WIDEBAND, LOW-NOISE, LOW-DISTORTION, FULLY-DIFFERENTIAL AMPLIFIER

Check for Samples: THS4511

FEATURES

- **Fully-Differential Architecture**
- **Common-Mode Input Range Includes the Negative Rail**
- **Unity-Gain Stable**
- **Bandwidth: 1.6 GHz (Gain = 0 dB)**
- **Slew Rate: 4900 V/µs**
- **1% Settling Time: 3.3 ns**
- **HD_2: –72 dBc at 70 MHz**
- **HD_3: –87 dBc at 70 MHz**
- **OIP_2: 76 dBm at 70 MHz**
- **OIP_3: 42 dBm at 70 MHz**
- **Input Voltage Noise: 2 nV/√Hz (f > 10 MHz)**
- **Noise Figure: 21.8 dB (50-Ω System, G = 6 dB)**
- **Output Common-Mode Control**
- **5-V Power-Supply Current: 39.2 mA**
- **Power-Down Capability: 0.65 mA**

APPLICATIONS

- **5-V Data-Acquisition Systems**
- **High Linearity ADC Amplifiers**
- **Wireless Communication**
- **Medical Imaging**
- **Test and Measurement**

RELATED PRODUCTS

DEVICE	MIN. GAIN	COMMON-MODE RANGE OF INPUT(1)
THS4508	6 dB	–0.3 V to 2.3 V
THS4509	6 dB	0.75 V to 4.25 V
THS4511	0 dB	–0.3 V to 2.3 V
THS4513	0 dB	0.75 V to 4.25 V

1. Assumes a 5-V single-ended power supply.

DESCRIPTION

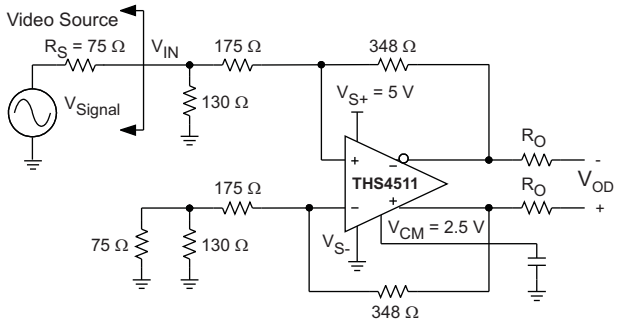
The THS4511 is a wideband, fully-differential operational amplifier designed for single-supply 5-V data-acquisition systems. It has very low noise at 2 nV/√Hz, and extremely low harmonic distortion of –72 dBc HD_2 and –87 dBc HD_3 at 70 MHz with 2 V_{PP}, G = 0 dB, and 200-Ω load. Slew rate is very high at 4900 Vµs and with settling time of 3.3 ns to 1% (2 V step) it is ideal for pulsed applications. It is designed for minimum gain of 0 dB.

To allow for dc coupling to analog-to-digital converters (ADCs), its unique output common-mode control circuit maintains the output common-mode voltage within 5-mV offset (typical) from the set voltage, when set within ±0.5 V of midsupply. The common-mode set point is set to midsupply by internal circuitry, which may be over-driven from an external source.

The THS4511 is a high-performance amplifier that has been optimized for use in 5-V single-supply data acquisition systems. The output has been optimized for best performance with its common-mode voltages set to midsupply, and the input has been optimized for performance over a wide range of common-mode input voltages. High performance at a low power-supply voltage enables single-supply 5-V data-acquisition systems while minimizing component count.

The THS4511 is offered in a quad, 16-pin leadless QFN package (RGT), and is characterized for operation over the full industrial temperature range from –40°C to +85°C.

Video Buffer, Single-Ended to Differential



Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PowerPAD is a trademark of Texas Instruments Incorporated.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

ABSOLUTE MAXIMUM RATINGS(1)

Over operating free-air temperature range, unless otherwise noted.

			UNIT
V_{SS}	Supply voltage	V_{S-} to V_{S+}	5.5 V
V_I	Input voltage		$\pm V_S$
V_{ID}	Differential input voltage		4 V
I_O	Output current		200 mA
	Continuous power dissipation		See Dissipation Ratings Table
T_J	Maximum junction temperature(2)		+150°C
T_J	Maximum junction temperature, continuous operation, long term reliability(3)		+125°C
T_A	Operating free-air temperature range		–40°C to +85°C
T_{STG}	Storage temperature range		–65°C to +150°C
	ESD ratings	HBM	2000 V
		CDM	1500 V
		MM	100 V

(1) Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not implied.
(2) The absolute maximum temperature under any condition is limited by the constraints of the silicon process.
(3) The maximum junction temperature for continuous operation is limited by the package constraints. Operation above this temperature may result in reduced reliability and/or lifetime of the device. The THS4511 incorporates a (QFN) exposed thermal pad on the underside of the chip. This acts as a heatsink and must be connected to a thermally-dissipative plane for proper power dissipation. Failure to do so may result in exceeding the maximum junction temperature which could permanently damage the device. See TI technical brief SLMA002 and SLMA004 for more information about using the QFN thermally-enhanced package.

DISSIPATION RATINGS TABLE

TERMINAL FUNCTIONS

TERMINAL (RGT PACKAGE)		DESCRIPTION
NO.	NAME	
1	NC	No internal connection
2	V_{IN-}	Inverting amplifier input
3	V_{OUT+}	Noninverting amplifier output
4, 9	CM	Common-mode voltage input
5-8	V_{S+}	Positive amplifier power supply input
10	V_{OUT-}	Inverted amplifier output
11	V_{IN+}	Noninverting amplifier input
12	$\overline{PD}$	Power-down; $\overline{PD}$ = logic low puts part into low power mode, $\overline{PD}$ = logic high or open for normal operation
13-16	V_{S-}	Negative amplifier power-supply input

ELECTRICAL CHARACTERISTICS: $V_{S+} - V_{S-} = 5$ V

Test conditions unless otherwise noted: $V_{S+} = 5$ V, $V_{S-} = 0$ V, G = 0 dB, CM = open, $V_O = 2\ V_{PP}$, $R_F = 349\ \Omega$, $R_L = 200\ \Omega$ differential, T = +25°C single-ended input, differential output, input referenced to ground, and output referenced to midsupply.

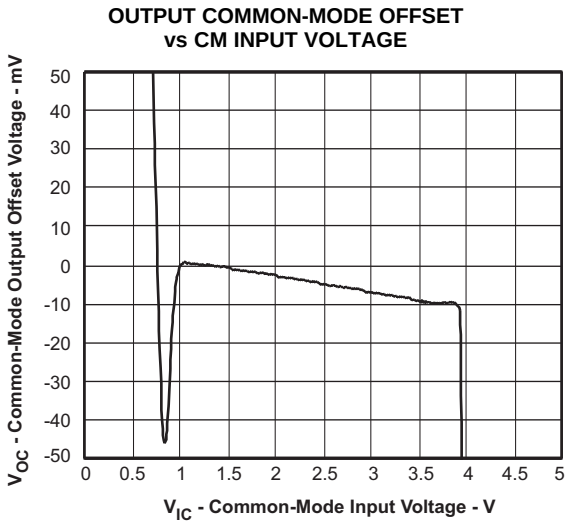

Figure 37.

TEST CIRCUITS

The THS4511 is tested with the following test circuits built on the evaluation module (EVM). For simplicity, the power-supply decoupling is not shown—see *Layout* in the *Application Information* section for recommendations. Depending on the test conditions, component values are changed per the following tables, or as otherwise noted. The signal generators used are ac-coupled 50-Ω sources, and a 0.22-µF capacitor and 49.9-Ω resistor to ground are inserted across R_{IT} on the alternate input to balance the circuit.

Table 1. Gain Component Values

GAIN	R_F	R_G	R_{IT}
0 dB	348 Ω	340 Ω	56.2 Ω
6 dB	348 Ω	165 Ω	61.9 Ω

Note the gain setting includes 50-Ω source impedance. Components are chosen to achieve gain and 50-Ω input termination.

Table 2. Load Component Values

R_L	R_O	R_{OT}	ATTEN.
100 Ω	25 Ω	Open	6 dB
200 Ω	86.6 Ω	69.8 Ω	16.8 dB
499 Ω	237 Ω	56.2 Ω	25.5 dB
1 kΩ	487 Ω	52.3 Ω	31.8 dB

Note the total load includes 50-Ω termination by the test equipment. Components are chosen to achieve load and 50-Ω line termination through a 1:1 transformer.

Due to the voltage divider on the output formed by the load component values, the amplifier output is attenuated. The column *Atten* in Table 2 shows the attenuation expected from the resistor divider. When using a transformer at the output as shown in Figure 39, the signal will see slightly more loss, and these numbers will be approximate.

Frequency Response

The circuit shown in Figure 38 is used to measure the frequency response of the circuit.

A network analyzer is used as the signal source and as the measurement device. The output impedance of the network analyzer is 50 Ω. R_{IT} and R_G are chosen to impedance match to 50 Ω, and to maintain the proper gain. To balance the amplifier, a 0.22-µF capacitor and 49.9-Ω resistor to ground are inserted across R_{IT} on the alternate input.

The output is probed using a high-impedance differential probe across the 100-Ω resistor. The gain is referred to the amplifier output by adding back the 6-dB loss due to the voltage divider on the output.

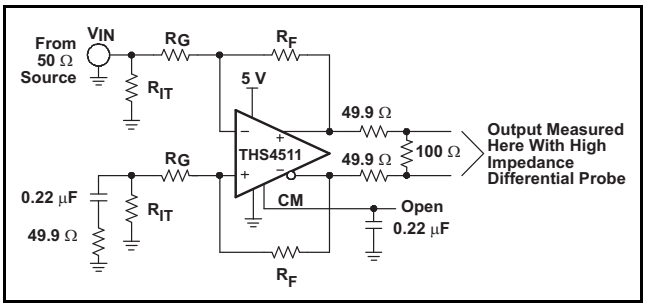

Figure 38. Frequency Response Test Circuit

Distortion and 1-dB Compression

The circuit shown in Figure 39 is used to measure harmonic distortion, intermodulation distortion, and 1-db compression point of the amplifier.

A signal generator is used as the signal source and the output is measured with a spectrum analyzer. The output impedance of the signal generator is 50 Ω. R_{IT} and R_G are chosen to impedance-match to 50 Ω, and to maintain the proper gain. To balance the amplifier, a 0.22-µF capacitor and 49.9-Ω resistor to ground are inserted across R_{IT} on the alternate input.

A low-pass filter is inserted in series with the input to reduce harmonics generated at the signal source. The level of the fundamental is measured, then a high-pass filter is inserted at the output to reduce the fundamental so that it does not generate distortion in the input of the spectrum analyzer.

The transformer used in the output to convert the signal from differential to single ended is an ADT1-1WT. It limits the frequency response of the circuit so that measurements cannot be made below approximately 1 MHz.

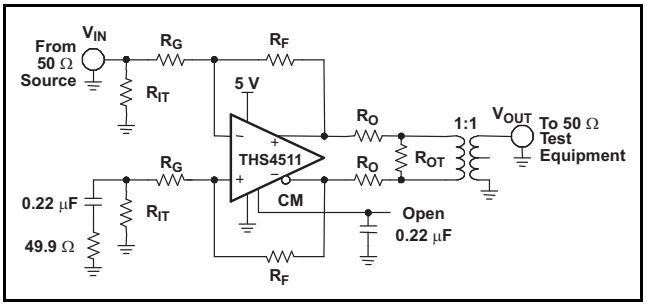

Figure 39. Distortion Test Circuit

The 1-dB compression point is measured with a spectrum analyzer with 50-Ω double termination or 100-Ω termination as shown in Table 2. The input power is increased until the output is 1 dB lower than expected. The number reported in the table data is the power delivered to the spectrum analyzer input. Add 3 dB to refer to the amplifier output.

S-Parameter, Slew Rate, Transient Response, Settling Time, Output Impedance, Overdrive, Output Voltage, and Turn-On/Off Time

The circuit shown in Figure 40 is used to measure s-parameters, slew rate, transient response, settling time, output impedance, overdrive recovery, output voltage swing, and turn-on/turn-off times of the amplifier. For output impedance, the signal is injected at V_{OUT} with V_{IN} left open and the drop across the 49.9-Ω resistor is used to calculate the impedance seen looking into the amplifier output.

Because S_{21} is measured single-ended at the load with 50-Ω double termination, add 12 dB to refer to the amplifier output as a differential signal.

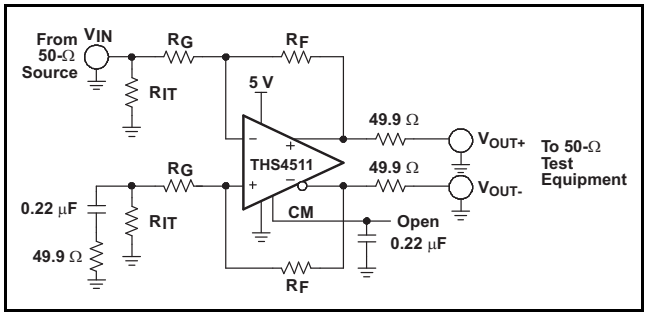

Figure 40. S-Parameter, SR, Transient Response, Settling Time, Z_O, Overdrive Recovery, V_{OUT} Swing, and Turn-On/Off Test Circuit

CM Input

The circuit shown in Figure 41 is used to measure the frequency response and input impedance of the CM input. Frequency response is measured single-ended at V_{OUT+} or $V_{OUT–}$ with the input injected at V_{IN}, R_{CM} = 0 Ω, and R_{CMT} = 49.9 Ω. The input impedance is measured with R_{CM} = 49.9 Ω with R_{CMT} = open, and calculated by measuring the voltage drop across R_{CM} to determine the input current.

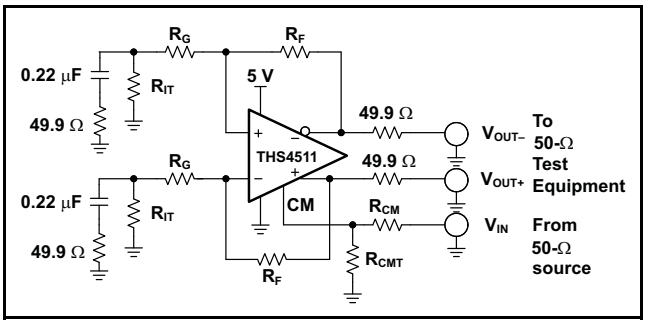

Figure 41. CM Input Test Circuit

CMRR and PSRR

The circuit shown in Figure 42 is used to measure the CMRR and PSRR of V_{S+} and $V_{S–}$. The input is switched appropriately to match the test being performed.

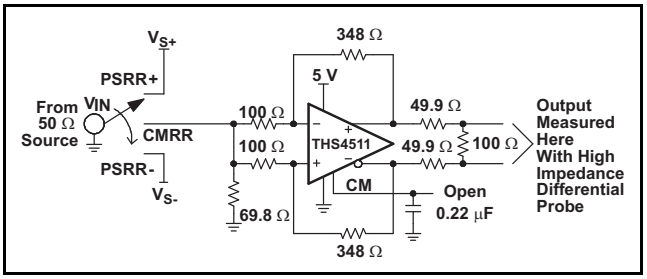

Figure 42. CMRR and PSRR Test Circuit

APPLICATION INFORMATION

APPLICATIONS

The following circuits show application information for the THS4511. For simplicity, power-supply decoupling capacitors are not shown in these diagrams. For more detail on the use and operation of fully-differential operational amplifiers refer to application report *Fully-Differential Amplifiers* (SLOA054).

Differential Input to Differential Output Amplifier

The THS4511 is a fully-differential operational amplifier, and can be used to amplify differential input signals to differential output signals. A basic block diagram of the circuit is shown in Figure 43 (CM input not shown). The gain of the circuit is set by R_F divided by R_G.

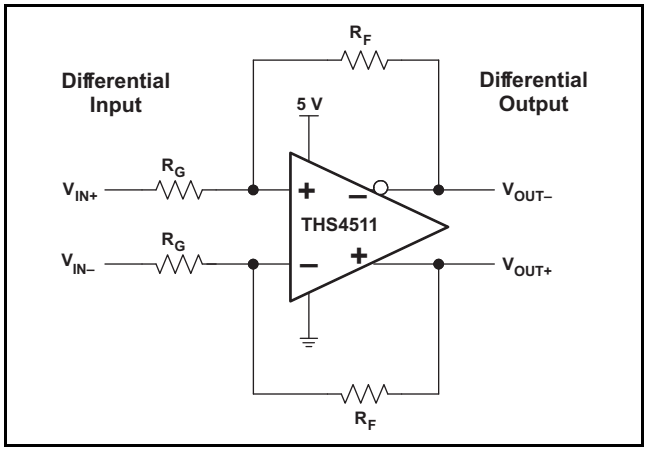

Figure 43. Differential Input to Differential Output Amplifier

Depending on the source and load, input and output termination can be accomplished by adding R_{IT} and R_O.

Single-Ended Input to Differential Output Amplifier

The THS4511 can be used to amplify and convert single-ended input signals to differential output signals. A basic block diagram of the circuit is shown in Figure 44 (CM input not shown). The gain of the circuit is again set by R_F divided by R_G.

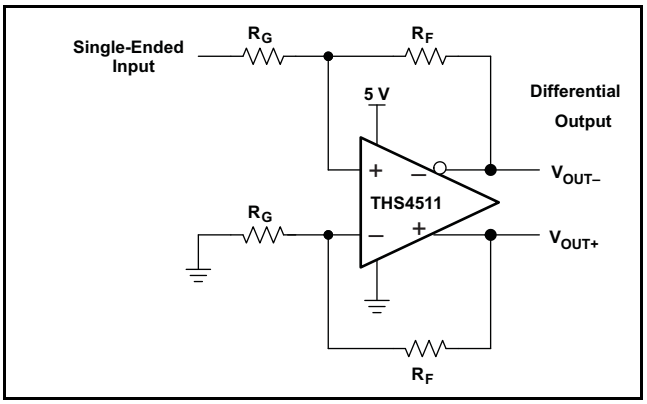

Figure 44. Single-Ended Input to Differential Output Amplifier

Input Common-Mode Voltage Range

The input common-model voltage of a fully-differential operational amplifier is the voltage at the (+) and (–) input pins of the operational amplifier.

It is important to not violate the input common-mode voltage range (V_{ICR}) of the operational amplifier. Assuming the operational amplifier is in linear operation the voltage across the input pins is only a few millivolts at most. So finding the voltage at one input pin determines the input common-mode voltage of the operational amplifier.

Treating the negative input as a summing node, the voltage is given by Equation 1:

$$V_{IC} = \left(V_{OUT+} \times \frac{R_G}{R_G + R_F} \right) + \left(V_{IN-} \times \frac{R_F}{R_G + R_F} \right) \quad (1)$$

To determine the V_{ICR} of the operational amplifier, the voltage at the negative input is evaluated at the extremes of V_{OUT+}.

As the gain of the operational amplifier increases, the input common-mode voltage becomes closer and closer to the input common-mode voltage of the source.

Setting the Output Common-Mode Voltage

The output common-mode voltage is set by the voltage at the CM pin(s). The internal common-mode control circuit maintains the output common-mode voltage within 5-mV offset (typical) from the set voltage, when set within 0.5 V of midsupply. If left unconnected, the common-mode set point is set to midsupply by internal circuitry, which may be overdriven from an external source. Figure 45 is representative of the CM input. The internal CM circuit has about 700 MHz of –3-dB bandwidth, which is required for best performance, but it is intended to be a dc-bias input pin. Bypass capacitors are recommended on this pin to reduce noise at the output. The external current required to overdrive the internal resistor divider is given by Equation 2:

$$I_{EXT} = \frac{2V_{CM} - (V_{S+} - V_{S-})}{50\ k\Omega} \quad (2)$$

where V_{CM} is the voltage applied to the CM pin, and V_{S+} ranges from 3.75 V to 5 V, and V_{S-} is 0 V (ground).

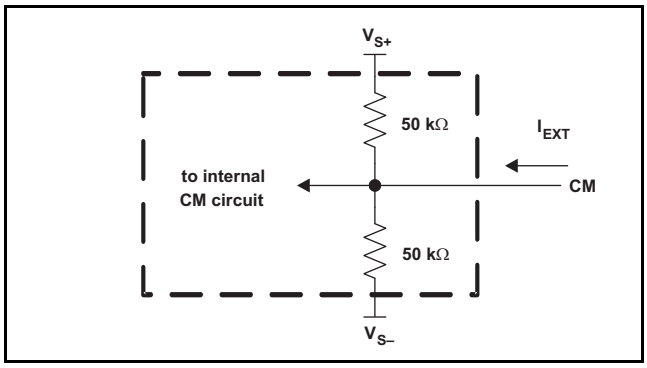

Figure 45. CM Input Circuit

Device Operation with Single Power Supplies Less than 5 V

The THS4511 is optimized to work in systems using 5-V single supplies, and the characterization data presented in this data sheet were taken with 5-V single-supply inputs. For ac-coupled systems or dc-coupled systems operating with supplies less than 5 V and greater than 3.75 V, the amplifier input common-mode range is maximized by adding pull-down resistors at the device inputs. The pull-down resistors provide additional loading at the input, and lower the common-mode voltage that is fed back into the device input through resistor R_F. Figure 46 shows the circuit configuration for this mode of operation where R_{PD} is added to the dc-coupled circuit to avoid violating the V_{ICR} of the operational amplifier. Note R_S and R_{IT} are added to the alternate input from the signal input to balance the amplifier. One resistor that is equal to the combined value $R_I = R_G + R_S \parallel R_{IT}$ can be placed at the alternate input.

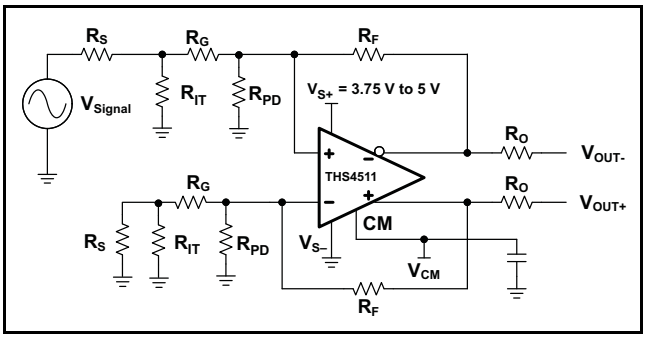

Figure 46. THS4511 DC-Coupled Single-Source Supply Range From 3.75 V to 5 V With R_{PD} Used To Set V_{IC}

Note that in Figure 46, the source is referenced to ground, as is the input termination resistor R_{IT}. The proper value of resistance to add can be calculated from Equation 3:

$$R_{PD} = \frac{1}{\frac{1}{R_F}\left[\frac{1.6}{\frac{V_{S+}}{2} - 1.6}\right] - \frac{1}{R_I}} \quad (3)$$

where $R_I = R_G + R_S \parallel R_{IT}$.

V_{S+} is the power-supply voltage, R_F is the feedback resistance, R_G is the gain-setting resistance, R_S is the signal source resistance, and R_{IT} is the termination resistance.

Table 3 is a modification of Table 1 to add the proper values with R_{PD} assuming V_{S+} = 3.75 V, a dc-coupled 50-Ω source impedance, and setting the output common-mode voltage to midsupply.

Table 3. R_{PD} Values for Various Gains, V_{S+} = 3.75 V, DC-coupled Signal Source

GAIN	R_F	R_G	R_{IT}	R_{PD}
0 dB	348 Ω	340 Ω	56.2 Ω	422 Ω
6 dB	348 Ω	169 Ω	64.9 Ω	86.6 Ω

If the signal originates from an ac-coupled 50-Ω source (see Figure 47), the equivalent dc-source resistance is an open circuit and $R_I = R_G + R_{IT}$. Table 4 is a modification of Table 1 to add the proper values with R_{PD} assuming V_{S+} = 3.75 V, an ac-coupled 50-Ω source impedance, and setting the output common-mode voltage to midsupply.

Table 4. R_{PD} Values for Various Gains, V_{S+} = 3.75 V, AC-Coupled Signal Source

GAIN	R_F	R_G	R_{IT}	R_{PD}
0 dB	348 Ω	340 Ω	56.2 Ω	390 Ω
6 dB	348 Ω	169 Ω	64.9 Ω	80.6 Ω

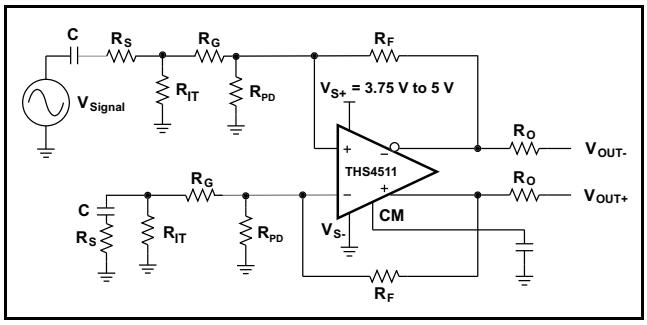

Figure 47. THS4511 AC-Coupled Single-Source Supply Range From 3.75 V to 5 V With R_{PD} Used To Set V_{IC}

Video Buffer

Figure 48 shows a possible application of the THS4508 as a dc-coupled video buffer with a gain of 2. Figure 49 shows a plot of the Y' signal originating from an HDTV 720p video system. The input signal includes a 3-level sync (minimum level at –0.3 V) and the portion of a video signal with maximum amplitude of 0.7 V. Although the buffer draws its power from a 5-V single-ended power supply, internal level shifters allow the buffer to support input signals which are as much as –0.3 V below ground. This allows maximum design flexibility while maintaining a minimum parts count. Figure 50 shows the differential output of the buffer. Note that the dc-coupled amplifier can introduce a dc offset on a signal applied at its input.

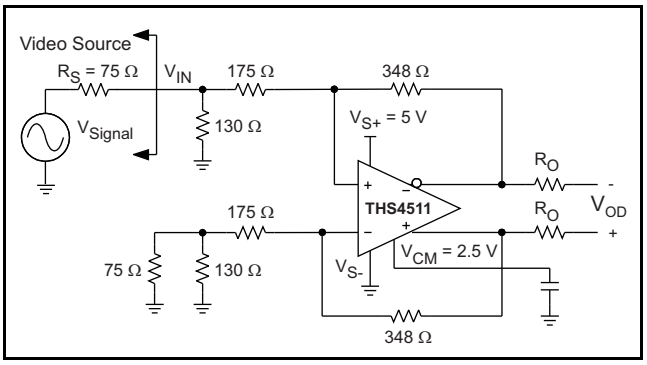

Figure 48. Single-Supply Video Buffer, Gain = 2

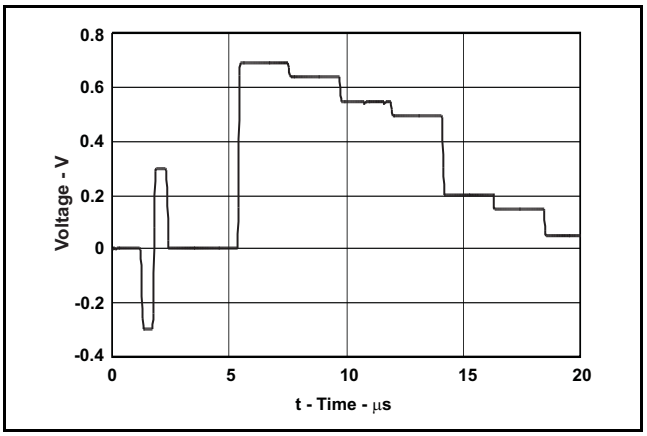

Figure 49. Y' Signal with 3-Level Sync and Video Signal

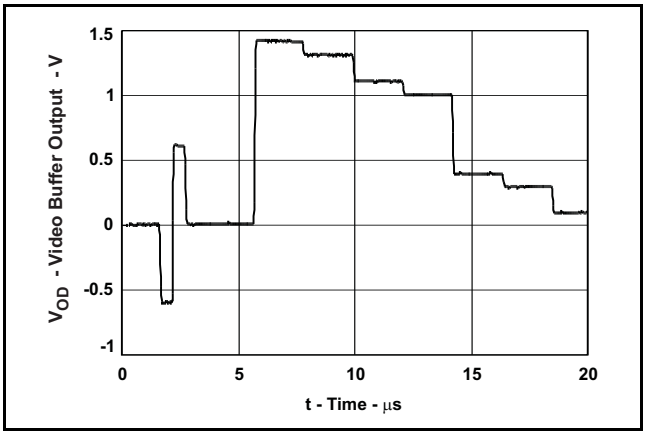

Figure 50. Video Buffer Differential Output Signal

THS4511 and ADS5500 Combined Performance

The THS4511 is designed to be a high-performance drive amplifier for high-performance data converters like the ADS5500 14-bit 125-MSPS ADC. Figure 51 shows a circuit combining the two devices. The THS4511 amplifier circuit provides 0 dB of gain, and converts the single-ended input signal to a differential output signal. The default common-mode output of the THS4511 (2.5 V) is not compatible with the required common-mode input of the ADS5500 (1.55 V), so dc-blocking capacitors are added (0.22 µF). Note that a biasing circuit (not shown in Figure 51) is needed to provide the required common-mode, dc-input for the ADS5500. The 100-Ω resistors and 2.7-pF capacitor between the THS4511 outputs and ADS5500 inputs along with the input capacitance of the ADS5500 limit the bandwidth of the signal to 115 MHz (–3 dB). For testing, a signal generator is used for the signal source. The generator is an ac-coupled 50-Ω source. A band-pass filter is inserted in series with the input to reduce harmonics and noise from the signal source. Input termination is accomplished via the 69.8-Ω resistor and 0.22-µF capacitor to ground in conjunction with the input impedance of the amplifier circuit. A 0.22-µF capacitor and 49.9-Ω resistor is inserted to ground across the 69.8-Ω resistor and 0.22-µF capacitor on the alternate input to balance the circuit. Gain is a function of the source impedance, termination, and 348-Ω feedback resistor. See Table 1 for component values to set proper 50-Ω termination for other common gains.

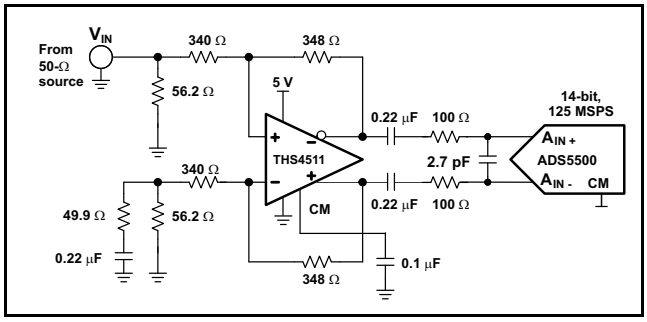

Figure 51. THS4511 and ADS5500 Circuit

THS4511 and ADS5424 Combined Performance

Figure 52 shows the THS4511 driving the ADS5424 ADC.

As before, the THS4511 amplifier provides 0 dB of gain, converts the single-ended input to differential, and sets the proper input common-mode voltage to the ADS5424. Input termination and circuit testing is the same as described above for the THS4511 and ADS5500 circuit.

The 225-Ω resistors and 2.7-pF capacitor between the THS4511 outputs and ADS5424 inputs (along with the input capacitance of the ADC) limit the bandwidth of the signal to about 100 MHz (–3 dB).

When the THS4511 is operated from a single power supply with V_{S+} = 5 V and $V_{S–}$ = ground, the 2.5-V output common-mode voltage is compatible with the recommended value of the ADS5424 input common-mode voltage (2.4 V).

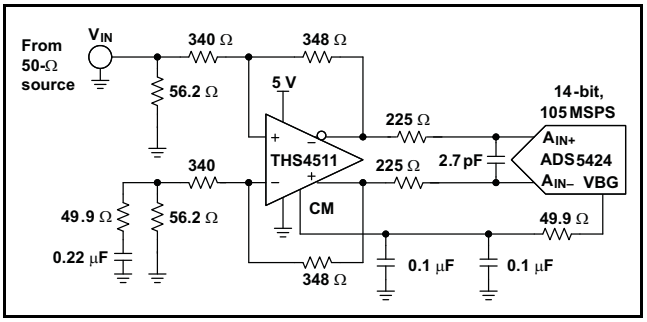

Figure 52. THS4511 and ADS5424 Circuit

Layout Recommendations

It is recommended to follow the layout of the external components near the amplifier, ground plane construction, and power routing of the EVM as closely as possible. General guidelines are:

1. Signal routing should be direct and as short as possible into and out of the operational amplifier circuit.
2. The feedback path should be short and direct; avoid vias.
3. Ground or power planes should be removed from directly under the amplifier input and output pins.
4. An output resistor is recommended on each output, as near to the output pin as possible.
5. Two 10-µF and two 0.1-µF power-supply decoupling capacitors should be placed as near to the power-supply pins as possible.
6. Two 0.1-µF capacitors should be placed between the CM input pins and ground. This configuration limits noise coupled into the pins. One each should be placed to ground near pin 4 and pin 9.
7. It is recommended to split the ground pane on layer 2 (L2) as shown below and to use a solid ground on layer 3 (L3). A single-point connection should be used between each split section on L2 and L3.
8. A single-point connection to ground on L2 is recommended for the input termination resistors R1 and R2. This configuration should be applied to the input gain resistors if termination is not used.
9. The recommended printed circuit board (PCB) footprint for the THS4511 is shown in Figure 54.

PowerPAD™ DESIGN CONSIDERATIONS

The THS4511 is available in a thermally-enhanced PowerPAD family of packages. These packages are constructed using a downset leadframe on which the die is mounted (see Figure 53a and Figure 53b). This arrangement results in the lead frame being exposed as a thermal pad on the underside of the package (see Figure 53c). Because this thermal pad has direct thermal contact with the die, excellent thermal performance can be achieved by providing a good thermal path away from the thermal pad.

Note that the THS4511 has no electrical connection between the PowerPAD and circuitry on the die. Connecting the PowerPAD to any potential voltage between V_{S+} and V_{S-} is acceptable. It is most important that it be connected for maximum heat dissipation.

The PowerPAD package allows both assembly and thermal management in one manufacturing operation.

During the surface-mount solder operation (when the leads are being soldered), the thermal pad can also be soldered to a copper area underneath the package. Through the use of thermal paths within this copper area, heat can be conducted away from the package into either a ground plane or other heat dissipating device.

The PowerPAD package represents a breakthrough in combining the small area and ease of assembly of surface-mount with the heretofore awkward mechanical methods of heatsinking.

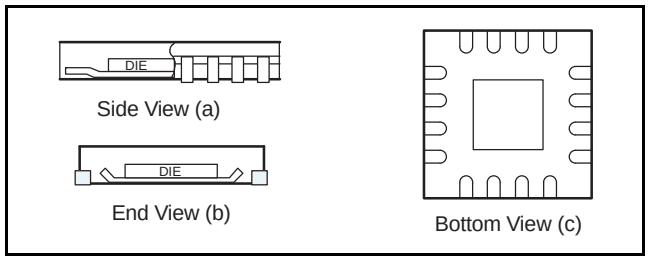

Figure 53. Views of Thermally-Enhanced Package

PowerPAD PCB LAYOUT CONSIDERATIONS

Although there are many ways to properly heatsink the PowerPAD package, the following steps illustrate the recommended approach.

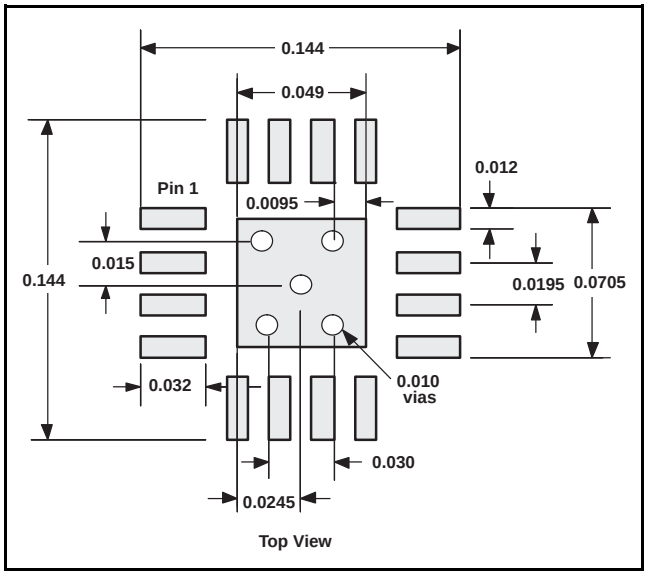

Figure 54. PowerPAD PCB Etch and Via Pattern

1. Prepare the PCB with a top side etch pattern as shown in Figure 54. There should be etch for the leads as well as etch for the thermal pad.
2. Place five holes in the area of the thermal pad. The holes should be 13 mils (0.013 in, 0.33 mm) in diameter. Keep them small so that solder wicking through the holes is not a problem during reflow.
3. Additional vias may be placed anywhere along the thermal plane outside of the thermal pad area. They help dissipate the heat generated by the IC. These additional vias may be larger than the 13-mil diameter vias directly under the thermal pad. They can be larger because they are not in the thermal pad area to be soldered, so that wicking is not a problem.
4. Connect all holes to the internal ground plane.
5. When connecting these holes to the ground plane, **do not** use the typical web or spoke via connection methodology. Web connections have a high thermal resistance connection that is useful for slowing the heat transfer during soldering operations. This resistance makes the soldering of vias that have plane connections easier. In this application, however, low thermal resistance is desired for the most efficient heat transfer. Therefore, the holes under the IC PowerPAD package should make the connection to the internal ground plane, with a complete connection around the entire circumference of the plated-through hole.
6. The top-side solder mask should leave the terminals of the package and the thermal pad area with its five holes exposed. The bottom-side solder mask should cover the five holes of the thermal pad area. This configuration prevents solder from being pulled away from the thermal pad area during the reflow process.
7. Apply solder paste to the exposed thermal pad area and all of the IC terminals.
8. With these preparatory steps in place, the IC is simply placed in position and run through the solder reflow operation as any standard surface-mount component. This process results in a part that is properly installed.

The next consideration is the package constraints. The two sources of heat within an amplifier are quiescent power and output power. The designer should never forget about the quiescent heat generated within the device, especially multi-amplifier devices. Because these devices have linear output stages (Class AB), most of the heat dissipation is at low output voltages with high output currents.

The other key factor when dealing with power dissipation is how the devices are mounted on the PCB. The PowerPAD devices are extremely useful for heat dissipation. But the device should always be soldered to a copper plane to fully use the heat dissipation properties of the PowerPAD. The SOIC package, on the other hand, is highly dependent on how it is mounted on the PCB. As more trace and copper area is placed around the device, θ_{JA} decreases and the heat dissipation capability increases. For a single package, the sum of the RMS output currents and voltages should be used to choose the proper package.

THS4511 EVM

Figure 55 is the THS4511 EVAL1 EVM schematic, layers 1 through 4 of the PCB are shown in Figure 56, and Table 5 is the bill of materials for the EVM as supplied from TI.

EVM WARNINGS AND RESTRICTIONS

It is important to operate this EVM within the input and output voltage ranges as specified in the table provided below.

INPUT RANGE, V_{S+} TO V_{S-}	**3.0 V TO 6.0 V**
Input Range, V_I	3.0 V to 6.0 V NOT TO EXCEED V_{S+} or V_{S-}
Output Range, V_O	3.0 V to 6.0 V NOT TO EXCEED V_{S+} or V_{S-}

Exceeding the specified input range may cause unexpected operation and/or irreversible damage to the EVM. If there are questions concerning the input range, please contact a TI field representative prior to connecting the input power.

Applying loads outside of the specified output range may result in unintended operation and/or possible permanent damage to the EVM. Please consult the product data sheet or EVM user's guide (if user's guide is available) prior to connecting any load to the EVM output. If there is uncertainty as to the load specification, please contact a TI field representative.

During normal operation, some circuit components may have case temperatures greater than +30°C. The EVM is designed to operate properly with certain components above +50°C as long as the input and output ranges are maintained. These components include but are not limited to linear regulators, switching transistors, pass transistors, and current sense resistors. These types of devices can be identified using the EVM schematic located in the material provided. When placing measurement probes near these devices during operation, please be aware that these devices may be very warm to the touch.

REVISION HISTORY

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision D (May 2007) to Revision E **Page**

- Updated document format to match current standards 1
- Deleted title and conditions of Typical Conditions table of graphs 6
- Added title and conditions to Typical Characteristics plots 7
- Changed item 9 in the *Layout Recommendations* section 23
- Added *PowerPAD Design Considerations* section 23
- Added *PowerPAD PCB Layout Considerations* section 24
- Moved Figure 54 and associated paragraph to *PowerPAD PCB Layout Considerations* section 24

PACKAGING INFORMATION

Orderable part number	Status (1)	Material type (2)	Package | Pins	Package qty | Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)
THS4511RGTT	Active	Production	VQFN (RGT) | 16	250 | SMALL T&R	Yes	NIPDAU	Level-2-260C-1 YEAR	-40 to 85	4511
THS4511RGTT.B	Active	Production	null (null) |	250 | SMALL T&R	-	NIPDAU	Level-2-260C-1 YEAR	See THS4511RGTT	4511

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
