

DACx3401 10 ビットおよび 8 ビット、電圧出力デジタル/アナログ・コンバータ、小型 2 × 2 WSON に不揮発性メモリと PMBus™ 互換 I²C インターフェイスを統合

1 特長

- 1 LSB の INL と DNL (10 ビットおよび 8 ビット)
- 幅広い動作範囲
 - 電源: 1.8V~5.5V
 - 温度範囲: -40°C~+125°C
- PMBus™ 互換の I²C インターフェイス
 - Standard、Fast、Fast+ モード
 - デジタル・スルーレート制御
 - V_{IH}: 1.62V (V_{DD} = 5.5V の場合)
- ユーザーがプログラム可能な不揮発性メモリ (NVM/EEPROM)
 - すべてのレジスタ設定の保存と復元
- プログラム可能な波形生成: 方形波、三角波、のこぎり波
- 医療用アラーム音生成をプログラム済み: 低、中、高優先度のアラーム
- 内部基準電圧
- 非常に低い消費電力: 1.8V で 0.2 mA
- 柔軟な起動方法: ハイ・インピーダンスまたは 10K-GND
- 小型パッケージ: 8 ピン WSON (2mm × 2mm)

2 アプリケーション

- ラック・サーバー
- 出口案内や非常時用の照明
- 車載 USB 充電
- バーコード・スキャナ
- アクティブ・アンテナ・システム (AAS) の mMIMO
- CPU (PLC コントローラ)

3 概要

10 ビットの DAC53401 と 8 ビットの DAC43401 (DACx3401) は、バッファ付き電圧出力デジタル/アナログ・コンバータ (DAC) のピン互換ファミリです。これらのデバイスは消費電力が非常に小さく、小型の 8 ピン WSON パッケージで供給されます。DACx3401 は、その機能セット、小型パッケージ、低消費電力から、LED 用および汎用バイアス・ポイント生成、電源制御、PWM 信号生成、医療用アラーム音生成などのアプリケーションに最適です。

これらのデバイスは不揮発性メモリ (NVM)、内部基準電圧、PMBus 互換の I²C インターフェイスを備えています。DACx3401 は内部基準電圧と電源のどちらかを基準電圧として動作し、1.8V~5.5V のフルスケール信号を出力します。また、I²C インターフェイスで通信を行います。これらのデバイスは、I²C の Standard モード、Fast モード、Fast+ モードをサポートしています。

DACx3401 は PMBus 電圧マージン・コマンド、ユーザー・プログラマブルな起動方法 (出力をハイ・インピーダンスにして起動可能)、スタンドアロンの波形ジェネレータ、医療用アラーム音ジェネレータ、専用フィードバック・ピンなどの豊富な機能を備えています。

DACx3401 は -40°C~+125°C の温度範囲で動作します。

製品情報⁽¹⁾

型番	パッケージ	本体サイズ(公称)
DAC53401	WSON (8)	2.00mm×2.00mm
DAC43401		

(1) 利用可能なすべてのパッケージについては、このデータシートの末尾にあるパッケージ・オプション情報を参照してください。

5 Device Comparison Table

DEVICE	RESOLUTION
DAC53401	10-bit
DAC43401	8-bit

6 Pin Configuration and Functions

Pin Functions

PIN		TYPE	DESCRIPTION
NAME	NO.		
A0	1	Input	Four-state address input
AGND	5	Ground	Ground reference point for all circuitry on the device
CAP	4	Input	External capacitor for the internal LDO. Connect a capacitor (0.5 μ F to 15 μ F) between CAP and AGND.
FB	7	Input	Voltage feedback pin
OUT	8	Output	Analog output voltage from DAC
SCL	2	Input	Serial interface clock. This pin must be connected to the supply voltage with an external pullup resistor.
SDA	3	Input/output	Data are clocked into or out of the input register. This pin is a bidirectional, and must be connected to the supply voltage with an external pullup resistor.
VDD	6	Power	Analog supply voltage: 1.8 V to 5.5 V

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
V _{DD}	Supply voltage, V _{DD} to A _{GND}	-0.3	6	V
	Digital input(s) to A _{GND}	-0.3	V _{DD} + 0.3	V
	CAP to A _{GND}	-0.3	1.65	V
	V _{FB} to A _{GND}	-0.3	V _{DD} + 0.3	
	V _{OUT} to A _{GND}	-0.3	V _{DD} + 0.3	
	Current into any pin	-10	10	mA
T _J	Junction temperature	-40	150	°C
T _{stg}	Storage temperature	-65	150	

- (1) Stresses beyond those listed under *Absolute Maximum Rating* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Condition*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins ⁽¹⁾	±2000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101, pins 1, 4, 5, 8 ⁽²⁾	±750	
		Charged device model (CDM), per JEDEC specification JESD22-C101, pins 2, 3, 6, 7 ⁽²⁾	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _{DD}	Positive supply voltage to ground (A _{GND})	1.71		5.5	V
V _{IH}	Digital input high voltage, 1.7 V < V _{DD} ≤ 5.5 V	1.62			V
V _{IL}	Digital input low voltage			0.4	V
T _A	Ambient temperature	-40		125	°C

7.4 Thermal Information

THERMAL METRIC ⁽¹⁾		DACx3401	UNIT
		DSG (WSON)	
		8 PINS	
R _{θJA}	Junction-to-ambient thermal resistance	49	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	50	°C/W
R _{θJB}	Junction-to-board thermal resistance	24.1	°C/W
Ψ _{JT}	Junction-to-top characterization parameter	1.1	°C/W
Ψ _{JB}	Junction-to-board characterization parameter	24.1	°C/W
R _{θJC(bot)}	Junction-to-case (bottom) thermal resistance	8.7	°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics application report](#).

7.5 Electrical Characteristics

all minimum/maximum specifications at $T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$ and typical specifications at $T_A = 25^\circ\text{C}$, $1.8\text{ V} \leq V_{DD} \leq 5.5\text{ V}$, DAC reference tied to VDD, gain = 1x, DAC output pin (OUT) loaded with resistive load ($R_L = 5\text{ k}\Omega$ to AGND) and capacitive load ($C_L = 200\text{ pF}$ to AGND), and digital inputs at VDD or AGND (unless otherwise noted)

8 Detailed Description

8.1 Overview

The 10-bit DAC53401 and 8-bit DAC43401 (DACx3401) are a pin-compatible family of buffered voltage-output, digital-to-analog converters (DACs). These DACs contain nonvolatile memory (NVM), an internal reference, and a PMBus-compatible I²C interface. The DACx3401 operate with either an internal reference or with a power supply as the reference, and provide a full-scale output of 1.8 V to 5.5 V.

The devices communicate through an I²C interface. These devices support I²C standard mode (100 kbps), fast mode (400 kbps), and fast+ mode (1 Mbps). These devices also support specific PMBus commands such as *turn on/off*, *margin high/low*, and more. The DACx3401 also include digital slew rate control, and support basic signal generation such as *square*, *ramp*, and *sawtooth* waveforms.

The DACx3401 devices have a power-on-reset (POR) circuit that makes sure all the registers start with default or user-programmed settings using NVM. The DAC output powers on in high-impedance mode (default); this setting can be programmed to 10k Ω -GND using NVM.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Digital-to-Analog Converter (DAC) Architecture

The DACx3401 family of devices consists of string architecture with an output buffer amplifier. The [Functional Block Diagram](#) section shows the DAC architecture within the block diagram. This DAC architecture operates from a 1.8-V to 5.5-V power supply. These devices consume only 0.2 mA of current when using a 1.8-V power supply. The DAC output pin starts up in high impedance mode making it an excellent choice for power-supply control applications. To change the power-up mode to 10kΩ-GND, program the DAC_PDN bit (address: D1h), and load these bits in the device NVM.

8.3.1.1 Reference Selection and DAC Transfer Function

The device writes the input data to the DAC data registers in straight-binary format. After a power-on or a reset event, the device sets all DAC registers to the values set in the NVM.

8.3.1.1.1 Power Supply as Reference

By default, the DACx3401 operate with the power-supply pin (VDD) as a reference. [式 1](#) shows DAC transfer function when the power-supply pin is used as reference.

$$V_{OUT} = \frac{DAC_DATA}{2^N} \times V_{DD}$$

where:

- N is the resolution in bits, either 8 (DAC43401) or 10 (DAC53401).
- DAC_DATA is the decimal equivalent of the binary code that is loaded to the DAC register.
- DAC_DATA ranges from 0 to $2^N - 1$.
- V_{DD} is used as the DAC reference voltage.

(1)

8.3.1.1.2 Internal Reference

The DACx3401 also contain an internal reference that is disabled by default. Enable the internal reference by writing 1 to REF_EN (address D1h). The internal reference generates a fixed 1.21-V voltage (typical). Using DAC_SPAN (address D1h) bits, gain of 1.5X, 2X, 3X, 4X can be achieved for the DAC output voltage (V_{OUT}) [式 2](#) shows DAC transfer function when the internal reference is used.

$$V_{OUT} = \frac{DAC_DATA}{2^N} \times V_{REF} \times GAIN$$

where:

- N is the resolution in bits, either 8 (DAC43401) or 10 (DAC53401).
- DAC_DATA is the decimal equivalent of the binary code that is loaded to the DAC register
- DAC_DATA ranges from 0 to $2^N - 1$.
- V_{REF} is the internal reference voltage = 1.21 V.
- GAIN = 1.5x, 2x, 3x, 4x based on DAC_SPAN (address D1h) bits.

(2)

Feature Description (continued)

8.3.2 DAC Update

The DAC output pin (OUT) is updated at the end of I²C DAC write frame.

8.3.2.1 DAC Update Busy

The DAC_UPDATE_BUSY bit (address D0h) is set to 1 by the device when certain DAC update operations, such as *function generation*, *transition to margin high or low*, or any of the medical alarms are in progress. When the DAC_UPDATE_BUSY bit is set to 1, do not write to any of the DAC registers. After the DAC update operation is completed (DAC_UPDATE_BUSY = 0), any of the DAC registers can be written.

8.3.3 Nonvolatile Memory (EEPROM or NVM)

The DACx3401 contain nonvolatile memory (NVM) bits. These memory bits are user programmable and erasable, and retain the set values in the absence of a power supply. All the register bits, as shown in 表 1, can be stored in the device NVM by setting NVM_PROG = 1 (address D3h). The NVM_BUSY bit (address D0h) is set to 1 by device when a NVM write or reload operation is ongoing. During this time, the device blocks all write operations to the device. The NVM_BUSY bit is set to 0 after the write or reload operation is complete; at this point, all write operations to the device are allowed. The default value for all the registers in the DACx3401 is loaded from NVM as soon as a POR event is issued. Do not perform a read operation from the DAC register while NVM_BUSY = 1.

The DACx3401 also implement NVM_RELOAD bit (address D3h). Set this bit to 1 for the device to start an NVM reload operation. After the operation is complete, the device autoresets this bit to 0. During the NVM_RELOAD operation, the NVM_BUSY bit is set to 1.

8.3.3.1 NVM Cyclic Redundancy Check

The DACx3401 implement a cyclic redundancy check (CRC) feature for the device NVM to make sure that the data stored in the device NVM is uncorrupted. There are two types of CRC alarm bits implemented in DACx3401: NVM_CRC_ALARM_USER and NVM_CRC_ALARM_INTERNAL. The NVM_CRC_ALARM_USER bit indicates the status of user-programmable NVM bits, and the NVM_CRC_ALARM_INTERNAL bit indicates the status of internal NVM bits. The CRC feature is implemented by storing a 10-Bit CRC (CRC-10-ATM) along with the NVM data each time NVM program operation (write or reload) is performed and during the device start up. The device reads the NVM data and validates the data with the stored CRC. The CRC alarm bits (NVM_CRC_ALARM_USER and NVM_CRC_ALARM_INTERNAL address D0h) report any errors after the data are read from the device NVM.

8.3.3.2 NVM_CRC_ALARM_USER Bit

A logic 1 on NVM_CRC_ALARM_USER bit indicates that the user-programmable NVM data is corrupt. During this condition, all registers in the DAC are initialized with factory reset values, and any DAC registers can be written to or read from. To reset the alarm bits to 0, issue a software reset (see the [Software Reset](#) section) command, or cycle power to the DAC. Alternatively, cycle the power to reload the user-programmable NVM bits.

8.3.3.3 NVM_CRC_ALARM_INTERNAL Bit

A logic 1 on NVM_CRC_ALARM_INTERNAL bit indicates that the internal NVM data is corrupt. During this condition, all registers in the DAC are initialized with factory reset values, and any DAC registers can be written to or read from. To reset the alarm bits to 0, issue a software reset (see the [Software Reset](#) section) command or cycle power to the DAC.

8.3.4 Programmable Slew Rate

When the DAC data registers are written, the voltage on DAC output (V_{OUT}) immediately transitions to the new code following the slew rate and settling time specified in the [Electrical Characteristics](#) table. The slew rate control feature allows the user to control the rate at which the output voltage (V_{OUT}) changes. When this feature is enabled (using SLEW_RATE[3:0] bits), the DAC output changes from the current code to the code in MARGIN_HIGH (address 25h) or MARGIN_LOW (address 26h) registers (when margin high or low commands are issued to the DAC) using the step and rate set in CODE_STEP and SLEW_RATE bits. With the default slew rate control setting (CODE_STEP and SLEW_RATE bits, address D1h), the output changes smoothly at a rate limited by the output drive circuitry and the attached load. Using this feature, the output steps digitally at a rate defined by bits CODE_STEP and SLEW_RATE on address D1h. SLEW_RATE defines the rate at which the digital slew updates; CODE_STEP defines the amount by which the output value changes at each update. [表 2](#) and [表 3](#) show different settings for CODE_STEP and SLEW_RATE.

When the slew rate control feature is used, the output changes happen at the programmed slew rate. This configuration results in a staircase formation at the output. Do not write to CODE_STEP, SLEW_RATE, or DAC_DATA during the output slew.

	1	1	1	0	4 μ s (per step)
	1	1	1	1	No slew (default)

8.3.5 Power-on-Reset (POR)

The DACx3401 family of devices includes a power-on reset (POR) function that controls the output voltage at power up. After the V_{DD} supply has been established, a POR event is issued. The POR causes all registers to initialize to default values, and communication with the device is valid only after a 30-ms, POR delay. The default value for all the registers in the DACx3401 is loaded from NVM as soon as the POR event is issued.

When the device powers up, a POR circuit sets the device to the default mode. The POR circuit requires specific V_{DD} levels, as indicated in [Figure 48](#), in order to make sure that the internal capacitors discharge and reset the device on power up. To make sure that a POR occurs, V_{DD} must be less than 0.7 V for at least 1 ms. When V_{DD} drops to less than 1.65 V, but remains greater than 0.7 V (shown as the undefined region), the device may or may not reset under all specified temperature and power-supply conditions. In this case, initiate a POR. When V_{DD} remains greater than 1.65 V, a POR does not occur.

Figure 48. Threshold Levels for V_{DD} POR Circuit

8.3.6 Software Reset

To initiate a device software reset event, write the reserved code 1010 to the SW_RESET (address D3h). A software reset initiates a POR event.

8.3.7 Device Lock Feature

The DACx3401 implement a device lock feature that prevents an accidental or unintended write to the DAC registers. The device locks all the registers when the DEVICE_LOCK bit (address D1h) is set to 1. To bypass the DEVICE_LOCK setting, write 0101 to the DEVICE_UNLOCK_CODE bits (address D3h).

8.3.8 PMBus Compatibility

PMBus is an I²C-based communication standard for power-supply management. PMBus contains standard command codes tailored to power supply applications. The DACx3401 implement some PMBus commands such as *Turn Off*, *Turn On*, *Margin Low*, *Margin High*, *Communication Failure Alert Bit (CML)*, as well as *PMBUS revision*. [Figure 49](#) shows typical PMBus connections. The EN_PMBus bit (Bit 12, address D1h) must be set to 1 to enable the PMBus protocol.

Similar to I²C, PMBus is a variable length packet of 8-bit data bytes, each with a receiver acknowledge, wrapped between a start and stop bit. The first byte is always a 7-bit *slave address* followed by a *write* bit, sometimes called the *even address* that identifies the intended receiver of the packet. The second byte is an 8-bit *command* byte, identifying the PMBus command being transmitted using the respective command code. After the command byte, the transmitter either sends data associated with the command to write to the receiver command register (from most significant byte to least significant byte), or sends a new start bit indicating the desire to read the data associated with the command register from the receiver. After, the receiver transmits the data following the same most significant byte first format (see [Table 10](#)).

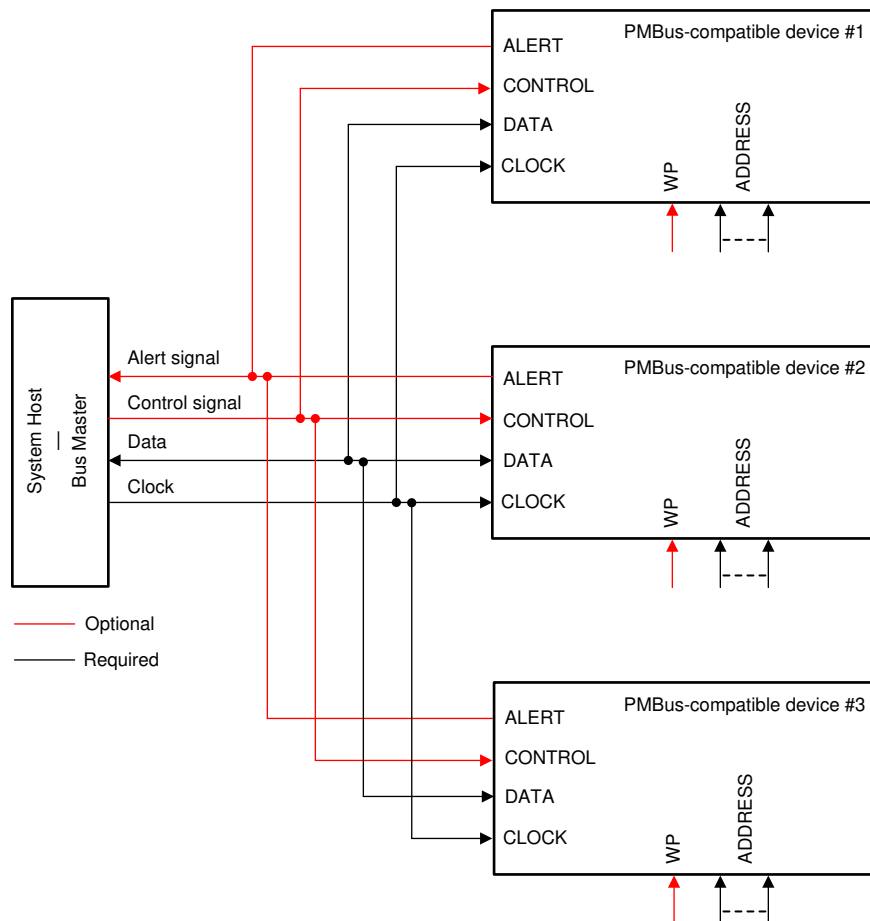

Figure 49. PMBus Connections

8.4 Device Functional Modes

8.4.1 Power Down Mode

The DACx3401 output amplifier and internal reference can be independently powered down through the DAC_PDN bits (address D1h). At power up, the DAC output and the internal reference are disabled by default. In power-down mode, the DAC output (OUT pin) is in a high-impedance state. To change this state to 10kΩ-A_{GND} (at power up), use the DAC_PDN bits (address D1h).

The DAC power-up state can be programmed to any state (power-down or normal mode) using the NVM. 表 4 shows the DAC power-down bits.

表 4. DAC Power-Down Bits

REGISTER ADDRESS AND NAME	DAC_PDN[1]	DAC_PDN[0]	DESCRIPTION
D1h, GENERAL_CONFIG	0	0	Power up
	0	1	Power down to 10 kΩ
	1	0	Power down to high impedance (HiZ) (default)
	1	1	Power down to 10 kΩ

8.4.2 Continuous Waveform Generation (CWG) Mode

The DACx3401 implement a continuous waveform generation feature. To set the device to this mode, set the START_FUNC_GEN (address D3h) to 1. In this mode, the DAC output pin (OUT) generates a continuous waveform based on the FUNC_CONFIG bits (address D1h). 表 5 shows the continuous waveforms that can be generated in this mode. The frequency of the waveform depends on the resistive and capacitive load on the OUT pin, high and low codes, and slew rate settings as shown in the following equations.

$$f_{\text{SQUARE-WAVE}} = \frac{1}{2 \times \text{SLEW_RATE}}$$

where:

- SLEW_RATE is the programmable DAC slew rate specified in 表 3. (3)

$$f_{\text{TRIANGLE-WAVE}} = \frac{1}{2 \times \text{SLEW_RATE} \times \left(\frac{\text{MARGIN_HIGH} - \text{MARGIN_LOW} + 1}{\text{CODE_STEP}} \right)}$$

where:

- SLEW_RATE is the programmable DAC slew rate specified in 表 3.
- MARGIN_HIGH and MARGIN_LOW are the programmable DAC codes.
- CODE_STEP is the programmable DAC step code in 表 2. (4)

$$f_{\text{SAWTOOTH-WAVE}} = \frac{1}{\text{SLEW_RATE} \times \left(\frac{\text{MARGIN_HIGH} - \text{MARGIN_LOW} + 1}{\text{CODE_STEP}} \right)}$$

where:

- SLEW_RATE is the programmable DAC slew rate specified in 表 3.
- MARGIN_HIGH and MARGIN_LOW are the programmable DAC codes.
- CODE_STEP is the programmable DAC step code in 表 2. (5)

表 5. FUNC_CONFIG bits

REGISTER ADDRESS AND NAME	FUNC_CONFIG[1]	FUNC_CONFIG[0]	DESCRIPTION
D1h, GENERAL_CONFIG	0	0	Generates a triangle wave between MARGIN_HIGH (address 25h) code to MARGIN_LOW (address 26h) code with slope defined by SLEW_RATE (address D1h) bits
	0	1	Generates Saw-Tooth wave between MARGIN_HIGH (address 25h) code to MARGIN_LOW (address 26h) code, with rising slope defined by SLEW_RATE (address D1h) bits and immediate falling edge
	1	0	Generates Saw-Tooth wave between MARGIN_HIGH (address 25h) code to MARGIN_LOW (address 26h) code, with falling slope defined by SLEW_RATE (address D1h) bits and immediate rising edge
	1	1	Generates a square wave between MARGIN_HIGH (address 25h) code to MARGIN_LOW (address 26h) code with pulse high and low period defined by SLEW_RATE (address D1h) bits

8.4.3 PMBus Compatibility Mode

The DACx3401 I²C interface implements some of the PMBus commands. 表 6 shows the supported PMBus commands that are implemented in DACx3401. The DAC uses MARGIN_LOW (address 26h), MARGIN_HIGH (address 25h) bits, SLEW_RATE, and CODE_STEP bits (address D1h) for PMBUS_OPERATION_CMD. The EN_PMBus bit (Bit 12, address D1h) must be set to 1 to enable the PMBus protocol.

表 6. PMBus Operation Commands

REGISTER ADDRESS AND NAME	PMBUS_OPERATION_CMD[15:8]	DESCRIPTION
01h, PMBUS_OPERATION	00h	Turn off
	80h	Turn on
	94h	Margin low
	A4h	Margin high

The DACx3401 also implement PMBus features such as group command protocol and communication time-out failure. The CML bit (address 78h) indicates a communication fault in the PMBus. This bit is reset by writing 1. In case of timeout, if the SDA line is held low, the SDA line stays low during the time-out event until next SCL pulse is received.

To get the PMBus version, read the PMBUS_VERSION bits (address 98h).

8.4.4 Medical Alarm Generation Mode

The DACx3401 are also used to generate continuous alarm tones for medical devices. Use a suitable analog mixer, audio amplifier, and a speaker to generate low, medium, or high priority alarm tones. See the [Application and Implementation](#) section for more details. The DACx3401 allow tunability and configurability to support different alarm generation. Using this approach, configurable medical alarm tones can be generated with a simple circuit, and with no need for runtime software.

8.4.4.1 Low-Priority Alarm

The MED_ALARM_LP bit (address D2h) is used to trigger a medical low-priority alarm generation. The DAC generates a continuous-alarm signal until this bit is set back to 0. After the bit is set to 0, the device does not abruptly end the alarm generation; the device stops only after completing the ongoing burst.

8.4.4.2 Medium-Priority Alarm

The MED_ALARM_MP bit (address D2h) is used to trigger a medical medium-priority alarm generation. The DAC generates a continuous-alarm signal until this bit is set back to 0. After the bit is set to 0, the device does not abruptly end the alarm generation; the device stops only after completing the ongoing burst.

8.4.4.3 High-Priority Alarm

The MED_ALARM_HP bit (address D2h) is used to trigger a medical high-priority alarm generation. The DAC generates a continuous-alarm signal until this bit is set back to 0. After the bit is set to 0, the device does not abruptly end the alarm generation; the device stops only after completing the ongoing burst.

8.4.4.4 Interburst Time

The INTERBURST_TIME bit (address D2h) is used set the time between two adjacent bursts. [表 7](#) lists the INTERBURST_TIME settings.

表 7. Interburst Time

REGISTER ADDRESS AND NAME	INTERBURST_TIME[1:0]	HIGH PRIORITY ALARM INTERBURST TIME	MEDIUM PRIORITY ALARM INTERBURST TIME	LOW PRIORITY ALARM INTERBURST TIME

	01	103 ms	153 ms	153 ms
	10	126 ms	176 ms	176 ms
	11	150 ms	200 ms	200 ms

8.5 Programming

The DACx3401 devices have a 2-wire serial interface (SCL and SDA), and one address pin (A0), as shown in the [Pin Configuration and Functions](#) section. The I²C bus consists of a data line (SDA) and a clock line (SCL) with pullup structures. When the bus is idle, both SDA and SCL lines are pulled high. All the I²C-compatible devices connect to the I²C bus through the open drain I/O pins, SDA and SCL.

The I²C specification states that the device that controls communication is called a *master*, and the devices that are controlled by the master are called *slaves*. The master device generates the SCL signal. The master device also generates special timing conditions (start condition, repeated start condition, and stop condition) on the bus to indicate the start or stop of a data transfer. Device addressing is completed by the master. The master device on an I²C bus is typically a microcontroller or digital signal processor (DSP). The DACx3401 family operates as a slave device on the I²C bus. A slave device acknowledges master commands, and upon master control, receives or transmits data.

Typically, the DACx3401 family operates as a slave receiver. A master device writes to the DACx3401, a slave receiver. However, if a master device requires the DACx3401 internal register data, the DACx3401 operate as a slave transmitter. In this case, the master device reads from the DACx3401. According to I²C terminology, read and write refer to the master device.

The DACx3401 family is a slave and supports the following data transfer modes:

- Standard mode (100 kbps)
- Fast mode (400 kbps)
- Fast+ mode (1.0 Mbps)

The data transfer protocol for standard and fast modes is exactly the same; therefore, both modes are referred to as F/S-mode in this document. The fast+ mode protocol is supported in terms of data transfer speed, but not output current. The low-level output current would be 3 mA; similar to the case of standard and fast modes. The DACx3401 family supports 7-bit addressing. The 10-bit addressing mode is not supported. The device supports the general call reset function. Sending the following sequence initiates a software reset within the device: start or repeated start, 0x00, 0x06, stop. The reset is asserted within the device on the rising edge of the ACK bit, following the second byte.

Other than specific timing signals, the I²C interface works with serial bytes. At the end of each byte, a ninth clock cycle generates and detects an acknowledge signal. Acknowledge is when the SDA line is pulled low during the high period of the ninth clock cycle. A not-acknowledge is when the SDA line is left high during the high period of the ninth clock cycle as shown in [Figure 50](#).

Figure 50. Acknowledge and Not Acknowledge on the I²C Bus

Programming (continued)

8.5.1 F/S Mode Protocol

The following steps explain a complete transaction in F/S mode.

1. The master initiates data transfer by generating a start condition. The start condition is when a high-to-low transition occurs on the SDA line while SCL is high, as shown in [Figure 51](#). All I²C-compatible devices recognize a start condition.
2. The master then generates the SCL pulses, and transmits the 7-bit address and the read/write direction bit (R/W) on the SDA line. During all transmissions, the master makes sure that data are valid. A valid data condition requires the SDA line to be stable during the entire high period of the clock pulse, as shown in [Figure 52](#). All devices recognize the address sent by the master and compare the address to the respective internal fixed address. Only the slave device with a matching address generates an acknowledge by pulling the SDA line low during the entire high period of the 9th SCL cycle, as shown in [Figure 50](#). When the master detects this acknowledge, the communication link with a slave has been established.
3. The master generates further SCL cycles to transmit (R/W bit 0) or receive (R/W bit 1) data to the slave. In either case, the receiver must acknowledge the data sent by the transmitter. The acknowledge signal can be generated by the master or by the slave, depending on which is the receiver. The 9-bit valid data sequences consists of 8-data bits and 1 acknowledge-bit, and can continue as long as necessary.
4. To signal the end of the data transfer, the master generates a stop condition by pulling the SDA line from low-to-high while the SCL line is high (see [Figure 51](#)). This action releases the bus and stops the communication link with the addressed slave. All I²C-compatible devices recognize the stop condition. Upon receipt of a stop condition, the bus is released, and all slave devices then wait for a start condition followed by a matching address.

Figure 51. Start and Stop Conditions

Figure 52. Bit Transfer on the I²C Bus

8.5.2 DACx3401 I²C Update Sequence

For a single update, the DACx3401 require a start condition, a valid I²C address byte, a command byte, and two data bytes, as listed in 表 10.

表 10. Update Sequence

MSB	LSB	ACK	MSB	...	LSB	ACK	MSB	...	LSB	ACK	MSB	...	LSB	ACK
Address (A) byte Address Byte				Command byte Command Byte				Data byte - MSDB Application Curves				Data byte - LSDB Application Curves			
DB [31:24]				DB [23:16]				DB [15:8]				DB [7:0]			

After each byte is received, the DACx3401 family acknowledges the byte by pulling the SDA line low during the high period of a single clock pulse, as shown in 图 53. These four bytes and acknowledge cycles make up the 36 clock cycles required for a single update to occur. A valid I²C address byte selects the DACx3401 devices.

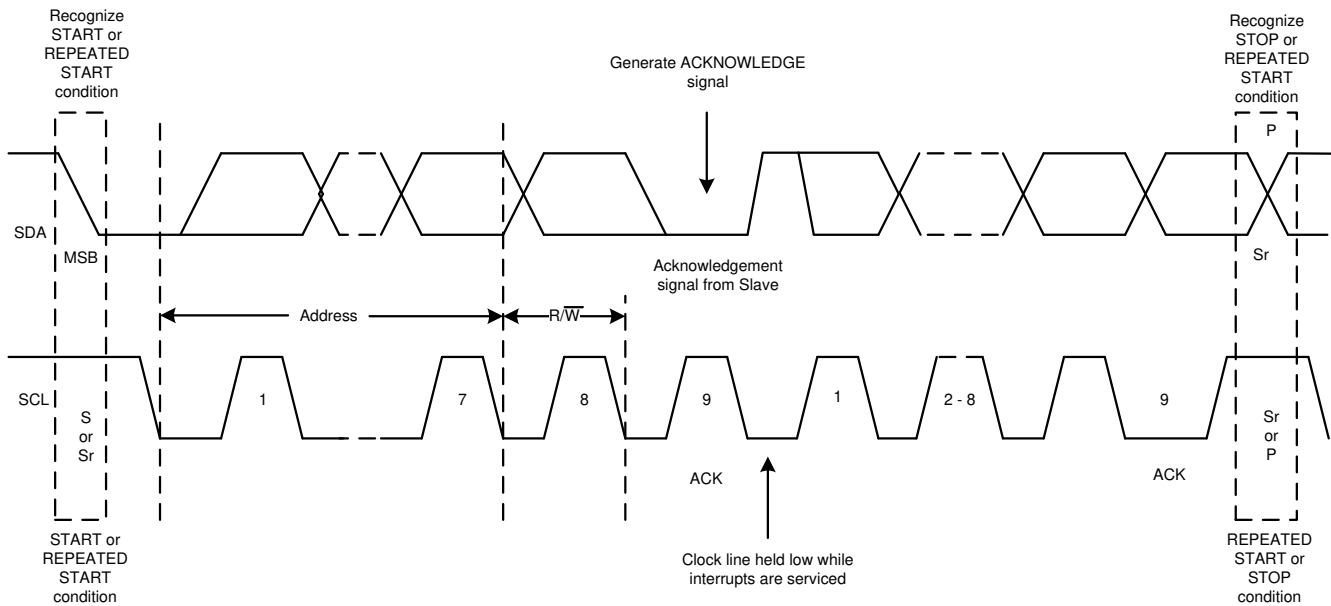

图 53. I²C Bus Protocol

The command byte sets the operating mode of the selected DACx3401 device. For a data update to occur when the operating mode is selected by this byte, the DACx3401 device must receive two data bytes: the most significant data byte (MSDB) and least significant data byte (LSDB). The DACx3401 device performs an update on the falling edge of the acknowledge signal that follows the LSDB.

When using fast mode (clock = 400 kHz), the maximum DAC update rate is limited to 10 kSPS. Using the fast+ mode (clock = 1 MHz), the maximum DAC update rate is limited to 25 kSPS. When a stop condition is received, the DACx3401 device releases the I²C bus and awaits a new start condition.

8.5.3 Address Byte

The address byte, as shown in 表 11, is the first byte received following the start condition from the master device. The first four bits (MSBs) of the address are factory preset to 1001. The next three bits of the address are controlled by the A0 pin. The A0 pin input can be connected to VDD, AGND, SCL, or SDA. The A0 pin is sampled during the first byte of each data frame to determine the address. The device latches the value of the address pin, and consequently responds to that particular address according to 表 12.

The DACx3401 family supports broadcast addressing, which can be used for synchronously updating or powering down multiple DACx3401 devices. The DACx3401 family is designed to work with other members of the family to support multichip synchronous updates. Using the broadcast address, the DACx3401 devices respond regardless of the states of the address pins. Broadcast is supported only in write mode.

表 11. Address Byte

COMMENT	MSB							LSB

8.5.5 I²C Read Sequence

To read any register the following command sequence must be used:

1. Send a start or repeated start command with a slave address and the R/ \bar{W} bit set to 0 for writing. The device acknowledges this event.
2. Send a command byte for the register to be read. The device acknowledges this event again.
3. Send a repeated start with the slave address and the R/ \bar{W} bit set to 1 for reading. The device acknowledges this event.
4. The device writes the MSDB byte of the addressed register. The master must acknowledge this byte.
5. Finally, the device writes out the LSDB of the register.

An alternative reading method allows for reading back the value of the last register written. The sequence is a start or repeated start with the slave address and the R/ \bar{W} bit set to 1, and the two bytes of the last register are read out.

Note that it is not possible to use the broadcast address for reading.

表 14. Read Sequence

9 Application and Implementation

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The DACx3401 are buffered, force-sense output, single-channel, DACs that include an NVM and internal reference and are available in a tiny 3 × 3 package. These DACs are designed for general-purpose applications in a wide range of end equipment. Some of the most common applications for these devices are power-supply margining and control, adaptive voltage scaling (AVS), *set-and-forget* LED biasing in mobile projectors, general-purpose function generation, medical alarm generation, and programmable comparator applications (such as smoke detectors, standalone PWM control loops, and offset and gain trimming in precision circuits).

9.2 Typical Applications

This section explains the design details of three primary applications of DACx3401: programmable LED biasing, power-supply margining, and medical alarm generation.

9.2.1 Programmable LED Biasing

LED and laser biasing or driving circuits often require accuracy and stability of the luminosity with respect to variation in temperature, electrical conditions, and physical characteristics. This accuracy and stability are most effectively achieved using a precision DAC, such as the DACx3401. The DACx3401 have additional features, such as the V_{FB} pin that compensates for the gate-to-source voltage of the transistor (V_{GS}) drop and the drift of the MOSFET. The NVM allows the microprocessor to *set-and-forget* the LED biasing value, even during a power cycle. [Figure 64](#) shows the circuit diagram for LED biasing.

Figure 64. LED Biasing

9.2.1.1 Design Requirements

- DAC output range: 0 V to 2.4 V
- LED current range: 0 mA to 20 mA

Typical Applications (continued)

9.2.1.2 Detailed Design Procedure

The DAC sets the source current of a MOSFET using the integrated buffer, as shown in [Figure 64](#). Connect the LED between the power supply and the drain of the MOSFET. This configuration allows the DAC to control or set the amount of current through the LED. The integrated buffer controls the gate-source voltage of the MOSFET inside the feedback loop, thus compensating this drop and corresponding drift due to temperature, current, and ageing of the MOSFET. Calculate the value of the LED current set by the DAC using [Equation 6](#). In order to generate 0 mA to 20 mA from a 0-V to 2.4-V DAC output range, the value of R_{SET} resistor is 120-Ω. Select the internal reference with a span of 2x. Given a V_{GS} of 1.2 V, the V_{DD} of the DAC must be at least 3.6 V. Select a V_{DD} of 5 V to allow variation of V_{GS} across temperature. When the V_{DD} headroom is a constraint, use a bipolar junction transistor (BJT) in place of the MOSFET. BJTs have much less V_{BE} drop as compared to a V_{GS} of a MOSFET. A MOSFET provides a much better match between the current through the set register and the LED current, as compared to a BJT.

$$I_{SET} = \frac{V_{DAC}}{R_{SET}} \tag{6}$$

The pseudocode for getting started with an LED biasing application is as follows:

```
//SYNTAX: WRITE <REGISTER NAME (Hex code)>, <MSB DATA>, <LSB DATA>
//Power-up the device, enable internal reference with 2x output span
WRITE GENERAL_CONFIG(0xD1), 0x11, 0xE5
//Write DAC code (12-bit aligned)
WRITE DAC_DATA(0x21), 0x07, 0xFC
//Write settings to the NVM
WRITE TRIGGER(0xD3), 0x00, 0x10
```

9.2.1.3 Application Curves

Typical Applications (continued)

9.2.2 Power-Supply Margining

A power-supply margining circuit is used to test and trim the output of a power converter. This circuit is used to test a system by margining the power supplies, for adaptive voltage scaling, or to program a desired value at the output. Adjustable power supplies, such as LDOs and DC/DC converters provide a feedback or adjust input that is used to set the desired output. A precision voltage-output DAC is the best choice for controlling the power-supply output linearly. [Figure 67](#) shows a control circuit for a switch-mode power supply (SMPS) using DACx3401. Typical applications of power-supply margining are communications equipment, enterprise servers, test and measurement, and general-purpose power-supply modules.

Figure 67. Power-Supply Margining

9.2.2.1 Design Requirements

- Power supply nominal output: 3.3 V
- Reference voltage of the converter (V_{FB}): 0.6 V
- Margin: $\pm 10\%$ (that is, 2.97 V to 3.63 V)
- DAC output range: 1.8 V
- Nominal current through R_1 and R_2 : 100 μA

9.2.2.2 Detailed Design Procedure

The DACx3401 features a Hi-Z power-down mode that is set by default at power-up, unless the device is programmed otherwise using the NVM. When the DAC output is at Hi-Z, the current through R_3 is zero and the SMPS is set at the nominal output voltage of 3.3 V. To have the same nominal condition when the DAC powers up, bring up the device at the same output as V_{FB} (that is 0.6 V). This configuration makes sure there is no current through R_3 even at power-up. Calculate R_1 as $(V_{OUT} - V_{FB}) / 100 \mu\text{A} = 27 \text{ k}\Omega$.

To achieve $\pm 10\%$ margin-high and margin-low conditions, the DAC must sink or source additional current through R_1 . Calculate the current from the DAC (I_{MARGIN}) using [Equation 7](#) as 12 μA .

$$I_{MARGIN} = \left(\frac{V_{OUT} \times (1 + \text{MARGIN}) - V_{FB}}{R_1} \right) - I_{NOMINAL}$$

where

- I_{MARGIN} is the margin current sourced or sinked from the DAC.
- MARGIN is the percentage margin value divided by 100.
- $I_{NOMINAL}$ is the nominal current through R_1 and R_2 .

(7)

In order to calculate the value of R_3 , first decide the DAC output range, and make sure to avoid the codes near zero-scale and full-scale for safe operation in the linear region. A DAC output of 20 mV is a safe consideration as the minimum output, and $(1.8 \text{ V} - 0.6 \text{ V} - 20 \text{ mV} = 1.18 \text{ V})$ as the maximum output. When the DAC output is at 20 mV, the power supply goes to margin high, and when the DAC output is at 1.18 V, the power supply goes to margin low. Calculate the value of R_3 using [Equation 8](#) as 48.3 $\text{k}\Omega$. Choose a standard resistor value and adjust the DAC outputs. Choosing $R_3 = 47 \text{ k}\Omega$ makes the DAC margin high code as 1.164 V and the DAC margin low code as 36 mV.

Typical Applications (continued)

$$R_3 = \frac{|V_{DAC} - V_{FB}|}{I_{MARGIN}} \tag{8}$$

The DACx3401 have a slew rate feature that is used to toggle between margin high, margin low, and nominal outputs with a defined slew rate. See the [GENERAL_CONFIG](#) register description for the slew rate setting details.

注

The MARGIN HIGH register value in DACx3401 results in the MARGIN LOW value at the power supply output. Similarly, the MARGIN LOW register value in DACx3401 results in the MARGIN HIGH value at the power-supply output.

The pseudocode for getting started with a power-supply control application is as follows:

```
//SYNTAX: WRITE <REGISTER NAME (Hex code)>, <MSB DATA>, <LSB DATA>
//Write DAC code (12-bit aligned) for nominal output
//For a 1.8-V output range, the 10-bit hex code for 0.6 V is 0x0155. With 12-
bit alignment, it becomes 0x0554
WRITE DAC_DATA(0x21), 0x05, 0x54
//Write DAC code (12-bit aligned) for margin-low output at the power supply
//For a 1.8-V output range, the 10-bit hex code for 1.164 V is 0x0296. With 12-
bit alignment, it becomes 0x0A58
WRITE DAC_MARGIN_HIGH(0x25), 0x0A, 0x58
//Write DAC code (12-bit aligned) for margin-high output at the power supply
//For a 1.8-V output range, the 10-bit hex code for 36 mV is 0x14. With 12-
bit alignment, it becomes 0x50
WRITE DAC_MARGIN_LOW(0x26), 0x00, 0x50
//Power-
up the device with enable internal reference with 1.5x output span. This will output the nominal
voltage (0.6 V)
//CODE_STEP: 2 LSB, SLEW_RATE: 25.6 μs
WRITE GENERAL_CONFIG(0xD1), 0x12, 0x14
//Trigger margin-low output at the power supply
WRITE TRIGGER(0xD3), 0x00, 0x80
//Trigger margin-high output at the power supply
WRITE TRIGGER(0xD3), 0x00, 0x40
//Write back DAC code (12-bit aligned) for nominal output
WRITE DAC_DATA(0x21), 0x05, 0x54
```

9.2.2.3 Application Curves

Typical Applications (continued)

9.2.3 Medical Alarm Generation

All medical devices implementing an alarm system shall comply to IEC60601-1-8 standard for medical alarms (as per IEC60601-1 Ed 3.1). The regulatory tests are done at a system level; therefore, system level acoustics play a major role in the compliance. A medical alarm is a common functional block in many medical devices. A portable implementation is needed that can also be customized to fit mechanical and audio or acoustic requirements. The DACx3401-based design is aimed at providing a programmable, standalone, and robust implementation at a very low cost.

There are three types of alarms with different timing requirements: low priority, medium priority, and high priority. Usually, for easy identification, different timings are employed for different equipment. Medical device manufacturers prefer using their signature melodies within the limits of the standard.

FIG 70. Medical Alarm

9.2.3.1 Design Requirements

- Alarm envelope rise and fall time: 26 ms
- Alarm pulse frequency: 610 Hz

9.2.3.2 Detailed Design Procedure

Two DACx3401 devices are required: one device to generate the pulse envelope and the burst, and the second device to generate the pulse frequency. As shown in FIG 70, mix both these signals together using the TLV342S amplifier with shutdown. Feed the combined signal to a power amplifier, such as the LM158, to drive the speaker. This design provides a gain of 2 at the speaker amplifier. The actual gain required in a system depends on the acoustic output requirements from the speaker. The RC high-pass filter, designed for a cut-off frequency of approximately 80 Hz at the input of LM158, removes the dc component from the signal so that this signal can be applied to the speaker directly. As per the medical alarm standard, the pulse frequency must be above 150 Hz. As a result of the square-wave pulse frequency and the mixing done by TLV342S, the speaker output has multiple harmonics of the fundamental pulse frequency, thus fulfilling the requirement of the medical alarm standard. The DACx3401 provide various options to program the pulse frequency and envelope timings. See the [Medical Alarm Generation Mode](#) section for the alarm configuration options. Calculate the frequency of a square wave or pulse frequency using 式 3. The square wave function has a limited number of frequencies because this function is programmed by the SLEW_RATE bit alone. To get a higher number of frequencies, generate a triangular waveform with comparator mode output. Generate the triangular waveform using 式 4. Set the DAC output in the comparator mode by fixing the V_{FB} pin to the midscale of the DAC using a resistive voltage divider from V_{DD} . Select V_{DD} as the reference in this case using the GENERAL_CONFIG register.

Typical Applications (continued)

The pseudocode for getting started with a medical alarm application using two DACs is as follows:

```
//SYNTAX: WRITE <REGISTER NAME (Hex code)>, <MSB DATA>, <LSB DATA>
//Power-up the first DAC, enable VDD reference
//SLEW_RATE: 1.6384 ms (Square wave frequency: 610 Hz)
WRITE GENERAL_CONFIG(0xD1), 0xD1, 0x58
//Set MARGIN_HIGH on the first DAC
WRITE DAC_MARGIN_HIGH(0x25), 0x0F, 0xFC
//Set MARGIN_LOW on the first DAC
WRITE DAC_MARGIN_LOW(0x26), 0x00, 0x00
//Trigger square wave generation on the first DAC
WRITE TRIGGER(0xD3), 0x01, 0x00
//Power-up the second DAC, enable VDD reference
//CODE_STEP: 8 LSB, SLEW_RATE: 204.8 μs x 1.75 = 358.4 μs (Envelope rise/fall times for full-
scale: ~26 ms)
WRITE GENERAL_CONFIG(0xD1), 0x1A, 0xE8
//OPTION-1: Configure the second DAC for low-priority alarm with minimum time settings and trigger
WRITE MED_ALARM_CONFIG(0xD2), 0x01, 0x00
//OPTION-2: Configure the second DAC for medium-priority alarm with minimum time settings and trigger
WRITE MED_ALARM_CONFIG(0xD2), 0x02, 0x00
//OPTION-3: Configure the second DAC for high-priority alarm with minimum time settings and trigger
WRITE MED_ALARM_CONFIG(0xD2), 0x04, 0x00
//Set MARGIN_HIGH on the second DAC
WRITE DAC_MARGIN_HIGH(0x25), 0x0F, 0xFC
//Set MARGIN_LOW on the second DAC
WRITE DAC_MARGIN_LOW(0x26), 0x00, 0x00
```

9.2.3.3 Application Curves

10 Power Supply Recommendations

The DACx3401 family of devices does not require specific supply sequencing. These devices require a single power supply, V_{DD} . Use a 0.1- μF decoupling capacitor for the V_{DD} pin. Use a bypass capacitor with a value greater than 1.5- μF for the CAP pin.

11 Layout

11.1 Layout Guidelines

The DACx3401 pin configuration separates the analog, digital, and power pins for an optimized layout. For signal integrity, separate the digital and analog traces, and place decoupling capacitors close to the device pins.

11.2 Layout Example

Figure 75 shows an example layout drawing with decoupling capacitors and pullup resistors.

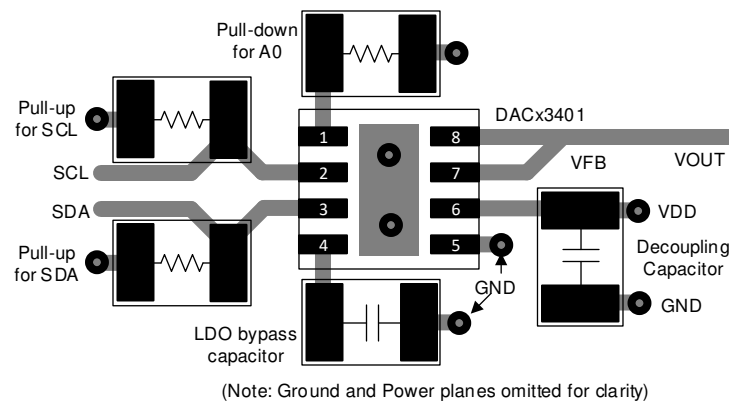

Figure 75. Layout Example

12.6 静電気放電に関する注意事項

すべての集積回路は、適切なESD保護方法を用いて、取扱いと保存を行うようにして下さい。

静電気放電はわずかな性能の低下から完全なデバイスの故障に至るまで、様々な損傷を与えます。高精度の集積回路は、損傷に対して敏感であり、極めてわずかなパラメータの変化により、デバイスに規定された仕様に適合しなくなる場合があります。

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
