

ADS7056 超低消費電力、超小型、14ビット、高速SAR ADC

1 特長

- 2.5MSPSのスループット
- 超小型SAR ADC
 - 占有面積2.25mm²のX2QFN-8パッケージ
- 広い動作範囲:
 - AVDD: 2.35V~3.6V
 - DVDD: 1.65V~3.6V (AVDDとは独立)
 - 温度範囲: -40°C~+125°C
- ユニポーラ入力範囲: 0V~AVDD
- 優れた性能:
 - 14ビットのNMC DNL、±2LSB INL
 - 2kHzで74.5dBのSINAD
 - 1MHzで73.7dBのSINAD
- 超低消費電力
 - 3.3V AVDD、2.5MSPSで3.5mW
 - 3.3V AVDD、100kSPSで158μW
- オフセット較正機能を搭載
- SPI互換のシリアル・インターフェイス: 60MHz
- JESD8-7A準拠のデジタルI/O

2 アプリケーション

- ソナー受信機
- 光ライン・カードおよびモジュール
- サーマル・イメージング
- 超音波流量計
- モータ制御
- 携帯ラジオ
- 環境センシング
- 火災および煙検出

3 概要

ADS7056 は、14ビット、2.5MSPSのアナログ/デジタル・コンバータ(ADC)です。このデバイスには、コンデンサをベースとした逐次比較型レジスタ(SAR) ADCが内蔵され、広いアナログ入力電圧範囲(2.35V~3.6Vの範囲のAVDDについて0V~AVDD)に対応しています。

SPI互換のシリアル・インターフェイスは、 \overline{CS} およびSCLK信号により制御されます。入力信号は \overline{CS} の立ち下がりエッジでサンプリングされ、変換とシリアル・データ出力にはSCLKが使用されます。このデバイスは広いデジタル電源範囲(1.65V~3.6V)に対応し、各種のホスト・コントローラと直接接続可能です。ADS7056は、通常のDVDD範囲(1.65V~1.95V)について、JESD8-7Aに準拠しています。

ADS7056は、8ピンのミニチュアX2QFNパッケージで供給され、拡張産業用温度範囲(-40°C~+125°C)で動作が規定されています。小型のフォーム・ファクタと非常に低い消費電力から、スペースに制限のあるアプリケーションやバッテリー駆動のアプリケーションに適しています。

製品情報⁽¹⁾

型番	パッケージ	本体サイズ(typ)
ADS7056	X2QFN (8)	1.50mm×1.50mm

(1) 利用可能なすべてのパッケージについては、このデータシートの末尾にある注文情報を参照してください。

標準アプリケーション

NOTE: ADS7056は、0805 (2012 metric) SMDコンポーネントよりも小型です。

5 Pin Configuration and Functions

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
AINM	8	Analog input	Analog signal input, negative
AINP	7	Analog input	Analog signal input, positive
AVDD	6	Supply	Analog power-supply input, also provides the reference voltage to the ADC
$\overline{\text{CS}}$	1	Digital input	Chip-select signal, active low
DVDD	4	Supply	Digital I/O supply voltage
GND	5	Supply	Ground for power supply, all analog and digital signals are referred to this pin
SCLK	3	Digital input	Serial clock
SDO	2	Digital output	Serial data out

6 Specifications

6.1 Absolute Maximum Ratings⁽¹⁾

	MIN	MAX	UNIT
AVDD to GND	−0.3	3.9	V
DVDD to GND	−0.3	3.9	V
AINP to GND	−0.3	AVDD + 0.3	V
AINM to GND	−0.3	0.3	V
Input current to any pin except supply pins	−10	10	mA
Digital input voltage to GND	−0.3	DVDD + 0.3	V
Storage temperature, T _{stg}	−60	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±1000	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
 (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
AVDD	Analog supply voltage range	2.35	3	3.6	V
DVDD	Digital supply voltage range	1.65	1.8	3.6	V
T _A	Operating free-air temperature	–40	25	125	°C

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		ADS7056	UNIT
		RUG (X2QFN)	
		8 PINS	
R _{θJA}	Junction-to-ambient thermal resistance	177.5	°C/W

7 Parameter Measurement Information

7.1 Digital Voltage Levels

The device complies with the JESD8-7A standard for DVDD from 1.65 V to 1.95 V. [Figure 35](#) shows voltage levels for the digital input and output pins.

Figure 35. Digital Voltage Levels as per the JESD8-7A Standard

8 Detailed Description

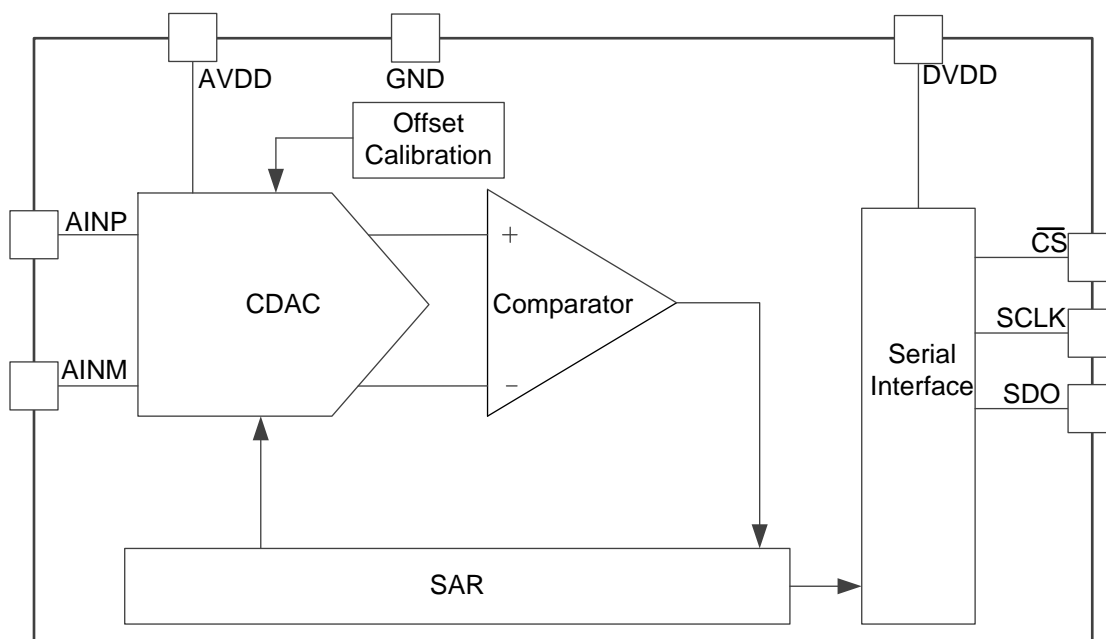

8.1 Overview

The ADS7056 is a 14-bit, 2.5-MSPS, analog-to-digital converter (ADC). The device includes a capacitor-based, successive-approximation register (SAR) ADC that supports a wide analog input voltage range (0 V to AVDD, for AVDD in the range of 2.35 V to 3.6 V). The device uses the AVDD supply voltage as the reference voltage for conversion of analog input to digital output and the AVDD supply voltage also powers the analog blocks of the device. The device has integrated offset calibration feature to calibrate its own offset; see the [OFFCAL State](#) section for details.

The SPI-compatible serial interface is controlled by the \overline{CS} and SCLK signals. The input signal is sampled with the \overline{CS} falling edge and SCLK is used for conversion and serial data output. The device supports a wide digital supply range (1.65 V to 3.6 V), enabling direct interface to a variety of host controllers. The ADS7056 complies with the JESD8-7A standard for a normal DVDD range (1.65 V to 1.95 V); see the [Digital Voltage Levels](#) section for details.

The ADS7056 is available in 8-pin, miniature, X2QFN package and is specified over extended industrial temperature range (–40°C to 125°C). Miniature form-factor and extremely low-power consumption make this device suitable for space-constrained, battery-powered applications.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Analog Input

The device supports a unipolar, single-ended analog input signal. Figure 36 shows a small-signal equivalent circuit of the sample-and-hold circuit. The sampling switch is represented by a resistance (R_{S1} and R_{S2} , typically $50\ \Omega$) in series with an ideal switch (SW_1 and SW_2). The sampling capacitors, C_{S1} and C_{S2} , are typically $16\ \text{pF}$.

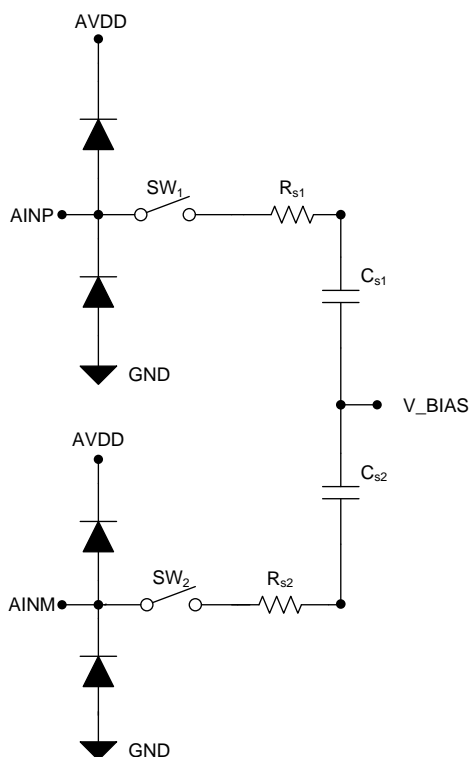

Figure 36. Equivalent Input Circuit for the Sampling Stage

During the acquisition process, both positive and negative inputs are individually sampled on C_{S1} and C_{S2} , respectively. During the conversion process, the device converts for the voltage difference between the two sampled values: $V_{AINP} - V_{AINM}$.

Each analog input pin has electrostatic discharge (ESD) protection diodes to AVDD and GND. Keep the analog inputs within the specified range to avoid turning the diodes on.

The full-scale analog input range (FSR) is 0 V to AVDD and the absolute input range on the AINM and AINP pins is $-0.1\ \text{V}$ to $\text{AVDD} + 0.1\ \text{V}$.

Feature Description (continued)

8.3.2 Reference

The device uses the analog supply voltage (AVDD) as the reference voltage for the analog-to-digital conversion. During the conversion process, the internal capacitors are switched to the AVDD pin as per the successive approximation algorithm. As shown in [Figure 37](#), a 3.3- μF (C_{AVDD}), low equivalent series resistance (ESR) ceramic capacitor is recommended to be placed between the AVDD and GND pins. The decoupling capacitor provides the instantaneous charge required by the internal circuit during the conversion process and maintains a stable dc voltage on the AVDD pin.

See the [Power Supply Recommendations](#) and [Layout Example](#) sections for component recommendations and layout guidelines.

Figure 37. Reference for the Device

Feature Description (continued)

8.3.3 ADC Transfer Function

The device supports a unipolar, single-ended analog input signal. The output is in straight binary format. Figure 38 and Table 1 show the ideal transfer characteristics for the device.

The least significant bit for the device is given by:

$$1 \text{ LSB} = V_{\text{REF}} / 2^N$$

where:

- V_{REF} = Voltage applied between the AVDD and GND pins and
- $N = 14$

(1)

Figure 38. Ideal Transfer Characteristics

Table 1. Transfer Characteristics

INPUT VOLTAGE (AINP – AINM)	CODE	DESCRIPTION	IDEAL OUTPUT CODE (Hex)
$\leq 1 \text{ LSB}$	NFSC	Negative full-scale code	0000
1 LSB to 2 LSBs	NFSC + 1	—	0001
$V_{\text{REF}} / 2$ to $V_{\text{REF}} / 2 + 1 \text{ LSB}$	MC	Mid code	1FFF
$V_{\text{REF}} / 2 + 1 \text{ LSB}$ to $V_{\text{REF}} / 2 + 2 \text{ LSBs}$	MC + 1	—	2000
$\geq V_{\text{REF}} - 1 \text{ LSB}$	PFSC	Positive full-scale code	3FFF

8.4 Device Functional Modes

The device supports a simple, SPI-compatible interface to the external host. On power-up, the device is in ACQ state. The \overline{CS} signal defines one conversion and serial data transfer frame. A frame starts with a \overline{CS} falling edge and ends with a \overline{CS} rising edge. The SDO pin is tri-stated when \overline{CS} is high. With \overline{CS} low, the clock provided on the SCLK pin is used for conversion and data transfer and the output data are available on the SDO pin.

As shown in Figure 39, the device supports three functional states: acquisition (ACQ), conversion (CNV), and offset calibration (OFFCAL). The device status depends on the \overline{CS} and SCLK signals provided by the host controller.

Figure 39. Functional State Diagram

8.4.1 ACQ State

In ACQ state, switches SW_1 and SW_2 connected to the analog input pins close and the device acquires the analog input signal on C_{S1} and C_{S2} . The device enters ACQ state at power-up, at the end of every conversion, and after completing the offset calibration. A \overline{CS} falling edge takes the device from ACQ state to CNV state.

The device consumes extremely low power from the AVDD and DVDD power supplies when in ACQ state.

Device Functional Modes (continued)

8.4.2 CNV State

In the CNV state, the device uses the external clock to convert the sampled analog input signal to an equivalent digital code as per the transfer function illustrated in [Figure 38](#). The conversion process requires a minimum of 18 SCLK falling edges to be provided within the frame. After the end of conversion process, the device automatically moves from CNV state to ACQ state. For acquisition of the next sample, a minimum time of t_{ACQ} must be provided.

[Figure 40](#) shows a detailed timing diagram for the serial interface. In the first serial transfer frame after power-up, the device provides the first data as all zeros. In any frame, the clocks provided on the SCLK pin are also used to transfer the output data for the previous conversion. A leading 0 is output on the SDO pin on the \overline{CS} falling edge. The most significant bit (MSB) of the output data is launched on the SDO pin on the rising edge after the first SCLK falling edge. Subsequent output bits are launched on the subsequent rising edges provided on SCLK. When all 14 output bits are shifted out, the device outputs 0's on the subsequent SCLK rising edges. The device enters ACQ state after 18 clocks and a minimum time of t_{ACQ} must be provided for acquiring the next sample. If the device is provided with less than 18 SCLK falling edges in the present serial transfer frame, the device provides an invalid conversion result in the next serial transfer frame.

Figure 40. Serial Interface Timing Diagram

8.4.3 OFFCAL State

In OFFCAL state, the device calibrates and corrects for its internal offset errors. In OFFCAL state, the sampling capacitors are disconnected from the analog input pins (AINP and AINM). The offset calibration is effective for all subsequent conversions until the device is powered off. An offset calibration cycle is recommended at power-up and whenever there is a significant change in the operating conditions for the device (such as in the AVDD voltage and operating temperature).

The host controller must provide a serial transfer frame as described in [Figure 41](#) or in [Figure 42](#) to enter OFFCAL state.

Device Functional Modes (continued)

8.4.3.1 Offset Calibration on Power-Up

On power-up, the host must provide 24 SCLKs in the first serial transfer to enter the OFFCAL state. The device provides 0's on SDO during offset calibration. For acquisition of the next sample, a minimum time of t_{ACQ} must be provided. If the host controller enters the OFFCAL state, but pulls the CS pin high before providing 24 SCLKs, then the offset calibration process is aborted and the device enters the ACQ state. Figure 41 and Table 2 provide the timing for offset calibration on power-up.

Figure 41. Timing for Offset Calibration on Power-Up

Table 2. Timing Specifications for Offset Calibration on Power-Up⁽¹⁾

		MIN	TYP	MAX	UNIT
t_{cycle}	Cycle time for offset calibration on power-up	$24 \times t_{CLK} + t_{ACQ}$			ns
t_{ACQ}	Acquisition time	95			ns
f_{SCLK}	Frequency of SCLK	60			MHz

(1) In addition to the timing specifications of Figure 41 and Table 2, the timing specifications described in Figure 2 and the [Timing Requirements](#) table are also applicable for offset calibration on power-up.

8.4.3.2 Offset Calibration During Normal Operation

During normal operation, the host must provide 64 SCLKs in the serial transfer frame to enter the OFFCAL state. The device provides the conversion result for the previous sample during the first 18 SCLKs and 0's on SDO for the rest of the SCLKs in the serial transfer frame. For acquisition of the next sample, a minimum time of t_{ACQ} must be provided. If the host controller enters the OFFCAL state, but pulls the \overline{CS} high before providing 64 SCLKs, then the offset calibration process is aborted and the device enters ACQ state. [Figure 42](#) and [Table 3](#) provide the timing for offset calibration during normal operation.

Figure 42. Timing for Offset Calibration During Normal Operation

Table 3. Timing Specifications for Offset Calibration During Normal Operation⁽¹⁾

		MIN	TYP	MAX	UNIT
t_{cycle}	Cycle time for offset calibration on power-up	$64 \times t_{CLK} + t_{ACQ}$			ns
t_{ACQ}	Acquisition time	95			ns
f_{SCLK}	Frequency of SCLK	60			MHz

- (1) In addition to the timing specifications of [Figure 42](#) and [Table 3](#), the timing specifications described in [Figure 2](#) and the [Timing Requirements](#) table are also applicable for offset calibration during normal operation.

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The two primary circuits required to maximize the performance of a high-precision, successive approximation register (SAR) analog-to-digital converter (ADC) are the input driver and the reference driver circuits. This section details some general principles for designing the input driver circuit, reference driver circuit, and provides typical application circuits designed for the device.

9.2 Typical Applications

9.2.1 Single-Supply Data Acquisition With the ADS7056

Figure 43. DAQ Circuit: Single-Supply DAQ

9.2.1.1 Design Requirements

The goal of the circuit shown in Figure 43 is to design a single-supply data acquisition (DAQ) circuit based on the ADS7056 with SNR greater than 74 dB and THD less than -85 dB for input frequencies of 2 kHz to 100 kHz at a throughput of 2.5 MSPS for applications such as sonar receivers and ultrasonic flow meters.

9.2.1.2 Detailed Design Procedure

The input driver circuit for a high-precision ADC mainly consists of two parts: a driving amplifier and charge kickback filter. Careful design of the front-end circuit is critical to meet the linearity and noise performance of a high-precision ADC.

Typical Applications (continued)

9.2.1.2.1 Low Distortion Charge Kickback Filter Design

Figure 44 shows the input circuit of a typical SAR ADC. During the acquisition phase, the SW switch closes and connects the sampling capacitor (C_{SH}) to the input driver circuit. This action introduces a transient on the input pins of the SAR ADC. An ideal amplifier with $0\ \Omega$ of output impedance and infinite current drive can settle this transient in zero time. For a real amplifier with non-zero output impedance and finite drive strength, this switched capacitor load can create stability issues.

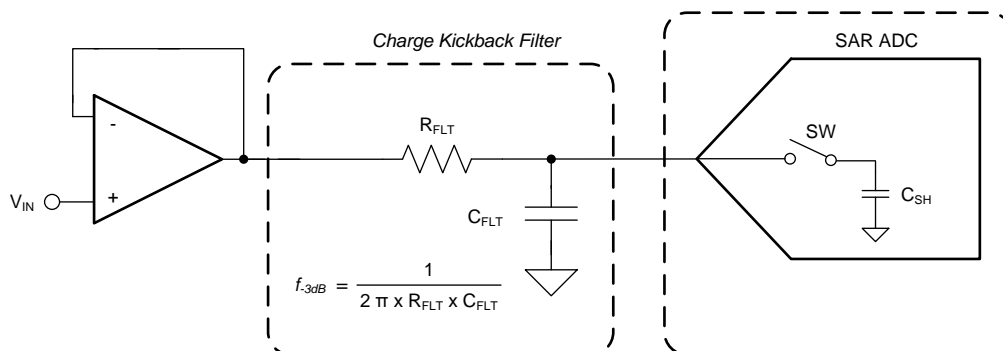

Figure 44. Input Sample-and-Hold Circuit for a Typical SAR ADC

For ac signals, the filter bandwidth must be kept low to band-limit the noise fed into the ADC input, thereby increasing the signal-to-noise ratio (SNR) of the system. Besides filtering the noise from the front-end drive circuitry, the RC filter also helps attenuate the sampling charge injection from the switched-capacitor input stage of the ADC. A filter capacitor, C_{FLT} , is connected across the ADC inputs. This capacitor helps reduce the sampling charge injection and provides a charge bucket to quickly charge the internal sample-and-hold capacitors during the acquisition process. As a rule of thumb, the value of this capacitor is at least 20 times the specified value of the ADC sampling capacitance. For this device, the input sampling capacitance is equal to 16 pF. Thus, the value of C_{FLT} is greater than 320 pF. Select a COG- or NPO-type capacitor because these capacitor types have a high-Q, low-temperature coefficient, and stable electrical characteristics under varying voltages, frequency, and time.

Driving capacitive loads can degrade the phase margin of the input amplifiers, thus making the amplifier marginally unstable. To avoid amplifier stability issues, series isolation resistors (R_{FLT}) are used at the output of the amplifiers. A higher value of R_{FLT} is helpful from the amplifier stability perspective, but adds distortion as a result of interactions with the nonlinear input impedance of the ADC. Distortion increases with source impedance, input signal frequency, and input signal amplitude. Therefore, the selection of R_{FLT} requires balancing the stability and distortion of the design.

Typical Applications (continued)

9.2.1.2.2 Input Amplifier Selection

Selection criteria for the input amplifiers is highly dependent on the input signal type as well as the performance goals of the data acquisition system. Some key amplifier specifications to consider when selecting an appropriate amplifier to drive the inputs of the ADC are:

- Small-signal bandwidth: select the small-signal bandwidth of the input amplifiers to be as high as possible after meeting the power budget of the system. Higher bandwidth reduces the closed-loop output impedance of the amplifier, thus allowing the amplifier to more easily drive the low cutoff frequency RC filter (see the [Low Distortion Charge Kickback Filter Design](#) section for details.) at the inputs of the ADC. Higher bandwidth also minimizes the harmonic distortion at higher input frequencies. Select the amplifier with the unity-gain bandwidth (UGB) as described in [Equation 2](#) to maintain the overall stability of the input driver circuit.

$$UGB \geq 4 \times \frac{1}{2\pi \times R_{FLT} \times C_{FLT}}$$

where:

- UGB = unity-gain bandwidth (2)
- Noise: noise contribution of the front-end amplifiers must be as low as possible to prevent any degradation in SNR performance of the system. Generally, to ensure that the noise performance of the data acquisition system is not limited by the front-end circuit, the total noise contribution from the front-end circuit must be kept below 20% of the input-referred noise of the ADC. As [Equation 3](#) explains, noise from the input driver circuit is band limited by designing a low cutoff frequency RC filter.

$$N_G \times \sqrt{\left(\frac{V_{1/f_AMP_PP}}{6.6}\right)^2 + e_{n_RMS}^2 \times \frac{\pi}{2} \times f_{-3dB}} \leq \frac{1}{5} \times \frac{V_{REF}}{2\sqrt{2}} \times 10^{-\left(\frac{SNR(dB)}{20}\right)}$$

where:

- V_{1/f_AMP_PP} is the peak-to-peak flicker noise in $\mu VRMS$
- e_{n_RMS} is the amplifier broadband noise
- f_{-3dB} is the -3 -dB bandwidth of the RC filter and
- N_G is the noise gain of the front-end circuit, which is equal to 1 in the buffer configuration (3)
- Distortion: both the ADC and the input driver introduce distortion in a data acquisition block. To ensure that the distortion performance of the data acquisition system is not limited by the front-end circuit, the distortion of the input driver must be at least 10 dB lower than the distortion of the ADC.

For the application circuit of [Figure 43](#), the [OPA836](#) is selected for its high bandwidth (205 MHz), low noise (4.6 nV/ \sqrt{Hz}), high output drive capacity (45 mA), and fast settling response (22 ns for 0.1% settling).

9.2.1.2.3 Reference Circuit

The analog supply voltage of the device is also used as a voltage reference for conversion. Decouple the AVDD pin with a 3.3- μF , low-ESR ceramic capacitor.

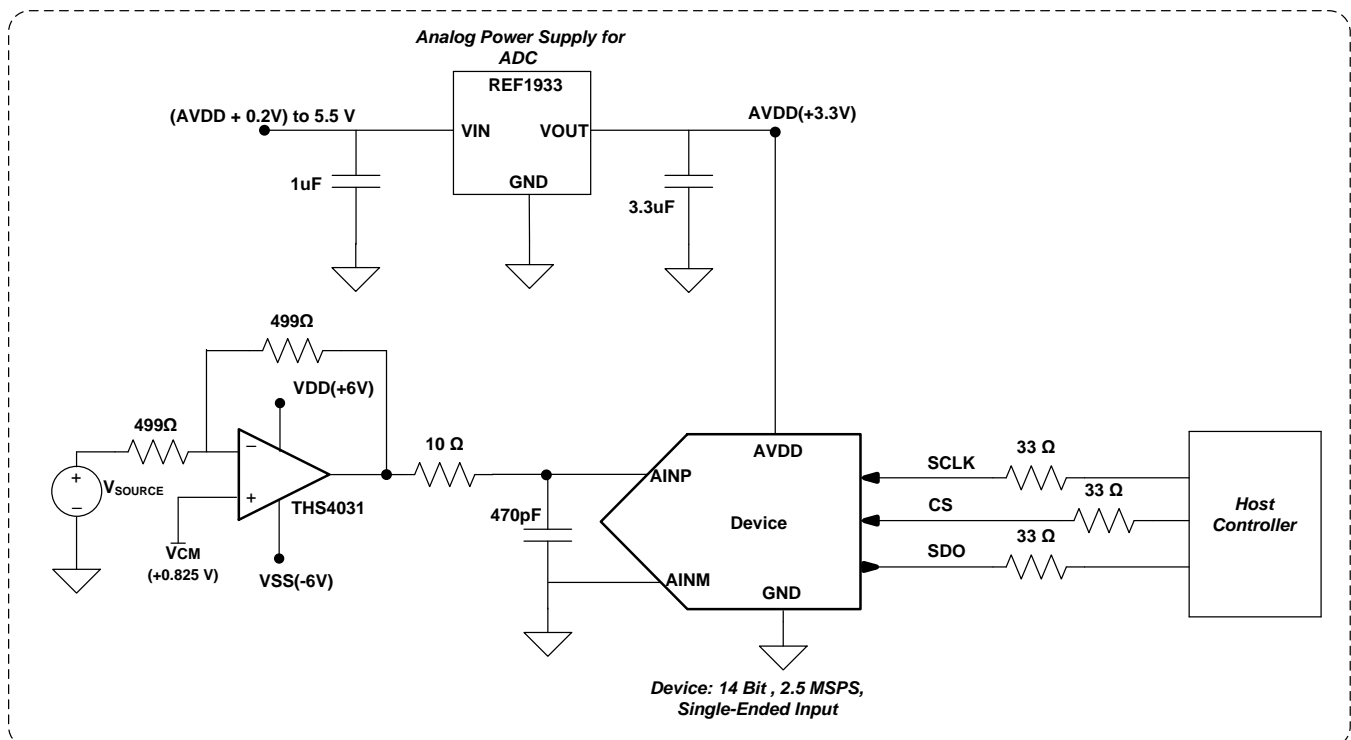

Typical Applications (continued)

9.2.1.3 Application Curves

Figure 45 and Figure 46 provide the measurement results for the circuit described in Figure 43.

9.2.2 High Bandwidth (1 MHz) Data Acquisition With the ADS7056

Typical Applications (continued)

9.2.2.1 Design Requirements

Applications such as ultrasonic flow meters, global positioning systems (GPS), handheld radios, and motor controls need analog-to-digital converters that are interfaced to high-frequency sensors (200 kHz to 1 MHz). The goal of the circuit described in [Figure 47](#) is to design a single-supply digital acquisition (DAQ) circuit based on the ADS7056 with SNR greater than 73 dB and THD less than –85 dB for input frequencies of 200 kHz to 1 MHz at a throughput of 2.5 MSPS.

9.2.2.2 Detailed Design Procedure

To achieve a SINAD greater than 73 dB, the operational amplifier must have high bandwidth in order to settle the input signal within the acquisition time of the ADC. The operational amplifier must have low noise to keep the total system noise below 20% of the input-referred noise of the ADC. For the application circuit shown in [Figure 47](#), the [THS4031](#) is selected for its high bandwidth (275 MHz), low total harmonic distortion of –90 dB at 1 MHz, and ultra-low noise of 1.6 nV/ $\sqrt{\text{Hz}}$. The THS4031 is powered up from dual power supply (VDD = 6 V and VSS = –6 V).

For chip-select signals, high-frequency system SNR performance is highly dependent on jitter. Thus, selecting a clock source with very low jitter (< 20-ps RMS) is recommended.

9.2.2.3 Application Curves

[Figure 48](#) shows the FFT plot for the ADS7056 with a 500-kHz input frequency used for the circuit in [Figure 47](#). [Figure 49](#) shows the FFT plot for the ADS7056 with a 1000-kHz input frequency used for the circuit in [Figure 47](#).

Typical Applications (continued)

9.2.3 14-Bit, 10-kSPS DAQ Circuit Optimized for DC Sensor Measurements

Figure 50. Interfacing the Device Directly With Sensors

In applications such as environmental sensors, gas detectors, and smoke or fire detectors where the input is very slow moving and the sensor can be connected directly to the device operating at a lower throughput rate, a DAQ circuit can be designed without the input driver for the ADC. This type of a use case is of particular interest for applications in which the primary goal is to achieve the absolute lowest power, size, and cost. Typical applications that fall into this category are low-power sensor applications (such as temperature, pressure, humidity, gas, and chemical).

9.2.3.1 Design Requirements

For this design example, use the parameters listed in [Table 4](#) as the input parameters.

Table 4. Design Parameters

DESIGN PARAMETER	GOAL VALUE
Throughput	10 kSPS
SNR at 100 Hz	74 dB
THD at 100 Hz	–85 dB
SINAD at 100 Hz	73 dB
ENOB	12 bits
Power	20 μ W

9.2.3.2 Detailed Design Procedure

The ADS7056 can be directly interfaced with sensors at lower throughput without the need of an amplifier buffer. The analog input source drive must be capable of driving the switched capacitor load of a SAR ADC and settling the analog input signal within the acquisition time of the SAR ADC. However, the output impedance of the sensor must be taken into account when interfacing a SAR ADC directly with sensors. Drive the analog input of the SAR ADC with a low impedance source. The input signal requires more acquisition time to settle to the desired accuracy because of the higher output impedance of the sensor. [Figure 50](#) shows the simplified circuit for a sensor as a voltage source with output impedance (R_{source}).

The acquisition time of a SAR ADC (such as the ADS7056) can be increased by reducing throughput in the following ways:

1. Reducing the SCLK frequency to reduce the throughput, or
2. Keeping the SCLK fixed at the highest permissible value (that is, 60 MHz for the device) and increasing the CS high time.

Table 5 lists the acquisition time for the above two cases for a throughput of 10 kSPS. Clearly, case 2 provides more acquisition time for the input signal to settle.

Table 5. Acquisition Time with Different SCLK Frequencies

CASE	SCLK	t_{cycle}	CONVERSION TIME (= $18 \times t_{\text{SCLK}}$)	ACQUISITION TIME (= $t_{\text{cycle}} - t_{\text{conv}}$)
1	0.24 MHz	100 μs	75 μs	25 μs
2	60 MHz	100 μs	0.3 μs	99.7 μs

9.2.3.3 Application Curve

When the output impedance of the sensor increases, the time required for the input signal to settle increases and the performance of the SAR ADC starts degrading if the input signal does not settle within the acquisition time of the ADC. The performance of the SAR ADC can be improved by reducing the throughput to provide enough time for the input signal to settle. Figure 51 provides the results for ENOB achieved from the ADS7056 for case 2 at different throughputs with different input impedances at the device input.

Figure 51. Effective Number of Bits (ENOB) Achieved From the ADS7056 at Different Throughputs

Table 6 shows the results and performance summary for this 14-bit, 10-kSPS DAQ circuit application.

Table 6. Results and Performance Summary for a 14-Bit, 10-kSPS DAQ Circuit for DC Sensor Measurements

DESIGN PARAMETER	GOAL VALUE	ACHIEVED RESULT
Throughput	10 kSPS	10 kSPS
SNR at 100 Hz	74 dB	75 dB
THD at 100 Hz	-85 dB	-89 dB
SINAD at 100 Hz	73 dB	74.3 dB
ENOB	12	12.05
Power	20 μW	17 μW

10 Power Supply Recommendations

10.1 AVDD and DVDD Supply Recommendations

The device has two separate power supplies: AVDD and DVDD. AVDD powers the analog blocks and is also used as the reference voltage for the analog-to-digital conversion. Always set the AVDD supply to be greater than or equal to the maximum input signal to avoid saturation of codes. Decouple the AVDD pin to the GND pin with a 3.3-μF ceramic decoupling capacitor.

DVDD is used for the interface circuits. Decouple the DVDD pin to the GND pin with a 1-μF ceramic decoupling capacitor. [Figure 52](#) shows the decoupling recommendations.

Figure 52. Power-Supply Decoupling

10.2 Optimizing Power Consumed by the Device

- Keep the analog supply voltage (AVDD) in the specified operating range and equal to the maximum analog input voltage.
- Keep the digital supply voltage (DVDD) in the specified operating range and at the lowest value supported by the host controller.
- Reduce the load capacitance on the SDO output.
- Run the device at the optimum throughput. Power consumption reduces proportionally with the throughput.

10.2.1 Estimating Digital Power Consumption

The current consumption from the DVDD supply depends on the DVDD voltage, the load capacitance on the SDO pin ($C_{\text{LOAD-SDO}}$), and the output code, and can be calculated as:

$$I_{\text{DVDD}} = C_{\text{LOAD-SDO}} \times V \times f$$

where:

- $C_{\text{LOAD-SDO}}$ = Load capacitance on the SDO pin
- V = DVDD supply voltage
- f = frequency of transitions on the SDO output

(4)

The number of transitions on the SDO output depends on the output code, and thus changes with the analog input. The maximum value of f occurs when data output on the SDO change on every SCLK (that is, for output codes of 2AAAh or 1555h). With an output code of 2AAAh, $f = 17.5$ MHz and when $C_{\text{LOAD-SDO}} = 20$ pF and DVDD = 1.8 V, $I_{\text{DVDD}} = 630$ μA.

11 Layout

11.1 Layout Guidelines

Figure 53 shows a board layout example for the device. The key considerations for layout are:

- Use a solid ground plane underneath the device and partition the PCB into analog and digital sections.
- Avoid crossing digital lines with the analog signal path and keep the analog input signals and the reference input signals away from noise sources.
- The power sources to the device must be clean and well-bypassed. Use C_{AVDD} decoupling capacitors in close proximity to the analog (AVDD) power supply pin.
- Use a C_{DVDD} decoupling capacitor close to the digital (DVDD) power-supply pin.
- Avoid placing vias between the AVDD and DVDD pins and the bypass capacitors.
- Connect the ground pin to the ground plane using a short, low-impedance path.
- Place the charge kickback filter components close to the device.

Among ceramic surface-mount capacitors, COG (NPO) ceramic capacitors are recommended because these components provide the most stable electrical properties over voltage, frequency, and temperature changes.

PACKAGING INFORMATION

Orderable part number	Status (1)	Material type (2)	Package Pins	Package qty Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)
ADS7056IRUGR	Active	Production	X2QFN (RUG) 8	3000 LARGE T&R	Yes	NIPDAUAG	Level-1-260C-UNLIM	-40 to 125	5I
ADS7056IRUGR.A	Active	Production	X2QFN (RUG) 8	3000 LARGE T&R	Yes	NIPDAUAG	Level-1-260C-UNLIM	-40 to 125	5I

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
