TPS20xxB Current-Limited, Power-Distribution Switches

1 Features

- High-side MOSFET: 70mΩ
- 500mA continuous current
- Thermal and short-circuit protection
- Accurate current limit (0.75A minimum, 1.25A maximum)
- Operating range: 2.7V to 5.5V
- Typical rise time: 0.6ms
- Undervoltage lockout
- Deglitched fault report ($\overline{OC}$)
- No $\overline{OC}$ glitch during power up
- Maximum standby supply current: 1µA (single, dual) or 2µA (triple, quad)
- Ambient temperature range: –40°C to 85°C
- Safety-Related Certifications
  - UL Listed
    - File No. E169910
    - Complies with UL2367
    - IEC62368-1 CB Certified
  - MET Listed
    - File No. E115731
    - Complies with UL2367
    - IEC62368-1 CB Certified
- Additional UL recognition for TPS2042B and TPS2052B for ganged configuration

2 Applications

- Heavy capacitive loads
- Short-circuit protections

3 Description

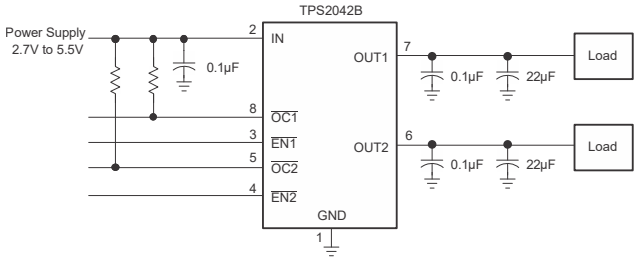

The TPS20xxB power-distribution switches are intended for applications which encounter heavy capacitive loads and short circuits. These devices incorporates 70mΩ N-channel MOSFET power switches for power-distribution systems that require multiple power switches in one package. A logic enable input controls each switch. Gate drive is provided by an internal charge pump designed to control the power-switch rise times and fall times to minimize current surges during switching. The charge pump requires no external components and allows operation from supplies as low as 2.7V.

When the output load exceeds the current-limit threshold or a short is present, the device limits the output current to a safe level by switching into a constant-current mode, pulling the overcurrent ($\overline{OCx}$) logic output low. When continuous heavy overloads and short circuits increase the power dissipation in the switch, causing the junction temperature to rise, a thermal protection circuit shuts off the switch to prevent damage. Recovery from a thermal shutdown is automatic once the device has cooled sufficiently. Internal circuitry establishes that the switch remains off until valid input voltage is present. This power-distribution switch is designed to set current limit at 1A (typical).

Package Information

PART NUMBER	PACKAGE(1)	PACKAGE SIZE(2)
TPS20xxB	D (SOIC, 8)	4.90mm × 3.91mm
	D (SOIC, 16)	9.90mm × 3.91mm
	DBV (SOT-23, 5)	2.90mm × 1.60mm
	DGN (HVSSOP, 8)	3.00mm × 3.00mm
	DRB (SON, 8)	3.00mm × 3.00mm

(1) For all available packages, see the orderable addendum at the end of the datasheet.
(2) The package size (length × width) is a nominal value and includes pins, where applicable.

T_{stg}	Storage temperature	–65	150	°C

(1) Operation outside the *Absolute Maximum Ratings* may cause permanent device damage. *Absolute Maximum Ratings* do not imply functional operation of the device at these or any other conditions beyond those listed under *Recommended Operating Conditions*. If used outside the *Recommended Operating Conditions* but within the *Absolute Maximum Ratings*, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.
(2) All voltages are with respect to GND.

6.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins (1)	±2000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins (2)	±500	

(1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

(1) Pulse-testing techniques maintain junction temperature close to ambient temperature; thermal effects must be taken into account separately.
(2) TPS20x1B and TPS20x2B devices in the D, DGN, and DBV packages do not have overcurrent trip thresholds. Current is limited to I_{OS} under different test condition. Check Section 8.3.7 for more details.
(3) The thermal shutdown only reacts under overcurrent conditions.

8 Detailed Description

8.1 Overview

The TPS20xxB are current-limited, power-distribution switches providing 0.5A continuous load current. These devices incorporates 70mΩ N-channel MOSFET power switches for power-distribution systems that require multiple power switches in one package. Gate driver is provided by an internal charge pump designed to minimize current surges during switching. The charge pump requires no external components and allows operation supplies as low as 2.7V.

8.3 Feature Description

8.3.1 Power Switch

The power switch is an N-channel MOSFET with a low on-state resistance. Configured as a high-side switch, the power switch prevents current flow from OUT to IN and IN to OUT when disabled. The power switch supplies a minimum current of 500mA.

8.3.2 Charge Pump

An internal charge pump supplies power to the driver circuit and provides the necessary voltage to pull the gate of the MOSFET above the source. The charge pump operates from input voltages as low as 2.7V and requires little supply current.

8.3.3 Driver

The driver controls the gate voltage of the power switch. To limit large current surges and reduce the associated electromagnetic interference (EMI) produced, the driver incorporates circuitry that controls the rise times and fall times of the output voltage.

8.3.4 Enable ($\overline{ENx}$)

The logic enable pin disables the power switch and the bias for the charge pump, driver, and other circuitry to reduce the supply current. The supply current reduces to less than 1µA or 2µA when a logic high is present on $\overline{EN}$. A logic zero input on $\overline{EN}$ restores bias to the drive and control circuits and turns the switch on. The enable input is compatible with both TTL and CMOS logic levels.

8.3.5 Enable (ENx)

The logic enable disables the power switch and the bias for the charge pump, driver, and other circuitry to reduce the supply current. The supply current is reduced to less than 1µA or 2µA when a logic low is present on ENx. A logic high input on ENx restores bias to the drive and control circuits and turns the switch on. The enable input is compatible with both TTL and CMOS logic levels.

8.3.6 Current Sense

A sense FET monitors the current supplied to the load. The sense FET measures current more efficiently than conventional resistance methods. When an overload or short circuit is encountered, the current-sense circuitry sends a control signal to the driver. The driver in turn reduces the gate voltage and drives the power FET into its saturation region, which switches the output into a constant-current mode and holds the current constant while varying the voltage on the load.

8.3.7 Overcurrent

A sense FET is employed to check for overcurrent conditions. Unlike current-sense resistors, sense FETs do not increase the series resistance of the current path. When an overcurrent condition is detected, the device maintains a constant output current and reduces the output voltage accordingly. Complete shutdown occurs only if the fault is present long enough to activate thermal limiting.

There are two kinds of current limit profiles for the TPS20xxB family of devices.

The TPS20x3BD, TPS20x4BD, and TPS20x2BDRB devices have an output I vs V characteristic similar to the plot labeled **Current Limit with Peaking** in Figure 8-5. This type of limiting can be characterized by two parameters, the overcurrent trip threshold (I_{OC}), and the short-circuit output current threshold (I_{OS}).

The TPS20x1B and TPS20x2B devices in the D, DGN, and DBV packages have an output I vs V characteristic similar to the plot labeled **Flat Current Limit** in Figure 8-5. This type of limiting is characterized by one parameter, the short-circuit current (I_{OS}).

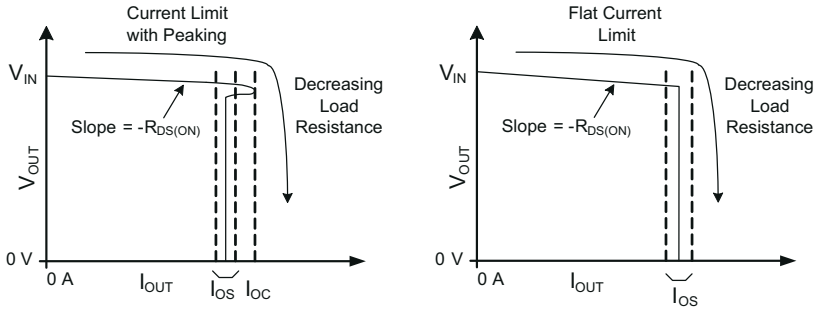

Figure 8-5. Current Limit Profiles

8.3.7.1 Overcurrent Conditions (TPS20x3BD, TPS20x4BD, and TPS20x2BDRB)

Three possible overload conditions can occur for TPS20x3BD, TPS20x4BD, and TPS20x2BDRB devices. In the first condition, the output shortens before the device is enabled or before $V_{I(IN)}$ is applied (see Figure 6-21 through Figure 6-24). The TPS20xxB senses the short and immediately switches into a constant-current output.

In the second condition, a short or an overload occurs while the device is enabled. At the instant the overload occurs, high currents can flow for a short period of time before the current-limit circuit can react. After the current-limit circuit has tripped (reached the overcurrent trip threshold (I_{OC})), the device switches into constant-current mode and current is limited at the short-circuit output current threshold (I_{OS}).

In the third condition, the load gradually increases beyond the recommended operating current. The current is permitted to rise until reaching the overcurrent trip threshold (I_{OC}) or until exceeding the thermal limit of the device. The TPS20x3BD, TPS20x4BD, and TPS20x2BDRB are capable of delivering current up to the current-limit threshold without damaging the device. Once the overcurrent trip threshold (I_{OC}) is reached, the device switches into its constant-current mode current is limited at the short-circuit output current threshold (I_{OS}).

8.3.7.2 Overcurrent Conditions (TPS20x1B and TPS20x2B in D, DGN, and DBV Packages)

Three possible overload conditions can occur for the TPS20x1B and TPS20x2B devices in the D, DGN, and DBV packages. In the first condition, the output shortens before the device is enabled or before $V_{I(IN)}$ is applied (see Figure 6-42 through Figure 6-45). The TPS20xxB senses the short and immediately switches into a constant-current output.

In the second condition, a short or an overload occurs while the device is enabled. At the instant the overload occurs, high currents can flow for a short period of time before the current-limit circuit can react. After the short-circuit output current threshold (I_{OS}) is reached, the device switches into constant-current mode.

In the third condition, the load gradually increases beyond the recommended operating current. After the short-circuit output current threshold (I_{OS}) is reached, the device switches into constant-current mode.

8.3.8 Overcurrent ($\overline{OCx}$)

The $\overline{OCx}$ open drain output is asserted (active low) when encountering an overcurrent or overtemperature condition. The output remains asserted until the removal of the overcurrent or overtemperature condition. A 10ms deglitch circuit prevents the $\overline{OCx}$ signal from oscillation or false triggering. If an overtemperature shutdown occurs, the $\overline{OCx}$ asserts instantaneously.

8.3.9 Thermal Sense

The TPS20xxB implements a thermal sensing to monitor the operating temperature of the power distribution switch. In an overcurrent or short-circuit condition, the junction temperature rises. When the die temperature rises to approximately 140°C due to overcurrent conditions, the internal thermal sense circuitry turns off the switch, thus preventing the device from damage. Hysteresis is built into the thermal sense, and after the device has cooled approximately 10 degrees, the switch turns back on. The switch continues to cycle off and on until the fault is removed. The open-drain false reporting output ($\overline{OCx}$) is asserted (active low) when an overtemperature shutdown or overcurrent occurs.

8.3.10 Undervoltage Lockout

A voltage sense circuit monitors the input voltage. When the input voltage is below approximately 2V, a control signal turns off the power switch.

8.4 Device Functional Modes

There are no other functional modes for TPS20xxB devices.

9 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

9.1 Application Information

9.1.1 Universal Serial Bus (USB) Applications

The universal serial bus (USB) interface is a 12Mb/s, or 1.5Mb/s, multiplexed serial bus designed for low-to-medium bandwidth PC peripherals (for example, keyboards, printers, scanners, and mice). The four-wire USB interface is conceived for dynamic attach-detach (hot plug-unplug) of peripherals. Two lines are provided for differential data, and two lines are provided for 5V power distribution.

USB data is a 3.3V level signal, but power is distributed at 5V to allow for voltage drops in cases where power is distributed through more than one hub across long cables. Each function must provide its own regulated 3.3V from the 5V input or its own internal power supply.

The USB specification defines the following five classes of devices, each differentiated by power-consumption requirements:

- Hosts and self-powered hubs (SPH)
- Bus-powered hubs (BPH)
- Low-power, bus-powered functions
- High-power, bus-powered functions
- Self-powered functions

Self-powered and bus-powered hubs distribute data and power to downstream functions. The TPS20xxB can provide power-distribution solutions to many of these classes of devices.

9.2.1.1 Design Requirements

Table 9-1. Design Parameters

DESIGN PARAMETER	VALUE
Input voltage	5V
Output1 voltage	5V
Output2 voltage	5V
Output1 current	0.5A
Output2 current	0.5A

9.2.1.2 Detailed Design Procedure

9.2.1.2.1 Power-Supply Considerations

TI recommends placing ceramic bypass capacitor from 0.01µF to 0.1µF between IN and GND, close to the device. When the output load is heavy, TI recommends placing a high-value electrolytic capacitor on the necessary output pins. This precaution reduces power-supply transients that can cause ringing on the input. Additionally, bypassing the output with a from 0.01µF to 0.1µF ceramic capacitor improves the immunity of the device to short-circuit transients.

9.2.1.2.2 $\overline{OC}$ Response

The $\overline{OCx}$ open-drain output is asserted (active low) when an overcurrent or overtemperature shutdown condition is encountered after a 10ms deglitch timeout. The output remains asserted until the overcurrent or overtemperature condition is removed. Connecting a heavy capacitive load to an enabled device can cause a momentary overcurrent condition; however, no false reporting on $\overline{OCx}$ occurs due to the 10ms deglitch circuit. The TPS20xxB is designed to eliminate false overcurrent reporting. The internal overcurrent deglitch eliminates the need for external components to remove unwanted pulses. $\overline{OCx}$ is not deglitched when the switch is turned off due to an overtemperature shutdown.

9.2.2 Host and Self-Powered and Bus-Powered Hubs

Hosts and self-powered hubs have a local power supply that powers the embedded functions and the downstream ports (see Figure 9-11 and Figure 9-12). This power supply must provide from 5.25V to 4.75V to the board side of the downstream connection under full-load and no-load conditions. Hosts and SPHs are required to have current-limit protection and must report overcurrent conditions to the USB controller. Typical SPHs are desktop PCs, monitors, printers, and stand-alone hubs.

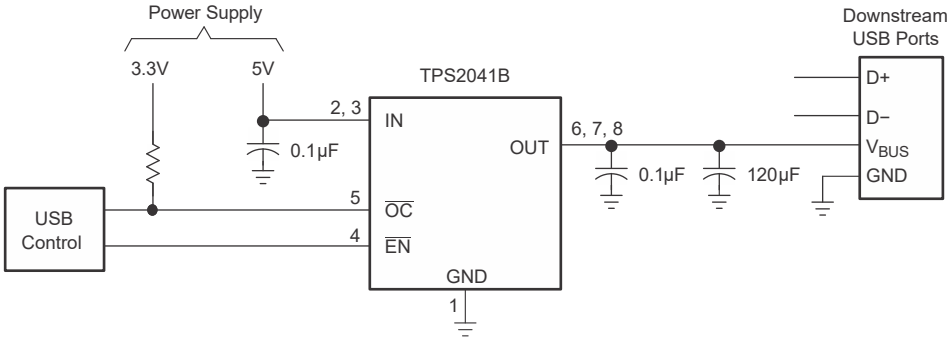

Figure 9-11. Typical One-Port USB Host and Self-Powered Hub

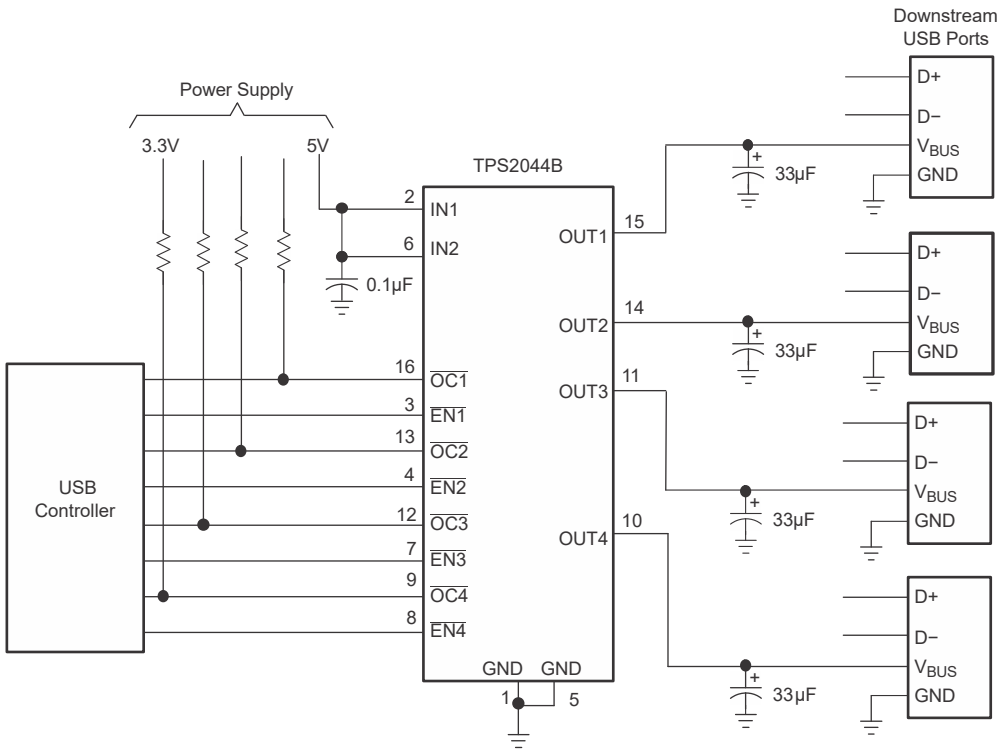

Figure 9-12. Typical Four-Port USB Host and Self-Powered Hub

9.2.2.1 Design Requirements

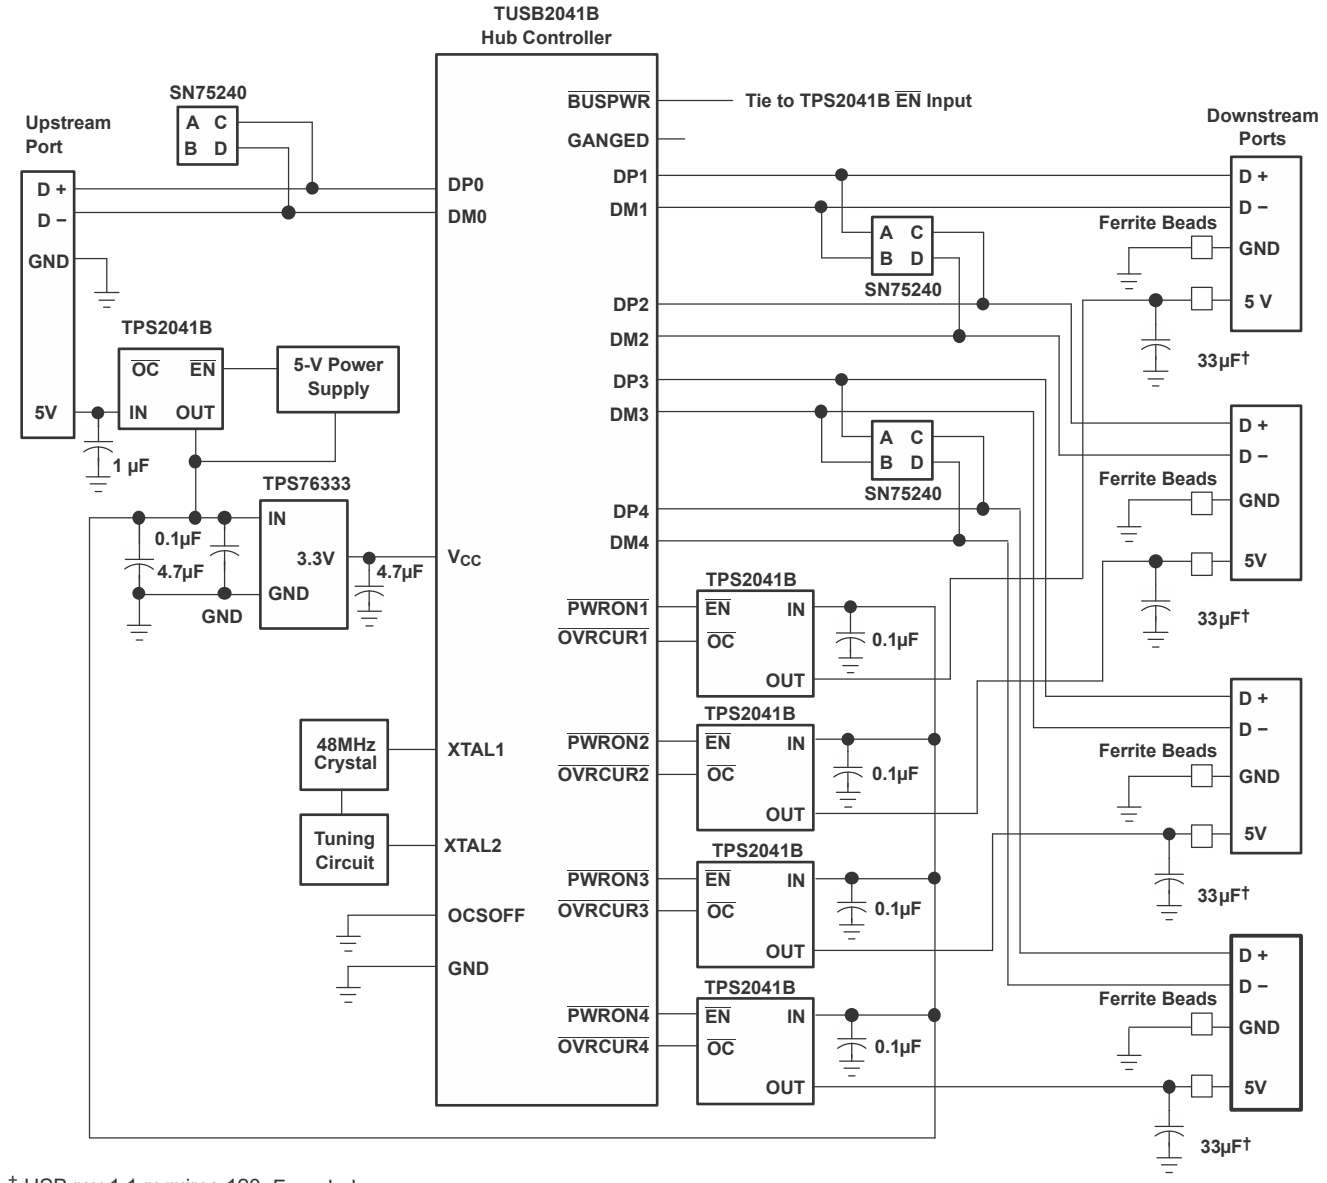

9.2.2.1.1 USB Power-Distribution Requirements

USB can be implemented in several ways, and, regardless of the type of USB device being developed, implement several power-distribution features.

- Hosts and self-powered hubs must:
  - Current-limit downstream ports
  - Report overcurrent conditions on USB V_{BUS}
- Bus-powered hubs must:
  - Enable/disable power to downstream ports
  - Power up at <100mA
  - Limit inrush current (<44Ω and 10µF)
- Functions must:
  - Limit inrush currents
  - Power up at <100mA

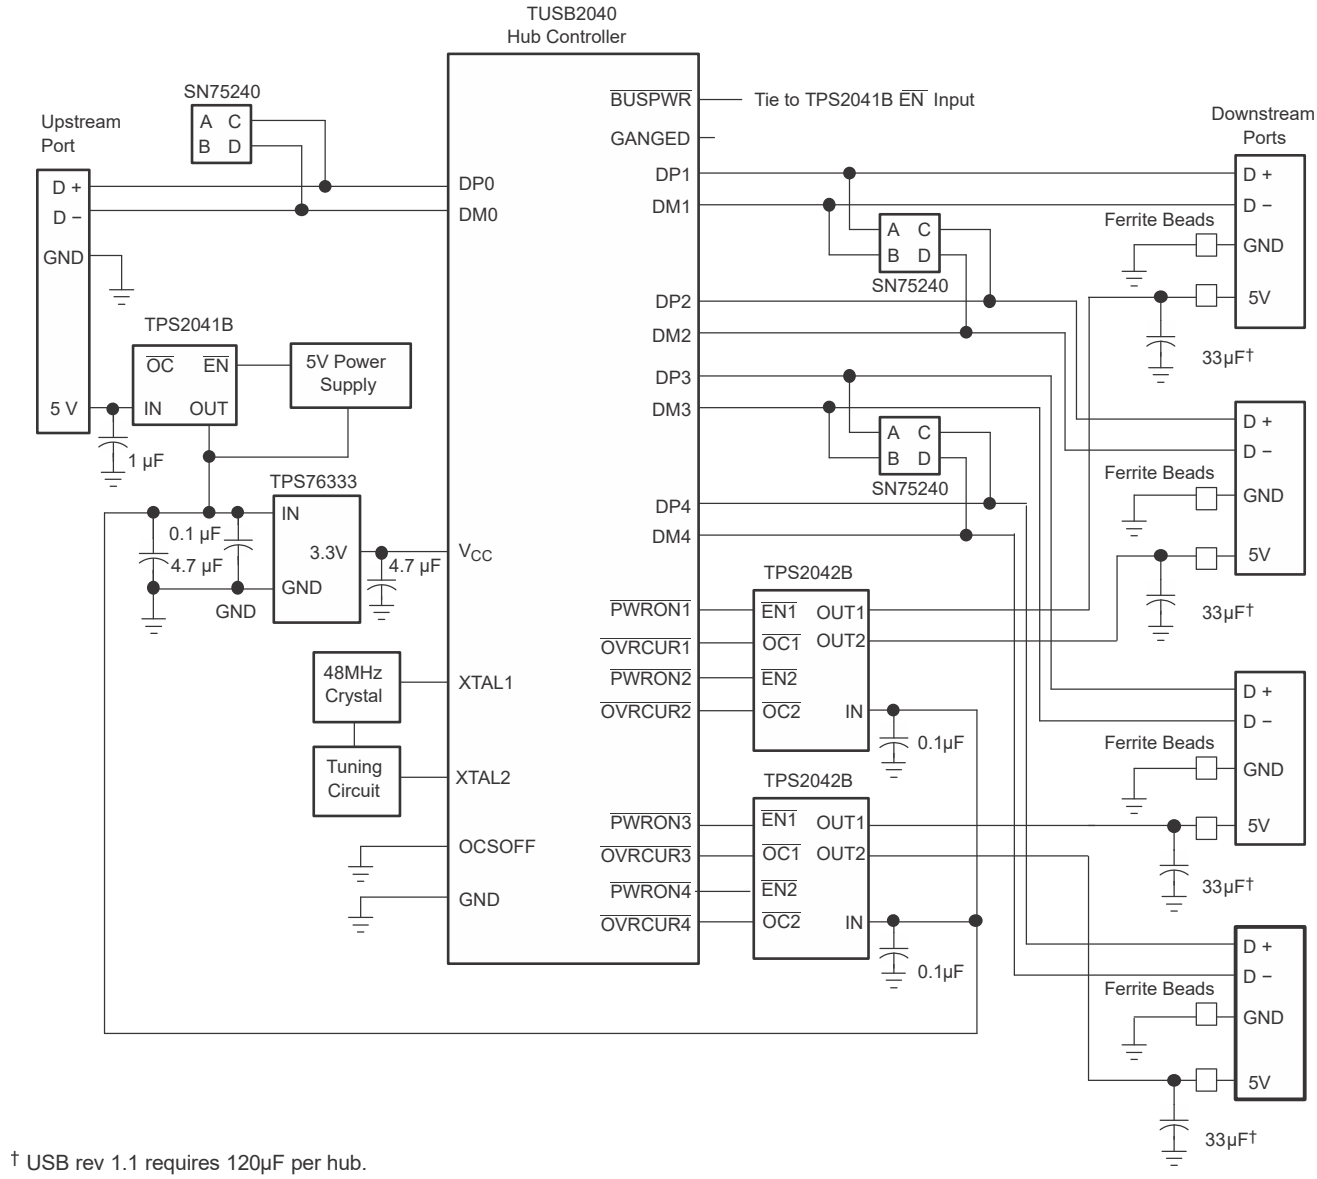

The feature set of the TPS20xxB allows TPS20xxB to meet each of these requirements. The integrated current-limiting and overcurrent reporting is required by hosts and self-powered hubs. The logic-level enable and controlled rise times meet the need of both input and output ports on bus-powered hubs, as well as the input ports for bus-powered functions (see Figure 9-13 through Figure 9-16).

9.2.2.2 Detailed Design Procedure

Bus-powered hubs obtain all power from upstream ports and often contain an embedded function. The hubs are required to power up with less than one unit load. The BPH usually has one embedded function, and power is always available to the controller of the hub. If the embedded function and hub require more than 100mA on power up, the power to the embedded function may need to be kept off until enumeration is completed. This can be accomplished by removing power or by shutting off the clock to the embedded function. Power switching the embedded function is not necessary if the aggregate power draw for the function and controller is less than one unit load. The total current drawn by the bus-powered device is the sum of the current to the controller, the embedded function, and the downstream ports, and it is limited to 500mA from an upstream port.

9.2.2.2.1 Low-Power Bus-Powered and High-Power Bus-Powered Functions

Both low-power and high-power bus-powered functions obtain all power from upstream ports; low-power functions always draw less than 100mA; high-power functions must draw less than 100mA at power up and

Copyright © 2026 Texas Instruments Incorporated

can draw up to 500mA after enumeration. If the load of the function is more than the parallel combination of 44 Ω and 10µF at power up, the device must implement inrush current limiting (see Figure 9-17).

9.2.3 Generic Hot-Plug Applications

In many applications it can be necessary to remove modules or PC boards while the main unit is still operating. These are considered hot-plug applications. Such implementations require the control of current surges seen by the main power supply and the card being inserted. The most effective way to control these surges is to limit and slowly ramp the current and voltage being applied to the card, similar to the way in which a power supply normally turns on. Due to the controlled rise times and fall times of the TPS20xxB, these devices can be used to provide a softer start-up to devices being hot-plugged into a powered system. The UVLO feature of the TPS20xxB also ensures that the switch is off after the card has been removed, and that the switch is off during the next insertion. The UVLO feature insures a soft start with a controlled rise time for every insertion of the card or module.

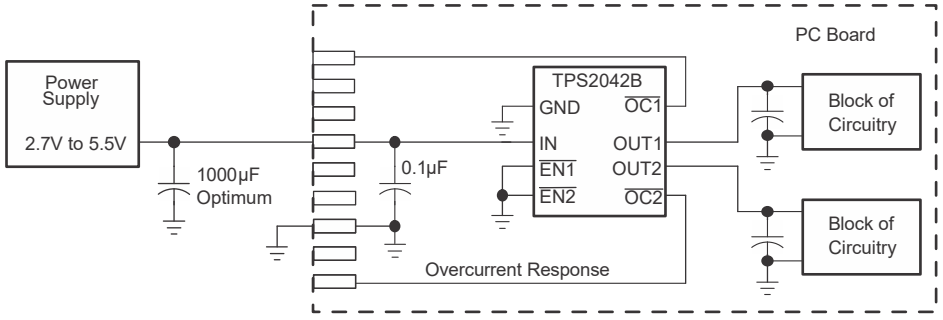

Figure 9-26. Typical Hot-Plug Implementation (Example, TPS2042B)

Copyright © 2026 Texas Instruments Incorporated

By placing the TPS20xxB between the V_{CC} input and the rest of the circuitry, the input power reaches these devices first after insertion. The typical rise time of the switch is approximately 1ms, providing a slow voltage ramp at the output of the device. This implementation controls system surge currents and provides a hot-plugging mechanism for any device.

9.2.3.1 Design Requirements

Table 9-2 shows the design parameters for this application.

Table 9-2. Design Parameters

DESIGN PARAMETER	VALUE
Input voltage	5V
Output1 voltage	5V
Output2 voltage	5V
Output1 current	0.5A
Output2 current	0.5A

9.2.3.2 Detailed Design Procedure

To begin the design process, know a few parameters. The designer must know the following:

- Normal input operation voltage
- Current limit

Input and output capacitance improves the performance of the device; the actual capacitance must be optimized for the particular application. For all applications, TI recommends a 0.1µF or greater ceramic bypass capacitor between IN and GND, as close to the device as possible for local noise decoupling. This precaution reduces ringing on the input due to power-supply transients. Additional input capacitance can be needed on the input to reduce voltage undershoot from exceeding the UVLO of other load share one power rail with TPS2042 device or overshoot from exceeding the absolute-maximum voltage of the device during heavy transient conditions. Preventing voltage undershoots and overshoots is especially important during bench testing when using long, inductive cables to connect the evaluation board to the bench power supply. Output capacitance is not required. TI recommends placing a high-value electrolytic capacitor on the output pin when large transient currents are expected on the output to reduce the undershoot, which is caused by the inductance of the output power bus just after a short has occurred and the TPS2042 device has abruptly reduced OUT current. Energy stored in the inductance drives the OUT voltage down and potentially negative as it discharges.

9.3 Power Supply Recommendations

9.3.1 Undervoltage Lockout (UVLO)

An undervoltage lockout establishes that the power switch is in the off state at power up. Whenever the input voltage falls below approximately 2V, the power switch is quickly turned off. The UVLO facilitates the design of hot-insertion systems where it is not possible to turn off the power switch before removing the input power. The UVLO also keeps the switch from turning on until the power supply has reached at least 2V, even if the switch is enabled. On reinsertion, the power switch turns on, with a controlled rise time to reduce EMI and voltage overshoots.

9.4 Layout

9.4.1 Layout Guidelines

- Place the 100nF bypass capacitor near the IN and GND pins, and make the connections using a low-inductance trace.
- Placing a high-value electrolytic capacitor and a 100nF bypass capacitor on the output pin is recommended when large transient currents are expected on the output.
- The PowerPAD must be directly connected to PCB ground plane using wide and short copper trace.

9.4.2 Layout Example

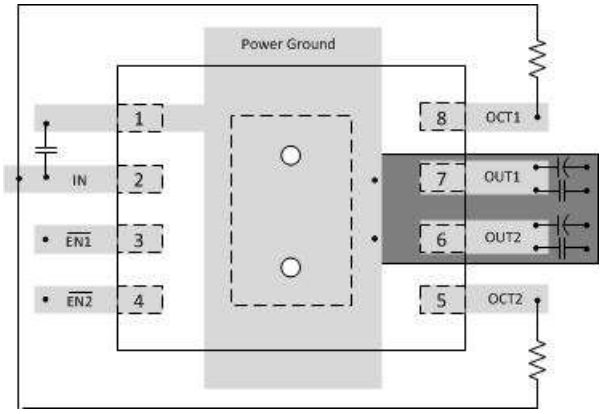

Figure 9-35. Layout Recommendation

9.4.3 Power Dissipation

The low on-resistance on the N-channel MOSFET allows the small surface-mount packages to pass large currents. The thermal resistances of these packages are high compared to those of power packages; it is good design practice to check power dissipation and junction temperature. Begin by determining the $r_{DS(on)}$ of the N-channel MOSFET relative to the input voltage and operating temperature. As an initial estimate, use the highest operating ambient temperature of interest and read $r_{DS(on)}$ from Figure 6-11. Using this value, calculate the power dissipation per switch using Equation:

$$D_P = r_{DS(on)} \times I^2$$

Multiply this number by the number of switches in use. This step renders the total power dissipation from the N-channel MOSFETs.

Finally, calculate the junction temperature with Equation:

$$T_J = P_D \times R_{\theta JA} + T_A$$

where

- T_A= Ambient temperature °C
- $R_{\theta JA}$ = Thermal resistance
- P_D = Total power dissipation based on number of switches in use

Compare the calculated junction temperature with the initial estimate. If the numbers are not within a few degrees, repeat the calculation, using the calculated value as the new estimate. Two or three iterations are generally sufficient to get a reasonable answer.

9.4.4 Thermal Protection

Thermal protection prevents damage to the IC when heavy-overload or short-circuit faults are present for extended periods of time. The TPS20xxB implements a thermal sensing to monitor the operating junction

temperature of the power distribution switch. In an overcurrent or short-circuit condition, the junction temperature rises due to excessive power dissipation. Once the die temperature rises to approximately 140°C due to overcurrent conditions, the internal thermal sense circuitry turns the power switch off, thus preventing the power switch from damage. Hysteresis is built into the thermal sense circuit, and after the device has cooled approximately 10°C, the switch turns back on. The switch continues to cycle in this manner until the load fault or input power is removed. The $\overline{\text{OC}}$x open-drain output is asserted (active low) when an overtemperature shutdown or overcurrent occurs.

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. Refernce JEDEC MO-178.
4. Body dimensions do not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.25 mm per side.
5. Support pin may differ or may not be present.
