JAJSI82B – MARCH 2014 – REVISED NOVEMBER 2019

TCA9543A 低電圧、2 チャネル、I²C バス・スイッチ、割り込みロジック / リセット機能付き

1 特長

- 1 対 2 の双方向変換スイッチ
- I²C バスおよび SMBus 互換
- 2 つのアクティブ LOW 割り込み入力
- アクティブ LOW の割り込み出力
- アクティブ LOW のリセット入力
- 2 本のアドレス・ピンにより、最大 4 個の TCA9543A を I²C バスに接続可能
- I²C バス経由で、任意の組み合わせのチャネルを選択可能
- 電源オン時は、すべてのスイッチ・チャネルが選択解除された状態
- 低い R_{ON} のスイッチ
- 1.8V、2.5V、3.3V、5V の各電圧のバス間で電圧レベルを変換
- 電源オン時のグリッチなし
- 活線挿抜をサポート
- 小さいスタンバイ電流
- 動作電源電圧範囲：1.65V～5.5V
- 5.5V 許容の入力
- 0～400kHz のクロック周波数
- JESD 78 準拠で 100mA 超のラッチアップ性能
- JESD 22 を超える ESD 保護
  - 4000V、人体モデル (A114-A)
  - 1500V、デバイス帯電モデル (C101)

2 アプリケーション

- サーバー
- ルーター (テレコム・スイッチング機器)
- ファクトリ・オートメーション
- I²C スレーブ・アドレス競合がある製品 (複数の同一温度センサなど)

3 概要

TCA9543A は、I²C バスで制御するデュアル双方向変換スイッチです。SCL/SDA の上流ペアが 2 つの下流ペア (チャネル) にファンアウトされます。プログラム可能な制御レジスタの設定により、個々の SCn/SDn チャネルまたは両方のチャネルを選択できます。2 つの割り込み入力 ($\overline{INT1}$～$\overline{INT0}$、各下流ペアに 1 つ) を備えています。1 つの割り込み出力 ($\overline{INT}$) が 2 つの割り込み入力の論理積として機能します。

アクティブ LOW のリセット入力 ($\overline{RESET}$) により、TCA9543A は下流の I²C バスの 1 つが LOW 状態に固着した状況から回復できます。$\overline{RESET}$ を LOW にすると、I²C ステート・マシンがリセットされ、両方のチャネルが選択解除されます (内部のパワー・オン・リセット機能と同様)。

5 概要（続き）

スイッチのパス・ゲートは、TCA9543A が出力する最大 HIGH 電圧を VCC ピンで制限できるように構成されています。これによって、ペアごとに異なるバス電圧を使用できるため、1.8V、2.5V、3.3Vの部品が、追加保護の必要なしに5Vの部品と通信を行えます。外付けのプルアップ抵抗により、各チャネルに求められる電圧レベルにバスをプルアップします。すべての I/O 端子は 5.5V 許容です。

PIN		DESCRIPTION
NO.	NAME	
1	A0	Address input 0. Connect directly to V_{CC} or ground.
2	A1	Address input 1. Connect directly to V_{CC} or ground.
3	$\overline{\text{RESET}}$	Active-low reset input. Connect to V_{CC} or V_{DPUM}(1) through a pull-up resistor, if not used.
4	$\overline{\text{INT0}}$	Active-low interrupt input 0. Connect to V_{DPU0}(1) through a pull-up resistor.
5	SD0	Serial data 0. Connect to V_{DPU0}(1) through a pull-up resistor.
6	SC0	Serial clock 0. Connect to V_{DPU0}(1) through a pull-up resistor.
7	GND	Ground
8	$\overline{\text{INT1}}$	Active-low interrupt input 1. Connect to V_{DPU1}(1) through a pull-up resistor.
9	SD1	Serial data 1. Connect to V_{DPU1}(1) through a pull-up resistor.
10	SC1	Serial clock 1. Connect to V_{DPU1}(1) through a pull-up resistor.
11	$\overline{\text{INT}}$	Active-low interrupt output. Connect to V_{DPUM}(1) through a pull-up resistor.
12	SCL	Serial clock line. Connect to V_{DPUM}(1) through a pull-up resistor.
13	SDA	Serial data line. Connect to V_{DPUM}(1) through a pull-up resistor.
14	VCC	Supply power

(1) V_{DPUX} is the pull-up reference voltage for the associated data line. V_{DPUM} is the master I^2C reference voltage while V_{DPU0} and V_{DPU1} are the slave channel reference voltages.

7 Specifications

7.1 Absolute Maximum Ratings(1)

over operating free-air temperature range (unless otherwise noted)

		MIN	MAX	UNIT
V_{CC}	Supply voltage range	–0.5	7	V
V_I	Input voltage range(2)	–0.5	7	V
I_I	Input current		±20	mA
I_O	Output current		±25	mA
	Continuous current through VCC		±100	mA
	Continuous current through GND		±100	mA
P_{tot}	Total power dissipation		400	mW
T_A	Operating free-air temperature range	–40	85	°C
T_{stg}	Storage temperature range	–60	150	°C

(1) Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) The input negative-voltage and output voltage ratings may be exceeded if the input and output current ratings are observed.

7.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001(1)	±4000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101(2)	±1500	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions(1)

			MIN	MAX	UNIT

9 Detailed Description

9.1 Overview

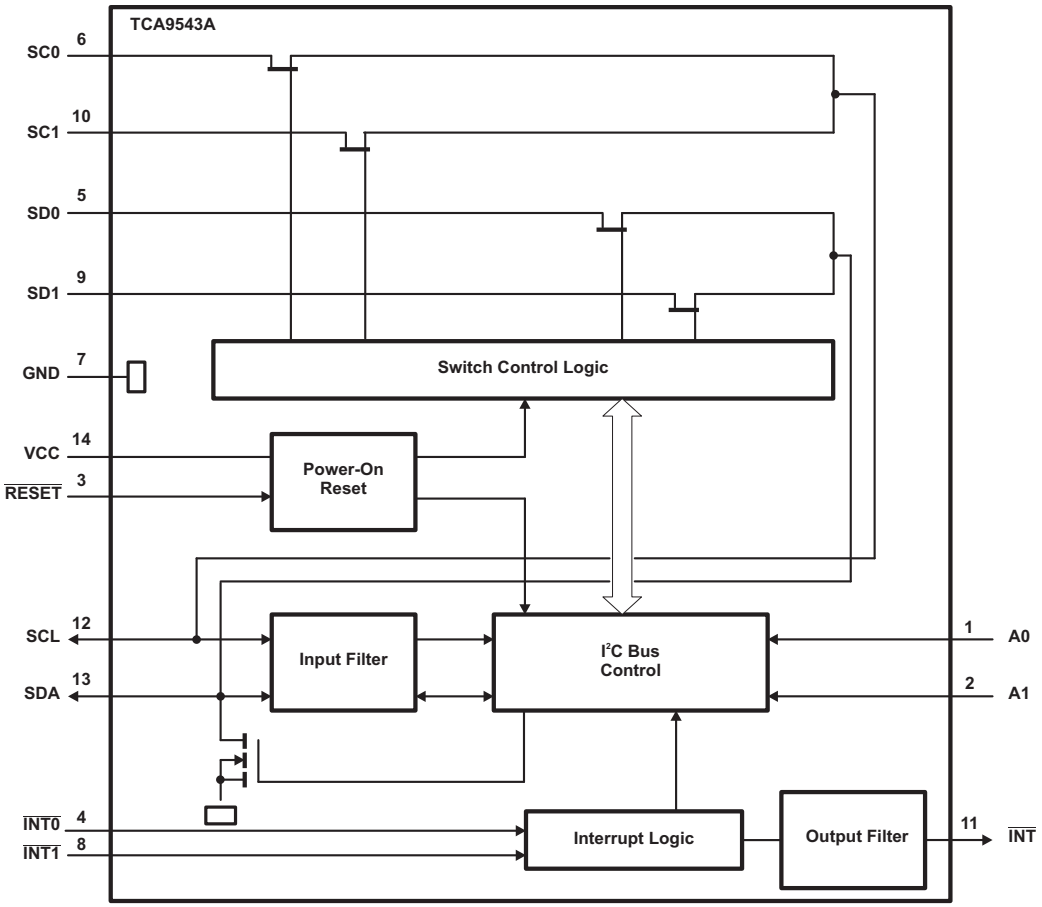
The TCA9543A is a 2-channel, bidirectional translating I^2C switch. The master SCL/SDA signal pair is directed to two channels of slave devices, SC0/SD0-SC1/SD1. Either individual downstream channel can be selected as well as both channels. The TCA9543A also supports interrupt signals in order for the master to detect an interrupt on the $\overline{INT}$ output terminal that can result from any of the slave devices connected to the $\overline{INT1}$-$\overline{INT0}$ input terminals.

The device offers an active-low $\overline{RESET}$ input which resets the state machine and allows the TCA9543A to recover should one of the downstream I^2C buses get stuck in a low state. The state machine of the device can also be reset by cycling the power supply, V_{CC}, also known as a power-on reset (POR). Either using the $\overline{RESET}$ function or causing a POR will cause both channels to be deselected.

The connections of the I^2C data path are controlled by the same I^2C master device that is switched to communicate with multiple I^2C slaves. After the successful acknowledgment of the slave address (hardware selectable by A0 and A1 terminals), a single 8-bit control register is written to or read from to determine the selected channels and state of the interrupts.

The TCA9543A may also be used for voltage translation, allowing the use of different bus voltages on each SCn/SDn pair such that 1.8-V, 2.5-V, or 3.3-V parts can communicate with 5-V parts. This is achieved by using external pull-up resistors to pull the bus up to the desired voltage for the master and each slave channel.

9.2 Functional Block Diagram



9.3 Feature Description

The TCA9543A is a dual channel bidirectional translating switch for I^2C buses that supports Standard-Mode (100 kHz) and Fast-Mode (400 kHz) operation. The TCA9543A features I^2C control using a single 8-bit control register in which bits 1 and 0 control the enabling and disabling of the two switch channels of I^2C data flow. The TCA9543A also supports interrupt signals for each slave channel and this data is held in bits 5 and 4 of the control register. Depending on the application, voltage translation of the I^2C bus can also be achieved using the TCA9543A to allow 1.8-V, 2.5-V, or 3.3-V parts to communicate with 5-V parts. Additionally, in the event that communication on the I^2C bus enters a fault state, the TCA9543A can be reset to resume normal operation using the $\overline{\text{RESET}}$ terminal feature or by a power-on reset which results from cycling power to the device.

9.4 Device Functional Modes

9.4.1 $\overline{\text{RESET}}$ Input

The $\overline{\text{RESET}}$ input can be used to recover the TCA9543A from a bus-fault condition. The registers and the I^2C state machine within this device initialize to their default states if this signal is asserted low for a minimum of t_{WL}. Both channels also are deselected in this case. $\overline{\text{RESET}}$ must be connected to V_{CC} through a pull-up resistor.

9.4.2 Power-On Reset

When power is applied to VCC, an internal power-on reset holds the TCA9543A in a reset condition until V_{CC} has reached V_{PORR}. At this point, the reset condition is released and the TCA9543A registers and I^2C state machine are initialized to their default states, all zeroes, causing all the channels to be deselected. Thereafter, V_{CC} must be lowered below V_{PORF} to reset the device.

9.5 Programming

9.5.1 I^2C Interface

The I^2C bus is for two-way, two-line communication between different ICs or modules. The two lines are a serial data line (SDA) and a serial clock line (SCL). Both lines must be connected to a positive supply via a pullup resistor when connected to the output stages of a device. Data transfer may be initiated only when the bus is not busy.

One data bit is transferred during each clock pulse. The data on the SDA line must remain stable during the high period of the clock pulse as changes in the data line at this time is interpreted as control signals (see Figure 8).

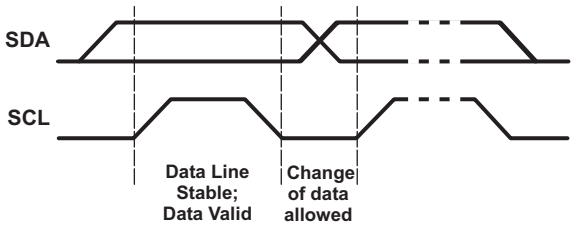


Figure 8. Bit Transfer

Both data and clock lines remain high when the bus is not busy. A high-to-low transition of the data line while the clock is high is defined as the start condition (S). A low-to-high transition of the data line while the clock is high is defined as the stop condition (P) (see Figure 9).

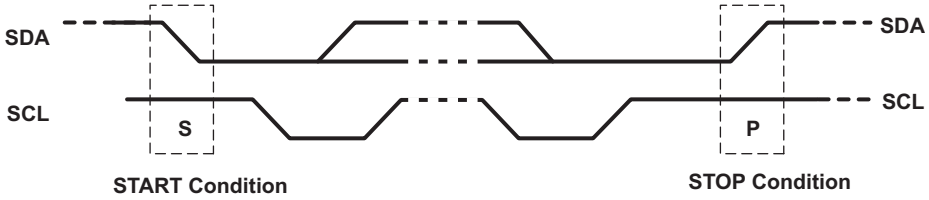

Figure 9. Definition of Start and Stop Conditions

Programming (continued)

A device generating a message is a transmitter; a device receiving a message is the receiver. The device that controls the message is the master and the devices that are controlled by the master are the slaves (see Figure 10).

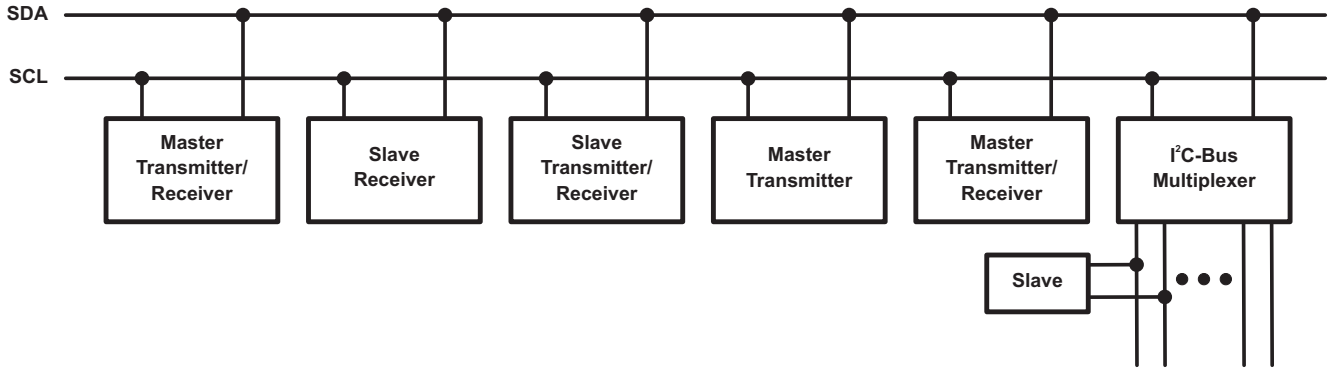

Figure 10. System Configuration

The number of data bytes transferred between the start and the stop conditions from transmitter to receiver is not limited. Each byte of eight bits is followed by one acknowledge (ACK) bit. The transmitter must release the SDA line before the receiver can send an ACK bit.

When a slave receiver is addressed, it must generate an ACK after the reception of each byte. Also, a master must generate an ACK after the reception of each byte that has been clocked out of the slave transmitter. The device that acknowledges must pull down the SDA line during the ACK clock pulse, so that the SDA line is stable low during the high pulse of the ACK-related clock period (see Figure 11). Setup and hold times must be taken into account.

A master receiver must signal an end of data to the transmitter by not generating an acknowledge (NACK) after the last byte has been clocked out of the slave. This is done by the master receiver by holding the SDA line high. In this event, the transmitter must release the data line to enable the master to generate a stop condition.

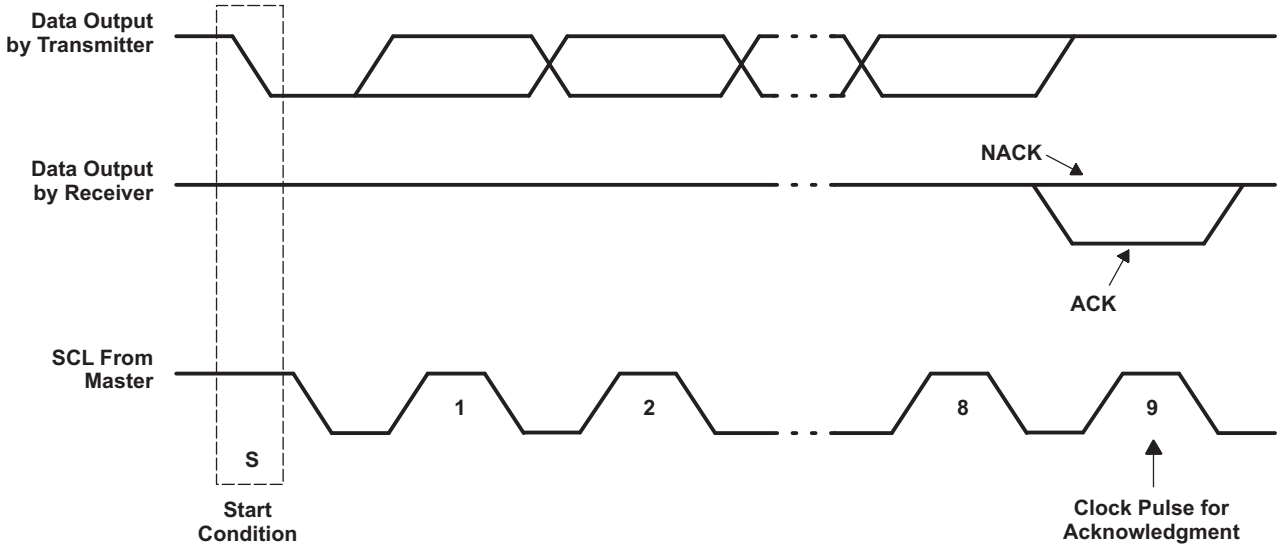

Figure 11. Acknowledgment on I²C Bus

Data is transmitted to the TCA9543A control register using the write mode shown in Figure 12.

Programming (continued)

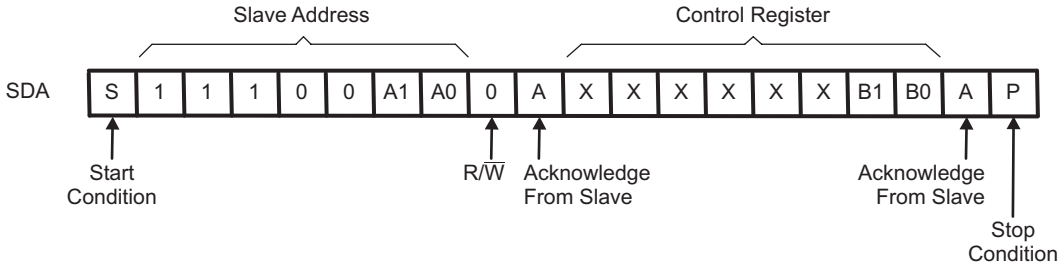

Figure 12. Write Control Register

Data is read from the TCA9543A control register using the read mode shown in Figure 13.

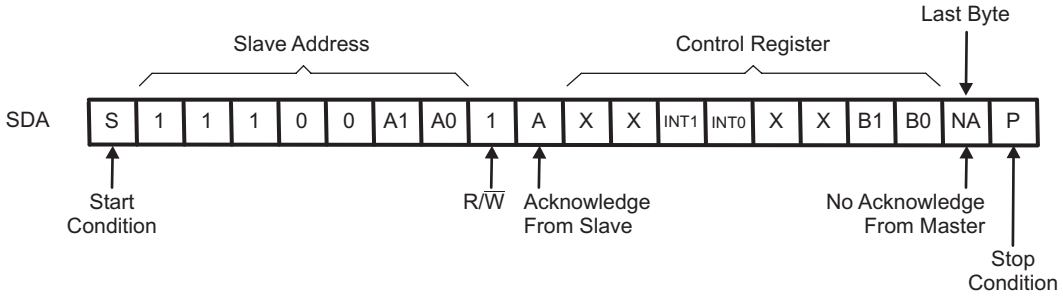

Figure 13. Read Control Register

9.6 Register Maps

9.6.1 Device Address

Following a start condition, the bus master must output the address of the slave it is accessing. The address of the TCA9543A is shown in Figure 14. To conserve power, no internal pullup resistors are incorporated on the hardware-selectable address terminals and they must be pulled high or low.

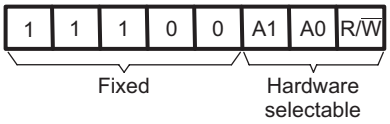

Figure 14. Slave Address TCA9543A

The last bit of the slave address defines the operation to be performed. When set to a logic 1, a read is selected, while a logic 0 selects a write operation.

9.6.2 Control Register Description

Following the successful acknowledgment of the slave address, the bus master sends a byte to the TCA9543A, which is stored in the control register (see Figure 15). If multiple bytes are received by the TCA9543A, it saves the last byte received. This register can be written and read via the I^2C bus.

Register Maps (continued)

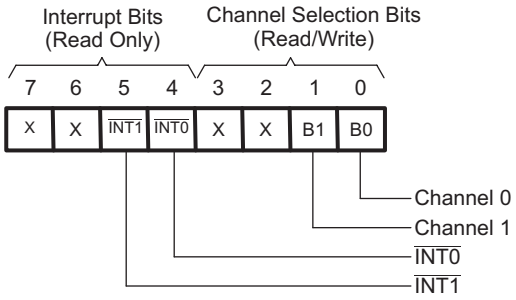

Figure 15. Control Register

9.6.3 Control Register Definition

One or both SCn/SDn downstream pairs, or channels, are selected by the contents of the control register (see Table 1). After the TCA9543A has been addressed, the control register is written. The two LSBs of the control byte are used to determine which channel or channels are to be selected. When a channel is selected, the channel becomes active after a stop condition has been placed on the I^2C bus. This ensures that all SCn/SDn lines are in a high state when the channel is made active, so that no false conditions are generated at the time of connection. A stop condition must occur always right after the acknowledge cycle.

(1) Channel 0 and channel 1 can be enabled at the same time. Care should be taken not to exceed the maximum bus capacitance.

9.6.4 Interrupt Handling

The TCA9543A provides two interrupt inputs (one for each channel) and one open-drain interrupt output (see Table 2). When an interrupt is generated by any device, it is detected by the TCA9543A and the interrupt output is driven low. The channel does not need to be active for detection of the interrupt. A bit also is set in the control register.

Bit 4 and Bit 5 of the control register correspond to the $\overline{INT0}$ and $\overline{INT1}$ inputs of the TCA9543A, respectively. Therefore, if an interrupt is generated by any device connected to channel 1, the state of the interrupt inputs is loaded into the control register when a read is accomplished. Likewise, an interrupt on any device connected to channel 0 would cause bit 4 of the control register to be set on the read. The master then can address the TCA9543A and read the contents of the control register to determine which channel contains the device generating the interrupt. The master then can reconfigure the TCA9543A to select this channel, and locate the device generating the interrupt and clear it.

It should be noted that more than one device can provide an interrupt on a channel, so it is up to the master to ensure that all devices on a channel are interrogated for an interrupt.

The interrupt inputs may be used as general-purpose inputs if the interrupt function is not required.

If unused, interrupt input(s) must be connected to V_{CC} through a pull-up resistor.

10 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information

Applications of the TCA9543A will contain an I^2C (or SMBus) master device and up to two I^2C slave devices. The downstream channels are ideally used to resolve I^2C slave address conflicts. For example, if two identical digital temperature sensors are needed in the application, one sensor can be connected at each channel: 0 and 1. When the temperature at a specific location needs to be read, the appropriate channel can be enabled and the other channel switched off, the data can be retrieved, and the I^2C master can move on and read the next channel.

In an application where the I^2C bus will contain many additional slave devices that do not result in I^2C slave address conflicts, these slave devices can be connected to any desired channel to distribute the total bus capacitance across both channels. If both switches will be enabled simultaneously, additional design requirements must be considered (See *Design Requirements* and *Detailed Design Procedure*).

10.2 Typical Application

A typical application of the TCA9543A contains anywhere from 1 to 3 separate data pull-up voltages, V_{DPUX} , one for the master device (V_{DPUM}) and one for each of the selectable slave channels (V_{DPU0} and V_{DPU1}). In the event where the master device and both slave devices operate at the same voltage, then the pass voltage, V_{pass} = V_{DPUX}. Once the maximum V_{pass} is known, V_{cc} can be selected easily using Figure 17. In an application where voltage translation is necessary, additional design requirements must be considered (See *Design Requirements*).

Figure 16 shows an application in which the TCA9543A can be used.

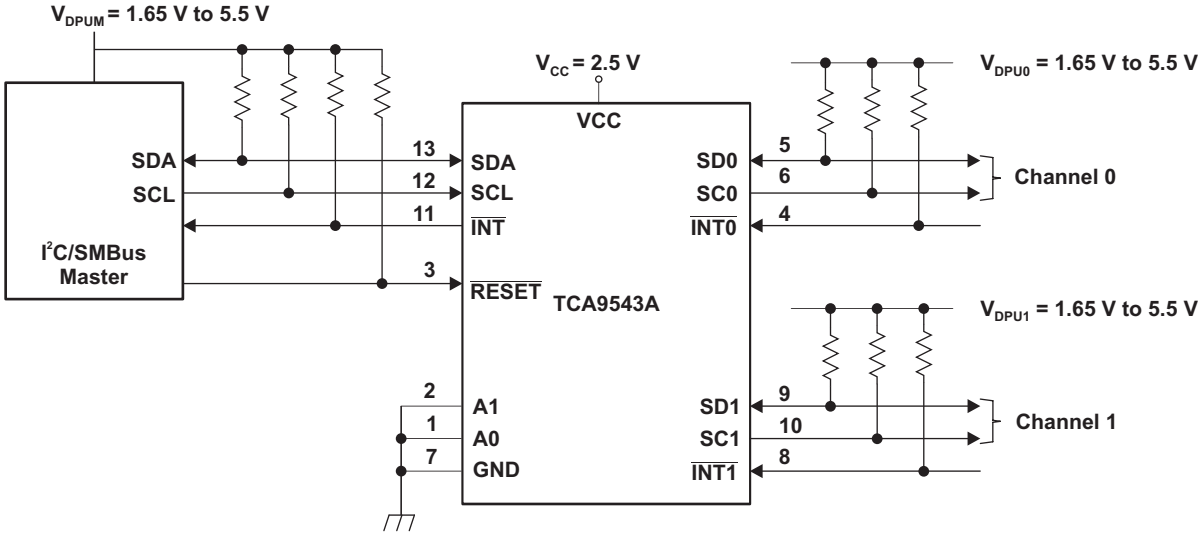

Figure 16. Typical Application Schematic

10.2.1 Design Requirements

The pull-up resistors on the $\overline{INT1}$-$\overline{INT0}$ terminals in the application schematic are not required in all applications. If the device generating the interrupt has an open-drain output structure or can be tri-stated, a pull-up resistor is required. If the device generating the interrupt has a push-pull output structure and cannot be tri-stated, a pull-up resistor is not required. The interrupt inputs should not be left floating in the application.

Typical Application (continued)

The A0 and A1 terminals are hardware selectable to control the slave address of the TCA9543A. These terminals may be tied directly to GND or V_{CC} in the application.

If both slave channels will be activated simultaneously in the application, then the total I_{OL} from SCL/SDA to GND on the master side will be the sum of the currents through all pull-up resistors, R_p.

The pass-gate transistors of the TCA9543A are constructed such that the V_{CC} voltage can be used to limit the maximum voltage that is passed from one I^2C bus to another.

Figure 17 shows the voltage characteristics of the pass-gate transistors (note that the graph was generated using data specified in the *Electrical Characteristics* section of this data sheet). In order for the TCA9543A to act as a voltage translator, the V_{pass} voltage must be equal to or lower than the lowest bus voltage. For example, if the main bus is running at 5 V and the downstream buses are 3.3 V and 2.7 V, V_{pass} must be equal to or below 2.7 V to effectively clamp the downstream bus voltages. As shown in Figure 17, $V_{pass(max)}$ is 2.7 V when the TCA9543A supply voltage is 4 V or lower, so the TCA9543A supply voltage could be set to 3.3 V. Pull-up resistors then can be used to bring the bus voltages to their appropriate levels (see Figure 16).

10.2.2 Detailed Design Procedure

Once all the slaves are assigned to the appropriate slave channels and bus voltages are identified, the pull-up resistors, R_p, for each of the buses need to be selected appropriately. The minimum pull-up resistance is a function of V_{DPUX}, $V_{OL,(max)}$, and I_{OL}:

$$R_{p(min)} = \frac{V_{DPUX} - V_{OL(max)}}{I_{OL}} \quad (1)$$

The maximum pull-up resistance is a function of the maximum rise time, t_r (300 ns for fast-mode operation, f_{SCL} = 400 kHz) and bus capacitance, C_b:

$$R_{p(max)} = \frac{t_r}{0.8473 \times C_b} \quad (2)$$

The maximum bus capacitance for an I^2C bus must not exceed 400 pF for fast-mode operation. The bus capacitance can be approximated by adding the capacitance of the TCA9543A, $C_{io(OFF)}$, the capacitance of wires/connections/traces, and the capacitance of each individual slave on a given channel. If both channels will be activated simultaneously, each of the slaves on both channels will contribute to total bus capacitance.

Typical Application (continued)

11 Power Supply Recommendations

The operating power-supply voltage range of the TCA9543A is 1.65-V to 5.5-V applied at the VCC terminal. When the TCA9543A is powered on for the first time or anytime the device needs to be reset by cycling the power supply, the power-on reset requirements must be followed to ensure the I^2C bus logic is initialized properly.

11.1 Power-On Reset Requirements

In the event of a glitch or data corruption, TCA9543A can be reset to its default conditions by using the power-on reset feature. Power-on reset requires that the device go through a power cycle to be completely reset. This reset also happens when the device is powered on for the first time in an application.

A power-on reset is shown in Figure 20.

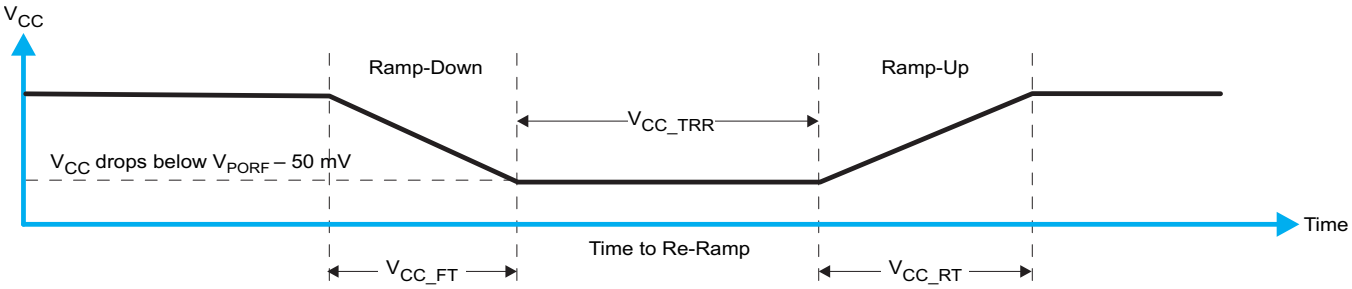

Figure 20. V_{CC} is Lowered Below the POR Threshold, Then Ramped Back Up to V_{CC}

Table 3 specifies the performance of the power-on reset feature for TCA9543A for both types of power-on reset.

Table 3. Recommended Supply Sequencing And Ramp Rates(1)

PARAMETER			MIN	TYP	MAX	UNIT
V_{CC_FT}	Fall time	See Figure 20	1		100	ms
V_{CC_RT}	Rise time	See Figure 20	0.1		100	ms
V_{CC_TRR}	Time to re-ramp (when V_{CC} drops below $V_{PORF(min)}$ – 50 mV or when V_{CC} drops to GND)	See Figure 20	40			µs
V_{CC_GH}	Level that V_{CC} can glitch down to, but not cause a functional disruption when V_{CC_GW} = 1 µs	See Figure 21			1.2	V
V_{CC_GW}	Glitch width that will not cause a functional disruption when V_{CC_GH} = 0.5 × V_{CC}	See Figure 21			10	µs
V_{PORF}	Voltage trip point of POR on falling V_{CC}	See Figure 22	0.8		1.25	V
V_{PORR}	Voltage trip point of POR on rising V_{CC}	See Figure 22	1.05		1.5	V

(1) All supply sequencing and ramp rate values are measured at T_A = 25°C

Glitches in the power supply can also affect the power-on reset performance of this device. The glitch width (V_{CC_GW}) and height (V_{CC_GH}) are dependent on each other. The bypass capacitance, source impedance, and device impedance are factors that affect power-on reset performance. Figure 21 and Table 3 provide more information on how to measure these specifications.

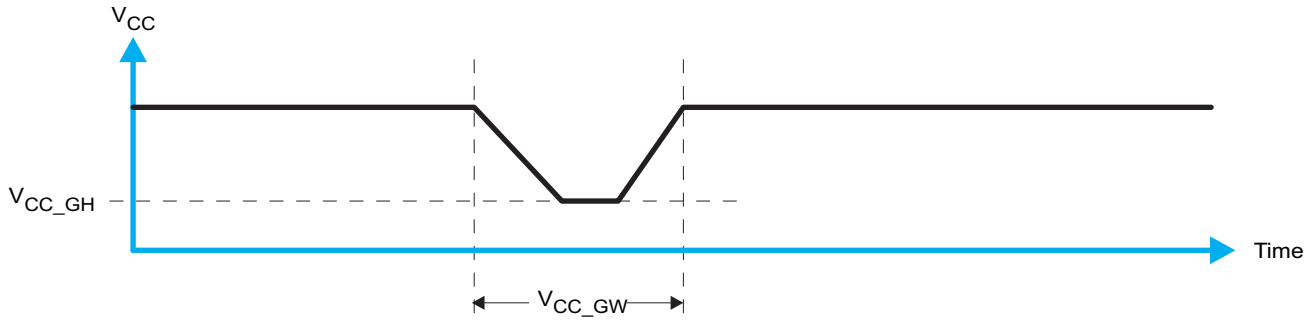

Figure 21. Glitch Width and Glitch Height

V_{POR} is critical to the power-on reset. V_{POR} is the voltage level at which the reset condition is released and all the registers and the I^2C/SMBus state machine are initialized to their default states. The value of V_{POR} differs based on the V_{CC} being lowered to or from 0. Figure 22 and Table 3 provide more details on this specification.

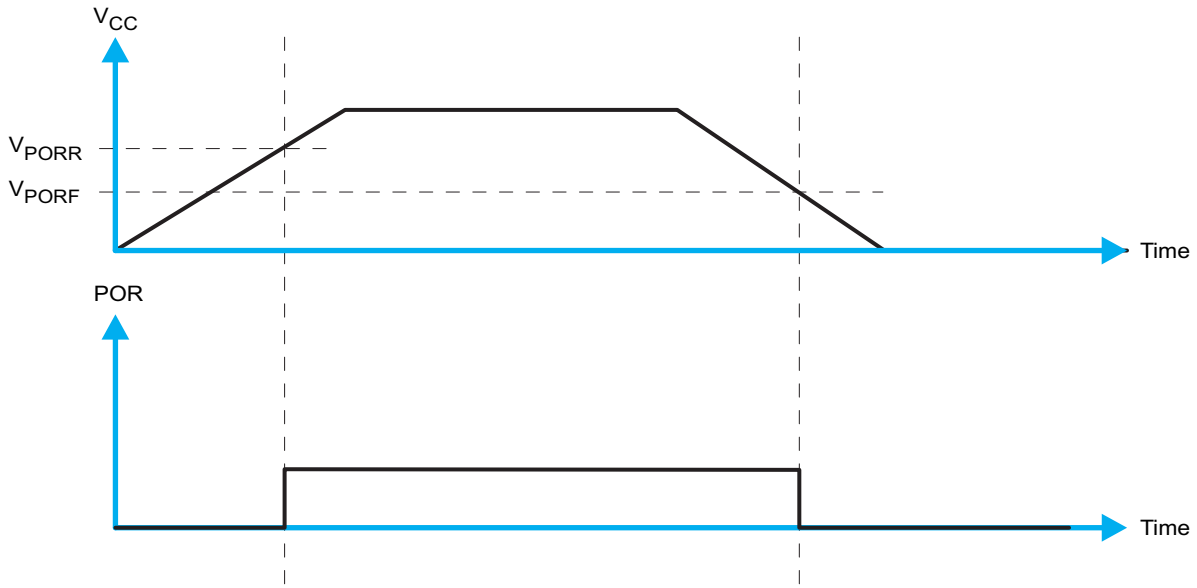

Figure 22. V_{POR}

12 Layout

12.1 Layout Guidelines

For PCB layout of the TCA9543A, common PCB layout practices should be followed but additional concerns related to high-speed data transfer such as matched impedances and differential pairs are not a concern for I^2C signal speeds. It is common to have a dedicated ground plane on an inner layer of the board and terminals that are connected to ground should have a low-impedance path to the ground plane in the form of wide polygon pours and multiple vias. By-pass and de-coupling capacitors are commonly used to control the voltage on the VCC terminal, using a larger capacitor to provide additional power in the event of a short power supply glitch and a smaller capacitor to filter out high-frequency ripple.

In an application where voltage translation is not required, all V_{DPUX} voltages and V_{CC} could be at the same potential and a single copper plane can connect all of the pull-up resistors to the appropriate reference voltage. In an application where voltage translation is required, V_{DPUM}, V_{DPU0}, and V_{DPU1}, may all be on the same layer of the board with split planes to isolate different voltage potentials.

To reduce the total I^2C bus capacitance added by PCB parasitics, data lines (SCn, SDn and $\overline{INTn}$) should be a short as possible and the widths of the traces should also be minimized (e.g. 5-10 mils depending on copper weight).

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
