ABSTRACT

One of the most predictable non-linear elements commonly available is the bipolar transistor. The relationship between collector current and emitter base voltage is precisely logarithmic from currents below one picoamp to currents above one milliamp. Using a matched pair of transistors and integrated circuit operational amplifiers, it is relatively easy to construct a linear to logarithmic converter with a dynamic range in excess of five decades.

NOTE: Texas Instruments recommends replacing 2N2920 and 2N3728 matched pairs with LM394 in all application circuits.

1 Introduction

The circuit in Figure 1 generates a logarithmic output voltage for a linear input current. Transistor Q₁ is used as the non-linear feedback element around an LM108 operational amplifier. Negative feedback is applied to the emitter of Q₁ through divider, R₁ and R₂, and the emitter base junction of Q₂. This forces the collector current of Q₁ to be exactly equal to the current through the input resistor. Transistor Q₂ is used as the feedback element of an LM101A operational amplifier. Negative feedback forces the collector current of Q₂ to equal the current through R₃. For the values shown, this current is 10 μA. Since the collector current of Q₂ remains constant, the emitter base voltage also remains constant. Therefore, only the V_{BE} of Q₁ varies with a change of input current. However, the output voltage is a function of the difference in emitter base voltages of Q₁ and Q₂:

\[ E_{OUT} = \frac{R₁ + R₂}{R₂} (V_{BE₂} - V_{BE₁}) \]  

(1)

For matched transistors operating at different collector currents, the emitter base differential is given by:

\[ \Delta V_{BE} = \frac{kT}{q} \log_e \frac{iC₁}{iC₂} \]  

(2)

where k is Boltzmann's constant, T is temperature in degrees Kelvin and q is the charge of an electron. Combining these two equations and writing the expression for the output voltage gives:

\[ E_{OUT} = \frac{-kT}{q} \left[ \frac{R₁ + R₂}{R₂} \right] \log_e \left[ \frac{E_{IN} R₃}{E_{REF} R₃} \right] \]  

(3)

for \( E_{IN} \geq 0 \). This shows that the output is proportional to the logarithm of the input voltage. The coefficient of the log term is directly proportional to absolute temperature. Without compensation, the scale factor will also vary directly with temperature. However, by making R₂ directly proportional to temperature, constant gain is obtained. The temperature compensation is typically 1% over a temperature range of −25°C to 100°C for the resistor specified. For limited temperature range applications, such as 0°C to 50°C, a 430 Ω sensistor in series with a 570 Ω resistor may be substituted for the 1k resistor, also with 1% accuracy. The divider, R₁ and R₂, sets the gain while the current through R₃ sets the zero. With the values given, the scale factor is 1V/decade and:

\[ E_{OUT} = - \left[ \log_{10} \left| \frac{E_{IN}}{E_{REF}} \right| + 5 \right] \]  

(4)

where the absolute value sign indicates that the dimensions of the quantity inside are to be ignored.

Log generator circuits are not limited to inverting operation. In fact, a feature of this circuit is the ease with which non-inverting operation is obtained. Supplying the input signal to A₂ and the reference current to A₁ results in a log output that is not inverted from the input. To achieve the same 100 dB dynamic range in the non-inverting configuration, an LM108 should be used for A₂, and an LM101A for A₁. Since the LM108 cannot use feedforward compensation, it is frequency compensated with the standard 30 pF capacitor. The only other change is the addition of a clamp diode connected from the emitter of Q₁ to ground. This prevents damage to the logging transistors if the input signal should go negative.
The log output is accurate to 1% for any current between 10 nA and 1 mA. This is equivalent to about 3% referred to the input. At currents over 500 μA the transistors used deviate from log characteristics due to resistance in the emitter, while at low currents, the offset current of the LM108 is the major source of error. These errors occur at the ends of the dynamic range, and from 40 nA to 400 μA the log converter is 1% accurate referred to the input. Both of the transistors are used in the grounded base connection, rather than the diode connection, to eliminate errors due to base current. Unfortunately, the grounded base connection increases the loop gain. More frequency compensation is necessary to prevent oscillation, and the log converter is necessarily slow. It may take 1 to 5 ms for the output to settle to 1% of its final value. This is especially true at low currents.

The circuit shown in Figure 2 is two orders of magnitude faster than the previous circuit and has a dynamic range of 80 dB. Operation is the same as the circuit in Figure 1, except the configuration optimizes speed rather than dynamic range. Transistor Q₁ is diode connected to allow the use of feedforward compensation on an LM101A operational amplifier. This compensation extends the bandwidth to 10 MHz and increases the slew rate. To prevent errors due to the finite h₁ₑ of Q₁ and the bias current of the LM101A, an LM102 voltage follower buffers the base current and input current. Although the log circuit will operate without the LM102, accuracy will degrade at low input currents. Amplifier A₂ is also compensated for maximum bandwidth. As with the previous log converter, R₁ and R₂ control the sensitivity; and R₃ controls the zero crossing of the transfer function. With the values shown the scale factor is 1V/decade and:

\[ E_{OUT} = -\left[ \log_{10} \left| \frac{E_{IN}}{R_{IN}} \right| + 4 \right] \]  

(5)

from less than 100 nA to 1 mA.

Anti-log or exponential generation is simply a matter of rearranging the circuitry. Figure 3 shows the circuitry of the log converter connected to generate an exponential output from a linear input. Amplifier A₁ in conjunction with transistor Q₁ drives the emitter of Q₂ in proportion to the input voltage. The collector current of Q₂ varies exponentially with the emitter-base voltage. This current is converted to a voltage by amplifier A₂. With the values given:

\[ E_{OUT} = 10^{\frac{E_{IN}}{R_{IN}}} \]  

(6)
Many non-linear functions such as $X^{\frac{1}{2}}$, $X^2$, $X^3$, $1/X$, $XY$, and $X/Y$ are easily generated with the use of logs. Multiplication becomes addition, division becomes subtraction and powers become gain coefficients of log terms. Figure 4 shows a circuit whose output is the cube of the input. Actually, any power function is available from this circuit by changing the values of $R_9$ and $R_{10}$ in accordance with the expression:

$$E_{\text{OUT}} = E_{\text{IN}} \frac{16.7 R_9}{R_9 + R_{10}}.$$  (7)

Note that when log and anti-log circuits are used to perform an operation with a linear output, no temperature compensating resistors at all are needed. If the log and anti-log transistors are at the same temperature, gain changes with temperature cancel. It is a good idea to use a heat sink which couples the two transistors to minimize thermal gradients. A 1°C temperature difference between the log and anti-log transistors results in a 0.3% error. Also, in the log converters, a 1°C difference between the log transistors and the compensating resistor results in a 0.3% error.

Either of the circuits in Figure 1 or Figure 2 may be used as dividers or reciprocal generators. Equation 3 shows the outputs of the log generators are actually the ratio of two currents: the input current and the current through $R_3$. When used as a log generator, the current through $R_3$ was held constant by connecting $R_3$ to a fixed voltage. Hence, the output was just the log of the input. If $R_3$ is driven by an input voltage, rather than the 15 V reference, the output of the log generator is the log ratio of the input current to the current through $R_3$. The anti-log of this voltage is the quotient. Of course, if the divisor is constant, the output is the reciprocal.

A complete one quadrant multiplier/divider is shown in Figure 5. It is basically the log generator shown in Figure 1 driving the anti-log generator shown in Figure 3. The log generator output from $A_1$ drives the base of $Q_4$ with a voltage proportional to the log of $E_1/E_2$. Transistor $Q_4$ adds a voltage proportional to the log of $E_2$ and drives the anti-log transistor, $Q_4$. The collector current of $Q_4$ is converted to an output voltage by $A_4$ and $R_7$, with the scale factor set by $R_7$ at $E_1/E_2/10E_2$.

Figure 2. Fast Log Generator
Measurement of transistor current gains over a wide range of operating currents is an application particularly suited to log multiplier/dividers. Using the circuit in Figure 5, PNP current gains can be measured at currents from 0.4 μA to 1 mA. The collector current is the input signal to $A_1$, the base current is the input signal to $A_2$, and a fixed voltage to $R_5$ sets the scale factor. Since $A_2$ holds the base at ground, a single resistor from the emitter to the positive supply is all that is needed to establish the operating current. The output is proportional to collector current divided by base current, or $h_{FE}$.

\[ E_{OUT} = \frac{I_C}{I_B} \]

**Figure 3. Anti-Log Generator**
In addition to their application in performing functional operations, log generators can provide a significant increase in the dynamic range of signal processing systems. Also, unlike a linear system, there is no loss in accuracy or resolution when the input signal is small compared to full scale. Over most of the dynamic range, the accuracy is a percent-of-signal rather than a percent-of-full-scale. For example, using log generators, a simple meter can display signals with 100 dB dynamic range or an oscilloscope can display a 10 mV and 10 V pulse simultaneously. Obviously, without the log generator, the low level signals are completely lost.

To achieve wide dynamic range with high accuracy, the input operational amplifier necessarily must have low offset voltage, bias current and offset current. The LM108 has a maximum bias current of $3 \text{ nA}$ and offset current of $400 \text{ pA}$ over a $-55^\circ C$ to $125^\circ C$ temperature range. By using equal source resistors, only the offset current of the LM108 causes an error. The offset current of the LM108 is as low as many FET amplifiers. Further, it has a low and constant temperature coefficient rather than doubling every $10^\circ C$. This results in greater accuracy over temperature than can be achieved with FET amplifiers. The offset voltage may be zeroed, if necessary, to improve accuracy with low input voltages.

The log converters are low level circuits and some care should be taken during construction. The input leads should be as short as possible and the input circuitry guarded against leakage currents. Solder residues can easily conduct leakage currents, therefore circuit boards should be cleaned before use. High quality glass or mica capacitors should be used on the inputs to minimize leakage currents. Also, when the $+15 \text{ V}$ supply is used as a reference, it must be well regulated.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have not been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
