TPS544628 4V to 16V Input, 6A, Remote Sense Synchronous Buck Converter With PMBus®

1 Features

- 4V to 16V input voltage range without external bias
- 2.7V to 16V input voltage range with external bias
- 3.1V to 4.5V external VCC bias support
- 18mΩ and 7.5mΩ MOSFETs (V_{VCC} = 3.3V)
- 6A continuous output current
- PMBus® 1.4 compliant
- Optimized 19-pin WQFN-HR package for efficiency and thermal performance
- 1% output voltage accuracy with internal feedback, T_J = –40°C to +150°C
- 0.4V to 5.5V output voltage range
- Differential remote sense
- D-CAP4 with ultra-fast load-step response supports all ceramic output capacitors
- User programmable NVM
- Selectable auto-skip Eco-mode for high light-load efficiency
- Programmable valley current limit
- 500kHz, 600kHz, 800kHz, 1.0MHz, 1.2MHz, 1.4MHz selectable switching frequency
- Programmable soft-start time
- Prebiased start-up capability
- Open-drain power-good output
- Overvoltage and undervoltage fault protection
- 3mm × 3mm (0.4mm pin pitch) and 3mm × 3.5mm (0.5 pin pitch) 19-pin QFN packages
- Pin-to-pin compatible with 20A TPS544B28 and 12A TPS544A28

2 Applications

- Data center compute
- Data center networking
- Industrial automation
- Baseband unit (BBU)

Simplified Schematic

3 Description

The TPS544628 device is a small, high-efficiency, synchronous buck converter with an adaptive on-time D-CAP4 control mode. The control method provides low minimum on-time and fast load-transient response across the entire output voltage range without requiring an external compensation network.

The TPS544628 device has differential remote sense, high-performance integrated MOSFETs, ±10% current telemetry accuracy ≥ 3A, and supports ±0.5% output voltage accuracy with internal feedback, VOSL = 1 or 0.5, and T_J = 0°C to +85°C. The device features accurate load and line regulation and Eco-mode or Forced Continuous Conduction Mode (FCCM) operation.

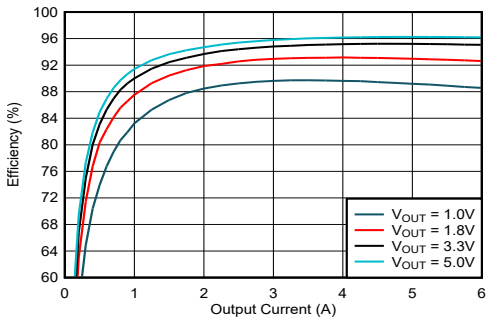

The PMBus® interface with 1MHz clock support gives a convenient, standardized digital interface for device configuration as well as output voltage, output current, and die temperature telemetry. Pinstrap options allow for the configuration of the overcurrent limit, fault response, internal or external feedback, output voltage selection, and switching frequency. Internal NVM is also available to store a variety of the PMBus parameters.

The TPS544628 device is a lead-free device. The device is RoHS compliant without exemption.

Package Information

PART NUMBER	PACKAGE(1)	PACKAGE SIZE(2)
TPS544628	VAN (WQFN-HR, 19)	3mm × 3mm
	RBH (WQFN-HR, 19)	3mm × 3.5mm

(1) For more information, see Section 11.
(2) The package size (length × width) is a nominal value and includes pins, where applicable.

Application Efficiency (V_{IN} = 12V, External V_{CC} = 3.3V, Fsw = 800kHz, L = 1µH, 6.5mΩ)

ADVANCE INFORMATION

An IMPORTANT NOTICE at the end of this data sheet addresses availability, warranty, changes, use in safety-critical applications, intellectual property matters and other important disclaimers. ADVANCE INFORMATION for preproduction products; subject to change without notice.

ADVANCE INFORMATION

ADVANCE INFORMATION

Table 4-1. Pin Functions

PIN		TYPE[1]	DESCRIPTION
NAME	NO		
PG	1	O	Open-drain power-good status signal. Connect an external pullup resistor to a voltage source. When the FB voltage moves outside the specified limits, PG goes low after the specified delay.
MS2	2	I	Multifunction select pin. A resistor from the MS2 pin to AGND selects the output voltage setting, VOUT_SCALE_LOOP, and internal or external feedback.
MS1	3	I	Multifunction select pin. A resistor from the MS1 pin to AGND selects the switching frequency, valley current limit threshold, and soft start time.
VIN	4, 12	P	Power-supply input pins for both the power stage MOSFETs and the internal LDO. Place the decoupling input capacitors from VIN pins to PGND pins as close as possible. A capacitor from each VIN to PGND close to IC is required.
PGND	5, 11	G	Ground return for the power stage. This pin is internally connected to the source of the low-side MOSFET. Place as many vias as possible beneath the PGND pins and as close as possible to the PGND pins. This action minimizes parasitic impedance and also lowers thermal resistance.
VCC	6	P	Internal 3V LDO output. A 3.1V to 4.5V external bias can be connected to this pin to save the power losses on the internal LDO. The voltage source on this pin powers both the internal circuitry and gate driver. Bypass with a 1µF, > 6.3V rating, ceramic capacitor from VCC pin to PGND. Place this capacitor as close to the VCC and PGND pins as possible to minimize loop inductance.
SW	7, 8, 9	O	Output switching terminal of the power converter. Connect this pin to the output inductor.
BST	10	I/O	Supply for the internal high-side MOSFET gate driver (boost terminal). Connect the bootstrap capacitor from this pin to SW node.
ADR	13	I	Address select pin. A resistor from the ADR pin to AGND selects the device address and the fault recovery (hiccup or latch-off) mode.
SDA	14	I	bi-directional serial data pin
SCL	15	I	serial clock pin
EN	16	I	Enable pin. The enable pin turns the DC/DC switching converter on or off. Floating EN pin before start-up disables the converter. The recommended maximum voltage applied to the EN pin is 5.5V. TI *does not* recommend connecting the EN pin to VIN pin directly.
VOS/FB	17	I	Output voltage feedback input. Positive input of the differential remote sense circuit, connect to the Vout sense point on the load side. When configured for external feedback, a resistor divider from the VOUT to GOS (tapped at FB pin) sets the output voltage.
GOS	18	I	Negative input of the differential remote sense circuit. Connect to a ground sense point near the load.
AGND	19	G	Analog ground return and reference for the internal control circuits.

5 Specifications

5.1 Absolute Maximum Ratings

Over operating junction temperature range (unless otherwise noted) (1)

		MIN	MAX	UNIT
Pin voltage	VIN	–0.3	19	V
Pin voltage	SW – PGND, DC	–0.3	19	V
Pin voltage	SW – PGND, transient < 10ns	–3	20	V
Pin voltage	VIN – SW, DC	–0.3	19	V
Pin voltage	VIN – SW, transient < 10ns	–3	25	V
Pin voltage	BOOT – PGND	–0.3	24.5	V
Pin voltage	BOOT – SW	–0.3	5.5	V
Pin voltage	MS1, MS2, SDA, SCL, VCC	–0.3	5	V
Pin voltage	VOS/FB, PG, EN	–0.3	6	V
Pin voltage	GOS, PGND	–0.3	0.3	V
Sink current	PG		15	mA
Operating junction temperature	T_J	–40	150	°C
Storage Temperature	Tstg	–55	150	°C

(1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.

5.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 (1)	±2000	V
		Charged-device model (CDM), per ANSI/ESDA/JEDEC JS-002 (2)	±500	

(1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

Over operating junction temperature range (unless otherwise noted)

			MIN	NOM	MAX	UNIT
V_{IN}	Input voltage range	Internal LDO	4		16	V
V_{IN}	Input voltage range	3.1V ≤ V_{VCC} External Bias ≤ 4.3V	2.7		16	V
Pin voltage		V_{GOS} versus V_{AGND}	–0.1		0.1	V
		EN, PG	–0.1		5.5	V
V_{VCC}	External bias range	V_{VIN} ≤ 16V	3.1		4.5	V
V_{OUT}	Output voltage range	VOUT	0.4		5.5	V
I_{PG}	Power-good sinking current	PG			10	mA
I_{OUT}	Output current	SW			6	A
IL_{PEAK}	Maximum peak inductor current	SW			12	A
T_J	Operating junction temperature		–40		150	°C

6 Detailed Description

6.1 Overview

The TPS544628 device is a high-efficiency, single-channel, small-sized synchronous buck converter. The device is designed for low output voltage point-of-load applications with 6A or lower output current in server, storage, and similar computing applications. The TPS544628 features proprietary D-CAP4 mode control combined with adaptive on-time architecture. This combination builds modern low-duty-ratio and ultra-fast load-step-response DC/DC converters in an excellent fashion. The output voltage set by the feedback voltage divider ranges from 0.4V to 5.5V. The conversion input voltage ranges from 2.7V to 16V, and the VCC input voltage ranges from 3.1V to 4.5V. The D-CAP4 modulator uses emulated current information to control the modulation. The D-CAP4 modulator reduces loop gain variation with different output voltages providing better transient response in higher output voltage applications. An advantage of this control scheme is that this control scheme does not require a phase-compensation network outside which makes the device easy-to-use and also allows low external component count. Another advantage of this control scheme is that this control scheme supports stable operation with all low ESR output capacitors (such as ceramic capacitors and low ESR polymer capacitors). Lastly, adaptive on-time control tracks the preset switching frequency over a wide range of input and output voltages while increasing switching frequency as needed during load-step transients.

6.3 Feature Description

6.3.1 D-CAP4 Control

The device uses D-CAP4 control architecture to achieve fast load transient response while maintaining ease-of-use. This control system incorporates an internal ripple generation network that emulates inductor current ripple and integrates with the voltage feedback signal, enabling both rapid response and precise output voltage regulation. D-CAP4 allows the use of very low-ESR output capacitors, including multi-layered ceramic capacitors (MLCC) and low-ESR polymer capacitors, without requiring external current sensing, ripple injection, or voltage compensation networks.

Unlike earlier D-CAP2 and D-CAP3 architectures, D-CAP4 employs a fixed ramp amplitude each switching cycle and a forward gain path to improve transient response and reduce pulse frequency jitter, while an error amplifier provides high DC set-point accuracy. A key advantage of D-CAP4 is the ability to minimize loop gain variation across the entire output voltage range, enabling consistent fast load transient response with a single ramp setting. The R-C time-constant of the internal ramp circuit sets the zero frequency of the ramp, similar to other R-C based internal ramp generation architectures. This reduced variation in loop gain eliminates the need for a feedforward capacitor to optimize transient response. Additionally, the fixed ramp amplitude architecture eliminates loop gain variation across input voltage.

The device offers four user-selectable compensation settings through (D4h) COMP. When internal reference DAC target voltages are ≥750mV, the device automatically increases the ramp amplitudes to compensate for higher effective loop gain and maintain stable setpoints for a wider range of reference voltages. SEL_SUMCOMP in (D4h) COMP shows the state of this compensation adjustment. Users can force SEL_SUMCOMP high or low by writing to the override bits in (D4h) COMP. For internal feedback, estimate V_{REF_DAC} by multiplying the output voltage by (29h) VOUT_SCALE_LOOP (for example, V_{OUT} = 1.6V and VOUT_SCALE_LOOP = 0.5 gives V_{REF_DAC} of 800mV). When using external feedback, V_{REF_DAC} equals the voltage on the VOS/FB pin. Note that the V_{REF_DAC} target only updates when the output is disabled, so crossing the 750mV threshold with (21h) VOUT_COMMAND while the device is regulating does not change the state of SEL_SUMCOMP. Table 6-1 details the available loop compensation settings accessible through the digital interface.

Table 6-1. COMP Enumeration List

Ramp	SEL_RAMP (b)	Relative Effective Ramp Amplitude	
		SEL_SUMCOMP = 0b	SEL_SUMCOMP = 1b
RAMP1	00	2.1×	3.3×
RAMP2	01	1.6×	2.4×
RAMP3	10	1.4×	2.0×
RAMP4	11	1×	1.5×

RAMP2 and RAMP3 result in similar loop bandwidth as the ramp amplitudes are similar. The primary difference between these two settings is the ramp zero frequency. The lower ramp zero location for RAMP3 increases phase margin. However, RAMP2 provides faster transient response than RAMP3 because RAMP2 gives higher gain across the entire frequency range due to higher ramp zero location with comparable ramp amplitudes. For most applications, RAMP3 must be used instead of RAMP2. RAMP3 can be used to provide phase boost in applications using an L-C whose double pole frequency allows using RAMP4 but where minimizing jitter is more important than faster transient response. TI recommends using the calculator in the technical documentation section of the TPS544628 Product Page when evaluating compensation settings and output L-C selection.

For any control topologies supporting no external compensation, there is a minimum range, maximum range, or both, for the output filter the control topologies can support. The output filter used for a typical buck converter is a low-pass L-C circuit. This L-C filter has double pole that Equation 1 shows.

$$f_P = \frac{1}{2\pi \times \sqrt{L_{OUT} \times C_{OUT}}} \quad (1)$$

ADVANCE INFORMATION

Copyright © 2026 Texas Instruments Incorporated

ADVANCE INFORMATION

At low frequencies, the overall loop gain is set by the output set-point resistor divider network and the internal gain of the device. The low frequency L-C double pole has a 180-degree drop in phase. At the output filter frequency, the gain rolls off at a –40dB per decade rate and the phase drops rapidly. The internal ripple generation network introduces a high-frequency zero that reduces the gain roll off from –40dB to –20dB per decade and increases the phase by 90 degrees per decade above the zero frequency.

The inductor and capacitor selected for the output filter must be such that the f_P double pole of Equation 1 is located no higher than the value calculated by using the scaling constants in Table 6-2. Increasing V_{REF} scales down the $f_{P(MAX)}$ because the internal D-CAP4 ramp amplitude remains constant. As the reference voltage increases, the relative ramp amplitude decreases, also decreasing the $f_{P(MAX)}$.

$$f_{p(MAX)} = \frac{10^3 \times K_{f_LC}}{\sqrt{V_{REF_DAC}}} \quad (2)$$

Table 6-2. Calculation Constant for Maximum L-C Double Pole

f_{SW} (kHz)	MAXIMUM L-C DOUBLE POLE CONSTANT K_{f_LC}							
	SEL_SUMCOMP = 0b0				SEL_SUMCOMP = 0b1			
	RAMP1	RAMP2	RAMP3	RAMP4	RAMP1	RAMP2	RAMP3	RAMP4
500	7.3	6.4	6.0	5.1	8.7	7.6	7.1	6.1
600	8.8	7.7	7.2	6.1	10.4	9.1	8.5	7.3
800	11.7	10.2	9.6	8.2	13.9	12.2	11.4	9.8
1000	14.6	12.8	12.0	10.2	17.4	15.2	14.2	12.2
1200	17.5	15.4	14.4	12.2	20.9	18.2	17.0	14.6
1400	20.4	17.9	16.8	14.3	24.4	21.3	19.9	17.1

An L-C double pole frequency that violates these guidelines for each setting can be possible, but must be validated in the application with measurements.

Note

For applications using dynamic voltage scaling through (21h) VOUT_COMMAND, TI recommends confirming the output L-C double pole frequency satisfies Equation 2 for all target voltages.

After identifying the application requirements, the output inductance is typically designed so the inductor peak-to-peak ripple current is approximately between 15% and 40% of the maximum output current in the application. Selecting very small output capacitance leads to a high frequency L-C double pole which causes the overall loop gain to stay high until the L-C double pole frequency. Given the zero from the internal ripple generation network is a relatively high frequency as well, the loop with very small output capacitance can have too high of a crossover frequency which can cause instability. In general, where reasonable (or smaller) output capacitance is desired, output ripple requirement and load transient requirement can be used to determine the necessary output capacitance for stable operation.

If MLCCs are used, consider the derating characteristics to determine the final output capacitance for the design. For example, when using an MLCC with specifications of 10µF, X5R and 6.3V, the derating by DC bias and AC bias are 80% and 50%, respectively. The effective derating is the product of these two factors, which in this case is 40% and 4µF. Consult with capacitor manufacturers for specific characteristics of the capacitors to be used in the application.

As a simplified rule, if an output capacitor with an ESR zero that is less than 10 × the L-C double pole frequency, TI recommends to ignore when calculating the L-C double pole frequency for stability purposes. The L-C double pole frequency must be recalculated using only the low ESR MLCCs. For more accurate analysis when using mixed type output capacitors, TI recommends simulations or measurements.

For the maximum output capacitance recommendation, select the inductor and capacitor values so that the L-C double pole frequency is no less than 1/100th of the switching frequency. With this starting point, verify the small signal response on the board and confirm that the phase margin at the loop crossover is greater than 45

Copyright © 2026 Texas Instruments Incorporated

degrees. The actual maximum output capacitance can go higher as long as phase margin is greater than 45 degrees. However, a small signal measurement (Bode plot) must be done to confirm the design.

For large output filters with an L-C double pole near 1/100th of the operating frequency, additional phase boost can be required. A feedforward capacitor placed in parallel with R_{FB_HS} can boost the phase when using external feedback. When using internal feedback, the user can adjust the internal loop response with SEL_LC_H in SYS_CFG_USER1. In practice, this can help boost phase margin for large output filters. See also the *Optimizing Transient Response of Internally Compensated dc-dc Converters With Feedforward Capacitor* application note.

Besides boosting the phase, a feedforward capacitor feeds more V_{OUT} node information into the FB node through AC coupling. This feedforward during load transient event enables faster response of the control loop to a V_{OUT} deviation. However, this feedforward during steady state operation also feeds more V_{OUT} ripple and noise into FB. High ripple and noise on FB usually leads to more jitter, or even double-pulse behavior. To determine the final feedforward capacitor value impacts to phase margin, consider load transient performance, ripple, and noise on FB. TI recommends using frequency analysis equipment to measure the crossover frequency and the phase margin.

6.3.2 Internal VCC LDO and Using External Bias On the VCC Pin

The TPS544628 has an internal 3.0V LDO featuring input from VIN and output to VCC. When the VIN voltage rises above the UVLO threshold ($VIN_{UVLO(R)}$), the internal LDO is enabled and starts regulating output voltage on the VCC pin. The VCC voltage provides the bias voltage for the internal analog and digital circuitry and also provides the supply voltage for the gate drivers. Bypass the VCC pin with a 1µF, at least 6.3V rating ceramic capacitor to PGND, and keep the VCC-PGND current return loop path to the device as small as possible. TI does not recommend bypassing VCC to AGND. See Section 8.4 for a recommended layout example for the VCC bypass capacitor.

An external bias that is above the output voltage of the internal LDO can override the internal LDO. This override enhances the efficiency of the converter because the VCC current now runs off this external bias instead of the internal linear regulator. An external bias between 3.1V and 4.5V can be used to provide additional efficiency enhancement by reducing the R_{DSON} of the integrated power MOSFETs.

The VCC UVLO circuit monitors the VCC pin voltage and disables the whole converter when VCC falls below the VCC UVLO falling threshold. Maintaining a stable and clean VCC voltage is required for a smooth operation of the device.

Considerations when using an external bias on the VCC pin are as follows:

- When the external bias is applied on the VCC pin early enough (for example, before EN signal comes in), the internal LDO pass device is always off and the internal analog circuits have a stable power supply rail at the power enable.
- TI does not recommend this consideration. When the external bias is applied on the VCC pin late (for example, after EN signal comes in), any power-up and power-down sequencing can be applied as long as there is no excess current pulled out of the VCC pin. With this sequence, be cautious of external discharge paths on the VCC pin which can pull a current higher than the current limit of the internal VCC LDO. A load exceeding the current limit of the internal VCC LDO can potentially pull the VCC voltage low and turn off the VCC LDO through the UVLO, thereby shutting down the converter output.
- A good power-up sequence is when at least one of VIN UVLO rising threshold or EN rising threshold is satisfied later than VCC UVLO rising threshold. For example, a practical power-up sequence is: VIN applied first, then the external bias applied, and then EN signal goes high.

6.3.2.1 Powering the Device From a Single Bus

The device works well when powered by a single V_{IN} configuration. In a single V_{IN} configuration, the internal LDO is typically powered by a 5V or 12V bus and generates a 3V output to bias the internal analog circuitry and power MOSFET gate drivers. The V_{IN} input range under this configuration is 4V to 16V for up to 6A load current. Figure 6-1 shows an example for this single V_{IN} configuration.

ADVANCE INFORMATION

ADVANCE INFORMATION

V_{IN} and EN are the two signals to enable the device. For start-up sequence, any sequence between the V_{IN} and EN signals can power the device up correctly.

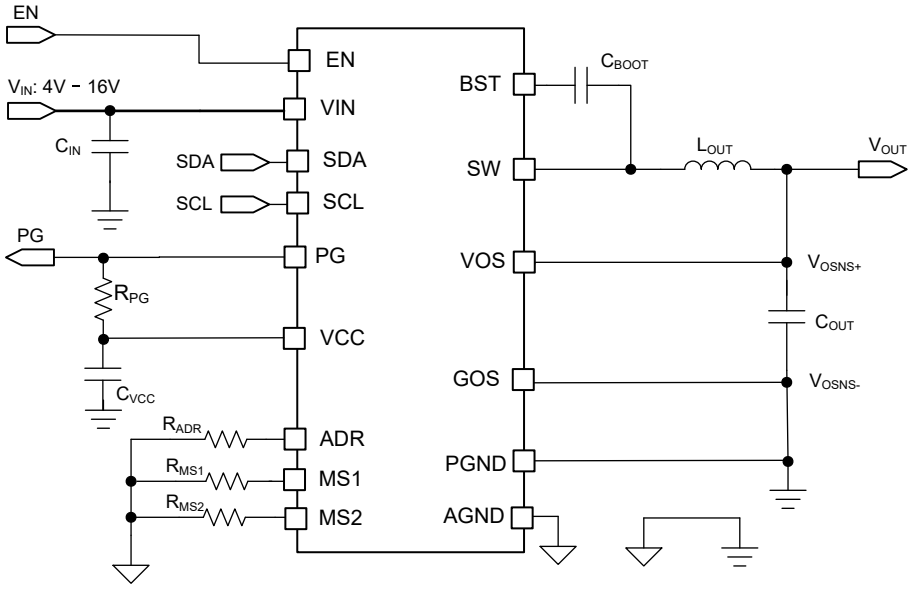

Figure 6-1. Single V_{IN} Configuration for a 12V Bus

6.3.2.2 Powering the Device From a Split-Rail Configuration

When an external bias, which is at a different level from main V_{IN} bus, is applied onto the V_{CC} pin the device can be configured to split-rail by using both the main V_{IN} bus and V_{CC} bias. Connecting a valid V_{CC} bias to V_{CC} pin overrides the internal LDO, thus saves power loss on the internal LDO. This configuration helps to improve overall system level efficiency but requires a valid V_{CC} bias. A 3.3V rail is the common choice as V_{CC} bias. With a stable V_{CC} bias, the recommended V_{IN} input range under this configuration is extended, from 2.7V to 16V. Additionally, because the internal digital circuitry is powered by V_{CC}, the user is able to communicate with a device with a V_{CC} bias but no V_{IN} bias.

The noise of the external bias affects the internal analog circuitry. To make sure of a proper operation, a clean, low-noise external bias and good local decoupling capacitor from V_{CC} pin to PGND pin are required. Figure 6-2 shows an example for this split rail configuration.

The V_{CC} external bias current during nominal operation varies with the bias voltage level and also the operating frequency. For example, by setting the device to skip-mode, the V_{CC} pin draws less current from the external bias when the frequency decreases under a light load condition. The typical V_{CC} external bias current under FCCM operation is listed in *Specifications* The external bias must be capable of supplying this current or the external bias voltage can drop and the internal LDO can no longer be overridden.

Under split rail configuration, V_{IN}, V_{CC} bias, and EN are the signals to enable the part. For start-up sequence, TI recommends that at least one of V_{IN} UVLO rising threshold or EN rising threshold is satisfied later than VCC bias application. A practical start-up sequence example is:

1. V_{IN} applied
2. External V_{CC} bias applied
3. EN signal goes high

Similarly, for power-down sequence, TI recommends that at least one of the V_{IN} UVLO falling threshold or the EN falling threshold is satisfied before the external V_{CC} bias supply turns off. If the external V_{CC} bias supply turns off first, the internal LDO of the device prevents the V_{CC} voltage from dropping below 3.0V and be loaded by other circuits powered by the external V_{CC} bias supply.

6.3.3 Multifunction Select (MS1) Pin

The device allows users to select the switching frequency, current limit, and soft start time by connecting a resistor from the MS1 pin to AGND pin. Table 6-3 lists the resistor values for the switching frequency, operation mode, and soft start selections. A ±1% tolerance resistor with a typical temperature coefficient of ±100ppm/°C is required for accurate detection across the device operating range.

The MS1 state is set and latched during the internal power-on delay period. Changing the MS1 pin resistance after the power-on delay does not change the status of the device.

To make sure the internal circuit detects the resistor value correctly, *do not* place any capacitor on the MS1 pin.

Table 6-3. MS1 Pin Selection

MS1 PIN RESISTANCE TO AGND (kΩ)	SWITCHING FREQUENCY (f_{SW}) (kHz)(1)	VALLEY CURRENT LIMIT (A)	SS TIME (ms)
0 / GND	600(2)	7(2)	1(2)
0.82	1200	7	1
1.2	600	7	4
1.8	800	7	4
2.2	1200	7	4
2.7	600	6	1
3.3	800	6	1

68	800	4	4
82	1200	4	4
≥ 118 (FLOAT/VCC)	800	7	1

(1) Switching frequency is based on 3.3V output voltage. Frequency varies with output voltage.
(2) Default value from factory. If NVM is programmed to a different value, the device uses the value that is programmed in the NVM.

6.3.4 Multifunction Select (MS2) Pin

The device allows users to select the output voltage by connecting a resistor from the MS2 pin to AGND pin. Table 6-4 lists the resistor values for output voltage selection. A ±1% tolerance resistor with a typical temperature coefficient of ±100ppm/°C is required for accurate detection across the device operating range.

In addition to expanded output voltage programmability through PMBus, the output voltage can also be set with an external feedback resistor divider using any of the 0.4V to 0.8V VOS/FB pin regulation settings.

Copyright © 2026 Texas Instruments Incorporated

The MS2 state is set and latched during the internal power-on delay period. Changing the MS2 pin resistance after the power-on delay does not change the status of the device.

To make sure the internal circuit detects the resistor value correctly, *do not* place any capacitor on the MS2 pin.

Table 6-4. MS2 Pin Selection

MS2 PIN RESISTANCE TO AGND (kΩ)	VOS/FB PIN REGULATION (V)	SUPPORTS EXTERNAL FEEDBACK
0 / GND	1.0(1)	No
0.82	0.4	Yes

≥118 (FLOAT/VCC)	3.3	No

(1) Default value from factory. If NVM is programmed to a different value, the device uses the value that is programmed in the NVM.

6.3.5 PMBus® Address (ADR) Pin

The device allows users to select the PMBus® device address and Fault Recovery Mode by connecting a resistor from the ADR pin to AGND pin. Table 6-5 lists the resistor values for address and fault recovery mode selection. A ±1% tolerance resistor with a typical temperature coefficient of ±100ppm/°C is required for accurate detection across the device operating range.

The ADR state is set and latched during the internal power-on delay period. Changing the ADR pin resistance after the power-on delay does not change the status of the device.

To make sure the internal circuit detects the resistor value correctly, *do not* place any capacitor on the ADR pin.

6.3.6 Output Voltage Setting

The TPS544628 supports output voltage setting with both internal feedback divider and external feedback divider. Regardless of internal or external feedback, the device must first regulate to one of a predefined list of boot voltages outlined in Table 6-6 before transitioning to other voltages is possible.

The following sections outline boot voltage selection and implications, voltage setting through internal feedback, and voltage setting through external feedback.

6.3.6.1 Setting VBOOT and VOUT_SCALE_LOOP

The TPS544628 supports 32 unique start-up voltage settings through (D5h) VBOOT. Of these, 24 are available through pinstrap by default, and all can be programmed into NVM. These settings determine both the start-up voltage the device begins regulating to during soft-start and the (29h) VOUT_SCALE_LOOP the device uses for the current power-on cycle. The (29h) VOUT_SCALE_LOOP value is latched during pinstrap detection at startup and cannot be changed until the next power-on cycle.

To provide the user greater flexibility, (D1h) SYS_CFG_USER1 contains an NRSA_L bit that adjusts the (29h) VOUT_SCALE_LOOP used for some boot voltages. This changes the range of possible voltages the user can access through (21h) VOUT_COMMAND in a power-on cycle, allowing them to slew to lower voltages than possible by default. After setting NRSA_L high, the user must store to NVM via STORE_USER_ALL and power cycle for the change to take effect.

Copyright © 2026 Texas Instruments Incorporated

Note

Changing (29h) VOUT_SCALE_LOOP for a given V_{OUT} with NRSA_L also changes the internal V_{REF_DAC} setpoint and can impact the compensation settings as outlined in Section 6.3.1.

The (D5h) VBOOT and (29h) VOUT_SCALE_LOOP settings are specified in Table 6-6:

Table 6-6. VBOOT Enumeration List

VBOOT [4:0] (dec)	VOUT_SCALE_LOOP (V/V)		V_{OUT} (V)
	NRSA_L = 0b	NRSA_L = 1b	
0	1	1	0.4
1	1	1	0.45
2	1	1	0.5
3	1	1	0.55

ADVANCE INFORMATION

6.3.6.2 Setting Output Voltage (Internal Feedback)

When using internal feedback without margining, the output is determined by two settings: (21h) VOUT_COMMAND and (29h) VOUT_SCALE_LOOP. (21h) VOUT_COMMAND is used to adjust the internal reference DAC input to the error amplifier and can be in the range from 0.25V to 0.9V. (29h) VOUT_SCALE_LOOP specifies the internal resistor divider gain of 1, 0.5, 0.25, or 0.125. As defined in (20h) VOUT_MODE, the LSB of (21h) VOUT_COMMAND is 0.976mV.

The range of recommended (21h) VOUT_COMMAND values is dependent upon the configured (29h) VOUT_SCALE_LOOP. The design does not limit the (21h) VOUT_COMMAND value to be within this recommended range. The maximum possible VOUT is 5.505V. The recommended output voltage range for each (29h) VOUT_SCALE_LOOP setting is defined in Table 6-7.

When PMBus or pin-strapping is used to set the regulated voltage, the commanded output voltage in volts is determined by a combination of (21h) VOUT_COMMAND, (25h) VOUT_MARGIN_HIGH, (26h) VOUT_MARGIN_LOW, (01h) OPERATION and (20h) VOUT_MODE as defined below in Equation 3.

$$V_{OUT} = \text{VOUT_MODE} \times (\text{VOUT_COMMAND} + ((\text{VOUT_MARGIN_HIGH} - 1) \times \text{VOUT_COMMAND} \times \text{OPERATION}[5]) - ((1 - \text{VOUT_MARGIN_LOW}) \times \text{VOUT_COMMAND} \times \text{OPERATION}[4])) \quad (3)$$

Table 6-7. Recommended Output Voltage Ranges

VOUT_SCALE_LOOP (V/V)	RECOMMENDED V_{OUT} RANGE (V)	RECOMMENDED VOUT_COMMAND RANGE (dec)
1	0.35 – 0.9	359 – 922
0.5	0.5 – 1.8	512 – 1844
0.25	1.4 – 3.6	1434 – 3687
0.125	2.8 – 5.505	2868 – 5637

6.3.6.3 Setting Output Voltage (External Feedback)

When using external feedback, a resistor divider consisting of R_{FB_T} and R_{FB_B} is used. Connect R_{FB_T} between the FB pin and the positive node of the load, and connect R_{FB_B} between the FB pin and GOS pin. The FB pin is regulated to the internal reference (V_{REF}). The recommended R_{FB_B} value is 10kΩ, ranging from 1kΩ to 20kΩ. Use Equation 4 to determine R_{FB_T}.

$$R_{FB_T} = \frac{V_{OUT} - V_{REF}}{V_{REF}} \times R_{FB_B} \quad (4)$$

When external feedback is used, only (D5h) VBOOT values with (29h) VOUT_SCALE_LOOP of 1 are supported (see Table 6-6). However, (21h) VOUT_COMMAND can still be used to dynamically change V_{REF} within the recommended range.

To improve the overall V_{OUT} accuracy, using ±1% accuracy or better resistors for the FB voltage divider is highly recommended. The FB voltage divider resistors must be kept near the device to minimize the trace length connected to the FB pin.

6.3.7 Switching Frequency

The TPS544628 allows the user to select the switching frequency through pin-strapping on MS1 or (33h) FREQUENCY_SWITCH and FCCM/PFM operation mode through the FCCM bit in (D1h) SYS_CFG_USER1. Table 6-8 lists the digitally programmable switching frequency options.

Table 6-8. FREQUENCY_SWITCH Enumeration List

FREQUENCY_SWITCH [3:0]		SWITCHING FREQUENCY (kHz)

6.3.8 Dynamic Voltage Slew Rate

The TPS544628 includes (27h) VOUT_TRANSITION_RATE to set the slew rate when changing the output voltage levels. Table 6-9 lists the selectable options.

Table 6-9. VOUT_TRANSITION_RATE Enumeration List

VOUT_TRANSITION_RATE [6:0]		SLEW RATE (mV/µs)
≥	≤	
0d	19d	1.625
20d	38d	3.25
39d	77d	6.5
78d	127d	13

During the output voltage transition, due to the quick charge or discharge of output capacitors, the power stage sees extra inrush current. This inrush current plus load current can trigger overcurrent protection when there is no sufficient room from OCL or NOC setting. For example, the positive inductor current during VOUT step-up transition goes higher than nominal operation. If the LS valley OCL threshold is set relatively low and does not allow the extra inrush current, the inductor current is potentially limited by the cycle-by-cycle overcurrent limit feature, thus the actual step-up slew rate is lower than the desired value. Similar situations can occur to VOUT step-down transitions with no load condition. The negative inductor current during VOUT step-down transition goes more negative than nominal operation. However, the inductor current is not allowed to go more negative than the negative OC threshold. Thus, triggering NOC operation during VOUT step-down transition results that the actual step-down slew rate is lower than the desired value.

6.3.9 Enable

When the EN pin voltage rises above the enable threshold voltage ($V_{EN(R)}$) and VIN rises above the VIN UVLO rising threshold, the device enters the internal power-up sequence.

The EN pin has an internal filter to avoid unexpected ON or OFF due to small glitches. The time constant of this RC filter is 2µs. For example, when applying 3.3V voltage source on the EN pin that jumps from 0V to 3.3V with an ideal rising edge, the internal EN signal reaches 2.1V after 2µs, which is 63.2% of applied 3.3V voltage level.

An internal pulldown resistor is implemented between the EN pin and AGND pin. With this pulldown resistor, floating the EN pin before start-up keeps the device in the disabled state. A resistor divider to the EN pin can be used to increase the input voltage the device begins the start-up sequence. The internal pulldown resistor must be accounted for when using an external resistor divider. To reduce impact to the EN rising and falling threshold, this internal pulldown resistor is 1MΩ. During nominal operation when the power stage switches, this large internal pulldown resistor can not have enough noise immunity to hold EN pin low for the device to enter the disabled state.

If an external resistor divider is connected to the EN pin, an additional 5µA current source is activated when the EN voltage exceeds the rising threshold to provide a programmable hysteresis based on the enable falling threshold voltage ($V_{EN(F)}$) and external resistors.

The recommended operating condition for the EN pin is a maximum of 5.5V. *Do not* connect the EN pin to the VIN pin directly if VIN can exceed 5.5V.

ADVANCE INFORMATION

6.3.10 Soft Start and Soft Stop

The device implements a selectable (0.5ms, 1ms, 2ms, or 4ms) soft-start time which can be configured via pinstrap or the digital interface. The soft-start time can be set digitally through (61h) TON_RISE as outlined in Table 6-10. The device also implements a soft-stop time mirroring the soft-start time that can be enabled and disabled in (01h) OPERATION. If soft-stop is not enabled, then the device responds as defined in Section 6.3.17 on disable.

Table 6-10. TON_RISE Enumeration List

TON_RISE [3:0]		SOFT-START TIME (ms)
≥	≤	
0d	1d	0.5
2d	3d	1
4d	7d	2
8d	15d	4

The device includes optional (60h) TON_DELAY between enable and start of switching and (64h) TOFF_DELAY between disable and start of voltage ramp down. Soft-Start and Soft-Stop Timing shows the timing.

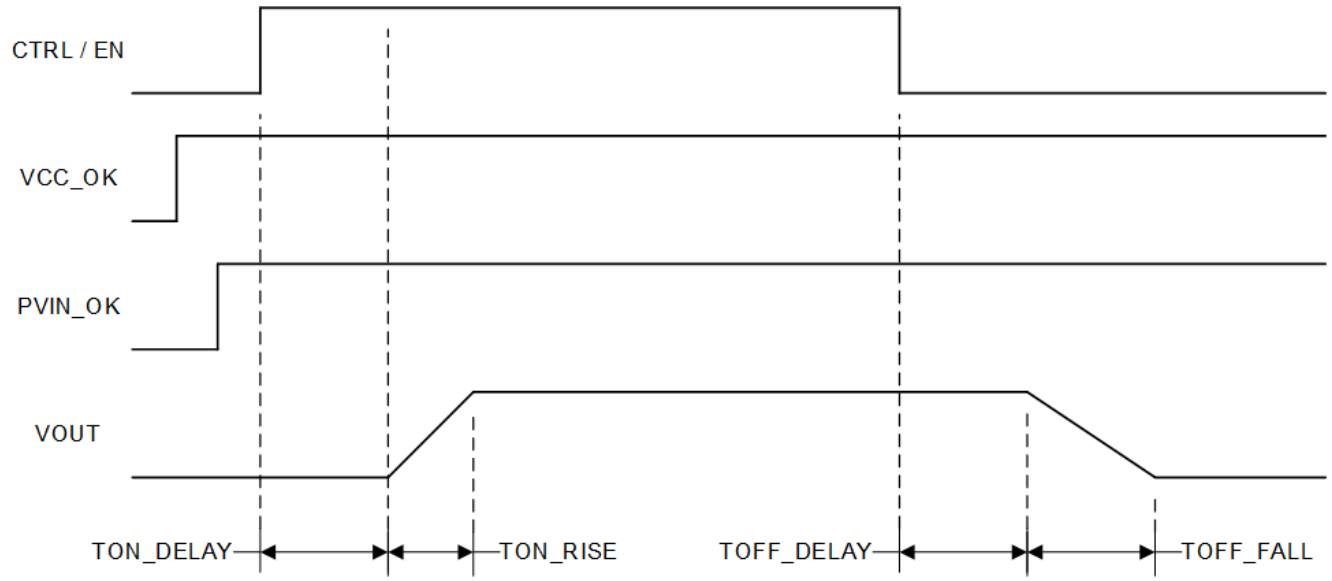

Figure 6-3. Soft-Start and Soft-Stop Timing

Note

In practice, the V_{OUT} fall time is not exactly equal to (65h) TOFF_FALL because the device stops switching after the output voltage is discharged to V_{OUT}= 50mV in internal feedback or V_{FB} = 50mV in external feedback.

6.3.11 Power Good

The device has a power-good (PG or PGOOD) output that goes high to indicate when the converter output is in regulation. The power-good output is an open-drain output and must be pulled up to the VCC pin or an external voltage source (< 5.5V) through a pullup resistor (typically 30.1kΩ) to go high. The recommended power-good pullup resistor value is 1kΩ to 100kΩ.

Copyright © 2026 Texas Instruments Incorporated

Note

For systems using an external voltage source to pull up the PG pin, TI recommends that this same external voltage source also be used to bias the VCC pin.

After the soft-start ramp finishes, the power-good signal becomes high after a internal delay t_{PG_DLY}. An internal soft-start done signal goes high when the SS voltage reaches $V_{SS(DONE)}$ to indicate the soft-start ramp has finished. If the FB voltage drops to 80% of the V_{REF} voltage or exceeds 116% of the V_{REF} voltage, the power-good signal latches low after a 4µs internal delay. The power-good signal can only be pulled high again after re-toggling EN or a reset of VIN.

If an OV event causes the FB voltage to exceed the OV threshold during soft start, but the FB voltage drops below the OV threshold before soft-start is completed, the power-good signal does not latch low until FB exceeds the OV threshold or drops below UV threshold. The OV or UV event must occur after the soft-start ramp finishes for the power-good signal to latch low. FB exceeding the OV threshold during soft start does, however, trigger the OV fault, and the devices response to OV (described in *Overvoltage and Undervoltage Protection*) typically pulls the output voltage below the UV threshold.

If the input supply fails to power up the device (for example, VIN and VCC both stay at zero volts) and this pin is pulled up through an external resistor, the power-good pin clamps low to the low-level specified in the POWER GOOD section in *Specifications*.

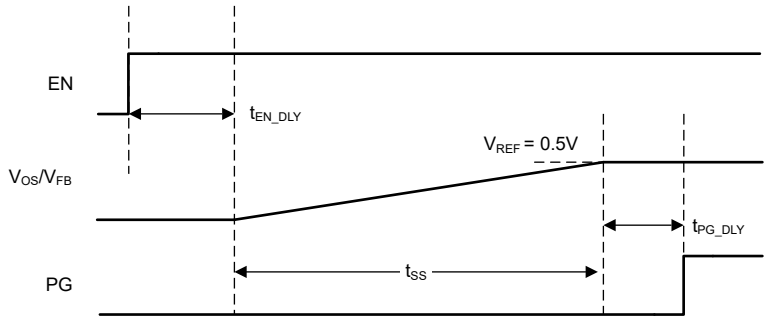

Figure 6-4. EN, SS, & PG Timing Diagram

6.3.12 Overvoltage and Undervoltage Protection

The device monitors a resistor-divided feedback voltage to detect overvoltage and undervoltage events. The OVP function enables when the output is enabled. The UVP function enables after the soft-start period is complete.

After soft start is complete, if the FB voltage becomes lower than 80% of the V_{REF} voltage, the UVP comparator trips and an internal UVP delay counter begins counting. After the 70µs UVP delay time, depending on the selected fault recovery mode in (45h) VOUT_UV_FAULT_RESPONSE, the device either hiccups and re-starts after a sleep time of 56ms or latches off both high-side and low-side MOSFETs. The latch-off fault can be cleared with a reset of VIN or by toggling the EN pin. When a UVP fault occurs, the VF bit in (79h) STATUS_WORD is set and can be cleared with (03h) CLEAR_FAULTS.

When the output is enabled, the FB voltage must rise above the 92.5% PG low-to-high threshold to clear the UVP comparator. If the FB voltage does not exceed the 92.5% threshold by the end of the soft-start period, the device responds to the undervoltage event.

During the UVP delay time, if the FB voltage becomes higher than the 92.5% PG low-to-high threshold, the undervoltage event is cleared and the timer is reset to zero. When the output voltage falls below the 80% UVP threshold again, the 70-µs timer re-starts.

When the FB voltage becomes higher than 116% of the V_{REF} voltage, the OVP comparator trips and the circuit latches the fault condition and drives the PG pin low. The high-side MOSFET turns off and the low-side MOSFET turns on until reaching a negative current limit I_{NOCL}. Upon reaching the negative current limit, the low-side

ADVANCE INFORMATION

Copyright © 2026 Texas Instruments Incorporated

MOSFET is turned off, and the high-side MOSFET is turned on again, for a proper on-time (determined by $V_O/V_{IN}/f_{SW}$). The device operates in this mode until the output voltage is pulled down under the UVP threshold. The device then responds to the undervoltage event as defined in (41h) VOUT_OV_FAULT_RESPONSE. When an OVP fault occurs, both the OVF bit in (78h) STATUS_BYTE and the VF bit in (79h) STATUS_WORD are set and can be cleared with (03h) CLEAR_FAULTS.

If there is an overvoltage condition before the output being enabled (such as a high prebiased output), the device responds to the overvoltage event as described above at the beginning of the soft-start period. The device waits until the completion of the soft-start period for UVP to be enabled, and depending on the selected fault recovery mode, the device either hiccups and re-starts after a sleep time of 56ms or latches off .

When the fault response is set through pinstrap, the fault response is identical for both OVP and UVP. However, if different responses are desired, the responses can be set independently through (41h) VOUT_OV_FAULT_RESPONSE and (45h) VOUT_UV_FAULT_RESPONSE

As an additional layer of protection, the device implements a fixed OVP that, unlike the percentage-based OVP, is active even before soft start is complete. The fixed OVP thresholds are determined by (29h) VOUT_SCALE_LOOP and can be enabled and disabled in (D1h) SYS_CFG_USER1. Table 6-11 shows the fixed OVP thresholds.

Table 6-11. Fixed OVP Thresholds

VOUT_SCALE_LOOP (V/V)	FIXED OVP THRESHOLD (V)
1	1.1
0.5	2.2
0.25	4.4
0.125	6.6

6.3.13 Remote Sense

The device integrates a remote sense amplifier across the VOS/FB and GOS pins. The remote sense function compensates for voltage drop on the PCB traces helping to maintain V_{OUT} accuracy under steady state operation and load transient events.

For internal feedback, the VOS/FB and GOS pins must be connected directly the point of remote sensing. For external feedback, the top of R_{FB_T} and GOS must be connected to the point of remote sensing. When external feedback is used, the voltage divider must be kept as close to the device as possible to minimize the trace length connected to the VOS/FB pin.

Regardless of internal or external feedback, connections from the sensing network to the remote location must be a pair of PCB traces with Kelvin sensing across a high-frequency local bypass capacitor of 0.1µF or higher. To maintain stable output voltage and minimize the ripple, the pair of remote sensing lines must stay away from any noise sources such as inductor and SW nodes, or high frequency clock lines. TI recommends to shield the pair of remote sensing lines with ground planes above and below.

Single-ended V_{OUT} sensing is often used for local sensing. For this configuration, connect either VOS (internal) or top of R_{FB_T} (external) to a high-frequency local bypass capacitor of 0.1µF or higher at point of local sense and short GOS to AGND.

The recommended GOS operating range (relative to the AGND pin) is –100mV to +100mV.

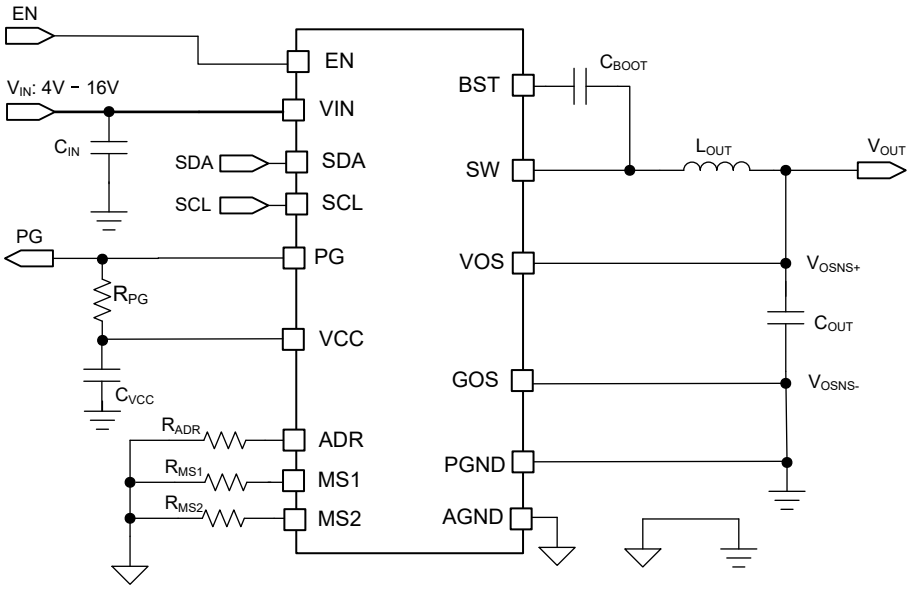

Figure 6-5. Output Voltage Setting Through Internal Feedback and Remote Sense

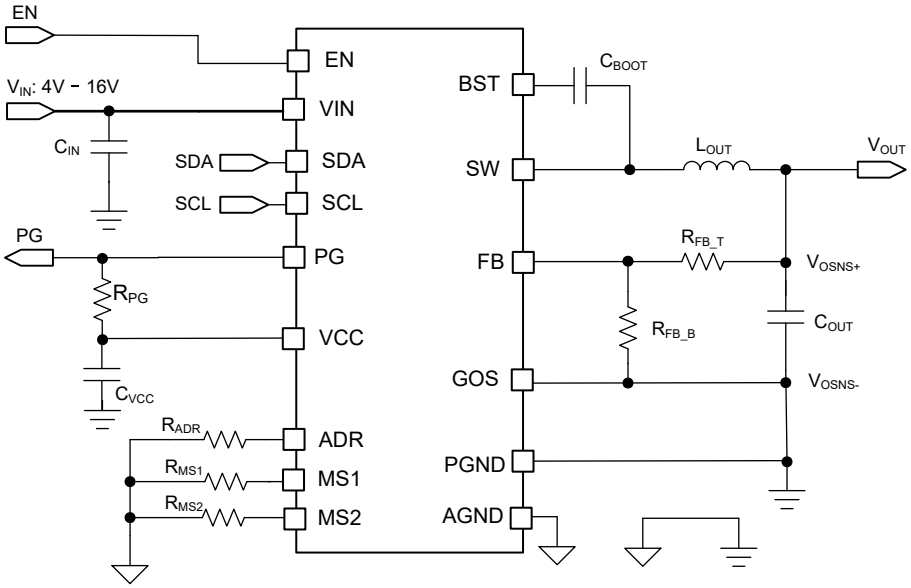

Figure 6-6. Output Voltage Setting Through External Feedback and Remote Sense

Some users prefer a blended sensing scheme where both local and remote sense information is fed back to the device. This topology has the added benefit of an extra layer of protection in the event the remote sense traces are damaged or disconnected. See Blended Remote Sense for an example of blended remote sense.

ADVANCE INFORMATION

ADVANCE INFORMATION

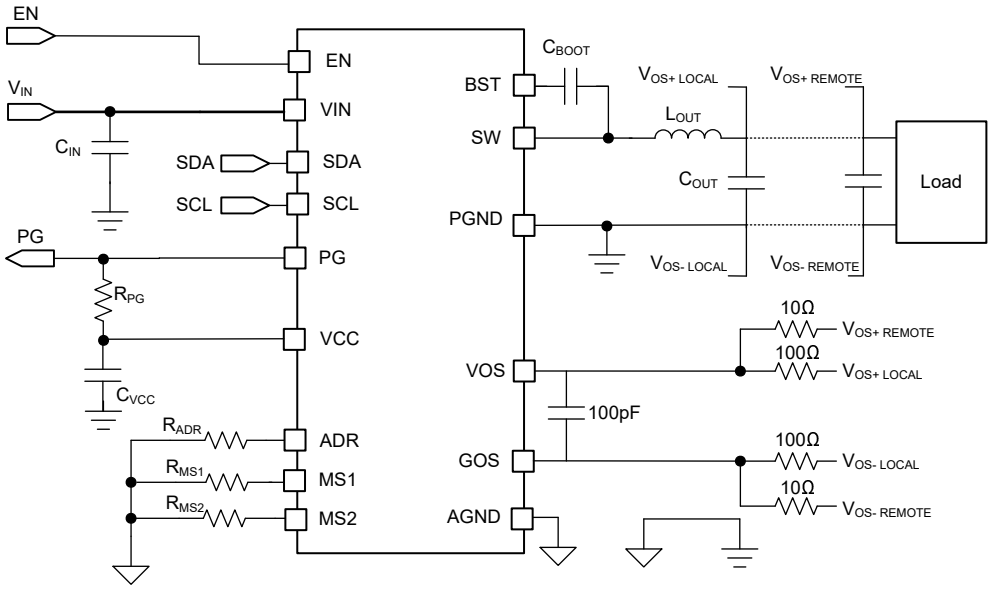

Figure 6-7. Blended Remote Sense

6.3.14 Low-side MOSFET Zero-Crossing

The device uses a zero-crossing (ZC) circuit to perform the zero inductor current detection during skip-mode operation. The ZC threshold is set to a small negative value before the low-side MOSFET is turned off, entering discontinuous conduction mode (DCM) operation. After entering DCM, the ZC threshold hysteresis increases the threshold to a small positive value after entering DCM. As a result, the device delivers better light-load efficiency.

When the load current increases enough such that the device exits DCM, the ZC circuit must detect 16 consecutive cycles of negative inductor current below the ZC threshold before returning to DCM. Only one cycle without ZC detection is required to exit DCM.

When the output is enabled, the ZC circuit is also enabled during the first 32 switching cycles while the device is in soft start. If the device is configured for FCCM, ZC is disabled and the device transitions to FCCM when soft start is complete. See *Soft Start* for a description on soft-start completion. If there are not at least 32 switching cycles before soft-start is done, such as during start-up with a high output prebias, the ZC is not disabled until the first high-side MOSFET on-time after soft-start done is complete.

6.3.15 Current Sense and Positive Overcurrent Protection

For a buck converter, during the on-time of the high-side MOSFET, the switch current increases at a linear rate determined by the input voltage, output voltage, on-time, and output inductor value. During the on-time of the low-side MOSFET, the current decreases linearly. The average value of the switch current equals the load current.

The output overcurrent limit (OCL) in the device is implemented using a cycle-by-cycle valley current detect control circuit. The inductor current is monitored during the on-time of the low-side MOSFET by measuring the low-side MOSFET drain-to-source current. If the measured drain-to-source current of the low-side MOSFET is above the current limit threshold, the low-side MOSFET stays ON until the current level becomes lower than the current limit threshold. This type of behavior reduces the average output current sourced by the device.

The OCL can be set through pinstrap as outlined in Section 6.3.3 along with through the digital interface through IOUT_OC_FAULT_LIMIT. Table 6-12 lists the digitally selectable OCL options.

Table 6-12. IOUT_OC_FAULT_LIMIT Enumeration List

IOUT_OC_FAULT_LIMIT [4:0]		OVERCURRENT LIMIT (A)
≥	≤	
0d	4d	2

Copyright © 2026 Texas Instruments Incorporated

Table 6-12. IOUT_OC_FAULT_LIMIT Enumeration List (continued)

IOUT_OC_FAULT_LIMIT [4:0]		OVERCURRENT LIMIT (A)
≥	≤	
5d	8d	4
9d	11d	5
12d	13d	6
14d	16d	7
17d	19d	7
20d	31d	7

During an overcurrent condition, the current to the load exceeds the current to the output capacitors. Thus, the output voltage tends to decrease. Eventually, when the output voltage falls below the undervoltage-protection threshold (80%), the UVP comparator detects the fall and shuts down the device after a wait time of 70µs. Depending on the fault recovery configuration, the device either hiccups or latches off, as described in *Overvoltage and Undervoltage Protection*.

Note

If an OCL condition happens during start-up, the device still has cycle-by-cycle current limit based on low-side valley current, but the UVP comparator does not shut down the device until after soft start has completed.

When a positive overccurent condition occurs, both the OCF bit in (78h) STATUS_BYTE and the CF bit in (79h) STATUS_WORD are set and can be cleared with (03h) CLEAR_FAULTS.

6.3.16 Low-side MOSFET Negative Current Limit

The device has a fixed, cycle-by-cycle negative overcurrent limit ($I_{LS(NOC)}$). Similar with the positive overcurrent limit, the inductor current is monitored during the on-time of the low-side MOSFET. To prevent too large negative current flowing through the low-side MOSFET, when the device detects a -3A current (typical threshold) through the low-side MOSFET, the device turns off the low-side MOSFET and then turns on the high-side MOSFET for the on-time set by the one-shot timer (determined by $V_{IN}/V_{OUT}/f_{SW}$). After the high-side MOSFET on-time expires, the low-side MOSFET turns on again.

The device must not trigger the -3A negative current limit threshold during nominal operation, unless a small inductor value that is too small is chosen or the inductor becomes saturated. This negative current limit is used to discharge output capacitors after an output OVP event. See also *Overvoltage and Undervoltage*.

When a negative overcurrent condition occurs, the CF bit in (79h) STATUS_WORD is set and can be cleared with (03h) CLEAR_FAULTS.

6.3.17 Output Voltage Discharge

When the device is disabled through EN or the digital interface, the device enables the output voltage discharge mode. This mode forces both high-side and low-side MOSFETs to latch off, but turns on the internal discharge MOSFET connected from SW to PGND to discharge the output voltage. After the FB voltage drops below 50mV, the discharge MOSFET is turned off.

If the device is configured for soft-stop in (01h) OPERATION, then the output voltage discharge mode is not used and the device instead responds as defined in Section 6.3.10.

6.3.18 UVLO Protection

The device monitors the voltage on both the VIN and the VCC pins.

When the VIN pin voltage is lower than the VIN_{UVLO} falling threshold voltage but the VCC pin is biased with an external voltage, the device stops switching. After the VIN voltage increases beyond the VIN_{UVLO} rising threshold voltage, the device re-initiates the soft start and switches again. VIN UVLO is a non-latch protection.

ADVANCE INFORMATION

6.3.19 Telemetry

The telemetry sub-system in the TPS544628 supports the following measurements:

- Output voltage through (8Bh) READ_VOUT
- Output current through READ_IOUT
- Die temperature through (8Dh) READ_TEMP

The ADC output is a single conversion of each measurement without rolling window averaging for fast refresh of these key system parameters. All parameters are measured on demand at time of function call. (8Bh) READ_VOUT always reports the voltage as measured between the VOS/FB and GOS pins, regardless of internal versus external feedback. Therefore, when external feedback is used, this function reports the reference voltage not the true output voltage.

6.3.20 Thermal Shutdown

The device monitors internal junction temperature. If the temperature exceeds the threshold value (typically 165°C), the device stops switching. When the temperature falls approximately 15°C below the threshold value, the device turns back on with a re-initiated soft start. Thermal shutdown is a non-latch protection.

When an overtemperature fault condition occurs, the OTF bit in (78h) STATUS_BYTE is set and can be cleared with (03h) CLEAR_FAULTS.

6.4 Device Functional Modes

6.4.1 Auto-Skip (PFM) Eco-mode Light Load Operation

If Skip (PFM)-mode is selected through the PMBus interface, the device automatically reduces the switching frequency at light-load conditions to maintain high efficiency. See the *Programming Registers* section on how to select the PFM mode.

As the output current decreases from heavy load condition, the inductor current also decreases until the valley of the inductor ripple current touches the zero-crossing threshold (*Low-side MOSFET Zero-Crossing*). The zero-crossing threshold sets the boundary between the continuous-conduction and discontinuous-conduction modes. The synchronous MOSFET turns off when this zero-crossing threshold is detected. As the load current decreases further, the converter runs into discontinuous-conduction mode (DCM). The on-time is maintained to a level approximately the same as during continuous-conduction mode operation so that discharging the output capacitor with a smaller load current to the level of the reference voltage requires more time. Use Equation 5 to calculate the transition point to light-load operation $I_{OUT(LL)}$ (for example: the boundary between continuous- and discontinuous-conduction mode).

For low output ripple, TI recommends using only ceramic output capacitors for designs that operate in skip-mode.

$$I_{OUT(LL)} = \frac{1}{2} \times \frac{(V_{IN} - V_O) \times V_O}{V_{IN}} \times \frac{1}{L \times f_{SW}} \quad (5)$$

6.4.2 Forced Continuous-Conduction Mode

If FCCM mode is selected through the PMBus interface, the controller operates in continuous-conduction mode (CCM) during light-load conditions. See the *Programming Registers* section on how to select the FCCM mode.

During FCCM, the switching frequency is maintained to an almost constant level over the entire load range, which is designed for applications requiring tight control of the switching frequency and output ripple at the cost of reduced light-load efficiency. Use Equation 5 to calculate the typical light-load operation boundary. Below this calculated load current, the device operates in FCCM.

7 Programming Registers

The Supported PMBus Registers and Default Values Table lists the implemented registers and also the default for the bit behavior and register values.

Table 7-1. Supported PMBus® Register and Default Values

REGISTER ADDRESS	REGISTER NAME	R/W	NVM	DEFAULT VALUE (HEX)	DEFAULT BEHAVIOR
01h	OPERATION	R/W	NO	00h	No voltage margining.
02h	ON_OFF_CONFIG	R/W	YES	16h	Turn ON/OFF by EN pin only. When turning off use TOFF_DELAY and TOFF_FALL.
03h	CLEAR_FAULTS	W	NO	N/A	Clear all faults.
10h	WRITE_PROTECT	R/W	YES	00h	All commands are writable.
15h	STORE_USER_ALL	W	NO	N/A	Stores all current storable register settings into NVM.
16h	RESTORE_USER_ALL	W	NO	N/A	Restores all storable register settings from NVM.
19h	CAPABILITY	R	NO	C0h	Defines the capability of the device.
20h	VOUT_MODE	R	NO	96h	Read only. See command description.
21h	VOUT_COMMAND	R/W	NO	VBOOT	Sets output voltage. Overridden by pinstrap on MS2.
25h	VOUT_MARGIN_HIGH	R/W	NO	210h	Sets the margin high percentage when enabled in OPERATION
26h	VOUT_MARGIN_LOW	R/W	NO	1F0h	Sets the margin low percentage when enabled in OPERATION
27h	VOUT_TRANSITION_RATE	R/W	NO	E81Ah	Sets the rate the output voltage changes in mV/µs. 3.25mV/µs by default.
29h	VOUT_SCALE_LOOP	R	NO	VBOOT	Sets internal resistor divider ratio. Overridden by pinstrap on MS2.
33h	FREQUENCY_SWITCH	R/W	YES	3805h	Sets the switching frequency. 600kHz by default. Overridden by pinstrap on MS1
41h	VOUT_OV_FAULT_RESPONSE	R/W	YES	BFh	Sets the Vout OV fault response. Hiccup by default. Overridden by pinstrap on ADR.
45h	VOUT_UV_FAULT_RESPONSE	R/W	YES	7Ah	Sets the Vout UV fault response. Hiccup by default. Overridden by pinstrap on ADR.
46h	IOUT_OC_FAULT_LIMIT	R/W	YES	F80Fh	Sets the Overcurrent Limit. 7A by default. Overridden by pinstrap on MS1.
60h	TON_DELAY	R/W	YES	0000h	50µs turn-on delay.
61h	TON_RISE	R/W	YES	F802h	1ms between start of switching and entry into regulation band. Overridden by pinstrap on MS1.
64h	TOFF_DELAY	R/W	YES	0000h	No turn-off delay.
65h	TOFF_FALL	R	NO	TON_RISE	Value mirrored between TON_RISE and TOFF_FALL
78h	STATUS_BYTE	R	NO	41h	Current status
79h	STATUS_WORD	R	NO	0841h	Current status
7Eh	STATUS_CML	R	NO	0h	Current status
80h	STATUS_MFR_SPECIFIC	R	NO	0h	Current status
8Bh	READ_VOUT	R	NO	N/A	Sensed output voltage.
8Ch	READ_IOUT	R	NO	N/A	Sensed output current.
8Dh	READ_TEMP1	R	NO	N/A	Sensed junction temperature.
98h	PMBUS_REVISION	R	NO	55h	PMBus 1.4
99h	MFR_ID	R	NO	4954h	ASCII for "TI"
9Ah	MFR_MODEL	R	NO	54462800h	IC part number.
9Bh	MFR_REVISION	R/W	YES	00h	All zeros.
ADh	IC_DEVICE_ID	R	NO	544954462800h	IC part number.
AEh	IC_DEVICE_REV	R	NO	09h	IC revision.
D1h	SYS_CFG_USER1	R/W	YES	51h	FCCM and Fixed OVF enabled. Top nibble of ADR is 5h.
D2h	PASSKEY	R/W	YES	00h	Passkey unset and unlocked.
D4h	COMP	R/W	YES	02h	See register description.

7.1.1 OPERATION (Address = 01h)

OPERATION is shown in Figure 7-1 and described in Table 7-4.

Return to the Summary Table.

Write Transaction: Write Byte
Read Transaction: Read Byte
Data Format: Unsigned Binary (1 byte)
NVM Back-up: No
Updates: On-the-fly

The OPERATION command is used to turn the device output on or off, in conjunction with the input from the EN pin, according to the configuration of the ON_OFF_CONFIG command. It is also used to set the output voltage to the upper or lower MARGIN levels, and select soft-stop when turned off through OPERATION.

Figure 7-1. OPERATION

7	6	5	4	3	2	1	0
ON	OFF	MARGIN				RESERVED	
R/W-0h	R/W-0h	R/W-0h				R-0h	

Table 7-4. OPERATION Field Descriptions

Bit	Field	Type	Reset	Description
7	ON	R/W	0h	Turn the device output on or off when the ON_OFF_CONFIG command is configured with its CMD bit high. There can be several other requirements that must be satisfied before the power conversion can begin. The input voltages must be above their UVLO thresholds and, if the CPR bit in ON_OFF_CONFIG is high, the enable pin must be high. 0h = The device output is off 1h = The device output is on
6	OFF	R/W	0h	Sets the turn-off behavior when commanding the device output off via OPERATION[7] (the ON bit transitions from 1 to 0) and when the ON_OFF_CONFIG command is configured with its CMD bit high. If the ON bit is 1, then the OFF bit is ignored. 0h = Immediately turn the device output off forcing the power stage to a high-Z state, not honoring the programmed TOFF_DELAY and programmed TOFF_FALL, when commanded off via OPERATION[7]. 1h = Soft off. Use the programmed turn-off delay in TOFF_DELAY and ramp down in TOFF_FALL when commanded off via OPERATION[7].
5-2	MARGIN	R/W	0h	Sets the margin state, independent of the OPERATION[7] bit value. Values other than those listed below are invalid/unsupported data. If margin is off, the output voltage source is VOUT_COMMAND and OV/UV faults behave normally as programmed in their respective fault response registers. 0h = Margin off and faults behave as programmed. 1h = Margin off and faults behave as programmed. 2h = Margin off and faults behave as programmed. 3h = Margin off and faults behave as programmed. 5h = Margin low (Ignore fault). Output voltage target uses VOUT_MARGIN_LOW. UV faults are ignored and do not trigger shut-down, but will trigger STATUS updates. 6h = Margin low (Act on fault). Output voltage target uses VOUT_MARGIN_LOW. OV/UV faults trigger per their respective fault response settings. 9h = Margin high (Ignore fault). Output voltage target uses VOUT_MARGIN_HIGH. OV faults are ignored and do not trigger shut-down, but will trigger STATUS updates. Ah = Margin high (Act on fault). Output voltage target uses VOUT_MARGIN_HIGH. OV/UV faults trigger per their respective fault response settings.

7.1.3 CLEAR_FAULTS (Address = 03h)

CLEAR_FAULTS is shown in Figure 7-3 and described in Table 7-6.

Return to the Summary Table.

Write Transaction: Send Byte
Read Transaction:N/A
Data Format: Data-less
NVM Back-up: No
Updates: On-the-fly

CLEAR_FAULTS is a command used to clear any fault bits that have been set. This command clears all bits in all status registers. CLEAR_FAULTS is a write-only command with no data.

The CLEAR_FAULTS command does not cause a unit that has latched off for a fault condition to restart. If the fault is still present when the bit is cleared, the fault bit is immediately set again and the host is notified by the usual means

7.1.5 STORE_USER_ALL (Address = 15h)

STORE_USER_ALL is shown in Figure 7-5 and described in Table 7-8.

Return to the Summary Table.

Write Transaction: Send Byte
Read Transaction: N/A
Data Format: Data-less
NVM Back-up: No
Updates: On-the-fly

The STORE_USER_ALL command instructs the PMBus device to store the current register settings to non-volatile memory.

Due to the EEPROM programming time, the duration of this command is approximately 125ms. For any incoming PMBus traffic while the device is busy programming EEPROM, the device will ACK its device address; but, NACK any other bytes (as well as returns all 1s for data) per PMBus Part II section 10.8.7. The device will not set any status for NACKd transactions during EEPROM programming.

EEPROM programming faults will set the cml bit in the (78h) STATUS_BYTE and the oth bit in the (7Eh) STATUS_CML registers.

NVM store operations are not recommended while the output is enabled (although the user is not explicitly prevented from doing so) as interruption can result in a corrupted NVM. Following issuance of an NVM store command, TI recommends disabling regulation and waiting a minimum of 125 ms before continuing.

7.1.6 RESTORE_USER_ALL (Address = 16h)

RESTORE_USER_ALL is shown in Figure 7-6 and described in Table 7-9.

Return to the Summary Table.

Write Transaction: Send Byte
Read Transaction: N/A
Data Format: Data-less
NVM Back-up: No
Updates: On-the-fly

The RESTORE_USER_ALL command instructs the PMBus device to copy the entire contents of the non-volatile User Store Memory to the matching locations in the Operating Memory. Any values set through a Pin Detection during the last power-cycle will overwrite the values in Operating Memory, also overwriting the value retrieved from the User Store.

Note

It is permitted to use the RESTORE_USER_ALL command while the output is enabled. However, PMBus commands will be ignored during the copy operation and there can be unpredictable, undesirable, or even catastrophic results if done while the output is enabled. TI recommendeds to turn the device output off before issuing this command through the method programmed into ON_OFF_CONFIG.

7.1.9 VOUT_COMMAND (Address = 21h)

VOUT_COMMAND is shown in Figure 7-9 and described in Table 7-12.

Return to the Summary Table.

Write Transaction: Write Word
Read Transaction: Read Word
Data Format: ULINEAR16 0.976mV per VOUT_MODE LSB
NVM Back-up: No
Updates: On-the-fly

When PMBus is used to set the regulated voltage, the commanded output voltage in volts is determined by a combination of VOUT_COMMAND, VOUT_MARGIN_HIGH, VOUT_MARGIN_LOW, and OPERATION commands. As stated in the description of the VOUT_MODE command, the VOUT_MODE step size is 0.976 mV.

The range of recommended VOUT_COMMAND values is dependent upon the configured (29h) VOUT_SCALE_LOOP. The design does not limit the VOUT_COMMAND value to be within this recommended range. However, there is a max clamp on VOUT_COMMAND to 5.5V. This max clamp is not affected when doing MARGIN_HIGH. There is no min clamp for low voltages.

At power up, the reset value of VOUT_COMMAND is derived from VBOOT/VOUT_SCALE_LOOP . When the rail is disabled by the mechanism programmed to ON_OFF_CONFIG or due to a fault, the value in VOUT_COMMAND is updated to VBOOT.

Note

This register can be changed during soft-start or soft-stop. However, the rail will continue to ramp up/down to the original target (VBOOT) at the rate programmed into TON_RISE/TOFF_FALL. After soft-start completes (and if VOUT_COMMAND is different from the VBOOT value), the device will immediately transition from the VBOOT value to the latest written VOUT_COMMAND at the programmed VOUT_TRANSITION_RATE.

During regulation, preemptive writes to VOUT_COMMAND are allowed even if the DAC is still slewing to a previously programmed VOUT_COMMAND. The device will immediately start slewing to the new target at the rate programmed into VOUT_TRANSITION_RATE.

7.1.12 VOUT_TRANSITION_RATE (Address = 27h)

VOUT_TRANSITION_RATE is shown in Figure 7-12 and described in Table 7-16.

Return to the Summary Table.

Write Transaction: Write Word
Read Transaction: Read Word
Data Format:LINEAR11
NVM Back-up: No
Updates: On-the-fly

When a PMBus device receives either a VOUT_COMMAND, or OPERATION (Margin High, Margin Low, Margin Off), that causes the output voltage to change, this command sets the rate in mV/us at which the output should change voltage. This commanded rate of change does not apply when the unit is commanded to turn on or to turn off.

Data Validity:
Writes to the read-only bits in the exponent and mantissa will be ignored and their value will not be updated. Every binary combination in the read/write mantissa bits is writeable and readable. However, the actual output voltage slew rate is set to the nearest supported setting. Additionally, the mantissa value restored from EEPROM is fixed for each supported setting.

7.1.21 TON_RISE (Address = 61h)

TON_RISE is shown in Figure 7-19 and described in Table 7-27.

Return to the Summary Table.

Write Transaction: Write Word
Read Transaction: Read Word
Data Format: LINEAR11
NVM Back-up: EEPROM
Updates: On-the-fly

The TON_RISE command sets the time, in milliseconds, from when the output starts to rise until the voltage has entered the regulation band, which effectively sets the slew rate of the reference DAC during the soft-start period. The soft-start time varies from the TON_RISE selection when VOUT_COMMAND is used for boot up. See section Start-Up and Shutdown for more details.

7.1.23 TOFF_FALL (Address = 65h)

TOFF_FALL is shown in Figure 7-21 and described in Table 7-30.

Return to the Summary Table.

Write Transaction: N/A
Read Transaction: Read Word
Data Format: LINEAR11
NVM Back-up: EEPROM
Updates: On-the-fly

The TOFF_FALL command sets the time, in milliseconds, from the end of the turn-off delay time until the reference DAC is commanded to 0mV. This command is used to cause the output voltage to decrease at a controlled rate, which effectively sets the slew rate of the reference DAC during the soft-off period. In the implementation of TOFF_FALL, the VREF DAC slew rate is adjusted for each of the supported 32 VBOOT levels to obtain a slew rate to have a soft-stop time close to (but not always exactly equal to) the target value. The selected slew rate for the 0.5ms TOFF_FALL is the same as shown in TON_RISE but with a negative slope. TOFF_FALL is scaled in the same manner as TON_RISE with the different settings.

In practice, the VOUT fall time is not exactly equal to TOFF_FALL value since the device stops switching once the output voltage is discharged to 50mV.

ADVANCE INFORMATION

7.1.24 STATUS_BYTE (Address = 78h)

STATUS_BYTE is shown in Figure 7-22 and described in Table 7-31.

Return to the Summary Table.

Write Transaction: N/A
Read Transaction: Read Byte
Data Format: Unsigned Binary (1 byte)
NVM Back-up: No
Updates: On-the-fly

The STATUS_BYTE command returns one byte of information with a summary of the most critical faults, such as overvoltage, overcurrent, overtemperature, etc. The supported STATUS_BYTE message content is described in the following table. The STATUS_BYTE is equal the low byte of STATUS_WORD. The conditions in the STATUS_BYTE are summary information only. They are asserted to inform the host as to which other STATUS registers should be checked in the event of a fault. Clearing individual faults is not supported. All fault bits must be cleared simultaneously via the (03h) CLEAR_FAULTS command .

Figure 7-22. STATUS_BYTE

Table 7-44. SYS_CFG_USER1 Field Descriptions

Bit	Field	Type	Reset	Description
7	RESERVED	R	0h	Reserved
6	FCCM	R/W	X	Forced CCM operation. **On reset the value will be determined by NVM.** 0h = DCM operation is enabled and automatically entered/exited based on zerocrossing detection of the LFET sensed current. 1h = Forces continuous conduction in the switching converter.
5	PMB_LOCK	R/W	X	This bit controls write access to the PASSKEY command. **On reset the value will be determined by NVM.** 0h = As defined in the PASSKEY command description. 1h = Writes to PASSKEY are NACKed with ivc.
4	ADDR_CFG	R/W	X	This bit selects the PMBus device address range selected by ADR pins pinstrap, as below: **On reset the value will be determined by NVM.** 0h = Top nibble of ADR is 2h. 1h = Top nibble of ADR is 3h. This bit takes effect only after writing it, sending a STORE_USER_ALL command and performing a POWER_ON_RESET, or sending the PMBus command RESTORE_USER_ALL.
3	RESERVED	R	0h	Reserved
2	SEL_LC_H	R/W	X	This bit adjusts the control loop response and can help boost phase margin for BOMs with large output LC (LC double pole around 10-15kHz). **On reset the value will be determined by NVM.** 0h = Default loop response. 1h = Modified loop response.
1	NRSA_L	R/W	X	This bit selects lower values of NRSA when set to 1 and higher values of NRSA when set to 0 for some vboot voltages. Refer to table in VOUT_SCALE_LOOP. **On reset the value will be determined by NVM.**
0	EN_FIX_OVF	R/W	X	This bit is used to enable the fixed OV fault. **On reset the value will be determined by NVM.** 0h = Fixed OVF is disabled. 1h = Fixed OVF is enabled.

ADVANCE INFORMATION

7.1.38 PASSKEY (Address = D2h)

PASSKEY is shown in Figure 7-36 and described in Table 7-45.

Return to the Summary Table.

Write Transaction: Write Block (1 byte)
Read Transaction: Read Block (3 byte)
Data Format: Unsigned Binary (1 byte)
NVM Back-up: EEPROM
Updates: On-the-fly

Passkey provides a user the ability to lock access to (15h) STORE_USER_ALL and (10h) WRITE_PROTECT with a user programmed 8-bit value. On reads, PASSKEY will return 3 bytes with the upper two bytes mirroring the NVM_CHECKSUM and the lowest byte reflecting the current PASSKEY status. When unlocked, the lowest byte of PASSKEY reads back 00h.

When PASSKEY is unlocked after Power On Reset or RESTORE_USER_ALL:
Non-volatile memory is unlocked. WRITE_PROTECT is unlocked and writeable. STORE_USER_ALL functions normally. A READ on PASSKEY will return 00h. WRITE will update PASSKEY, but the value must be stored to NVM via STORE_USER_ALL to take effect.

When PASSKEY is locked after Power On Reset or RESTORE_USER_ALL:
Non-volatile memory is locked. STORE_USER_ALL and WRITE_PROTECT shall be NACKED as "UNSUPPORTED or INVALID DATA."
A READ on PASSKEY will report a value of:
– 10h if no invalid attemps have been made to unlock PASSKEY
– 11h if One invalid attempt has been made to unlock PASSKEY
– 12h if Two invalid attempts have been made to unlock PASSKEY
– 1Fh if Three or more invalid attempts have been made to unlock PASSKEY.

The invalid access attempt counter will be reset only after a Power On Reset.

After PASSKEY is set, a RESTORE_USER_ALL or WRITE to PASSKEY with incorrect value will increment the counter as outlined above. After 3 incorrect attempts, further WRITE attempts will be ACKed, with no STATUS bits set, but the PASSKEY shall remain locked even if the matching PASSKEY value is written. If the WRITE data matches the PASSKEY and less than three invalid attempts have been made, PASSKEY will now read back the current PASSKEY value, and can be overwritten with a new value (including 00h which will leave the device unlocked).The invalid attempt counter will be reset to 0. STORE_USER_ALL and WRITE_PROTECT will allow write access. A STORE_USER_ALL command must be issued for the new PASSKEY value to take effect.

7.1.41 NVM_CHECKSUM (Address = D9h)

NVM_CHECKSUM is shown in Figure 7-39 and described in Table 7-50.

Return to the Summary Table.

Write Transaction: N/A
Read Transaction: Read Word
Data Format: Unsigned Binary (2 bytes)
NVM Back-up: No
Updates: On power cycle or RESTORE_USER_ALL

This command contains CRC value from reading contents of the non-volatile memory (NVM). The value of the checksum will be calculated as CRC-16 (polynomial 8005h). The checksum will be calculated in 8 parallel slices. Any padding needed to make the last word of the input 8 bits will be 0s. The checksum value will be stored in NVM to ensure the integrity of the STORE function. Any corrupted data that happens during a STORE operation will be detected on RESTORE when the user compares the calculated NVM_CHECKSUM with a known good value that is expected.

8 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

8.1 Application Information

The TPS544628 device is a high-efficiency, single-channel, small-sized, synchronous buck converter. The device is designed for low output voltage point-of-load applications with 6A or lower output current in server, storage, and similar computing applications. The TPS544628 features proprietary D-CAP4 mode control combined with adaptive on-time architecture. This combination builds modern low-duty-ratio and ultra-fast load-step-response DC/DC converters in an excellent fashion. The output voltage ranges from to 5.5V. The conversion input voltage ranges from 2.7V to 16V, and the VCC input voltage ranges from 3.1V to 5.3V. The D-CAP4 mode uses emulated current information to control the modulation. An advantage of this control scheme is that this control scheme does not require an external phase-compensation network, which makes the device easy-to-use and also allows for a low external component count. Another advantage of this control scheme is that the control scheme supports stable operation with all low ESR output capacitors (such as ceramic capacitor and low ESR polymer capacitor). Adaptive on-time control tracks the preset switching frequency over a wide range of input and output voltages while increasing switching frequency as needed during a load-step transient.

8.2 Typical Application

The schematic shows a typical application for the TPS544628. This example describes the design procedure of converting an input voltage range of 8V to 16V down to 3.3V with a maximum output current of 6A.

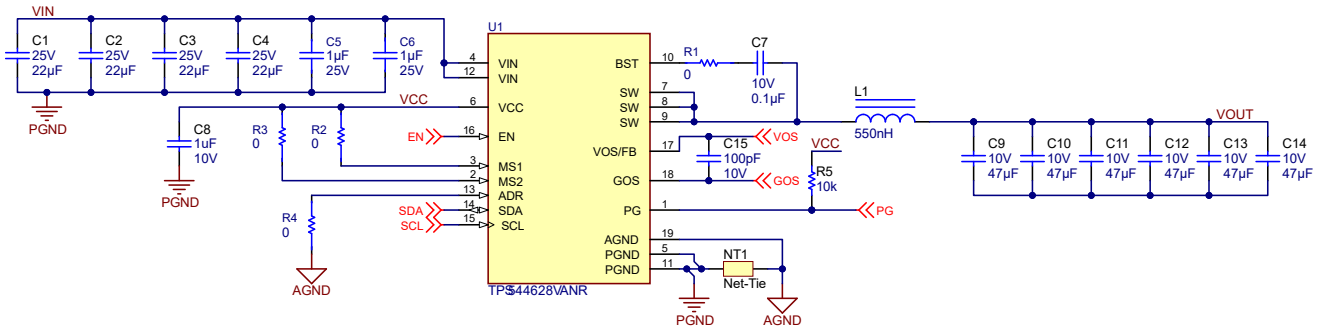

Figure 8-1. Application Circuit Diagram

ADVANCE INFORMATION

8.2.1 Design Requirements

This design uses the parameters listed in the following table.

Table 8-1. Design Example Specifications

SPECIFICATION	TEST CONDITIONS		MIN	TYP	MAX	UNIT
V_{IN} voltage range			8	12	16	V
Input current	V_{IN} = 8V, I_{OUT} = 6A			2.58		A
V_{IN} start voltage	Set by EN pin resistor divider			3.84		V
Output voltage setpoint	V_{OUT} = 3.3V set by MS2 pin selection.			3.3		V
Output current range	V_{IN} = 8V to 16V		0		6	A
Load transient response	I_{OUT} = 0A to 3A	Voltage change		–99		mV
	I_{OUT} = 3A to 0A	Voltage change		99		mV
Output ripple voltage	I_{OUT} = 6A			16		mVPP
Soft-start time	From start of switching to V_{OUT} = 3.3V, t_{SS} = 1ms setting		0.8	1	1.2	ms
Current limit	OCP = 7A setting by MS1 pin selection		6	7	8	A
Switching frequency (f_{SW})	f_{SW} = 800kHz setting by MS1 pin selection			800		kHz
IC case temperature	I_{OUT} = 6A, 15-minute soak			35.1		°C

8.2.2 Detailed Design Procedure

The external component selection is a simple process using D-CAP4 mode. Select the external components using the following steps. The following sections use the TPS544B28 (20A) design procedure as an example, but the equations remain the same.

8.2.2.1 Output Voltage Setting Point

The MS2 pin selects the device output voltage configuration as well as FCCM or PFM operation based on Table 6-4. For this design, use the internal FB configuration option.

If an output voltage other than those is available in Table 6-4 is needed, the external feedback configuration allows the output voltage to be programmed by a voltage-divider resistors, R1 and R2. Connect R1 between the VOS/FB pin and the output, and connect R2 between the VOS/FB pin and GOS. The recommended R2 value is 10kΩ, but the value can also be set to another value between the range of 1kΩ to 20kΩ. Use Equation 6 to determine R1.

$$R1 = R2 \times \left(\frac{V_{OUT}}{V_{REF}} - 1\right) \quad (6)$$

8.2.2.2 Choose the Switching Frequency

For this design, use the internal feedback mode, and the switching frequency is configured by tying the MS1 pin to a pin-strap resistor, GND, or VCC. See also Table 6-3.

Switching frequency selection is a tradeoff between higher efficiency and smaller system design size. Lower switching frequency yields higher overall efficiency but relatively bigger external components. Higher switching frequencies cause additional switching losses which impact efficiency and thermal performance. For this design, connect MS1 pin to VCC to set the switching frequency to 800kHz.

When selecting the switching frequency of a buck converter, the minimum on-time and minimum off-time must be considered. Equation 7 calculates the maximum f_{SW} before being limited by the minimum on-time. When hitting the minimum on-time limits of a converter with D-CAP4 control, the effective switching frequency changes to keep the output voltage regulated. This calculation ignores resistive drops in the converter to give a worst case estimation.

$$f_{SW(max)} = \frac{V_{OUT}}{V_{IN(max)}} \times \frac{1}{t_{ON_MIN}} = \frac{3.3\ V}{16\ V} \times \frac{1}{25\ ns} = 8250\ kHz \quad (7)$$

ADVANCE INFORMATION

Copyright © 2026 Texas Instruments Incorporated

ADVANCE INFORMATION

Equation 8 calculates the maximum f_{SW} before being limited by the minimum off-time. When hitting the minimum off-time limits of a converter with D-CAP4 control, the operating duty cycle maxes out and the output voltage begins to drop with the input voltage. This equation requires the DC resistance of the inductor, R_{DCR}, selected in the following step so this preliminary calculation assumes a resistance of 1.4mΩ. If operating near the maximum f_{SW} limited by the minimum off-time, the variation in resistance across temperature must be considered when using Equation 9. The selected f_{SW} of 800kHz is below the two calculated maximum values.

$$f_{SW}(max) = \frac{V_{IN}(min) - V_{OUT} - I_{OUT}(max) \times \left(R_{DCR} + R_{DS(ON)_HS}\right)}{t_{OFF_MIN}(max) \times \left(V_{IN}(min) - I_{OUT}(max) \times \left(R_{DS(ON)_HS} - R_{DS(ON)_LS}\right)\right)} \quad (8)$$

$$f_{SW}(max) = \frac{8\ V - 3.3\ V - 6\ A \times (1.4\ m\Omega + 21\ m\Omega)}{150\ ns \times (8\ V - 6\ A \times (21\ m\Omega - 7\ m\Omega))} = 3845\ kHz \quad (9)$$

8.2.2.3 Choose the Inductor

To calculate the value of the output inductor (L_{OUT}), use Equation 10. The output capacitor filters the inductor-ripple current ($I_{IND(ripple)}$). Therefore, selecting a high inductor-ripple current impacts the selection of the output capacitor because the output capacitor must have a ripple-current rating equal to or greater than the inductor-ripple current. Larger ripple current increases output ripple voltage, but improves signal-to-noise ratio and helps to stabilize operation. Generally speaking, the inductance value must set the ripple current at approximately 15% to 40% of the maximum output current for a balanced performance.

For this design, the inductor-ripple current is set to 30% of 20A output current. With a 800kHz switching frequency, 16V as maximum V_{IN}, and 3.3V as the output voltage, Based on these parameters, Equation 10 calculates an inductance of 0.546µH. A nearest standard value of 0.55µH is chosen.

$$L = \frac{(V_{IN}(max) - V_{OUT}) \times V_{OUT}}{I_{RIPPLE} \times V_{IN}(max) \times f_{SW}} = \frac{(16\ V - 3.3\ V) \times 3.3\ V}{0.3 \times 20A \times 16\ V \times 800\ kHz} = 0.546\ \mu H \quad (10)$$

The inductor requires a low DCR to achieve good efficiency. The inductor also requires enough room above peak inductor current before saturation. Use Equation 11 to estimate the inductor current ripple. For this design, by tying the MS1 pin to GND with a ≥ 118kΩ resistor, $I_{OC(valley)}$ is set to 21A, thus peak inductor current under maximum V_{IN} is calculated as 22.98 with Equation 12.

$$I_{RIPPLE} = \frac{(V_{IN}(max) - V_{OUT}) \times V_{OUT}}{L \times V_{IN}(max) \times f_{SW}} = \frac{(16\ V - 3.3\ V) \times 3.3\ V}{0.55\mu H \times 16\ V \times 800\ kHz} = 5.95\ A \quad (11)$$

$$I_{L(PEAK)} = I_{OUT} + \frac{I_{RIPPLE}}{2} = 20\ A + \frac{5.95\ A}{2} = 22.98\ A \quad (12)$$

$$I_{L(RMS)} = \sqrt{{I_{OUT}}^2 + \frac{{I_{RIPPLE}}^2}{12}} = \sqrt{{20\ A}^2 + \frac{{5.95\ A}^2}{12}} = 20.07\ A \quad (13)$$

The selected inductance is a Coilcraft XAL7070-551MEB. This inductance has a saturation current rating of 43A , RMS current rating of 29A and a DCR of 1.6mΩ maximum. This inductor is selected for the low DCR to get high efficiency.

8.2.2.4 Choose the Output Capacitor

There are three considerations for selecting the value of the output capacitor:

1. Stability
2. Steady state output voltage ripple
3. Regulator transient response to a change load current

First, calculate the minimum output capacitance based on these three requirements. Equation 15 calculates the minimum capacitance to keep the LC double pole below the $f_{P(MAX)}$ in Table 6-2 to meet stability requirements. To calculate the $f_{P(MAX)}$, locate the correct K_{f_LC} in Table 6-2. By default, this part comes pre-programmed with RAMP3 and SEL_SUMCOMP = 0 as the compensation settings. In this example, K_{f_LC} = 9.6 and V_{REF_DAC} =

Copyright © 2026 Texas Instruments Incorporated

VOUT_COMMAND × VOSL = 3.3V × 0.125V/V = 0.4125V. After determining the correct K_{f_LC} and V_{REF_DAC}, plug both values into Equation 2. For this example application, $f_{P(MAX)}$ = 14.947kHz. Plug the calculated $f_{P(MAX)}$ into Equation 14 to determine the minimum required C_{out} for stability. Equation 15 calculates the minimum capacitance to meet the steady state output voltage ripple requirement of 16mV. These calculations are for CCM operation and does not include the portion of the output voltage ripple caused by the ESR or ESL of the output capacitors.

$$C_{OUT_STABLITY} > \left(\frac{1}{2\pi \times f_{P(MAX)}}\right)^2 \times \frac{1}{L_{OUT}} = \left(\frac{1}{2\pi \times 14.947\text{kHz}}\right)^2 \times \frac{1}{0.55\mu\text{H}} = 207\mu\text{F} \quad (14)$$

$$C_{OUT_RIPPLE} > \frac{I_{RIPPLE}}{8 \times V_{RIPPLE} \times f_{SW}} = \frac{5.95\text{A}}{8 \times 16\text{mV} \times 800\text{kHz}} = 58.1\mu\text{F} \quad (15)$$

Equation 17 and Equation 18 calculate the minimum capacitance to meet the transient response requirement of 99mV with a 10A step. These equations calculate the necessary output capacitance to hold the output voltage steady while the inductor current ramps up or ramps down after a load step.

$$C_{OUT_UNDERSHOOT} > \frac{L \times {I_{STEP}}^2 \times \left(\frac{V_{OUT}}{V_{IN}(\text{min}) \times f_{SW}} + t_{OFF_MIN}(\text{max})\right)}{2 \times V_{TRANS} \times V_{OUT} \times \left(\frac{V_{IN}(\text{min}) - V_{OUT}}{V_{IN}(\text{min}) \times f_{SW}} - t_{OFF_MIN}(\text{max})\right)} \quad (16)$$

$$C_{OUT_UNDERSHOOT} > \frac{0.55\mu\text{H} \times {10\text{A}}^2 \times \left(\frac{3.3\text{V}}{8\text{V} \times 800\text{kHz}} + 150\text{ns}\right)}{2 \times 99\text{mV} \times 3.3\text{V} \times \left(\frac{8\text{V} - 3.3\text{V}}{8\text{V} \times 800\text{kHz}} - 150\text{ns}\right)} = 95.9\mu\text{F} \quad (17)$$

$$C_{OUT_OVERSHOOT} > \frac{L \times {I_{STEP}}^2}{2 \times V_{TRANS} \times V_{OUT}} = \frac{0.55\mu\text{H} \times {10\text{A}}^2}{2 \times 99\text{mV} \times 3.3\text{V}} = 84.2\mu\text{F} \quad (18)$$

The output capacitance needed to meet the overshoot requirement is the highest value, so this sets the required minimum output capacitance for this example. Stability requirements can also limit the maximum output capacitance. Equation 19 calculates the recommended maximum output capacitance. This calculation keeps the LC double pole above 1/100th the f_{SW}.

$$C_{OUT_STABILITY} < \left(\frac{50}{\pi \times f_{SW}}\right)^2 \times \frac{1}{L} = \left(\frac{50}{\pi \times 800\text{kHz}}\right)^2 \times \frac{1}{0.55\mu\text{H}} = 720\mu\text{F} \quad (19)$$

Using more output capacitance is possible, but the stability must be checked through a bode plot or transient response measurement. The selected output capacitance is 6 × 47µF, 10V ceramic capacitors. When using ceramic capacitors, the capacitance must be derated due to DC and AC bias effects. The selected capacitors derate to 75% the nominal value giving an effective total capacitance of 211µF. This effective capacitance meets the minimum and maximum requirements.

This application uses all ceramic capacitors so the effects of ESR on the ripple and transient are ignored. If using non ceramic capacitors, as a starting point, the ESR must be below the values calculated in Equation 20 to meet the ripple requirement and Equation 21 to meet the transient requirement. For more accurate calculations or if using mixed output capacitors, the impedance of the output capacitors must be used to determine if the ripple and transient requirements can be met.

$$R_{ESR_RIPPLE} < \frac{V_{RIPPLE}}{I_{RIPPLE}} = \frac{26\text{mV}}{5.95\text{A}} = 4.4\text{m}\Omega \quad (20)$$

$$R_{ESR_TRANS} < \frac{V_{TRANS}}{I_{STEP}} = \frac{99\text{mV}}{10\text{A}} = 9.9\text{m}\Omega \quad (21)$$

ADVANCE INFORMATION

ADVANCE INFORMATION

8.2.2.5 Choose the Input Capacitors (C_{IN})

The device requires input bypass capacitors between both pairs of VIN and PGND pins to bypass the power-stage. The bypass capacitors must be placed as close as possible to the pins of the IC as the layout allows. At least 20µF nominal of ceramic capacitance and two high-frequency ceramic bypass capacitors are required. A 0.1µF to 1µF capacitor must be placed as close as possible to both VIN pins 4 and 12 on the same side of the board of the device to provide the required high frequency bypass, to reduce the high frequency overshoot and undershoot on across the power-stage on the VIN and SW pins. TI recommends at least 1µF of bypass capacitance as close as possible to each VIN pin to minimize the input voltage ripple. The ceramic capacitors must be a high-quality dielectric of X6S or better for the high capacitance-to-volume ratio and stable characteristics across temperature. In addition to this requirement, more bulk capacitance can be needed on the input depending on the application to minimize variations on the input voltage during transient conditions.

Use Equation 22 to calculate the input capacitance required to meet a specific input ripple target. A recommended target input voltage ripple is 5% the minimum input voltage, 400mV in this example. The calculated input capacitance is 4.5µF. This example meets these two requirements with 2 × 10µF ceramic capacitors.

$$C_{IN} > \frac{V_{OUT} \times I_{OUT} \times \left(1 - \frac{V_{OUT}}{V_{IN}(min)}\right)}{f_{SW} \times V_{IN}(min) \times V_{IN_RIPPLE}} = \frac{3.3V \times 6A \times \left(1 - \frac{3.3V}{8V}\right)}{800\,kHz \times 8V \times 400mV} = 4.5\mu F \quad (22)$$

The capacitor must also have an RMS current rating greater than the maximum input RMS current in the application. Use Equation 24 to calculate the input RMS current the input capacitors must support. The result is 3A in this example. The ceramic input capacitors have a current rating greater than this value.

$$I_{CIN(RMS)} = \sqrt{\frac{V_{OUT}}{V_{IN}(min)} \times \left(\frac{(V_{IN}(min) - V_{OUT})}{V_{IN}(min)} \times {I_{OUT}}^2 + \frac{{I_{RIPPLE}}^2}{12}\right)} \quad (23)$$

$$I_{CIN(RMS)} = \sqrt{\frac{3.3V}{8V} \times \left(\frac{(8V - 3.3V)}{8V} \times 6^2 + \frac{1.8^2}{12}\right)} = 3A \quad (24)$$

For applications requiring bulk capacitance on the input, such as ones with low input voltage and high current, TI recommends the selection process in *How to select input capacitors for a buck converter* analog design journal.

8.2.2.6 VCC Bypass Capacitor

At a minimum, a 1.0µF, at least 6.3V rating, X5R ceramic bypass capacitor is needed on VCC pin located as close to the pin as the layout allows. Use the smallest sized capacitor possible, such as an 0402 package, to minimize the loop from the VCC pin to the PGND pin.

8.2.2.7 BOOT Capacitor

At a minimum, a 0.1µF, 10V, X5R ceramic bypass capacitor is needed between the BOOT and SW pins located as close to the pin as the layout allows.

8.2.2.8 PG Pullup Resistor

The PG pin is open-drain, so a pullup resistor is required when using this pin. The recommended value is between 1kΩ and 100kΩ.

8.2.2.9 Choose the PMBus® Address and Fault Recovery Mode

A resistor between the ADR pin and AGND sets the preconfigured PMBus address and Fault Recovery Mode in the memory map. Refer to Table 6-5for the list of PMBus addresses and Fault Recovery Modes selectable by an external resistor. In this application, shorting the pin to AGND using a 0Ω resistor selects a PMBus address of 21h and the Hiccup Fault Recovery Mode.

8.3 Power Supply Recommendations

The device is designed to operate from an input voltage supply range between 4V and 16V. Both input supplies (VIN and VCC bias) must be well regulated. Proper bypassing of input supplies (VIN and VCC bias) is also critical for noise performance, as are PCB layout and grounding scheme. See the recommendations in *Layout.*

ADVANCE INFORMATION

8.4 Layout

8.4.1 Layout Guidelines

Before beginning a design using the device, consider the following:

- Make VIN, PGND, and SW traces as wide as possible to reduce trace impedance and improve heat dissipation.
- Place the power components (including input and output capacitors, the inductor, and the IC) on the top side of the PCB. To shield and isolate the small signal traces from noisy power lines, insert at least one solid ground inner plane.
- Placement of the VIN decoupling capacitors are important for the power MOSFET robustness. A 1µF/25V/0402 ceramic high-frequency bypass capacitor on each VIN pin (pins 4 and 12) is required, connected to the adjacent PGND pins (pins 5 and 11 respectively). Place the remaining ceramic input capacitance next to these high frequency bypass capacitors. The remaining input capacitance can be placed on the other side of the board, but use as many vias as possible to minimize impedance between the capacitors and the pins of the IC.
- Place as many vias as possible below and near the PGND pins. This action minimizes parasitic impedance and also lowers thermal resistance.
- Use vias near both VIN pins and provide a low impedance connection between them through an internal layer. A via can also be placed below each of the VIN pins.
- Place the VCC decoupling capacitor as close as possible to the device, with a short return to PGND (pin 5). Make sure the VCC decoupling loop is small and use traces with a width of 12 mil or wider to route the connection.
- Place the BOOT capacitor as close as possible to the BOOT and SW pins. Use traces with a width of 12 mil or wider to route the connection.
- The PCB trace, which connects the SW pin and high-voltage side of the inductor, is defined as switch node. The switch node must be as short and wide as possible.
- If using external feedback, always place the feedback resistors near the device to minimize the FB trace distance, no matter single-end sensing or remote sensing.
  - For remote sensing, the connections from the FB voltage divider resistors to the remote location must be a differential pair of PCB traces, and must implement Kelvin sensing across a bypass capacitor of 0.1µF or higher. The ground connection of the remote sensing signal must be connected to GOS pin. The V_{OUT} connection of the remote sensing signal must be connected to the feedback resistor divider with the bottom feedback resistor terminated to the GOS pin. To maintain stable output voltage and minimize the ripple, the pair of remote sensing lines must stay away from any noise sources such as inductor and SW nodes, or high frequency clock lines. TI recommends to shield the pair of remote sensing lines with ground planes above and below.
  - For single-end sensing, connect the top feedback resistor between the FB pin and the output voltage to a high-frequency local output bypass capacitor of 0.1µF or higher, and short GOS to AGND with a short trace.
- Connect the AGND pin (pin 19) to the PGND pins (pins 5 and 11) beneath the device.
- Avoid routing the PG signal and any other noisy signals in the application near noise sensitive signals, such as VOS/FB and GOS to limit coupling.
- See *Layout Example* for the layout recommendation.

All trademarks are the property of their respective owners.

9.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.
