Introduction

A major benefit of using a Hall effect sensor in position sense applications is that the sensor eliminates the physical contact required to determine position in mechanical designs. This occurs due to the permeation of magnetic flux from a nearby magnet, which can be used by a linear Hall effect sensor to produce an output that varies with the changing input field. The magnetic field permeates through air, dust and grime, plastics, and other generally non-ferromagnetic materials. As a result, the sensor can be conveniently placed anywhere a measurable magnetic field is present to provide feedback. One particular challenge that is present when using a linear output Hall effect sensor is that the magnetic flux density is inversely proportional to the square of the distance from the magnet. As a result, this adds some complexity to position calculations as linear steps produce a non-linear change on the output. While this can be calibrated for any particular magnet, one useful configuration is to orient the magnet and sensor in a slide-by configuration. Here, instead of traveling directly towards the sensor, the magnet travels just above the sensor in a linear path.

Slide-By for One Dimensional Sensors

As an example, consider the arrangement of a one-dimensional sensor, such as DRV5055 shown in Figure 1 with the magnet traveling either direction along the black line which is parallel to the Y axis. In this example, the pictured magnet is approximately 22 mm thick with a radius of approximately 3 mm.

In this configuration, the sensor detects the component of the field vector, which is directed along the Z-axis. The resulting input to the sensor over the course of travel for this magnet has an interesting behavior. There is a region approximately the same length of the magnet which produces a linear change in field. With this input, it is now simpler to monitor change in position by measuring in the linear input region.

Figure 2. Slide-By Input Field

This can also be easily adapted to increase overall stroke length through the addition of multiple sensors. The process involved with this type of design is discussed in greater detail in Linear Hall Effect Sensor Array Design.

Slide-By for 3D Sensors

The one dimensional case is limited in range by the length of the magnet. Travel outside the linear input region produces uncertainty in position as there are now two positions that map to the same input magnitude. The uncertainty is resolved by using a three dimensional sensor instead. With this sensor type, an input field shown in Figure 3 is displayed.

Figure 1. Slide-By Magnet Orientation

Figure 3. Slide-By Input Field for 3D Sensors
Using this input, three distinct input regions can be defined. The linear region provides the best correlation for linear motion, but based on the \( Y \) component, it is now possible to distinguish the direction approach of the magnet in the non-linear regions as well. Suppose a -6 mT limit is set for \( B_y \) to correspond to the peak values of \( B_z \).

When \( B_y \) exceeds this threshold, the magnet is known to be in the linear sensing region. For \( B_y \) below the threshold, then the sign of \( B_z \) indicates whether the approach is from the right or left. Calibrations can be used to determine the position in this non-linear region, and accuracy diminishes as the magnet moves further from the sensor.

Slide-By using Angle Calculations

A similar and advantageous approach uses a 3D sensor, but this time the magnet pole is directed normal to the sensor face rather than parallel. The magnetic field profile across the magnet travel is similar to the previous example.

As the magnet is moved along the \( Y \) axis, this motion produces inputs as shown in Figure 6. In this case, the magnet is much smaller than before with an approximate thickness of 5 mm and a radius of 3 mm. As a result of the orientation change of the magnet, the linear region is now observed on the \( B_y \) component. The width of this region for this particular case is only 6 mm.

Using this data, it is possible to use only \( B_y \) to track position, but using the arctangent function enables position detection over a much wider range.

Electrical Angle: \[ \theta = \arctan \left( \frac{B_z}{B_y} \right) \] (1)

Comparing the calculated electrical angle based on the magnetic field inputs to the actual mechanical angle between the magnet and sensor reveals an interesting behavior.

Figure 3. 3D Slide-By Input Field

Figure 4. Input Field Regions

Figure 5. Slide-By Mechanical Angle

Figure 6. Angle Measurement Inputs

Figure 7. Measured Angle vs. Position
While there is a significant error between these two calculations as a result of using magnetic field inputs which do not strictly follow a sinusoidal behavior, it is apparent that the general form of the electrical angle calculation follows the behavior of the mechanical angle. Given this similarity, it can be possible to adjust the electrical calculation to match the actual mechanical angle.

When using TMAG5170, it is possible to apply both a gain and offset correction to a single channel which can be represented as $\alpha$ and $\delta$, respectively. Additionally, it is apparent that a second scalar can be beneficial to decrease the overall magnitude. This scalar is represented by $\beta$. This correction can be applied by a microcontroller which is recording the outputs of TMAG5170. Closer analysis also shows that a scaling factor, $\gamma$, that increases with angle, can also be helpful in aligning the asymptotic behavior of the two curves at the furthest magnet positions. An example equation based alignment with each of these factors is shown in Equation 2 and Equation 3.

$$\theta' = \tan^{-1}\left(\alpha \times (B_z + \delta) B_y\right)$$  \hspace{1cm} (2)

$$\theta = \beta \times \theta' - \gamma \times \sin(\theta')$$  \hspace{1cm} (3)

### Bench Evaluation Tool

To enable demonstration of this function, see the attachment for TMAG5170 EVM shown in Figure 8. Files to enable 3D printing this attachment and physical geometry are available in TMAG5170 Slide-By Attachment.

### Figure 9. Configuration 1

### Figure 10. Configuration 2

### Figure 11. Configuration 3

Note that these results can vary from system to system as sensitivity error, offset, noise, and mechanical variations. These variations can impact these results, which are the theoretical best case behavior. Additional calibration factors can be implemented to improve overall accuracy.
