LMH6503 Wideband, Low Power, Linear Variable Gain Amplifier

Check for Samples: LMH6503

**FEATURES**

- $V_S = \pm 5V$, $T_A = 25^\circ C$, $R_F = 1k\Omega$, $R_G = 174\Omega$, $R_L = 100\Omega$, $A_V = A_{V(MAX)} = 10$, Typical Values Unless Specified.
- -3dB BW 135MHz
- Gain Control BW 100MHz
- Adjustment Range (Typical Over Temp) 70dB
- Gain Matching (Limit) $\pm 0.7$dB
- Slew Rate 1800V/\mu s
- Supply Current (No Load) 37mA
- Linear Output Current $\pm 75$mA
- Output Voltage ($R_L = 100\Omega$, $V_O = 2V_{PP}$) $-57$dBc
- Replacement for CLC522

**APPLICATIONS**

- Variable Attenuator
- AGC
- Voltage Controller Filter
- Multiplier

**DESCRIPTION**

The LMH™6503 is a wideband, DC coupled, differential input, voltage controlled gain stage followed by a high-speed current feedback Op Amp which can directly drive a low impedance load. Gain adjustment range is more than 70dB for up to 10MHz.

Maximum gain is set by external components and the gain can be reduced all the way to cut-off. Power consumption is 370mW with a speed of 135MHz. Output referred DC offset voltage is less than 350mV over the entire gain control voltage range. Device-to-device Gain matching is within 0.7dB at maximum gain. Furthermore, gain at any $V_G$ is tested and the tolerance is ensured. The output current feedback Op Amp allows high frequency large signals (Slew Rate = 1800V/\mu s) and can also drive heavy load current (75mA). Differential inputs allow common mode rejection in low level amplification or in applications where signals are carried over relatively long wires. For single ended operation, the unused input can easily be tied to ground (or to a virtual half-supply in single supply application). Inverting or non-inverting gains could be obtained by choosing one input polarity or the other.

To further increase versatility when used in a single supply application, gain control range is set to be from $-1V$ to $+1V$ relative to pin 11 potential (ground pin). In single supply operation, this ground pin is tied to a “virtual” half supply. Gain control pin has high input impedance to simplify its drive requirement. Gain control is linear in V/V throughout the gain adjustment range. Maximum gain can be set to be anywhere between 1V/V to 100V/V or higher. For linear in dB gain control applications, see LMH6502 datasheet.

The LMH6503 is available in the SOIC-14 and TSSOP-14 package.
Figure 1. Gain vs. $V_G$ for Various Temperature

Typical Application

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

(1) Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not ensured. For ensured specifications, see the Electrical Characteristics tables.

(2) If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office/Distributors for availability and specifications.

(3) Human body model: 1.5kΩ in series with 100pF. Machine model: 0Ω in series with 200pF.

(4) The maximum output current (\(I_{OUT}\)) is determined by device power dissipation limitations or value specified, whichever is lower.

(1) Electrical Table values apply only for factory testing conditions at the temperature indicated. Factory testing conditions result in very limited self-heating of the device such that $T_J = T_A$. No ensured specification of parametric performance is indicated in the electrical tables under conditions of internal self-heating where $T_J > T_A$.

(2) Typical values represent the most likely parametric norm. Bold numbers refer to over temperature limits.

(3) Flat Band Attenuation (Relative To Max Gain) Range Definition: Specified as the attenuation range from maximum which allows gain flatness specified (either $\pm 0.2dB$ or $\pm 0.1dB$), relative to $A_{VMAX}$ gain. For example, for $f<30MHz$, here are the Flat Band Attenuation ranges: $\pm 0.2dB$: 10V/V down to 1V/V=20dB range $\pm 0.1dB$: 10V/V down to 4.7V/V=6.5dB range

(4) Gain Control Frequency Response Schematic:

(5) Slew Rate is the average of the rising and falling rates.

(6) CMRR definition: $[\Delta V_{OUT}/\Delta V_{CM}]_{A_{V}}$ with 0.1V differential input voltage. $\Delta V_{OUT}$ is the change in output voltage with offset shift subtracted out.

(7) Positive current corresponds to current flowing in the device.

(8) Drift determined by dividing the change in parameter distribution at temperature extremes by the total temperature change.

(9) +PSRR definition: $[\Delta V_{OUT}/\Delta V^+]_{A_{V}}$. -PSRR definition: $[\Delta V_{OUT}/\Delta V^-]_{A_{V}}$ with 0.1V differential input voltage. $\Delta V_{OUT}$ is the change in output voltage with offset shift subtracted out.

(10) CMRR definition: $[\Delta V_{OUT}/\Delta V_{CM}]_{A_{V}}$ with 0.1V differential input voltage. $\Delta V_{OUT}$ is the change in output voltage with offset shift subtracted out.

Figure 58.
APPLICATION INFORMATION

THEORY OF OPERATION

The LMH6503 is a linear wideband variable-gain amplifier as illustrated in Figure 59. A voltage input signal may be applied differentially between the two inputs (+V\textsubscript{IN}, −V\textsubscript{IN}), or single-endedly by grounding one of the two unused inputs. The LMH6503 input buffers convert the input voltage to a current (I\textsubscript{RG}) that is a function of the differential input voltage (V\textsubscript{INPUT} = (+V\textsubscript{IN}) - (−V\textsubscript{IN})) and the value of the gain setting resistor (R\textsubscript{G}). This current (I\textsubscript{RG}) is then mirrored to a gain stage with a current gain of K (1.72 nominal). The voltage controlled two-quadrant multiplier attenuates this current which is then converted to a voltage via the output amplifier. This output amplifier is a current feedback op amp configured as a Transimpedance amplifier. Its Transimpedance gain is the feedback resistor (R\textsubscript{F}). The input signal, output, and gain control are all voltages. The output voltage can easily be calculated as shown in Equation 1:

\[
V_{\text{OUT}} = I_{\text{RG}} \times K \times \left( \frac{V_{\text{G}} + 1}{2} \right) \times R_{\text{F}} \quad \text{FOR} \quad -1 < V_{\text{G}} < +1
\]  

(1)

Where K = 1.72 (Nominal)

since:

\[
I_{\text{RG}} = \frac{V_{\text{INPUT}}}{R_{\text{G}}}
\]

(2)

The gain of the LMH6503 is therefore a function of three external variables: R\textsubscript{G}, R\textsubscript{F}, and V\textsubscript{G} as expressed in Equation 3:

\[
A_{\text{V}} = \frac{R_{\text{F}}}{R_{\text{G}}} \times 1.72 \times \left( \frac{V_{\text{G}} + 1}{2} \right)
\]

(3)

The gain control voltage (V\textsubscript{G}) has an ideal input range of −1V < V\textsubscript{G} < +1V. At V\textsubscript{G} = +1V, the gain of the LMH6503 is at its maximum as expressed in Equation 4:

\[
A_{\text{V}} = 1.72 \times \frac{R_{\text{F}}}{R_{\text{G}}}
\]

(4)

Notice also that Equation 4 holds for both differential and single-ended operation.

Figure 59. LMH6503 Functional Block Diagram
CHOOSING $R_F$ AND $R_G$

$R_G$ is calculated using Equation 5. $V_{\text{INPUTMAX}}$ is the maximum peak input voltage ($V_{\text{pk}}$) determined by the application. $I_{\text{RGMAX}}$ is the maximum allowable current through $R_G$ and is typically 2.3mA. Once $A_{\text{VMAX}}$ is determined from the minimum input and desired output voltages, $R_F$ is then determined using Equation 6. These values of $R_F$ and $R_G$ are the minimum possible values that meet the input voltage and maximum gain constraints. Scaling the resistor values will decrease bandwidth and improve stability.

$$R_G = \frac{V_{\text{INPUTMAX}}}{I_{\text{RGMAX}}} \tag{5}$$

$$R_F = \frac{1}{K} \cdot R_G \cdot A_{\text{VMAX}} \tag{6}$$

Figure 60 illustrates the resulting LMH6503 bandwidths as a function of the maximum (y axis) and minimum (related to x axis) input voltages when $V_{\text{OUT}}$ is held constant at 1V$_{\text{PP}}$.

ADJUSTING OFFSETS

Treating the offsets introduced by the input and output stages of the LMH6503 is accomplished with a two step process. The offset voltage of the output stage is treated by first applying $-1.1$V on $V_G$, which effectively isolates the input stage and multiplier core from the output stage. As illustrated in Figure 61, the trim pot located at R14 on the LMH6503 Evaluation Board (LMH730033) should then be adjusted in order to null the offset voltage seen at the LMH6503’s output (pin 10).
Once this is accomplished, the offset errors introduced by the input stage and multiplier core can then be treated. The second step requires the absence of an input signal and matched source impedances on the two input pins in order to cancel the bias current errors. This done, then +1.1V should be applied to \( V_G \) and the trim pot located at \( R_{10} \) adjusted in order to null the offset voltage seen at the LMH6503’s output. If a more limited gain range is anticipated, the above adjustments should be made at these operating points. These steps will minimize the output offset voltage. However, since the offset term itself varies with the gain setting, the correction is not perfect and some residual output offset will remain.

**GAIN ACCURACY**

Defined as the ratio of measured gain (V/V), at a certain \( V_G \), to the best fit line drawn through the typical gain (V/V) distribution for \(-1V < V_G < 1V\) (results expressed in dB) (See Figure 62). The best fit gain \( (A_V) \) is given by:

\[
A_V \(\text{V/V}\) = 4.87V_G + 4.61
\]  
(7)

For: \(-1V \leq V_G \leq +1V\), \( R_F = 1k\Omega \), \( R_S = 174\Omega \)

(8)

For a \( V_G \) range, the value specified in the tables represents the worst case accuracy over the entire range. The “Typical” value would be the worst case ratio between the “Typical Gain” and the best fit line. The “Max” value would be the worst case between the max/min gain limit and the best fit line.

**GAIN MATCHING**

Defined as the limit on gain variation at a certain \( V_G \) (expressed in dB) (See Figure 62). Specified as "Max" only (no "Typical"). For a \( V_G \) range, the value specified represents the worst case matching over the entire range. The "Max" value would be the worst case ratio between the max/min gain limit and the typical gain.
Figure 62. Gain Accuracy and Gain Matching Parameters Defined

NOISE

Figure 63 describes the LMH6503’s output-referred spot noise density as a function of frequency with $A_{V\text{MAX}} = 10\text{V/V}$. The plot includes all the noise contributing terms. However, with both inputs terminated in 50Ω, the input noise contribution is minimal. At $A_{V\text{MAX}} = 10\text{V/V}$, the LMH6503 has a typical flat-band input-referred spot noise density ($e_{in}$) of 6.6nV/√Hz. For applications with −3dB BW extending well into the flat-band region, the input RMS voltage noise can be determined from the following single-pole model:

$$V_{\text{RMS}} = e_{in} \times \sqrt{1.57 \times (-3\text{dB BANDWIDTH})}$$

(9)

Figure 63. Output Referred Voltage Noise vs. Frequency
CIRCUIT LAYOUT CONSIDERATIONS

Good high-frequency operation requires all of the de-coupling capacitors shown in Figure 64 to be placed as close as possible to the power supply pins in order to insure a proper high-frequency low-impedance bypass. Adequate ground plane and low inductive power returns are also required of the layout. Minimizing the parasitic capacitances at pins 3, 4, 5, 6, 9, 10 and 12 will assure best high frequency performance. The parasitic inductance of component leads or traces to pins 4, 5 and 9 should also be kept to a minimum. Parasitic or load capacitance, $C_L$, on the output (pin 10) degrades phase margin and can lead to frequency response peaking or circuit oscillation. The LMH6503 is fully stable when driving a 100Ω load. With reduced load (e.g. 1kΩ) there is a possibility of instability at very high frequencies beyond 400MHz especially with a capacitive load. When the LMH6503 is connected to a light load as such, it is recommended to add a snubber network to the output (e.g. 100Ω and 39pF in series tied between the LMH6503 output and ground). $C_L$ can also be isolated from the output by placing a small resistor in series with the output (pin 10).

![Figure 64. Required Power Supply Decoupling](image)

Component parasitics also influence high frequency results. Therefore it is recommended to use metal film resistors such as RN55D or leadless components such as surface mount devices. High profile sockets are not recommended.

Texas Instruments suggests the following evaluation board as a guide for high frequency layout and as an aid in device testing and characterization:

<table>

<td>SOIC-14</td>
<td>LMH730033</td>
</tr>
</tbody>
</table>

SINGLE SUPPLY OPERATION

It is possible to operate the LMH6503 with a single supply. To do so, tie pin 11 (GND) to a potential about mid point between $V^+$ and $V^-$. Two examples are shown in Figure 65 & Figure 66.
OPERATING AT LOWER SUPPLY VOLTAGES

The LMH6503 is rated for operation down to 5V supplies (V⁺ - V⁻). There are some specifications shown for operation at ±2.5V within the data sheet (i.e. Frequency Response, CMRR, PSRR, Gain vs. V_G, etc.). Compared to ±5V operation, at lower supplies:

a) V_G range constricts. Referring to Figure 67, note that V_G_MAX (V_G voltage required to get maximum gain) is 0.5V (V_S = ±2.5V) compared to 1.0V for V_S = ±5V. At the same time, gain cut-off (V_G_MIN) would shift to −0.5V from -1V with V_S = ±5V.

Table 1 shows the approximate expressions for various V_G voltages as a function of V_S:

![AC Coupled Single Supply VGA](image)

Figure 65. AC Coupled Single Supply VGA

![Transformer Coupled Single Supply VGA](image)

Figure 66. Transformer Coupled Single Supply VGA
Table 1. \( V_G \) Definition Based on \( V^- \)

<table>
<thead>
<tr>
<th>( V_G )</th>
<th>Definition</th>
<th>Expression (V)</th>
</tr>
</thead>
<tbody>
<tr>
<td>( V_G_{\text{MIN}} )</td>
<td>Gain Cut-off</td>
<td>( 0.2 \times V^- )</td>
</tr>
<tr>
<td>( V_G_{\text{MID}} )</td>
<td>( A_{\text{VMAX}}/2 )</td>
<td>0</td>
</tr>
<tr>
<td>( V_G_{\text{MAX}} )</td>
<td></td>
<td>( -0.2 \times V^- )</td>
</tr>
</tbody>
</table>

b) \( V_G_{\text{LIMIT}} \) (maximum permissible voltage on \( V_G \)) is reduced. This is due to limitations within the device arising from transistor headroom. Beyond this limit, device performance will be affected (non-destructive). Referring to Figure 67, note that with \( V^+ = 2.5V \), and \( V^- = -4V \), \( V_G_{\text{LIMIT}} \) is approaching \( V_G_{\text{MAX}} \) and already "Max gain" is reduced by 1dB. This means that operating under these conditions has reduced the maximum permissible voltage on \( V_G \) to a level below what is needed to get Max gain. If supply voltages are asymmetrical, reference Figure 67 and Figure 68 plots to make sure the region of operation is not overly restricted by the "pinching" of \( V_G_{\text{LIMIT}} \) and \( V_G_{\text{MAX}} \) curves.

c) "Max_gain" reduces. There is an intrinsic reduction in max gain when the total supply voltage is reduced (see Figure 43). In addition, there is the more drastic mechanism described in "b" above and shown in Figure 67.

Similar plots for \( V^+ = 5V \) operation are shown in Figure 68 for comparison and reference.

Application Circuits

FOUR-QUADRANT MULTIPLIER

Applications requiring multiplication, squaring or other non-linear functions can be implemented with four-quadrant multipliers. The LMH6503 implements a four-quadrant multiplier as illustrated in Figure 69:

\[
V_{\text{OUT}} = \left(\frac{V_{\text{BASEBAND}} \cdot V_{\text{CARRIER}}}{K} \right) \cdot \frac{2R_G}{K}
\]

**Figure 69. Four Quadrant Multiplier**

FREQUENCY SHAPING

Frequency shaping and bandwidth extension of the LMH6503 can be accomplished using parallel networks connected across the \(R_G\) ports. The network shown in the Figure 70 schematic will effectively extend the LMH6503's bandwidth.

**Figure 70. Frequency Shaping**

2nd ORDER TUNABLE BANDPASS FILTER

The LMH6503 Variable-Gain Amplifier placed into a feedback loop provides signal processing function such as in a 2nd order tunable bandpass filter. The center frequency of the 2nd order bandpass shown in Figure 71 is adjusted through the use of the LMH6503's gain control voltage, \(V_G\). The integrators implemented with two sections of a LMH6682, provide the coefficients for the transfer function.
\[
\frac{V_O}{V_{IN}} = \left[ -\frac{1}{n} \right] \frac{1}{s^2 + s + \frac{1}{p} + \frac{1}{CR_B} + \frac{p}{C^2 R_T^2}}
\]

\[p = 1.72 \frac{R_F}{R_Y}, \quad Q = \frac{\sqrt{p R_B}}{R_Y}, \quad \omega_0 = \frac{\sqrt{p}}{CR_Y}\]

Figure 71. Tunable Bandpass Filter

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE**: TI has discontinued the production of the device.

(2) **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
- **RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
- **Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.** - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) **Lead/Ball Finish** - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
