LM5071 Power Over Ethernet PD Controller with Auxiliary Power Interface

Check for Samples: LM5071

FEATURES

• Compatible with 12V AC Adapters
• Fully Compliant 802.3af Power Interface Port
• 80V, 1Ω, 400 mA Internal MOSFET
• Detection Resistor Disconnect Function
• Programmable Classification Current
• Programmable Under-voltage Lockout with Programmable Hysteresis
• Thermal Shutdown Protection
• Auxiliary Power Enable Pin
• Current Mode Pulse Width Modulator
• Supports both Isolated and Non-Isolated Applications
• Error Amplifier and Reference for Non-Isolated Applications
• Programmable Oscillator Frequency
• Programmable Soft-Start
• 80% Maximum Duty Cycle Limiter, Slope Compensation (-80 device)
• 50% Maximum Duty Cycle Limiter, No Slope Compensation (-50 device)

PACKAGES

• TSSOP-16

DESCRIPTION

The LM5071 power interface port and pulse width modulation (PWM) controller provides a complete integrated solution for Powered Devices (PD) that connect into Power over Ethernet (PoE) systems. The LM5071 is specifically designed for the PD that must accept power from auxiliary sources such as AC adapters. The auxiliary power interface of the LM5071 activates the PWM controller when the ac adapter is connected to power the PD when PoE network power is unavailable. The LM5071 integrates an 80V, 400mA line connection switch and associated control for a fully IEEE 802.3af compliant interface with a full featured current mode pulse width modulator dc-dc converter. All power sequencing requirements between the controller interface and switch mode power supply (SMPS) are integrated into the IC.

(1) Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is intended to be functional. For specifications and test conditions, see Electrical Characteristics. The absolute maximum rating of \(V_{IN}, RTN\) to \(V_{EE}\) is derated to (-0.3V to 76V) at -40°C.

(2) If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office/Distributors for availability and specifications.

(3) For detailed information on soldering the plastic TSSOP package, refer to the Packaging Databook available from Texas Instruments.

(1) Min and Max limits are 100% production tested at 25 °C. Limits over the operating temperature range are specified through correlation using Statistical Quality Control (SQC) methods. Limits are used to calculate Texas Instruments’ Average Outgoing Quality Level (AOQL).

(2) The Vcc regulator requires an external source whenever the Vin pin is below 13V with respect to RTN. An external load on Vcc increases this startup voltage requirement.

(3) Device thermal limitations may limit usable range.

Specialized Block Diagrams

Figure 12. Top Level Block Diagram
Figure 13. PWM Controller Block Diagram
The LM5071 power interface port and pulse width modulation (PWM) controller provides a complete integrated solution for Powered Devices (PD) that connect into Power over Ethernet (PoE) systems. Major features of the PD interface portion of the IC include detection, classification, thermal limit, programmable undervoltage lockout, and current limit monitoring. The device also includes a high-voltage start-up bias regulator that operates over a wide input range up to 60V. The switch mode power supply (SMPS) control portion of the IC includes power good sensing, $V_{CC}$ regulator under-voltage lockout, cycle-by-cycle current limit, error amplifier, slope compensation, soft-start, and oscillator sync capability. This high speed BiCMOS IC has total propagation delays less than 100ns and a 1MHz capable oscillator programmed by a single external resistor. The LM5071 PWM controller provides current-mode control for dc-dc converter topologies requiring a single drive output, such as Flyback and Forward topologies. The LM5071 PWM enables all of the advantages of current-mode control including line feed-forward, cycle-by-cycle current limit and simplified loop compensation. The oscillator ramp is internally buffered and added to the PWM comparator input ramp to provide slope compensation necessary for current mode control at duty cycles greater than 50% (-80 suffix only).

**Modes of Operation**

The LM5071 PD interface is designed to provide a fully compliant IEEE 802.3af system. As such, the modes of operation take into account the barrel rectifiers often utilized to correctly polarize the dc input from the Ethernet cable.

<table>
<thead>
<tr>
<th>Input Voltage $V_{IN}$ wrt $V_{EE}$</th>
<th>Mode of Operation</th>
</tr>

<td>Normal Powered Operation</td>
</tr>
</tbody>
</table>

An external signature resistor is connected to $V_{EE}$ when $V_{IN}$ exceeds 1.8V, initiating detection mode. During detection mode, quiescent current drawn by the LM5071 is less than 10uA. Between 10.0V and 12.5V, the device enters classification mode and the signature resistor is disabled. The nominal range for classification mode is 11.5V to 25.0V. The classification current is turned off once the classification range voltage is exceeded, to reduce power dissipation. Between 25.0V and UVLO release, the device is in a standby state, awaiting the input voltage to reach the operational range to complete the power up sequence. Once the $V_{IN}$ voltage increases above the upper UVLO threshold voltage, the internal power MOSFET is enabled to deliver a constant current to charge the input capacitor of the dc-dc converter. When the MOSFET Vds voltage falls below 1.5V, the internal Power Good signal enables the SMPS controller. The LM5071 is specified to operate with an input voltage as high as 60.0V. The SMPS controller and internal MOSFET are disabled when $V_{IN}$ falls to the lower UVLO threshold.

**Detection Signature**

To detect a potential powered device candidate, the PSE (Power Sourcing Equipment) will apply a voltage from 2.8V to 10V across the input terminals of the PD. The voltage can be of either polarity so a diode barrel network is required on both lines to ensure this capability. The PSE will take two measurements, separated by at least 1V and 2ms of time. The voltage ramp between measurement points will not exceed 0.1V/us. The delta voltage / delta current calculation is then performed; if the detected impedance is above 23.75k$\Omega$ and below 26.25k$\Omega$, the PSE will consider a PD to be present. If the impedance is less than 15$\Omega$ or greater than 33k$\Omega$ a PD will be considered not present and will not receive power. Impedances between these values may or may not indicate the presence of a valid PD. The LM5071 will enable the signature resistor at a controller input voltage of 1.5V to take into account the diode voltage drops. An external signature resistor should be placed between the VIN and R_SIG pins. The signature resistor is in parallel with the external UVLO resistor divider, and its value should be calculated accordingly. Targeting 24.5k$\Omega$ increases margin in the signature design as the input bridge rectifier diodes contribute to the series resistance measured at the PD input terminals. The PSE will tolerate no more than 1.9V of offset voltage (caused by the external diodes) or more than 10uA of offset current (bias current). The input capacitance must be greater than 0.05uF and less than 0.12uF. To increase efficiency, the signature resistor is disabled by the LM5071 controller once the input voltage is above the detection range (> 11V).
Classification

To classify the PD, the PSE will present a voltage between 14.5V and 20.5V to the PD. The LM5071 enables classification mode at a nominal input voltage of 11.5V. An internal 1.5V linear regulator and an external resistor connected to the RCLASS pin provide classification programming current. Table 1 shows the external classification resistor required for a particular class.

The classification current flows through the IC into the classification resistor. The suggested resistor values take into account the bias current flowing into the IC. A different desired RCLASS can be calculated by dividing 1.5V by the desired classification current.

Per the IEEE 802.3af specification, classification is optional, and the PSE will default to class 0 if a valid classification current is not detected. If PD classification is not desired (i.e., Class 0), simply leave the RCLASS pin open. The classification time period may not last longer than 75ms as per IEEE 802.3af. The LM5071 will remain in classification mode until VIN is greater than 25V.

Undervoltage Lockout (UVLO)

The IEEE 802.3af specification states that the PSE will supply power to the PD within 400ms after completion of detection. The LM5071 contains a programmable line Under Voltage Lock Out (UVLO) circuit. The first resistor should be connected between the VIN to UVLO pins; the bottom resistor in the divider should be connected between the UVLO and UVLORTN pins.

The divider must be designed such that the voltage at the UVLO pin equals 2.0V when VIN reaches the desired minimum operating level. If the UVLO threshold is not met, the interface control and SMPS control will remain in standby.

UVLO hysteresis is accomplished with an internal 10μA current source that is switched on and off into the impedance of the UVLO set point divider. When the UVLO threshold is exceeded, the current source is activated to instantly raise the voltage at the UVLO pin. When the UVLO pin voltage falls below the 2.00V threshold, the current source is turned off, causing the voltage at the UVLO pin to fall. The LM5071 UVLO thresholds cannot be programmed lower than 25V, the AUX pin should be used to force UVLO release below 25V.

There are many additional uses for the UVLO pin. The UVLO function can also be used to implement a remote enable / disable function. Pulling the UVLO pin down below the UVLO threshold disables the interface and SMPS controller unless forced on via AUX pin operation.

AUX Pin Operation

The AUX pin can be used to force operation (UVLO release) of the interface and switching regulator at any input voltage above 9.5V. This is especially useful for auxiliary input (wall transformer) input voltages. The pin has a 2.5V threshold (0.5V hysteresis) and an input impedance of approximately 350kΩ. The input resistor provides a defined pull down impedance if the pin is left open by the user. An external pull down resistor should be used to provide additional noise immunity. The resultant pin voltage from the external resistor divider should be well above the 2.5V threshold to ensure proper auxiliary operation. See Figure 14 for an example of a simple yet robust auxiliary configuration.
Power Supply Operation

Once the UVLO threshold has been satisfied, the interface controller of the LM5071 will charge up the SMPS input capacitor through the internal power MOSFET. This load capacitance provides input filtering for the power converter section and must be at least 5uF per the IEEE 802.3af specification. To accomplish the charging in a controlled manner, the power MOSFET is current limited to 100mA.

The SMPS controller will not initiate operation until the load capacitor is completely charged. The power sequencing between the interface circuitry and the SMPS controller occurs automatically within the LM5071. Detection circuitry monitors the RTN pin to detect interface startup completion. When the RTN pin potential drops below 1.5V with respect to $V_{EE}$, the $V_{CC}$ regulator of the SMPS controller is enabled. The soft-start function is enabled once the $V_{CC}$ regulator achieves minimum operating voltage. The inrush current limit only applies to the initial charging phase. The interface power MOSFET current limit will revert to the default protection current limit of 390mA once the SMPS is powered up and the soft-start pin sequence begins.

High Voltage Start-up Regulator

The LM5071 contains an internal high voltage startup regulator that allows the input pin ($V_{IN}$) to be connected directly to line voltages as high as 60V. The regulator output is internally current limited to 15mA. The recommended capacitance range for the $V_{CC}$ regulator output is 0.1uF to 10uF. When the voltage on the $V_{CC}$ pin reaches the regulation point of 7.8V, the controller output is enabled. The controller will remain enabled until $V_{CC}$ falls below 6.25V.

In typical applications, a transformer auxiliary winding is diode connected to the $V_{CC}$ pin. This winding should raise the $V_{CC}$ voltage above 8.1V to shut off the internal startup regulator. Though not required, powering $V_{CC}$ from an auxiliary winding improves conversion efficiency while reducing the power dissipated in the controller. The external $V_{CC}$ capacitor must be selected such that the capacitor maintains the $V_{CC}$ voltage greater than the $V_{CC}$ UVLO falling threshold (6.25V) during the initial start-up. During a fault condition when the converter auxiliary winding is inactive, external current draw on the $V_{CC}$ line should be limited such that the power dissipated in the start-up regulator does not exceed the maximum power dissipation capability of the LM5071 package.

If the $V_{CC}$ auxiliary winding is used with a low voltage auxiliary supply (wall transformer), the VCC pin could back feed through the LM5071 to the VIN pin. A diode from VCC to VIN should be used to clamp the VCC pin and prevent this internal back feed. The winding voltage will remain the same and extra power will be dissipated in the series resistor. Also, note that when using a very low voltage auxiliary supply (<14V), a diode from the AUX supply to the VCC pin should be used to ensure VCC startup.
Error Amplifier

An internal high gain error amplifier is provided within the LM5071. The amplifier’s non-inverting reference is set to a fixed reference voltage of 1.25V. The inverting input is connected to the FB pin. In non-isolated applications, the power converter output is connected to the FB pin via voltage scaling resistors. Loop compensation components are connected between the COMP and FB pins. For most isolated applications the error amplifier function is implemented on the secondary side of the converter and the internal error amplifier is not used. The internal error amplifier is configured as an open drain output and can be disabled by connecting the FB pin to ARTN. An internal 5K pull-up resistor between a 5V reference and COMP can be used as the pull-up for an optocoupler in isolated applications.

Current Limit / Current Sense

The LM5071 provides a cycle-by-cycle over current protection function. Current limit is accomplished by an internal current sense comparator. If the voltage at the current sense comparator input CS exceeds 0.5V with respect to RTN/ARTN, the output pulse will be immediately terminated. A small RC filter, located near the CS pin of the controller, is recommended to filter noise from the current sense signal. The CS input has an internal MOSFET which discharges the CS pin capacitance at the conclusion of every cycle. The discharge device remains on an additional 50ns after the beginning of the new cycle to attenuate the leading edge spike on the current sense signal.

The LM5071 current sense and PWM comparators are very fast, and may respond to short duration noise pulses. Layout considerations are critical for the current sense filter and sense resistor. The capacitor associated with the CS filter must be located very close to the device and connected directly to the pins of the controller (CS and ARTN). If a current sense transformer is used, both leads of the transformer secondary should be routed to the sense resistor and the current sense filter network. A sense resistor located in the source of the primary power MOSFET may be used for current sensing, but a low inductance resistor is required. When designing with a current sense resistor, all of the noise sensitive low power ground connections should be connected together local to the controller and a single connection should be made to the high current power return (sense resistor ground point).
Oscillator, Shutdown and Sync Capability

A single external resistor connected between the RT and ARTN pins sets the LM5071 oscillator frequency. Internal to the LM5071–50 device (50% duty cycle limited option) is an oscillator divide by two circuit. This divide by two circuit creates an exact 50% duty cycle clock which is used internally to create a precise 50% duty cycle limit function. Because of this divide by two, the internal oscillator actually operates at twice the frequency of the output (OUT). For the LM5071–80 device the oscillator frequency and the operational output frequency are the same. To set a desired output operational frequency (F), the RT resistor can be calculated from:

LM5071-80:

\[ \text{RT} = \frac{1}{F \times 165 \times 10^{-12}} \]

LM5071-50:

\[ \text{RT} = \frac{1}{F \times 330 \times 10^{-12}} \]

The LM5071 can also be synchronized to an external clock. The external clock must have a higher frequency than the free running oscillator frequency set by the RT resistor. The clock signal should be capacitively coupled into the RT pin with a 100pF capacitor. A peak voltage level greater than 3.7 volts at the RT pin is required for detection of the sync pulse. The sync pulse width should be set between 15 to 150ns by the external components. The RT resistor is always required, whether the oscillator is free running or externally synchronized. The voltage at the RT pin is internally regulated to ±2 volts. The RT resistor should be located very close to the device and connected directly to the pins of the controller (RT and ARTN).

PWM Comparator / Slope Compensation

The PWM comparator compares the current ramp signal with the loop error voltage derived from the error amplifier output. The error amplifier output voltage at the COMP pin is offset by 1.4V and then further attenuated by a 3:1 resistor divider. The PWM comparator polarity is such that 0 Volts on the COMP pin will result in zero duty cycle at the controller output. For duty cycles greater than 50 percent, current mode control circuits are subject to sub-harmonic oscillation. By adding an additional fixed slope voltage ramp signal (slope compensation) to the current sense signal, this oscillation can be avoided. The LM5071-80 integrates this slope compensation by summing a current ramp generated by the oscillator with the current sense signal. Additional slope compensation may be added by increasing the source impedance of the current sense signal (with an external resistor between the CS pin and current sense resistor). Since the LM5071-50 is not capable of duty cycles greater than 50%, there is no slope compensation feature in this device.

Soft-Start

The softstart feature allows the power converter to gradually reach the initial steady state operating point, thereby reducing start-up stresses, output overshoot and current surges. At power on, after the \( V_{CC} \) undervoltage lockout threshold is satisfied, an internal 10μA current source charges an external capacitor connected to the SS pin. The capacitor voltage will ramp up slowly and will limit the COMP pin voltage and the duty cycle of the output pulses.

Gate Driver and Maximum Duty Cycle Limit

The LM5071 provides an internal gate driver (OUT), which can source and sink a peak current of 800mA. The LM5071 is available in two duty cycle limit options. The maximum output duty cycle is typically 80% for the LM5071-80 option and precisely equal to 50% for the LM5071-50 option. The maximum duty cycle function for the LM5071-50 is accomplished with an internal toggle flip-flop which ensures an accurate duty cycle limit. The internal oscillator frequency of the LM5071-50 is therefore twice the operating frequency of the PWM controller (OUT pin).

The 80% maximum duty cycle limit of the LM5071-80 is determined by the internal oscillator and varies more than the 50% limit of the LM5071-50. For the LM5071-80, the internal oscillator frequency and the operational frequency of the PWM controller are equal.
Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event the maximum junction temperature is exceeded. This feature prevents catastrophic failures from accidental device overheating. When activated, typically at 165 degrees Celsius, the controller is forced into a low power standby state, disabling the output driver, bias regulator, main interface pass MOSFET, and classification regulator if enabled. After the temperature is reduced (typical hysteresis = 25 °C) the V_{CC} regulator will be enabled and a softstart sequence initiated.

Thermal shutdown is not enabled during auxiliary power operation as the power MOSFET is not running any current and should not experience an over-temperature condition. If the drain of the MOSFET exceeds 2.5V with respect to VEE (internal Power Good de-assertion), PoE UVLO becomes de-asserted (insertion of PoE or other 48V supply), or the auxiliary power is removed, thermal limit will be re-enabled immediately.

1. The marketing status values are defined as follows:
   - **ACTIVE**: Product device recommended for new designs.
   - **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
   - **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
   - **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
   - **OBSOLETE**: TI has discontinued the production of the device.

2. **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

   - **RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
   - **Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

3. **MSL, Peak Temp.** - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

4. There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

5. Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

6. Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
4. This dimension does not include interlead flash. Interlead flash shall not exceed 0.25 mm per side.
5. Reference JEDEC registration MO-153.
NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
9. Board assembly site may have different recommendations for stencil design.
