LM25149-Q1 42-V Automotive Synchronous Buck DC/DC Controller with Ultra-Low IQ and Integrated Active EMI Filter

1 Features

- **AEC-Q100 qualified for automotive applications:**
  - Device temperature grade 1: -40°C to +125°C ambient operating temperature
- **Two integrated EMI mitigation mechanisms**
  - Active EMI filter for enhanced EMI performance at lower frequencies
  - Dual random spread spectrum (DRSS) for enhanced EMI performance across low and high-frequency bands
  - EMI reduced by an average of 25 dBµV
  - Reduces the external differential-mode filter size by 50% and lowers systems cost
- **Versatile synchronous buck DC/DC controller**
  - Wide input voltage range of 3.5 V to 42 V
  - 1% accurate, fixed 3.3-V, 5-V, 12-V, or adjustable outputs from 0.8 V to 36 V
  - 150°C maximum junction temperature
  - Shutdown mode current: 2.2 µA
  - No-load standby current: 9 µA
- **Switching frequency from 100 kHz to 2.2 MHz**
  - SYNC in and SYNC out capability
- **Inherent protection features for robust design**
  - Internal hiccup-mode overcurrent protection
  - ENABLE and PGOOD functions
  - VCC, VDDA, and gate-drive UVLO protection
  - Internal or external loop compensation
  - Thermal shutdown protection with hysteresis
- **Create a custom design using the LM25149-Q1 with WEBENCH® Power Designer**

2 Applications

- **Automotive electronic systems**
- **Infotainment systems, instrument clusters, ADAS**
- **High-voltage battery-operated systems**

3 Description

The LM25149-Q1 is a 42-V synchronous buck DC/DC controller for high-current single-output applications. Refer to the Errata. The device uses peak current-mode control architecture for easy loop compensation, fast transient response, and excellent load and line regulation. The LM25149-Q1 can be set up in interleaved mode (paralleled output) with accurate current sharing for high-current applications. The LM25149-Q1 can operate at input voltages as low as 3.5 V, at nearly 100% duty cycle if needed.

The LM25149-Q1 has two unique EMI reduction features: active EMI filter and Dual Random Spread Spectrum (DRSS). Active EMI filter senses any noise or ripple voltage on the DC input bus and injects an out-of-phase cancellation signal to reduce the noise or ripple voltage. DRSS combines a low-frequency triangular and high-frequency random modulation to optimize EMI performance in the low-frequency and high-frequency radio frequency bands.

Typical Application Schematic

CISPR 25 EMI Performance 150 kHz - 30 MHz

An IMPORTANT NOTICE at the end of this data sheet addresses availability, warranty, changes, use in safety-critical applications, intellectual property matters and other important disclaimers. ADVANCE INFORMATION for preproduction products; subject to change without notice.
5 Description (continued)

Additional features of the LM25149-Q1 include 150°C maximum junction temperature operation, user-selectable diode emulation for lower current consumption at light-load conditions, open-drain Power-Good flag for fault reporting and output monitoring, precision enable input, monotonic start-up into prebiased load, integrated VCC bias supply regulator, internal 2.8-ms soft-start time, and thermal shutdown protection with automatic recovery.

The LM25149-Q1 controller comes in a 3.5-mm × 5.5-mm thermally-enhanced, 24-pin VQFN package with wettable flank pins to facilitate optical inspection during manufacturing.
6 Pin Configuration and Functions

Connect the exposed pad to AGND and PGND on the PCB.

### 6.1 Wettable Flanks

100% automated visual inspection (AVI) post-assembly is typically required to meet reliability and robustness standards. Standard quad-flat no-lead (QFN) packages do not have solderable or exposed pins and terminals that are easily viewed. It is therefore difficult to visually determine whether or not the package is successfully soldered onto the printed-circuit board (PCB). The wettable-flank process was developed to resolve the issue of side-lead wetting of leadless packaging. The LM25149-Q1 is assembled using a 24-pin VQFN package with wettable flanks to provide a visual indicator of solderability, which reduces the inspection time and manufacturing costs.

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

8 Detailed Description
8.1 Overview

The LM25149-Q1 is a switching controller that features all of the functions necessary to implement a high-efficiency synchronous buck power supply operating over a wide input voltage range from 3.5 V to 42 V. The LM25149 is configured to provide a fixed 3.3-V, 5-V, or 12-V output, or an adjustable output between 0.8 V to 36 V. This easy-to-use controller integrates high-side and low-side MOSFET drivers capable of sourcing 2.2-A and sinking 3.2-A peak current. Adaptive dead-time control is designed to minimize body diode conduction during switching transitions.

Current-mode control using a shunt resistor or inductor DCR current sensing provides inherent line feedforward, cycle-by-cycle peak current limiting, and easy loop compensation. It also supports a wide duty cycle range for high input voltage and low-dropout applications as well as when a high step-down conversion ratio (for example, 10-to-1) is required. The oscillator frequency is user-programmable between 100 kHz to 2.2 MHz, and the frequency can be synchronized as high as 2.5 MHz by applying an external clock to the PFM/SYNC pin.

An external bias supply can be connected to VCCX to maximize efficiency in high input voltage applications. A user-selectable diode emulation feature enables discontinuous conduction mode (DCM) operation to further improve efficiency and reduce power dissipation during light-load conditions. Fault protection features include current limiting, thermal shutdown, UVLO, and remote shutdown capability.

The LM25149-Q1 incorporates features to simplify the compliance with automotive EMI requirements (CISPR 25). Active EMI filter (AEF) and Dual Random Spread Spectrum (DRSS) techniques reduce the peak harmonic EMI signature.

The LM25149-Q1 is provided in a 24-pin VQFN package with a wettable flank pinout and an exposed pad to aid in thermal dissipation.
8.2 Functional Block Diagram
8.3 Feature Description

8.3.1 Input Voltage Range (V\textsubscript{IN})

The LM25149-Q1 operational input voltage range is from 3.5 V to 42 V. The device is intended for step-down conversions from 12-V and 24-V automotive supply rails. The application circuit in Figure 9-5 shows all the necessary components to implement an LM25149-Q1 based wide-V\textsubscript{IN} single-output step-down regulator using a single supply. The LM25149-Q1 uses an internal LDO to provide a 5-V VCC bias rail for the gate drive and control circuits (assuming the input voltage is higher than 5 V with additional voltage margin necessary for the sub-regulator dropout specification).

In high input voltage applications, take extra care to ensure that the VIN and SW pins do not exceed their absolute maximum voltage rating of 47 V during line or load transient events. Voltage excursions that exceed the input voltage can damage the IC.

8.3.2 High-Voltage Bias Supply Regulator (VCC, VCCX, VDDA)

The LM25149-Q1 contains an internal high-voltage VCC bias regulator that provides the bias supply for the PWM controller and the gate drivers for the external MOSFETs. The input voltage pin (VIN) can be connected directly to an input voltage source up to 42 V. However, when the input voltage is below the VCC setpoint level, the VCC voltage tracks VIN minus a small voltage drop.

The VCC regulator output current limit is 110 mA (minimum). At power up, the controller sources current into the capacitor connected at the VCC pin. When the VCC voltage exceeds 3.3 V and the EN pin is connected to a voltage greater than 1 V, the soft-start sequence begins. The output remains active unless the VCC voltage falls below the VCC UVLO falling threshold of 3.1 V (typical) or EN is switched to a low state. Connect a ceramic capacitor from VCC to PGND. The recommended range of the VCC capacitor is from 2.2 µF to 10 µF.

An internal 5-V linear regulator generates the VDDA bias supply. Bypass VDDA with a 100-nF ceramic capacitor to achieve a low-noise internal bias rail. Normally VDDA is 5 V. However, there is one condition where VDDA regulates at 3.3-V, this is in PFM mode with a light or no-load on the output.

Minimize the internal power dissipation of the VCC regulator by connecting VCCX to a 5-V output or to an external 5-V supply. If the VCCX voltage is above 4.3 V, VCCX is internally connected to VCC and the internal VCC regulator is disabled. Tie VCCX to PGND if it is unused. Never connect VCCX to a voltage greater than 6.5 V. If an external supply is connected to VCCX to power the LM25149-Q1, VIN must be greater than the external bias voltage during all conditions to avoid damage to the controller.

8.3.3 Enable (EN)

The EN pin can be connected to a voltage as high as 42 V. The LM25149-Q1 has a precision enable. When the EN voltage is greater than 1 V, V\textsubscript{OUT} is enabled. If the EN pin is pulled below 0.5 V, the LM25149-Q1 is in shutdown with an I\textsubscript{Q} of 2.2 µA (typical) current draw from VIN. When the enable voltage is between 0.5 V and 1 V, the LM25149-Q1 is in standby mode. When the controller is in standby mode, the VCC regulator is active, and the controller is not switching. Under these conditions, the I\textsubscript{Q} current is 100 µA typical. The LM25149-Q1 is enabled with a logic level voltage greater than 2.0 V, and a voltage less than 0.4 V disables the LM25149-Q1. However, many applications benefit from using a resistor divider R\textsubscript{UV1} and R\textsubscript{UV2}, as shown in Figure 8-4, to establish a precision UVLO level. TI does not recommend leaving the EN pin floating.

Use Equation 1 and Equation 2 to calculate the UVLO resistors given the required input turnon and turnoff voltages.

\[
R_{UV1} = \frac{V_{IN(on)} - V_{IN(0ff)}}{I_{HYS}} \tag{1}
\]

\[
R_{UV2} = R_{UV1} \cdot \frac{V_{EN}}{V_{IN(on)} - V_{EN}} \tag{2}
\]
8.3.4 Power Good Monitor (PG)

The LM25149-Q1 includes an output voltage monitoring signal for \( V_{\text{OUT}} \) to simplify sequencing and supervision. The Power Good signal is used for start-up sequencing of downstream converters, fault protection, and output monitoring. The power-good output (PG) switches to a high impedance open-drain state when the output voltage is in regulation. The PG switches low when the output voltage drops below the lower power-good threshold (92% typical) or rises above the upper power-good threshold (110% typical). A 25-\( \mu \)s deglitch filter prevents false tripping of the power-good signal during transients. TI recommends a pullup resistor of 100 k\( \Omega \) (typical) from PG to the relevant logic rail. PG is asserted low during soft start and when the buck regulator is disabled.

When the LM25149-Q1 is configured as a primary controller, the PG pin is becomes a synchronization clock output for the Secondary controller. The synchronization signal is a logic level, 180° out-of-phase with the primary HO driver output.

8.3.5 Switching Frequency (RT)

The LM25149-Q1 oscillator is programmed by a resistor between RT and AGND to set an oscillator frequency between 100 kHz to 2.2 MHz. Calculate the RT resistance for a given switching frequency using Equation 3.

\[
R_T (\text{k}\Omega) = \frac{10^6}{F_{\text{SW}} (\text{kHz})} - 53 \quad \text{(3)}
\]

Under low \( V_{\text{IN}} \) conditions when the on-time of the high-side MOSFET exceeds the programmed oscillator period, the LM25149-Q1 extends the switching period until the PWM latch is reset by the current sense ramp exceeding the controller compensation voltage.

The approximate input voltage level at which this occurs is given by Equation 4, where \( t_{\text{SW}} \) is the switching period and \( t_{\text{OFF(min)}} \) is the minimum off-time of 60 ns.

\[
V_{\text{IN(min)}} = V_{\text{OUT}} \cdot \frac{t_{\text{SW}}}{t_{\text{SW}} - t_{\text{OFF(min)}}} \quad \text{(4)}
\]

8.3.6 Active EMI Filter

Active EMI filter provides a higher level of EMI attenuation and a smaller solution size than a standard passive \( \pi \)-filters. Passive \( \pi \)-filter use large inductors and capacitors to attenuate the ripple and noise on the input DC.
bus. Passive filters are typically most effective at reducing the switching frequency harmonics to comply with EMI in the low-frequency range, less than 30 MHz.

Active EMI filter has a high gain, wide bandwidth (approximately 20 MHz), and a low output impedance that can source and sink current. It senses (at the SEN pin) any disturbance on the DC input bus and injects (at the INJ pin) a cancellation signal out of phase with the noise source to reduce the conducted emissions.

To maintain low $I_Q$ at light loads, the LM25149-Q1 automatically enables active EMI filter when the load current is greater than 40% of the current limit value, and disables active EMI filter when the load current is less then 30% of the current limit value. Active EMI filter is disabled by pulling the CNFG pin below 0.8 V after the LM25149-Q1 has been configured.

![Active EMI Filter](image)

**Figure 8-2. Active EMI Filter**

### 8.3.7 Dual Random Spread Spectrum (DRSS)

The LM25149-Q1 provides a digital spread spectrum, which reduces the EMI of the power supply over a wide frequency range. DRSS combines a low-frequency triangular modulation profile with a high frequency cycle-by-cycle random modulation profile. The low-frequency triangular modulation improves performance in lower radio frequency bands, while the high-frequency random modulation improves performance in higher radio frequency bands.

Spread spectrum works by converting a narrowband signal into a wideband signal that spreads the energy over multiple frequencies. Since industry standards require different EMI receiver resolution bandwidth (RBW) settings for different frequency bands, the RBW has an impact on the spread spectrum performance. For example, the CISPR 25 EMI receiver RBW in the frequency band from 150 kHz to 30 MHz is 9 kHz. For frequencies greater than 30 MHz, the RBW is 120 kHz. DRSS is able to simultaneously improve the EMI performance in the high and low RBWs with its low-frequency triangular modulation profile and high frequency cycle-by-cycle random modulation. DRSS can reduce conducted emissions by 15 dBμV in the low-frequency band (150 kHz to 30 MHz) and 5 dBμV in the high-frequency band (30 MHz to 108 MHz).

To enable DRSS, connect either a 41.2-kΩ or 71.5-kΩ resistor from CNFG to AGND. DRSS is disabled when an external clock is applied to the PFM/SYNC pin.
8.3.8 Soft-Start
The LM25149-Q1 has an internal 2.8-ms soft-start timer (typical). The soft-start feature allows the regulator to gradually reach the steady-state operating point, thus reducing start-up stresses and surges.

8.3.9 Output Voltage Setpoint (FB)
The LM25149-Q1 output can be independently configured for one of three fixed output voltages without external feedback resistors, or adjusted to the desired voltage using an external resistor divider. Set the output to 3.3-V by connecting FB directly to VDDA. Alternatively, set the output to either 5-V or 12-V by installing a 24.9-kΩ or 49.9 kΩ resistor, between FB and VDDA, respectively. See Table 8-1. The configuration settings are latched and cannot be changed until the LM25149-Q1 is powered down (with the VCC voltage decreasing below its falling UVLO threshold) and then powered up again (VCC rises above the 3.4 V typical).

<table>

<tbody>
<tr>
<td>0 Ω</td>
<td>3.3 V</td>
</tr>
<tr>
<td>24.9 kΩ</td>
<td>5 V</td>
</tr>
<tr>
<td>49 kΩ</td>
<td>12 V</td>
</tr>
<tr>
<td>NA</td>
<td>External FB divider</td>
</tr>
</tbody>
</table>

Alternatively, set the output voltage with an external resistive divider from the output to the FB pin. The output voltage adjustment range is between 0.8 V to 36 V. The regulation threshold at FB is 0.8 V (VREF). Use Equation 5 to calculate the upper and lower feedback resistors, designated RFB1 and RFB2:

$$R_{FB1} = \left( \frac{V_{OUT}}{V_{REF}} - 1 \right) R_{FB2}$$

The recommended starting value for RFB2 is between 10 kΩ and 20 kΩ.

If a low-IQ operation is required, take care when selecting the external resistors. The extra current drawn from the external divider is added to the LM25149-Q1 ISTANDBY current (9 µA typical). The divider current reflected to VIN is divided down by the ratio of VOUT / VIN.

8.3.10 Minimum Controllable On-Time
There are two limitations to the minimum output voltage adjustment range: the LM25149-Q1 voltage reference of 0.8 V and the minimum controllable switch-node pulse width, tON(min).

ION(min) effectively limits the voltage step-down conversion ratio VOUT / VIN at a given switching frequency. For fixed-frequency PWM operation, the voltage conversion ratio must satisfy Equation 6.
\[
\frac{V_{\text{OUT}}}{V_{\text{IN}}} > t_{\text{ON(min)}} \cdot F_{\text{SW}}
\]

where

- \(t_{\text{ON(min)}}\) is 49 ns (typical)
- \(F_{\text{SW}}\) is the switching frequency

If the desired voltage conversion ratio does not meet the above condition, the LM25149-Q1 transitions from fixed switching frequency operation to a pulse-skipping mode to maintain output voltage regulation. For example, if the desired output voltage is 5 V with an input voltage of 24 V and switching frequency of 2.1 MHz, the voltage conversion ratio test in Equation 7 is satisfied.

\[
\frac{5 \text{ V}}{24 \text{ V}} > 59 \text{ ns} \cdot 2.1 \text{ MHz}
\]

\[
0.208 > 0.124
\]

For wide-\(V_{\text{IN}}\) applications and low output voltages, an alternative is to reduce the LM25149-Q1 switching frequency to meet the requirement of Equation 6.

### 8.3.11 Error Amplifier and PWM Comparator (FB, EXTCOMP)

The LM25149-Q1 has a high-gain transconductance amplifier that generates an error current proportional to the difference between the feedback voltage and an internal precision reference (0.8 V). The control loop compensation is configured two ways. The first is using the internal compensation amplifier, which has a transconductance of 30 \(\mu\)S. Internal compensation is configured by connecting the EXTCOMP pin through a 100-kΩ resistance to VDDA. If a 100-kΩ resistor is not detected, the LM25149-Q1 defaults to the external loop compensation network. The transconductance of the amplifier for external compensation is 1200 \(\mu\)S. This is latched and cannot be re-configured on the fly. Use an external compensation network if higher performance is required to meet a stringent transient response. To re-configure the compensation (internal or external), remove power and allow VCC to drop below its VCC\text{UVLO} threshold, which is 3.3 V typical.

A type-II compensation network is generally recommended for peak current-mode control.

### 8.3.12 Slope Compensation

The LM25149-Q1 provides internal slope compensation for stable operation with peak current-mode control and a duty cycle greater than 50%. Calculate the buck inductance to provide a slope compensation contribution equal to one times the inductor downslope using Equation 8.

\[
L_{\text{O-IDEAL}} (\mu\text{H}) = \frac{V_{\text{OUT}} (\text{V}) \cdot R_{\text{S}} (\text{m}\Omega)}{24 \cdot F_{\text{SW}} (\text{MHz})}
\]

- A lower inductance value generally increases the peak-to-peak inductor current, which minimizes size and cost, and improves transient response at the cost of reduced light-load efficiency due to higher cores losses and peak currents.
- A higher inductance value generally decreases the peak-to-peak inductor current, reducing switch peak and RMS currents at the cost of requiring larger output capacitors to meet load-transient specifications.

### 8.3.13 Inductor Current Sense (ISNS+, VOUT)

There are two methods to sense the inductor current of the buck power stage. The first uses a current sense resistor (also known as a shunt) in series with the inductor, and the second avails of the DC resistance of the inductor (DCR current sensing).
Table 8-2. Errata

<table>
<thead>
<tr>
<th>ITEM</th>
<th>OBSERVED BEHAVIOR</th>
<th>COMMENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>When the switch-node voltage rises faster than 3 V/µs, a noise may be injected between PGND and VOUT. If the output current is operating close to current limit, the noise can prematurely trip the current limit comparator causing the HO to turn off immediately. This issue is more apparent at higher $V_{IN}$ where the switch node rises very quickly. The same effect has been observed in PFM where an internal comparator is observing if the output of the CSA is exceeding 20% the current limit value. In this case, the normal 20% $I_{lim}$ pulse becomes much smaller.</td>
<td>The issue will be fixed in the final silicon.</td>
</tr>
</tbody>
</table>

8.3.13.1 Shunt Current Sensing

Figure 8-4 illustrates inductor current sensing using a shunt resistor. This configuration continuously monitors the inductor current to provide accurate overcurrent protection across the operating temperature range. For optimal current sense accuracy and overcurrent protection, use a low inductance ±1% tolerance shunt resistor between the inductor and the output, with a Kelvin connection to the LM25149-Q1 current sense amplifier.

If the peak voltage signal sensed from ISNS+ to VOUT exceeds the current limit threshold of 60 mV, the current limit comparator immediately terminates HO output for cycle-by-cycle current limiting. Calculate the shunt resistance using Equation 9.

$$R_S = \frac{V_{CS-TH}}{I_{OUT(CL)} + \frac{\Delta I_L}{2}}$$

(9)

where

- $V_{CS-TH}$ is current sense threshold of 60 mV
- $I_{OUT(CL)}$ is the overcurrent setpoint that is set higher than the maximum load current to avoid tripping the overcurrent comparator during load transients
- $\Delta I_L$ is the peak-to-peak inductor ripple current

![Figure 8-4. Shunt Current Sensing Implementation](image)

The SS voltage is clamped 150 mV above FB during an overcurrent condition. Sixteen overcurrent events must occur before the SS clamp is enabled. This ensures that SS can be pulled low during brief overcurrent events, preventing output voltage overshoot during recovery.
8.3.13.2 Inductor DCR Current Sensing

For high-power applications that do not require accurate current-limit protection, inductor DCR current sensing is preferable. This technique provides lossless and continuous monitoring of the inductor current using an RC sense network in parallel with the inductor. Select an inductor with a low DCR tolerance to achieve a typical current limit accuracy within the range of 10% to 15% at room temperature. Components $R_{CS}$ and $C_{CS}$ in Figure 8-5 create a low-pass filter across the inductor to enable differential sensing of the voltage across the inductor DCR.

![Figure 8-5. Inductor DCR Current Sensing Implementation](image)

The voltage drop across the sense capacitor in the s-domain is given by Equation 10. When the $R_{CS}C_{CS}$ time constant is equal to $L_{O}/R_{DCR}$, the voltage developed across the sense capacitor, $C_{CS}$, is a replica of the inductor DCR voltage and accurate current sensing is achieved. If the $R_{CS}C_{CS}$ time constant is not equal to the $L_{O}/R_{DCR}$ time constant, there is a sensing error as follows:

- $R_{CS}C_{CS} > L_{O}/R_{DCR}$ → the DC level is correct, but the AC amplitude is attenuated.
- $R_{CS}C_{CS} < L_{O}/R_{DCR}$ → the DC level is correct, but the AC amplitude is amplified.

Choose the $C_{CS}$ capacitance greater than or equal to 0.1 μF to maintain a low-impedance sensing network, thus reducing the susceptibility of noise pickup from the switch node. Carefully observe Section 11.1 to make sure that noise and DC errors do not corrupt the current sense signals applied between the ISNS+ and VOUT pins.

8.3.14 Hiccup Mode Current Limiting

The LM25149-Q1 includes an internal hiccup-mode protection function. After an overload is detected, 512 cycles of cycle-by-cycle current limiting occurs. The 512-cycle counter is reset if four consecutive switching cycles occur without exceeding the current limit threshold. Once the 512-cycle counter has expired, the internal soft start is pulled low, the HO and LO driver outputs are disabled, and the 16384 counter is enabled. After the counter reaches 16384, the internal soft start is enabled and the output restarts. The hiccup-mode current limit is disabled during soft start until the FB voltage exceeds 0.4 V.

8.3.15 High-Side and Low-Side Gate Drivers (HO, LO)

The LM25149-Q1 contains N-channel MOSFET gate drivers and an associated high-side level shifter to drive the external N-channel MOSFET. The high-side gate driver works in conjunction with an internal bootstrap diode $D_{BOOT}$ and bootstrap capacitor $C_{BOOT}$. During the conduction interval of the low-side MOSFET, the SW
voltage is approximately 0 V and C\(_{\text{BOOT}}\) charges from VCC through the internal D\(_{\text{BOOT}}\). TI recommends a 0.1-μF ceramic capacitor connected with short traces between the C\(_{\text{BOOT}}\) and SW pins.

The LO and HO outputs are controlled with an adaptive dead-time methodology so that both outputs (HO and LO) are never on at the same time, preventing cross conduction. Before the LO driver output is allowed to turn on, the adaptive dead-time logic first disabled HO and waits for the HO-to-SW voltage to drop below 2 V typical. LO is allow to turn on after a small delay (HO fall to LO rising delay). Similarly, the HO turnon is delayed until the LO voltage has dropped below 2 V. This technique ensures adequate dead-time for any size N-channel MOSFET component or parallel MOSFET configurations.

Caution is advised when adding series gate resistors, as this can impact the effective dead-time. The selected N-channel high-side MOSFET determines the appropriate bootstrap capacitance value C\(_{\text{BOOT}}\) in according to Equation 11.

\[
C_{\text{BOOT}} = \frac{Q_G}{\Delta V_{\text{CBBOOT}}}
\]  

(11)

where

- \(Q_G\) is the total gate charge of the high-side MOSFET at the applicable gate drive voltage
- \(\Delta V_{\text{CBBOOT}}\) is the voltage variation of the high-side MOSFET driver after turnon

To determine \(C_{\text{BOOT}}\), choose \(\Delta V_{\text{BST}}\) so that the available gate drive voltage is not significantly impacted. An acceptable range of \(\Delta V_{\text{BST}}\) is 100 mV to 300 mV. The bootstrap capacitor must be a low-ESR ceramic capacitor, typically 0.1 µF. Use high-side and low-side MOSFETs with logic-level gate threshold voltages.

### 8.3.16 Output Configurations (CNFG)

The LM25149-Q1 can be configured as a primary controller (interleaved mode) or as a secondary controller for paralleling the outputs for high-current applications with a resistor R\(_{\text{CNFG}}\). This resistor also configures if Spread Spectrum is enabled or disabled. See Table 8-4. Once the VCC voltage is above 3.3 V (typical), the CNFG pin is monitored and latched. The configuration cannot be changed on the fly the LM25149-Q1 must be powered down, and VCC must drop below 3.3 V. Figure 8-6 shows the configuration timing diagram.

When the LM25149-Q1 is configured with Spread Spectrum enabled, as a primary controller with spread spectrum (R\(_{\text{CNFG}}\) 41.2 kΩ or 71.5 kΩ), the LM25149-Q1 cannot be synchronized to an external clock.

After the configuration has been latched, the CNFG pin becomes an enable input for active EMI filter, where a logic high (> 2 V) enables the active EMI filter and a logic low (< 0.8 V) disables AEF.

8.3.17 Single-Output Two-phase Operation

To configure for two-phase operation, two LM25149-Q1 controllers are required. The LM25149-Q1 can only be configured in a single or dual-phase configuration, where both outputs are tied together. Additional phases cannot be added. Refer to Figure 8-7. Configure the first controller (CNTRL1) as a primary controller and the second controller (CNTRL2) as a secondary. To configure CNTRL1 as a primary controller, install a 54-kΩ or a 71.5-kΩ resistor from CNFG to AGND. To configure the CNTRL2 as a secondary controller, install a 90.9-kΩ resistor from CNFG to AGND. This disables the error amplifier of CNTRL2, placing it into a high-impedance state. Connect the EXTCOMP pins of the primary and secondary together. The PG/SYNCOUT of the primary is a logic-level output. Refer to Section 7.5 for voltage levels. Connect PG/SYNCOUT of the primary to PFM/SYNC (SYNCIN) of the secondary controller. The SYNCOUT of the primary controller is 180° out-of-phase and facilitates interleaved operation. RT is not used for the oscillator when the LM25149-Q1 is in secondary controller mode, but instead is used for slope compensation. Therefore, select the RT resistance to be the same as that of the primary controller. The oscillator is derived from the primary controller. When in primary/secondary mode, enable both controllers simultaneously for start-up. After the power supply has started, pull the secondary EN pin low (< 0.8 V) for phase shedding to reduce the I_Q current.

If an external SYNCIN signal is applied after start-up while in primary/secondary mode, there is a two-clock cycle delay before the LM25149-Q1 locks on to the external synchronization signal.
Figure 8-7. Schematic Configured for Single-Output Multi-Phase Operation

In PFM pulse skipping to reduce the \( I_Q \) current, the primary controller disables its synchronization clock output, so phase shedding is not supported. Phase shedding is supported in FPWM only. In FPWM, enable or disable the secondary controller as needed to support higher load current or better light-load efficiency, respectively. When the secondary is disabled and then re-enabled, its internal soft start is be pulled low and the LM25149-Q1 goes through a normal soft-start turnon.

For more information, see Benefits of a Multiphase Buck Converter and Multiphase Buck Design From Start to Finish.
8.4 Device Functional Modes

8.4.1 Standby Modes

The LM25149-Q1 operates with peak current-mode control such that the compensation voltage is proportional to the peak inductor current. During no-load or light-load conditions, the output capacitor discharges very slowly. As a result, the compensation voltage does not demand the driver output pulses on a cycle-by-cycle basis. When the LM25149-Q1 controller detects 16 missed switching cycles, it enters standby mode and switches to a low $I_Q$ state to reduce the current drawn from the input. For the LM25149-Q1 to go into standby mode, the controller must be programmed for diode emulation (tie PFM/SYNC to VDDA).

In standby modes and normal mode, the typical low-$I_Q$ is 9 μA with a 3.3-V output.

8.4.2 Pulse Frequency Modulation and Synchronization (PFM/SYNC)

A synchronous buck regulator implemented with a low-side synchronous MOSFET rather than a diode has the capability to sink negative current from the output during light-load, overvoltage, and pre-bias start-up conditions. The LM25149-Q1 provides a diode emulation feature that can be enabled to prevent reverse (drain-to-source) current flow in the low-side MOSFET. When configured for diode emulation mode, the low-side MOSFET is switched off when reverse current flow is detected by sensing of the SW voltage using a zero-cross comparator. The benefit of this configuration is lower power loss during light-load conditions; the disadvantage of diode emulation mode is slower light-load transient response.

Diode emulation is configured with the PFM/SYNC pin. To enable diode emulation and thus achieve low-$I_Q$ current at light loads, connect PFM/SYNC to VDDA. If FPWM or continuous conduction mode (CCM) operation is desired, tie PFM/SYNC to AGND. Note that diode emulation is automatically engaged to prevent reverse current flow during a prebias start-up in PFM. A gradual change from DCM to CCM operation provides monotonic start-up performance.

To synchronize the LM25149-Q1 to an external source, apply a logic-level clock to the PFM/SYNC pin. The LM25149-Q1 can be synchronized to ±20% of the programmed frequency up to a maximum of 2.5 MHz. If there is an RT resistor and a synchronization signal, the LM25149-Q1 ignores the RT resistor and synchronizes to the external clock. Under low-$V_{IN}$ conditions when the minimum off-time is reached, the synchronization signal is ignored, allowing the switching frequency to be reduce to maintain output voltage regulation.

8.4.3 Thermal Shutdown

The LM25149-Q1 includes an internal junction temperature monitor. If the temperature exceeds 175°C (typical), thermal shutdown occurs. When entering thermal shutdown, the device:

1. Turns off the high-side and low-side MOSFETs.
2. Pulls SS and PG/SYNC low.
3. Turns off the VCC regulator.
4. Initiates a soft-start sequence when the die temperature decreases by the thermal shutdown hysteresis of 15°C (typical).

This is a non-latching protection and as such the device cycles into and out of thermal shutdown if the fault persists.
9 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

9.1 Application Information

9.1.1 Power Train Components

A comprehensive understanding of the buck regulator power train components is critical to successfully completing a synchronous buck regulator design. The following section discuss the output inductor, input and output capacitors, power MOSFETs, and EMI input filter.

9.1.1.1 Buck Inductor

For most applications, choose a buck inductance such that the inductor ripple current, $\Delta I_L$, is between 30% to 50% of the maximum DC output current at nominal input voltage. Choose the inductance using Equation 12 based on a peak inductor current given by Equation 13.

$$L_O = \frac{V_{OUT}}{\Delta I_L \cdot F_{SW}} \left(1 - \frac{V_{OUT}}{V_{IN}}\right)$$  \hfill (12)

$$I_{L(peak)} = I_{OUT} + \frac{\Delta I_L}{2}$$  \hfill (13)

Check the inductor data sheet to make sure that the saturation current of the inductor is well above the peak inductor current of a particular design. Ferrite designs have very low core loss and are preferred at high switching frequencies, so design goals can then concentrate on copper loss and preventing saturation. Low inductor core loss is evidenced by reduced no-load input current and higher light-load efficiency. However, ferrite core materials exhibit a hard saturation characteristic and the inductance collapses abruptly when the saturation current is exceeded. This results in an abrupt increase in inductor ripple current and higher output voltage ripple, not to mention reduced efficiency and compromised reliability. Note that the saturation current of an inductor generally decreases as its core temperature increases. Of course, accurate overcurrent protection is key to avoiding inductor saturation.

9.1.1.2 Output Capacitors

Ordinarily, the output capacitor energy storage of the regulator combined with the control loop response are prescribed to maintain the integrity of the output voltage within the dynamic (transient) tolerance specifications. The usual boundaries restricting the output capacitor in power management applications are driven by finite available PCB area, component footprint and profile, and cost. The capacitor parasitics—equivalent series resistance (ESR) and equivalent series inductance (ESL)—take greater precedence in shaping the load transient response of the regulator as the load step amplitude and slew rate increase.

The output capacitor, $C_{OUT}$, filters the inductor ripple current and provides a reservoir of charge for step-load transient events. Typically, ceramic capacitors provide extremely low ESR to reduce the output voltage ripple and noise spikes, while tantalum and electrolytic capacitors provide a large bulk capacitance in a relatively compact footprint for transient loading events.

Based on the static specification of peak-to-peak output voltage ripple denoted by $\Delta V_{OUT}$, choose an output capacitance that is larger than that given by Equation 14.
\[
C_{OUT} \geq \frac{\Delta I_L}{8 \cdot F_{SW} \sqrt{\Delta V_{OUT}^2 - (R_{ESR} \cdot \Delta I_L)^2}}
\]  
(14)

Figure 9-1 conceptually illustrates the relevant current waveforms during both load step-up and step-down transitions. As shown, the large-signal slew rate of the inductor current is limited as the inductor current ramps to match the new load-current level following a load transient. This slew-rate limiting exacerbates the deficit of charge in the output capacitor, which must be replenished as fast as possible during and after the load step-up transient. Similarly, during and after a load step-down transient, the slew rate limiting of the inductor current adds to the surplus of charge in the output capacitor that must be depleted as quickly as possible.

In a typical regulator application of 12-V input to low output voltage (for example, 3.3 V), the load-off transient represents the worst case in terms of output voltage transient deviation. In that conversion ratio application, the steady-state duty cycle is approximately 28% and the large-signal inductor current slew rate when the duty cycle collapses to zero is approximately \(-V_{OUT} / L\). Compared to a load-on transient, the inductor current takes much longer to transition to the required level. The surplus of charge in the output capacitor causes the output voltage to significantly overshoot. In fact, to deplete this excess charge from the output capacitor as quickly as possible, the inductor current must ramp below its nominal level following the load step. In this scenario, a large output capacitance can be advantageously employed to absorb the excess charge and minimize the voltage overshoot.

To meet the dynamic specification of output voltage overshoot during such a load-off transient (denoted as \(\Delta V_{OVERSHOOT}\) with step reduction in output current given by \(\Delta I_{OUT}\)), the output capacitance should be larger than:

\[
C_{OUT} \geq \frac{L_O \cdot \Delta I_{OUT}^2}{(V_{OUT} + \Delta V_{OVERSHOOT})^2 - V_{OUT}^2}
\]  
(15)

The ESR of a capacitor is provided in the manufacturer’s data sheet either explicitly as a specification or implicitly in the impedance versus frequency curve. Depending on type, size, and construction, electrolytic capacitors have significant ESR, 5 mΩ and above, and relatively large ESL, 5 nH to 20 nH. PCB traces contribute some parasitic resistance and inductance as well. Ceramic output capacitors, on the other hand, have
low ESR and ESL contributions at the switching frequency, and the capacitive impedance component dominates. However, depending on package and voltage rating of the ceramic capacitor, the effective capacitance can drop quite significantly with applied DC voltage and operating temperature.

Ignoring the ESR term in Equation 14 gives a quick estimation of the minimum ceramic capacitance necessary to meet the output ripple specification. Two to four 47-µF, 10-V, X7R capacitors in 1206 or 1210 footprint is a common choice for a 5-V output. Use Equation 15 to determine if additional capacitance is necessary to meet the load-off transient overshoot specification.

A composite implementation of ceramic and electrolytic capacitors highlights the rationale for paralleling capacitors of dissimilar chemistries yet complementary performance. The frequency response of each capacitor is accretive in that each capacitor provides desirable performance over a certain portion of the frequency range. While the ceramic provides excellent mid- and high-frequency decoupling characteristics with its low ESR and ESL to minimize the switching frequency output ripple, the electrolytic device with its large bulk capacitance provides low-frequency energy storage to cope with load transient demands.

9.1.1.3 Input Capacitors

Input capacitors are necessary to limit the input ripple voltage to the buck power stage due to switching-frequency AC currents. TI recommends using X7S or X7R dielectric ceramic capacitors to provide low impedance and high RMS current rating over a wide temperature range. To minimize the parasitic inductance in the switching loop, position the input capacitors as close as possible to the drain of the high-side MOSFET and the source of the low-side MOSFET. The input capacitor RMS current for a single-channel buck regulator is given by Equation 16.

\[ I_{\text{IN}, \text{rms}} = \sqrt{D \cdot\left(\frac{I_{\text{OUT}}^2 \cdot (1-D) + \Delta L^2}{12}\right)} \]  

The highest input capacitor RMS current occurs at \( D = 0.5 \), at which point the RMS current rating of the input capacitors should be greater than half the output current.

Ideally, the DC component of input current is provided by the input voltage source and the AC component by the input filter capacitors. Neglecting inductor ripple current, the input capacitors source current of amplitude \( I_{\text{OUT}} - I_{\text{IN}} \) during the D interval and sinks \( I_{\text{IN}} \) during the 1\(-\)D interval. Thus, the input capacitors conduct a square-wave current of peak-to-peak amplitude equal to the output current. It follows that the resultant capacitive component of AC ripple voltage is a triangular waveform. Together with the ESR-related ripple component, the peak-to-peak ripple voltage amplitude is given by Equation 17.

\[ \Delta V_{\text{IN}} = \frac{I_{\text{OUT}} \cdot D \cdot (1-D)}{F_{\text{SW}} \cdot C_{\text{IN}}} + I_{\text{OUT}} \cdot R_{\text{ESR}} \]  

The input capacitance required for a particular load current, based on an input voltage ripple specification of \( \Delta V_{\text{IN}} \), is given by Equation 18.

\[ C_{\text{IN}} \geq \frac{D \cdot (1-D) \cdot I_{\text{OUT}}}{F_{\text{SW}} \cdot (\Delta V_{\text{IN}} - R_{\text{ESR}} \cdot I_{\text{OUT}})} \]  

Low-ESR ceramic capacitors can be placed in parallel with higher valued bulk capacitance to provide optimized input filtering for the regulator and damping to mitigate the effects of input parasitic inductance resonating with high-Q ceramics. One bulk capacitor of sufficiently high current rating and four 10-µF 50-V X7R ceramic decoupling capacitors are usually sufficient for 12-V battery automotive applications. Select the input bulk capacitor based on its ripple current rating and operating temperature range.

Of course, a two-channel buck regulator with 180° out-of-phase interleaved switching provides input ripple current cancellation and reduced input capacitor current stress. The above equations represent valid calculations when one output is disabled and the other output is fully loaded.
### 9.1.1.4 Power MOSFETs

The choice of power MOSFETs has significant impact on DC/DC regulator performance. A MOSFET with low on-state resistance, $R_{DS(on)}$, reduces conduction loss, whereas low parasitic capacitances enable faster transition times and reduced switching loss. Normally, the lower the $R_{DS(on)}$ of a MOSFET, the higher the gate charge and output charge ($Q_G$ and $Q_{OSS}$, respectively), and vice versa. As a result, the product of $R_{DS(on)}$ and $Q_G$ is commonly specified as a MOSFET figure-of-merit. Low thermal resistance of a given package ensures that the MOSFET power dissipation does not result in excessive MOSFET die temperature.

The main parameters affecting power MOSFET selection in a LM25149-Q1 application are as follows:

- $R_{DS(on)}$ at $V_{GS} = 5\, \text{V}$
- Drain-source voltage rating, $BV_{DSS}$, typically 40 V, 60 V, or 80 V, depending on the maximum input voltage
- Gate charge parameters at $V_{GS} = 5\, \text{V}$
- Output charge, $Q_{OSS}$, at the relevant input voltage
- Body diode reverse recovery charge, $Q_{RR}$
- Gate threshold voltage, $V_{GS(th)}$, derived from the Miller plateau evident in the $Q_G$ versus $V_{GS}$ plot in the MOSFET data sheet. With a Miller plateau voltage typically in the range of 2 V to 3 V, the 5-V gate drive amplitude of the LM25149-Q1 provides an adequately-enhanced MOSFET when on and a margin against Cdvs/dt shoot-through when off.

The MOSFET-related power losses for one channel are summarized by the equations presented in Table 9-1, where suffixes one and two represent high-side and low-side MOSFET parameters, respectively. While the influence of inductor ripple current is considered, second-order loss modes, such as those related to parasitic inductances and SW node ringing, are not included. Consult the Quickstart Calculator, available for download from the LM25149-Q1 product folder, to assist with power loss calculations.

</tbody>
</table>

1. Gate drive loss is apportioned based on the internal gate resistance of the MOSFET, externally added series gate resistance and the relevant driver resistance of the LM25149-Q1.
2. MOSFET $R_{DS(on)}$ has a positive temperature coefficient of approximately 4500 ppm/°C. The MOSFET junction temperature, $T_J$, and its rise over ambient temperature is dependent upon the device total power dissipation and its thermal impedance. When operating at or near minimum input voltage, make sure that the MOSFET $R_{DS(on)}$ is rated for the available gate drive voltage.
3. $D' = 1-D$ is the duty cycle complement.
4. MOSFET output capacitances, $C_{oss1}$ and $C_{oss2}$, are highly non-linear with voltage. These capacitances are charged losslessly by the inductor current at high-side MOSFET turnoff. During turnon, however, a current flows from the input to charge the output capacitance of the low-side MOSFET. $E_{oss1}$, the energy of $C_{oss1}$, is dissipated at turnon, but this is offset by the stored energy $E_{oss2}$ on $C_{oss2}$.
5. MOSFET body diode reverse recovery charge, $Q_{RR}$, depends on many parameters, particularly forward current, current transition speed and temperature.

The high-side (control) MOSFET carries the inductor current during the PWM on-time (or D interval) and typically incurs most of the switching losses. It is, therefore, imperative to choose a high-side MOSFET that balances conduction and switching loss contributions. The total power dissipation in the high-side MOSFET is the sum of...
the losses due to conduction, switching (voltage-current overlap), output charge, and typically two-thirds of the net loss attributed to body diode reverse recovery.

The low-side (synchronous) MOSFET carries the inductor current when the high-side MOSFET is off (or during the 1–D interval). The low-side MOSFET switching loss is negligible as it is switched at zero voltage – current just commutates from the channel to the body diode or vice versa during the transition deadtimes. LM25149-Q1, with its adaptive gate drive timing, minimizes body diode conduction losses when both MOSFETs are off. Such losses scale directly with switching frequency.

In high step-down ratio applications, the low-side MOSFET carries the current for a large portion of the switching period. Therefore, to attain high efficiency, it is critical to optimize the low-side MOSFET for low $R_{DS(on)}$. In cases where the conduction loss is too high or the target $R_{DS(on)}$ is lower than available in a single MOSFET, connect two low-side MOSFETs in parallel. The total power dissipation of the low-side MOSFET is the sum of the losses due to channel conduction, body diode conduction, and typically one-third of the net loss attributed to body diode reverse recovery. The LM25149-Q1 is well suited to drive TI’s portfolio of NexFET™ power MOSFETs.

### 9.1.1.5 EMI Filter

Switching regulators exhibit negative input impedance, which is lowest at the minimum input voltage. An underdamped LC filter exhibits a high output impedance at the resonant frequency of the filter. For stability, the filter output impedance must be less than the absolute value of the converter input impedance.

$$Z_{IN} = \left| \frac{V_{IN(min)}}{P_{IN}} \right|^2$$  \hspace{1cm} (19)

The Passive EMI filter design steps are as follows:

- Calculate the required attenuation of the EMI filter at the switching frequency, where $C_{IN}$ represents the existing capacitance at the input of the switching converter.
- Input filter inductor $L_{IN}$ is usually selected between 1 μH and 10 μH, but it can be lower to reduce losses in a high-current design.
- Calculate input filter capacitor $C_{F}$.

![Figure 9-2. Passive π-Stage EMI Filter for Buck Regulator](image)

By calculating the first harmonic current from the Fourier series of the input current waveform and multiplying it by the input impedance (the impedance is defined by the existing input capacitor $C_{IN}$), a formula is derived to obtain the required attenuation as shown by Equation 20.

$$\text{Attn} = 20\log\left(\frac{L_{(PEAK)}}{\pi^2 \cdot F_{SW} \cdot C_{IN}} \cdot \sin(\pi \cdot D_{MAX}) \cdot \frac{1}{1 \mu V} \right) - V_{MAX}$$  \hspace{1cm} (20)

where
• \( V_{\text{MAX}} \) is the allowed dB\( \mu \)V noise level for the applicable conducted EMI specification, for example CISPR 25 Class 5
• \( C_{\text{IN}} \) is the existing input capacitance of the buck regulator
• \( D_{\text{MAX}} \) is the maximum duty cycle
• \( I_{\text{PEAK}} \) is the peak inductor current

For filter design purposes, the current at the input can be modeled as a square-wave. Determine the passive EMI filter capacitance \( C_{\text{F}} \) from Equation 21.

\[
C_{\text{F}} = \frac{1}{L_{\text{IN}}} \left( \frac{10^{40} \cdot \text{Atron}}{2\pi \cdot F_{\text{SW}}} \right)^2
\]  

(21)

Adding an input filter to a switching regulator modifies the control-to-output transfer function. The output impedance of the filter must be sufficiently small so that the input filter does not significantly affect the loop gain of the buck converter. The impedance peaks at the filter resonant frequency. The resonant frequency of the passive filter is given by Equation 22.

\[
f_{\text{res}} = \frac{1}{2\pi \sqrt{L_{\text{IN}} \cdot C_{\text{F}}}}
\]  

(22)

The purpose of \( R_{\text{D}} \) is to reduce the peak output impedance of the filter at the resonant frequency. Capacitor \( C_{\text{D}} \) blocks the DC component of the input voltage to avoid excessive power dissipation in \( R_{\text{D}} \). Capacitor \( C_{\text{D}} \) should have lower impedance than \( R_{\text{D}} \) at the resonant frequency with a capacitance value greater than that of the input capacitor \( C_{\text{IN}} \). This prevents \( C_{\text{IN}} \) from interfering with the cutoff frequency of the main filter. Added input damping is needed when the output impedance of the filter is high at the resonant frequency (Q of filter formed by \( L_{\text{IN}} \) and \( C_{\text{IN}} \) is too high). An electrolytic capacitor \( C_{\text{D}} \) can be used for input damping with a value given by Equation 23.

\[
C_{\text{D}} \geq 4 \cdot C_{\text{IN}}
\]  

(23)

Select the input damping resistor \( R_{\text{D}} \) using Equation 24.

\[
R_{\text{D}} = \frac{L_{\text{IN}}}{\sqrt{C_{\text{IN}}}}
\]  

(24)

9.1.1.6 Active EMI Filter

Active EMI filtering uses a capacitive multiplier to reduce the magnitude of the LC filtering components. Extra compensation components are needed, but the reduction in LC size outweigh the required network. The active EMI filter design steps are as follows:

• Calculate the required attenuation of the EMI filter at the switching frequency, similar to the passive EMI filter.
• Select input filter inductor \( L_{\text{IN}} \) between 0.47 \( \mu \)H and 4.7 \( \mu \)H, lower than the passive EMI inductor.
• Use recommended values for sensing and compensation components \( C_{\text{SEN}}, C_{\text{AEFC}}, R_{\text{AEFC}}, C_{\text{INC}}, \) and \( R_{\text{INC}} \).
• Calculate active EMI injection capacitor \( C_{\text{INJ}} \).
• Calculate active EMI damping resistor \( R_{\text{DAMP}} \).
• For low-frequency designs (\( F_{\text{SW}} \leq 1 \text{ MHz} \)), calculate the active EMI damping capacitance \( C_{\text{DAMP}} \).
Figure 9-3. Active EMI Filter for a Buck Regulator

Use Equation 21 to determine attenuation required. Recommended compensation and sensing values are listed in Table 9-2. Use low $F_{SW}$ component values if $F_{SW} \leq 1$ MHz and high $F_{SW}$ component values if $F_{SW} > 1$ MHz.

Table 9-2. Recommended Active EMI Compensation Component Values

Select desired $L_{IN}$. Determine the Active EMI filter capacitance $C_{INJ}$ from Equation 25.

$$C_{INJ} = \frac{1}{C_{SEN} \cdot C_{AEFC}} \left( \frac{10^{40}}{2\pi \cdot F_{SW}} \right)^2$$

Determine the Active EMI damping resistor $R_{DAMP}$ from Equation 26.

$$R_{DAMP} = \sqrt{\frac{C_{SEN} \cdot L_{IN}}{C_{AEFC} \cdot C_{INJ}}}$$

Determine the Active EMI damping capacitance $C_{DAMP}$ from Equation 27. $C_{DAMP}$ is not needed for $F_{SW} > 1$ MHz.

$$C_{DAMP} = \frac{1}{2} \cdot C_{INJ}$$

Select input damping capacitor $C_{D}$ using Equation 23. Select the input damping resistor $R_{D}$ using Equation 24.
9.1.2 Error Amplifier and Compensation

A Type-II compensator using a transconductance error amplifier (EA) is shown in Figure 9-4. The dominant pole of the EA open-loop gain is set by the EA output resistance, $R_{O-EA}$, and effective bandwidth-limiting capacitance, $C_{BW}$, as shown by Equation 28.

$$G_{EA(open-loop)}(s) = -\frac{g_m \cdot R_{O-EA}}{1 + s \cdot R_{O-EA} \cdot C_{BW}}$$

(28)

The EA high-frequency pole is neglected in the above expression. The compensator transfer function from output voltage to COMP node, including the gain contribution from the (internal or external) feedback resistor network, is calculated in Equation 29.

$$G_c(s) = \frac{\hat{v}_c(s)}{\hat{v}_{out}(s)} = \frac{V_{REF}}{V_{OUT}} \cdot \frac{g_m \cdot R_{O-EA} \cdot \left(1 + \frac{s}{\omega_{z1}}\right)}{\left(1 + \frac{s}{\omega_{p1}}\right) \left(1 + \frac{s}{\omega_{p2}}\right)}$$

(29)

where

- $V_{REF}$ is the feedback voltage reference of 0.8 V
- $g_m$ is the EA gain transconductance of 1200 μS
- $R_{O-EA}$ is the error amplifier output impedance of 64 MΩ

$$\omega_{z1} = \frac{1}{R_{COMP} \cdot C_{COMP}}$$

(30)

$$\omega_{p1} = \frac{1}{R_{O-EA} \cdot (C_{COMP} + C_{HF} + C_{BW})} \approx \frac{1}{R_{O-EA} \cdot C_{COMP}}$$

(31)

$$\omega_{p2} = \frac{1}{R_{COMP} \cdot (C_{COMP} + (C_{HF} + C_{BW}))} \approx \frac{1}{R_{COMP} \cdot C_{HF}}$$

(32)

The EA compensation components create a pole close to the origin, a zero, and a high-frequency pole. Typically, $R_{COMP} << R_{O-EA}$ and $C_{COMP} >> C_{BW}$ and $C_{HF}$, so the approximations are valid.

![Figure 9-4. Error Amplifier and Compensation Network](image-url)
9.2 Typical Applications

9.2.1 Design 1 – High Efficiency 2.1 MHz Buck Regulator

Figure 9-5 shows the schematic diagram of a single-output synchronous buck regulator with output voltage of 5 V and a rated load current of 8 A. In this example, the target half-load and full-load efficiencies are 93.5% and 92.5%, respectively, based on a nominal input voltage of 12 V that ranges from 5.5 V to 36 V. The switching frequency is set at 2.1 MHz by resistor $R_{RT}$. The 5-V output is connected to VCCX to reduce IC bias power dissipation and improve efficiency. An output voltage of 3.3 V is also feasible simply by connecting FB to VDDA (tie VCCX to GND in this case).

$$V_{IN} = 5.5 \text{V...36} \text{V}$$

![Schematic Diagram](image)

Figure 9-5. Application Circuit 1 With LM25149-Q1 Buck Regulator at 2.1 MHz

**Note**

This and subsequent design examples are provided herein to showcase the LM25149-Q1 controller in several different applications. Depending on the source impedance of the input supply bus, an electrolytic capacitor can be required at the input to ensure stability, particularly at low input voltage and high output current operating conditions. See Section 10 for more detail.
9.2.1.1 Design Requirements

Table 9-3 shows the intended input, output, and performance parameters for this automotive design example. Reference the LM25149-Q1EVM-2100 evaluation module.

The switching frequency is set at 2.1 MHz by resistor \( R_{RT} \). In terms of control loop performance, the target loop crossover frequency is 60 kHz with a phase margin greater than 50°.

The selected buck regulator powertrain components are cited in Table 9-4, and many of the components are available from multiple vendors. The MOSFETs in particular are chosen for both lowest conduction and switching power loss, as discussed in detail in Section 9.1.1.4. This design uses a low-DCR, metal-powder composite inductor, and ceramic output capacitor implementation.

9.2.1.2 Detailed Design Procedure

9.2.1.2.1 Custom Design With WEBENCH® Tools

Click here to create a custom design using the LM25149-Q1 device with the WEBENCH® Power Designer.

1. Start by entering the input voltage \( V_{IN} \), output voltage \( V_{OUT} \), and output current \( I_{OUT} \) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:
- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WEBENCH.

9.2.1.2.2 Custom Design With Excel Quickstart Tool

Select components based on the regulator specifications using the Quickstart Calculator available for download from the LM25149-Q1 product folder.

9.2.1.2.3 Buck Inductor

1. Use Equation 33 to calculate the required buck inductance based on a 30% inductor ripple current at nominal input voltages.

\[
L_O = \frac{V_{OUT}}{\Delta L_O \cdot F_{SW}} \left( 1 - \frac{V_{OUT}}{V_{IN(nom)}} \right) = \frac{5 \text{ V}}{2.4 \text{ A} \cdot 2.1 \text{ MHz}} \left( 1 - \frac{5 \text{ V}}{12 \text{ V}} \right) = 0.58 \mu \text{H} \tag{33}
\]

2. Select a standard inductor value of 0.56 \( \mu \)H. Use Equation 34 to calculate the peak inductor currents at maximum steady-state input voltage. Subharmonic oscillation occurs with a duty cycle greater than 50% for peak current-mode control. For design simplification, the LM25149-Q1 has an internal slope compensation ramp proportional to the switching frequency that is added to the current sense signal to damp any tendency toward subharmonic oscillation.

\[
I_{LO(PK)} = I_{OUT} + \frac{\Delta L_O}{2} = I_{OUT} + \frac{V_{OUT}}{2 \cdot L_O \cdot F_{SW}} \left( 1 - \frac{V_{OUT}}{V_{IN(max)}} \right) = 8 \text{ A} + \frac{5 \text{ V}}{0.56 \mu \text{H} \cdot 2.1 \text{ MHz}} \left( 1 - \frac{5 \text{ V}}{18 \text{ V}} \right) = 9.53 \text{ A} \tag{34}
\]

3. Based on Equation 8, use Equation 35 to cross-check the inductance to set a slope compensation close to the ideal one times the inductor current downslope.

\[
L_{O(sc)} = \frac{V_{OUT} \cdot R_S}{24 \cdot F_{SW}} = \frac{5 \text{ V} \cdot 5 \text{ m} \Omega}{24 \cdot 2.1 \text{ MHz}} = 0.5 \mu \text{H} \tag{35}
\]

9.2.1.2.4 Current-Sense Resistance

1. Calculate the current-sense resistance based on a maximum peak current capability of at least 25% higher than the peak inductor current at full load to provide sufficient margin during start-up and load-on transients. Calculate the current sense resistances using Equation 36.

\[
R_S = \frac{V_{CS-TH}}{1.25 \cdot I_{LO(PK)}} = \frac{60 \text{ mV}}{1.25 \cdot 9.53 \text{ A}} = 5.04 \text{ m} \Omega \tag{36}
\]

where
• $V_{CS-TH}$ is the 60-mV current limit threshold

2. Select a standard resistance value of 5 mΩ for the shunt. An 0508 footprint component with wide aspect ratio termination design provides 1-W power rating, low parasitic series inductance, and compact PCB layout. Carefully adhere to the layout guidelines in Section 11.1 to make sure that noise and DC errors do not corrupt the differential current-sense voltages measured at the ISNS+ and VOUT pins.

3. Place the shunt resistor close to the inductor.

4. Use Kelvin-sense connections, and route the sense lines differentially from the shunt to the LM25149-Q1.

5. The CS-to-output propagation delay (related to the current limit comparator, internal logic, and power MOSFET gate drivers) causes the peak current to increase above the calculated current limit threshold. For a total propagation delay $t_{DELAY-ISNS+}$ of 40 ns, use Equation 37 to calculate the worst-case peak inductor current with the output shorted.

$$I_{LO-PK(SC)} = \frac{V_{CS-TH}}{R_S} + \frac{V_{IN(max)} \cdot t_{DELAY-ISNS+}}{L_O} = \frac{60 \text{mV}}{5 \text{mΩ}} + \frac{18 \text{V} \cdot 45 \text{ns}}{0.56 \text{μH}} = 13.5 \text{A}$$

(37)

6. Based on this result, select an inductor with saturation current greater than 16 A across the full operating temperature range.

### 9.2.1.2.5 Output Capacitors

1. Use Equation 38 to estimate the output capacitance required to manage the output voltage overshoot during a load-off transient (from full load to no load) assuming a load transient deviation specification of 1.5% (75 mV for a 5-V output).

$$C_{OUT} \geq \frac{L_O \cdot \Delta I_{OUT}^2}{(V_{OUT} + \Delta V_{OVERSHOOT})^2 - V_{OUT}^2} = \frac{0.56 \text{μH} \cdot (8 \text{A})^2}{(5 \text{V} + 75 \text{mV})^2 - (5 \text{V})^2} = 47.4 \text{μF}$$

(38)

2. Noting the voltage coefficient of ceramic capacitors where the effective capacitance decreases significantly with applied voltage, select four 47-μF, 10-V, X7S, 1210 ceramic output capacitors. Generally, when sufficient capacitance is used to satisfy the load-off transient response requirement, the voltage undershoot during a no-load to full-load transient is also satisfactory.

3. Use Equation 39 to estimate the peak-peak output voltage ripple at nominal input voltage.

$$\Delta V_{OUT} = \sqrt{\left(\frac{\Delta I_O}{8 \cdot f_{SW} \cdot C_{OUT}}\right)^2 + \left(R_{ESR} \cdot \Delta I_O\right)^2} = \sqrt{\left(\frac{2.54 \text{A}}{8 \cdot 2.1 \text{MHz} \cdot 44 \text{μF}}\right)^2 + \left(1 \text{mΩ} \cdot 2.54 \text{A}\right)^2} = 4.3 \text{mV}$$

(39)

where

- $R_{ESR}$ is the effective equivalent series resistance (ESR) of the output capacitors
- 44 μF is the total effective (derated) ceramic output capacitance at 5 V

4. Use Equation 40 to calculate the output capacitor RMS ripple current using and verify that the ripple current is within the capacitor ripple current rating.

$$I_{CO(RMS)} = \frac{\Delta I_O}{\sqrt{12}} = \frac{2.54 \text{A}}{\sqrt{12}} = 0.73 \text{A}$$

(40)

### 9.2.1.2.6 Input Capacitors

A power supply input typically has a relatively high source impedance at the switching frequency. Good-quality input capacitors are necessary to limit the input ripple voltage. In general, the ripple current splits between the input capacitors based on the relative impedance of the capacitors at the switching frequency.

1. Select the input capacitors with sufficient voltage and RMS ripple current ratings.

2. Use Equation 41 to calculate the input capacitor RMS ripple current assuming a worst-case duty-cycle operating point of 50%.
\[ I_{\text{CIN(RMS)}} = I_{\text{OUT}} \cdot \sqrt{0.5 \cdot (1 - 0.5)} = 4 \text{ A} \]  

(41)

3. Use Equation 42 to find the required input capacitance.

\[
C_{\text{IN}} \geq \frac{D \cdot (1 - D) \cdot I_{\text{OUT}}}{F_{\text{SW}} \cdot (\Delta V_{\text{IN}} - R_{\text{ESR}} \cdot I_{\text{OUT}})} = \frac{0.5 \cdot (1 - 0.5) \cdot 8 \text{ A}}{2.1 \text{ MHz} \cdot (120 \text{ mV} - 2 \text{ m}\Omega \cdot 8 \text{ A})} = 9.2 \mu\text{F}
\]

(42)

where

- \( \Delta V_{\text{IN}} \) is the input peak-to-peak ripple voltage specification
- \( R_{\text{ESR}} \) is the input capacitor ESR

4. Recognizing the voltage coefficient of ceramic capacitors, select two 10-µF, 50-V, X7R, 1210 ceramic input capacitors. Place these capacitors adjacent to the power MOSFETs. See Section 11.1.1 for more detail.

5. Use four 10-nF, 50-V, X7R, 0603 ceramic capacitors near the high-side MOSFET to supply the high di/dt current during MOSFET switching transitions. Such capacitors offer high self-resonant frequency (SRF) and low effective impedance above 100 MHz. The result is lower power loop parasitic inductance, thus minimizing switch-node voltage overshoot and ringing for lower conducted and radiated EMI signature. Refer to Section 11.1 for more detail.

9.2.1.2.7 Frequency Set Resistor

Calculate the RT resistance for a switching frequency of 2.1 MHz using Equation 43. Choose a standard E96 value of 9.53 kΩ.

\[
R_T (\text{k}\Omega) = \frac{10^6}{F_{\text{SW}} (\text{kHz})} = \frac{10^6}{2100 \text{ kHz}} = 9.4 \text{ k}\Omega
\]

(43)

9.2.1.2.8 Feedback Resistors

If an output voltage setpoint other than 3.3 V or 5 V is required (or to measure a bode plot when using either of the fixed output voltage options), determine the feedback resistances using Equation 44.

\[
R_{\text{FB1}} = R_{\text{FB2}} \cdot \left( \frac{V_{\text{OUT1}}}{V_{\text{REF}}} - 1 \right) = 15 \text{ k}\Omega \cdot \left( \frac{5 \text{ V}}{1.2 \text{ V}} - 1 \right) = 47.5 \text{ k}\Omega
\]

(44)

9.2.1.2.9 Compensation Components

Choose compensation components for a stable control loop using the procedure outlined as follows:

1. Based on a specified loop gain crossover frequency, \( f_C \), of 60 kHz, use Equation 45 to calculate \( R_{\text{COMP}} \), assuming an effective output capacitance of 100 µF. Choose a standard value for \( R_{\text{COMP}} \) of 10 kΩ.

\[
R_{\text{COMP}} = 2\pi \cdot f_C \cdot \frac{V_{\text{OUT}}}{V_{\text{REF}}} \cdot \frac{R_S \cdot G_{\text{CS}} \cdot C_{\text{OUT}}}{g_m} \cdot \frac{5 \text{ V}}{0.8 \text{ V}} \cdot \frac{5 \text{ m}\Omega \cdot 10 \mu\text{F}}{1200 \mu\text{S}} \cdot 100 \mu\text{F} = 9.82 \text{ k}\Omega
\]

(45)

2. To provide adequate phase boost at crossover while also allowing a fast settling time during a load or line transient, select \( C_{\text{COMP}} \) to place a zero at the higher of (1) one tenth of the crossover frequency, or (2) the load pole. Choose a standard value for \( C_{\text{COMP}} \) of 2.7 nF.

\[
C_{\text{COMP}} = \frac{10}{2\pi \cdot f_C \cdot R_{\text{COMP}}} = \frac{10}{2\pi \cdot 60 \text{ kHz} \cdot 10 \text{ k}\Omega} = 2.65 \text{ nF}
\]

(46)
Such a low capacitance value also helps to avoid output voltage overshoot when recovering from dropout (when the input voltage is less than the output voltage setpoint and \(V_{\text{COMP}}\) is railed high).

3. Calculate \(C_{\text{HF}}\) to create a pole at the ESR zero and to attenuate high-frequency noise at COMP. \(C_{\text{BW}}\) is the bandwidth-limiting capacitance of the error amplifier. \(C_{\text{HF}}\) may not be significant enough to be necessary in some designs, like this one. \(C_{\text{HF}}\) can be unpopulated, or used with a small 22 pF for more noise filtering.

\[
C_{\text{HF}} = \frac{1}{2\pi \cdot f_{\text{ESR}} \cdot R_{\text{COMP}}} - C_{\text{BW}} = \frac{1}{2\pi \cdot 500\text{kHz} \cdot 10\text{ k}\Omega} - 31\text{ pF} = 0.8\text{ pF}
\]

(47)

**Note**

Set a fast loop with high \(R_{\text{COMP}}\) and low \(C_{\text{COMP}}\) values to improve the response when recovering from operation in dropout.

For technical solutions, industry trends, and insights for designing and managing power supplies, please refer to TI’s technical articles.

### 9.2.1.2.10 Active EMI Components

Choose active EMI filter components for sufficient attenuation using the following procedure.

1. Refer to *Active EMI Filter* for sensing and compensation components.
2. Based on a selected \(L_{\text{IN}}\) of 0.68 \(\mu\)H and a required attenuation of 60 dB, use Equation 48 to calculate \(C_{\text{INJ}}\).

   Choose a standard value for \(C_{\text{INJ}}\) of 0.47 \(\mu\)F.

   \[
   C_{\text{INJ}} = \frac{1}{\frac{C_{\text{SEN}}}{C_{\text{AEFC}}} \cdot L_{\text{IN}}} \left( \frac{10^{40}}{2\pi \cdot F_{\text{SW}}} \right)^2 \frac{1}{100\text{ nF} \cdot 0.68\text{ }\mu\text{H}} \left( \frac{10^{40}}{2\pi \cdot 2.1\text{ MHz}} \right)^2 = 0.42\text{ }\mu\text{F}
   \]

   (48)

3. To prevent the active EMI filter from undamped resonance with the \(L_{\text{IN}}\) inductor, use Equation 49 to select an adequate \(R_{\text{DAMP}}\). Choose a standard value for \(R_{\text{DAMP}}\) of 5.01 \(\Omega\).

   \[
   R_{\text{DAMP}} = \sqrt{\frac{C_{\text{SEN}}}{C_{\text{AEFC}}} \cdot \frac{L_{\text{IN}}}{C_{\text{INJ}}} \left( \frac{100\text{ nF} \cdot 0.68\text{ }\mu\text{H}}{5\text{ nF} \cdot 0.47\text{ }\mu\text{F}} \right)} = 5.4\text{ }\Omega
   \]

   (49)

**Note**

For 2.1-MHz designs \(C_{\text{DAMP}}\) is not required.

9.2.2 Design 2 – High Efficiency 440 kHz Buck Regulator

Figure 9-18 shows the schematic diagram of a single-output synchronous buck regulator with output voltage of 5 V and a rated load current of 10 A. In this example, the target half-load and full-load efficiencies are 97% and 95%, respectively, based on a nominal input voltage of 12 V that ranges from 5.5 V to 36 V. The switching frequency is set at 440 kHz by resistor R\textsubscript{RT}. The 5-V output is connected to VCCX to reduce IC bias power dissipation and improve efficiency. An output voltage of 3.3 V is also feasible simply by connecting FB to VDDA (tie VCCX to GND in this case).
9.2.2.1 Design Requirements

Table 9-5 shows the intended input, output, and performance parameters for this automotive design example.

10 Power Supply Recommendations

The LM25149-Q1 buck controller is designed to operate from a wide input voltage range of 3.5 V to 42 V. The characteristics of the input supply must be compatible with Section 7.1 and Section 7.3. In addition, the input supply must be capable of delivering the required input current to the fully-loaded regulator. Estimate the average input current with Equation 50.

\[
I_{IN} = \frac{P_{OUT}}{V_{IN} \cdot \eta}
\]  

(50)

where

- \( \eta \) is the efficiency

If the regulator is connected to an input supply through long wires or PCB traces with a large impedance, take special care to achieve stable performance. The parasitic inductance and resistance of the input cables can have an adverse affect on converter operation. The parasitic inductance in combination with the low-ESR ceramic input capacitors form an underdamped resonant circuit. This circuit can cause overvoltage transients at \( VIN \) each time the input supply is cycled ON and OFF. The parasitic resistance causes the input voltage to dip during a load transient. The best way to solve such issues is to reduce the distance from the input supply to the regulator and use an aluminum or polymer input capacitor in parallel with the ceramics. The moderate ESR of the electrolytic capacitors helps damp the input resonant circuit and reduce any voltage overshoots. A capacitance in the range of 10 \( \mu F \) to 47 \( \mu F \) is usually sufficient to provide parallel input damping and helps to hold the input voltage steady during large load transients.

An EMI input filter is often used in front of the regulator that, unless carefully designed, can lead to instability as well as some of the effects mentioned above. The application report Simple Success with Conducted EMI for DC-DC Converters (SNVA489) provides helpful suggestions when designing an input filter for any switching regulator.
11 Layout
11.1 Layout Guidelines

Proper PCB design and layout is important in a high-current, fast-switching circuit (with high current and voltage slew rates) to achieve a robust and reliable design. As expected, certain issues must be considered before designing a PCB layout using the LM25149-Q1. The high-frequency power loop of a buck regulator power stage is denoted by loop 1 in the shaded area of Figure 11-1. The topological architecture of a buck regulator means that particularly high di/dt current flows in the components of loop 1, and it becomes mandatory to reduce the parasitic inductance of this loop by minimizing its effective loop area. Also important are the gate drive loops of the high-side and low-side MOSFETs, denoted by 2 and 3, respectively, in Figure 11-1.

Figure 11-1. DC/DC Regulator Ground System With Power Stage and Gate Drive Circuit Switching Loops

11.1.1 Power Stage Layout

1. Input capacitors, output capacitors, and MOSFETs are the constituent components of the power stage of a buck regulator and are typically placed on the top side of the PCB (solder side). The benefits of convective heat transfer are maximized because of leveraging any system-level airflow. In a two-sided PCB layout, small-signal components are typically placed on the bottom side (component side). Insert at least one inner plane, connected to ground, to shield and isolate the small-signal traces from noisy power traces and lines.

2. The DC/DC regulator has several high-current loops. Minimize the area of these loops in order to suppress generated switching noise and optimize switching performance.
   - Loop 1: The most important loop area to minimize is the path from the input capacitor or capacitors through the high- and low-side MOSFETs, and back to the capacitor or capacitors through the ground connection. Connect the input capacitor or capacitors negative terminal close to the source of the low-side MOSFET (at ground). Similarly, connect the input capacitor or capacitors positive terminal close to the drain of the high-side MOSFET (at VIN). Refer to loop 1 of Figure 11-1.
   - Another loop, not as critical as loop 1, is the path from the low-side MOSFET through the inductor and output capacitor or capacitors, and back to source of the low-side MOSFET through ground. Connect the source of the low-side MOSFET and negative terminal of the output capacitor or capacitors at ground as close as possible.
3. The PCB trace defined as SW node, which connects to the source of the high-side (control) MOSFET, the drain of the low-side (synchronous) MOSFET and the high-voltage side of the inductor, must be short and wide. However, the SW connection is a source of injected EMI and thus must not be too large.

4. Follow any layout considerations of the MOSFETs as recommended by the MOSFET manufacturer, including pad geometry and solder paste stencil design.

5. The SW pin connects to the switch node of the power conversion stage and acts as the return path for the high-side gate driver. The parasitic inductance inherent to loop 1 in Figure 11-1 and the output capacitance (C\text{OSS}) of both power MOSFETs form a resonant circuit that induces high frequency (greater than 50 MHz) ringing at the SW node. The voltage peak of this ringing, if not controlled, can be significantly higher than the input voltage. Make sure that the peak ringing amplitude does not exceed the absolute maximum rating limit for the SW pin. In many cases, a series resistor and capacitor snubber network connected from the SW node to GND damps the ringing and decreases the peak amplitude. Provide provisions for snubber network components in the PCB layout. If testing reveals that the ringing amplitude at the SW pin is excessive, then include snubber components as needed.

11.1.2 Gate-Drive Layout

The LM25149-Q1 high-side and low-side gate drivers incorporate short propagation delays, adaptive dead-time control, and low-impedance output stages capable of delivering large peak currents with very fast rise and fall times to facilitate rapid turnon and turnoff transitions of the power MOSFETs. Very high di/dt can cause unacceptable ringing if the trace lengths and impedances are not well controlled.

Minimization of stray or parasitic gate loop inductance is key to optimizing gate drive switching performance, whether it be series gate inductance that resonates with MOSFET gate capacitance or common source inductance (common to gate and power loops) that provides a negative feedback component opposing the gate drive command, thereby increasing MOSFET switching times. The following loops are important:

- Loop 2: high-side MOSFET, Q\text{1}. During the high-side MOSFET turnon, high current flows from the bootstrap (boot) capacitor through the gate driver and high-side MOSFET, and back to the negative terminal of the boot capacitor through the SW connection. Conversely, to turn off the high-side MOSFET, high current flows from the gate of the high-side MOSFET through the gate driver and SW, and back to the source of the high-side MOSFET through the SW trace. Refer to loop 2 of Figure 11-1.

- Loop 3: low-side MOSFET, Q\text{2}. During the low-side MOSFET turnon, high current flows from the VCC decoupling capacitor through the gate driver and low-side MOSFET, and back to the negative terminal of the capacitor through ground. Conversely, to turn off the low-side MOSFET, high current flows from the gate of the low-side MOSFET through the gate driver and GND, and back to the source of the low-side MOSFET through ground. Refer to loop 3 of Figure 11-1.

TI strongly recommends following circuit layout guidelines when designing with high-speed MOSFET gate drive circuits.

1. Connections from gate driver outputs, HO and LO, to the respective gates of the high-side or low-side MOSFETs must be as short as possible to reduce series parasitic inductance. Be aware that peak gate drive currents can be as high as 3.3 A. Use 0.65 mm (25 mils) or wider traces. Use via or vias, if necessary, of at least 0.5 mm (20 mils) diameter along these traces. Route HO and SW gate traces as a differential pair from the LM25149-Q1 to the high-side MOSFET, taking advantage of flux cancellation.

2. Minimize the current loop path from the VCC and HB pins through their respective capacitors as these provide the high instantaneous current, up to 3.3 A, to charge the MOSFET gate capacitances. Specifically, locate the bootstrap capacitor, C\text{BST}, close to the CBOOT and SW pins of the LM25149-Q1 to minimize the area of loop 2 associated with the high-side driver. Similarly, locate the VCC capacitor, C\text{VCC}, close to the VCC and PGND pins of the LM25149-Q1 to minimize the area of loop 3 associated with the low-side driver.

11.1.3 PWM Controller Layout

With the proviso to locate the controller as close as possible to the power MOSFETs to minimize gate driver trace runs, the components related to the analog and feedback signals as well as current sensing are considered in the following:

1. Separate power and signal traces, and use a ground plane to provide noise shielding.

2. Place all sensitive analog traces and components related to COMP, FB, ISNS+, and RT away from high-voltage switching nodes such as SW, HO, LO, or CBOOT to avoid mutual coupling. Use internal layer or
layers as ground plane or planes. Pay particular attention to shielding the feedback (FB) and current sense (ISNS+ and VOUT) traces from power traces and components.

3. Locate the upper and lower feedback resistors (if required) close to the FB pin, keeping the FB trace as short as possible. Route the trace from the upper feedback resistor to the required output voltage sense point at the load.

4. Route the ISNS+ and VOUT sense traces as differential pairs to minimize noise pickup and use Kelvin connections to the applicable shunt resistor (if shunt current sensing is used) or to the sense capacitor (if inductor DCR current sensing is used).

5. Minimize the loop area from the VCC and VIN pins through their respective decoupling capacitors to the PGND pin. Locate these capacitors as close as possible to the LM25149-Q1.

### 11.1.4 Active EMI Layout

Active EMI layout is critical for enhanced EMI performance. Layout considerations are as follows:

1. Connect AVSS to a quiet GND connection, further from IC if possible. Keep decoupling capacitor $C_{AEFVDDA}$ close to the AEFVDDA pin and AVSS GND connection. See capacitor C23 in Figure 11-2.

2. Route the SEN and INJ traces differentially as close together as possible on an internal quiet layer. Avoid noisy layer or layers carrying high-voltage traces.

3. Place the active EMI compensation components $C_{AEFC}$, $R_{AEFC}$, and $R_{AEFDC}$ close together and near the $V_{IN-EMI}$ node to the input filter inductor.

4. $C_{SEN}$ and $C_{INJ}$ components should be placed directly outside of the compensation loop.

5. Place input compensation components $R_{AEFC}$ and $C_{AEFC}$ nearby the other Active EMI components. Ensure the GND connection is far away from any noise sources. Do not connect the input compensation GND near the powerstage.

6. Route REFAGND directly to the GND of the input power connector. Do not tie to the GND plane connection. The REFAGND trace can partially shield the SEN and INJ differential pair on the way to the input power connector.

### 11.1.5 Thermal Design and Layout

The useful operating temperature range of a PWM controller with integrated gate drivers and bias supply LDO regulator is greatly affected by the following:

- Average gate drive current requirements of the power MOSFETs
- Switching frequency
- Operating input voltage (affecting bias regulator LDO voltage drop and hence its power dissipation)
- Thermal characteristics of the package and operating environment

For a PWM controller to be useful over a particular temperature range, the package must allow for the efficient removal of the heat produced while keeping the junction temperature within rated limits. The LM25149-Q1 controller is available in a small 4-mm × 4-mm 24-pin VQFN PowerPAD package to cover a range of application requirements. **Section 11.1.5** summarizes the thermal metrics of this package.

The 24-pin VQFN package offers a means of removing heat from the semiconductor die through the exposed thermal pad at the base of the package. While the exposed pad of the package is not directly connected to any leads of the package, it is thermally connected to the substrate of the LM25149-Q1 device (ground). This allows a significant improvement in heat sinking, and it becomes imperative that the PCB is designed with thermal lands, thermal vias, and a ground plane to complete the heat removal subsystem. The exposed pad of the LM25149-Q1 is soldered to the ground-connected copper land on the PCB directly underneath the device package, reducing the thermal resistance to a very low value.

Numerous vias with a 0.3-mm diameter connected from the thermal land to the internal and solder-side ground plane or planes are vital to help dissipation. In a multi-layer PCB design, a solid ground plane is typically placed on the PCB layer below the power components. Not only does this provide a plane for the power stage currents to flow but it also represents a thermally conductive path away from the heat generating devices.

The thermal characteristics of the MOSFETs also are significant. The drain pads of the high-side MOSFETs are normally connected to a VIN plane for heat sinking. The drain pads of the low-side MOSFETs are tied to the SW plane, but the SW plane area is purposely kept as small as possible to mitigate EMI concerns.
11.1.6 Ground Plane Design

As mentioned previously, TI recommends using one or more of the inner PCB layers as a solid ground plane. A ground plane offers shielding for sensitive circuits and traces and also provides a quiet reference potential for the control circuitry. In particular, a full ground plane on the layer directly underneath the power stage components is essential. Connect the source terminal of the low-side MOSFET and return terminals of the input and output capacitors to this ground plane. Connect the PGND and AGND pins of the controller at the DAP and then connect to the system ground plane using an array of vias under the DAP. The PGND nets contain noise at the switching frequency and can bounce because of load current variations. The power traces for PGND, VIN, and SW can be restricted to one side of the ground plane, for example on the top layer. The other side of the ground plane contains much less noise and is ideal for sensitive analog trace routes.

11.2 Layout Example

Figure 11-2 shows a single-sided layout of a synchronous buck regulator with discrete power MOSFETs, Q1 and Q2, in SON 5-mm × 6-mm case size. The power stage is surrounded by a GND pad geometry to connect an EMI shield if needed. The design uses layer 2 of the PCB as a power-loop return path directly underneath the top layer to create a low-area switching power loop of approximately 2 mm². This loop area, and hence parasitic inductance, must be as small as possible to minimize EMI as well as switch-node voltage overshoot and ringing.

The high-frequency power loop current flows through MOSFETs Q1 and Q2, through the power ground plane on layer 2, and back to VIN through the 0402 ceramic capacitors C17 through C22. The currents flowing in opposing directions in the vertical loop configuration provide field self-cancellation, reducing parasitic inductance. Figure 11-4 shows a side view to illustrate the concept of creating a low-profile, self-canceling loop in a multilayer PCB structure. The layer-2 GND plane layer, shown in Figure 11-3, provides a tightly-coupled current return path directly under the MOSFETs to the source terminals of Q2.

Six 10-nF input capacitors with small 0402 or 0603 case size are placed in parallel very close to the drain of Q1. The low equivalent series inductance (ESL) and high self-resonant frequency (SRF) of the small footprint capacitors yield excellent high-frequency performance. The negative terminals of these capacitors are connected to the layer-2 GND plane with multiple 12-mil (0.3-mm) diameter vias, further minimizing parasitic loop inductance.
Additional guidelines to improve noise immunity and reduce EMI are as follows:

- Make the ground connections to the LM25149-Q1 controller as shown in Figure 11-2. Create a power ground directly connected to all high-power components and an analog ground plane for sensitive analog components. The analog ground plane for AGND and power ground plane for PGND must be connected at a single point directly under the IC – at the die attach pad (DAP).
- Connect the MOSFETs (switch node) directly to the inductor terminal with short copper connections (without vias) as this net has high dv/dt and contributes to radiated EMI. The single-layer routing of the switch-node connection means that switch-node vias with high dv/dt do not appear on the bottom side of the PCB. This avoids e-field coupling to the reference ground plane during the EMI test. VIN and PGND plane copper pours shield the polygon connecting the MOSFETs to the inductor terminal, further reducing the radiated EMI signature.
- Place the EMI filter components on the bottom side of the PCB so that they are shielded from the power stage components on the top side.

12 Device and Documentation Support

12.1 Device Support

12.1.1 Development Support

With an input operating voltage as low as 3.5 V and up to 100 V as specified in Table 12-1, the LM5140/1/3/6/9-Q1 family of synchronous buck controllers from TI provides flexibility, scalability and optimized solution size for a range of applications. These controllers enable DC/DC solutions with high density, low EMI and increased flexibility. All controllers are rated for a maximum operating junction temperature of 150°C and have AEC-Q100 grade 1 qualification.

12.1.2 Custom Design With WEBENCH® Tools

Click here to create a custom design using the LM25149-Q1 device with the WEBENCH® Power Designer.

1. Start by entering the input voltage ($V_{IN}$), output voltage ($V_{OUT}$), and output current ($I_{OUT}$) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer gives a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:
• Run electrical simulations to see important waveforms and circuit performance
• Run thermal simulations to understand board thermal performance
• Export customized schematic and layout into popular CAD formats
• Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WEBENCH.

12.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

12.7 Glossary

TIGlossary This glossary lists and explains terms, acronyms, and definitions.

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE**: TI has discontinued the production of the device.

(2) **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as “Pb-Free”.

**RoHS Exempt**: TI defines “RoHS Exempt” to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.** - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer**: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are undertaken to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
