**features**
- Dual 10-Bit Voltage Output DAC
- Programmable Settling Time
  - 3 µs in Fast Mode
  - 10 µs in Slow Mode
- Compatible With TMS320 and SPI™ Serial Ports
- Differential Nonlinearity <0.1 LSB Typ
- Monotonic Over Temperature
- Direct Replacement for TLC5617A

**applications**
- Digital Servo Control Loops
- Digital Offset and Gain Adjustment
- Industrial Process Control
- Machine and Motion Control Devices
- Mass Storage Devices

**description**

The TLV5617A is a dual 10-bit voltage output DAC with a flexible 3-wire serial interface. The serial interface is compatible with TMS320, SPI™, QSPI™, and Microwire™ serial ports. It is programmed with a 16-bit serial string containing 4 control bits and 10 data bits.

The resistor string output voltage is buffered by a x2 gain rail-to-rail output buffer. The buffer features a Class-AB output stage to improve stability and reduce settling time. The programmable settling time of the DAC allows the designer to optimize speed versus power dissipation.

Implemented with a CMOS process, the device is designed for single supply operation from 2.7 V to 5.5 V. It is available in an 8-pin SOIC package in standard commercial and industrial temperature ranges.

</tbody>
</table>

NOTES: 4. The relative accuracy of integral nonlinearity (INL), sometimes referred to as linearity error, is the maximum deviation of the output from the line between zero and full scale, excluding the effects of zero-code and full-scale errors.
5. The differential nonlinearity (DNL), sometimes referred to as differential error, is the difference between the measured and ideal 1-LSB amplitude change of any two adjacent codes.
6. Zero-scale error is the deviation from zero voltage output when the digital input code is zero.
7. Zero-scale error temperature coefficient is given by:

\[
E_{ZS \ TC} = \frac{E_{ZS}(T_{max}) - E_{ZS}(T_{min})}{2V_{ref} \times 10^6}(T_{max} - T_{min})
\]

8. Gain error is the deviation from the ideal output (2V_{ref} – 1 LSB) with an output load of 10 kΩ.
9. Gain temperature coefficient is given by:

\[
E_{G \ TC} = \frac{E_{G}(T_{max}) - E_{G}(T_{min})}{2V_{ref} \times 10^6}(T_{max} - T_{min})
\]

NOTES: 11. Settling time is the time for the output signal to remain within ±0.5 LSB of the final measured value for a digital input code change of 0x020 to 0xFD0 and 0xFD0 to 0x020 respectively. Not tested, assured by design.
12. Settling time is the time for the output signal to remain within ±0.5 LSB of the final measured value for a digital input code change of one count. Not tested, assured by design.
13. Slew rate determines the time it takes for a change of the DAC output from 10% to 90% of full-scale voltage.

APPLICATION INFORMATION

general function

The TLV5617A is a dual 10-bit, single-supply DAC, based on a resistor-string architecture. It consists of a serial interface, speed and power-down control logic, a resistor string, and a rail-to-rail output buffer.

The output voltage (full scale determined by the reference) is given by:

\[ V = 2 \times \text{REF} \times \frac{\text{CODE}}{2^n} \]

Where REF is the reference voltage and CODE is the digital input value within the range of 0 to \(2^n-1\), where \(n=10\) (bits). The 16-bit data word, consisting of control bits and the new DAC value, is illustrated in the data format section. A power-on reset initially resets the internal latches to a defined state (all bits zero).

serial interface

A falling edge of CS starts shifting the data bit-per-bit (starting with the MSB) to the internal register on the falling edges of SCLK. After 16 bits have been transferred or CS rises, the content of the shift register is moved to the target latches (DAC A, DAC B, BUFFER, CONTROL), depending on the control bits within the data word.

Figure 12 shows examples of how to connect the TLV5617A to TMS320, SPI, and Microwire.

![Figure 12. Three-Wire Interface](image)

Notes on SPI and Microwire: Before the controller starts the data transfer, the software has to generate a falling edge on the pin connected to CS. If the word width is 8 bits (SPI and Microwire) two write operations must be performed to program the TLV5617A. After the write operation(s), the holding registers or the control register of the DAC update automatically on the rising CS edge, ending the write cycle to the DAC. Note: After transfer of the LSB during a data or control write cycle, one additional rising edge on SCLK is required to reset the internal state machine. This edge can occur when CS is high or low, but must occur before the next falling CS edge that begins the following write cycle. Refer to the timing diagram for more information.

serial clock frequency and update rate

The maximum serial clock frequency is given by:

\[ f_{\text{sclk max}} = \frac{1}{t_{\text{wh min}} + t_{\text{w min}}} = 20 \text{ MHz} \]

The maximum update rate is:

\[ f_{\text{updatemax}} = \frac{1}{16 (t_{\text{wh min}} + t_{\text{w min}})} = 1.25 \text{ MHz} \]

Note that the maximum update rate is just a theoretical value for the serial interface, as the settling time of the TLV5617A should also be considered.
**APPLICATION INFORMATION**

**data format**

The 16-bit data word for the TLV5617A consists of two parts:

- Program bits \((D15..D12)\)
- New data \((D11..D0)\)

<table>
<thead>
<tr>
<th>D15</th>

</tbody>
</table>

SPD: Speed control bit  
1 \(\rightarrow\) fast mode  
0 \(\rightarrow\) slow mode

PWR: Power control bit  
1 \(\rightarrow\) power down  
0 \(\rightarrow\) normal operation

On power up, SPD and PWR are reset to 0 (slow mode and normal operation)

The following table lists all possible combinations of register-select bits:

<table>
<thead>
<tr>
<th>R1</th>
<th>R0</th>
<th>REGISTER</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Write data to DAC B and BUFFER</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Write data to BUFFER</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Write data to DAC A and update DAC B with BUFFER content</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

The meaning of the 12 data bits depends on the register. If one of the DAC registers or the BUFFER is selected, then the 12 data bits determine the new DAC value:

**examples of operation**

- Set DAC A output, select fast mode:

  Write new DAC A value and update DAC A output:

  \[
  \begin{array}{cccccccccccc}
  D15 & D14 & D13 & D12 & D11 & D10 & D9  & D8  & D7  & D6  & D5  & D4  & D3  & D2  & D1  & D0 \\
  1   & 1   & 0   & 0   &     &     &     &     &     &     &     &     &     &     & 0   & 0 \\
  \end{array}
  \]

The DAC A output is updated on the rising clock edge after D0 is sampled.

- Set DAC B output, select fast mode:

  Write new DAC B value to BUFFER and update DAC B output:

  \[
  \begin{array}{cccccccccccc}
  D15 & D14 & D13 & D12 & D11 & D10 & D9  & D8  & D7  & D6  & D5  & D4  & D3  & D2  & D1  & D0 \\
  0   & 1   & 0   & 0   &     &     &     &     &     &     &     &     &     &     & 0   & 0 \\
  \end{array}
  \]

The DAC A output is updated on the rising clock edge after D0 is sampled.

- Set DAC A value, set DAC B value, update both simultaneously, select slow mode:
  1. Write data for DAC B to BUFFER:

  \[
  \begin{array}{cccccccccccc}
  D15 & D14 & D13 & D12 & D11 & D10 & D9  & D8  & D7  & D6  & D5  & D4  & D3  & D2  & D1  & D0 \\
  0   & 0   & 0   & 1   &     &     &     &     &     &     &     &     &     &     & 0   & 0 \\
  \end{array}
  \]

  2. Write new DAC A value and update DAC A and B simultaneously:

  \[
  \begin{array}{cccccccccccc}
  D15 & D14 & D13 & D12 & D11 & D10 & D9  & D8  & D7  & D6  & D5  & D4  & D3  & D2  & D1  & D0 \\
  1   & 0   & 0   & 0   &     &     &     &     &     &     &     &     &     &     & 0   & 0 \\
  \end{array}
  \]
APPLICATION INFORMATION

examples of operation (continued)

Both outputs are updated on the rising clock edge after D0 from the DAC A data word is sampled.

- Set powerdown mode:

X = Don’t care

linearity, offset, and gain error using single ended supplies

When an amplifier is operated from a single supply, the voltage offset can still be either positive or negative. With a positive offset, the output voltage changes on the first code change. With a negative offset, the output voltage may not change with the first code, depending on the magnitude of the offset voltage.

The output amplifier attempts to drive the output to a negative voltage. However, because the most negative supply rail is ground, the output cannot drive below ground and clamps the output at 0 V.

The output voltage then remains at zero until the input code value produces a sufficient positive output voltage to overcome the negative offset voltage, resulting in the transfer function shown in Figure 13.

![Figure 13. Effect of Negative Offset (Single Supply)](image)

This offset error, not the linearity error, produces this breakpoint. The transfer function would have followed the dotted line if the output buffer could drive below the ground rail.

For a DAC, linearity is measured between zero-input code (all inputs 0) and full-scale code (all inputs 1) after offset and full scale are adjusted out or accounted for in some way. However, single supply operation does not allow for adjustment when the offset is negative due to the breakpoint in the transfer function. So the linearity is measured between full-scale code and the lowest code that produces a positive output voltage.

definitions of specifications and terminology

integral nonlinearity (INL)

The relative accuracy or integral nonlinearity (INL), sometimes referred to as linearity error, is the maximum deviation of the output from the line between zero and full scale excluding the effects of zero code and full-scale errors.

differential nonlinearity (DNL)

The differential nonlinearity (DNL), sometimes referred to as differential error, is the difference between the measured and ideal 1 LSB amplitude change of any two adjacent codes. Monotonic means the output voltage changes in the same direction (or remains constant) as a change in the digital input code.
definitions of specifications and terminology (continued)

zero-scale error (E_{ZS})

Zero-scale error is defined as the deviation of the output from 0 V at a digital input value of 0.

gain error (E_G)

Gain error is the error in slope of the DAC transfer function.

total harmonic distortion (THD)

THD is the ratio of the rms value of the first six harmonic components to the value of the fundamental signal. The value for THD is expressed in decibels.

signal-to-noise ratio + distortion (S/N+D)

S/N+D is the ratio of the rms value of the output signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

spurious free dynamic range (SFDR)

Spurious free dynamic range is the difference between the rms value of the output signal and the rms value of the largest spurious signal within a specified bandwidth. The value for SFDR is expressed in decibels.

(1) The marketing status values are defined as follows:
**ACTIVE:** Product device recommended for new designs.
**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.
**OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. **RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

NOTES:

1. Linear dimensions are in inches [millimeters]. Dimensions in parenthesis are for reference only. Controlling dimensions are in inches. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed .006 [0.15] per side.
4. This dimension does not include interlead flash.
5. Reference JEDEC registration MS-012, variation AA.
NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
NOTES: (continued)

8. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

9. Board assembly site may have different recommendations for stencil design.
