About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data manual, rather a companion guide that should be used alongside the device-specific data manual to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data manual. This allows the data manual to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

Glossary

TI Glossary This glossary lists and explains terms, acronyms, and definitions.

Related Documentation From Texas Instruments

Chapter 1

► C28x SYSTEM RESOURCES

The following chapters describe the C28x Configuration and System Resources.

1.1 Technical Reference Manual Overview

The block diagram for the F2838x device is shown in Figure 1-1. This Technical Reference Manual is organized into five major sections:

- C28x SYSTEM RESOURCES

  These chapters describe the C28x CPU subsystem, C28x Boot ROM, device configuration, and other system peripherals.

- ANALOG PERIPHERALS

  These chapters describe the Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), Comparator Subsystem (CMPSS), and general analog subsystem configuration.

- CONTROL PERIPHERALS

  These chapters describe the Enhanced Capture (eCAP), High Resolution Capture (HRCAP), Enhanced Pulse Width Modulator (ePWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- COMMUNICATION PERIPHERALS

  These chapters describe the communication peripherals available to the C28x subsystem such as the I2C, SCI, FSI, McBSP, PMBUS, and SPI. The CAN, EtherCAT, and USB peripherals are also described in this section and can be assigned to the CM subsystem.

- CONNECTIVITY MANAGER (CM)

  These chapters describe the Connectivity Manager (CM) subsystem as well as the AES, GCRC, CM-I2C, CM-UART, SSI, and Ethernet peripherals.

Chapter 2

C2000™ Microcontrollers Software Support

This chapter discusses the C2000Ware for the C2000™ microcontrollers. The C2000Ware can be downloaded from: www.ti.com/tool/C2000WARE

2.1 Introduction

C2000Ware for the C2000™ microcontrollers is a cohesive set of development software and documentation designed to minimize software development time. From device-specific drivers and libraries to device peripheral examples, C2000Ware provides a solid foundation to begin development and evaluation of your product.

C2000Ware can be downloaded from: www.ti.com/tool/C2000WARE

2.2 C2000Ware Structure

The C2000Ware software package is organized into the following directory structure as shown in Table 2-1.

Table 2-1. C2000Ware Root Directories

Directory Name	Description
boards	Contains the hardware design schematics, BOM, Gerber files, and documentation for C2000 controlCARDS.
device_support	Contains all device-specific support files, bit field headers and device development user's guides.
docs	Contains the C2000Ware package user's guides and the HTML index page of all package documentation.
driverlib	Contains the device-specific driver library and driver-based peripheral examples.
libraries	Contains the device-specific and core libraries.

2.3 Documentation

Within C2000Ware, there is an extensive amount of development documentation ranging from board design documentation, to library user's guides, to driver API documentation. The "boards" directory contains all the hardware design, BOM, Gerber files, and more for controlCARDs. To assist with locating the necessary documentation, an HTML page is provided that contains a full list of all the documents in the C2000Ware package. Locate this page in the "docs" directory.

2.4 Devices

C2000Ware contains the necessary software and documentation to jumpstart development for C2000™ microcontrollers. Each device includes device-specific common source files, peripheral example projects, bit field headers, and if available, a device peripheral driver library. Additionally, documentation is provided for each device on how to set up a CCS project, as well as give an overview of all the included example projects and assist with troubleshooting. For devices with a driver library, documentation is also included that details all the peripheral APIs available.

To learn more about C2000™ microcontrollers, visit: www.ti.com/c2000.

2.5 Libraries

The libraries included in C2000Ware range from fixed-point and floating-point math libraries, to specialized DSP libraries, as well as calibration libraries. Each library includes documentation and examples, where applicable. Additionally, the Flash API files and boot ROM source code are located in the "libraries" directory.

2.6 Code Composer Studio™ Integrated Development Environment (IDE)

Code Composer Studio™ is an integrated development environment (IDE) that supports TI's microcontroller and embedded processors portfolio. The Code Composer Studio™ IDE comprises a suite of tools used to develop and debug embedded applications. The latest version of Code Composer Studio™ IDE can be obtained at: www.ti.com/ccstudio

All projects and examples in C2000Ware are built for and tested with the Code Composer Studio™ IDE. Although the Code Composer Studio™ IDE is not included with the C2000Ware installer, Code Composer Studio™ IDE is easily obtainable in a variety of versions.

2.7 SysConfig and PinMUX Tool

To help simplify configuration challenges and accelerate software development, Texas Instruments™ created SysConfig, an intuitive and comprehensive collection of graphical utilities for configuring pins, peripherals, subsystems, and other components. SysConfig helps you manage, expose, and resolve conflicts visually so that you have more time to create differentiated applications.

The tool's output includes C header and code files that can be used with C2000Ware examples or used to configure custom software.

The SysConfig tool automatically selects the pinmux settings that satisfy the entered requirements. The SysConfig tool is delivered integrated in the Code Composer Studio™ IDE, in the C2000Ware GPIO example, as a standalone installer, or can be used by way of the cloud tools portal at: dev.ti.com

Chapter 3

C28x System Control and Interrupts

This chapter explains system control and interrupts for the C28x cores found on this MCU. The system control module configures and manages the overall operation of the device, and provides information about the device status. Configurable features in system control include reset control, NMI operation, peripheral interrupts, power control, clock control, and low-power modes.

3.1 C28x System Control Introduction

On this device, the CPU1 subsystem acts as a master, and by default (upon reset), it owns all the configuration and control. Through software running on CPU1, peripherals and I/Os can be configured to be accessible by the CPU2 subsystem or the CM subsystem and the chosen configurations can be locked.

The PLL clock configuration is also owned by the CPU1 subsystem by default, but a clock control semaphore is provided by which CPU2 can grab access to the clock configuration registers.

Each CPU can be independently configured to accept interrupts from different peripherals. The interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. All stages must be configured and enabled for an interrupt to propagate to the CPU.

Each CPU has its own NMI module to handle different exceptions during run time. If the NMI was on CPU1, any NMI exception that is unhandled before the NMI Watchdog (NMIWD) timer expiration will reset the entire device. If the NMI was on the CPU2 subsystem, then the CPU2 subsystem alone will be reset, in which case the CPU1 subsystem will be informed by another NMI that the CPU2 subsystem was reset because of NMIWD timer expiration.

Each CPU subsystem has its own watchdog timer module for software to use. Watchdog timer expiration on CPU2 will reset the CPU2 subsystem alone when configured to generate a reset, but watchdog timer expiration on CPU1 will reset the entire device.

Except for a CPU2 standalone internal reset such as CPU2.NMIWD or CPU2.WD each time the device is reset, the CPU2 subsystem will be held under reset until the CPU1 subsystem brings it out of reset. This is done by the boot ROM software running on the CPU1 core.

The register space of the device system control module can be found in Section 3.16.

This chapter explains the system control module on both the CPU subsystems.

3.2 System Control Functional Description

The system control module provides the following capabilities:

- Device identification and configuration registers
- Reset control
- Exceptions and Interrupt control
- Safety and error handling features of the device
- Power control
- Clock control
- Low Power modes
- Security module
- Inter-Processor Communication (IPC)

3.2.1 Device Identification

Device identification registers provide information on device class, device family, revision, part number, pin count, and device qualification status.

All of the device information is part of the DEV_CFG_REGS space and is accessible only by the software running on the CPU1 subsystem.

The C28x device identification registers are: PARTIDL, PARTIDH, and REVID.

A 256-bit Unique ID (UID) is available in UID_REGS. The 256 bits are separated into these registers:

- UID_PSRAND0-5: 192 bits of pseudo-random data
- UID_UNIQUE: 32-bit unique data; the value in this register will be unique across all devices with the same PARTIDH
- UID_CHECKSUM: 32-bit fletcher checksum of UID_PSRAND0-5 and UID_UNIQUE and calculated as either little- or big-endian during factory testing
- CPU ID: 16-bit location in OTP. The value at this location provides the information about CPU (CPU1 or CPU2).

3.2.2 Device Configuration Registers

Several registers provide users with configuration information for the C28x subsystems for debug and identification purposes. This information includes the features of the peripherals and how much RAM and FLASH memory is available on this part.

These registers are part of DEV_CFG_REGS space and are accessible only by the software running on the CPU1 subsystem.

- DC0 – DC27: Device Configuration or Capabilities registers.
  If a particular bit in these registers is set to 1, then the associated/feature or module is available in the device.
- PERCNF: Peripheral configuration register.
  This register configures ADC capabilities, and enables or disables the USB internal PHY.
- CPUID: CPU identification register.
  This register is available for software to identify on which CPU the software is executing.

3.3 Resets

This section explains the types and effects of the different resets on this device.

3.3.1 Reset Sources

Table 3-1 summarizes the various reset signals and their effect on the device. CM subsystem resets are described in Section 41.2.

Table 3-1. Reset Signals

Reset Source	CPU1 Core Reset (C28x, TMU, FPU, VCRC)	CPU1 Peripheral Reset	CPU2 Core Reset (C28x, TMU, FPU, VCRC)	CPU2 and CM Peripheral Reset	CPU2 and CM Held In Reset	JTAG / Debug Logic Reset	IOs	XRSn Output
POR	Yes	Yes	Yes	Yes	Yes	Yes	Hi-Z	Yes
XRSn Pin	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SIMRESET.XRSn	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.$\overline{\text{WDRS}}$	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.$\overline{\text{NMIWDRS}}$	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.$\overline{\text{SYSRS}}$ (Debugger Reset)	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SIMRESET.CPU1RSn	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.$\overline{\text{SCCRESET}}$	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.$\overline{\text{HWBISTRS}}$	Yes	-	-	-	-	-	-	-
CPU2.$\overline{\text{SYSRS}}$ (Debugger Reset)	-	-	Yes	Yes	-	-	-	-
CPU2.$\overline{\text{WDRS}}$	-	-	Yes	Yes	-	-	-	-
CPU2.$\overline{\text{NMIWDRS}}$	-	-	Yes	Yes	-	-	-	-
CPU2.$\overline{\text{SCCRESET}}$	-	-	Yes	Yes	-	-	-	-
CPU2.$\overline{\text{HWBISTRS}}$	-	-	Yes	-	-	-	-	-
ECAT_RESET_OUT	Yes	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
TRSTn	-	-	-	-	-	Yes	-	-

Note

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain their state across multiple resets. These can only be cleared by a power-on reset (POR) or by writing 1 to the corresponding bit in RESCCLR register (status can be cleared by writing 1 to RESC register bits also). Each CPU has a RESC register, referred to as CPU1.RESC and CPU2.RESC.

The resets can be divided into a few groups:

- Chip-level resets (XRSn, POR, CPU1.$\overline{\text{WDRS}}$, and CPU1.$\overline{\text{NMIWDRS}}$, SIMRESET.XRSn, ECAT_RESET_OUT (if enabled)), which reset all or almost all of the device.
- System resets (CPU1.$\overline{\text{SYSRS}}$ and CPU1.$\overline{\text{SCCRESET}}$, SIMRESET.CPU1RSn), which reset a large subset of the device but maintain some system-level configuration.
- CPU2 subsystem resets (CPU2.$\overline{\text{SYSRS}}$, CPU2.$\overline{\text{WDRS}}$, CPU2.$\overline{\text{NMIWDRS}}$, and CPU2.$\overline{\text{SCCRESET}}$), which reset only CPU2 and the peripherals owned by it.
- Special resets (CPU1.$\overline{\text{HWBISTRS}}$, CPU2.$\overline{\text{HWBISTRS}}$, and TRSTn), which enable specific device functions.

Whenever the CPU1 subsystem is reset, CPU2, CM and the peripherals owned by them also get reset and held in reset until CPU1 brings CPU2 and CM out of reset by writing to the CPU2RESCTL and CMRESCTL registers respectively. This is done by user application code on CPU1.

Many peripheral modules have individual resets accessible through the system control registers. For information about a module's reset state, refer to the appropriate chapter for that module.

After a POR the boot ROMs clear all of the system and message RAMs on both CPUs.

3.3.2 External Reset (XRSn)

The external reset ($\overline{\text{XRS}}$) is the main chip-level reset for the device. $\overline{\text{XRS}}$ resets both C28x CPUs , the CM subsystem, all peripherals and I/O pin configurations, and most of the system control registers. $\overline{\text{XRS}}$ also holds CPU2 and the CM subsystem in reset. There is a dedicated open-drain pin for XRSn. This pin can be used to drive reset pins for other ICs in the application, and can be driven by an external source. The XRSn is driven internally during watchdog, NMI, and power-on resets.

The XRSn bit in the RESC register is set whenever $\overline{\text{XRS}}$ is driven low for any reason. This bit is then cleared by the boot ROM.

3.3.3 Simulate External Reset

In some cases, there can be a need to simulate the external reset ($\overline{\text{XRS}}$) in software. This can be done by setting XRSn bit to 1 in SIMRESET register by CPU1 software. This toggles $\overline{\text{XRS}}$ pin; hence, resets full device (just like external reset).

After this reset SIMRESET_XRSn bit in the RESC register is set. Software can read this bit to know the cause of reset and clear the status by writing 1 into corresponding bit in RESCCLR register.

3.3.4 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The $\overline{\text{XRS}}$ pin is held low for the duration of the POR. In most applications, $\overline{\text{XRS}}$ is held low long enough to reset other system ICs, but some applications may require a longer pulse. In these cases, $\overline{\text{XRS}}$ can be driven low externally to provide the correct reset duration. A POR resets everything that $\overline{\text{XRS}}$ does, along with a few other registers – the reset cause register (RESC), the NMI shadow flag register (NMISHDFLG).

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

3.3.5 Debugger Reset ($\overline{\text{SYSRS}}$)

During development, it is sometimes necessary to reset the CPU and the peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, each CPU has a subsystem reset, which can be triggered by a debugger using Code Composer Studio IDE. CPU2 subsystem reset (CPU2.$\overline{\text{SYSRS}}$) resets only CPU2, the peripherals owned by it, clock gating and LPM configuration. It does not hold CPU2 in reset. CPU1 subsystem reset (CPU1.$\overline{\text{SYSRS}}$) resets CPU1, the peripherals owned by it, many system control registers (including its clock gating and LPM configuration and the peripherals' CPU ownership), and all I/O pin configurations. It also produces a CPU2.$\overline{\text{SYSRS}}$ and CM.RESETn and holds both, CPU2 and CM, in reset (CCS Gel file has code to release CPU2 and CM out of reset on CPU1 debug reset).

Neither $\overline{\text{SYSRS}}$ resets the ICEPick debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see Section 3.3.4).

3.3.6 Simulate CPU1 Reset

In some cases, there can be a need to simulate the CPU1 reset (CPU1.$\overline{\text{SYSRS}}$) in software. This can be done by setting CPU1RSn bit to 1 in SIMRESET register by CPU1 software. This toggles CPU1.$\overline{\text{SYSRS}}$ signals; hence, resetting CPU1 as well as CPU2 and CM subsystem (just like the debugger reset).

After this reset SIMRESET_CPU1RSn bit in the RESC register is set. Software can read this bit to know the cause of reset and clear the status by writing 1 into corresponding bit in RESCCLR register.

3.3.7 Watchdog Reset (WDRS)

Each CPU has a watchdog timer that can optionally trigger a reset that lasts for 512 INTOSC1 cycles. CPU1 watchdog reset (CPU1.WDRS) produces an XRS. CPU2 watchdog reset (CPU2.WDRS) produces a CPU2.SYSRS and triggers an NMI on CPU1.

After a watchdog reset, the WDRSn bit in RESC is set. Software can read this bit to know the cause of reset and clear the status by writing 1 into corresponding bit in RESCCLR register.

3.3.8 NMI Watchdog Reset (NMIWDRS)

Each CPU has a non-maskable interrupt (NMI) module that detects hardware errors in the system. Each NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. CPU1 NMI watchdog reset (CPU1.NMIWDRS) produces an XRS. CPU2 NMI watchdog reset (CPU2.NMIWDRS) produces a CPU2.SYSRS and triggers an NMI on CPU1.

After an NMI watchdog reset, the NMIWDRSn bit in RESC is set.

3.3.9 Secure Code Copy Reset (SCCRESET)

Dual-zone Code Security Module (DCSM) on this device locks read access to secure memories of each CPU subsystem. To facilitate CRC checks and copying of CLA code, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a secure copy or CRC function, the DCSM triggers a reset. CPU1'security reset (CPU1.SCCRESET) is similar to a CPU1.SYSRS, and CPU2 security reset (CPU2.SCCRESET) is similar to a CPU2.SYSRS. However, the security reset also resets the debug logic to deny access to a potential attacker.

After a security reset, the SCCRESETn bit in RESC is set. Software can read this bit to know the cause of reset and clear the status by writing 1 into corresponding bit in RESCCLR register.

3.3.10 ESC Reset Output

The user can configure the EtherCAT Slave Controller (ESC) module to drive the XRSn pin low whenever the ESC module receives a reset. This is done by setting the DEVICE_RESET_EN bit to 1 in the ECAT_RESET_DEST_CONFIG register of the ESC module (EtherCAT subsystem). By default this is not enabled. Since this toggles the XRSn pin, all effects of an external XRSn reset take effect.

After an ECAT_RESET_OUT reset, the ECAT_RESET_OUT bit in RESC is set. Software can read this bit to know the cause of reset and clear the status by writing 1 into corresponding bit in RESCCLR register.

3.3.11 Test Reset (TRST)

The ICEPick debug module and associated JTAG logic has a reset (TRST) that is controlled by a dedicated pin. This reset is normally active unless the user connects a debugger to the device. For more information on the debug module, see the TI Processors Wiki page on ICEPick: http://processors.wiki.ti.com/index.php/ICEPICK.

The TRST does not have a normal RESC bit, but the TRSTn_pin_status bit indicates the state of the pin.

3.4 Peripheral Interrupts

This section explains the peripheral interrupt handling on the device. Non-maskable interrupts are covered in Section 3.5. Software interrupts and emulation interrupts are not covered in this document. For information on those, see the *TMS320C28x CPU and Instruction Set Reference Guide*.

3.4.1 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause its current execution and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead or program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until it is processed. The enable registers block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from a list called the vector table.

3.4.2 Interrupt Architecture

The C28x CPU has fourteen peripheral interrupt lines. Two of them (INT13 and INT14) are connected directly to CPU timers 1 and 2, respectively. The remaining twelve are connected to peripheral interrupt signals through the enhanced Peripheral Interrupt Expansion module (ePIE, or PIE as a shortened version). The PIE multiplexes up to sixteen peripheral interrupts into each CPU interrupt line. It also expands the vector table to allow each interrupt to have its own ISR. This allows the CPU to support a large number of peripherals.

An interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. Each stage has its own enable and flag registers. This system allows the CPU to handle one interrupt while others are pending, implement and prioritize nested interrupts in software, and disable interrupts during certain critical tasks.

Figure 3-1 shows the interrupt architecture for this device.

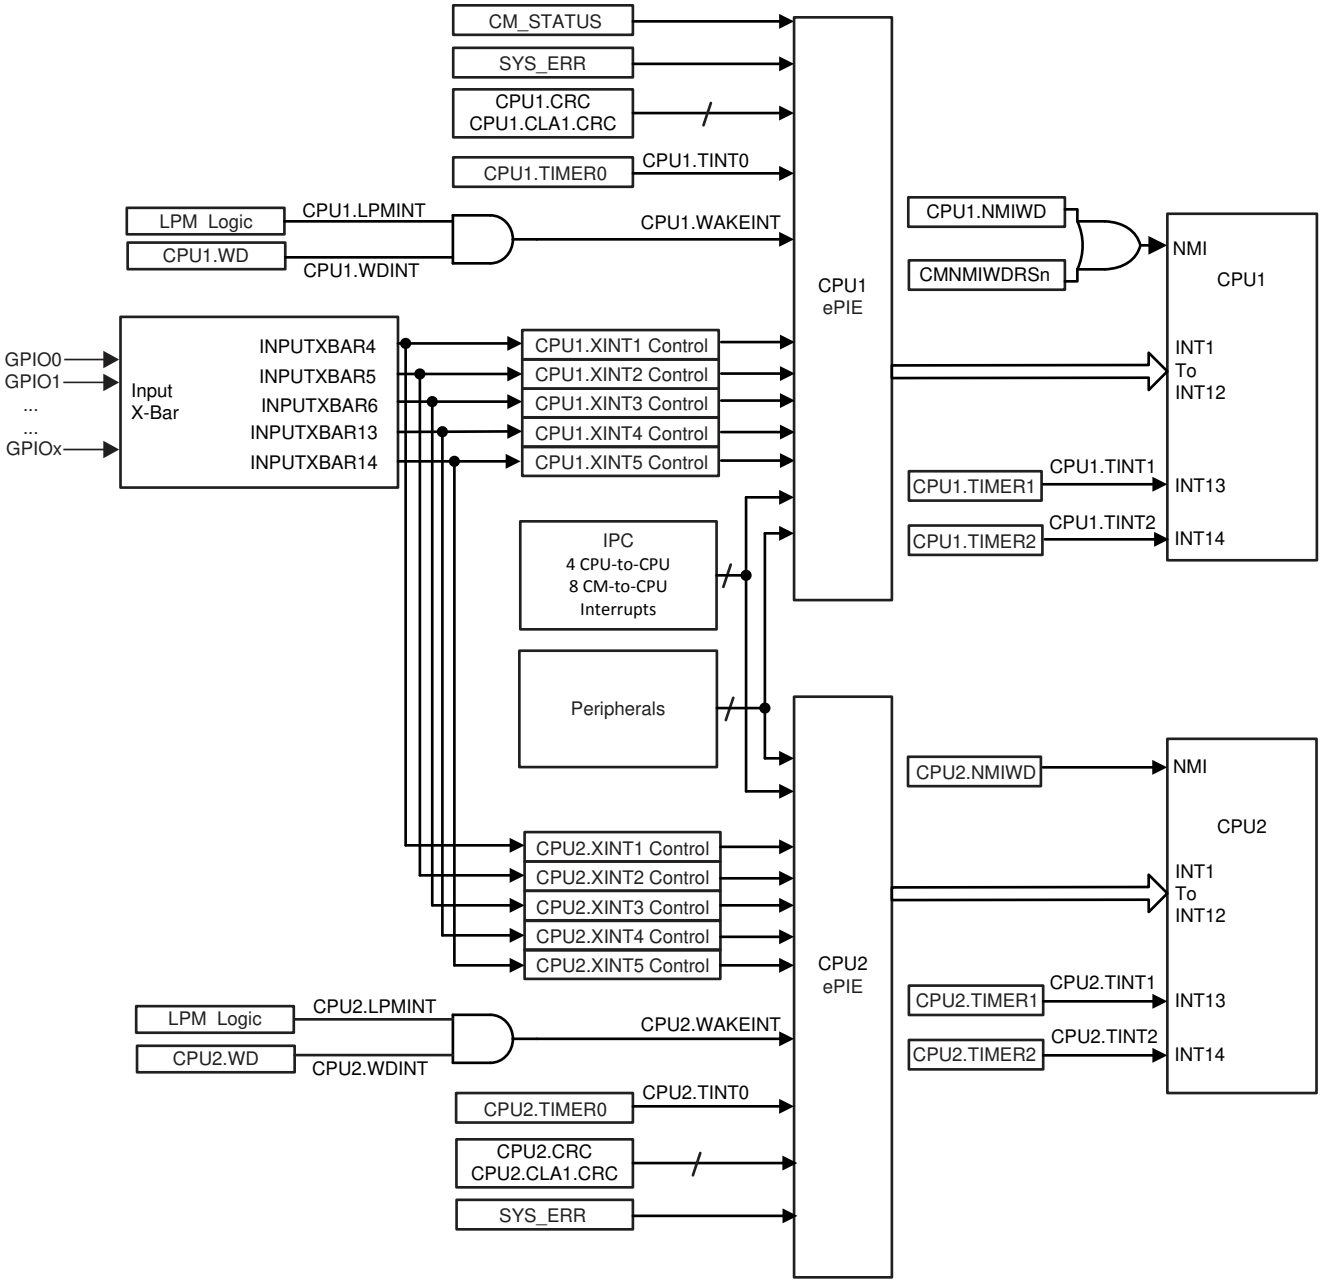

Figure 3-1. Device Interrupt Architecture

3.4.2.1 Peripheral Stage

Each peripheral has its own unique interrupt configuration, which is described in that peripheral's chapter. Some peripherals allow multiple events to trigger the same interrupt signal. For example, a communications peripheral might use the same interrupt to indicate that data has been received or that there has been a transmission error. The cause of the interrupt can be determined by reading the peripheral's status register. Often, the bits in the status register must be cleared manually before another interrupt will be generated.

3.4.2.2 PIE Stage

The PIE provides individual flag and enable register bits for each of the peripheral interrupt signals, which are sometimes called PIE channels. These channels are grouped according to their associated CPU interrupt. Each PIE group has one 16-bit enable register (PIEIERx), one 16-bit flag register (PIEIFRx), and one bit in the PIE acknowledge register (PIEACK). The PIEACK register bit acts as a common interrupt mask for the entire PIE group.

When the CPU receives an interrupt, it fetches the address of the ISR from the PIE. The PIE returns the vector for the lowest-numbered channel in the group that is both flagged and enabled. This gives lower-numbered interrupts a higher priority when multiple interrupts are pending.

If no interrupt is both flagged and enabled, the PIE returns the vector for channel 1. This condition will not happen unless software changes the state of the PIE while an interrupt is propagating. Section 3.4.4 contains procedures for safely modifying the PIE configuration once interrupts have been enabled.

3.4.2.3 CPU Stage

Like the PIE, the CPU provides flag and enable register bits for each of its interrupts. There is one enable register (IER) and one flag register (IFR), both of which are internal CPU registers. There is also a global interrupt mask, which is controlled by the INTM bit in the ST1 register. This mask can be set and cleared using the CPU's SETC instruction. In C code, C2000Ware's DINT and EINT macros can be used for this purpose.

Writes to IER and INTM are atomic operations. In particular, if INTM is cleared, the next instruction in the pipeline will run with interrupts disabled. No software delays are needed.

3.4.2.4 Dual-CPU Interrupt Handling

Each CPU has its own PIE. Both PIEs must be configured independently.

Some interrupts come from shared peripherals that can be owned by either CPU, such as the ADCs and SPIs. These interrupts are sent to both PIEs regardless of the ownership of the peripheral. Thus, a peripheral owned by one CPU can cause an interrupt on the other CPU, if that interrupt is enabled in the other CPU's PIE.

3.4.3 Interrupt Entry Sequence

Figure 3-2 shows how peripheral interrupts propagate to the CPU.

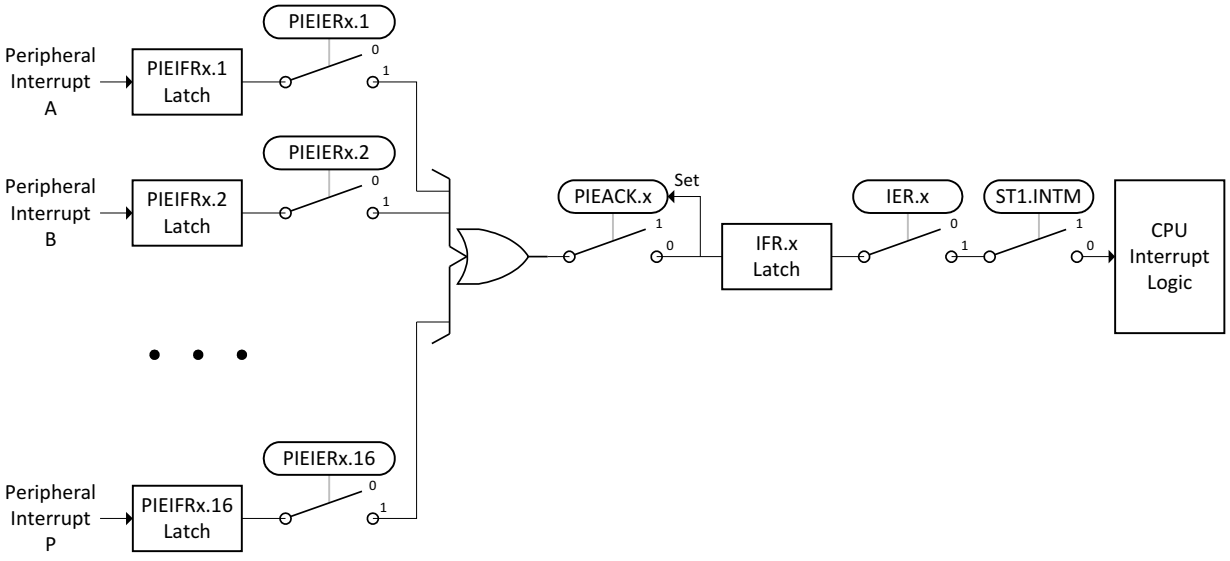

Figure 3-2. Interrupt Propagation Path

When a peripheral generates an interrupt (on PIE group x, channel y), it triggers the following sequence of events:

1. The interrupt is latched in PIEIFRx.y.
2. If PIEIERx.y is set, the interrupt propagates.
3. If PIEACK.x is clear, the interrupt propagates and PIEACK.x is set.
4. The interrupt is latched in IFR.x.
5. If IER.x is set, the interrupt propagates.
6. If INTM is clear, the CPU receives the interrupt.
7. Any instructions in the D2 or later stage of the pipeline are run to completion. Instructions in earlier stages are flushed.
8. The CPU saves its context on the stack.
9. IFR.x and IER.x are cleared. INTM is set. EALLOW is cleared.
10. The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared.
11. The CPU branches to the ISR.

The interrupt latency is the time between PIEIFRx.y latching the interrupt and the first ISR instruction entering the execution stage of the CPU pipeline. The minimum interrupt latency is 14 SYSCLK cycles. Wait states on the ISR or stack memories will add to the latency. External interrupts add a minimum of two SYSCLK cycles for GPIO synchronization plus extra time for input qualification (if used). Loops created using the C28x RPT instruction cannot be interrupted.

3.4.4 Configuring and Using Interrupts

At power-up, no interrupts are enabled by default. The PIEIER and IER registers are cleared and INTM is set. The application code is responsible for configuring and enabling all peripheral interrupts.

3.4.4.1 Enabling Interrupts

To enable a peripheral interrupt, perform the following steps:

1. Disable interrupts globally (DINT or SETC INTM).
2. Enable the PIE by setting the ENPIE bit of the PIECTRL register.
3. Write the ISR vector for each interrupt to the appropriate location in the PIE vector table, which is found in Table 3-2.
4. Set the appropriate PIEIERx bit for each interrupt. The PIE group and channel assignments are found in Table 3-2.
5. Set the CPU IER bit for any PIE group containing enabled interrupts.
6. Enable the interrupt in the peripheral.
7. Enable interrupts globally (EINT or CLRC INTM).

Step 4 does not apply to the Timer1 and Timer2 interrupts, which connect directly to the CPU.

3.4.4.2 Handling Interrupts

ISRs are similar to normal functions, but must do the following:

1. Save and restore the state of certain CPU registers (if used).
2. Clear the PIEACK bit for the interrupt group.
3. Return using the IRET instruction.

Requirements 1 and 3 are handled automatically by the TMS320C28x C compiler if the function is defined using the __interrupt keyword. For information on this keyword, see the Keywords section of the *TMS320C28x Optimizing C/C++ Compiler v6.2.4 User's Guide*. For information on writing assembly code to handle interrupts, see the Standard Operation for Maskable Interrupts section of the *TMS320C28x CPU and Instruction Set Reference Guide*.

The PIEACK bit for the interrupt group must be cleared manually in user code. This is normally done at the end of the ISR. If the PIEACK bit is not cleared, the CPU will not receive any further interrupts from that group. This does not apply to the Timer1 and Timer2 interrupts, which do not go through the PIE.

3.4.4.3 Disabling Interrupts

To disable all interrupts, set the CPU's global interrupt mask via DINT or SETC INTM. It is not necessary to add NOPs after setting INTM or modifying IER – the next instruction will execute with interrupts disabled.

Individual interrupts can be disabled using the PIEIERx registers, but care must be taken to avoid race conditions. If an interrupt signal is already propagating when the PIEIER write completes, it may reach the CPU and trigger a spurious interrupt condition. To avoid this, use the following procedure:

1. Disable interrupts globally (DINT or SETC INTM).
2. Clear the PIEIER bit for the interrupt.
3. Wait 5 cycles to make sure that any propagating interrupt has reached the CPU IFR register.
4. Clear the CPU IFR bit for the interrupt's PIE group.
5. Clear the PIEACK bit for the interrupt's PIE group.
6. Enable interrupts globally (EINT or CLRC INTM).

Interrupt groups can be disabled using the CPU IER register. This cannot cause a race condition, so no special procedure is needed.

PIEIFR bits must never be cleared in software since the read/modify/write operation may cause incoming interrupts to be lost. The only safe way to clear a PIEIFR bit is to have the CPU take the interrupt. The following procedure can be used to bypass the normal ISR:

1. Disable interrupts globally (DINT or SETC INTM).
2. Modify the PIE vector table to map the PIEIFR bit's interrupt vector to an empty ISR. This ISR will only contain a return from interrupt instruction (IRET).
3. Disable the interrupt in the peripheral registers.
4. Enable interrupts globally (EINT or CLRC INTM).
5. Wait for the pending interrupt to be serviced by the empty ISR.
6. Disable interrupts globally.
7. Modify the PIE vector table to map the interrupt vector back to its original ISR.
8. Clear the PIEACK bit for the interrupt's PIE group.
9. Enable interrupts globally.

3.4.4.4 Nesting Interrupts

By default, interrupts do not nest. It is possible to nest and prioritize interrupts via software control of the IER and PIEIERx registers. Example code can be found in C2000Ware and documentation is available at software-dl.ti.com/C2000/docs/c28x_interrupt_nesting/html/index.html.

3.4.5 PIE Channel Mapping

Table 3-2 shows the PIE group and channel assignments for each peripheral interrupt. Each row is a group, and each column is a channel within that group. When multiple interrupts are pending, the lowest-numbered channel in the lowest-numbered group is serviced first. Thus, the interrupts at the top of the table have the highest priority, and the interrupts at the bottom have the lowest priority.

Note

Cells marked "-" are Reserved. CPUx is CPU1 for CPU1 PIE and CPU2 for CPU2 PIE.

3.4.5.1 PIE Interrupt Priority

3.4.5.1.1 Channel Priority

For every PIE group, the low number channels in the group have the highest priority. For instance in PIE group 1, channel 1.1 has priority over channel 1.3. If those two enabled interrupts occurred simultaneously, channel 1.1 will be serviced first with channel 1.3 left pending. Once the ISR for channel 1.1 completes and provided there are no other enabled and pending interrupts for PIE group 1, channel 1.3 will be serviced. However, for the CPU to service any more interrupts from a PIE group, PIEACK for the group must be cleared. For this specific example, in order for channel 1.3 to be serviced, channel 1.1's ISR has to clear PIEACK for group 1.

The following example describes an alternative scenario: channel 1.1 is currently being serviced by the CPU, channel 1.3 is pending and before channel 1.1's ISR completes, channel 1.2 which is enabled also comes in. Since channel 1.2 has a higher priority than channel 1.3, the CPU will service channel 1.2 and channel 1.3 will still be left pending. Using the steps from the Interrupt Entry Sequence (Section 3.4.3), channel 1.2 interrupt can happen as late as step 10 (The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared) and it will still be serviced ahead of channel 1.3.

3.4.5.1.2 Group Priority

Generally, the lowest channel in the lowest PIE group has the highest priority. An example of this is channels 1.1 and 2.1. Those two channels have the highest priority in their respective groups. If the interrupts for those two enabled channels happened simultaneously and provided there are no other enabled and pending interrupts, channel 1.1 will be serviced first by the CPU with channel 2.1 left pending.

However, there are cases where channel priority supersedes group priority. This special case happens depending on which step the CPU is currently at in the Interrupt Entry Sequence (Section 3.4.3).

The following illustrates an example of this special case.

The CPU is about to service channel 2.3 and is currently going through the steps in the Interrupt Entry Sequence (Section 3.4.3).

1. As the CPU reaches step 10 (The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared), two enabled interrupts: channel 1.1 and channel 2.1 come in.
2. Due to channel priority, channel 2.1 will be serviced ahead of channel 2.3. However, group priority dictates that channel 1.1 be serviced ahead of channels 2.1 and 2.3.
3. Channel priority supersedes here and channel 2.1 will be serviced ahead of 1.1 and 2.3.
4. After channel 2.1 completes, channel 1.1 is serviced followed by channel 2.3.

Group priority is only guaranteed if no interrupts are currently being serviced, that is, the Interrupt Entry Sequence (Section 3.4.3) is not executing.

3.4.6 System Error and CM Status Interrupts

SYS_ERR and CM_STATUS consolidate several sources of interrupts. These sources set the respective bit in the SYS_ERR_INT_FLG and CM_STATUS_INT_FLG registers. Any set bit in the SYS_ERR_INT_FLG and CM_STATUS_INT_FLG registers will also set the GINT (Global Interrupt) bit. GINT has to be cleared before anymore SYS_ERR or CM_STATUS interrupts are generated. If GINT is cleared with the source flags still set, another SYS_ERR or CM_STATUS interrupt will be fired, therefore it is recommended to clear the source flags before clearing GINT.

Figure 3-3 shows the sources for SYS_ERR and CM_STATUS interrupts.

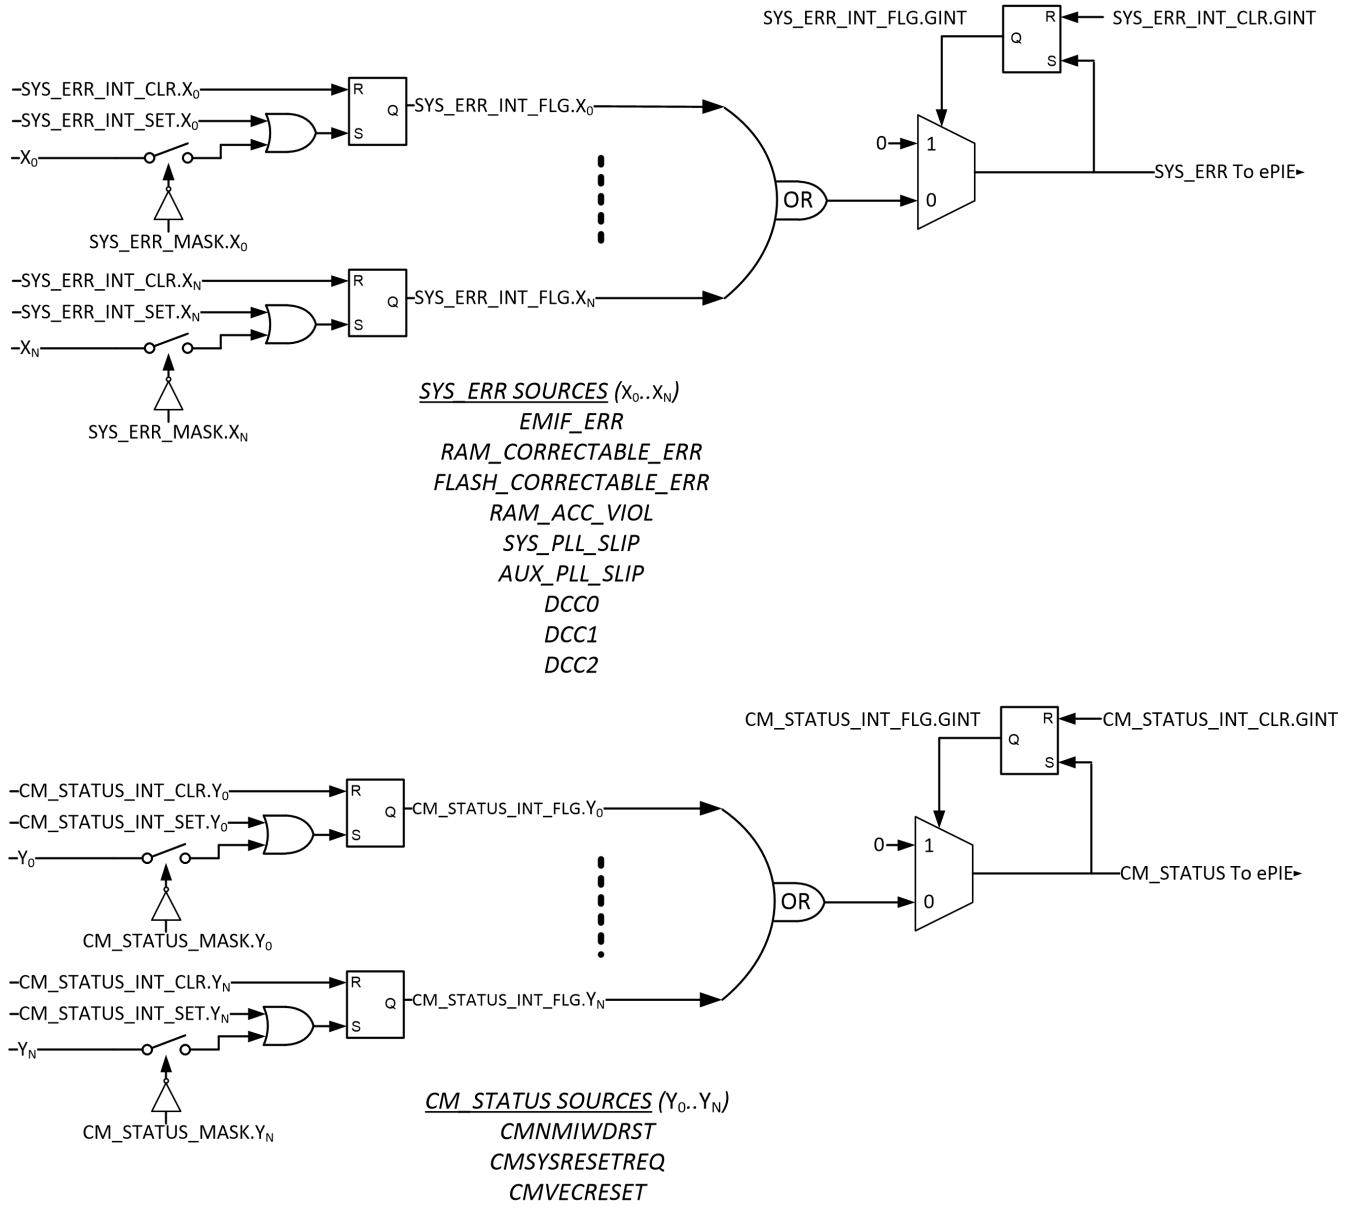

Figure 3-3. System Error and CM Status Interrupt Sources

3.4.7 Vector Tables

Table 3-3 shows the CPU interrupt vector table. The vectors for INT1–INT12 are not used in this device. The reset vector is fetched from the boot ROM instead of from this table.

Table 3-3. CPU Interrupt Vectors

Name	Vector ID	Address	Size (x16)	Description	Core Priority	ePIE Group Priority
Reset	0	0x0000 0D00	2	Reset is always fetched from location 0x003F_FFC0 in Boot ROM	1 (Highest)	-

3.5 Exceptions and Non-Maskable Interrupts

This section describes system-level error conditions that can trigger a non-maskable interrupt (NMI). The interrupt allows the application to respond to the error.

3.5.1 Configuring and Using NMIs

Each CPU subsystem has its own NMI module. This section will provide detail of NMI on C28x subsystems. An incoming NMI sets a status bit in the NMIFLG register and starts the NMI watchdog counter. This counter is clocked by the SYSCLK, and if it reaches the value programmed in NMIWDPRD register, it triggers an NMI watchdog reset (NMIWDRS). To prevent this, the NMI handler must clear the flag bit using the NMIFLGCLR register. Once all flag bits are clear, the NMIINT bit in the NMIFLG register should be cleared to allow future NMIs to be taken.

The NMI module is enabled by the boot ROM during the startup process. To respond to NMIs, an NMI handler vector must be written to the PIE vector table.

3.5.2 Emulation Considerations

The NMI watchdog counter behaves as follows under debug conditions:

CPU Suspended:	When the CPU is suspended, the NMI watchdog counter is suspended.
Run-Free Mode:	When the CPU is placed in run-free mode, the NMI watchdog counter resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the NMI watchdog counter is suspended. The counter remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the NMI watchdog counter operates as normal.

3.5.3 NMI Sources

There are several types of hardware errors that can trigger an NMI. Additional information about the error is usually available from the module that detects it.

3.5.3.1 Missing Clock Detection

The missing clock detection logic monitors OSCCLK for failure. If the OSCCLK source stops, the PLL is bypassed, OSCCLK is connected to INTOSC1, and NMIs are fired to both CPUs. For more information on missing clock detection, see Section 3.7.7.1.

3.5.3.2 RAM Uncorrectable Error

A single-bit parity error, double-bit ECC data error, or single-bit ECC address error in a RAM read will trigger an NMI. This applies to CPU, CLA, and DMA reads. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on RAM error detection, see Section 3.12.1.9.

3.5.3.3 Flash Uncorrectable ECC Error

A double-bit ECC data error or single-bit ECC address error in a Flash read will trigger an NMI. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt.

3.5.3.4 ROM Uncorrectable Error

On this device ROM has a parity feature and a parity mismatch during read or execution will trigger an NMI.

3.5.3.5 NMI Vector Fetch Mismatch

Each CPU's Peripheral Interrupt Expansion module (PIE) has redundant vector tables. If a mismatch in these tables is detected during a vector fetch, a user-specified error handler is run instead of the ISR. If the vector fetch was caused by an NMI, a second NMI is fired to the other CPU. Mismatches for other interrupts do not trigger an NMI. For more information about the vector address check, see Section 3.6.2.

3.5.3.6 CPU2 Watchdog or NMI Watchdog Reset

A watchdog reset or NMI watchdog reset on CPU2 will trigger an NMI on CPU1. Since a CPU1 reset also resets CPU2, this NMI source is not available on CPU2. Watchdog interrupts do not trigger an NMI.

3.5.3.7 CM NMI Watchdog Reset

A NMI watchdog reset on CM can generate NMI on CPU1. To enable this feature user need to set CMNMIWDRST configuration bit in CMTOCPU1NMICTL register.

3.5.3.8 EtherCAT Reset out

A reset out from EtherCAT module can generate NMI on CPU1. To enable this feature user need to set CPU_NMI_EN configuration bit in ESCSS_RESET_DEST_CONFIG register.

3.5.3.9 CRC Fail

A CRC fail result from BGCRC module can generate NMI to respective CPU. By default this NMI is enable. To disable this feature user need to configure NMIDIS configuration field in BGCRC_CTRL1 register with value "1010".

3.5.3.10 ERAD NMI

ERAD module can generate NMI based on different events which user can configure in ERAD.

3.5.4 Illegal Instruction Trap (ITRAP)

If the CPU tries to execute an illegal instruction, it generates a special interrupt called an illegal instruction trap (ITRAP). This interrupt is non-maskable and has its own vector in the PIE vector table. For more information about ITRAPs, see the Illegal-Instruction Trap section of the *TMS320C28x DSP CPU and Instruction Set Reference Guide*.

Note

A RAM fetch access violation will trigger an ITRAP in addition to the normal peripheral interrupt for RAM access violations. The CPU will handle the ITRAP first.

3.6 Safety Features

This section gives details on features that monitor device operation during run-time to detect any error in operation.

3.6.1 Write Protection on Registers

3.6.1.1 LOCK Protection on System Configuration Registers

Several system configuration registers are protected from spurious CPU writes by “LOCK” registers. Once these associated LOCK register bits are set, the respective locked registers can no longer be modified by software. See the register descriptions for details.

3.6.1.2 EALLOW Protection

Several control registers are protected from spurious CPU writes by the EALLOW protection mechanism. The EALLOW bit in status register 1 (ST1) indicates the state of protection as shown in Table 3-5.

Table 3-5. Access to EALLOW-Protected Registers

EALLOW Bit	CPU Writes	CPU Reads	JTAG Writes	JTAG Reads
0	Ignored	Allowed	Allowed(1)	Allowed
1	Allowed	Allowed	Allowed	Allowed

(1) The EALLOW bit is overridden via the JTAG port, allowing full access of protected registers during debug from the Code Composer Studio IDE.

At reset, the EALLOW bit is cleared, enabling EALLOW protection. While protected, all writes to protected registers by the CPU are ignored and only CPU reads, JTAG reads, and JTAG writes are allowed. If this bit is set, by executing the EALLOW instruction, the CPU is allowed to write freely to protected registers. After modifying registers, the registers can once again be protected by executing the EDIS instruction to clear the EALLOW bit.

3.6.2 CPU1 and CPU2 ePIE Vector Address Validity Check

The ePIE vector table on each CPU is duplicated into these two parts:

- Main ePIE Vector Table mapped from 0xD00 to 0xEFF in the C28x memory space
- Redundant ePIE Vector Table mapped from 0x1000D00 to 0x1000EFF in the C28x memory space

Following is the behavior of accesses to the ePIE memories:

- Data Writes to Main Vector Table: Writes to both memories
- Data Writes to Redundant Vector Table: Writes only to the Redundant Vector Table
- Vector Fetch: Data from both the vector tables are compared
- Data Read: Can read the Main and Redundant vector table separately

On every vector fetch from the ePIE, a hardware comparison (no cycle penalty is incurred to do the comparison) of both the vector table outputs is performed and if there is a mismatch between the two vector table outputs, the following occurs:

1. If the PIEVERRADDR register (default value 0x3F FFFF) is not initialized, the default error handler at address 0x3FFFBE gets executed.

   But, when the PIEVERRADDR register is initialized to the address of the user-defined routine, the user-defined routine is executed instead of the default error handler.

   Note: Each CPU has a copy of the PIE Vector Fetch Error Handler register (CPU1.PIEVERRADDR and CPU2.PIEVERRADDR).
2. Hardware also generates EPWM Trip signals that trip the PWM outputs using TRIPIN15.
3. An NMI to the other CPU is sent, if the current mismatch is during a vector fetch. For example, on an NMI vector fetch error for CPU2, an NMI is also fired to CPU1.NMIWD.

If there is no mismatch, the correct vector is jammed onto the C28 program control.

3.6.3 NMIWDs

Each CPU has user-programmable NMIWD period registers, in which users can set a limit on how much time they want to allocate for the device to acknowledge the NMI. If the NMI is not acknowledged, it will cause a device reset.

3.6.4 ECC and Parity Enabled RAMs, Shared RAMs Protection

Each CPU subsystem has different RAM blocks. Some RAM blocks are ECC-enabled and others are parity-enabled. All single-bit errors in ECC RAM are auto-corrected and an error counter is incremented every time a single bit error is detected. If the error counter reaches a predefined user configured limit, an interrupt is generated to the corresponding CPU. Refer to Section 3.12 for more details on RAM errors.

All uncorrectable double-bit errors end up triggering an NMI to corresponding CPUs.

3.6.5 ECC Enabled Flash Memory

When ECC is programmed and enabled, Flash single-bit errors are corrected automatically by ECC logic before giving data to the CPU, but they are not corrected in Flash memory. Flash memory will still contain wrong data until another erase/program operation happens to correct the Flash contents. Irrespective of whether the error interrupt is enabled or disabled, single-bit errors are always corrected before giving data to the CPU. When the interrupt is disabled, users can check the single-bit error counter register for any single-bit error occurrences. The error counter stops incrementing once its value is equal to the threshold + 1. It is always suggested to set the threshold register to a non-zero value so that the error counter can increment. It is up to the user to decide the threshold value at which they have to reprogram the Flash with the correct data.

When ECC is programmed and enabled, Flash uncorrectable errors end up triggering an NMI to the respective CPU. Refer to Section 3.12 for more details on Flash error correction and error catching mechanisms.

3.6.6 ERRORSTS Pin

The ERRORSTS pin is an ‘always output’ pin and remains high until an error is detected inside the chip. On an error, the ERRORSTS pin goes low (default polarity) until the corresponding internal error status flag for that error source is cleared. Figure 3-4 shows the functionality of the ERRORSTS pin.

The ERRORSTS pin is tri-stated until the chip power-rails ramp up to the lower operational limit. As the ERRORSTS pin is an active-low pin (default polarity), users who care about the state of this pin during power-up must connect an external pull-down on this pin.

Following enhancement has been made on this device for ERRORSTS pin logic:

- Polarity of Error pin has been made configurable (default setting is active-low polarity).
- To enable testing of the Error pin, capability to force and clear the Error pin from software has been provided.
- Additional sources of Error have been added to ERRORSTS:
  - CPU1 Watchdog reset
  - Error on a PIE vector fetch
  - NMI on CM

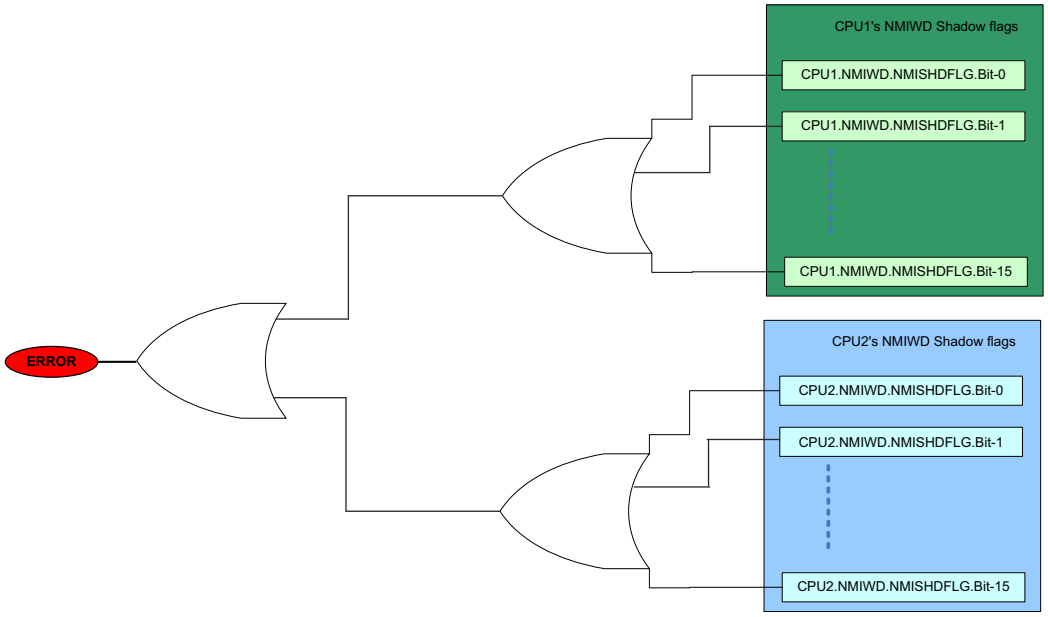

Figure 3-4. ERRORSTS Pin Diagram

3.7 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. Figure 3-5 provides an overview of the device's clocking system.

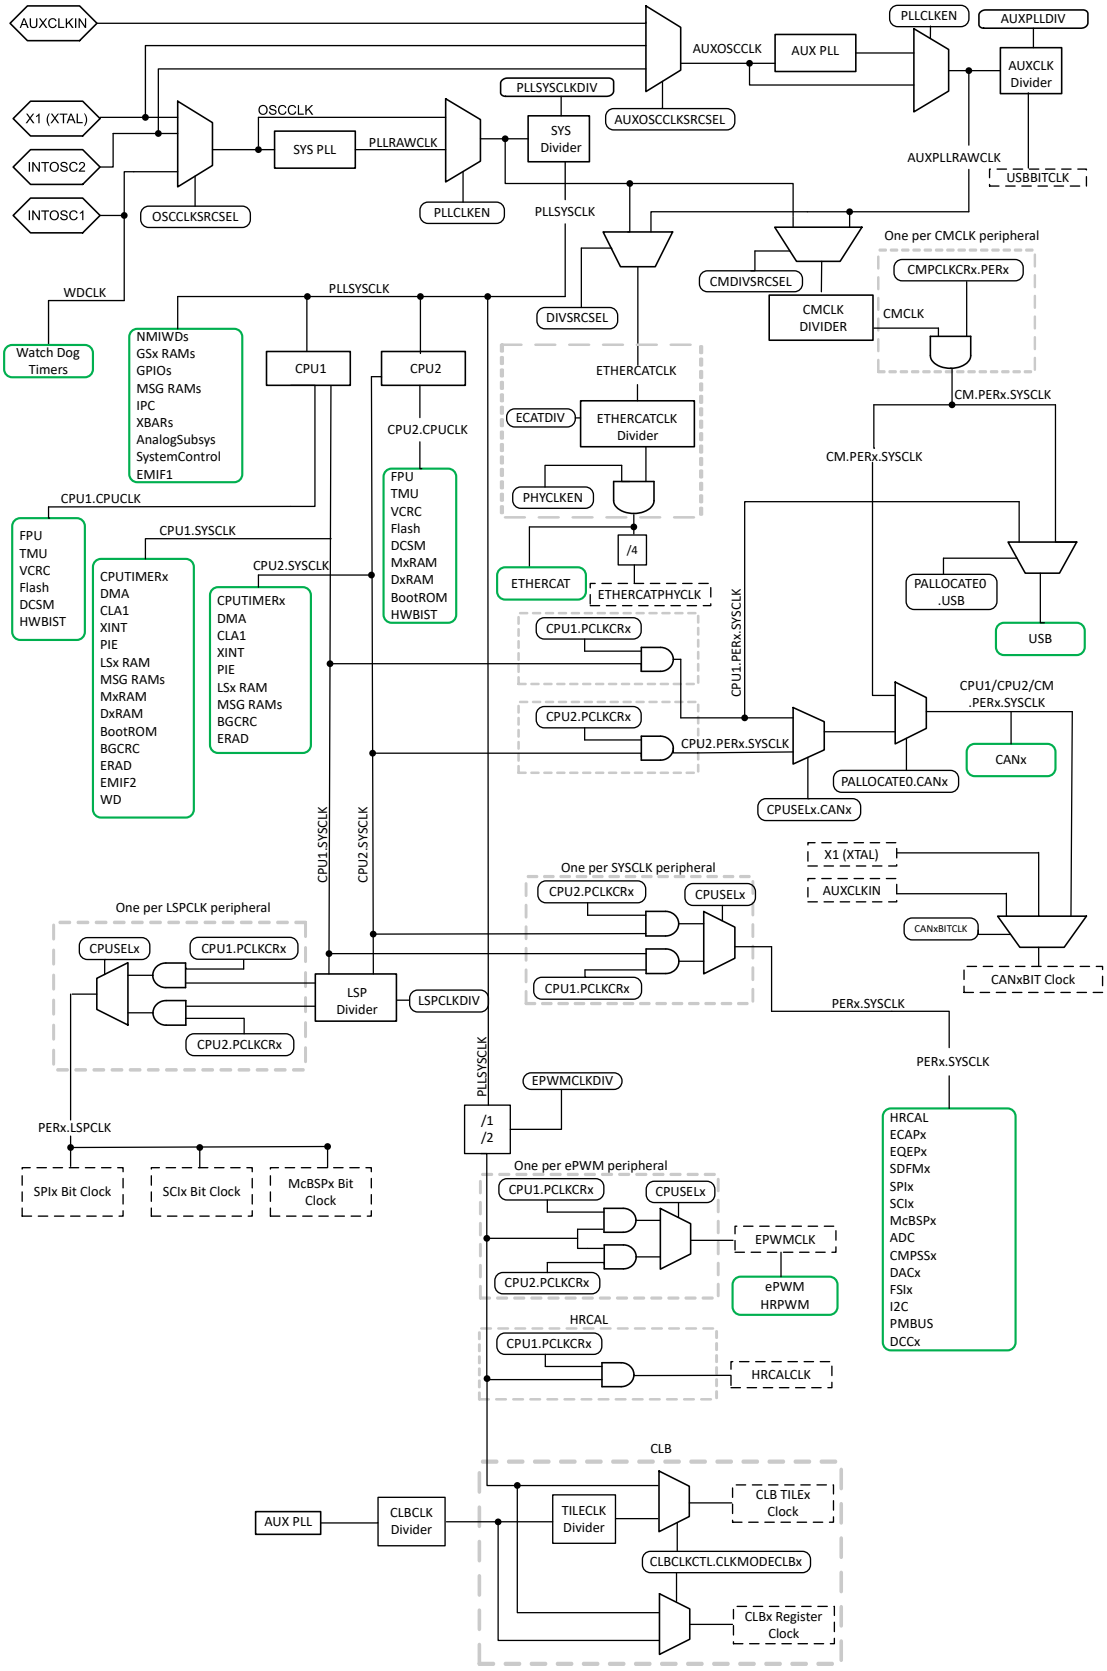

Figure 3-5. Clocking System

3.7.1 Clock Sources

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but must provide answers to the following questions:

1. What is the desired CPU frequency?
2. Are there any additional communication protocols or peripherals, such as CAN or USB, required?
3. What types of external oscillators or clock sources are available?

If CAN or USB is required, an external clock source with a precise frequency must be used as a reference clock. Otherwise, use only INTOSC2 and avoid the need for more external components.

All of the clocks in the device are derived from one of four clock sources.

3.7.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10 MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source, and is the default system clock at reset. It is used to run the boot ROM and can be used as the system clock source for the application.

Note

INTOSC2's frequency tolerance is too loose to meet the timing requirements for some peripherals such as CAN and USB, so an external clock must be used to support those features.

3.7.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10 MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 may also be manually selected as the system and auxiliary clock source for debug purposes.

3.7.1.3 External Oscillator (XTAL)

The dedicated X1 and X2 pins support an external clock source (XTAL), which can be used as the main system and auxiliary clock source. Frequency limits and timing requirements can be found in the device datasheet. Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal should be connected to X1 while X2 is left unconnected, as shown in Figure 3-6.

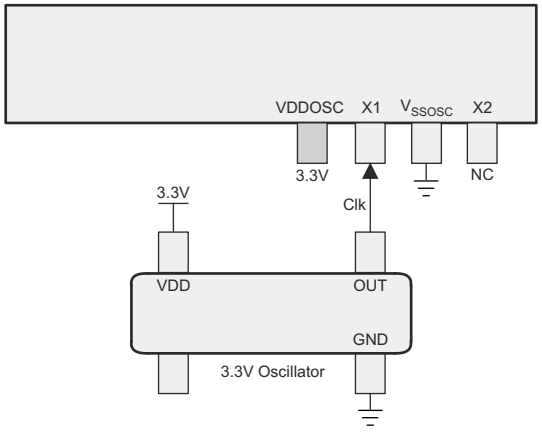

Figure 3-6. Single-ended 3.3V External Clock

- An external crystal. The crystal should be connected across X1 and X2 with its load capacitors connected to VSSOSC as shown in Figure 3-7.

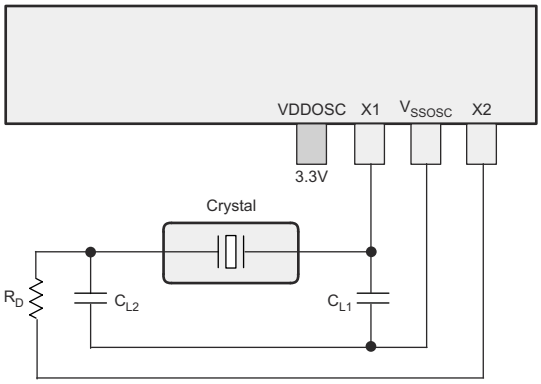

Figure 3-7. External Crystal

- An external resonator. The resonator should be connected across X1 and X2 with its ground connected to VSSOSC as shown in Figure 3-8.

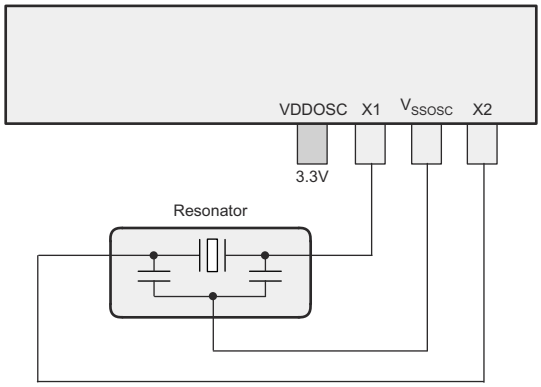

Figure 3-8. External Resonator

3.7.1.4 Auxiliary Clock Input (AUXCLKIN)

An additional external clock source is supported on GPIO133 (AUXCLKIN). This must be a single-ended 3.3V external clock. It can be used as the clock source for the USB, CAN, and Communication Manager Subsystem. Frequency limits and timing requirements can be found in the device datasheet. The external clock should be connected directly to the GPIO133 pin, as shown in Figure 3-9.

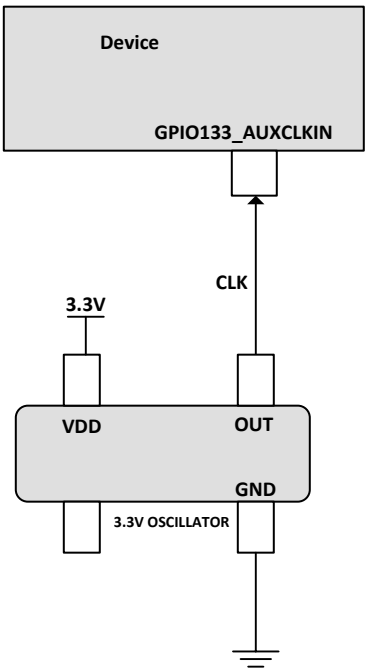

Figure 3-9. AUXCLKIN

3.7.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (via PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

3.7.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the master reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK may be used directly or fed through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock, and is connected to INTOSC2.

3.7.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at the maximum rated operating frequency, and in most applications generates the main system clock. This PLL uses OSCCLK as a reference. For configuration instructions, see Section 3.7.6.

3.7.2.3 Auxiliary Oscillator Clock (AUXOSCCLK)

One of INTOSC2, XTAL, or AUXCLKIN may be chosen to be the auxiliary reference clock (AUXOSCCLK) for the USB module. (This selection does not affect the CAN bit clock, which uses AUXCLKIN directly). AUXOSCCLK may be used directly or fed through the auxiliary PLL to reach a higher frequency. At reset, AUXOSCCLK is connected to INTOSC2, but only an external oscillator can meet the USB timing requirements.

3.7.2.4 Auxiliary PLL Output Clock (AUXPLLRAWCLK)

The auxiliary PLL is used to generate a clock for USB, CAN, EtherCAT, and the CM Subsystem. This PLL uses AUXOSCCLK as a reference. For configuration instructions, see Section 3.7.6.

3.7.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

3.7.3.1 System Clock (PLLSYSCLK)

The system control registers, GS RAMs, IPC module, GPIO qualification, and NMI watchdog timers have their own clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK may be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured via the SYSCLKDIVSEL register.

3.7.3.2 CPU Clock (CPUCLK)

Each CPU has its own clock (CPU1.CPUCLK and CPU2.CPUCLK) which is used to clock the CPU, its coprocessors, its private RAMs (M0, M1, D0, and D1), and its boot ROM and Flash wrapper. This clock is identical to PLLSYSCLK, but is gated when the CPU enters IDLE or STANDBY mode.

3.7.3.3 CPU Subsystem Clock (SYSCLK and PERx.SYSCLK)

Each CPU provides a clock (CPU1.SYSCLK and CPU2.SYSCLK) to its CLA, DMA, and most owned peripherals. This clock is identical to PLLSYSCLK, but is gated when the CPU enters STANDBY mode.

Each peripheral clock can be connected to either CPU1.SYSCLK or CPU2.SYSCLK. This selection is made by CPU1 via the CPUSELx registers. Each peripheral clock also has its own independent clock gating which is controlled by the CPU's PCLKCRx registers. By default, the ePWM, EMIF1, and EMIF2 clocks each have an additional /2 divider, which is required to support CPU frequencies over 100 MHz. At slower CPU frequencies, these dividers can be disabled via the PERCLKDIVSEL register.

A peripheral may be assigned to either CPU. That is, code for a peripheral can be executed from either CPU1 or CPU2. CPUSELx register is used to assign a peripheral to either CPU1 or CPU2. This register must be configured prior to enabling the clock for the chosen peripheral since the clock for each peripheral is derived from the selected CPU subsystem. The clock multiplexer controlled by the CPUSELx register is not glitch-free. Therefore the CPUSELx register must be configured before the PCLKCRx register. Note that the reset for each peripheral is also driven from the selected CPU.

Note

Application needs to wait for 5 SYSCLK cycles after enabling clock to the peripherals when using PCLKCRx.

3.7.3.4 Low-Speed Peripheral Clock (LSPCLK and PERx.LSPCLK)

The SCI, SPI, and McBSP modules can communicate at bit rates that are much slower than the CPU frequency. These modules are connected to a shared clock divider, which generates a low-speed peripheral clock (LSPCLK) derived from SYSCLK. LSPCLK uses a /4 divider by default, but the ratio can be changed via the LOSPCP register. Each SCI, SPI, and McBSP module's clock (PERx.LSPCLK) can be gated independently via the PCLKCRx registers.

3.7.3.5 USB Auxiliary Clock (AUXPLLCLK)

The USB module requires a fixed 60 MHz clock for bit sampling. Since the main system clock is usually not a multiple of 60 MHz, the correct frequency cannot be achieved with a simple divider. Instead, the USB clock is provided through an auxiliary clock path (AUXPLLCLK), which can use an independent clock source and PLL to generate the correct frequency.

USB clock tolerances are very tight. As stated in section 7.1.11 of the USB 2.0 specification, low-speed devices (1.50 Mb/s) have a tolerance of +/- 1.5% , while high-speed devices (12.000 Mb/s) have a tolerance of +/- 0.25%. Typically these tolerances are achieved by using an external crystal or resonator as the source for AUXOSCCLK.

3.7.3.6 CAN Bit Clock

The required frequency tolerance for the CAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of PERx.SYSCLK) may not be precise enough, the bit clock can also be connected to XTAL or AUXCLKIN via the CLKSRCCTL2 register. There is an independent selection for each CAN module.

3.7.3.7 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PERx.SYSCLK. Timer 2 is connected to PERx.SYSCLK by default, but may also be connected to INTOSC1, INTOSC2, XTAL, or AUXPLLCLK via the TMR2CLKCTL register. This register also provides a separate pre-scale divider for timer 2. If a source other than SYSCLK is used, the SYSCLK frequency must be at least twice the source frequency to ensure correct sampling. Each CPU has its own independent CPU timers and TMR2CLKCTL register.

The main reason to use a non-SYSCLK source would be for internal frequency measurement. In most applications, timer 2 will run off of the SYSCLK.

3.7.4 External Clock Output (XCLKOUT)

It is sometimes necessary to observe a clock directly for debug and testing purposes. The external clock output (XCLKOUT) feature supports this by connecting a clock to an external pin, GPIO73. The available clock sources are PLLSYSCLK, PLLRAWCLK, CPU1.SYSCLK, AUXPLLRAWCLK, CPU2.SYSCLK, ,INTOSC1, and INTOSC2.

To use XCLKOUT, first select the clock source via the CLKSRCCTL3 register. Next, select the desired output divider via the XCLKOUTDIVSEL register. Finally, connect GPIO73 to mux channel 3 using the GPIO configuration registers.

3.7.5 Clock Connectivity

Table 3-6 provide details on the clock connections of every module present in the device.

Table 3-6. Clock Connections Sorted by Clock Domain

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	Shared Modules
CPUx.CPUCLK	CPU1	CPU2	
	CPU1VCRC	CPU2.VCRC

3.7.6 PLL/AUXPLL

The PLL/AUXPLL is responsible for synthesizing an output frequency from the input clock (from the oscillator); Figure 3-10 shows a simple block diagram of the PLL/AUXPLL. The PLL/AUXPLL divides the reference input for a lower frequency input into the PLL/AUXPLL by (REFDIV+1). Then multiplies this internal frequency by IMULT to get the VCO output clock. The PLL/AUXPLL output is divided by (ODIV+1) to generate PLLRAWCLK/ AUXPLLRAWCLK which is further divided by SYSCLKDIVSEL.PLLSYSCLKDIV/AUXCLKDIVSEL.AUXPLLDIV to generate PLLSYSCLK/AUXCLK

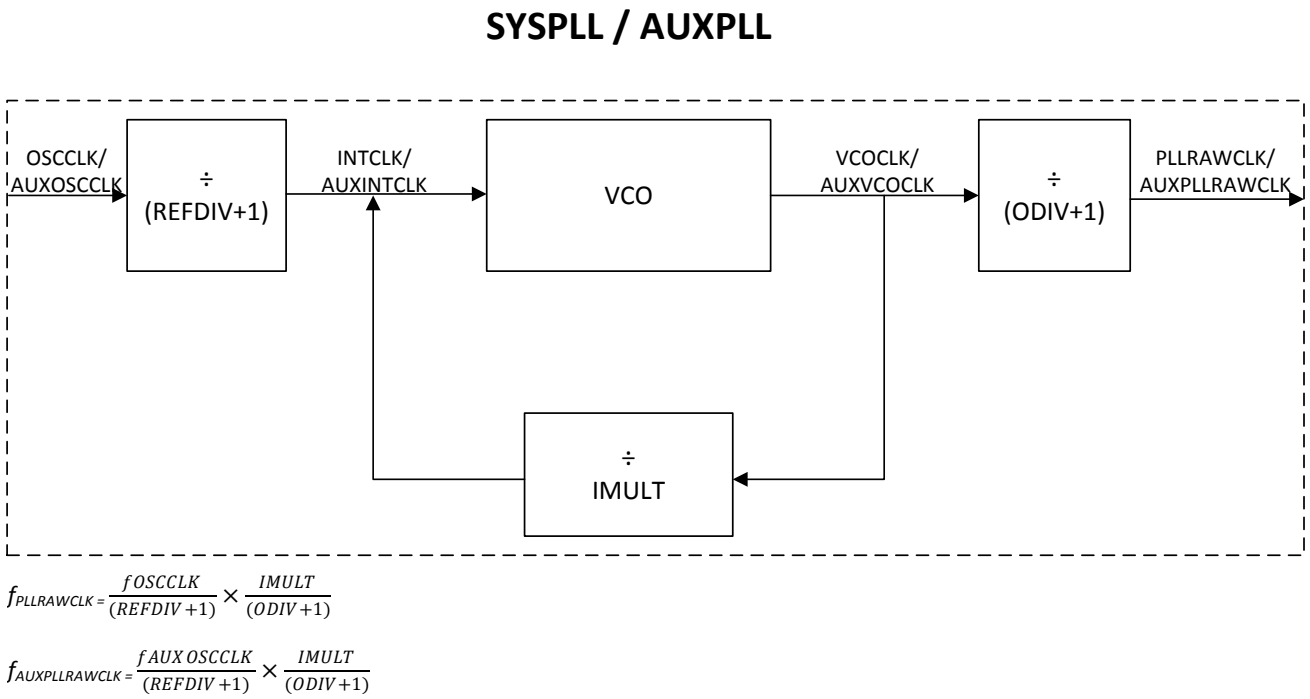

Figure 3-10. PLL/AUXPLL

3.7.6.1 Choosing PLL Settings

There are two PLLs (SYSPLL and AUXPLL) and equations shown in Figure 3-10 should be used to configure respective PLL

IMULT is the integer value of the multiplier.

REFDIV is the reference divider for the OSCCLK/AUXOSCCLK.

ODIV is the output divider of the PLLRAWCLK/AUXPLLRAWCLK.

PLLSYSCLKDIV is the system clock divider.

AUXPLLDIV is the auxiliary clock divider.

For the permissible values of the multipliers and dividers, see the documentation for their respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the data manual.

Note

The system clock frequency (PLLSYSCLK) may not exceed the limit specified in the datasheet. This limit does not allow for oscillator tolerance.

The clock source and PLL configuration registers are shared between the two CPUs (CPU1 and CPU2). Register access is controlled by way of a semaphore, which is described in the *Interprocessor Communication (IPC)* chapter.

3.7.6.2 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure should be used to set up the desired application configuration:

Refer to your device SysCtl_setClock() function inside C2000Ware installation for an example.

Recommended sequence to set up the system PLL:

1. Bypass the PLL by clearing SYSPLLCTL1[PLLCLKEN] and wait for at least 120 CPU clock cycles by adding 120 NOP instructions.
2. Power down the PLL by writing to SYSPLLCTL1.PLLEN = 0 and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
3. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL and wait for at least 300 CPU clock cycles by adding 300 NOP instructions.
4. Set the system clock divider to "/1" to ensure the fastest PLL configuration by clearing SYSCLKDIVSEL[PLLSYSCLKDIV].
5. Set the IMULT, REFDIV & ODIV simultaneously by writing 32-bit value in SYSPLLMULT at once. This will automatically enable the PLL. Be sure the settings for multiplier and dividers do not violate the frequency specifications as defined in the data sheet.
6. Wait for PLL to lock by polling for lock status bit to go high, that is, SYSPLLSTS.LOCKS = 1
7. Configure DCC with reference clock as OSCCLK and clock under measurement as PLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, do not enable PLLRAWCLK as SYSCLK, stop here and troubleshoot. Refer to DCC chapter for more information on its configuration and usage.
8. If the PLLRAWCLK is within the valid range, then set the system clock divider one setting higher than the final desired value. For example ClkCfgRegs.SYSCLKDIVSEL.bit.PLLSYSCLKDIV = divsel + 1. This limits the current increase when switching to the PLL.
9. Switch to the PLL as the system clock by setting SYSPLLCTL1[PLLCLKEN] and wait for 200 PLLSYSCLK cycles for current to stabilize by adding 200 NOP instructions.
10. Change the system clock divider (PLLSYSCLKDIV) to the appropriate value.

Note

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
2. At least 120 CPU clock cycles delay is needed after bypassing PLL, that is, SYSPLLCTL1.PLLCLKEN=0.
3. At least 60 CPU clock cycles delay is needed after PLL is powered down, that is, SYSPLLCTL1.PLLEN=0.
4. At least 300 CPU clock cycles delay is needed after OSSCLK source is changed.
5. PLL SLIP bit is not supported. DCC should be used to check the validity of the PLL clock. This feature is included as part of SysCtl_setClock() function inside C2000Ware.

3.7.6.3 USB Auxiliary Clock Setup

Refer to your device SysCtl_setAuxClock() function inside C2000Ware installation for an example.

If USB functionality is needed, the auxiliary clock (AUXPLLCLK) must be configured to produce 60 MHz. The procedure is similar to the system clock setup:

1. Bypass the PLL by clearing AUXPLLCTL1[PLLCLKEN] and wait for at least 120 CPU clock cycles by adding 120 NOP instructions..
2. Power down the PLL by writing to AUXPLLCTL1.PLLEN=0 and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
3. Select the reference clock source (AUXOSCCLK) by writing to CLKSRCCTL2.AUXOSCCLKSRCSEL and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
4. Set the IMULT, REFDIV & ODIV simultaneously by writing 32-bit value in AUXPLLMULT at once. This will automatically enable the PLL. Be sure the settings for multiplier and dividers do not violate the frequency specifications as defined in the data sheet.
5. Wait for PLL to lock by polling for lock status bit to go high (AUXPLLSTS.LOCKS = 1)
6. Configure DCC with reference clock as AUXOSCCLK and clock under measurement as AUXPLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, stop here and troubleshoot. Refer to DCC chapter for more information on its configuration and usage.
7. Connect the auxiliary PLL output clock (AUXPLLRAWCLK) to AUXPLLCLK by writing a 1 to AUXPLLCTL1.PLLCLKEN.

The auxiliary clock configuration can be changed at run time. Changing the AUXOSCCLK source will automatically bypass the PLL and set the multiplier to zero. Changing the multiplier from one non-zero value to another will temporarily bypass the PLL until it re-locks.

Note

1. AUXPLL must be bypassed and powered down manually before changing the AUXOSCCLK source.
2. At least 120 CPU clock cycles delay is needed after bypassing PLL, that is, AUXPLLCTL1.PLLCLKEN = 0.
3. At least 60 CPU clock cycles delay is needed after PLL is powered down, that is, AUXPLLCTL1.PLLEN = 0.
4. At least 60 CPU clock cycles delay is needed after AUXOSSCLK source is changed.
5. AUXPLL SLIP bit is not supported. DCC should be used to check the validity of the AUXPLL clock. This feature is included as part of SysCtl_setAuxClock() function inside C2000Ware.

3.7.6.4 SYS PLL / AUX PLL Bypass

If the application requires the PLL clock to be bypassed from the system, then the application needs to configure SYSPLLCTL1.PLLCLKEN=0 or AUXPLLCTL1.PLLCLKEN=0. It takes up to 120 CPU clock cycles before the bypass is effective. In the meantime, if PLLSYSCLKDIV / AUXPLLDIV is reduced to a lower value (for example, from /2 to /1 or /4 to /2), the device may be clocked above the maximum rated frequency and can lead to unpredictable device behavior. Hence, a delay of 120 CPU clock cycles is required after bypassing the PLL from the enable state, that is, going from PLLCLKEN=1 to PLLCLKEN=0.

3.7.7 Clock (OSCCLK) Failure Detection

To achieve safety diagnostic, Missing Clock Detection (MCD) can be used.

Table 3-7 lists the details.

Table 3-7. Clock Source (OSCCLK) Failure Detection

Clock Failure Detection Circuitry	Clocks Detected	Time for Detection (in Cycles)	Limitations
Missing Clock Detection (MCD)	INTOSC2, XTAL/X1	8192 INTOSC1 cycles	Cannot detect INTOSC1 clock failure.

3.7.7.1 Missing Clock Detection Logic

The missing clock detect (MCD) logic detects OSCCLK failure, using INTOSC1 as the reference clock source. This circuit only detects complete loss of OSCCLK and doesn't do any detection of frequency drift on the OSCCLK.

This circuit monitors the OSCLK (primary clock) using the 10 MHz clock provided by the INTOSC1 (secondary clock) as a backup clock. This circuit functions as:

1. The primary clock (OSCCLK) clock keeps ticking a 7-bit counter (named as MCDPCNT). This counter is asynchronously reset with XRSn.
2. The secondary clock (INTOSC1) clock keeps ticking a 13-bit counter (named as MCDSCNT). This counter is asynchronously reset with XRSn.
3. Each time MCDPCNT overflows, the MCDSCNT counter is reset. Thus, if OSCCLK is present or not slower than INTOSC1 by a factor of 64, MCDSCNT never overflows.
4. If OSCCLK stops for some reason or is slower than INTOSC1 by at least a factor of 64, the MCDSCNT overflows and a missing clock condition is detected on OSCCLK.
5. The above check is continuously active, unless the MCD is disabled using MCDCR register (by making the MCLKOFF bit 1).
6. If the circuit ever detects a missing OSCCLK, the following occurs:
   - The MCDSTS flag is set.
   - The MCDSCNT counter is frozen to prevent further missing clock detection.
   - The CLOCKFAIL signal goes high, which generates TRIP events to PWM modules and fires NMIs to CPU1.NMIWDand CPU2.NMIWD.
   - PLL is forcefully bypassed and OSCCLK source is switched to INTOSC1 (System Clock Frequency = INTOSC1 Freq (10MHz)/SYSDIV). PLLMULT is zeroed out automatically in this case.
   - While the MCDSTS bit is set, the OSCCLKSRCSEL bits have no effect and OSCCLK is forcefully connected to INTOSC1.
   - PLLRAWCLK going to the system is switched to INTOSC1 automatically.
7. If the MCLKCLR bit is written (this is a W=1 bit), MCDSTS bit is cleared and OSCCLK source is decided by the OSCCLKSRCSEL bits. Writing to MCLKCLR also clears the MCDPCNT and MCDSCNT counters to allow the circuit re-evaluate missing clock detection. If the user wants to lock the PLL after missing clock detection, switch the clock source to INTOSC1 (using OSCCLKSRCSEL register), do a MCLKCLR, and re-lock the PLL.
8. The MCD is enabled at power up.

Figure 3-11 shows the missing clock logic functional flow.

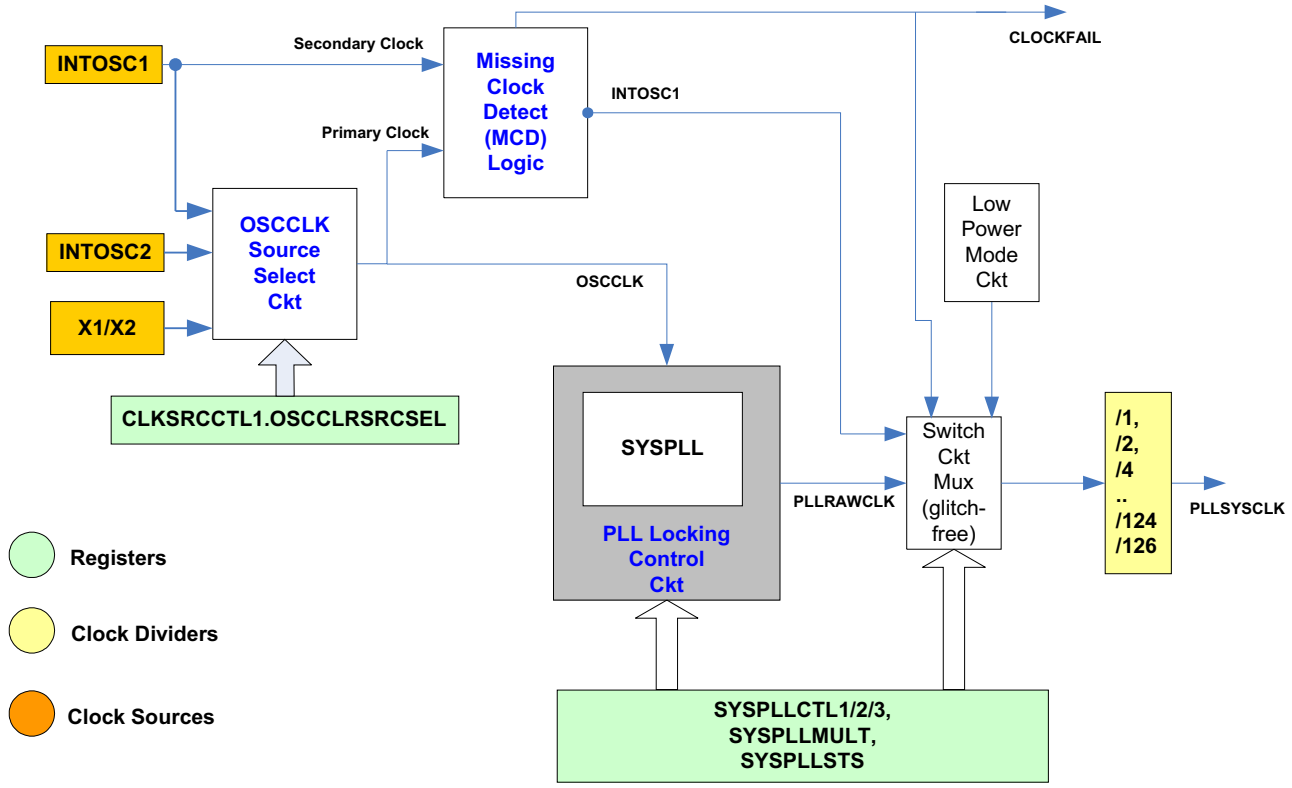

Figure 3-11. Missing Clock Detection Logic

Note

On a complete clock failure when OSCCLK is dead, it may take a maximum time of 8192 INTOSC1 cycles (that is, 0.8192 ms) before CLOCKFAIL signal goes high, after which:

- NMI is generated
- OSCCLK is switched to INTOSC1
- PWM Trip happens

3.8 Clock Configuration Semaphore

Both CPUs can access the PLL and peripheral clock configuration registers. The clock configuration semaphore allows one CPU to access the registers without being interrupted by the other CPU.

The clock configuration semaphore is implemented as a two-bit field in a register with special write protections. This register requires a key field to be written at the same time as the semaphore bits. The possible semaphore states are:

00 or 11	Either CPU writes to the semaphore. CPU1 has control of the clock configuration registers by default. 00 is the reset state.
01	CPU2 has exclusive control of the clock configuration registers and exclusive write access to the semaphore.
10	CPU1 has exclusive control of the clock configuration registers and exclusive write access to the semaphore.

Each CPU is only allowed to take control of the clock configuration registers for itself. However, CPU1 can force both semaphores into the default state (00) at any time by putting CPU2 into reset. Figure 3-12 shows the allowed states and state transitions.

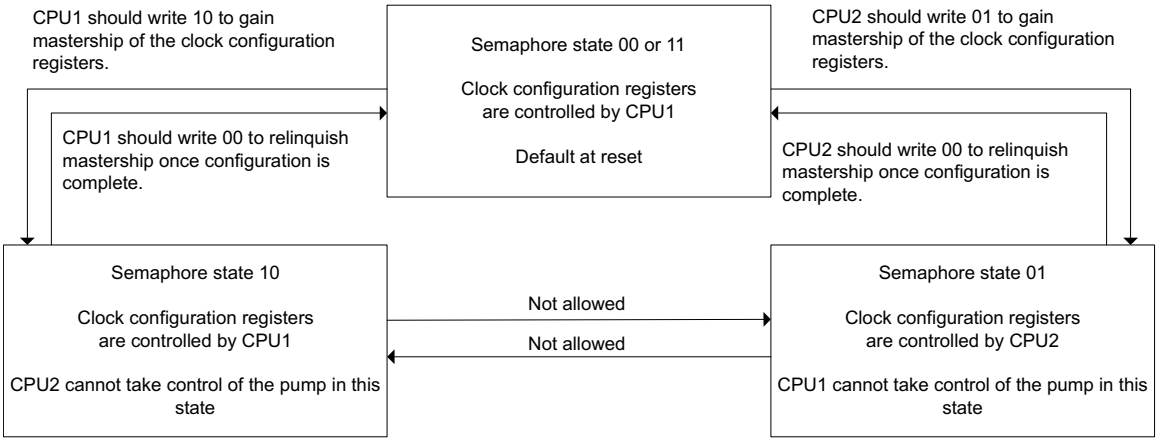

Figure 3-12. Clock Configuration Semaphore (CLKSEM) State Transitions

3.9 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU-Timers (TIMER0/1/2) shown in Figure 3-13.

CPU-Timer2 is reserved for real-time operating system uses (for example, TI-RTOS), but if CPU-Timer2 is not used by real-time operating systems then, CPU-Timer2 can also be used for other applications. The CPU-Timer0 and CPU-Timer1 run off of SYSCLK. The CPU-Timer2 normally runs off of SYSCLK, but can also use INTOSC1, INTOSC2, XTAL, and AUXPLLCLK. The CPU-Timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in Figure 3-14.

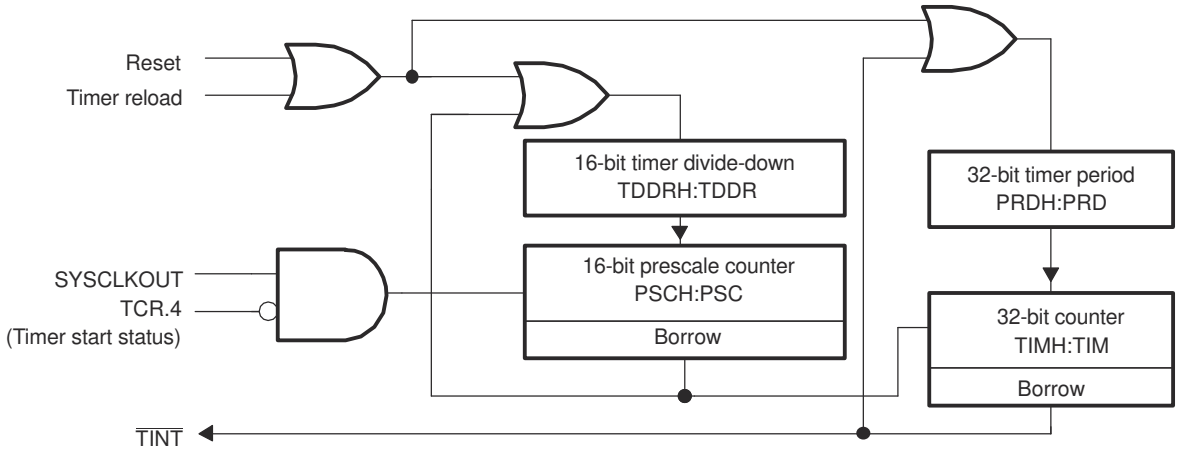

Figure 3-13. CPU-Timers

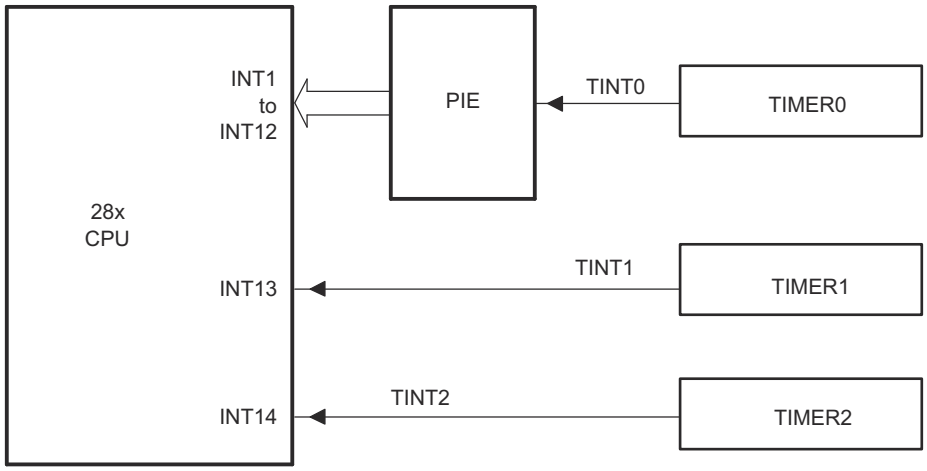

A. The timer registers are connected to the memory bus of the C28x processor.
B. The CPU Timers are synchronized to SYSCLKOUT.

Figure 3-14. CPU-Timer Interrupts Signals and Output Signal

The general operation of the CPU-Timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD.
- The counter decrements once every (TPR[TDDRH:TDDR]+1) SYSCLKOUT cycles, where TDDRH:TDDR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in Section 3.16 are used to configure the timers.

3.10 Watchdog Timers

The watchdog module generates an output pulse 512 watchdog clocks (WDCLKs) wide whenever the 8-bit watchdog up counter has reached its maximum value. The watchdog clock source is INTOSC1. Software must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled. Figure 3-15 shows the various functional blocks within the watchdog module.

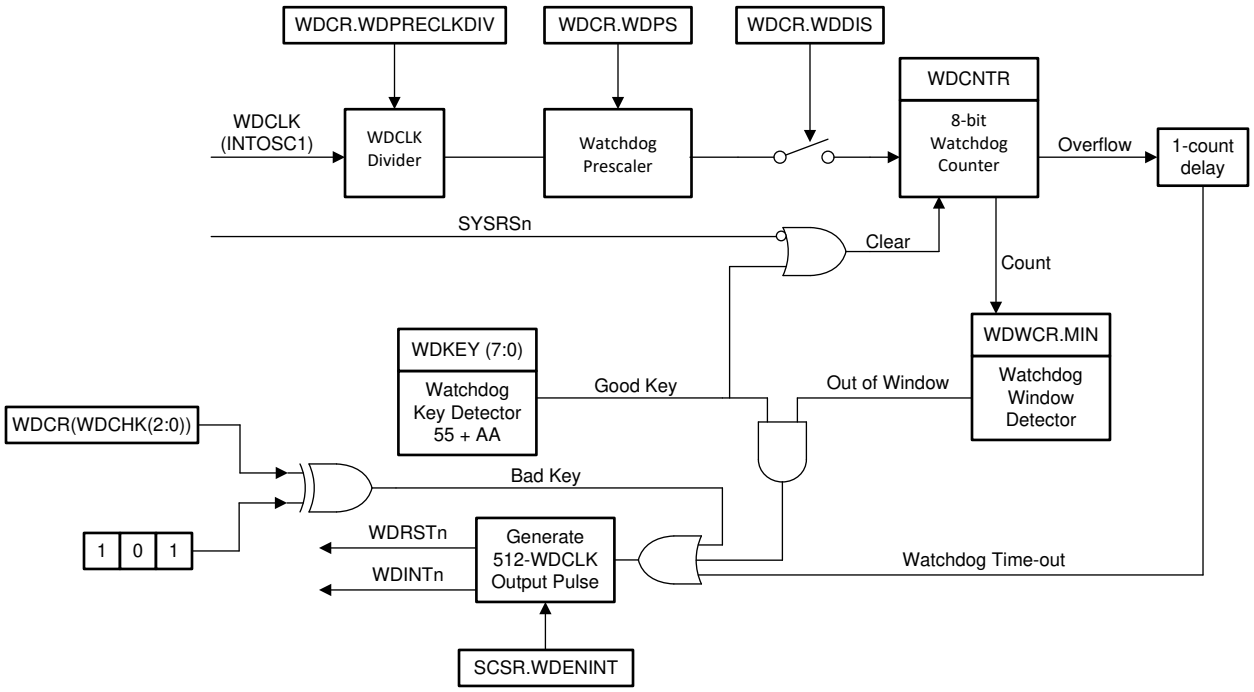

Figure 3-15. CPU Watchdog Timer Module

3.10.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

Table 3-8. Example Watchdog Key Sequences

Step	Value Written to WDKEY	Result
1	0xAA	No action
2	0xAA	No action
3	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
4	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
5	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
6	0xAA	WDCNTR is reset.
7	0xAA	No action
8	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
9	0xAA	WDCNTR is reset.
10	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
11	0x32	Improper value written to WDKEY. No action, WDCNTR no longer enabled to be reset by next 0xAA.
12	0xAA	No action due to previous invalid value.
13	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
14	0xAA	WDCNTR is reset.

Step 3 in Table 3-8 is the first action that enables the WDCNTR to be reset. The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCNTR overflow or writing the incorrect value to the WDCR[WDCHK] bits resets the device and sets the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset was caused by the watchdog. After doing this, the program must clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

3.10.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value will take effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR will trigger a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

3.10.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ($\overline{\text{WDRST}}$) or assert an interrupt ($\overline{\text{WDINT}}$), if the watchdog counter reaches the maximum value. The behavior of each condition is:

- **Reset mode:**

  If the watchdog is configured to reset the device, then the $\overline{\text{WDRST}}$ signal pulls the device reset ($\overline{\text{XRS}}$) pin low for 512 OSCCLK cycles when the watchdog counter reaches the maximum value.
- **Interrupt mode:**

  When the watchdog counter expires, the watchdog counter asserts an interrupt by driving the $\overline{\text{WDINT}}$ signal low for 512 OSCCLK cycles. The falling edge of $\overline{\text{WDINT}}$ triggers a WAKEINT interrupt in the PIE, if the interrupt is enabled. Because the PIE is edge-triggered, re-enabling the WAKEINT while $\overline{\text{WDINT}}$ is active does not produce a duplicate interrupt.

  To avoid unexpected behavior, software must not change the configuration of the watchdog while $\overline{\text{WDINT}}$ is active. For example, changing from interrupt mode to reset mode while $\overline{\text{WDINT}}$ is active immediately resets the device. Disabling the watchdog while $\overline{\text{WDINT}}$ is active causes a duplicate interrupt if the watchdog is later re-enabled. If a debug reset is issued while $\overline{\text{WDINT}}$ is active, the reset cause register (RESC) shows a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of $\overline{\text{WDINT}}$.

3.10.4 Watchdog Operation in Low Power Modes

In IDLE mode, the watchdog interrupt ($\overline{\text{WDINT}}$) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. As with any other peripheral, the watchdog interrupt will trigger a WAKEINT interrupt in the PIE during IDLE mode. User software must determine which peripheral caused the interrupt.

In STANDBY mode, all of the clocks to the peripherals are turned off within the CPU subsystem. The only peripheral that remains functional is the watchdog since the watchdog module runs off the oscillator clock (OSCCLK). The $\overline{\text{WDINT}}$ signal is fed to the Low Power Modes (LPM) block so that it can be used to wake the CPU from STANDBY low power mode. This feature is enabled by setting LPMCR.WDINTE = 1. See Section 3.11 for details.

Note: If the watchdog interrupt is used to wake-up from an IDLE or STANDBY low power mode condition, software must make sure that the $\overline{\text{WDINT}}$ signal goes back high before attempting to reenter the IDLE or STANDBY mode. The $\overline{\text{WDINT}}$ signal will be held low for 512 OSCCLK cycles when the watchdog interrupt is generated. The current state of $\overline{\text{WDINT}}$ can be determined by reading the watchdog interrupt status bit (WDINTS) bit in the SCSR register. WDINTS follows the state of $\overline{\text{WDINT}}$ by two SYSCLKOUT cycles.

3.10.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

CPU Suspended:	When the CPU is suspended, the watchdog clock (WDCLK) is suspended
Run-Free Mode:	When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the watchdog operates as normal.

3.11 Low Power Modes

This device has two clock-gating, low-power modes. All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the *TMS320C28x CPU and Instruction Set Reference Guide*.

Low-power modes should not be entered into while a Flash program or erase is ongoing.

The application should verify the following before entering STANDBY:

1. Check the value of the GPIODAT register of the pin selected for STANDBY(GPIOLPMSEL0/1) prior to entering the Low-Power mode to ensure that the wake event has not already been asserted.
2. The LPMCR.QUALSTDBY register should be set to a value greater than the ratio of INTOSC1/PLLSYSCLK to ensure proper wake up.

3.11.1 IDLE

IDLE is a standard feature of the C28x CPU. In this mode, the CPU clock is gated while all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events. When one CPU is in IDLE, there is no effect on the other CPU subsystem.

Any enabled interrupt wakes up the CPU from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

3.11.2 STANDBY

STANDBY is a more aggressive low-power mode that gates both the CPU clock and any peripheral clocks derived from the CPU SYSCLK. The watchdog, however, is left active. Like IDLE, this mode affects only one CPU subsystem. The other CPU subsystem and all of the peripherals are unaffected. STANDBY is best used for an application where the wake-up signal comes from an external system (or CPU subsystem) rather than a peripheral input.

An NMI (or optionally) a watchdog interrupt or a configured GPIO can wake the CPU from STANDBY mode. Each GPIO from GPIO0-63 can be configured to wake the CPU when the GPIO are driven active low. Upon wakeup, the CPU receives the WAKEINT interrupt if configured.

IPC interrupt 1 (flag 0), an NMI fired to the other CPU, or (optionally) a watchdog interrupt, wakes up the CPU subsystem from STANDBY mode. Any of GPIO0-63 can also be configured to wake up the subsystem when the GPIO are driven active low. Upon wake up, the CPU receives a WAKEINT interrupt, even if the CPU was woken by an IPCINT1 signal.

To enter STANDBY mode:

1. Set LPMCR.LPM to 0x1.
2. Enable the WAKEINT interrupt in the PIE.
3. For watchdog interrupt wakeup, set LPMCR.WDINTE to 1 and configure the watchdog to generate interrupts.
4. For GPIO wakeup, set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module, and set LPMCR.QUALSTDBY to select the number of OSCCLK cycles for input qualification.
5. Execute the IDLE instruction to enter STANDBY.

To wake up from Standby mode:

1. Configure the desired GPIO to trigger the wakeup.
2. Drive the selected GPIO signal low; the signal must remain low for the number of OSCCLK cycles specified in the QUALSTDBY bits in the LPMCR register. If the signal is sampled high during this period, the count restarts.

At the end of the qualification period, the PLL enables the CLKIN to the CPU and the WAKEINT interrupt is latched in the PIE block. The WAKEINT interrupt can also triggered by IPCINT1 sent from the other CPU and a watchdog interrupt.

The CPU is now out of STANDBY mode and can resume normal execution.

If CPU2 is in STANDBY mode, writing a 1 to the RESET bit of the CPU2RESCTL register has no effect. CPU2 can be reset by any chip-level reset (POR, XRSn, CPU1.WDRSn, or CPU1.NMIWDRSn). Alternately, CPU2 can be woken up by any configured wake-up event.

If CPU2 is in STANDBY mode and the debugger is connected, executing a debug reset on CPU2 has no effect. To wake up the CPU2 with the debugger, Click Run, Single Step, or Step over in the Debug toolbar. CCS IDE prompts the user requesting to bring the CPU out of the low-power mode. Click Yes. This wakes up CPU2 from STANDBY and continues execution.

3.12 Memory Controller Module

This device has CPU1 subsystem, CPU2 subsystem, and CM subsystem. This section describes the memory controller used for CPU1 and CPU2 subsystem.

The different RAMs available on CPU1 and CPU2 subsystem have different characteristics. Some are:

- Dedicated to each CPU (M0, M1, and Dx RAMs),
- Shared between the CPU and a CLA (LSx RAM),
- Shared between the CPU and DMA of both subsystems (GSx RAM), and
- Used to send and receive messages between processors (MSGRAM).
- Used to exchange data between CLA and DMA

All these RAMs are highly configurable to achieve control for write access and fetch access from different masters. There are also RAMs - called IPC MSGRAMs - that are used for interprocessor communication. All RAMs are enabled with the ECC or parity feature (both data and address). Some of the dedicated memories are secure memory as well. Refer to Chapter 6 for more details. Each RAM has a controller that takes care of the access protection/security related checks and ECC/Parity features for that RAM. Figure 3-16 shows the configuration of these RAMs.

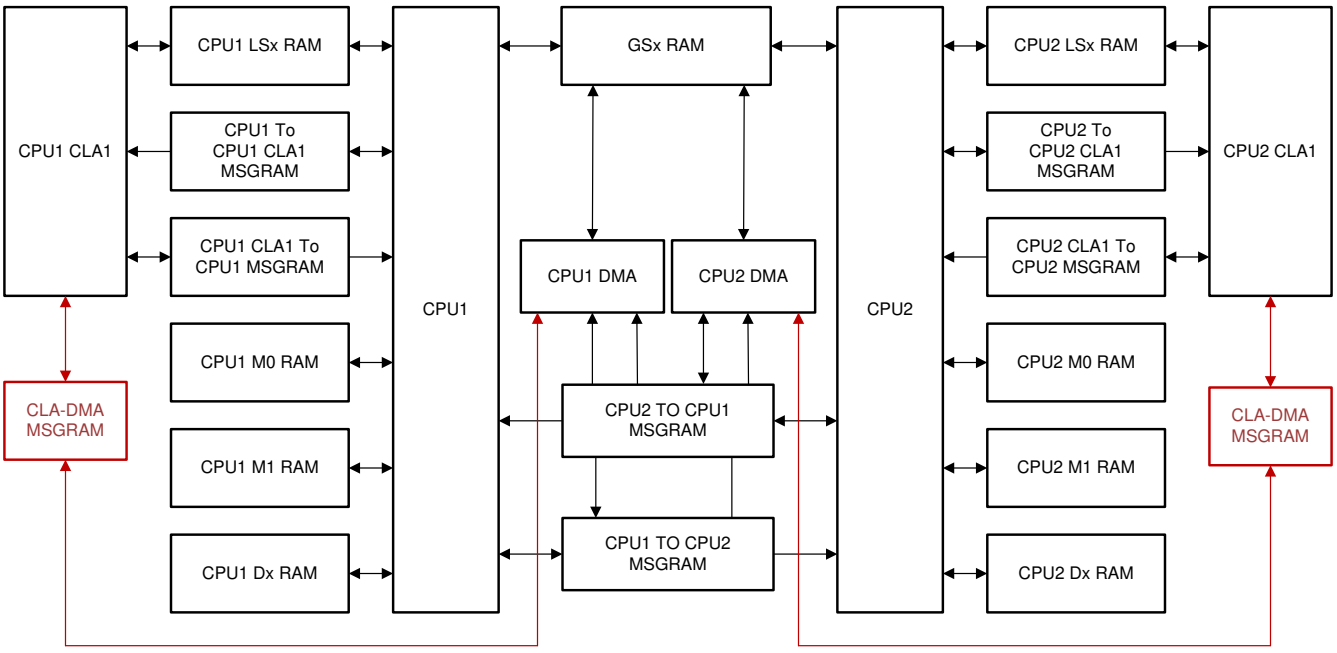

Figure 3-16. Memory Architecture

Note

All RAMs on these devices are SRAMs.

3.12.1 Functional Description

This section further defines and discusses the dedicated RAMs, shared RAMs, and MSG RAMs on this device.

3.12.1.1 Dedicated RAM (Dx RAM)

Each CPU subsystem has four dedicated RAM blocks: M0, M1, D0, and D1. M0/M1 memories are small blocks of memory that are tightly coupled with the CPU. Only the CPU has access to these memories. No other masters (including DMA) have any access to these memories.

All dedicated RAMs have the ECC feature. All dedicated memories are secure memory (except for M0/M1) and have the access protection (CPU write protection/CPU fetch protection) feature. Each type of access protection for each RAM block can be enabled/disabled by configuring the specific bit in the access protection register, allocated to each subsystem (DxACCPROT).

3.12.1.2 Local Shared RAM (LSx RAM)

RAM blocks that are dedicated to each subsystem and are accessible to the respective CPU and CLA only, are called local shared RAMs (LSx RAMs). All such memories are secure memory and have the ECC feature. By default, these memories are dedicated to the CPU only, and the user can choose to share these memories with the CLA by appropriately configuring the MSEL_LSx bit field in the LSxMSEL register. Further, when these memories are shared between the CPU and CLA, the user can choose to use these memories as CLA program memory by configuring the CLAPGM_LSx bit field in the LSxCLAPGM registers. CPU access to all memory blocks, which are programmed as CLA program memory, are blocked.

All these RAMs have the access protection (CPU write and CPU fetch) feature. Each type of access protection for each RAM block can be enabled or disabled by configuring the specific bit in the local shared RAM access protection registers, mapped to each CPU subsystem. Table 3-9 shows the LSx RAM features.

Table 3-9. Local Shared RAM

MSEL_LSx	CLAPGM_LSx	CPUx Allowed Access	CPUx.CLA1 Allowed Access	Comment
00	X	All	-	LSx memory is configured as CPU dedicated RAM
01	0	All	Data Read Data Write	LSx memory is shared between CPU and CLA1
01	1	Emulation Read Emulation Write	Fetch Only Emulation Read Emulation Write	LSx memory is CLA1 program memory

3.12.1.3 Global Shared RAM (GSx RAM)

RAM blocks that are accessible from both the CPU and their respective DMA are called global shared RAMs (GSx RAMs). Each shared RAM can be owned by either CPU subsystem based on the configuration of their respective bits (one bit for each GSx memory) in the GSxMSEL register. When a particular GSx RAM block is owned by the CPU1 subsystem, CPU1 and CPU1.DMA have full access to that RAM block, whereas CPU2 and CPU2.DMA have only read access to that RAM block (no fetch/write access). Similarly, when a particular GSx RAM block is owned by the CPU2 subsystem, CPU1 and CPU1.DMA has only read access (no fetch/write access) to that RAM block, whereas CPU2 and CPU2.DMA has full access to that RAM block. Table 3-10 shows the features of the GSx RAM.

Table 3-10. Global Shared RAM

GSxMSEL	CPU1	CPU1	CPU1	CPU1.DMA	CPU1.DMA	CPU2	CPU2	CPU2	CPU2.DMA	CPU2.DMA
	Fetch	Read	Write	Read	Write	Fetch	Read	Write	Read	Write
0	Yes	Yes	Yes	Yes	Yes	No	Yes	No	Yes	No
1	No	Yes	No	Yes	No	Yes	Yes	Yes	Yes	Yes

Note

Emulation/Debugger access is allowed from both the CPUs, irrespective of the GSxMSEL setting.

Like other shared RAMs, these RAMs also have different levels of access protection that can be enabled or disabled by configuring specific bits in the GSxACCPROT registers mapped in each subsystem.

Master select and access protection configuration for each GSx RAM block can be individually locked by the user to prevent further update to these bit fields. The user can also choose to permanently lock the configuration to individual bit fields by setting the specific bit fields in the GSxCOMMIT register (refer to the register description for more details). Once configuration is committed for a particular GSx RAM block, it can not be changed further until CPUx.$\overline{\text{SYSRS}}$ is issued. Only the CPU1 software can change the master select configuration by writing into the GSxMSEL register, mapped on the CPU1. The GSxMSEL register, which is mapped to the CPU2 subsystem, is a status register that can only be used by CPU2 software to know the master ownership for each GSx RAM block.

3.12.1.4 CPU Message RAM (CPU MSG RAM)

These RAM blocks can be used to share data between CPU1 and CPU2. Since these RAMs are used for interprocessor communication, they are also called IPC RAMs. The CPU MSGRAMs have CPU and DMA read and write access from its own CPU subsystem, and has CPU and DMA read only access from the other subsystem.

This RAM has parity.

3.12.1.5 CLA Message RAM (CLA MSGRAM)

These RAM blocks can be used to share data between the CPU and CLA. The CLA has read and write access to the "CLA to CPU MSGRAM." The CPU has read and write access to the "CPU to CLA MSGRAM." The CPU and CLA both have read access to both MSGRAMs.

This RAM has parity.

3.12.1.6 CLA-DMA MSG RAM

These RAMs blocks can be used to share data between CLA and DMA. The CLA has read and write access to the "CLA to DMA MSGRAM." The DMA has read and write access to the "DMA to CLA MSGRAM." The CLA and DMA both have read access to both MSGRAMs.

3.12.1.7 Access Arbitration

For a shared RAM, multiple accesses can happen at a given time. The maximum number of accesses to any shared RAM at any given time depends on the type of shared RAM. On this device, a combination of a fixed and round robin scheme is followed to arbitrate multiple access at any given time. Accesses from the same masters are arbitrated in a fixed priority manner, but the accesses from different masters are arbitrated using the round robin scheme.

The following is the order of fixed priority for CPU accesses:

1. Data Write/Program Write
2. Data Read
3. Program Read/Program Fetch

The following is the order of fixed priority for CLA accesses:

1. Data Write
2. Data Read/Program Fetch

Figure 3-17 represents the arbitration scheme on global shared memories:

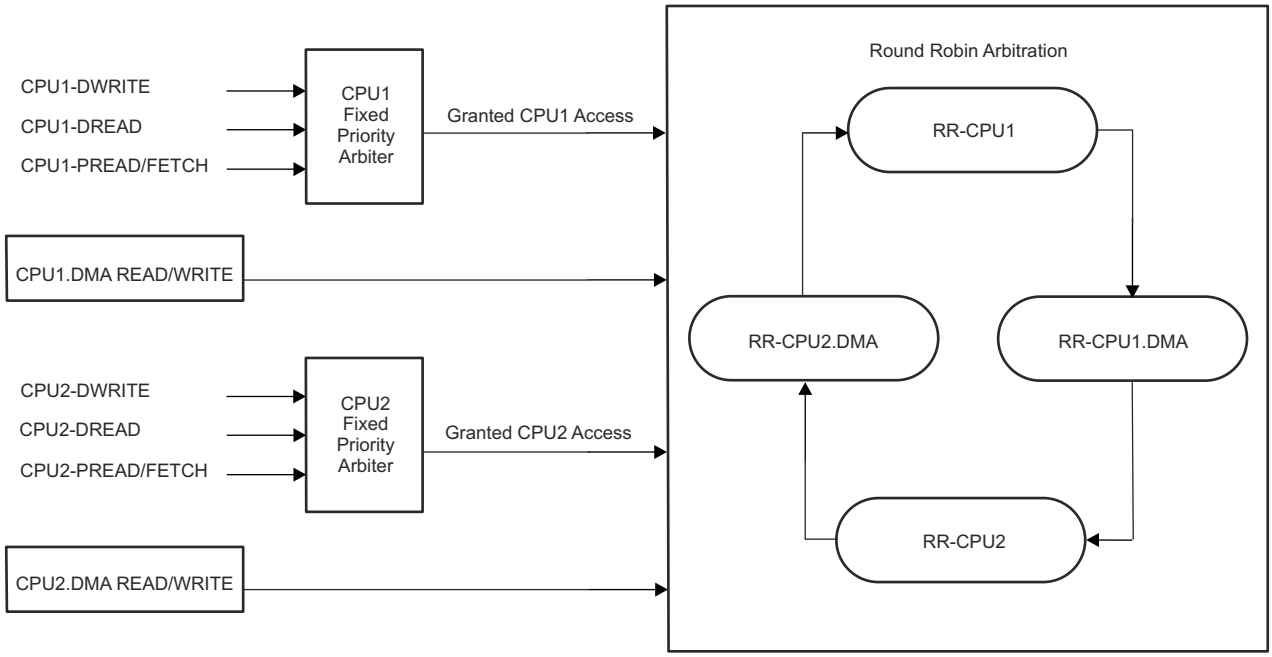

Figure 3-17. Arbitration Scheme on Global Shared Memories

Figure 3-18 represents the arbitration scheme on local shared memories.

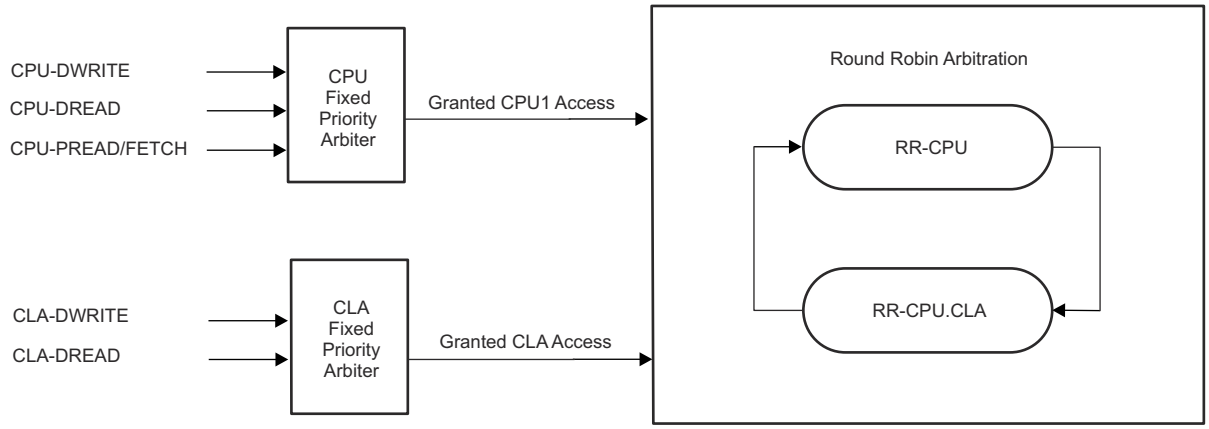

Figure 3-18. Arbitration Scheme on Local Shared Memories

3.12.1.8 Access Protection

All RAM blocks on both subsystems have different levels of protection. This feature allows the user to enable or disable specific access to individual RAM blocks from individual masters. There is no protection for read accesses, hence reads are always allowed from all the masters which have access to that RAM block.

The following sections describe the different kinds of protection available for RAM blocks on this device.

Note: For debug accesses, all the protections are disabled.

3.12.1.8.1 CPU Fetch Protection

A CPU has execution permission from a memory, only if that memory is dedicated to that CPU or the respective subsystem is master for that memory (in case of GSx memory). When fetch accesses are allowed based on the mastership, fetch accesses can be further protected by setting the FETCHPROTx bit of the specific register to 1. If fetch access is done by the CPU to a memory where CPU fetch protection is enabled, a fetch protection violation occurs.

There are two types of fetch protection violations:

- Non-master CPU fetch protection violation
- Master CPU fetch protection violation

If a fetch access is made to a memory by a non-master CPU, the fetch access is called a non-master fetch protection violation. If a fetch access is made to a dedicated or shared memory by the master CPU, and FETCHPROTx is set to 1 for that memory, the violation is called a master CPU fetch protection violation.

If a fetch protection violation occurs, the violation results in an ITRAP for CPU. A flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, get latched into the appropriate CPU fetch access violation address register.

3.12.1.8.2 CPU Write Protection

A CPU has write permission to a memory only if that memory is dedicated to that CPU, or if the respective subsystem is the master for that memory (in case of GSx memory). When write accesses are allowed based on the mastership, write accesses can be further protected by setting the CPUWRPROTx bit of the specific register to 1. If write access is done by a CPU to memory where the write access is protected, a write protection violation occurs.

There are two types of CPU write protection violations:

- Non-master CPU write protection violation
- Master CPU write protection violation
  If a write access is made to a dedicated or shared memory by the master CPU and CPUWRPROTx is set to 1 for that memory, the violation is called a master CPU write protection violation.

If a write protection violation occurs, write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU write access violation address register. Also, an access violation interrupt is generated if enabled in the interrupt enable register.

3.12.1.8.3 CPU Read Protection

For local shared RAM, if memory is shared between the CPU and the CLA, the CPU only has access if the memory is configured as data RAM for the CLA. If the memory is programmed as program RAM, all the access from the CPU, including a read, is blocked and the violation is considered as a non-master access violation.

If a read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU read access violation address register. Also, if enabled in the interrupt enable register, an access violation interrupt is generated.

3.12.1.8.4 CLA Fetch Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as data RAM for the CLA, any fetch access from the CLA to that particular LSx RAM results in a CLA fetch protection violation, which is a non-master access violation.

If a CLA fetch protection violation occurs, the violation results in a MSTOP, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA fetch access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

3.12.1.8.5 CLA Write Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as program RAM for the CLA, any data write access from the CLA to that particular LSx RAM results in a CLA write protection violation, which is a non-master access violation. Similarly any data write access from CLA to CPUTOCLA or DMATOCLA MSGRAM results in a CLA write protection violation, which is a non-master access violation.

If a CLA write protection violation occurs, write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA write access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

3.12.1.8.6 CLA Read Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as program RAM for the CLA, any data read access from the CLA to that particular LSx RAM results in a CLA read protection violation, which is a non-master access violation.

If a CLA read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA read access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

3.12.1.8.7 DMA Write Protection

The CPU1 or CPU2 DMA has write permission to a GSx memory only if the respective subsystem is master for that memory. When write accesses from a DMA are allowed based on the mastership, the write access can be further protected by setting the DMAWRPROTx bit of a specific register to 1. If write access is done by the DMA to protected memory, a write protection violation occurs.

There are two types of DMA write protection violations:

- Non-master DMA write protection violation (applicable to GSx RAMs and DMATOCLA MSGRAM)
- Master DMA write protection violation

If a write access is made to GSx memory by a non-master DMA, the write is called a non-master write protection violation. If a write access is made to a dedicated or shared memory by a master DMA, and DMAWRPROTx is set to 1 for that memory, the write is called a master DMA write protection violation.

If a DMA write protection violation occurs, the write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred gets latched into the appropriate DMA write access violation address register. Also, an access violation interrupt is generated to the respective CPU, if enabled in the interrupt enable register. These are dedicated registers for each subsystem.

Note 1: All access protections are ignored during debug accesses. Write access to a protected memory go through when the write access is done by way of the debugger, irrespective of the write protection configuration for that memory.

Note 2: In the case of local shared RAM, if memory is shared between the CPU and the CLA, the CPU only has access if the memory is configured as data RAM for the CLA. If the memory is programmed as program RAM, all the access from the CPU (including read) and data access from the CLA is blocked, and the violation is considered as a non-master access violation. If the memory is configured as dedicated to the CPU, all access from the CLA is blocked and the violation is considered a non-master access violation.

3.12.1.9 Memory Error Detection, Correction and Error Handling

These devices have memory error detection and correction features to satisfy safety standards requirements. These requirements warrant the addition of detection mechanisms for finite dangerous failures.

In this device, all dedicated RAMs and LSx RAMs support error correction code (ECC) protection and other shared RAMs have parity protection. The ECC scheme used is Single Error Correction Double Error Detection (SECDED). The parity scheme used is even parity. ECC/Parity will cover the data bits stored in memory as well as address.

ECC/Parity calculation is done inside the memory controller module and then calculated. ECC/Parity is written into the memory along with the data. ECC/Parity is computed for 16-bit data; hence, for each 32-bit data, there will be three 7-bit ECC codes (or 3-bit parity), two of which are for data and a third one for the address.

3.12.1.9.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For parity memory, only a single-bit error gets detected, whereas in the case of ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable error and uncorrectable errors. The following are characteristics of these errors:

- Parity errors are always uncorrectable errors
- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are also uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the master. It is also written back into the memory to prevent double-bit error due to another single-bit error at the same memory address.

Note

ECC/Parity for address is calculated for address offset only (based on RAM block size) of corresponding 32-bit aligned address. In case of LSx RAM which are 4KB RAM block, only 11 LSB of 32-bit aligned address are used. So if address is 0x8F8F, address ECC (or Parity) will be calculated for address 0x78E (11-bit offset of 32-bit aligned address). Similarly for 8KB RAM block,12-bit address offset will be used.

3.12.1.9.2 Error Handling

For each correctable error, the count in the correctable error count register increments by one. When the value in this count register becomes equal to the value configured into the correctable error threshold register, an interrupt is generated to the respective CPU, that is, if the interrupt is enabled in the correctable interrupt enable register. The user needs to configure the correctable error threshold register based on the system requirements. Also, the address for which the error occurred, gets latched into the master-specific status register and a flag gets set. Each of these registers are dedicated for each CPU subsystem.

If there are uncorrectable errors, an NMI gets generated for the respective CPU. In this case, the address for which the error occurred, also gets latched into the master-specific address status register, and a flag gets set.

Table 3-11 summarizes different error situations that can arise. These need to be handled appropriately in the software, using the status and interrupt indications provided.

Table 3-11. Error Handling in Different Scenarios

Access Type	Error Found In	Error Type	Status Indication	Error Notification
Reads	Data read from memory	Uncorrectable Error (Single-bit error for Parity RAMs OR Double bit Error for ECC RAMs)	Yes -CPUx/CPUx.DMA/CPUx.CLA1 CPU/DMA/CLA Read Error Address Register Data returned to CPUx/ CPUx.DMA/CPUx.CLA1 is incorrect	NMI for CPUx access NMI for CPUx.DMA access NMI to CPU for CPUx.CLA1 access
Reads	Data read from memory	Single-bit error for ECC RAMs	Yes - CPUx/CPUx.DMA CPU/DMA Read Error Address Register Increment single error counter	Interrupt when error counter reaches the user programmable threshold for single errors
Reads	Address	Address error	Yes - CPUx/CPUx.DMA/CPUx.CLA1 CPU/DMA/CLA Read Address Error Register Data returned to CPUx/ CPUx.DMA/CPUx.CLA1 is incorrect	NMI to CPU for CPUx access NMI to CPU for CPUx.DMA access NMI to CPU for CPUx.CLA1 access

Note

In the case of an uncorrectable error during fetch on the CPU, there is the possibility of getting an ITRAP before an NMI exception, since garbage instructions enter into the CPU pipeline before the NMI gets generated.

During debug accesses, correctable as well as uncorrectable errors are masked.

3.12.1.10 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic is part of safety critical logic, safety applications need to make sure that the logic is always working fine (during run time also). To enable this, different test modes are provided to generate ecc/parity error in RAM locations. These test modes can be configured in RAM Test registers of different RAM blocks. (for example, for D0 RAM, TEST_D0 bit in DxTEST register). Different test modes are for different usage. In test mode user can modify the data bits (without modifying the ECC/Parity bits) or ECC/Parity bits directly. Using this feature, an ECC/Parity error can be injected into data. Since an uncorrectable error generates NMI, you can avoid generating this during test mode as one of the test modes (11) is provided where NMI generation gets disabled. This mode is just like functional mode except NMI generation on uncorrectable error.

Note

The memory-map for ECC/Parity bits and data bits are the same. Choose a different test mode (10) to access ECC/Parity bits.

The following tables show the bit mapping for the ECC and Parity bits when the bits are read in RAMTEST mode using their respective addresses.

Table 3-12. Mapping of ECC Bits in Read Data from ECC/Parity Address Map

Data Bits Location in Read Data	Content (ECC Memory)
6:0	ECC Code for lower 16 bits of data
7	Not Used
14:8	ECC Code for upper 16 bits of data
15	Not Used
22:16	ECC Code for address
31:23	Not Used

Table 3-13. Mapping of Parity Bits in Read Data from ECC/Parity Address Map

Data Bits Location in Read Data	Content (Parity Memory)
0	Parity for lower 16 bits of data
7:1	Not Used
8	Parity for upper 16 bits of data
15:9	Not Used
16	Parity for address
31:17	Not Used

Following is the sequence that must be followed to test the ecc/parity logic.

- Set the test mode to 01 or 10, depending on whether data field or ecc/parity field needs to be written.
- Write the data pattern into the memory.
- Set the test mode to 11 to read from memory and exercise the ecc/parity logic.
- Check the test log registers to verify the correctness of the logic.
- The above sequence can be repeated for any number of data patterns.
- Once the test is complete, re-initialize the locations used in test, and set the test mode to 00 that changes the RAM block back into functional mode.

3.12.1.11 ROM Test

ROMs are read only memory, unlike RAMs, data or parity bits cannot be modified to introduce errors for diagnostic coverage of parity checking logic. Following method is used to check health of parity checking logic in ROMs.

- Added duplicate Parity check logic and feed the same data into duplicate parity checker
- Generate uncorrectable error if parity check status of these two separate parity checkers do not match

Probability of both circuits having fault is unlikely hence Parity Errors are certainly detected.

To generate the error, a test bit FORCE_ERROR is added. When the FORCE_ERROR bit is set, the parity bit going to one of the party checkers is inverted thereby introducing an uncorrectable error. An uncorrectable error is generated only if there is an error on all parity checkers that is: address, data [15:0], and data [31:16]. This makes sure that all three parity checkers are working as expected.

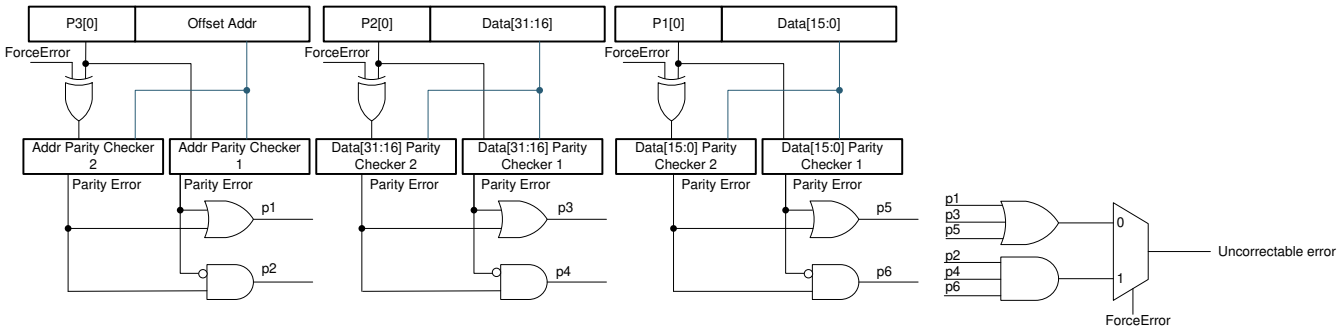

Figure 3-19. ROM Parity Checking Logic

3.12.1.12 RAM Initialization

To make sure that read/fetch from uninitialized RAM locations do not cause ECC or parity errors, the RAM_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and respective ECC/Parity bits accordingly. This can be initiated by setting the INIT bit to 1 for the specific RAM block in INIT registers. To check the status of RAM initialization, software must poll for the INITDONE bit for that RAM block in the INITDONE register to be set. Unless this bit gets set, no access must be made to that RAM memory block.

In the case of GSx memory, only the CPU of the subsystem that is configured as the master for the particular GSx RAM block can initiate the RAM initialization.

Note

The INIT bit must not be set again until the INITDONE bit for the corresponding RAM block has been polled to be set.

None of the masters must access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization does not happen correctly.

3.13 JTAG

Gel files perform certain initialization tasks. This helps the users in a debug environment. However, when executed standalone (without the emulator connected) the application could potentially not work as expected, since there is no gel file to perform those initializations. For example, gel file disables watchdog. If user code does not service the watchdog in the application (or fails to disable the watchdog), there would be a difference in how the application behaves with the debugger and without the debugger.

Common tasks performed by the gel files (but not boot-ROM):

- On Reset:
  - Disable Flash ECC on some devices.
    - Disabling ECC only when using Flash API functions, see the Flash API User Guide for details. Otherwise, TI suggests to always program ECC and enable ECC-check.
  - Disable Watchdog
  - Enable CLA clock
  - Select real-time mode or C28x mode
- On Restart:
  - Select real-time mode or C28x mode
  - Clear IER and IFR
- On Target Connect:
  - Select real-time mode or C28x mode

For more information, see *C2000 MCU JTAG Connectivity Debug*.

3.13.1 JTAG Noise and TAP_STATUS

The TAP_STATUS register reflects the status of the JTAG TAP at any given time. Normally when no JTAG is connected to the device, the status can be IDLE. In some cases with excessive PCB noise, there can be unwanted TMS and TCK toggles that take JTAG out of the IDLE state. When persistent, this can ultimately lead to unwanted activation of the JTAG Boundary Scan or some other JTAG mode that can interfere with the intended application. To avoid this scenario, place strong enough pull resistors on the board to prevent noise from activating JTAG. As a debug tool, the TAP_STATUS register can be polled by the application code to detect if this is a cause of device disturbance. The SOFTPRES40[JTAG_nTRST] register can also be used to reset the JTAG TAP through software. Use this reset register with caution, as this prevents connecting a debugger unless the code qualifies writes to this register with some other GPIO state or other means to distinguish between noise and debugger accesses.

3.14 System Control Register Configuration Restrictions

Memory-mapped registers in the System Control operate on INTOSC1 clock domain; hence, any CPU writes to these registers requires a delay between subsequent writes otherwise a second write can be lost. The application needs to take this into consideration and add a delay in terms of the number of NOP instructions after every write to these registers that are mentioned in Table 3-14. The formula to compute delay between subsequent writes:

Delay (in SYSCLK cycles) = 3 × (F_{SYSCLK} ÷ $F_{INTOSC1}$) + 9

For Example - For SYSCLK = 100200 MHz

Delay (in SYSCLK cycles) = 3 × (100 MHz ÷ 10 MHz) + 9 = 39 SYSCLK cycles

Table 3-14. System Control Registers Impacted

3.15.1 SYSCTL Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/sysctl

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.1.1 Missing clock detection (MCD)

FILE: sysctl_ex1_missing_clock_detection.c

This example demonstrates the missing clock detection functionality and the way to handle it. Once the MCD is simulated by disconnecting the OSCCLK to the MCD module an NMI would be generated. This NMI determines that an MCD was generated due to a clock failure which is handled in the ISR.

Before an MCD the clock frequency would be as per device initialization (200Mhz). Post MCD the frequency would move to 10Mhz or INTOSC1.

The example also shows how we can lock the PLL after missing clock, detection, by first explicitly switching the clock source to INTOSC1, resetting the missing clock detect circuit and then re-locking the PLL. Post a re-lock the clock frequency would be 200Mhz but using the INTOSC1 as clock source.

External Connections

- None.

Watch Variables

- *fail* - Indicates that a missing clock was either not detected or was not handled correctly.
- *mcd_clkfail_isr* - Indicates that the missing clock failure caused an NMI to be triggered and called an the ISR to handle it.
- *mcd_detect* - Indicates that a missing clock was detected.
- *result* - Status of a successful handling of missing clock detection

3.15.1.2 XCLKOUT (External Clock Output) Configuration

FILE: sysctl_ex2_xclkout_config.c

This example demonstrates how to configure the XCLKOUT pin for observing internal clocks through an external pin, for debugging and testing purposes.

In this example, we are using INTOSC1 as the XCLKOUT clock source and configuring the divider as 8. Expected frequency of XCLKOUT = (INTOSC1 freq)/8 = 10/8 = 1.25MHz

View the XCLKOUT on GPIO73 using an oscilloscope.

3.15.2 MEMCFG Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/memcfg

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.2.1 Correctable & Uncorrectable Memory Error Handling

FILE: memcfg_ex1_error_handling.c

This example demonstrates error handling in case of various erroneous memory read/write operations. Error handling in case of CPU read/write violations, correctable & uncorrectable memory errors has been demonstrated. Correctable memory errors & violations can generate SYS_INT interrupt to CPU while uncorrectable errors lead to NMI generation.

External Connections

- None

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

3.15.2.2 Shared RAM Management (CPU1) - C28X_DUAL

FILE: memcfg_ex1_ram_management_cpu1.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS14 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to cpu1RWArray and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from cpu2RArray and writes a modified pattern to cpu2RWArray. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from cpu1RArray and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- cpu1RWArray[] is mapped to shared RAM GS1
- cpu1RArray[] is mapped to shared RAM GS0
- cpu2RArray[] is mapped to shared RAM GS1
- cpu2RWArray[] is mapped to shared RAM GS0
- cpuTimer0ISR in CPU2 is copied to shared RAM GS14, toggles LED1
- cpuTimer0ISR in CPU1 is copied to shared RAM GS15, toggles LED2

Watch Variables

- error Indicates that the data written is not correctly received by the other CPU.

3.15.2.3 Shared RAM Management (CPU2) - C28X_DUAL

FILE: memcfg_ex1_ram_management_cpu2.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS14 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to cpu1RWArray and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from cpu2RArray and writes a modified pattern to cpu2RWArray. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from cpu1RArray and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- cpu1RWArray[] is mapped to shared RAM GS1
- cpu1RArray[] is mapped to shared RAM GS0
- cpu2RArray[] is mapped to shared RAM GS1
- cpu2RWArray[] is mapped to shared RAM GS0
- cpuTimer0ISR in CPU2 is copied to shared RAM GS14, toggles LED1
- cpuTimer0ISR in CPU1 is copied to shared RAM GS15, toggles LED2

3.15.2.4 Demonstrate memconfig diagnostics and error handling. - CM

FILE: memcfg_ex1_error_handling.c

This example demonstrates how to configure the diagnostic mode and induce ECC errors. This example induces single and two bit ECC errors in E0RAM and tries to read the corrupted location in diagnostic and functional mode. cm_common_config_c28x example needs to be run on C28x1 before running this example on the CM core

External Connections

- None

Watch Variables

- *testStatus* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errorGlobalCount* - Error counter
- *retx* - Individual test status

3.15.2.5 Shared RAM Management (CPU1) - C28X_DUAL

FILE: memcfg_ex2_ram_sysconfig_cpu1.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS14 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to cpu1RWArray and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from cpu2RArray and writes a modified pattern to cpu2RWArray. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from cpu1RArray and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- cpu1RWArray[] is mapped to shared RAM GS1
- cpu1RArray[] is mapped to shared RAM GS0
- cpu2RArray[] is mapped to shared RAM GS1
- cpu2RWArray[] is mapped to shared RAM GS0
- cpuTimer0ISR in CPU2 is copied to shared RAM GS14, toggles LED1
- cpuTimer0ISR in CPU1 is copied to shared RAM GS15, toggles LED2

Watch Variables

- error Indicates that the data written is not correctly received by the other CPU.

3.15.2.6 Shared RAM Management (CPU2) - C28X_DUAL

FILE: memcfg_ex2_ram_sysconfig_cpu2.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS14 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to cpu1RWArray and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from cpu2RArray and writes a modified pattern to cpu2RWArray. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from cpu1RArray and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- cpu1RWArray[] is mapped to shared RAM GS1
- cpu1RArray[] is mapped to shared RAM GS0
- cpu2RArray[] is mapped to shared RAM GS1
- cpu2RWArray[] is mapped to shared RAM GS0
- cpuTimer0ISR in CPU2 is copied to shared RAM GS14, toggles LED1
- cpuTimer0ISR in CPU1 is copied to shared RAM GS15, toggles LED2

3.15.3 NMI Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/nmi

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.3.1 NMI handling - C28X_DUAL

FILE: nmi_ex1_cpu1handling.c

This example demonstrates how to handle an NMI.

The watchdog of CPU2 is configured to reset the core once the watchdog overflows and in the CPU1 the NMI is triggered. The NMI status is read and is verified to be due to CPU2 Watchdog reset. The NMI ISR reboots the CPU2 core and the process is repeated.

Watch Variables

- nmi_isr_count Indicates the number of times the NMI ISR was hit because of CPU2 watchdog reset.

3.15.3.2 Watchdog Reset - C28X_DUAL

FILE: nmi_ex1_cpu2wdreset.c

This example shows how to configure the watchdog to reset CPU2 which will trigger an NMI in CPU1. LED1 is toggled at the start of main indicating CPU reset.

External Connections

- None.

Watch Variables

- loopCount - The number of loops performed while not in ISR

3.15.3.3 NMI handling - C28X_DUAL

FILE: nmi_ex2_sysconfig_cpu1.c

This example demonstrates how to handle an NMI.

The watchdog of CPU2 is configured to reset the core once the watchdog overflows and in the CPU1 the NMI is triggered. The NMI status is read and is verified to be due to CPU2 Watchdog reset. The NMI ISR reboots the CPU2 core and the process is repeated.

Watch Variables

- nmi_isr_count Indicates the number of times the NMI ISR was hit because of CPU2 watchdog reset.

3.15.3.4 Watchdog Reset - C28X_DUAL

FILE: nmi_ex2_sysconfig_cpu2.c

This example shows how to configure the watchdog to reset CPU2 which will trigger an NMI in CPU1. LED1 is toggled at the start of main indicating CPU reset.

External Connections

- None.

Watch Variables

- loopCount - The number of loops performed while not in ISR

3.15.4 TIMER Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/timer

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.4.1 CPU Timers

FILE: timer_ex1_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

External Connections

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.15.4.2 CPU Timers - CM

FILE: timer_ex1_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

Before running this example, please run the cm_common_config_c28x Example from the c28x folder. It will initialize the clock and configure the GPIOs.

External Connections

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.15.4.3 CPU Timers

FILE: timer_ex1_cputimers_sysconfig.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

External Connections

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.15.5 WATCHDOG Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/watchdog

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.5.1 Watchdog

FILE: watchdog_ex1_service.c

This example shows how to service the watchdog or generate a wakeup interrupt using the watchdog. By default the example will generate a Wake interrupt. To service the watchdog and not generate the interrupt, uncomment the SysCtl_serviceWatchdog() line in the main for loop.

External Connections

- None.

Watch Variables

- wakeCount - The number of times entered into the watchdog ISR
- loopCount - The number of loops performed while not in ISR

3.15.5.2 Windowed watchdog expiry with NMI handling - CM

FILE: watchdog_ex1_nmi_handling.c

This program demonstrates an NMI generation to the CM4 core when the Windowed watchdog (WWD) expires.

A delay is provided after enabling the WWD to make the watchdog count up from 0 to 0xFF. Once 0 is reached, an NMI is triggered. Currently on triggering an NMI, a status flag is set indicating if the NMI was handled after the WWD expired.

External Connections

- None

Watch Variables

- *wdstatus* - Indicates if the WWD caused an NMI on expiry.
- *cmnmi* - Indicates if the NMI was handled after the WWD expired
- *fail* - Status if the Windowed watchdog expired generating an NMI with proper NMI handling

3.16 System Control Registers

This section describes the various System Control Registers.

3.16.1 SYSCTRL Base Address Table (C28)

Table 3-15. SYSCTRL Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected

3.16.2 ACCESS_PROTECTION_REGS Registers

Table 3-16 lists the memory-mapped registers for the ACCESS_PROTECTION_REGS registers. All register offset addresses not listed in Table 3-16 should be considered as reserved locations and the register contents should not be modified.

Table 3-16. ACCESS_PROTECTION_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	NMAVFLG	Non-Master Access Violation Flag Register		Go
2h	NMAVSET	Non-Master Access Violation Flag Set Register	EALLOW	Go
4h	NMAVCLR	Non-Master Access Violation Flag Clear Register	EALLOW	Go
6h	NMAVINTEN	Non-Master Access Violation Interrupt Enable Register	EALLOW	Go
8h	NMCPURDAVADDR	Non-Master CPU Read Access Violation Address		Go
Ah	NMCPUWRAVADDR	Non-Master CPU Write Access Violation Address		Go
Ch	NMCPUFAVADDR	Non-Master CPU Fetch Access Violation Address		Go
Eh	NMDMAWRAVADDR	Non-Master DMA Write Access Violation Address		Go
10h	NMCLA1RDAVADDR	Non-Master CLA1 Read Access Violation Address		Go
12h	NMCLA1WRAVADDR	Non-Master CLA1 Write Access Violation Address		Go
14h	NMCLA1FAVADDR	Non-Master CLA1 Fetch Access Violation Address		Go
1Ch	NMDMARDAVADDR	Non-Master DMA Read Access Violation Address		Go
20h	MAVFLG	Master Access Violation Flag Register		Go
22h	MAVSET	Master Access Violation Flag Set Register	EALLOW	Go
24h	MAVCLR	Master Access Violation Flag Clear Register	EALLOW	Go
26h	MAVINTEN	Master Access Violation Interrupt Enable Register	EALLOW	Go
28h	MCPUFAVADDR	Master CPU Fetch Access Violation Address		Go
2Ah	MCPUWRAVADDR	Master CPU Write Access Violation Address		Go
2Ch	MDMAWRAVADDR	Master DMA Write Access Violation Address		Go

Complex bit access types are encoded to fit into small table cells. Table 3-17 shows the codes that are used for access types in this section.

Table 3-17. ACCESS_PROTECTION_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 3-17. ACCESS_PROTECTION_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.2.1 NMAVFLG Register (Offset = 0h) [Reset = 0h]

NMAVFLG is shown in Figure 3-20 and described in Table 3-18.

Return to the Summary Table.

3.16.3 CLK_CFG_REGS Registers

Table 3-37 lists the memory-mapped registers for the CLK_CFG_REGS registers. All register offset addresses not listed in Table 3-37 should be considered as reserved locations and the register contents should not be modified.

Table 3-37. CLK_CFG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CLKSEM	Clock Control Semaphore Register	EALLOW	Go
2h	CLKCFGLOCK1	Lock bit for CLKCFG registers	EALLOW	Go
8h	CLKSRCCTL1	Clock Source Control register-1	EALLOW	Go
Ah	CLKSRCCTL2	Clock Source Control register-2	EALLOW	Go
Ch	CLKSRCCTL3	Clock Source Control register-3	EALLOW	Go
Eh	SYSPLLCTL1	SYSPLL Control register-1	EALLOW	Go
14h	SYSPLLMULT	SYSPLL Multiplier register	EALLOW	Go
16h	SYSPLLSTS	SYSPLL Status register		Go
18h	AUXPLLCTL1	AUXPLL Control register-1	EALLOW	Go
1Eh	AUXPLLMULT	AUXPLL Multiplier register	EALLOW	Go
20h	AUXPLLSTS	AUXPLL Status register		Go
22h	SYSCLKDIVSEL	System Clock Divider Select register	EALLOW	Go
24h	AUXCLKDIVSEL	Auxillary Clock Divider Select register	EALLOW	Go
26h	PERCLKDIVSEL	Peripheral Clock Divider Selet register	EALLOW	Go
28h	XCLKOUTDIVSEL	XCLKOUT Divider Select register	EALLOW	Go
2Ah	CLBCLKCTL	CLB Clocking Control Register	EALLOW	Go
2Ch	LOSPCP	Low Speed Clock Source Prescalar	EALLOW	Go
2Eh	MCDCR	Missing Clock Detect Control Register	EALLOW	Go
30h	X1CNT	10-bit Counter on X1 Clock		Go
32h	XTALCR	XTAL Control Register	EALLOW	Go
36h	ETHERCATCLKCTL	ETHERCATCLKCTL	EALLOW	Go
38h	CMCLKCTL	CMCLKCTL	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-38 shows the codes that are used for access types in this section.

Table 3-38. CLK_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 3-38. CLK_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.3.1 CLKSEM Register (Offset = 0h) [Reset = 0h]

CLKSEM is shown in Figure 3-39 and described in Table 3-39.

Return to the Summary Table.

Clock Control Semaphore Register

Figure 3-39. CLKSEM Register

RESERVED														SEM	
R-0-0h														R/W-0h	

Table 3-39. CLKSEM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Writing the value 0xa5a5 will allow the writing of the SEM bits, else writes are ignored. Reads will return 0. Note: [1] Due to this KEY, only 32-bit writes will succeed (provided the KEY matches). 16-bit writes to the upper or lower half of this register will be ignored Reset type: CPU1.SYSRSn
15-2	RESERVED	R-0	0h	Reserved
1-0	SEM	R/W	0h	This register provides a mechanism to acquire all the CLKCFG registers (except this register) by CPU1 or CPU2. A CPU can perform read/writes to any of the CLKCFG registers (except this register) only if it owns the semaphore. Otherwise, writes are ignored and reads will return 0x0. Semaphore State Transitions: A value of 00, 10, 11 gives ownership to CPU1 A value of 01 gives ownership to CPU2. The following are the only state transitions allowed on these bits. 00,11 <-> 01 (allowed by CPU2) 00,11 <-> 10 (allowed by CPU1) If a CPU doesn't own the CLK_CFG_REGS set of registers (as defined by the state of this semaphore), reads from that CPU to all those registers return 0x0 and writes are ignore. Note that this is not true of CLKSEM register. The CLKSEM register's reads and writes are always allowed from both CPU1 and CPU2. Reset type: CPU1.SYSRSn

3.16.3.2 CLKCFGLOCK1 Register (Offset = 2h) [Reset = 0h]

CLKCFGLOCK1 is shown in Figure 3-40 and described in Table 3-40.

Return to the Summary Table.

Lock bit for CLKCFG registers
Notes:
[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect
[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Reads to the registers which have LOCK protection are always allowed Reset type: CPU1.SYSRSn

3.16.3.3 CLKSRCCTL1 Register (Offset = 8h) [Reset = 0h]

CLKSRCCTL1 is shown in Figure 3-41 and described in Table 3-41.

Return to the Summary Table.

Clock Source Control register-1
This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

Table 3-41. CLKSRCCTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OSCCLKSRCSEL	R/W	0h	Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK. 00 = INTOSC2 (default on reset) 01 = External Oscillator (XTAL) 10 = INTOSC1 11 = reserved (default to INTOSC1) At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier. Notes: [1] Reserved selection defaults to 00 configuration [2] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL. [3] Any writes to this bit must be followed with at least 300 CPU Cycles of wait time by adding at least 300 NOP instructions. [4] Changing the OSCCLKSRC while PLL is running and used by system (i.e. PLLCLKEN=1), can lead to dead System Clock. User needs to first bypass the PLL clock from the system by PLLCLKEN=0, and then change the OSCCLK source. Reset type: XRSn

3.16.3.4 CLKSRCCTL2 Register (Offset = Ah) [Reset = 0h]

CLKSRCCTL2 is shown in Figure 3-42 and described in Table 3-42.

Return to the Summary Table.

Clock Source Control register-2
This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

This divider sits in front of the PLLSYSCLK x0 = /1 of PLLSYSCLK x1 = /2 of PLLSYSLCK (default on reset) Note: Refer to the EPWM User Guide for maximum EPWM Frequency Reset type: CPU1.SYSRSn

3.16.3.15 XCLKOUTDIVSEL Register (Offset = 28h) [Reset = 3h]

XCLKOUTDIVSEL is shown in Figure 3-53 and described in Table 3-53.

Return to the Summary Table.

XCLKOUT Divider Select register
This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

0	CMDIVSRCSEL	R/W	0h	0: Auxillary PLL is the source for the CM clock divider. 1: System PLL is the source for CM clock divider. Reset type: XRSn

3.16.4 CM_CONF_REGS Registers

Table 3-61 lists the memory-mapped registers for the CM_CONF_REGS registers. All register offset addresses not listed in Table 3-61 should be considered as reserved locations and the register contents should not be modified.

Table 3-61. CM_CONF_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CMRESCTL	CM Reset Control Register	EALLOW	Go
2h	CMTOCPU1NMICTL	CM To CPU1 NMI Control register	EALLOW	Go
4h	CMTOCPU1INTCTL	CM To CPU1 interrupt Control register	EALLOW	Go
20h	PALLOCATE0	CM Peripheral Allocation Register.	EALLOW	Go
3FEh	CM_CONF_REGS_LOCK	CM Configuration Registers Lock	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-62 shows the codes that are used for access types in this section.

Table 3-62. CM_CONF_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.4.1 CMRESCTL Register (Offset = 0h) [Reset = 1h]

CMRESCTL is shown in Figure 3-61 and described in Table 3-63.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 3-69 shows the codes that are used for access types in this section.

Table 3-69. CPU_SYS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read

Table 3-69. CPU_SYS_REGS Access Type Codes (continued)

Access Type	Code	Description
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.5.1 CPUSYSLOCK1 Register (Offset = 0h) [Reset = 0h]

CPUSYSLOCK1 is shown in Figure 3-66 and described in Table 3-70.

Return to the Summary Table.

Lock bit for CPUSYS registers
Notes:
[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect
[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

3.16.5.28 TMR2CLKCTL Register (Offset = 7Ch) [Reset = 0h]

TMR2CLKCTL is shown in Figure 3-93 and described in Table 3-97.

Return to the Summary Table.

Timer2 Clock Measurement functionality control register
This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

3.16.6 CPU_ID_REGS Registers

Table 3-102 lists the memory-mapped registers for the CPU_ID_REGS registers. All register offset addresses not listed in Table 3-102 should be considered as reserved locations and the register contents should not be modified.

Table 3-102. CPU_ID_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CPUID	Indicates CPU1 or CPU2		Go

Complex bit access types are encoded to fit into small table cells. Table 3-103 shows the codes that are used for access types in this section.

Table 3-103. CPU_ID_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.6.1 CPUID Register (Offset = 0h) [Reset = X]

CPUID is shown in Figure 3-98 and described in Table 3-104.

Return to the Summary Table.

This register can be used to identify on which CPU the code is executing.

Bit	Field	Type	Reset	Description
31-1	RESERVED	R-0	0h	Reserved
0	LOCK_AC_WR	R/WSonce	0h	Defines Access control definition for the CPUx as: 1: Access Control registers are Read Only 0: Read/Write Access allowed to Access Control registers. Writing '1' sets the bit, writing '0' has no effect. Reset type: CPUx.SYSRSn

3.16.8 CPUTIMER_REGS Registers

Table 3-182 lists the memory-mapped registers for the CPUTIMER_REGS registers. All register offset addresses not listed in Table 3-182 should be considered as reserved locations and the register contents should not be modified.

Table 3-182. CPUTIMER_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	TIM	CPU-Timer, Counter Register		Go
2h	PRD	CPU-Timer, Period Register		Go
4h	TCR	CPU-Timer, Control Register		Go
6h	TPR	CPU-Timer, Prescale Register		Go
7h	TPRH	CPU-Timer, Prescale Register High		Go

Complex bit access types are encoded to fit into small table cells. Table 3-183 shows the codes that are used for access types in this section.

Table 3-183. CPUTIMER_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.8.1 TIM Register (Offset = 0h) [Reset = FFFFh]

TIM is shown in Figure 3-174 and described in Table 3-184.

Return to the Summary Table.

CPU-Timer, Counter Register

Figure 3-174. TIM Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

Table 3-184. TIM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Counter Registers The TIMH register holds the high 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Counter Registers The TIM register holds the low 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn

3.16.8.2 PRD Register (Offset = 2h) [Reset = FFFFh]

PRD is shown in Figure 3-175 and described in Table 3-185.

Return to the Summary Table.

CPU-Timer, Period Register

Figure 3-175. PRD Register

MSW																LSW															
R/W-0h																R/W-FFFFh															

Table 3-185. PRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Period Registers The PRDH register holds the high 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Period Registers The PRD register holds the low 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn

3.16.8.3 TCR Register (Offset = 4h) [Reset = 1h]

TCR is shown in Figure 3-176 and described in Table 3-186.

Return to the Summary Table.

CPU-Timer, Control Register

Figure 3-176. TCR Register

15	14	13	12	11	10	9	8
TIF	TIE	RESERVED		FREE	SOFT	RESERVED	
R/W1C-0h	R/W-0h	R-0h		R/W-0h	R/W-0h	R-0h	
7	**6**	**5**	**4**	**3**	**2**	**1**	**0**
RESERVED		TRB	TSS	RESERVED			
R-0h		R/W-0h	R/W-0h	R-1h			

Table 3-186. TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	TIF	R/W1C	0h	CPU-Timer Overflow Flag. TIF indicates whether a timer overflow has happened since TIF was last cleared. TIF is not cleared automatically and does not need to be cleared to enable the next timer interrupt. Reset type: SYSRSn 0h (R/W) = The CPU-Timer has not decremented to zero. Writes of 0 are ignored. 1h (R/W) = This flag gets set when the CPU-timer decrements to zero. Writing a 1 to this bit clears the flag.
14	TIE	R/W	0h	CPU-Timer Interrupt Enable. Reset type: SYSRSn 0h (R/W) = The CPU-Timer interrupt is disabled. 1h (R/W) = The CPU-Timer interrupt is enabled. If the timer decrements to zero, and TIE is set, the timer asserts its interrupt request.
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run. If FREE is 0, then the SOFT bit controls the emulation behavior. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop) (SOFT bit controls the emulation behavior) 1h (R/W) = Free Run (SOFT bit is don't care, counter is free running)
10	SOFT	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run (that is, free runs). In this case, SOFT is a don't care. But if FREE is 0, then SOFT takes effect. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop). (ONLY if FREE=0, if FREE=1 this bit is don't care) 1h (R/W) = Stop after the TIMH:TIM decrements to 0 (soft stop) In the SOFT STOP mode, the timer generates an interrupt before shutting down (since reaching 0 is the interrupt causing condition). (ONLY if FREE=0, if FREE=1 this bit is don't care)
9-6	RESERVED	R	0h	Reserved

Table 3-186. TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	TRB	R/W	0h	Timer reload Reset type: SYSRSn 0h (R/W) = The TRB bit is always read as zero. Writes of 0 are ignored. 1h (R/W) = When you write a 1 to TRB, the TIMH:TIM is loaded with the value in the PRDH:PRD, and the prescaler counter (PSCH:PSC) is loaded with the value in the timer dividedown register (TDDRH:TDDR).
4	TSS	R/W	0h	CPU-Timer stop status bit. TSS is a 1-bit flag that stops or starts the CPU-timer. Reset type: SYSRSn 0h (R/W) = Reads of 0 indicate the CPU-timer is running. To start or restart the CPU-timer, set TSS to 0. At reset, TSS is cleared to 0 and the CPU-timer immediately starts. 1h (R/W) = Reads of 1 indicate that the CPU-timer is stopped. To stop the CPU-timer, set TSS to 1.
3-0	RESERVED	R	1h	Reserved

3.16.8.4 TPR Register (Offset = 6h) [Reset = 0h]

TPR is shown in Figure 3-177 and described in Table 3-187.

Return to the Summary Table.

CPU-Timer, Prescale Register

PSC							
R-0h							
7	6	5	4	3	2	1	0
TDDR							
R/W-0h							

Table 3-187. TPR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	PSC	R	0h	CPU-Timer Prescale Counter. These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0. Reset type: SYSRSn
7-0	TDDR	R/W	0h	CPU-Timer Divide-Down. Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software. Reset type: SYSRSn

3.16.8.5 TPRH Register (Offset = 7h) [Reset = 0h]

TPRH is shown in Figure 3-178 and described in Table 3-188.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 3-190 shows the codes that are used for access types in this section.

Table 3-190. DEV_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.9.1 DEVCFGLOCK1 Register (Offset = 0h) [Reset = 0h]

DEVCFGLOCK1 is shown in Figure 3-179 and described in Table 3-191.

Return to the Summary Table.

Lock bit for DEVCFG registers
The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed
Note:
Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

Since this gets corrected by the ECC mechanism, this value shouldn't be treated as an error condition. Reset type: XRSn

3.16.9.8 SOFTPRES0 Register (Offset = 82h) [Reset = 0h]

SOFTPRES0 is shown in Figure 3-186 and described in Table 3-198.

Return to the Summary Table.

Processing Block Software Reset register
When bits in this register are set, the respective module is in reset. All design data is lost and the module registers are returned to their reset states. Bits must be manually cleared after being set.

3.16.9.21 SOFTPRES16 Register (Offset = A2h) [Reset = 0h]

SOFTPRES16 is shown in Figure 3-199 and described in Table 3-211.

Return to the Summary Table.

Processing Block Software Reset register
When bits in this register are set, the respective module is in reset. All design data is lost and the module registers are returned to their reset states. Bits must be manually cleared after being set.

3.16.9.33 CPUSEL7 Register (Offset = E4h) [Reset = 0h]

CPUSEL7 is shown in Figure 3-211 and described in Table 3-223.

Return to the Summary Table.

CPU Select register for common peripherals
This register must be configured prior to enabling the peripheral clocks.
The clock for each peripheral is derived from the selected CPU subsystem. The clock mux controlled by this register is not glitch-free, therefore the CPUSELx register must be configured before the PCLKCRx register.
The reset for each peripheral is also driven from the selected CPU.

Table 3-233. CPU2RESCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Write to this register succeeds only if this field is written with a value of 0xa5a5 Note: [1] Due to this KEY, only 32-bit writes will succeed (provided the KEY matches). 16-bit writes to the upper or lower half of this register will be ignored Reset type: CPU1.SYSRSn
15-1	RESERVED	R-0	0h	Reserved
0	RESET	R/W	1h	This bit controls the reset input of CPU2 core. 1: CPU2 is held in reset (CPU2.RSn = 0) 0: CPU2 reset is deactivated (CPU2.RSn = 1) Note: [1] If CPU2 is not used at-all by an application, it's advisable to put CPU2 in STANDBY mode rather than in reset to save on active power component on the CPU2 subsystem. This is because, all clocks keep toggling when reset is active on the CPU2 sub-system. [2] Note: If CPU2 is in Standby mode, writing to this bit will have no effect. CPU2 may be reset by any Chip-level reset (POR, XRSn, CPU1.WDRSn, or CPU1.NMIWDRSn). Alternately CPU2 may be woken up by any configured wake-up event. Reset type: CPU1.SYSRSn

3.16.9.44 RSTSTAT Register (Offset = 124h) [Reset = 0h]

RSTSTAT is shown in Figure 3-222 and described in Table 3-234.

3.16.9.47 ECAPTYPE Register (Offset = 19Bh) [Reset = 0h]

ECAPTYPE is shown in Figure 3-225 and described in Table 3-237.

Return to the Summary Table.

Based on the configuration enables disables features associated with the SDFM type.

Figure 3-225. ECAPTYPE Register

15	14	13	12	11	10	9	8
LOCK	RESERVED						
R/WSonce-0h	R-0-0h						
7	6	5	4	3	2	1	0
RESERVED						TYPE	
R-0-0h						R/W-0h	

Table 3-237. ECAPTYPE Register Field Descriptions

Bit	Field	Type	Reset	Description
15	LOCK	R/WSonce	0h	1: Write to this register is not allowed. 0: Write to this register is allowed. Reset type: CPU1.SYSRSn
14-2	RESERVED	R-0	0h	Reserved
1-0	TYPE	R/W	0h	"00,10,11" : 1. No EALLOW protection to ECAP registers. "01" : 1. ECAP registers are EALLOW protected. Reset type: CPU1.SYSRSn

3.16.9.48 SDFMTYPE Register (Offset = 19Ch) [Reset = 0h]

SDFMTYPE is shown in Figure 3-226 and described in Table 3-238.

Return to the Summary Table.

Based on the configuration enables disables features associated with the SDFM type.

Figure 3-226. SDFMTYPE Register

15	14	13	12	11	10	9	8
LOCK	RESERVED						
R/WSonce-0h	R-0-0h						
7	6	5	4	3	2	1	0
RESERVED						TYPE	
R-0-0h						R/W-0h	

Table 3-238. SDFMTYPE Register Field Descriptions

Bit	Field	Type	Reset	Description
15	LOCK	R/WSonce	0h	1: Write to this register is not allowed. 0: Write to this register is allowed. Reset type: CPU1.SYSRSn
14-2	RESERVED	R-0	0h	Reserved
1-0	TYPE	R/W	0h	"00,10,11" : 1. Data Ready conditions combined with the fault conditions on the SDFM interrupt line. 2. Data ready interrupts from individual filters are not generated. "01" : 1. Data Ready conditions do not generate the SDFMINT. 2. Each filter generates a separate data ready interrupts. Reset type: CPU1.SYSRSn

3.16.9.49 MEMMAPTYPE Register (Offset = 19Eh) [Reset = 0h]

MEMMAPTYPE is shown in Figure 3-227 and described in Table 3-239.

Return to the Summary Table.

Based on the configuration enables the memory map.

Figure 3-227. MEMMAPTYPE Register

15	14	13	12	11	10	9	8
LOCK	RESERVED						
R/WSonce-0h	R-0-0h						
7	6	5	4	3	2	1	0
RESERVED						TYPE	
R-0-0h						R/W-0h	

Table 3-239. MEMMAPTYPE Register Field Descriptions

Bit	Field	Type	Reset	Description
15	LOCK	R/WSonce	0h	1: Write to this register is not allowed. 0: Write to this register is allowed. Reset type: CPU1.SYSRSn
14-2	RESERVED	R-0	0h	Reserved
1-0	TYPE	R/W	0h	"00,10,11" : 1. Disables re-mapping SDRAM in lower 128kb of address space. "01" : 1. Enables re-mapping SDRAM in lower 128kb of address space. Reset type: CPU1.SYSRSn

3.16.10 DMA_CLA_SRC_SEL_REGS Registers

Table 3-240 lists the memory-mapped registers for the DMA_CLA_SRC_SEL_REGS registers. All register offset addresses not listed in Table 3-240 should be considered as reserved locations and the register contents should not be modified.

Table 3-240. DMA_CLA_SRC_SEL_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CLA1TASKSRCSELLOCK	CLA1 Task Trigger Source Select Lock Register	EALLOW	Go
4h	DMACHSRCSELLOCK	DMA Channel Triger Source Select Lock Register	EALLOW	Go
6h	CLA1TASKSRCSEL1	CLA1 Task Trigger Source Select Register-1	EALLOW	Go
8h	CLA1TASKSRCSEL2	CLA1 Task Trigger Source Select Register-2	EALLOW	Go
16h	DMACHSRCSEL1	DMA Channel Trigger Source Select Register-1	EALLOW	Go
18h	DMACHSRCSEL2	DMA Channel Trigger Source Select Register-2	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-241 shows the codes that are used for access types in this section.

Table 3-241. DMA_CLA_SRC_SEL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.10.1 CLA1TASKSRCSELLOCK Register (Offset = 0h) [Reset = 0h]

CLA1TASKSRCSELLOCK is shown in Figure 3-228 and described in Table 3-242.

Return to the Summary Table.

Table 3-274. GSxTEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	TEST_GS15	R/W	0h	Selects the defferent modes for GS15 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
29-28	TEST_GS14	R/W	0h	Selects the defferent modes for GS14 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
27-26	TEST_GS13	R/W	0h	Selects the defferent modes for GS13 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn

Table 3-274. GSxTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25-24	TEST_GS12	R/W	0h	Selects the defferent modes for GS12 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
23-22	TEST_GS11	R/W	0h	Selects the defferent modes for GS11 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
21-20	TEST_GS10	R/W	0h	Selects the defferent modes for GS10 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
19-18	TEST_GS9	R/W	0h	Selects the defferent modes for GS9 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
17-16	TEST_GS8	R/W	0h	Selects the defferent modes for GS8 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
15-14	TEST_GS7	R/W	0h	Selects the defferent modes for GS7 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn

Table 3-274. GSxTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13-12	TEST_GS6	R/W	0h	Selects the defferent modes for GS6 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
11-10	TEST_GS5	R/W	0h	Selects the defferent modes for GS5 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
9-8	TEST_GS4	R/W	0h	Selects the defferent modes for GS4 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
7-6	TEST_GS3	R/W	0h	Selects the defferent modes for GS3 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
5-4	TEST_GS2	R/W	0h	Selects the defferent modes for GS2 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn
3-2	TEST_GS1	R/W	0h	Selects the defferent modes for GS1 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn

Table 3-274. GSxTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	TEST_GS0	R/W	0h	Selects the defferent modes for GS0 RAM: 00: Functional Mode. 01: Writes are allowed to data bits only. No write to parity bits. 10: Writes are allowed to parity bits only. No write to data bits. 11: Same as functional mode, but interrupt/nmi is not generated on error. Note: Any non zero value would enable CPU writes over-riding write access protection if any and will not generate a access protection violation. Reset type: SYSRSn

Complex bit access types are encoded to fit into small table cells. Table 3-293 shows the codes that are used for access types in this section.

Table 3-293. MEMORY_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 3-293. MEMORY_ERROR_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.12.1 UCERRFLG Register (Offset = 0h) [Reset = 0h]

UCERRFLG is shown in Figure 3-276 and described in Table 3-294.

Return to the Summary Table.

3.16.13 NMI_INTRUPT_REGS Registers

Table 3-312 lists the memory-mapped registers for the NMI_INTRUPT_REGS registers. All register offset addresses not listed in Table 3-312 should be considered as reserved locations and the register contents should not be modified.

Table 3-312. NMI_INTRUPT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	NMICFG	NMI Configuration Register	EALLOW	Go
1h	NMIFLG	NMI Flag Register (SYSRsn Clear)		Go
2h	NMIFLGCLR	NMI Flag Clear Register	EALLOW	Go
3h	NMIFLGFRC	NMI Flag Force Register	EALLOW	Go
4h	NMIWDCNT	NMI Watchdog Counter Register		Go
5h	NMIWDPRD	NMI Watchdog Period Register	EALLOW	Go
6h	NMISHDFLG	NMI Shadow Flag Register		Go
7h	ERRORSTS	Error pin status		Go
8h	ERRORSTSCLR	ERRORSTS clear register	EALLOW	Go
9h	ERRORSTSFRC	ERRORSTS force register	EALLOW	Go
Ah	ERRORCTL	Error pin control register	EALLOW	Go
Bh	ERRORLOCK	Lock register to Error pin registers.	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-313 shows the codes that are used for access types in this section.

Table 3-313. NMI_INTRUPT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.13.1 NMICFG Register (Offset = 0h) [Reset = 0h]

NMICFG is shown in Figure 3-294 and described in Table 3-314.

Bit	Field	Type	Reset	Description
15	MCAN_ERR	R	0h	0 MCAN module has not generated an ECC error. 1 MCAN module has generated an ECC error. [1] This bit is reserved for CPU2.NMIFLG register Reset type: SYSRSn
14	CRC_FAIL	R	0h	0 CPUCRC and CLACRC check has not failed. 1 CPUCRC or CLACRC check has failed. Reset type: SYSRSn
13	ECATNMIn	R	0h	0 No reset request from EtherCAT IP. 1 NMI generated from EtherCAT IP. No further NMI pulses are generated until this flag is cleared by the user. [1] This bit is reserved for CPU2.NMIFLG register Reset type: SYSRSn
12	CMNMIWDRSn	R	0h	CM NMIWDRSn Reset Indication Flag: This bit indicates if CM's NMIWDRSn was fired or not. 0 No CM.NMIWDRsn was fired 1 CM.NMIWDRSn was fired to CM [1] This bit is reserved for CPU2.NMIFLG register Reset type: SYSRSn
11	RESERVED	R	0h	Reserved
10	CPU2NMIWDRSn	R	0h	CPU2 NMIWDRSn Reset Indication Flag: This bit indicates if CPU2's NMIWDRSn was fired or not. 0 No CPU2.NMIWDRsn was fired 1 CPU2.NMIWDRSn was fired to CPU2 Note: [1] This bit is reserved for CPU2.NMIFLG register Reset type: SYSRSn
9	CPU2WDRSn	R	0h	CPU2 WDRSn Reset Indication Flag: This bit indicates if CPU2's WDRSn was fired or not. 0 No CPU2.WDRsn was fired 1 CPU2.WDRSn was fired to CPU2 Note: [1] This bit is reserved for CPU2.NMIFLG register Reset type: SYSRSn
8	CLBNMI	R	0h	Configurable Logic Block NMI Flag: This bit indicates if an NMI was generated by the Configurable Logic Block. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0,No Configurable Logic Block NMI pending 1,Configurable Logic Block NMI generated Reset type: SYSRSn

Table 3-315. NMIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	ERADNMI	R	0h	ERAD Module NMI Flag: This bit indicates if an NMI was generated by the ERAD Module. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0,No ERAD NMI pending 1,ERAD NMI generated Reset type: SYSRSn
6	PIEVECTERR	R	0h	PIE Vector Fetch Error Flag: This bit indicates if an error occurred on an Vector Fecth by the CPU in the device. In Dual core system CPU1.NMIWD gets an NMI on an Vector fetch Error on CPU2. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0,No Vector Fetch Error condition (on the other CPU) pending 1,Vector Fetch error condition (on the other CPU) generated Reset type: SYSRSn
5	CPU2HWBISTERR	R	0h	HW BIST Error NMI Flag: This bit indicates if the time out error or a signature mismatch error condition during hardware BIST of C28 CPU2 occurred. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0,No C28 HWBIST error condition pending 1,C28 BIST error condition generated Reset type: SYSRSn
4	CPU1HWBISTERR	R	0h	HW BIST Error NMI Flag: This bit indicates if the time out error or a signature mismatch error condition during hardware BIST of C28 CPU1 occurred. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0,No C28 HWBIST error condition pending 1,C28 BIST error condition generated Reset type: SYSRSn
3	FLUNCERR	R	0h	Flash Uncorrectable Error NMI Flag: This bit indicates if an uncorrectable error occurred on a C28 Flash access and that condition is latched. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0,No C28 Flash uncorrectable error condition pending 1,C28 Flash uncorrectable error condition generated Reset type: SYSRSn
2	RAMUNCERR	R	0h	RAM Uncorrectable Error NMI Flag: This bit indicates if an uncorrectable error occurred on a RAM access (by any master) and that condition is latched. This bit can only be cleared by the user writing to the corresponding clear bit in the NMIFLGCLR register or by an SYSRSn reset: 0,No RAM uncorrectable error condition pending 1,RAM uncorrectable error condition generated Note: This nmi is a combination of uncorrectable error in RAMs and ROMs. ROM parity error would also set this flag. Reset type: SYSRSn
1	CLOCKFAIL	R	0h	Clock Fail Interrupt Flag: These bits indicates if the CLOCKFAIL condition is latched. These bits can only be cleared by the user writing to the respective bit in the NMIFLGCLR register or by an SYSRSn reset: 0,No CLOCKFAIL Condition Pending 1,CLOCKFAIL Condition Generated Reset type: SYSRSn

Table 3-315. NMIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	NMIINT	R	0h	NMI Interrupt Flag: This bit indicates if an NMI interrupt was generated. This bit can only be cleared by the user writing to the respective bit in the NMIFLGCLR register or by an SYSRSn reset: 0 No NMI Interrupt Generated 1 NMI Interrupt Generated No further NMI interrupts pulses are generated until this flag is cleared by the user. Reset type: SYSRSn

3.16.13.3 NMIFLGCLR Register (Offset = 2h) [Reset = 0h]

NMIFLGCLR is shown in Figure 3-296 and described in Table 3-316.

Return to the Summary Table.

7	6	5	4	3	2	1	0
NMIWDCNT							
R-0h							

Table 3-318. NMIWDCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	NMIWDCNT	R	0h	NMI Watchdog Counter: This 16-bit incremental counter will start incrementing whenever any one of the enabled FAIL flags are set. If the counter reaches the period value, an NMIRSn signal is fired which will then resets the system. The counter will reset to zero when it reaches the period value and will then restart counting if any of the enabled FAIL flags are set. If no enabled FAIL flag is set, then the counter will reset to zero and remain at zero until an enabled FAIL flag is set. Normally, the software would respond to the NMI interrupt generated and clear the offending FLAG(s) before the NMI watchdog triggers a reset. In some situations, the software may decide to allow the watchdog to reset the device anyway. The counter is clocked at the SYSCLKOUT rate. Reset type: SYSRSn

3.16.13.6 NMIWDPRD Register (Offset = 5h) [Reset = FFFFh]

NMIWDPRD is shown in Figure 3-299 and described in Table 3-319.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 3-327 shows the codes that are used for access types in this section.

Table 3-327. PIE_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		

Table 3-327. PIE_CTRL_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.14.1 PIECTRL Register (Offset = 0h) [Reset = 0h]

PIECTRL is shown in Figure 3-306 and described in Table 3-328.

Return to the Summary Table.

Table 3-328. PIECTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-1	PIEVECT	R	0h	These bits indicate the vector address of the vector fetched from the ePIE vector table. The least significant bit of the address is ignored and only bits 1 to 15 of the address are shown. The vector value can be read by the user to determine which interrupt generated the vector fetch. Note: When a NMI is serviced, the PIEVECT bit-field does not reflect the vector as it does for other interrupts. Reset type: SYSRSn
0	ENPIE	R/W	0h	Enable vector fetching from ePIE block. This bit must be set to 1 for peripheral interrupts to work. All ePIE registers (PIEACK, PIEIFR, PIEIER) can be accessed even when the ePIE block is disabled. Reset type: SYSRSn

3.16.14.2 PIEACK Register (Offset = 1h) [Reset = 0h]

PIEACK is shown in Figure 3-307 and described in Table 3-329.

Return to the Summary Table.

Acknowledge Register
When an interrupt propagates from the ePIE to a CPU interrupt line, the interrupt group's PIEACK bit is set. This prevents other interrupts in that group from propagating to the CPU while the first interrupt is handled. Writing a 1 to a PIEACK bit clears it and allows another interrupt from the corresponding group to propagate. ISRs for PIE interrupts should clear the group's PIEACK bit before returning from the interrupt.
Writes of 0 are ignored.

3.16.14.3 PIEIER1 Register (Offset = 2h) [Reset = 0h]

PIEIER1 is shown in Figure 3-308 and described in Table 3-330.

Return to the Summary Table.

Interrupt Group 1 Enable Register
These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).
Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.
Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

3.16.14.4 PIEIFR1 Register (Offset = 3h) [Reset = 0h]

PIEIFR1 is shown in Figure 3-309 and described in Table 3-331.

Return to the Summary Table.

Interrupt Group 1 Flag Register
These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).
When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.
NOTE: PIE IFR flags can be written to create software interrupts.
The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.14.8 PIEIFR3 Register (Offset = 7h) [Reset = 0h]

PIEIFR3 is shown in Figure 3-313 and described in Table 3-335.

Return to the Summary Table.

Interrupt Group 3 Flag Register
These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).
When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.
NOTE: PIE IFR flags can be written to create software interrupts.
The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.14.16 PIEIFR7 Register (Offset = Fh) [Reset = 0h]

PIEIFR7 is shown in Figure 3-321 and described in Table 3-343.

Return to the Summary Table.

Interrupt Group 7 Flag Register
These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).
When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.
NOTE: PIE IFR flags can be written to create software interrupts.
The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.14.25 PIEIER12 Register (Offset = 18h) [Reset = 0h]

PIEIER12 is shown in Figure 3-330 and described in Table 3-352.

Return to the Summary Table.

Interrupt Group 12 Enable Register
These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).
Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.
Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

3.16.14.26 PIEIFR12 Register (Offset = 19h) [Reset = 0h]

PIEIFR12 is shown in Figure 3-331 and described in Table 3-353.

Return to the Summary Table.

Interrupt Group 12 Flag Register
These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).
When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.
NOTE: PIE IFR flags can be written to create software interrupts.
The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

Notes: [1] Any bit in this register, once set can only be creaed through a CPU1.SYSRSn. Write of 0 to any bit of this regtister has no effect [2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed Reset type: CPU1.SYSRSn
0	SYNCSELECT	R/WSonce	0h	SYNCSELECT Register Lock bit: 0: Respective register is not locked 1: Respective register is locked. Notes: [1] Any bit in this register, once set can only be creaed through a CPU1.SYSRSn. Write of 0 to any bit of this regtister has no effect [2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed Reset type: CPU1.SYSRSn

3.16.18 SYS_STATUS_REGS Registers

Table 3-365 lists the memory-mapped registers for the SYS_STATUS_REGS registers. All register offset addresses not listed in Table 3-365 should be considered as reserved locations and the register contents should not be modified.

Table 3-365. SYS_STATUS_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CM_STATUS_INT_FLG	Status of interrupts due to multiple sources of Cortex-M4 reset.		Go
2h	CM_STATUS_INT_CLR	CM_STATUS_INT_FLG clear register		Go
4h	CM_STATUS_INT_SET	CM_STATUS_INT_FLG set register	EALLOW	Go
6h	CM_STATUS_MASK	CM_STATUS_MASK register	EALLOW	Go
10h	SYS_ERR_INT_FLG	Status of interrupts due to multiple different errors in the system.		Go
12h	SYS_ERR_INT_CLR	SYS_ERR_INT_FLG clear register		Go
14h	SYS_ERR_INT_SET	SYS_ERR_INT_FLG set register	EALLOW	Go
16h	SYS_ERR_MASK	SYS_ERR_MASK register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-366 shows the codes that are used for access types in this section.

Table 3-366. SYS_STATUS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.18.1 CM_STATUS_INT_FLG Register (Offset = 0h) [Reset = 0h]

CM_STATUS_INT_FLG is shown in Figure 3-337 and described in Table 3-367.

Return to the Summary Table.

Status of interrupts due to multiple sources of Cortex-M4 reset.
Note: This register is present only on CPU1.

Table 3-375 lists the memory-mapped registers for the TEST_ERROR_REGS registers. All register offset addresses not listed in Table 3-375 should be considered as reserved locations and the register contents should not be modified.

Table 3-375. TEST_ERROR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CPU_RAM_TEST_ERROR_STS	Ram Test: Error Status Register		Go
2h	CPU_RAM_TEST_ERROR_STS_CLR	Ram Test: Error Status Clear Register		Go
4h	CPU_RAM_TEST_ERROR_ADDR	Ram Test: Error address register		Go

Complex bit access types are encoded to fit into small table cells. Table 3-376 shows the codes that are used for access types in this section.

Table 3-376. TEST_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.19.1 CPU_RAM_TEST_ERROR_STS Register (Offset = 0h) [Reset = 0h]

CPU_RAM_TEST_ERROR_STS is shown in Figure 3-345 and described in Table 3-377.

Return to the Summary Table.

3.16.21 WD_REGS Registers

Table 3-390 lists the memory-mapped registers for the WD_REGS registers. All register offset addresses not listed in Table 3-390 should be considered as reserved locations and the register contents should not be modified.

Table 3-390. WD_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
22h	SCSR	System Control & Status Register	EALLOW	Go
23h	WDCNTR	Watchdog Counter Register	EALLOW	Go
25h	WDKEY	Watchdog Reset Key Register	EALLOW	Go
29h	WDCR	Watchdog Control Register	EALLOW	Go
2Ah	WDWCR	Watchdog Windowed Control Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-391 shows the codes that are used for access types in this section.

Table 3-391. WD_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.21.1 SCSR Register (Offset = 22h) [Reset = 5h]

SCSR is shown in Figure 3-356 and described in Table 3-392.

Return to the Summary Table.

System Control & Status Register
It is recommended to only use 16 bit accesses to write to this register. Use a read-modify-write instruction may inadvertently clear other bits.

Figure 3-356. SCSR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0-0h							
7	6	5	4	3	2	1	0
RESERVED					WDINTS	WDENINT	WDOVERRIDE
R-0-0h					R-1h	R/W-0h	R/W1C-1h

Table 3-392. SCSR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R-0	0h	Reserved
2	WDINTS	R	1h	Watchdog Interrupt Status This bit indicates the state of the active-low watchdog interrupt signal (synchronized to SYSCLK). If the watchdog interrupt is used to wake the system from a low-power mode, then that mode should only be entered while this bit is high. Likewise, this bit must go high before the watchdog can be safely disabled and re-enabled. Reset type: SYSRSn 0h (R/W) = The watchdog interrupt signal is active. 1h (R/W) = The watchdog interrupt signal is inactive.
1	WDENINT	R/W	0h	Watchdog Interrupt Enable/Reset Disable This bit determines whether the watchdog triggers an interrupt (WAKE/WDOG) or a reset (WDRS) when the counter expires. Reset type: SYSRSn 0h (R/W) = Counter expiration triggers a reset. This is the default state on power-up and after any system reset. 1h (R/W) = Counter expiration triggers an interrupt.
0	WDOVERRIDE	R/W1C	1h	If this bit is set to 1, the user is allowed to change the state of the Watchdog disable (WDDIS) bit in the Watchdog Control (WDCR) register. If the WDOVERRIDE bit is cleared, by writing a 1 the WDDIS bit cannot be modified by the user. Writing a 0 will have no effect. If this bit is cleared, then it will remain in this state until a reset occurs. The current state of this bit is readable by the user. Reset type: SYSRSn

3.16.21.2 WDCNTR Register (Offset = 23h) [Reset = 0h]

WDCNTR is shown in Figure 3-357 and described in Table 3-393.

Return to the Summary Table.

Watchdog Counter Register

Figure 3-357. WDCNTR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0-0h							
7	6	5	4	3	2	1	0
WDCNTR							
R-0h							

Table 3-393. WDCNTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7-0	WDCNTR	R	0h	Watchdog Counter These bits contain the current value of the watchdog counter. This counter increments with each WDCLK (INTOSC1) cycle. If the counter overflows, either an interrupt or a reset is generated based on the value of the WDINTEN bit in the SCSR register. If the correct value is written to the WDKEY register, this counter is reset to zero. Reset type: IORSn

3.16.21.3 WDKEY Register (Offset = 25h) [Reset = 0h]

WDKEY is shown in Figure 3-358 and described in Table 3-394.

Return to the Summary Table.

Watchdog Reset Key Register

Figure 3-358. WDKEY Register

15	14	13	12	11	10	9	8
RESERVED							
R-0-0h							
7	6	5	4	3	2	1	0
WDKEY

Table 3-394. WDKEY Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7-0	WDKEY	R/W	0h	Watchdog Counter Reset Writing 0x55 followed by 0xAA will cause the watchdog counter to reset to zero, preventing an overflow. Writing other values has no effect. Reads of this register return the value of the WDCR register. Reset type: IORSn

3.16.21.4 WDCR Register (Offset = 29h) [Reset = 0h]

WDCR is shown in Figure 3-359 and described in Table 3-395.

Return to the Summary Table.

Watchdog Control Register
This memory mapped register requires a delay between subsequent writes to the register, otherwise a second write can be lost. The required delay is 69 SYSCLK cycles for a 200 MHz device, 45 SYSCLK cycles for a 120 MHz device, and 39 SYSCLK cycles for a 100 MHz device. This delay can be realized by adding NOP instructions corresponding to the required delay cycles.

Figure 3-359. WDCR Register

WDFLG	WDDIS	WDCHK			WDPS		
R/W1S-0h	R/W-0h	R-0/W-0h			R/W-0h		

Table 3-395. WDCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-12	RESERVED	R-0	0h	Reserved
11-8	WDPRECLKDIV	R/W	0h	Watchdog Clock Pre-divider These bits determine the watchdog clock pre-divider, which is the first of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: PREDIVCLK = INTOSC1 / Pre-divider WDCLK = PREDIVCLK / Prescaler Reset type: IORSn 0h (R/W) = PREDIVCLK = INTOSC1 / 512 1h (R/W) = PREDIVCLK = INTOSC1 / 1024 2h (R/W) = PREDIVCLK = INTOSC1 / 2048 3h (R/W) = PREDIVCLK = INTOSC1 / 4096 4h (R/W) = Reserved 5h (R/W) = Reserved 6h (R/W) = Reserved 7h (R/W) = Reserved 8h (R/W) = PREDIVCLK = INTOSC1 / 2 9h (R/W) = PREDIVCLK = INTOSC1 / 4 Ah (R/W) = PREDIVCLK = INTOSC1 / 8 Bh (R/W) = PREDIVCLK = INTOSC1 / 16 Ch (R/W) = PREDIVCLK = INTOSC1 / 32 Dh (R/W) = PREDIVCLK = INTOSC1 / 64 Eh (R/W) = PREDIVCLK = INTOSC1 / 128 Fh (R/W) = PREDIVCLK = INTOSC1 / 256
7	WDFLG	R/W1S	0h	Watchdog reset status flag bit. This bit, if set, indicates a watchdog reset (WDRSTn) generated the reset condition. If 0, then it was en external device or power-up reset condition. This bit remains latched until the user writes a 1 to clear the condition. Writes of 0 will be ignored. Reset type: IORSn
6	WDDIS	R/W	0h	Watchdog Disable Setting this bit disables the watchdog module. Clearing this bit enables the watchdog module. This bit can be locked by the WDOVERRIDE bit in the SCSR register. The watchdog is enabled on reset. Reset type: IORSn

Table 3-395. WDCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5-3	WDCHK	R-0/W	0h	Watchdog Check Bits During any write to this register, these bits must be written with the value 101 (binary). Writing any other value will immediately trigger the watchdog reset or interrupt. Reset type: IORSn
2-0	WDPS	R/W	0h	Watchdog Clock Prescaler These bits determine the watchdog clock prescaler, which is the second of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: PREDIVCLK = INTOSC1 / Pre-divider WDCLK = PREDIVCLK / Prescaler The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default prescaler value is 1. Reset type: IORSn 0h (R/W) = WDCLK = PREDIVCLK / 1 1h (R/W) = WDCLK = PREDIVCLK / 1 2h (R/W) = WDCLK = PREDIVCLK / 2 3h (R/W) = WDCLK = PREDIVCLK / 4 4h (R/W) = WDCLK = PREDIVCLK / 8 5h (R/W) = WDCLK = PREDIVCLK / 16 6h (R/W) = WDCLK = PREDIVCLK / 32 7h (R/W) = WDCLK = PREDIVCLK / 64

3.16.21.5 WDWCR Register (Offset = 2Ah) [Reset = 0h]

WDWCR is shown in Figure 3-360 and described in Table 3-396.

Return to the Summary Table.

Watchdog Windowed Control Register

Figure 3-360. WDWCR Register

INTCTR							
R-0h							

Table 3-404. XINT1CTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	INTCTR	R	0h	This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset. Reset type: SYSRSn

3.16.22.7 XINT2CTR Register (Offset = 9h) [Reset = 0h]

XINT2CTR is shown in Figure 3-367 and described in Table 3-405.

Return to the Summary Table.

Chapter 4

C28x Processor

This chapter contains a short description of the C28x processor and extended instruction sets.

Further information can be found in the following documents:

- *TMS320C28x CPU and Instruction Set Reference Guide*
- *TMS320C28x Extended Instruction Sets Technical Reference Manual*
- *Accelerators: Enhancing the Capabilities of the C2000 MCU Family Technical Brief*
- *TMS320C28x FPU Primer Application Report*

4.1 Introduction

The C28x CPU is a 32-bit fixed-point processor. This device draws from the best features of digital signal processing, reduced instruction set computing (RISC), microcontroller architectures, firmware, and tool sets.

For more information on CPU architecture and instruction set, see the *TMS320C28x CPU and Instruction Set Reference Guide*.

4.3 Features

The CPU features include a modified Harvard architecture and circular addressing. The RISC features are single-cycle instruction execution, register-to-register operations, and modified Harvard architecture. The microcontroller features include ease of use through an intuitive instruction set, byte packing and unpacking, and bit manipulation. The modified Harvard architecture of the CPU enables instruction and data fetches to be performed in parallel. The CPU can read instructions and data while it writes data simultaneously to maintain the single-cycle instruction operation across the pipeline.

4.4 Floating-Point Unit

The C28x plus floating-point (C28x+FPU64) processor extends the capabilities of the C28x fixed-point CPU by adding registers and instructions to support IEEE single-precision and double-precision floating point operations.

Devices with the C28x+FPU64 include the standard C28x register set plus an additional set of floating-point unit registers. The additional floating-point unit registers are the following:

- Eight floating-point result registers, RnH (where n = 0–7)
- Floating-point Status Register (STF)
- Repeat Block Register (RB)

All of the floating-point registers, except the repeat block register, are shadowed. This shadowing can be used in high-priority interrupts for fast context save and restore of the floating-point registers.

For more information, see the *TMS320C28x Extended Instruction Sets Technical Reference Manual*.

4.5 Trigonometric Math Unit (TMU)

The trigonometric math unit (TMU) extends the capabilities of a C28x+FPU64 by adding instructions and leveraging existing FPU64 instructions to speed up the execution of common trigonometric and arithmetic operations listed in Table 4-1.

Table 4-1. TMU Supported Instructions

Instructions	C Equivalent Operation	Pipeline Cycles
MPY2PIF32/64 RaH,RbH	a = b * 2pi	2/3
DIV2PIF32/64 RaH,RbH	a = b / 2pi	2/3
DIVF32/64 RaH,RbH,RcH	a = b/c	5
SQRTF32/64 RaH,RbH	a = sqrt(b)	5
SINPUF32/64 RaH,RbH	a = sin(b*2pi)	4
COSPUF32/64 RaH,RbH	a = cos(b*2pi)	4
ATANPUF32/64 RaH,RbH	a = atan(b)/2pi	4
QUADF32/64 RaH,RbH,RcH,RdH	Operation to assist in calculating ATANPU2	5

No changes have been made to existing instructions, pipeline or memory bus architecture. All TMU instructions use the existing FPU register set (R0H to R7H) to carry out their operations.

For more information, see the *TMS320C28x Extended Instruction Sets Technical Reference Manual*.

4.6 VCRC Unit

Cyclic redundancy check (CRC) algorithms provide a straightforward method for verifying data integrity over large data blocks, communication packets, or code sections. The C28x+VCRC can perform 8-bit, 16-bit, 24-bit, and 32-bit CRCs. A CRC result register contains the current CRC, which is updated whenever a CRC instruction is executed.

The following are the CRC polynomials used by the CRC calculation logic of VCRC:

- CRC8 polynomial = 0x07
- CRC16 polynomial1 = 0x8005
- CRC16 polynomial2 = 0x1021
- CRC24 polynomial = 0x5d6dcb
- CRC32 polynomial1 = 0x04c11db7
- CRC32 polynomial2 = 0x1edc6f41

This module can calculate CRCs for a byte of data in a single cycle. The CRC calculation for CRC8, CRC16, CRC24 and CRC32 is done byte-wise (instead of computing on a complete 16-bit or 32-bit data read by the C28x core) to match the byte-wise computation requirement mandated by various standards.

The VCRC Unit also allows the user to provide the size (1b-32b) and value of any polynomial to fit custom CRC requirements. The CRC execution time increases to 3 cycles when using a custom polynomial.

For more information, see the *TMS320C28x Extended Instruction Sets Technical Reference Manual*.

Chapter 5

ROM Code and Peripheral Booting

This chapter describes the boot flow and functionality of the CPU1, CPU2, and Connectivity Manager (CM) subsystems.

5.1 Introduction

The purpose of this chapter is to explain the boot read-only memory (ROM) code functionality for CPU1, CPU2, and CM cores, including the boot procedure. It also discusses the functions and features of the boot ROM code, and provides details about the ROM memory map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence will initialize the device to run the application code. For CPU1, the boot ROM also contains peripheral bootloaders which can be used to load an application into RAM. These bootloaders can be disabled for safety or security purposes.

Refer to Table 5-1 for details on available boot features across CPU1, CPU2, and CM. Additionally, Table 5-2 shows the sizes of the various ROMs on the device.

Table 5-1. Boot System Overview

Boot Feature	CPU1 (Master)	CPU2	CM
Initiate boot process	Device Reset	CPU1 Application	CPU1 Application
Boot mode selection	GPIOs	IPC Register	IPC Register
Supported boot modes: • Flash boot • Secure Flash boot • RAM boot	Yes	Yes	Yes
Boot to User OTP	No	Yes	Yes
Copy from IPC Message RAM and boot to RAM	No	Yes	Yes
Peripheral boot loader support	Yes	No	No

Table 5-2. ROM Memory

ROM	CPU1 Size	CPU2 Size	CM Size
Unsecure boot ROM	192 KB	64 KB	64 KB
Secure ROM	64 KB	64 KB	32 KB
CLA data ROM	8 KB	8 KB	N/A

5.1.1 ROM Related Collateral

Expert Materials

- *C2000 Software Controlled Firmware Update Process Application Report*

5.2 Device Boot Sequence

The boot sequence describes the general boot ROM procedure each time a CPU core is reset. CPU1 is the master and always boots first. Once CPU1 boots to the application, then the user's application code in CPU1 can configure CPU2/CM boot IPC registers and release CPU2/CM from reset to boot. Table 5-3, Table 5-4, and Table 5-5 detail the general overview of the boot-up procedures for each core.

During boot, each CPU's boot ROM code updates a boot status location in RAM that details the actions taken during this process. Additionally, CPU2 writes the boot status to the CPU2TOCPU1IPCBOOTSTS register and CM writes to CMTOCPU1IPCBOOTSTS to communicate the statuses to CPU1.

Refer to Section 5.7.11 for more details.

Table 5-3. CPU1 Boot ROM Sequence

Step	CPU1 Action
1	After reset, check for HWBIST reset. If it is a HWBIST reset, immediately branch and return to the user application. If it is not a HWBIST reset, then continue boot and check the FUSE error register for any errors and handle accordingly.
2	Clock configuration and Flash power-up
3	Peripheral trimming and device configuration registers are loaded from OTP.
4	On power-on reset (POR), all CPU1 RAMs are initialized.
5	Non-maskable interrupt (NMI) handling is enabled and DCSM initialization is performed.
6	Device calibration is performed; trimming the specified peripherals with set OTP values.
7	Determine if polling the GPIO pins are needed for determining the boot mode and, if so, read the boot mode GPIO pins to determine the boot mode to run.
8	Based on the boot mode and options, the appropriate boot sequence is executed. Refer to Section 5.5.1 for a flow chart of the CPU1 boot sequences.

Table 5-4. CPU2 Boot ROM Sequence

Step	CPU2 Action
1	CPU2 is released from reset by CPU1 application.
2	Once CPU1TOCPU2IPCFLG0 is set, read the CPU1TOCPU2IPCBOOTMODE register. If it is not set correctly or has an invalid value, the IPC error command is sent to CPU1 and the CPU2 core will enter an infinite loop and will not continue booting until the user corrects the register values and reset the CPU2.
3	Flash power-up
4	On POR, all CPU2 RAMs are initialized.
5	NMI handling is enabled.
6	Based on the boot mode set in CPU1TOCPU2IPCBOOTMODE register, CPU2 either enters "wait for command" mode to wait for a future CPU1 boot mode command or CPU2 executes the requested boot sequence. Refer to Section 5.5.2 for a flow chart of the CPU2 boot sequences.

Table 5-5. CM Boot ROM Sequence

Step	CM Action
1	CM is released from reset by the CPU1 application.
2	Once CPU1TOCMIPCFLG0 is set, read the CPU1TOCMIPCBOOTMODE register.If it is not set correctly or has an invalid value, the IPC error command is sent to CPU1 and the CM will enter an infinite loop and will not continue booting until the user corrects the register values and reset the CM.
3	Flash power-up
4	On POR, all CM RAMs are initialized.
5	NMI handling is enabled.
6	Based on the boot mode set in CPU1TOCPU2IPCBOOTMODE register, CM either enters "wait for command" mode to wait for a future CPU1 boot mode command or CM executes the requested boot sequence. Refer to Section 5.5.3 for a flow chart of the CM boot sequences.

5.3 Device Boot Modes

This section explains the default boot modes, as well as all the available boot modes supported on this device. The CPU1 boot ROM uses the boot mode select, general purpose input/output (GPIO) pins to determine the boot mode configuration. CPU2 boot ROM uses the CPU1TOCPU2IPCBOOTMODE register to determine the boot mode configuration and CM boot ROM uses the CPU1TOCMIPCBOOTMODE register to determine the boot mode configuration.

Table 5-6 shows the CPU1 boot mode options available for selection by the default boot mode select pins. Users have the option to program the device to customize the boot modes selectable in the boot-up table as well as the boot mode select pin GPIOs used.

All the available boot modes on the device are described in Table 5-8.

Table 5-6. Device Default Boot Modes for CPU1

Boot Mode	GPIO72 (Default boot mode select pin 1)	GPIO84 (Default boot mode select pin 0)
Parallel IO	0	0
SCI / Wait Boot(1)	0	1
CAN	1	0
Flash / USB(2)	1	1

(1) SCI boot mode can be used as a wait boot mode as long as SCI continues to wait for an 'A' or 'a' during the SCI autobaud lock process.
(2) On an unprogrammed device, selecting Flash boot when the default Flash entry address is unprogrammed switches the boot mode from Flash boot to USB boot. See Table 5-7 for more details.

Table 5-7. CPU1 Flash-to-USB Boot Decision Table

Value at Flash Entry Point Address	Reason for Value	Realized Boot Mode
0x00000000	Flash is locked/secured	Boot to Flash
0xFFFFFFFF	Flash is not programmed	USB Boot
Any other value	Flash is programmed	Boot to Flash

Note

The switch of Flash boot mode to USB boot mode when Flash is not programmed is only available as part of the default boot mode table on an unprogrammed device. Once a custom boot table is programmed in OTP or RAM, a selection of Flash boot mode does not switch to USB boot even when Flash is unprogrammed.

Table 5-8. All Available Boot Modes

Boot Mode	CPU Support	Details
Parallel IO	CPU1	
SCI / Wait	CPU1	
CAN	CPU1	
Flash	CPU1, CPU2, CM	
Wait	CPU1, CPU2, CM	Refer to Section 5.7.7 for functional details of the boot modes.
RAM	CPU1, CPU2, CM	
SPI	CPU1	Refer to Section 5.7.8 for boot table values and GPIOs for the boot modes.
I2C	CPU1	
USB	CPU1	
Secure Flash	CPU1, CPU2, CM	
User OTP	CPU2, CM	
IPC Message Copy to RAM	CPU2, CM	

Note

All the peripheral boot modes that are supported use the first instance of the peripheral module (SCIA, SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SCI boot, it is actually referring to the first module instance, which means the SCI boot on the SCIA port. The same applies to the other peripheral boots.

5.4 Device Boot Configurations

This section details what boot configurations are available and how to configure them. This device supports from 0 boot mode select pins up to 3 boot mode select pins as well as from 1 configured boot mode up to 8 configured boot modes.

To change and configure the device from the default settings to custom settings for your application, use the following process:

1. Determine all the various ways you want application to be able to boot. (For example: Primary boot option of Flash boot for your main application, secondary boot option of CAN boot for firmware updates, tertiary boot option of SCI boot for debugging, etc)
2. Based on the number of boot modes needed, determine how many boot mode select pins (BMSPs) are required to select between your selected boot modes. (For example: 2 BMSPs are required to select between 3 boot mode options)
3. Assign the required BMSPs to a physical GPIO pin. (For example, BMSP0 to GPIO50, BMSP1 to GPIO51, and BMSP2 left as default which is disabled). Refer to Section 5.4.1 for all the details on performing these configurations.
4. Assign the determined boot mode definitions to indexes in your custom boot table that correlate to the decoded value of the BMSPs. For example, BOOTDEF0=Boot to Flash, BOOTDEF1=CAN Boot, BOOTDEF2=SCI Boot; all other BOOTDEFx are left as default/nothing). Refer to Section 5.4.2 for all the details on setting up and configuring the custom boot mode table.

Additionally, Section 5.4.3 provides some example use cases on how to configure the BMSPs and custom boot tables.

5.4.1 Configuring Boot Mode Pins for CPU1

This section explains how the boot mode select pins can be customized by the user, by programming the BOOTPINCONFIG location (refer to Table 5-9) in the user-configurable dual-zone security module (DCSM) OTP. The location in the DCSM OTP is Z1-BOOTPINCONFIG or Z2-BOOTPINCONFIG. When debugging, EMUBOOTPINCONFIG is the emulation equivalent of Z1-BOOTPINCONFIG/Z2-BOOTPINCONFIG, and can be programmed to experiment with different boot modes without writing to OTP. The device can be programmed to use 0, 1, 2, or 3 boot mode select pins as needed.

Note

When using Z2-BOOTPINCONFIG, the configurations programmed in this location will take priority over the configurations in Z1-BOOTPINCONFIG. It is **recommended** to use Z1-BOOTPINCONFIG first and then if OTP configurations need to be altered, switch to using Z2-BOOTPINCONFIG.

Table 5-9. CPU1 BOOTPINCONFIG Bit Fields

Bit	Name	Description
31:24	Key	Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid For EMUBOOTPINCONFIG only, write 0xA5 to emulate the standalone boot flow and use the BMSPs/OTP BOOTDEF table
23:16	Boot Mode Select Pin 2 (BMSP2)	Refer to BMSP0 description except for BMSP2
15:8	Boot Mode Select Pin 1 (BMSP1)	Refer to BMSP0 description except for BMSP1
7:0	Boot Mode Select Pin 0 (BMSP0)	Set to the GPIO pin to be used during boot (up to 255). 0x0 = GPIO0; 0x01 = GPIO1 and so on Writing 0xFF disables BMSP0 and this pin is no longer used to select the boot mode.

Note

The following GPIOs **cannot** be used as a BMSP. If selected for a particular BMSP, the boot ROM automatically selects the factory default GPIO (the factory default for BMSP2 is 0xFF, which disables the BMSP).

- GPIO 42 and GPIO 43
- GPIO 169 to 255

Table 5-10. CPU1 Standalone Boot Mode Select Pin Decoding

BOOTPIN_CONFIG Key	BMSP0	BMSP1	BMSP2	Realized Boot Mode
!= 0x5A	Don't Care	Don't Care	Don't Care	Boot as defined by the factory default BMSPs
= 0x5A	0xFF	0xFF	0xFF	Boot as defined in the boot table for boot mode 0 (All BMSPs disabled)
	Valid GPIO	0xFF	0xFF	Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled)
	0xFF	Valid GPIO	0xFF	Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled)
	0xFF	0xFF	Valid GPIO	Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled)
	Valid GPIO	Valid GPIO	0xFF	Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled)
	Valid GPIO	0xFF	Valid GPIO	Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled)
	0xFF	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled)
	Valid GPIO	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Invalid GPIO	Valid GPIO	Valid GPIO	BMSP0 is reset to the factory default BMSP0 GPIO Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Valid GPIO	Invalid GPIO	Valid GPIO	BMSP1 is reset to the factory default BMSP1 GPIO Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Valid GPIO	Valid GPIO	Invalid GPIO	BMSP2 is reset to the factory default state, which is disabled Boot as defined by the values of BMSP0 and BMSP1

Note

When decoding the boot mode, BMSP0 is the least-significant-bit and BMSP2 is the most-significant-bit of the boot table index value. It is **recommended** when disabling BMSPs to start with disabling BMSP2. For example, in an instance when only using BMSP2 (BMSP1 and BMSP0 are disabled), then only the boot table indexes of 0 and 4 will be selectable. In the instance when using only BMSP0, then the selectable boot table indexes are 0 and 1.

5.4.2 Configuring Boot Mode Table Options for CPU1

This section explains how to configure the boot definition table, BOOTDEF, for CPU1. The 64-bit location is located in user-configurable DCSM OTP in the Z1-BOOTDEF-LOW and Z1-BOOTDEF-HIGH locations. When debugging, EMUBOOTDEF-LOW and EMUBOOTDEF-HIGH are the emulation equivalents of Z1-BOOTDEF-LOW and Z1-BOOTDEF-HIGH, and can be programmed to experiment with different boot mode options without writing to OTP. The range of customization to the boot definition table depends on how many boot mode select pins (BMSP) are being used. For example, 0 BMSPs equals to 1 table entry, 1 BMSP equals to 2 table entries, 2 BMSPs equals to 4 table entries, and 3 BMSPs equals to 8 table entries. Refer to Section 5.4.3 for examples on how to setup the BOOTPIN_CONFIG and BOOTDEF values.

Note

The locations Z2-BOOTDEF-LOW and Z2-BOOTDEF-HIGH will be used instead of Z1-BOOTDEF-LOW and Z1-BOOTDEF-HIGH locations when Z2-BOOTPINCONFIG is configured. Refer to Section 5.4.1 for more details on BOOTPIN_CONFIG usage.

Table 5-11. CPU1 BOOTDEF Bit Fields

BOOTDEF Name	Byte Position	Name	Description
BOOT_DEF0	7:0	BOOT_DEF0 Mode/Options	Set the boot mode for index 0 of the boot table. Different boot modes and their options can include, for example, a boot mode that uses different GPIOs for a specific bootloader or a different Flash entry point address. Any unsupported boot mode will cause the device to either go to wait boot or boot to Flash. Refer to Section 5.7.8 for valid BOOTDEF values to set in the table.
BOOT_DEF1	15:8	BOOT_DEF1 Mode/Options	Refer to BOOT_DEF0 description
BOOT_DEF2	23:16	BOOT_DEF2 Mode/Options	
BOOT_DEF3	31:24	BOOT_DEF3 Mode/Options	
BOOT_DEF4	39:32	BOOT_DEF4 Mode/Options	
BOOT_DEF5	47:40	BOOT_DEF5 Mode/Options	
BOOT_DEF6	55:48	BOOT_DEF6 Mode/Options	
BOOT_DEF7	63:56	BOOT_DEF7 Mode/Options	

5.4.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins and boot modes.

5.4.3.1 Zero Boot Mode Select Pins

This use case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to Flash.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
   - Set BOOTPIN_CONFIG.BMSP0 to 0xFF
   - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
   - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
   - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to Section 5.7.8 for valid BOOTDEF values to set in the table.
   - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 0.
   - Refer to Section 5.7.3 for the available Flash entry points.

Table 5-12. Zero Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	Flash Boot (0x03)

5.4.3.2 One Boot Mode Select Pin

This use case demonstrates a scenario for an application using one boot mode select pin to select between booting to Flash or using CAN boot.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
   - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
   - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
   - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
   - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to Section 5.7.8 for valid BOOTDEF values to set in the table.
   - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
   - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.

Table 5-13. One Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)

5.4.3.3 Three Boot Mode Select Pins

This use case demonstrates a scenario for an application using three boot mode select pins to select between various boot modes in the custom boot table.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
   - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
   - Set BOOTPIN_CONFIG.BMSP1 to a user specified GPIO, such as 0x1 for GPIO1
   - Set BOOTPIN_CONFIG.BMSP2 to a user specified GPIO, such as 0x2 for GPIO2
   - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to Section 5.7.8 for valid BOOTDEF values to set in the table.
   - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
   - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.
   - Set BOOTDEF.BOOTDEF2 to 0x24 for booting to wait boot (alternate option). This sets wait boot to boot table index 2.
   - Set BOOTDEF.BOOTDEF3 to 0x66 for SPI booting (alternate GPIO option 3). This sets SPI boot to boot table index 3.
   - Set BOOTDEF.BOOTDEF4 to 0x43 for booting to Flash (entry address option 2). This sets Flash boot to boot table index 4.
   - Set BOOTDEF.BOOTDEF5 to 0x09 for USB booting. This sets USB boot to boot table index 5.

Table 5-14. Three Boot Pins Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)
2	Wait Boot - Alt (0x24)
3	SPI - Alt3 (0x66)
4	Flash Boot - Alt2 (0x43)
5	USB Boot (0x09)

5.5 Device Boot Flow Diagrams

This section details the boot flow diagrams for CPU1, CPU2, and CM.

5.5.1 CPU1 Boot Flow

Upon reset, CPU1 follows the boot flow shown in Figure 5-1. Depending on whether a JTAG debugger is connected to the device, CPU1 will either continue booting following the emulation boot flow or standalone boot flow. Figure 5-2 shows the emulation boot flow when JTAG debugger is connected. Figure 5-3 shows the standalone boot flow when no JTAG debugger is connected to the device.

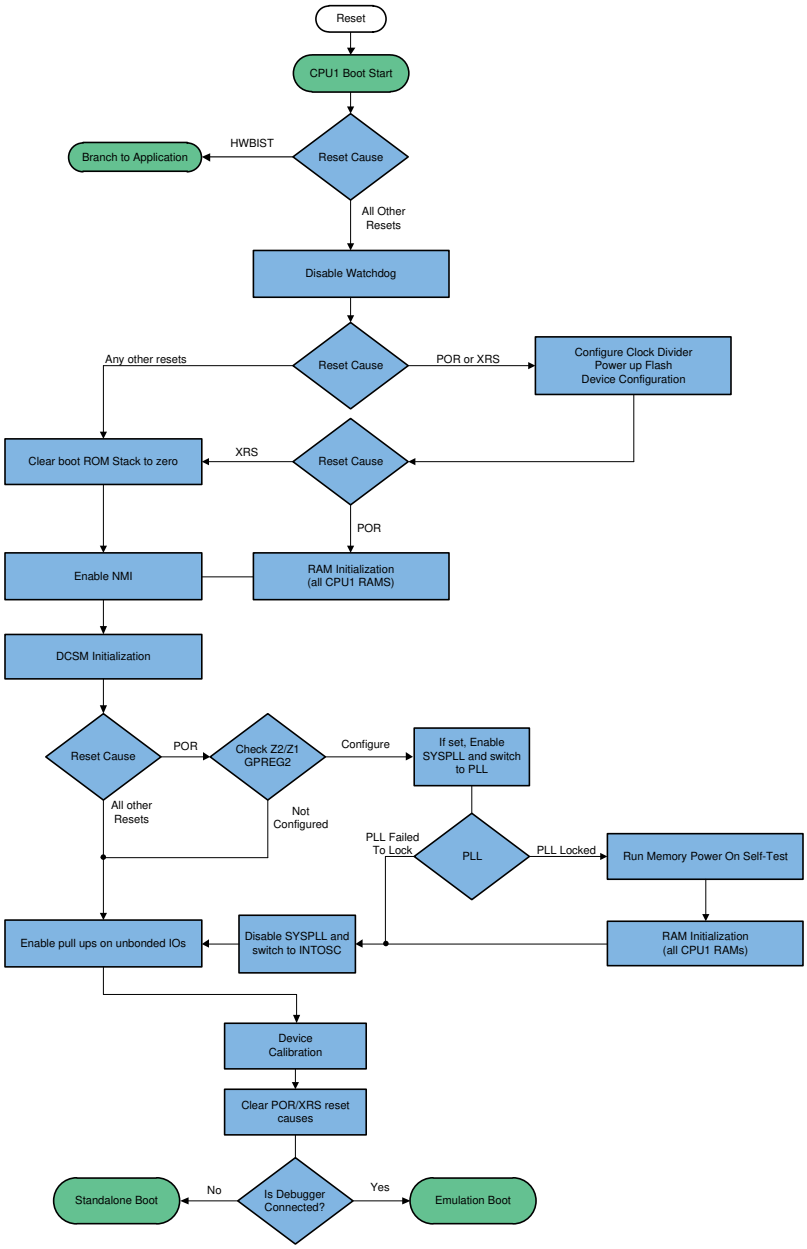

Figure 5-1. CPU1 Device Boot Flow

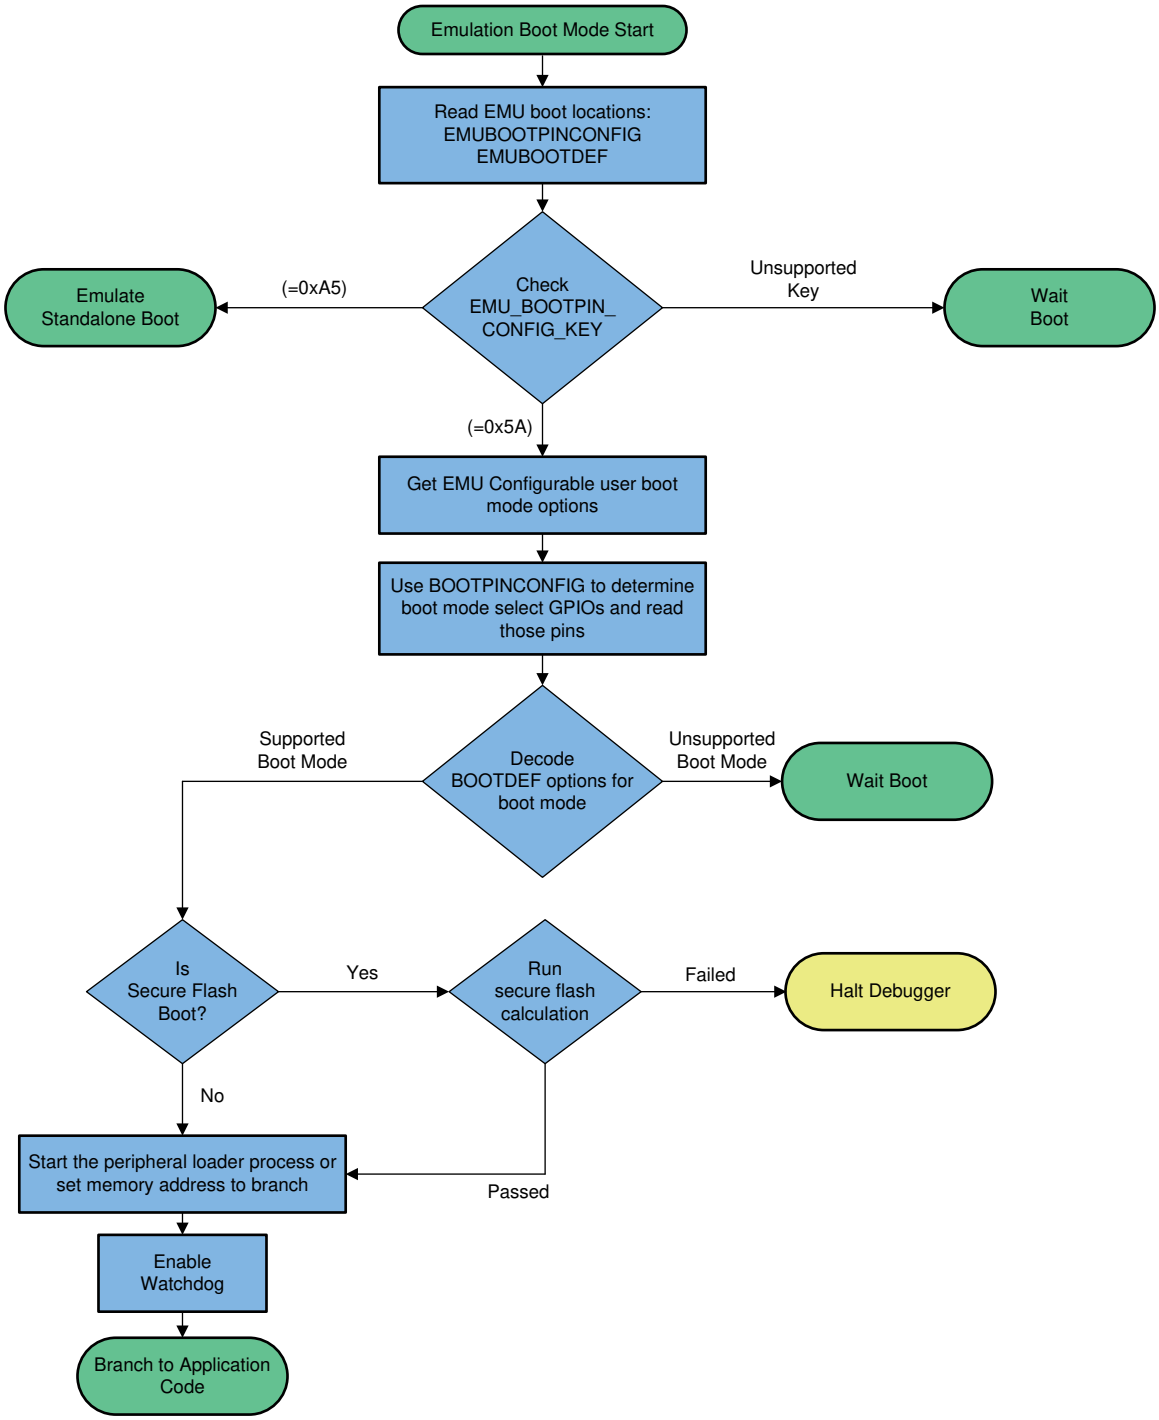

Figure 5-2. CPU1 Emulation Boot Flow

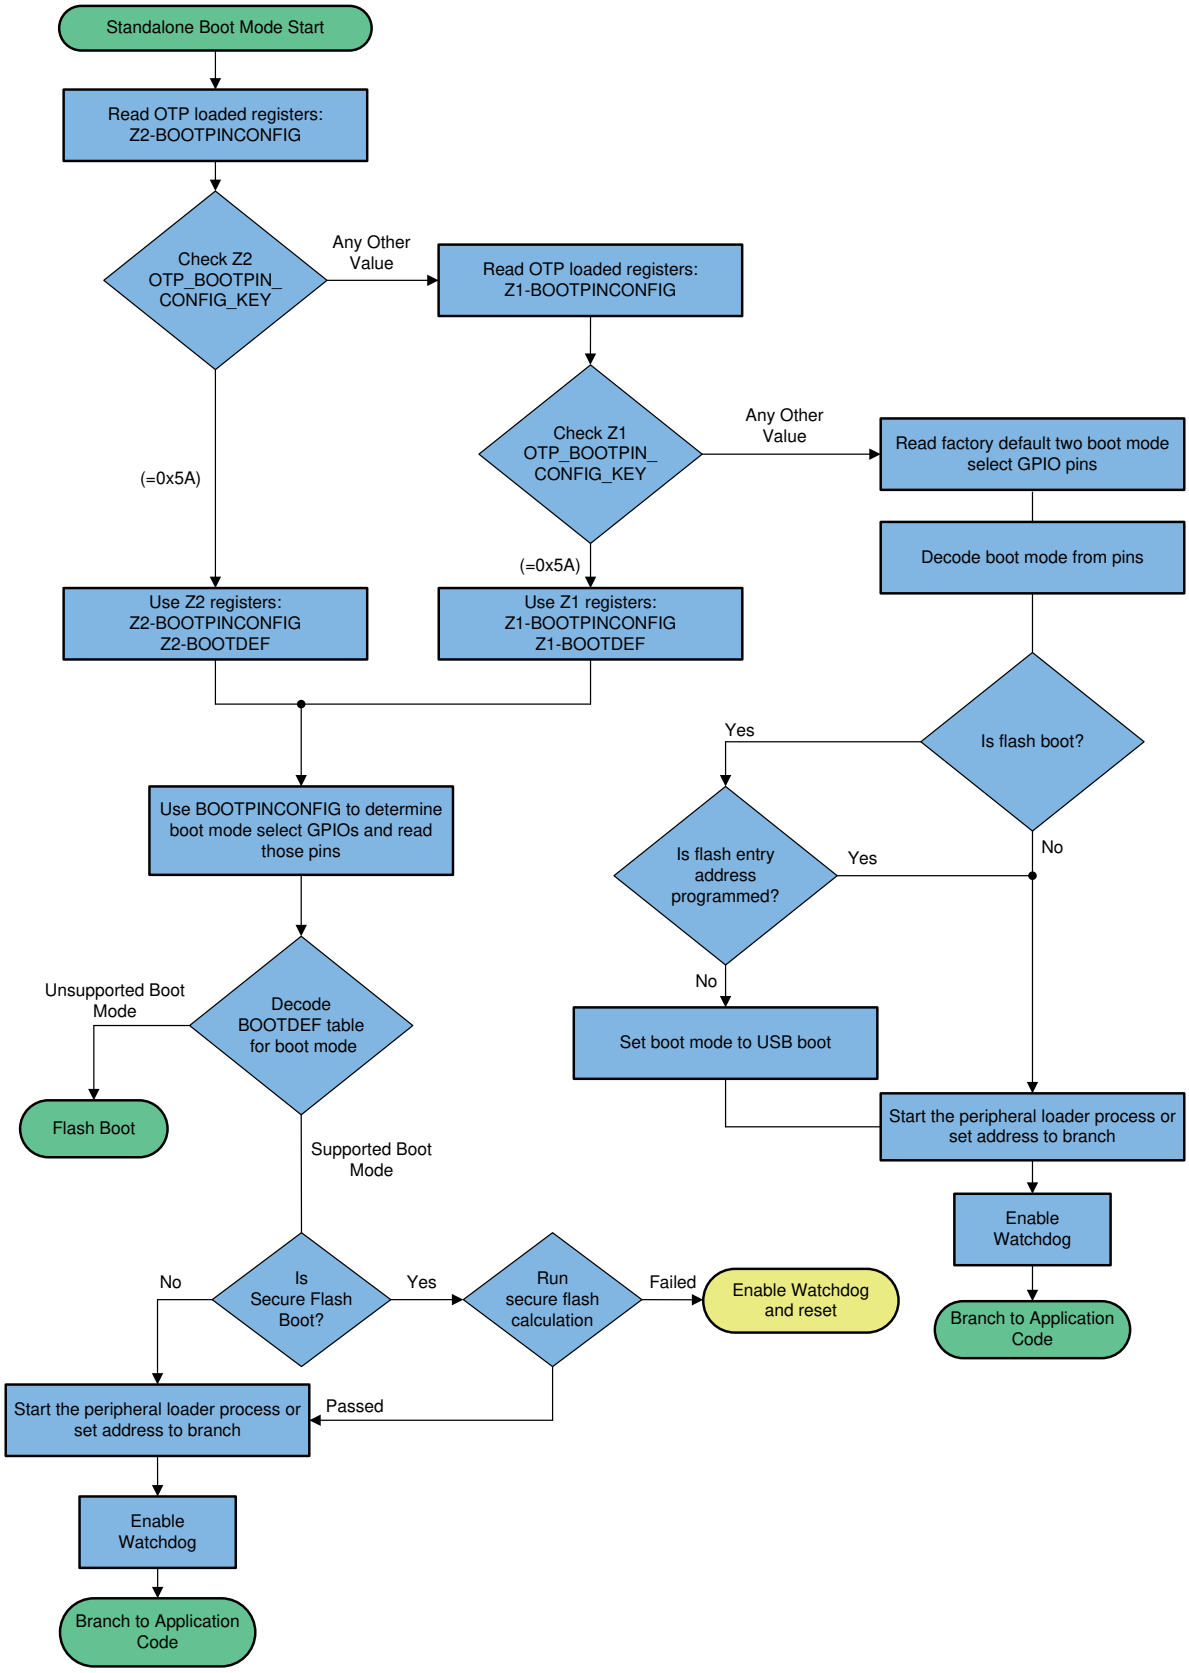

Figure 5-3. CPU1 Standalone Boot Flow

5.5.2 CPU2 Boot Flow

Upon reset, CPU2 follows the boot flow shown in Figure 5-4. CPU2 only boots once configured and released from reset by CPU1. Refer to Section 5.7.2 for more details.

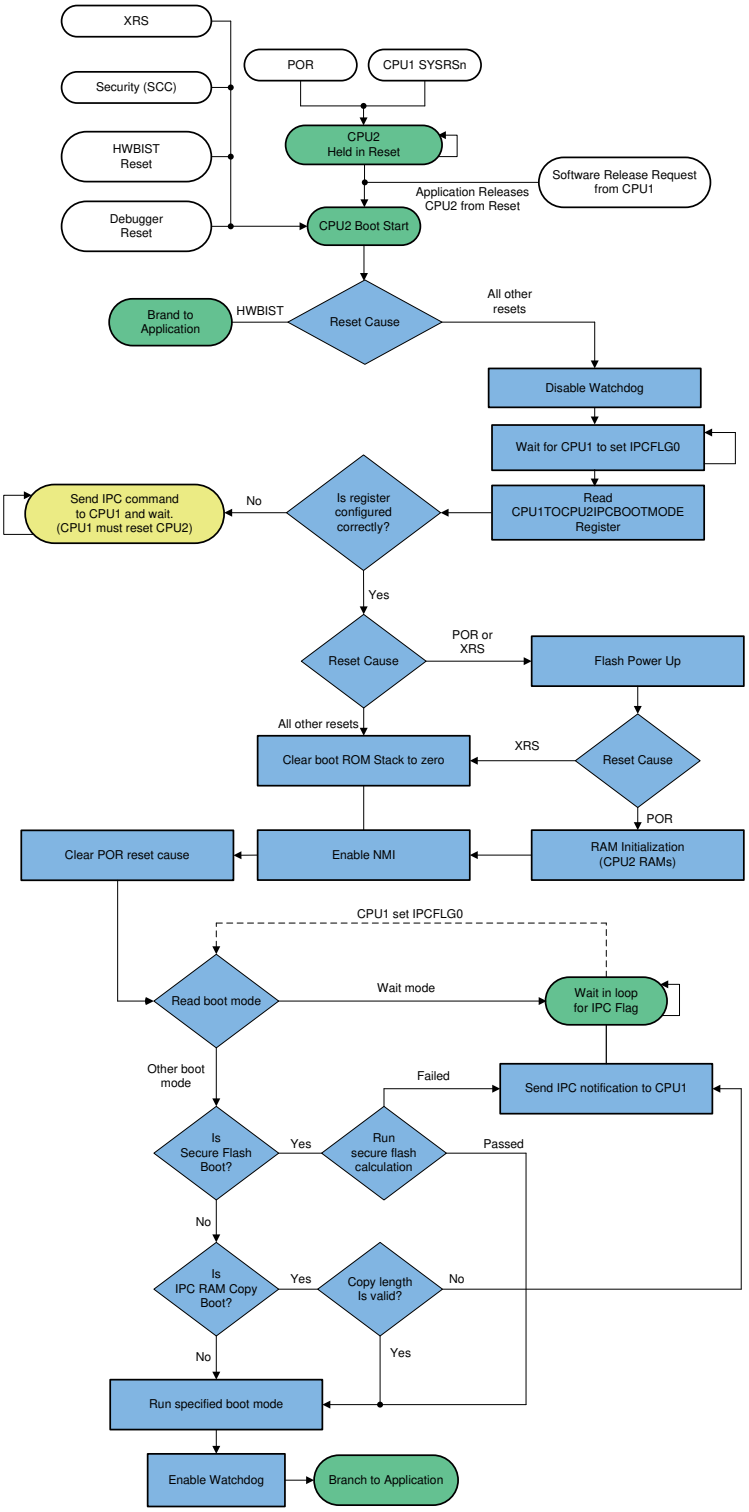

Figure 5-4. CPU2 Boot Flow

5.5.3 Connectivity Manager (CM) Boot Flow

Upon reset, CM follows the boot flow shown in Figure 5-5. CM only boots once configured and released from reset by CPU1. Refer to Section 5.7.2 for more details.

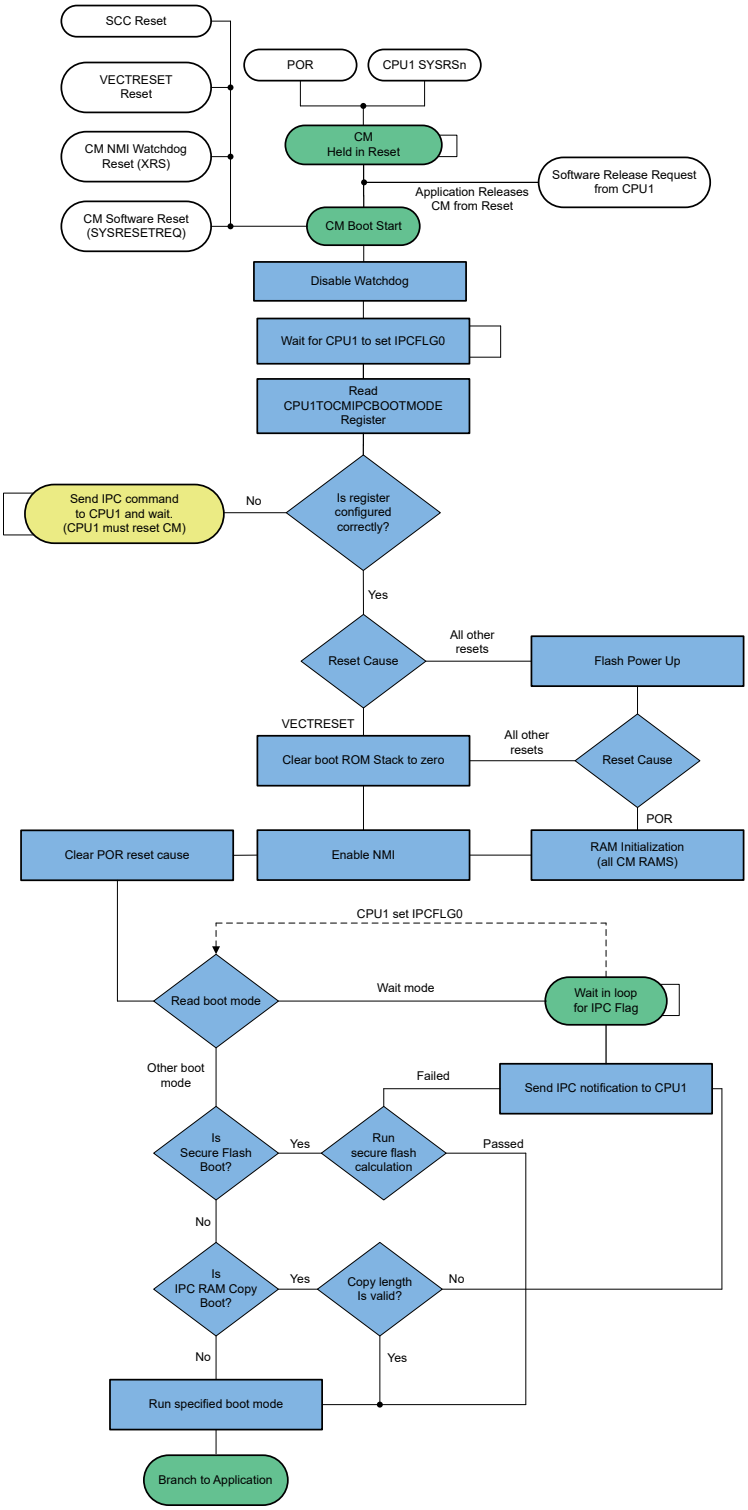

Figure 5-5. CM Boot Flow

5.6 Device Reset and Exception Handling

5.6.1 Reset Causes and Handling

Table 5-15 explains the actions each boot ROM performs upon reset for a specific reset cause.

Table 5-15. Boot ROM Reset Causes and Actions

Reset Source	CPU1 Boot ROM Action	CPU2 Boot ROM Action	CM Boot ROM Action
Power on Reset (POR)	1. Configure Clock Divider 2. Flash Power Up 3. Device configuration and trimming 4. RAM Initialization 5. Continue default boot flow	1. Flash Power Up 2. RAM Initialization 3. Continue default boot flow	1. Flash Power Up 2. RAM Initialization 3. Continue default boot flow
External Reset (XRS) For CPU1, XRS triggers include: • Watchdog Reset • NMI Watchdog Reset • EtherCAT Reset • SIMRESET XRS	1. Configure Clock Divider 2. Flash Power Up 3. Device configuration and trimming 4. Clear RAM for boot stack 5. Continue default boot flow	1. Flash Power Up 2. Clear RAM for boot stack 3. Continue default boot flow	1. Flash Power Up 2. Clear RAM for boot stack 3. Continue default boot flow
Hardware Built-In Self Test (HWBIST)	1. Read HWBIST return address 2. If set, branch to address 3. If not set, continue boot following "Debugger Reset" boot flow actions	1. Read HWBIST return address 2. If set, branch to address 3. If not set, continue boot following "Debugger Reset" boot flow actions	Not Applicable
Secure Copy Code (SCC) Reset (CPU1, CPU2) Watchdog Reset (CPU2) NMI Watchdog Reset (CPU2) Execute Override Logic (EOL) Reset (CM)	1. Clear RAM for boot stack 2. Continue default boot flow	1. Clear RAM for boot stack 2. Continue default boot flow	1. Flash Power Up 2. Clear RAM for boot stack 3. Continue default boot flow
SIMRESET_CPU1	1. Clear RAM for boot stack 2. Continue default boot flow	Not Applicable	Not Applicable
Debugger Reset (CPU1, CPU2) VECTRESET (CM)	1. Clear RAM for boot stack 2. Continue default boot flow	1. Clear RAM for boot stack 2. Continue default boot flow	1. Clear RAM for boot stack 2. Continue default boot flow

5.6.2 Exceptions and Interrupts Handling

Table 5-16 explains the actions each boot ROM performs if any exceptions that can occur happen during boot. The exception handling philosophy for CPU1, in most cases, is to log the error and continue booting to reach the application. The exception handling philosophy for CPU2 and CM is to log the error, notify CPU1, and let CPU1 handle the action.

For any CPU2 NMI event sources, CPU2 NMI handler will clear the NMI flag to stop the NMI watchdog counter and prevent CPU2 from resetting. The error pin will go low or high (depending on the polarity configuration on the error pin and the reset type) temporarily before the NMI flag is cleared. Therefore, a shorter pulse width of the error pin signal means CPU2 (or CM) is the source of the error. Following this, CPU2 sends an error IPC message to CPU1 in order for CPU1 to handle the error and reset CPU2.

For any CM NMI event sources, the CM NMI handler will clear the NMI flag to stop the NMI watchdog counter and prevent CM from resetting. The error pin will go low or high (depending on the polarity configuration on the error pin and the reset type) temporarily before the NMI flag is cleared. Therefore, a shorter pulse width of the error pin signal means CM (or CPU2) is the source of the error. Following this, the CM sends an error IPC message to CPU1 in order for CPU1 to handle the error and reset CM.

Table 5-16. Boot ROM Exceptions and Actions

Exception Event Source	CPU1 Boot ROM Action	CPU2 Boot ROM Action	CM Boot ROM Action	Event Logged
Single-bit error in FUSEERR	Ignore and continue to boot	No action	No action	No
Multi-bit error in FUSEERR	Reset the device	No action	No action	No
Clock Fail	Clear the NMI flag and continue to boot	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
RAM Uncorrectable Error ROM Parity Error	Perform RAM initialization and reset the device	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes(1)
Flash Uncorrectable Error	Reset the device	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
HWBIST Error	Clear the NMI flag and continue to boot	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	No action	Yes
PIE Vector Mismatch(2)	Fetch error handler address, if address is configured, call handler, else reset the device	Fetch error handler address, if address is configured, call handler, else clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	No action	Yes
Embedded Real-time Analysis and Diagnostic (ERAD) NMI	Clear the NMI flag and continue to boot	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	No action	Yes
MCAN Uncorrectable Error	Clear the NMI flag and continue to boot	No action	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
EtherCAT NMI	Clear the NMI flag and continue to boot	No action	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
ITRAP Exception	Record memory address of where the illegal instruction was executed and let device reset	Send IPC to CPU1 with memory address of the illegal instruction and wait in loop	No action	Yes
Invalid IPCBOOTMODE Value upon Reset	No action	Send IPC to CPU1 and wait in loop	Send IPC to CPU1 and wait in loop	Yes
Secure Flash Boot Failure	Enable watchdog and let device reset	Send IPC to CPU1 and return to wait boot mode	Send IPC to CPU1 and return to wait boot mode	Yes
Hard Fault Exception	No action	No action	Update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
Any Unsupported Interrupt	Ignore and continue to boot	Ignore and continue to boot	Update boot status to CPU1, send error IPC to CPU1 with the interrupt exception number, and wait in loop	Yes (CM Only)

(1) For CPU1, a RAM uncorrectable error or ROM parity error will clear the boot status information stored in RAM because a RAM initialization is performed to attempt to correct the error. Since the boot status information is erased, this exception can be identified in that a NMIWD reset occurred and all the RAMs are erased.
(2) A PIE vector mismatch in one core (such as CPU1 or CPU2) will trigger the PIE vector mismatch interrupt in other cores.

5.7 Boot ROM Description

This section explains the details regarding the device boot ROMs.

5.7.1 CPU1 Boot ROM Configuration Registers

CPU1 boot ROM code involves several memory addresses and registers used during execution. There are two sets of configurations; one for emulation and one for standalone boot flow. The emulation locations located in RAM emulate the OTP configurations and can be written to as many times as needed. The user configurable DCSM OTP locations used in the standalone boot flow program the device OTP and hence can only be written once. For bit field configuration details for BOOTPIN-CONFIG and BOOTDEF, see Section 5.4.1 and Section 5.4.2.

Additionally, the CPU1 boot ROM supports boot configurations from DCSM zone 1 and zone 2 registers. Zone 2 configurations will supercede zone 1 configurations, so it is recommended to use zone 1 configurations and use zone 2 as a secondary option.

Note

All boot configurations for CPU2 and CM are set through CPU1TOCPU2IPCBOOTMODE and CPU1TOCMIPCBOOTMODE registers. See more details in Section 5.7.2.

Table 5-17. CPU1 Boot ROM Registers

Boot Flow	Register Name	Boot ROM Name	Register Address	User OTP Address
Emulation	-	EMUBOOTPINCONFIG	0x0000 0D00	-
	-	EMUBOOTDEF-LOW	0x0000 0D04	-
	-	EMUBOOTDEF-HIGH	0x0000 0D06	-
Standalone (Using Z1)	Z1-GPREG1	Z1-BOOTPINCONFIG	0x0005 F008	0x0007 8008
	Z1-GPREG2	Z1-BOOT-GPREG2	0x0005 F00A	0x0007 800A
	Z1-GPREG3	Z1-BOOTDEF-LOW	0x0005 F00C	0x0007 800C
	Z1-GPREG4	Z1-BOOTDEF-HIGH	0x0005 F00E	0x0007 800E
Standalone (Using Z2)	Z2-GPREG1	Z2-BOOTPINCONFIG	0x0005 F088	0x0007 8208
	Z2-GPREG2	Z2-BOOT-GPREG2	0x0005 F08A	0x0007 820A
	Z2-GPREG3	Z2-BOOTDEF-LOW	0x0005 F08C	0x0007 820C
	Z2-GPREG4	Z2-BOOTDEF-HIGH	0x0005 F08E	0x0007 820E

5.7.1.1 GPREG2 Usage and MPOST Configuration

Table 5-18 explains how the bit field values from the user configurable DCSM OTP location, Z1-BOOT-GPREG2 or Z2-BOOT-GPREG2, are decoded by CPU1 boot ROM. For more information, see *C2000™ Memory Power-On Self-Test (M-POST)* .

Table 5-18. CPU1 DCSM Z1/Z2 GPREG2 Bit Fields

Bit	Name	Description	Boot ROM Action
31:24	Key	Write 0x5A to these 8 bits to indicate to the boot ROM code that the bits in this register are valid	If set to 0x5A, boot ROM uses the values in this register. If set to any other value, boot ROM ignores values in this register.
23:8	Reserved	Reserved	No Action
7:4	Run MPOST(1) (2)	When configured to a valid value, MPOST (Memory Power on Self-Test) is run on all device memories	0x0 = MPOST is run with PLL enabled for high speed (110 MHz). 0xC = MPOST is run with PLL enabled for medium speed (80 MHz). 0x3 = MPOST is run with PLL enabled for low speed (60 MHz). 0x9 = MPOST is run using INTOSC2 with PLL disabled (10 MHz). Any other value = MPOST does not run.
3:0	Reserved	Reserved	No Action

(1) If MPOST is configured to run with PLL enabled and the PLL fails to lock, then the MPOST run is skipped. This does not apply if MPOST is configured to use INTOSC2 with PLL disabled.

(2) Note that EtherCAT gets de-asserted and released from reset using the EtherCATs peripheral software reset register during MPOST. The EtherCAT state is not restored back into the reset state.

5.7.2 Booting CPU2 and CM

This section details the boot up flow for CPU2 and CM. This includes the process, how to configure IPCBOOTMODE, and the error IPC commands that CPU2/CM report to CPU1.

5.7.2.1 Boot Up Procedure

The boot configurations for CPU2 and CM are set by the CPU1 application. The CPU1 application configures the clocks for CPU2/CM, sets the boot mode and other parameters in the IPCBOOTMODE register, and releases CPU2/CM from reset to boot.

CPU2 and CM have two states where CPU1 can configure their boot mode. The first state occurs before CPU2/CM boot and when they are still in reset. The second state occurs after CPU2/CM have been released from reset to wait boot mode where the cores wait for an IPC flag to be set by CPU1 to indicate that a boot mode has been set in the IPCBOOTMODE register. The procedures that CPU1 must follow are detailed in Table 5-19 and Table 5-20.

Note

Regardless of reset source, CPU2 and CM each require their respective IPCFLG0 to be set by CPU1 on **every reset** in order to confirm the contents of IPCBOOTMODE are valid and continue their boot process.

Table 5-19. CPU2 Boot Procedure

CPU2 State	CPU1 Application Actions
Held in Reset	1. Configures CPU2 clocks 2. Configures the CPU1TOCPU2IPCBOOTMODE register (Refer to Section 5.7.2.2 for configuration details) 3. Sets CPU1TOCPU2IPCFLG0(1) 4. Releases CPU2 from being held in reset
In Wait Boot Mode waiting for the IPC Flag	1. Configures the CPU1TOCPU2IPCBOOTMODE register (Refer to Section 5.7.2.2 for configuration details) 2. Sets CPU1TOCPU2IPCFLG0(1)

(1) CPU2 will ACK and clear this IPC flag during boot up.

Table 5-20. CM Boot Procedure

CM State	CPU1 Application Actions
Held in Reset	1. Configures CM clocks 2. Configures the CPU1TOCMIPCBOOTMODE register (Refer to Section 5.7.2.2 for configuration details) 3. Sets CPU1TOCMIPCFLG0(1) 4. Releases CM from being held in reset
In Wait Boot Mode waiting for IPC Flag	1. Configures the CPU1TOCMIPCBOOTMODE register (Refer to Section 5.7.2.2 for configuration details) 2. Sets CPU1TOCMIPCFLG0(1)

(1) CM will ACK and clear this IPC flag during boot up.

5.7.2.2 IPCBOOTMODE Details

This section details the CPU1TOCPU2IPCBOOTMODE and CPU1TOCMIPCBOOTMODE register bit-field configurations and requirements for booting CPU2/CM.

Note

If any of the bit-fields of CPU1TOCPU2IPCBOOTMODE or CPU1TOCMIPCBOOTMODE registers are set with invalid values, an error IPC command is sent to CPU1. CPU2/CM then enter a wait loop where CPU2/CM wait for CPU1 to re-configure the IPCBOOTMODE register correctly and issue a reset to the respective core.

Table 5-21. CPU1TOCPU2IPCBOOTMODE Register Details

Bit	Name	Valid Values	Description
31:24	Key	0x5A	Key must be set for this register to be considered valid.
23:20	Reserved	-	Reserved
19:16	IPC Message RAM Copy Length	0x0 = 0 words (Boot mode not used) 0x1 = 100 words 0x2 = 200 words ... 0x9 = 900 words 0xA = 1000 words(1)	Sets the data length (in words) for the "Copy from IPC Message RAM and Boot to M1RAM" boot mode. This is the number words to be copied from CPU1TOCPU2MSGRAM1 to CPU2 M1RAM. If not using this boot mode, set value to 0x0.
15:8	CPU2 Device Frequency	0xA = 10 MHz(2) 0xB = 11 MHz ... 0xC8 = 200 MHz(2)	Sets the clock frequency (in MHz) that CPU2 is configured at.
7:0	CPU2 Boot Mode	0x0 = None/Wait Boot 0x03 = Flash Boot Option 0 (Sector 0) 0x23 = Flash Boot Option 1 (Sector 4) 0x43 = Flash Boot Option 2 (Sector 8) 0x63 = Flash Boot Option 3 (Sector 13) 0x0A = Secure Flash Boot Option 0 (Sector 0) 0x2A = Secure Flash Boot Option 1 (Sector 4) 0x4A = Secure Flash Boot Option 2 (Sector 8) 0x6A = Secure Flash Boot Option 3 (Sector 13) 0x0C = IPC Message RAM copy and boot to M1RAM 0x05 = Boot to M0RAM 0x0B = Boot to User OTP	Sets the boot mode for CPU2

(1) Values greater than 0xA are invalid.
(2) Values less than 0xA (10 MHz) or greater than 0xC8 (200 MHz) are invalid.

Table 5-22. CPU1TOCMIPCBOOTMODE Register Details

Bit	Name	Valid Values	Description
31:24	Key	0x5A	Key must be set for this register to be considered valid.
23:20	Reserved	-	Reserved
19:16	IPC Message RAM Copy Length	0x0 = 0 words / 0 bytes (Boot mode not used) 0x1 = 100 words / 200 bytes 0x2 = 200 words / 400 bytes ... 0x9 = 900 words / 1800 bytes 0xA = 1000 words / 2000 bytes(1)	Sets the data length (in words) for the "Copy from IPC Message RAM and Boot to S0RAM" boot mode. This is the number words to be copied from CPU1TOCMMSGRAM1 to CM S0RAM. If not using this boot mode, set value to 0x0.
15:8	CM Device Frequency	0xA = 10 MHz(2) 0xB = 11 MHz ... 0x7D = 125 MHz(2)	Sets the clock frequency (in MHz) that CM is configured at.
7:0	CM Boot Mode	0x0 = None/Wait Boot 0x03 = Flash Boot Option 0 (Sector 0) 0x23 = Flash Boot Option 1 (Sector 4) 0x43 = Flash Boot Option 2 (Sector 8) 0x63 = Flash Boot Option 3 (Sector 13) 0x0A = Secure Flash Boot Option 0 (Sector 0) 0x2A = Secure Flash Boot Option 1 (Sector 4) 0x4A = Secure Flash Boot Option 2 (Sector 8) 0x6A = Secure Flash Boot Option 3 (Sector 13) 0x0C = IPC Message RAM copy and boot to S0RAM 0x05 = Boot to S0RAM 0x0B = Boot to User OTP	Sets the boot mode for CM

(1) Values greater than 0xA are invalid.
(2) Values less than 0xA (10 MHz) or greater than 0x7D (125 MHz) are invalid.

5.7.2.3 Error IPC Command Table

This section details the IPC commands that CPU2 or CM can send to CPU1 to notify CPU1 regarding an error that occurred.

Note

After CPU2 or CM sends the error IPC command to CPU1, CPU2/CM will set CPU2TOCPU1IPCFLG0/CMTOCPU1IPCFLG0.

Table 5-23. CPU2 to CPU1 Error IPC Commands

Description	IPCSENDCOM Value	IPCSENDADDR Value
No Command	0x0000 0000	Not Used
IPCBOOTMODE Value(s) Incorrect	0xFFFF FFFF	Not Used
CPU2 in ITRAP	0xFFFF FFFE	If RAM is accessible, the address for the source of the ITRAP will be provided
CPU2 got NMI	0xFFFF FFFA	Not Used
CPU2 Secure Flash CMAC Calculation Failed	0xFFFF FFF9	Not Used

Table 5-24. CM to CPU1 Error IPC Commands

Description	IPCSENDCOM Value	IPCSENDADDR Value
No Command	0x0000 0000	Not Used
IPCBOOTMODE Value(s) Incorrect	0xFFFF FFFF	Not Used
CM got Hard Fault Exception	0xFFFF FFFE	Not Used
CM got Unsupported Interrupt	0xFFFF FFFB	Active Exception Number
CM got NMI	0xFFFF FFFA	Not Used
CM Secure Flash CMAC Calculation Failed	0xFFFF FFF9	Not Used

5.7.3 Entry Points

This section gives details about the entry point addresses for various boot modes. These entry points direct the boot ROM what address to branch to at the end of booting as per the selected boot mode.

Table 5-25. Entry Point Addresses for CPU1

Entry Point	Details	Address
Flash / Secure Flash (Option 0)	Flash Sector 0	0x0008 0000
Flash / Secure Flash (Option 1)	Flash Sector 4	0x0008 8000
Flash / Secure Flash (Option 2)	Flash Sector 8	0x000A 8000
Flash / Secure Flash (Option 3)	Flash Sector 13	0x000B E000
RAM	M0RAM	0x0000 0000

Table 5-26. Entry Point Addresses for CPU2

Entry Point	Details	Address
Flash / Secure Flash (Option 0)	Flash Sector 0	0x0008 0000
Flash / Secure Flash (Option 1)	Flash Sector 4	0x0008 8000
Flash / Secure Flash (Option 2)	Flash Sector 8	0x000A 8000
Flash / Secure Flash (Option 3)	Flash Sector 13	0x000B E000
RAM	M0RAM	0x0000 0000
CPU1 IPC Message RAM Copy to CPU2 RAM	M1RAM	0x0000 0400
User OTP	CPU2 User OTP	0x0007 8000

Table 5-27. Entry Point Addresses for CM

Entry Point	Details	Address
Flash / Secure Flash (Option 0)	Flash Sector 0	0x0020 0000
Flash / Secure Flash (Option 1)	Flash Sector 4	0x0021 0000
Flash / Secure Flash (Option 2)	Flash Sector 8	0x0025 0000
Flash / Secure Flash (Option 3)	Flash Sector 13	0x0027 C000
RAM	S0RAM	0x2000 0800
CPU1 IPC Message RAM Copy to CM RAM	S0RAM	0x2000 0800
User OTP	CM User OTP	0x003C 0000

5.7.4 Wait Points

During boot ROM execution, there are situations where the CPU may enter a wait loop in the code. This state can occur for a variety of reasons. Table 5-28, Table 5-29, and Table 5-30 detail the address ranges that the CPU PC register for each core will fall between if boot has entered one of these instances.

Table 5-28. Wait Point Addresses for CPU1

Silicon Rev0 Address Range	Silicon RevA Address Range	Description
0x3FB100 – 0x3FB106	0x3FB112 – 0x3FB117	In Wait Boot Mode
0x3FBEE2 – 0x3FBF09	0x3FBEEB – 0x3FBF12	In SCI Boot waiting on autobaud lock
0x3FE839 – 0x3FE92D	0x3FE839 – 0x3FE92D	In NMI Handler
0x3FE7F1 – 0x3FE823	0x3FE7F1 – 0x3FE823	In PIE Vector Mismatch Handler
0x3FE944 – 0x3FE970	0x3FE944 – 0x3FE970	In ITRAP ISR
0x3FB12A – 0x3FB12E	0x3FB13C – 0x3FB142	Failed secure Flash CMAC verification loop

Table 5-29. Wait Point Addresses for CPU2

Silicon Rev0,A Address Range	Description
0x3FB41D – 0x3FB42B	In Wait Boot Mode waiting for boot command
0x3FB459 – 0x3FB503	In NMI Handler
0x3FB504 – 0x3FB559	In ITRAP ISR
0x3FB173 – 0x3FB1B7	In loop due to invalid CPU1TOCPU2IPCBOOTMODE value(s) and/or CPU1TOCPU2IPCFLG0 is not set

Table 5-30. Wait Point Addresses for CM

Silicon Rev0,A Address Range	Description
0x180C – 0x1818	In Wait Boot Mode waiting for boot command
0x4018 – 0x41C2	In NMI Handler
0x41C4 – 0x41E8	In Hard Fault Handler
0x41EA – 0x421A	In Default Interrupt Handler
0x1618 – 0x16C4	In loop due to invalid CPU1TOCMIPCBOOTMODE value(s) and/or CPU1TOCMIPCFLG0 is not set

5.7.5 Memory Maps

This section details the ROM memory maps.

5.7.5.1 Boot ROM Memory Maps

Table 5-31. CPU1 Boot ROM Memory Map

Memory	Origin Address	Length (Words)
ROM Signature	0x003E 8000	0x0002
AES Tables	0x003E 8002	0x1400

Data (Run)	0x0000 F870	0x078A
Version (Run)	0x0000 FFFA	0x0006

Table 5-35. CPU2 CLA Data ROM Memory Map

Memory	Origin Address	Length (Words)
FFT Tables (Load)	0x0100 1070	0x0800
Data (Load)	0x0100 1870	0x078A
Version (Load)	0x0100 1FFA	0x0006
FFT Tables (Run)	0x0000 F070	0x0800
Data (Run)	0x0000 F870	0x078A
Version (Run)	0x0000 FFFA	0x0006

5.7.5.3 Reserved RAM Memory Maps

This section details memory usage in RAM that is reserved for boot ROM to use. These memory sections must be reserved in the user application.

Table 5-36. CPU1 Reserved RAM Memory Map

Memory	Description	Origin Address	End Address	Length (Words)
RAM	Boot Status, Boot Mode, MPOST Status, Boot Stack	0x0000 0002	0x0000 01B0	0x01AF

Table 5-37. CPU2 Reserved RAM Memory Map

Memory	Description	Origin Address	End Address	Length (Words)
RAM	Boot Status, Boot Mode, Boot Stack	0x0000 0002	0x0000 01A8	0x01A7

Table 5-38. CM Reserved RAM Memory Map

Memory	Description	Origin Address	End Address	Length (Bytes)
RAM	Boot Status, Boot Mode, Boot Stack	0x2000 0000	0x2000 07FF	0x0800

5.7.6 ROM Tables

Table 5-39 details the boot ROM and CLA ROM symbol libraries that can be integrated into an application to use the available ROM functions and tables.

Table 5-39. ROM Symbol Tables

ROM Symbols	Library Name	Location
ROM Bootloaders and Functions	F2838xCPU1_BootROM_Symbols	Under */libraries/boot_rom* in C2000Ware
FPU32 and FPU64 Tables	F2838xCPU1_BootROM_Symbols F2838xCPU2_BootROM_Symbols	
AES Tables	F2838xCPU1_BootROM_Symbols F2838xCPU2_BootROM_Symbols	
CLA Data ROM	F2838xCPU1_CLADATAROM_Symbols F2838xCPU2_CLADATAROM_Symbols	
IQmath	F2838xCPU1_IQMathROM_Symbols F2838xCPU2_IQMathROM_Symbols	
Secure Zone Functions	F2838xCPU1_SecureZoneCode_Symbols F2838xCPU2_SecureZoneCode_Symbols F2838xCM_SecureZoneCode_Symbols	

5.7.7 Boot Modes and Loaders

The available boot modes and bootloaders supported on this device are detailed in this section.

5.7.7.1 Boot Modes

Table 5-40 details the available boot modes that do not involve a peripheral boot loader.

Table 5-40. Boot Mode Availability

Boot Mode	CPU Support
Wait Boot	CPU1, CPU2, CM
Flash Boot	CPU1, CPU2, CM
Secure Flash Boot	CPU1, CPU2, CM
RAM Boot	CPU1, CPU2, CM
User OTP Boot	CPU2, CM
IPC Message Copy to RAM Boot	CPU2, CM

5.7.7.1.1 Wait Boot

The wait boot mode puts the CPU in a loop and does not branch to the user application code. The device can either enter wait boot mode through configuration or because an error occurred during boot up. TI recommends using wait boot when using a debugger to avoid any JTAG complications. CPU2 and CM can exit wait boot mode and run a different boot mode when CPU1 sets the respective CPU IPCFLG0. More information regarding this can found at Section 5.7.2.

Table 5-41. Reasons for Entering Wait Boot

CPU	Actions Resulting in Wait Boot
CPU1	• Wait boot is selected by user configuration • Decoded boot mode is unrecognized/invalid when a debugger is connected to the device • The emulation BOOTPIN_CONFIG key is not set to 0xA5 or 0x5A
CPU2	• Wait boot is selected by user configuration • Decoded boot mode is unrecognized/invalid when a debugger is connected to the device • Secure Flash boot CMAC calculation returns failure • IPC Message copy to RAM length specified is invalid (out of range) when trying to use this boot mode
CM	• Wait boot is selected by user configuration • Decoded boot mode is unrecognized/invalid when a debugger is connected to the device • Secure Flash boot CMAC calculation returns failure • IPC Message copy to RAM length specified is invalid (out of range) when trying to use this boot mode

5.7.7.1.2 Flash Boot

Flash boot mode branches to the configured memory address in Flash. Refer to Section 5.7.3 for all the available Flash address options.

For CPU1, on an unprogrammed device, Flash boot can be switched to USB boot. See more details in Section 5.3.

5.7.7.1.3 Secure Flash Boot

Secure Flash boot mode is similar to Flash boot mode in that the boot flow branches to the configured memory address in Flash except only after the Flash memory contents have been authenticated. The Flash authentication uses a Cipher-based Message Authentication Protocol (CMAC) to authenticate 16-KB of Flash starting from the configured Flash entry point address. The CMAC calculation requires a user-defined 128-bit key programmed in the CPU1 User OTP Zone 1 Header OTP CMACKEY bit field. Additionally, the user must calculate the golden CMAC tag based on the 16-KB Flash memory range and store it along with the user code at a hardcoded address in Flash. During secure Flash boot, the calculated CMAC tag is compared to the user golden CMAC tag in Flash to determine the pass/fail status of the CMAC authentication. When authentication passes, boot flow continues and branches to Flash to begin executing the application. When authentication fails, the boot flow actions performed vary by core. Refer to Table 5-43 for details on failure actions for each core.

For the available secure Flash boot entry address options, refer to Section 5.7.3.

For generating the secure Flash golden CMAC tag for CPU1 or CPU2, refer to the section “Using Secure Flash Boot on TMS320F2838x Devices” in the *TMS320C28x Assembly Language Tools User’s Guide* for instructions.

For generating the secure Flash golden CMAC tag for CM, refer to the ARM Assembly Language Tools v19.6.0.STS, within section “Using Secure Flash Boot on TMS320F2838x Devices” for instructions.

Note

- User must make sure that the Flash sector that encompasses the configured Flash entry point and the first 16KB of Flash is assigned to Zone 1 for any cores setup to use secure Flash boot.
- Recommended to use device JTAGLOCK when using secure Flash boot.
- If only using secure Flash boot for CPU2/CM, then the CPU1 application must first dummy load the Z1 OTP CMACKEY before releasing CPU2/CM from reset. When dummy loading, CPU1 application must first disable Flash data caching, then perform the dummy load, and then the application can re-enable Flash data caching.

Table 5-42. Secure Flash Tag and Key Details

Name	Address	Details
CMAC Golden Tag (128-bit)	**CPU1/CPU2:** *Flash Entry Point Address* + 0x2 **CM:** *Flash Entry Point Address* + 0x4	Located in Flash, offset from the entry point address, by 2 words (CPU1/CPU2) or 4 bytes (CM). When CMAC calculations are performed, the golden tag location in memory is considered all 0xFs. Refer to Example 5-1 for an example regarding linker configuration on CPU1. Lower memory contains the tag's MSW and higher memory contains the LSW **Example (on CPU1):** Tag = 0x00112233 44556677 8899AABB CCDDEEFF Address 0x0 = 0x00112233 Address 0x2 = 0x44556677 Address 0x4 = 0x8899AABB Address 0x6 = 0xCCDDEEFF

Table 5-42. Secure Flash Tag and Key Details (continued)

Name	Address	Details
CMAC 128-Bit Key	0x0007 8018	Located in CPU1 Zone 1 User Header OTP (CMACKEY0, CMACKEY1, CMACKEY2, CMACKEY3) CMACKEY0 contains the key's MSW and CMACKEY3 contains the LSW **Example:** Key = 0x00112233 44556677 8899AABB CCDDEEFF CMACKEY0 = 0x00112233 CMACKEY1 = 0x44556677 CMACKEY2 = 0x8899AABB CMACKEY3 = 0xCCDDEEFF

Table 5-43. Secure Flash Authentication Failure Actions

CPU	Action on Failed Authentication
CPU1	Reset the device (If using debugger, device halts)
CPU2	Send IPC message to CPU1, update CPU2 boot status to indicate failure, and return to wait boot
CM	Send IPC message to CPU1, update CM boot status to indicate failure, and return to wait boot

Table 5-44. Secure Flash on all CPUs Recommended Flow

Step	Action
1	Secure Flash boot CPU1
2	CPU1 application configures CPU2 and CM to boot using *Secure Flash Boot* and releases CPU2/CM from reset
3	CPU2 and CM perform secure Flash boot
4	CPU2 and CM applications signal to CPU1 using IPC that booting is complete
5	For CPU1/CPU2/CM, any Flash beyond the first 16KB from the entry point that is planned for use must be authenticated by the user using a different CMAC golden tag embedded at an address somewhere within the already authenticated 16KB of Flash

Example 5-1. Secure Flash CPU1 Linker File Example

```
MEMORY
{
/* Code Start branch to _c_int00 */
BEGIN : origin = 0x80000, length = 0x0002
/* User calculated golden CMAC tag for Flash Sector 0 */
GOLDEN_CMAC_TAG : origin = 0x80002, length = 0x0008
/* Flash Sector 0 containing application code */
FLASH_SECTOR_0 : origin = 0x8000A, length = 0x1FF6
.
.
.
}
```

5.7.7.1.4 RAM Boot

RAM boot mode branches to the configured memory address in RAM. Refer to Section 5.7.3 for all the available RAM address options.

5.7.7.1.5 User OTP Boot

User OTP boot mode branches to the configured memory address in User OTP. Refer to Section 5.7.3 for all the available user OTP address options.

5.7.7.1.6 IPC Message Copy to RAM Boot

IPC message copy to RAM involves copying application code from CPU1 IPC message RAM 1 to CPU2/CM destination RAM for execution. The maximum copy length size is 1000 words (2000 bytes) and the minimum is 100 words (200 bytes). Refer to Table 5-45 for details regarding configuration and execution flow of this boot mode.

Table 5-45. IPC Message Copy Steps

Step	Action
1	CPU1 application links CPU2/CM code to copy in either CPU1TOCPU2MSGRAM1 or CPU1TOCMMSGRAM1.
2	CPU1 application configures CPU2/CM IPCBOOTMODE with the copy length and IPC message copy as the boot mode. See Section 5.7.2.2 for more IPCBOOTMODE details.
3	Once CPU2/CM is released from reset to boot, CPU2/CM begins copying from CPU1TOCPU2MSGRAM1/ CPU1TOCMMSGRAM1 to their destination RAM. Refer to Table 5-46 for destination RAM details.
4	Once the copying is complete, CPU2/CM boot branches to the entry address of the destination RAM and begins executing the application.

Table 5-46. IPC Message Copy Destination Address

CPU	RAM	Destination Address Range(1) (For maximum copy length of 1000 words)
CPU2	M1RAM	0x0000 0400 to 0x0000 07E6
CM	S0RAM	0x2000 0800 to 0x2000 0FCC

(1) This memory must be allocated and reserved in the CPU2/CM application linker command file when using this boot mode.

5.7.7.2 Bootloaders

This section details the available boot modes that use a peripheral boot loader. For more specific details on the supported data stream structure used by the following bootloaders, refer to Section 5.8.1.

Note

These are only available on CPU1.

5.7.7.2.1 SCI Boot Mode

The SCI boot mode asynchronously transfers code from SCI-A to internal memory. This boot mode only supports an incoming 8-bit data stream and follows the data flow as outlined in Example 5-2.

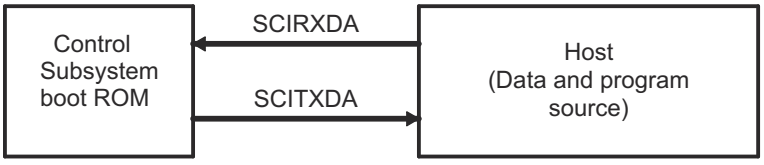

Figure 5-6. Overview of SCI Bootloader Operation

The device communicates with the external host by communication through the SCI-A peripheral. The autobaud feature of the SCI port is used to lock baud rates with the host. For this reason the SCI loader is very flexible and you can use a number of different baud rates to communicate with the device.

After each data transfer, the bootloader echoes back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications can work well, this slew rate can limit reliable auto-baud detection at higher baud rates (typically beyond 100 kbaud) and cause the auto-baud lock feature to fail. To avoid this, the following is recommended:

1. Achieve a baud-lock between the host and SCI bootloader using a lower baud rate.
2. Load the incoming application or custom loader at this lower baud rate.
3. The host can then handshake with the loaded application to set the SCI baud rate register to the desired high baud rate.

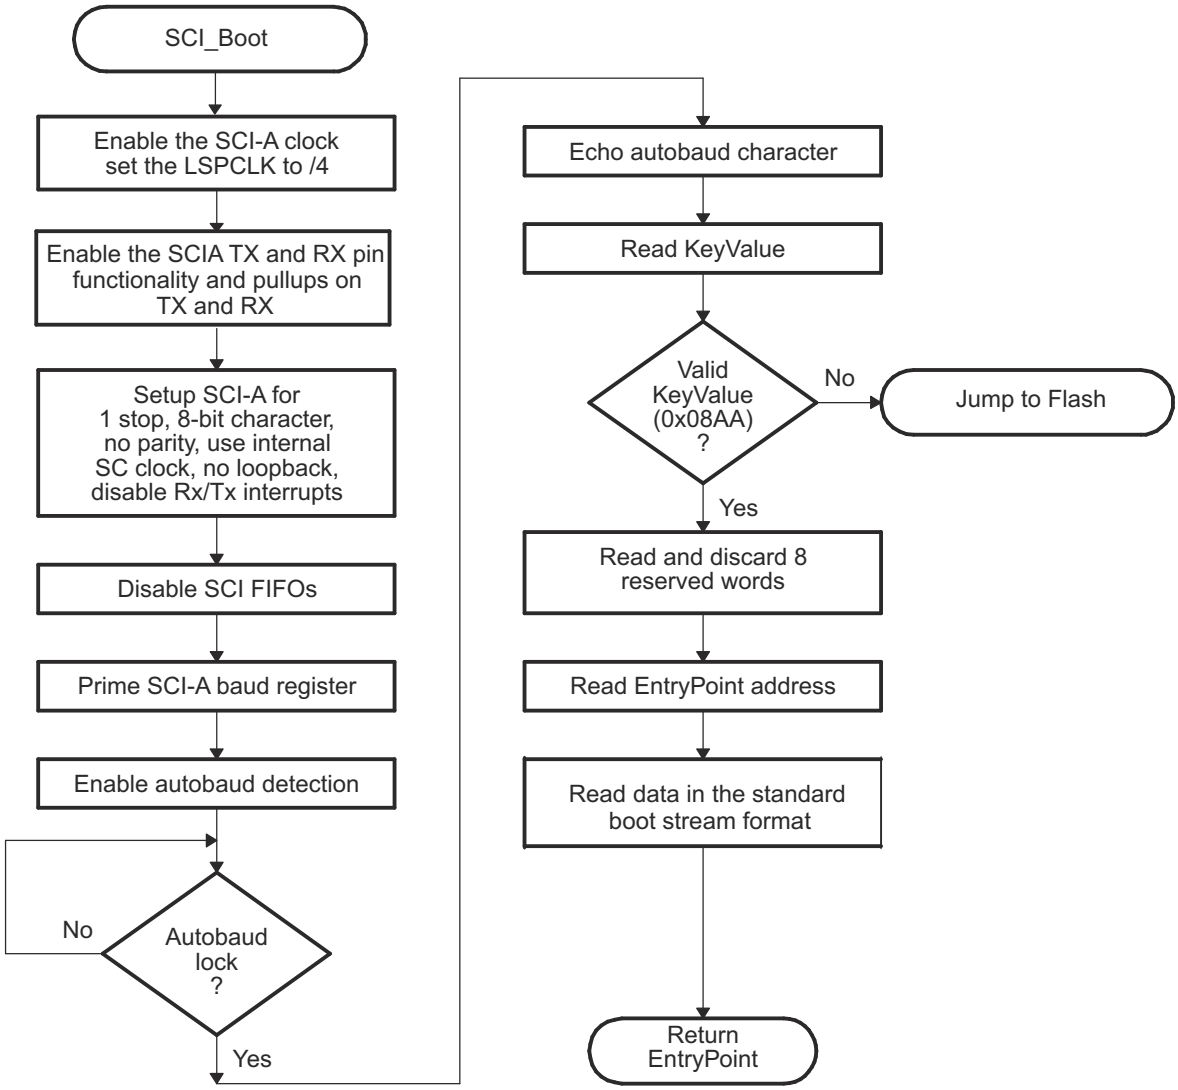

Figure 5-7. Overview of SCI Boot Function

5.7.7.2.2 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial Flash device to be present on the SPI-A pins as indicated in Figure 5-8. The SPI bootloader supports an 8-bit data stream and does not support a 16-bit data stream.

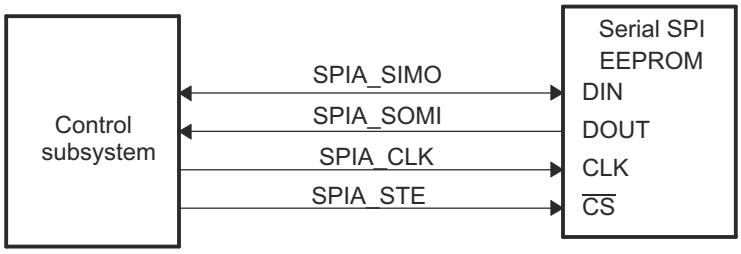

Figure 5-8. SPI Loader

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or Flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial Flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character, internal SPICLK master mode and talk mode, clock phase = 1, polarity = 0, using the slowest baud rate.

If the download is to be performed from an SPI port on another device, then that device must be set up to operate in the slave mode and mimic a serial SPI EEPROM. Immediately after entering the SPI_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized. The initialization is done at the slowest speed possible. Once the SPI is initialized and the key value read, specify a change in baud rate or low-speed peripheral clock.

Table 5-47. SPI 8-Bit Data Stream

Byte	Contents
1	LSB: AA (KeyValue for memory width = 8-bits)
2	MSB: 08h (KeyValue for memory width = 8-bits)
3	LSB: LOSPCP
4	MSB: SPIBRR
5	LSB: reserved for future use
6	MSB: reserved for future use
...	...
...	Reserved
	...
17	LSB: reserved for future use
18	MSB: reserved for future use
19	LSB: Upper half (MSW) of Entry point PC[23:16]
20	MSB: Upper half (MSW) of Entry point PC[31:24] (Note: Always 0x00)
21	LSB: Lower half (LSW) of Entry point PC[7:0]
22	MSB: Lower half (LSW) of Entry point PC[15:8]
...	....
...	Data for this section.
	...
...	Blocks of data in the format size/destination address/data as shown in the generic data stream description
...	...
...	Data for this section.
	...
n	LSB: 00h
n+1	MSB: 00h - indicates the end of the source

The data transfer is done in "burst" mode from the serial SPI EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence follows:

1. The SPI-A port is initialized.
2. The GPIO pin, as defined by SPI option configured from Table 5-61, is used as a chip-select for the serial SPI EEPROM or Flash.
3. The SPI-A outputs a read command for the serial SPI EEPROM or Flash.
4. The SPI-A sends the serial SPI EEPROM an address 0x0000; that is, the host requires that the EEPROM or Flash must have the downloadable packet starting at address 0x0000 in the EEPROM or Flash. The loader is compatible with both 16-bit addresses and 24-bit addresses.
5. The next word fetched must match the key value for an 8-bit data stream (0x08AA). The least significant byte of this word is the byte read first and the most significant byte is the next byte fetched. This is true of all word transfers on the SPI. If the key value does not match, then the load is aborted and the bootloader jumps to Flash.
6. The next two bytes fetched can be used to change the value of the low speed peripheral clock register (LOSPCP) and the SPI baud rate register (SPIBRR). The first byte read is the LOSPCP value and the second byte read is the SPIBRR value. The next seven words are reserved for future enhancements. The SPI bootloader reads these seven words and discards them.
7. The next two words makeup the 32-bit entry point address where execution continues after the boot load process is complete. This is typically the entry point for the program being downloaded through the SPI port.
8. Multiple blocks of code and data are then copied into memory from the external serial SPI EEPROM through the SPI port. The blocks of code are organized in the standard data stream structure presented earlier. This is done until a block size of 0x0000 is encountered. At that point in time the entry point address is returned to the calling routine that then exits the bootloader and resumes execution at the address specified.

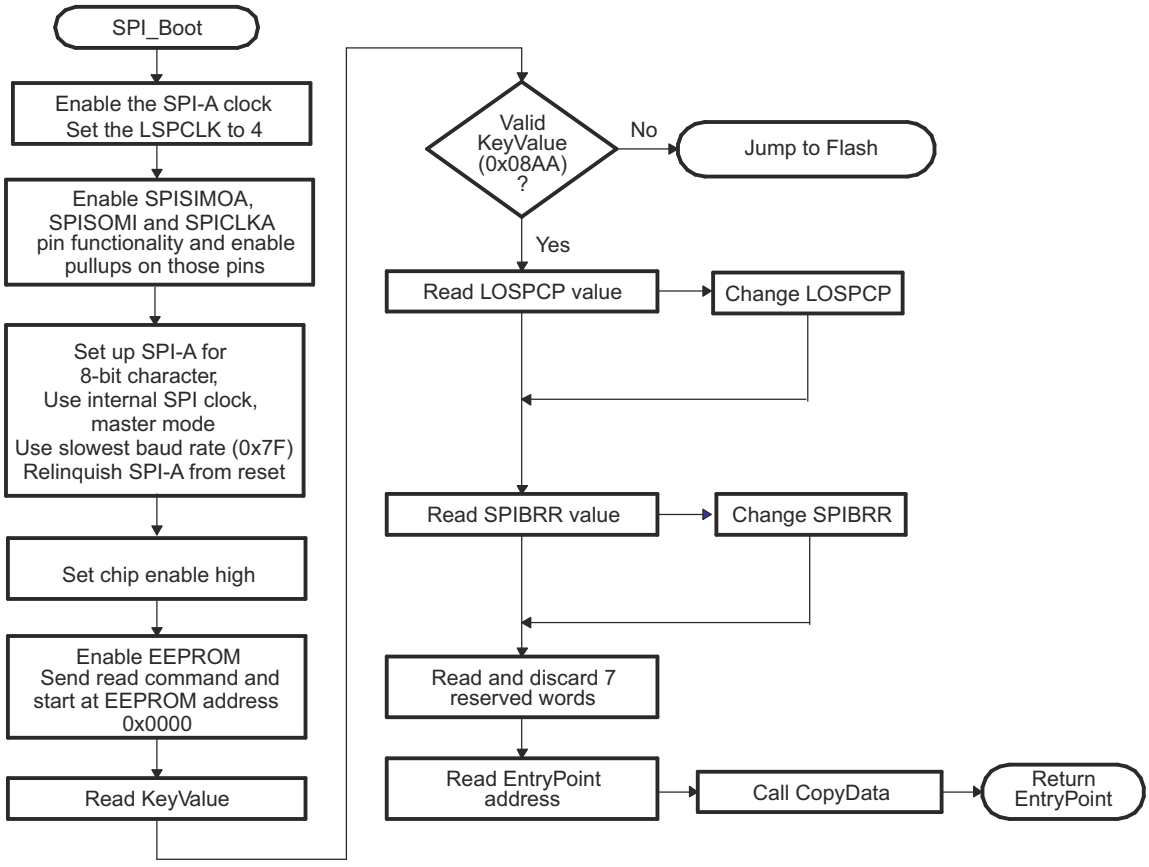

Figure 5-9. Data Transfer From EEPROM Flow

5.7.7.2.3 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as indicated in Figure 5-10. The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

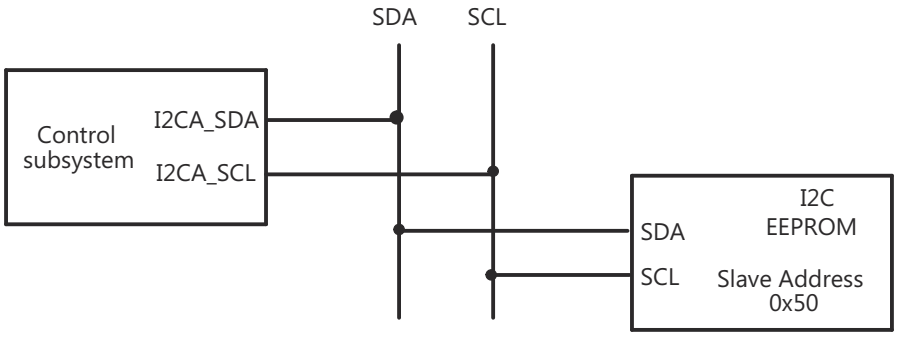

Figure 5-10. EEPROM Device at Address 0x50

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the slave mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at slave address 0x50.

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100-kHz bit rate (standard I2C mode) when the system clock is 10 MHz. These registers can be modified after receiving the first few bytes from the EEPROM. This allows the communication to be increased up to a 400-kHz bit rate (fast I2C mode) during the remaining data reads.

Arbitration, bus busy, and slave signals are not checked. Therefore, no other master is allowed to control the bus during this initialization phase. If the application requires another master during I2C boot mode, that master must be configured to hold off sending any I2C messages until the application software signals that the application is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages (I2C_Get Word). If a non-acknowledgment is received during the data read messages, the I2C bus hangs. Table 5-48 shows the 8-bit data stream used by the I2C.

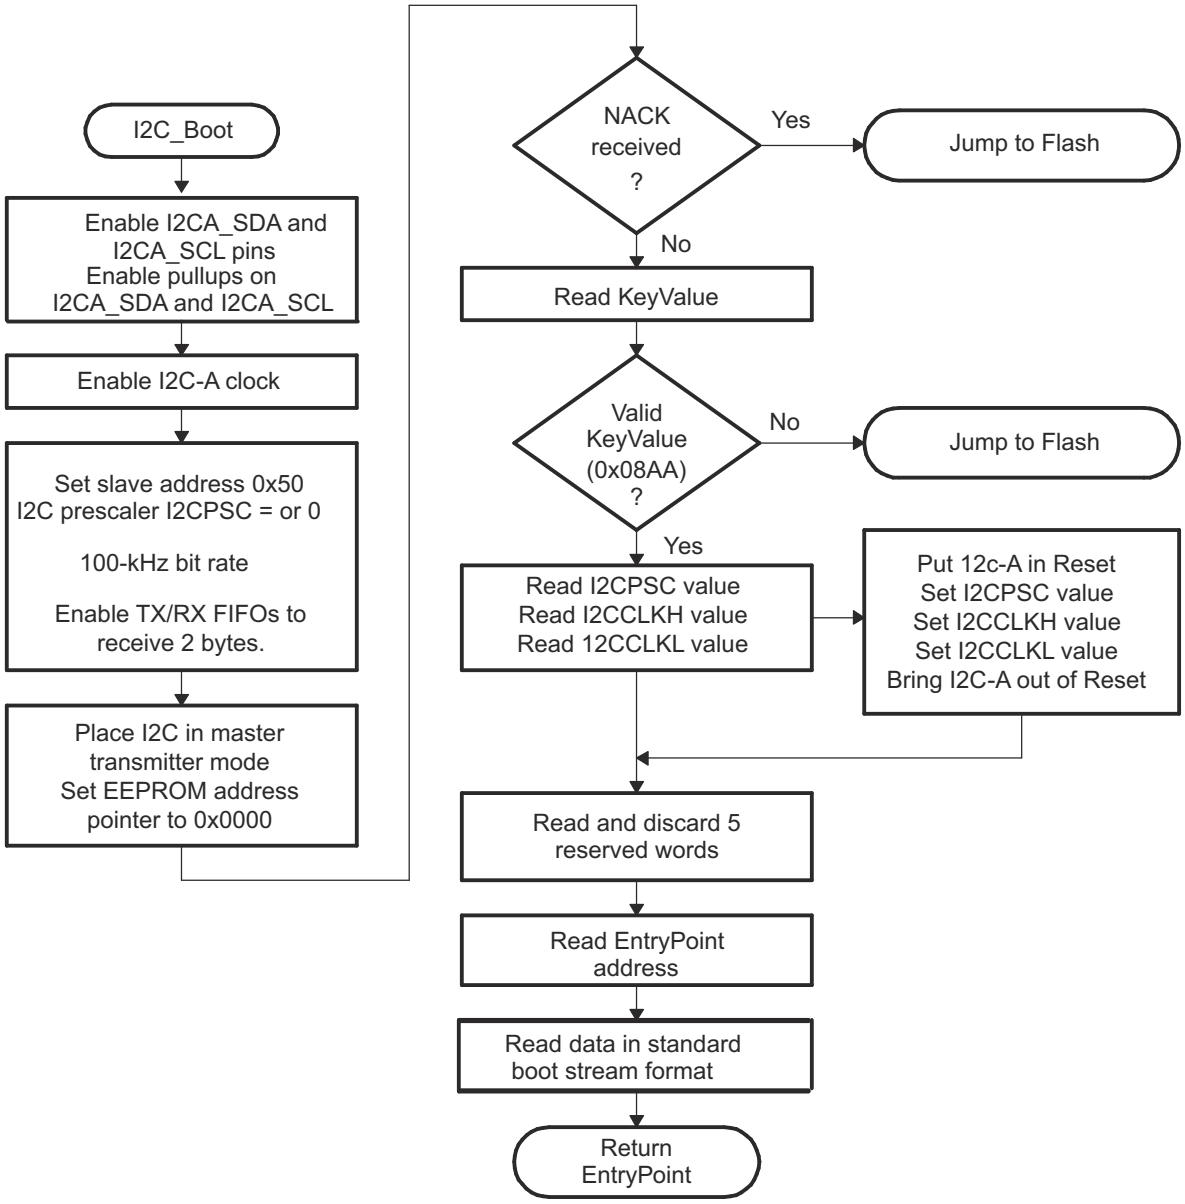

Figure 5-11. Overview of I2C Boot Function

Table 5-48. I2C 8-Bit Data Stream

Byte	Contents
1	LSB: AA (KeyValue for memory width = 8 bits)
2	MSB: 08h (KeyValue for memory width = 8 bits)
3	LSB: I2CPSC[7:0]
4	reserved
5	LSB: I2CCLKH[7:0]
6	MSB: I2CCLKH[15:8]
7	LSB: I2CCLKL[7:0]
8	MSB: I2CCLKL[15:8]
...	...
...	Data for this section.
	...
17	LSB: Reserved for future use
18	MSB: Reserved for future use
19	LSB: Upper half of entry point PC
20	MSB: Upper half of entry point PC[22:16] (Note: Always 0x00)
21	LSB: Lower half of entry point PC[15:8]
22	MSB: Lower half of entry point PC[7:0]
...	...
...	Data for this section.
	...
	Blocks of data in the format size/destination address/data as shown in the generic data stream description.
...	...
...	Data for this section.
	...
n	LSB: 00h
n+1	MSB: 00h - indicates the end of the source

The I2C EEPROM protocol required by the I2C bootloader is shown in Figure 5-12 and Figure 5-13. The first communication, which sets the EEPROM address pointer to 0x0000 and reads the KeyValue (0x08AA), is shown in Figure 5-12. All subsequent reads are shown in Figure 5-13 and are read two bytes at a time.

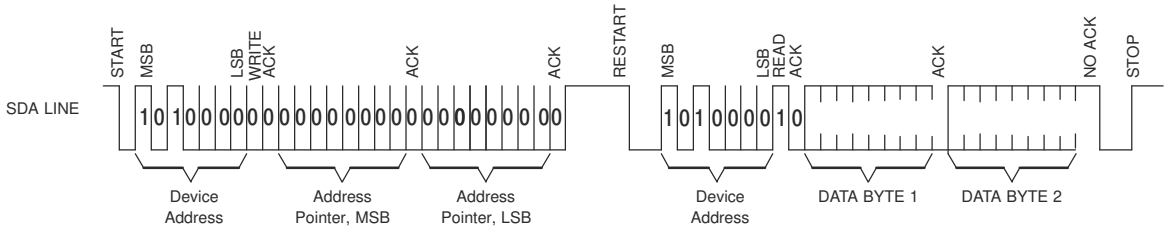

Figure 5-12. Random Read

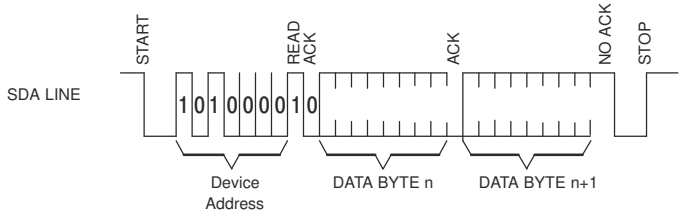

Figure 5-13. Sequential Read

5.7.7.2.4 Parallel Boot Mode

The parallel general purpose I/O (GPIO) boot mode asynchronously transfers code from GPIO88, GPIO62:GPIO58, GPIO90:GPIO89 to internal memory. Each value is eight bits long and follows the same data flow as outlined in Figure 5-14.

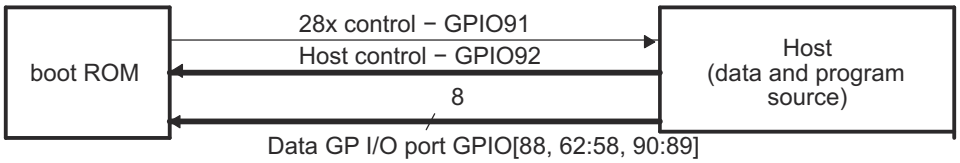

Figure 5-14. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the GPIO92 and GPIO91 lines. The handshake protocol shown in Figure 5-15 must be used to successfully transfer each word using GPIO[88, 62:58, 90:89]. This protocol is very robust and allows for a slower or faster host to communicate with the master subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The least significant byte (LSB) is read first followed by the most significant byte (MSB). In this case, data is read from GPIO[88, 62:58, 90:89].

The 8-bit data stream is shown in Table 5-49.

Table 5-49. Parallel GPIO Boot 8-Bit Data Stream

Bytes		GPIO[88,62:58,90:89] (Byte 1 of 2)	GPIO[88,62:58,90:89] (Byte 2 of 2)	Description
1	2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3	4	00	00	8 reserved words (words 2 - 9)
...	...	...	...	...
17	18	00	00	Last reserved word
19	20	BB	00	Entry point PC[22:16]
21	22	DD	CC	Entry point PC[15:0] (PC = 0x00BBCCDD)
23	24	NN	MM	Block size of the first block of data to load = 0xMMNN words
25	26	BB	AA	Destination address of first block Addr[31:16]
27	28	DD	CC	Destination address of first block Addr[15:0] (Addr = 0xAABBCCDD)
29	30	BB	AA	First word of the first block in the source being loaded = 0xAABB
... ...				... Data for this section. ...
.		BB	AA	Last word of the first block of the source being loaded = 0xAABB
.		NN	MM	Block size of the 2nd block to load = 0xMMNN words
.		BB	AA	Destination address of second block Addr[31:16]
.		DD	CC	Destination address of second block Addr[15:0]
.		BB	AA	First word of the second block in the source being loaded
.				…
n	n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2	n+3	00	00	Block size of 0000h - indicates end of the source program

The device first signals the host that the device is ready to begin data transfer by pulling the GPIO91 pin low. The host load then initiates the data transfer by pulling the GPIO92 pin low. The complete protocol is shown in Figure 5-15.

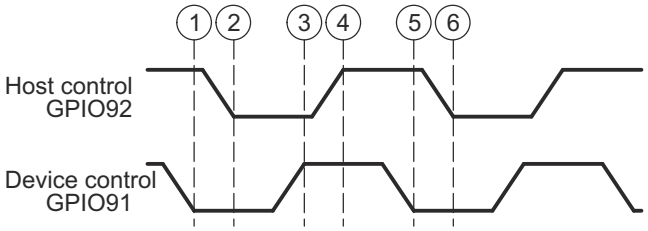

Figure 5-15. Parallel GPIO Bootloader Handshake Protocol

1. The device indicates the device is ready to start receiving data by pulling the GPIO91 pin low.
2. The bootloader waits until the host puts data on GPIO [88,62:58,90:89]. The host signals to the device that data is ready by pulling the GPIO92 pin low.
3. The device reads the data and signals the host that the read is complete by pulling GPIO91 high.
4. The bootloader waits until the host acknowledges the device by pulling GPIO92 high.
5. The device again indicates the device is ready for more data by pulling the GPIO91 pin low.

This process is repeated for each data value to be sent.

Figure 5-16 shows an overview of the Parallel GPIO bootloader flow.

Figure 5-17 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode, as the host waits for the device and the device waits for the host. In this manner, the protocol works with both a host running faster and a host running slower than the device.

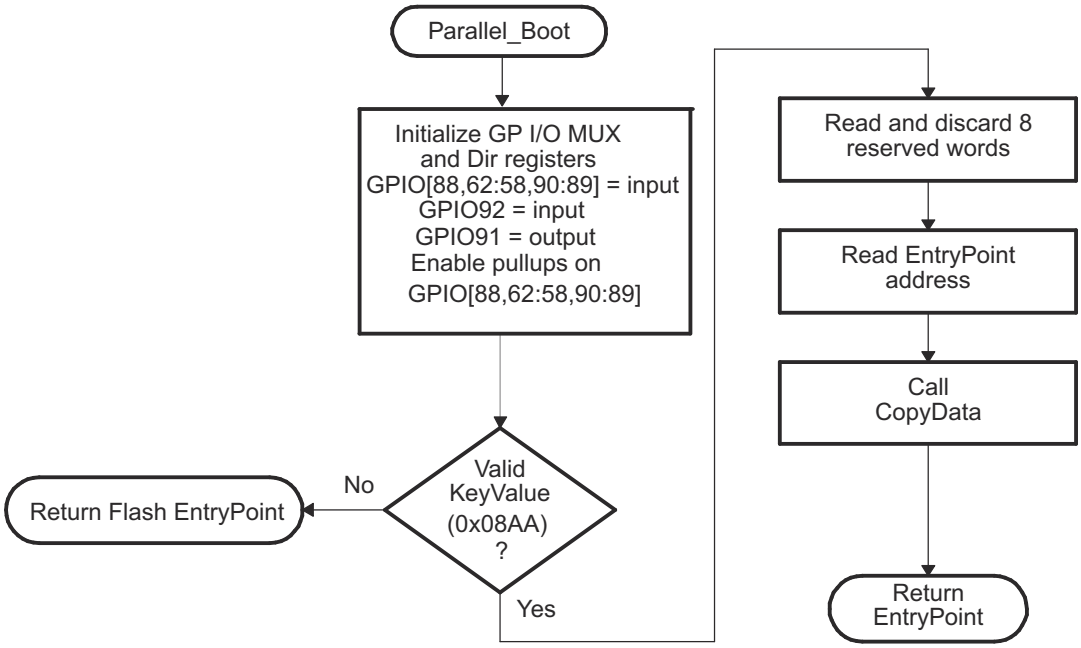

Figure 5-16. Parallel GPIO Mode Overview

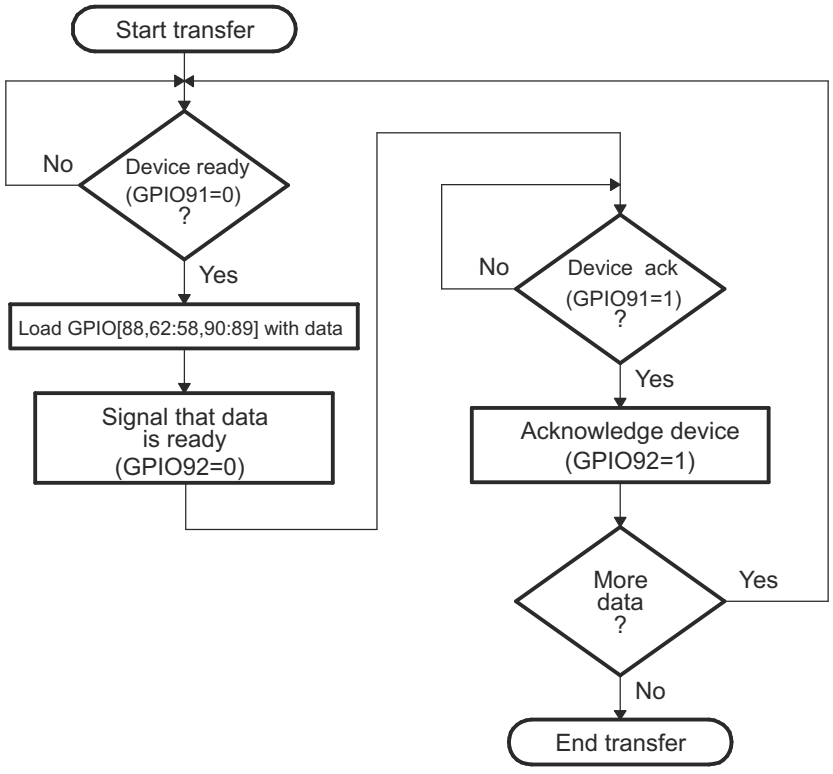

Figure 5-17. Parallel GPIO Mode - Host Transfer Flow

Figure 5-18 shows the flow used to read a single word of data from the parallel port.

- **8-bit data stream**

  The 8-bit routine, shown in Figure 5-18, discards the upper eight bits of the first read from the port and treats the lower eight bits masked with GPIO89 in bit position 7 and GPIO90 in bit position 6 as the least-significant byte (LSB) of the word to be fetched. The routine then performs a second read to fetch the most-significant byte (MSB). The routine then combines the MSB and LSB into a single 16-bit value to be passed back to the calling routine.

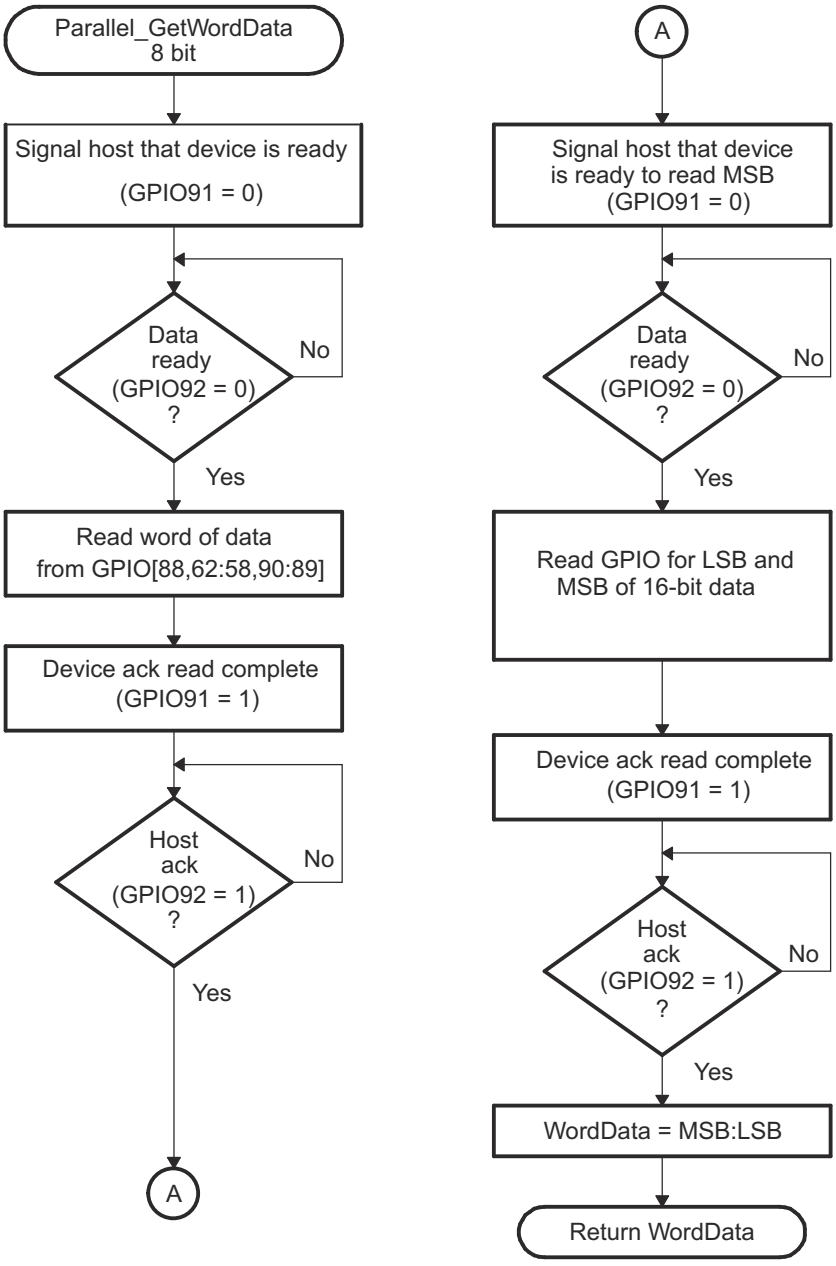

Figure 5-18. 8-Bit Parallel GetWord Function

5.7.7.2.5 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory. The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The host can download a kernel to reconfigure the CAN if higher data throughput is desired.

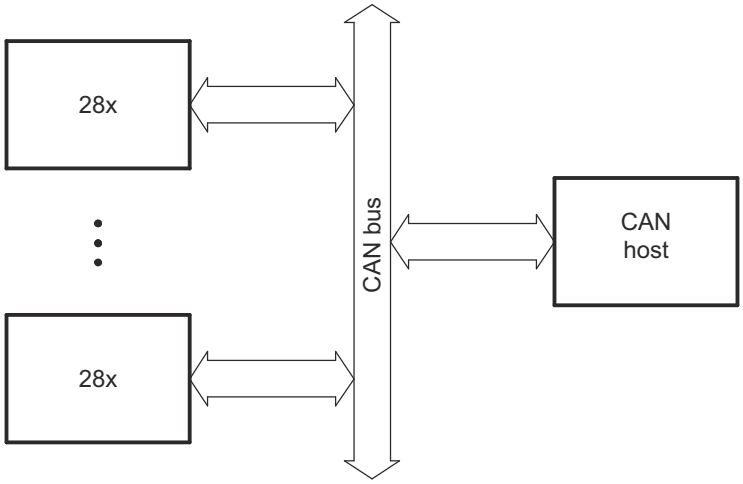

Figure 5-19. Overview of CAN-A Bootloader Operation

The bit timing registers are programmed in such a way that a 100-kbps bit rate is achieved with a 20-MHz external oscillator, a shown in Table 5-50.

Table 5-50. Bit-Rate Value for Internal Oscillators

OSCCLK	SYSCLK	Bit Rate
20 MHz	10 MHz	100 kbps

The SYSCLKOUT values shown are the reset values with the default PLL setting. The BRP and bit-time values are hard-coded to 10 and 20, respectively.

Note

The CPU1 CAN boot loader uses XTAL as the bit clock source and INTOSC2 as the system clock source.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN host must transmit only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN bootloader is identical to the SCI bootloader. The data sequence for the CAN bootloader is shown in Table 5-51.

Table 5-51. CAN 8-Bit Data Stream

Bytes		Byte 1 of 2	Byte 2 of 2	Description
1	2	AA	08	0x08AA (KeyValue for memory width = 16 bits)

n+2	n+3	00	00	Block size of 0000h - indicates end of the source program

5.7.7.2.6 USB Boot Mode

In USB boot mode, the device enumerates with vendor ID 0x1CBE and product ID 0x00FF. The device descriptor and interface descriptor both show the class as 0xFF (vendor-specific), the subclass as 0x00, and the protocol as 0x00. After enumeration, the device waits for data. Data must be sent using bulk OUT transfers to endpoint 1. The data is interpreted as a series of 8-bit bytes in the standard data stream format described in Section 5.8.1, shown here in Table 5-52. No reserved bytes are used. Once the data transfer is complete (block size of 0x0000 sent), the device disconnects from the USB bus, allowing other software to make use of the module if desired. Figure 5-20 illustrates the flow for USB boot mode.

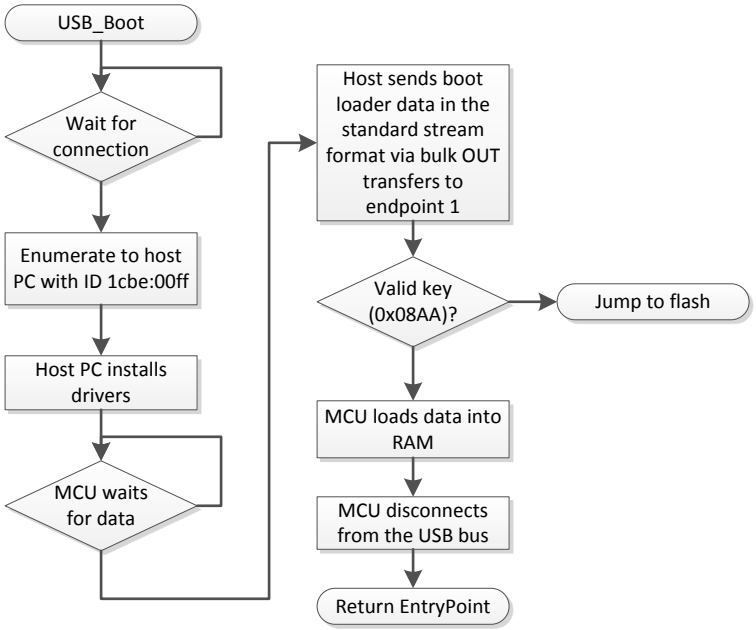

Figure 5-20. USB Boot Flow

Table 5-52. USB 8-Bit Data Stream

Bytes		First Byte (LSB)	Second Byte (MSB)	Description
1	2	AA	08	0x08AA (KeyValue for memory width = 16bits)
3	4	00	00	reserved
5	6	00	00	reserved
7	8	00	00	reserved

21	22	DD	CC	Entry point PC[15:0] (PC = 0xAABBCCDD)
23	24	NN	MM	Block size of the first block of data to load = 0xMMNN words
25	26	BB	AA	Destination address of the first block Addr[31:16]
27	28	DD	CC	Destination address of the first block Addr[15:0] (Addr = 0xAABBCCDD)
29	30	BB	AA	First word of the first block in the source being loaded = 0xAABB
...				....
...				Data for this section.
				...
.		BB	AA	Last word of the first block of the source being loaded = 0xAABB
.		NN	MM	Block size of the 2nd block to load = 0xMMNN words
.		BB	AA	Destination address of the second block Addr[31:16]
.		DD	CC	Destination address of the second block Addr[15:0]
.		BB	AA	First word of the second block in the source being loaded
.				…
n	n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2	n+3	00	00	Block size of 0000h - indicates end of the source program

Implementing PC-side USB software is not trivial. It is recommended to use the TI-provided tools and drivers to load data in USB boot mode. Hex and binary files for loader tools can be generated from COFF (.out) files using the hex2000 tool. To produce a plain binary file in the boot loader format, use the following command line:

hex2000 -boot -b Program_to_Load.out -o Binary_Loader_Data.dat

For more information on hex2000, see the *TMS320C28x Assembly Language Tools User's Guide*.

Note

INTOSC2 must be enabled before invoking the USB boot loader. If INTOSC2 is not enabled, the boot loader hangs. A debugger reset or SCC reset does not enable INTOSC2, if INTOSC2 has been disabled by the application.

5.7.8 GPIO Assignments for CPU1

This section details the GPIOs and boot option values used for each CPU1 boot mode set in the BOOT_DEF memory location located at Z1-BOOTDEF-LOW/ Z2-BOOTDEF-LOW and Z1-BOOTDEF-HIGH/ Z2-BOOTDEF-HIGH. Refer to Section 5.4.2 on how to configure BOOT_DEF. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

Note

These configurations only apply to CPU1. Refer to Section 5.7.2 for details on configuring CPU2 and CM boot modes.

5.7.9 Secure ROM Function APIs

Within secure ROM of each core, functions are available to be called by the application to perform EXEONLY Flash/RAM tasks in a secure manner.

Note

The application must disable interrupts before calling one of the EXEONLY function APIs.

If a vector fetch request is given by the CPU (C28 or CM, depending on the subsystem) while the corresponding program counter (PC) is within the EXEONLY function API code of the Secure ROM, a reset occurs (RSN, if from C28; SYSRESETn, if from CM). The consequence of this is if an NMI, ITRAP, or Bus Fault occurs while the PC is executing one of the EXEONLY API functions, the NMI/ITRAP/Fault cannot be serviced because a reset occurs to that subsystem.

The **secure copy code zone 1 and zone 2 functions** allow EXEONLY Flash to be copied to EXEONLY RAM in a secure manner. The source must be from EXEONLY Flash and the destination to EXEONLY RAM. There is no support to copy EXEONLY ROM or EXEONLY RAM to RAM. Both Flash and RAM must be set to EXEONLY and configured for the same zone. Additionally, the copy size must not cross over the Flash sector boundary. Any violations of these requirements results in a failure status returned. Upon successful copy of the data, the number of 16-bit words copied is returned.

Table 5-63. Secure Copy Code Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU1, CPU2, CM	Uint16 **SecureCopyCodeZ1**(Uint32 size, Uint16 *dst, Uint16 *src) Uint16 **SecureCopyCodeZ2**(Uint32 size, Uint16 *dst, Uint16 *src)	*size* : The number of 16-bit words to copy *dst* : The destination memory address in EXEONLY RAM *src* : The source memory address in EXEONLY Flash	0xXXXX : Returns the number of 16-bit words copied 0x0000 : Indicates one of the following: Copy length is zero; Copy size crosses over Flash sector boundary; Flash and RAM do not belong to the same zone; Flash or RAM are not set to EXEONLY; Error occurred during data copy

The **secure CRC calculation zone 1 and zone 2 functions** allow a safety CRC check of EXEONLY memory in a secure manner. The CRC length provided must be a value from 1 to 8 where 1 represents a CRC size of 32 16-bit words and 8 represents a CRC size of 4096 16-bit words. The source address specifies the starting address for the CRC and the destination address is the location that the resulting CRC value is stored. The source and destination memories must be configured for the same zone. Additionally, the CRC length must not cross over the Flash sector or RAM block boundary. On the CM, there is an additional requirement that CRCLOCK is not enabled. Any violations of these requirements results in a failure status returned. Upon successful CRC, the number of 16-bit words CRC'd is returned.

Table 5-64. Secure CRC Calculation Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU1, CPU2, CM	Uint16 **SecureCRCCalcZ1**(Uint16 len_id, Uint16 *dst, Uint16 *src) Uint16 **SecureCRCCalcZ2**(Uint16 size, Uint16 *dst, Uint16 *src)	*len_id* : A number from 1 to 8 which corresponds to length options of 32, 64, 128, 256, 512, 1024, 2048, or 4096 16-bit words *dst* : The destination memory address for resulting CRC *src* : The source memory address to begin CRC calculation	0xXXXX : Returns the number of 16-bit words CRC'd 0x0000 : Indicates one of the following: Invalid length option; Source address is not modulo of length value; Destination address is not within secure RAM; CRC size crosses over Flash sector or RAM block boundary; The source and destination memory do not belong to the same zone; On CM, CRCLOCK is enabled

The **calculate CMAC (Cipher-based Message Authentication Code) function** calculates a CMAC tag for a specified memory range using the user-set CMAC key in OTP and returns pass or failure depending if the calculated tag matches the golden tag. The memory address range provided must align to a 128-bit boundary (split evenly into 128-bit blocks). If this requirement is not met, the function returns a status indicating a boundary violation. When using the CM CMAC function, there is an additional requirement that the CM must be running in privileged mode.

For generating the secure Flash golden CMAC tag for CPU1 or CPU2, refer to the section "Using Secure Flash Boot on TMS320F2838x Devices" in the *TMS320C28x Assembly Language Tools User's Guide* for instructions.

For generating the secure Flash golden CMAC tag for CM, refer to the ARM Assembly Language Tools v19.6.0.STS, within section "Using Secure Flash Boot on TMS320F2838x Devices" for instructions.

The 128-bit golden CMAC tag:

- Must be stored inside of the memory address range that the calculation is performed on.
- Another golden CMAC tag (from a different memory address range that is being authenticated) can not be nested inside a different CMAC authentication memory address range. (For example, a CMAC on addresses 0x1000 to 0x2000 can not contain the golden CMAC tag for memory address ranges 0x4000 to 0x5000).
- The starting address of the golden CMAC tag must align to a 32-bit boundary, such as 0x80002 on CPU1/CPU2 or 0x200004 on the CM.
- The CMAC calculation treats the memory addresses containing the golden tag as all ones.

Note

If calling this function, without running the secure Flash boot mode, then a dummy load must be performed for the Z1 OTP CMACKEY before calling the function. Additionally, the Flash data caching can be disabled before performing the dummy load and then the Flash data caching can be re-enabled after the dummy load.

Table 5-65. Secure Flash CMAC Calculation Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU1	uint32_t **CPU1BROM_calculateCMAC**(uint32_t startAddress, uint32_t endAddress, uint32_t tagAddress)	*startAddress* : The starting memory address for the calculation (Example: 0x80000) *endAddress* : The ending memory address for the calculation (Example: 0x82000) *tagAddress* : The starting memory address of where the golden CMAC tag is stored. (Example: 0x80002)	0xFFFFFFFF : The calculated CMAC tag does not match the golden tag (failure) 0xA5A5A5A5 : The memory address range is not aligned to a 128-bit boundary or length is zero 0x00000000 : The calculated CMAC tag matches the golden tag (pass)
CPU2	uint32_t **CPU2BROM_calculateCMAC**(uint32_t startAddress, uint32_t endAddress, uint32_t tagAddress)	*startAddress* : The starting memory address for the calculation (Example: 0x80000) *endAddress* : The ending memory address for the calculation (Example: 0x82000) *tagAddress* : The starting memory address of where the golden CMAC tag is stored. (Example: 0x80002)	0xFFFFFFFF : The calculated CMAC tag does not match the golden tag (failure) 0xA5A5A5A5 : The memory address range is not aligned to a 128-bit boundary or length is zero 0x00000000 : The calculated CMAC tag matches the golden tag (pass)

Table 5-65. Secure Flash CMAC Calculation Function (continued)

CPU	Function Prototype	Function Parameters	Function Return Value
CM	uint32_t **CMBROM_calculateCMAC**(uint32_t startAddress, uint32_t endAddress, uint32_t tagAddress)	*startAddress* : The starting memory address for the calculation (Example: 0x200000) *endAddress* : The ending memory address for the calculation (Example: 0x200000) *tagAddress* : The starting memory address of where the golden CMAC tag is stored. (Example: 0x200004)	0xFFFFFFFF : The calculated CMAC tag does not match the golden tag (failure) 0xA5A5A5A5 : The memory address range is not aligned to a 128-bit boundary or length is zero 0x5A5A5A5A : The CM is not running in privileged mode 0xE1E1E1E1: The CM AES engine timed out. AES engine can not be working as expected. 0x00000000 : The calculated CMAC tag matches the golden tag (pass)

5.7.10 Clock Initializations

During boot-up, the boot ROM initializes the device clocking, depending upon the reset source, to assist in faster boot time response. Clock configurations are performed by the boot ROM code only for POR and XRS reset types. For all other resets, the boot ROM starts executing with the clocks that were already set up before reset.

Note

Only CPU1 performs clock configurations during boot up. CPU1 application configures clocks for CPU2 and CM before releasing them from reset. Refer to Section 5.7.2 for more details.

If the PLL is used during the CPU1 boot process, it will be bypassed by the boot ROM code before branching to the user application.

Table 5-66. CPU1 Boot Clock Sources

Source	Frequency	Description
INTOSC2	10 MHz	Default clock source
INTOSC1	10 MHz	Set as clock source if missing clock is detected at power up or right after device reset
SYSPLL	110 MHz, 80 MHz, or 60 MHz	Enabled only as part of MPOST boot flow. PLL is bypassed and disabled after memory test has completed. See more details regarding enabling MPOST in Section 5.7.1.1.
SYSPLL and AUXPLL	SYSPLL = 180 MHz AUXPLL = 60 MHz	Enabled only as part of USB Bootloader. Both PLLs are bypassed and disabled after the bootloader actions complete.

Table 5-67. CPU1 Clock State After Boot

Reset Source	Clock State
POR/XRS	1. Using INTOSC2 2. System clock divider set to /1
All other Resets	Maintain clocks setup before device reset.

5.7.11 Boot Status information

Boot ROM keeps a record of the various actions and events that occur during boot ROM execution. The reason for this is because NMI and other exceptions are enabled by default in the device and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can read this boot status and take the necessary actions per application's needs to handle these events.

5.7.11.1 CPU1 Booting Status

CPU1 boot ROM health and booting status is written to a 32-bit address in M0RAM. This status is cleared on a POR or XRS reset. The previous status is retained on any other reset. For example, a user should clear the status before performing a debugger device reset in order to view the latest boot ROM actions reflected in the status.

Table 5-68. CPU1 Boot Status Address

Description	Address
CPU1 Boot ROM Status	0x0000 0002

Table 5-69. CPU1 Boot Status Bit Fields

Bit	Description
31	CPU1 Boot ROM has finished running
30	Missing clock NMI occurred
29	RAM Uncorrectable Error NMI or ROM Parity Error occurred
28	Flash Uncorrectable Error NMI occurred
27	HWBIST NMI occurred
26	PIE Vector NMI occurred
25	RL NMI occurred
24	PIE Mismatch occurred
23	ITRAP occurred
22	ERAD NMI occurred
21	EtherCAT NMI occurred
20	MCAN NMI occurred
19	SYSPLL or AUXPLL failed to enable
18	MPOST (Memory Power On Self-Test) Complete
17	RAM Initialization Complete
16	DCSM Initialization Complete
15	HWBIST Reset Handled
14	POR Reset Handled
13	XRS Reset Handled
12	All Resets Handled
11:8	Not Used
7:0	0x0 = Invalid / No Status set yet 0x1 = CPU1 Boot ROM has started running 0x2 = Running Flash Boot 0x3 = Running Secure Flash Boot 0x4 = Running Parallel Boot 0x5 = Running RAM Boot 0x6 = Running SCI Boot 0x7 = Running SPI Boot 0x8 = Running I2C Boot 0x9 = Running CAN Boot 0xA = Running USB Boot 0xB = Running Wait Boot

5.7.11.2 CPU2 Booting Status

CPU2 boot ROM health and booting status is written to a 32-bit address in M0RAM. This status is cleared on every CPU2 reset. Additionally, a copy of the status is written to CPU2TOCPU1IPCBOOTSTS for CPU1 to have access to CPU2's boot status.

Table 5-70. CPU2 Boot ROM Status Address

Description	Address
CPU2 Boot ROM Status	0x0000 0002

Table 5-71. CPU2 Boot Status Bit Fields

Bit	Description
31	CPU2 Boot ROM has finished running
30	Missing clock NMI occurred
29	RAM Uncorrectable Error NMI or ROM Parity Error occurred
28	Flash Uncorrectable Error NMI occurred
27	HWBIST NMI occurred
26	PIE Vector NMI occurred
25	RL NMI occurred
24	PIE Mismatch occurred
23	ITRAP occurred
22	ERAD NMI occurred
21	Secure Flash Boot CMAC returned failure
20	Not Used
19	Invalid length specified in CPU1TOCPU2IPCBOOTMODE for IPC message RAM copy length
18	Invalid (or missing configuration) in CPU1TOCPU2IPCBOOTMODE
17	RAM Initialization Complete
16	Not Used
15	HWBIST Reset Handled
14	POR Reset Handled
13	XRS Reset Handled
12	All Resets Handled
11:8	Not Used
7:0	0x0 = Invalid / No Status set yet 0x1 = CPU2 Boot ROM has started running 0x2 = Running Flash Boot 0x3 = Running Secure Flash Boot 0x4 = Running IPC Message Copy to RAM Boot 0x5 = Running RAM Boot 0x6 = Running User OTP Boot 0x7 = Running Wait Boot 0x8 = Waiting for CPU1 to set CPU1TOCPU2IPCFLG0 to allow CPU2 to start booting

5.7.11.3 CM Booting Status

CM boot ROM health and booting status is written to a 32-bit address in S0RAM. This status is cleared on every CM reset. Additionally, a copy of the status is written to CMTOCPU1IPCBOOTSTS for CPU1 to have access to the CM's boot status.

Table 5-72. CM Boot ROM Status Address

Description	Address
CM Boot ROM Status	0x2000 0000

Table 5-73. CM Boot Status Bit Fields

Bit	Description
31	CM Boot ROM has finished running
30	Missing clock NMI occurred
29	RAM Uncorrectable Error NMI or ROM Parity Error occurred
28	Flash Uncorrectable Error NMI occurred
27	MCAN NMI occurred
26	Windowed Watchdog NMI occurred
25	An EtherCAT NMI occurred
24	Not Used

19	Invalid length specified in CPU1TOCMIPCBOOTMODE for IPC message RAM copy length
18	Invalid (or missing configuration) in CPU1TOCMIPCBOOTMODE
17	RAM Initialization Complete
16:15	Not Used
14	POR Reset Handled
13	Not Used
12	All Resets Handled
11:8	Not Used
7:0	0x0 = Invalid / No Status set yet 0x1 = CM Boot ROM has started running 0x2 = Running Flash Boot 0x3 = Running Secure Flash Boot 0x4 = Running IPC Message Copy to RAM Boot 0x5 = Running RAM Boot 0x6 = Running User OTP Boot 0x7 = Running Wait Boot 0x8 = Waiting for CPU1 to set CPU1TOCMIPCFLG0 to allow CM to start booting

5.7.11.4 Boot Mode and MPOST (Memory Power On Self-Test) Status

Once the boot mode is decoded during the boot flow for each core, the boot mode value is written to RAM. Additionally, on CPU1, when running the MPOST POR memory test, the test result is written to RAM.

For more information, see the *C2000™ Memory Power-On Self-Test (M-POST) Application Report*.

Table 5-74. Boot Mode and MPOST Status Addresses

Description	Address
CPU1 Boot Mode	0x0000 0004
CPU2 Boot Mode	0x0000 0004
CM Boot Mode	0x2000 0004
MPOST Result (CPU1 Only)	0x0000 0006

5.7.12 ROM Version

The ROM revision and release date information is stored at the ROM locations specified in this section. Reading a revision number value of “0x100” represents version “1.0”, “0x101” represents version “1.1”, and so on. Reading a revision date value of “0x0916” represents “09/16” or “September 2016”.

Table 5-75. Boot ROM Version Information for CPU1

Start Address	End Address	Contents	Silicon Revision 0 Values	Silicon Revision A Values

5.8 Application Notes for Using the Bootloaders

5.8.1 Boot Data Stream Structure

This section details the data transfer protocols or stream structures that allow boot data transfer between boot ROM and host device. This data transfer protocol is compatible to the respective bootloaders on C2000 devices.

5.8.1.1 Bootloader Data Stream Structure

The following table and associated examples show the structure of the data stream incoming to the bootloader. The basic structure is the same for all the bootloaders and is based on the C54x source data stream generated by the C54x hex utility. The C28x hex utility (hex2000.exe) has been updated to support this structure. The hex2000.exe utility is included with the C2000 code generation tools. All values in the data stream structure are in hex. Refer to The C2000 Hex Utility for more details on using the C28x hex utility to convert a project to this format.

The first 16-bit word in the data stream is known as the key value. The key value is used to tell the bootloader the width of the incoming stream: 8 or 16 bits. Note that not all bootloaders accept both 8- and 16-bit streams. Refer to the detailed information on each loader for the valid data stream width. For an 8-bit data stream, the key value is 0x08AA and for a 16-bit stream the key value is 0x10AA. If a bootloader receives an invalid key value, then the load is aborted.

The next eight words are used to initialize register values or otherwise enhance the bootloader by passing values to the bootloader. If a bootloader does not use these values, then the values are reserved for future use and the bootloader simply reads the value and then discards the value. Currently only the SPI and I2C and parallel bootloaders use these words to initialize registers.

The tenth and eleventh words comprise the 22-bit entry point address. This address is used to initialize the PC after the boot load is complete. This address is most likely the entry point of the program downloaded by the bootloader.

The twelfth word in the data stream is the size of the first data block to be transferred. The size of the block is defined as 8-bit data stream format. For example, to transfer a block of 20 8-bit data values from an 8-bit data stream, the block size is 0x000A to indicate 10 16-bit words.

The next two words indicate to the loader the destination address of the block of data. Following the size and address is the 16-bit words that makeup that block of data.

This pattern of block size/destination address repeats for each block of data to be transferred. Once all the blocks have been transferred, a block size of 0x0000 signals to the loader that the transfer is complete. At this point, the loader returns the entry point address to the calling routine that exits. Execution continues at the entry point address as determined by the input data stream contents.

Table 5-78. LSB/MSB Loading Sequence in 8-Bit Data Stream

Byte		Contents	
		LSB (First Byte of 2)	MSB (Second Byte of 2)
1	2	LSB: AA (KeyValue for memory width = 8 bits)	MSB: 08h (KeyValue for memory width = 8 bits)
3	4	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
5	6	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
7	8	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
...	...	...	...
...	...	...	...
17	18	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
19	20	LSB: Upper half of Entry point PC[23:16]	MSB: Upper half of entry point PC[31:24] (Always 0x00)
21	22	LSB: Lower half of Entry point PC[7:0]	MSB: Lower half of Entry point PC[15:8]
23	24	LSB: Block size in words of the first block to load. If the block size is 0, this indicates the end of the source program; otherwise, another block follows. For example, a block size of 0x000A indicates 10 words or 20 bytes in the block.	MSB: block size
25	26	LSB: MSW destination address, first block Addr[23:16]	MSB: MSW destination address, first block Addr[31:24]
27	28	LSB: LSW destination address, first block Addr[7:0]	MSB: LSW destination address, first block Addr[15:8]
29	30	LSB: First word of the first block being loaded	MSB: First word of the first block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the first block to load	MSB: Last word of the first block to load
.	.	LSB: Block size of the second block	MSB: Block size of the second block
.	.	LSB: MSW destination address, second block Addr[23:16]	MSB: MSW destination address, second block Addr[31:24]
.	.	LSB: LSW destination address, second block Addr[7:0]	MSB: LSW destination address, second block Addr[15:8]
.	.	LSB: First word of the second block being loaded	MSB: First word of the second block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the second block	MSB: Last word of the second block
.	.	LSB: Block size of the last block	MSB: Block size of the last block
.	.	LSB: MSW of destination address of last block Addr[23:16]	MSB: MSW destination address, last block Addr[31:24]
.	.	LSB: LSW destination address, last block Addr[7:0]	MSB: LSW destination address, last block Addr[15:8]
.	.	LSB: First word of the last block being loaded	MSB: First word of the last block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the last block	MSB: Last word of the last block
n	n+1	LSB: 00h	MSB: 00h - indicates the end of the source

Example 5-2. Data Stream Structure 8-bit

```
AA 08        ; 0x08AA 8-bit key value
00 00 00 00  ; 8 reserved words
00 00 00 00
00 00 00 00
00 00 00 00
3F 00 00 80  ; 0x003F8000 EntryAddr, starting point after boot load completes
05 00        ; 0x0005 - First block consists of 5 16-bit words
3F 00 10 90  ; 0x003F9010 - First block will be loaded starting at 0x3F9010
01 00        ; Data loaded = 0x0001 0x0002 0x0003 0x0004 0x0005
02 00
03 00
04 00
05 00
02 00        ; 0x0002 - 2nd block consists of 2 16-bit words
3F 00 00 80  ; 0x003F8000 - 2nd block will be loaded starting at 0x3F8000
00 77        ; Data loaded = 0x7700 0x7625
25 76
00 00        ; 0x0000 - Size of 0 indicates end of data stream
After load has completed the following memory values will have been initialized as follows:
Location Value
0x3F9010 0x0001
0x3F9011 0x0002
0x3F9012 0x0003
0x3F9013 0x0004
0x3F9014 0x0005
0x3F8000 0x7700
0x3F8001 0x7625
PC Begins execution at 0x3F8000
```

5.8.2 The C2000 Hex Utility

To use the features of the bootloader, you must generate a data stream and boot table as described in Section 5.8.1.1. The hex conversion utility tool, included with the 28x code generation tools, can generate the required data stream including the required boot table. This section describes the hex2000 utility. An example of a file conversion performed by hex2000 is described in Example 5-3.

The hex utility supports creation of the boot table required for the SCI, SPI, I2C, CAN, and parallel I/O loaders. That is, the hex utility adds the required information to the file such as the key value, reserved bits, entry point, address, block start address, block length and terminating value. The contents of the boot table vary slightly depending on the boot mode and the options selected when running the hex conversion utility. The actual file format required by the host (ASCII, binary, hex, and so on) differs from one specific application to another and some additional conversion may be required.

To build the boot table, follow these steps:

1. **Assemble or compile the code.**

   This creates the object files that then is used by the linker to create a single output file.
2. **Link the file.**

   The linker combines all of the object files into a single output file in common object file format (ELF). The specified linker command file is used by the linker to allocate the code sections to different memory blocks. Each block of the boot table data corresponds to an initialized section in the ELF file. Uninitialized sections are not converted by the hex conversion utility. The following options can be useful:

The linker -m option can be used to generate a map file. This map file shows all of the sections that were created, their location in memory, and their length. It can be useful to check this file to make sure that the initialized sections are where you expect them to be.

The linker -w option configures the linker to show if the linker assigned a section to a memory region automatically. For example, if you have a section in your code called .TI.ramfunc.

3. **Run the hex conversion utility.**

   Choose the appropriate options for the desired boot mode and run the hex conversion utility to convert the ELF file produced by the linker to a boot table.

See the *TMS320C28x Assembly Language Tools User's Guide* and the *TMS320C28x Optimizing C/C++ Compiler User's Guide* for more information on the compiling and linking process.

Table 5-79 summarizes the hex conversion utility options available for the bootloader. See the *TMS320C28x Assembly Language Tools User's Guide* for a detailed description of the hex2000 operations used to generate a boot table. Updates are made to support the I2C boot. See the Codegen release notes for the latest information.

Table 5-79. Boot Loader Options

Option	Description
-boot	Convert all sections into bootable form (use instead of a SECTIONS directive)
-sci8	Specify the source of the bootloader table as the SCI-A port, 8-bit mode
-spi8	Specify the source of the bootloader table as the SPI-A port, 8-bit mode
-gpio8	Specify the source of the bootloader table as the GPIO port, 8-bit mode
-bootorg value	Specify the source address of the bootloader table
-lospcp value	Specify the initial value for the LOSPCP register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-spibrr value	Specify the initial value for the SPIBRR register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-e value	Specify the entry point at which to begin execution after boot loading. The value can be an address or a global symbol. This value is optional. The entry point can be defined at compile time using the linker -e option to assign the entry point to a global symbol. The entry point for a C program is normally _c_int00 unless defined otherwise by the -e linker option.
-i2c8	Specify the source of the bootloader table as the I2C-A port, 8-bit
-i2cpsc value	Specify the value for the I2CPSC register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM. This value is truncated to the least-significant eight bits and must be set to maintain an I2C module clock of 7-12 MHz.
-i2cclkh value	Specify the value for the I2CCLKH register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.
-i2cclkl value	Specify the value for the I2CCLKL register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.

Example 5-3. HEX2000.exe Command Syntax

```
C: HEX2000 GPIO34TOG.OUT -boot -gpio8 -a
Where:
- boot Convert all sections into bootable form.
- gpio8 Use the GPIO in 8-bit mode data format. The eCAN uses the same data format as the GPIO in
8-bit mode.
- a Select ASCII-Hex as the output format.
```

5.9 Software

5.9.1 BOOT Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/boot

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

5.9.1.1 CM Secure Flash Boot

FILE: boot_ex1_cpu1_cpu2_cm_secure_flash_cm.c

This example demonstrates how to use the secure flash boot mode for CM. (Requires CPU1 example application)

Secure flash boot performs a CMAC authentication on the entry sector of flash upon device boot up. If authentication passes, the application will begin execution. Learn more on the secure flash boot mode in the device technical reference manual.

This project shows how to use the C2000 HEX Utility to generate a CMAC Tag based on a user CMAC key and embed the value into the flash application. Additionally, the example details the method to call the CMAC API from the user application to calculate CMAC on other flash sectors beyond the the application entry flash sector.

Determining Pass/Fail without debugger connected: CM - ControlCARD LED3.
- LED off = Secure Boot failed
- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed

External Connections
- None.

Watch Variables
- None.

5.9.1.2 CPU1 Secure Flash Boot

FILE: boot_ex1_cpu1_cpu2_cm_secure_flash_cpu1.c

This example demonstrates how to use the secure flash boot mode for CPU1 as well as release CPU2 and CM for secure flash boot.

Secure flash boot performs a CMAC authentication on the entry sector of flash upon device boot up. If authentication passes, the application will begin execution. Learn more on the secure flash boot mode in the device technical reference manual.

This project shows how to use the C2000 HEX Utility to generate a CMAC Tag based on a user CMAC key and embed the value into the flash application. Additionally, the example details the method to call the CMAC API from the user application to calculate CMAC on other flash sectors beyond the the application entry flash sector.

How to Run:
- Load application into CPU1 flash (as well as CPU2 and CM applications)
- Disconnect and reconnect to only CPU1
- In memory window, set address 0xD00/D01 to 0x5AFFFFFF and address 0xD04 to 0x000A (This sets emulation boot to secure flash boot)
- Reset CPU1 via CCS and click resume
- Observe the LEDs

Determining Pass/Fail without debugger connected: *CPU1* - ControlCARD LED1.
- LED off = Secure Boot failed
- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed *CPU2* - ControlCARD LED2.
- LED off = Secure Boot failed

- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed *CM* - ControlCARD LED3.
- LED off = Secure Boot failed
- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed

External Connections

- None.

Watch Variables

- cpu1_SuccessfullyBooted - True when CPU1 full flash CMAC authentication passes. Otherwise, false.
- cpu2_SuccessfullyBooted - True when CPU2 full flash CMAC authentication passes and CPU1 receives IPC. Otherwise, false.
- cm_SuccessfullyBooted - True when CM full flash CMAC authentication passes and CPU1 receives IPC. Otherwise, false.

5.9.1.3 CPU2 Secure Flash Boot

FILE: boot_ex1_cpu1_cpu2_cm_secure_flash_cpu2.c

This example demonstrates how to use the secure flash boot mode for CPU2. (Requires CPU1 example application)

Secure flash boot performs a CMAC authentication on the entry sector of flash upon device boot up. If authentication passes, the application will begin execution. Learn more on the secure flash boot mode in the device technical reference manual.

This project shows how to use the C2000 HEX Utility to generate a CMAC Tag based on a user CMAC key and embed the value into the flash application. Additionally, the example details the method to call the CMAC API from the user application to calculate CMAC on other flash sectors beyond the the application entry flash sector.

Determining Pass/Fail without debugger connected: CPU2 - ControlCARD LED2.

- LED off = Secure Boot failed
- LED On (Solid) = Secure Boot Passed, Full Flash CMAC failed
- LED Blinking = Secure Boot Passed and Full Flash CMAC passed

External Connections

- None.

Watch Variables

Chapter 6

Dual Code Security Module (DCSM)

This chapter explains the dual code security module.

6.1 Introduction

The dual code security module (DCSM) is a security feature incorporated in this device. It prevents access and visibility to on-chip secure memories (and other secure resources) by unauthorized persons. It also prevents duplication and reverse-engineering of proprietary code. The term “secure” means that access to on-chip secure memories and resources is blocked. The term “unsecure” means that access is allowed; that is, the contents of the memory could be read by any means (for example, through a debugging tool such as Code Composer Studio™ IDE.

There are two security zones, Zone1 (Z1) and Zone2 (Z2). Unlike earlier C2000 devices where each CPU subsystem had two security zones, on this device, both security zones are shared by each CPU subsystem. This means secure resources from each CPU subsystem are allocated to Zone1 or Zone2. All the security configurations are controlled by the CPU1 subsystem only (programmed in CPU1 USER OTP). Other CPU subsystems have only read access to these configurations via their own memory map registers.

6.1.1 DCSM Related Collateral

Getting Started Materials

- *C2000 DCSM Security Tool Application Report*
- *C2000 Unique Device Number Application Report*
- *Enhancing Device Security by Using JTAGLOCK Feature Application Report*
- *Secure BOOT On C2000 Device Application Report*

6.2 Functional Description

The security module restricts the CPU access to on-chip secure memory and resources without interrupting or stalling CPU execution. When a read occurs to a secure memory location, the read returns a zero value and CPU execution continues with the next instruction. This, in effect, blocks read and write access to secure memories through the JTAG port or external peripherals.

The code security mechanism offers protection for two zones, Zone1 (Z1) and Zone2 (Z2). The security mechanism for both the zones is identical. Each zone has its own dedicated secure resource and allocated secure resource. The following are different secure resources available on this device:

- **OTP:** Each zone has its own dedicated secure OTP (USER OTP) on CPU1 subsystem. This contains the security configurations for the individual zone. If a zone is secure, its USER OTP content (including CSM passwords) can be read (execution not allowed) only if the zone is unlocked using the password match flow (PMF).
- **RAM:** All Dx and LSx RAMs on C28x and C0/C1 RAMs on the Connectivity Manager(CM) can be secure RAM on this device. On this device IPC MSG RAMs between different subsystems can also be configured to be secure RAM. This enables secure message exchange between CPU subsystems. These RAMs can be allocated to either zone by configuring the respective GRABRAM locations in the CPU1 USER OTP.
- **Flash Sectors:** Flash sectors of each CPU subsystems can be made secure on this device. Each Flash sector can be allocated to either zone by configuring the respective GRABSECT locations in the CPU1 USER OTP.
- **Secure ROM:** This device also has secure ROM on each CPU subsystem which is EXEONLY-protected. These ROM contains specific function for the user, provided by TI.

Table 6-1 shows the status of a RAM block/Flash sector based on the configuration in the GRABRAM/ GRABSECT register.

The security of each zone is ensured by its own 128-bit (four 32-bit words) password (CSM password). The password for each zone is stored in CPU1 USER OTP. A zone can be unsecured by executing the password match flow (PMF), described in Section 6.7.4.

Table 6-1. RAM/Flash Status

Zone 1 GRAMRAMx/GRABSECTx Bits	Zone 2 GRAMRAMx/GRABSECT Bits	Ownership and Accessibility
01	10	RAM block/Flash Sector belongs to Zone1
01	11(2)	RAM block/Flash Sector belongs to Zone1
10	01	RAM block/Flash Sector belongs to Zone2
11(1)	01	RAM block/Flash Sector belongs to Zone2
10	10	RAM block/Flash Sector is unsecure
11	11	If both zones are unsecure, then RAM block/Flash is unsecure. RAM block/Flash Sector inaccessible if either of the zone is secure (CSM passwords are programmed). User should never leave these values default (11) if CSM passwords are programmed for even one zone.

(1) Zone1 must be unsecure. Assumption in this case is that user is not using Zone1 so none of the fields, including passwords, in Zone1 USER OTP are programmed by user hence Zone1 will always be unsecure.
(2) Zone2 must be unsecure. Assumption in this case is that user is not using Zone2 so none of the fields, including passwords, in Zone2 USER OTP are programmed by user hence Zone2 will always be unsecure.

Note

You should never program any other values in these fields. Failing any these conditions for a RAM block/Flash sector will make that RAM block/Flash sector inaccessible.

There are three types of accesses:

- Data/program reads: Data reads to a secure memory are always blocked unless the program is executing from a memory that belongs to the same zone. Data reads to unsecure memory are always allowed.
- JTAG access: JTAG accesses are always blocked when a memory is secure.
- Instruction fetches (calls, jumps, code executions, ISRs): Instruction fetches are never blocked.

Table 6-2 shows the levels of security.

Table 6-2. Security Levels

PMF Executed With Correct Password?	Operating Mode of the Zone	Program Fetch Location	Security Description
No	Secure	Outside secure memory	Only instruction fetches by the CPU are allowed to secure memory. In other words, code can still be executed, but not read.
No	Secure	Inside secure memory	CPU has full access (except for EXEONLY memories where read is not allowed). JTAG port cannot read the secured memory contents.
Yes	Unsecure	Anywhere	Full access for CPU and JTAG port to secure memory of that zone.

6.2.1 CSM Passwords

Unlike earlier C2000™ devices, on this device ALL_1 value (0xFFFFFFFF,0xFFFFFFFF,0xFFFFFFFF,0xFFFFFFFF) for CSM password for a zone does not unsecure the zone. Instead, if for any zone the CSM password values get loaded as ALL_1 from USER OTP, the device will be in BLOCKED state. Due to this reason TI will program a few bits in the second 32-bit password value (ZxOTP_CSMPSWD1) in every zone select block of each zone with value '0'. The default value for this password location is chosen in a manner that the respective ECC value remains ALL_1. Due to this, the CSMPSWD1 value programmed by TI for every zone select block is different. See Table 6-3 for ZxOTP_CSMPSWD1 value, programmed by TI on every device. Since ECC is not programmed, the user will be able to change this value by flipping the bits which are '1' to '0' but leaving the ones which are already programmed by TI as '0'. BOOTROM code will write the default password value into the KEYx register to unlock the device as part of device initialization sequence.

If the password locations of a zone have all 128 bits as zeros (ALL_0), that zone becomes permanently secure (LOCKED state), regardless of the contents of the CSMKEYx registers which means the zone cannot be unlocked using PMF, the password match flow described in Section 6.7.4. Therefore, the user should never use ALL_0 as password. A password of ALL_0 will prevent debug of secure code or reprogramming the Flash sectors. CSMKEYx registers are user-accessible registers that are used to unsecure the zones.

Table 6-3. Default Value of ZxOTP (Programmed by TI)

Zone Select Block	Zone1 USER OTP		Zone2 USER OTP	
	Address	Value	Address	Value
JLM_ENABLE (JTAGLOCK)	0x00078006	0xffff000f	NA	NA
PSWDLOCK	0x00078010	0xfb7fffff	0x00078210	0x1f7fffff
CRCLOCK	0x00078012	0x7fffffff	0x00078212	0x3fffffff
JTAGPSWDH0	0x00078014	0x4bffffff	NA	NA
JTAGPSWDH1	0x00078016	0x3fffffff	NA	NA
Zone_Select_Block0	0x00078022 (CSMPSWD1)	0x4d7fffff	0x00078222 (CSMPSWD1)	0x1f7fffff
Zone_Select_Block0	0x0007803e (JTAGPSWDL1)	0x2bffffff	NA	NA
Zone_Select_Block1	0x00078042 (CSMPSWD1)	0x5f7fffff	0x00078242 (CSMPSWD1)	0xe57fffff
Zone_Select_Block1	0x0007805e (JTAGPSWDL1)	0x27ffffff	NA	NA
Zone_Select_Block2	0x00078062 (CSMPSWD1)	0x1dffffff	0x00078262 (CSMPSWD1)	0x4fffffff
Zone_Select_Block2	0x0007807e (JTAGPSWDL1)	0x7b7fffff	NA	NA
Zone_Select_Block3	0x00078082 (CSMPSWD1)	0xaf7fffff	0x00078282 (CSMPSWD1)	0xe37fffff
Zone_Select_Block3	0x0007809e (JTAGPSWDL1)	0xc9ffffff	NA	NA
Zone_Select_Block4	0x000780a2 (CSMPSWD1)	0x1bffffff	0x000782a2 (CSMPSWD1)	0x57ffffff
Zone_Select_Block4	0x000780be (JTAGPSWDL1)	0x7d7fffff	NA	NA
Zone_Select_Block5	0x000780c2 (CSMPSWD1)	0x17ffffff	0x000782c2 (CSMPSWD1)	0x5bffffff
Zone_Select_Block5	0x000780de (JTAGPSWDL1)	0x6f7fffff	NA	NA
Zone_Select_Block6	0x000780e2 (CSMPSWD1)	0xbd7fffff	0x000782e2 (CSMPSWD1)	0xf17fffff
Zone_Select_Block6	0x000780fe (JTAGPSWDL1)	0x33ffffff	NA	NA
Zone_Select_Block7	0x00078102 (CSMPSWD1)	0x9f7fffff	0x00078302 (CSMPSWD1)	0x3b7fffff
Zone_Select_Block7	0x0007811e (JTAGPSWDL1)	0x0fffffff	NA	NA

Zone_Select_Block12	0x000781a2 (CSMPSWD1)	0x7d7fffff	0x000783a2 (CSMPSWD1)	0x2f7fffff
Zone_Select_Block12	0x000781be (JTAGPSWDL1)	0x1bffffff	NA	NA
Zone_Select_Block13	0x000781c2 (CSMPSWD1)	0x6f7fffff	0x000783c2 (CSMPSWD1)	0xcb7fffff
Zone_Select_Block13	0x000781de (JTAGPSWDL1)	0x17ffffff	NA	NA
Zone_Select_Block14	0x000781e2 (CSMPSWD1)	0x33ffffff	0x000783e2 (CSMPSWD1)	0x97ffffff
Zone_Select_Block14	0x000781fe (JTAGPSWDL1)	0xbd7fffff	NA	NA

6.2.2 Emulation Code Security Logic (ECSL)

In addition to the CSM, the emulation code security logic (ECSL) has been implemented using a 64-bit password (part of existing CSM password) for each zone to prevent unauthorized users from stepping through secure code. A halt in secure code while the emulator is connected will trip the ECSL and break the emulation connection. To allow emulation of secure code, while maintaining the CSM protection against secure memory reads, the user must write the correct 64-bit password into the CSMKEY (0/1) registers, which matches the password value stored in the USER OTP of that zone. This will disable the ECSL for the specific zone.

When initially debugging a device with the password locations in OTP programmed (secured), the emulator takes some time to take control of the CPU. During this time, the CPU will start running and may execute an instruction that performs an access to a protected ECSL area and if the CPU is halted when the program counter (PC) is pointing to a secure location, the ECSL will trip and cause the emulator connection to be broken.

The solution to this problem is:

- Use the Wait Boot Mode boot option. In this mode, the CPU will be in a loop and hence will not jump to the user application code. Using this BOOTMODE, the user can connect to CCS and debug the code.

6.2.3 CPU Secure Logic

The CPU Secure Logic (CPUSL) on this device prevents a hacker from reading the CPU registers in a watch window while code is running in a secure zone. All accesses to CPU registers when the PC points to a secure location are blocked by this logic. The only exception to this is read access to the PC. It is highly recommended not to write into the CPU register in this case, because proper code execution may get affected. If the CSM is unlocked using the CSM password match flow, the CPUSL logic also gets disabled.

6.2.4 Execute-Only Protection

To achieve a higher level of security on secure Flash sectors and RAM blocks that store critical user code (instruction opcodes), the Execute-Only protection feature is provided. When the Execute-Only protection is turned on for any secure Flash sector or RAM block, data reads to that Flash sector or RAM block are disallowed from any code (even from secure code). Execute-only protection for a Flash sector and RAM block can be turned on by configuring the bit field associated for that particular sector/RAM block in the zone's (which has ownership of that sector/RAM block) EXEONLYSECT and EXEONLYRAM register, respectively.

6.2.5 Password Lock

The password locations in USER OTP for each zone can be locked by programming the zone’s PSWDLOCK field with any value other than “1111” (0xF) at the PSWDLOCK location in OTP. Until the passwords of a zone are locked, password locations will not be secure and can be read from the debugger as well as code running from non-secure memory. This feature can be used by the user to avoid accidental locking of the zone while programming the Flash sectors during the software development phase. On a fresh device the value for password lock fields for all zones at the PSWDLOCK location in OTP will be “1111” which means the password for all zones will be unlocked.

Note

Password unlock only makes password locations non-secure. All other secure memories remains secure as per security settings. Since password locations are non-secure, anyone can read the password and make the zone un-secure by running through PMF, user must program PSWDLOCK locations to lock the password before sending the device in field.

6.2.6 JTAGLOCK

Sometimes you want to disable the JTAG access on a device to avoid any debug access to it. This can be done by using the JTAGLOCK feature on this device. You need to follow a two step process to enable the JTAGLOCK feature (both steps can be performed at the same time).

1. Program the JTAG passwords. This device has a 128-bit JTAG password that needs to be programmed in Z1 USER OTP of CPU1. JTAG passwords are split into two parts, JTAGPSWDH and JTAGPSWDL. JTAGPSWDH is part of the Z1 USER OTP header and JTAGPSWDL is part of the Z1 Zone Select Block (ZSB). What this means is program JTAGPSWDH once and change the JTAGPSWDL multiple times, if needed. The Code Composer Studio™ IDE has an integrated tool that you need to use to unlock the JTAGLOCK on the device.
2. After programming the JTAG passwords, you need to enable the JTAGLOCK module (JLM) by programming bit [3:0] of Z1OTP_JLM_ENABLE with any value other than 0xF. It is recommended to program all four bits with a value 0x0.

For more details on how to enable and disable the JTAGLOCK feature, refer to the *Enhancing Device Security by Using JTAGLOCK Feature Application Report*.

6.2.7 Link Pointer and Zone Select

For each of the two security zones, a dedicated OTP block exists on CPU1 that holds the configuration related to zone's security. The following are user programmable configurations:

- ZxOTP_LINKPOINTER1
- ZxOTP_LINKPOINTER2
- ZxOTP_LINKPOINTER3
- Z1OTP_JLM_ENABLE
- ZxOTP_GPREG1
- ZxOTP_GPREG2
- ZxOTP_GPREG3
- ZxOTP_GPREG4
- ZxOTP_PSWDLOCK
- ZxOTP_CRCLOCK
- Z1OTP_JTAGPSWDH
- Z1OTP_CMACKEY
- ZxOTP_CSMPSWD0
- ZxOTP_CSMPSWD1
- ZxOTP_CSMPSWD2
- ZxOTP_CSMPSWD3
- ZxOTP_GRABSECT1
- ZxOTP_GRABSECT2
- ZxOTP_GRABSECT3
- ZxOTP_GRABRAM1
- ZxOTP_GRABRAM2
- ZxOTP_GRABRAM3
- ZxOTP_EXEONLYSECT1
- ZxOTP_EXEONLYSECT2
- ZxOTP_EXEONLYRAM1
- Z1OTP_JTAGPSWDL

Since OTP cannot be erased, the following configurations are placed in zone select blocks of each zone's OTP Flash of both the banks:

- ZxOTP_CSMPSWD0
- ZxOTP_CSMPSWD1
- ZxOTP_CSMPSWD2
- ZxOTP_CSMPSWD3
- ZxOTP_GRABSECT1
- ZxOTP_GRABSECT2
- ZxOTP_GRABSECT3
- ZxOTP_GRABRAM1
- ZxOTP_GRABRAM2
- ZxOTP_GRABRAM3
- ZxOTP_EXEONLYSECT1
- ZxOTP_EXEONLYSECT2
- ZxOTP_EXEONLYRAM1
- Z1OTP_JTAGPSWDL

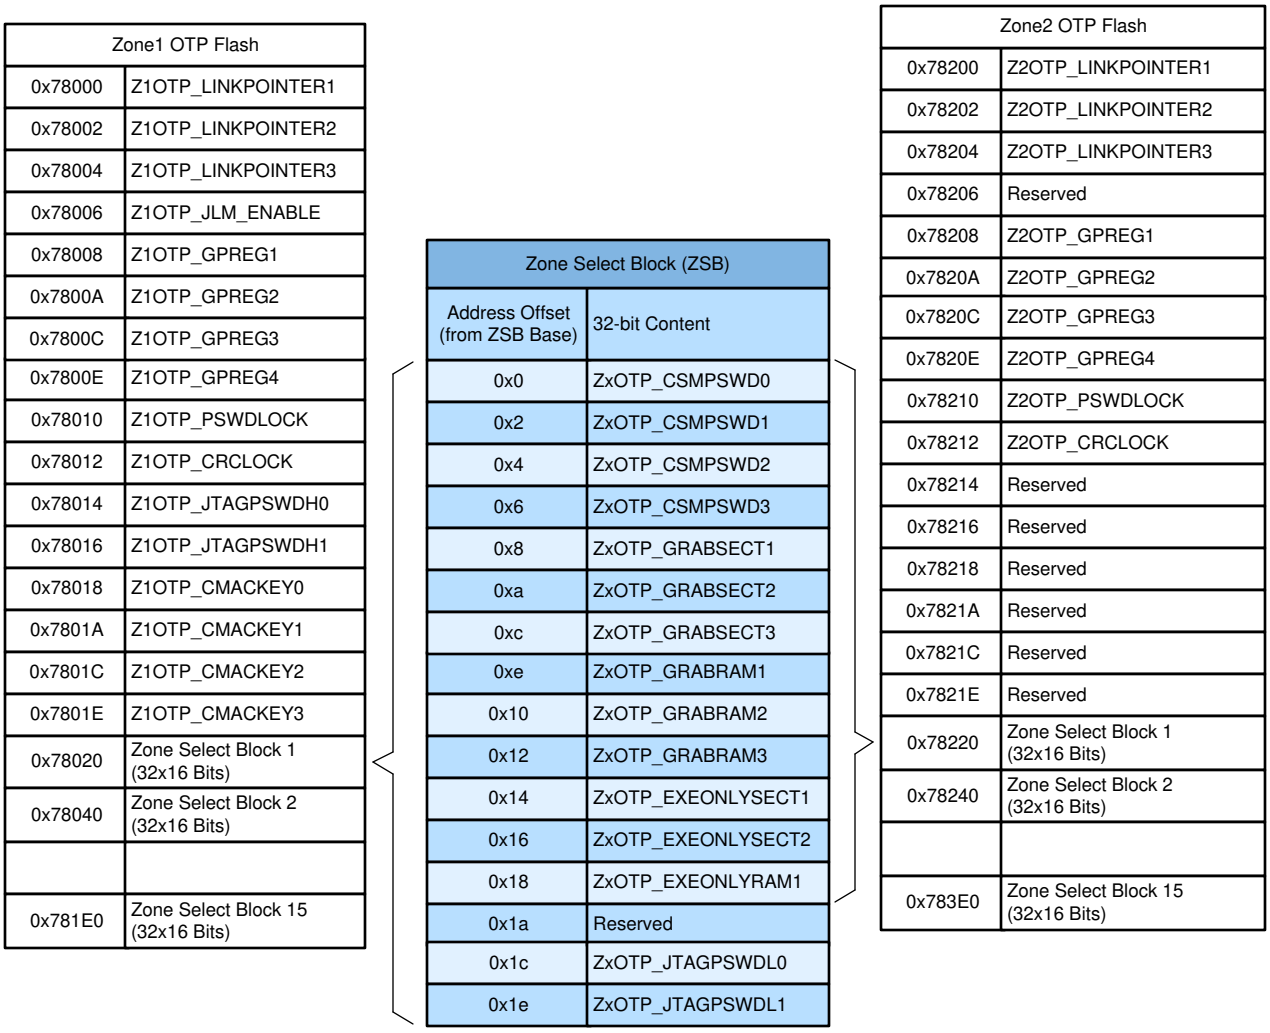
The location of the valid zone select block in OTP is decided based on the value of three 14-bit link pointers (Zx-LINKPOINTERx) programmed in the OTP of each zone. All OTP locations except link pointers and Z1OTP_JLM_ENABLE locations are protected with ECC. Since the link pointer locations are not protected with ECC, three link pointers are provided that need to be programmed with the same value. The final value of the link pointer is resolved in hardware, when a dummy read is done to all the link pointers, by comparing all the three values (bit-wise voting logic). Since in OTP, a '1' can be flipped by the user to '0' but '0' can not be flipped to '1' (no erase operation for OTP), the most significant bit position in the resolved link pointer which is '0', defines the valid base address for the zone select block. While generating the final link pointer value, if the bit pattern is not one of those listed in Figure 6-1, the final link pointer value becomes All_1 (0xFFFF_FFFF), which selects the Zone-Select-Block1 (also known as the default zone select block).

Zx-LINKPOINTER	Selected ZSB	Zone1 ZSB Address	Zone2 ZSB Address
32xxxxxxxxxxxxxxxx11111111111111	ZSB1	0x78020	0x78220
32xxxxxxxxxxxxxxxx11111111111110	ZSB2	0x78040	0x78240
32xxxxxxxxxxxxxxxx11111111111100	ZSB3	0x78060	0x78260
32xxxxxxxxxxxxxxxx11111111111000	ZSB4	0x78080	0x78280
32xxxxxxxxxxxxxxxx11111111110000	ZSB5	0x780a0	0x782a0
32xxxxxxxxxxxxxxxx11111111100000	ZSB6	0x780c0	0x782c0
32xxxxxxxxxxxxxxxx11111111000000	ZSB7	0x780e0	0x782e0
32xxxxxxxxxxxxxxxx11111110000000	ZSB8	0x78100	0x78300
32xxxxxxxxxxxxxxxx11111100000000	ZSB9	0x78120	0x78320
32xxxxxxxxxxxxxxxx11111000000000	ZSB10	0x78140	0x78340
32xxxxxxxxxxxxxxxx11110000000000	ZSB11	0x78160	0x78360
32xxxxxxxxxxxxxxxx11100000000000	ZSB12	0x78180	0x78380
32xxxxxxxxxxxxxxxx11000000000000	ZSB13	0x781a0	0x783a0
32xxxxxxxxxxxxxxxx10000000000000	ZSB14	0x781c0	0x783c0
32xxxxxxxxxxxxxxxx00000000000000	ZSB15	0x781e0	0x783e0

Figure 6-1. Storage of Zone-Select Bits in OTP

Note

Address locations for other security settings that are not part of Zone Select blocks can be programmed only once; therefore, you can program the blocks towards the end of the development cycle.



Zone1 OTP Flash	
0x78000	Z1OTP_LINKPOINTER1
0x78002	Z1OTP_LINKPOINTER2
0x78004	Z1OTP_LINKPOINTER3
0x78006	Z1OTP_JLM_ENABLE
0x78008	Z1OTP_GPREG1
0x7800A	Z1OTP_GPREG2
0x7800C	Z1OTP_GPREG3

0x7821C	Reserved
0x7821E	Reserved
0x78220	Zone Select Block 1 (32x16 Bits)
0x78240	Zone Select Block 2 (32x16 Bits)
0x783E0	Zone Select Block 15 (32x16 Bits)

Figure 6-2. Location of Zone-Select Block Based on Link-Pointer

CAUTION

USER OTP is ECC protected. You must program the ECC value while programming the security setting in USER OTP. Failing to program the correct ECC value causes the device to be blocked permanently and you have to replace the device.

6.2.8 C Code Example to Get Zone Select Block Addr for Zone1

```
unsigned long LinkPointer;
unsigned long *Zone1SelBlockPtr;
int Bitpos = 13;
int ZeroFound = 0;
// Read Z1-Linkpointer register of DCSM module.
LinkPointer = *(unsigned long *)0x5F000;
// Bits 31 to 15 as most-sigificant 0 are reserved LinkPointer options
LinkPointer = LinkPointer << 18;
while ((ZeroFound == 0) && (bitpos > -1))
{
if ((LinkPointer & 0x80000000) == 0)
{
ZeroFound = 1;
Zone1SelBlockPtr = (unsigned long *)(0x78000 + ((bitpos + 2)*32));
}
else
{
bitpos--;
LinkPointer = LinkPointer << 1;
}
}
if (ZeroFound == 0)
{
//Default in case there is no zero found.
Zone1SelBlockPtr = (unsigned long *)0x78020;
}
```

6.3 Flash and OTP Erase/Program

On this device, OTP as well as normal Flash, are secure resources. Each zone has its own dedicated CPU1 OTP, whereas normal Flash sectors can be allocated to any zone based on the value programmed in the GRABSECTx location in OTP. Each zone has its own 128bit CSM passwords. Read and write accesses are not allowed to resources assigned to Z1 by code running from memory allocated to Z2 and vice versa. Before programming any secure Flash sector the user must either unlock the zone to which that particular sector belongs using PMF or execute the Flash programming code from secure memory which belongs to the same zone. The same is the case for erasing any secure Flash sector. To program the security settings in CPU1 OTP Flash, the user must unlock the CSM of the respective zone. Unless the zone is unlocked, security settings in OTP Flash can not be updated. The OTP content cannot be erased.

A semaphore mechanism is provided to avoid the program/erase conflict between Z1 and Z2. A zone needs to grab this semaphore to successfully complete the erase/program operation on the secure Flash sectors allocated to that zone. A semaphore can be grabbed by a zone by writing the appropriate value in the SEM field of the FLSEM register. For further details of this field, see the register description.

6.4 Secure Copy Code

In some applications, the user may want to copy the code from secure Flash to secure RAM for better performance. The user cannot do this for EXEONLY Flash sectors because EXEONLY secure memories cannot be read from anywhere. TI provides specific “Secure Copy Code” library functions for each zone to enable the user to copy content from EXEONLY secure Flash sectors to EXEONLY RAM blocks. These functions do the copy-code operation in a highly secure environment and allow a copy to be performed only when the following conditions are met:

- The secure RAM block and the secure Flash sector belong to the same zone.
- Both the secure RAM block and the secure Flash sector have EXEONLY protection enabled.

For further usage of these library functions, see the device-specific Boot ROM documentation.

6.5 SecureCRC

Since reads from EXEONLY memories are not allowed, you cannot calculate the CRC on content in EXEONLY memories using the CRC engine available on this device (for example, VCRC, GCRC) or software. In some safety-critical applications, the user may have to calculate the CRC even on these memories. To enable this without compromising on security, TI provides specific “SecureCRC” library functions for each zone. These functions do the CRC calculation in highly secure environment and allow a CRC calculation to be performed only when the following conditions are met:

- The source address should be modulo the number of words (based on length_id) for which the CRC needs to be calculated.
- The destination address should belong to the same zone as the source address.

For further usage of these library functions, see the device-specific Boot ROM documentation.

Note

You must disable all the interrupts before calling the secure functions in ROM. If there is a vector fetch during secure function execution, the CPU gets reset immediately.

Disclaimer: The Code Security Module (CSM) included on this device was designed to password protect the data stored in the associated memory and is warranted by Texas Instruments (TI), in accordance with its standard terms and conditions, to conform to TI's published specifications for the warranty period applicable for this device. TI DOES NOT, HOWEVER, WARRANT OR REPRESENT THAT THE CSM CANNOT BE COMPROMISED OR BREACHED OR THAT THE DATA STORED IN THE ASSOCIATED MEMORY CANNOT BE ACCESSED THROUGH OTHER MEANS. MOREOVER, EXCEPT AS SET FORTH ABOVE, TI MAKES NO WARRANTIES OR REPRESENTATIONS CONCERNING THE CSM OR OPERATION OF THIS DEVICE, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL TI BE LIABLE FOR ANY CONSEQUENTIAL, SPECIAL, INDIRECT, INCIDENTAL, OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING IN ANY WAY OUT OF YOUR USE OF THE CSM OR THIS DEVICE, WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. EXCLUDED DAMAGES INCLUDE, BUT ARE NOT LIMITED TO LOSS OF DATA, LOSS OF GOODWILL, LOSS OF USE OR INTERRUPTION OF BUSINESS OR OTHER ECONOMIC LOSS.

6.6 CSM Impact on Other On-Chip Resources

On this device, some of the memories are not secure. To avoid any potential hacking when the device is in the default state (post reset), accesses (all types) to all memories (secure as well as non-secure, except BOOT-ROM and OTP) are disabled until proper security initialization is done. This means that after reset none of the memory resources except BOOT_ROM and OTP is accessible to the user.

The following steps are required by CPU1 after reset (any type of reset) to initialize the security on device.

Security Initialization

- Dummy Read to address location of SECDC (0x703F0, TI-reserved register) in TI OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER1 in Z1 OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER2 in Z1 OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER3 in Z1 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER1 in Z2 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER2 in Z2 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER3 in Z2 OTP
- Dummy Read to address location Z1OTP_JLM_ENABLE in Z1 OTP
- Dummy Read to address location of Z1OTP_GPREG1, Z1OTP_GPREG2, Z1OTP_GPREG3, Z1OTP_GPREG4 in Z1 OTP
- Dummy Read to address location of Z1OTP_PSWDLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP_CRCLOCK in Z1 OTP

- Dummy Read to address location of Z1OTP_JTAGPSWDH0, Z1OTP_JTAGPSWDH1 in Z1 OTP
- Dummy Read to address location of Z2OTP_GPREG1, Z2OTP_GPREG2, Z2OTP_GPREG3, Z2OTP_GPREG4 in Z2 OTP
- Dummy Read to address location of Z2OTP_PSWDLOCK in Z2 OTP
- Dummy Read to address location of Z2OTP_CRCLOCK in Z2 OTP
- Read to memory map register of Z1_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of Z1OTP_GRABSECT1, Z1OTP_GRABSECT2, Z1OTP_GRABSECT3 in Z1 OTP
- Dummy read to address location of Z1OTP_GRABRAM1, Z1OTP_GRABRAM2, Z1OTP_GRABRAM3 in Z1 OTP
- Dummy read to address location of Z1OTP_EXEONLYSECT1, Z1OTP_EXEONLYSECT2 in Z1 OTP
- Dummy read to address location of Z1OTP_EXEONLYRAM1 in Z1 OTP
- Dummy Read to address location of Z1OTP_JTAGPSWDL0, Z1OTP_JTAGPSWDL1 in Z1 OTP
- Read to memory map register of Z2_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of Z2OTP_GRABSECT1, Z2OTP_GRABSECT2, Z2OTP_GRABSECT3 in Z2 OTP
- Dummy read to address location of Z2OTP_GRABRAM1, Z2OTP_GRABRAM2, Z2OTP_GRABRAM3 in Z2 OTP
- Dummy read to address location of Z2OTP_EXEONLYSECT1, Z2OTP_EXEONLYSECT2 in Z2 OTP
- Dummy read to address location of Z2OTP_EXEONLYRAM1 in Z2 OTP

Note

Security Initialization is done by CPU1 BOOTROM code on all the resets (as part of device initialization) which assert CPU1 SYSRSn. This will not be part of user application code

The order of initialization matters hence if a memory watch window with the USER OTP address is opened in the debugger (CCS) the security initialization could occur in an incorrect order, locking the device down. To avoid this, user should not keep a memory window with USER OTP address opened in the debugger(CCS) when performing a reset.

6.7 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project. However, security is needed once a robust code is developed for a zone. Before such a code is programmed in the Flash memory, a CSM password should be chosen to secure the zone. Once a CSM password is in place for a zone, the zone is secured (programming a password at the appropriate locations and either performing a device reset or setting the FORCESEC bit (Zx_CR.31) is the action that secures the device). From that time on, access to debug the contents of secure memory by any means (via JTAG, code running off external/on-chip memory, and so forth) requires a valid password. A password is not needed to run the code out of secure memory (such as in a typical end-user usage); however, access to secure memory contents for debug purposes, requires a password.

6.7.1 Environments That Require Security Unlocking

The following are the typical situations under which unsecuring the zone can be required:

- Code development using debuggers (such as Code Composer Studio). This is the most common environment during the design phase of a product.
- Flash programming using TI's Flash utilities such as Code Composer Studio On-Chip Flash Programmer plug-in or the Uniflash tool. Flash programming is common during code development and testing. Once the user supplies the necessary password, the Flash utilities disable the security logic before attempting to program the Flash. In custom programming solutions that use the Flash API supplied by TI, unlocking the CSM can be avoided by executing the Flash programming algorithms from secure memory.
- Custom environment defined by the application
  In addition to the above, access to secure memory contents can be required in situations such as:
  - Using the on-chip bootloader to load code or data into secure SARAM or to erase and program the Flash.
  - Executing code from on-chip unsecure memory and requiring access to secure memory for the lookup table. This is not a suggested operating condition as supplying the password from external code could compromise code security.

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. Figure 6-3 explains the sequence of operation that is required every time the user attempts to unsecure a particular zone. A code example is listed for clarity.

6.7.2 CSM Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes (32-bit writes) to CSMKEY(0/1/2/3) registers. Figure 6-3 shows how PMF helps to initialize the security logic registers and disable security logic.

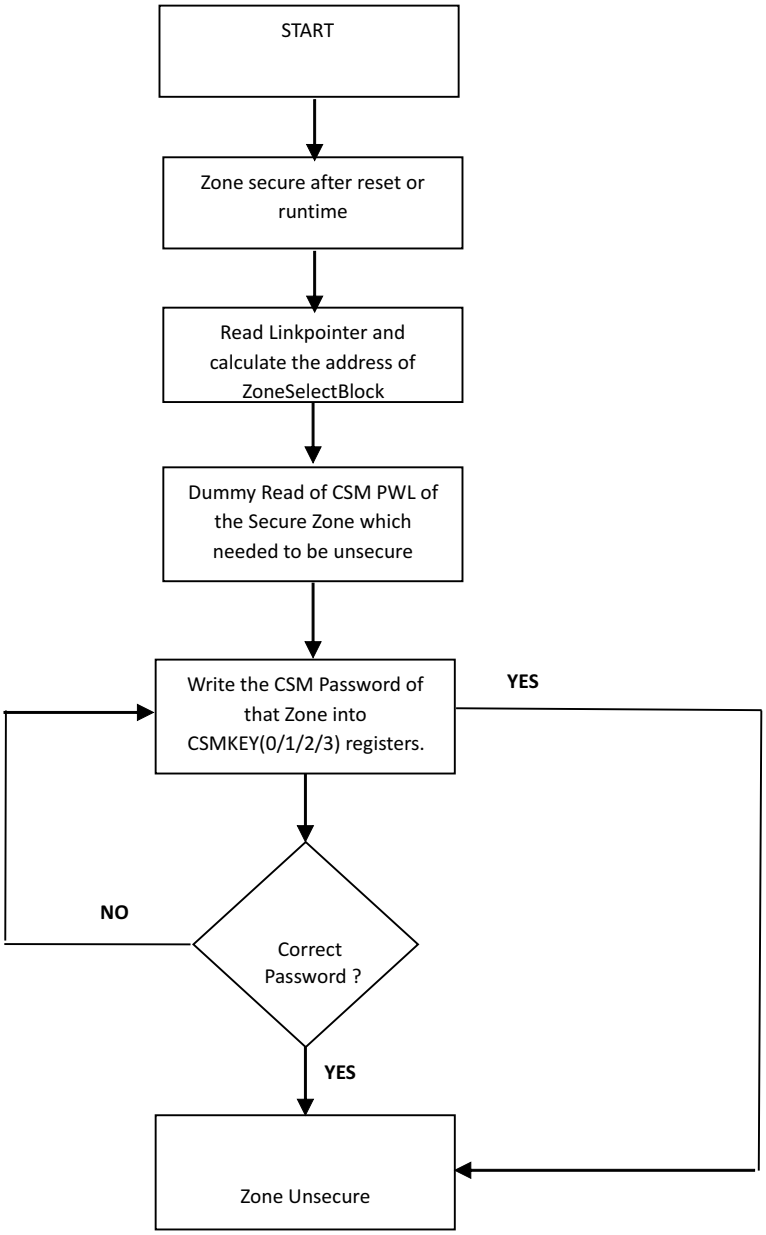

Figure 6-3. CSM Password Match Flow (PMF)

6.7.3 C Code Example to Unsecure C28x Zone1

```
volatile long int *CSM = (volatile long int *)5F010; //CSM register file volatile
long int *CSMPWL = (volatile long int *)0x78020; //CSM Password location (assuming default Zone
select block)
volatile int tmp;
int I;
// Read the 128-bits of the CSM password locations (PWL)
//
for (I=0;I<4; I++) tmp = *CSMPWL++;
// Write the 128-bit password to the CSMKEY registers
// If this password matches that stored in the
// CSLPWL then the CSM will become unsecure. If it does not
// match, then the zone will remain secure.
// An example password of: // 0x1111222233334444555566667777888 is used.
*CSM++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*CSM++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
*CSM++ = 0x66665555; // Register Z1_CSMKEY2 at 0x5F014
*CSM++ = 0x88887777; // Register Z1_CSMKEY3 at 0x5F016
```

6.7.4 C Code Example to Resecure C28x Zone1

```
volatile int *Z1_CR = 0x5F019; //CSMSCR register
//Set FORCESEC bit
*Z1_CR = 0x8000;
```

Note

User must use the FORCESEC feature to resecure the zone from same subsystem that has unlocked the zone. For example, if CM subsystem has unlocked the Zone1 by entering the CSM password in CSMKEYx ,then only CM subsystem should resecure the Zone1 using FORCESEC feature.

6.7.5 Environments That Require ECSL Unlocking

The following are the typical situations under which unsecuring can be required:

- The user develops some main IP, and then outsources peripheral functions to a subcontractor who must be able to run the user code during debug and may halt while main IP code is running. If ECSL is not unlocked, then Code Composer Studio connections will get disconnected, which can be inconvenient for the user. Note that unlocking ECSL does not enable access to secure code but only avoids disconnection of CCS (JTAG).

6.7.6 ECSL Password Match Flow

A password match flow (PMF) is essentially a sequence of eight dummy reads from password locations (PWL) followed by two writes to KEY registers. Figure 6-4 shows how the PMF helps to initialize the security logic registers and disable security logic.

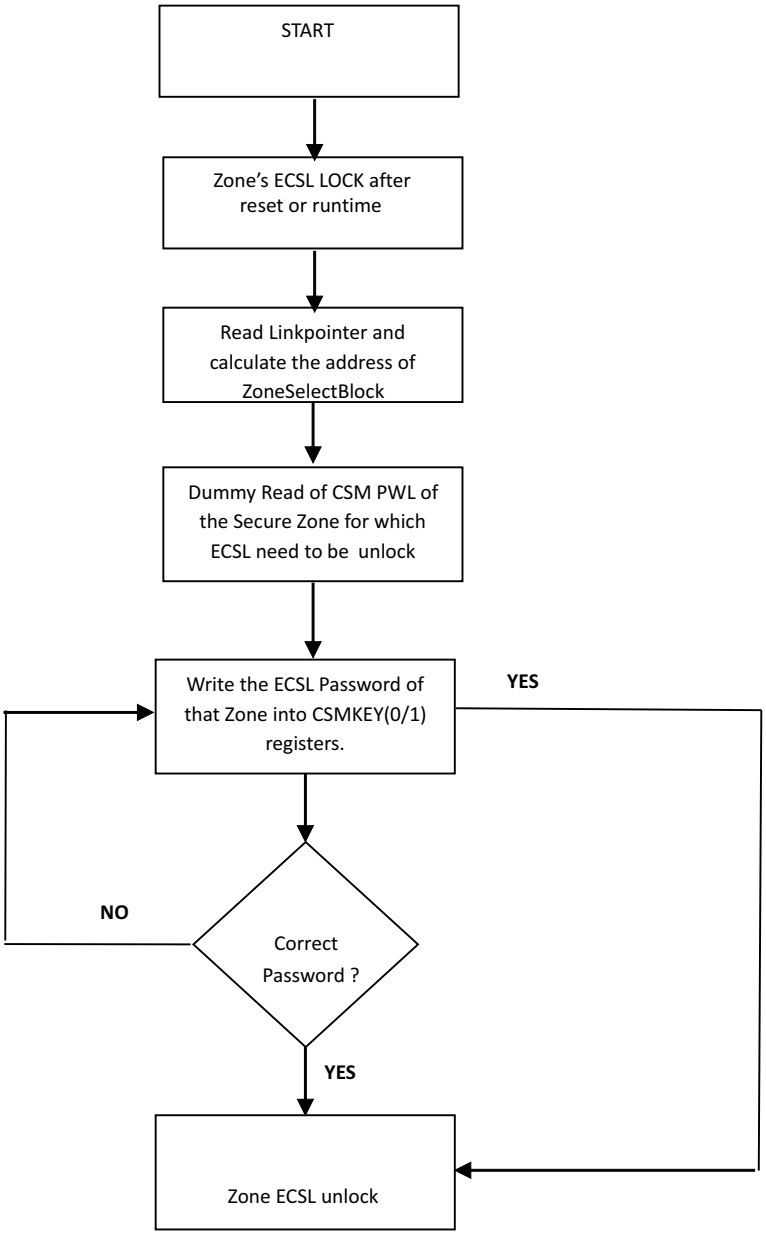

Figure 6-4. ECSL Password Match Flow (PMF)

6.7.7 ECSL Disable Considerations for any Zone

A zone with ECSL enabled should have a predetermined ECSL password stored in the ECSL password locations in Flash (same as lower 64 bits of CSM passwords). The following are steps to disable the ECSL for any particular zone:

- Perform a dummy read of CSM password locations of that Zone.
- Write the password into the CSMKEY0/1 registers, corresponding to that Zone.
- If the password is correct, the ECSL gets disabled; otherwise, it stays enabled.

6.7.7.1 C Code Example to Disable ECSL for C28x-Zone1

```
volatile long int *ECSL = (volatile int *)0x5F010; //ECSL register file
volatile long int *ECSLPWL = (volatile int *)0x78028; //ECSL Password location (assuming default
Zone sel block)
volatile int tmp;
int I;
// Read the 64-bits of the password locations (PWL).
for (I=0;I<2; I++) tmp = *ECSLPWL++;
// Write the 64-bit password to the CSMKEYx registers
// If this password matches that stored in the
// CSMPWL then ECSL will get disable. If it does not
// match, then the zone will remain secure.
// An example password of: // 0x1111222233334444 is used.
*ECSL++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*ECSL++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
```

Note

If the CM subsystem is out of reset when ECSL is unlocked by any of the subsystem, one must reset the CM before trying to lock the ECSL again. Unless CM is reset, ECSL can not be locked again by entering the incorrect KEY or using the FORCESEC.

6.7.8 Device Unique ID

CPU1 TI OTP contains a 256-bit value that is made up of both random and sequential parts. This value can be used as a seed for code encryption. The starting address of the value is 0x7020C. The first 192 bits are random, the next 32 bits are sequential, and the last 32 bits are a checksum value.

6.8 Software

6.8.1 DCSM Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dcsm

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

6.8.1.1 Empty DCSM Tool Example

FILE: dcsm_security_tool.c This example is an empty project setup for DCSM Tool and Driverlib development. For guidance refer to: *C2000 DCSM Security Tool*

6.8.1.2 DCSM Memory Access control by master CPU1 - C28X_CM

FILE: dcsm_ex1_cpu_access_control.c

This example demonstrates how to configure the 1st Zone Select Block in the OTP to allocate CM's C0RAM to zone 1 & CM's C1RAM to zone 2, later accessed by CM. Zone1 | Zone2 | CM's C0RAM | CM's C1RAM | In this example, zoning of memories is done by the OTP programming whose values are configured in dcsm_ex1_f2838x_dcsm_zxotp.asm while the securing functionalities are done through this file. It demonstrates how to control the access of the memories which would later be accessed by CM. This would even do a dummy read of the password needed by CM to unsecure the memory. The communication between the 2 CPUs are done using IPC (Inter process communication) through a synch function. This enables the CPU Core to wait until the expected task is completed on the other core.

External Connections

- None.

Watch Variables

- *result* - Status of Memory Access control by CPU1
- *set_error* - Count of errors occurring during the execution of the example.

Before running the example, the below configuration is expected to be done through the dcsm_ex1_f2838x_dcsm_zxotp.asm :

- Allocate CM's C0RAM to zone 1 , C1RAM to zone 2 ZSBx_Z1_GRABRAM2R 0x0AAAAA09 ZSBx_Z2_GRABRAM2R 0x0AAAAA06
- Password of zone 1 is 0xFFFFFFFF4D7FFFFFFFFFFFFFFFFFFFFF
- Password of zone 2 is 0xFFFFFFFF1F7FFFFFFFFFFFFFFFFFFFFF

6.8.1.3 DCSM Memory Access by CPU2 - C28X_DUAL

FILE: dcsm_ex1_cpu2_memory_access.c

This example demonstrates how the access of the memory is affected when the memories are secured by CPU1. CPU1 allocate CPU2's LS4-LS5 to zone 1 & CPU2's LS6-LS7 to zone 2 using the 1st Zone Select Block. Zone1 | Zone2 | CPU2's LS4-LS5 | CPU2's LS6-LS7 | It writes some data in the zones and checks after the CPU1 does a memory locking and matches with the data set . Further, once the CPU2 unlocks the memories, it matches with the data set written before CPU1 lock. Ideally after locking, zone1 should not be readable(or reads a 0 value) and zone2 that is not secured matches the written data set. It demonstrates how to lock and and unlock zone by showing where to put the password and how to check if it is secured or unsecured.

The communication between the 2 CPUs are handled using IPC (Inter process communication) through a synch function. This enables the CPU Core to wait until the expected task is completed on the other core.

External Connections

- None.

Watch Variables

- *result* - Status of CPU2's secure memory access

- *set_error*, error_not_locked ,error_not_unlocked ,error1 - Count of errors occurring during the execution of the example.
- *Zone1_Locked_Array* - Array demonstrating secured memory
- *Unsecure_mem_Array* - Array demonstrating Unsecured memory

6.8.1.4 DCSM Memory Access control by CPU1 - C28X_DUAL

FILE: dcsm_ex1_cpu1_access_control.c

This example demonstrates how to configure the 1st Zone Select Block in the OTP needed to allocate CPU2's LS4-LS5 to zone 1 & CPU2's LS6-LS7 to zone 2, later accessed by CPU2. Zone1 | Zone2 | CPU2's LS4-LS5 | CPU2's LS6-LS7 | In this example, zoning of memories is done by the OTP programming whose values are configured in dcsm_ex1_f2838x_dcsm_zxotp.asm while the securing functionalities are done through this file. It demonstrates how to control the access of the memories which would later be accessed by CPU2. This would even do a dummy read of the password needed by CPU2 to unsecure the memory. The communication between the 2 CPUs are done using IPC (Inter process communication) through a sync function. This enables the CPU Core to wait until the expected task is completed on the other core.

External Connections

- None.

Watch Variables

- *result* - Status of Memory Access control by CPU1
- *set_error* - Count of errors occurring during the execution of the example.

Before running the example, the below configuration is expected to be done through the dcsm_ex1_f2838x_dcsm_zxotp.asm :

- Allocate CPU2's LS4-LS5 to zone 1 , LS6-LS7 to zone 2 ZSBx_Z1_GRABRAM3R 0x0000A500 ZSBx_Z2_GRABRAM3R 0x00005A00
- Password of zone 1 is 0xFFFFFFFF4D7FFFFFFFFFFFFFFFFFFFF
- Password of zone 2 is 0xFFFFFFFF1F7FFFFFFFFFFFFFFFFFFFF

6.8.1.5 DCSM Memory partitioning Example

FILE: dcsm_ex1_secure_memory_partition.c

This example demonstrates how to configure and use DCSM. It configures the 1st Zone Select Block in the OTP to change the zone passwords and allocates LS0-LS3 to zone 1 & LS4-LS7 to zone 2. Zone1 | Zone2 | LS0-LS3 | LS4-LS7 | In this example, zoning of memories is done by the OTP programming whose values are configured in dcsm_ex1_f2838x_dcsm_zxotp.asm while the securing functionalities are done through this file. It writes some data in the zones and checks before locking and after locking and matches with the data set . Ideally after locking zone1, the data set stored in zone1 should not be readable(or reads a 0 value) and zone2 that is not secured matches the written data set. It demonstrates how to lock and and unlock zones by showing where to put the password and how to check if it is secured or unsecured.

External Connections

- None.

Watch Variables

- *result* - Status of Secure memory partitioning done through OTP programming.
- *set_error*, error_not_locked ,error_not_unlocked ,error1 - Count of errors occurring during the execution of the example.
- *Zone1_Locked_Array* - Array demonstrating secured memory
- *Unsecure_mem_Array* - Array demonstrating Unsecured memory

Before running the example, the below configuration is expected to be done through the dcsm_ex1_f2838x_dcsm_zxotp.asm :

- Allocate LS0-LS3 to zone 1 , LS4-LS7 to zone 2 ZSBx_Z1_GRABRAM1R 0x000AAA55 ZSBx_Z2_GRABRAM1R 0x000A55AA
- Password of zone 1 is 0xFFFFFFFF4D7FFFFFFFFFFFFFFFFFFFF

- Password of zone 2 is 0xFFFFFFFF1F7FFFFFFFFFFFFFFFFFFFFF

DCSM_unlockZone*CSM function should not be called in an actual application, should only be used for once to program the OTP memory. Ensure flash data cache is disabled before calling this function.

6.8.1.6 DCSM Memory Access by CM - C28X_CM

FILE: dcsm_ex1_cm_memory_access.c

This example demonstrates how the access of the memory is affected when the memories are secured by CPU1. CPU1 allocate CM's C0RAM to zone 1 & CM's C1RAM to zone 2 using the 1st Zone Select Block. Zone1 | Zone2 | CM's C0RAM | CM's C1RAM | It writes some data in the zones and checks after the CPU1 does a memory locking and matches with the data set . Further, once the CM unlocks the memories, it matches with the data set written before CPU1 lock. Ideally after locking, zone1 should not be readable(or reads a 0 value) and zone2 that is not secured matches the written data set. It demonstrates how to lock and and unlock zone by showing where to put the password and how to check if it is secured or unsecured.

The communication between the 2 CPUs are handled using IPC (Inter process communication) through a sync function. This enables the CPU Core to wait until the expected task is completed on the other core.

External Connections

- None.

Watch Variables

- *result* - Status of CM's secure memory access
- *set_error*, error_not_locked ,error_not_unlocked ,error1 - Count of errors occurring during the execution of the example.
- *Zone1_Locked_Array* - Array demonstrating secured memory
- *Unsecure_mem_Array* - Array demonstrating Unsecured memory

6.9 DCSM Registers

This section describes the various DCSM Registers.

Note

Except for the SECERRSTAT, SECERRCLR, and SECERRFRC registers, all other registers (non-OTP space) are mapped on all three subsystems. For the CM subsystem, a x8 offset needs to be used.

6.9.1 DCSM Base Address Table (C28)

Table 6-4. DCSM Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
DcsmZ1Regs	DCSM_Z1_REGS	DCSM_Z1_BASE	0x0005_F000	YES	YES	-	-	YES
DcsmZ2Regs	DCSM_Z2_REGS	DCSM_Z2_BASE	0x0005_F080	YES	YES	-	-	YES

Complex bit access types are encoded to fit into small table cells. Table 6-7 shows the codes that are used for access types in this section.

Table 6-7. DCSM_Z1_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write

Table 6-7. DCSM_Z1_REGS Access Type Codes (continued)

Access Type	Code	Description
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.9.3.1 Z1_LINKPOINTER Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = FFFFC000h]

Z1_LINKPOINTER is shown in Figure 6-5 and described in Table 6-8.

Return to the Summary Table.

54h	2Ah	Z2_EXEONLYRAM1R	Zone 2 Execute Only RAM Status Register 1		Go

Complex bit access types are encoded to fit into small table cells. Table 6-39 shows the codes that are used for access types in this section.

Table 6-39. DCSM_Z2_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 6-39. DCSM_Z2_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.9.4.1 Z2_LINKPOINTER Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = FFFFC000h]

Z2_LINKPOINTER is shown in Figure 6-35 and described in Table 6-40.

Return to the Summary Table.

8	EXEONLY_RAM8	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[8] when a read is issued to Z2_EXEONLYRAM address location in OTP. 0 : Execute-Only protection is enabled for CPU1 D0 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 D0 RAM (only if it's allocated to Zone2) Reset type: SYSRSn
7	EXEONLY_RAM7	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[7] when a read is issued to Z2_EXEONLYRAM address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS7 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS7 RAM (only if it's allocated to Zone2) Reset type: SYSRSn
6	EXEONLY_RAM6	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[6] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS6 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS6 RAM (only if it's allocated to Zone2) Reset type: SYSRSn
5	EXEONLY_RAM5	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[5] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS5 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS5 RAM (only if it's allocated to Zone2) Reset type: SYSRSn
4	EXEONLY_RAM4	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[4] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS4 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS4 RAM (only if it's allocated to Zone2) Reset type: SYSRSn
3	EXEONLY_RAM3	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[3] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS3 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS3 RAM (only if it's allocated to Zone2) Reset type: SYSRSn
2	EXEONLY_RAM2	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[2] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS2 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS2 RAM (only if it's allocated to Zone2) Reset type: SYSRSn

Table 6-60. Z2_EXEONLYRAM1R Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	EXEONLY_RAM1	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[1] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS1 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS1 RAM (only if it's allocated to Zone2) Reset type: SYSRSn
0	EXEONLY_RAM0	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[0] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS0 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS0 RAM (only if it's allocated to Zone2) Reset type: SYSRSn

6.9.5 DCSM_COMMON_REGS Registers

Table 6-61 lists the memory-mapped registers for the DCSM_COMMON_REGS registers. All register offset addresses not listed in Table 6-61 should be considered as reserved locations and the register contents should not be modified.

Table 6-61. DCSM_COMMON_REGS Registers

Offset (x8)	Offset (x16)	Acronym	Register Name	Write Protection	Section
0h	0h	FLSEM	Flash Wrapper Semaphore Register	EALLOW	Go
10h	8h	SECTSTAT1	Flash Sectors Status Register 1		Go
14h	Ah	SECTSTAT2	Flash Sectors Status Register 2		Go
18h	Ch	SECTSTAT3	Flash Sectors Status Register 3		Go
20h	10h	RAMSTAT1	RAM Status Register 1		Go
24h	12h	RAMSTAT2	RAM Status Register 2		Go
28h	14h	RAMSTAT3	RAM Status Register 3		Go
30h	18h	SECERRSTAT	Security Error Status Register		Go
34h	1Ah	SECERRCLR	Security Error Clear Register		Go
38h	1Ch	SECERRFRC	Security Error Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 6-62 shows the codes that are used for access types in this section.

Table 6-62. DCSM_COMMON_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.9.5.1 FLSEM Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 0h]

FLSEM is shown in Figure 6-56 and described in Table 6-63.

Return to the Summary Table.

Table 6-72. SECERRFRC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	In order to write to the ERR bits, 0x5a5a must be written to these key bits at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every write to ERR. Reads will return 0. Reset type: N/A
15-1	RESERVED	R	0h	Reserved
0	ERR	R-0/W1S	0h	A write of '1', along with the proper KEY, sets the SECERRSTST.ERR bit. Write of '0' is ignored. This bit always reads back '0'. Reset type: N/A

6.9.6 DCSM_Z1_OTP Registers

Table 6-73 lists the memory-mapped registers for the DCSM_Z1_OTP registers. All register offset addresses not listed in Table 6-73 should be considered as reserved locations and the register contents should not be modified.

Table 6-73. DCSM_Z1_OTP Registers

Offset (x8)	Offset (x16)	Acronym	Register Name	Write Protection	Section
0h	0h	Z1OTP_LINKPOINTER1	Zone 1 Link Pointer1		Go
4h	2h	Z1OTP_LINKPOINTER2	Zone 1 Link Pointer2		Go
8h	4h	Z1OTP_LINKPOINTER3	Zone 1 Link Pointer3		Go
Ch	6h	Z1OTP_JLM_ENABLE	Zone 1 JTAGLOCK Enable Register		Go
10h	8h	Z1OTP_GPREG1	Zone 1 General Purpose Register 1		Go
14h	Ah	Z1OTP_GPREG2	Zone 1 General Purpose Register 2		Go
18h	Ch	Z1OTP_GPREG3	Zone 1 General Purpose Register 3		Go
1Ch	Eh	Z1OTP_GPREG4	Zone 1 General Purpose Register 4		Go
20h	10h	Z1OTP_PSWDLOCK	Secure Password Lock		Go
24h	12h	Z1OTP_CRCLOCK	Secure CRC Lock		Go
28h	14h	Z1OTP_JTAGPSWDH0	JTAG Lock Permanent Password 0		Go
2Ch	16h	Z1OTP_JTAGPSWDH1	JTAG Lock Permanent Password 1		Go
30h	18h	Z1OTP_CMACKEY0	Secure Boot CMAC Key 0		Go
34h	1Ah	Z1OTP_CMACKEY1	Secure Boot CMAC Key 1		Go
38h	1Ch	Z1OTP_CMACKEY2	Secure Boot CMAC Key 2		Go
3Ch	1Eh	Z1OTP_CMACKEY3	Secure Boot CMAC Key 3		Go

Complex bit access types are encoded to fit into small table cells. Table 6-74 shows the codes that are used for access types in this section.

Table 6-74. DCSM_Z1_OTP Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.9.6.1 Z1OTP_LINKPOINTER1 Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = FFFFFFFFh]

Chapter 7

Background CRC-32 (BGCRC)

The Background CRC (BGCRC) module that helps to identify memory faults and corruption, is discussed in this chapter.

7.1 Introduction

The Background CRC (BGCRC) module computes a CRC-32 on a configurable block of memory. It accomplishes this by fetching the specified block of memory during idle cycles (when the CPU, CLA, or DMA is not accessing the memory block). The calculated CRC-32 value is compared against a golden CRC-32 value to indicate a pass or fail. In essence, the BGCRC helps identify memory faults and corruption. There are two BGCRC modules (CPU_CRC and CLA_CRC) per CPU subsystem. The two BGCRC modules differ only in the memories they test.

7.1.1 BGCRC Related Collateral

Getting Started Materials

- *CRC Engines in C2000 Devices Application Report*

7.1.2 Features

The BGCRC module has the following features:

- One cycle CRC-32 computation on 32 bits of data
- No CPU bandwidth impact for zero wait state memory
- Minimal CPU bandwidth impact for non-zero wait state memory
- Dual operation modes (CRC-32 mode and scrub mode)
- Watchdog timer to time CRC-32 completion
- Ability to pause and resume CRC-32 computation

7.1.3 Block Diagram

Figure 7-1 shows the BGCRC block diagram.

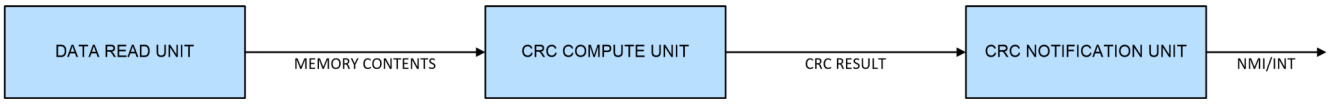

Figure 7-1. BGCRC Block Diagram

7.1.4 Memory Wait States and Memory Map

Figure 7-2 shows the memory map of the BGCRC module. M0, M1, D[x]RAM, MSGRAM, LS[x]RAM, and GS[x]RAM are all zero wait-state memories. BGCRC accesses these memories with minimal impact on normal program operation. For instance, if a BGCRC access is being made to a zero wait-state memory in the current cycle, the earliest the operating program can make access to the same memory location is in the next cycle. Similarly for the non-zero wait state memories SECROM, DATAROM and BOOTROM, the worst case delay for functional access after a BGCRC access is the wait-state amount.

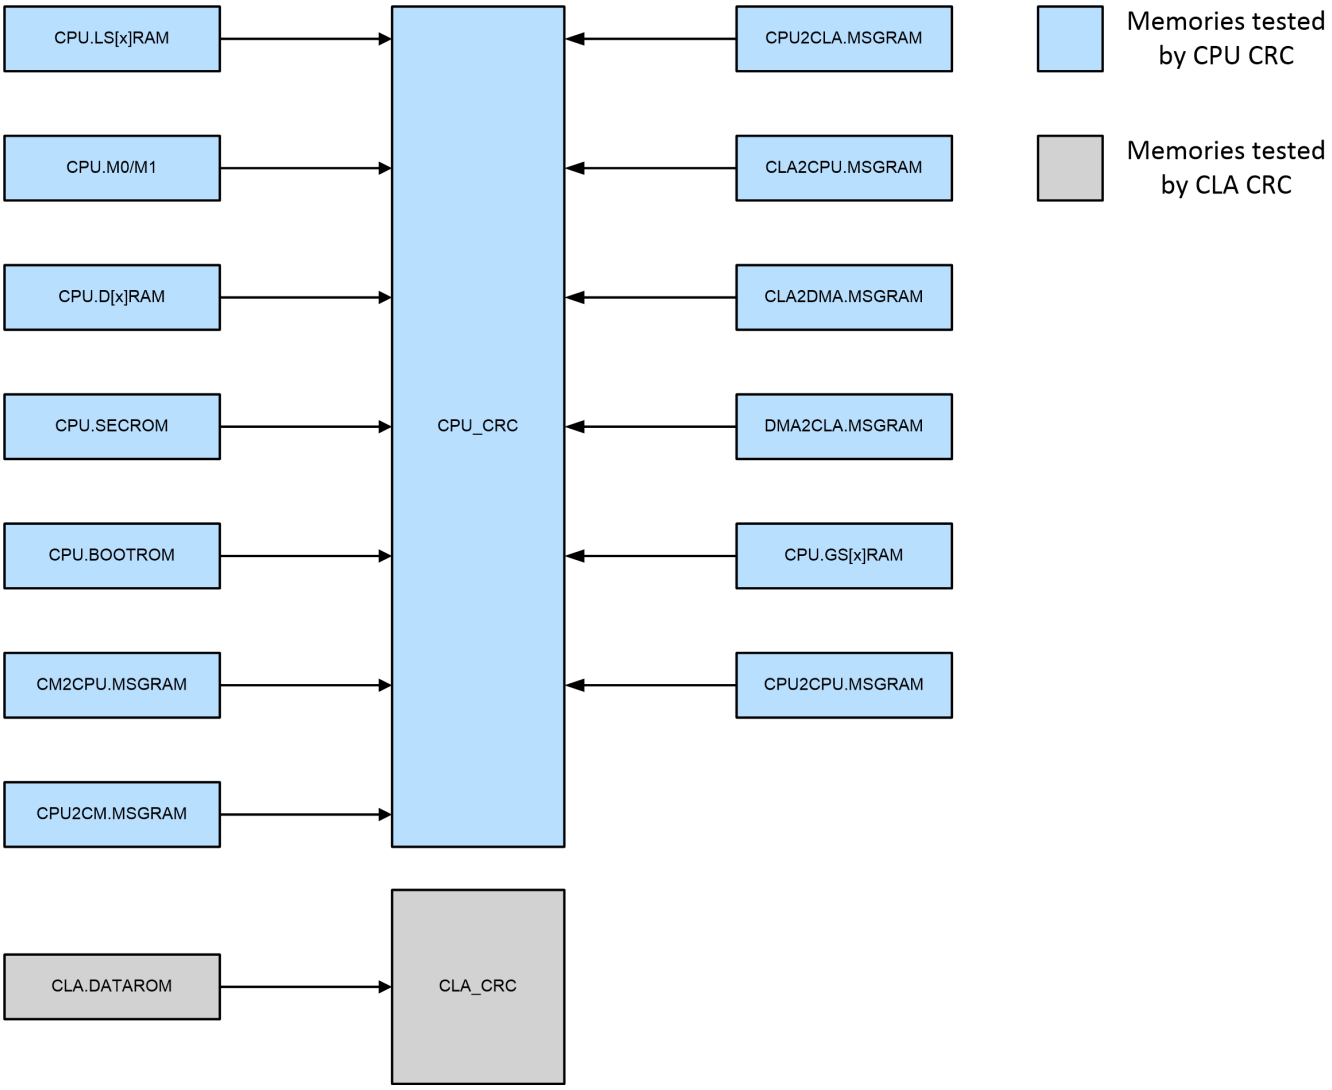

Figure 7-2. BGCRC Memory Map

7.2 Functional Description

The CRC-32 calculation of the BGCRC module can be kicked off by configuring the register BGCRC_EN.START to 1010. Once started, the module performs the background memory checks without CPU or CLA intervention. However, on completion of the CRC-32 calculation or in the event of a failure, the CPU or CLA is notified through an interrupt and task, respectively.

As highlighted in the overview, there are two BGCRC modules per CPU subsystem. CPU_CRC that is configurable by the CPU can only generate an interrupt. CLA_CRC however, can be configured by both the CPU and CLA and can generate an interrupt to the CPU or task for the CLA.

7.2.1 Data Read Unit

Once the CRC-32 calculation is started, the BGCRC module continuously reads data from memory as a background process. These reads happen during the idle times (when the CPU, CLA or DMA is not accessing the memory block) and so does not impact functional access. The data read unit only reads data if there is no pending functional access. The data read unit begins operation by reading a block of data BGCRC_CTRL2.BLOCK_SIZE from address BGCRC_START_ADDR. Note that BGCRC_START_ADDR must be 0x80 word aligned. For a non-0x80 word aligned BGCRC_START_ADDR, the LSB bits are zeroed out to get a 0x80 word aligned BGCRC_START_ADDR. For instance, if the programmed BGCRC_START_ADDR = 0x1AF3, the internal 0x80 word aligned start address is 0x1A80.

When the data read unit reads a block of data, ECC and parity are checked. Any ECC or parity errors that occur during the read is indicated by setting the respective NMI and generating an interrupt if configured as so. The BGCRC module, however, does not write back the corrected memory contents on the occurrence of a correctable ECC error. Writing back the corrected values should be handled by software.

7.2.2 CRC-32 Compute Unit

After the data read unit reads a block of data, the data read unit feeds this data to the CRC-32 compute unit. This unit computes the CRC-32 using the standard polynomial 0x04C11DB7 (x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1). The CRC-32 unit retrieves 32-bit of data at a time from the block of data to compute the polynomial. This computation takes 1 cycle. For instance, the CRC-32 calculation for 1KB block of data is 256 cycles, 1 cycle for each of the 256 32-bit chunks. The initial value for the CRC-32 computation can be configured using BGCRC_SEED.

After the CRC-32 calculation is complete for a data block, the final result is loaded into BGCRC_RESULT. Note that BGCRC_RESULT only contains the final calculation for the whole data block; intermediate 32-bit calculations do not update BGCRC_RESULT. The value in BGCRC_RESULT is compared against the value in BGCRC_GOLDEN by hardware and the NMI/Interrupt flags are set accordingly by the CRC notification unit.

Once CRC-32 calculation is commenced, the calculation can be halted by setting BGCRC_CTRL2.TEST_HALT to 1010. Clearing this bit resumes CRC-32 calculation from the halt point.

7.2.3 CRC Notification Unit

After the CRC-32 compute unit completes the CRC-32 calculation for a block of data or fails to complete the calculation within BGCRC_WD_MIN and BGCRC_WD_MAX, if configured, the CRC-32 compute unit sends out a NMI/Interrupt on the occurrence of a pass or fail. In addition, during a data read by the data read unit, if an ECC or parity error occurs, the CRC notification unit can send out a NMI/Interrupt. In the case of an ECC or parity error, the BGCRC stops operation and BGCRC_CURR_ADDR contains the memory address that caused the ECC or parity error. The contents of BGCRC_CURR_ADDR in addition to the NMI/Interrupt flags can be used to debug a BGCRC failure.

7.2.3.1 CPU Interrupt, CLA Task and NMI

The BGCRC module has configurable interrupt and NMI lines. NMIs are enabled by default but can be disabled by writing 0xA to BGCRC_CTRL1.NMIDIS register. Conversely, all interrupts are disabled by default but can be enabled by writing 0x7E to BGCRC_INTEN register. When an error occurs in the BGCRC, the BGCRC can be configured to generate an NMI or interrupt. Since NMIs are enabled by default, all BGCRC errors cause an NMI. Figure 7-3 and Figure 7-4 show the NMI and Interrupt lines, respectively.

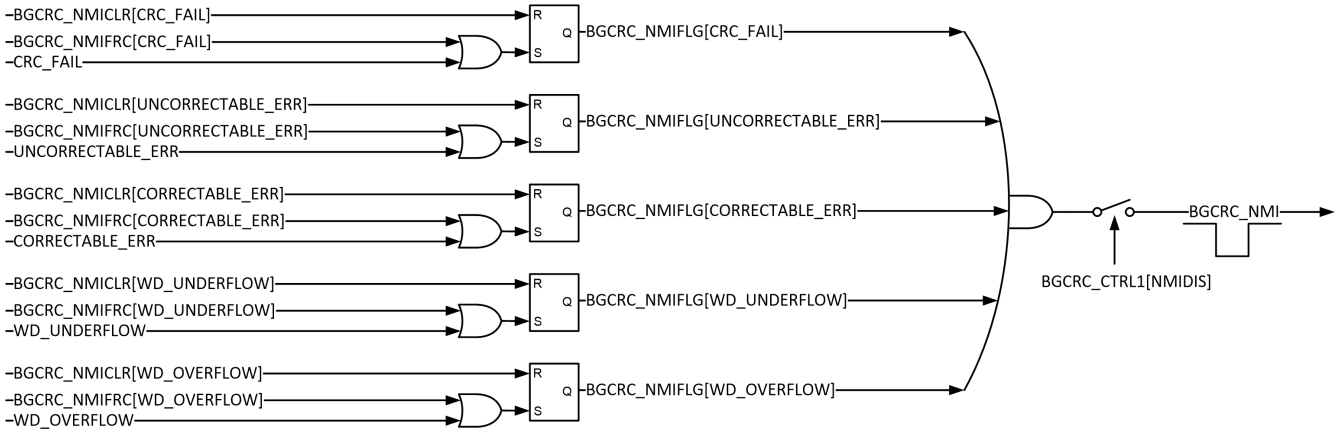

Figure 7-3. BGCRC NMI

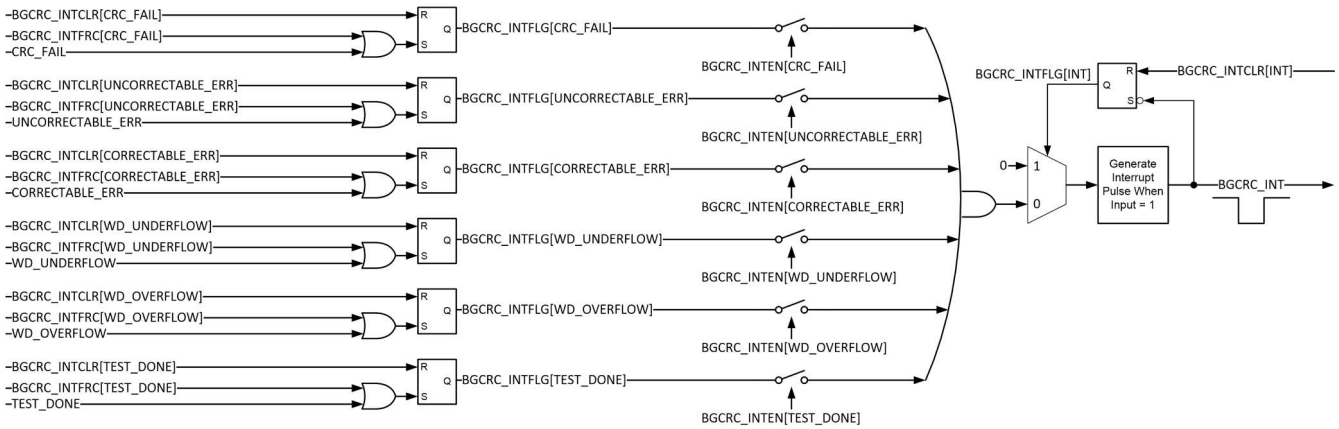

Figure 7-4. BGCRC Interrupt

7.2.4 Operating Modes

BGCRC module supports two modes of operation: CRC mode and scrub mode. The mode of operation can be configured by clearing or setting the register BGCRC_CTRL2.SCRUB_MODE.

7.2.4.1 CRC Mode

In CRC mode, the BGCRC module operates as explained in Section 7.2.2. CRC-32 calculation is performed on a block of data and the result compared against a golden value. ECC and parity errors are checked in this mode. Result mismatch, ECC or parity error can trigger an NMI/Interrupt.

7.2.4.2 Scrub Mode

In scrub mode, the CRC-32 result is not compared against the golden value and BGCRC_RESULT register is not updated. ECC and parity errors are also checked in this mode. However unlike CRC mode, NMI/Interrupt are only from ECC or parity error. In scrub mode, Parity and ECC bits of the memory block need to be initialized by the CPU and/or CLA.

7.2.5 BGCRC Watchdog

The BGCRC module has an embedded windowed watchdog that is used as a diagnostic to check memory test completion within the expected time window. This can protect against hardware defects that can cause the memory check not to complete in the allotted time, which may not be caught by the system watchdog as the error can be due to the CLA or DMA having continuous access. Windowing also helps detect additional failure modes in the watchdog operation, for example, stuck watchdog.

The BGCRC watchdog is enabled by default and starts when the BGCRC module begins reading from memory. The watchdog can be disabled using the register BGCRC_WD_CFG.WDDIS. The BGCRC watchdog counter is a 32-bit counter with the value reflected in BGCRC_WD_CNT register. The lower and upper window settings are configured using BGCRC_WD_MIN and BGCRC_WD_MAX, respectively. BGCRC_WD_MIN and BGCRC_WD_MAX need to be configured before the test is started and should not be changed while the BGCRC is operating. If configured, an NMI or interrupt is triggered if the memory test fails to complete within the configured time window. The counter stops on completion of the CRC-32 check done, CRC-32 check failure and ECC/Parity errors. The counter is reset when the next memory check begins.

The BGCRC watchdog can be halted by configuring the BGCRC_WD_CFG.WDDIS register. After the watchdog resumes from being halted, the counter starts counting from the previous count unless a new memory check operation is initiated. The counter is not halted when CRC-32 computation halts but by default halts during a debug halt. The behavior of the watchdog during emulation can be changed by configuring the appropriate BGCRC registers. In addition, due to the changing nature of memory contents during emulation, it is not recommended to run BGCRC during emulation. CRC-32 computation continues during a watchdog failure and software needs to address this condition.

7.2.6 Hardware and Software Faults Protection

The configuration registers are protected using a lock and commit configuration. Each of the configuration registers can be individually locked and committed. The register once locked, can no longer be updated until the lock is removed. However if the register lock is committed, no further writes is permitted until the device is reset. It is recommended to lock the registers after configuration to protect against corruption due to software faults. In addition, registers critical to the module functionality and fault detection are implemented using multi-bit fields to protect against hardware faults.

7.3 Application of the BGCRC

This section contains use case scenarios of how the BGCRC module can be configured to test a block of memory. However, the use case scenarios presented are for reference only and do not cover all the possible application scenarios. These use case scenarios could be used as a starting point to configure the BGCRC module for specific applications.

7.3.1 Software Configuration

The configuration registers for the BGCRC can be split into three groups (see Table 7-1):

- **CFG1:** Registers that determine the operating mode and configured at the beginning.
- **CFG2:** Registers that need to be updated during kickoff of a new test.
- **CFG3:** Registers used for test and error management.

CFG1 registers are expected to be locked and committed after initial configuration. It is recommended to lock the CFG2 and CFG3 registers after configuration. Figure 7-5 shows the BGCRC execution sequence.

Table 7-1. BGCRC Register Groups

CFG1 - One Time Configuration Registers	CFG2 - Periodic Configuration Registers	CFG3 - Registers Used for Test and Error Management
BGCRC_CTRL1	BGCRC_EN	BGCRC_NMICLR
BGCRC_WD_CFG	BGCRC_CTRL2	BGCRC_INTCLR
BGCRC_INTEN	BGCRC_START_ADDR	BGCRC_NMIFRC
BGCRC_SEED	BGCRC_GOLDEN	BGCRC_INTFRC
	BGCRC_WD_MIN	
	BGCRC_WD_MAX	

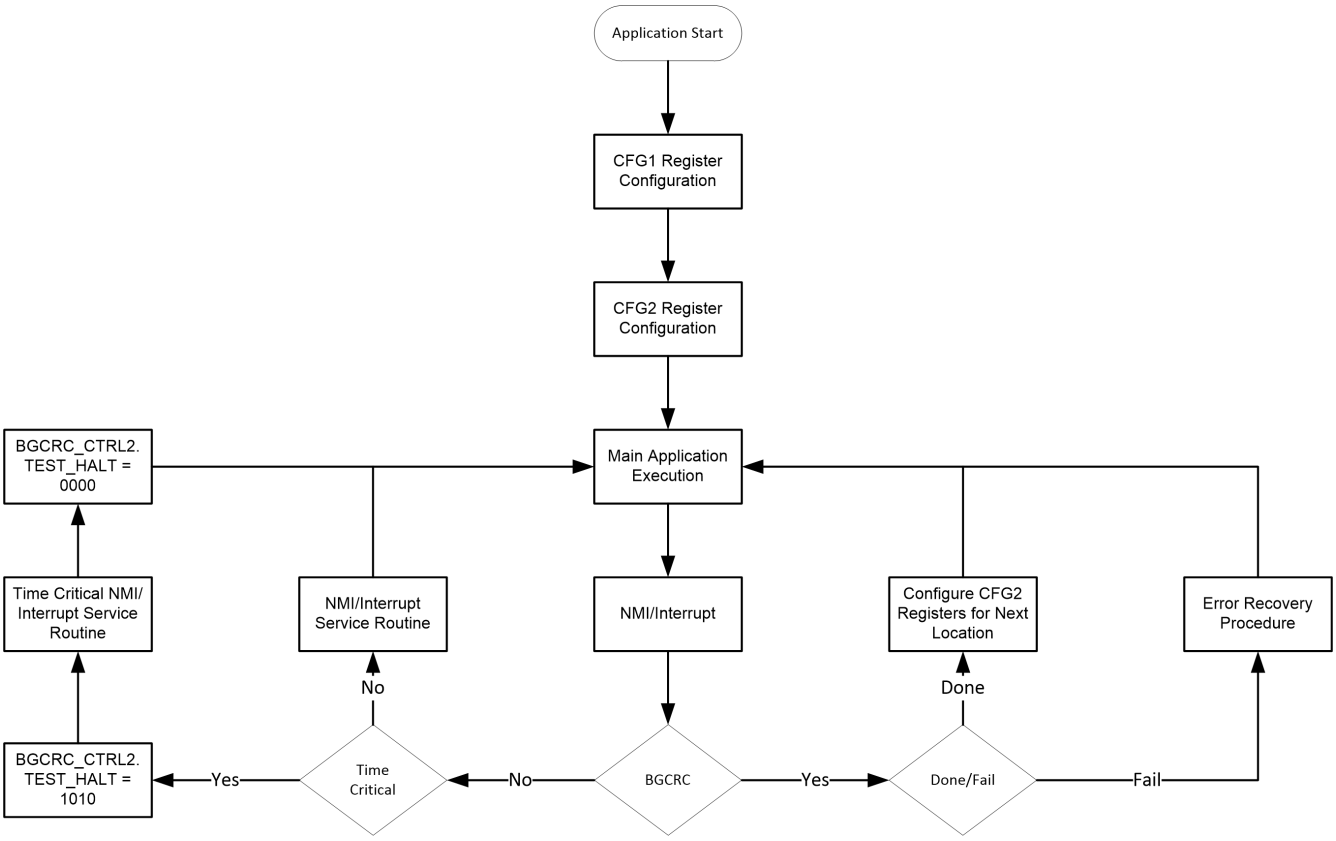

Figure 7-5. BGCRC Execution Sequence Flow

7.3.2 Decision on Error Response Severity

The error sources for BGCRC are:

- Test completion before BGCRC_WD_MIN.
- Test completed after BGCRC_WD_MAX.
- Mismatch between the calculated CRC and golden CRC.
- Uncorrectable error during data read (single bit error for parity memory or double bit error for ECC memory).
- Correctable error during memory read (single bit error for ECC memory).

Error severity can be chosen as either NMI or interrupt. By default, error severity is set to NMI. It is not possible to configure error response for each individual error source. The response can be chosen as either interrupt or NMI for all error sources. When error severity is chosen as NMI, ERROR_STS pin is asserted during an error. CPU and CLA should be assigned the same error severity.

7.3.3 Decision of Controller for CLA_CRC

CPU_CRC can only be kicked off by the CPU. However, CLA_CRC can be kicked off by the CPU or CLA. If BGCRC error severity is chosen as NMI, it is possible to handle the background test using the CLA and error response with the CPU. Once the controller for BGCRC is chosen, it is possible to prevent accesses from other controllers by using the system-level access protection configuration.

7.3.4 Execution of Time Critical Code from Wait-Stated Memories

BGCRC access to functionally wait-stated memories is also wait-stated by the same number. Since it is impossible to predict the next functional access, any ongoing BGCRC access has to complete before functional access is granted. To mitigate delay in functional access, the BGCRC can be halted when time-critical code that accesses the wait-stated memories is in progress. When BGCRC execution is halted, the BGCRC watchdog is not halted. This is consistent with the safety requirement to complete the background test in a predictable window irrespective of the user code. In such scenarios, it is recommended to adjust the upper BGCRC watchdog window limit to account for the halt duration during functional access. However, if required, the BGCRC watchdog can be disabled.

7.3.5 BGCRC Execution

Two notes about BGCRC execution are:

- BGCRC task can run as a background task once kicked off.
- BGCRC task does not impact functional execution for zero-wait stated memories. For memories with higher wait-states, the BGCRC engine can be halted to make functional execution predictable.

Figure 7-6 shows a few examples of BGCRC execution sequences.

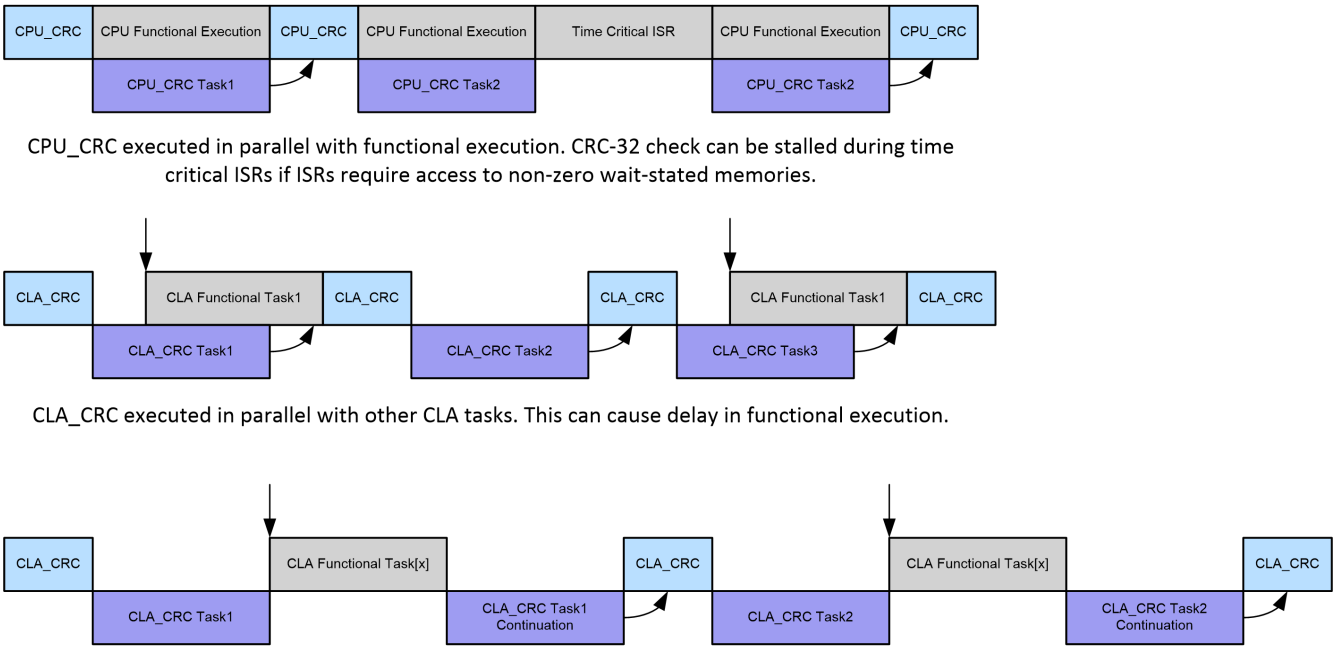

Figure 7-6. BGCRC Execution Sequence Example

7.3.6 Debug/Error Response for BGCRC Errors

The BGCRC error severity can be decoded by reading the BGCRC_INTFLG or BGCRC_NMIFLG. The errors can be:

- **WD_OVERFLOW/WD_UNDERFLOW:** The test did not complete in the programmed window. System timing needs to be checked to understand reason for non-completion of the test. BGCRC_CURR_ADDR and BGCRC_WD_CNT indicate how far the test progressed.
- **UNCORRECTABLE_ERR:** BGCRC_CURR_ADDR contains the address of the memory location causing the error. This error is due to single bit failure for Parity SRAM or double bit failure for ECC SRAM. The memory location can be reloaded (if possible, for cases where code is copied from Flash) to see if the problem resolves. If the problem persists, the problem can be a permanent defect.
- **CORRECTABLE_ERR:** This error is due to single bit failure for ECC SRAM. If the problem location is accessed again (execution from the location for execute only memory or reading the location in other cases), the expectation is that the single bit error is corrected. If the single bit error is not corrected, this can be an indication of a permanent defect.
- **CRC_FAIL:** This indicates a failure in the computation of the CRC-32 value. This error does not occur in scrub mode. For SRAMs with protection, in the absence of code bugs, this error is less likely since the error is most often manifest as a correctable/uncorrectable error. Code bugs can cause failure if the code inadvertently writes to a wrong address thus causing a CRC-32 error.

7.3.7 BGCRC Golden CRC-32 Value Computation

The C28x is a little-endian, 16-bit word addressable CPU. Therefore, the 32-bit value of 0x12345678 stored at address 0x100 is stored in the C28x memory as shown in Table 7-2.

Table 7-2. Data Address Location Example 1

Address	0x100	0x101
Data	0x5678	0x1234

The BGCRC order of byte calculations of the above example is 0x78, 0x56, 0x34, 0x12 and yields 0x6A330D2D. The 32-bit polynomial 0x04C11DB7 is used with an initialization vector of 0x00000000. The following code snippet shows the effective bit processing. Processing for all 32-bits within a word occurs in a single cycle within the BGCRC hardware.

```
seed = 0x0UL; //Initialize With Seed
poly = 0x04C11DB7UL: //32-Bit Polynomial
crc32 = seed;

for(i=0; i<dataSize; i++)
{
         byteSwappedData = ((data[i] & 0x000000FF) << 24)|
                         = ((data[i] & 0x0000FF00) << 8) |
                         = ((data[i] & 0x00FF0000) >> 8) |
                         = ((data[i] & 0xFF000000) >> 24);

        crc32 = byteSwappedData^crc32;
        for(j=0; j<32; j++)
        {
            if(crc32 & 0x80000000) crc32 = (crc32 << 1)^poly;
            else crc32 = crc32 << 1;

            crc32 = crc32 & 0xFFFFFFFF;
        }
}
```

A second example (Table 7-3) with two 32-bit words, 0x12345678 and 0x9ABCDEF0 at address 0x100 and 0x102 successively, would calculate the bytes in the order 0x78, 0x56, 0x34, 0x12, 0xDE, 0xBC, and 0x9A and yield 0x7E0B4164.

Table 7-3. Data Address Location Example 2

Address	0x100	0x101	0x102	0x103
Data	0x5678	0x1234	0xDEF0	0x9ABC

All data input to the BGCRC must align to a 32-bit boundary, both in the starting address and the size. It is possible to include 16-bit data within the span of data; however, when the data is read by the BGCRC, it always assume 32-bits and conform to the above calculation order. For example, if two 16-bit words (0xA0B1 and 0xC2D3) were placed in between the previous two 32-bit words (Table 7-4), the calculations would be performed in byte order 0x78, 0x56, 0x34, 0x12, 0xB1, 0xA0, 0xD3, 0xC2, 0xF0, 0xDE, 0xBC, and 0x9A and yield 0x2AEFD987.

Table 7-4. Data Address Location Example 3

Address	0x100	0x101	0x102	0x103	0x104	0x105
Data	0x5678	0x1234	0xA0B1	0xC2D3	0xDEF0	0x9ABC

7.4 Software

7.4.1 BGCRC Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/bgcrc

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

7.4.1.1 BGCRC CPU Interrupt Example

FILE: bgcrc_ex1_cpuinterrupt.c

This example demonstrates how to configure and trigger BGCRC from the CPU. BGCRC module is configured for 1 KB of GS0 RAM which is programmed with a known data. The pre-computed CRC value is used as the golden CRC value. Interrupt is generated once the computation is done and checks if no error flags are raised Calculation uses the 32-bit polynomial 0x04C11DB7 and seed value 0x00000000.

External Connections

- None.

Watch Variables

- pass - This should be 1.
- runStatus - BGCRC running status. This will be BGCRC_ACTIVE if the module is running, BGCRC_IDLE if the module is idle

7.4.1.2 BGCRC Example with Watchdog and Lock

FILE: bgcrc_ex2_cpubgcrc_basic.c

This example demonstrates how to configure and trigger BGCRC from the CPU. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 1kB of GS0 RAM which is programmed with random data. The golden CRC value for comparison is computed using software method. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

External Connections

- None.

Watch Variables

- pass
- bgcrcDone

7.4.1.3 CLA-BGCRC Example in CRC mode

FILE: bgcrc_ex3_clabgcrc_crcmode.c

This example demonstrates how to configure and trigger CLABGCRC from the CPU. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 1kB of CLA ROM memory. The golden CRC value for comparison is computed using software method. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

External Connections

- None.

Watch Variables

- pass
- bgcrcDone

7.4.1.4 CLA-BGCRC Example in Scrub Mode

FILE: bgcrc_ex4_clabgcrc_scrubmode.c

This example demonstrates how to configure and trigger CLA-BGCRC in Scrub mode. In Scrub mode, CRC of data is not compared with the golden CRC. Error check is done using the ECC/Parity logic. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 256 bytes of CLA ROM memory. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

External Connections

- None.

Watch Variables

- pass
- bgcrcDone

7.5 BGCRC Registers

This section describes the Background CRC registers.

7.5.1 BGCRC Base Address Table (C28)

Table 7-5. BGCRC Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
BgcrcCla1Regs	BGCRC_REGS	BGCRC_CLA1_BASE	0x0000_6380	YES	YES	-	YES	YES
BgcrcCpuRegs	BGCRC_REGS	BGCRC_CPU_BASE	0x0000_6340	YES	YES	-	-	YES

7.5.2 BGCRC_REGS Registers

Table 7-6 lists the memory-mapped registers for the BGCRC_REGS registers. All register offset addresses not listed in Table 7-6 should be considered as reserved locations and the register contents should not be modified.

Table 7-6. BGCRC_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	BGCRC_EN	BGCRC Enable	EALLOW	Go
2h	BGCRC_CTRL1	BGCRC Control register 1	EALLOW	Go
4h	BGCRC_CTRL2	BGCRC Control register 2	EALLOW	Go
6h	BGCRC_START_ADDR	Start address for the BGCRC check	EALLOW	Go
8h	BGCRC_SEED	Seed for CRC calculation	EALLOW	Go
Eh	BGCRC_GOLDEN	Golden CRC to be compared against	EALLOW	Go
10h	BGCRC_RESULT	CRC calculated		Go
12h	BGCRC_CURR_ADDR	Current address regsiter		Go
1Ch	BGCRC_WD_CFG	BGCRC windowed watchdog configuration	EALLOW	Go
1Eh	BGCRC_WD_MIN	BGCRC windowed watchdog min value	EALLOW	Go
20h	BGCRC_WD_MAX	BGCRC windowed watchdog max value	EALLOW	Go
22h	BGCRC_WD_CNT	BGCRC windowed watchdog count		Go
2Ah	BGCRC_NMIFLG	BGCRC NMI flag register		Go
2Ch	BGCRC_NMICLR	BGCRC NMI flag clear register	EALLOW	Go
2Eh	BGCRC_NMIFRC	BGCRC NMI flag force register	EALLOW	Go
34h	BGCRC_INTEN	Interrupt enable	EALLOW	Go
36h	BGCRC_INTFLG	Interrupt flag		Go
38h	BGCRC_INTCLR	Interrupt flag clear	EALLOW	Go
3Ah	BGCRC_INTFRC	Interrupt flag force	EALLOW	Go
3Ch	BGCRC_LOCK	BGCRC register map lockconfiguration	EALLOW	Go
3Eh	BGCRC_COMMIT	BGCRC register map commit configuration	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 7-7 shows the codes that are used for access types in this section.

Table 7-7. BGCRC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 7-7. BGCRC_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.5.2.1 BGCRC_EN Register (Offset = 0h) [Reset = 0h]

BGCRC_EN is shown in Figure 7-7 and described in Table 7-8.

Return to the Summary Table.

BGCRC Enable

Figure 7-7. BGCRC_EN Register

Chapter 8

Control Law Accelerator (CLA)

The Control Law Accelerator (CLA) Type-2 is an independent, fully-programmable, 32-bit floating-point math processor that brings concurrent control-loop execution to the C28x family. The low interrupt latency of the CLA allows the CLA to read ADC samples "just-in-time." This significantly reduces the ADC sample to output delay to enable faster system response and higher MHz control loops. By using the CLA to service time-critical control loops, the main CPU is free to perform other system tasks such as communications and diagnostics. This chapter provides an overview of the architectural structure and components of the control law accelerator.

8.1 Introduction

The Control Law Accelerator extends the capabilities of the C28x CPU by adding parallel processing. Time-critical control loops serviced by the CLA can achieve low ADC sample to output delay. Thus, the CLA enables faster system response and higher frequency control loops. Utilizing the CLA for time-critical tasks frees up the main CPU to perform other system and communication functions concurrently.

8.1.1 Features

The following is a list of major features of the CLA:

- C compilers are available for CLA software development.
- Clocked at the same rate as the main CPU (SYSCLKOUT).
- An independent architecture allowing CLA algorithm execution independent of the main C28x CPU.
  - Complete bus architecture:
    - Program Address Bus (PAB) and Program Data Bus (PDB)
    - Data Read Address Bus (DRAB), Data Read Data Bus (DRDB), Data Write Address Bus (DWAB), and Data Write Data Bus (DWDB)
  - Independent eight stage pipeline.
  - 16-bit program counter (MPC)
  - Four 32-bit result registers (MR0-MR3)
  - Two 16-bit auxiliary registers (MAR0, MAR1)
  - Status register (MSTF)
- Instruction set includes:
  - IEEE single-precision (32-bit) floating-point math operations
  - Floating-point math with parallel load or store
  - Floating-point multiply with parallel add or subtract
  - 1/X and 1/sqrt(X) estimations
  - Data type conversions.
  - Conditional branch and call
  - Data load/store operations
- The CLA program code can consist of up to eight tasks or interrupt service routines, or seven tasks and a main background task.
  - The start address of each task is specified by the MVECT registers.
  - No limit on task size as long as the tasks fit within the configurable CLA program memory space.
  - One task is serviced at a time until completion. There is no nesting of tasks.
  - Upon task completion a task-specific interrupt is flagged within the PIE.
  - When a task finishes the next highest-priority pending task is automatically started.
  - The Type-2 CLA can have a main task that runs continuously in the background, while other high priority events trigger a foreground task.
- Task trigger mechanisms:
  - C28x CPU using the IACK instruction
  - Task1 to Task8: up to 256 possible trigger sources from peripherals connected to the shared bus on which the CLA assumes secondary ownership.
  - Task8 can be set to be the background task, while Tasks 1 through 7 take peripheral triggers.
- Memory and Shared Peripherals:
  - Two dedicated message RAMs for communication between the CLA and the main CPU.
  - Two dedicated message RAMs for communication between the CLA and the DMA.
  - The C28x CPU can map CLA program and data memory to the main CPU space or CLA space.

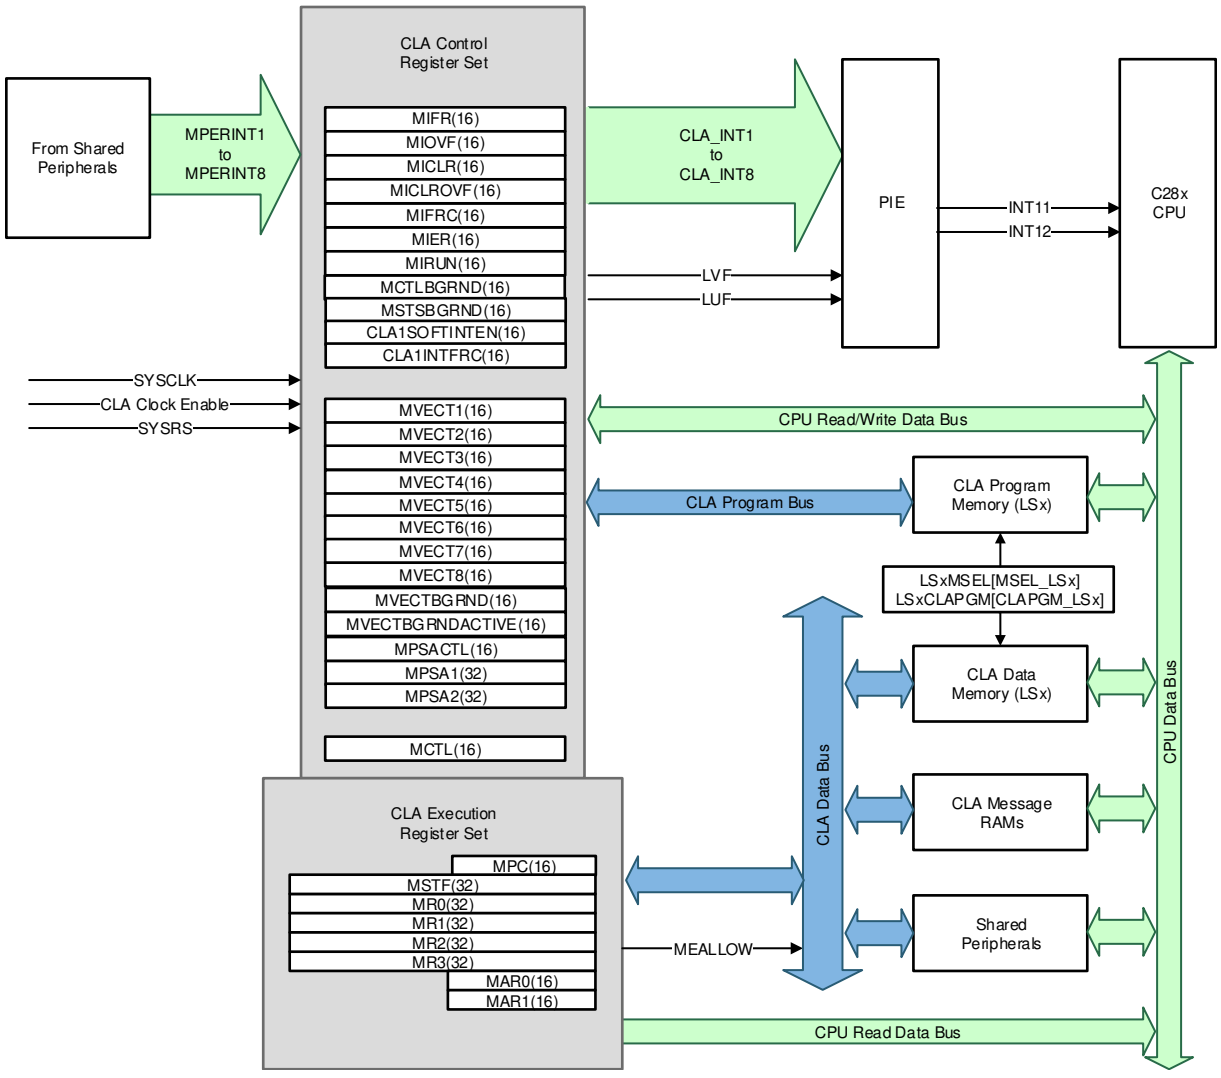

Figure 8-1. CLA (Type 2) Block Diagram

8.2 CLA Interface

This section describes how the C28x main CPU can interface to the CLA and conversely.

8.2.1 CLA Memory

The CLA can access three types of memory: program, data and message RAMs. The behavior and arbitration for each type of memory is described in this chapter. The CLA RAMs are protected by the DCSM module. Refer to the *Dual Code Security Module (DCSM)* section of the *System Control and Interrupts* chapter for more details on the security scheme.

- **CLA Program Memory**

  The CLA program can be loaded with any of the local shared memories (LSxRAM). At reset, all memory blocks are mapped to the CPU. While mapped to the CPU space, the CPU can copy the CLA program code into the memory. During debug, the memory can also be loaded directly by the Code Composer Studio™ IDE.

  Once the memory is initialized with CLA code, the CPU maps the memory to the CLA program space by:
  1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
  2. Specifying the memory block as a code block for the CLA by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit.

  When a memory block is configured as CLA program memory, debug accesses are allowed only on cycles where the CLA is not fetching a new instruction. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

  All CLA program fetches are performed as 32-bit read operations and all opcodes must be aligned to an even address. Since all CLA opcodes are 32-bits, this alignment occurs naturally.

- **CLA Data Memory**

  Any of the device's LSxRAMs can serve as data memory blocks to the CLA. At reset, all blocks are mapped to the CPU memory space, whereby the CPU can initialize the memory with data tables, coefficients, and so on, for the CLA to use.

  Once the memory is initialized with CLA data, the CPU maps the memory to the CLA data space by:
  1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
  2. Specifying the memory block as a data block for the CLA by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. The value of this bit at reset is 0.

  When a memory block is configured as CLA data memory, CLA read and write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROTx registers. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.
- **CLA Shared Message RAMs**

  There are two memory blocks for data sharing and communication between the CLA and the CPU . The message RAMs are always mapped to both CPU and CLA memory spaces, and only data access is allowed; no program fetches can be performed.
  - **CLA to CPU Message RAM:** The CLA can use this block to pass data to the CPU. This block is both readable and writable by the CLA. This block is also readable by the CPU but writes by the CPU are ignored.
  - **CPU to CLA Message RAM:** The CPU can use this block to pass data and messages to the CLA. This message RAM is both readable and writable by the CPU. The CLA can perform reads but writes by the CLA are ignored.

8.2.2 CLA Memory Bus

The CLA has dedicated bus architecture similar to that of the C28x CPU where there are separate program read, data read, and data write buses. Thus, there can be simultaneous instruction fetch, data read, and data write in a single cycle. Like the C28x CPU, the CLA expects memory logic to align any 32-bit read or write to an even address. If the address-generation logic generates an odd address, the CLA can begin reading or writing at the previous even address. This alignment does not affect the address values generated by the address-generation logic.

- **CLA Program Bus**

  The CLA program bus has an access range of 32K 32-bit instructions. Since all CLA instructions are 32 bits, this bus always fetches 32 bits at a time and the opcodes must be even-word aligned. The amount of program space available for the CLA is limited to the number of available LSxRAM blocks. This number is device-dependent and can be described in the device-specific data manual.

- **CLA Data Read Bus**

  The CLA data read bus has a 64K x 16 address range. The bus can perform 16 or 32-bit reads and can automatically stall if there are memory access conflicts. The data read bus has access to both the message RAMs, CLA data memory, and the shared peripherals.

- **CLA Data Write Bus**

  The CLA data write bus has a 64K x 16 address range. This bus can perform 16 or 32-bit writes. The bus can automatically stall if there are memory access conflicts. The data write bus has access to the CLA to CPU message RAM, CLA data memory, and the shared peripherals.

8.2.3 Shared Peripherals and EALLOW Protection

For a given CPU subsystem, the CPU, CLA, and DMA can share access to some peripherals. There is a 3-way arbitration among the different master's that is described in Section 8.3. Each peripheral has an access control register with two bit fields, CPUnAC, CLAnAC, and DMAnAC (n being the instance) that determine what kind of access is given to that particular master.

Note

The CLA read access time to the bus is 2-wait states while write access is 0-wait.

Refer to the device data sheet for the list of peripherals connected to the bus.

Several peripheral control registers are protected from spurious 28x CPU writes by the EALLOW protection mechanism. These same registers are also protected from spurious CLA writes. The EALLOW bit in the CPU status register 1 (ST1) indicates the state of protection for the CPU. Likewise, the MEALLOW bit in the CLA status register (MSTF) indicates the state of write protection for the CLA. The MEALLOW CLA instruction enables write access by the CLA to EALLOW protected registers. Likewise, the MEDIS CLA instruction disables write access. This way the CLA can enable and disable write access independent of the CPU.

The ADC offers the option to generate an early interrupt pulse at the start of a sample conversion. If this option is used to start an ADC-triggered CLA task, use the intervening cycles until the completion of the conversion to perform preliminary calculations or loads and stores before finally reading the ADC value. The CLA pipeline activity for this scenario is shown in Section 8.5.

8.2.4 CLA Tasks and Interrupt Vectors

The CLA program code is divided up into tasks or interrupt service routines. Tasks do not have a fixed starting location or length. The CLA program memory can be divided up as desired. The CLA uses the contents of the interrupt vectors (MVECT1 to MVECT8) to determine where a task begins; tasks are terminated by the MSTOP instruction.

The CLA supports eight tasks. Task 1 has the highest priority and task 8 has the lowest priority. The Type-2 CLA offers the option of setting the lowest priority task, for example, task 8, as a background task that, once triggered, runs continuously until the user either terminates the task or resets the CLA or the device. The remaining tasks, 1 through 7, maintain their priority levels and interrupt the background task when triggered.

The background task is enabled by setting the BGEN bit in the MCTLBGRND register; this causes the hardware to disable task 8 in the MIER register. The background task derives the interrupt vector from the MVECTBGRND register instead of MVECT8.

A task can be requested by a peripheral interrupt or by software:

- **Peripheral interrupt trigger**

  Each task can be triggered by software-selectable interrupt sources. The trigger for each task is defined by writing an appropriate value to the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field. Each option specifies an interrupt source from a specific peripheral on the shared bus. The peripheral interrupt triggers are listed in Table 8-1.

  For example, task 1 (MVECT1) can be set to trigger on EPWMINT1 by writing 36 to DmaClaSrcSelRegs.CLA1TASKSRCSEL1.TASK1. To disable the triggering of a task by a peripheral, set the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field to 0. Note that a CLA task only triggers on a level transition (an edge) of the configured interrupt source.

- **Software Trigger**

  CPU software can trigger tasks by writing to the MIFRC register or by the IACK instruction. Using the IACK instruction is more efficient because the instruction does not require the need to issue an EALLOW to set MIFR bits. Set the MCTL[IACKE] bit to enable the IACK feature. Each bit in the operand of the IACK instruction corresponds to a task. For example, IACK #0x0001 sets bit 0 in the MIFR register to start task 1. Likewise, IACK #0x0003 set bits 0 and 1 in the MIFR register to start task 1 and task 2.
- **Background Task**

The Type-2 CLA allows the use of Task 8 as a background task that runs continuously until Task 8 disables the task or resets the device (or the CLA using a soft reset). The background task vector is given by the MVECTBGRND register and the operation is controlled by the MCTLBGRND register; the task is enabled by setting the BGEN bit to 1. Then start the task through software by writing a 1 to the BGSTART bit (TRIGEN must be 0), or through a peripheral by setting the TRIGEN bit to 1 and then setting the trigger source in the bit-field, DmaClaSrcSelRegs.CLA1TASKSRCSEL2.bit.TASK8. By default, the background task is interruptible; the highest priority pending task is executed first. When a task completes and there are not any pending tasks, the execution returns to the background task. The CLA keeps track of the branching point by saving the return address to the MVECTBGRNDACTIVE register, and then popping this address to the MPC when execution returns. Choose to make sections of the background task uninterruptible by possibly doing this with the MSETC BGINTM assembly instruction.

Subsequently, enabling interrupts with the MCLRC BGINTM instruction.

The background interrupt mask bit, BGINTM, can be queried in the MSTSBGRND register. This register also provides the current status of the background task. If the task is currently executing, the RUN bit is set to 1, if another trigger for the background task is received while the task has already started, the overflow (BGOVF) bit is set.

The CLA has their own fetch mechanism and can run and execute a task independently of the CPU. Only one task is serviced at a time; there is no nesting of tasks unless the background task in enabled, then one level of nesting is possible. The task currently running is indicated in the MIRUN register; if the background task is enabled and running, the task is reflected in the MSTSBGRND register (the RUN bit).

Interrupts that have been received but not yet serviced are indicated in the flag register (MIFR). If an interrupt request from a peripheral is received and that same task is already flagged, then the overflow flag bit is set. Overflow flags remain set until the flags are cleared by the CPU. If the CLA is idle (no task is currently running) or is executing the background task, then the highest priority interrupt request that is both flagged (MIFR) and enabled (MIER) starts.

The flow is as follows:

1. The associated RUN register bit is set (MIRUN) and the flag bit (MIFR) is cleared.
2. The CLA begins execution at the location indicated by the associated interrupt vector (MVECTx). MVECT contains the absolute 16-bit address of the task in the lower 64K memory space. If a task is interrupting the background task then the current program address is stored in the MVECTBGRNDACTIVE register before execution jumps to the task; this saved address is restored to the MPC when the task completes and execution returns to the background task.
3. The CLA executes instructions until the MSTOP instruction is found. This indicates the end of the task.
4. The MIRUN bit is cleared.
5. The task-specific interrupt to the PIE is issued. This informs the main CPU that the task has completed.
6. The CLA returns to idle (or to the background task, if enabled). Once a task completes the next highest-priority pending task is automatically serviced and this sequence repeats.

8.2.5 CLA Software Interrupt to CPU

The CLA can issue a software interrupt to the C28x CPU at any point in the code through the use of the CLA1SOFTINTEN and CLA1INTFRC registers. See Section 8.8 for a description of these registers. If a software interrupt is selected for a CLA task, then an end-of-task interrupt is not issued to the C28x CPU when that task completes.

8.3 CLA, DMA, and CPU Arbitration

Typically, CLA activity is independent of the CPU activity. Under the circumstance where the CLA, DMA, or CPU attempt to concurrently access memory or a peripheral register within the same interface, an arbitration procedure will occur. This section describes this arbitration.

The arbitration follows a fixed arbitration scheme with highest priority first:

1. DMA WRITE
2. DMA READ
3. CLA WRITE
4. CLA READ
5. CPU WRITE
6. CPU READ

Refer to the Memory Controller Module section of the *System Control and Interrupts* chapter.

8.3.1 CLA Message RAM

Message RAMs consist of four blocks:

- CLA to CPU Message RAM
- CPU to CLA Message RAM
- DMA to CLA Message RAM
- CLA to DMA Message RAM

These blocks are useful for passing data between the CLA and CPU or CLA and DMA. No opcode fetches, from either the CLA or CPU, are allowed from the message RAMs. A write protection violation is not generated if the CLA attempts to write to the CPU to CLA or DMA to CLA message RAM, but the write is ignored. The arbitration scheme for the message RAMs are the same as those for the shared memories, described in the Memory Controller Module section of the *System Control and Interrupts* chapter.

The message RAMs have the following characteristics:

- CLA to CPU Message RAM:
  The following accesses are allowed:
  - CPU reads
  - CLA data reads and writes
  - CPU debug reads and writes

  The following accesses are ignored:
  - CPU writes
- CPU to CLA Message RAM:
  The following accesses are allowed:
  - CPU reads and writes
  - CLA reads
  - CPU debug reads and writes

  The following accesses are ignored:
  - CLA writes

8.3.2 Peripheral Registers (ePWM, HRPWM, Comparator)

Accesses to the registers follow these rules:

- If both the CPU and CLA request access at the same time, then the CLA has priority and the main CPU is stalled.
- If a CPU access is in-progress and another CPU access is pending, then the CLA has priority over the pending CPU access. In this case, the CLA access begins when the current CPU access completes.
- While a CPU access is in-progress, any incoming CLA access is stalled.
- While a CLA access is in-progress, any incoming CPU access is stalled.
- A CPU write operation has priority over a CPU read operation.
- A CLA write operation has priority over a CLA read operation.
- If the CPU is performing a read-modify-write operation and the CLA performs a write to the same location, the CLA write can be lost if the operation occurs in-between the CPU read and write. For this reason, do not mix CPU and CLA accesses to same location.

8.4 CLA Configuration and Debug

This section discusses the steps necessary to configure and debug the CLA.

8.4.1 Building a CLA Application

The control law accelerator can be programmed in either CLA assembly code, using the instructions described in Section 8.7, or a reduced subset of the C language. CLA assembly code resides in the same project with C28x code. The only restriction is the CLA code must be in the assembly section. This can be easily done using the **.sect** assembly directive. This does not prevent CLA and C28x code from being linked into the same memory region in the linker command file.

System and CLA initialization are performed by the main CPU. This can typically be done in C or C++ but can also include C28x assembly code. The main CPU also copies the CLA code to the program memory and, if needed, initialize the CLA data RAMs. Once system initialization is complete and the application begins, the CLA services the interrupts using the CLA assembly code (or tasks). The main CPU can perform other tasks concurrently with CLA program execution.

The CLA Type 2 requires Codegen V16.9.1.LTS or later with the compiler switch: --cla_support=cla2.

8.4.2 Typical CLA Initialization Sequence

A typical CLA initialization sequence is performed by the main CPU as described in this section.

1. **Copy CLA code into the CLA program RAM**

   The source for the CLA code can initially reside in the Flash or a data stream from a communications peripheral or anywhere the main CPU can access. The debugger can also be used to load code directly to the CLA program RAM during development.
2. **Initialize CLA data RAM, if necessary**

   Populate the CLA data RAM with any required data coefficients or constants.
3. **Configure the CLA registers**

   Configure the CLA registers, but keep interrupts disabled until later (leave MIER = 0):
   - **Enable the CLA peripheral clock using the assigned PCLKCRn register**

     The peripheral clock control (PCLKCRn) registers are defined in the *System Control and Interrupts* chapter.
   - **Populate the CLA task interrupt vectors**
     - MVECT1 to MVECT8

       Each vector needs to be initialized with the start address of the task to be executed when the CLA receives the associated interrupt. This address is the full 16-bit starting address of the task in the lower 64K section of memory.
     - MVECT1 to MVECT7, and MVECTBGRND

       When using the background task, the vector (MVECTBGRND) must be loaded with the start address of the task in lower 64K of memory. Note that Task 8 is ignored when the background task is enabled.
   - **Select the task interrupt sources**

     For each task select the interrupt source in the CLA1TASKSRCSELx register. If a task is software triggered, select no interrupt. Since the background task takes the place of Task 8, the task uses the same peripheral trigger source as task 8.
   - **Enable IACK to start a task from software, if desired**

     To enable the IACK instruction to start a task set the MCTL[IACKE] bit. Using the IACK instruction avoids having to set and clear the EALLOW bit. If the background task is enabled, the IACK bit for task 8 is ignored; the user must, instead, write to the BGSTART bit of the MCTLBGRND register to start the background task (TRIGEN can be 0 to avoid a peripheral trigger from causing an overflow, for example, MSTSBGRND.BGOVF is set to 1).

- **Map CLA data RAM to CLA space, if necessary**

  Map the data RAM to the CLA space by first, assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit, and then specifying the memory block as a CLA data block by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. When an LSx memory is configured as a CLA data memory, the CLA read/write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROTx registers.
- **Map CLA program RAM to CLA space**

  Map the CLA program RAM to CLA space by first assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit, and then specifying the memory block as CLA code memory by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. When an LSx memory is configured as CLA program memory, only debug accesses are allowed on cycles in which the CLA is not fetching a new instruction.

4. **Initialize the PIE vector table and registers**

   When a CLA task completes, the associated interrupt in the PIE is flagged. The CLA overflow and underflow flags also have associated interrupts within the PIE.
5. **Enable CLA tasks/interrupts**

   Set appropriate bits in the interrupt enable register (MIER) to allow the CLA to service interrupts. Note that a CLA task only triggers on a level transition (a falling edge) of the configured interrupt source. If a peripheral is enabled and an interrupt fires before the CLA is configured, then the CLA does not recognize the interrupt edge and does not respond. To avoid this, configure the CLA before the peripherals or clear any pending peripheral interrupts before setting bits in the MIER register.
6. **Initialize other peripherals**

   Initialize any peripherals (such as ePWM, ADC, and others) that generate interrupt triggers for enabled CLA tasks.

   The CLA is now ready to service interrupts and the message RAMs can be used to pass data between the CPU and the CLA. Mapping of the CLA program and data RAMs typically occurs only during the initialization process. If the RAM mapping needs to be changed after initialization, the CLA interrupts must be disabled and all tasks must be completed (by checking the MIRUN register) prior to modifying the RAM ownership.

8.4.3 Debugging CLA Code

Debugging the CLA code is a simple process that occurs independently of the main CPU. The type 2 CLA adds a true software breakpoint feature.

8.4.3.1 Software Breakpoint Support (MDEBUGSTOP1)

The MDEBUGSTOP1 instruction is meant to be used as a software breakpoint; the instruction on which the execution must halt is replaced with this instruction.

The MDEBUGSTOP1 and MDEBUGSTOP instructions differ in how the CLA pipeline is treated. When halted, the MDEBUGSTOP1 instruction flushes all the instructions that have already been fetched; on a single-step or run-free command, the CLA refetches the same instruction that it replaced. Table 8-2 illustrates the pipeline behavior.

Table 8-2. Pipeline Behavior of the MDEBUGSTOP1 Instruction

Cycles	F1	F2	D1	D2	R1	R2	E	W	Comments
1	i1								
2	i2	i1							
3	i3	i2	i1						
4	i4	i3	i2	i1					
5	MDEBUG STOP1	i4	i3	i2	i1				
6	i6	MDEBUG STOP1	i4	i3	i2	i1			
7	i7	i6	MDEBUG STOP1	i4	i3	i2	i1		
9	i8	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	i1	CLA halted
10	i5(MDEBUGS TOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	CLA step/run
11	i6	i5(MDEBUGS TOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	CLA step/run
12	i7	i6	i5(MDEBUGS TOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	CLA step/run
13	i8	i7	i6	i5(MDEBUGS TOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	CLA step/run

A software breakpoint is placed at instruction i5. The instruction, i5, is then replaced with MDEBUGSTOP1. It takes 3 cycles for the MDEBUGSTOP1 to reach the D2 phase at which point the instructions i6, i7, and i8 that were previously fetched are now flushed from the pipeline. The instruction, i5, is then re-fetched and execution continues as before.

8.4.3.2 Legacy Breakpoint Support (MDEBUGSTOP)

1. **Insert a breakpoint in CLA code**

   Insert a CLA breakpoint (MDEBUGSTOP instruction) into the code where the CLA is to halt, then rebuild and reload the code. Because the CLA does not flush the pipeline when in single-step, the MDEBUGSTOP instruction must be inserted as part of the code. The debugger cannot insert the MDEBUGSTOP instruction as needed.

   If CLA breakpoints are not enabled, then the MDEBUGSTOP instruction is ignored and is treated as a MNOP. The MDEBUGSTOP instruction can be placed anywhere in the CLA code as long as the MDEBUGSTOP instruction is not within three instructions of a MBCNDD, MCCNDD, or MRCNDD instruction. When programming in C, the user can use the __mdebugstop() intrinsic instead; the compiler makes sure that the placement of the MDEBUSTOP instruction in the generated assembly does not violate any of the pipeline restrictions.
2. **Enable CLA breakpoints**

   Enable the CLA breakpoints in the debugger. In the Code Composer Studio™ IDE, this is done by connecting to the CLA core (or tap) from the debug perspective. Breakpoints are disabled when the core is disconnected.
3. **Start the task**

   There are three ways to start the task:
   a. The peripheral can assert an interrupt,
   b. The main CPU can execute an IACK instruction, or
   c. The user can manually write to the MIFRC register in the debugger window

   When the task starts, the CLA executes instructions until the MDEBUGSTOP is in the D2 phase of the pipeline. At this point, the CLA halts and the pipeline is frozen. The MPC register reflects the address of the MDEBUGSTOP instruction.

4. **Single-step the CLA code**

   Once halted, the user can single-step the CLA code. The behavior of a CLA single-step is different than the main C28x. When issuing a CLA single-step, the pipeline is clocked only one cycle and then again frozen. On the C28x CPU, the pipeline is flushed for each single-step.

   Run to the next MDEBUGSTOP or to the end of the task. If another task is pending, the task automatically starts when run to the end of the task.

   Note

   A CLA fetch has higher priority than CPU debug reads. For this reason, it is possible for the CLA to permanently block CPU debug accesses if the CLA is executing in a loop. This can occur when initially developing CLA code due to a bug that causes an infinite loop. To avoid locking up the main CPU, the program memory returns all 0x0000 for CPU debug reads when the CLA is running. When the CLA is halted or idle, then normal CPU debug read and write access to CLA program memory can be performed.

   If the CLA gets caught in an infinite loop, use a soft or hard reset to exit the condition. A debugger reset also exits the condition.

   There are special cases that can occur when single-stepping a task such that the program counter, MPC, reaches the MSTOP instruction at the end of the task.

   - **MPC halts at or after the MSTOP with a task already pending**

     If single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if continuing to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.
   - **MPC halts at or after the MSTOP with no task pending**

     In this case, if single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if continuing to single-step through the MSTOP instruction of "task A."

     Depending on exactly when the new task comes in, to reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, start single-stepping "task B."

     This case can be handled slightly differently if there is control over when "task B" comes in (for example, using the IACK instruction to start the task). In this case, the task is single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B," run free to force the CLA out of the debug state. Once this is done, force "task B" and continue debugging.

5. **Disable CLA breakpoints, if desired**

   In the Code Composer Studio™ IDE, disable the CLA breakpoints by disconnecting the CLA core in the debug perspective. Make sure to first issue a run or reset; otherwise, the CLA is halted and no other tasks start.

8.4.4 CLA Illegal Opcode Behavior

If the CLA fetches an opcode that does not correspond to a legal instruction, it will behave as follows:

- The CLA will halt with the illegal opcode in the D2 phase of the pipeline as if it were a breakpoint. This will occur whether CLA breakpoints are enabled or not.
- The CLA will issue the task-specific interrupt to the PIE.
- The MIRUN bit for the task will remain set.

Further single-stepping is ignored once execution halts due to an illegal op-code. To exit this situation, issue either a soft or hard reset of the CLA as described in Section 8.4.5.

8.4.5 Resetting the CLA

There are times when resetting the CLA is needed. For example, during code debug the CLA can enter an infinite loop due to a code bug. The CLA has two types of resets: hard and soft. Both of these resets can be performed by the debugger or by the main CPU.

- **Hard Reset** Writing a 1 to the MCTL[HARDRESET] bit performs a hard reset of the CLA. The behavior of a hard reset is the same as a system reset (using $\overline{\text{XRS}}$ or the debugger). In this case, all CLA configuration and execution registers can be set to their default state and CLA execution halts.
- **Soft Reset** Writing a 1 to the MCTL[SOFTRESET] bit performs a soft reset of the CLA. If a task is executing, the task halts and the associated MIRUN bit is cleared. All bits within the interrupt enable (MIER) register are also cleared, so that no new tasks start. In addition, the background task's start bit (MCTLBGRN.BGSTART) and trigger enable bit (MCTLBGRND.TRIGEN) are reset. The MVECTBGRNACTIVE is set to the value of MVECTBGRND, and the status register (MSTSBGRND) is also reset.

8.5 Pipeline

This section describes the CLA pipeline stages and presents cases where pipeline alignment must be considered.

8.5.1 Pipeline Overview

The CLA pipeline is very similar to the C28x pipeline with eight stages:

1. **Fetch 1 (F1):** During the F1 stage the program read address is placed on the CLA program address bus.
2. **Fetch 2 (F2):** During the F2 stage the instruction is read using the CLA program data bus.
3. **Decode 1 (D1):** During D1 the instruction is decoded.
4. **Decode 2 (D2):** Generate the data read address. Changes to MAR0 and MAR1 due to post-increment using indirect addressing takes place in the D2 phase. Conditional branch decisions are also made at this stage based on the MSTF register flags.
5. **Read 1 (R1):** Place the data read address on the CLA data-read address bus. If a memory conflict exists, the R1 stage will be stalled.
6. **Read 2 (R2):** Read the data value using the CLA data read data bus.
7. **Execute (EXE):** Execute the operation. Changes to MAR0 and MAR1 due to loading an immediate value or value from memory take place in this stage.
8. **Write (W):** Place the write address and write data on the CLA write data bus. If a memory conflict exists, the W stage will be stalled.

8.5.2 CLA Pipeline Alignment

The majority of the CLA instructions do not require any special pipeline considerations. This section lists the few operations that do require special consideration.

- **Write Followed by Read**

  In both the C28x pipeline and the CLA pipeline, the read operation occurs before the write. This means that if a read operation immediately follows a write, then the read completes first as shown in Table 8-3. In most cases this does not cause a problem since the contents of one memory location does not depend on the state of another. For accesses to peripherals where a write to one location can affect the value in another location, the code must wait for the write to complete before issuing the read as shown in Table 8-4.

  This behavior is different for the C28x CPU. For the C28x CPU, any write followed by read to the same location is protected by what is called write-followed-by-read protection. This protection automatically stalls the pipeline so that the write completes before the read. In addition, some peripheral frames are protected such that a C28x CPU write to one location within the frame always completes before a read to the frame. The CLA does not have this protection mechanism. Instead, the code must wait to perform the read.

Table 8-3. Write Followed by Read - Read Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2 MMOV16 MR2, @Reg2	I2	I1						
		I2	I1					
			I2	I1				
				I2	I1			
					I2	I1		
						I2	I1	
							I2	I1

Table 8-4. Write Followed by Read - Write Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2	I2	I1						
I3	I3	I2	I1					
I4	I4	I3	I2	I1				
I5 MMOV16 MR2, @Reg2	I5	I4	I3	I2	I1			
		I5	I4	I3	I2	I1		
			I5	I4	I3	I2	I1	
				I5	I4	I3	I2	I1
					I5	I4	I3	
						I5	I4	
							I5	

- **Delayed Conditional instructions: MBCNDD, MCCNDD, and MRCNDD**

  Referring to Example 8-1, the following applies to delayed conditional instructions:
  - **I1:** I1 is the last instruction that can effect the CNDF flags for the branch, call, or return instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD, MCCNDD, or MRCNDD is in the D2 phase.
  - **I2, I3, and I4:** The three instructions preceding MBCNDD can change the MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the branch, call, or return instruction. These three instructions must not be a MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
  - **I5, I6, and I7:** The three instructions following a branch, call, or return are always executed irrespective of whether the condition is true or not. These instructions must not be MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

  For a more detailed description, refer to the description for MBCNDD, MCCNDD, and MRCNDD.

Example 8-1. Code Fragment For MBCNDD, MCCNDD, or MRCNDD

```
  <Instruction 1>    ; I1 Last instruction that can affect flags for
                     ;     the branch, call or return operation
  <Instruction 2>    ; I2 Cannot be stop, branch, call or return
  <Instruction 3>    ; I3 Cannot be stop, branch, call or return
  <Instruction 4>    ; I4 Cannot be stop, branch, call or return
  <branch/call/ret>  ; MBCNDD, MCCNDD or MRCNDD
                     ; I5-I7: Three instructions after are always
                     ; executed whether the branch/call or return is
                     ; taken or not
  <Instruction 5>    ; I5 Cannot be stop, branch, call or return
  <Instruction 6>    ; I6 Cannot be stop, branch, call or return
  <Instruction 7>    ; I7 Cannot be stop, branch, call or return
  <Instruction 8>    ; I8
  <Instruction 9>    ; I9
  ....
```

- **Stop or Halting a Task: MSTOP and MDEBUGSTOP**

  The MSTOP and MDEBUGSTOP instructions cannot be placed three instructions before or after a conditional branch, call or return instruction (MBCNDD, MCCNDD, or MRCNDD). Refer to Example 8-1. To single-step through a branch/call or return, insert the MDEBUGSTOP at least four instructions back and step from there.

- **Loading MAR0 or MAR1**
  A load of auxiliary register MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Referring to Example 8-2, the following applies when loading the auxiliary registers:
  – **I1 and I2**

    The two instructions following the load instruction use the value in MAR0 or MAR1 before the update occurs.
  – **I3**

    Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #_X.
  – **I4**

    Starting with the 4th instruction MAR0 or MAR1 has the new value.

Example 8-2. Code Fragment for Loading MAR0 or MAR1

```
; Assume MAR0 is 50 and #_X is 20

   MMOVI16 MAR0, #_X ; Load MAR0 with address of X (20)
   <Instruction 1>   ; I1 Will use the old value of MAR0 (50)
   <Instruction 2>   ; I2 Will use the old value of MAR0 (50)
   <Instruction 3>   ; I3 Cannot use MAR0
   <Instruction 4>   ; I4 Will use the new value of MAR0 (20)
   <Instruction 5>   ; I5 Will use the new value of MAR0 (20
   ....
```

- **Background Task Interrupted Close to a Branch**

  When the background task is running, if another task request happens (and MSTSBGRND.BGINTM is not set), then the following sequence of operations happen.

  – A check is made to determine if the following instructions are not in the pipeline (D2 – R2).
    - MBCNDD
    - MCCNDD
    - MRCNDD

  If any of the above instructions are present in the pipeline, the back ground task continues to execute until such time when the condition is satisfied. Once the condition is satisfied, the following actions are performed:
  – The MPC value of the D1 phase instruction is saved to the MVECTBGRNDACTIVE register.
  – The run status bit of the background task (MSTSBGRND.RUNSTS) is cleared.
  – An MSTOP instruction is forced into the D2 phase of the pipeline; causing the background task to terminate.

  When the background task terminates, the CLA picks the next highest pending task and begins execution. Note that while the background task is pending, the background task has the lowest priority and, therefore, yields to any other pending task. Once all pending non-background tasks have completed execution, the CLA restores the program counter (MPC), that is, loads the address from the MVECTBGRNDACTIVE register to the MPC, sets the background status to RUN (MSTSBGRND.RUN = 1), and continues execution from that point.

- **MSTOP in the Background Task**
  If an MSTOP instruction occurs in the D1 phase while the background task is running, the following sequence of operations happens:
  - The RUN bit (MSTSBGRND.RUN) is cleared.
  - The address stored in MVECTBGRND is copied over to MVECTBGRNDACTIVE.
  - An interrupt, signaling the background task has completed execution, is generated. This interrupt signal is ANDed with the interrupt from Task 8 and fed to the PIE. Note that if an illegal instruction occurs inside the background task, the interrupt for task 8 is fired.
  - When the background task terminates, the CLA resumes arbitration among the pending tasks.

8.5.2.1 ADC Early Interrupt to CLA Response

The ADC can be configured to generate an early interrupt pulse before the ADC conversion completes. If this option is used to start a CLA task, the CLA is able to read the result as soon as the conversion result is available in the ADC result register. This combination of just-in-time sampling along with the low interrupt response of the CLA enable faster system response and higher frequency control loops. The CLA task trigger to first instruction fetch interrupt latency is 4 cycles.

Timings for ADC conversions are shown in the timing diagrams of the ADC chapter. If the ADCCLK is a divided down version of the SYSCLK, the user has to account for the conversion time in SYSCLK cycles.

For example, if using the 12-bit ADC with ADCCLK at SYSCLK / 4, the ADC can take 10.5 ADCCLK x 4 SYSCLK = 42 SYSCLK cycles to complete a conversion. If using the ADC in 16-bit mode at the same ADCCLK, the ADC can take 29.5 ADCCLK x 4 SYSCLK = 118 SYSCLK cycles, and so on.

From a CLA perspective, the pipeline activity is shown in Table 8-5 for an N-cycle (SYSCLK) ADC conversion. The N-2 instruction arrives in the R2 phase just in time to read the result register. While the prior instructions enter the R2 phase of the pipeline too soon to read the conversion, the instructions can be efficiently used for pre-processing calculations needed by the task.

Table 8-5. ADC to CLA Early Interrupt Response

ADC Activity	CLA Activity	F1	F2	D1	D2	R1	R2	E	W
Sample									
Sample

$Conversion_{(Cycle\ N-5)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-7)}$	$I_{(Cycle\ N-8)}$	$I_{(Cycle\ N-9)}$	$I_{(Cycle\ N-10)}$		
$Conversion_{(Cycle\ N-4)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-7)}$	$I_{(Cycle\ N-8)}$	$I_{(Cycle\ N-9)}$		
$Conversion_{(Cycle\ N-3)}$	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-7)}$	$I_{(Cycle\ N-8)}$		
$Conversion_{(Cycle\ N-2)}$	**Read RESULT**	**Read RESULT**	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-7)}$		
$Conversion_{(Cycle\ N-1)}$			**Read RESULT**	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$		
$Conversion_{(Cycle\ N-0)}$				**Read RESULT**	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$		
Conversion Complete					**Read RESULT**	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$		
RESULT Latched						**Read RESULT**	$I_{(Cycle\ N-3)}$		
RESULT Available							**Read RESULT**		

The ADCINTCYCLE register of the ADC can be programmed by the application to adjust the generation of the interrupt pulse to align with the ADC read operation. For example, if the first instruction in the task reads the ADC and the conversion time is N SYSCLK cycles, then the delay programmed is (N-2) - 4 = N-6.

8.5.3 Parallel Instructions

Parallel instructions are single opcodes that perform two operations in parallel. The following types of parallel instructions are available: math operation in parallel with a move operation, or two math operations in parallel. Both operations complete in a single cycle and there are no special pipeline alignment requirements.

Example 8-3. Math Operation with Parallel Load

```
;  MADDF32 || MMOV32 instruction: 32-bit floating-point add with parallel move
;  MADDF32 is a 1 cycle operation
;  MMOV32 is a 1 cycle operation
         MADDF32    MR0,  MR1, #2     ; MR0 = MR1 + 2,
      || MMOV32   MR1,  @Val           ; MR1 gets the contents of Val
                                       ; <-- MMOV32 completes here (MR1 is valid)
                                       ; <-- DDF32 completes here (MR0 is valid)
         MMPYF32 MR0, MR0, MR1         ; Any instruction, can use MR1 and/or MR0
```

Example 8-4. Multiply with Parallel Add

```
;  MMPYF32 || MADDF32 instruction: 32-bit floating-point multiply with parallel add
;  MMPYF32 is a 1 cycle operation
;  MADDF32 is a 1 cycle operation
     MMPYF32 MR0, MR1, MR3         ; MR0 = MR1 * MR3
 ||  MADDF32 MR1, MR2, MR0         ; MR1 = MR2 + MR0 (Uses value of MR0 before MMPYF32)
                                   ; <-- MMPYF32 and MADDF32 complete here (MR0 and MR1 are valid)
     MMPYF32 MR1, MR1, MR0         ; Any instruction, can use MR1 and/or MR0
```

8.5.4 CLA Task Execution Latency

The CLA task execution latency depends on the state of the system:

- CLA task trigger of new task (normal or background) without background task active:

  Task takes 8 cycles from CLA task trigger to first instruction of task to reach the D2 phase of pipeline.

  Note

  If background task has been configured in the system, then the compiler during code compilation adds context save instructions at the start of each regular task and restore instructions at end of each task so that register content can be saved and restored in case a background task is executing while the regular task is triggered. When a regular task is entered, this compiler-generated context save instruction is the first instruction of the task.

- CLA task trigger of normal task when background task is active:

  Task takes 9 cycles from CLA task trigger to first instruction of normal task to reach the D2 phase of pipeline. There is a difference of one clock cycle to force the MSTOP in the D2 phase of the background task before the task exits as compared to a new task trigger without the background task active.

  Note

  If the MBCNDD/MCCNDD/MRCNDD instructions in the background task are in the D2 phase of the pipeline when a new task gets triggered, the task takes a minimum of 3 more cycles to complete these uninterruptible instructions adding to the delay.

- Returning to background task from normal task:

  The task takes 5 cycles to return from a normal task to resume the background task instruction at the D2 phase of the pipeline.

8.6 Software

8.6.1 CLA Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/cla

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

8.6.1.1 CLA arcsine(x) using a lookup table (cla_asin_cpu01) - C28X_DUAL

FILE: cla_ex1_asin_cpu1.c

In this example, cpu1 will be used to initialize the clocks Task 1 of the CLA on cpu2 will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table. It is recommended to run the c28x1 core first, followed by the C28x2 core.

Memory Allocation

- CLA1 Math Tables (RAMLS0)
  - CLAasinTable - Lookup table
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fVal - Sample input to the lookup algorithm

Watch Variables

- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

8.6.1.2 CLA Arcsine Example. - C28X_DUAL

FILE: cla_ex1_asin_cpu2.c Dual Core arcsine example. This example demonstrates how to run CLA tasks on cpu2.cla1 It is recommended to run the c28x1 core first, followed by the C28x2 core.

8.6.1.3 CLA arcsine(x) using a lookup table (cla_asin_cpu01)

FILE: cla_ex1_asin.c

In this example, Task 1 of the CLA will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table.

Note that since this example does not use background CLA task, the compile flag cla_background_task is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

Memory Allocation

- CLA1 Math Tables (RAMLS0)
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fVal - Sample input to the lookup algorithm

Watch Variables

- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

8.6.1.4 CLA 2 Pole 2 Zero Infinite Impulse Response Filter (cla_iir2p2z_cpu01) - C28X_DUAL

FILE: cla_ex2_iir2p2z_cpu1.c

This example implements a Transposed Direct Form II IIR filter, commonly known as a Biquad. The input vector is a software simulated noisy signal that is fed to the biquad one sample at a time, filtered and then stored in an output buffer for storage. It is recommended to run the c28x1 core first, followed by the C28x2 core.

Memory Allocation

- CLA1 Data RAM 1 (RAML2)
  - S1_A - Feedback coefficients
  - S1_B - Feedforward coefficients
- CLA1 to CPU Message RAM
  - yn - Output of the Biquad
- CPU to CLA1 Message RAM
  - xn - Sample input to the filter

Watch Variables

- pass
- fail

8.6.1.5 CLA 2-pole 2-zero IIR Filter Example for F2837xD. - C28X_DUAL

FILE: cla_ex2_iir2p2z_cpu2.c Dual Core iir2p2z example. This example demonstrates how to run CLA tasks on cpu2.cla1 It is recommended to run the c28x1 core first, followed by the C28x2 core.

8.6.1.6 CLA arctangent(x) using a lookup table (cla_atan_cpu01)

FILE: cla_ex2_atan.c

In this example, Task 1 of the CLA will calculate the arctangent of an input argument using a lookup table.

Note that since this example does not use background CLA task, the compile flag cla_background_task is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

Memory Allocation

- CLA1 Math Tables (RAMLS0)
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fNum - Numerator of sample input
  - fDen - Denominator of sample input

Watch Variables

- fVal - Argument to task 1
- fResult - Result of arctan(fVal)

8.6.1.7 CLA background nesting task

FILE: cla_ex3_background_nesting_task.c

This example configures CLA task 1 to be triggered by EPWM1 running at 2 Hz (period = 0.5s). A background task is configured to be triggered by CPU timer running at .5 Hz (period = 2s). CLA task 1 toggles LED1 at the start and end of the task and the background task toggles LED2 at the start and end of the task. Background task will be preempted by Task1 and hence LED1 will be toggling even while LED2 is ON.

Note that the compile flag cla_background_task is turned on in this project. Enabling background task adds additional context save/restore cycles during task switching thus increasing the overall trigger-to-task latency. If the application does not use the background CLA task, it is recommended to turn this flag off for better performance. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

8.6.1.8 Controlling PWM output using CLA

FILE: cla_ex4_pwm_control.c

This example showcases how to update PWM signal output using CLA. EPWM1 is configured to generate complementary signals on both of its channels of fixed frequency 100 KHz. EPWM4 is configured to trigger a periodic CLA control task of frequency 10 KHz. The CLA task implements a very simple logic to vary the duty of the EPWM1 outputs by increasing it by 0.1 in every iteration and maintaining it in the range of 0.1-0.9. For actual use-cases, the control logic could be modified to much more complex depending upon the application. The other CLA task (CLA task 8) is triggered by software at beginning to initialize the CLA global variables

External Connections

- Observe GPIO0 (EPWM1A) on oscilloscope
- Observe GPIO1 (EPWM1B) on oscilloscope

Watch Variables

- duty

8.6.1.9 Just-in-time ADC sampling with CLA

FILE: cla_ex5_adc_just_in_time.c

This example showcases how to utilize early-interrupt feature of ADC in combination with the low interrupt response of CLA to enable faster system response and achieve high frequency control loops. EPWM1 is configured to generate a PWM output signal of frequency 1 MHz and this is also used to trigger the ADC sampling at each cycle. ADCA is configured to sample the input on Channel 0 and to generate the early interrupt at the end of S/H + offset cycles. This interrupt is used to trigger the CLA control task. The CLA task implements the control logic to update the duty of the PWM output based on reading the ADC sample data just-in-time i.e. as soon as the ADC results gets latched.The early interrupt feature and low interrupt latency of CLA allows to do some pre-processing as well before reading the ADC data and still completes updating the PWM output before the next interrupts comes in i.e. data read and PWM update is done within a 1 MHz cycle. For illustration purposes, 3-point moving average filter is used to simulate some processing and few steps of the filtering code are done before reading the ADC result which we consider as pre-processing code. The ADC interrupt offset is programmed based on the cycles consumed by the pre-processing code.

The calculation for interrupt offset value is as follows :- -ADC acquisition cycles programmed = 10 SYSCLKS -Conversion time for 12-bit data = 10.5 ADCCLKS = N = 42 SYSCLKS -CLA task trigger to first instruction in Fetch delay = 4 -Let the interrupt offset value be 'x' -The code inside CLA control task before ADC read takes below cycles : Setting up profiling gpio : 3 cycles Pre-processing : 13 cycles Total = 3 + 13 = 16 cycles

As described in device TRM, in order to read just-in-time the total delay before reading ADC should be (N-2) cycles = 40 i.e. : x + 4 + 16 = 40 : x = 20

NOTE :- The optimization is off for this project and the cycles quoted above corresponds to that case.

GPIO2 is used for profiling purposes. GPIO2 is set at the beginning of CLA task 1 and is reset at the end of the task. Thus ON time of GPIO2 indicates the CLA activity. In order to validate the example functionality , observe the GPIO0 (PWM output) and GPIO2 (profiling GPIO) on CRO. The cycles difference between the rising edge of the GPIO0 and GPIO2 indicate the total delay from the time of ADC trigger to setting up of profiling GPIO inside CLA task which should be around 44 cycles (220 ns) based on the above calculation.

External Connections

- Provide constant DC input on ADCA0 for quick validation. GND -> Should observe PWM output duty = 0.1 3.3V -> Should observe PWM output duty = 0.9 Can also provide analog input in range 0 - 3.3V upto fs / 10 = 100 KHz for observing continuous duty variations
- Observe GPIO0 on oscilloscope
- Observe GPIO2 on oscilloscope

Watch Variables

- None

8.6.1.10 Optimal offloading of control algorithms to CLA

FILE: cla_ex6_cpu_offloading.c

This example showcases how to optimally offload the control algorithms from CPU to CLA in order to meet the system requirements. In this example, two control loops are simulated, the faster one (loop1) running at 200 KHz and the slower one (loop2) running at 20 KHz. Loop1 senses the first parameter at ADCA Channel 0, runs the PI controller to achieve the target and contributes to the duty of EPWM1A output with 80% weightage. Loop2 senses the second parameter at ADCB Channel 2, runs the PI controller and contributes to the duty of EPWM1A output with 20% weightage. It is important to note that since these are just software simulated control loops but there is no actual physical process involved and hence updating the duty is not going to have any affect on sampled inputs. ADCA is configured to oversample the first parameter using SOCs 0-3 to suppress the noise and similarly ADCB is used to oversample the second parameter. EPWM4 and EPWM5 are configured to trigger the ADCA and ADCB sampling at loop1 and loop2 frequencies respectively. Once the conversion of all 4 SOCs complete, a CPU ISR or a CLA task is triggered based on the user-configuration. There is also a background task running in the main loop which disables the entire system including PWM output and the control loops when "system_OFF" is set to 1. The system gets enabled again once "system_OFF" is restored back to 0. By default system_OFF is set to 0 but it's value can be updated dynamically by adding it to expression window and writing to it. DCL library is included in the project to make use of optimal PI controllers used in both the loops. User-configurable pre-defined symbol "run_loop1_cla" has been added to the project options in order to specify whether to run the loop1 on C28x or CLA. GPIO2 and GPIO3 are used to profile the execution of loop1 and loop2.

For run_loop1_cla == 0 i.e. both loops running on CPU -> Loop1 Utilization = ~77.5% (measured using profiling GPIO2) -> Loop2 Utilization = ~6% (measured using profiling GPIO3) -> Background task in a while loop -> Total CPU utilization is greater than Utilization bound (UB) Hence the system is non-schedulable, lower priority task (Loop2) execution never completes (no toggling observed on GPIO3) and also background task never gets chance to execute

For run_loop1_cla == 1 i.e. high frequency control loop (loop1) is offloaded to CLA while loop2 runs on CPU -> Loop1 Utilization (CLA) = ~73% -> Loop2 Utilization (CPU)= ~6% -> Total CPU utilization has come down to just ~6% Hence the system is perfectly schedulable, no miss happens for any of the loops and offloading of loop1 to CLA saves CPU bandwidth to execute background tasks as well

For quick inspection of the example functionality, constant DC HIGH/LOW inputs can be provided to the analog channels instead of varying analog voltages. The target value for both the loops are set as some intermediate value i.e. 3500 corresponds to ~2.8V. Now since the sensed inputs are constant and not same as target so the controller outputs will get saturated soon to either 1 or 0. Thus the "duty" variable can take only fixed values based on the equations used in the loops. Infact the duty output would be very intutive, for instance if both inputs are LOW(GND), the controller will try to produce the maximum duty as the target is higher than sensed value hence the duty should be 1.0(0.2 + 0.8) but will get saturated to 0.9(the maximum value defined). Similarly if both inputs are made HIGH, the duty will be 0.1 (the minimum saturation value defined). The final duty table is shown below :

External Connections

- Observe GPIO2 (Loop1 Profiling) on oscilloscope
- Observe GPIO3 (Loop2 Profiling) on oscilloscope
- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Provide constant HIGH(3.3V)/LOW(0V) on both ADCA Ch0 and ADCB Ch2 for quick validation, the following duty value should be observable at EPWM1A for various combinations if the system is perfectly schedulable i.e. both loops gets chance to execute properly :- A0 B2 duty GND GND 0.9 3.3V GND 0.2 GND 3.3V 0.8 3.3V 3.3V 0.1 Note :- The optimization is OFF for this project and all the profiling data quoted above corresponds to this case.

8.6.1.11 Handling shared resources across C28x and CLA

FILE: cla_ex7_shared_resource_handling.c

This example showcases how to handle shared resource challenges across C28x and CLA. As the peripherals are shared between CLA and the CPU, overlapping read-modify-write to the registers by them can lead to data race conditions ultimately leading to data violation or incorrect functionality. In this example, CPU ISR and CLA tasks runs independently. CPU ISR gets triggered by EPWM4 @10KHz and toggles the EPWM1B output via software by controlling CSFB bits of AQCSFRC. CLA task gets triggered by EPWM5 @100Khz and toggles the EPWM1A output via software by controlling CSFA bits of AQCSFRC. Thus in this process both CPU and CLA do read-modify -write to AQCSFRC register independently at different frequencies so there is chance of race condition and updates due to one of them can get lost/. overwritten. This can be clearly observed by updating "phase_shift_ON" to 0U and probing the EPWM1A and 1B outputs on a scope.

This is a standard critical section problem and can be handled by software handshaking mechanism like mutex etc. But most of the real-time control applications are time-sensitive and cannot afford addition software overhead hence this example suggests an alternative hardware based technique to avoid shared resource conflicts between CPU and CLA. The phase shifting mechanism of the EPWM modules is utilized to schedule the CLA task and CPU ISR as desired. EPWM4 generates a synchronous pulse every ZERO event and provides a phase shift of 20 cycles to EPWM5. This way both CLA task and C28x ISR runs at original frequencies i.e. 100KHz and 10KHz but CLA task leads with a phase offset of 20 cycles wrt CPU ISR. Hence concurrent read-modify-writes to AQCSFRC never happens and the EPWM1A and EPWM1B outputs behave as desired i.e. consistent 50 KHz PWM output on EPWM1A and 5 KHz PWM output on EPWM1B with a duty ~50% on both should be generated. In order to utilize this phase shifting mechanism in this example, please make sure "phase_shift_ON" is set to 1.

External Connections

- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Observe GPIO1 (EPWM1B Output) on oscilloscope
- Observe GPIO2 (CLA Task Profiling) on oscilloscope
- Observe GPIO3 (CPU ISR Profiling) on oscilloscope

Note :- The phase offset value can easily be configured by updating TBPHS register to schedule the CLA task and C28x ISR as desired depending upon the application need so as to avoid overlapping register writes by CPU and CLA

Note :- The optimization is on and set to O2 for the project and all the results quoted correspond to this case.

8.7 Instruction Set

This section describes the assembly language instructions of the control law accelerator. Also described are parallel operations, conditional operations, resource constraints, and addressing modes. The instructions listed here are independent from C28x and C28x+FPU instruction sets.

8.7.1 Instruction Descriptions

This section gives detailed information on the instruction set. Each instruction may present the following information:

- Operands
- Opcode
- Description
- Exceptions
- Pipeline
- Examples
- See also

The example INSTRUCTION is shown to familiarize you with the way each instruction is described. The example describes the kind of information you will find in each part of the individual instruction description and where to obtain more information. CLA instructions follow the same format as the C28x; the source operand(s) are always on the right and the destination operand(s) are on the left.

The explanations for the syntax of the operands used in the instruction descriptions for the C28x CLA are given in Table 8-6.

Table 8-6. Operand Nomenclature

Symbol	Description
#16FHi	16-bit immediate (hex or float) value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FHiHex	16-bit immediate hex value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value
#32Fhex	32-bit immediate value that represents an IEEE 32-bit floating-point value
#32F	Immediate float value represented in floating-point representation
#0.0	Immediate zero
#SHIFT	Immediate value of 1 to 32 used for arithmetic and logical shifts.
addr	Opcode field indicating the addressing mode
CNDF	Condition to test the flags in the MSTF register
FLAG	Selected flags from MSTF register (OR) 8 bit mask indicating which floating-point status flags to change
MAR0	auxiliary register 0
MAR1	auxiliary register 1
MARx	Either MAR0 or MAR1
mem16	16-bit memory location accessed using direct, indirect, or offset addressing modes
mem32	32-bit memory location accessed using direct, indirect, or offset addressing modes
MRa	MR0 to MR3 registers
MRb	MR0 to MR3 registers
MRc	MR0 to MR3 registers
MRd	MR0 to MR3 registers
MRe	MR0 to MR3 registers
MRf	MR0 to MR3 registers
MSTF	CLA Floating-point Status Register
shift	Opcode field indicating the number of bits to shift.

Table 8-6. Operand Nomenclature (continued)

Symbol	Description
VALUE	Flag value of 0 or 1 for selected flag (OR) 8 bit mask indicating the flag value; 0 or 1

Each instruction has a table that gives a list of the operands and a short description. Instructions always have their destination operand(s) first followed by the source operand(s).

Table 8-7. INSTRUCTION dest, source1, source2 Short Description

	Description
dest1	Description for the 1st operand for the instruction
source1	Description for the 2nd operand for the instruction
source2	Description for the 3rd operand for the instruction
Opcode	This section shows the opcode for the instruction
Description	Detailed description of the instruction execution is described. Any constraints on the operands imposed by the processor or the assembler are discussed.
Restrictions	Any constraints on the operands or use of the instruction imposed by the processor are discussed.
Pipeline	This section describes the instruction in terms of pipeline cycles as described in Section 8.5
Example	Examples of instruction execution. If applicable, register and memory values are given before and after instruction execution. Some examples are code fragments while other examples are full tasks that assume the CLA is correctly configured and the main CPU has passed it data.
Operands	Each instruction has a table that gives a list of the operands and a short description. Instructions always have their destination operand(s) first followed by the source operand(s).

8.7.2 Addressing Modes and Encoding

The CLA uses the same address to access data and registers as the main CPU. For example, if the main CPU accesses an ePWM register at address 0x00 6800, then the CLA accesses the register using address 0x6800. Since all CLA accessible memory and registers are within the low 64k x 16 of memory, only the low 16-bits of the address are used by the CLA.

To address the CLA data memory, message RAMs and shared peripherals, the CLA supports two addressing modes:

- Direct addressing mode: Uses the address of the variable or register directly.
- Indirect addressing with 16-bit post increment. This mode uses either XAR0 or XAR1.

The CLA does not use a data page pointer or a stack pointer. The two addressing modes are encoded as shown Table 8-8.

Table 8-8. Addressing Modes

Addressing Mode	'addr' Opcode Field Encode(1)	Description
@dir	**0000**	**Direct Addressing Mode** Example 1: MMOV32 MR1, @_VarA Example 2: MMOV32 MR1, @_EPwm1Regs.CMPA.all In this case, the 'mmmm mmmm mmmm mmmm' opcode field is populated with the 16-bit address of the variable. This is the low 16-bits of the address to access the variable using the main CPU. For example, @_VarA populates the address of the variable VarA. and @_EPwm1Regs.CMPA.all populates the address of the CMPA register.
***MAR0[#imm16]++**	**0001**	**MAR0 Indirect Addressing with 16-bit Immediate Post Increment**
***MAR1[#imm16]++**	**0010**	**MAR1 Indirect Addressing with 16-bit Immediate Post Increment** addr = MAR0 (or MAR1) Access memory using the address stored in MAR0 (or MAR1). MAR0 (or MAR1) += #imm16 Then post increment MAR0 (or MAR1) by #imm16. Example 1: MMOV32 MR0, *MAR0[2]++ Example 2: MMOV32 MR1, *MAR1[-2]++ For a post increment of 0, the assembler accepts both *MAR0 and *MAR0[0]++. The 'mmmm mmmm mmmm mmmm' opcode field is populated with the signed 16-bit pointer offset. For example, if #imm16 is 2, then the opcode field is 0x0002. Likewise, if #imm16 is -2, then the opcode field is 0xFFFE. If addition of the 16-bit immediate causes overflow, then the value wraps around on a 16-bit boundary.
***MAR0+[#imm16]**	**0101**	**MAR0 Offset Addressing with 16-bit Immediate Offset**
***MAR1+[#imm16]**	**0110**	**MAR1 Offset Addressing with 16-bit Immediate Offset** addr = MAR0 (or MAR1) + #imm16to the base Add the offset #imm16 address stored in MAR0(MAR1) to access the desired memory location Example 1: MMOV32 MR0, *MAR0+[2] Example 1: MMOV32 MR1, *MAR1+[-2] The ‘mmmm mmmm mmmm mmmm’ opcode field is populated with the signed 16-bit pointer offset. For example, if #imm16 is 2, then the opcode field is 0x0002. Likewise, if #imm16 is -2, then the opcode field is 0xFFFE. If the addition of the 16-bit immediate causes overflow, the value wraps around on a 16-bit boundary.

(1) Values not shown are reserved.

Encoding for the shift fields in the MASR32, MLSR32 and MLSL32 instructions is shown in Table 8-9.

Table 8-9. Shift Field Encoding

Shift Value	'shift' Opcode Field Encode
1	0000
2	0001
3	0010
....	....
32	1111

For instructions that use MRx (where x can be 'a' through 'f') as operands, the trailing alphabet appears in the opcode as a two-bit field. For example:

```
MMPYF32 MRa, MRb, MRc ||
MADDF32 MRd, MRe, MRf
```

whose opcode is,

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

The two-bit field specifies one of four working registers according to Table 8-10.

Table 8-10. Operand Encoding

Two-Bit Field	Working Register
00	MR0
01	MR1
10	MR2
11	MR3

Table 8-11 shows the condition field encoding for conditional instructions such as MNEGF, MSWAPF, MBCNDD, MCCNDD, and MRCNDD.

Table 8-11. Condition Field Encoding

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

8.7.3 Instructions

The instructions are listed alphabetically.

Instruction Set Summary

MABSF32 MRa, MRb

32-Bit Floating-Point Absolute Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0010 0000
```

Description

The absolute value of MRb is loaded into MRa. Only the sign bit of the operand is modified by the MABSF32 instruction.

```
if (MRb < 0) {MRa = -MRb};
        else {MRa =  MRb};
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = 0;
ZF = 0;
if ( MRa(30:23) == 0) ZF = 1;
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #-2.0 ; MR0 = -2.0 (0xC0000000)
MABSF32 MR0, MR0  ; MR0 = 2.0 (0x40000000), ZF = NF = 0
MMOVIZ MR0, #5.0  ; MR0 = 5.0 (0x40A00000)
MABSF32 MR0, MR0  ; MR0 = 5.0 (0x40A00000), ZF = NF = 0
MMOVIZ MR0, #0.0  ; MR0 = 0.0
MABSF32 MR0, MR0  ; MR0 = 0.0 ZF = 1, NF = 0
```

See also

MNEGF32 MRa, MRb {, CNDF}

MADD32 MRa, MRb, MRc

32-Bit Integer Add

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 000cc bbaa
MSW: 0111 1110 1100 0000
```

Description

32-bit integer addition of MRb and MRc.

```
MRa(31:0) = MRb(31:0) + MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; };
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
;       B = (int32)2
;       C = (int32)-7
;
; Calculate Y2 = A + B + C
;
_Cla1Task1:
       MMOV32 MR0, @_A       ; MR0 = 1 (0x00000001)
       MMOV32 MR1, @_B       ; MR1 = 2 (0x00000002)
       MMOV32 MR2, @_C       ; MR2 = -7 (0xFFFFFFF9)
       MADD32 MR3, MR0, MR1 ; A + B
       MADD32 MR3, MR2, MR3 ; A + B + C = -4 (0xFFFFFFFC)
       MMOV32 @_y2, MR3      ; Store y2
       MSTOP                 ; end of task
```

MXOR32 MRa, MRb, MRc
MSUB32 MRa, MRb, MRc

MADDF32 MRa, #16FHi, MRb

32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
  MADDF32 MR0, #2.0, MR1    ; MR0 = 2.0 + MR1
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
  MADDF32 MR2, #-2.5, MR3   ; MR2 = -2.5 + MR3
; Add to MR3 the value 0x3FC00000 (1.5)
; Store the result in MR3
  MADDF32 MR3, #0x3FC0, MR3 ; MR3 = 1.5 + MR3
```

32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, #16FHi, MRb.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 000 0000 00cc bbaa
MSW: 0111 1100 0010 0000
```

Description

Add the contents of MRc to the contents of MRb and load the result into MRa.

```
MRa = MRb + MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given M1, X1, and B1 are 32-bit floating-point numbers
; Calculate Y1 = M1*X1+B1
;
_Cla1Task1:
   MMOV32 MR0,@M1      ; Load MR0 with M1
   MMOV32 MR1,@X1      ; Load MR1 with X1
   MMPYF32 MR1,MR1,MR0 ; Multiply M1*X1
|| MMOV32 MR0,@B1      ; and in parallel load MR0 with B1
   MADDF32 MR1,MR1,MR0 ; Add M*X1 to B1 and store in MR1
   MMOV32 @Y1,MR1      ; Store the result
   MSTOP               ; end of task
```

32-Bit Floating-Point Addition with Parallel Move

Operands

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3)
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This is the destination of the MMOV32.
MRa	CLA floating-point source register for the MMOV32 (MR0 to MR3)

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0101 ffee ddaa addr
```

Description

Perform an MADDF32 and a MMOV32 in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of MRa to the 32-bit location mem32.

```
MRd = MRe + MRf;
[mem32] = MRa;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

Both MADDF32 and MMOV32 complete in a single cycle.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) + C
;
_Cla1Task2:
   MMOV32   MR0, @_A         ; Load MR0 with A
   MMOV32   MR1, @_B         ; Load MR1 with B
   MMPYF32  MR1, MR1, MR0    ; Multiply A*B
|| MMOV32   MR0, @_C         ;     and in parallel load MR0 with C
   MADDF32  MR1, MR1, MR0    ; Add (A*B) to C
|| MMOV32   @_Y2, MR1        ;     and in parallel store A*B
   MMOV32   @_Y3, MR1        ; Store the A*B + C
   MSTOP                     ; end of task
```

32-Bit Floating-Point Addition with Parallel Move

Operands

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3). MRd cannot be the same register as MRa.
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRa	CLA floating-point destination register for the MMOV32 (MR0 to MR3). MRa cannot be the same register as MRd.
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source for the MMOV32.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0001 ffee ddaa addr
```

Description

Perform an MADDF32 and a MMOV32 operation in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of the 32-bit location mem32 to MRa.

```
MRd = MRe + MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MADDF32 and the MMOV32 must be unique. That is, MRa and MRd cannot be the same register.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

The MMOV32 Instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; };
```

Pipeline

The MADDF32 and the MMOV32 both complete in a single cycle.

Bitwise AND

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0110 0000
```

Description

Bitwise AND of MRb with MRc.

```
MRa(31:0) = MRb(31:0) AND MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ   MR0,    #0x5555  ; MR0 = 0x5555AAAA
MMOVXI   MR0,    #0xAAAA
MMOVIZ   MR1,    #0x5432  ; MR1 = 0x5432FEDC

Arithmetic Shift Right

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 0100 0000
```

Description

Arithmetic shift right of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Arithmetic Shift(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given m2 = (int32)32
;       x2 = (int32)64
;       b2 = (int32)-128
;
; Calculate
;       m2 = m2/2
;       x2 = x2/4
;       b2 = b2/8
;
_Cla1Task2:

MBCNDD 16BitDest {, CNDF}

Branch Conditional Delayed

Operands

16BitDest	16-bit destination if condition is true
CNDF	Optional condition tested

Opcode

```
LSW: dest dest dest dest
MSW: 0111 1001 1000 cndf
```

Description

If the specified condition is true, then branch by adding the signed 16BitDest value to the MPC value. Otherwise, continue without branching. If the address overflows, the address wraps around. Therefore, a value of "0xFFFE" puts the MPC back to the MBCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC += 16BitDest;
```

CNDF is one of the following conditions:

Encode[1]	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF[2]	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Restrictions

The MBCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more information.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

MBCNDD 16BitDest {, CNDF} (continued)

Branch Conditional Delayed

Pipeline

The MBCNDD instruction alone is a single-cycle instruction. As shown in Table 8-12, 6 instruction slots are executed for each branch; 3 slots before the branch instruction (I2-I4) and 3 slots after the branch instruction (I5-I7). The total number of cycles for a branch taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a branch can, therefore, range from 1 to 7 cycles. The number of cycles for a branch taken cannot be the same as for a branch not taken.

Referring to Table 8-12 and Table 8-13, the instructions before and after MBCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MBCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
  - The three instructions proceeding MBCNDD can change MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the MBCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

```
<Instruction 1>   ; I1 Last instruction that can affect flags for
                  ; the MBCNDD operation
<Instruction 2>   ; I2 Cannot be stop, branch, call or return

MRCNDD CNDF

MCCNDD 16BitDest {, CNDF}

Call Conditional Delayed

Operands

16BitDest	16-bit destination if condition is true
CNDF	Optional condition to be tested

Opcode

```
LSW: dest dest dest dest
MSW: 0111 1001 1001 cndf
```

Description

If the specified condition is true, then store the return address in the RPC field of MSTF and make the call by adding the signed 16BitDest value to the MPC value. Otherwise, continue code execution without making the call. If the address overflows, the address wraps around. Therefore a value of "0xFFFE" puts the MPC back to the MCCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE)
{
    RPC = return address;
    MPC += 16BitDest;
};
```

CNDF is one of the following conditions:

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Restrictions

The MCCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more details.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

MCCNDD 16BitDest {, CNDF} (continued)

Call Conditional Delayed

Pipeline

The MCCNDD instruction alone is a single-cycle instruction. As shown in Table 8-14, 6 instruction slots are executed for each call; 3 before the call instruction (I2-I4) and 3 after the call instruction (I5-I7). The total number of cycles for a call taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a call can, therefore, range from 1 to 7 cycles. The number of cycles for a call taken cannot be the same as for a call not taken.

Referring to the following code fragment and the pipeline diagrams in Table 8-14 and Table 8-15, the instructions before and after MCCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MCCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MCCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
  - The three instructions proceeding MCCNDD can change MSTF flags but have no effect on whether the MCCNDD instruction makes the call or not. This is because the flag modification occurs after the D2 phase of the MCCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

MCLRC BGINTM

Clear Background Task Interrupt Mask

Operands

None	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 0111 0000
```

Description

This instruction clears the background task interrupt mask (BGINTM) bit in the MSTSBGRND register, allowing any code thereafter to be interrupted by a higher priority task. This instruction clears the BGINTM bit at the end of the D2 phase.

Note

This instruction does not require the MEALLOW bit to be asserted before or deasserted after clearing BGINTM.

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MCLRC BGINTM        ; Allow the background task to be
                    ; interrupted by clearing the
                    ; MSTSBGRND.BGINTM bit
```

MSETC BGINTM

MCMP32 MRa, MRb

32-Bit Integer Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0010 0000
```

Description

Set ZF and NF flags on the result of MRa - MRb where MRa and MRb are 32-bit integers. For a floating-point compare, refer to MCMPF32.

Note

A known hardware issue exists in the MCMP32 instruction. Signed-integer comparisons using MCMP32 alone set the status bits in a way that is not useful for comparison when the difference between the two operands is too large, such as when the inputs have opposite sign and are near the extreme 32-bit signed values. This affects both signed and unsigned integer comparisons.

The compiler (version 18.1.5.LTS or higher) has implemented a workaround for this issue. The compiler checks the upper bits of the operands by performing a floating point comparison before proceeding to do the integer comparison or subtraction.

The compiler flag --cla_signed_compare_workaround enables this workaround.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
If(MRa ==    MRb) {ZF=1; NF=0;}
If(MRa >  MRb) {ZF=0; NF=0;}
If(MRa <  MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Behavior of ZF and NF flags for different comparisons
;
; Given A = (int32)1
;       B = (int32)2
;       C = (int32)-7
;
    MMOV32 MR0, @_A ; MR0 = 1 (0x00000001)
    MMOV32 MR1, @_B ; MR1 = 2 (0x00000002)
    MMOV32 MR2, @_C ; MR2 = -7 (0xFFFFFFF9)
    MCMP32 MR2, MR2 ; NF = 0, ZF = 1
    MCMP32 MR0, MR1 ; NF = 1, ZF = 0
    MCMP32 MR1, MR0 ; NF = 0, ZF = 0
```

See also

MADD32 MRa, MRb, MRc
MSUB32 MRa, MRb, MRc

MCMPF32 MRa, MRb

32-Bit Floating-Point Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0000 0000
```

Description

Set ZF and NF flags on the result of MRa - MRb. The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE format offsetting the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- A denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == MRb)   {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Behavior of ZF and NF flags for different comparisons
    MMOVIZ    MR1, #-2.0  ; MR1 = -2.0 (0xC0000000)
    MMOVIZ    MR0, #5.0   ; MR0 = 5.0 (0x40A00000)
    MCMPF32   MR1, MR0    ; ZF = 0, NF = 1
    MCMPF32   MR0, MR1    ; ZF = 0, NF = 0
    MCMPF32   MR0, MR0    ; ZF = 1, NF = 0
```

MMAXF32 MRa, MRb
MMINF32 MRa, #16FHi
MMINF32 MRa, MRb

MCMPF32 MRa, #16FHi

32-Bit Floating-Point Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1100 00aa
```

Description

Compare the value in MRa with the floating-point value represented by the immediate operand. Set the ZF and NF flags on (MRa - #16FHi:0).

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE floating-point format offsets the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- Denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == #16FHi:0) {ZF=1, NF=0;}
If(MRa > #16FHi:0) {ZF=0, NF=0;}
If(MRa < #16FHi:0) {ZF=0, NF=1;}
```

Pipeline

This is a single-cycle instruction

Example 1

```
; Behavior of ZF and NF flags for different comparisons
  MMOVIZ      MR1, #-2.0  ; MR1 = -2.0 (0xC0000000)
  MMOVIZ      MR0, #5.0   ; MR0 = 5.0 (0x40A00000)
  MCMPF32     MR1, #-2.2  ; ZF = 0, NF = 0
  MCMPF32     MR0, #6.5   ; ZF = 0, NF = 1
  MCMPF32     MR0, #5.0   ; ZF = 1, NF = 0
```

MDEBUGSTOP

Debug Stop Task

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 0110 0000
```

Description

When CLA breakpoints are enabled, the MDEBUGSTOP instruction is used to halt a task so that the task can be debugged. That is, MDEBUGSTOP is the CLA breakpoint. If CLA breakpoints are not enabled, the MDEBUGSTOP instruction behaves like a MNOP. Unlike the MSTOP, the MIRUN flag is not cleared and an interrupt is not issued. A single-step or run operation continues execution of the task.

Restrictions

The MDEBUGSTOP instruction cannot be placed 3 instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

See also

MSTOP , MDEBUGSTOP1

MDEBUGSTOP1

Software Breakpoint

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 0011 0000
```

Description

The instruction at which a software breakpoint is placed is replaced by the MDEBUGSTOP1 instruction. The instruction halts execution once the instruction reaches the D2 phase in the pipeline; at that point, the subsequent instructions that were fetched, after the halt, are flushed from the pipeline. The replace instruction is re-fetched after this and execution continues normally (either in run or step mode).

See Section 8.4.3 for a detailed explanation of the operation.

Restrictions

The MDEBUGSTOP1 instruction cannot be placed 3 instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

MSTOP, MDEBUGSTOP

MEALLOW

Enable CLA Write Access to EALLOW Protected Registers

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 1001 0000
```

Description

This instruction sets the MEALLOW bit in the CLA status register MSTF. When this bit is set, the CLA is allowed write access to EALLOW protected registers. To again protect against CLA writes to protected registers, use the MEDIS instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from Code Composer Studio.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
   .cdecls C,LIST,"CLAShared.h"
   ...
_Cla1Task1:
   ...
   MEALLOW                            ; Allow CLA write access
   MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; Write to TZSEL
   MEDIS                              ; Disallow CLA write access
   ...
   ...
   MSTOP
```

MEDIS

MEDIS

Disable CLA Write Access to EALLOW Protected Registers

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 1011 0000
```

Description

This instruction clears the MEALLOW bit in the CLA status register MSTF. When this bit is clear, the CLA is not allowed write access to EALLOW-protected registers. To enable CLA writes to protected registers, use the MEALLOW instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from the Code Composer Studio™ IDE.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
   .cdecls C,LIST,"CLAShared.h"
   ...
_Cla1Task1:
   ...
   MEALLOW                            ; Allow CLA write access
   MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; Write to TZSEL
   MEDIS                              ; Disallow CLA write access
   ...
   ...
   MSTOP
```

MEINVF32 MRa, MRb

32-Bit Floating-Point Reciprocal Approximation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0000 0000
```

Description

This operation generates an estimate of 1/X in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/X);
Ye = Ye*(2.0 - Ye*X);
Ye = Ye*(2.0 - Ye*X);
```

After two iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEINVF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/MRb;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEINVF32 generates an underflow condition.
- LVF = 1 if MEINVF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Calculate Num/Den using a Newton-Raphson algorithum for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;
_Cla1Task1:
    MMOV32 MR1, @_Den      ; MR1 = Den
    MEINVF32 MR2, MR1      ; MR2 = Ye = Estimate(1/Den)
    MMPYF32 MR3, MR2, MR1  ; MR3 = Ye*Den
    MSUBF32 MR3, #2.0, MR3 ; MR3 = 2.0 - Ye*Den
    MMPYF32 MR2, MR2, MR3  ; MR2 = Ye = Ye*(2.0 - Ye*Den)
    MMPYF32 MR3, MR2, MR1  ; MR3 = Ye*Den
 || MMOV32 MR0, @_Num      ; MR0 = Num
    MSUBF32 MR3, #2.0, MR3 ; MR3 = 2.0 - Ye*Den
    MMPYF32 MR2, MR2, MR3  ; MR2 = Ye = Ye*(2.0 - Ye*Den)
 || MMOV32 MR1, @_Den      ; Reload Den To Set Sign
    MNEGF32 MR0, MR0, EQ   ; if(Den == 0.0) Change Sign Of Num
    MMPYF32 MR0, MR2, MR0  ; MR0 = Y = Ye*Num
    MMOV32 @_Dest, MR0     ; Store result
    MSTOP                  ; end of task
```

MEISQRTF32 MRa, MRb

32-Bit Floating-Point Square-Root Reciprocal Approximation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0100 0000
```

Description

This operation generates an estimate of 1/sqrt(X) in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/sqrt(X));
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
```

After 2 iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEISQRTF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/sqrt (MRb);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEISQRTF32 generates an underflow condition.
- LVF = 1 if MEISQRTF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Y = sqrt(X)
; Ye = Estimate(1/sqrt(X));
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Y = X*Ye
;
_Cla1Task3:
    MMOV32 MR0, @_x          ; MR0 = X
    MEISQRTF32 MR1, MR0      ; MR1 = Ye = Estimate(1/sqrt(X))
    MMOV32 MR1, @_x, EQ      ; if(X == 0.0) Ye = 0.0
    MMPYF32 MR3, MR0, #0.5   ; MR3 = X*0.5
    MMPYF32 MR2, MR1, MR3    ; MR2 = Ye*X*0.5
    MMPYF32 MR2, MR1, MR2    ; MR2 = Ye*Ye*X*0.5
    MSUBF32 MR2, #1.5, MR2   ; MR2 = 1.5 - Ye*Ye*X*0.5
    MMPYF32 MR1, MR1, MR2    ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
    MMPYF32 MR2, MR1, MR3    ; MR2 = Ye*X*0.5
    MMPYF32 MR2, MR1, MR2    ; MR2 = Ye*Ye*X*0.5
    MSUBF32 MR2, #1.5, MR2   ; MR2 = 1.5 - Ye*Ye*X*0.5
    MMPYF32 MR1, MR1, MR2    ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
    MMPYF32 MR0, MR1, MR0    ; MR0 = Y = Ye*X
    MMOV32 @_y, MR0          ; Store Y = sqrt(X)
    MSTOP                    ; end of task
```

MF32TOUI16 MRa, MRb

Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1010 0000
```

Description

Convert the 32-bit floating point value in MRb to an unsigned 16-bit integer value and truncate to zero. The result is stored in MRa. To instead round the integer to the nearest even value, use the MF32TOUI16R instruction.

```
MRa(15:0) = F32TOUI16(MRb);
MRa(31:16) = 0x0000;
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ      MR0, #9.0     ; MR0 = 9.0 (0x41100000)
MF32TOUI16  MR1, MR0      ; MR1(15:0) = MF32TOUI16(MR0) = 9 (0x0009)
                          ; MR1(31:16) = 0x0000
MMOVIZ      MR2, #-9.0    ; MR2 = -9.0 (0xC1100000)
MF32TOUI16  MR3, MR2      ; MR3(15:0) = MF32TOUI16(MR2) = 0 (0x0000)
                          ; MR3(31:16) = 0x0000

MI16TOF32 MRa, mem16

Convert 16-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location to be converted

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 00aa addr
```

Description

Convert the 16-bit signed integer indicated by the mem16 pointer to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI16TOF32[mem16];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction:

Example

```
; Assume A = 4 (0x0004)
;        B = -4 (0xFFFC)
   MI16TOF32 MR0, @_A ; MR0 = MI16TOF32(A) = 4.0 (0x40800000)
   MI16TOF32 MR1, @_B ; MR1 = MI16TOF32(B) = -4.0 (0xC0800000
```

MI32TOF32 MRa, mem32

Convert 32-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory source for the MMOV32 operation.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0100 01aa addr
```

Description

Convert the 32-bit signed integer indicated by mem32 to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI32TOF32[mem32];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Given X, M and B are IQ24 numbers:
; X = IQ24(+2.5) = 0x02800000
; M = IQ24(+1.5) = 0x01800000
; B = IQ24(-0.5) = 0xFF800000
;
; Calculate Y = X * M + B
;
; Convert M, X, and B from IQ24 to float
;
_Cla1Task3:
   MI32TOF32 MR0, @_M          ; MR0 = 0x4BC00000
   MI32TOF32 MR1, @_X          ; MR1 = 0x4C200000

MI32TOF32 MRa, MRb

Convert 32-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 1000 0000
```

Description

Convert the signed 32-bit integer in MRb to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI32TOF32(MRb);
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
   MMOVIZ    MR2, #0x1111 ; MR2(31:16) = 4369 (0x1111)
   MMOVXI    MR2, #0x1111 ; MR2(15:0) = 4369 (0x1111)
                          ; MR2 = +286331153 (0x11111111)
   MI32TOF32 MR3, MR2     ; MR3 = MI32TOF32 (MR2) = 286331153.0 (0x4D888888)
```

MLSL32 MRa, #SHIFT

Logical Shift Left

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1100 0000
```

Description

Logical shift-left of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Logical Shift Left(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given m2 = (int32)32
;       x2 = (int32)64
;       b2 = (int32)-128
;
; Calculate:
;       m2 = m2*2
;       x2 = x2*4
;       b2 = b2*8
;
_Cla1Task3:
   MMOV32 MR0, @_m2    ; MR0 = 32 (0x00000020)
   MMOV32 MR1, @_x2    ; MR1 = 64 (0x00000040)
   MMOV32 MR2, @_b2    ; MR2 = -128 (0xFFFFFF80)
   MLSL32 MR0, #1      ; MR0 = 64 (0x00000040)
   MLSL32 MR1, #2      ; MR1 = 256 (0x00000100)
   MLSL32 MR2, #3      ; MR2 = -1024 (0xFFFFFC00)
   MMOV32 @_m2, MR0    ; Store results
   MMOV32 @_x2, MR1
   MMOV32 @_b2, MR2
   MSTOP               ; end of task
```

MLSR32 MRa, #SHIFT

Logical Shift Right

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1000 0000
```

Description

Logical shift-right of MRa by the number of bits indicated. The number of bits can be 1 to 32. Unlike the arithmetic shift (MASR32), the logical shift does not preserve the number's sign bit. Every bit in the operand is moved the specified number of bit positions, and the vacant bit positions are filled in with zeros.

```
MARa(31:0) = Logical Shift Right(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Illustrate the difference between MASR32 and MLSR32
MMOVIZ MR0, #0xAAAA    ; MR0 = 0xAAAA5555
MMOVXI MR0, #0x5555
MMOV32 MR1, MR0        ; MR1 = 0xAAAA5555
MMOV32 MR2, MR0        ; MR2 = 0xAAAA5555
MASR32 MR1, #1         ; MR1 = 0xD5552AAA
MLSR32 MR2, #1         ; MR2 = 0x55552AAA
MASR32 MR1, #1         ; MR1 = 0xEAAA9555
MLSR32 MR2, #1         ; MR2 = 0x2AAA9555
MASR32 MR1, #6         ; MR1 = 0xFFAAAA55
MLSR32 MR2, #6         ; MR2 = 0x00AAAA55
```

MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32

32-Bit Floating-Point Multiply and Accumulate with Parallel Move

Operands

MR3	floating-point destination/source register MR3 for the add operation
MR2	CLA floating-point source register MR2 for the add operation
MRd	CLA floating-point destination register (MR0 to MR3) for the multiply operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRf	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRa	CLA floating-point destination register for the MMOV32 operation (MR0 to MR3). MRa cannot be MR3 or the same register as MRd.
mem32	32-bit source for the MMOV32 operation

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0011 ffee ddaa addr
```

Description

Multiply and accumulate the contents of floating-point registers and move from register to memory. The destination register for the MMOV32 cannot be the same as the destination registers for the MMACF32.

```
MR3 = MR3 + MR2;
MRd = MRe * MRf;
MRa = [mem32];
```

Restrictions

The destination registers for the MMACF32 and the MMOV32 must be unique. That is, MRa cannot be MR3 and MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMACF32 (add or multiply) generates an underflow condition.
- LVF = 1 if MMACF32 (add or multiply) generates an overflow condition.

MMOV32 sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

Pipeline

MMACF32 and MMOV32 complete in a single cycle.

MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32 (continued)

MMAXF32 MRa, MRb

32-Bit Floating-Point Maximum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0010 0000
```

Description

```
if(MRa < MRb) MRa = MRb;
```

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == MRb)  {ZF=1; NF=0;}
if(MRa > MRb) {ZF=0; NF=0;}
if(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example 1

```
MMOVIZ   MR0, #5.0  ; MR0 =  5.0  (0x40A00000)
MMOVIZ   MR1, #-2.0 ; MR1 = -2.0  (0xC0000000)
MMOVIZ   MR2, #-1.5 ; MR2 = -1.5  (0xBFC00000)
MMAXF32   MR2, MR1  ; MR2 = -1.5, ZF = NF = 0
MMAXF32   MR1, MR2  ; MR1 = -1.5, ZF = 0, NF = 1
MMAXF32   MR2, MR0  ; MR2 =  5.0, ZF = 0, NF = 1
MAXF32   MR0, MR2   ; MR2 =  5.0, ZF = 1, NF = 0
```

MMAXF32 MRa, MRb (continued)

32-Bit Floating-Point Maximum

Example 2

```
; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store the value in Result
;
_Cla1Task1:

MMAXF32 MRa, #16FHi

32-Bit Floating-Point Maximum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0000 00aa
```

Description

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is larger, then load the value into MRa.

```
if(MRa < #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0)  {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR0, #5.0  ; MR0 =  5.0  (0x40A00000)
MMOVIZ    MR1, #4.0  ; MR1 =  4.0  (0x40800000)
MMOVIZ    MR2, #-1.5 ; MR2 = -1.5  (0xBFC00000)
MMAXF32   MR0, #5.5  ; MR0 =  5.5, ZF = 0, NF = 1
MMAXF32   MR1, #2.5  ; MR1 =  4.0, ZF = 0, NF = 0
MMAXF32   MR2, #-1.0 ; MR2 = -1.0, ZF = 0, NF = 1
MMAXF32   MR2, #-1.0 ; MR2 = -1.5, ZF = 1, NF = 0
```

MMINF32 MRa, MRb

32-Bit Floating-Point Minimum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0100 0000
```

Description

```
if(MRa > MRb) MRa = MRb;
```

Special cases for the output from the MMINF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == MRb)  {ZF=1; NF=0;}
if(MRa > MRb) {ZF=0; NF=0;}
if(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example 1

```
MMOVIZ MR0, #5.0  ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0  ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMINF32 MR0, MR1  ; MR0 = 4.0, ZF = 0, NF = 0
MMINF32 MR1, MR2  ; MR1 = -1.5, ZF = 0, NF = 0
MMINF32 MR2, MR1  ; MR2 = -1.5, ZF = 1, NF = 0
MMINF32 MR1, MR0  ; MR2 = -1.5, ZF = 0, NF = 1
```

MMINF32 MRa, #16FHi

32-Bit Floating-Point Minimum

Operands

MRa	floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0100 00aa
```

Description

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is smaller, then load the value into MRa.

```
if(MRa > #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMINF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0)   {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ   MR0, #5.0   ; MR0 =  5.0  (0x40A00000)
MMOVIZ   MR1, #4.0   ; MR1 =  4.0  (0x40800000)
MMOVIZ   MR2, #-1.5  ; MR2 = -1.5  (0xBFC00000)
MMINF32  MR0, #5.5   ; MR0 =  5.0, ZF = 0, NF = 1
MMINF32  MR1, #2.5   ; MR1 =  2.5, ZF = 0, NF = 0
MMINF32  MR2, #-1.0  ; MR2 = -1.5, ZF = 0, NF = 1
MMINF32  MR2, #-1.5  ; MR2 = -1.5, ZF = 1, NF = 0
```

MMOV16 MARx, MRa, #16I

Load the Auxiliary Register with MRa + 16-bit Immediate Value

Operands

MARx	Auxiliary register MAR0 or MAR1
MRa	CLA Floating-point register (MR0 to MR3)
#16I	16-bit immediate value

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR0, MRa, #16I)
MSW: 0111 1111 1101 00AA
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR1, MRa, #16I)
MSW: 0111 1111 1111 00AA
```

Description

Load the auxiliary register, MAR0 or MAR1, with MRa(15:0) + 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARx = MRa(15:0) + #16I;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

  The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.
- **I3**

  Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #_X.
- **I4**

  Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOVI16.

```
; Assume MAR0 is 50, MR0 is 10, and #_X is 20
  MMOV16 MAR0, MR0, #_X        ; Load MAR0 with address of X (20) + MR0 (10)
  <Instruction 1>         ; I1 Uses the old value of MAR0 (50)
  <Instruction 2>         ; I2 Uses the old value of MAR0 (50)
  <Instruction 3>         ; I3 Cannot use MAR0
  <Instruction 4>         ; I4 Uses the new value of MAR0 (30)
  <Instruction 5>         ; I5
```

MMOV16 MARx, MRa, #16I (continued)

MMOV16 MARx, mem16

Load MAR1 with 16-bit Value

Operands

MARx	CLA auxiliary register MAR0 or MAR1
mem16	16-bit destination memory accessed using one of the available addressing modes

Opcode

```
LSW: mmmm mmmm mmmm mmmm (Opcode for MMOV16 MAR0, mem16)
MSW: 0111 0110 0000 addr
LSW: mmmm mmmm mmmm mmmm (Opcode for MMOV16 MAR1, mem16)
MSW: 0111 0110 0100 addr
```

Description

Load MAR0 or MAR1 with the 16-bit value pointed to by mem16. Refer to the Pipeline section for important information regarding this instruction.

```
MAR1 = [mem16];
```

Flags

No flags MSTF flags are affected.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

  The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.
- **I3**

  Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #_X.
- **I4**

  Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOV16.

```
; Assume MAR0 is 50 and @_X is 20
MMOV16 MAR0, @_X    ; Load MAR0 with the contents of X (20)
<Instruction 1>     ; I1 Uses the old value of MAR0 (50)
<Instruction 2>     ; I2 Uses the old value of MAR0 (50)
<Instruction 3>     ; I3 Cannot use MAR0
<Instruction 4>     ; I4 Uses the new value of MAR0 (20)
<Instruction 5>     ; I5
....
```

MMOV32 mem32, MRa

Move 32-Bit Floating-Point Register Contents to Memory

Operands

MRa	floating-point register (MR0 to MR3)
mem32	32-bit destination memory accessed using one of the available addressing modes

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0100 11aa addr
```

Description

Move from MRa to 32-bit memory location indicated by mem32.

```
[mem32] = MRa;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected.

Pipeline

This is a single-cycle instruction.

Example

```
; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating-point arrays;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1
; 3rd multiply: C = X2 * Y2
; 4th multiply: D = X3 * Y3
; 5th multiply: E = X3 * Y3;
; Result = A + B + C + D + E
;
_Cla1Task1:

MMOV32 mem32, MSTF

MMOV32 mem32, MSTF

Move 32-Bit MSTF Register to Memory

Operands

MSTF	Floating-point status register
mem32	32-bit destination memory

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0100 addr
```

Description

Copy the CLA floating-point status register, MSTF, to memory.

```
[mem32] = MSTF;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

One of the uses of this instruction is to save off the return PC (RPC) prior to calling a function. The decision to jump to a function is made when the MCCNDD is in the decode2 (D2) phase of the pipeline; the RPC is also updated in this phase. The actual jump occurs 3 cycles later when MCCNDD enters the execution (E) phase. You must save the old RPC before MCCNDD updates in the D2 phase; that is, save MSTF 3 instructions prior to the function call.

Example

The following example illustrates the pipeline flow for the context save (of the flags and RPC) prior to a function call. The first column in the comments shows the pipeline stages for the MMOV32 instruction while the second column pertains to the MCCNDD instruction.

```
 MMOV32 @_temp, MSTF ; D2|   |
MNOP                 ; R1|F1| MCCNDD is fetched
MNOP                 ; R2|F2|
MNOP                 ; E |D1|
MCCNDD _bar, UNC     ; W |D2| old RPC written to memory,
                     ;   |  | RPC updated with MPC+1
MNOP                 ;   |R1|
MNOP                 ;   |R2|
MNOP                 ;   |E | execution branches to _bar
```

MMOV32 mem32, MRa

MMOV32 MRa, mem32 {, CNDF}

Conditional 32-Bit Move

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes
CNDF	Optional condition

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 00cn dfaa addr
```

Description

If the condition is true, then move the 32-bit value referenced by mem32 to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = [mem32];
```

CNDF is one of the following conditions:

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
  NF = MRa(31);
  ZF = 0;
  if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
}
  else No flags modified;
```

Pipeline

This is a single-cycle instruction.

MMOV32 MRa, mem32 {, CNDF} (continued)

Conditional 32-Bit Move

Example

```
; Given A, B, X, M1 and M2 are 32-bit floating-point numbers
;
; if(A == B) calculate Y = X*M1
; if(A! = B) calculate Y = X*M2
;
_Cla1Task5:
    MMOV32    MR0, @_A
    MMOV32    MR1, @_B
    MCMPF32   MR0, MR1
    MMOV32    MR2, @_M1, EQ  ; if A == B, MR2 = M1
                             ;     Y = M1*X
    MMOV32    MR2, @_M2, NEQ ; if A! = B, MR2 = M2
                             ;     Y = M2*X
    MMOV32    MR3, @_X
    MMPYF32   MR3, MR2, MR3  ; Calculate Y
    MMOV32    @_Y, MR3       ; Store Y
    MSTOP                    ; end of task
```

Conditional 32-Bit Move

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
CNDF	Optional condition

Opcode

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1100 0000
```

Description

If the condition is true, then move the 32-bit value in MRb to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = MRb;
```

CNDF is one of the following conditions:

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
 {
   NF = MRa(31); ZF = 0;
   if(MRa(30:23) == 0) {ZF = 1; NF = 0;}
}
else No flags modified;
```

Pipeline

This is a single-cycle instruction.

MMOV32 MRa, MRb {, CNDF} (continued)

Conditional 32-Bit Move

Example

```
; Given: X = 8.0
;        Y = 7.0
;        A = 2.0
;        B = 5.0
; _ClaTask1
    MMOV32   MR3, @_X      ; MR3 = X = 8.0
    MMOV32   MR0, @_Y      ; MR0 = Y = 7.0
    MMAXF32  MR3, MR0      ; ZF = 0, NF = 0, MR3 = 8.0
    MMOV32   MR1, @_A, GT  ; true, MR1 = A = 2.0
    MMOV32   MR1, @_B, LT  ; false, does not load MR1
    MMOV32   MR2, MR1, GT  ; true, MR2 = MR1 = 2.0
    MMOV32   MR2, MR0, LT  ; false, does not load MR2
    MSTOP
```

MMOV32 MSTF, mem32

Move 32-Bit Value from Memory to the MSTF Register

Operands

MSTF	CLA status register
mem32	32-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0000 addr
```

Description

Move from memory to the CLA's status register MSTF. This instruction is most useful when nesting function calls (using MCCNDD).

```
MSTF = [mem32];
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Loading the status register can overwrite all flags and the RPC field. The MEALLOW field is not affected.

Pipeline

This is a single-cycle instruction.

```

MMOVD32 MRa, mem32 (continued)

Move 32-Bit Value from Memory with Data Copy

See also MMOV32 MRa, mem32 {,CNDF}

MMOVF32 MRa, #32F

Load the 32-Bits of a 32-Bit Floating-Point Register

Operands

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex MMOVXI MRa, #16FLoHex
```

MRa	CLA floating-point destination register (MR0 to MR3)
#32F	Immediate float value represented in floating-point representation

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

Description

This instruction accepts the immediate operand only in floating-point representation. To specify the immediate value as a hex value (IEEE 32-bit floating- point format), use the MOVI32 MRa, #32FHex instruction.

Load the 32-bits of MRa with the immediate float value represented by #32F.

#32F is a float value represented in floating-point representation. The assembler only accepts a float value represented in floating-point representation. That is, 3.0 can only be represented as #3.0 (#0x40400000 results in an error).

```
MRa = #32F;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32F, this instruction takes one or two cycles. If all of the lower 16-bits of the IEEE 32-bit floating-point format of #32F are zeros, then the assembler converts MMOVF32 into only an MMOVIZ instruction. If the lower 16-bits of the IEEE 32-bit floating-point format of #32F are not zeros, then the assembler converts MMOVF32 into MMOVIZ and MMOVXI instructions.

Example

```
MMOVF32 MR1, #3.0     ; MR1 = 3.0 (0x40400000)
                      ; Assembler converts this instruction as
                      ; MMOVIZ MR1, #0x4040
MMOVF32 MR2, #0.0     ; MR2 = 0.0 (0x00000000)
                      ; Assembler converts this instruction as
                      ; MMOVIZ MR2, #0x0
MMOVF32 MR3, #12.265  ; MR3 = 12.625 (0x41443D71)
                      ; Assembler converts this instruction as
                      ; MMOVIZ MR3, #0x4144
                      ; MMOVXI MR3, #0x3D71
```

MMOVIZ MRa, #16FHi
MMOVXI MRa, #16FLoHex
MMOVI32 MRa, #32FHex

MMOVI16 MARx, #16I

Load the Auxiliary Register with the 16-Bit Immediate Value

Operands

MARx	Auxiliary register MAR0 or MAR1
#16I	16-bit immediate value

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR0, #16I)
MSW: 0111 1111 1100 0000
LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR1, #16I)
MSW: 0111 1111 1110 0000
```

Description

Load the auxiliary register, MAR0 or MAR1, with a 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARx = #16I;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The immediate load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

  The two instructions following MMOVI16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.
- **I3**

  Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #_X.
- **I4**

  Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOVI16.

```
;  Assume MAR0 is 50 and #_X is 20
MMOVI16 MAR0, #_X             ; Load MAR0 with address of X (20)
<Instruction 1>          ; I1 Uses the old value of MAR0 (50)
<Instruction 2>          ; I2 Uses the old value of MAR0 (50)
<Instruction 3>          ; I3 Cannot use MAR0
<Instruction 4>          ; I4 Uses the new value of MAR0 (20)
<Instruction 5>          ; I5
....
```

MMOVI16 MARx, #16I (continued)

Load the Auxiliary Register with the 16-Bit Immediate Value

I6	I6	I5	I4	I3	I2	I1	MMOVI16	

MMOVI32 MRa, #32FHex

Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate

Operands

MRa	Floating-point register (MR0 to MR3)
#32FHex	A 32-bit immediate value that represents an IEEE 32-bit floating-point value.

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex
MMOVXI MRa, #16FLoHex
```

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

Description

This instruction only accepts a hex value as the immediate operand. To specify the immediate value with a floating-point representation, use the MMOVF32 MRa, #32F instruction.

Load the 32-bits of MRa with the immediate 32-bit hex value represented by #32FHex.

#32FHex is a 32-bit immediate hex value that represents the IEEE 32-bit floating-point value of a floating-point number. The assembler only accepts a hex immediate value. That is, 3.0 can only be represented as #0x40400000 (#3.0 results in an error).

```
MRa = #32FHex;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32FHex, this instruction takes one or two cycles. If all of the lower 16-bits of #32FHex are zeros, then the assembler converts MOVI32 to an MMOVIZ instruction. If the lower 16-bits of #32FHex are not zeros, then the assembler converts MOVI32 to MMOVIZ and MMOVXI instructions.

Example

```
MOVI32   MR1, #0x40400000 ; MR1 = 0x40400000
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR1, #0x4040
MOVI32  MR2, #0x00000000  ; MR2 = 0x00000000
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR2, #0x0
MOVI32  MR3, #0x40004001  ; MR3 = 0x40004001
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR3, #0x4000
                          ; MMOVXI MR3, #0x4001
MOVI32  MR0, #0x00004040  ; MR0 = 0x00004040
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR0, #0x0000
                          ; MMOVXI MR0, #0x4040
```

MMOVI32 MRa, #32FHex (continued)

Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate

MMOVXI MRa, #16FLoHex
MMOVF32 MRa, #32F

MMOVIZ MRa, #16FHi

Load the Upper 16-Bits of a 32-Bit Floating-Point Register

Operands

MRa	Floating-point register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0100 00aa
```

Description

Load the upper 16-bits of MRa with the immediate value #16FHi and clear the low 16-bits of MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. The assembler only accepts a decimal or hex immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

By itself, MMOVIZ is useful for loading a floating-point register with a constant in which the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). If a constant requires all 32-bits of a floating-point register to be initialized, then use MMOVIZ along with the MMOVXI instruction.

```
MRa(31:16) = #16FHi;
MRa(15:0)  = 0;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Load MR0 and MR1 with -1.5 (0xBFC00000)
     MMOVIZ    MR0, #0xBFC0      ; MR0 = 0xBFC00000 (1.5)
     MMOVIZ    MR1, #-1.5        ; MR1 = -1.5 (0xBFC00000)
; Load MR2 with pi = 3.141593 (0x40490FDB)
     MMOVIZ    MR2, #0x4049      ; MR2 = 0x40490000
     MMOVXI    MR2, #0x0FDB      ; MR2 = 0x40490FDB
```

MMOVZ16 MRa, mem16

Load MRx with 16-Bit Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 10aa addr
```

Description

Move the 16-bit value referenced by mem16 to the floating-point register indicated by MRa.

```
MRa(31:16) = 0;
MRa(15:0) = [mem16];
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = 0;
if (MRa(31:0)== 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

MMOVXI MRa, #16FLoHex

Move Immediate Value to the Lower 16-Bits of a Floating-Point Register

Operands

MRa	CLA floating-point register (MR0 to MR3)
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits are not modified.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1000 00aa
```

Description

Load the lower 16-bits of MRa with the immediate value #16FLoHex. #16FLoHex represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits of MRa are not modified. MMOVXI can be combined with the MMOVIZ instruction to initialize all 32-bits of a MRa register.

```
MRa(15:0) = #16FLoHex;
MRa(31:16) = Unchanged;
```

Flags

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Load MR0 with pi = 3.141593 (0x40490FDB)
    MMOVIZ      MR0,#0x4049   ; MR0 = 0x40490000
    MMOVXI      MR0,#0x0FDB   ; MR0 = 0x40490FDB
```

MMPYF32 MRa, #16FHi, MRb

32-Bit Floating-Point Multiply

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1000 bbaa
```

Description

Multiply MRb with the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb * #16FHi:0;
```

This instruction can also be written as MMPYF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
; Same as example 2 but #16FHi is represented in float
    MMOVIZ    MR3, #2.0       ; MR3 = 2.0 (0x40000000)
    MMPYF32   MR0, #3.0, MR3 ; MR0 = 3.0 * MR3 = 6.0 (0x40C00000)
    MMOV32    @_X, MR0        ; Save the result in variable X
```

Example 2

```
; Same as example 1 but #16FHi is represented in Hex
    MMOVIZ    MR3, #2.0          ; MR3 = 2.0 (0x40000000)
    MMPYF32   MR0, #0x4040, MR3 ; MR0 = 0x4040 * MR3 = 6.0 (0x40C00000)
    MMOV32    @_X, MR0           ; Save the result in variable X
```

32-Bit Floating-Point Multiply

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1000 bbaa
```

Description

Multiply MRb with the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb * #16FHi:0;
```

This instruction can also be written as MMPYF32 MRa, #16FHi, MRb.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
;Same as example 2 but #16FHi is represented in float
    MMOVIZ    MR3, #2.0        ; MR3 = 2.0 (0x40000000)
    MMPYF32   MR0, MR3, #3.0   ; MR0 = MR3 * 3.0 = 6.0 (0x40C00000)
    MMOV32    @_X, MR0         ; Save the result in variable X
```

Example 2

```
;Same as example 1 but #16FHi is represented in Hex
    MMOVIZ    MR3, #2.0           ; MR3 = 2.0 (0x40000000)
    MMPYF32   MR0, MR3, #0x4040   ; MR0 = MR3 * 0x4040 = 6.0 (0x40C00000)
    MMOV32    @_X, MR0            ; Save the result in variable X
```

32-Bit Floating-Point Multiply with Parallel Add

Operands

MRa	CLA floating-point destination register for MMPYF32 (MR0 to MR3) MRa cannot be the same register as MRd
MRb	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRc	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRd	CLA floating-point destination register for MADDF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for MADDF32 (MR0 to MR3)

Opcode

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

Description

Multiply the contents of two floating-point registers with parallel addition of two registers.

```
MRa = MRb * MRc;
MRd = MRe + MRf;
```

Restrictions

The destination register for the MMPYF32 and the MADDF32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 or MADDF32 generates an underflow condition.
- LVF = 1 if MMPYF32 or MADDF32 generates an overflow condition.

Pipeline

Both MMPYF32 and MADDF32 complete in a single cycle.

MMPYF32 MRd, MRe, MRf ||MMOV32 MRa, mem32

32-Bit Floating-Point Multiply with Parallel Move

Operands

MRd	CLA floating-point destination register for MMPYF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRf	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRa	CLA floating-point destination register for MMOV32 (MR0 to MR3) MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source of MMOV32.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0000 ffee ddaa addr
```

Description

Multiply the contents of two floating-point registers and load another.

```
MRd = MRe * MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MMPYF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

Pipeline

Both MMPYF32 and MMOV32 complete in a single cycle.

Example 1

```
; Given M1, X1, and B1 are 32-bit floating point
; Calculate Y1 = M1*X1+B1
;
_Cla1Task1:
    MMOV32     MR0, @M1         ; Load MR0 with M1
    MMOV32     MR1, @X1         ; Load MR1 with X1
    MMPYF32    MR1, MR1, MR0    ; Multiply M1*X1
||  MMOV32     MR0, @B1         ; and in parallel load MR0 with B1
    MADDF32    MR1, MR1, MR0    ; Add M*X1 to B1 and store in MR1
    MMOV32     @Y1, MR1         ; Store the result
    MSTOP                       ; end of task
```

MMPYF32 MRd, MRe, MRf ||MMOV32 MRa, mem32 (continued)

32-Bit Floating-Point Multiply with Parallel Move

Example 2

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) * C
;
_Cla1Task2:
    MMOV32    MR0, @A         ; Load MR0 with A
    MMOV32    MR1, @B         ; Load MR1 with B
    MMPYF32   MR1, MR1, MR0   ; Multiply A*B
||  MMOV32    MR0, @C         ; and in parallel load MR0 with C
    MMPYF32   MR1, MR1, MR0   ; Multiply (A*B) by C
||  MMOV32    @Y2, MR1        ; and in parallel store A*B
    MMOV32    @Y3, MR1        ; Store the result
    MSTOP                     ; end of task
```

32-Bit Floating-Point Multiply with Parallel Move

Operands

MRd	CLA floating-point destination register for MMPYF32 (MR0 to MR3)
MRe	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRf	CLA floating-point source register for MMPYF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This is the destination of MMOV32.
MRa	CLA floating-point source register for MMOV32 (MR0 to MR3)

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0100 ffee ddaa addr
```

Description

Multiply the contents of two floating-point registers and move from memory to register.

```
MRd = MRe * MRf;
[mem32] = MRa;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

MMPYF32 and MMOV32 both complete in a single cycle.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) * C
;

MRf	CLA floating-point source register for MSUBF32 (MR0 to MR3)

Opcode

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0100 0000
```

Description

Multiply the contents of two floating-point registers with parallel subtraction of two registers.

```
MRa = MRb * MRc;
MRd = MRe - MRf;
```

Restrictions

The destination register for the MMPYF32 and the MSUBF32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 or MSUBF32 generates an underflow condition.
- LVF = 1 if MMPYF32 or MSUBF32 generates an overflow condition.

Pipeline

MMPYF32 and MSUBF32 both complete in a single cycle.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A - B)
;
_Cla1Task2:
     MMOV32   MR0, @A          ; Load MR0 with A
     MMOV32   MR1, @B          ; Load MR1 with B
     MMPYF32  MR2, MR0, MR1    ; Multiply (A*B)
||   MSUBF32  MR3, MR0, MR1    ; and in parallel Sub (A-B)
     MMOV32   @Y2, MR2         ; Store A*B
     MMOV32   @Y3, MR3         ; Store A-B
     MSTOP                     ; end of task
```

MNEGF32 MRa, MRb{, CNDF}

Conditional Negation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
CNDF	Condition tested

Opcode

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1000 0000
```

Description

```
if (CNDF == true) {MRa = - MRb; }
else {MRa = MRb; }
```

CNDF is one of the following conditions:

Encode[1]	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF[2]	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

Pipeline

This is a single-cycle instruction.

MNEGF32 MRa, MRb{, CNDF} (continued)

Conditional Negation

Example 1

```
; Show the basic operation of MNEGF32
;
     MMOVIZ    MR0, #5.0       ; MR0 = 5.0 (0x40A00000)
     MMOVIZ    MR1, #4.0       ; MR1 = 4.0 (0x40800000)

    MNOP                         ; Pad to seperate MBCNDD and MSTOP
    MNOP                         ; Pad to seperate MBCNDD and MSTOP
    MSTOP                        ; End of task
```

MOR32 MRa, MRb, MRc

Bitwise OR

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1000 0000
```

Description

Bitwise OR of MRb with MRc.

```
MARa(31:0) = MARb(31:0) OR MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI    MR0, #0xAAAA
MMOVIZ    MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI    MR1, #0xFEDC
                       ; 0101 OR 0101 = 0101 (5)
                       ; 0101 OR 0100 = 0101 (5)
                       ; 0101 OR 0011 = 0111 (7)
                       ; 0101 OR 0010 = 0111 (7)
                       ; 1010 OR 1111 = 1111 (F)
                       ; 1010 OR 1110 = 1110 (E)
                       ; 1010 OR 1101 = 1111 (F)
                       ; 1010 OR 1100 = 1110 (E)
MOR32 MR2, MR1, MR0    ; MR3 = 0x5555FEFE
```

MRCNDD {CNDF}

Return Conditional Delayed

Operands

CNDF	Optional condition

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1001 1010 cndf
```

Description

If the specified condition is true, then the RPC field of MSTF is loaded into MPC and fetching continues from that location. Otherwise, program fetches continue without the return.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC = RPC;
```

CNDF is one of the following conditions:

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MRCNDD instruction by itself is a single-cycle instruction. As shown in Table 8-19, 6 instruction slots are executed for each return; 3 slots before the return instruction (d5-d7) and 3 slots after the return instruction (d8-d10). The total number of cycles for a return taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a return can, therefore, range from 1 to 7 cycles. The number of cycles for a return taken cannot be the same as for a return not taken.

MRCNDD {CNDF} (continued)

Return Conditional Delayed

Referring to the following code fragment and the pipeline diagrams in Table 8-19 and Table 8-20, the instructions before and after MRCNDD have the following properties:

```
;
;
<Instruction 1>     ; I1 Last instruction that can affect flags for
                    ; the MCCNDD operation
<Instruction 2>     ; I2 Cannot be stop, branch, call or return
<Instruction 3>     ; I3 Cannot be stop, branch, call or return
<Instruction 4>     ; I4 Cannot be stop, branch, call or return
MCCNDD _func, NEQ   ; Call to func if not eqal to zero
                    ; Three instructions after MCCNDD are always
                    ; executed whether the call is taken or not
<Instruction 5>     ; I5 Cannot be stop, branch, call or return
<Instruction 6>     ; I6 Cannot be stop, branch, call or return
<Instruction 7>     ; I7 Cannot be stop, branch, call or return
<Instruction 8>     ; I8 The address of this instruction is saved
                    ; in the RPC field of the MSTF register.
                    ; Upon return this value is loaded into MPC
                    ; and fetching continues from this point.
<Instruction 9>     ; I9
<Instruction 10>    ; I10
....
....
_func:
<Destination 1>     ; d1 Can be any instruction
<Destination 2>     ; d2

<Destination 12>    ; d12
....
....
MSTOP
....
```

- **d4**
  - d4 is the last instruction that can effect the CNDF flags for the MRCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to return or not when MRCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for d4.
- **d5, d6, and d7**
  - The three instructions proceeding MRCNDD can change MSTF flags but have no effect on whether the MRCNDD instruction makes the return or not. This is because the flag modification occurs after the D2 phase of the MRCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **d8, d9, and d10**
  - The three instructions following MRCNDD are always executed irrespective of whether the return is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

MRCNDD {CNDF} (continued)

Return Conditional Delayed

MSETC BGINTM

Set Background Task Interrupt Mask

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 0101 0000
```

Description

This instruction sets the background task interrupt mask (BGINTM) bit in the MSTSBGRND register, making any code thereafter uninterruptible. No other higher priority task is able to interrupt the background task until the BGINTM is cleared. This instruction sets the BGINTM bit at the end of the D2 phase.

This instruction does not require the MEALLOW bit to be asserted before, or de-asserted after, setting BGINTM.

Flags

This instruction does not modify the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MSETC BGINTM          ; Set the MSTSBGRND.BGINTM bit
                      ; to prevent any other tasks from
                      ; interrupting the background task
```

MCLRC BGINTM

MSETFLG FLAG, VALUE

Set or Clear Selected Floating-Point Status Flags

Operands

FLAG	8-bit mask indicating which floating-point status flags to change.
VALUE	8-bit mask indicating the flag value: 0 or 1.

Opcode

```
LSW: FFFF FFFF VVVV VVVV
MSW: 0111 1001 1100 0000
```

Description

The MSETFLG instruction is used to set or clear selected floating-point status flags in the MSTF register. The FLAG field is an 11-bit value that indicates which flags are changed. That is, if a FLAG bit is set to 1, that flag is changed; all other flags are not modified. The bit mapping of the FLAG field is:

9	8	7	6	5	4	3	2	1	0
RNDF32	Reserved		TF	Reserved		ZF	NF	LUF	LVF

The VALUE field indicates the value the flag can be set to: 0 or 1.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Any flag can be modified by this instruction. The MEALLOW and RPC fields cannot be modified with this instruction.

Pipeline

This is a single-cycle instruction.

Example

To make it easier and legible, the assembler accepts a FLAG=VALUE syntax for the MSTFLG operation as:

```
MSETFLG RNDF32=0, TF=0, NF=1; FLAG = 11000100; VALUE = 00XXX1XX;
```

MSTOP

Stop Task

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 1000 0000
```

Description

The MSTOP instruction must be placed to indicate the end of each task. In addition, placing MSTOP in unused memory locations within the CLA program RAM can be useful for debugging and preventing run away CLA code. When MSTOP enters the D2 phase of the pipeline, the MIRUN flag for the task is cleared and the associated interrupt is flagged in the PIE vector table.

There are three special cases that can occur when single-stepping a task such that the MPC reaches the MSTOP instruction.

1. If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if you continue to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.
2. In this case, you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if you continue to single-step through the MSTOP instruction of "task A". It depends on exactly when the new task comes in. To reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B".
3. Case 2 can be handled slightly differently if there is control over when "task B" comes in (for example using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B", run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

Restrictions

The MSTOP instruction cannot be placed 3 instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

MSTOP (continued)

Stop Task

Pipeline

This is a single-cycle instruction. Table 8-21 shows the pipeline behavior of the MSTOP instruction. The MSTOP instruction cannot be placed with 3 instructions of a MBCNDD, MCCNDD, or MRCNDD instruction.

Table 8-21. Pipeline Activity for MSTOP

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1	I1							
I2	I2	I1

MDEBUGSTOP , MDEBUGSTOP1

MSUB32 MRa, MRb, MRc

32-Bit Integer Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1110 0000
```

Description

32-bit integer addition of MRb and MRc.

```
MARa(31:0) = MARb(31:0) - MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
;       B = (int32)2
;       C = (int32)-7
;
;
Calculate Y2 = A - B - C
;
_Cla1Task3:
   MMOV32   MR0, @_A          ; MR0 = 1 (0x00000001)
   MMOV32   MR1, @_B          ; MR1 = 2 (0x00000002)
   MMOV32   MR2, @_C          ; MR2 = -7 (0xFFFFFFF9)
   MSUB32   MR3, MR0, MR1     ; A + B
   MSUB32   MR3, MR3, MR2     ; A + B + C = 6 (0x0000006)
   MMOV32   @_y2, MR3         ; Store y2
   MSTOP                      ; End of task
```

32-Bit Floating-Point Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to R1)
MRb	CLA floating-point source register (MR0 to R1)
MRc	CLA floating-point source register (MR0 to R1)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0100 0000
```

Description

Subtract the contents of two floating-point registers

```
MRa = MRb - MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = A + B - C
;
_Cla1Task5:
   MMOV32    MR0, @_A      ; Load MR0 with A
   MMOV32    MR1, @_B      ; Load MR1 with B
   MADDF32   MR0, MR1, MR0 ; Add A + B
|| MMOV32    MR1, @_C      ;   and in parallel load C
   MSUBF32   MR0, MR0, MR1 ; Subtract C from (A + B)
   MMOV32    @Y,  MR0      ; (A+B) - C
   MSTOP                   ; end of task
```

MSUBF32 MRa, #16FHi, MRb

32-Bit Floating-Point Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to R1)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to R1)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0000 baaa
```

Description

Subtract MRb from the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = #16FHi:0 - MRb;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Y = sqrt(X)
; Ye = Estimate(1/sqrt(X));
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Y = X*Ye
;
_cla1Task3:
   MMOV32     MR0, @_x           ; MR0 = X
   MEISQRTF32 MR1, MR0           ; MR1 = Ye = Estimate(1/sqrt(X))
   MMOV32     MR1, @_x, EQ       ; if(X == 0.0) Ye = 0.0
   MMPYF32    MR3, MR0, #0.5     ; MR3 = X*0.5
   MMPYF32    MR2, MR1, MR3      ; MR2 = Ye*X*0.5
   MMPYF32    MR2, MR1, MR2      ; MR2 = Ye*Ye*X*0.5
   MSUBF32    MR2, #1.5, MR2     ; MR2 = 1.5 - Ye*Ye*X*0.5
   MMPYF32    MR1, MR1, MR2      ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
   MMPYF32    MR2, MR1, MR3      ; MR2 = Ye*X*0.5
   MMPYF32    MR2, MR1, MR2      ; MR2 = Ye*Ye*X*0.5
   MSUBF32    MR2, #1.5, MR2     ; MR2 = 1.5 - Ye*Ye*X*0.5
   MMPYF32    MR1, MR1, MR2      ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
   MMPYF32    MR0, MR1, MR0      ; MR0 = Y = Ye*X
   MMOV32     @_y, MR0           ; Store Y = sqrt(X)
   MSTOP                         ; end of task
```

MSUBF32 MRd, MRe, MRf ||MMOV32 MRa, mem32

32-Bit Floating-Point Subtraction with Parallel Move

Operands

MRd	CLA floating-point destination register (MR0 to MR3) for the MSUBF32 operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRf	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRa	CLA floating-point destination register (MR0 to MR3) for the MMOV32 operation MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. Source for the MMOV32 operation.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0010 ffee ddaa addr
```

Description

Subtract the contents of two floating-point registers and move from memory to a floating-point register.

```
MRd = MRe - MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MSUBF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags.

Pipeline

Both MSUBF32 and MMOV32 complete in a single cycle.

Example

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

MSWAPF MRa, MRb {, CNDF}

Conditional Swap

Operands

MRa	CLA floating-point register (MR0 to MR3)
MRb	CLA floating-point register (MR0 to MR3)
CNDF	Optional condition tested based on the MSTF flags

Opcode

```
LSW: 0000 0000 CNDF bbaa
MSW: 0111 1011 0000 0000
```

Description

Conditional swap of MRa and MRb.

```
if (CNDF == true) swap MRa and MRb;
```

CNDF is one of the following conditions:

Encode[1]	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF[2]	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected

Pipeline

This is a single-cycle instruction.

    MNOP                         ; Always executed
    MNOP                         ; Always executed
    MSTOP                        ; End of task
```

MTESTTF CNDF

Test MSTF Register Flag Condition

Operands

CNDF	Condition to test based on MSTF flags

Opcode

```
LSW: 0000 0000 0000 cndf
MSW: 0111 1111 0100 0000
```

Description

Test the CLA floating-point condition and if true, set the MSTF[TF] flag. If the condition is false, clear the MSTF[TF] flag. This is useful for temporarily storing a condition for later use.

```
if (CNDF == true) TF = 1;
else TF = 0;
```

CNDF is one of the following conditions:

Encode[1]	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF[2]	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	No	No	No	No

```
TF = 0;
if (CNDF == true) TF = 1;
```

Note: If (CNDF == UNC or UNCF), the TF flag is set to 1.

Pipeline

This is a single-cycle instruction.

MTESTTF CNDF (continued)

Test MSTF Register Flag Condition

Example

```
; if (State == 0.1)
;    RampState = RampState || RAMPMASK
; else if (State == 0.01)
;    CoastState = CoastState || COASTMASK
; else
;    SteadyState = SteadyState || STEADYMASK
;
_Cla1Task2:
   MMOV32    MR0, @_State
   MCMPF32   MR0, #0.1         ; Affects flags for 1st MBCNDD (A)
   MCMPF32   MR0, #0.01        ; Check used by 2nd MBCNDD (B)
   MTESTTF   EQ                ; Store EQ flag in TF for 2nd MBCNDD (B)
   MNOP
   MBCNDD    _Skip1, NEQ       ; (A) If State != 0.1, go to Skip1
   MMOV32    MR1, @_RampState  ; Always executed
   MMOVXI    MR2, #RAMPMASK    ; Always executed
   MOR32     MR1, MR2          ; Always executed
   MMOV32    @_RampState, MR1  ; Execute if (A) branch not taken
   MSTOP                       ; end of task if (A) branch not taken
_Skip1:
   MMOV32    MR3, @_SteadyState
   MMOVXI    MR2, #STEADYMASK
   MOR32     MR3, MR2
   MBCNDD    _Skip2, NTF       ; (B) if State != .01, go to Skip2
   MMOV32    MR1, @_CoastState ; Always executed
   MMOVXI    MR2, #COASTMASK   ; Always executed
   MOR32     MR1, MR2          ; Always executed
   MMOV32    @_CoastState, MR1 ; Execute if (B) branch not taken
   MSTOP                       ; end of task if (B) branch not taken
_Skip2:
   MMOV32 @_SteadyState, MR3   ; Executed if (B) branch taken
   MSTOP
```

MUI16TOF32 MRa, mem16

Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 01aa addr
```

Description

When converting F32 to I16/UI16 data format, the MF32TOI16/UI16 operation truncates to zero while the MF32TOI16R/UI16R operation rounds to the nearest (even) value.

```
MRa = UI16TOF32[mem16];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1110 0000
```

Description

Convert an unsigned 16-bit integer to a 32-bit floating-point value. When converting float32 to I16/UI16 data format, the MF32TOI16/UI16 operation truncates to zero while the MF32TOI16R/UI16R operation rounds to the nearest (even) value.

```
MRa = UI16TOF32[MRb];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVXI MR1, #0x800F ; MR1(15:0) = 32783 (0x800F)
MUI16TOF32 MR0, MR1 ; MR0 = UI16TOF32 (MR1(15:0))
                    ; = 32783.0 (0x47000F00)
```

MXOR32 MRa, MRb, MRc

Bitwise Exclusive Or

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1010 0000
```

Description Bitwise XOR of MRb with MRc.

```
MARa(31:0) = MARb(31:0) XOR MRc(31:0);
```

Flags This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #0x5555   ; MR0 = 0x5555AAAA
  MMOVXI MR0, #0xAAAA
  MMOVIZ MR1, #0x5432   ; MR1 = 0x5432FEDC
  MMOVXI MR1, #0xFEDC
  ; 0101 XOR 0101 = 0000 (0)
  ; 0101 XOR 0100 = 0001 (1)
  ; 0101 XOR 0011 = 0110 (6)
  ; 0101 XOR 0010 = 0111 (7)
  ; 1010 XOR 1111 = 0101 (5)
  ; 1010 XOR 1110 = 0100 (4)
  ; 1010 XOR 1101 = 0111 (7)
  ; 1010 XOR 1100 = 0110 (6)
  MXOR32 MR2, MR1, MR0  ; MR3 = 0x01675476

8.8 CLA Registers

This section describes the Control Law Accelerator registers.

8.8.1 CLA Base Address Table (C28)

Table 8-22. CLA Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
Cla1Regs	CLA_REGS	CLA1_BASE	0x0000_1400	YES	YES	-	-	-

8.8.2 CLA_ONLY_REGS Registers

Table 8-23 lists the memory-mapped registers for the CLA_ONLY_REGS registers. All register offset addresses not listed in Table 8-23 should be considered as reserved locations and the register contents should not be modified.

Table 8-23. CLA_ONLY_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
80h	_MVECTBGRNDACTIVE	Active register for MVECTBGRND.	EALLOW	Go
C0h	_MPSACTL	CLA PSA Control Register	EALLOW	Go
C2h	_MPSA1	CLA PSA1 Register	EALLOW	Go
C4h	_MPSA2	CLA PSA2 Register	EALLOW	Go
E0h	SOFTINTEN	CLA Software Interrupt Enable Register		Go
E2h	SOFTINTFRC	CLA Software Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 8-24 shows the codes that are used for access types in this section.

Table 8-24. CLA_ONLY_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.8.2.1 _MVECTBGRNDACTIVE Register (Offset = 80h) [Reset = 0h]

_MVECTBGRNDACTIVE is shown in Figure 8-2 and described in Table 8-25.

Return to the Summary Table.

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

Figure 8-2. _MVECTBGRNDACTIVE Register

2h	SOFTINTFRC	CLA Software Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 8-32 shows the codes that are used for access types in this section.

Table 8-32. CLA_SOFTINT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.8.3.1 SOFTINTEN Register (Offset = 0h) [Reset = 0h]

SOFTINTEN is shown in Figure 8-8 and described in Table 8-33.

Return to the Summary Table.

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA.

8.8.3.2 SOFTINTFRC Register (Offset = 2h) [Reset = 0h]

SOFTINTFRC is shown in Figure 8-9 and described in Table 8-34.

Return to the Summary Table.

Writing a value of 1 in a bit will generate the corresponding task interrupt.This register is only accessible by the CLA (not the CPU).

W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.8.4.1 MVECT1 Register (Offset = 0h) [Reset = 0h]

MVECT1 is shown in Figure 8-10 and described in Table 8-37.

Return to the Summary Table.

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

Figure 8-10. MVECT1 Register

Table 8-37. MVECT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	MVECT	R/W	0h	MPC Start Address: These bits specify the start address for the given interrupt (task). The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions. There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

8.8.4.2 MVECT2 Register (Offset = 1h) [Reset = 0h]

MVECT2 is shown in Figure 8-11 and described in Table 8-38.

Return to the Summary Table.

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

8.8.4.4 MVECT4 Register (Offset = 3h) [Reset = 0h]

MVECT4 is shown in Figure 8-13 and described in Table 8-40.

Return to the Summary Table.

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

8.8.4.5 MVECT5 Register (Offset = 4h) [Reset = 0h]

MVECT5 is shown in Figure 8-14 and described in Table 8-41.

Return to the Summary Table.

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

8.8.4.6 MVECT6 Register (Offset = 5h) [Reset = 0h]

MVECT6 is shown in Figure 8-15 and described in Table 8-42.

Return to the Summary Table.

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

8.8.4.8 MVECT8 Register (Offset = 7h) [Reset = 0h]

MVECT8 is shown in Figure 8-17 and described in Table 8-44.

Return to the Summary Table.

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED					IACKE	SOFTRESET	HARDRESET
R-0h					R/W-0h	R-0/W1S-0h	R-0/W1S-0h

Table 8-45. MCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	IACKE	R/W	0h	IACK Operation Enable Bit: Writing a "1" to this bit will enable the IACK operation for setting the MIFR bits in the same manner as the MIFRC register (write of "1" will set respective MIFR bit). At reset, this feature is disabled. This feature enables the C28 CPU to efficiently trigger a task. Note: IACK operation should ignore EALLOW status of C28 core when accessing the MIFRC register. Reset type: SYSRSn 0h (R/W) = The CLA ignores the IACK instruction. (default) 1h (R/W) = Enable the main CPU to use the IACK #16bit instruction to set MIFR bits in the same manner as writing to the MIFRC register. Each bit in the operand, #16bit, corresponds to a bit in the MIFRC register. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger a CLA task through software. Examples IACK #0x0001 Write a 1 to MIFRC bit 0 to force task 1 IACK #0x0003 Write a 1 to MIFRC bit 0 and 1 to force task 1 and task 2
1	SOFTRESET	R-0/W1S	0h	Soft Reset Bit: Writing a "1" to this bit will stop a current task, clear the RUN flag and also clear all bits in the MIER register. Writes of "0" are ignored and reads always return a "0". Note: After issuing SOFTRESET command, user should wait at least 1 clock cycle before attempting to write to MIER register. Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 are ignored. 1h (R/W) = Writing a 1 will cause a soft reset of the CLA. This will stop the current task, clear the MIRUN flag and clear all bits in the MIER register. After a soft reset you must wait at least 1 SYSCLKOUT cycle before reconfiguring the MIER bits. If these two operations are done back-to-back then the MIER bits will not get set.
0	HARDRESET	R-0/W1S	0h	Hard Reset Bit: Writing a "1" to this bit will cause a HARD reset on the CLA. The behavior of a HARD reset is the same as a system reset SYSRSn on the CLA. Writes of "0" are ignored and reads always return a "0". Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 are ignored. 1h (R/W) = Writing a 1 will cause a hard reset of the CLA. This will set all CLA registers to their default state.

8.8.4.10 _MVECTBGRNDACTIVE Register (Offset = 1Bh) [Reset = 0h]

_MVECTBGRNDACTIVE is shown in Figure 8-19 and described in Table 8-46.

Return to the Summary Table.

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

Figure 8-19. _MVECTBGRNDACTIVE Register

Bit	Field	Type	Reset	Description
15-0	i16	R	0h	Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0. Reset type: SYSRSn

8.8.4.11 SOFTINTEN Register (Offset = 1Ch) [Reset = 0h]

SOFTINTEN is shown in Figure 8-20 and described in Table 8-47.

Return to the Summary Table.

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA. Only reads are allowed from CPU. Writes are not allowed from CPU.

8.8.4.15 MIFR Register (Offset = 20h) [Reset = 0h]

MIFR is shown in Figure 8-24 and described in Table 8-51.

Return to the Summary Table.

Each bit in the interrupt flag register corresponds to a CLA task. The corresponding bit is automatically set when the task request is received from the peripheral interrupt. The bit can also be set by the main CPU writing to the MIFRC register or using the IACK instruction to start the task. To use the IACK instruction to begin a task first enable this feature in the MCTL register. If the bit is already set when a new peripheral interrupt is received, then the corresponding overflow bit will be set in the MIOVF register.
The corresponding MIFR bit is automatically cleared when the task begins execution. This will occur if the interrupt is enabled in the MIER register and no other higher priority task is pending. The bits can also be cleared manually by writing to the MICLR register. Writes to the MIFR register are ignored.

8.8.4.16 MIOVF Register (Offset = 21h) [Reset = 0h]

MIOVF is shown in Figure 8-25 and described in Table 8-52.

Return to the Summary Table.

Each bit in the overflow flag register corresponds to a CLA task. The bit is set when an interrupt overflow event has occurred for the specific task. An overflow event occurs when the MIFR register bit is already set when a new interrupt is received from a peripheral source. The MIOVF bits are only affected by peripheral interrupt events. They do not respond to a task request by the main CPU IACK instruction or by directly setting MIFR bits. The overflow flag will remain latched and can only be cleared by writing to the overflow flag clear (MICLROVF) register. Writes to the MIOVF register are ignored.

8.8.4.17 MIFRC Register (Offset = 22h) [Reset = 0h]

MIFRC is shown in Figure 8-26 and described in Table 8-53.

Return to the Summary Table.

The interrupt force register can be used by the main CPU to start tasks through software. Writing a 1 to a MIFRC bit will set the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0. The IACK #16bit operation can also be used to start tasks and has the same effect as the MIFRC register. To enable IACK to set MIFR bits you must first set the MCTL[IACKE] bit. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger CLA tasks through software.

8.8.4.18 MICLR Register (Offset = 23h) [Reset = 0h]

MICLR is shown in Figure 8-27 and described in Table 8-54.

Return to the Summary Table.

Normally bits in the MIFR register are automatically cleared when a task begins. The interrupt flag clear register can be used to instead manually clear bits in the interrupt flag (MIFR) register. Writing a 1 to a MICLR bit will clear the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0.

3	INT4	R-0/W1S	0h	Writing a "1" to any of the bits will clear the corresponding MIFR bit. Writes of "0" are ignored. Reads always return 0. Notes: [1] Refer to MIFR register description for handling of boundary conditions. Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 have no effect 1h (R/W) = Write a 1 to clear the task 4 interrupt flag
2	INT3	R-0/W1S	0h	Writing a "1" to any of the bits will clear the corresponding MIFR bit. Writes of "0" are ignored. Reads always return 0. Notes: [1] Refer to MIFR register description for handling of boundary conditions. Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 have no effect 1h (R/W) = Write a 1 to clear the task 3 interrupt flag
1	INT2	R-0/W1S	0h	Writing a "1" to any of the bits will clear the corresponding MIFR bit. Writes of "0" are ignored. Reads always return 0. Notes: [1] Refer to MIFR register description for handling of boundary conditions. Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 have no effect 1h (R/W) = Write a 1 to clear the task 2 interrupt flag
0	INT1	R-0/W1S	0h	Writing a "1" to any of the bits will clear the corresponding MIFR bit. Writes of "0" are ignored. Reads always return 0. Notes: [1] Refer to MIFR register description for handling of boundary conditions. Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 have no effect 1h (R/W) = Write a 1 to clear the task 1 interrupt flag

8.8.4.19 MICLROVF Register (Offset = 24h) [Reset = 0h]

MICLROVF is shown in Figure 8-28 and described in Table 8-55.

Return to the Summary Table.

Overflow flag bits in the MIOVF register are latched until manually cleared using the MICLROVF register. Writing a 1 to a MICLROVF bit will clear the corresponding bit in the MIOVF register. Writes of 0 are ignored and reads always return 0.

8.8.4.20 MIER Register (Offset = 25h) [Reset = 0h]

MIER is shown in Figure 8-29 and described in Table 8-56.

Return to the Summary Table.

Setting the bits in the interrupt enable register (MIER) allow an incoming interrupt or main CPU software to start the corresponding CLA task. Writing a 0 will block the task, but the interrupt request will still be latched in the flag register (MIFLG). Setting the MIER register bit to 0 while the corresponding task is executing will have no effect on the task. The task will continue to run until it hits the MSTOP instruction. When a soft reset is issued, the MIER bits are cleared. There should always be at least a 1 SYSCLKOUT delay between issuing the soft reset and reconfiguring the MIER bits.

8.8.4.21 MIRUN Register (Offset = 26h) [Reset = 0h]

MIRUN is shown in Figure 8-30 and described in Table 8-57.

Return to the Summary Table.

The interrupt run status register (MIRUN) indicates which task is currently executing. Only one MIRUN bit will ever be set to a 1 at any given time. The bit is automatically cleared when the task competes and the respective interrupt is fed to the peripheral interrupt expansion (PIE) block of the device. This lets the main CPU know when a task has completed. The main CPU can stop a currently running task by writing to the MCTL[SOFTRESET] bit. This will clear the MIRUN flag and stop the task. In this case no interrupt will be generated to the PIE.

8.8.4.25 _MSTF Register (Offset = 2Eh) [Reset = 0h]

_MSTF is shown in Figure 8-34 and described in Table 8-61.

Return to the Summary Table.

The CLA status register (MSTF) reflects the results of different operations. These are the basic rules for the flags:
- Zero and negative flags are cleared or set based on:
- floating-point moves to registers
- the result of compare, minimum, maximum, negative and absolute value operations
- the integer result of operations such as MMOV16, MAND32, MOR32, MXOR32, MCMP32, MASR32, MLSR32
- Overflow and underflow flags are set by floating-point math instructions such as multiply, add, subtract and 1/x. These flags may also be connected to the peripheral interrupt expansion (PIE) block on your device. This can be useful for debugging underflow and overflow conditions within an application.

Chapter 9

Configurable Logic Block (CLB)

This chapter describes the features and operation of the configurable logic block (CLB) that is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions.

9.1 Introduction

The configurable logic block (CLB) is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions. The CLB is able to enhance existing peripherals through a set of crossbar interconnections, which provide a high level of connectivity to existing control peripherals such as enhanced pulse width modulators (ePWM), enhanced capture modules (eCAP), and enhanced quadrature encoder pulse modules (eQEP). The crossbars also allow the CLB to be connected to external GPIO pins. In this way, the CLB can be configured to interact with device peripherals to perform small logical functions such as simple PWM generators, or to implement custom serial data exchange protocols.

The CLB peripheral is configured through the CLB tool. For more information on the CLB tool, available examples, application reports, and user's guide, refer to the following location in your C2000WARE package (C2000Ware_2_00_00_03 and higher): C2000WARE_INSTALL_LOCATION\utilities\clb_tool\clb_syscfg\doc

9.2 Description

The CLB subsystem contains a number of identical tiles. There are four such tiles in the CLB subsystem; other devices can contain more or fewer tiles. Tiles are numbered 1 to N, where N is the total tile count on the device. Each tile contains combinational and sequential logic blocks, as well as other dedicated hardware to be described later in this document. Figure 9-1 shows the structure of the CLB subsystem in the device.

The tile contains the core logic, providing the logic reconfiguration capability. Each CLB tile is associated with a separate CPU interface, which contains the registers needed to control and configure the logic in the tile. The CPU interface also contains data transfer buffers that can be used as part of the configurable logic to exchange data with the rest of the device. Figure 9-2 shows the connections between the tile, the CPU interface, and the device.

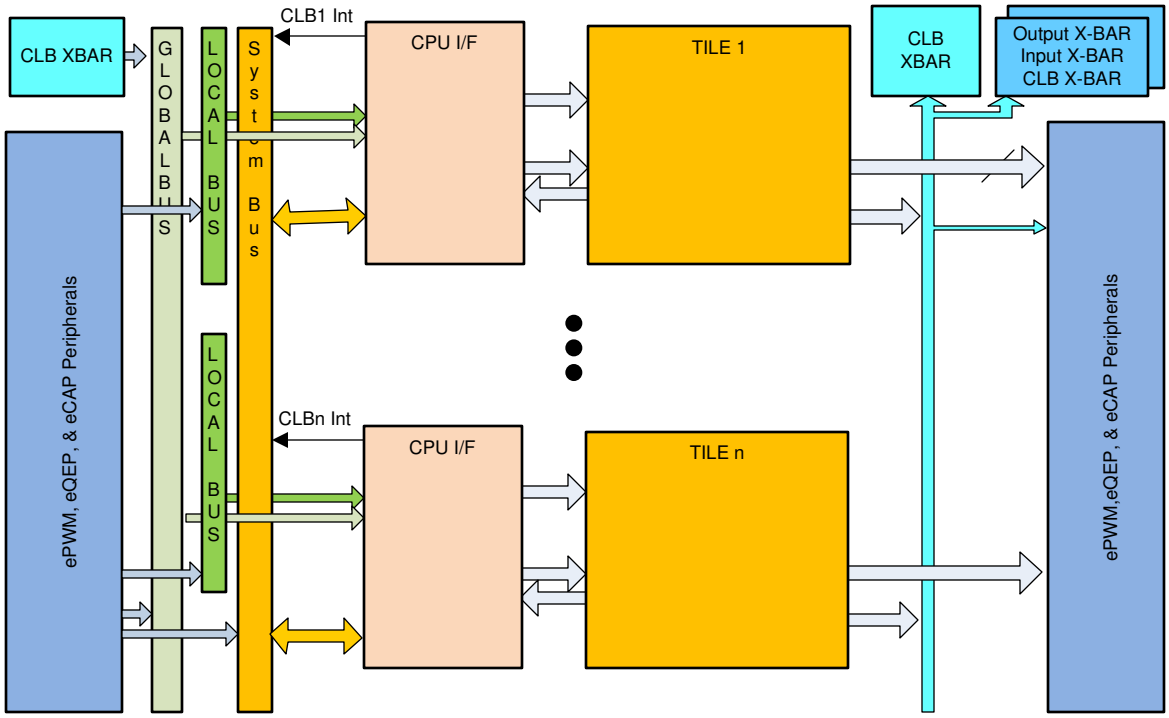

Figure 9-1. Block Diagram of the CLB Subsystem in the Device

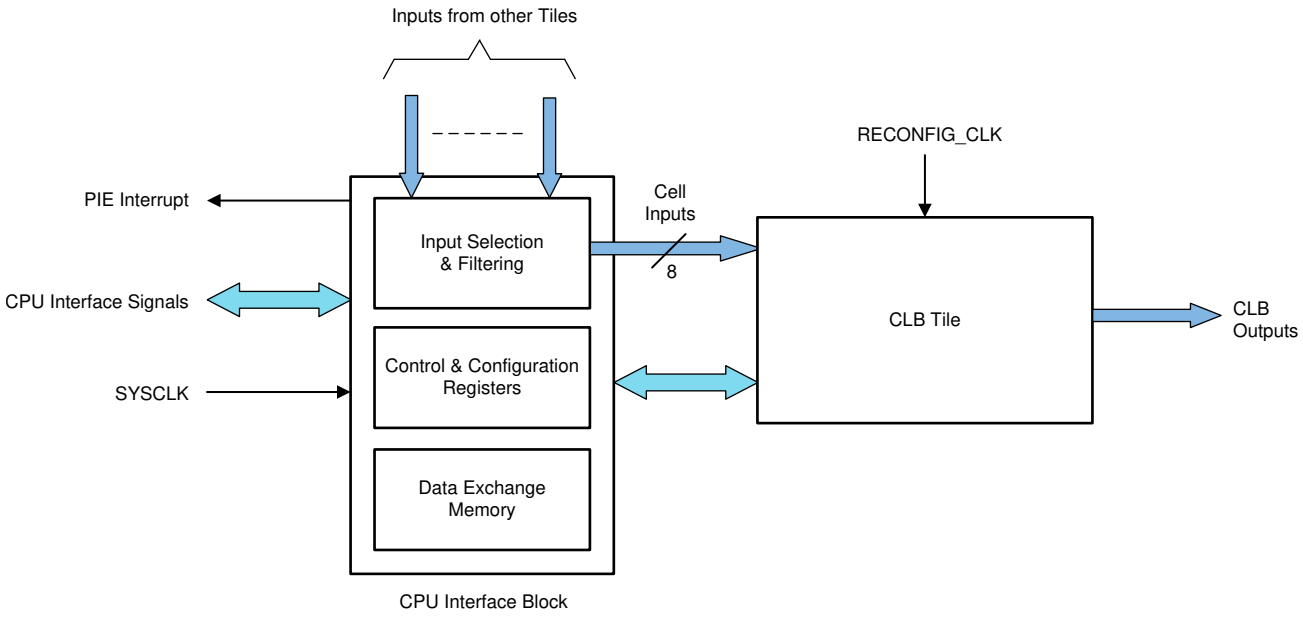

Figure 9-2. Block Diagram of a CLB Tile and CPU Interface

9.2.1 CLB Clock

In this device, the CLB clock is called CLBx clock that can be enabled or disabled by SYSCTL_PERIPH_CLK_CLBx through the SysCtl_enablePeripheral function. The maximum frequency is 150 MHz and the clock can be enabled and configured by modifying the CLBx clock.

Note

When clock frequencies are above 100 MHz (ex: 150 MHz), PIPELINE mode must be enabled.

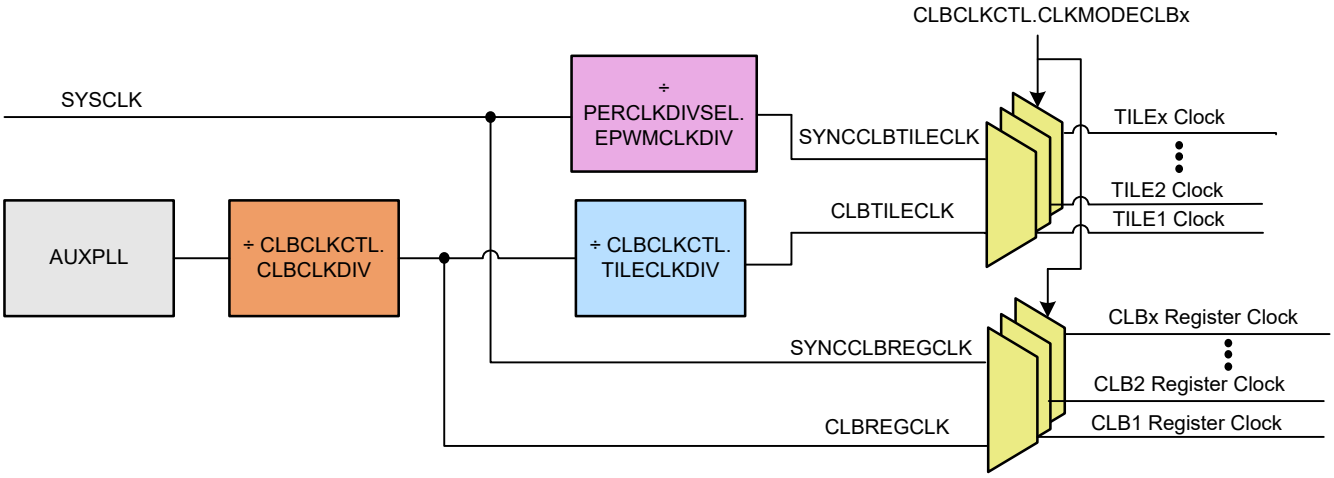

Figure 9-3. CLB Clocking

The CLB TILE clock and CLB register clock can be in ASYNC/SYNC mode with the SYSCLK. An example CLB clock configuration is shown in Table 9-1. Check the device data sheet for details on clocking specifications.

Table 9-1. Example CLB Clocking Configuration

Clock	SYNC Mode (CLKMODECLBx = 0)	ASYNC Mode (CLKMODECLBx = 1)	
		TILECLKDIV = 1	TILECLKDIV = 0
CLB Register Clock	SYSCLK	SYSCLK	SYSCLK
CLB TILE Clock	SYSCLK	SYSCLK / 2	SYSCLK

Starting with CLB Type 2, a clock prescalar module is available. The prescalar module can generate a prescaled version of the CLB clock signal that can be used as an input to the CLB TILEs.

Note

The prescaler logic does not change the actual clocking speed of the CLB. The prescalar generates a strobe (that can toggle at the defined prescaled rate) that is made available as another input signal to the CLB logic and the strobe is only used when required.

The prescalar module is shown in Figure 9-4.

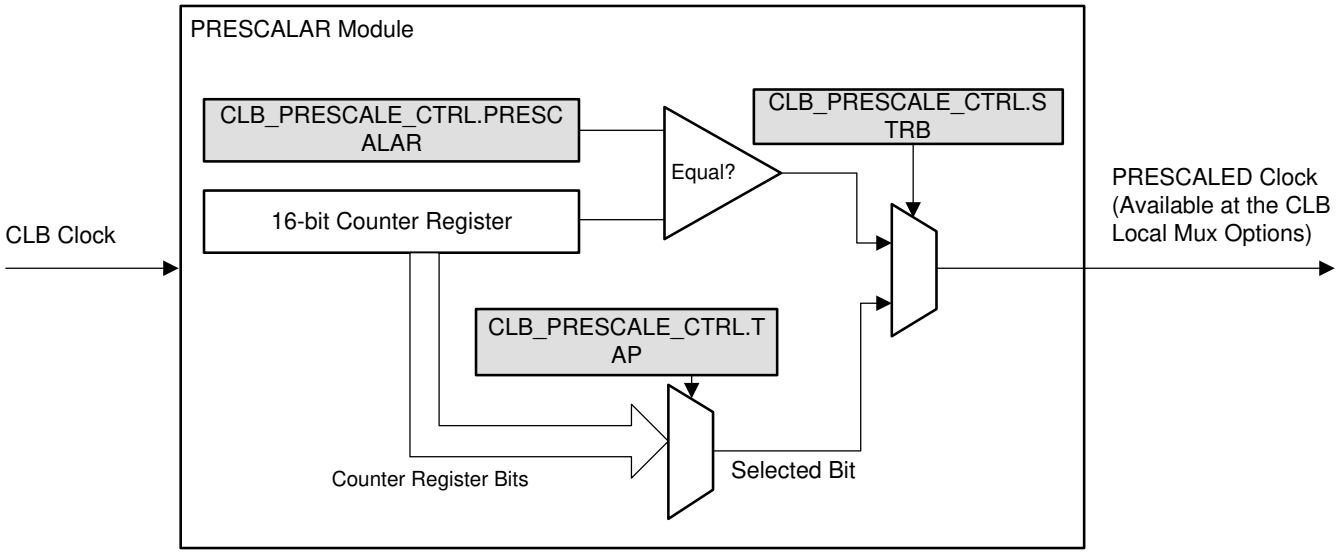

Figure 9-4. CLB Clock Prescalar

9.3 CLB Input/Output Connection

9.3.1 Overview

There are four instances of the CLB module in the device. Each CLB instance has a common set of input signals referred to as global input signals. Additionally, each CLB instance has a specific set of input signals that are unique to each instance, and are referred to as local input signals. Each of the eight inputs of a CLB can be chosen from any of the global input signals or the local input signals.

Note

Signals routed into the CLB using the XBAR must be synchronized within the CLB itself.

9.3.2 CLB Input Selection

Each CLB module has eight inputs that are applied to the reconfigurable logic cell. Each of these inputs can be selectively driven by a predefined set of signals. A two-level mux structure allows each input of each CLB instance to select a signal.

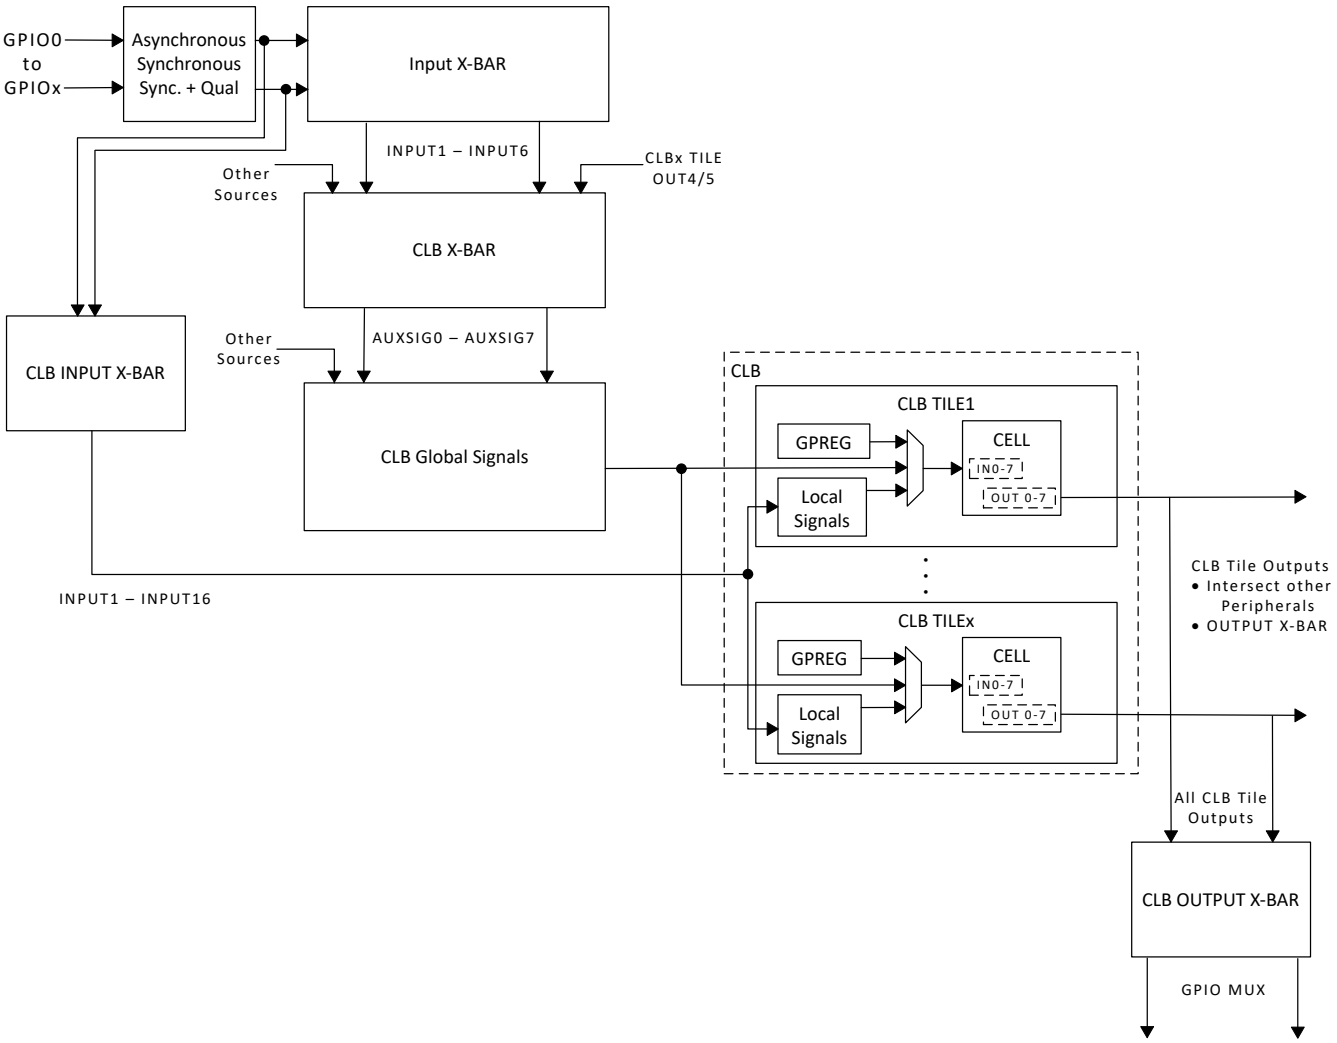

Figure 9-5. GPIO to CLB Tile Connections

A set of signals is common to all the CLB instances. These are referred to as global inputs in Figure 9-6. A separate set of signals is unique to each instance of the CLB. These are referred to as local inputs in Figure 9-6.

Registers CLB_LCL_MUX_SEL_1 and CLB_LCL_MUX_SEL_2 control the local mux selection for each of the eight inputs. The mux control registers CLB_GLBL_MUX_SEL_1 and CLB_GLBL_MUX_SEL_2 control the global mux selection for each of the eight inputs.

The local mux select value of 0 causes the selected global mux input signal to be connected to the corresponding CLB Input. For example, setting CLB_LCL_MUX_SEL_IN_0 = 0 and CLB_GLBL_MUX_SEL_IN_0 = 8 causes the global mux input number 8 to be connected to CLB Input 0. The input filter feature can be used to enable edge detection on the CLB inputs. The input filter feature can also synchronize the input with the CLB clock.

The global mux settings are shown in Table 9-2 and Table 9-3. The local input mux settings are shown in Table 9-4 and Table 9-5.

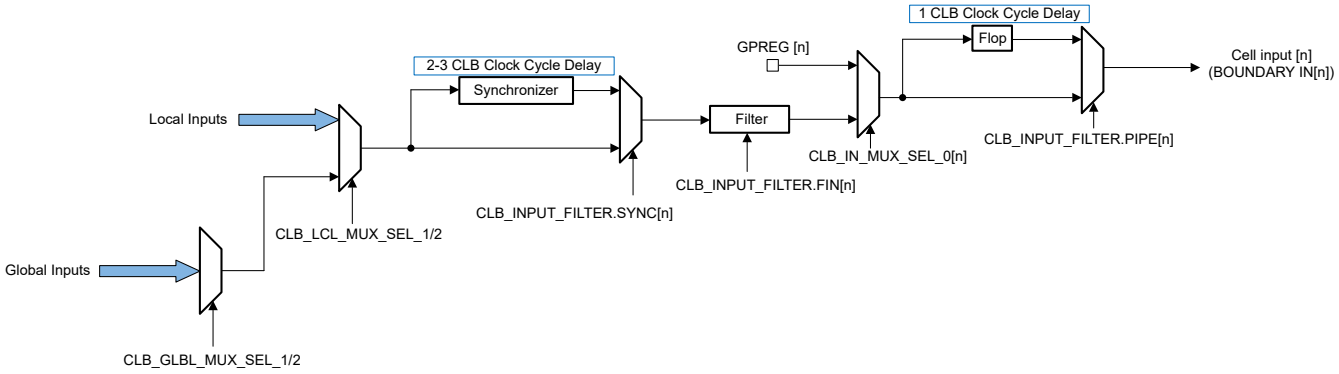

Figure 9-6. CLB Input Mux and Filter

Figure 9-7 shows an example of how to use synchronization for an asynchronous signal, in this case the ePWM signal. Figure 9-8 shows an instance of using input pipelining for a synchronous signal, which here is the ePWM TBCLK signal. Note that these two input configurations are not used simultaneously, and each have their own cycle delay that add to the input path.

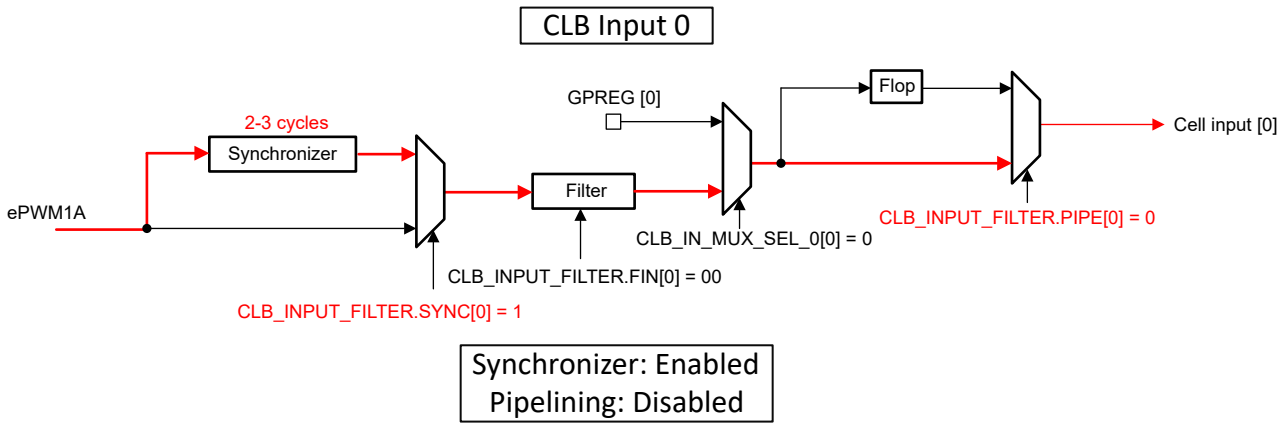

Figure 9-7. CLB Input Synchronization Example

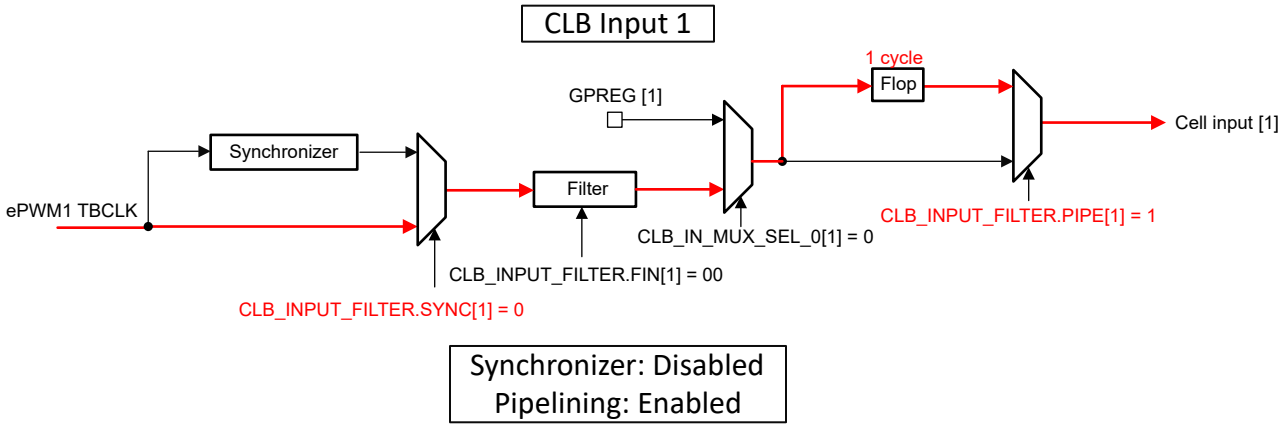

Figure 9-8. CLB Input Pipelining Example

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

If a signal in the following table indicates that synchronization is not required, as the signal is already synchronous, then pipelining is required and must be enabled using the PIPE bit in the CLB_INPUT_FILTER register. This pipelining adds a 1 CLB clock cycle delay to the input. This is not to be mistaken with the PIPELINE_EN bit in the CLB_LOAD_EN register, which controls pipelining of the CLB operations in the HLC and counter blocks. This PIPELINE_EN bit is also used when the device is run above 100 MHz. Having synchronization and pipelining both enabled or both disabled is not recommended. Enabling both synchronization and pipelining introduces a delay of more than 2-3 CLB clock cycles on the signal path. Disabling both allows the completely asynchronous signal to be routed as an input.

126	ECAT_SYNC0	ECAT_SYNC0	ECAT_SYNC0	ECAT_SYNC0	Disable
127	ECAT_SYNC1	ECAT_SYNC1	ECAT_SYNC1	ECAT_SYNC1	Disable

Note

EPWMxA_OE and EPWMxB_OE refer to trip outputs from the respective EPWM module.

EPWMxA_AQ and EPWMxB_AQ refer to the output of the AQ submodule in the respective EPWM module.

EPWMxA_DB and EPWMBx_DB refer to the output of the DB submodule in the respective EPWM module.

ECAT_SYNC0 and ECAT_SYNC1 must not be gated off, if EtherCAT is allocated to CM.

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

If a signal in the following table indicates that synchronization is not required, as the signal is already synchronous, then pipelining is required and must be enabled using the PIPE bit in the CLB_INPUT_FILTER register. This pipelining adds a 1 CLB clock cycle delay to the input. This is not to be mistaken with the PIPELINE_EN bit in the CLB_LOAD_EN register, which controls pipelining of the CLB operations in the HLC and counter blocks. This PIPELINE_EN bit is also used when the device is run above 100 MHz. Having synchronization and pipelining both enabled or both disabled is not recommended. Enabling both synchronization and pipelining introduces a delay of more than 2-3 CLB clock cycles on the signal path. Disabling both allows the completely asynchronous signal to be routed as an input.

Table 9-4. Local Signals and Mux Selection

The GPREG is accessible by the CPU and the bits of this register can be used as BOUNDARY INPUTs for the CLB Tiles. For example, CLB1s GPREG[0] can be used as BOUNDARY IN0 (Cell Input 0) for the corresponding CLB Tile.

To connect multiple tiles to each other, you can use the CLBx OUT4/5 and connect to CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

Another option is to connect the CLBx OUT0-7 to a GPIO and then use the INPUT X-BAR to bring the signal back in to the device and connect to the CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

To use GPIOs as inputs to the CLB, you must utilize the Input X-BAR and the CLB X-BAR. Figure 9-5 shows how GPIOs can be used as inputs to the CLB tiles.

9.3.3 CLB Output Selection

The eight outputs of the CLB are replicated to create 32 output signals. Each of these 32 outputs has a separate enable bit defined in the CLB output enable register, CLB_OUT_EN. The CLB outputs go to the ePWM, eCAP, eQEP and the crossbar module in the device. This allows the user to enhance the functionality of these modules with the CLB. Figure 9-9 shows the CLB outputs.

The user has the capability to disable updated to the CLB_OUT_EN register by blocking access to the register through setting the CLB_MISC_ACCESS_CTRL.BLKEN bit. The eight outputs are replicated to generate a total of 32 outputs (shown in Figure 9-9). Some of these new outputs can be used for TILE to TILE connection through the CLB Global Mux inputs.

Note

The output from OUTLUT0 is connected to OUT0, OUT8, OUT16, and OUT24. While the signal is the same, each OUTy has access to a different peripheral as shown in Section 9.3.4. Likewise, OUTLUT1 is connected to OUT1, OUT9, OUT17, and OUT25, and are the same signal.

CLBx_OUT12 through CLBx_OUT15 are unregistered and asynchronous to the CLB clock.

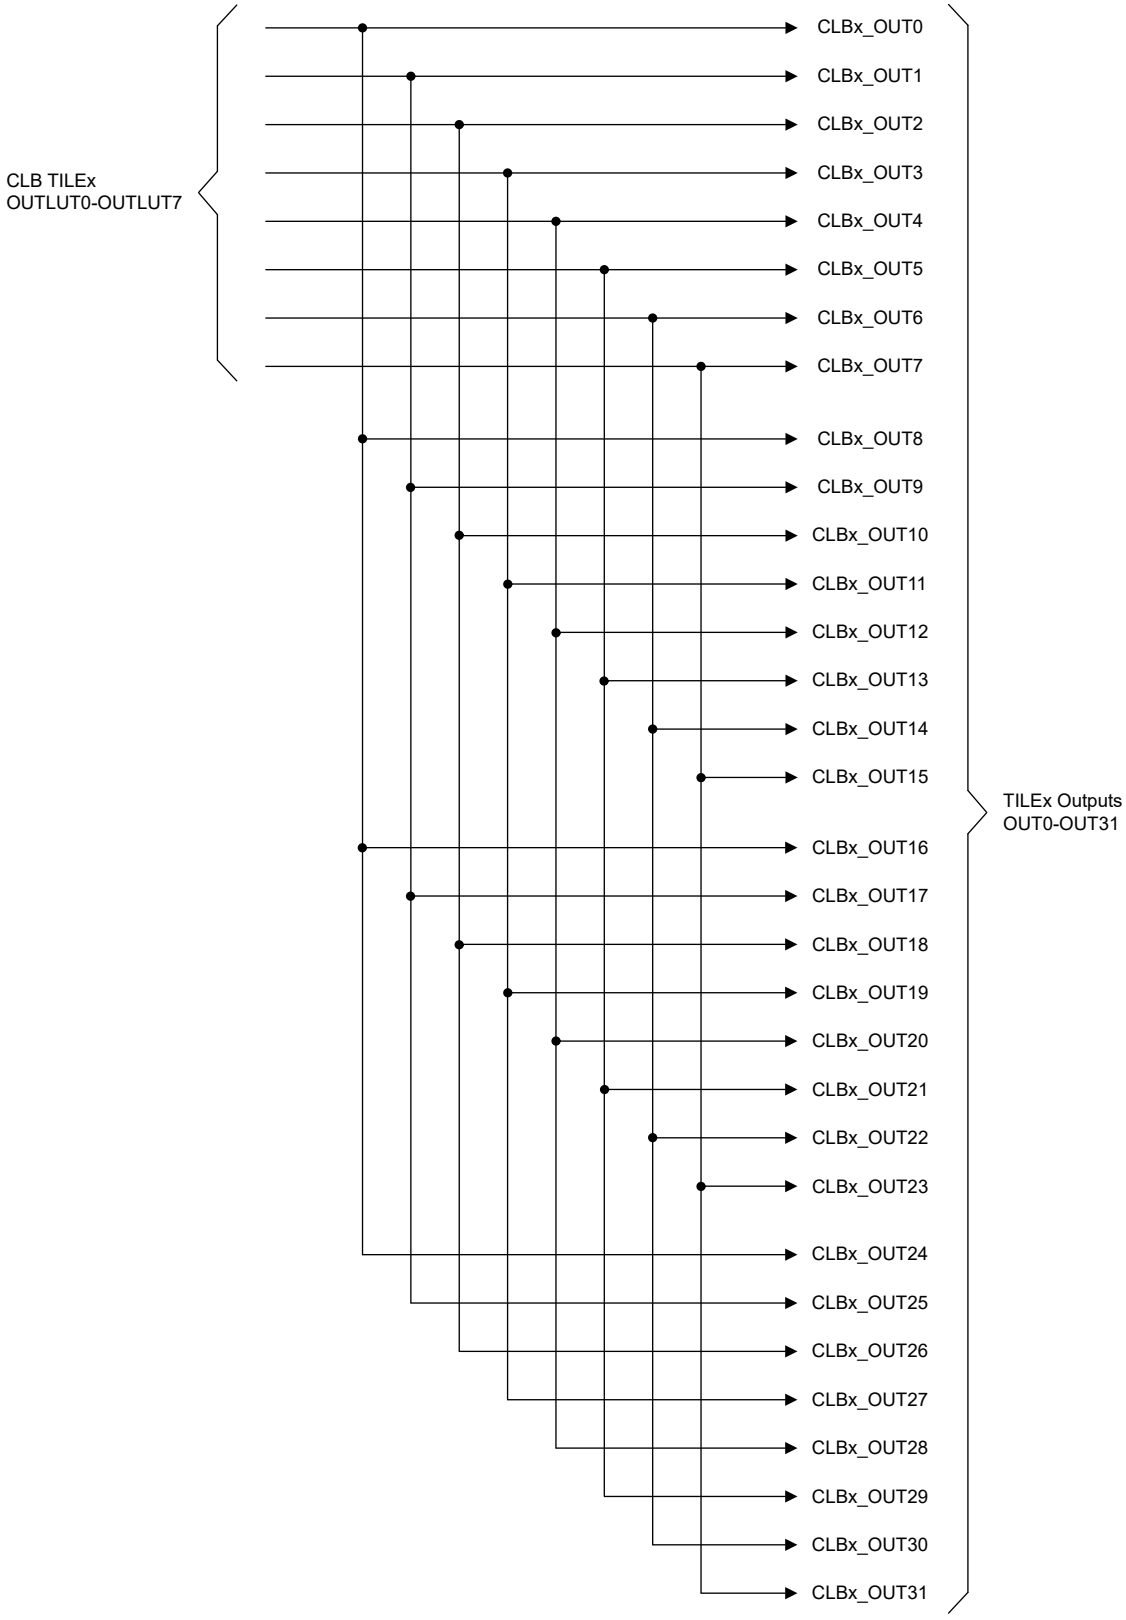

Figure 9-9. CLB Outputs

9.3.4 CLB Output Signal Multiplexer

Each CLB output signal passes through an external multiplexer that intersects a specific peripheral signal, see Figure 9-10. The output of the multiplexer is connected to the destination of the original peripheral signal and the default multiplexer setting is that the peripheral signal is passed through. The multiplexer is controlled by bit[n] in the CLB output enable register CLB_OUT_EN.

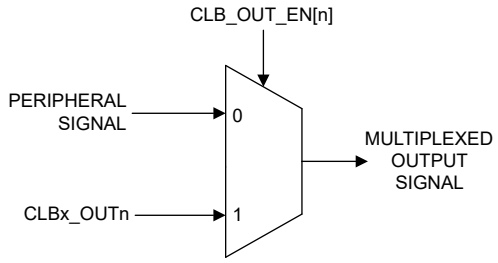

Figure 9-10. CLB Output Signal Multiplexer

For example, if the CLB1 OUT0 must override the EPWM1A signal, the OUPTUT ENABLE bit for OUT0 must be set to 1.

Table 9-6 and Table 9-7 shows the allocation of peripheral signals and the CLB outputs.

9.4 CLB Tile

The purpose of the CLB tile is to provide the logic reconfiguration capability of the CLB. The CLB tile contains the following submodules:

- **Counter:** The counter submodule can be configured as an adder, a counter, or a shifter. When functioning as an adder, the counter submodule can either add or subtract. When functioning as a counter, the counter submodule can count up or count down. When functioning as a shifter, the counter submodule can shift left or shift right. The counter event inputs, as well as the reset input, can be freely connected to any of the other submodules in the same tile. Starting with CLB Type 2, the counter module can also operate as a serializer or linear feedback shift register. There are three counters in each tile.
- **LUT4:** The LUT4 submodule has a 4-input look-up table functionality and is capable of realizing any combinatorial Boolean equation of up to four inputs. There are three LUT4 submodules in each CLB tile.
- **FSM:** The Finite State Machine (FSM) submodule can be configured either as a single four-state finite state machine, or as two independent two-state finite state machines. The FSM accepts two external inputs, and generates two state outputs and one combination output. When not used as a state machine, the FSM submodule can accept two external inputs and function as a 4-input LUT. There are three FSM submodules in each CLB tile.
- **Output LUT:** The output LUT is a 3-input lookup table submodule capable of realizing any combinatorial Boolean equation of up to three inputs. There are eight such blocks in a CLB tile, each associated with one of the tile outputs.
- **Asynchronous Output Conditioning Block:** The primary purpose of the Asynchronous Output Conditioning (AOC) block is to provide asynchronous conditioning capabilities on the TILE outputs or directly on the inputs of the TILE.
- **High Level Controller:** The High Level Controller (HLC) submodule is an event-driven block that can handle up to four concurrent events. The event can be an activity on any of the other block outputs. A predefined set of operations is executed when each event occurs. The HLC also provides a data exchange and interrupt mechanism to the CPU subsystem. There are four working registers (R0, R1, R2, and R3) that can be used for basic operations, and to modify or set up values for the three counter blocks. Unlike the other submodules, there is only one HLC in each CLB tile.
- **Static Switch Block:** The static switch block provides dynamic connectivity between all of the blocks listed above. Submodules can be connected by the user, with the only restriction that the submodules must not form a combinational loop within the tile.

A CLB tile consists of three sets each of the counter block, FSM, and LUT4, one high-level controller, and eight output LUT blocks. The submodule numbering is shown in Figure 9-11.

The functionality of the LUT submodules is configured using a register field containing the binary pattern of the output of the desired look-up table. For example, a 4-input LUT has 16 possible input permutations, each of which corresponds to a desired binary 0 or 1 at the output. The register field can, therefore, be 16-bits in length, with each bit representing the desired result of a binary pattern. Input pattern sequences start at 0000 and continue sequentially to 1111. A similar method is used to encode the 16-bit state equations in the FSM submodule.

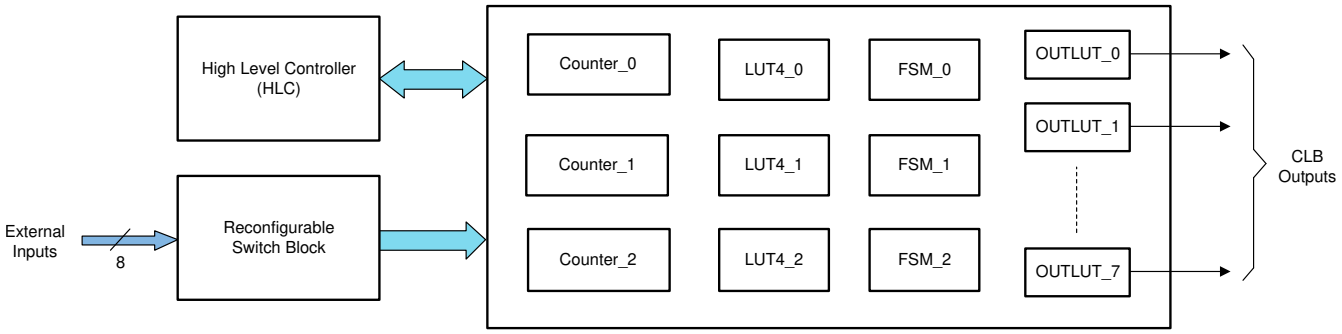

Figure 9-11. CLB Tile Submodules

9.4.1 Static Switch Block

The Static Switch Block provides the configurable connectivity between the submodules in the CLB tile. The outputs of all the submodules and the eight external inputs are connected to a common internal bus inside the tile. Every input port has a 32-to-1 multiplexer and an associated 5-bit selection value that allows the user to select one of the inputs on the bus. The only restrictions are certain signals (described below) that are tied off in the design to prevent creation of accidental combinatorial loops.

Table 9-8. Output Table

Bit Position	Signal Connection	Comment
0	Always 0	This select value is used to tie an input to 0.
1	COUNTER_0 MATCH2

Table 9-9. Input Table

Module Name	Port Name	Description
Counter Block	RESET	Acts as an active high reset when used as a counter
	MODE_0	Acts as an enable when used as a counter. The counter counts only when this input is 1.
	MODE_1	Acts as a direction control when used as a counter. If this input is 1, then the counter counts up; else, the counter counts down.
LUT	IN0	Input 0 of the 4-input LUT.
	IN1	Input 1 of the 4-input LUT.
	IN2	Input 2 of the 4-input LUT.
	IN3	Input 3 of the 4-input LUT.
FSM	EXT_IN0	Input 0 of the FSM block.
	EXT_IN1	Input 1 of the FSM block.
	EXTRA_EXT_IN0	Extra external input 0 of the FSM block. This input matters only if configured in the LUT mode.
	EXTRA_EXT_IN1	Extra external input 1 of the FSM block. This input matters only if configured in the LUT mode.

The static switch block allows the user to define the input connection of any submodule to come from any of the outputs in Table 9-8. It is therefore easy to create a combinatorial loop. To prevent this, certain paths are broken in the input path of each submodule. These port positions are tied to 0, as shown in Table 9-10.

Table 9-10. Ports Tied Off to Prevent Combinatorial Loops

Module Name	Ports of Input MUX Tied Off to 0 to Prevent Combinational Loops
LUT_0	LUT_0 , LUT_1, and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
FSM_0	LUT_1 and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
LUT_1	LUT_1 and LUT_2 output, FSM_1 and FSM_2 output.
FSM_1	LUT_2 output, FSM_1 and FSM_2 output.
LUT_2	LUT_2 output, FSM_2 output.
FSM_2	FSM_2 output.

9.4.2 Counter Block

9.4.2.1 Counter Description

The counter block is a complex functional submodule that can be configured either as a counter, an adder, or a shifter. Apart from the normal operational control, this block has a dedicated EVENT input, which can trigger an addition, subtraction or shift operation, or load data into the counter register. The inputs to the counter submodule are shown in Figure 9-12.

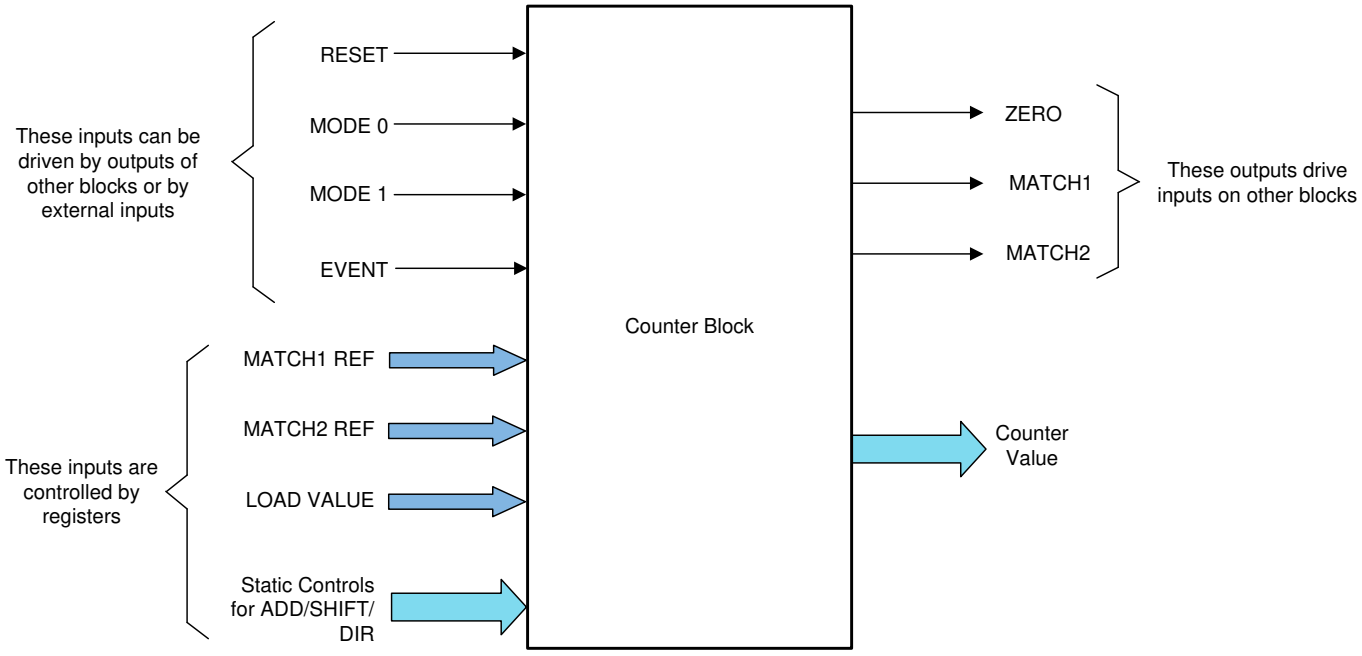

Figure 9-12. Counter Block

9.4.2.2 Counter Operation

At the heart of the counter block is a 32-bit count register. This register can either be loaded statically before counting commences, or dynamically at run time. The operation of the counter submodule is determined by the inputs described below. Note that each of the inputs can be connected to the outputs of any of the other blocks in the CLB tile. These connections are made by configuring the static switch block.

The counter inputs are:

- **RESET:** This is the highest priority input and takes precedence over all other inputs. The input is level sensitive and as long as the input remains high, the counter resets to 0 on the next clock cycle.
- **MODE_0:** This input is an enable for the counter. The counter begins counting (up or down depending on the MODE_1 setting) only when this input is high. If this input is low, then no counting takes place.
- **MODE_1:** This input is the direction control for the counter. If this input is high, then the counter increments on every clock cycle where MODE_0 is high. If this input is low, then the counter decrements on every clock cycle where MODE_0 is high. The counter wraps around to 0x00000000 after 0xFFFFFFFF when counting up. The counter wraps around to 0xFFFFFFFF after 0x00000000 when counting down. The only exception to this is when an EVENT occurs at exactly the same time, causing a different value to be loaded into the counter.

- **EVENT:** This input is defined for the purpose of triggering actions in the counter based on certain events. The event itself can be any of the outputs of the other blocks or an external input to the tile. The counter's static control inputs define the behavior of the counter on an active event. An active event is defined as a rising edge on the EVENT input. The counter can be configured to perform one of the following actions:
  - Load a predefined 32-bit value from the LOAD VALUE register into the count register
  - Shift the contents of the counter register left or right by a predefined amount between 0 and 31
  - Add or subtract a predefined 32-bit value. Addition and subtraction are treated as 32-bit unsigned operations and there is no saturation.

  Note that the effect of a rising edge on the EVENT input only lasts for one cycle. On the next cycle, the counter operation continues based on the MODE_0, MODE_1, and RESET inputs.

MATCH1 REF and MATCH2 REF are 32-bit reference values that are used to generate the MATCH1 and MATCH2 outputs. The MATCH1 output becomes active high whenever the counter register value matches the 32-bit MATCH1 REF value. MATCH2 behaves in a similar manner in relation to the MATCH2 REF register. The reference values for MATCH1 and MATCH2 can either be setup once before the start of operation, or can be modified dynamically. The High Level Controller can load desired values into the MATCH1 REF and MATCH2 REF registers.

Note that the counter load and match registers are not memory-mapped. For more information, see Section 9.5.2.

The three logic outputs of the counter block are:

- **ZERO:** This output goes high whenever the counter register is 0.
- **MATCH1:** This output goes high whenever the counter register is equal to the MATCH1 REF input register.
- **MATCH2:** This output goes high whenever the counter register is equal to the MATCH2 REF input register.

The operation of the counter block is controlled by the CFG_MISC_CTRL register. The following three bits of this register are relevant for each counter. The "x" below refers to the counter instance; 0, 1, or 2. For more information, see the CLB_MISC_CONTROL register description located in Section 9.10.

- COUNT_EVENT_CTRL_x: This bit defines whether the counter performs an addition or a shift on an event. A value of 0 means that on an event, the counter loads the static value; 1 means an add/shift operation is performed. This bit must be 0 for indirect loads and HLC loads of the counter to take effect.
- COUNT_ADD_SHIFT_x. 1 means add, 0 means shift.
- COUNT_DIR_x. 1 means left shift or add. 0 means right shift or subtract.

Table 9-11 shows the logical operation of the counter block in terms of the inputs and control register bits. Count up and down modes are the normal operation with EVENT = 0. The operations on the CNTVAL register are:

Load: CNTVAL = EVENT_LOAD_VAL

Shift right: CNTVAL = CNTVAL >> EVENT_LOAD_VAL

Shift left: CNTVAL = CNTVAL << EVENT_LOAD_VAL

Subtract: CNTVAL = CNTVAL - EVENT_LOAD_VAL

Add: CNTVAL = CNTVAL + EVENT_LOAD_VAL

Table 9-11. Counter Block Operating Modes

EVENT	MODE_0	MODE_1	COUNT_EVENT_CTRL_x	COUNT_ADD_SHIFT_x	COUNT_DIR_x	Action on CNTVAL
0	0	0	X	X	X	None
0	0	1	X	X	X	None
0	1	0	X	X	X	Count down
0	1	1	X	X	X	Count up
1	X	X	0	X	X	Load
1	X	X	1	0	0	Shift right
1	X	X	1	0	1	Shift left
1	X	X	1	1	0	Subtract
1	X	X	1	1	1	Add

9.4.2.3 Serializer Mode

Starting with CLB Type 2, the Counter module can operate as a serializer. In this mode of operation, this module acts as a shift register (also referred to as a serializer). In serializer mode of operation, the EVENT input is used to shift one bit of data into the serializer. Either of MATCH1 and MATCH2 can be configured to send out the shift register data.Using the MATCH1/2_TAP_SEL bit of CLB_COUNT_MATCH_TAP_SEL, any bit position of the counter can be brought out on the MATCH1/MATCH2 outputs. The shifting and direction of the counter in this mode is controlled by MODE_0 (enable) and MODE_1 (direction).

To enable the Serializer mode, CLB_MISC_CONTROL.COUNT_SERIALIZER_0 (for Counter 0) must be set.

9.4.2.4 Linear Feedback Shift Register (LFSR) Mode

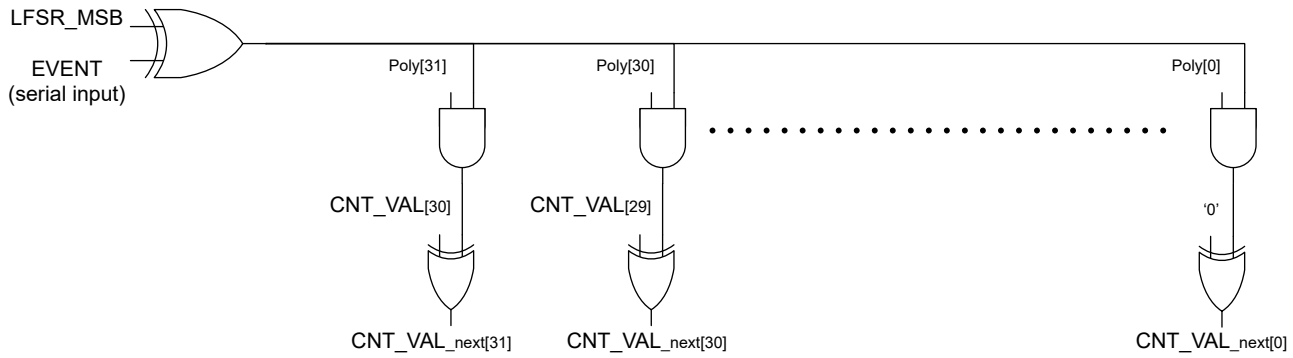
Starting with CLB Type 2, the Counter module operates as a linear feedback shift register. By configuring the characteristics of the LFSR, the counter module is used to compute the CRC on a serial bit stream. The polynomial for LFSR is in the MATCH2 reference register. The feedback bit position is in the MATCH1 reference register.

To enable the LFSR mode, CLB_MISC_CONTROL.COUNT_SERIALIZER_0 (for Counter 0) must be set along with COUNT0_LFSR_EN.

There are two types of LSFR that can be selected by changing the MODE1 value (0 or 1), as shown in Figure 9-13.

Structure for LFSR Type 1 (MODE_1 = 0)

CNT_VAL is the 32-bit counter's active register
CNT_VAL_next is the 32-bit value to be written into CNT_VAL on the next active cycle (clock edge when MODE_0 == 1)
LFSR_MSB = CNT_VAL[MATCH1_REF[4:0]]
Poly[31:0] is MATCH2_REF which acts as the CRC polynomial



Structure for LFSR Type 2 (MODE_1 = 1)

CNT_VAL is the 32-bit counter register
CNT_VAL_next is the 32-bit value to be written into CNT_VAL on the next active cycle (clock edge when MODE_0 == 1)
LFSR_MSB = CNT_VAL[MATCH1_REF[4:0]]
Poly[31:0] is MATCH2_REF which acts as the CRC polynomial

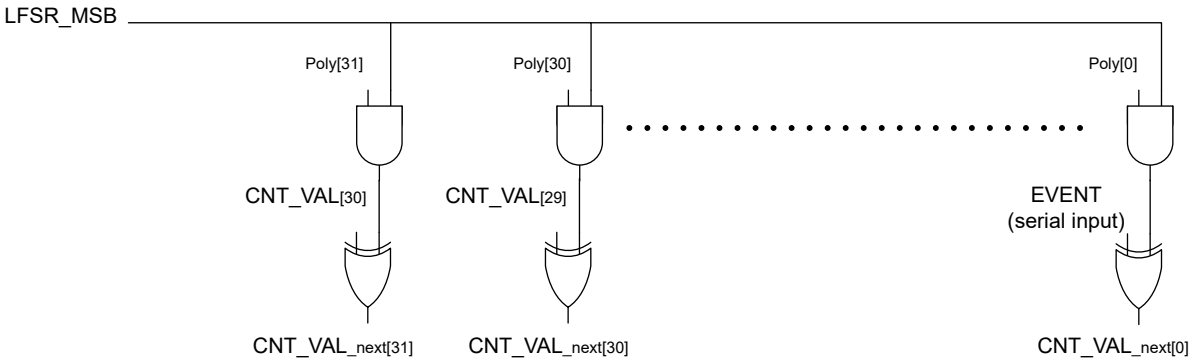


Figure 9-13. LFSR Modes

9.4.3 FSM Block

The Finite State Machine (FSM) block provides the ability to build programmable finite state machines with up to four states. The FSM block has two register bits and two external inputs, and can be programmed either as two 2-state machines or as a single 4-state machine. For additional flexibility, there are two auxiliary inputs (EXTRA_EXT_IN0 and EXTRA_EXT_IN1) that can be used to create larger combinational functions by giving up a state functionality. The structure of the FSM is shown in Figure 9-14.

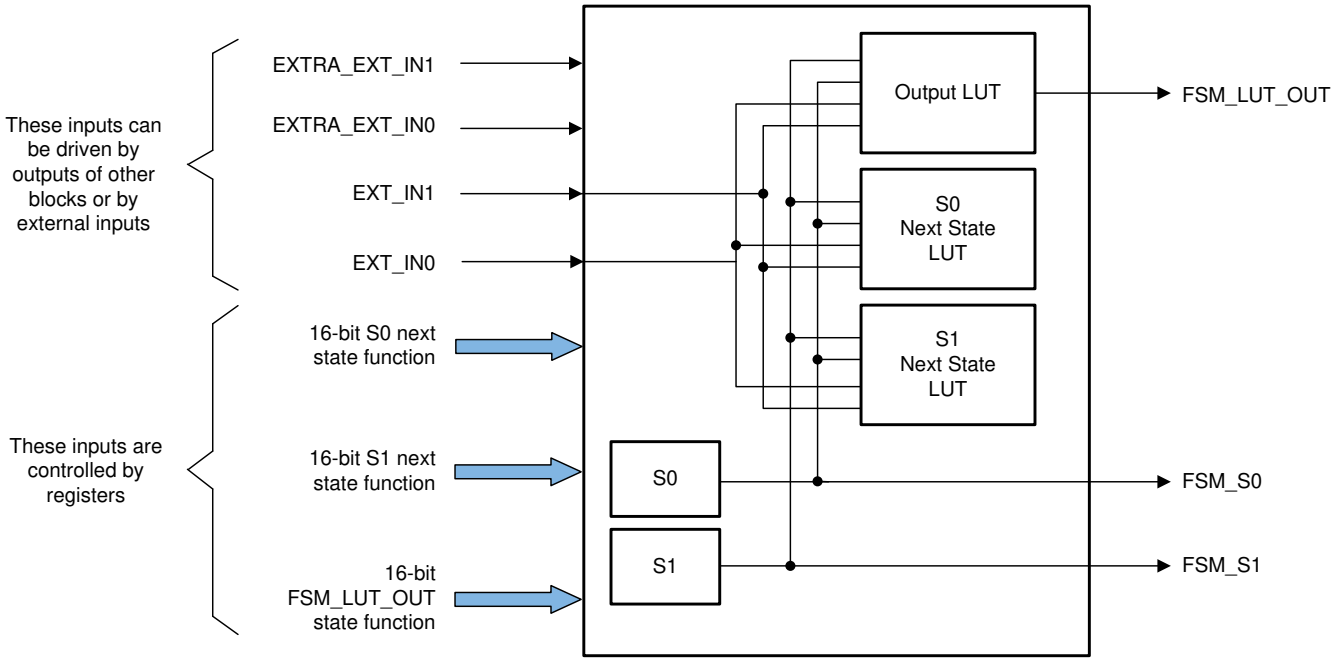

Figure 9-14. FSM Block

The signals and functionality of the FSM block are:

- **EXT_IN0 and EXT_IN1:** These are the two external inputs that can be used to control the output FSM_LUT_OUT or either of the states S0 and S1.
- **S0** and **S1** are two state bits that have independent state control equations.
- **16-bit S0 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S0.
- **16-bit S1 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S1.
- **16-bit output equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the output value of FSM_LUT_OUT. An additional level of configurability is provided such that FSM_LUT_OUT can use extra inputs in case the states S0 and S1 are unused.

  One extra bit is used to select EXTRA_EXT_IN0 instead of S0. One extra bit is used to select EXTRA_EXT_IN1 instead of S1. Using these, one can effectively build 3-input or a 4-input LUT for the FSM_LUT_OUT by giving up one or two state bits, respectively.

The CFG_MISC_CTRL register controls the operation of the FSM block. Two bits in this register are used for each FSM Block to determine whether the FSM output LUT function uses the state variable S0/S1, or the corresponding extra external input signal FSM_EXTRA_EXT_INx. A 0 means use the state bit, and a 1 means use the FSM_EXTRA_EXT_IN0 / FSM_EXTRA_EXT_IN1 signal.

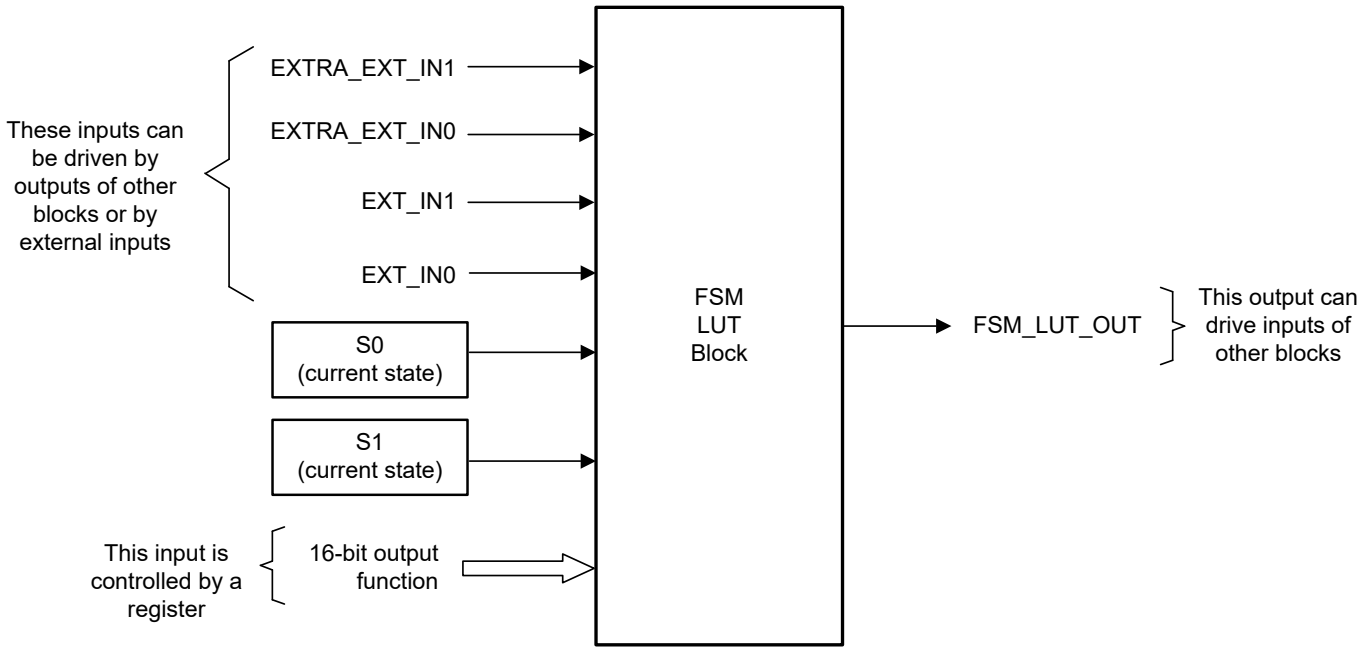

Figure 9-15. FSM LUT Block

9.4.4 LUT4 Block

This is a simple four input Look-Up table (LUT) block with inputs IN0, IN1, IN2, and IN3 (see Figure 9-16). Any combinatorial Boolean equation using the four inputs can be realized by programming the 16-bit control register associated with each LUT4 block. For more information, see the LUT4 register descriptions located in Section 9.10.

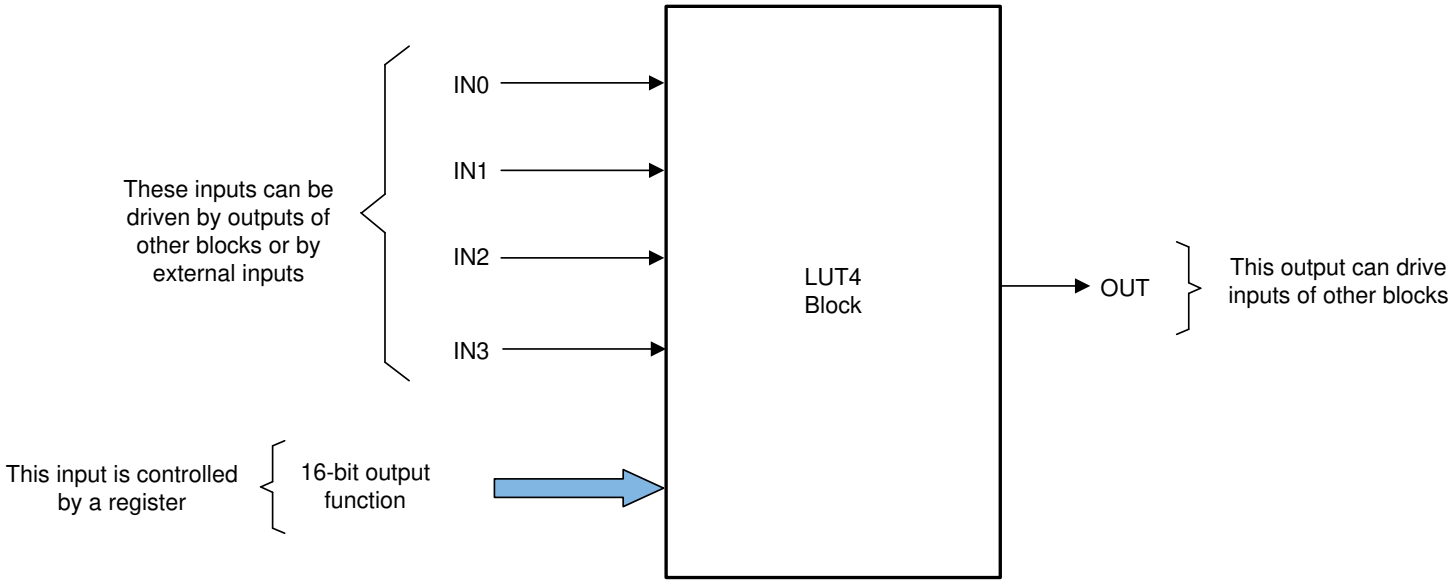

Figure 9-16. LUT4 Block

9.4.5 Output LUT Block

The output LUT block (Figure 9-17) is very similar in functionality to the LUT4 block, except that the output LUT block has three inputs. Unlike the other sub blocks, the outputs of these blocks are meant to go out of the tile and hence cannot be used by any other block within the tile. Any combinatorial function of the three inputs can be realized by the output LUT block. For more information, see the output LUT register descriptions located in Section 9.10.

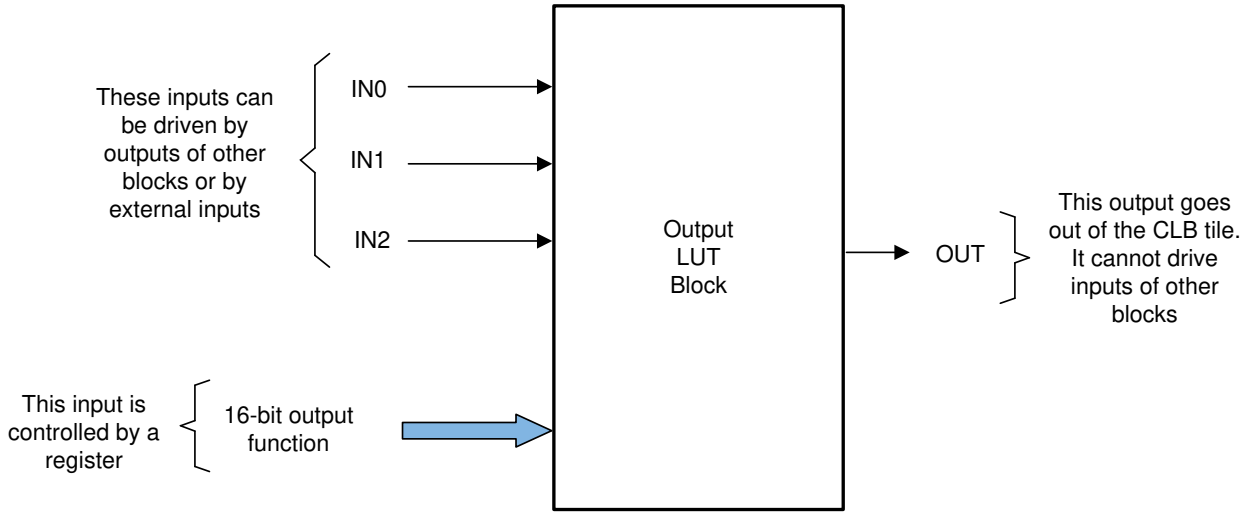

Figure 9-17. Output LUT Block

9.4.6 Asynchronous Output Conditioning (AOC) Block

The logic in the AOC block is organized into three stages with the inputs passing through different types of logic modification at each stage before proceeding to the next level. This is shown in Figure 9-18.

There are 8 inputs to this block. Each of these 8 inputs can pick the corresponding BOUNDARY input to the CLB or the CLB TILE output (for example, the INPUT 0 of the AOC block can choose between CLB BOUNDARY INPUT0 and CLB TILE OUTPUT 0). If the CLB TILE OUTPUT 0 is selected, the CLB TILE OUTPUT 0 is always registered before being sent to the subsequent asynchronous signal conditioning stages. In each of the three stages, there is always an option to do nothing and just send the signal as is to the next stage (bypass).

Stage 1: The input signal can be inverted before sending the signal to the next stage.

Stage 2: The signal coming from Stage 1 can be GATED with a gating control signal. The gating control signal can either be from a software register or can be any of the CLB TILE outputs. The GATING function can be a logical AND, OR, or XOR.

Stage 3: The input signal can be used to either set or clear the output on the rising edge of the signal. This is a purely asynchronous set/clear that occurs without needing any clocks. The release control signal, when high, restores the output to the default state (HIGH if asynchronous clear is selected and LOW if asynchronous set is selected). The release control signal can be either from a software register or can be any of the CLB TILE outputs. Optionally, instead of any of the asynchronous set and clear operations, the input signal can just be delayed by a clock cycle.

The interaction of the CLB TILE and the AOC block is shown in Figure 9-19.

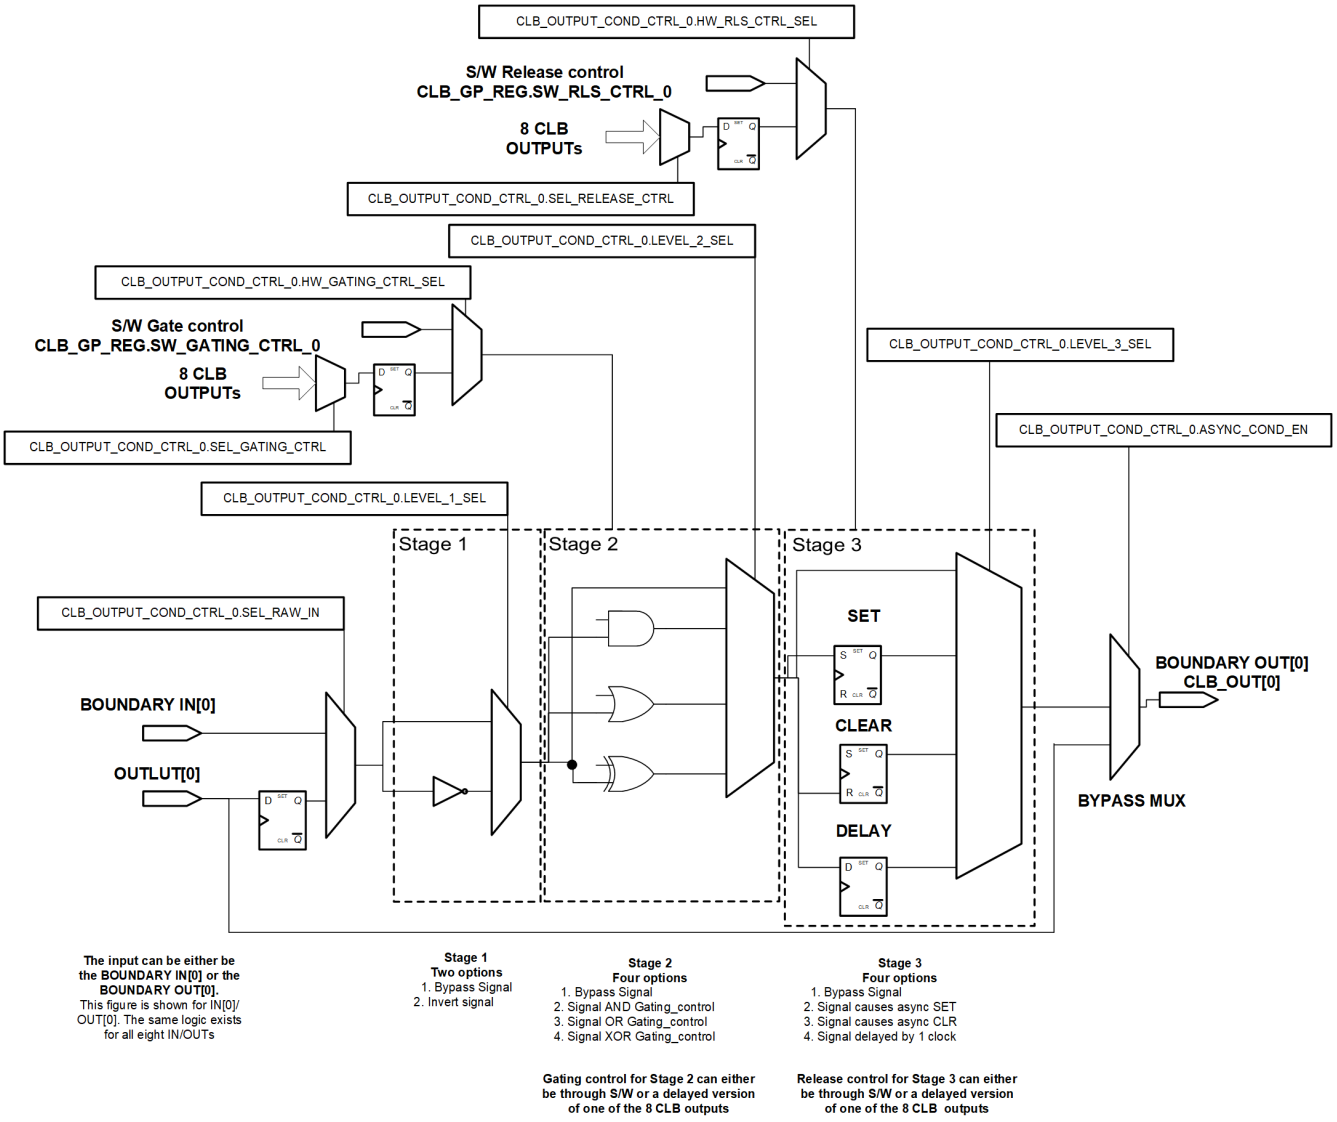

Figure 9-18. AOC Block

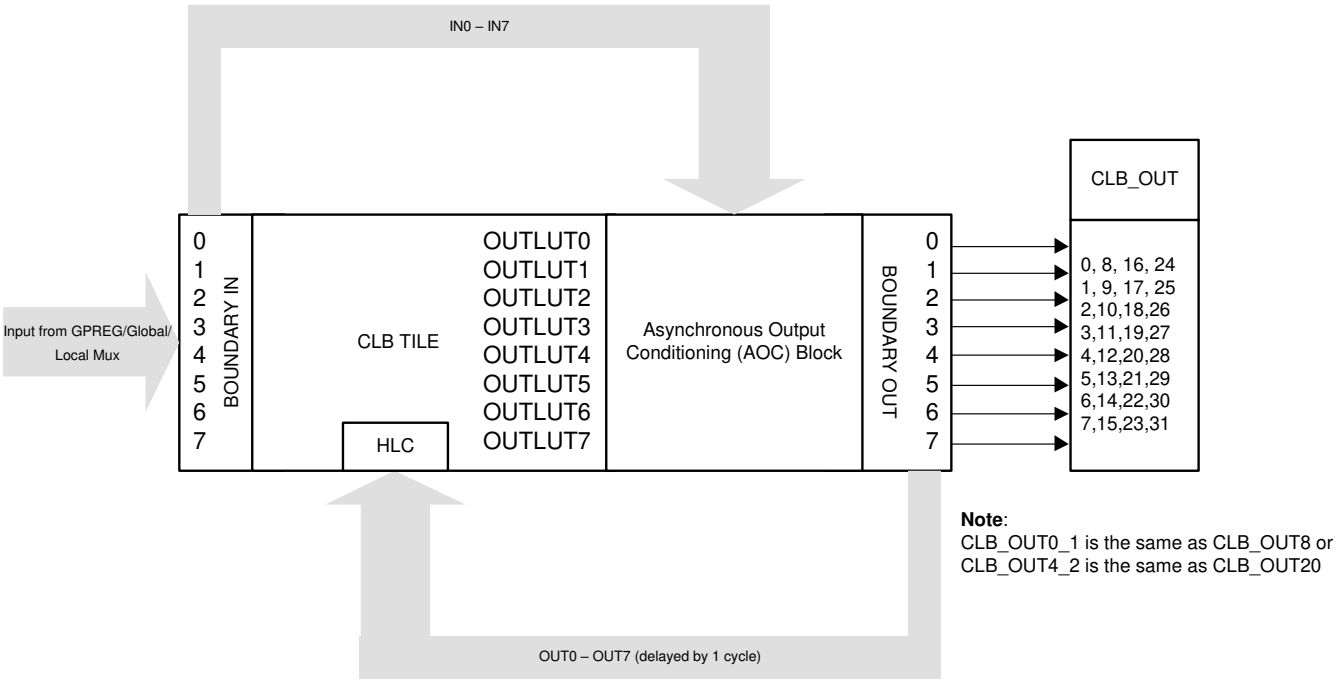

Figure 9-19. AOC Block and The CLB TILE

Note

Only CLB_OUT12 to CLB_OUT15 can be used as ASYNC outputs. This is the same as CLB_OUT4_1 to CLB_OUT7_1. GPIO Output XBAR can be used to route the OUT4_1 and OUT5_1 ASYNC outputs to GPIOs.

9.4.7 High Level Controller (HLC)

The High Level Controller (HLC) is significantly more complex than the other blocks in the CLB tile. The HLC performs two main functions:

- Provides a means of communication and data exchange with the rest of the device. This is done through two methods: a global access path to four general purpose HLC registers (R0 through R3) and PUSH and PULL FIFOs between the CPU and the HLC. The general-purpose HLC registers are designed to only be written to during device configuration time. To avoid unexpected behavior, the HLC registers must not be written to during run-time operation. The PUSH and PULL FIFOs are the primary avenues of data exchange during run-time, refer to Section 9.4.7.4 for more information.
- Provides a programmable, event-based action system, which performs computation, manipulation of logic functionality, and data movement. In other words, events can be configured to trigger a predefined set of actions in the CLB tile, or to initiate data exchange with the rest of the device.

The architecture of the HLC is shown in Figure 9-20. The HLC is an event-based system capable of handling up to four simultaneous events that can be selected from any outputs of the other blocks within the tile or from an external input.

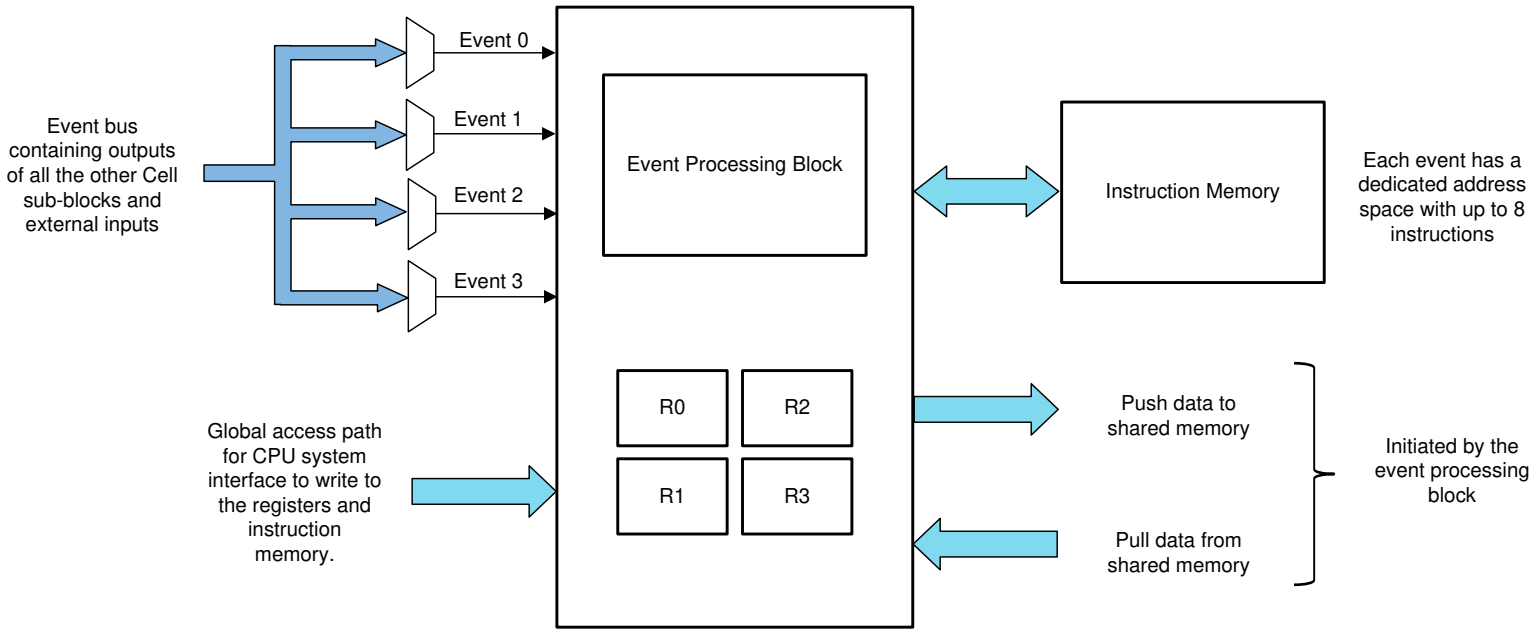

Figure 9-20. High Level Controller Block

9.4.7.1 High Level Controller Events

Each of the four HLC events has a dedicated address from which instructions are executed. Events are selected from the set of signals listed in Table 9-12. The lowest numbered event (Event 0) has the highest priority, and the highest numbered event (Event 3) has the lowest priority.

Table 9-12. HLC Event List

Index	HLC Event Mux
0	Always 0
1	COUNTER_0 MATCH2
2	COUNTER_0 ZERO
3	COUNTER_0 MATCH1
4	FSM_0 STATE_BIT_0
5	FSM_0 STATE_BIT_1
6	FSM_0 LUT output
7	LUT4_0 output
8	Always 1

9.4.7.2 High Level Controller Instructions

The instruction memory supports up to eight instructions per event. Each instruction sequence gets triggered on the rising edge of the corresponding event. Starting with CLB Type 2, the option to trigger the execution of instructions using both falling edge and rising edge is available.

The HLC memory supports up to eight instructions per event, starting at the beginning of the fixed address range shown in Table 9-14. An instruction sequence is triggered on the rising edge of the corresponding event. If two or more events occur simultaneously, the associated instruction sequences each are executed sequentially in priority order.

Table 9-14. HLC Instruction Address Ranges

Address	Instructions for
00000 to 00111	Event 0
01000 to 01111	Event 1
10000 to 10111	Event 2
11000 to 11111	Event 3

The HLC instruction format is shown in Table 9-15.

Table 9-15. HLC Instruction Format

Last Instruction Bit	5-Bit Opcode	3-Bit Source	3-Bit Destination
This bit when set to 1 stops execution after the current instruction.	MOV 00000 MOV_T1 00001 MOV_T2 00010 PUSH 00011 PULL 00100 ADD 00101 SUB 00110 INTR 00111	Source can be R0, R1, R2, R3, C0, C1, C2.	Destination can be R0, R1, R2, R3, C0, C1, C2. Note that for ADD/SUB instructions, only R0, R1, R2, or R3 can be the destination.

R0, R1, R2, and R3 are four 32-bit general-purpose registers in the HLC. C0, C1, and C2 are three counter registers present in the CLB tile. <Src> is used to indicate the source and <Dest> is used to indicate the destination. Table 9-16 describes the HLC instructions.

Table 9-16. HLC Instruction Description

Instruction	Description
ADD <Src>, <Dest>	This instruction performs an unsigned 32-bit addition. <Dest> = <Dest> + <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3.
INTR <6-bit constant>	This instruction flags an interrupt through the CPU interface. The 6-bit constant is stored in the interrupt flag register CLB_INTR_TAG_REG. If multiple INTR instructions are called consecutively, only the first one has an effect. When multiple INTR calls are needed, each can be separated by other HLC instructions to make sure the interrupt calls take effect. **Note** Starting with CLB Type 2, NMI can be generated by the CLB. This feature is DISABLED by default and must be enabled (**CLB_LOAD_EN.NMI_EN**).
MOV <Src>, <Dest>	This instruction moves <Src> to <Dest>. Both <Src> and <Dest> can be any of R0, R1, R2, R3, C0, C1, or C2. The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and HLC loads of the counter to take effect.

Table 9-16. HLC Instruction Description (continued)

Instruction	Description
MOV_T1 <Src>, <Dest>	This instruction moves <Src> to the Match1 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match1 register of any of the counters C0, C1, or C2. Examples are: • This instruction moves the count value in C1 into register R0: MOV_T1 C1 R0 • This instruction moves the value in R2 into the Match1 register of counter C0: MOV_T1 R2 C0
MOV_T2 <Src>, <Dest>	This instruction is similar to MOV_T1. The instruction moves <Src> to the Match2 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match2 register of any of the counters C0, C1, or C2.
PULL <Dest>	This instruction transfers data from the data exchange pull memory buffer in the CPU interface to the <Dest> register. <Dest> can be any of R0, R1, R2, or R3. The PULL instruction is used as seen from the High Level Controller and a PULL operation reads (pulls) data from an internal 4-word FIFO.
PUSH <Src>	This instruction transfers data from <Src> to the data exchange push memory buffer in the CPU interface. <Src> can be any of R0, R1, R2, R3, C0, C1, or C2. The PUSH instruction is used as seen from the High Level Controller and pushes data into an internal 4 word FIFO.
SUB <Src>, <Dest>	This instruction performs an unsigned 32-bit subtraction. <Dest> = <Dest> - <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3.

MOV, MOV_T1, MOV_T2, ADD, SUB, and INTR instructions take one cycle to execute. PUSH and PULL require two cycles to execute. Note that the PUSH and PULL instructions are pipeline protected, meaning that a register can be used immediately after a PUSH/PULL to that register.

For multiple events triggered simultaneously, if the last instruction in the higher priority event is a PUSH or a PULL, there is an additional cycle delay between the end of the higher priority event and the start of the next event. If the last instruction is not a PUSH or PULL, then there is no cycle delay between the events.

9.4.7.3 <Src> and <Dest>

Three bits are used to encode the <Src> and <Dest> registers as shown in Table 9-17.

Table 9-17. HLC Register Encoding

Bits	Register
000	R0
001	R1
010	R2
011	R3
100	C0
101	C1
110	C2

9.4.7.4 Operation of the PUSH and PULL Instructions (Overflow and Underflow Detection)

The PUSH and PULL operations of the HLC are intended for data exchange with the host system. There are separate FIFO buffers for PUSH and PULL operations. For example, a series of PUSH operations write to successive locations in a linearly mapped-memory buffer. The PUSH buffer and the PULL buffer are mapped at address offsets shown in the *Registers* section.

The CPU can read from and write to the PUSH and PULL buffers, respectively, to exchange data with the HLC. Data pushed by the HLC is read by the CPU from the PUSH buffers. Data sent from the CPU to the HLC is written by the CPU to the PULL buffer and is read by the HLC using the PULL instruction.

Refer to *clb_ex13_push_pull* for guidance on properly using the PUSH and PULL buffers. To make use of one of the CLB inputs as a GPREG, have this input indicate when data is written to the FIFO by the CPU.

There are separate PUSH and PULL address pointers that increment each time the HLC performs a PUSH or PULL operation. These address pointers are also memory-mapped so that the CPU can determine their value. These address pointers are also writable and can be reset by the CPU at any time.

Overflow and underflow detection is done by simply reading the values of the PUSH and PULL address pointers.

In the CLB module of the device, the depth of the PUSH and PULL FIFOs is four 32-bit words each. If the CPU starts a fresh data transfer to the PULL buffers and sees the address pointer greater than four, then an underflow has occurred since the HLC has pulled more data than the number of words written by the CPU into the buffer.

9.5 CPU Interface

9.5.1 Register Description

There are three classes of registers that are used to control and configure the CLB tile. This specification only describes the offset addresses of the registers. The absolute register addresses are different for each CLB tile. The three instances of the various blocks (LUT4, FSM, and Counter Block) are numbered 0, 1, and 2.

- **Logic configuration registers (0x000 – 0x0FF):** These registers control the core reconfiguration logic for the tile. All registers in this group are EALLOW protected and also protected by the LOCK register.
- **Top level control registers (0x100 – 0x1FF):** These registers are used for top level and device related control of the CLB. These registers typically control mux selects for inputs, global enables, and so forth, and are accessible by normal memory mapped access. Some of these registers have EALLOW and LOCK protection.
- **Data exchange registers (0x200 – 0x3FF):** These registers are used to exchange data between the CLB and the rest of the device. The registers are accessible by normal memory-mapped access and no EALLOW or LOCK protection exists.

Note

EALLOW protection means that the write access to the register is enabled only when the EALLOW instruction has been executed prior to the write access. The complementary EDIS instruction disables access to all registers protected in this way. For more information, see Section 9.10.

9.5.2 Non-Memory Mapped Registers

The memory-mapped CLB registers are described later in this chapter; however, many of the CLB resources including counters, the instruction memory of the High Level Controller, and the HLC general-purpose registers (R0 through R3) are only indirectly accessible through a local interface bus and are not memory-mapped. These registers are accessible through the two memory-mapped registers CLB_LOAD_DATA and CLB_LOAD_ADDR. Note that the general-purpose registers R0 through R3 must only be written to during configuration-time and are not intended to be written to during run-time. Writes during run-time can lead to unexpected behavior. If run-time data exchange is desired, refer to Section 9.4.7.4.

Load the data to be written into the CLB_LOAD_DATA register, then load the appropriate address into CLB_LOAD_ADDR to determine where this data is written. Writing a 1 to bit position 0 in the CLB_LOAD_EN register then causes an internal write operation to be triggered. The address allocation for the CLB_LOAD_ADDR register is shown in Table 9-18.

Note

The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and for HLC loads of the counter to take effect.

Table 9-18. Non-Memory Mapped Register Addresses

Address (Binary)	Resource
000000 to 000010	Counter 0 to 2 Load value
000100 to 000110	Counter 0 to 2 Match1 value
001000 to 001010	Counter 0 to 2 Match2 value
001100 to 001111	R0 to R3 of High Level Controller
100000 to 100111	Instructions for Event 0
101000 to 101111	Instructions for Event 1
110000 to 110111	Instructions for Event 2
111000 to 111111	Instructions for Event 3

Use the following steps to load the value 0x11223344 into the general purpose R0 register:

1. Write 0x11223344 to CLB_LOAD_DATA.
2. Write 0xc to CLB_LOAD_ADDR.
3. Write 0x1 to CLB_LOAD_EN.

Note

Even though HLC registers are accessible by the CPU, your application code needs to make sure that no other CLB internal logics are updating the same HLC register at the same time, causing a race condition.

9.6 DMA Access

The DMA does not have access to the CLB memory-mapped registers, including the PUSH and PULL FIFO registers. For more information, refer to Section 9.10.

9.7 CLB Data Export Through SPI RX Buffer

For a continuous export of data from the CLB peripherals, SPI RX buffers can be used. CLB data can be exported through the SPI RX buffers without CPU/CLA interventions.

For the F2838x devices, CLB1 to CLB4 have access to SPIA to SPID, respectively, as shown in Table 9-19.

Table 9-19. CLB to SPI RX Access

CLB Instance	SPI Instance
CLB1	SPIA
CLB2	SPIB
CLB3	SPIC
CLB4	SPID

When the CLB to SPI data exporting is enabled, 16-bit data can be exported from CLB to SPI RX buffers. The 32-bit HLC R0 register is the data that is exported to the SPI RX buffers. The user can select which 16-bit range of the HLC R0 is exported by configuring the **CLB_SPI_DATA_CTRL_HI.SHIFT**. The CLB also controls when HLC R0 data must be transferred to the SPI RX buffer through **CLB_SPI_DATA_CTRL_HI.STRB** that selects one of the HLC event signals from the static switch block.

When CLB to SPI data exporting is required, note:

- The selected SPI transmit functionality is not affected.
- Even though the data is being pushed into the SPI RX buffers by the CLB, the SPI RX interrupt and the DMA trigger for SPI RX in the respective peripherals must be configured.
- The SPI can resume normal operation when the CLB to SPI data exporting is disabled.

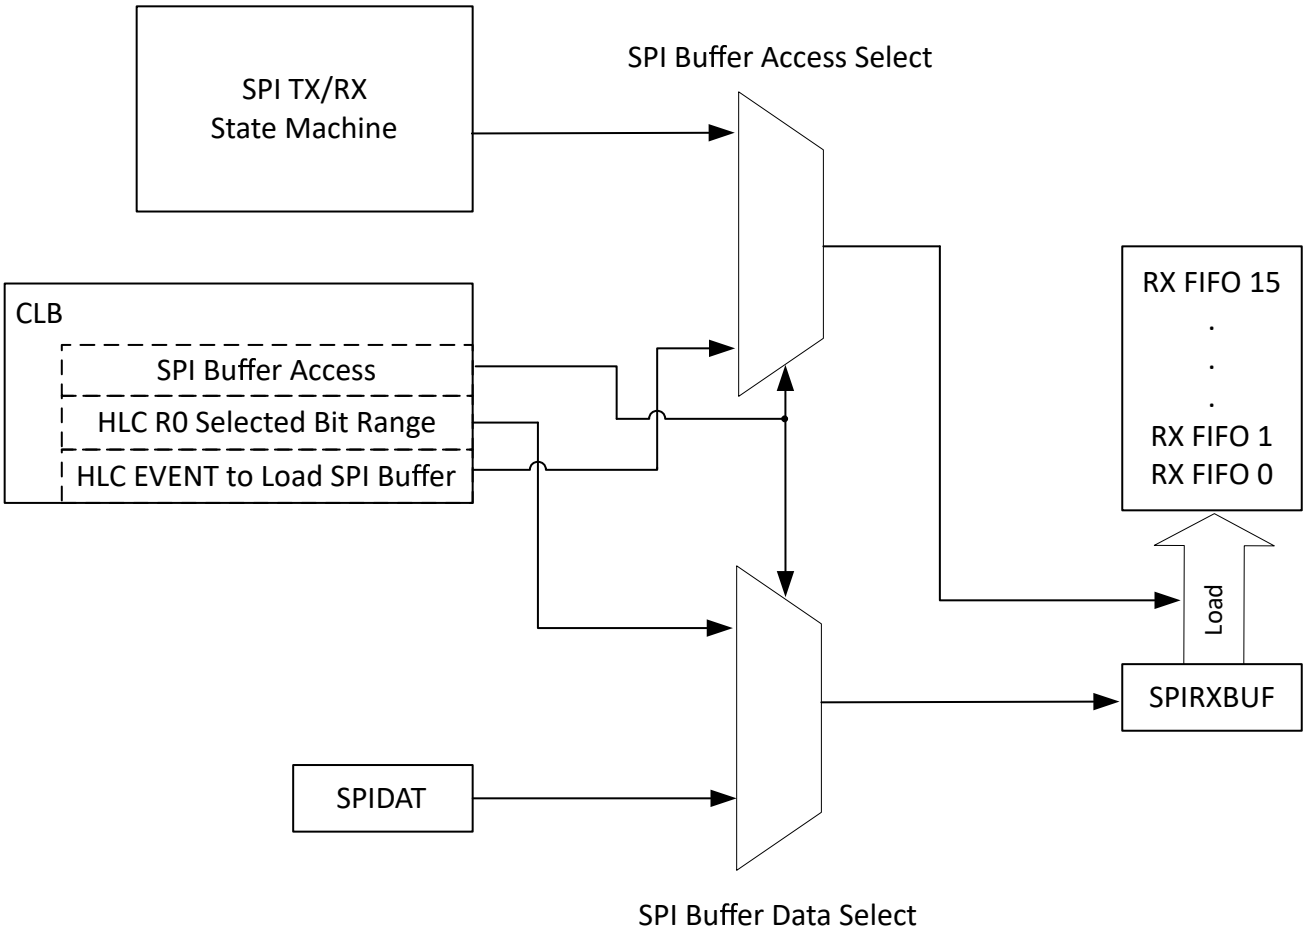

Figure 9-21. CLB Control of SPI RX Buffer

9.8 CLB Pipeline Mode

When operating the CLB TILE at frequencies higher than 100 MHz, the Pipeline mode MUST be enabled. When CLB Pipeline mode is enabled, the operations of the HLC and COUNTER modules are changed.

- When operating at higher frequencies that require Pipeline mode to be enabled, the pipelined versions of the the CLB CELL OUTPUTs are brought into the HLC. The Pipeline mode causes the CELL outputs delayed by 1 clock cycle to be used as the source of the HLC event triggers.
- In Pipeline mode, the COUNTER module's add/sub/shift operations, which are triggered by an event, use the value of the counter in the previous clock cycle (pipelined).

To enable the CLB Pipeline mode, set the CLB_LOAD_EN.PIPELINE_EN.

9.9 Software

9.9.1 CLB Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/clb

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

9.9.1.1 CLB Empty Project

FILE: empty.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

9.9.1.2 CLB Combinational Logic

FILE: clb_ex1_combinatorial_logic.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

The objective of this example is to prevent simultaneous high or low outputs on a PWM pair. PWM modules 1 and 2 are configured to generate identical waveforms based on a fixed frequency up-count mode.

9.9.1.3 CLB GPIO Input Filter

FILE: clb_ex2_gpio_input_filter.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example demonstrates use of finite state machines (FSMs) and counters to implement a simple ‘glitch’ filter which might, for example, be applied to an incoming GPIO signal to remove unwanted short duration pulses.

9.9.1.4 CLB Auxilary PWM

FILE: clb_ex3_auxiliary_pwm.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example configures a CLB tile as an auxiliary PWM generator. The example uses combinatorial logic (LUTs), state machines (FSMs), counters, and the high level controller (HLC) to demonstrate the PWM output generation capabilities using CLB.

9.9.1.5 CLB PWM Protection

FILE: clb_ex4_pwm_protection.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example extends the features of example 1 to ensure an active high complementary pair PWM configuration always operates with a minimum value of dead-band irrespective of how the generating PWM module is configured. The example illustrates the configuration of four separate PWM tiles to implement PWM protection on four PWM modules. The outputs of PWM modules 1 to 4 are operated on by CLB tiles 1 to 4, respectively.

9.9.1.6 CLB Event Window

FILE: clb_ex5_event_window.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example uses the counter, FSM, and HLC sub-modules of the CLB to implement an event timing feature which detects whether an interrupt service routine takes too long to respond to an interrupt. The example configures four PWM modules to operate in up-count mode and generate a low-to-high edge on a timer zero match event. The zero match event also triggers a PWM ISR which, for the purposes of this example, contains a dummy payload of variable length. At the end of the ISR, a write operation takes place to a CLB GP register to indicate the ISR has ended.

9.9.1.7 CLB Signal Generator

FILE: clb_ex6_siggen.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example uses CLB1 to generate a rectangular wave and CLB2 to check the rectangular wave generated by CLB1 doesn't exceed the defined duty cycle and period limits.

9.9.1.8 CLB State Machine

FILE: clb_ex7_state_machine.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\Designing With the C2000 CLB.pdf This application report describes the process of creating this CLB example and can be used as guidance on desiging custom logic with the CLB. This example uses all submodules inside a CLB TILE in order to implement a complete system.

9.9.1.9 CLB External Signal AND Gate

FILE: clb_ex8_external_signal_AND_gate.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, two external signals from two GPIOs are passed through the Input X-BAR and the CLB X-BAR to the CLB TILE. Inside the CLB module these two signals are ANDED. The output of the AND gate is then exported to a GPIO, using Output X-BAR.

9.9.1.10 CLB Timer

FILE: clb_ex9_timer.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a COUNTER module is used to create timed events. The use of the GP Register is shown. Through setting/clearing the bits in the GP register, the timer is started, stopped or changes direction. The output of the timer event (1-clock cycle) is exported to a GPIO. Interrupts are generated from the timer event using the HLC module. A GPIO is also toggled inside the CLB ISR. The indirect CLB register access is used to update the timer's event match value and the active counter register to modify the frequency of the timer.

9.9.1.11 CLB Timer Two States

FILE: clb_ex10_timer_two_states.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the timer is setup the same as the previous example. The difference is the use of the FSM submodule to toggle the output of the CLB which is then exported to a GPIO. The FSM module acts as a single bit memory block. Interrupts are setup in the same format as the previous example. The interrupt delay of the CLB can be seen by comparing the output of the CLB and the GPIO toggled in the ISR.

9.9.1.12 CLB Interrupt Tag

FILE: clb_ex11_interrupt_tag.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a timer is setup with two different match values. These two events are used by the HLC submodule to generate interrupts. The interrupt TAG is used to differentiate between the interrupt generated due to the match1 event of the CLB counter and the match2 event of the CLB counter.

9.9.1.13 CLB Output Intersect

FILE: clb_ex12_output_intersect.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the CLB module is set up the same as the external_AND_gate example. However, instead of the output being exported to the GPIO using Output X-BAR, the output is exported to the GPIO by replacing the output of ePWM1. This is done by configuring the GPIO for EPWM1A output, followed by enabling output intersection.

9.9.1.14 CLB PUSH PULL

FILE: clb_ex13_push_pull.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the use of the PUSH-PULL interface is shown. Multiple COUNTER submodules, HLC submodule, FSM submodules, and OUTLUT submodules are used. The PUSH-PULL interface is used alongside the GP register to update the COUNTER submodules' event frequencies.

9.9.1.15 CLB Multi Tile

FILE: clb_ex14_multi_tile.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a CLB TILE is passed to the input of another CLB TILE. The output of the second CLB TILE is then exported to a GPIO, showcasing how two CLB TILEs can be used in series.

9.9.1.16 CLB Tile to Tile Delay

FILE: clb_ex15_tile_to_tile_delay.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a GPIO is taken into the CLB TILE through INPUT XBAR and the CLB XBAR. The signal is forwarded by the TILE to the next TILE. This time the signal only goes through the CLB XBAR and NOT the Input XBAR. This is done to show that delays are added when the signals are passed from TILE to TILE and the delay is NOT characterized. The user should always avoid passing signals with timing requirements between tiles. The COUNTER modules inside the CLBs will count the amount of delay in cycles.

9.9.1.17 CLB based One-shot PWM

FILE: clb_ex17_one_shot_pwm.c

For the detailed description of this example, please refer to :
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

9.9.1.18 CLB AOC Control

FILE: clb_ex18_aoc.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the Asynchronous Output Conditioning block is used to asynchronously AND gate the input signals to the CLB. This module is only available for CLB types 2 and up.

9.9.1.19 CLB AOC Release Control

FILE: clb_ex19_aoc_release_control.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the Asynchronous Output Conditioning block is used to asynchronously set/release the input signals to the CLB. This module is only available for CLB types 2 and up.

9.9.1.20 CLB XBARs

FILE: clb_ex20_clbxbars.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB INPUTXBAR and CLB OUTPUTXBAR are used to take input signals from GPIOs into the CLB TILEs and take output signal from the TILE to GPIOs. The availability of these XBARs are device dependent.

9.9.1.21 CLB AOC Control

FILE: clb_ex21_clockprescalar_nmi.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the clock prescalar of the CLB module is used to divide down the CLB clock and use it as an input to the TILE logic. Also the HLC module is used to generate NMI interrupts. This module is only available for CLB types 2 and up.

9.9.1.22 CLB Serializer

FILE: clb_ex22_serializer.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB COUNTER is used in serializer mode to act as a shift register. This module is only available for CLB types 2 and up.

9.9.1.23 CLB LFSR

FILE: clb_ex23_lfsr.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB COUNTER module is used in Linear Feedback Shift Register (LFSR) mode. This module is only available for CLB types 2 and up.

9.9.1.24 CLB Lock Output Mask

FILE: clb_ex24_lock_output_mask.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the lock outpt mask feature of the CLB is used to lock the selected output signal override settings. This module is only available for CLB types 3 and up.

9.9.1.25 CLB INPUT Pipeline Mode

FILE: clb_ex25_input_pipeline.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB Input Pipeline mode is enable to delay the input signal by a clock cycle. This module is only available for CLB types 3 and up.

9.9.1.26 CLB Clocking and PIPELINE Mode

FILE: clb_ex26_clocking_pipeline.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB pipeline mode is enable and affects the behavior of the CLB COUNTERs and HLC. This module is only available for CLB types 3 and up.

9.9.1.27 CLB SPI Data Export

FILE: clb_ex27_spi_data_export.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the high speed data export feature of the CLB is used and one of the HLC registers is exported out of the CLB module using the SPI RX buffer. This module is only available for CLB types 3 and up.

9.9.1.28 CLB SPI Data Export DMA

FILE: clb_ex28_spi_data_export_dma.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the high speed data export feature of the CLB is used and one of the HLC registers is exported out of the CLB module using the SPI RX buffer. The data received in the SPI RX buffer is transferred to memory using DMA. This module is only available for CLB types 3 and up.

9.9.1.29 CLB Trip Zone Timestamp

FILE: clb_ex29_timestamp.c

This example displays how to timestamp interrupts generated by the CLB. An interrupt is generated when ePWM1 is tripped.

ePWM1 is configured to be interrupted by TZ1 and TZ2, both one shot trip sources.

The CLB is configured as follows:
- COUNTER0 and COUNTER1 continually count when the program begins.
- COUNTER0 timestamps TZ1 and COUNTER1 timestamps TZ2.
- COUNTER2 increments once when COUNTER0/COUNTER1 overflows using LUT2.
- FSM0/1 are configured to sync counters and stop COUNTER0/1 when an interrupt is received.
- TZ1 (GPIO12) and TZ2 (GPIO13) are routed as inputs through CLBXBAR.
- BOUNDARY.boundaryInput0 denotes TZ1. On rising edge, HLC issues an interrupt with tag 12.
- BOUDNARY.in1 denotes TZ2. On rising edge, HLC issues an interrupt with tag 13.
- BOUNDARY.boundaryInput7 serves as a simultaneous enable for COUNTER0/1 to begin counting.

TZ1 is tripped when GPIO12 is connected to GND. TZ2 is tripped when GPIO13 is connected to GND. When an interrupt occurs, the interrupt handler determines the initial trip source and stores this value in a variable 'initialTripZone'.

View these variables in Debug Expressions tab:

initialTripZone: stores the first TZ to have been tripped tz1Counter64bit: stores the counter value at the instant that TZ1 is tripped. tz2Counter64bit: stores the counter value at the instant that TZ2 is tripped.

9.9.1.30 CLB CRC

FILE: clb_ex30_cyclic_redundancy_check.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the CLB module is used to perform the cyclic redundancy check (C.R.C.) with twelve messages in bits checked with ten different CRC polynomials.

First element passed in is message length, second is the message stored in input_data

This example is only available for CLB types 2 and up.

The known values in the output_data are compared with expected values from the CLB-based CRC calculation. A total of 120 messages are verified, and the number of matching messages are displayed in passCount

Variables to add to Watch Expressions in debug view: passCount - number of messages that match between generated and known CRC values failCount - number of messages that fail the CRC value verification

9.10 CLB Registers

This section describes the Configurable Logic Block Registers.

9.10.1 CLB Base Address Table (C28)

Table 9-20. CLB Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected

9.10.2 CLB_LOGIC_CONFIG_REGS Registers

Table 9-21 lists the memory-mapped registers for the CLB_LOGIC_CONFIG_REGS registers. All register offset addresses not listed in Table 9-21 should be considered as reserved locations and the register contents should not be modified.

Table 9-21. CLB_LOGIC_CONFIG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
2h	CLB_COUNT_RESET	Counter Block RESET	EALLOW, LOCK	Go

Offset	Acronym	Register Name	Write Protection	Section
51h	CLB_SPI_DATA_CTRL_HI	CLB to SPI buffer control High	EALLOW, LOCK	Go

Complex bit access types are encoded to fit into small table cells. Table 9-22 shows the codes that are used for access types in this section.

Table 9-22. CLB_LOGIC_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

9.10.2.1 CLB_COUNT_RESET Register (Offset = 2h) [Reset = 0h]

CLB_COUNT_RESET is shown in Figure 9-22 and described in Table 9-23.

Return to the Summary Table.

Counter Block RESET

Table 9-62. CLB_SPI_DATA_CTRL_HI Register Field Descriptions

Bit	Field	Type	Reset	Description
15-13	RESERVED	R/W1C	0h	Reserved
12-8	SHIFT	R/W1C	0h	This is a 5 bit value which denotes the first bit position of register R0 from which the Least Significant Bit of the output data should start. 00000 Output data is R0[15:0] 00001 Output data is R0[16:1] 00010 Output data is R0[17:2] 00011 Output data is R0[18:3] ... ... 10000 Output data is R0[31:16] Reset type: SYSRSn
7-5	RESERVED	R/W1C	0h	Reserved
4-0	STRB	R/W1C	0h	This is a 5 bit value which selects one of the HLC_EVENT inputs to be treated as the data_valid strobe Reset type: SYSRSn

9.10.3 CLB_LOGIC_CONTROL_REGS Registers

Table 9-63 lists the memory-mapped registers for the CLB_LOGIC_CONTROL_REGS registers. All register offset addresses not listed in Table 9-63 should be considered as reserved locations and the register contents should not be modified.

Table 9-63. CLB_LOGIC_CONTROL_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CLB_LOAD_EN	Global enable & indirect load enable control	LOCK (only Global Enable Bit is LOCK protected)	Go
2h	CLB_LOAD_ADDR	Indirect address		Go
4h	CLB_LOAD_DATA	Data for indirect loads		Go
6h	CLB_INPUT_FILTER	Input filter selection for both edge detection and synchronizers	LOCK	Go
8h	CLB_IN_MUX_SEL_0	Input selection to decide between Signals and GP register	LOCK	Go
Ah	CLB_LCL_MUX_SEL_1	Input Mux selection for local mux	LOCK	Go
Ch	CLB_LCL_MUX_SEL_2	Input Mux selection for local mux	LOCK	Go
Eh	CLB_BUF_PTR	PUSH and PULL pointers		Go
10h	CLB_GP_REG	General purpose register for CELL inputs		Go
12h	CLB_OUT_EN	CELL output enable register		Go
14h	CLB_GLBL_MUX_SEL_1	Global Mux select for CELL inputs	LOCK	Go
16h	CLB_GLBL_MUX_SEL_2	Global Mux select for CELL inputs	LOCK	Go
18h	CLB_PRESCALE_CTRL	Prescaler register control	LOCK	Go
20h	CLB_INTR_TAG_REG	Interrupt Tag register		Go
22h	CLB_LOCK	Lock control register	EALLOW	Go
24h	CLB_HLC_INSTR_READ_PTR	HLC instruction read pointer		Go
26h	CLB_HLC_INSTR_VALUE	HLC instruction read value		Go
2Eh	CLB_DBG_OUT_2	Visibility for CLB inputs and final asynchronous outputs		Go
30h	CLB_DBG_R0	R0 of High level Controller		Go
32h	CLB_DBG_R1	R1 of High level Controller		Go
34h	CLB_DBG_R2	R2 of High level Controller		Go
36h	CLB_DBG_R3	R3 of High level Controller		Go
38h	CLB_DBG_C0	Count of Unit 0		Go
3Ah	CLB_DBG_C1	Count of Unit 1		Go
3Ch	CLB_DBG_C2	Count of Unit 2		Go
3Eh	CLB_DBG_OUT	Outputs of various units in the Cell		Go

Complex bit access types are encoded to fit into small table cells. Table 9-64 shows the codes that are used for access types in this section.

Table 9-64. CLB_LOGIC_CONTROL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s

Table 9-64. CLB_LOGIC_CONTROL_REGS Access Type Codes (continued)

Access Type	Code	Description
R-1	R -1	Read Returns 1s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

9.10.3.1 CLB_LOAD_EN Register (Offset = 0h) [Reset = 0h]

CLB_LOAD_EN is shown in Figure 9-62 and described in Table 9-65.

Return to the Summary Table.

Global enable & indirect load enable control

R-0-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 9-65. CLB_LOAD_EN Register Field Descriptions

Bit	Field	Type	Reset	Description
15-5	RESERVED	R-0	0h	Reserved
4	PIPELINE_EN	R/W	0h	This bit controls pipelining of all the CLB operations in HLC and Counter blocks. Pipelined operation is enabled when this bit is set to 1. Reset type: SYSRSn
3	NMI_EN	R/W	0h	This bit controls the generation of NMI along with the interrupt whenever a INTR operation is executed by the HLC. NMI generation is disabled by default. It will be enabled when this bit is set to 1. Reset type: SYSRSn
2	STOP	R/W	0h	This bit defines the behaviour of the sequential elements in the CELL during debug HALTs of the CPU. If this bit is set to 0, the debug HALT condition is ignored. Reset type: SYSRSn
1	GLOBAL_EN	R/W	0h	This bit is a global enable signal for the logic in the CELL. This also acts as a soft reset for the CELL logic. CLB outputs (including LUTs and OUTLUTs) will be gated when this bit is cleared from 1 to 0, i.e., the CLB outputs will be low when GLOBAL_EN is low. Additionally, the FSM and AOC blocks will also be reset. Note that when this bit goes low, the COUNTER blocks and HLC are simply halted, but they will NOT be reset internally. This allows the ability to preload these submodules when GLOBAL_EN is 0. This bit is normally set after all the other configuration settings are completed. This bit is LOCK protected. Reset type: SYSRSn
0	LOAD_EN	R/W	0h	A write with this bit set to 1 will pulse the Load Enable signal for the indirect register loads in the CELL. Reset type: SYSRSn

9.10.3.2 CLB_LOAD_ADDR Register (Offset = 2h) [Reset = 0h]

CLB_LOAD_ADDR is shown in Figure 9-63 and described in Table 9-66.

Return to the Summary Table.

Table 9-77. CLB_PRESCALE_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	PRESCALE	R/W	0h	16-bit Value of prescaler to be used for the counter as reference to reset when reaching this value. The counter is a simple incrementing counter which will count up to the reference value and reset to 0 and this cycle will continue as long as the counter is enabled. This 16-bit register value is used as a reference for the 16-bit counter to reset to zero whenever count reaches this value. Reset type: SYSRSn
15-6	RESERVED	R-0	0h	Reserved
5-2	TAP	R/W	0h	TAP Select value. These 4 bits will be used as a select to tap one of the 16 register bit position of the counter as the output. 0000 selects Counter Bit position 0 0001 selects Counter Bit position 1 .... 1111 selects Counter Bit position 15 Reset type: SYSRSn
1	STRB	R/W	0h	When set to 0, a strobe output will be sent out whenever the counter value matches the PRESCALE_VALUE. When set to 1, the output of the counter register bit position as selected by TAP_SELECT_VALUE will be sent out. Reset type: SYSRSn
0	CLKEN	R/W	0h	Enable the prescale clock/strobe generator. A 16-bit counter is used to either generate a strobe or send out a selected counter bit position to the CLB CELL. This is meant to be a general purpose strobe/prescaled clock which can be used by the CELL logic if needed. This will be sent to the CELL through one of the LCL_IN MUX ports. Reset type: SYSRSn

9.10.3.14 CLB_INTR_TAG_REG Register (Offset = 20h) [Reset = 0h]

CLB_INTR_TAG_REG is shown in Figure 9-75 and described in Table 9-78.

9.10.4 CLB_DATA_EXCHANGE_REGS Registers

Table 9-91 lists the memory-mapped registers for the CLB_DATA_EXCHANGE_REGS registers. All register offset addresses not listed in Table 9-91 should be considered as reserved locations and the register contents should not be modified.

Table 9-91. CLB_DATA_EXCHANGE_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CLB_PUSH	CLB_PUSH FIFO Registers (from HLC)		Go
40h	CLB_PULL	CLB_PULL FIFO Registers (TO HLC)		Go

Complex bit access types are encoded to fit into small table cells. Table 9-92 shows the codes that are used for access types in this section.

Table 9-92. CLB_DATA_EXCHANGE_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Chapter 10

Dual-Clock Comparator (DCC)

This chapter describes the Dual-Clock Comparator (DCC) module.

10.1 Introduction

The dual-clock comparator module is used for evaluating and monitoring the clock input based on a second clock, which can be a more accurate and reliable version. This instrumentation is used to detect faults in clock source or clock structures, thereby enhancing the system's safety metrics.

10.1.1 Features

The main features of each of the DCC modules are:

- Allows the application to make sure that a fixed ratio is maintained between frequencies of two clock signals.
- Supports the definition of a programmable tolerance window in terms of the number of reference clock cycles.
- Supports continuous monitoring without requiring application intervention.
- Supports a single-sequence mode for spot measurements.
- Allows the selection of a clock source for each of the counters, resulting in several specific use cases.

10.1.2 Block Diagram

Figure 10-1 shows how the DCC connects to the rest of the system. Figure 10-2 shows the main concept of the DCC module.

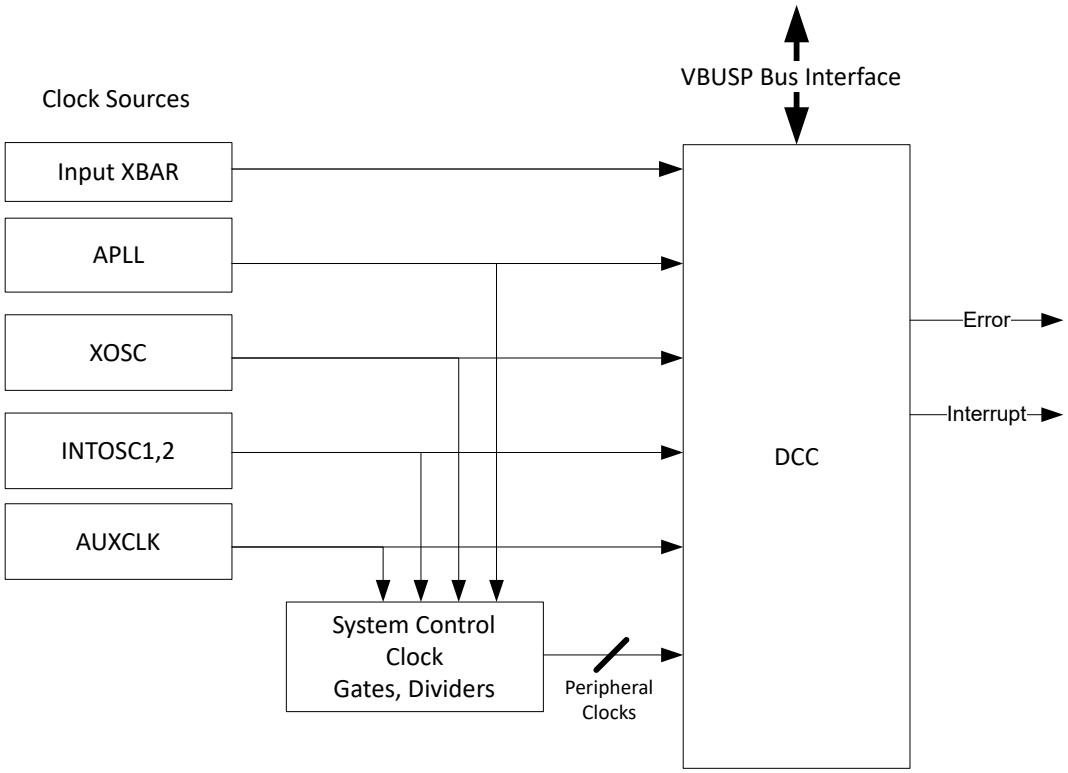

Figure 10-1. DCC Module Overview

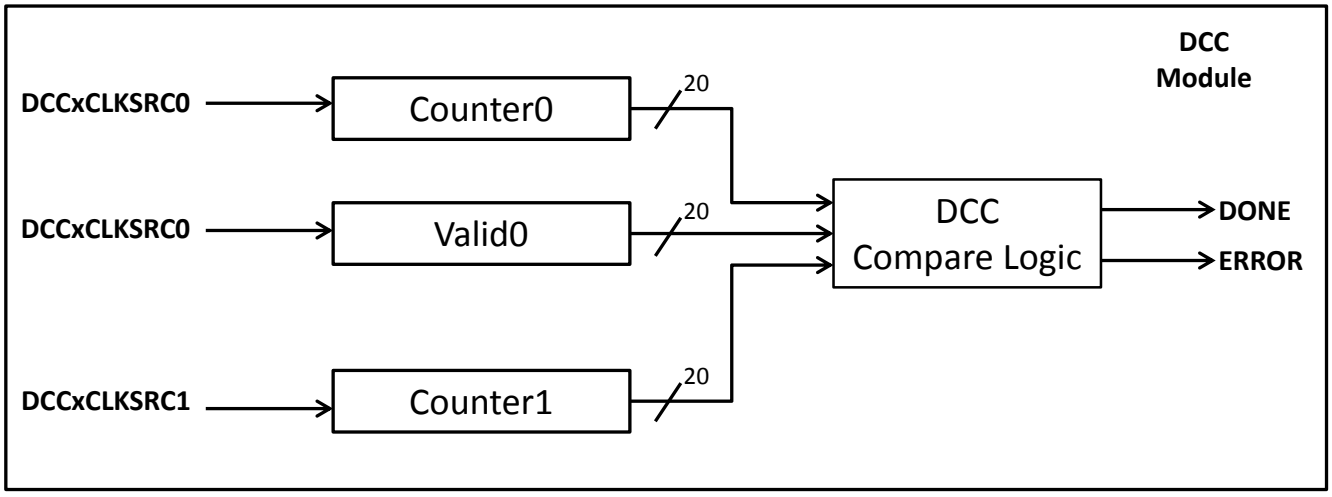

Figure 10-2. DCC Operation

10.2 Module Operation

As shown in Figure 10-2, DCC contains three counters – Counter0, Valid0 and Counter1. Initially, all counters are loaded with their user-defined, pre-load value. Counter0 and Counter1 start decrementing once the DCC is enabled at rates determined by the frequencies of Clock0 and Clock1, respectively. When Counter0 equals 0 (expires), the Valid0 counter decrements at a rate determined by Clock0. If Counter1 decrements to 0 in the valid window, then no error is generated and Clock1 is considered to be good within allowable tolerance as configured by the user.

10.2.1 Configuring DCC Counters

Counter0 and Counter1 are configured based on the ratio between the frequencies of Clock0 and Clock1 (Fclk1×Counter0 = Fclk0×Counter1). The Valid0 counter provides tolerance and is configured based on the error in DCC. Since Clock0 and Clock1 are asynchronous, the start and stop of the counters do not occur synchronously. Hence, while configuring the counters, two different sources of errors must be accounted for:

- DCC Errors due to the asynchronous timing of Clock0 and Clock1: this depends on the frequency of Clock0 and Clock1:
  - If Fclk1 > Fclk0, then Async. Error (in Clock0 cycles) = 2 + 2×(max(Fsysclk/Fclk0))
  - If Fclk1 < Fclk0, then Async. Error (in Clock0 cycles) = 2×(Fclk0/Fclk1) + 2×(max(Fsysclk/Fclk0))
  - If Fclk1 is unknown, then Async. Error (in Clock0 cycles) = 2 + 2×(Fsysclk/Fclk0)
- Digitization Error = 8 Clock0 cycles

DCC Error (in Clock0 Cycles) = Async. Error + Digitization Error

DCC error shows up as a frequency error for clock under measurement. This error is DCC induced and does not represent error in frequency of clock under measurement. The application needs to take this into consideration while configuring the counters, and determine a desirable tolerance for DCC error that defines the window of measurement. To illustrate:

Window (in Clock0 Cycles) = (DCC Error) / (0.01×Tolerance)

For example, if DCC Error is 10 and the tolerance desired is +/-0.1%, then:

Window (in Clock0 Cycles) = 10/(0.01×0.1) = 10000

Based on above formula for Window, if the desired tolerance is low, then the counter values are large and increase the window of measurement. This means that counter values for a tolerance of 0.1% are larger than that of 0.2%. So, based on the application defined tolerance, define the window of measurement in terms of Clock0 cycles.

The clock under measurement can have an allowed frequency error. If this error is expected, then the error can also be accounted while configuring counters. For example, if measuring INTOSC1/2 frequency using an external crystal as a reference clock, the allowable tolerance of INTOSC1/2 (for example, +/-1%) can be accounted for and factored into the counter configuration. The formula is:

Frequency Error Allowed (in Clock0 Cycles) = Window × (Allowable Frequency Tolerance (in %) / 100)

Total Error (in Clock0 Cycles) = DCC Error + Frequency Error Allowed

The following equations are used to configure counter values:

Counter0 (DCCCNTSEED0) = Window - Total Error

Valid0 (DCCVALIDSEED0) = 2 × Total Error

Counter1 (DCCCNTSEED1) = Window × (Fclk1/Fclk0)

Note

Counter1 is a 20-bit counter, so the maximum possible value cannot exceed 1048575. If the value does exceed, then increase the desired Tolerance for DCC error, so that Window of measurement is lowered. The following formula can be used to compute minimum tolerance possible:

Tolerance (%) = (100 × DCC Error × (Fclk1/Fclk0)) / 1048575

10.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot-checking the frequency of a signal.

Example-1: Validating PLLRAWCLK frequency

A practical example of the usage is to validate the PLL output clock frequency using the XTAL as the reference clock. Assume XTAL is 10 MHz, PLL output frequency is 100 MHz, SYSCLK is 100 MHz, allowable Frequency Tolerance is 0.1%, and DCC Tolerance required is 0.1%. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as XTAL, and Clock1 source for Counter1 as PLL output clock.
- Based on the equations defined in Section 10.2.1, calculated seed values for Counters can be Counter0 = 29940; Valid0 = 120; Counter1 = 300000
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from their seed values.
- When Counter0 reaches zero, Counter0 automatically triggers the Valid0 counter.
- When Valid0 reaches zero and Counter1 is not zero, an ERROR status flag is set and a "DCC error" is sent to the PIE. Counter1 is frozen so that the counter stops counting down any further. The application can enable an interrupt to be generated from the PIE whenever this DCC error is indicated. Refer to Table 3-2 to know the channel mapping of DCC Interrupt.
- The application then needs to clear the ERROR status flag and restart the DCC module so that the module is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected, or Clock0 is slower than expected. This error includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This error includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

Another example of single-shot mode is to measure the frequency of AUXCLKIN (unknown frequency) using INTOSC1 (10 MHz) as the reference clock and SYSCLK is 10 MHz. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as INTOSC1 (10 MHz), and Clock1 source for Counter1 as AUXCLKIN.
- Now configure counter values using equations in Section 10.2.1. For tolerance = ±0.1%, Total Error = 10 clock0 cycles; Window = 10000 clock0 cycles; Counter0 = 9990; Valid0 = 20. Since Clock1 frequency (Fclk1) is unknown, the Counter1 value can be set to the maximum value, 1048575 (0xFFFFF).
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from their seed values.
- Since Counter1 is set to the maximum value, 1048575, the counter does not expire when Counter0 and Valid0 have expired. This generates an error that is expected and the application ignores this error and uses Counter1 values to compute the frequency of Clock1 (Fclk1).
- Knowing the frequency of Clock0 (INTOSC1), Fclk0 = 10 MHz, and using Equation 1, the frequency of AUXCLKIN, Fclk1, can be measured:

$$Fclk1 = \frac{Fclk0 \times (1048575 - Meas.Counter1)}{(Counter0 + Valid0)} = \frac{10 \times (1048575 - Meas.Counter1)}{(9990 + 20)} \quad (1)$$

10.2.3 Continuous Monitoring Mode

In this mode, the DCC is used by the application to make sure that two clock signals maintain the correct frequency ratio. Suppose the application wants to make sure that the PLL output signal always maintains a fixed frequency relationship with the XTAL:

- In this case, the application can use the XTAL as the Clock0 signal (for Counter0 and Valid0) and the PLL output as the Clock1 (for Counter1).
- The seed values of Counter0, Valid0 and Counter1 are selected based on the equations defined in Section 10.2.1 such that if the actual frequencies of Clock0 and Clock1 are equal to their expected frequencies, then the Counter1 reaches zero during the count down of the Valid0 counter.
- If the Counter1 reaches zero during the count down of the Valid0 counter, then all the counters (Counter0, Valid0, Counter1) are reloaded with their initial seed values.
- This sequence of counting down and checking then continues as long as there is no error, or until the DCC module is disabled.
- The counters must get reloaded if the application resets and restarts the DCC module.

Error Conditions:

An error condition is generated by one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected or Clock0 is slower than expected. This condition includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This condition includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

10.2.4 Error Conditions

While operating in continuous mode, the counters get reloaded with the seed values and continue counting down under the following conditions:

- The module is reset or restarted by the application, OR
- Counter0, Valid 0, and Counter1 all reach 0 without any error.

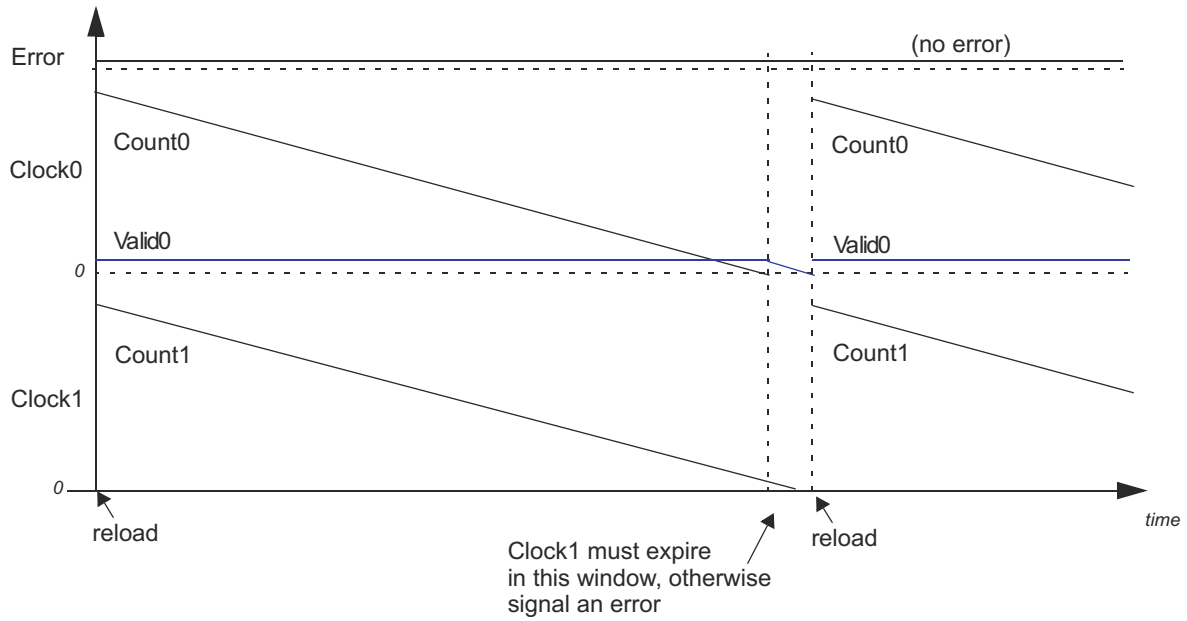

Figure 10-3. Counter Relationship

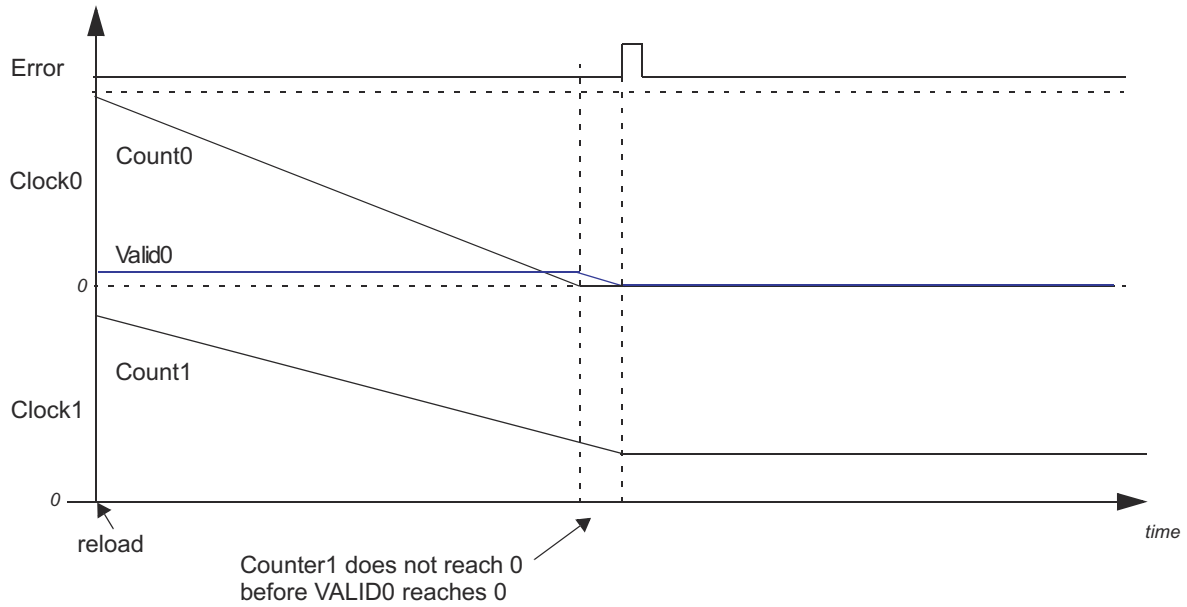

Figure 10-4. Clock1 Slower Than Clock0 - Results in an Error and Stops Counting

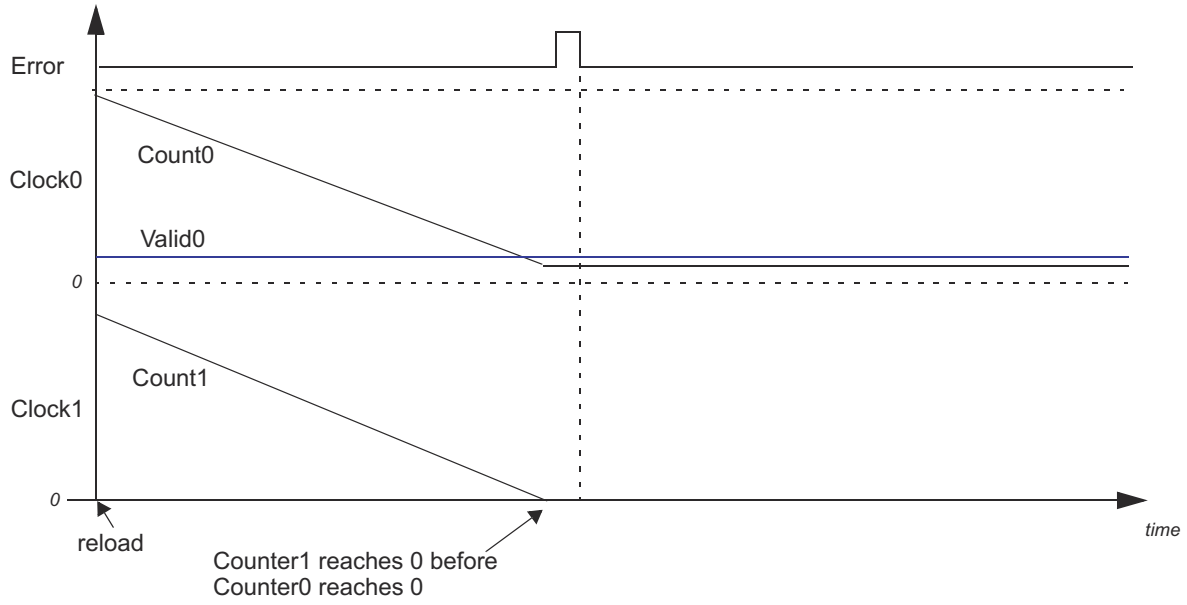

Figure 10-5. Clock1 Faster Than Clock0 - Results in an Error and Stops Counting

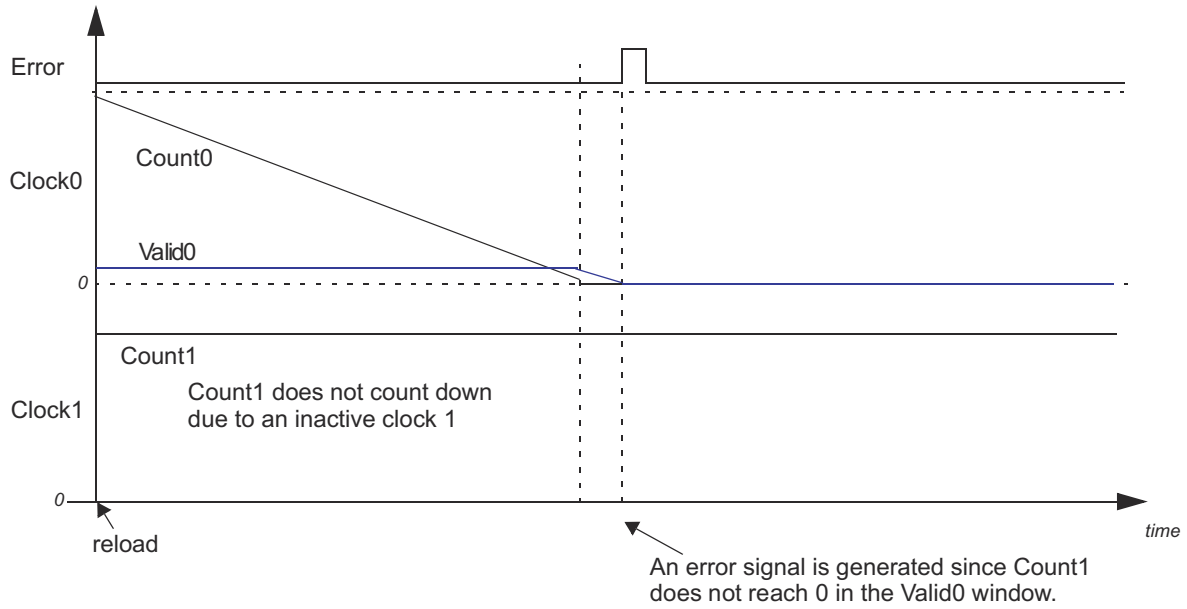

Figure 10-6. Clock1 Not Present - Results in an Error and Stops Counting

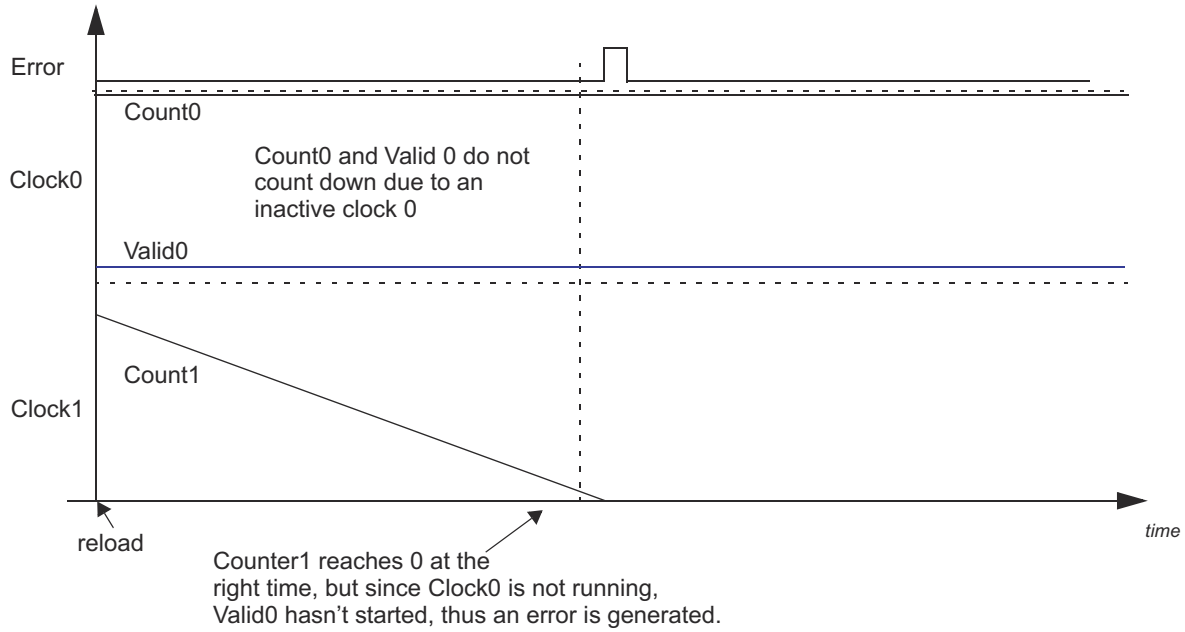

Figure 10-7. Clock0 Not Present - Results in an Error and Stops Counting

10.3 Interrupts

DCC generates an interrupt on either of two events:

- DCC finishes counting and all the counters expire within a defined window indicating DONE operation, provided DCCGCTRL.DONENA=1.
- DCC finishes counting with error where counters do not expire in a defined window. This indicates an ERROR event, and sets an interrupt provided DCCGCTRL.ERRENA=1.

Interrupts generated by DONE or ERROR events are ORed and flagged as SYS_ERR_INT, which goes to INT1.10 in Table 3-2. The application interrupt service routine needs to check the status flag inside the DCCSTATUS register to determine whether the interrupt is due to ERROR or DONE.

10.4 Software

10.4.1 DCC Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dcc

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

10.4.1.1 DCC Single shot Clock verification

FILE: dcc_ex1_single_shot_verification.c

This program uses the XTAL clock as a reference clock to verify the frequency of the PLLRAW clock.

The Dual-Clock Comparator Module 0 is used for the clock verification. The clocksource0 is the reference clock (Fclk0 = 25Mhz) and the clocksource1 is the clock that needs to be verified (Fclk1 = 200Mhz). Seed is the value that gets loaded into the Counter.

Please refer to the TRM for details on counter seed values to be set.

External Connections

- None

Watch Variables

- *status/result* - Status of the PLLRAW clock verification

10.4.1.2 DCC Single shot Clock measurement

FILE: dcc_ex2_single_shot_measurement.c

This program demonstrates Single Shot measurement of the INTOSC2 clock post trim using XTAL as the reference clock.

The Dual-Clock Comparator Module 0 is used for the clock measurement. The clocksource0 is the reference clock (Fclk0 = 25Mhz) and the clocksource1 is the clock that needs to be measured (Fclk1 = 10Mhz). Since the frequency of the clock1 needs to be measured an initial seed is set to the max value of the counter.

Please refer to the TRM for details on counter seed values to be set.

External Connections

- None

Watch Variables

- *result* - Status if the INTOSC2 clock measurement completed successfully.
- *meas_freq1* - measured clock frequency, in this case for INTOSC2.

10.4.1.3 DCC Continuous clock monitoring

FILE: dcc_ex3_continuous_monitoring_of_clock.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC2 as the reference clock. This would trigger an interrupt on any error, causing the decrement/ reload of counters to stop.

The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 200Mhz). The clock0 and clock1 seed are set to achieve a window of 500us. Seed is the value that gets loaded into the Counter. For the sake of demo a slight variance is given to clock1 seed value to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *status/result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated

10.4.1.4 DCC Continuous clock monitoring

FILE: dcc_ex3_continuous_monitoring_of_clock_syscfg.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC2 as the reference clock. This would trigger an interrupt on any error, causing the decrement/ reload of counters to stop. The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 200Mhz). The clock0 and clock1 seed are set automatically by the error tolerances defined in the sysconfig file included this project. For the sake of demo an un-realistic tolerance is assumed to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *status/result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated

10.4.1.5 DCC Detection of clock failure

FILE: dcc_ex4_clock_fail_detect.c

This program demonstrates clock failure detection on continuous monitoring of the PLL Clock in the system using XTAL as the osc clock source. Once the oscillator clock fails, it would trigger a DCC error interrupt, causing the decrement/ reload of counters to stop. In this examples, the clock failure is simulated by turning off the XTAL oscillator. Once the ISR is serviced, the osc source is changed to INTOSC1 and the PLL is turned off.

The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 25Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 200Mhz). Seed is the value that gets loaded into the Counter.

In the current example, the XTAL is expected to be a Resonator running in Crystal mode which is later switched off to simulate the clock failure. If an SE Crystal is used, you will need to physically disconnect the clock on the board. Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *status/result* - Status of the clock failure detection

10.5 DCC Registers

This section describes the Dual Clock Comparator Registers.

Note

The DCC is used by Boot ROM; hence, the register values could be different than the hardware reset value. You need to make sure to configure the values of these registers to the desired value before enabling the DCC.

10.5.1 DCC Base Address Table (C28)

Table 10-1. DCC Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
Dcc0Regs	DCC_REGS	DCC0_BASE	0x0005_E700	YES	-	-	-	YES
Dcc1Regs	DCC_REGS	DCC1_BASE	0x0005_E740	YES	-	-	-	YES
Dcc2Regs	DCC_REGS	DCC2_BASE	0x0005_E780	YES	-	-	-	YES

10.5.2 DCC_REGS Registers

Table 10-2 lists the memory-mapped registers for the DCC_REGS registers. All register offset addresses not listed in Table 10-2 should be considered as reserved locations and the register contents should not be modified.

Table 10-2. DCC_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	DCCGCTRL	Starts / stops the counters. Clears the error signal.		Go
8h	DCCCNTSEED0	Seed value for the counter attached to Clock Source 0.		Go
Ch	DCCVALIDSEED0	Seed value for the timeout counter attached to Clock Source 0.		Go
10h	DCCCNTSEED1	Seed value for the counter attached to Clock Source 1.		Go
14h	DCCSTATUS	Specifies the status of the DCC Module.		Go
18h	DCCCNT0	Value of the counter attached to Clock Source 0.		Go
1Ch	DCCVALID0	Value of the valid counter attached to Clock Source 0.		Go
20h	DCCCNT1	Value of the counter attached to Clock Source 1.		Go
24h	DCCCLKSRC1	Selects the clock source for Counter 1.		Go
28h	DCCCLKSRC0	Selects the clock source for Counter 0.		Go

Complex bit access types are encoded to fit into small table cells. Table 10-3 shows the codes that are used for access types in this section.

Table 10-3. DCC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.5.2.1 DCCGCTRL Register (Offset = 0h) [Reset = 5555h]

DCCGCTRL is shown in Figure 10-8 and described in Table 10-4.

Return to the Summary Table.

Starts / stops the counters. Clears the error signal.

Figure 10-8. DCCGCTRL Register

Chapter 11

Direct Memory Access (DMA)

The direct memory access (DMA) module provides a hardware method of transferring data between peripherals and memory without intervention from the CPU; thereby, freeing up bandwidth for other system functions. Additionally, the DMA has the capability to orthogonally rearrange the data as the data is transferred as well as “ping-pong” data between buffers. These features are useful for structuring data into blocks for CPU processing.

11.1 Introduction

The strength of a controller is not measured purely in processor speed, but in total system capabilities. As a part of the equation, any time the CPU bandwidth for a given function can be reduced, the greater the system capabilities. Many times applications spend a significant amount of their bandwidth moving data, whether moving data from off-chip memory to on-chip memory, from a peripheral such as an analog-to-digital converter (ADC) to RAM, or from one peripheral to another. Furthermore, many times this data comes in a format that is not conducive to the optimum processing powers of the CPU. The DMA module described in this chapter has the ability to free up CPU bandwidth and rearrange the data into a pattern for more streamlined processing.

The DMA module is an event-based machine, meaning the DMA module requires a peripheral or software trigger to start a DMA transfer. Although the DMA module can be made into a periodic time-driven machine by configuring a timer as the DMA trigger source, there is no mechanism within the module itself to start memory transfers periodically. The DMA module has six independent DMA channels that can be configured separately and each channel contains their own independent PIE interrupt to let the CPU know when a DMA transfer has either started or completed. Five of the six channels are exactly the same, while Channel 1 has the ability to be configured at a higher priority than the others. At the heart of the DMA is a state machine and tightly coupled address control logic. This address control logic allows for rearrangement of the block of data during the transfer as well as the process of ping-ponging data between buffers. Each of these features is discussed in detail in this chapter.

11.1.1 Features

DMA features include:

- Six channels with independent PIE interrupts
- Each DMA channel can be triggered from multiple peripheral trigger sources independently
- Word Size: 16-bit or 32-bit (SPI limited to 16-bit)
- Throughput: 3 cycles/word without arbitration

11.1.2 Block Diagram

Figure 11-1 shows a device-level block diagram of the DMA.

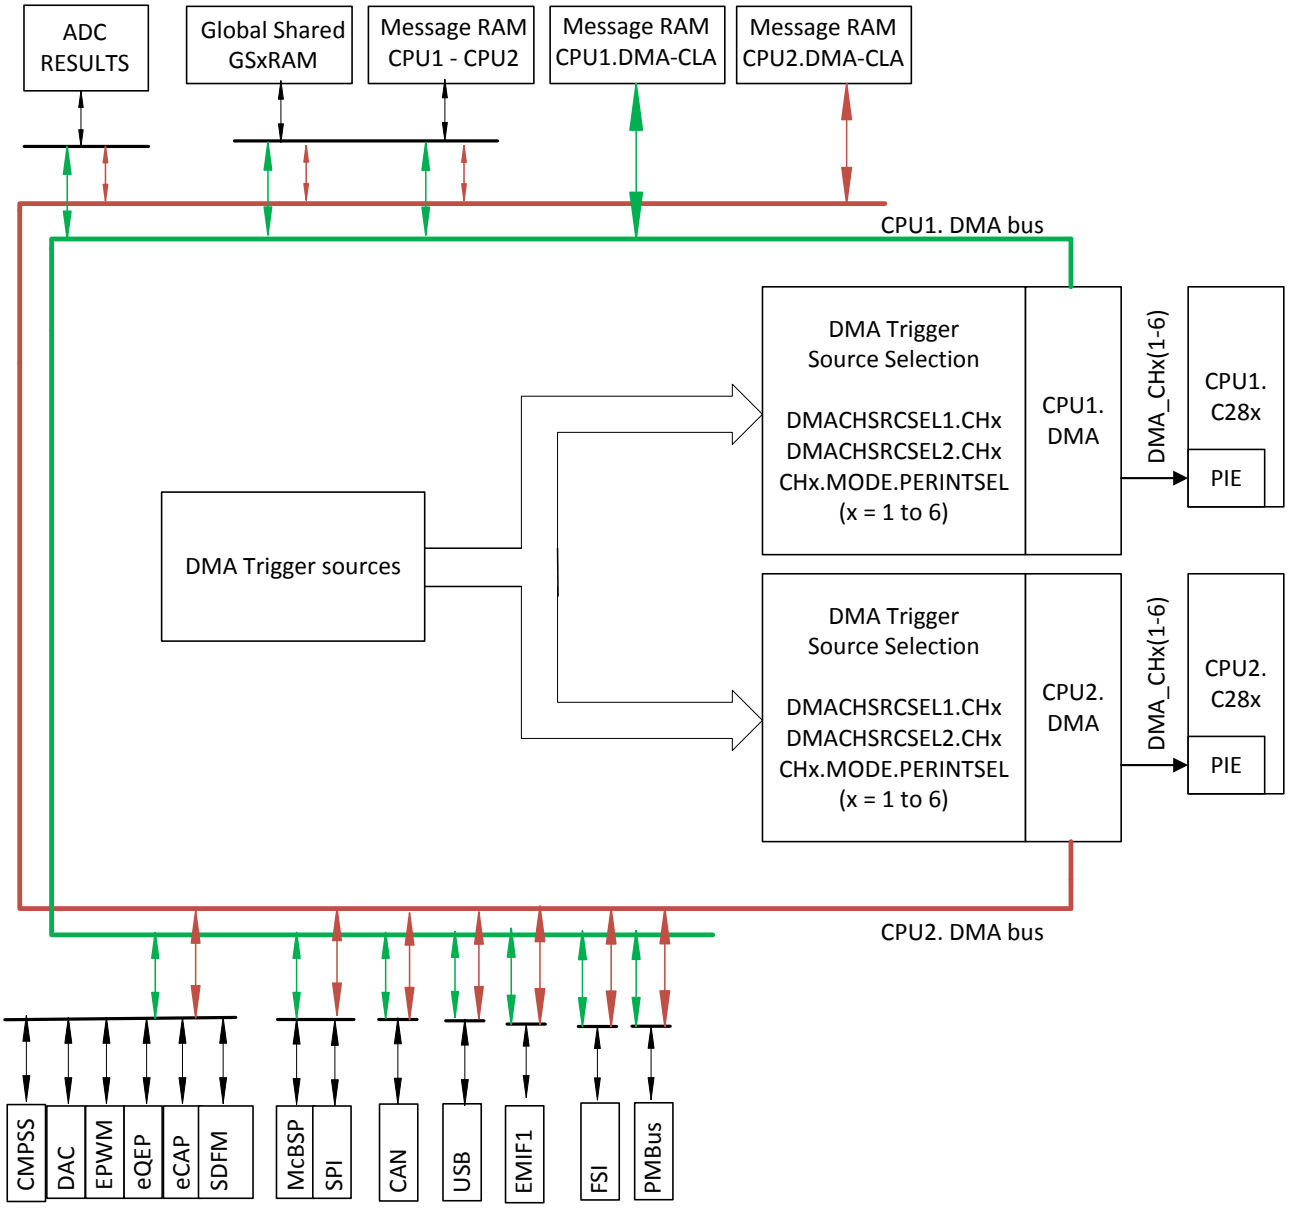

Figure 11-1. DMA Block Diagram

11.2 Architecture

11.2.1 Peripheral Interrupt Event Trigger Sources

Each DMA Channel can be configured to trigger by software and other peripheral triggers events. DMACHSRCSELx register can be used to configure DMA Trigger sources for each DMA channel. CHx.MODE.PERINTSEL register bit field can be set to channel number (CHx.MODE.PERINTSEL = x) as shown in Figure 11-2. Included in these DMA Trigger sources are five external interrupt signals that can be connected to most of the general-purpose input/output (GPIO) pins on the device. This adds significant flexibility to the event trigger capabilities. Upon receipt of a peripheral interrupt event signal, the DMA automatically sends a clear signal to the interrupt source so that subsequent interrupt events occur.

Note

To use the system-level DMA Trigger source selection, the DMA internal trigger source selection configuration for each channel can be done using the DMACHSRCSELx register and the CHx.MODE.PERINTSEL register. See Table 11-1 or the DMACHSRCSELx register definition for a complete list of DMA trigger sources.

Regardless of the value of the MODE.CHx[PERINTSEL] bit field, software can always force a trigger by using the CONTROL.CHx[PERINTFRC] bit. Likewise, software can always clear a pending DMA trigger using the CONTROL.CHx[PERINTCLR] bit.

Once a particular peripheral trigger event sets a channel's PERINTFLG bit, the bit remains pending until the priority logic of the state machine starts the burst transfer for that channel. Once the burst transfer starts, the flag is cleared. If a new peripheral trigger event is generated while a burst is in progress, the burst completes before responding to the new peripheral trigger event (after proper prioritization). If a third peripheral trigger event occurs before the pending event is serviced, an error flag is set in the CONTROL.CHx[OVRFLG] bit. If a peripheral trigger event occurs at the same time as the latched flag is being cleared, the trigger event has priority and the PERINTFLG remains set.

Figure 11-3 shows a diagram of the trigger select circuit.

Table 11-1 shows the peripheral trigger source options that are available for each channel.

CAUTION

See the Device Errata "ADC:DMA Read of Stale Result" Advisory regarding the potential for the DMA to read the ADC result registers before the result is ready

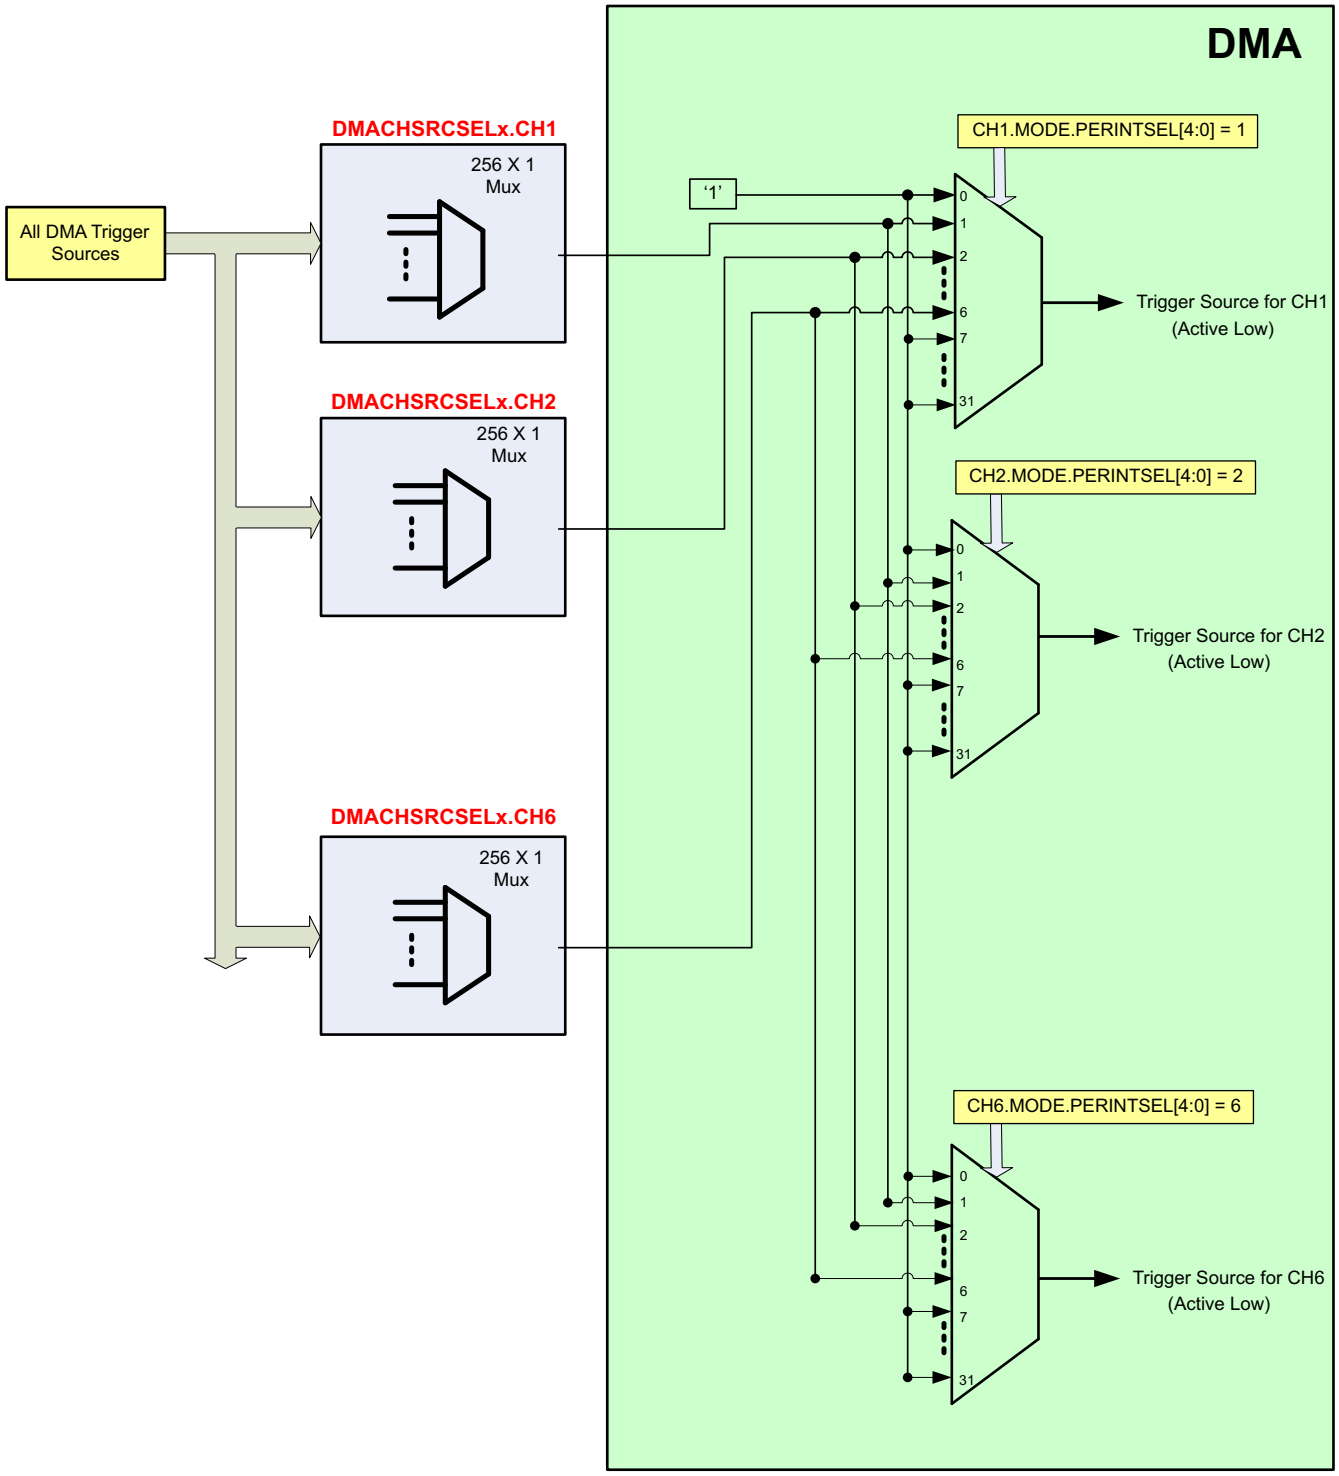

Figure 11-2. DMA Trigger Architecture

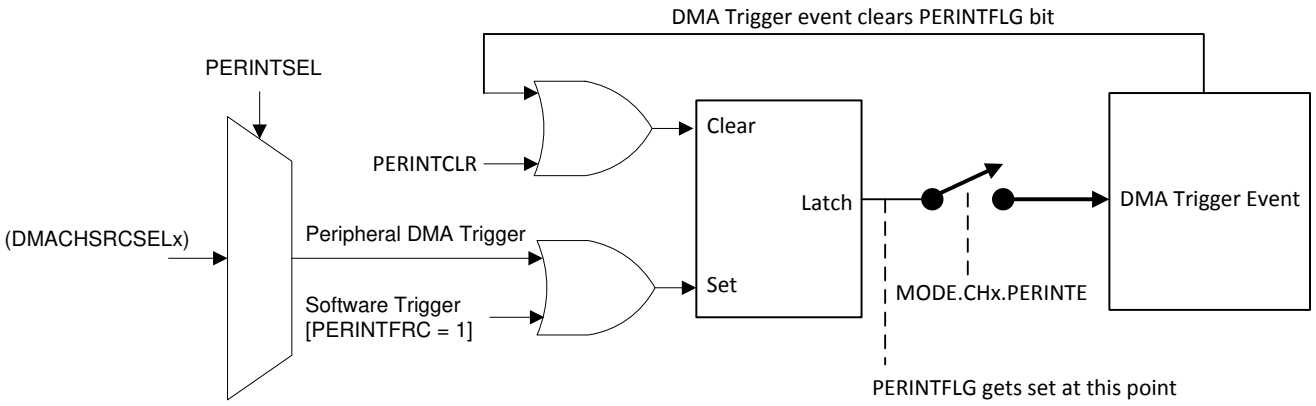

Note: See Figure 11-2.

11.2.2 DMA Bus

The DMA bus architecture consists of a 32-bit address bus, a 32-bit data read bus, and a 32-bit data write bus. Memories and register locations connected to the DMA bus by way of interfaces that sometimes share resources with the CPU memory or peripheral bus. Arbitration rules are defined in Section 11.5.

11.3 Address Pointer and Transfer Control

The DMA state machine is, at the most basic level, two nested loops.

Burst (Inner) Loop:

The burst (inner) loop transfers a programmable number of words set by (BURST_SIZE + 1) register when a DMA channel trigger (Peripheral or Software trigger) is received. The BURST_SIZE register allows a maximum of 32 sixteen-bit words to be transferred in one burst. Each DMA channel supports both 16-bit or 32-bit word burst that can be controlled by MODE.DATASIZE bit field. Each DMA channel contains a shadowed address pointer for the source (SRC_ADDR_SHADOW) and the destination (DST_ADDR_SHADOW) address. At the beginning of each transfer, the shadowed version of each pointer is copied into the respective active (SRC_ADDR_ACTIVE or DST_ADDR_ACTIVE) register. During the burst loop, after each word is transferred, the signed value contained in the appropriate source or destination BURST_STEP register is added to the active register:

SRC_ADDR_ACTIVE = SRC_ADDR_ACTIVE + SRC_BURST_STEP

DST_ADDR_ACTIVE = DST_ADDR_ACTIVE + DST_BURST_STEP

The burst (inner) loop transfers a burst of data when a DMA Channel Trigger (Peripheral or Software trigger) is received.

Transfer (Outer) Loop:

The Transfer (outer) loop transfers a programmable number of bursts set by (TRANSFER_SIZE + 1) register for each channel. Since TRANSFER_SIZE is a 16-bit register, the total size of a transfer allowed is well beyond any practical requirement. During the transfer loop, after each burst is complete, there are two methods that can be used to modify the active address pointer:

Method 1 (Default): When address wrapping is disabled (SRC_WRAP_SIZE or DST_WRAP_SIZE is greater than TRANSFER_SIZE), active address pointer is updated as shown below

SRC_ADDR_ACTIVE = SRC_ADDR_ACTIVE + SRC_TRANSFER_STEP

DST_ADDR_ACTIVE = DST_ADDR_ACTIVE + DST_TRANSFER_STEP

Method 2: Address wrapping gets enabled when SRC_WRAP_SIZE or DST_WRAP_SIZE is less than TRANSFER_SIZE. This allows the channel to wrap multiple times within a single transfer. When the number of

bursts is equal to (SRC/DST_WRAP_SIZE + 1) register, the state machine modifies the active address pointers as:

SRC_BEG_ADDR_ACTIVE = SRC_BEG_ADDR_ACTIVE + SRC_WRAP_STEP

DST_BEG_ADDR_ACTIVE = DST_BEG_ADDR_ACTIVE + DST_WRAP_STEP

SRC_ADDR_ACTIVE = SRC_BEG_ADDR_ACTIVE

DST_ADDR_ACTIVE = DST_BEG_ADDR_ACTIVE

At the end of DMA transfer, DMA can have transferred (BURST_SIZE + 1) x (TRANSFER_SIZE + 1) words.

OneShot Mode:

OneShot mode is disabled by default.

When OneShot mode is disabled (MODE.CHx[ONESHOT] = 0), DMA transfers one burst [(BURST_SIZE + 1) words] of data each time a DMA Channel Trigger is received. After the burst is completed, the state machine moves on to the next pending channel in the priority scheme, even if another trigger for the channel just completed is pending. This feature keeps any single channel from monopolizing the DMA bus.

When OneShot mode is enabled (MODE.CHx[ONESHOT] = 1), DMA transfers all the bursts [(BURST_SIZE + 1) x (TRANSFER_SIZE + 1) words] on a single DMA channel trigger. Be careful when using this mode, since this can create a condition where one trigger uses up the majority of the DMA bandwidth.

Continuous Mode:

Continuous mode is disabled by default.

When Continuous mode is disabled (MODE.CHx[CONTINUOUS] = 0), DMA state machine disables channel after all bursts in a transfer loop (TRANSFER_COUNT = 0) are complete. The channel must be re-enabled by setting the RUN bit in the CONTROL register before another transfer can be started on that channel.

When Continuous mode is enabled (MODE.CHx[CONTINUOUS] = 1), DMA state machine keep channel active even after all bursts in a transfer loop (TRANSFER_COUNT = 0) are complete.

Each DMA channel can trigger their own EPIE interrupt for each DMA transfer either at start of DMA transfer or end of DMA transfer using MODE.CHx[CHINTMODE] bit.

Source/Destination Address Pointers (SRC/DST_ADDR)	The value written into the shadow register is the start address of the first location where data is read or written to. At the beginning of a transfer the shadow register (SRC/DST_ADDR_SHADOW) is copied into the active register (SRC/DST_ADDR_ACTIVE). The active register performs as the current address pointer.
Source/Destination Begin Address Pointers (SRC/DST_BEG_ADDR)	This is the wrap pointer. The value written into the shadow register (SRC/DST_BEG_ADDR_SHADOW) is loaded into the active register (SRC/DST_BEG_ADDR_ACTIVE) at the start of a transfer. On a wrap condition, the active register (SRC/DST_BEG_ADDR_ACTIVE) is incremented by the signed value in the appropriate SRC/DST_WRAP_STEP register prior to being loaded into the active register (SRC/DST_ADDR_ACTIVE).

For each channel, the transfer process can be controlled with the following size values:

Source and Destination Burst Size (BURST_SIZE)

This specifies the number of words to be transferred in a burst.

This value is loaded into the BURST_COUNT register at the beginning of each burst. The BURST_COUNT decrements each word that is transferred and when the register reaches a zero value, the burst is complete, indicating that the next channel can be serviced. The behavior of the current channel is defined by the ONE_SHOT bit in the MODE register. The maximum size of the burst is dictated by the type of peripheral. For the ADC, the burst size can be all 16 registers (if all 16 registers are used). For RAM, the burst size can be up to the maximum allowed by the BURST_SIZE register, which is 32. See Table 11-2 to understand how BURST_SIZE register affects the number of 16-bit words transferred with respect to DATASIZE.

Table 11-2. BURSTSIZE versus DATASIZE Behavior

BURSTSIZE	Number of 16-bit words transferred in

*	*	*
*	*	*
*	*	*
30	31	32
31	32	32

Source and Destination Transfer Size (TRANSFER_SIZE)

This specifies the number of bursts to be transferred per CPU interrupt (if enabled).

Whether this interrupt is generated at the beginning or the end of the transfer is defined in the CHINTMODE bit in the MODE register. Whether the channel remains enabled or not after the transfer is completed is defined by the CONTINUOUS bit in the MODE register. The TRANSFER_SIZE register is loaded into the TRANSFER_COUNT register at the beginning of each transfer. The TRANSFER_COUNT register keeps track of how many bursts of data the channel has transferred and when the register reaches zero, the DMA transfer is complete.

Source/Destination Wrap Size (SRC/ DST_WRAP_SIZE)

This specifies the number of bursts to be transferred before the current address pointer wraps around to the beginning.

This feature is used to implement a circular addressing type function. This value is loaded into the appropriate SRC/DST_WRAP_COUNT register at the beginning of each transfer. The SRC/DST_WRAP_COUNT registers keep track of how many bursts of data the channel has transferred and when the registers reach zero, the wrap procedure is performed on the appropriate source or destination address pointer. A separate size and count register is allocated for source and destination pointers. To disable the wrap function, assign the value of these registers to be larger than the TRANSFER_SIZE.

Note

The value written to the SIZE registers is one less than the intended size. So, to transfer three 16-bit words, the value 2 can be placed in the SIZE register.

Regardless of the state of the DATASIZE bit, the value specified in the SIZE registers are for 16-bit addresses. So, to transfer three 32-bit words, the value 5 can be placed in the SIZE register.

For each source/destination pointer, the address changes can be controlled with the following step values:

Source/Destination Burst Step (SRC/ DST_BURST_STEP)

Within each burst transfer, the address source and destination step sizes are specified by these registers.

This value is a signed 2s compliment number so that the address pointer can be incremented or decremented as required. If no increment is desired, such as when accessing the data receive or transmit registers in a communication peripheral, the value of these registers can be set to zero.

Source/Destination Transfer Step (SRC/ DST_TRANSFER_STEP)

This specifies the address offset to start the next burst transfer after completing the current burst transfer.

This is used in cases where registers or data memory locations are spaced at constant intervals. This value is a signed 2s compliment number so that the address pointer can be incremented or decremented as required.

Source/Destination Wrap Step (SRC/ DST_WRAP_STEP)

When the wrap counter reaches zero, this value specifies the number of words to add/subtract from the SRC/DST_BEG_ADDR pointer and hence sets the new start address.

This implements a circular type of addressing mode, useful in many applications. This value is a signed 2s compliment number so that the address pointer can be incremented or decremented as required.

Note

Regardless of the state of the DATASIZE bit, the value specified in the STEP registers are for 16-bit addresses. So, to increment one 32-bit address, a value of 2 can be placed in these registers.

Channel Interrupt Mode (CHINTMODE)

This mode bit selects whether the DMA interrupt from the respective channel is generated at the beginning of a new transfer or at the end of the transfer.

If implementing a ping-pong buffer scheme with continuous mode of operation, then the interrupt can be generated at the beginning, just after the working registers are copied to the shadow set. If the DMA does not operate in continuous mode, then the interrupt is typically generated at the end when the transfer is complete.

All of the previous features and modes are shown in Figure 11-4. The following items are in reference to Figure 11-4.

- The *HALT* points represent where the channel halts operation when interrupted by a high priority channel 1 trigger, or when the HALT command is set, or when an emulation halt is issued and the FREE bit is cleared to 0.
- The SRC/DST_ADDR_ACTIVE registers are not affected by SRC/DST_BEG_ADDR_ACTIVE at the start of a transfer. SRC/DST_BEG_ADDR_ACTIVE only affects the SRC/DST_ADDR_ACTIVE registers on a wrap. Following is what happens when a transfer first starts:
  - SRC/DST_BEG_ADDR_SHADOW remains unchanged.
  - SRC/DST_ADDR_SHADOW remains unchanged.
  - SRC/DST_BEG_ADDR_ACTIVE = SRC/DST_BEG_ADDR_SHADOW
  - SRC/DST_ADDR_ACTIVE = SRC/DST_ADDR_SHADOW
- The active registers get updated when a wrap occurs. The shadow registers remain unchanged. Specifically:
  - SRC/DST_BEG_ADDR_SHADOW remains unchanged.
  - SRC/DST_ADDR_SHADOW remains unchanged.
  - SRC/DST_BEG_ADDR_ACTIVE += SRC/DST_WRAP_STEP
  - SRC/DST_ADDR_ACTIVE = SRC/DST_BEG_ADDR_ACTIVE
- The best way to remember this is:
  - The shadow registers never change except by software.
  - The active registers never change except by hardware, and a shadow register is only copied into their own active register, never an active register by another name.

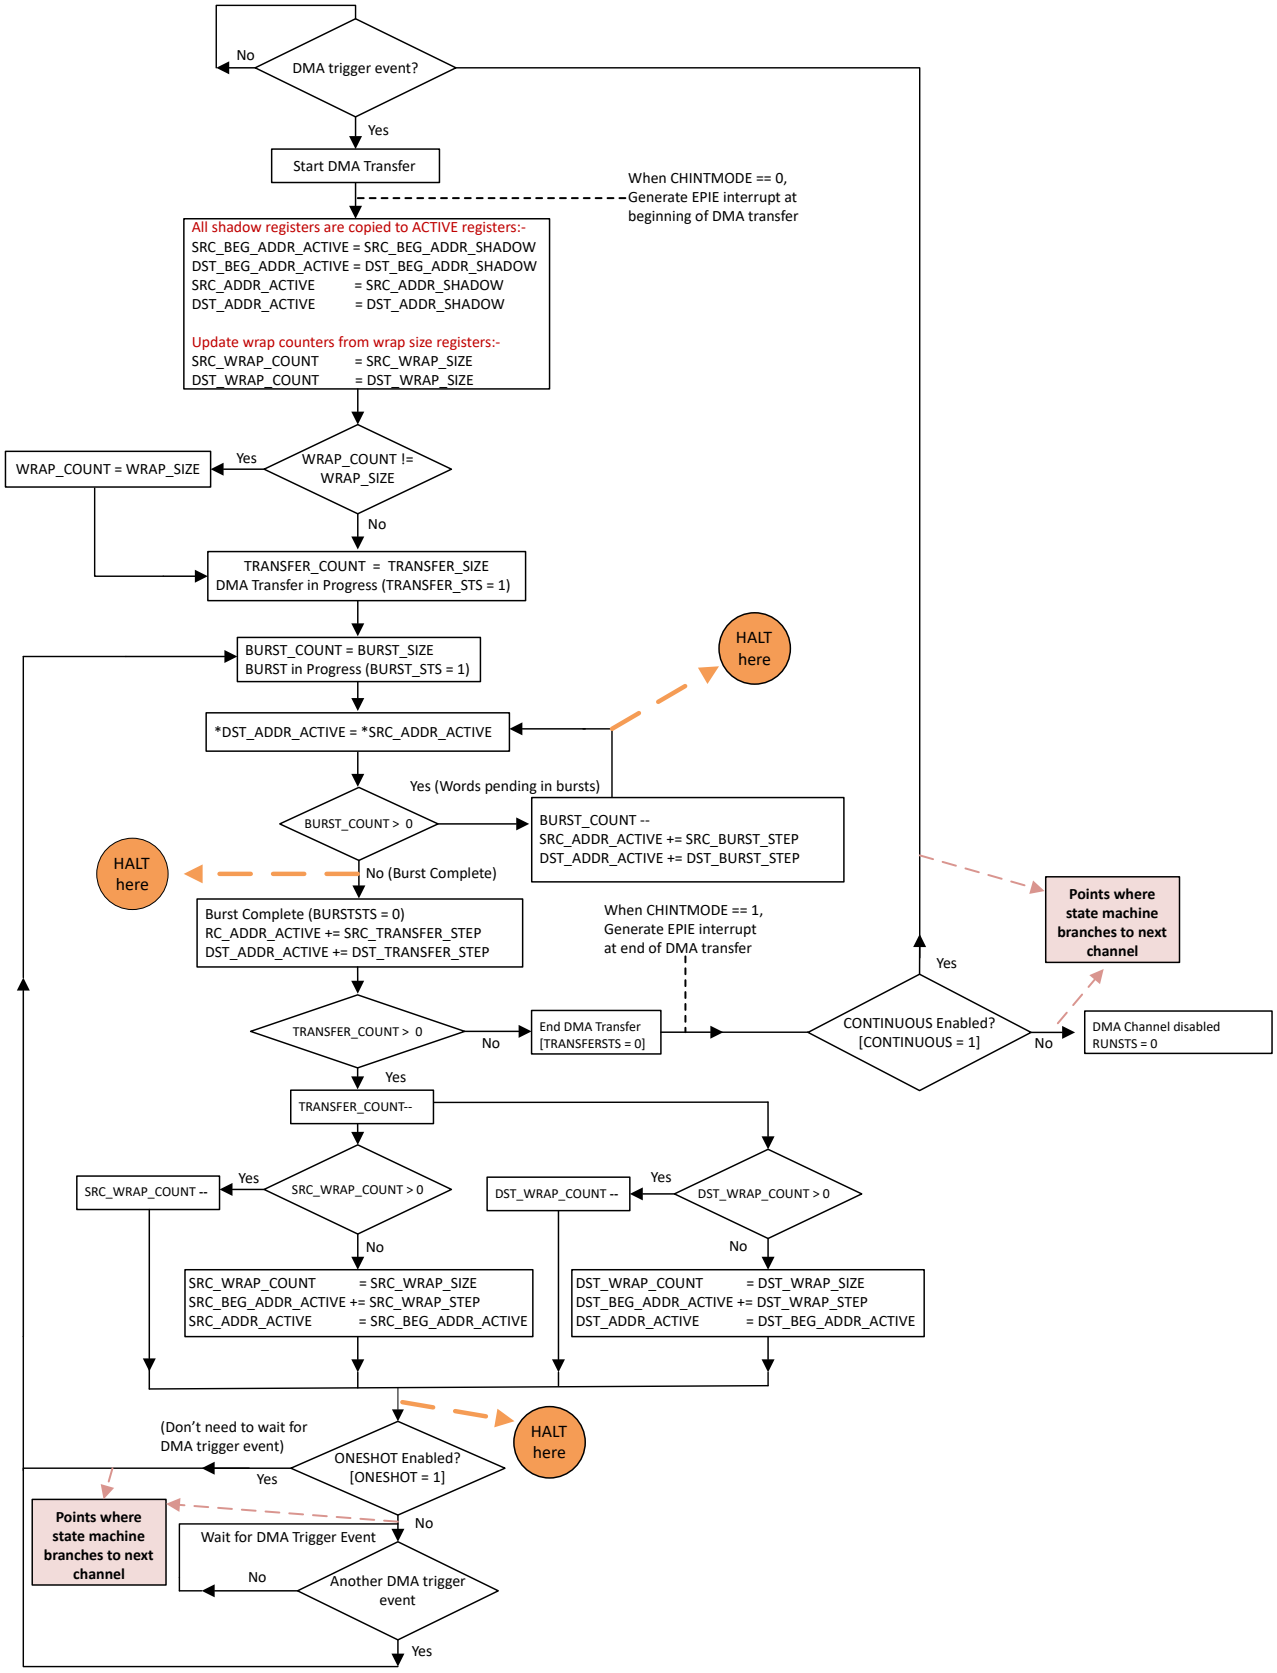

Figure 11-4. DMA State Diagram

11.4 Pipeline Timing and Throughput

In addition to the pipeline there are a few other behaviors of the DMA that affect the total throughput:

- A 1-cycle delay is added at the beginning of each burst
- A 1-cycle delay is added when returning from a CH1 high-priority interrupt
- Collisions with the CPU can add delay slots (see Section 11.5)
- 32-bit transfers run at double the speed of a 16-bit transfer (takes the same amount of time to transfer a 32-bit word as to transfer a 16-bit word)

For example, to transfer 128 16-bit words from GS0 RAM to GS3 RAM, a channel can be configured to transfer 8 bursts of 16 words/burst. This gives:

8 bursts * [(3 cycles/word * 16 words/burst) + 1] = 392 cycles

If instead the channel were configured to transfer the same amount of data 32 bits at a time (the word size is configured to 32 bits), the transfer can take:

8 bursts * [(3 cycles/word * 8 words/burst) + 1] = 200 cycles

The DMA module consists of a 3-stage pipeline as shown in Figure 11-5 and Figure 11-6.

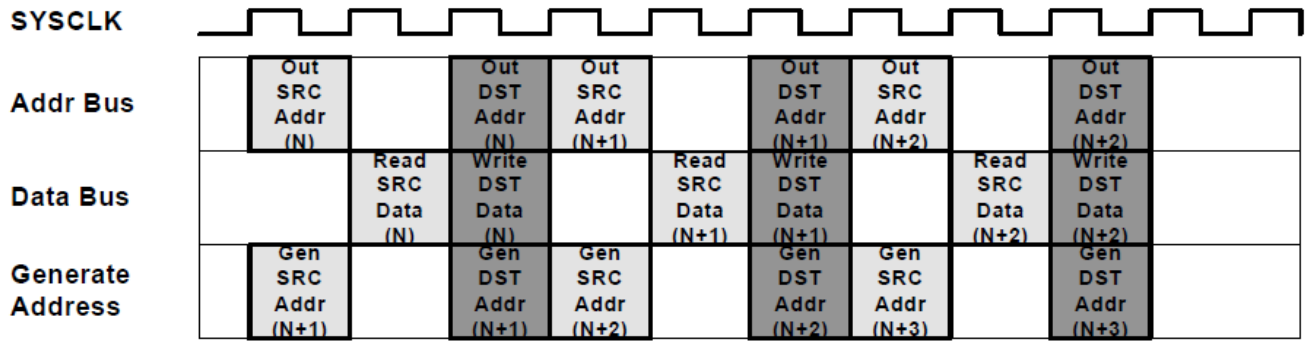

Figure 11-5. 3-Stage Pipeline DMA Transfer

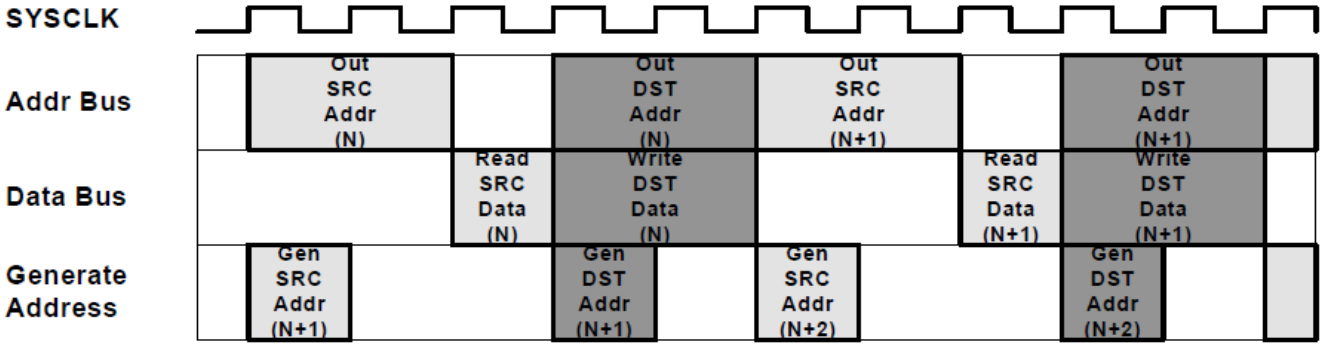

Figure 11-6. 3-stage Pipeline with One Read Stall

11.5 CPU and CLA Arbitration

Typically, DMA activity is independent of CPU and CLA activity. However, when the DMA and CPU (or CLA) try to access the same peripheral at the same time, an arbitration procedure is required to resolve the conflict. All instances of the same peripheral type conflict with each other. For instance, CAN-A and CAN-B conflict. Accesses to global shared RAM, across different instances, do not have this conflict. Different peripheral types can share a bus interface, which creates further opportunities for conflicts. These bus interfaces are:

- Peripheral frame 1: ePWM, eCAP, eQEP, CMPSS, DAC , SDFM
- Peripheral frame 2: PMBus, SPI , FSI

Conflict Example: The CLA is accessing DAC-A while the DMA is simultaneously accessing DAC-B.

Conflict Example: The CPU is accessing an SPI FIFO while the DMA is simultaneously accessing a PMBus register.

Non-conflict Example: The CPU is accessing a shared ePWM while the DMA is accessing an SPI.

Non-conflict Example: The CPU is accessing GS0 while the DMA is accessing GS1

The exception to all this is the ADC result registers, which are duplicated for each bus master. The CPU, DMA, and CLA can all simultaneously read these result registers with no stalls or arbitration needed for any master.

A DMA transfer consists of four phases: send source address, read source data, send destination address, and write destination data (see Section 11.4). Suppose CPU accesses a peripheral/memory causing conflict in middle of a DMA transfer, CPU is stalled till the current DMA access is complete and not until the completion of whole DMA transfer.

The following priority schemes are implemented for the various interfaces on the device:

- The arbitration follows a fixed arbitration scheme with highest priority first:
  - DMA WRITE
  - DMA READ
  - CLA WRITE
  - CLA READ
  - CPU WRITE
  - CPU READ
- The priority scheme for GSx RAM accesses is round-robin.
- The ADC results are duplicated for CPU, CLA, and DMA so that no arbitration is needed when reading the result registers. This allows all masters to access the ADC result registers simultaneously without delay.

Note

If the CPU is performing a read-modify-write operation and the DMA performs a write to the same location, the DMA write may be lost if the operation occurs in between the CPU read and the CPU write. Avoid mixing CPU writes with DMA writes to the same locations.

Arbitration within DMA channels is based on a round-robin priority (or) Channel 1 high priority scheme described in Section 11.6.

11.6 Channel Priority

Two priority schemes exist when determining channel priority: Round-robin mode and Channel 1 high-priority mode.

11.6.1 Round-Robin Mode

In this mode, all channels have *equal* priority and each enabled channel is serviced in round-robin fashion as:

CH1 → CH2 → CH3 → CH4 → CH5 → CH6 → CH1 → CH2 → …

In the case above, after each channel has transferred a burst of words, the next channel is serviced. The user can specify the size of the burst for each channel. Once CH6 (or the last enabled channel) has been serviced, and no other channels are pending, the round-robin state machine enters an idle state.

From the idle state, channel 1 (if enabled) is always serviced first. However, if the DMA is currently processing another channel x, all other pending channels between x and the end of the round are serviced before CH1. All the channels are of *equal* priority. For instance, take an example where CH1, CH4, and CH5 are enabled in round-robin mode and CH4 is currently being processed. Then CH1 and CH5 both receive an interrupt trigger from their respective peripherals before CH4 completes. CH1 and CH5 are now both pending. When CH4 completes the burst, CH5 is serviced next. Only after CH5 completes is CH1 serviced. Upon completion of CH1, if there are no more channels pending, the round-robin state machine enters an idle state.

A more complicated example is:

- Assume all channels are enabled, and the DMA is in an idle state,
- Initially a trigger occurs on CH1, CH3, and CH5 on the same cycle,
- When the CH1 burst transfer starts, requests from CH3 and CH5 are pending,
- Before completion of the CH1 burst, the DMA receives a request from CH2. Now the pending requests are from CH2, CH3, and CH5,
- After completing the CH1 burst, CH2 is serviced since this channel is next in the round-robin scheme after CH1.
- After the burst from CH2 is finished, the CH3 burst is serviced, followed by CH5 burst.
- Now while the CH5 burst is being serviced, the DMA receives a request from CH1, CH3, and CH6.
- The burst from CH6 starts after the completion of the CH5 burst, since this channel is the next channel after CH5 in the round-robin scheme.
- This is followed by the CH1 burst and then the CH3 burst
- After the CH3 burst finishes, assuming no more triggers have occurred, the round-robin state machine enters an idle state.

The round-robin state machine can be reset to the idle state using the DMACTRL[PRIORITYRESET] bit.

11.6.2 Channel 1 High-Priority Mode

In this mode, Channel 1 has high priority over all the other channels. Channels 2 to 6 have equal priority and each enabled channel is serviced in a round-robin fashion.

Higher priority:	CH1
Lower priority:	CH2 → CH3 → CH4 → CH5 → CH6 → CH2 → …

Given an example where CH1, CH4, and CH5 are enabled in Channel 1 high-priority mode and CH4 is currently being processed. Then CH1 and CH5 both receive an interrupt trigger from their respective peripherals before CH4 completes. CH1 and CH5 are now both pending. When the current CH4 word transfer is completed, regardless of whether the DMA has completed the entire CH4 burst, CH4 execution is suspended and CH1 is serviced. After the CH1 burst completes, CH4 resumes execution.

Upon completion of CH4, CH5 is serviced. After CH5 completes, if there are no more channels pending, the round-robin state machine enters an idle state.

Typically Channel 1 is used in this mode for the ADC, since the data rate is so high. However, Channel 1 high-priority mode can be used in conjunction with any peripheral.

Note

High-priority mode and ONESHOT mode cannot be used at the same time on Channel 1. Other channels can use ONESHOT mode when Channel 1 is in high-priority mode.

11.7 Overrun Detection Feature

The DMA contains overrun detection logic. When a peripheral event trigger is received by the DMA, the PERINTFLG bit in the CONTROL register is set, pending the channel to the DMA state machine. When the burst for that channel is started, the PERINTFLG is cleared. If however, between the time that the PERINTFLG bit is set by an event trigger and cleared by the start of the burst, an additional event trigger arrives, the second trigger is lost. This condition sets the OVRFLG bit in the CONTROL register as in Figure 11-7. If the overrun interrupt is enabled, the channel interrupt is generated to the PIE module.

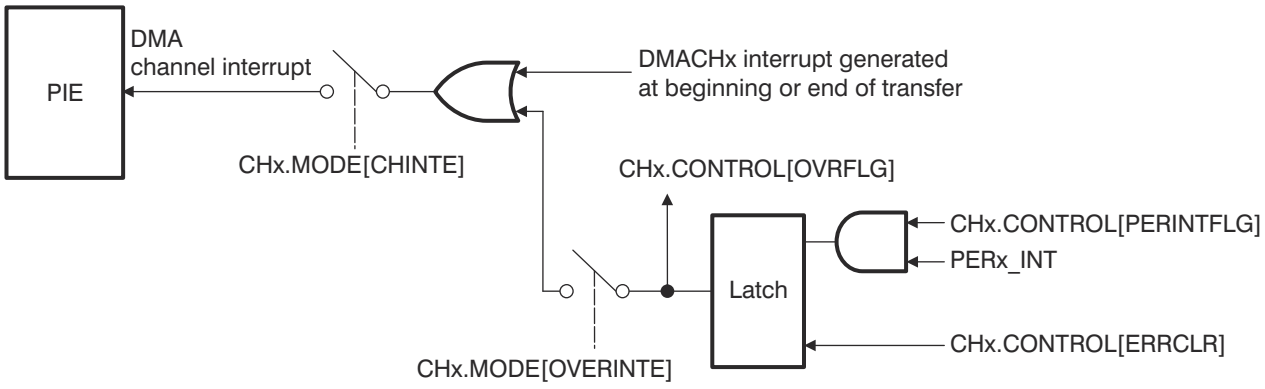

Figure 11-7. Overrun Detection Logic

11.8 Software

11.8.1 DMA Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dma

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

11.8.1.1 DMA GSRAM Transfer (dma_ex1_gsram_transfer)

FILE: dma_ex1_gsram_transfer.c

This example uses one DMA channel to transfer data from a buffer in RAMGS0 to a buffer in RAMGS1. The example sets the DMA channel PERINTFRC bit repeatedly until the transfer of 16 bursts (where each burst is 8 16-bit words) has been completed. When the whole transfer is complete, it will trigger the DMA interrupt.

Watch Variables
- *sData* - Data to send
- *rData* - Received data

11.8.1.2 DMA Transfer Shared Peripheral - C28X_DUAL

FILE: dma_ex1_shared_periph_cpu1.c

This example shows how to initiate a DMA transfer on CPU1 from a shared peripheral which is owned by CPU2. In this specific example, a timer ISR is used on CPU2 to initiate a SPI transfer which will trigger the CPU1 DMA. CPU1's DMA will then in turn update the ePWM1 CMPA value for the PWM which it owns. The PWM output can be observed on the GPIO pins. It is recommended to run the c28x1 core first, followed by the C28x2 core.

Watch Pins
- GPIO0 and GPIO1 - ePWM output can be viewed with oscilloscope

11.8.1.3 DMA Transfer for Shared Peripheral Example (CPU2) - C28X_DUAL

FILE: dma_ex1_shared_periph_cpu2.c

This example shows how to initiate a DMA transfer on CPU1 from a shared peripheral that is owned by CPU2. In this specific example, a timer ISR is used on CPU2 to initiate a SPI transfer that triggers the CPU1 DMA. CPU1 DMA then updates the ePWM1 CMPA value for the PWM that the DMA owns. The PWM output can be observed on the GPIO pins. It is recommended to run the c28x1 core first, followed by the C28x2 core.

11.8.1.4 DMA GSRAM Transfer (dma_ex2_gsram_transfer)

FILE: dma_ex2_gsram_transfer.c

This example uses one DMA channel to transfer data from a buffer in RAMGS0 to a buffer in RAMGS1. The example sets the DMA channel PERINTFRC bit repeatedly until the transfer of 16 bursts (where each burst is 8 16-bit words) has been completed. When the whole transfer is complete, it will trigger the DMA interrupt.

Watch Variables
- *sData* - Data to send
- *rData* - Received data

11.8.1.5 DMA Transfer Shared Peripheral - C28X_DUAL

FILE: dma_ex2_sysconfig_cpu1.c

This example shows how to initiate a DMA transfer on CPU1 from a shared peripheral which is owned by CPU2. In this specific example, a timer ISR is used on CPU2 to initiate a SPI transfer which will trigger the CPU1 DMA. CPU1's DMA will then in turn update the ePWM1 CMPA value for the PWM which it owns. The PWM output can be observed on the GPIO pins. It is recommended to run the c28x1 core first, followed by the C28x2 core.

Watch Pins

- GPIO0 and GPIO1 - ePWM output can be viewed with oscilloscope

11.9 DMA Registers

This section describes the C28x Direct Memory Access Registers.

11.9.1 DMA Base Address Table (C28)

Table 11-3. DMA Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
DmaRegs	DMA_REGS	DMA_BASE	0x0000_1000	YES	YES	-	-	-
Dmach1Regs	DMA_CH_REGS	DMA_CH1_BASE	0x0000_1020	YES	YES	-	-	-
Dmach2Regs	DMA_CH_REGS	DMA_CH2_BASE	0x0000_1040	YES	YES	-	-	-
Dmach3Regs	DMA_CH_REGS	DMA_CH3_BASE	0x0000_1060	YES	YES	-	-	-
Dmach4Regs	DMA_CH_REGS	DMA_CH4_BASE	0x0000_1080	YES	YES	-	-	-
Dmach5Regs	DMA_CH_REGS	DMA_CH5_BASE	0x0000_10A0	YES	YES	-	-	-
Dmach6Regs	DMA_CH_REGS	DMA_CH6_BASE	0x0000_10C0	YES	YES	-	-	-

11.9.2 DMA_REGS Registers

Table 11-4 lists the memory-mapped registers for the DMA_REGS registers. All register offset addresses not listed in Table 11-4 should be considered as reserved locations and the register contents should not be modified.

Table 11-4. DMA_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	DMACTRL	DMA Control Register	EALLOW	Go
1h	DEBUGCTRL	Debug Control Register	EALLOW	Go
4h	PRIORITYCTRL1	Priority Control 1 Register	EALLOW	Go
6h	PRIORITYSTAT	Priority Status Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 11-5 shows the codes that are used for access types in this section.

Table 11-5. DMA_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

11.9.2.1 DMACTRL Register (Offset = 0h) [Reset = 0h]

DMACTRL is shown in Figure 11-8 and described in Table 11-6.

Return to the Summary Table.

DMA Control Register

Table 11-6. DMACTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-2	RESERVED	R	0h	Reserved
1	PRIORITYRESET	R-0/W1S	0h	The priority reset bit resets the round-robin state machine when a 1 is written. Service starts from the first enabled channel. Writes of 0 are ignored and this bit always reads back a 0. When a 1 is written to this bit, any pending burst transfer completes before resetting the channel priority machine. If CH1 is configured as a high-priority channel, and this bit is written to while CH1 is servicing a burst, both the CH1 burst and the next pending low-priority burst are completed before the state machine is reset. If CH1 is high-priority, the state machine restarts from CH2 (or the next highest enabled channel). Reset type: SYSRSn
0	HARDRESET	R-0/W1S	0h	Writing a 1 to the hard reset bit resets the whole DMA and aborts any current access (similar to applying a device reset). Writes of 0 are ignored and this bit always reads back a 0. For a soft reset, a bit is provided for each channel to perform a gentler reset. Refer to the channel control registers. When writing to this bit, there is a one cycle delay before it takes effect. Hence, a one-cycle delay (such as a NOP instruction) is required in software before attempting to access any other DMA register. Reset type: SYSRSn

11.9.2.2 DEBUGCTRL Register (Offset = 1h) [Reset = 0h]

DEBUGCTRL is shown in Figure 11-9 and described in Table 11-7.

Return to the Summary Table.

Debug Control Register

Figure 11-9. DEBUGCTRL Register

OVRINTE	RESERVED		PERINTSEL				
R/W-0h	R-0h		R/W-0h				

Table 11-12. MODE Register Field Descriptions

Bit	Field	Type	Reset	Description
15	CHINTE	R/W	0h	Channel Interrupt Enable Bit This bit enables the DMA channel's CPU interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt disabled 1h (R/W) = Interrupt enabled
14	DATASIZE	R/W	0h	Data Size Mode Bit This bit determines whether the DMA channel transfers 16 bits or 32 bits of data per read/write operation. Regardless of this setting, all data lengths and offsets in other DMA registers refer to 16- bit words. The pointer step increments must be configured to accomodate 32-bit words. Reset type: SYSRSn 0h (R/W) = 16-bit data transfer size 1h (R/W) = 32-bit data transfer size
13	RESERVED	R/W	0h	Reserved
12	RESERVED	R/W	0h	Reserved
11	CONTINUOUS	R/W	0h	Continuous Mode Bit If this bit is set to 1, then the channel re-initializes when TRANSFER_COUNT is zero and waits for the next event trigger. Otherwise, the DMA stops and clears the RUNSTS bit. Reset type: SYSRSn
10	ONESHOT	R/W	0h	One Shot Mode If this bit is set to 1, each peripheral event trigger causes the channel to perform an entire transfer. Otherwise, the channel only performs one burst per trigger. Reset type: SYSRSn
9	CHINTMODE	R/W	0h	Channel Interrupt Generation Mode This bit specifies when the DMA channel generates a CPU interrupt for a transfer. Reset type: SYSRSn 0h (R/W) = Generate interrupt at beginning of new transfer 1h (R/W) = Generate interrupt at end of transfer.
8	PERINTE	R/W	0h	Peripheral Event Trigger Enable This bit enables peripheral event triggers on the DMA channel. Reset type: SYSRSn 0h (R/W) = Peripheral event trigger disabled. Neither the selected peripheral nor software can start a DMA burst. 1h (R/W) = Peripheral event trigger enabled.

Table 11-12. MODE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	OVRINTE	R/W	0h	Overflow Interrupt Enable The bit determines whether the DMA module generates a CPU interrupt when it detects an overflow event. Reset type: SYSRSn 0h (R/W) = Overflow interrupt disabled 1h (R/W) = Overflow interrupt enabled
6-5	RESERVED	R	0h	Reserved
4-0	PERINTSEL	R/W	0h	Peripheral Event Trigger Source Select These are legacy bits and should be set to the channel number. The actual source selection is done via the DMACHSRCSELn registers, which are part of the DMA_CLA_SRC_SEL_REGS group. Reset type: SYSRSn

11.9.3.2 CONTROL Register (Offset = 1h) [Reset = 0h]

CONTROL is shown in Figure 11-13 and described in Table 11-13.

Return to the Summary Table.

Control Register

Figure 11-13. CONTROL Register

15	14	13	12	11	10	9	8
RESERVED	OVRFLG	RUNSTS	BURSTSTS	TRANSFERSTS	RESERVED	RESERVED	PERINTFLG

Table 11-13. CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	OVRFLG	R	0h	Overflow Flag This bit indicates that a peripheral event trigger was received while PERINTFLG was already set. It can be cleared by writing to the ERRCLR bit. Reset type: SYSRSn 0h (R/W) = No overflow detected 1h (R/W) = Overflow detected
13	RUNSTS	R	0h	Run Status Flag This bit indicates that the DMA channel is ready to respond to peripheral event triggers. This bit is set when a 1 is written to the RUN bit. It is cleared when a transfer completes (TRANSFER_COUNT = 0) and continuous mode is disabled, or when the HARDRESET, SOFTRESET, or HALT bit is set. Reset type: SYSRSn 0h (R/W) = The channel is disabled 1h (R/W) = The channel is enabled
12	BURSTSTS	R	0h	Burst Status Flag This bit is set when a DMA burst begins. The BURST_COUNT is set to the BURST_SIZE. This bit is cleared when BURST_COUNT reaches zero, or when the HARDRESET or SOFTRESET bit is set. Reset type: SYSRSn 0h (R/W) = No burst activity 1h (R/W) = The DMA is currently servicing or suspending a burst transfer from this channel
11	TRANSFERSTS	R	0h	Transfer Status Flag This bit is set when a DMA transfer begins. The address registers are copied to the shadow set and the TRANSFER_COUNT is set to the TRANSFER_SIZE. This bit is cleared when TRANSFER_COUNT reaches zero, or when the HARDRESET or SOFTRESET bit is set. Reset type: SYSRSn 0h (R/W) = No transfer activity 1h (R/W) = The channel is currently in the middle of a transfer regardless of whether a burst of data is actively being transferred or not
10	RESERVED	R	0h	Reserved
9	RESERVED	R	0h	Reserved

Table 11-13. CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	PERINTFLG	R	0h	Peripheral Event Trigger Flag This bit indicates whether a peripheral event trigger has arrived. This bit is automatically cleared when the first burst transfer begins. Reset type: SYSRSn 0h (R/W) = Waiting for event trigger 1h (R/W) = Event trigger pending
7	ERRCLR	R-0/W1S	0h	Clear Error Writing a 1 to this bit will clear the OVRFLG bit. This is normally done when initializing the DMA module or if an overflow condition is detected. If an overflow event occurs at the same time this bit is set, the overrun has priority and the OVRFLG bit is set. Reset type: SYSRSn
6	RESERVED	R-0/W1S	0h	Reserved
5	RESERVED	R-0/W1S	0h	Reserved
4	PERINTCLR	R-0/W1S	0h	Clear Peripheral Event Trigger Writing a 1 to this bit clears PERINTFLG, which cancels a pending event trigger. This is normally done when initializing the DMA module. If an event trigger arrives at the same time this bit is set, the trigger has priority and PERINTFLG is set. Reset type: SYSRSn
3	PERINTFRC	R-0/W1S	0h	Force Peripheral Event Trigger If the PERINTE bit of the MODE register is set, writing a 1 to this bit sets PERINTFLG, which triggers a DMA burst. This bit can be used to start a DMA transfer in software. Reset type: SYSRSn
2	SOFTRESET	R-0/W1S	0h	Channel Soft Reset Writing a 1 to this bit places the channel into its default state after the current read/write access has completed: RUNSTS = 0 TRANSFERSTS = 0 BURSTSTS = 0 BURST_COUNT = 0 TRANSFER_COUNT = 0 SRC_WRAP_COUNT = 0 DST_WRAP_COUNT = 0 When writing to this bit, there is a one cycle delay before it takes effect. Hence, a one-cycle delay (such as a NOP instruction) is required in software before attempting to access any other DMA register. Reset type: SYSRSn
1	HALT	R-0/W1S	0h	Halt Channel Writing a 1 to this bit halts the DMA channel in its current state after any ongoing read/write access has completed. Reset type: SYSRSn
0	RUN	R-0/W1S	0h	Run Channel Writing a 1 to this bit enables the DMA channel and sets the RUNSTS bit to 1. This bit is also used to resume after a channel halt. The RUN bit is typically used to start the DMA channel after configuration. The channel will then wait for the first peripheral event trigger (PERINTFLG == 1) to start a burst. Reset type: SYSRSn

11.9.3.3 BURST_SIZE Register (Offset = 2h) [Reset = 0h]

BURST_SIZE is shown in Figure 11-14 and described in Table 11-14.

Return to the Summary Table.

Chapter 12

External Memory Interface (EMIF)

This chapter describes the external memory interface (EMIF).

Further information can be found in the following documents:

Accessing External SDRAM on the TMS320F2837x/2807x Microcontrollers Using C/C++ Application Report

Design and Usage Guidelines for the C2000™ External Memory Interface (EMIF) Application Report

12.1 Introduction

This device supports dual-core architecture. To have a dedicated EMIF for each CPU subsystem, the device supports two EMIF modules — EMIF1 and EMIF2, as shown in Figure 12-1. Both modules are exactly the same with the same feature set, but have different address/data sizes. EMIF1 is shared between the CPU1 and CPU2 subsystem, whereas EMIF2 is dedicated to the CPU1 subsystem.

Table 12-1 gives the configuration for two EMIF modules.

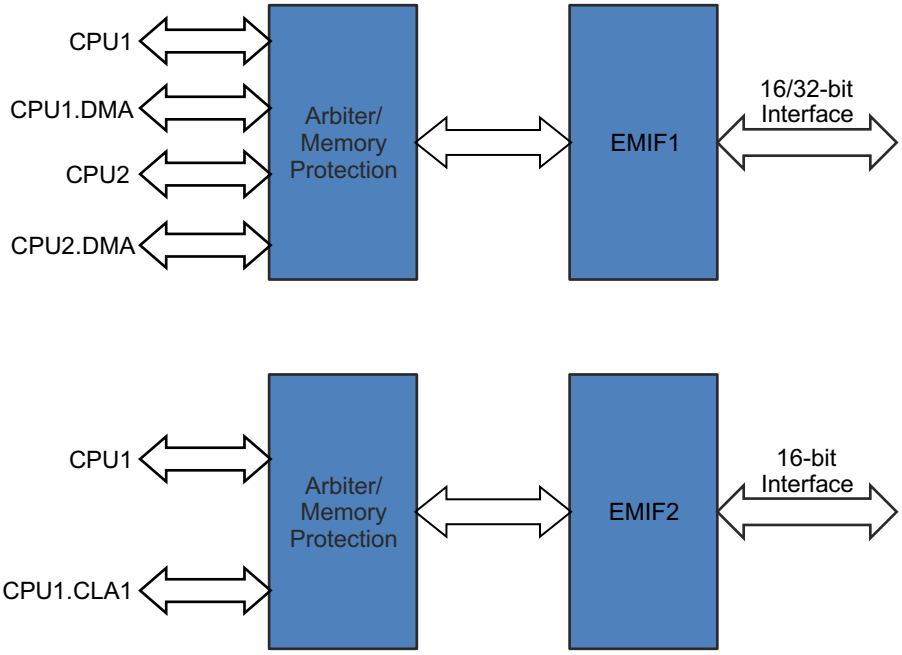

Figure 12-1. EMIF Module Overview

Table 12-1. Configuration for EMIF1 and EMIF2 Modules

	EMIF1	EMIF2
176-Pin Package	Yes	NA
337- Pin Package	Yes	Yes
Maximum Data Width	32	16
Maximum Address Width	22 (Some of the EMIF1 pins are muxed with each other. Refer to Section 12.2.11 for usage)	13
SDRAM CSx Support	1 (CS0)	1 (CS0)
ASRAM CSx Support	3 (CS2/CS3/CS4)	1 (CS2)

Note

Subsequent sections in this chapter provide the details on the generic EMIF module. Unless otherwise specified, pin names are used from EMIF1 to define the functionality.

12.1.1 EMIF Related Collateral

Foundational Materials

- C2000 Academy - EMIF

Getting Started Materials

Expert Materials

- *Accessing External SDRAM on the TMS320F2837x/2807x Microcontrollers Using C/C++ Application Report*
  - In addition to the devices in the title, this material also applies to other devices with EMIF.

12.1.2 Purpose of the Peripheral

This EMIF memory controller is compliant with the JESD21-C SDR SDRAM memories utilizing a 32-bit/16-bit data bus. The purpose of this EMIF is to provide a means for the CPU to connect to a variety of external devices including:

- Single data rate (SDR) SDRAM
- Asynchronous devices including NOR Flash and SRAM

A common use for the EMIF is to interface with both a Flash device and an SDRAM device simultaneously. Section 12.3 contains an example of operating the EMIF in this configuration.

12.1.3 Features

The EMIF controller includes many features to enhance the ease and flexibility of connecting to the external SDR SDRAM and asynchronous devices.

12.1.3.1 Asynchronous Memory Support

The EMIF controller supports asynchronous:

- SRAM memories
- NOR Flash memories

There is an external wait input that allows slower asynchronous memories to extend the memory access. The EMIF module supports more than one chip select (enable). Each chip select has the following individually programmable attributes:

- Data bus width
- Read cycle timings: setup, hold, strobe
- Write cycle timings: setup, hold, strobe
- Bus turnaround time
- Extended wait option with programmable timeout
- Select strobe option

12.1.3.2 Synchronous DRAM Memory Support

The EMIF module supports 16-bit/32-bit SDRAM in addition to the asynchronous memories listed in Section 12.1.3.1. The EMIF module has a single SDRAM chip select. SDRAM configurations that are supported are:

- One, two and four bank SDRAM devices
- Devices with eight, nine, ten, and eleven column address
- CAS latency of two or three clock cycles
- 16-bit/32-bit data bus width
- 3.3V LVCMOS interface

Additionally, the EMIF supports placing the SDRAM in self-refresh and power-down modes. The self-refresh mode allows the SDRAM to be put in a low-power state while still retaining memory contents, since the SDRAM continues to refresh itself even without clocks from the microcontroller. The power-down mode achieves even lower power, except the microcontroller must periodically wake up and issue refreshes if data retention is required.

Note that the EMIF module does not support mobile SDRAM devices.

12.1.4 Functional Block Diagram

Figure 12-2 illustrates the connections between the EMIF and its internal requesters, along with the external EMIF pins. Section 12.2.2 contains a description of the entities internal to the MCU that can send requests to the EMIF, along with their prioritization. Section 12.2.3 describes the EMIF external pins and summarizes their purpose when interfacing with the SDRAM and asynchronous devices.

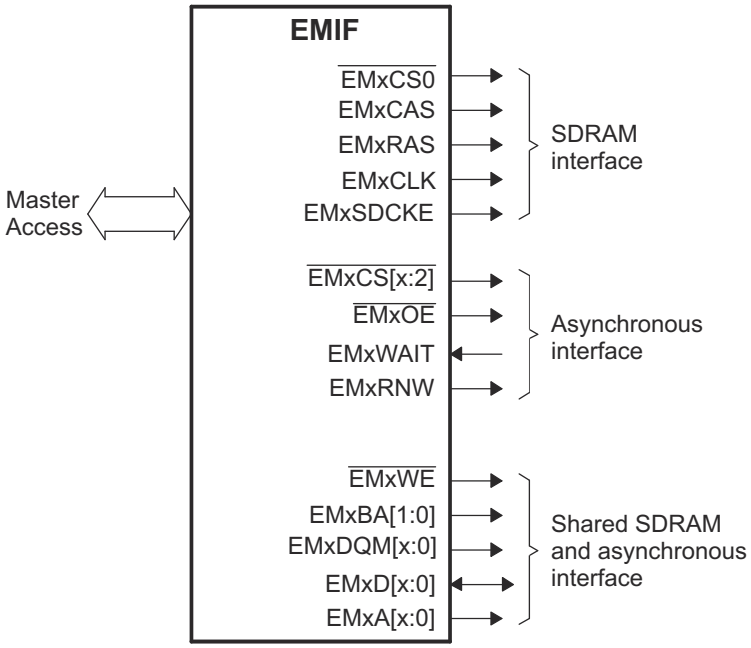

Figure 12-2. EMIF Functional Block Diagram

12.1.5 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

12.2 EMIF Module Architecture

This section provides details about the architecture and operation of the EMIF. Both the SDRAM and asynchronous interface are covered, along with other system-related configurations such as clock control.

12.2.1 EMIF Clock Control

The EMIF clock is output on the EMxCLK pin and must be used when interfacing to external SDRAM devices. The EMIF module gets the PLLSYSCLK clock domain as the input. The user can choose to run the EMIF at PLLSYSCLK/1 or PLLSYSCLK/2 clock frequency by configuring the EMIFxCLKDIV field in the PERCLKDIVSEL register in the *Clock Control* module.

12.2.2 EMIF Requests

Different sources within the MCU can make requests to the EMIF. These requests consist of accesses to the SDRAM memory, the asynchronous memory, and the EMIF registers. The EMIF can process only one request at a time. Therefore, a high performance master arbitration block exists within the MCU to provide prioritized requests from the different sources to the EMIF. The sources are:

- CPU1
- CPU1.DMA
- CPU2
- CPU2.DMA

If a request is submitted from two or more sources simultaneously, the crossbar switch will forward the highest priority request to the EMIF first. Upon completion of a request, the master arbitration block again evaluates the pending requests and forwards the highest priority pending request to the EMIF.

The master arbitration block always allows RD access from any of the masters. But for WR access (or execute access), the master arbitration block only allows access of masters from a CPU subsystem that takes master ownership of the EMIF module based on the configuration in the EMIF1MSEL register in the *Memory Controller* module. Note that only the EMIF1 has access from both the CPU subsystems; hence, the concept of grab-semaphore is applicable for the EMIF1 only.

When the EMIF receives a request, it may or may not be immediately processed. In some cases, the EMIF will perform one or more auto refresh cycles before processing the request. For details on the EMIF internal arbitration between performing requests and performing auto refresh cycles, see Section 12.2.13.

12.2.3 EMIF Signal Descriptions

This section describes the function of each of the EMIF signals.

Table 12-2. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories

Pins	I/O	Description
EM1D[x:0]	I/O	**EMIF data bus.**
EM1A[x:0]	O	**EMIF address bus.** When interfacing to an SDRAM device, these pins are primarily used to provide the row and column address to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in Table 12-14. EM1A[10] is also used during the PRE command to select which banks to deactivate. When interfacing to an asynchronous device, these pins are used in conjunction with the EM1BA pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in Section 12.2.6.1.
EM1BA[1:0]	O	**EMIF bank address.** When interfacing to an SDRAM device, these pins are used to provide the bank address inputs to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in Table 12-14. When interfacing to an asynchronous device, these pins are used in conjunction with the EM1A pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in Section 12.2.6.1.
EM1DQM[x:0]	O	**Active-low byte enables.** When interfacing to SDRAM, these pins are connected to the DQM pins of the SDRAM to individually enable/disable each of the bytes in a data access. When interfacing to an asynchronous device, these pins are connected to byte enables. See Section 12.2.6 for details.
$\overline{\text{EM1WE}}$	O	**Active-low write enable.** When interfacing to SDRAM, this pin is connected to the nWE pin of the SDRAM and is used to send commands to the device. When interfacing to an asynchronous device, this pin provides a signal which is active-low during the strobe period of an asynchronous write access cycle.

Table 12-3. EMIF Pins Specific to SDRAM

Pins	I/O	Description
$\overline{\text{EM1CS0}}$	O	**Active-low chip enable pin for SDRAM devices.** This pin is connected to the chip-select pin of the attached SDRAM device and is used for enabling/disabling commands. By default, EMIF keeps this SDRAM chip select active, even if EMIF is not interfaced with an SDRAM device. This pin is deactivated when accessing the asynchronous memory bank and is reactivated on completion of the asynchronous access.
EM1RAS	O	**Active-low row address strobe pin.** This pin is connected to the nRAS pin of the attached SDRAM device and is used for sending commands to the device.
EM1CAS	O	**Active-low column address strobe pin.** This pin is connected to the nCAS pin of the attached SDRAM device and is used for sending commands to the device.
EM1SDCKE	O	**Clock enable pin.** This pin is connected to the CKE pin of the attached SDRAM device and is used for issuing the SELF REFRESH command which places the device in self-refresh mode. See Section 12.2.5.7 for details.
EM1CLK	O	**SDRAM clock pin.** This pin is connected to the CLK pin of the attached SDRAM device. See Section 12.2.1 for details on the clock signal.

Table 12-4. EMIF Pins Specific to Asynchronous Memory

Pins	I/O	Description
$\overline{\text{EM1CS}}$[4:2]	O	**Active-low chip enable pins for asynchronous devices.** These pins are meant to be connected to the chip-select pins of the attached asynchronous device. These pins are active only during accesses to the asynchronous memory.
EM1WAIT	I	**Wait input with programmable polarity / NAND Flash ready input.** A connected asynchronous device can extend the strobe period of an access cycle by asserting the EM1WAIT input to EMIF as described in Section 12.2.6.6. To enable this functionality, the EW bit in the asynchronous 1 configuration register (ASYNC_CS2_CFG) must be set to 1. In addition, the WP0 bit in ASYNC_CS2_CFG must be configured to define the polarity of the EM1WAIT pin. When the CS2NAND/CS3NAND/CS4NAND/CS5NAND bit in the NAND Flash control register (NANDFCR) is set, this pin instead functions as a NAND Flash ready input.
$\overline{\text{EM1OE}}$	O	**Active-low pin enable for asynchronous devices.** This pin provides a signal which is active-low during the strobe period of an asynchronous read access cycle.
EM1RNW	O	**EMIF asynchronous read/write control.** This pin stays high during reads and stays low during writes (same duration as CS).

12.2.4 EMIF Signal Multiplexing Control

Several EMIF signals are multiplexed with other functions on this microcontroller. Refer to the multiplexing section of the *General-Purpose Input/Output (GPIO)* chapter for more information on how to enable the output of these EMIF signals.

12.2.5 SDRAM Controller and Interface

The EMIF controller provides a glueless interface to most standard SDR SDRAM devices and supports features like self-refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The following sections include details on how to Interface and properly configure the EMIF to perform read and write operations to externally connected SDR SDRAM devices. Also, Section 12.3 provides a detailed example of interfacing the EMIF to a common SDRAM device.

12.2.5.1 SDRAM Commands

The EMIF controller supports the SDRAM commands described in Table 12-5. Table 12-6 shows the truth table for the SDRAM commands, and an example timing waveform of the PRE command is shown in Figure 12-3. EM1A[10] is pulled low in this example to deactivate only the bank specified by the EM1BA pins.

Table 12-5. EMIF SDRAM Commands

Command	Function
PRE	**Precharge.** Depending on the value of EM1A[10], the PRE command either deactivates the open row in all banks (EM1A[10] = 1) or only the bank specified by the EM1BA[1:0] pins (EM1A[10] = 0).
ACTV	**Activate**. The ACTV command activates the selected row in a particular bank for the current access.
READ	**Read.** The READ command outputs the starting column address and signals the SDRAM to begin the burst read operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.
WRT	**Write.** The WRT command outputs the starting column address and signals the SDRAM to begin the burst write operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.
BT	**Burst terminate**. The BT command is used to truncate the current read or write burst request. On this device, all the SDRAM accesses are single access except when EMIF controller splits a single access into multiple access (for example, a 32-bit access from CPU is split into two 16-bit accesses if external SDRAM device is 16 bit (NM =1).
LMR	**Load mode register**. The LMR command sets the mode register of the attached SDRAM devices and is only issued during the SDRAM initialization sequence described in Section 12.2.5.4.
REFR	**Auto refresh**. The REFR command signals the SDRAM to perform an auto refresh according to the internal address.
SLFR	**Self refresh**. The self-refresh command places the SDRAM into self-refresh mode, during which the SDRAM provides its own clock signal and auto refresh cycles.
NOP	**No operation**. The NOP command is issued during all cycles in which one of the above commands is not issued.

Table 12-6. Truth Table for SDRAM Commands

SDRAM Pins:	CKE	nCS	nRAS	nCAS	nWE	BA[1:0]	A[12:11]	A[10]	A[9:0]

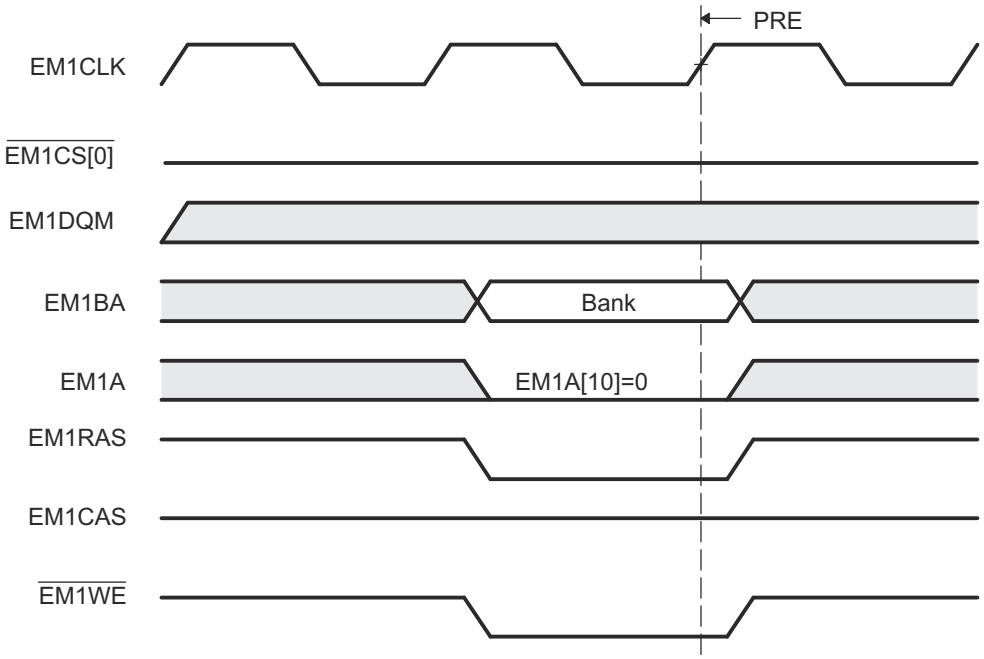

Figure 12-3. Timing Waveform of SDRAM PRE Command

12.2.5.2 Interfacing to SDRAM

The EMIF supports a glueless interface to SDRAM devices with the following characteristics:

- Pre-charge bit is A[10]
- The number of column address bits is 8, 9, 10, or 11.
- The number of row address bits is 13, 14, 15, or 16.
- The number of internal banks is 1, 2, or 4.

Figure 12-4 shows an interface between the EMIF and a 2M × 16 × 4 bank SDRAM device, and Figure 12-5 shows an interface between the EMIF and a 512K × 16 × 2 bank SDRAM device. For devices supporting 16-bit interface, refer to Table 12-7 for list of commonly-supported SDRAM devices and the required connections for the address pins.

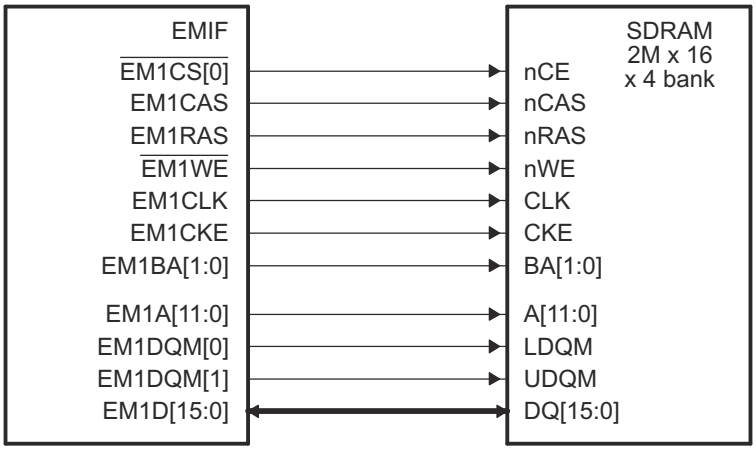

Figure 12-4. EMIF to 2M × 16 × 4 Bank SDRAM Interface

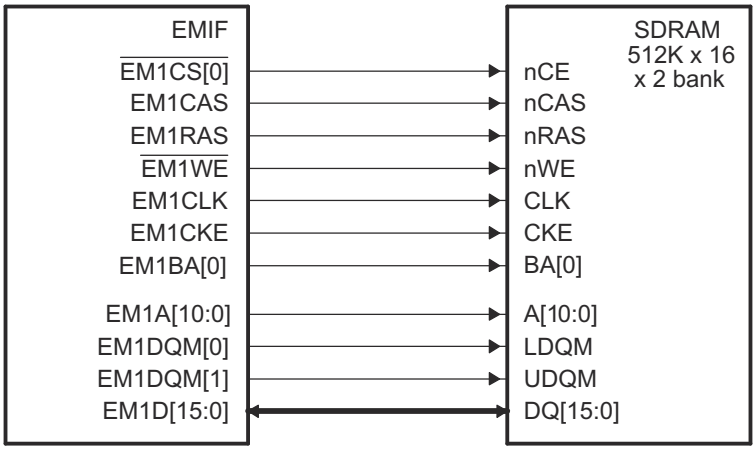

Figure 12-5. EMIF to 512K × 16 × 2 Bank SDRAM Interface

Table 12-7. 16-bit EMIF Address Pin Connections

SDRAM Size	Width	Banks	Device	Address Pins
16M bits	×16	2	SDRAM	A[10:0]
			EMIF	EM1A[10:0]
64M bits	×16	4	SDRAM	A[11:0]

			EMIF	EM1A[12:0]
512M bits	x16	4	SDRAM	A[12:0]
			EMIF	EM1A[12:0]

12.2.5.3 SDRAM Configuration Registers

The operation of the EMIF SDRAM interface is controlled by programming the appropriate configuration registers. This section describes the purpose and function of each configuration register, but Section 12.5 can be referred to for a more detailed description of each register, including the default registers values and bit-field positions. The following tables list the four such configuration registers, along with a description of each of their programmable fields.

Note

Writing to any of the fields: NM, CL, IBANK, and PAGESIZE in the SDRAM configuration register (SDRAM_CR) causes the EMIF to abandon whatever the EMIF is currently doing and trigger the SDRAM initialization procedure described in Section 12.2.5.4.

Table 12-8. Description of the SDRAM Configuration Register (SDRAM_CR)

Parameter	Description
SR	This bit controls entering and exiting of the self-refresh mode
PD	This bit controls entering and exiting of the power-down mode. If both SR and PD bits are set, the EMIF goes into self-refresh mode.
PDWR	Perform refreshes during power down. Writing a 1 to this bit causes the EMIF to exit the power-down state and issue an AUTO REFRESH command every time Refresh May level is set. This bit must be set along with PD when entering power-down mode.
NM	**Narrow Mode.** This bit defines the width of the data bus between the EMIF and the attached SDRAM device. When set to 1, the data bus is set to 16-bits. When set to 0, the data bus is set to 32-bits.
CL	**CAS latency.** This field defines the number of clock cycles between when an SDRAM issues a READ command and when the first piece of data appears on the bus. The value in this field is sent to the attached SDRAM device using the LOAD MODE REGISTER command during the SDRAM initialization procedure as described in Section 12.2.5.4. Only, values of 2h (CAS latency = 2) and 3h (CAS latency = 3) are supported and must be written to this field. While updating the CL field, BIT11_9LOCK bit field must be set to 1 simultaneously.
IBANK	**Number of Internal SDRAM Banks.** This field defines the number of banks inside the attached SDRAM devices in the following way: • When IBANK = 0, 1 internal bank is used • When IBANK = 1h, 2 internal banks are used • When IBANK = 2h, 4 internal banks are used This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See Section 12.2.5.11 for details.
PAGESIZE	**Page Size.** This field defines the internal page size of the attached SDRAM devices in the following way: • When PAGESIZE = 0, 256-word pages are used • When PAGESIZE = 1h, 512-word pages are used • When PAGESIZE = 2h, 1024-word pages are used • When PAGESIZE = 3h, 2048-word pages are used This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See Section 12.2.5.11 for details.

Table 12-9. Description of the SDRAM Refresh Control Register (SDRAM_RCR)

Parameter	Description
RR	**Refresh Rate**. This field controls the rate at which attached SDRAM devices are refreshed. The following equation can be used to determine the required value of RR for an SDRAM device: • RR = f_{EM1CLK} / (Required SDRAM Refresh Rate) More information about the operation of the SDRAM refresh controller is found in Section 12.2.5.6.

Table 12-10. Description of the SDRAM Timing Register (SDRAM_TR)

Parameter	Description
T_RFC T_RP T_RCD T_WR T_RAS T_RC T_RRD	**SDRAM Timing Parameters.** These fields configure the EMIF to comply with the AC timing requirements of the attached SDRAM devices. This allows the EMIF to avoid violating SDRAM timing constraints and to more efficiently schedule operations. More details about each of these parameters can be found in the SDRAM_TR register description. These parameters must be set to satisfy the corresponding timing requirements found in the SDRAM data sheet.

Table 12-11. Description of the SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG)

Parameter	Description
T_XS	**Self Refresh Exit Parameter.** The T_XS field of this register informs the EMIF about the minimum number of EM1CLK cycles required between exiting self-refresh and issuing any command. This parameter must be set to satisfy the t_{XSR} value for the attached SDRAM device.

12.2.5.4 SDRAM Auto-Initialization Sequence

The EMIF automatically performs an SDRAM initialization sequence, regardless of whether the EMIF is interfaced to an SDRAM device, when either of the following two events occur:

- The EMIF comes out of reset. No memory accesses to the SDRAM and asynchronous interfaces are performed until this auto-initialization is complete.
- A write is performed to any of the three least significant bytes of the SDRAM configuration register (SDRAM_CR)

An SDRAM initialization sequence consists of the following steps:

1. If the initialization sequence is activated by a write to SDRAM_CR, and if any of the SDRAM banks are open, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks. This is done so that the maximum ACTV to PRE timing for an SDRAM is not violated.
2. The EMIF drives EM1SDCKE high and begins continuously issuing NOP commands until eight SDRAM refresh intervals have elapsed. An SDRAM refresh interval is equal to the value of the RR field of the SDRAM refresh control register (SDRAM_RCR), divided by the frequency of EM1CLK (RR/f_{EM1CLK}). This step is used to avoid violating the power-up constraint of most SDRAM devices that requires 200 µs (sometimes 100 µs) between receiving stable Vdd and CLK and the issuing of a PRE command. Depending on the frequency of EM1CLK, this step may or may not be sufficient to avoid violating the SDRAM constraint. See Section 12.2.5.5 for more information.
3. After the refresh intervals have elapsed, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks.
4. The EMIF issues eight AUTO REFRESH commands.
5. The EMIF issues the LMR command with the EM1A[9:0] pins set as described in Table 12-12.
6. Finally, the EMIF performs a refresh cycle, which consists of the following steps:
   a. Issuing a PRE command with EM1A[10] held high if any banks are open
   b. Issuing an REF command

Table 12-12. SDRAM LOAD MODE REGISTER Command

EM1A[9:7]	EM1A[6:4]	EM1A[3]	EM1A[2:0]
0 (Write bursts are of the programmed burst length in EM1A[2:0])	These bits control the CAS latency of the SDRAM and are set according to CL field in the SDRAM configuration register (SDRAM_CR) as follows: • If CL = 2, EM1A[6:4] = 2h (CAS latency = 2) • If CL = 3, EM1A[6:4] = 3h (CAS latency = 3)	0 (Sequential Burst Type. Interleaved Burst Type not supported)	These bits control the burst length of the SDRAM and are set according to the NM field in the SDRAM configuration register (SDRAM_CR) as follows: • If NM = 0, EM1A[2:0] = 2h (Burst Length = 4) • If NM = 1, EM1A[2:0] = 3h (Burst Length = 8)

12.2.5.5 SDRAM Configuration Procedure

There are two different SDRAM configuration procedures. Although the EMIF automatically performs the SDRAM initialization sequence described in Section 12.2.5.4 when coming out of reset, it is recommended to follow one of the procedures before performing any EMIF memory requests.

Procedure A must be followed if the SDRAM power-up constraint was not violated during the SDRAM auto-initialization sequence detailed in Section 12.2.5.4 on coming out of Reset. The SDRAM power-up constraint specifies that 200 µs (sometimes 100 µs) must exist between receiving stable Vdd and CLK and the issuing of a PRE command.

Procedure B must be followed if the SDRAM power-up constraint was violated. The 200 µs (100 µs) SDRAM power-up constraint is violated, if the frequency of EM1CLK is greater than 50 MHz (100 MHz for 100 µs SDRAM power-up constraint) during SDRAM Auto-Initialization Sequence. Procedure B must be followed if there is any doubt that the power-up constraint was not met.

Procedure A — Following is the procedure to be followed if the SDRAM power-up constraint was NOT violated:

1. Place the SDRAM into self-refresh mode by setting the SR bit of SDRAM_CR to 1. The SDRAM can be placed into self-refresh mode when changing the frequency of the EM1CLK to avoid incurring the 200 µs power-up constraint again.
2. Configure the desired EMIF1 clock (EM1CLK) frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data manual.
3. Remove the SDRAM from self-refresh mode by clearing the SR bit of the SDRAM_CR to 0.
4. Program SDRAM_TR and SDR_EXT_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
5. Program the RR field of SDRAM_RCR to match that of the attached device's refresh interval. See Section 12.2.5.6.1 details on determining the appropriate value.
6. Program the SDRAM_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in Section 12.2.5.4 to be re-run. This second initialization generally takes much less time due to the increased frequency of EM1CLK.

Procedure B — Following is the procedure to be followed if the SDRAM power-up constraint was violated:

1. Configure the desired EM1CLK clock frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data manual.
2. Program SDRAM_TR and SDR_EXT_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
3. Program the RR field of the SDRAM_RCR such that the following equation is satisfied: $(RR \times 8)/(f_{EM1CLK}) >$ 200 µs (sometimes 100 µs). For example, an EM1CLK frequency of 100 MHz requires setting RR to 2501 (9C5h) or higher to meet a 200 µs constraint.
4. Program the SDRAM_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in Section 12.2.5.4 to be re-run with the new value of RR.
5. Perform a read from the SDRAM to make sure that step 5 of this procedure occurs after the initialization process has completed. Alternatively, wait for 200 µs instead of performing a read.
6. Finally, program the RR field to match that of the attached device's refresh interval. See Section 12.2.5.6.1 details on determining the appropriate value.

After following the above procedure, the EMIF is ready to perform accesses to the attached SDRAM device.

12.2.5.6 EMIF Refresh Controller

An SDRAM device requires that each of the rows be refreshed at a minimum required rate. The EMIF can meet this constraint by performing auto refresh cycles at or above this required rate. An auto-refresh cycle consists of issuing a PRE command to all banks of the SDRAM device followed by issuing a REFR command. To inform the EMIF of the required rate for performing auto refresh cycles, the RR field of the SDRAM refresh control register (SDRAM_RCR) must be programmed. The EMIF uses this value along with two internal counters to automatically perform auto refresh cycles at the required rate. The auto-refresh cycles cannot be disabled, even if the EMIF is not interfaced with an SDRAM. The remainder of this section details the EMIF's refresh scheme and provides an example for determining the appropriate value to place in the RR field of the SDRAM_RCR.

The two counters used to perform auto-refresh cycles are a 13-bit refresh interval counter and a 4-bit refresh backlog counter. At reset and upon writing to the RR field, the refresh interval counter is loaded with the value from RR field and begins decrementing, by one, each EMIF clock cycle. When the refresh interval counter reaches zero, the following actions occur:

- The refresh interval counter is reloaded with the value from the RR field and restarts decrementing.
- The 4-bit refresh backlog counter increments unless the counter has already reached the maximum value.

The refresh backlog counter records the number of auto refresh cycles that the EMIF currently has outstanding. This counter is decremented by one each time an auto refresh cycle is performed and incremented by one each time the refresh interval counter expires. The refresh backlog counter saturates at the values of 0000b and 1111b. The EMIF uses the refresh backlog counter to determine the urgency with which an auto refresh cycle must be performed. The four levels of urgency are described in Table 12-13. This refresh scheme allows the required refreshes to be performed with minimal impact on access requests.

Table 12-13. Refresh Urgency Levels

Urgency Level	Refresh Backlog Counter Range	Action Taken
Refresh May	1-3	An auto-refresh cycle is performed only if the EMIF has no requests pending and none of the SDRAM banks are open.
Refresh Release	4-7	An auto-refresh cycle is performed if the EMIF has no requests pending, regardless of whether any SDRAM banks are open.
Refresh Need	8-11	An auto-refresh cycle is performed at the completion of the current access unless there are read requests pending.
Refresh Must	12-15	Multiple auto-refresh cycles are performed at the completion of the current access until the Refresh Release urgency level is reached. At that point, the EMIF can begin servicing any new read or write requests.

12.2.5.6.1 Determining the Appropriate Value for the RR Field

The value that must be programmed into the RR field of the SDRAM_RCR must can be calculated by using the frequency of the EM1CLK signal (f_{EM1CLK}) and the required refresh rate of the SDRAM ($f_{Refresh}$). The following formula can be used:

$RR = f_{EM1CLK} / f_{Refresh}$

The SDRAM data sheet often communicates the required SDRAM Refresh Rate in terms of the number of REFR commands required in a given time interval. The required SDRAM Refresh Rate in the formula above can therefore be calculated by dividing the number of required cycles per time interval (n_{cycles}) by the time interval given in the data manual ($t_{Refresh\ Period}$) :

$f_{Refresh} = n_{cycles} / t_{Refresh\ Period}$

Combining these formulas, the value that must be programmed into the RR field can be computed as:

$RR = f_{EM1CLK} \times t_{Refresh\ Period} / n_{cycles}$

The following example illustrates calculating the value of RR. Given that:

- f_{EM1CLK} = 100 MHz (frequency of EMIF clock)
- $t_{Refresh\ Period}$ = 64 ms (required refresh interval of the SDRAM)
- n_{cycles} = 8192 (number of cycles in a refresh interval for the SDRAM)

RR can be calculated as:

RR = 100 MHz × 64 ms/8192

RR = 781.25

RR = 782 cycles = 30Eh cycles

12.2.5.7 Self-Refresh Mode

The EMIF can be programmed to enter the self-refresh state by setting the SR bit of SDRAM_CR to 1. This causes the EMIF to issue the SLFR command after completing any outstanding SDRAM access requests and clearing the refresh backlog counter by performing one or more auto refresh cycles. This places the attached SDRAM device into self-refresh mode in which the EMIF consumes a minimal amount of power while performing the refresh cycles.

While in the self-refresh state, the EMIF continues to service asynchronous bank requests and register accesses as normal, with one caveat. The EMIF does not park the data bus following a read to asynchronous memory while in the self-refresh state. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state to prevent floating inputs on the data bus. More information about data bus parking can be found in Section 12.2.7.

The EMIF exits from the self-refresh state, if either of the following events occur:

- The SR bit of SDRAM_CR is cleared to 0.
- An SDRAM accesses is requested.

The EMIF exits from the self-refresh state by driving EM1SDCKE high and performing an auto refresh cycle.

The attached SDRAM device must also be placed into self-refresh mode when changing the frequency of EM1CLK. If the frequency of EM1CLK changes while the SDRAM is not in self-refresh mode, Procedure B in Section 12.2.5.5 must be followed to reinitialize the device.

12.2.5.8 Power-Down Mode

To support low-power modes, the EMIF can be requested to issue a POWER DOWN command to the SDRAM by setting the PD bit in the SDRAM configuration register (SDRAM_CR). When this bit is set, the EMIF continues normal operation until all outstanding memory access requests have been serviced and the SDRAM refresh backlog (if there is one) has been cleared. At this point, the EMIF enters the power-down state. Upon entering this state, the EMIF issues a POWER DOWN command (same as a NOP command but driving the EM1SDCKE low on the same cycle). The EMIF then maintains the EM1SDCKE low until the EMIF exits the power-down state.

Since the EMIF services the refresh backlog before the EMIF enters the power-down state, all internal banks of the SDRAM are closed (precharged) prior to issuing the POWER DOWN command. Therefore, the EMIF only supports precharge power-down. The EMIF does not support active power-down, where internal banks of the SDRAM are open (active) before the POWER DOWN command is issued.

During the power-down state, the EMIF services the SDRAM, asynchronous memory, and register accesses as normal, returning to the power-down state upon completion.

The PDWR bit in the SDRAM_CR indicates whether the EMIF must perform refreshes in power-down state. If the PDWR bit is set, the EMIF exits the power-down state every time the Refresh Must level is set, performs AUTO REFRESH commands to the SDRAM, and returns back to the power-down state. This evenly distributes the refreshes to the SDRAM in power-down state. If the PDWR bit is not set, the EMIF does not perform any refreshes to the SDRAM. Therefore, the data integrity of the SDRAM is not maintained upon power-down exit, if the PDWR bit is not set.

If the PD bit is cleared while in the power-down state, the EMIF comes out of the power-down state. The EMIF:

- Drives EM1SDCKE high
- Enters the idle state

12.2.5.9 SDRAM Read Operation

When the EMIF receives a read request to the SDRAM from one of the requesters listed in Section 12.2.2, the EMIF performs one or more read access cycles. A read access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a READ command while specifying the desired bank and column address. EM1A[10] is held low during the READ command to avoid auto-precharging. The READ command signals the SDRAM device to output data from the specified address while EMIF issues NOP commands. Following a READ command, the CL field of the SDRAM configuration register (SDRAM_CR) defines how many delay cycles are present before the read data appears on the data bus. This is referred to as the CAS latency.

Figure 12-6 shows the signal waveforms for a basic SDRAM read operation in which multiple data is read from a single page. On this device, burst accesses are not supported; hence, the EMIF issues a READ command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM_CR) to 1 and CPU (or any other master) does a 32-bit READ access, a burst access is issued with a size of two.

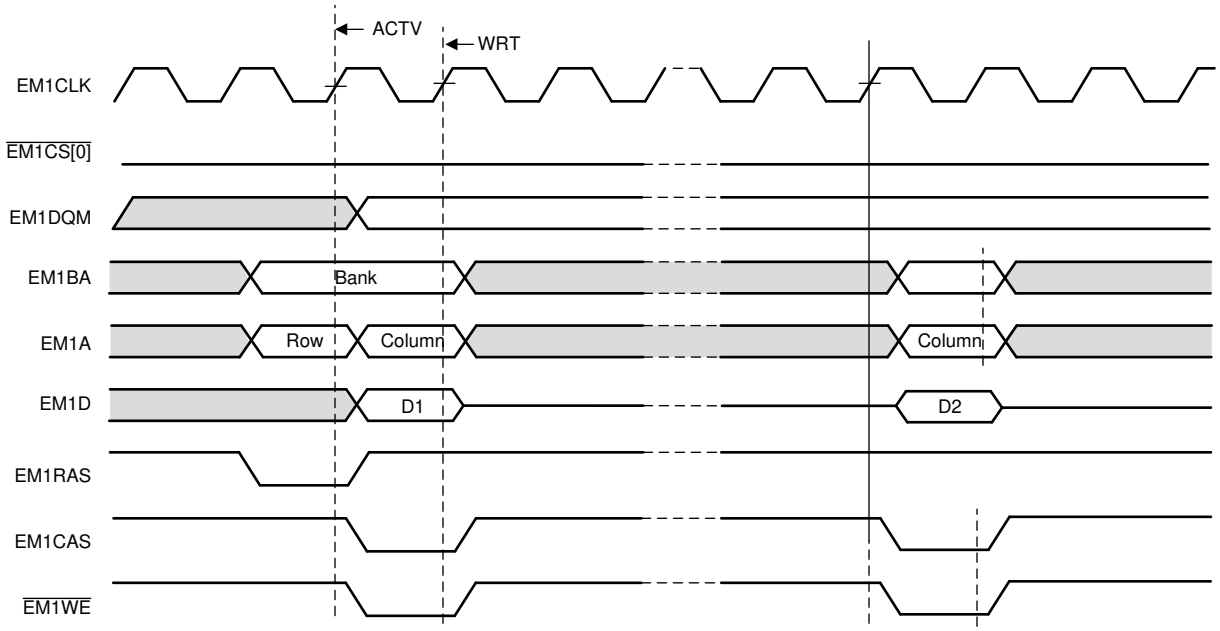

Figure 12-6. Timing Waveform for Basic SDRAM Read Operation

Several other pins are also active during a read access. The EM1DQM[x:0] pins are driven low during the READ commands and are kept low during the NOP commands that correspond to the burst request. The state of the other EMIF pins during each command can be found in Table 12-6.

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data manual. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands between various commands during an access. Refer to the register description of SDRAM_TR in the SDTIMER register for more details on the various timing parameters.

12.2.5.10 SDRAM Write Operations

When the EMIF receives a write request to SDRAM from one of the requesters listed in Section 12.2.2, the EMIF performs one or more write-access cycles. A write-access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a WRT command while specifying the desired bank and column address. EM1A[10] is held low during the WRT command to avoid auto-precharging. The WRT command signals the SDRAM device to start writing the given data to the specified address while the EMIF issues NOP commands. On this device, burst accesses are not supported; hence, the EMIF issues a WRITE command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM_CR) to 1 and CPU (or any other master) does a 32bit WRITE access, a burst access is issued with size of two.

Figure 12-7 shows the signal waveforms for a basic SDRAM write operation.

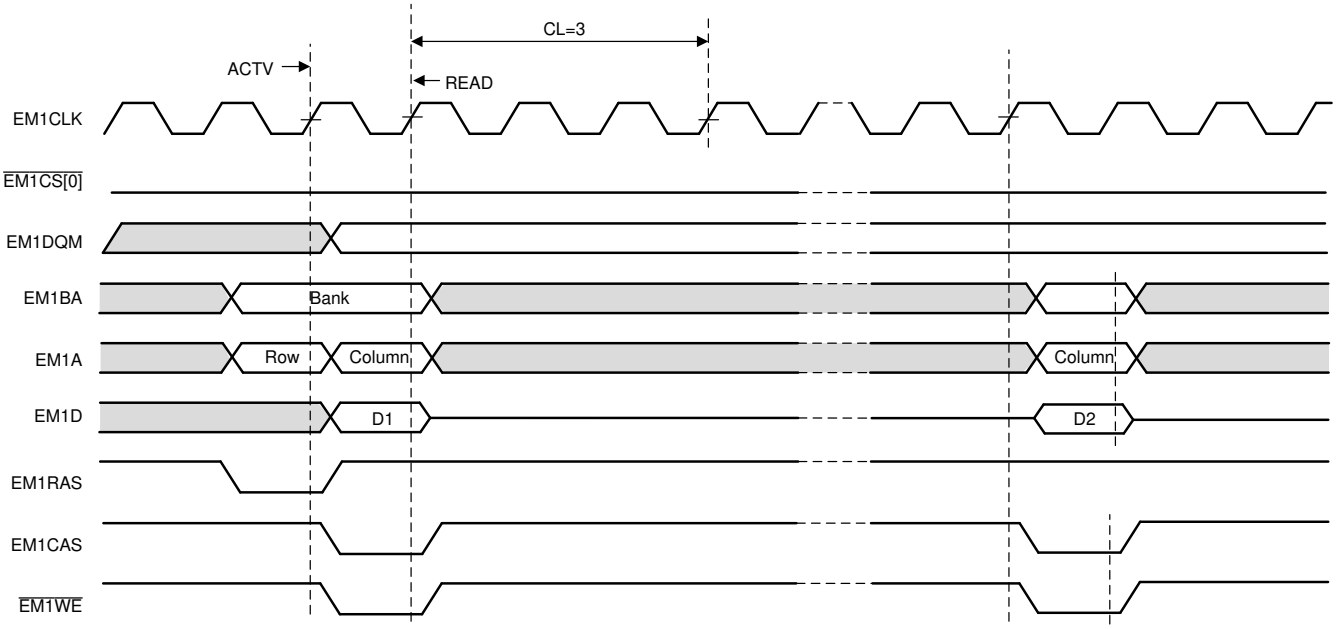

Figure 12-7. Timing Waveform for Basic SDRAM Write Operation

The EMIF truncates a series of bursting data if the remaining addresses of the burst are not part of the write request. The EMIF can truncate the burst in three ways:

- By issuing another WRT to the same page
- By issuing a PRE command to prepare for accessing a different page of the same bank
- By issuing a BT command to prepare for accessing a page in a different bank

Several other pins are also active during a write access. The EM1DQM[x:0] pins are driven to select which bytes of the data word are written to the SDRAM device. The pins are also used to mask out entire undesired data words during a burst access. The state of the other EMIF pins during each command can be found in Table 12-6.

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data sheet. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands during various cycles of an access. Refer to the register description of SDRAM_TR in the SDTIMR register for more details on the various timing parameters.

12.2.5.11 Mapping from Logical Address to EMIF Pins

When the EMIF receives an SDRAM access request, it must convert the address of the access into the appropriate signals to send to the SDRAM device. The details of this address mapping are shown in Table 12-14 for 32-bit operation and in Table 12-15 for 16-bit operation. Using the settings of the IBANK and PAGESIZE fields of the SDRAM configuration register (SDRAM_CR), the EMIF determines which bits of the logical address will be mapped to the SDRAM row, column, and bank addresses.

As the logical address is incremented by one halfword (16-bit operation), the column address is likewise incremented by one until a page boundary is reached. When the logical address increments across a page boundary, the EMIF moves into the same page in the next bank of the attached device by incrementing the bank address EM1BA and resetting the column address. The page in the previous bank is left open until it is necessary to close it. This method of traversal through the SDRAM banks helps maximize the number of open banks inside of the SDRAM and results in an efficient use of the device. There is no limitation on the number of banks that can be open at one time, but only one page within a bank can be open at a time.

The EMIF uses the EM1DQM[3:0] pins during a WRT command to mask out selected bytes or entire words. The EM1DQM[3:0] pins are always low during a READ command.

Table 12-14. Mapping from Logical Address to EMIF Pins for 32-bit SDRAM

IBANK	PAGESIZE	Logical Address													
		31:27	26	25	24	23	22	21:14	13	12	11	10	9	8:1	0
0	0	-						Row Address						Col Address	EM1DQM[2]/EM1DQM[3]
1	0	-						Row Address					EM1BA[0]	Col Address	EM1DQM[2]/EM1DQM[3]
2	0	-						Row Address				EM1BA[1:0]		Col Address	EM1DQM[2]/EM1DQM[3]
0	1	-						Row Address					Column Address		EM1DQM[2]/EM1DQM[3]
1	1	-						Row Address			EM1BA[0]		Column Address		EM1DQM[2]/EM1DQM[3]
2	1	-						Row Address			EM1BA[1:0]		Column Address		EM1DQM[2]/EM1DQM[3]
0	2	-						Row Address				Column Address			EM1DQM[2]/EM1DQM[3]
1	2	-						Row Address			EM1BA[0]	Column Address			EM1DQM[2]/EM1DQM[3]
2	2	-						Row Address		EM1BA[1:0]		Column Address			EM1DQM[2]/EM1DQM[3]
0	3	-						Row Address			Column Address				EM1DQM[2]/EM1DQM[3]
1	3	-						Row Address		EM1BA[0]	Column Address				EM1DQM[2]/EM1DQM[3]
2	3	-						Row Address		EM1BA[1:0]	Column Address				EM1DQM[2]/EM1DQM[3]

Table 12-15. Mapping from Logical Address to EMIF Pins for 16-bit SDRAM

IBANK	PAGESIZE	Logical Address												
		31:26	25	24	23	22	21	20:13	12	11	10	9	8	7:0
0	0	-						Row Address						Col Address
1	0	-						Row Address					EM1BA[0]	Col Address
2	0	-						Row Address				EM1BA[1:0]		Col Address
0	1	-						Row Address					Column Address	
1	1	-						Row Address				EM1BA[0]	Column Address	
2	1	-						Row Address			EM1BA[1:0]		Column Address	
0	2	-						Row Address				Column Address		
1	2	-						Row Address			EM1BA[0]	Column Address		
2	2	-						Row Address		EM1BA[1:0]		Column Address		
0	3	-						Row Address			Column Address			
1	3	-						Row Address		EM1BA[0]	Column Address			
2	3	-						Row Address		EM1BA[1:0]	Column Address			

Note

The upper bit of the row address is used only when addressing 256-Mbit and 512-Mbit SDRAM memories.

12.2.6 Asynchronous Controller and Interface

The EMIF easily interfaces to a variety of asynchronous devices including NOR Flash and SRAM. It can be operated in two major modes (see Table 12-16):

- Normal Mode
- Select Strobe Mode

Table 12-16. Normal Mode vs. Select Strobe Mode

Mode	Function of EM1DQM pins	Operation of $\overline{\text{EM1CS}}$[4:2]
Normal Mode	Byte enables	Active during the entire asynchronous access cycle
Select Strobe Mode	Byte enables	Active only during the strobe period of an access cycle

The first mode of operation is normal mode, in which the EM1DQM pins of the EMIF function as byte enables. In this mode, the $\overline{\text{EM1CS}}$[4:2] pins behave as typical chip select signals, remaining active for the duration of the asynchronous access. See Section 12.2.6.1 for an example interface with multiple 8-bit devices.

The second mode of operation is select strobe mode, in which the $\overline{\text{EM1CS}}$[4:2] pins act as a strobe, active only during the strobe period of an access. In this mode, the EM1DQM pins of the EMIF function as standard byte enables for reads and writes. A summary of the differences between the two modes of operation are shown in Table 12-16. Refer to Section 12.2.6.4 for the details of asynchronous operations in normal mode, and to Section 12.2.6.5 for the details of asynchronous operations in select strobe mode. The EMIF hardware defaults to normal mode, but can be manually switched to select strobe mode by setting the SS bit in the asynchronous *m* (m = 1, 2, 3, or 4) configuration register (CE*n*CFG) (*n* = 2, 3, or 4). Throughout the chapter, *m* can hold the values 1, 2, 3 or 4; and *n* can hold the values 2, 3, or 4.

In both normal mode and select strobe mode, EMIF can be configured to operate in a sub-mode called NAND Flash Mode. In NAND Flash Mode, the EMIF is able to calculate an error correction code (ECC) for transfers up to 512 bytes.

The EMIF also provides configurable cycle timing parameters and an extended wait mode that allows the connected device to extend the strobe period of an access cycle. The following sections describe the features related to interfacing with external asynchronous devices.

12.2.6.1 Interfacing to Asynchronous Memory

Figure 12-8 shows the EMIF's external pins used in interfacing with an asynchronous device. In $\overline{\text{EM1CS}}$[n], n = 2, 3, or 4.

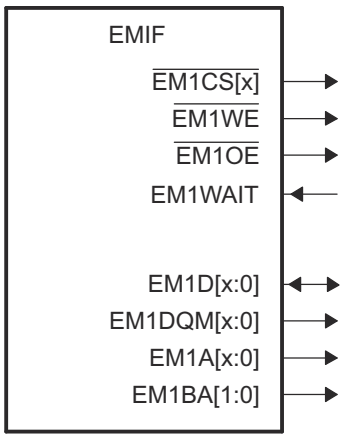

Figure 12-8. EMIF Asynchronous Interface

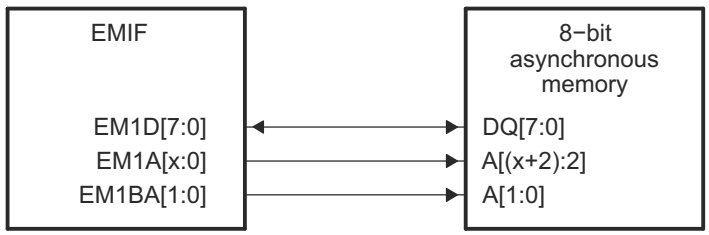
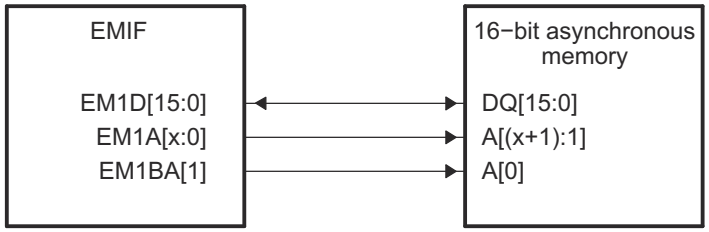
Of special note is the connection between the EMIF and the external device's address bus. The EMIF address pin EM1A[0] always provides the least-significant bit of a 32-bit word address. Therefore, when interfacing to a 16-bit or 8-bit asynchronous device, the EM1BA[1] and EM1BA[0] pins provide the least-significant bits of the halfword or byte address, respectively. Figure 12-9 and Figure 12-10 show the mapping between the EMIF and the connected device's data and address pins for various programmed data bus widths. The data bus width can be configured in the asynchronous *n* configuration register (ASYNC_CS*n*_CR).

Figure 12-10 shows an interface between the EMIF and an external memory with byte enables. The EMIF must be operated in either normal mode or select strobe mode when using this interface, so that the EM1DQM signals operate as byte enables.



a) EMIF to 8-bit memory interface



b) EMIF to 16-bit memory interface

Figure 12-9. EMIF to 8-bit/16-bit Memory Interface

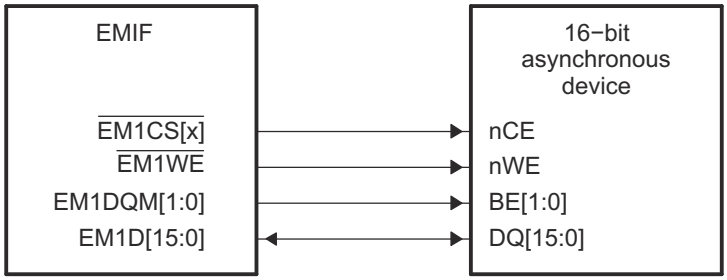


Figure 12-10. Common Asynchronous Interface

12.2.6.2 Accessing Larger Asynchronous Memories

If a device such as a large asynchronous Flash needs to be attached to the EMIF, then GPIO pins may be used to control the Flash device upper address lines.

12.2.6.3 Configuring EMIF for Asynchronous Accesses

The operation of the EMIF's asynchronous interface can be configured by programming the appropriate register fields. The reset value and bit position for each register field can be found in Section 12.5. The following tables list the register fields that can be programmed and describe the purpose of each field. These registers can be programmed prior to accessing the external memory, and the transfer following a write to these registers uses the new configuration.

Table 12-17. Description of the Asynchronous *m* Configuration Register (ASYNC_CSn_CR)

Parameter	Description
SS	**Select Strobe mode.** This bit selects the EMIF's mode of operation in the following way: • SS = 0 selects Normal Mode – EM1DQM pins function as byte enables – $\overline{\text{EM1CS}}$[4:2] active for duration of access • SS = 1 selects Select Strobe Mode – EM1DQM pins function as byte enables – $\overline{\text{EM1CS}}$[4:2] acts as a strobe.
EW	**Extended Wait Mode enable.** • EW = 0 disables Extended Wait Mode • EW = 1 enables Extended Wait Mode When set to 1, the EMIF enables the Extended Wait Mode in which the strobe width of an access cycle can be extended in response to the assertion of the EM1WAIT pin. The WP*n* bit in the asynchronous wait cycle configuration register (AWCC) controls the polarity of the EM1WAIT pin. Extended Wait Mode must not be used while in NAND Flash Mode. See Section 12.2.6.6 for more details on this mode of operation.
W_SETUP/R_SETUP	**Read/Write setup widths.** These fields define the number of EMIF clock cycles of setup time for the address pins (EM1A), byte enables (EM1DQM), and asynchronous chip enable ($\overline{\text{EM1CS}}$[4:2]) before the read strobe pin (EM103) or write strobe pin ($\overline{\text{EM1WE}}$) falls, minus one cycle. For writes, the W_SETUP field also defines the setup time for the data pins (EM1D). Refer to the asynchronous device 's data sheet to determine the appropriate setting for this field.
W_STROBE/R_STROBE	**Read/Write strobe widths.** These fields define the number of EMIF clock cycles between the falling and rising of the read strobe pin (EM103) or write strobe pin (EM1WEn), minus one cycle. If Extended Wait Mode is enabled by setting the EW field in the asynchronous *n* configuration register (ASYNC_CS*n*_CR), these fields must be set to a value greater than zero. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.
W_HOLD/R_HOLD	**Read/Write hold widths.** These fields define the number of EMIF clock cycles of hold time for the address pins (EM1A and EM1BA), byte enables (EM1DQM), and asynchronous chip enable ($\overline{\text{EM1CS}}$[4:2]) after the read strobe pin (EM103) or write strobe pin ($\overline{\text{EM1WE}}$) rises, minus one cycle. For writes, the W_HOLD field also defines the hold time for the data pins (EM1D). Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.
TA	**Minimum turnaround time.** This field defines the minimum number of EMIF clock cycles between asynchronous reads and writes, minus one cycle. The purpose of this feature is to avoid contention on the bus. The value written to this field also determines the number of cycles that are inserted between asynchronous accesses and SDRAM accesses. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.

Table 12-17. Description of the Asynchronous *m* Configuration Register (ASYNC_CSn_CR) (continued)

Parameter	Description
ASIZE	**Asynchronous Device Bus Width.** This field determines the data bus width of the asynchronous interface in the following way: • ASIZE = 0 selects an 8-bit bus • ASIZE = 1 selects a 16-bit bus • ASIZE = 2 selects a 32-bit bus The configuration of ASIZE determines the function of the EM1A and EM1BA pins as described in Section 12.2.6.1. This field also determines the number of external accesses required to fulfill a request generated by one of the sources mentioned in Section 12.2.2. For example, a request for a 32-bit word requires four external access when ASIZE = 0. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.

Table 12-18. Description of the Asynchronous Wait Cycle Configuration Register (ASYNC_WCCR)

Parameter	Description
WP*n*	**EM_WAIT Polarity.** • WP*n* = 0 selects active-low polarity • WP*n* = 1 selects active-high polarity When set to 1, the EMIF waits if the EM1WAIT pin is high. When cleared to 0, the EMIF waits if the EM1WAIT pin is low. The EMIF must have the Extended Wait Mode enabled for the EM1WAIT pin to affect the width of the strobe period. The polarity of the EM1WAIT signal is not programmable in NAND Flash Mode.
MAX_EXT_WAIT	**Maximum Extended Wait Cycles.** This field configures the number of EMIF clock cycles the EMIF waits for the EM1WAIT pin to be deactivated during the strobe period of an access cycle. The maximum number of EMIF clock cycles the EMIF waits is determined by the following formula: Maximum Extended Wait Cycles = (MAX_EXT_WAIT + 1) × 16 If the EM1WAIT pin is not deactivated within the time specified by this field, the EMIF resumes the access cycle, registering whatever data is on the bus and proceeding to the hold period of the access cycle. This situation is referred to as an Asynchronous Timeout. An Asynchronous Timeout generates an interrupt, if the interrupt has been enabled in the EMIF interrupt mask set register (INT_MSK_SET). Refer to Section 12.2.9.1 for more information about EMIF interrupts. Extended Wait Mode can not be used while in NAND Flash Mode.

Table 12-19. Description of EMIF Interrupt Mask Set Register (INT_MSK_SET)

Parameter	Description
WR_MASK_SET	**Wait Rise Mask Set.** Writing a 1 enables an interrupt to be generated when a rising edge on EM1WAIT occurs.
AT_MASK_SET	**Asynchronous Timeout Mask Set.** Writing a 1 to this bit enables an interrupt to be generated when an Asynchronous Timeout occurs.

Table 12-20. Description of EMIF Interrupt Mast Clear Register (INT_MSK_CLR)

Parameter	Description
WR_MASK_CLR	**Wait Rise Mask Clear.** Writing a 1 to this bit disables the interrupt, clearing the WR_MASK_SET bit in EMIF interrupt mask set register (INT_MSK_SET).
AT_MASK_CLR	**Asynchronous Timeout Mask Clear.** Writing a 1 to this bit prevents an interrupt from being generated when an Asynchronous Timeout occurs.

Note

The EMIF performs SDRAM refreshes even if the SDRAM interface is not used. If using only the ASRAM interface, then SDRAM refreshes impact the ASRAM performance. To avoid this, set PD=1 in the SDRAM_CR register (Emif1Regs.SDRAM_CR.bit.PD=1). This bit can be updated only if there are no pending EMIF accesses.

12.2.6.4 Read and Write Operations in Normal Mode

Normal mode is the asynchronous interface's default mode of operation. It is selected when the SS bit in the asynchronous *n* configuration register (ASYNC_CS*n*_CR) is cleared to 0. In this mode, the EM1DQM pins operate as byte enables. Section 12.2.6.4.1 and Section 12.2.6.4.2 explain the details of read and write operations while in normal mode.

12.2.6.4.1 Asynchronous Read Operations (Normal Mode)

Note

During an entire asynchronous read operation, the $\overline{\text{EM1WE}}$ pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in Section 12.2.2 request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 12.2.13. In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by EMIF until the entire request is fulfilled. The details of an asynchronous read operation in normal mode are described in Table 12-21. Also, Figure 12-11 shows an example timing diagram of a basic read operation.

Table 12-21. Asynchronous Read Operation in Normal Mode

Time Interval	Pin Activity in Normal Mode
Turnaround period	Once the read operation becomes the highest priority task for EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CS*n*_CR). Between each access (write or read), the EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS*n*_CR. • The address pins EM1A and EM1BA become valid and carry the values described in Section 12.2.6.1. • $\overline{\text{EM1CS}}$[4:2] falls to enable the external device (if not already low from a previous operation)

Table 12-21. Asynchronous Read Operation in Normal Mode (continued)

Time Interval	Pin Activity in Normal Mode
Strobe period	The following actions occur during the strobe period of a read operation: 1. $\overline{\text{EM1OE}}$ falls at the start of the strobe period 2. On the rising edge of the clock that is concurrent with the end of the strobe period: • $\overline{\text{EM1OE}}$ rises • The data on the EM1Dx bus is sampled by EMIF. In Figure 12-11, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. Section 12.2.6.6 contains more details on using the EM1WAIT pin.
End of the hold period	At the end of the hold period: • The address pins EM1A and EM1BA become invalid • $\overline{\text{EM1CS}}$[4:2] rises (if no more operations are required to complete the current request) The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turn-round cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, EMIF instead enters directly into the turnaround period for the pending read or write operation.

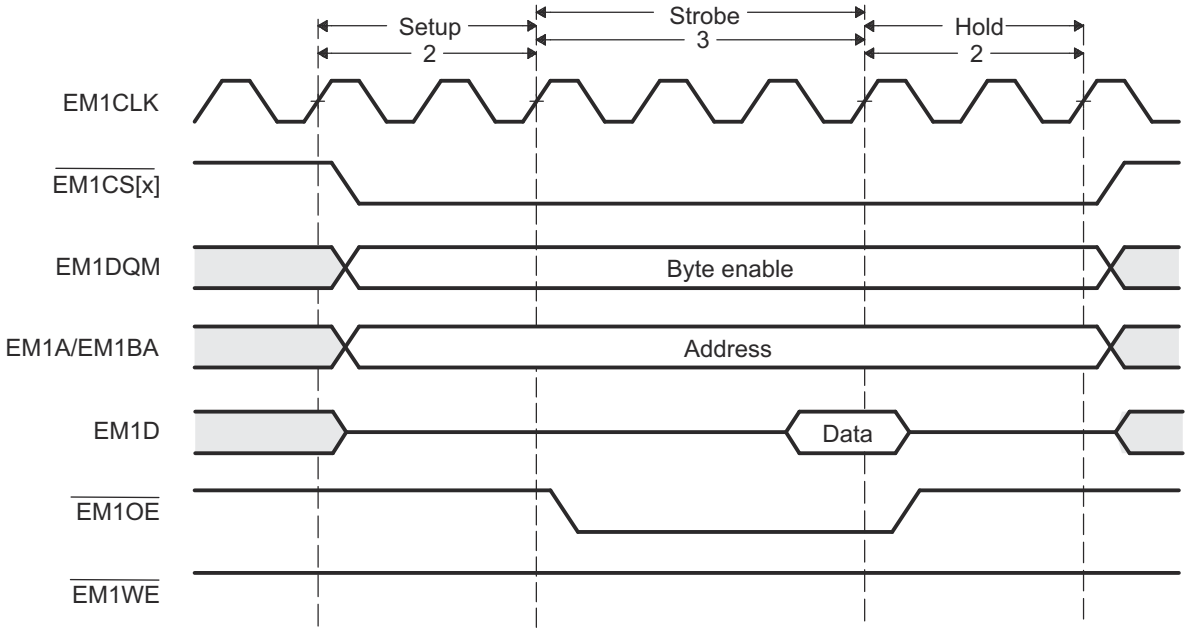

Figure 12-11. Timing Waveform of an Asynchronous Read Cycle in Normal Mode

12.2.6.4.2 Asynchronous Write Operations (Normal Mode)

Note

During an entire asynchronous write operation, the $\overline{\text{EM1OE}}$ pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in Section 12.2.2 request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 12.2.13. In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in normal mode are described in Table 12-22. Also, Figure 12-12 shows an example timing diagram of a basic write operation.

Table 12-22. Asynchronous Write Operation in Normal Mode

Time Interval	Pin Activity in Normal Mode
Turnaround period	Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CS*n*_CR). Between each access (write or read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CS*n*_CR. • The address pins EM1A and EM1BA and the data pins EM1Dx become valid. The EM1A and EM1BA pins carry the values described in Section 12.2.6.1. • $\overline{\text{EM1CS}}$[4:2] falls to enable the external device (if not already low from a previous operation).
Strobe period	The following actions occur at the start of the strobe period of a write operation: 1. $\overline{\text{EM1WE}}$ falls 2. The EM1DQM pins become valid as byte enables. The following actions occur on the rising edge of the clock that is concurrent with the end of the strobe period: 1. $\overline{\text{EM1WE}}$ rises 2. The EM1DQM pins deactivate In Figure 12-12, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to accept the data. Section 12.2.6.6 contains more details on using the EM1WAIT pin.
End of the hold period	At the end of the hold period: • The address pins EM1Ax and EM1BAx become invalid • The data pins become invalid • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) rises (if no more operations are required to complete the current request) The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.

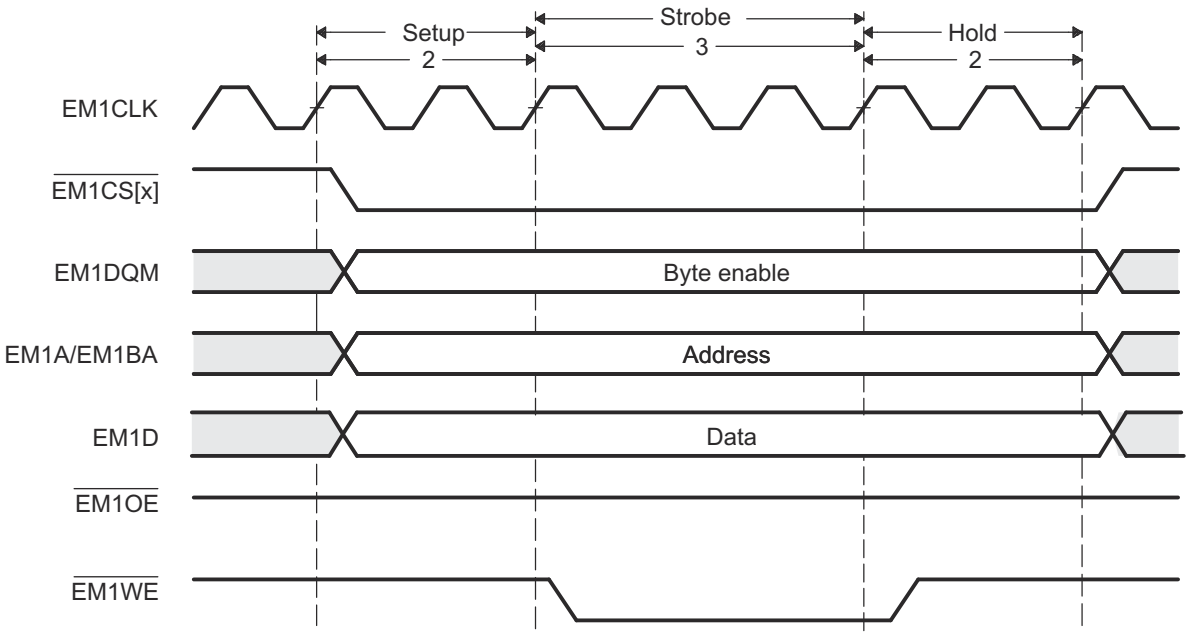

Figure 12-12. Timing Waveform of an Asynchronous Write Cycle in Normal Mode

12.2.6.5 Read and Write Operation in Select Strobe Mode

Select Strobe Mode is the EMIF's second mode of operation. It is selected when the SS bit of the asynchronous *n* configuration register (ASYNC_CSn_CR) is set to 1. In this mode, the EM1DQM pins operate as byte enables and the $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) pin is only active during the strobe period of an access cycle. Section 12.2.6.4.1 and Section 12.2.6.4.2 explain the details of read and write operations while in select strobe mode.

12.2.6.5.1 Asynchronous Read Operations (Select Strobe Mode)

Note

During the entirety of an asynchronous read operation, the EM1WEn pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in Section 12.2.2 request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 12.2.13. In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous read operation in select strobe mode are described in Table 12-23. Also, Figure 12-13 shows an example timing diagram of a basic read operation.

Table 12-23. Asynchronous Read Operation in Select Strobe Mode

Time Interval	Pin Activity in Select Strobe Mode
Turnaround period	Once the read operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CSn_CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS*n*_CR. • The address pins EM1A and EM1BA become valid and carry the values described in Section 12.2.6.1. • The EM1DQM pins become valid as byte enables.

Strobe period	The following actions occur during the strobe period of a read operation:
	1. $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1OE}}$ fall at the start of the strobe period
	2. On the rising edge of the clock that is concurrent with the end of the strobe period:
	  • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM10E}}$ rise
	  • The data on the EM1D bus is sampled by EMIF.
	In Figure 12-13, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. Section 12.2.6.6 contains more details on using the EM1WAIT pin.

End of the hold period	At the end of the hold period: • The address pins EM1A and EM1BA become invalid • The EM1DQM pins become invalid The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.

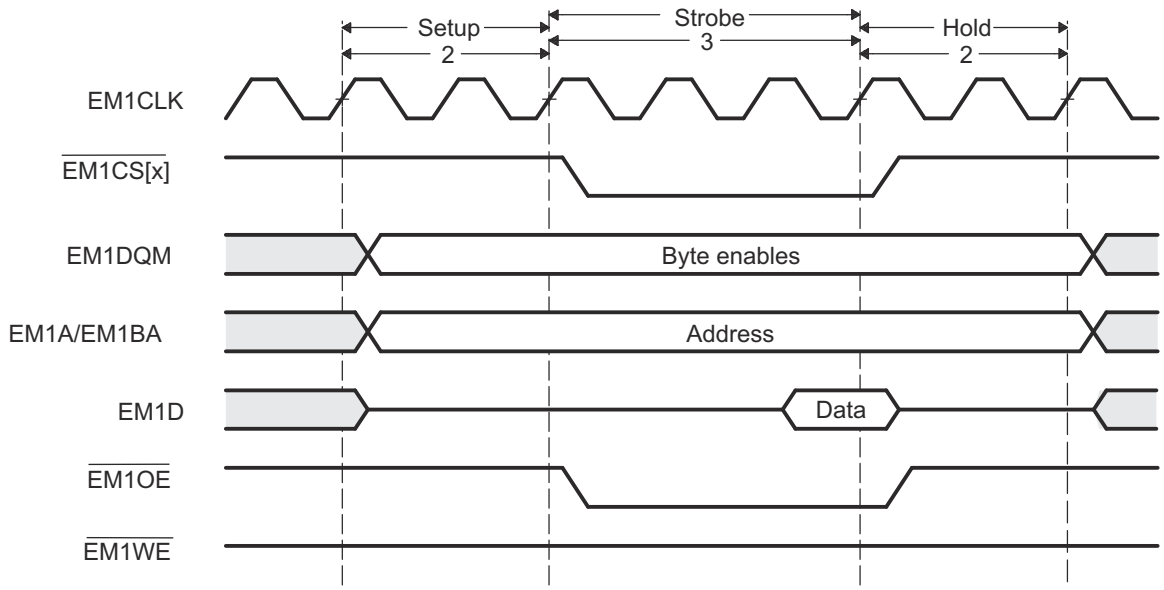

Figure 12-13. Timing Waveform of an Asynchronous Read Cycle in Select Strobe Mode

12.2.6.5.2 Asynchronous Write Operations (Select Strobe Mode)

Note

During the entirety of an asynchronous write operation, the $\overline{\text{EM1OE}}$ pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in Section 12.2.2 request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 12.2.13. In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in select strobe mode are described in Table 12-24. Also, Figure 12-14 shows an example timing diagram of a basic write operation.

Table 12-24. Asynchronous Write Operation in Select Strobe Mode

Time Interval	Pin Activity in Select Strobe Mode
Turnaround period	Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CSn_CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CSn_CR. • The address pins EM1A and EM1BA and the data pins EM1D become valid. The EM1A and EM1BA pins carry the values described in Section 12.2.6.1. • The EM1DQM pins become active as byte enables.
Strobe period	The following actions occur at the start of the strobe period of a write operation: • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1WE}}$ fall The following actions occur on the rising edge of the clock which is concurrent with the end of the strobe period: • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1WE}}$ rise In Figure 12-14, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to accept the data. Section 12.2.6.6 contains more details on using the EM1WAIT pin.
End of the hold period	At the end of the hold period: • The address pins EM1A and EM1BA become invalid • The data pins become invalid • The EM1DQM pins become invalid The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.

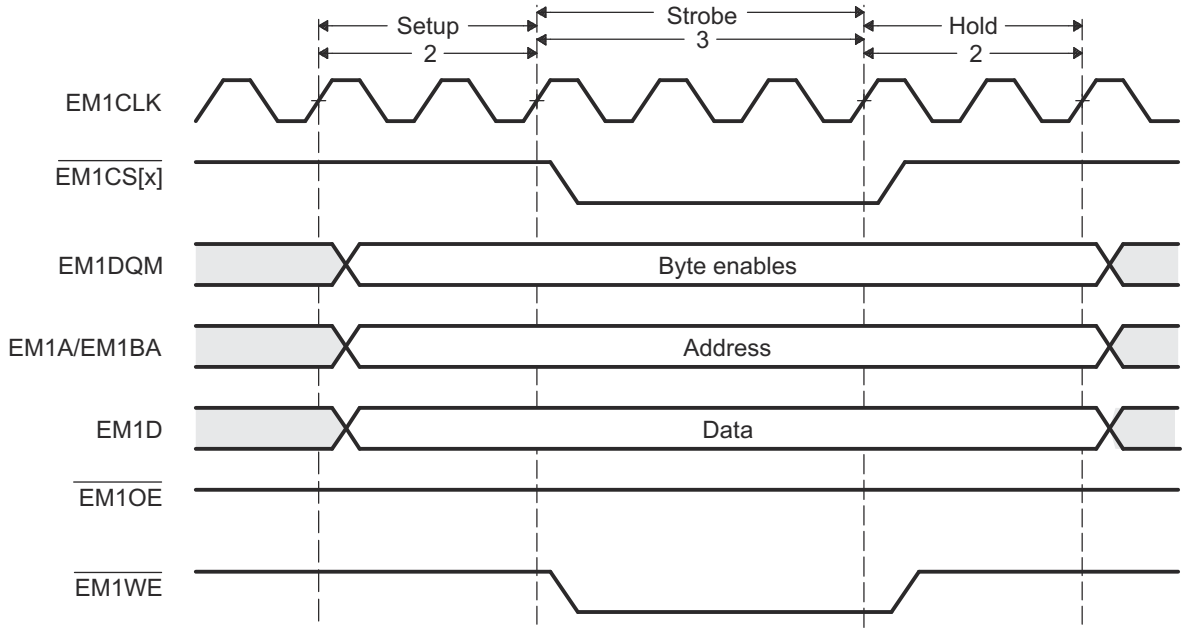

Figure 12-14. Timing Waveform of an Asynchronous Write Cycle in Select Strobe Mode

12.2.6.6 Extended Wait Mode and the EM1WAIT Pin

The EMIF supports the extend wait mode. This is a mode in which the external asynchronous device may assert control over the length of the strobe period. The extended wait mode can be entered by setting the EW bit in the asynchronous *n* configuration register (ASYNC_CS*n*_CR (*n* = 2, 3, or 4). When this bit is set, the EMIF monitors the EM1WAIT pin to determine if the attached device wishes to extend the strobe period of the current access cycle beyond the programmed number of clock cycles.

When the EMIF detects that the EM1WAIT pin has been asserted, it will begin inserting extra strobe cycles into the operation until the EM1WAIT pin is deactivated by the external device. The EMIF will then return to the last cycle of the programmed strobe period and the operation will proceed as usual from this point. Please refer to the device data manual for details on the timing requirements of the EM1WAIT signal.

The EM1WAIT pin cannot be used to extend the strobe period indefinitely. The programmable MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC) determines the maximum number of EM1CLK cycles the strobe period may be extended beyond the programmed length. When the counter expires, the EMIF proceeds to the hold period of the operation regardless of the state of the EM1WAIT pin. The EMIF can also generate an interrupt upon expiration of this counter. See Section 12.2.9.1 for details on enabling this interrupt.

For the EMIF to function properly in the extended wait mode, the WP*n* bit of AWCC must be programmed to match the polarity of the EM1WAIT pin. In its reset state of 1, the EMIF will insert wait cycles when the EM1WAIT pin is sampled high. When set to 0, the EMIF will insert wait cycles only when EM1WAIT is sampled low. This programmability allows for a glueless connection to larger variety of asynchronous devices.

Finally, a restriction is placed on the strobe period timing parameters when operating in extended wait mode. Specifically, the sum of the W_SETUP and W_STROBE fields must be greater than four, and the sum of the R_SETUP and R_STROBE fields must be greater than four for the EMIF to recognize the EM1WAIT pin has been asserted. The W_SETUP, W_STROBE, R_SETUP, and R_STROBE fields are in ASYNC_CS*n*_CR.

12.2.7 Data Bus Parking

The EMIF always drives the data bus to the previous write data value when the EMIF is idle. This feature is called data bus parking. Only when the EMIF issues a read command to the external memory does the EMIF stop driving the data bus. After the EMIF latches the last read data, the EMIF immediately parks the data bus again.

The one exception to this behavior occurs after performing an asynchronous read operation while the EMIF is in the self-refresh state. In this situation, the read operation is not followed by the EMIF parking the data bus. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state, to prevent floating inputs on the data bus. External pull-ups, such as 10-kohm resistors, must be placed on the 16 EMIF data bus pins (that do not have internal pull-ups) if required to perform reads in this situation. The precise resistor value must be chosen so that the worst case combined off-state leakage currents do not cause the voltage levels on the associated pins to drop below the high-level input voltage requirement.

For information about the self-refresh state, see Section 12.2.5.7.

12.2.8 Reset and Initialization Considerations

The EMIF memory controller has two active-low reset signals, CHIP_RST_n and MOD_G_RST_n. Both these reset signals are driven by the device system reset signal. This device does not offer the flexibility to reset just the EMIF state machine without also resetting the EMIF controller's memory-mapped registers. As soon as the device system reset is released (driven high), the EMIF memory controller immediately begins its initialization sequence. Command and data stored in the EMIF memory controller FIFOs are lost. Refer to Section 12.2 for more information on conditions that can cause a device system reset to be asserted.

When system reset is released, the EMIF automatically begins running the SDRAM initialization sequence described in Section 12.2.5.4. Even though the initialization procedure is automatic, a special procedure, found in Section 12.2.5.5 must still be followed.

12.2.9 Interrupt Support

The EMIF supports a single interrupt to the CPU. Section 12.2.9.1 details the generation and internal masking of EMIF interrupts.

12.2.9.1 Interrupt Events

There are three conditions that can cause the EMIF to generate an interrupt to the CPU. These conditions are:

- A rising edge on the EM1WAIT signal (wait rise interrupt)
- An asynchronous time out
- Usage of unsupported addressing mode (line trap interrupt)

The wait rise interrupt occurs when a rising edge is detected on EM1WAIT signal. This interrupt generation is not affected by the WP*n* bit in the asynchronous wait cycle configuration register (ASYNC_WCCR). The asynchronous time out interrupt condition occurs when the attached asynchronous device fails to deassert the EM1WAIT pin within the number of cycles defined by the MAX_EXT_WAIT bit in AWCC (this happens only in extended wait mode). The EMIF supports only linear incrementing and cache line wrap addressing modes . If an access request for an unsupported addressing mode is received, the EMIF sets the LT bit in the EMIF interrupt raw register (INT_RAW) and treats the request as a linear incrementing request.

Only when the interrupt is enabled by setting the appropriate bit (WR_MASK_SET/AT_MASK_SET/ LT_MASK_SET) in the EMIF interrupt mask set register (INT_MSK_SET) to 1, is the interrupt sent to the CPU. Once enabled, the interrupt can be disabled by writing a 1 to the corresponding bit in the EMIF interrupt mask clear register (INT_MSK_CLR). The bit fields in both the INT_MSK_SET and INT_MSK_CLR can be used to indicate whether the interrupt is enabled. When the interrupt is enabled, the corresponding bit field in both the INT_MSK_SET and INT_MSK_CLR have a value of 1; when the interrupt is disabled, the corresponding bit field has a value of 0.

The EMIF interrupt raw register (INT_RAW) and the IF interrupt mask register (INT_MSK) indicate the status of each interrupt. The appropriate bit (WR/AT/LT) in INT_RAW is set when the interrupt condition occurs, whether or not the interrupt has been enabled. However, the appropriate bit (WR_MASKED/AT_MASKED/LT_MASKED) in INT_MSK is set only when the interrupt condition occurs and the interrupt is enabled. Writing a 1 to the bit in INT_RAW clears the INT_RAW bit as well as the corresponding bit in INT_MSK. Table 12-25 contains a brief summary of the interrupt status and control bit fields. See Section 12.5 for complete details on the register fields.

Table 12-25. Interrupt Monitor and Control Bit Fields

Register Name	Bit Name	Description
EMIF interrupt raw register (INT_RAW)	WR	This bit is set when an rising edge on the EM1WAIT signal occurs. Writing a 1 clears the WR bit as well as the WR_MASKED bit in INT_MSK.
	AT	This bit is set when an asynchronous timeout occurs. Writing a 1 clears the AT bit as well as the AT_MASKED bit in INT_MSK.
	LT	This bit is set when an unsupported addressing mode is used. Writing a 1 clears LT bit as well as the LT_MASKED bit in INT_MSK.
EMIF interrupt mask register (INT_MSK)	WR_MASKED	This bit is set only when a rising edge on the EM1WAIT signal occurs and the interrupt has been enabled by writing a 1 to the WR_MASK_SET bit in INT_MSK_SET.
	AT_MASKED	This bit is set only when an asynchronous timeout occurs and the interrupt has been enabled by writing a 1 to the AT_MASK_SET bit in INT_MSK_SET.
	LT_MASKED	This bit is set only when line trap interrupt occurs and the interrupt has been enabled by writing a 1 to the LT_MASK_SET bit in INT_MSK_SET.
EMIF interrupt mask set register (INT_MSK_SET)	WR_MASK_SET	Writing a 1 to this bit enables the wait rise interrupt.
	AT_MASK_SET	Writing a 1 to this bit enables the asynchronous timeout interrupt.
	LT_MASK_SET	Writing a 1 to this bit enables the line trap interrupt.
EMIF interrupt mask clear register (INT_MSK_CLR)	WR_MASK_CLR	Writing a 1 to this bit disables the wait rise interrupt.
	AT_MASK_CLR	Writing a 1 to this bit disables the asynchronous timeout interrupt.
	LT_MASK_CLR	Writing a 1 to this bit disables the line trap interrupt.

12.2.10 DMA Event Support

The EMIF memory controller is a DMA slave peripheral and therefore does not generate DMA events. Data read and write requests may be made directly, by masters and the DMA.

12.2.11 EMIF Signal Multiplexing

For details on the EMIF signal multiplexing, see the *GPIO* chapter, I/O Multiplexing Module section, of this technical reference manual.

12.2.12 Memory Map

For information describing the device memory-map, see your device-specific data manual.

12.2.13 Priority and Arbitration

Section 12.2.2 describes the external prioritization and arbitration among requests from different sources within the microcontroller. The result of this external arbitration is that only one request is presented to the EMIF at a time. Once the EMIF completes a request, the external arbiter then provides the EMIF with the next pending request.

Internally, the EMIF undertakes memory device transactions according to a strict priority scheme. The highest priority events are:

- A device reset.
- A write to any of the three least significant bytes of the SDRAM configuration register (SDRAM_CR).

Either of these events will cause the EMIF to immediately commence its initialization sequence as described in Section 12.2.5.4.

Once the EMIF has completed its initialization sequence, it performs memory transactions according to the following priority scheme (highest priority listed first):

1. If the EMIF's backlog refresh counter is at the Refresh Must urgency level, the EMIF performs multiple SDRAM auto-refresh cycles until the Refresh Release urgency level is reached.
2. If an SDRAM or asynchronous read has been requested, the EMIF performs a read operation.
3. If the EMIF's backlog refresh counter is at the Refresh Need urgency level, the EMIF performs an SDRAM auto refresh cycle.
4. If an SDRAM or asynchronous write has been requested, the EMIF performs a write operation.
5. If the EMIF's backlog refresh counter is at the Refresh May or Refresh Release urgency level, the EMIF performs an SDRAM auto refresh cycle.
6. If the value of the SR bit in SDRAM_CR has been set to 1, the EMIF will enter the self-refresh state as described in Section 12.2.5.7.

After taking one of the actions listed above, the EMIF then returns to the top of the priority list to determine its next action.

Because the EMIF does not issue auto-refresh cycles when in the self-refresh state, the above priority scheme does not apply when in this state. See Section 12.2.5.7 for details on the operation of the EMIF when in the self-refresh state.

12.2.14 System Considerations

This section describes various system considerations to keep in mind when operating the EMIF.

12.2.14.1 Asynchronous Request Times

In a system that interfaces to both SDRAM and asynchronous memory, the asynchronous requests must not take longer than the smaller of the following two values:

- t_{RAS} (typically 120 µs) - to avoid violating the maximum time allowed between issuing an ACTV and PRE command to the SDRAM.
- $t_{Refresh\ Rate}$ × 11 (typically 15.7 µs × 11 = 172.7 µs) - to avoid refresh violations on the SDRAM.

The length of an asynchronous request is controlled by multiple factors, the primary factor being the number of access cycles required to complete the request. For example, an asynchronous request for 4 bytes will require four access cycles using an 8-bit data bus and only two access cycle using a 16-bit data bus. The maximum request size that the EMIF can be sent is 16 words, therefore the maximum number of access cycles per memory request is 64 when the EMIF is configured with an 8-bit data bus. The length of the individual access cycles that make up the asynchronous request is determined by the programmed setup, strobe, hold, and turnaround values, but can also be extended with the assertion of the EM1WAIT input signal up to a programmed maximum limit. It is up to the user to make sure that an entire asynchronous request does not exceed the timing values listed above when also interfacing to an SDRAM device. This can be done by limiting the asynchronous timing parameters.

12.2.15 Power Management

Power dissipation from the EMIF memory controller may be managed by following methods:

- Self-refresh mode
- Power-down mode
- Gating input clocks to the module off

Gating input clocks off to the EMIF memory controller achieves higher power savings when compared to the power savings of self-refresh or power down mode. The input clock to EMIF can be turned off through the use of the Global Clock Module (GCM). Before gating clocks off, the EMIF memory controller must place the SDR SDRAM memory in self-refresh mode. If the external memory requires a continuous clock, the VCLK3 clock domain must not be turned off because this may result in data corruption. See the following subsections for the proper procedures to follow when stopping EMIF memory controller clocks.

12.2.15.1 Power Management Using Self-Refresh Mode

The EMIF memory controller can be placed into a self-refresh state in order to place the attached SDRAM devices into self-refresh mode, which consumes less power for most SDRAM devices. In this state, the attached SDRAM device uses an internal clock to perform its own auto refresh cycles. This maintains the validity of the data in the SDRAM without the need for any external commands. Refer to Section 12.2.5.7 for more details on placing the EMIF into the self-refresh state.

12.2.15.2 Power Management Using Power Down Mode

In the power down mode, the EMIF drives EM1SDCKE low to lower the power consumption. EM1SDCKE goes high when there is a need to send refresh (REFR) commands, after which EM1SDCKE is again driven low. EM1SDCKE remains low until any request arrives. Refer to Section 12.2.5.8 for more details on placing the EMIF in power-down mode.

12.2.16 Emulation Considerations

The EMIF remains fully functional during emulation halts in order to allow emulation access to external memory.

12.3 Example Configuration

This section presents an example of interfacing the EMIF1 to both an SDR SDRAM device and an asynchronous Flash device.

12.3.1 Hardware Interface

Figure 12-15 shows the hardware interface between the EMIF, a Samsung K4S641632H-TC(L)70 64Mb SDRAM device, and a SHARP LH28F800BJE-PTTL90 8Mb Flash memory. The connection between EMIF and the SDRAM is straightforward, but the connection between the EMIF and the Flash deserves a detailed look.

The address inputs for the Flash are provided by three sources. The A[18:0] address inputs are provided by a combination of the EM1A and EM1BA pins according to Section 12.2.6.1, and a set of GPIO pins. The RD/nBY signal from Flash is connected to EM1WAIT pin of the EMIF.

Finally, this example configuration connects the $\overline{\text{EM1WE}}$ pin to the nWE input of the Flash and operates the EMIF in select strobe mode.

12.3.2 Software Configuration

The following sections describe how to configure the EMIF registers and bit fields to interface the EMIF with the Samsung K4S641632H-TC(L)70 SDRAM and the SHARP LH28F800BJE-PTTL90 8Mb Flash memory.

12.3.2.1 Configuring the SDRAM Interface

This section describes how to configure the EMIF to interface with the Samsung K4S641632H-TC(L)70 SDRAM with a clock frequency of f_{EM1CLK} = 100 MHz. Procedure A described in Section 12.2.5.5 is followed that assumes that the SDRAM power-up timing constraints were met during the SDRAM auto-initialization sequence after reset.

12.3.2.1.1 PLL Programming for EMIF to K4S641632H-TC(L)70 Interface

If the system PLL is programmed to provide a SYSCLK frequency > 100 MHz, then configure the EMIF1CLKDIV field in the PERSYSCLKDIVSEL register to make EM1CLK = SYSCLK/2 (default configuration). Before doing this, the SDRAM must be placed in self-refresh mode by setting the SR bit in the SDRAM configuration register. Once the EM1CLK frequency has been configured, remove the SDRAM from self-refresh by clearing the SR bit in SDRAM_CR.

Table 12-26. SR Field Value For EMIF to K4S641632H-TC(L)70 Interface

Field	Value	Purpose
SR	1 then 0	To place the EMIF into the self-refresh state

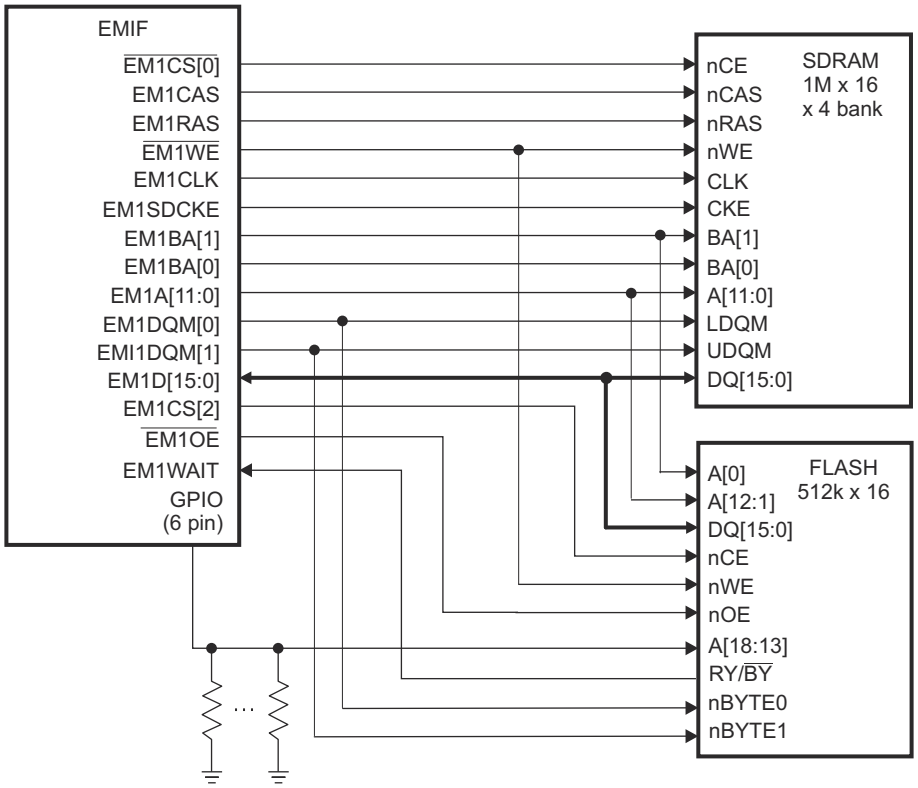

Figure 12-15. Example Configuration Interface

12.3.2.1.2 SDRAM Timing Register (SDRAM_TR) Settings for EMIF to K4S641632H-TC(L)70 Interface

The fields of the SDRAM timing register (SDRAM_TR) must be programmed first as described in Table 12-27 to satisfy the required timing parameters for the K4S641632H-TC(L)70. Based on these calculations, a value of 6111 4610h must be written to the SDRAM_TR. Figure 12-16 shows a graphical description of how the SDRAM_TR must be programmed.

Table 12-27. SDRAM_TR Field Calculations for EMIF to K4S641632H-TC(L)70 Interface

Field Name	Formula	Value from K4S641632H-TC(L)70 Data Sheet	Value Calculated for Field
T_RFC	T_RFC >= (t_{RFC} × f_{EM1CLK}) - 1	t_{RC} = 68 ns (min)(1)	6
T_RP	T_RP >= (t_{RP} × f_{EM1CLK}) - 1	t_{RP} = 20 ns (min)	1
T_RCD	T_RCD >= (t_{RCD} × f_{EM1CLK}) - 1	t_{RCD} = 20 ns (min)	1
T_WR	T_WR >= (t_{WR} × f_{EM1CLK}) - 1	t_{RDL} = 2 CLK = 20 ns (min)(2)	1
T_RAS	T_RAS >= (t_{RAS} × f_{EM1CLK}) - 1	t_{RAS} = 49 ns (min)	4
T_RC	T_RC >= (t_{RC} × f_{EM1CLK}) - 1	t_{RC} = 68 ns (min)	6
T_RRD	T_RRD >= (t_{RRD} × f_{EM1CLK}) - 1	t_{RRD} = 14 ns (min)	1

(1) The Samsung data sheet does not specify a t_{RFC} value. Instead, Samsung specifies t_{RC} as the minimum auto refresh period.
(2) The Samsung data sheet does not specify a t_{WR} value. Instead, Samsung specifies t_{RDL} as last data in to row precharge minimum delay.

Figure 12-16. SDRAM Timing Register (SDRAM_TR)

31	30	29	28	27	26	24	23	22	21	20	19	18	17	16

12.3.2.1.3 SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM self-refresh exit timing register (SDSRETR) must be programmed second to satisfy the t_{XSR} timing requirement from the K4S641632H-TC(L)70 data sheet. Table 12-28 shows the calculation of the proper value to program into the T_XS field of this register. Based on this calculation, a value of 6h must be written to the SDSRETR. Figure 12-17 shows how the SDSRETR must be programmed.

Table 12-28. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface

Field Name	Formula	Value from K4S641632H-TC(L)70 Data Sheet	Value Calculated for Field
T_XS	T_XS >= (t_{XSR} × f_{EM1CLK}) - 1	t_{RC} = 68 ns (min)(1)	6

(1) The Samsung data sheet does not specify a t_{XSR} value. Instead, Samsung specifies t_{RC} as the minimum required time after CKE going high to complete self-refresh exit.

Figure 12-17. SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG)

12.3.2.1.4 SDRAM Refresh Control Register (SDRAM_RCR) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM refresh control register (SDRAM_RCR) can next be programmed to satisfy the required refresh rate of the K4S641632H-TC(L)70. Table 12-29 shows the calculation of the proper value to program into the RR field of this register. Based on this calculation, a value of 61Ah must be written to the SDRAM_RCR. Figure 12-18 shows how the SDRAM_RCR must be programmed.

Table 12-29. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface

Field Name	Formula	Values	Value Calculated for Field
RR	RR ≤ f_{EM1CLK} × $t_{Refresh\ Period}$ / n_{cycles}	From SDRAM data sheet: $t_{Refresh\ Period}$ = 64 ms; n_{cycles} = 4096 EMIF clock rate: f_{EM1CLK} = 100 MHz	RR = 1562 cycles = 61Ah cycles

Figure 12-18. SDRAM Refresh Control Register (SDRAM_RCR)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved			RR												

12.3.2.1.5 SDRAM Configuration Register (SDRAM_CR) Settings for EMIF to K4S641632H-TC(L)70 Interface

Finally, the fields of the SDRAM configuration register (SDRAM_CR) must be programmed as described in Table 12-30 to properly interface with the K4S641632H-TC(L)70 device. Based on these settings, a value of 4720h must be written to the SDRAM_CR. Figure 12-19 shows how the SDRAM_CR must be programmed. The EMIF is now ready to perform read and write accesses to the SDRAM.

Table 12-30. SDRAM_CR Field Values For EMIF to K4S641632H-TC(L)70 Interface

Field	Value	Purpose
SR	0	To avoid placing the EMIF into the self-refresh state
NM	1	To configure the EMIF for a 16-bit data bus
CL	011b	To select a CAS latency of 3
BIT11_9LOCK	1	To allow the CL field to be written
IBANK	010b	To select 4 internal SDRAM banks
PAGESIZE	0	To select a page size of 256 words

Figure 12-19. SDRAM Configuration Register (SDRAM_CR)

12.3.2.2 Configuring the Flash Interface

This section describes how to configure the EMIF to interface with the SHARP LH28F800BJE-PTTL90 8Mb Flash memory with a clock frequency of f_{EM1CLK} = 100 MHz.

12.3.2.2.1 Asynchronous 1 Configuration Register (ASYNC_CS2_CFG) Settings for EMIF to LH28F800BJE-PTTL90 Interface

The asynchronous 1 configuration register (ASYNC_CS2_CFG) is the only register that is necessary to program for this asynchronous interface. The SS bit must be set to 1 to enable select strobe command and the ASIZE field can be set to 1 to select a 16-bit interface. The other fields in this register control the shaping of the EMIF signals, and the proper values can be determined by referring to the AC Characteristics in the Flash data sheet and the device data sheet. Table 12-31 and Table 12-32 show the pertinent AC Characteristics for reads and writes to the Flash device, and Figure 12-20 and Figure 12-21 show the associated timing waveforms. Finally, Figure 12-22 shows programming the ASYNC_CS2_CFG with the calculated values.

Table 12-31. AC Characteristics for a Read Access

AC Characteristic	Device	Definition	Minimum	Maximum	Unit
t_{SU}	EMIF	Setup time, read EM1D before EM1OE high	15		ns
t_{H}	EMIF	Data hold time, read EM1D after EM1OE high	0		ns
t_{ELQV}	Flash	nCE to Output Delay		90	ns
t_{EHQZ}	Flash	nCE High to Output in High Impedance		55	ns

Table 12-32. AC Characteristics for a Write Access

AC Characteristic	Device	Definition	Minimum	Maximum	Unit
t_{AVAV}	Flash	Write Cycle Time	90		ns
t_{ELEH}	Flash	nCE Pulse Width Low	50		ns
t_{EHEL}	Flash	nCE Pulse Width High (not shown in Figure 12-21)	30		ns

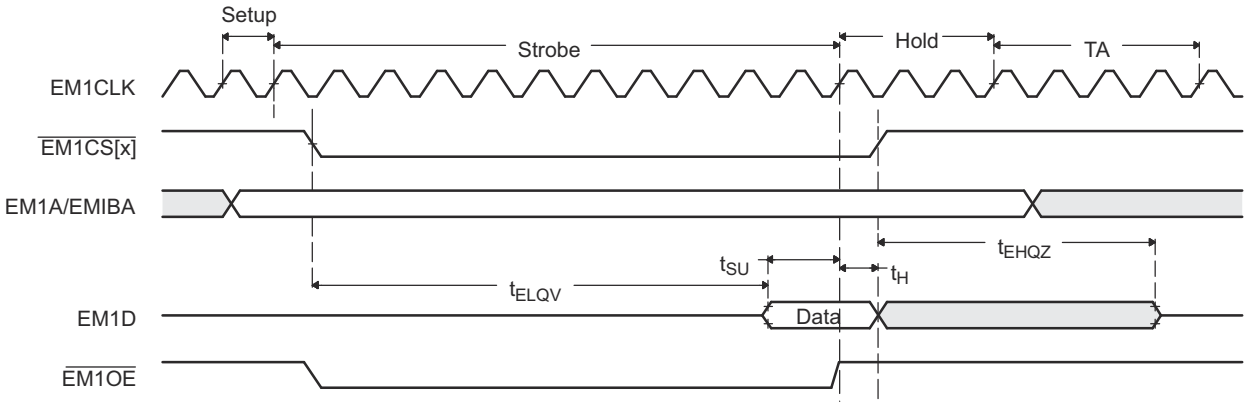

Figure 12-20. LH28F800BJE-PTTL90 to EMIF Read Timing Waveforms

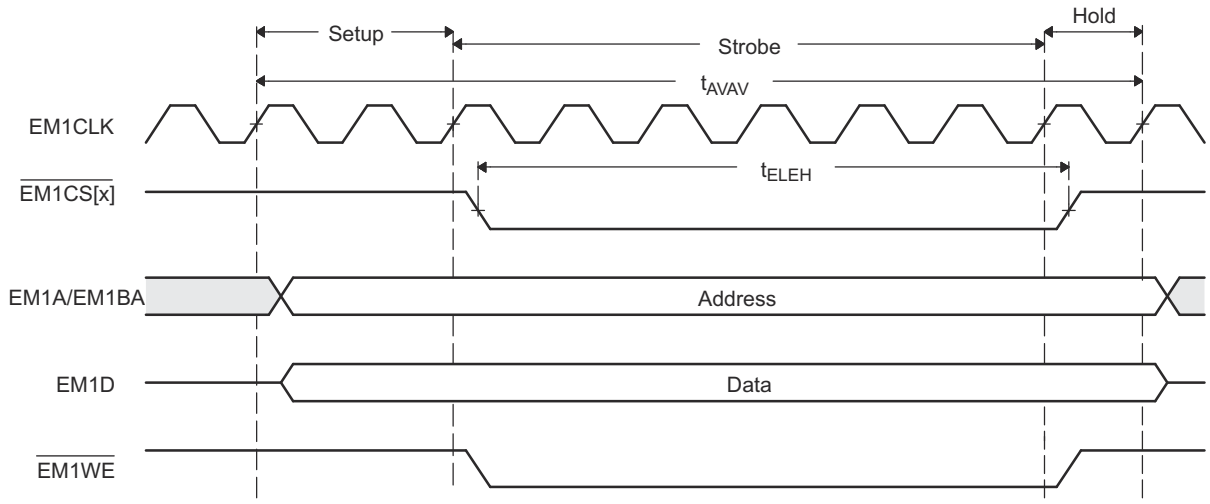

Figure 12-21. LH28F800BJE-PTTL90 to EMIF Write Timing Waveforms

The R_STROBE field must be set to meet the following equation:

$R\_STROBE >= (t_{ELQV} + t_{SU}) \times f_{EM1CLK} - 1$

R_STROBE >= (90 ns + 15 ns) × 200 MHz - 1

R_STROBE >= 20

R_STROBE = 20

The R_HOLD field must be large enough to satisfy EMIF Data hold time, t_H:

$R\_HOLD > = t_H \times f_{EM1CLK} - 1$

R_HOLD >= 0 ns × 200 MHz - 1

R_HOLD >= -1

The R_HOLD field must also combine with the TA field to satisfy the Flash's nCE High to Output in High Impedance time, t_{EHQZ}:

$R\_HOLD + TA >= t_{EHQZ} \times f_{EM1CLK} - 2$

R_HOLD + TA >= 55 ns × 200 MHz - 2

R_HOLD + TA >= 9

The largest value that can be programmed into the TA field is 3h, therefore the following values must be used:

R_HOLD = 6

TA = 3

For Writes, the W_STROBE field must be set to satisfy the Flash's nCE Pulse Width constraint, t_{ELEH}:

$W\_STROBE >= t_{ELEH} \times f_{EM1CLK} - 1$

W_STROBE >= 50 ns × 200 MHz - 1

W_STROBE >= 9

The W_SETUP and W_HOLD fields must combine to satisfy the Flash's nCE Pulse Width High constraint, t_{EHEL}:

W_SETUP + W_HOLD > = t_{EHEL} × f_{EM1CLK} - 2

W_SETUP + W_HOLD > = 30 ns × 200 MHz - 2

W_SETUP + W_HOLD > = 4

In addition, the entire Write access length must satisfy the Flash minimum Write Cycle Time, t_{AVAV}:

W_SETUP + W_STROBE + W_HOLD >= t_{AVAV} × f_{EM1CLK} - 3

W_SETUP + W_STROBE + W_HOLD >= 90 ns × 200 MHz - 3

W_SETUP + W_STROBE + W_HOLD >= 15

Solving the above equations for the Write fields results in the following:

W_SETUP = 4

W_STROBE = 10

W_HOLD = 1

Adding a 5 ns (1 cycle) margin to each of the periods (excluding TA that is already at the maximum) in this example produces the following recommended values:

W_SETUP = 5h

W_STROBE = Bh

W_HOLD = 2h

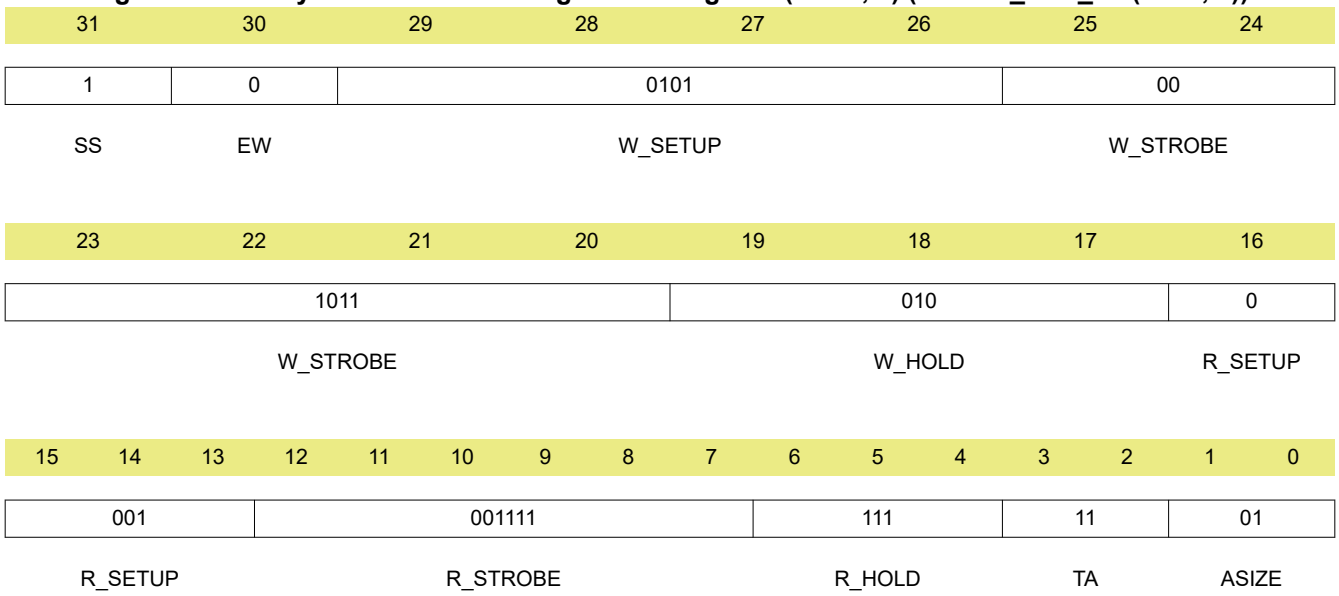
R_SETUP = 1h

R_STROBE = 15h

R_HOLD = 7h

TA = 3h

Figure 12-22. Asynchronous *m* Configuration Register (*m* = 1, 2) (ASYNC_CS*n*_CR(*n* = 2, 3))



12.4 Software

12.4.1 EMIF Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/emif

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

12.4.1.1 Pin setup for EMIF module accessing ASRAM.

FILE: emif_asram_pin_setup.c

This example configures pins for EMIF in ASYNC mode.

12.4.1.2 EMIF1 ASYNC module accessing 16bit ASRAM.

FILE: emif_ex1_16bit_asram.c

This example configures EMIF1 in 16bit ASYNC mode and uses CS2 as chip enable.

External Connections

- External ASRAM memory (CY7C1041CV33 -10ZSXA) daughter card

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

12.4.1.3 EMIF1 ASYNC module accessing 16bit ASRAM through CPU1 and CPU2. - C28X_DUAL

FILE: emif_ex1_16bit_asram_dual_access_cpu1.c

This example configures EMIF1 in 16bit ASYNC mode and uses CS2 as chip enable. The EMIF1 ownership is passed between CPU1 and CPU2 to access different memory regions. Initially CPU2 grabs and configures the EMIF1, thereafter both CPU1 and CPU2 grabs EMIF1 to access different memory regions in external memory.

External Connections

- External ASRAM memory (CY7C1041CV33 -10ZSXA) daughter card

Watch Variables

- *testStatusGlobalCPU1* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobalCPU1* - Error counter

12.4.1.4 EMIF1 ASYNC module accessing 16bit ASRAM trhough CPU1 and CPU2. - C28X_DUAL

FILE: emif_ex1_16bit_asram_dual_access_cpu2.c

This example configures EMIF1 in 16bit ASYNC mode and uses CS2 as chip enable. The EMIF1 ownership is passed between CPU1 and CPU2 to access different memory regions. Initially CPU2 grabs and configures the EMIF1, thereafter both CPU1 and CPU2 grabs EMIF1 to access different memory regions in external memory.

External Connections

- External ASRAM memory (CY7C1041CV33 -10ZSXA) daughter card

Watch Variables

- *testStatusGlobalCPU2* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobalCPU2* - Error counter

12.4.1.5 EMIF1 module accessing 16bit ASRAM as code memory.

FILE: emif_ex2_16bit_asram_codemem.c

This example configures EMIF1 in 16bit ASYNC mode and uses CS2 as chip enable. This example enables use of ASRAM as code memory.

External Connections

- External ASRAM memory (CY7C1041CV33 -10ZSXA) daughter card

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

12.4.1.6 EMIF1 module accessing 16bit SDRAM using memcpy_fast_far().

FILE: emif_ex3_16bit_sdram_far.c

This example configures EMIF1 in 16bit SYNC mode and uses CS0 as chip enable.It will first write to an array in the SDRAM and then read it back using the FPU function, memcpy_fast_far(), for both operations.

The buffer in SDRAM will be placed in the .farbss memory on account of the fact that its assigned the attribute "far" indicating it lies beyond the 22-bit program address space. The compiler will take care to avoid using instructions such as PREAD, which uses the Program Read Bus, or addressing modes restricted to the lower 22-bit space when accessing data with the attribute "far".

The memory space beyond 22-bits must be treated as data space for load/store operations only. The user is cautioned against using this space for either instructions or working memory. *External Connections*

- External SDR-SDRAM memory (MT48LC32M16A2 -75) daughter card

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

12.4.1.7 EMIF1 module accessing 16bit SDRAM then puts into Self Refresh mode before entering Low Power Mode.

FILE: emif_ex4_16bit_sdram_far_lpm.c

This example configures EMIF1 in 16bit SYNC mode and uses CS0 as chip enable. This example puts SDRAM into self refresh before entering standby mode. Watchdog timer is configured to trigger WAKEINT interrupt.

As soon as the watchdog timer expires, the device should wake up, SDRAM should come out of self refresh mode and GPIO11 can be observed to toggle.

External Connections

- External SDR-SDRAM memory (MT48LC32M16A2 -75) daughter card

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

12.4.1.8 EMIF1 module accessing 32bit SDRAM using DMA.

FILE: emif_ex5_16bit_sdram_dma.c

This example configures EMIF1 in 16bit SYNC(SDRAM) mode and uses CS0 as chip enable. It will first write to an array in the SDRAM and then read it back, using the DMA for both operations.

The buffer in SDRAM will be placed in the .farbss memory on account of the fact that its assigned the attribute "far" indicating it lies beyond the 22-bit program address space. The compiler will take care to avoid using instructions such as PREAD, which uses the Program Read Bus, or addressing modes restricted to the lower 22-bit space when accessing data with the attribute "far".

The memory space beyond 22-bits must be treated as data space for load/store operations only. The user is cautioned against using this space for either instructions or working memory. *External Connections*

- External SDR-SDRAM (Micron MT48LC32M16A2 "P -75 C") daughter card.

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

12.4.1.9 EMIF1 module accessing 16bit SDRAM using alternate address mapping.

FILE: emif_ex6_16bit_sdram_nonfar.c

This example configures EMIF1 in 16bit SYNC mode and uses CS0 as chip enable.It will first write to an array in the SDRAM and then read it back.

The buffer in SDRAM will be placed in the emif_cs0_nonfar memory section which is dual mapped with CS2 memory range. This has been done to keep the SDRAM memory range within 22-bit address range in order to generate optimal code. EMIF1 Async RAM accesses will not be issued at the same time and program space reads & fetches will be allowed to SDRAM in non-far range.

External Connections

- External SDR-SDRAM memory (MT48LC32M16A2 -75) daughter card

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

12.4.1.10 EMIF1 ASYNC module accessing 16bit ASRAM HIC FSI

FILE: emif_ex7_16bit_asram_hic_fsi.c

This example configures EMIF1 in 16bit ASYNC mode and uses CS2 as chip enable. This can be run with hic_ex3_config_16bit_fsi example on F28002x device. This is run first followed by the run of F28002x device example. This example configures EMIF1 in 16-bit ASYNC mode and uses CS2 as chip enable to access Host Interface Controller(HIC) on F28002X device

This follows example configuration for performance critical applications described in the Application note titled "Application guide for peripheral expansion using HIC"(SPRACR2).

-This example sets up the EMIF CS2 for ASRAM interface to access the Host interface Controller. This uses the Direct Access Mode of the HIC. -The example on F28002x side sets up the FSI module for internal loopback Sets up the Host interface Controller for direct access mode

- Sends a HIC_INIT_DONE_TOKEN after which this example accesses the FSI of the device side over HIC direct access
- Fills the Transmit frame and triggers transmit
- Receives an interrupt when the frame is received on the device side FSI(uses GPIO04 connected to HIC_INT, configured for XINT1)
- reads the FSI received frame and checks for correctness This demonstrates the usage of Direct access mode and 16 bit mode of HIC module. *External Connections*
  - This example will not work on F2838x Control Card and has been tested in TI Internal Validation platform.

Watch Variables

- *errCountGlobal* - Error counter
- *xint1Count* - Number of times HIC Interrupt is received for FSI Receive event

12.4.1.11 EMIF1 ASYNC module accessing 8bit HIC controller.

FILE: emif_ex8_8bit_asram_hic_adc.c

This can be run with hic_ex2_config_8bit example on F28002x device. This is run first followed by the run of F28002x device. This example configures EMIF1 in 8 bit ASYNC mode and uses CS2 as chip enable to access Host Interface controller on F28002X device It uses Select Strobe mode of EMIF Controller.

This follows example configuration for pin constrained applications described in the Application note titled Application guide for peripheral expansion using HIC(SPRACR2).

- This uses 8 bit ASRAM with control signals as explained in the note. uses the Mailbox access mode of Host interface Controller
- This sets up the EMIF waits for HIC_INIT_DONE_TOKEN from device
- sends HIC_START_TOKEN to the device to signal the device to start sampling the Analog channels
- The device sends periodic HIC_DATA_TOKEN token
- The samples are available in the HIC D2H Buffer
- Uses the HIC_INT interrupt from device(which is mapped to GPIO4, XINT1) Refer F28002X device TRM for further details on HIC.

External Connections

- This example will not work on F2838x Control Card and has been tested in TI Internal Validation platform.

Watch Variables

- *sampleCount* - Number of samples of data received from device.
- *xint1Count* - Number interrupts received from device.

12.5 EMIF Registers

This section describes the External Memory Interface Registers.

12.5.1 EMIF Base Address Table (C28)

Table 12-33. EMIF Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
Emif1ConfigRegs	EMIF1_CONFIG_REGS	EMIF1CONFIG_BASE	0x0005_F4C0	YES	YES	-	-	YES
Emif2ConfigRegs	EMIF2_CONFIG_REGS	EMIF2CONFIG_BASE	0x0005_F4E0	YES	-	-	-	YES
Emif1Regs	EMIF_REGS	EMIF1_BASE	0x0004_7000	YES	YES	-	-	YES
Emif2Regs	EMIF_REGS	EMIF2_BASE	0x0004_7800	YES	-	-	-	YES

12.5.2 EMIF_REGS Registers

Table 12-34 lists the memory-mapped registers for the EMIF_REGS registers. All register offset addresses not listed in Table 12-34 should be considered as reserved locations and the register contents should not be modified.

Table 12-34. EMIF_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	RCSR	Revision Code and Status Register		Go
2h	ASYNC_WCCR	Async Wait Cycle Config Register		Go
4h	SDRAM_CR	SDRAM (EMxCS0n) Config Register		Go
6h	SDRAM_RCR	SDRAM Refresh Control Register		Go
8h	ASYNC_CS2_CR	Async 1 (EMxCS2n) Config Register		Go
Ah	ASYNC_CS3_CR	Async 2 (EMxCS3n) Config Register		Go
Ch	ASYNC_CS4_CR	Async 3 (EMxCS4n) Config Register		Go
10h	SDRAM_TR	SDRAM Timing Register		Go
18h	TOTAL_SDRAM_AR	Total SDRAM Accesses Register		Go
1Ah	TOTAL_SDRAM_ACTR	Total SDRAM Activate Register		Go
1Eh	SDR_EXT_TMNG	SDRAM SR/PD Exit Timing Register		Go
20h	INT_RAW	Interrupt Raw Register		Go
22h	INT_MSK	Interrupt Masked Register		Go
24h	INT_MSK_SET	Interrupt Mask Set Register		Go
26h	INT_MSK_CLR	Interrupt Mask Clear Register		Go

Complex bit access types are encoded to fit into small table cells. Table 12-35 shows the codes that are used for access types in this section.

Table 12-35. EMIF_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 12-35. EMIF_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

12.5.2.1 RCSR Register (Offset = 0h) [Reset = 40000205h]

RCSR is shown in Figure 12-23 and described in Table 12-36.

Return to the Summary Table.

Revision Code and Status Register

Table 12-38. SDRAM_CR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SR	R/W	0h	Self Refresh. Writing a 1 to this bit will cause connected SDRAM devices to be placed into Self Refresh mode and the EMIF to enter the self refresh state. In this state the EMIF will service all asynchronous memory accesses immediately but any SDRAM access will take at least t_ras + 1 cycles due to the time required for the SDRAM devices to out of Self Refresh mode. If an SDRAM access immediately follows the setting of the sr bit, the access will take t_ras + t_xs + 2 cycles. If both sr and pd bits are set, the EMIF will go into Self Refresh. Reset type: SYSRSn
30	PD	R/W	0h	Power Down. Writing a 1 to this bit will cause connected SDRAM devices to be placed into Power Down mode. If both sr and pd bits are set, the EMIF will go into Self Refresh. Reset type: SYSRSn
29	PDWR	R/W	0h	Perform refreshes during Power Down. Writing a 1 to this bit will cause the EMIF to exit the power down state and issue an AUTO REFRESH command every time Refresh May level is set. Reset type: SYSRSn
28-26	RESERVED	R	0h	Reserved
25-23	RESERVED	R/W	0h	Reserved

31-16	RESERVED	R	0h	Reserved
15-6	RESERVED	R	0h	Reserved
5-2	WR_MASKED	R/W1S	0h	Masked Wait Rise. Set to 1 by hardware to indicate rising edge on the corresponding EMxWAIT has been detected, only if the wr_mask_set bit in the Interrupt Mask Set register is set to 1. The WPx bits in the Async Wait Cycle Config register has no effect on these bits. Writing a 1 will clear these bits as well as the wr bits in the Interrupt Raw register. Writing a 0 has no effect. Reset type: SYSRSn
1	LT_MASKED	R/W1S	0h	Masked Line Trap. Set to 1 by hardware to indicate illegal memory access type or invalid cache line size, only if the lt_mask_set bit in the Interrupt Mask Set register is set to 1. Writing a 1 will clear this bit as well as the lt bit in the Interrupt Raw register. Writing a 0 has no effect. Reset type: SYSRSn
0	AT_MASKED	R/W1S	0h	Masked Asynchronous Timeout. Set to 1 by hardware to indicate that during an extended asynchronous memory access cycle, the EMxWAIT signal did not go inactive within the number of cycles defined by the max_ext_wait field in Async Wait Cycle Config register, only if the at_mask_set bit in the Interrupt Mask Set register is set to 1. Writing a 1 will clear this bit as well as the at bit in the Interrupt Raw register. Writing a 0 has no effect. Reset type: SYSRSn

12.5.2.14 INT_MSK_SET Register (Offset = 24h) [Reset = 0h]

INT_MSK_SET is shown in Figure 12-36 and described in Table 12-49.

Return to the Summary Table.

1	LT_MASK_CLR	R/W1S	0h	Mask clear for lt_masked bit in the Interrupt Masked Register. Writing a 1 will disable the interrupt, and clear this bit as well as the lt_mask_set bit in the Interrupt Mask Set register. Writing a 0 has no effect. Reset type: SYSRSn
0	AT_MASK_CLR	R/W1S	0h	Mask clear for at_masked bit in the Interrupt Masked Register. Writing a 1 will disable the interrupt, and clear this bit as well as the at_mask_set bit in the Interrupt Mask Set register. Writing a 0 has no effect. Reset type: SYSRSn

12.5.3 EMIF1_CONFIG_REGS Registers

Table 12-51 lists the memory-mapped registers for the EMIF1_CONFIG_REGS registers. All register offset addresses not listed in Table 12-51 should be considered as reserved locations and the register contents should not be modified.

Table 12-51. EMIF1_CONFIG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	EMIF1LOCK	EMIF1 Config Lock Register	EALLOW	Go
2h	EMIF1COMMIT	EMIF1 Config Lock Commit Register	EALLOW	Go
4h	EMIF1MSEL	EMIF1 Master Sel Register	EALLOW	Go
8h	EMIF1ACCPROT0	EMIF1 Config Register 0	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 12-52 shows the codes that are used for access types in this section.

Table 12-52. EMIF1_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

12.5.3.1 EMIF1LOCK Register (Offset = 0h) [Reset = 0h]

EMIF1LOCK is shown in Figure 12-38 and described in Table 12-53.

Return to the Summary Table.

0	FETCHPROT_EMIF1	R/W	0h	Fetch Protection For EMIF1: 0: CPU Fetches are allowed. 1: CPU Fetches are blocked. Reset type: SYSRSn

12.5.4 EMIF2_CONFIG_REGS Registers

Table 12-57 lists the memory-mapped registers for the EMIF2_CONFIG_REGS registers. All register offset addresses not listed in Table 12-57 should be considered as reserved locations and the register contents should not be modified.

Table 12-57. EMIF2_CONFIG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	EMIF2LOCK	EMIF2 Config Lock Register		Go
2h	EMIF2COMMIT	EMIF2 Config Lock Commit Register	EALLOW	Go
8h	EMIF2ACCPROT0	EMIF2 Config Register 0	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 12-58 shows the codes that are used for access types in this section.

Table 12-58. EMIF2_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

12.5.4.1 EMIF2LOCK Register (Offset = 0h) [Reset = 0h]

EMIF2LOCK is shown in Figure 12-42 and described in Table 12-59.

Return to the Summary Table.
