1 Features

- **Wide supply range:**
  - Dual supply: ±5 V to ±22 V
  - Single supply: 8 V to 44 V
- **Integrated fault protection:**
  - Overvoltage protection, source to supplies or source to drain: ±85 V
  - Overvoltage protection: ±60 V
  - Power-off protection: ±60 V
  - Adjustable overvoltage triggering thresholds
    - \( V_{FP} \): 3 V to \( V_{DD} \)
    - \( V_{FN} \): 0 V to \( V_{SS} \)
  - Interrupt flags to indicate overall and specific fault channel information
  - Non-fault channels continue to operate with low leakage currents
  - Output clamped to the fault supply in overvoltage condition
- **Latch-up immunity by device construction**
- **1.8-V Logic capable**
- **Fail-safe logic: up to 44 V independent of supply**
- **Break-before-make switching**
- **Industry-standard TSSOP and smaller WQFN package**

2 Applications

- Factory automation and control
- Programmable logic controllers (PLC)
- Analog input modules
- Semiconductor test equipment
- Battery test equipment
- Servo drive control module
- Data acquisition systems (DAQ)

3 Description

The TMUX7348F and TMUX7349F are modern complementary metal-oxide semiconductor (CMOS) analog multiplexers in 8:1 (single ended) and 4:1 (differential) configurations. The devices work well with dual supplies (±5 V to ±22 V), a single supply (8 V to 44 V), or asymmetric supplies (such as \( V_{DD} = 12 \) V, \( V_{SS} = –5 \) V). The overvoltage protection is available in powered and powered-off conditions, making the TMUX7348F and TMUX7349F devices suitable for applications where power supply sequencing cannot be precisely controlled.

The device blocks fault voltages up to +60 V and –60 V relative to ground in both powered and powered-off conditions. When no power supplies are present, the switch channels remain in the OFF state regardless of switch input conditions and logic control status. Under normal operation conditions, if the analog input signal level on any \( S_x \) pin exceeds positive fault supply (\( V_{FP} \)) or negative fault supply (\( V_{FN} \)) by a threshold voltage (\( V_T \)), the channel turns OFF and the \( S_x \) pin becomes high impedance. When the fault channel is selected, the drain pin (D or Dx) is pulled to the fault supply voltage (\( V_{FF} \) or \( V_{FN} \)) that was exceeded. The devices provide two active-low interrupt flags (FF and SF) to provide details of the fault. The FF flag indicates if any of the source inputs are experiencing a fault condition, while the SF flag is used to decode which specific inputs are experiencing a fault condition.

The low capacitance, low charge injection, and integrated fault protection enables the TMUX7348F and TMUX7349F devices to be used in front end data acquisition applications where high performance and high robustness are both critical. The devices are available in standard TSSOP package and smaller WQFN package (ideal if PCB space is limited).

(1) \( V_{DD} \) and \( V_{SS} \) can be any value as long as \( 8 \text{ V} \leq (V_{DD} - V_{SS}) \leq 44 \text{ V} \).
(2) Under a fault condition, the potential difference between source pin (Sx) and supply pins (\( V_{DD} \) and \( V_{SS} \)) or source pin (Sx) and drain pins (D, Dx) may not exceed 85 V.
(3) Fault supplies are tied to the primary supplies (\( V_{FP} = V_{DD}, V_{FN} = V_{SS} \)).

8 Parameter Measurement Information

8.1 On-Resistance

The on-resistance of the TMUX7348F and TMUX7349F is the ohmic resistance across the source (Sx) and drain (Dx) pins of the device. The on-resistance varies with input voltage and supply voltage. The symbol $R_{ON}$ is used to denote on-resistance. The measurement setup used to measure $R_{ON}$ is shown in Figure 8-1. $\Delta R_{ON}$ represents the difference between the $R_{ON}$ of any two channels, while $R_{ON\_FLAT}$ denotes the flatness that is defined as the difference between the maximum and minimum value of on-resistance measured over the specified analog signal range.

![Figure 8-1. On-Resistance Measurement Setup](image)

8.2 Off-Leakage Current

There are two types of leakage currents associated with a switch during the off state:

1. Source off-leakage current $I_{S\_OFF}$: the leakage current flowing into or out of the source pin when the switch is off.
2. Drain off-leakage current $I_{D\_OFF}$: the leakage current flowing into or out of the drain pin when the switch is off.

Figure 8-2 shows the setup used to measure both off-leakage currents.

![Figure 8-2. Off-Leakage Measurement Setup](image)
8.3 On-Leakage Current

Source on-leakage current ($I_{S(ON)}$) and drain on-leakage current ($I_{D(ON)}$) denote the channel leakage currents when the switch is in the on state. $I_{S(ON)}$ is measured with the drain floating, while $I_{D(ON)}$ is measured with the source floating. Figure 8-3 shows the circuit used for measuring the on-leakage currents.

![Figure 8-3. On-Leakage Measurement Setup](image_url)

8.4 Input and Output Leakage Current Under Overvoltage Fault

If any of the source pin voltage goes above the fault supplies ($V_{FP}$ or $V_{FN}$), the overvoltage protection feature of the TMUX7348F and TMUX7349F is triggered to turn off the switch under fault, keeping the fault channel in high-impedance state. $I_{S(FA)}$ and $I_{D(FA)}$ denotes the input and output leakage current under overvoltage fault conditions, respectively. For $I_{D(FA)}$, the device is disabled to measure leakage current on the drain pin without being impacted by the 40 kΩ impedance to the fault supply. When the overvoltage fault occurs, the supply (or supplies) can either be in normal operating condition (Figure 8-4) or abnormal operating condition (Figure 8-5). During abnormal operating condition, the supply (or supplies) can either be unpowered ($V_{DD} = V_{SS} = V_{FN} = V_{FP} = 0$ V) or floating ($V_{DD} = V_{SS} = V_{FN} = V_{FP} = $ No Connection), and remains within the leakage performance specifications.

8.5 Break-Before-Make Delay

The break-before-make delay is a safety feature of the TMUX7348F and TMUX7349F. The ON switches first break the connection before the OFF switches make connection. The time delay between the break and the make is known as break-before-make delay. Figure 8-6 shows the setup used to measure break-before-make delay, denoted by the symbol $t_{BBM}$.

![Diagram showing the measurement setup for break-before-make delay](image)

Figure 8-6. Break-Before-Make Delay Measurement Setup
8.6 Enable Delay Time

$t_{ON(EN)}$ time is defined as the time taken by the output of the TMUX7348F and TMUX7349F to rise to a 90% final value after the EN signal has risen to a 50% final value. $t_{OFF(EN)}$ is defined as the time taken by the output of the TMUX7348F and TMUX7349F to fall to a 10% initial value after the EN signal has fallen to a 50% initial value. Figure 8-7 shows the setup used to measure the enable delay time.

![Figure 8-7. Enable Delay Measurement Setup](image)

8.7 Transition Time

Transition time is defined as the time taken by the output of the device to rise (to 90% of the transition) or fall (to 10% of the transition) after the address signal (Ax) has fallen or risen to 50% of the transition. Figure 8-8 shows the setup used to measure transition time, denoted by the symbol $t_{TRAN}$.

![Figure 8-8. Transition Time Measurement Setup](image)
8.8 Fault Response Time

Fault response time ($t_{\text{RESPONSE}}$) measures the delay between the source voltage exceeding the fault supply voltage ($V_{FP}$ or $V_{FN}$) by 0.5 V and the drain voltage failing to 50% of the maximum output voltage. Figure 8-9 shows the setup used to measure $t_{\text{RESPONSE}}$.

8.9 Fault Recovery Time

Fault recovery time ($t_{\text{RECOVERY}}$) measures the delay between the source voltage falling from overvoltage condition to below fault supply voltage ($V_{FP}$ or $V_{FN}$) plus 0.5 V and the drain voltage rising from 0 V to 50% of the final output voltage. Figure 8-10 shows the setup used to measure $t_{\text{RECOVERY}}$. 
### 8.10 Fault Flag Response Time

Fault flag response time ($t_{\text{RESPONSE(FLAG)}}$) measures the delay between the source voltage exceeding the fault supply voltage ($V_{FP}$ or $V_{FN}$) by 0.5 V and the general fault flag (FF) pin or specific fault flag (SF) pin to go below 10% of its original value. Figure 8-11 shows the setup used to measure $t_{\text{RESPONSE(FLAG)}}$.

![Figure 8-11. Fault Flag Response Time Measurement Setup](image)

### 8.11 Fault Flag Recovery Time

Fault flag recovery time ($t_{\text{RECOVERY(FLAG)}}$) measures the delay between the source voltage falling from overvoltage condition to below fault supply voltage ($V_{FP}$ or $V_{FN}$) plus 0.5 V and the general fault flag (FF) pin or the specific fault flag (SF) pin to rise above 3 V with 5 V external pull-up. Figure 8-12 shows the setup used to measure $t_{\text{RECOVERY(FLAG)}}$.

![Figure 8-12. Fault Flag Recovery Time Measurement Setup](image)
8.12 Charge Injection

Charge injection is a measure of the glitch impulse transferred from the logic input to the analog output during switching, and is denoted by the symbol $Q_{\text{INJ}}$. Figure 8-13 shows the setup used to measure charge injection from the source to drain.

Figure 8-13. Charge-Injection Measurement Setup

8.13 Off Isolation

Off isolation is defined as the ratio of the signal at the drain pin ($D_x$) of the device when a signal is applied to the source pin ($S_x$) of an off-channel. Figure 8-14 shows the setup used to measure, and the equation used to calculate off isolation.

Figure 8-14. Off Isolation Measurement Setup
8.14 Crosstalk

There are two types of crosstalk that can be defined for the devices:

1. Intra-channel crosstalk ($X_{\text{TALK(INTRA)}}$): the voltage at the source pin ($S_x$) of an off-switch input, when a signal is applied at the source pin of an on-switch input in the same channel, as shown in Figure 8-15.

2. Inter-channel crosstalk ($X_{\text{TALK(INTER)}}$): the voltage at the source pin ($S_x$) of an on-switch input, when a signal is applied at the source pin of an on-switch input in a different channel, as shown in Figure 8-16. Inter-channel crosstalk applies only to the TMUX7349F device.

\[
\text{Intra-channel Crosstalk} = 20 \times \log \left( \frac{V_{\text{OUT}}}{V_S} \right)
\]

\[
\text{Inter-channel Crosstalk} = 20 \times \log \left( \frac{V_{\text{OUT}}}{V_S} \right)
\]

**Figure 8-15. Intra-Channel Crosstalk Measurement Setup**

**Figure 8-16. Inter-Channel Crosstalk Measurement Setup**
8.15 Bandwidth

Bandwidth (BW) is defined as the range of frequencies that are attenuated by < 3 dB when the input is applied to the source pin (Sx) of an on-channel, and the output is measured at the drain pin (D or Dx) of the TMUX7348F and TMUX7349F. Figure 8-17 shows the setup used to measure bandwidth of the switch.

\[
\text{Bandwidth} = 20 \times \log_{10} \frac{V_{\text{OUT}}}{V_S}
\]

Figure 8-17. Bandwidth Measurement Setup

8.16 THD + Noise

The total harmonic distortion (THD) of a signal is a measurement of the harmonic distortion, and is defined as the ratio of the sum of the powers of all harmonic components to the power of the fundamental frequency at the multiplexer output. The on-resistance of the TMUX7348F and TMUX7349F varies with the amplitude of the input signal and results in distortion when the drain pin is connected to a low-impedance load. Total harmonic distortion plus noise is denoted as THD+N. Figure 8-18 shows the setup used to measure THD+N of the devices.

9 Detailed Description

9.1 Overview

The TMUX7348F and TMUX7349F are a modern complementary metal-oxide semiconductor (CMOS) analog multiplexers in 8:1 (single ended) and 4:1 (differential) configurations. The devices work well with dual supplies (±5 V to ±22 V), a single supply (8 V to 44 V), or asymmetric supplies (such as $V_{DD} = 15$ V, $V_{SS} = -5$ V). The devices have an overvoltage protection feature on the source pins under powered and powered-off conditions, allowing them to be used in harsh industrial environments.

9.2 Functional Block Diagram
9.3 Feature Description

9.3.1 Flat ON-Resistance

The TMUX7348F and TMUX7349F are designed with a special switch architecture to produce ultra-flat on-resistance ($R_{\text{ON}}$) across most of the switch input operation region. The flat $R_{\text{ON}}$ response allows the device to be used in precision sensor applications since the $R_{\text{ON}}$ is controlled regardless of the signals sampled. The architecture is implemented without a charge pump so no unwanted noise is produced from the device to affect sampling accuracy.

9.3.2 Protection Features

The TMUX7348F and TMUX7349F offer a number of protection features to enable robust system implementations.

9.3.2.1 Input Voltage Tolerance

The maximum voltage that can be applied to any source input pin is +60 V or -60 V, regardless of supply voltage. This allows the device to handle typical voltage fault condition in industrial applications. It shall be cautioned that the device is rated to handle a maximum stress of 85 V across different pins, such as the following:

1. **Between source pins and supply rails:**
   
   For example, if the device is powered by $V_{\text{DD}}$ supply of 20 V, then the maximum negative signal level on any source pin is –60 V to maintain the 60 V maximum rating on any source pin. If the device is powered by $V_{\text{DD}}$ supply of 40 V, then the maximum negative signal level on any source pin is reduced to –45 V to maintain the 85 V maximum rating across the source pin and the supply.

2. **Between source pins and one or more of the drain pins:**
   
   For example, if channel S1(A) is ON and the voltage on S1(A) pin is 40 V. In this case, the drain voltage is also 40 V. The maximum negative voltage on any of the other source pins is –45 V to maintain the 85 V maximum rating across the source pin and the drain pin.

9.3.2.2 Powered-Off Protection

When the supplies of TMUX7348F and TMUX7349F are removed ($V_{\text{DD}}$/ $V_{\text{SS}}$ = 0 V or floating), the source (Sx) pins of the device remain in the high impedance (Hi-Z) state, and the source (Sx) and drain (Dx) pins of the device remain within the leakage performance mentioned in the Electrical Characteristics. Powered-off protection minimizes system complexity by removing the need to control the power supply sequencing of the system. The feature prevents errant voltages on the input source pins from reaching the rest of the system and maintains isolation when the system is powering up. Without powered-off protection, the signal on the input source pins can back-power the supply rails through the internal ESD diodes and potentially cause damage to the system. For more information on powered-off protection refer to the *Eliminate Power Sequencing with Powered-Off Protection Signal Switches* application brief.

The switch remains OFF regardless of whether the $V_{\text{DD}}$ and $V_{\text{SS}}$ supplies are 0 V or floating. A GND reference must always be present to ensure proper operation. Source and drain voltage levels of up to ±60 V are blocked in the powered-off condition.

9.3.2.3 Fail-Safe Logic

Fail-safe logic circuitry allows voltages on the logic control pins to be applied before the supply pins, protecting the device from potential damage. The switch is specified to be in the OFF state, regardless of the state of the logic signals. The logic inputs are protected against positive faults of up to +44 V in the powered-off condition, but do not offer protection against the negative overvoltage condition.

Fail-safe logic also allows the TMUX7348F and TMUX7349F devices to interface with a voltage greater than $V_{\text{DD}}$ during normal operation to add maximum flexibility in system design. For example, with a $V_{\text{DD}}$ of = 15 V, the logic control pins could be connected to +24 V for a logic high signal which allows different types of signals, such as analog feedback voltages, to be used when controlling the logic inputs. Regardless of the supply voltage, the logic inputs can be interfaced as high as 44 V.
9.3.2.4 Overvoltage Protection and Detection

The TMUX7348F and TMUX7349F detect overvoltage inputs by comparing the voltage on a source pin (Sx) with the fault supplies (V\textsubscript{FP} and V\textsubscript{FN}). A signal is considered overvoltage if it exceeds the fault supply voltages by the threshold voltage (V\textsubscript{T}).

When an overvoltage is detected, the switch automatically turns OFF regardless of the logic controls. The source pin becomes high impedance and ensures only small leakage current flows through the switch and the overvoltage does not appear on the drain. When the overvoltage channel is selected by the logic control, the drain pin (D or Dx) is pulled to the supply that was exceeded. For example, if the source voltage exceeds V\textsubscript{FP}, then the drain output is pulled to V\textsubscript{FP}. If the source voltage exceeds V\textsubscript{FN}, then the drain output is pulled to V\textsubscript{FN}. The pull-up impedance is approximately 40 k\ohm, and as a result, the drain current is limited to roughly 1 mA during a shorted load (to GND) condition.

Figure 9-1 shows a detailed view of how the pullup or down controls the output state of the drain pin under a fault scenario.

V\textsubscript{FP} and V\textsubscript{FN} are required fault supplies that set the level at which the overvoltage protection is engaged. V\textsubscript{FP} can be supplied from 3 V to V\textsubscript{DD}, while the V\textsubscript{FN} can be supplied from V\textsubscript{SS} to 0 V. If the fault supplies are not available in the system, the V\textsubscript{FP} pin must be connected to V\textsubscript{DD}, while the V\textsubscript{FN} pin must be connected to V\textsubscript{SS}. In this case, overvoltage protection then engages at the primary supply voltages V\textsubscript{DD} and V\textsubscript{SS}.

9.3.2.5 Adjacent Channel Operation During Fault

When the logic pins are set to a channel under a fault, the overvoltage detection will trigger, the switch will open, and the drain pin will be pulled up or down as described in Section 9.3.2.4. During such an event, all other channels not under a fault can continue to operate as normal. For example, if S1 voltage exceeds V\textsubscript{FP}, and the logic pins are set to S1, the drain output is pulled to V\textsubscript{FP}. Then if the logic pins are changed to set S4, which is not in overvoltage or undervoltage, the drain will disconnect from the pullup to V\textsubscript{FP} and the S4 switch will be enabled and connected to the drain, operating as normal. If the logic pins are switched back to S1, the S4 switch will be disabled, the drain pin will be pulled up to V\textsubscript{FP} again, and the switch from S1 to drain will not be enabled until the overvoltage fault is removed.

9.3.2.6 ESD Protection

All pins on the TMUX7348F and TMUX7349F support HBM ESD protection level up to ±3.5 kV, which helps the device from getting ESD damages during the manufacturing process.

The drain pins (D or Dx) have internal ESD protection diodes to the fault supplies V\textsubscript{FP} and V\textsubscript{FN}. Therefore, the voltage at the drain pins must not exceed the fault supply voltages to prevent excessive diode current. The source pins have specialized ESD protection that allows the signal voltage to reach ±60 V regardless of the supply voltage level. Exceeding ±60 V on any source input may damage the ESD protection circuitry on the device and cause the device to malfunction if the damage is excessive.
9.3.2.7 Latch-Up Immunity

Latch-up is a condition where a low impedance path is created between a supply pin and ground. This condition is caused by a trigger (current injection or overvoltage), but once activated, the low impedance path remains even after the trigger is no longer present. This low impedance path may cause system upset or catastrophic damage due to excessive current levels. The latch-up condition typically requires a power cycle to eliminate the low impedance path.

The TMUX7348F and TMUX7349F devices are constructed on silicon on insulator (SOI) based process where an oxide layer is added between the PMOS and NMOS transistor of each CMOS switch to prevent parasitic structures from forming. The oxide layer is also known as an insulating trench and prevents triggering of latch up events due to overvoltage or current injections. The latch-up immunity feature allows the TMUX7348F and TMUX7349F to be used in harsh environments. For more information on latch-up immunity refer to the Using Latch-Up Immune Multiplexers to Help Improve System Reliability application report.

9.3.2.8 EMC Protection

The TMUX7348F and TMUX7349F are not intended for standalone electromagnetic compatibility (EMC) protection in industrial applications. There are three common high voltage transient specifications that govern industrial high voltage transient specification: IEC61000-4-2 (ESD), IEC61000-4-4 (EFT), and IEC61000-4-5 (surge immunity). A transient voltage suppressor (TVS), along with some low-value series current limiting resistors, are required to prevent source input voltages from going above the rated ±60 V limits.

When selecting a TVS protection device, it is critical to ensure that the maximum working voltage is greater than both the normal operating range of the input source pins to be protected and any known system common-mode overvoltage that may be present due to incorrect wiring, loss of power, or short circuit. Figure 9-2 shows an example of the proper design window when selecting a TVS device.

Region 1 denotes normal operation region of TMUX7348F and TMUX7349F where the input source voltages stay below the fault supplies $V_{FP}$ and $V_{FN}$. Region 2 represents the range of possible persistent DC (or long duration AC overvoltage fault) presented on the source input pins. Region 3 represents the margin between any known DC overvoltage level and the absolute maximum rating of the TMUX7348F and TMUX7349F. The TVS breakdown voltage must be selected to be less than the absolute maximum rating of the TMUX7348F and TMUX7349F, but greater than any known possible persistent DC or long duration AC overvoltage fault to avoid triggering the TVS inadvertently. Region 4 represents the margin system designers must impose when selecting the TVS protection device to prevent accidental triggering of ESD cells of the TMUX7348F and TMUX7349F devices.

Figure 9-2. System Operation Regions and Proper Region of Selecting a TVS Protection Device
9.3.3 Overvoltage Fault Flags

The voltages on the source input pins of the TMUX7348F and TMUX7349F are continuously monitored, and the status of whether an overvoltage condition occurs is indicated by an active low general fault flag (FF). The voltage on the FF pin indicates if any of the source input pins are experiencing an overvoltage condition. If any source pin voltage exceeds the fault supply voltages by a $V_T$, the FF output is pulled-down to below $V_{OL}$.

The specific fault (SF) output pins, on the other hand, can be used to decode which inputs are experiencing an overvoltage condition. The SF pin is pulled-down to below $V_{OL}$ when an overvoltage condition is detected on a specific source input pin, depending on the state of the A0, A1, A2, and EN logic pins (see Table 9-1 and Table 9-2).

Both the FF pin and SF pin are open-drain output and external pull-up resistors of 1 kΩ are recommended. The pull-up voltage can be in the range of 1.8 V to 5.5 V, depending on the controller voltage the device interfaces with.

9.3.4 Bidirectional and Rail-to-Rail Operation

The TMUX7348F and TMUX7349F conducts equally well from source (Sx) to drain (D or Dx) or from drain (D or Dx) to source (Sx). Each signal path has very similar characteristics in both directions. It is important to note, however, that the overvoltage protection is implemented only on the source (Sx) side. The voltage on the drain is only allowed to swing between $V_{FP}$ and $V_{FN}$ and no overvoltage protection is available on the drain side.

The primary supplies ($V_{DD}$ and $V_{SS}$) define the on-resistance profile of the switch channel, whereas the fault voltage supplies ($V_{FP}$ and $V_{FN}$) define the signal range that can be passed through from source to drain of the device. It is good practice to use voltages on $V_{FP}$ and $V_{FN}$ that are lower than $V_{DD}$ and $V_{SS}$ to take advantage of the flat on-resistance region of the device for better input-to-output linearity. The flatest on-resistance region extends from $V_{SS}$ to roughly 3 V below $V_{DD}$. Once the signal is within 3 V of $V_{DD}$ the on-resistance will exponentially increase and may impact desired signal transmission.

9.3.5 1.8 V Logic Compatible Inputs

The TMUX7348F and TMUX7349F devices have 1.8 V logic compatible control for all logic control inputs. 1.8 V logic level inputs allows the TMUX7348F and TMUX7349F to interface with processors that have lower logic I/O rails and eliminates the need for an external translator, which saves both space and BOM cost. For more information on 1.8 V logic implementations refer to Simplifying Design with 1.8 V Logic Muxes and Switches.

9.3.6 Integrated Pull-Down Resistor on Logic Pins

The TMUX7348F and TMUX7349F have internal weak pull-down resistors to GND to ensure the logic pins are not left floating. The value of this pull-down resistor is approximately 4 MΩ, but is clamped to about 1 μA at higher voltages. This feature integrates up to four external components and reduces system size and cost.

9.4 Device Functional Modes

The TMUX7348F and TMUX7349F offer two modes of operation (Normal Mode and Fault Mode) depending on whether any of the input pins experience an overvoltage condition.

9.4.1 Normal Mode

In Normal mode operation, signals of up to $V_{FP}$ and $V_{FN}$ can be passed through the switch from source (Sx) to drain (D or Dx) or from drain (D or Dx) to source (Sx). According to Table 9-1 and Table 9-2, the address (Ax) pins and the enable (EN) pin determine which switch path to turn on. The following conditions must be satisfied for the switch to stay in the ON condition:

- The difference between the primary supplies ($V_{DD} - V_{SS}$) must be higher or equal to 8 V. With a minimum $V_{DD}$ of 5 V.
- $V_{FP}$ must be between 3 V and $V_{DD}$, and $V_{FN}$ must be between $V_{SS}$ and 0 V.
- The input signals on the source (Sx) or the drain (D or Dx) must be be between $V_{FP} + V_{T}$ and $V_{FN} - V_{T}$.
- The logic control (Ax and EN) must have selected the switch.
9.4.2 Fault Mode

The TMUX7348F and TMUX7349F enters into Fault mode when any of the input signals on the source (Sx) pins exceed $V_{FP}$ or $V_{FN}$ by a threshold voltage $V_T$. Under the overvoltage condition, the switch input experiencing the fault automatically turns OFF regardless of the logic status, and the source pin becomes high impedance with a negligible amount of leakage current flowing through the switch. When the fault channel is selected by the logic control, the drain pin (D or Dx) is pulled to the fault supply that was exceeded through a 40 kΩ internal resistor.

In the Fault mode, the general fault flag (FF) is asserted low. The specific flag (SF) is asserted low when a specific input path is selected, according to Table 9-1 and Table 9-2.

The overvoltage protection is provided only for the source (Sx) input pins. The drain (D or Dx) pin, if used as signal input, must stay in between $V_{FP}$ and $V_{FN}$ at all time since no overvoltage protection is implemented on the drain pin.

10 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

10.1 Application Information

The TMUX7348F and TMUX7349F are part of the fault protected switches and multiplexers family of devices. The ability to protect downstream components from overvoltage events up to ±60 V makes these switches and multiplexers suitable for harsh environments.

10.2 Typical Application

In analog input programmable logic controllers (PLC) a multiplexer is often used to switch multiple sensors to a single ADC. By using a multiplexer, the number of components in the system can be reduced to save system cost and size. In a PLC module a ±10 V input signal range is common for interfacing with external field transmitters and sensors; however, there are a number of fault cases that may occur that can be damaging to many of the integrated circuits. Such fault conditions may include, but are not limited to, human error from wiring connections incorrectly, component failure or wire shorts, electromagnetic interference (EMI) or transient disturbances, and so forth.

10.2.2 Detailed Design Procedure

The image shows the case where an incorrect wiring condition occurred and one of the input connectors has been shorted to the power board supply voltage. If the board supply voltage is higher than the fault voltage supply of the multiplexer, then the TMUX7348F or TMUX7349F will disconnect the source input from passing the signal to protect the downstream ADC. The drain pin of the mux will be pulled up to the fault voltage supply voltage $V_{FP}$ through a 40 kΩ resistor to allow the ADC to determine a fault condition has occurred.

10.2.3 Application Curves

The example application utilizes the fault protection of the TMUX7348F or TMUX7349F to protect downstream components from potential miswiring conditions from the Power Module board. Figure 10-2 shows an example of positive overvoltage fault response with a fast fault ramp rate of 58 V/µs. Figure 10-3 shows the extremely flat on-resistance across source voltage while operating within a common signal range of ±10 V. These features make the TMUX7348F or TMUX7349F an ideal solution for factory automation applications that may face various fault conditions but also require excellent linearity and low distortion.

11 Power Supply Recommendations

The TMUX7348F and TMUX7349F operate across a wide supply range of ±5 V to ±22 V (8 V to 44 V in single-supply mode). They also perform well with asymmetrical supplies such as $V_{DD} = 12$ V and $V_{SS} = -5$ V. For improved supply noise immunity, use a supply decoupling capacitor ranging from 0.1 µF to 10 µF at both the $V_{DD}$ and $V_{SS}$ pins to ground. Always ensure the ground (GND) connection is established before supplies are ramped.

The fault supplies ($V_{FP}$ and $V_{FN}$) provide the current required to operate the fault protection, and thus, must be low impedance supplies. They can be derived from the primary supplies by using a resistor divider and buffer or be an independent supply rail. The fault supplies must not exceed the primary supplies as it might cause unexpected behavior of the switch. Use a supply decoupling capacitor ranging from 0.1 µF to 10 µF at both the $V_{FP}$ and $V_{FN}$ pins to ground for improved supply noise immunity.

The positive supply ($V_{DD}$) must be ramped before the positive fault rail ($V_{FP}$) for proper power sequencing of the TMUX7348F and TMUX7349F. Similarly, the negative supply ($V_{SS}$) must be ramped before the negative fault voltage rail ($V_{FN}$).

12 Layout

12.1 Layout Guidelines

The following images illustrate examples of a PCB layout with the TMUX7348F and TMUX7349F. Some key considerations are:

- For reliable operation, connect a decoupling capacitor ranging from 0.1 µF to 10 µF between $V_{DD}$ and $V_{SS}$ to GND. We recommend a 0.1 µF and 1 µF capacitor, placing the lowest value capacitor as close to the pin as possible. Make sure that the capacitor voltage rating is sufficient for the $V_{DD}$ and $V_{SS}$ supplies.
- Multiple decoupling capacitors can be used if there is a lot of noise in the system. For example, a 0.1-µF and 1-µF can be placed on the supply pins. If multiple capacitors are used, placing the lowest value capacitor closest to the supply pin is recommended.
- Keep the input lines as short as possible.
- Use a solid ground plane to help distribute heat and reduce electromagnetic interference (EMI) noise pickup.
- Do not run sensitive analog traces in parallel with digital traces. Avoid crossing digital and analog traces if possible, and only make perpendicular crossings when necessary.

13.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.
