1 Features

- High-Performance Static CMOS Technology
  - 150 MHz (6.67-ns Cycle Time)
  - Low-Power (1.8-V Core @ 135 MHz, 1.9-V Core @ 150 MHz, 3.3-V I/O) Design
- JTAG Boundary Scan Support†
- High-Performance 32-Bit CPU (TMS320C28x)
  - 16 x 16 and 32 x 32 MAC Operations
  - 16 x 16 Dual MAC
  - Harvard Bus Architecture
  - Atomic Operations
  - Fast Interrupt Response and Processing
  - Unified Memory Programming Model
  - 4M Linear Program/Data Address Reach
  - Code-Efficient (in C/C++ and Assembly)
  - Code and Pin Compatible to F2810, F2811, and F2812 devices
  - TMS320F24x/LF240x Processor Source Code Compatible
- On-Chip Memory
  - 20K x 16 Total Single-Access RAM (SARAM)
    - L0 and L1: 2 Blocks of 4K x 16 Each SARAM
    - L2 and L3: 2 Blocks of 1K X 16 SARAM
    - H0: 1 Block of 8K x 16 SARAM
    - M0 and M1: 2 Blocks of 1K x 16 Each SARAM
- SPI, SCI, and GPIO Boot Loader Modes to Support Loading Code From Off-chip Sources to On-chip RAM. SPI Boot Mode Supports Loading From an External Serial EEPROM.
- Boot ROM (4K x 16)
  - With Software Boot Modes
  - Standard Math Tables
- External Interface (2812)
  - Up to 1M Total Memory
  - Programmable Wait States
  - Programmable Read/Write Strobe Timing
  - Three Individual Chip Selects
- Clock and System Control
  - Dynamic PLL Ratio Changes Supported
  - On-Chip Oscillator
  - Watchdog Timer Module
- Three External Interrupts
- Peripheral Interrupt Expansion (PIE) Block That Supports 45 Peripheral Interrupts
- Three 32-Bit CPU-Timers
- Motor Control Peripherals
  - Two Event Managers (EVA, EVB)
  - Compatible to 240xA Devices
- Serial Port Peripherals
  - Serial Peripheral Interface (SPI)
  - Two Serial Communications Interfaces (SCIs), Standard UART
  - Enhanced Controller Area Network (eCAN)
  - Multichannel Buffered Serial Port (McBSP)
- 12-Bit ADC, 16 Channels
  - 2 x 8 Channel Input Multiplexer
  - Two Sample-and-Hold
  - Single/Simultaneous Conversions
  - Fast Conversion Rate: 80 ns/12.5 MSPS
- Up to 56 General Purpose I/O (GPIO) Pins
- Advanced Emulation Features
  - Analysis and Breakpoint Functions
  - Real-Time Debug via Hardware
- Development Tools Include
  - ANSI C/C++ Compiler/Assembler/Linker
  - Code Composer Studio™ IDE
  - DSP/BIOS™
  - JTAG Scan Controllers†
- Low-Power Modes and Power Savings
  - IDLE, STANDBY, HALT Modes Supported
  - Disable Individual Peripheral Clocks
- Package Options
  - 179-Ball MicroStar BGA™ With External Memory Interface (GHH), (ZHH) (2812)
  - 176-Pin Low-Profile Quad Flatpack (LQFP) With External Memory Interface (PGF) (2812)
  - 128-Pin LQFP Without External Memory Interface (PBK) (2811)
- Temperature Options:
  - A: −40°C to 85°C (GHH, ZHH, PGF, PBK)
  - S: −40°C to 125°C (GHH, ZHH, PGF, PBK)
  - Q: −40°C to 125°C (PGF, PBK)

2 Introduction

This section provides a summary of each device’s features, lists the pin assignments, and describes the function of each pin. This document also provides detailed descriptions of peripherals, electrical specifications, parameter measurement information, and mechanical data about the available packaging.

2.1 Description

The TMS320R2811 and TMS320R2812 devices, members of the TMS320C28x™ DSP generation, are highly integrated, high-performance solutions for demanding control applications. The functional blocks and the memory maps are described in Section 3, Functional Overview.

Throughout this document, TMS320R2811 and TMS320R2812 are abbreviated as R2811 and R2812, respectively.
2.2 Device Summary

Table 2–1 provides a summary of each device’s features.

2.3 Pin Assignments

Figure 2–1 illustrates the ball locations for the 179-ball GHH and ZHH ball grid array (BGA) packages. Figure 2–2 shows the pin assignments for the 176-pin PGF low-profile quad flatpack (LQFP) and Figure 2–3 shows the pin assignments for the 128-pin PBK LQFP. Table 2–2 describes the function(s) of each pin.

2.3.1 Terminal Assignments for the GHH and ZHH Packages

See Table 2–2 for a description of each terminal’s function(s).

![Figure 2–1. TMS320R2812 179-Ball GHH and ZHH MicroStar BGA™ (Bottom View)](image-url)
2.3.2 Pin Assignments for the PGF Package

The TMS320R2812 176-pin PGF low-profile quad flatpack (LQFP) pin assignments are shown in Figure 2−2. See Table 2−2 for a description of each pin’s function(s).
2.3.3 Pin Assignments for the PBK Package

The TMS320R2811 128-pin PBK low-profile quad flatpack (LQFP) pin assignments are shown in Figure 2–3. See Table 2–2 for a description of each pin’s function(s).

† Typical drive strength of the output buffer for all pins is 4 mA except for TDO, XCLKOUT, XF, XINTF, EMU0, and EMU1 pins, which are 8 mA.
‡ I = Input, O = Output, Z = High impedance
§ PU = pin has internal pullup; PD = pin has internal pulldown. Pullup/pulldown strength is given in Section 6.3. The pullups/pulldowns are enabled in boundary-scan mode.
## Table 2-2. Signal Descriptions† (Continued)

<table>
<thead>
<tr>
<th>NAME</th>
<th>PIN NO.</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMP/MC</td>
<td>F1, 17</td>
<td>Microprocessor/Microcomputer Mode Select. Switches between microprocessor and microcomputer mode. When high, Zone 7 is enabled on the external interface. When low, Zone 7 is disabled from the external interface, and on-chip boot ROM may be accessed instead. This signal is latched into the XINTCNF2 register on a reset and the user can modify this bit in software. The state of the XMP/MC pin is ignored after reset.</td>
</tr>
<tr>
<td>XHOLD</td>
<td>E7, 159</td>
<td>External Hold Request. XHOLD, when active (low), requests the XINTF to release the external bus and place all buses and strobes into a high-impedance state. The XINTF will release the bus when any current access is complete and there are no pending accesses on the XINTF.</td>
</tr>
<tr>
<td>XHOLDA</td>
<td>K10, 82</td>
<td>External Hold Acknowledge. XHOLDA is driven active (low) when the XINTF has granted a XHOLD request. All XINTF buses and strobe signals will be in a high-impedance state. XHOLDA is released when the XHOLD signal is released. External devices should only drive the external bus when XHOLDA is active (low).</td>
</tr>
<tr>
<td>XZCS0AND1</td>
<td>P1, 44</td>
<td>XINTF Zone 0 and Zone 1 Chip Select. XZCS0AND1 is active (low) when an access to the XINTF Zone 0 or Zone 1 is performed.</td>
</tr>

Table 2–2. Signal Descriptions† (Continued)

![Table](image)

**NAME** | **PIN NO.** | **I/O/Z‡** | **PU/PD§** | **DESCRIPTION**
--- | --- | --- | --- | ---
JTAG | | | |
TRST | B12 | 135 | 98 | I | PD
TCK | A12 | 136 | 99 | I | PU
TMS | D13 | 126 | 92 | I | PU
TDI | C13 | 131 | 96 | I | PU
TDO | D12 | 127 | 93 | O/Z | –
EMU0 | D11 | 137 | 100 | I/O/Z | PU

**JTAG test reset with internal pull down.** TRST, when driven high, gives the scan system control of the operations of the device. If this signal is not connected or driven low, the device operates in its functional mode, and the test reset signals are ignored.

**NOTE:** Do not use pullup resistors on TRST; it has an internal pullup device. TRST is an active high test pin and must be maintained low at all times during normal device operation. In a low-noise environment, TRST may be left floating. In other instances, an external pullup resistor is highly recommended. The value of this resistor should be based on drive strength of the debugger pods applicable to the design. A 2.2-kΩ resistor generally offers adequate protection. Since this is application-specific, it is recommended that each target board be validated for proper operation of the debugger and the application.

**TCK** | A12 | 136 | 99 | I | PU
**JTAG test clock with internal pullup**

**TMS** | D13 | 126 | 92 | I | PU
**JTAG test-mode select (TMS) with internal pullup. This serial control input is clocked into the TAP controller on the rising edge of TCK.**

**TDI** | C13 | 131 | 96 | I | PU
**JTAG test data input (TDI) with internal pullup. TDI is clocked into the selected register (instruction or data) on a rising edge of TCK.**

**TDO** | D12 | 127 | 93 | O/Z | –
**JTAG scan out, test data output (TDO). The contents of the selected register (instruction or data) is shifted out of TDO on the falling edge of TCK.**

**EMU0** | D11 | 137 | 100 | I/O/Z | PU
**Emulator pin 0. When TRST is driven high, this pin is used as an interrupt to or from the emulator system and is defined as input/output through the JTAG scan. This pin is also used to put the device into boundary-scan mode. With the EMU0 pin at a logic-high state and the EMU1 pin at a logic-low state, a rising edge on the TRST pin would latch the device into boundary-scan mode.**

**NOTE:** An external pullup resistor is recommended on this pin. The value of this resistor should be based on the drive strength of the debugger pods applicable to the design. A 2.2-kΩ to 4.7-kΩ resistor is generally adequate. Since this is application-specific, it is recommended that each target board be validated for proper operation of the debugger and the application.

† Typical drive strength of the output buffer for all pins is 4 mA except for TDO, XCLKOUT, XF, XINTF, EMU0, and EMU1 pins, which are 8 mA.
‡ I = Input, O = Output, Z = High impedance
§ PU = pin has internal pullup; PD = pin has internal pulldown. Pullup/pulldown strength is given in Section 6.3. The pullups/pulldowns are enabled in boundary-scan mode.

† Typical drive strength of the output buffer for all pins is 4 mA except for TDO, XCLKOUT, XF, XINTF, EMU0, and EMU1 pins, which are 8 mA.
‡ I = Input, O = Output, Z = High impedance
§ PU = pin has internal pullup; PD = pin has internal pulldown. Pullup/pulldown strength is given in Section 6.3. The pullups/pulldowns are enabled in boundary-scan mode.

**NOTE:**

Other than the power supply pins, no pin should be driven before the 3.3-V rail has reached recommended operating conditions. However, it is acceptable for an I/O pin to ramp along with the 3.3-V supply.
3 Functional Overview

Figure 3–1. Functional Block Diagram

† 45 of the possible 96 interrupts are used on the devices.
‡ XINTF is available on the R2812 devices only.

#### Legend:
- Only one of these vector maps—M0 vector, PIE vector, BROM vector, XINTF vector—should be enabled at a time.

**NOTES:**

A. Memory blocks are not to scale.
B. Reserved locations are reserved for future expansion. Application should not access these areas.
C. Boot ROM and Zone 7 memory maps are active either in on-chip or XINTF zone depending on MP/MC, not in both.
D. Peripheral Frame 0, Peripheral Frame 1, and Peripheral Frame 2 memory maps are restricted to data memory only. User program cannot access these memory maps in program space.
E. “Protected” means the order of Write followed by Read operations is preserved rather than the pipeline order.
F. Certain memory ranges are EALLOW protected against spurious writes after configuration.
G. Zones 0 and 1 and Zones 6 and 7 share the same chip select; hence, these memory blocks have mirrored locations.
H. The passwords are set to all ones.

**Figure 3–2. R2812 Memory Map (See Notes A through H)**
Figure 3–3. R2811 Memory Map (See Notes A through F)
The low 64K of the memory-address range maps into the data space of the 240x. The “High 64K” of the memory address range maps into the program space of the 24x/240x. 24x/240x-compatible code will only execute from the “High 64K” memory area. Hence, the top 32K of H0 SARAM block can be used to run 24x/240x-compatible code (if MP/MC mode is low) or, on the 2812, code can be executed from XINTF Zone 7 (if MP/MC mode is high).

The XINTF consists of five independent zones. One zone has its own chip select and the remaining four zones share two chip selects. Each zone can be programmed with its own timing (wait states) and to either sample or ignore external ready signal. This makes interfacing to external peripherals easy and glueless.

**NOTE:**

The chip selects of XINTF Zone 0 and Zone 1 are merged together into a single chip select (XZCS0AND1); and the chip selects of XINTF Zone 6 and Zone 7 are merged together into a single chip select (XZCS6AND7). See Section 3.5, “External Interface, XINTF (2812 only)”, for details.

Peripheral Frame 1, Peripheral Frame 2, and XINTF Zone 1 are grouped together so as to enable these blocks to be “write/read peripheral block protected”. The “protected” mode ensures that all accesses to these blocks happen as written. Because of the C28x pipeline, a write immediately followed by a read, to different memory locations, will appear in reverse order on the memory bus of the CPU. This can cause problems in certain peripheral applications where the user expected the write to occur first (as written). The C28x CPU supports a block protection mode where a region of memory can be protected so as to make sure that operations occur as written (the penalty is extra cycles are added to align the operations). This mode is programmable and by default, it will protect the selected zones.

On the 2812, at reset, XINTF Zone 7 is accessed if the XMP/MC pin is pulled high. This signal selects microprocessor or microcomputer mode of operation. In microprocessor mode, Zone 7 is mapped to high memory such that the vector table is fetched externally. The Boot ROM is disabled in this mode. In microcomputer mode, Zone 7 is disabled such that the vectors are fetched from Boot ROM. This allows the user to either boot from on-chip memory or from off-chip memory. The state of the XMP/MC signal on reset is stored in an MP/MC mode bit in the XINTCNF2 register. The user can change this mode in software and hence control the mapping of Boot ROM and XINTF Zone 7. No other memory blocks are affected by XMP/MC.

I/O space is not supported on the 2812 XINTF.

The wait states for the various spaces in the memory map area are listed in Table 3–1.

3.2 Brief Descriptions

3.2.1 C28x CPU

The C28x™ DSP generation is the newest member of the TMS320C2000™ DSP platform. The C28x is source code compatible to the 24x/240x DSP devices, hence existing 240x users can leverage their significant software investment. Additionally, the C28x is a very efficient C/C++ engine, hence enabling users to develop not only their system control software in a high-level language, but also enables math algorithms to be developed using C/C++. The C28x is as efficient in DSP math tasks as it is in system control tasks that typically are handled by microcontroller devices. This efficiency removes the need for a second processor in many systems. The 32 x 32-bit MAC capabilities of the C28x and its 64-bit processing capabilities, enable the C28x to efficiently handle higher numerical resolution problems that would otherwise demand a more expensive floating-point processor solution. Add to this the fast interrupt response with automatic context save of critical registers, resulting in a device that is capable of servicing many asynchronous events with minimal latency. The C28x has an 8-level-deep protected pipeline with pipelined memory accesses. This pipelining enables the C28x to execute at high speeds without resorting to expensive high-speed memories. Special branch-look-ahead hardware minimizes the latency for conditional discontinuities. Special store conditional operations further improve performance.

3.2.2 Memory Bus (Harvard Bus Architecture)

As with many DSP type devices, multiple busses are used to move data between the memories and peripherals and the CPU. The R28x memory bus architecture contains a program read bus, data read bus and data write bus. The program read bus consists of 22 address lines and 32 data lines. The data read and write busses consist of 32 address lines and 32 data lines each. The 32-bit-wide data busses enable single cycle 32-bit operations. The multiple-bus architecture, commonly termed “Harvard Bus”, enables the R28x to fetch an instruction, read a data value, and write a data value in a single cycle. All peripherals and memories attached to the memory bus prioritize memory accesses.

Generally, the priority of memory bus accesses can be summarized as follows:

| Highest: | Data Writes (Simultaneous data and program writes cannot occur on the memory bus.) |
| Program Writes (Simultaneous data and program writes cannot occur on the memory bus.) |
| Data Reads |
| Program Reads (Simultaneous program reads and fetches cannot occur on the memory bus.) |

| Lowest: | Fetches (Simultaneous program reads and fetches cannot occur on the memory bus.) |

3.2.3 Peripheral Bus

To enable migration of peripherals between various Texas Instruments (TI) DSP family of devices, R281x adopts a peripheral bus standard for peripheral interconnect. The peripheral bus bridge multiplexes the various busses that make up the processor “Memory Bus” into a single bus consisting of 16 address lines and 16 or 32 data lines and associated control signals. Two versions of the peripheral bus are supported on R281x. One version only supports 16-bit accesses (called peripheral frame 2) and this retains compatibility with C240x-compatible peripherals. The other version supports both 16- and 32-bit accesses (called peripheral frame 1).

C28x and TMS320C2000 are trademarks of Texas Instruments.
3.2.4 Real-Time JTAG and Analysis

R281x implements the standard IEEE 1149.1 JTAG interface. Additionally, R281x supports real-time mode of operation whereby the contents of memory, peripheral and register locations can be modified while the processor is running and executing code and servicing interrupts. The user can also single step through non-time critical code while enabling time-critical interrupts to be serviced without interference. R281x implements the real-time mode in hardware within the CPU. This is a unique feature to R281x, no software monitor is required. Additionally, special analysis hardware is provided which allows the user to set hardware breakpoint or data/address watch-points and generate various user selectable break events when a match occurs.

3.2.5 External Interface (XINTF) (2812 Only)

This asynchronous interface consists of 19 address lines, 16 data lines, and three chip-select lines. The chip-select lines are mapped to five external zones, Zones 0, 1, 2, 6, and 7. Zones 0 and 1 share a single chip-select; Zones 6 and 7 also share a single chip-select. Each of the five zones can be programmed with a different number of wait states, strobe signal setup and hold timing and each zone can be programmed for extending wait states externally or not. The programmable wait-state, chip-select and programmable strobe timing enables glueless interface to external memories and peripherals.

3.2.6 M0, M1 SARAMs

All C28x devices contain these two blocks of single access memory, each 1K x 16 in size. The stack pointer points to the beginning of block M1 on reset. The M0 block overlaps the 240x device B0, B1, B2 RAM blocks and hence the mapping of data variables on the 240x devices can remain at the same physical address on C28x devices. The M0 and M1 blocks, like all other memory blocks on C28x devices, are mapped to both program and data space. Hence, the user can use M0 and M1 to execute code or for data variables. The partitioning is performed within the linker. The C28x device presents a unified memory map to the programmer. This makes for easier programming in high-level languages.

3.2.7 L0, L1, L2, L3, H0 SARAMs

R281x contains an additional 18K x 16 of single-access RAM (SARAM), divided into 5 blocks (4K + 4K +1K +1K+ 8K). Each block can be independently accessed, minimizing pipeline stalls. Each block is mapped to both program and data space.

3.2.8 Boot ROM

The Boot ROM is factory-programmed with boot-loading software. The Boot ROM program executes after device reset and checks several GPIO pins to determine which boot mode to enter. For example, the user can select to download new software to internal RAM through one of several serial ports. Other boot modes exist as well. The Boot ROM also contains standard tables, such as SIN/COS waveforms, for use in math-related algorithms. Table 3–2 shows the details of how various boot modes may be invoked. See the TMS320F28x DSP Boot ROM Reference Guide (literature number SPRS095), for more information.

‡ Extra care must be taken due to any effect toggling SPICLK to select a boot mode may have on external logic.
§ If the boot mode selected is H0, then no external code is loaded by the bootloader.

3.2.9 Security

R281x devices contain a non-utilizable code security module for compatibility with C281x and F281x devices. The passwords for the security module are hard-wired in the device as all 0xFFFF. After a device reset, the L0 and L1 SARAM blocks are in a locked condition until a dummy read of the passwords is performed. The R281x Boot ROM performs a dummy read of the password locations. If execution after reset begins directly in external memory on R2812 devices (i.e., MP/MC = 1), the user should perform 8 dummy reads, one each from address 0x3F7FF8 through 0x3F7FFFF.

3.2.10 Peripheral Interrupt Expansion (PIE) Block

The PIE block serves to multiplex numerous interrupt sources into a smaller set of interrupt inputs. The PIE block can support up to 96 peripheral interrupts. On R281x, 45 of the possible 96 interrupts are used by peripherals. The 96 interrupts are grouped into blocks of 8 and each group is fed into 1 of 12 CPU interrupt lines (INT1 to INT12). Each of the 96 interrupts is, supported by its own vector stored in a dedicated RAM block that can be overwritten by the user. The vector is, automatically fetched by the CPU on servicing the interrupt. It takes 8 CPU clock cycles to fetch the vector and save critical CPU registers. Hence the CPU can quickly respond to interrupt events. Prioritization of interrupts is controlled in hardware and software. Each individual interrupt can be enabled/disabled within the PIE block.

3.2.11 External Interrupts (XINT1, 2, 13, XNMI)

R281x supports three masked external interrupts (XINT1, 2, 13). XINT13 is combined with one non-masked external interrupt (XNMI). The combined signal name is XNMI_XINT13. Each of the interrupts can be selected for negative or positive edge triggering and can also be enabled/disabled (including the XNMI). The masked interrupts also contain a 16-bit free running up counter, which is reset to zero when a valid interrupt edge is detected. This counter can be used to accurately time stamp the interrupt.

3.2.12 Oscillator and PLL

R281x can be clocked by an external oscillator or by a crystal attached to the on-chip oscillator circuit. A PLL is provided supporting up to 10-input clock-scaling ratios. The PLL ratios can be changed on-the-fly in software, enabling the user to scale back on operating frequency if lower power operation is desired. Refer to the Electrical Specification section for timing details. The PLL block can be set in bypass mode.

3.2.13 Watchdog

R281x supports a watchdog timer. The user software must regularly reset the watchdog counter within a certain time frame; otherwise, the watchdog will generate a reset to the processor. The watchdog can be disabled if necessary.
3.2.14 **Peripheral Clocking**

The clocks to each individual peripheral can be enabled/disabled so as to reduce power consumption when a peripheral is not in use. Additionally, the system clock to the serial ports (except eCAN) and the event managers, CAP and QEP blocks can be scaled relative to the CPU clock. This enables the timing of peripherals to be decoupled from increasing CPU clock speeds.

3.2.15 **Low-Power Modes**

R281x devices are full static CMOS devices. Three low-power modes are provided:

**IDLE:** Place CPU into low-power mode. Peripheral clocks may be turned off selectively and only those peripherals that need to function during IDLE are left operating. An enabled interrupt from an active peripheral will wake the processor from IDLE mode.

**STANDBY:** Turn off clock to CPU and peripherals. This mode leaves the oscillator and PLL functional. An external interrupt event will wake the processor and the peripherals. Execution begins on the next valid cycle after detection of the interrupt event.

**HALT:** Turn off oscillator. This mode basically shuts down the device and places it in the lowest possible power consumption mode. Only a reset or XNMI will wake the device from this mode.

3.2.16 **Peripheral Frames 0, 1, 2 (PFN)**

R281x segregates peripherals into three sections. The mapping of peripherals is as follows:

**PF0:**
- XINTF: External Interface Configuration Registers (2812 only)
- PIE: PIE Interrupt Enable and Control Registers Plus PIE Vector Table
- Timers: CPU-Timers 0, 1, 2 Registers

**PF1:**
- eCAN: eCAN Mailbox and Control Registers

**PF2:**
- SYS: System Control Registers
- GPIO: GPIO MUX Configuration and Control Registers
- EV: Event Manager (EVA/EVB) Control Registers
- McBSP: McBSP Control and TX/RX Registers
- SCI: Serial Communications Interface (SCI) Control and RX/TX Registers
- SPI: Serial Peripheral Interface (SPI) Control and RX/TX Registers
- ADC: 12-Bit ADC Registers

3.2.17 **General-Purpose Input/Output (GPIO) Multiplexer**

Most of the peripheral signals are multiplexed with general-purpose I/O (GPIO) signals. This enables the user to use a pin as GPIO if the peripheral signal or function is not used. On reset, all GPIO pins are configured as inputs. The user can then individually program each pin for GPIO mode or Peripheral Signal mode. For specific inputs, the user can also select the number of input qualification cycles. This is to filter unwanted noise glitches.

3.2.18 **32-Bit CPU-Timers (0, 1, 2)**

CPU-Timers 0, 1, and 2 are identical 32-bit timers with presettable periods and with 16-bit clock prescaling. The timers have a 32-bit count down register, which generates an interrupt when the counter reaches zero. The counter is decremented at the CPU clock speed divided by the prescale value setting. When the counter reaches zero, it is automatically reloaded with a 32-bit period value. CPU-Timer 2 is reserved for Real-Time OS (RTOS)/BIOS applications. CPU-Timer 2 is reserved for the DSP/BIOS real-time operating system (DSP/BIOS RTOS), and is connected to INT14 of the CPU. CPU-Timer 1 is for general use, and is connected to INT13 of the CPU. CPU-Timer 0 is also for general use, and is connected to the PIE block.
3.2.19 Control Peripherals

R281x supports the following peripherals which are used for embedded control and communication:

**EV:** The event manager module includes general-purpose timers, full-compare/PWM units, capture inputs (CAP) and quadrature-encoder pulse (QEP) circuits. Two such event managers are provided which enable two three-phase motors to be driven or four two-phase motors. The event managers on R281x are compatible to the event managers on the 240x devices (with some minor enhancements).

**ADC:** The ADC block is a 12-bit converter, single ended, 16-channels. It contains two sample-and-hold units for simultaneous sampling.

3.2.20 Serial Port Peripherals

R281x supports the following serial communication peripherals:

**eCAN:** This is the enhanced version of the CAN peripheral. It supports 32 mailboxes, time stamping of messages, and is CAN 2.0B-compliant.

**McBSP:** This is the multichannel buffered serial port that is used to connect to E1/T1 lines, phone-quality codecs for modem applications or high-quality stereo-quality Audio DAC devices. The McBSP receive and transmit registers are supported by a 16-level FIFO. This significantly reduces the overhead for servicing this peripheral.

**SPI:** The SPI is a high-speed, synchronous serial I/O port that allows a serial bit stream of programmed length (one to sixteen bits) to be shifted into and out of the device at a programmable bit-transfer rate. Normally, the SPI is used for communications between the DSP controller and external peripherals or another processor. Typical applications include external I/O or peripheral expansion through devices such as shift registers, display drivers, and ADCs. Multi-device communications are supported by the master/slave operation of the SPI. On R281x, the port supports a 16-level, receive and transmit FIFO for reducing servicing overhead.

**SCI:** The serial communications interface is a two-wire asynchronous serial port, commonly known as UART. On R281x, the port supports a 16-level, receive and transmit FIFO for reducing servicing overhead.

3.3 Register Map

R281x devices contain three peripheral register spaces. The spaces are categorized as follows:

- **Peripheral Frame 0:** These are peripherals that are mapped directly to the CPU memory bus. See Table 3–3.
- **Peripheral Frame 1:** These are peripherals that are mapped to the 32-bit peripheral bus. See Table 3–4.
- **Peripheral Frame 2:** These are peripherals that are mapped to the 16-bit peripheral bus. See Table 3–5.
### Table 3-3. Peripheral Frame 0 Registers†

† Peripheral Frame 2 only allows 16-bit accesses. All 32-bit accesses are ignored (invalid data may be returned or written).

### 3.4 Device Emulation Registers

These registers are used to control the protection mode of the C28x CPU and to monitor some critical device signals. The registers are defined in Table 3–6.
### 3.5 External Interface, XINTF (2812 Only)

This section gives a top-level view of the external interface (XINTF) that is implemented on the 2812 devices.

The external interface is a non-multiplexed asynchronous bus, similar to the C240x external interface. The external interface on the 2812 is mapped into five fixed zones shown in Figure 3–4.

Figure 3–4 shows the 2812 XINTF signals.

The operation and timing of the external interface, can be controlled by the registers listed in Table 3–7.

#### Table 3–7. XINTF Configuration and Control Register Mappings

### 3.5.1 Timing Registers

XINTF signal timing can be tuned to match specific external device requirements such as setup and hold times to strobe signals for contention avoidance and maximizing bus efficiency. The timing parameters can be configured individually for each zone. This allows the programmer to maximize the efficiency of the bus, based on the type of memory or peripheral that the user needs to access. All XINTF timing values are with respect to XTIMCLK, which is equal to or one-half of the SYSCLKOUT rate, as shown in Figure 6–26.

For detailed information on the XINTF timing and configuration register bit fields, see the *TMS320F28x DSP External Interface (XINTF) Reference Guide* (literature number SPRU067).

### 3.5.2 XREVISION Register

The XREVISION register contains a unique number to identify the particular version of XINTF used in the product. For the 2812, this register will be configured as described in Table 3–8.

#### Table 3–8. XREVISION Register Bit Definitions

</table>
NOTES: 
A. The mapping of XINTF Zone 7 is dependent on the XMP/MC device input signal and the MP/MC mode bit (bit 8 of XINTCNF2 register). Zones 0, 1, 2, and 6 are always enabled.
B. Each zone can be programmed with different wait states, setup and hold timing, and is supported by zone chip selects (XZCS0AND1, XZCS2, XZCS6AND7), which toggle when an access to a particular zone is performed. These features enable glueless connection to many external memories and peripherals.
C. The chip selects for Zone 0 and 1 are ANDed internally together to form one chip select (XZCS0AND1). Any external memory that is connected to XZCS0AND1 is dually mapped to both Zones 0 and Zone 1.
D. The chip selects for Zone 6 and 7 are ANDed internally together to form one chip select (XZCS6AND7). Any external memory that is connected to XZCS6AND7 is dually mapped to both Zones 6 and Zone 7. This means that if Zone 7 is disabled (via the MP/MC mode) then any external memory is still accessible via Zone 6 address space.
E. XCLKOUT is also pinned out on the 2810 and 2811.

Figure 3–4. External Interface Block Diagram
3.6 Interrupts

Figure 3–5 shows how the various interrupt sources are multiplexed within R281x devices.

Figure 3–6 shows how the interrupts are multiplexed using the PIE block. Eight PIE block interrupts are grouped into one CPU interrupt. In total, 12 CPU interrupt groups, with 8 interrupts per group equals 96 possible interrupts. On R281x, 45 of these are used by peripherals as shown in Table 3–9.

† Out of a possible 96 interrupts, 45 are currently used by peripherals.

† Out of the 96 possible interrupts, 45 interrupts are currently used. The remaining interrupts are reserved for future devices. These interrupts can be used as software interrupts if they are enabled at the PIEIFRx level, provided none of the interrupts within the group is being used by a peripheral. Otherwise, interrupts coming in from peripherals may be lost by accidentally clearing their flag while modifying the PIEIFR.

To summarize, there are two safe cases when the reserved interrupts could be used as software interrupts:

1) No peripheral within the group is asserting interrupts.
2) No peripheral interrupts are assigned to the group (example PIE group 12).

Each external interrupt can be enabled/disabled or qualified using positive or negative going edge. For more information, see the *TMS320F28x System Control and Interrupts Reference Guide* (literature number SPRU078).
3.7 System Control

This section describes R281x oscillator, PLL and clocking mechanisms, the watchdog function and the low power modes. Figure 3–7 shows the various clock and reset domains in R281x devices that will be discussed.

Figure 3–7. Clock and Reset Domains

The PLL, clocking, watchdog and low-power modes are controlled by the registers listed in Table 3–12.

NOTE A: CLKin is the clock input to the CPU. SYSCLKOUT is the output clock of the CPU. They are of the same frequency.

</tbody>
</table>

† All of the above registers can only be accessed, by executing the EALLOW instruction.
‡ The PLL control register (PLLCR) is reset to a known state by the XRS signal only. Emulation reset (through Code Composer Studio) will not reset PLLCR.

### 3.7.1 OSC and PLL Block

Figure 3–8 shows the OSC and PLL block on R281x.
The on-chip oscillator circuit enables a crystal to be attached to R281x devices using the X1/XCLKIN and X2 pins. If a crystal is not used, then an external oscillator can be directly connected to the X1/XCLKIN pin and the X2 pin is left unconnected. The logic-high level in this case should not exceed VDD. The PLLCR bits [3:0] set the clocking ratio.

† The PLLCR register is reset to a known state by the XRS reset line. If a reset is issued by the debugger, the PLL clocking ratio is not changed.

### 3.7.2 Loss of Input Clock

In PLL enabled mode, if the input clock XCLKIN or the oscillator clock is removed or absent, the PLL will still issue a “limp-mode” clock. The limp-mode clock will continue to clock the CPU and peripherals at a typical frequency of 1–4 MHz. The PLLCR register should have been written to with a non-zero value for this feature to work.
Normally, when the input clocks are present, the watchdog counter will decrement to initiate a watchdog reset or WDINT interrupt. However, when the external input clock fails, the watchdog counter will stop decrementing (i.e., the watchdog counter does not change with the limp-mode clock). This condition could be used by the application firmware to detect the input clock failure and initiate necessary shut-down procedure for the system.

3.7.3 PLL-Based Clock Module

R281x has an on-chip, PLL-based clock module. This module provides all the necessary clocking signals for the device, as well as control for low-power mode entry. The PLL has a 4-bit ratio control to select different CPU clock rates. The watchdog module should be disabled before writing to the PLLCR register. It can be re-enabled (if need be) after the PLL module has stabilized, which takes 131072 XCLKIN cycles.

The PLL-based clock module provides two modes of operation:

- **Crystal-operation**
  This mode allows the use of an external crystal/resonator to provide the time base to the device.

- **External clock source operation**
  This mode allows the internal oscillator to be bypassed. The device clocks are generated from an external clock source input on the X1/XCLKIN pin.

![Diagram of PLL-Based Clock Module](image)

**NOTE A:** TI recommends that customers have the resonator/crystal vendor characterize the operation of their device with the DSP chip. The resonator/crystal vendor has the equipment and expertise to tune the tank circuit. The vendor can also advise the customer regarding the proper tank component values that will ensure start-up and stability over the entire operating range.

**Figure 3–9. Recommended Crystal/Clock Connection**

**Table 3–14. Possible PLL Configuration Modes**

<table>
<thead>
<tr>
<th>PLL MODE</th>
<th>REMARKS</th>
<th>SYSCLKOUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLL Disabled</td>
<td>Invoked by tying XPLLDIS pin low upon reset. PLL block is completely disabled. Clock input to the CPU (CLKIN) is directly derived from the clock signal present at the X1/XCLKIN pin.</td>
<td>XCLKIN</td>
</tr>
<tr>
<td>PLL Bypassed</td>
<td>Default PLL configuration upon power-up, if PLL is not disabled. The PLL itself is bypassed. However, the /2 module in the PLL block divides the clock input at the X1/XCLKIN pin by two before feeding it to the CPU.</td>
<td>XCLKIN/2</td>
</tr>
<tr>
<td>PLL Enabled</td>
<td>Achieved by writing a non-zero value “n” into PLLCR register. The /2 module in the PLL block now divides the output of the PLL by two before feeding it to the CPU.</td>
<td>(XCLKIN * n) / 2</td>
</tr>
</tbody>
</table>

3.7.4 External Reference Oscillator Clock Option

The typical specifications for the external quartz crystal for a frequency of 30 MHz are listed below:

- Fundamental mode, parallel resonant
- \( C_L \) (load capacitance) = 12 pF
- \( C_{L1} = C_{L2} = 24 \) pF
- \( C_{shunt} = 6 \) pF
- ESR range = 25 to 40 \( \Omega \)
### 3.7.5 Watchdog Block

The watchdog block on R281x is identical to the one used on the 240x devices. The watchdog module generates an output pulse, 512 oscillator clocks wide (OSCCLK), whenever the 8-bit watchdog up counter has reached its maximum value. To prevent this, the user disables the counter or the software must periodically write a 0x55 + 0xAA sequence into the watchdog key register which will reset the watchdog counter. Figure 3–10 shows the various functional blocks within the watchdog module.

![Watchdog Module Diagram](image)

**NOTE A:** The **WDRST** signal is driven low for 512 OSCCLK cycles.

**Figure 3–10. Watchdog Module**

The **WDINT** signal enables the watchdog to be used as a wakeup from IDLE/STANDBY mode timer.

In STANDBY mode, all peripherals are turned off on the device. The only peripheral that remains functional is the watchdog. The Watchdog module will run off the PLL clock or the oscillator clock. The **WDINT** signal is fed to the LPM block so that it can wake the device from STANDBY (if enabled). See Section 3.7.6, Low-Power Modes Block, for more details.

In IDLE mode, the **WDINT** signal can generate an interrupt to the CPU, via the PIE, to take the CPU out of IDLE mode.

In HALT mode, this feature cannot be used because the oscillator (and PLL) are turned off and hence so is the WATCHDOG.

### 3.7.6 Low-Power Modes Block

The low-power modes on R281x are similar to the 240x devices. Table 3–15 summarizes the various modes.
### Table 3–15. R281x Low-Power Modes

</tr>
</tbody>
</table>

† The Exit column lists which signals or under what conditions the low power mode will be exited. A low signal, on any of the signals, will exit the low power condition. This signal must be kept low long enough for an interrupt to be recognized by the device. Otherwise the IDLE mode will not be exited and the device will go back into the indicated low power mode.
‡ The IDLE mode on the C28x behaves differently than on the 24x/240x. On the C28x, the clock output from the core (SYSCLKOUT) is still functional while on the 24x/240x the clock is turned off.
§ On the C28x, the JTAG port can still function even if the core clock (CLKIN) is turned off.

The various low-power modes operate as follows:

**IDLE Mode:**
This mode is exited by any enabled interrupt or an XNMI that is recognized by the processor. The LPM block performs no tasks during this mode as long as the LPMCR0(LPM) bits are set to 0,0.

**STANDBY Mode:**
All other signals (including XNMI) will wake the device from STANDBY mode if selected by the LPMCR1 register. The user will need to select which signal(s) will wake the device. The selected signal(s) are also qualified by the OSCCLK before waking the device. The number of OSCCLKs is specified in the LPMCR0 register.

**HALT Mode:**
Only the XRS and XNMI external signals can wake the device from HALT mode. The XNMI input to the core has an enable/disable bit. Hence, it is safe to use the XNMI signal for this function.

**NOTE:** The low-power modes do not affect the state of the output pins (PWM pins included). They will be in whatever state the code left them when the IDLE instruction was executed.
4 Peripherals

The integrated peripherals of R281x are described in the following subsections:

- Three 32-bit CPU-Timers
- Two event-manager modules (EVA, EVB)
- Enhanced analog-to-digital converter (ADC) module
- Enhanced controller area network (eCAN) module
- Multichannel buffered serial port (McBSP) module
- Serial communications interface modules (SCI-A, SCI-B)
- Serial peripheral interface (SPI) module
- Digital I/O and shared pin functions

4.1 32-Bit CPU-Timers 0/1/2

There are three 32-bit CPU-timers on R281x devices (CPU-TIMER0/1/2).

CPU-Timer 1 is reserved for TI system functions and Timer 2 is reserved for DSP/BIOS. CPU-Timer 0 can be used in user applications. These timers are different from the general-purpose (GP) timers that are present in the Event Manager modules (EVA, EVB).

**NOTE:** If the application is not using DSP/BIOS, then CPU-Timers 1 and 2 can be used in the application.

![Figure 4−1. CPU-Timers](image-url)
In R281x devices, the timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in Figure 4–2.

**Figure 4–2. CPU-Timer Interrupts Signals and Output Signal (See Notes A and B)**

The general operation of the timer is as follows: The 32-bit counter register “TIMH:TIM” is loaded with the value in the period register “PRDH:PRD”. The counter register, decrements at the SYSCLKOUT rate of the C28x. When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse. The registers listed in Table 4–1 are used to configure the timers. For more information, see the *TMS320F28x System Control and Interrupts Reference Guide* (literature number SPRU078).

4.2 Event Manager Modules (EVA, EVB)

The event-manager modules include general-purpose (GP) timers, full-compare/PWM units, capture units, and quadrature-encoder pulse (QEP) circuits. EVA and EVB timers, compare units, and capture units function identically. However, timer/unit names differ for EVA and EVB. Table 4–2 shows the module and signal names used. Table 4–2 shows the features and functionality available for the event-manager modules and highlights EVA nomenclature.

Event managers A and B have identical peripheral register sets with EVA starting at 7400h and EVB starting at 7500h. The paragraphs in this section describe the function of GP timers, compare units, capture units, and QEPs using EVA nomenclature. These paragraphs are applicable to EVB with regard to function—however, module/signal names would differ. Table 4–3 lists the EVA registers. For more information, see the *TMS320F28x DSP Event Manager (EV) Reference Guide* (literature number SPRU065).

† The EV-B register set is identical except the address range is from 0x00−7500 to 0x00−753F. The above registers are mapped to Zone 2. This space allows only 16-bit accesses. 32-bit accesses produce undefined results.
‡ New register compared to 24x/240x
4.2.1 General-Purpose (GP) Timers

There are two GP timers. The GP timer x (x = 1 or 2 for EVA; x = 3 or 4 for EVB) includes:

- A 16-bit timer, up-/down-counter, TxCNT, for reads or writes
- A 16-bit timer-compare register, TxCMPR (double-buffered with shadow register), for reads or writes
- A 16-bit timer-period register, TxPR (double-buffered with shadow register), for reads or writes
- A 16-bit timer-control register, TxCON, for reads or writes
- Selectable internal or external input clocks
• A programmable prescaler for internal or external clock inputs
• Control and interrupt logic, for four maskable interrupts: underflow, overflow, timer compare, and period interrupts
• A selectable direction input pin (TDIRx) (to count up or down when directional up-/down-count mode is selected)

The GP timers can be operated independently or synchronized with each other. The compare register associated with each GP timer can be used for compare function and PWM-waveform generation. There are three continuous modes of operations for each GP timer in up- or up/down-counting operations. Internal or external input clocks with programmable prescaler are used for each GP timer. GP timers also provide the time base for the other event-manager submodules: GP timer 1 for all the compares and PWM circuits, GP timer 2/1 for the capture units and the quadrature-pulse counting operations. Double-buffering of the period and compare registers allows programmable change of the timer (PWM) period and the compare/PWM pulse width as needed.

4.2.2 Full-Compare Units

There are three full-compare units on each event manager. These compare units use GP timer1 as the time base and generate six outputs for compare and PWM-waveform generation using programmable deadband circuit. The state of each of the six outputs is configured independently. The compare registers of the compare units are double-buffered, allowing programmable change of the compare/PWM pulse widths as needed.

4.2.3 Programmable Deadband Generator

Deadband generation can be enabled/disabled for each compare unit output individually. The deadband-generator circuit produces two outputs (with or without deadband zone) for each compare unit output signal. The output states of the deadband generator are configurable and changeable as needed by way of the double-buffered ACTRx register.

4.2.4 PWM Waveform Generation

Up to eight PWM waveforms (outputs) can be generated simultaneously by each event manager: three independent pairs (six outputs) by the three full-compare units with programmable deadbands, and two independent PWMs by the GP-timer compares.

4.2.5 Double Update PWM Mode

The R281x Event Manager supports “Double Update PWM Mode.” This mode refers to a PWM operation mode in which the position of the leading edge and the position of the trailing edge of a PWM pulse are independently modifiable in each PWM period. To support this mode, the compare register that determines the position of the edges of a PWM pulse must allow (buffered) compare value update once at the beginning of a PWM period and another time in the middle of a PWM period. The compare registers in R281x Event Managers are all buffered and support three compare value reload/update (value in buffer becoming active) modes. These modes have earlier been documented as compare value reload conditions. The reload condition that supports double update PWM mode is reloaded on Underflow (beginning of PWM period) OR Period (middle of PWM period). Double update PWM mode can be achieved by using this condition for compare value reload.

4.2.6 PWM Characteristics

Characteristics of the PWMs are as follows:
• 16-bit registers
• Wide range of programmable deadband for the PWM output pairs
• Change of the PWM carrier frequency for PWM frequency wobbling as needed
• Change of the PWM pulse widths within and after each PWM period as needed

• External-maskable power and drive-protection interrupts

• Pulse-pattern-generator circuit, for programmable generation of asymmetric, symmetric, and four-space vector PWM waveforms

• Minimized CPU overhead using auto-reload of the compare and period registers

• The PWM pins are driven to a high-impedance state when the \texttt{PDPINTx} pin is driven low and \textbf{after} \texttt{PDPINTx} signal qualification. The \texttt{PDPINTx} pin (after qualification) is reflected in bit 8 of the \texttt{COMCONx} register.
  
  - \texttt{PDPINTA} pin status is reflected in bit 8 of \texttt{COMCONA} register.
  
  - \texttt{PDPINTB} pin status is reflected in bit 8 of \texttt{COMCONB} register.

• \texttt{EXTCON} register bits provide options to individually trip control for each PWM pair of signals

\section*{4.2.7 Capture Unit}

The capture unit provides a logging function for different events or transitions. The values of the selected GP timer counter is captured and stored in the two-level-deep FIFO stacks when selected transitions are detected on capture input pins, \texttt{CAPx} (\(x = 1, 2, \) or 3 for EVA; and \(x = 4, 5, \) or 6 for EVB). The capture unit consists of three capture circuits.

- Capture units include the following features:
  
  - One 16-bit capture control register, \texttt{CAPCONx} (R/W)
  
  - One 16-bit capture FIFO status register, \texttt{CAPFIFOx}
  
  - Selection of GP timer 1/2 (for EVA) or 3/4 (for EVB) as the time base
  
  - Three 16-bit 2-level-deep FIFO stacks, one for each capture unit
  
  - Three capture input pins (\texttt{CAP1/2/3} for EVA, \texttt{CAP4/5/6} for EVB)—one input pin per capture unit. [All inputs are synchronized with the device (CPU) clock. In order for a transition to be captured, the input must hold at its current level to meet the input qualification circuitry requirements. The input pins \texttt{CAP1/2} and \texttt{CAP4/5} can also be used as QEP inputs to the QEP circuit.]
  
  - User-specified transition (rising edge, falling edge, or both edges) detection
  
  - Three maskable interrupt flags, one for each capture unit
  
  - The capture pins can also be used as general-purpose interrupt pins, if they are not used for the capture function.

\section*{4.2.8 Quadrature-Encoder Pulse (QEP) Circuit}

Two capture inputs (\texttt{CAP1} and \texttt{CAP2} for EVA; \texttt{CAP4} and \texttt{CAP5} for EVB) can be used to interface the on-chip QEP circuit with a quadrature encoder pulse. Full synchronization of these inputs is performed on-chip. Direction or leading-quadrature pulse sequence is detected, and GP timer 2/4 is incremented or decremented by the rising and falling edges of the two input signals (four times the frequency of either input pulse).

With \texttt{EXTCONA} register bits, the EVA QEP circuit can use \texttt{CAP3} as a capture index pin as well. Similarly, with \texttt{EXTCONB} register bits, the EVB QEP circuit can use \texttt{CAP6} as a capture index pin.

\section*{4.2.9 External ADC Start-of-Conversion}

EVA/EVB start-of-conversion (SOC) can be sent to an external pin (\texttt{EVASOC/EVBSOC}) for external ADC interface. \texttt{EVASOC} and \texttt{EVBSOC} are MUXed with \texttt{T2CTRIP} and \texttt{T4CTRIP}, respectively.
4.3 Enhanced Analog-to-Digital Converter (ADC) Module

A simplified functional block diagram of the ADC module is shown in Figure 4−4. The ADC module consists of a 12-bit ADC with a built-in sample-and-hold (S/H) circuit. Functions of the ADC module include:

- 12-bit ADC core with built-in S/H
- Analog input: 0.0 V to 3.0 V (Voltages above 3.0 V produce full-scale conversion results.)
- Fast conversion rate: 80 ns at 25-MHz ADC clock, 12.5 MSPS
- 16-channel, MUXed inputs
- Autosequencing capability provides up to 16 “autoconversions” in a single session. Each conversion can be programmed to select any 1 of 16 input channels
- Sequencer can be operated as two independent 8-state sequencers or as one large 16-state sequencer (i.e., two cascaded 8-state sequencers)
- Sixteen result registers (individually addressable) to store conversion values
  - The digital value of the input analog voltage is derived by:
    \[
    \text{Digital Value} = \begin{cases} 
      0, & \text{when input } \leq 0 \text{ V} \\
      4096 \times \frac{\text{Input Analog Voltage} - \text{ADCLO}}{3}, & \text{when } 0 \text{ V} < \text{input} < 3 \text{ V} \\
      4095, & \text{when input } \geq 3 \text{ V}
    \end{cases}
    \]
- Multiple triggers as sources for the start-of-conversion (SOC) sequence
  - S/W – software immediate start
  - EVA – Event manager A (multiple event sources within EVA)
  - EVB – Event manager B (multiple event sources within EVB)
- Flexible interrupt control allows interrupt request on every end-of-sequence (EOS) or every other EOS
- Sequencer can operate in “start/stop” mode, allowing multiple “time-sequenced triggers” to synchronize conversions
- EVA and EVB triggers can operate independently in dual-sequencer mode
- Sample-and-hold (S/H) acquisition time window has separate prescale control

The ADC module in R281x has been enhanced to provide flexible interface to event managers A and B. The ADC interface is built around a fast, 12-bit ADC module with a fast conversion rate of 80 ns at 25-MHz ADC clock. The ADC module has 16 channels, configurable as two independent 8-channel modules to service event managers A and B. The two independent 8-channel modules can be cascaded to form a 16-channel module. Although there are multiple input channels and two sequencers, there is only one converter in the ADC module. Figure 4−4 shows the block diagram of the R281x ADC module.

The two 8-channel modules have the capability to autosequence a series of conversions, each module has the choice of selecting any one of the respective eight channels available through an analog MUX. In the cascaded mode, the autosequencer functions as a single 16-channel sequencer. On each sequencer, once the conversion is complete, the selected channel value is stored in its respective RESULT register. Autosequencing allows the system to convert the same channel multiple times, allowing the user to perform oversampling algorithms. This gives increased resolution over traditional single-sampled conversion results.
To obtain the specified accuracy of the ADC, proper board layout is very critical. To the best extent possible, traces leading to the ADCIN pins should not run in close proximity to the digital signal paths. This is to minimize switching noise on the digital lines from getting coupled to the ADC inputs. Furthermore, proper isolation techniques must be used to isolate the ADC module power pins \( V_{DDA1}/V_{DDA2}, AV_{DDREFBG} \) from the digital supply. Figure 4−5 shows the ADC pin connections for R281x devices.

Notes:

1. The ADC registers are accessed at the SYSCLKOUT rate. The internal timing of the ADC module is controlled by the high-speed peripheral clock (HSPCLK).

2. The behavior of the ADC module based on the state of the ADCENCLK and HALT signals is as follows:

   **ADCENCLK:** On reset, this signal will be low. While reset is active-low (XRS) the clock to the register will still function. This is necessary to make sure all registers and modes go into their default reset state. The analog module will however be in a low-power inactive state. As soon as reset goes high, then the clock to the registers will be disabled. When the user sets the ADCENCLK signal high, then the clocks to the registers will be enabled and the analog module will be enabled. There will be a certain time delay (ms range) before the ADC is stable and can be used.

   **HALT:** This signal only affects the analog module. It does not affect the registers. If low, the ADC module is powered. If high, the ADC module goes into low-power mode. The HALT mode will stop the clock to the CPU, which will stop the HSPCLK. Therefore the ADC register logic will be turned off indirectly.

Figure 4−5 shows the ADC pin-biasing for internal reference and Figure 4−6 shows the ADC pin-biasing for external reference.

NOTES:
A. External decoupling capacitors are recommended on all power pins.
B. Analog inputs must be driven from an operational amplifier that does not degrade the ADC performance.
C. It is recommended that buffered external references be provided with a voltage difference of (ADCREFP–ADCREFM) = 1 V ± 0.1% or better.

External reference is enabled using bit 8 in the ADCTRL3 Register at ADC power up. In this mode, the accuracy of external reference is critical for overall gain. The voltage ADCREFP–ADCREFM will determine the overall accuracy. Do not enable internal references when external references are connected to ADCREFP and ADCREFM. See the TMS320F28x DSP Analog-to-Digital Converter (ADC) Reference Guide (literature number SPRU060) for more information.

Figure 4–6. ADC Pin Connections With External Reference
The ADC operation is configured, controlled, and monitored by the registers listed in Table 4–4.

† The above registers are Peripheral Frame 2 Registers.
4.4 Enhanced Controller Area Network (eCAN) Module

The CAN module has the following features:

- Fully compliant with CAN protocol, version 2.0B
- Supports data rates up to 1 Mbps
- Thirty-two mailboxes, each with the following properties:
  - Configurable as receive or transmit
  - Configurable with standard or extended identifier
  - Has a programmable receive mask
  - Supports data and remote frame
  - Composed of 0 to 8 bytes of data
  - Uses a 32-bit time stamp on receive and transmit message
  - Protects against reception of new message
  - Holds the dynamically programmable priority of transmit message
  - Employs a programmable interrupt scheme with two interrupt levels
  - Employs a programmable alarm on transmission or reception time-out
- Low-power mode
- Programmable wake-up on bus activity
- Automatic reply to a remote request message
- Automatic retransmission of a frame in case of loss of arbitration or error
- 32-bit local network time counter synchronized by a specific message (communication in conjunction with mailbox 16)
- Self-test mode
  - Operates in a loopback mode receiving its own message. A “dummy” acknowledge is provided, thereby eliminating the need for another node to provide the acknowledge bit.

NOTE: For a SYSCLKOUT of 150 MHz, the smallest bit rate possible is 23.4 kbps.

The 28x CAN has passed the conformance test per ISO/DIS 16845. Contact TI for further details.

Figure 4–8. eCAN Memory Map

- **eCAN Memory (512 Bytes)**
  - Control and Status Registers
  - Local Acceptance Masks (LAM) (32 × 32-Bit RAM)
  - Message Object Time Stamps (MOTS) (32 × 32-Bit RAM)
  - Message Object Time-Out (MOTO) (32 × 32-Bit RAM)

- **eCAN Memory RAM (512 Bytes)**
  - Mailbox 0
  - Mailbox 1
  - Mailbox 2
  - Mailbox 3
  - Mailbox 4
  - Mailbox 28
  - Mailbox 29
  - Mailbox 30
  - Mailbox 31

- **Message Mailbox (16 Bytes)**
  - Message Identifier − MSGID
  - Message Control − MSGCTRL
  - Message Data Low − MDL
  - Message Data High − MDH
The CAN registers listed in Table 4–6 are used by the CPU to configure and control the CAN controller and the message objects. eCAN control registers only support 32-bit read/write operations. Mailbox RAM can be accessed as 16 bits or 32 bits. 32-bit accesses are aligned to an even boundary.

† These registers are mapped to Peripheral Frame 1.
4.5 Multichannel Buffered Serial Port (McBSP) Module

The McBSP module has the following features:

- Compatible to McBSP in TMS320C54x™ / TMS320C55x™ DSP devices, except the DMA features
- Full-duplex communication
- Double-buffered data registers which allow a continuous data stream
- Independent framing and clocking for receive and transmit
- External shift clock generation or an internal programmable frequency shift clock
- A wide selection of data sizes including 8-, 12-, 16-, 20-, 24-, or 32-bits
- 8-bit data transfers with LSB or MSB first
- Programmable polarity for both frame synchronization and data clocks
- Highly programmable internal clock and frame generation
- Support A-bis mode
- Direct interface to industry-standard CODECs, Analog Interface Chips (AICs), and other serially connected A/D and D/A devices
- Works with SPI-compatible devices
- Two 16 x 16-level FIFO for Transmit channel
- Two 16 x 16-level FIFO for Receive channel

The following application interfaces can be supported on the McBSP:

- T1/E1 framers
- MVIP switching-compatible and ST-BUS-compliant devices including:
  - MVIP framers
  - H.100 framers
  - SCSA framers
  - IOM-2 compliant devices
  - AC97-compliant devices (the necessary multiphase frame synchronization capability is provided.)
  - IIS-compliant devices
- McBSP clock rate = \( \frac{\text{CLKSRG}}{1 + \text{CLKGDIV}} \), where CLKSRG source could be LSPCLK, CLXX, or CLKR.

Serial port performance is limited by I/O buffer switching speed. Internal prescalers must be adjusted such that the peripheral speed is less than the I/O buffer speed limit—20-MHz maximum.

Figure 4–9 shows the block diagram of the McBSP module with FIFO, interfaced to the R281x version of Peripheral Frame 2.
Figure 4-9. McBSP Module With FIFO
Table 4–7 provides a summary of the McBSP registers.

4.6 Serial Communications Interface (SCI) Module

R281x devices include two serial communications interface (SCI) modules. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format. The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. Both can be operated independently or simultaneously in the full-duplex mode. To ensure data integrity, the SCI checks received data for break detection, parity, overrun, and framing errors. The bit rate is programmable to over 65000 different speeds through a 16-bit baud-select register.

Features of each SCI module include:

- Two external pins:
  - SCITXD: SCI transmit-output pin
  - SCIRXD: SCI receive-input pin

NOTE: Both pins can be used as GPIO if not used for SCI.
• Baud rate programmable to 64K different rates
  \[
  \text{Baud rate} = \frac{LSPCLK}{(BRR + 1) \times 8}, \quad \text{when } BRR \neq 0
  \]
  \[
  = \frac{LSPCLK}{16}, \quad \text{when } BRR = 0
  \]
  Serial port performance is limited by I/O buffer switching speed. Internal prescalers must be adjusted such that the peripheral speed is less than the I/O buffer speed limit—20 MHz maximum.
• Data-word format
  − One start bit
  − Data-word length programmable from one to eight bits
  − Optional even/odd/no parity bit
  − One or two stop bits
• Four error-detection flags: parity, overrun, framing, and break detection
• Two wake-up multiprocessor modes: idle-line and address bit
• Half- or full-duplex operation
• Double-buffered receive and transmit functions
• Transmitter and receiver operations can be accomplished through interrupt-driven or polled algorithms with status flags.
  − Transmitter: TXRDY flag (transmitter-buffer register is ready to receive another character) and TX EMPTY flag (transmitter-shift register is empty)
  − Receiver: RXRDY flag (receiver-buffer register is ready to receive another character), BRKDT flag (break condition occurred), and RX ERROR flag (monitoring four interrupt conditions)
• Separate enable bits for transmitter and receiver interrupts (except BRKDT)
• Max bit rate = \( \frac{150 \, \text{MHz}}{2 \times 8} = 9.375 \times 10^6 \, \text{b/s} \)
• NRZ (non-return-to-zero) format
• Ten SCI module control registers located in the control register frame beginning at address 7050h
  All registers in this module are 8-bit registers that are connected to Peripheral Frame 2. When a register is accessed, the register data is in the lower byte (7–0), and the upper byte (15–8) is read as zeros. Writing to the upper byte has no effect.
Enhanced features:
• Auto baud-detect hardware logic
• 16-level transmit/receive FIFO
Figure 4−10 shows the SCI module block diagram.
The SCI port operation is configured and controlled by the registers listed in Table 4–8 and Table 4–9.

† Shaded registers are new registers for the FIFO mode.
‡ Registers in this table are mapped to peripheral bus 16 space. This space only allows 16-bit accesses. 32-bit accesses produce undefined results.

### 4.7 Serial Peripheral Interface (SPI) Module

R281x devices include the four-pin serial peripheral interface (SPI) module. The SPI is a high-speed, synchronous serial I/O port that allows a serial bit stream of programmed length (one to sixteen bits) to be shifted into and out of the device at a programmable bit-transfer rate. Normally, the SPI is used for communications between the DSP controller and external peripherals or another processor. Typical applications include external I/O or peripheral expansion through devices such as shift registers, display drivers, and ADCs. Multidevice communications are supported by the master/slave operation of the SPI.
The SPI module features include:

- Four external pins:
  - SPISOMI: SPI slave-output/master-input pin
  - SPISIMO: SPI slave-input/master-output pin
  - SPISTE: SPI slave transmit-enable pin
  - SPICLK: SPI serial-clock pin

  NOTE: All four pins can be used as GPIO, if the SPI module is not used.

- Two operational modes: master and slave

- Baud rate: 125 different programmable rates

  \[
  \text{Baud rate} = \frac{\text{LSPCLK}}{\left(\text{SPIBRR} + 1\right)}, \quad \text{when BRR} \neq 0
  \]

  \[
  = \frac{\text{LSPCLK}}{4}, \quad \text{when BRR} = 0, 1, 2, 3
  \]

  Serial port performance is limited by I/O buffer switching speed. Internal prescalers must be adjusted such that the peripheral speed is less than the I/O buffer speed limit—20 MHz maximum.

- Data word length: one to sixteen data bits

- Four clocking schemes (controlled by clock polarity and clock phase bits) include:
  - Falling edge without phase delay: SPICLK active-high. SPI transmits data on the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
  - Falling edge with phase delay: SPICLK active-high. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge without phase delay: SPICLK inactive-low. SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge with phase delay: SPICLK inactive-low. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.

- Simultaneous receive and transmit operation (transmit function can be disabled in software)

- Transmitter and receiver operations are accomplished through either interrupt-driven or polled algorithms.

- Nine SPI module control registers: Located in control register frame beginning at address 7040h.

  All registers in this module are 16-bit registers that are connected to Peripheral Frame 2. When a register is accessed, the register data is in the lower byte (7–0), and the upper byte (15–8) is read as zeros. Writing to the upper byte has no effect.

Enhanced feature:

- 16-level transmit/receive FIFO
- Delayed transmit control
The SPI port operation is configured and controlled by the registers listed in Table 4–10.

Figure 4–11. Serial Peripheral Interface Module Block Diagram (Slave Mode)
4.8 GPIO MUX

The GPIO MUX registers, are used to select the operation of shared pins on R281x devices. The pins can be individually selected to operate as “Digital I/O” or connected to “Peripheral I/O” signals (via the GPxMUX registers). If selected for “Digital I/O” mode, registers are provided to configure the pin direction (via the GPxDIR registers) and to qualify the input signal to remove unwanted noise (via the GPxQUAL) registers. Table 4−11 lists the GPIO MUX Registers.

† Reserved locations will return undefined values and writes will be ignored.
‡ These registers are NOT EALLOW protected. The above registers will typically be accessed regularly by the user.
Figure 4–12 shows how the various register bits select the various modes of operation for GPIO function.

**NOTES:**

A. In the GPIO mode, when the GPIO pin is configured for output operation, reading the GPxDAT data register only gives the value written, not the value at the pin. In the peripheral mode, the state of the pin can be read through the GPxDAT register, provided the corresponding direction bit is zero (input mode).

B. Some selected input signals are qualified by the SYSCLKOUT. The GPxQUAL register specifies the qualification sampling period. The sampling window is 6 samples wide and the output is only changed when all samples are the same (all 0’s or all 1’s). This feature removes unwanted spikes from the input signal.

**Figure 4–12. GPIO/Peripheral Pin MUXing**

**NOTE:**

The input function of the GPIO pin and the input path to the peripheral are always enabled. It is the output function of the GPIO pin that is multiplexed with the output path of the primary (peripheral) function. Since the output buffer of a pin connects back to the input buffer, any GPIO signal present at the pin will be propagated to the peripheral module as well. Therefore, when a pin is configured for GPIO operation, the corresponding peripheral functionality (and interrupt-generating capability) must be disabled. Otherwise, interrupts may be inadvertently triggered. This is especially critical when the PDPINTA and PDPINTB pins are used as GPIO pins, since a value of zero for GPDDAT.0 or GPDDAT.5 (PDPINTx) will put PWM pins in a high-impedance state. The CxTRIP and TxCTRIP pins will also put the corresponding PWM pins in high impedance, if they are driven low (as GPIO pins) and bit EXTCONx.0 = 1.
Development Support

Texas Instruments (TI) offers an extensive line of development tools for the C28x™ generation of DSPs, including tools to evaluate the performance of the processors, generate code, develop algorithm implementations, and fully integrate and debug software and hardware modules.

The following products support development of R281x-based applications:

Software Development Tools
- Code Composer Studio™ Integrated Development Environment (IDE)
  - C/C++ Compiler
  - Code generation tools
  - Assembler/Linker
  - Cycle Accurate Simulator
- Application algorithms
- Sample applications code

Hardware Development Tools
- R2812 eZdsp
- JTAG-based emulators – SPI515, XDS510PP, XDS510PP Plus, XDS510 USB
- Universal 5-V dc power supply
- Documentation and cables

5.1 Device and Development Support Tool Nomenclature
To designate the stages in the product development cycle, TI assigns prefixes to the part numbers of all [TMS320] DSP devices and support tools. Each [TMS320] DSP commercial family member has one of three prefixes: TMX, TMP, or TMS (e.g., TMS320R2812GHH). Texas Instruments recommends two of three possible prefix designators for its support tools: TMDX and TMDS. These prefixes represent evolutionary stages of product development from engineering prototypes (TMX/TMDX) through fully qualified production devices/tools (TMS/TMDS).

- **TMX** Experimental device that is not necessarily representative of the final device’s electrical specifications
- **TMP** Final silicon die that conforms to the device’s electrical specifications but has not completed quality and reliability verification
- **TMS** Fully qualified production device

Support tool development evolutionary flow:

- **TMDX** Development-support product that has not yet completed Texas Instruments internal qualification testing.
- **TMDS** Fully qualified development-support product

TMX and TMP devices and TMDX development–support tools are shipped against the following disclaimer:

“Developmental product is intended for internal evaluation purposes.”

TMS devices and TMDS development-support tools have been characterized fully, and the quality and reliability of the device have been demonstrated fully. TI’s standard warranty applies.

TMS320 is a trademark of Texas Instruments.
Predictions show that prototype devices (TMX or TMP) have a greater failure rate than the standard production devices. Texas Instruments recommends that these devices not be used in any production system because their expected end-use failure rate still is undefined. Only qualified production devices are to be used.

TI device nomenclature also includes a suffix with the device family name. This suffix indicates the package type (for example, PBK) and temperature range (for example, A). Figure 5–1 provides a legend for reading the complete device name for any TMS320x28x family member.

![Device Nomenclature Legend](image)

5.2 Documentation Support

Extensive documentation supports all of the TMS320™ DSP family generations of devices from product announcement through applications development. The types of documentation available include: data sheets and data manuals, with design specifications; and hardware and software applications. Useful reference documentation includes:

- **TMS320C28x DSP CPU and Instruction Set Reference Guide** (literature number SPRU430) describes the central processing unit (CPU) and the assembly language instructions of the TMS320C28x fixed-point digital signal processors (DSPs). It also describes emulation features available on these DSPs.

- **TMS320x281x Analog-to-Digital Converter (ADC) Reference Guide** (literature number SPRU060) describes the ADC module. The module is a 12-bit pipelined ADC. The analog circuits of this converter, referred to as the core in this document, include the front-end analog multiplexers (MUXs), sample-and-hold (S/H) circuits, the conversion core, voltage regulators, and other analog supporting circuits. Digital circuits, referred to as the wrapper in this document, include programmable conversion sequencer, result registers, interface to analog circuits, interface to device peripheral bus, and interface to other on-chip modules.

- **TMS320x281x Boot ROM Reference Guide** (literature number SPRU095) describes the purpose and features of the bootloader (factory-programmed boot-loading software). It also describes other contents of the device on-chip boot ROM and identifies where all of the information is located within that memory.

- **TMS320x281x Event Manager (EV) Reference Guide** (literature number SPRU065) describes the EV modules that provide a broad range of functions and features that are particularly useful in motion control and motor control applications. The EV modules include general-purpose (GP) timers, full-compare/PWM units, capture units, and quadrature-encoder pulse (QEP) circuits.
TMS320x281x External Interface (XINTF) Reference Guide (literature number SPRU067) describes the external interface (XINTF) of the 281x digital signal processors (DSPs).

TMS320x281x Multi-channel Buffered Serial Ports (McBSPs) Reference Guide (literature number SPRU061) describes the McBSP available on the 281x devices. The McBSPs allow direct interface between a DSP and other devices in a system.

TMS320x281x System Control and Interrupts Reference Guide (literature number SPRU078) describes the various interrupts and system control features of the 281x digital signal processors (DSPs).

TMS320x281x, 280x Enhanced Controller Area Network (eCAN) Reference Guide (literature number SPRU074) describes the eCAN that uses established protocol to communicate serially with other controllers in electrically noisy environments. With 32 fully configurable mailboxes and time-stamping feature, the eCAN module provides a versatile and robust serial communication interface. The eCAN module implemented in the C28x DSP is compatible with the CAN 2.0B standard (active).

TMS320x281x, 280x Peripheral Reference Guide (literature number SPRU566) describes the peripheral reference guides of the 28x digital signal processors (DSPs).

TMS320x281x, 280x Serial Communication Interface (SCI) Reference Guide (literature number SPRU051) describes the SCI that is a two-wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format.

3.3 V DSP for Digital Motor Control Application Report (literature number SPRA550) describes the eCAN that is a two-wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format.

3.3 V DSP for Digital Motor Control Application Report (literature number SPRA550) New generations of motor control digital signal processors (DSPs) lower their supply voltages from 5 V to 3.3 V to offer higher performance at lower cost. Replacing traditional 5-V digital control circuitry by 3.3-V designs introduce no additional system cost and no significant complication in interfacing with TTL and CMOS compatible components, as well as with mixed voltage ICs such as power transistor gate drivers. Just like 5-V based designs, good engineering practice should be exercised to minimize noise and EMI effects by proper component layout and PCB design when 3.3-V DSP, ADC, and digital circuitry are used in a mixed signal environment, with high and low voltage analog and switching signals, such as a motor control system. In addition, software techniques such as Random PWM method can be used by special features of the Texas Instruments (TI) TMS320C24xx DSP controllers to significantly reduce noise effects caused by EMI radiation.

This application report reviews designs of 3.3-V DSP versus 5-V DSP for low HP motor control applications. The application report first describes a scenario of a 3.3-V-only motor controller indicating that for most applications, no significant issue of interfacing between 3.3 V and 5 V exists. Cost-effective 3.3-V – 5-V interfacing techniques are then discussed for the situations where such interfacing is needed. On-chip 3.3-V ADC versus 5-V ADC is also discussed. Sensitivity and noise effects in 3.3-V and 5-V ADC conversions are addressed. Guidelines for component layout and printed circuit board (PCB) design that can reduce system’s noise and EMI effects are summarized in the last section.

The TMS320C28x Instruction Set Simulator Technical Overview (literature number SPRU608) describes the simulator, available within the Code Composer Studio for TMS320C2000 IDE, that simulates the instruction set of the C28x core.

TMS320C28x DSP/BIOS Application Programming Interface (API) Reference Guide (literature number SPRU625) describes development using DSP/BIOS.
TMS320C28x Assembly Language Tools User’s Guide (literature number SPRU513) describes the assembly language tools (assembler and other tools used to develop assembly language code), assembler directives, macros, common object file format, and symbolic debugging directives for the TMS320C28x™ device.

TMS320C28x Optimizing C Compiler User’s Guide (literature number SPRU514) describes the TMS320C28x™ C/C++ compiler. This compiler accepts ANSI standard C/C++ source code and produces TMS320™ DSP assembly language source code for the TMS320C28x device.

Programming Examples for the TMS320F281x eCAN (literature number SPRA876) contains several programming examples to illustrate how the eCAN module is set up for different modes of operation. The objective is to help you come up to speed quickly in programming the eCAN. All programs have been extensively commented to aid easy understanding. The CANalyzer tool from Vector CANtech, Inc. was used to monitor and control the bus operation. All projects and CANalyzer configuration files are included in the attached SPRA876.zip file.

TMS320F2810, TMS320F2811, TMS320F2812 ADC Calibration (literature number SPRA989) describes a method for improving the absolute accuracy of the 12-bit analog-to-digital converter (ADC) found on the F2810/F2811/F2812 devices. Due to inherent gain and offset errors, the absolute accuracy of the ADC is impacted. The methods described in this application note can improve the absolute accuracy of the ADC to achieve levels better than 0.5%. This application note is accompanied by an example program (ADCcalibration.zip) that executes from RAM on the F2812 EzDSP.

A series of DSP textbooks is published by Prentice-Hall and John Wiley & Sons to support digital signal processing research and education. The TMS320™ DSP newsletter, Details on Signal Processing, is published quarterly and distributed to update TMS320™ DSP customers on product information.

Updated information on the TMS320™ DSP controllers can be found on the worldwide web at: http://www.ti.com.

To send comments regarding this data manual, use the comments@books.sc.ti.com email address, which is a repository for feedback. For questions and support, contact the Product Information Center listed at the http://www.ti.com/sc/docs/pic/home.htm site.
6 Electrical Specifications

This section provides the absolute maximum ratings and the recommended operating conditions for the TMS320R281x DSPs.

6.1 Absolute Maximum Ratings

Unless otherwise noted, the list of absolute maximum ratings are specified over operating temperature ranges. Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under Section 6.2 is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability. All voltage values are with respect to VSS.

Supply voltage range, $V_{DDIO}$, $V_{DDA1}$, $V_{DDA2}$, $V_{DDAIO}$, and $AV_{DDREFBG}$ .......................... $-0.3\,\text{V}$ to $4.6\,\text{V}$

Supply voltage range, $V_{DD}$, $V_{DD1}$ .............................................. $-0.5\,\text{V}$ to $2.5\,\text{V}$

Input voltage range, $V_{IN}$ ................................................................. $-0.3\,\text{V}$ to $4.6\,\text{V}$

Output voltage range, $V_{O}$ ............................................................... $-0.3\,\text{V}$ to $4.6\,\text{V}$

Input clamp current, $I_{IK}$ ($V_{IN} < 0$ or $V_{IN} > V_{DDIO}$)† ................................................................. $\pm\,20\,\text{mA}$

Output clamp current, $I_{OK}$ ($V_{O} < 0$ or $V_{O} > V_{DDIO}$) ................................................................. $\pm\,20\,\text{mA}$

Operating ambient temperature ranges, $T_A$: A version (GHH, ZHH, PGF, PBK)‡ .......................... $-40^\circ\text{C}$ to $85^\circ\text{C}$

$T_A$: S/Q version (GHH, ZHH, PGF, PBK)‡ .......................... $-40^\circ\text{C}$ to $125^\circ\text{C}$

$T_A$: Q version (PGF, PBK)‡ ...................................................... $-40^\circ\text{C}$ to $125^\circ\text{C}$

Storage temperature range, $T_{stg}$† ................................................................. $-65^\circ\text{C}$ to $150^\circ\text{C}$

† Continuous clamp current per pin is $2\,\text{mA}$

‡ Long-term high-temperature storage and/or extended use at maximum temperature conditions may result in a reduction of overall device life.

For additional information, see *IC Package Thermal Metrics Application Report* (literature number SPRA953) and *Reliability Data for TMS320LF24x and TMS320F281x Devices Application Report* (literature number SPRA963).

§ Replaced by Q temperature option from silicon revision E onwards

† IDDA includes current into VDDA1, VDDA2, VDD1, AVDDREFBG, and VDDAIO pins.
‡ MAX numbers are at 125°C, and max voltage (VDD = 2.0 V; VDDIO, VDDA = 3.6 V).

**NOTE:**
HALT and STANDBY modes cannot be used when the PLL is disabled.

### 6.5 Current Consumption Graphs

![Current Consumption Graph](image)

**NOTES:**
A. Test conditions are as defined in Table 6–4 for operational currents.
B. IDD represents the total current drawn from the 1.8-V rail (VDD). It includes a small amount of current (<1 mA) drawn by VDD1.
C. IDDA represents the current drawn by VDDA1 and VDDA2 rails.
D. Total 3.3-V current is the sum of IDDIO and IDDA. It includes a trivial amount of current (<1 mA) drawn by VDDAIO.

**Figure 6–1. Typical Current Consumption Over Frequency**
6.6 Reducing Current Consumption

28x DSPs incorporate a unique method to reduce the device current consumption. A reduction in current consumption can be achieved by turning off the clock to any peripheral module which is not used in a given application. Table 6–1 indicates the typical reduction in current consumption achieved by turning off the clocks to various peripherals.

Table 6–1. Typical Current Consumption by Various Peripherals (at 150 MHz)†

</tr>
</tbody>
</table>

† All peripheral clocks are disabled upon reset. Writing to/reading from peripheral registers is possible only after the peripheral clocks are turned on.

‡ This number represents the current drawn by the digital portion of the ADC module. Turning off the clock to the ADC module results in the elimination of the current drawn by the analog portion of the ADC (IDD_{A}) as well.

6.7 Power Sequencing Requirements

Power sequencing is not required on the R281x devices. In other words, 3.3-V and 1.8-V (or 1.9-V) can ramp together. R281x can also be used on boards that have F281x power sequencing implemented; however, if the 1.8-V (or 1.9-V) rail lags the 3.3-V rail, the GPIO pins are undefined until the 1.8-V rail reaches at least 1 V.
6.8 Signal Transition Levels

Some of the signals use different reference voltages, see the recommended operating conditions table. Output levels are driven to a minimum logic-high level of 2.4 V and to a maximum logic-low level of 0.4 V.

Figure 6–3 shows output levels.

![Figure 6–3. Output Levels](image)

Output transition times are specified as follows:

- For a high-to-low transition, the level at which the output is said to be no longer high is below 80% of the total voltage range and lower and the level at which the output is said to be low is 20% of the total voltage range and lower.

- For a low-to-high transition, the level at which the output is said to be no longer low is 20% of the total voltage range and higher and the level at which the output is said to be high is 80% of the total voltage range and higher.

Figure 6–4 shows the input levels.

![Figure 6–4. Input Levels](image)

Input transition times are specified as follows:

- For a high-to-low transition on an input signal, the level at which the input is said to be no longer high is 90% of the total voltage range and lower and the level at which the input is said to be low is 10% of the total voltage range and lower.

- For a low-to-high transition on an input signal, the level at which the input is said to be no longer low is 10% of the total voltage range and higher and the level at which the input is said to be high is 90% of the total voltage range and higher.

**NOTE:** See the individual timing diagrams for levels used for testing timing parameters.
6.9 **Timing Parameter Symbology**

Timing parameter symbols used are created in accordance with JEDEC Standard 100. To shorten the symbols, some of the pin names and other related terminology have been abbreviated as follows:

<table>
<thead>
<tr>
<th>Letters and symbols and their meanings:</th>
</tr>
</thead>
<tbody>
<tr>
<td>H</td>
</tr>
<tr>
<td>L</td>
</tr>
<tr>
<td>V</td>
</tr>
<tr>
<td>X</td>
</tr>
<tr>
<td>Z</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Lowercase subscripts and their meanings:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
<tr>
<td>c</td>
</tr>
<tr>
<td>d</td>
</tr>
<tr>
<td>f</td>
</tr>
<tr>
<td>h</td>
</tr>
<tr>
<td>r</td>
</tr>
<tr>
<td>su</td>
</tr>
<tr>
<td>t</td>
</tr>
<tr>
<td>v</td>
</tr>
<tr>
<td>w</td>
</tr>
</tbody>
</table>

6.10 **General Notes on Timing Parameters**

All output signals from the 28x devices (including XCLKOUT) are derived from an internal clock such that all output transitions for a given half-cycle occur with a minimum of skewing relative to each other.

The signal combinations shown in the following timing diagrams may not necessarily represent actual cycles. For actual cycle examples, see the appropriate cycle description section of this document.

6.11 **Test Load Circuit**

This test load circuit is used to measure all switching characteristics provided in this document.

**NOTE:** The data sheet provides timing at the device pin. For output timing analysis, the tester pin electronics and its transmission line effects must be taken into account. A transmission line with a delay of 2 ns or longer can be used to produce the desired transmission line effect. The transmission line is intended as a load only. It is not necessary to add or subtract the transmission line delay (2 ns or longer) from the data sheet timing.

Input requirements in this data sheet are tested with an input slew rate of < 4 Volts per nanosecond (4 V/ns) at the device pin.

**Figure 6–5. 3.3-V Test Load Circuit**
6.12 Device Clock Table

This section provides the timing requirements and switching characteristics for the various clock options available on R281x DSPs. Table 6–2 lists the cycle times of various clocks.

† The maximum value for ADCCLK frequency is 25 MHz. For SYSCLKOUT values of 25 MHz or lower, ADCCLK has to be SYSCLKOUT/2 or lower.
ADCCLK = SYSCLKOUT is not a valid mode for any value of SYSCLKOUT.
‡ This is the default reset value if SYSCLKOUT = 150 MHz.

6.13 Clock Requirements and Characteristics

6.13.1 Input Clock Requirements

The clock provided at the XCLKIN pin generates the internal CPU clock cycle.

† If external oscillator/clock source are used, reset time has to be low at least for 1 ms after V_DD reaches 1.5 V.
‡ Dependent on crystal/resonator and board design.
Electrical Specifications

V_{DDIO}, V_{DDA} (3.3 V) (See Note A)

V_{DD}, V_{DD1} (1.8 V (or 1.9 V))

XCLKIN

X1

XCLKOUT

XRS

Address/Data Valid. Internal Boot-ROM Code Execution Phase

Notes:

A. V_{DDAn} = V_{DDA1}V_{DDA2} and AV_{DDREFBG}
B. Upon power up, SYSCLKOUT is XCLKIN/2 if the PLL is enabled. Since both the XTIMCLK and CLKMODE bits in the XINTCNF2 register come up with a reset state of 1, SYSCLKOUT is further divided by 4 before it appears at XCLKOUT. This explains why XCLKOUT = XCLKIN/8 during this phase.
C. After reset, the Boot ROM code executes instructions for 1260 SYSCLKOUT cycles (SYSCLKOUT = XCLKIN/2) and then samples BOOT Mode pins. Based on the status of the Boot Mode pin, the boot code branches to destination memory or boot code function in ROM. The BOOT Mode pins should be held high/low for at least 2520 XCLKIN cycles from boot ROM execution time for proper selection of Boot modes.
If Boot ROM code executes after power-on conditions (in debugger environment), the Boot code execution time is based on the current SYSCLKOUT speed. The SYSCLKOUT will be based on user environment and could be with or without PLL enabled.
D. The state of the GPIO pins is undefined (i.e., they could be input or output) until the 1.8-V (or 1.9-V) supply reaches at least 1 V and 3.3-V supply reaches 2.5 V.

† QUALSTDBY is a 6-bit field in the LPMCR0 register.
‡ This is the time taken to begin execution of the instruction that immediately follows the IDLE instruction. Execution of an ISR (triggered by the wake-up) signal involves additional latency.
NOTES: A. IDLE instruction is executed to put the device into STANDBY mode.
B. The PLL block responds to the STANDBY signal. SYSCLKOUT is held for approximately 32 cycles before being turned off. This 32-cycle delay enables the CPU pipe and any other pending operations to flush properly.
C. The device is now in STANDBY mode.
D. The external wake-up signal is driven active (negative edge triggered shown as an example).
E. After a latency period, the STANDBY mode is exited.
F. Normal operation resumes. The device will respond to the interrupt (if enabled).

<td>Cycles</td>
</tr>
</tbody>
</table>
† XCLKOUT = SYSCLKOUT

NOTES:
A. IDLE instruction is executed to put the device into HALT mode.
B. The PLL block responds to the HALT signal. SYSCLKOUT is held for another 32 cycles before the oscillator is turned off and the CLKIN to the core is stopped. This 32-cycle delay enables the CPU pipe and any other pending operations to flush properly.
C. Clocks to the peripherals are turned off and the internal oscillator and PLL are shut down. The device is now in HALT mode and consumes absolute minimum power.
D. When XNMI is driven active, the oscillator is turned on; but the PLL is not activated. The pulse duration of 2t_C(CI) is applicable when an external oscillator is used. If the internal oscillator is used, the oscillator wake-up time should be added to this parameter.
E. When XNMI is deactivated, it initiates the PLL lock sequence, which takes 131,072 X1/XCLKIN cycles.
F. When CLKIN to the core is enabled, the device will respond to the interrupt (if enabled), after a latency. The HALT mode is now exited.
G. Normal operation resumes.

¶ The QUALPRD bit field value can range from 0 (no qualification) through 0xFF (510 SYSCLKOUT cycles). The qualification sampling period is 2n SYSCLKOUT cycles, where “n” is the value stored in the QUALPRD bit field. As an example, when QUALPRD = 1, the qualification sampling period is \( 1 \times 2 = 2 \) SYSCLKOUT cycles (i.e., the input is sampled every 2 SYSCLKOUT cycles). Six such samples will be taken over five sampling windows, each window being 2n SYSCLKOUT cycles. For QUALPRD = 1, the minimum width that is needed is \( 5 \times 2 = 10 \) SYSCLKOUT cycles. However, since the external signal is driven asynchronously, a 11-SYSCLKOUT-wide pulse ensures reliable recognition.

# Maximum input frequency to the QEP = \( \min[HSPCLK/2, 20 \text{ MHz}] \)

\( IQT = \frac{t_c(SCO)}{2^{QUALPRD}} \times 5 + \frac{t_c(SCO) \times 2 \times QUALPRD}{} \).

Figure 6–18. External Interrupt Timing

Figure 6–19. General-Purpose Output Timing
6.18 General-Purpose Input/Output (GPIO) – Input Timing

NOTES:  
A. This glitch will be ignored by the input qualifier. The QUALPRD bit field specifies the qualification sampling period. It can vary from 00 to 0xFF. Input qualification is not applicable when QUALPRD = 00. For any other value "n", the qualification sampling period in 2n SYSCLKOUT cycles (i.e., at every 2n SYSCLKOUT cycle, the GPIO pin will be sampled). Six consecutive samples must be of the same value for a given input to be recognized.
B. For the qualifier to detect the change, the input should be stable for 10 SYSCLKOUT cycles or greater. In other words, the inputs should be stable for (5 x QUALPRD x 2) SYSCLKOUT cycles. This would ensure six sampling windows for detection to occur. Since external signals are driven asynchronously, an 11-SYSCLKOUT-wide pulse ensures reliable recognition.

† \(t_c\)XTIM − Cycle time, XTIMCLK
‡ WS refers to the number of wait states inserted by hardware when using XREADY. If the zone is configured to ignore XREADY (USEREADY = 0), then WS = 0.

Minimum wait state requirements must be met when configuring each zone’s XTIMING register. These requirements are in addition to any timing requirements as specified by that device’s data sheet. No internal device hardware is included to detect illegal settings.

- If the XREADY signal is ignored (USEREADY = 0), then:
  1. Lead: \(LR \geq t_c\)XTIM \(\leq t_c\)XTIM
  2. Core: \(AW \geq t_c\)XTIM

These requirements result in the following XTIMING register configuration restrictions§:

<table>
<thead>
<tr>
<th>XRDLEAD</th>
<th>XRDACTIVE</th>
<th>XRDTRAIL</th>
<th>XWRLEAD</th>
<th>XWRACTIVE</th>
<th>XWRTRAIL</th>
<th>X2TIMING</th>
</tr>
</thead>
<tbody>

<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0, 1</td>
</tr>
</tbody>
</table>

§ No hardware to detect illegal XTIMING configurations
If the XREADY signal is sampled in the Synchronous mode (USEREADY = 1, READYMODE = 0), then:

1. Lead:
   
   \[ LR \geq t_{c(\text{XTIM})} \]
   
   \[ LW \geq t_{c(\text{XTIM})} \]

2. Active:
   
   \[ AR \geq 2 \times t_{c(\text{XTIM})} \]
   
   \[ AW \geq 2 \times t_{c(\text{XTIM})} \]

**NOTE:** Restriction does not include external hardware wait states

These requirements result in the following XTIMING register configuration restrictions:

<table>
<thead>
<tr>
<th>XRDLEAD</th>
<th>XRDACTIVE</th>
<th>XRDTRAIL</th>
<th>XWRLEAD</th>
<th>XWRACTIVE</th>
<th>XWRTRAIL</th>
<th>X2TIMING</th>
</tr>
</thead>
<tbody>

**Figure 6–26. Relationship Between XTIMCLK and SYSLCLKOUT**

### 6.22 XINTF Signal Alignment to XCLKOUT

For each XINTF access, the number of lead, active, and trail cycles is based on the internal clock XTIMCLK. Strobes such as XRD, XWE, and zone chip-select (XZCS) change state in relationship to the rising edge of XTIMCLK. The external clock, XCLKOUT, can be configured to be either equal to or one-half the frequency of XTIMCLK.

For the case where XCLKOUT = XTIMCLK, all of the XINTF strobes will change state with respect to the rising edge of XCLKOUT. For the case where XCLKOUT = one-half XTIMCLK, some strobes will change state either on the rising edge of XCLKOUT or the falling edge of XCLKOUT. In the XINTF timing tables, the notation XCOHL is used to indicate that the parameter is with respect to either case; XCLKOUT rising edge (high) or XCLKOUT falling edge (low). If the parameter is always with respect to the rising edge of XCLKOUT, the notation XCOH is used.
For the case where XCLKOUT = one-half XTIMCLK, the XCLKOUT edge with which the change will be aligned can be determined based on the number of XTIMCLK cycles from the start of the access to the point at which the signal changes. If this number of XTIMCLK cycles is even, the alignment will be with respect to the rising edge of XCLKOUT. If this number is odd, then the signal will change with respect to the falling edge of XCLKOUT. Examples include the following:

- Strobes that change at the beginning of an access always align to the rising edge of XCLKOUT. This is because all XINTF accesses begin with respect to the rising edge of XCLKOUT.
  
  Examples:  
  XZCSL Zone chip-select active low  
  XRNWL XR/W active low  

- Strobes that change at the beginning of the active period will align to the rising edge of XCLKOUT if the total number of lead XTIMCLK cycles for the access is even. If the number of lead XTIMCLK cycles is odd, then the alignment will be with respect to the falling edge of XCLKOUT.
  
  Examples:  
  XRDL XRD active low  
  XWEL XWE active low  

- Strobes that change at the beginning of the trail period will align to the rising edge of XCLKOUT if the total number of lead + active XTIMCLK cycles (including hardware waitstates) for the access is even. If the number of lead + active XTIMCLK cycles (including hardware waitstates) is odd, then the alignment will be with respect to the falling edge of XCLKOUT.
  
  Examples:  
  XRDH XRD inactive high  
  XWEH XWE inactive high  

- Strobes that change at the end of the access will align to the rising edge of XCLKOUT if the total number of lead + active + trail XTIMCLK cycles (including hardware waitstates) is even. If the number of lead + active + trail XTIMCLK cycles (including hardware waitstates) is odd, then the alignment will be with respect to the falling edge of XCLKOUT.
  
  Examples:  
  XZCSH Zone chip-select inactive high  
  XRNWH XR/W inactive high

</tbody>
</table>

NOTES:

A. All XINTF accesses (lead period) begin on the rising edge of XCLKOUT. When necessary, the device will insert an alignment cycle before an access to meet this requirement.

B. During alignment cycles, all signals will transition to their inactive state.

C. For USEREADY = 0, the external XREADY input signal is ignored.

D. XA[0:18] will hold the last address put on the bus during inactive cycles, including alignment cycles.

§ The first XREADY (Synch) sample occurs with respect to E in Figure 6–29:

$E = (XRDLEAD + XRDACTIVE) t_{c}(XTIM)$

When first sampled, if XREADY (Synch) is found to be high, then the access will complete. If XREADY (Synch) is found to be low, it will be sampled again each $t_{c}(XTIM)$ until it is found to be high.

For each sample (n) the setup time (D) with respect to the beginning of the access can be calculated as:

$D = (XRDLEAD + XRDACTIVE + n – 1) t_{c}(XTIM) – l_{su}(XRDYSynchL)XCOHL$

where n is the sample number: n = 1, 2, 3, and so forth.

† N/A = “Don’t care” for this example.
**NOTES:**

A. All XINTF accesses (lead period) begin on the rising edge of XCLKOUT. When necessary, the device will insert an alignment cycle before an access to meet this requirement.

B. During alignment cycles, all signals will transition to their inactive state.

C. During inactive cycles, the XINTF address bus will always hold the last address put out on the bus. This includes alignment cycles.

D. For each sample, setup time from the beginning of the access can be calculated as:
\[
D = (XRDLEAD + XRDACTIVE - 3 + n) t_c(XTIM) - tsu(XRDYasynchL)XCOHL
\]
where \(n\) is the sample number: \(n = 1, 2, 3,\) and so forth.

E. Reference for the first sample is with respect to this point:
\[
E = (XRDLEAD + XRDACTIVE - 2) t_c(XTIM)
\]

6.27 XHOLD and XHOLDA

If the HOLD mode bit is set while XHOLD and XHOLDA are both low (external bus accesses granted), the XHOLDA signal is forced high (at the end of the current cycle) and the external interface is taken out of high-impedance mode.

On a reset (XRS), the HOLD mode bit is set to 0. If the XHOLD signal is active low on a system reset, the bus and all signal strobes must be in high-impedance mode, and the XHOLDA signal is also driven active low.

When HOLD mode is enabled and XHOLDA is active low (external bus grant active), the CPU can still execute code from internal memory. If an access is made to the external interface, the CPU is stalled until the XHOLD signal is removed.

An external DMA request, when granted, places the following signals in a high-impedance mode:

<table>
<thead>
<tr>
<th>Signal</th>
<th>States</th>
</tr>
</thead>
<tbody>
<tr>
<td>XA[18:0]</td>
<td>XZCS0AND1</td>
</tr>
<tr>
<td>XD[15:0]</td>
<td>XZCS2</td>
</tr>
<tr>
<td>XWE, XRD</td>
<td>XZCS6AND7</td>
</tr>
<tr>
<td>XR/W</td>
<td></td>
</tr>
</tbody>
</table>

All other signals not listed in this group remain in their default or functional operational modes during these signal events.
6.28 XHOLD/XHOLDA Timing

Table 6−39. XHOLD/XHOLDA Timing Requirements (XCLKOUT = XTIMCLK)†‡

<table>
<thead>
<tr>
<th></th>
<th>MIN</th>
<th>MAX</th>
<th>UNIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>( t_{d(HL-HiZ)} )</td>
<td>4t_\text{c(XTIM)}</td>
<td>ns</td>

<td>ns</td>
<td></td>
</tr>
<tr>
<td>td(HH-BV) Delay time, XHOLD high to Bus valid</td>
<td>6t_c(XTIM)</td>
<td>ns</td>
<td></td>
</tr>
</tbody>
</table>

† When a low signal is detected on XHOLD, all pending XINTF accesses will be completed before the bus is placed in a high-impedance state.
‡ The state of XHOLD is latched on the rising edge of XTIMCLK.
§ After the XHOLD is detected low or high, all bus transitions and XHOLDA transitions will occur with respect to the rising edge of XCLKOUT. Thus, for this mode where XCLKOUT = 1/2 XTIMCLK, the transitions can occur up to 1 XTIMCLK cycle earlier than the maximum value specified.

NOTES:
A All pending XINTF accesses are completed.
B Normal XINTF operation resumes.

Figure 6-34. XHOLD/XHOLDA Timing Requirements (XCLKOUT = 1/2 XTIMCLK)
6.29  On-Chip Analog-to-Digital Converter

6.29.1  ADC Absolute Maximum Ratings†

Supply voltage range, \( V_{SSA1/VSSA2} \) to \( V_{DDA1/VDDA2/AVDDREFBG} \) \(-0.3\) V to 4.6 V
\( V_{SS1} \) to \( V_{DD1} \) \(-0.3\) V to 2.5 V

Analog Input (ADCIN) Clamp Current, total (max) \( \pm 20\) mA‡

† Unless otherwise noted, the list of absolute maximum ratings are specified over operating conditions. Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

‡ The analog inputs have an internal clamping circuit that clamps the voltage to a diode drop above \( V_{DDA} \) or below \( V_{SS} \). The continuous clamp current per pin is \( \pm 2 \) mA.

<td>V</td>
</tr>
</tbody>
</table>

**NOTES:**

1. Tested at 12.5-MHz ADCCLK
2. If SYSCLKOUT ≤ 25 MHz, ADC clock ≤ SYSCLKOUT/2
3. 1 LSB has the weighted value of 3.0/4096 = 0.732 mV.
4. A single trimmed internal band gap reference sources both ADCREFP and ADCREFM signals, and hence, these voltages track together. The ADC converter uses the difference between these two as its reference. The total gain error will be the combination of the gain error shown here and the voltage reference accuracy (ADCREFP - ADCREFM). A software-based calibration procedure is recommended for better accuracy. See F2812 ADC Calibration Application Note (literature number SPRA989) and Section 5.2, Documentation Support, for relevant documents.
5. In this mode, the accuracy of external reference is critical for overall gain. The voltage difference (ADCREFP-ADCREFM) will determine the overall accuracy.
6. Voltages above $V_{DDA} + 0.3$ V or below $V_{SS} - 0.3$ V applied to an analog input pin may temporarily affect the conversion of another pin. To avoid this, the analog inputs should be kept within these limits.

† These delays are necessary and recommended to make the ADC analog reference circuit stable before conversions are initiated. If conversions are started without these delays, the ADC results will show a higher gain. For power down, all three bits can be cleared at the same time.
6.29.5 Detailed Description

6.29.5.1 Reference Voltage

The on-chip ADC has a built-in reference, which provides the reference voltages for the ADC. ADCVREFP is set to 2.0 V and ADCVREFM is set to 1.0 V.

6.29.5.2 Analog Inputs

The on-chip ADC consists of 16 analog inputs, which are sampled either one at a time or two channels at a time. These inputs are software-selectable.

6.29.5.3 Converter

The on-chip ADC uses a 12-bit four-stage pipeline architecture, which achieves a high sample rate with low power consumption.

6.29.5.4 Conversion Modes

The conversion can be performed in two different conversion modes:

- Sequential sampling mode (SMODE = 0)
- Simultaneous sampling mode (SMODE = 1)

6.29.6 Sequential Sampling Mode (Single-Channel) (SMODE = 0)

In sequential sampling mode, the ADC can continuously convert input signals on any of the channels (Ax to Bx). The ADC can start conversions on event triggers from the Event Managers (EVA/EVB), software trigger, or from an external ADCSOC signal. If the SMODE bit is 0, the ADC will do conversions on the selected channel on every Sample/Hold pulse. The conversion time and latency of the Result register update are explained below. The ADC interrupt flags are set a few SYSCLKOUT cycles after the Result register update. The selected channels will be sampled at every falling edge of the Sample/Hold pulse. The Sample/Hold pulse width can be programmed to be 1 ADC clock wide (minimum) or 16 ADC clocks wide (maximum).

</tr>
</tbody>
</table>
6.29.7 Simultaneous Sampling Mode (Dual-Channel) (SMODE = 1)

In simultaneous mode, the ADC can continuously convert input signals on any one pair of channels (A0/B0 to A7/B7). The ADC can start conversions on event triggers from the Event Managers (EVA/EVB), software trigger, or from an external ADCSOC signal. If the SMODE bit is 1, the ADC will do conversions on two selected channels on every Sample/Hold pulse. The conversion time and latency of the Result register update are explained below. The ADC interrupt flags are set a few SYSCLOCKOUT cycles after the Result register update. The selected channels will be sampled simultaneously at the falling edge of the Sample/Hold pulse. The Sample/Hold pulse width can be programmed to be 1 ADC clock wide (minimum) or 16 ADC clocks wide (maximum).

NOTE: In Simultaneous mode, the ADCIN channel pair select has to be A0/B0, A1/B1, ..., A7/B7, and not in other combinations (such as A1/B3, etc.).

6.29.8 Definitions of Specifications and Terminology

Integral Nonlinearity

Integral nonlinearity refers to the deviation of each individual code from a line drawn from zero through full scale. The point used as zero occurs 1/2 LSB before the first code transition. The full-scale point is defined as level 1/2 LSB beyond the last code transition. The deviation is measured from the center of each particular code to the true straight line between these two points.

Differential Nonlinearity

An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value. A differential nonlinearity error of less than \( \pm 1 \) LSB ensures no missing codes.

Zero Offset

The major carry transition should occur when the analog input is at zero volts. Zero error is defined as the deviation of the actual transition from that point.

Gain Error

The first code transition should occur at an analog value 1/2 LSB above negative full scale. The last transition should occur at an analog value 1 1/2 LSB below the nominal full scale. Gain error is the deviation of the actual difference between first and last code transitions and the ideal difference between first and last code transitions.

Signal-to-Noise Ratio + Distortion (SINAD)

SINAD is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for SINAD is expressed in decibels.

Effective Number of Bits (ENOB)

For a sine wave, SINAD can be expressed in terms of the number of bits. Using the following formula,

\[
N = \frac{(\text{SINAD} - 1.76)}{6.02}
\]

it is possible to get a measure of performance expressed as \( N \), the effective number of bits. Thus, effective number of bits for a device for sine wave inputs at a given input frequency can be calculated directly from its measured SINAD.

Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.

Spurious Free Dynamic Range (SFDR)

SFDR is the difference in dB between the rms amplitude of the input signal and the peak spurious signal.
### 6.30 Multichannel Buffered Serial Port (McBSP) Timing

† Polarity bits CLKRP = CLKXP = FSRP = FSXP = 0. If the polarity of any of the signals is inverted, then the timing references of that signal are also inverted.

‡ 2P = 1/CLKG in ns. CLKG is the output of sample rate generator mux. CLKG = CLKSRG \( \frac{1}{C0041} \times \frac{CLKGDV}{(1 + CLKGDV)} \).

CLKSRG can be LSPCLK, CLKX, CLKR as source. CLKSRG ≤ (SYSCLKOUT/2). McBSP performance is limited by I/O buffer switching speed.

§ Internal clock prescalers must be adjusted such that the McBSP clock (CLKG, CLKX, CLKR) speeds are not greater than the I/O buffer speed limit (20 MHz).

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE**: TI has discontinued the production of the device.

(2) **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.** - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) **Lead/Ball Finish** - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.
In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

C. Micro Star BGA configuration
PBK (S-PQFP-G128)  PLASTIC QUAD FLATPACK

NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Falls within JEDEC MS-026
NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil metal load solder paste. Refer to IPC–7525 for other stencil recommendations.
D. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.
Images above are just a representation of the package family, actual package may vary. Refer to the product data sheet for package details.
NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs.
4. Reference JEDEC registration MS-026.
NOTES: (continued)

5. Publication IPC-7351 may have alternate designs.
6. Solder mask tolerances between and around signal pads can vary based on board fabrication site.

NOTES: (continued)

7. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

8. Board assembly site may have different recommendations for stencil design.
NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This is a Pb-free solder ball design.
NOTES: (continued)

4. Final dimensions may vary due to manufacturing tolerance considerations and also routing constraints. See Texas Instruments Literature No. SSZA002 (www.ti.com/lit/ssza002).
NOTES: (continued)

5. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release.
