ABSTRACT

In applications like home inverter and UPS where high currents are measured using general-purpose op amps, measuring the current accurately is often challenging. Because low-resistance resistors are used to improve efficiency, the input offset of an op amp significantly contributes to the error in measured voltages. The INA181 device can help overcome this problem. This application note demonstrates current sensing using the INA181 to replace the traditional current sensing using general-purpose op amps. The INA181 has lower input offset voltage and is a low-cost device. The device can also operate at the high common-mode voltage of 26 V and can be used in low-side and high-side sensing. Because the INA181 can sense bidirectional current with the reference voltage, a single-channel device can replace the conventional way of using inverting and noninverting topology with general-purpose op amps. This application note also lists error calculations of the solution with reference voltage generated from the TL431 and TLV431 devices.

1 Introduction

1.1 High-Side and Low-Side Current Sensing

In high-side current sensing, the sense resistor is placed between the positive supply and load. In low-side current sensing, the sense resistor is placed between load and common ground. Figure 1 and Figure 2 show the high-side and low-side current sensors, respectively.

Figure 1. High-Side Current Sensor

Figure 2. Low-Side Current Sensor

Susceptibility to ground disturbance, parasitic error, and the inability to detect load shorts are major drawbacks in low-side current sensing. To implement high-side current sensing, op amps must have high CMRR and high common-mode voltage ranges. Unlike the low-side method, the high-side method provides protection against the load short.

1.2 Differential Current Sensing Approach

The errors caused by ground disturbance and parasitic resistance are avoided using a difference amplifier for current sensing. This approach can be used for low-side and high-side methods.

Figure 3. Difference Amplifier
1.3 Conventional Method

Figure 4 shows the conventional method using general-purpose op amps for bidirectional current sensing. This method is low-side current sensing, and the ground disturbance causes an error in the measured current value.

![Figure 4. Conventional Method of Current Sensing](image)

Other than ground disturbance and parasitic resistance errors, general-purpose op amps have an offset voltage in mV. Using the example of inverter application, if a general-purpose op amp has a 5-mV offset voltage, it causes an error of 5 A for a sense resistance of 1 mΩ. As a result, the wattage error is approximately 10%. In addition, ground disturbance and parasitic resistance add more error.

2 Current Sensing Using INA181

2.1 INA181

Important features of the INA181 device follow:

- Cost-optimized, bidirectional current-sense amplifier with accurate internal resistors
- Single-rail supply range: 2.7 V to 5.5 V
- Output swing to the supply voltage: \( V_{\text{supply}} - 0.02 \) V
- Common-mode voltage range: \(-0.2 \) V to 26 V
- Offset voltage:
  - 150 µV at \( V_{\text{CM}} = 0 \) V
  - 500 µV at \( V_{\text{CM}} = 12 \) V
- Accuracy:
  - Maximum gain error of 1%
  - Maximum offset drift of 1 µV/°C

Gain options: 20 V/V, 50 V/V, 100 V/V, and 200 V/V
2.2 Design Calculations of Sensing With INA181

2.2.1 Design for the System With a 5-V Supply Bus

Figure 5 shows the design where the INA181 device is used for bidirectional current sensing, whereas the TL431 device is used to provide an accurate reference of 2.5 V. The major advantage of this design is that it has the least number of external components, resulting in a minimum error and low cost. The 250-Ω series resistor connected between the supply and cathode of TL431 limits the current to 10 mA. The output of the circuit is given by Equation 1

\[ V_{OUT} = V_{REF} + (V_{SENSE} \times \text{Gain}) \]  

(1)

For a system with a maximum current limit of 90 A, calculations follow.

- Limitation on negative voltage at input IN+ in low-side sensing in case of negative current. INA181 can operate until \( V_{CM} = -0.2 \) V, thus for \( \text{Gain} = 20 \) V/V.

\[ -0.2 = 2.5 - \left( \frac{500}{525} \right) \times (2.5 + V_{IN+}) \]  

(2)

Thus, \( V_{IN+} \) can go up to \(-0.3352\) V without violating the \( V_{CM} \) limit of the op amp.

- Limitation of \( V_{SENSE} \):
  The output swing can be obtained from 2.5 V to 5 V as well as from 2.5 V to 0 V. Thus, the maximum value of \( \text{Gain} \times V_{SENSE(\text{MAX})} \) can go to 2.5 V. Selecting \( \text{Gain} \times V_{SENSE(\text{MAX})} = 2.4 \) V and \( \text{Gain} = 20 \) V/V, then \( V_{SENSE(\text{MAX})} = 0.12 \) V.

Because \( V_{SENSE} = I_{SENSE} \times R_{SENSE} \), and \( I_{SENSE(\text{MAX})} = 90 \) A, then \( R_{SENSE} = 1.3 \) mΩ. Thus, in inverter applications with a maximum discharging current of 90 A and maximum charging current of 60 A:

- When \( I_{SENSE} = 90 \) A, \( V_{OUT} = 2.5 + (0.12 \times 20) = 4.9 \) V
- When \( I_{SENSE} = -60 \) A, \( V_{OUT} = 2.5 - (0.08 \times 20) = 0.9 \) V

Thus, overcurrent limits can be set as 4.9 V for \( I_{SENSE} = 90 \) A, and as 0.9 V for \( I_{SENSE} = -60 \) A.
2.2.2 Design for the System With a 3.3-V Supply Bus

The TLV431 has a 1.24-V reference in this design, which is the only change. This design can also be modified for systems with a 5-V bus. Figure 6 shows the circuit.

![Bidirectional Current Sensing Using INA181 and TLV431](image)

Figure 6. Bidirectional Current Sensing Using INA181 and TLV431

For a system with a maximum current limit of 90 A, calculations follow.

- Limitation on negative voltage at input IN+ in low-side sensing in case of –ve current: INA181 can operate up to VCM = −0.2 V, thus for Gain = 20 V/V.

  \[ \text{Gain} = \frac{1.24 - \left( \frac{500}{525} \right) \times (1.24 + V_{IN+})}{-0.2} \]

  Thus, \( V_{IN+} \) can go up to –0.2721 V without violating the VCM limit of the op amp. (3)

- Limitation of \( V_{SENSE} \):
  For negative current, output can go from 1.24 V to 0 V. Thus, \( V_{SENSE} \) is limited by the maximum value of negative current.

  Selecting \( \text{Gain} \times V_{SENSE(\text{MAX})} = 1.2 \text{ V} \).

  Gain = 20 V/V, thus, \( V_{SENSE(\text{MAX})} = 0.06 \text{ V} \).

  For an inverter application, charging current is typically 2/3 of the charging current. Thus, taking the maximum negative current of 60 A:

  - \( V_{SENSE} = I_{SENSE} \times R_{SENSE} \) and \( I_{SENSE(\text{MAX})} = -60 \text{ A} \rightarrow R_{SENSE} = 1 \text{ m}\Omega \)
  - When \( I_{SENSE} = 90 \text{ A}, V_{OUT} = 1.24 + (0.09 \times 20) = 3.04 \text{ V} \)
  - When \( I_{SENSE} = -60 \text{ A}, V_{OUT} = 1.24 - (0.06 \times 20) = 0.04 \text{ V} \)

  Thus, the overcurrent limits can be set as 3.04 V for \( I_{SENSE} = 90 \text{ A} \), and as 0.04 V for \( I_{SENSE} = -60 \text{ A} \).
2.3 Error Calculations

2.3.1 Worst-Case Error in Current Sensing Using General-Purpose Op Amps

2.3.1.1 Input Offset Error

Assuming the $R_{\text{SENSE}}$ equals 1 mΩ for a 90-A current application, the worst-case $V_{\text{OS}}$, including temperature drift, is approximately 6 mV, resulting in:

\[
\% \text{ Offset Error} = 7\%
\]  

(4)

2.3.1.2 Gain Error

Assuming the 2% tolerance error of external resistors used, the worst-case gain error is 4%.

\[
\text{Total % error} = \sqrt{(7)^2 + (4)^2} = 8.1\%
\]  

(5)

For a 720-W inverter application, it results into approximately 58 W. This calculation does not include other errors (such as input bias current error or error due to input offset current).

2.3.2 Worst-Case Error in Bidirectional Current Sensing Using INA181 and TL431

2.3.2.1 Errors Due to INA181

2.3.2.1.1 Offset Error

The input offset voltage in the INA181 device is 150 µV. Including the temperature drift for an application operating up to 55°C maximum, the input offset voltage is 180 µV. Thus:

\[
\% \text{ Offset Error} = \frac{\text{Offset Voltage}}{V_{\text{SENSE}}} = 0.15\%
\]  

(6)

The maximum value of $V_{\text{SENSE}}$ is 120 mV. Thus, the offset error is 0.15%.

2.3.2.1.2 Gain Error

The INA181 device has a maximum gain error of 1%.

2.3.2.2 Error in the Reference TL431

The typical deviation in $V_{\text{REF}}$ value over its full operating temperature range is 14 mV. It can also have $\Delta V_{\text{REF}}$ of 12 mV in the worst case. Thus, the maximum $V_{\text{REF}}$ error is 26 mV.

\[
\% V_{\text{REF}} \text{ Error} = \frac{26}{20 \times (V_{\text{SENSE}})}
\]  

(7)

Maximum $V_{\text{SENSE}}$ is 120 mV, meaning $\% V_{\text{REF}} = 1.1\%$.

\[
\% \text{ Total Error} = \sqrt{(1)^2 + (0.15)^2 + (1.1)^2} = 1.1\%
\]  

(8)

Thus, this design has a maximum calculated error of 1.494%. In an example of a 720-W inverter, the worst-case wattage error is 10.75 W.
2.3.3 Worst-Case Error in Bidirectional Current Sensing Using INA181 and TL431 Devices

2.3.3.1 Errors Due to INA181

2.3.3.1.1 Offset Error

The input offset voltage in the INA181 device is 150 µV. Including temperature drift for an application operating up to 55°C maximum, the input offset voltage is 180 µV. Thus:

\[
\text{% Offset Error} = \frac{\text{Offset Voltage}}{V_{\text{SENSE}}}\]

Maximum value of \(V_{\text{SENSE}}\) is 0.09 mV. Thus, the offset error is 0.20%.

2.3.3.1.2 Gain Error

The INA181 device has a maximum gain error of 1%.

2.3.4 Error in the Reference TL431

The typical deviation in \(V_{\text{REF}}\) value over its full operating temperature range is 6 mV. It can also have \(\Delta V_{\text{REF}}\) of 4 mV in the worst case. Thus, maximum \(V_{\text{REF}}\) error is 10 mV.

\[
\text{%} V_{\text{REF}}\text{ Error} = \frac{10}{20 \times (V_{\text{SENSE}})}
\]

Maximum \(V_{\text{SENSE}}\) is 90 mV, meaning \(\% V_{\text{REF}} = 0.55\%\).

\[
\text{% Total Error} = \sqrt{(1)^2 + (0.2)^2 + (0.55)^2} = 1.26\%
\]

Thus, this design has a maximum calculated error of 1.26%. In an example of a 720-W inverter, the worst-case wattage error is 9 W.

3 Test Results

Table 1 and Table 2 list the output of bidirectional current-sensing circuits using INA181 and TL431 devices for positive and negative currents.
