TPSM82864A/TPSM82866A 2.4-V to 5.5-V Input, 4-A/6-A Step-Down Power Module with an Integrated Inductor in a 3.5-mm × 4.0-mm Thin Overmolded QFN Package

1 Features
- Up to 96% efficiency
- Excellent thermal performance
- CISPR-11 class-B compliant
- 1% output voltage accuracy
- DCS-Control topology for fast transient response
- 1.4-mm or 1.8-mm ultra-low profile QFN package
- 2.4-V to 5.5-V input voltage range
- Same device part number provides either:
  - 0.6-V to V_IN adjustable output voltage
  - 13 integrated fixed output voltage options
- Power-good indicator with window comparator
- 2.4-MHz switching frequency
- Forced PWM or power save mode
- 4-µA operating quiescent current
- Output voltage discharge
- 100% duty cycle mode
- Hiccup short-circuit protection
- Thermal shutdown
- –40°C to 125°C operating temperature range
- 3.5-mm × 4.0-mm QFN package with 0.5-mm pitch
- 35-mm² solution size

2 Applications
- Core supply for FPGAs, CPUs, ASICs
- Optical modules
- Medical imaging
- Industrial transport
- Factory automation and control
- Aerospace and defense

3 Description
The TPSM8286xA device family consists of 4-A and 6-A step-down converter power modules optimized for small solution size and high efficiency. The power modules integrate a synchronous step-down converter and an inductor to simplify design, reduce external components, and save PCB area. The low-profile and compact solution is suitable for automated assembly by standard surface mount equipment.

Tight output voltage accuracy, even with small output capacitors, is achieved through the DCS-Control architecture and its excellent load transient performance. At medium-to-heavy loads, the converter operates in PWM mode and automatically enters Power save mode operation at light load to maintain high efficiency over the entire load current range. The devices can also be forced in PWM mode operation for the smallest output voltage ripple.

The EN and PG pins, which support sequencing configurations, bring a flexible system design. An integrated soft start reduces the inrush current required from the input supply. Overtemperature protection and hiccup short circuit protection deliver a robust and reliable solution.

8 Detailed Description

8.1 Overview

The TPSM8286xA synchronous step-down converter power module is based on DCS-Control (Direct Control with Seamless transition into power save mode). This is an advanced regulation topology that combines the advantages of hysteretic, voltage, and current mode control. The DCS-Control topology operates in PWM (pulse width modulation) mode for medium-to-heavy load conditions and in PSM (power save mode) at light load currents. In PWM, the converter operates with its nominal switching frequency of 2.4 MHz, having a controlled frequency variation over the input voltage range. As the load current decreases, the converter enters power save mode, reducing the switching frequency and minimizing the quiescent current of the IC to achieve high efficiency over the entire load current range. DCS-Control supports both operation modes using a single building block and, therefore, has a seamless transition from PWM to PSM without effects on the output voltage. The TPSM8286xA offers excellent DC voltage regulation and load transient regulation, combined with low output voltage ripple, minimizing interference with RF circuits.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Power Save Mode

As the load current decreases, the device seamlessly enters power save mode (PSM) operation. In PSM, the converter operates with a reduced switching frequency and a minimum quiescent current to maintain high efficiency. Power save mode is based on a fixed on-time architecture, as shown in Equation 1.

\[
\text{t}_{\text{ON}} = \frac{V_{\text{OUT}}}{V_{\text{IN}}} \times 416\text{ns}
\]  

(1)
The switching frequency in PSM is estimated as:

$$f_{\text{PSM}} = \frac{2 \times I_{\text{OUT}}}{t_{\text{ON}} \times V_{\text{IN}} / V_{\text{OUT}} \times \frac{V_{\text{IN}} - V_{\text{OUT}}}{220\text{nH}}}$$ (2)

The load current at which PSM is entered is at one half of the ripple current of the inductor and it can be estimated as:

$$I_{\text{Load(PSM-entry)}} = \frac{V_{\text{IN}} \times t_{\text{ON}}}{2} \times \frac{1 - V_{\text{OUT}}}{V_{\text{IN}}}$$ (3)

In power save mode, the output voltage rises slightly above the nominal output voltage. This effect is minimized by increasing the output capacitance.

8.3.2 Forced PWM Mode

After the device has powered up and ramped up VOUT, the VSET/MODE pin acts as a digital input. With a high level on the VSET/MODE pin, the device enters forced PWM (FPWM) mode and operates with a constant switching frequency over the entire load range, even at very light loads. This reduces the output voltage ripple and allows simple filtering of the switching frequency for noise-sensitive applications but lowers efficiency at light loads.

8.3.3 Optimized Transient Performance from PWM to PSM Operation

For most converters, the load transient response in PWM mode is improved compared to PSM, since the converter reacts faster on the load step and actively sinks energy on the load release. As an additional feature, the TPSM8286xA automatically stays in PWM mode for 128 cycles after a heavy load release in order to bring the output voltage back to the regulation level faster. After these 128 cycles of PWM mode, it automatically returns to PSM (if VSET/MODE is low). See Figure 8-1. Without this optimization, the output voltage overshoot would be higher.

![Figure 8-1](http://www.ti.com)

**Figure 8-1. Optimized Transient Performance from PWM to PSM**
8.3.4 Low Dropout Operation (100% Duty Cycle)

The device offers a low dropout operation by entering 100% duty cycle mode if the input voltage comes close to the target output voltage. In this mode, the high-side MOSFET switch is constantly turned on. This is particularly useful in battery-powered applications to achieve the longest operation time by taking full advantage of the whole battery voltage range. The minimum input voltage to maintain a minimum output voltage is given by:

\[ V_{\text{IN}}(\text{min}) = V_{\text{OUT}}(\text{min}) + I_{\text{OUT}}(\text{max}) \times R_{\text{DP}} \]  

where

- \( V_{\text{OUT}}(\text{min}) \) = Minimum output voltage the load can accept
- \( I_{\text{OUT}}(\text{max}) \) = Maximum output current
- \( R_{\text{DP}} \) = Resistance from VIN to VOUT (high-side \( R_{\text{DS(on)}} + R_{\text{DC}} \) of the inductor)

8.3.5 Soft Start

After enabling the device, there is a 650-µs enable delay (\( t_{\text{Delay}} \)) before the device starts switching. The \( t_{\text{Delay}} \) time varies with the VSET/MODE resistor used and is longest with a resistance of 249 k or higher. After the enable delay, an internal soft-start circuit ramps up the output voltage in 1 ms (\( t_{\text{Ramp}} \)). This avoids excessive inrush current and creates a smooth output voltage ramp up. It also prevents excessive voltage drops of batteries that have a high internal impedance. Figure 8-2 shows the start-up sequence.

![Figure 8-2. Start-Up Sequence](image)

The device is able to start into a pre-biased output capacitor. It starts with the applied bias voltage and ramps the output voltage to its nominal value.

8.3.6 Switch Current Limit and HICCUP Short-Circuit Protection

The switch current limit prevents the device from high inductor current and from drawing excessive current from the battery or input voltage rail. Excessive current can occur with a heavy load or shorted output circuit condition. If the inductor current reaches the threshold \( I_{\text{LIM}} \), cycle by cycle, the high-side MOSFET is turned off and the low-side MOSFET is turned on until the inductor current ramps down to the low-side MOSFET current limit.

When the high-side MOSFET current limit is triggered 256 times, the device stops switching. The device then automatically re-starts with soft start after a typical delay time of 16 ms has passed. The device repeats this mode until the high load condition disappears. This HICCUP short-circuit protection reduces the current consumed from the input supply because the device only draws input current approximately 10% of the time during an overload condition. Figure 9-23 shows the hiccup short circuit protection.

The low-side MOSFET also contains a negative current limit to prevent excessive current from flowing back through the inductor to the input. If the low-side sinking current limit is exceeded, the low-side MOSFET is turned off. In this scenario, both MOSFETs are off until the start of the next cycle. The negative current limit is only active in forced PWM mode.
8.3.7 Undervoltage Lockout

To avoid mis-operation of the device at low input voltages, undervoltage lockout (UVLO) disables the device when the input voltage is lower than $V_{UVLO}$. When the input voltage recovers, the device automatically returns to operation with soft start.

8.3.8 Thermal Shutdown

When the junction temperature exceeds $T_{JSD}$, the device goes into thermal shutdown, stops switching, and activates the output voltage discharge. When the device temperature falls below the threshold by the hysteresis, the device returns to normal operation automatically with soft start.
8.4 Device Functional Modes

8.4.1 Enable and Disable (EN)

The device is enabled by setting the EN pin to a logic high. Accordingly, shutdown mode is forced if the EN pin is pulled low. In shutdown mode, the internal power switches as well as the entire control circuitry are turned off. An internal switch smoothly discharges the output through the VOS pin in shutdown mode. Do not leave the EN pin floating.

The typical enable threshold value of the EN pin is 0.66 V for rising input signals and the typical shutdown threshold is 0.52 V for falling input signals.

8.4.2 Output Discharge

The purpose of the output discharge function is to ensure a defined down-ramp of the output voltage when the device is disabled and to keep the output voltage close to 0 V. The output discharge is active when the EN pin is set to a logic low and during thermal shutdown. The discharge is active down to an input voltage of 1.6 V (typical).

8.4.3 Power Good (PG)

The device has an open-drain power-good pin, which is specified to sink up to 2 mA. The power-good output requires a pullup resistor connected to any voltage rail less than 5.5 V. The PG signal can be used for sequencing of multiple rails by connecting it to the EN pin of other converters. Leave the PG pin unconnected when not used. Table 8-1 shows the typical PG pin logic.

8.4.4 Output Voltage and Mode Selection (VSET/MODE)

The TPSM8286xA family devices are configurable as either an adjustable output voltage or a fixed output voltage, depending on the needs of each individual application. This feature simplifies the logistics during mass production, as one part number offers several fixed output voltage options as well as an adjustable output voltage option. During the enable delay (t_{Delay}), the device configuration is set by an external resistor connected to the VSET/MODE pin through an internal R2D (resistor to digital) converter. This configures the V_{REF} input to the error amplifier (EA) to be either the V_{FB} voltage (0.6-V typical) or the selected output voltage. Table 8-2 shows the options.

The R2D converter has an internal current source, which applies current through the external resistor, and an internal ADC, which reads back the resulting voltage level. Depending on the detected resistance, the output voltage is set. Once this R2D conversion is finished, the current source is turned off to avoid current flowing through the external resistor. Make sure that the additional leakage current path is less than 20 nA and the capacitance is not greater than 30 pF from this pin to GND during R2D conversion, otherwise a false V_{OUT} value is set. For more details, refer to the Benefits of a Resistor-to-Digital Converter in Ultra-Low Power Supplies White Paper. When the device is set to a fixed output voltage, the FB pin must be connected to the output directly. See Figure 8-4.

**Figure 8-4. Fixed Output Voltage Application Circuit**

After the start-up period (t_{Start-up}), a different operation mode can be selected. When VSET/MODE is set to high, the device is in forced PWM mode. Otherwise, the device is in power save mode.
9 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

9.1 Application Information

The TPSM8286xA is a synchronous step-down converter power module family. The following section discusses the selection of the external components to complete the power supply design. The required power inductor is integrated inside the TPSM8286xA. The integrated shielded inductor has a value of 0.22 µH with a ±20% tolerance. The TPSM82864A and TPSM82866A are pin-to-pin and BOM-to-BOM compatible. Both devices give the same efficiency and performance and are different only in their rated output current.

9.2.2 Detailed Design Procedure

9.2.2.1 Setting The Output Voltage

With the VSET/MODE pin set high or low, an adjustable output voltage is set by an external resistor divider according to Equation 5:

\[
R1 = R2 \left( \frac{V_{OUT}}{V_{FB}} - 1 \right) = R2 \left( \frac{V_{OUT}}{0.6V} - 1 \right)
\]

(5)

To keep the feedback (FB) net robust from noise, set R2 equal to or lower than 100 kΩ to have at least 6 µA of current in the voltage divider. Lower values of FB resistors achieve better noise immunity but lower light-load efficiency, as explained in the Design Considerations for a Resistive Feedback Divider in a DC/DC Converter Technical Brief.

When a fixed output voltage is selected, connect the FB pin directly to the output. R1 and R2 are not needed, as \( V_{OUT} \) is set through a resistor on the VSET/MODE pin. Select the recommended resistor value from the list in Table 8-2.

9.2.2.2 Input and Output Capacitor Selection

For the best output and input voltage filtering, low-ESR ceramic capacitors are required. The input capacitor minimizes input voltage ripple, suppresses input voltage spikes, and provides a stable system rail for the device. The input capacitor must be placed between VIN and PGND as close as possible to those pins. For most applications, 22 µF is sufficient, though a larger value reduces input current ripple. The input capacitor plays an important role in the EMI performance of the system as explained in the Simplify Low EMI Design With Power Modules White Paper.

The architecture of the device allows the use of tiny ceramic output capacitors with low equivalent series resistance (ESR). These capacitors provide low output voltage ripple and are recommended. The capacitor value can range from 2 × 22 µF up to 150 µF. The recommended typical output capacitors are 2 × 22-µF or 1 × 47-µF with an X5R or better dielectric. Values over 150 µF can degrade the loop stability of the converter.

Ceramic capacitors have a DC-Bias effect, which has a strong influence on the final effective capacitance. Choose the right capacitor carefully in combination with considering its package size and voltage rating. Make sure that the effective input capacitance is at least 10 µF and the effective output capacitance is at least 22 µF.

10 Power Supply Recommendations

The device is designed to operate from an input voltage supply range from 2.4 V to 5.5 V. The average input current of the TPSM8286xA is calculated as:

\[
I_{IN} = \frac{1}{\eta} \times \frac{V_{OUT} \times I_{OUT}}{V_{IN}} \tag{6}
\]

Make sure that the input power supply has a sufficient current rating for the application. The power supply must avoid a fast ramp down. The falling ramp speed must be slower than 10 mV/μs if the input voltage drops below \(V_{UVLO}\).
11 Layout

11.1 Layout Guidelines

A proper layout is critical for the operation of any switched mode power supply, especially at high switching frequencies. Therefore, the PCB layout of the TPSM8286xA demands careful attention to ensure best performance. A poor layout can lead to issues like the following:

- Bad line and load regulation
- Instability
- Increased EMI radiation
- Noise sensitivity

Refer to the *Five Steps to a Great PCB Layout for a Step-Down Converter Technical Brief* for a detailed discussion of general best practices. The following are specific recommendations for the TPSM8286xA:

- Place the input capacitor as close as possible to the VIN and PGND pins of the device. This is the most critical component placement. Route the input capacitor directly to the VIN and PGND pins avoiding vias.
- Place the output capacitor close to the VOUT and PGND pins and route it directly avoiding vias.
- Place the FB resistors R1 and R2 close to the FB and AGND pins and place R4 close to the VSET/MODE pin to minimize noise pickup.
- The sense traces connected to the VOS pin is a signal trace. Take special care to avoid noise being induced. Keep the trace away from SW.
- To improve thermal performance, use GND vias under the exposed thermal pad. Directly connect the AGND and PGND pins to the exposed thermal pad with copper on the top PCB layer.
- Refer to Figure 11-1 for an example of component placement, routing, and thermal design.
- The recommended land pattern for the TPSM8286xA is shown at the end of this data sheet. For best manufacturing results, it is important to create the pads as solder mask defined (SMD) when some pins (such as VIN, VOUT, and PGND) are connected to large copper planes. Using SMD pads keeps each pad the same size and avoids solder pulling the device during reflow.

11.2 Layout Example

![Figure 11-1. Layout Example](image-url)
11.2.1 Thermal Considerations

The TPSM8286xA power module temperature must be kept less than the maximum rating of 125°C. The following are three basic approaches for enhancing thermal performance:

- Improve the power dissipation capability of the PCB design.
- Improve the thermal coupling of the component to the PCB.
- Introduce airflow into the system.

To estimate the approximate module temperature of the TPSM8286xA, apply the typical efficiency stated in this data sheet to the desired application condition to compute the power dissipation of the module. Then, calculate the module temperature rise by multiplying the power dissipation by its thermal resistance. Using this method to compute the maximum device temperature, the Safe Operating Area (SOA) graphs demonstrate the required derating in maximum output current at high ambient temperatures. For more details on how to use the thermal parameters in real applications, see the *Thermal Characteristics of Linear and Logic Packages Using JEDEC PCB Designs Application Report* and *Semiconductor and IC Package Thermal Metrics Application Report.*

12.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

1. The marketing status values are defined as follows:
   - **ACTIVE**: Product device recommended for new designs.
   - **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
   - **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
   - **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
   - **OBSOLETE**: TI has discontinued the production of the device.

2. **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
   - **RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
   - **Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

3. **MSL, Peak Temp.** - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

4. There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

5. Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

6. **Lead finish/Ball material** - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
