sample for every CLKPRESCALE cycles of SYSCLK. Old data from the FIFO is discarded.

The digital trip filters are disabled by default. To enable and configure the digital trip filters, write the desired values to the ADCPPBTRIPxFILCTL and ADCPPBTRIPxFILCLKCTL registers. Note that for SAMPWIN, THRESH and PRESCALE, the filter adds 1 to the value in the register field (for example, write 15 to SAMPWIN to enable a filter sample window of 16). To clear the FIFO and re-initialize the filter, write 1 to the FILINIT bit in the ADCPPBTRIPxFILCTL register.

22.8.5 PPB Oversampling

This ADC has built-in support for oversampling in the post-processing block, including an accumulator, min/max for peak detection, and outlier removal. The oversampling support module exists at the output of the sample correction module, as shown in Figure 22-23. The oversampling module works by accumulating results in partial registers until either the sample count limit defined in the ADCPPBxLIMIT register is reached , an external hardware sync event occurs, or the software forces a sync event by writing to the SWSYNC bit in the ADCPPBxCONFIG2 register.

22.8.5.1 Accumulation, Minimum, Maximum, and Average Functions

At the end of each ADC sample conversion, the PPB updates the partial result registers ADCPPBxPSUM, ADCPPBxPMIN, and ADCPPBxPMAX with the newly processed conversion result from the ADCPPBxRESULT register, and the partial conversion count register (ADCPPBxPCOUNT) increments by 1. When the partial conversion count equals the limit defined in ADCPPBxLIMIT, or the PPB receives a hardware or software sync signal, the PPB takes the following actions:

1. The PPB loads the values of the respective partial result registers into the final result registers ADCPPBxPSUM, ADCPPBxPMIN, and ADCPPBxPMAX.
2. The PPB loads the partial count in ADCPPBxPCOUNT into the final conversion count register ADCPPBxCOUNT.
3. The partial count register and partial result registers reset to zero.
4. The ADC generates an oversampling interrupt (OSINTx) event pulse, which triggers a CPU interrupt if so configured in the ADCINTSEL1N2 or ADCINTSEL3N4 registers.

The PPB can also be configured to generate an oversampling interrupt when there is a hardware or software sync event. To trigger an OSINTx pulse when a sync event occurs, write 1 to the OSINTSEL bit in the ADCPPBxCONFIG2 register.

The PPB can automatically compute the average of the accumulated samples if ADCPPBxLIMIT is set to a power of 2 (up to a maximum of 1024 samples). To perform automatic averaging over 2^n samples, set the SHIFT field in the ADCPPBxCONFIG2 register to n. When this field is set, the PPB divides the value of ADCPPBxPSUM by 2^n before loading into ADCPPBxSUM.

To compute an average from the accumulated sum when the number of samples is not a power of 2, divide the value of ADCPPBxSUM by the value of ADCPPBxCOUNT using the CPU.

Note

When using a sync signal to the repeater module and post-processing block to reset the ADC, note that the repeater sync signal does not stop or abort any pending SOCs. If both sync signals are issued simultaneously, any additional pending SOCs can propagate through the post-processing block after the sync signal has been issued. To fully clear or reset the ADC when using the repeater and PPB accumulation logic together:

1. Disable the repeater module trigger source.
2. Reset the trigger repeater by issuing a sync signal to the repeater module.
3. Wait for any pending SOCs to complete.
4. Finally, issue a sync signal to the post-processing block to complete the ADC reset.

22.8.5.2 Outlier Rejection

The post-processing block enables the application to easily perform outlier rejection, by eliminating the largest and smallest samples during each SOC burst. To eliminate outliers, the following formula can be used in a software routine or ISR:

$$\text{Average} = \frac{(\text{ADCPPBxSUM} - \text{ADCPPBxMAX} - \text{ADCPPBxMIN})}{(\text{ADCPPBxCOUNT} - 2)} \quad (14)$$

22.9 Result Safety Checker

For safety-critical applications, this device provides the ability to automatically compare ADC conversion results from multiple ADC modules against each other for consistency. The number of available safety checker tiles is specified in the device data sheet. Each ADC checker tile captures conversion results from the associated ADCs as soon as the conversions are complete, and compares the absolute value of the difference to the configured tolerance. If the computed delta is out of range, the checker can generate a trip event signal that is sent to an ePWM or output crossbar, and can also trigger an CPU interrupt. Figure 22-27 illustrates the structure and operation of an ADC result safety checker tile.

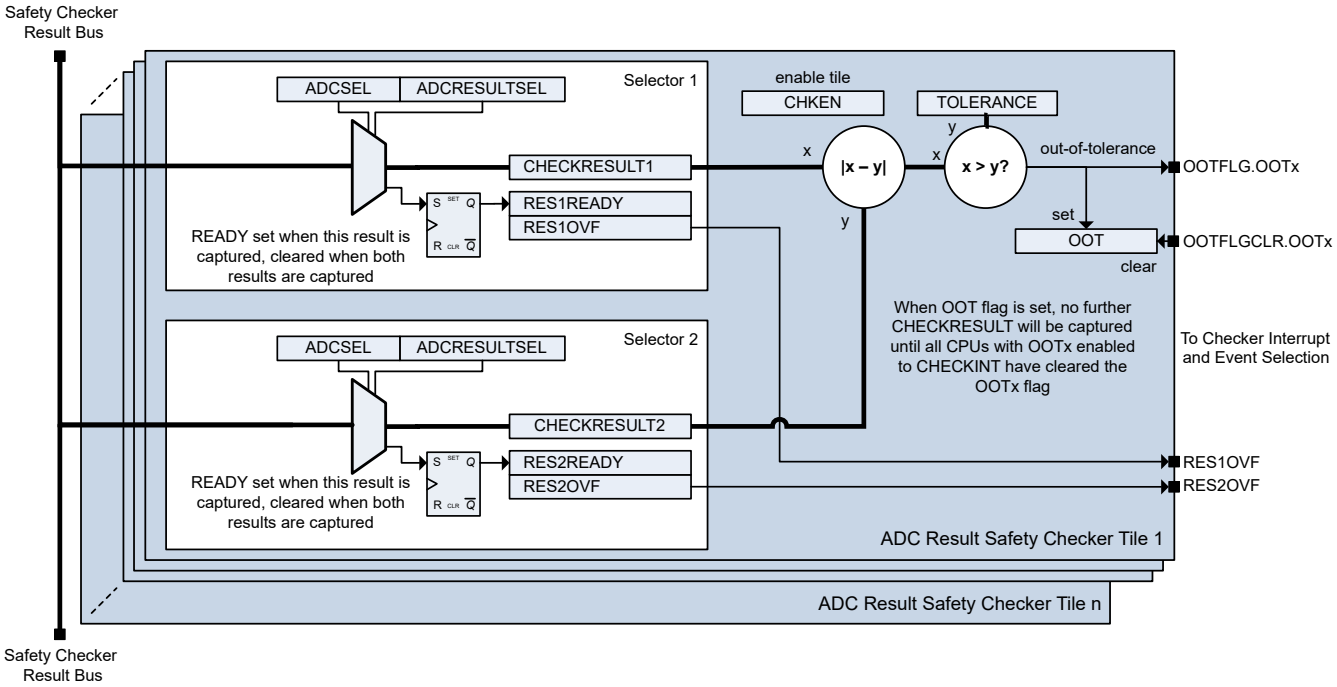

Figure 22-27. ADC Safety Checker Tile Diagram

Copyright © 2025Texas Instruments

22.9.1 Result Safety Checker Operation

Each ADC result safety checker tile can be configured to automatically compare two ADC conversion results against a set tolerance value, and generate an interrupt if an out-of-tolerance (OOT) event occurs. The selected results can be from the same ADC instance, or from different ADCs. The safety checker tiles exist outside of the ADC module, enabling the user application to compare results from two separate ADCs. To enable result safety checking, the application must first configure one or more ADCs to enable output of the desired results to the safety checker bus, and then configure the safety checker tile to compare those results.

To configure an ADC result safety checker tile:

1. Enable output of the desired ADC results for each ADC by writing to the ADC_REGSn.ADCSAFECHECKRESEN register. For each SOC, any one of the conversion result, PPB result, or PPB sum can be enabled for output to the safety checker bus by writing to ADCSAFECHECKRESEN.SOCxCHKEN.
2. Select the first result to compare by writing to the ADC_SAFECHECK_REGSn.ADCRESSEL1 register. Write to the ADCRESSEL1.ADCSEL field to select the ADC instance to test, and write to the ADCRESSEL1.ADCRESULTSEL field to select the corresponding SOC conversion result from that ADC to compare.
3. Select the second result to compare by writing to the ADC_SAFECHECK_REGSn.ADCRESSEL2 register. Write to ADCRESSEL2.ADCSEL to select the ADC instance to test, and write to ADCRESSEL2.ADCRESULTSEL to select the SOC conversion result from that ADC to compare. Any one of the SOC results, PPB module results or PPB sums can be selected in the ADCRESULTSEL field.
4. Configure the checker tolerance by writing to the ADC_SAFECHECK_REGSn.TOLERANCE register. The safety check result is out of tolerance if the difference between the two conversion results exceeds the value configured in TOLERANCE.
5. Enable the checker tile by writing 1 to ADC_SAFECHECK_REGSn.CHECKCONFIG.CHKEN.
6. Optionally, write 1 to ADC_SAFECHECK_REGSn.CHECKCONFIG.SWSYNC to force a reset of any currently set result safety checker event flags.

Each of the two result selectors waits for the configured ADC result to become available on the bus. When an ADC result becomes available, the checker reads the result into the CHECKRESULTx register, and sets the CHECKSTATUS.RESxRDY flag. Once both results are available, the checker clears the RESxRDY flags, compares the two results against each other, and sets the CHECKSTATUS.OOT flag if the configured tolerance is exceeded. This flag is also reflected in the corresponding bit for the selected checker tile in the OOTFLG register, and can be cleared by writing 1 to the corresponding bit in the OOTFLGCLR register. The checker does not perform any new comparisons while the OOT flag is set; to enable new comparisons, the flag must be cleared.

If two conversion results arrive in one selector before the other selector result becomes available, the checker sets the RESxOVF flag. This overflow flag does not prevent the comparison from occurring—the flag is for information only. To clear the overflow flag, write 1 to the corresponding bit for the selected checker tile in the RESxOVFCLR register.

22.9.2 Result Safety Checker Interrupts and Events

Each ADC result safety checker tile can generate an interrupt signal from out-of-tolerance (OOT) flags and result overflow flags (RESxOVF). These events are aggregated into a single interrupt signal, CHECKINT. Figure 22-28 shows a block diagram of the result checker interrupt aggregation. To enable a checker flag as a source for CHECKINT, write 1 to the corresponding bit in the CHECKINTSEL1, CHECKINTSEL2 or CHECKINTSEL3 register. To clear a previously set checker interrupt flag, write 1 to the CHECKINTFLGCLR.CHECKINTCLR register.

Copyright © 2025Texas Instruments

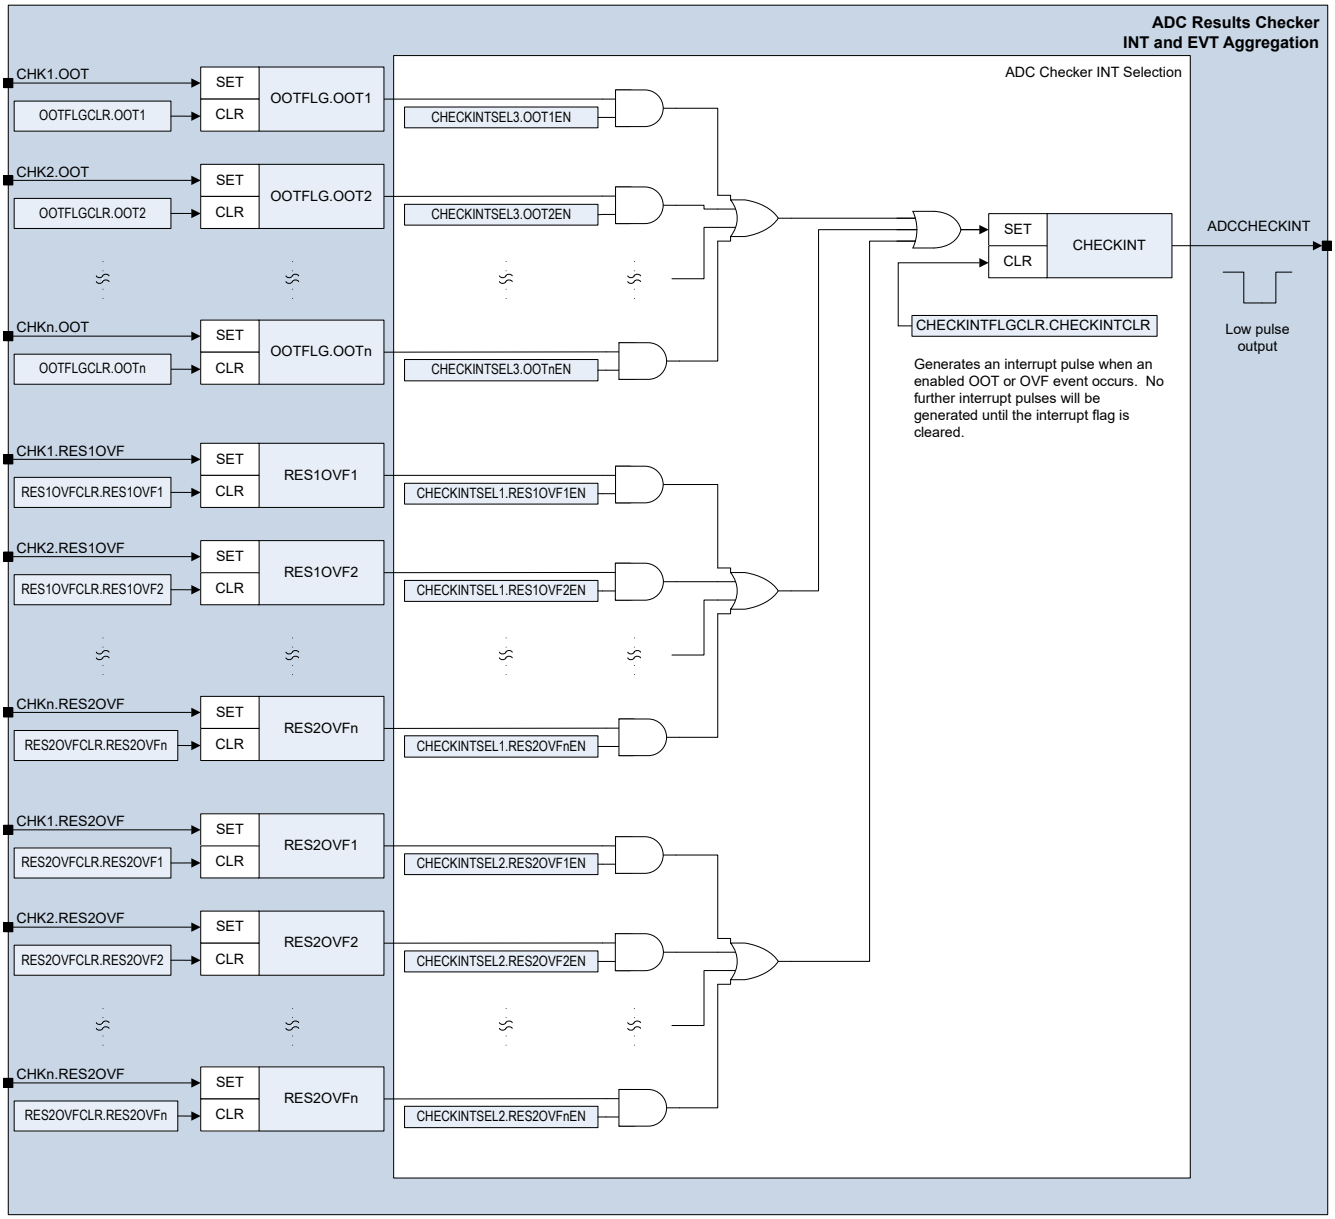

Figure 22-28. ADC Result Checker Interrupt Aggregation

In addition, safety checker tiles can also generate events that can be sent to the X-BAR, so that automatic hardware actions such as an ePWM trip can be generated. This device has 4 checker event signals (CHECKEVTx) that can be generated. For each event signal, any number of checker tile OOT or OVF flags can be aggregated into the single event signal. Figure 22-29 shows a block diagram of the ADC result checker event aggregation. To enable a checker flag as a source for a CHECKEVT signal, write 1 to the corresponding bit in the CHECKEVTxSEL1, CHECKEVTxSEL2 or CHECKEVTxSEL3 registers.

22.10 Opens/Shorts Detection Circuit (OSDETECT)

The opens/shorts detection circuit (OSDETECT) can be used to detect pin faults in the system. The circuit connects to the ADC input after the channel select multiplexer but before the S+H circuit as shown in Figure 22-30.

Note

- The divider resistance tolerances can vary widely; hence, this feature must not be used to check for conversion accuracy.
- See the data sheet for implementation and availability of analog input channels.
- Due to high drive impedance, a S+H duration much longer than the ADC minimum is needed.

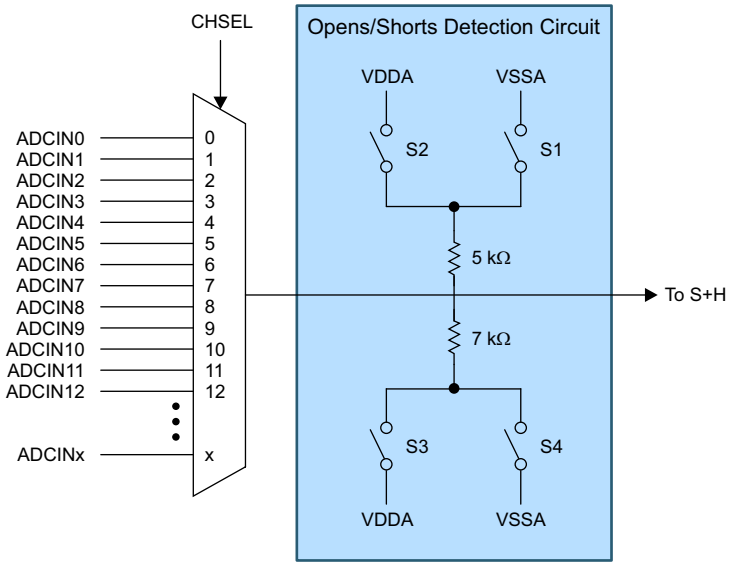

Figure 22-30. Opens/Shorts Detection Circuit

The circuit can be operated by writing a value to the DETECTCFG field in the ADCOSDETECT register. This causes the circuit to source a voltage onto the input during the S+H phase of any conversion. The voltage and drive strength of the OSDETECT circuit for different DETECTCFG settings is given in Table 22-10.

Table 22-10. DETECTCFG Settings

ADCOSDETECT. DETECTCFG	Source Voltage	S4	S3	S2	S1	Drive Impedance
0	Off	Open	Open	Open	Open	Open
1	Zero Scale	Closed	Open	Open	Closed	5K || 7K
2	Full Scale	Open	Closed	Closed	Open	5K || 7K
3	5/12 VDDA	Open	Closed	Open	Closed	5K || 7K
4	7/12 VDDA	Closed	Open	Closed	Open	5K || 7K
5	Zero Scale	Open	Open	Open	Closed	5K
6	Full Scale	Open	Open	Closed	Open	5K
7	Zero Scale	Closed	Open	Open	Open	7K

22.10.1 Open Short Detection Implementation

A representative circuit with the Open-short Detection (OSDETECT) implementation consists of the signal source with series resistance R_S, shunt capacitor C_P, the equivalent OSDETECT resistance $R_{OSDETECT}$ and voltage $V_{OSDETECT}$ is shown in Figure 22-31 and can be used as a basis to calculate the signal level going in to the sampling capacitor. $R_{OSDETECT}$ and $V_{OSDETECT}$ are the equivalent input resistance and voltage source contributed by the OSDETECT circuit with values shown in Table 22-10 for the different configuration settings. Refer to Figure 22-31 when deriving the input signal to S/H if signal source V_S is driving while the OSDETECT feature is enabled.

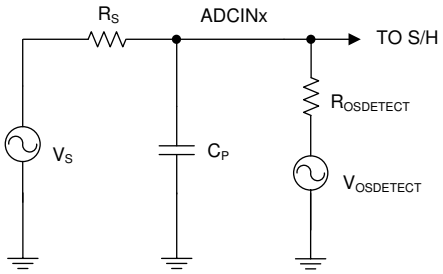

Figure 22-31. Input Circuit Equivalent with OSDETECT Enabled

The input impedance R_S and C_P are integral parts of the signal source or can have been implemented in the design to precondition the signal or to control signal settling time to meet S/H requirements. The input path has to be considered when using the OSDETECT feature, as this affects the conversion results. For instance, driving an input signal when this feature is enabled connects signal V_S to the OSDETECT circuit through R_S and affects the ADC results. Larger C_P values (in the order greater than hundreds of pF) require using higher ACQPS to make sure the signal at the input has settled prior to conversion.

To enable the circuit:

1. Configure the ADC for conversion (for example, channel, SOC, ACQPS, prescaler, trigger, and so on).
2. Set up the ADCOSDETECT register for the desired voltage divider connection as shown in Table 22-10.
3. Initiate a conversion and inspect the conversion result.

Interpret the results based on what is driving on the input side and what are the values of R_S and C_P. If the V_S signal can be disconnected from the input pin, the circuit can be used to detect open and shorted input pins as described in the following sections.

22.10.2 Detecting an Open Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with good drive strength (pin not open) is minimally affected. However, if the pin is open, the sampled voltages is close to the source voltages specified in Table 22-10.

22.10.3 Detecting a Shorted Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with finite drive strength (pin not shorted) is pulled toward each sourced voltage. However, if the pin is shorted, the signal remains at the same voltage.

22.11 Power-Up Sequence

Upon device power-up or system level reset, the ADC is powered down and disabled. When powering up the ADC, the following sequence must be used:

1. Set the bit to enable the desired ADC clock in the PCLKCR13 register.
2. Set the desired ADC clock divider in the PRESCALE field of ADCCTL2. Note that ADCCLK must be divided down to meet the maximum ADCCLK frequency provided in the device data sheet.
3. Power up the ADC by setting the ADCPWDNZ bit in ADCCTL1.
4. Allow a delay before sampling. See the data sheet for the necessary time.

If multiple ADCs are powered up simultaneously, steps 1 and step 3 can each be done for all ADCs in one write instruction. Also, only one delay is necessary as long as the delay occurs after all the ADCs have begun powering up.

22.12 ADC Calibration

During the fabrication and test process, Texas Instruments calibrates the gain, offset, and linearity of the ADCs and the offset of the buffered DACs. These trim settings are stored in M0 RAM during device boot, and can be loaded using C-callable functions.

- The Device_cal() function copies the trim values for ADC and DAC offset from M0 RAM to the respective trim registers.
- The trim functions in Device_cal() can be called individually in the F29x Software Development Kit (F29-SDK) as ADC_setOffsetTrim(), ADC_setINLTrim() and DAC_setOffsetTrim(). These functions fetch production test trim values from M0 RAM locations, and write the values to the corresponding analog module register destinations.

Until the appropriate factory trim is loaded, the ADC and other analog modules are not specified to operate within the data sheet specifications. Similarly, if trim values other than the factory settings are placed into the trim registers, the ADC (and other modules) is not specified to operate within the data sheet specifications.

The boot ROM calls the calibration functions, so trim values are initially populated without user intervention. However, if the trims are cleared due to a module reset or modified for some other reason, then the user must call the calibration functions (defined in the software development kit header files).

22.12.1 ADC Zero Offset Calibration

ADC offset error is determined and calibrated during factory testing. However, the user still has the option to perform offset calibration if the end application specifically requires this. This section describes how to perform offset calibration using internal VREFLO connection for single-ended operation, and external channels for differential operation. Refer to the register descriptions for ADCCTL2.OFFTRIMMODE, ADCOFFTRIM, ADCOFFTRIM2 and ADCOFFTRIM3 for proper offset correction parameters. The F29x Software Development Kit (F29-SDK) function ADC_setMode() sets the value of OFFTRIMMODE to 1. In this mode, the ADC selects the appropriate offset calibration values from one of the three ADCOFFTRIMx registers, depending on the signal mode and channel type (odd or even) used.

Zero offset error is defined as the difference from 0 that occurs when converting a voltage at VREFLO (for single-ended operation), or the difference from MAX_CODE/2 when converting ADCINxP = ADCINxN (for differential mode). The zero offset error can be positive or negative. To correct this error, an adjustment of equal magnitude and opposite polarity is written into the ADCOFFTRIMx register. The value contained in this register is applied before the results are available in the ADC result registers. This operation is fully contained within the ADC core, so the timing of the results is not affected, and the full dynamic range of the ADC is maintained for any trim value.

Note

Regardless of the converter resolution, the size of each ADCOFFTRIMx step is (VREFHI-VREFLO)/ 65536.

Copyright © 2025Texas Instruments

Use the following procedure to re-calibrate the ADC offset in 12-bit single-ended mode:

1. Set ADCOFFTRIMx to +112 steps (0x70). This adds an artificial offset to account for negative offset that can reside in the ADC core.
2. Perform some multiple of 16 conversions on VREFLO (internal connection), accumulating the results (for example, 32 × 16 conversions = 512 conversions). Use the maximum value of ACQPS to make sure longer settling time to account for parasitic impedance of internal VREFLO connections. To sample internal VREFLO channels, use the driverlib function ADC_setupSOCRefloChannel(). After VREFLO conversion has taken place, call ADC_disableIntRefloConnection() to disconnect the ADC input multiplexer from the internal VREFLO connection.
3. Divide the accumulated result by the multiple of 16 (for example, for 512 conversions, divide by 32).
4. Set ADCOFFTRIMx to 112 – result from step 3.

Use the following procedure to recalibrate the ADC offset in 16-bit or 12-bit differential mode:

1. Set ADCOFFTRIMx to no adjustment (0x00).
2. Short ADCINxP and ADCINyN together (external connection) to a voltage near Vrefcm and accumulate some multiple of 16 conversions (for example, 32 × 16 conversions = 512 conversions).
3. Divide the accumulated result by the number of conversions (for example, for 512 conversions, divide by 512 for 16-bit mode, or divide by 32 for 12-bit mode).
4. Set ADCOFFTRIMx to 0 – result from step 3).

22.13 ADC Timings

The process of converting an analog voltage to a digital value is broken down into an S+H phase and a conversion phase. The ADC sample and hold circuits (S+H) are clocked by SYSCLK while the ADC conversion process is clocked by ADCCLK. ADCCLK is generated by dividing down SYSCLK based on the PRESCALE field in the ADCCTL2 register.

The S+H duration is the value of the ACQPS field of the SOC being converted, plus one, times the SYSCLK period. The user must make sure that this duration exceeds both 1 ADCCLK period and the minimum S+H duration specified in the data sheet. The conversion time is approximately 10.5 ADCCLK cycles in 12-bit mode and 29.5 ADCCLK cycles in 16-bit mode. The exact conversion time is always a whole number of SYSCLK cycles. See the timing diagrams and tables in Section 22.13.1 for exact timings.

22.13.1 ADC Timing Diagrams

The following diagrams show the ADC conversion timings for two SOCs given the following assumptions:

- SOC0 and SOC1 are configured to use the same trigger.
- No other SOCs are converting or pending when the trigger occurs.
- The round robin pointer is in a state that causes SOC0 to convert first.
- ADCINTSEL is configured to set an ADCINT flag upon end of conversion for SOC0 (whether this flag propagates through to the CPU to cause an interrupt is determined by the configurations in the Interrupt Controller module).

Table 22-11 describes the parameters in the following timing diagrams. Table 22-12

Table 22-11. ADC Timing Parameter Descriptions

Parameter	Description
t_{SH}	The duration of the S+H window. At the end of this window, the value on the S+H capacitor becomes the voltage to be converted into a digital value. The duration is given by (ACQPS + 1) SYSCLK cycles. ACQPS can be configured individually for each SOC, so t_{SH} is not necessarily the same for different SOCs. **Note:** The value on the S+H capacitor is captured approximately 5ns before the end of the S+H window regardless of device clock settings.
t_{LAT}	The time from the end of the S+H window until the ADC results latch in the ADCRESULTx register. If the ADCRESULTx register is read before this time, the previous conversion results are returned.

Copyright © 2025Texas Instruments

Table 22-11. ADC Timing Parameter Descriptions (continued)

Parameter	Description
t_{EOC}	The time from the end of the S+H window until the S+H window for the next ADC conversion can begin. In 16-bit mode, this coincides with the latching of the conversion results, while in 12-bit mode, the subsequent sample can start before the conversion results are latched.
t_{INT}	The time from the end of the S+H window until an ADCINT flag is set (if configured). If the INTPULSEPOS bit in the ADCCTL1 register is set, t_{INT} coincides with the end of conversion (EOC) signal. If the INTPULSEPOS bit is 0, and the OFFSET field in the ADCINTCYCLE register is not 0, then there is a delay of OFFSET SYSCLK cycles before the ADCINT flag is set. This delay can be used to enter the ISR or trigger the RTDMA exactly when the sample is ready. If the INTPULSEPOS bit is 0, t_{INT} coincides with the end of the S+H window. If t_{INT} triggers a read of the ADC result register (directly through RTDMA or indirectly by triggering an ISR that reads the result), care must be taken to make sure the read occurs after the results latch (otherwise, the previous results are read).
t_{DMA}	The time from the end of the S+H window until a RTDMA read of the ADC conversion result is triggered, when ADCCTL1.TDMAEN = 1. If TDMAEN is set to 0, then the RTDMA trigger occurs at T_{INT}. In certain conditions, the ADCINT flag can be set before the ADCRESULT value is latched. To make sure that the RTDMA read occurs after the ADCRESULT value has been latched, write 1 to ADCCTL1.TDMAEN to enable RTDMA timings.

Table 22-12. ADC Timings in 12-bit Mode

ADCCLK Prescale		SYSCLK Cycles				
ADCCTL2. PRESCALE	Prescale Ratio	t_{EOC}	t_{LAT}	t_{INT} (Early)(1)	t_{INT} (Late)	t_{DMA}
0	1	11	13	0	11	13
2	2	21	23	0	21	23
3	2.5	26	28	0	26	28
4	3	31	34	0	31	34
5	3.5	36	39	0	36	39
6	4	41	44	0	41	44
7	4.5	46	49	0	46	49
8	5	51	55	0	51	55
9	5.5	56	60	0	56	60
10	6	61	65	0	61	65
11	6.5	66	70	0	66	70
12	7	71	76	0	71	76
13	7.5	76	81	0	76	81
14	8	81	86	0	81	86
15	8.5	86	91	0	86	91

(1) By default, t_{INT} occurs one SYSCLK cycle after the S+H window, if INTPULSEPOS is 0. This can be changed by writing to the OFFSET field in the ADCINTCYCLE register.

Table 22-13. ADC Timings in 16-bit Mode

ADCCLK Prescale		SYSCLK Cycles				
ADCCTL2. PRESCALE	Prescale Ratio	t_{EOC}	t_{LAT}	t_{INT} (Early)(1)	t_{INT} (Late)	t_{DMA}
0	1	31	32	0	31	32
2	2	60	61	0	60	61
3	2.5	75	75	0	75	75
4	3	90	91	0	90	91
5	3.5	104	106	0	104	106
6	4	119	120	0	119	120
7	4.5	134	134	0	134	134
8	5	149	150	0	149	150
9	5.5	163	165	0	163	165
10	6	178	179	0	178	179
11	6.5	193	193	0	193	193
12	7	208	209	0	208	209
13	7.5	222	224	0	222	224
14	8	237	238	0	237	238
15	8.5	252	252	0	252	252

(1) By default, t_{INT} occurs one SYSCLK cycle after the S+H window, if INTPULSEPOS is 0. This can be changed by writing to the OFFSET field in the ADCINTCYCLE register.

22.13.2 Post-Processing Block Timings

The value of ADCRESULT is always available at time t_{LAT}, as specified in Section 22.13.1 . The value of ADCPPBxRESULT, and the limit and zero-crossing comparisons are available 1 SYSCLK cycle later, as long as multiple PPB instances do not point to the same SOC. Table 22-14 shows PPB result availability timings when there are no SOCs shared between multiple PPBs. In cases where multiple PPBs point to the same SOC, PPB results become available sequentially, starting with the lowest numbered PPB. The first ADCPPBxRESULT becomes available 1 SYSCLK cycle after t_{LAT}, and each subsequent ADCPPBxRESULT becomes available 1 SYSCLK cycle after the previous PPB has completed the limit and zero-crossing comparison. The serialized PPB results are therefore spaced 2 or 3 SYSCLK cycles apart, depending on whether the comparison uses ADCPPBxRESULT or PSUM/SUM respectively. This timing is as shown in Table 22-15. PPB aggregation values (PSUM, SUM, PCOUNT, COUNT, PMAX, MAX, PMIN, MIN, PMINI, MINI, PMAXI, MAXI) are available 1 cycle after the associated ADCPPBxRESULT becomes available.

Furthermore, the LIMIT and zero-crossing compares occur 1 cycle after the compared results become available. In the case that the comparison is done against ADCPPBxRESULT, the comparison occurs 1 SYSCLK cycle after ADCPPBxRESULT becomes available. In the case that the comparison is done against PSUM or SUM, the comparison occurs 2 SYSCLK cycles after ADCPPBxRESULT is available.

Copyright © 2025Texas Instruments

Table 22-14. PPB Result Timings (One PPB per SOC)

Register	Description	Results Available
ADCRESULTy	ADC result	t_{LAT}
ADCPPBxRESULT	PPB result	t_{LAT} + 1 SYSCLK
ADCPPBxPSUM	Oversampling partial sum	t_{LAT} + 2 SYSCLK
ADCPPBxSUM	Oversampling sum	t_{LAT} + 2 SYSCLK
ADCPPBxPCOUNT	Oversampling partial sample count	t_{LAT} + 2 SYSCLK
ADCPPBxCOUNT	Oversampling sample count	t_{LAT} + 2 SYSCLK
ADCPPBxPMAX	Partial max	t_{LAT} + 2 SYSCLK
ADCPPBxMAX	Final max	t_{LAT} + 2 SYSCLK
ADCPPBxPMAXI	Partial index of max	t_{LAT} + 2 SYSCLK

22.14 Additional Information

The following sections contain additional practical information.

22.14.1 Ensuring Synchronous Operation

For best performance, all ADCs on the device must be operated synchronously. The device data sheet specifies the performance in both synchronous and asynchronous mode for those parameters which differ between the modes of operation.

To make sure of synchronous operation, all ADCs on the device must operate in lockstep. This is accomplished by writing configurations to all ADCs that cause the sampling and conversion phases of all ADCs to be exactly aligned. The easiest way to accomplish this is to write identical values to the SOC configurations for each ADC for trigger select and ACQPS (S+H duration). In addition, synchronous ADCs must also configure identical values for the SOC priority control, burst mode, burst trigger, and burst size.

On some products, ADC types can be combined on the device for versatility. Synchronous operation can be restricted when operating different ADC types simultaneously. Consult the device data sheet, if there are restrictions on simultaneous operation of ADCs of different types to understand if ADC performance is impacted.

22.14.1.1 Basic Synchronous Operation

The following example configures two SOCs each on ADCA and ADCC with identical trigger select and ACQPS values. This results in synchronous operation between ADCA and ADCC. For devices with more than two ADCs, the same principles can be used to synchronize all the ADCs.

```
Example: Basic Synchronous Operation
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1;      //SOC1 converts ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
```

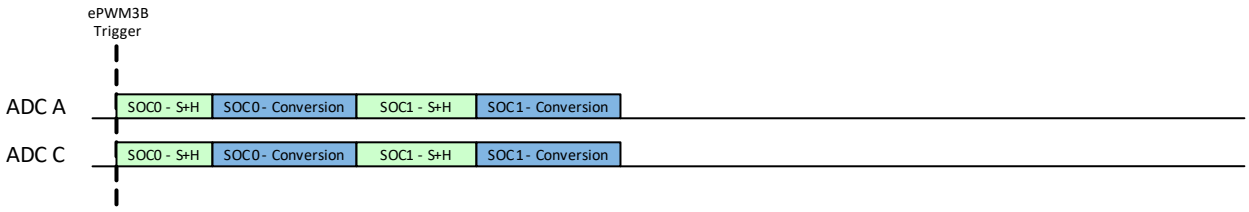

Figure 22-36. Example: Basic Synchronous Operation

Several things can be noted from Figure 22-36. First, while the ACQPS values must be the same for SOCs with the same number, different ACQPS values can be used for SOCs with different numbers. Because of this, synchronous operation does not require a single global S+H time, but instead only channels sampled simultaneously require identical S+H durations. Another important point from this example is that any channel select value can be used for any SOC. Finally, this example assumes round-robin operation. If high-priority SOCs are to be used, the priority must be configured the same on all ADCs.

Copyright © 2025Texas Instruments

22.14.1.2 Synchronous Operation with Multiple Trigger Sources

As long as each set of SOCs has identical trigger select and ACQPS settings, multiple trigger sources can be used while still achieving synchronous operation.

The following example demonstrates synchronous operation between ADCA and ADCC while using three SOCs and two trigger sources. Figure 22-37 demonstrates that any combination of relative trigger timings still results in synchronous operation.

```
Example: Synchronous Operation With Multiple Trigger Sources
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1;      //SOC1 converts ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0;      //SOC2 converts ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19;     //SOC2 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 2;    //SOC2 begins conversion on CPU Timer1
AdccRegs.ADCSOC2CTL.bit.CHSEL = 2;      //SOC2 converts ADCINC2
AdccRegs.ADCSOC2CTL.bit.ACQPS = 19;     //SOC2 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC2CTL.bit.TRIGSEL = 2;    //SOC2 begins conversion on CPU Timer1
```

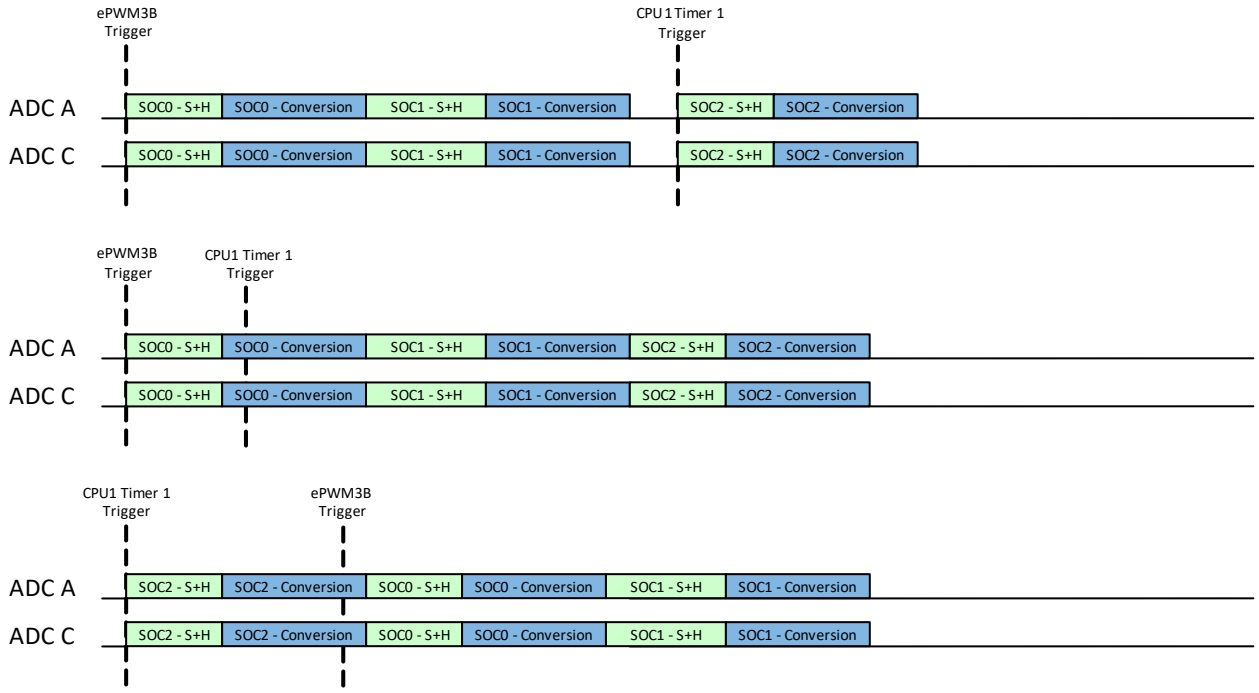

Figure 22-37. Example: Synchronous Operation with Multiple Trigger Sources

Note that any trigger source that can be selected in the TRIGSEL field can be used except for software triggering. There is no way to issue the software triggers for all ADCs simultaneously, so this results in asynchronous operation. ADCINT1 or ADCINT2 can also be used as a trigger when the ADCINTSOCSEL1 and ADCINTSOCSEL2 registers are configured identically for all ADCs and software triggering is not used to start the chain of conversions.

Copyright © 2025Texas Instruments

22.14.1.3 Synchronous Operation with Uneven SOC Numbers

If only one trigger source is used, one ADC can use more SOCs than the other ADCs while still operating synchronously.

```
Example: Synchronous Operation With Uneven SOC Numbers
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1;      //SOC1 converts ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0;      //SOC2 converts ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 30;     //SOC2 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 10;   //SOC2 begins conversion on ePWM3 SOCB
```

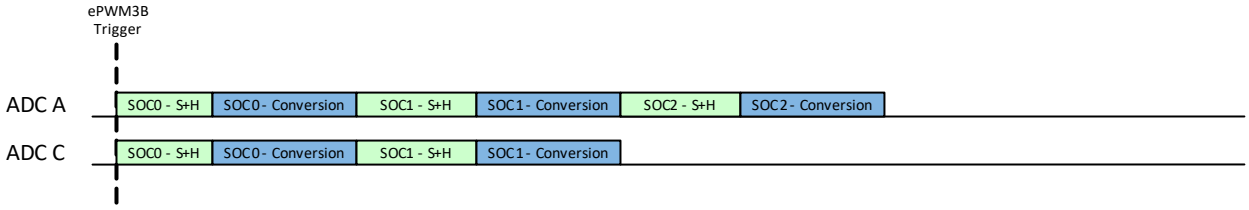

Figure 22-38. Example: Synchronous Operation with Uneven SOC Numbers

Note that if the trigger comes again before all SOCs have completed the conversions, ADCC begins converting immediately on SOC0 while ADCA does not start converting SOC0 again until SOC2 is complete. This results in asynchronous operation, so care must be taken to not overflow the trigger.

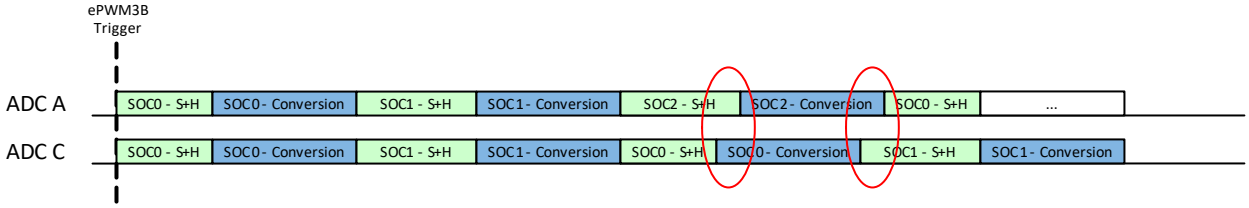

Figure 22-39. Example: Asynchronous Operation with Uneven SOC Numbers – Trigger Overflow

Copyright © 2025Texas Instruments

22.14.1.4 Synchronous Operation with Different Resolutions

Configuring different ADCs to use different resolutions results in asynchronous operation. This occurs because the conversion time for 12-bit mode and 16-bit mode are different. Synchronous operation requires both the start and end of the conversion phase to be aligned, so even using the same S+H window duration does not result in synchronous operation.

```
Example: Asynchronous Operation with Different Resolutions
//ADCA = 12-bit mode
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 50;     //SOC0 uses sample duration of 51 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

//ADCB = 16-bit mode
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0/B1
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 50;     //SOC0 uses sample duration of 51 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
```

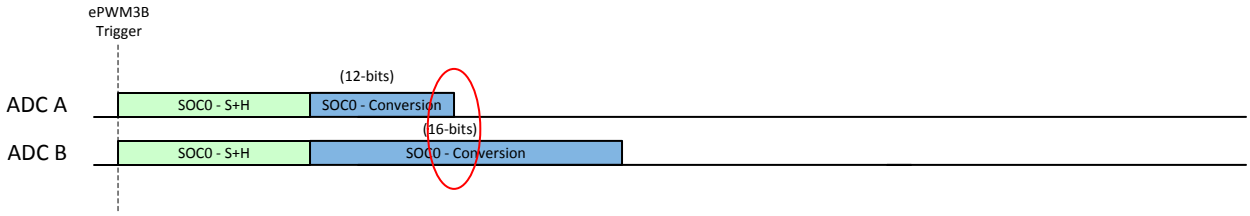

Figure 22-40. Example: Asynchronous Operation with Different Resolutions

To achieve synchronous operation while using both 12-bit and 16-bit resolution, conversions must be done in parallel at one resolution. Once conversions are complete at one resolution, the CPU must switch the resolution on all ADCs and then cause another trigger (this trigger must not be a software SOC force, as all ADCs cannot be started simultaneously using this method).

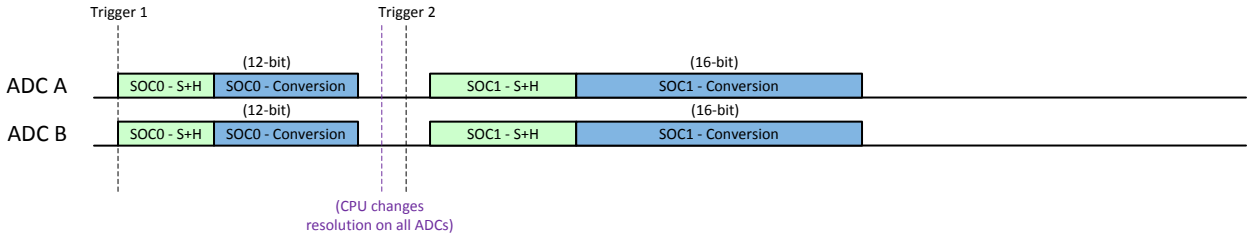

Figure 22-41. Example: Synchronous Operation with Different Resolutions

Copyright © 2025Texas Instruments

22.14.1.5 Non-overlapping Conversions

If conversion timings can be made sure to not overlap by the user, then all the SOCs on all ADCs do not have to be identically configured to achieve performance equivalent to synchronous operation. For example, if the two ADC triggers in a system come from two ePWM sources that are always 180-degrees out-of-phase, then SOC0 can be used for both ADCA and ADCC with different trigger sources and different ACQPS values.

```
Example: Operation with Non-overlapping Conversions
//ePWM3 SOCA and SOCB are 180 degrees out of phase
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 9;    //SOC0 begins conversion on ePWM3 SOCA
```

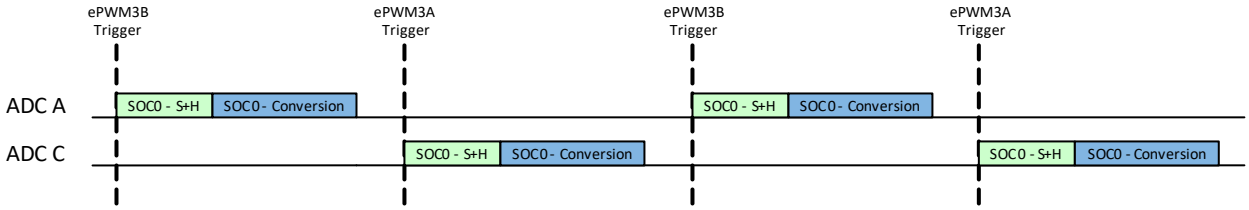

Figure 22-42. Example: Synchronous Equivalent Operation with Non-Overlapping Conversions

22.14.2 Choosing an Acquisition Window Duration

For correct operation, the input signal to the ADC must be allowed adequate time to charge the sample and hold capacitor, Ch. Typically, the S+H duration is chosen such that the sampling capacitor is charged to within ½ LSB or ¼ LSB of the final value, depending on the tolerable settling error.

The best methodology to determine the required settling time is to simulate the ADC and ADC driving circuits to make sure adequate settling performance. See *ADC Input Circuit Evaluation for C2000 MCUs* and *Charge-Sharing Driving Circuits for C2000 ADCs* for additional guidance on ADC signal conditioning circuit design and evaluation.

An approximation of the required settling time can also be determined using an RC settling model. The time constant for the model is given by the equation:

$$\tau = (R_S + R_{on}) \times C_h + R_S \times \left(C_S + C_p\right) \tag{15}$$

And the number of time constants needed is given by the equation:

$$k = ln\left(\frac{2^n}{settling\ error}\right) - ln\left(\frac{C_S + C_P}{CH}\right) \tag{16}$$

So the total S+H time must be set to at least:

$$t = k \cdot \tau \tag{17}$$

Copyright © 2025Texas Instruments

Where the following parameters are provided by the ADC input model in the device data sheet:

- n = ADC resolution (in bits)
- R_{ON} = ADC sampling switch resistance (provided in Ω)
- C_H = ADC sampling capacitor (provided in pF)
- C_p = ADC channel parasitic input capacitance (provided in pF)

And the following parameters are dependent on the application design:

- settling error = tolerable settling error (in LSBs)
- R_s = ADC driving circuit source impedance (typically in Ω or kΩ)
- C_S = capacitance on ADC input pin (typically in pF or nF)

For example, assuming the following parameters:

- n = 12-bits
- R_{ON} = 500Ω
- C_H = 12.5pF
- C_p = 12.7pF
- settling error = ¼ LSB
- R_s = 180Ω
- C_s = 150pF

The time constant is calculated as:

$$\tau = (180\Omega + 500\Omega) \times 12.5pF + 180\Omega \times (150pF + 12.7pF) = 37.8ns \quad (18)$$

And the number of required time constants is:

$$k = ln\left(\frac{2^{12}}{0.25}\right) - ln\left(\frac{150pF + 12.7pF}{12.5pF}\right) = 9.70 - 2.57 = 7.13 \quad (19)$$

So the S+H time must be set to at least: 37.8ns × 7.13 = 270ns

If SYSCLK = 200MHz , then each SYSCLK cycle is 5ns. S+H duration is 270ns/5ns = 54 SYSCLK cycles, so ACQPS for this input is set to at least CEILING(54.0) – 1 = 53.

While this gives a rough estimate of the required acquisition window, a better method is to setup a circuit with the ADC input model, a model of the source impedance/capacitance, and any board parasitics in SPICE (or similar software) and simulate to verify that the sampling capacitor settles to the desired accuracy.

Note

The device data sheet specifies a minimum ADC S+H window duration. Do not use an ACQPS value that gives a duration less than this specification.

Copyright © 2025Texas Instruments

22.14.3 Achieving Simultaneous Sampling

While each ADC does not have dual S+H circuits, achieving simultaneous sampling is accomplished by setting the SOC triggers on two or more ADC modules to use the same trigger source. The following example demonstrates simultaneous sampling on 3 ADCs based on the ePWM3 event. ADCINA3, ADCINB2, and ADCINC5 are sampled. An acquisition window of 20 SYSCLK cycles is used, but different durations are possible. The following example assumes all ADCs are configured for 12-bit mode operation.

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 3;        //SOC0 converts ADCINA3
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 2;        //SOC0 converts ADCINB2
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 5;        //SOC0 converts ADCINC5
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
```

When the ePWM3 trigger is received, all 3 ADCs begin converting in parallel immediately. All results are stored in the ADCRESULT0 register for each ADC. Note that this assumes that all ADCs are idle when the trigger is received. If one or more ADCs is busy, the samples do not happen at exactly the same time.

22.14.4 Result Register Mapping

The ADC results and the ADC PPB results are duplicated for each memory bus controller in the system. Bus controllers include all C29x cores and RTDMAs present on the specific part family and part number. For each bus controller, no access configuration is needed to allow read access to the result registers, and no contention occurs in cases where multiple bus controllers try to read the ADC results simultaneously.

22.14.5 Internal Temperature Sensor

The internal temperature sensor measures the junction temperature of the device. The output of the sensor can be sampled with the ADC through an internal connection. This can be enabled on channel ADCIN20 on ADCA, ADCIN20 on ADCC, and on the CMPSS3_HP3 and CMPSS5_HP3 inputs by setting the ENABLE bit in the TSNSCTL register.

To convert the temperature sensor reading into a temperature, pass the temperature sensor reading to the ADC_getTemperatureC() function in the ADC driverlib.

Note

To sample the temperature sensor, the ADC must be in single-ended 12-bit mode.

If the temperature sensor is sampled in 16-bit mode, this can cause incorrect ADC results.

Copyright © 2025Texas Instruments

22.14.6 Designing an External Reference Circuit

Figure 22-43 shows the basic organization of the external voltage reference generation circuitry. TI recommends that a single reference voltage generation source is shared by all ADC modules. This minimizes reference voltage mismatch between ADC modules. For best performance, the externally generated reference voltage must be buffered by a precision op-amp with good bandwidth and low output impedance before being driven into the ADC reference pin. A capacitor between the high and low reference pins must be placed on the PCB as close to the pins as practical to help absorb high-frequency currents. A series resistor (typically <1Ω) in series with this capacitor is sometimes necessary to maintain op-amp stability.

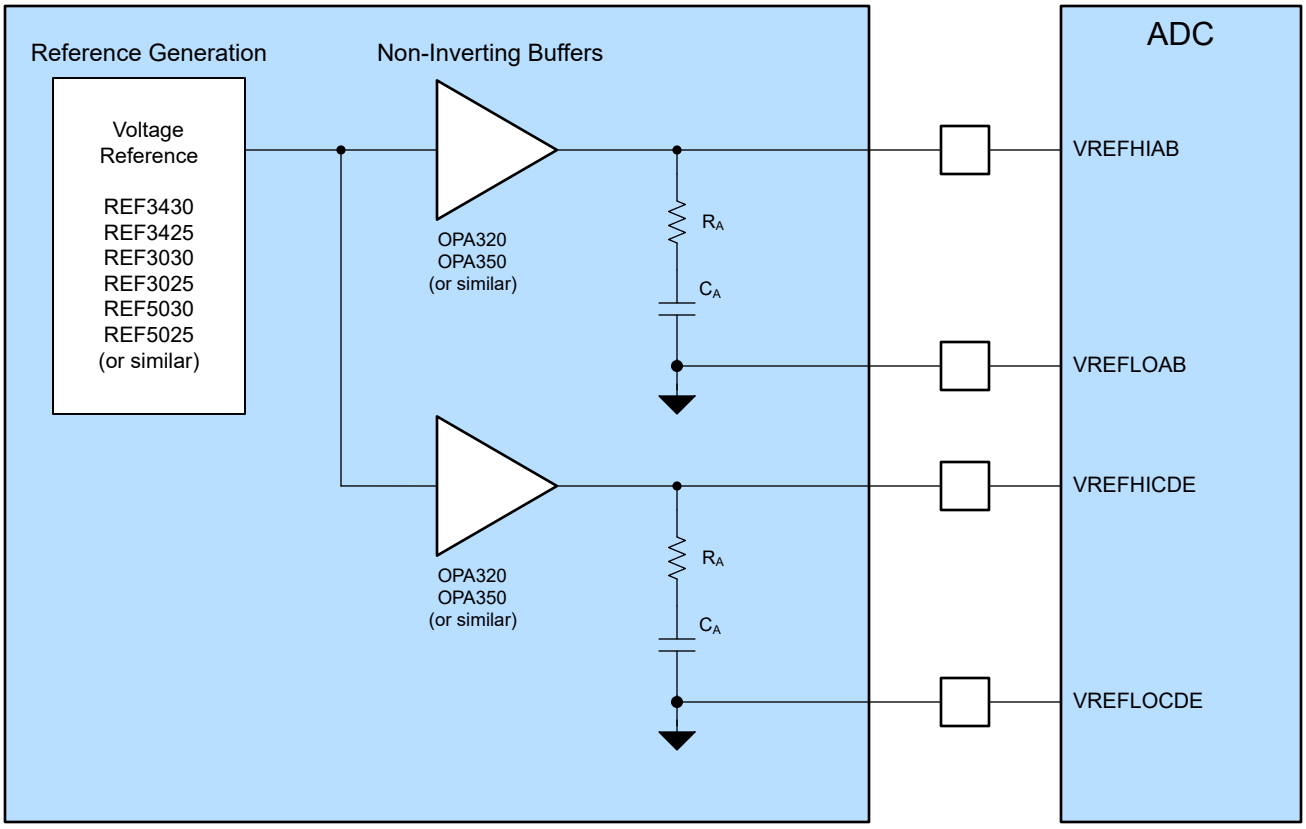

Figure 22-43. ADC Reference System

Copyright © 2025Texas Instruments

22.14.7 Internal Test Mode

For diagnostic purposes, the ADC can sample various internal node voltages using a special input selection mux called INTERNALTEST. The INTERNALTEST mux can be sampled on the ADCIN23 input channel of any of the ADC modules. Additionally, redundant INTERNALTEST connections are available on ADC-A channel ADCIN16, and on ADC-B channel ADCIN18. Internal test mode can be used to sample the VDDCORE voltage, VREFLO, VDDA, VSSA, and the CMPSS DAC outputs.

To enable internal test mode, write the desired node selection to the TESTSEL field of the INTERNALTESTCTL analog subsystem register. For details of internal test mux connections to various internal device voltage nodes, refer to the INTERNALTESTCTL register description.

To disable internal test mode, write 0 to the TESTSEL field of the INTERNALTESTCTL register.

When using internal test mode, the following special considerations apply:

- The minimum sampling window size (ACQPS) when converting INTERNALTEST is 2.56µs (512 SYSCLK cycles at 200MHz SYSCLK).
- The effective resolution of the CMPSS DAC outputs to INTERNALTEST is 6 bits.

For more information on the CMPSS module and how to configure the CMPSS DAC, see the *Comparator Subsystem (CMPSS)* chapter.

Note

For functional safety and to prevent unintended writes to the INTERNALTESTCTL register, write 1 to CONFIGLOCK.LOCKBIT in ANALOG_SUBSYS_REGS. When set, this bit prevents any further writes to the INTERNALTESTCTL register from taking effect until the next device reset.

22.14.8 ADC Gain and Offset Calibration

Using a dedicated input channel, gain balancing between multiple ADCs can be performed. By calculating the relative gain error between the ADCs, conversion results can be post-processed in software such that each ADC has the same output for each equivalent input.

To perform gain calibration, configure the ADC SOC to sample channel ADCIN21. On this channel, the voltage sampled by all ADCs when triggered is (VREFHI × 0.9).

ADC offset can also be calibrated by using dedicated input channels to measure the reference low voltage. VREFLOAB can be measured by sampling channel ADCIN22 on ADC-C, ADC-D, and ADC-E. VREFLOCDE can be measured on ADC-A and ADC-B by sampling channel ADCIN17 for the odd channel, and ADCIN22 for the even channel.

22.15.2 ADC Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location: f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/adc

Cloud access to these examples is available at the following link: dev.ti.com F29x SDK Examples.

Copyright © 2025Texas Instruments

22.15.2.1 Using Analog Subsystems Lab - Sysconfig - SINGLE_CORE

FILE: adc_academy_lab.c

This example is an empty project setup for Driverlib development. The objective of this lab exercise is to become familiar with the programming and operation of the on-chip analog-to-digital converter (ADC). The microcontroller (MCU) will be setup to sample a single ADC input channel at a prescribed sampling rate and store the conversion result in a circular memory buffer. In the second part of this lab exercise, the digital-to-analog converter (DAC) will be explored. *External Connections*

- Refer to Academy Lab instruction for exact pin for your device/board

Watch Variables

- None.

22.15.2.2 ADC Software Triggering - SINGLE_CORE

FILE: adc_ex1_soc_software.c

This example converts some voltages on ADCA and ADCC based on a software trigger.

The ADCC will not convert until ADCA is complete, so the ADCs will not run asynchronously. However, this is much less efficient than allowing the ADCs to convert synchronously in parallel (for example, by using an ePWM trigger).

External Connections

- A0, A1, C2, and C3 should be connected to signals to convert

Watch Variables

- *myADC0Result0* - Digital representation of the voltage on pin A0
- *myADC0Result1* - Digital representation of the voltage on pin A1
- *myADC1Result0* - Digital representation of the voltage on pin C2
- *myADC1Result1* - Digital representation of the voltage on pin C3

22.15.2.3 ADC ePWM Triggering - SINGLE_CORE

FILE: adc_ex2_soc_epwm.c

This example sets up ePWM1 to periodically trigger a conversion on ADCA.

External Connections

- A0 should be connected to a signal to convert

Watch Variables

- *myADC0Results* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is determined based on the period of the ePWM timer.

22.15.2.4 ADC Temperature Sensor Conversion - SINGLE_CORE

FILE: adc_ex3_temp_sensor.c

This example sets up the ePWM to periodically trigger the ADC. The ADC converts the internal connection to the temperature sensor, which is then interpreted as a temperature by calling the ADC_getTemperatureC() function.

Watch Variables

- *sensorSample* - The raw reading from the temperature sensor
- *sensorTemp* - The interpretation of the sensor sample as a temperature in degrees Celsius.

22.15.2.5 ADC Synchronous SOC Software Force (adc_soc_software_sync) - SINGLE_CORE

FILE: adc_ex4_software_sync.c

This example converts some voltages on ADCA and ADCC using input 5 of the input X-BAR as a software force. Input 5 is triggered by toggling GPIO0, but any spare GPIO could be used. This method will ensure that both ADCs start converting at exactly the same time.

Copyright © 2025Texas Instruments

External Connections

- A0, A1, C0, C1 pins should be connected to signals to convert

Watch Variables

- *myADC0Result0* : a digital representation of the voltage on pin A0
- *myADC0Result1* : a digital representation of the voltage on pin A1
- *myADC1Result0* : a digital representation of the voltage on pin C0
- *myADC1Result1* : a digital representation of the voltage on pin C1

22.15.2.6 ADC Continuous Triggering (adc_soc_continuous) - SINGLE_CORE

FILE: adc_ex5_soc_continuous.c

This example sets up the ADC to convert continuously, achieving maximum sampling rate.

External Connections

- A0 pin should be connected to signal to convert

Watch Variables

- *adcAResults* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is the minimum possible based on the ADC speed.

22.15.2.7 ADC Continuous Conversions Read by DMA (adc_soc_continuous_dma) - SINGLE_CORE

FILE: adc_ex6_continuous_dma.c

This example sets up two ADC channels to convert simultaneously. The results will be transferred by the DMA into a buffer in RAM.

External Connections

- A3 & C3 pins should be connected to signals to convert

Watch Variables

- *myADC0DataBuffer* : a digital representation of the voltage on pin A3
- *myADC1DataBuffer* : a digital representation of the voltage on pin C3

22.15.2.8 ADC PPB Offset (adc_ppb_offset) - SINGLE_CORE

FILE: adc_ex7_ppb_offset.c

This example software triggers the ADC. Some SOCs have automatic offset adjustment applied by the post-processing block. After the program runs, the memory will contain ADC & post-processing block(PPB) results.

External Connections

- A0, C0 pins should be connected to signals to convert

Watch Variables

- *myADC0Result* : a digital representation of the voltage on pin A0
- *myADC0PPBResult* : a digital representation of the voltage on pin A0, minus 100 LSBs of automatically added offset
- *myADC1Result* : a digital representation of the voltage on pin C0
- *myADC1PPBResult* : a digital representation of the voltage on pin C0 plus 100 LSBs of automatically added offset

22.15.2.9 ADC PPB Limits (adc_ppb_limits) - SINGLE_CORE

FILE: adc_ex8_ppb_limits.c

This example sets up the ePWM to periodically trigger the ADC. If the results are outside of the defined range, the post-processing block will generate an interrupt.

The default limits are 1000LSBs and 3000LSBs. With VREFHI set to 3.3V, the PPB will generate an interrupt if the input voltage goes above about 2.4V or below about 0.8V.

Copyright © 2025Texas Instruments

External Connections

- A0 should be connected to a signal to convert

Watch Variables

- None

22.15.2.10 ADC PPB Delay Capture (adc_ppb_delay) - SINGLE_CORE

FILE: adc_ex9_ppb_delay.c

This example demonstrates delay capture using the post-processing block.

Two asynchronous ADC triggers are setup:

- ePWM1, with period 2048, triggering SOC0 to convert on pin A0
- ePWM2, with period 9999, triggering SOC1 to convert on pin A1
  Each conversion generates an ISR at the end of the conversion. In the ISR for SOC0, a conversion counter is incremented and the PPB is checked to determine if the sample was delayed.
  After the program runs, the memory will contain:

conversion : the sequence of conversions using SOC0 that were delayed

- *delay* : the corresponding delay of each of the delayed conversions

22.15.2.11 ADC ePWM Triggering Multiple SOC - SINGLE_CORE

FILE: adc_ex10_multiple_soc_epwm.c

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA and ADCC. This example demonstrates multiple ADCs working together to process of a batch of conversions using the available parallelism across multiple ADCs.

ADCA Interrupt ISRs are used to read results of both ADCA and ADCC.

External Connections

- A0, A1, A2 and C2, C3, C4 pins should be connected to signals to be converted.

Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcCResult0* - Digital representation of the voltage on pin C2
- *adcCResult1* - Digital representation of the voltage on pin C3
- *adcCResult2* - Digital representation of the voltage on pin C4

22.15.2.12 ADC Burst Mode - SINGLE_CORE

FILE: adc_ex11_burst_mode_epwm.c

This example sets up ePWM1 to periodically trigger ADCA using burst mode. This allows for different channels to be sampled with each burst.

Each burst triggers 3 conversions. A0 and A1 are part of every burst while the third conversion rotates between A2, A3, and A4. This allows high importance signals to be sampled at high speed while lower priority signals can be sampled at a lower rate.

ADCA Interrupt ISRs are used to read results for ADCA.

External Connections

- A0, A1, A2, A3, A4

Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1

Copyright © 2025Texas Instruments

- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcAResult3* - Digital representation of the voltage on pin A3
- *adcAResult4* - Digital representation of the voltage on pin A4

22.15.2.13 ADC Burst Mode Oversampling - SINGLE_CORE

FILE: adc_ex12_burst_mode_oversampling.c

This example is an ADC oversampling example implemented with software. The ADC SOCs are configured in burst mode, triggered by the ePWM SOC A event trigger.

External Connection

- A2

Watch Variables

- *lv_results* - Array of digital values measured on pin A2 (oversampling is configured by Oversampling_Amount)

22.15.2.14 ADC SOC Oversampling - SINGLE_CORE

FILE: adc_ex13_soc_oversampling.c

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA including multiple SOCs that all convert A2 to achieve oversampling on A2.

ADCA Interrupt ISRs are used to read results of ADCA.

External Connections

- A0, A1, A2 should be connected to signals to be converted.

Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2

22.15.2.15 ADC PPB PWM trip (adc_ppb_pwm_trip) - SINGLE_CORE

FILE: adc_ex14_ppb_pwm_trip.c

This example demonstrates EPWM tripping through ADC limit detection PPB block. ADCAINT1 is configured to periodically trigger the ADCA channel 2 post initial software forced trigger. The limit detection post-processing block(PPB) is configured and if the ADC results are outside of the defined range, the post-processing block will generate an ADCxEVTy event. This event is configured as EPWM trip source through configuring EPWM XBAR and corresponding EPWM's trip zone and digital compare sub-modules. The example showcases

- one-shot
- cycle-by-cycle
- and direct tripping of PWMs through ADCAEVT1 source via Digital compare submodule.

The default limits are 0LSBs and 3600LSBs. With VREFHI set to 3.3V, the PPB will generate a trip event if the input voltage goes above about 2.9V.

External Connections

- A2 should be connected to a signal to convert
- Observe the following signals on an oscilloscope
  - ePWM1(GPIO0 - GPIO1)
  - ePWM2(GPIO2 - GPIO3)
  - ePWM3(GPIO4 - GPIO5)
-

Watch Variables

- adcA2Results - digital representation of the voltage on pin A2

Copyright © 2025Texas Instruments

22.15.2.16 ADC Trigger Repeater Oversampling - SINGLE_CORE

FILE: adc_ex15_trigger_repeater_oversampling.c

This example configures ADC for oversampling using trigger repeater block. The ePWM1 is configured to periodically trigger the ADC SOC and the trigger repeater module is configured to generate 4 repeated pulses. Post-processing block will take the repeated pulses, accumulates them and stores the results in ppb sum register.

External Connections

- A0 should be connected to signals to convert.

Watch Variables

- *myADC0Result* - Digital representation of the voltage on pin A0
- *myPPB0Result* - Digital representation of the voltage of the 4 repeated pulses on pin A0

22.15.2.17 ADC Trigger Repeater Undersampling - SINGLE_CORE

FILE: adc_ex16_trigger_repeater_undersampling.c

This example configures ADC for undersampling using trigger repeater block. The ePWM1 is configured to periodically trigger the ADC SOC and the trigger repeater module is configured to generate 1 pulse out of three pulses. Post-processing block will take the undersampled pulse, accumulates them and stores the results in ppb sum register.

External Connections

- A0 should be connected to signals to convert.

Watch Variables

- *myADC0Result* - Digital representation of the voltage on pin A0
- *myPPB0Result* - Digital representation of the voltage of the undersample pulse on pin A0

22.15.2.18 ADC Safety Checker - SINGLE_CORE

FILE: adc_ex17_safety_checker.c

This example compares the absolute value of the two ADC conversion results with the set tolerance value.

The ADCA is used with A0 and A1 to compare the two ADC conversions. If the difference between two conversion results exceeds the value configured as tolerance then the ADC result safety checker tile generates an interrupt signal from out-of-tolerance.

External Connections

- A0 and A1 should be connected to signals to convert.

Watch Variables

- *myADC0Result0* - Digital representation of the voltage on pin A0
- *myADC0Result1* - Digital representation of the voltage on pin A1
- *tolerance* - Set digital tolerance limit for ADC safety checker
- *count* - number of times the OOT flag is generated

22.15.2.19 ADC Fast Oversampling (with Trigger Repeater) - SINGLE_CORE

FILE: adc_ex18_fast_oversampling.c

This example configures the ADC to perform oversampling using the trigger repeater block. It uses a "fast oversampling" technique that takes advantage of the fact that the sample-and-hold capacitor is already at or close to the input signal voltage after the first conversion. This technique uses two SOCs to perform oversampling: the first SOC is configured for a single conversion with the regular ACQPS value, and the second SOC is configured to use the trigger repeater and has a reduced ACQPS value, enabling faster oversampling.

The ePWM1 is configured to periodically trigger the first ADC SOC, and the trigger repeater is configured to trigger the second SOC. The trigger source of repeater module itself is also ePWM1. Because of round-robin

Copyright © 2025Texas Instruments

priority, the two SOCs convert back-to-back in order. The post-processing block accumulates the oversampled conversions and stores them in the PPBSUM register.

External Connections

- A0 should be connected to the signal to convert.

Watch Variables

- *myADC0Results* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is determined based on the period of the ePWM timer.

Copyright © 2025Texas Instruments

22.16 ADC Registers

This section describes the ADC Registers.

22.16.2 ADC_RESULT_REGS Registers

Table 22-18 lists the memory-mapped registers for the ADC_RESULT_REGS registers. All register offset addresses not listed in Table 22-18 should be considered as reserved locations and the register contents should not be modified.

Table 22-18. ADC_RESULT_REGS Registers

Offset	Acronym	Register Name	Protection
0h	ADCRESULT0	ADC Result 0 Register	
2h	ADCRESULT1	ADC Result 1 Register	
4h	ADCRESULT2	ADC Result 2 Register	
6h	ADCRESULT3	ADC Result 3 Register	
8h	ADCRESULT4	ADC Result 4 Register	
Ah	ADCRESULT5	ADC Result 5 Register	
Ch	ADCRESULT6	ADC Result 6 Register	
Eh	ADCRESULT7	ADC Result 7 Register	
10h	ADCRESULT8	ADC Result 8 Register	
12h	ADCRESULT9	ADC Result 9 Register	
14h	ADCRESULT10	ADC Result 10 Register	
16h	ADCRESULT11	ADC Result 11 Register	
18h	ADCRESULT12	ADC Result 12 Register	
1Ah	ADCRESULT13	ADC Result 13 Register	
1Ch	ADCRESULT14	ADC Result 14 Register	
1Eh	ADCRESULT15	ADC Result 15 Register	
20h	ADCRESULT16	ADC Result 16 Register	
22h	ADCRESULT17	ADC Result 17 Register	
24h	ADCRESULT18	ADC Result 18 Register	
26h	ADCRESULT19	ADC Result 19 Register	
28h	ADCRESULT20	ADC Result 20 Register	
2Ah	ADCRESULT21	ADC Result 21 Register	
2Ch	ADCRESULT22	ADC Result 22 Register	
2Eh	ADCRESULT23	ADC Result 23 Register	
30h	ADCRESULT24	ADC Result 24 Register	
32h	ADCRESULT25	ADC Result 25 Register	
34h	ADCRESULT26	ADC Result 26 Register	
36h	ADCRESULT27	ADC Result 27 Register	
38h	ADCRESULT28	ADC Result 28 Register	
3Ah	ADCRESULT29	ADC Result 29 Register	
3Ch	ADCRESULT30	ADC Result 30 Register	
3Eh	ADCRESULT31	ADC Result 31 Register	
40h	ADCPPB1RESULT	ADC Post Processing Block 1 Result Register	
44h	ADCPPB2RESULT	ADC Post Processing Block 2 Result Register	
48h	ADCPPB3RESULT	ADC Post Processing Block 3 Result Register	
4Ch	ADCPPB4RESULT	ADC Post Processing Block 4 Result Register	
50h	ADCPPB1SUM	ADC PPB 1 Final Sum Result Register	
54h	ADCPPB1COUNT	ADC PPB1 Final Conversion Count Register	
58h	ADCPPB2SUM	ADC PPB 2 Final Sum Result Register	
5Ch	ADCPPB2COUNT	ADC PPB2 Final Conversion Count Register

Table 22-18. ADC_RESULT_REGS Registers (continued)

Offset	Acronym	Register Name	Protection
60h	ADCPPB3SUM	ADC PPB 3 Final Sum Result Register	
64h	ADCPPB3COUNT	ADC PPB3 Final Conversion Count Register	
68h	ADCPPB4SUM	ADC PPB 4 Final Sum Result Register	
6Ch	ADCPPB4COUNT	ADC PPB4 Final Conversion Count Register	
70h	ADCPPB1MAX	ADC PPB 1 Final Max Result Register	
74h	ADCPPB1MAXI	ADC PPB 1 Final Max Index Result Register	
78h	ADCPPB1MIN	ADC PPB 1 Final Min Result Register	
7Ch	ADCPPB1MINI	ADC PPB 1 Final Min Index Result Register	
80h	ADCPPB2MAX	ADC PPB 2 Final Max Result Register	
84h	ADCPPB2MAXI	ADC PPB 2 Final Max Index Result Register	
88h	ADCPPB2MIN	ADC PPB 2 Final Min Result Register	
8Ch	ADCPPB2MINI	ADC PPB 2 Final Min Index Result Register	
90h	ADCPPB3MAX	ADC PPB 3 Final Max Result Register	
94h	ADCPPB3MAXI	ADC PPB 3 Final Max Index Result Register	
98h	ADCPPB3MIN	ADC PPB 3 Final Min Result Register	
9Ch	ADCPPB3MINI	ADC PPB 3 Final Min Index Result Register	
A0h	ADCPPB4MAX	ADC PPB 4 Final Max Result Register	
A4h	ADCPPB4MAXI	ADC PPB 4 Final Max Index Result Register	
A8h	ADCPPB4MIN	ADC PPB 4 Final Min Result Register	
ACh	ADCPPB4MINI	ADC PPB 4 Final Min Index Result Register	

Complex bit access types are encoded to fit into small table cells. Table 22-19 shows the codes that are used for access types in this section.

Table 22-19. ADC_RESULT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Bit	Field	Type	Reset	Description
31-17	SIGN	R	0h	Sign Extended Bits. These bits reflect the same value as bit 16. Reset type: SYSRSn
16-0	MIN	R	0h	Post Processing Block 1 Oversampling Final Min. When either a count-match event occurs (PCOUNT = LIMIT) or PPB1 receives a sync. event, the value of PMIN is loaded into this register. In the case of a count-match event, the max loaded into this register includes the value from the most recent conversion. This result is available 1 SYSCLK cycle after the associated ADCPPB1RESULT is available (only in case of a count-match event). This will be 2 SYSCLK cycles after the associated ADCRESULT is available, unless multiple PPBs point to the same SOC (refer to the ADCPPB1RESULT timing information). Reset type: SYSRSn

Complex bit access types are encoded to fit into small table cells. Table 22-81 shows the codes that are used for access types in this section.

Table 22-141. ADC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

R/W-0h	R-0h				R/W-0h	R-0h	

Table 22-143. ADCCTL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	TDMAEN	R/W	0h	ADC Power Down (active low). This bit controls the power up and power down of all the analog circuitry inside the analog core. 0 DMA is triggered at the same time as the CPU interrupt 1 DMA is always triggered at tDMA regardless or whether the ADC is in early interrupt mode or late interrupt mode Reset type: SYSRSn
14	EXTMUXPRESELECTEN	R/W	0h	If th the ADC SOC sequence is deterministic, the ADCEXTMUX pins can be set earlier: at the end of the S+H window of the previous conversion instead of the beginning of the S+H window of the current conversion. This allows some of the external mux settling time to be pipelined with the previous conversion's conversion time. However, this will not work in the case where high-priority SOCs can arrive asynchronously. 0 ADCEXTMUX pins only change at beginning of S+H window 1 ADCEXTMUX pins are set after the end of S+H window based on pending SOCs Reset type: SYSRSn
13	ADCBSY	R	0h	ADC Busy. Set when ADC SOC is generated, cleared by hardware four ADC clocks after negative edge of S/H pulse. Used by the ADC state machine to determine if ADC is available to sample. 0 ADC is available to sample next channel 1 ADC is busy and cannot sample another channel Reset type: SYSRSn

Table 22-163. ADCINTSOCSEL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11-10	SOC5	R/W	0h	SOC5 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC5. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC5. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC5. 10 ADCINT2 will trigger SOC5. 11 Invalid selection. Reset type: SYSRSn
9-8	SOC4	R/W	0h	SOC4 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC4. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC4. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC4. 10 ADCINT2 will trigger SOC4. 11 Invalid selection. Reset type: SYSRSn
7-6	SOC3	R/W	0h	SOC3 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC3. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC3. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC3. 10 ADCINT2 will trigger SOC3. 11 Invalid selection. Reset type: SYSRSn
5-4	SOC2	R/W	0h	SOC2 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC2. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC2. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC2. 10 ADCINT2 will trigger SOC2. 11 Invalid selection. Reset type: SYSRSn
3-2	SOC1	R/W	0h	SOC1 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC1. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC1. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC1. 10 ADCINT2 will trigger SOC1. 11 Invalid selection. Reset type: SYSRSn
1-0	SOC0	R/W	0h	SOC0 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC0. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC0. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC0. 10 ADCINT2 will trigger SOC0. 11 Invalid selection. Reset type: SYSRSn

Table 22-165. ADCINTSOCSEL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
23-22	SOC27	R/W	0h	SOC27 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC27. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC27. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC27. 10 ADCINT2 will trigger SOC27. 11 Invalid selection. Reset type: SYSRSn
21-20	SOC26	R/W	0h	SOC26 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC26. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC26. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC26. 10 ADCINT2 will trigger SOC26. 11 Invalid selection. Reset type: SYSRSn
19-18	SOC25	R/W	0h	SOC25 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC25. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC25. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC25. 10 ADCINT2 will trigger SOC25. 11 Invalid selection. Reset type: SYSRSn
17-16	SOC24	R/W	0h	SOC24 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC24. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC24. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC24. 10 ADCINT2 will trigger SOC24. 11 Invalid selection. Reset type: SYSRSn
15-14	SOC23	R/W	0h	SOC23 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC23. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC23. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC23. 10 ADCINT2 will trigger SOC23. 11 Invalid selection. Reset type: SYSRSn
13-12	SOC22	R/W	0h	SOC22 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC22. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC22. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC22. 10 ADCINT2 will trigger SOC22. 11 Invalid selection. Reset type: SYSRSn

Table 22-167. ADCSOCFLG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SOC31	R	0h	SOC31 Start of Conversion Flag. Indicates the state of SOC31 conversions. 0 No sample pending for SOC15. 1 Trigger has been received and sample is pending for SOC15. This bit will be automatically cleared when the SOC15 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
30	SOC30	R	0h	SOC30 Start of Conversion Flag. Indicates the state of SOC30 conversions. 0 No sample pending for SOC14. 1 Trigger has been received and sample is pending for SOC14. This bit will be automatically cleared when the SOC14 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

Table 22-167. ADCSOCFLG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
29	SOC29	R	0h	SOC29 Start of Conversion Flag. Indicates the state of SOC29 conversions. 0 No sample pending for SOC13. 1 Trigger has been received and sample is pending for SOC13. This bit will be automatically cleared when the SOC13 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
28	SOC28	R	0h	SOC28 Start of Conversion Flag. Indicates the state of SOC28 conversions. 0 No sample pending for SOC12. 1 Trigger has been received and sample is pending for SOC12. This bit will be automatically cleared when the SOC12 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
27	SOC27	R	0h	SOC27 Start of Conversion Flag. Indicates the state of SOC27 conversions. 0 No sample pending for SOC11. 1 Trigger has been received and sample is pending for SOC11. This bit will be automatically cleared when the SOC11 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
26	SOC26	R	0h	SOC26 Start of Conversion Flag. Indicates the state of SOC26 conversions. 0 No sample pending for SOC10. 1 Trigger has been received and sample is pending for SOC10. This bit will be automatically cleared when the SOC10 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

This bit will be automatically cleared when the SOC6 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

Table 22-167. ADCSOCFLG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SOC5	R	0h	SOC5 Start of Conversion Flag. Indicates the state of SOC5 conversions. 0 No sample pending for SOC5. 1 Trigger has been received and sample is pending for SOC5. This bit will be automatically cleared when the SOC5 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
4	SOC4	R	0h	SOC4 Start of Conversion Flag. Indicates the state of SOC4 conversions. 0 No sample pending for SOC4. 1 Trigger has been received and sample is pending for SOC4. This bit will be automatically cleared when the SOC4 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
3	SOC3	R	0h	SOC3 Start of Conversion Flag. Indicates the state of SOC3 conversions. 0 No sample pending for SOC3. 1 Trigger has been received and sample is pending for SOC3. This bit will be automatically cleared when the SOC3 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
2	SOC2	R	0h	SOC2 Start of Conversion Flag. Indicates the state of SOC2 conversions. 0 No sample pending for SOC2. 1 Trigger has been received and sample is pending for SOC2. This bit will be automatically cleared when the SOC2 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

Table 22-167. ADCSOCFLG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SOC1	R	0h	SOC1 Start of Conversion Flag. Indicates the state of SOC1 conversions. 0 No sample pending for SOC1. 1 Trigger has been received and sample is pending for SOC1. This bit will be automatically cleared when the SOC1 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
0	SOC0	R	0h	SOC0 Start of Conversion Flag. Indicates the state of SOC0 conversions. 0 No sample pending for SOC0. 1 Trigger has been received and sample is pending for SOC0. This bit will be automatically cleared when the SOC0 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

Table 22-169. ADCSOCFRC1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SOC31	R-0/W1S	0h	SOC31 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC31 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC31 flag bit to 1. This will cause a conversion to start once priority is given to SOC31. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC31 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
30	SOC30	R-0/W1S	0h	SOC30 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC30 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC30 flag bit to 1. This will cause a conversion to start once priority is given to SOC30. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC30 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Table 22-169. ADCSOCFRC1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
29	SOC29	R-0/W1S	0h	SOC29 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC29 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC29 flag bit to 1. This will cause a conversion to start once priority is given to SOC29. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC29 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
28	SOC28	R-0/W1S	0h	SOC28 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC28 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC28 flag bit to 1. This will cause a conversion to start once priority is given to SOC28. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC28 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
27	SOC27	R-0/W1S	0h	SOC27 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC27 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC27 flag bit to 1. This will cause a conversion to start once priority is given to SOC27. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC27 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
26	SOC26	R-0/W1S	0h	SOC26 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC26 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC26 flag bit to 1. This will cause a conversion to start once priority is given to SOC26. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC26 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Bit	Field	Type	Reset	Description
25	SOC25	R-0/W1S	0h	SOC25 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC25 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC25 flag bit to 1. This will cause a conversion to start once priority is given to SOC25. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC25 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
24	SOC24	R-0/W1S	0h	SOC24 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC24 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC24 flag bit to 1. This will cause a conversion to start once priority is given to SOC24. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC24 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
23	SOC23	R-0/W1S	0h	SOC23 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC23 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC23 flag bit to 1. This will cause a conversion to start once priority is given to SOC23. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC23 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
22	SOC22	R-0/W1S	0h	SOC22 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC22 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC22 flag bit to 1. This will cause a conversion to start once priority is given to SOC22. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC22 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Bit	Field	Type	Reset	Description
21	SOC21	R-0/W1S	0h	SOC21 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC21 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC21 flag bit to 1. This will cause a conversion to start once priority is given to SOC21. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC21 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
20	SOC20	R-0/W1S	0h	SOC20 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC20 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC20 flag bit to 1. This will cause a conversion to start once priority is given to SOC20. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC20 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
19	SOC19	R-0/W1S	0h	SOC19 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC19 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC19 flag bit to 1. This will cause a conversion to start once priority is given to SOC19. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC19 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
18	SOC18	R-0/W1S	0h	SOC18 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC18 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC18 flag bit to 1. This will cause a conversion to start once priority is given to SOC18. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC18 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Table 22-169. ADCSOCFRC1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17	SOC17	R-0/W1S	0h	SOC17 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC17 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC17 flag bit to 1. This will cause a conversion to start once priority is given to SOC17. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC17 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
16	SOC16	R-0/W1S	0h	SOC16 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC16 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC16 flag bit to 1. This will cause a conversion to start once priority is given to SOC16. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC16 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
15	SOC15	R-0/W1S	0h	SOC15 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC15 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC15 flag bit to 1. This will cause a conversion to start once priority is given to SOC15. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC15 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
14	SOC14	R-0/W1S	0h	SOC14 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC14 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC14 flag bit to 1. This will cause a conversion to start once priority is given to SOC14. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC14 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Bit	Field	Type	Reset	Description
5	SOC5	R-0/W1S	0h	SOC5 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC5 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC5 flag bit to 1. This will cause a conversion to start once priority is given to SOC5. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC5 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
4	SOC4	R-0/W1S	0h	SOC4 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC4 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC4 flag bit to 1. This will cause a conversion to start once priority is given to SOC4. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC4 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
3	SOC3	R-0/W1S	0h	SOC3 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC3 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC3 flag bit to 1. This will cause a conversion to start once priority is given to SOC3. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC3 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
2	SOC2	R-0/W1S	0h	SOC2 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC2 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC2 flag bit to 1. This will cause a conversion to start once priority is given to SOC2. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC2 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Table 22-169. ADCSOCFRC1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SOC1	R-0/W1S	0h	SOC1 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC1 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC1 flag bit to 1. This will cause a conversion to start once priority is given to SOC1. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC1 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
0	SOC0	R-0/W1S	0h	SOC0 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC0 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC0 flag bit to 1. This will cause a conversion to start once priority is given to SOC0. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC0 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Table 22-171. ADCSOCOVF1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SOC31	R	0h	SOC31 Start of Conversion Overflow Flag. Indicates an SOC31 event was generated in hardware while an existing SOC31 event was already pending. 0 No SOC31 event overflow. 1 SOC31 event overflow. An overflow condition does not stop SOC31 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
30	SOC30	R	0h	SOC30 Start of Conversion Overflow Flag. Indicates an SOC30 event was generated in hardware while an existing SOC30 event was already pending. 0 No SOC30 event overflow. 1 SOC30 event overflow. An overflow condition does not stop SOC30 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
29	SOC29	R	0h	SOC29 Start of Conversion Overflow Flag. Indicates an SOC29 event was generated in hardware while an existing SOC29 event was already pending. 0 No SOC29 event overflow. 1 SOC29 event overflow. An overflow condition does not stop SOC29 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

Table 22-171. ADCSOCOVF1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	SOC28	R	0h	SOC28 Start of Conversion Overflow Flag. Indicates an SOC28 event was generated in hardware while an existing SOC28 event was already pending. 0 No SOC28 event overflow. 1 SOC28 event overflow. An overflow condition does not stop SOC28 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
27	SOC27	R	0h	SOC27 Start of Conversion Overflow Flag. Indicates an SOC27 event was generated in hardware while an existing SOC27 event was already pending. 0 No SOC27 event overflow. 1 SOC27 event overflow. An overflow condition does not stop SOC27 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
26	SOC26	R	0h	SOC26 Start of Conversion Overflow Flag. Indicates an SOC26 event was generated in hardware while an existing SOC26 event was already pending. 0 No SOC26 event overflow. 1 SOC26 event overflow. An overflow condition does not stop SOC26 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
25	SOC25	R	0h	SOC25 Start of Conversion Overflow Flag. Indicates an SOC25 event was generated in hardware while an existing SOC25 event was already pending. 0 No SOC25 event overflow. 1 SOC25 event overflow. An overflow condition does not stop SOC25 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
24	SOC24	R	0h	SOC24 Start of Conversion Overflow Flag. Indicates an SOC24 event was generated in hardware while an existing SOC24 event was already pending. 0 No SOC24 event overflow. 1 SOC24 event overflow. An overflow condition does not stop SOC24 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
23	SOC23	R	0h	SOC23 Start of Conversion Overflow Flag. Indicates an SOC23 event was generated in hardware while an existing SOC23 event was already pending. 0 No SOC23 event overflow. 1 SOC23 event overflow. An overflow condition does not stop SOC23 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

Table 22-171. ADCSOCOVF1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	SOC22	R	0h	SOC22 Start of Conversion Overflow Flag. Indicates an SOC22 event was generated in hardware while an existing SOC22 event was already pending. 0 No SOC22 event overflow. 1 SOC22 event overflow. An overflow condition does not stop SOC22 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
21	SOC21	R	0h	SOC21 Start of Conversion Overflow Flag. Indicates an SOC21 event was generated in hardware while an existing SOC21 event was already pending. 0 No SOC21 event overflow. 1 SOC21 event overflow. An overflow condition does not stop SOC21 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
20	SOC20	R	0h	SOC20 Start of Conversion Overflow Flag. Indicates an SOC20 event was generated in hardware while an existing SOC20 event was already pending. 0 No SOC20 event overflow. 1 SOC20 event overflow. An overflow condition does not stop SOC20 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
19	SOC19	R	0h	SOC19 Start of Conversion Overflow Flag. Indicates an SOC19 event was generated in hardware while an existing SOC19 event was already pending. 0 No SOC19 event overflow. 1 SOC19 event overflow. An overflow condition does not stop SOC19 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
18	SOC18	R	0h	SOC18 Start of Conversion Overflow Flag. Indicates an SOC18 event was generated in hardware while an existing SOC18 event was already pending. 0 No SOC18 event overflow. 1 SOC18 event overflow. An overflow condition does not stop SOC18 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
17	SOC17	R	0h	SOC17 Start of Conversion Overflow Flag. Indicates an SOC17 event was generated in hardware while an existing SOC17 event was already pending. 0 No SOC17 event overflow. 1 SOC17 event overflow. An overflow condition does not stop SOC17 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

Bit	Field	Type	Reset	Description
10	SOC10	R	0h	SOC10 Start of Conversion Overflow Flag. Indicates an SOC10 event was generated in hardware while an existing SOC10 event was already pending. 0 No SOC10 event overflow. 1 SOC10 event overflow. An overflow condition does not stop SOC10 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
9	SOC9	R	0h	SOC9 Start of Conversion Overflow Flag. Indicates an SOC9 event was generated in hardware while an existing SOC9 event was already pending. 0 No SOC9 event overflow. 1 SOC9 event overflow. An overflow condition does not stop SOC9 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
8	SOC8	R	0h	SOC8 Start of Conversion Overflow Flag. Indicates an SOC8 event was generated in hardware while an existing SOC8 event was already pending. 0 No SOC8 event overflow. 1 SOC8 event overflow. An overflow condition does not stop SOC8 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
7	SOC7	R	0h	SOC7 Start of Conversion Overflow Flag. Indicates an SOC7 event was generated in hardware while an existing SOC7 event was already pending. 0 No SOC7 event overflow. 1 SOC7 event overflow. An overflow condition does not stop SOC7 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
6	SOC6	R	0h	SOC6 Start of Conversion Overflow Flag. Indicates an SOC6 event was generated in hardware while an existing SOC6 event was already pending. 0 No SOC6 event overflow. 1 SOC6 event overflow. An overflow condition does not stop SOC6 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
5	SOC5	R	0h	SOC5 Start of Conversion Overflow Flag. Indicates an SOC5 event was generated in hardware while an existing SOC5 event was already pending. 0 No SOC5 event overflow. 1 SOC5 event overflow. An overflow condition does not stop SOC5 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

Table 22-173. ADCSOCOVFCLR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	SOC16	R-0/W1S	0h	SOC16 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC16 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC16 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
15	SOC15	R-0/W1S	0h	SOC15 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC15 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC15 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
14	SOC14	R-0/W1S	0h	SOC14 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC14 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC14 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
13	SOC13	R-0/W1S	0h	SOC13 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC13 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC13 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
12	SOC12	R-0/W1S	0h	SOC12 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC12 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC12 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
11	SOC11	R-0/W1S	0h	SOC11 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC11 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC11 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn

Table 22-173. ADCSOCOVFCLR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	SOC10	R-0/W1S	0h	SOC10 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC10 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC10 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
9	SOC9	R-0/W1S	0h	SOC9 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC9 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC9 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
8	SOC8	R-0/W1S	0h	SOC8 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC8 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC8 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
7	SOC7	R-0/W1S	0h	SOC7 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC7 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC7 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
6	SOC6	R-0/W1S	0h	SOC6 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC6 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC6 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
5	SOC5	R-0/W1S	0h	SOC5 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC5 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC5 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn

Table 22-173. ADCSOCOVFCLR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	SOC4	R-0/W1S	0h	SOC4 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC4 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC4 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
3	SOC3	R-0/W1S	0h	SOC3 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC3 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC3 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
2	SOC2	R-0/W1S	0h	SOC2 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC2 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC2 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
1	SOC1	R-0/W1S	0h	SOC1 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC1 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC1 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
0	SOC0	R-0/W1S	0h	SOC0 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC0 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC0 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn

OFFTRIM							
R/W-0h							

Table 22-253. ADCOFFTRIM Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	OFFTRIM12BSEODD	R/W	0h	If ADCCLT2.OFFTRIMMODE = 1, then this register will supply offset trim when the ADC is in 12-bit single-ended mode for odd channels. Range is +127 steps to -128 steps (2's compliment format). Regardless of the converter resolution, the size of each trim step is (VREFHI-VREFLO)/65536. Reset type: XRSn
7-0	OFFTRIM	R/W	0h	ADC Offset Trim. Adjusts the conversion results of the converter up or down to account for offset error in the ADC. A different offset trim is required for each combination of resolution and signal mode. If ADCCTL2.OFFTRIMMODE = 0, then using the AdcSetMode function to set the resolution and signal mode will ensure that the correct offset trim is loaded into this register. If ADCCLT2.OFFTRIMMODE = 1, then this register will supply offset trim only when the ADC is in 12-bit single-ended mode and only for even channels. Range is +127 steps to -128 steps (2's compliment format). Regardless of the converter resolution, the size of each trim step is (VREFHI-VREFLO)/65536. Reset type: XRSn

59 ADCPPB1CONFIG Register (Offset = D4h) [Reset = 0000h]

ADCPPB1CONFIG is shown in Figure 22-162 and described in Table 22-140.

Return to the Summary Table.

ADC PPB{#} Config Register

Figure 22-162. ADCPPB1CONFIG Register

15	14	13	12	11	10	9	8
RESERVED							DELTAEN
R-0h							R/W-0h
7	6	5	4	3	2	1	0
TWOSCOMPEN	ABSEN	CBCEN	CONFIG				
R/W-0h	R/W-0h	R/W-0h	R/W-0h				

Table 22-259. ADCPPB1CONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
15-9	RESERVED	R	0h	Reserved
8	DELTAEN	R/W	0h	ADC Post Processing Block 1 enable delta (difference) from last sample calcualtion. When set, the ADCPPB1RESULT register will contain the difference between the most recent conversion result and the last value that would have been loaded into the ADCPPB1RESULT (if the delta calculation wasn't enabled). The delta calculation occurs after OFFREF, TWOSCOMPEN, and ABSEN calculations are applied. 0 Delta calculation disabled: no modification to ADCPPB1RESULT 1 ADCPPB1RESULT = ADCPPB1RESULT'[t] - ADCPPB1RESULT'[t - 1] Where ADCPPB1RESULT' is the value that would have been loaded into ADCPPB1RESULT without delta calculation Reset type: SYSRSn
7	TWOSCOMPEN	R/W	0h	ADC Post Processing Block 1 Two's Complement Enable. When set this bit enables the post conversion hardware processing circuit that performs a two's complement on the output of the offset/reference subtraction unit before storing the result in the ADCPPB1RESULT register. 0 ADCPPB1RESULT = ADCRESULTx - ADCPPB1OFFREF 1 ADCPPB1RESULT = ADCPPB1OFFREF - ADCRESULTx Reset type: SYSRSn
6	ABSEN	R/W	0h	ADC Post Processing Block 1 Absolute Value Enable. When set this bit enables absolute value calculation on the ADCRESULx associated with ADCPPB1. This occurs before the TWOSCOMPEN logic is evaluated (so enabling both TWOSCOMPEN and ABSEN will always result in a negative value stored in ADCPPBxRESULT) 0 ADCPPB1RESULT = ADCRESULTx - ADCPPB1OFFREF 1 ADCPPB1RESULT = abs(ADCRESULTx - ADCPPB1OFFREF) Reset type: SYSRSn
5	CBCEN	R/W	0h	ADC Post Processing Block Cycle By Cycle Enable. When set, this bit enables the post conversion hardware processing circuit to automatically clear the ADCEVTSTAT on a conversion if the event condition is no longer present. Reset type: SYSRSn

RESERVED							DELTAEN
R-0h							R/W-0h
7	6	5	4	3	2	1	0
TWOSCOMPEN	ABSEN	CBCEN	CONFIG				
R/W-0h	R/W-0h	R/W-0h	R/W-3h				

Table 22-307. ADCPPB4CONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
15-9	RESERVED	R	0h	Reserved
8	DELTAEN	R/W	0h	ADC Post Processing Block 4 enable delta (difference) from last sample calcualtion. When set, the ADCPPB4RESULT register will contain the difference between the most recent conversion result and the last value that would have been loaded into the ADCPPB4RESULT (if the delta calculation wasn't enabled). The delta calculation occurs after OFFREF, TWOSCOMPEN, and ABSEN calculations are applied. 0 Delta calculation disabled: no modification to ADCPPB4RESULT 1 ADCPPB4RESULT = ADCPPB4RESULT'[t] - ADCPPB4RESULT'[t - 1] Where ADCPPB4RESULT' is the value that would have been loaded into ADCPPB4RESULT without delta calculation Reset type: SYSRSn
7	TWOSCOMPEN	R/W	0h	ADC Post Processing Block 4 Two's Complement Enable. When set this bit enables the post conversion hardware processing circuit that performs a two's complement on the output of the offset/reference subtraction unit before storing the result in the ADCPPB4RESULT register. 0 ADCPPB4RESULT = ADCRESULTx - ADCPPB4OFFREF 1 ADCPPB4RESULT = ADCPPB4OFFREF - ADCRESULTx Reset type: SYSRSn
6	ABSEN	R/W	0h	ADC Post Processing Block 4 Absolute Value Enable. When set this bit enables absolute value calculation on the ADCRESULx associated with ADCPPB4. This occurs before the TWOSCOMPEN logic is evaluated (so enabling both TWOSCOMPEN and ABSEN will always result in a negative value stored in ADCPPBxRESULT) 0 ADCPPB4RESULT = ADCRESULTx - ADCPPB4OFFREF 1 ADCPPB4RESULT = abs(ADCRESULTx - ADCPPB4OFFREF) Reset type: SYSRSn
5	CBCEN	R/W	0h	ADC Post Processing Block Cycle By Cycle Enable. When set, this bit enables the post conversion hardware processing circuit to automatically clear the ADCEVTSTAT on a conversion if the event condition is no longer present. Reset type: SYSRSn

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-0	OFFCAL	R/W	0h	ADC Post Processing Block 4 Offset Correction. This bit field can be used to digitally remove any system level offset inherent in the ADCIN circuit. This 10-bit signed value is subtracted from the ADC output before being stored in the ADCRESULT register. 000h No change. The ADC output is stored directly into ADCRESULT. 001h ADC output - 1 is stored into ADCRESULT. 002h ADC output - 2 is stored into ADCRESULT. ... 200h ADC output + 512 is stored into ADCRESULT. ... 3FFh ADC output + 1 is stored into ADCRESULT. NOTE: In 16-bit mode, the subtraction will saturate at 0000h and FFFFh before being stored into the ADCRESULT register. In 12-bit mode, the subtraction will saturate at 0000h and 0FFFh before being stored into the ADCRESULT register. Note: in the case that multiple PPBs point to the same SOC, only the OFFCAL of the lowest numbered PPB will be applied. Reset type: SYSRSn

Copyright © 2025Texas Instruments

86 ADCPPB4OFFREF Register (Offset = 13Ah) [Reset = 0000h]

ADCPPB4OFFREF is shown in Figure 22-189 and described in Table 22-167.

Return to the Summary Table.

Table 22-343. REP1CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	TRIGGEROVF	R/W1C	0h	ADC Trigger Repeater 1 Oversampled Trigger Overflow. Indicates that a trigger was dropped because a trigger arrived while the repeater was still generating repeated oversampled triggers (NCOUNT was not 0 or SOCs associated with Repeater 1 were still pending). Writing a 1 will clear this flag. Note: This flag won't be set in undersampling mode or when NSEL = 0 if a trigger arrives before the previous SOCs have completed, the trigger will be passed and the overflow flags of the SOCs that were still pending will be set. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority and the overflow bit will not be set Reset type: SYSRSn
6	PHASEOVF	R/W1C	0h	ADC Trigger Repeater 1 Phase Delay Overflow. Indicates that a trigger was dropped because a trigger arrived when the phase delay logic was still waiting to send the delayed trigger (PHASECOUNT was not 0). Writing a 1 will clear this flag. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority and the overflow bit will not be set Reset type: SYSRSn
5	RESERVED	R	0h	Reserved
4	RESERVED	R	0h	Reserved
3	MODULEBUSY	R	0h	ADC Trigger Repeater 1 Module Busy indicator. In oversampling mode: 0 = Repeater 1 is idle and can accept a new repeated trigger in oversampling mode 1 = Repeater 1 still has repeated triggers remaining (NCOUNT > 0) or associated SOCs are still pending (SOCBUSY is 1) If a new oversampled trigger is received while the module is still busy, the TRIGGEROVF bit will be set and the trigger will be ignored. Reset type: SYSRSn
2	RESERVED	R	0h	Reserved
1	ACTIVEMODE	R	0h	When a trigger is recived in oversampling or undersampling mode the value of MODE is copied to ACTIVEMODE. ACTIVEMODE determines if the repeater will repeat of filter triggers. Changes to MODE while the repeater is working therefore won't cause any changes in functionality until the module becomes idle and then a new trigger is received. 0 = module is oversampling 1 = module is undersampling Reset type: SYSRSn
0	MODE	R/W	0h	ADC trigger repeater 1 mode selection. Select either oversampling or undersampling mode. In oversampling mode, when the trigger selected by REP1CTL.TRIGSEL is received, the repeater will repeat the trigger REP1N.NSEL + 1 times. In undersampling mode, when the trigger selected by REP1CTL.TRIGSEL is received the first time, the repeater will pass the trigger through. The next REP1N.NSEL triggers will be ignored. 0 = oversampling 1 = undersampling Reset type: SYSRSn

Copyright © 2025Texas Instruments

102 REP1N Register (Offset = 198h) [Reset = 00000000h]

REP1N is shown in Figure 22-205 and described in Table 22-183.

Return to the Summary Table.

Table 22-353. REP2CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	TRIGGEROVF	R/W1C	0h	ADC Trigger Repeater 2 Oversampled Trigger Overflow. Indicates that a trigger was dropped because a trigger arrived while the repeater was still generating repeated oversampled triggers (NCOUNT was not 0 or SOCs associated with Repeater 2 were still pending). Writing a 1 will clear this flag. Note: This flag won't be set in undersampling mode or when NSEL = 0 if a trigger arrives before the previous SOCs have completed, the trigger will be passed and the overflow flags of the SOCs that were still pending will be set. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority and the overflow bit will not be set Reset type: SYSRSn
6	PHASEOVF	R/W1C	0h	ADC Trigger Repeater 2 Phase Delay Overflow. Indicates that a trigger was dropped because a trigger arrived when the phase delay logic was still waiting to send the delayed trigger (PHASECOUNT was not 0). Writing a 1 will clear this flag. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority and the overflow bit will not be set Reset type: SYSRSn
5	RESERVED	R	0h	Reserved
4	RESERVED	R	0h	Reserved
3	MODULEBUSY	R	0h	ADC Trigger Repeater 2 Module Busy indicator. In oversampling mode: 0 = Repeater 2 is idle and can accept a new repeated trigger in oversampling mode 1 = Repeater 2 still has repeated triggers remaining (NCOUNT > 0) or associated SOCs are still pending (SOCBUSY is 1) If a new oversampled trigger is received while the module is still busy, the TRIGGEROVF bit will be set and the trigger will be ignored. Reset type: SYSRSn
2	RESERVED	R	0h	Reserved
1	ACTIVEMODE	R	0h	When a trigger is recived in oversampling or undersampling mode the value of MODE is copied to ACTIVEMODE. ACTIVEMODE determines if the repeater will repeat of filter triggers. Changes to MODE while the repeater is working therefore won't cause any changes in functionality until the module becomes idle and then a new trigger is received. 0 = module is oversampling 1 = module is undersampling Reset type: SYSRSn
0	MODE	R/W	0h	ADC trigger repeater 2 mode selection. Select either oversampling or undersampling mode. In oversampling mode, when the trigger selected by REP2CTL.TRIGSEL is received, the repeater will repeat the trigger REP2N.NSEL + 1 times. In undersampling mode, when the trigger selected by REP2CTL.TRIGSEL is received the first time, the repeater will pass the trigger through. The next REP2N.NSEL triggers will be ignored. 0 = oversampling 1 = undersampling Reset type: SYSRSn

Table 22-405. ADCPPB3PSUM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	SIGN	R	0h	Sign Extended Bits. These bits reflect the same value as bit 23. Reset type: SYSRSn
23-0	PSUM	R	0h	Post Processing Block 3 Oversampling Partial Sum. Each time a new result propagates through the PPB signal chain and latches into ADCPPB3RESULT the result is subsequently accumulated into this register. This register is reset when either a count-match event occurs (PCOUNT = LIMIT) or PPB3 receives a sync. event. This result is available 1 SYSCLK cycle after the associated ADCPPB3RESULT is available. This will be 2 SYSCLK cycles after the associated ADCRESULT is available, unless multiple PPBs point to the same SOC. In the case of multiple PPBs associated with the same SOC, the lowest numbered PPB's result will be available 2 SYSCLK cycles after the associated ADCRESULT. Subsequent results (in order from lowest numbered PPB to highest) will each become available every 2-3 SYSCLK cycles. Reset type: SYSRSn

R/W-0h		R-0h	R/W-0h	R-0/W1S-0h	R-0h	R/W-0h	
7	6	5	4	3	2	1	0
SYNCINSEL				SHIFT			
R/W-0h				R/W-0h			

Table 22-421. ADCPPB4CONFIG2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	COMPSEL	R/W	0h	Post Processing Block 4 Compare Source Select. This field determines whether ADCPPB4RESULT, ADCPPB4PSUM, or ADCPPB4SUM is used for the zero-crossing detect logic and threshold compare. 00 = ADCPPB4RESULT is used for compare logic 01 = ADCPPB4PSUM is used for compare logic 10 = ADCPPB4SUM is used for compare logic 11 = Reserved Note: when ADCPPB4PSUM is selected as the compare source and when a LIMIT match occurs (ADCPPB4LIMIT equals ADCPPB4COUNT) the ADCPPB4PSUM register will be cleared and the final sum will be loaded into ADCPPB4SUM. For this sample, the final sum, ADCPPB4SUM will be used for the compariosn instead of ADCPPB4PSUM. Reset type: SYSRSn
13	RESERVED	R	0h	Reserved
12	OSINTSEL	R/W	0h	Post Processing Block 4 Interrupt Source Select. OSINT4 can be used to trigger an ADC interrupt (ADCINT1 through ADCINT4) via selection in the ADCINT1N2 or ADCINT3N4. This selection determines if a sync. event can trigger OSINT4 in addition to a PCOUNT = LIMIT event. 0 = OSINT4 will be generated from PCOUNT = LIMIT only 1 = OSTIN4 will be generated form PCOUNT = LIMIT or a sync. event. Note: If a SYNC event would cause an OSINT one cycle after OSINT would have been cause by PCOUNT = LIMIT match, then the second OSINT is ignored. Reset type: SYSRSn
11	SWSYNC	R-0/W1S	0h	PPB 4 software force sync. On a sync. event, all partial registers transfer to the final registers and are then reset. Note: In the case where the software force occurs at the same time that a new sample is added to the PSUM and the PSUM is being used for a high or low limit compare, then the comparison will not occur. Reset type: SYSRSn
10	RESERVED	R	0h	Reserved

22.16.4 ADC_SAFECHECK_REGS Registers

Table 22-228 lists the memory-mapped registers for the ADC_SAFECHECK_REGS registers. All register offset addresses not listed in Table 22-228 should be considered as reserved locations and the register contents should not be modified.

Table 22-434. ADC_SAFECHECK_REGS Registers

Offset	Acronym	Register Name	Protection
0h	CHECKCONFIG	ADC Check Configuration Register	
4h	CHECKSTATUS	ADC Check Status Register	
8h	ADCRESSEL1	ADC Check 1 Select Register	
Ch	ADCRESSEL2	ADC Check 2 Select Register	
10h	TOLERANCE	ADC Check Tolerance Register	
18h	CHECKRESULT1	ADC Check Captured Result 1	
1Ch	CHECKRESULT2	ADC Check Captured Result 2	

Complex bit access types are encoded to fit into small table cells. Table 22-229 shows the codes that are used for access types in this section.

Table 22-435. ADC_SAFECHECK_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Table 22-451. ADC_SAFECHECK_INTEVT_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Table 22-465. CHECKINTFLG Register Field Descriptions

Bit	Field	Type	Reset	Description
15-1	RESERVED	R	0h	Reserved
0	CHECKINT	R	0h	ADC results safety checker subsytem interrupt flag. Indicates that one or more configured OOT or OVF conditions have occurred in the individual safety checker modules. In the ISR, clear all serviced OOT or OVF flags first (using the OOTFLGCLR and OVFFLGCLR registers), then clear this flag using the CHKINTFLGCLR register. The CHECKINTSEL1 and CHECKINTSEL2 registers are used to select which OOT and OVF flags from the individual checker modules can trigger this interrupt. Reset type: SYSRSn

22.16.6 ADC_GLOBAL_REGS Registers

Table 22-262 lists the memory-mapped registers for the ADC_GLOBAL_REGS registers. All register offset addresses not listed in Table 22-262 should be considered as reserved locations and the register contents should not be modified.

Table 22-498. ADC_GLOBAL_REGS Registers

Offset	Acronym	Register Name	Protection
0h	ADCSOCFRCGB	ADC Global SOC Force	PARITY
4h	ADCSOCFRCGBSEL	ADC Global SOC Force Select	PARITY
8h	PARITY_TEST_ALT1	Enables parity test	

Complex bit access types are encoded to fit into small table cells. Table 22-263 shows the codes that are used for access types in this section.

Table 22-499. ADC_GLOBAL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Table 22-505. PARITY_TEST_ALT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: SYSRSn

Chapter 23

Buffered Digital-to-Analog Converter (DAC)

The buffered digital-to-analog converter (DAC) is an analog module that can output a programmable, arbitrary reference voltage.

23.1 Introduction....3925
23.2 Using the DAC....3926
23.3 Lock Registers....3927
23.4 Software....3928
23.5 DAC Registers....3929

Copyright © 2025Texas Instruments

23.1 Introduction

The buffered DAC module consists of an internal 12-bit DAC and an analog output buffer that is capable of driving an external load. For driving even higher loads than typical, a trade-off can be made between load size and output voltage swing. For the load conditions of the buffered DAC, see the device-specific data sheet. The buffered DAC can be used as a general-purpose DAC to generate a DC voltage in addition to AC waveforms such as sine waves, square waves, triangle waves and so forth. Software writes to the DAC value register can take effect immediately or can be synchronized with EPWMSYNCPER events.

  - NOTE: This is a non-TI (third party) site.

23.1.2 DAC Features

Each buffered DAC has the following features:

- 12-bit programmable internal DAC
- Selectable reference voltage source
- x1 and x2 gain modes when using internal VREFHI
- Ability to synchronize with EPWMSYNCPER

23.1.3 Block Diagram

The block diagram for the buffered DAC is shown in Figure 23-1.

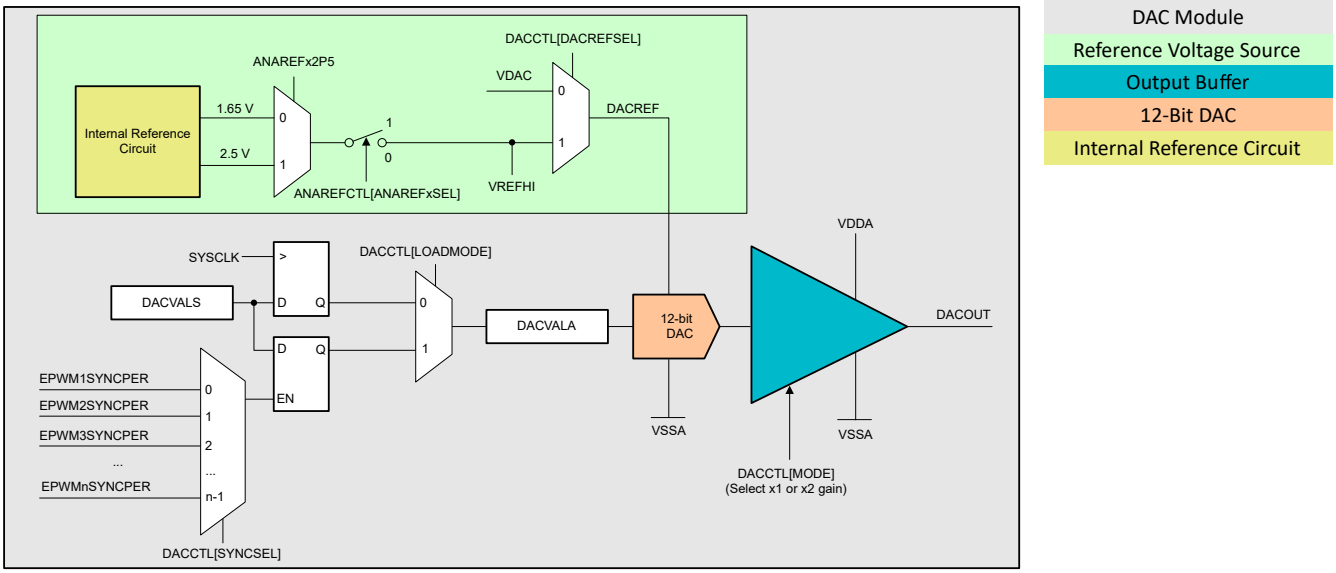

Figure 23-1. DAC Module Block Diagram

Copyright © 2025Texas Instruments

23.2 Using the DAC

The internal DAC's reference voltage source, DACREF, is selectable between VDAC and VREFHI. The x2 gain mode is only available when VREFHI is set as DACREF and internal reference mode is used, which can be configured by DACCTL[MODE] register. The internal reference circuit generates 1.65V and 2.5V. To select either 2.5V or 1.65V, configure ANAREF2P5 register and set ANAREFSEL register to 0 (see the *Analog Subsystem* chapter on how to switch to internal reference mode). Even though the buffered DAC has an x2 gain mode, the maximum output voltage from the buffered DAC is not greater than VDDA. Table 23-1 lists the gain mode combinations supported by the buffered DAC. In this table, x = A or B, X = Don't Care, VDAC/ VREFHI = 2.5v, VDDA = 3.3v, and DACVAL = 4095.

Table 23-1. DAC Supported Gain Mode Combinations

DACREFSEL	ANAREFSEL	ANAREF2P5	Reference Source	Reference Voltage (V)	Mode	Maximum DAC Output (V)	Support Status
0	X	X	External	VDAC	0	2.5	Supported
0	X	X	External	VDAC	1	2.5	Not Supported
1	0	0	Internal	1.65	0	1.65	Not Supported
1	0	0	Internal	1.65	1	3.3	Supported
1	0	1	Internal	2.5	0	2.5	Supported
1	0	1	Internal	2.5	1	2.5	Not Supported
1	1	X	External	VREFHI	0	2.5	Supported
1	1	X	External	VREFHI	1	2.5	Not Supported

Two sets of DACVAL registers, DACVALA and DACVALS, are present in the buffered DAC module. DACVALA is a read-only register that actively controls the buffered DAC value. DACVALS is a writable shadow register that loads into DACVALA either immediately or synchronized with the next EPWMSYNCPER event. If the clock to the buffered DAC is disabled while the buffered DAC is outputting a voltage, the output voltage remains unaffected, but DACVALA and DACVALS is no longer updated with register writes. Enabling the clock to the buffered DAC restores the DAC to the state before the clock was disabled.

The output of the internal DAC is calculated with the following equation:

$$DACOUT = \frac{DACVALA * DACREF}{4096} \quad (20)$$

The output buffer of the buffered DAC can exhibit non-linear behavior near the supply rails (VDDA/VSSA). To determine the linear range of the buffered DAC, see the device-specific data sheet.

23.2.1 Initialization Sequence

1. Enable the buffered DAC clock.
2. Set DACREF with DACREFSEL.
3. Power up the buffered DAC with DACOUTEN.
4. Wait for the power-up time to elapse before outputting a voltage. To determine the power-up time of the buffered DAC, see the device data sheet.
5. For predictable behavior of the buffered DAC, consecutive writes to DACVALS must be spaced apart according to the settling time of the buffered DAC. To determine the settling time of the buffered DAC, see the device data sheet.

Copyright © 2025Texas Instruments

23.2.2 DAC Offset Adjustment

Zero offset error is defined as the difference between the voltage at midcode (2048) and 1.25V (for 2.5V reference voltage). DAC offset error is calibrated at 2.5V reference voltage and loaded into the DAC offset trim register as part of the Device_cal() function. If the DAC is used at any reference voltage other than 2.5V, the offset trim must be adjusted to make sure the offset error performance stays within the device-specific data sheet limits. The DAC offset register is a 16-bit register that contains the 8-bit signed offset trim in the lower half of the register. Use the function call DAC_tuneOffsetTrim() found in the F29x Software Development Kit (F29-SDK) to adjust the offset.

23.2.3 EPWMSYNCPER Signal

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the *Time-Base Submodule* section of the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACVALA when DACCTL [LOADMODE] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at a high level and DACVALA is immediately loaded from DACVALS irrespective of the value of DACCTL [LOADMODE]. Due to this, configure the EPWM first before setting DACCTL [LOADMODE] to 1.

Note

The name of the sync signal that the GPDAC (general purposed DAC) receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/ EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

23.3 Lock Registers

A DACLOCK register is provided to prevent spurious writes from modifying the DACCTL, DACVALS, and DACOUTEN registers. Once a register is protected through DACLOCK, write access are locked out until the device is reset.

Chapter 24

Comparator Subsystem (CMPSS)

The Comparator Subsystem (CMPSS) consists of analog comparators and supporting circuits that are useful for power applications such as peak current mode control, switched-mode power, power factor correction, voltage trip monitoring, and so forth.

See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

24.1 Introduction

The comparator subsystem is built around a number of modules. Each subsystem contains two comparators, two reference 12-bit DACs, and two digital filters. The subsystem also includes two ramp generators. The ramp generators ramp up and down.Comparators are denoted "H" or "L" within each module where “H” and “L” represent high and low, respectively. Each comparator generates a digital output which indicates whether the voltage on the positive input is greater than the voltage on the negative input. The positive input of the comparator is driven from an external pin (see the *Analog Subsystem* chapter for mux options available to the CMPSS). The negative input can be driven by an external pin or by the programmable reference 12-bit DAC . Each comparator output passes through a programmable digital filter that can remove spurious trip signals. An unfiltered output is also available if filtering is not required.

Two ramp generator circuits are optionally available to control the reference 12-bit DAC values for the high and low comparators in the subsystem.The DAC along with a wrapper can be used to generate a ramp which is used for slope compensation in Peak Current Mode Control (PCMC) and other applications.The subsystem also works with the EPWM to support Diode Emulation Mode.

24.1.1 Features

Each CMPSS includes:

- Two analog comparators
- Two independently programmable reference 12-bit DACs
- Dual decrementing/incrementing ramp generators
- Two digital filters, max filter clock prescale = 2^{24}
- Ability to synchronize submodules with EPWMSYNCPER
- Ability to synchronize output with SYSCLK
- Ability to latch output
- Ability to invert output
- Option to use hysteresis on the input
- Option for negative input of comparator to be driven by an external signal or by the reference DAC
- The DAC reference voltage can be set to VDDA or VDAC
- External connection to CMPSS filters
- Diode Emulation Logic (DEL) support
- Ramp generator prescaler
- CMPSS Type-6 supports connection with ePWM Type-5
- CMPSS based Low Power Mode (LPM) wakeup

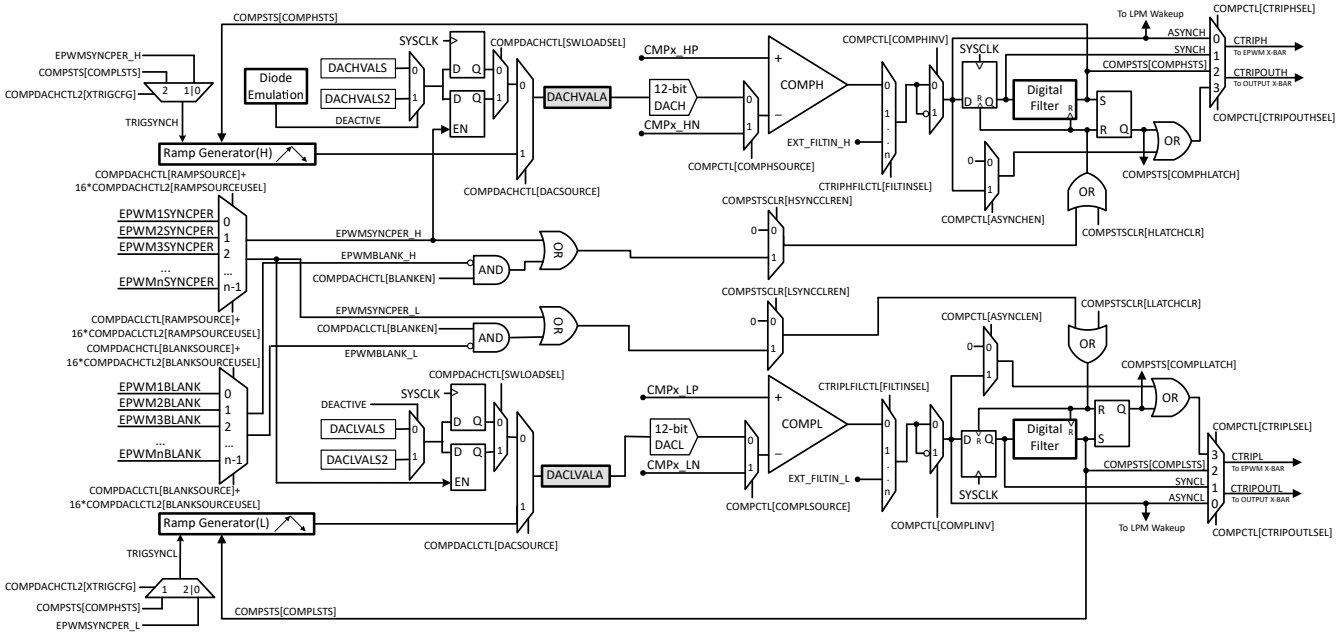
- CTRIPxOUTx(x= "H" or "L") signals are connected to the Output X-BAR for external signaling. See the *General-Purpose Input/Output (GPIO)* chapter for more details on the Output X-BAR mux configuration.



Note

CMPxDACOUTEN only exists for the CMPSS 1 module on this device (CMP1LDACOUTEN in the CMPSSCTL register)

Figure 24-1. CMPSS Module Block Diagram

24.2 Comparator

The comparator generates a high digital output when the voltage on the positive input is greater than the voltage on the negative input, and a low digital output when the voltage on the positive input is less than the voltage on the negative input. The comparator is illustrated in Figure 24-2.

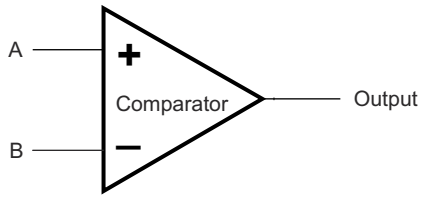


Figure 24-2. Comparator Block Diagram

Voltages	Output
Voltage A > Voltage B	1
Voltage A < Voltage B	0

Copyright © 2025Texas Instruments

24.3 Reference DAC

Each reference 12-bit DAC can be configured to drive a reference voltage into the negative input of the respective comparator. Some CMPSS instances also allow the low DAC output to be routed to a pin to act as an external DAC. In this case, all other CMPSS module functionality is not useable, including the high DAC, both comparators, ramp generation, and the digital filters.

Two sets of DACxVAL registers, DACxVALA and DACxVALS, are present for each reference 12-bit DAC. DACxVALA is a read-only register that actively controls the reference 12-bit DAC value. DACxVALS is a writable shadow register that loads into DACxVALA either immediately or synchronized with the next EPWMSYNCPER event. The high and low reference 12-bit DAC (DACx) can optionally source the register DACxVALA value from the ramp generator instead of the register DACxVALS.

The operating range of the reference 12-bit DAC is bounded by DACREF and VSSA. The high-voltage reference is VDDA by default, but the high voltage reference can be configured to be VDAC using the COMPDACHCTL register. The reference 12-bit DAC is illustrated in Figure 24-3.

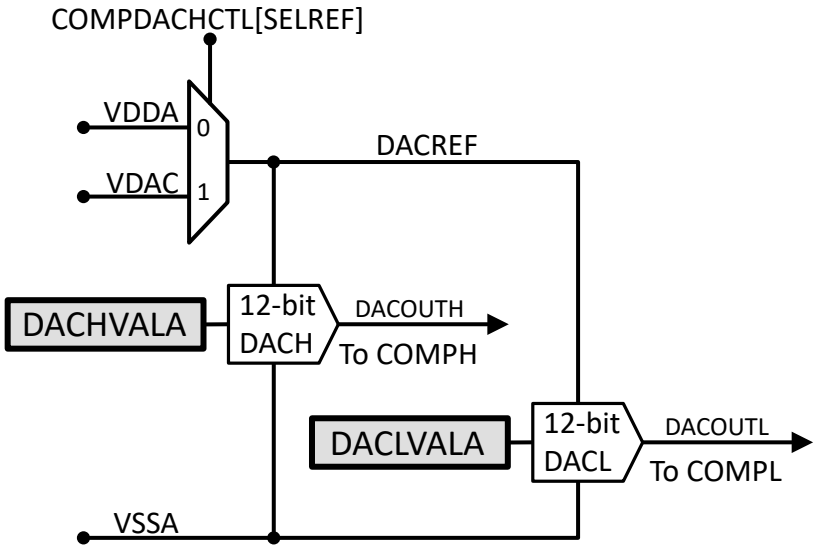

Figure 24-3. Reference DAC Block Diagram

The output of the reference 12-bit DAC can be calculated as:

$$DACOUT = \frac{(1 + DACVALA)*DACREF}{4096} \quad (21)$$

Copyright © 2025Texas Instruments

Note

- In the situations where both the DACH and DACL are driving the high and low comparators, a trip on one comparator can temporarily disturb the DAC output of the other comparator. The amount and length of time of this disturbance is specified in the device data sheet as “CMPSS DAC output disturbance” and “CMPSS DAC disturbance time”, respectively.

  Users must design the system carefully so that if the input signal crosses either DACH or DACL and trips the associated comparator, the input signal stays more than a “CMPSS DAC output disturbance” away from the other comparator trip point for “CMPSS DAC disturbance time”.
- The DACH setting must always be higher than the DACL setting. If the user is not using the DACL, the DACLVALS register must be set to 0 to avoid the comparator COMPL from tripping and affecting the DACH. In this case, there is no limitation on the DACHVALS setting. Accordingly, when not using the DACH, the user must set the DACHVALS register to the maximum.
- The CMPSS instance can be enabled before programming the reference DAC values.

24.4 Ramp Generator

This section discusses the characteristics and behavior of the ramp generator.

24.4.1 Ramp Generator Overview

The ramp generator produces a falling or rising ramp input for the high-reference 12-bit DAC and the low-reference 12-bit DAC when selected. In this mode, the reference 12-bit DAC uses the most-significant 12 bits of the RAMPSTS countdown register as the input. The low 4 bits of the RAMPSTS countdown register effectively act as a prescale for the falling or rising ramp rate configurable with RAMPxSTEPVALA. There is an additional dedicated prescaler for the ramp generator configurable with the RAMPCLKDIV register.

The ramp generator is enabled by setting DACSOURCE = 1. When DACSOURCE = 1 is selected, the value of RAMPSTS is loaded from RAMPxREFS and the register remains static until the selected TRIGSYNC signal is received. After receiving the selected TRIGSYNC signal, the value of RAMPxSTEPVALA is subtracted from RAMPSTS on every subsequent SYSCLK cycle.

To prevent the subtraction from commencing a SYSCLK cycle after a TRIGSYNC event, the RAMPDLYA register that serves as a delay counter can be used to hold off the RAMPSTS subtraction or addition. On receiving a TRIGSYNC event, the value of RAMPDLYA is decremented by one on every SYSCLK cycle until the register reaches zero. So, the RAMPSTS subtraction only begins when RAMPDLYA is zero.Similarly, in increment mode (RAMPDIR = 1), the RAMPSTS addition only begins when RAMPDLYA is zero.

Note

- For the ramp decrement mode of operation, set the registers COMPXINV and RAMPDIR to 0, and for the ramp increment mode of operation, set the registers COMPXINV and RAMPDIR to 1.

Copyright © 2025Texas Instruments

24.4.2 Ramp Generator Behavior

The ramp generator makes state changes on every rising edge of DACSOURCE, TRIGSYNC, and COMPHSTS.

On the rising edge of DACSOURCE: the registers RAMPxREFA, RAMPxSTEPVALA, and RAMPDLYA are loaded with the shadow registers. Also, the register RAMPSTS is loaded with RAMPxREFS.

On the rising edge of the selected TRIGSYNC: the registers RAMPxREFA, RAMPxSTEPVALA, and RAMPDLYA are loaded with the shadow registers. Also, the register RAMPSTS is loaded with RAMPxREFS and starts decrementing in the decrement mode (RAMPDIR = 0) or incrementing in the increment mode (RAMPDIR = 1) when RAMPDLYA counter reaches zero.

On the rising edge of COMPHSTS with RAMPLOADSEL = 1: the registers RAMPxREFA, RAMPxSTEPVALA, and RAMPDLYA are loaded with the shadow registers. Also, the register RAMPSTS is loaded with RAMPxREFS and stops decrementing in the decrement mode (RAMPDIR = 0) or incrementing in the increment mode (RAMPDIR = 1).

On the rising edge of COMPHSTS with RAMPLOADSEL = 0: the register RAMPSTS is loaded with RAMPxREFA. So, the register RAMPSTS stops decrementing and incrementing in the decrement mode and the increment mode, respectively.

Additionally, if the value of RAMPSTS reaches zero and the ramp generator is in the decrement mode (RAMPDIR = 0), the RAMPSTS register remains static at zero until the next TRIGSYNC is received. If the ramp generator is in the increment mode (RAMPDIR = 1) and the value of RAMPSTS reaches 0xFFFF, the RAMPSTS register value remains at that value until the next TRIGSYNC is received. These state changes are illustrated in the ramp generator block diagram in Figure 24-4.

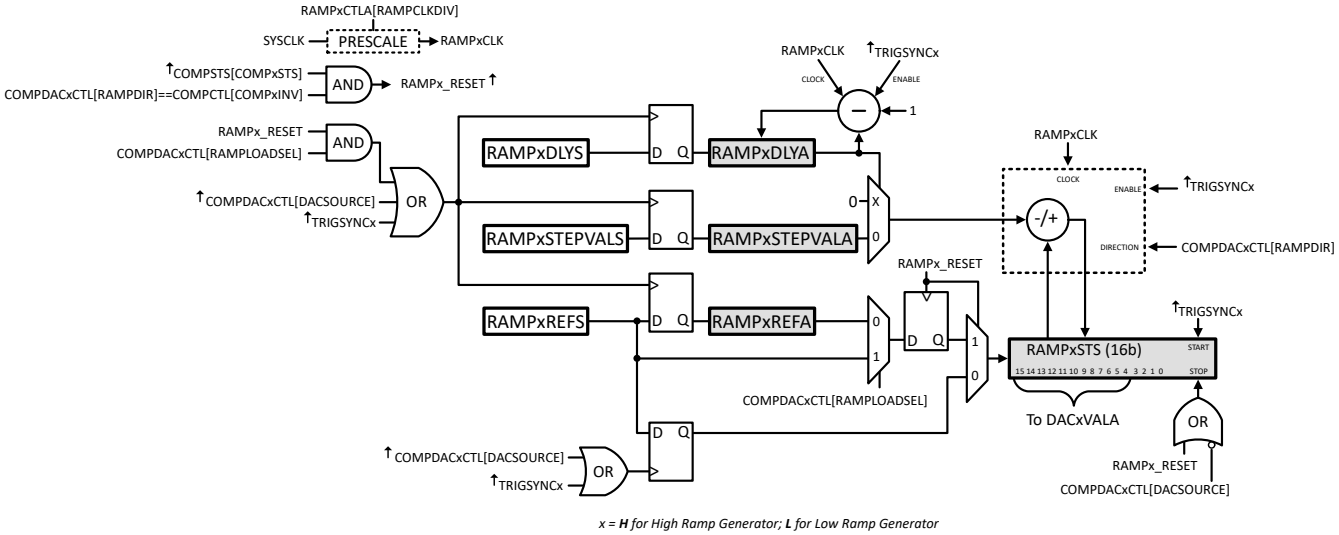

Figure 24-4. Ramp Generator Block Diagram

Copyright © 2025Texas Instruments

24.4.3 Ramp Generator Behavior at Corner Cases

Since the ramp generator makes state changes on every rising edge of TRIGSYNCx and COMPHSTS, the following behavior can be expected on instances when these two events occur simultaneously or very close together.

Case 1: COMPHSTS rising edge occurs one or more cycles before TRIGSYNC rising edge.
RAMPSTS stops decrementing on COMPHSTS rising edge event. RAMPSTS starts decrementing on TRIGSYNCx rising edge event when RAMPDLYA reaches 0.

Case 2: COMPHSTS rising edge occurs simultaneously as TRIGSYNCx rising edge.
EPWMSYNCPER rising edge event takes precedence and RAMPSTS starts decrementing when RAMPDLYA reaches 0. COMPHSTS rising edge event is ignored and does not halt RAMPSTS.

Case 3: COMPHSTS rising edge occurs one or more cycles after TRIGSYNCx rising edge but before RAMPDLYA reaches 0.
RAMPSTS does not decrement when RAMPDLYA reaches 0.

Case 4: COMPHSTS rising edge occurs simultaneously as RAMPDLYA reaches 0 from TRIGSYNCx rising edge.
RAMPSTS does not decrement.

This behavior is also illustrated in Figure 24-5.

Note

For the ramp decrement mode of operation, set the registers COMPXINV and RAMPDIR to 0, and for the ramp increment mode of operation, set the registers COMPXINV and RAMPDIR to 1.

24.5 Digital Filter

The digital filter works on a window of FIFO samples (SAMPWIN) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than SAMPWIN / 2 and less than or equal to SAMPWIN.

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every prescale system clocks. Old data from the FIFO is discarded.

Note that for SAMPWIN, THRESH and CLKPRESCALE, the internal number used by the digital filter is + 1 in all cases. In essence, samples = SAMPWIN + 1, threshold = THRESH + 1 and prescale = CLKPRESCALE + 1.

A conceptual model of the digital filter is shown in Figure 24-6.

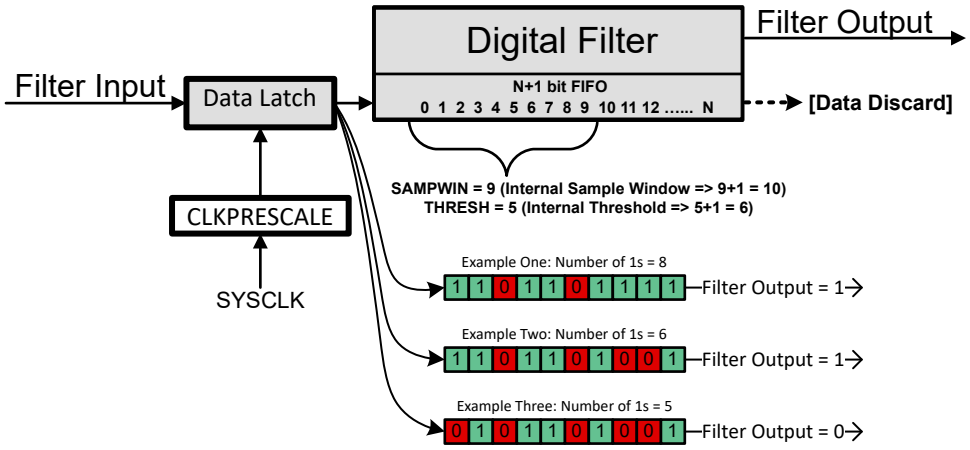

Figure 24-6. Digital Filter Behavior

Equivalent C code of the filter implementation is:

```
if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}
```

Copyright © 2025Texas Instruments

24.5.1 Filter Initialization Sequence

For proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure and enable the comparator for operation.
2. Configure the digital filter parameters for operation:
   - Set SAMPWIN for the number of samples to monitor in the FIFO window.
   - Set THRESH for the threshold required for majority qualification.
   - Set CLKPRESCALE for the digital filter clock prescale value.
3. Initialize the sample values in the digital FIFO window by setting FILINIT.
4. Clear COMPSTS latch using COMPSTSCLR, if the latched path is desired.
5. Configure the CTRIP and CTRIPOUT signal paths.
6. If desired, configure the destination module, for example, ePWM, GPIO, and so on to accept the filtered signals.

24.6 Using the CMPSS

24.6.1 LATCHCLR, EPWMSYNCPER, and EPWMBLANK Signals

The LATCHCLR signal holds the digital filter, synchronization block, and the latch output in reset (0) after the required delays. The LATCHCLR signal is activated in software using xLATCHCLR (x = H or L). The LATCHCLR signal can also be activated by EPWMSYNCPER when xSYNCCLREN (x = H or L) is set. If a longer LATCHCLR signal is required, the EPWMBLANK signal can be used to extend the LATCHCLR signal by setting BLANKEN.

EPWMSYNCPER and EPWMBLANK (BLANKWDW) come from the Time-Base and Digital Compare submodules of the EPWM, respectively. For a detailed description of how these two signals are generated, refer to the respective submodule section in the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACxVALA when COMPDACCTL[SWLOADSEL] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at level high and DACxVALA is loaded immediately from DACxVALS irrespective of the value of COMPDACCTL[SWLOADSEL]. Due to this, configure the EPWM first before setting COMPDACCTL[SWLOADSEL] to 1.

Note

The name of the sync signal that the CMPSS receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of what are these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

24.6.2 Synchronizer, Digital Filter, and Latch Delays

The synchronization block adds 1-2 SYSCLK cycle delays. If the digital filter is bypassed (all filter settings are 0), the digital filter adds 2 SYSCLK cycle delays. The latch adds 1 SYSCLK cycle delay.

Copyright © 2025Texas Instruments

24.6.3 Calibrating the CMPSS

The CMPSS has two sources of offset errors: comparator offset error and compdac offset error. In the data sheet, the comparator offset error is referred to as ***Input referred offset error*** and compdac offset error is referred to as ***Static offset error***. See the device data sheet for the values.

If both inputs of the comparator are driven from a pin, only the comparator offset error applies. However if the inverting input of the comparator is driven from the compdac, then only the compdac offset error applies. This is because the compdac offset error includes comparator offset error.

Due to the offset errors, the CMPSS must be calibrated to make sure trips happen at the expected levels. The following flow outlines how the calibration can be performed if the inverting input of the comparator is driven from the compdac.

Notes before calibration:

1. A static DC signal is required on the non-inverting input of the comparator.
2. Hysteresis can be disabled for calibration and can be re-enabled after calibration is complete.
3. A noisy input can make calibration difficult, so use the latch with non-zero filter settings depending on how noisy is the signal on the non-inverting input.

This approach sweeps down the compdac:

1. Set the starting compdac value to max, 0xFFF.
   - Optional: Instead of setting the starting compdac value to maximum, set to ***Vtarget*** + ***Static offset error*** + ***Margin***. Where ***Vtarget*** is the approximate DC voltage on the non-inverting input, ***Static offset error*** is the compdac offset error specification and ***Margin*** is some amount of guard band. This can lead to a faster calibration but only works if ***Vtarget*** is known. Alternatively, if ***Vtarget*** is unknown, the ADC can be used to convert ***Vtarget***.
2. Decrement compdac value by 1.
3. Wait for compdac to settle.
4. Clear latch.
5. Wait for possible latch set.
6. If latch is set, trip code is found exit.
   - Optional: The trip code can be double checked by:
     a. Increasing compdac value by 1.
     b. Clear latch.
     c. Wait for possible latch set.
     d. Latch can be unset.
7. If latch is unset, go back to step 2 and repeat.

It is also possible to calibrate the CMPSS, if both inputs of the comparator are driven from a pin. For this case, the flow stays the same but the voltage on the inverting pin of the comparator is swept externally.

24.6.4 Enabling and Disabling the CMPSS Clock

If the clock to the CMPSS module is disabled while the comparator is active, the following behavior can be expected:

- The comparator remains unaffected and continues to trip from voltages on the inputs.
- If the reference 12-bit DAC is driving the negative input of the comparator, the voltage on the negative input remains static and unaffected but DACVALA can no longer be updated from the ramp generator or DACVALS.
- The ramp generator, synchronize block and digital filter freeze on the current states.

Enabling the clock to the CMPSS restores the clock to the state before the clock was disabled.

24.7.2 CMPSS Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location: f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/cmpss

Cloud access to these examples is available at the following link: dev.ti.com F29x SDK Examples.

24.7.2.1 CMPSS Asynchronous Trip - SINGLE_CORE

FILE: cmpss_ex1_asynch.c

This example enables the CMPSS1 COMPH comparator and feeds the asynchronous CTRIPOUTH signal to the GPIO4/OUTPUTXBAR3 pin and CTRIPH to GPIO1/EPWM1B.

CMPSS is configured to generate trip signals to trip the EPWM signals. CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2. An EPWM signal is generated at GPIO1 and is configured to be tripped by CTRIPOUTH.

When a low input(VSS) is provided to CMPIN1P,
- Trip signal(GPIO4) output is low
- PWM1B(GPIO1) gives a PWM signal

When a high input(higher than VDD/2) is provided to CMPIN1P,
- Trip signal(GPIO4) output turns high
- PWM1B(GPIO1) gets tripped and outputs as high

External Connections
- Give input on CMPIN1P
- Outputs can be observed on GPIO4 and GPIO1 using an oscilloscope

Watch Variables
- None

24.7.2.2 CMPSS Digital Filter Configuration - SINGLE_CORE

FILE: cmpss_ex2_digital_filter.c

This example enables the CMPSS1 COMPH comparator and feeds the output through the digital filter to the GPIO4/OUTPUTXBAR3 pin.

CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2.

When a low input(VSS) is provided to CMPIN1P,
- GPIO4 output is low

Copyright © 2025Texas Instruments

When a high input(higher than VDD/2) is provided to CMPIN1P,

- GPIO4 output turns high

24.8 CMPSS Registers

This Section describes the CMPSS Registers.

The following chapters describe the control peripherals.

Technical Reference Manual Overview

The block diagram is shown in Block Diagram. This Technical Reference Manual is organized into five major sections:

- C29x SYSTEM RESOURCES

  These chapters describe the C29x CPU subsystem, C29x Boot ROM, device configuration, and other system peripherals.

- ANALOG PERIPHERALS

  These chapters describe the general analog subsystem configuration, Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

- CONTROL PERIPHERALS

  These chapters describe the Enhanced Capture (eCAP), High-Resolution Capture (HRCAP), Enhanced Pulse-Width Modulator (ePWM) with High-Resolution Pulse-Width Modulator (HRPWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- COMMUNICATION PERIPHERALS

  These chapters describe the communication peripherals available to the C29x subsystem such as the EtherCAT, FSI, I2C, PMBUS, UART, LIN, SPI, and SENT.

- SECURITY PERIPHERALS

  This chapter describes the safety peripherals available to the C29x subsystem such as the Hardware Security Module (HSM) and Cryptographic Accelerator.

Chapter 25

Enhanced Capture (eCAP)

This chapter describes the enhanced capture (eCAP) module, which is used in systems where accurate timing of external events is important.

The enhanced capture (eCAP) module is a Type 3 eCAP. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with an eCAP module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

25.1 Introduction

25.1.1 Features

The features of the eCAP module include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed by way of Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module features described in this chapter include:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single-shot capture of up to four event time-stamps
- Continuous mode capture of time stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- When not used in capture mode, the eCAP module can be configured as a single-channel PWM output

The capture functionality of the Type 1 eCAP is enhanced from the Type 0 eCAP with the following added features:

- Event filter reset bit:
  - Writing a 1 to ECCTL2[CTRFILTRESET] clears the event filter, the modulo counter, and any pending interrupts flags. Resetting the bit is useful for initialization and debug. Note that this is not applicable for signal monitoring interrupts, which do not get affected by the event filter reset bit.
- Modulo counter status bits:
  - The modulo counter (ECCTL2 [MODCNTRSTS]) indicates which capture register is loaded next. In the Type 0 eCAP, to know the current state of the modulo counter was not possible
- RTDMA trigger source:
  - eCAPxDMA was added as a RTDMA trigger. CEVT[1-4] can be configured as the source for eCAPxDMA.
- Input multiplexer:
  - ECCTL0 [INPUTSEL] selects one of 128 input signals, which are detailed in Section 25.3 .

The capture functionality of the Type 2 eCAP is enhanced from the Type 1 eCAP with the following added features:

- Added ECAPxSYNCINSEL register:
  - ECAPxSYNCINSEL register is added for each eCAP to select an external SYNCIN. Every eCAP can have a separate SYNCIN signal.

The capture functionality of the Type 3 eCAP is enhanced from the Type 2 eCAP with the following added features:

- Two signal monitoring units to monitor edge, pulse width, and period
  - Signal monitoring can optionally be tightly coupled with ePWM global load strobes and trip events
- Increased the number of multiplexed capture inputs from 128 to 256
- RTDMA event generation capability in PWM mode of operation
- ADC SOC generation capability, to trigger ADC conversion

25.2 Description

The eCAP module represents one complete capture channel that can be instantiated multiple times, depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Capture inputs can be connected using the Input X-BAR
- 256:1 input multiplexer
- Output X-BAR is used to configure output in APWM mode
- 32-bit time base (counter)
- 4 × 32-bit time-stamp capture registers (CAP1-CAP4)
- Four-stage sequencer (modulo4 counter) that is synchronized to external events, eCAP pin rising/falling edges.
- Modulo counter status register (MODCNTRSTS) to indicate sequencer state
- Independent edge polarity (rising/falling edge) selection for all four events
- Input capture signal prescaling (from 2-62 or bypass)
- One-shot compare register (two bits) to freeze captures after 1-4 time-stamp events
- Control for continuous time-stamp captures using a four-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the four capture events
- Separate RTDMA trigger
- Signal monitoring capability for edge, pulse width, and period
- RTDMA event generation capability in APWM mode
- ADC SOC event generation capability, to trigger ADC conversion

Copyright © 2025Texas Instruments

25.3 Configuring Device Pins for the eCAP

The Input X-BAR connects the device pins to the module as input. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to synchronous or asynchronous mode by setting the GPxQSELn register bits. Using synchronized inputs can help with noise immunity but affects the eCAP accuracy by ±2 cycles. The internal pull-ups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals.

A 128:1 input multiplexer must also be configured (see Figure 25-3). This multiplexer can select a variety of inputs by configuring ECCTL0.INPUTSEL.

The Output X-BAR must be used to connect output signals to the OUTPUTXBARx output locations. The GPIO mux must then be configured to connect the OUTPUTXBARx lines to any of several IO pins with the GPIO mux. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and X-BAR configuration.

Note

ECAPxIN has to be at least 2 * SYSCLK-cycles wide to be properly captured by the eCAP module; otherwise, the input pulse can get missed from sampling by the SYSCLK .

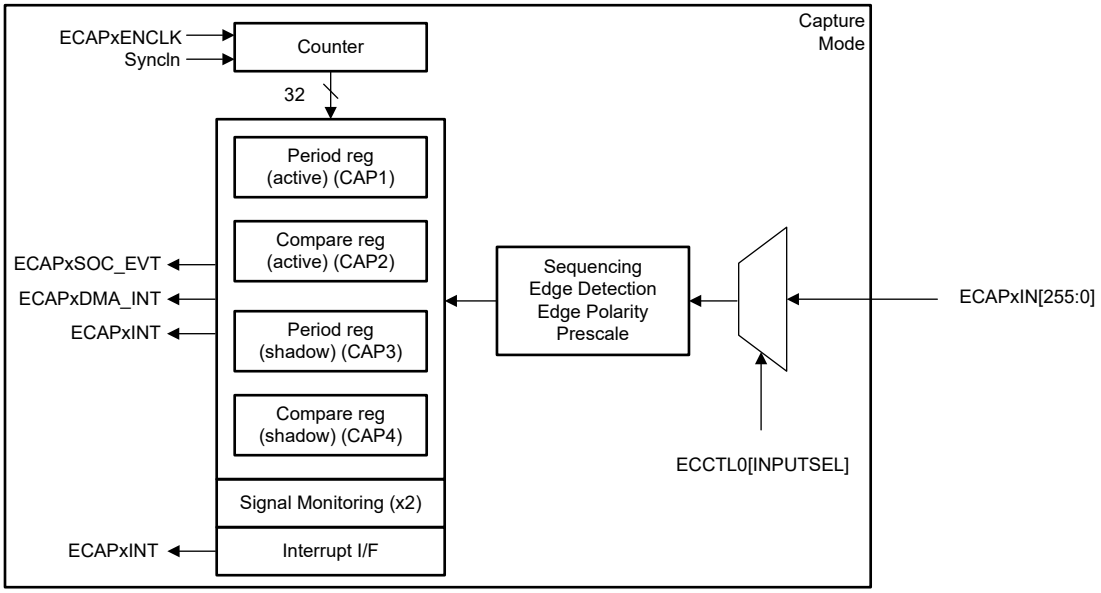
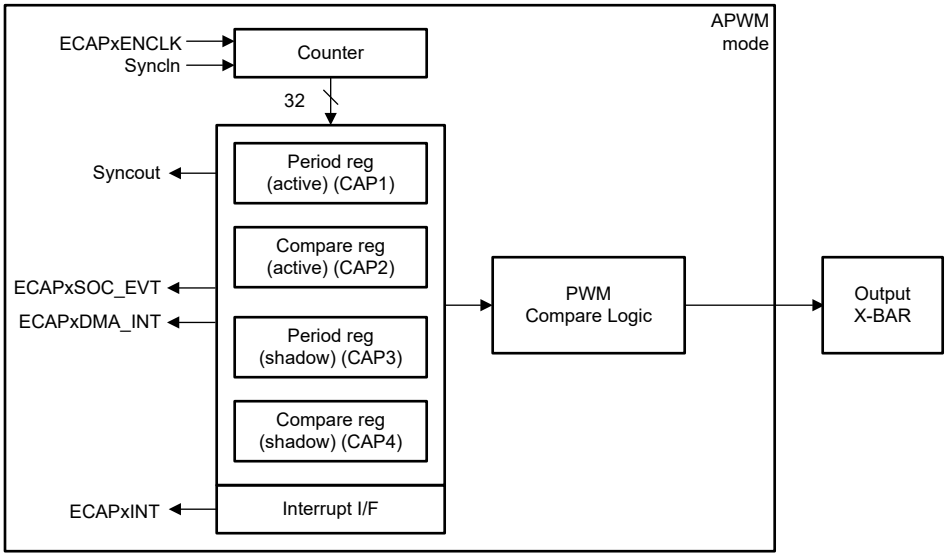
25.4 Capture and APWM Operating Mode

Use the eCAP module resources to implement a single-channel PWM generator (with 32-bit capabilities) when the eCAP module is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and compare shadow registers, respectively. Figure 25-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 25-2 further descries the output of the eCAP in APWM mode based on the CMP and PRD values.





Note

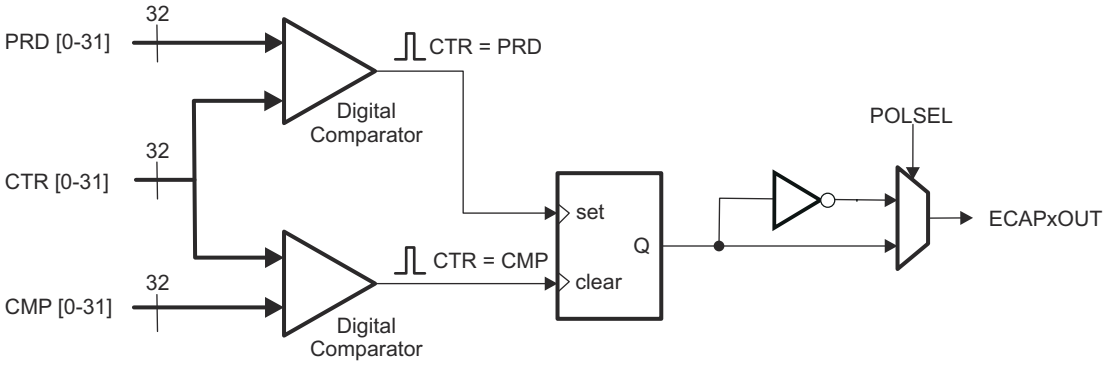
A single pin is shared between CAP and APWM functions. In capture mode, the pin is an input; in APWM mode, the pin is an output.

Copyright © 2025Texas Instruments

Note

In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

Figure 25-1. Capture and APWM Modes of Operation



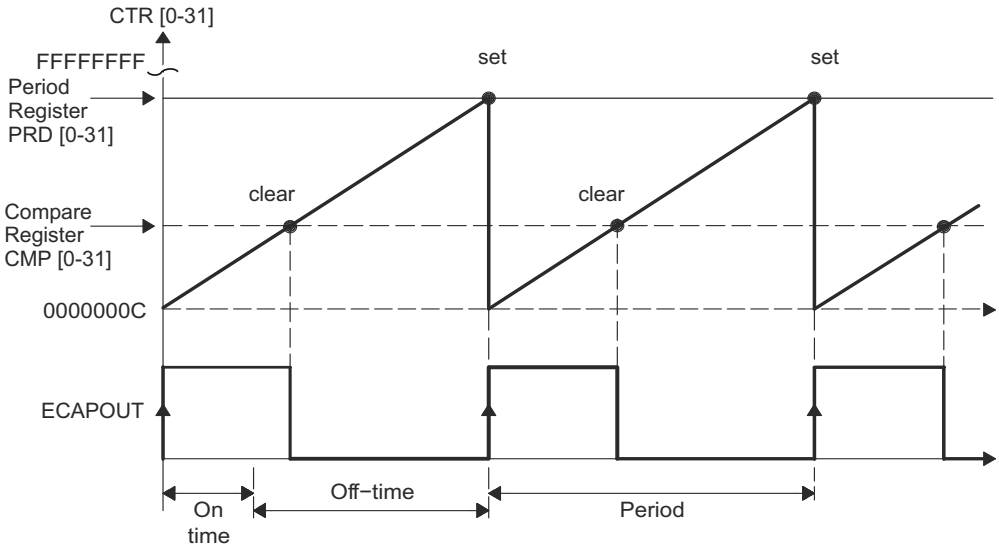


Figure 25-2. Counter Compare and PRD Effects on the eCAP Output in APWM Mode

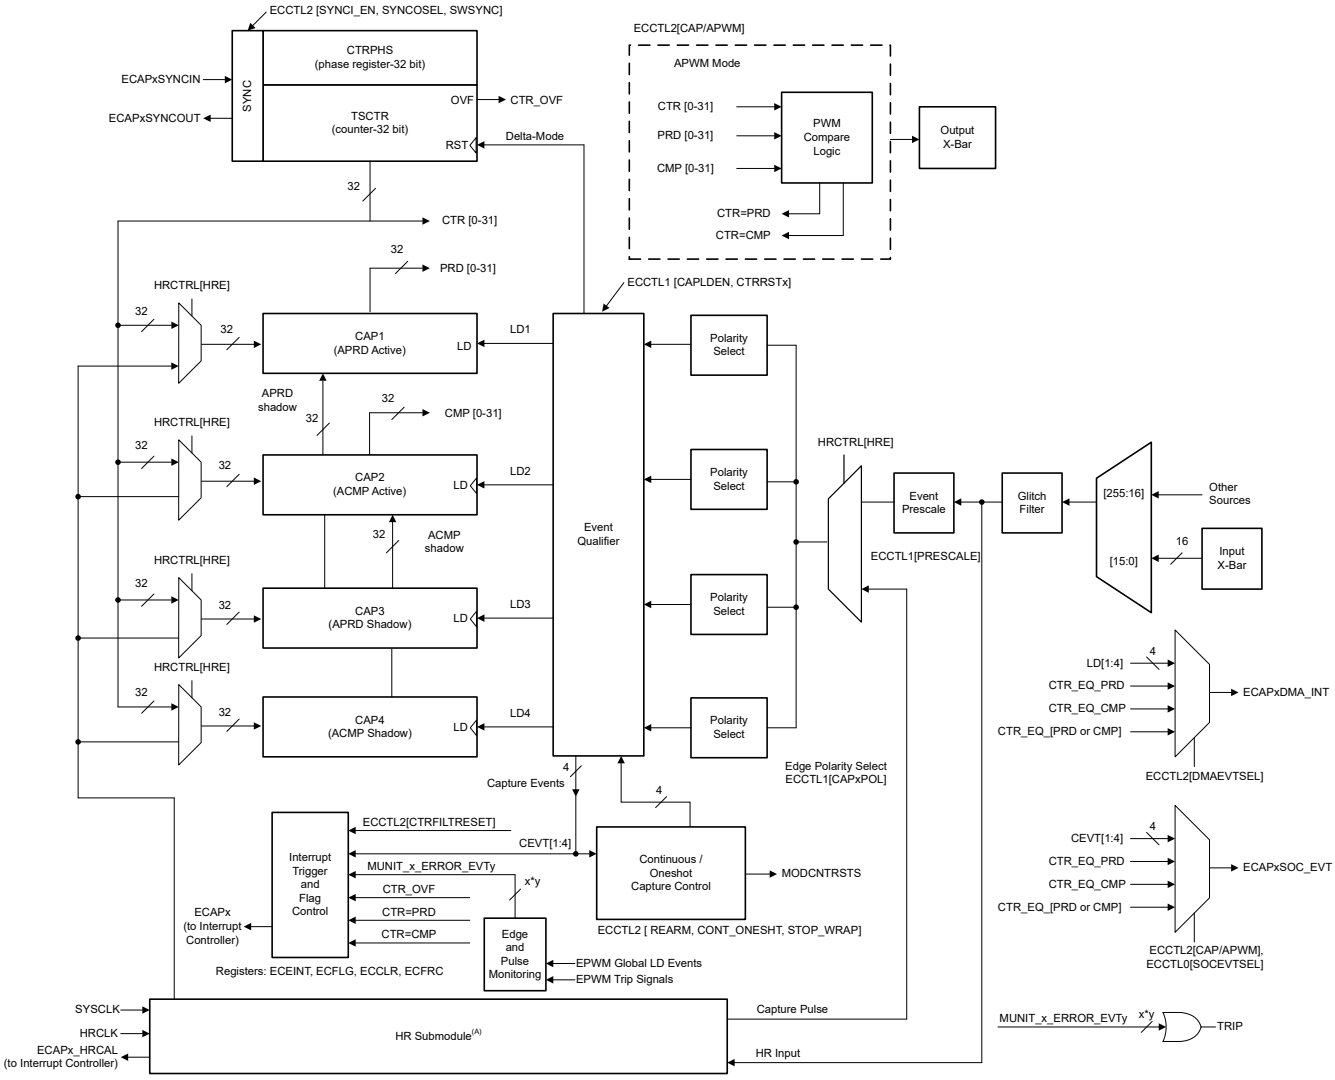
25.5 Capture Mode Description

Figure 25-3 shows the various components that implement the capture function.



Note

The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

Figure 25-3. eCAP Block Diagram

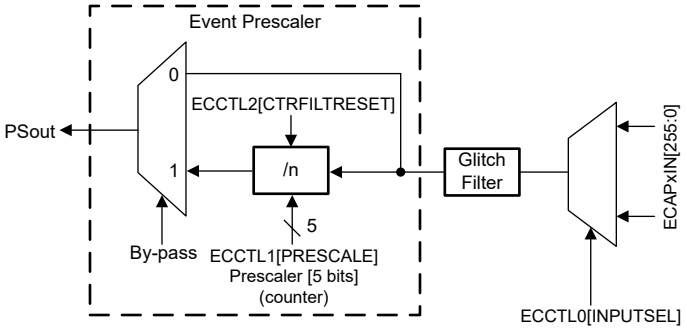
25.5.1 Event Prescaler

An input capture signal (pulse train) can be prescaled by N = 2-62 (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 25-4 shows a functional diagram and Figure 25-5 shows the operation of the prescale function. The event prescaler can be reset by setting the ECCTL2.CTRFILTRESET register bit.



Note

When a prescale value of 1 is chosen (ECCTL1[13:9] = 0,0,0,0,0), the input capture signal bypasses the prescale logic completely.

Note

The first Rise edge after Prescale configuration change is not passed to Capture logic, prescaler value takes into effect on the second rising edge after the configuration.

Figure 25-4. Event Prescale Control

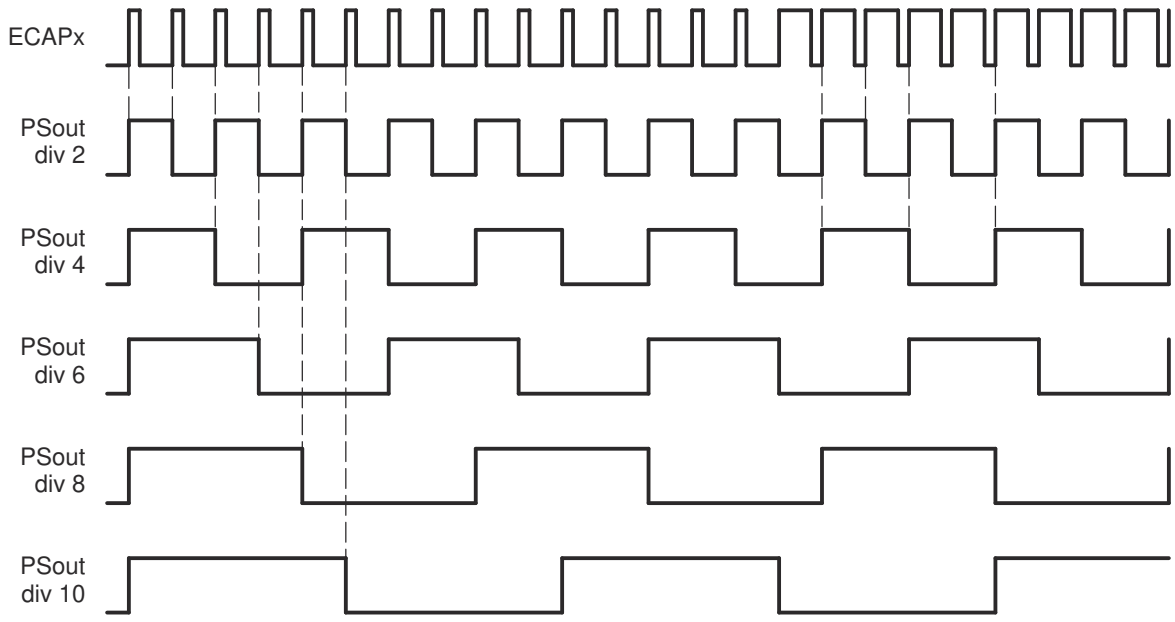


Figure 25-5. Prescale Function Waveforms

25.5.2 Glitch Filter

A glitch filter is included to reduce internal and external noise glitches on the source signal being measured by the eCAP.

The glitch filter can be used to filter out glitches of a specified time period in terms of SYSCLK cycles. The supported range is from 1 to 15 cycles. By default, the glitch filter is disabled (ECCCTL0[QUALPRD] = 0) to maintain compatibility.

Note

The glitch filter can be disabled when using HRCAP as the filter changes the pulse width of the signal. Also note that when enabled, the glitch filter delays the signal by QUALPRD+1, which must be accounted for in applications utilizing the feature.

25.5.3 Edge Polarity Select and Qualifier

Functionality and features include:

- Four independent edge polarity (rising edge/falling edge) selection muxes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to the respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

25.5.4 Continuous/One-Shot Control

Operation of eCAP in Continuous/One-Shot mode:

- The Mod4 (2-bit) counter is incremented using edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- During one-shot operation, a 2-bit stop register (STOP_WRAP) is used to compare the Mod4 counter output, and when equal, stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. In this mode, if TSCCTR counter is configured to reset on capture event (CEVTx) by configuring ECCTL1.CTRRSTx bit, the operation still keeps resetting the TSCCTR counter on capture event (CEVTx) after the STOP_WRAP value is reached and re-arm (REARM) has not occurred.

The continuous/one-shot block controls the start, stop and reset (zero) functions of the Mod4 counter, using a mono-shot type of action that can be triggered by the stop-value comparator and re-armed using software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time stamps).

Re-arming prepares the eCAP module for another capture sequence. Also, re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

25.5.5 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked using the system clock.

A phase register is provided to achieve synchronization with other counters using a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then the counter value is reset to 0 by any of the LD1-LD4 signals.

25.5.6 CAP1-CAP4 Registers

These 32-bit registers are supplied by the 32-bit counter timer bus, CTR[0-31], and are loaded (capture a time-stamp) when the respective LD inputs are strobed.

Control bit CAPLDEN can inhibit loading of the capture registers. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

25.5.7 eCAP Synchronization

eCAP modules can be synchronized with each other by selecting a common SYNCIN source. SYNCIN source for eCAP can be either software sync-in or external sync-in. The external sync-in signal can come from eCAP, X-Bar, or ePWM. The SWSYNC of the eCAP module is logical ORed with the SYNC signal as shown in Figure 25-7. The SYNC signal is defined by the selection of ECAPxSYNCINSEL[SEL] as shown in Figure 25-8.

The synchronization input source selection (ECAPSYNCINSEL) is the same as the ePWM Sync Input selection scheme. Please refer to the following table for the valid selection values table.

Note

ECAPxSYNCOUT going to the ECAPSYNCIN multiplexer is disabled. For example, ECAP1SYNCOUT cannot be a sync in to ECAP1, but ECAP1SYNCOUT can be a sync in to ECAP2, ECAP3, and so on.

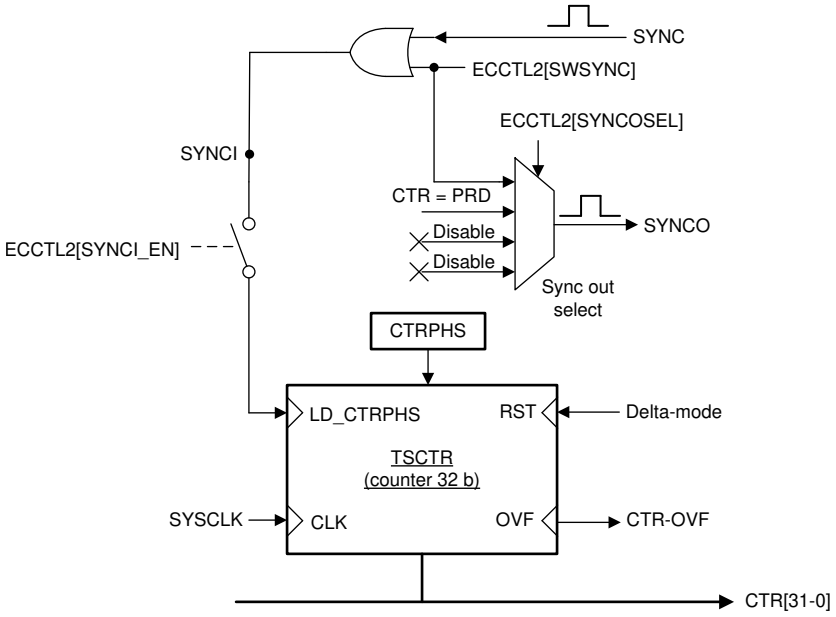

Figure 25-7. Details of the Counter and Synchronization Block

Copyright © 2025Texas Instruments

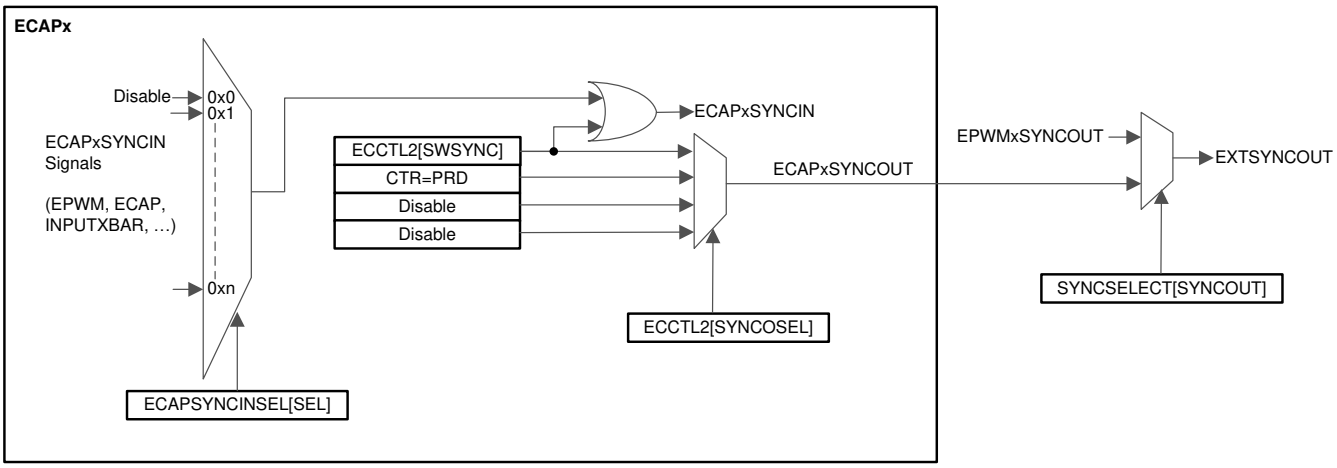

Figure 25-8. eCAP Synchronization Scheme

25.5.7.1 Example 1 - Using SWSYNC with ECAP Module

Implement the following steps to use SWSYNC with ECAP1 and ECAP2.

- Configure ECAP[1..2].ECAPSYNCINSEL.SEL = 0x0 to disable external SYNCIN coming to eCAP1.
- Configure ECAP[1..2].ECCTL2.SWSYNC = 0x1, to force Software Synchronization of the TSCTR counter.

To use SWSYNC with other eCAP modules, make sure that the previous eCAP chain is not generating a SYNCOUT signal that interferes with the software synchronization.

25.5.8 Interrupt Control

Operation and features of the eCAP interrupt control include (see Figure 25-9):

- An interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).
- An interrupt can be generated on signal monitoring errors (MUNIT_1_ERROR_EVT1, MUNIT_1_ERROR_EVT1, MUNIT_2_ERROR_EVT1, MUNIT_2_ERROR_EVT2)
- A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).
- The capture events are edge and sequencer-qualified (ordered in time) by the polarity select and Mod4 gating, respectively.
- One of these events can be selected as the interrupt source (from the eCAPx module) going to the Interrupt Controller.
- Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR=PRD, CTR=CMP) can be generated.
- An additional four interrupt events (MUNIT_1_ERROR_EVT1, MUNIT_1_ERROR_EVT1, MUNIT_2_ERROR_EVT1, MUNIT_2_ERROR_EVT2) can be generated from the signal monitoring unit.
- The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIPE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event using the interrupt clear register (ECCLR) before any other interrupt pulses are generated. All interrupt flags are cleared upon an event filter reset by writing a 1 to ECCTL2[CLRFILTRESET]. To force an interrupt event, use the interrupt force register (ECFRC). This is useful for test purposes.

Copyright © 2025Texas Instruments

Note

The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR=PRD, CTR=CMP flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

25.5.9 RTDMA Interrupt

On Type 0 eCAP modules, the CPU was required to begin data transfers using RTDMA. New to the Type 1 eCAP, a separate RTDMA Trigger (ECAP_DMA_INT) enables continuous transfer of capture data from eCAP registers to on-chip memory using RTDMA. Any one of the four available interrupt events (LD1, LD2, LD3, and LD4) can be selected as the trigger source for ECAP_DMA_INT using ECCTL2 [DMAEVTSEL].

New to the Type 3 eCAP is the ability to trigger RTDMA events in APWM mode. Any one of three available events (period match, compare match, or both) can be selected as the trigger source for ECAP_DMA_INT using ECCTL2 [DMAEVTSEL].

25.5.10 ADC SOC Event

Type 3 introduces the capability to generate ADC SOC events in capture mode and in APWM mode of operation. The ability to start ADC conversions allows for increased APWM functionality, as well as the ability to synchronize capture events with ADC samples.

In capture mode, one of the four available interrupt events (CEVT1, CEVT2, CEVT3, and CEVT4) can be selected as ECAP_SOC_EVT using ECCCTL0[SOCEVTSEL].

In APWM mode, any one of three available events (period match, compare match, or both) can be selected as ECAP_SOC_EVT using ECCCTL0[SOCEVTSEL].

25.5.11 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0].

25.5.12 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison by way of 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, the contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved using shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers, either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.
- During initialization, write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates during run-time, use the shadow registers.

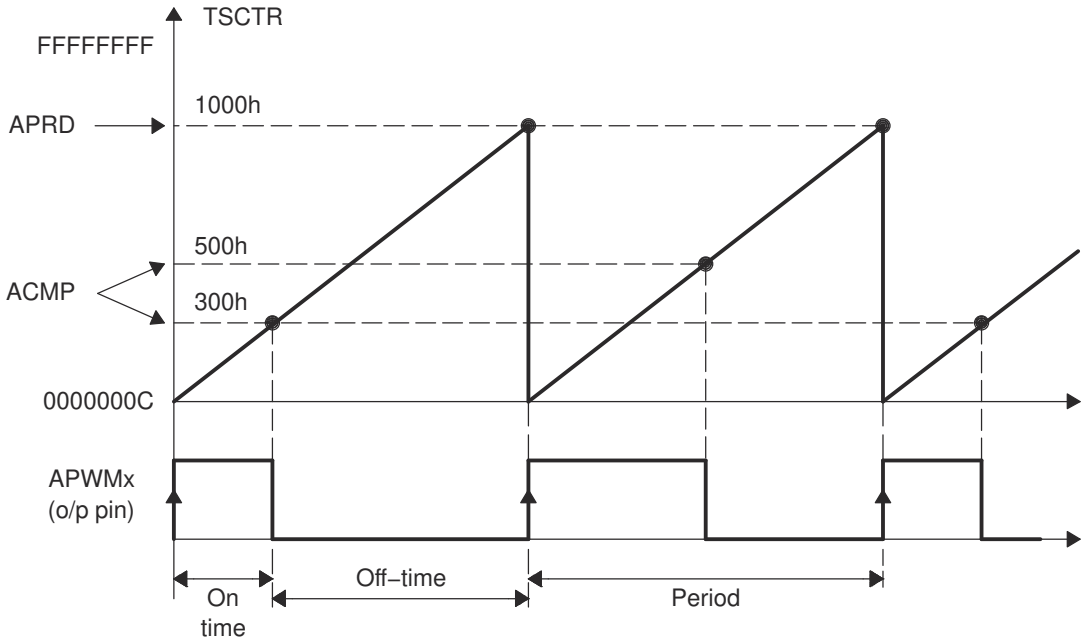

Figure 25-10. PWM Waveform Details Of APWM Mode Operation

Copyright © 2025Texas Instruments

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

```
CMP = 0x00000000, output low for duration of period (0% duty)
```

```
CMP = 0x00000001, output high 1 cycle
```

```
CMP = 0x00000002, output high 2 cycles
```

```
CMP = PERIOD, output high except for 1 cycle (<100% duty)
```

```
CMP = PERIOD+1, output high for complete period (100% duty)
```

```
CMP > PERIOD+1, output high for complete period
```

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

```
CMP = 0x00000000, output high for duration of period (0% duty)
```

```
CMP = 0x00000001, output low 1 cycle
```

```
CMP = 0x00000002, output low 2 cycles
```

```
CMP = PERIOD, output low except for 1 cycle (<100% duty)
```

```
CMP = PERIOD+1, output low for complete period (100% duty)
```

```
CMP > PERIOD+1, output low for complete period
```

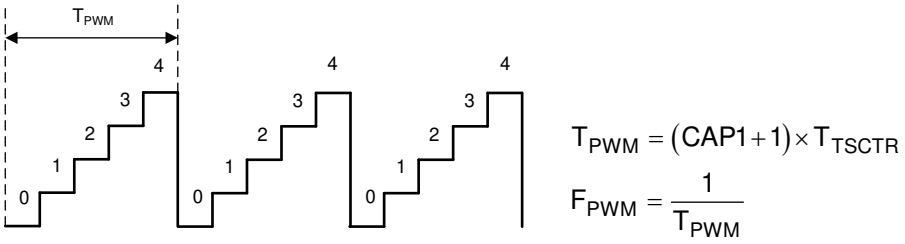

Figure 25-11. Time-Base Frequency and Period Calculation

25.5.13 Signal Monitoring Unit

The signal monitoring unit can be used for edge, pulse width, and period monitoring of ECAP input signals. This allows for detection that is useful for many applications. For example, EPWM pulse width boundary monitoring can be accomplished for safety applications.

The high-level features of the signal monitoring unit include:

- Measure pulse width (high or low) and check if the pulse width is in expected range
- Measure period (rise-to-rise or fall-to-fall) and check if the period is in expected range
- Monitor signal edge (rise or fall) and check if the signal edge occurs in a user-programmed time window

Copyright © 2025Texas Instruments

25.5.13.1 Pulse Width and Period Monitoring

The signal monitoring unit has the ability to measure pulse width (either low or high) or period (rise-to-rise edge or fall-to-fall edge) and automatically generate an error when the pulse width is outside of a programmable expected range.

The expected pulse width range is programmable using the following configuration registers (or their respective shadow registers):

- MUNIT_#_MIN programs the minimum pulse width capture value
- MUNIT_#_MAX programs the maximum pulse width capture value

Any pulse width outside of these programmed bounds triggers one of two error events:

- MUNIT_#_ERROR_EVT1 generated when measured pulse width is less than MUNIT_#_MIN
- MUNIT_#_ERROR_EVT2 generated when measured pulse width is greater than MUNIT_#_MAX

The following diagram provides an example in which the measured pulse width exceeds the MAX value, generating an ERROR_EVT2 event.

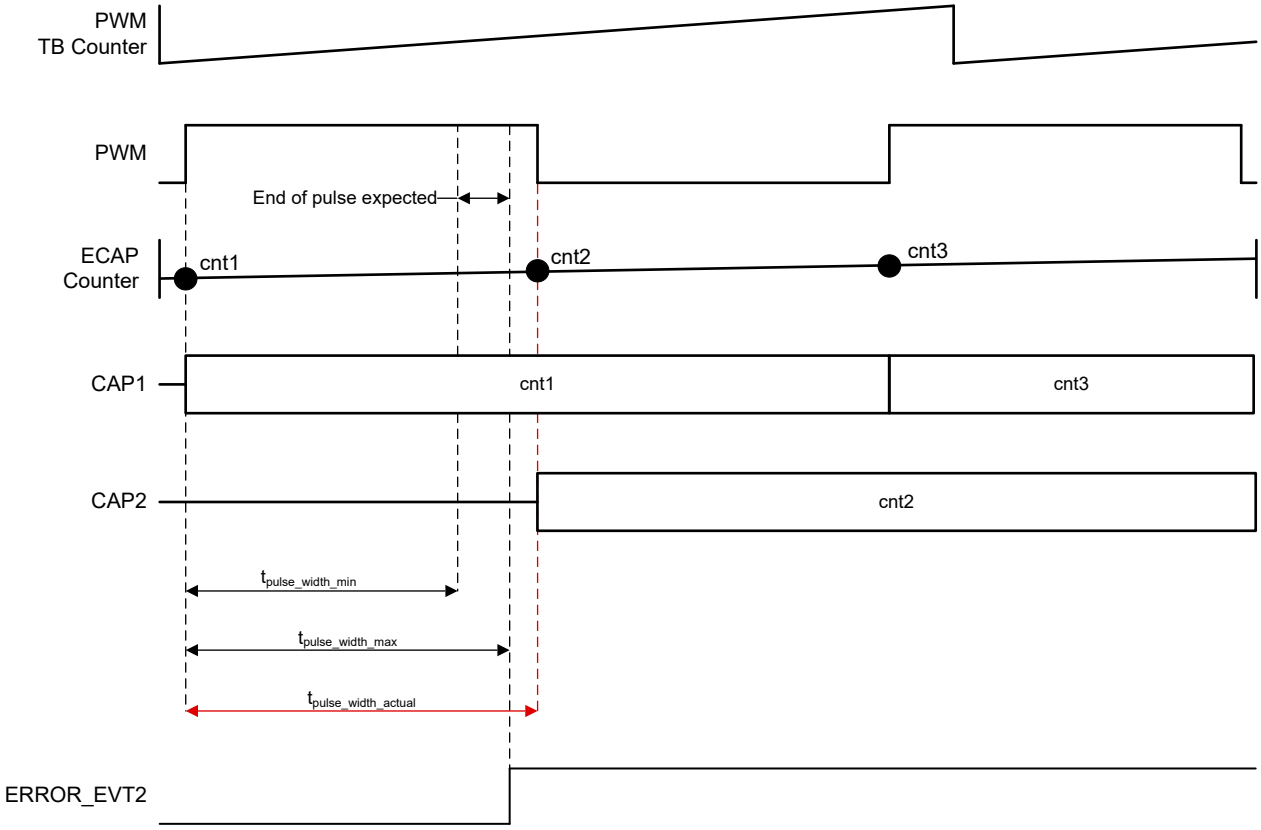

Figure 25-12. ECAP Signal Monitoring Unit Pulse Width Error Example

Configuration Requirements

To enable this mode, the following settings must be configured:

- Absolute mode must be set for the ECAP counter, so that the counter is free running and does not get reset on any capture events
- Continuous mode must be enabled (one-shot mode can be used, but is not recommended given the short duration)
- Sync feature for the counter must be disabled (ECCTL2.SYNCI_EN = 0)
- A minimum of two captures must be enabled (ECCTL2.STOP_WRAP >= 1, and at least CAP1 and CAP2 enabled)

Copyright © 2025Texas Instruments

- Capture Edge (ECCTL1.CAPxPOL) of used capture modules (any of CAP1 to CAP4) must be configured to capture two edges of interest
  - High pulse: one rising edge and one falling edge
  - Low pulse: one rising edge and one falling edge
  - Period rise-to-rise: two rising edges
  - Period fall-to-fall: two falling edges

Note

If a pulse width is greater than the MAX value, a second edge can arrive late or never even occur. Because of this, the DISABLE_EARLY_MAX_ERR field in the MUNIT_#_CTL register can be used to choose when a MAX error occurs. By setting the bit to 0, an error is generated as soon as the pulse width is greater than the specified maximum value. By setting the bit to 1, an error is generated when the second event has occurred.

Global load for shadow registers

eCAP has the ability to control the shadow register updates of the signal monitoring unit regsiters via any of the selected ePWMs through the MUNIT_COMMON_CTL.GLDSTRBSEL. The table below defines the connections of this register to the load strobe source.

25.5.13.1.1 eCAP - eCAP Global Strobe Selection

Table 25-2. eCAP Global Strobe Selection

25.5.13.2 Edge Monitoring

The signal monitoring unit has the ability to monitor and check if a rise or fall edge occurs within a specified time window and automatically generate an error when an edge occurs outside of this window.

The time window of an expected edge event can be programmed using the following configuration registers (or their respective shadow registers):

- MUNIT_#_MIN programs the minimum pulse width capture value
- MUNIT_#_MAX programs the maximum pulse with capture value

Copyright © 2025Texas Instruments

Any edge that occurs outside of these programmed bounds triggers the following error event:

- MUNIT_#_ERROR_EVT1 generated when edge occurs outside the bounds of MUNIT_#_MIN and MUNIT_#_MAX.

Additionally, ERROR_EVT2 is generated if either MIN or MAX did not occur between two sync events.

The following diagram provides an example in which a rising edge does not occur during the expected window, generating an ERROR_EVT1 event.

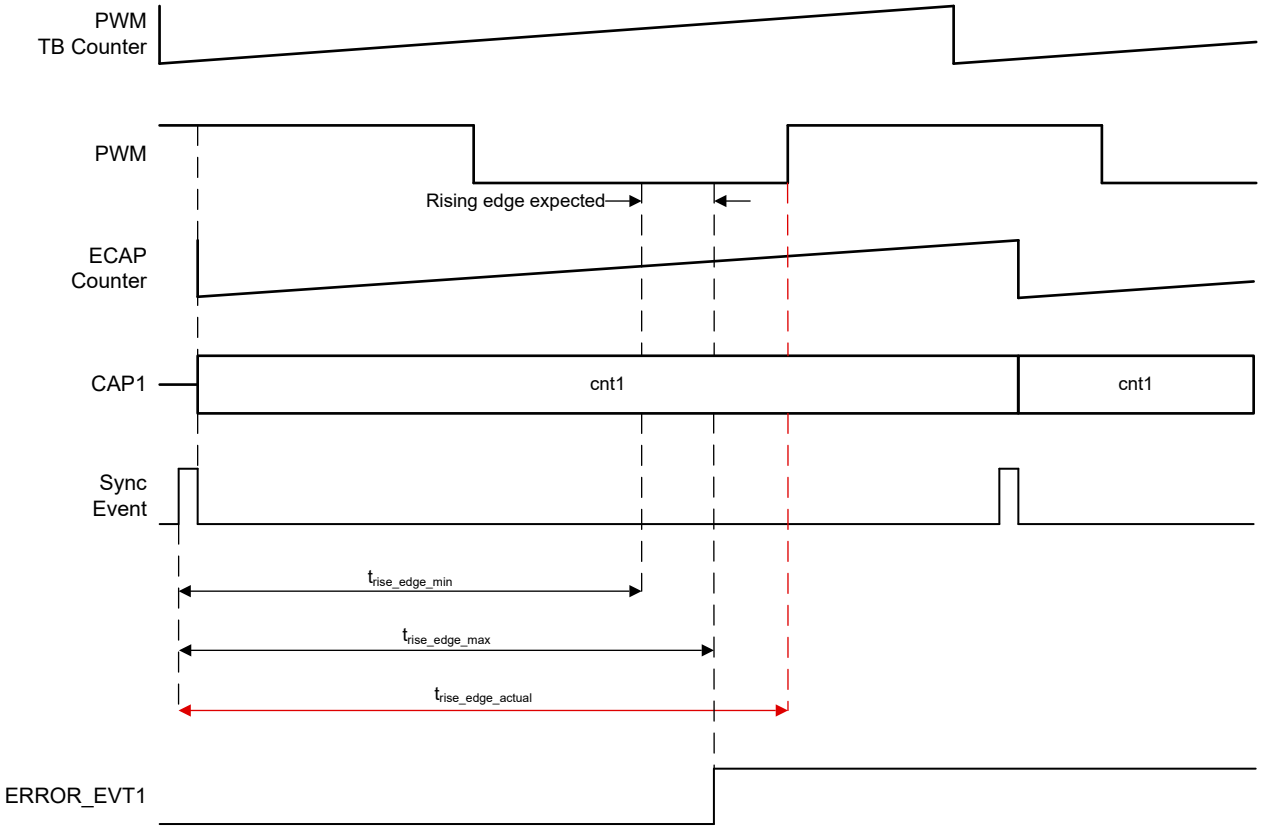

Figure 25-13. ECAP Signal Monitoring Unit Edge Error Example

Configuration Requirements

To enable this mode, the following settings must be configured:

- The ECAP counter must be synced with an EPWM module
- Absolute mode must be set for the ECAP counter, so that the counter is free running and does not get reset on any capture events
- Continuous mode can be enabled (one-shot mode can be used, but is not recommended given the modes short duration)
- A minimum of one capture can be enabled (ECCTL2.STOP_WRAP >= 0, and at least CAP1 enabled)
- Capture Edge (ECCTL1.CAPxPOL) of used capture modules (any of CAP1 to CAP4) must be configured to capture an edge of interest
- The time window defined using MIN and MAX can not cross the sync boundary

Copyright © 2025Texas Instruments

Note

The following are important considerations when configuring the edge monitoring feature:

- If the EPWM counter or ECAP counter are loaded with a non-zero phase value, the MIN and MAX values must be adjusted accordingly in SW. This also applies when the glitch filter is enabled, as the glitch filter delays the signal by QUALPRD+1
- The edge monitoring logic restarts on a sync event. This is to avoid any deadlock in case MIN, MAX, or both events do not occur between two sync events. ERROR_EVT2 is generated, if MIN or MAX match did not occur between two sync events
- The time window defined using MIN and MAX can not cross the sync boundary

Copyright © 2025Texas Instruments

25.6 Application of the eCAP Module

The following sections provide applications examples to show how to operate the eCAP module.

25.6.1 Example 1 - Absolute Time-Stamp Operation Rising-Edge Trigger

Figure 25-14 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFFFFFF (maximum value), the Mod4 counter wraps around to 00000000 (not shown in Figure 25-14), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram (after the fourth event); hence, event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

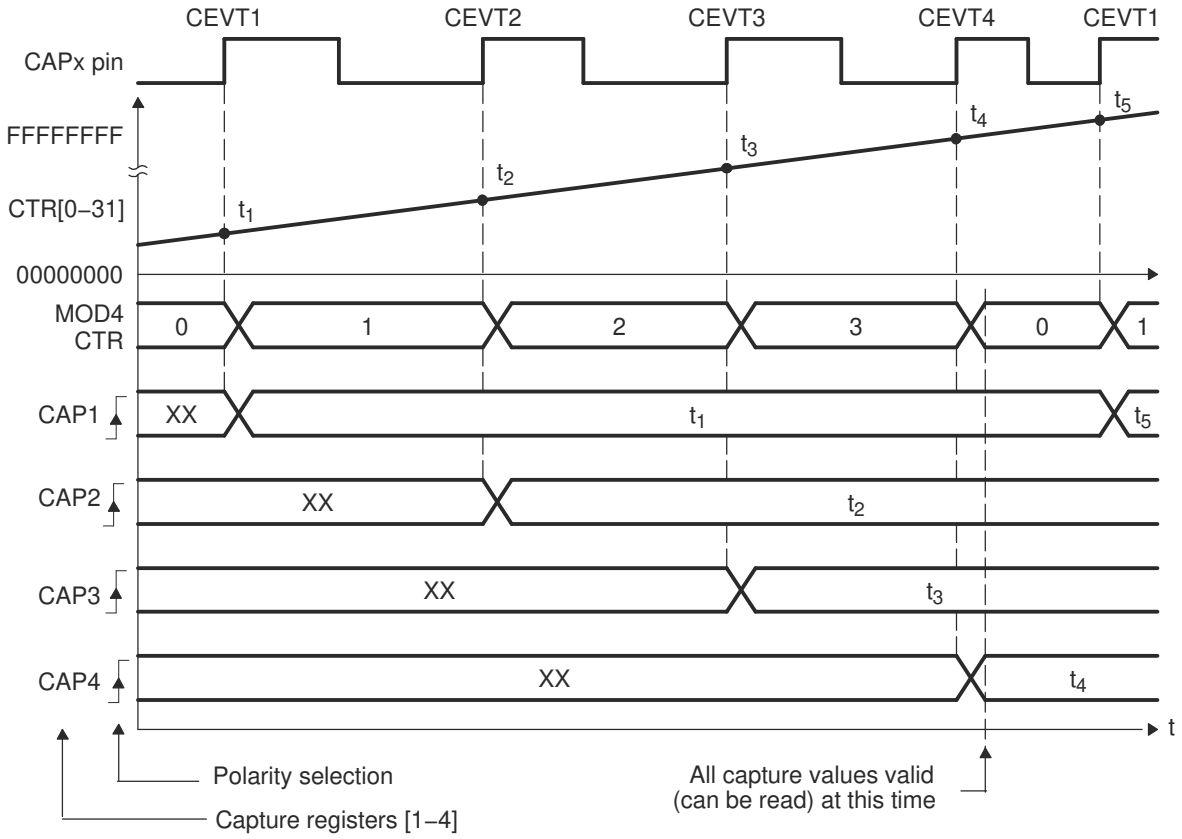

Figure 25-14. Capture Sequence for Absolute Time-stamp and Rising-Edge Detect

Copyright © 2025Texas Instruments

25.6.2 Example 2 - Absolute Time-Stamp Operation Rising- and Falling-Edge Trigger

In Figure 25-15, the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 = $t_3 - t_1$, Period2 = $t_5 - t_3$, …and so on. Duty Cycle1 (on-time %) = $(t_2 - t_1)$ / Period1 x 100%, and so on. Duty Cycle1 (off-time %) = $(t_3 - t_2)$ / Period1 x 100%, and so on.

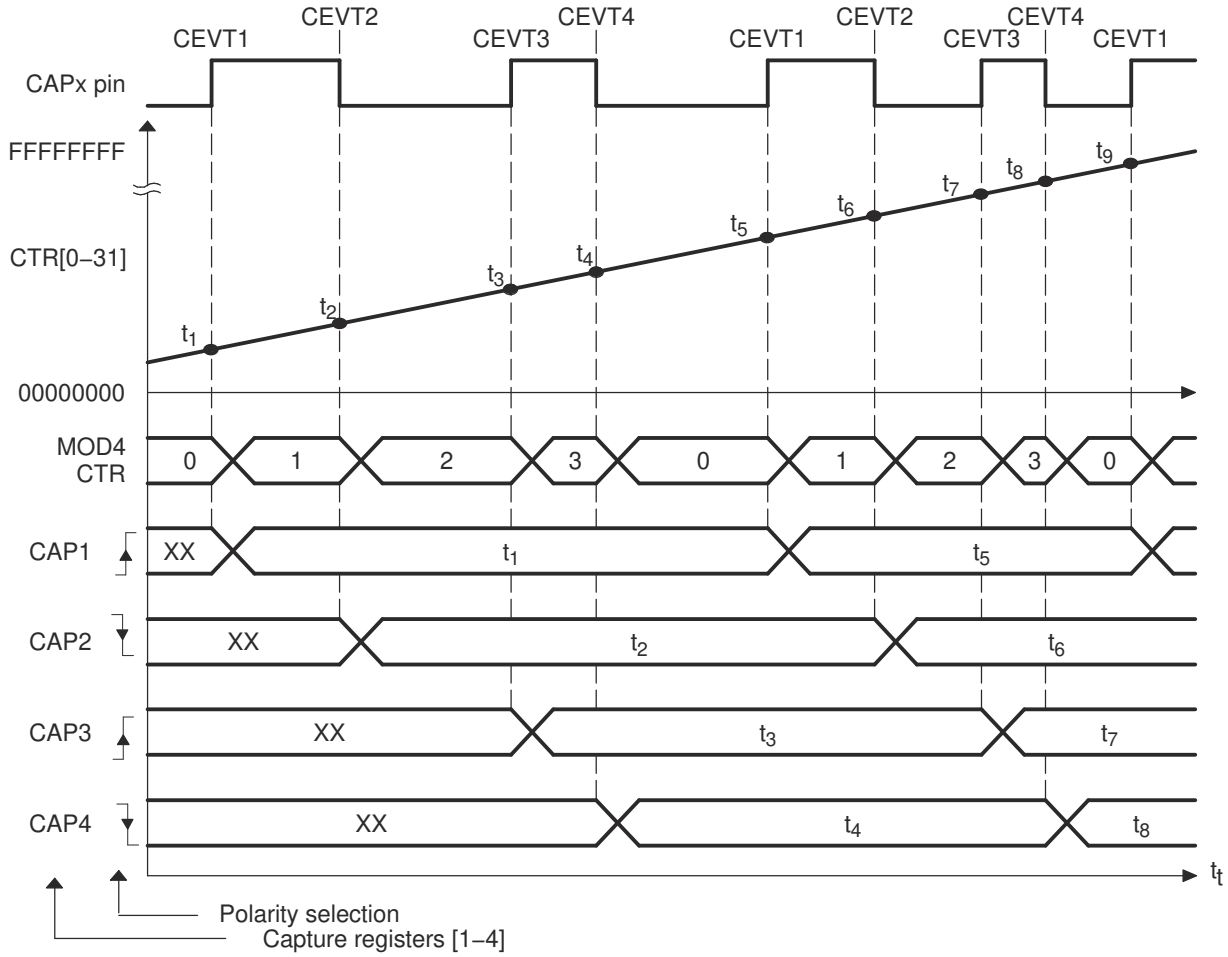

Figure 25-15. Capture Sequence for Absolute Time-stamp with Rising- and Falling-Edge Detect

Copyright © 2025Texas Instruments

25.6.3 Example 3 - Time Difference (Delta) Operation Rising-Edge Trigger

Figure 25-16 shows how the eCAP module can be used to collect delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is reset back to zero on every valid event. Here capture events are qualified as rising edge only. On an event, TSCTR contents (Time-Stamp) is captured first, and then TSCTR is reset to zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFFFFFF (maximum value), before the next event, the Mod4 counter wraps around to 00000000 and continues, a CNTOVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. The advantage of Delta-time mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is, Period1 = T_1, Period2 = T_2, and so on. As shown in Figure 25-16, the CEVT1 event is a good trigger point to read the timing data, T_1, T_2, T_3, T_4 are all valid here.

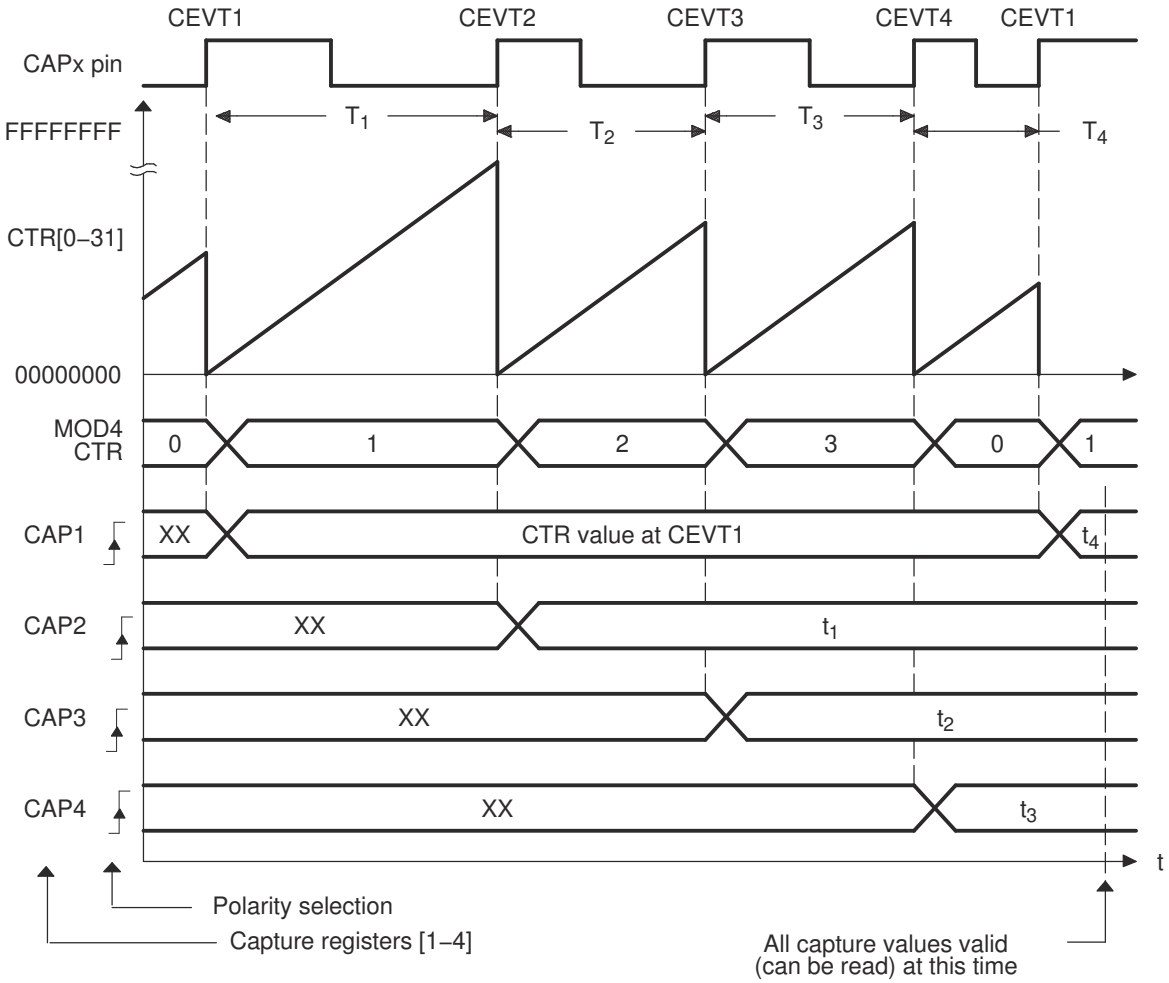

Figure 25-16. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect

Copyright © 2025Texas Instruments

25.6.4 Example 4 - Time Difference (Delta) Operation Rising- and Falling-Edge Trigger

In Figure 25-17, the eCAP operating mode is almost the same as in previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 = T_1+T_2, Period2 = T_3+T_4, and so on. Duty Cycle1 (on-time %) = T_1 / Period1 x 100%, Duty Cycle1 (off-time %) = T_2 / Period1 x 100%, and so on.

During initialization, write to the active registers for both period and compare. This action automatically copies the init values into the shadow values. For subsequent compare updates during run-time, the shadow registers must be used.

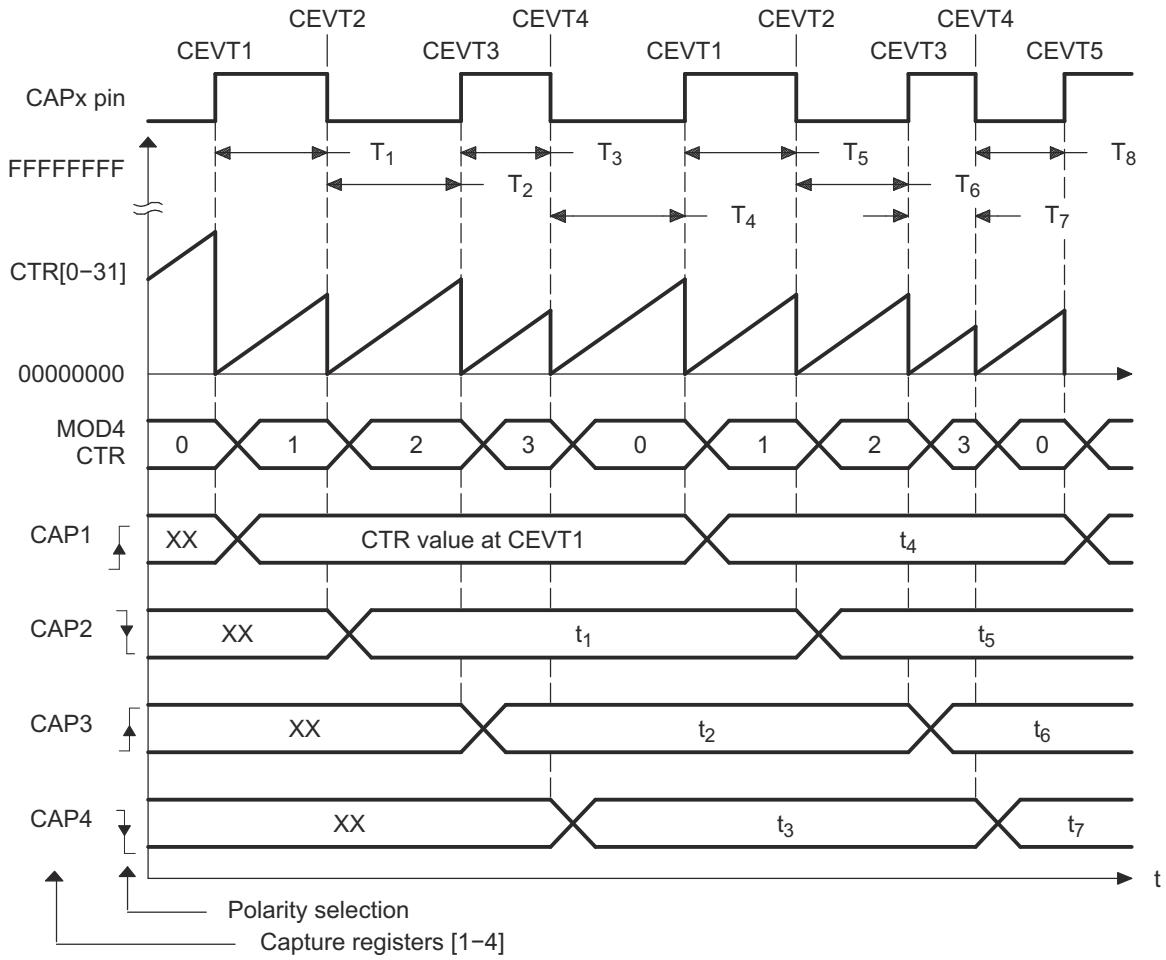

Figure 25-17. Capture Sequence for Delta Mode Time-stamp with Rising- and Falling-Edge Detect

25.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here, a very simple single-channel PWM waveform is generated from the APWMx output pin. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

25.7.1 Example 1 - Simple PWM Generation (Independent Channels)

25.8.2 ECAP Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location: f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/ecap

Cloud access to these examples is available at the following link: dev.ti.com F29x SDK Examples.

25.8.2.1 eCAP APWM Phase-shift Example - SINGLE_CORE

FILE: ecap_academy_lab.c

This lab sets up the eCAP1 to capture ePWM1's GPIO0 output. ePWM1 is configured to output a certain waveform. ePWM2 is configured to generate a SOCA to sample the GPIO0 signal. ADCA is used to sample the output and stores the samples to AdcBuf.

25.8.2.2 eCAP APWM Example - SINGLE_CORE

FILE: ecap_ex1_apwm.c

This program sets up the eCAP module in APWM mode. The PWM waveform will come out on GPIO5. The frequency of PWM is configured to vary between 10Hz and 20Hz using the shadow registers to load the next period/compare values.

25.8.2.3 eCAP Capture PWM Example - SINGLE_CORE

FILE: ecap_ex2_capture_pwm.c

This example configures ePWM3A for:
- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1 is configured to capture the time between rising and falling edge of the ePWM3A output.

External Connections
- eCAP1 is on GPIO16
- ePWM1A is on GPIO4
- Connect GPIO4 to GPIO16.

Watch Variables
- *ecap1PassCount* - Successful captures.
- *ecap1IntCount* - Interrupt counts.

25.8.2.4 eCAP APWM Phase-shift Example - SINGLE_CORE

FILE: ecap_ex3_apwm_phase_shift.c

This program sets up the eCAP1 and eCAP2 modules in APWM mode to generate the two phase-shifted PWM outputs of same duty and frequency value The frequency, duty and phase values can be programmed of choice by updating the defined macros. By default 10 Khz frequency, 50% duty and 30% phase shift values are used. eCAP2 output leads the eCAP1 output by 30% GPIO0 and GPIO1 are used as eCAP1/2 outputs and can be probed using analyzer/CRO to observe the waveforms.

25.8.2.5 ecap_ex4_dma_transfer - SINGLE_CORE

FILE: ecap_ex4_dma_transfer.c

This example demonstrates the use of DMA with ECAP. EPWM1A is set up with TBPRD = 1000 and CMP = 500 (50% duty). DMA is used to transfer the capture values from ECAP capture registers to a buffer. EPWM1A signal is being fed to ECAP using inputXbar(Xbar7 is used by ECAP).

Watch Variables
- *myEcapDataBuffer* - Capture values captured by ECAP.

External Connections

Copyright © 2025Texas Instruments

- EPWM1A is on GPIO0.

Table 25-24. ECCTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	MODCNTRSTS	R/W	0h	This bit field reads current status on modulo counter 00b (R) = CAP1 register gets loaded on next capture event. 01b (R) = CAP2 register gets loaded on next capture event. 10b (R) = CAP3 register gets loaded on next capture event. 11b (R) = CAP4 register gets loaded on next capture event. Reset type: CPU1.SYSRSn
13-12	DMAEVTSEL	R/W	0h	DMA event select Capture Mode: 00b (R/W) = DMA interrupt source is CEVT1 01b (R/W) = DMA interrupt source is CEVT2 10b (R/W) = DMA interrupt source is CEVT3 11b (R/W) = DMA interrupt source is CEVT4 APWM Mode: 00b (R/W) = DMA interrupt source is period match 01b (R/W) = DMA interrupt source is compare match 10b (R/W) = DMA interrupt source is period match or compare match 11b (R/W) = Disabled Reset type: CPU1.SYSRSn
11	CTRFILTRESET	R-0/W1C	0h	Reset Bit 0h (R) = No effect 1h (W) = Resets event filter, counter, modulo counter and CEVT[1,2,3,4] and CNTOVF , HRERROR flags Note: This provides an ability start capture module from known state in case spurious inputs are captured while ECAP is configured. Reset type: CPU1.SYSRSn
10	APWMPOL	R/W	0h	APWM output polarity select. This is applicable only in APWM operating mode. Reset type: SYSRSn 0h (R/W) = Output is active high (Compare value defines high time) 1h (R/W) = Output is active low (Compare value defines low time)

Copyright © 2025Texas Instruments

Table 25-24. ECCTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	CAP_APWM	R/W	0h	CAP/APWM operating mode select Reset type: SYSRSn 0h (R/W) = ECAP module operates in capture mode. This mode forces the following configuration: - Inhibits TSCTR resets via CTR = PRD event - Inhibits shadow loads on CAP1 and 2 registers - Permits user to enable CAP1-4 register load - CAPx/APWMx pin operates as a capture input 1h (R/W) = ECAP module operates in APWM mode. This mode forces the following configuration: - Resets TSCTR on CTR = PRD event (period boundary - Permits shadow loading on CAP1 and 2 registers - Disables loading of time-stamps into CAP1-4 registers - CAPx/APWMx pin operates as a APWM output
8	SWSYNC	R-0/W1S	0h	Software-forced Counter (TSCTR) Synchronizer. This provides the user a method to generate a synchronization pulse through software. In APWM mode, the synchronization pulse can also be sourced from the CTR = PRD event. Reset type: SYSRSn 0h (R/W) = Writing a zero has no effect. Reading always returns a zero 1h (R/W) = Writing a one forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to a zero.
7-6	SYNCO_SEL	R/W	0h	Sync-Out Select Reset type: SYSRSn 0h (R/W) = sync out signal is SWSYNC 1h (R/W) = Select CTR = PRD event to be the sync-out signal. Note: Selection CTR = PRD is meaningful only in APWM mode 2h (R/W) = Disable sync out signal 3h (R/W) = Disable sync out signal
5	SYNCI_EN	R/W	0h	Counter (TSCTR) Sync-In select mode Reset type: SYSRSn 0h (R/W) = Disable sync-in option 1h (R/W) = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCI signal or a S/W force event.
4	TSCTRSTOP	R/W	0h	Time Stamp (TSCTR) Counter Stop (freeze) Control Reset type: SYSRSn 0h (R/W) = TSCTR stopped 1h (R/W) = TSCTR free-running
3	REARM	R-0/W1S	0h	Re-Arming Control. Note: The re-arm function is valid in one shot or continuous mode Reset type: SYSRSn 0h (R/W) = Has no effect (reading always returns a 0) 1h (R/W) = Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to zero 2) Unfreezes the Mod4 counter 3) Enables capture register loads

Copyright © 2025Texas Instruments

Table 25-24. ECCTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-1	STOP_WRAP	R/W	3h	Stop value for one-shot mode. This is the number (between 1-4) of captures allowed to occur before the CAP(1-4) registers are frozen, that is, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1-4) of the capture register in which the circular buffer wraps around and starts again. Notes: STOP_WRAP is compared to Mod4 counter and, when equal, 2 actions occur: - Mod4 counter is stopped (frozen) - Capture register loads are inhibited In one-shot mode, further interrupt events are blocked until re-armed. Reset type: SYSRSn 0h (R/W) = Stop after Capture Event 1 in one-shot mode Wrap after Capture Event 1 in continuous mode. 1h (R/W) = Stop after Capture Event 2 in one-shot mode Wrap after Capture Event 2 in continuous mode. 2h (R/W) = Stop after Capture Event 3 in one-shot mode Wrap after Capture Event 3 in continuous mode. 3h (R/W) = Stop after Capture Event 4 in one-shot mode Wrap after Capture Event 4 in continuous mode.
0	CONT_ONESHT	R/W	0h	Continuous or one-shot mode control (applicable only in capture mode) Reset type: SYSRSn 0h (R/W) = Operate in continuous mode 1h (R/W) = Operate in one-Shot mode

10 ECEINT Register (Offset = 2Ch) [Reset = 0000h]

ECEINT is shown in Figure 25-28 and described in Table 25-16.

Return to the Summary Table.

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers.
The proper procedure for configuring peripheral modes and interrupts is as follows:
- Disable global interrupts
- Stop eCAP counter
- Disable eCAP interrupts
- Configure peripheral registers
- Clear spurious eCAP interrupt flags
- Enable eCAP interrupts
- Start eCAP counter
- Enable global interrupts

25.9.3 ECAP_SIGNAL_MONITORING Registers

Table 25-21 lists the memory-mapped registers for the ECAP_SIGNAL_MONITORING registers. All register offset addresses not listed in Table 25-21 should be considered as reserved locations and the register contents should not be modified.

Table 25-35. ECAP_SIGNAL_MONITORING Registers

Offset	Acronym	Register Name	Protection
0h	MUNIT_COMMON_CTL	Control registers for monitoring unit {#}	
40h	MUNIT_1_CTL	Control registers for monitoring unit 1	
44h	MUNIT_1_SHADOW_CTL	Shadow control registers for monitoring unit 1	
50h	MUNIT_1_MIN	Min value for monitoring unit 1	
54h	MUNIT_1_MAX	Max value for monitoring unit 1	
58h	MUNIT_1_MIN_SHADOW	Shadow register for Min value of monitoring unit 1	
5Ch	MUNIT_1_MAX_SHADOW	Shadow register for Max value of monitoring unit 1	
60h	MUNIT_1_DEBUG_RANGE_MIN	Observed Min value of check being enabled on minotoring unit 1	
64h	MUNIT_1_DEBUG_RANGE_MAX	Observed Max value of check being enabled on minotoring unit 1	
80h	MUNIT_2_CTL	Control registers for monitoring unit 2	
84h	MUNIT_2_SHADOW_CTL	Shadow control registers for monitoring unit 2	
90h	MUNIT_2_MIN	Min value for monitoring unit 2	
94h	MUNIT_2_MAX	Max value for monitoring unit 2	
98h	MUNIT_2_MIN_SHADOW	Shadow register for Min value of monitoring unit 2	
9Ch	MUNIT_2_MAX_SHADOW	Shadow register for Max value of monitoring unit 2	
A0h	MUNIT_2_DEBUG_RANGE_MIN	Observed Min value of check being enabled on minotoring unit 2	
A4h	MUNIT_2_DEBUG_RANGE_MAX	Observed Max value of check being enabled on minotoring unit 2	

Complex bit access types are encoded to fit into small table cells. Table 25-22 shows the codes that are used for access types in this section.

Table 25-36. ECAP_SIGNAL_MONITORING Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Chapter 26

High Resolution Capture (HRCAP)

This chapter describes the operation of the high resolution capture (HRCAP) module. The HRCAP submodule described here is part of the Type1 eCAP. HRCAP measures the width of external pulses to a higher degree of accuracy than the eCAP module. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with an HRCAP module of the same type, to determine the differences between types, and for a list of device-specific differences within a type. A detailed description of all referenced functions can be found in the F29x Software Development Kit (F29-SDK) documentation.

26.1 Introduction 4158
26.2 Operational Details 4159
26.3 Known Exceptions 4162
26.4 Software 4163
26.5 HRCAP Registers 4163

26.1 Introduction

Uses for the HRCAP module include:

- Capacitive touch applications
- High-resolution period and duty cycle measurements of pulse train cycles
- Instantaneous speed measurements
- Instantaneous frequency measurements
- Voltage measurements across an isolation boundary
- Distance/sonar measurement and scanning
- Measuring flow

26.1.1 HRCAP Related Collateral

Foundational Materials

- C28x Academy - HRCAP

Getting Started Materials

- *Leveraging High Resolution Capture (HRCAP) for Single Wire Data Transfer Application Report*

26.1.2 Features

The HRCAP module includes the following features:

- Pulse-width capture in either non-high-resolution or high-resolution modes
- Absolute mode pulse-width capture
- Continuous or one-shot capture
- Interrupt on either falling or rising edge
- Continuous mode capture of pulse widths in 4-deep buffer
- Hardware calibration logic for precision high-resolution capture

All of the previous resources are available on any pin using the Input X-BAR.

26.1.3 Description

Improvements from the Type 0 HRCAP are:

- Simplified calibration scheme:
  - HRCAP is always functional; never offline to perform calibration
  - Calibration is always running in the background; drastically reduced software overhead to calibrate
- Reduced software overhead to compute fractional bits
- Fractional and integer portions are packed into 32 bits
- All eCAP hardware is accessible when using the HRCAP enhancements. See Section 26.3 for practical considerations.
- Usage of the HRCAP is now unified with the eCAP

The HRCAP enhancement has been added to eCAP 5 and eCAP 6 to allow signals to be captured asynchronously to SYSCLK. Each HRCAP submodule includes one capture channel in addition to a hardware calibration block. All eCAP hardware is accessible when using the HRCAP enhancements; however, using the Event Filter or the Input Qualifier is not valid, as these are synchronous to SYSCLK.

Each HRCAP-capable channel has the following independent key resources:

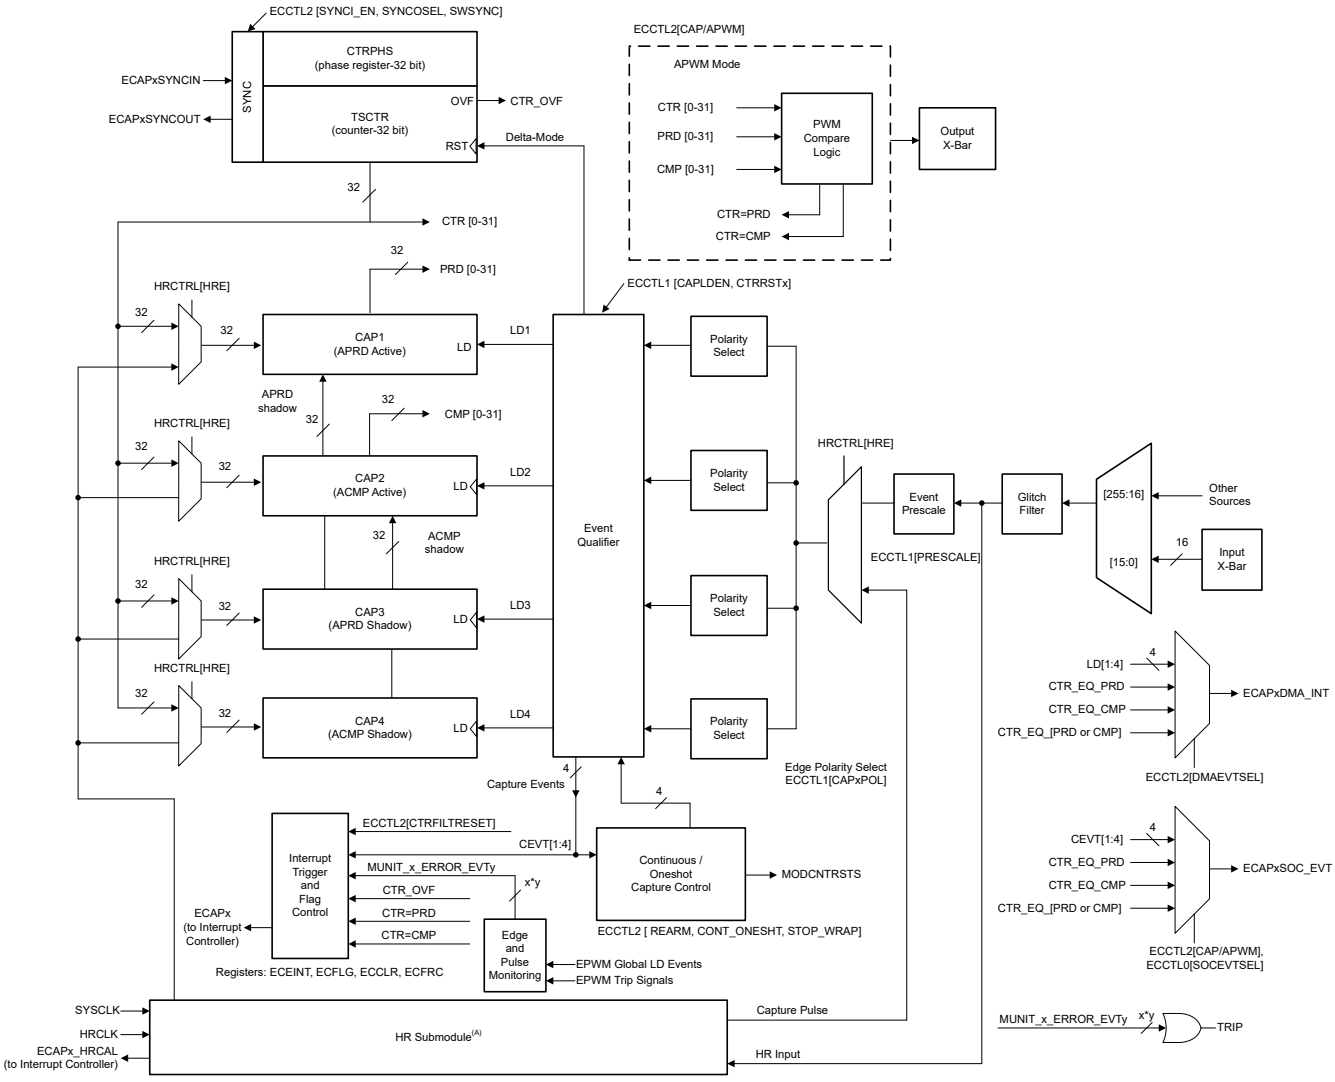
- All hardware of the respective eCAP
- High-resolution calibration logic
- Dedicated calibration interrupt

Copyright © 2025Texas Instruments

26.2 Operational Details

Figure 26-1 shows the various components that implement the high-resolution capture functionality of the eCAP module. Note that existing eCAP resources are reused, which requires that the eCAP module is set up before using the HRCAP enhancements. For simplicity, absolute timestamp measurements are recommended. See Section 26.3 for more details.

All HRCAP measurements are relative-time measures, in terms of minimum step size. Calibration hardware as well as software functions, have been provided to convert relative-time measurements to time-converted measurements in terms of seconds. The calibration hardware and software is only required if time-converted measurements are required.



Note

The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

Figure 26-1. HRCAP Operations Block Diagram

Copyright © 2025Texas Instruments

26.2.1 HRCAP Clocking

Unlike previous Type-0 HRCAP modules, the Type-1 eCAP, with HRCAP functionality, does not require a second PLL. However, the module still requires both SYSCLK and a second asynchronous clock source called HRCLK. The HRCLK is sensitive to changes in both temperature and voltage. For this reason, when using time-converted measurements, it is required to make periodic continuous calibrations.

26.2.2 HRCAP Initialization Sequence

Following are the HRCAP initialization sequence steps. When using the HRCAP to take relative-time measurements, only steps 1-5 are required. When using the HRCAP to take time-converted measurements, all steps are required.

1. Enable HRCLK using HRCAP_enableHighResolutionClock()
2. Delay 1µs
3. Enable HR mode using HRCAP_enableHighResolution()
4. Delay 1µs
5. Configure the eCAP module as desired, including interrupts
6. Set calibration period using HRCAP_setCalibrationPeriod()
7. Enable continuous calibration using HRCAP_setCalibrationMode()
8. Enable interrupts using HRCAP_enableCalibrationInterrupt()
9. Start calibration using HRCAP_startCalibration()

26.2.3 HRCAP Interrupts

The HRCAP enhancements leverage the existing eCAP interrupts (see *Interrupt Control* in the ECAP chapter) in addition to HRCALINT, which is used exclusively by the hardware calibration block. HRCALINT can be triggered by the following conditions:

1. SYSCLKCTR = HRCALIBPERIOD
2. SYSCLKCTR or HRCLKCTR experience an overflow condition

Figure 26-2 shows this logic.

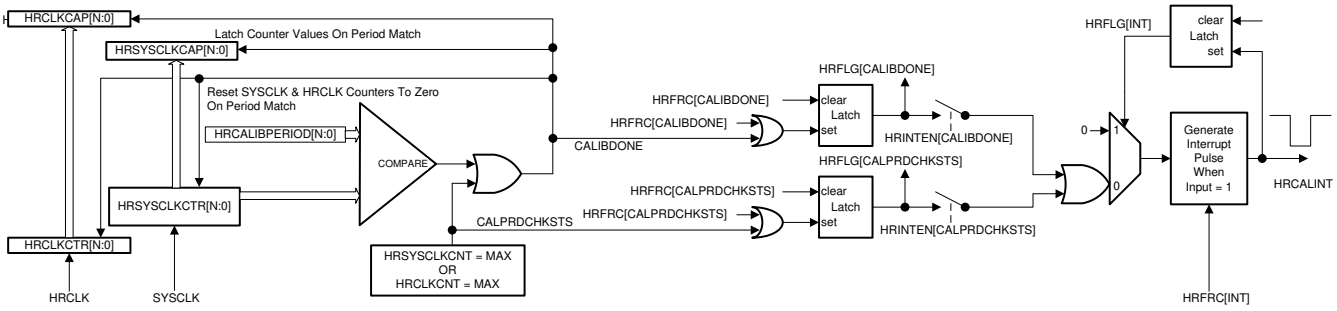


Figure 26-2. HRCAP Calibration

Copyright © 2025Texas Instruments

26.2.4 HRCAP Calibration

Note

For HRCAP calibration to work, the system needs to operate at SYSCLK frequency > 100MHz.

The following section applies only to time-converted measurements; calibration for relative-time measurements is not required. All values captured by the HRCAP submodule are in number of HRCLK cycles. The HRCLK speed varies widely with temperature and voltage, thus a scale factor is required to convert the capture value to the SYSCLK domain. For the same reason, periodically recalculate the scale factor. The HRCAP submodule has a calibration block to reduce software overhead when calculating a scale factor between HRCLK and SYSCLK.

The calibration block contains the following key resources:

- **HRSYSCLKCNT:** A 32-bit counter connected to SYSCLK. The counter starts counting when CALIBSTART is set.
- **HRCLKCNT:** A 32-bit counter connected to HRCLK. The counter starts counting when CALIBSTART is set.
- **HRCALIBPERIOD:** Calibration period, calibration is stopped when HRSYSCLKCNT is equal to the value in this register.
- **HRSYSCLKCAP:** On a calibration period match, the value of HRSYSCLKCNT is captured into HRSYSCLKCAP.
- **HRCLKCAP:** On a calibration period match, the value of HRCLKCNT is captured into HRCLKCAP.
- **HRCALINT:** An interrupt that occurs on a calibration period match, or when one of the counter registers experiences an overflow condition.

The calibration logic consists of two free-running counters; one clocked by HRCLK(HRCLKCTR) and one clocked by SYSCLK(HRSYSCLKCTR). When HRSYSCLKCTR is equal to HRCALIBPERIOD, the calibration block captures and resets both counter values, then triggers an interrupt, indicating a new scale factor is ready to be calculated. The scale factor can be found by dividing HRSYSCLKCAP by HRCLKCAP (see Equation 22). A DriverLib function, HRCAP_getScaleFactor, has been provided to determine the scale factor. This function can be called inside of the calibration interrupt service routine. If one of the counters experiences overflow, the CALPRDCHKSTS flag is set. The full details of the calibration block are described in Figure 26-2.

$$ScaleFactor = \frac{HRSYSCLKCAP}{HRCLKCAP} \quad (22)$$

Note

- Even with calibration, noise on the 1.2V VDD supply negatively affects the standard deviation of the HRCAP submodule. Care can be taken to make sure that the 1.2V supply is clean, and that noisy internal events such as enabling and disabling clock trees have been minimized while using the HRCAP submodule.
- When HRCLK > SYSCLK, calibration stops immaturely to mitigate improper calibration, SYSCLK must be set to at least 100MHz.

Copyright © 2025Texas Instruments

26.2.4.1 Applying the Scale Factor

A DriverLib function has been provided to apply the scale factor to a capture value, HRCAP_getEventTimeStampNanoseconds(). Equation 23 shows how to convert a raw count to seconds without using the DriverLib function.

$$Measurement(ns) = \frac{RawCount \times scaleFactor}{128} * SysClkPrd(ns) \quad (23)$$

Table 26-1. Scale Factor

Parameter	Explanation
RawCount	Capture value as read from ECAP_REGS_CAP1-4
ScaleFactor(1)	The Scale factor as calculated from Equation 23
128	Constant determined by the hardware of the HRCAP submodule
SysClkPrd(nS)	Period of the system clock
Measurement(nS)	Signal converted to nS

(1) The scale factor is not automatically applied to captured values. The user is required to apply the scale factor to all captured values as shown in Equation 23.

26.3 Known Exceptions

In HRCAP mode:

- Enabling and disabling core clocks negatively affects the standard deviation of the HRCAP submodule. Do not enable or disable core clocks while taking measurements.
- TSCTR is not writable; however, TSCTR can be reset using ECCTL2[CTRFILTRESET]
- Input synchronization is not applicable when using the HRCAP enhancements, because the HRCAP submodule is asynchronous to SYSCLK.
- The Event Filter functionality is not applicable for HRCAP, which defeats the purpose of HRCAP as the Event Filter's output is synchronous to SYSCLK.
- The best practice is to use absolute time mode for high-resolution mode. If time difference mode is used, it can lead to inaccurate results if the fractional value is not taken into consideration for capture events that have reset the time base counter.
  - Actual Capture Value = (Capture Value) – (fractional value of reference event that reset the counter)
- For high-frequency input signals, the CPU can not be able to cope with the speed of the captures. In such a case, one-shot mode is recommended. This mode allows the device to capture up to four edges before waiting to be serviced when the CPU is ready. This is applicable for the eCAP as well; however, in that case the event filter can be used to reduce the rate of captures.

26.4 Software

26.4.1 HRCAP Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location: f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/hrcap

Cloud access to these examples is available at the following link: dev.ti.com F29x SDK Examples.

26.4.1.1 HRCAP Capture and Calibration Example - SINGLE_CORE

FILE: hrcap_ex1_capture.c

This example configures an ECAP to use HRCAP functionality to capture time between edges on input GPIO2.

External Connections
The user must provide a signal to GPIO2. XCLKOUT has been configured to an output GPIO and can be externally jumped to serve this purpose. See Sysconfig file for XCLKOUT GPIO selected.

Watch Variables
- onTime1, onTime2
- offTime1, offTime2
- period1, period2

26.5 HRCAP Registers

This Section describes the HRCAP Registers.

26.5.2 HRCAP_REGS Registers

Table 26-3 lists the memory-mapped registers for the HRCAP_REGS registers. All register offset addresses not listed in Table 26-3 should be considered as reserved locations and the register contents should not be modified.

Table 26-3. HRCAP_REGS Registers

Offset	Acronym	Register Name	Protection
0h	HRCTL	High-Res Control Register	
8h	HRINTEN	High-Res Calibration Interrupt Enable Register	
Ch	HRFLG	High-Res Calibration Interrupt Flag Register	
10h	HRCLR	High-Res Calibration Interrupt Clear Register	
14h	HRFRC	High-Res Calibration Interrupt Force Register	
18h	HRCALPRD	High-Res Calibration Period Register	
1Ch	HRSYSCLKCTR	High-Res Calibration SYSCLK Counter Register	
20h	HRSYSCLKCAP	High-Res Calibration SYSCLK Capture Register	
24h	HRCLKCTR	High-Res Calibration HRCLK Counter Register	
28h	HRCLKCAP	High-Res Calibration HRCLK Capture Register	

Complex bit access types are encoded to fit into small table cells. Table 26-4 shows the codes that are used for access types in this section.

Table 26-4. HRCAP_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

Chapter 27

Enhanced Pulse Width Modulator (ePWM)

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipment. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral can also perform a digital-to-analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a power DAC.

This chapter is applicable for ePWM type 5. Type 5 EPWM is fully compatible with type 4 EPWM. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with an ePWM module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

27.1 Introduction

This chapter includes an overview and information about each submodule:

- Time Base (TB) Submodule
- Counter Compare (CC) Submodule
- Action Qualifier (AQ) Submodule
- Dead-Band Generator (DB) Submodule
- PWM Chopper (PC) Submodule
- Trip Zone (TZ) Submodule
- Diode Emulation (DE) Submodule
- Minimum Dead-Band (MINDB) and Illegal Combo Logic (ICL) Submodule
- Event Trigger (ET) Submodule
- Digital Compare (DC) Submodule

The ePWM Type 5 is functionally compatible to Type 4. Type 5 has the following enhancements in addition to the Type 4 features:

- **PWM SYNC Related Enhancements:** Additional external sync option is added in to the EPWMSYNCSEL register. This allows for the configuration of up to 3 independent sync chains with external sync options.
- **Linking and Global Load Enhancements:** DBRED:DBREDHR and DBREDHR and DBFED:DBFEDHR have the ability to be linked across ePWM modules.

  Global load pulse selection for shadow to active load can now occur when the time-base counter equals CMPCU, CMPCD, CMPDU, or CMPDD.
- **XCMP Complex Waveform Generator:** XCMP mode has been added to allow for generation of multiple ePWM pulses, with high resolution, in a given ePWM cycle. Up to 8 new compare registers are added to achieve this functionality.
- **Digital Compare Submodule Enhancements:** Event detection within the digital compare capture module is able to detect an occurrence of a trip event in a configured time window.

  Pulse selection for blanking and capture alignment now includes a blanking window mix selection (BLANKPULSEMIX). This is added for LLC topologies where blanking window settings need to be changed on the fly - providing greater configurability to do this.
- **Trip-Zone Submodule Enhancements:** A CAPEVENT signal can generate a CBC or One-shot trip event.
- **Diode Emulation Submodule:** The diode emulation mode was added to provide hardware features and the necessary hooks into other IPs to implement a robust diode mode sense and control in a noisy environment.
- **Minimum Dead-Band and Illegal Combo Logic Submodule:** The minimum dead-band logic was added to provide the ability to configure the minimum dead-band duration between a complimentary set of ePWMs.

  To detect and make sure that under no circumstances, the ePWM states result in potentially hazardous combinations, a Look Up Table (LUT) has been added that can be used to re-configure the ePWM outputs.
- **Event Trigger Submodule Enhancements:** To enable unevenly spaced over-sampling of the ePWM period, the event trigger module trigger select is modified such that multiple events can trigger SOCA, SOCB, and INT events (ETINTMIX).

The ePWM Type 4 is functionally compatible to Type 2 (a Type 3 does not exist). Type 4 has the following enhancements in addition to the Type 2 features:

- **Register Address Map:** Additional registers are required for new features on ePWM Type 4. The ePWM register address space has been remapped for better alignment and easy usage.
- **Delayed Trip Functionality:** Changes have been added to achieve deadband insertion capabilities to support, for example, delayed trip functionality needed for peak current mode control type application scenarios. This has been accomplished by allowing comparator events to go into the Action Qualifier as a trigger event (Events T1 and T2). If comparator T1 / T2 events are used to edit the PWM, changes to the PWM waveform do not take place immediately. Instead, the waveform synchronizes to the next TBCLK.
- **Dead-Band Generator Submodule Enhancements:** Shadowing of the DBCTL register to allow dynamic configuration changes.

Copyright © 2025Texas Instruments

- **One Shot and Global Load of Registers:** The ePWM Type 4 allows one shot and global load capability from shadow to active registers to avoid partial loads in, for example, multiphase applications. ePWM Type 4 also allows a programmable prescale of shadow to active load events. ePWM Type 4 Global Load can simplify ePWM software by removing interrupts and making sure that all registers are loaded at the same time.
- **Trip-Zone Submodule Enhancements:** Independent flags have been added to reflect the trip status for each of the TZ sources. Changes have been made to the trip-zone submodule to support certain power converter switching techniques like valley switching.
- **Digital Compare Submodule Enhancements:** Blanking window filter register width has been increased from 8 to 16 bits. DCCAP functionality has been enhanced to provide more programmability.
- **PWM SYNC Related Enhancements:** The ePWM Type 4 allows PWM SYNCOUT generation based on CMPC and CMPD events. These events can also be used for PWMSYNC pulse selection.

The ePWM Type 2 is fully compatible to Type 1. Type 2 has the following enhancements in addition to the Type 1 features:

- **High-Resolution Dead-Band Capability:** High-resolution capability is added to dead-band RED and FED in half-cycle clocking mode.
- **Dead-Band Generator Submodule Enhancements:** The ePWM Type 2 has features to enable both RED and FED on either PWM outputs. Provides increased dead band with 14-bit counters and dead-band / dead-band high-resolution registers are shadowed
- **High-Resolution Extension available on ePWMxB outputs:** Provides the ability to enable high-resolution period and duty cycle control on ePWMxB outputs. This is discussed in more detail in Section 27.18 .
- **Counter Compare Submodule Enhancements:** The ePWM Type 2 allows interrupts and SOC events to be generated by additional counter compares CMPC and CMPD.
- **Event Trigger Submodule Enhancements:** Prescaling logic to issue interrupt requests and ADC start of conversion expanded up to every 15 events. This submodule allows software initialization of event counters on SYNC event.
- **Digital Compare Submodule Enhancements:** Digital Compare Trip Select logic [DCTRIPSEL] has up to 12 external trip sources selected by the Input X-BAR logic in addition to an ability to OR all of them (up to 14 [external and internal sources]) to create the respective DCxEVTs.
- **Simultaneous Writes to TBPRD and CMPx Registers:** This feature allows writes to TBPRD, CMPA:CMPAHR, CMPB:CMPBHR, CMPC and CMPD of any ePWM module to be tied to any other ePWM module, and also allows all ePWM modules to be tied to a particular ePWM module if desired.
- **Shadow to Active Load on SYNC of TBPRD and CMP Registers:** This feature supports simultaneous writes of TBPRD and CMPA/B/C/D registers.

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention and must be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel submodules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand the operation quickly.

In this document, the letter x within a signal or submodule name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

Type0 to Type1 Enhancements

- **Increased Dead-Band Resolution:** Dead-band clocking has been enhanced to allow half-cycle clocking to double resolution.
- **Enhanced Interrupt and SOC Generation:** Interrupts and ADC start-of-conversion can now be generated on both the TBCTR == zero and TBCTR == period events. This feature enables dual edge PWM control.

Copyright © 2025Texas Instruments

Additionally, the ADC start-of-conversion can be generated from an event defined in the digital compare submodule.

- **High-Resolution Period Capability:** Provides the ability to enable high-resolution period. This is discussed in more detail in Section 27.18 .
- **Digital Compare Submodule:** The digital compare submodule enhances the event triggering and trip zone submodules by providing filtering, blanking and improved trip functionality to digital compare signals. Such features are essential for peak current mode control and for support of analog comparators.

Note

The name of the sync signal that goes to the CMPSS has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see Table 27-2.

27.1.2 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in Figure 27-1. Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in Section 27.18 . See the device data sheet to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together by way of a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture

Copyright © 2025Texas Instruments

peripheral submodules (eCAP). The number of submodules is device-dependent and based on target application needs. Submodules can also operate standalone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in Figure 27-1. The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected can differ from what is shown in Figure 27-1. See Section 27.4.3.3 for the synchronization scheme for a particular device. Each ePWM module consists of ten submodules and is connected within a system by way of the signals shown in Figure 27-2.

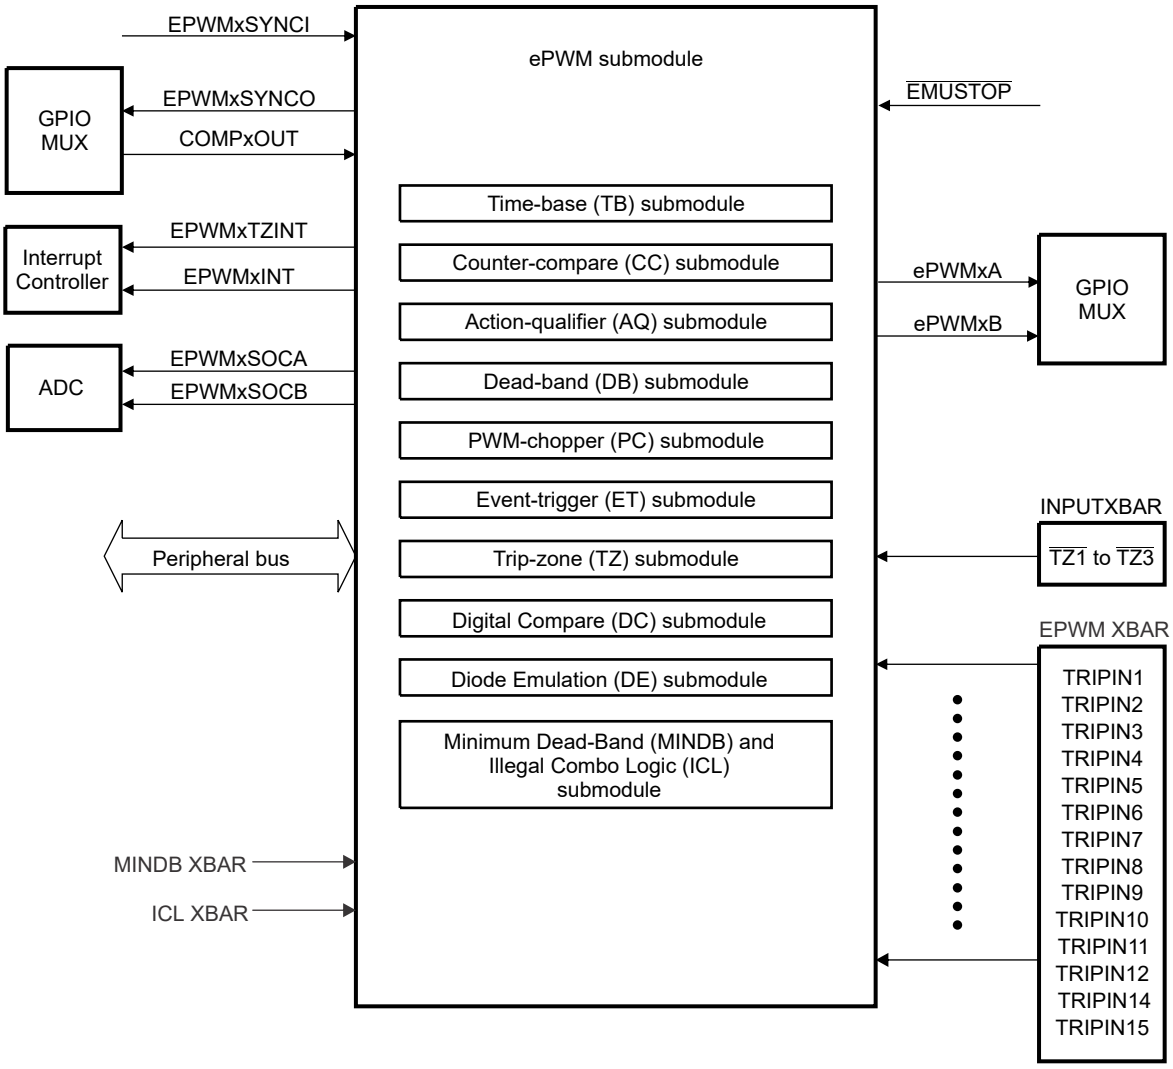

Figure 27-2. Submodules and Signal Connections for an ePWM Module

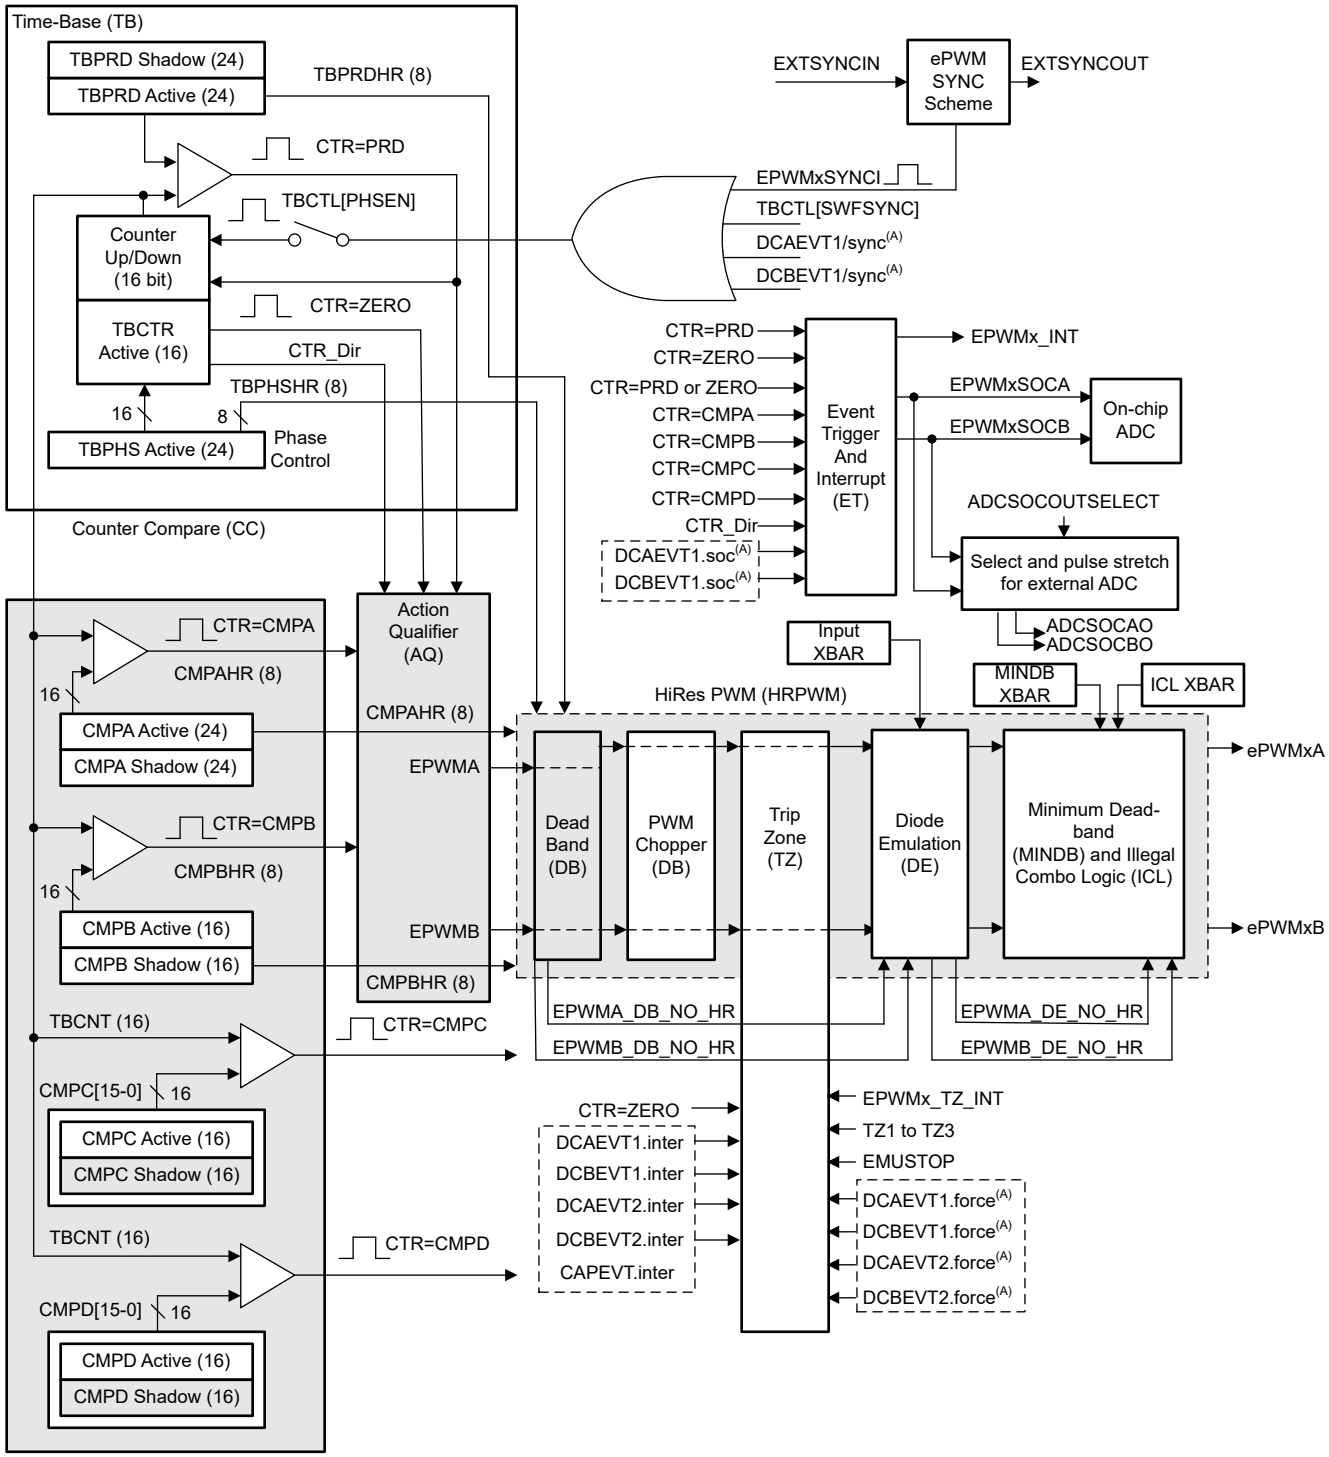
Copyright © 2025Texas Instruments

Figure 27-3 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB):** The PWM output signals are made available external to the device.
- **Trip-zone signals ($\overline{TZ1}$ to $\overline{TZ6}$):** These input signals alert the ePWM module of fault conditions external to the ePWM module. Each submodule on a device can be configured to either use or ignore any of the trip-zone signals. The $\overline{TZ1}$ to $\overline{TZ3}$ trip-zone signals can be configured as asynchronous inputs through the GPIO peripheral using the Input X-BAR logic, refer to Figure 27-75. $\overline{TZ6}$ is connected to the $\overline{EMUSTOP}$ output from the CPU. This allows configuring a trip action when the clock fails or the CPU halts.
- **Time-base synchronization input (EPWMxSYNCI), output (EPWMxSYNCO), and peripheral (EPWMxSYNCPER) signals:** Each ePWM module can be synchronized with other ePWM modules or other peripherals, using EPWMSYNCINSEL. Each ePWM module can also generate a synchronization output signal. The source of the EPWMxSYNCOUT can be selected and enabled by EPWMSYNCOUTEN and TBCTL2.OSHTSYNCMODE. For more information, see Section 27.4.3.3 .

  Each ePWM module also generates another PWMSYNC signal called EPWMxSYNCPER. EPWMxSYNCPER goes to the GPDAC and CMPSS for synchronization purposes. Functionality is configured using the HRPCTL register, but has no relation with the HRPWM. For more information on how EPWMxSYNCPER is used by the GPDAC and CMPSS, see the respective chapters.
- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB):** Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Whichever event triggers the start of conversion is configured in the event-trigger submodule of the ePWM.
- **Comparator output signals (COMPxOUT):** Output signals from the comparator module can be applied through the Input X-BAR and EPWM X-BAR to one or all of the 15 trip inputs [TRIPIN1-TRIPIN15] and in conjunction with the trip zone signals can generate digital compare events.
- **Peripheral bus:** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

Copyright © 2025Texas Instruments



Note

These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

Figure 27-3. ePWM Modules and Critical Internal Signal Interconnects

27.2 Configuring Device Pins

To connect the device input pins to the module, the Input X-BAR and EPWM X-BAR must be used. Some examples of when an external signal can be needed are TZx, TRIPx, and EXTSYNCIN. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to asynchronous mode by setting the appropriate GPxQSEL register bits to 11b. The internal pullups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV GPyPUD register can invert the signals.

The GPIO mux registers must be configured for this peripheral. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

27.3 ePWM Modules Overview

Ten submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

Table 27-1 lists the key submodules together with a list of the main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, see the counter-compare submodule in Section 27.5 for relevant details.

Table 27-1. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time Base (TB)	• Scale the time-base clock (TBCLK) relative to the ePWM clock (EPWMCLK). • Configure the PWM time-base counter (TBCTR) frequency or period. • Set the mode for the time-base counter: – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Simultaneous writes to the TBPRD registers on all PWM's corresponding to the configuration on EPWMXLINKCFG. • Configure how the time-base counter behaves when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module • Configure one shot and global load of registers in this module.
Counter Compare (CC)	• Specify the PWM duty cycle for output EPWMxA and output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output • Specify the programmable delay for interrupt and SOC generation with additional comparators • Simultaneous writes to the CMPA, CMPB, CMPC, CMPD registers on all PWM's corresponding to the configuration on EPWMXLINKCFG. • Configure one shot and global load of registers in this module. • Generate up to four pulses in one ePWM period through the complex waveform (XCMP) mode feature

Copyright © 2025Texas Instruments

Table 27-1. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Action Qualifier (AQ)	• Specify the type of action taken when a time-base counter-compare, trip-zone submodule, or comparator event occurs: – No action taken – Output EPWMxA and EPWMxB switched high – Output EPWMxA and EPWMxB switched low – Output EPWMxA and EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead band through software • Configure one shot and global load of registers in this module.
Dead-Band Generator (DB)	• Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification. • Option to enable half-cycle clocking for double resolution. • Allow ePWMxB phase shifting with respect to the ePWMxA output. • Configure one shot and global load of registers in this module. • Simultaneous writes to the DBRED, DBREDHR, DBFED, DBFEDHR registers on all PWM's corresponding to the configuration on EPWMXLINKCFG.
PWM Chopper (PC)	• Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM chopper module entirely. In this case the PWM waveform is passed through without modification.
Trip Zone (TZ)	• Configure the ePWM module to react to one, all, or none of the trip-zone signals or digital compare events. • Specify the trip action taken when a fault occurs: – Force EPWMxA and EPWMxB high – Force EPWMxA and EPWMxB low – Force EPWMxA and EPWMxB to a high-impedance state – Configure EPWMxA and EPWMxB to ignore any trip condition. • Configure how often the ePWM reacts to each trip-zone signal: – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely. • Programmable option for cycle-by-cycle trip clear • If desired, independently configure trip actions taken when time-base counter is counting down.
Diode Emulation(DE)	• Choose any of the comparator outputs as trips to detect entry into DE mode. • Monitor the DE mode duration and generate a trip event to PWMs. • Ability to switch the comparator thresholds, dynamically in hardware upon DE mode entry. • Cycle-by-cycle and one-shot modes of clearing/de-evaluating the DE condition.
Minimum Dead-Band (MINDB) and Illegal Combo Logic (ICL)	• Add a minimum amount of delay between ePWM channels • Define non-supported output combinations and drive output high or low if combination occurs
Event Trigger (ET)	• Enable the ePWM events that trigger an interrupt. • Enable ePWM events that trigger an ADC start-of-conversion event. • Specify the rate at which events cause triggers (every occurrence or every 2nd or up to 15th occurrence) • Poll, set, or clear event flags

Copyright © 2025Texas Instruments

Table 27-1. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Digital Compare (DC)	• Enables comparator (COMP) module outputs and trip zone signals which are configured using the Input X-BAR to create events and filtered events • Specify event-filtering options to capture TBCTR counter, generate blanking window, or insert delay in PWM output or time-base counter based on captured value.

27.4 Time-Base (TB) Submodule

Each ePWM module has a time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system.

Figure 27-4 illustrates the time-base submodule within the ePWM.

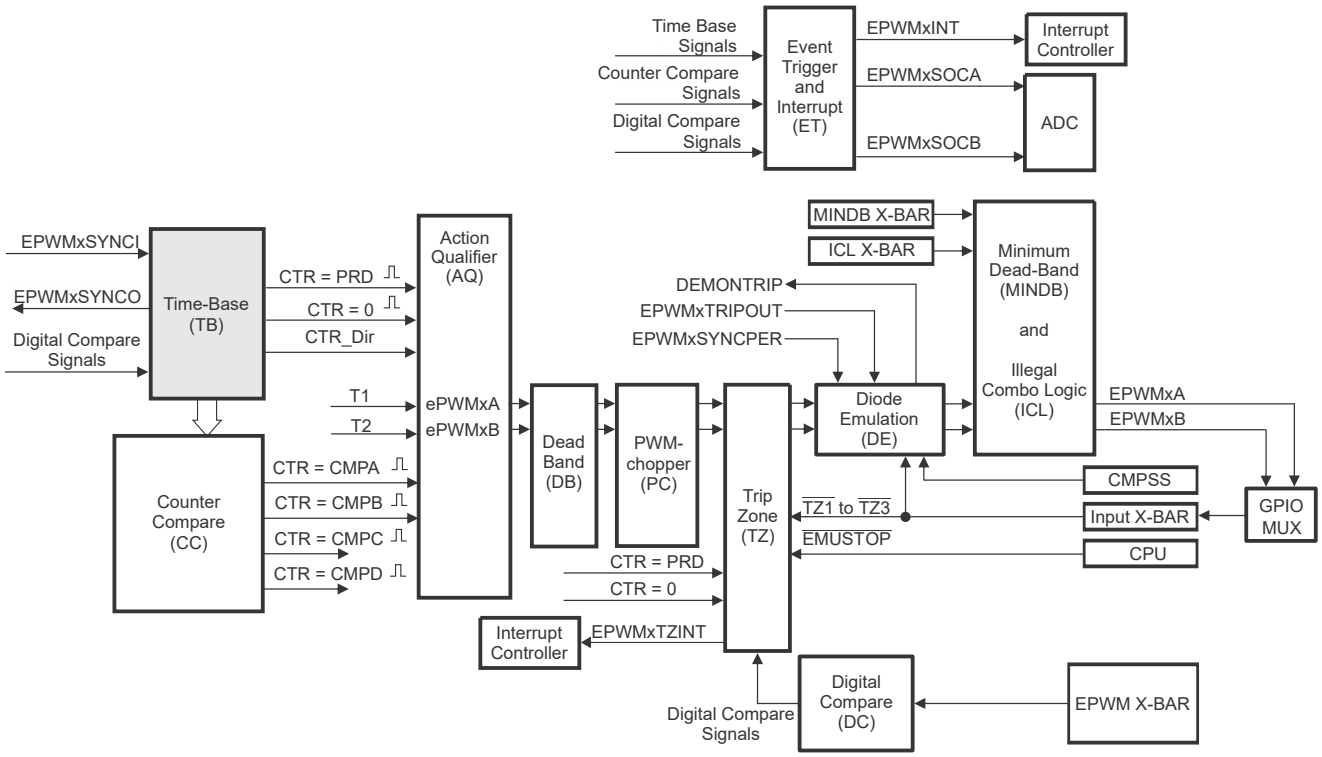

Figure 27-4. Time-Base Submodule

27.4.1 Purpose of the Time-Base Submodule

The time-base submodule can be configured for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00).
- Configure the rate of the time-base clock; a prescaled version of the ePWM clock (EPWMCLK). This allows the time-base counter to increment/decrement at a slower rate.

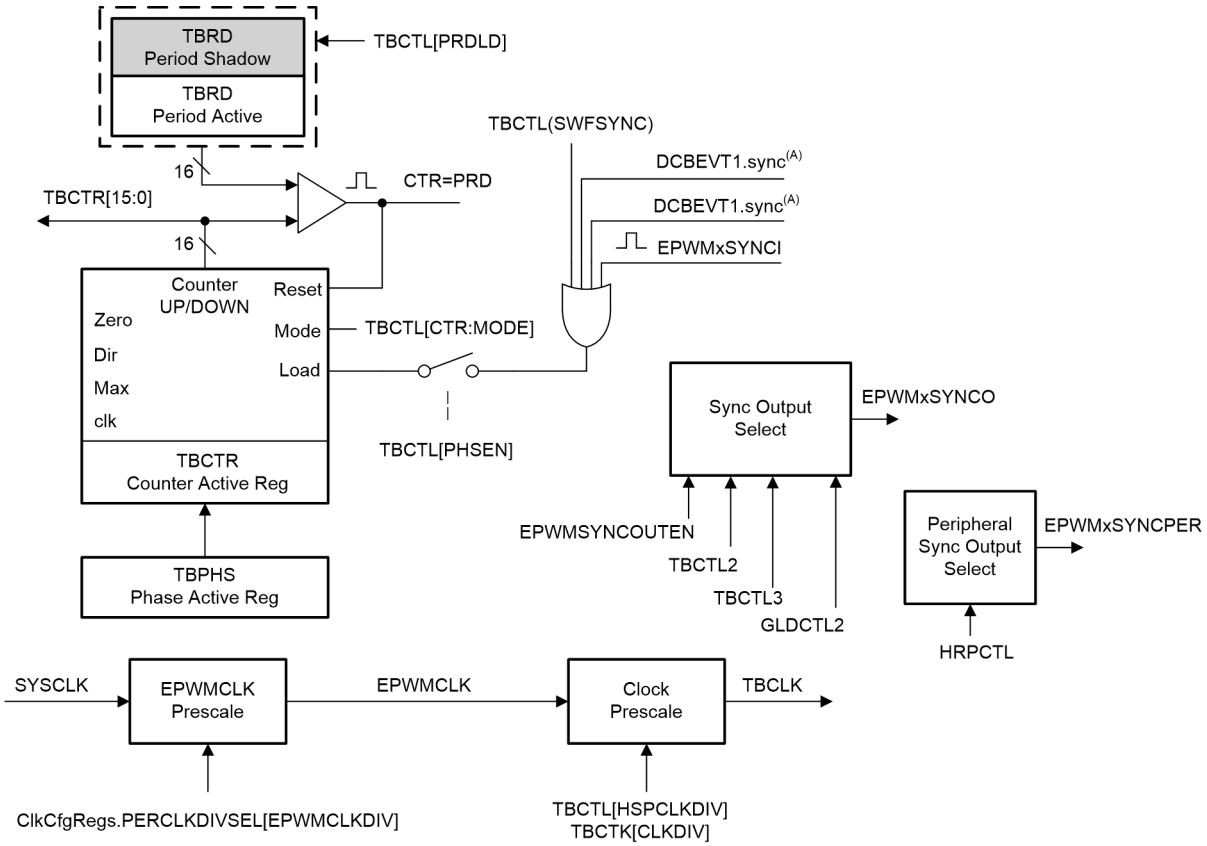
Copyright © 2025Texas Instruments

Note

If required by the application code to update the TBCTR value through software while the TBCTR is counting, note that the time-base module needs at least 1 TBCLK cycle for the time-base related events to be realized. Hence, the TBCTR can be written with TBCTR = PRD-1 instead of TBCTR = PRD (in case the counter is counting up) and can be written as TBCTR = 1 instead of TBCTR = 0 (in case the counter is counting down) for the events to be realized.

27.4.2 Controlling and Monitoring the Time-Base Submodule

The block diagram in Figure 27-5 shows the critical signals and registers of the time-base submodule. Table 27-2 provides descriptions of the key signals associated with the time-base submodule.



A. These signals are generated by the digital compare (DC) submodule.

Figure 27-5. Time-Base Submodule Signals and Registers

Copyright © 2025Texas Instruments

Table 27-2. Key Time-Base Signals

Signal	Description
EPWMxSYNCI	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of other ePWM modules. For more information on all of the signals available for synchronization, see EPWMSYNCINSEL. For information on the synchronization order of a particular device, see Section 27.4.3.3 .
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of other ePWM modules. Using EPWMSYNCOUTEN, TBCTL2, TBCTL3 and GLDCTL2, the source of the output pulse is selected.
EPWMxSYNCPER	Time-base peripheral synchronization output. This output signal is used to synchronize the GPDAC and CMPSS to the EPWM. The output signal can be configured using the HRPCTL register. Note that this signal has no relation with the HRPWM.
CTR = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.
CTR = Zero	Time-base counter equal to zero This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x00.
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCTR = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic
CTR_dir	Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. The signal is high when the counter is increasing and the signal is low when the counter is decreasing.
CTR_max	Time-base counter equal max value. (TBCTR = 0xFFFF) Generated event when the TBCTR value reaches the maximum value. This signal is only used only as a status bit
TBCLK	Time-base clock. This is a prescaled version of the ePWM clock (EPWMCLK) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

Copyright © 2025Texas Instruments

27.4.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 27-6 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the ePWM clock (EPWMCLK).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down Count Mode:** In up-down count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until the counter reaches zero. At this point, the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In up-count mode, the time-base counter starts from zero and increments until the counter reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until the counter reaches zero. When the counter reaches zero, the time-base counter is reset to the period value and begins to decrement once again.

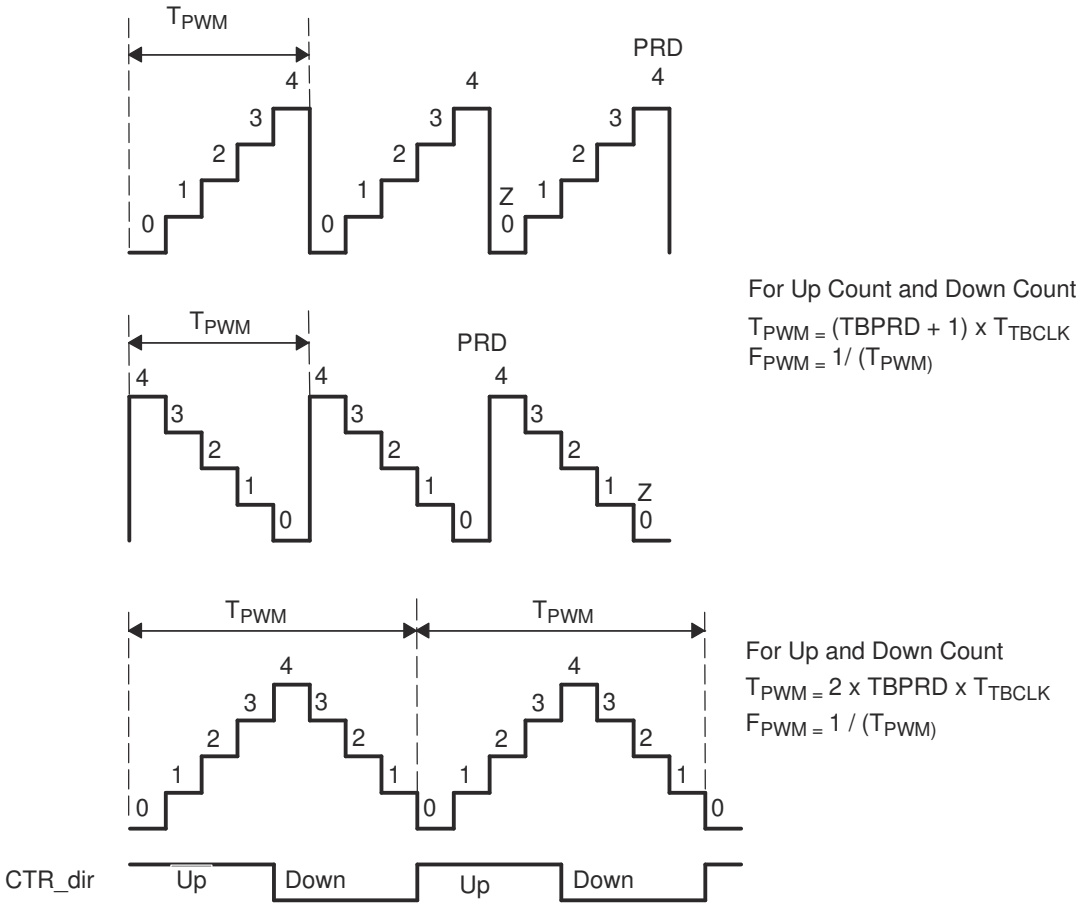


Figure 27-6. Time-Base Frequency and Period

Copyright © 2025Texas Instruments

27.4.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers provide a temporary holding location for the active register and have no direct effect on any control hardware. At a strategic point in time, the shadow register content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDLD] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The TBPRD shadow register is enabled when TBCTL[PRDLD] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x00) and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. The PRDLDSYNC bit is valid only if TBCTL[PRDLD] = 0. By default the TBPRD shadow register is enabled. The sources for the SYNC input is explained in Section 27.4.3.3 .

  The global load control mechanism can also be used with the time-base period register by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL). Global load control mechanism is explained in Section 27.4.7 .
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (TBCTL[PRDLD] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

27.4.3.2 Time-Base Clock Synchronization

The TBCLKSYNC bit in the peripheral clock enable registers allows all users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks in the PCLKCRx register
2. Set TBCLKSYNC = 0
3. Configure ePWM modules
4. Set TBCLKSYNC = 1

In a multicore environment, GTBCLKSYNC can be used to override the core-specific TBCLKSYNC. When GTBCLKSYNC is set, TBCLKSYNC is ignored in all cores and therefore clearing or setting the TBCLKSYNC has no affect. If this feature is not required, GTBCLKSYNC must be cleared. In a multicore environment where different ePWM modules are assigned to different cores, the GTBCLKSYNC bit can be used to enable and disable the Time-Base clock of all ePWM modules simultaneously.

Copyright © 2025Texas Instruments

27.4.3.3 Time-Base Counter Synchronization

The ePWM synchronization scheme allows for increased flexibility of synchronization of the ePWM modules. Each ePWM module has a synchronization input (SYNCI), a synchronization output (SYNCO) and a peripheral synchronization output (SYNCPER). In Figure 27-7, EXTSYNCIN1 is sourced from INPUTXBAR5 and EXTSYNCIN2 is sourced from INPUTXBAR6, which can be configured to select any GPIO as the synchronization input.

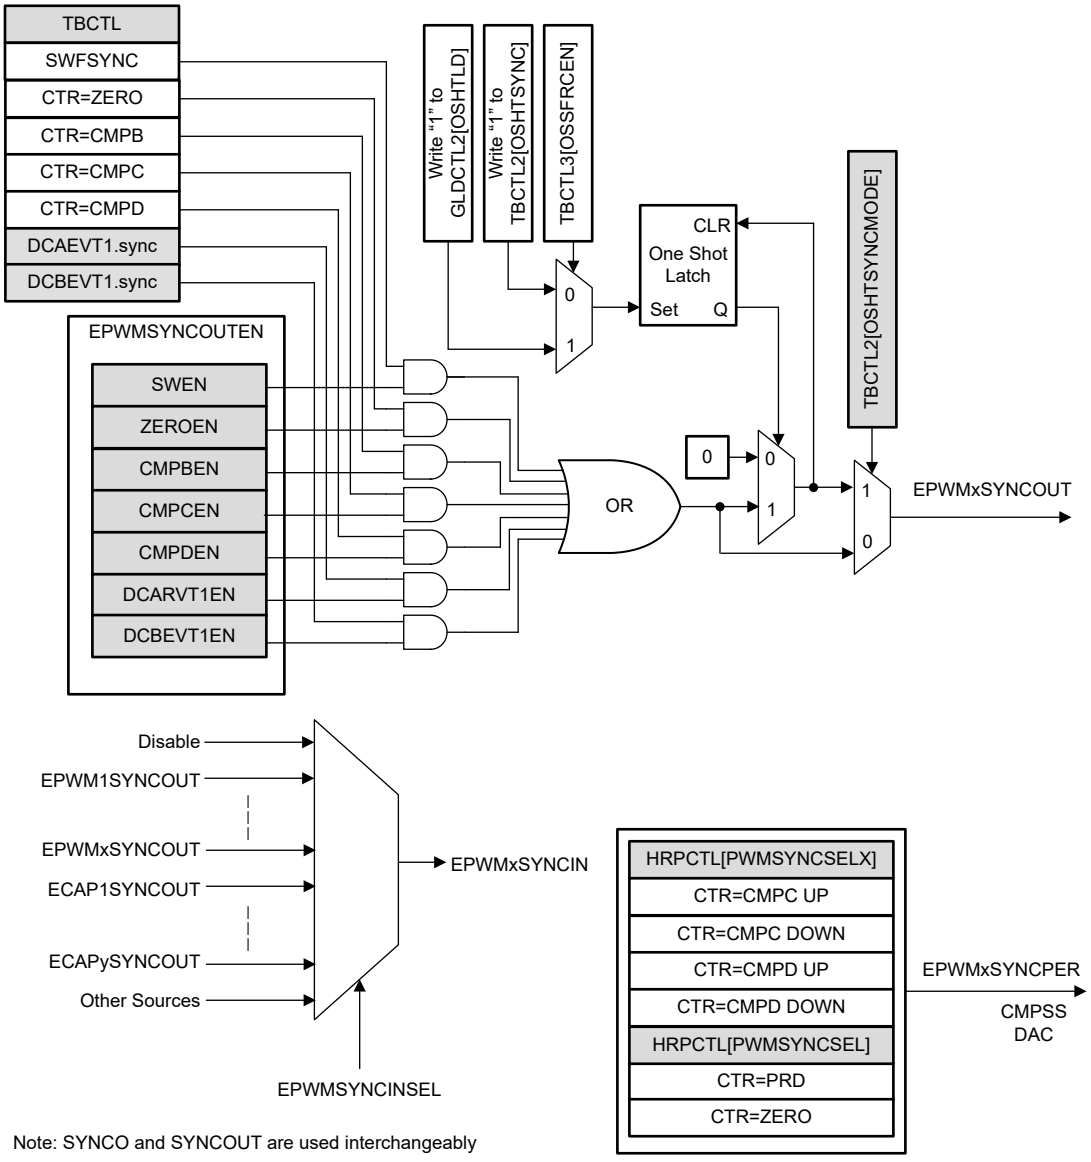

Figure 27-7. Time-Base Counter Synchronization Scheme

Copyright © 2025Texas Instruments

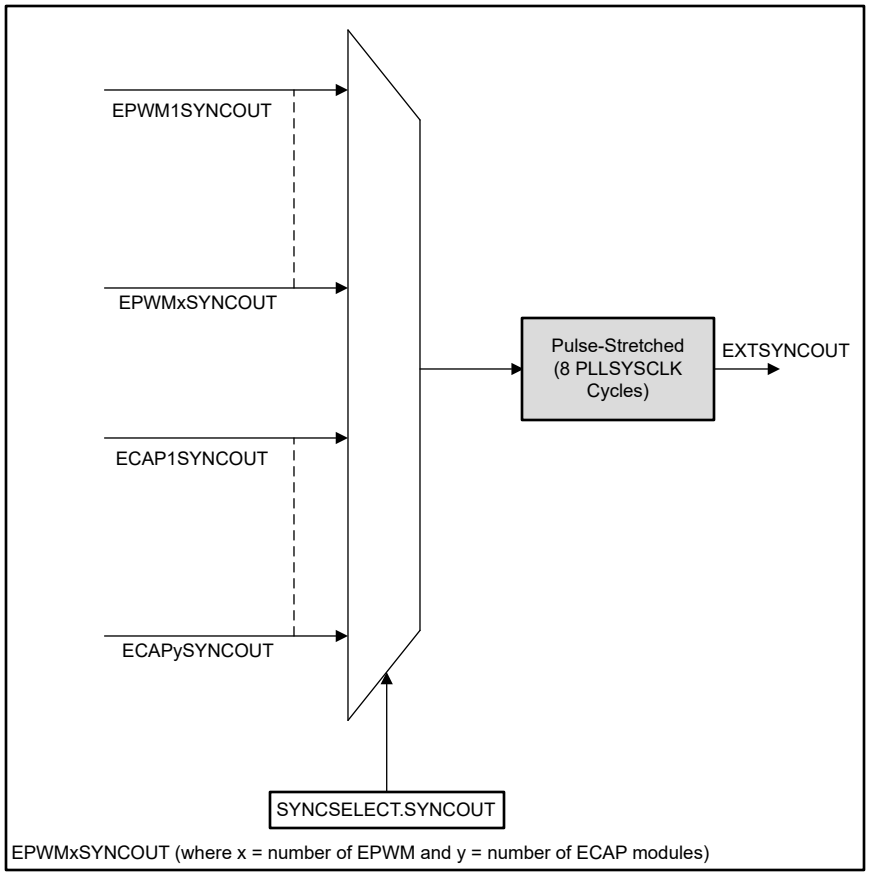

Figure 27-8. ePWM External SYNC Output

Note

See the data sheet for the number of ePWM and eCAP modules available on your specific device.

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module is automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

  The delay from internal control module to target modules is given by:
  - if (TBCLK = EPWMCLK): 2 x EPWMCLK
  - if (TBCLK < EPWMCLK): 1 x TBCLK
- **Software Forced Synchronization Pulse:** Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.
- **Digital Compare Event Synchronization Pulse:** DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCI.

Note

If the EPWMxSYNCI signal is held high, the sync does not continuously occur. The EPWMxSYNCI is rising edge activated. Don't use multiple edges in a PWM cycle if sync functionality is used.

Copyright © 2025Texas Instruments

Note

When modifying the TBPHS register during run-time, missed action qualifier events can occur due to sudden jumps in the TBCTR value at the time of the SYNCIN pulse. To recreate the behavior of missed action qualifier events, configure an action qualifier event on a T1 or T2 event on a SYNCIN event. The T1 or T2 action qualifier event must be enabled and disabled during runtime depending on the value of TBPHS.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PHSDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PHSDIR bit is ignored in count-up or count-down modes. See Figure 27-9 through Figure 27-12 for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse.

27.4.3.4 ePWM SYNC Selection

Table 27-3 specifies the sources for the ePWM SYNC input and output.

27.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. This bit is part of the device's clock enable registers and is described in the *System Control and Interrupts* section of this manual. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is:

1. Enable the individual ePWM module clocks. This is described in the *System Control and Interrupts* chapter.
2. Set TBCLKSYNC = 0. This stops the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKSYNC = 1.

27.4.5 Simultaneous Writes Between ePWM Register Instances

For variable frequency applications, there is a need for simultaneous writes of TBPRD and CMPx registers between ePWM modules. This prevents situations where a CTR = 0 or CTR = PRD pulse forces a shadow to active load of these registers before all registers are updated between ePWM modules (resulting in some registers being loaded from new shadow values while others are loaded from old shadow values). To support this, an ePWM instance linking scheme for all registers in an ePWM instance has been added. There is now a dedicated XLINK region in the memory map to support writes to any of the ePWM registers to reflect in other ePWM instances. All ePWM individual module instances are mirrored to the XLINK region by configuring the SYSCTLs EPWMXLINKCFG Register bit. If multiple ePWM instances have this feature enabled, then any writes in the XLINK region of an ePWM instance reflects to all other ePWM instances that have the ePWM instances enabled. If the write occurs in the individual register memory space, then the update only reflects on that individual ePWM. Any reads to mirrored regions return 0.

Note

Writes to any location that has no ePWM instance mapped to the location still mirror in all locations that are enabled.

Example:

Linking PWMs 1, 2, 3 using Driverlib results in SysCtl_enableEPWMXLINK(SYSCTL_EPWM1_XLINK | SYSCTL_EPWM2_XLINK | SYSCTL_EPWM3_XLINK);

Write to the XLINK region of PWM 1 to write to EPWM 1, 2, 3 using the XLINK_BASE address results in EPWM_setCounterCompareValue(EPWM1XLINK_BASE, EPWM_COUNTER_COMPARE_A, CMPAVAL);

Any writes to the EPWMnXLINK_BASE memory region writes to all other PWMs. If you only want to update an independent PWMs register value, then do not use the XLINK base memory-mapped regions. Following is an example to write to EPWM1 CMPA value independently of other linked PWM 2, 3:

EPWM_setCounterCompareValue(EPWM1_BASE, EPWM_COUNTER_COMPARE_A, CMPAVAL);

Copyright © 2025Texas Instruments

27.4.6 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode that is asymmetrical
- Down-count mode that is asymmetrical
- Up-down-count that is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

27.4.7 Global Load

Figure 27-13 shows the signals and registers associated with the global load feature.

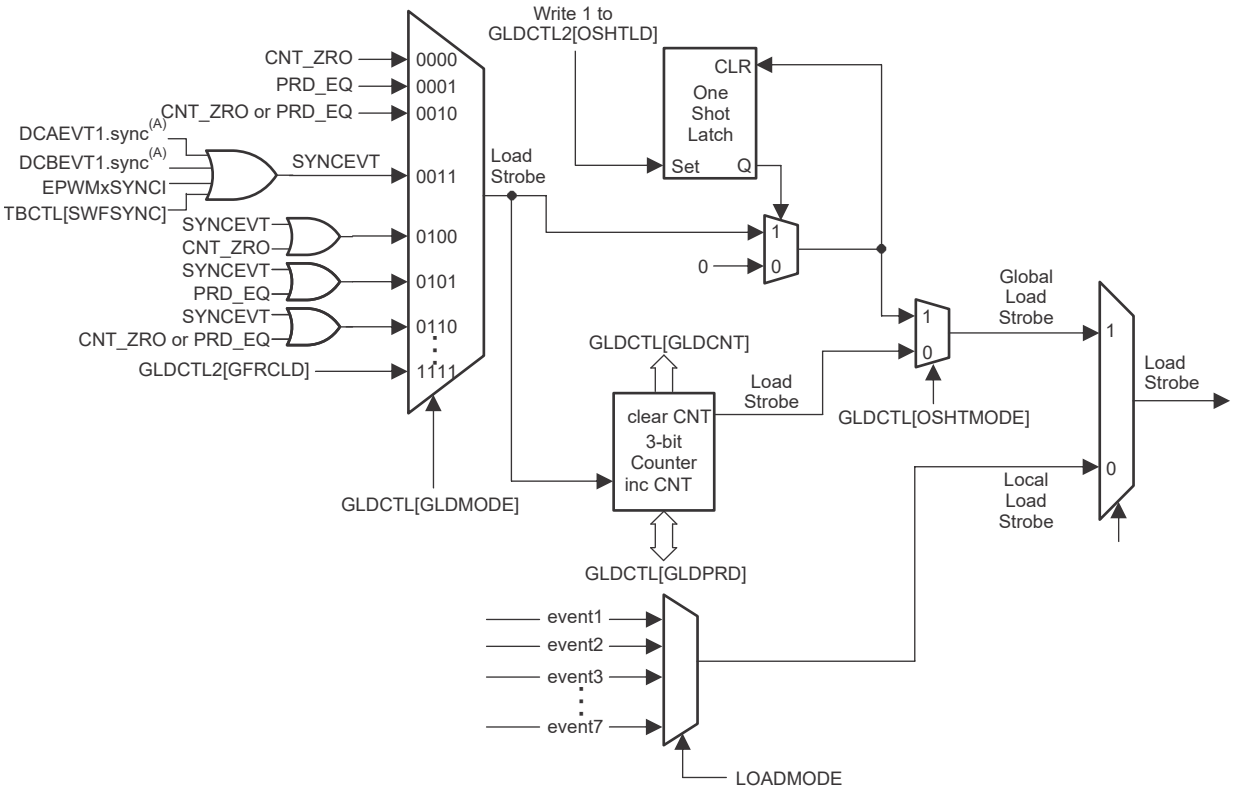

Figure 27-13. Global Load: Signals and Registers

Note

The SYNCEVT signal is only propagated through when PHSEN is SET.

When this feature is enabled, the transfer of contents from the shadow register to the active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL[GLDMODE]). When GLDCTL[GLD] = 1, shadow to active load event selection bits for individual shadowed registers are ignored and global load mode takes effect for the corresponding registers enabled by GLDCFG[REGx].

When GLDCTL[GLD] = 1 and GLDCFG[REGx] = 0, global load mode does not affect the corresponding register (REGx). Shadow to active load event selection bits for individual shadowed registers decide how the transfer of contents from shadow register to active register takes place.

27.4.7.1 Global Load Pulse Pre-Scalar

This feature provides the capability to choose shadow to active transfers to happen once in 'N' occurrences of selected global load pulse (GLDCTL[GLDMODE]). This pre-scale functionality is not available for registers that cannot or are not configured to use the global load mechanism (that is, GLDCTL[GLD] = 0 or GLDCFG[REGx] = 0).

Copyright © 2025Texas Instruments

27.4.7.2 One-Shot Load Mode

Note

Using global load in one-shot load mode, global load of registers may get delayed when a write to the GLDCTL2.OSHTLD register occurs within 3 TBCLKs of the global load event

This feature allows users to cause the shadow register to active register transfers to occur once. When GLDCTL2[OSHTLD] = 1 the shadow to active register transfer, for registers that are configured to use the global load mechanism, takes place on the event selected by GLDCTL[GLDMODE].

Software force loading of contents from shadow register to active register is possible by using GLDCTL2[GFRCLD]. This, along with the one-shot load mode feature discussed above, provides a method to correctly update multiple PWM registers in one or more PWM modules at certain PWM events or, if desired, in the same clock cycle. This is very useful in variable frequency applications and/or multiphase interleaved applications.

27.4.7.3 One-Shot Sync Mode

To enable the one-shot sync mode to generate a SYNCOUT pulse, configure the TBCTL2[OSHTSYNCMODE] bit and set the TBCTL2[OSHTSYNC] bit as shown in Figure 27-14.

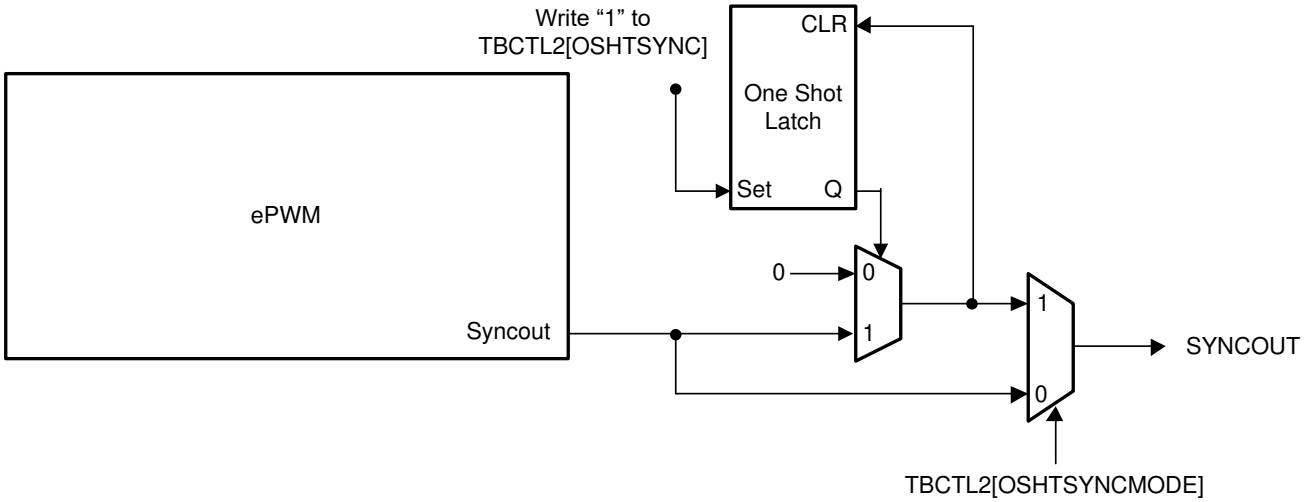

Figure 27-14. One-Shot Sync Mode

27.5 Counter-Compare (CC) Submodule

Figure 27-15 illustrates the counter-compare submodule within the ePWM.

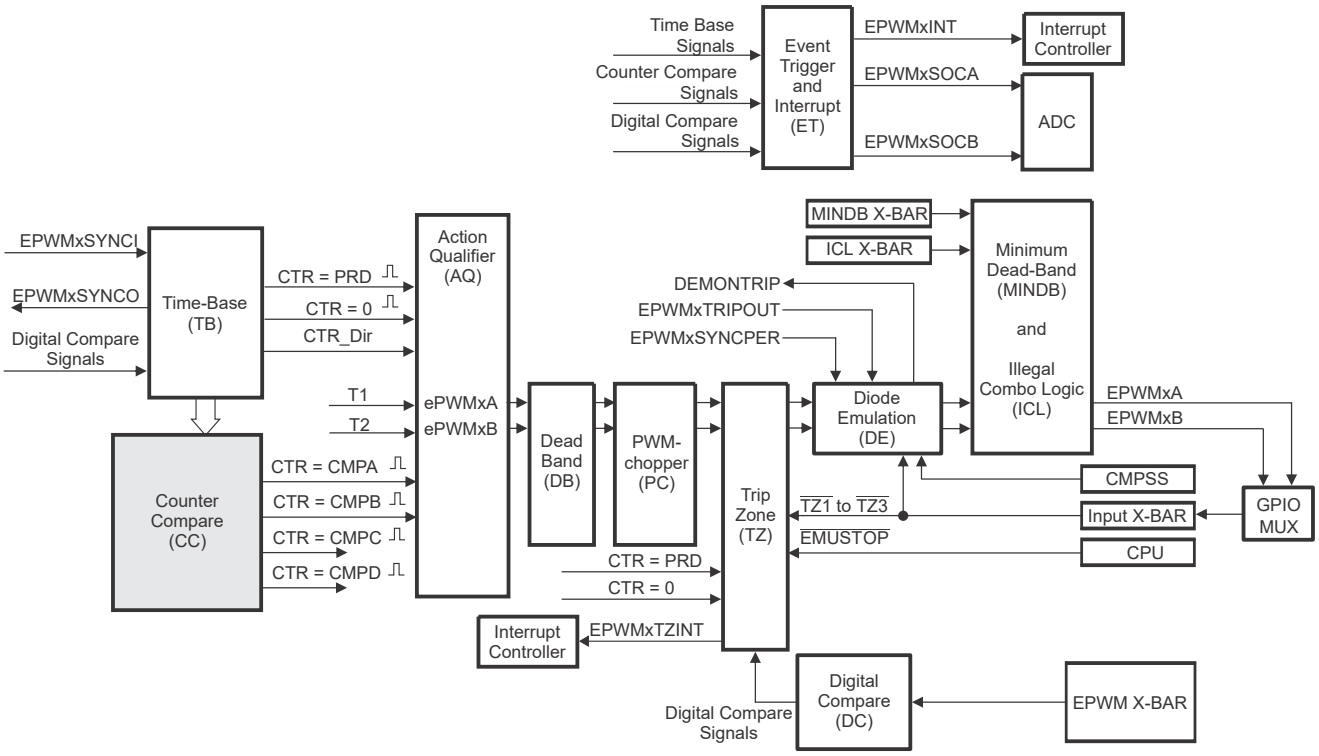

Figure 27-15. Counter-Compare Submodule

27.5.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA), counter-compare B (CMPB), counter-compare C (CMPC), and counter-compare D (CMPD) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

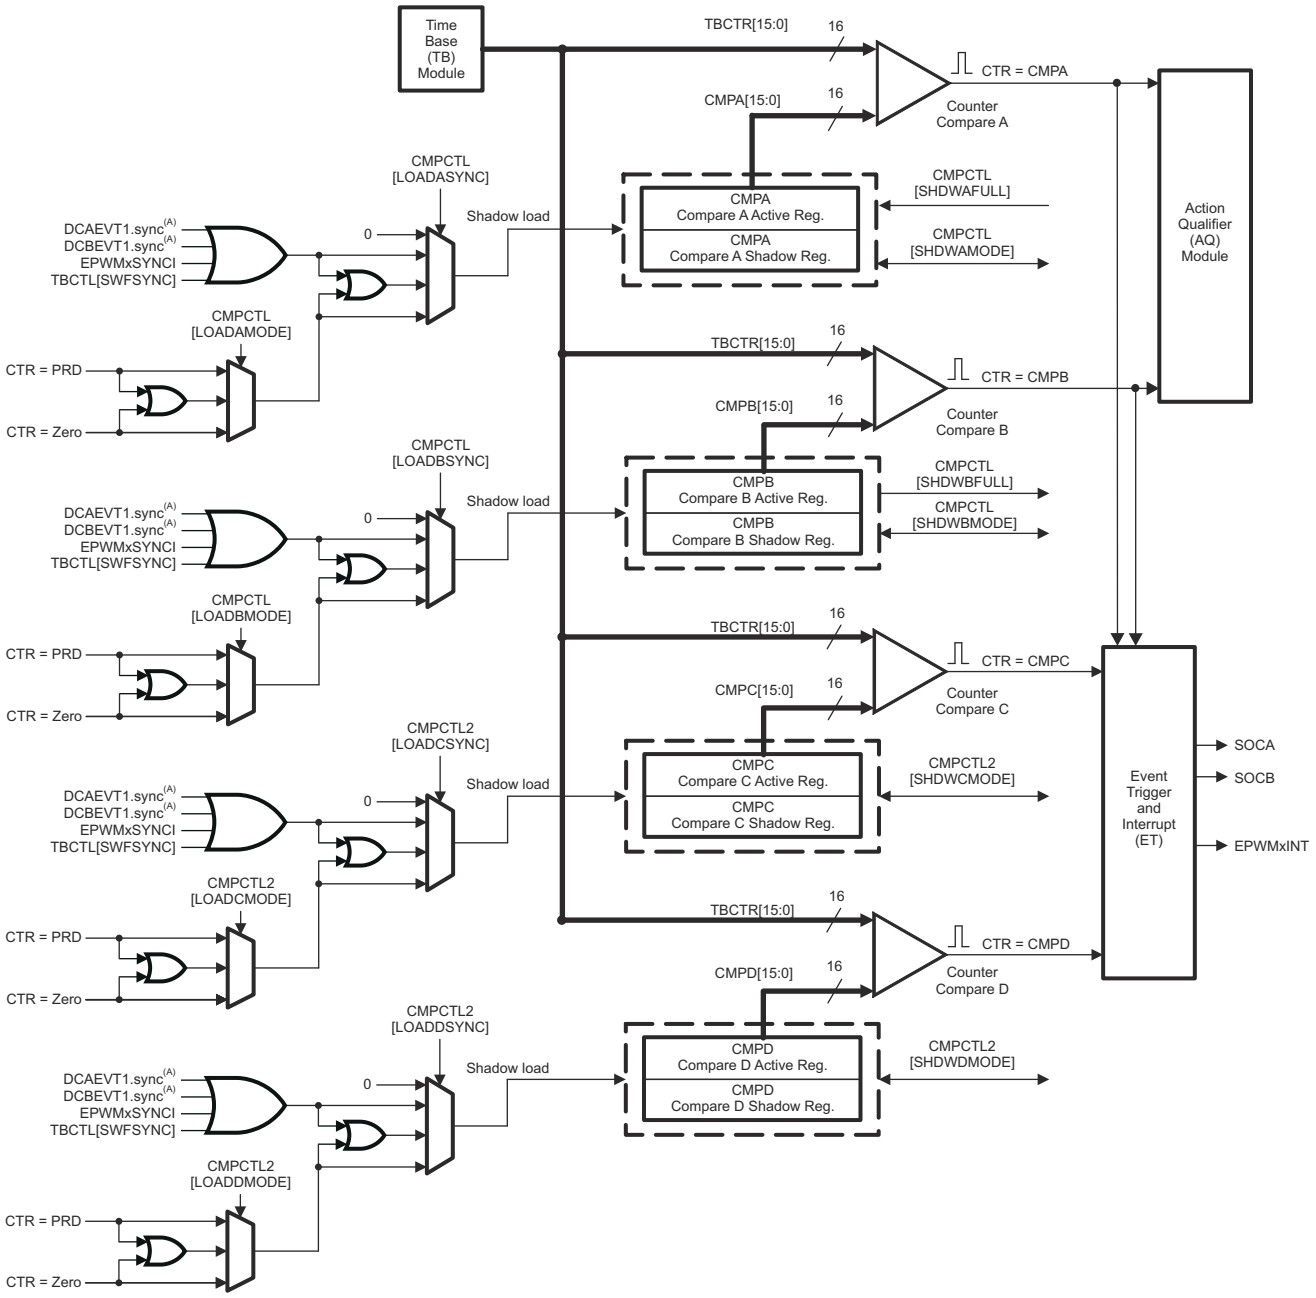
The counter-compare:

- Generates events based on programmable time stamps using the CMPA, CMPB, CMPC, and CMPD registers:
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
  - CTR = CMPC: Time-base counter equals counter-compare C register (TBCTR = CMPC)
  - CTR = CMPD: Time-base counter equals counter-compare D register (TBCTR = CMPD)
- Controls the PWM duty cycle, if the action-qualifier submodule is configured appropriately using counter-compare A (CMPA) and counter-compare B (CMPB)
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

Copyright © 2025Texas Instruments

27.5.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is shown in Figure 27-16.



Note

These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and $\overline{TZ}$ signals).

Figure 27-16. Detailed View of the Counter-Compare Submodule

Copyright © 2025Texas Instruments

27.5.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating events that can be used in the action-qualifier and event-trigger submodules. There are four independent compare events:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).
3. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC). This event can be used to generate an event in the event trigger submodule only.
4. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD). This event can be used to generate an event in the event trigger submodule only

For up-count or down-count mode, each event occurs only once per cycle. For up-down count mode, each event occurs twice per cycle if the compare value is between 0x00-TBPRD; and once per cycle if the compare value is equal to 0x00 or equal to TBPRD. These events are applies to the action-qualifier submodule where the events are qualified by the counter direction and converted into actions if enabled. Refer to Section 27.6.1 for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. The register that is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPC shadow register and CMPD shadow register, respectively. The behavior of the two load modes is:

Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE], CMPCTL[LOADBMODE], CMPCTL[LOADASYNC], and CMPCTL[LOADBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCI or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADAMODE/LOADBMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Note

Refer to Section 27.6.5 for valid configurations of CMPA/CMPB and LOADAMODE/LOADBMODE.

Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL[SHDWAMODE] = 1 or CMPCTL[SHDWBMODE] = 1), then a read from or a write to the register goes directly to the active register.

Copyright © 2025Texas Instruments

Additional Comparators

The counter-compare submodule on ePWMs type 2 and later are responsible for generating two additional independent compare events based on two compare registers, which is fed to Event Trigger submodule:

1. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC).
2. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD).

The counter-compare registers CMPC and CMPD each have an associated shadow register. By default this register is shadowed. The memory address of the active register and the shadow register is identical. The value in the active CMPC and CMPD register is compared to the time-base counter (TBCTR). When the values are equal, the counter compare module generates a “time-base counter equal to counter compare C or counter compare D ” event respectively. Shadowing of this register is enabled and disabled by the CMPCTL2[SHDWCMODE] and CMPCTL2[SHDWDMODE] bit. These bits enable and disable the CMPC shadow register and CMPD shadow register respectively. The behavior of the two load modes is described below:

Shadow Mode:

The shadow mode for the CMPC is enabled by clearing the CMPCTL2[SHDWCMODE] bit and the shadow register for CMPD is enabled by clearing the CMPCTL2[SHDWDMODE] bit. Shadow mode is enabled by default for both CMPC and CMPD.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL2[LOADCMODE], CMPCTL2[LOADDMODE], CMPCTL2[LOADCSYNC], and CMPCTL2[LOADDSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCI or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADCMODE/LOADDMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL2[SHDWCMODE] = 1 or CMPCTL2[SHDWDMODE] = 1), then a read from or a write to the register goes directly to the active register.

Global Load Support

The global load control mechanism can also be used for all counter-compare registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When the global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in Section 27.4.7 .

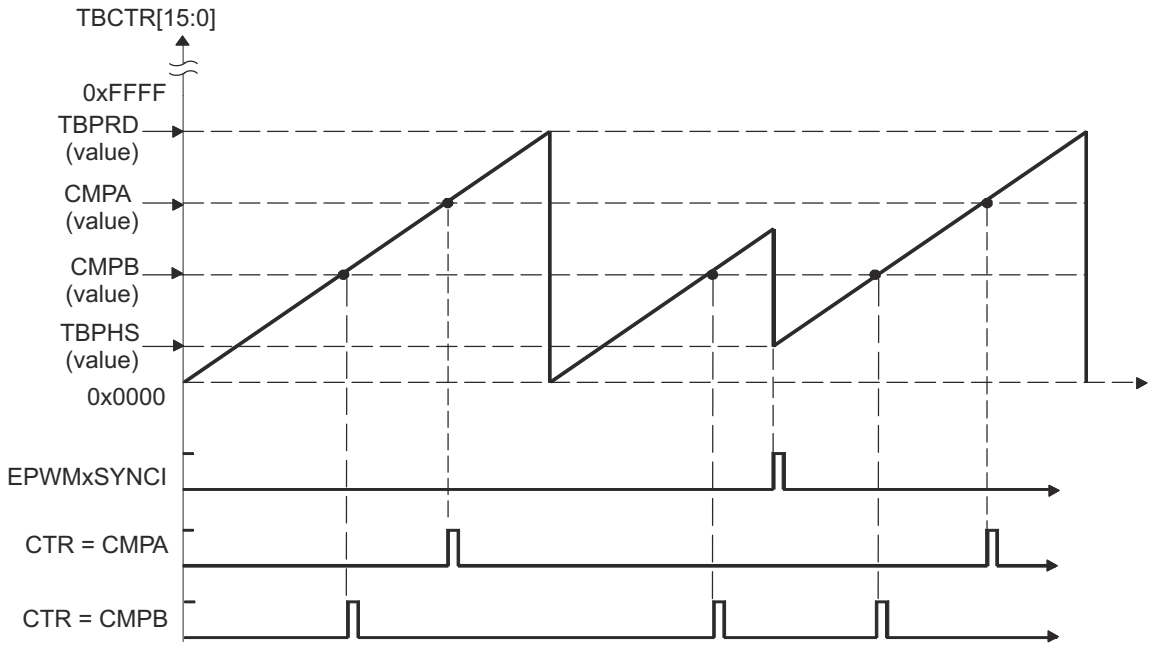
27.5.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in Figure 27-17 through Figure 27-20 show when events are generated and how the EPWMxSYNCI signal interacts.

Copyright © 2025Texas Instruments



Note

An EPWMxSYNCI external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

27.6 Action-Qualifier (AQ) Submodule

The action-qualifier submodule has the most important role in waveform construction and PWM generation. The action-qualifier submodule decides which events are converted into various action types, thereby, producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 27-21 illustrates the action-qualifier submodule within the ePWM.

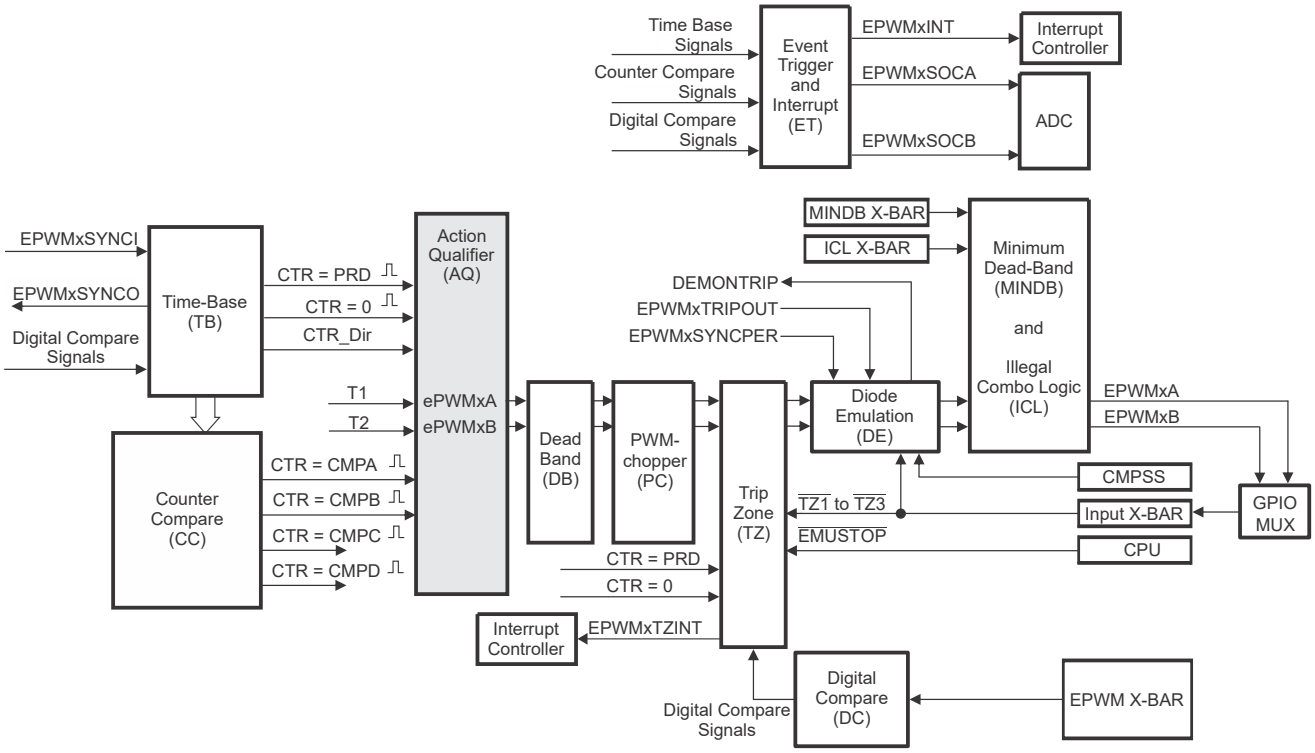

Figure 27-21. Action-Qualifier Submodule

27.6.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- T1, T2 events: Trigger events based on comparator, trip or syncin events
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when the time-base counter is decreasing

Copyright © 2025Texas Instruments

27.6.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is shown in Figure 27-22 and monitored by way of the registers in the *ePWM Registers* section.

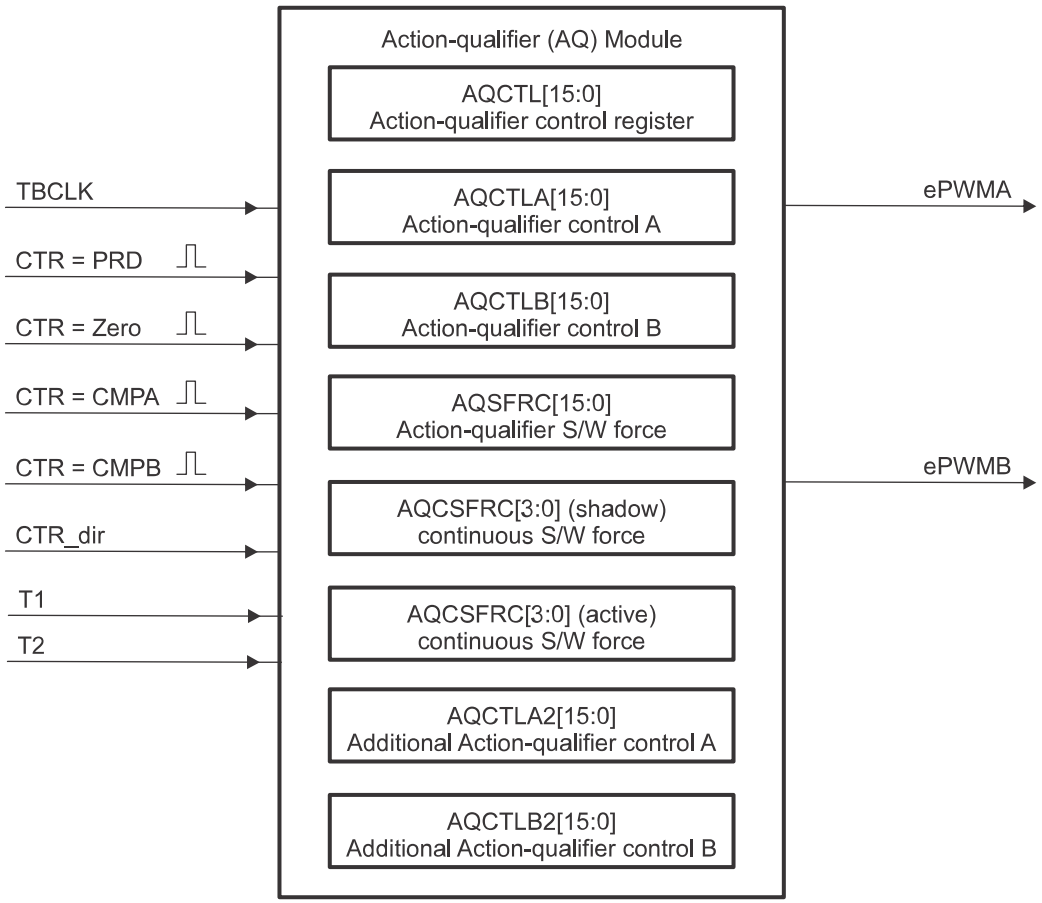

Figure 27-22. Action-Qualifier Submodule Inputs and Outputs

For convenience, the possible input events are summarized again in Table 27-4.

Table 27-4. Action-Qualifier Submodule Possible Input Events

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCTR = TBPRD
CTR = Zero	Time-base counter equal to 0	TBCTR = 0x00
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCTR = CMPB
T1 event	Based on comparator, trip, or syncin events	None
T2 event	Based on comparator, trip, or syncin events	None
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by the AQSFRC and AQCSFRC registers.

Copyright © 2025Texas Instruments

Note

If the CSFA is not used in shadow mode, the RLDCSF bit must be configured to disable shadow mode.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the description in Section 27.13 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured using the control registers found in the *ePWM Registers* section.

For clarity, the illustrations in this chapter use a set of symbolic actions. These symbols are summarized in Figure 27-23. Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and the time positions are programmed by way of the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"(the default at reset).

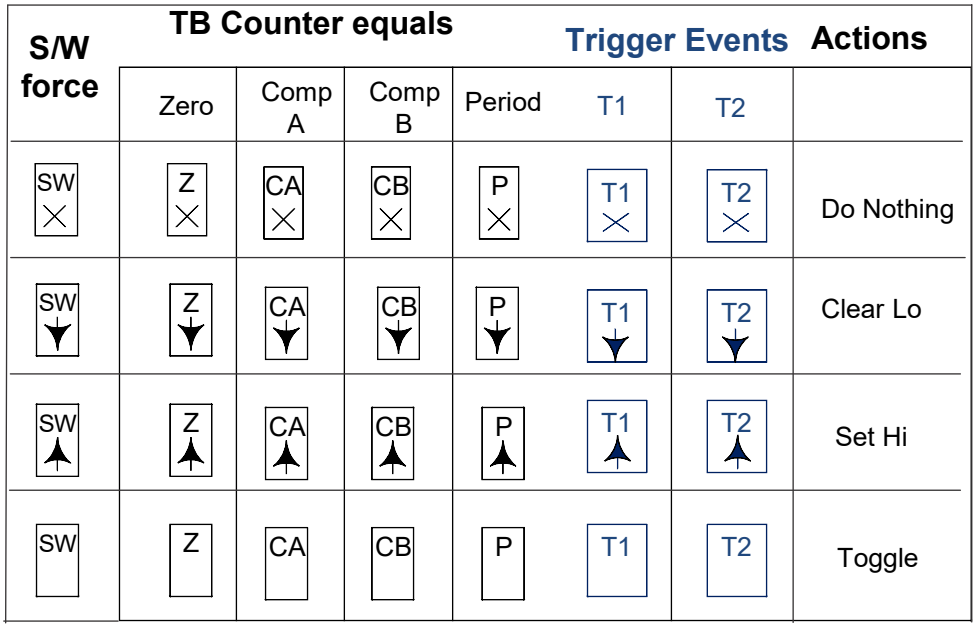

Figure 27-23. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

The Action Qualifier Trigger Event Source Selection register (AQTSRCSEL) is used to select the source for T1 and T2 events. T1/T2 selection and configuration of a trip/digital-compare event in Action Qualifier submodule is independent of the configuration of that event in the Trip-Zone submodule. A particular trip event can or cannot be configured to cause trip action in the Trip Zone submodule, but the same event can be used by the Action Qualifier to generate T1/T2 for controlling PWM generation.

Copyright © 2025Texas Instruments

27.6.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case, events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down count mode are shown in Table 27-5. A priority level of 1 is the highest priority and level 10 is the lowest. The priority changes slightly depending on the direction of TBCTR.

Table 27-5. Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD	Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1
1 (Highest)	Software forced event	Software forced event
2	T1 on up-count (T1U)	T1 on down-count (T1D)
3	T2 on up-count (T2U)	T2 on down-count (T2D)
4	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
5	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
6 (Lowest)	Counter equals zero	Counter equals period (TBPRD)

Table 27-6 shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up; therefore, down-count events never are taken.

Table 27-6. Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	T1 on up-count (T1U)
4	T2 on up-count (T2U)
5	Counter equal to CMPB on up-count (CBU)
6	Counter equal to CMPA on up-count (CAU)
7 (Lowest)	Counter equal to Zero

Table 27-7 shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down; therefore, up-count events never are taken.

Table 27-7. Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	T1 on down-count (T1D)
4	T2 on down-count (T2D)
5	Counter equal to CMPB on down-count (CBD)
6	Counter equal to CMPA on down-count (CAD)
7 (Lowest)	Counter equal to period (TBPRD)

Copyright © 2025Texas Instruments

It is possible to set the compare value greater than the period. In this case, the action takes place as shown in Table 27-8.

Table 27-8. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAD/CBD
Up-Count Mode	If CMPA/CMPB ≤ TBPRD period, then the event occurs on a compare match (TBCTR=CMPA or CMPB).	Never occurs.
	If CMPA/CMPB > TBPRD, then the event does not occur.	
Down-Count Mode	Never occurs.	If CMPA/CMPB < TBPRD, the event occurs on a compare match (TBCTR=CMPA or CMPB).
		If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCTR=TBPRD).
Up-Down Count Mode	If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB).	If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB).
	If CMPA/CMPB is ≥ TBPRD, the event occurs on a period match (TBCTR = TBPRD).	If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCTR=TBPRD).

27.6.4 AQCTLA and AQCTLB Shadow Mode Operations

To enable Action Qualifier mode changes which must occur at the end of a period even when the phase changes, shadowing of the AQCTLA and AQCTLB registers has been added on ePWMs type 2 and later. Additionally, shadow to active load on SYNC of these registers is supported as well. Shadowing of this register is enabled and disabled by the AQCTL[SHDWAQAMODE] and AQCTL[SHDWAQBMODE] bits. These bits enable and disable the AQCTLA shadow register and AQCTLB shadow register, respectively. The behavior of the two load modes is:

Shadow Mode:

The shadow mode for the AQCTLA is enabled by setting the AQCTL[SHDWAQAMODE] bit, and the shadow register for AQCTLB is enabled by setting the AQCTL[SHDWAQBMODE] bit. Shadow mode is disabled by default for both AQCTLA and AQCTLB

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the AQCTL[LDAQAMODE], AQCTL[LDAQBMODE], AQCTL[LDAQASYNC], and AQCTL[LDAQBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCI or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LDAQAMODE/LDAQBMODE

Global Load Support

Global load control mechanism can also be used for AQCTLA:AQCTLA2, AQCTLB:AQCTLB2, and AQCSFRC registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected, the transfer of contents from shadow register to active register for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in Section 27.4.7 .

Immediate Load Mode:

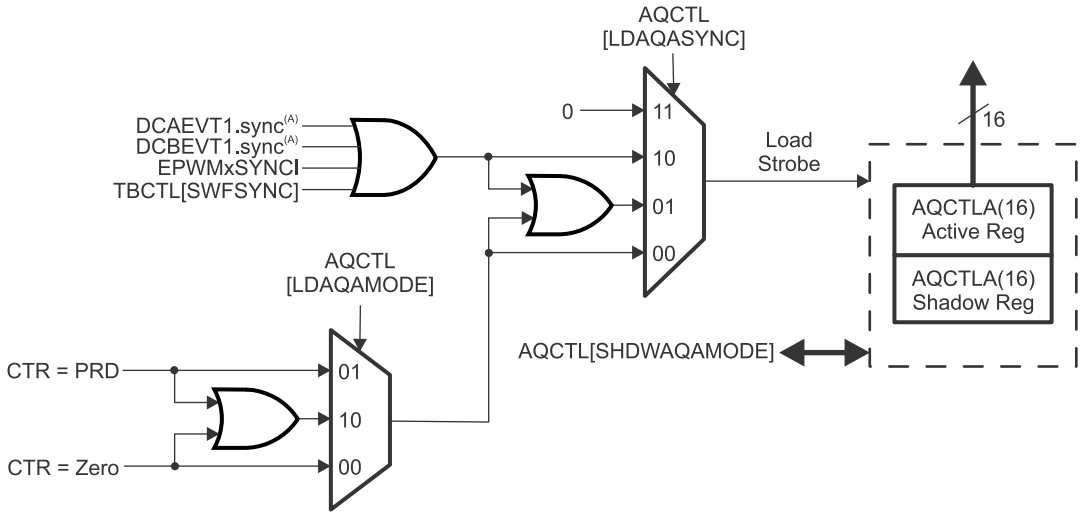
If the immediate load mode is selected (that is, AQCTL[SHDWAQAMODE] = 0 or AQCTL[SHDWAQBMODE] = 0), then a read from or a write to the register goes directly to the active register. See Figure 27-24 and Figure 27-25.

Copyright © 2025Texas Instruments

Note

Shadow to Active Load of Action Qualifier Output A/B Control Register [AQCTLA and AQCTLB] on CMPA = 0 or CMPB = 0 boundary

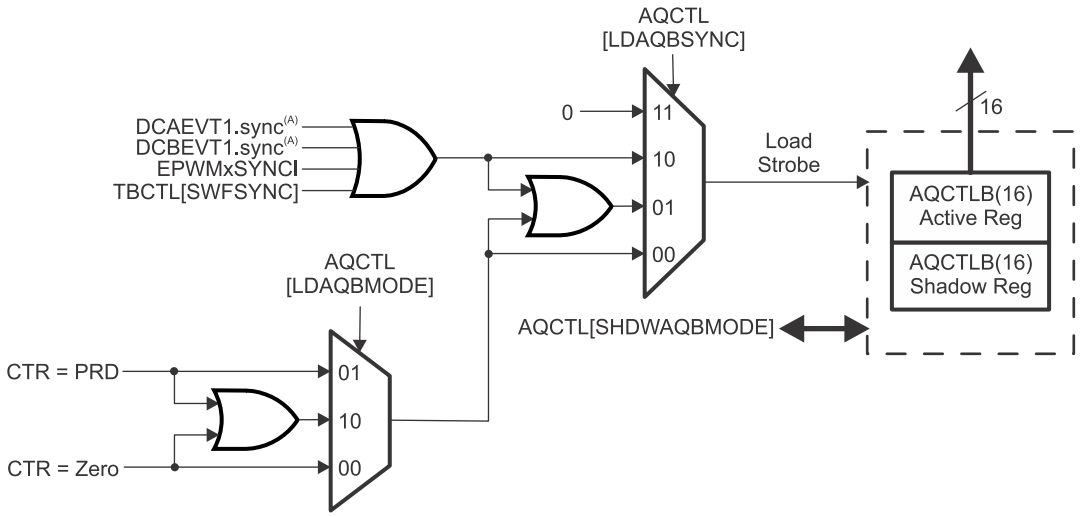
If the Counter-Compare A Register (CMPA) or Counter-Compare B Register (CMPB) is set to a value of 0 and the action qualifier action on AQCTLA and AQCTLB is configured to occur in the same instant as a shadow to active load (that is, CMPA = 0 and AQCTLA shadow to active load on TBCTR = 0 using AQCTL register LDAQAMODE and LDAQAMODE bits), then both events enter contention. It is recommended to use a Non-Zero Counter-Compare when using Shadow to Active Load of Action Qualifier Output A/B Control Register on TBCTR = 0 boundary.



Note

These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and $\overline{TZ}$ signals).

Figure 27-24. AQCTL[SHDWAQAMODE]



Copyright © 2025Texas Instruments

Note

These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and $\overline{TZ}$ signals).

Figure 27-25. AQCTL[SHDWAQBMODE]

27.6.5 Configuration Requirements for Common Waveforms

Note

The waveforms in this chapter show the behavior of the ePWMs for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from the respective shadow registers once every period. Specify when the update takes place: either when the time-base counter reaches zero or when the time-base counter reaches the period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down count mode to generate a symmetric PWM:

- If loading CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If loading CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

  This means there is always a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM, you **must** load CMPA/CMPB on TBPRD. When CMPA/CMPB is not loaded on TBCTR=PRD, boundary conditions can occur depending on the timing of the write and the value written to CMPA/CMPB. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

When using up-count mode to generate an asymmetric PWM with deadband enabled:

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met (CMPX < Deadband) or (CMPX > PRD – Deadband), the actions specified by the AQCTL register for CMPX do not take effect. To avoid this, the AQCTL settings must be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Make sure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

When using up-down count mode to generate an asymmetric PWM with deadband enabled:

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met (CMPX < Deadband/2) or (CMPX > PRD – (Deadband)/2), the actions specified by the AQCTL register for CMPX do not take effect. To avoid this, the AQCTL settings must be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Make sure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

See *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control*.

Figure 27-26 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode, 0%-100% DC modulation is achieved by using equal compare matches on the up

Copyright © 2025Texas Instruments

count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing, the CMPA match pulls the PWM output high. Likewise when the counter is decrementing, the compare match pulls the PWM signal low. When CMPA = 0, the PWM signal is high for the entire period giving a 100% duty waveform. When CMPA = TBPRD, the PWM signal is low achieving 0% duty.

Copyright © 2025Texas Instruments

When using this configuration in practice, if loading CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If loading CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there is always a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

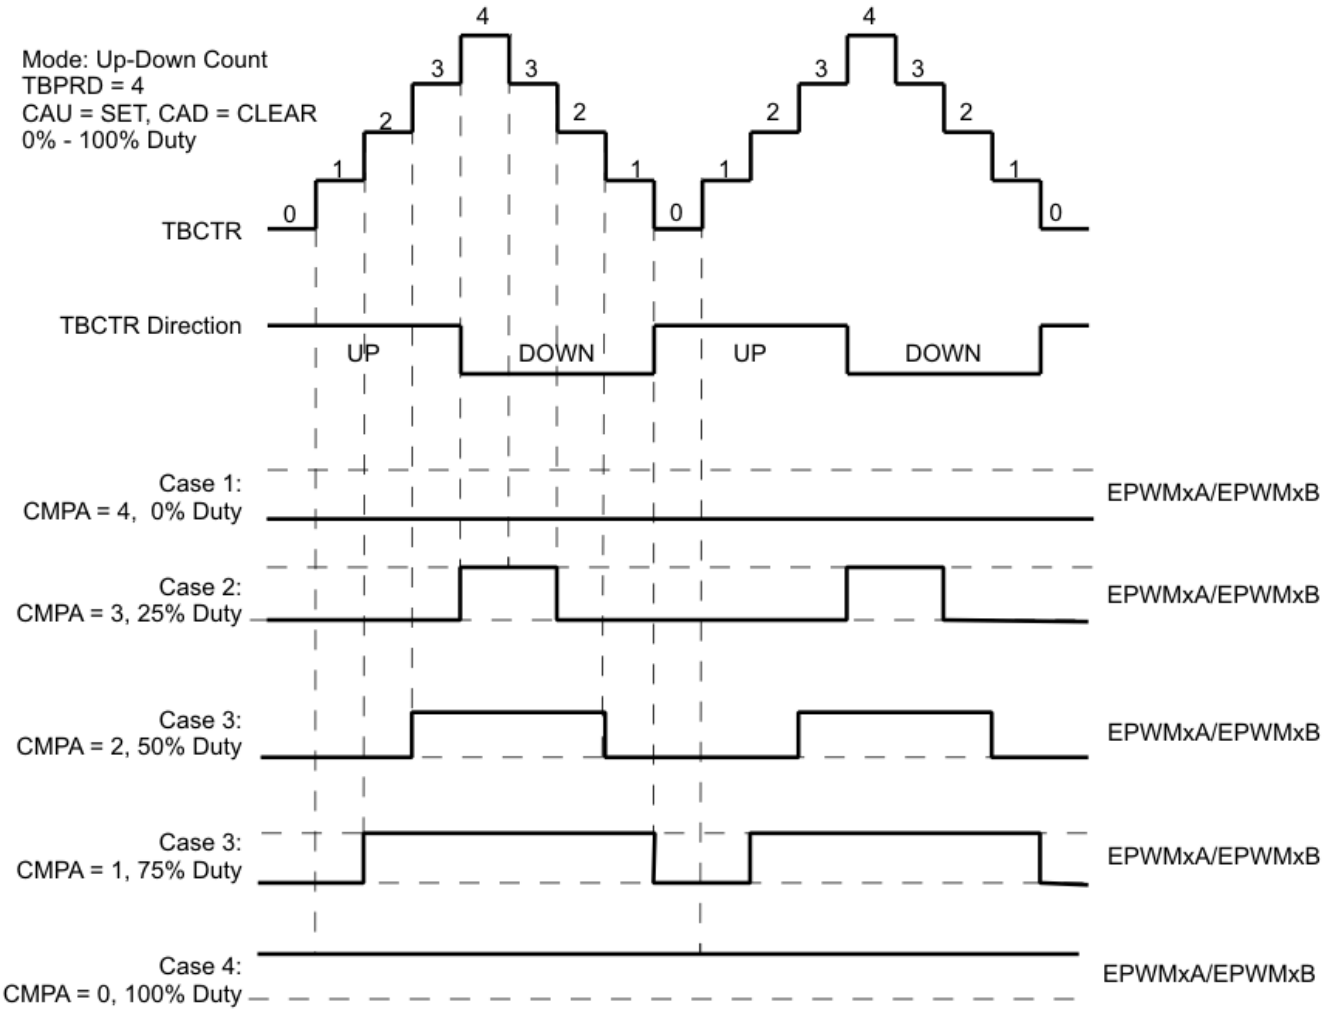


Figure 27-26. Up-Down Count Mode Symmetrical Waveform

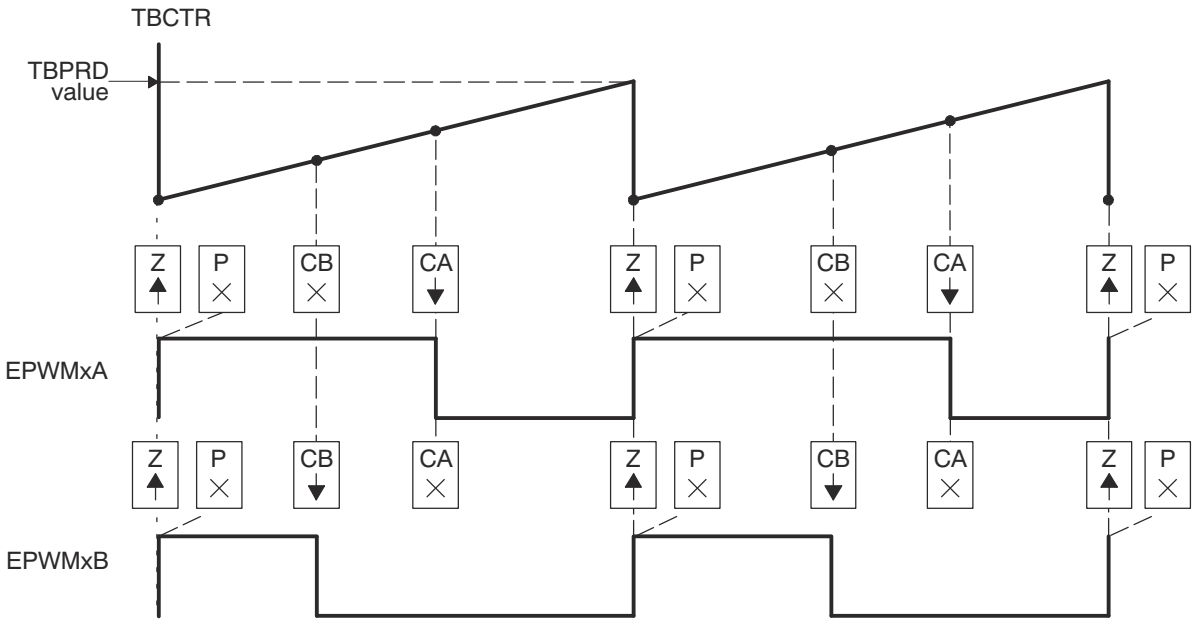
The PWM waveforms in Figure 27-27 through Figure 27-32 show some common action-qualifier configurations. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in the respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means count-up-and count-down mode, Up means up-count mode and Down means down-count mode
- Sym = Symmetric, Asym = Asymmetric

Copyright © 2025Texas Instruments



Note

PWM period = (TBPRD + 1) × T_{TBCLK}

Note

Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).

Note

Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).

Note

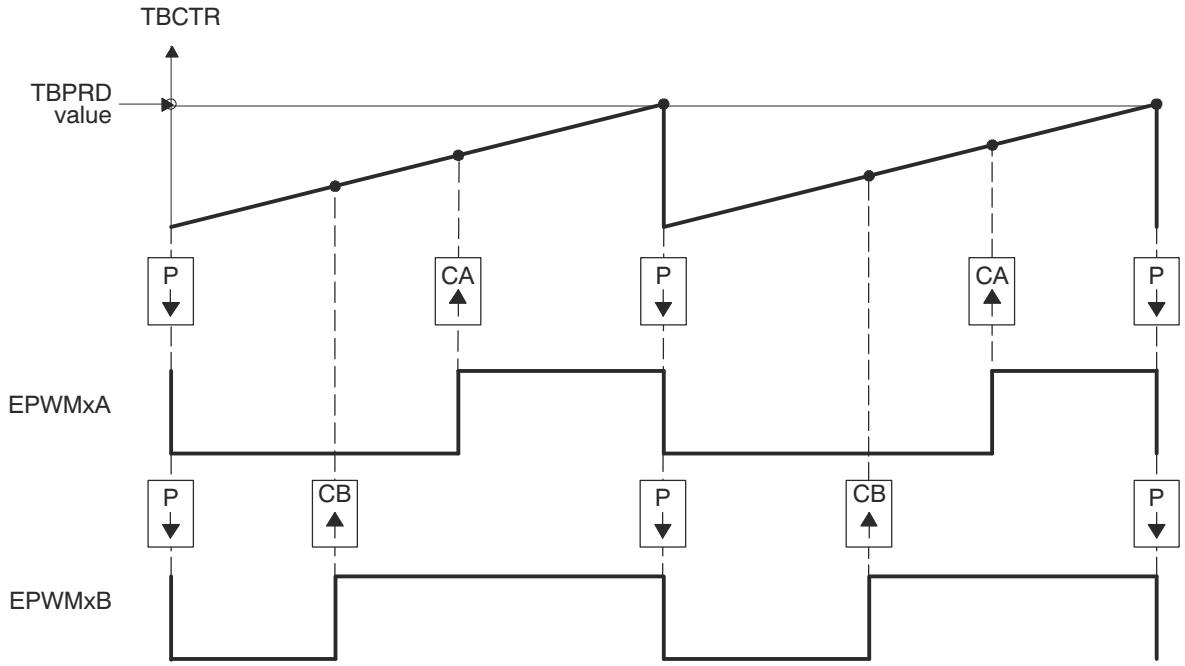
The "Do Nothing" actions (X) are shown for completeness, but are not shown on subsequent diagrams.

Note

Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

Figure 27-27. Up, Single Edge Asymmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB—Active High

Copyright © 2025Texas Instruments



Note

PWM period = (TBPRD + 1) × T_{TBCLK}

Note

Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).

Note

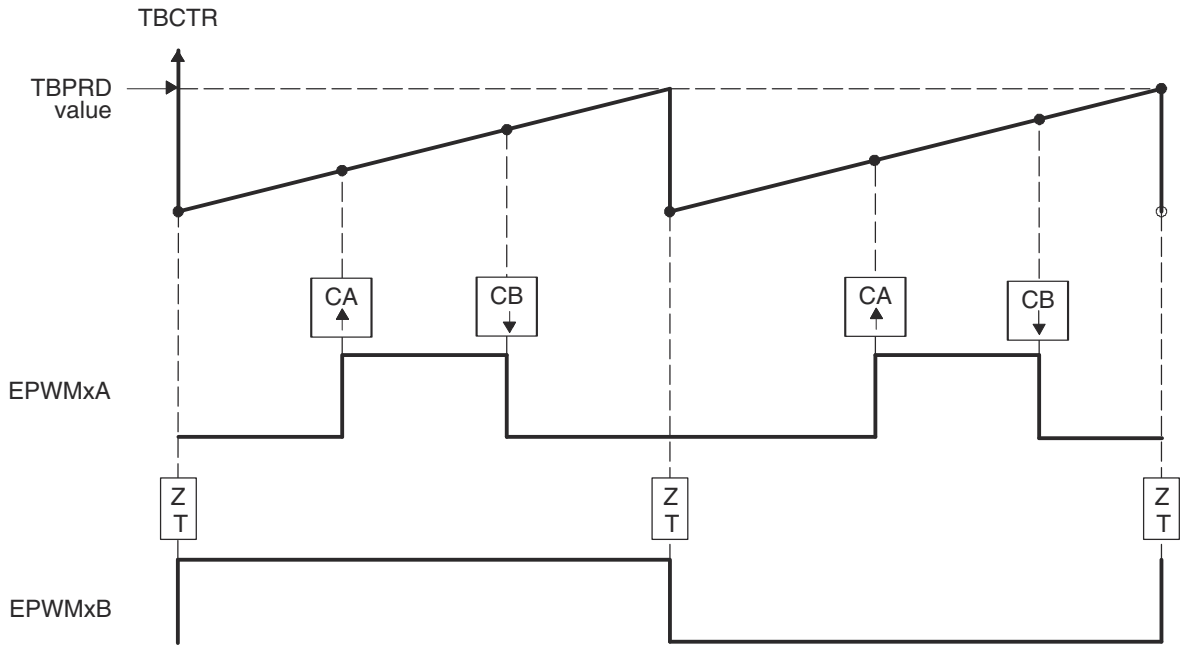
Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).

Note

Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

Figure 27-28. Up, Single Edge Asymmetric Waveform with Independent Modulation on EPWMxA and EPWMxB—Active Low

Copyright © 2025Texas Instruments



Note

PWM frequency = $1/((TBPRD + 1) \times T_{TBCLK})$

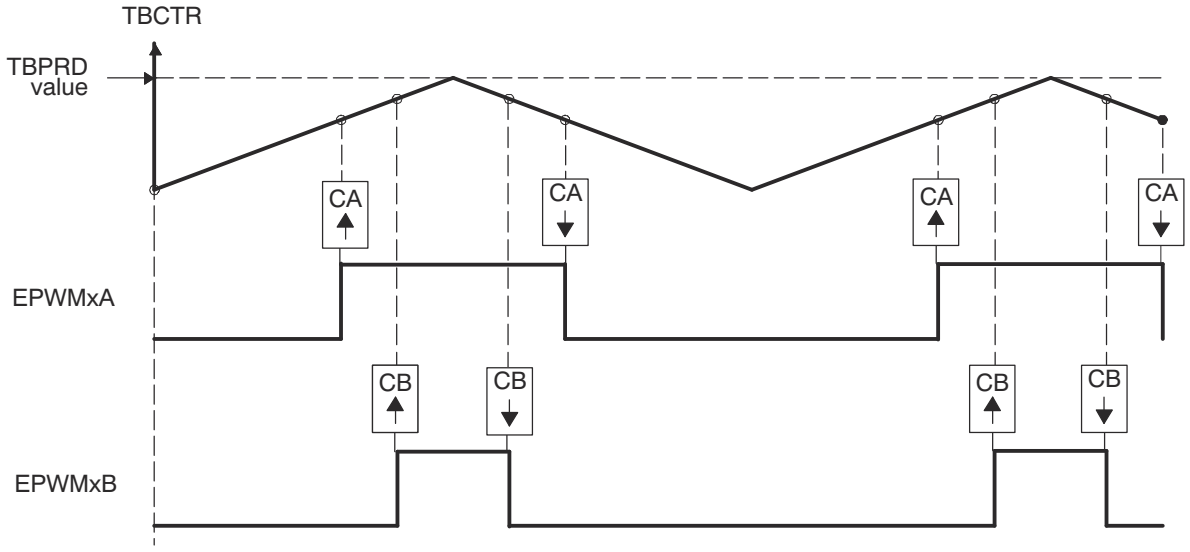
Note

Pulse can be placed anywhere within the PWM cycle (0000 - TBPRD)

Note

High time duty proportional to (CMPB - CMPA)

Figure 27-29. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA



Copyright © 2025Texas Instruments

Note

PWM period = 2 x TBPRD × T_{TBCLK}

Note

Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).

Note

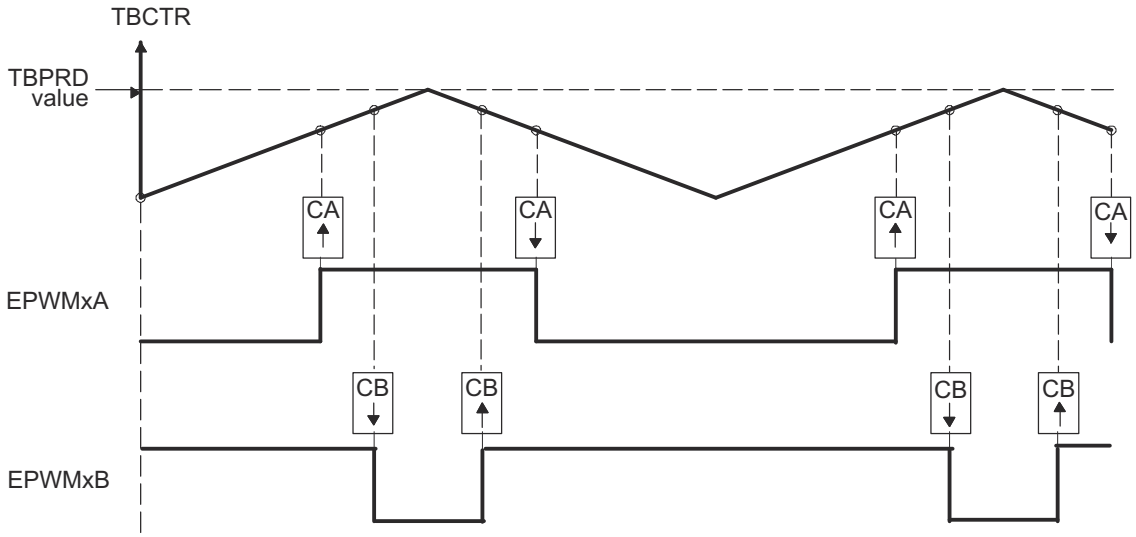
Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).

Note

Outputs EPWMxA and EPWMxB can drive independent power switches.

Figure 27-30. Up-Down Count, Dual-Edge Symmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB — Active Low

Copyright © 2025Texas Instruments



Note

PWM period = 2 × TBPRD × T_{TBCLK}

Note

Duty modulation for EPWMxA is set by CMPA, and is active low, that is, low time duty proportional to CMPA.

Note

Duty modulation for EPWMxB is set by CMPB and is active high, that is, high time duty proportional to CMPB.

Note

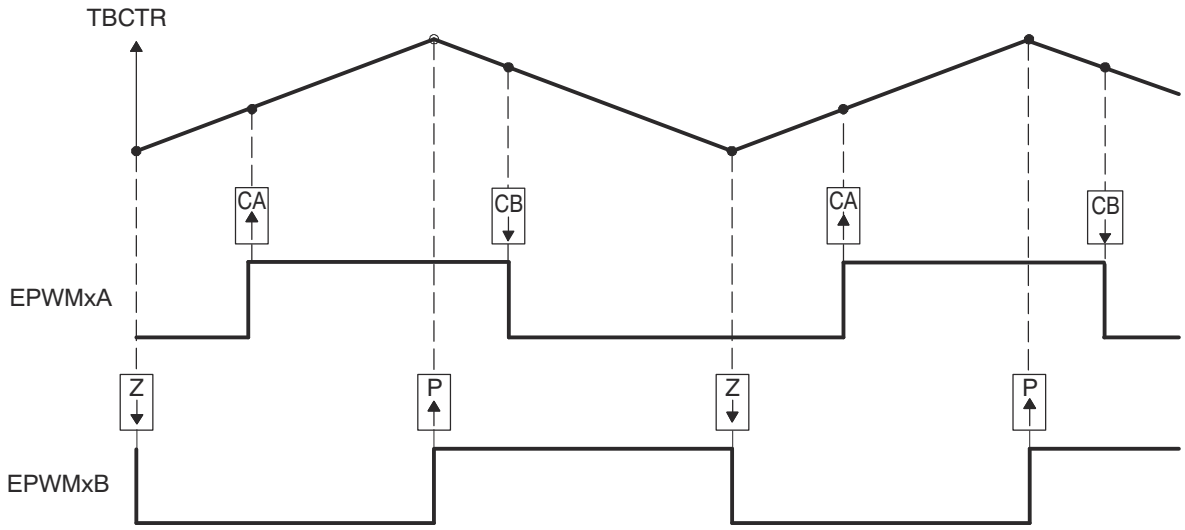
Outputs EPWMx can drive upper/lower (complementary) power switches.

Note

Dead-band = CMPB - CMPA (fully programmable edge placement by software). Note the dead-band module is also available if the more classical edge delay method is required.

Figure 27-31. Up-Down Count, Dual-Edge Symmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB — Complementary

Copyright © 2025Texas Instruments



Note

PWM period = 2 × TBPRD × TBCLK

Note

Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.

Note

Duty modulation for EPWMxA is set by CMPA and CMPB.

Note

Low time duty for EPWMxA is proportional to (CMPA + CMPB).

Note

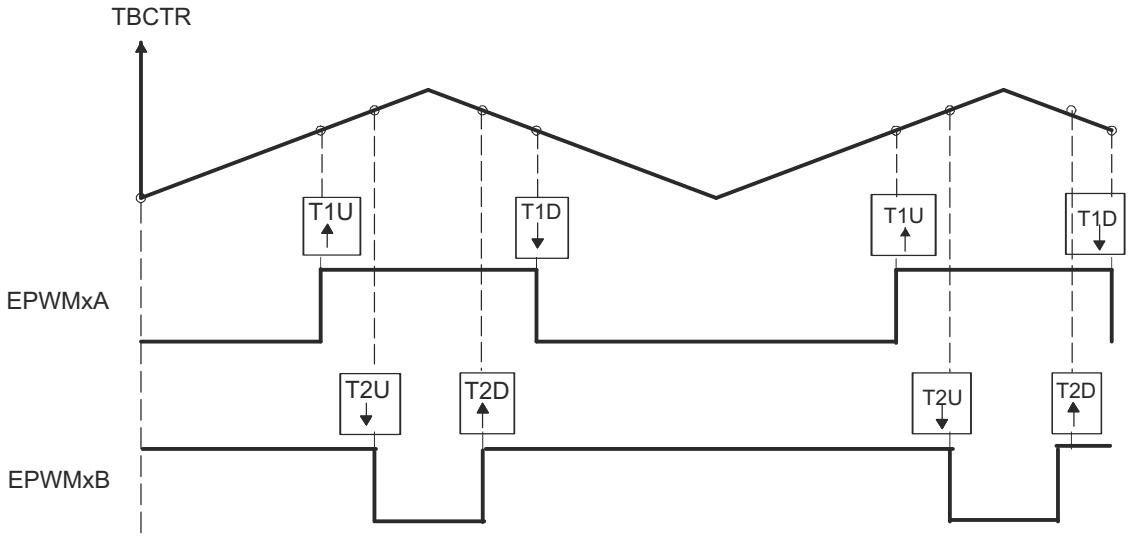
To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Clear on CMPA, Set on CMPB).

Note

Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB).

Figure 27-32. Up-Down Count, Dual-Edge Asymmetric Waveform, with Independent Modulation on EPWMxA—Active Low

Copyright © 2025Texas Instruments



Note

PWM period = 2 × TBPRD × TTBCLK

Note

Independent T1 event actions when counter is counting up and when the counter is counting down are used to generate EPWMxA output.

Note

Independent T2 event actions when counter is counting up and when the counter is counting down are used to generate EPWMxB output.

Note

TZ1 is selected as the source for T1.

Note

TZ2 is selected as the source for T2.

Figure 27-33. Up-Down Count, PWM Waveform Generation Utilizing T1 and T2 Events

27.7 XCMP Complex Waveform Generator Mode

The XCMP complex waveform generator mode is available in the type 5 ePWM and is enabled when XCMPEN is set. The main feature of the XCMP mode is to generate multiple ePWM pulses, with high resolution edge placement if needed, within one ePWM period.

XCMP features include:

- Up to eight counter compare registers XCMP1-XCMP8
- High resolution (HRPWM) edge placement support
- Up-Count counter mode support

Note

Down-Count and Up-Down-Count counter modes are not supported

- Pulse generation is only supported on XCMP1-8 matches (no support for counter events such as PRD and ZRO, or T1/T2 events)
- ePWM module synchronization is not allowed in XCMP mode

Copyright © 2025Texas Instruments

Note

The application software must disable the ePWM synchronization when XCMP mode is enabled.

- XCMP1-8 are loaded through CMPA and CMPB
- The eight XCMPn registers, can be allocated to either CMPA or CMPB through the application software configuration
- XAQCTLA and XAQCTLB registers determine the actions taken on the ePWM output for each XCMP1-8 counter matches
- Up to three ePWM period cycles can be configured at once through three shadow buffers
  - Each shadow buffer contains shadow registers for XCMP1-8, XTBPRD, XAQCTLA, XAQCTLB, CMPC, CMPD, and XMINMAX (which is used for CAPEVT signal generation)
  - Shadow buffer SHDW2 and SHDW3 can be repeated up to eight times
- All ePWM modules can be linked to trigger the start of the shadow loading at the same time through EPWMXLINKXLOAD

Note

Enabling and disabling XCMP mode during run time can cause unintended events to occur. The recommendation is to stay in XCMP mode if XCMP mode is enabled. If enabling and disabling XCMP mode during run time is required, a peripheral reset is required after disabling XCMP mode on the PWM module.

27.7.1 XCMP Allocation to CMPA and CMPB

The first criteria that must be selected is whether both EPWM channel A and channel B outputs are required. If both channel A and channel B are required, XCMP registers must be assigned to both CMPA and CMPB. The XCMPn registers loaded to CMPA are used for configuring the A channel through XAQCTLA actions. The XCMPn registers loaded to CMPB are used for configuring the B channel through XAQCTLB actions.

XCMP allocation to CMPA and CMPB is done through XCMPCTL1.XCMPSPLIT. If both channel A and channel B are required in the system, then the XCMPCTL1.XCMPSPLIT must be set. This allows CMPA to use XCMP1-n (where n has a maximum value of 4) while CMPB uses XCMP5-m (where m has a maximum value of 8). If only channel A is needed, then XCMPCTL1.XCMPSPLIT must be cleared, allowing CMPA to use XCMP1-n (where n has a maximum value of 8), which means up to eight edges can be generated on channel A.

Note

The maximum number of edges that channel B can have is four, when XCMP5-8 are allocated to CMPB and all four XCMP5-8 are used by setting the XCMPB_ALLOC to use all available XCMPs.

XCMPA_ALLOC and XCMPB_ALLOC determines how many of the available XCMPs for each CMPA and CMPB must be used in the ePWM configuration.

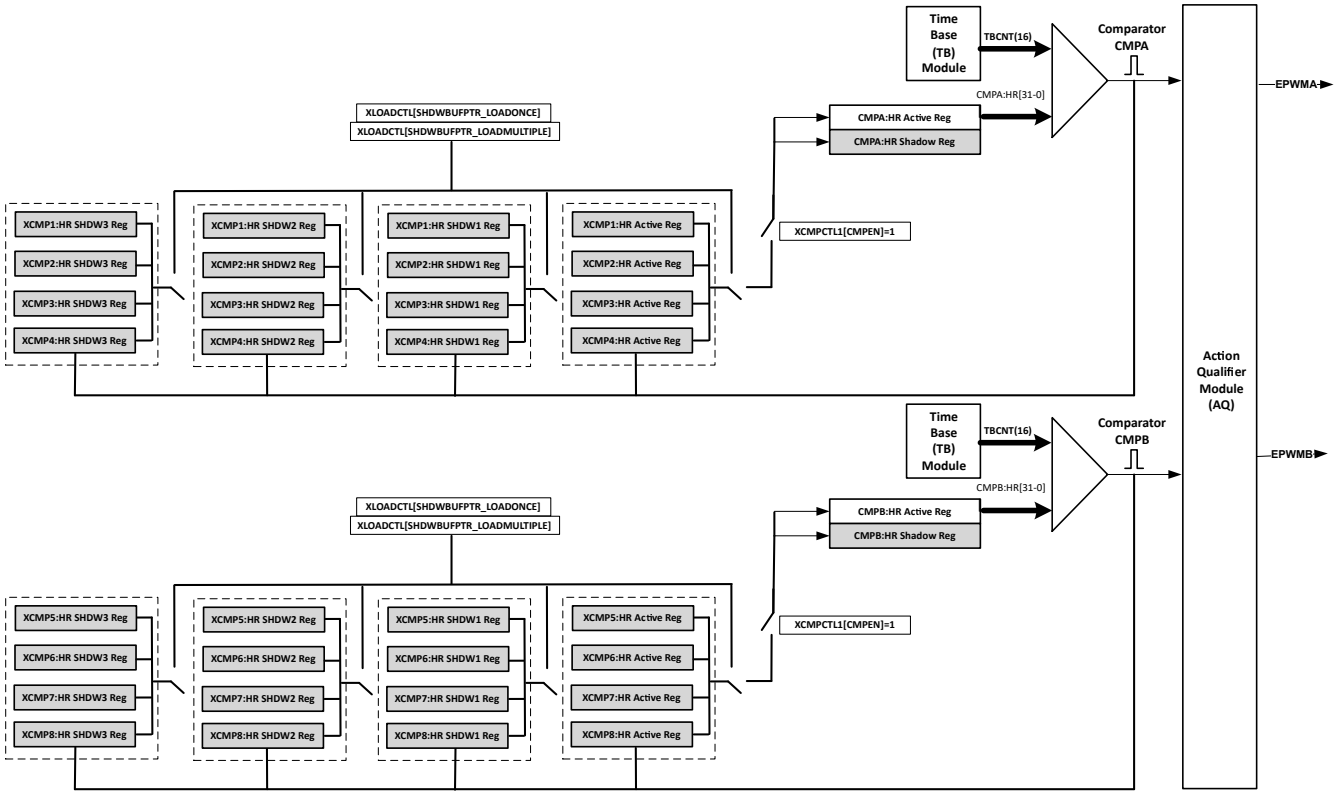

Figure 27-35. XCMP1-4 Allocated to CMPA and XCMP5-8 Allocated to CMPB

27.7.2 XCMP Shadow Buffers

Three SHDW buffers are available for XCMP configurations. Each SHDW buffer contains the XCMP1-8 values (CMPA and CMPB values), XTBPRD (TBPRD value), XCMPC (CMPC value), XCMPD (CMPD value), XAQCTLA and XAQCTLB. Each SHDW buffer also contains the XMINMAX values which are used for CAPEVT signal generation.

With the Three SHDW buffer (SHDW1, SHDW2 and SHDW3) the values used for the upcoming ePWM period cycles can be buffered.

Copyright © 2025Texas Instruments

With XCMPEN set, the load of the active registers are controlled by the XLOADCTL and XLOAD registers. The shadow to active loading of the registers (other than XMINMAX, XCMPC, XCMPD) are always done three cycles prior to TBCTR==ZERO event. XMINMAX, XCMPC and XCMPD shadow loading is done at TBCTR==PRD.

There are two load modes configured by XLOADCTL[LOADMODE]:

- **LOADONCE** Mode (XLOADCTL[LOADMODE] = 0)
  - In LOADONCE mode, XLOADCTL[SHDWBUFPTR_ LOADONCE] is used to set the pointer location of the shadow buffer.
  - XLOADCTL[SHDWBUFPTR_ LOADONCE] is set by the user and is **NOT** automatically decremented. Upon the occurrence of the first load strobe (write of '1' to XLOAD[STARTLD] bit), active register set is loaded from the XLOADCTL[SHDWBUFPTR_ LOADONCE] SHDW selected by the user. Further load strobes are ignored, and ePWM waveform generation continues with the active register set until next XLOAD[STARTLD] is initiated.
  - When the software sets the XLOAD[STARTLD] bit again, the active register set is loaded from the XLOADCTL[SHDWBUFPTR_ LOADONCE] SHDW selected by the user. If the user wants to initiate a SHDW load from a different shadow register set, then the software can update the XLOADCTL[SHDWBUFPTR_ LOADONCE] register accordingly before setting the XLOAD[STARTLD].

Copyright © 2025Texas Instruments

- **LOADMULTIPLE** Mode (XLOADCTL[LOADMODE] = 1)
  - XLOADCTL[SHDWBUFPTR_ LOADMULTIPLE] always points to the current shadow register set that is loaded into the active registers set.
  - Setting the XLOAD[STARTLD] bit initiates a load strobe. The SHDW buffer pointer resets to XLOADCTL[SHDWLEVEL] and the corresponding buffer contents are loaded to the active register set. When the next valid load strobe arrives, XLOADCTL[SHDWBUFPTR_ LOADMULTIPLE] is decremented by 1 and the corresponding buffer contents are loaded to the active register set. This continues until the XLOADCTL[SHDWBUFPTR_ LOADMULTIPLE] value reaches 1. At this time SHDW1 values get copied to the active register set. Further load strobes are ignored and the ePWM waveform generation continues with the active register set until next XLOAD[STARTLD] is initiated.
  - Once the XLOADCTL[SHDWBUFPTR_ LOADMULTIPLE] value reaches 1, no further decrements to the this pointer are done until the next STARTLD initiation. This means the XLOADCTL[SHDWBUFPTR_ LOADMULTIPLE] remains at value of '1', indicating that the SHDW1 register set is in use till the next load initiation by user.
  - For a SHDWLEVEL of 3 buffers SHDW3 is loaded first followed by SHDW2 and SHDW1. Then until the next STARTLD write by the software, the SHDW1 values are in use.

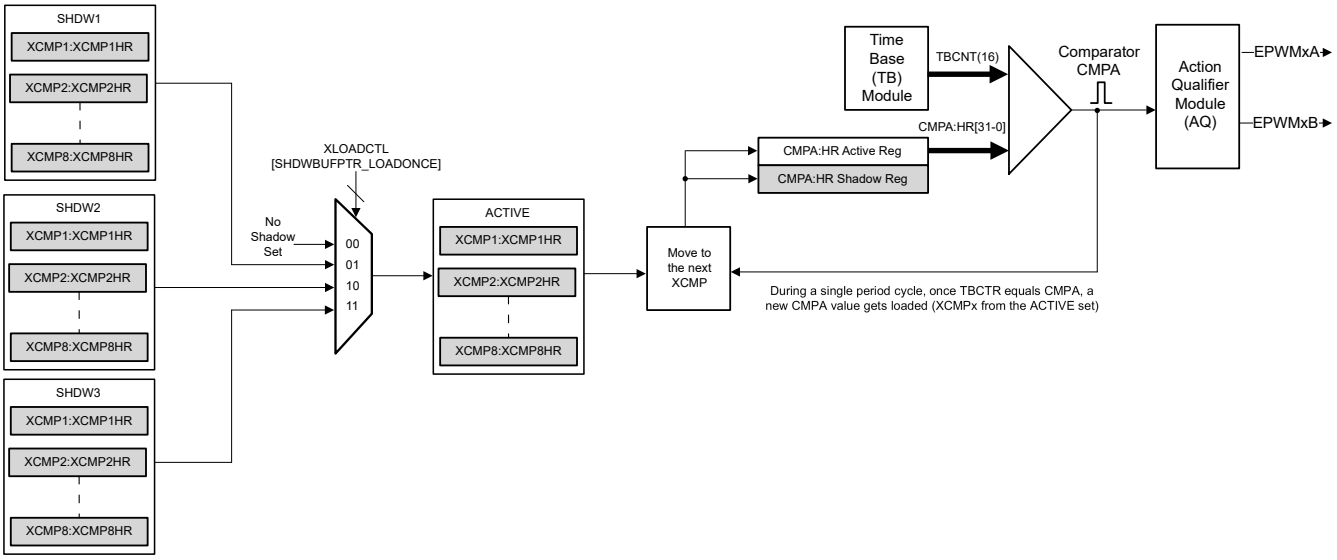

Figure 27-36. XCMP- Load Once Functionality

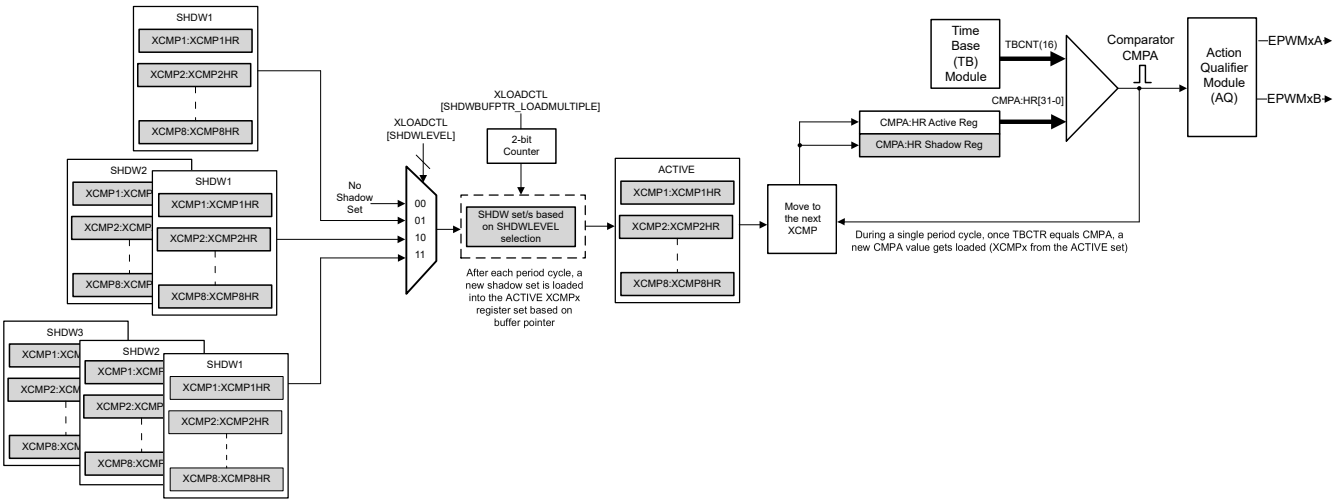

Figure 27-37. XCMP- Load Multiple Functionality

Copyright © 2025Texas Instruments

With this new loading scheme, the global load functionality also changes when using XCMP mode. In this new configuration, once a write to STARLD occurs, the next time the time base counter equals zero or a force load software write occurs, the shadow buffer pointers get reset, based on the load mode (load once or load multiple).

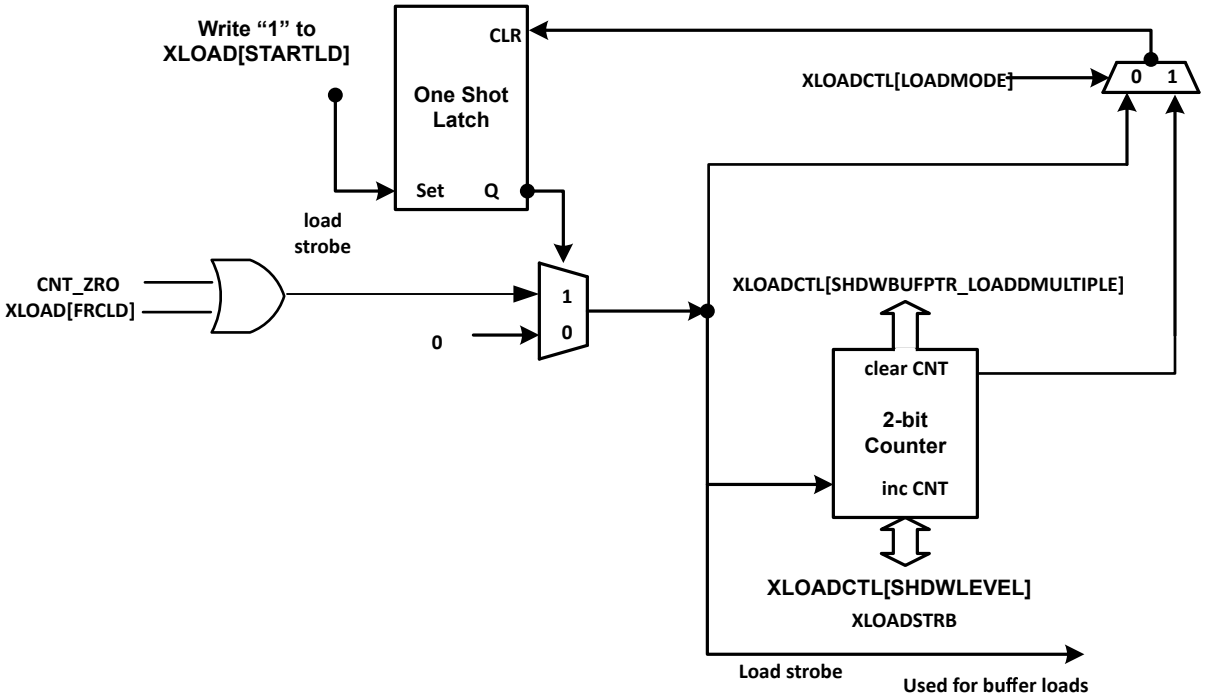

Figure 27-38. Global Load: Signals and Registers

Shadow buffers can also be repeated more than once. Shadow buffer repeat counters are:

- Users can optionally repeat each shadow buffer multiple times. This option sets the repeat count for SHDWn buffers before the pointer moves to the SHDW(n-1) buffer. SHDW1 buffer by default repeats until the next load is initiated by the software and hence there is no configurable repeat option for SHDW1 buffer.
- Repeat counter option of the shadow buffers is applicable in LOADMULTIPLE mode. In the LOADONCE mode, user can manually keep track of the repeat counts and move to the SHDW pointer buffer.
- Each shadow buffer has a 3-bit counter. Each buffer can be set to repeat up to 8 times before moving the pointer to the next buffer.
- XLOADCTL[RPTBUF2PRD] and XLOADCTL[RPTBUF3PRD] are used to control the repeat period for each SHDW buffer.

No shadowing can be set by setting the XLOADCTL[SHDWLEVEL] to '0'. In this case, the ACTIVE registers are available for use (XCMP1_ACTIVE, XCMP2_ACTIVE, and so on).

27.7.3 XCMP Operation

The XCMP complex waveform generation mode is described in this section.

The XCMP mode can be used to generate multiple edges within one ePWM period. The application software must write the location of the ePWM waveform edges to the XCMP registers. Each XCMPn register assigned and used for an ePWM CMPx (CMPA or CMPB) must be spaced out according to the following guidelines to make sure of correct waveform generation.

Copyright © 2025Texas Instruments

Figure 27-39 shows an example of four XCMP values being loaded into CMPA during one period cycle and the remaining four XCMP values being used for CMPB. When the action for the last XCMP value loaded into CMPA/CMPB in a period is met, the last value for CMPA/CMPB remains until the next time TBCTR = 0 due to a new shadow set load.

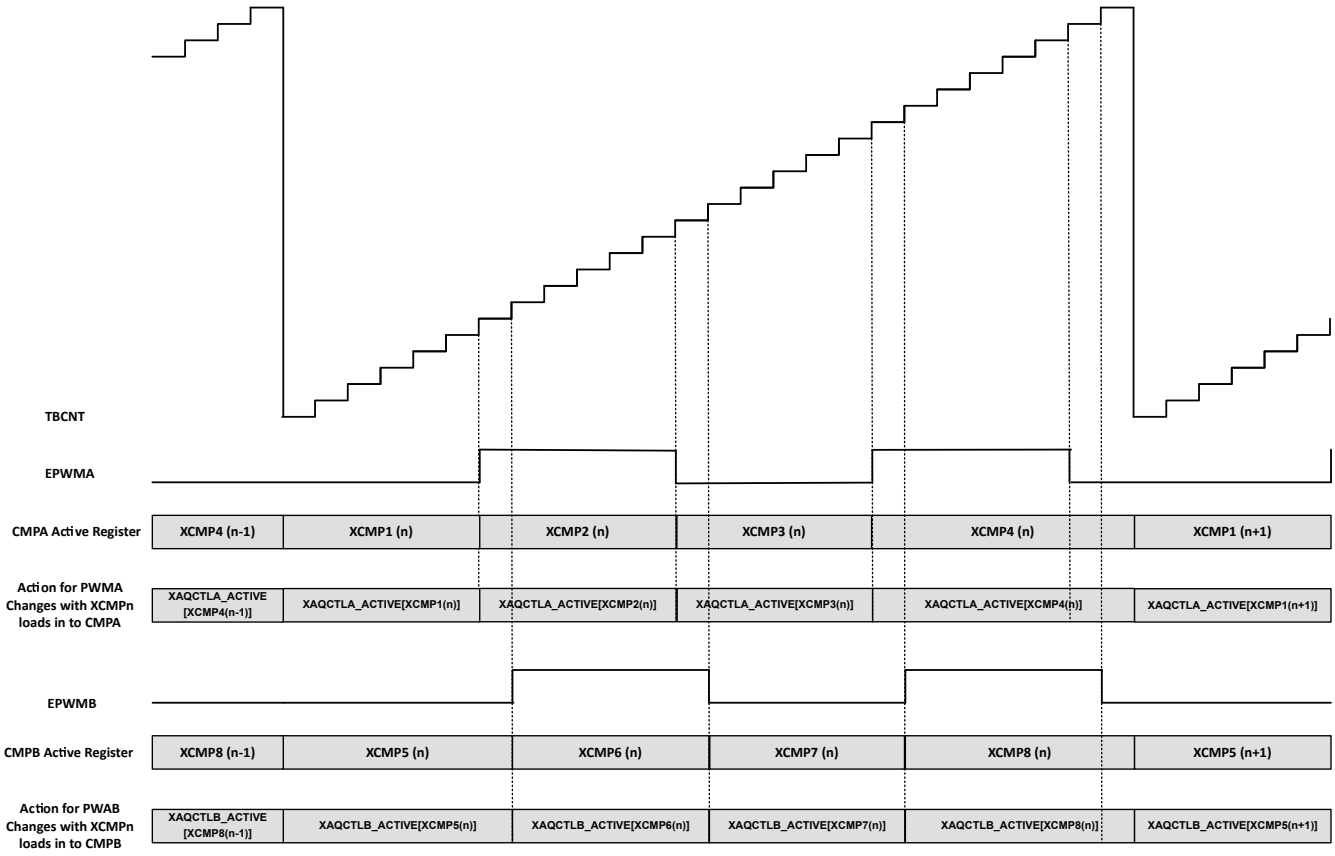

Figure 27-39. CMPA and CMPB Values being Loaded from XCMP Registers

Assume XCMP1-3 are assigned and used by CMPA (XCMP4 is not used), and XCMP5-6 are assigned and used by CMPB (XCMP7 and XCMP8 are not used):

- For XCMP1-8 to be split between CMPA and CMPB, software must write XCMPCTL1[XCMPSPLIT] = 1
- For CMPA to only use XCMP1-3, software must write XCMPCTL1[CMPA_ALLOC] = 3
- For CMPB to only use XCMP5-6, software must write XCMPCTL1[CMPB_ALLOC] = 6

For XCMP1-3 in this scenario, since all are used by CMPA, the values written to XCMP1, XCMP2, and XCMP3 must:

- Without high-resolution edge placement requirement: XCMP(n+1) ≥ (XCMPn) + 1
- With high-resolution edge placement requirement: XCMP(n+1) > (XCMPn) + 3
  - The HR component does not get applied when trying to place an edge at XTBPRD - 3.

The requirements above for the minimum difference between XCMP(n+1) and XCMPn must be met in the application software.

The actions taken for each XCMP1-8 must be configured in XAQCTLA and XAQCTLB.

If shadowing is required then the XCMP1-8, XAQCTLA and XAQCTLB values must be written to the corresponding shadow buffer. As an example, Table 27-9 shows how the shadow buffers are used in LOADMULTIPLE mode.

Copyright © 2025Texas Instruments

The SHDW buffers 2 and 3 can also be repeated more than once by using the RPTBUF2PRD and RPTBUF3PRD.

Table 27-9. SHDW Buffer Loading Example

	XCMPn, XTBPRD			XTBPRD, TBPRD	XCMPn: XCMPnHR	CMPA: CMPAHR	What happens next?
	SHDW3FULL	SHDW2FULL	SHDW1FULL	Active	Active	Active	
CPU Initialization	Set	Set	Set				Registers initialized by CPU. Load event occurs.
ePWM Cycle 1	Clear	Set	Set	XTBPRD_SHDW3	XCMPn_SHDW3	XCMPn_SHDW3	SHDWBUFPTR set to 3
ePWM Cycle 2	Clear	Clear	Set	XTBPRD_SHDW2	XCMPn_SHDW2	XCMPn_SHDW2	SHDWBUFPTR set to 2
ePWM Cycle 3	Clear	Clear	Clear	XTBPRD_SHDW1	XCMPn_SHDW1	XCMPn_SHDW1	SHDWBUFPTR set to 1
ePWM Cycle 4	Clear	Clear	Clear	XTBPRD_SHDW1	XCMPn_SHDW1	XCMPn_SHDW1	SHDWBUFPTR set to 1 No shadow to active loading from buffer. Operation continues with values in XCMPn_ACTIVE registers.
ePWM Cycle 5	Clear	Clear	Clear	XTBPRD_SHDW1	XCMPn_SHDW1	XCMPn_SHDW1	SHDWBUFPTR set to 1 Continues operation with same values in XCMPn_ACTIVE until the next buffer load event
CPU Load (During ePWM Cycle 5)	Set	Set	Set	XTBPRD_SHDW1	XCMPn_SHDW1	XCMPn_SHDW1	CPU loads new shadow value set. Load event occurs. SHDWBUFPTR set to 3
ePWM Cycle 6	Clear	Set	Set	XTBPRD_SHDW3	XCMPn_SHDW3	XCMPn_SHDW3	SHDWBUFPTR set to 3
ePWM Cycle 7	Clear	Clear	Set	XTBPRD_SHDW2	XCMPn_SHDW2	XCMPn_SHDW2	SHDWBUFPTR set to 2
ePWM Cycle 8	Clear	Clear	Clear	XTBPRD_SHDW1	XCMPn_SHDW1	XCMPn_SHDW1	SHDWBUFPTR set to 1
ePWM Cycle 9	Clear	Clear	Clear	XTBPRD_SHDW1	XCMPn_SHDW1	XCMPn_SHDW1	Continues operation with the same values in XCMPn_ACTIVE until the next buffer load event. SHDWBUFPTR set to 1
ePWM Cycle 10	Set	Set	Set	XTBPRD_SHDW1	XCMPn_SHDW1	XCMPn_SHDW1	CPU loads new shadow register set. Load event occurs. SHDWBUFPTR set to 3

27.8 Dead-Band Generator (DB) Submodule

Figure 27-40 illustrates the dead-band submodule within the ePWM.

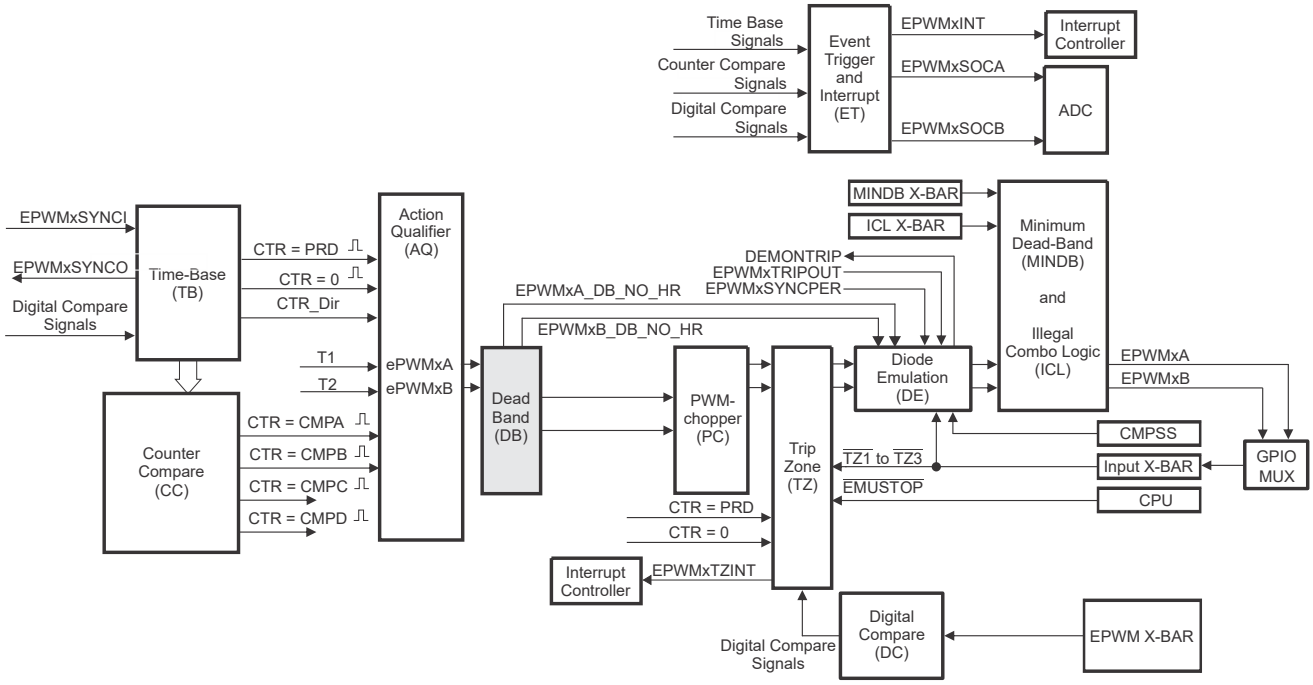

Figure 27-40. Dead_Band Submodule

27.8.1 Purpose of the Dead-Band Submodule

The action-qualifier (AQ) module section discussed how the AQ module can generate the required dead band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead band with polarity control is required, then the dead-band submodule described here must be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

Copyright © 2025Texas Instruments

27.8.2 Dead-band Submodule Additional Operating Modes

On type 1 ePWM RED can appear on one channel output and FED can appear on the other channel output.

The following list shows the distinct difference between type 1 and type 4 modules with respect to dead-band operating modes:

- By adding S6, S7, and S8 in Figure 27-41, RED and FED can appear on both the A-channel and B-channel outputs. Additionally, both RED and FED together can be applied to either the A-channel or B-channel outputs to allow B-channel phase shifting with respect to the A-channel.

Note

Phase shifting B-channel with respect to the A-channel using the dead-band submodule additional operating modes has limitations with respect to the choice of RED and FED delay with respect to the operating duty cycle of the ePWMxA and ePWMxB outputs.

- The dead-band counters have also been increased to 14 bits
- Deadband and deadband high-resolution registers are now shadowed
- High-resolution deadband RED and FED have been enabled using the DBREDHR and DBFEDHR registers

Note

The PWM chopper is not enabled when high-resolution deadband is enabled.

High-resolution deadband RED and FED requires half-cycle clocking mode (DBCTL[HALFCYCLE] = 1).

Cannot have both RED and FED together applied to both ePWMxA and ePWMxB. RED and FED together can be applied only to either OutA OR OutB.

Phase shifting B-channel with respect to the A-channel: When PWMxB is derived from PWMxA using the DEDB_MODE bit and by delaying rising edge and falling edge by the phase shift amount. When the duty cycle value on PWMxA is less than this phase shift amount, PWMxA's falling edge has precedence over the delayed rising edge for PWMxB. Make sure the duty cycle value of the current waveform applied to the dead-band module is greater than the required phase shift amount.

The Type 4 action qualifier and dead-band outputs of the ePWM module are delayed by one TBCLK cycle in comparison to the Type 2 ePWM module, although the Type 4 behavior is the same as the Type 3 PWM. Both PWMA and PWMB signals are delayed under all circumstances.

Copyright © 2025Texas Instruments

Shadow Mode:

The shadow mode for the DBRED is enabled by setting the DBCTL[SHDWDBREDMODE] bit and the shadow register for DBFED is enabled by setting the DBCTL [SHDWDBFEDMODE] bit. Shadow mode is disabled by default for both DBRED and DBFED

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL [LOADREDMODE] and DBCTL [LOADFEDMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

The DBCTL register can be shadowed. The shadow mode for DBCTL is enabled by setting the DBCTL2[SHDWDBCTLMODE] bit. If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL2[LOADDBCTLMODE] register bit:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

Note

The application software must enable shadow load mode in the DBCTL[SHDWDBREDMODE] and DBCTL[SHDWDBFEDMODE] **before** programming values for the DBRED and DBFED registers. If the shadow register is enabled **after** programming the DBRED and DBFED registers, the DBRED and DBFED registers are loaded with a value of 0.

Global Load Support

Global load control mechanism can also be used for DBRED:DBREDHR, DBFED:DBFEDHR, and DBCTL registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The Global load control mechanism is explained in Section 27.4.7 .

Note

When DBRED/DBFED active is loaded with a new shadow value while DB counters are counting, the new DBRED/DBFED value only affects the NEXT PWMx edge and not the current edge.

A Deadband value of zero cannot be used when the Global Shadow to Active Load is set to occur at CTR=ZERO. Similarly, a Deadband value of PRD cannot be used when the Global Shadow to Active Load is set to occur at CTR=PRD.

27.8.3 Operational Highlights for the Dead-Band Submodule

The configuration options for the dead-band submodule are shown in Figure 27-41.

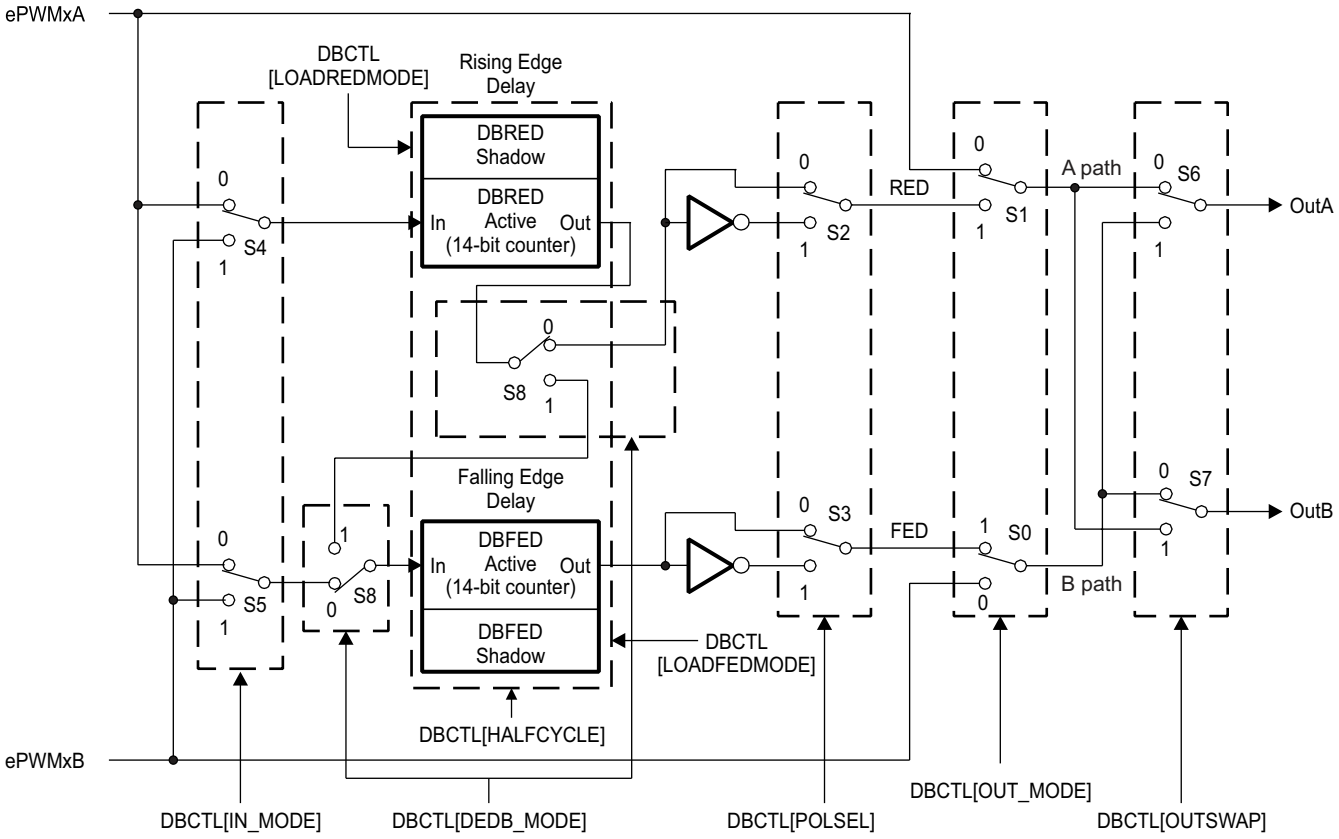

Figure 27-41. Configuration Options for the Dead-Band Submodule

Although all combinations are supported, not all are typical usage modes. Table 27-10 documents some classical dead-band configurations. These modes assume that the DBCTL[IN_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 27-10 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED):** Allows the user to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings:** These represent typical polarity configurations that can address all the active-high and active-low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 27-42. Note that to generate equivalent waveforms to Figure 27-42, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge delay (RED) and Mode 7: Bypass falling-edge delay (FED):** Finally the last two entries in Table 27-10 show combinations where either the falling-edge delay (FED) or rising-edge delay (RED) blocks are bypassed.

Figure 27-42 shows waveforms for typical cases where 0% < duty < 100%.

Table 27-10. Classical Dead-Band Operating Modes

Mode	Mode Description	DBCTL[POLSEL]		DBCTL[OUT_MODE]	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	X	X	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling-Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising-Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

Table 27-11. Additional Dead-Band Operating Modes

Mode Description	DBCTL[DEDB-MODE]	DBCTL[OUTSWAP]	
	S8	S6	S7
EPWMxA and EPWMxB signals are as defined by OUT-MODE bits.	0	0	0
EPWMxA = A-path as defined by OUT-MODE bits. EPWMxB = A-path as defined by OUT-MODE bits (rising-edge delay or delay-bypassed A-signal path)	0	0	1
EPWMxA = B-path as defined by OUT-MODE bits (falling-edge delay or delay-bypassed B-signal path) EPWMxB = B-path as defined by OUT-MODE bits	0	1	0
EPWMxA = B-path as defined by OUT-MODE bits (falling-edge delay or delay-bypassed B-signal path) EPWMxB = A-path as defined by OUT-MODE bits (rising-edge delay or delay-bypassed A-signal path)	0	1	1
Rising-edge delay applied to EPWMxA / EPWMxB as selected by S4 switch (IN-MODE bits) on A signal path only. Falling-edge delay applied to EPWMxA / EPWMxB as selected by S5 switch (IN-MODE bits) on B signal path only.	0	X	X
Rising-edge delay and falling-edge delay applied to source selected by S4 switch (IN-MODE bits) and output to B signal path only.(1)	1	X	X

(1) When this bit is set to 1, the user can always either set OUT_MODE bits such that Apath = InA or set OUTSWAP bits such that EPWMxA=Bpath. Otherwise, EPWMxA is invalid.

Copyright © 2025Texas Instruments

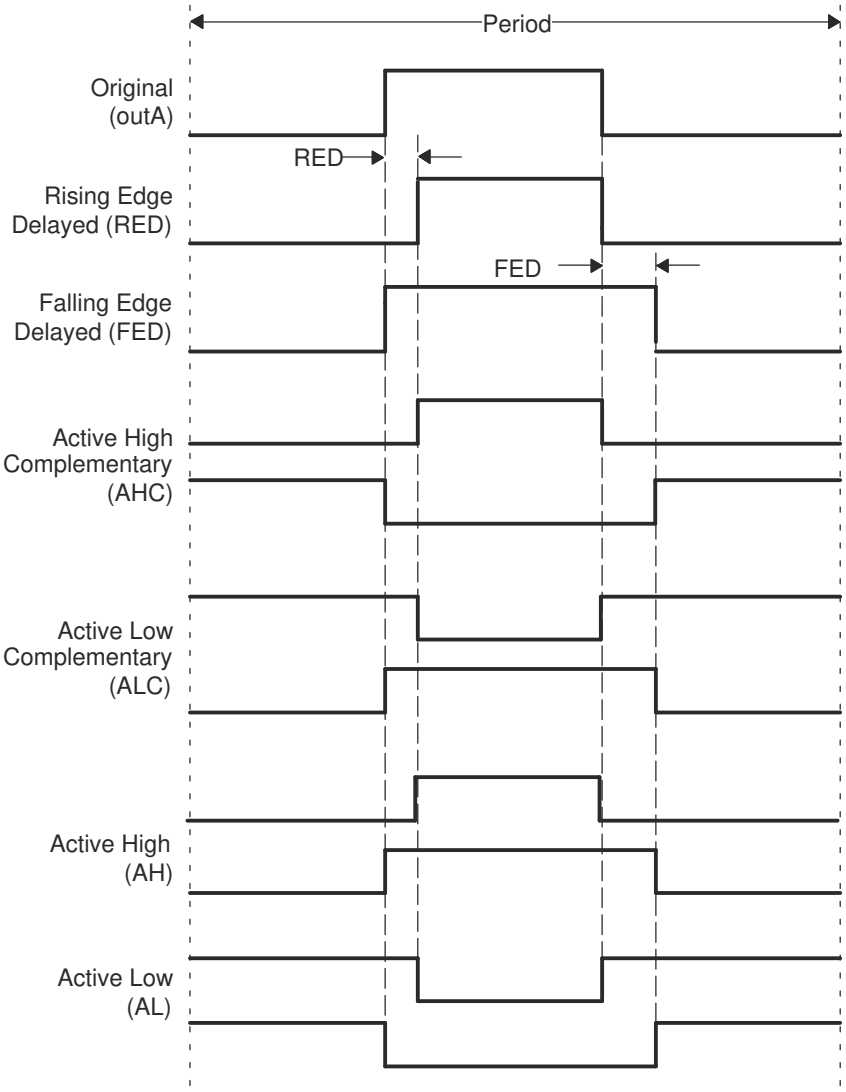

Figure 27-42. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and the value represents the number of TBCLK (time-base clock) pulses by which a signal edge is delayed. For example, the formula to calculate falling-edge-delay and rising-edge-delay is:

$FED = DBFED \times T_{TBCLK}$

$RED = DBRED \times T_{TBCLK}$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of EPWMCLK.

Copyright © 2025Texas Instruments

For convenience, delay values for various TBCLK options are shown in Table 27-12. The ePWM input clock frequency that these delay values been computed by is 100MHz.

Table 27-12. Dead-Band Delay Values in µs as a Function of DBFED and DBRED

Dead-Band Value	Dead-Band Delay (µs)		
DBFED, DBRED	TBCLK = EPWMCLK/1	TBCLK = EPWMCLK /2	TBCLK = EPWMCLK/4
1	0.01	0.02	0.04
5	0.05	0.10	0.20
10	0.10	0.20	0.40
100	1.00	2.00	4.00
200	2.00	4.00	8.00
400	4.00	8.00	16.00
500	5.00	10.00	20.00
600	6.00	12.00	24.00
700	7.00	14.00	28.00
800	8.00	16.00	32.00
900	9.00	18.00	36.00
1000	10.00	20.00	40.00

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$FED = DBFED \times T_{TBCLK}/2$

$RED = DBRED \times T_{TBCLK}/2$

27.9 PWM Chopper (PC) Submodule

The PWM chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if pulse transformer-based gate drivers to control the power switching elements are needed.

Figure 27-43 illustrates the PWM chopper submodule within the ePWM.

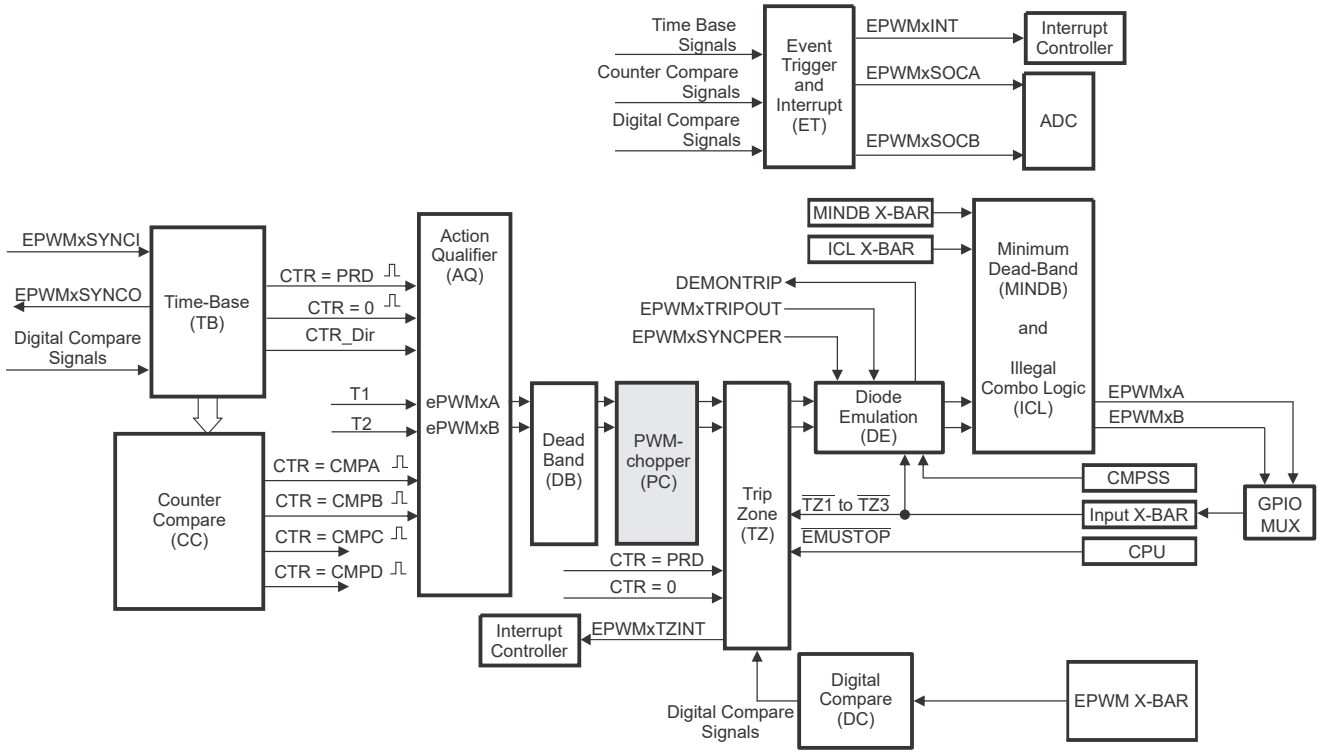

Figure 27-43. PWM Chopper Submodule

27.9.1 Purpose of the PWM Chopper Submodule

The key functions of the PWM chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

27.9.2 Operational Highlights for the PWM Chopper Submodule

Figure 27-44 shows the operational details of the PWM chopper submodule. The carrier clock is derived from EPWMCLK. The clock frequency and duty cycle are controlled using the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to make sure hard and fast power switch turn on, while the subsequent pulses sustain pulses, making sure the power switch remains on. The one-shot width is programmed using the OSHTWTH bits. The PWM chopper submodule can be fully disabled (bypassed) using the CHPEN bit.

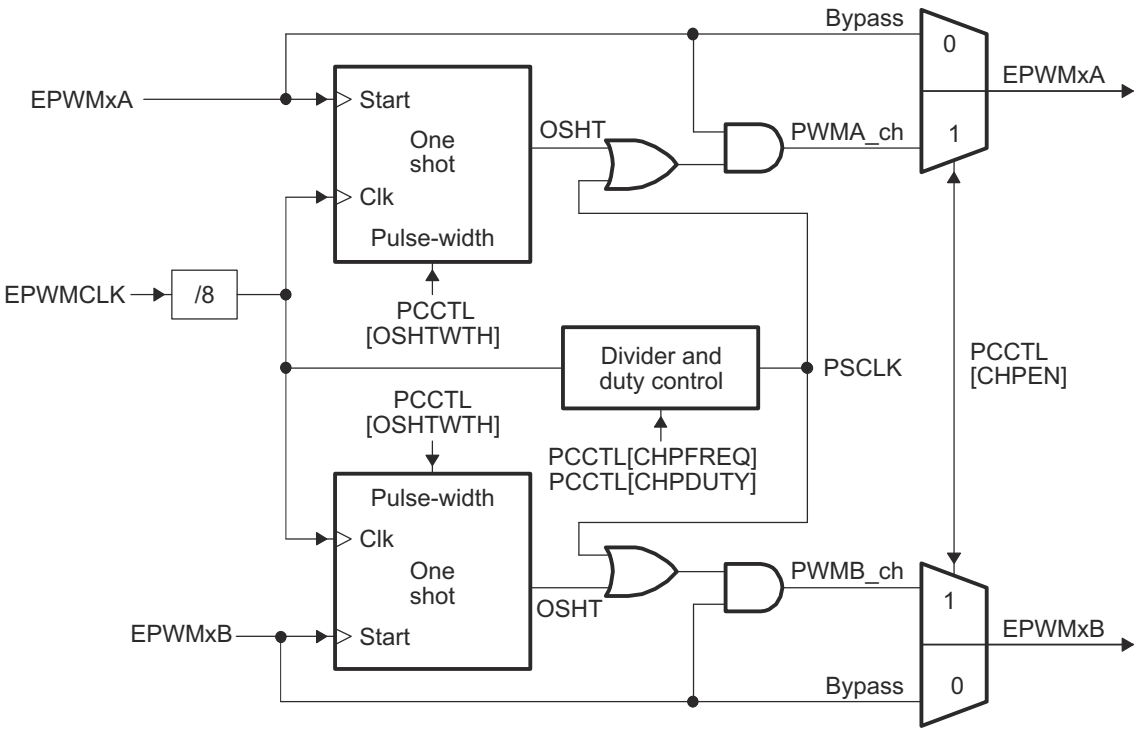

Figure 27-44. PWM Chopper Submodule Operational Details

27.9.3 Waveforms

Figure 27-45 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

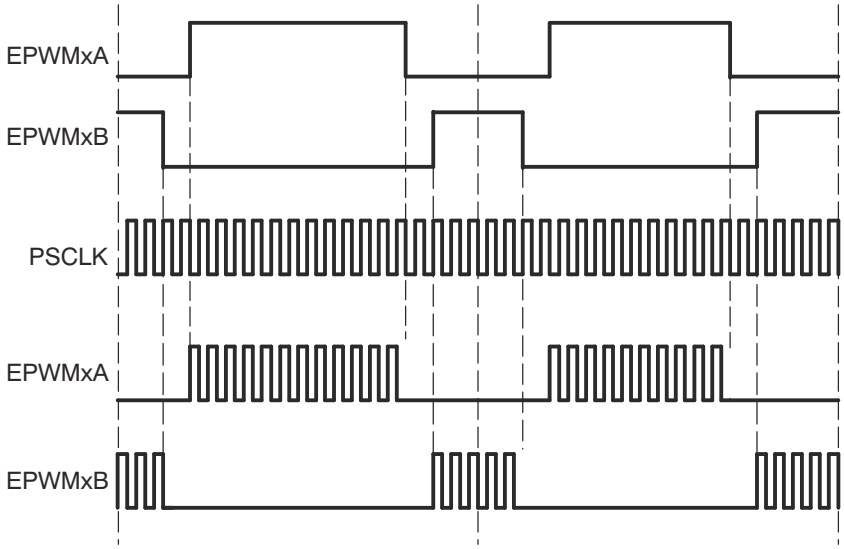

Figure 27-45. Simple PWM Chopper Submodule Waveforms Showing Chopping Action Only

Copyright © 2025Texas Instruments

27.9.3.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{EPWMCLK} \times 8 \times OSHTWTH$$

Where $T_{EPWMCLK}$ is the period of the system clock (EPWMCLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 27-46 shows the first and subsequent sustaining pulses and Table 27-13 gives the possible pulse width values for a EPWMCLK = 80MHz.

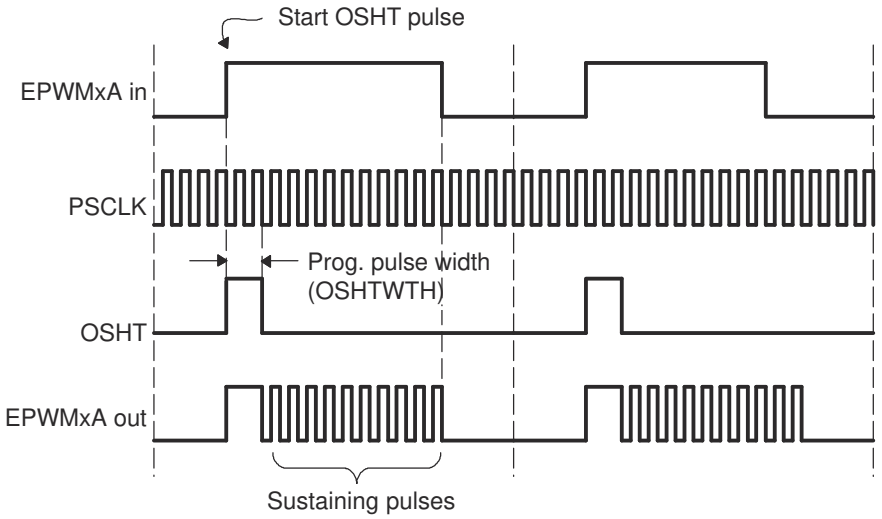

Figure 27-46. PWM Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

27.9.3.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses make sure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized using software control.

Figure 27-47 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

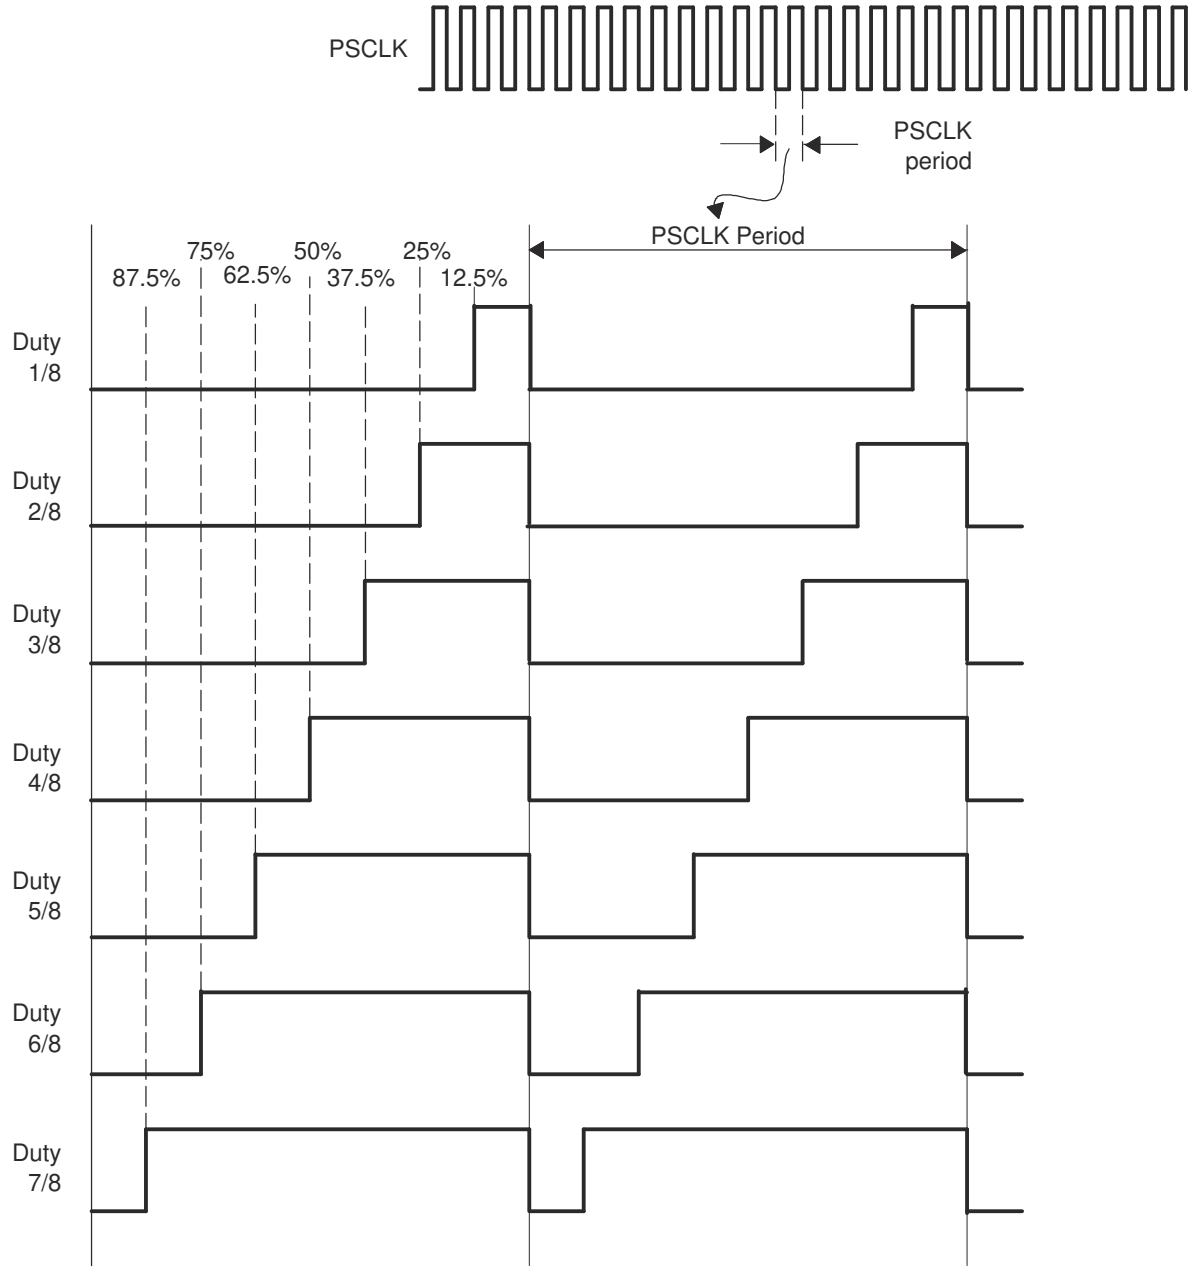

Figure 27-47. PWM Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

27.10 Trip-Zone (TZ) Submodule

Each ePWM module is connected to six $\overline{TZn}$ signals ($\overline{TZ1}$ to $\overline{TZ6}$). $\overline{TZ1}$ to $\overline{TZ3}$ are sourced from the GPIO mux. $\overline{TZ4}$ is sourced from an inverted EQEPxERR signal on those devices with an EQEP module. $\overline{TZ5}$ is connected to the system clock fail logic, and $\overline{TZ6}$ is sourced from the EMUSTOP output from the CPU. These signals indicate external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

Figure 27-48 illustrates the trip-zone submodule within the ePWM.

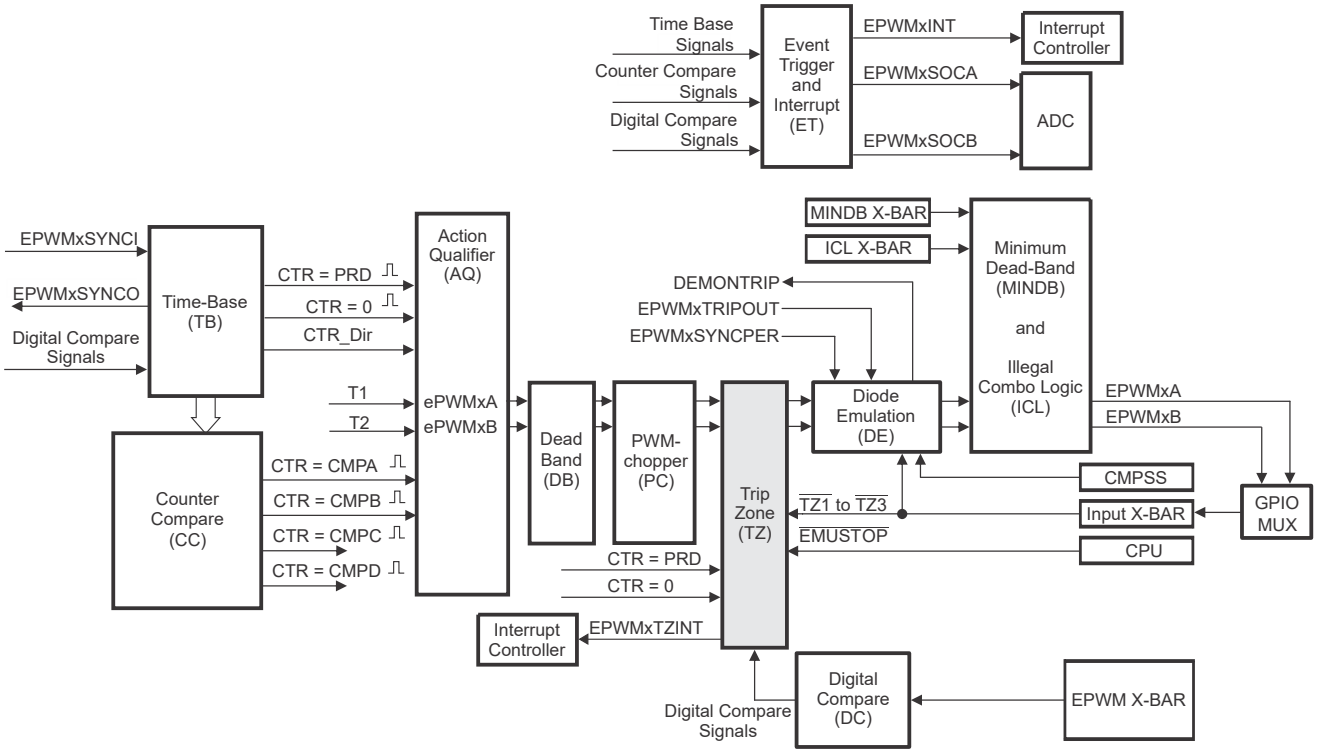

Figure 27-48. Trip-Zone Submodule

27.10.1 Purpose of the Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs $\overline{TZ1}$ to $\overline{TZ6}$ can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and $\overline{TZ1}$ to $\overline{TZ3}$ signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if the trip-zone submodule is not required.

Copyright © 2025Texas Instruments

27.10.2 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals $\overline{TZ1}$ to $\overline{TZ6}$ (also collectively referred to as $\overline{TZn}$) are active-low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, the indication is that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals can or cannot be synchronized to the ePWMclock (EPWMCLK) and digitally filtered within the GPIO MUX block. A minimum of 3 × TBCLK low pulse width on $\overline{TZn}$ inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition cannot be latched by CBC or OST latches. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on $\overline{TZn}$ inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the *System Control and Interrupts* chapter.

Each $\overline{TZn}$ input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input), respectively.

- **Cycle-by-Cycle (CBC):**

  When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and EPWMxB outputs. Table 27-14 lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up or while the counter is counting down by appropriately configuring bits in the TZCTL2 register. Actions specified in the TZCTL2 register take effect only when the ETZE bit in TZCTL2 is set.

  Additionally, when a cycle-by-cycle trip event occurs, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller. A corresponding flag for the event that caused the CBC event is also set in register TZCBCFLG.

  If the CBC interrupt is enabled using the TZEINT register and DCAEVT2 or DCBEVT2 are selected as CBC trip sources using the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

  The specified condition on the inputs is automatically cleared based on the selection made with TZCLR[CBCPULSE] if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset on each TBCTR ZERO match. The TZFLG[CBC] and TZCBCFLG flag bits remain set until the flag bits are manually cleared by writing to the TZCLR[CBC] and TZCBCCLR flag bits. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] and TZCBCFLG register bits are cleared, then these bits are again immediately set.

- **One-Shot (OSHT):**

  When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and EPWMxB output. Table 27-14 lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and while the counter is counting down by appropriately configuring bits in TZCTL2 register. Actions specified in TZCTL2 register take effect only when ETZE bit in TZCTL2 is set.

  Additionally, when a one-shot trip event occurs, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller. A corresponding flag for the event that caused the OST event is also set in register TZOSTFLG. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit. If desired, the TZOSTFLG register bit can be cleared by manually writing to the corresponding bit in the TZOSTCLR register.

Copyright © 2025Texas Instruments

If the one-shot interrupt is enabled using the TZEINT register and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources using the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

Note

Clear the TZFLG and TZOSTFLG flags after making sure that the TRIPIN source of the OST has become inactive. Otherwise, if interrupts are enabled, depending on when the flags are cleared, an OST interrupt can occur and the OST flags are zero.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

Note

When using DCAEVT1/2.force and DCBEVT1/2.force for one-shot or CBC trip event, set the DCxCTL.EVTxFRCSYNCSEL = 0 (sync path). If DCxCTL.EVTxFRCSYNCSEL = 1 (async path), then set DCxCTL.EVTxLATSEL = 1 to latch the async condition.

A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected using the DCTRIPSEL register and can be either trip zone input pins or analog comparator CMPSSx signals. For more information on the digital compare submodule signals, see Section 27.14 .

When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and EPWMxB output. Table 27-14 lists the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and while the counter is counting down by appropriately configuring bits in TZCTLDCA and TZCTLDCB register. Actions specified in TZCTLDCA and TZCTLDCB registers take effect only when ETZE bit in TZCTL2 is set.

In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller.

The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit remains set until the flag is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then the flag is again immediately set.

- **Edge detection within a programmable TBCTR range (CAPEVT):**

An edge detection within a programmable TBCTR range is added in type 5 ePWM. When a CAPIN edge does not occur within a specified range of TBCTR values, the CAPEVT signal is generated. The TBCTR range during which a CAPIN edge must occur is determined by XMINMAX_ACTIVE register. A gating signal CAPGATE can also be used to gate the CAPIN edge. For more information on the CAPEVT signal, see Section 27.14.4.4 .

In addition, the EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller.

The TZFLG[CAPEVT] flag bit remains set until the flag is manually cleared by writing to the TZCLR[CAPEVT] bit. If the CAPEVT event is still present when the TZFLG[CAPEVT] flag is cleared, then the flag is again immediately set.

Copyright © 2025Texas Instruments

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL, TZCTL2, TZCTLDCA, and TZCTLDCB register bit fields. Some of the possible actions, shown in Table 27-14, can be taken on a trip event.

The trip signal generated by the ePWM module can be selected through the TZTRIPOUTSEL register. This register has an ORed version of all the enabled trip signals. The TRIPOUT signal is routed to eCAP Trip Mux,PWM-XBAR and Output-XBAR.

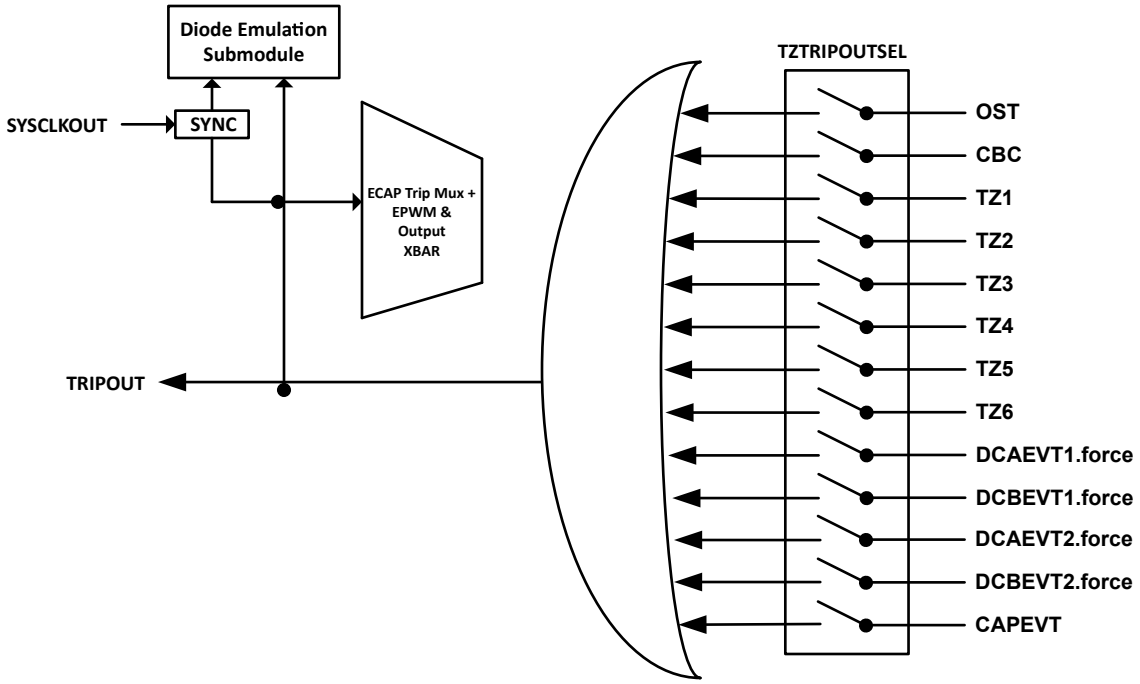

Figure 27-49. Trip-Zone TRIPOUT Selection

Table 27-14. Possible Actions On a Trip Event

TZCTL Register Bitfield Settings	EPWMxA and EPWMxB	Comment
0,0	High-Impedance	Tripped
0,1	Force to High State	Tripped
1,0	Force to Low State	Tripped
1,1	No Change	Do Nothing. No change is made to the output.

Trip-Zone Configurations

Scenario A:
A one-shot trip event on $\overline{TZ1}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A is forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B is forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A is forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B is forced high on a trip event.

Scenario B:
A cycle-by-cycle event on $\overline{TZ5}$ pulls both EPWM1A, EPWM1B low.
A one-shot event on $\overline{TZ1}$ or $\overline{TZ6}$ puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables $\overline{TZ5}$ as a cycle-by-cycle event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A is forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B is forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables $\overline{TZ6}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A is put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B ignores the trip event.

Note

When configuring the GPIOs and INPUT X-BAR/EPWM X-BAR options, be aware that a change in the X-BAR input selections can cause an unwanted event. Therefore, set up the GPIO and X-BAR input configurations before enabling the ePWM Trip-Zone. If a requirement is to change the GPIO/X-BAR configurations while the ePWM Trip-Zone is enabled, the user can turn off the TRIPs by clearing the TZSEL register and reconfiguring the TRIP selection (TZSEL) after the INPUT XBAR selection is changed.

27.10.3 Generating Trip Event Interrupts

Figure 27-50 and Figure 27-51 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 27.14 .

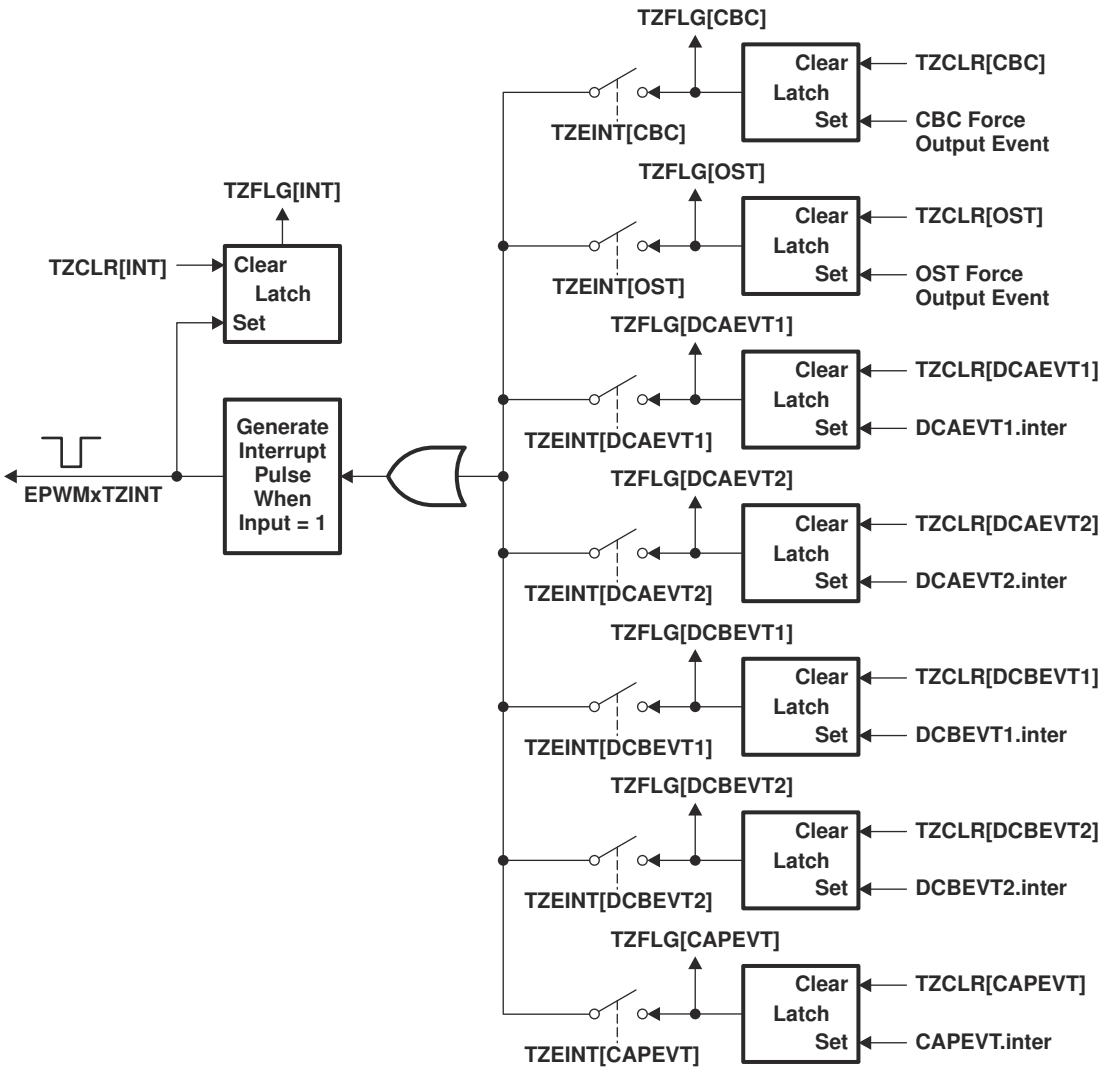

Figure 27-51. Trip-Zone Submodule Interrupt Logic

The CAPEVT signal is generated from the Capture Control Logic and is available in type 5 EPWM.

These individual flags for the CBC, OST, and DCxEVTy can be used to detect the source of the EPWMxTZINT Interrupt. When multiple sources are used to generate the EPWMxTZINT interrupt, reading and clearing the flags takes different actions based on the specific event.

27.11 Diode Emulation (DE) Submodule

The purpose of the Diode Emulation logic is to provide hardware features and the necessary hooks into other IPs to implement robust diode mode sense and control in a noisy environment.

Diode Emulation features include:

- Ability to choose any of the comparator outputs as trips to detect entry into DE mode.
- Ability to switch the comparator thresholds, dynamically in hardware upon DE mode entry.
- Two modes of clearing/de-evaluating the DE condition:
  - Software clear
  - Cycle-by-cycle clear on PWMSYNC event
- Configurable source selects of ePWM in DE mode.
- Ability to monitor the DE mode duration and generate a trip event to ePWMs.

Figure 27-52 illustrates the diode emulation submodule within the ePWM.

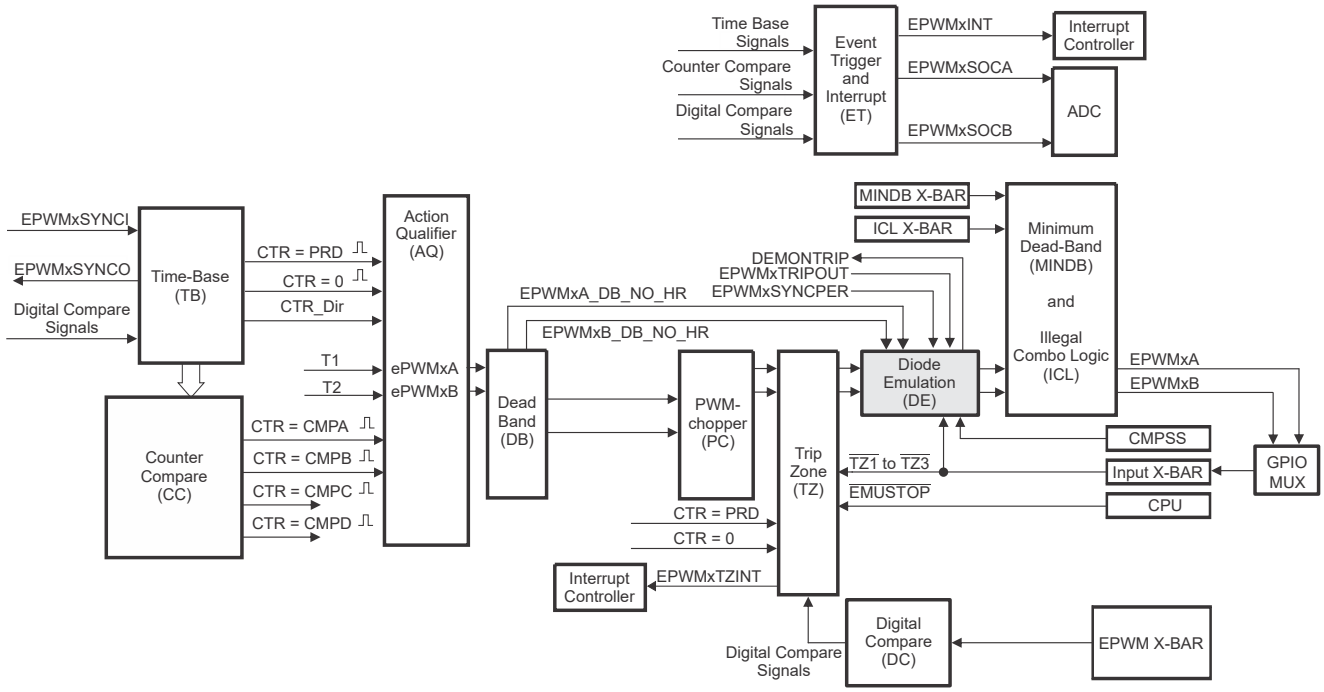

Figure 27-52. Diode Emulation Submodule

Figure 27-53 shows the interfaces to the DE block. As can be seen from the diagram, DE function is associated with an instance of ePWMx. The EPWMxA and EPWMxB signals from a given instance of ePWM module pass through the associated DE block and minimum dead band logic. In addition to EPWMxA and EPWMxB, two signals, EPWMxA_DB_NO_HR and EPWMxB_DB_NO_HR are tapped from the ePWM modules. These two signals are PWM signals that are tapped before the signals pass through the trip zone, high-resolution delay lines and come from the dead-band submodule outputs. If high-resolution is not used, then EPWMxA_DB_NO_HR andEPWMxB_DB_NO_HR are just the outputs of the dead-band submodule.

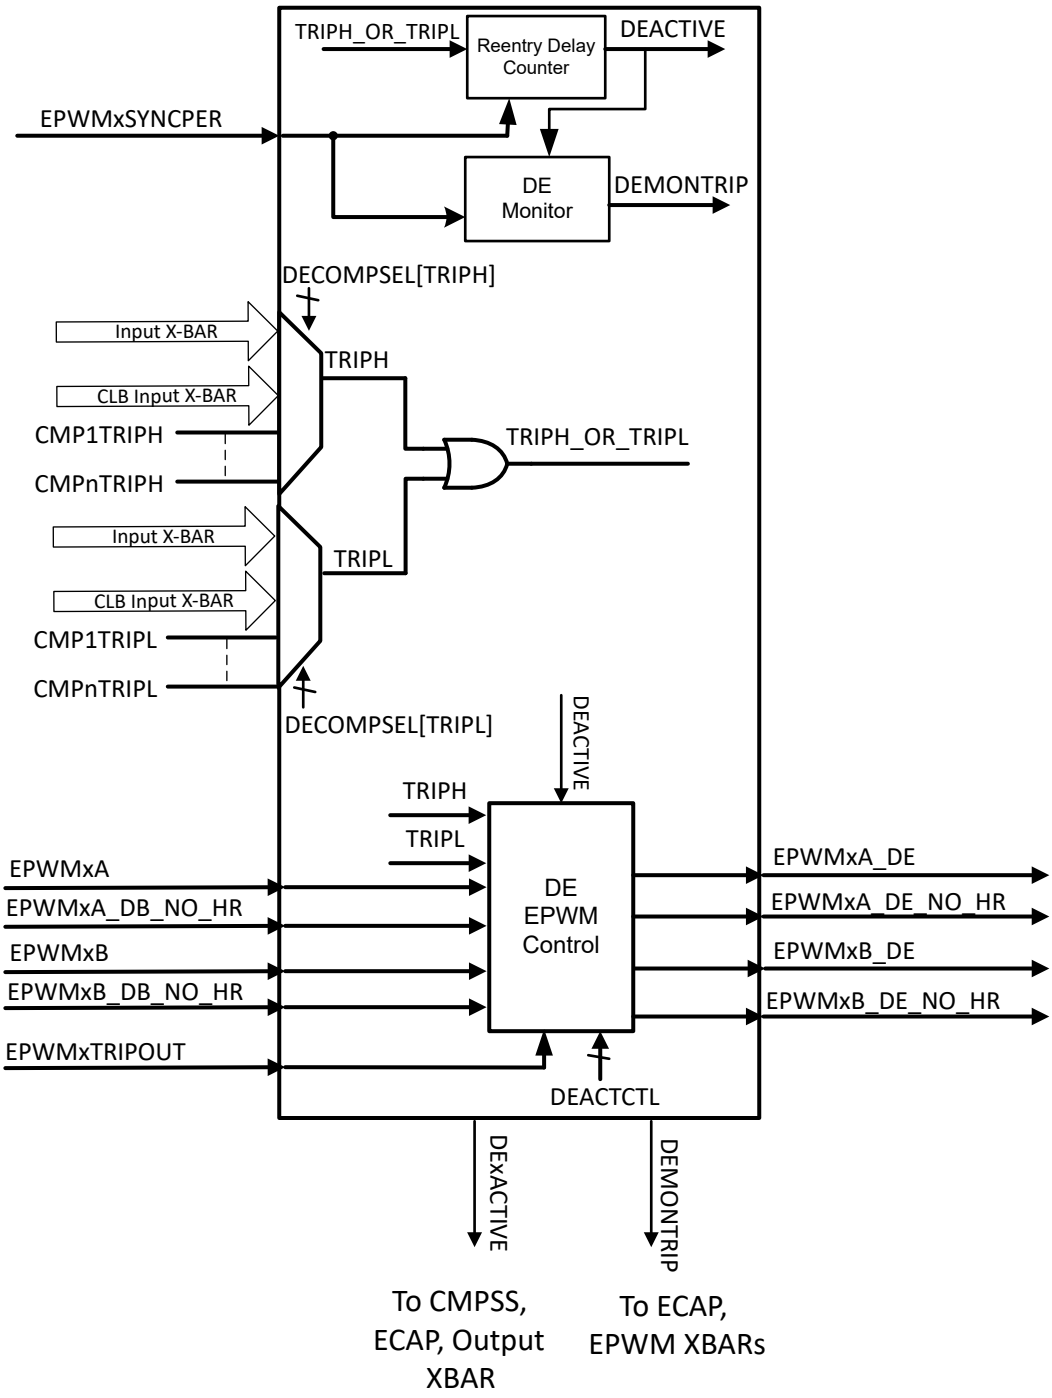

Figure 27-53. Diode Emulation Block Diagram

Copyright © 2025Texas Instruments

The DE block can be configured to select one of the comparators or one of the outputs of the Input X-Bar or CLB Input X-Bar, as source of trip signals (TRIPH, TRIPL). The selected comparator is responsible for monitoring the current in the external power converter. Comparator thresholds (High and Low threshold) can be set such that, any breach of these thresholds indicates a need to switch to the DE mode.

Once DE mode is entered, indicated by setting of DEACTIVE flag, the ePWMs sent out of DE block are controlled by configuration registers in the DE block, and are not be the same as ePWMA/B from the associated ePWM instance. Once the DEACTIVE flag is set, the threshold settings of the selected CMPSS are switched to a new set of values (a narrower region). DEACTIVE flag from all of the ePWM instances are hooked up to all the comparator sub-systems (CMPSSy) to enable threshold value switch on DE mode entry. Refer to the CMPSS chapter for more details on how the new threshold values are set.

Copyright © 2025Texas Instruments

27.11.1 DEACTIVE Mode

DE mode is entered when TRIPH_OR_TRIPL signal from the selected comparator (CMPSS) goes high. Once the diode emulation mode is entered, typically TRIPH or TRIPL are set and cleared in a sequence (at a given instance of time, TRIPH is high or TRIPL is high – never both) until the current settles within the threshold band.

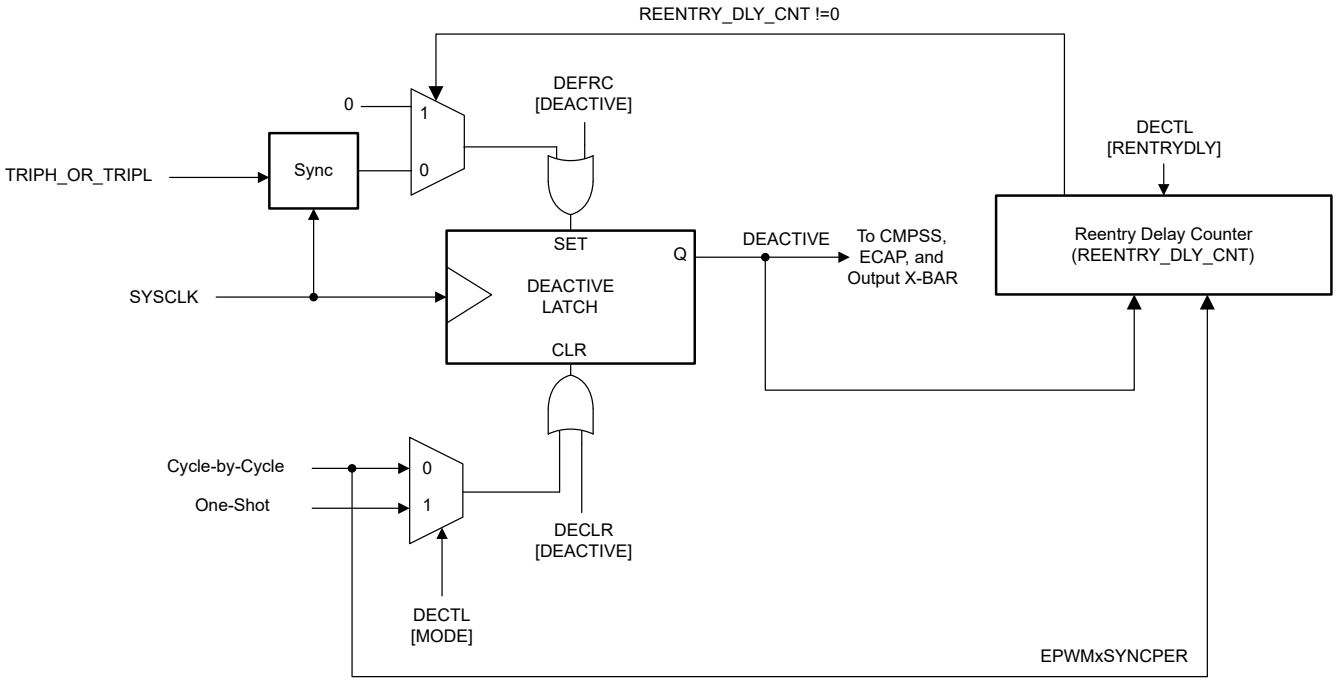

Figure 27-54. DEACTIVE Flag Functionality

Once the DEACTIVE flag is set, the thresholds on CMPSS are changed to an alternate set of thresholds, and also ePWMA/B out of DE function are being controlled by the DEACTCTL register settings. Figure 27-55 demonstrates an example timing diagram illustrating entry into DE mode.

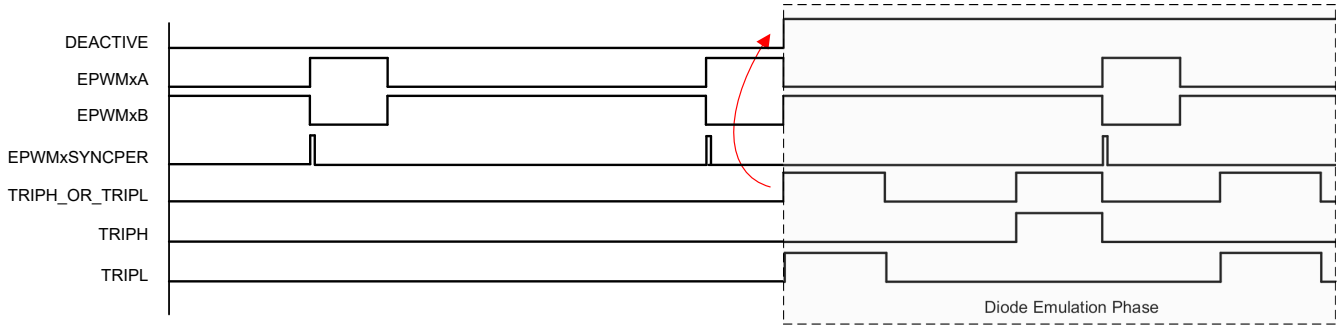

Figure 27-55. Example Timing Sequence Illustrating DE Mode Entry

Copyright © 2025Texas Instruments

27.11.2 Exiting DE Mode

DE mode can be exited in two ways, based on the DECTL[MODE] setting:

- Software clear of DEACTIVE flag, DECLR[CLR]
- Cycle-by-cycle clear mode, in which TRIPH_OR_TRIPL is evaluated on every EPWMxSYNCPER and if the trip condition is not present, then DEACTIVE flag is cleared. Figure 27-56 illustrates the clearing of the DEACTIVE flag based on EPWMxSYNCPER.

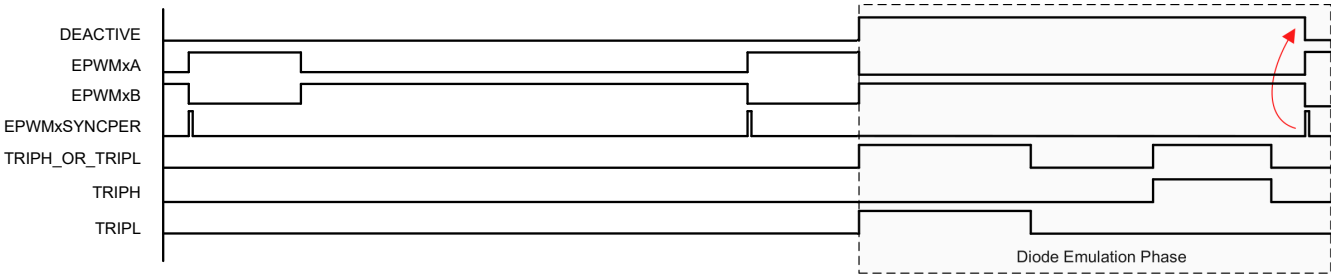

Figure 27-56. Cycle-by-Cycle Mode

27.11.3 Re-Entering DE Mode

Once DE mode is exited, DE mode can be delayed for a certain duration until reentry. This is accomplished by configuring the DECTL[REENTRYDLY] field. REENTRYDLY determines the window in which TRIP signals are prevented from setting the DEACTIVE flag. On a falling edge of DEACTIVE, an internal counter is loaded with the DECTL[REENTRYDLY] value. The counter is decremented on every EPWMxSYNCPER as long as the count value is greater than 0. While the count value is greater than 0, TRIP signals are blocked and DEACTIVE flag is not set even if TRIP events are active.

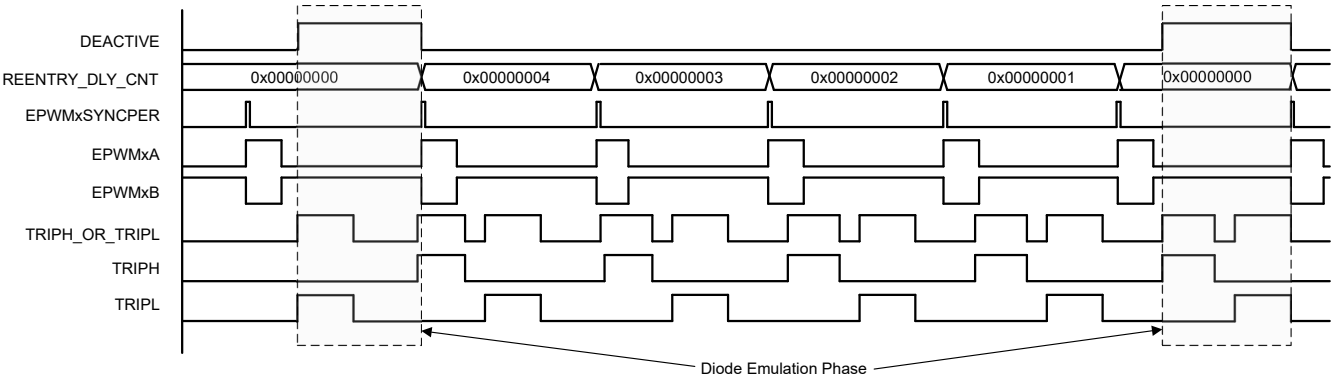

Figure 27-57. DE Mode Reentry Sequence

Figure 27-58 illustrates the circuit driving the EPWMxA/B signals from the DE block. As can be observed, when DEACTIVE flag is not set, EPWMxA_DE, EPWMxB_DE, EPWMxA_DE_NO_HR, and EPWMxB_DE_NO_HR are driven by EPWMA/B and EPWMA/B_DB_NO_HR respectfully. When DEACTIVE flag is set, EPWMA/B_DE are be driven by TRIPH, TRIPL, constant 0, or a constant 1 signal based on the configuration of the DEATCTL[PWMA], DEATCTL[PWMB], DEATCTL[TRIPSELA], DEATCTL[TRIPSELB] fields. When a PWMTRIP signal from the associated ePWM trips, EPWMA/B_DE are be driven by the input PWM signals configured through the DECTL[TRIPENABLE] field.

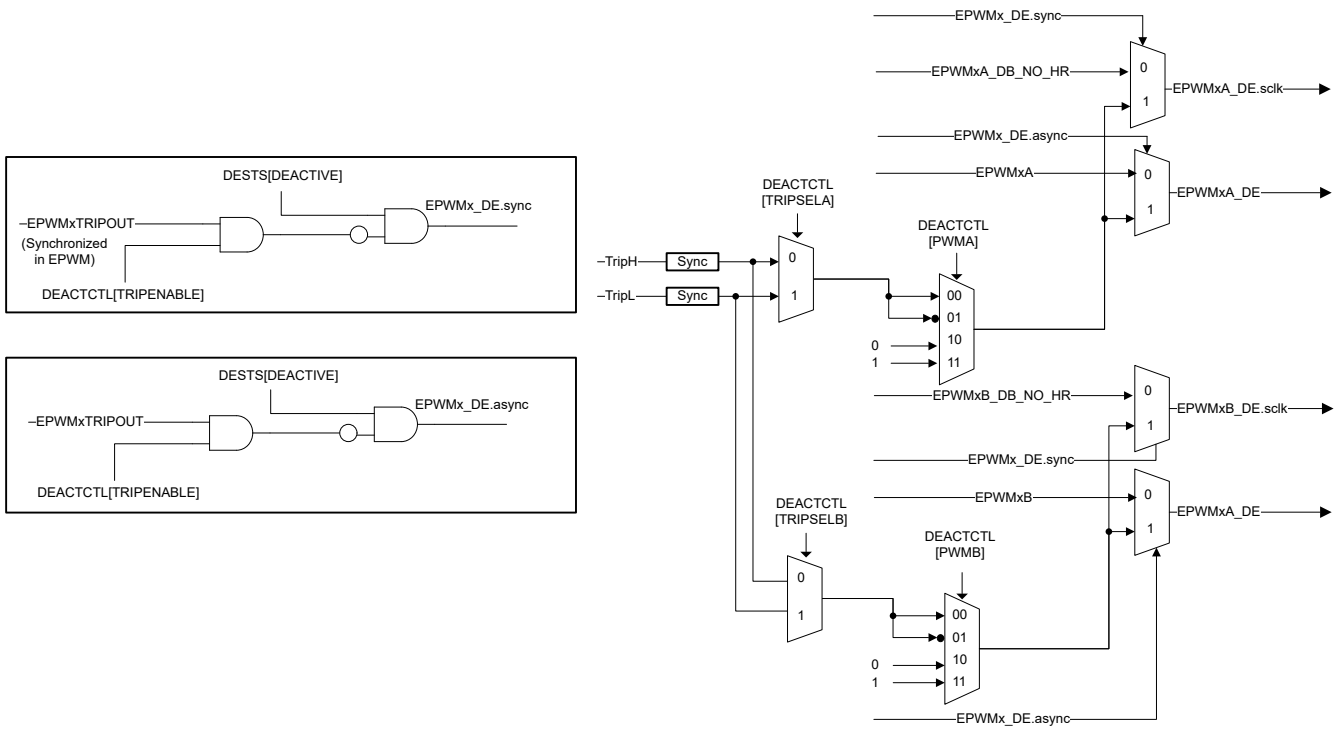

Figure 27-58. Diode Emulation Circuit

Figure 27-59 shows an example waveform, in which DEACTCTL[PWMA] is configured to select TripL as the source, DEACTCTL[PWMB] is configured to select TripH as the source and DEACTCTL[PWMAPOL] and DEACTCTL[PWMBPOL] are both 0.

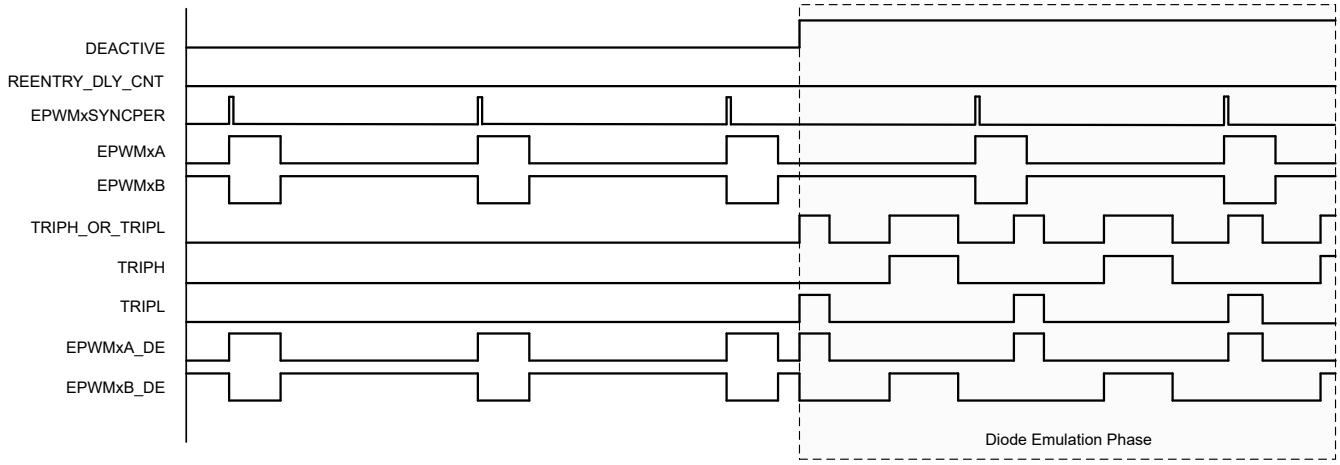

Figure 27-59. Diode Emulation Mode Timing Diagram

Copyright © 2025Texas Instruments

27.11.4 DE Monitor

To detect extended DE phase, which is beyond the expected duration, a DE mode monitor counter, DEMONCNT, is provided. This 16-bit counter monitors the frequency of diode mode trip events. The counter if enabled, DEMONCTL[ENABLE], increments on a PWMSYNC event, in steps of DEMONSTEP[INCSTEP] when TRIPH_OR_TRIPL is high, and decrements on a PWMSYNC event, in steps of DEMONSTEP[DECSTEP] when TRIPH_OR_TRIPL is low. If counter exceeds DEMONTHRES[THRESHOLD], then a DEMONTRIP pulse is generated and the counter is cleared. The counter value is saturated to 0 during an underflow and 0xffff on an overflow. The counter is cleared when DECTL[ENABLE] is cleared.

27.12 Minimum Dead-Band (MINDB) + Illegal Combination Logic (ICL) Submodules

Figure 27-61 illustrates the minimum dead-band and illegal combo submodule within the ePWM.

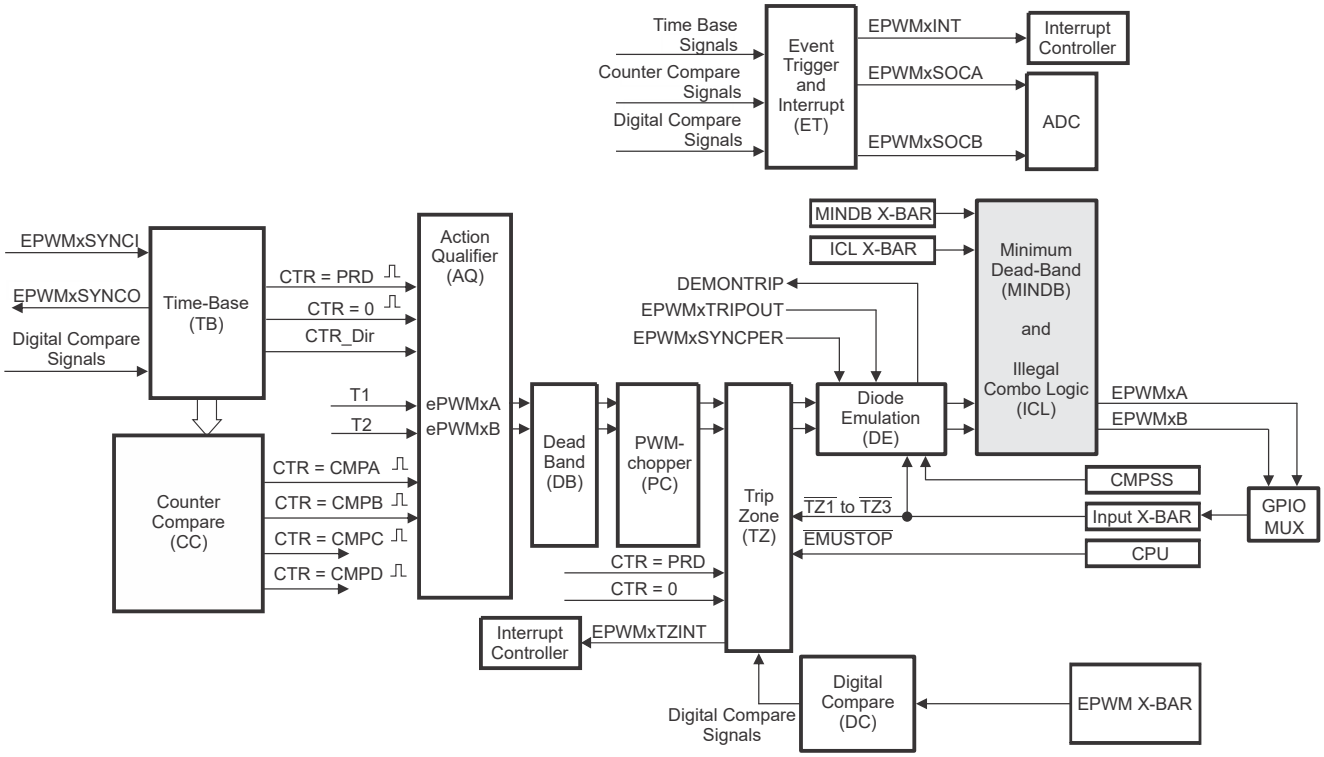

Figure 27-61. Minimum Dead-Band and Illegal Combo Logic Submodule

Copyright © 2025Texas Instruments

27.12.1 Minimum Dead-Band (MINDB)

To make sure that the minimum dead band property is not violated, as the application switches between normal mode and DE mode and due to the PWMs potentially switching based on trip inputs, a minimum dead band circuitry show in Figure 27-62 is required.

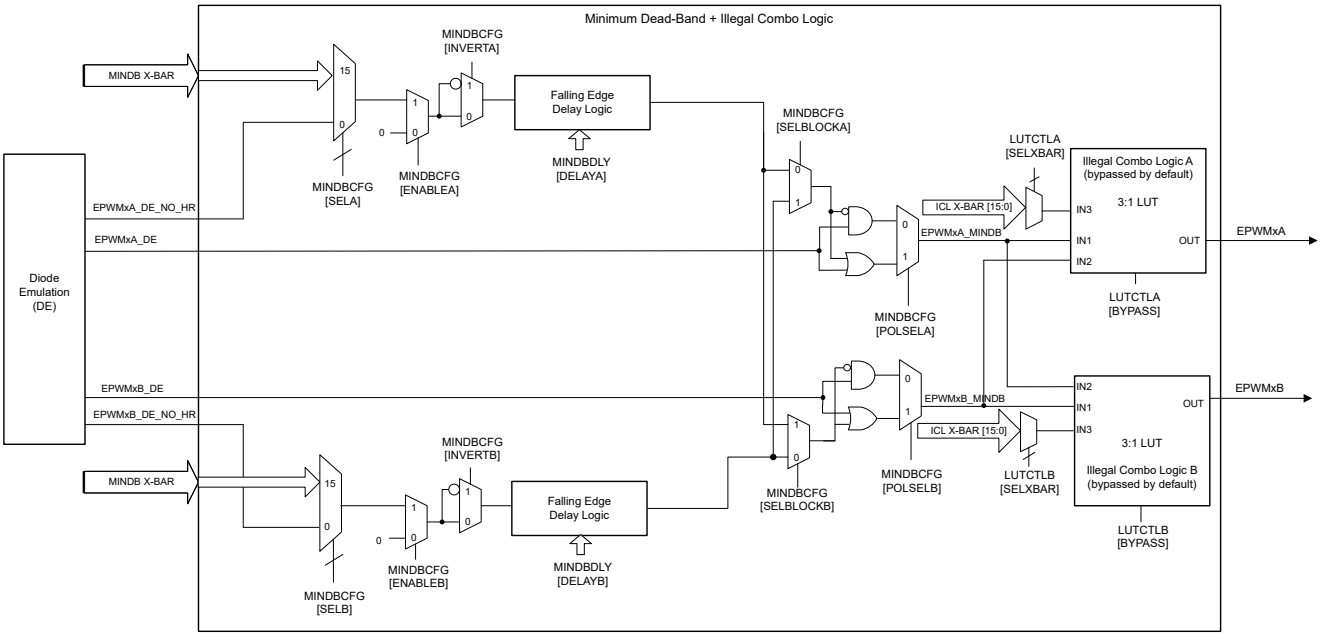

Figure 27-62. Minimum Dead-Band and Illegal Combo Logic Block Diagram

The minimum dead band block provides the ability to configure the minimum dead band duration between a complimentary set of PWMs.

Minimum dead-band logic involves generating a blocking signal (BLOCKA, BLOCKB) after the falling edge of the EPWMA/B_DE. These block signals are used to block transition on the other signal. The input to BLOCKA(B) signal generators is configurable. Normally the sources are EPWMA/B_DB_NO_HR. However, there is a provision provided to select any of the MINDB X-BAR outputs. This provides flexibility to support some of the other application scenarios.

The selected source is fed to the BLOCK signal generation logic. Block signal generation involves, detecting the falling edge based on which BLOCK signal goes high and stretching the BLOCK signal for DELAYA/B cycles, which are software configurable.

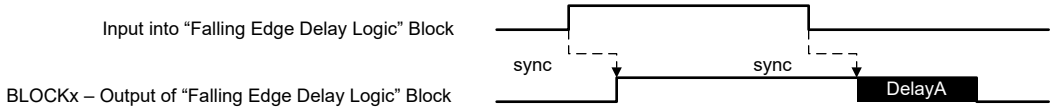

Figure 27-63. Minimum Dead-Band Block Signal Generation

Copyright © 2025Texas Instruments

In Figure 27-64 and Figure 27-65, EPWMxA_DE and BLOCKB are getting ANDed and EPWMxB_DE and BLOCKA are getting ANDed.

Note

Red shade is indicative of incorrect scenario.

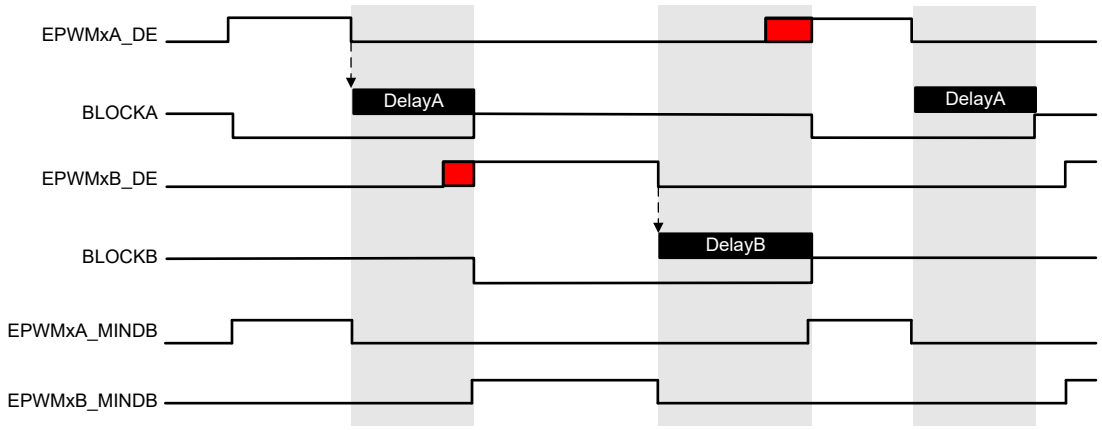

Figure 27-64. Example: Rising Edge on EPWMxA_DE and EPWMxB_DE While Delay is Being Applied

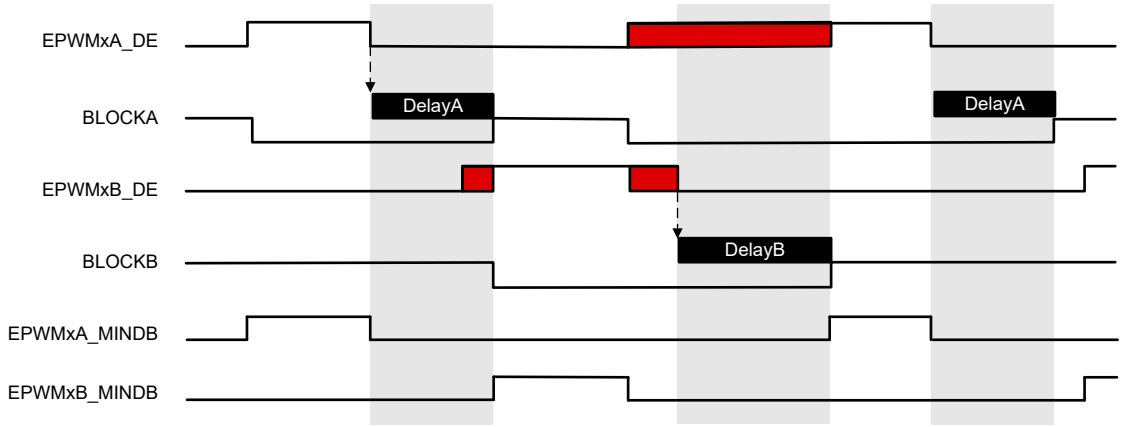

Figure 27-65. Example: Rising Edge on EPWMxA_DE while EPWMxB_DE is Still High

Figure 27-66 illustrates that a rising edge during the delay application does not affect the BLOCKA generation, same behavior is applied to BLOCKB.

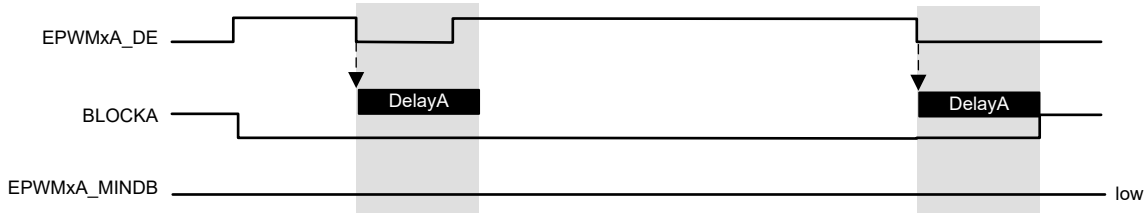

Figure 27-66. Rising Edge During Delay

Copyright © 2025Texas Instruments

Figure 27-67 showcases what happens when another falling edge occurs during the delay application. In this scenario, BLOCKA stays low until both DELAYA values are complete, same behavior is applied to BLOCKB.

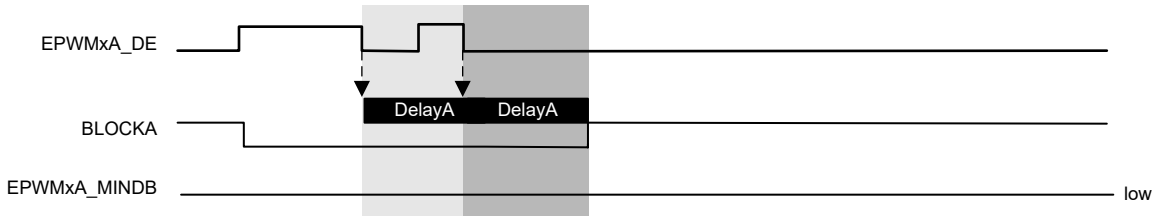

Figure 27-67. Rising Edge and Falling Edge During Delay

Note

The BLOCKA and BLOCKB signals require at least 2 TBCLK to apply to either ePWMxA and ePWMxB output.

27.12.2 Illegal Combo Logic (ICL)

As PWM generation logic gets more configurable and the interaction between multiple PWM instances increases, there is potential for corner cases during applications resulting in unintended PWM states. To detect and make sure that under no circumstance, the PWM states result in potentially hazardous combinations, a Look Up Table (LUT) has been added. By default, the LUT logic is bypassed, LUTXTLx[BYPASS]. When not bypassed, based on the combination of values on Input 3 (IN3), Input 2 (IN2), and Input 1 (IN1), the value driven on OUT is determined by the bits in the LUTCTLx [23:16] register. Input 3 into the LUT comes from one of the ICL X-BAR inputs.

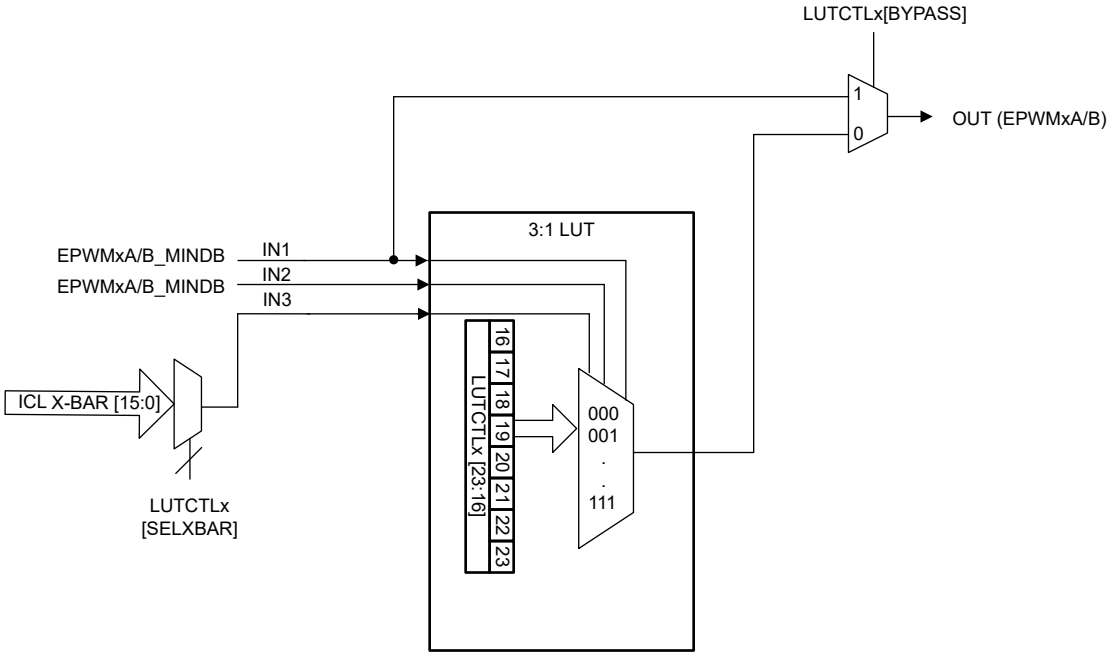

Figure 27-68. Illegal Combo Logic Block Diagram

27.13 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare, and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Up to every fifteenth event
- Provides full visibility of event generation using event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and a start of conversion pulse to the ADC when a selected event occurs.

Figure 27-69 illustrates the event-trigger submodule within the ePWM.

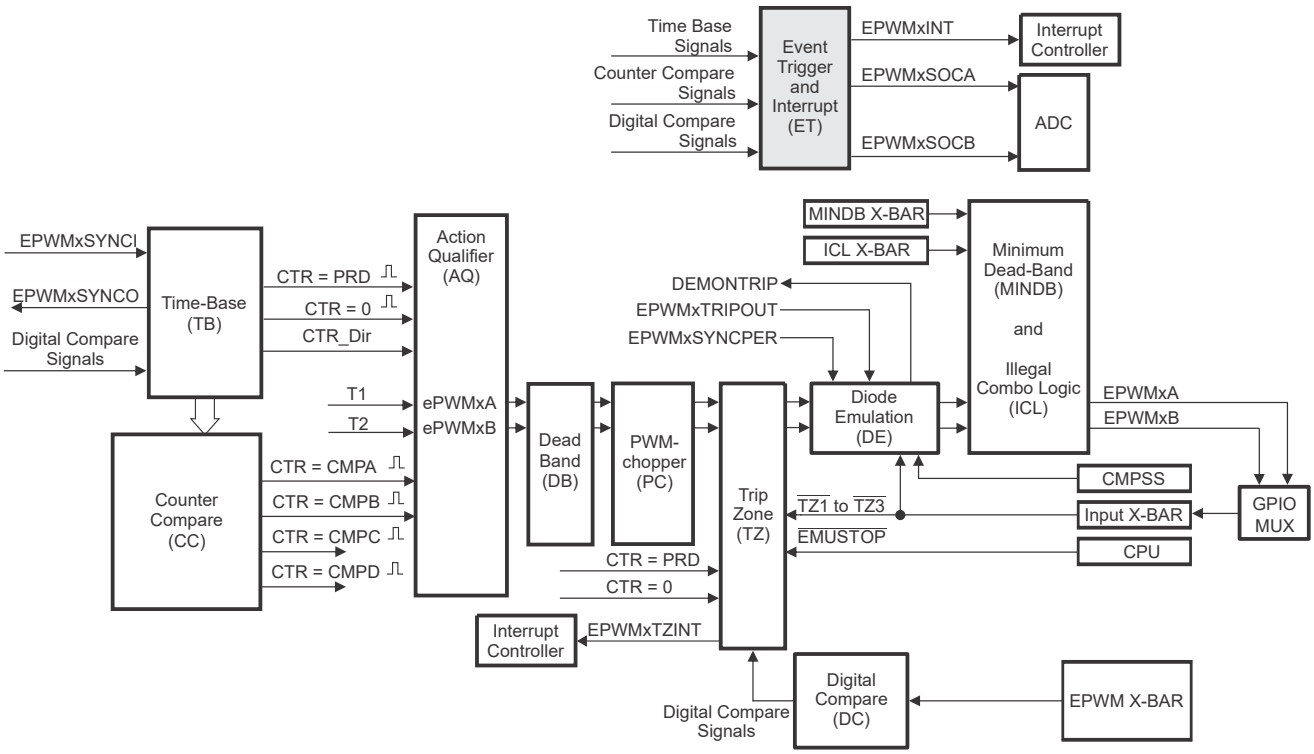

Figure 27-69. Event-Trigger Submodule

Copyright © 2025Texas Instruments

27.13.1 Operational Overview of the ePWM Event-Trigger Submodule

The event-trigger submodule monitors various event conditions (shown as inputs on the left side of Figure 27-70) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Up to every fifteenth event

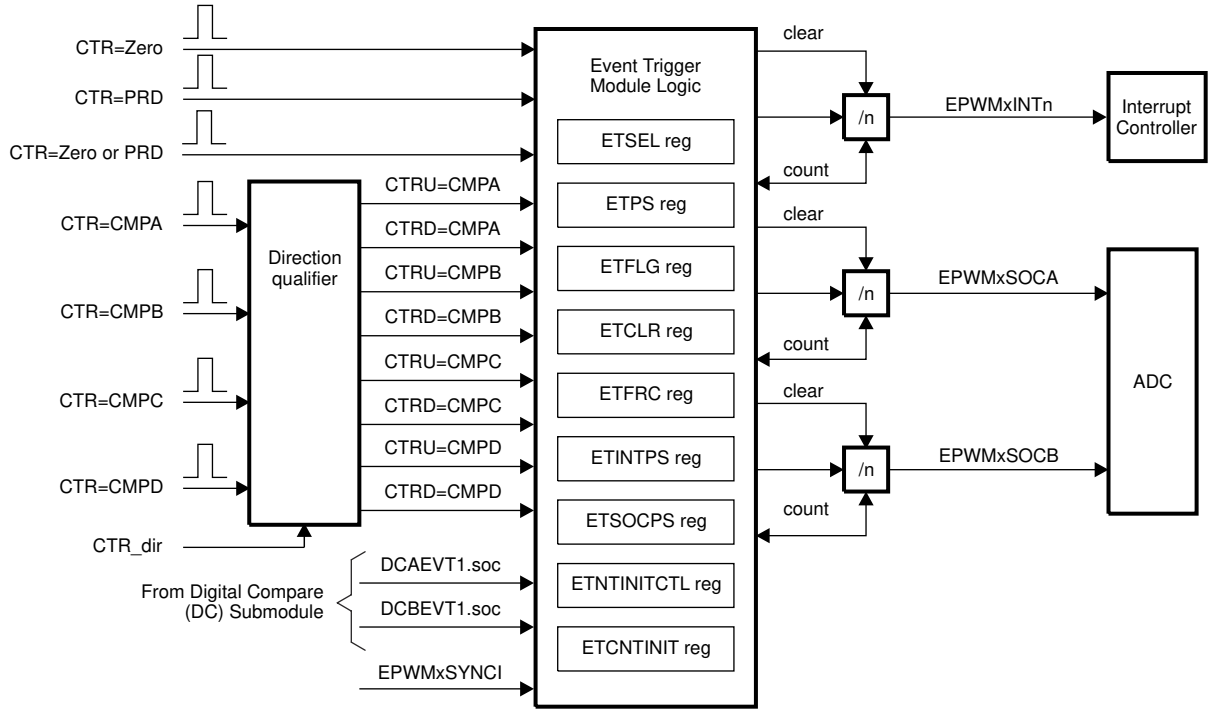

Figure 27-70. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

- ETSEL - This selects which of the possible events trigger an interrupt or start an ADC conversion.
- ETPS - This programs the event prescaling options mentioned above.
- ETFLG - These are flag bits indicating status of the selected and prescaled events.
- ETCLR - These bits allow clearing the flag bits in the ETFLG register using software.
- ETFRC - These bits allow software forcing of an event. Useful for debugging or software intervention.
- ETINTPS - This programs the interrupt event prescaling options, supporting count and period up to 15 events.
- ETSOCPS - This programs the SOC event prescaling options, supporting count and period up to 15 events.
- ETCNTINITCTL - These bits enable ETCNTINIT initialization using SYNC event or using software force.
- ETCNTINIT - These bits allow initializing INT/SOCA/SOCB counters on SYNC events (or software force) with user programmed value.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in Figure 27-71, Figure 27-72, and Figure 27-73.

Figure 27-71 shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event.
- Generate an interrupt on every second event.
- Generate an interrupt on every third event.

Copyright © 2025Texas Instruments

The selection made on ETPS[INTPSSEL] bit determines whether ETINTPS register, INTCNT2 and INTPRD2 bit fields determine frequency of events (interrupt once every 0-15 events).

The event that can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) and (ETSEL[INTSELCMP]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x00).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x00 || TBCTR = TBPRD).
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is incrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is decrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is incrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter ETPS[INTCNT] or ETINTPS[INTCNT2] register bits based off of the selection made using ETPS[INTPSSEL]. That is, when the specified event occurs the ETPS[INTCNT] or ETINTPS[INTCNT2] bits are incremented until the bits reach the value specified by ETPS[INTPRD] or ETINTPS[INTPRD2] determined again by the selection made in ETPS[INTPSSEL]. When ETPS[INTCNT] = ETPS[INTPRD], the counter stops counting and the counter output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When ETPS[INTCNT] reaches ETPS[INTPRD], the following behavior occurs. [The following behavior is also applicable to ETINTPS[INTCNT2] and ETINTPS[INTPRD2]:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter begins counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when the counter reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter holds the output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing a 0 to the INTPRD bits automatically clears the counter (INTCNT = 0) and the counter output resets (so no interrupts are generated). For all other writes to INTPRD, INTCNT retains the previous value. INTCNT resets when INTCNT overflows. Writing a 1 to the ETFRC[INT] bit increments the event counter INTCNT. The counter behaves as previously described when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events are detected and the ETFRC[INT] bit is also ignored. The same applies to ETINTPS[INTCNT2] and ETINTPS[INTPRD2].

The previous definition means that an interrupt on every event, on every second event, or on every third event if using the INTCNT and INTPRD can be generated. An interrupt on every event up to 15 events if using the INTCNT2 and INTPRD2 can be generated.

The INTCNT2 value can be initialized with the value from ETCNTINIT[INTINIT] based on the selection made in ETCNTINITCTL[INTINITEN]. When ETCNTINITCTL[INTINITEN] is set, then initialization of INTCNT2 counter with contents of ETCNTINIT[INTINIT] on a SYNC event or software force is determined by ETCNTINITCTL[INTINITFRC].

Copyright © 2025Texas Instruments

ETINTMIX, ETSOCAMIX and ETSOCBMIX Signals

In type 5 ePWM, the Event-Trigger submodule can generate and use ETINTMIX, ETSOCAMIX and ETSOCBMIX signals.

- **ETINTMIX**: This signal is a generated from the ORed combination of the sources enabled in the ETINTMIXEN register. The ETINTMIX signal can be used as a source for the EPWMxINT interrupt.
- **ETSOCAMIX**: This signal is a generated from the ORed combination of the sources enabled in the ETSOCAMIXEN register. The ETSOCAMIX signal can be used as a source for the EPWMxSOCA trigger signal.
- **ETSOCBMIX**: This signal is a generated from the ORed combination of the sources enabled in the ETSOCBMIXEN register. The ETSOCBMIX signal can be used as a source for the EPWMxSOCB trigger signal

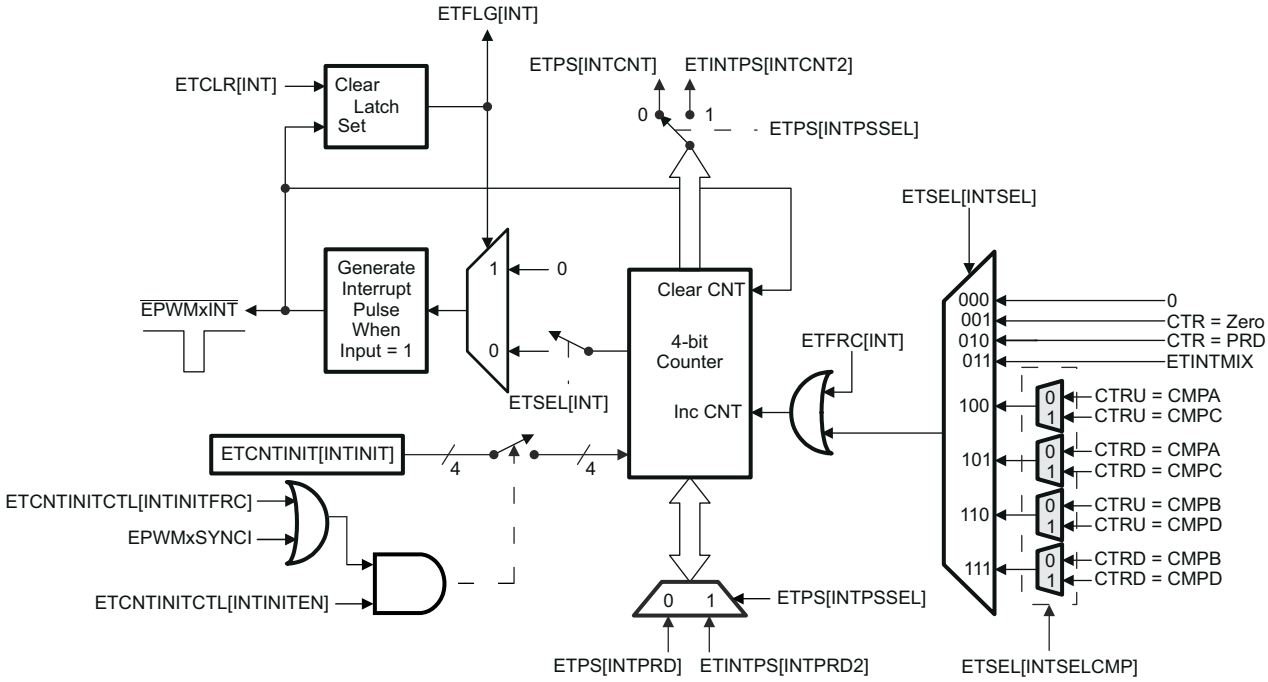

Figure 27-71. Event-Trigger Interrupt Generator

Figure 27-72 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The enhancements include SOCASELCMP and SOCBSELCMP bit fields defined in the ETSEL register enable CMPC and CMPD events respectively to cause a start of conversion. The ETPS[SOCPSSEL] bit field determines whether SOCACNT2 and SOCAPRD2 take control or not. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but the interrupt generator does not stop further pulse generation. The enable and disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that triggers an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule. The SOCACNT2 initialization scheme is very similar to the interrupt generator with respective enable, value initialize and SYNC or software force options.

Note

NOTE: The DCBEVT1.soc signals are generated by the Digital Compare (DC) submodule in Section 27.14 .

Figure 27-73. Event-Trigger SOCB Pulse Generator

27.14 Digital Compare (DC) Submodule

Figure 27-74 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The eCAP input signals are sourced from the Input X-BAR signals as shown in Figure 27-75.

On this device, any of the GPIO pins can be flexibly mapped to be the trip-zone input and trip inputs to the trip-zone submodule and digital compare submodule. The Input X-BAR Input Select (INPUTxSELECT) register defines which GPIO pins gets assigned to be the trip-zone inputs/trip inputs.

The digital compare (DC) submodule compares signals external to the ePWM module (for instance, CMPSSx signals from the analog comparators) to directly generate PWM events/actions which then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

Note

The user is responsible for driving the correct state on the selected pin before enabling the clock and configuring the trip input for the respective ePWM peripheral to avoid spurious latch of the TRIP signal.

27.14.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- Analog comparator (COMP) module outputs fed though the Input X-BAR, EPWM X-BAR, externally using the GPIO peripheral, interrupt controller signals, ECC error signals, TZ1, $\overline{TZ2}$, and $\overline{TZ3}$ inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events that can then either be filtered or applied directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

27.14.2 Enhanced Trip Action Using CMPSS

To allow multiple CMPSS at a time to affect DCA/BEVTx events and trip actions, there is a OR logic to bring together ALL trip inputs (up to 15) from sources external to the ePWM module and feed into DCAH, DCAL, DCBH, and DCBL as a “combinational input” using the DCTRIPSEL register. This is configured by selecting “Trip combination input” (value of 0xF) in the DCTRIPSEL register.

There is a discrete choice of which trip inputs to put through the combinational logic for generating the DCAH, DCAL, DCBH, and DCBL signals. This is achieved using the DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL, and DCBLTRIPSEL register selections. Inputs selected for combinational input are passed through to the DCTRIPSEL register.

27.14.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis

When using the CMPSS to trip the ePWM on a cycle-by-cycle basis, steps can be taken to prevent an asserted comparator trip state in one PWM cycle from extending into the following cycle. The CMPSS can be used to signal a trip condition to the downstream ePWM modules. For applications like peak current mode control, only one trip event per PWM cycle is expected. Under certain conditions, it is possible for a sustained or late trip event (arriving near the end of a PWM cycle) to carry over into the next PWM cycle if precautions are not taken. If either the CMPSS Digital Filter or the ePWM Digital Compare (DC) submodule is configured to qualify the comparator trip signal, “N” number of clock cycles of qualification are introduced before the ePWM trip logic can respond to logic changes of the trip signal. Once an ePWM trip condition is qualified, the trip condition remains active for N clock cycles after the comparator trip signal has de-asserted. If a qualified comparator trip signal remains asserted within N clock cycles prior to the end of a PWM cycle, the trip condition is not cleared until after the following PWM cycle has started. Thus, the new PWM cycle detects a trip condition as soon as the cycle begins.

To avoid this undesired trip condition, the application can take steps to make sure that the qualified trip signal seen by the ePWM trip logic is deasserted prior to the end of each PWM cycle. This can be accomplished through various methods:

- Design the system such that a comparator trip is not asserted within N clock cycles prior to the end of the PWM cycle.
- Activate blanking of the comparator trip signal using the ePWM event filter at least two clock cycles prior to the PWMSYNCPER signal and continue blanking for at least N clock cycles into the next PWM cycle.
- If the CMPSS COMPxLATCH path is used, clear the COMPxLATCH at least N clock cycles prior to the end of the PWM cycle. The latch can be cleared by software (using COMPSTSCLR) or by generating an early PWMSYNCPER signal. The ePWM modules on this device include the ability to generate PWMSYNCPER upon a CMPC or CMPD match (using HRPCTL) for arbitrary PWMSYNCPER placement within the PWM cycle.

27.14.4 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

27.14.4.1 Digital Compare Events

As described in Section 27.14.1 , trip zone inputs ($\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$) and CMPSSx signals from the analog comparator (COMP) module can be selected using the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

Note

The $\overline{TZn}$ signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active-high or active-low inputs. ePWM outputs are asynchronously tripped when either the $\overline{TZn}$, DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of 3 × TBCLK sync pulse width is required. If pulse width is < 3*TBCLK sync pulse width, the trip condition can or can not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in Event Filtering. Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:** DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (using TZCTL, TZCTLDCA, TZCTLDCB register configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (using the TZSEL register), the DCAEVT1/2.force signals can effect the trip action using the TZCTL or TZCTL2 register configurations. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

  The priority of conflicting actions on the TZCTL, TZCTL2, TZCTLDCA and TZCTLDCB registers is as follows (highest priority overrides lower priority):

  Output EPWMxA:
  - TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)
  - TZAU (highest) -> DCAEVT1U -> DCAEVT2U (lowest)
  - TZAD (highest) -> DCAEVT1D -> DCAEVT2D (lowest)

  Output EPWMxB:
  - TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)
  - TZBU (highest) -> DCBEVT1U -> DCBEVT2U (lowest)
  - TZBD (highest) -> DCBEVT1D -> DCBEVT2D (lowest)
- **interrupt signal:** DCAEVT1/2.interrupt signals generate trip zone interrupts to the interrupt controller. To enable the interrupt, set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set to clear the interrupt.
- **soc signal:** The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse using the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse using the ETSEL[SOCBSEL] bit.
- **sync signal:** The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCI input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

Copyright © 2025Texas Instruments

Figure 27-76 and Figure 27-77 show how the DCxEVT1, DCxEVT2, or DCEVTFLT signals are processed to generate the digital compare A and B event force, interrupt, soc and sync signals.

In some of the applications like Phase Shifted Full Bridge (PSFB) Converters, it is required that different actions are taken on a CBC trip event and an OST trip event. This can be achieved using the DCxEVT1LAT.

- This latch can be cleared on CNT = 0, CTR = PRD, and CNT = 0 OR CTR = PRD events based on the setting of DCxCTL.EVTy.LATCLRSEL setting. This is similar to CBC latch clear mechanism.
- DCxEVTy.force signal can be chosen to be either the latched version or the unlatched version based on DCxCTL.EVTyLATSEL value.
- The status of DCxEVTyLAT signal can be accessed by reading DCxCTL.EVTyLAT field.

27.14.4.2 Event Filtering

Blank Control Logic: The DCAEVT1/2 and DCBEVT1/2 events can be filtered using event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs can be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blank control logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. Blank control logic is used to define a blanking window, which ignores all event occurrences on the signal while the window is active. The blanking window is configured in the DCFCTL, DCFOFFSET, and DCFWINDOW registers. The DCFCTL register enables the blanking window and aligns the blanking window to either a CTR = PRD pulse or a CTR = 0 pulse or both CTR = PRD and CTR = 0 as specified by DCFCTL[PULSESEL]. DCFCTL[SRCSEL] selects the DCxEVTy event source for the DCEVTFILT signal. An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before. Figure 27-78 shows the details of the event filtering logic.

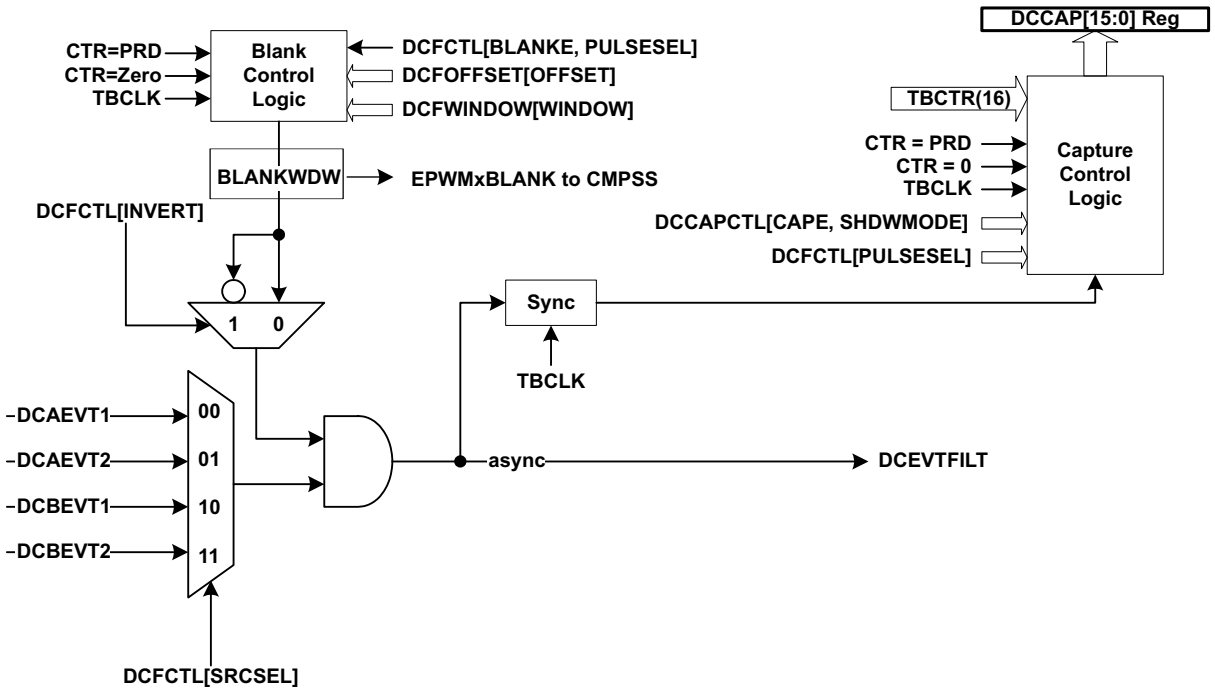

Figure 27-78. Event Filtering

Capture Control Logic: The event filtering can also capture the TBCTR value of the selected DCxEVTy event as configured in the DCCAPCTL register. When capture control logic is enabled, the selected DCxEVTy event triggers capture of the TBCTR to the active register. The CPU reads directly from the active register unless shadow mode is enabled by DCCAPCTL[SHDWMODE]. When shadow mode is enabled, the active register information is copied to shadow register on the event specified by DCFCCTL[PULSESEL], and the CPU reads from the shadow register. After the selected DCxEVTy event, no further capture events occur until the event specified by DCCAPCTL[CAPMODE]. The CAPMODE can be configured two ways: (1) no further capture events occur until the event defined by DCFCTL[PULSESEL] or (2) no further capture events occur until the compare-event flag at DCCAPCTL[CAPSTS] is cleared by DCCAPCTL[CAPCLR].

Note

You must configure the ePWM blanking window appropriately so that the Trip Input stays valid for at least 3 ePWM cycles after the blanking window has expired.

Copyright © 2025Texas Instruments

Figure 27-79 illustrates several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

BLANKPULSEMIX and DCCAPMIX Signals

The CAPCTL MUX (available in the Capture Control Logic) and DCFCTL MUX (available for Blank Control Logic and Capture Control Logic) have new options in type 5 ePWM which allows them to select the DCCAPMIX or BLANKPULSEMIX signal respectively.

In type 5 ePWM, the shadow load signal for the Capture Control Logic can be different from the blanking window alignment signal (which is selected by DCFCTL[PULSESEL]). The CAPCTL mux can be configured to use the DCCAPMIX signal

27.14.4.3 Valley Switching

Event filtering depicts the valley switching function along with the event filtering logic described in Event Filtering. This function can be used to achieve programmable valley switching without any additional external circuitry. This module provides an on-chip hardware mechanism that can:

- Capture the oscillation period
- Accurately delay the PWM switching instant
- Allow a programmable number of edges before the delay takes effect
- Provide multiple choices of triggers and events
- Allow easy adaptability for optimum performance under changing system/operating conditions

The DCxEVTy signal needs further processing to support valley switching. Here is a brief description of how valley switching function is enabled:

1. Select one of the DCxEVTy events as input to the valley switching block (DCFCTL[SRCSEL]) with an option to add the blanking window (Blank Control Logic). This is where the comparator output (or external input) above is selected as an input to the valley switching block.
2. Configure the edge filter to capture 'n' rising, falling or both edges through the edge selection logic (DCFCTL[EDGEMODE, EDGECOUNT]).
3. Select the correct event to reset and restart the edge filter (VCAPCTL[TRIGSEL]). Edge capturing event is triggered or armed by this selected edge.
4. Enable valley capture logic (VCAPCTL[VCAPE]).
5. Select the start edge that indicates the start of capture for oscillation period measurement (VCNTCFG[STARTEDGE]). This is where the 16-bit counter starts counting.
6. Select the stop edge (VCNTCFG[STOPEDGE]) that indicates the edge at which the 16-bit counter stops counting. The captured counter value (CNTVAL) provides oscillation period information.
   - The STOPEDGE value must always be greater than STARTEDGE value.
7. Configure and apply the captured delay (CNTVAL) to the edge filtered DCxEVTy signal. The CNTVAL value can be applied as is or applied in conjunction with a software programmed value (useful for offset adjustment) (SWVDELVAL) or only a fraction of the delay can be applied with or without SWVDELVAL. This is useful to correctly apply a delay corresponding to the valley point. (VCAPCTL[VDELAYDIV])
8. Configure VCAPCTL[EDGEFILTDLYSEL] to apply hardware delay based on the captured value above.

Once the counter is stopped, counter value is copied into CNTVAL register and counter is reset to zero. No further captures are done until the logic is triggered again by occurrence of event selected by VCAPCTL[TRIGSEL]. In this implementation, the software trigger is used as the source for VCAPCTL[TRIGSEL]. Upon occurrence of the trigger event, irrespective of the current status of the counter, the counter is reset and starts counting from zero upon occurrence of the STARTEDGE. Similarly, upon occurrence of the trigger event, the edge filter is reset and starts counting from zero upon occurrence of the STARTEDGE.

Output from the valley switching block (DCEVTFILT) is then used to synchronize the PWM time-base. The process is shown in Figure 27-81.

Note

A specific application example showcasing the usage of valley switching hardware and software is available in the F29x Software Development Kit (F29-SDK).

27.14.4.4 Event Detection

This logic is primarily intended to detect an occurrence of a trip event in a configured time window. The window is configured by MIN and MAX values configured in the XMINMAX register sets.

Figure 27-82 indicates the window spread across MIN and MAX bounds and the edge of the chosen signal occurring in that window. The purpose of this block is to detect the occurrence of such edge. If no such edge occurs, this module generates a trip event as well as an interrupt, if configured.

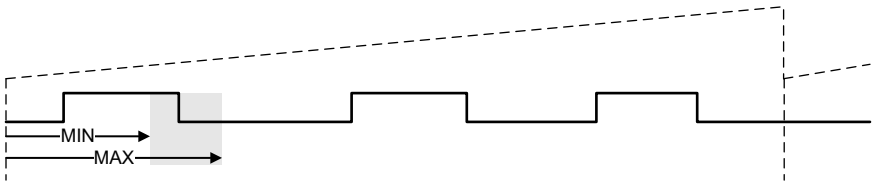

Figure 27-82. MIN, MAX Settings and Window for Capture Event Detection

Copyright © 2025Texas Instruments

27.14.4.4.1 Input Signal Detection

The CAPTRIPSEL, CAPINTRIPSEL and CAPGATETRIPSEL muxes are used for signal selection. Figure 27-83 shows how the CAPIN and CAPGATE signal source is selected.

CAPIN Input: This signal (any input coming from EPWM X-BAR) can be configured as the signal input on which the edge detection logic is performed.

CAPGATE Input: This signal (any input coming from EPWM X-BAR) can be configured as the gating signal to Min/Max logic. This signal gates the CAPIN input signal.

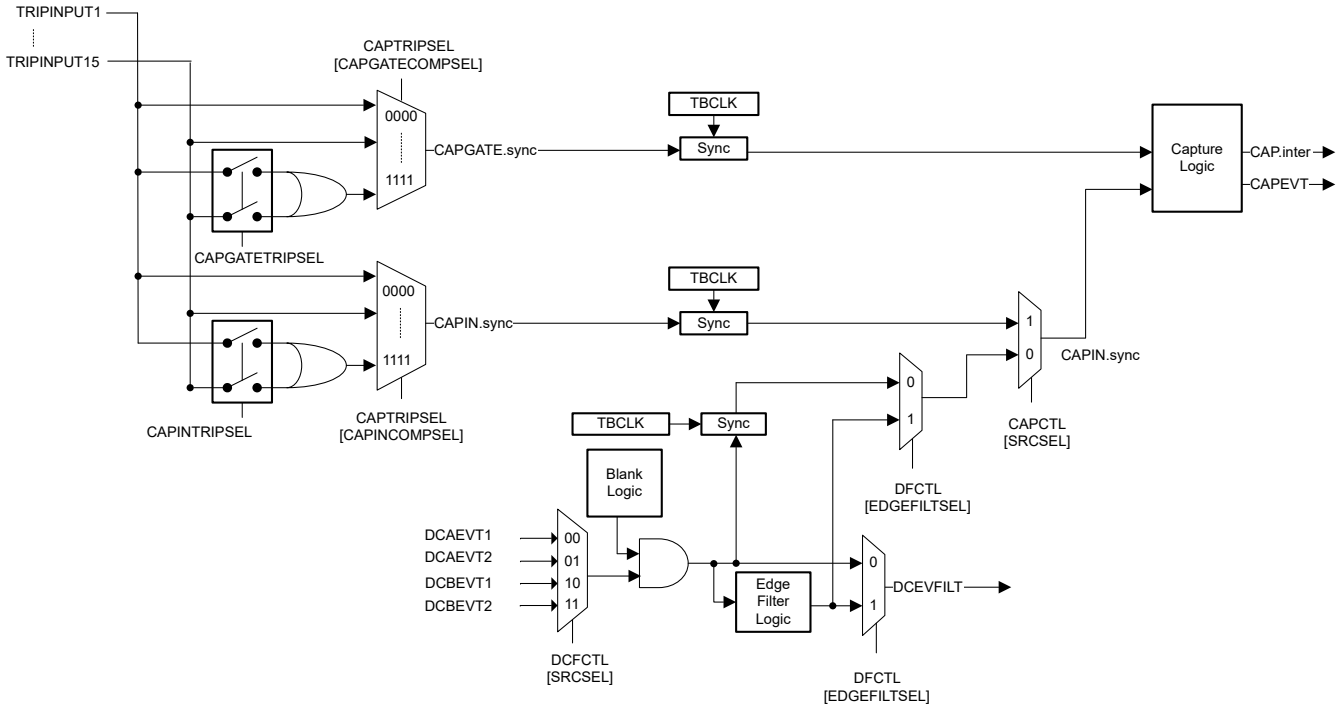

Figure 27-83. CAPIN and CAPGATE Source Selection

Once selected, Figure 27-84 demonstrates how the CAPGATE and CAPIN signals propagate into the counter capture logic. The logic works in the following way:

- CAPCTL[GATEPOL] is used for the polarity selection of the gating input to be optionally inverted or tied to a 0 or 1.
- CAPCTL[CAPINPOL] can be used to select the edge polarity of CAPIN.sync signal. CAPIN.sync signal is selected from the DCEVTFILT options and the CAPIN signal using CAPCTL[SRCSEL] bits.

Copyright © 2025Texas Instruments

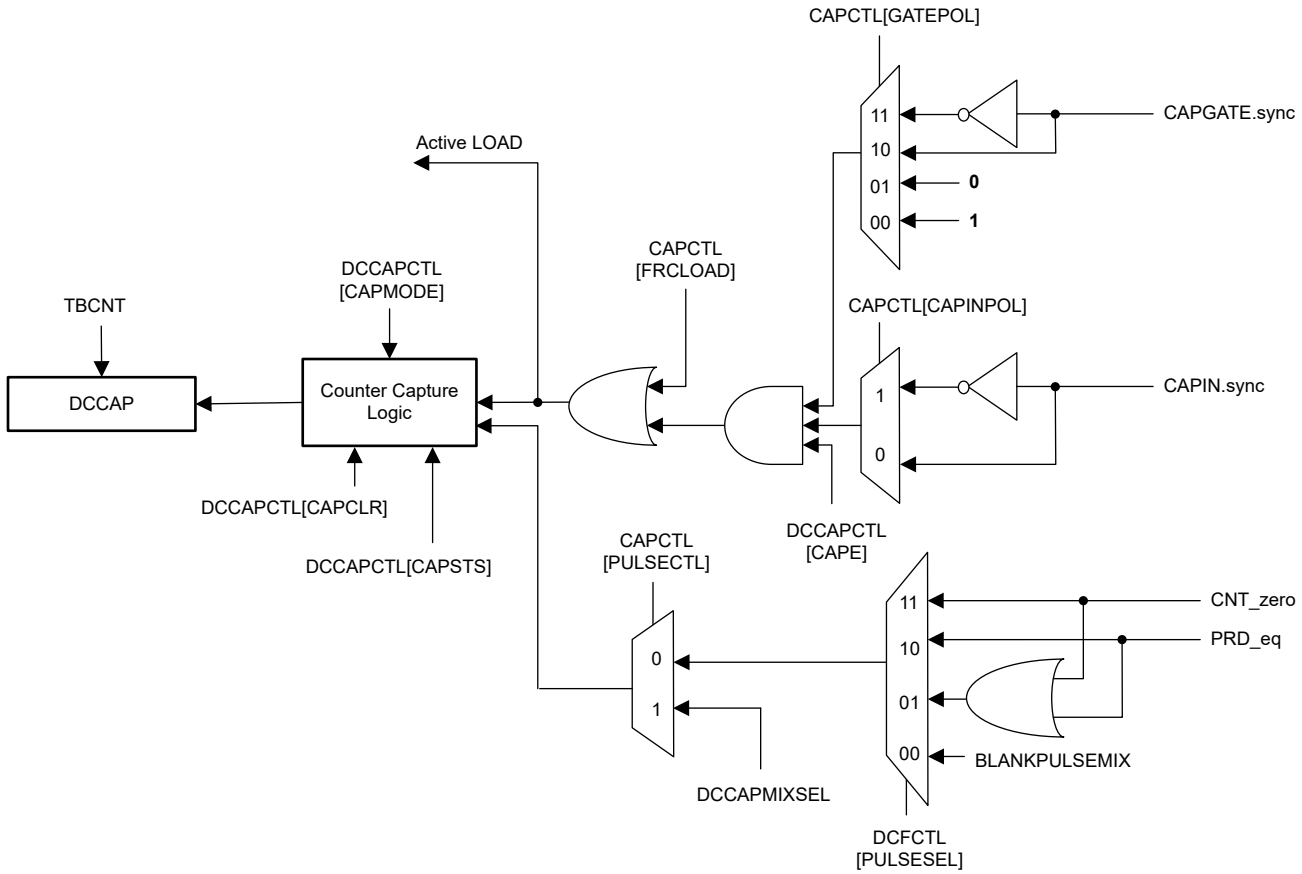

Figure 27-84. Counter Capture Logic

27.14.4.4.2 MIN and MAX Detection Circuit

The XMINMAX register has XMIN and XMAX fields that can be programmed to set the MIN and MAX limits of the programmable edge detection window. These registers have 3-level buffering similar to the XCMPn registers. The shadow to active loading of these registers is always in sync with the buffer pointers. Any shadow to active loads occur as per the XLOAD register configuration defined for the XCMPn registers such that the MIN and MAX values used are always in line with the corresponding XPRD/XCMPn values used for a given PWM cycle.

Copyright © 2025Texas Instruments

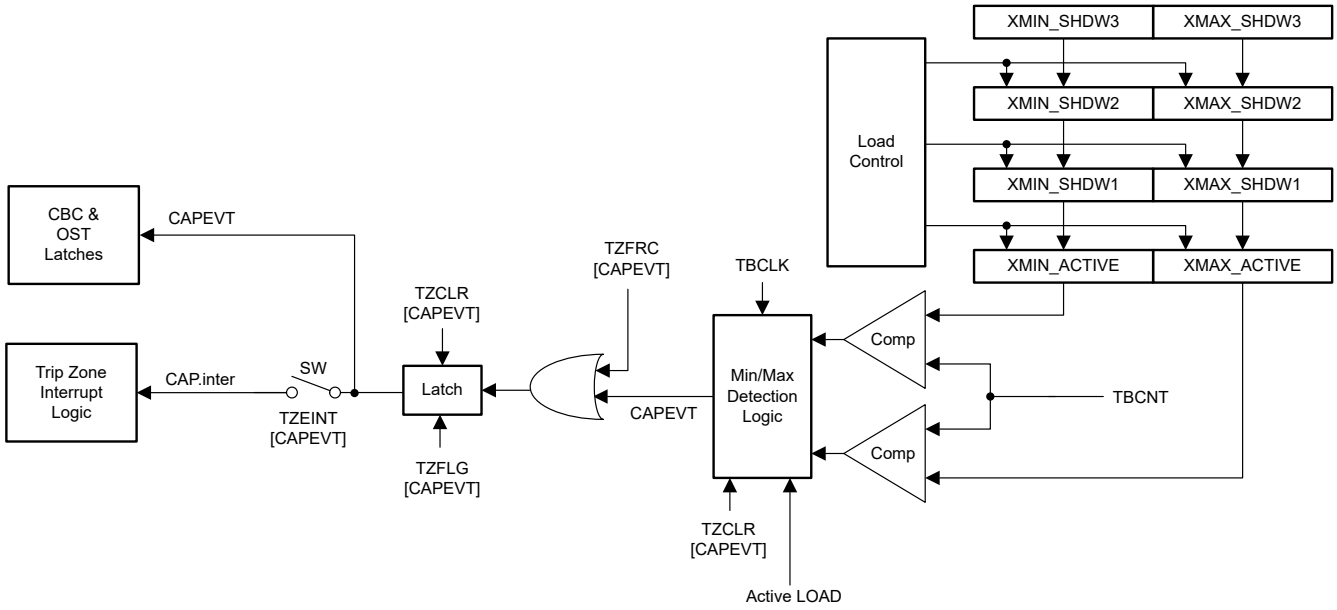

Figure 27-85. MIN and MAX Threshold Detection Logic

The logic works in the following way:

- The TBCNT value is continually monitored and compared against the active MIN value. Match of TBCNT to the active MIN value triggers the edge monitoring occurrence.
- When the TBCNT value reached the MIN value, the active LOAD signal is monitored waiting for an edge event to occur.
- If an edge vent occurs before TBCNT reaches the active MAX value, then no further action is taken. The logic resets and TBCNT is compared to the active MIN value again.
- If no edge occurs and TBCNT reaches the active MAX value, then the CAPEVT signal is set high and a CAP interrupt signal can also be generated. The CAPEVT signal needs to be cleared through software for TBCNT to be monitored against the MIN value again.

The Min and Max monitoring is enabled and disabled in three ways:

- By enabling/disabling the circuit using the DCCAPCTL[CAPE] bit.
- By the CAPGATE signal that can be sourced from an TRIPINPUT signal to the module.
- By writing the same value into the XMIN and XMAX bits.

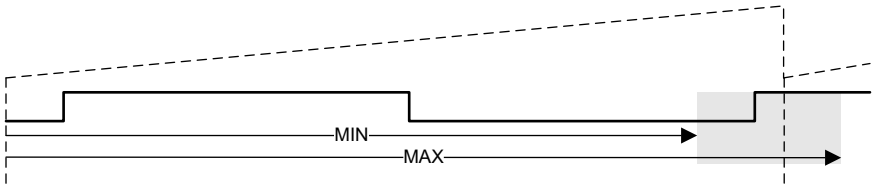

Figure 27-86. Capture Logic Boundary Condition

Note

Possible boundary condition of MIN/MAX window exceeding the period value: In this case, the XMAX bit can have a value lower than the XMIN bit such that the window can go over the period boundary.

Event Detection Filter

Type-5 ePWM supports event detection in the window specified through XMIN/MAX_ACTIVE/SHADOW registers. Each time an event is not detected a trip event or interrupt is generated. Type-6 ePWM provides

Copyright © 2025Texas Instruments

an ability to filter these events based on threshold value and generate trip/interrupt only if event is not detected more than the provided threshold.

Referring to #unique_1158/unique_1158_Connect_42_FIG_G1G_WBM_FHC, if number of 1s sampled on CAPEVT in sample size (configured by XCMP_FILCTL[SAMPWIN]) is more than the threshold (configured by XCMP_FILCTL[THRESH]), the filtered CAPEVT is generated and this can be configured to generate trip or interrupt instead of the raw CAPEVT.

27.16 Applications to Power Topologies

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

27.16.1 Overview of Multiple Modules

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 27-88. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

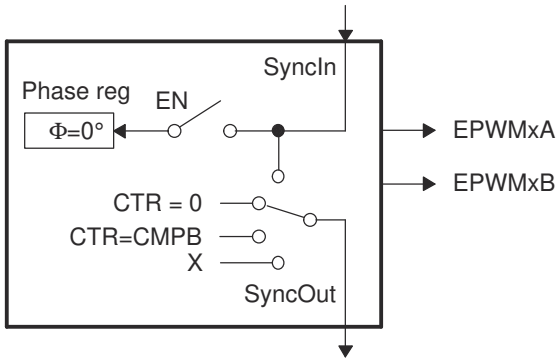

Figure 27-88. Simplified ePWM Module

Copyright © 2025Texas Instruments

27.16.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Sync Source mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Sync Source mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Sync Source mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Sync Source mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module can also choose to load the counter with a new phase value on a SyncIn strobe input or choose to ignore the value (that is, by the enable switch). Although various combinations are possible, the two most common—Sync Source module and Sync Receiver module modes—are shown in Figure 27-89.

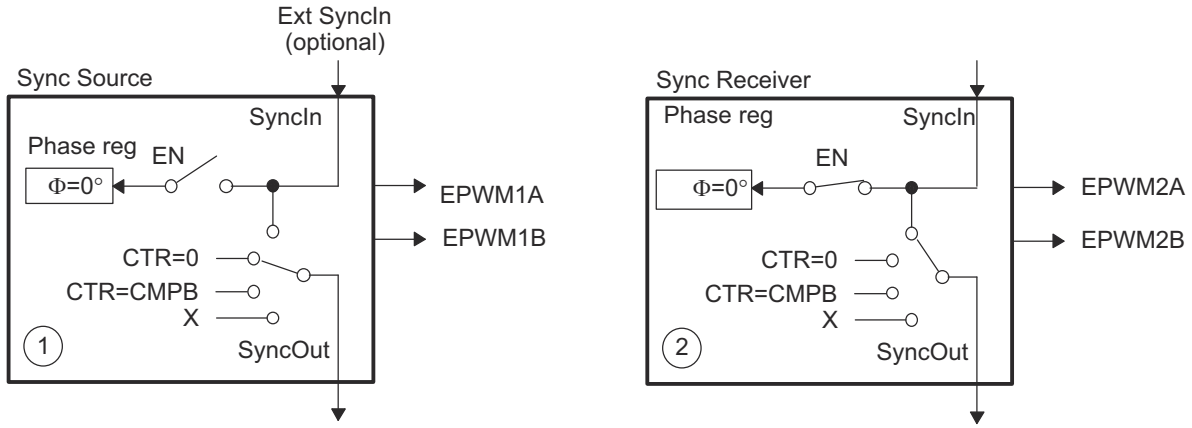

Figure 27-89. EPWM1 Configured as a Typical Sync Source, EPWM2 Configured as a Sync Receiver

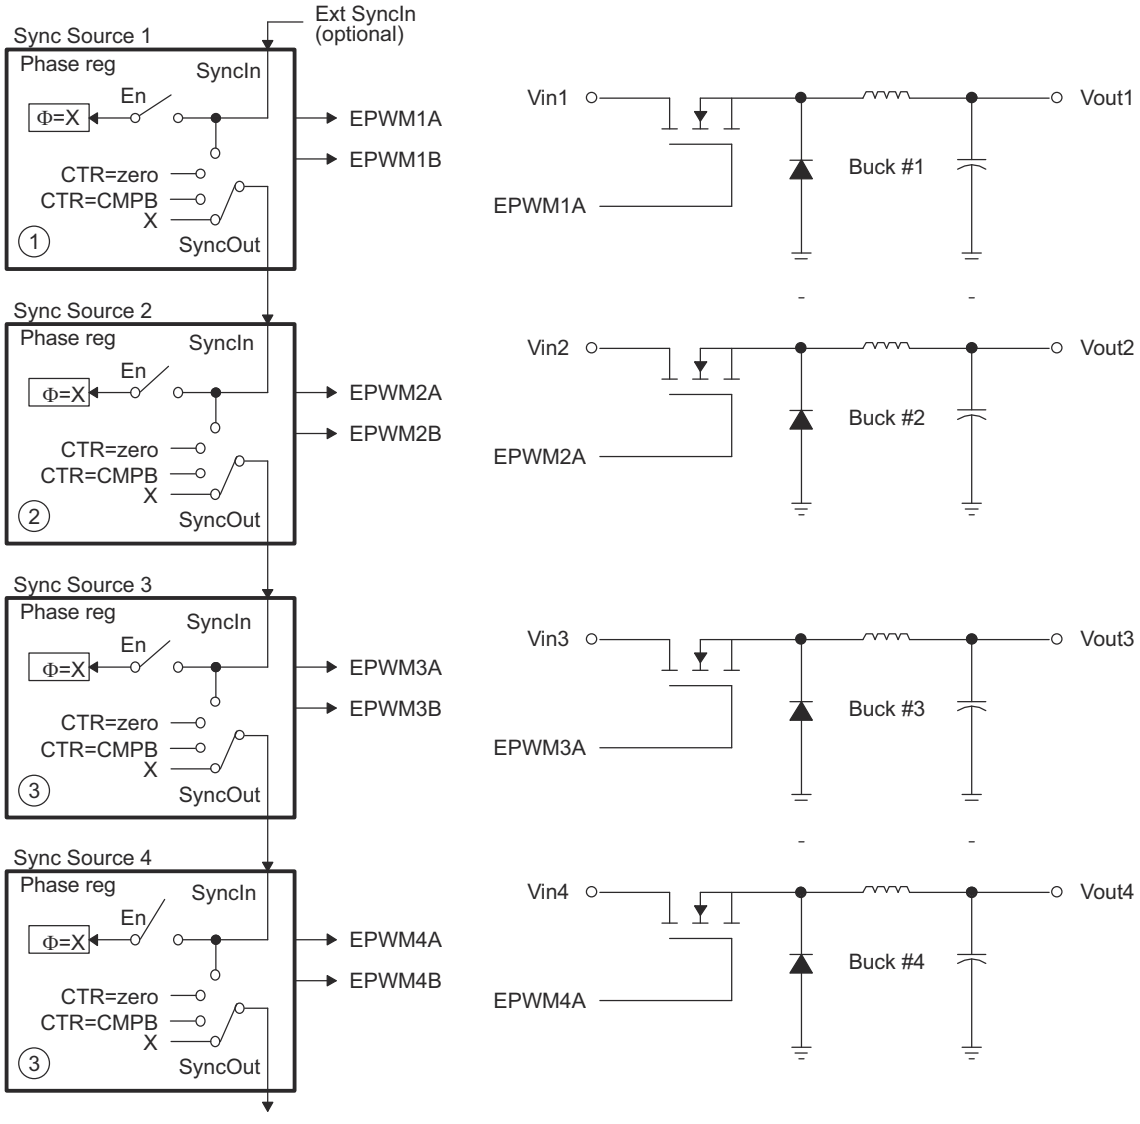
27.16.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a sync source can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 27-90 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Sync Sources and no synchronization is used. Figure 27-91 shows the waveforms generated by the setup shown in Figure 27-90; note that only three waveforms are shown, although there are four stages.



Note

φ = X indicates value in phase register is a "don't care"

Figure 27-90. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$

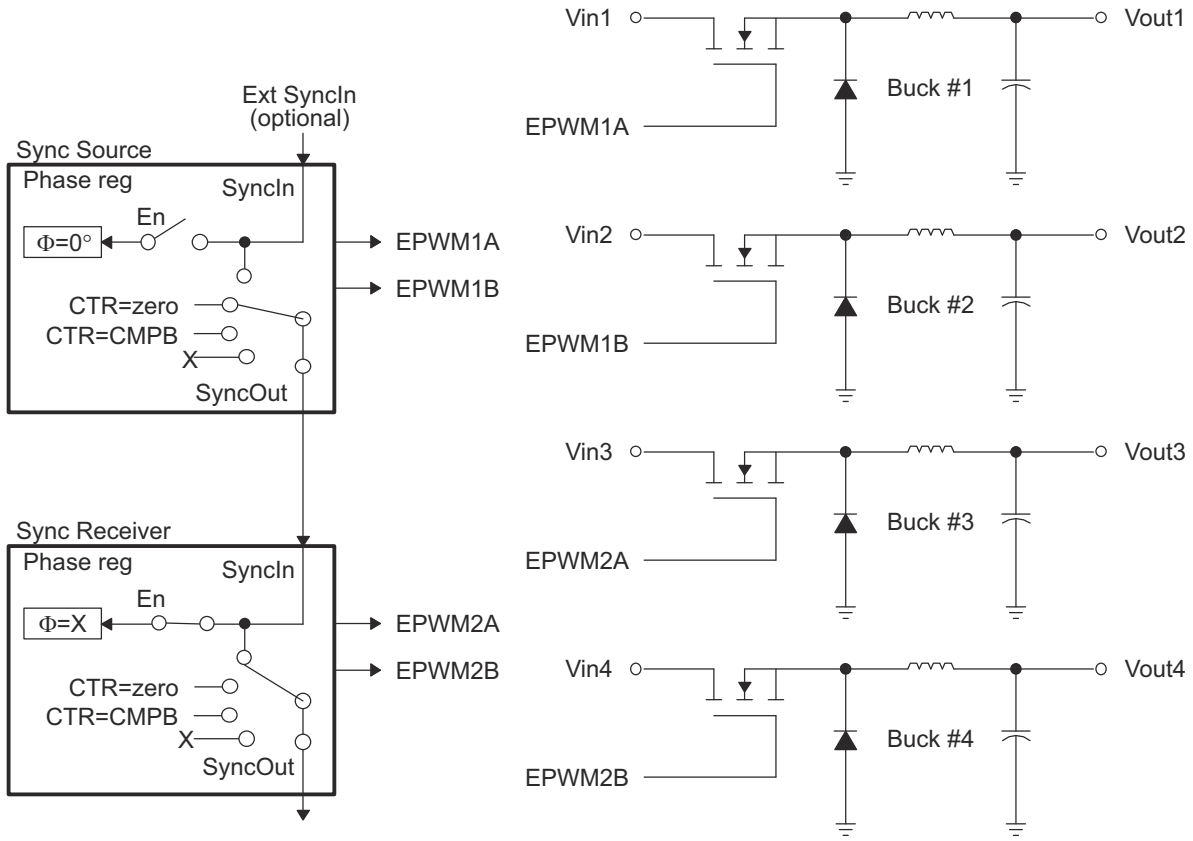
27.16.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 is configured as a sync receiver and operates at integer multiple (N) frequencies of module 1. The sync signal from sync source to sync receiver makes sure these modules remain locked. Figure 27-92 shows such a configuration; Figure 27-93 shows the waveforms generated by the configuration.



Note

φ = X indicates value in phase register is a "don't care"

27.16.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 27-94 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 27-95 shows the waveforms generated by the configuration shown in Figure 27-94.

ePWM module 2 (sync receiver) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by ePWM module 3 and also, most importantly, to remain in synchronization with sync source ePWM module 1.

27.16.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase inverter case. In such a case, six switching elements are controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A sync receivers configuration easily addresses this requirement. Figure 27-96 shows how six PWM modules control two independent 3-phase inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are sync source as in Figure 27-96), or both inverters can be synchronized by using one sync source (module 1) and five sync receivers. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, and 3 (also all equal).

27.16.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of power topologies that rely on phase relationship between legs (or stages) for correct operation. As described in the time-base submodule section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, Figure 27-98 shows a sync source and sync receiver module with a phase relationship of 120° (that is, the sync receiver leads the sync source).

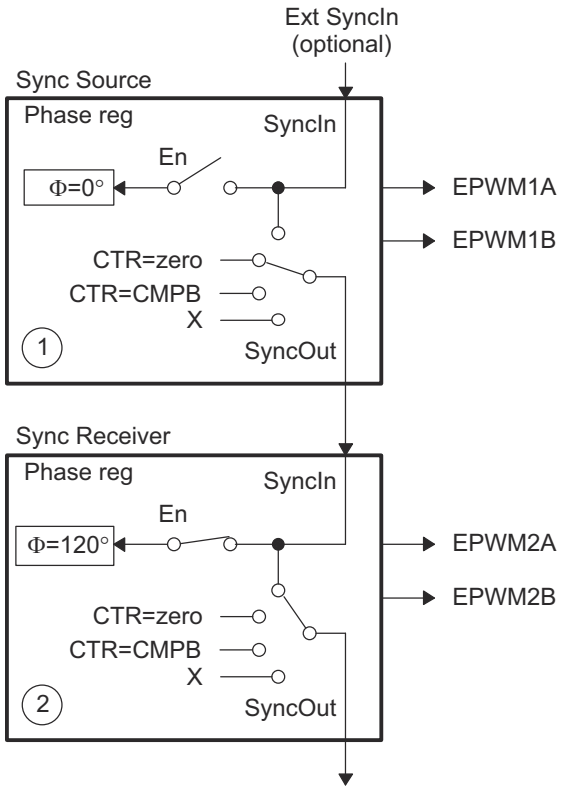

Figure 27-98. Configuring Two PWM Modules for Phase Control

Figure 27-99 shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both sync source and sync receiver. For the sync receiver, TBPHS = 200 (that is, 200/600 x 360° = 120°). Whenever the sync source generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the sync receiver TBCTR register so the sync receiver time-base is always leading the sync source time-base by 120°.

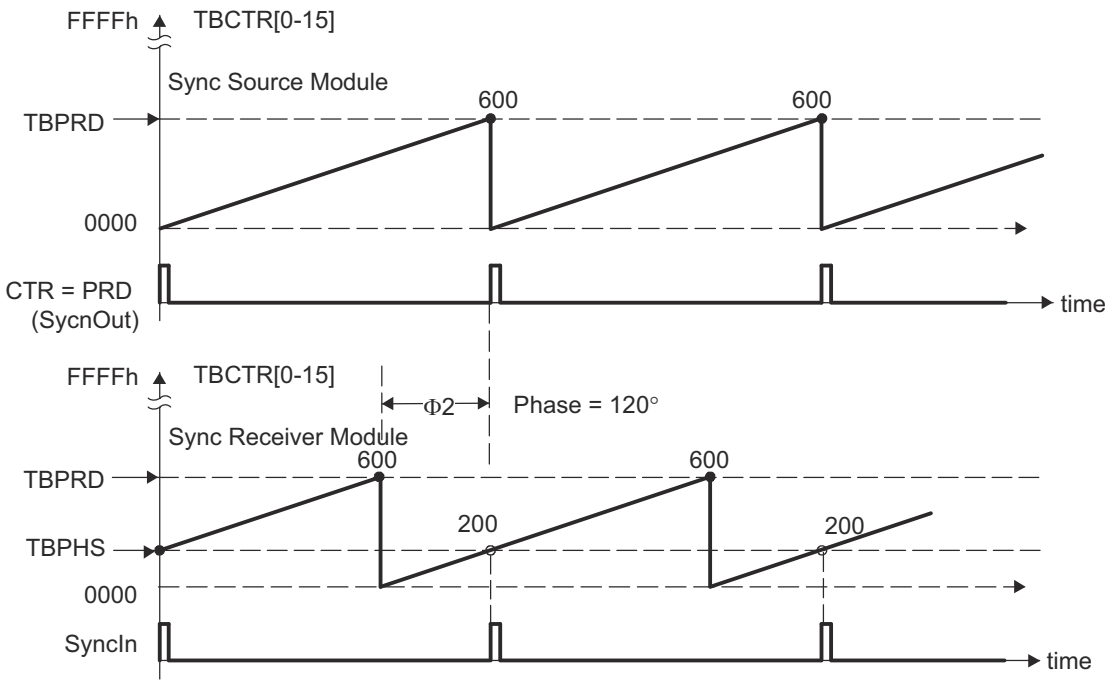

Figure 27-99. Timing Waveforms Associated with Phase Control Between Two Modules

27.16.8 Controlling a 3-Phase Interleaved DC/DC Converter

A popular power topology that makes use of phase-offset between modules is shown in Figure 27-100. This system uses three PWM modules, with module 1 configured as the sync receiver. To work, the phase relationship between adjacent modules must be F = 120°. This is achieved by setting the sync receiver TBPHS registers 2 and 3 with values of 1/3 and 2/3 of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then TBPHS (sync receiver 2) = 200 and TBPHS (sync receiver 3) = 400. Both sync receiver modules are synchronized to the sync source module 1.

This concept can be extended to four or more phases, by setting the TBPHS values appropriately. The following formula gives the TBPHS values for N phases:

$$TBPHS(N,M) = (TBPRD/N) \times (M - 1)$$

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N = 3), TBPRD = 600,

TBPHS(3,2) = (600/3) × (2 - 1) = 200 (that is, Phase value for Sync Receiver module 2)

TBPHS(3,3) = 400 (that is, Phase value for Sync Receiver module 3)

Figure 27-101 shows the waveforms for the configuration in Figure 27-100.

27.16.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in Figure 27-102 assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge.* Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. Figure 27-103 shows a sync source and sync receiver module combination synchronized together to control a full H-bridge. In this case, both sync source and sync receiver modules are required to switch at the same PWM frequency. The phase is controlled by using the sync receiver phase register (TBPHS). The sync source phase register is not used and therefore can be initialized to zero.

27.16.10 Controlling a Peak Current Mode Controlled Buck Module

Peak current control techniques offer a number of benefits like automatic over current limiting, fast correction for input voltage variations and reducing magnetic saturation. Figure 27-104 shows the use of ePWM1A along with the on-chip analog comparator for buck converter topology. The output current is sensed through a current sense resistor and fed to the positive terminal of the on-chip comparator. The internal programmable 12-bit DAC can be used to provide a reference peak current at the negative terminal of the comparator. Alternatively, an external reference can be connected at this input. The comparator output is an input to the Digital compare sub-module. The ePWM module is configured in such a way so as to trip the ePWM1A output as soon as the sensed current reaches the peak reference value. A cycle-by-cycle trip mechanism is used. Figure 27-105 shows the waveforms generated by the configuration.

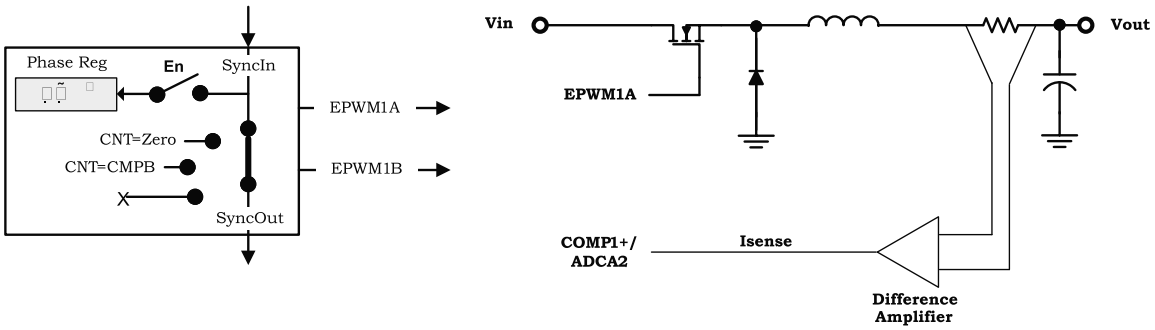

Figure 27-104. Peak Current Mode Control of Buck Converter

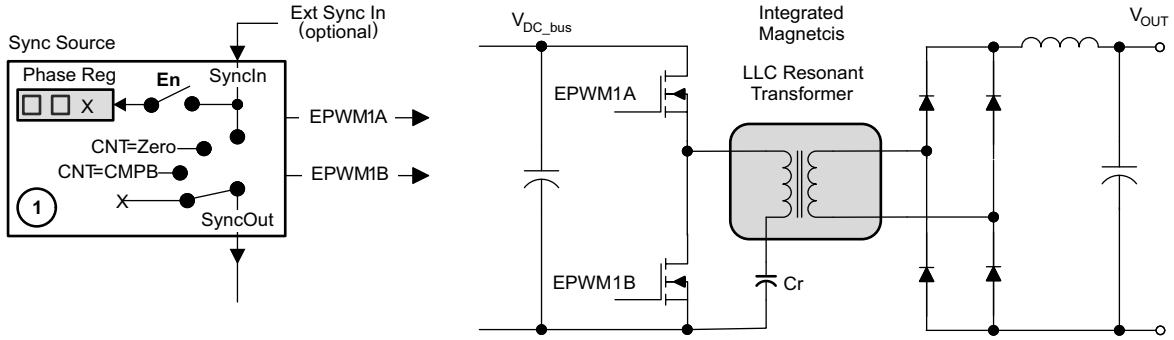
27.16.11 Controlling H-Bridge LLC Resonant Converter

Various topologies of resonant converters are well-known in the field of power electronics for many years. In addition to these, H-bridge LLC resonant converter topology has recently gained popularity in many consumer electronics applications where high efficiency and power density are required. In this example, single channel configuration of ePWM1 is detailed, yet the configuration can easily be extended to multichannel. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead the parameter is frequency. Although the deadband is not controlled and kept constant as 300ns (that is, 30 at 100MHz TBCLK), the user can update the deadband in real time to enhance the efficiency by adjusting enough time delay for soft switching.



NOTE Θ = X indicates value in phase register is a “don’t care”

Figure 27-106. Control of Two Resonant Converter Stages

27.17 Register Lock Protection

The register lock protection mechanism is added to protect the critical ePWM registers from being corrupted by accidental writes in case of runaway code. The register EPWMLOCK contains the definition of Lock bits (Table 27-16 shows the lock bits and the corresponding registers). This register also has a KEY field; writes to this register succeed only if the KEY field is written with a value of 0xa5a5. Refer to the register descriptions for more details.

Table 27-16. Lock Bits and Corresponding Registers

Bit Field	Definition	Registers Locked
HRLOCK	HRPWM Register Set Lock	HRCNFG, HRPWR, HRMSTEP, HRPCTL
GLLOCK	Global Load Register Set Lock	GLDCTL, GLDCFG
TZCFGLOCK	TripZone Register Set Lock	TZSEL, TZDCSEL, TZCTL, TZCTL2, TZCTLDCA, TZCTLDCB, TZEINT
TZCLRLOCK	TripZone Clear Register Set Lock	TZCLR, TZCBCCLR, TZOSTCLR, TZFRC
DCLOCK	Digital Compare Register Set Lock	DCTRIPSEL, DCACTL, DCBCTL, DCFCTL, DCCAPCTL, DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL, DCBLTRIPSEL

Note

Due to the presence of the KEY field in the same register, only 32-bit writes succeed if the KEY matches. The 16-bit writes to the upper or lower half of this register are ignored.

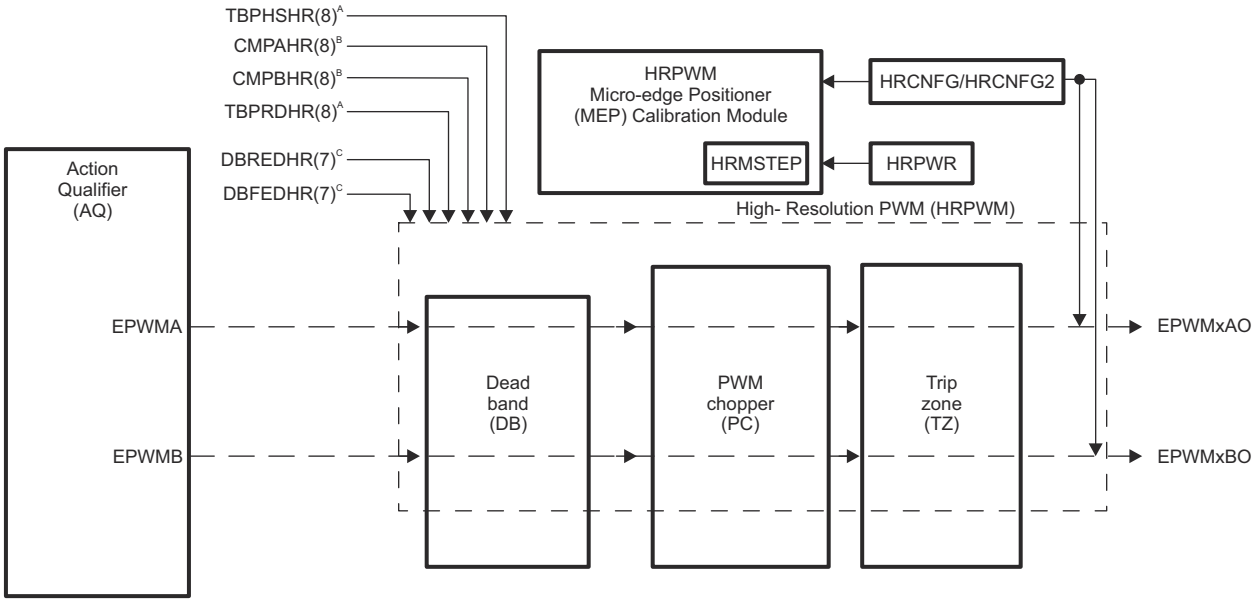
27.18 High-Resolution Pulse Width Modulator (HRPWM)

Figure 27-108 shows a block diagram of the HRPWM. This module extends the time resolution capabilities of the conventionally derived digital pulse width modulator (PWM). HRPWM is typically used when PWM resolution falls below approximately 9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A, Compare B and Phase registers
- Implemented using the A and B signal path of PWM, that is, on the EPWMxA and EPWMxB output
- Dead band high-resolution control for falling and rising edge delay in half cycle clocking operation
- Self-check diagnostics software mode to check if the micro edge positioner (MEP) logic is running how designed
- Enables high-resolution output swapping on the EPWMxA and EPWMxB output
- Enables high-resolution output on EPWMxB signal output using inversion of EPWMxA signal output
- Enables high-resolution period, duty and phase control on the EPWMxA and EPWMxB output on devices with an ePWM module

Note

See the device data sheet to determine if your device has an ePWM module with high-resolution period support.



Note

Note

From ePWM counter-compare (CC) submodule

Note

From ePWM Deadband (DB) submodule

Figure 27-108. HRPWM Block Diagram

Copyright © 2025Texas Instruments

The ePWM peripheral is used to perform a function mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 27-109, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

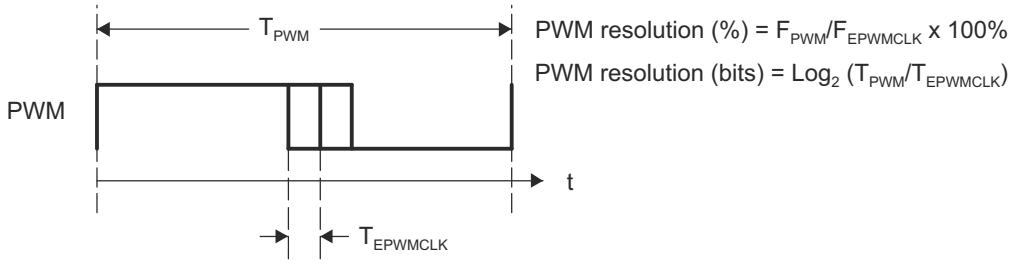

Figure 27-109. Resolution Calculations for Conventionally Generated PWM

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, consider using HRPWM. As an example of improved performance offered by HRPWM, Table 27-17 shows resolution in bits for various PWM frequencies. These values assume a MEP step size of 180ps. See the device data sheet for typical and maximum performance specifications for the MEP.

Table 27-17. Resolution for PWM and HRPWM

PWM Frequency (kHz)	Regular Resolution (PWM) 100MHz EPWMCLK		High Resolution (HRPWM)	
	Bits	%	Bits	%
20	12.3	0.02	18.1	0.000
50	11	0.05	16.8	0.001
100	10	0.1	15.8	0.002
150	9.4	0.15	15.2	0.003
200	9	0.2	14.8	0.004
250	8.6	0.25	14.4	0.005
500	7.6	0.5	13.4	0.009
1000	6.6	1	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2	11.4	0.036

Although each application can differ, typical low-frequency PWM operation (below 250kHz) does not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multiphase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

27.18.1 Operational Description of HRPWM

The HRPWM is based on micro-edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150ps. See the device data sheet for the typical MEP step size on a particular device. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running as designed under all operating conditions. Details on software diagnostics and functions are in Section 27.18.1.7 .

Figure 27-110 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled using an 8-bit field in the Compare A extension register (CMPAHR). The same operating logic applies to CMPBHR as well.

To generate an HRPWM waveform, configure the ePWM registers to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the ePWM registers to extend edge resolution. Although many programming combinations are possible, only a few are needed and practical. These methods are described in Section 27.18.1.8 .

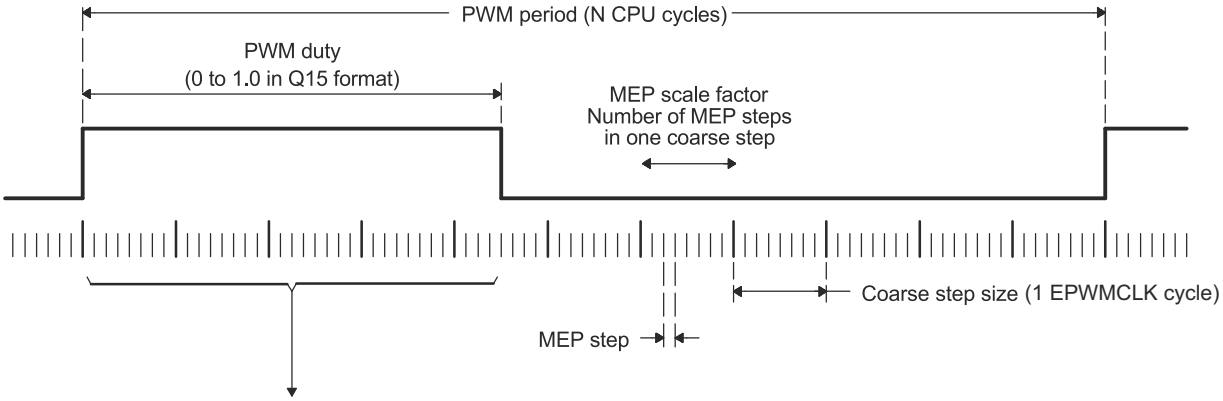

Figure 27-110. Operating Logic Using MEP

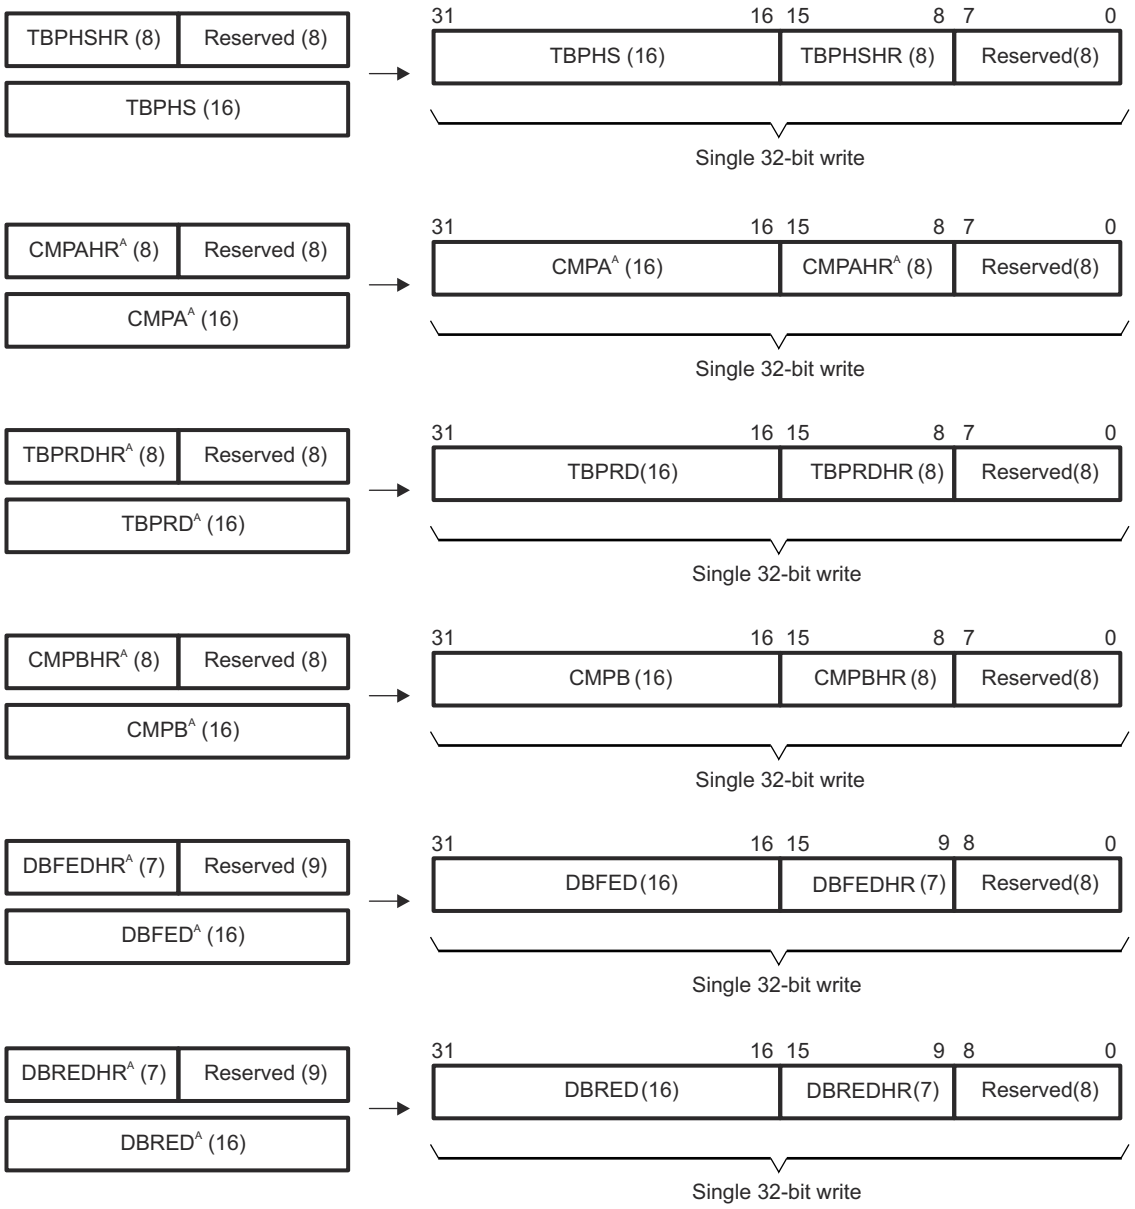
27.18.1.1 Controlling the HRPWM Capabilities

The MEP of the HRPWM is controlled by six extension registers. These HRPWM registers are concatenated with the 16-bit TBPHS, TBPRD, CMPA, CMPBM, DBREDM, and DBFEDM registers used to control PWM operation.

- TBPHSHR - Time Base Phase High Resolution Register
- CMPAHR - Counter Compare A High Resolution Register; CMPAHR is for use with the AQ output of Channel A, and is not related to CMPA
- TBPRDHR - Time Base Period High Resolution Register. (available on some devices)
- CMPBHR - Counter Compare B High Resolution Register; CMPBHR is for use with the AQ output of Channel B, and is not related to CMPB
- DBREDHR - Dead-band Generator Rising Edge Delay High Resolution Register
- DBFEDHR - Dead-band Generator Falling Edge Delay High Resolution Register

Copyright © 2025Texas Instruments



Note

Dependent upon your device, these registers can be mirrored and can be written to at two different memory locations.

Figure 27-111. HRPWM Extension Registers and Memory Configuration

Note

HRPWM capabilities on Deadband Rising Edge Delay and Falling Edge Delay is applicable only during dead band half cycle clocking Operation. The number of MEP steps is half in size [bits 15:9] than duty and phase high-resolution registers for the same reason.

A minimum of 4 cycles difference (including the HR component) between adjacent XCMP values must be maintained to make sure of minimum pulse width when HR is enabled. A difference of less than 4 cycles would result in incorrect HR placement.

Copyright © 2025Texas Instruments

HRPWM capabilities are controlled using the Channel A and B PWM signal path. HRPWM support on the Dead band signal path is available by properly configuring the HRCNFG2 register. shows how the HRPWM interfaces with the 8-bit extension registers.

Copyright © 2025Texas Instruments

27.18.1.2 HRPWM Source Clock

Each HRPWM module is clocked from the respective EPWMxCLK. HRCAL has a separate clock. For example, HRPWM1 is sourced from EPWM1CLK while HRPWM2 is clocked from the EPWM2CLK. Figure 27-112 shows the HRCAL and HRPWM modules are sourced from the respective ePWM clock source.

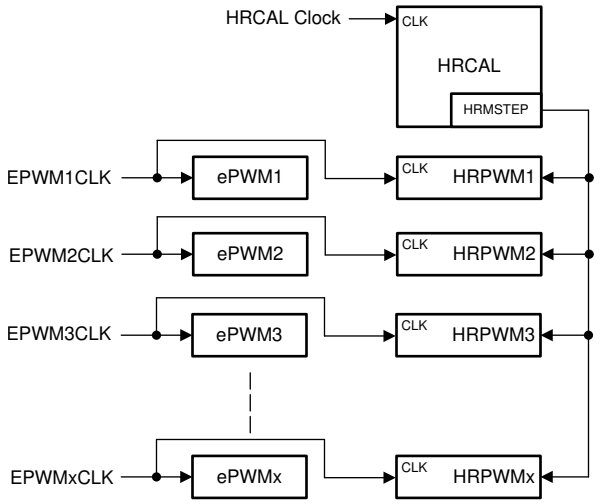


Figure 27-112. HRPWM and HRCAL Source Clock

27.18.1.3 Configuring the HRPWM

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register in that particular ePWM module's register space. This register provides the following configuration options:

Edge Mode The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE) or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control (CMPA or CMPB high-resolution control), while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge (TBPHS or TBPRD high-resolution control).

Control Mode The MEP is programmed to be controlled either from the CMPAHR/CMPBHR register in case of duty cycle control or the TBPHSHR register (phase control). RE or FE control mode can be used with the CMPAHR or CMPBHR register. BE control mode can be used with the TBPHSHR register. When the MEP is controlled from the TBPRDHR register (period control), the duty cycle and phase can also be controlled using the respective high-resolution registers.

Note

If TBPHSHR control mode is used, TBPHSHR applies the HR delay on the secondary PWM to the right from its original waveform irrespective of its counter mode and direction of counter after a sync event.

Shadow Mode This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR, CMPBHR, and TBPRDHR registers and can be chosen to be the same as the regular load option for the CMPA/CMPB register. If TBPHSHR is used, then this option has no effect.

High-Resolution B Signal Control The B signal path of an ePWM channel can generate a high-resolution output by outputting an inverted version of the high-resolution ePWMxA signal on the ePWMxB pin. A Type 2 or Type 4 HRPWM module can also enable high-resolution features on the B signal path independently of the A signal path as well.

Copyright © 2025Texas Instruments

Swap ePWMxA and ePWMxB Outputs	This mode enables the swapping of the high-resolution A and B outputs. The mode selection allows either A and B Outputs Unchanged or A Output Comes Out On B and B Output Comes Out On A.
Auto-conversion Mode	This mode is used in conjunction with the scale factor optimization (SFO) software only. For a type 4 HRPWM module, below is a description of the Auto-conversion Mode taking CMPAHR as an example. If auto-conversion is enabled, CMPAHR = fraction(PWMduty * PWMperiod)<<8. The scale factor optimization software calculates the MEP scale factor in the background code and automatically updates the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module then uses the values in the HRMSTEP and CMPAHR registers to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle and moves the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, the CMPAHR register behaves like a type 0 HRPWM module and CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor + 0.5)<<8). All calculations need to be performed by your code in this mode, and the HRMSTEP register is ignored. Auto-conversion for high-resolution period has the same behavior as auto-conversion for high-resolution duty cycle. Auto-conversion must always be enabled for high-resolution period mode.

Note

If the HRPWM module is configured in UP-DOWN counter mode, the shadow mode for the HRPWM registers must be set to load on both ZERO AND PERIOD. New values from the user are loaded to the shadow registers only at CTR = ZERO, but the shadow mode of for the registers must be set to both ZERO AND PERIOD. The CTR = PRD event is used for specific internal logic inside the HRPWM module.

Auto-conversion Mode performs the calculation for CMPBHR , DBREDHR, and DBFEDHR. The scale factor optimization software calculates the MEP scale factor in the background code and automatically updates the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module then uses the values in the HRMSTEP and CMPBHR or DBREDHR/DBFEDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional components and moves the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, CMPBHR behaves the same as CMPAHR. CMPBHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor + 0.5)<<8).

Linking CMPBHR to CMPAHR

Starting with EPWM Type 5, the user has the option to link the CMPBHR value to the CMPAHR value. This allows for EPWM channel A and EPWM channel B outputs to both be controlled by CMPAHR. This feature is enabled through the CMPCTL.LINKDUTYHR register. This feature is commonly used when the HRPWM is configured for complimentary output mode. When writing to CMPAHR, CMPBHR is automatically updated but does not reflect the current value in the register. All writes to CMPBHR are ignored.

Copyright © 2025Texas Instruments

27.18.1.4 Configuring High-Resolution in Deadband Rising-Edge and Falling-Edge Delay

Once the ePWM has been configured to provide conventional PWM of a given frequency, polarity, and dead band enabled in half-cycle clocking mode, the high-resolution operation on dead band RED and FED lines are enabled by programming the HRCNFG2 register in that particular ePWM module register space. This register provides the following configuration options:

Edge Mode The MEP can be programmed to provide precise position control on the dead band rising edge (RED), dead band falling edge (FED), or both edges (rising edge of DBRED signal and falling edge of DBFED signal) at the same time.

Control Mode Selects the time event that loads the shadow value in the active register for DBRED and DBFED in high-resolution mode. Select the pulse to match the selection in the ePWM DBCTL[LOADREDMODE] and DBCTL[LOADFEDMODE] bits.

27.18.1.5 Principle of Operation

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps (see the device data sheet for typical MEP step size). The MEP works with the TBM and CCM registers to be certain that time steps are applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies, and other operating conditions. Table 27-18 shows the typical range of operating frequencies supported by the HRPWM.

Table 27-18. Relationship Between MEP Steps, PWM Frequency, and Resolution

System (MHz)	MEP Steps Per EPWMCLK (1)(2)(3)	PWM Minimum (Hz) (4)	PWM Maximum (MHz)	Resolution at Maximum (Bits) (5)
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

(1) TBCLK = EPWMCLK.
(2) Table data based on a MEP time resolution of 180ps (this is an example value. See the device data sheet for MEP limits)
(3) MEP steps applied = $T_{EPWMCLK}$/180ps in this example.
(4) PWM minimum frequency is based on a maximum period value,(TBPRD = 65535). PWM mode is asymmetrical up-count.
(5) Resolution in bits is given for the maximum PWM frequency stated.

Copyright © 2025Texas Instruments

27.18.1.5.1 Edge Positioning

Note

The following example is presented using the [CMPA:CMPAHR] register combination. The theory of operation and equations are the same, if intending to use the [CMPBM:CMPBHRM] for duty cycle control.

In a typical power control loop, a digital controller issues a duty command, usually expressed in a per unit or percentage terms. Assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on time and the required converter PWM frequency is 1.25MHz. In conventional PWM generation with a system clock of 100MHz, the duty cycle choices are in the vicinity of 40.5%. As shown in Figure 27-113, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that can be attained. This is equivalent to an edge position of 320ns instead of the desired 324ns. This data is shown in Table 27-19.

By utilizing the MEP, an edge position much closer to the desired point of 324ns can be achieved. Table 27-19 shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) positions the edge at 323.96ns, resulting in almost zero error. In this example, assume that the MEP has a step resolution of 180ps.

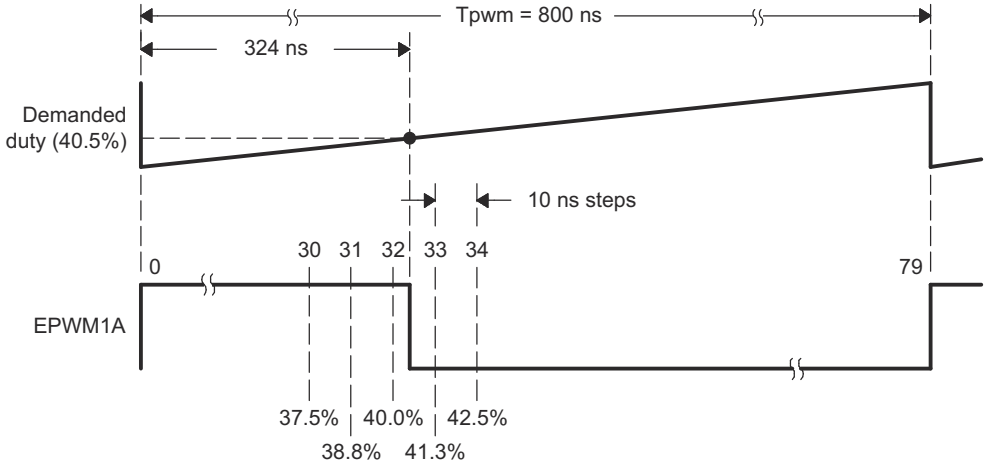

Figure 27-113. Required PWM Waveform for a Requested Duty = 40.5%

Table 27-19. CMPA versus Duty (left), and [CMPA:CMPAHR] versus Duty (right)

CMPA (count)[1][2][3]	Duty (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	***35.0***	280	32	18	***40.405***	323.24
29	***36.3***	290	32	19	***40.428***	323.42
30	***37.5***	300	32	20	***40.450***	323.60
31	***38.8***	310	32	21	***40.473***	323.78
32	***40.0***	320	32	22	***40.495***	323.96
33	***41.3***	330	32	23	***40.518***	324.14
34	***42.5***	340	32	24	***40.540***	324.32
			32	25	***40.563***	324.50
Required			32	26	***40.585***	324.68
32.40	***40.5***	324	32	27	***40.608***	324.86

(1) Assumed MEP step size for the above example = 180ps. See the device-specific data sheet for typical and maximum MEP values.
(2) TBCLK = 100MHz, 10ns
(3) For a PWM Period register value of 80 counts, PWM Period = 80 * 10ns = 800ns, PWM frequency = 1/800ns = 1.25MHz

Copyright © 2025Texas Instruments

27.18.1.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard CMPA and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in nanoseconds (ns). Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

TBCLK	=	10ns (100MHz)
PWM frequency	=	1.25MHz (1/800ns)
Required PWM duty cycle, **PWMDuty**	=	0.405 (40.5%)
PWM period in terms of coarse steps, **PWMPeriod** (800ns/10ns)	=	80
Number of MEP steps per coarse step at 180ps (10ns/180ps), **MEP_ScaleFactor**	=	55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	=	0.5 (0080h in Q8 format)

Step 1: Percentage Integer Duty value conversion for CMPA register

CMPA register value	=	int(**PWMDuty***PWMPeriod**); int means integer part
	=	int(0.405 * 80)
	=	int(32.4)
CMPA register value	=	32 (20h)

Step 2: Fractional value conversion for CMPAHR register

CMPAHR	=	(frac(**PWMDuty***PWMPeriod**)*MEP_ScaleFactor** + 0.5) <<8); frac means fractional part
	=	(frac(32.4) * 55 + 0.5) <<8; Shifting is to move the value to the high byte of CMPAHR.
	=	(0.4 * 55 + 0.5) <<8
	=	(22 + 0.5) <<8
	=	22.5 * 256; Shifting left by 8 is the same as multiplying by 256.
	=	5760 (1680h)
CMPAHR	=	1680h CMPAHR value = 1600h (lower 8 bits are ignored by hardware).

Copyright © 2025Texas Instruments

Note

If the AUTOCONV bit (HRCNFG.6) is set and the MEP_ScaleFactor is in the HRMSTEP register, then CMPAHR / CMPBHR register value = frac (PWMDuty*PWMperiod<<8). The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

The MEP scale factor (MEP_ScaleFactor) varies with the system clock and DSP operating conditions. TI provides an MEP scale factor optimizing (SFO) software C function, which uses the built in diagnostics in each HRPWM and returns the best scale factor for a given operating point.

The scale factor varies slowly over a limited range so the optimizing C function can be run very slowly in a background loop.

The CMPA, CMPB, CMPAHR and CMPBHR registers are configured in memory so that the 32-bit data capability of the CPU can write this as a single concatenated value, that is, [CMPA:CMPAHR], [CMPB:CMPBHR], and so on.

The mapping scheme has been implemented in both C and assembly, as shown in Section 27.18.1.8 . The actual implementation takes advantage of the 32-bit CPU architecture and is somewhat different from the steps shown in Section 27.18.1.5.2 .

For time-critical control loops where every cycle counts, the assembly version is recommended. This is a cycle optimized function (11 EPWMCLK cycles) that takes a Q15 duty value as input and writes a single [CMPA:CMPAHR] value.

27.18.1.5.3 Duty Cycle Range Limitation

In high-resolution mode, the MEP is not active for 100% of the PWM period and becomes operational:

- Three EPWMCLK cycles after the period starts when high-resolution period (TBPRDHR) control is not enabled.
- When high-resolution period (TBPRDHR) control is enabled using the HRPCTL register:
  - In up-count mode: three EPWMCLK cycles after the period starts until three EPWMCLK cycles before the period ends.
  - In up-down count mode: when counting up, three cycles after CTR = 0 until three cycles before CTR = PRD, and when counting down, three cycles after CTR = PRD until three cycles before CTR = 0.
- When using DBREDHR or DBFEDHR, DBRED or DBFED (the register corresponding to the edge with high-resolution displacement) must be greater than or equal to 7.

Duty cycle range limitations are illustrated in Figure 27-114 to Figure 27-117. This limitation imposes a duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. When high-resolution period control is disabled, regular PWM duty control is fully operational down to 0% duty cycle despite the unavailability of HRPWM features in the first three cycles. In most applications, this cannot be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle. To better understand the useable duty cycle range, see Table 27-20. When high-resolution period control is enabled (HRPCTL[HRPE] = 1), the duty cycle must not fall within the restricted range; otherwise, there can be undefined behavior on the ePWMxA output.

Copyright © 2025Texas Instruments

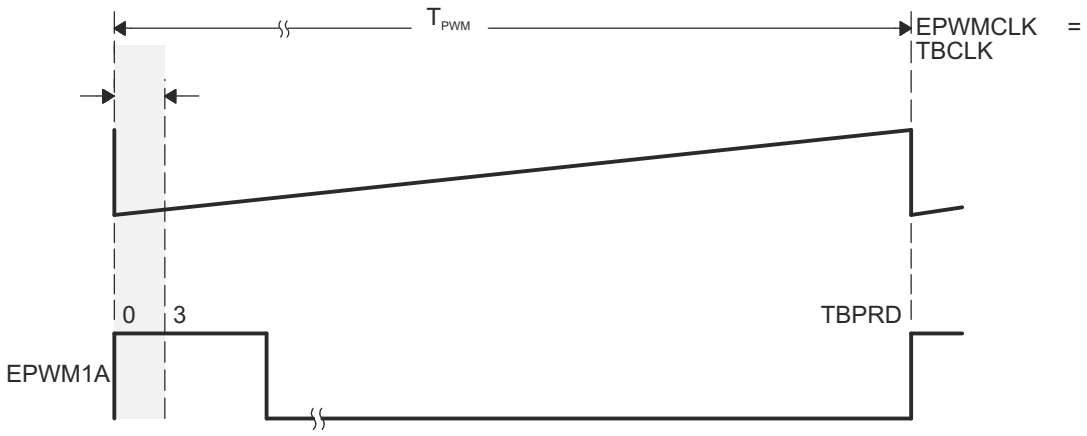

Figure 27-114. Low % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)

Table 27-20. Duty Cycle Range Limitation for Three EPWMCLK/TBCLK Cycles

PWM Frequency(1) (kHz)	3 Cycles Minimum Duty	3 Cycles Maximum Duty(2)
200	0.6%	99.4%
400	1.2%	98.8%
600	1.8%	98.2%
800	2.4%	97.6%
1000	3%	97%
1200	3.6%	96.4%
1400	4.2%	95.8%
1600	4.8%	95.2%
1800	5.4%	94.6%
2000	6%	94%

(1) EPWMCLK = TBCLK = 100MHz

(2) This limitation applies only if high-resolution period (TBPRDHR) control is enabled.

If the application demands HRPWM operation below the minimum duty cycle limitation, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP when high-resolution period is disabled (HRPCTL[HRPE] = 0). This is illustrated in Figure 27-115. In this configuration, the minimum duty cycle limitation is no longer an issue. However, there is a maximum duty limitation with same percent numbers as given in Table 27-20.

CAUTION

If the application has enabled high-resolution period control (HRPCTL[HRPE] = 1), the duty cycle must not fall within the restricted range; otherwise, there can be undefined behavior on the ePWM output.

27.18.1.5.4 High-Resolution Period

High-resolution period control using the MEP logic is supported on devices with a Type 1 ePWM module or greater.

Note

When high-resolution period control is enabled, on ePWMxA only, and not ePWMxB output and conversely, the non high-resolution output has ±1 TBCLK cycle jitter in up-count mode and ±2 TBCLK cycle jitter in up-down count mode.

One-shot load mode must not be used when high-resolution mode is enabled.

When high-resolution period is enabled (HRPCTL[HRPE] = 1) and shadow-to-active loading is configured to load on a sync event (TBCTL2[PRDLDSYNC] = 0x1 or 0x2), the load happens every ZERO event instead of the sync event. Refer to the device-specific errata for a work around.

The scaling procedure described for duty cycle in Section 27.18.1.5.2 applies for high-resolution period as well:

Assumptions for this example:

TBCLK	= 10ns (100MHz)
Required PWM frequency	= 175kHz (period of 571.428)
Number of MEP steps per coarse step at 180ps (10ns/180ps), (MEP_ScaleFactor)	= 55
Value to keep TBPRDHR within range of 1-255 and fractional rounding constant (default value)	= 0.5 (0080h in Q8 format)

Problem:

In up-count mode:

- If TBPRD = 571, then PWM frequency = 174.82kHz (period = (571 + 1) × T_{TBCLK}).
- If TBPRD = 570, then PWM frequency = 175.13kHz (period = (570 + 1) × T_{TBCLK}).

In up-down count mode:

- If TBPRD = 286, then PWM frequency = 174.82kHz (period = (286 × 2) × T_{TBCLK}).
- If TBPRD = 285, then PWM frequency = 175.44kHz (period = (285 × 2) × T_{TBCLK}).

Solution:

With 55 MEP steps per coarse step at 180ps each:

Step 1: Percentage Integer Period value conversion for TBPRD register

Integer period value	= 571 × T_{TBCLK}
	= int (571.428) × T_{TBCLK}
	= int (PWMperiod) × T_{TBCLK}
In up-count mode:	
TBPRD	= 570 (TBPRD = period value - 1)
	= 023Ah
In up-down count mode:	= 285 (TBPRD = period value/2)
TBPRD	= 011Dh

Copyright © 2025Texas Instruments

Step 2: Fractional value conversion for TBPRDHR register

In up-count mode:

TBPRDHR register value	= (frac(PWMperiod) * MEP_ScaleFactor + 0.5)
If auto-conversion enabled and HRMSTEP =	
MEP_ScaleFactor value (55):	= frac (PWMperiod) << 8 (Shifting is to move the value to the high byte of TBPRDHR)
TBPRDHR register value	= frac (571.428) << 8
	= 0.428 * 256
	= 6D00h
The auto-conversion then automatically performs the calculation, such that TBPRDHR MEP delay is scaled by hardware to:	= ((TBPRDHR(15:0) >> 8) × HRMSTEP + 80h) << 8
	= (006Dh * 55 + 80h) >> 8
	= (17EBh) >> 8
Period MEP delay	= 0017h MEP Steps

In up-down count mode:

TBPRDHR register value	= (frac(PWMperiod) * MEP_ScaleFactor + 0.5)
If auto-conversion enabled and HRMSTEP =	
MEP_ScaleFactor value (55):	= frac (PWMperiod / 2) << 8 (Shifting is to move the value to the high byte of TBPRDHR)
TBPRDHR register value	= frac (285.714) << 8
	= 0.714 * 256
	= B600h
The auto-conversion then automatically performs the calculation, such that TBPRDHR MEP delay is scaled by hardware to:	= ((TBPRDHR(15:0) >> 8) × HRMSTEP + 80h) << 8
	= (00B6h * 55 + 80h) >> 8
	= (279Ah) >> 8
Period MEP delay	= 0027h MEP Steps

27.18.1.5.4.1 High-Resolution Period Configuration

To use high-resolution period, the ePWMx module must be initialized in the exact order presented.

The following steps use CMPA with shadow registers and the corresponding HRCNFG bits for high-resolution operation on EPWMxA. For high-resolution operation on EPWMxB, make the appropriate substitutions with the B channel fields.

1. Enable ePWMx clock
2. Enable HRPWM clock
3. Disable TBCLKSYNC
4. Configure ePWMx registers - AQ, TBPRD, CC, and so on.
   - ePWMx can only be configured for up-count or up-down count modes. High-resolution period is not compatible with down-count mode.
   - TBPRD and CC registers must be configured for shadow loads.
   - CMPCTL[LOADAMODE]
     - In up-count mode: CMPCTL[LOADAMODE] = 1 (load on CTR = PRD)
     - In up-down count mode: CMPCTL[LOADAMODE] = 2 (load on CTR = 0 or CTR = PRD)
5. Configure the HRCNFG register such that:
   - HRCNFG[HRLOAD] = 2 (load on either CTR = 0 or CTR = PRD)
   - HRCNFG[AUTOCONV] = 1 (Enable auto-conversion)
   - HRCNFG[EDGMODE] = 3 (MEP control on both edges)
6. For TBPHS:TBPHSHR synchronization with high-resolution period, set both HRPCTL[TBPSHRLOADE] = 1 and TBCTL[PHSEN] = 1. In up-down count mode these bits must be set to 1 regardless of the contents of TBPHSHR.
7. Enable high-resolution period control (HRPCTL[HRPE] = 1)
8. Enable TBCLKSYNC
9. TBCTL[SWFSYNC] = 1
10. HRMSTEP must contain an accurate MEP scale factor (# of MEP steps per EPWMCLK coarse step) because auto-conversion is enabled. The MEP scale factor can be acquired using the SFO() function described in Section 27.18.2 .
11. To control high-resolution period, write to the TBPRDHR(M) registers.

Note

When high-resolution period mode is enabled, an EPWMxSYNC pulse introduces ±1-2 cycle jitter to the PWM (±1 cycle in up-count mode and ±2 cycle in up-down count mode). Otherwise, the jitter occurs on every PWM cycle with the synchronization pulse.

When a software synchronization pulse can be issued only once during high-resolution period initialization. If a software sync pulse is applied while the PWM is running, the jitter appears on the PWM output at the time of the sync pulse.

Copyright © 2025Texas Instruments

27.18.1.6 Deadband High-Resolution Operation

Note

In up-count mode, the dead-band module is not available when any high-resolution mode is enabled.

Assumptions for this example:

System clock	= 10ns (100MHz)
Deadband enabled in half-cycle mode, TBCLK = EPWMCLK	
Required PWM frequency	1.33MHz (1/750ns)
Required PWM duty cycle	0.5 (50%)
Required Deadband Rising-Edge Delay	5% over duty
Required Deadband Rising-Edge Delay in ns	(0.05 * 375ns) = 18.75ns

Note

Similar to the duty cycle restrictions when using HRPWM, the DBRED and DBFED values must be greater than 3 to use high-resolution deadband.

Deadband delay values as a function of DBFED and DBRED:

When half-cycle clocking is enabled, the formula to calculate the falling-edge delay (FED) and rising-edge delay (RED) becomes:

FED = DBFED * TBCLK / 2

RED = DBRED * TBCLK / 2

DBRED and DBFED calculated values:

Required Deadband Rising-Edge Delay in ns = 18.75ns

DBRED = RED / (TBCLK / 2)

DBRED = 18.75ns/5ns

DBRED Required = 3.75ns

With 55 MEP steps per coarse step at 180ps each:

Copyright © 2025Texas Instruments

Step 1: Integer Deadband value conversion for DBREDM register

Integer DBRED value	= int (RED / (TBCLK / 2))
	= int (3.75)
DBRED	= 3

Step 2: Fractional value conversion for Deadband high-resolution register DBREDHR

DBREDHR register value	= (frac(DBRED Required) * MEP_ScaleFactor + 0.5) << 8 (Shifting is to move the value to the high byte of DBREDHR)
	= (frac (3.75) * 55 + 0.5) << 8
	= (0.75 * 55 + 0.5) << 8
	= (41.75) * 256 Shifting left by 8 is the same as multiplying by 256.
DBREDHR value	= 29C0h MEP Steps
	Hardware ignores lower 9 bits in the above calculated DBREDHR value

Note

If the AUTOCONV bit (HRCNFG.6) is set and the MEP_ScaleFactor is in the HRMSTEP register, then DBREDHR:DBRED = frac((required DB value) < <8). The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

27.18.1.7 Scale Factor Optimizing Software (SFO)

The micro edge positioner (MEP) logic is capable of placing an edge in one of 255 discrete time steps. As previously mentioned, the size of these steps is on the order of 150ps (see the device data sheet for typical MEP step size on your device). The MEP step size varies based on worst-case process parameters, operating temperature, and voltage. MEP step size increases with decreasing voltage and increasing temperature and decreases with increasing voltage and decreasing temperature. Applications that use the HRPWM feature can use the TI-supplied MEP scale factor optimization (SFO) software function. The SFO function helps to dynamically determine the number of MEP steps per EPWMCLK period while the HRPWM is in operation.

To utilize the MEP capabilities effectively, the correct value for the MEP scaling factor needs to be known by the software. To accomplish this, the HRPWM module has built in self-check and diagnostic capabilities that can be used to determine the optimum MEP scale factor value for any operating condition. TI provides a C-callable library containing one SFO function that utilizes this hardware and determines the optimum MEP scale factor. As such, MEP control and diagnostics registers are reserved for TI use.

A detailed description of the SFO library - SFO_TI_Build_V8.lib software can be found in SFO Library Software - SFO TI_Build_V8.lib.

27.18.1.8 HRPWM Examples Using Optimized Assembly Code

The best way to understand how to use the HRPWM capabilities is through two real examples:

1. Simple buck converter using asymmetrical PWM (count-up) with active high polarity.
2. DAC function using simple R+C reconstruction filter.

The following examples all have initialization and configuration code written in C. To make these easier to understand, the #defines shown below are used.

Section 27.18.1.8.1 assumes MEP step size of 150ps and does not use the SFO library.

#Defines for HRPWM Header Files

```
// HRPWM (High Resolution PWM) //
================================
// HRCNFG
#define HR_Disable 0x0
#define HR_REP 0x1          // Rising Edge position
#define HR_FEP 0x2          // Falling Edge position
#define HR_BEP 0x3          // Both Edge position #define HR_CMP 0x0 // CMPAHR controlled
#define HR_PHS 0x1          // TBPHSHR controlled #define HR_CTR_ZERO 0x0 // CTR = Zero event
#define HR_CTR_PRD 0x1      // CTR = Period event
#define HR_CTR_ZERO_PRD 0x2 // CTR = ZERO or Period event
#define HR_NORM_B  0x0      // Normal ePWMxB output
#define HR_INVERT_B 0x1     // ePWMxB is inverted ePWMxA output
```

27.18.1.8.1 Implementing a Simple Buck Converter

In this example, the PWM requirements are:

- PWM frequency = 1MHz (that is, TBPRD = 100)
- PWM mode = asymmetrical, up-count
- Resolution = 12.7 bits (with a MEP step size of 150ps)

Figure 27-118 and Figure 27-119 show the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

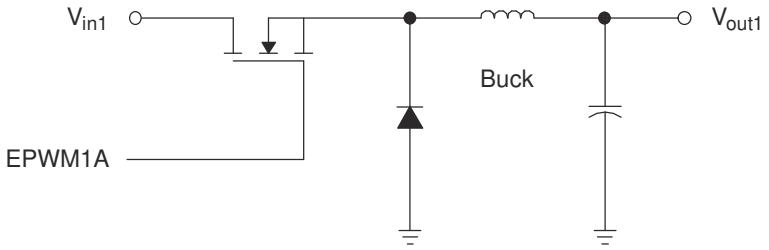

Figure 27-118. Simple Buck Controlled Converter Using a Single PWM

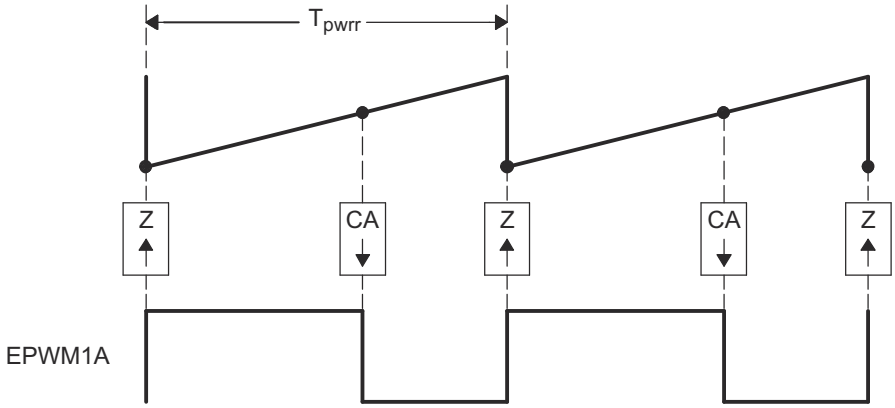

Figure 27-119. PWM Waveform Generated for Simple Buck Controlled Converter

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

Section 27.18.1.8.1.1 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

This example assumes MEP step size of 150ps and does not use the SFO library.

Section 27.18.1.8.1.1 shows an assembly example of run-time code for the HRPWM buck converter.

27.18.1.8.2 Implementing a DAC Function Using an R+C Reconstruction Filter

In this example, the PWM requirements are:

- PWM frequency = 400kHz (that is, TBPRD = 250)
- PWM mode = Asymmetrical, Up-count
- Resolution = 14 bits (MEP step size = 150ps)

Figure 27-120 and Figure 27-121 show the DAC function and the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

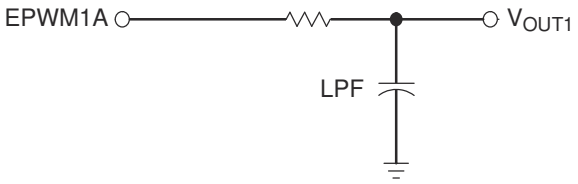

Figure 27-120. Simple Reconstruction Filter for a PWM-based DAC

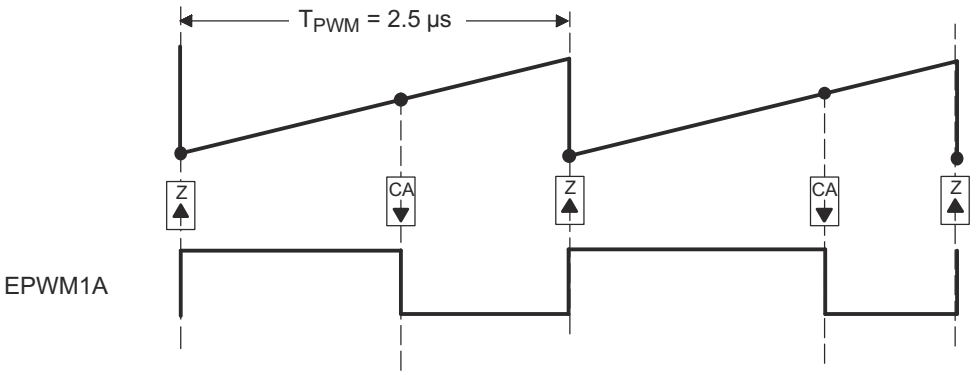

Figure 27-121. PWM Waveform Generated for the PWM DAC Function

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

This example assumes a typical MEP_SP and does not use the SFO library.

Section 27.18.1.8.2.1 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

Section 27.18.1.8.2.1 shows an assembly example of run-time code that can execute in a high-speed ISR loop.

27.18.2 SFO Library Software - SFO_TI_Build_V8.lib

Table 27-21 lists several features of the SFO_TI_Build_V8.lib library.

Table 27-21. SFO Library Features

	SFO_TI_Build_V8.lib	Unit
Completion-checking?	Yes	Function return value
Typical cycles required for SFO() to update MEP_ScaleFactor if called repetitively without interrupts	130,000	EPWMCLK cycles

27.18.2.1 Scale Factor Optimizer Function - int SFO()

This routine drives the micro-edge positioner (MEP) calibration module to run SFO diagnostics and determine the appropriate MEP scale factor (number of MEP steps per coarse EPWMCLK step) for a device at any given time.

If EPWMCLK = TBCLK = 100MHz and assuming the MEP step size is 150ps, the typical scale factor value at 100MHz = 66 MEP steps per TBCLK unit (10ns)

The function returns a MEP scale factor value:

MEP_ScaleFactor = Number of MEP steps per EPWMCLK

Constraints when using this function:

- SFO() can be used with a minimum EPWMCLK = TBCLK = 50MHz. MEP diagnostics logic uses EPWMCLK and not TBCLK, so the EPWMCLK restriction is an important constraint. Below 50MHz with device process variation, the MEP step size can decrease under cold temperature and high core voltage conditions to such a point that 255 MEP steps do not span an entire EPWMCLK cycle.
- At any time, SFO() can be called to run SFO diagnostics on the MEP calibration module.

Usage:

- SFO() can be called at any time in the background while the ePWM channels are running in HRPWM mode. The scale factor result obtained can be applied to all ePWM channels running in HRPWM mode because the function makes use of the diagnostics logic in the MEP calibration module (which runs independently of ePWM channels).
- This routine returns a 1 when calibration is finished and a new scale factor has been calculated or returns a 0 if calibration is still running. The routine returns a 2 if there is an error, and the MEP_ScaleFactor is greater than the maximum 255 fine steps per coarse EPWMCLK cycle. In this case, the HRMSTEP register maintains the last MEP scale factor value less than 256 for auto conversion.
- All ePWM modules operating in HRPWM incur only a 3 EPWMCLK cycle minimum duty cycle limitation when high-resolution period control is not used. If high-resolution period control is enabled, there is an additional duty cycle limitation 3-EPWMCLK cycles before the end of the PWM period (see Section 27.18.1.5.3).
- The SFO() function also updates the HRMSTEP register with the scale factor result. If the HRCNFG[AUTOCONV] bit is set, the application software is responsible only for setting CMPAHR = fraction(PWMduty*PWMperiod) << 8 or CMPBHR = fraction(PWMduty*PWMperiod) << 8 or TBPRDHR = fraction (PWMperiod) while running SFO() in the background. The MEP Calibration Module then uses the values in the HRMSTEP and CMPAHR/CMPBHR/TBPRDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle or period and move the high-resolution ePWM signal edge accordingly.
- If the HRCNFG[AUTOCONV] bit is clear, the HRMSTEP register is ignored. The application software needs to perform the necessary calculations manually so that:
  - CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor) << 8 + 0x080.
  - Similar behavior applies for TBPHSHR, CMPBHR, DBREDHR, and DBFEDHR. Auto-conversion must be enabled when using TBPRDHR.

The following code snippet shows how to use the HRPWM DUTY using driverlib functions.

```
float32_t dutyFine = 85.62;
float32_t count = (dutyFine * (float32_t)(EPWM_TIMER_TBPRD << 8))/100;
uint32_t compCount = (count);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_A, compCount);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_B, compCount);
```

The routine can be run as a background task in a slow loop requiring negligible CPU cycles. The repetition rate at which an SFO function needs to be executed depends on the application's operating environment. As with all digital CMOS devices, temperature and supply voltage variations have an effect on MEP operation. However, in most applications these parameters vary slowly and therefore is often sufficient to execute the SFO function once every 5 to 10 seconds. If more rapid variations are expected, then execution can be performed more frequently to match the application. Note there is no high limit restriction on the SFO function repetition rate; hence, the SFO function can execute as quickly as the background loop is capable.

While using the HRPWM feature, HRPWM logic is not active for the first 3 EPWMCLK cycles of the PWM period (and the last 3 EPWMCLK cycles of the PWM period if TBPRDHR is used). While running the application in this configuration, if high-resolution period control is disabled (HRPCTL[HRPE = 0]) and the CMPA/CMPB register value is less than 3 cycles, then the CMPAHR/CMPBHR register must be cleared to zero. If high-resolution period control is enabled (HRPCTL[HRPE = 1]), the CMPA register value must not fall below 3 or above TBPRD-3.This can avoid any unexpected transitions on the PWM signal.

27.18.2.2 Software Usage

The software library function SFO(), calculates the MEP scale factor for the HRPWM-supported ePWM modules. The scale factor is an integer value in the range 1-255, and represents the number of micro step edge positions available for a system clock period. The scale factor value is returned in an integer variable called MEP_ScaleFactor. For example, see Table 27-22.

Table 27-22. Factor Values

Software Function call	Functional Description	Updated Variables
SFO()	Returns MEP scale factor in the HRMSTEP register	MEP_ScaleFactor and HRMSTEP register.

To use the HRPWM feature of the ePWMs, it is recommended that the SFO function be used as described here.

Step 1. Add "Include" Files

The SFO_V8.h file needs to be included as follows. This include file is mandatory while using the SFO library function. For the SFO() to operate, the appropriate (Device)_Device.h and (Device)_Epwm_defines.h must be included in the project. These include files are optional if customized header files are used in the end applications.

A Sample of How to Add "Include" Files

```
#include "F28x7x_Device.h"         // F28x7x Headerfile
#include "F28x7x_EPwm_defines.h"   // init defines
#include "SFO_V8.h"                // SFO lib functions (needed for HRPWM)
```

Copyright © 2025Texas Instruments

Step 2. Element Declaration

Declare an integer variable for the scale factor value as shown below.

Declaring an Element

```
int MEP_ScaleFactor = 0;   //scale factor value
volatile struct EPWM_REGS *ePWM[] = {0, &EPwm1Regs, &EPwm2Regs, &EPwm3Regs,
&EPwm4Regs};
```

Step 3. MEP_ScaleFactor Initialization

The SFO() function does not require a starting scale factor value in MEP_ScaleFactor. Prior to using the MEP_ScaleFactor variable in application code, SFO() can be called to drive the MEP calibration module to calculate an MEP_ScaleFactor value.

As part of the one-time initialization code prior to using MEP_ScaleFactor, include the following:

Initializing With a Scale Factor Value

```
MEP_ScaleFactor initialized using function SFO ()
while (SFO() == 0) {} // MEP_ScaleFactor calculated by MEP Cal Module
```

Step 4. Application Code

While the application is running, fluctuations in both device temperature and supply voltage can be expected. To be sure that good Scale Factors are used for each ePWM module, the SFO function can be re-run periodically as part of a slower back-ground loop. Some examples of this are shown here.

Note

See the HRPWM_SFO example in the device-specific C/C++ header files and peripheral examples available from the TI website.

SFO Function Calls

```
main ()
 {
 int status;
    // User code
    // ePWM1, 2, 3, 4 are running in HRPWM mode
    // The status variable returns 1 once a new MEP_ScaleFactor has been
    // calculated by the MEP Calibration Module running SFO
    // diagnostics.
status = SFO();
if(status==2) {ESTOP0;}   // The function returns a 2 if MEP_ScaleFactor is greater
                          // than the maximum 255 allowed (error condition)
 }
```

27.19.3 EPWM Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location: f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/epwm

Cloud access to these examples is available at the following link: dev.ti.com F29x SDK Examples.

27.19.3.1 ePWM Trip Zone - SINGLE_CORE

FILE: epwm_ex1_trip_zone.c

This example configures ePWM1 and ePWM2 as follows

- ePWM1 has TZ1 as one shot trip source

Copyright © 2025Texas Instruments

- ePWM2 has TZ1 as cycle by cycle trip source

Initially tie TZ1 high. During the test, monitor ePWM1 or ePWM2 outputs on a scope. Pull TZ1 low to see the effect.

External Connections
- ePWM1A is on GPIO0
- ePWM2A is on GPIO2
- TZ1 is on GPIO12

This example also makes use of the Input X-BAR. GPIO12 (the external trigger) is routed to the input X-BAR, from which it is routed to TZ1.

The TZ-Event is defined such that ePWM1A will undergo a One-Shot Trip and ePWM2A will undergo a Cycle-By-Cycle Trip.

27.19.3.2 ePWM Up Down Count Action Qualifier with FRAMESEL and IPC - MULTI_CORE

FILE: epwm_ex1_cpu1_cpu3_framesel_multi_c29x1.c

This example demonstrates multi-core ePWM control with FRAMESEL capabilities. It combines IPC communication between C29x1 and C29x3 cores with ePWM Action Qualifier functionality using up/down count mode.

The example configures ePWM4, ePWM5, ePWM6 on CPU1 to produce waveforms with independent modulation on ePWMxA and ePWMxB. The TB counter is in up/down count mode and demonstrates FRAMESEL functionality across ePWM modules and CPUs.

When using CCS for debugging this Multi-core example, after launching the debug session,
- Connect to CPU1 and load only the c29x1.out.
- After the program is loaded, run CPU1.
- Once c29x1 configures and releases CPU3 out of reset, the program stops.
- Connect to CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU3 target and load the symbols.

For FLASH configuration, this example is run in FLASH BANKMODE2, where CPU3 has access to FLASH (FRI-2). Refer to the Flash Plugin documentation to know about changing FLASH BANKMODEs and more. Additionally, the CPAx and CDAx RAMs are used for allocating various RAM sections. *External Connections*
- View the ePWM4A/B, ePWM5A/B, and ePWM6A/B waveforms on oscilloscope

Watch Variables

27.19.3.4 ePWM Up Down Count Action Qualifier - SINGLE_CORE

FILE: epwm_ex2_updown_aq.c

This example configures ePWM1, ePWM2, ePWM3 to produce a waveform with independent modulation on ePWMxA and ePWMxB.

The compare values CMPA and CMPB are modified within the ePWM's ISR.

The TB counter is in up/down count mode for this example.

View the ePWM1A/B(GPIO0 & GPIO1), ePWM2A/B(GPIO2 &GPIO3) and ePWM3A/B(GPIO4 & GPIO5) waveforms on oscilloscope.

27.19.3.5 ePWM Synchronization - SINGLE_CORE

FILE: epwm_ex3_synchronization.c

This example configures ePWM1, ePWM2, ePWM3 and ePWM4 as follows

- ePWM1 without phase shift as sync source
- ePWM2 with phase shift of 300 TBCLKs
- ePWM3 with phase shift of 600 TBCLKs
- ePWM4 with phase shift of 900 TBCLKs

External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B

Watch Variables

- None.

27.19.3.6 ePWM Digital Compare - SINGLE_CORE

FILE: epwm_ex4_digital_compare.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO2 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO2's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND

External Connections

Copyright © 2025Texas Instruments

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 TZ1, pull this pin low to trip the ePWM

Watch Variables

- None.

27.19.3.7 ePWM Digital Compare Event Filter Blanking Window - SINGLE_CORE

FILE: epwm_ex5_digital_compare_event_filter.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO2 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO2's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND
- ePWM1 with DCBEVT1 forcing the ePWM output LOW
- GPIO2 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO2's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND
- DCBEVT1 uses the filtered version of DCBEVT1
- The DCFILT signal uses the blanking window to ignore the DCBEVT1 for the duration of DC Blanking window

External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 TRIPIN1, pull this pin low to trip the ePWM

Watch Variables

- None.

27.19.3.8 ePWM Valley Switching - SINGLE_CORE

FILE: epwm_ex6_valley_switching.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- ePWM1 with DCBEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- DCBEVT1 uses the filtered version of DCBEVT1
- The DCFILT signal uses the valley switching module to delay the
- DCFILT signal by a software defined DELAY value.

External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1 (Output Pin, toggled through software)

Watch Variables

- None.

27.19.3.9 ePWM Digital Compare Edge Filter - SINGLE_CORE

FILE: epwm_ex7_edge_filter.c

Copyright © 2025Texas Instruments

This example configures ePWM1 as follows

- ePWM1 with DCBEVT2 forcing the ePWM output LOW as a CBC source
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCBEVT2
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- The DCBEVT2 is the source for DCFILT
- The DCFILT will count edges of the DCBEVT2 and generate a signal to to trip the ePWM on the 4th edge of DCBEVT2

External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1 (Output Pin, toggled through software)

Watch Variables

- None.

27.19.3.10 ePWM Deadband - SINGLE_CORE

FILE: epwm_ex8_deadband.c

This example configures ePWM1 through ePWM6 as follows

- ePWM1 with Deadband disabled (Reference)
- ePWM2 with Deadband Active High
- ePWM3 with Deadband Active Low
- ePWM4 with Deadband Active High Complimentary
- ePWM5 with Deadband Active Low Complimentary
- ePWM6 with Deadband Output Swap (switch A and B outputs)

External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B
- GPIO8 EPWM5A
- GPIO9 EPWM5B
- GPIO14 EPWM6A
- GPIO11 EPWM6B

Watch Variables

- None.

27.19.3.11 ePWM DMA - SINGLE_CORE

FILE: epwm_ex9_dma.c

This example configures ePWM1 and DMA as follows:

- ePWM1 is set up to generate PWM waveforms
- DMA5 is set up to update the CMPAHR, CMPA, CMPBHR and CMPB every period with the next value in the configuration array. This allows the user to create a DMA enabled fifo for all the CMPx and CMPxHR registers to generate unconventional PWM waveforms.
- DMA6 is set up to update the TBPHSHR, TBPHS, TBPRDHR and TBPRD every period with the next value in the configuration array.

Copyright © 2025Texas Instruments

- Other registers such as AQCTL can be controlled through the DMA as well by following the same procedure. (Not used in this example)

External Connections
- GPIO0 EPWM1A
- GPIO1 EPWM1B

Watch Variables
- None.

27.19.3.12 ePWM Chopper - SINGLE_CORE

FILE: epwm_ex10_chopper.c

This example configures ePWM1, ePWM2, ePWM3 and ePWM4 as follows
- ePWM1 with Chopper disabled (Reference)
- ePWM2 with chopper enabled at 1/8 duty cycle
- ePWM3 with chopper enabled at 6/8 duty cycle
- ePWM4 with chopper enabled at 1/2 duty cycle with One-Shot Pulse enabled

External Connections
- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B

Watch Variables
- None.

27.19.3.13 EPWM Configure Signal - SINGLE_CORE

FILE: epwm_ex11_configure_signal.c

This example configures ePWM1, ePWM2, ePWM3 to produce signal of desired frequency and duty. It also configures phase between the configured modules.

Signal of 10kHz with duty of 0.5 is configured on ePWMxA & ePWMxB with ePWMxB inverted. Also, phase of 120 degree is configured between ePWM1 to ePWM3 signals.

During the test, monitor ePWM1, ePWM2, and/or ePWM3 outputs on an oscilloscope.

- ePWM1A is on GPIO0
- ePWM1B is on GPIO1
- ePWM2A is on GPIO2
- ePWM2B is on GPIO3
- ePWM3A is on GPIO4
- ePWM3B is on GPIO5

27.19.3.14 Realization of Monoshot mode - SINGLE_CORE

FILE: epwm_ex12_monoshot_mode.c

This example showcases how to generate monoshot PWM output based on external trigger i.e. generating just a single pulse output on receipt of an external trigger. And the next pulse will be generated only when the next trigger comes. The example utilizes external synchronization and T1 action qualifier event features to achieve the desired output.

Copyright © 2025Texas Instruments

ePWM1 is used to generate the monoshot output and ePWM2 is used an external trigger for that. No external connections are required as ePWM2A is fed as the trigger using Input X-BAR automatically.

ePWM1 is configured to generated a single pulse of 0.5us when received an external trigger. This is achieved by enabling the phase synchronization feature and configuring EPWMxSYNCI as EXTSYNCIN1. And this EPWMxSYNCI is also configured as T1 event of action qualifier to set output HIGH while "CTR = PRD" action is used to set output LOW.

ePWM2 is configured to generate a 100 KHz signal with a duty of 1% (to simulate a rising edge trigger) which is routed to EXTSYNCIN1 using Input XBAR.

Observe GPIO0 (EPWM1A : Monoshot Output) and GPIO2(EPWM2 : External Trigger) on oscilloscope.

27.19.3.15 EPWM Action Qualifier (epwm_up_aq) - SINGLE_CORE

FILE: epwm_ex13_up_aq.c

This example configures ePWM1, ePWM2, ePWM3 to produce an waveform with independent modulation on EPWMxA and EPWMxB.

The compare values CMPA and CMPB are modified within the ePWM's ISR.

The TB counter is in up count mode for this example.

View the EPWM1A/B(GPIO0 & GPIO1), EPWM2A/B(GPIO2 & GPIO3) and EPWM3A/B(GPIO4 & GPIO5) waveforms via an oscilloscope.

27.19.3.16 ePWM XCMP Mode - SINGLE_CORE

FILE: epwm_ex15_xcmp_multiple_edges.c

(Note - base frequency and duty cycle of all ePWM's are 50 KHz and 50% respectively. Value of TBPRD = 1999)
This example configures ePWM1, ePWM2, ePWM4, ePWM6 and ePWM8 as follows

- ePWM1A is allocated all XCMP1-8 registers. ePWM1B has no output.
  - New duty cycle = 50%, new frequency = 200 KHz
  - No Shadow registers used
- ePWM2A is allocated XCMP1-4 and ePWM2B is allocated XCMP5-8 registers.
  - A and B waveforms are complimentary
  - New duty cycle = 50%, new frequency = 100 KHz
  - No Shadow registers used
- ePWM4 is configured same as ePWM2 with Minimum Deadband.
  - Minimum Deadband of 200 SYSCLK cycles provided (200 * (1/200 MHz) = 1 micro second)
  - This implies dead band of 1 us is visible on output of ePWM4A and ePWM4B after their falling edge
  - New duty cycle = 40%, new frequency = 100 KHz
- ePWM6A is allocated XCMP1-4 registers.
  - 3 Shadow register sets used with LOADMULTIPLE mode
  - Shadow set 2 repeated 2 times, Shadow set 3 repeated 4 times
  - ISR to update all Shadow registers with new values after they repeat
  - This means Shadow3 is active for 5 periods, Shadow2 is active for 3 periods and Shadow1 is active for 1 period before their new values are visible in output
- ePWM8A is allocated XCMP1-4 registers.
  - 3 Shadow register sets used with LOADONCE mode
  - Only Shadow set 3 is loaded from every period
  - ISR updates Shadow 3 register with new values every 5 periods

External Connections

- ePWM1A is on GPIO0
- ePWM2A is on GPIO2 and ePWM2B is on GPIO3
- ePWM4A is on GPIO6 and ePWM4B is on GPIO7

Copyright © 2025Texas Instruments

- ePWM6A is on GPIO14
- ePWM8A is on GPIO10
- Monitor GPIO24 for ePWM6A new Shadow register value loading
- Monitor GPIO25 for ePWM8A new Shadow register value loading

Shadow register updations for ePWM6 and ePWM8:

- Only XCMP1 and XCMP4 are updated
- Update values are +/- 20 TBCTR steps depending on direction of updation
- GPIO24 is toggled every 9 cycles for ePWM6 after cycling through all Shadow buffers and loading new values Similarly GPIO25 is toggled every 5 cycles for ePWM8

27.19.3.17 ePWM Event Detection - SINGLE_CORE

FILE: epwm_ex16_event_detection.c

(Note - base frequency and duty cycle of all ePWM's are 50 KHz and 50% respectively. Value of TBPRD = 1999) This example configures ePWM1 and ePWM2 in identical fashion with XCMP1-8 allocated to channel A. No shadow registers are used.

- XCMP1 = 250, XMP2 = 500, XCMP3 = 750 ..... XCMP 8 = 1750.
- In ePWM1, XMIN = 300 and XMAX = 400.
  - This window has no edge and generates a CAPEVT pulse every period.
- In ePWM2, XMIN = 300 and XMAX = 600.
  - This window has an edge and doesn't generate CAPEVT pulse signal.

External Connections

- ePWM1A is on GPIO0
- ePWM2A is on GPIO2
- ePWM1 Tripout is on GPIO24
- ePWM2 Tripout is on GPIO25
- LED1 is on GPIO31 (For control card)
- LED2 is on GPIO34 (For control card)

CAPIN and CAPGATE signals are both sourced as Trip4 for ePWM1 and Trip5 for ePWM2. Trip4 and Trip5 are routed from the INPUT X-BAR through EPWM-XBAR which feeds into the Digital Compare submodule. CAPEVT signal is used as Tripout and Trip-Zone interrupt source.

For ePWM1, Trip-Zone ISR configured to make LED1 blink 1 second on/off. For ePWM2, Trip-Zone ISR configured to make LED2 turn on if an interrupt ever occurs.

27.19.4 HRPWM Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location: f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/hrpwm

Cloud access to these examples is available at the following link: dev.ti.com F29x SDK Examples.

27.19.4.1 HRPWM Duty Control with SFO - SINGLE_CORE

FILE: hrpwm_ex1_duty_sfo.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

int SFO();

- updates MEP_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP_ScaleFactor value
- returns 2 if error: MEP_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)

Copyright © 2025Texas Instruments

- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

External Connections

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

27.19.4.2 HRPWM Period Control - SINGLE_CORE

FILE: hrpwm_ex3_prd_updown_sfo.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up-Down count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

int SFO();

- updates MEP_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP_ScaleFactor value
- returns 2 if error: MEP_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

External Connections

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

27.19.4.3 HRPWM XCMP Mode - SINGLE_CORE

FILE: hrpwm_ex8_xcmp_multiple_edges.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

int SFO();

- updates MEP_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP_ScaleFactor value
- returns 2 if error: MEP_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the XCMP MODE with HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

- ePWM1A is allocated for XCMP1-4 and ePWM1B is allocated XCMP5-8 registers.
  - No Shadow registers used *External Connections*
    - Monitor ePWM1 A/B pins on an oscilloscope.
    - ePWM1A is on GPIO0
    - ePWM1B is on GPIO1

27.20 EPWM Registers

This Section describes the EPWM Registers.

27.20.2 EPWM_REGS Registers

Table 27-26 lists the memory-mapped registers for the EPWM_REGS registers. All register offset addresses not listed in Table 27-26 should be considered as reserved locations and the register contents should not be modified.

Table 27-26. EPWM_REGS Registers

Offset	Acronym	Register Name	Protection
0h	TBCTL	Time Base Control Register	
2h	TBCTL2	Time Base Control Register 2	
6h	EPWMSYNCINSEL	EPWMxSYNCIN Source Select Register	
8h	TBCTR	Time Base Counter Register	
Ah	TBSTS	Time Base Status Register	
Ch	EPWMSYNCOUTEN	EPWMxSYNCOUT Source Enable Register	
Eh	TBCTL3	Time Base Control Register 3	
10h	CMPCTL	Counter Compare Control Register	
12h	CMPCTL2	Counter Compare Control Register 2	
18h	DBCTL	Dead-Band Generator Control Register	
1Ah	DBCTL2	Dead-Band Generator Control Register 2	
20h	AQCTL	Action Qualifier Control Register	
22h	AQTSRCSEL	Action Qualifier Trigger Event Source Select Register

1FCh	VCNTVAL	Hardware Valley Counter Register	

Complex bit access types are encoded to fit into small table cells. Table 27-27 shows the codes that are used for access types in this section.

Table 27-27. EPWM_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

1 TBCTL Register (Offset = 0h) [Reset = 0083h]

TBCTL is shown in Figure 27-122 and described in Table 27-28.

Return to the Summary Table.

Time Base Control Register

Figure 27-122. TBCTL Register

15	14	13	12	11	10	9	8
FREE_SOFT		PHSDIR	CLKDIV			HSPCLKDIV	
R/W-0h		R/W-0h	R/W-0h			R/W-1h	
7	6	5	4	3	2	1	0
HSPCLKDIV	SWFSYNC	RESERVED		PRDLD	PHSEN	CTRMODE	
R/W-1h	R-0/W1S-0h	R-0h		R/W-0h	R/W-0h	R/W-3h	

Table 27-29. TBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events 00: Stop after the next time-base counter increment or decrement 01: Stop when counter completes a whole cycle: - Up-count mode: stop when the time-base counter = period (TBCTR = TBPRD) - Down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) - Up-down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) 1x: Free run Reset type: SYSRSn
13	PHSDIR	R/W	0h	Phase Direction Bit This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event.. In the up-count and down-count modes this bit is ignored. 0: Count down after the synchronization event. 1: Count up after the synchronization event. Reset type: SYSRSn
12-10	CLKDIV	R/W	0h	Time Base Clock Pre-Scale Bits These bits select the time base clock pre-scale value (TBCLK = EPWMCLK/(HSPCLKDIV * CLKDIV): 000: /1 (default on reset) 001: /2 010: /4 011: /8 100: /16 101: /32 110: /64 111: /128 Reset type: SYSRSn

Table 27-29. TBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-7	HSPCLKDIV	R/W	1h	High Speed Time Base Clock Pre-Scale Bits These bits determine part of the time-base clock prescale value. TBCLK = EPWMCLK / (HSPCLKDIV x CLKDIV). This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral. 000: /1 001: /2 (default on reset) 010: /4 011: /6 100: /8 101: /10 110: /12 111: /14 Reset type: SYSRSn
6	SWFSYNC	R-0/W1S	0h	Software Forced Sync Pulse 0: Writing a 0 has no effect and reads always return a 0. 1: Writing a 1 forces a one-time synchronization pulse to be generated. SWFSYNC can be enabled to affect EPWMxSYNCO by setting the EPWMSYNCOUTEN.SWEN bit. Reset type: SYSRSn
5-4	RESERVED	R	0h	Reserved
3	PRDLD	R/W	0h	Active Period Reg Load from Shadow Select 0: The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to zero and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. A write/read to the TBPRD register accesses the shadow register. 1: Immediate Mode (Shadow register bypassed): A write or read to the TBPRD register accesses the active register. Reset type: SYSRSn
2	PHSEN	R/W	0h	Counter Reg Load from Phase Reg Enable 0: Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS). 1: Allow Counter to be loaded from the Phase register (TBPHS) and shadow to active load events when an EPWMxSYNCI input signal occurs or a software-forced sync signal, see bit 6. Reset type: SYSRSn
1-0	CTRMODE	R/W	3h	Counter Mode The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 00: Up-count mode 01: Down-count mode 10: Up-down count mode 11: Freeze counter operation (default on reset) Reset type: SYSRSn

Table 27-47. DBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	HALFCYCLE	R/W	0h	Half Cycle Clocking Enable Bit 0: Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate. 1: Half cycle clocking enabled. The dead-band counters are clocked at TBCLK*2. Reset type: SYSRSn
14	DEDB_MODE	R/W	0h	Dead Band Dual-Edge B Mode Control (S8 switch) 0: Rising edge delay applied to InA/InB as selected by S4 switch (IN-MODE bits) on A signal path only. Falling edge delay applied to InA/InB as selected by S5 switch (INMODE bits) on B signal path only. 1: Rising edge delay and falling edge delay applied to source selected by S4 switch (INMODE bits) and output to B signal path only. Note: When this bit is set to 1, user should always either set OUT_MODE bits such that Apath = InA OR OUTSWAP bits such that OutA=Bpath otherwise, OutA will be invalid. Reset type: SYSRSn
13-12	OUTSWAP	R/W	0h	Dead Band Output Swap Control Bit 13 controls the S6 switch and bit 12 controls the S7 switch. 00: OutA and OutB signals are as defined by OUT-MODE bits. 01: OutA = A-path as defined by OUT-MODE bits. OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). 10: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = B-path as defined by OUT-MODE bits. 11: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). Reset type: SYSRSn

Copyright © 2025Texas Instruments

Table 27-47. DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	SHDWDBFEDMODE	R/W	0h	FED Dead-Band Load Mode 0: Immediate mode. Only the active DBFED register is used. All writes/reads via the CPU directly access the active register for immediate 'FED dead-band action.' 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn
10	SHDWDBREDMODE	R/W	0h	RED Dead-Band Load Mode 0: Immediate mode. Only the active DBRED register is used. All writes/reads via the CPU directly access the active register for immediate 'RED dead-band action.' 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn
9-8	LOADFEDMODE	R/W	0h	Active DBFED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
7-6	LOADREDMODE	R/W	0h	Active DBRED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
5-4	IN_MODE	R/W	0h	Dead-Band Input Mode Control Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays. 00: EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 01: EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 10: EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 11: EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal. Reset type: SYSRSn

Table 27-47. DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	POLSEL	R/W	0h	Polarity Select Control Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0x0. Other enhanced modes are also possible, but not regarded as typical usage modes. 00: Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 01: Active low complementary (ALC) mode. EPWMxA is inverted. 10: Active high complementary (AHC). EPWMxB is inverted. 11: Active low (AL) mode. Both EPWMxA and EPWMxB are inverted. Reset type: SYSRSn
1-0	OUT_MODE	R/W	0h	Dead-Band Output Mode Control Bit 1 controls the S1 switch and bit 0 controls the S0 switch. 00: DBM is fully disabled or by-passed. In this mode the POLSEL and IN-MODE bits have no effect. 01: Apath = InA (delay is by-passed for A signal path) Bpath = FED (Falling Edge Delay in B signal path) 10: Apath = RED (Rising Edge Delay in A signal path) Bpath = InB (delay is by-passed for B signal path) 11: DBM is fully enabled (i.e. both RED and FED active) Reset type: SYSRSn

Table 27-61. HRCNFG Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	RESERVED	R/W	0h	Reserved
13	RESERVED	R-0	0h	Reserved
12-11	HRLOADB	R/W	0h	Shadow Mode Bit Selects the time event that loads the CMPBHR shadow value into the active register. 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Load on CMPB_EQ (Translator Event CMPB-3) Reset type: SYSRSn
10	CTLMODEB	R/W	0h	Control Mode Bits Selects the register (CMP/TBPRD or TBPHS) that controls the MEP: 0: CMPBHR(8) or TBPRDHR(8) Register controls the edge position (i.e., this is duty or period control mode). (Default on Reset) 1: TBPHSHR(8) Register controls the edge position (i.e., this is phase control mode). Reset type: SYSRSn
9-8	EDGMODEB	R/W	0h	Edge Mode Bits Selects the edge of the PWM that is controlled by the micro-edge position (MEP) logic: 00: HRPWM capability is disabled (default on reset) 01: MEP control of rising edge (CMPBHR) 10: MEP control of falling edge (CMPBHR) 11: MEP control of both edges (TBPHSHR or TBPRDHR) Reset type: SYSRSn
7	SWAPAB	R/W	0h	Swap ePWM A & B Output Signals This bit enables the swapping of the A & B signal outputs. The selection is as follows: 0: ePWMxA and ePWMxB outputs are unchanged. 1: ePWMxA signal appears on ePWMxB output and ePWMxB signal appears on ePWMxA output. Reset type: SYSRSn

Copyright © 2025Texas Instruments

Table 27-61. HRCNFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	AUTOCONV	R/W	0h	Auto Convert Delay Line Value Selects whether the fractional duty cycle/period/phase in the CMPAHR/TBPRDHR/TBPHSHR register is automatically scaled by the MEP scale factor in the HRMSTEP register or manually scaled by calculations in application software. The SFO library function automatically updates the HRMSTEP register with the appropriate MEP scale factor. 0: Automatic HRMSTEP scaling is disabled. 1: Automatic HRMSTEP scaling is enabled. If application software is manually scaling the fractional duty cycle, or phase (i.e. software sets CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor)<<8 + 0x080 for duty cycle), then this mode must be disabled. Reset type: SYSRSn
5	SELOUTB	R/W	0h	EPWMxB Output Select Bit This bit selects which signal is output on the ePWMxB channel output. The inversion will take the high resolution mode into account and the inverted signal will contain any high resolution modification. The inversion takes place as the last step in modifying the ePWMxB signal. 0: ePWMxB output is normal. 1: ePWMxB output is inverted version of ePWMxA signal. Reset type: SYSRSn
4-3	HRLOAD	R/W	0h	Shadow Mode Bit Selects the time event that loads the CMPAHR shadow value into the active register. 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Load on CMPA_EQ (Translator Event CMPA-3) Reset type: SYSRSn
2	CTLMODE	R/W	0h	Control Mode Bits Selects the register (CMP/TBPRD or TBPHS) that controls the MEP: 0: CMPAHR(8) or TBPRDHR(8) Register controls the edge position (i.e., this is duty or period control mode). (Default on Reset) 1: TBPHSHR(8) Register controls the edge position (i.e., this is phase control mode). Reset type: SYSRSn
1-0	EDGMODE	R/W	0h	Edge Mode Bits Selects the edge of the PWM that is controlled by the micro-edge position (MEP) logic: 00: HRPWM capability is disabled (default on reset) 01: MEP control of rising edge (CMPAHR) 10: MEP control of falling edge (CMPAHR) 11: MEP control of both edges (TBPHSHR or TBPRDHR) Reset type: SYSRSn

3	RESERVED	R/W	0h	Reserved
2	TBPHSHRLOADE	R/W	0h	TBPHSHR Load Enable This bit allows you to synchronize ePWM modules with a high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event. This allows for multiple ePWM modules operating at the same frequency to be phase aligned with high-resolution. 0: Disables synchronization of high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event: 1: Synchronize the high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital comparator synchronization event. The phase is synchronized using the contents of the high-resolution phase TBPHSHR register. The TBCTL[PHSEN] bit which enables the loading of the TBCTR register with TBPHS register value on a SYNCIN or TBCTL[SWFSYNC] event works independently. However, users need to enable this bit also if they want to control phase in conjunction with the high-resolution period feature. This bit and the TBCTL[PHSEN] bit must be set to 1 when high-resolution period is enabled for up-down count mode even if TBPHSHR = 0x0000. This bit does not need to be set when only high-resolution duty is enabled. Reset type: SYSRSn

33 TBPHS Register (Offset = C0h) [Reset = 00000000h]

TBPHS is shown in Figure 27-154 and described in Table 27-60.

Return to the Summary Table.

Time Base Phase High

Figure 27-154. TBPHS Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TBPHS																TBPHSHR															
R/W-0h																R/W-0h															

Table 27-93. TBPHS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	TBPHS	R/W	0h	Phase Offset Register These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. - If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase. - If TBCTL[PHSEN] = 1, then the time-base counter (TBCTR) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization. Reset type: SYSRSn
15-0	TBPHSHR	R/W	0h	Phase Offset (High Resolution) Register. TBPHSHR must not be used. Instead TRREM (HRPWM remainder register) must be used to mimic the functionality of TBPHSHR. The lower 8 bits in this register are ignored - writes are ignored and reads return zero Reset type: SYSRSn

Copyright © 2025Texas Instruments

34 TBPRDHR Register (Offset = C4h) [Reset = 0000h]

TBPRDHR is shown in Figure 27-155 and described in Table 27-61.

Return to the Summary Table.

Table 27-97. TBPRD Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TBPRD	R/W	0h	Time Base Period Register These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDLD] bit. By default this register is shadowed. - If TBCTL[PRDLD] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero. - If TBCTL[PRDLD] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. - The active and shadow registers share the same memory map address. Reset type: SYSRSn

36 CMPA Register (Offset = D4h) [Reset = 00000000h]

CMPA is shown in Figure 27-157 and described in Table 27-63.

Return to the Summary Table.

Counter Compare A Register

Figure 27-157. CMPA Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMPA																CMPAHR															
R/W-0h																R/W-0h															

Table 27-99. CMPA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	CMPA	R/W	0h	Compare A Register The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a 'time-base counter equal to counter compare A' event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include: - Do nothing the event is ignored. - Clear: Pull the EPWMxA and/or EPWMxB signal low - Set: Pull the EPWMxA and/or EPWMxB signal high - Toggle the EPWMxA and/or EPWMxB signal Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed. - If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register. - Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full. - If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. - In either mode, the active and shadow registers share the same memory map address. Reset type: SYSRSn
15-0	CMPAHR	R/W	0h	Compare A HRPWM Extension Register The UPPER 8-bits contain the high-resolution portion (most significant 8-bits) of the counter-compare A value. CMPA:CMPAHR can be accessed in a single 32-bit read/write. Shadowing is enabled and disabled by the CMPCTL[SHDWAMODE] bit as described for the CMPA register. The lower 8 bits in this register are ignored Reset type: SYSRSn

Copyright © 2025Texas Instruments

37 CMPB Register (Offset = D8h) [Reset = 00000000h]

CMPB is shown in Figure 27-158 and described in Table 27-64.

Return to the Summary Table.

Compare B Register

Figure 27-158. CMPB Register

2	OST	R	0h	Latched Status Flag for A One-Shot Trip Event 0: No one-shot trip event has occurred. 1: Indicates a trip event has occurred on a pin selected as a one-shot trip source. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

Copyright © 2025Texas Instruments

Table 27-127. TZFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	CBC	R	0h	Latched Status Flag for Cycle-By-Cycle Trip Event 0: No cycle-by-cycle trip event has occurred. 1: Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x00) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x00 no matter where in the cycle the CBC flag is cleared. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn
0	INT	R	0h	Latched Trip Interrupt Status Flag 0: Indicates no interrupt has been generated. 1: Indicates an EPWMx_TZINT PIE interrupt was generated because of a trip condition. No further EPWMx_TZINT PIE interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

Copyright © 2025Texas Instruments

51 TZCBCFLG Register (Offset = 128h) [Reset = 0000h]

Table 27-145. ETPS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-8	SOCAPRD	R/W	0h	ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Period Select These bits determine how many selected ETSEL[SOCASEL] events need to occur before an EPWMxSOCA pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCAEN] = 1). The SOCA pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCA] = 1). Once the SOCA pulse is generated, the ETPS[SOCACNT] bits will automatically be cleared. 00: Disable the SOCA event counter. No EPWMxSOCA pulse will be generated 01: Generate the EPWMxSOCA pulse on the first event: ETPS[SOCACNT] = 0,1 10: Generate the EPWMxSOCA pulse on the second event: ETPS[SOCACNT] = 1,0 11: Generate the EPWMxSOCA pulse on the third event: ETPS[SOCACNT] = 1,1 Reset type: SYSRSn
7-6	RESERVED	R-0	0h	Reserved
5	SOCPSSEL	R/W	0h	EPWMxSOC A/B Pre-Scale Selection Bits 0: Selects ETPS [SOCACNT/SOCBCNT] and [SOCAPRD/ SOCBPRD] registers to determine frequency of events (SOC pulse once every 0-3 events). 1: Selects ETSOCPS [SOCACNT2/SOCBCNT2] and [SOCAPRD2/ SOCBPRD2] registers to determine frequency of events (SOC pulse once every 0-15 events). Reset type: SYSRSn
4	INTPSSEL	R/W	0h	EPWMxINTn Pre-Scale Selection Bits 0: Selects ETPS [INTCNT, and INTPRD] registers to determine frequency of events (interrupt once every 0-3 events). 1: Selects ETINTPS [INTCNT2, and INTPRD2] registers to determine frequency of events (interrupt once every 0-15 events). Reset type: SYSRSn
3-2	INTCNT	R	0h	ePWM Interrupt Event (EPWMx_INT) Counter Register These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD]. 00: No events have occurred. 01: 1 event has occurred. 10: 2 events have occurred. 11: 3 events have occurred. Reset type: SYSRSn

Copyright © 2025Texas Instruments

Table 27-145. ETPS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	INTPRD	R/W	0h	ePWM Interrupt (EPWMx_INT) Period Select These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented. 00: Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored. 01: Generate an interrupt on the first event INTCNT = 01 (first event) 10: Generate interrupt on ETPS[INTCNT] = 1,0 (second event) 11: Generate interrupt on ETPS[INTCNT] = 1,1 (third event) Reset type: SYSRSn

This bit is used for test purposes. Reset type: SYSRSn
2	SOCA	R-0/W1S	0h	SOCA Force Bit The SOCA pulse will only be generated if the event is enabled in the ETSEL register. The ETFLG[SOCA] flag bit will be set regardless. 0: Writing 0 to this bit will be ignored. Always reads back a 0. 1: Generates a pulse on EPWMxSOCA and set the SOCAFLG bit. This bit is used for test purposes. Reset type: SYSRSn
1	RESERVED	R-0	0h	Reserved
0	INT	R-0/W1S	0h	INT Force Bit The interrupt will only be generated if the event is enabled in the ETSEL register. The INT flag bit will be set regardless. 0: Writing 0 to this bit will be ignored. Always reads back a 0. 1: Generates an interrupt on EPWMxINT and set the INT flag bit. This bit is used for test purposes. Reset type: SYSRSn

RESERVED						SHDWMODE	CAPE
R-0-0h						R/W-0h	R/W-0h

Table 27-175. DCCAPCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	CAPMODE	R/W	0h	Counter Capture Mode 0: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs, further trip (capture) events are ignored until the next PRD_eq or CNT_zero event (as selected by the PULSESEL bit in the DCFCTL register) re-triggers the capture mechanism. If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value. If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value. 1: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs - it will set the CAPSTS flag and further trip (capture) events are ignored until this bit is cleared. CAPSTS can be cleared by writing to CAPCLR bit in DCCAPCTL register and it re-triggers the capture mechanism. If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value. If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value. Reset type: SYSRSn
14	CAPCLR	R-0/W1S	0h	DC Capture Latched Status Clear Flag 0: Writing a 0 has no effect. 1: Writing a 1 will clear this CAPSTS (set) condition. Reset type: SYSRSn
13	CAPSTS	R	0h	Latched Status Flag for Capture Event 0: No DC capture event occurred. 1: A DC capture event has occurred. Reset type: SYSRSn
12-2	RESERVED	R-0	0h	Reserved

R/W-0h							
7	6	5	4	3	2	1	0
DCFOFFSET							
R/W-0h							

Table 27-177. DCFOFFSET Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	DCFOFFSET	R/W	0h	Blanking Window Offset These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted. Reset type: SYSRSn

Copyright © 2025Texas Instruments

76 DCFOFFSETCNT Register (Offset = 194h) [Reset = 0000h]

DCFOFFSETCNT is shown in Figure 27-197 and described in Table 27-103.

Return to the Summary Table.

Digital Compare Filter Offset Counter Register

Table 27-189. DCCAP Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	DCCAP	R	0h	Digital Compare Time-Base Counter Capture To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low to high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed. - If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value. - If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory map address. Reset type: SYSRSn
