TPS7A24 200-mA, 18-V, Ultra-Low I_Q, Low-Dropout Voltage Regulator

1 Features
- Ultra-low I_Q: 2.0 µA
- Input voltage: 2.4 V to 18 V
- Output voltage options available:
  - Fixed: 1.25 V to 5.5 V
  - Adjustable: 1.24 V to 17.75 V
- 2% accuracy over temperature
- Low dropout: 250 mV (max) at 200 mA
- Active overshoot pulldown protection
- Thermal shutdown and overcurrent protection
- Operating junction temperature: −40°C to +125°C
- Stable with 1-µF output capacitors
- Package: 5-pin SOT-23

2 Applications
- Smoke and heat detectors
- Thermostats
- Motion detectors (PIR, uWave, and so forth)
- Cordless power tools
- Appliance battery packs
- Electricity meters
- Water meters

3 Description
The TPS7A24 low-dropout (LDO) linear voltage regulator supports a 2.4-V to 18-V input voltage range with ultra-low quiescent current (I_Q). These features help modern appliances meet increasingly stringent energy requirements and help extend battery life in portable-power solutions.

The TPS7A24 is available in both fixed and adjustable versions. The fixed-voltage version eliminates external resistors and minimizes printed circuit board (PCB) area. For more flexibility or higher output voltages, the adjustable version uses feedback resistors to set the output voltage from 1.24 V to 17.75 V. Both versions have 2% output regulation accuracy that provides precision regulation for microcontroller (MCU) references.

The TPS7A24 LDO operates more efficiently than standard linear regulators because the maximum dropout voltage is less than 250 mV at 200 mA of current. This maximum dropout voltage allows for 92.8% efficiency from a 3.55-V input voltage (V_IN) to a 3.3-V output voltage (V_OUT).

7 Detailed Description

7.1 Overview

The TPS7A24 is an 18-V, low quiescent current, low-dropout (LDO) linear regulator. The low $I_Q$ performance makes the TPS7A24 an excellent choice for battery-powered or line-power applications that are expected to meet increasingly stringent standby-power standards. The fixed-output versions have the advantage of providing better accuracy with fewer external components, whereas the adjustable version has the flexibility for a far wider output voltage range.

The 2% accuracy over temperature makes this device an excellent choice for meeting a wide range of microcontroller power requirements.

For increased reliability, the TPS7A24 also incorporates overcurrent, overshoot pulldown, and thermal shutdown protection. The operating junction temperature is $-40^\circ\text{C}$ to $+125^\circ\text{C}$, and adds margin for applications concerned with higher working ambient temperatures.

7.2 Functional Block Diagrams

![Figure 17. Adjustable Version Block Diagram](image)
7.3 Feature Description

7.3.1 Output Enable

The enable pin for the device is an active-high pin. The output voltage is enabled when the voltage of the enable pin is greater than the high-level input voltage of the EN pin and disabled with the enable pin voltage is less than the low-level input voltage of the EN pin. If independent control of the output voltage is not needed, connect the enable pin to the input of the device.

7.3.2 Dropout Voltage

Dropout voltage (\(V_{DO}\)) is defined as the input voltage minus the output voltage (\(V_{IN} - V_{OUT}\)) at the rated output current (\(I_{RATED}\)), where the pass transistor is fully on. \(I_{RATED}\) is the maximum \(I_{OUT}\) listed in the Recommended Operating Conditions table. The pass transistor is in the ohmic or triode region of operation, and acts as a switch. The dropout voltage indirectly specifies a minimum input voltage greater than the nominal programmed output voltage at which the output voltage is expected to stay in regulation. If the input voltage falls to less than the nominal output voltage, then the output voltage falls as well.

For a CMOS regulator, the dropout voltage is determined by the drain-source on-state resistance (\(R_{DS(ON)}\)) of the pass transistor. Therefore, if the linear regulator operates at less than the rated current, the dropout voltage for that current scales accordingly. Use Equation 1 to calculate the \(R_{DS(ON)}\) of the device.

\[
R_{DS(ON)} = \frac{V_{DO}}{I_{RATED}}
\]  

(1)

7.3.3 Current Limit

The device has an internal current limit circuit that protects the regulator during transient high-load current faults or shorting events. The current limit is a brickwall scheme. In a high-load current fault, the brickwall scheme limits the output current to the current limit (\(I_{CL}\)). \(I_{CL}\) is listed in the Electrical Characteristics table.

The output voltage is not regulated when the device is in current limit. When a current limit event occurs, the device begins to heat up because of the increase in power dissipation. When the device is in brickwall current limit, the pass transistor dissipates power \([(V_{IN} - V_{OUT}) \times I_{CL}]\). If thermal shutdown is triggered, the device turns off. After the device cools down, the internal thermal shutdown circuit turns the device back on. If the output current fault condition continues, the device cycles between current limit and thermal shutdown. For more information on current limits, see the Know Your Limits application report.
Feature Description (continued)

Figure 19 shows a diagram of the current limit.

![Figure 19. Current Limit](image)

7.3.4 Undervoltage Lockout (UVLO)

The device has an independent undervoltage lockout (UVLO) circuit that monitors the input voltage, allowing a controlled and consistent turn on and off of the output voltage. To prevent the device from turning off if the input drops during turn on, the UVLO has hysteresis as specified in the Electrical Characteristics table.

7.3.5 Thermal Shutdown

The device contains a thermal shutdown protection circuit to disable the device when the junction temperature ($T_J$) of the pass transistor rises to $T_{SD(shutdown)}(typical)$. Thermal shutdown hysteresis assures that the device resets (turns on) when the temperature falls to $T_{SD(reset)}(typical)$.

The thermal time-constant of the semiconductor die is fairly short, thus the device may cycle on and off when thermal shutdown is reached until power dissipation is reduced. Power dissipation during startup can be high from large $V_{IN} - V_{OUT}$ voltage drops across the device or from high inrush currents charging large output capacitors. Under some conditions, the thermal shutdown protection disables the device before startup completes.

When the thermal limit is triggered with load currents near the value of the current limit, the output may oscillate prior to the output switching off.

For reliable operation, limit the junction temperature to the maximum listed in the Recommended Operating Conditions table. Operation above this maximum temperature causes the device to exceed its operational specifications. Although the internal protection circuitry of the device is designed to protect against thermal overall conditions, this circuitry is not intended to replace proper heat sinking. Continuously running the device into thermal shutdown or above the maximum recommended junction temperature reduces long-term reliability.

7.3.6 Active Overshoot Pulldown Circuitry

This device has pulldown circuitry connected to $V_{OUT}$. This circuitry is a 100-μA current sink, in series with a 5.5-kΩ resistor, controlled by $V_{EN}$. When $V_{EN}$ is below $V_{EN(LOW)}$, the pulldown circuitry is disabled and the LDO output is in high-impedance mode.

If the output voltage is more than 2% above nominal voltage when $V_{EN} \geq V_{EN(LOW)}$, the pulldown circuitry turns on and the output is pulled down until the output voltage is within 2% from the nominal voltage. This feature helps reduce overshoot during the transient response.
7.4 Device Functional Modes

7.4.1 Device Functional Mode Comparison

The *Device Functional Mode Comparison* table shows the conditions that lead to the different modes of operation. See the *Electrical Characteristics* table for parameter values.

<table>
<thead>
<tr>
<th>OPERATING MODE</th>
<th>PARAMETER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal operation</td>
<td>( V_{IN} &gt; V_{OUT(nom)} + V_{DO} ) and ( V_{IN} &gt; V_{IN(min)} )</td>
</tr>
<tr>
<td>Dropout operation</td>
<td>( V_{IN(min)} &lt; V_{IN} &lt; V_{OUT(nom)} + V_{DO} )</td>
</tr>
<tr>
<td>Disabled (any true condition</td>
<td>( V_{IN} &lt; V_{UVLO} )</td>
</tr>
<tr>
<td>disables the device)</td>
<td></td>
</tr>
</tbody>
</table>

7.4.2 Normal Operation

The device regulates to the nominal output voltage when the following conditions are met:

- The input voltage is greater than the nominal output voltage plus the dropout voltage \( (V_{OUT(nom)} + V_{DO}) \)
- The output current is less than the current limit \( (I_{OUT} < I_{CL}) \)
- The device junction temperature is less than the thermal shutdown temperature \( (T_{J} < T_{SD}) \)
- The enable voltage has previously exceeded the enable rising threshold voltage and has not yet decreased to less than the enable falling threshold

7.4.3 Dropout Operation

If the input voltage is lower than the nominal output voltage plus the specified dropout voltage, but all other conditions are met for normal operation, the device operates in dropout mode. In this mode, the output voltage tracks the input voltage. During this mode, the transient performance of the device becomes significantly degraded because the pass transistor is in the ohmic or triode region, and acts as a switch. Line or load transients in dropout can result in large output-voltage deviations.

When the device is in a steady dropout state (defined as when the device is in dropout, \( V_{IN} < V_{OUT(NOM)} + V_{DO} \) directly after being in a normal regulation state, but *not* during startup), the pass transistor is driven into the ohmic or triode region. When the input voltage returns to a value greater than or equal to the nominal output voltage plus the dropout voltage \( (V_{OUT(NOM)} + V_{DO}) \), the output voltage can overshoot for a short period of time while the device pulls the pass transistor back into the linear region.

7.4.4 Disabled

The output of the device can be shutdown by forcing the voltage of the enable pin to less than the maximum EN pin low-level input voltage (see the *Electrical Characteristics* table). When disabled, the pass transistor is turned off and internal circuits are shutdown.
8 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

8.1.1 Adjustable Device Feedback Resistors
The adjustable-version device requires external feedback divider resistors to set the output voltage. $V_{OUT}$ is set using the feedback divider resistors, $R_1$ and $R_2$, according to the following equation:

$$V_{OUT} = V_{FB} \times (1 + \frac{R_1}{R_2})$$ (2)

To ignore the FB pin current error term in the $V_{OUT}$ equation, set the feedback divider current to 100x the FB pin current listed in the Electrical Characteristics table. This setting provides the maximum feedback divider series resistance, as shown in the following equation:

$$R_1 + R_2 \leq \frac{V_{OUT}}{(I_{FB} \times 100)}$$ (3)

8.1.2 Recommended Capacitor Types
The device is designed to be stable using low equivalent series resistance (ESR) capacitors at the input and output. Multilayer ceramic capacitors have become the industry standard for these types of applications and are recommended, but must be used with good judgment. Ceramic capacitors that employ X7R-, X5R-, and C0G-rated dielectric materials provide relatively good capacitive stability across temperature, whereas the use of Y5V-rated capacitors is discouraged because of large variations in capacitance.

Regardless of the ceramic capacitor type selected, the effective capacitance varies with operating voltage and temperature. As a rule of thumb, expect the effective capacitance to decrease by as much as 50%. The input and output capacitors recommended in the Recommended Operating Conditions table account for an effective capacitance of approximately 50% of the nominal value.

8.1.3 Input and Output Capacitor Requirements
Although an input capacitor is not required for stability, good analog design practice is to connect a capacitor from IN to GND. This capacitor counteracts reactive input sources and improves transient response, input ripple, and PSRR. An input capacitor is recommended if the source impedance is more than 0.5 Ω. A higher value capacitor may be necessary if large, fast load transient or line transients are anticipated or if the device is located several inches from the input power source.

Dynamic performance of the device is improved with the use of an output capacitor. Use an output capacitor within the range specified in the Recommended Operating Conditions table for stability.

The effective output capacitance value is recommended to not exceed 50 µF.

8.1.4 Reverse Current
Excessive reverse current can damage this device. Reverse current flows through the intrinsic body diode of the pass transistor instead of the normal conducting channel. At high magnitudes, this current flow degrades the long-term reliability of the device.

Conditions where reverse current can occur are outlined in this section, all of which can exceed the absolute maximum rating of $V_{OUT} \leq V_{IN} + 0.3$ V.

- If the device has a large $C_{OUT}$ and the input supply collapses with little or no load current
- The output is biased when the input supply is not established
- The output is biased above the input supply
Application Information (continued)

If reverse current flow is expected in the application, external protection is recommended to protect the device. Reverse current is not limited in the device, so external limiting is required if extended reverse voltage operation is anticipated.

Figure 20 shows one approach for protecting the device.

![Figure 20. Example Circuit for Reverse Current Protection Using a Schottky Diode](image)

Figure 21 shows another, more commonly used, approach in high input voltage applications.

![Figure 21. Reverse Current Prevention Using a Diode Before the LDO](image)

8.1.5 Feed-Forward Capacitor (C_{FF})

For the adjustable-voltage version device, a feed-forward capacitor (C_{FF}) can be connected from the OUT pin to the FB pin. C_{FF} improves transient, noise, and PSRR performance, but is not required for regulator stability. Recommended C_{FF} values are listed in the Recommended Operating Conditions table. A higher capacitance C_{FF} can be used; however, the startup time increases. For a detailed description of C_{FF} tradeoffs, see the Pros and Cons of Using a Feedforward Capacitor with a Low-Dropout Regulator application report.

8.1.6 Power Dissipation (P_{D})

Circuit reliability requires consideration of the device power dissipation, location of the circuit on the printed circuit board (PCB), and correct sizing of the thermal plane. The PCB area around the regulator must have few or no other heat-generating devices that cause added thermal stress.

To first-order approximation, power dissipation in the regulator depends on the input-to-output voltage difference and load conditions. Equation 4 calculates power dissipation (P_{D}).

\[ P_D = (V_{IN} - V_{OUT}) \times I_{OUT} \]  

\[ \text{(4)} \]

**NOTE**

Power dissipation can be minimized, and therefore greater efficiency can be achieved, by correct selection of the system voltage rails. For the lowest power dissipation use the minimum input voltage required for correct output regulation.
For devices with a thermal pad, the primary heat conduction path for the device package is through the thermal pad to the PCB. Solder the thermal pad to a copper pad area under the device. This pad area must contain an array of plated vias that conduct heat to additional copper planes for increased heat dissipation.

The maximum power dissipation determines the maximum allowable ambient temperature ($T_A$) for the device. According to Equation 5, power dissipation and junction temperature are most often related by the junction-to-ambient thermal resistance ($R_{th_{JA}}$) of the combined PCB and device package and the temperature of the ambient air ($T_A$).

$$T_J = T_A + (R_{th_{JA}} \times P_D)$$ (5)

Thermal resistance ($R_{th_{JA}}$) is highly dependent on the heat-spreading capability built into the particular PCB design, and therefore varies according to the total copper area, copper weight, and location of the planes. The junction-to-ambient thermal resistance listed in the Thermal Information table is determined by the JEDEC standard PCB and copper-spreading area, and is used as a relative measure of package thermal performance.

### 8.1.7 Estimating Junction Temperature

The JEDEC standard now recommends the use of psi (Ψ) thermal metrics to estimate the junction temperatures of the linear regulator when in-circuit on a typical PCB board application. These metrics are not thermal resistance parameters and instead offer a practical and relative way to estimate junction temperature. These psi metrics are determined to be significantly independent of the copper area available for heat-spreading. The Thermal Information table lists the primary thermal metrics, which are the junction-to-top characterization parameter ($\psi_{JT}$) and junction-to-board characterization parameter ($\psi_{JB}$). These parameters provide two methods for calculating the junction temperature ($T_J$). As described in the Junction-to-Top Characterization parameter ($\psi_{JT}$) with the temperature at the center-top of the device package ($T_T$) to calculate the junction temperature. As described in the Junction-to-Board Characterization parameter ($\psi_{JB}$) with the PCB surface temperature 1 mm from the device package ($T_B$) to calculate the junction temperature.

$$T_J = T_T + \psi_{JT} \times P_D$$

where:
- $P_D$ is the dissipated power
- $T_T$ is the temperature at the center-top of the device package

(6)

$$T_J = T_B + \psi_{JB} \times P_D$$

where
- $T_B$ is the PCB surface temperature measured 1 mm from the device package and centered on the package edge

(7)

For detailed information on the thermal metrics and how to use them, see the Semiconductor and IC Package Thermal Metrics application report.
Application Information (continued)

8.1.8 Special Consideration for Line Transients

During a line transient, the response of this LDO to a very large or fast input voltage change can cause a brief shutdown lasting up to a few hundred microseconds from the voltage transition. This shutdown can be avoided by reducing the voltage step size, increasing the transition time, or a combination of both. Figure 22 provides a boundary to follow to avoid this behavior. If necessary, reduce slew rate and the voltage step size to stay below the curve.

![Figure 22. Recommended Input Voltage Step and Slew Rate in a Line Transient](figure)

8.2 Typical Application

8.2.1 Design Requirements

Table 2 summarizes the design requirements for Figure 23.

<table>
<thead>
<tr>
<th>PARAMETER</th>
<th>DESIGN VALUES</th>
</tr>
</thead>
<tbody>
<tr>
<td>( V_{IN} )</td>
<td>5.3 V</td>
</tr>
<tr>
<td>( V_{OUT} )</td>
<td>3.3 V ±2%</td>
</tr>
<tr>
<td>( I_{IN} ) (no load)</td>
<td>&lt; 5 µA</td>
</tr>
<tr>
<td>( I_{OUT} ) (max)</td>
<td>200 mA</td>
</tr>
<tr>
<td>( T_{A} )</td>
<td>57.88°C (max)</td>
</tr>
</tbody>
</table>
8.2.2 Detailed Design Procedure

Select a 3.3-V output, fixed or adjustable device to generate the 3.3-V rail. The fixed-version LDO has internal feedback divider resistors, and thus has lower quiescent current. The adjustable-version LDO requires external feedback divider resistors, and is described in the Selecting Feedback Divider Resistors section.

8.2.2.1 Transient Response

As with any regulator, increasing the output capacitor value reduces over- and undershoot magnitude, but increases transient response duration.

8.2.2.2 Selecting Feedback Divider Resistors

For this design example, \( V_{OUT} \) is set to 5 V. The following equations set the output voltage:

\[
V_{OUT} = V_{FB} \times \left( 1 + \frac{R_1}{R_2} \right) \tag{8}
\]

\[
R_1 + R_2 \leq \frac{V_{OUT}}{I_{FB(TYP)} \times 100} \tag{9}
\]

For improved output accuracy, use Equation 9 and \( I_{FB(TYP)} = 10 \, \text{nA} \) as listed in the Electrical Characteristics table to calculate the upper limit for series feedback resistance, \( R_1 + R_2 \leq 5 \, \text{M} \Omega \).

The control-loop error amplifier drives the FB pin to the same voltage as the internal reference (\( V_{FB} = 1.24 \, \text{V} \) as listed in the Electrical Characteristics table). Use Equation 8 to determine the ratio of \( \frac{R_1}{R_2} = 1.66 \). Use this ratio and solve Equation 9 for \( R_2 \). Now calculate the upper limit for \( R_2 \leq 1.24 \, \text{M} \Omega \). Select a standard value resistor of \( R_2 = 1.18 \, \text{M} \Omega \).

Reference Equation 8 and solve for \( R_1 \):

\[
R_1 = \frac{V_{OUT}}{V_{FB} - 1} \times R_2 \tag{10}
\]

From Equation 10, \( R_1 = 1.96 \, \text{M} \Omega \) can be determined. From Equation 8, select \( V_{OUT} = 3.299 \, \text{V} \).

8.2.2.3 Thermal Dissipation

Junction temperature can be determined using the junction-to-ambient thermal resistance (\( R_{JUA} \)) and the total power dissipation (\( P_D \)). Use Equation 11 to calculate the power dissipation. Multiply \( P_D \) by \( R_{JUA} \) and add the ambient temperature \( T_A \), as Equation 12 shows, to calculate the junction temperature \( T_J \).

\[
P_D = (I_{GND} + I_{OUT}) \times (V_{IN} - V_{OUT}) \tag{11}
\]

\[
T_J = R_{JUA} \times P_D + T_A \tag{12}
\]

Equation 13 calculates the maximum ambient temperature. Equation 14 calculates the maximum ambient temperature for typical design applications.

\[
T_{A(MAX)} = T_{J(MAX)} - (R_{JUA} \times P_D) \tag{13}
\]

\[
T_{A(MAX)} = 125^{\circ}\text{C} - [167.8^{\circ}\text{C/W} \times (5.3 \, \text{V} - 3.3 \, \text{V}) \times 0.2A] = 57.88^{\circ}\text{C} \tag{14}
\]

8.2.3 Application Curve

![Figure 24. Line Transient (4.3 V to 5.3 V)](image-url)
9 Power Supply Recommendations

The device is designed to operate with an input supply range of 2.4 V to 18 V. If the input supply is noisy, additional input capacitors with low ESR can help improve output noise performance. Connect a low output impedance power supply to the input pin of the TPS7A24. In order to optimize regulation, refer to the Feature Description section for more information on operation modes and performance features.

10 Layout

10.1 Layout Guidelines

- Place input and output capacitors as close to the device pins as possible
- Use copper planes for device connections to optimize thermal performance
- Place thermal vias around the device to distribute heat

10.2 Layout Examples

![Adjustable Version Layout Example](image1)

**Figure 25. Adjustable Version Layout Example**

![Fixed Version Layout Example](image2)

(1) For the most current package and ordering information see the Package Option Addendum at the end of this document, or visit the device product folder at www.ti.com.

11.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. In the upper right corner, click on Alert me to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

11.3 Community Resources

TI E2E™ support forums are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

11.4 Trademarks

E2E is a trademark of Texas Instruments. All other trademarks are the property of their respective owners.

11.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

11.6 Glossary

SLYZ022 — TI Glossary.
This glossary lists and explains terms, acronyms, and definitions.

12 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE**: TI has discontinued the production of the device.

(2) **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substances do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
- **RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
- **Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.**: The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
