Trademarks	133
1 ► C28x SYSTEM RESOURCES	134
1.1 Technical Reference Manual Overview	134
2 C2000™ Microcontrollers Software Support	136
2.1 Introduction	137
2.2 C2000Ware Structure	137
2.3 Documentation	137
2.4 Devices	137
2.5 Libraries	137
2.6 Code Composer Studio™ Integrated Development Environment (IDE)	137
2.7 SysConfig and PinMUX Tool	138
3 C28x System Control and Interrupts	139
3.1 C28x System Control Introduction	140
3.1.1 SYSCTL Related Collateral	140
3.2 System Control Functional Description	141
3.2.1 Device Identification	141
3.2.2 Device Configuration Registers	141
3.3 Resets	142
3.3.1 Reset Sources	142
3.3.2 External Reset (XRSn)	143
3.3.3 Simulate External Reset	143
3.3.4 Power-On Reset (POR)	143
3.3.5 Debugger Reset (SYSRS)	143
3.3.6 Simulate CPU1 Reset	143
3.3.7 Watchdog Reset (WDRS)	144
3.3.8 NMI Watchdog Reset (NMIWDRS)	144
3.3.9 Secure Code Copy Reset (SCCRESET)	144
3.3.10 ESC Reset Output	144
3.3.11 Test Reset (TRST)	144
3.4 Peripheral Interrupts	145
3.4.1 Interrupt Concepts	145
3.4.2 Interrupt Architecture	145
3.4.3 Interrupt Entry Sequence	147
3.4.4 Configuring and Using Interrupts	148
3.4.5 PIE Channel Mapping	150
3.4.6 System Error and CM Status Interrupts	152
3.4.7 Vector Tables	153
3.5 Exceptions and Non-Maskable Interrupts	159
3.5.1 Configuring and Using NMIs	159
3.5.2 Emulation Considerations	159
3.5.3 NMI Sources	159
3.5.4 Illegal Instruction Trap (ITRAP)	160
3.6 Safety Features	161

3.6.1 Write Protection on Registers.....	161
3.6.2 CPU1 and CPU2 ePIE Vector Address Validity Check.....	162
3.6.3 NMIWDs.....	162
3.6.4 ECC and Parity Enabled RAMs, Shared RAMs Protection.....	162
3.6.5 ECC Enabled Flash Memory.....	162
3.6.6 ERRORSTS Pin.....	163
3.7 Clocking.....	163
3.7.1 Clock Sources.....	165
3.7.2 Derived Clocks.....	167
3.7.3 Device Clock Domains.....	168
3.7.4 External Clock Output (XCLKOUT).....	169
3.7.5 Clock Connectivity.....	169
3.7.6 PLL/AUXPLL.....	171
3.7.7 Clock (OSCCLK) Failure Detection.....	174
3.8 Clock Configuration Semaphore.....	176
3.9 32-Bit CPU Timers 0/1/2.....	177
3.10 Watchdog Timers.....	178
3.10.1 Servicing the Watchdog Timer.....	179
3.10.2 Minimum Window Check.....	179
3.10.3 Watchdog Reset or Watchdog Interrupt Mode.....	180
3.10.4 Watchdog Operation in Low-Power Modes.....	180
3.10.5 Emulation Considerations.....	180
3.11 Low-Power Modes.....	181
3.11.1 IDLE.....	181
3.11.2 STANDBY.....	181
3.12 Memory Controller Module.....	182
3.12.1 Functional Description.....	183
3.13 JTAG.....	192
3.13.1 JTAG Noise and TAP_STATUS.....	192
3.14 System Control Register Configuration Restrictions.....	193
3.15 Software.....	194
3.15.1 SYSCTL Examples.....	194
3.15.2 MEMCFG Examples.....	194
3.15.3 NMI Examples.....	197
3.15.4 TIMER Examples.....	198
3.15.5 WATCHDOG Examples.....	199
3.16 System Control Registers.....	200
3.16.1 SYSCTRL Base Address Table (C28).....	200
3.16.2 ACCESS_PROTECTION_REGS Registers.....	201
3.16.3 CLK_CFG_REGS Registers.....	225
3.16.4 CM_CONF_REGS Registers.....	256
3.16.5 CPU_SYS_REGS Registers.....	263
3.16.6 CPU_ID_REGS Registers.....	311
3.16.7 CPU1_PERIPH_AC_REGS Registers.....	313
3.16.8 CPUTIMER_REGS Registers.....	392
3.16.9 DEV_CFG_REGS Registers.....	399
3.16.10 DMA_CLA_SRC_SEL_REGS Registers.....	458
3.16.11 MEM_CFG_REGS Registers.....	465
3.16.12 MEMORY_ERROR_REGS Registers.....	540
3.16.13 NMI_INTERRUPT_REGS Registers.....	560
3.16.14 PIE_CTRL_REGS Registers.....	580
3.16.15 ROM_PREFETCH_REGS Registers.....	632
3.16.16 ROM_WAIT_STATE_REGS Registers.....	634
3.16.17 SYNC_SOC_REGS Registers.....	636
3.16.18 SYS_STATUS_REGS Registers.....	643
3.16.19 TEST_ERROR_REGS Registers.....	656
3.16.20 UID_REGS Registers.....	660
3.16.21 WD_REGS Registers.....	669
3.16.22 XINT_REGS Registers.....	676
3.16.23 Register to Driverlib Function Mapping.....	685
4 C28x Processor.....	709

4.1 Introduction.....	710
4.2 C28X Related Collateral.....	710
4.3 Features.....	710
4.4 Floating-Point Unit.....	711
4.5 Trigonometric Math Unit (TMU).....	711
4.6 VCRC Unit.....	712
5 ROM Code and Peripheral Booting.....	713
5.1 Introduction.....	714
5.1.1 ROM Related Collateral.....	714
5.2 Device Boot Sequence.....	715
5.3 Device Boot Modes.....	716
5.4 Device Boot Configurations.....	717
5.4.1 Configuring Boot Mode Pins for CPU1.....	718
5.4.2 Configuring Boot Mode Table Options for CPU1.....	720
5.4.3 Boot Mode Example Use Cases.....	721
5.5 Device Boot Flow Diagrams.....	723
5.5.1 CPU1 Boot Flow.....	723
5.5.2 CPU2 Boot Flow.....	726
5.5.3 Connectivity Manager (CM) Boot Flow.....	727
5.6 Device Reset and Exception Handling.....	728
5.6.1 Reset Causes and Handling.....	728
5.6.2 Exceptions and Interrupts Handling.....	728
5.7 Boot ROM Description.....	730
5.7.1 CPU1 Boot ROM Configuration Registers.....	730
5.7.2 Booting CPU2 and CM.....	732
5.7.3 Entry Points.....	736
5.7.4 Wait Points.....	737
5.7.5 Memory Maps.....	738
5.7.6 ROM Tables.....	740
5.7.7 Boot Modes and Loaders.....	741
5.7.8 GPIO Assignments for CPU1.....	759
5.7.9 Secure ROM Function APIs.....	762
5.7.10 Clock Initializations.....	765
5.7.11 Boot Status information.....	765
5.7.12 ROM Version.....	769
5.8 Application Notes for Using the Bootloaders.....	770
5.8.1 Boot Data Stream Structure.....	770
5.8.2 The C2000 Hex Utility.....	772
5.9 Software.....	774
5.9.1 BOOT Examples.....	774
6 Dual Code Security Module (DCSM).....	776
6.1 Introduction.....	777
6.1.1 DCSM Related Collateral.....	777
6.2 Functional Description.....	777
6.2.1 CSM Passwords.....	779
6.2.2 Emulation Code Security Logic (ECSL).....	781
6.2.3 CPU Secure Logic.....	781
6.2.4 Execute-Only Protection.....	781
6.2.5 Password Lock.....	781
6.2.6 JTAGLOCK.....	782
6.2.7 Link Pointer and Zone Select.....	782
6.2.8 C Code Example to Get Zone Select Block Addr for Zone1.....	785
6.3 Flash and OTP Erase/Program.....	785
6.4 Secure Copy Code.....	785
6.5 SecureCRC.....	786
6.6 CSM Impact on Other On-Chip Resources.....	787
6.7 Incorporating Code Security in User Applications.....	788
6.7.1 Environments That Require Security Unlocking.....	788
6.7.2 CSM Password Match Flow.....	789
6.7.3 C Code Example to Unsecure C28x Zone1.....	790
6.7.4 C Code Example to Resecure C28x Zone1.....	790

6.7.5 Environments That Require ECSL Unlocking.....	790
6.7.6 ECSL Password Match Flow.....	791
6.7.7 ECSL Disable Considerations for any Zone.....	792
6.7.8 Device Unique ID.....	792
6.8 Software.....	793
6.8.1 DCSM Examples.....	793
6.9 DCSM Registers.....	795
6.9.1 DCSM Base Address Table (C28).....	795
6.9.2 CM DCSM Base Address Table (CM).....	796
6.9.3 DCSM_Z1_REGS Registers.....	797
6.9.4 DCSM_Z2_REGS Registers.....	847
6.9.5 DCSM_COMMON_REGS Registers.....	887
6.9.6 DCSM_Z1_OTP Registers.....	908
6.9.7 DCSM_Z2_OTP Registers.....	925
7 Background CRC-32 (BGCRC)	935
7.1 Introduction.....	936
7.1.1 BGCRC Related Collateral.....	936
7.1.2 Features.....	936
7.1.3 Block Diagram.....	936
7.1.4 Memory Wait States and Memory Map.....	937
7.2 Functional Description.....	938
7.2.1 Data Read Unit.....	938
7.2.2 CRC-32 Compute Unit.....	938
7.2.3 CRC Notification Unit.....	939
7.2.4 Operating Modes.....	940
7.2.5 BGCRC Watchdog.....	940
7.2.6 Hardware and Software Faults Protection.....	940
7.3 Application of the BGCRC.....	940
7.3.1 Software Configuration.....	941
7.3.2 Decision on Error Response Severity.....	942
7.3.3 Decision of Controller for CLA_CRC.....	942
7.3.4 Execution of Time Critical Code from Wait-States Memories.....	942
7.3.5 BGCRC Execution.....	942
7.3.6 Debug/Error Response for BGCRC Errors.....	943
7.3.7 BGCRC Golden CRC-32 Value Computation.....	944
7.4 Software.....	945
7.4.1 BGCRC Examples.....	945
7.5 BGCRC Registers.....	946
7.5.1 BGCRC Base Address Table (C28).....	946
7.5.2 BGCRC_REGS Registers.....	947
7.5.3 BGCRC Registers to Driverlib Functions.....	973
8 Control Law Accelerator (CLA)	975
8.1 Introduction.....	976
8.1.1 Features.....	976
8.1.2 CLA Related Collateral.....	976
8.1.3 Block Diagram.....	977
8.2 CLA Interface.....	978
8.2.1 CLA Memory.....	978
8.2.2 CLA Memory Bus.....	979
8.2.3 Shared Peripherals and EALLOW Protection.....	980
8.2.4 CLA Tasks and Interrupt Vectors.....	980
8.2.5 CLA Software Interrupt to CPU.....	985
8.3 CLA, DMA, and CPU Arbitration.....	985
8.3.1 CLA Message RAM.....	986
8.3.2 Peripheral Registers (ePWM, HRPWM, Comparator).....	986
8.4 CLA Configuration and Debug.....	987
8.4.1 Building a CLA Application.....	987
8.4.2 Typical CLA Initialization Sequence.....	987
8.4.3 Debugging CLA Code.....	989
8.4.4 CLA Illegal Opcode Behavior.....	991
8.4.5 Resetting the CLA.....	992

8.5 Pipeline.....	992
8.5.1 Pipeline Overview.....	992
8.5.2 CLA Pipeline Alignment.....	993
8.5.3 Parallel Instructions.....	998
8.5.4 CLA Task Execution Latency.....	998
8.6 Software.....	999
8.6.1 CLA Examples.....	999
8.7 Instruction Set.....	1004
8.7.1 Instruction Descriptions.....	1004
8.7.2 Addressing Modes and Encoding.....	1005
8.7.3 Instructions.....	1008
8.8 CLA Registers.....	1138
8.8.1 CLA Base Address Table (C28).....	1138
8.8.2 CLA_ONLY_REGS Registers.....	1139
8.8.3 CLA_SOFTINT_REGS Registers.....	1148
8.8.4 CLA_REGS Registers.....	1152
8.8.5 CLA Registers to Driverlib Functions.....	1200
9 Configurable Logic Block (CLB).....	1203
9.1 Introduction.....	1204
9.1.1 CLB Related Collateral.....	1204
9.2 Description.....	1204
9.2.1 CLB Clock.....	1206
9.3 CLB Input/Output Connection.....	1208
9.3.1 Overview.....	1208
9.3.2 CLB Input Selection.....	1208
9.3.3 CLB Output Selection.....	1222
9.3.4 CLB Output Signal Multiplexer.....	1224
9.4 CLB Tile.....	1227
9.4.1 Static Switch Block.....	1228
9.4.2 Counter Block.....	1230
9.4.3 FSM Block.....	1234
9.4.4 LUT4 Block.....	1236
9.4.5 Output LUT Block.....	1236
9.4.6 Asynchronous Output Conditioning (AOC) Block.....	1237
9.4.7 High Level Controller (HLC).....	1240
9.5 CPU Interface.....	1245
9.5.1 Register Description.....	1245
9.5.2 Non-Memory Mapped Registers.....	1246
9.6 DMA Access.....	1246
9.7 CLB Data Export Through SPI RX Buffer.....	1247
9.8 CLB Pipeline Mode.....	1248
9.9 Software.....	1249
9.9.1 CLB Examples.....	1249
9.10 CLB Registers.....	1254
9.10.1 CLB Base Address Table (C28).....	1254
9.10.2 CLB_LOGIC_CONFIG_REGS Registers.....	1256
9.10.3 CLB_LOGIC_CONTROL_REGS Registers.....	1308
9.10.4 CLB_DATA_EXCHANGE_REGS Registers.....	1341
9.10.5 CLB Registers to Driverlib Functions.....	1343
10 Dual-Clock Comparator (DCC).....	1347
10.1 Introduction.....	1348
10.1.1 Features.....	1348
10.1.2 Block Diagram.....	1348
10.2 Module Operation.....	1349
10.2.1 Configuring DCC Counters.....	1350
10.2.2 Single-Shot Measurement Mode.....	1351
10.2.3 Continuous Monitoring Mode.....	1352
10.2.4 Error Conditions.....	1353
10.3 Interrupts.....	1355
10.4 Software.....	1356
10.4.1 DCC Examples.....	1356

10.5 DCC Registers.....	1358
10.5.1 DCC Base Address Table (C28).....	1358
10.5.2 DCC_REGS Registers.....	1359
10.5.3 DCC Registers to Driverlib Functions.....	1369
11 Direct Memory Access (DMA).....	1371
11.1 Introduction.....	1372
11.1.1 Features.....	1372
11.1.2 Block Diagram.....	1373
11.2 Architecture.....	1374
11.2.1 Peripheral Interrupt Event Trigger Sources.....	1374
11.2.2 DMA Bus.....	1379
11.3 Address Pointer and Transfer Control.....	1379
11.4 Pipeline Timing and Throughput.....	1385
11.5 CPU and CLA Arbitration.....	1386
11.6 Channel Priority.....	1387
11.6.1 Round-Robin Mode.....	1387
11.6.2 Channel 1 High-Priority Mode.....	1388
11.7 Overrun Detection Feature.....	1388
11.8 Software.....	1389
11.8.1 DMA Examples.....	1389
11.9 DMA Registers.....	1390
11.9.1 DMA Base Address Table (C28).....	1390
11.9.2 DMA_REGS Registers.....	1391
11.9.3 DMA_CH_REGS Registers.....	1396
11.9.4 DMA Registers to Driverlib Functions.....	1422
12 External Memory Interface (EMIF).....	1425
12.1 Introduction.....	1426
12.1.1 Purpose of the Peripheral.....	1427
12.1.2 EMIF Related Collateral.....	1427
12.1.3 Features.....	1428
12.1.4 Functional Block Diagram.....	1429
12.1.5 Configuring Device Pins.....	1429
12.2 EMIF Module Architecture.....	1430
12.2.1 EMIF Clock Control.....	1430
12.2.2 EMIF Requests.....	1430
12.2.3 EMIF Signal Descriptions.....	1431
12.2.4 EMIF Signal Multiplexing Control.....	1432
12.2.5 SDRAM Controller and Interface.....	1432
12.2.6 Asynchronous Controller and Interface.....	1445
12.2.7 Data Bus Parking.....	1457
12.2.8 Reset and Initialization Considerations.....	1457
12.2.9 Interrupt Support.....	1457
12.2.10 DMA Event Support.....	1458
12.2.11 EMIF Signal Multiplexing.....	1458
12.2.12 Memory Map.....	1458
12.2.13 Priority and Arbitration.....	1459
12.2.14 System Considerations.....	1459
12.2.15 Power Management.....	1460
12.2.16 Emulation Considerations.....	1460
12.3 Example Configuration.....	1460
12.3.1 Hardware Interface.....	1460
12.3.2 Software Configuration.....	1461
12.4 Software.....	1469
12.4.1 EMIF Examples.....	1469
12.5 EMIF Registers.....	1472
12.5.1 EMIF Base Address Table (C28).....	1472
12.5.2 EMIF_REGS Registers.....	1473
12.5.3 EMIF1_CONFIG_REGS Registers.....	1493
12.5.4 EMIF2_CONFIG_REGS Registers.....	1498
12.5.5 EMIF Registers to Driverlib Functions.....	1501
13 Flash Module.....	1503

13.1 Introduction to Flash and OTP Memory.....	1504
13.1.1 FLASH Related Collateral.....	1504
13.1.2 Features.....	1504
13.1.3 Flash Tools.....	1505
13.1.4 Default Flash Configuration.....	1505
13.2 Flash Bank, OTP, and Pump.....	1505
13.3 Flash Module Controller (FMC).....	1506
13.4 Flash and OTP Memory Power-Down Modes and Wakeup.....	1507
13.5 Active Grace Period.....	1508
13.6 Flash and OTP Memory Performance.....	1509
13.7 Flash Read Interface.....	1509
13.7.1 C28x-FMC (CPU1-FMC and CPU2-FMC) Flash Read Interface.....	1509
13.7.2 M4-FMC (CM-FMC) Flash Read Interface.....	1512
13.8 Flash Erase and Program.....	1515
13.8.1 Erase.....	1515
13.8.2 Program.....	1515
13.8.3 Verify.....	1515
13.9 Error Correction Code (ECC) Protection.....	1516
13.9.1 Single-Bit Data Error.....	1517
13.9.2 Uncorrectable Error.....	1518
13.9.3 SECEDED Logic Correctness Check.....	1519
13.10 Reserved Locations Within Flash and OTP Memory.....	1520
13.11 Migrating an Application from RAM to Flash.....	1520
13.12 Procedure to Change the Flash Control Registers.....	1521
13.13 Flash Pump Ownership Semaphore.....	1521
13.14 Software.....	1523
13.14.1 FLASH Examples.....	1523
13.15 Flash Registers.....	1524
13.15.1 FLASH Base Address Table (C28).....	1524
13.15.2 CM FLASH Base Address Table (CM).....	1524
13.15.3 FLASH_CTRL_REGS Registers.....	1525
13.15.4 FLASH_ECC_REGS Registers.....	1534
13.15.5 CM_FLASH_CTRL_REGS Registers.....	1557
13.15.6 CM_FLASH_ECC_REGS Registers.....	1567
13.15.7 FLASH_PUMP_SEMAPHORE_REGS Registers.....	1591
13.15.8 FLASH Registers to Driverlib Functions.....	1592
14 Embedded Real-time Analysis and Diagnostic (ERAD).....	1595
14.1 Introduction.....	1596
14.1.1 ERAD Related Collateral.....	1596
14.2 Enhanced Bus Comparator Unit.....	1597
14.2.1 Enhanced Bus Comparator Unit Operations.....	1597
14.2.2 Event Masking and Exporting.....	1598
14.3 System Event Counter Unit.....	1599
14.3.1 System Event Counter Modes.....	1599
14.3.2 Reset on Event.....	1603
14.3.3 Operation Conditions.....	1604
14.4 ERAD Ownership, Initialization and Reset.....	1604
14.5 ERAD Programming Sequence.....	1605
14.5.1 Hardware Breakpoint and Hardware Watch Point Programming Sequence.....	1605
14.5.2 Timer and Counter Programming Sequence.....	1606
14.6 Cyclic Redundancy Check Unit.....	1606
14.6.1 CRC Unit Qualifier.....	1607
14.6.2 CRC Unit Programming Sequence.....	1608
14.7 Program Counter Trace.....	1609
14.7.1 Functional Block Diagram.....	1610
14.7.2 Trace Qualification Modes.....	1611
14.7.3 Trace Memory.....	1611
14.7.4 Trace Input Signal Conditioning.....	1612
14.7.5 PC Trace Software Operation.....	1613
14.7.6 Trace Operation in Debug Mode.....	1613
14.8 Software.....	1614

14.8.1 ERAD Examples.....	1614
14.9 ERAD Registers.....	1621
14.9.1 ERAD Base Address Table (C28).....	1621
14.9.2 ERAD_GLOBAL_REGS Registers.....	1623
14.9.3 ERAD_HWBP_REGS Registers.....	1646
14.9.4 ERAD_COUNTER_REGS Registers.....	1653
14.9.5 ERAD_CRC_GLOBAL_REGS Registers.....	1664
14.9.6 ERAD_CRC_REGS Registers.....	1667
14.9.7 ERAD Registers to Driverlib Functions.....	1670
15 General-Purpose Input/Output (GPIO).....	1673
15.1 Introduction.....	1674
15.1.1 GPIO Related Collateral.....	1676
15.2 Configuration Overview.....	1676
15.3 Digital General-Purpose I/O Control.....	1677
15.4 Input Qualification.....	1678
15.4.1 No Synchronization (Asynchronous Input).....	1678
15.4.2 Synchronization to SYSCLKOUT Only.....	1678
15.4.3 Qualification Using a Sampling Window.....	1679
15.5 USB Signals.....	1682
15.6 SPI Signals.....	1682
15.7 GPIO and Peripheral Muxing.....	1683
15.7.1 GPIO Muxing.....	1683
15.7.2 Peripheral Muxing.....	1690
15.8 Internal Pullup Configuration Requirements.....	1692
15.9 Software.....	1693
15.9.1 GPIO Examples.....	1693
15.9.2 LED Examples.....	1693
15.10 GPIO Registers.....	1694
15.10.1 GPIO Base Address Table (C28).....	1694
15.10.2 CM GPIO Base Address Table (CM).....	1695
15.10.3 GPIO_CTRL_REGS Registers.....	1696
15.10.4 GPIO_DATA_REGS Registers.....	1862
15.10.5 GPIO_DATA_READ_REGS Registers.....	1912
15.10.6 CM_GPIO_DATA_REGS Registers.....	1919
15.10.7 CM_GPIO_DATA_READ_REGS Registers.....	1969
15.10.8 GPIO Registers to Driverlib Functions.....	1977
16 Interprocessor Communication (IPC).....	1984
16.1 Introduction.....	1985
16.2 Message RAMs.....	1985
16.3 IPC Flags and Interrupts.....	1988
16.4 IPC Command Registers.....	1988

17.1.1 CLB Input X-BAR.....	2193
17.2 ePWM, CLB, and GPIO Output X-BAR.....	2194
17.2.1 ePWM X-BAR.....	2194
17.2.2 CLB X-BAR.....	2196

17.2.3 GPIO Output X-BAR.....	2199
17.2.4 CLB Output X-BAR.....	2201
17.2.5 X-BAR Flags.....	2202
17.3 XBAR Registers.....	2204
17.3.1 XBAR Base Address Table (C28).....	2204
17.3.2 INPUT_XBAR_REGS Registers.....	2205
17.3.3 XBAR_REGS Registers.....	2224
17.3.4 EPWM_XBAR_REGS Registers.....	2257
17.3.5 CLB_XBAR_REGS Registers.....	2350
17.3.6 OUTPUT_XBAR_REGS Registers.....	2443
17.3.7 Register to Driverlib Function Mapping.....	2544
18 ► ANALOG PERIPHERALS.....	2550
18.1 Technical Reference Manual Overview.....	2550
19 Analog Subsystem.....	2552
19.1 Introduction.....	2553
19.1.1 Features.....	2553
19.1.2 Block Diagram.....	2553
19.2 Optimizing Power-Up Time.....	2556
19.3 Analog Subsystem Registers.....	2557
19.3.1 ASBSYS Base Address Table (C28).....	2557
19.3.2 ANALOG_SUBSYS_REGS Registers.....	2558
20 Analog-to-Digital Converter (ADC).....	2567
20.1 Introduction.....	2568
20.1.1 ADC Related Collateral.....	2568
20.1.2 Features.....	2569
20.1.3 Block Diagram.....	2570
20.2 ADC Configurability.....	2571
20.2.1 Clock Configuration.....	2571
20.2.2 Resolution.....	2571
20.2.3 Voltage Reference.....	2572
20.2.4 Signal Mode.....	2572
20.2.5 Expected Conversion Results.....	2573
20.2.6 Interpreting Conversion Results.....	2574
20.3 SOC Principle of Operation.....	2575
20.3.1 SOC Configuration.....	2576
20.3.2 Trigger Operation.....	2576
20.3.3 ADC Acquisition (Sample and Hold) Window.....	2576
20.3.4 ADC Input Models.....	2577
20.3.5 Channel Selection.....	2578
20.4 SOC Configuration Examples.....	2579
20.4.1 Single Conversion from ePWM Trigger.....	2579
20.4.2 Oversampled Conversion from ePWM Trigger.....	2579
20.4.3 Multiple Conversions from CPU Timer Trigger.....	2580
20.4.4 Software Triggering of SOC.....	2581
20.5 ADC Conversion Priority.....	2581
20.6 Burst Mode.....	2584
20.6.1 Burst Mode Example.....	2584
20.6.2 Burst Mode Priority Example.....	2585
20.7 EOC and Interrupt Operation.....	2586
20.7.1 Interrupt Overflow.....	2587
20.7.2 Continue to Interrupt Mode.....	2587
20.7.3 Early Interrupt Configuration Mode.....	2587
20.8 Post-Processing Blocks.....	2588
20.8.1 PPB Offset Correction.....	2589
20.8.2 PPB Error Calculation.....	2589
20.8.3 PPB Limit Detection and Zero-Crossing Detection.....	2589
20.8.4 PPB Sample Delay Capture.....	2591
20.9 Opens/Shorts Detection Circuit (OSDETECT).....	2592
20.9.1 Implementation.....	2593
20.9.2 Detecting an Open Input Pin.....	2593
20.9.3 Detecting a Shorted Input Pin.....	2593

20.10 Power-Up Sequence.....	2594
20.11 ADC Calibration.....	2594
20.11.1 ADC Zero Offset Calibration.....	2595
20.11.2 ADC Calibration Routines in OTP Memory.....	2596
20.12 ADC Timings.....	2596
20.12.1 ADC Timing Diagrams.....	2596
20.13 Additional Information.....	2602
20.13.1 Ensuring Synchronous Operation.....	2602
20.13.2 Choosing an Acquisition Window Duration.....	2606
20.13.3 Achieving Simultaneous Sampling.....	2608
20.13.4 Result Register Mapping.....	2608
20.13.5 Internal Temperature Sensor.....	2608
20.13.6 Designing an External Reference Circuit.....	2608
20.14 Software.....	2611
20.14.1 ADC Examples.....	2611
20.15 ADC Registers.....	2618
20.15.1 ADC Base Address Table (C28).....	2618
20.15.2 ADC_REGS Registers.....	2619
20.15.3 ADC_RESULT_REGS Registers.....	2753
20.15.4 ADC Registers to Driverlib Functions.....	2773
21 Buffered Digital-to-Analog Converter (DAC).....	2779
21.1 Introduction.....	2780
21.1.1 DAC Related Collateral.....	2780
21.1.2 Features.....	2780
21.1.3 Block Diagram.....	2780
21.2 Using the DAC.....	2781
21.2.1 Initialization Sequence.....	2781
21.2.2 DAC Offset Adjustment.....	2782
21.2.3 EPWMSYNCPER Signal.....	2782
21.3 Lock Registers.....	2782
21.4 Software.....	2783
21.4.1 DAC Examples.....	2783
21.5 DAC Registers.....	2783
21.5.1 DAC Base Address Table (C28).....	2783
21.5.2 DAC_REGS Registers.....	2784
21.5.3 DAC Registers to Driverlib Functions.....	2791
22 Comparator Subsystem (CMPSS).....	2793
22.1 Introduction.....	2794
22.1.1 CMPSS Related Collateral.....	2794
22.1.2 Features.....	2794
22.1.3 Block Diagram.....	2795
22.2 Comparator.....	2795
22.3 Reference DAC.....	2796
22.4 Ramp Generator.....	2797
22.4.1 Ramp Generator Overview.....	2797
22.4.2 Ramp Generator Behavior.....	2798
22.4.3 Ramp Generator Behavior at Corner Cases.....	2799
22.5 Digital Filter.....	2800
22.5.1 Filter Initialization Sequence.....	2801
22.6 Using the CMPSS.....	2801
22.6.1 LATCHCLR, EPWMSYNCPER, and EPWMBLANK Signals.....	2801
22.6.2 Synchronizer, Digital Filter, and Latch Delays.....	2801
22.6.3 Calibrating the CMPSS.....	2802
22.6.4 Enabling and Disabling the CMPSS Clock.....	2802
22.7 Software.....	2803
22.7.1 CMPSS Examples.....	2803
22.8 CMPSS Registers.....	2804
22.8.1 CMPSS Base Address Table (C28).....	2804
22.8.2 CMPSS_REGS Registers.....	2805
22.8.3 CMPSS Registers to Driverlib Functions.....	2829
23 ► CONTROL PERIPHERALS.....	2832

23.1 Technical Reference Manual Overview.....	2832
24 Enhanced Capture (eCAP).....	2834
24.1 Introduction.....	2835
24.1.1 Features.....	2835
24.1.2 ECAP Related Collateral.....	2835
24.2 Description.....	2836
24.3 Configuring Device Pins for the eCAP.....	2837
24.4 Capture and APWM Operating Mode.....	2842
24.5 Capture Mode Description.....	2844
24.5.1 Event Prescaler.....	2845
24.5.2 Edge Polarity Select and Qualifier.....	2845
24.5.3 Continuous/One-Shot Control.....	2846
24.5.4 32-Bit Counter and Phase Control.....	2847
24.5.5 CAP1-CAP4 Registers.....	2847
24.5.6 eCAP Synchronization.....	2847
24.5.7 Interrupt Control.....	2848
24.5.8 DMA Interrupt.....	2850
24.5.9 Shadow Load and Lockout Control.....	2850
24.5.10 APWM Mode Operation.....	2850
24.6 Application of the eCAP Module.....	2852
24.6.1 Example 1 - Absolute Time-Stamp Operation Rising-Edge Trigger.....	2852
24.6.2 Example 2 - Absolute Time-Stamp Operation Rising- and Falling-Edge Trigger.....	2853
24.6.3 Example 3 - Time Difference (Delta) Operation Rising-Edge Trigger.....	2854
24.6.4 Example 4 - Time Difference (Delta) Operation Rising- and Falling-Edge Trigger.....	2855
24.7 Application of the APWM Mode.....	2856
24.7.1 Example 1 - Simple PWM Generation (Independent Channels).....	2856
24.8 Software.....	2857
24.8.1 ECAP Examples.....	2857
24.9 eCAP Registers.....	2858
24.9.1 ECAP Base Address Table (C28).....	2858
24.9.2 ECAP_REGS Registers.....	2859
24.9.3 ECAP Registers to Driverlib Functions.....	2877
25 High Resolution Capture (HRCAP).....	2880
25.1 Introduction.....	2881
25.1.1 HRCAP Related Collateral.....	2881
25.1.2 Features.....	2881
25.1.3 Description.....	2881
25.2 Operational Details.....	2882
25.2.1 HRCAP Clocking.....	2884
25.2.2 HRCAP Initialization Sequence.....	2884
25.2.3 HRCAP Interrupts.....	2884
25.2.4 HRCAP Calibration.....	2885
25.3 Known Exceptions.....	2886
25.4 Software.....	2887
25.4.1 HRCAP Examples.....	2887
25.5 HRCAP Registers.....	2887
25.5.1 HRCAP Base Address Table (C28).....	2887
25.5.2 HRCAP_REGS Registers.....	2888
25.5.3 HRCAP Registers to Driverlib Functions.....	2899
26 Enhanced Pulse Width Modulator (ePWM).....	2901
26.1 Introduction.....	2902
26.1.1 EPWM Related Collateral.....	2903
26.1.2 Submodule Overview.....	2904
26.2 Configuring Device Pins.....	2909
26.3 ePWM Modules Overview.....	2909
26.4 Time-Base (TB) Submodule.....	2911
26.4.1 Purpose of the Time-Base Submodule.....	2911
26.4.2 Controlling and Monitoring the Time-Base Submodule.....	2912
26.4.3 Calculating PWM Period and Frequency.....	2914
26.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules.....	2919
26.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules.....	2919

26.4.6 Time-Base Counter Modes and Timing Waveforms.....	2919
26.4.7 Global Load.....	2924
26.5 Counter-Compare (CC) Submodule.....	2926
26.5.1 Purpose of the Counter-Compare Submodule.....	2926
26.5.2 Controlling and Monitoring the Counter-Compare Submodule.....	2927
26.5.3 Operational Highlights for the Counter-Compare Submodule.....	2928
26.5.4 Count Mode Timing Waveforms.....	2929
26.6 Action-Qualifier (AQ) Submodule.....	2932
26.6.1 Purpose of the Action-Qualifier Submodule.....	2932
26.6.2 Action-Qualifier Submodule Control and Status Register Definitions.....	2933
26.6.3 Action-Qualifier Event Priority.....	2935
26.6.4 AQCTLA and AQCTLB Shadow Mode Operations.....	2936
26.6.5 Configuration Requirements for Common Waveforms.....	2938
26.7 Dead-Band Generator (DB) Submodule.....	2945
26.7.1 Purpose of the Dead-Band Submodule.....	2945
26.7.2 Dead-band Submodule Additional Operating Modes.....	2946
26.7.3 Operational Highlights for the Dead-Band Submodule.....	2948
26.8 PWM Chopper (PC) Submodule.....	2952
26.8.1 Purpose of the PWM Chopper Submodule.....	2952
26.8.2 Operational Highlights for the PWM Chopper Submodule.....	2952
26.8.3 Waveforms.....	2953
26.9 Trip-Zone (TZ) Submodule.....	2956
26.9.1 Purpose of the Trip-Zone Submodule.....	2956
26.9.2 Operational Highlights for the Trip-Zone Submodule.....	2957
26.9.3 Generating Trip Event Interrupts.....	2959
26.10 Event-Trigger (ET) Submodule.....	2962
26.10.1 Operational Overview of the ePWM Event-Trigger Submodule.....	2963
26.11 Digital Compare (DC) Submodule.....	2967
26.11.1 Purpose of the Digital Compare Submodule.....	2969
26.11.2 Enhanced Trip Action Using CMPSS.....	2969
26.11.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis.....	2969
26.11.4 Operation Highlights of the Digital Compare Submodule.....	2970
26.12 ePWM Crossbar (X-BAR).....	2977
26.13 Applications to Power Topologies.....	2978
26.13.1 Overview of Multiple Modules.....	2978
26.13.2 Key Configuration Capabilities.....	2979
26.13.3 Controlling Multiple Buck Converters With Independent Frequencies.....	2980
26.13.4 Controlling Multiple Buck Converters With Same Frequencies.....	2982
26.13.5 Controlling Multiple Half H-Bridge (HHB) Converters.....	2984
26.13.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM).....	2986
26.13.7 Practical Applications Using Phase Control Between PWM Modules.....	2988
26.13.8 Controlling a 3-Phase Interleaved DC/DC Converter.....	2989
26.13.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter.....	2992
26.13.10 Controlling a Peak Current Mode Controlled Buck Module.....	2994
26.13.11 Controlling H-Bridge LLC Resonant Converter.....	2995
26.14 Register Lock Protection.....	2996
26.15 High-Resolution Pulse Width Modulator (HRPWM).....	2997
26.15.1 Operational Description of HRPWM.....	2999
26.15.2 SFO Library Software - SFO_TI_Build_V8.lib.....	3020
26.16 Software.....	3023
26.16.1 EPWM Examples.....	3023
26.16.2 HRPWM Examples.....	3027
26.17 ePWM Registers.....	3030
26.17.1 EPWM Base Address Table (C28).....	3030
26.17.2 EPWM_REGS Registers.....	3031
26.17.3 SYNC_SOC_REGS Registers.....	3159
26.17.4 Register to Driverlib Function Mapping.....	3166
27 Enhanced Quadrature Encoder Pulse (eQEP).....	3178
27.1 Introduction.....	3179
27.1.1 EQEP Related Collateral.....	3181
27.2 Configuring Device Pins.....	3181

27.3 Description.....	3182
27.3.1 EQEP Inputs.....	3182
27.3.2 Functional Description.....	3185
27.3.3 eQEP Memory Map.....	3186
27.4 Quadrature Decoder Unit (QDU).....	3187
27.4.1 Position Counter Input Modes.....	3187
27.4.2 eQEP Input Polarity Selection.....	3190
27.4.3 Position-Compare Sync Output.....	3190
27.5 Position Counter and Control Unit (PCCU).....	3190
27.5.1 Position Counter Operating Modes.....	3190
27.5.2 Position Counter Latch.....	3193
27.5.3 Position Counter Initialization.....	3195
27.5.4 eQEP Position-compare Unit.....	3196
27.6 eQEP Edge Capture Unit.....	3198
27.7 eQEP Watchdog.....	3202
27.8 eQEP Unit Timer Base.....	3202
27.9 QMA Module.....	3203
27.9.1 Modes of Operation.....	3204
27.9.2 Interrupt and Error Generation.....	3205
27.10 eQEP Interrupt Structure.....	3206
27.11 Software.....	3207
27.11.1 EQEP Examples.....	3207
27.12 eQEP Registers.....	3210
27.12.1 EQEP Base Address Table (C28).....	3210
27.12.2 EQEP_REGS Registers.....	3211
27.12.3 EQEP Registers to Driverlib Functions.....	3248
28 Sigma Delta Filter Module (SDFM).....	3251
28.1 Introduction.....	3252
28.1.1 SDFM Related Collateral.....	3252
28.1.2 Features.....	3253
28.1.3 Block Diagram.....	3254
28.2 Configuring Device Pins.....	3256
28.3 Input Qualification.....	3257
28.4 Input Control Unit.....	3258
28.5 SDFM Clock Control.....	3258
28.6 Sinc Filter.....	3259
28.6.1 Data Rate and Latency of the Sinc Filter.....	3261
28.7 Data (Primary) Filter Unit.....	3262
28.7.1 32-bit or 16-bit Data Filter Output Representation.....	3263
28.7.2 Data FIFO.....	3263
28.7.3 SDSYNC Event.....	3265
28.8 Comparator (Secondary) Filter Unit.....	3268
28.8.1 Higher Threshold (HLT) Comparators.....	3270
28.8.2 Lower Threshold (LLT) Comparators.....	3270
28.8.3 Digital Filter.....	3271
28.9 Theoretical SDFM Filter Output.....	3272
28.10 Interrupt Unit.....	3274
28.10.1 SDFM (SDyERR) Interrupt Sources.....	3274
28.10.2 Data Ready (DRINT) Interrupt Sources.....	3275
28.11 Software.....	3277
28.11.1 SDFM Examples.....	3277
28.12 SDFM Registers.....	3281
28.12.1 SDFM Base Address Table (C28).....	3281
28.12.2 SDFM_REGS Registers.....	3282
28.12.3 SDFM Registers to Driverlib Functions.....	3376
29 ► COMMUNICATION PERIPHERALS.....	3382

31.5.1 ECAT Base Address Table (C28).....	3525
31.5.2 ESCSS_REGS Registers.....	3526
31.5.3 ESCSS_CONFIG_REGS Registers.....	3552
31.5.4 ESC_SS Registers to Driverlib Functions.....	3561
32 Fast Serial Interface (FSI).....	3565
32.1 Introduction.....	3566
32.1.1 FSI Related Collateral.....	3566
32.1.2 FSI Features.....	3566
32.2 System-level Integration.....	3567
32.2.1 CPU Interface.....	3567
32.2.2 Signal Description.....	3569
32.2.3 FSI Interrupts.....	3570
32.2.4 CLA Task Triggering.....	3572
32.2.5 DMA Interface.....	3572
32.2.6 External Frame Trigger Mux.....	3573
32.3 FSI Functional Description.....	3574
32.3.1 Introduction to Operation	3574
32.3.2 FSI Transmitter Module.....	3575
32.3.3 FSI Receiver Module.....	3581
32.3.4 Frame Format.....	3587
32.3.5 Flush Sequence.....	3591
32.3.6 Internal Loopback.....	3592
32.3.7 CRC Generation.....	3592
32.3.8 ECC Module.....	3593
32.3.9 Tag Matching.....	3594
32.3.10 TDM Configurations.....	3594
32.3.11 FSI-SPI Compatibility Mode.....	3598
32.4 FSI Programing Guide.....	3602
32.4.1 Establishing the Communication Link.....	3602
32.4.2 Register Protection.....	3604
32.4.3 Emulation Mode.....	3604
32.5 Software.....	3605
32.5.1 FSI Examples.....	3605
32.6 FSI Registers.....	3615
32.6.1 FSI Base Address Table (C28).....	3615
32.6.2 FSI_TX_REGS Registers.....	3616
32.6.3 FSI_RX_REGS Registers.....	3642
32.6.4 FSI Registers to Driverlib Functions.....	3683
33 Inter-Integrated Circuit Module (I2C).....	3688

33.1 Introduction.....	3689
33.1.1 I2C Related Collateral.....	3689
33.1.2 Features.....	3690
33.1.3 Features Not Supported.....	3690
33.1.4 Functional Overview.....	3691
33.1.5 Clock Generation.....	3692
33.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH).....	3693
33.2 Configuring Device Pins.....	3694
33.3 I2C Module Operational Details.....	3694
33.3.1 Input and Output Voltage Levels.....	3694
33.3.2 Selecting Pullup Resistors.....	3694
33.3.3 Data Validity.....	3694
33.3.4 Operating Modes.....	3695
33.3.5 I2C Module START and STOP Conditions.....	3699
33.3.6 Non-repeat Mode versus Repeat Mode.....	3700
33.3.7 Serial Data Formats.....	3700
33.3.8 Clock Synchronization.....	3703
33.3.9 Arbitration.....	3704
33.3.10 Digital Loopback Mode.....	3705
33.3.11 NACK Bit Generation.....	3706
33.4 Interrupt Requests Generated by the I2C Module.....	3706
33.4.1 Basic I2C Interrupt Requests.....	3707
33.4.2 I2C FIFO Interrupts.....	3710
33.5 Resetting or Disabling the I2C Module.....	3710
33.6 Software.....	3711
33.6.1 I2C Examples.....	3711
33.7 I2C Registers.....	3713
33.7.1 I2C Base Address Table (C28).....	3713
33.7.2 I2C_REGS Registers.....	3714
33.7.3 I2C Registers to Driverlib Functions.....	3737
34 Multichannel Buffered Serial Port (McBSP).....	3739
34.1 Introduction.....	3740
34.1.1 MCBSP Related Collateral.....	3740
34.1.2 Features of the McBSPs.....	3740
34.1.3 McBSP Pins/Signals.....	3741
34.2 Configuring Device Pins.....	3741
34.3 McBSP Operation.....	3742
34.3.1 Data Transfer Process of McBSPs.....	3743
34.3.2 Companding (Compressing and Expanding) Data.....	3743
34.3.3 Clocking and Framing Data.....	3745
34.3.4 Frame Phases.....	3747
34.3.5 McBSP Reception.....	3750
34.3.6 McBSP Transmission.....	3751
34.3.7 Interrupts and DMA Events Generated by a McBSP.....	3752
34.4 McBSP Sample Rate Generator.....	3752
34.4.1 Block Diagram.....	3753
34.4.2 Frame Synchronization Generation in the Sample Rate Generator.....	3756
34.4.3 Synchronizing Sample Rate Generator Outputs to an External Clock.....	3756
34.4.4 Reset and Initialization Procedure for the Sample Rate Generator.....	3758
34.5 McBSP Exception/Error Conditions.....	3759
34.5.1 Types of Errors.....	3759
34.5.2 Overrun in the Receiver.....	3760
34.5.3 Unexpected Receive Frame-Synchronization Pulse.....	3761
34.5.4 Overwrite in the Transmitter.....	3763
34.5.5 Underflow in the Transmitter.....	3764
34.5.6 Unexpected Transmit Frame-Synchronization Pulse.....	3765
34.6 Multichannel Selection Modes.....	3768
34.6.1 Channels, Blocks, and Partitions.....	3768
34.6.2 Multichannel Selection.....	3769
34.6.3 Configuring a Frame for Multichannel Selection.....	3769
34.6.4 Using Two Partitions.....	3769

34.6.5 Using Eight Partitions.....	3771
34.6.6 Receive Multichannel Selection Mode.....	3772
34.6.7 Transmit Multichannel Selection Modes.....	3773
34.6.8 Using Interrupts Between Block Transfers.....	3774
34.7 SPI Operation Using the Clock Stop Mode.....	3776
34.7.1 SPI Protocol.....	3776
34.7.2 Clock Stop Mode.....	3776
34.7.3 Enable and Configure the Clock Stop Mode.....	3777
34.7.4 Clock Stop Mode Timing Diagrams.....	3778
34.7.5 Procedure for Configuring a McBSP for SPI Operation.....	3780
34.7.6 McBSP as the SPI Master	3780
34.7.7 McBSP as an SPI Slave	3782
34.8 Receiver Configuration.....	3783
34.8.1 Programming the McBSP Registers for the Desired Receiver Operation.....	3783
34.8.2 Resetting and Enabling the Receiver.....	3784
34.8.3 Set the Receiver Pins to Operate as McBSP Pins.....	3785
34.8.4 Digital Loopback Mode.....	3785
34.8.5 Clock Stop Mode.....	3785
34.8.6 Receive Multichannel Selection Mode.....	3786
34.8.7 Receive Frame Phases.....	3786
34.8.8 Receive Word Lengths.....	3787
34.8.9 Receive Frame Length.....	3788
34.8.10 Receive Frame-Synchronization Ignore Function.....	3789
34.8.11 Receive Companding Mode.....	3790
34.8.12 Receive Data Delay.....	3792
34.8.13 Receive Sign-Extension and Justification Mode.....	3794
34.8.14 Receive Interrupt Mode.....	3795
34.8.15 Receive Frame-Synchronization Mode.....	3795
34.8.16 Receive Frame-Synchronization Polarity.....	3797
34.8.17 Receive Clock Mode.....	3800
34.8.18 Receive Clock Polarity.....	3801
34.8.19 SRG Clock Divide-Down Value.....	3803
34.8.20 SRG Clock Synchronization Mode.....	3803
34.8.21 SRG Clock Mode (Choose an Input Clock).....	3804
34.8.22 SRG Input Clock Polarity.....	3804
34.9 Transmitter Configuration.....	3805
34.9.1 Programming the McBSP Registers for the Desired Transmitter Operation.....	3805
34.9.2 Resetting and Enabling the Transmitter.....	3806
34.9.3 Set the Transmitter Pins to Operate as McBSP Pins.....	3806
34.9.4 Digital Loopback Mode.....	3807
34.9.5 Clock Stop Mode.....	3807
34.9.6 Transmit Multichannel Selection Mode.....	3808
34.9.7 XCERs Used in the Transmit Multichannel Selection Mode.....	3809
34.9.8 Transmit Frame Phases.....	3811
34.9.9 Transmit Word Lengths.....	3811
34.9.10 Transmit Frame Length.....	3812
34.9.11 Enable/Disable the Transmit Frame-Synchronization Ignore Function.....	3813
34.9.12 Transmit Companding Mode.....	3814
34.9.13 Transmit Data Delay.....	3815
34.9.14 Transmit DXENA Mode.....	3817
34.9.15 Transmit Interrupt Mode.....	3817
34.9.16 Transmit Frame-Synchronization Mode.....	3818
34.9.17 Transmit Frame-Synchronization Polarity.....	3819
34.9.18 SRG Frame-Synchronization Period and Pulse Width.....	3820
34.9.19 Transmit Clock Mode.....	3821
34.9.20 Transmit Clock Polarity.....	3821
34.10 Emulation and Reset Considerations.....	3823
34.10.1 McBSP Emulation Mode.....	3823
34.10.2 Resetting and Initializing McBSPs.....	3823
34.11 Data Packing Examples.....	3826
34.11.1 Data Packing Using Frame Length and Word Length.....	3826

34.11.2 Data Packing Using Word Length and the Frame-Synchronization Ignore Function.....	3828
34.12 Interrupt Generation.....	3829
34.12.1 McBSP Receive Interrupt Generation.....	3829
34.12.2 McBSP Transmit Interrupt Generation.....	3830
34.12.3 Error Flags.....	3830
34.13 McBSP Modes.....	3831
34.14 Special Case: External Device is the Transmit Frame Master	3831
34.15 Software.....	3833
34.15.1 MCBSP Examples.....	3833
34.16 McBSP Registers.....	3836
34.16.1 MCBSP Base Address Table (C28).....	3836
34.16.2 McBSP_REGS Registers.....	3837
34.16.3 MCBSP Registers to Driverlib Functions.....	3881
35 Power Management Bus Module (PMBus).....	3885
35.1 Introduction.....	3886
35.1.1 PMBUS Related Collateral.....	3886
35.1.2 Features.....	3886
35.1.3 Block Diagram.....	3887
35.2 Configuring Device Pins.....	3887
35.3 Slave Mode Operation.....	3888
35.3.1 Configuration.....	3888
35.3.2 Message Handling.....	3889
35.4 Master Mode Operation.....	3899
35.4.1 Configuration.....	3899
35.4.2 Message Handling.....	3899
35.5 PMBus Registers.....	3910
35.5.1 PMBUS Base Address Table (C28).....	3910
35.5.2 PMBUS_REGS Registers.....	3911
35.5.3 PMBUS Registers to Driverlib Functions.....	3931
36 Serial Communications Interface (SCI).....	3933
36.1 Introduction.....	3934
36.1.1 Features.....	3934
36.1.2 SCI Related Collateral.....	3935
36.1.3 Block Diagram.....	3935
36.2 Architecture.....	3935
36.3 SCI Module Signal Summary.....	3935
36.4 Configuring Device Pins.....	3937
36.5 Multiprocessor and Asynchronous Communication Modes.....	3937
36.6 SCI Programmable Data Format.....	3938
36.7 SCI Multiprocessor Communication.....	3939
36.7.1 Recognizing the Address Byte.....	3939
36.7.2 Controlling the SCI TX and RX Features.....	3939
36.7.3 Receipt Sequence.....	3939
36.8 Idle-Line Multiprocessor Mode.....	3940
36.8.1 Idle-Line Mode Steps.....	3940
36.8.2 Block Start Signal.....	3941
36.8.3 Wake-Up Temporary (WUT) Flag.....	3941
36.8.4 Receiver Operation.....	3941
36.9 Address-Bit Multiprocessor Mode.....	3942
36.9.1 Sending an Address.....	3942
36.10 SCI Communication Format.....	3943
36.10.1 Receiver Signals in Communication Modes.....	3944
36.10.2 Transmitter Signals in Communication Modes.....	3945
36.11 SCI Port Interrupts.....	3946
36.11.1 Break Detect.....	3947
36.12 SCI Baud Rate Calculations.....	3947
36.13 SCI Enhanced Features.....	3948
36.13.1 SCI FIFO Description.....	3948
36.13.2 SCI Auto-Baud.....	3950
36.13.3 Autobaud-Detect Sequence.....	3950
36.14 Software.....	3951

36.14.1 SCI Examples.....	3951
36.15 SCI Registers.....	3953
36.15.1 SCI Base Address Table (C28).....	3953
36.15.2 SCI_REGS Registers.....	3954
36.15.3 SCI Registers to Driverlib Functions.....	3975
37 Serial Peripheral Interface (SPI)	3978
37.1 Introduction.....	3979
37.1.1 Features.....	3979
37.1.2 SPI Related Collateral.....	3979
37.1.3 Block Diagram.....	3980
37.2 System-Level Integration.....	3981
37.2.1 SPI Module Signals.....	3981
37.2.2 Configuring Device Pins.....	3982
37.2.3 SPI Interrupts.....	3982
37.2.4 DMA Support.....	3984
37.3 SPI Operation.....	3985
37.3.1 Introduction to Operation.....	3985
37.3.2 Master Mode.....	3986
37.3.3 Slave Mode.....	3987
37.3.4 Data Format.....	3989
37.3.5 Baud Rate Selection.....	3990
37.3.6 SPI Clocking Schemes.....	3991
37.3.7 SPI FIFO Description.....	3992
37.3.8 SPI DMA Transfers.....	3993
37.3.9 SPI High-Speed Mode.....	3994
37.3.10 SPI 3-Wire Mode Description.....	3994
37.4 Programming Procedure.....	3996
37.4.1 Initialization Upon Reset.....	3996
37.4.2 Configuring the SPI.....	3996
37.4.3 Configuring the SPI for High-Speed Mode.....	3997
37.4.4 Data Transfer Example.....	3998
37.4.5 SPI 3-Wire Mode Code Examples.....	3999
37.4.6 SPI STEINV Bit in Digital Audio Transfers.....	4001
37.5 Software.....	4002
37.5.1 SPI Examples.....	4002
37.6 SPI Registers.....	4005
37.6.1 SPI Base Address Table (C28).....	4005
37.6.2 SPI_REGS Registers.....	4006
37.6.3 SPI Registers to Driverlib Functions.....	4024
38 Universal Serial Bus (USB) Controller	4026
38.1 Introduction.....	4027
38.1.1 Features.....	4027
38.1.2 USB Related Collateral.....	4027
38.1.3 Block Diagram.....	4028
38.2 Functional Description.....	4030
38.2.1 Operation as a Device.....	4030
38.2.2 Operation as a Host.....	4035
38.2.3 DMA Operation.....	4039
38.2.4 Address/Data Bus Bridge.....	4039
38.3 Initialization and Configuration.....	4041
38.3.1 Pin Configuration.....	4041
38.3.2 Endpoint Configuration.....	4042
38.4 USB Global Interrupts.....	4042
38.5 Software.....	4043
38.5.1 USB Examples.....	4043
38.6 USB Registers.....	4048
38.6.1 USB Base Address Table (C28).....	4048
38.6.2 USB_REGS Registers.....	4049
38.6.3 USB Registers to Driverlib Functions.....	4195

47 Synchronous Serial Interface (SSI).....	5362

47.1 Introduction.....	5363
47.1.1 Features.....	5363
47.1.2 Block Diagram.....	5363
47.2 Functional Description.....	5365
47.2.1 Bit Rate Generation.....	5365
47.2.2 FIFO Operation.....	5365
47.2.3 SSInFSS Function.....	5366
47.2.4 Interrupts.....	5366
47.2.5 Frame Formats.....	5367
47.2.6 DMA Operation.....	5372
47.3 Initialization and Configuration.....	5373
47.4 Software.....	5374
47.4.1 SSI Examples.....	5374
47.5 SSI Registers.....	5374
47.5.1 SSI Base Addresses.....	5374
47.5.2 SSI_REGS Registers.....	5375
48 Universal Asynchronous Receiver/Transmitter (UART).....	5407
48.1 Introduction.....	5408
48.1.1 Features.....	5408
48.1.2 Block Diagram.....	5408
48.2 Functional Description.....	5408
48.2.1 Transmit and Receive Logic.....	5409
48.2.2 Baud-Rate Generation.....	5410
48.2.3 Data Transmission.....	5411
48.2.4 Serial IR (SIR).....	5411
48.2.5 9-Bit UART Mode.....	5412
48.2.6 FIFO Operation.....	5413
48.2.7 Interrupts.....	5413
48.2.8 Loopback Operation.....	5414
48.2.9 DMA Operation.....	5414
48.3 Initialization and Configuration.....	5415
48.4 Software.....	5416
48.4.1 UART Examples.....	5416
48.5 UART Registers.....	5417
48.5.1 UART Base Addresses.....	5417
48.5.2 UART_REGS Registers.....	5418
48.5.3 UART_REGS_WRITE Registers.....	5458
49 Micro Direct Memory Access (μDMA).....	5460
49.1 Introduction.....	5461
49.1.1 Features.....	5461
49.1.2 Block Diagram.....	5462
49.2 Functional Description.....	5462
49.2.1 Channel Assignments.....	5463
49.2.2 Priority.....	5464
49.2.3 Arbitration Size.....	5464
49.2.4 Request Types.....	5464
49.2.5 Channel Configuration.....	5465
49.2.6 Transfer Modes.....	5467
49.2.7 Transfer Size and Increment.....	5475
49.2.8 Peripheral Interface.....	5475
49.2.9 Software Request.....	5476
49.2.10 Interrupts and Errors.....	5476
49.3 Initialization and Configuration.....	5476
49.3.1 Module Initialization.....	5476
49.3.2 Configuring a Memory-to-Memory Transfer.....	5476
49.3.3 Configuring a Peripheral for Simple Transmit.....	5478
49.3.4 Configuring a Peripheral for Ping-Pong Receive.....	5480
49.3.5 Configuring Channel Assignments.....	5482
49.4 Software.....	5483
49.4.1 UDMA Examples.....	5483
49.5 μDMA Registers.....	5483

49.5.1 μ DMA Base Addresses.....	5483
49.5.2 UDMAREGS Registers.....	5484
49.5.3 UDMACHDES Registers.....	5515
50 Revision History.....	5521

About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data sheet, rather a companion guide that should be used alongside the device-specific data sheet to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data sheet. This allows the data sheet to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

Note

Texas Instruments is transitioning to use more inclusive terminology. Some language may be different than what you expect to see for certain technology areas.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
 - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
 - Reserved bits in a register figure can have one of multiple meanings:
 - Not implemented on the device
 - Reserved for future device expansion
 - Reserved for TI testing
 - Reserved configurations of the device that are not supported
 - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

Glossary

TI Glossary This glossary lists and explains terms, acronyms, and definitions.

Related Documentation From Texas Instruments

The following chapters describe the C28x Configuration and System Resources.

1.1 Technical Reference Manual Overview

The block diagram for the F2838x device is shown in [Figure 1-1](#). This Technical Reference Manual is organized into five major sections:

- [C28x SYSTEM RESOURCES](#)

These chapters describe the C28x CPU subsystem, C28x Boot ROM, device configuration, and other system peripherals.

- [ANALOG PERIPHERALS](#)

These chapters describe the Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), Comparator Subsystem (CMPSS), and general analog subsystem configuration.

- [CONTROL PERIPHERALS](#)

These chapters describe the Enhanced Capture (eCAP), High Resolution Capture (HRCAP), Enhanced Pulse Width Modulator (ePWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- [COMMUNICATION PERIPHERALS](#)

These chapters describe the communication peripherals available to the C28x subsystem such as the I2C, SCI, FSI, McBSP, PMBUS, and SPI. The CAN, EtherCAT, and USB peripherals are also described in this section and can be assigned to the CM subsystem.

- [CONNECTIVITY MANAGER \(CM\)](#)

These chapters describe the Connectivity Manager (CM) subsystem as well as the AES, GCRC, CM-I2C, CM-UART, SSI, and Ethernet peripherals.

Chapter 2 **C2000™ Microcontrollers Software Support**

This chapter discusses the C2000Ware for the C2000™ microcontrollers. The C2000Ware can be downloaded from: www.ti.com/tool/C2000WARE

2.1 Introduction.....	137
2.2 C2000Ware Structure.....	137
2.3 Documentation.....	137
2.4 Devices.....	137
2.5 Libraries.....	137
2.6 Code Composer Studio™ Integrated Development Environment (IDE).....	137
2.7 SysConfig and PinMUX Tool.....	138

2.1 Introduction

C2000Ware for the C2000™ microcontrollers is a cohesive set of development software and documentation designed to minimize software development time. From device-specific drivers and libraries to device peripheral examples, C2000Ware provides a solid foundation to begin development and evaluation of your product.

C2000Ware can be downloaded from: www.ti.com/tool/C2000WARE

2.2 C2000Ware Structure

The C2000Ware software package is organized into the following directory structure as shown in [Table 2-1](#).

Table 2-1. C2000Ware Root Directories

Directory Name	Description
boards	Contains the hardware design schematics, BOM, Gerber files, and documentation for C2000 controlCARDS.
device_support	Contains all device-specific support files, bit field headers and device development user's guides.
docs	Contains the C2000Ware package user's guides and the HTML index page of all package documentation.
driverlib	Contains the device-specific driver library and driver-based peripheral examples.
libraries	Contains the device-specific and core libraries.

2.3 Documentation

Within C2000Ware, there is an extensive amount of development documentation ranging from board design documentation, to library user's guides, to driver API documentation. The "boards" directory contains all the hardware design, BOM, Gerber files, and more for controlCARDS. To assist with locating the necessary documentation, an HTML page is provided that contains a full list of all the documents in the C2000Ware package. Locate this page in the "docs" directory.

2.4 Devices

C2000Ware contains the necessary software and documentation to jumpstart development for C2000™ microcontrollers. Each device includes device-specific common source files, peripheral example projects, bit field headers, and if available, a device peripheral driver library. Additionally, documentation is provided for each device on how to set up a CCS project, as well as give an overview of all the included example projects and assist with troubleshooting. For devices with a driver library, documentation is also included that details all the peripheral APIs available.

To learn more about C2000™ microcontrollers, visit: www.ti.com/c2000.

2.5 Libraries

The libraries included in C2000Ware range from fixed-point and floating-point math libraries, to specialized DSP libraries, as well as calibration libraries. Each library includes documentation and examples, where applicable. Additionally, the Flash API files and boot ROM source code are located in the "libraries" directory.

2.6 Code Composer Studio™ Integrated Development Environment (IDE)

Code Composer Studio™ is an integrated development environment (IDE) that supports TI's microcontroller and embedded processors portfolio. The Code Composer Studio™ IDE comprises a suite of tools used to develop and debug embedded applications. The latest version of Code Composer Studio™ IDE can be obtained at: www.ti.com/ccstudio

All projects and examples in C2000Ware are built for and tested with the Code Composer Studio™ IDE. Although the Code Composer Studio™ IDE is not included with the C2000Ware installer, Code Composer Studio™ IDE is easily obtainable in a variety of versions.

2.7 SysConfig and PinMUX Tool

To help simplify configuration challenges and accelerate software development, Texas Instruments™ created SysConfig, an intuitive and comprehensive collection of graphical utilities for configuring pins, peripherals, subsystems, and other components. SysConfig helps you manage, expose, and resolve conflicts visually so that you have more time to create differentiated applications.

The tool's output includes C header and code files that can be used with C2000Ware examples or used to configure custom software.

The SysConfig tool automatically selects the pinmux settings that satisfy the entered requirements. The SysConfig tool is delivered integrated in the Code Composer Studio™ IDE, in the C2000Ware GPIO example, as a standalone installer, or can be used by way of the cloud tools portal at: dev.ti.com

Chapter 3

C28x System Control and Interrupts

This chapter explains system control and interrupts for the C28x cores found on this MCU. The system control module configures and manages the overall operation of the device, and provides information about the device status. Configurable features in system control include reset control, NMI operation, peripheral interrupts, power control, clock control, and low-power modes.

3.1 C28x System Control Introduction

On this device, the CPU1 subsystem acts as a master, and by default (upon reset), the CPU owns all the configuration and control. Through software running on CPU1, peripherals and I/Os can be configured to be accessible by the CPU2 subsystem or the CM subsystem and the chosen configurations can be locked.

The PLL clock configuration is also owned by the CPU1 subsystem by default, but a clock control semaphore is provided by which CPU2 can grab access to the clock configuration registers.

Each CPU can be independently configured to accept interrupts from different peripherals. The interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. All stages must be configured and enabled for an interrupt to propagate to the CPU.

Each CPU has an NMI module to handle different exceptions during run time. If the NMI was on CPU1, any NMI exception that is unhandled before the NMI Watchdog (NMIWD) timer expiration resets the entire device. If the NMI was on the CPU2 subsystem, then the CPU2 subsystem alone is reset, in which case the CPU1 subsystem is informed by another NMI that the CPU2 subsystem was reset because of an NMIWD timer expiration.

Each CPU subsystem has a watchdog timer module for software to use. Watchdog timer expiration on CPU2 resets only the CPU2 subsystem when configured to generate a reset, but watchdog timer expiration on CPU1 resets the entire device.

Except for a CPU2 standalone internal reset such as CPU2.NMIWD or CPU2.WD each time the device is reset, the CPU2 subsystem is held under reset until the CPU1 subsystem brings CPU2 out of reset. This is done by the boot ROM software running on the CPU1 core.

The register space of the device system control module can be found in [Section 3.16](#).

This chapter explains the system control module on both the CPU subsystems.

3.2 System Control Functional Description

The system control module provides the following capabilities:

- Device identification and configuration registers
- Reset control
- Exceptions and Interrupt control
- Safety and error handling features of the device
- Power control
- Clock control
- Low Power modes
- Security module
- Inter-Processor Communication (IPC)

3.2.1 Device Identification

Device identification registers provide information on device class, device family, revision, part number, pin count, and device qualification status.

All of the device information is part of the DEV_CFG_REGS space and is accessible only by the software running on the CPU1 subsystem.

The C28x device identification registers are: PARTIDL, PARTIDH, and REVID.

A 256-bit Unique ID (UID) is available in UID_REGS. The 256 bits are separated into registers:

- UID_PSRAND0-5: 192 bits of pseudo-random data
- UID_UNIQUE: 32-bit unique data; the value in this register is unique across all devices with the same PARTIDH
- UID_CHECKSUM: 32-bit Fletcher checksum of UID_PSRAND0-5 and UID_UNIQUE and calculated as either little- or big-endian during factory testing
- CPU ID: 16-bit location in OTP. The value at this location provides the information about CPU (CPU1 or CPU2).

3.2.2 Device Configuration Registers

Several registers provide users with configuration information for the C28x subsystems for debug and identification purposes. This information includes the features of the peripherals and how much RAM and FLASH memory is available on this part.

These registers are part of DEV_CFG_REGS space and are accessible only by the software running on the CPU1 subsystem.

- DC0 – DC27: Device Configuration or Capabilities registers.
If a particular bit in these registers is set to 1, then the associated/feature or module is available in the device.
- PERCNF: Peripheral configuration register.
This register configures ADC capabilities, and enables or disables the USB internal PHY.
- CPUID: CPU identification register.
This register is available for software to identify on which CPU the software is executing.

3.3 Resets

This section explains the types and effects of the different resets on this device.

3.3.1 Reset Sources

[Table 3-1](#) summarizes the various reset signals and their effect on the device. CM subsystem resets are described in [Section 41.2](#).

Table 3-1. Reset Signals

Reset Source	CPU1 Core Reset (C28x, TMU, FPU, VCRC)	CPU1 Peripheral Reset	CPU2 Core Reset (C28x, TMU, FPU, VCRC)	CPU2 and CM Peripheral Reset	CPU2 and CM Held In Reset	JTAG / Debug Logic Reset	IOs	XRSn Output
POR	Yes	Yes	Yes	Yes	Yes	Yes	Hi-Z	Yes
XRSn Pin	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SIMRESET.XRSn	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.WDRS	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.NMIWDRS	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.SYSRS (Debugger Reset)	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SIMRESET.CPU1RSn	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SCCRESET	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.HWBISTR	Yes	-	-	-	-	-	-	-
CPU2.SYSRS (Debugger Reset)	-	-	Yes	Yes	-	-	-	-
CPU2.WDRS	-	-	Yes	Yes	-	-	-	-
CPU2.NMIWDRS	-	-	Yes	Yes	-	-	-	-
CPU2.SCCRESET	-	-	Yes	Yes	-	-	-	-
CPU2.HWBISTR	-	-	Yes	-	-	-	-	-
ECAT_RESET_OUT	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
TRSTn	-	-	-	-	-	Yes	-	-

Note

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain their state across multiple resets. These can only be cleared by a power-on reset (POR) or by writing 1 to the corresponding bit in RESCCLR register (status can be cleared by writing 1 to RESC register bits also). Each CPU has a RESC register, referred to as CPU1.RESC and CPU2.RESC.

The resets can be divided into a few groups:

- Chip-level resets (XRSn, POR, CPU1.WDRS, and CPU1.NMIWDRS, SIMRESET.XRSn, ECAT_RESET_OUT (if enabled)), which reset all or almost all of the device.
- System resets (CPU1.SYSRS and CPU1.SCCRESET, SIMRESET.CPU1RSn), which reset a large subset of the device but maintain some system-level configuration.
- CPU2 subsystem resets (CPU2.SYSRS, CPU2.WDRS, CPU2.NMIWDRS, and CPU2.SCCRESET), which reset only CPU2 and the peripherals owned by it.
- Special resets (CPU1.HWBISTR, CPU2.HWBISTR, and TRSTn), which enable specific device functions.

Whenever the CPU1 subsystem is reset, CPU2, CM and the peripherals owned by them also get reset and held in reset until CPU1 brings CPU2 and CM out of reset by writing to the CPU2RESCTL and CMRESCTL registers respectively. This is done by user application code on CPU1.

Many peripheral modules have individual resets accessible through the system control registers. For information about a module's reset state, refer to the appropriate chapter for that module.

After a POR the boot ROMs clear all of the system and message RAMs on both CPUs.

3.3.2 External Reset ($\overline{XRSn}$)

The external reset ($\overline{XRS}$) is the main chip-level reset for the device. $\overline{XRS}$ resets both C28x CPUs, the CM subsystem, all peripherals and I/O pin configurations, and most of the system control registers. $\overline{XRS}$ also holds CPU2 and the CM subsystem in reset. There is a dedicated open-drain pin for $\overline{XRSn}$. This pin can be used to drive reset pins for other ICs in the application, and can be driven by an external source. The $\overline{XRSn}$ is driven internally during watchdog, NMI, and power-on resets.

The $\overline{XRSn}$ bit in the RESC register is set whenever $\overline{XRS}$ is driven low for any reason. This bit is then cleared by the boot ROM.

3.3.3 Simulate External Reset

The user can simulate an external reset ($\overline{XRS}$) in software. This can be done by setting the $\overline{XRSn}$ bit to 1 in the SIMRESET register by CPU1 software. This toggles the $\overline{XRS}$ pin; hence, resetting the full device (just like external reset).

After this reset, the SIMRESET_ $\overline{XRSn}$ bit in the RESC register is set. Software can read this bit to know the cause of the reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

3.3.4 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The $\overline{XRS}$ pin is held low for the duration of the POR. In most applications, $\overline{XRS}$ is held low long enough to reset other system ICs, but some applications may require a longer pulse. In these cases, $\overline{XRS}$ can be driven low externally to provide the correct reset duration. A POR resets everything that $\overline{XRS}$ does, along with a few other registers – the reset cause register (RESC), the NMI shadow flag register (NMISHDFLG).

After a POR, the POR and $\overline{XRSn}$ bits in RESC are set. These bits are then cleared by the boot ROM.

3.3.5 Debugger Reset ($\overline{SYSRS}$)

During development, it is sometimes necessary to reset the CPU and the peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, each CPU has a subsystem reset, which can be triggered by a debugger using Code Composer Studio IDE. CPU2 subsystem reset (CPU2. $\overline{SYSRS}$) resets only CPU2, the peripherals owned by it, clock gating and LPM configuration. It does not hold CPU2 in reset. CPU1 subsystem reset (CPU1. $\overline{SYSRS}$) resets CPU1, the peripherals owned by it, many system control registers (including its clock gating and LPM configuration and the peripherals' CPU ownership), and all I/O pin configurations. It also produces a CPU2. $\overline{SYSRS}$ and CM.RESETn and holds both, CPU2 and CM, in reset (CCS Gel file has code to release CPU2 and CM out of reset on CPU1 debug reset).

Neither $\overline{SYSRS}$ resets the ICEPick debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see [Section 3.3.4](#)).

3.3.6 Simulate CPU1 Reset

The user can simulate a CPU1 reset (CPU1. $\overline{SYSRS}$) in software. This can be done by setting CPU1RSn bit to 1 in the SIMRESET register by CPU1 software. This toggles the CPU1. $\overline{SYSRS}$ signals; hence, resetting the CPU1 as well as the CPU2 and CM subsystem (just like the debugger reset).

After this reset, the SIMRESET_CPU1RSn bit in the RESC register is set. Software can read this bit to know the cause of the reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

3.3.7 Watchdog Reset ($\overline{WDRS}$)

Each CPU has a watchdog timer that can optionally trigger a reset that lasts for 512 INTOSC1 cycles. CPU1 watchdog reset (CPU1. $\overline{WDRS}$) produces an $\overline{XRS}$. CPU2 watchdog reset (CPU2. $\overline{WDRS}$) produces a CPU2. $\overline{SYSRS}$ and triggers an NMI on CPU1.

After a watchdog reset, the WDRSn bit in RESC is set. Software can read this bit to know the cause of reset and clear the status by writing 1 into corresponding bit in RESCCLR register.

3.3.8 NMI Watchdog Reset ($\overline{NMIWDRS}$)

Each CPU has a non-maskable interrupt (NMI) module that detects hardware errors in the system. Each NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. CPU1 NMI watchdog reset (CPU1. $\overline{NMIWDRS}$) produces an $\overline{XRS}$. CPU2 NMI watchdog reset (CPU2. $\overline{NMIWDRS}$) produces a CPU2. $\overline{SYSRS}$ and triggers an NMI on CPU1.

After an NMI watchdog reset, the NMIWDRSn bit in RESC is set.

3.3.9 Secure Code Copy Reset ($\overline{SCCRESET}$)

Dual-zone Code Security Module (DCSM) on this device locks read access to secure memories of each CPU subsystem. To facilitate CRC checks and copying of CLA code, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a secure copy or CRC function, the DCSM triggers a reset. CPU1 security reset (CPU1. $\overline{SCCRESET}$) is similar to a CPU1. $\overline{SYSRS}$, and CPU2 security reset (CPU2. $\overline{SCCRESET}$) is similar to a CPU2. $\overline{SYSRS}$. However, the security reset also resets the debug logic to deny access to a potential attacker.

After a security reset, the SCCRESETn bit in RESC is set. Software can read this bit to know the cause of reset and clear the status by writing 1 into corresponding bit in RESCCLR register.

3.3.10 ESC Reset Output

The user can configure the EtherCAT Slave Controller (ESC) module to drive the XRSn pin low whenever the ESC module receives a reset. This is done by setting the DEVICE_RESET_EN bit to 1 in the ECAT_RESET_DEST_CONFIG register of the ESC module (EtherCAT subsystem). By default this is not enabled. Since this toggles the XRSn pin, all effects of an external XRSn reset take effect.

After an ECAT_RESET_OUT reset, the ECAT_RESET_OUT bit in RESC is set. Software can read this bit to know the cause of reset and clear the status by writing 1 into corresponding bit in RESCCLR register.

3.3.11 Test Reset ($\overline{TRST}$)

The ICEPick debug module and associated JTAG logic has a reset ($\overline{TRST}$) that is controlled by a dedicated pin. This reset is normally active unless the user connects a debugger to the device. For more information on the debug module, see the TI Processors Wiki page on ICEPick: <http://processors.wiki.ti.com/index.php/ICEPICK>.

The $\overline{TRST}$ does not have a normal RESC bit, but the TRSTn_pin_status bit indicates the state of the pin.

3.4 Peripheral Interrupts

This section explains the peripheral interrupt handling on the device. Non-maskable interrupts are covered in [Section 3.5](#). Software interrupts and emulation interrupts are not covered in this document. For information on those, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

3.4.1 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause its current execution and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead or program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until it is processed. The enable registers block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from a list called the vector table.

3.4.2 Interrupt Architecture

The C28x CPU has fourteen peripheral interrupt lines. Two of them (INT13 and INT14) are connected directly to CPU timers 1 and 2, respectively. The remaining twelve are connected to peripheral interrupt signals through the enhanced Peripheral Interrupt Expansion module (ePIE, or PIE as a shortened version). The PIE multiplexes up to sixteen peripheral interrupts into each CPU interrupt line. It also expands the vector table to allow each interrupt to have its own ISR. This allows the CPU to support a large number of peripherals.

An interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. Each stage has its own enable and flag registers. This system allows the CPU to handle one interrupt while others are pending, implement and prioritize nested interrupts in software, and disable interrupts during certain critical tasks.

[Figure 3-1](#) shows the interrupt architecture for this device.

Figure 3-1. Device Interrupt Architecture

3.4.2.1 Peripheral Stage

Each peripheral has a unique interrupt configuration, which is described in that peripheral's chapter. Some peripherals allow multiple events to trigger the same interrupt signal. For example, a communications peripheral can use the same interrupt to indicate that data has been received or that there has been a transmission error. The cause of the interrupt can be determined by reading the peripheral's status register. Often, the bits in the status register must be cleared manually before another interrupt is generated.

3.4.2.2 PIE Stage

The PIE provides individual flag and enable register bits for each of the peripheral interrupt signals, which are sometimes called PIE channels. These channels are grouped according to the associated CPU interrupt. Each PIE group has one 16-bit enable register (PIEIERx), one 16-bit flag register (PIEIFRx), and one bit in the PIE acknowledge register (PIEACK). The PIEACK register bit acts as a common interrupt mask for the entire PIE group.

When the CPU receives an interrupt, the CPU fetches the address of the ISR from the PIE. The PIE returns the vector for the lowest-numbered channel in the group that is both flagged and enabled. This gives lower-numbered interrupts a higher priority when multiple interrupts are pending.

If no interrupt is both flagged and enabled, the PIE returns the vector for channel 1. This condition does not happen unless software changes the state of the PIE while an interrupt is propagating. [Section 3.4.4](#) contains procedures for safely modifying the PIE configuration once interrupts have been enabled.

3.4.2.3 CPU Stage

Like the PIE, the CPU provides flag and enable register bits for each of the interrupts. There is one enable register (IER) and one flag register (IFR), both of which are internal CPU registers. There is also a global interrupt mask, which is controlled by the INTM bit in the ST1 register. This mask can be set and cleared using the CPU's SETC instruction. In C code, C2000Ware's DINT and EINT macros can be used for this purpose.

Writes to IER and INTM are atomic operations. In particular, if INTM is cleared, the next instruction in the pipeline runs with interrupts disabled. No software delays are needed.

3.4.2.4 Dual-CPU Interrupt Handling

Each CPU has its own PIE. Both PIEs must be configured independently.

Some interrupts come from shared peripherals that can be owned by either CPU, such as the ADCs and SPIs. These interrupts are sent to both PIEs regardless of the ownership of the peripheral. Thus, a peripheral owned by one CPU can cause an interrupt on the other CPU, if that interrupt is enabled in the other CPU's PIE.

3.4.3 Interrupt Entry Sequence

[Figure 3-2](#) shows how peripheral interrupts propagate to the CPU.

Figure 3-2. Interrupt Propagation Path

When a peripheral generates an interrupt (on PIE group x, channel y), the interrupt triggers the following sequence of events:

1. The interrupt is latched in PIEIFRx.y.
2. If PIEIERx.y is set, the interrupt propagates.
3. If PIEACK.x is clear, the interrupt propagates and PIEACK.x is set.
4. The interrupt is latched in IFR.x.
5. If IER.x is set, the interrupt propagates.
6. If INTM is clear, the CPU receives the interrupt.
7. Any instructions in the D2 or later stage of the pipeline are run to completion. Instructions in earlier stages are flushed.
8. The CPU saves the context on the stack.
9. IFR.x and IER.x are cleared. INTM is set. EALLOW is cleared.
10. The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared.
11. The CPU branches to the ISR.

The interrupt latency is the time between PIEIFRx.y latching the interrupt and the first ISR instruction entering the execution stage of the CPU pipeline. The minimum interrupt latency is 14 SYSCLK cycles. Wait states on the ISR or stack memories add to the latency. External interrupts add a minimum of 2 SYSCLK cycles for GPIO synchronization plus extra time for input qualification (if used). Loops created using the C28x RPT instruction cannot be interrupted.

3.4.4 Configuring and Using Interrupts

At power-up, no interrupts are enabled by default. The PIEIER and IER registers are cleared and INTM is set. The application code is responsible for configuring and enabling all peripheral interrupts.

3.4.4.1 Enabling Interrupts

To enable a peripheral interrupt, perform the following steps:

1. Disable interrupts globally (DINT or SETC INTM).
2. Enable the PIE by setting the ENPIE bit of the PIELCTRL register.
3. Write the ISR vector for each interrupt to the appropriate location in the PIE vector table, which is found in [Section 3.4.7](#).
4. Set the appropriate PIEIERx bit for each interrupt. The PIE group and channel assignments are found in [Section 3.4.7](#).
5. Set the CPU IER bit for any PIE group containing enabled interrupts.
6. Enable the interrupt in the peripheral.
7. Enable interrupts globally (EINT or CLRC INTM).

Step 4 does not apply to the Timer1 and Timer2 interrupts, which connect directly to the CPU.

3.4.4.2 Handling Interrupts

ISRs are similar to normal functions, but must do the following:

1. Save and restore the state of certain CPU registers (if used).
2. Clear the PIEACK bit for the interrupt group.
3. Return using the IRET instruction.

Requirements 1 and 3 are handled automatically by the TMS320C28x C compiler if the function is defined using the `__interrupt` keyword. For information on this keyword, see the Keywords section of the [TMS320C28x Optimizing C/C++ Compiler v6.2.4 User's Guide](#). For information on writing assembly code to handle interrupts, see the Standard Operation for Maskable Interrupts section of the [TMS320C28x CPU and Instruction Set Reference Guide](#).

The PIEACK bit for the interrupt group must be cleared manually in user code. This is normally done at the end of the ISR. If the PIEACK bit is not cleared, the CPU does not receive any further interrupts from that group. This does not apply to the Timer1 and Timer2 interrupts, which do not go through the PIE.

3.4.4.3 Disabling Interrupts

To disable all interrupts, set the CPU global interrupt mask using DINT or SETC INTM. It is not necessary to add NOPs after setting INTM or modifying IER – the next instruction executes with interrupts disabled.

Individual interrupts can be disabled using the PIEIERx registers, but care must be taken to avoid race conditions. If an interrupt signal is already propagating when the PIEIER write completes, the interrupt may reach the CPU and trigger a spurious interrupt condition. To avoid this, use the following procedure:

1. Disable interrupts globally (DINT or SETC INTM).
2. Clear the PIEIER bit for the interrupt.
3. Wait 5 cycles to make sure that any propagating interrupt has reached the CPU IFR register.
4. Clear the CPU IFR bit for the interrupt's PIE group.
5. Clear the PIEACK bit for the interrupt's PIE group.
6. Enable interrupts globally (EINT or CLRC INTM).

Interrupt groups can be disabled using the CPU IER register. This cannot cause a race condition, so no special procedure is needed.

PIEIFR bits must never be cleared in software since the read/modify/write operation may cause incoming interrupts to be lost. The only safe way to clear a PIEIFR bit is to have the CPU take the interrupt. The following procedure can be used to bypass the normal ISR:

1. Disable interrupts globally (DINT or SETC INTM).
2. Modify the PIE vector table to map the PIEIFR bit's interrupt vector to an empty ISR. This ISR only contains a return from interrupt instruction (IRET).
3. Disable the interrupt in the peripheral registers.
4. Enable interrupts globally (EINT or CLRC INTM).
5. Wait for the pending interrupt to be serviced by the empty ISR.
6. Disable interrupts globally.
7. Modify the PIE vector table to map the interrupt vector back to the original ISR.
8. Clear the PIEACK bit for the interrupt's PIE group.
9. Enable interrupts globally.

3.4.4.4 Nesting Interrupts

By default, interrupts do not nest. It is possible to nest and prioritize interrupts via software control of the IER and PIEIERx registers. Example code can be found in C2000Ware and documentation is available at software-dl.ti.com/C2000/docs/c28x_interrupt_nesting/html/index.html.

3.4.5 PIE Channel Mapping

Table 3-2 shows the PIE group and channel assignments for each peripheral interrupt. Each row is a group, and each column is a channel within that group. When multiple interrupts are pending, the lowest-numbered channel in the lowest-numbered group is serviced first. Thus, the interrupts at the top of the table have the highest priority, and the interrupts at the bottom have the lowest priority.

Note

Cells marked "-" are Reserved. CPUx is CPU1 for CPU1 PIE and CPU2 for CPU2 PIE.

3.4.5.1 PIE Interrupt Priority

3.4.5.1.1 Channel Priority

For every PIE group, the low number channels in the group have the highest priority. For instance in PIE group 1, channel 1.1 has priority over channel 1.3. If those two enabled interrupts occurred simultaneously, channel 1.1 is serviced first with channel 1.3 left pending. Once the ISR for channel 1.1 completes and provided there are no other enabled and pending interrupts for PIE group 1, channel 1.3 is serviced. However, for the CPU to service any more interrupts from a PIE group, PIEACK for the group must be cleared. For this specific example, for channel 1.3 to be serviced, channel 1.1's ISR has to clear PIEACK for group 1.

The following example describes an alternative scenario: channel 1.1 is currently being serviced by the CPU, channel 1.3 is pending and before channel 1.1's ISR completes, channel 1.2 that is enabled also comes in. Since channel 1.2 has a higher priority than channel 1.3, the CPU services channel 1.2 and channel 1.3 is still left pending. Using the steps from the Interrupt Entry Sequence ([Section 3.4.3](#)), channel 1.2 interrupt can happen as late as step 10 (the CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared) and the channel 1.2 interrupt is still serviced ahead of channel 1.3.

3.4.5.1.2 Group Priority

Generally, the lowest channel in the lowest PIE group has the highest priority. An example of this is channels 1.1 and 2.1. Those two channels have the highest priority in the respective groups. If the interrupts for those two enabled channels happened simultaneously and provided there are no other enabled and pending interrupts, channel 1.1 is serviced first by the CPU with channel 2.1 left pending.

However, there are cases where channel priority supersedes group priority. This special case happens depending on which step the CPU is currently at in the Interrupt Entry Sequence ([Section 3.4.3](#)).

The following illustrates an example of this special case.

The CPU is about to service channel 2.3 and is currently going through the steps in the Interrupt Entry Sequence ([Section 3.4.3](#)).

1. As the CPU reaches step 10 (the CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared), two enabled interrupts: channel 1.1 and channel 2.1 come in.
2. Due to channel priority, channel 2.1 is serviced ahead of channel 2.3. However, group priority dictates that channel 1.1 be serviced ahead of channels 2.1 and 2.3.
3. Channel priority supersedes here and channel 2.1 is serviced ahead of 1.1 and 2.3.
4. After channel 2.1 completes, channel 1.1 is serviced followed by channel 2.3.

Group priority is only maintained if no interrupts are currently being serviced, that is, the Interrupt Entry Sequence ([Section 3.4.3](#)) is not executing.

3.4.6 System Error and CM Status Interrupts

SYS_ERR and CM_STATUS consolidate several sources of interrupts. These sources set the respective bit in the SYS_ERR_INT_FLG and CM_STATUS_INT_FLG registers. Any set bit in the SYS_ERR_INT_FLG and CM_STATUS_INT_FLG registers also sets the GINT (Global Interrupt) bit. GINT has to be cleared before anymore SYS_ERR or CM_STATUS interrupts are generated. If GINT is cleared with the source flags still set, another SYS_ERR or CM_STATUS interrupt is fired; therefore, clear the source flags before clearing GINT.

Figure 3-3 shows the sources for SYS_ERR and CM_STATUS interrupts.

Figure 3-3. System Error and CM Status Interrupt Sources

3.4.7 Vector Tables

Table 3-3 shows the CPU interrupt vector table. The vectors for INT1–INT12 are not used in this device. The reset vector is fetched from the boot ROM instead of from this table.

Table 3-3. CPU Interrupt Vectors

Name	Vector ID	Address	Size (x16)	Description	Core Priority	ePIE Group Priority
Reset	0	0x0000 0D00	2	Reset is always fetched from location 0x003F_FFC0 in Boot ROM	1 (Highest)	-

3.5 Exceptions and Non-Maskable Interrupts

This section describes system-level error conditions that can trigger a non-maskable interrupt (NMI). The interrupt allows the application to respond to the error.

3.5.1 Configuring and Using NMIs

Each CPU subsystem has an NMI module. This section provides details of the NMI module. An incoming NMI sets a status bit in the NMIFLG register and starts the NMI watchdog counter. This counter is clocked by the SYSCLK, and if the counter reaches the value programmed in NMIWDPRD register, the counter triggers an NMI watchdog reset (NMIWDRS). To prevent this, the NMI handler must clear the flag bit using the NMIFLGCLR register. Once all flag bits are clear, the NMIINT bit in the NMIFLG register must be cleared to allow future NMIs to be taken.

The NMI module is enabled by the boot ROM during the startup process. To respond to NMIs, an NMI handler vector must be written to the PIE vector table.

3.5.2 Emulation Considerations

The NMI watchdog counter behaves as follows under debug conditions:

CPU Suspended:	When the CPU is suspended, the NMI watchdog counter is suspended.
Run-Free Mode:	When the CPU is placed in run-free mode, the NMI watchdog counter resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the NMI watchdog counter is suspended. The counter remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the NMI watchdog counter operates as normal.

3.5.3 NMI Sources

There are several types of hardware errors that can trigger an NMI. Additional information about the error is usually available from the module that detects it.

3.5.3.1 Missing Clock Detection

The missing clock detection logic monitors OSCCLK for failure. If the OSCCLK source stops, the PLL is bypassed, OSCCLK is connected to INTOSC1, and NMIs are fired to both CPUs. For more information on missing clock detection, see [Section 3.7.7.1](#).

3.5.3.2 RAM Uncorrectable Error

A single-bit parity error, double-bit ECC data error, or single-bit ECC address error in a RAM read triggers an NMI. This applies to CPU, CLA, and DMA reads. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on RAM error detection, see [Section 3.12.1.9](#).

3.5.3.3 Flash Uncorrectable ECC Error

A double-bit ECC data error or single-bit ECC address error in a Flash read triggers an NMI. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt.

3.5.3.4 ROM Uncorrectable Error

On this device, ROM has a parity feature and a parity mismatch during read or execution triggers an NMI.

3.5.3.5 NMI Vector Fetch Mismatch

Each CPU's Peripheral Interrupt Expansion module (PIE) has redundant vector tables. If a mismatch in these tables is detected during a vector fetch, a user-specified error handler is run instead of the ISR. If the vector fetch was caused by an NMI, a second NMI is fired to the other CPU. Mismatches for other interrupts do not trigger an NMI. For more information about the vector address check, see [Section 3.6.2](#).

3.5.3.6 CPU2 Watchdog or NMI Watchdog Reset

A watchdog reset or NMI watchdog reset on CPU2 triggers an NMI on CPU1. Since a CPU1 reset also resets CPU2, this NMI source is not available on CPU2. Watchdog interrupts do not trigger an NMI.

3.5.3.7 CM NMI Watchdog Reset

A NMI watchdog reset on CM can generate NMI on CPU1. To enable this feature user need to set CMNMIWDRST configuration bit in CMTOCPU1NMICTL register.

3.5.3.8 EtherCAT Reset out

A reset out from EtherCAT module can generate NMI on CPU1. To enable this feature user need to set CPU_NMI_EN configuration bit in ESCSS_RESET_DEST_CONFIG register.

3.5.3.9 CRC Fail

A CRC fail result from BGCRC module can generate NMI to respective CPU. By default this NMI is enable. To disable this feature user need to configure NMIDIS configuration field in BGCRC_CTRL1 register with value "1010".

3.5.3.10 ERAD NMI

ERAD module can generate NMI based on different events which user can configure in ERAD.

3.5.4 Illegal Instruction Trap (ITRAP)

If the CPU tries to execute an illegal instruction, the CPU generates a special interrupt called an illegal instruction trap (ITRAP). This interrupt is non-maskable and has a vector in the PIE vector table. For more information about ITRAPs, see the Illegal-Instruction Trap section of the [TMS320C28x DSP CPU and Instruction Set Reference Guide](#).

Note

A RAM fetch access violation triggers an ITRAP in addition to the normal peripheral interrupt for RAM access violations. The CPU handles the ITRAP first.

3.6 Safety Features

This section gives details on features that monitor device operation during run-time to detect any error in operation.

3.6.1 Write Protection on Registers

3.6.1.1 LOCK Protection on System Configuration Registers

Several system configuration registers are protected from spurious CPU writes by “LOCK” registers. Once these associated LOCK register bits are set, the respective locked registers can no longer be modified by software. See the register descriptions for details.

3.6.1.2 EALLOW Protection

Several control registers are protected from spurious CPU writes by the EALLOW protection mechanism. The EALLOW bit in status register 1 (ST1) indicates the state of protection as shown in [Table 3-5](#).

Table 3-5. Access to EALLOW-Protected Registers

EALLOW Bit	CPU Writes	CPU Reads	JTAG Writes	JTAG Reads
0	Ignored	Allowed	Allowed ⁽¹⁾	Allowed
1	Allowed	Allowed	Allowed	Allowed

(1) The EALLOW bit is overridden via the JTAG port, allowing full access of protected registers during debug from the Code Composer Studio IDE.

At reset, the EALLOW bit is cleared, enabling EALLOW protection. While protected, all writes to protected registers by the CPU are ignored and only CPU reads, JTAG reads, and JTAG writes are allowed. If this bit is set, by executing the EALLOW instruction, the CPU is allowed to write freely to protected registers. After modifying registers, the registers can once again be protected by executing the EDIS instruction to clear the EALLOW bit.

3.6.2 CPU1 and CPU2 ePIE Vector Address Validity Check

The ePIE vector table on each CPU is duplicated into these two parts:

- Main ePIE Vector Table mapped from 0xD00 to 0xEFF in the C28x memory space
- Redundant ePIE Vector Table mapped from 0x1000D00 to 0x1000EFF in the C28x memory space

Following is the behavior of accesses to the ePIE memories:

- Data Writes to Main Vector Table: Writes to both memories
- Data Writes to Redundant Vector Table: Writes only to the Redundant Vector Table
- Vector Fetch: Data from both the vector tables are compared
- Data Read: Can read the Main and Redundant vector table separately

On every vector fetch from the ePIE, a hardware comparison (no cycle penalty is incurred to do the comparison) of both the vector table outputs is performed and if there is a mismatch between the two vector table outputs, the following occurs:

1. If the PIEVERRADDR register (default value 0x3F FFFF) is not initialized, the default error handler at address 0x3FFFBE gets executed.

But, when the PIEVERRADDR register is initialized to the address of the user-defined routine, the user-defined routine is executed instead of the default error handler.

Note: Each CPU has a copy of the PIE Vector Fetch Error Handler register (CPU1.PIEVERRADDR and CPU2.PIEVERRADDR).

2. Hardware also generates EPWM Trip signals that trip the PWM outputs using TRIPIN15.
3. An NMI to the other CPU is sent, if the current mismatch is during a vector fetch. For example, on an NMI vector fetch error for CPU2, an NMI is also fired to CPU1.NMIWD.

If there is no mismatch, the correct vector is jammed onto the C28 program control.

3.6.3 NMIWDs

Each CPU has user-programmable NMIWD period registers, in which users can set a limit on how much time to allocate for the device to acknowledge the NMI. If the NMI is not acknowledged, a device reset occurs.

3.6.4 ECC and Parity Enabled RAMs, Shared RAMs Protection

Each CPU subsystem has different RAM blocks. Some RAM blocks are ECC-enabled and others are parity-enabled. All single-bit errors in ECC RAM are auto-corrected and an error counter is incremented every time a single bit error is detected. If the error counter reaches a predefined user configured limit, an interrupt is generated to the corresponding CPU. Refer to [Section 3.12](#) for more details on RAM errors.

All uncorrectable double-bit errors end up triggering an NMI to corresponding CPUs.

3.6.5 ECC Enabled Flash Memory

When ECC is programmed and enabled, Flash single-bit errors are corrected automatically by ECC logic before giving data to the CPU, but the errors are not corrected in Flash memory. Flash memory still contains wrong data until another erase/program operation happens to correct the Flash contents. Irrespective of whether the error interrupt is enabled or disabled, single-bit errors are always corrected before giving data to the CPU. When the interrupt is disabled, users can check the single-bit error counter register for any single-bit error occurrences. The error counter stops incrementing once the value is equal to the threshold + 1. Set the threshold register to a non-zero value so that the error counter can increment. The user must decide the threshold value at which to reprogram the Flash with the correct data.

When ECC is programmed and enabled, Flash uncorrectable errors end up triggering an NMI to the respective CPU. Refer to [Section 3.12](#) for more details on Flash error correction and error catching mechanisms.

3.6.6 ERRORSTS Pin

The ERRORSTS pin is an 'always output' pin and remains high until an error is detected inside the chip. On an error, the ERRORSTS pin goes low (default polarity) until the corresponding internal error status flag for that error source is cleared. [Figure 3-4](#) shows the functionality of the ERRORSTS pin.

The ERRORSTS pin is tri-stated until the chip power-rails ramp up to the lower operational limit. As the ERRORSTS pin is an active-low pin (default polarity), users who care about the state of this pin during power-up must connect an external pull-down on this pin.

Following enhancement has been made on this device for ERRORSTS pin logic:

- Polarity of Error pin has been made configurable (default setting is active-low polarity).
- To enable testing of the Error pin, capability to force and clear the Error pin from software has been provided.
- Additional sources of Error have been added to ERRORSTS:
 - CPU1 Watchdog reset
 - Error on a PIE vector fetch
 - NMI on CM

Figure 3-4. ERRORSTS Pin Diagram

3.7 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. [Figure 3-5](#) provides an overview of the device's clocking system.

3.7.1 Clock Sources

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but must provide answers to the following questions:

1. What is the desired CPU frequency?
2. Are there any additional communication protocols or peripherals, such as CAN or USB, required?
3. What types of external oscillators or clock sources are available?

If CAN or USB is required, an external clock source with a precise frequency must be used as a reference clock. Otherwise, use only INTOSC2 and avoid the need for more external components.

All of the clocks in the device are derived from one of four clock sources.

3.7.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source, and is the default system clock at reset. It is used to run the boot ROM and can be used as the system clock source for the application.

Note

INTOSC2's frequency tolerance is too loose to meet the timing requirements for some peripherals such as CAN and USB, so an external clock must be used to support those features.

3.7.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 may also be manually selected as the system and auxiliary clock source for debug purposes.

3.7.1.3 External Oscillator (XTAL)

The dedicated X1 and X2 pins support an external clock source (XTAL), which can be used as the main system and auxiliary clock source. Frequency limits and timing requirements can be found in the [TMS320F2838x Real-Time Microcontrollers With Connectivity Manager Data Sheet](#). Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal must be connected to X1 while X2 is left unconnected, as shown in [Figure 3-6](#).

Figure 3-6. Single-ended 3.3V External Clock

- An external crystal. The crystal must be connected across X1 and X2 with the load capacitors connected to VSSOSC as shown in [Figure 3-7](#).

Figure 3-7. External Crystal

- An external resonator. The resonator must be connected across X1 and X2 with the ground connected to VSSOSC as shown in [Figure 3-8](#).

Figure 3-8. External Resonator

3.7.1.4 Auxiliary Clock Input (AUXCLKIN)

An additional external clock source is supported on GPIO133 (AUXCLKIN). This must be a single-ended 3.3V external clock and can be used as the clock source for the USB, CAN, and Communication Manager Subsystem. Frequency limits and timing requirements can be found in the [TMS320F2838x Real-Time Microcontrollers With Connectivity Manager Data Sheet](#). The external clock must be connected directly to the GPIO133 pin, as shown in Figure 3-9.

Figure 3-9. AUXCLKIN

3.7.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (using the PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

3.7.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the master reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK may be used directly or fed through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock, and is connected to INTOSC2.

3.7.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at the maximum rated operating frequency, and in most applications generates the main system clock. This PLL uses OSCCLK as a reference. For configuration instructions, see [Section 3.7.6](#).

3.7.2.3 Auxiliary Oscillator Clock (AUXOSCCLK)

One of INTOSC2, XTAL, or AUXCLKIN may be chosen to be the auxiliary reference clock (AUXOSCCLK) for the USB module. (This selection does not affect the CAN bit clock, which uses AUXCLKIN directly). AUXOSCCLK may be used directly or fed through the auxiliary PLL to reach a higher frequency. At reset, AUXOSCCLK is connected to INTOSC2, but only an external oscillator can meet the USB timing requirements.

3.7.2.4 Auxiliary PLL Output Clock (AUXPLLRAWCLK)

The auxiliary PLL is used to generate a clock for USB, CAN, EtherCAT, and the CM Subsystem. This PLL uses AUXOSCCLK as a reference. For configuration instructions, see [Section 3.7.6](#).

3.7.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

3.7.3.1 System Clock (PLLSYSCLK)

The system control registers, GS RAMs, IPC module, GPIO qualification, and NMI watchdog timers have their own clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK may be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured via the SYSCLKDIVSEL register.

3.7.3.2 CPU Clock (CPUCLK)

Each CPU has a clock (CPU1.CPUCLK and CPU2.CPUCLK) that is used to clock the CPU, the coprocessors, the private RAMs (M0, M1, D0, and D1), and the boot ROM and Flash wrapper. This clock is identical to PLLSYSCLK, but is gated when the CPU enters IDLE or STANDBY mode.

3.7.3.3 CPU Subsystem Clock (SYSCLK and PERx.SYSCLK)

Each CPU provides a clock (CPU1.SYSCLK and CPU2.SYSCLK) to its CLA, DMA, and most owned peripherals. This clock is identical to PLLSYSCLK, but is gated when the CPU enters STANDBY mode.

Each peripheral clock can be connected to either CPU1.SYSCLK or CPU2.SYSCLK. This selection is made by CPU1 using the CPUSELx registers. Each peripheral clock also has an independent clock gating that is controlled by the CPU PCLKCRx registers. By default, the ePWM, EMIF1, and EMIF2 clocks each have an additional /2 divider, which is required to support CPU frequencies over 100MHz. At slower CPU frequencies, these dividers can be disabled via the PERCLKDIVSEL register.

A peripheral may be assigned to either CPU. That is, code for a peripheral can be executed from either CPU1 or CPU2. CPUSELx register is used to assign a peripheral to either CPU1 or CPU2. This register must be configured before enabling the clock for the chosen peripheral since the clock for each peripheral is derived from the selected CPU subsystem. The clock multiplexer controlled by the CPUSELx register is not glitch-free. Therefore the CPUSELx register must be configured before the PCLKCRx register. Note that the reset for each peripheral is also driven from the selected CPU.

Note

The application needs to wait for 5 SYSCLK cycles after enabling the clock to the peripherals when using PCLKCRx.

3.7.3.4 Low-Speed Peripheral Clock (LSPCLK and PERx.LSPCLK)

The SCI, SPI, and McBSP modules can communicate at bit rates that are much slower than the CPU frequency. These modules are connected to a shared clock divider, which generates a low-speed peripheral clock (LSPCLK) derived from SYSCLK. LSPCLK uses a /4 divider by default, but the ratio can be changed via the LOSPCP register. Each SCI, SPI, and McBSP module's clock (PERx.LSPCLK) can be gated independently using the PCLKCRx registers.

3.7.3.5 USB Auxiliary Clock (AUXPLLCLK)

The USB module requires a fixed 60MHz clock for bit sampling. Since the main system clock is usually not a multiple of 60MHz, the correct frequency cannot be achieved with a simple divider. Instead, the USB clock is provided through an auxiliary clock path (AUXPLLCLK), which can use an independent clock source and PLL to generate the correct frequency.

USB clock tolerances are very tight. As stated in section 7.1.11 of the USB 2.0 specification, low-speed devices (1.50 Mb/s) have a tolerance of +/- 1.5%, while high-speed devices (12.000Mb/s) have a tolerance of +/- 0.25%. Typically these tolerances are achieved by using an external crystal or resonator as the source for AUXOSCCLK.

3.7.3.6 CAN Bit Clock

The required frequency tolerance for the CAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of PERx.SYSCLK) may not be precise enough, the bit clock can also be connected to XTAL or AUXCLKIN via the CLKSRCCTL2 register. There is an independent selection for each CAN module.

3.7.3.7 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PERx.SYSCLK. Timer 2 is connected to PERx.SYSCLK by default, but may also be connected to INTOSC1, INTOSC2, XTAL, or AUXPLLCLK via the TMR2CLKCTL register. This register also provides a separate pre-scale divider for timer 2. If a source other than SYSCLK is used, the SYSCLK frequency must be at least twice the source frequency to ensure correct sampling. Each CPU has independent CPU timers and TMR2CLKCTL register.

The main reason to use a non-SYSCLK source is for internal frequency measurement. In most applications, timer 2 runs off of the SYSCLK.

3.7.4 External Clock Output (XCLKOUT)

It is sometimes necessary to observe a clock directly for debug and testing purposes. The external clock output (XCLKOUT) feature supports this by connecting a clock to an external pin, GPIO73. The available clock sources are PLLSYSCLK, PLLRAWCLK, CPU1.SYSCLK, AUXPLLRAWCLK, CPU2.SYSCLK, INTOSC1, and INTOSC2.

To use XCLKOUT, first select the clock source via the CLKSRCCTL3 register. Next, select the desired output divider via the XCLKOUTDIVSEL register. Finally, connect GPIO73 to mux channel 3 using the GPIO configuration registers.

3.7.5 Clock Connectivity

Table 3-6 provide details on the clock connections of every module present in the device.

Table 3-6. Clock Connections Sorted by Clock Domain

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	Shared Modules

3.7.6 PLL/AUXPLL

The PLL/AUXPLL is responsible for synthesizing an output frequency from the input clock (from the oscillator); [Figure 3-10](#) shows a simple block diagram of the PLL/AUXPLL. The PLL/AUXPLL divides the reference input for a lower frequency input into the PLL/AUXPLL by (REFDIV+1). Then multiplies this internal frequency by IMULT to get the VCO output clock. The PLL/AUXPLL output is divided by (ODIV+1) to generate PLLRAWCLK/ AUXPLLRAWCLK which is further divided by SYSCLKDIVSEL.PLLSYSCLKDIV/AUXCLKDIVSEL.AUXPLLDIV to generate PLLSYSCLK/AUXCLK

SYSPLL / AUXPLL

$$f_{PLLRAWCLK} = \frac{f_{OSCCLK}}{(REFDIV+1)} \times \frac{IMULT}{(ODIV+1)}$$

$$f_{AUXPLLRAWCLK} = \frac{f_{AUXOSCCLK}}{(REFDIV+1)} \times \frac{IMULT}{(ODIV+1)}$$

Figure 3-10. PLL/AUXPLL

3.7.6.1 Choosing PLL Settings

There are two PLLs (SYSPLL and AUXPLL) and equations shown in [Figure 3-10](#) must be used to configure the respective PLL.

IMULT is the integer value of the multiplier.

REFDIV is the reference divider for the OSCCLK/AUXOSCCLK.

ODIV is the output divider of the PLLRAWCLK/AUXPLLRAWCLK.

PLLSYSCLKDIV is the system clock divider.

AUXPLLDIV is the auxiliary clock divider.

For the permissible values of the multipliers and dividers, see the documentation for the respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the [TMS320F2838x Real-Time Microcontrollers With Connectivity Manager Data Sheet](#).

Note

The system clock frequency (PLLSYSCLK) can not exceed the limit specified in the [TMS320F2838x Real-Time Microcontrollers With Connectivity Manager Data Sheet](#). This limit does not allow for oscillator tolerance.

The clock source and PLL configuration registers are shared between the two CPUs (CPU1 and CPU2). Register access is controlled by way of a semaphore, which is described in [Chapter 16](#).

3.7.6.2 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure is used to set up the desired application configuration:

Refer to your device SysCtl_setClock() function inside C2000Ware installation for an example.

Recommended sequence to set up the system PLL:

1. Bypass the PLL by clearing SYSPLLCTL1[PLLCLKEN] and wait for at least 120 CPU clock cycles by adding 120 NOP instructions.
2. Power down the PLL by writing to SYSPLLCTL1.PLEN = 0 and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
3. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL and wait for at least 300 CPU clock cycles by adding 300 NOP instructions.
4. Set the system clock divider to /1 to make sure the fastest PLL configuration by clearing SYSCLKDIVSEL[PLLSYSCLKDIV].
5. Set the IMULT, REFDIV, and ODIV simultaneously by writing a 32-bit value in SYSPLLMULT at once to automatically enable the PLL. Be sure the settings for multiplier and dividers do not violate the frequency specifications as defined in the [TMS320F2838x Real-Time Microcontrollers With Connectivity Manager Data Sheet](#).
6. Wait for PLL to lock by polling for the lock status bit to go high, that is, SYSPLLSTS.LOCKS = 1
7. Configure DCC with reference clock as OSCCLK and clock under measurement as PLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, do not enable PLLRAWCLK as SYSCLK, stop here and troubleshoot. Refer to [Chapter 10](#) for more information on the configuration and usage.
8. If the PLLRAWCLK is within the valid range, then set the system clock divider one setting higher than the final desired value. For example ClkCfgRegs.SYSCLKDIVSEL.bit.PLLSYSCLKDIV = divsel + 1. This limits the current increase when switching to the PLL.
9. Switch to the PLL as the system clock by setting SYSPLLCTL1[PLLCLKEN] and wait for 200 PLLSYSCLK cycles for the current to stabilize by adding 200 NOP instructions.
10. Change the system clock divider (PLLSYSCLKDIV) to the appropriate value.

Note

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
2. At least a 120 CPU clock cycle delay is needed after bypassing PLL, that is, `SYSPLLCTL1.PLLCLKEN = 0`.
3. At least a 60 CPU clock cycle delay is needed after PLL is powered down, that is, `SYSPLLCTL1.PLEN = 0`.
4. At least a 300 CPU clock cycle delay is needed after the OSCCLK source is changed.
5. PLL SLIP bit is not supported. The DCC must be used to check the validity of the PLL clock. This feature is included as part of the `SysCtl_setClock()` function inside C2000Ware.

3.7.6.3 USB Auxiliary Clock Setup

Refer to your device `SysCtl_setAuxClock()` function inside C2000Ware installation for an example.

If USB functionality is needed, the auxiliary clock (AUXPLLCLK) must be configured to produce 60MHz. The procedure is similar to the system clock setup:

1. Bypass the PLL by clearing `AUXPLLCTL1[PLLCLKEN]` and wait for at least 120 CPU clock cycles by adding 120 NOP instructions.
2. Power down the PLL by writing to `AUXPLLCTL1.PLEN = 0` and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
3. Select the reference clock source (AUXOSCCLK) by writing to `CLKSRCCTL2.AUXOSCCLKSRCSEL` and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
4. Set the `IMULT`, `REFDIV`, and `ODIV` simultaneously by writing a 32-bit value in `AUXPLLMULT` at once to automatically enable the PLL. Be sure the settings for multiplier and dividers do not violate the frequency specifications as defined in the [TMS320F2838x Real-Time Microcontrollers With Connectivity Manager Data Sheet](#).
5. Wait for PLL to lock by polling for the lock status bit to go high (`AUXPLLSTS.LOCKS = 1`).
6. Configure DCC with reference clock as `AUXOSCCLK` and clock under measurement as `AUXPLLRAWCLK`, and verify the frequency of the PLL. If the frequency is out of range, stop here and troubleshoot. Refer to [Chapter 10](#) for more information on the configuration and usage.
7. Connect the auxiliary PLL output clock (AUXPLLRAWCLK) to AUXPLLCLK by writing a 1 to `AUXPLLCTL1.PLLCLKEN`.

The auxiliary clock configuration can be changed at run time. Changing the `AUXOSCCLK` source automatically bypasses the PLL and sets the multiplier to zero. Changing the multiplier from one non-zero value to another temporarily bypasses the PLL until the PLL re-locks.

Note

1. AUXPLL must be bypassed and powered down manually before changing the AUXOSCCLK source.
2. At least a 120 CPU clock cycle delay is needed after bypassing PLL, that is, `AUXPLLCTL1.PLLCLKEN = 0`.
3. At least a 60 CPU clock cycle delay is needed after PLL is powered down, that is, `AUXPLLCTL1.PLEN = 0`.
4. At least a 60 CPU clock cycle delay is needed after AUXOSCCLK source is changed.
5. AUXPLL SLIP bit is not supported. The DCC must be used to check the validity of the AUXPLL clock. This feature is included as part of the `SysCtl_setAuxClock()` function inside C2000Ware.

3.7.6.4 SYS PLL / AUX PLL Bypass

If the application requires the PLL clock to be bypassed from the system, then the application needs to configure `SYSPLLCTL1.PLLCLKEN=0` or `AUXPLLCTL1.PLLCLKEN=0`. It takes up to 120 CPU clock cycles before the bypass is effective. In the meantime, if `PLLSYSCLKDIV` / `AUXPLLDIV` is reduced to a lower value (for example, from /2 to /1 or /4 to /2), the device may be clocked above the maximum rated frequency and can lead to unpredictable device behavior. Hence, a delay of 120 CPU clock cycles is required after bypassing the PLL from the enable state, that is, going from `PLLCLKEN=1` to `PLLCLKEN=0`.

3.7.7 Clock (OSCCLK) Failure Detection

To achieve safety diagnostic, Missing Clock Detection (MCD) can be used.

[Table 3-7](#) lists the details.

Table 3-7. Clock Source (OSCCLK) Failure Detection

Clock Failure Detection Circuitry	Clocks Detected	Time for Detection (in Cycles)	Limitations
Missing Clock Detection (MCD)	INTOSC2, XTAL/X1	8192 INTOSC1 cycles	Cannot detect INTOSC1 clock failure.

3.7.7.1 Missing Clock Detection Logic

The missing clock detect (MCD) logic detects OSCCLK failure, using INTOSC1 as the reference clock source. This circuit only detects complete loss of OSCCLK and doesn't do any detection of frequency drift on the OSCCLK.

This circuit monitors the OSCCLK (primary clock) using the 10MHz clock provided by the INTOSC1 (secondary clock) as a backup clock. This circuit functions as:

1. The primary clock (OSCCLK) clock keeps ticking a 7-bit counter (named MCDPCNT). This counter is asynchronously reset with `XRSn`.
2. The secondary clock (INTOSC1) clock keeps ticking a 13-bit counter (named MCDSCNT). This counter is asynchronously reset with `XRSn`.
3. Each time MCDPCNT overflows, the MCDSCNT counter is reset. Thus, if OSCCLK is present or not slower than INTOSC1 by a factor of 64, MCDSCNT never overflows.
4. If OSCCLK stops for some reason or is slower than INTOSC1 by at least a factor of 64, the MCDSCNT overflows and a missing clock condition is detected on OSCCLK.
5. The above check is continuously active, unless the MCD is disabled using the MCDPCR register (by making the MCLKOFF bit 1).
6. If the circuit ever detects a missing OSCCLK, the following occurs:
 - The MCDSTS flag is set.
 - The MCDSCNT counter is frozen to prevent further missing clock detection.
 - The CLOCKFAIL signal goes high, which generates TRIP events to PWM modules and fires NMIs to CPU1.NMIWD and CPU2.NMIWD.
 - PLL is forcefully bypassed and the OSCCLK source is switched to INTOSC1 (System Clock Frequency = INTOSC1 Freq (10MHz)/SYSDIV). PLLMULT is zeroed out automatically in this case.
 - While the MCDSTS bit is set, the OSCCLKSRCSEL bits have no effect and OSCCLK is forcefully connected to INTOSC1.
 - PLLRAWCLK going to the system is switched to INTOSC1 automatically.
7. If the MCLKCLR bit is written (this is a W=1 bit), the MCDSTS bit is cleared and the OSCCLK source is decided by the OSCCLKSRCSEL bits. Writing to MCLKCLR also clears the MCDPCNT and MCDSCNT counters to allow the circuit to re-evaluate missing clock detection. If the user wants to lock the PLL after missing clock detection, switch the clock source to INTOSC1 (using OSCCLKSRCSEL register), do an MCLKCLR, and re-lock the PLL.
8. The MCD is enabled at power up.

Figure 3-11 shows the missing clock logic functional flow.

Figure 3-11. Missing Clock Detection Logic

Note

On a complete clock failure when OSCCLK is dead, it may take a maximum time of 8192 INTOSC1 cycles (that is, 0.8192ms) before the CLOCKFAIL signal goes high, after which:

- NMI is generated
- OSCCLK is switched to INTOSC1
- PWM Trip happens

3.8 Clock Configuration Semaphore

Both CPUs can access the PLL and peripheral clock configuration registers. The clock configuration semaphore allows one CPU to access the registers without being interrupted by the other CPU.

The clock configuration semaphore is implemented as a two-bit field in a register with special write protections. This register requires a key field to be written at the same time as the semaphore bits. The possible semaphore states are:

00 or 11	Either CPU writes to the semaphore. CPU1 has control of the clock configuration registers by default. 00 is the reset state.
01	CPU2 has exclusive control of the clock configuration registers and exclusive write access to the semaphore.
10	CPU1 has exclusive control of the clock configuration registers and exclusive write access to the semaphore.

Each CPU is only allowed to take control of the clock configuration registers for itself. However, CPU1 can force both semaphores into the default state (00) at any time by putting CPU2 into reset. [Figure 3-12](#) shows the allowed states and state transitions.

Figure 3-12. Clock Configuration Semaphore (CLKSEM) State Transitions

3.9 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU-Timers (TIMER0/1/2) shown in Figure 3-13.

CPU-Timer2 is reserved for real-time operating system uses (for example, TI-RTOS), but if CPU-Timer2 is not used by real-time operating systems then, CPU-Timer2 can also be used for other applications. The CPU-Timer0 and CPU-Timer1 run off of SYSCLK. The CPU-Timer2 normally runs off of SYSCLK, but can also use INTOSC1, INTOSC2, XTAL, and AUXPLLCLK. The CPU-Timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in Figure 3-14.

Figure 3-13. CPU-Timers

- The timer registers are connected to the memory bus of the C28x processor.
- The CPU Timers are synchronized to SYSCLKOUT.

Figure 3-14. CPU-Timer Interrupts Signals and Output Signal

The general operation of the CPU-Timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD.
- The counter decrements once every (TPR[TDDR:TDDB]+1) SYSCLKOUT cycles, where TDDR:TDDB is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in Section 3.16 are used to configure the timers.

3.10 Watchdog Timers

The watchdog module generates an output pulse 512 watchdog clocks (WDCLKs) wide whenever the 8-bit watchdog up counter has reached its maximum value. The watchdog clock source is INTOSC1. Software must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled. Figure 3-15 shows the various functional blocks within the watchdog module.

Figure 3-15. CPU Watchdog Timer Module

3.10.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

Table 3-8. Example Watchdog Key Sequences

Step	Value Written to WDKEY	Result
1	0xAA	No action
2	0xAA	No action
3	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
4	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
5	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
6	0xAA	WDCNTR is reset.
7	0xAA	No action
8	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
9	0xAA	WDCNTR is reset.
10	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
11	0x32	Improper value written to WDKEY. No action, WDCNTR no longer enabled to be reset by next 0xAA.
12	0xAA	No action due to previous invalid value.
13	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
14	0xAA	WDCNTR is reset.

Step 3 in [Table 3-8](#) is the first action that enables the WDCNTR to be reset. The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCNTR overflow or writing the incorrect value to the WDCR[WDCHK] bits resets the device and sets the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset was caused by the watchdog. After doing this, the program must clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

3.10.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value takes effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR triggers a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

3.10.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ($\overline{\text{WDRST}}$) or assert an interrupt ($\overline{\text{WDINT}}$), if the watchdog counter reaches the maximum value. The behavior of each condition is:

- **Reset mode:**

If the watchdog is configured to reset the device, then the $\overline{\text{WDRST}}$ signal pulls the device reset ($\overline{\text{XRS}}$) pin low for 512 INTOSC1 cycles when the watchdog counter reaches the maximum value.

- **Interrupt mode:**

When the watchdog counter expires, the watchdog counter asserts an interrupt by driving the $\overline{\text{WDINT}}$ signal low for 512 INTOSC1 cycles. The falling edge of $\overline{\text{WDINT}}$ triggers a WAKEINT interrupt in the PIE, if the interrupt is enabled. Because the PIE is edge-triggered, re-enabling the WAKEINT while $\overline{\text{WDINT}}$ is active does not produce a duplicate interrupt.

To avoid unexpected behavior, software must not change the configuration of the watchdog while $\overline{\text{WDINT}}$ is active. For example, changing from interrupt mode to reset mode while $\overline{\text{WDINT}}$ is active immediately resets the device. Disabling the watchdog while $\overline{\text{WDINT}}$ is active causes a duplicate interrupt if the watchdog is later re-enabled. If a debug reset is issued while $\overline{\text{WDINT}}$ is active, the reset cause register (RESC) shows a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of $\overline{\text{WDINT}}$.

3.10.4 Watchdog Operation in Low-Power Modes

In IDLE mode, the watchdog interrupt ($\overline{\text{WDINT}}$) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. As with any other peripheral, the watchdog interrupt triggers a WAKEINT interrupt in the PIE during IDLE mode. User software must determine which peripheral caused the interrupt.

In STANDBY mode, all of the clocks to the peripherals are turned off within the CPU subsystem. The only peripheral that remains functional is the watchdog since the watchdog module runs off the oscillator clock (OSCCLK). The $\overline{\text{WDINT}}$ signal is applied to the Low Power Modes (LPM) block so that the signal can be used to wake the CPU from STANDBY low-power mode. This feature is enabled by setting LPMC.RWDINTE = 1. See [Section 3.11](#) for details.

Note: If the watchdog interrupt is used to wake-up from an IDLE or STANDBY low-power mode condition, software must make sure that the $\overline{\text{WDINT}}$ signal goes back high before attempting to reenter the IDLE or STANDBY mode. The $\overline{\text{WDINT}}$ signal is held low for 512 INTOSC1 cycles when the watchdog interrupt is generated. The current state of $\overline{\text{WDINT}}$ can be determined by reading the watchdog interrupt status bit (WDINTS) bit in the SCSR register. WDINTS follows the state of $\overline{\text{WDINT}}$ by two SYSCLKOUT cycles.

3.10.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

CPU Suspended:	When the CPU is suspended, the watchdog clock (WDCLK) is suspended
Run-Free Mode:	When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the watchdog operates as normal.

3.11 Low-Power Modes

This device has two clock-gating, low-power modes. All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the [TMS320C28x CPU and Instruction Set Reference Guide](#).

Low-power modes should not be entered into while a Flash program or erase is ongoing.

The application should verify the following before entering STANDBY:

1. Check the value of the GPIODAT register of the pin selected for STANDBY(GPIOLPMSEL0/1) before entering the low-power mode to ensure that the wake event has not already been asserted.
2. The LPMCR.QUALSTDBY register should be set to a value greater than the ratio of INTOSC1/PLLSYSCLK to ensure proper wake up.

3.11.1 IDLE

IDLE is a standard feature of the C28x CPU. In this mode, the CPU clock is gated while all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events. When one CPU is in IDLE, there is no effect on the other CPU subsystem.

Any enabled interrupt wakes up the CPU from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

3.11.2 STANDBY

STANDBY is a more aggressive low-power mode that gates both the CPU clock and any peripheral clocks derived from the CPU SYSCLK. The watchdog, however, is left active. Like IDLE, this mode affects only one CPU subsystem. The other CPU subsystem and all of the peripherals are unaffected. STANDBY is best used for an application where the wake-up signal comes from an external system (or CPU subsystem) rather than a peripheral input.

An NMI (or optionally) a watchdog interrupt or a configured GPIO can wake the CPU from STANDBY mode. Each GPIO from GPIO0-63 can be configured to wake the CPU when the GPIO are driven active low. Upon wakeup, the CPU receives the WAKEINT interrupt if configured.

IPC interrupt 1 (flag 0), an NMI fired to the other CPU, or (optionally) a watchdog interrupt, wakes up the CPU subsystem from STANDBY mode. Any of GPIO0-63 can also be configured to wake up the subsystem when the GPIO are driven active low. Upon wake up, the CPU receives a WAKEINT interrupt, even if the CPU was woken by an IPCINT1 signal.

To enter STANDBY mode:

1. Set LPMCR.LPM to 0x1.
2. Enable the WAKEINT interrupt in the PIE.
3. For watchdog interrupt wakeup, set LPMCR.WDINTE to 1 and configure the watchdog to generate interrupts.
4. For GPIO wakeup, set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module, and set LPMCR.QUALSTDBY to select the number of OSCCLK cycles for input qualification.
5. Execute the IDLE instruction to enter STANDBY.

To wake up from Standby mode:

1. Configure the desired GPIO to trigger the wakeup.
2. Drive the selected GPIO signal low; the signal must remain low for the number of OSCCLK cycles specified in the QUALSTDBY bits in the LPMCR register. If the signal is sampled high during this period, the count restarts.

At the end of the qualification period, the PLL enables the CLKIN to the CPU and the WAKEINT interrupt is latched in the PIE block. The WAKEINT interrupt can also triggered by IPCINT1 sent from the other CPU and a watchdog interrupt.

The CPU is now out of STANDBY mode and can resume normal execution.

If CPU2 is in STANDBY mode, writing a 1 to the RESET bit of the CPU2RESCTL register has no effect. CPU2 can be reset by any chip-level reset (POR, XRSn, CPU1.WDRSn, or CPU1.NMIWDRSn). Alternately, CPU2 can be woken up by any configured wake-up event.

If CPU2 is in STANDBY mode and the debugger is connected, executing a debug reset on CPU2 has no effect. To wake up the CPU2 with the debugger, Click Run, Single Step, or Step over in the Debug toolbar. CCS IDE prompts the user requesting to bring the CPU out of the low-power mode. Click Yes. This wakes up CPU2 from STANDBY and continues execution.

3.12 Memory Controller Module

This device has CPU1 subsystem, CPU2 subsystem, and CM subsystem. This section describes the memory controller used for CPU1 and CPU2 subsystem.

The different RAMs available on CPU1 and CPU2 subsystem have different characteristics. Some are:

- Dedicated to each CPU (M0, M1, and Dx RAMs),
- Shared between the CPU and a CLA (LSx RAM),
- Shared between the CPU and DMA of both subsystems (GSx RAM), and
- Used to send and receive messages between processors (MSGRAM).
- Used to exchange data between CLA and DMA

All these RAMs are highly configurable to achieve control for write access and fetch access from different masters. There are also RAMs - called IPC MSGRAMs - that are used for interprocessor communication. All RAMs are enabled with the ECC or parity feature (both data and address). Some of the dedicated memories are secure memory as well. Refer to [Chapter 6](#) for more details. Each RAM has a controller that takes care of the access protection/security related checks and ECC/Parity features for that RAM. [Figure 3-16](#) shows the configuration of these RAMs.

Figure 3-16. Memory Architecture

Note

All RAMs on these devices are SRAMs.

3.12.1 Functional Description

This section further defines and discusses the dedicated RAMs, shared RAMs, and MSG RAMs on this device.

3.12.1.1 Dedicated RAM (Dx RAM)

Each CPU subsystem has four dedicated RAM blocks: M0, M1, D0, and D1. M0/M1 memories are small blocks of memory that are tightly coupled with the CPU. Only the CPU has access to these memories. No other masters (including DMA) have any access to these memories.

All dedicated RAMs have the ECC feature. All dedicated memories are secure memory (except for M0/M1) and have the access protection (CPU write protection/CPU fetch protection) feature. Each type of access protection for each RAM block can be enabled/disabled by configuring the specific bit in the access protection register, allocated to each subsystem (DxACCPROT).

3.12.1.2 Local Shared RAM (LSx RAM)

RAM blocks that are dedicated to each subsystem and are accessible to the respective CPU and CLA only, are called local shared RAMs (LSx RAMs). All such memories are secure memory and have the ECC feature. By default, these memories are dedicated to the CPU only, and the user can choose to share these memories with the CLA by appropriately configuring the MSEL_LSx bit field in the LSxMSEL register. Further, when these memories are shared between the CPU and CLA, the user can choose to use these memories as CLA program memory by configuring the CLAPGM_LSx bit field in the LSxCLAPGM registers. CPU access to all memory blocks, which are programmed as CLA program memory, are blocked.

All these RAMs have the access protection (CPU write and CPU fetch) feature. Each type of access protection for each RAM block can be enabled or disabled by configuring the specific bit in the local shared RAM access protection registers, mapped to each CPU subsystem. [Table 3-9](#) shows the LSx RAM features.

Table 3-9. Local Shared RAM

MSEL_LSx	CLAPGM_LSx	CPUx Allowed Access	CPUx.CLA1 Allowed Access	Comment
00	X	All	-	LSx memory is configured as CPU dedicated RAM
01	0	All	Data Read Data Write	LSx memory is shared between CPU and CLA1
01	1	Emulation Read Emulation Write	Fetch Only Emulation Read Emulation Write	LSx memory is CLA1 program memory

3.12.1.3 Global Shared RAM (GSx RAM)

RAM blocks that are accessible from both the CPU and their respective DMA are called global shared RAMs (GSx RAMs). Each shared RAM can be owned by either CPU subsystem based on the configuration of their respective bits (one bit for each GSx memory) in the GSxMSEL register. When a particular GSx RAM block is owned by the CPU1 subsystem, CPU1 and CPU1.DMA have full access to that RAM block, whereas CPU2 and CPU2.DMA have only read access to that RAM block (no fetch/write access). Similarly, when a particular GSx RAM block is owned by the CPU2 subsystem, CPU1 and CPU1.DMA has only read access (no fetch/write access) to that RAM block, whereas CPU2 and CPU2.DMA has full access to that RAM block. [Table 3-10](#) shows the features of the GSx RAM.

Table 3-10. Global Shared RAM

GSxMSEL	CPU1	CPU1	CPU1	CPU1.DMA	CPU1.DMA	CPU2	CPU2	CPU2	CPU2.DMA	CPU2.DMA
	Fetch	Read	Write	Read	Write	Fetch	Read	Write	Read	Write
0	Yes	Yes	Yes	Yes	Yes	No	Yes	No	Yes	No
1	No	Yes	No	Yes	No	Yes	Yes	Yes	Yes	Yes

Note

Emulation/Debugger access is allowed from both the CPUs, irrespective of the GSxMSEL setting.

Like other shared RAMs, these RAMs also have different levels of access protection that can be enabled or disabled by configuring specific bits in the GSxACCPROT registers mapped in each subsystem.

Master select and access protection configuration for each GSx RAM block can be individually locked by the user to prevent further update to these bit fields. The user can also choose to permanently lock the configuration to individual bit fields by setting the specific bit fields in the GSxCOMMIT register (refer to the register description for more details). Once configuration is committed for a particular GSx RAM block, it can not be changed further until CPUx.SYSRS is issued. Only the CPU1 software can change the master select configuration by writing into the GSxMSEL register, mapped on the CPU1. The GSxMSEL register, which is mapped to the CPU2 subsystem, is a status register that can only be used by CPU2 software to know the master ownership for each GSx RAM block.

3.12.1.4 CPU Message RAM (CPU MSG RAM)

These RAM blocks can be used to share data between CPU1 and CPU2. Since these RAMs are used for interprocessor communication, they are also called IPC RAMs. The CPU MSGRAMs have CPU and DMA read and write access from its own CPU subsystem, and has CPU and DMA read only access from the other subsystem.

This RAM has parity.

3.12.1.5 CLA Message RAM (CLA MSGRAM)

These RAM blocks can be used to share data between the CPU and CLA. The CLA has read and write access to the "CLA to CPU MSGRAM." The CPU has read and write access to the "CPU to CLA MSGRAM." The CPU and CLA both have read access to both MSGRAMs.

This RAM has parity.

3.12.1.6 CLA-DMA MSG RAM

These RAMs blocks can be used to share data between CLA and DMA. The CLA has read and write access to the "CLA to DMA MSGRAM." The DMA has read and write access to the "DMA to CLA MSGRAM." The CLA and DMA both have read access to both MSGRAMs.

3.12.1.7 Access Arbitration

For a shared RAM, multiple accesses can happen at a given time. The maximum number of accesses to any shared RAM at any given time depends on the type of shared RAM. On this device, a combination of a fixed and round robin scheme is followed to arbitrate multiple access at any given time. Accesses from the same masters are arbitrated in a fixed priority manner, but the accesses from different masters are arbitrated using the round robin scheme.

The following is the order of fixed priority for CPU accesses:

1. Data Write/Program Write
2. Data Read
3. Program Read/Program Fetch

The following is the order of fixed priority for CLA accesses:

1. Data Write
2. Data Read/Program Fetch

Figure 3-17 represents the arbitration scheme on global shared memories:

Figure 3-17. Arbitration Scheme on Global Shared Memories

Figure 3-18 represents the arbitration scheme on local shared memories.

Figure 3-18. Arbitration Scheme on Local Shared Memories

3.12.1.8 Access Protection

All RAM blocks on both subsystems have different levels of protection. This feature allows the user to enable or disable specific access to individual RAM blocks from individual masters. There is no protection for read accesses, hence reads are always allowed from all the masters which have access to that RAM block.

The following sections describe the different kinds of protection available for RAM blocks on this device.

Note: For debug accesses, all the protections are disabled.

3.12.1.8.1 CPU Fetch Protection

A CPU has execution permission from a memory, only if that memory is dedicated to that CPU or the respective subsystem is master for that memory (in case of GSx memory). When fetch accesses are allowed based on the mastership, fetch accesses can be further protected by setting the FETCHPROTx bit of the specific register to 1. If fetch access is done by the CPU to a memory where CPU fetch protection is enabled, a fetch protection violation occurs.

There are two types of fetch protection violations:

- Non-master CPU fetch protection violation
- Master CPU fetch protection violation

If a fetch access is made to a memory by a non-master CPU, the fetch access is called a non-master fetch protection violation. If a fetch access is made to a dedicated or shared memory by the master CPU, and FETCHPROTx is set to 1 for that memory, the violation is called a master CPU fetch protection violation.

If a fetch protection violation occurs, the violation results in an ITRAP for CPU. A flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, get latched into the appropriate CPU fetch access violation address register.

3.12.1.8.2 CPU Write Protection

A CPU has write permission to a memory only if that memory is dedicated to that CPU, or if the respective subsystem is the master for that memory (in case of GSx memory). When write accesses are allowed based on the mastership, write accesses can be further protected by setting the CPUWRPROTx bit of the specific register to 1. If write access is done by a CPU to memory where the write access is protected, a write protection violation occurs.

There are two types of CPU write protection violations:

- Non-master CPU write protection violation
- Master CPU write protection violation

If a write access is made to a dedicated or shared memory by the master CPU and CPUWRPROTx is set to 1 for that memory, the violation is called a master CPU write protection violation.

If a write protection violation occurs, write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU write access violation address register. Also, an access violation interrupt is generated if enabled in the interrupt enable register.

3.12.1.8.3 CPU Read Protection

For local shared RAM, if memory is shared between the CPU and the CLA, the CPU only has access if the memory is configured as data RAM for the CLA. If the memory is programmed as program RAM, all the access from the CPU, including a read, is blocked and the violation is considered as a non-master access violation.

If a read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU read access violation address register. Also, if enabled in the interrupt enable register, an access violation interrupt is generated.

3.12.1.8.4 CLA Fetch Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as data RAM for the CLA, any fetch access from the CLA to that particular LSx RAM results in a CLA fetch protection violation, which is a non-master access violation.

If a CLA fetch protection violation occurs, the violation results in a MSTOP, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA fetch access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

3.12.1.8.5 CLA Write Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as program RAM for the CLA, any data write access from the CLA to that particular LSx RAM results in a CLA write protection violation, which is a non-master access violation. Similarly any data write access from CLA to CPUTOCLA or DMATOCCLA MSGRAM results in a CLA write protection violation, which is a non-master access violation.

If a CLA write protection violation occurs, write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA write access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

3.12.1.8.6 CLA Read Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as program RAM for the CLA, any data read access from the CLA to that particular LSx RAM results in a CLA read protection violation, which is a non-master access violation.

If a CLA read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA read access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

3.12.1.8.7 DMA Write Protection

The CPU1 or CPU2 DMA has write permission to a GSx memory only if the respective subsystem is master for that memory. When write accesses from a DMA are allowed based on the mastership, the write access can be further protected by setting the DMAWRPROTx bit of a specific register to 1. If write access is done by the DMA to protected memory, a write protection violation occurs.

There are two types of DMA write protection violations:

- Non-master DMA write protection violation (applicable to GSx RAMs and DMATOCCLA MSGRAM)
- Master DMA write protection violation

If a write access is made to GSx memory by a non-master DMA, the write is called a non-master write protection violation. If a write access is made to a dedicated or shared memory by a master DMA, and DMAWRPROTx is set to 1 for that memory, the write is called a master DMA write protection violation.

If a DMA write protection violation occurs, the write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred gets latched into the appropriate DMA write access violation address register. Also, an access violation interrupt is generated to the respective CPU, if enabled in the interrupt enable register. These are dedicated registers for each subsystem.

Note 1: All access protections are ignored during debug accesses. Write access to a protected memory go through when the write access is done by way of the debugger, irrespective of the write protection configuration for that memory.

Note 2: In the case of local shared RAM, if memory is shared between the CPU and the CLA, the CPU only has access if the memory is configured as data RAM for the CLA. If the memory is programmed as program RAM, all the access from the CPU (including read) and data access from the CLA is blocked, and the violation is considered as a non-master access violation. If the memory is configured as dedicated to the CPU, all access from the CLA is blocked and the violation is considered a non-master access violation.

3.12.1.9 Memory Error Detection, Correction and Error Handling

These devices have memory error detection and correction features to satisfy safety standards requirements. These requirements warrant the addition of detection mechanisms for finite dangerous failures.

In this device, all dedicated RAMs and LSx RAMs support error correction code (ECC) protection and other shared RAMs have parity protection. The ECC scheme used is Single Error Correction Double Error Detection (SECEDED). The parity scheme used is even parity. ECC/Parity covers the data bits stored in memory as well as address.

ECC/Parity calculation is done inside the memory controller module and then calculated. ECC/Parity is written into the memory along with the data. ECC/Parity is computed for 16-bit data; hence, for each 32-bit data, there is three 7-bit ECC codes (or 3-bit parity), two of which are for data and a third one for the address.

3.12.1.9.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For parity memory, only a single-bit error gets detected, whereas in the case of ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable error and uncorrectable errors. The following are characteristics of these errors:

- Parity errors are always uncorrectable errors
- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are also uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the master. It is also written back into the memory to prevent double-bit error due to another single-bit error at the same memory address.

Note

ECC/Parity for the address is calculated for the address offset only (based on RAM block size) of the corresponding 32-bit aligned address. In case of LSx RAM that are 4KB RAM block, only 11 LSB of the 32-bit aligned address are used. So if address is 0x8F8F, address ECC (or Parity) is calculated for address 0x78E (11-bit offset of the 32-bit aligned address). Similarly for 8KB RAM block, the 12-bit address offset is used.

3.12.1.9.2 Error Handling

For each correctable error, the count in the correctable error count register increments by one. When the value in this count register becomes equal to the value configured into the correctable error threshold register, an interrupt is generated to the respective CPU, that is, if the interrupt is enabled in the correctable interrupt enable register. The user needs to configure the correctable error threshold register based on the system requirements. Also, the address for which the error occurred, gets latched into the master-specific status register and a flag gets set. Each of these registers are dedicated for each CPU subsystem.

If there are uncorrectable errors, an NMI gets generated for the respective CPU. In this case, the address for which the error occurred, also gets latched into the master-specific address status register, and a flag gets set.

[Table 3-11](#) summarizes different error situations that can arise. These need to be handled appropriately in the software, using the status and interrupt indications provided.

Table 3-11. Error Handling in Different Scenarios

Access Type	Error Found In	Error Type	Status Indication	Error Notification
Reads	Data read from memory	Uncorrectable Error (Single-bit error for Parity RAMs OR Double bit Error for ECC RAMs)	Yes -CPUx/CPUx.DMA/CPUx.CLA1 CPU/DMA/CLA Read Error Address Register Data returned to CPUx/ CPUx.DMA/CPUx.CLA1 is incorrect	NMI for CPUx access NMI for CPUx.DMA access NMI to CPU for CPUx.CLA1 access
Reads	Data read from memory	Single-bit error for ECC RAMs	Yes - CPUx/CPUx.DMA CPU/DMA Read Error Address Register Increment single error counter	Interrupt when error counter reaches the user programmable threshold for single errors
Reads	Address	Address error	Yes - CPUx/CPUx.DMA/CPUx.CLA1 CPU/DMA/CLA Read Address Error Register Data returned to CPUx/ CPUx.DMA/CPUx.CLA1 is incorrect	NMI to CPU for CPUx access NMI to CPU for CPUx.DMA access NMI to CPU for CPUx.CLA1 access

Note

In the case of an uncorrectable error during fetch on the CPU, there is the possibility of getting an ITRAP before an NMI exception, since garbage instructions enter into the CPU pipeline before the NMI gets generated.

During debug accesses, correctable as well as uncorrectable errors are masked.

3.12.1.10 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic is part of safety critical logic, safety applications need to make sure that the logic is always working fine (during run time also). To enable this, different test modes are provided to generate ecc/parity error in RAM locations. These test modes can be configured in RAM Test registers of different RAM blocks. (for example, for D0 RAM, TEST_D0 bit in DxTEST register). Different test modes are for different usage. In test mode user can modify the data bits (without modifying the ECC/Parity bits) or ECC/Parity bits directly. Using this feature, an ECC/Parity error can be injected into data. Since an uncorrectable error generates NMI, you can avoid generating this during test mode as one of the test modes (11) is provided where NMI generation gets disabled. This mode is just like functional mode except NMI generation on uncorrectable error.

Note

The memory-map for ECC/Parity bits and data bits are the same. Choose a different test mode (10) to access ECC/Parity bits.

The following tables show the bit mapping for the ECC and Parity bits when the bits are read in RAMTEST mode using their respective addresses.

Table 3-12. Mapping of ECC Bits in Read Data from ECC/Parity Address Map

Data Bits Location in Read Data	Content (ECC Memory)
6:0	ECC Code for lower 16 bits of data
7	Not Used
14:8	ECC Code for upper 16 bits of data
15	Not Used
22:16	ECC Code for address
31:23	Not Used

Table 3-13. Mapping of Parity Bits in Read Data from ECC/Parity Address Map

Data Bits Location in Read Data	Content (Parity Memory)
0	Parity for lower 16 bits of data
7:1	Not Used
8	Parity for upper 16 bits of data
15:9	Not Used
16	Parity for address
31:17	Not Used

Following is the sequence that must be followed to test the ecc/parity logic.

- Set the test mode to 01 or 10, depending on whether data field or ecc/parity field needs to be written.
- Write the data pattern into the memory.
- Set the test mode to 11 to read from memory and exercise the ecc/parity logic.
- Check the test log registers to verify the correctness of the logic.
- The above sequence can be repeated for any number of data patterns.
- Once the test is complete, re-initialize the locations used in test, and set the test mode to 00 that changes the RAM block back into functional mode.

3.12.1.11 ROM Test

ROMs are read only memory, unlike RAMs, data or parity bits cannot be modified to introduce errors for diagnostic coverage of parity checking logic. Following method is used to check health of parity checking logic in ROMs.

- Added duplicate Parity check logic and feed the same data into duplicate parity checker
- Generate uncorrectable error if parity check status of these two separate parity checkers do not match

Probability of both circuits having fault is unlikely hence Parity Errors are certainly detected.

To generate the error, a test bit **FORCE_ERROR** is added. When the **FORCE_ERROR** bit is set, the parity bit going to one of the party checkers is inverted thereby introducing an uncorrectable error. An uncorrectable error is generated only if there is an error on all parity checkers that is: address, data [15:0], and data [31:16]. This makes sure that all three parity checkers are working as expected.

Figure 3-19. ROM Parity Checking Logic

3.12.1.12 RAM Initialization

To make sure that read/fetch from uninitialized RAM locations do not cause ECC or parity errors, the **RAM_INIT** feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and respective ECC/Parity bits accordingly. This can be initiated by setting the **INIT** bit to 1 for the specific RAM block in **INIT** registers. To check the status of RAM initialization, software must poll for the **INITDONE** bit for that RAM block in the **INITDONE** register to be set. Unless this bit gets set, no access must be made to that RAM memory block.

In the case of GSx memory, only the CPU of the subsystem that is configured as the master for the particular GSx RAM block can initiate the RAM initialization.

Note

The **INIT** bit must not be set again until the **INITDONE** bit for the corresponding RAM block has been polled to be set.

None of the masters must access the memory while initialization is taking place. If memory is accessed before **RAMINITDONE** is set, the memory read/write as well as initialization does not happen correctly.

3.13 JTAG

Gel files perform certain initialization tasks. This helps the users in a debug environment. However, when executed standalone (without the emulator connected) the application could potentially not work as expected, since there is no gel file to perform those initializations. For example, gel file disables watchdog. If user code does not service the watchdog in the application (or fails to disable the watchdog), there would be a difference in how the application behaves with the debugger and without the debugger.

Common tasks performed by the gel files (but not boot-ROM):

- On Reset:
 - Disable Flash ECC on some devices.
 - Disabling ECC only when using Flash API functions, see the Flash API User Guide for details. Otherwise, TI suggests to always program ECC and enable ECC-check.
 - Disable Watchdog
 - Enable CLA clock
 - Select real-time mode or C28x mode
- On Restart:
 - Select real-time mode or C28x mode
 - Clear IER and IFR
- On Target Connect:
 - Select real-time mode or C28x mode

For more information, see [C2000 MCU JTAG Connectivity Debug](#).

3.13.1 JTAG Noise and TAP_STATUS

The TAP_STATUS register reflects the status of the JTAG TAP at any given time. Normally when no JTAG is connected to the device, the status can be IDLE. In some cases with excessive PCB noise, there can be unwanted TMS and TCK toggles that take JTAG out of the IDLE state. When persistent, this can ultimately lead to unwanted activation of the JTAG Boundary Scan or some other JTAG mode that can interfere with the intended application. To avoid this scenario, place strong enough pull resistors on the board to prevent noise from activating JTAG. As a debug tool, the TAP_STATUS register can be polled by the application code to detect if this is a cause of device disturbance. The SOFTPRES40[JTAG_nTRST] register can also be used to reset the JTAG TAP through software. Use this reset register with caution, as this prevents connecting a debugger unless the code qualifies writes to this register with some other GPIO state or other means to distinguish between noise and debugger accesses.

3.14 System Control Register Configuration Restrictions

Memory-mapped registers in the System Control operate on INTOSC1 clock domain; hence, any CPU writes to these registers requires a delay between subsequent writes otherwise a second write can be lost. The application needs to take this into consideration and add a delay in terms of the number of NOP instructions after every write to these registers that are mentioned in [Table 3-14](#). The formula to compute delay between subsequent writes:

$$\text{Delay (in SYSCLK cycles)} = 3 \times (F_{\text{SYSCLK}} \div F_{\text{INTOSC1}}) + 9$$

For Example - For SYSCLK = 100MHz

$$\text{Delay (in SYSCLK cycles)} = 3 \times (100\text{MHz} \div 10\text{MHz}) + 9 = 39 \text{ SYSCLK cycles}$$

Table 3-14. System Control Registers Impacted

3.15 Software

3.15.1 SYSCCTL Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/sysctl

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

3.15.1.1 Missing clock detection (MCD)

FILE: sysctl_ex1_missing_clock_detection.c

This example demonstrates the missing clock detection functionality and the way to handle it. Once the MCD is simulated by disconnecting the OSCCLK to the MCD module an NMI would be generated. This NMI determines that an MCD was generated due to a clock failure which is handled in the ISR.

Before an MCD the clock frequency would be as per device initialization (200Mhz). Post MCD the frequency would move to 10Mhz or INTOSC1.

The example also shows how we can lock the PLL after missing clock, detection, by first explicitly switching the clock source to INTOSC1, resetting the missing clock detect circuit and then re-locking the PLL. Post a re-lock the clock frequency would be 200Mhz but using the INTOSC1 as clock source.

External Connections

- None.

Watch Variables

- *fail* - Indicates that a missing clock was either not detected or was not handled correctly.
- *mcd_clkfail_isr* - Indicates that the missing clock failure caused an NMI to be triggered and called an the ISR to handle it.
- *mcd_detect* - Indicates that a missing clock was detected.
- *result* - Status of a successful handling of missing clock detection

3.15.1.2 XCLKOUT (External Clock Output) Configuration

FILE: sysctl_ex2_xclkout_config.c

This example demonstrates how to configure the XCLKOUT pin for observing internal clocks through an external pin, for debugging and testing purposes.

In this example, we are using INTOSC1 as the XCLKOUT clock source and configuring the divider as 8.
Expected frequency of XCLKOUT = (INTOSC1 freq)/8 = 10/8 = 1.25MHz

View the XCLKOUT on GPIO73 using an oscilloscope.

3.15.2 MEMCFG Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/memcfg

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

3.15.2.1 Correctable & Uncorrectable Memory Error Handling

FILE: memcfg_ex1_error_handling.c

This example demonstrates error handling in case of various erroneous memory read/write operations. Error handling in case of CPU read/write violations, correctable & uncorrectable memory errors has been demonstrated. Correctable memory errors & violations can generate SYS_INT interrupt to CPU while uncorrectable errors lead to NMI generation.

External Connections

- None

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

3.15.2.2 Shared RAM Management (CPU1) - C28X_DUAL

FILE: memcfg_ex1_ram_management_cpu1.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS14 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to *cpu1RWArray* and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from *cpu2RArray* and writes a modified pattern to *cpu2RWArray*. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from *cpu1RArray* and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- *cpu1RWArray[]* is mapped to shared RAM GS1
- *cpu1RArray[]* is mapped to shared RAM GS0
- *cpu2RArray[]* is mapped to shared RAM GS1
- *cpu2RWArray[]* is mapped to shared RAM GS0
- *cpuTimer0ISR* in CPU2 is copied to shared RAM GS14, toggles LED1
- *cpuTimer0ISR* in CPU1 is copied to shared RAM GS15, toggles LED2

Watch Variables

- *error* Indicates that the data written is not correctly received by the other CPU.

3.15.2.3 Shared RAM Management (CPU2) - C28X_DUAL

FILE: memcfg_ex1_ram_management_cpu2.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS14 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to *cpu1RWArray* and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from *cpu2RArray* and writes a modified pattern to *cpu2RWArray*. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from *cpu1RArray* and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- *cpu1RWArray[]* is mapped to shared RAM GS1
- *cpu1RArray[]* is mapped to shared RAM GS0
- *cpu2RArray[]* is mapped to shared RAM GS1
- *cpu2RWArray[]* is mapped to shared RAM GS0
- *cpuTimer0ISR* in CPU2 is copied to shared RAM GS14, toggles LED1
- *cpuTimer0ISR* in CPU1 is copied to shared RAM GS15, toggles LED2

3.15.2.4 Demonstrate memconfig diagnostics and error handling. - CM

FILE: memcfg_ex1_error_handling.c

This example demonstrates how to configure the diagnostic mode and induce ECC errors. This example induces single and two bit ECC errors in E0RAM and tries to read the corrupted location in diagnostic and functional mode. cm_common_config_c28x example needs to be run on C28x1 before running this example on the CM core

External Connections

- None

Watch Variables

- *testStatus* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errorGlobalCount* - Error counter
- *retx* - Individual test status

3.15.2.5 Shared RAM Management (CPU1) - C28X_DUAL

FILE: memcfg_ex2_ram_sysconfig_cpu1.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS14 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to cpu1RWArray and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from cpu2RArray and writes a modified pattern to cpu2RWArray. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from cpu1RArray and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- cpu1RWArray[] is mapped to shared RAM GS1
- cpu1RArray[] is mapped to shared RAM GS0
- cpu2RArray[] is mapped to shared RAM GS1
- cpu2RWArray[] is mapped to shared RAM GS0
- cpuTimer0ISR in CPU2 is copied to shared RAM GS14, toggles LED1
- cpuTimer0ISR in CPU1 is copied to shared RAM GS15, toggles LED2

Watch Variables

- error Indicates that the data written is not correctly received by the other CPU.

3.15.2.6 Shared RAM Management (CPU2) - C28X_DUAL

FILE: memcfg_ex2_ram_sysconfig_cpu2.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS14 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to cpu1RWArray and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from cpu2RArray and writes a modified pattern to cpu2RWArray. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from cpu1RArray and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- cpu1RWArray[] is mapped to shared RAM GS1
- cpu1RArray[] is mapped to shared RAM GS0
- cpu2RArray[] is mapped to shared RAM GS1
- cpu2RWArray[] is mapped to shared RAM GS0
- cpuTimer0ISR in CPU2 is copied to shared RAM GS14, toggles LED1
- cpuTimer0ISR in CPU1 is copied to shared RAM GS15, toggles LED2

3.15.3 NMI Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/nmi

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

3.15.3.1 NMI handling - C28X_DUAL

FILE: nmi_ex1_cpu1handling.c

This example demonstrates how to handle an NMI.

The watchdog of CPU2 is configured to reset the core once the watchdog overflows and in the CPU1 the NMI is triggered. The NMI status is read and is verified to be due to CPU2 Watchdog reset. The NMI ISR reboots the CPU2 core and the process is repeated.

Watch Variables

- nmi_isr_count Indicates the number of times the NMI ISR was hit because of CPU2 watchdog reset.

3.15.3.2 Watchdog Reset - C28X_DUAL

FILE: nmi_ex1_cpu2wdreset.c

This example shows how to configure the watchdog to reset CPU2 which will trigger an NMI in CPU1. LED1 is toggled at the start of main indicating CPU reset.

External Connections

- None.

Watch Variables

- loopCount - The number of loops performed while not in ISR

3.15.3.3 NMI handling - C28X_DUAL

FILE: nmi_ex2_sysconfig_cpu1.c

This example demonstrates how to handle an NMI.

The watchdog of CPU2 is configured to reset the core once the watchdog overflows and in the CPU1 the NMI is triggered. The NMI status is read and is verified to be due to CPU2 Watchdog reset. The NMI ISR reboots the CPU2 core and the process is repeated.

Watch Variables

- nmi_isr_count Indicates the number of times the NMI ISR was hit because of CPU2 watchdog reset.

3.15.3.4 Watchdog Reset - C28X_DUAL

FILE: nmi_ex2_sysconfig_cpu2.c

This example shows how to configure the watchdog to reset CPU2 which will trigger an NMI in CPU1. LED1 is toggled at the start of main indicating CPU reset.

External Connections

- None.

Watch Variables

- loopCount - The number of loops performed while not in ISR

3.15.4 TIMER Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:

C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/timer

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

3.15.4.1 CPU Timers

FILE: timer_ex1_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt. In order to migrate the project within syscfg to any device, click the switch button under the device view and select your corresponding device to migrate, saving the project will auto-migrate your project settings.

External Connections

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.15.4.2 CPU Timers - CM

FILE: timer_ex1_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

Before running this example, please run the cm_common_config_c28x Example from the c28x folder. It will initialize the clock and configure the GPIOs.

External Connections

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.15.4.3 CPU Timers

FILE: timer_ex1_cputimers_sysconfig.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.15.5 WATCHDOG Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/watchdog

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

3.15.5.1 Watchdog

FILE: watchdog_ex1_service.c

This example shows how to service the watchdog or generate a wakeup interrupt using the watchdog. By default the example will generate a Wake interrupt. To service the watchdog and not generate the interrupt, uncomment the SysCtl_serviceWatchdog() line in the main for loop.

External Connections

- None.

Watch Variables

- wakeCount - The number of times entered into the watchdog ISR
- loopCount - The number of loops performed while not in ISR

3.15.5.2 Windowed watchdog expiry with NMI handling - CM

FILE: watchdog_ex1_nmi_handling.c

This program demonstrates an NMI generation to the CM4 core when the Windowed watchdog (WWD) expires.

A delay is provided after enabling the WWD to make the watchdog count up from 0 to 0xFF. Once 0 is reached, an NMI is triggered. Currently on triggering an NMI, a status flag is set indicating if the NMI was handled after the WWD expired.

External Connections

- None

Watch Variables

- wdstatus - Indicates if the WWD caused an NMI on expiry.
- cmnmi - Indicates if the NMI was handled after the WWD expired
- fail - Status if the Windowed watchdog expired generating an NMI with proper NMI handling

3.16 System Control Registers

This section describes the various System Control Registers.

3.16.1 SYSCTRL Base Address Table (C28)

Table 3-15. SYSCTRL Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected

2Ch	MDMAWRAVADDR	Master DMA Write Access Violation Address		Go

Complex bit access types are encoded to fit into small table cells. Table 3-17 shows the codes that are used for access types in this section.

Table 3-17. ACCESS_PROTECTION_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 3-17. ACCESS_PROTECTION_REGS Access
Type Codes (continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.2.1 NMAVFLG Register (Offset = 0h) [Reset = 0h]

NMAVFLG is shown in [Figure 3-20](#) and described in [Table 3-18](#).

Return to the [Summary Table](#).

3.16.3 CLK_CFG_REGS Registers

Table 3-37 lists the memory-mapped registers for the CLK_CFG_REGS registers. All register offset addresses not listed in Table 3-37 should be considered as reserved locations and the register contents should not be modified.

Table 3-37. CLK_CFG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CLKSEM	Clock Control Semaphore Register	EALLOW	Go
2h	CLKCFGLOCK1	Lock bit for CLKCFG registers	EALLOW	Go
8h	CLKSRCCTL1	Clock Source Control register-1	EALLOW	Go
Ah	CLKSRCCTL2	Clock Source Control register-2	EALLOW	Go
Ch	CLKSRCCTL3	Clock Source Control register-3	EALLOW	Go
Eh	SYSPLLCTL1	SYSPLL Control register-1	EALLOW	Go
14h	SYSPLLMULT	SYSPLL Multiplier register	EALLOW	Go
16h	SYSPLLSTS	SYSPLL Status register		Go
18h	AUXPLLCTL1	AUXPLL Control register-1	EALLOW	Go
1Eh	AUXPLLMULT	AUXPLL Multiplier register	EALLOW	Go
20h	AUXPLLSTS	AUXPLL Status register		Go
22h	SYSCLKDIVSEL	System Clock Divider Select register	EALLOW	Go
24h	AUXCLKDIVSEL	Auxillary Clock Divider Select register	EALLOW	Go
26h	PERCLKDIVSEL	Peripheral Clock Divider Selet register	EALLOW	Go
28h	XCLKOUTDIVSEL	XCLKOUT Divider Select register	EALLOW	Go
2Ah	CLBCLKCTL	CLB Clocking Control Register	EALLOW	Go
2Ch	LOSPCP	Low Speed Clock Source Prescaler	EALLOW	Go
2Eh	MDCDR	Missing Clock Detect Control Register	EALLOW	Go
30h	X1CNT	10-bit Counter on X1 Clock		Go
32h	XTALCR	XTAL Control Register	EALLOW	Go
36h	ETHERCATCLKCTL	ETHERCATCLKCTL	EALLOW	Go
38h	CMCLKCTL	CMCLKCTL	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-38 shows the codes that are used for access types in this section.

Table 3-38. CLK_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 3-38. CLK_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.3.1 CLKSEM Register (Offset = 0h) [Reset = 00000000h]

CLKSEM is shown in [Figure 3-39](#) and described in [Table 3-39](#).

Return to the [Summary Table](#).

Clock Control Semaphore Register

RESERVED														SEM	
R-0-0h														R/W-0h	

Table 3-39. CLKSEM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Writing the value 0xa5a5 will allow the writing of the SEM bits, else writes are ignored. Reads will return 0. Note: [1] Due to this KEY, only 32-bit writes will succeed (provided the KEY matches). 16-bit writes to the upper or lower half of this register will be ignored Reset type: CPU1.SYSRSn
15-2	RESERVED	R-0	0h	Reserved
1-0	SEM	R/W	0h	This register provides a mechanism to acquire all the CLKCFG registers (except this register) by CPU1 or CPU2. A CPU can perform read/writes to any of the CLKCFG registers (except this register) only if it owns the semaphore. Otherwise, writes are ignored and reads will return 0x0. Semaphore State Transitions: A value of 00, 10, 11 gives ownership to CPU1 A value of 01 gives ownership to CPU2. The following are the only state transitions allowed on these bits. 00,11 <-> 01 (allowed by CPU2) 00,11 <-> 10 (allowed by CPU1) If a CPU doesn't own the CLK_CFG_REGS set of registers (as defined by the state of this semaphore), reads from that CPU to all those registers return 0x0 and writes are ignore. Note that this is not true of CLKSEM register. The CLKSEM register's reads and writes are always allowed from both CPU1 and CPU2. Reset type: CPU1.SYSRSn

3.16.3.2 CLKCFGLOCK1 Register (Offset = 2h) [Reset = 00000000h]

CLKCFGLOCK1 is shown in [Figure 3-40](#) and described in [Table 3-40](#).

Return to the [Summary Table](#).

Lock bit for CLKCFG registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

15-6	RESERVED	R-0	0h	Reserved
5	RESERVED	R/W	0h	Reserved
4	XTALOFF	R/W	0h	Crystal (External) Oscillator Off Bit: This bit turns external oscillator off: 0 = Crystal (External) Oscillator On (default on reset) 1 = Crystal (External) Oscillator Off NOTE: Ensure no resources are using a clock source prior to disabling it. For example OSCCLKSRCSEL (SYSPLL), AUXOSCCLKSRCSEL (AUXPLL), CANxBCLKSEL (CAN Clock), TMR2CLKSRCSEL (CPUTIMER2) and XCLKOUTSEL(XCLKOUT). Reset type: XRSn
3	INTOSC2OFF_NOTSUPPORTED	R/W	0h	RESERVED: This bit is not supported any more, and should not be set to 1. Note: If this bit is set to 1 it will turn OFF INTOSC2 and lead to PLL failure Reset type: XRSn
2	RESERVED	R-0	0h	Reserved

Table 3-41. CLKSRCCTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OSCCLKSRCSEL	R/W	0h	Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK. 00 = INTOSC2 (default on reset) 01 = External Oscillator (XTAL) 10 = INTOSC1 11 = reserved (default to INTOSC1) At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier. Notes: [1] Reserved selection defaults to 00 configuration [2] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL. [3] Any writes to this bit must be followed with at least 300 CPU Cycles of wait time by adding at least 300 NOP instructions. [4] Changing the OSCCLKSRC while PLL is running and used by system (i.e. PLLCLKEN=1), can lead to dead System Clock. User needs to first bypass the PLL clock from the system by PLLCLKEN=0, and then change the OSCCLK source. Reset type: XRSn

3.16.3.4 CLKSRCCTL2 Register (Offset = Ah) [Reset = 00000000h]

CLKSRCCTL2 is shown in [Figure 3-42](#) and described in [Table 3-42](#).

Return to the [Summary Table](#).

Clock Source Control register-2

This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

3.16.4 CM_CONF_REGS Registers

Table 3-61 lists the memory-mapped registers for the CM_CONF_REGS registers. All register offset addresses not listed in Table 3-61 should be considered as reserved locations and the register contents should not be modified.

Table 3-61. CM_CONF_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CMRESCTL	CM Reset Control Register	EALLOW	Go
2h	CMTOCPU1NMICTL	CM To CPU1 NMI Control register	EALLOW	Go
4h	CMTOCPU1INTCTL	CM To CPU1 interrupt Control register	EALLOW	Go
20h	PALLOCATE0	CM Peripheral Allocation Register.	EALLOW	Go
3FEh	CM_CONF_REGS_LOCK	CM Configuration Registers Lock	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-62 shows the codes that are used for access types in this section.

Table 3-62. CM_CONF_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.4.1 CMRESCTL Register (Offset = 0h) [Reset = 00000001h]

CMRESCTL is shown in [Figure 3-61](#) and described in [Table 3-63](#).

Return to the [Summary Table](#).

Software reset of CM.

3.16.4.4 PALLOCATE0 Register (Offset = 20h) [Reset = 00000010h]

PALLOCATE0 is shown in [Figure 3-64](#) and described in [Table 3-66](#).

Return to the [Summary Table](#).

CM Peripheral Allocation Register for shared peripherals.

This register must be configured prior to enabling the peripheral clocks.

The clock for each peripheral is derived from the selected CPU subsystem. The clock mux controlled by this register is not glitch-free, therefore the PALLOCATEx register must be configured before the PCLKCRx register.

3.16.5.28 TMR2CLKCTL Register (Offset = 7Ch) [Reset = 00000000h]

TMR2CLKCTL is shown in [Figure 3-93](#) and described in [Table 3-97](#).

Return to the [Summary Table](#).

Timer2 Clock Measurement functionality control register

This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

Complex bit access types are encoded to fit into small table cells. [Table 3-106](#) shows the codes that are used for access types in this section.

Table 3-106. CPU1_PERIPH_AC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s

Table 3-106. CPU1_PERIPH_AC_REGS Access Type Codes (continued)

Access Type	Code	Description
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.7.1 ADCA_AC Register (Offset = 0h) [Reset = 0000003Fh]

ADCA_AC is shown in [Figure 3-99](#) and described in [Table 3-107](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

R/W-0h																R/W-FFFFh															

Table 3-184. TIM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Counter Registers The TIMH register holds the high 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Counter Registers The TIM register holds the low 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn

3.16.8.2 PRD Register (Offset = 2h) [Reset = 0000FFFFh]

PRD is shown in [Figure 3-175](#) and described in [Table 3-185](#).

Return to the [Summary Table](#).

CPU-Timer, Period Register

Figure 3-175. PRD Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

Table 3-185. PRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Period Registers The PRDH register holds the high 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRStn
15-0	LSW	R/W	FFFFh	CPU-Timer Period Registers The PRD register holds the low 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRStn

3.16.8.3 TCR Register (Offset = 4h) [Reset = 0001h]

TCR is shown in [Figure 3-176](#) and described in [Table 3-186](#).

Return to the [Summary Table](#).

CPU-Timer, Control Register

Figure 3-176. TCR Register

15	14	13	12	11	10	9	8
TIF	TIE	RESERVED		FREE	SOFT	RESERVED	
R/W1C-0h	R/W-0h	R-0h		R/W-0h	R/W-0h	R-0h	
7	6	5	4	3	2	1	0
RESERVED		TRB	TSS	RESERVED			
R-0h		R/W-0h	R/W-0h	R-1h			

Table 3-186. TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	TIF	R/W1C	0h	CPU-Timer Overflow Flag. TIF indicates whether a timer overflow has happened since TIF was last cleared. TIF is not cleared automatically and does not need to be cleared to enable the next timer interrupt. Reset type: SYSRSn 0h (R/W) = The CPU-Timer has not decremented to zero. Writes of 0 are ignored. 1h (R/W) = This flag gets set when the CPU-timer decrements to zero. Writing a 1 to this bit clears the flag.
14	TIE	R/W	0h	CPU-Timer Interrupt Enable. Reset type: SYSRSn 0h (R/W) = The CPU-Timer interrupt is disabled. 1h (R/W) = The CPU-Timer interrupt is enabled. If the timer decrements to zero, and TIE is set, the timer asserts its interrupt request.
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run. If FREE is 0, then the SOFT bit controls the emulation behavior. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop) (SOFT bit controls the emulation behavior) 1h (R/W) = Free Run (SOFT bit is don't care, counter is free running)
10	SOFT	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run (that is, free runs). In this case, SOFT is a don't care. But if FREE is 0, then SOFT takes effect. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop). (ONLY if FREE=0, if FREE=1 this bit is don't care) 1h (R/W) = Stop after the TIMH:TIM decrements to 0 (soft stop) In the SOFT STOP mode, the timer generates an interrupt before shutting down (since reaching 0 is the interrupt causing condition). (ONLY if FREE=0, if FREE=1 this bit is don't care)
9-6	RESERVED	R	0h	Reserved

Table 3-186. TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	TRB	R/W	0h	Timer reload Reset type: SYSRSn 0h (R/W) = The TRB bit is always read as zero. Writes of 0 are ignored. 1h (R/W) = When you write a 1 to TRB, the TIMH:TIM is loaded with the value in the PRDH:PRD, and the prescaler counter (PSCH:PSC) is loaded with the value in the timer dividedown register (TDDR:TDDR).
4	TSS	R/W	0h	CPU-Timer stop status bit. TSS is a 1-bit flag that stops or starts the CPU-timer. Reset type: SYSRSn 0h (R/W) = Reads of 0 indicate the CPU-timer is running. To start or restart the CPU-timer, set TSS to 0. At reset, TSS is cleared to 0 and the CPU-timer immediately starts. 1h (R/W) = Reads of 1 indicate that the CPU-timer is stopped. To stop the CPU-timer, set TSS to 1.
3-0	RESERVED	R	1h	Reserved

3.16.8.4 TPR Register (Offset = 6h) [Reset = 0000h]

TPR is shown in [Figure 3-177](#) and described in [Table 3-187](#).

Return to the [Summary Table](#).

CPU-Timer, Prescale Register

Figure 3-177. TPR Register

15	14	13	12	11	10	9	8
PSC							
R-0h							
7	6	5	4	3	2	1	0
TDDR							
R/W-0h							

Table 3-187. TPR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	PSC	R	0h	CPU-Timer Prescale Counter. These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0. Reset type: SYSRSn
7-0	TDDR	R/W	0h	CPU-Timer Divide-Down. Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software. Reset type: SYSRSn

3.16.8.5 TPRH Register (Offset = 7h) [Reset = 0000h]

TPRH is shown in [Figure 3-178](#) and described in [Table 3-188](#).

Return to the [Summary Table](#).

Complex bit access types are encoded to fit into small table cells. [Table 3-190](#) shows the codes that are used for access types in this section.

Table 3-190. DEV_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.9.1 DEVCFGLOCK1 Register (Offset = 0h) [Reset = 00000000h]

DEVCFGLOCK1 is shown in [Figure 3-179](#) and described in [Table 3-191](#).

Return to the [Summary Table](#).

Lock bit for DEVCFG registers

The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Note:

Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

Figure 3-179. DEVCFGLOCK1 Register

3.16.9.2 DEVCFGLOCK2 Register (Offset = 2h) [Reset = 00000000h]

DEVCFGLOCK2 is shown in [Figure 3-180](#) and described in [Table 3-192](#).

Return to the [Summary Table](#).

Lock bit for DEVCFG registers

The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Note:

Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

3.16.9.26 SOFTPRES23 Register (Offset = B0h) [Reset = 00000001h]

SOFTPRES23 is shown in [Figure 3-204](#) and described in [Table 3-216](#).

Return to the [Summary Table](#).

Peripheral Software Reset register

When bits in this register are set, the respective peripheral is in reset. All data is lost and the peripheral registers are returned to their reset states. Bits must be manually cleared after being set.

3.16.9.38 CPUSEL14 Register (Offset = F2h) [Reset = 00000000h]

CPUSEL14 is shown in [Figure 3-216](#) and described in [Table 3-228](#).

Return to the [Summary Table](#).

CPU Select register for common peripherals

This register must be configured prior to enabling the peripheral clocks.

The clock for each peripheral is derived from the selected CPU subsystem. The clock mux controlled by this register is not glitch-free, therefore the CPUSELx register must be configured before the PCLKCRx register.

The reset for each peripheral is also driven from the selected CPU.

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Write to this register succeeds only if this field is written with a value of 0xa5a5 Note: [1] Due to this KEY, only 32-bit writes will succeed (provided the KEY matches). 16-bit writes to the upper or lower half of this register will be ignored Reset type: CPU1.SYSRSn
15-1	RESERVED	R-0	0h	Reserved
0	RESET	R/W	1h	This bit controls the reset input of CPU2 core. 1: CPU2 is held in reset (CPU2.RSn = 0) 0: CPU2 reset is deactivated (CPU2.RSn = 1) Note: [1] If CPU2 is not used at-all by an application, it's advisable to put CPU2 in STANDBY mode rather than in reset to save on active power component on the CPU2 subsystem. This is because, all clocks keep toggling when reset is active on the CPU2 sub-system. [2] Note: If CPU2 is in Standby mode, writing to this bit will have no effect. CPU2 may be reset by any Chip-level reset (POR, XRSn, CPU1.WDRSn, or CPU1.NMIWDRSn). Alternately CPU2 may be woken up by any configured wake-up event. Reset type: CPU1.SYSRSn

3.16.9.44 RSTSTAT Register (Offset = 124h) [Reset = 0000h]

RSTSTAT is shown in [Figure 3-222](#) and described in [Table 3-234](#).

3.16.10 DMA_CLA_SRC_SEL_REGS Registers

Table 3-240 lists the memory-mapped registers for the DMA_CLA_SRC_SEL_REGS registers. All register offset addresses not listed in Table 3-240 should be considered as reserved locations and the register contents should not be modified.

Table 3-240. DMA_CLA_SRC_SEL_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CLA1TASKSRCSELLOCK	CLA1 Task Trigger Source Select Lock Register	EALLOW	Go
4h	DMACHSRCSELLOCK	DMA Channel Trigger Source Select Lock Register	EALLOW	Go
6h	CLA1TASKSRCSEL1	CLA1 Task Trigger Source Select Register-1	EALLOW	Go
8h	CLA1TASKSRCSEL2	CLA1 Task Trigger Source Select Register-2	EALLOW	Go
16h	DMACHSRCSEL1	DMA Channel Trigger Source Select Register-1	EALLOW	Go
18h	DMACHSRCSEL2	DMA Channel Trigger Source Select Register-2	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-241 shows the codes that are used for access types in this section.

Table 3-241. DMA_CLA_SRC_SEL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.10.1 CLA1TASKSRCSELLOCK Register (Offset = 0h) [Reset = 00000000h]

Table 3-248. MEM_CFG_REGS Registers (continued)

Offset	Acronym	Register Name	Write Protection	Section
AAh	PERI_MEM_TEST_LOCK	Peripheral Memory Test Lock Register		Go
ACh	PERI_MEM_TEST_CONTROL	Peripheral Memory Test control Register		Go

Complex bit access types are encoded to fit into small table cells. [Table 3-249](#) shows the codes that are used for access types in this section.

Table 3-249. MEM_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.11.1 DxLOCK Register (Offset = 0h) [Reset = 00000000h]

DxLOCK is shown in [Figure 3-234](#) and described in [Table 3-250](#).

Return to the [Summary Table](#).

Table 3-274. GSxTEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	TEST_GS15	R/W	0h	Selects the different modes for GS15 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
29-28	TEST_GS14	R/W	0h	Selects the different modes for GS14 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
27-26	TEST_GS13	R/W	0h	Selects the different modes for GS13 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn

Table 3-274. GSxTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25-24	TEST_GS12	R/W	0h	Selects the different modes for GS12 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
23-22	TEST_GS11	R/W	0h	Selects the different modes for GS11 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
21-20	TEST_GS10	R/W	0h	Selects the different modes for GS10 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
19-18	TEST_GS9	R/W	0h	Selects the different modes for GS9 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
17-16	TEST_GS8	R/W	0h	Selects the different modes for GS8 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
15-14	TEST_GS7	R/W	0h	Selects the different modes for GS7 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn

Table 3-274. GSxTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13-12	TEST_GS6	R/W	0h	Selects the different modes for GS6 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
11-10	TEST_GS5	R/W	0h	Selects the different modes for GS5 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
9-8	TEST_GS4	R/W	0h	Selects the different modes for GS4 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
7-6	TEST_GS3	R/W	0h	Selects the different modes for GS3 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
5-4	TEST_GS2	R/W	0h	Selects the different modes for GS2 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
3-2	TEST_GS1	R/W	0h	Selects the different modes for GS1 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn

Table 3-274. GSxTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	TEST_GS0	R/W	0h	Selects the different modes for GS0 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn

38h	CEINTEN	Correctable Error Interrupt Enable Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-293 shows the codes that are used for access types in this section.

Table 3-293. MEMORY_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 3-293. MEMORY_ERROR_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.12.1 UCERRFLG Register (Offset = 0h) [Reset = 00000000h]

3.16.13 NMI_INTRUPT_REGS Registers

Table 3-312 lists the memory-mapped registers for the NMI_INTRUPT_REGS registers. All register offset addresses not listed in Table 3-312 should be considered as reserved locations and the register contents should not be modified.

Table 3-312. NMI_INTRUPT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	NMICFG	NMI Configuration Register	EALLOW	Go
1h	NMIFLG	NMI Flag Register (SYSRsn Clear)		Go
2h	NMIFLGCLR	NMI Flag Clear Register	EALLOW	Go
3h	NMIFLGFRC	NMI Flag Force Register	EALLOW	Go
4h	NMIWDCNT	NMI Watchdog Counter Register		Go
5h	NMIWDPRD	NMI Watchdog Period Register	EALLOW	Go
6h	NMISHDFLG	NMI Shadow Flag Register		Go
7h	ERRORSTS	Error pin status		Go
8h	ERRORSTSCLR	ERRORSTS clear register	EALLOW	Go
9h	ERRORSTSFRC	ERRORSTS force register	EALLOW	Go
Ah	ERRORCTL	Error pin control register	EALLOW	Go
Bh	ERRORLOCK	Lock register to Error pin registers.	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-313 shows the codes that are used for access types in this section.

Table 3-313. NMI_INTRUPT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.13.1 NMICFG Register (Offset = 0h) [Reset = 0000h]

NMICFG is shown in [Figure 3-294](#) and described in [Table 3-314](#).

Return to the [Summary Table](#).

9	CPU2WDRSn	R	0h	CPU2 WDRSn Reset Indication Flag: This bit indicates if CPU2's WDRSn was fired or not. 0 No CPU2.WDRSn was fired 1 CPU2.WDRSn was fired to CPU2 Note: [1] This bit is reserved for CPU2.NMIFLG register Reset type: SYSRSn

Table 3-315. NMIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	CLBNMI	R	0h	Configurable Logic Block NMI Flag: This bit indicates if an NMI was generated by the Configurable Logic Block. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0, No Configurable Logic Block NMI pending 1, Configurable Logic Block NMI generated Reset type: SYSRSn
7	ERADNMI	R	0h	ERAD Module NMI Flag: This bit indicates if an NMI was generated by the ERAD Module. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0, No ERAD NMI pending 1, ERAD NMI generated Reset type: SYSRSn
6	PIVECTERR	R	0h	PIE Vector Fetch Error Flag: This bit indicates if an error occurred on an Vector Fetch by the CPU in the device. In Dual core system CPU1.NMIWD gets an NMI on an Vector fetch Error on CPU2. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0, No Vector Fetch Error condition (on the other CPU) pending 1, Vector Fetch error condition (on the other CPU) generated Reset type: SYSRSn
5	CPU2HWBISTERR	R	0h	HW BIST Error NMI Flag: This bit indicates if the time out error or a signature mismatch error condition during hardware BIST of C28 CPU2 occurred. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0, No C28 HWBIST error condition pending 1, C28 BIST error condition generated Reset type: SYSRSn
4	CPU1HWBISTERR	R	0h	HW BIST Error NMI Flag: This bit indicates if the time out error or a signature mismatch error condition during hardware BIST of C28 CPU1 occurred. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0, No C28 HWBIST error condition pending 1, C28 BIST error condition generated Reset type: SYSRSn
3	FLUNCERR	R	0h	Flash Uncorrectable Error NMI Flag: This bit indicates if an uncorrectable error occurred on a C28 Flash access and that condition is latched. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0, No C28 Flash uncorrectable error condition pending 1, C28 Flash uncorrectable error condition generated Reset type: SYSRSn
2	RAMUNCERR	R	0h	RAM Uncorrectable Error NMI Flag: This bit indicates if an uncorrectable error occurred on a RAM access (by any master) and that condition is latched. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0, No RAM uncorrectable error condition pending 1, RAM uncorrectable error condition generated Note: This nmi is a combination of uncorrectable error in RAMs and ROMs. ROM parity error would also set this flag. Reset type: SYSRSn

Table 3-315. NMIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	CLOCKFAIL	R	0h	Clock Fail Interrupt Flag: These bits indicates if the CLOCKFAIL condition is latched. These bits can only be cleared by the user writing to the respective bit in the NMIFLGCLR register or by an SYSRSn reset: 0, No CLOCKFAIL Condition Pending 1, CLOCKFAIL Condition Generated Reset type: SYSRSn
0	NMIINT	R	0h	NMI Interrupt Flag: This bit indicates if an NMI interrupt was generated. This bit can only be cleared by the user writing to the respective bit in the NMIFLGCLR register or by an SYSRSn reset: 0 No NMI Interrupt Generated 1 NMI Interrupt Generated No further NMI interrupts pulses are generated until this flag is cleared by the user. Reset type: SYSRSn

3.16.13.3 NMIFLGCLR Register (Offset = 2h) [Reset = 0000h]

NMIFLGCLR is shown in [Figure 3-296](#) and described in [Table 3-316](#).

Return to the [Summary Table](#).

7	6	5	4	3	2	1	0
NMIWDCNT							
R-0h							

Table 3-318. NMIWDCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	NMIWDCNT	R	0h	NMI Watchdog Counter: This 16-bit incremental counter will start incrementing whenever any one of the enabled FAIL flags are set. If the counter reaches the period value, an NMIRSn signal is fired which will then resets the system. The counter will reset to zero when it reaches the period value and will then restart counting if any of the enabled FAIL flags are set. If no enabled FAIL flag is set, then the counter will reset to zero and remain at zero until an enabled FAIL flag is set. Normally, the software would respond to the NMI interrupt generated and clear the offending FLAG(s) before the NMI watchdog triggers a reset. In some situations, the software may decide to allow the watchdog to reset the device anyway. The counter is clocked at the SYSCLKOUT rate. Reset type: SYSRSn

3.16.13.6 NMIWDPRD Register (Offset = 5h) [Reset = FFFFh]

NMIWDPRD is shown in [Figure 3-299](#) and described in [Table 3-319](#).

R-0h							R/W-0h

Table 3-328. PIECTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-1	PIEVECT	R	0h	These bits indicate the vector address of the vector fetched from the ePIE vector table. The least significant bit of the address is ignored and only bits 1 to 15 of the address are shown. The vector value can be read by the user to determine which interrupt generated the vector fetch. Note: When a NMI is serviced, the PIEVECT bit-field does not reflect the vector as it does for other interrupts. Reset type: SYSRSn
0	ENPIE	R/W	0h	Enable vector fetching from ePIE block. This bit must be set to 1 for peripheral interrupts to work. All ePIE registers (PIEACK, PIEIFR, PIEIER) can be accessed even when the ePIE block is disabled. Reset type: SYSRSn

3.16.14.2 PIEACK Register (Offset = 1h) [Reset = 0000h]

PIEACK is shown in [Figure 3-307](#) and described in [Table 3-329](#).

Return to the [Summary Table](#).

Acknowledge Register

When an interrupt propagates from the ePIE to a CPU interrupt line, the interrupt group's PIEACK bit is set. This prevents other interrupts in that group from propagating to the CPU while the first interrupt is handled. Writing a 1 to a PIEACK bit clears it and allows another interrupt from the corresponding group to propagate. ISRs for PIE interrupts should clear the group's PIEACK bit before returning from the interrupt.

Writes of 0 are ignored.

3.16.14.4 PIEIFR1 Register (Offset = 3h) [Reset = 0000h]

PIEIFR1 is shown in [Figure 3-309](#) and described in [Table 3-331](#).

Return to the [Summary Table](#).

Interrupt Group 1 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.14.10 PIEIFR4 Register (Offset = 9h) [Reset = 0000h]

PIEIFR4 is shown in [Figure 3-315](#) and described in [Table 3-337](#).

Return to the [Summary Table](#).

Interrupt Group 4 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.14.18 PIEIFR8 Register (Offset = 11h) [Reset = 0000h]

PIEIFR8 is shown in [Figure 3-323](#) and described in [Table 3-345](#).

Return to the [Summary Table](#).

Interrupt Group 8 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.14.26 PIEIFR12 Register (Offset = 19h) [Reset = 0000h]

PIEIFR12 is shown in [Figure 3-331](#) and described in [Table 3-353](#).

Return to the [Summary Table](#).

Interrupt Group 12 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

Notes: [1] Any bit in this register, once set can only be created through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect [2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed Reset type: CPU1.SYSRSn
0	SYNCSELECT	R/WOnce	0h	SYNCSELECT Register Lock bit: 0: Respective register is not locked 1: Respective register is locked. Notes: [1] Any bit in this register, once set can only be created through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect [2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed Reset type: CPU1.SYSRSn

3.16.18 SYS_STATUS_REGS Registers

Table 3-365 lists the memory-mapped registers for the SYS_STATUS_REGS registers. All register offset addresses not listed in Table 3-365 should be considered as reserved locations and the register contents should not be modified.

Table 3-365. SYS_STATUS_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CM_STATUS_INT_FLG	Status of interrupts due to multiple sources of Cortex-M4 reset.		Go
2h	CM_STATUS_INT_CLR	CM_STATUS_INT_FLG clear register		Go
4h	CM_STATUS_INT_SET	CM_STATUS_INT_FLG set register	EALLOW	Go
6h	CM_STATUS_MASK	CM_STATUS_MASK register	EALLOW	Go
10h	SYS_ERR_INT_FLG	Status of interrupts due to multiple different errors in the system.		Go
12h	SYS_ERR_INT_CLR	SYS_ERR_INT_FLG clear register		Go
14h	SYS_ERR_INT_SET	SYS_ERR_INT_FLG set register	EALLOW	Go
16h	SYS_ERR_MASK	SYS_ERR_MASK register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-366 shows the codes that are used for access types in this section.

Table 3-366. SYS_STATUS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.18.1 CM_STATUS_INT_FLG Register (Offset = 0h) [Reset = 00000000h]

CM_STATUS_INT_FLG is shown in [Figure 3-337](#) and described in [Table 3-367](#).

Return to the [Summary Table](#).

Status of interrupts due to multiple sources of Cortex-M4 reset.

Note: This register is present only on CPU1.

3.16.19 TEST_ERROR_REGS Registers

Table 3-375 lists the memory-mapped registers for the TEST_ERROR_REGS registers. All register offset addresses not listed in Table 3-375 should be considered as reserved locations and the register contents should not be modified.

Table 3-375. TEST_ERROR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CPU_RAM_TEST_ERROR_STS	Ram Test: Error Status Register		Go
2h	CPU_RAM_TEST_ERROR_STS_CLR	Ram Test: Error Status Clear Register		Go
4h	CPU_RAM_TEST_ERROR_ADDR	Ram Test: Error address register		Go

Complex bit access types are encoded to fit into small table cells. Table 3-376 shows the codes that are used for access types in this section.

Table 3-376. TEST_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.19.1 CPU_RAM_TEST_ERROR_STS Register (Offset = 0h) [Reset = 00000000h]

3.16.21 WD_REGS Registers

Table 3-390 lists the memory-mapped registers for the WD_REGS registers. All register offset addresses not listed in Table 3-390 should be considered as reserved locations and the register contents should not be modified.

Table 3-390. WD_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
22h	SCSR	System Control & Status Register	EALLOW	Go
23h	WDCNTR	Watchdog Counter Register	EALLOW	Go
25h	WDKEY	Watchdog Reset Key Register	EALLOW	Go
29h	WDCR	Watchdog Control Register	EALLOW	Go
2Ah	WDWCR	Watchdog Windowed Control Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-391 shows the codes that are used for access types in this section.

Table 3-391. WD_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.21.1 SCSR Register (Offset = 22h) [Reset = 0005h]

SCSR is shown in [Figure 3-356](#) and described in [Table 3-392](#).

Return to the [Summary Table](#).

System Control & Status Register

It is recommended to only use 16 bit accesses to write to this register. Use a read-modify-write instruction may inadvertently clear other bits.

Figure 3-356. SCSR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0-0h							
7	6	5	4	3	2	1	0
RESERVED					WDINTS	WDENINT	WDOVERRIDE
R-0-0h					R-1h	R/W-0h	R/W1C-1h

Table 3-392. SCSR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R-0	0h	Reserved
2	WDINTS	R	1h	Watchdog Interrupt Status This bit indicates the state of the active-low watchdog interrupt signal (synchronized to SYSCLK). If the watchdog interrupt is used to wake the system from a low-power mode, then that mode should only be entered while this bit is high. Likewise, this bit must go high before the watchdog can be safely disabled and re-enabled. Reset type: SYSRSn 0h (R/W) = The watchdog interrupt signal is active. 1h (R/W) = The watchdog interrupt signal is inactive.
1	WDENINT	R/W	0h	Watchdog Interrupt Enable/Reset Disable This bit determines whether the watchdog triggers an interrupt (WAKE/WDOG) or a reset (WDRS) when the counter expires. Reset type: SYSRSn 0h (R/W) = Counter expiration triggers a reset. This is the default state on power-up and after any system reset. 1h (R/W) = Counter expiration triggers an interrupt.
0	WDOVERRIDE	R/W1C	1h	If this bit is set to 1, the user is allowed to change the state of the Watchdog disable (WDDIS) bit in the Watchdog Control (WDCR) register. If the WDOVERRIDE bit is cleared, by writing a 1 the WDDIS bit cannot be modified by the user. Writing a 0 will have no effect. If this bit is cleared, then it will remain in this state until a reset occurs. The current state of this bit is readable by the user. Reset type: SYSRSn

3.16.21.2 WDCNTR Register (Offset = 23h) [Reset = 0000h]

WDCNTR is shown in [Figure 3-357](#) and described in [Table 3-393](#).

Return to the [Summary Table](#).

Watchdog Counter Register

15	14	13	12	11	10	9	8
RESERVED							
R-0-0h							
7	6	5	4	3	2	1	0
WDCNTR							
R-0h							

Table 3-393. WDCNTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7-0	WDCNTR	R	0h	Watchdog Counter These bits contain the current value of the watchdog counter. This counter increments with each WDCLK (INTOSC1) cycle. If the counter overflows, either an interrupt or a reset is generated based on the value of the WDINTEN bit in the SCSR register. If the correct value is written to the WDKEY register, this counter is reset to zero. Reset type: IORSn

3.16.21.3 WDKEY Register (Offset = 25h) [Reset = 0000h]

WDKEY is shown in [Figure 3-358](#) and described in [Table 3-394](#).

Return to the [Summary Table](#).

Watchdog Reset Key Register

Figure 3-358. WDKEY Register

15	14	13	12	11	10	9	8

Table 3-394. WDKEY Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7-0	WDKEY	R/W	0h	Watchdog Counter Reset Writing 0x55 followed by 0xAA will cause the watchdog counter to reset to zero, preventing an overflow. Writing other values has no effect. Reads of this register return the value of the WDCR register. Reset type: IORSn

3.16.21.4 WDCR Register (Offset = 29h) [Reset = 0000h]

WDCR is shown in [Figure 3-359](#) and described in [Table 3-395](#).

Return to the [Summary Table](#).

Watchdog Control Register

This memory mapped register requires a delay between subsequent writes to the register, otherwise a second write can be lost. The required delay is 69 SYSCLK cycles for a 200 MHz device, 45 SYSCLK cycles for a 120 MHz device, and 39 SYSCLK cycles for a 100 MHz device. This delay can be realized by adding NOP instructions corresponding to the required delay cycles.

R/W1S-0h	R/W-0h	R-0/W-0h			R/W-0h		

Table 3-395. WDCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-12	RESERVED	R-0	0h	Reserved
11-8	WDPRECLKDIV	R/W	0h	Watchdog Clock Pre-divider These bits determine the watchdog clock pre-divider, which is the first of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $PREDIVCLK = INTOSC1 / \text{Pre-divider}$ $WDCLK = PREDIVCLK / \text{Prescaler}$ Reset type: IORSn 0h (R/W) = $PREDIVCLK = INTOSC1 / 512$ 1h (R/W) = $PREDIVCLK = INTOSC1 / 1024$ 2h (R/W) = $PREDIVCLK = INTOSC1 / 2048$ 3h (R/W) = $PREDIVCLK = INTOSC1 / 4096$ 4h (R/W) = Reserved 5h (R/W) = Reserved 6h (R/W) = Reserved 7h (R/W) = Reserved 8h (R/W) = $PREDIVCLK = INTOSC1 / 2$ 9h (R/W) = $PREDIVCLK = INTOSC1 / 4$ Ah (R/W) = $PREDIVCLK = INTOSC1 / 8$ Bh (R/W) = $PREDIVCLK = INTOSC1 / 16$ Ch (R/W) = $PREDIVCLK = INTOSC1 / 32$ Dh (R/W) = $PREDIVCLK = INTOSC1 / 64$ Eh (R/W) = $PREDIVCLK = INTOSC1 / 128$ Fh (R/W) = $PREDIVCLK = INTOSC1 / 256$
7	WDFLG	R/W1S	0h	Watchdog reset status flag bit. This bit, if set, indicates a watchdog reset (WDRSTn) generated the reset condition. If 0, then it was an external device or power-up reset condition. This bit remains latched until the user writes a 1 to clear the condition. Writes of 0 will be ignored. Reset type: IORSn
6	WDDIS	R/W	0h	Watchdog Disable Setting this bit disables the watchdog module. Clearing this bit enables the watchdog module. This bit can be locked by the WDOVERRIDE bit in the SCSR register. The watchdog is enabled on reset. Reset type: IORSn

Table 3-395. WDCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5-3	WDCHK	R-0/W	0h	Watchdog Check Bits During any write to this register, these bits must be written with the value 101 (binary). Writing any other value will immediately trigger the watchdog reset or interrupt. Reset type: IORSn
2-0	WDPS	R/W	0h	Watchdog Clock Prescaler These bits determine the watchdog clock prescaler, which is the second of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $\text{PREDIVCLK} = \text{INTOSC1} / \text{Pre-divider}$ $\text{WDCLK} = \text{PREDIVCLK} / \text{Prescaler}$ The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default prescaler value is 1. Reset type: IORSn 0h (R/W) = WDCLK = PREDIVCLK / 1 1h (R/W) = WDCLK = PREDIVCLK / 1 2h (R/W) = WDCLK = PREDIVCLK / 2 3h (R/W) = WDCLK = PREDIVCLK / 4 4h (R/W) = WDCLK = PREDIVCLK / 8 5h (R/W) = WDCLK = PREDIVCLK / 16 6h (R/W) = WDCLK = PREDIVCLK / 32 7h (R/W) = WDCLK = PREDIVCLK / 64

3.16.21.5 WDWCR Register (Offset = 2Ah) [Reset = 0000h]

WDWCR is shown in [Figure 3-360](#) and described in [Table 3-396](#).

Return to the [Summary Table](#).

Table 3-396. WDWCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-9	RESERVED	R-0	0h	Reserved
8	FIRSTKEY	R	0h	This bit indicates if the 1st valid WDKEY (0x55 + 0xAA) got detected after MIN was configured to a non-zero value 0: First Valid Key after non-zero MIN configuration has not happened yet 1: First Valid key after non-zero MIN configuration got detected Notes: [1] If MIN = 0, this bit is never set [2] If MIN is changed back to 0x0 from a non-zero value, this bit is auto-cleared [3] This bit is added for debug purposes only Reset type: IORSn
7-0	MIN	R/W	0h	Watchdog Window Threshold These bits specify the lower limit of the watchdog counter reset window. If the counter is reset via the WDKEY register before the counter value reaches the value in this register, the watchdog immediately triggers a reset or interrupt. Reset type: IORSn

3.16.22 XINT_REGS Registers

Table 3-397 lists the memory-mapped registers for the XINT_REGS registers. All register offset addresses not listed in Table 3-397 should be considered as reserved locations and the register contents should not be modified.

Table 3-397. XINT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	XINT1CR	XINT1 configuration register		Go
1h	XINT2CR	XINT2 configuration register		Go

7	6	5	4	3	2	1	0
INTCTR							
R-0h							

Table 3-404. XINT1CTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	INTCTR	R	0h	This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset. Reset type: SYSRSn

3.16.22.7 XINT2CTR Register (Offset = 9h) [Reset = 0000h]

XINT2CTR is shown in [Figure 3-367](#) and described in [Table 3-405](#).

Return to the [Summary Table](#).

4.1 Introduction

The C28x CPU is a 32-bit fixed-point processor. This device draws from the best features of digital signal processing, reduced instruction set computing (RISC), microcontroller architectures, firmware, and tool sets.

For more information on CPU architecture and instruction set, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

4.3 Features

The CPU features include a modified Harvard architecture and circular addressing. The RISC features are single-cycle instruction execution, register-to-register operations, and modified Harvard architecture. The microcontroller features include ease of use through an intuitive instruction set, byte packing and unpacking, and bit manipulation. The modified Harvard architecture of the CPU enables instruction and data fetches to be performed in parallel. The CPU can read instructions and data while it writes data simultaneously to maintain the single-cycle instruction operation across the pipeline.

4.4 Floating-Point Unit

The C28x plus floating-point (C28x+FPU64) processor extends the capabilities of the C28x fixed-point CPU by adding registers and instructions to support IEEE single-precision and double-precision floating point operations.

Devices with the C28x+FPU64 include the standard C28x register set plus an additional set of floating-point unit registers. The additional floating-point unit registers are the following:

- Eight floating-point result registers, RnH (where n = 0–7)
- Floating-point Status Register (STF)
- Repeat Block Register (RB)

All of the floating-point registers, except the repeat block register, are shadowed. This shadowing can be used in high-priority interrupts for fast context save and restore of the floating-point registers.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

4.5 Trigonometric Math Unit (TMU)

The trigonometric math unit (TMU) extends the capabilities of a C28x+FPU64 by adding instructions and leveraging existing FPU64 instructions to speed up the execution of common trigonometric and arithmetic operations listed in [Table 4-1](#).

Table 4-1. TMU Supported Instructions

Instructions	C Equivalent Operation	Pipeline Cycles
MPY2PIF32/64 RaH,RbH	$a = b * 2\pi$	2/3
DIV2PIF32/64 RaH,RbH	$a = b / 2\pi$	2/3
DIVF32/64 RaH,RbH,RcH	$a = b/c$	5
SQRTF32/64 RaH,RbH	$a = \text{sqrt}(b)$	5
SINPUF32/64 RaH,RbH	$a = \sin(b*2\pi)$	4
COSPUF32/64 RaH,RbH	$a = \cos(b*2\pi)$	4
ATANPUF32/64 RaH,RbH	$a = \text{atan}(b)/2\pi$	4
QUADF32/64 RaH,RbH,RcH,RdH	Operation to assist in calculating ATANPU2	5

No changes have been made to existing instructions, pipeline, or memory bus architecture. All TMU instructions use the existing FPU register set (R0H to R7H) to carry out the operations.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

4.6 VCRC Unit

Cyclic redundancy check (CRC) algorithms provide a straightforward method for verifying data integrity over large data blocks, communication packets, or code sections. The C28x+VCRC can perform 8-bit, 16-bit, 24-bit, and 32-bit CRCs. A CRC result register contains the current CRC, which is updated whenever a CRC instruction is executed.

The following are the CRC polynomials used by the CRC calculation logic of VCRC:

- CRC8 polynomial = 0x07
- CRC16 polynomial1 = 0x8005
- CRC16 polynomial2 = 0x1021
- CRC24 polynomial = 0x5D 6DCB
- CRC32 polynomial1 = 0x04C1 1DB7
- CRC32 polynomial2 = 0x1EDC 6F41

This module can calculate CRCs for a byte of data in a single cycle. The CRC calculation for CRC8, CRC16, CRC24 and CRC32 is done byte-wise (instead of computing on a complete 16-bit or 32-bit data read by the C28x core) to match the byte-wise computation requirement mandated by various standards.

The VCRC Unit also allows the user to provide the size (1b-32b) and value of any polynomial to fit custom CRC requirements. The CRC execution time increases to 3 cycles when using a custom polynomial.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

Chapter 5

ROM Code and Peripheral Booting

This chapter describes the boot flow and functionality of the CPU1, CPU2, and Connectivity Manager (CM) subsystems.

5.1 Introduction.....	714
5.2 Device Boot Sequence.....	715
5.3 Device Boot Modes.....	716
5.4 Device Boot Configurations.....	717
5.5 Device Boot Flow Diagrams.....	723
5.6 Device Reset and Exception Handling.....	728
5.7 Boot ROM Description.....	730
5.8 Application Notes for Using the Bootloaders.....	770
5.9 Software.....	774

5.1 Introduction

The purpose of this chapter is to explain the boot read-only memory (ROM) code functionality for CPU1, CPU2, and CM cores, including the boot procedure. It also discusses the functions and features of the boot ROM code, and provides details about the ROM memory map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence will initialize the device to run the application code. For CPU1, the boot ROM also contains peripheral bootloaders which can be used to load an application into RAM. These bootloaders can be disabled for safety or security purposes.

Refer to [Table 5-1](#) for details on available boot features across CPU1, CPU2, and CM. Additionally, [Table 5-2](#) shows the sizes of the various ROMs on the device.

Table 5-1. Boot System Overview

Boot Feature	CPU1 (Master)	CPU2	CM
Initiate boot process	Device Reset	CPU1 Application	CPU1 Application
Boot mode selection	GPIOs	IPC Register	IPC Register
Supported boot modes: - Flash boot - Secure Flash boot - RAM boot	Yes	Yes	Yes
Boot to User OTP	No	Yes	Yes
Copy from IPC Message RAM and boot to RAM	No	Yes	Yes
Peripheral boot loader support	Yes	No	No

Table 5-2. ROM Memory

ROM	CPU1 Size	CPU2 Size	CM Size
Unsecure boot ROM	192 KB	64 KB	64 KB
Secure ROM	64 KB	64 KB	32 KB
CLA data ROM	8 KB	8 KB	N/A

5.2 Device Boot Sequence

The boot sequence describes the general boot ROM procedure each time a CPU core is reset. CPU1 is the master and always boots first. Once CPU1 boots to the application, then the user's application code in CPU1 can configure CPU2/CM boot IPC registers and release CPU2/CM from reset to boot. [Table 5-3](#), [Table 5-4](#), and [Table 5-5](#) detail the general overview of the boot-up procedures for each core.

During boot, each CPU's boot ROM code updates a boot status location in RAM that details the actions taken during this process. Additionally, CPU2 writes the boot status to the CPU2TOCPU1IPCBOOTSTS register and CM writes to CMTOCPU1IPCBOOTSTS to communicate the statuses to CPU1.

Refer to [Section 5.7.11](#) for more details.

Table 5-3. CPU1 Boot ROM Sequence

Step	CPU1 Action
1	After reset, check for HWBIST reset. If it is a HWBIST reset, immediately branch and return to the user application. If it is not a HWBIST reset, then continue boot and check the FUSE error register for any errors and handle accordingly.
2	Clock configuration and Flash power-up
3	Peripheral trimming and device configuration registers are loaded from OTP.
4	On power-on reset (POR), all CPU1 RAMs are initialized.
5	Non-maskable interrupt (NMI) handling is enabled and DCSM initialization is performed.
6	Device calibration is performed; trimming the specified peripherals with set OTP values.
7	Determine if polling the GPIO pins are needed for determining the boot mode and, if so, read the boot mode GPIO pins to determine the boot mode to run.
8	Based on the boot mode and options, the appropriate boot sequence is executed. Refer to Section 5.5.1 for a flow chart of the CPU1 boot sequences.

Table 5-4. CPU2 Boot ROM Sequence

Step	CPU2 Action
1	CPU2 is released from reset by CPU1 application.
2	Once CPU1TOCPU2IPCFLG0 is set, read the CPU1TOCPU2IPCBOOTMODE register. If it is not set correctly or has an invalid value, the IPC error command is sent to CPU1 and the CPU2 core will enter an infinite loop and will not continue booting until the user corrects the register values and reset the CPU2.
3	Flash power-up
4	On POR, all CPU2 RAMs are initialized.
5	NMI handling is enabled.
6	Based on the boot mode set in CPU1TOCPU2IPCBOOTMODE register, CPU2 either enters "wait for command" mode to wait for a future CPU1 boot mode command or CPU2 executes the requested boot sequence. Refer to Section 5.5.2 for a flow chart of the CPU2 boot sequences.

Table 5-5. CM Boot ROM Sequence

Step	CM Action
1	CM is released from reset by the CPU1 application.
2	Once CPU1TOCMIPCFLG0 is set, read the CPU1TOCMIPCBOOTMODE register. If it is not set correctly or has an invalid value, the IPC error command is sent to CPU1 and the CM will enter an infinite loop and will not continue booting until the user corrects the register values and reset the CM.
3	Flash power-up
4	On POR, all CM RAMs are initialized.
5	NMI handling is enabled.
6	Based on the boot mode set in CPU1TOCPU2IPCBOOTMODE register, CM either enters "wait for command" mode to wait for a future CPU1 boot mode command or CM executes the requested boot sequence. Refer to Section 5.5.3 for a flow chart of the CM boot sequences.

5.3 Device Boot Modes

This section explains the default boot modes, as well as all the available boot modes supported on this device. The CPU1 boot ROM uses the boot mode select, general purpose input/output (GPIO) pins to determine the boot mode configuration. CPU2 boot ROM uses the CPU1TOCPU2IPCBOOTMODE register to determine the boot mode configuration and CM boot ROM uses the CPU1TOCMIPCBOOTMODE register to determine the boot mode configuration.

[Table 5-6](#) shows the CPU1 boot mode options available for selection by the default boot mode select pins. Users have the option to program the device to customize the boot modes selectable in the boot-up table as well as the boot mode select pin GPIOs used.

All the available boot modes on the device are described in [Table 5-8](#).

Table 5-6. Device Default Boot Modes for CPU1

Boot Mode	GPIO72 (Default boot mode select pin 1)	GPIO84 (Default boot mode select pin 0)
Parallel IO	0	0
SCI / Wait Boot ⁽¹⁾	0	1
CAN	1	0
Flash / USB ⁽²⁾	1	1

- (1) SCI boot mode can be used as a wait boot mode as long as SCI continues to wait for an 'A' or 'a' during the SCI autobaud lock process.
- (2) On an unprogrammed device, selecting Flash boot when the default Flash entry address is unprogrammed switches the boot mode from Flash boot to USB boot. See [Table 5-7](#) for more details.

Table 5-7. CPU1 Flash-to-USB Boot Decision Table

Value at Flash Entry Point Address	Reason for Value	Realized Boot Mode
0x00000000	Flash is locked/secured	Boot to Flash
0xFFFFFFFF	Flash is not programmed	USB Boot
Any other value	Flash is programmed	Boot to Flash

Note

The switch of Flash boot mode to USB boot mode when Flash is not programmed is only available as part of the default boot mode table on an unprogrammed device. Once a custom boot table is programmed in OTP or RAM, a selection of Flash boot mode does not switch to USB boot even when Flash is unprogrammed.

Table 5-8. All Available Boot Modes

Boot Mode	CPU Support	Details
Parallel IO	CPU1	
SCI / Wait	CPU1	
CAN	CPU1	
Flash	CPU1, CPU2, CM	
Wait	CPU1, CPU2, CM	Refer to Section 5.7.7 for functional details of the boot modes.
RAM	CPU1, CPU2, CM	
SPI	CPU1	Refer to Section 5.7.8 for boot table values and GPIOs for the boot modes.
I2C	CPU1	
USB	CPU1	
Secure Flash	CPU1, CPU2, CM	
User OTP	CPU2, CM	
IPC Message Copy to RAM	CPU2, CM	

Note

All the peripheral boot modes that are supported use the first instance of the peripheral module (SCIA, SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SCI boot, it is actually referring to the first module instance, which means the SCI boot on the SCIA port. The same applies to the other peripheral boots.

5.4 Device Boot Configurations

This section details what boot configurations are available and how to configure them. This device supports from 0 boot mode select pins up to 3 boot mode select pins as well as from 1 configured boot mode up to 8 configured boot modes.

To change and configure the device from the default settings to custom settings for your application, use the following process:

1. Determine all the various ways you want application to be able to boot. (For example: Primary boot option of Flash boot for your main application, secondary boot option of CAN boot for firmware updates, tertiary boot option of SCI boot for debugging, etc)
2. Based on the number of boot modes needed, determine how many boot mode select pins (BMSPs) are required to select between your selected boot modes. (For example: 2 BMSPs are required to select between 3 boot mode options)
3. Assign the required BMSPs to a physical GPIO pin. (For example, BMSP0 to GPIO50, BMSP1 to GPIO51, and BMSP2 left as default which is disabled). Refer to [Section 5.4.1](#) for all the details on performing these configurations.
4. Assign the determined boot mode definitions to indexes in your custom boot table that correlate to the decoded value of the BMSPs. For example, BOOTDEF0=Boot to Flash, BOOTDEF1=CAN Boot, BOOTDEF2=SCI Boot; all other BOOTDEFx are left as default/nothing). Refer to [Section 5.4.2](#) for all the details on setting up and configuring the custom boot mode table.

Additionally, [Section 5.4.3](#) provides some example use cases on how to configure the BMSPs and custom boot tables.

5.4.1 Configuring Boot Mode Pins for CPU1

This section explains how the boot mode select pins can be customized by the user, by programming the BOOTPINCONFIG location (refer to [Table 5-9](#)) in the user-configurable dual-zone security module (DCSM) OTP. The location in the DCSM OTP is Z1-BOOTPINCONFIG or Z2-BOOTPINCONFIG. When debugging, EMUBOOTPINCONFIG is the emulation equivalent of Z1-BOOTPINCONFIG/Z2-BOOTPINCONFIG, and can be programmed to experiment with different boot modes without writing to OTP. The device can be programmed to use 0, 1, 2, or 3 boot mode select pins as needed.

Note

When using Z2-BOOTPINCONFIG, the configurations programmed in this location will take priority over the configurations in Z1-BOOTPINCONFIG. It is **recommended** to use Z1-BOOTPINCONFIG first and then if OTP configurations need to be altered, switch to using Z2-BOOTPINCONFIG.

Table 5-9. CPU1 BOOTPINCONFIG Bit Fields

Bit	Name	Description
31:24	Key	Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid For EMUBOOTPINCONFIG only, write 0xA5 to emulate the standalone boot flow and use the BMSPs/OTP BOOTDEF table
23:16	Boot Mode Select Pin 2 (BMSP2)	Refer to BMSP0 description except for BMSP2
15:8	Boot Mode Select Pin 1 (BMSP1)	Refer to BMSP0 description except for BMSP1
7:0	Boot Mode Select Pin 0 (BMSP0)	Set to the GPIO pin to be used during boot (up to 255). 0x0 = GPIO0; 0x01 = GPIO1 and so on Writing 0xFF disables BMSP0 and this pin is no longer used to select the boot mode.

Note

The following GPIOs **cannot** be used as a BMSP. If selected for a particular BMSP, the boot ROM automatically selects the factory default GPIO (the factory default for BMSP2 is 0xFF, which disables the BMSP).

- GPIO 42 and GPIO 43
- GPIO 169 to 255

Table 5-10. CPU1 Standalone Boot Mode Select Pin Decoding

BOOTPIN_CONFIG Key	BMSP0	BMSP1	BMSP2	Realized Boot Mode
!= 0x5A	Don't Care	Don't Care	Don't Care	Boot as defined by the factory default BMSPs
= 0x5A	0xFF	0xFF	0xFF	Boot as defined in the boot table for boot mode 0 (All BMSPs disabled)
	Valid GPIO	0xFF	0xFF	Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled)
	0xFF	Valid GPIO	0xFF	Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled)
	0xFF	0xFF	Valid GPIO	Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled)
	Valid GPIO	Valid GPIO	0xFF	Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled)
	Valid GPIO	0xFF	Valid GPIO	Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled)
	0xFF	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled)
	Valid GPIO	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Invalid GPIO	Valid GPIO	Valid GPIO	BMSP0 is reset to the factory default BMSP0 GPIO Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Valid GPIO	Invalid GPIO	Valid GPIO	BMSP1 is reset to the factory default BMSP1 GPIO Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Valid GPIO	Valid GPIO	Invalid GPIO	BMSP2 is reset to the factory default state, which is disabled Boot as defined by the values of BMSP0 and BMSP1

Note

When decoding the boot mode, BMSP0 is the least-significant-bit and BMSP2 is the most-significant-bit of the boot table index value. It is **recommended** when disabling BMSPs to start with disabling BMSP2. For example, in an instance when only using BMSP2 (BMSP1 and BMSP0 are disabled), then only the boot table indexes of 0 and 4 will be selectable. In the instance when using only BMSP0, then the selectable boot table indexes are 0 and 1.

5.4.2 Configuring Boot Mode Table Options for CPU1

This section explains how to configure the boot definition table, BOOTDEF, for CPU1. The 64-bit location is located in user-configurable DCSM OTP in the Z1-BOOTDEF-LOW and Z1-BOOTDEF-HIGH locations. When debugging, EMUBOOTDEF-LOW and EMUBOOTDEF-HIGH are the emulation equivalents of Z1-BOOTDEF-LOW and Z1-BOOTDEF-HIGH, and can be programmed to experiment with different boot mode options without writing to OTP. The range of customization to the boot definition table depends on how many boot mode select pins (BMSP) are being used. For example, 0 BMSPs equals to 1 table entry, 1 BMSP equals to 2 table entries, 2 BMSPs equals to 4 table entries, and 3 BMSPs equals to 8 table entries. Refer to [Section 5.4.3](#) for examples on how to setup the BOOTPIN_CONFIG and BOOTDEF values.

Note

The locations Z2-BOOTDEF-LOW and Z2-BOOTDEF-HIGH will be used instead of Z1-BOOTDEF-LOW and Z1-BOOTDEF-HIGH locations when Z2-BOOTPINCONFIG is configured. Refer to [Section 5.4.1](#) for more details on BOOTPIN_CONFIG usage.

Table 5-11. CPU1 BOOTDEF Bit Fields

BOOTDEF Name	Byte Position	Name	Description
BOOT_DEF0	7:0	BOOT_DEF0 Mode/Options	Set the boot mode for index 0 of the boot table. Different boot modes and their options can include, for example, a boot mode that uses different GPIOs for a specific bootloader or a different Flash entry point address. Any unsupported boot mode will cause the device to either go to wait boot or boot to Flash. Refer to Section 5.7.8 for valid BOOTDEF values to set in the table.
BOOT_DEF1	15:8	BOOT_DEF1 Mode/Options	Refer to BOOT_DEF0 description
BOOT_DEF2	23:16	BOOT_DEF2 Mode/Options	
BOOT_DEF3	31:24	BOOT_DEF3 Mode/Options	
BOOT_DEF4	39:32	BOOT_DEF4 Mode/Options	
BOOT_DEF5	47:40	BOOT_DEF5 Mode/Options	
BOOT_DEF6	55:48	BOOT_DEF6 Mode/Options	
BOOT_DEF7	63:56	BOOT_DEF7 Mode/Options	

5.4.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins and boot modes.

5.4.3.1 Zero Boot Mode Select Pins

This use case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to Flash.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
 - Set BOOTPIN_CONFIG.BMSP0 to 0xFF
 - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
 - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
 - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 5.7.8](#) for valid BOOTDEF values to set in the table.
 - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 0.
 - Refer to [Section 5.7.3](#) for the available Flash entry points.

Table 5-12. Zero Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	Flash Boot (0x03)

5.4.3.2 One Boot Mode Select Pin

This use case demonstrates a scenario for an application using one boot mode select pin to select between booting to Flash or using CAN boot.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
 - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
 - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
 - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
 - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 5.7.8](#) for valid BOOTDEF values to set in the table.
 - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
 - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.

Table 5-13. One Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)

5.4.3.3 Three Boot Mode Select Pins

This use case demonstrates a scenario for an application using three boot mode select pins to select between various boot modes in the custom boot table.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
 - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
 - Set BOOTPIN_CONFIG.BMSP1 to a user specified GPIO, such as 0x1 for GPIO1
 - Set BOOTPIN_CONFIG.BMSP2 to a user specified GPIO, such as 0x2 for GPIO2
 - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 5.7.8](#) for valid BOOTDEF values to set in the table.
 - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
 - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.
 - Set BOOTDEF.BOOTDEF2 to 0x24 for booting to wait boot (alternate option). This sets wait boot to boot table index 2.
 - Set BOOTDEF.BOOTDEF3 to 0x66 for SPI booting (alternate GPIO option 3). This sets SPI boot to boot table index 3.
 - Set BOOTDEF.BOOTDEF4 to 0x43 for booting to Flash (entry address option 2). This sets Flash boot to boot table index 4.
 - Set BOOTDEF.BOOTDEF5 to 0x09 for USB booting. This sets USB boot to boot table index 5.

Table 5-14. Three Boot Pins Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)
2	Wait Boot - Alt (0x24)
3	SPI - Alt3 (0x66)
4	Flash Boot - Alt2 (0x43)
5	USB Boot (0x09)

5.5 Device Boot Flow Diagrams

This section details the boot flow diagrams for CPU1, CPU2, and CM.

5.5.1 CPU1 Boot Flow

Upon reset, CPU1 follows the boot flow shown in [Figure 5-1](#). Depending on whether a JTAG debugger is connected to the device, CPU1 will either continue booting following the emulation boot flow or standalone boot flow. [Figure 5-2](#) shows the emulation boot flow when JTAG debugger is connected. [Figure 5-3](#) shows the standalone boot flow when no JTAG debugger is connected to the device.

Figure 5-1. CPU1 Device Boot Flow

Figure 5-2. CPU1 Emulation Boot Flow

Figure 5-3. CPU1 Standalone Boot Flow

5.5.2 CPU2 Boot Flow

Upon reset, CPU2 follows the boot flow shown in [Figure 5-4](#). CPU2 only boots once configured and released from reset by CPU1. Refer to [Section 5.7.2](#) for more details.

Figure 5-4. CPU2 Boot Flow

5.5.3 Connectivity Manager (CM) Boot Flow

Upon reset, CM follows the boot flow shown in [Figure 5-5](#). CM only boots once configured and released from reset by CPU1. Refer to [Section 5.7.2](#) for more details.

Figure 5-5. CM Boot Flow

5.6 Device Reset and Exception Handling

5.6.1 Reset Causes and Handling

Table 5-15 explains the actions each boot ROM performs upon reset for a specific reset cause.

Table 5-15. Boot ROM Reset Causes and Actions

Reset Source	CPU1 Boot ROM Action	CPU2 Boot ROM Action	CM Boot ROM Action
Power on Reset (POR)	1. Configure Clock Divider 2. Flash Power Up 3. Device configuration and trimming 4. RAM Initialization 5. Continue default boot flow	1. Flash Power Up 2. RAM Initialization 3. Continue default boot flow	1. Flash Power Up 2. RAM Initialization 3. Continue default boot flow
External Reset (XRS) For CPU1, XRS triggers include: • Watchdog Reset • NMI Watchdog Reset • EtherCAT Reset • SIMRESET XRS	1. Configure Clock Divider 2. Flash Power Up 3. Device configuration and trimming 4. Clear RAM for boot stack 5. Continue default boot flow	1. Flash Power Up 2. Clear RAM for boot stack 3. Continue default boot flow	1. Flash Power Up 2. Clear RAM for boot stack 3. Continue default boot flow
Hardware Built-In Self Test (HWBIST)	1. Read HWBIST return address 2. If set, branch to address 3. If not set, continue boot following "Debugger Reset" boot flow actions	1. Read HWBIST return address 2. If set, branch to address 3. If not set, continue boot following "Debugger Reset" boot flow actions	Not Applicable
Secure Copy Code (SCC) Reset (CPU1, CPU2) Watchdog Reset (CPU2) NMI Watchdog Reset (CPU2) Execute Override Logic (EOL) Reset (CM)	1. Clear RAM for boot stack 2. Continue default boot flow	1. Clear RAM for boot stack 2. Continue default boot flow	1. Flash Power Up 2. Clear RAM for boot stack 3. Continue default boot flow
SIMRESET_CPU1	1. Clear RAM for boot stack 2. Continue default boot flow	Not Applicable	Not Applicable
Debugger Reset (CPU1, CPU2) VECTRESET (CM)	1. Clear RAM for boot stack 2. Continue default boot flow	1. Clear RAM for boot stack 2. Continue default boot flow	1. Clear RAM for boot stack 2. Continue default boot flow

5.6.2 Exceptions and Interrupts Handling

Table 5-16 explains the actions each boot ROM performs if any exceptions that can occur happen during boot. The exception handling philosophy for CPU1, in most cases, is to log the error and continue booting to reach the application. The exception handling philosophy for CPU2 and CM is to log the error, notify CPU1, and let CPU1 handle the action.

For any CPU2 NMI event sources, CPU2 NMI handler will clear the NMI flag to stop the NMI watchdog counter and prevent CPU2 from resetting. The error pin will go low or high (depending on the polarity configuration on the error pin and the reset type) temporarily before the NMI flag is cleared. Therefore, a shorter pulse width of the error pin signal means CPU2 (or CM) is the source of the error. Following this, CPU2 sends an error IPC message to CPU1 in order for CPU1 to handle the error and reset CPU2.

For any CM NMI event sources, the CM NMI handler will clear the NMI flag to stop the NMI watchdog counter and prevent CM from resetting. The error pin will go low or high (depending on the polarity configuration on the error pin and the reset type) temporarily before the NMI flag is cleared. Therefore, a shorter pulse width of the error pin signal means CM (or CPU2) is the source of the error. Following this, the CM sends an error IPC message to CPU1 in order for CPU1 to handle the error and reset CM.

Table 5-16. Boot ROM Exceptions and Actions

Exception Event Source	CPU1 Boot ROM Action	CPU2 Boot ROM Action	CM Boot ROM Action	Event Logged
Single-bit error in FUSEERR	Ignore and continue to boot	No action	No action	No
Multi-bit error in FUSEERR	Reset the device	No action	No action	No
Clock Fail	Clear the NMI flag and continue to boot	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
RAM Uncorrectable Error ROM Parity Error	Perform RAM initialization and reset the device	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes ⁽¹⁾
Flash Uncorrectable Error	Reset the device	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
HWBIST Error	Clear the NMI flag and continue to boot	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	No action	Yes
PIE Vector Mismatch ⁽²⁾	Fetch error handler address, if address is configured, call handler, else reset the device	Fetch error handler address, if address is configured, call handler, else clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	No action	Yes
Embedded Real-time Analysis and Diagnostic (ERAD) NMI	Clear the NMI flag and continue to boot	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	No action	Yes
MCAN Uncorrectable Error	Clear the NMI flag and continue to boot	No action	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
EtherCAT NMI	Clear the NMI flag and continue to boot	No action	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
ITRAP Exception	Record memory address of where the illegal instruction was executed and let device reset	Send IPC to CPU1 with memory address of the illegal instruction and wait in loop	No action	Yes
Invalid IPCBOOTMODE Value upon Reset	No action	Send IPC to CPU1 and wait in loop	Send IPC to CPU1 and wait in loop	Yes
Secure Flash Boot Failure	Enable watchdog and let device reset	Send IPC to CPU1 and return to wait boot mode	Send IPC to CPU1 and return to wait boot mode	Yes
Hard Fault Exception	No action	No action	Update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
Any Unsupported Interrupt	Ignore and continue to boot	Ignore and continue to boot	Update boot status to CPU1, send error IPC to CPU1 with the interrupt exception number, and wait in loop	Yes (CM Only)

- (1) For CPU1, a RAM uncorrectable error or ROM parity error will clear the boot status information stored in RAM because a RAM initialization is performed to attempt to correct the error. Since the boot status information is erased, this exception can be identified in that a NMIWD reset occurred and all the RAMs are erased.

- (2) A PIE vector mismatch in one core (such as CPU1 or CPU2) will trigger the PIE vector mismatch interrupt in other cores.

5.7 Boot ROM Description

This section explains the details regarding the device boot ROMs.

5.7.1 CPU1 Boot ROM Configuration Registers

CPU1 boot ROM code involves several memory addresses and registers used during execution. There are two sets of configurations; one for emulation and one for standalone boot flow. The emulation locations located in RAM emulate the OTP configurations and can be written to as many times as needed. The user configurable DCSM OTP locations used in the standalone boot flow program the device OTP and hence can only be written once. For bit field configuration details for BOOTPIN-CONFIG and BOOTDEF, see [Section 5.4.1](#) and [Section 5.4.2](#).

Additionally, the CPU1 boot ROM supports boot configurations from DCSM zone 1 and zone 2 registers. Zone 2 configurations will supercede zone 1 configurations, so it is recommended to use zone 1 configurations and use zone 2 as a secondary option.

Note

All boot configurations for CPU2 and CM are set through CPU1TOCPU2IPCBOOTMODE and CPU1TOCMIPCBOOTMODE registers. See more details in [Section 5.7.2](#).

Table 5-17. CPU1 Boot ROM Registers

Boot Flow	Register Name	Boot ROM Name	Register Address	User OTP Address
Emulation	-	EMUBOOTPINCONFIG	0x0000 0D00	-
	-	EMUBOOTDEF-LOW	0x0000 0D04	-
	-	EMUBOOTDEF-HIGH	0x0000 0D06	-
Standalone (Using Z1)	Z1-GPREG1	Z1-BOOTPINCONFIG	0x0005 F008	0x0007 8008
	Z1-GPREG2	Z1-BOOT-GPREG2	0x0005 F00A	0x0007 800A
	Z1-GPREG3	Z1-BOOTDEF-LOW	0x0005 F00C	0x0007 800C
	Z1-GPREG4	Z1-BOOTDEF-HIGH	0x0005 F00E	0x0007 800E
Standalone (Using Z2)	Z2-GPREG1	Z2-BOOTPINCONFIG	0x0005 F088	0x0007 8208
	Z2-GPREG2	Z2-BOOT-GPREG2	0x0005 F08A	0x0007 820A
	Z2-GPREG3	Z2-BOOTDEF-LOW	0x0005 F08C	0x0007 820C
	Z2-GPREG4	Z2-BOOTDEF-HIGH	0x0005 F08E	0x0007 820E

5.7.1.1 GPREG2 Usage and MPOST Configuration

Table 5-18 explains how the bit field values from the user configurable DCSM OTP location, Z1-BOOT-GPREG2 or Z2-BOOT-GPREG2, are decoded by CPU1 boot ROM. For more information, see [C2000™ Memory Power-On Self-Test \(M-POST\)](#).

Table 5-18. CPU1 DCSM Z1/Z2 GPREG2 Bit Fields

Bit	Name	Description	Boot ROM Action
31:24	Key	Write 0x5A to these 8 bits to indicate to the boot ROM code that the bits in this register are valid	If set to 0x5A, boot ROM uses the values in this register. If set to any other value, boot ROM ignores values in this register.
23:8	Reserved	Reserved	No Action
7:4	Run MPOST ^{(1) (2)}	When configured to a valid value, MPOST (Memory Power on Self-Test) is run on all device memories	0x0 = MPOST is run with PLL enabled for high speed (110 MHz). 0xC = MPOST is run with PLL enabled for medium speed (80 MHz). 0x3 = MPOST is run with PLL enabled for low speed (60 MHz). 0x9 = MPOST is run using INTOSC2 with PLL disabled (10 MHz). Any other value = MPOST does not run.
3:0	Reserved	Reserved	No Action

- (1) If MPOST is configured to run with PLL enabled and the PLL fails to lock, then the MPOST run is skipped. This does not apply if MPOST is configured to use INTOSC2 with PLL disabled.
- (2) Note that EtherCAT gets de-asserted and released from reset using the EtherCATs peripheral software reset register during MPOST. The EtherCAT state is not restored back into the reset state.

5.7.2 Booting CPU2 and CM

This section details the boot up flow for CPU2 and CM. This includes the process, how to configure IPCBOOTMODE, and the error IPC commands that CPU2/CM report to CPU1.

5.7.2.1 Boot Up Procedure

The boot configurations for CPU2 and CM are set by the CPU1 application. The CPU1 application configures the clocks for CPU2/CM, sets the boot mode and other parameters in the IPCBOOTMODE register, and releases CPU2/CM from reset to boot.

CPU2 and CM have two states where CPU1 can configure their boot mode. The first state occurs before CPU2/CM boot and when they are still in reset. The second state occurs after CPU2/CM have been released from reset to wait boot mode where the cores wait for an IPC flag to be set by CPU1 to indicate that a boot mode has been set in the IPCBOOTMODE register. The procedures that CPU1 must follow are detailed in [Table 5-19](#) and [Table 5-20](#).

Note

Regardless of reset source, CPU2 and CM each require their respective IPCFLG0 to be set by CPU1 on **every reset** in order to confirm the contents of IPCBOOTMODE are valid and continue their boot process.

Table 5-19. CPU2 Boot Procedure

CPU2 State	CPU1 Application Actions
Held in Reset	1. Configures CPU2 clocks 2. Configures the CPU1TOCPU2IPCBOOTMODE register (Refer to Section 5.7.2.2 for configuration details) 3. Sets CPU1TOCPU2IPCFLG0⁽¹⁾ 4. Releases CPU2 from being held in reset
In Wait Boot Mode waiting for the IPC Flag	1. Configures the CPU1TOCPU2IPCBOOTMODE register (Refer to Section 5.7.2.2 for configuration details) 2. Sets CPU1TOCPU2IPCFLG0⁽¹⁾

(1) CPU2 will ACK and clear this IPC flag during boot up.

Table 5-20. CM Boot Procedure

CM State	CPU1 Application Actions
Held in Reset	1. Configures CM clocks 2. Configures the CPU1TOCMIPCBOOTMODE register (Refer to Section 5.7.2.2 for configuration details) 3. Sets CPU1TOCMIPCFLG0⁽¹⁾ 4. Releases CM from being held in reset
In Wait Boot Mode waiting for IPC Flag	1. Configures the CPU1TOCMIPCBOOTMODE register (Refer to Section 5.7.2.2 for configuration details) 2. Sets CPU1TOCMIPCFLG0⁽¹⁾

(1) CM will ACK and clear this IPC flag during boot up.

5.7.2.2 IPCBOOTMODE Details

This section details the CPU1TOCPU2IPCBOOTMODE and CPU1TOCMIPCBOOTMODE register bit-field configurations and requirements for booting CPU2/CM.

Note

If any of the bit-fields of CPU1TOCPU2IPCBOOTMODE or CPU1TOCMIPCBOOTMODE registers are set with invalid values, an error IPC command is sent to CPU1. CPU2/CM then enter a wait loop where CPU2/CM wait for CPU1 to re-configure the IPCBOOTMODE register correctly and issue a reset to the respective core.

Table 5-21. CPU1TOCPU2IPCBOOTMODE Register Details

Bit	Name	Valid Values	Description
31:24	Key	0x5A	Key must be set for this register to be considered valid.
23:20	Reserved	-	Reserved
19:16	IPC Message RAM Copy Length	0x0 = 0 words (Boot mode not used) 0x1 = 100 words 0x2 = 200 words ... 0x9 = 900 words 0xA = 1000 words ⁽¹⁾	Sets the data length (in words) for the "Copy from IPC Message RAM and Boot to M1RAM" boot mode. This is the number words to be copied from CPU1TOCPU2MSGGRAM1 to CPU2 M1RAM. If not using this boot mode, set value to 0x0.
15:8	CPU2 Device Frequency	0xA = 10 MHz ⁽²⁾ 0xB = 11 MHz ... 0xC8 = 200 MHz ⁽²⁾	Sets the clock frequency (in MHz) that CPU2 is configured at.
7:0	CPU2 Boot Mode	0x0 = None/Wait Boot 0x03 = Flash Boot Option 0 (Sector 0) 0x23 = Flash Boot Option 1 (Sector 4) 0x43 = Flash Boot Option 2 (Sector 8) 0x63 = Flash Boot Option 3 (Sector 13) 0x0A = Secure Flash Boot Option 0 (Sector 0) 0x2A = Secure Flash Boot Option 1 (Sector 4) 0x4A = Secure Flash Boot Option 2 (Sector 8) 0x6A = Secure Flash Boot Option 3 (Sector 13) 0x0C = IPC Message RAM copy and boot to M1RAM 0x05 = Boot to M0RAM 0x0B = Boot to User OTP	Sets the boot mode for CPU2

(1) Values greater than 0xA are invalid.

(2) Values less than 0xA (10 MHz) or greater than 0xC8 (200 MHz) are invalid.

Table 5-22. CPU1TOCMIPCBOOTMODE Register Details

Bit	Name	Valid Values	Description
31:24	Key	0x5A	Key must be set for this register to be considered valid.
23:20	Reserved	-	Reserved
19:16	IPC Message RAM Copy Length	0x0 = 0 words / 0 bytes (Boot mode not used) 0x1 = 100 words / 200 bytes 0x2 = 200 words / 400 bytes ... 0x9 = 900 words / 1800 bytes 0xA = 1000 words / 2000 bytes ⁽¹⁾	Sets the data length (in words) for the "Copy from IPC Message RAM and Boot to S0RAM" boot mode. This is the number words to be copied from CPU1TOCMMSGGRAM1 to CM S0RAM. If not using this boot mode, set value to 0x0.
15:8	CM Device Frequency	0xA = 10 MHz ⁽²⁾ 0xB = 11 MHz ... 0x7D = 125 MHz ⁽²⁾	Sets the clock frequency (in MHz) that CM is configured at.
7:0	CM Boot Mode	0x0 = None/Wait Boot 0x03 = Flash Boot Option 0 (Sector 0) 0x23 = Flash Boot Option 1 (Sector 4) 0x43 = Flash Boot Option 2 (Sector 8) 0x63 = Flash Boot Option 3 (Sector 13) 0x0A = Secure Flash Boot Option 0 (Sector 0) 0x2A = Secure Flash Boot Option 1 (Sector 4) 0x4A = Secure Flash Boot Option 2 (Sector 8) 0x6A = Secure Flash Boot Option 3 (Sector 13) 0x0C = IPC Message RAM copy and boot to S0RAM 0x05 = Boot to S0RAM 0x0B = Boot to User OTP	Sets the boot mode for CM

(1) Values greater than 0xA are invalid.

(2) Values less than 0xA (10 MHz) or greater than 0x7D (125 MHz) are invalid.

5.7.2.3 Error IPC Command Table

This section details the IPC commands that CPU2 or CM can send to CPU1 to notify CPU1 regarding an error that occurred.

Note

After CPU2 or CM sends the error IPC command to CPU1, CPU2/CM will set CPU2TOCPU1IPCFLG0/CMTOCPU1IPCFLG0.

Table 5-23. CPU2 to CPU1 Error IPC Commands

Description	IPCSENDCOM Value	IPCSENDADDR Value
No Command	0x0000 0000	Not Used
IPCBOOTMODE Value(s) Incorrect	0xFFFF FFFF	Not Used
CPU2 in ITRAP	0xFFFF FFFE	If RAM is accessible, the address for the source of the ITRAP will be provided
CPU2 got NMI	0xFFFF FFFA	Not Used
CPU2 Secure Flash CMAC Calculation Failed	0xFFFF FFF9	Not Used

Table 5-24. CM to CPU1 Error IPC Commands

Description	IPCSENDCOM Value	IPCSENDADDR Value
No Command	0x0000 0000	Not Used
IPCBOOTMODE Value(s) Incorrect	0xFFFF FFFF	Not Used
CM got Hard Fault Exception	0xFFFF FFFE	Not Used
CM got Unsupported Interrupt	0xFFFF FFFB	Active Exception Number
CM got NMI	0xFFFF FFFA	Not Used
CM Secure Flash CMAC Calculation Failed	0xFFFF FFF9	Not Used

5.7.3 Entry Points

This section gives details about the entry point addresses for various boot modes. These entry points direct the boot ROM what address to branch to at the end of booting as per the selected boot mode.

Table 5-25. Entry Point Addresses for CPU1

Entry Point	Details	Address
Flash / Secure Flash (Option 0)	Flash Sector 0	0x0008 0000
Flash / Secure Flash (Option 1)	Flash Sector 4	0x0008 8000
Flash / Secure Flash (Option 2)	Flash Sector 8	0x000A 8000

User OTP	CM User OTP	0x003C 0000

5.7.4 Wait Points

During boot ROM execution, there are situations where the CPU may enter a wait loop in the code. This state can occur for a variety of reasons. [Table 5-28](#), [Table 5-29](#), and [Table 5-30](#) detail the address ranges that the CPU PC register for each core will fall between if boot has entered one of these instances.

Table 5-28. Wait Point Addresses for CPU1

Silicon Rev0 Address Range	Silicon RevA Address Range	Description
0x3FB100 – 0x3FB106	0x3FB112 – 0x3FB117	In Wait Boot Mode
0x3FBEE2 – 0x3FBF09	0x3FBEEB – 0x3FBF12	In SCI Boot waiting on autobaud lock
0x3FE839 – 0x3FE92D	0x3FE839 – 0x3FE92D	In NMI Handler
0x3FE7F1 – 0x3FE823	0x3FE7F1 – 0x3FE823	In PIE Vector Mismatch Handler
0x3FE944 – 0x3FE970	0x3FE944 – 0x3FE970	In ITRAP ISR
0x3FB12A – 0x3FB12E	0x3FB13C – 0x3FB142	Failed secure Flash CMAC verification loop

Table 5-29. Wait Point Addresses for CPU2

Silicon Rev0,A Address Range	Description
0x3FB41D – 0x3FB42B	In Wait Boot Mode waiting for boot command
0x3FB459 – 0x3FB503	In NMI Handler
0x3FB504 – 0x3FB559	In ITRAP ISR
0x3FB173 – 0x3FB1B7	In loop due to invalid CPU1TOCPU2IPCBOOTMODE value(s) and/or CPU1TOCPU2IPCFLG0 is not set

Table 5-30. Wait Point Addresses for CM

Silicon Rev0,A Address Range	Description
0x180C – 0x1818	In Wait Boot Mode waiting for boot command
0x4018 – 0x41C2	In NMI Handler
0x41C4 – 0x41E8	In Hard Fault Handler
0x41EA – 0x421A	In Default Interrupt Handler
0x1618 – 0x16C4	In loop due to invalid CPU1TOCMIPCBOOTMODE value(s) and/or CPU1TOCMIPCFLG0 is not set

5.7.5 Memory Maps

This section details the ROM memory maps.

5.7.5.1 Boot ROM Memory Maps

Table 5-31. CPU1 Boot ROM Memory Map

Memory	Origin Address	Length (Words)
ROM Signature	0x003E 8000	0x0002

5.7.5.3 Reserved RAM Memory Maps

This section details memory usage in RAM that is reserved for boot ROM to use. These memory sections must be reserved in the user application.

Table 5-36. CPU1 Reserved RAM Memory Map

Memory	Description	Origin Address	End Address	Length (Words)
RAM	Boot Status, Boot Mode, MPOST Status, Boot Stack	0x0000 0002	0x0000 01B0	0x01AF

Table 5-37. CPU2 Reserved RAM Memory Map

Memory	Description	Origin Address	End Address	Length (Words)
RAM	Boot Status, Boot Mode, Boot Stack	0x0000 0002	0x0000 01A8	0x01A7

Table 5-38. CM Reserved RAM Memory Map

Memory	Description	Origin Address	End Address	Length (Bytes)
RAM	Boot Status, Boot Mode, Boot Stack	0x2000 0000	0x2000 07FF	0x0800

5.7.6 ROM Tables

[Table 5-39](#) details the boot ROM and CLA ROM symbol libraries that can be integrated into an application to use the available ROM functions and tables.

Table 5-39. ROM Symbol Tables

ROM Symbols	Library Name	Location
ROM Bootloaders and Functions	F2838xCPU1_BootROM_Symbols	Under <code>/libraries/boot_rom</code> in C2000Ware
FPU32 and FPU64 Tables	F2838xCPU1_BootROM_Symbols F2838xCPU2_BootROM_Symbols	
AES Tables	F2838xCPU1_BootROM_Symbols F2838xCPU2_BootROM_Symbols	
CLA Data ROM	F2838xCPU1_CLADATAROM_Symbols F2838xCPU2_CLADATAROM_Symbols	
IQmath	F2838xCPU1_IQMathROM_Symbols F2838xCPU2_IQMathROM_Symbols	
Secure Zone Functions	F2838xCPU1_SecureZoneCode_Symbols F2838xCPU2_SecureZoneCode_Symbols F2838xCM_SecureZoneCode_Symbols	

5.7.7 Boot Modes and Loaders

The available boot modes and bootloaders supported on this device are detailed in this section.

5.7.7.1 Boot Modes

[Table 5-40](#) details the available boot modes that do not involve a peripheral boot loader.

Table 5-40. Boot Mode Availability

Boot Mode	CPU Support
Wait Boot	CPU1, CPU2, CM
Flash Boot	CPU1, CPU2, CM
Secure Flash Boot	CPU1, CPU2, CM
RAM Boot	CPU1, CPU2, CM
User OTP Boot	CPU2, CM
IPC Message Copy to RAM Boot	CPU2, CM

5.7.7.1.1 Wait Boot

The wait boot mode puts the CPU in a loop and does not branch to the user application code. The device can either enter wait boot mode through configuration or because an error occurred during boot up. TI recommends using wait boot when using a debugger to avoid any JTAG complications. CPU2 and CM can exit wait boot mode and run a different boot mode when CPU1 sets the respective CPU IPCFLG0. More information regarding this can found at [Section 5.7.2](#).

Table 5-41. Reasons for Entering Wait Boot

CPU	Actions Resulting in Wait Boot
CPU1	- Wait boot is selected by user configuration - Decoded boot mode is unrecognized/invalid when a debugger is connected to the device - The emulation BOOTPIN_CONFIG key is not set to 0xA5 or 0x5A
CPU2	- Wait boot is selected by user configuration - Decoded boot mode is unrecognized/invalid when a debugger is connected to the device - Secure Flash boot CMAC calculation returns failure - IPC Message copy to RAM length specified is invalid (out of range) when trying to use this boot mode
CM	- Wait boot is selected by user configuration - Decoded boot mode is unrecognized/invalid when a debugger is connected to the device - Secure Flash boot CMAC calculation returns failure - IPC Message copy to RAM length specified is invalid (out of range) when trying to use this boot mode

5.7.7.1.2 Flash Boot

Flash boot mode branches to the configured memory address in Flash. Refer to [Section 5.7.3](#) for all the available Flash address options.

For CPU1, on an unprogrammed device, Flash boot can be switched to USB boot. See more details in [Section 5.3](#).

5.7.7.1.3 Secure Flash Boot

Secure Flash boot mode is similar to Flash boot mode in that the boot flow branches to the configured memory address in Flash except only after the Flash memory contents have been authenticated. The Flash authentication uses a Cipher-based Message Authentication Protocol (CMAC) to authenticate 16-KB of Flash starting from the configured Flash entry point address. The CMAC calculation requires a user-defined 128-bit key programmed in the CPU1 User OTP Zone 1 Header OTP CMACKEY bit field. Additionally, the user must calculate the golden CMAC tag based on the 16-KB Flash memory range and store it along with the user code at a hardcoded address in Flash. During secure Flash boot, the calculated CMAC tag is compared to the user golden CMAC tag in Flash to determine the pass/fail status of the CMAC authentication. When authentication passes, boot flow continues and branches to Flash to begin executing the application. When authentication fails, the boot flow actions performed vary by core. Refer to [Table 5-43](#) for details on failure actions for each core.

For the available secure Flash boot entry address options, refer to [Section 5.7.3](#).

For generating the secure Flash golden CMAC tag for CPU1 or CPU2, refer to the section “Using Secure Flash Boot on TMS320F2838x Devices” in the [TMS320C28x Assembly Language Tools User's Guide](#) for instructions.

For generating the secure Flash golden CMAC tag for CM, refer to the [ARM Assembly Language Tools v19.6.0.STS](#), within section “Using Secure Flash Boot on TMS320F2838x Devices” for instructions.

Note

- User must make sure that the Flash sector that encompasses the configured Flash entry point and the first 16KB of Flash is assigned to Zone 1 for any cores setup to use secure Flash boot.
- Recommended to use device JTAGLOCK when using secure Flash boot.
- If only using secure Flash boot for CPU2/CM, then the CPU1 application must first dummy load the Z1 OTP CMACKEY before releasing CPU2/CM from reset. When dummy loading, CPU1 application must first disable Flash data caching, then perform the dummy load, and then the application can re-enable Flash data caching.

Table 5-42. Secure Flash Tag and Key Details

Name	Address	Details
CMAC Golden Tag (128-bit)	CPU1/CPU2: <i>Flash Entry Point Address + 0x2</i> CM: <i>Flash Entry Point Address + 0x4</i>	Located in Flash, offset from the entry point address, by 2 words (CPU1/CPU2) or 4 bytes (CM). When CMAC calculations are performed, the golden tag location in memory is considered all 0xFs. Refer to Example 5-1 for an example regarding linker configuration on CPU1. Lower memory contains the tag's MSW and higher memory contains the LSW Example (on CPU1): Tag = 0x00112233 44556677 8899AABB CCDDEEFF Address 0x0 = 0x00112233 Address 0x2 = 0x44556677 Address 0x4 = 0x8899AABB Address 0x6 = 0xCCDDEEFF

Table 5-42. Secure Flash Tag and Key Details (continued)

Name	Address	Details
CMAC 128-Bit Key	0x0007 8018	Located in CPU1 Zone 1 User Header OTP (CMACKEY0, CMACKEY1, CMACKEY2, CMACKEY3) CMACKEY0 contains the key's MSW and CMACKEY3 contains the LSW Example: Key = 0x00112233 44556677 8899AABB CCDDEEFF CMACKEY0 = 0x00112233 CMACKEY1 = 0x44556677 CMACKEY2 = 0x8899AABB CMACKEY3 = 0xCCDDEEFF

Table 5-43. Secure Flash Authentication Failure Actions

CPU	Action on Failed Authentication
CPU1	Reset the device (If using debugger, device halts)
CPU2	Send IPC message to CPU1, update CPU2 boot status to indicate failure, and return to wait boot
CM	Send IPC message to CPU1, update CM boot status to indicate failure, and return to wait boot

Table 5-44. Secure Flash on all CPUs Recommended Flow

Step	Action
1	Secure Flash boot CPU1
2	CPU1 application configures CPU2 and CM to boot using <i>Secure Flash Boot</i> and releases CPU2/CM from reset
3	CPU2 and CM perform secure Flash boot
4	CPU2 and CM applications signal to CPU1 using IPC that booting is complete
5	For CPU1/CPU2/CM, any Flash beyond the first 16KB from the entry point that is planned for use must be authenticated by the user using a different CMAC golden tag embedded at an address somewhere within the already authenticated 16KB of Flash

Example 5-1. Secure Flash CPU1 Linker File Example

```

MEMORY
{
  /* Code Start branch to _c_int00 */
  BEGIN : origin = 0x80000, length = 0x0002
  /* User calculated golden CMAC tag for Flash Sector 0 */
  GOLDEN_CMAL_TAG : origin = 0x80002, length = 0x0008
  /* Flash Sector 0 containing application code */
  FLASH_SECTOR_0 : origin = 0x8000A, length = 0x1FF6
  .
  .
  .
}
```

5.7.7.1.4 RAM Boot

RAM boot mode branches to the configured memory address in RAM. Refer to [Section 5.7.3](#) for all the available RAM address options.

5.7.7.1.5 User OTP Boot

User OTP boot mode branches to the configured memory address in User OTP. Refer to [Section 5.7.3](#) for all the available user OTP address options.

5.7.7.1.6 IPC Message Copy to RAM Boot

IPC message copy to RAM involves copying application code from CPU1 IPC message RAM 1 to CPU2/CM destination RAM for execution. The maximum copy length size is 1000 words (2000 bytes) and the minimum is 100 words (200 bytes). Refer to [Table 5-45](#) for details regarding configuration and execution flow of this boot mode.

Table 5-45. IPC Message Copy Steps

Step	Action
1	CPU1 application links CPU2/CM code to copy in either CPU1TOCPU2MSGRAM1 or CPU1TOCMMSGRAM1.
2	CPU1 application configures CPU2/CM IPCBOOTMODE with the copy length and IPC message copy as the boot mode. See Section 5.7.2.2 for more IPCBOOTMODE details.
3	Once CPU2/CM is released from reset to boot, CPU2/CM begins copying from CPU1TOCPU2MSGRAM1/ CPU1TOCMMSGRAM1 to their destination RAM. Refer to Table 5-46 for destination RAM details.
4	Once the copying is complete, CPU2/CM boot branches to the entry address of the destination RAM and begins executing the application.

Table 5-46. IPC Message Copy Destination Address

CPU	RAM	Destination Address Range ⁽¹⁾ (For maximum copy length of 1000 words)
CPU2	M1RAM	0x0000 0400 to 0x0000 07E6
CM	S0RAM	0x2000 0800 to 0x2000 0FCC

(1) This memory must be allocated and reserved in the CPU2/CM application linker command file when using this boot mode.

5.7.7.2 Bootloaders

This section details the available boot modes that use a peripheral boot loader. For more specific details on the supported data stream structure used by the following bootloaders, refer to [Section 5.8.1](#).

Note

These are only available on CPU1.

5.7.7.2.1 SCI Boot Mode

The SCI boot mode asynchronously transfers code from SCI-A to internal memory. This boot mode only supports an incoming 8-bit data stream and follows the data flow as outlined in [Example 5-2](#).

Figure 5-6. Overview of SCI Bootloader Operation

The device communicates with the external host by communication through the SCI-A peripheral. The autobaud feature of the SCI port is used to lock baud rates with the host. For this reason the SCI loader is very flexible and you can use a number of different baud rates to communicate with the device.

After each data transfer, the bootloader echoes back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications can work well, this slew rate can limit reliable auto-baud detection at higher baud rates (typically beyond 100 kbaud) and cause the auto-baud lock feature to fail. To avoid this, the following is recommended:

1. Achieve a baud-lock between the host and SCI bootloader using a lower baud rate.
2. Load the incoming application or custom loader at this lower baud rate.
3. The host can then handshake with the loaded application to set the SCI baud rate register to the desired high baud rate.

Figure 5-7. Overview of SCI Boot Function

5.7.7.2.2 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial Flash device to be present on the SPI-A pins as indicated in [Figure 5-8](#). The SPI bootloader supports an 8-bit data stream and does not support a 16-bit data stream.

Figure 5-8. SPI Loader

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or Flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial Flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character, internal SPICLK master mode and talk mode, clock phase = 1, polarity = 0, using the slowest baud rate.

If the download is to be performed from an SPI port on another device, then that device must be set up to operate in the slave mode and mimic a serial SPI EEPROM. Immediately after entering the SPI_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized. The initialization is done at the slowest speed possible. Once the SPI is initialized and the key value read, specify a change in baud rate or low-speed peripheral clock.

Table 5-47. SPI 8-Bit Data Stream

...	...
...	Data for this section.
...	...
n	LSB: 00h
n+1	MSB: 00h - indicates the end of the source

The data transfer is done in "burst" mode from the serial SPI EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence follows:

1. The SPI-A port is initialized.
2. The GPIO pin, as defined by SPI option configured from [Table 5-61](#), is used as a chip-select for the serial SPI EEPROM or Flash.
3. The SPI-A outputs a read command for the serial SPI EEPROM or Flash.
4. The SPI-A sends the serial SPI EEPROM an address 0x0000; that is, the host requires that the EEPROM or Flash must have the downloadable packet starting at address 0x0000 in the EEPROM or Flash. The loader is compatible with both 16-bit addresses and 24-bit addresses.
5. The next word fetched must match the key value for an 8-bit data stream (0x08AA). The least significant byte of this word is the byte read first and the most significant byte is the next byte fetched. This is true of all word transfers on the SPI. If the key value does not match, then the load is aborted and the bootloader jumps to Flash.
6. The next two bytes fetched can be used to change the value of the low speed peripheral clock register (LOSPCP) and the SPI baud rate register (SPIBRR). The first byte read is the LOSPCP value and the second byte read is the SPIBRR value. The next seven words are reserved for future enhancements. The SPI bootloader reads these seven words and discards them.
7. The next two words makeup the 32-bit entry point address where execution continues after the boot load process is complete. This is typically the entry point for the program being downloaded through the SPI port.
8. Multiple blocks of code and data are then copied into memory from the external serial SPI EEPROM through the SPI port. The blocks of code are organized in the standard data stream structure presented earlier. This is done until a block size of 0x0000 is encountered. At that point in time the entry point address is returned to the calling routine that then exits the bootloader and resumes execution at the address specified.

Figure 5-9. Data Transfer From EEPROM Flow

5.7.7.2.3 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as indicated in [Figure 5-10](#). The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

Figure 5-10. EEPROM Device at Address 0x50

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the slave mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at slave address 0x50.

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100kHz bit rate (standard I2C mode) when the system clock is 10MHz. These registers can be modified after receiving the first few bytes from the EEPROM. This allows the communication to be increased up to a 400kHz bit rate (fast I2C mode) during the remaining data reads.

Arbitration, bus busy, and slave signals are not checked. Therefore, no other master is allowed to control the bus during this initialization phase. If the application requires another master during I2C boot mode, that master must be configured to hold off sending any I2C messages until the application software signals that the application is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages (I2C_Get Word). If a non-acknowledgment is received during the data read messages, the I2C bus hangs. [Table 5-48](#) shows the 8-bit data stream used by the I2C.

...	Data for this section.
...	...
...	Blocks of data in the format size/destination address/data as shown in the generic data stream description.
...	...
...	Data for this section.
...	...
n	LSB: 00h
n+1	MSB: 00h - indicates the end of the source

The I2C EEPROM protocol required by the I2C bootloader is shown in [Figure 5-12](#) and [Figure 5-13](#). The first communication, which sets the EEPROM address pointer to 0x0000 and reads the KeyValue (0x08AA), is shown in [Figure 5-12](#). All subsequent reads are shown in [Figure 5-13](#) and are read two bytes at a time.

Figure 5-12. Random Read

Figure 5-13. Sequential Read

5.7.7.2.4 Parallel Boot Mode

The parallel general-purpose I/O (GPIO) boot mode asynchronously transfers code from GPIO88, GPIO62:GPIO58, GPIO90:GPIO89 to internal memory. Each value is 8-bits long and follows the same data flow as outlined in [Figure 5-14](#).

Figure 5-14. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the GPIO92 and GPIO91 lines. The handshake protocol shown in [Figure 5-15](#) must be used to successfully transfer each word using GPIO[88, 62:58, 90:89]. This protocol is very robust and allows for a slower or faster host to communicate with the master subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The least-significant byte (LSB) is read first followed by the most-significant byte (MSB). In this case, data is read from GPIO[88, 62:58, 90:89].

The 8-bit data stream is shown in [Table 5-49](#).

Table 5-49. Parallel GPIO Boot 8-Bit Data Stream

Bytes	GPIO[88,62:58,90:89] (Byte 1 of 2)	GPIO[88,62:58,90:89] (Byte 2 of 2)	Description
1 2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3 4	00	00	8 reserved words (words 2 - 9)
...	...	...	...
17 18	00	00	Last reserved word
19 20	BB	00	Entry point PC[22:16]
21 22	DD	CC	Entry point PC[15:0] (PC = 0x00BB CCDD)
23 24	NN	MM	Block size of the first block of data to load = 0xMMNN words
25 26	BB	AA	Destination address of first block Addr[31:16]
27 28	DD	CC	Destination address of first block Addr[15:0] (Addr = 0xAABBCCDD)
29 30	BB	AA	First word of the first block in the source being loaded = 0xAABB
...			...
...			Data for this section.
...			...
.	BB	AA	Last word of the first block of the source being loaded = 0xAABB
.	NN	MM	Block size of the 2nd block to load = 0xMMNN words
.	BB	AA	Destination address of second block Addr[31:16]
.	DD	CC	Destination address of second block Addr[15:0]
.	BB	AA	First word of the second block in the source being loaded
.			...
n n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2 n+3	00	00	Block size of 0000h - indicates end of the source program

The device first signals the host that the device is ready to begin data transfer by pulling the GPIO91 pin low. The host load then initiates the data transfer by pulling the GPIO92 pin low. The complete protocol is shown in Figure 5-15.

Figure 5-15. Parallel GPIO Bootloader Handshake Protocol

1. The device indicates the device is ready to start receiving data by pulling the GPIO91 pin low.
2. The bootloader waits until the host puts data on GPIO [88,62:58,90:89]. The host signals to the device that data is ready by pulling the GPIO92 pin low.
3. The device reads the data and signals the host that the read is complete by pulling GPIO91 high.
4. The bootloader waits until the host acknowledges the device by pulling GPIO92 high.
5. The device again indicates the device is ready for more data by pulling the GPIO91 pin low.

This process is repeated for each data value to be sent.

Figure 5-16 shows an overview of the Parallel GPIO bootloader flow.

Figure 5-17 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode, as the host waits for the device and the device waits for the host. In this manner, the protocol works with both a host running faster and a host running slower than the device.

Figure 5-16. Parallel GPIO Mode Overview

Figure 5-17. Parallel GPIO Mode - Host Transfer Flow

Figure 5-18 shows the flow used to read a single word of data from the parallel port.

• 8-bit data stream

The 8-bit routine, shown in Figure 5-18, discards the upper 8 bits of the first read from the port and treats the lower 8 bits masked with GPIO89 in bit position 7 and GPIO90 in bit position 6 as the least-significant byte (LSB) of the word to be fetched. The routine then performs a second read to fetch the most-significant byte (MSB). The routine then combines the MSB and LSB into a single 16-bit value to be passed back to the calling routine.

Figure 5-18. 8-Bit Parallel GetWord Function

5.7.7.2.5 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory. The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The host can download a kernel to reconfigure the CAN if higher data throughput is desired.

Figure 5-19. Overview of CAN-A Bootloader Operation

The bit timing registers are programmed in such a way that a 100kbps bit rate is achieved with a 20MHz external oscillator, a shown in [Table 5-50](#).

Table 5-50. Bit-Rate Value for Internal Oscillators

OSCCLK	SYSCLK	Bit Rate
20MHz	10MHz	100kbps

The SYSCLKOUT values shown are the reset values with the default PLL setting. The BRP and bit-time values are hard-coded to 10 and 20, respectively.

Note

The CPU1 CAN boot loader uses XTAL as the bit clock source and INTOSC2 as the system clock source.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN host must transmit only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN bootloader is identical to the SCI bootloader. The data sequence for the CAN bootloader is shown in [Table 5-51](#).

Table 5-51. CAN 8-Bit Data Stream

Bytes	Byte 1 of 2	Byte 2 of 2	Description
1 2	AA	08	0x08AA (KeyValue for memory width = 16 bits)

5.7.7.2.6 USB Boot Mode

In USB boot mode, the device enumerates with vendor ID 0x1CBE and product ID 0x00FF. The device descriptor and interface descriptor both show the class as 0xFF (vendor-specific), the subclass as 0x00, and the protocol as 0x00. After enumeration, the device waits for data. Data must be sent using bulk OUT transfers to endpoint 1. The data is interpreted as a series of 8-bit bytes in the standard data stream format described in [Section 5.8.1](#), shown here in [Table 5-52](#). No reserved bytes are used. Once the data transfer is complete (block size of 0x0000 sent), the device disconnects from the USB bus, allowing other software to make use of the module if desired. [Figure 5-20](#) illustrates the flow for USB boot mode.

Figure 5-20. USB Boot Flow

Table 5-52. USB 8-Bit Data Stream

Bytes	First Byte (LSB)	Second Byte (MSB)	Description
1 2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3 4	00	00	reserved
5 6	00	00	reserved
7 8	00	00	reserved

29 30	BB	AA	First word of the first block in the source being loaded = 0xAABB
...			
...			Data for this section.
...			...
.	BB	AA	Last word of the first block of the source being loaded = 0xAABB
.	NN	MM	Block size of the 2nd block to load = 0xMMNN words
.	BB	AA	Destination address of the second block Addr[31:16]
.	DD	CC	Destination address of the second block Addr[15:0]
.	BB	AA	First word of the second block in the source being loaded
.			...
n n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2 n+3	00	00	Block size of 0000h - indicates end of the source program

Implementing PC-side USB software is not trivial. It is recommended to use the TI-provided tools and drivers to load data in USB boot mode. Hex and binary files for loader tools can be generated from COFF (.out) files using the hex2000 tool. To produce a plain binary file in the boot loader format, use the following command line:

```
hex2000 -boot -b Program_to_Load.out -o Binary_Loader_Data.dat
```

For more information on hex2000, see the [TMS320C28x Assembly Language Tools User's Guide](#).

Note

INTOSC2 must be enabled before invoking the USB boot loader. If INTOSC2 is not enabled, the boot loader hangs. A debugger reset or SCC reset does not enable INTOSC2, if INTOSC2 has been disabled by the application.

5.7.8 GPIO Assignments for CPU1

This section details the GPIOs and boot option values used for each CPU1 boot mode set in the BOOT_DEF memory location located at Z1-BOOTDEF-LOW/ Z2-BOOTDEF-LOW and Z1-BOOTDEF-HIGH/ Z2-BOOTDEF-HIGH. Refer to [Section 5.4.2](#) on how to configure BOOT_DEF. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

Note

These configurations only apply to CPU1. Refer to [Section 5.7.2](#) for details on configuring CPU2 and CM boot modes.

5.7.9 Secure ROM Function APIs

Within secure ROM of each core, functions are available to be called by the application to perform EXEONLY Flash/RAM tasks in a secure manner.

Note

The application must disable interrupts before calling one of the EXEONLY function APIs.

If a vector fetch request is given by the CPU (C28 or CM, depending on the subsystem) while the corresponding program counter (PC) is within the EXEONLY function API code of the Secure ROM, a reset occurs (RSN, if from C28; SYSRESETn, if from CM). The consequence of this is if an NMI, ITRAP, or Bus Fault occurs while the PC is executing one of the EXEONLY API functions, the NMI/ITRAP/Fault cannot be serviced because a reset occurs to that subsystem.

The **secure copy code zone 1 and zone 2 functions** allow EXEONLY Flash to be copied to EXEONLY RAM in a secure manner. The source must be from EXEONLY Flash and the destination to EXEONLY RAM. There is no support to copy EXEONLY ROM or EXEONLY RAM to RAM. Both Flash and RAM must be set to EXEONLY and configured for the same zone. Additionally, the copy size must not cross over the Flash sector boundary. Any violations of these requirements results in a failure status returned. Upon successful copy of the data, the number of 16-bit words copied is returned.

Table 5-63. Secure Copy Code Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU1, CPU2, CM	Uint16 SecureCopyCodeZ1 (Uint32 size, Uint16 *dst, Uint16 *src)	size : The number of 16-bit words to copy dst : The destination memory address in EXEONLY RAM src : The source memory address in EXEONLY Flash	0xFFFF : Returns the number of 16-bit words copied 0x0000 : Indicates one of the following: Copy length is zero; Copy size crosses over Flash sector boundary; Flash and RAM do not belong to the same zone; Flash or RAM are not set to EXEONLY; Error occurred during data copy
	Uint16 SecureCopyCodeZ2 (Uint32 size, Uint16 *dst, Uint16 *src)		

The **secure CRC calculation zone 1 and zone 2 functions** allow a safety CRC check of EXEONLY memory in a secure manner. The CRC length provided must be a value from 1 to 8 where 1 represents a CRC size of 32 16-bit words and 8 represents a CRC size of 4096 16-bit words. The source address specifies the starting address for the CRC and the destination address is the location that the resulting CRC value is stored. The source and destination memories must be configured for the same zone. Additionally, the CRC length must not cross over the Flash sector or RAM block boundary. On the CM, there is an additional requirement that CRCLOCK is not enabled. Any violations of these requirements results in a failure status returned. Upon successful CRC, the number of 16-bit words CRC'd is returned.

Table 5-64. Secure CRC Calculation Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU1, CPU2, CM	Uint16 SecureCRCCalcZ1 (Uint16 len_id, Uint16 *dst, Uint16 *src)	<i>len_id</i> : A number from 1 to 8 which corresponds to length options of 32, 64, 128, 256, 512, 1024, 2048, or 4096 16-bit words	0xFFFF : Returns the number of 16-bit words CRC'd
	Uint16 SecureCRCCalcZ2 (Uint16 size, Uint16 *dst, Uint16 *src)	<i>dst</i> : The destination memory address for resulting CRC <i>src</i> : The source memory address to begin CRC calculation	0x0000 : Indicates one of the following: Invalid length option; Source address is not modulo of length value; Destination address is not within secure RAM; CRC size crosses over Flash sector or RAM block boundary; The source and destination memory do not belong to the same zone; On CM, CRCLOCK is enabled

The **calculate CMAC (Cipher-based Message Authentication Code)** function calculates a CMAC tag for a specified memory range using the user-set CMAC key in OTP and returns pass or failure depending if the calculated tag matches the golden tag. The memory address range provided must align to a 128-bit boundary (split evenly into 128-bit blocks). If this requirement is not met, the function returns a status indicating a boundary violation. When using the CM CMAC function, there is an additional requirement that the CM must be running in privileged mode.

For generating the secure Flash golden CMAC tag for CPU1 or CPU2, refer to the section "Using Secure Flash Boot on TMS320F2838x Devices" in the [TMS320C28x Assembly Language Tools User's Guide](#) for instructions.

For generating the secure Flash golden CMAC tag for CM, refer to the [ARM Assembly Language Tools v19.6.0.STS](#), within section "Using Secure Flash Boot on TMS320F2838x Devices" for instructions.

The 128-bit golden CMAC tag:

- Must be stored inside of the memory address range that the calculation is performed on.
- Another golden CMAC tag (from a different memory address range that is being authenticated) can not be nested inside a different CMAC authentication memory address range. (For example, a CMAC on addresses 0x1000 to 0x2000 can not contain the golden CMAC tag for memory address ranges 0x4000 to 0x5000).
- The starting address of the golden CMAC tag must align to a 32-bit boundary, such as 0x80002 on CPU1/ CPU2 or 0x200004 on the CM.
- The CMAC calculation treats the memory addresses containing the golden tag as all ones.

Note

If calling this function, without running the secure Flash boot mode, then a dummy load must be performed for the Z1 OTP CMACKEY before calling the function. Additionally, the Flash data caching can be disabled before performing the dummy load and then the Flash data caching can be re-enabled after the dummy load.

Table 5-65. Secure Flash CMAC Calculation Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU1	uint32_t CPU1BROM_calculateCMAC (uint32_t startAddress, uint32_t endAddress, uint32_t tagAddress)	<i>startAddress</i> : The starting memory address for the calculation (Example: 0x80000)	0xFFFF FFFF : The calculated CMAC tag does not match the golden tag (failure)
		<i>endAddress</i> : The ending memory address for the calculation (Example: 0x82000)	0xA5A5 A5A5 : The memory address range is not aligned to a 128-bit boundary or length is zero
		<i>tagAddress</i> : The starting memory address of where the golden CMAC tag is stored. (Example: 0x80002)	0x0000 0000 : The calculated CMAC tag matches the golden tag (pass)

Table 5-65. Secure Flash CMAC Calculation Function (continued)

CPU	Function Prototype	Function Parameters	Function Return Value
CPU2	<code>uint32_t CPU2BROM_calculateCMAC(uint32_t startAddress, uint32_t endAddress, uint32_t tagAddress)</code>	<i>startAddress</i> : The starting memory address for the calculation (Example: 0x80000) <i>endAddress</i> : The ending memory address for the calculation (Example: 0x82000) <i>tagAddress</i> : The starting memory address of where the golden CMAC tag is stored. (Example: 0x80002)	0xFFFF FFFF : The calculated CMAC tag does not match the golden tag (failure) 0xA5A5 A5A5 : The memory address range is not aligned to a 128-bit boundary or length is zero 0x0000 0000 : The calculated CMAC tag matches the golden tag (pass)
CM	<code>uint32_t CMBROM_calculateCMAC(uint32_t startAddress, uint32_t endAddress, uint32_t tagAddress)</code>	<i>startAddress</i> : The starting memory address for the calculation (Example: 0x200000) <i>endAddress</i> : The ending memory address for the calculation (Example: 0x200000) <i>tagAddress</i> : The starting memory address of where the golden CMAC tag is stored. (Example: 0x200004)	0xFFFF FFFF : The calculated CMAC tag does not match the golden tag (failure) 0xA5A5 A5A5 : The memory address range is not aligned to a 128-bit boundary or length is zero 0x5A5A 5A5A : The CM is not running in privileged mode 0xE1E1 E1E1 : The CM AES engine timed out. AES engine can not be working as expected. 0x0000 0000 : The calculated CMAC tag matches the golden tag (pass)

5.7.10 Clock Initializations

During boot-up, the boot ROM initializes the device clocking, depending upon the reset source, to assist in faster boot time response. Clock configurations are performed by the boot ROM code only for POR and XRS reset types. For all other resets, the boot ROM starts executing with the clocks that were already set up before reset.

Note

Only CPU1 performs clock configurations during boot up. CPU1 application configures clocks for CPU2 and CM before releasing them from reset. Refer to [Section 5.7.2](#) for more details.

If the PLL is used during the CPU1 boot process, the PLL is bypassed by the boot ROM code before branching to the user application.

Table 5-66. CPU1 Boot Clock Sources

Source	Frequency	Description
INTOSC2	10MHz	Default clock source
INTOSC1	10MHz	Set as clock source if missing clock is detected at power up or right after device reset
SYSPLL	110MHz, 80MHz, or 60MHz	Enabled only as part of MPOST boot flow. PLL is bypassed and disabled after memory test has completed. See more details regarding enabling MPOST in Section 5.7.1.1 .
SYSPLL and AUXPLL	SYSPLL = 180MHz AUXPLL = 60MHz	Enabled only as part of USB Bootloader. Both PLLs are bypassed and disabled after the bootloader actions complete.

Table 5-67. CPU1 Clock State After Boot

Reset Source	Clock State
POR/XRS	1. Using INTOSC2 2. System clock divider set to /1
All other Resets	Maintain clocks setup before device reset.

5.7.11 Boot Status information

Boot ROM keeps a record of the various actions and events that occur during boot ROM execution. The reason for this is because NMI and other exceptions are enabled by default in the device and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can read this boot status and take the necessary actions per application's needs to handle these events.

5.7.11.1 CPU1 Booting Status

CPU1 boot ROM health and booting status is written to a 32-bit address in M0RAM. This status is cleared on a POR or XRS reset. The previous status is retained on any other reset. For example, a user should clear the status before performing a debugger device reset in order to view the latest boot ROM actions reflected in the status.

Table 5-68. CPU1 Boot Status Address

Description	Address
CPU1 Boot ROM Status	0x0000 0002

Table 5-69. CPU1 Boot Status Bit Fields

Bit	Description
31	CPU1 Boot ROM has finished running
30	Missing clock NMI occurred
29	RAM Uncorrectable Error NMI or ROM Parity Error occurred
28	Flash Uncorrectable Error NMI occurred
27	HWBIST NMI occurred
26	PIE Vector NMI occurred
25	RL NMI occurred
24	PIE Mismatch occurred
23	ITRAP occurred
22	ERAD NMI occurred
21	EtherCAT NMI occurred
20	MCAN NMI occurred
19	SYSPLL or AUXPLL failed to enable
18	MPOST (Memory Power On Self-Test) Complete
17	RAM Initialization Complete
16	DCSM Initialization Complete
15	HWBIST Reset Handled
14	POR Reset Handled
13	XRS Reset Handled
12	All Resets Handled
11:8	Not Used
7:0	0x0 = Invalid / No Status set yet 0x1 = CPU1 Boot ROM has started running 0x2 = Running Flash Boot 0x3 = Running Secure Flash Boot 0x4 = Running Parallel Boot 0x5 = Running RAM Boot 0x6 = Running SCI Boot 0x7 = Running SPI Boot 0x8 = Running I2C Boot 0x9 = Running CAN Boot 0xA = Running USB Boot 0xB = Running Wait Boot

5.7.11.2 CPU2 Booting Status

CPU2 boot ROM health and booting status is written to a 32-bit address in M0RAM. This status is cleared on every CPU2 reset. Additionally, a copy of the status is written to CPU2TOCPU1PCBOOTSTS for CPU1 to have access to CPU2's boot status.

Table 5-70. CPU2 Boot ROM Status Address

Description	Address
CPU2 Boot ROM Status	0x0000 0002

Table 5-71. CPU2 Boot Status Bit Fields

Bit	Description
31	CPU2 Boot ROM has finished running
30	Missing clock NMI occurred
29	RAM Uncorrectable Error NMI or ROM Parity Error occurred
28	Flash Uncorrectable Error NMI occurred
27	HWBIST NMI occurred
26	PIE Vector NMI occurred
25	RL NMI occurred
24	PIE Mismatch occurred

5.7.11.3 CM Booting Status

CM boot ROM health and booting status is written to a 32-bit address in S0RAM. This status is cleared on every CM reset. Additionally, a copy of the status is written to CMTOCPU1IPCBOOTSTS for CPU1 to have access to the CM's boot status.

Table 5-72. CM Boot ROM Status Address

Description	Address
CM Boot ROM Status	0x2000 0000

Table 5-73. CM Boot Status Bit Fields

Bit	Description
31	CM Boot ROM has finished running

5.7.11.4 Boot Mode and MPOST (Memory Power On Self-Test) Status

Once the boot mode is decoded during the boot flow for each core, the boot mode value is written to RAM. Additionally, on CPU1, when running the MPOST POR memory test, the test result is written to RAM.

For more information, see the [C2000™ Memory Power-On Self-Test \(M-POST\) Application Report](#).

Table 5-74. Boot Mode and MPOST Status Addresses

Description	Address
CPU1 Boot Mode	0x0000 0004
CPU2 Boot Mode	0x0000 0004
CM Boot Mode	0x2000 0004
MPOST Result (CPU1 Only)	0x0000 0006

5.7.12 ROM Version

The ROM revision and release date information is stored at the ROM locations specified in this section. Reading a revision number value of “0x100” represents version “1.0”, “0x101” represents version “1.1”, and so on. Reading a revision date value of “0x0916” represents “09/16” or “September 2016”.

Table 5-75. Boot ROM Version Information for CPU1

Start Address	End Address	Contents	Silicon Revision 0 Values	Silicon Revision A Values
0x003F FF7A	0x003F FF7A	Revision Number	0x0100	0x0200
0x003F FF7B	0x003F FF7B	Revision Date	0x0418	0x0819

5.8 Application Notes for Using the Bootloaders

5.8.1 Boot Data Stream Structure

This section details the data transfer protocols or stream structures that allow boot data transfer between boot ROM and host device. This data transfer protocol is compatible to the respective bootloaders on C2000 devices.

5.8.1.1 Bootloader Data Stream Structure

The following table and associated examples show the structure of the data stream incoming to the bootloader. The basic structure is the same for all the bootloaders and is based on the C54x source data stream generated by the C54x hex utility. The C28x hex utility (hex2000.exe) has been updated to support this structure. The hex2000.exe utility is included with the C2000 code generation tools. All values in the data stream structure are in hex. Refer to [The C2000 Hex Utility](#) for more details on using the C28x hex utility to convert a project to this format.

The first 16-bit word in the data stream is known as the key value. The key value is used to tell the bootloader the width of the incoming stream: 8 or 16 bits. Note that not all bootloaders accept both 8- and 16-bit streams. Refer to the detailed information on each loader for the valid data stream width. For an 8-bit data stream, the key value is 0x08AA and for a 16-bit stream the key value is 0x10AA. If a bootloader receives an invalid key value, then the load is aborted.

The next eight words are used to initialize register values or otherwise enhance the bootloader by passing values to the bootloader. If a bootloader does not use these values, then the values are reserved for future use and the bootloader simply reads the value and then discards the value. Currently only the SPI and I2C and parallel bootloaders use these words to initialize registers.

The tenth and eleventh words comprise the 22-bit entry point address. This address is used to initialize the PC after the boot load is complete. This address is most likely the entry point of the program downloaded by the bootloader.

The twelfth word in the data stream is the size of the first data block to be transferred. The size of the block is defined as 8-bit data stream format. For example, to transfer a block of 20 8-bit data values from an 8-bit data stream, the block size is 0x000A to indicate 10 16-bit words.

The next two words indicate to the loader the destination address of the block of data. Following the size and address is the 16-bit words that makeup that block of data.

This pattern of block size/destination address repeats for each block of data to be transferred. Once all the blocks have been transferred, a block size of 0x0000 signals to the loader that the transfer is complete. At this point, the loader returns the entry point address to the calling routine that exits. Execution continues at the entry point address as determined by the input data stream contents.

Table 5-78. LSB/MSB Loading Sequence in 8-Bit Data Stream

Byte		Contents	
LSB (First Byte of 2)		MSB (Second Byte of 2)	
1	2	LSB: AA (KeyValue for memory width = 8 bits)	MSB: 08h (KeyValue for memory width = 8 bits)
3	4	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
5	6	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
7	8	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
...	...	...	...
17	18	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
19	20	LSB: Upper half of Entry point PC[23:16]	MSB: Upper half of entry point PC[31:24] (Always 0x00)
21	22	LSB: Lower half of Entry point PC[7:0]	MSB: Lower half of Entry point PC[15:8]
23	24	LSB: Block size in words of the first block to load. If the block size is 0, this indicates the end of the source program; otherwise, another block follows. For example, a block size of 0x000A indicates 10 words or 20 bytes in the block.	MSB: block size
25	26	LSB: MSW destination address, first block Addr[23:16]	MSB: MSW destination address, first block Addr[31:24]
27	28	LSB: LSW destination address, first block Addr[7:0]	MSB: LSW destination address, first block Addr[15:8]
29	30	LSB: First word of the first block being loaded	MSB: First word of the first block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the first block to load	MSB: Last word of the first block to load
.	.	LSB: Block size of the second block	MSB: Block size of the second block
.	.	LSB: MSW destination address, second block Addr[23:16]	MSB: MSW destination address, second block Addr[31:24]
.	.	LSB: LSW destination address, second block Addr[7:0]	MSB: LSW destination address, second block Addr[15:8]
.	.	LSB: First word of the second block being loaded	MSB: First word of the second block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the second block	MSB: Last word of the second block
.	.	LSB: Block size of the last block	MSB: Block size of the last block
.	.	LSB: MSW of destination address of last block Addr[23:16]	MSB: MSW destination address, last block Addr[31:24]
.	.	LSB: LSW destination address, last block Addr[7:0]	MSB: LSW destination address, last block Addr[15:8]
.	.	LSB: First word of the last block being loaded	MSB: First word of the last block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the last block	MSB: Last word of the last block
n	n+1	LSB: 00h	MSB: 00h - indicates the end of the source

Example 5-2. Data Stream Structure 8-bit

```

AA 08      ; 0x08AA 8-bit key value
00 00 00 00 ; 8 reserved words
00 00 00 00
00 00 00 00
00 00 00 00
3F 00 00 80 ; 0x003F8000 EntryAddr, starting point after boot load completes
05 00      ; 0x0005 - First block consists of 5 16-bit words
3F 00 10 90 ; 0x003F9010 - First block is loaded starting at 0x3F9010
01 00      ; Data loaded = 0x0001 0x0002 0x0003 0x0004 0x0005
02 00
03 00
04 00
05 00
02 00      ; 0x0002 - 2nd block consists of 2 16-bit words
3F 00 00 80 ; 0x003F8000 - 2nd block is loaded starting at 0x3F8000
00 77      ; Data loaded = 0x7700 0x7625
25 76
00 00      ; 0x0000 - Size of 0 indicates end of data stream
After load has completed, the following memory values are initialized as follows:
Location Value
0x3F9010 0x0001
0x3F9011 0x0002
0x3F9012 0x0003
0x3F9013 0x0004
0x3F9014 0x0005
0x3F8000 0x7700
0x3F8001 0x7625
PC Begins execution at 0x3F8000

```

5.8.2 The C2000 Hex Utility

To use the features of the bootloader, you must generate a data stream and boot table as described in [Section 5.8.1.1](#). The hex conversion utility tool, included with the 28x code generation tools, can generate the required data stream including the required boot table. This section describes the hex2000 utility. An example of a file conversion performed by hex2000 is described in [Example 5-3](#).

The hex utility supports creation of the boot table required for the SCI, SPI, I2C, CAN, and parallel I/O loaders. That is, the hex utility adds the required information to the file such as the key value, reserved bits, entry point, address, block start address, block length and terminating value. The contents of the boot table vary slightly depending on the boot mode and the options selected when running the hex conversion utility. The actual file format required by the host (ASCII, binary, hex, and so on) differs from one specific application to another and some additional conversion can be required.

To build the boot table, follow these steps:

1. **Assemble or compile the code.** This creates the object files that then is used by the linker to create a single output file.
2. **Link the file.** The linker combines all of the object files into a single output file in common object file format (ELF). The specified linker command file is used by the linker to allocate the code sections to different memory blocks. Each block of the boot table data corresponds to an initialized section in the ELF file. Uninitialized sections are not converted by the hex conversion utility. The following options can be useful:

The linker -m option can be used to generate a map file. This map file shows all of the sections that were created, the location in memory, and the length. Check this file to make sure that the initialized sections are where you expect them.

The linker -w option configures the linker to show if the linker assigned a section to a memory region automatically. For example, if you have a section in your code called .TI.ramfunc.

3. **Run the hex conversion utility.** Choose the appropriate options for the desired boot mode and run the hex conversion utility to convert the ELF file produced by the linker to a boot table.

See the [TMS320C28x Assembly Language Tools User's Guide](#) and the [TMS320C28x Optimizing C/C++ Compiler User's Guide](#) for more information on the compiling and linking process.

Table 5-79 summarizes the hex conversion utility options available for the bootloader. See the [TMS320C28x Assembly Language Tools User's Guide](#) for a detailed description of the hex2000 operations used to generate a boot table. Updates are made to support the I2C boot. See the Codegen release notes for the latest information.

Table 5-79. Boot Loader Options

Option	Description
-boot	Convert all sections into bootable form (use instead of a SECTIONS directive)
-sci8	Specify the source of the bootloader table as the SCI-A port, 8-bit mode
-spi8	Specify the source of the bootloader table as the SPI-A port, 8-bit mode
-gpio8	Specify the source of the bootloader table as the GPIO port, 8-bit mode
-bootorg value	Specify the source address of the bootloader table
-lospcp value	Specify the initial value for the LOSPCP register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-spibrr value	Specify the initial value for the SPIBRR register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-e value	Specify the entry point at which to begin execution after boot loading. The value can be an address or a global symbol. This value is optional. The entry point can be defined at compile time using the linker -e option to assign the entry point to a global symbol. The entry point for a C program is normally _c_int00 unless defined otherwise by the -e linker option.
-i2c8	Specify the source of the bootloader table as the I2C-A port, 8-bit
-i2cpsc value	Specify the value for the I2CPSC register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM. This value is truncated to the least-significant eight bits and must be set to maintain an I2C module clock of 7 to 12MHz.
-i2cclkh value	Specify the value for the I2CCLKH register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.
-i2cclkl value	Specify the value for the I2CCLKL register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.

Example 5-3. HEX2000.exe Command Syntax

```
C: HEX2000 GPIO34TOG.OUT -boot -gpio8 -a
where:
- boot Convert all sections into bootable form.
- gpio8 Use the GPIO in 8-bit mode data format. The eCAN uses the same data format as the GPIO in
8-bit mode.
- a Select ASCII-Hex as the output format.
```

5.9 Software

5.9.1 BOOT Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/boot

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

5.9.1.1 CM Secure Flash Boot

FILE: boot_ex1_cpu1_cpu2_cm_secure_flash_cm.c

This example demonstrates how to use the secure flash boot mode for CM. (Requires CPU1 example application)

Secure flash boot performs a CMAC authentication on the entry sector of flash upon device boot up. If authentication passes, the application will begin execution. Learn more on the secure flash boot mode in the device technical reference manual.

This project shows how to use the C2000 HEX Utility to generate a CMAC Tag based on a user CMAC key and embed the value into the flash application. Additionally, the example details the method to call the CMAC API from the user application to calculate CMAC on other flash sectors beyond the the application entry flash sector.

Determining Pass/Fail without debugger connected: CM - ControlCARD LED3.

- LED off = Secure Boot failed
- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed

External Connections

- None.

Watch Variables

- None.

5.9.1.2 CPU1 Secure Flash Boot

FILE: boot_ex1_cpu1_cpu2_cm_secure_flash_cpu1.c

This example demonstrates how to use the secure flash boot mode for CPU1 as well as release CPU2 and CM for secure flash boot.

Secure flash boot performs a CMAC authentication on the entry sector of flash upon device boot up. If authentication passes, the application will begin execution. Learn more on the secure flash boot mode in the device technical reference manual.

This project shows how to use the C2000 HEX Utility to generate a CMAC Tag based on a user CMAC key and embed the value into the flash application. Additionally, the example details the method to call the CMAC API from the user application to calculate CMAC on other flash sectors beyond the the application entry flash sector.

How to Run:

- Load application into CPU1 flash (as well as CPU2 and CM applications)
- Disconnect and reconnect to only CPU1
- In memory window, set address 0xD00/D01 to 0x5AFFFFFF and address 0xD04 to 0x000A (This sets emulation boot to secure flash boot)
- Reset CPU1 via CCS and click resume
- Observe the LEDs

Determining Pass/Fail without debugger connected: CPU1 - ControlCARD LED1.

- LED off = Secure Boot failed
- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed CPU2 - ControlCARD LED2.

- LED off = Secure Boot failed
- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed *CM* - ControlCARD LED3.
- LED off = Secure Boot failed
- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed

External Connections

- None.

Watch Variables

- `cpu1_SuccessfullyBooted` - True when CPU1 full flash CMAC authentication passes. Otherwise, false.
- `cpu2_SuccessfullyBooted` - True when CPU2 full flash CMAC authentication passes and CPU1 receives IPC. Otherwise, false.
- `cm_SuccessfullyBooted` - True when CM full flash CMAC authentication passes and CPU1 receives IPC. Otherwise, false.

5.9.1.3 CPU2 Secure Flash Boot

FILE: `boot_ex1_cpu1_cpu2_cm_secure_flash_cpu2.c`

This example demonstrates how to use the secure flash boot mode for CPU2. (Requires CPU1 example application)

Secure flash boot performs a CMAC authentication on the entry sector of flash upon device boot up. If authentication passes, the application will begin execution. Learn more on the secure flash boot mode in the device technical reference manual.

This project shows how to use the C2000 HEX Utility to generate a CMAC Tag based on a user CMAC key and embed the value into the flash application. Additionally, the example details the method to call the CMAC API from the user application to calculate CMAC on other flash sectors beyond the the application entry flash sector.

Determining Pass/Fail without debugger connected: CPU2 - ControlCARD LED2.

- LED off = Secure Boot failed
- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed

External Connections

- None.

Watch Variables

- None.

Chapter 6

Dual Code Security Module (DCSM)

This chapter explains the dual code security module.

6.1 Introduction.....	777
6.2 Functional Description.....	777
6.3 Flash and OTP Erase/Program.....	785
6.4 Secure Copy Code.....	785
6.5 SecureCRC.....	786
6.6 CSM Impact on Other On-Chip Resources.....	787
6.7 Incorporating Code Security in User Applications.....	788
6.8 Software.....	793
6.9 DCSM Registers.....	795

6.1 Introduction

The dual code security module (DCSM) is a security feature incorporated in this device. It prevents access and visibility to on-chip secure memories (and other secure resources) by unauthorized persons. It also prevents duplication and reverse-engineering of proprietary code. The term “secure” means that access to on-chip secure memories and resources is blocked. The term “unsecure” means that access is allowed; that is, the contents of the memory could be read by any means (for example, through a debugging tool such as Code Composer Studio™ IDE).

There are two security zones, Zone1 (Z1) and Zone2 (Z2). Unlike earlier C2000 devices where each CPU subsystem had two security zones, on this device, both security zones are shared by each CPU subsystem. This means secure resources from each CPU subsystem are allocated to Zone1 or Zone2. All the security configurations are controlled by the CPU1 subsystem only (programmed in CPU1 USER OTP). Other CPU subsystems have only read access to these configurations via their own memory map registers.

6.1.1 DCSM Related Collateral

Getting Started Materials

- [C2000 DCSM Security Tool Application Report](#)
- [C2000 Unique Device Number Application Report](#)
- [Enhancing Device Security by Using JTAGLOCK Feature Application Report](#)
- [Secure BOOT On C2000 Device Application Report](#)

6.2 Functional Description

The security module restricts the CPU access to on-chip secure memory and resources without interrupting or stalling CPU execution. When a read occurs to a secure memory location, the read returns a zero value and CPU execution continues with the next instruction. This, in effect, blocks read and write access to secure memories through the JTAG port or external peripherals.

The code security mechanism offers protection for two zones, Zone1 (Z1) and Zone2 (Z2). The security mechanism for both the zones is identical. Each zone has its own dedicated secure resource and allocated secure resource. The following are different secure resources available on this device:

- **OTP:** Each zone has its own dedicated secure OTP (USER OTP) on CPU1 subsystem. This contains the security configurations for the individual zone. If a zone is secure, its USER OTP content (including CSM passwords) can be read (execution not allowed) only if the zone is unlocked using the password match flow (PMF).
- **RAM:** All Dx and LSx RAMs on C28x and C0/C1 RAMs on the Connectivity Manager(CM) can be secure RAM on this device. On this device IPC MSG RAMs between different subsystems can also be configured to be secure RAM. This enables secure message exchange between CPU subsystems. These RAMs can be allocated to either zone by configuring the respective GRABRAM locations in the CPU1 USER OTP.
- **Flash Sectors:** Flash sectors of each CPU subsystems can be made secure on this device. Each Flash sector can be allocated to either zone by configuring the respective GRABSECT locations in the CPU1 USER OTP.
- **Secure ROM:** This device also has secure ROM on each CPU subsystem which is EXEONLY-protected. These ROM contains specific function for the user, provided by TI.

[Table 6-1](#) shows the status of a RAM block/Flash sector based on the configuration in the GRABRAM/GRABSECT register.

The security of each zone is ensured by its own 128-bit (four 32-bit words) password (CSM password). The password for each zone is stored in CPU1 USER OTP. A zone can be unsecured by executing the password match flow (PMF), described in [Section 6.7.4](#).

Table 6-1. RAM/Flash Status

Zone 1 GRAMRAMx/GRABSECTx Bits	Zone 2 GRAMRAMx/GRABSECTx Bits	Ownership and Accessibility
01	10	RAM block/Flash Sector belongs to Zone1
01	11 ⁽²⁾	RAM block/Flash Sector belongs to Zone1
10	01	RAM block/Flash Sector belongs to Zone2
11 ⁽¹⁾	01	RAM block/Flash Sector belongs to Zone2
10	10	RAM block/Flash Sector is unsecure
11	11	If both zones are unsecure, then RAM block/Flash is unsecure. RAM block/Flash Sector inaccessible if either of the zone is secure (CSM passwords are programmed). User should never leave these values default (11) if CSM passwords are programmed for even one zone.

- (1) Zone1 must be unsecure. Assumption in this case is that user is not using Zone1 so none of the fields, including passwords, in Zone1 USER OTP are programmed by user hence Zone1 will always be unsecure.
- (2) Zone2 must be unsecure. Assumption in this case is that user is not using Zone2 so none of the fields, including passwords, in Zone2 USER OTP are programmed by user hence Zone2 will always be unsecure.

Note

You should never program any other values in these fields. Failing any these conditions for a RAM block/Flash sector will make that RAM block/Flash sector inaccessible.

There are three types of accesses:

- Data/program reads: Data reads to a secure memory are always blocked unless the program is executing from a memory that belongs to the same zone. Data reads to unsecure memory are always allowed.
- JTAG access: JTAG accesses are always blocked when a memory is secure.
- Instruction fetches (calls, jumps, code executions, ISRs): Instruction fetches are never blocked.

Table 6-2 shows the levels of security.

Table 6-2. Security Levels

PMF Executed With Correct Password?	Operating Mode of the Zone	Program Fetch Location	Security Description
No	Secure	Outside secure memory	Only instruction fetches by the CPU are allowed to secure memory. In other words, code can still be executed, but not read.
No	Secure	Inside secure memory	CPU has full access (except for EXEONLY memories where read is not allowed). JTAG port cannot read the secured memory contents.
Yes	Unsecure	Anywhere	Full access for CPU and JTAG port to secure memory of that zone.

6.2.1 CSM Passwords

Unlike earlier C2000™ devices, on this device ALL_1 value (0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF) for CSM password for a zone does not unsecure the zone. Instead, if for any zone the CSM password values get loaded as ALL_1 from USER OTP, the device is in a BLOCKED state. Due to this reason, TI programs a few bits in the second 32-bit password value (ZxOTP_CSMPSWD1) in every zone select block of each zone with a value 0. The default value for this password location is chosen in a manner that the respective ECC value remains ALL_1. Due to this, the CSMPSWD1 value programmed by TI for every zone select block is different. See [Table 6-3](#) for ZxOTP_CSMPSWD1 value, programmed by TI on every device. Since ECC is not programmed, the user is able to change this value by flipping the bits that are 1 to 0 but leaving the ones that are already programmed by TI as 0. BOOTROM code writes the default password value into the KEYx register to unlock the device as part of device initialization sequence.

If the password locations of a zone have all 128 bits as zeros (ALL_0), that zone becomes permanently secure (LOCKED state), regardless of the contents of the CSMKEYx registers, which means the zone cannot be unlocked using PMF, see the password match flow described in [Section 6.7.4](#). Therefore, the user can never use ALL_0 as a password. A password of ALL_0 prevents debug of secure code or reprogramming the Flash sectors. CSMKEYx registers are user-accessible registers that are used to unsecure the zones.

Table 6-3. Default Value of ZxOTP (Programmed by TI)

Zone Select Block	Zone1 USER OTP		Zone2 USER OTP	
	Address	Value	Address	Value
JLM_ENABLE (JTAGLOCK)	0x0007 8006	0xFFFF 000F	NA	NA
PSWDLOCK	0x0007 8010	0xFB7F FFFF	0x00078210	0x1F7F FFFF

6.2.2 Emulation Code Security Logic (ECSL)

In addition to the CSM, the emulation code security logic (ECSL) has been implemented using a 64-bit password (part of existing CSM password) for each zone to prevent unauthorized users from stepping through secure code. A halt in secure code while the emulator is connected will trip the ECSL and break the emulation connection. To allow emulation of secure code, while maintaining the CSM protection against secure memory reads, the user must write the correct 64-bit password into the CSMKEY (0/1) registers, which matches the password value stored in the USER OTP of that zone. This will disable the ECSL for the specific zone.

When initially debugging a device with the password locations in OTP programmed (secured), the emulator takes some time to take control of the CPU. During this time, the CPU will start running and may execute an instruction that performs an access to a protected ECSL area and if the CPU is halted when the program counter (PC) is pointing to a secure location, the ECSL will trip and cause the emulator connection to be broken.

The solution to this problem is:

- Use the Wait Boot Mode boot option. In this mode, the CPU will be in a loop and hence will not jump to the user application code. Using this BOOTMODE, the user can connect to CCS and debug the code.

6.2.3 CPU Secure Logic

The CPU Secure Logic (CPUSL) on this device prevents a hacker from reading the CPU registers in a watch window while code is running in a secure zone. All accesses to CPU registers when the PC points to a secure location are blocked by this logic. The only exception to this is read access to the PC. It is highly recommended not to write into the CPU register in this case, because proper code execution may get affected. If the CSM is unlocked using the CSM password match flow, the CPUSL logic also gets disabled.

6.2.4 Execute-Only Protection

To achieve a higher level of security on secure Flash sectors and RAM blocks that store critical user code (instruction opcodes), the Execute-Only protection feature is provided. When the Execute-Only protection is turned on for any secure Flash sector or RAM block, data reads to that Flash sector or RAM block are disallowed from any code (even from secure code). Execute-only protection for a Flash sector and RAM block can be turned on by configuring the bit field associated for that particular sector/RAM block in the zone's (which has ownership of that sector/RAM block) EXEONLYSECT and EXEONLYRAM register, respectively.

6.2.5 Password Lock

The password locations in USER OTP for each zone can be locked by programming the zone's PSWDLOCK field with any value other than "1111" (0xF) at the PSWDLOCK location in OTP. Until the passwords of a zone are locked, password locations will not be secure and can be read from the debugger as well as code running from non-secure memory. This feature can be used by the user to avoid accidental locking of the zone while programming the Flash sectors during the software development phase. On a fresh device the value for password lock fields for all zones at the PSWDLOCK location in OTP will be "1111" which means the password for all zones will be unlocked.

Note

Password unlock only makes password locations non-secure. All other secure memories remains secure as per security settings. Since password locations are non-secure, anyone can read the password and make the zone un-secure by running through PMF, user must program PSWDLOCK locations to lock the password before sending the device in field.

6.2.6 JTAGLOCK

Sometimes you want to disable the JTAG access on a device to avoid any debug access to it. This can be done by using the JTAGLOCK feature on this device. You need to follow a two step process to enable the JTAGLOCK feature (both steps can be performed at the same time).

1. Program the JTAG passwords. This device has a 128-bit JTAG password that needs to be programmed in Z1 USER OTP of CPU1. JTAG passwords are split into two parts, JTAGPSWDH and JTAGPSWDL. JTAGPSWDH is part of the Z1 USER OTP header and JTAGPSWDL is part of the Z1 Zone Select Block (ZSB). What this means is program JTAGPSWDH once and change the JTAGPSWDL multiple times, if needed. The Code Composer Studio™ IDE has an integrated tool that you need to use to unlock the JTAGLOCK on the device.
2. After programming the JTAG passwords, you need to enable the JTAGLOCK module (JLM) by programming bit [3:0] of Z1OTP_JLM_ENABLE with any value other than 0xF. It is recommended to program all four bits with a value 0x0.

For more details on how to enable and disable the JTAGLOCK feature, refer to the [Enhancing Device Security by Using JTAGLOCK Feature Application Report](#).

6.2.7 Link Pointer and Zone Select

For each of the two security zones, a dedicated OTP block exists on CPU1 that holds the configuration related to zone's security. The following are user programmable configurations:

- | | |
|----------------------|----------------------|
| • ZxOTP_LINKPOINTER1 | • ZxOTP_CSMPSWD1 |
| • ZxOTP_LINKPOINTER2 | • ZxOTP_CSMPSWD2 |
| • ZxOTP_LINKPOINTER3 | • ZxOTP_CSMPSWD3 |
| • Z1OTP_JLM_ENABLE | • ZxOTP_GRABSECT1 |
| • ZxOTP_GPREG1 | • ZxOTP_GRABSECT2 |
| • ZxOTP_GPREG2 | • ZxOTP_GRABSECT3 |
| • ZxOTP_GPREG3 | • ZxOTP_GRABRAM1 |
| • ZxOTP_GPREG4 | • ZxOTP_GRABRAM2 |
| • ZxOTP_PSWDLOCK | • ZxOTP_GRABRAM3 |
| • ZxOTP_CRCLOCK | • ZxOTP_EXEONLYSECT1 |
| • Z1OTP_JTAGPSWDH | • ZxOTP_EXEONLYSECT2 |
| • Z1OTP_CMACKKEY | • ZxOTP_EXEONLYRAM1 |
| • ZxOTP_CSMPSWD0 | • Z1OTP_JTAGPSWDL |

Since OTP cannot be erased, the following configurations are placed in zone select blocks of each zone's OTP Flash of both the banks:

- | | |
|-------------------|----------------------|
| • ZxOTP_CSMPSWD0 | • ZxOTP_GRABRAM1 |
| • ZxOTP_CSMPSWD1 | • ZxOTP_GRABRAM2 |
| • ZxOTP_CSMPSWD2 | • ZxOTP_GRABRAM3 |
| • ZxOTP_CSMPSWD3 | • ZxOTP_EXEONLYSECT1 |
| • ZxOTP_GRABSECT1 | • ZxOTP_EXEONLYSECT2 |
| • ZxOTP_GRABSECT2 | • ZxOTP_EXEONLYRAM1 |
| • ZxOTP_GRABSECT3 | • Z1OTP_JTAGPSWDL |

The location of the valid zone select block in OTP is decided based on the value of three 14-bit link pointers (Zx-LINKPOINTERx) programmed in the OTP of each zone. All OTP locations except link pointers and Z1OTP_JLM_ENABLE locations are protected with ECC. Since the link pointer locations are not protected with ECC, three link pointers are provided that need to be programmed with the same value. The final value of the link pointer is resolved in hardware, when a dummy read is done to all the link pointers, by comparing all the three values (bit-wise voting logic). Since in OTP, a '1' can be flipped by the user to '0' but '0' can not be flipped to '1' (no erase operation for OTP), the most significant bit position in the resolved link pointer which is '0', defines the valid base address for the zone select block. While generating the final link pointer value, if the bit pattern is not one of those listed in [Figure 6-1](#), the final link pointer value becomes All_1 (0xFFFF_FFFF), which selects the Zone-Select-Block1 (also known as the default zone select block).

Zx-LINKPOINTER	Selected ZSB	Zone1 ZSB Address	Zone2 ZSB Address
32xxxxxxxxxxxxxxxx111111111111	ZSB1	0x78020	0x78220
32xxxxxxxxxxxxxxxx111111111110	ZSB2	0x78040	0x78240
32xxxxxxxxxxxxxxxx1111111111100	ZSB3	0x78060	0x78260
32xxxxxxxxxxxxxxxx11111111111000	ZSB4	0x78080	0x78280
32xxxxxxxxxxxxxxxx111111111110000	ZSB5	0x780a0	0x782a0
32xxxxxxxxxxxxxxxx1111111111100000	ZSB6	0x780c0	0x782c0
32xxxxxxxxxxxxxxxx11111111111000000	ZSB7	0x780e0	0x782e0
32xxxxxxxxxxxxxxxx111111110000000	ZSB8	0x78100	0x78300
32xxxxxxxxxxxxxxxx1111111100000000	ZSB9	0x78120	0x78320
32xxxxxxxxxxxxxxxx111111000000000	ZSB10	0x78140	0x78340
32xxxxxxxxxxxxxxxx111100000000000	ZSB11	0x78160	0x78360
32xxxxxxxxxxxxxxxx111000000000000	ZSB12	0x78180	0x78380
32xxxxxxxxxxxxxxxx110000000000000	ZSB13	0x781a0	0x783a0
32xxxxxxxxxxxxxxxx100000000000000	ZSB14	0x781c0	0x783c0
32xxxxxxxxxxxxxxxx000000000000000	ZSB15	0x781e0	0x783e0

Figure 6-1. Storage of Zone-Select Bits in OTP

Note

Address locations for other security settings that are not part of Zone Select blocks can be programmed only once; therefore, you can program the blocks towards the end of the development cycle.

Figure 6-2. Location of Zone-Select Block Based on Link-Pointer

CAUTION

USER OTP is ECC protected. You must program the ECC value while programming the security setting in USER OTP. Failing to program the correct ECC value causes the device to be blocked permanently and you have to replace the device.

6.2.8 C Code Example to Get Zone Select Block Addr for Zone1

```

unsigned long LinkPointer;
unsigned long *ZoneSelBlockPtr;
int Bitpos = 13;
int ZeroFound = 0;
// Read Z1-Linkpointer register of DCSM module.
LinkPointer = *(unsigned long *)0x5F000;
// Bits 31 to 15 as most-significant 0 are reserved LinkPointer options
LinkPointer = LinkPointer << 18;
while ((ZeroFound == 0) && (bitpos > -1))
{
    if ((LinkPointer & 0x80000000) == 0)
    {
        ZeroFound = 1;
        ZoneSelBlockPtr = (unsigned long *) (0x78000 + ((bitpos + 2)*32));
    }
    Else
    {
        bitpos--;
        LinkPointer = LinkPointer << 1;
    }
}
if (ZeroFound == 0)
{
    //Default in case there is no zero found.
    ZoneSelBlockPtr = (unsigned long *)0x78020;
}

```

6.3 Flash and OTP Erase/Program

On this device, OTP as well as normal Flash, are secure resources. Each zone has its own dedicated CPU1 OTP, whereas normal Flash sectors can be allocated to any zone based on the value programmed in the GRABSECTx location in OTP. Each zone has its own 128bit CSM passwords. Read and write accesses are not allowed to resources assigned to Z1 by code running from memory allocated to Z2 and vice versa. Before programming any secure Flash sector the user must either unlock the zone to which that particular sector belongs using PMF or execute the Flash programming code from secure memory which belongs to the same zone. The same is the case for erasing any secure Flash sector. To program the security settings in CPU1 OTP Flash, the user must unlock the CSM of the respective zone. Unless the zone is unlocked, security settings in OTP Flash can not be updated. The OTP content cannot be erased.

A semaphore mechanism is provided to avoid the program/erase conflict between Z1 and Z2. A zone needs to grab this semaphore to successfully complete the erase/program operation on the secure Flash sectors allocated to that zone. A semaphore can be grabbed by a zone by writing the appropriate value in the SEM field of the FLSEM register. For further details of this field, see the register description.

6.4 Secure Copy Code

In some applications, the user may want to copy the code from secure Flash to secure RAM for better performance. The user cannot do this for EXEONLY Flash sectors because EXEONLY secure memories cannot be read from anywhere. TI provides specific “Secure Copy Code” library functions for each zone to enable the user to copy content from EXEONLY secure Flash sectors to EXEONLY RAM blocks. These functions do the copy-code operation in a highly secure environment and allow a copy to be performed only when the following conditions are met:

- The secure RAM block and the secure Flash sector belong to the same zone.
- Both the secure RAM block and the secure Flash sector have EXEONLY protection enabled.

For further usage of these library functions, see the device-specific Boot ROM documentation.

6.5 SecureCRC

Since reads from EXEONLY memories are not allowed, you cannot calculate the CRC on content in EXEONLY memories using the CRC engine available on this device (for example, VCRC, GCRC) or software. In some safety-critical applications, the user may have to calculate the CRC even on these memories. To enable this without compromising on security, TI provides specific “SecureCRC” library functions for each zone. These functions do the CRC calculation in highly secure environment and allow a CRC calculation to be performed only when the following conditions are met:

- The source address should be modulo the number of words (based on length_id) for which the CRC needs to be calculated.
- The destination address should belong to the same zone as the source address.

For further usage of these library functions, see the device-specific Boot ROM documentation.

Note

You must disable all the interrupts before calling the secure functions in ROM. If there is a vector fetch during secure function execution, the CPU gets reset immediately.

Disclaimer: The Code Security Module (CSM) included on this device was designed to password protect the data stored in the associated memory and is warranted by Texas Instruments (TI), in accordance with its standard terms and conditions, to conform to TI's published specifications for the warranty period applicable for this device. TI DOES NOT, HOWEVER, WARRANT OR REPRESENT THAT THE CSM CANNOT BE COMPROMISED OR BREACHED OR THAT THE DATA STORED IN THE ASSOCIATED MEMORY CANNOT BE ACCESSED THROUGH OTHER MEANS. MOREOVER, EXCEPT AS SET FORTH ABOVE, TI MAKES NO WARRANTIES OR REPRESENTATIONS CONCERNING THE CSM OR OPERATION OF THIS DEVICE, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL TI BE LIABLE FOR ANY CONSEQUENTIAL, SPECIAL, INDIRECT, INCIDENTAL, OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING IN ANY WAY OUT OF YOUR USE OF THE CSM OR THIS DEVICE, WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. EXCLUDED DAMAGES INCLUDE, BUT ARE NOT LIMITED TO LOSS OF DATA, LOSS OF GOODWILL, LOSS OF USE OR INTERRUPTION OF BUSINESS OR OTHER ECONOMIC LOSS.

6.6 CSM Impact on Other On-Chip Resources

On this device, some of the memories are not secure. To avoid any potential hacking when the device is in the default state (post reset), accesses (all types) to all memories (secure as well as non-secure, except BOOT-ROM and OTP) are disabled until proper security initialization is done. This means that after reset none of the memory resources except BOOT_ROM and OTP is accessible to the user.

The following steps are required by CPU1 after reset (any type of reset) to initialize the security on device.

Security Initialization

- Dummy Read to address location of SECD (0x703F0, TI-reserved register) in TI OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER1 in Z1 OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER2 in Z1 OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER3 in Z1 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER1 in Z2 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER2 in Z2 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER3 in Z2 OTP
- Dummy Read to address location Z1OTP_JLM_ENABLE in Z1 OTP
- Dummy Read to address location of Z1OTP_GPREG1, Z1OTP_GPREG2, Z1OTP_GPREG3, Z1OTP_GPREG4 in Z1 OTP
- Dummy Read to address location of Z1OTP_PSWDLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP_CRCLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP_JTAGPSWDH0, Z1OTP_JTAGPSWDH1 in Z1 OTP
- Dummy Read to address location of Z2OTP_GPREG1, Z2OTP_GPREG2, Z2OTP_GPREG3, Z2OTP_GPREG4 in Z2 OTP
- Dummy Read to address location of Z2OTP_PSWDLOCK in Z2 OTP
- Dummy Read to address location of Z2OTP_CRCLOCK in Z2 OTP
- Read to memory map register of Z1_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of Z1OTP_GRABSECT1, Z1OTP_GRABSECT2, Z1OTP_GRABSECT3 in Z1 OTP
- Dummy read to address location of Z1OTP_GRABRAM1, Z1OTP_GRABRAM2, Z1OTP_GRABRAM3 in Z1 OTP
- Dummy read to address location of Z1OTP_EXEONLYSECT1, Z1OTP_EXEONLYSECT2 in Z1 OTP
- Dummy read to address location of Z1OTP_EXEONLYRAM1 in Z1 OTP
- Dummy Read to address location of Z1OTP_JTAGPSWDL0, Z1OTP_JTAGPSWDL1 in Z1 OTP
- Read to memory map register of Z2_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of Z2OTP_GRABSECT1, Z2OTP_GRABSECT2, Z2OTP_GRABSECT3 in Z2 OTP
- Dummy read to address location of Z2OTP_GRABRAM1, Z2OTP_GRABRAM2, Z2OTP_GRABRAM3 in Z2 OTP
- Dummy read to address location of Z2OTP_EXEONLYSECT1, Z2OTP_EXEONLYSECT2 in Z2 OTP
- Dummy read to address location of Z2OTP_EXEONLYRAM1 in Z2 OTP

Note

Security Initialization is done by CPU1 BOOTROM code on all the resets (as part of device initialization) that assert CPU1 SYSRSn. This is not part of user application code

The order of initialization matters; hence, if a memory watch window with the USER OTP address is opened in the debugger (CCS IDE) the security initialization can occur in an incorrect order, locking the device down. To avoid this, the user must not keep a memory window with USER OTP address opened in the debugger (CCS IDE) when performing a reset.

6.7 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project. However, security is needed once a robust code is developed for a zone. Before such a code is programmed in the Flash memory, a CSM password should be chosen to secure the zone. Once a CSM password is in place for a zone, the zone is secured (programming a password at the appropriate locations and either performing a device reset or setting the FORCESEC bit (Zx_CR.31) is the action that secures the device). From that time on, access to debug the contents of secure memory by any means (via JTAG, code running off external/on-chip memory, and so forth) requires a valid password. A password is not needed to run the code out of secure memory (such as in a typical end-user usage); however, access to secure memory contents for debug purposes, requires a password.

6.7.1 Environments That Require Security Unlocking

The following are the typical situations under which unsecuring the zone can be required:

- Code development using debuggers (such as Code Composer Studio). This is the most common environment during the design phase of a product.
- Flash programming using TI's Flash utilities such as Code Composer Studio On-Chip Flash Programmer plug-in or the Uniflash tool. Flash programming is common during code development and testing. Once the user supplies the necessary password, the Flash utilities disable the security logic before attempting to program the Flash. In custom programming solutions that use the Flash API supplied by TI, unlocking the CSM can be avoided by executing the Flash programming algorithms from secure memory.
- Custom environment defined by the application
 - In addition to the above, access to secure memory contents can be required in situations such as:
 - Using the on-chip bootloader to load code or data into secure SARAM or to erase and program the Flash.
 - Executing code from on-chip unsecure memory and requiring access to secure memory for the lookup table. This is not a suggested operating condition as supplying the password from external code could compromise code security.

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. [Figure 6-3](#) explains the sequence of operation that is required every time the user attempts to unsecure a particular zone. A code example is listed for clarity.

6.7.2 CSM Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes (32-bit writes) to CSMKEY(0/1/2/3) registers. [Figure 6-3](#) shows how PMF helps to initialize the security logic registers and disable security logic.

Figure 6-3. CSM Password Match Flow (PMF)

6.7.3 C Code Example to Unsecure C28x Zone1

```
volatile long int *CSM = (volatile long int *)5F010; //CSM register file volatile
long int *CSMPWL = (volatile long int *)0x78020; //CSM Password location (assuming default zone
select block)
volatile int tmp;
int I;
// Read the 128-bits of the CSM password locations (PWL)
//
for (I=0;I<4; I++) tmp = *CSMPWL++;
// Write the 128-bit password to the CSMKEY registers
// If this password matches that stored in the
// CSLPWL then the CSM will become unsecure. If it does not
// match, then the zone will remain secure.
// An example password of: // 0x11112222333344445555666677778888 is used.
*CSM++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*CSM++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
*CSM++ = 0x66665555; // Register Z1_CSMKEY2 at 0x5F014
*CSM++ = 0x88887777; // Register Z1_CSMKEY3 at 0x5F016
```

6.7.4 C Code Example to Resecure C28x Zone1

```
volatile int *Z1_CR = 0x5F019; //CSMSCR register
//Set FORCESEC bit
*Z1_CR = 0x8000;
```

Note

User must use the FORCESEC feature to resecure the zone from same subsystem that has unlocked the zone. For example, if CM subsystem has unlocked the Zone1 by entering the CSM password in CSMKEYx, then only CM subsystem should resecure the Zone1 using FORCESEC feature.

6.7.5 Environments That Require ECSL Unlocking

The following are the typical situations under which unsecuring can be required:

- The user develops some main IP, and then outsources peripheral functions to a subcontractor who must be able to run the user code during debug and may halt while main IP code is running. If ECSL is not unlocked, then Code Composer Studio connections will get disconnected, which can be inconvenient for the user. Note that unlocking ECSL does not enable access to secure code but only avoids disconnection of CCS (JTAG).

6.7.6 ECSL Password Match Flow

A password match flow (PMF) is essentially a sequence of eight dummy reads from password locations (PWL) followed by two writes to KEY registers. Figure 6-4 shows how the PMF helps to initialize the security logic registers and disable security logic.

Figure 6-4. ECSL Password Match Flow (PMF)

6.7.7 ECSL Disable Considerations for any Zone

A zone with ECSL enabled should have a predetermined ECSL password stored in the ECSL password locations in Flash (same as lower 64 bits of CSM passwords). The following are steps to disable the ECSL for any particular zone:

- Perform a dummy read of CSM password locations of that Zone.
- Write the password into the CSMKEY0/1 registers, corresponding to that Zone.
- If the password is correct, the ECSL gets disabled; otherwise, it stays enabled.

6.7.7.1 C Code Example to Disable ECSL for C28x-Zone1

```
volatile long int *ECSL = (volatile int *)0x5F010; //ECSL register file
volatile long int *ECSLPWL = (volatile int *)0x78028; //ECSL Password location (assuming default
Zone sel block)
volatile int tmp;
int I;
// Read the 64-bits of the password locations (PWL).
for (I=0; I<2; I++) tmp = *ECSLPWL++;
// Write the 64-bit password to the CSMKEYx registers
// If this password matches that stored in the
// CSMPWL then ECSL will get disable. If it does not
// match, then the zone will remain secure.
// An example password of: // 0x1111222233334444 is used.
*ECSL++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*ECSL++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
```

Note

If the CM subsystem is out of reset when ECSL is unlocked by any of the subsystem, one must reset the CM before trying to lock the ECSL again. Unless CM is reset, ECSL can not be locked again by entering the incorrect KEY or using the FORCESEC.

6.7.8 Device Unique ID

CPU1 TI OTP contains a 256-bit value that is made up of both random and sequential parts. This value can be used as a seed for code encryption. The starting address of the value is 0x7020C. The first 192 bits are random, the next 32 bits are sequential, and the last 32 bits are a checksum value.

6.8 Software

6.8.1 DCSM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dcsm

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

6.8.1.1 Empty DCSM Tool Example

FILE: dcsm_security_tool.c This example is an empty project setup for DCSM Tool and Driverlib development.
For guidance refer to: [C2000 DCSM Security Tool](#)

6.8.1.2 DCSM Memory Access control by master CPU1 - C28X_CM

FILE: dcsm_ex1_cpu_access_control.c

This example demonstrates how to configure the 1st Zone Select Block in the OTP to allocate CM's C0RAM to zone 1 & CM's C1RAM to zone 2, later accessed by CM. Zone1 | Zone2 | CM's C0RAM | CM's C1RAM | In this example, zoning of memories is done by the OTP programming whose values are configured in dcsm_ex1_f2838x_dcsm_zxotp.asm while the securing functionalities are done through this file. It demonstrates how to control the access of the memories which would later be accessed by CM. This would even do a dummy read of the password needed by CM to unsecure the memory. The communication between the 2 CPUs are done using IPC (Inter process communication) through a synch function. This enables the CPU Core to wait until the expected task is completed on the other core.

External Connections

- None.

Watch Variables

- *result* - Status of Memory Access control by CPU1
- *set_error* - Count of errors occurring during the execution of the example.

Before running the example, the below configuration is expected to be done through the dcsm_ex1_f2838x_dcsm_zxotp.asm :

- Allocate CM's C0RAM to zone 1 , C1RAM to zone 2 ZSBx_Z1_GRABRAM2R 0x0AAAAA09
ZSBx_Z2_GRABRAM2R 0x0AAAAA06
- Password of zone 1 is 0xFFFFFFFF4D7FFFFFFFFFFFFFFFFFFFFFFF
- Password of zone 2 is 0xFFFFFFFF1F7FFFFFFFFFFFFFFFFFFFFFFF

6.8.1.3 DCSM Memory Access by CPU2 - C28X_DUAL

FILE: dcsm_ex1_cpu2_memory_access.c

This example demonstrates how the access of the memory is affected when the memories are secured by CPU1. CPU1 allocate CPU2's LS4-LS5 to zone 1 & CPU2's LS6-LS7 to zone 2 using the 1st Zone Select Block. Zone1 | Zone2 | CPU2's LS4-LS5 | CPU2's LS6-LS7 | It writes some data in the zones and checks after the CPU1 does a memory locking and matches with the data set . Further, once the CPU2 unlocks the memories, it matches with the data set written before CPU1 lock. Ideally after locking, zone1 should not be readable(or reads a 0 value) and zone2 that is not secured matches the written data set. It demonstrates how to lock and and unlock zone by showing where to put the password and how to check if it is secured or unsecured.

The communication between the 2 CPUs are handled using IPC (Inter process communication) through a synch function. This enables the CPU Core to wait until the expected task is completed on the other core.

External Connections

- None.

Watch Variables

- *result* - Status of CPU2's secure memory access

- `set_error`, `error_not_locked`, `error_not_unlocked`, `error1` - Count of errors occurring during the execution of the example.
- `Zone1_Locked_Array` - Array demonstrating secured memory
- `Unsecure_mem_Array` - Array demonstrating Unsecured memory

6.8.1.4 DCSM Memory Access control by CPU1 - C28X_DUAL

FILE: `dcsm_ex1_cpu1_access_control.c`

This example demonstrates how to configure the 1st Zone Select Block in the OTP needed to allocate CPU2's LS4-LS5 to zone 1 & CPU2's LS6-LS7 to zone 2, later accessed by CPU2. Zone1 | Zone2 | CPU2's LS4-LS5 | CPU2's LS6-LS7 | In this example, zoning of memories is done by the OTP programming whose values are configured in `dcsm_ex1_f2838x_dcsm_zxotp.asm` while the securing functionalities are done through this file. It demonstrates how to control the access of the memories which would later be accessed by CPU2. This would even do a dummy read of the password needed by CPU2 to unsecure the memory. The communication between the 2 CPUs are done using IPC (Inter process communication) through a sync function. This enables the CPU Core to wait until the expected task is completed on the other core.

External Connections

- None.

Watch Variables

- `result` - Status of Memory Access control by CPU1
- `set_error` - Count of errors occurring during the execution of the example.

Before running the example, the below configuration is expected to be done through the `dcsm_ex1_f2838x_dcsm_zxotp.asm` :

- Allocate CPU2's LS4-LS5 to zone 1 , LS6-LS7 to zone 2 ZSBx_Z1_GRABRAM3R 0x0000A500
ZSBx_Z2_GRABRAM3R 0x00005A00
- Password of zone 1 is 0xFFFFFFFF4D7FFFFFFFFFFFFFFFFFFFFFFF
- Password of zone 2 is 0xFFFFFFFF1F7FFFFFFFFFFFFFFFFFFFFFFF

6.8.1.5 DCSM Memory partitioning Example

FILE: `dcsm_ex1_secure_memory_partition.c`

This example demonstrates how to configure and use DCSM. It configures the 1st Zone Select Block in the OTP to change the zone passwords and allocates LS0-LS3 to zone 1 & LS4-LS7 to zone 2. Zone1 | Zone2 | LS0-LS3 | LS4-LS7 | In this example, zoning of memories is done by the OTP programming whose values are configured in `dcsm_ex1_f2838x_dcsm_zxotp.asm` while the securing functionalities are done through this file. It writes some data in the zones and checks before locking and after locking and matches with the data set . Ideally after locking zone1, the data set stored in zone1 should not be readable(or reads a 0 value) and zone2 that is not secured matches the written data set. It demonstrates how to lock and and unlock zones by showing where to put the password and how to check if it is secured or unsecured.

External Connections

- None.

Watch Variables

- `result` - Status of Secure memory partitioning done through OTP programming.
- `set_error`, `error_not_locked`, `error_not_unlocked`, `error1` - Count of errors occurring during the execution of the example.
- `Zone1_Locked_Array` - Array demonstrating secured memory
- `Unsecure_mem_Array` - Array demonstrating Unsecured memory

Before running the example, the below configuration is expected to be done through the `dcsm_ex1_f2838x_dcsm_zxotp.asm` :

- Allocate LS0-LS3 to zone 1 , LS4-LS7 to zone 2 ZSBx_Z1_GRABRAM1R 0x000AAA55
ZSBx_Z2_GRABRAM1R 0x000A55AA
- Password of zone 1 is 0xFFFFFFFF4D7FFFFFFFFFFFFFFFFFFFFFFF
- Password of zone 2 is 0xFFFFFFFF1F7FFFFFFFFFFFFFFFFFFFFFFF

DCSM_unlockZone*CSM function should not be called in an actual application, should only be used for once to program the OTP memory. Ensure flash data cache is disabled before calling this function.

6.8.1.6 DCSM Memory Access by CM - C28X_CM

FILE: dcsm_ex1_cm_memory_access.c

This example demonstrates how the access of the memory is affected when the memories are secured by CPU1. CPU1 allocate CM's C0RAM to zone 1 & CM's C1RAM to zone 2 using the 1st Zone Select Block. Zone1 | Zone2 | CM's C0RAM | CM's C1RAM | It writes some data in the zones and checks after the CPU1 does a memory locking and matches with the data set . Further, once the CM unlocks the memories, it matches with the data set written before CPU1 lock. Ideally after locking, zone1 should not be readable(or reads a 0 value) and zone2 that is not secured matches the written data set. It demonstrates how to lock and and unlock zone by showing where to put the password and how to check if it is secured or unsecured.

The communication between the 2 CPUs are handled using IPC (Inter process communication) through a sync function. This enables the CPU Core to wait until the expected task is completed on the other core.

External Connections

- None.

Watch Variables

- *result* - Status of CM's secure memory access
- *set_error*, *error_not_locked* ,*error_not_unlocked* ,*error1* - Count of errors occurring during the execution of the example.
- *Zone1_Locked_Array* - Array demonstrating secured memory
- *Unsecure_mem_Array* - Array demonstrating Unsecured memory

6.9 DCSM Registers

This section describes the various DCSM Registers.

Note

Except for the SECERRSTAT, SECERRCLR, and SECERRFRC registers, all other registers (non-OTP space) are mapped on all three subsystems. For the CM subsystem, a x8 offset needs to be used.

6.9.1 DCSM Base Address Table (C28)

Table 6-4. DCSM Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
DcsmZ1Regs	DCSM_Z1_REGS	DCSM_Z1_BASE	0x0005_F000	YES	YES	-	-	YES
DcsmZ2Regs	DCSM_Z2_REGS	DCSM_Z2_BASE	0x0005_F080	YES	YES	-	-	YES
DcsmCommonRegs	DCSM_COMMON_REGS	DCSMCOMMON_BASE	0x0005_F0C0	YES	YES	-	-	YES
DcsmZ1OtpRegs	DCSM_Z1_OTP	DCSM_Z1OTP_BASE	0x0007_8000	YES	-	-	-	-
DcsmZ2OtpRegs	DCSM_Z2_OTP	DCSM_Z2OTP_BASE	0x0007_8200	YES	-	-	-	-

6.9.2 CM DCSM Base Address Table (CM)

Table 6-5. CM DCSM Base Address Table (CM)

DriverLib Name	Base Address	μDMA Access	Ethernet DMA Access
DCSM_Z1_BASE	0x4008_5000	-	-
DCSM_Z2_BASE	0x4008_5100	-	-
DCSMCOMMON_BASE	0x4008_5180	-	-

6.9.3 DCSM_Z1_REGS Registers

Table 6-6 lists the memory-mapped registers for the DCSM_Z1_REGS registers. All register offset addresses not listed in Table 6-6 should be considered as reserved locations and the register contents should not be modified.

Table 6-6. DCSM_Z1_REGS Registers

Offset (x8)	Offset (x16)	Acronym	Register Name	Write Protection	Section
0h	0h	Z1_LINKPOINTER	Zone 1 Link Pointer		Go

9-8	GRAB_SECT4	R	0h	Value in this field gets loaded from Z2_GRABSECT3[9:8] when a read is issued to address location of Z2_GRABSECT3 in OTP. 00 : Invalid. CPU2 Flash Sector 4 is inaccessible. 01 : Request to allocate CPU2 Flash Sector 4 to Zone2. 10 : No request for CPU2 Flash Sector 4 11 : No request for CPU2 Flash Sector 4 when this zone is UNLOCKED. Else CPU2 Flash Sector 4 is inaccessible if this zone is LOCKED. Reset type: SYSRSn
7-6	GRAB_SECT3	R	0h	Value in this field gets loaded from Z2_GRABSECT3[7:6] when a read is issued to address location of Z2_GRABSECT3 in OTP. 00 : Invalid. CPU2 Flash Sector 3 is inaccessible. 01 : Request to allocate CPU2 Flash Sector 3 to Zone2. 10 : No request for CPU2 Flash Sector 3 11 : No request for CPU2 Flash Sector 3 when this zone is UNLOCKED. Else CPU2 Flash Sector 3 is inaccessible if this zone is LOCKED. Reset type: SYSRSn
5-4	GRAB_SECT2	R	0h	Value in this field gets loaded from Z2_GRABSECT3[5:4] when a read is issued to address location of Z2_GRABSECT3 in OTP. 00 : Invalid. CPU2 Flash Sector 2 is inaccessible. 01 : Request to allocate CPU2 Flash Sector 2 to Zone2. 10 : No request for CPU2 Flash Sector 2 11 : No request for CPU2 Flash Sector 2 when this zone is UNLOCKED. Else CPU2 Flash Sector 2 is inaccessible if this zone is LOCKED. Reset type: SYSRSn
3-2	GRAB_SECT1	R	0h	Value in this field gets loaded from Z2_GRABSECT3[3:2] when a read is issued to address location of Z2_GRABSECT3 in OTP. 00 : Invalid. CPU2 Flash Sector 1 is inaccessible. 01 : Request to allocate CPU2 Flash Sector 1 to Zone2. 10 : No request for CPU2 Flash Sector 1 11 : No request for CPU2 Flash Sector 1 when this zone is UNLOCKED. Else CPU2 Flash Sector 1 is inaccessible if this zone is LOCKED. Reset type: SYSRSn
1-0	GRAB_SECT0	R	0h	Value in this field gets loaded from Z2_GRABSECT3[1:0] when a read is issued to address location of Z2_GRABSECT3 in OTP. 00 : Invalid. CPU2 Flash Sector 0 is inaccessible. 01 : Request to allocate CPU2 Flash Sector 0 to Zone2. 10 : No request for CPU2 Flash Sector 0 11 : No request for CPU2 Flash Sector 0 when this zone is UNLOCKED. Else CPU2 Flash Sector 0 is inaccessible if this zone is LOCKED. Reset type: SYSRSn

3	EXEONLY_RAM3	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[3] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS3 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS3 RAM (only if it's allocated to Zone2) Reset type: SYSRSn
2	EXEONLY_RAM2	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[2] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS2 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS2 RAM (only if it's allocated to Zone2) Reset type: SYSRSn

Table 6-60. Z2_EXEONLYRAM1R Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	EXEONLY_RAM1	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[1] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS1 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS1 RAM (only if it's allocated to Zone2) Reset type: SYSRSn
0	EXEONLY_RAM0	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[0] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS0 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS0 RAM (only if it's allocated to Zone2) Reset type: SYSRSn

6.9.5 DCSM_COMMON_REGS Registers

Table 6-61 lists the memory-mapped registers for the DCSM_COMMON_REGS registers. All register offset addresses not listed in Table 6-61 should be considered as reserved locations and the register contents should not be modified.

Table 6-61. DCSM_COMMON_REGS Registers

Offset (x8)	Offset (x16)	Acronym	Register Name	Write Protection	Section
0h	0h	FLSEM	Flash Wrapper Semaphore Register	EALLOW	Go
10h	8h	SECTSTAT1	Flash Sectors Status Register 1		Go
14h	Ah	SECTSTAT2	Flash Sectors Status Register 2		Go
18h	Ch	SECTSTAT3	Flash Sectors Status Register 3		Go
20h	10h	RAMSTAT1	RAM Status Register 1		Go
24h	12h	RAMSTAT2	RAM Status Register 2		Go
28h	14h	RAMSTAT3	RAM Status Register 3		Go
30h	18h	SECERRSTAT	Security Error Status Register		Go
34h	1Ah	SECERRCLR	Security Error Clear Register		Go
38h	1Ch	SECERRFRC	Security Error Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 6-62 shows the codes that are used for access types in this section.

Table 6-62. DCSM_COMMON_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.9.5.1 FLSEM Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 00000000h]

FLSEM is shown in [Figure 6-56](#) and described in [Table 6-63](#).

Return to the [Summary Table](#).

Chapter 7

Background CRC-32 (BGCRC)

The Background CRC (BGCRC) module that helps to identify memory faults and corruption, is discussed in this chapter.

7.1 Introduction.....	936
7.2 Functional Description.....	938
7.3 Application of the BGCRC.....	940
7.4 Software.....	945
7.5 BGCRC Registers.....	946

7.1 Introduction

The Background CRC (BGCRC) module computes a CRC-32 on a configurable block of memory. It accomplishes this by fetching the specified block of memory during idle cycles (when the CPU, CLA, or DMA is not accessing the memory block). The calculated CRC-32 value is compared against a golden CRC-32 value to indicate a pass or fail. In essence, the BGCRC helps identify memory faults and corruption. There are two BGCRC modules (CPU_CRC and CLA_CRC) per CPU subsystem. The two BGCRC modules differ only in the memories they test.

7.1.1 BGCRC Related Collateral

Getting Started Materials

- [CRC Engines in C2000 Devices Application Report](#)

7.1.2 Features

The BGCRC module has the following features:

- One cycle CRC-32 computation on 32 bits of data
- No CPU bandwidth impact for zero wait state memory
- Minimal CPU bandwidth impact for non-zero wait state memory
- Dual operation modes (CRC-32 mode and scrub mode)
- Watchdog timer to time CRC-32 completion
- Ability to pause and resume CRC-32 computation

7.1.3 Block Diagram

Figure 7-1 shows the BGCRC block diagram.

Figure 7-1. BGCRC Block Diagram

7.1.4 Memory Wait States and Memory Map

Figure 7-2 shows the memory map of the BGCRC module. M0, M1, D[x]RAM, MSGRAM, LS[x]RAM, and GS[x]RAM are all zero wait-state memories. BGCRC accesses these memories with minimal impact on normal program operation. For instance, if a BGCRC access is being made to a zero wait-state memory in the current cycle, the earliest the operating program can make access to the same memory location is in the next cycle. Similarly for the non-zero wait state memories SECROM, DATAROM and BOOTROM, the worst case delay for functional access after a BGCRC access is the wait-state amount.

Figure 7-2. BGCRC Memory Map

7.2 Functional Description

The CRC-32 calculation of the BGCRC module can be kicked off by configuring the register BGCRC_EN.START to 1010. Once started, the module performs the background memory checks without CPU or CLA intervention. However, on completion of the CRC-32 calculation or in the event of a failure, the CPU or CLA is notified through an interrupt and task, respectively.

As highlighted in the overview, there are two BGCRC modules per CPU subsystem. CPU_CRC that is configurable by the CPU can only generate an interrupt. CLA_CRC however, can be configured by both the CPU and CLA and can generate an interrupt to the CPU or task for the CLA.

7.2.1 Data Read Unit

Once the CRC-32 calculation is started, the BGCRC module continuously reads data from memory as a background process. These reads happen during the idle times (when the CPU, CLA or DMA is not accessing the memory block) and so does not impact functional access. The data read unit only reads data if there is no pending functional access. The data read unit begins operation by reading a block of data BGCRC_CTRL2.BLOCK_SIZE from address BGCRC_START_ADDR. Note that BGCRC_START_ADDR must be 0x80 word aligned. For a non-0x80 word aligned BGCRC_START_ADDR, the LSB bits are zeroed out to get a 0x80 word aligned BGCRC_START_ADDR. For instance, if the programmed BGCRC_START_ADDR = 0x1AF3, the internal 0x80 word aligned start address is 0x1A80.

When the data read unit reads a block of data, ECC and parity are checked. Any ECC or parity errors that occur during the read is indicated by setting the respective NMI and generating an interrupt if configured as so. The BGCRC module, however, does not write back the corrected memory contents on the occurrence of a correctable ECC error. Writing back the corrected values is handled by software.

7.2.2 CRC-32 Compute Unit

After the data read unit reads a block of data, the data read unit feeds this data to the CRC-32 compute unit. This unit computes the CRC-32 using the standard polynomial $0x04C11DB7$ ($x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$). The CRC-32 unit retrieves 32-bit of data at a time from the block of data to compute the polynomial. This computation takes 1 cycle. For instance, the CRC-32 calculation for 1KB block of data is 256 cycles, 1 cycle for each of the 256 32-bit chunks. The initial value for the CRC-32 computation can be configured using BGCRC_SEED.

After the CRC-32 calculation is complete for a data block, the final result is loaded into BGCRC_RESULT. Note that BGCRC_RESULT only contains the final calculation for the whole data block; intermediate 32-bit calculations do not update BGCRC_RESULT. The value in BGCRC_RESULT is compared against the value in BGCRC_GOLDEN by hardware and the NMI/Interrupt flags are set accordingly by the CRC notification unit.

Once CRC-32 calculation is commenced, the calculation can be halted by setting BGCRC_CTRL2.TEST_HALT to 1010. Clearing this bit resumes CRC-32 calculation from the halt point.

7.2.3 CRC Notification Unit

After the CRC-32 compute unit completes the CRC-32 calculation for a block of data or fails to complete the calculation within BGCRC_WD_MIN and BGCRC_WD_MAX, if configured, the CRC-32 compute unit sends out a NMI/Interrupt on the occurrence of a pass or fail. In addition, during a data read by the data read unit, if an ECC or parity error occurs, the CRC notification unit can send out a NMI/Interrupt. In the case of an ECC or parity error, the BGCRC stops operation and BGCRC_CURR_ADDR contains the memory address that caused the ECC or parity error. The contents of BGCRC_CURR_ADDR in addition to the NMI/Interrupt flags can be used to debug a BGCRC failure.

7.2.3.1 CPU Interrupt, CLA Task and NMI

The BGCRC module has configurable interrupt and NMI lines. NMIs are enabled by default but can be disabled by writing 0xA to BGCRC_CTRL1.NMIDIS register. Conversely, all interrupts are disabled by default but can be enabled by writing 0x7E to BGCRC_INTEN register. When an error occurs in the BGCRC, the BGCRC can be configured to generate an NMI or interrupt. Since NMIs are enabled by default, all BGCRC errors cause an NMI. Figure 7-3 and Figure 7-4 show the NMI and Interrupt lines, respectively.

Figure 7-3. BGCRC NMI

Figure 7-4. BGCRC Interrupt

7.2.4 Operating Modes

BGCRC module supports two modes of operation: CRC mode and scrub mode. The mode of operation can be configured by clearing or setting the register BGCRC_CTRL2.SCRUB_MODE.

7.2.4.1 CRC Mode

In CRC mode, the BGCRC module operates as explained in [Section 7.2.2](#). CRC-32 calculation is performed on a block of data and the result compared against a golden value. ECC and parity errors are checked in this mode. Result mismatch, ECC or parity error can trigger an NMI/Interrupt.

7.2.4.2 Scrub Mode

In scrub mode, the CRC-32 result is not compared against the golden value and BGCRC_RESULT register is not updated. ECC and parity errors are also checked in this mode. However unlike CRC mode, NMI/Interrupt are only from ECC or parity error. In scrub mode, Parity and ECC bits of the memory block need to be initialized by the CPU and/or CLA.

7.2.5 BGCRC Watchdog

The BGCRC module has an embedded windowed watchdog that is used as a diagnostic to check memory test completion within the expected time window. This can protect against hardware defects that can cause the memory check not to complete in the allotted time, which cannot be caught by the system watchdog as the error can be due to the CLA or DMA having continuous access. Windowing also helps detect additional failure modes in the watchdog operation, for example, stuck watchdog.

The BGCRC watchdog is enabled by default and starts when the BGCRC module begins reading from memory. The watchdog can be disabled using the register BGCRC_WD_CFG.WDDIS. The BGCRC watchdog counter is a 32-bit counter with the value reflected in BGCRC_WD_CNT register. The lower and upper window settings are configured using BGCRC_WD_MIN and BGCRC_WD_MAX, respectively. BGCRC_WD_MIN and BGCRC_WD_MAX need to be configured before the test is started and must not be changed while the BGCRC is operating. If configured, an NMI or interrupt is triggered if the memory test fails to complete within the configured time window. The counter stops on completion of the CRC-32 check done, CRC-32 check failure and ECC/Parity errors. The counter is reset when the next memory check begins.

The BGCRC watchdog can be halted by configuring the BGCRC_WD_CFG.WDDIS register. After the watchdog resumes from being halted, the counter starts counting from the previous count unless a new memory check operation is initiated. The counter is not halted when CRC-32 computation halts but by default halts during a debug halt. The behavior of the watchdog during emulation can be changed by configuring the appropriate BGCRC registers. In addition, due to the changing nature of memory contents during emulation, it is not recommended to run BGCRC during emulation. CRC-32 computation continues during a watchdog failure and software needs to address this condition.

7.2.6 Hardware and Software Faults Protection

The configuration registers are protected using a lock and commit configuration. Each of the configuration registers can be individually locked and committed. The register once locked, can no longer be updated until the lock is removed. However if the register lock is committed, no further writes is permitted until the device is reset. It is recommended to lock the registers after configuration to protect against corruption due to software faults. In addition, registers critical to the module functionality and fault detection are implemented using multi-bit fields to protect against hardware faults.

7.3 Application of the BGCRC

This section contains use case scenarios of how the BGCRC module can be configured to test a block of memory. However, the use case scenarios presented are for reference only and do not cover all the possible application scenarios. These use case scenarios can be used as a starting point to configure the BGCRC module for specific applications.

7.3.1 Software Configuration

The configuration registers for the BGCRC can be split into three groups (see [Table 7-1](#)):

- **CFG1:** Registers that determine the operating mode and configured at the beginning.
- **CFG2:** Registers that need to be updated during kickoff of a new test.
- **CFG3:** Registers used for test and error management.

CFG1 registers are expected to be locked and committed after initial configuration. It is recommended to lock the CFG2 and CFG3 registers after configuration. [Figure 7-5](#) shows the BGCRC execution sequence.

Table 7-1. BGCRC Register Groups

CFG1 - One Time Configuration Registers	CFG2 - Periodic Configuration Registers	CFG3 - Registers Used for Test and Error Management
BGCRC_CTRL1	BGCRC_EN	BGCRC_NMICLR
BGCRC_WD_CFG	BGCRC_CTRL2	BGCRC_INTCLR
BGCRC_INTEN	BGCRC_START_ADDR	BGCRC_NMIFRC
BGCRC_SEED	BGCRC_GOLDEN	BGCRC_INTFRC
	BGCRC_WD_MIN	
	BGCRC_WD_MAX	

Figure 7-5. BGCRC Execution Sequence Flow

7.3.2 Decision on Error Response Severity

The error sources for BGCRC are:

- Test completion before BGCRC_WD_MIN.
- Test completed after BGCRC_WD_MAX.
- Mismatch between the calculated CRC and golden CRC.
- Uncorrectable error during data read (single bit error for parity memory or double bit error for ECC memory).
- Correctable error during memory read (single bit error for ECC memory).

Error severity can be chosen as either NMI or interrupt. By default, error severity is set to NMI. It is not possible to configure error response for each individual error source. The response can be chosen as either interrupt or NMI for all error sources. When error severity is chosen as NMI, ERROR_STS pin is asserted during an error. CPU and CLA must be assigned the same error severity.

7.3.3 Decision of Controller for CLA_CRC

CPU_CRC can only be kicked off by the CPU. However, CLA_CRC can be kicked off by the CPU or CLA. If BGCRC error severity is chosen as NMI, it is possible to handle the background test using the CLA and error response with the CPU. Once the controller for BGCRC is chosen, it is possible to prevent accesses from other controllers by using the system-level access protection configuration.

7.3.4 Execution of Time Critical Code from Wait-Styled Memories

BGCRC access to functionally wait-styled memories is also wait-styled by the same number. Since it is impossible to predict the next functional access, any ongoing BGCRC access has to complete before functional access is granted. To mitigate delay in functional access, the BGCRC can be halted when time-critical code that accesses the wait-styled memories is in progress. When BGCRC execution is halted, the BGCRC watchdog is not halted. This is consistent with the safety requirement to complete the background test in a predictable window irrespective of the user code. In such scenarios, it is recommended to adjust the upper BGCRC watchdog window limit to account for the halt duration during functional access. However, if required, the BGCRC watchdog can be disabled.

7.3.5 BGCRC Execution

Two notes about BGCRC execution are:

- BGCRC task can run as a background task once kicked off.
- BGCRC task does not impact functional execution for zero-wait styled memories. For memories with higher wait-states, the BGCRC engine can be halted to make functional execution predictable.

[Figure 7-6](#) shows a few examples of BGCRC execution sequences.

CPU_CRC executed in parallel with functional execution. CRC-32 check can be stalled during time critical ISRs if ISRs require access to non-zero wait-stated memories.

CLA_CRC executed in parallel with other CLA tasks. This can cause delay in functional execution.

Functional tasks prioritized over CLA_CRC tasks. CLA_CRC will be stalled by functional tasks to avoid delays in functional execution.

Figure 7-6. BGCRC Execution Sequence Example

7.3.6 Debug/Error Response for BGCRC Errors

The BGCRC error severity can be decoded by reading the BGCRC_INTFLG or BGCRC_NMIFLG. The errors can be:

- **WD_OVERFLOW/WD_UNDERFLOW:** The test did not complete in the programmed window. System timing needs to be checked to understand reason for non-completion of the test. BGCRC_CURR_ADDR and BGCRC_WD_CNT indicate how far the test progressed.
- **UNCORRECTABLE_ERR:** BGCRC_CURR_ADDR contains the address of the memory location causing the error. This error is due to single bit failure for Parity SRAM or double bit failure for ECC SRAM. The memory location can be reloaded (if possible, for cases where code is copied from Flash) to see if the problem resolves. If the problem persists, the problem can be a permanent defect.
- **CORRECTABLE_ERR:** This error is due to single bit failure for ECC SRAM. If the problem location is accessed again (execution from the location for execute only memory or reading the location in other cases), the expectation is that the single bit error is corrected. If the single bit error is not corrected, this can be an indication of a permanent defect.
- **CRC_FAIL:** This indicates a failure in the computation of the CRC-32 value. This error does not occur in scrub mode. For SRAMs with protection, in the absence of code bugs, this error is less likely since the error is most often manifest as a correctable/uncorrectable error. Code bugs can cause failure if the code inadvertently writes to a wrong address thus causing a CRC-32 error.

7.3.7 BGCRC Golden CRC-32 Value Computation

The C28x is a little-endian, 16-bit word addressable CPU. Therefore, the 32-bit value of 0x12345678 stored at address 0x100 is stored in the C28x memory as shown in [Table 7-2](#).

Table 7-2. Data Address Location Example 1

Address	0x100	0x101
Data	0x5678	0x1234

The BGCRC order of byte calculations of the above example is 0x78, 0x56, 0x34, 0x12 and yields 0x6A330D2D. The 32-bit polynomial 0x04C11DB7 is used with an initialization vector of 0x00000000. The following code snippet shows the effective bit processing. Processing for all 32-bits within a word occurs in a single cycle within the BGCRC hardware.

```
seed = 0x0UL; //Initialize with Seed
poly = 0x04C11DB7UL; //32-Bit Polynomial
crc32 = seed;

for(i=0; i<dataSize; i++)
{
    byteSwappedData = ((data[i] & 0x000000FF) << 24) |
                      = ((data[i] & 0x0000FF00) << 8) |
                      = ((data[i] & 0x00FF0000) >> 8) |
                      = ((data[i] & 0xFF000000) >> 24);

    crc32 = byteSwappedData^crc32;
    for(j=0; j<32; j++)
    {
        if(crc32 & 0x80000000) crc32 = (crc32 << 1)^poly;
        else crc32 = crc32 << 1;

        crc32 = crc32 & 0xFFFFFFFF;
    }
}
```

A second example ([Table 7-3](#)) with two 32-bit words, 0x12345678 and 0x9ABCDEF0 at address 0x100 and 0x102 successively, calculates the bytes in the order 0x78, 0x56, 0x34, 0x12, 0xDE, 0xBC, and 0x9A and yield 0x7E0B4164.

Table 7-3. Data Address Location Example 2

Address	0x100	0x101	0x102	0x103
Data	0x5678	0x1234	0xDEF0	0x9ABC

All data input to the BGCRC must align to a 32-bit boundary, both in the starting address and the size. It is possible to include 16-bit data within the span of data; however, when the data is read by the BGCRC, it always assume 32-bits and conform to the above calculation order. For example, if two 16-bit words (0xA0B1 and 0xC2D3) were placed in between the previous two 32-bit words ([Table 7-4](#)), the calculations are performed in byte order 0x78, 0x56, 0x34, 0x12, 0xB1, 0xA0, 0xD3, 0xC2, 0xF0, 0xDE, 0xBC, and 0x9A and yield 0x2AEFD987.

Table 7-4. Data Address Location Example 3

Address	0x100	0x101	0x102	0x103	0x104	0x105
Data	0x5678	0x1234	0xA0B1	0xC2D3	0xDEF0	0x9ABC

7.4 Software

7.4.1 BGCR Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/bgcr

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

7.4.1.1 BGCR CPU Interrupt Example

FILE: bgcr_ex1_cpuinterrupt.c

This example demonstrates how to configure and trigger BGCR from the CPU. BGCR module is configured for 1 KB of GS0 RAM which is programmed with a known data. The pre-computed CRC value is used as the golden CRC value. Interrupt is generated once the computation is done and checks if no error flags are raised. Calculation uses the 32-bit polynomial 0x04C11DB7 and seed value 0x00000000.

External Connections

- None.

Watch Variables

- pass - This should be 1.
- runStatus - BGCR running status. This will be BGCR_ACTIVE if the module is running, BGCR_IDLE if the module is idle

7.4.1.2 BGCR Example with Watchdog and Lock

FILE: bgcr_ex2_cpdbgcr_basic.c

This example demonstrates how to configure and trigger BGCR from the CPU. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 1kB of GS0 RAM which is programmed with random data. The golden CRC value for comparison is computed using software method. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

External Connections

- None.

Watch Variables

- pass
- bgcrDone

7.4.1.3 CLA-BGCR Example in CRC mode

FILE: bgcr_ex3_clabgcr_crcmode.c

This example demonstrates how to configure and trigger CLABGCR from the CPU. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 1kB of CLA ROM memory. The golden CRC value for comparison is computed using software method. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

External Connections

- None.

Watch Variables

- pass
- bgcrcDone

7.4.1.4 CLA-BGCR Example in Scrub Mode

FILE: bgcrc_ex4_clabgcrc_scrubmode.c

This example demonstrates how to configure and trigger CLA-BGCR in Scrub mode. In Scrub mode, CRC of data is not compared with the golden CRC. Error check is done using the ECC/Parity logic. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 256 bytes of CLA ROM memory. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

External Connections

- None.

Watch Variables

- pass
- bgcrcDone

7.5 BGCR Registers

This section describes the Background CRC registers.

7.5.1 BGCR Base Address Table (C28)

Table 7-5. BGCR Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
BgcrcCla1Regs	BGCRC_REGS	BGCRC_CLA1_BASE	0x0000_6380	YES	YES	-	YES	YES
BgcrcCpuRegs	BGCRC_REGS	BGCRC_CPU_BASE	0x0000_6340	YES	YES	-	-	YES

7.5.2 BGCRC_REGS Registers

Table 7-6 lists the memory-mapped registers for the BGCRC_REGS registers. All register offset addresses not listed in Table 7-6 should be considered as reserved locations and the register contents should not be modified.

Table 7-6. BGCRC_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	BGCRC_EN	BGCRC Enable	EALLOW	Go
2h	BGCRC_CTRL1	BGCRC Control register 1	EALLOW	Go
4h	BGCRC_CTRL2	BGCRC Control register 2	EALLOW	Go
6h	BGCRC_START_ADDR	Start address for the BGCRC check	EALLOW	Go
8h	BGCRC_SEED	Seed for CRC calculation	EALLOW	Go
Eh	BGCRC_GOLDEN	Golden CRC to be compared against	EALLOW	Go
10h	BGCRC_RESULT	CRC calculated		Go
12h	BGCRC_CURR_ADDR	Current address register		Go
1Ch	BGCRC_WD_CFG	BGCRC windowed watchdog configuration	EALLOW	Go
1Eh	BGCRC_WD_MIN	BGCRC windowed watchdog min value	EALLOW	Go
20h	BGCRC_WD_MAX	BGCRC windowed watchdog max value	EALLOW	Go
22h	BGCRC_WD_CNT	BGCRC windowed watchdog count		Go
2Ah	BGCRC_NMIFLG	BGCRC NMI flag register		Go
2Ch	BGCRC_NMICLR	BGCRC NMI flag clear register	EALLOW	Go
2Eh	BGCRC_NMIFRC	BGCRC NMI flag force register	EALLOW	Go
34h	BGCRC_INTEN	Interrupt enable	EALLOW	Go
36h	BGCRC_INTFLG	Interrupt flag		Go
38h	BGCRC_INTCLR	Interrupt flag clear	EALLOW	Go
3Ah	BGCRC_INTFRC	Interrupt flag force	EALLOW	Go
3Ch	BGCRC_LOCK	BGCRC register map lock configuration	EALLOW	Go
3Eh	BGCRC_COMMIT	BGCRC register map commit configuration	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 7-7 shows the codes that are used for access types in this section.

Table 7-7. BGCRC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WSonce	WSonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

7.5.2.1 BGCRC_EN Register (Offset = 0h) [Reset = 00000000h]

BGCRC_EN is shown in [Figure 7-7](#) and described in [Table 7-8](#).

Return to the [Summary Table](#).

The Control Law Accelerator (CLA) Type-2 is an independent, fully-programmable, 32-bit floating-point math processor that brings concurrent control-loop execution to the C28x family. The low interrupt latency of the CLA allows the CLA to read ADC samples "just-in-time." This significantly reduces the ADC sample to output delay to enable faster system response and higher MHz control loops. By using the CLA to service time-critical control loops, the main CPU is free to perform other system tasks such as communications and diagnostics. This chapter provides an overview of the architectural structure and components of the control law accelerator.

8.1 Introduction

The Control Law Accelerator extends the capabilities of the C28x CPU by adding parallel processing. Time-critical control loops serviced by the CLA can achieve low ADC sample to output delay. Thus, the CLA enables faster system response and higher frequency control loops. Utilizing the CLA for time-critical tasks frees up the main CPU to perform other system and communication functions concurrently.

8.1.1 Features

The following is a list of major features of the CLA:

- C compilers are available for CLA software development.
- Clocked at the same rate as the main CPU (SYSCLKOUT).
- An independent architecture allowing CLA algorithm execution independent of the main C28x CPU.
 - Complete bus architecture:
 - Program Address Bus (PAB) and Program Data Bus (PDB)
 - Data Read Address Bus (DRAB), Data Read Data Bus (DRDB), Data Write Address Bus (DWAB), and Data Write Data Bus (DWDB)
 - Independent eight stage pipeline.
 - 16-bit program counter (MPC)
 - Four 32-bit result registers (MR0-MR3)
 - Two 16-bit auxiliary registers (MAR0, MAR1)
 - Status register (MSTF)
- Instruction set includes:
 - IEEE single-precision (32-bit) floating-point math operations
 - Floating-point math with parallel load or store
 - Floating-point multiply with parallel add or subtract
 - 1/X and 1/sqrt(X) estimations
 - Data type conversions.
 - Conditional branch and call
 - Data load/store operations
- The CLA program code can consist of up to eight tasks or interrupt service routines, or seven tasks and a main background task.
 - The start address of each task is specified by the MVECT registers.
 - No limit on task size as long as the tasks fit within the configurable CLA program memory space.
 - One task is serviced at a time until completion. There is no nesting of tasks.
 - Upon task completion a task-specific interrupt is flagged within the PIE.
 - When a task finishes the next highest-priority pending task is automatically started.
 - The Type-2 CLA can have a main task that runs continuously in the background, while other high priority events trigger a foreground task.
- Task trigger mechanisms:
 - C28x CPU using the IACK instruction
 - Task1 to Task8: up to 256 possible trigger sources from peripherals connected to the shared bus on which the CLA assumes secondary ownership.
 - Task8 can be set to be the background task, while Tasks 1 through 7 take peripheral triggers.
- Memory and Shared Peripherals:
 - Two dedicated message RAMs for communication between the CLA and the main CPU.
 - Two dedicated message RAMs for communication between the CLA and the DMA.
 - The C28x CPU can map CLA program and data memory to the main CPU space or CLA space.

8.1.3 Block Diagram

Figure 8-1 is a block diagram of the CLA.

Figure 8-1. CLA Block Diagram

8.2 CLA Interface

This section describes how the C28x main CPU can interface to the CLA and conversely.

8.2.1 CLA Memory

The CLA can access three types of memory: program, data and message RAMs. The behavior and arbitration for each type of memory is described in this chapter. The CLA RAMs are protected by the DCSM module. Refer to the *Dual Code Security Module (DCSM)* section of the *System Control and Interrupts* chapter for more details on the security scheme.

- **CLA Program Memory**

The CLA program can be loaded with any of the local shared memories (LSxRAM). At reset, all memory blocks are mapped to the CPU. While mapped to the CPU space, the CPU can copy the CLA program code into the memory. During debug, the memory can also be loaded directly by the Code Composer Studio™ IDE.

Once the memory is initialized with CLA code, the CPU maps the memory to the CLA program space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
2. Specifying the memory block as a code block for the CLA by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit.

When a memory block is configured as CLA program memory, debug accesses are allowed only on cycles where the CLA is not fetching a new instruction. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

All CLA program fetches are performed as 32-bit read operations and all opcodes must be aligned to an even address. Since all CLA opcodes are 32-bits, this alignment occurs naturally.

- **CLA Data Memory**

Any of the device's LSxRAMs can serve as data memory blocks to the CLA. At reset, all blocks are mapped to the CPU memory space, whereby the CPU can initialize the memory with data tables, coefficients, and so on, for the CLA to use.

Once the memory is initialized with CLA data, the CPU maps the memory to the CLA data space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
2. Specifying the memory block as a data block for the CLA by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. The value of this bit at reset is 0.

When a memory block is configured as CLA data memory, CLA read and write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROT registers. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

- **CLA Shared Message RAMs**

There are two memory blocks for data sharing and communication between the CLA and the CPU. The message RAMs are always mapped to both CPU and CLA memory spaces, and only data access is allowed; no program fetches can be performed.

- **CLA to CPU Message RAM:** The CLA can use this block to pass data to the CPU. This block is both readable and writable by the CLA. This block is also readable by the CPU but writes by the CPU are ignored.
- **CPU to CLA Message RAM:** The CPU can use this block to pass data and messages to the CLA. This message RAM is both readable and writable by the CPU. The CLA can perform reads but writes by the CLA are ignored.

8.2.2 CLA Memory Bus

The CLA has dedicated bus architecture similar to that of the C28x CPU where there are separate program read, data read, and data write buses. Thus, there can be simultaneous instruction fetch, data read, and data write in a single cycle. Like the C28x CPU, the CLA expects memory logic to align any 32-bit read or write to an even address. If the address-generation logic generates an odd address, the CLA can begin reading or writing at the previous even address. This alignment does not affect the address values generated by the address-generation logic.

- **CLA Program Bus**

The CLA program bus has an access range of 32K 32-bit instructions. Since all CLA instructions are 32 bits, this bus always fetches 32 bits at a time and the opcodes must be even-word aligned. The amount of program space available for the CLA is limited to the number of available LSxRAM blocks. This number is device-dependent and can be described in the data sheet.

- **CLA Data Read Bus**

The CLA data read bus has a 64K x 16 address range. The bus can perform 16 or 32-bit reads and can automatically stall if there are memory access conflicts. The data read bus has access to both the message RAMs, CLA data memory, and the shared peripherals.

- **CLA Data Write Bus**

The CLA data write bus has a 64K x 16 address range. This bus can perform 16 or 32-bit writes. The bus can automatically stall if there are memory access conflicts. The data write bus has access to the CLA to CPU message RAM, CLA data memory, and the shared peripherals.

8.2.3 Shared Peripherals and EALLOW Protection

For a given CPU subsystem, the CPU, CLA, and DMA can share access to some peripherals. There is a 3-way arbitration among the different master's that is described in [Section 8.3](#). Each peripheral has an access control register with two bit fields, CPUAnAC, CLAnAC, and DMAAnAC (n being the instance) that determine what kind of access is given to that particular master.

Note

The CLA read access time to the bus is 2-wait states while write access is 0-wait.

Refer to the device data sheet for the list of peripherals connected to the bus.

Several peripheral control registers are protected from spurious 28x CPU writes by the EALLOW protection mechanism. These same registers are also protected from spurious CLA writes. The EALLOW bit in the CPU status register 1 (ST1) indicates the state of protection for the CPU. Likewise, the MEALLOW bit in the CLA status register (MSTF) indicates the state of write protection for the CLA. The MEALLOW CLA instruction enables write access by the CLA to EALLOW protected registers. Likewise, the MEDIS CLA instruction disables write access. This way the CLA can enable and disable write access independent of the CPU.

The ADC offers the option to generate an early interrupt pulse at the start of a sample conversion. If this option is used to start an ADC-triggered CLA task, use the intervening cycles until the completion of the conversion to perform preliminary calculations or loads and stores before finally reading the ADC value. The CLA pipeline activity for this scenario is shown in [Section 8.5](#).

8.2.4 CLA Tasks and Interrupt Vectors

The CLA program code is divided up into tasks or interrupt service routines. Tasks do not have a fixed starting location or length. The CLA program memory can be divided up as desired. The CLA uses the contents of the interrupt vectors (MVECT1 to MVECT8) to determine where a task begins; tasks are terminated by the MSTOP instruction.

The CLA supports eight tasks. Task 1 has the highest priority and task 8 has the lowest priority. The Type-2 CLA offers the option of setting the lowest priority task, for example, task 8, as a background task that, once triggered, runs continuously until the user either terminates the task or resets the CLA or the device. The remaining tasks, 1 through 7, maintain the priority levels and interrupt the background task when triggered.

The background task is enabled by setting the BGEN bit in the MCTLBGRND register; this causes the hardware to disable task 8 in the MIER register. The background task derives the interrupt vector from the MVECTBGRND register instead of MVECT8.

A task can be requested by a peripheral interrupt or by software:

- **Peripheral interrupt trigger**

Each task can be triggered by software-selectable interrupt sources. The trigger for each task is defined by writing an appropriate value to the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field. Each option specifies an interrupt source from a specific peripheral on the shared bus. The peripheral interrupt triggers are listed in [Table 8-1](#).

For example, task 1 (MVECT1) can be set to trigger on EPWMINT1 by writing 36 to DmaClaSrcSelRegs.CLA1TASKSRCSEL1.TASK1. To disable the triggering of a task by a peripheral, set the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field to 0. Note that a CLA task only triggers on a level transition (an edge) of the configured interrupt source.

- **Software Trigger**

CPU software can trigger tasks by writing to the MIFRC register or by the IACK instruction. Using the IACK instruction is more efficient because the instruction does not require the need to issue an EALLOW to set MIFR bits. Set the MCTL[IACKE] bit to enable the IACK feature. Each bit in the operand of the IACK instruction corresponds to a task. For example, IACK #0x0001 sets bit 0 in the MIFR register to start task 1. Likewise, IACK #0x0003 set bits 0 and 1 in the MIFR register to start task 1 and task 2.

- **Background Task**

The Type-2 CLA allows the use of Task 8 as a background task that runs continuously until Task 8 disables the task or resets the device (or the CLA using a soft reset). The background task vector is given by the MVECTBGRND register and the operation is controlled by the MCTLBGRND register; the task is enabled by setting the BGEN bit to 1. Then start the task through software by writing a 1 to the BGSTART bit (TRIGEN must be 0), or through a peripheral by setting the TRIGEN bit to 1 and then setting the trigger source in the bit-field, DmaClaSrcSelRegs.CLA1TASKSRCSEL2.bit.TASK8. By default, the background task is interruptible; the highest priority pending task is executed first. When a task completes and there are not any pending tasks, the execution returns to the background task. The CLA keeps track of the branching point by saving the return address to the MVECTBGRNDACTIVE register, and then popping this address to the MPC when execution returns. Choose to make sections of the background task uninterruptible by possibly doing this with the MSETC BGINTM assembly instruction.

Subsequently, enabling interrupts with the MCLRC BGINTM instruction.

The background interrupt mask bit, BGINTM, can be queried in the MSTSBGRND register. This register also provides the current status of the background task. If the task is currently executing, the RUN bit is set to 1, if another trigger for the background task is received while the task has already started, the overflow (BGOVF) bit is set.

The CLA has a fetch mechanism and can run and execute a task independently of the CPU. Only one task is serviced at a time; there is no nesting of tasks unless the background task is enabled, then one level of nesting is possible. The task currently running is indicated in the MIRUN register; if the background task is enabled and running, the task is reflected in the MSTSBGRND register (the RUN bit).

Interrupts that have been received but not yet serviced are indicated in the flag register (MIFR). If an interrupt request from a peripheral is received and that same task is already flagged, then the overflow flag bit is set. Overflow flags remain set until the flags are cleared by the CPU. If the CLA is idle (no task is currently running) or is executing the background task, then the highest priority interrupt request that is both flagged (MIFR) and enabled (MIER) starts.

The flow is as follows:

1. The associated RUN register bit is set (MIRUN) and the flag bit (MIFR) is cleared.
2. The CLA begins execution at the location indicated by the associated interrupt vector (MVECTx). MVECT contains the absolute 16-bit address of the task in the lower 64K memory space. If a task is interrupting the background task then the current program address is stored in the MVECTBGRNDACTIVE register before execution jumps to the task; this saved address is restored to the MPC when the task completes and execution returns to the background task.
3. The CLA executes instructions until the MSTOP instruction is found. This indicates the end of the task.
4. The MIRUN bit is cleared.
5. The task-specific interrupt to the PIE is issued. This informs the main CPU that the task has completed.
6. The CLA returns to idle (or to the background task, if enabled). Once a task completes the next highest-priority pending task is automatically serviced and this sequence repeats.

8.2.5 CLA Software Interrupt to CPU

The CLA can issue a software interrupt to the C28x CPU at any point in the code through the use of the CLA1SOFTINTEN and CLA1INTFRC registers. See [Section 8.8](#) for a description of these registers. If a software interrupt is selected for a CLA task, then an end-of-task interrupt is not issued to the C28x CPU when that task completes.

8.3 CLA, DMA, and CPU Arbitration

Typically, CLA activity is independent of the CPU activity. Under the circumstance where the CLA, DMA, or CPU attempt to concurrently access memory or a peripheral register within the same interface, an arbitration procedure occurs. This section describes this arbitration.

The arbitration follows a fixed arbitration scheme with highest priority first:

1. DMA WRITE
2. DMA READ
3. CLA WRITE
4. CLA READ
5. CPU WRITE
6. CPU READ

Refer to the Memory Controller Module section of the *System Control and Interrupts* chapter.

8.3.1 CLA Message RAM

Message RAMs consist of four blocks:

- CLA to CPU Message RAM
- CPU to CLA Message RAM
- DMA to CLA Message RAM
- CLA to DMA Message RAM

These blocks are useful for passing data between the CLA and CPU or CLA and DMA. No opcode fetches, from either the CLA or CPU, are allowed from the message RAMs. A write protection violation is not generated if the CLA attempts to write to the CPU to CLA or DMA to CLA message RAM, but the write is ignored. The arbitration scheme for the message RAMs are the same as those for the shared memories, described in the Memory Controller Module section of the *System Control and Interrupts* chapter.

The message RAMs have the following characteristics:

- CLA to CPU Message RAM:
The following accesses are allowed:
 - CPU reads
 - CLA data reads and writes
 - CPU debug reads and writes
The following accesses are ignored:
 - CPU writes
- CPU to CLA Message RAM:
The following accesses are allowed:
 - CPU reads and writes
 - CLA reads
 - CPU debug reads and writes
The following accesses are ignored:
 - CLA writes

8.3.2 Peripheral Registers (ePWM, HRPWM, Comparator)

Accesses to the registers follow these rules:

- If both the CPU and CLA request access at the same time, then the CLA has priority and the main CPU is stalled.
- If a CPU access is in-progress and another CPU access is pending, then the CLA has priority over the pending CPU access. In this case, the CLA access begins when the current CPU access completes.
- While a CPU access is in-progress, any incoming CLA access is stalled.
- While a CLA access is in-progress, any incoming CPU access is stalled.
- A CPU write operation has priority over a CPU read operation.
- A CLA write operation has priority over a CLA read operation.
- If the CPU is performing a read-modify-write operation and the CLA performs a write to the same location, the CLA write can be lost if the operation occurs in-between the CPU read and write. For this reason, do not mix CPU and CLA accesses to same location.

8.4 CLA Configuration and Debug

This section discusses the steps necessary to configure and debug the CLA.

8.4.1 Building a CLA Application

The control law accelerator can be programmed in either CLA assembly code, using the instructions described in [Section 8.7](#), or a reduced subset of the C language. CLA assembly code resides in the same project with C28x code. The only restriction is the CLA code must be in the assembly section. This can be easily done using the `.sect` assembly directive. This does not prevent CLA and C28x code from being linked into the same memory region in the linker command file.

System and CLA initialization are performed by the main CPU. This can typically be done in C or C++ but can also include C28x assembly code. The main CPU also copies the CLA code to the program memory and, if needed, initialize the CLA data RAMs. Once system initialization is complete and the application begins, the CLA services the interrupts using the CLA assembly code (or tasks). The main CPU can perform other tasks concurrently with CLA program execution.

The CLA Type 2 requires Codegen V16.9.1.LTS or later with the compiler switch: `--cla_support=cla2`.

8.4.2 Typical CLA Initialization Sequence

A typical CLA initialization sequence is performed by the main CPU as described in this section.

1. **Copy CLA code into the CLA program RAM:** The source for the CLA code can initially reside in the Flash or a data stream from a communications peripheral or anywhere the main CPU can access. The debugger can also be used to load code directly to the CLA program RAM during development.
2. **Initialize CLA data RAM, if necessary:** Populate the CLA data RAM with any required data coefficients or constants.
3. **Configure the CLA registers:** Configure the CLA registers, but keep interrupts disabled until later (leave MIER = 0):
 - **Enable the CLA peripheral clock using the assigned PCLKCRn register:** The peripheral clock control (PCLKCRn) registers are defined in the *System Control and Interrupts* chapter.
 - **Populate the CLA task interrupt vectors:**
 - MVECT1 to MVECT8
 Each vector needs to be initialized with the start address of the task to be executed when the CLA receives the associated interrupt. This address is the full 16-bit starting address of the task in the lower 64K section of memory.
 - MVECT1 to MVECT7, and MVECTBGRND
 When using the background task, the vector (MVECTBGRND) must be loaded with the start address of the task in lower 64K of memory. Note that Task 8 is ignored when the background task is enabled.
 - **Select the task interrupt sources:** For each task select the interrupt source in the CLA1TASKSRCSELx register. If a task is software triggered, select no interrupt. Since the background task takes the place of Task 8, the task uses the same peripheral trigger source as task 8.
 - **Enable IACK to start a task from software, if desired:** To enable the IACK instruction to start a task set the MCTL[IACKE] bit. Using the IACK instruction avoids having to set and clear the EALLOW bit. If the background task is enabled, the IACK bit for task 8 is ignored; the user must, instead, write to the BGSTART bit of the MCTLBGRND register to start the background task (TRIGEN can be 0 to avoid a peripheral trigger from causing an overflow, for example, MSTSBGRND.BGOVF is set to 1).
 - **Map CLA data RAM to CLA space, if necessary:** Map the data RAM to the CLA space by first, assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_Lx] bit, and then specifying the memory block as a CLA data block by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM_Lx] bit. When an LSx memory is configured as a CLA data memory, the CLA read/write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROTx registers.

- **Map CLA program RAM to CLA space:** Map the CLA program RAM to CLA space by first assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit, and then specifying the memory block as CLA code memory by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. When an LSx memory is configured as CLA program memory, only debug accesses are allowed on cycles in which the CLA is not fetching a new instruction.
- 4. **Initialize the PIE vector table and registers:** When a CLA task completes, the associated interrupt in the PIE is flagged. The CLA overflow and underflow flags also have associated interrupts within the PIE.
- 5. **Enable CLA tasks/interrupts:** Set appropriate bits in the interrupt enable register (MIER) to allow the CLA to service interrupts. Note that a CLA task only triggers on a level transition (a falling edge) of the configured interrupt source. If a peripheral is enabled and an interrupt fires before the CLA is configured, then the CLA does not recognize the interrupt edge and does not respond. To avoid this, configure the CLA before the peripherals or clear any pending peripheral interrupts before setting bits in the MIER register.
- 6. **Initialize other peripherals:** Initialize any peripherals (such as ePWM, ADC, and others) that generate interrupt triggers for enabled CLA tasks.

The CLA is now ready to service interrupts and the message RAMs can be used to pass data between the CPU and the CLA. Mapping of the CLA program and data RAMs typically occurs only during the initialization process. If the RAM mapping needs to be changed after initialization, the CLA interrupts must be disabled and all tasks must be completed (by checking the MIRUN register) prior to modifying the RAM ownership.

8.4.3 Debugging CLA Code

Debugging the CLA code is a simple process that occurs independently of the main CPU. The type 2 CLA adds a true software breakpoint feature.

8.4.3.1 Software Breakpoint Support (MDEBUGSTOP1)

The MDEBUGSTOP1 instruction is meant to be used as a software breakpoint; the instruction on which the execution must halt is replaced with this instruction.

The MDEBUGSTOP1 and MDEBUGSTOP instructions differ in how the CLA pipeline is treated. When halted, the MDEBUGSTOP1 instruction flushes all the instructions that have already been fetched; on a single-step or run-free command, the CLA refetches the same instruction that it replaced. [Table 8-2](#) illustrates the pipeline behavior.

Table 8-2. Pipeline Behavior of the MDEBUGSTOP1 Instruction

Cycles	F1	F2	D1	D2	R1	R2	E	W	Comments
1	i1								
2	i2	i1							
3	i3	i2	i1						
4	i4	i3	i2	i1					
5	MDEBUG STOP1	i4	i3	i2	i1				
6	i6	MDEBUG STOP1	i4	i3	i2	i1			
7	i7	i6	MDEBUG STOP1	i4	i3	i2	i1		
9	i8	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	i1	CLA halted
10	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	CLA step/run
11	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	CLA step/run
12	i7	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	CLA step/run
13	i8	i7	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	CLA step/run

A software breakpoint is placed at instruction i5. The instruction, i5, is then replaced with MDEBUGSTOP1. It takes 3 cycles for the MDEBUGSTOP1 to reach the D2 phase at which point the instructions i6, i7, and i8 that were previously fetched are now flushed from the pipeline. The instruction, i5, is then re-fetched and execution continues as before.

8.4.3.2 Legacy Breakpoint Support (MDEBUSTOP)

1. Insert a breakpoint in CLA code

Insert a CLA breakpoint (MDEBUSTOP instruction) into the code where the CLA is to halt, then rebuild and reload the code. Because the CLA does not flush the pipeline when in single-step, the MDEBUSTOP instruction must be inserted as part of the code. The debugger cannot insert the MDEBUSTOP instruction as needed.

If CLA breakpoints are not enabled, then the MDEBUSTOP instruction is ignored and is treated as a MNOP. The MDEBUSTOP instruction can be placed anywhere in the CLA code as long as the MDEBUSTOP instruction is not within three instructions of a MBCNDD, MCCNDD, or MRCNDD instruction. When programming in C, the user can use the `__mdebugstop()` intrinsic instead; the compiler makes sure that the placement of the MDEBUSTOP instruction in the generated assembly does not violate any of the pipeline restrictions.

2. Enable CLA breakpoints

Enable the CLA breakpoints in the debugger. In the Code Composer Studio™ IDE, this is done by connecting to the CLA core (or tap) from the debug perspective. Breakpoints are disabled when the core is disconnected.

3. Start the task

There are three ways to start the task:

- a. The peripheral can assert an interrupt,
- b. The main CPU can execute an IACK instruction, or
- c. The user can manually write to the MIFRC register in the debugger window

When the task starts, the CLA executes instructions until the MDEBUSTOP is in the D2 phase of the pipeline. At this point, the CLA halts and the pipeline is frozen. The MPC register reflects the address of the MDEBUSTOP instruction.

4. Single-step the CLA code

Once halted, the user can single-step the CLA code. The behavior of a CLA single-step is different than the main C28x. When issuing a CLA single-step, the pipeline is clocked only one cycle and then again frozen. On the C28x CPU, the pipeline is flushed for each single-step.

Run to the next MDEBUGSTOP or to the end of the task. If another task is pending, the task automatically starts when run to the end of the task.

Note

A CLA fetch has higher priority than CPU debug reads. For this reason, the CLA to permanently block CPU debug accesses if the CLA is executing in a loop is possible. This can occur when initially developing CLA code due to a bug that causes an infinite loop. To avoid locking up the main CPU, the program memory returns all 0x0000 for CPU debug reads when the CLA is running. When the CLA is halted or idle, then normal CPU debug read and write access to CLA program memory can be performed.

If the CLA gets caught in an infinite loop, use a soft or hard reset to exit the condition. A debugger reset also exits the condition.

There are special cases that can occur when single-stepping a task such that the program counter, MPC, reaches the MSTOP instruction at the end of the task.

- **MPC halts at or after the MSTOP with a task already pending**

If single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if continuing to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.

- **MPC halts at or after the MSTOP with no task pending**

In this case, if single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if continuing to single-step through the MSTOP instruction of "task A."

Depending on exactly when the new task comes in, to reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, start single-stepping "task B."

This case can be handled slightly differently if there is control over when "task B" comes in (for example, using the IACK instruction to start the task). In this case, the task is single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B," run free to force the CLA out of the debug state. Once this is done, force "task B" and continue debugging.

5. Disable CLA breakpoints, if desired

In the Code Composer Studio™ IDE, disable the CLA breakpoints by disconnecting the CLA core in the debug perspective. Make sure to first issue a run or reset; otherwise, the CLA is halted and no other tasks start.

8.4.4 CLA Illegal Opcode Behavior

If the CLA fetches an opcode that does not correspond to a legal instruction, the CLA behaves as follows:

- The CLA halts with the illegal opcode in the D2 phase of the pipeline as if a breakpoint. This occurs whether CLA breakpoints are enabled or not.
- The CLA issues the task-specific interrupt to the PIE.
- The MIRUN bit for the task remains set.

Further single-stepping is ignored once execution halts due to an illegal op-code. To exit this situation, issue either a soft or hard reset of the CLA as described in [Section 8.4.5](#).

8.4.5 Resetting the CLA

There are times when resetting the CLA is needed. For example, during code debug the CLA can enter an infinite loop due to a code bug. The CLA has two types of resets: hard and soft. Both of these resets can be performed by the debugger or by the main CPU.

- **Hard Reset** Writing a 1 to the MCTL[HARDRESET] bit performs a hard reset of the CLA. The behavior of a hard reset is the same as a system reset (using $\overline{\text{XRS}}$ or the debugger). In this case, all CLA configuration and execution registers can be set to the default state and CLA execution halts.
- **Soft Reset** Writing a 1 to the MCTL[SOFTRESET] bit performs a soft reset of the CLA. If a task is executing, the task halts and the associated MIRUN bit is cleared. All bits within the interrupt enable (MIER) register are also cleared, so that no new tasks start. In addition, the background task start bit (MCTLBGRN.BGSTART) and trigger enable bit (MCTLBGRND.TRIGEN) are reset. The MVECTBGRNACTIVE is set to the value of MVECTBGRND, and the status register (MSTSBGRND) is also reset.

8.5 Pipeline

This section describes the CLA pipeline stages and presents cases where pipeline alignment must be considered.

8.5.1 Pipeline Overview

The CLA pipeline is very similar to the C28x pipeline with eight stages:

1. **Fetch 1 (F1):** During the F1 stage the program read address is placed on the CLA program address bus.
2. **Fetch 2 (F2):** During the F2 stage the instruction is read using the CLA program data bus.
3. **Decode 1 (D1):** During D1 the instruction is decoded.
4. **Decode 2 (D2):** Generate the data read address. Changes to MAR0 and MAR1 due to post-increment using indirect addressing takes place in the D2 phase. Conditional branch decisions are also made at this stage based on the MSTF register flags.
5. **Read 1 (R1):** Place the data read address on the CLA data-read address bus. If a memory conflict exists, the R1 stage is stalled.
6. **Read 2 (R2):** Read the data value using the CLA data read data bus.
7. **Execute (EXE):** Execute the operation. Changes to MAR0 and MAR1 due to loading an immediate value or value from memory take place in this stage.
8. **Write (W):** Place the write address and write data on the CLA write data bus. If a memory conflict exists, the W stage is stalled.

8.5.2 CLA Pipeline Alignment

The majority of the CLA instructions do not require any special pipeline considerations. This section lists the few operations that do require special consideration.

- Write Followed by Read**

In both the C28x pipeline and the CLA pipeline, the read operation occurs before the write. This means that if a read operation immediately follows a write, then the read completes first as shown in [Table 8-3](#). In most cases this does not cause a problem since the contents of one memory location does not depend on the state of another. For accesses to peripherals where a write to one location can affect the value in another location, the code must wait for the write to complete before issuing the read as shown in [Table 8-4](#).

This behavior is different for the C28x CPU. For the C28x CPU, any write followed by read to the same location is protected by what is called write-followed-by-read protection. This protection automatically stalls the pipeline so that the write completes before the read. In addition, some peripheral frames are protected such that a C28x CPU write to one location within the frame always completes before a read to the frame. The CLA does not have this protection mechanism. Instead, the code must wait to perform the read.

Table 8-3. Write Followed by Read - Read Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2 MMOV16 MR2, @Reg2	I2	I1						
		I2	I1					
			I2	I1				
				I2	I1			
					I2	I1		
						I2	I1	
							I2	I1

Table 8-4. Write Followed by Read - Write Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2	I2	I1						
I3	I3	I2	I1					
I4	I4	I3	I2	I1				
I5 MMOV16 MR2, @Reg2	I5	I4	I3	I2	I1			
		I5	I4	I3	I2	I1		
			I5	I4	I3	I2	I1	
				I5	I4	I3	I2	I1
					I5	I4	I3	
						I5	I4	
							I5	

• Delayed Conditional instructions: MBCNDD, MCCNDD, and MRCNDD

Referring to [Example 8-1](#), the following applies to delayed conditional instructions:

- **I1:** I1 is the last instruction that can effect the CNDF flags for the branch, call, or return instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD, MCCNDD, or MRCNDD is in the D2 phase.
- **I2, I3, and I4:** The three instructions preceding MBCNDD can change the MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the branch, call, or return instruction. These three instructions must not be a MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7:** The three instructions following a branch, call, or return are always executed irrespective of whether the condition is true or not. These instructions must not be MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

For a more detailed description, refer to the description for [MBCNDD](#), [MCCNDD](#), and [MRCNDD](#).

Example 8-1. Code Fragment For MBCNDD, MCCNDD, or MRCNDD

```
<Instruction 1>      ; I1 Last instruction that can affect flags for
                    ;   the branch, call or return operation
<Instruction 2>      ; I2 Cannot be stop, branch, call or return
<Instruction 3>      ; I3 Cannot be stop, branch, call or return
<Instruction 4>      ; I4 Cannot be stop, branch, call or return
<branch/call/ret>    ; MBCNDD, MCCNDD or MRCNDD
                    ; I5-I7: Three instructions after are always
                    ;   executed whether the branch/call or return is
                    ;   taken or not
<Instruction 5>      ; I5 Cannot be stop, branch, call or return
<Instruction 6>      ; I6 Cannot be stop, branch, call or return
<Instruction 7>      ; I7 Cannot be stop, branch, call or return
<Instruction 8>      ; I8
<Instruction 9>      ; I9
....
```

• Stop or Halting a Task: MSTOP and MDEBUGSTOP

The MSTOP and MDEBUGSTOP instructions cannot be placed three instructions before or after a conditional branch, call or return instruction (MBCNDD, MCCNDD, or MRCNDD). Refer to [Example 8-1](#). To single-step through a branch/call or return, insert the MDEBUGSTOP at least four instructions back and step from there.

• Loading MAR0 or MAR1

A load of auxiliary register MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Referring to [Example 8-2](#), the following applies when loading the auxiliary registers:

- **I1 and I2:** The two instructions following the load instruction use the value in MAR0 or MAR1 before the update occurs.
- **I3:** Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #_X.
- **I4:** Starting with the 4th instruction MAR0 or MAR1 has the new value.

Example 8-2. Code Fragment for Loading MAR0 or MAR1

```
; Assume MAR0 is 50 and #_X is 20
MMOVI16 MAR0, #_X ; Load MAR0 with address of X (20)
<Instruction 1>    ; I1 uses the old value of MAR0 (50)
<Instruction 2>    ; I2 uses the old value of MAR0 (50)
<Instruction 3>    ; I3 Cannot use MAR0
<Instruction 4>    ; I4 uses the new value of MAR0 (20)
<Instruction 5>    ; I5 uses the new value of MAR0 (20)
....
```

• Background Task Interrupted Close to a Branch

When the background task is running, if another task request happens (and MSTSBGRND.BGINTM is not set), then the following sequence of operations happen.

- A check is made to determine if the following instructions are not in the pipeline (D2 – R2).
 - MBCNDD
 - MCCNDD
 - MRCNDD

If any of the above instructions are present in the pipeline, the back ground task continues to execute until such time when the condition is satisfied. Once the condition is satisfied, the following actions are performed:

- The MPC value of the D1 phase instruction is saved to the MVECTBGRNDACTIVE register.
- The run status bit of the background task (MSTSBGRND.RUNSTS) is cleared.
- An MSTOP instruction is forced into the D2 phase of the pipeline; causing the background task to terminate.

When the background task terminates, the CLA picks the next highest pending task and begins execution. Note that while the background task is pending, the background task has the lowest priority and, therefore, yields to any other pending task. Once all pending non-background tasks have completed execution, the CLA restores the program counter (MPC), that is, loads the address from the MVECTBGRNDACTIVE register to the MPC, sets the background status to RUN (MSTSBGRND.RUN = 1), and continues execution from that point.

- **MSTOP in the Background Task**

If an MSTOP instruction occurs in the D1 phase while the background task is running, the following sequence of operations happens:

- The RUN bit (MSTSBGRND.RUN) is cleared.
- The address stored in MVECTBGRND is copied over to MVECTBGRNDACTIVE.
- An interrupt, signaling the background task has completed execution, is generated. This interrupt signal is ANDed with the interrupt from Task 8 and fed to the PIE. Note that if an illegal instruction occurs inside the background task, the interrupt for task 8 is fired.
- When the background task terminates, the CLA resumes arbitration among the pending tasks.

8.5.2.1 ADC Early Interrupt to CLA Response

The ADC can be configured to generate an early interrupt pulse before the ADC conversion completes. If this option is used to start a CLA task, the CLA is able to read the result as soon as the conversion result is available in the ADC result register. This combination of just-in-time sampling along with the low interrupt response of the CLA enable faster system response and higher frequency control loops. The CLA task trigger to first instruction fetch interrupt latency is 4 cycles.

Timings for ADC conversions are shown in the timing diagrams of the ADC chapter. If the ADCCLK is a divided down version of the SYSCLK, the user has to account for the conversion time in SYSCLK cycles.

For example, if using the 12-bit ADC with ADCCLK at SYSCLK / 4, the ADC can take $10.5 \text{ ADCCLK} \times 4 \text{ SYSCLK} = 42 \text{ SYSCLK}$ cycles to complete a conversion. If using the ADC in 16-bit mode at the same ADCCLK, the ADC can take $29.5 \text{ ADCCLK} \times 4 \text{ SYSCLK} = 118 \text{ SYSCLK}$ cycles, and so on.

From a CLA perspective, the pipeline activity is shown in [Table 8-5](#) for an N-cycle (SYSCLK) ADC conversion. The N-2 instruction arrives in the R2 phase just in time to read the result register. While the prior instructions enter the R2 phase of the pipeline too soon to read the conversion, the instructions can be efficiently used for pre-processing calculations needed by the task.

Table 8-5. ADC to CLA Early Interrupt Response

ADC Activity	CLA Activity	F1	F2	D1	D2	R1	R2	E	W
Sample									
Sample									
...									
Sample									
Conversion _(Cycle 1)	Interrupt Received								
Conversion _(Cycle 2)	Task Startup								
Conversion _(Cycle 3)	Task Startup								
Conversion _(Cycle 4)	I _(Cycle 4)	I _(Cycle 4)							
Conversion _(Cycle 5)	I _(Cycle 5)	I _(Cycle 5)	I _(Cycle 4)						
Conversion _(...)	...	...	...	...	...	...	...		
Conversion _(Cycle N-6)	I _(Cycle N-6)	I _(Cycle N-6)	I _(Cycle N-7)	I _(Cycle N-8)	I _(Cycle N-9)	I _(Cycle N-10)	I _(Cycle N-11)		
Conversion _(Cycle N-5)	I _(Cycle N-5)	I _(Cycle N-5)	I _(Cycle N-6)	I _(Cycle N-7)	I _(Cycle N-8)	I _(Cycle N-9)	I _(Cycle N-10)		
Conversion _(Cycle N-4)	I _(Cycle N-4)	I _(Cycle N-4)	I _(Cycle N-5)	I _(Cycle N-6)	I _(Cycle N-7)	I _(Cycle N-8)	I _(Cycle N-9)		
Conversion _(Cycle N-3)	I _(Cycle N-3)	I _(Cycle N-3)	I _(Cycle N-4)	I _(Cycle N-5)	I _(Cycle N-6)	I _(Cycle N-7)	I _(Cycle N-8)		
Conversion _(Cycle N-2)	Read RESULT	Read RESULT	I _(Cycle N-3)	I _(Cycle N-4)	I _(Cycle N-5)	I _(Cycle N-6)	I _(Cycle N-7)		
Conversion _(Cycle N-1)			Read RESULT	I _(Cycle N-3)	I _(Cycle N-4)	I _(Cycle N-5)	I _(Cycle N-6)		
Conversion _(Cycle N-0)				Read RESULT	I _(Cycle N-3)	I _(Cycle N-4)	I _(Cycle N-5)		
Conversion Complete					Read RESULT	I _(Cycle N-3)	I _(Cycle N-4)		
RESULT Latched						Read RESULT	I _(Cycle N-3)		
RESULT Available							Read RESULT		

The ADCINTCYCLE register of the ADC can be programmed by the application to adjust the generation of the interrupt pulse to align with the ADC read operation. For example, if the first instruction in the task reads the ADC and the conversion time is N SYSCLK cycles, then the delay programmed is $(N-2) - 4 = N-6$.

8.5.3 Parallel Instructions

Parallel instructions are single opcodes that perform two operations in parallel. The following types of parallel instructions are available: math operation in parallel with a move operation, or two math operations in parallel. Both operations complete in a single cycle and there are no special pipeline alignment requirements.

Example 8-3. Math Operation with Parallel Load

```
; MADDF32 || MMOV32 instruction: 32-bit floating-point add with parallel move
; MADDF32 is a 1 cycle operation
; MMOV32 is a 1 cycle operation
; MADDF32 MR0, MR1, #2      ; MR0 = MR1 + 2,
; || MMOV32 MR1, @val        ; MR1 gets the contents of val
;                               ; <-- MMOV32 completes here (MR1 is valid)
;                               ; <-- DDF32 completes here (MR0 is valid)
;                               ; Any instruction, can use MR1 and/or MR0
MMPYF32 MR0, MR0, MR1
```

Example 8-4. Multiply with Parallel Add

```
; MMPYF32 || MADDF32 instruction: 32-bit floating-point multiply with parallel add
; MMPYF32 is a 1 cycle operation
; MADDF32 is a 1 cycle operation
; MMPYF32 MR0, MR1, MR3      ; MR0 = MR1 * MR3
; || MADDF32 MR1, MR2, MR0    ; MR1 = MR2 + MR0 (Uses value of MR0 before MMPYF32)
;                               ; <-- MMPYF32 and MADDF32 complete here (MR0 and MR1 are valid)
;                               ; Any instruction, can use MR1 and/or MR0
MMPYF32 MR1, MR1, MR0
```

8.5.4 CLA Task Execution Latency

The CLA task execution latency depends on the state of the system:

- CLA task trigger of new task (normal or background) without background task active:

Task takes 8 cycles from CLA task trigger to first instruction of task to reach the D2 phase of pipeline.

Note

If background task has been configured in the system, then the compiler during code compilation adds context save instructions at the start of each regular task and restore instructions at end of each task so that register content can be saved and restored in case a background task is executing while the regular task is triggered. When a regular task is entered, this compiler-generated context save instruction is the first instruction of the task.

- CLA task trigger of normal task when background task is active:

Task takes 9 cycles from CLA task trigger to first instruction of normal task to reach the D2 phase of pipeline. There is a difference of one clock cycle to force the MSTOP in the D2 phase of the background task before the task exits as compared to a new task trigger without the background task active.

Note

If the MBCNDD/MCCNDD/MRCNDD instructions in the background task are in the D2 phase of the pipeline when a new task gets triggered, the task takes a minimum of 3 more cycles to complete these uninterruptible instructions adding to the delay.

- Returning to background task from normal task:

The task takes 5 cycles to return from a normal task to resume the background task instruction at the D2 phase of the pipeline.

8.6 Software

8.6.1 CLA Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/cla

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

8.6.1.1 CLA arcsine(x) using a lookup table (cla_asin_cpu01)

FILE: cla_ex1_asin.c

In this example, Task 1 of the CLA will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table.

Note that since this example does not use background CLA task, the compile flag `cla_background_task` is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

Memory Allocation

- CLA1 Math Tables (RAMLS0)
- CLA1 to CPU Message RAM
 - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
 - fVal - Sample input to the lookup algorithm

Watch Variables

- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

8.6.1.2 CLA arcsine(x) using a lookup table (cla_asin_cpu01) - C28X_DUAL

FILE: cla_ex1_asin_cpu1.c

In this example, cpu1 will be used to initialize the clocks Task 1 of the CLA on cpu2 will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table. It is recommended to run the c28x1 core first, followed by the C28x2 core.

Memory Allocation

- CLA1 Math Tables (RAMLS0)
 - CLAasinTable - Lookup table
- CLA1 to CPU Message RAM
 - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
 - fVal - Sample input to the lookup algorithm

Watch Variables

- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

8.6.1.3 CLA Arcsine Example. - C28X_DUAL

FILE: cla_ex1_asin_cpu2.c Dual Core arcsine example. This example demonstrates how to run CLA tasks on cpu2.cla1 It is recommended to run the c28x1 core first, followed by the C28x2 core.

8.6.1.4 CLA arctangent(x) using a lookup table (cla_atan_cpu01)

FILE: cla_ex2_atan.c

In this example, Task 1 of the CLA will calculate the arctangent of an input argument using a lookup table.

Note that since this example does not use background CLA task, the compile flag `cla_background_task` is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

Memory Allocation

- CLA1 Math Tables (RAMLS0)
- CLA1 to CPU Message RAM
 - `fResult` - Result of the lookup algorithm
- CPU to CLA1 Message RAM
 - `fNum` - Numerator of sample input
 - `fDen` - Denominator of sample input

Watch Variables

- `fVal` - Argument to task 1
- `fResult` - Result of `arctan(fVal)`

8.6.1.5 CLA 2 Pole 2 Zero Infinite Impulse Response Filter (`cla_iir2p2z_cpu01`) - C28X_DUAL

FILE: `cla_ex2_iir2p2z_cpu1.c`

This example implements a Transposed Direct Form II IIR filter, commonly known as a Biquad. The input vector is a software simulated noisy signal that is fed to the biquad one sample at a time, filtered and then stored in an output buffer for storage. It is recommended to run the c28x1 core first, followed by the C28x2 core.

Memory Allocation

- CLA1 Data RAM 1 (RAML2)
 - `S1_A` - Feedback coefficients
 - `S1_B` - Feedforward coefficients
- CLA1 to CPU Message RAM
 - `yn` - Output of the Biquad
- CPU to CLA1 Message RAM
 - `xn` - Sample input to the filter

Watch Variables

- `fBiquadOutput`
- `pass`
- `fail`

8.6.1.6 CLA 2-pole 2-zero IIR Filter Example for F2837xD. - C28X_DUAL

FILE: `cla_ex2_iir2p2z_cpu2.c` Dual Core iir2p2z example. This example demonstrates how to run CLA tasks on `cpu2.cla1`. It is recommended to run the c28x1 core first, followed by the C28x2 core.

8.6.1.7 CLA background nesting task

FILE: `cla_ex3_background_nesting_task.c`

This example configures CLA task 1 to be triggered by EPWM1 running at 2 Hz (period = 0.5s). A background task is configured to be triggered by CPU timer running at .5 Hz (period = 2s). CLA task 1 toggles LED1 at the start and end of the task and the background task toggles LED2 at the start and end of the task. Background task will be preempted by Task1 and hence LED1 will be toggling even while LED2 is ON.

Note that the compile flag `cla_background_task` is turned on in this project. Enabling background task adds additional context save/restore cycles during task switching thus increasing the overall trigger-to-task latency. If the application does not use the background CLA task, it is recommended to turn this flag off for better performance. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

8.6.1.8 Controlling PWM output using CLA

FILE: cla_ex4_pwm_control.c

This example showcases how to update PWM signal output using CLA. EPWM1 is configured to generate complementary signals on both of its channels of fixed frequency 100 KHz. EPWM4 is configured to trigger a periodic CLA control task of frequency 10 KHz. The CLA task implements a very simple logic to vary the duty of the EPWM1 outputs by increasing it by 0.1 in every iteration and maintaining it in the range of 0.1-0.9. For actual use-cases, the control logic could be modified to much more complex depending upon the application. The other CLA task (CLA task 8) is triggered by software at beginning to initialize the CLA global variables

External Connections

- Observe GPIO0 (EPWM1A) on oscilloscope
- Observe GPIO1 (EPWM1B) on oscilloscope

Watch Variables

8.6.1.9 Just-in-time ADC sampling with CLA

FILE: cla_ex5_adc_just_in_time.c

This example showcases how to utilize early-interrupt feature of ADC in combination with the low interrupt response of CLA to enable faster system response and achieve high frequency control loops. EPWM1 is configured to generate a PWM output signal of frequency 1 MHz and this is also used to trigger the ADC sampling at each cycle. ADCA is configured to sample the input on Channel 0 and to generate the early interrupt at the end of S/H + offset cycles. This interrupt is used to trigger the CLA control task. The CLA task implements the control logic to update the duty of the PWM output based on reading the ADC sample data just-in-time i.e. as soon as the ADC results gets latched. The early interrupt feature and low interrupt latency of CLA allows to do some pre-processing as well before reading the ADC data and still completes updating the PWM output before the next interrupts comes in i.e. data read and PWM update is done within a 1 MHz cycle. For illustration purposes, 3-point moving average filter is used to simulate some processing and few steps of the filtering code are done before reading the ADC result which we consider as pre-processing code. The ADC interrupt offset is programmed based on the cycles consumed by the pre-processing code.

The calculation for interrupt offset value is as follows :-
 -ADC acquisition cycles programmed = 10 SYSCLKS
 -Conversion time for 12-bit data = 10.5 ADCCLKS = N = 42 SYSCLKS
 -CLA task trigger to first instruction in Fetch delay = 4
 -Let the interrupt offset value be 'x'
 -The code inside CLA control task before ADC read takes below cycles :
 Setting up profiling gpio : 3 cycles
 Pre-processing : 13 cycles
 Total = 3 + 13 = 16 cycles

As described in device TRM, in order to read just-in-time the total delay before reading ADC should be (N-2) cycles = 40 i.e. : $x + 4 + 16 = 40$: $x = 20$

NOTE :- The optimization is off for this project and the cycles quoted above corresponds to that case.

GPIO2 is used for profiling purposes. GPIO2 is set at the beginning of CLA task 1 and is reset at the end of the task. Thus ON time of GPIO2 indicates the CLA activity. In order to validate the example functionality, observe the GPIO0 (PWM output) and GPIO2 (profiling GPIO) on CRO. The cycles difference between the rising edge of the GPIO0 and GPIO2 indicate the total delay from the time of ADC trigger to setting up of profiling GPIO inside CLA task which should be around 44 cycles (220 ns) based on the above calculation.

External Connections

- Provide constant DC input on ADCA0 for quick validation. GND -> Should observe PWM output duty = 0.1
 3.3V -> Should observe PWM output duty = 0.9 Can also provide analog input in range 0 - 3.3V upto fs / 10 = 100 KHz for observing continuous duty variations

- Observe GPIO0 on oscilloscope
- Observe GPIO2 on oscilloscope

Watch Variables

- None

8.6.1.10 Optimal offloading of control algorithms to CLA

FILE: cla_ex6_cpu_offloading.c

This example showcases how to optimally offload the control algorithms from CPU to CLA in order to meet the system requirements. In this example, two control loops are simulated, the faster one (loop1) running at 200 KHz and the slower one (loop2) running at 20 KHz. Loop1 senses the first parameter at ADCA Channel 0, runs the PI controller to achieve the target and contributes to the duty of EPWM1A output with 80% weightage. Loop2 senses the second parameter at ADCB Channel 2, runs the PI controller and contributes to the duty of EPWM1A output with 20% weightage. It is important to note that since these are just software simulated control loops but there is no actual physical process involved and hence updating the duty is not going to have any affect on sampled inputs. ADCA is configured to oversample the first parameter using SOCs 0-3 to suppress the noise and similarly ADCB is used to oversample the second parameter. EPWM4 and EPWM5 are configured to trigger the ADCA and ADCB sampling at loop1 and loop2 frequencies respectively. Once the conversion of all 4 SOCs complete, a CPU ISR or a CLA task is triggered based on the user-configuration. There is also a background task running in the main loop which disables the entire system including PWM output and the control loops when "system_OFF" is set to 1. The system gets enabled again once "system_OFF" is restored back to 0. By default system_OFF is set to 0 but it's value can be updated dynamically by adding it to expression window and writing to it. DCL library is included in the project to make use of optimal PI controllers used in both the loops. User-configurable pre-defined symbol "run_loop1_cla" has been added to the project options in order to specify whether to run the loop1 on C28x or CLA. GPIO2 and GPIO3 are used to profile the execution of loop1 and loop2.

For run_loop1_cla == 0 i.e. both loops running on CPU -> Loop1 Utilization = ~77.5% (measured using profiling GPIO2) -> Loop2 Utilization = ~6% (measured using profiling GPIO3) -> Background task in a while loop -> Total CPU utilization is greater than Utilization bound (UB) Hence the system is non-schedulable, lower priority task (Loop2) execution never completes (no toggling observed on GPIO3) and also background task never gets chance to execute

For run_loop1_cla == 1 i.e. high frequency control loop (loop1) is offloaded to CLA while loop2 runs on CPU -> Loop1 Utilization (CLA) = ~73% -> Loop2 Utilization (CPU) = ~6% -> Total CPU utilization has come down to just ~6% Hence the system is perfectly schedulable, no miss happens for any of the loops and offloading of loop1 to CLA saves CPU bandwidth to execute background tasks as well

For quick inspection of the example functionality, constant DC HIGH/LOW inputs can be provided to the analog channels instead of varying analog voltages. The target value for both the loops are set as some intermediate value i.e. 3500 corresponds to ~2.8V. Now since the sensed inputs are constant and not same as target so the controller outputs will get saturated soon to either 1 or 0. Thus the "duty" variable can take only fixed values based on the equations used in the loops. Infact the duty output would be very intuitive, for instance if both inputs are LOW(GND), the controller will try to produce the maximum duty as the target is higher than sensed value hence the duty should be 1.0(0.2 + 0.8) but will get saturated to 0.9(the maximum value defined). Similarly if both inputs are made HIGH, the duty will be 0.1 (the minimum saturation value defined). The final duty table is shown below :

External Connections

- Observe GPIO2 (Loop1 Profiling) on oscilloscope
- Observe GPIO3 (Loop2 Profiling) on oscilloscope
- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Provide constant HIGH(3.3V)/LOW(0V) on both ADCA Ch0 and ADCB Ch2 for quick validation, the following duty value should be observable at EPWM1A for various combinations if the system is perfectly schedulable i.e. both loops gets chance to execute properly :- A0 B2 duty GND GND 0.9 3.3V GND 0.2 GND 3.3V

0.8 3.3V 3.3V 0.1 Note :- The optimization is OFF for this project and all the profiling data quoted above corresponds to this case.

8.6.1.11 Handling shared resources across C28x and CLA

FILE: cla_ex7_shared_resource_handling.c

This example showcases how to handle shared resource challenges across C28x and CLA. As the peripherals are shared between CLA and the CPU, overlapping read-modify-write to the registers by them can lead to data race conditions ultimately leading to data violation or incorrect functionality. In this example, CPU ISR and CLA tasks runs independently. CPU ISR gets triggered by EPWM4 @10KHz and toggles the EPWM1B output via software by controlling CSFB bits of AQCSFRC. CLA task gets triggered by EPWM5 @100KHz and toggles the EPWM1A output via software by controlling CSFA bits of AQCSFRC. Thus in this process both CPU and CLA do read-modify -write to AQCSFRC register independently at different frequencies so there is chance of race condition and updates due to one of them can get lost/. overwritten. This can be clearly observed by updating "phase_shift_ON" to 0U and probing the EPWM1A and 1B outputs on a scope.

This is a standard critical section problem and can be handled by software handshaking mechanism like mutex etc. But most of the real-time control applications are time-sensitive and cannot afford addition software overhead hence this example suggests an alternative hardware based technique to avoid shared resource conflicts between CPU and CLA. The phase shifting mechanism of the EPWM modules is utilized to schedule the CLA task and CPU ISR as desired. EPWM4 generates a synchronous pulse every ZERO event and provides a phase shift of 20 cycles to EPWM5. This way both CLA task and C28x ISR runs at original frequencies i.e. 100KHz and 10KHz but CLA task leads with a phase offset of 20 cycles wrt CPU ISR. Hence concurrent read-modify-writes to AQCSFRC never happens and the EPWM1A and EPWM1B outputs behave as desired i.e. consistent 50 KHz PWM output on EPWM1A and 5 KHz PWM output on EPWM1B with a duty ~50% on both should be generated. In order to utilize this phase shifting mechanism in this example, please make sure "phase_shift_ON" is set to 1.

External Connections

- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Observe GPIO1 (EPWM1B Output) on oscilloscope
- Observe GPIO2 (CLA Task Profiling) on oscilloscope
- Observe GPIO3 (CPU ISR Profiling) on oscilloscope

Note :- The phase offset value can easily be configured by updating TBPHS register to schedule the CLA task and C28x ISR as desired depending upon the application need so as to avoid overlapping register writes by CPU and CLA

Note :- The optimization is on and set to O2 for the project and all the results quoted correspond to this case.

8.7 Instruction Set

This section describes the assembly language instructions of the control law accelerator. Also described are parallel operations, conditional operations, resource constraints, and addressing modes. The instructions listed here are independent from C28x and C28x+FPU instruction sets.

8.7.1 Instruction Descriptions

This section gives detailed information on the instruction set. Each instruction presents the following information:

- Operands
- Opcode
- Description
- Exceptions
- Pipeline
- Examples
- See also

The example INSTRUCTION is shown to familiarize you with the way each instruction is described. The example describes the kind of information you find in each part of the individual instruction description and where to obtain more information. CLA instructions follow the same format as the C28x instructions; the source operands are always on the right and the destination operands are on the left.

The explanations for the syntax of the operands used in the instruction descriptions for the CLA are given in [Table 8-6](#).

Table 8-6. Operand Nomenclature

Symbol	Description
#16FHi	16-bit immediate (hex or float) value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FHiHex	16-bit immediate hex value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value
#32Fhex	32-bit immediate value that represents an IEEE 32-bit floating-point value
#32F	Immediate float value represented in floating-point representation
#0.0	Immediate zero
#SHIFT	Immediate value of 1 to 32 used for arithmetic and logical shifts.
addr	Opcode field indicating the addressing mode
CNDF	Condition to test the flags in the MSTF register
FLAG	Selected flags from MSTF register (OR) 8 bit mask indicating which floating-point status flags to change
MAR0	Auxiliary register 0
MAR1	Auxiliary register 1
MARx	Either MAR0 or MAR1
mem16	16-bit memory location accessed using direct, indirect, or offset addressing modes
mem32	32-bit memory location accessed using direct, indirect, or offset addressing modes
MRa	MR0 to MR3 registers
MRb	MR0 to MR3 registers
MRc	MR0 to MR3 registers
MRd	MR0 to MR3 registers
MRe	MR0 to MR3 registers
MRf	MR0 to MR3 registers
MSTF	CLA Floating-point Status Register
shift	Opcode field indicating the number of bits to shift.
VALUE	Flag value of 0 or 1 for selected flag (OR) 8 bit mask indicating the flag value; 0 or 1

Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

Table 8-7. INSTRUCTION dest, source1, source2 Short Description

	Description
dest1	Description for the 1st operand for the instruction
source1	Description for the 2nd operand for the instruction
source2	Description for the 3rd operand for the instruction
Opcode	This section shows the opcode for the instruction
Description	Detailed description of the instruction execution is described. Any constraints on the operands imposed by the processor or the assembler are discussed.
Restrictions	Any constraints on the operands or use of the instruction imposed by the processor are discussed.
Pipeline	This section describes the instruction in terms of pipeline cycles as described in Section 8.5
Example	Examples of instruction execution. If applicable, register and memory values are given before and after instruction execution. Some examples are code fragments while other examples are full tasks that assume the CLA is correctly configured and the main CPU has passed the CLA data.
Operands	Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

8.7.2 Addressing Modes and Encoding

The CLA uses the same address to access data and registers as the main CPU. For example, if the main CPU accesses an ePWM register at address 0x00 6800, then the CLA accesses the register using address 0x6800. Since all CLA accessible memory and registers are within the low 64k x 16 of memory, only the low 16-bits of the address are used by the CLA.

To address the CLA data memory, message RAMs and shared peripherals, the CLA supports two addressing modes:

- Direct addressing mode: Uses the address of the variable or register directly.
- Indirect addressing with 16-bit post increment. This mode uses either XAR0 or XAR1.

The CLA does not use a data page pointer or a stack pointer. The two addressing modes are encoded as shown [Table 8-8](#).

Table 8-8. Addressing Modes

Addressing Mode	'addr' Opcode Field Encode ⁽¹⁾	Description
@dir	0000	Direct Addressing Mode Example 1: <code>MMOV32 MR1, @_VarA</code> Example 2: <code>MMOV32 MR1, @_EPwm1Regs.CMPA.all</code> In this case, the 'mmmm mmmm mmmm mmmm' opcode field is populated with the 16-bit address of the variable. This is the low 16-bits of the address to access the variable using the main CPU. For example, <code>@_VarA</code> populates the address of the variable VarA. and <code>@_EPwm1Regs.CMPA.all</code> populates the address of the CMPA register.
*MAR0[#imm16]++	0001	MAR0 Indirect Addressing with 16-bit Immediate Post Increment MAR1 Indirect Addressing with 16-bit Immediate Post Increment addr = MAR0 (or MAR1) Access memory using the address stored in MAR0 (or MAR1). MAR0 (or MAR1) += #imm16 Then post increment MAR0 (or MAR1) by #imm16. #imm16 Example 1: <code>MMOV32 MR0, *MAR0[2]++</code> Example 2: <code>MMOV32 MR1, *MAR1[-2]++</code> For a post increment of 0, the assembler accepts both <code>*MAR0</code> and <code>*MAR0[0]++</code> . The 'mmmm mmmm mmmm mmmm' opcode field is populated with the signed 16-bit pointer offset. For example, if #imm16 is 2, then the opcode field is 0x0002. Likewise, if #imm16 is -2, then the opcode field is 0xFFFF. If addition of the 16-bit immediate causes overflow, then the value wraps around on a 16-bit boundary.
*MAR1[#imm16]++	0010	
*MAR0+[#imm16]	0101	MAR0 Offset Addressing with 16-bit Immediate Offset MAR1 Offset Addressing with 16-bit Immediate Offset addr = MAR0 Add the offset #imm16 (or MAR1) + #imm16to address stored in MAR0(MAR1) to access the desired memory the base location Example 1: <code>MMOV32 MR0, *MAR0+[2]</code> Example 1: <code>MMOV32 MR1, *MAR1+[-2]</code> The 'mmmm mmmm mmmm mmmm' opcode field is populated with the signed 16-bit pointer offset. For example, if #imm16 is 2, then the opcode field is 0x0002. Likewise, if #imm16 is -2, then the opcode field is 0xFFFF. If the addition of the 16-bit immediate causes overflow, the value wraps around on a 16-bit boundary.
*MAR1+[#imm16]	0110	

(1) Values not shown are reserved.

Encoding for the shift fields in the MASR32, MLSR32 and MLSL32 instructions is shown in [Table 8-9](#).**Table 8-9. Shift Field Encoding**

Shift Value	'shift' Opcode Field Encode
1	0000
2	0001
3	0010
....	
32	1111

For instructions that use MRx (where x can be 'a' through 'f') as operands, the trailing alphabet appears in the opcode as a two-bit field. For example:

```
MMPYF32 MRa, MRb, MRc ||
MADDF32 MRd, MRe, MRf
```

whose opcode is,

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

The two-bit field specifies one of four working registers according to [Table 8-10](#).

Table 8-10. Operand Encoding

Two-Bit Field	Working Register
00	MR0
01	MR1
10	MR2
11	MR3

[Table 8-11](#) shows the condition field encoding for conditional instructions such as MNEGF, MSWAPF, MBCNDD, MCCNDD, and MRCNDD.

Table 8-11. Condition Field Encoding

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

8.7.3 Instructions

The instructions are listed alphabetically.

Instruction Set Summary

MABSF32 MRa, MRb — 32-Bit Floating-Point Absolute Value.....	1010
MADD32 MRa, MRb, MRc — 32-Bit Integer Add.....	1011
MADDF32 MRa, #16FHi, MRb — 32-Bit Floating-Point Addition.....	1012
MADDF32 MRa, MRb, #16FHi — 32-Bit Floating-Point Addition.....	1014
MADDF32 MRa, MRb, MRc — 32-Bit Floating-Point Addition.....	1016
MADDF32 MRd, MRe, MRf MMOV32 mem32, MRa — 32-Bit Floating-Point Addition with Parallel Move....	1017
MADDF32 MRd, MRe, MRf MMOV32 MRa, mem32 — 32-Bit Floating-Point Addition with Parallel Move...	1018
MAND32 MRa, MRb, MRc — Bitwise AND.....	1020
MASR32 MRa, #SHIFT — Arithmetic Shift Right.....	1021
MBCNDD 16BitDest {, CNDF} — Branch Conditional Delayed.....	1023
MCCNDD 16BitDest {, CNDF} — Call Conditional Delayed.....	1028
MCLRC BGINTM — Clear Background Task Interrupt Mask.....	1032
MCMP32 MRa, MRb — 32-Bit Integer Compare for Equal, Less Than or Greater Than.....	1033
MCMPF32 MRa, MRb — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than.....	1035
MCMPF32 MRa, #16FHi — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than.....	1036
MDEBUGSTOP — Debug Stop Task.....	1038
MDEBUGSTOP1 — Software Breakpoint.....	1039
MEALLOW — Enable CLA Write Access to EALLOW Protected Registers.....	1040
MEDIS — Disable CLA Write Access to EALLOW Protected Registers.....	1041
MEINVF32 MRa, MRb — 32-Bit Floating-Point Reciprocal Approximation.....	1042
MEISQRTF32 MRa, MRb — 32-Bit Floating-Point Square-Root Reciprocal Approximation.....	1044
MF32TOI16 MRa, MRb — Convert 32-Bit Floating-Point Value to 16-Bit Integer.....	1046
MF32TOI16R MRa, MRb — Convert 32-Bit Floating-Point Value to 16-Bit Integer and Round.....	1047
MF32TOI32 MRa, MRb — Convert 32-Bit Floating-Point Value to 32-Bit Integer.....	1048
MF32TOUI16 MRa, MRb — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer	1050
MF32TOUI16R MRa, MRb — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer and Round.....	1051
MF32TOUI32 MRa, MRb — Convert 32-Bit Floating-Point Value to 32-Bit Unsigned Integer	1052
MFRACF32 MRa, MRb — Fractional Portion of a 32-Bit Floating-Point Value.....	1053
MI16TOF32 MRa, MRb — Convert 16-Bit Integer to 32-Bit Floating-Point Value	1054
MI16TOF32 MRa, mem16 — Convert 16-Bit Integer to 32-Bit Floating-Point Value	1055
MI32TOF32 MRa, mem32 — Convert 32-Bit Integer to 32-Bit Floating-Point Value	1056
MI32TOF32 MRa, MRb — Convert 32-Bit Integer to 32-Bit Floating-Point Value	1057
MLSL32 MRa, #SHIFT — Logical Shift Left.....	1058
MLSR32 MRa, #SHIFT — Logical Shift Right.....	1060
MMACF32 MR3, MR2, MRd, MRe, MRf MMOV32 MRa, mem32 — 32-Bit Floating-Point Multiply and Accumulate with Parallel Move.....	1061
MMAXF32 MRa, MRb — 32-Bit Floating-Point Maximum.....	1064
MMAXF32 MRa, #16FHi — 32-Bit Floating-Point Maximum.....	1066
MMINF32 MRa, MRb — 32-Bit Floating-Point Minimum.....	1068
MMINF32 MRa, #16FHi — 32-Bit Floating-Point Minimum.....	1070
MMOV16 MARx, MRa, #16I — Load the Auxiliary Register with MRa + 16-bit Immediate Value.....	1072
MMOV16 MARx, mem16 — Load MAR1 with 16-bit Value.....	1075
MMOV16 mem16, MARx — Move 16-Bit Auxiliary Register Contents to Memory.....	1078
MMOV16 mem16, MRa — Move 16-Bit Floating-Point Register Contents to Memory.....	1079
MMOV32 mem32, MRa — Move 32-Bit Floating-Point Register Contents to Memory	1081
MMOV32 mem32, MSTF — Move 32-Bit MSTF Register to Memory.....	1083
MMOV32 MRa, mem32 {, CNDF} — Conditional 32-Bit Move.....	1084
MMOV32 MRa, MRb {, CNDF} — Conditional 32-Bit Move.....	1086
MMOV32 MSTF, mem32 — Move 32-Bit Value from Memory to the MSTF Register.....	1088

MMOVD32 MRa, mem32 — Move 32-Bit Value from Memory with Data Copy.....	1089
MMOVF32 MRa, #32F — Load the 32-Bits of a 32-Bit Floating-Point Register.....	1091
MMOVI16 MARx, #16I — Load the Auxiliary Register with the 16-Bit Immediate Value.....	1093
MMOVI32 MRa, #32FHex — Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate.....	1095
MMOVIZ MRa, #16FHi — Load the Upper 16-Bits of a 32-Bit Floating-Point Register	1097
MMOVZ16 MRa, mem16 — Load MRx with 16-Bit Value.....	1098
MMOVXI MRa, #16FLoHex — Move Immediate Value to the Lower 16-Bits of a Floating-Point Register.....	1099

MABSF32 MRa, MRb
32-Bit Floating-Point Absolute Value
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0010 0000
```

Description

The absolute value of MRb is loaded into MRa. Only the sign bit of the operand is modified by the MABSF32 instruction.

```
if (MRb < 0) {MRa = -MRb};
else {MRa = MRb};
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = 0;
ZF = 0;
if ( MRa(30:23) == 0) ZF = 1;
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #-2.0 ; MR0 = -2.0 (0xC0000000)
MABSF32 MR0, MR0 ; MR0 = 2.0 (0x40000000), ZF = NF = 0
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MABSF32 MR0, MR0 ; MR0 = 5.0 (0x40A00000), ZF = NF = 0
MMOVIZ MR0, #0.0 ; MR0 = 0.0
MABSF32 MR0, MR0 ; MR0 = 0.0 ZF = 1, NF = 0
```

MADD32 MRa, MRb, MRc

32-Bit Integer Add

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 000cc bbaa
MSW: 0111 1110 1100 0000
```

Description

32-bit integer addition of MRb and MRc.

```
MRa(31:0) = MRb(31:0) + MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; };
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
; B = (int32)2
; C = (int32)-7
;
; Calculate Y2 = A + B + C
;
_Cla1Task1:
    MOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
    MOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
    MOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
    MADD32 MR3, MR0, MR1 ; A + B
    MADD32 MR3, MR2, MR3 ; A + B + C = -4 (0xFFFFFFFFC)
    MOV32 @_y2, MR3      ; Store y2
    MSTOP                ; end of task
```

MADDF32 MRa, #16FHi, MRb
32-Bit Floating-Point Addition
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
MADDF32 MR0, #2.0, MR1 ; MR0 = 2.0 + MR1
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
MADDF32 MR2, #-2.5, MR3 ; MR2 = -2.5 + MR3
; Add to MR3 the value 0x3FC00000 (1.5)
; Store the result in MR3
MADDF32 MR3, #0x3FC0, MR3 ; MR3 = 1.5 + MR3
```

MADDF32 MRa, MRb, #16FHi
32-Bit Floating-Point Addition
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, #16FHi, MRb.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

32-Bit Floating-Point Addition
Example 1

```
; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store the value in Result
;
;
_Cla1Task1:
    MMOV16    MAR1, #_X          ; Start address
    MUI16TOF32 MR0, @_len        ; Length of the array
    MNOP      ; delay for MAR1 load
    MNOP      ; delay for MAR1 load
    MMOV32    MR1, *MAR1[2]++    ; MR1 = X0
LOOP
    MMOV32    MR2, *MAR1[2]++    ; MR2 = next element
    MMAXF32   MR1, MR2          ; MR1 = MAX(MR1, MR2)
    MADDF32   MR0, MR0, #-1.0    ; Decrement the counter
    MCMPF32   MR0, #0.0         ; Set/clear flags for MBCNDD
    MNOP
    MNOP
    MNOP
    MBCNDD   LOOP, NEQ          ; Branch if not equal to zero
    MMOV32   @_Result, MR1      ; Always executed
    MNOP      ; Always executed
    MNOP      ; Always executed
    MSTOP      ; End of task
```

Example 2

```
; Show the basic operation of MADDF32
;
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
    MADDF32 MR0, MR1, #2.0      ; MR0 = MR1 + 2.0
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
    MADDF32 MR2, MR3, #-2.5     ; MR2 = MR3 + (-2.5)
; Add to MR0 the value 0x3FC00000 (1.5)
; Store the result in MR0
    MADDF32 MR0, MR0, #0x3FC0   ; MR0 = MR0 + 1.5
```

MADDF32 MRa, MRb, MRc**32-Bit Floating-Point Addition****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 000 0000 00cc bbaa
MSW: 0111 1100 0010 0000
```

Description

Add the contents of MRc to the contents of MRb and load the result into MRa.

```
MRa = MRb + MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given M1, X1, and B1 are 32-bit floating-point numbers
; Calculate Y1 = M1*X1+B1
;
;_Cla1Task1:
  MMOV32 MR0,@M1      ; Load MR0 with M1
  MMOV32 MR1,@X1       ; Load MR1 with X1
  MPPYF32 MR1,MR1,MR0  ; Multiply M1*X1
|| MMOV32 MR0,@B1      ; and in parallel load MR0 with B1
  MADDF32 MR1,MR1,MR0  ; Add M*X1 to B1 and store in MR1
  MMOV32 @Y1,MR1       ; Store the result
  MSTOP                ; end of task
```

MADDF32 MRd, MRe, MRf||MMOV32 mem32, MRa
32-Bit Floating-Point Addition with Parallel Move
Operands

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3)
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This is the destination of the MMOV32.
MRa	CLA floating-point source register for the MMOV32 (MR0 to MR3)

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0101 ffee ddaa addr
```

Description

Perform an MADDF32 and a MMOV32 in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of MRa to the 32-bit location mem32.

```
MRd = MRe + MRf;
[mem32] = MRa;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

Both MADDF32 and MMOV32 complete in a single cycle.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) + C
;
;
_cla1Task2:
    MMOV32    MR0, @_A      ; Load MR0 with A
    MMOV32    MR1, @_B      ; Load MR1 with B
    MMPYF32   MR1, MR1, MR0 ; Multiply A*B
|| MMOV32     MR0, @_C      ; and in parallel load MR0 with C
    MADDF32   MR1, MR1, MR0 ; Add (A*B) to C
|| MMOV32     @_Y2, MR1     ; and in parallel store A*B
    MMOV32    @_Y3, MR1     ; Store the A*B + C
    MSTOP                      ; end of task
```

MADDF32 MRd, MRe, MRf ||MMOV32 MRa, mem32**32-Bit Floating-Point Addition with Parallel Move****Operands**

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3). MRd cannot be the same register as MRa.
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRa	CLA floating-point destination register for the MMOV32 (MR0 to MR3). MRa cannot be the same register as MRd.
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source for the MMOV32.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0001 ffee ddaa addr
```

Description

Perform an MADDF32 and a MMOV32 operation in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of the 32-bit location mem32 to MRa.

```
MRd = MRe + MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MADDF32 and the MMOV32 must be unique. That is, MRa and MRd cannot be the same register.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

The MMOV32 Instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; };
```

Pipeline

The MADDF32 and the MMOV32 both complete in a single cycle.

Arithmetic Shift Right

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 0100 0000
```

Description

Arithmetic shift right of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Arithmetic Shift(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given m2 = (int32)32
; x2 = (int32)64
; b2 = (int32)-128
;
; calculate
; m2 = m2/2
; x2 = x2/4
; b2 = b2/8
;
_cla1Task2:
    MMOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
    MMOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
    MMOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFF80)
    MASR32 MR0, #1 ; MR0 = 16 (0x00000010)
    MASR32 MR1, #2 ; MR1 = 16 (0x00000010)
    MASR32 MR2, #3 ; MR2 = -16 (0xFFFFF0)
    MMOV32 @_m2, MR0 ; store results
    MMOV32 @_x2, MR1
    MMOV32 @_b2, MR2
    MSTOP ; end of task
```

MBCNDD 16BitDest {, CNDF}
Branch Conditional Delayed
Operands

16BitDest	16-bit destination if condition is true
CNDF	Optional condition tested

Opcode

```
LSW: dest dest dest dest
MSW: 0111 1001 1000 cndf
```

Description

If the specified condition is true, then branch by adding the signed 16BitDest value to the MPC value. Otherwise, continue without branching. If the address overflows, the address wraps around. Therefore, a value of "0xFFFFE" puts the MPC back to the MBCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC += 16BitDest;
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Restrictions

The MBCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more information.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

MBCNDD 16BitDest {, CNDF} (continued)
Branch Conditional Delayed
Pipeline

The MBCNDD instruction alone is a single-cycle instruction. As shown in [Table 8-12](#), 6 instruction slots are executed for each branch; 3 slots before the branch instruction (I2-I4) and 3 slots after the branch instruction (I5-I7). The total number of cycles for a branch taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a branch can, therefore, range from 1 to 7 cycles. The number of cycles for a branch taken cannot be the same as for a branch not taken.

Referring to [Table 8-12](#) and [Table 8-13](#), the instructions before and after MBCNDD have the following properties:

- **I1**
 - I1 is the last instruction that can effect the CNDF flags for the MBCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD is in the D2 phase.
 - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
 - The three instructions proceeding MBCNDD can change MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the MBCNDD instruction.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
 - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

```

[MRCNDD CNDF](#)

MCCNDD 16BitDest {, CNDF}***Call Conditional Delayed*****Operands**

16BitDest	16-bit destination if condition is true
CNDF	Optional condition to be tested

Opcode

```
LSW: dest dest dest dest
MSW: 0111 1001 1001 cndf
```

Description

If the specified condition is true, then store the return address in the RPC field of MSTF and make the call by adding the signed 16BitDest value to the MPC value. Otherwise, continue code execution without making the call. If the address overflows, the address wraps around. Therefore a value of "0xFFFE" puts the MPC back to the MCCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE)
{
    RPC = return address;
    MPC += 16BitDest;
};
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Restrictions

The MCCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more details.

Flags

This instruction does not modify flags in the MSTF register.

MCCNDD 16BitDest {, CNDF} (continued)
Call Conditional Delayed

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MCCNDD instruction alone is a single-cycle instruction. As shown in [Table 8-14](#), 6 instruction slots are executed for each call; 3 before the call instruction (I2-I4) and 3 after the call instruction (I5-I7). The total number of cycles for a call taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a call can, therefore, range from 1 to 7 cycles. The number of cycles for a call taken cannot be the same as for a call not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 8-14](#) and [Table 8-15](#), the instructions before and after MCCNDD have the following properties:

- **I1**
 - I1 is the last instruction that can effect the CNDF flags for the MCCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MCCNDD is in the D2 phase.
 - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
 - The three instructions proceeding MCCNDD can change MSTF flags but have no effect on whether the MCCNDD instruction makes the call or not. This is because the flag modification occurs after the D2 phase of the MCCNDD instruction.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
 - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

MCLRC BGINTM***Clear Background Task Interrupt Mask*****Operands**

None	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0111 0000

Description

This instruction clears the background task interrupt mask (BGINTM) bit in the MSTSBGRND register, allowing any code thereafter to be interrupted by a higher priority task. This instruction clears the BGINTM bit at the end of the D2 phase.

Note

This instruction does not require the MEALLOW bit to be asserted before or deasserted after clearing BGINTM.

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

MCLRC BGINTM	; Allow the background task to be ; interrupted by clearing the ; MSTSBGRND.BGINTM bit
--------------	--

MCMP32 MRa, MRb

32-Bit Integer Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0010 0000
```

Description

Set ZF and NF flags on the result of MRa - MRb where MRa and MRb are 32-bit integers. For a floating-point compare, refer to [MCMPF32](#).

Note

A known hardware issue exists in the MCMP32 instruction. Signed-integer comparisons using MCMP32 alone set the status bits in a way that is not useful for comparison when the difference between the two operands is too large, such as when the inputs have opposite sign and are near the extreme 32-bit signed values. This affects both signed and unsigned integer comparisons.

The compiler (version 18.1.5.LTS or higher) has implemented a workaround for this issue. The compiler checks the upper bits of the operands by performing a floating point comparison before proceeding to do the integer comparison or subtraction.

The compiler flag `--cla_signed_compare_workaround` enables this workaround.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Behavior of ZF and NF flags for different comparisons
;
; Given A = (int32)1
;        B = (int32)2
;        C = (int32)-7
;
MMOV32 MR0, @_A ; MR0 = 1 (0x00000001)
MMOV32 MR1, @_B ; MR1 = 2 (0x00000002)
MMOV32 MR2, @_C ; MR2 = -7 (0xFFFFFFF9)
MCMP32 MR2, MR2 ; NF = 0, ZF = 1
MCMP32 MR0, MR1 ; NF = 1, ZF = 0
MCMP32 MR1, MR0 ; NF = 0, ZF = 0
```

MCMP32 MRa, MRb (continued)***32-Bit Integer Compare for Equal, Less Than or Greater Than***

See also[MADD32 MRa, MRb, MRc](#)
[MSUB32 MRa, MRb, MRc](#)

MCMPF32 MRa, MRb

32-Bit Floating-Point Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0000 0000
```

Description

Set ZF and NF flags on the result of MRa - MRb. The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE format offsetting the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- A denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, MR0 ; ZF = 0, NF = 1
MCMPF32 MR0, MR1 ; ZF = 0, NF = 0

MCMPF32 MRa, #16FHi**32-Bit Floating-Point Compare for Equal, Less Than or Greater Than****Operands**

MRa	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1100 00aa
```

Description

Compare the value in MRa with the floating-point value represented by the immediate operand. Set the ZF and NF flags on (MRa - #16FHi:0).

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE floating-point format offsets the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- Denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == #16FHi:0) {ZF=1, NF=0;}
If(MRa > #16FHi:0) {ZF=0, NF=0;}
If(MRa < #16FHi:0) {ZF=0, NF=1;}
```

Pipeline

This is a single-cycle instruction

Example 1

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ    MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ    MR0, #5.0  ; MR0 = 5.0 (0x40A00000)
MCMPF32    MR1, #-2.2 ; ZF = 0, NF = 0
MCMPF32    MR0, #6.5  ; ZF = 0, NF = 1
MCMPF32    MR0, #5.0  ; ZF = 1, NF = 0
```

MDEBUGSTOP***Debug Stop Task*****Operands**

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0110 0000

Description

When CLA breakpoints are enabled, the MDEBUGSTOP instruction is used to halt a task so that the task can be debugged. That is, MDEBUGSTOP is the CLA breakpoint. If CLA breakpoints are not enabled, the MDEBUGSTOP instruction behaves like a MNOP. Unlike the MSTOP, the MIRUN flag is not cleared and an interrupt is not issued. A single-step or run operation continues execution of the task.

Restrictions

The MDEBUGSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

See also

[MSTOP](#) , [MDEBUGSTOP1](#)

MDEBUGSTOP1

Software Breakpoint

Operands

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0011 0000

Description

The instruction at which a software breakpoint is placed is replaced by the MDEBUGSTOP1 instruction. The instruction halts execution once the instruction reaches the D2 phase in the pipeline; at that point, the subsequent instructions that were fetched, after the halt, are flushed from the pipeline. The replace instruction is re-fetched after this and execution continues normally (either in run or step mode).

See [Section 8.4.3](#) for a detailed explanation of the operation.

Restrictions

The MDEBUGSTOP1 instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

MEALLOW

Enable CLA Write Access to EALLOW Protected Registers

Operands

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1001 0000

Description

This instruction sets the MEALLOW bit in the CLA status register MSTF. When this bit is set, the CLA is allowed write access to EALLOW protected registers. To again protect against CLA writes to protected registers, use the MEDIS instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from Code Composer Studio.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
.cdec1s C,LIST,"CLAShared.h"
...
_Cla1Task1:
...
    MEALLOW                ; Allow CLA write access
    MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; Write to TZSEL
    MEDIS                  ; Disallow CLA write access
    ...
    ...
    MSTOP
```

See also

[MEDIS](#)

MEDIS

Disable CLA Write Access to EALLOW Protected Registers

Operands

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1011 0000

Description

This instruction clears the MEALLOW bit in the CLA status register MSTF. When this bit is clear, the CLA is not allowed write access to EALLOW-protected registers. To enable CLA writes to protected registers, use the MEALLOW instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from the Code Composer Studio™ IDE.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
.cdec1s C,LIST,"CLAShared.h"
...
_Cla1Task1:
...
    MEALLOW                ; Allow CLA write access
    MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; Write to TZSEL
    MEDIS                  ; Disallow CLA write access
    ...
    ...
    MSTOP
```

MEINVF32 MRa, MRb

32-Bit Floating-Point Reciprocal Approximation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0000 0000
```

Description

This operation generates an estimate of $1/X$ in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/X);
Ye = Ye*(2.0 - Ye*X);
Ye = Ye*(2.0 - Ye*X);
```

After two iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEINVF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/MRb;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEINVF32 generates an underflow condition.
- LVF = 1 if MEINVF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

MEINVF32 MRa, MRb (continued)

32-Bit Floating-Point Reciprocal Approximation

Example

```
; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;
;_Cla1Task1:
  MMOV32 MR1, @_Den      ; MR1 = Den
  MEINVF32 MR2, MR1      ; MR2 = Ye = Estimate(1/Den)
  MPMYF32 MR3, MR2, MR1  ; MR3 = Ye*Den
  MSUBF32 MR3, #2.0, MR3  ; MR3 = 2.0 - Ye*Den
  MPMYF32 MR2, MR2, MR3  ; MR2 = Ye = Ye*(2.0 - Ye*Den)
  MPMYF32 MR3, MR2, MR1  ; MR3 = Ye*Den
| | MMOV32 MR0, @_Num     ; MR0 = Num
  MSUBF32 MR3, #2.0, MR3  ; MR3 = 2.0 - Ye*Den
  MPMYF32 MR2, MR2, MR3  ; MR2 = Ye = Ye*(2.0 - Ye*Den)
| | MMOV32 MR1, @_Den     ; Reload Den To Set Sign
  MNEGF32 MR0, MR0, EQ    ; if(Den == 0.0) Change Sign of Num
  MPMYF32 MR0, MR2, MR0   ; MR0 = Y = Ye*Num
  MMOV32 @_Dest, MR0      ; Store result
  MSTOP                  ; end of task
```

MEISQRTF32 MRa, MRb**32-Bit Floating-Point Square-Root Reciprocal Approximation****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0100 0000
```

Description

This operation generates an estimate of $1/\sqrt{X}$ in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/sqrt(X));
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
```

After 2 iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEISQRTF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/sqrt (MRb);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEISQRTF32 generates an underflow condition.
- LVF = 1 if MEISQRTF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

MF32TOUI16R MRa, MRb
Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer and Round
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1100 0000
```

Description

Convert the 32-bit floating-point value in MRb to an unsigned 16-bit integer and round to the closest even value. The result is stored in MRa. To instead truncate the converted value, use the MF32TOUI16 instruction.

```
MRa(15:0) = MF32TOUI16round(MRb);
MRa(31:16) = 0x0000;
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ      MR0, #0x412C    ; MR0 = 0x412C
MMOVXI      MR0, #0xCCCCD   ; MR0 = 0xCCCCD ; MR0 = 10.8 (0x412CCCCD)
MF32TOUI16R MR1, MR0        ; MR1(15:0) = MF32TOUI16round(MR0) = 11 (0x000B)
                                ; MR1(31:16) = 0x0000
MMOVF32     MR2, #-10.8     ; MR2 = -10.8 (0x0xc12CCCCD)
MF32TOUI16R MR3, MR2        ; MR3(15:0) = MF32TOUI16round(MR2) = 0 (0x0000)
                                ; MR3(31:16) = 0x0000
```

MF32TOUI32 MRa, MRb
Convert 32-Bit Floating-Point Value to 32-Bit Unsigned Integer
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 1010 0000
```

Description

Convert the 32-bit floating-point value in MRb to an unsigned 32-bit integer and store the result in MRa.

```
MRa = F32TOUI32(MRb);
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR0, #12.5 ; MR0 = 12.5 (0x41480000)
MF32TOUI32 MR0, MR0  ; MR0 = MF32TOUI32 (MR0) = 12 (0x0000000c)
MMOVIZ    MR1, #-6.5 ; MR1 = -6.5 (0xc0d00000)
MF32TOUI32 MR2, MR1  ; MR2 = MF32TOUI32 (MR1) = 0.0 (0x00000000)
```

MFRACF32 MRa, MRb
Fractional Portion of a 32-Bit Floating-Point Value
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0000 0000
```

Description

Returns in MRa the fractional portion of the 32-bit floating-point value in MRb

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR2, #19.625 ; MR2 = 19.625 (0x419D0000)
MFRACF32  MR3, MR2     ; MR3 = MFRACF32(MR2) = 0.625 (0x3F200000)0
```

MI16TOF32 MRa, MRb

Convert 16-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1000 0000
```

Description

Convert the 16-bit signed integer in MRb to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI16TOF32(MRb);
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR0, #0x0000    ; MR0(31:16) = 0.0 (0x0000)
MMOVXI    MR0, #0x0004    ; MR0(15:0) = 4.0 (0x0004)
MI16TOF32 MR1, MR0        ; MR1 = MI16TOF32 (MR0) = 4.0 (0x40800000)
MMOVIZ    MR2, #0x0000    ; MR2(31:16) = 0.0 (0x0000)
MMOVXI    MR2, #0xFFFC    ; MR2(15:0) = -4.0 (0xFFFC)
MI16TOF32 MR3, MR2        ; MR3 = MI16TOF32 (MR2) = -4.0 (0xc0800000)
MSTOP
```

MI16TOF32 MRa, mem16
Convert 16-Bit Integer to 32-Bit Floating-Point Value
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location to be converted

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 00aa addr
```

Description

Convert the 16-bit signed integer indicated by the mem16 pointer to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI16TOF32[mem16];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction:

Example

```
; Assume A = 4 (0x0004)
; B = -4 (0xFFFC)
MI16TOF32 MR0, @_A ; MR0 = MI16TOF32(A) = 4.0 (0x40800000)
MI16TOF32 MR1, @_B ; MR1 = MI16TOF32(B) = -4.0 (0xc0800000)
```

MLSL32 MRa, #SHIFT

Logical Shift Left

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1100 0000
```

Description

Logical shift-left of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Logical Shift Left(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given m2 = (int32)32
; x2 = (int32)64
; b2 = (int32)-128
;
; calculate:
; m2 = m2*2
; x2 = x2*4
; b2 = b2*8
;
_cla1Task3:
    MMIOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
    MMIOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
    MMIOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFF80)
    MLSL32 MR0, #1 ; MR0 = 64 (0x00000040)
    MLSL32 MR1, #2 ; MR1 = 256 (0x00000100)
    MLSL32 MR2, #3 ; MR2 = -1024 (0xFFFFFC00)
    MMIOV32 @_m2, MR0 ; Store results
    MMIOV32 @_x2, MR1
    MMIOV32 @_b2, MR2
    MSTOP ; end of task
```

MLSL32 MRa, #SHIFT (continued)***Logical Shift Left***

MLSR32 MRa, #SHIFT**Logical Shift Right****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1000 0000
```

Description

Logical shift-right of MRa by the number of bits indicated. The number of bits can be 1 to 32. Unlike the arithmetic shift (MASR32), the logical shift does not preserve the number's sign bit. Every bit in the operand is moved the specified number of bit positions, and the vacant bit positions are filled in with zeros.

```
MARa(31:0) = Logical Shift Right(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Illustrate the difference between MASR32 and MLSR32
MMOVIZ MR0, #0xAAAA ; MR0 = 0xAAAA5555
MMOVXI MR0, #0x5555
MMOV32 MR1, MR0 ; MR1 = 0xAAAA5555
MMOV32 MR2, MR0 ; MR2 = 0xAAAA5555
MASR32 MR1, #1 ; MR1 = 0xD5552AAA
MLSR32 MR2, #1 ; MR2 = 0x55552AAA
MASR32 MR1, #1 ; MR1 = 0xEAAA9555
MLSR32 MR2, #1 ; MR2 = 0x2AAA9555
MASR32 MR1, #6 ; MR1 = 0xFFAAA555
MLSR32 MR2, #6 ; MR2 = 0x00AAA555
```

MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32
32-Bit Floating-Point Multiply and Accumulate with Parallel Move
Operands

MR3	floating-point destination/source register MR3 for the add operation
MR2	CLA floating-point source register MR2 for the add operation
MRd	CLA floating-point destination register (MR0 to MR3) for the multiply operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRf	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRa	CLA floating-point destination register for the MMOV32 operation (MR0 to MR3). MRa cannot be MR3 or the same register as MRd.
mem32	32-bit source for the MMOV32 operation

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0011 ffee ddaa addr
```

Description

Multiply and accumulate the contents of floating-point registers and move from register to memory. The destination register for the MMOV32 cannot be the same as the destination registers for the MMACF32.

```
MR3 = MR3 + MR2;
MRd = MRe * MRf;
MRa = [mem32];
```

Restrictions

The destination registers for the MMACF32 and the MMOV32 must be unique. That is, MRa cannot be MR3 and MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMACF32 (add or multiply) generates an underflow condition.
- LVF = 1 if MMACF32 (add or multiply) generates an overflow condition.

MMOV32 sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

Pipeline

MMACF32 and MMOV32 complete in a single cycle.

MMACF32 MR3, MR2, MRd, MRf ||MMOV32 MRa, mem32 (continued)

32-Bit Floating-Point Multiply and Accumulate with Parallel Move

MMAXF32 MRa, MRb**32-Bit Floating-Point Maximum****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0010 0000
```

Description

```
if(MRa < MRb) MRa = MRb;
```

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == MRb) {ZF=1; NF=0;}
if(MRa > MRb) {ZF=0; NF=0;}
if(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example 1

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBF000000)
MMAXF32 MR2, MR1 ; MR2 = -1.5, ZF = NF = 0
MMAXF32 MR1, MR2 ; MR1 = -1.5, ZF = 0, NF = 1
MMAXF32 MR2, MR0 ; MR2 = 5.0, ZF = 0, NF = 1
MAXF32 MR0, MR2 ; MR2 = 5.0, ZF = 1, NF = 0
```

MMAXF32 MRa, #16FHi**32-Bit Floating-Point Maximum****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0000 00aa
```

Description

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is larger, then load the value into MRa.

```
if(MRa < #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0) {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMAXF32 MR0, #5.5 ; MR0 = 5.5, ZF = 0, NF = 1
MMAXF32 MR1, #2.5 ; MR1 = 4.0, ZF = 0, NF = 0
MMAXF32 MR2, #-1.0 ; MR2 = -1.0, ZF = 0, NF = 1
MMAXF32 MR2, #-1.0 ; MR2 = -1.5, ZF = 1, NF = 0
```

MMOV16 MARx, MRa, #16I

Load the Auxiliary Register with MRa + 16-bit Immediate Value

Operands

MARx	Auxiliary register MAR0 or MAR1
MRa	CLA Floating-point register (MR0 to MR3)
#16I	16-bit immediate value

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR0, MRa, #16I)
MSW: 0111 1111 1101 00AA
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR1, MRa, #16I)
MSW: 0111 1111 1111 00AA
```

Description

Load the auxiliary register, MAR0 or MAR1, with MRa(15:0) + 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARx = MRa(15:0) + #16I;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- I1 and I2**

The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #_X.

- I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOV16.

```
; Assume MAR0 is 50, MR0 is 10, and #_X is 20
MMOV16 MAR0, MR0, #_X ; Load MAR0 with address of x (20) + MR0 (10)
<Instruction 1> ; I1 Uses the old value of MAR0 (50)
<Instruction 2> ; I2 Uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 Uses the new value of MAR0 (30)
<Instruction 5> ; I5
```

```

Description

Load MAR0 or MAR1 with the 16-bit value pointed to by mem16. Refer to the Pipeline section for important information regarding this instruction.

```
MAR1 = [mem16];
```

Flags

No flags MSTF flags are affected.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- I1 and I2**

The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #_X.

- I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOV16.

```

; Assume MAR0 is 50 and @_X is 20
MMOV16 MAR0, @_X ; Load MAR0 with the contents of x (20)
<Instruction 1> ; I1 Uses the old value of MAR0 (50)
<Instruction 2> ; I2 Uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 Uses the new value of MAR0 (20)
<Instruction 5> ; I5
....

```

MMOV16 MARx, mem16 (continued)
Load MAR1 with 16-bit Value

MMOV16 mem16, MARx
Move 16-Bit Auxiliary Register Contents to Memory
Operands

mem16	16-bit destination memory accessed using one of the available addressing modes
MARx	CLA auxiliary register MAR0 or MAR1

Opcode

```

LSW: mmmm mmmm mmmm mmmm (Opcode for MMOV16 mem16, MAR0)
MSW: 0111 0110 1000 addr
LSW: mmmm mmmm mmmm mmmm (Opcode for MMOV16 mem16, MAR1)
MSW: 0111 0110 1100 addr

```

Description

Store the contents of MAR0 or MAR1 in the 16-bit memory location pointed to by mem16.

```
[mem16] = MAR0;
```

Flags

No flags MSTF flags are affected.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

MMOV16 mem16, MRa
Move 16-Bit Floating-Point Register Contents to Memory
Operands

mem16	16-bit destination memory accessed using one of the available addressing modes
MRa	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 11aa addr
```

Description

Move 16-bit value from the lower 16-bits of the floating-point register (MRa(15:0)) to the location pointed to by mem16.

```
[mem16] = MRa(15:0);
```

Flags

No flags MSTF flags are affected.

Pipeline

This is a single-cycle instruction.

MMOV16 mem16, MRa (continued)
Move 16-Bit Floating-Point Register Contents to Memory
Example

```

; This task logs the last NUM_DATA_POINTS
; ADCRESULT1 values in the array VoltageCLA
;
; when the last element in the array has been
; filled, the task goes back to the
; the first element.
;
; Before starting the ADC conversions, force
; Task 8 to initialize the ConversionCount to zero
;
; The ADC is set to sample (acquire) for 15 SYSCLK cycles
; or 75ns. After the capacitor has captured the analog
; value, the ADC triggers this task early.
; It takes 10.5 ADCCLKs to complete a conversion,
; the ADCCLK being SYSCLK/4
;   T_sys = 1/200MHz = 5ns
;   T_adc = 4*T_sys = 20ns
; The ADC takes 10.5 * 4 or 42 SYSCLK cycles to complete
; a conversion. The ADC result register can be read on the
; 36th instruction after the task begins.
;

[MMOV32 mem32, MSTF](#)

MMOV32 mem32, MSTF
Move 32-Bit MSTF Register to Memory
Operands

MSTF	Floating-point status register
mem32	32-bit destination memory

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0100 addr
```

Description

Copy the CLA floating-point status register, MSTF, to memory.

```
[mem32] = MSTF;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

One of the uses of this instruction is to save off the return PC (RPC) prior to calling a function. The decision to jump to a function is made when the MCCNDD is in the decode2 (D2) phase of the pipeline; the RPC is also updated in this phase. The actual jump occurs 3 cycles later when MCCNDD enters the execution (E) phase. You must save the old RPC before MCCNDD updates in the D2 phase; that is, save MSTF 3 instructions prior to the function call.

Example

The following example illustrates the pipeline flow for the context save (of the flags and RPC) prior to a function call. The first column in the comments shows the pipeline stages for the MMOV32 instruction while the second column pertains to the MCCNDD instruction.

```
MMOV32 @_temp, MSTF ; D2 | |
MNOP                 ; R1 | F1 | MCCNDD is fetched
MNOP                 ; R2 | F2 |
MNOP                 ; E  | D1 |
MCCNDD _bar, UNC     ; W  | D2 | old RPC written to memory,
                     ;    |   | RPC updated with MPC+1
MNOP                 ;    | R1 |
MNOP                 ;    | R2 |
MNOP                 ;    | E  | execution branches to _bar
```

[MMOV32 mem32, MRa](#)

MMOV32 MRa, mem32 {, CNDF}**Conditional 32-Bit Move****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes
CNDF	Optional condition

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 00cn dfaa addr
```

Description

If the condition is true, then move the 32-bit value referenced by mem32 to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = [mem32];
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
    NF = MRa(31);
    ZF = 0;
    if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
}
else No flags modified;
```

MMOV32 MRa, mem32 {, CNDF} (continued)

Conditional 32-Bit Move

Pipeline

This is a single-cycle instruction.

Example

```

; Given A, B, X, M1 and M2 are 32-bit floating-point numbers
;
; if(A == B) calculate Y = X*M1
; if(A != B) calculate Y = X*M2
;
_Cla1Task5:
    MMOV32    MR0, @_A
    MMOV32    MR1, @_B
    MCMPF32    MR0, MR1
    MMOV32    MR2, @_M1, EQ    ; if A == B, MR2 = M1
                                ; Y = M1*X
    MMOV32    MR2, @_M2, NEQ    ; if A != B, MR2 = M2
                                ; Y = M2*X

    MMOV32    MR3, @_X
    MPPYF32    MR3, MR2, MR3    ; Calculate Y
    MMOV32    @_Y, MR3          ; Store Y
    MSTOP
                                ; end of task

```

MRb	CLA floating-point source register (MR0 to MR3)
CNDF	Optional condition

Opcode

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1100 0000
```

Description

If the condition is true, then move the 32-bit value in MRb to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = MRb;
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
    NF = MRa(31); ZF = 0;
    if(MRa(30:23) == 0) {ZF = 1; NF = 0;}
}
else No flags modified;
```

MMOV32 MRa, MRb {, CNDF} (continued)

Conditional 32-Bit Move

Pipeline

This is a single-cycle instruction.

Example

```

; Given: X = 8.0
;         Y = 7.0
;         A = 2.0
;         B = 5.0
; _ClaTask1
MMOV32 MR3, @_X      ; MR3 = X = 8.0
MMOV32 MR0, @_Y      ; MR0 = Y = 7.0
MMAXF32 MR3, MR0      ; ZF = 0, NF = 0, MR3 = 8.0
MMOV32 MR1, @_A, GT   ; true, MR1 = A = 2.0
MMOV32 MR1, @_B, LT   ; false, does not load MR1
MMOV32 MR2, MR1, GT   ; true, MR2 = MR1 = 2.0
MMOV32 MR2, MR0, LT   ; false, does not load MR2
MSTOP

```

[MMOV32 MRa, mem32 {,CNDF}](#)

MMOV32 MSTF, mem32
Move 32-Bit Value from Memory to the MSTF Register
Operands

MSTF	CLA status register
mem32	32-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0000 addr
```

Description

Move from memory to the CLA's status register MSTF. This instruction is most useful when nesting function calls (using MCCNDD).

```
MSTF = [mem32];
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Loading the status register can overwrite all flags and the RPC field. The MEALLOW field is not affected.

Pipeline

This is a single-cycle instruction.

See also
[MMOV32 MRa, mem32 {,CNDF}](#)

MMOVF32 MRa, #32F

Load the 32-Bits of a 32-Bit Floating-Point Register

Operands

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex MMOVXI MRa, #16FLoHex
```

MRa	CLA floating-point destination register (MR0 to MR3)
#32F	Immediate float value represented in floating-point representation

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

Description

This instruction accepts the immediate operand only in floating-point representation. To specify the immediate value as a hex value (IEEE 32-bit floating-point format), use the MMOV32 MRa, #32FHex instruction.

Load the 32-bits of MRa with the immediate float value represented by #32F.

#32F is a float value represented in floating-point representation. The assembler only accepts a float value represented in floating-point representation. That is, 3.0 can only be represented as #3.0 (#0x40400000 results in an error).

```
MRa = #32F;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32F, this instruction takes one or two cycles. If all of the lower 16-bits of the IEEE 32-bit floating-point format of #32F are zeros, then the assembler converts MMOVF32 into only an MMOVIZ instruction. If the lower 16-bits of the IEEE 32-bit floating-point format of #32F are not zeros, then the assembler converts MMOVF32 into MMOVIZ and MMOVXI instructions.

Example

```
MMOVF32 MR1, #3.0      ; MR1 = 3.0 (0x40400000)
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR1, #0x4040
MMOVF32 MR2, #0.0      ; MR2 = 0.0 (0x00000000)
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR2, #0x0
MMOVF32 MR3, #12.265    ; MR3 = 12.625 (0x41443D71)
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR3, #0x4144
                        ; MMOVXI MR3, #0x3D71
```

MMOVF32 MRa, #32F (continued)

MMOVI16 MARx, #16I

Load the Auxiliary Register with the 16-Bit Immediate Value

Operands

MARx	Auxiliary register MAR0 or MAR1
#16I	16-bit immediate value

Opcode

```

LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR0, #16I)
MSW: 0111 1111 1100 0000
LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR1, #16I)
MSW: 0111 1111 1110 0000

```

Description

Load the auxiliary register, MAR0 or MAR1, with a 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARX = #16I;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The immediate load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- I1 and I2**

The two instructions following MMOVI16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #_X.

- I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOVI16.

```

; Assume MAR0 is 50 and #_X is 20
MMOVI16 MAR0, #_X          ; Load MAR0 with address of X (20)
<Instruction 1>             ; I1 Uses the old value of MAR0 (50)
<Instruction 2>             ; I2 Uses the old value of MAR0 (50)
<Instruction 3>             ; I3 Cannot use MAR0
<Instruction 4>             ; I4 Uses the new value of MAR0 (20)
<Instruction 5>             ; I5
....

```

MMOVI16 MARx, #16I (continued)
Load the Auxiliary Register with the 16-Bit Immediate Value
Table 8-18. Pipeline Activity for MMOVI16 MAR0/MAR1, #16I

Instruction	F1	F2	D1	D2	R1	R2	E	W
MMOVI16 MAR0, #_X	MMOVI16							
I1	I1	MMOVI16						
I2	I2	I1	MMOVI16					
I3	I3	I2	I1	MMOVI16				
I4	I4	I3	I2	I1	MMOVI16			
I5	I5	I4	I3	I2	I1	MMOVI16		
I6	I6	I5	I4	I3	I2	I1	MMOVI16	

MMOVI32 MRa, #32FHex

Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate

Operands

MRa	Floating-point register (MR0 to MR3)
#32FHex	A 32-bit immediate value that represents an IEEE 32-bit floating-point value.

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex
MMOVXI MRa, #16FLoHex
```

Opcode

```
LSW: I I I I I I I I I I (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0 1 1 1 1 0 0 0 0 1 0 0 0 0 a a
LSW: I I I I I I I I I I (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0 1 1 1 1 0 0 0 1 0 0 0 0 0 a a
```

Description

This instruction only accepts a hex value as the immediate operand. To specify the immediate value with a floating-point representation, use the MMOVF32 MRa, #32F instruction.

Load the 32-bits of MRa with the immediate 32-bit hex value represented by #32FHex.

#32FHex is a 32-bit immediate hex value that represents the IEEE 32-bit floating-point value of a floating-point number. The assembler only accepts a hex immediate value. That is, 3.0 can only be represented as #0x40400000 (#3.0 results in an error).

```
MRa = #32FHex;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32FHex, this instruction takes one or two cycles. If all of the lower 16-bits of #32FHex are zeros, then the assembler converts MOVIZ to an MMOVIZ instruction. If the lower 16-bits of #32FHex are not zeros, then the assembler converts MOVIZ to MMOVIZ and MMOVXI instructions.

MMOVI32 MRa, #32FHex (continued)
Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate
Example

```

MMOVI32  MR1, #0x40400000 ; MR1 = 0x40400000
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR1, #0x4040
MMOVI32  MR2, #0x00000000 ; MR2 = 0x00000000
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR2, #0x0
MMOVI32  MR3, #0x40004001 ; MR3 = 0x40004001
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR3, #0x4000
                        ; MMOVXI MR3, #0x4001
MMOVI32  MR0, #0x00004040 ; MR0 = 0x00004040
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR0, #0x0000
                        ; MMOVXI MR0, #0x4040

```

MMOVIZ MRa, #16FHi
Load the Upper 16-Bits of a 32-Bit Floating-Point Register
Operands

MRa	Floating-point register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0100 00aa
```

Description

Load the upper 16-bits of MRa with the immediate value #16FHi and clear the low 16-bits of MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. The assembler only accepts a decimal or hex immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

MMOVIZ is useful for loading a floating-point register with a constant in which the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). If a constant requires all 32-bits of a floating-point register to be initialized, then use MMOVIZ along with the MMOVXI instruction.

```
MRa(31:16) = #16FHi;
MRa(15:0) = 0;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Load MR0 and MR1 with -1.5 (0xBFC00000)
MMOVIZ MR0, #0xBFC0      ; MR0 = 0xBFC00000 (1.5)
MMOVIZ MR1, #-1.5        ; MR1 = -1.5 (0xBFC00000)
; Load MR2 with pi = 3.141593 (0x40490FDB)
MMOVIZ MR2, #0x4049      ; MR2 = 0x40490000
MMOVXI MR2, #0x0FDB      ; MR2 = 0x40490FDB
```

MMOVZ16 MRa, mem16
Load MRx with 16-Bit Value
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 10aa addr
```

Description

Move the 16-bit value referenced by mem16 to the floating-point register indicated by MRa.

```
MRa(31:16) = 0;
MRa(15:0) = [mem16];
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = 0;
if (MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

MMOVXI MRa, #16FLoHex
Move Immediate Value to the Lower 16-Bits of a Floating-Point Register
Operands

MRa	CLA floating-point register (MR0 to MR3)
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits are not modified.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1000 00aa
```

Description

Load the lower 16-bits of MRa with the immediate value #16FLoHex. #16FLoHex represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits of MRa are not modified. MMOVXI can be combined with the MMOVIZ instruction to initialize all 32-bits of a MRa register.

```
MRa(15:0) = #16FLoHex;
MRa(31:16) = Unchanged;
```

Flags

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Load MR0 with pi = 3.141593 (0x40490FDB)
MMOVIZ    MR0,#0x4049    ; MR0 = 0x40490000
MMOVXI    MR0,#0x0FDB    ; MR0 = 0x40490FDB
```

MMPYF32 MRa, MRb, MRc**32-Bit Floating-Point Multiply****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0000 0000
```

Description

Multiply the contents of two floating-point registers.

```
MRa = MRb * MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)

MMPYF32 MRa, #16FHi, MRb

32-Bit Floating-Point Multiply

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1000 bbaa
```

Description

Multiply MRb with the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb * #16FHi:0;
```

This instruction can also be written as MMPYF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
; Same as example 2 but #16FHi is represented in float

MMPYF32 MRa, MRb, #16FHi

32-Bit Floating-Point Multiply

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1000 bbaa
```

Description

Multiply MRb with the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb * #16FHi:0;
```

This instruction can also be written as MMPYF32 MRa, #16FHi, MRb.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
;Same as example 2 but #16FHi is represented in float

32-Bit Floating-Point Multiply with Parallel Add

Operands

MRa	CLA floating-point destination register for MMPYF32 (MR0 to MR3) MRa cannot be the same register as MRd
MRb	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRC	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRd	CLA floating-point destination register for MADDF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for MADDF32 (MR0 to MR3)

Opcode

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

Description

Multiply the contents of two floating-point registers with parallel addition of two registers.

```
MRa = MRb * MRC;
MRd = MRe + MRf;
```

Restrictions

The destination register for the MMPYF32 and the MADDF32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 or MADDF32 generates an underflow condition.
- LVF = 1 if MMPYF32 or MADDF32 generates an overflow condition.

Pipeline

Both MMPYF32 and MADDF32 complete in a single cycle.

MMPYF32 MRa, MRb, MRc||MADDF32 MRd, MRe, MRf (continued)

32-Bit Floating-Point Multiply with Parallel Add

Example

```

; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating-point arrays
;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1
; 3rd multiply: C = X2 * Y2
; 4th multiply: D = X3 * Y3
; 5th multiply: E = X3 * Y3
;
; Result = A + B + C + D + E
;
_Cla1Task1:
    MMOV16    MAR0, #_X          ; MAR0 points to X array
    MMOV16    MAR1, #_Y          ; MAR1 points to Y array
    MNOP                      ; Delay for MAR0, MAR1 load
    MNOP                      ; Delay for MAR0, MAR1 load
    ; <-- MAR0 valid
    MMOV32    MR0, *MAR0[2]++    ; MR0 = X0, MAR0 += 2
    ; <-- MAR1 valid
    MMOV32    MR1, *MAR1[2]++    ; MR1 = Y0, MAR1 += 2
    MMPYF32    MR2, MR0, MR1      ; MR2 = A = X0 * Y0
    || MMOV32    MR0, *MAR0[2]++    ; In parallel MR0 = X1, MAR0 += 2
    MMOV32    MR1, *MAR1[2]++    ; MR1 = Y1, MAR1 += 2
    MMPYF32    MR3, MR0, MR1      ; MR3 = B = X1 * Y1
    || MMOV32    MR0, *MAR0[2]++    ; In parallel MR0 = X2, MAR0 += 2
    MMOV32    MR1, *MAR1[2]++    ; MR1 = Y2, MAR2 += 2
    MMACF32    MR3, MR2, MR2, MR0, MR1 ; MR3 = A + B, MR2 = C = X2 * Y2
    || MMOV32    MR0, *MAR0[2]++    ; In parallel MR0 = X3
    MMOV32    MR1, *MAR1[2]++    ; MR1 = Y3
    MMACF32    MR3, MR2, MR2, MR0, MR1 ; MR3 = (A + B) + C, MR2 = D = X3 * Y3
    || MMOV32    MR0, *MAR0[2]++    ; In parallel MR0 = X4
    MMOV32    MR1, *MAR1[2]++    ; MR1 = Y4
    MMPYF32    MR2, MR0, MR1      ; MR2 = E = X4 * Y4
    || MADDF32    MR3, MR3, MR2    ; in parallel MR3 = (A + B + C) + D
    ; MR3 = (A + B + C + D) + E
    MMOV32    @_Result, MR3      ; Store the result
    MSTOP                      ; end of task

```

MMPYF32 MRd, MRe, MRf ||MMOV32 MRa, mem32
32-Bit Floating-Point Multiply with Parallel Move
Operands

MRd	CLA floating-point destination register for MMPYF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRf	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRa	CLA floating-point destination register for MMOV32 (MR0 to MR3) MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source of MMOV32.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0000 ffee ddaa addr
```

Description

Multiply the contents of two floating-point registers and load another.

```
MRd = MRe * MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MMPYF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register..

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

Pipeline

Both MMPYF32 and MMOV32 complete in a single cycle.

Example 1

```
; Given M1, X1, and B1 are 32-bit floating point
; Calculate Y1 = M1*X1+B1
;
_ClalTask1:
    MMOV32    MR0, @M1      ; Load MR0 with M1

```

MOR32 MRa, MRb, MRc

Bitwise OR

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1000 0000
```

Description

Bitwise OR of MRb with MRc.

```
MARa(31:0) = MARb(31:0) OR MRC(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI MR0, #0xAAAA
MMOVIZ MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI MR1, #0xFEDC
; 0101 OR 0101 = 0101 (5)

MRCNDD {CNDF}

Return Conditional Delayed

Operands

CNDF	Optional condition
------	--------------------

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1001 1010 cndf

Description

If the specified condition is true, then the RPC field of MSTF is loaded into MPC and fetching continues from that location. Otherwise, program fetches continue without the return.

Refer to the Pipeline section for important information regarding this instruction.

if (CNDF == TRUE) MPC = RPC;

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MRCNDD instruction is a single-cycle instruction. As shown in [Table 8-19](#), 6 instruction slots are executed for each return; 3 slots before the return instruction (d5-d7) and 3 slots after the return instruction (d8-d10). The total number of cycles for a return taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled.

MRCNDD {CNDF} (continued)
Return Conditional Delayed

The effective number of cycles for a return can, therefore, range from 1 to 7 cycles. The number of cycles for a return taken cannot be the same as for a return not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 8-19](#) and [Table 8-20](#), the instructions before and after MRCNDD have the following properties:

```

;
;
<Instruction 1>    ; I1 Last instruction that can affect flags for
                  ; the MCCNDD operation
<Instruction 2>    ; I2 Cannot be stop, branch, call or return
<Instruction 3>    ; I3 Cannot be stop, branch, call or return
<Instruction 4>    ; I4 Cannot be stop, branch, call or return
MCCNDD _func, NEQ  ; Call to func if not equal to zero
                  ; Three instructions after MCCNDD are always
                  ; executed whether the call is taken or not
<Instruction 5>    ; I5 Cannot be stop, branch, call or return
<Instruction 6>    ; I6 Cannot be stop, branch, call or return
<Instruction 7>    ; I7 Cannot be stop, branch, call or return
<Instruction 8>    ; I8 The address of this instruction is saved
                  ; in the RPC field of the MSTF register.
                  ; Upon return this value is loaded into MPC
                  ; and fetching continues from this point.
<Instruction 9>    ; I9

```

- **d4**
 - d4 is the last instruction that can effect the CNDF flags for the MRCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to return or not when MRCNDD is in the D2 phase.
 - There are no restrictions on the type of instruction for d4.
- **d5, d6, and d7**
 - The three instructions proceeding MRCNDD can change MSTF flags but have no effect on whether the MRCNDD instruction makes the return or not. This is because the flag modification occurs after the D2 phase of the MRCNDD instruction.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **d8, d9, and d10**
 - The three instructions following MRCNDD are always executed irrespective of whether the return is taken or not.

MRCNDD {CNDF} (continued)
Return Conditional Delayed

- These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

MSETC BGINTM

Set Background Task Interrupt Mask

Operands

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0101 0000

Description

This instruction sets the background task interrupt mask (BGINTM) bit in the MSTSBGRND register, making any code thereafter uninterruptible. No other higher priority task is able to interrupt the background task until the BGINTM is cleared. This instruction sets the BGINTM bit at the end of the D2 phase.

This instruction does not require the MEALLOW bit to be asserted before, or de-asserted after, setting BGINTM.

Flags

This instruction does not modify the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

MSETC BGINTM	; Set the MSTSBGRND.BGINTM bit ; to prevent any other tasks from ; interrupting the background task
--------------	---

See also

[MCLRC BGINTM](#)

MSETFLG FLAG, VALUE

Set or Clear Selected Floating-Point Status Flags

Operands

FLAG	8-bit mask indicating which floating-point status flags to change.
VALUE	8-bit mask indicating the flag value: 0 or 1.

Opcode

```
LSW: FFFF FFFF VVVV VVVV
MSW: 0111 1001 1100 0000
```

Description

The MSETFLG instruction is used to set or clear selected floating-point status flags in the MSTF register. The FLAG field is an 11-bit value that indicates which flags are changed. That is, if a FLAG bit is set to 1, that flag is changed; all other flags are not modified. The bit mapping of the FLAG field is:

9	8	7	6	5	4	3	2	1	0
RNDF 32	Reserved		TF	Reserved		ZF	NF	LUF	LVF

The VALUE field indicates the value the flag can be set to: 0 or 1.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Any flag can be modified by this instruction. The MEALLOW and RPC fields cannot be modified with this instruction.

Pipeline

This is a single-cycle instruction.

Example

To make it easier and legible, the assembler accepts a FLAG=VALUE syntax for the MSETFLG operation as:

```
MSETFLG RNDF32=0, TF=0, NF=1; FLAG = 11000100; VALUE = 00XXX1XX;
```

MSTOP

Stop Task

Operands

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1000 0000

Description

The MSTOP instruction must be placed to indicate the end of each task. In addition, placing MSTOP in unused memory locations within the CLA program RAM can be useful for debugging and preventing run away CLA code. When MSTOP enters the D2 phase of the pipeline, the MIRUN flag for the task is cleared and the associated interrupt is flagged in the PIE vector table.

There are three special cases that can occur when single-stepping a task such that the MPC reaches the MSTOP instruction.

1. If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if you continue to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.
2. In this case, you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if you continue to single-step through the MSTOP instruction of "task A". It depends on exactly when the new task comes in. To reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B".
3. Case 2 can be handled slightly differently if there is control over when "task B" comes in (for example using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B", run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

Restrictions

The MSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

MSTOP (continued)

Stop Task

Pipeline

This is a single-cycle instruction. [Table 8-21](#) shows the pipeline behavior of the MSTOP instruction. The MSTOP instruction cannot be placed with 3 instructions of a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

Table 8-21. Pipeline Activity for MSTOP

MSUB32 MRa, MRb, MRc

32-Bit Integer Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1110 0000
```

Description

32-bit integer addition of MRb and MRc.

```
MARa(31:0) = MARb(31:0) - MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
;         B = (int32)2
;         C = (int32)-7
;
; Calculate Y2 = A - B - C
;
_Cla1Task3:
    MMOV32    MR0, @_A        ; MR0 = 1 (0x00000001)
    MMOV32    MR1, @_B        ; MR1 = 2 (0x00000002)
    MMOV32    MR2, @_C        ; MR2 = -7 (0xFFFFFFFF9)
    MSUB32    MR3, MR0, MR1    ; A + B
    MSUB32    MR3, MR3, MR2    ; A + B + C = 6 (0x00000006)
    MMOV32    @_y2, MR3       ; Store y2
    MSTOP
```

MSUBF32 MRa, MRb, MRc**32-Bit Floating-Point Subtraction****Operands**

MRa	CLA floating-point destination register (MR0 to R1)
MRb	CLA floating-point source register (MR0 to R1)
MRc	CLA floating-point source register (MR0 to R1)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0100 0000
```

Description

Subtract the contents of two floating-point registers

```
MRa = MRb - MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = A + B - C
;
;_Cla1Task5:
  MMOV32  MR0, @_A      ; Load MR0 with A

MSUBF32 MRa, #16FHi, MRb
32-Bit Floating-Point Subtraction
Operands

MRa	CLA floating-point destination register (MR0 to R1)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to R1)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0000 baaa
```

Description

Subtract MRb from the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = #16FHi:0 - MRb;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

MSUBF32 MRa, #16FHi, MRb (continued)

MSUBF32 MRd, MRe, MRf ||MMOV32 MRa, mem32
32-Bit Floating-Point Subtraction with Parallel Move
Operands

MRd	CLA floating-point destination register (MR0 to MR3) for the MSUBF32 operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRf	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRa	CLA floating-point destination register (MR0 to MR3) for the MMOV32 operation MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. Source for the MMOV32 operation.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0010 ffee ddaa addr
```

Description

Subtract the contents of two floating-point registers and move from memory to a floating-point register.

```
MRd = MRe - MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MSUBF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags.

Pipeline

Both MSUBF32 and MMOV32 complete in a single cycle.

Example

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

MSWAPF MRa, MRb {, CNDF}
Conditional Swap
Operands

MRa	CLA floating-point register (MR0 to MR3)
MRb	CLA floating-point register (MR0 to MR3)
CNDF	Optional condition tested based on the MSTF flags

Opcode

```
LSW: 0000 0000 CNDF bbaa
MSW: 0111 1011 0000 0000
```

Description

Conditional swap of MRa and MRb.

```
if (CNDF == true) swap MRa and MRb;
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected

Pipeline

This is a single-cycle instruction.

MSWAPF MRa, MRb {, CNDF} (continued)

```

MTESTTF CNDF

Test MSTF Register Flag Condition

Operands

CNDF	Condition to test based on MSTF flags
------	---------------------------------------

Opcode

```
LSW: 0000 0000 0000 cndf
MSW: 0111 1111 0100 0000
```

Description

Test the CLA floating-point condition and if true, set the MSTF[TF] flag. If the condition is false, clear the MSTF[TF] flag. This is useful for temporarily storing a condition for later use.

```
if (CNDF == true) TF = 1;
else TF = 0;
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	No	No	No	No

```
TF = 0;
if (CNDF == true) TF = 1;
```

Note: If (CNDF == UNC or UNCF), the TF flag is set to 1.

Pipeline

This is a single-cycle instruction.

MTESTTF CNDF (continued)
Test MSTF Register Flag Condition
Example

```

; if (State == 0.1)
;   RampState = RampState || RAMPMASK
; else if (State == 0.01)
;   CoastState = CoastState || COASTMASK
; else
;   SteadyState = SteadyState || STEADYMASK
;
_Cla1Task2:
  MMOV32    MR0, @_State
  MCMPF32   MR0, #0.1           ; Affects flags for 1st MBCNDD (A)
  MCMPF32   MR0, #0.01          ; Check used by 2nd MBCNDD (B)
  MTESTTF   EQ                  ; Store EQ flag in TF for 2nd MBCNDD (B)
  MNOP
  MBCNDD    _Skip1, NEQ          ; (A) If State != 0.1, go to Skip1
  MMOV32    MR1, @_RampState     ; Always executed
  MMOVXI    MR2, #RAMPMASK       ; Always executed
  MOR32     MR1, MR2             ; Always executed
  MMOV32    @_RampState, MR1     ; Execute if (A) branch not taken
  MSTOP     ; end of task if (A) branch not taken
_Skip1:
  MMOV32    MR3, @_SteadyState
  MMOVXI    MR2, #STEADYMASK
  MOR32     MR3, MR2
  MBCNDD    _Skip2, NTF          ; (B) if State != .01, go to Skip2

  MMOV32    @_CoastState, MR1    ; Execute if (B) branch not taken
  MSTOP     ; end of task if (B) branch not taken
_Skip2:
  MMOV32    @_SteadyState, MR3    ; Executed if (B) branch taken
  MSTOP

```

MUI16TOF32 MRa, mem16
Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 01aa addr
```

Description

When converting F32 to I16/UI16 data format, the MF32TOI16/UI16 operation truncates to zero while the MF32TOI16R/UI16R operation rounds to the nearest (even) value.

```
MRa = UI16TOF32[mem16];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

MUI16TOF32 MRa, MRb
Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1110 0000
```

Description

Convert an unsigned 16-bit integer to a 32-bit floating-point value. When converting float32 to I16/UI16 data format, the MF32TOI16/UI16 operation truncates to zero while the MF32TOI16R/UI16R operation rounds to the nearest (even) value.

```
MRa = UI16TOF32[MRb];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVXI MR1, #0x800F ; MR1(15:0) = 32783 (0x800F)
MUI16TOF32 MR0, MR1 ; MR0 = UI16TOF32 (MR1(15:0))
                    ; = 32783.0 (0x47000F00)
```

MXOR32 MRa, MRb, MRc

Bitwise Exclusive Or

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1010 0000
```

Description

Bitwise XOR of MRb with MRc.

```
MARa(31:0) = MARb(31:0) XOR MRC(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI MR0, #0xAAAA
MMOVIZ MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI MR1, #0xFEDC
; 0101 XOR 0101 = 0000 (0)
; 0101 XOR 0100 = 0001 (1)
; 0101 XOR 0011 = 0110 (6)
; 0101 XOR 0010 = 0111 (7)
; 1010 XOR 1111 = 0101 (5)
; 1010 XOR 1110 = 0100 (4)
; 1010 XOR 1101 = 0111 (7)
; 1010 XOR 1100 = 0110 (6)
MXOR32 MR2, MR1, MR0 ; MR3 = 0x01675476

8.8 CLA Registers

This section describes the Control Law Accelerator registers.

8.8.1 CLA Base Address Table (C28)

Table 8-22. CLA Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
Cla1Regs	CLA_REGS	CLA1_BASE	0x0000_1400	YES	YES	-	-	-

8.8.2 CLA_ONLY_REGS Registers

Table 8-23 lists the memory-mapped registers for the CLA_ONLY_REGS registers. All register offset addresses not listed in Table 8-23 should be considered as reserved locations and the register contents should not be modified.

Table 8-23. CLA_ONLY_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
80h	_MVECTBGRNDACTIVE	Active register for MVECTBGRND.	EALLOW	Go
C0h	_MPSACTL	CLA PSA Control Register	EALLOW	Go
C2h	_MPSA1	CLA PSA1 Register	EALLOW	Go
C4h	_MPSA2	CLA PSA2 Register	EALLOW	Go
E0h	SOFTINTEN	CLA Software Interrupt Enable Register		Go
E2h	SOFTINTFRC	CLA Software Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 8-24 shows the codes that are used for access types in this section.

Table 8-24. CLA_ONLY_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.8.2.1 _MVECTBGRNDACTIVE Register (Offset = 80h) [Reset = 0000h]

_MVECTBGRNDACTIVE is shown in [Figure 8-2](#) and described in [Table 8-25](#).

Return to the [Summary Table](#).

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

Figure 8-2. _MVECTBGRNDACTIVE Register

3	TASK4	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn
2	TASK3	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn
1	TASK2	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn
0	TASK1	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn

8.8.3 CLA_SOFTINT_REGS Registers

[Table 8-31](#) lists the memory-mapped registers for the CLA_SOFTINT_REGS registers. All register offset addresses not listed in [Table 8-31](#) should be considered as reserved locations and the register contents should not be modified.

Table 8-31. CLA_SOFTINT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SOFTINTEN	CLA Software Interrupt Enable Register		Go
2h	SOFTINTFRC	CLA Software Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. [Table 8-32](#) shows the codes that are used for access types in this section.

Table 8-32. CLA_SOFTINT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.8.3.1 SOFTINTEN Register (Offset = 0h) [Reset = 0000h]

SOFTINTEN is shown in [Figure 8-8](#) and described in [Table 8-33](#).

Return to the [Summary Table](#).

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA.

8.8.3.2 SOFTINTFRC Register (Offset = 2h) [Reset = 0000h]

SOFTINTFRC is shown in [Figure 8-9](#) and described in [Table 8-34](#).

Return to the [Summary Table](#).

Writing a value of 1 in a bit will generate the corresponding task interrupt. This register is only accessible by the CLA (not the CPU).

W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.8.4.1 MVECT1 Register (Offset = 0h) [Reset = 0000h]

MVECT1 is shown in [Figure 8-10](#) and described in [Table 8-37](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

Figure 8-10. MVECT1 Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED					IACKE	SOFTRESET	HARDRESET
R-0h					R/W-0h	R-0/W1S-0h	R-0/W1S-0h

Table 8-45. MCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	IACKE	R/W	0h	IACK Operation Enable Bit: Writing a '1' to this bit will enable the IACK operation for setting the MIFR bits in the same manner as the MIFRC register (write of '1' will set respective MIFR bit). At reset, this feature is disabled. This feature enables the C28 CPU to efficiently trigger a task. Note: IACK operation should ignore EALLOW status of C28 core when accessing the MIFRC register. Reset type: SYSRSn 0h (R/W) = The CLA ignores the IACK instruction. (default) 1h (R/W) = Enable the main CPU to use the IACK #16bit instruction to set MIFR bits in the same manner as writing to the MIFRC register. Each bit in the operand, #16bit, corresponds to a bit in the MIFRC register. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger a CLA task through software. Examples IACK #0x0001 Write a 1 to MIFRC bit 0 to force task 1 IACK #0x0003 Write a 1 to MIFRC bit 0 and 1 to force task 1 and task 2
1	SOFTRESET	R-0/W1S	0h	Soft Reset Bit: Writing a '1' to this bit will stop a current task, clear the RUN flag and also clear all bits in the MIER register. Writes of '0' are ignored and reads always return a '0'. Note: After issuing SOFTRESET command, user should wait at least 1 clock cycle before attempting to write to MIER register. Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 are ignored. 1h (R/W) = Writing a 1 will cause a soft reset of the CLA. This will stop the current task, clear the MIRUN flag and clear all bits in the MIER register. After a soft reset you must wait at least 1 SYSCLKOUT cycle before reconfiguring the MIER bits. If these two operations are done back-to-back then the MIER bits will not get set.
0	HARDRESET	R-0/W1S	0h	Hard Reset Bit: Writing a '1' to this bit will cause a HARD reset on the CLA. The behavior of a HARD reset is the same as a system reset SYSRSn on the CLA. Writes of '0' are ignored and reads always return a '0'. Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 are ignored. 1h (R/W) = Writing a 1 will cause a hard reset of the CLA. This will set all CLA registers to their default state.

8.8.4.10 _MVECTBGRNDACTIVE Register (Offset = 1Bh) [Reset = 0000h]

_MVECTBGRNDACTIVE is shown in [Figure 8-19](#) and described in [Table 8-46](#).

Return to the [Summary Table](#).

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

Figure 8-19. _MVECTBGRNDACTIVE Register

8.8.4.15 MIFR Register (Offset = 20h) [Reset = 0000h]

MIFR is shown in [Figure 8-24](#) and described in [Table 8-51](#).

Return to the [Summary Table](#).

Each bit in the interrupt flag register corresponds to a CLA task. The corresponding bit is automatically set when the task request is received from the peripheral interrupt. The bit can also be set by the main CPU writing to the MIFRC register or using the IACK instruction to start the task. To use the IACK instruction to begin a task first enable this feature in the MCTL register. If the bit is already set when a new peripheral interrupt is received, then the corresponding overflow bit will be set in the MIOVF register.

The corresponding MIFR bit is automatically cleared when the task begins execution. This will occur if the interrupt is enabled in the MIER register and no other higher priority task is pending. The bits can also be cleared manually by writing to the MICLR register. Writes to the MIFR register are ignored.

8.8.4.16 MIOVF Register (Offset = 21h) [Reset = 0000h]

MIOVF is shown in [Figure 8-25](#) and described in [Table 8-52](#).

Return to the [Summary Table](#).

Each bit in the overflow flag register corresponds to a CLA task. The bit is set when an interrupt overflow event has occurred for the specific task. An overflow event occurs when the MIFR register bit is already set when a new interrupt is received from a peripheral source. The MIOVF bits are only affected by peripheral interrupt events. They do not respond to a task request by the main CPU IACK instruction or by directly setting MIFR bits. The overflow flag will remain latched and can only be cleared by writing to the overflow flag clear (MICLROVF) register. Writes to the MIOVF register are ignored.

8.8.4.17 MIFRC Register (Offset = 22h) [Reset = 0000h]

MIFRC is shown in [Figure 8-26](#) and described in [Table 8-53](#).

Return to the [Summary Table](#).

The interrupt force register can be used by the main CPU to start tasks through software. Writing a 1 to a MIFRC bit will set the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0. The IACK #16bit operation can also be used to start tasks and has the same effect as the MIFRC register. To enable IACK to set MIFR bits you must first set the MCTL[IACKE] bit. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger CLA tasks through software.

8.8.4.18 MICLR Register (Offset = 23h) [Reset = 0000h]

MICLR is shown in [Figure 8-27](#) and described in [Table 8-54](#).

Return to the [Summary Table](#).

Normally bits in the MIFR register are automatically cleared when a task begins. The interrupt flag clear register can be used to instead manually clear bits in the interrupt flag (MIFR) register. Writing a 1 to a MICLR bit will clear the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0.

8.8.4.20 MIER Register (Offset = 25h) [Reset = 0000h]

MIER is shown in [Figure 8-29](#) and described in [Table 8-56](#).

Return to the [Summary Table](#).

Setting the bits in the interrupt enable register (MIER) allow an incoming interrupt or main CPU software to start the corresponding CLA task. Writing a 0 will block the task, but the interrupt request will still be latched in the flag register (MIFLG). Setting the MIER register bit to 0 while the corresponding task is executing will have no effect on the task. The task will continue to run until it hits the MSTOP instruction. When a soft reset is issued, the MIER bits are cleared. There should always be at least a 1 SYSCLKOUT delay between issuing the soft reset and reconfiguring the MIER bits.

8.8.4.21 MIRUN Register (Offset = 26h) [Reset = 0000h]

MIRUN is shown in [Figure 8-30](#) and described in [Table 8-57](#).

Return to the [Summary Table](#).

The interrupt run status register (MIRUN) indicates which task is currently executing. Only one MIRUN bit will ever be set to a 1 at any given time. The bit is automatically cleared when the task completes and the respective interrupt is fed to the peripheral interrupt expansion (PIE) block of the device. This lets the main CPU know when a task has completed. The main CPU can stop a currently running task by writing to the MCTL[SOFTRESET] bit. This will clear the MIRUN flag and stop the task. In this case no interrupt will be generated to the PIE.

8.8.4.25 _MSTF Register (Offset = 2Eh) [Reset = 00000000h]

_MSTF is shown in [Figure 8-34](#) and described in [Table 8-61](#).

Return to the [Summary Table](#).

The CLA status register (MSTF) reflects the results of different operations. These are the basic rules for the flags:

- Zero and negative flags are cleared or set based on:
- floating-point moves to registers
- the result of compare, minimum, maximum, negative and absolute value operations
- the integer result of operations such as MMOV16, MAND32, MOR32, MXOR32, MCMP32, MASR32, MLRS32
- Overflow and underflow flags are set by floating-point math instructions such as multiply, add, subtract and 1/x. These flags may also be connected to the peripheral interrupt expansion (PIE) block on your device. This can be useful for debugging underflow and overflow conditions within an application.

Chapter 9

Configurable Logic Block (CLB)

This chapter describes the features and operation of the configurable logic block (CLB) that is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions.

9.1 Introduction	1204
9.2 Description	1204
9.3 CLB Input/Output Connection	1208
9.4 CLB Tile	1227
9.5 CPU Interface	1245
9.6 DMA Access	1246
9.7 CLB Data Export Through SPI RX Buffer	1247
9.8 CLB Pipeline Mode	1248
9.9 Software	1249
9.10 CLB Registers	1254

9.1 Introduction

The configurable logic block (CLB) is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions. The CLB is able to enhance existing peripherals through a set of crossbar interconnections, which provide a high level of connectivity to existing control peripherals such as enhanced pulse width modulators (ePWM), enhanced capture modules (eCAP), and enhanced quadrature encoder pulse modules (eQEP). The crossbars also allow the CLB to be connected to external GPIO pins. In this way, the CLB can be configured to interact with device peripherals to perform small logical functions such as simple PWM generators, or to implement custom serial data exchange protocols.

The CLB peripheral is configured through the CLB tool. For more information on the CLB tool, available examples, application reports, and user's guide, refer to the following location in your C2000WARE package (C2000Ware_2_00_00_03 and higher): C2000WARE_INSTALL_LOCATION\utilities\clb_tool\clb_syscfg\doc

9.2 Description

The CLB subsystem contains a number of identical tiles. There are four such tiles in the CLB subsystem; other devices can contain more or fewer tiles. Tiles are numbered 1 to N, where N is the total tile count on the device. Each tile contains combinational and sequential logic blocks, as well as other dedicated hardware to be described later in this document. [Figure 9-1](#) shows the structure of the CLB subsystem in the device.

The tile contains the core logic, providing the logic reconfiguration capability. Each CLB tile is associated with a separate CPU interface, which contains the registers needed to control and configure the logic in the tile. The CPU interface also contains data transfer buffers that can be used as part of the configurable logic to exchange data with the rest of the device. [Figure 9-2](#) shows the connections between the tile, the CPU interface, and the device.

Figure 9-1. Block Diagram of the CLB Subsystem in the Device

Figure 9-2. Block Diagram of a CLB Tile and CPU Interface

9.2.1 CLB Clock

In this device, the CLB clock is called CLBx clock that can be enabled or disabled by SYSCTL_PERIPH_CLK_CLBx through the SysCtl_enablePeripheral function. The maximum frequency is 150MHz and the clock can be enabled and configured by modifying the CLBx clock.

Note

When clock frequencies are above 100MHz (for example, 150MHz), PIPELINE mode must be enabled.

Figure 9-3. CLB Clocking

The CLB TILE clock and CLB register clock can be in ASYNC/SYNC mode with the SYSCLK. An example CLB clock configuration is shown in Table 9-1. Check the device data sheet for details on clocking specifications.

Table 9-1. Example CLB Clocking Configuration

Clock	SYNC Mode (CLKMODECLBx = 0)	ASYNC Mode (CLKMODECLBx = 1)	
		TILECLKDIV = 1	TILECLKDIV = 0
CLB Register Clock	SYSCLK	SYSCLK	SYSCLK
CLB TILE Clock	SYSCLK	SYSCLK / 2	SYSCLK

Starting with CLB Type 2, a clock prescaler module is available. The prescaler module can generate a prescaled version of the CLB clock signal that can be used as an input to the CLB TILE's counter.

Note

The prescaler logic does not change the actual clocking speed of the CLB. The prescaler generates a strobe (that can toggle at the defined prescaled rate) that is made available as another input signal to the CLB logic and the strobe is only used when required.

The prescaler module is shown in Figure 9-4.

Figure 9-4. CLB Clock Prescaler

9.3 CLB Input/Output Connection

9.3.1 Overview

There are four instances of the CLB module in the device. Each CLB instance has a common set of input signals referred to as global input signals. Additionally, each CLB instance has a specific set of input signals that are unique to each instance, and are referred to as local input signals. Each of the eight inputs of a CLB can be chosen from any of the global input signals or the local input signals.

Note

Signals routed into the CLB using the XBAR must be synchronized within the CLB.

9.3.2 CLB Input Selection

Each CLB module has eight inputs that are applied to the reconfigurable logic cell. Each of these inputs can be selectively driven by a predefined set of signals. A two-level mux structure allows each input of each CLB instance to select a signal.

Figure 9-5. GPIO to CLB Tile Connections

A set of signals is common to all the CLB instances. These are referred to as global inputs in [Figure 9-6](#). A separate set of signals is unique to each instance of the CLB. These are referred to as local inputs in [Figure 9-6](#).

Registers CLB_LCL_MUX_SEL_1 and CLB_LCL_MUX_SEL_2 control the local mux selection for each of the eight inputs. The mux control registers CLB_GLBL_MUX_SEL_1 and CLB_GLBL_MUX_SEL_2 control the global mux selection for each of the eight inputs.

The local mux select value of 0 causes the selected global mux input signal to be connected to the corresponding CLB Input. For example, setting CLB_LCL_MUX_SEL_IN_0 = 0 and CLB_GLBL_MUX_SEL_IN_0 = 8 causes the global mux input number 8 to be connected to CLB Input 0. The input filter feature can be used to enable edge detection on the CLB inputs. The input filter feature can also synchronize the input with the CLB clock.

The global mux settings are shown in [Table 9-2](#) and [Table 9-3](#). The local input mux settings are shown in [Table 9-4](#) and [Table 9-5](#).

Figure 9-6. CLB Input Mux and Filter

[Figure 9-7](#) shows an example of how to use synchronization for an asynchronous signal, in this case the ePWM signal. [Figure 9-8](#) shows an instance of using input pipelining for a synchronous signal, which here is the ePWM TBCLK signal. Note that these two input configurations are not used simultaneously, and each have a cycle delay that adds to the input path.

Figure 9-7. CLB Input Synchronization Example

Figure 9-8. CLB Input Pipelining Example

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

If a signal in the following table indicates that synchronization is not required, as the signal is already synchronous, then pipelining is required and must be enabled using the PIPE bit in the CLB_INPUT_FILTER register. This pipelining adds a 1 CLB clock cycle delay to the input. This is not to be mistaken with the PIPELINE_EN bit in the CLB_LOAD_EN register, which controls pipelining of the CLB operations in the HLC and counter blocks. This PIPELINE_EN bit is also used when the device is run above 100MHz. Having synchronization and pipelining both enabled or both disabled is not recommended. Enabling both synchronization and pipelining introduces a delay of more than 2-3 CLB clock cycles on the signal path. Disabling both allows the completely asynchronous signal to be routed as an input.

Table 9-2. Global Signals and Mux Selection

121	SPIC_SOMI_IN	SPIC_SOMI_IN	SPIC_SOMI_IN	SPIC_SOMI_IN	Enable
122	SPIC_STE_OUT	SPIC_STE_OUT	SPIC_STE_OUT	SPIC_STE_OUT	Enable
123	SPID_CLK_OUT	SPID_CLK_OUT	SPID_CLK_OUT	SPID_CLK_OUT	Enable
124	SPID_SOMI_IN	SPID_SOMI_IN	SPID_SOMI_IN	SPID_SOMI_IN	Enable
125	SPID_STE_OUT	SPID_STE_OUT	SPID_STE_OUT	SPID_STE_OUT	Enable
126	ECAT_SYNC0	ECAT_SYNC0	ECAT_SYNC0	ECAT_SYNC0	Disable
127	ECAT_SYNC1	ECAT_SYNC1	ECAT_SYNC1	ECAT_SYNC1	Disable

Note

EPWMxA_OE and EPWMxB_OE refer to trip outputs from the respective EPWM module.

EPWMxA_AQ and EPWMxB_AQ refer to the output of the AQ submodule in the respective EPWM module.

EPWMxA_DB and EPWMBx_DB refer to the output of the DB submodule in the respective EPWM module.

ECAT_SYNC0 and ECAT_SYNC1 must not be gated off, if EtherCAT is allocated to CM.

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.
