**TMUX1574 Low-Capacitance, 2:1 (SPDT) 4-Channel, Powered-Off Protected Switch with 1.8 V Logic**

### 1 Features
- Wide supply range: 1.5 V to 5.5 V
- Low on-capacitance: 7.5 pF
- Low on-resistance: 2 Ω
- High bandwidth: 2 GHz
- -40°C to +125°C operating temperature
- 1.8 V Logic Compatible
- Supports Input Voltage Beyond Supply
- Integrated Pull Down Resistor on Logic Pins
- Bidirectional Signal Path
- Fail-Safe Logic
- Powered-off Protection up to 3.6 V Signals
  - Pinout compatible to SN74CBTLV3257

### 2 Applications
- Flash memory sharing
- JTAG multiplexing
- SPI multiplexing
- eMMC multiplexing
- Servers
- Data center switches & routers
- Wireless infrastructure
- PC & notebooks
- Building automation
- Grid infrastructure
- ePOS
- Appliances

### 3 Description
The TMUX1574 is a complementary metal-oxide semiconductor (CMOS) switch. The TMUX1574 offers 2:1 SPDT switch configuration with 4-channels. Wide operating supply of 1.5 V to 5.5 V allows for use in a broad array of applications from servers and communication equipment to industrial applications. The device supports bidirectional analog and digital signals on the source (SxA, SxB) and drain (Dx) pins and can pass signals above supply up to VDD x 2, with a maximum input/output voltage of 5.5 V.

**Powered-off Protection** up to 3.6 V on the signal path of the TMUX1574 provides isolation when the supply voltage is removed (VDD = 0 V). Without this protection feature, switches can back-power the supply rail through an internal ESD diode and cause potential damage to the system.

**Fail-Safe Logic** circuitry allows voltages on the logic control pins to be applied before the supply pin, protecting the device from potential damage. All control inputs have 1.8 V logic compatible thresholds, ensuring both TTL and CMOS logic compatibility when operating in the valid supply voltage range. Integrated pull down resistor on the logic pins removes external components to reduce system size and cost.

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

(2) The algebraic convention, whereby the most negative value is a minimum and the most positive value is a maximum.

(3) All voltages are with respect to ground, unless otherwise specified.

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7 Parameter Measurement Information

7.1 On-Resistance

The on-resistance of a device is the ohmic resistance between the source (Sx) and drain (Dx) pins of the device. The on-resistance varies with input voltage and supply voltage. The symbol $R_{ON}$ is used to denote on-resistance. The measurement setup used to measure $R_{ON}$ is shown in Figure 27. Voltage (V) and current ($I_{SD}$) are measured using this setup, and $R_{ON}$ is computed as shown below with $R_{ON} = V / I_{SD}$:

![Figure 27. On-Resistance Measurement Setup](image)

7.2 Off-Leakage Current

Source leakage current is defined as the leakage current flowing into or out of the source pin when the switch is off. This current is denoted by the symbol $I_{S\ (OFF)}$.

Drain leakage current is defined as the leakage current flowing into or out of the drain pin when the switch is off. This current is denoted by the symbol $I_{D\ (OFF)}$.

The setup used to measure both off-leakage currents is shown in Figure 28.

![Figure 28. Off-Leakage Measurement Setup](image)
7.3 On-Leakage Current

Source on-leakage current is defined as the leakage current flowing into or out of the source pin when the switch is on. This current is denoted by the symbol $I_{S(ON)}$.

Drain on-leakage current is defined as the leakage current flowing into or out of the drain pin when the switch is on. This current is denoted by the symbol $I_{D(ON)}$.

Either the source pin or drain pin is left floating during the measurement. Figure 29 shows the circuit used for measuring the on-leakage current, denoted by $I_{S(ON)}$ or $I_{D(ON)}$.

![Figure 29. On-Leakage Measurement Setup](image)

7.4 $I_{POFF}$ Leakage Current

$I_{POFF}$ leakage current is defined as the leakage current flowing into or out of the source pin when the device is powered off. This current is denoted by the symbol $I_{POFF}$.

The setup used to measure both $I_{POFF}$ leakage current is shown in Figure 30.

![Figure 30. $I_{POFF}$ Leakage Measurement Setup](image)
7.5 Transition Time

Transition time is defined as the time taken by the output of the device to rise or fall 10% after the select signal has risen or fallen past the logic threshold. The 10% transition measurement is utilized to provide the timing of the device. The time constant from the load resistance and load capacitance can be added to the transition time to calculate system level timing. Figure 31 shows the setup used to measure transition time, denoted by the symbol $t_{\text{TRANSITION}}$.

![Figure 31. Transition-Time Measurement Setup](image)

7.6 $t_{\text{ON (EN)}}$ and $t_{\text{OFF (EN)}}$ Time

The $t_{\text{ON (EN)}}$ time is defined as the time taken by the output of the device to rise to 90% after the enable has fallen past the logic threshold. The 90% measurement is used to provide the timing of the device being enabled in the system. Figure 32 shows the setup used to measure the enable time, denoted by the symbol $t_{\text{ON (EN)}}$.

The $t_{\text{OFF (EN)}}$ time is defined as the time taken by the output of the device to fall to 90% after the enable has fallen past the logic threshold. The 90% measurement is used to provide the timing of the device being disabled in the system. Figure 32 shows the setup used to measure enable time, denoted by the symbol $t_{\text{OFF (EN)}}$.

![Figure 32. $t_{\text{ON (EN)}}$ and $t_{\text{OFF (EN)}}$ Time Measurement Setup](image)
7.7 \( t_{\text{ON} (VDD)} \) and \( t_{\text{OFF} (VDD)} \) Time

The \( t_{\text{ON} (VDD)} \) time is defined as the time taken by the output of the device to rise to 90% after the supply has risen past the supply threshold. The 90% measurement is used to provide the timing of the device turning on in the system. Figure 33 shows the setup used to measure turn on time, denoted by the symbol \( t_{\text{ON} (VDD)} \).

The \( t_{\text{OFF} (VDD)} \) time is defined as the time taken by the output of the device to fall to 90% after the supply has fallen past the supply threshold. The 90% measurement is used to provide the timing of the device turning off in the system. Figure 33 shows the setup used to measure turn off time, denoted by the symbol \( t_{\text{OFF} (VDD)} \).

---

7.8 Break-Before-Make Delay

Break-before-make delay is a safety feature that prevents two inputs from connecting when the device is switching. The output first breaks from the on-state switch before making the connection with the next on-state switch. The time delay between the break and the make is known as break-before-make delay. Figure 34 shows the setup used to measure break-before-make delay, denoted by the symbol \( t_{\text{OPEN(BBM)}} \).

---

**Figure 33.** \( t_{\text{ON} (VDD)} \) and \( t_{\text{OFF} (VDD)} \) Time Measurement Setup

**Figure 34.** Break-Before-Make Delay Measurement Setup
7.9 Propagation Delay

Propagation delay is defined as the time taken by the output of the device to rise or fall 50% after the input signal has risen or fallen past the 50% threshold. Figure 35 shows the setup used to measure propagation delay, denoted by the symbol $t_{PD}$.

![Diagram of Propagation Delay Measurement Setup](image)

Figure 35. Propagation Delay Measurement Setup

7.10 Skew

Skew is defined as the difference between propagation delays of any two outputs of the same device. The skew measurement is taken from the output of one channel rising or falling past 50% to a second channel rising or falling past the 50% threshold when the input signals are switched at the same time. Figure 36 shows the setup used to measure skew, denoted by the symbol $t_{SK}$.

![Diagram of Skew Measurement Setup](image)

Figure 36. Skew Measurement Setup
7.11 Charge Injection

The amount of charge injected into the source or drain of the device during the falling or rising edge of the gate signal is known as charge injection, and is denoted by the symbol \( Q_C \). Figure 37 shows the setup used to measure charge injection from source (Sx) to drain (Dx).

\[
Q_C = C_x \times \Delta V_{OUT}
\]

![Figure 37. Charge-Injection Measurement Setup](image)

7.12 Capacitance

The parasitic capacitance of the device is captured at the source (Sx), drain (Dx), and select (SELx) pins. The capacitance is measured in both the on and off state and is denoted by the symbol \( C_{ON} \) and \( C_{OFF} \). Figure 38 shows the setup used to measure capacitance.

![Figure 38. Capacitance Measurement Setup](image)
7.13 Off Isolation

Off isolation is defined as the ratio of the signal at the drain pin (Dx) of the device when a signal is applied to the source pin (Sx) of an off-channel. The characteristic impedance, $Z_0$, for the measurement is 50 \( \Omega \). Figure 39 shows the setup used to measure off isolation. Use off isolation equation to compute off isolation.

$$\text{Off Isolation} = 20 \cdot \log \left( \frac{V_{\text{OUT}}}{V_S} \right)$$  \hspace{1cm} (1)

7.14 Channel-to-Channel Crosstalk

Crosstalk is defined as the ratio of the signal at the drain pin (Dx) of a different channel, when a signal is applied at the source pin (Sx) of an on-channel. The characteristic impedance, $Z_0$, for the measurement is 50 \( \Omega \). Figure 40 shows the setup used to measure, and the equation used to compute crosstalk.

$$\text{Channel-to-Channel Crosstalk} = 20 \cdot \log \left( \frac{V_{\text{OUT}}}{V_S} \right)$$  \hspace{1cm} (2)
7.15 Bandwidth

Bandwidth is defined as the range of frequencies that are attenuated by less than 3 dB when the input is applied to the source pin (Sx) of an on-channel, and the output is measured at the drain pin (Dx) of the device. The characteristic impedance, \( Z_0 \), for the measurement is 50 \( \Omega \). Figure 41 shows the setup used to measure bandwidth.

\[
\text{Attenuation} = 20 \times \log \left( \frac{V_{\text{OUT}}}{V_S} \right)
\]

8 Detailed Description

8.1 Overview

The TMUX1574 is a high speed 2:1 (SPDT) 4-ch. switch with powered-off protection up to 3.6 V. Wide operating supply of 1.5 V to 5.5 V allows for use in a wide array of applications from servers and communication equipment to industrial applications. The device supports bidirectional analog and digital signals on the source (SxA, SxB) and drain (Dx) pins. The wide bandwidth of this switch allows little or no attenuation of high-speed signals at the outputs to pass with minimum edge and phase distortion as well as propagation delay.

The enable (EN) pin is an active-low logic pin that controls the connection between the source (SxA, SxB) and drain (Dx) pins of the device. The select pin (SEL) controls the state of all four channels of the TMUX1574 and determines which source pin is connected to the drain. Fail-Safe Logic circuitry allows voltages on the logic control pins to be applied before the supply pin, protecting the device from potential damage. All logic control inputs have 1.8V logic compatible thresholds, ensuring both TTL and CMOS logic compatibility when operating in the valid supply voltage range.

Powered-off protection up to 3.6 V on the signal path of the TMUX1574 provides isolation when the supply voltage is removed (V_{DD} = 0 V). Without this protection feature, the system can back-power the supply rail through an internal ESD diode and cause potential damage to the system.

8.2 Functional Block Diagram

![Functional Block Diagram](image)

8.3 Feature Description

8.3.1 Bidirectional Operation

The TMUX1574 conducts equally well from source (SxA, SxB) to drain (Dx) or from drain (Dx) to source (SxA, SxB). Each channel has very similar characteristics in both directions and supports both analog and digital signals.

8.3.2 Beyond Supply Operation

When the TMUX1574 is powered from 1.5 V to 5.5 V, the valid signal path input/output voltage ranges from GND to V_{DD} x 2, with a maximum input/output voltage of 5.5 V.

Example 1: If the TMUX1574 is powered at 1.5V, the signal range is 0 V to 3 V.

Example 2: If the TMUX1574 is powered at 3V, the signal range is 0 V to 5.5 V.

Example 3: If the TMUX1574 is powered at 5.5V, the signal range is 0 V to 5.5 V.

Other voltage levels not mentioned in the examples support Beyond Supply Operation as long as the supply voltage falls within the recommended operation conditions of 1.5 V to 5.5 V.
Feature Description (continued)

8.3.3 1.8 V Logic Compatible Inputs

The TMUX1574 has 1.8-V logic compatible control inputs. Regardless of the \( V_{DD} \) voltage, the control input thresholds remain fixed, allowing a 1.8-V processor GPIO to control the TMUX1574 without the need for an external translator. This saves both space and BOM cost. For more information on 1.8 V logic implementations, refer to Simplifying Design with 1.8 V logic Muxes and Switches.

8.3.4 Powered-off Protection

Powered-off protection up to 3.6 V on the signal path of the TMUX1574 provides isolation when the supply voltage is removed \( (V_{DD} = 0 \text{ V}) \). When the TMUX1574 is powered-off, the I/Os of the device remain in a high-Z state. Powered-off protection minimizes system complexity by removing the need for power supply sequencing on the signal path. The device performance remains within the leakage performance mentioned in the Electrical Specifications. For more information on powered-off protection, refer to Eliminate Power Sequencing with Powered-off Protection Signal Switches.

8.3.5 Fail-Safe Logic

The TMUX1574 has Fail-Safe Logic on the control input pins \( (SELx) \) which allows for operation up to 5.5 V, regardless of the state of the supply pin. This feature allows voltages on the control pins to be applied before the supply pin, protecting the device from potential damage. Fail-Safe Logic minimizes system complexity by removing the need for power supply sequencing on the logic control pins. For example, the Fail-Safe Logic feature allows the select pins of the TMUX1574 to be ramped to 5.5 V while \( V_{DD} = 0 \text{ V} \). Additionally, the feature enables operation of the TMUX1574 with \( V_{DD} = 1.5 \text{ V} \) while allowing the select pins to interface with a logic level of another device up to 5.5 V.

8.3.6 Low Capacitance

The TMUX1574 has very low capacitance in both the ON and OFF states on the source and drain pins. Low capacitance helps to reduce large overshoots and ringing of an amplifier circuit when the switch is connected to the feedback network. Additionally, low capacitance improves system settling time by reducing the switch time constant formed by the On-resistance and On-capacitance. For more information on the benefits of low capacitance refer to Improve Stability Issues with Low \( C_{ON} \) Multiplexers.

8.3.7 Integrated Pull-Down Resistors

The TMUX1574 has internal weak pull-down resistors \( (6 \text{ MΩ}) \) to GND to ensure the logic pins are not left floating. This feature integrates up to four external components and reduces system size and cost.
8.4 Device Functional Modes

The enable (EN) pin is an active-low logic pin that controls the connection between the source (SxA, SxB) and drain (Dx) pins of the device. When the enable pin is pulled high, all switches are turned off. When the enable is pulled low, the select pin controls the signal path selection. The select pin (SEL) controls the state of all four channels of the TMUX1574 and determines which source pin is connected to the drain pins. When the select pin is pulled low, the SxA pin conducts to the corresponding Dx pins. When the select pin is pulled high, the SxB pin conducts to the corresponding Dx pins. The TMUX1574 logic pins have internal weak pull-down resistors (6 MΩ) to GND so that it powers-on in a known state.

The TMUX1574 can be operated without any external components except for the supply decoupling capacitors. Unused logic control pins should be tied to GND or VDD in order to ensure the device does not consume additional current as highlighted in Implications of Slow or Floating CMOS Inputs. Unused signal path inputs (SxA, SxB, or Dx) should be connected to GND.

9 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information
The TMUX15xx family offers high-speed system performance across a wide operating supply (1.5 V to 5.5 V) and operating temperature (-40°C to +125°C). The TMUX1574 supports a number of features that improve system performance such as 1.8 V logic compatibility, supports input voltages beyond supply, Fail-Safe Logic, and Powered-off Protection up to 3.6 V. These features make the TMUX15xx a family of protection multiplexers and switches that can reduce system complexity, board size, and overall system cost.

9.2 Typical Application
Common applications that require the features of the TMUX1574 include multiplexing various protocols from a possessor or MCU such as SPI, JTAG, or standard GPIO signals. The TMUX1574 provides superior isolation performance when the device is powered. The added benefit of powered-off protection allows a system to minimize complexity by eliminating the need for power sequencing in hot-swap and live insertion applications. The example shown in Figure 42 illustrates the use of the TMUX1574 to multiplex an SPI bus to multiple flash memory devices.

9.2.2 Detailed Design Procedure

The TMUX1574 can be operated without any external components except for the supply decoupling capacitors. The TMUX1574 has internal weak pull-down resistors (6 MΩ) to GND so that it powers-on with the switches in a known state. All inputs signals passing through the switch must fall within the recommend operating conditions of the TMUX1574 including signal range and continuous current. For this design example, with a supply of 3.3 V, the signals can range from 0 V to 3.3 V when the device is powered. This example can also utilize the Powered-off Protection feature and the inputs can range from 0 V to 3.6 V when V_{DD} = 0 V. The max continuous current can be 25 mA. Due to the voltage range and high speed capability, the TMUX1574 example is suitable for use in SPI, JTAG, and I2S applications. Refer to *Enabling SPI-based flash memory expansion by using multiplexers* for more information on using switches and multiplexers for SPI protocol expansion.

9.2.3 Application Curves

Two important specifications when using a switch or multiplexer to pass signals are the device propagation delay and skew.

![Figure 43. Propagation Delay and Skew Measurement](image)

10 Power Supply Recommendations

The TMUX1574 operates across a wide supply range of 1.5 V to 5.5 V. Do not exceed the absolute maximum ratings because stresses beyond the listed ratings can cause permanent damage to the devices.

Power-supply bypassing improves noise margin and prevents switching noise propagation from the V_{DD} supply to other components. Good power-supply decoupling is important to achieve optimum performance. For improved supply noise immunity, use a supply decoupling capacitor ranging from 0.1 μF to 10 μF from V_{DD} to ground. Place the bypass capacitors as close to the power supply pins of the device as possible using low-impedance connections. TI recommends using multi-layer ceramic chip capacitors (MLCCs) that offer low equivalent series resistance (ESR) and inductance (ESL) characteristics for power-supply decoupling purposes. For very sensitive systems, or for systems in harsh noise environments, avoiding the use of vias for connecting the capacitors to the device pins may offer superior noise immunity. The use of multiple vias in parallel lowers the overall inductance and is beneficial for connections to ground planes.
11 Layout

11.1 Layout Guidelines

When a PCB trace turns a corner at a 90° angle, a reflection can occur. A reflection occurs primarily because of the change of width of the trace. At the apex of the turn, the trace width increases to 1.414 times the width. This increase upsets the transmission-line characteristics, especially the distributed capacitance and self–inductance of the trace which results in the reflection. Not all PCB traces can be straight and therefore some traces must turn corners. Figure 44 shows progressively better techniques of rounding corners. Only the last example (BEST) maintains constant trace width and minimizes reflections.

![Figure 44. Trace Example](image)

Route the high-speed signals using a minimum of vias and corners which reduces signal reflections and impedance changes. When a via must be used, increase the clearance size around it to minimize its capacitance. Each via introduces discontinuities in the signal's transmission line and increases the chance of picking up interference from the other layers of the board. Be careful when designing test points, through-hole pins are not recommended at high frequencies.

Do not route high speed signal traces under or near crystals, oscillators, clock signal generators, switching regulators, mounting holes, magnetic devices or ICs that use or duplicate clock signals.

Avoid stubs on the high-speed signals traces because they cause signal reflections.

Route all high-speed signal traces over continuous GND planes, with no interruptions.

Avoid crossing over anti-etch, commonly found with plane splits.

When working with high frequencies, a printed circuit board with at least four layers is recommended; two signal layers separated by a ground and power layer as shown in Figure 45.

![Figure 45. Example Layout](image)

The majority of signal traces must run on a single layer, preferably Signal 1. Immediately next to this layer must be the GND plane, which is solid with no cuts. Avoid running signal traces across a split in the ground or power plane. When running across split planes is unavoidable, sufficient decoupling must be used. Minimizing the number of signal vias reduces EMI by reducing inductance at high frequencies.

Figure 46 illustrates an example of a PCB layout with the TMUX1574. Some key considerations are:
Layout Guidelines (continued)

Decouple the $V_{DD}$ pin with a 0.1-$\mu$F capacitor, placed as close to the pin as possible. Make sure that the capacitor voltage rating is sufficient for the $V_{DD}$ supply.

High-speed switches require proper layout and design procedures for optimum performance.

Keep the input lines as short as possible.

Use a solid ground plane to help reduce electromagnetic interference (EMI) noise pickup.

Do not run sensitive analog traces in parallel with digital traces. Avoid crossing digital and analog traces if possible, and only make perpendicular crossings when necessary.

(1) The marketing status values are defined as follows:
- **ACTIVE:** Product device recommended for new designs.
- **LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
- **RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
- **Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.:** The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
4. This dimension does not include interlead flash. Interlead flash shall not exceed 0.25 mm per side.
5. Reference JEDEC registration MO-153.
6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
NOTES: (continued)

8. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
9. Board assembly site may have different recommendations for stencil design.
