

OPAx607-Q1 車載用、50MHz、レール・ツー・レール出力 CMOS オペアンプ

1 特長

- 車載アプリケーション認定済み
- 下記内容で AEC-Q100 認定済み:
 - 温度グレード 1: -40°C ~ +125°C, TA
- ゲイン帯域幅積 (GBW): 50MHz
- 静止電流: 900µA (標準値)
- 入力オフセット・ドリフト: 1.5µV/°C (最大値)
- オフセット電圧: 120µV (標準値)
- 入力バイアス電流: 10pA (最大値)
- レール・ツー・レール出力 (RRO)
- 電源電圧範囲: 2.2V ~ 5.5V

2 アプリケーション

- DC/DC コンバータ
- インバータおよびモーター制御
- オンボード・チャージャ (OBC) とワイヤレス・チャージャ
- E-Turbo (電子ターボ)
- HVAC (エアコン) コンプレッサ・モジュール
- ジェスチャ

3 概要

OPA607-Q1 および OPA2607-Q1 デバイスは、最小 6V/V のゲインで安定に動作する、ノイズが 3.8nV/√Hz、GBW が 50MHz の非補償型汎用 CMOS オペアンプです。低い電圧オフセット・ドリフト (dVOS/dT) と広い帯域幅の OPAx607-Q1 デバイスは、ローサイド電流センシングや TIA (トランスインピーダンス・アンプ) のような低コストの汎用アプリケーションに最適です。高インピーダンスの CMOS 入力を備えた OPAx607-Q1 デバイスは、高い出力インピーダンスを持つセンサ (圧電トランスデューサなど) と接続するのに理想的なアンプです。

OPAx607-Q1 デバイスのレール・ツー・レール出力 (RRO) は、電源レールから 8mV の電圧まで出力振幅を拡大できるため、ダイナミック・レンジを最大限に広げることができます。

OPAx607-Q1 は、最小 2.2V (±1.1V)、最大 5.5V (±2.75V) の低い電源電圧で動作するよう最適化されており、また、-40°C ~ +125°C の温度範囲での動作が規定されています。

製品情報(1)

部品番号	パッケージ	本体サイズ (公称)
OPA607-Q1	SOT23 (5)	2.90mm × 1.60mm
OPA2607-Q1	VSSOP (8)	3.00mm × 3.00mm

(1) 利用可能なすべてのパッケージについては、このデータシートの末尾にある注文情報を参照してください。

V _{S-}	4	—	Negative (lowest) supply or ground (for single-supply operation)
V _{S+}	8	—	Positive (highest) supply

7 Specifications

7.1 Absolute Maximum Ratings

Over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
$(V_{S+}) - (V_{S-})$	Supply voltage, V_S		6	V
V_{IN+}, V_{IN-}	Input voltage	$(V_{S-}) - 0.5$	$(V_{S+}) + 0.5$	V
V_{ID}	Differential input voltage ⁽⁴⁾		±5	V
I_I	Continuous input current ⁽²⁾		±10	mA
I_O	Continuous output current ⁽³⁾		±20	mA
	Continuous power dissipation	See Thermal Information		
T_J	Maximum junction temperature		150	°C
T_A	Operating free-air temperature	-40	150	°C
T_{stg}	Storage temperature	-65	150	°C

- (1) Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not supported.
- (2) Input terminals are diode-clamped to the power-supply rails. Input signals that can swing more than 0.5 V beyond the supply rails should be current limited to 10 mA or less.
- (3) Short-circuit to ground, one amplifier per package.
- (4) Long term drift of offset voltage (> 1mV) if a differential input in excess of ≈ 2V is applied continuously between the IN+ and IN- pins at elevated temperatures.

7.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per AEC Q100-002 ⁽¹⁾	±2000	V
		Charged-device model (CDM), per AEC Q100-011	±1000	

- (1) AEC Q100-002 indicates that HBM stressing shall be in accordance with ANSI/ESDA/JEDEC JS-001 Specification

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V_S	Supply voltage ($V_{S+}) - (V_{S-})$	2.2		5.5	V
		±1.1		±2.75	
T_A	Ambient operating temperature	-40	25	125	°C

7.4 Thermal Information

THERMAL METRIC ⁽¹⁾		OPA607-Q1		UNIT
		DBV (SOT23)	DGK (VSSOP8)	
		5 PINS	8 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	196.5	179	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	118.7	71	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	64.5	101	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	41.1	13.7	°C/W
Ψ_{JB}	Junction-to-board characterization parameter	64.2	100	°C/W

8 Detailed Description

8.1 Overview

The OPAx607-Q1 devices are low-noise, rail-to-rail output (RRO) operational amplifiers (op amp). The devices operate from a supply voltage of 2.2 V to 5.5 V. The input common-mode voltage range also extends down to the negative rail allowing the OPAx607-Q1 to be used in most single-supply applications. Rail-to-rail output swing significantly increases dynamic range, especially in low-supply, voltage-range applications, which results in complete usage of the full-scale range of the consecutive analog-to-digital converters (ADCs). The decoupled architecture allows for a favorable tradeoff of low-quiescent current for a very-high gain-bandwidth product (GBW) and low-distortion performance in high-gain applications.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Operating Voltage

The OPAx607-Q1 operational amplifiers are fully specified and assured for operation from 2.2 V to 5.5 V, applicable from -40°C to $+125^{\circ}\text{C}$. The OPAx607-Q1 devices are completely operational with asymmetric, symmetric and single supply voltages applied across the supply pins. The total voltage (that is, $(V_{S+}) - (V_{S-})$) must be less than the supply voltage mentioned in [セクション 7.1](#).

8.3.2 Rail-to-Rail Output and Driving Capacitive Loads

Designed as a low-power, low-voltage operational amplifier, the OPAx607-Q1 devices are capable of delivering a robust output drive. For resistive loads of 10 k Ω , the output swings to within a few millivolts of either supply rail, regardless of the applied power-supply voltage. Different load conditions change the ability of the amplifier to swing close to the rails. The OPAx607-Q1 devices drive up to a nominal capacitive load of 47 pF on the output with no special consideration and without the need of a series isolation resistor R_{ISO} while still being able to achieve 45° of phase margin. When driving capacitive loads greater than 47 pF, TI recommends using R_{ISO} as shown in [図 8-1](#) in series with the output as close to the device as possible. Refer to [図 7-18](#) for looking up different values of R_{ISO} required for C_L to achieve 45° phase margin. Without R_{ISO} , the external capacitance (C_L) interacts with the output impedance (Z_O) of the amplifier, resulting in stability issues. Inserting R_{ISO} isolates C_L from Z_O and restores the phase margin. [図 8-1](#) shows the test circuit.

図 8-1. Input Current Protection and Driving Capacitive Loads

[図 8-2](#) and [図 8-3](#) show the phase margin achieved with varying R_{ISO} with different values of C_L .

8.3.3 Input and ESD Protection

When the primary design goal is a linear amplifier with high CMRR, do not exceed the op amp input common-mode voltage range (V_{CM}). This CMRR is used to set the common-mode input range specifications in [セクション 7.1](#). The typical V_{CM} specifications for the OPAx607-Q1 devices are from the negative rail to 1.1 V below the positive rail. Assuming the op amp is in linear operation, the voltage difference between the input pins is small (ideally 0 V) and the input common-mode voltage can be analyzed at either input pin; the other input pin is assumed to be at the same potential. The voltage at V_{IN+} is easy to evaluate. In a noninverting configuration ([図 8-1](#)) the input signal, V_{IN+} , must not exceed the V_{CM} rating. However, in an inverting amplifier configuration, V_{IN+} must be connected to the voltage within V_{CM} . The input signal applied at V_{IN-} can be any voltage, such that the output voltage swings with a headroom of 10 mV from either of the supply rails.

The input voltage limits have fixed headroom to the power rails and track the power-supply voltages. For single 5-V supply, the linear input voltage range is 0 V to 3.9 V and with a 2.2-V supply this range is 0 V to 1.1 V. The headroom to each power-supply rail is the same in either case: 0 V and 1.1 V. A weak NMOS input pair from V_{IN+} to $V_{IN+} - 1.1$ V ensures that an output phase reversal issue does not occur when the V_{CM} is violated.

図 8-4. Internal ESD Structure

The OPAx607-Q1 devices also incorporate internal electrostatic discharge (ESD) protection circuits on all pins. For the input and output pins, this protection primarily consists of current-steering diodes connected between the input and power-supply pins. These ESD protection diodes provides input overdrive protection, as long as the current is limited with a series resistor to 10 mA, as stated in [セクション 7.1](#). [図 8-1](#) shows a series input resistor can be added to the driven input to limit the input current.

8.3.4 Decompensated Architecture with Wide Gain-Bandwidth Product

Amplifiers such as the OPAx607-Q1 devices are not unity-gain stable are referred to as *decompensated amplifiers*. The decompensated architecture typically allows for higher GBW, higher slew rate, and lower noise compared to a unity-gain stable amplifier with similar quiescent currents. The increased available bandwidth reduces the rise time and the settling time of the op amp, allowing for sampling at faster rates in an ADC-based signal chain.

As shown in [Figure 8-5](#), the dominant pole f_d is moved to the frequency f_1 in the case of a decompensated op amp. The solid A_{OL} plot is the open-loop gain plot of a traditional unity-gain stable op amp. The change in internal compensation in a decompensated amp such as the OPAx607-Q1, increase the bandwidth for the same amount of power. That is, the decompensated op amp has an increased bandwidth to power ratio when compared to a unity-gain stable op amp of equivalent architecture. Besides the advantages in the above mentioned parameters, an increased slew rate and a better distortion (HD2 and HD3) value is achieved because of the higher available loop-gain, compared to its unity-gain counterpart. The most important factor to consider is ensuring that the op amp is in a noise gain (NG) greater than G_{min} . A value of NG lower than G_{min} results in instability, as shown in [Figure 8-5](#), because the $1/\beta$ curve intersects the A_{OL} curve at 40 dB/decade. This method of analyzing stability is called the *rate of closure method*. See the [precision lab training videos](#) from TI for a better understanding on device stability and for different techniques of ensuring stability.

Figure 8-5. Gain vs Frequency Characteristics for a Unity-Gain Stable Op Amp and a Decompensated Op Amp

The OPAx607-Q1 devices are stable in a noise gain of 6 V/V (15.56 dB) or higher in conventional gain circuits; see [Figure 8-6](#). The device has 9 MHz of small-signal bandwidth (SSBW) in this gain configuration with approximately 65° of phase margin. The high GBW and low voltage noise of the OPAx607-Q1 devices make them suitable for general-purpose, high-gain applications.

8.4 Device Functional Modes

The Automotive grade of the OPAx607-Q1 family has only one functional modes: normal operating mode. The PD mode exists only in some of the packages made available in the industrial grade of the OPAx607-Q1 family.

8.4.1 Normal Operating Mode

The OPAx607-Q1 devices are operational when the power-supply voltage is between 2.2 V (± 1.1 V) and 5.5 V (± 2.75 V). Most newer systems use a single power supply to improve efficiency and simplify the power tree design. The OPAx607-Q1 devices can be used with a single-supply power (V_{S-} connected to GND) with no change in performance from split supply, as long as the input and output pins are biased within the linear operating region of the device. The valid input and output voltage ranges are given in [セクション 7.5](#). The outputs nominally swing rail-to-rail with approximately 10-mV headroom required for linear operation. The inputs can typically swing up to the negative rail (typically ground) and to within 1.1 V from the positive supply. [図 8-6](#) shows changing from a ± 2.5 -V split supply to a 5-V single-supply.

图 8-6. Single-Supply and Dual-Supply Operation

9 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The OPAx607-Q1 devices feature a 50-MHz GBW with 900 μA of supply current, providing good AC performance at low-power consumption. The low input noise voltage of $3.8 \text{ nV}/\sqrt{\text{Hz}}$, the approximate pA of bias current, and a typical input offset voltage of 0.1 mV make the device very suitable for both AC and DC applications.

9.2 Typical Applications

9.2.1 100-k Ω Gain Transimpedance Design

The high GBW and low input voltage and current noise for the OPAx607-Q1 devices make it an excellent wideband transimpedance amplifier for moderate to high transimpedance gains.

图 9-1. Wideband, High-Sensitivity, Transimpedance Amplifier

9.2.1.1 Design Requirements

Design a high-bandwidth, high-transimpedance-gain amplifier with the design requirements shown in 表 9-1.

表 9-1. Design Requirements

TARGET BANDWIDTH (MHz)	TRANSIMPEDANCE-GAIN (k Ω)	PHOTODIODE CAPACITANCE (pF)
2	100	3

9.2.1.2 Detailed Design Procedure

Designs that require high bandwidth from a large area detector with relatively high transimpedance-gain benefit from the low input voltage noise of the OPAx607-Q1 devices. Use the Excel™ calculator available at [What You Need To Know About Transimpedance Amplifiers – Part 1](#) to help with the component selection based on total input capacitance and C_{TOT}. C_{TOT} is referred as C_{IN} in the calculator. C_{TOT} is the sum of C_D, C_{DIFF}, and C_{CM} which is 20 pF. Using this value of C_{TOT}, and the targeted closed-loop bandwidth (f_{-3dB}) of 2 MHz and transimpedance gain of 100 kΩ results in amplifier GBW of approximately 50 MHz and a feedback capacitance (C_F) of 1.1 pF as shown in [Figure 9-2](#). These results are for a Butterworth response with a Q = 0.707 and a phase margin of approximately 65° which corresponds to 4.3% overshoot.

Calculator II		
Closed-loop TIA Bandwidth (f _{-3dB})	2.00	MHz
Feedback Resistance (R _F)	100.00	kOhm
Input Capacitance (C _{IN})	20.00	pF
Opamp Gain Bandwidth Product (GBP)	50.27	MHz
Feedback Capacitance (C _F)	1.110	pF

Figure 9-2. Results of Inputting Design Parameters in the TIA Calculator

The OPA607-Q1's 50 MHz GBW, is suitable for the above design requirements. If the required feedback capacitance C_F comes out to be a very low value capacitor to be practically achievable, a T-Network capacitor circuit as shown below can be used. A very low capacitor value (C_{EQ}) can be achieved between Port₁ and Port₂ using standard value capacitors in a T-Network circuit as shown in [Figure 9-3](#).

$$C_{EQ} = \frac{C_1 \times C_2}{C_1 + C_2 + C_T} \quad (1)$$

Figure 9-3. T-Network

9.2.1.3 Application Curves

9.2.2 Noninverting Gain of 3 V/V

The OPAx607-Q1 devices are normally stable in noise gain configurations (see [SBOA066](#)) of greater than 6 V/V when conventional feedback networks are used, which is discussed in [セクション 8.3.4](#). The OPAx607-Q1 devices can be configured in noise gains of less than 6 V/V by using capacitors in the feedback path and between the inputs to maintain the desired gain at lower frequencies and increase the gain greater than 6 V/V at higher frequencies such that the amplifier is stable. Configuration (a) in [図 9-6](#) shows OPAx607-Q1 devices configured in a gain of 3 V/V by using capacitors and resistors to shape the noise gain and achieve a phase margin of approximately 56° that is very close to the phase margin achieved for the conventional 6 V/V configuration (b) in [図 9-6](#).

The key benefit of using a decompensated amplifier (such as the OPAx607-Q1) below the minimum stable gain, is that it takes advantage of the low noise and low distortion performance at quiescent powers smaller than comparable unity-gain stable architectures. By reducing the 100-pF input capacitor, higher closed-loop bandwidth can be achieved at the expense of increased peaking and reduced phase margin. Ensure that low parasitic capacitance layout techniques on the IN– pin are as small as 1 pF to 2 pF of parasitic capacitance on the inverting input, which will require tweaking the noise-shaping component values to get a flat frequency response and the desired phase margin. Configurations in [図 9-6](#) does not take into account this parasitic capacitance but it must be considered for practical purposes. Details on the benefits of decompensated architectures are discussed in [Using a decompensated op amp for improved performance](#). The *one-capacitor, externally compensated type* method is used for noise gain shaping in the below circuit.

In a difference amplifier circuit, typically used for low side current sensing applications, the (noise gain) = (signal gain + 1).

図 9-6. Noninverting Gain of 3 V/V, 6 V/V Configurations, and Difference Amplifier in Signal Gain of 2 V/V

图 9-7. Small-Signal Frequency Response in Gains of 3V/V (a) and 6V/V (b)

图 9-8. Small-Signal Frequency Response of Difference Amplifier (c) With and Without Noise Gain Shaping

9.2.3 High-Input Impedance (Hi-Z), High-Gain Signal Front-End

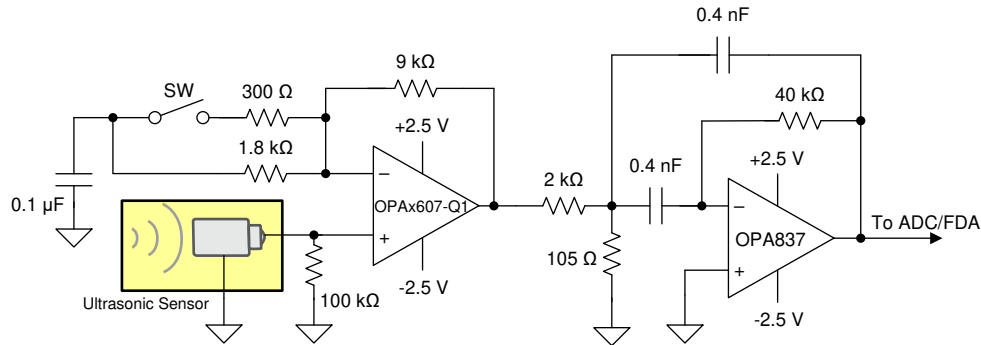

图 9-9. Hi-Z, High-Gain Front-End Circuit

9.2.3.1 Design Requirements

The objective is to design a high-input impedance, high-dynamic range, signal-conditioning front-end. An example application for such a front-end circuit is the receive signal chain in an ultrasonic-based end equipment (EE) such as fish finders, printers and flow meters. 表 9-2 lists the design requirements for this application.

表 9-2. Design Parameters

PARAMETER	DESIGN REQUIREMENT
Amplifier supply	±2.5 V
Input signal frequency	200 kHz
Minimum voltage	300 μVrms
Minimum SNR at 300 μVrms	40 dB

9.2.3.2 Detailed Design Procedure

To achieve a SNR of greater than 40 dB for signals from 300 μ Vrms to 30 mV the front-end stage has two gain settings: 6 V/V and 31 V/V. The SW (switch, relay, or analog mux) can be dynamically toggled to ensure maximum sensitivity to the receiving signal. The OPAX607-Q1 devices prove to be an attractive solution for this front-end signal chain because of the right balance of low noise and high input impedance. The ultrasonic sensors (for example, piezo crystal) have high output impedance. The OPAX607-Q1 devices have an input bias current of 20 pA (maximum). This small bias current results in reduced distortion and signal loss across the source impedance when compared with a bipolar amplifier with input bias currents in the range of a few hundreds of nano-amperes. The OPAX607-Q1's high-gain front-end is followed by a narrowband band-pass filter that is tuned to a 200-kHz center frequency. The narrowband filter is designed using the OPA837. OPA837 can be used as a variable gain mux / PGA as shown in TIDA-01565. In this application section the OPA837-based band-pass filter was designed using the techniques mentioned in the [Filter Design in Thirty Seconds application report](#).

 9-11 shows the frequency response of circuit in  9-9. As shown in  9-11, the frequency response is a high-Q factor band-pass filter centered around 200 kHz. Designing such a high-Q band-pass filter helps eliminate white band noise along with other interferences present in the circuitry, resulting in a high SNR signal chain. The OPAX607-Q1's front-end combined with the OPA837-based band-pass filter help to achieve a total gain of 33 dB (44 V/V) or 50 dB (316 V/V) based on the SW (switch) position.

9.2.3.3 Application Curves

9.2.4 Low-Cost, Low Side, High-Speed Current Sensing

图 9-12. Low Side Current Sensing

9.2.4.1 Design Requirements

The objective is to design a high-speed, high-gain bidirectional current-sensing circuit for power systems and motor drive systems. [セクション 9.2.4.2](#) lists the design requirements of this application.

表 9-3. Design Parameters

PARAMETER	DESIGN REQUIREMENT
Amplifier and ADC supply	3.3 V
Peak current to be measured from load to ground	20 A
Peak current to be measured from ground to load	12 A
Required Accuracy of current measurement	0.1%
Signal-Setting time at ADC input	< 1 μs
Current sensing direction	Bidirectional

9.2.4.2 Detailed Design Procedure

The aim of this application section is to measure bidirectional current with relatively high accuracy in a low-side-sensing-based, high-frequency switching system.

As shown in [图 9-12](#), a single op amp of high bandwidth is capable of sensing current in a high gain configuration as well as have the required effective bandwidth to drive the consecutive SAR ADC input. The SAR ADC can be a standalone ADC or integrated inside a Micro-controller.

$$V_{OUT} = (20 \text{ k}\Omega / 1 \text{ k}\Omega \times V_{DIFF}) + V_{REF}, \text{ where } V_{DIFF} = I_{SH} \times R_{SH} \quad (2)$$

The reference voltage is 1.24 V. When the I_{SH} flowing across R_{SH} equals zero, the V_{OUT} of the difference amplifier sits ideal at 1.24 V.

When the current (I_{SH}) flows from LOAD to GND, the output of the OPAx607-Q1 increase above 1.24 V with a value equal to $20 \times V_{SH}$ and when the current flows from GND to LOAD (in the opposite direction) the output of the OPAx607-Q1 decrease below 1.24 V with a value proportional to $20 \times V_{SH}$.

One of the main challenges in a high speed current sensing design is to choose an op amp of with sufficient GBW that can drive a SAR ADC, while still being able to gain the signal by the required amount. The 0.1% and 0.01% settling of OPAx607-Q1 can found in [セクション 7.5](#). Another key care about is to ensure the op amp output rises in less than 1 μs so as to feed the output to a comparator for short-circuit protection. This comparator based short circuit protection loop is extremely fast and enables to turn off the switching devices very quickly. This requirement makes a low cost high speed part like the OPAx607-Q1 very desirable in a current-sensing circuit. Equation of the rise time as a function of bandwidth is shown below.

$$t_R \text{ (10\% to 90\%)} = 0.35 \text{ Hz / BW} \tag{3}$$

For an ADC like ADS7042 running at a sampling rate of 500 kSPS of a clock of 12.5 MHz, the effective bandwidth of the op amp required to drive such an ADC is approximately 2.7 MHz. See the [TI precision lab](#) videos on driving SAR ADCs to understand the underlying calculation. The OPAx607-Q1 has a GBW of 50 MHz. With a gain of 20 V/V, the closed loop bandwidth turns out to approximately 2.5 MHz, making this device the most suitable, cost-optimized amplifier for this application. The RC charge bucket (240 Ω and 688 pF in [Figure 9-12](#)) designed at the input of the SAR ADC is derived from the calculations provided in the SAR ADC precision lab videos. The fundamental concept behind the design of this charge bucket filter is to ensure that the sample and hold capacitor is charged to the required final voltage within the acquisition window of the ADC.

As shown in [Figure 9-14](#), a DC accuracy of higher than 0.05% is achieved with the OPAx607-Q1. The simulations are captured with and without voltage offset calibration. Frequency response shown in [Figure 9-13](#) indicate different signal bandwidth at V_{OUT} , V_{ADC} and with and without C_F of 220 pF.

9.2.4.3 Application Curves

10 Power Supply Recommendations

The OPAx607-Q1 devices are specified for operation from 2.2 V to 5.5 V (± 1.1 V to ± 2.75 V), applicable from -40°C to $+125^\circ\text{C}$. Place 0.1- μF bypass capacitors close to the power-supply pins to reduce errors coupling in from noisy or high-impedance power supplies.

CAUTION

Supply voltages larger than 6 V can permanently damage the device (see [セクション 7.1](#)).

For more detailed information on bypass capacitor placement, see [セクション 11.1](#).

11 Layout

11.1 Layout Guidelines

For best operational performance of the device, use good printed circuit board (PCB) layout practices, including:

- Noise can propagate into analog circuitry through the power-supply pins of the circuit as a whole and of the operational amplifier. Bypass capacitors are used to reduce the coupled noise by providing low-impedance power sources local to the analog circuitry.
 - Connect low-equivalent series resistance (ESR), 0.1- μ F ceramic bypass capacitors between each supply pin and ground, placed as close to the device as possible. A single bypass capacitor from V+ to ground is applicable for single-supply applications.
- Separate grounding for analog and digital portions of the circuitry is one of the simplest and most effective methods of noise suppression. One or more layers on multilayer PCBs are usually devoted to ground planes. A ground plane helps distribute heat and reduces electromagnetic interference (EMI) noise pickup. Make sure to physically separate digital and analog grounds, paying attention to the flow of the ground current.
- To reduce parasitic coupling, run the input traces as far away from the supply or output traces as possible. If these traces cannot be kept separate, crossing the sensitive trace perpendicularly is much better than crossing in parallel with the noisy trace.
- Place the external components as close to the device as possible. Keeping R_F and R_G close to the inverting input minimizes parasitic capacitance; see [Figure 11-1](#) and [Figure 11-2](#).
- Keep the length of input traces as short as possible. Always remember that the input traces are the most sensitive part of the circuit.
- Consider a driven, low-impedance guard ring around the critical traces. A guard ring can significantly reduce leakage currents from nearby traces that are at different potentials.

12.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

13 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
OPA2607QDGKRQ1	ACTIVE	VSSOP	DGK	8	2500	RoHS & Green	NIPDAU	Level-1-260C-UNLIM	-40 to 125	2FST	Samples
OPA607QDBVRQ1	ACTIVE	SOT-23	DBV	5	3000	RoHS & Green	NIPDAU	Level-1-260C-UNLIM	-40 to 125	6QBV	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
