IMPORTANT NOTICE

Texas Instruments (TI) reserves the right to make changes to its products or to discontinue any semiconductor product or service without notice, and advises its customers to obtain the latest version of relevant information to verify, before placing orders, that the information being relied on is current.

TI warrants performance of its semiconductor products and related software to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Certain application using semiconductor products may involve potential risks of death, personal injury, or severe property or environmental damage ("Critical Applications").

TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, INTENDED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT APPLICATIONS, DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS.

Inclusion of TI products in such applications is understood to be fully at the risk of the customer. Use of TI products in such applications requires the written approval of an appropriate TI officer. Questions concerning potential risk applications should be directed to TI through a local SC sales office.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards should be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance, customer product design, software performance, or infringement of patents or services described herein. Nor does TI warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used.

TRADEMARKS

TI is a trademark of Texas Instruments Incorporated.

Other brands and names are the property of their respective owners.

Accessing TMS320C5x Memory-Mapped Registers in C – C5XREGS.H

Abstract

The most common reason for accessing memory-mapped registers is to control the 'C5x peripherals. This document discusses how to access the TMS320C5x memory-mapped registers in C.

Design Problem

How do I access the TMS320C5x memory-mapped registers in C?

Solution

Accessing most of the 'C5x registers from C is easily accomplished using pointers since most of the registers are memory mapped. The most common reason for accessing memory-mapped registers is to control the 'C5x peripherals. Refer to the 'C5x Users Guide for a list of the memory-mapped registers and their associated addresses. As an example, the 'C5x serial-port control register, SPC, memory mapped at address 0x0022, could be declared in C as follows:

```
volatile unsigned int *spcr =
    (volatile unsigned int *) 0x0022;
```

Note the volatile modifier since this register changes independent of program control. The register can be written to, and read from, as follows:

```
*spcr = 0xc8; /* Load SPC with 0xc8 */
currentXRDYValue = *spcr & 0x800
                ; /* Check XRDY bit of SPC */
```

However, this does not lead to the most readable code. By using bit-field data structures to describe the bit fields of the register, more readable code can be developed. For example, consider the following data structure for the serial-port control register.

```
typedef union
{
    unsigned int intval;
    struct
    {
        unsigned int r_0      :1; /* Reserved */
        unsigned int dlb      :1; /* Dig Loopback Mode */
        unsigned int fo       :1; /* Format */
        unsigned int fsm      :1; /* Frame Synch Mode */
        unsigned int mcm      :1; /* Clock Mode */
        unsigned int txm      :1; /* Transmit Mode */
        unsigned int xrst     :1; /* Transmit Reset */
        unsigned int rrst     :1; /* Receive Reset */
        unsigned int in0      :1; /* Input 0 */
        unsigned int in1      :1; /* Input 1 */
        unsigned int rrdy     :1; /* Receive Ready */
        unsigned int xrdy     :1; /* Transmit Ready */
        unsigned int xsrempty :1
                ; /* Xmt Shift Reg Emty */
        unsigned int rsrfull  :1
                ; /* Rec Shift Reg Full */
        unsigned int soft     :1; /* Soft */
        unsigned int free     :1; /* Free run */
    };
};
```

```
    } bitval;  
} SPC_REG;
```

The bit XRDY can now be read as follows:

```
volatile SPC_REG *spcPtr =  
    (volatile SPC_REG *) 0x0022;  
currentXRDYValue = spcPtr -> bitval.xrdy;
```

The TMS320 BBS contains the self-extracting file, C5XREGS.EXE. This file contains a C header file, C5XREGS.H, that can be included (i.e., #included) in your C programs to assist in accessing 'C5x peripheral registers as well as all of the 'C5x memory-mapped registers. Where appropriate, bit-field data structures are also defined. The remainder of this document will describe its usage.

To use C5XREGS.H, simply include the file in your C program. Each memory-mapped register has two entities associated with it: (1) a macro that defines its address and (2) a type definition that describes the bit fields and the memory-mapped register. The macros for the address have two components for each register: one for the actual address and one to typecast the address as a pointer to a data structure that defines the memory-mapped register. The following code segment describes the address macros for the serial-port control register:

```
#define SPC_BASE 0X0022  
#define SPC_ADDR  
    ((volatile SPC_REG*) ((char*) SPC_BASE))
```

Two different methods have been used to type define the registers. For registers with bit fields, such as the SPC and interrupt mask register, IMR, data structures have been created that comprise a union of a 16-bit integer component, named intval, and a bit-field component, named bitval. This also includes registers that have some reserved component, such as the 5-bit TREG1 register. The bit-field data structure for the serial-port control register given above is such an example. Registers that have no bit field definition, such as the serial-port receive register, DRR, are defined as either signed or unsigned integers.

To access registers defined as bit-field data structures, use the following syntax:

```
/* Set FSM.XRST and RRST bits of the SPC */  
SPC_ADDR->intval = 0xc8;
```

To increase the readability of such assignments, macros for setting the bits have also been defined. The following example illustrates the use of these macros to accomplish the same thing:

```
/* Set FSM, XRST and RRST bits of the SPC */  
SPC_ADDR->intval = FSM | XRST | RRST;
```

The previous examples set the serial port for Frame Sync Mode and resets the transmit and receive sides of the serial port. Additional macros have been defined such that the user only need to type SPC instead of SPC_ADDR->intval. Therefore the last example could be expressed as follows:

```
SPC = FSM | XRST | RRST;
```

Alternatively, the bit fields could have been used as follows to accomplish the same task:

```
SPC_ADDR->bitval.fsm = 1;  
SPC_ADDR->bitval.xrst = 1;  
SPC_ADDR->bitval.rrst = 1;
```

To access registers that are not defined as bit-field data structures, use the following syntax:

```
*DXR = outputValue;
```

The previous example writes outputValue to the serial-port transmit register.

To declare a pointer to the serial-port control register, use the following syntax:

```
volatile SPC_REG *sPCR = SPC_ADDR;
```

The register is accessed as follows:

```
sPCR->intval = 0xc8;  
fsmbit = sPCR->bitval.fsm;
```
