## 3 概要

LM139A-MILデバイスは4つの独立した電圧コンパレータで構成され、広い電圧範囲の単一電源で動作するよう設計されています。デュアル電源での動作も可能です。この場合、2つの電源の差が2V～36Vで、 $V_{CC}$ が入力同相電圧よりも1.5V以上高いことが条件です。消費電流は、電源電圧に依存しません。出力を他のオープン・コレクタ出力に接続し、ワイヤードAND関係を構築できます。

LM139A-MILデバイスは、軍事用温度範囲-55°C～+125°C全体での動作が規定されています。

(1) All characteristics are measured with zero common-mode input voltage, unless otherwise specified.

(2) The voltage at either input or common-mode must not be allowed to go negative by more than 0.3 V. The upper end of the common-mode voltage range is  $V_{CC+} - 1.5$  V; however, one input can exceed  $V_{CC}$ , and the comparator will provide a proper output state as long as the other input remains in the common-mode range. Either or both inputs can go to 30 V without damage.

## 7 Detailed Description

### 7.1 Overview

The LM139A-MIL is a quad comparator with the ability to operate up to an absolute maximum of 36 V on the supply pin. This standard device has proven ubiquity and versatility across a wide range of applications. This is due to very wide supply voltages range (2 V up to 32 V), low  $I_Q$ , and fast response of the device.

The open-drain output allows the user to configure the output logic low voltage ( $V_{OL}$ ) and allows the comparator to be used in AND functionality.

### 7.2 Functional Block Diagram

Figure 6. Schematic (Each Comparator)

### 7.3 Feature Description

The comparator consists of a PNP Darlington pair input, allowing the device to operate with very high gain and fast response with minimal input bias current. The input Darlington pair creates a limit on the input common-mode voltage capability, allowing the comparator to accurately function from ground to  $(V_{CC} - 1.5\text{ V})$  differential input. Allow for  $(V_{CC} - 2\text{ V})$  at cold temperature.

The output consists of an open-collector NPN (pulldown or low-side) transistor. The output NPN sinks current when the negative input voltage is higher than the positive input voltage and the offset voltage. The  $V_{OL}$  is resistive and scales with the output current. See the *Specifications* section for  $V_{OL}$  values with respect to the output current.

### 7.4 Device Functional Modes

#### 7.4.1 Voltage Comparison

The comparator operates solely as a voltage comparator, comparing the differential voltage between the positive and negative pins and outputting a logic low or high impedance (logic high with pullup) based on the input differential polarity.

## 8 Application and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Validate and test the design implementation to confirm system functionality.

### 8.1 Application Information

Typically, a comparator compares either a single signal to a reference, or to two different signals. Many users take advantage of the open-drain output to drive the comparison logic output to a logic voltage level to an MCU or logic device. The wide supply range and high voltage capability makes LM139A-MIL optimal for level shifting to a higher or lower voltage.

### 8.2 Typical Application

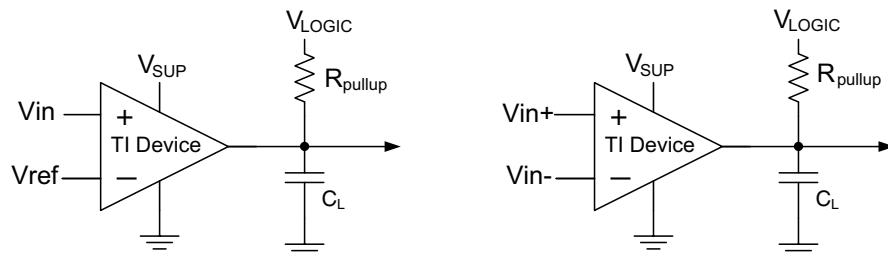

Figure 7. Single-ended and Differential Comparator Configurations

#### 8.2.1 Design Requirements

For this design example, use the parameters listed in [Table 1](#) as the input parameters.

Table 1. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
Input Voltage Range	0 V to $V_{SUP}$ -1.5 V
Supply Voltage	4.5 V to $V_{CC}$ maximum
Logic Supply Voltage	0 V to $V_{CC}$ maximum
Output Current ( $R_{PULLUP}$ )	1 $\mu$ A to 4 mA
Input Overdrive Voltage	100 mV
Reference Voltage	2.5 V
Load Capacitance ( $C_L$ )	15 pF

#### 8.2.2 Detailed Design Procedure

When using the LM139A-MIL in a general comparator application, determine the following:

- Input voltage range
- Minimum overdrive voltage
- Output and drive current
- Response time

##### 8.2.2.1 Input Voltage Range

When choosing the input voltage range, the input common-mode voltage range ( $V_{ICR}$ ) must be taken into account. If temperature operation is above or below 25°C the  $V_{ICR}$  can range from 0 V to  $V_{CC}$ - 2 V. This limits the input voltage range to as high as  $V_{CC}$ - 2 V and as low as 0 V. Operation outside of this range can yield incorrect comparisons.

The following list describes the outcomes of some input voltage situations.

- When both IN– and IN+ are both within the common-mode range:
  - If IN– is higher than IN+ and the offset voltage, the output is low and the output transistor is sinking current
  - If IN– is lower than IN+ and the offset voltage, the output is high impedance and the output transistor is not conducting
- When IN– is higher than common mode and IN+ is within common mode, the output is low and the output transistor is sinking current
- When IN+ is higher than common mode and IN– is within common mode, the output is high impedance and the output transistor is not conducting
- When IN– and IN+ are both higher than common mode, the output is low and the output transistor is sinking current

#### **8.2.2.2 Minimum Overdrive Voltage**

Overdrive voltage is the differential voltage produced between the positive and negative inputs of the comparator over the offset voltage ( $V_{IO}$ ). To make an accurate comparison, the overdrive voltage ( $V_{OD}$ ) must be higher than the input offset voltage ( $V_{IO}$ ). Overdrive voltage can also determine the response time of the comparator, with the response time decreasing with increasing overdrive. [Figure 8](#) and [Figure 9](#) show positive and negative response times with respect to overdrive voltage.

#### **8.2.2.3 Output and Drive Current**

Output current is determined by the load and pullup resistance and logic and pullup voltage. The output current produces a low-level output voltage ( $V_{OL}$ ) from the comparator, where  $V_{OL}$  is proportional to the output current.

The output current can also effect the transient response.

#### **8.2.2.4 Response Time**

Response time is a function of input over-drive. See the [Typical Characteristics](#) graphs for typical response times. The rise and fall times can be determined by the load capacitance ( $C_L$ ), load/pull-up resistance ( $R_{PULLUP}$ ) and equivalent collector-emitter resistance ( $R_{CE}$ ).

- The rise time ( $\tau_R$ ) is approximately  $\tau_R \sim R_{PULLUP} \times C_L$
- The fall time ( $\tau_F$ ) is approximately  $\tau_F \sim R_{CE} \times C_L$ 
  - $R_{CE}$  can be determined by taking the slope of [Figure 3](#) in its linear region at the desired temperature, or by dividing the  $V_{OL}$  by  $I_{OUT}$

## LM139A-MIL

JAJSDB9 – JUNE 2017

### 8.2.3 Application Curves

Figure 8 and Figure 9 were generated with scope probe parasitic capacitance of 50 pF.

## 9 Power Supply Recommendations

For fast response and comparison applications with noisy or AC inputs, use a bypass capacitor on the supply pin to reject any variation on the supply voltage. This variation can affect the common-mode range of the comparator input and create an inaccurate comparison.

## 10 Layout

### 10.1 Layout Guidelines

To create an accurate comparator application without hysteresis, maintain a stable power supply with minimized noise and glitches, which can affect the high level input common-mode voltage range. To achieve this accuracy, add a bypass capacitor between the supply voltage and ground. Place a bypass capacitor on the positive power supply and negative supply (if available).

#### NOTE

If a negative supply is not being used, do not place a capacitor between the GND pin of the device and system ground.
