About This Manual

Channel decoding of voice and low bit-rate data channels found in third generation (3G) cellular standards requires decoding of convolutional encoded data. The Viterbi-decoder coprocessor 2 (VCP2) provided in the C6474 devices has been designed to perform Viterbi decoding for IS2000 and 3GPP wireless standards. The VCP2 coprocessor has been designed to perform forward-error correction for 2G and 3G wireless systems. The VCP2 coprocessor offers a very cost effective and synergistic solution when combined with Texas Instruments (TI) DSPs. The VCP2 supports 1941 12.2 Kbps class A 3G voice channels running at 333 MHz. This document describes the operation and programming of the VCP2.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers are shown with the suffix h. For example, the following number is 40 hexadecimal (decimal 64): 40h.
- Registers in this document are shown in figures and described in tables.
 - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties below. A legend explains the notation used for the properties.
 - Reserved bits in a register figure designate a bit that is used for future device expansion.
- The term "word" describes a 32-bit value.

TMS320C6474 Viterbi-Decoder Coprocessor 2

Channel decoding of voice and low bit-rate data channels found in cellular standards such as 2.5G, 3G, and WiMAX requires the decoding of convolutional encoded data. The Viterbi-decoder coprocessor 2 (VCP2) provided in the C6474 devices performs Viterbi decoding for IS2000 and 3GPP wireless standards. The VCP2 coprocessor also performs forward-error correction for 2G and 3G wireless systems. The VCP2 coprocessor offers a very cost effective and synergistic solution when combined with Texas Instruments (TI) DSPs. The VCP2 supports 1941 12.2 Kbps class A 3G voice channels running at 333 MHz.

1 Features

The VCP2 provides:

- High flexibility:
 - Variable constraint length, $K = 5, 6, 7, 8, \text{ or } 9$
 - User-supplied code coefficients
 - Code rates ($1/2, 1/3, \text{ or } 1/4$)
 - Configurable trace back settings (convergence distance, frame structure)
 - Branch metrics calculation and depuncturing done in software by the DSP
- System and development cost optimization:
 - The VCP2 releases DSP resources for other processing
 - Reduces board space and power consumption by performing on-chip decoding
 - Communication between the DSP and the VCP2 is performed through the high-performance EDMA3 engine
 - Uses its own optimized working memories
 - Provides debug capabilities during frame processing
 - Libraries are provided for reduced development time

2 Introduction

A convolutional code is generated by passing the information sequence to be transmitted through a linear finite-state shift register. The VCP2 is able to decode only a subset of those codes known as a single-shift register, nonrecursive convolutional code (an example is given in [Figure 1](#)). Important parameters for this type of codes are:

- The constraint length K (length of the delay line, the VCP2 supports K values from 5 to 9).
- The rate R given by $R = k/n$ where k is the number of information bits needed to produce n output bits also known as codewords (the VCP2 supports 1/2, 1/3, and 1/4 codes with rates).
- The generator polynomials G_n describe how the outputs are generated from the inputs.

Figure 1. Convolutional Encoder Example Block Diagram

NOTE: $K = 3$, $R = k/n = 1/3$, $G_0 = (100)_8$, $G_1 = (101)_8$, $G_2 = (111)_8$ 0/000 means input is 0, output0 is 0, output1 is 0, output2 is 0. There are $2^{(K-1)}$ states and 2^k incoming branches per state.

From the parameters, we can derive a trellis diagram providing a useful representation of the code, but whose complexity grows exponentially with the constraint length K . [Figure 2](#) shows the trellis diagram of the code from [Figure 1](#). The fact that there is a limited number of possible transitions from one state to another makes the code powerful and will be used in the decoding process.

As a maximum-likelihood sequence estimation (MLSE) decoder, the Viterbi decoder identifies the code sequence with the highest probability of matching the transmitted sequence based on the received sequence.

The Viterbi algorithm is composed of a metric update and a traceback routine. The metric update performs a forward recursion in the trellis over a finite number of symbol periods where probabilities are accumulated (the VCP2 accumulates on 13 bits) for each individual state based on the current input symbol (branch metric information). The accumulated metric is known as path metrics or state metrics. Once a path through the trellis is identified, the traceback routine performs a backward recursion in the trellis and outputs hard decisions or soft decisions.

Figure 2. Trellis Diagram for Convolutional Encoder Example

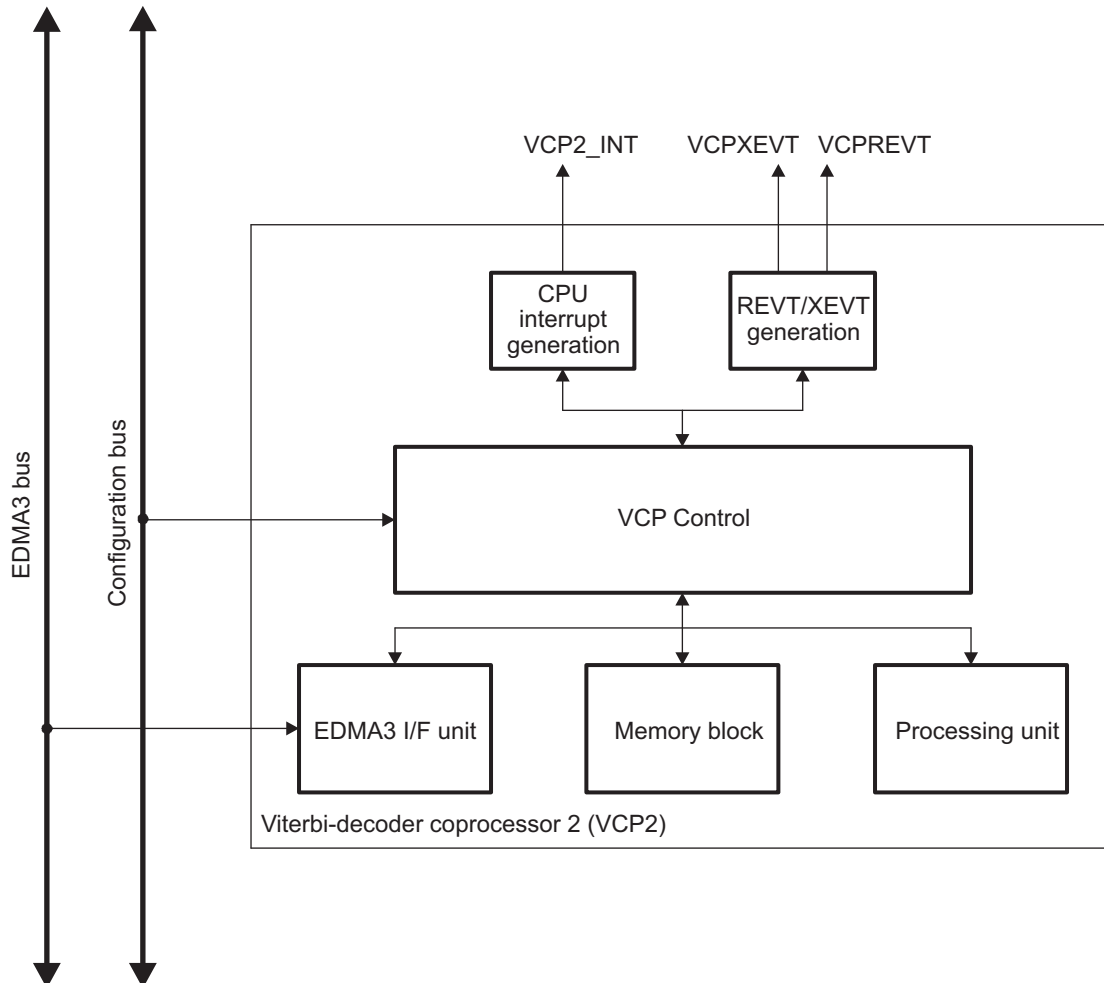

NOTE: $K = 3$, $R = k/n = 1/3$, $G_0 = (100)_8$, $G_1 = (101)_8$, $G_2 = (111)_8$ 0/000 means input is 0, output1 is 0, output2 is 0, output3 is 0. There are $2^{(K-1)}$ states and 2^k incoming branches per state.

3 Overview

The DSP controls the operation of the VCP2 (Figure 3) using memory-mapped registers. The DSP typically sends and receives data using synchronized EDMA3 transfers through the 64-bit EDMA3 bus. The VCP2 sends two synchronization events to the EDMA3: a receive event (VCPREVT) and a transmit event (VCPXEVT). The VCP2 input data corresponds to the branch metrics and the output data to the hard decisions or soft decisions.

Figure 3. VCP2 Block Diagram

4 Input Data

4.1 Branch Metrics Calculations

The branch metrics (BM) are calculated by the DSP and stored in the DSP memory subsystem as 8-bit signed values. Per symbol interval T , for a rate $R = k/n$ and a constraint length K , there are a total of 2^{K-1+k} branches in the trellis. For rate $1/n$ codes, only 2^{n-1} branch metrics need to be computed per symbol period and passed to the VCP2. Moreover, n symbols are required to calculate 1 branch metric.

Assuming BSPK modulated bits ($0 \rightarrow 1, 1 \rightarrow -1$), the branch metrics are calculated as follows:

- Rate 1/2: there are 2 branch metrics per symbol period
 - $BM_0(t) = r_0(t) + r_1(t)$
 - $BM_1(t) = r_0(t) - r_1(t)$

where $r(t)$ is the received codeword at time t (2 symbols, $r_0(t)$ is the symbol corresponding to the encoder upper branch, see [Figure 1](#)).

- Rate 1/3: there are 4 branch metrics per symbol period
 - $BM_0(t) = r_0(t) + r_1(t) + r_2(t)$
 - $BM_1(t) = r_0(t) + r_1(t) - r_2(t)$
 - $BM_2(t) = r_0(t) - r_1(t) + r_2(t)$
 - $BM_3(t) = r_0(t) - r_1(t) - r_2(t)$

where $r(t)$ is the received codeword (3 symbols, $r_0(t)$ is the symbol corresponding to the encoder upper branch, see [Figure 1](#)).

- Rate 1/4: there are 8 branch metrics per symbol period
 - $BM_0(t) = r_0(t) + r_1(t) + r_2(t) + r_3(t)$
 - $BM_1(t) = r_0(t) + r_1(t) + r_2(t) - r_3(t)$
 - $BM_2(t) = r_0(t) + r_1(t) - r_2(t) + r_3(t)$
 - $BM_3(t) = r_0(t) + r_1(t) - r_2(t) - r_3(t)$
 - $BM_4(t) = r_0(t) - r_1(t) + r_2(t) + r_3(t)$
 - $BM_5(t) = r_0(t) - r_1(t) + r_2(t) - r_3(t)$
 - $BM_6(t) = r_0(t) - r_1(t) - r_2(t) + r_3(t)$
 - $BM_7(t) = r_0(t) - r_1(t) - r_2(t) - r_3(t)$

where $r(t)$ is the received codeword (4 symbols, $r_0(t)$ is the symbol corresponding to the encoder upper branch, see [Figure 1](#)).

The data must be sent to the VCP2 as described in [Table 1](#), [Table 2](#), and [Table 3](#) for rates 1/2, 1/3, and 1/4, respectively (the base address must be double-word aligned).

The branch metrics can be saved in the DSP memory subsystem in either their native format or packed in words (user implementation). When working in big-endian mode, the VCP2 endian mode register (VCPEND) indicates if the data is 32-bit word packed or native 8-bit format and the VCP2 will handle the endianness byte swapping accordingly (see [Section 7](#)).

Table 1. Branch Metrics for Rate 1/2

| Address (hex) | Data | | | |
|---------------|--------------|--------------|--------------|--------------|
| | MSB | | | LSB |
| Base | $BM_1(t=T)$ | $BM_0(t=T)$ | $BM_1(t=0)$ | $BM_0(t=0)$ |
| Base + 4h | $BM_1(t=3T)$ | $BM_0(t=3T)$ | $BM_1(t=2T)$ | $BM_0(t=2T)$ |
| Base + 8h | ... | | | |

Table 2. Branch Metrics for Rate 1/3

| Address (hex) | Data | | | |
|---------------|-----------------------|-----------------------|-----------------------|-----------------------|
| | MSB | | | LSB |
| Base | BM ₃ (t=0) | BM ₂ (t=0) | BM ₁ (t=0) | BM ₀ (t=0) |
| Base + 4h | BM ₃ (t=T) | BM ₂ (t=T) | BM ₁ (t=T) | BM ₀ (t=T) |
| Base + 8h | ... | | | |

Table 3. Branch Metrics for Rate 1/4

| Address (hex) | Data | | | |
|---------------|-----------------------|-----------------------|-----------------------|-----------------------|
| | MSB | | | LSB |
| Base | BM ₃ (t=0) | BM ₂ (t=0) | BM ₁ (t=0) | BM ₀ (t=0) |
| Base + 4h | BM ₇ (t=0) | BM ₆ (t=0) | BM ₅ (t=0) | BM ₄ (t=0) |
| Base + 8h | BM ₃ (t=T) | BM ₂ (t=T) | BM ₁ (t=T) | BM ₀ (t=T) |
| Base + Ch | BM ₇ (t=T) | BM ₆ (t=T) | BM ₅ (t=T) | BM ₄ (t=T) |
| Base + 10h | ... | | | |

The state metric accumulation resolution is 13 bits on the VCP2. Consequently, full 8-bit dynamic range is available for branch metrics on the C6474 VCP2, for all constraint lengths and all code rates.

4.2 Soft Input Dynamic Ranges

The VCP2 implementation implies that the soft inputs need to be quantized so that the branch metrics satisfy the following bound B_1 (branch metrics upper bound - absolute value):

$$2^{(C-1)} - 1 \geq (2 \times (K-1) + 2) \times B_1$$

K is the constraint length and C determines the truncation of state metrics that can be performed without loss of decoding performance.

The VCP2 is designed with $C = 13$. The branch metrics can have a maximum dynamic range of 7 + 1 sign bits [-128; +127]. This gives another branch metrics upper bound $B_2 \leq 128$.

So for a given constraint length, $\min(B_1, B_2)$ gives the final branch metrics maximum bound B .

To satisfy B in the branch metrics calculation, the soft input values, delivered as 8-bit-signed equalized values, are linearly scaled with the following formula where $1/n$ is the rate.

$$\text{Scaled} = \min(B_1, B_2)/n \times \text{SoftValue}/128$$

Example

$K = 9$, then $B_1 \leq 227.5$ and the branch metrics range B_2 is [-128; +127]. So the branch metrics need to be in [-128; +127] range.

If rate 1/3, $128/3 \approx 42$, so the soft inputs need to be scaled by a factor of 0.333333 and saturated within the range [-42; +42].

Table 4 summarizes the calculations for the different constraint length and rate:

Table 4. VCP2 Soft Inputs Quantization

| 1/Rate | K | Scaling Factor | Range |
|--------|---------------|----------------|------------|
| 2 | 5, 6, 7, 8, 9 | 0.5 | [-64; +63] |
| 3 | 5, 6, 7, 8, 9 | 0.333333 | [-42; +42] |
| 4 | 5, 6, 7, 8, 9 | 0.25 | [-31; +31] |

5 Decision Data

The VCP2 can be configured to generate either hard decisions (one bit per decision), or soft decisions (8-bit value per decision). Ordering of the VCP2 decisions depends on the OUT_ORDER field of VCPIC3 and the SD field of VCPEND. If the DSP is set to work in big-endian mode and the results are soft decisions (see the VCP2 endian mode register, [Section 6.2](#)). The decisions buffer start address must be double-word aligned and the buffer size must be a multiple of 8 bytes.

The soft decisions in the VCP2 are initially computed with the path metrics at 13-bit values. The results are then clipped to 8-bit signed integer values before being stored in the traceback soft decision memory.

6 Registers

The VCP2 contains several memory-mapped registers accessible by the CPU, the IDMA, the QDMA, and the EDMA3. A configuration-bus access is faster than an EDMA3-bus access for isolated accesses (typically when accessing control registers). EDMA3-bus accesses are used for EDMA3 transfers and provide maximum throughput to/from the VCP2. The registers are listed in [Table 5](#). For the memory map and full register addresses, see the device-specific data manual.

The branch metric and traceback decision memories contents are not accessible and the memories can be regarded as FIFOs by the DSP, meaning you do not have to perform any indexing on the addresses.

Table 5. VCP2 Registers

| EDMA3 Bus Offsets | Configuration Bus Offsets | Acronym | Register Name | See |
|-------------------|---------------------------|----------|--|------------------------------|

Table 6. VCP2 Memories

| EDMA3 Bus Offsets | Acronym | Name | Size |
|-------------------|---------|-------------------------|-----------|
| 1000h | BM | Branch Metrics (BM) | 512 Bytes |
| 2000h | SM | State Metric (SM) | 448 Bytes |
| 3000h | TBHD | Traceback Hard Decision | 4K Bytes |
| 6000h | TBSD | Traceback Soft Decision | 16K Bytes |
| F000h | IO | Decoded Bits (IO) | 512 Bytes |

6.1 VCP2 Input Configuration Register 0 (VCPIC0)

The VCP2 input configuration register 0 (VCPIC0) is shown in [Figure 4](#) and described in [Table 7](#).

Figure 4. VCP2 Input Configuration Register 0 (VCPIC0)

| | | | | |
|-------|-------|-------|-------|---|
| 31 | 24 23 | 16 15 | 8 7 | 0 |
| POLY3 | POLY2 | POLY1 | POLY0 | |
| R/W-0 | R/W-0 | R/W-0 | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7. VCP2 Input Configuration Register 0 (VCPIC0) Field Descriptions

| Bit | Field | Value | Description ⁽¹⁾ |
|-------|-------|-------|--|
| 31-24 | POLY3 | 0-FFh | Polynomial generator G_3 (see Section 9.2). |
| 23-16 | POLY2 | 0-FFh | Polynomial generator G_2 (see Section 9.2). |
| 15-8 | POLY1 | 0-FFh | Polynomial generator G_1 (see Section 9.2). |
| 7-0 | POLY0 | 0-FFh | Polynomial generator G_0 (see Section 9.2). |

⁽¹⁾ The polynomial generators are 9-bit values defined as $G(z) = b_8z^{-8} + b_7z^{-7} + b_6z^{-6} + b_5z^{-5} + b_4z^{-4} + b_3z^{-3} + b_2z^{-2} + b_1z^{-1} + b_0$, but only 8 bits are passed in the POLY n bitfields so that b_1 is the most significant bit and b_8 is the least significant bit (b_0 is not passed, but set by the internal VCP hardware).

6.2 VCP2 Input Configuration Register 1 (VCPIC1)

The VCP2 input configuration register 1 (VCPIC1) is shown in [Figure 5](#) and described in [Table 8](#).

Figure 5. VCP2 Input Configuration Register 1 (VCPIC1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8. VCP2 Input Configuration Register 1 (VCPIC1) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31-29 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 28 | YAMEN | 0 | Yamamoto algorithm is disabled. |
| | | 1 | Yamamoto algorithm is enabled. |
| 27-16 | YAMT | 0-FFFh | Yamamoto threshold value bits. See Section 8.2 . |
| 15-0 | Reserved | 0 | Reserved. These reserved bit locations must be 0. A value written to this field has no effect. |

6.3 VCP2 Input Configuration Register 2 (VCPIC2)

The VCP2 input configuration register 2 (VCPIC2) is shown in [Figure 6](#) and described in [Table 9](#).

Figure 6. VCP2 Input Configuration Register 2 (VCPIC2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9. VCP2 Input Configuration Register 2 (VCPIC2) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------|---------|---|
| 31-16 | R | 0-FFFFh | Reliability length bits (see Section 8.1). |
| 15-0 | FL | 0-FFFFh | Frame length bits (see Section 8.1). |

6.4 VCP2 Input Configuration Register 3 (VCPIC3)

The VCP2 input configuration register 3 (VCPIC3) is shown in [Figure 7](#) and described in [Table 10](#).

Figure 7. VCP2 Input Configuration Register 3 (VCPIC3)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10. VCP2 Input Configuration Register 3 (VCPIC3) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------|---------|--|
| 31-29 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 28 | OUT_ORDER | 0 and 1 | Defines the order of VCP output for decoded data. |
| | | 0 | 0 to 31 |
| | | 1 | 31 to 0 |
| 27-25 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 24 | ITBEN | 0 and 1 | Traceback state index enable/disable. |
| | | 0 | Disabled |
| | | 1 | Initialization of traceback starting state is enabled |
| 23-16 | ITBI | 0-FFh | Traceback state index. The index of the starting state for the traceback unit. |
| 15-0 | C | 0-FFFFh | Convergence distance bits. The length of the convergent section of the siding window. This is only used if $f > F + (K-1)$ in mixed mode, or if $f > F + C$ in convergence mode. |

6.5 VCP2 Input Configuration Register 4 (VCPIC4)

The VCP2 input configuration register 4 (VCPIC4) is shown in [Figure 8](#) and described in [Table 11](#).

Figure 8. VCP2 Input Configuration Register 4 (VCPIC4)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 11. VCP2 Input Configuration Register 4 (VCPIC4) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|---|
| 31-29 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 28-16 | IMINS | 0-1FFFh | Minimum initial state metric (13 bits). |
| 15-13 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 12-0 | IMAXS | 0-1FFFh | Maximum initial state metric (13 bits). |

6.6 VCP2 Input Configuration Register 5 (VCPIC5)

The VCP2 input configuration register 5 (VCPIC5) is shown in [Figure 9](#) and described in [Table 12](#).

Figure 9. VCP2 Input Configuration Register 5 (VCPIC5)

| | | | | | | | | | | |
|----------|-------|-------|----------|----|----|-------|----|-------|----|---|
| 31 | 30 | 29 | 28 | 27 | 25 | 24 | 20 | 19 | 16 | |
| SDHD | OUTF | TB | Reserved | | | SYMR | | SYMX | | |
| R/W-0 | R/W-0 | R/W-0 | R/W-0 | | | R/W-0 | | R/W-0 | | |
| 15 | | | | | | 8 | 7 | | | 0 |
| Reserved | | | | | | IMAXI | | | | |
| R/W-0 | | | | | | R/W-0 | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 12. VCP2 Input Configuration Register 5 (VCPIC5) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------------------|---|
| 31 | SDHD | 0 1 | Output decision type select bit. Hard decisions Soft decisions |
| 30 | OUTF | 0 1 | Output parameters read flag bit. VCPREVT is not generated by VCP for output parameters read VCPREVT generated by VCP for output parameters read |
| 29-28 | TB | 0 1h 2h 3h | Traceback mode select bits. Not allowed Tailed, $F \leq F_{\max}$ ⁽¹⁾ Convergent, (no tail bits) Mixed, $F \geq F_{\max}$ and tail bits are used |
| 27-25 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 24-20 | SYMR | 0-1Fh | Determines decision buffer length in output FIFO. When programming register values for the SYMR bits, always subtract 1 from the value calculated. Valid values for the SYMR bits are from 0 to 1Fh. For hard decision: If $F \leq 2048$; then $SYMR = \text{ceil}[f/64] - 1$ If $F > 2048$; then $SYMR = 15$ or 31 For soft decision: If $F \leq 256$; then $SYMR = \text{ceil}[f/8] - 1$ If $F > 256$; then $SYMR = 15$ or 31 |
| 19-16 | SYMX | 0-Fh | Determines branch metrics buffer length in input FIFO. For information on selecting the appropriate SYMX value, see Section 8.3 . |
| 15-8 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 7-0 | IMAXI | 0-FFh | Maximum initial state metric value bits. IMAXI bits determine which state should be initialized with the maximum state metrics value (IMAXS) bits in VCPIC4; all the other states are initialized with the value in the IMINS bits. |

⁽¹⁾ For more details on F_{\max} , see [Section 8.1.4](#).

6.7 VCP2 Output Register 0 (VCPOUT0)

The VCP2 output register 0 (VCPOUT0) is shown in [Figure 10](#) and described in [Table 13](#).

Figure 10. VCP2 Output Register 0 (VCPOUT0)

Table 14. VCP2 Output Register 1 (VCPOUT1) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31-17 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 16 | YAM | 0 1 | Yamamoto bit result. This bit is a quality indicator bit and is only used if the Yamamoto logic is enabled. See Section 8.2 . At least one trellis stage had an absolute difference less than the Yamamoto threshold and the decided frame has poor quality No trellis stage had an absolute difference less than the Yamamoto threshold and the frame has good quality |
| 15-8 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 7-0 | FMAXI | 0-FFFh | State index for the state with the final maximum state metric. There are $2^{(k-1)}$ state metrics for each trellis stage. Valid range for FMAXI is 0 to $2^{(k-1)} - 1$. |

6.9 VCP2 Execution Register (VCPEXE)

The VCP2 execution register (VCPEXE) is shown in [Figure 12](#) and described in [Table 15](#).

Figure 12. VCP2 Execution Register (VCPEXE)

| | | | | |
|-------|----------|---|---------|---|
| 31 | Reserved | 4 | 3 | 0 |
| R/W-0 | | | COMMAND | |
| | | | W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

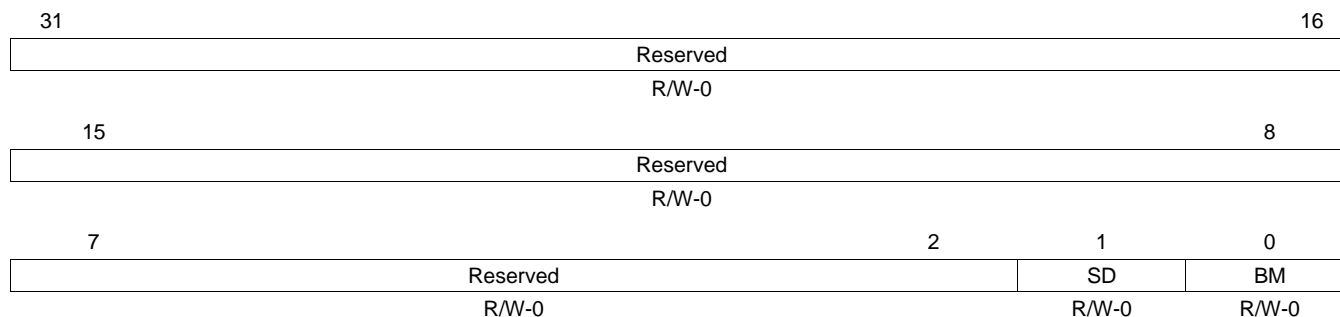

Table 15. VCP2 Execution Register (VCPEXE) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|--------|--|
| 31-4 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 3-0 | COMMAND | 0 | Reserved (no instruction) |
| | | 1h | Start VCP (normal mode) |
| | | 2h | Halt or Pause VCP (debug mode). The VCP is halted (or paused) after processing the state metric for the current sliding window and before the start of the traceback. |
| | | 3h | Restart VCP and process one sliding window (debug mode). The VCP is restarted from the pause state and begins the traceback operation. The VCP is again paused after processing the state metrics for next sliding window. |
| | | 4h | Restart VCP (debug mode). The VCP is restarted from the paused state and begins the traceback operation. The VCP will run to normal completion. |
| | | 5h | Stop. Soft reset all VCP registers to their initial condition. All registers in the VCP are reset in this mode except for the execution register, endian register, emulation register, and other internal registers. |
| | | 6h-FFh | Reserved |

6.10 VCP2 Endian Mode Register (VCPEND)

The VCP2 endian mode register (VCPEND) is shown in Figure 13 and described in Table 16. VCPEND has an effect only in big-endian mode.

Figure 13. VCP2 Endian Mode Register (VCPEND)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16. VCP2 Endian Mode Register (VCPEND) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-2 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 1 | SD | 0 | Traceback soft-decision memory format select bit. 32-bit-word packed. |
| | | 1 | Native format (8 bits). |
| 0 | BM | 0 | Branch metrics memory format select bit. 32-bit-word packed. |
| | | 1 | Native format (8 bits). |

6.11 VCP2 Status Register 0 (VCPSTAT0)

The VCP2 status register 0 (VCPSTAT0) is shown in [Figure 14](#) and described in [Table 17](#).

Figure 14. VCP2 Status Register 0 (VCPSTAT0)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17. VCP2 Status Register 0 (VCPSTAT0) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|--|
| 31-29 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 28-12 | NSYMPROC | | Number of symbols processed bits. The NSYMPROC bits indicate how many symbols have been processed in the state metric unit with respect to time. The maximum number of processed stages is equal to $f + (k-1)$ in tailed or mixed mode. The maximum number of processed stages is equal to $f + c$ in convergent mode. |
| 11-7 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 6 | EMUHALT | 0 1 | Emulation halt status bit. 0 No halt due to emulation. 1 Halt due to emulation. |
| 5 | OFFUL | 0 1 | Output FIFO buffer full status bit. 0 Output FIFO buffer is not full. 1 Output FIFO buffer is full. |
| 4 | IFEMP | 0 1 | Input FIFO buffer empty status bit. 0 Input FIFO buffer is not empty. 1 Input FIFO buffer is empty. |
| 3 | WIC | 0 1 | Waiting for input configuration bit. The WIC bit indicates that the VCP is waiting for new input control parameters to be written. This bit is always set after decoding of a user channel. 0 Not waiting for input configuration words. 1 Waiting for input configuration words. |
| 2 | ERR | 0 1 | VCP error status bit. The ERR bit is cleared as soon as the DSP reads the VCP error register (VCPERR). 0 No error. 1 VCP paused due to error. |
| 1 | RUN | 0 1 | VCP running status bit. 0 VCP is not running. 1 VCP is running. |
| 0 | PAUSE | 0 1 | VCP pause status bit. 0 VCP is not paused. The UNPAUSE command is acknowledged by clearing the PAUSE bit. 1 VCP is paused. The PAUSE command is acknowledged by setting the PAUSE bit. The PAUSE bit can also be set, if the input FIFO buffer is becoming empty or if the output FIFO buffer is full. |

6.12 VCP2 Status Register 1 (VCPSTAT1)

The VCP2 status register 1 (VCPSTAT1) is shown in [Figure 15](#) and described in [Table 18](#).

Figure 15. VCP2 Status Register 1 (VCPSTAT1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18. VCP2 Status Register 1 (VCPSTAT1) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------|---------|--|
| 31-16 | NSYMOF | 0-FFFFh | Number of symbols in the output FIFO buffer. |
| 15-0 | NSYMIF | 0-FFFFh | Number of symbols in the input FIFO buffer. |

6.13 VCP2 Error Register (VCPERR)

The VCP2 error register (VCPERR) is shown in [Figure 16](#) and described in [Table 19](#).

Figure 16. VCP2 Error Register (VCPERR)

Table 19. VCP2 Error Register (VCPERR) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|-------|-------|-----------------------|
| 0 | ERROR | 0 | No error is detected. |
| | | 1 | An error has occurred |

6.14 VCP2 Emulation Control Register (VCPEMU)

The VCP2 emulation control register (VCPEMU) is shown in [Figure 17](#) and described in [Table 20](#).

Figure 17. VCP2 Emulation Control Register (VCPEMU)

| | | | |
|----|----------|---|-------|
| 31 | Reserved | 1 | 0 |
| | R/W-0 | | FREE |
| | | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20. VCP2 Emulation Control Register (VCPEMU) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-1 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. |
| 0 | FREE | 0 | Reserved |
| | | 1 | Free run mode - vcp_emususp signal and functions normally. |

7 Endianness

The VCP endian mode register (VCPEND) is intended to solve possible big-endian issues and is, therefore, used only when the DSP is in big-endian mode. Depending on whether the data is saved in the DSP memory subsystem in its native format or is 32-bit word packed, data interpretation will be different.

7.1 Branch Metrics

When the data are saved in their 8-bit native format (BM = 1), they must be organized in the DSP memory as described in [Table 22](#). When the data are packed on 32-bit words (BM = 0), they must be organized in the DSP memory as described in [Table 23](#).

Table 21. Branch Metrics

| Little_big_endian | BM | Description (MSB to LSB) |
|-------------------|----|---|
| 0 | 0 | 3,2,1,0,7,6,5,4 ⇒ 7,6,5,4,3,2,1,0 (bytes) |
| 0 | 1 | 0,1,2,3,4,5,6,7 ⇒ 7,6,5,4,3,2,1,0 (bytes) |

7.1.1 Hard Decisions

The VCP2 hard-decisions bit ordering within the 32-bit hard-decision word is programmable via the OUT_ORDER = 0 register, such that the oldest bit can be either in the MSB or the LSB position.

Figure 22. Trellis Stage Ordering of Hard Decisions in 32-Bit Word (OUT_ORDER = 0)

| | | | | | | | |
|------------|----------------|-----|-----------------|-----------------|-----|-----------------|-----------------|
| 63 | 62 | ... | 32 | 31 | ... | 1 | 0 |
| Stage N | Stage N - 1 | ... | Stage N - 31 | Stage N - 32 | ... | Stage N - 62 | Stage N - 63 |

OUT_ORDER = 1 orders the hard-decision data in the order it is calculated in the state metric computation, from 31 to 0 in the 32-bit word output.

Figure 23. Trellis Stage Ordering of Hard Decisions in 32-Bit Word (OUT_ORDER = 1)

7.1.2 Soft Decisions

The VCP2 soft decisions are 8-bit results and output 64 bits at a time. The soft decisions are organized as shown in Table 24, based on the CPU's endianness and whether SD is set for native or 32-bit packed results.

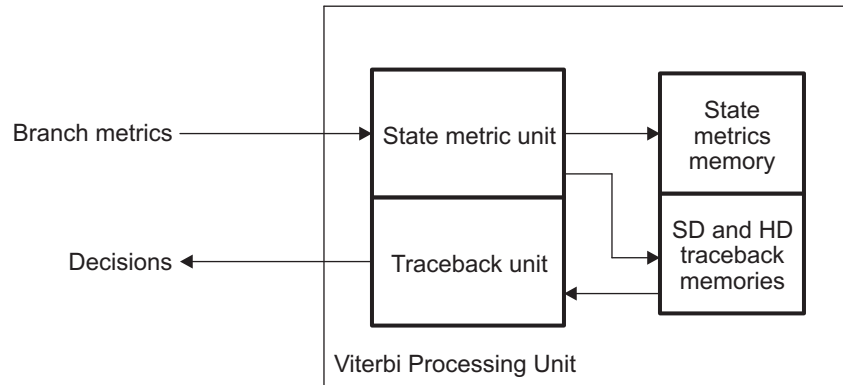

Table 24. Soft Decision Organization

| Little_big_endian | BM | Description (MSB to LSB) |
|-------------------|----|---|
| 0 | 0 | 7,6,5,4,3,2,1,0 ⇒ 3, 2, 1, 0, 7, 6, 5, 4 (bytes) |
| 0 | 1 | 7,6,5,4,3,2,1,0 ⇒ 0, 1, 2, 3, 4, 5, 6, 7 (bytes) |
| 1 | 0 | Endianness manager has no effect 7,6,5,4,3,2,1,0 ⇒ 7,6,5,4,3,2,1,0 (bytes) |
| 1 | 1 | Endianness manager has no effect 7,6,5,4,3,2,1,0 ⇒ 7,6,5,4,3,2,1,0 (bytes) |

8 Architecture

The VCP2 processing unit is shown in Figure 24. The state metrics unit performs the Viterbi forward recursion using branch metrics as inputs and updates the states metrics for all states (add/compare/select or ACS operations) at every trellis stage. The state metrics memory is not accessible by the DSP. The traceback unit performs the Viterbi backward recursion and generates hard decisions or soft decisions. The traceback memories are not directly accessible by the DSP.

Figure 24. Processing Unit

8.1 Sliding-Windows Processing

The traceback hard-decision memory can store up to 32768 traceback bits and there are $2^{(K-1)}$ bits stored at each trellis stage. Therefore, the traceback hard-decision memory can store decisions of $32768/2^{(K-1)}$ symbols. The traceback soft-decision memory can store up to 8192 traceback soft values and, therefore, contain up to 8192 soft decisions of $8192/2^{(K-1)}$ symbols. Assume a terminated frame of length F (excluding tail bits) and a constraint length K , F and K determine whether all decisions can be stored in the traceback memories.

If the decisions do not fit in the traceback HD/SD memory, then the convergent or mixed mode is used and the original frame is segmented into sliding windows (SW); otherwise, the traceback mode is set to tailed and no segmentation is required.

8.1.1 Tailed Traceback Mode

This mode is used when a full frame resides within the coprocessor traceback memory (see Figure 25). The state metrics are computed over $F + K - 1$ symbols, the traceback is initialized with the tailed state and executed over $F + K - 1$ symbols. It should be noted that only F decisions are output. They are output in reverse order and in blocks of user-defined size.

Figure 25. Tailed Traceback Mode

8.1.2 Mixed Traceback Mode

This mode is used when the frame is terminated and does not fit within the coprocessor traceback memory. The frame is split into sliding windows (see Figure 26). The state metrics are computed over $F + K - 1$ symbols, the traceback is initialized with the tailed state and executed over $F + K - 1$ symbols. It should be noted that only F decisions are output in blocks of user-defined size (see Section 8.3). The state metrics computation of sliding window $I + 1$ is done in parallel with the traceback computation of sliding window I . Tailed traceback type is used on the last sliding window.

8.1.3 Convergent Traceback Mode

This mode is used with non-terminated frames or when you want to decode a portion of the frame. When the frame does not fit into the coprocessor traceback memory, then the frame is split into sliding windows (see Figure 27). The state metrics are computed over $F + C$ symbols, the traceback is initialized with the tailed state and executed over $F + C$ symbols. It should be noted that only F decisions are output in blocks of user-defined size (see Section 8.4). The state metrics computation of sliding window $I + 1$ is done in parallel with the traceback computation of sliding window I .

Figure 26. Mixed Traceback Mode-Example With Five Sliding Windows

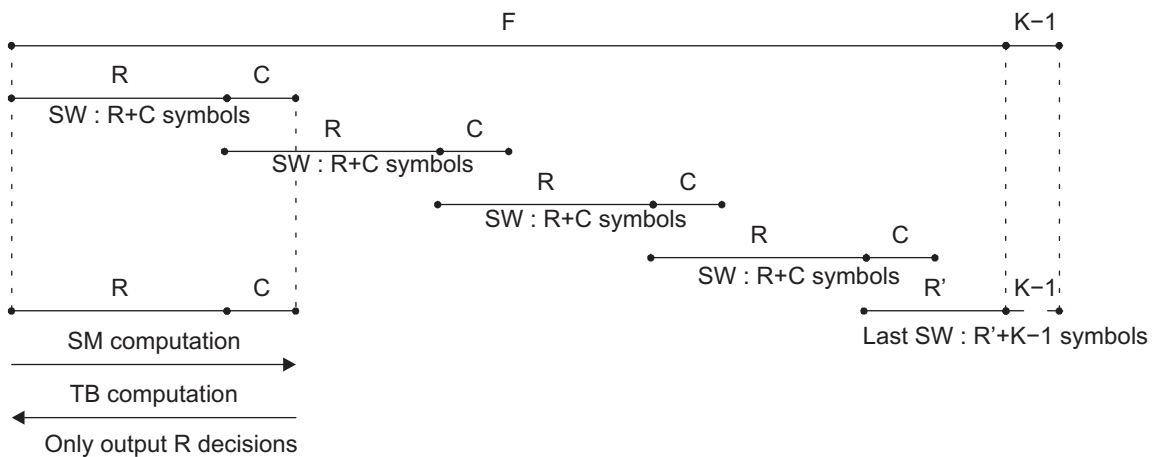

Figure 27. Convergent Traceback Mode-Example With Five Sliding Windows

8.1.4 F, R, and C Limitations

VCP2 has increased the traceback soft-decision memory and output FIFO compared to the memory in VCP. The traceback soft-decision memory size has been increased from 1024 × 96 bits to 2048 × 64 bits. The output FIFO memory has been increased from 32 × 64 bits to 64 × 64 bits. In addition, the soft-decision resolution is increased internally to 13 bits and is clipped to 8 bits when output from VCP2. These memory sizes have an effect on the F_{\max} parameter (i.e., the max. frame size for tailed processing), and the $(R+C)_{\max}$ parameter (i.e., the max. sliding window length for mixed/convergent processing).

The differences between VCP and VCP2 are related to F_{\max} , $(R+C)_{\max}$, and C. The impact on VCP2 performance is as follows:

- Soft decisions:
 - Allowed values for C are $C = N \cdot (K - 1)$, where N is a convergence multiplier. [Table 25](#) and [Table 26](#) show the possible values of N for each value of K for hard and soft decisions.
 - R is constrained to be less than or equal to 248.
 - F_{\max} and $(R+C)_{\max}$ for VCP2 have been increased over VCP. This change reduces the number of sliding windows and, therefore, decreases the number of VCP2 cycles needed for traceback. Overall, there is no major improvement in the processing delay because a larger portion of cycles is spent in state metric accumulation, which is largely unaffected by the choice of R and C.
- Hard decisions:
 - $(R+C)_{\max}$ for mixed/convergent processing for hard decisions has been increased from 605 to 635 for $K = 6$, and from 1020 to 2044 for $K = 5$. As with soft decisions, this change results in a small decrease in VCP2 cycle counts during traceback.

The procedure to calculate the reliability length is as follows [the reliability length cannot be larger than 1920, $C \leq 1920 - (k - 1)$]:

1. Determine the convergence length.
2. Determine the number of sliding windows: $N_{sw} = \text{ceil}(f / [(r + c)_{\max} - c])$.
3. Determine the reliability length: $R = m \times \text{ceil}[f / (N_{sw} \times m)]$.
4. If hard decisions are being used and $R > 1920$ or if soft decisions are being used and $R > 248$, then increment the number of sliding windows and go back to step 3.
5. For hard decision and soft-decision limits, see [Table 25](#) and [Table 26](#).

Table 25. Traceback Soft Decision Sliding Window Limits

| K | Maximum Frame Size | F_{\max} | $(r + c)_{\max}$ | Multiple (m) | Convergent Multiplier (N) | Special Constraint |
|---|--------------------|------------|------------------|--------------|---------------------------|--------------------|
| 9 | 64 | 56 | 60 | 4 | 3,6 | |
| 8 | 112 | 105 | 105 | 7 | 3,6,9,12 | |
| 7 | 192 | 186 | 186 | 6 | 3,6,9,12,15,18 | |
| 6 | 320 | 315 | 315 | 5 | 3,6,9,12,15,18 | $r \leq 248$ |
| 5 | 1024 | 1020 | 320 | 4 | 3,6,9,12,15,18 | $r \leq 248$ |

Table 26. Traceback Hard Decision Sliding Window Limits

| K | Maximum Frame Size | F_{\max} | $(r + c)_{\max}$ | Multiple (m) | Convergent Multiplier (N) |
|---|--------------------|------------|------------------|--------------|---------------------------|
| 9 | 128 | 120 | 124 | 4 | 3,6,9,12,15 |
| 8 | 224 | 217 | 217 | 7 | 3,6,9,12,15,18 |
| 7 | 384 | 378 | 378 | 6 | 3,6,9,12,15,18 |
| 6 | 640 | 635 | 635 | 5 | 3,6,9,12,15,18 |
| 5 | 2048 | 2044 | 2044 | 4 | 3,6,9,12,15,18 |

8.2 Yamamoto Parameters

During the standard forward recursion, an entity called the Yamamoto bit is computed for each state and updated every symbol interval. The Yamamoto bit was proposed by Hirosuke Yamamoto (Hirosuke Yamamoto, *Viterbi Decoding Algorithm for Convolutional Codes with Repeat Request*, IEEE Transactions on Information Theory, Vol. IT-26, No. 5, September 1980).

Basically, a bit (the Yamamoto bit) is associated with each state in the decoding process. Initially, all the Yamamoto bits are set (1). During the decoding process, the Yamamoto bit for a particular state comes from a couple of decisions made on the path metrics and the Yamamoto bit of previous states. The metrics of all paths leading to a particular state are compared. If the difference between any two metrics is less than a given threshold (YAMT bits in VCPIC1), then the Yamamoto bit is cleared; otherwise, the Yamamoto bit is inherited from the previous state of the path with the largest metric. The end result of this process (YAM bit in VCPOUT1) yields a zero (0) if anywhere along the decoding path there was a point where the decision between two paths was ambiguous. The YAM bit can therefore be used as a binary frame quality indicator.

The Yamamoto algorithm can be enabled or disabled by toggling the YAMEN bit in VCPIC1.

8.3 Input FIFO (Branch Metrics)

Figure 28 shows how the FIFO is used in either a double- or quad-buffering scheme. The VCP2 generates a VCPXEVT synchronization event each time the $nx1/4$ of the buffer is empty, where ($n = 1, 2, 3, 4$) or ($n = 2, 4$), depending on the value of SYMX.

VCPIC5 contains the SYMX bits, which define the buffer length as well as the VCPXEVT event rate. The maximum allocatable size for the buffer in the input FIFO is 16 64-bit words.

SYMX defines the branch metric buffer length (minus one) to be transmitted to the VCP for each VCPXEVT. Table 27 has the valid values for SYMX, along with the corresponding number of 64-bit transfers. If the number of 64 bit transfers is 16, then the double buffering scheme is used and VCPXEVTs will be generated when half the FIFO is empty (either top or bottom half). If the number of 64-bit transfers is 8, then a quad buffering scheme is used and VCPXEVTs are generated as each quarter of the FIFO is emptied. The VCP2 only generates as many VCPXEVTs as needed to produce all the BMs required based on the SYMX value, frame length, and rate. In other words, no potential excess VCPXEVTs will be generated based on the FIFO being partially empty at the end of processing.

Table 27. Code Rate versus SYMX

| Code Rate | SYMX | Number of 64-Bit Transfers |
|-----------|------|----------------------------|
| 1/4 | 3 | 16 |
| 1/4 | 1 | 8 |
| 1/3 | 7 | 16 |
| 1/3 | 3 | 8 |
| 1/2 | 15 | 16 |
| 1/2 | 7 | 8 |

Figure 28. Input FIFO (Branch Metrics)

8.4 Output FIFO (Decisions)

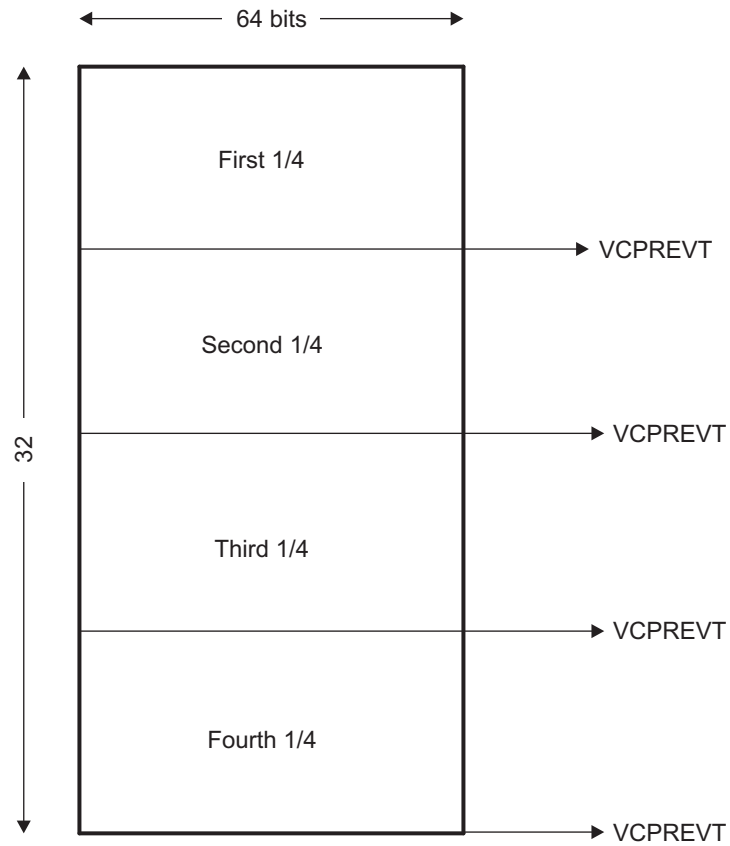

Figure 29 shows how the output FIFO is used in either a double- or quad-buffering scheme. The VCP2 generates a VCPREVT synchronization event each time the $n \times 1/4$ of the buffer is empty, where ($n = 1, 2, 3, 4$) or ($n = 2, 4$), depending on the value of SYMR.

VCPI5 contains the SYMR bits, which define the buffer length, as well as the VCPREVT event rate. The maximum size for buffer is 16 64-bit words.

- For hard decisions:
 - If $F \leq 2048$, then $\text{symr} = \text{ceil}[f/64]-1$
 - If $F > 2048$, then $\text{symr} = 15$ or 31
- For soft decisions:
 - If $F \leq 256$, then $\text{symr} = \text{ceil}[f/8]-1$
 - If $F > 256$, then $\text{symr} = 15$ or 31

If SYMR = 31, double buffering is used and a VCPREVT is generated when the first or second half of the buffer is filled. If SYMR = 15, then VCPREVT is generated after each quarter of the buffer is filled. When $F \leq 2048$ for HD or $F \leq 256$ for SD outputs and SYMR is determined as described above, a single VCPREVT is generated once all decisions have been written to the output FIFO.

Figure 29. Output FIFO (Decisions Data)

9 Programming

The VCP2 requires setting up the following context per user channel:

- 3 to 4 EDMA3 parameters (see [Table 28](#))
- The input configurations parameters

Several user channels can be programmed prior to starting the VCP2. A suggested implementation is to use the EDMA3 interrupt generation capabilities [see the *TMS320C6474 DSP Enhanced DMA (EDMA3) Controller User's Guide (SPRUG11)*] and program the EDMA3 to generate an interrupt after the user channel's last VCPREVT synchronized EDMA3 transfer has completed.

Table 28. Required EDMA3 Links Per User Channel

| Direction ⁽¹⁾ | Data | Usage | Required/Optional |
|--------------------------|--------------------------------|---|---------------------|
| Transmit | Input configuration parameters | Send the input configuration parameters | Required |
| Transmit | Branch metrics | Send branch metrics | Required |
| Receive | Decisions | Read decisions | Required |
| Receive | Output parameters | Read output parameters | Optional (OUTF bit) |

⁽¹⁾ Transmit direction (DSP → VCP), receive direction (VCP → DSP)

9.1 EDMA3 Resources

9.1.1 VCP2 Dedicated EDMA3 Resources

Within the available 64 EDMA3 channel event sources, two are assigned to the VCP2: event 28 and event 29.

- Event 28 is associated to the VCP2 receive event (VCPREVT) and is used as the synchronization event for EDMA3 transfers from the VCP2 to the DSP (receive). EDMA3 channel 28 is primarily intended to serve VCP2-to-DSP transfers.
- Event 29 is associated to the VCP2 transmit event (VCPXEVT) and is used as the synchronization event for EDMA3 transfers from the DSP to the VCP2 (transmit). EDMA3 channel 29 is primarily intended to serve DSP-to-VCP2 transfers.

9.1.2 Special VCP2 EDMA3 Programming Considerations

The EDMA parameters consist of eight words as shown in [Figure 30](#). All EDMA transfers, in the context of the VCP, must contain an even number of words, and have source and destination addresses double-word aligned.

All EDMA transfers must be double-word aligned and the ACNT for the VCP EDMA transfer must be a multiple of 8. Single-word transfers that are not double-word aligned cause errors in the TCP2/VCP2 memory.

For more information, see the *TMS320C6474 DSP Enhanced DMA (EDMA3) Controller User's Guide (SPRUG11)*.

Figure 30. EDMA3 Parameters Structure

9.1.2.1 Input Configuration Parameters Transfer

This EDMA3 transfer to the input configuration parameters is a 6-word VCPXEVTT frame-synchronized transfer. The OPTIONS should be set as:

- ITCCEN = 0 (Intermediate transfer complete chaining is disabled)
- TCCEN = 0 (Transfer complete chaining is disabled)
- ITCINTEN = 0 (Intermediate transfer complete interrupt is disabled)
- WIMODE = 0 (Normal operation)
- TCINTEN = 0 (Transfer complete interrupt is disabled)
- TCC = 1 to 63 (Transfer complete code)
- TCCMODE = 0 (Normal completion)
- FWID = Don't care
- STAT = 0 (Entry is updated as normal)
- SYNCDIM = 0 (A-sync transfer, each event triggers the transfer of ACNT elements)
- DAM = 0 (Dst address within an array increments. Dst is not a FIFO.)
- SAM = 0 (Src Address within an array increments. Src is not a FIFO.)
- SOURCE ADDRESS: User input configuration parameters start address
- ACNT = 24 (Number of bytes in an array)
- BCNT = 1 (Number of arrays in a frame)
- Destination Address: VCPIC0
- SRCBIDX = 0
- DSTBIDX = 0
- SRCCIDX = 0
- DSTCIDX = 0
- CCNT = 1 (Number of frames in a block)

Upon completion, this EDMA3 transfer is linked to the EDMA3 for branch metrics transfer parameters.

9.1.2.2 Branch Metrics Transfer

This EDMA3 transfer to the branch metrics FIFO is a VCPXEVTT frame-synchronized transfer. The OPTIONS should be set as:

- ITCCEN = 0 (Intermediate transfer complete chaining is disabled)
- TCCEN = 0 (Transfer complete chaining is disabled)
- ITCINTEN = 0 (Intermediate transfer complete interrupt is disabled)
- TCINTEN = 1 (Transfer complete interrupt is Enabled)
- WIMODE = 0 (Normal operation)
- TCC = 1 to 63 (Transfer complete code)
- TCCMODE = 0 (Normal completion)
- FWID = Don't care
- STAT = 0 (Entry is updated as normal)
- SYNCDIM = 0 (A-sync transfer, each event triggers the transfer of ACNT elements)
- DAM = 1 (Dst address is fixed. Dst is a FIFO.)
- SAM = 0 (Src Address within an array increments. Src is not a FIFO.)
- SOURCE ADDRESS: Branch Metrics Array start address
- ACNT = $4 \times (\text{SYM}X + 1) \times 2^{(f-1)}$ (Number of branch metrics bytes in an array)
- BCNT = CEIL(TNBM/ACNT) (Number of arrays in a frame)

Where TNBM = Total Number of Branch Metrics, in bytes

To calculate total number of branch metrics data in bytes:

For mixed and tailed traceback mode, Total number of Branch Metrics = $(F + K - 1) \times (2^{(f-1)})$

For convergent mode, Total number of Branch Metrics = $(F + C) \times (2^{(r-1)})$

- DESTINATION ADDRESS: VCPWBM branch metrics FIFO address
- SRCBIDX = ACNT
- DSTBIDX = 0
- SRCCIDX = 0
- DSTCIDX = 0
- CCNT = 1 (Number of frames in a block)

Upon completion, this EDMA3 transfer is linked to one of the following:

- The DMA input configuration parameters transfer parameters of the next user channel, if there is one ready to be decoded.
- Dummy DMA transfer parameters, if there are no more user channels ready to be decoded [for information on how to set up a dummy Xfer, see the *TMS320C6474 DSP Enhanced DMA (EDMA3) Controller User's Guide (SPRUG11)*]. Do not link to a NULL transfer, as the secondary event register will set the event flag for Event 29. The final VCPXEVT is generated upon the reading of the decisions and output registers, which is intended to transfer the input configuration of the next user channel. If a NULL transfer link is in place, the final VCPXEVT will set the event 29 flag of SER and no further VCP execution will occur until it is cleared.

9.1.2.3 Decisions Transfer

EDMA3 transfers from the decision buffer are VCPREVT frame-synchronized transfers. The programming of these transfers depend on the decision type and the traceback mode.

Upon completion, this EDMA3 transfer is linked to one of the following:

1. The decisions EDMA3 transfer parameters of the next user channel, if there is one ready to be decoded and the OUTF bit is 0.
2. Null EDMA3 transfer parameters (with all zeros), if there are no more user channels ready to be decoded and the OUTF bit is 0.
3. The output parameters EDMA3 transfer parameters, if the OUTF bit is 1.

9.1.2.4 Hard-Decisions Mode

The OPTIONS should be set as:

- ITCCEN = 0 (Intermediate transfer complete chaining is disabled)
- TCCEN = 0 (Transfer complete chaining is disabled)
- ITCINTEN = 0 (Intermediate transfer complete interrupt is disabled)
- TCINTEN = 0 (Transfer complete interrupt is disabled)
- WIMODE = 0 (Normal operation)
- TCC = 1 to 63 (Transfer complete code)
- TCCMODE = 0 (Normal completion)
- FWID = Don't care
- STAT = 0 (Entry is updated as normal)
- SYNCDIM = 0 (A-sync transfer, each event triggers the transfer of ACNT elements)
- DAM = 0 (Dst address within an array increments. Dst is not a FIFO.)
- SAM = 1 (Src Address is fixed. Src is a FIFO.)
- SOURCE ADDRESS: VCPRDECS Decision FIFO address
- ACNT = $(\text{SYMR}+1) \times 8$ (Number of hard decision bytes in an array)
- BCNT = $\text{CEIL}(\text{TNHD}/\text{ACNT})$ (Number of arrays in a frame) Where TNHD is the total number of hard decisions in bytes (Framelength/8).
- Destination Address: hard-decision array address
- SRCBIDX = 0
- DSTBIDX = ACNT
- SRCCIDX = 0

- DSTCIDX = 0
- CCNT = 1 (Number of frames in a block)

9.1.2.5 **Soft-Decisions Mode**

The OPTIONS should be set as:

- ITCCEN = 0 (Intermediate transfer complete chaining is disabled)
- TCCEN = 0 (Transfer complete chaining is disabled)
- ITCINTEN = 0 (Intermediate transfer complete interrupt is disabled)
- TCINTEN = 0 (Transfer complete interrupt is disabled)
- WIMODE = 0 (Normal operation)
- TCC = 1 to 63 (Transfer complete code)
- TCCMODE = 0 (Normal completion)
- FWID = Don't care
- STAT = 0 (Entry is updated as normal)
- SYNCDIM = 0 (A-sync transfer, each event triggers the transfer of ACNT elements)
- DAM = 0 (Dst address within an array increments. Dst is not a FIFO.)
- SAM = 1 (Src Address is fixed. Src is a FIFO.)
- SOURCE ADDRESS: VCPRDECS Decision FIFO address
- ACNT = (SYMR+1) × 8 (Number of soft decision bytes in an array)
- BCNT = CEIL(TNSD/ACNT) (Number of arrays in a frame) Where TNSD is the total number of soft decisions (framelength)
- Destination Address: soft-decision array address
- SRCBIDX = 0
- DSTBIDX = ACNT
- SRCCIDX = 0
- DSTCIDX = 0
- CCNT = 1 (Number of frames in a block)

9.1.2.6 **Output Parameters Transfer**

This transfer is optional and depends on the OUTF bit. It is a 2- to 32-bit word VCPREVT frame synchronized transfer. The OPTIONS should be set as:

- ITCCEN = 0 (Intermediate transfer complete chaining is disabled)
- TCCEN = 0 (Transfer complete chaining is disabled)
- ITCINTEN = 0 (Intermediate transfer complete interrupt is disabled)
- TCINTEN = 0 (Transfer complete interrupt is disabled)
- WIMODE = 0 (Normal operation)
- TCC = 1 to 63 (Transfer complete code)
- TCCMODE = 0 (Normal completion)
- FWID = Don't care
- STAT = 0 (Entry is updated as normal)
- SYNCDIM = 0 (A-sync transfer, each event triggers the transfer of ACNT elements)
- DAM = 0 (Dst address within an array increments. Dst is not a FIFO.)
- SAM = 0 (Src Address within an array increments. Src is not a FIFO.)
- SOURCE ADDRESS: VCP2 output register 0 address
- ACNT = 8
- BCNT = 1
- Destination Address: output register store array address
- SRCBIDX = 0
- DSTBIDX = 0

- SRCCIDX = 0
- DSTCIDX = 0
- CCNT = 1 (Number of frames in a block)

Upon completion, this EDMA3 transfer is linked to one of the following:

- The EDMA3 decisions transfer parameters of the next user channel, if there is one ready to be decoded.
- Null EDMA3 transfer parameters (with all zeros), if there are no more user channels ready to be decoded.

9.2 Input Configuration Words

The input configuration words should reflect the parameters of the user channels to be decoded.

The POLY n bits in VCPIC0 correspond to the generator polynomials in the encoder (see [Figure 1](#)). The values in each POLY n bit field must be entered in reverse order. The POLY n least-significant bit is set by the VCP2 logic.

- For rate 1/2, POLY0 and POLY1 are required.
- For rate 1/3, POLY0, POLY1, and POLY2 are required.
- For rate 1/4, all the POLY n bits are required.

The YAMT and YAMEN bits in VCPIC1 are described in [Section 8.2](#).

The F and R bits in VCPIC2, the C bit in VCPIC3, and the TB bits in VCPIC5 are described in [Section 8.1](#).

The IMAXI bits in VCPIC5 determine which state should be initialized with the maximum state metrics value (IMAXS), all the other states are initialized with the minimum state metrics value (IMINS). The IMAXI can range from 0 to $2^{K-1}-1$. The IMAXS and IMINS are 13-bit signed values.

The SYMX and SYMR bits in VCPIC5 are described in [Section 8.3](#) and [Section 8.4](#).

The OUTF bit in VCPIC5 indicates whether the VCP should generate a VCPREVT for reading the output parameters. The OUTF bit setting will impact the EDMA3 programming (see [Section 9.1.2.3](#)).

10 Output Parameters

The FMAXS and FMINS bits in VCPOUT0 indicate the final maximum and minimum state metric values, respectively. The FMAXI bit in VCPOUT1 indicates the state index for the state with the final maximum state metric.

The YAM bit in VCPOUT1 is described in [Section 8.2](#).

11 Event Generation

11.1 VCPXEVT Generation

A VCP2 transmit event (VCPXEVT) is generated when any of the following conditions appear:

- A START command write in VCPEXE.
- All input control words have been received and are correct.
- Top one-fourth and half or bottom one-fourth and half of the input FIFO buffer (see [Figure 28](#)) is empty.
- After all decisions have been read and OUTF is cleared, or if all decisions have been read and the output registers have been read and OUTF is set. Note that this extra XEVT pulls the next set of input configurations via EDMA3. If EDMA3 is not set up to link in another set of input configurations, then a dummy transfer should be set up to avoid an SER event flag being set for the EDMA3 parameter entry. If the flag is set, it effectively locks the VCP2, and must be cleared before any future events can be processed for that entry.

11.2 VCPREVT Generation

A VCP2 receive event (VCPREVT) is generated when any of the following conditions appear:

- The traceback unit has written top one fourth and half or bottom one-fourth and half of the output FIFO buffer (see [Figure 29](#)).
- After the traceback is completed (the whole frame has been decoded).
- OUTF bit in VCPIC5 is 1 and all decisions have been read to read the output registers.

12 Operational Modes

- 0: Value at reset or value written by the coprocessor when previous instruction is read and its execution is ongoing. DSP may test the status word in the output control memory to check if the instruction is being executed.
- 1: Start - CPU orders the coprocessor to start a processing block. The first action of the coprocessor is then to generate the first XEVT to trigger DMA transfer of the input control words.
- 2: Pause - CPU orders the coprocessor to pause a processing block at the beginning of traceback.
- 3: Unpause (single_traceback) - CPU orders the coprocessor to restart at the beginning of traceback and halt at next traceback.
- 4: Unpause (finish_traceback) - CPU orders the coprocessor to restart at the beginning of traceback and complete decode.
- Stop - CPU orders the coprocessor to reset. The coprocessor resets all VCP2 registers.

12.1 Debugging Features

Visibility into the internal operation of the VCP2 (i.e., the state metric accumulation, traceback memory) is available to the CPU via a pause command. However, since the *pause* command is not synchronized with the internal VCP2 state machine but is rather sent from the CPU at a random moment in time, this feature is of limited use.

The *pause* command on the VCP2 is augmented to provide visibility into VCP2 operation on a sliding window basis. Instead of using the normal *start* command which tells the VCP2 to perform a complete decode of one frame (including input/output transfers via EDMA3), *halt at beginning of traceback* and *resume until next traceback* commands are used, and the internal VCP2 memories can be inspected at various points in the decoding process. The procedure for using this command is as follows:

- VCP2 configuration and branch metrics are prepared
- A *halt at beginning of traceback* command is sent
- The VCP2 generates necessary interrupts to the EDMA3 to transfer input configuration and to start transferring branch metrics. The VCP2 performs state metric accumulation as branch metrics become available. When it reaches the end of the first sliding window (i.e., the reliability portion and the convergence portion), the VCP2 halts.
- The CPU polls the VCP2 status register until the VCP2 state changes from running to paused. At that point, the state metrics memory can be inspected, as well as the traceback memory. To perform an inspection, halt the CPU via a software breakpoint set at an appropriate point in the code, for instance. Then, the memory can be inspected visually via the debugger GUI, or, alternatively, the CPU can copy the relevant internal VCP2 memories to another location for later analysis.
 - The CPU sends the *resume until next traceback* command to the VCP2.
 - The VCP2 performs the traceback, generates a portion of hard or soft decisions, and continues with state metric accumulation until the end of the next sliding window (i.e., another number of R stages, where R is the reliability length).
 - The process continues until the decoding is complete. Alternatively, the decoding process can be run to completion after any sliding window by sending the *resume to completion* command instead of the *resume until next traceback* command.

13 Errors and Status

When the coprocessor detects an error, the coprocessor sets the status and error words, then sends an interrupt to the CPU. Any coprocessor processing is paused and the DSP must reset or start the coprocessor. An error occurs if the VCP2 receives an invalid value in the input configuration parameters. If an error is detected, the VCPERR bit field is set accordingly, the ERR bit in VCPSTAT0 is set, the VCP2_INT interrupt is generated, and no processing is engaged. The only way to restart the VCP2 is to read VCPERR and send another START command. VCP2_INT has an interrupt selector value of 32. For details on how to set up interrupts, see the *TMS320C6000 DSP Interrupt Selector Reference Guide (SPRU646)*.

The status registers are provided for debugging purposes and are best used when either the processor is halted or the VCP2 is halted. If an error occurs, the VCP2 is halted and a VCP2_INT interrupt is generated that can be mapped to a CPU interrupt. There may be cases where you would want to view the status registers when the VCP2 is still running. One such case is when the VCP2 seems to have taken a long time in processing the current frame. In such cases, a watchdog timer should be used and set according to the frame length and VCP2 configuration, in addition to some overhead to allow for EDMA3 usage.

Appendix A Revision History

This revision history highlights the technical changes made to the document in this revision.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
