1. Calculate the number of words to be received. [NUM_WORDS]
2. Calculate the necessary FIFO level [RXFFIL]
3. Calculate the total number of DMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the DMA Burst. [DMA_BURST_SIZE]
5. Configure DMA using the calculated values.
6. Configure SPI with FIFO using the calculated values.

To receive 200 words from SPI using the DMA:

NUM_WORDS = 200

RXFFIL: 4

DMA_TRANSFER_SIZE: (NUM_WORDS /RXFFIL) – 1 = (200/4) – 1 = 49 (50 transfers)

DMA_BURST_SIZE = RXFFIL-1 = 3 (4 words per burst)

Note

Avoid setting RXFFIL to 0h to make sure proper DMA configuration.

37.3.9 SPI High-Speed Mode

The SPI module is capable of reaching full-duplex communication speeds up to LSPCLK/4 (where LSPCLK equals SYSCLK). For the maximum rated speed, refer the device data manual.

To achieve the maximum full-duplex speeds, the following restrictions are placed on the design:

- Single master to single slave configuration is supported.
- Loading on the pins must not exceed the value stated in the device data manual.

When configuring the GPIOs to support high-speed mode, refer to Section 37.2.2.1 for more information.

37.3.10 SPI 3-Wire Mode Description

SPI 3-wire mode allows for SPI communication over three pins instead of the normal four pins.

In master mode, if the TRIWIRE bit is set, enabling 3-wire SPI mode, SPISIMOx becomes the bi-directional SPIMOMIx (SPI master out, master in) pin, and SPISOMIx is no longer used by the SPI. In slave mode, if the TRIWIRE bit is set, SPISOMIx becomes the bi-directional SPISISOx (SPI slave in, slave out) pin, and SPISIMOx is no longer used by the SPI.

Table 37-4 indicates the pin function differences between 3-wire and 4-wire SPI mode for a master and slave SPI.

Table 37-4. 4-wire versus 3-wire SPI Pin Functions

4-wire SPI	3-wire SPI (Master)	3-wire SPI (Slave)
SPICLKx	SPICLKx	SPICLKx
SPISTEx	SPISTEx	SPISTEx
SPISIMOx	SPIMOMIx	Free
SPISOMIx	Free	SPISISOx

Because in 3-wire mode, the receive and transmit paths within the SPI are connected, any data transmitted by the SPI module is also received by itself. The application software must take care to perform a dummy read to clear the SPI data register of the additional received data.

The TALK bit plays an important role in 3-wire SPI mode. The bit must be set to transmit data and cleared prior to reading data. In master mode, in order to initiate a read, the application software must write dummy data to the SPI data register (SPIDAT or SPIRXBUF) while the TALK bit is cleared (no data is transmitted out the SPIMOMI pin) before reading from the data register.

Figure 37-9 and Figure 37-10 illustrate 3-wire master and slave mode.

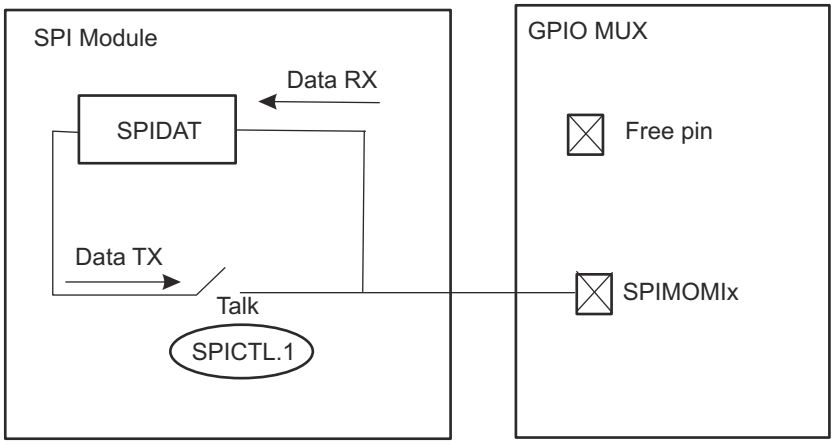

Figure 37-9. SPI 3-wire Master Mode

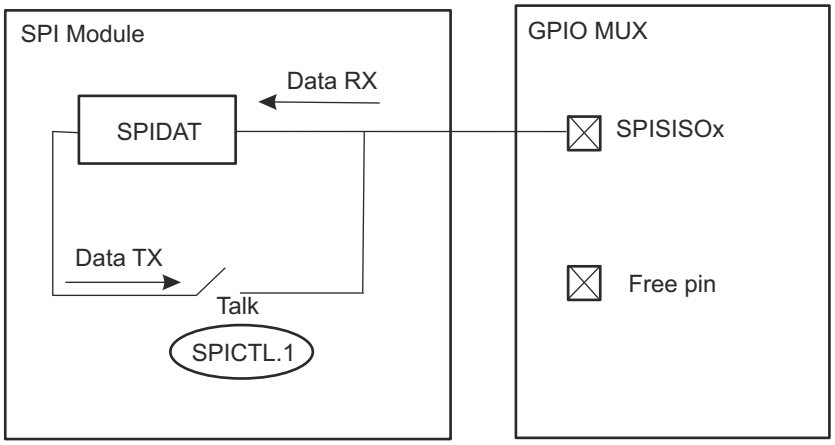

Figure 37-10. SPI 3-wire Slave Mode

Table 37-5 indicates how data is received or transmitted in the various SPI modes while the TALK bit is set or cleared.

Table 37-5. 3-Wire SPI Pin Configuration

Pin Mode	SPIPRI[TRIWIRE]	SPICTL[TALK]	SPISIMO	SPISOMI
		Master Mode		
4-wire	0	X	TX	RX
3-pin mode	1	0	RX	Disconnect from SPI
		1	TX/RX	
		Slave Mode		
4-wire	0	X	RX	TX
3-pin mode	1	0	Disconnect from SPI	RX
		1		TX/RX

37.4 Programming Procedure

This section describes the procedure for configuring the SPI for the various modes of operation.

37.4.1 Initialization Upon Reset

A system reset forces the SPI peripheral into the following default configuration:

- Unit is configured as a slave module (MASTER_SLAVE = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h

37.4.2 Configuring the SPI

This section describes the procedure in which to configure the SPI module for operation. To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPISWRESET bit before making initialization changes, and then set this bit after initialization is complete. While the SPI is held in reset (SPISWRESET = 0), configuration can be changed in any order. The following list shows the SPI configuration procedure in a logical order. However, the SPI registers can be written with single 16-bit writes, so the order is not required with the exception of SPISWRESET.

Note

Do not change the SPI configuration when communication is in progress.

To change the SPI configuration:

1. Clear the SPI Software Reset bit (SPISWRESET) to 0 to force the SPI to the reset state.
2. Configure the SPI as desired:
   - Select either master or slave mode (MASTER_SLAVE).
   - Choose SPICLK polarity and phase (CLKPOLARITY and CLK_PHASE).
   - Set the desired baud rate (SPIBRR).
   - Enable high speed mode, if desired (HS_MODE).
   - Set the SPI character length (SPICHAR).
   - Clear the SPI Flags (OVERRUN_FLAG, INT_FLAG).
   - Enable $\overline{\text{SPISTE}}$ inversion (STEINV), if needed.
   - Enable 3-wire mode (TRIWIRE), if needed.
   - If using FIFO enhancements:
     - Enable the FIFO enhancements (SPIFFENA).
     - Clear the FIFO Flags (TXFFINTCLR, RXFFOVFCLR, and RXFFINTCLR).
     - Release transmit and receive FIFO resets (TXFIFO and RXFIFORESET).
     - Release SPI FIFO channels from reset (SPIRST).
3. If interrupts are used:
   - In non-FIFO mode, enable the receiver overrun and/or SPI interrupts (OVERRUNINTENA and SPIINTENA).
   - In FIFO mode, set the transmit and receive interrupt levels (TXFFIL and RXFFIL) then enable the interrupts (TXFFIENA and RXFFIENA).
4. Set SPISWRESET to 1 to release the SPI from the reset state.

37.4.3 Configuring the SPI for High-Speed Mode

To achieve the maximum rated speeds, the following settings must be made. This example assumes that the device is operating at 100 MHz.

Set LSPCLK equal to SYSCLK:

```
ClkCfgRegs.LOSPCP.bit.LSPCLKDIV = 0;
```

Select the appropriate Pin Mux options in GPIO_CTRL_REGS.

During the SPI configuration procedure:

Set HS_MODE to 1.

```
SpiaRegs.SPICCR.bit.HS_MODE = 0x1;
```

Set SPIBRR to 3. SPICLK = LSPCLK/(SPIBRR+1) = 25- MHz

```
SpiaRegs.SPIBRR = 0x3;
```

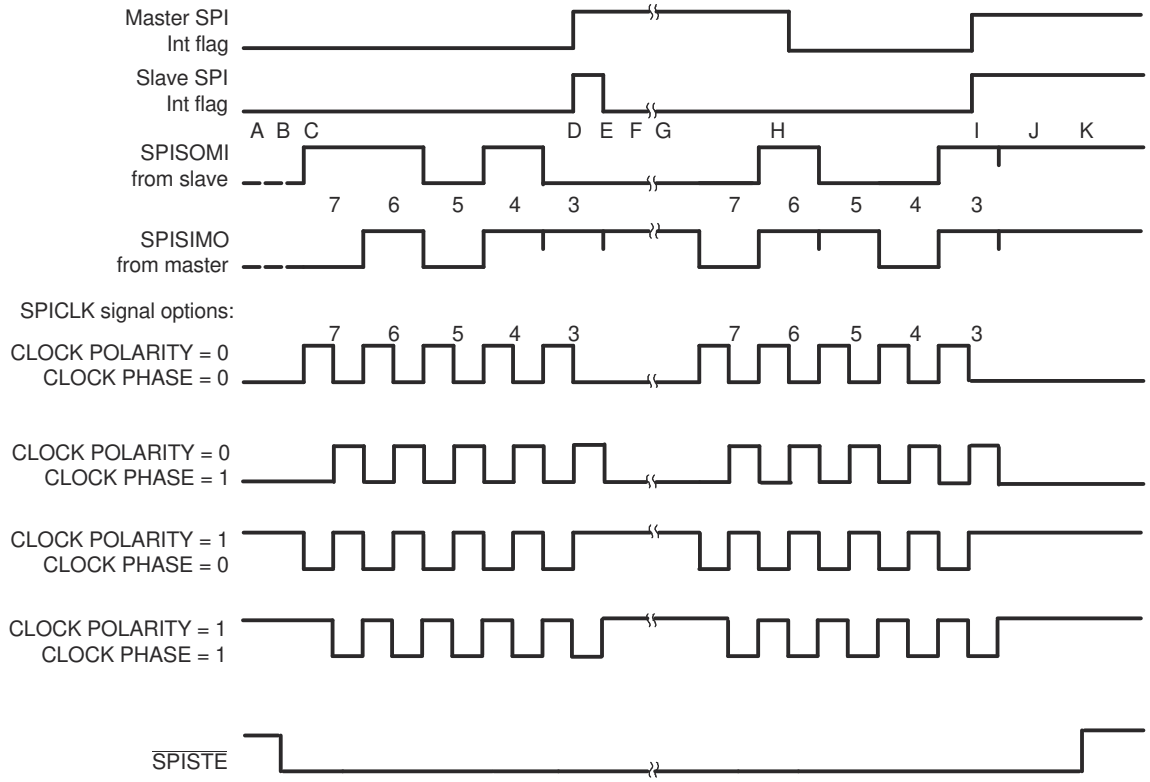
There are no other differences in the configuration from normal SPI operation. Sending and receiving data, DMA operation, and interrupts operates without change.

37.4.4 Data Transfer Example

The timing diagram shown in Figure 37-11 shows an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK asymmetrical (Figure 37-8) shares similar characterizations with Figure 37-11 except that the data transfer is one LSPCLK cycle longer per bit during the low pulse (CLKPOLARITY = 0) or during the high pulse (CLKPOLARITY = 1) of the SPICLK.

Figure 37-11 is applicable for 8-bit SPI only and is not for C28x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.



A. Slave writes 0D0h to SPIDAT and waits for the master to shift out the data.
B. Master sets the slave $\overline{\text{SPISTE}}$ signal low (active).
C. Master writes 058h to SPIDAT, which starts the transmission procedure.
D. First byte is finished and sets the interrupt flags.
E. Slave reads 0Bh from its SPIRXBUF (right-justified).
F. Slave writes 04Ch to SPIDAT and waits for the master to shift out the data.
G. Master writes 06Ch to SPIDAT, which starts the transmission procedure.
H. Master reads 01Ah from the SPIRXBUF (right-justified).
I. Second byte is finished and sets the interrupt flags.
J. Master reads 89h and the slave reads 8Dh from their respective SPIRXBUF. After the user software masks off the unused bits, the master receives 09h and the slave receives 0Dh.
K. Master clears the slave $\overline{\text{SPISTE}}$ signal high (inactive).

Figure 37-11. Five Bits per Character

37.4.5 SPI 3-Wire Mode Code Examples

In addition to the normal SPI initialization, to configure the SPI module for 3-wire mode, the TRIWIRE bit (SPIPRI.0) must be set to 1. After initialization, there are several considerations to take into account when transmitting and receiving data in 3-wire master and slave mode. The following examples demonstrate these considerations.

In 3-wire master mode, SPICLKx, $\overline{\text{SPISTE}}$x, and SPISIMOx pins must be configured as SPI pins (SPISOMIx pin can be configured as non-SPI pin). When the master transmits, the master receives the data the master transmits (because SPISIMOx and SPISOMIx are connected internally in 3-wire mode). Therefore, the junk data received must be cleared from the receive buffer every time data is transmitted.

Example 37-4. 3-Wire Master Mode Transmit

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data; // Master transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data from itself
                                                // bc it rx'd same data tx'd
```

To receive data in 3-wire master mode, the master must clear the TALK (SPICTL.1) bit to 0 to close the transmit path and then transmit dummy data in order to initiate the transfer from the slave. Because the TALK bit is 0, unlike in transmit mode, the master dummy data does not appear on the SPISIMOx pin, and the master does not receive its own dummy data. Instead, the data from the slave is received by the master.

Example 37-5. 3-Wire Master Mode Receive

```
Uint16 rdata;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
     SpiaRegs.SPITXBUF = dummy;                 // Send dummy to start tx
     // NOTE: because TALK = 0, data does not tx onto SPISIMOA pin
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data received
     rdata = SpiaRegs.SPIRXBUF;                 // Master reads data
```

In 3-wire slave mode, SPICLKx, SPISTEx, and SPISOMIx pins must be configured as SPI pins (SPISIMOx pin can be configured as non-SPI pin). Like in master mode, when transmitting, the slave receives the data it transmits and must clear this junk data from its receive buffer.

Example 37-6. 3-Wire Slave Mode Transmit

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data;                  // Slave transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data from itself
```

As in 3-wire master mode, the TALK bit must be cleared to 0. Otherwise, the slave receives data normally.

Example 37-7. 3-Wire Slave Mode Receive

```
Uint16 rdata;
    SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
    rdata = SpiaRegs.SPIRXBUF;                 // Slave reads data
```

37.4.6 SPI STEINV Bit in Digital Audio Transfers

On those devices with two SPI modules, enabling the STEINV bit on one of the SPI modules allows the pair of SPIs to receive both left and right-channel digital audio data in slave mode. The SPI module that receives a normal active-low $\overline{\text{SPISTE}}$ signal stores right-channel data, and the SPI module that receives an inverted active-high $\overline{\text{SPISTE}}$ signal stores left-channel data from the master. To receive digital audio data from a digital audio interface receiver, the SPI modules can be connected as shown in Figure 37-12.

Note

This configuration is only applicable to slave mode (MASTER_SLAVE = 0). When the SPI is configured as master (MASTER_SLAVE = 1), the STEINV bit has no effect on the $\overline{\text{SPISTE}}$ pin.

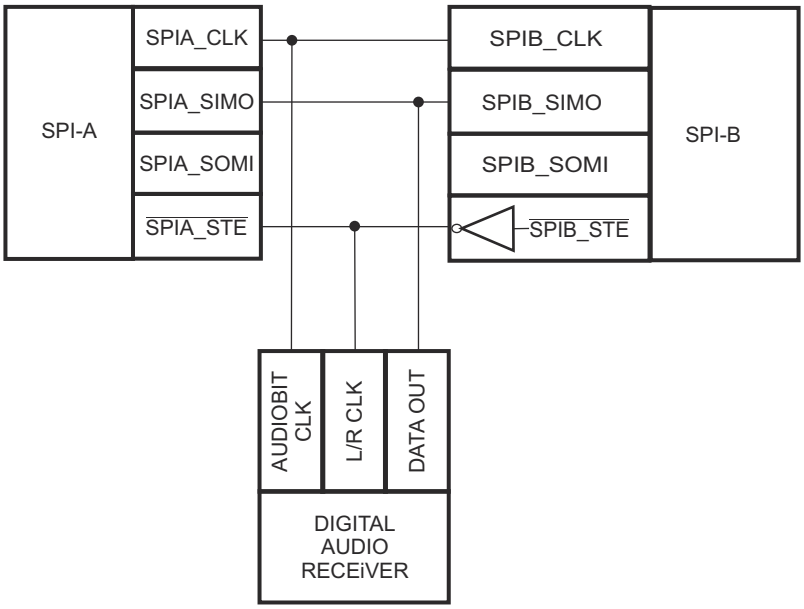


Figure 37-12. SPI Digital Audio Receiver Configuration Using Two SPIs

Standard C28x SPI timing requirements limit the number of digital audio interface formats supported using the 2-SPI configuration with the STEINV bit. See the device data manual electrical specifications for SPI timing requirements. With the SPI clock phase configured such that the CLKPOLARITY bit is 0 and the CLK_PHASE bit is 1 (data latched on rising edge of clock), standard right-justified digital audio interface data format is supported as shown in Figure 37-13.

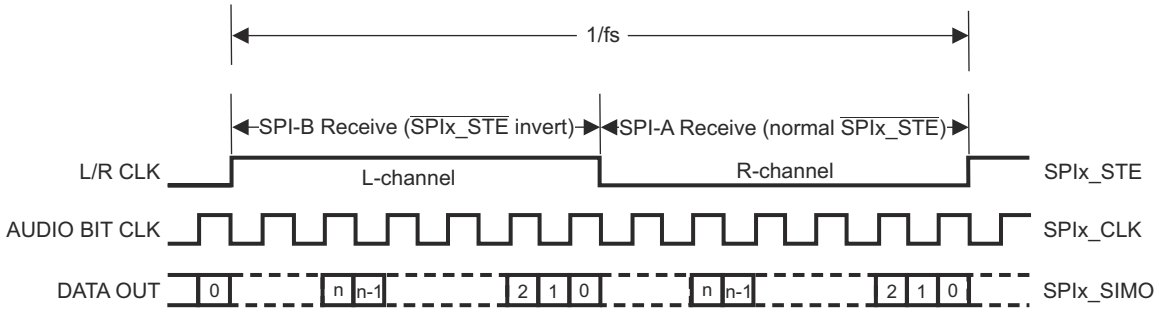

Figure 37-13. Standard Right-Justified Digital Audio Data Format

37.5 Software

37.5.1 SPI Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/spi

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

37.5.1.1 SPI Digital Loopback

FILE: spi_ex1_loopback.c

This program uses the internal loopback test mode of the SPI module. This is a very basic loopback that does not use the FIFOs or interrupts. A stream of data is sent and then compared to the received stream. The pinmux and SPI modules are configure through the sysconfig file.

The sent data looks like this:
0000 0001 0002 0003 0004 0005 0006 0007 .... FFFE FFFF 0000

This pattern is repeated forever.

External Connections
- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data

37.5.1.2 SPI Digital Loopback with FIFO Interrupts

FILE: spi_ex2_loopback_fifo_interrupts.c

This program uses the internal loopback test mode of the SPI module. Both the SPI FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

External Connections
- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

37.5.1.3 SPI Digital External Loopback without FIFO Interrupts

FILE: spi_ex3_external_loopback.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and interrupts are not used in this example. SPIA is configured as a peripheral and SPI B is configured as controller. This example demonstrates full duplex communication where both controller and peripheral transmits and receives data simultaneously.

External Connections

- GPIO24 and GPIO16 - SPIPICO
- GPIO25 and GPIO17 - SPIPOCI
- GPIO26 and GPIO18 - SPICLK
- GPIO27 and GPIO19 - SPIPTE

Watch Variables

- *TxData_SPIA* - Data send from SPIA (peripheral)
- *TxData_SPIB* - Data send from SPIB (controller)
- *RxData_SPIA* - Data received by SPIA (peripheral)
- *RxData_SPIB* - Data received by SPIB (controller)

37.5.1.4 SPI Digital External Loopback with FIFO Interrupts

FILE: spi_ex4_external_loopback_fifo_interrupts.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and their interrupts are used. SPIA is configured as a peripheral and receives data from SPI B which is configured as a controller.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

External Connections

- GPIO24 and GPIO16 - SPIPICO
- GPIO25 and GPIO17 - SPIPOCI
- GPIO26 and GPIO18 - SPICLK
- GPIO27 and GPIO19 - SPIPTE

Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

37.5.1.5 SPI Digital Loopback with DMA

FILE: spi_ex5_loopback_dma.c

This program uses the internal loopback test mode of the SPI module. Both DMA interrupts and the SPI FIFOs are used. When the SPI transmit FIFO has enough space (as indicated by its FIFO level interrupt signal), the DMA will transfer data from global variable sData into the FIFO. This will be transmitted to the receive FIFO via the internal loopback.

When enough data has been placed in the receive FIFO (as indicated by its FIFO level interrupt signal), the DMA will transfer the data from the FIFO into global variable rData.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

External Connections

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data

37.5.1.6 SPI EEPROM

FILE: spi_ex6_eeprom.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256.

External Connections
ExternalConnections
- Connect external SPI EEPROM
- Connect GPIO16 (PICO) to external EEPROM SI pin
- Connect GPIO17 (POCI) to external EEPROM SO pin
- Connect GPIO18 (CLK) to external EEPROM SCK pin
- Connect GPIO11 (CS) to external EEPROM CS pin
- Connect the external EEPROM VCC and GND pins

Watch Variables
- writeBuffer - Data that is written to external EEPROM
- readBuffer - Data that is read back from EEPROM
- error - Error count

37.5.1.7 SPI DMA EEPROM

FILE: spi_ex7_eeprom_dma.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI using DMA and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256.

External Connections
ExternalConnections
- Connect external SPI EEPROM
- Connect GPIO16 (PICO) to external EEPROM SI pin
- Connect GPIO17 (POCI) to external EEPROM SO pin
- Connect GPIO18 (CLK) to external EEPROM SCK pin
- Connect GPIO11 (CS) to external EEPROM CS pin
- Connect the external EEPROM VCC and GND pins

Watch Variables
- writeBuffer - Data that is written to external EEPROM
- SPI_DMA_Handle.RXdata - Data that is read back from EEPROM when number of received bytes is less than 4
- SPI_DMA_Handle.pSPIRXDMA->pbuffer - Start address of received data from EEPROM
- error - Error count

37.6 SPI Registers

This section describes the Serial Peripheral Interface registers. It is important to note that the SPI registers only allow 16-bit accesses.

37.6.1 SPI Base Address Table (C28)

Table 37-6. SPI Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
SpiaRegs	SPI_REGS	SPIA_BASE	0x0000_6100	YES	YES	YES	YES	YES
SpibRegs	SPI_REGS	SPIB_BASE	0x0000_6110	YES	YES	YES	YES	YES
SpicRegs	SPI_REGS	SPIC_BASE	0x0000_6120	YES	YES	YES	YES	YES
SpidRegs	SPI_REGS	SPID_BASE	0x0000_6130	YES	YES	YES	YES	YES

37.6.2 SPI_REGS Registers

Table 37-7 lists the memory-mapped registers for the SPI_REGS registers. All register offset addresses not listed in Table 37-7 should be considered as reserved locations and the register contents should not be modified.

Table 37-7. SPI_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SPICCR	SPI Configuration Control Register		Go
1h	SPICTL	SPI Operation Control Register		Go
2h	SPISTS	SPI Status Register		Go
4h	SPIBRR	SPI Baud Rate Register		Go
6h	SPIRXEMU	SPI Emulation Buffer Register		Go
7h	SPIRXBUF	SPI Serial Input Buffer Register		Go
8h	SPITXBUF	SPI Serial Output Buffer Register		Go
9h	SPIDAT	SPI Serial Data Register		Go
Ah	SPIFFTX	SPI FIFO Transmit Register		Go
Bh	SPIFFRX	SPI FIFO Receive Register		Go
Ch	SPIFFCT	SPI FIFO Control Register		Go
Fh	SPIPRI	SPI Priority Control Register		Go

Complex bit access types are encoded to fit into small table cells. Table 37-8 shows the codes that are used for access types in this section.

Table 37-8. SPI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

37.6.2.1 SPICCR Register (Offset = 0h) [Reset = 0h]

SPICCR is shown in Figure 37-14 and described in Table 37-9.

Return to the Summary Table.

SPICCR controls the setup of the SPI for operation.

Figure 37-14. SPICCR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
SPISWRESET	CLKPOLARITY	HS_MODE	SPILBK	SPICHAR			
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h			

Table 37-9. SPICCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	SPISWRESET	R/W	0h	SPI Software Reset When changing configuration, you should clear this bit before the changes and set this bit before resuming operation. Reset type: SYSRSn 0h (R/W) = Initializes the SPI operating flags to the reset condition. Specifically, the RECEIVER OVERRUN Flag bit (SPISTS.7), the SPI INT FLAG bit (SPISTS.6), and the TXBUF FULL Flag bit (SPISTS.5) are cleared. SPISTE will become inactive. SPICLK will be immediately driven to 0 regardless of the clock polarity. The SPI configuration remains unchanged. 1h (R/W) = SPI is ready to transmit or receive the next character. When the SPI SW RESET bit is a 0, a character written to the transmitter will not be shifted out when this bit is set. A new character must be written to the serial data register. SPICLK will be returned to its inactive state one SPICLK cycle after this bit is set.
6	CLKPOLARITY	R/W	0h	Shift Clock Polarity This bit controls the polarity of the SPICLK signal. CLOCK POLARITY and POLARITY CLOCK PHASE (SPICTL.3) control four clocking schemes on the SPICLK pin. Reset type: SYSRSn 0h (R/W) = Data is output on rising edge and input on falling edge. When no SPI data is sent, SPICLK is at low level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the rising edge of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first rising edge of the SPICLK signal and on subsequent falling edges of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. 1h (R/W) = Data is output on falling edge and input on rising edge. When no SPI data is sent, SPICLK is at high level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the falling edge of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first falling edge of the SPICLK signal and on subsequent rising edges of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal.

Table 37-9. SPICCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	HS_MODE	R/W	0h	High Speed Mode Enable Bits This bit determines if the High Speed mode is enabled. The correct GPIOs should be selected in the GPxGMUX/GPxMUX registers. Reset type: SYSRSn 0h (R/W) = SPI High Speed mode disabled. This is the default value after reset. 1h (R/W) = SPI High Speed mode enabled,
4	SPILBK	R/W	0h	SPI Loopback Mode Select Loopback mode allows module validation during device testing. This mode is valid only in master mode of the SPI. Reset type: SYSRSn 0h (R/W) = SPI loopback mode disabled. This is the default value after reset. 1h (R/W) = SPI loopback mode enabled, SIMO/SOMI lines are connected internally. Used for module self-tests.
3-0	SPICHAR	R/W	0h	Character Length Control Bits These four bits determine the number of bits to be shifted in or SPI CHAR0 out as a single character during one shift sequence. SPICHAR = Word length - 1 Reset type: SYSRSn 0h (R/W) = 1-bit word 1h (R/W) = 2-bit word 7h (R/W) = 8-bit word Fh (R/W) = 16-bit word

37.6.2.2 SPICTL Register (Offset = 1h) [Reset = 0h]

SPICTL is shown in Figure 37-15 and described in Table 37-10.

Return to the Summary Table.

SPICTL controls data transmission, the SPI's ability to generate interrupts, the SPICLK phase, and the operational mode (slave or master).

Figure 37-15. SPICTL Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED			OVERRUNINTENA	CLK_PHASE	MASTER_SLAVE	TALK	SPIINTENA
R-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 37-10. SPICTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-5	RESERVED	R	0h	Reserved
4	OVERRUNINTENA	R/W	0h	Overrun Interrupt Enable Overrun Interrupt Enable. Setting this bit causes an interrupt to be generated when the RECEIVER OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by the RECEIVER OVERRUN Flag bit and the SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. Reset type: SYSRSn 0h (R/W) = Disable RECEIVER OVERRUN interrupts. 1h (R/W) = Enable RECEIVER_OVERRUN interrupts.
3	CLK_PHASE	R/W	0h	SPI Clock Phase Select This bit controls the phase of the SPICLK signal. CLOCK PHASE and CLOCK POLARITY (SPICCR.6) make four different clocking schemes possible (see clocking figures in SPI chapter). When operating with CLOCK PHASE high, the SPI (master or slave) makes the first bit of data available after SPIDAT is written and before the first edge of the SPICLK signal, regardless of which SPI mode is being used. Reset type: SYSRSn 0h (R/W) = Normal SPI clocking scheme, depending on the CLOCK POLARITY bit (SPICCR.6). 1h (R/W) = SPICLK signal delayed by one half-cycle. Polarity determined by the CLOCK POLARITY bit.
2	MASTER_SLAVE	R/W	0h	SPI Network Mode Control This bit determines whether the SPI is a network master or slave. SLAVE During reset initialization, the SPI is automatically configured as a network slave. Reset type: SYSRSn 0h (R/W) = SPI is configured as a slave. 1h (R/W) = SPI is configured as a master.

Table 37-10. SPICTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	TALK	R/W	0h	Transmit Enable The TALK bit can disable data transmission (master or slave) by placing the serial data output in the high-impedance state. If this bit is disabled during a transmission, the transmit shift register continues to operate until the previous character is shifted out. When the TALK bit is disabled, the SPI is still able to receive characters and update the status flags. TALK is cleared (disabled) by a system reset. Reset type: SYSRSn 0h (R/W) = Disables transmission: - Slave mode operation: If not previously configured as a general-purpose I/O pin, the SPISOMI pin will be put in the high-impedance state. - Master mode operation: If not previously configured as a general-purpose I/O pin, the SPISIMO pin will be put in the high-impedance state. 1h (R/W) = Enables transmission For the 4-pin option, ensure to enable the receiver's SPISTEn input pin.
0	SPIINTENA	R/W	0h	SPI Interrupt Enable This bit controls the SPI's ability to generate a transmit/receive interrupt. The SPI INT FLAG bit (SPISTS.6) is unaffected by this bit. Reset type: SYSRSn 0h (R/W) = Disables the interrupt. 1h (R/W) = Enables the interrupt.

37.6.2.3 SPISTS Register (Offset = 2h) [Reset = 0h]

SPISTS is shown in Figure 37-16 and described in Table 37-11.

Return to the Summary Table.

SPISTS contains interrupt and status bits.

Table 37-11. SPISTS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	OVERRUN_FLAG	W1C	0h	SPI Receiver Overrun Flag This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit is cleared in one of three ways: - Writing a 1 to this bit - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited. Reset type: SYSRSn 0h (R/W) = A receive overrun condition has not occurred. 1h (R/W) = The last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application). Writing a '1' will clear this bit. The RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received.

Table 37-11. SPISTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	INT_FLAG	RC	0h	SPI Interrupt Flag SPI INT FLAG is a read-only flag. Hardware sets this bit to indicate that the SPI has completed sending or receiving the last bit and is ready to be serviced. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. The received character is placed in the receiver buffer at the same time this bit is set. This bit is cleared in one of three ways: - Reading SPIRXBUF - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system Note: This bit should not be used if FIFO mode is enabled. The internal process of copying the received word from SPIRXBUF to the Receive FIFO will clear this bit. Use the FIFO status, or FIFO interrupt bits for similar functionality. Reset type: SYSRSn 0h (R/W) = No full words have been received or transmitted. 1h (R/W) = Indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced.
5	BUFFULL_FLAG	R	0h	SPI Transmit Buffer Full Flag This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete. Reset type: SYSRSn 0h (R/W) = Transmit buffer is not full. 1h (R/W) = Transmit buffer is full.
4-0	RESERVED	R	0h	Reserved

37.6.2.4 SPIBRR Register (Offset = 4h) [Reset = 0h]

SPIBRR is shown in Figure 37-17 and described in Table 37-12.

Return to the Summary Table.

SPIBRR contains the bits used for baud-rate selection.

Figure 37-17. SPIBRR Register

15	14	13	12	11	10	9	8

R-0h	R/W-0h						

Table 37-12. SPIBRR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6-0	SPI_BIT_RATE	R/W	0h	SPI Baud Rate Control These bits determine the bit transfer rate if the SPI is the network SPI BIT RATE 0 master. There are 125 data-transfer rates (each a function of the CPU clock, LSPCLK) that can be selected. One data bit is shifted per SPICLK cycle. (SPICLK is the baud rate clock output on the SPICLK pin.) If the SPI is a network slave, the module receives a clock on the SPICLK pin from the network master. Therefore, these bits have no effect on the SPICLK signal. The frequency of the input clock from the master should not exceed the slave SPI's LSPCLK signal divided by 4. In master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin. The SPI baud rates are determined by the following formula: For SPIBRR = 3 to 127: SPI Baud Rate = LSPCLK / (SPIBRR + 1) For SPIBRR = 0, 1, or 2: SPI Baud Rate = LSPCLK / 4 Reset type: SYSRSn 3h (R/W) = SPI Baud Rate = LSPCLK/4 4h (R/W) = SPI Baud Rate = LSPCLK/5 7Eh (R/W) = SPI Baud Rate = LSPCLK/127 7Fh (R/W) = SPI Baud Rate = LSPCLK/128

37.6.2.5 SPIRXEMU Register (Offset = 6h) [Reset = 0h]

SPIRXEMU is shown in Figure 37-18 and described in Table 37-13.

Return to the Summary Table.

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit of SPISTS. This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

Figure 37-18. SPIRXEMU Register

ERXBn							
R-0h							

Table 37-13. SPIRXEMU Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	ERXBn	R	0h	Emulation Buffer Received Data SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set. This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately. It is recommended that you view SPIRXEMU in the normal emulator run mode. Reset type: SYSRSn

37.6.2.6 SPIRXBUF Register (Offset = 7h) [Reset = 0h]

SPIRXBUF is shown in Figure 37-19 and described in Table 37-14.

Return to the Summary Table.

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit in SPISTS. If FIFO mode is enabled, reading this register will also decrement the RXFFST counter in SPIFFRX.

Figure 37-19. SPIRXBUF Register

Table 37-14. SPIRXBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	RXBn	R	0h	Received Data Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register. Reset type: SYSRSn

37.6.2.7 SPITXBUF Register (Offset = 8h) [Reset = 0h]

SPITXBUF is shown in Figure 37-20 and described in Table 37-15.

Return to the Summary Table.

SPITXBUF stores the next character to be transmitted. Writing to this register sets the TX BUF FULL Flag bit in SPISTS. When the transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no transmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set.
In master mode, if no transmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

15-0	TXBn	R/W	0h	Transmit Data Buffer This is where the next character to be transmitted is stored. When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared. Writes to SPITXBUF must be left-justified. Reset type: SYSRSn

37.6.2.8 SPIDAT Register (Offset = 9h) [Reset = 0h]

SPIDAT is shown in Figure 37-21 and described in Table 37-16.

Return to the Summary Table.

SPIDAT is the transmit and receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

Table 37-18. SPIFFRX Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RXFFOVF	R	0h	Receive FIFO Overflow Flag Reset type: SYSRSn 0h (R/W) = Receive FIFO has not overflowed. This is a read-only bit. 1h (R/W) = Receive FIFO has overflowed, read-only bit. More than 16 words have been received in to the FIFO, and the first received word is lost.
14	RXFFOVFCLR	W	0h	Receive FIFO Overflow Clear Reset type: SYSRSn 0h (R/W) = Write 0 does not affect RXFFOVF flag bit, Bit reads back a zero. 1h (R/W) = Write 1 to clear SPIFFRX[RXFFOVF].
13	RXFIFORESET	R/W	1h	Receive FIFO Reset Reset type: SYSRSn 0h (R/W) = Write 0 to reset the FIFO pointer to zero, and hold in reset. 1h (R/W) = Re-enable receive FIFO operation.
12-8	RXFFST	R	0h	Receive FIFO Status Reset type: SYSRSn 0h (R/W) = Receive FIFO is empty. 1h (R/W) = Receive FIFO has 1 word. 2h (R/W) = Receive FIFO has 2 words. 10h (R/W) = Receive FIFO has 16 words, which is the maximum. 1Fh (R/W) = Reserved.
7	RXFFINT	R	0h	Receive FIFO Interrupt Flag Reset type: SYSRSn 0h (R/W) = RXFIFO interrupt has not occurred. This is a read-only bit. 1h (R/W) = RXFIFO interrupt has occurred. This is a read-only bit.
6	RXFFINTCLR	W	0h	Receive FIFO Interrupt Clear Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on RXFIFINT flag bit, Bit reads back a zero. 1h (R/W) = Write 1 to clear SPIFFRX[RXFFINT] flag
5	RXFFIENA	R/W	0h	RX FIFO Interrupt Enable Reset type: SYSRSn 0h (R/W) = RX FIFO interrupt based on RXFFIL match (greater than or equal to) will be disabled. 1h (R/W) = RX FIFO interrupt based on RXFFIL match (greater than or equal to) will be enabled.

Table 37-18. SPIFFRX Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-0	RXFFIL	R/W	1Fh	Receive FIFO Interrupt Level Bits Receive FIFO generates an interrupt when the FIFO status bits (RXFFST4-0) are greater than or equal to the FIFO level bits (RXFFIL4-0). The default value of these bits after reset is 11111. This avoids frequent interrupts after reset, as the receive FIFO will be empty most of the time. Reset type: SYSRSn 0h (R/W) = A RX FIFO interrupt request is generated when there is 0 or more words in the RX buffer. 1h (R/W) = A RX FIFO interrupt request is generated when there are 1 or more words in the RX buffer. 2h (R/W) = A RX FIFO interrupt request is generated when there are 2 or more words in the RX buffer. 10h (R/W) = A RX FIFO interrupt request is generated when there are 16 words in the RX buffer. 1Fh (R/W) = Reserved.

37.6.2.11 SPIFFCT Register (Offset = Ch) [Reset = 0h]

SPIFFCT is shown in Figure 37-24 and described in Table 37-19.

Return to the Summary Table.

SPIFFCT controls the FIFO transmit delay bits.

Figure 37-24. SPIFFCT Register

TXDLY							
R/W-0h							

Table 37-19. SPIFFCT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7-0	TXDLY	R/W	0h	FIFO Transmit Delay Bits These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 serial clock cycles and a maximum of 255 serial clock cycles. In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In the FIFO mode TXBUF should not be treated as one additional level of buffer. Reset type: SYSRSn 0h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF immediately upon completion of transmission of the previous word. 1h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF1 serial clock cycle after completion of transmission of the previous word. 2h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 2 serial clock cycles after completion of transmission of the previous word. FFh (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 255 serial clock cycles after completion of transmission of the previous word.

37.6.2.12 SPIPRI Register (Offset = Fh) [Reset = 0h]

SPIPRI is shown in Figure 37-25 and described in Table 37-20.

Return to the Summary Table.

SPIPRI controls auxiliary functions for the SPI including emulation control, SPISTE inversion, and 3-wire control.

Figure 37-25. SPIPRI Register

15	14	13	12	11	10	9	8

Table 37-20. SPIPRI Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RESERVED	R/W	0h	Reserved
5	SOFT	R/W	0h	Emulation Soft Run This bit only has an effect when the FREE bit is 0. Reset type: SYSRSn 0h (R/W) = Transmission stops midway in the bit stream while TSUSPEND is asserted. Once TSUSPEND is deasserted without a system reset, the remainder of the bits pending in the DATBUF are shifted. Example: If SPIDAT has shifted 3 out of 8 bits, the communication freezes right there. However, if TSUSPEND is later deasserted without resetting the SPI, SPI starts transmitting from where it had stopped (fourth bit in this case) and will transmit 8 bits from that point. 1h (R/W) = If the emulation suspend occurs before the start of a transmission, (that is, before the first SPICLK pulse) then the transmission will not occur. If the emulation suspend occurs after the start of a transmission, then the data will be shifted out to completion. When the start of transmission occurs is dependent on the baud rate used. Standard SPI mode: Stop after transmitting the words in the shift register and buffer. That is, after TXBUF and SPIDAT are empty. In FIFO mode: Stop after transmitting the words in the shift register and buffer. That is, after TX FIFO and SPIDAT are empty.
4	FREE	R/W	0h	Emulation Free Run These bits determine what occurs when an emulation suspend occurs (for example, when the debugger hits a breakpoint). The peripheral can continue whatever it is doing (free-run mode) or, if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete. Reset type: SYSRSn 0h (R/W) = Emulation mode is selected by the SOFT bit 1h (R/W) = Free run, continue SPI operation regardless of suspend or when the suspend occurred.
3-2	RESERVED	R	0h	Reserved
1	STEINV	R/W	0h	SPISTEn Inversion Bit On devices with 2 SPI modules, inverting the SPISTE signal on one of the modules allows the device to receive left and right- channel digital audio data. This bit is only applicable to slave mode. Writing to this bit while configured as master (MASTER_SLAVE = 1) has no effect Reset type: SYSRSn 0h (R/W) = SPISTEn is active low (normal) 1h (R/W) = SPISTE is active high (inverted)

Table 37-20. SPIPRI Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	TRIWIRE	R/W	0h	SPI 3-wire Mode Enable Reset type: SYSRSn 0h (R/W) = Normal 4-wire SPI mode. 1h (R/W) = 3-wire SPI mode enabled. The unused pin becomes a GPIO pin. In master mode, the SPISIMO pin becomes the SPIMOMI (master receive and transmit) pin and SPISOMI is free for non-SPI use. In slave mode, the SPISOMI pin becomes the SPISISO (slave receive and transmit) pin and SPISIMO is free for non-SPI use.

Chapter 38

Universal Serial Bus (USB) Controller

This chapter discusses the features and functions of the universal serial bus (USB) controller.

38.1 Introduction

The USB controller operates as a full-speed function controller during point-to-point communications with the USB host. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. The USB controller has thirty-two endpoints, one-half of them being for IN transactions and one-half of them being for OUT transactions. One IN and one OUT endpoint are fixed-function endpoints used for control transfers; the others are defined by firmware. A dynamically sizeable FIFO supports queuing multiple packets. Software-controlled connect and disconnect allow flexibility during USB device startup.

38.1.1 Features

The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) operation in host and device modes as well as low-speed (1.5 Mbps) operation in host mode
- Integrated PHY
- Three transfer types: Control, Interrupt, and Bulk
- Thirty-two endpoints
  - One dedicated control IN endpoint and one dedicated control OUT endpoint
  - Fifteen configurable IN endpoints and fifteen configurable OUT endpoints
- Four KB dedicated endpoint memory

38.1.3 Block Diagram

The USB block diagram is shown in Figure 38-1.

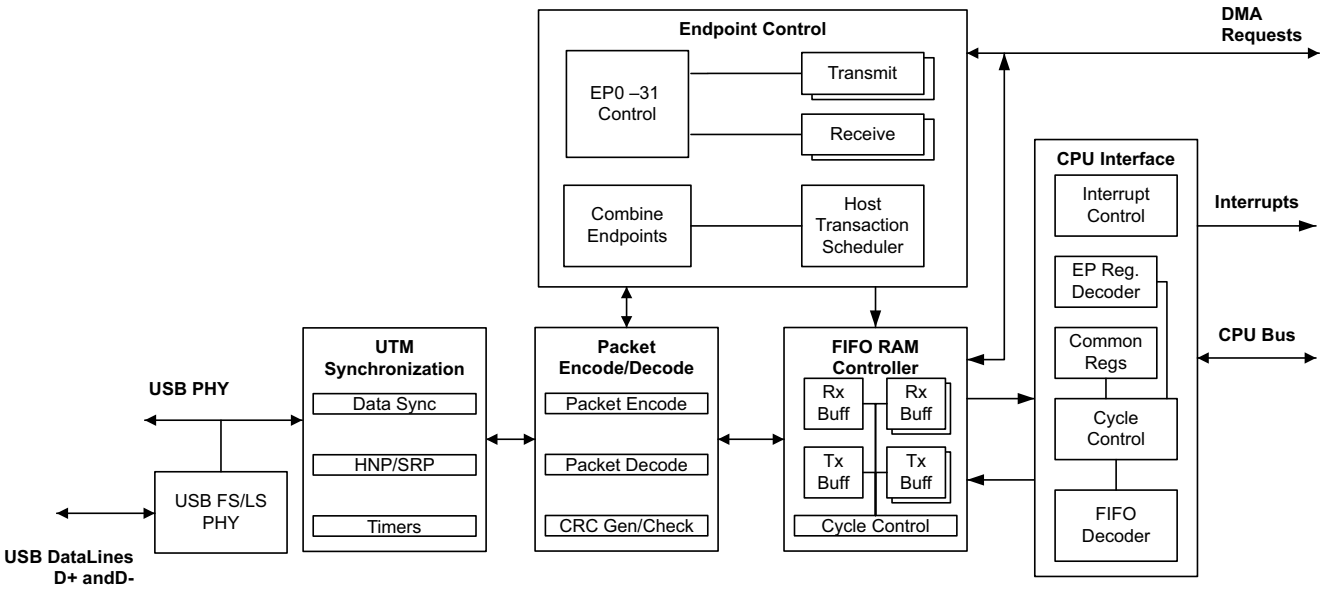

Figure 38-1. USB Block Diagram

38.1.3.1 Signal Description

The USB controller requires a total of three signals (D+, D-, and V_{Bus}) to operate in device mode and two signals (D+, D-) to operate in embedded host mode. Because of the differential signaling needed for USB, the D+ and D- pins have special buffers to support USB. As such, their position on the chip is not user-selectable. The D+ and D- pins at reset are, by default, GPIOs and must be configured before being used as USB function pins. Bits 10 and 11 in the GPIO B Analog Mode Select register (GPBAMSEL) must be set to choose the USB function. The signals USB bus voltage (V_{BUS}), external power enable (EPEN), and power fault (PFLT) are not hardwired to any pin and some applications require these signals be implemented in software using a GPIO. Software that implements these signals is available in the USB software library.

38.1.3.2 VBus Recommendations

Most applications do not need to monitor V_{Bus}. Because of this, a dedicated V_{Bus} monitoring pin was not included on this microcontroller. If you are designing a bus-powered device application or an embedded host application, you do not need to monitor V_{Bus}. If you are designing a self-powered device, you need to actively monitor the state of the V_{Bus} pin to make sure compliance with the USB specification. In Section 7.1.5 and Section 7.2.1 of the USB Specification Revision 2.0™:

- "The voltage source on the [speed identification] pull-up resistor must be derived from or controlled by the power supplied on the USB cable such that when V_{BUS} is removed, the pull-up resistor does not supply current on the data line to which it is attached.
- When V_{BUS} is removed, the device must remove power from the D+/D- pull-up resistor within 10 seconds.
- Later in the timing tables (Section 7.3.2) of the USB Specification 2.0, it is also stated that the D+/D- pull-up resistor must be applied within 100 ms of V_{Bus} reaching a valid level."

Meeting the above specification is easy because of the slow timing requirements. The hardware part of the V_{Bus} monitoring is discussed in this chapter. The corresponding software is discussed briefly, but for examples and an explanation, consult the USB software guide.

The pins of this microcontroller are not 5-V tolerant, and because of this, the V_{Bus} signal cannot be directly connected to a GPIO pin. Directly connecting 5 V to a pin of the microcontroller destroys the I/O buffer of the pin

and possibly more of the chip. The most cost-effective way of making any pin capable of reading a 5-V input is to use a series resistance in conjunction with the ESD diode clamps already present inside the device on every pin. It is recommended to use a 100-kΩ series resistor between the V_{Bus} signal and the pin chosen to monitor it. A diagram of this setup is shown in Figure 38-2.

In Figure 38-2, if V_{Bus} is above or below 3.3 V and 0 V, respectively, one of the ESD clamp diodes is forward-biased, allowing current to flow through the 100-kΩ resistor. The purpose of the diode clamps is to protect the pins of the microcontroller from very short over voltage spikes of a high magnitude. The diode clamps do this by clamping the voltage excursion to one of the supply rails. We are effectively requiring the ESD clamps to do the same thing the clamps were designed to do, but instead of a short high magnitude pulse, we are giving the clamps a long low magnitude static value using the 100-kΩ resistor.

Any pin that has digital input and output functionality can potentially be used to monitor V_{Bus}, but the use of an interrupt-capable GPIO is recommended. A pin that does not have external interrupt capability can also be used, but the input state of the pin must be polled periodically by the application software to make sure appropriate action is taken whenever V_{Bus} is applied or removed. If an interrupt-capable GPIO is chosen, the GPIO can be configured to generate an interrupt on both the rising and falling edge. More information on external interrupts can be found in the *System Control and Interrupts* chapter. Example code that implements V_{Bus} monitoring using external interrupts and takes the appropriate actions is documented in the USB Software Guide and can be found in the associated USB software package.

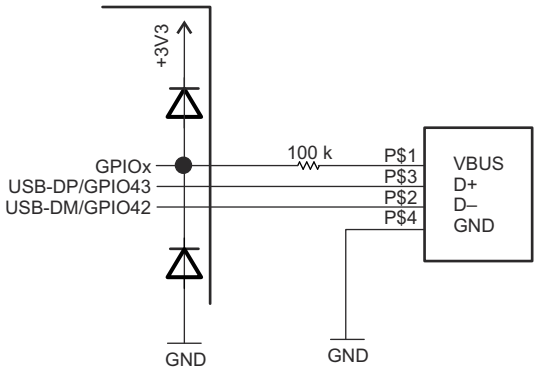

Figure 38-2. USB Scheme

38.2 Functional Description

The USB controller can be configured to act as either a dedicated host or device. However, when the USB controller is acting as a self-powered device, a GPIO input or analog comparator input must be connected to V_{BUS} and configured to generate an interrupt when the V_{BUS} level drops. This interrupt is used to disable the pullup resistor on the USB0DP signal.

Note

When USB is used in the system, the minimum system frequency is 30 MHz.

38.2.1 Operation as a Device

This section describes how the USB controller performs when the USB controller is being used as a USB device. IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of start of frame (SOF) are all described.

When in device mode, IN transactions are controlled by the endpoint transmit interface and uses the transmit endpoint registers for the given endpoint. OUT transactions are handled with the endpoints receive interface and use the receive endpoint registers for the given endpoint. When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint. Note the following:

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint for a USB device. However, in most cases the USB device must use the dedicated control endpoint on the USB controller’s endpoint 0.

38.2.1.1 Control and Configurable Endpoints

When operating as a device, the USB controller provides two dedicated control endpoints (IN and OUT). The remaining available configurable endpoints (one-half IN and one-half OUT) can be used for communications with a host controller. The endpoint number and direction associated with an endpoint is directly related to the register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface. Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions. The remaining six endpoints can be configured as control, bulk, or interrupt endpoints. The six endpoints can be treated as three configurable IN and three configurable OUT endpoints. The endpoint pairs are not required to have the same type for their IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair can be a bulk endpoint, while the IN portion of that endpoint pair can be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

38.2.1.1.1 IN Transactions as a Device

When operating as a USB device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the configurable IN endpoints are determined by the USB Transmit FIFO Start Address (USBTXFIFOADD) register. The maximum size of a data packet that can be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the USB Maximum Transmit Data Endpoint n (USBTXMAXPn) register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

Note

The maximum packet size set for any endpoint must not exceed the FIFO size. The USBTXMAXPn register cannot be written to while data is in the FIFO as unexpected results can occur.

Single-Packet Buffering

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ) register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the USB Transmit Control and Status Endpoint n Low (USBTXCSRLn) register must be set. If the AUTOSET bit in the USB Transmit Control and Status Endpoint n High (USBTXCSRHn) register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

Double-Packet Buffering

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the USBTXCSRLn register must be set. If the AUTOSET bit in the USBTXCSRHn register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the USBTXCSRLn register at this point indicates how many packets can be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

Note

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

38.2.1.1.2 Out Transactions as a Device

When in device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the configurable OUT endpoints are determined by the USB Receive FIFO Start Address (USBRXFIFOADD) register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the USB Maximum Receive Data Endpoint n (USBRXMAXPn) register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

Note

In all cases, the maximum packet size must not exceed the FIFO size.

Single-Packet Buffering

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the USB Receive Control and Status Endpoint n Low (USBRXCSRL[*n*]) register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the USB Receive Control and Status Endpoint n High (USBRXCSRH[*n*]) register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

Double-Packet Buffering

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the USBRXCSRL[*n*] register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

Note

The FULL bit in USBRXCSRL[*n*] is not set when the first packet is received. The FULL bit is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the USBRXCSRH[*n*] register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

Note

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

38.2.1.1.3 Scheduling

The device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

38.2.1.1.4 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

Stalled Control Transfer

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the USB Control and Status Endpoint 0 Low (USBCSRL0) register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what must have been the last packet.
3. The Host sends more than USBRXMAXPn bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

Zero Length OUT Data Packets

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets must only be received after the entire length of the device request has been transferred. However, if the Host sends a zero-length OUT data packet before the entire length of device request has been transferred, the Host is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the USBCSRL0 register.

Setting the Device Address

When a Host is attempting to enumerate the USB device, the Host requests that the device change the address from zero to some other value. The address is changed by writing the value that the Host requested to the USB Device Functional Address (USBFADDR) register. However, care must be taken when writing to USBFADDR to avoid changing the address before the transaction is complete. This register must only be set after the SET_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the device has left the STATUS phase. In the case of a SET_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the device has responded to the IN request, the USBFADDR register must be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

Note

If the USBFADDR register is set to the new value as soon as the device receives the OUT transaction with the SET_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the device.

38.2.1.1.5 Device Mode Suspend

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the USB Interrupt Enable (USBIE) register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the USB Power (USBPOWER) register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling. To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state.

38.2.1.1.6 Start of Frame

When the USB controller is operating in device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the USB Frame Value (USBFRAME) register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the USBFRAME register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

38.2.1.1.7 USB Reset

When the USB controller is in device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the USBFADDR register
- Clears the USB Endpoint Index (USBEPIDX) register
- Flushes all endpoint FIFOs
- Clears all control/status registers
- Enables all endpoint interrupts
- Generates a RESET interrupt

38.2.1.1.8 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the SOFTCONN bit of the USBPOWER register. When the SOFTCONN bit is set, the PHY is placed in the normal mode, and the USB0DP/USB0DM lines of the USB bus are enabled. At the same time, the USB controller is placed into a state that does not respond to any USB signaling except a USB RESET. When the SOFTCONN bit is cleared, the PHY is put into non-driving mode, USB0DP and USB0DM are tristated, and the USB controller appears to other devices on the USB bus as if the USB controller has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the SOFTCONN bit has been set. The application software can then choose when to set the PHY into the normal mode. Systems with a lengthy initialization procedure can use this to make sure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the SOFTCONN bit has been set, the USB controller can be disconnected by clearing this bit.

Note

The USB controller does not generate an interrupt when the device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

38.2.2 Operation as a Host

When the USB controller is operating in Host mode, the USB controller can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub. Control, bulk, and interrupt transactions

are supported. This section describes the USB controller's actions when the USB controller is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in device mode, the FIFOs for endpoints must take into account the maximum packet size for an endpoint.

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint to communicate with a device. However, in most cases the USB controller must use the dedicated control endpoint to communicate with a device's endpoint 0.

38.2.2.1 Endpoint Registers

The endpoint registers are used to control the USB endpoint interfaces which communicate with devices that are connected. The endpoints consist of a dedicated control IN endpoint and a dedicated control OUT endpoint. The remaining available endpoints are configurable, with one-half of them being OUT endpoints, and one-half of them being IN endpoints. See Section 38.1.1 for the number of available endpoints on this device.

The dedicated control interface can only be used for control transactions to endpoint 0 of devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, or interrupt endpoints.

These USB interfaces can be used to simultaneously schedule as many as fifteen independent OUT and fifteen independent IN transactions to any endpoints on any device. The IN and OUT controls are paired together in the same set of registers for the respective endpoints. However, the IN and OUT controls can be configured to communicate with different types of endpoints and different endpoints on devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a device's bulk OUT endpoint 1, while the IN portion is communicating with a device's interrupt IN endpoint 2.

Before accessing any device, whether for point-to-point communications or for communications via a hub, the relevant USB Receive Functional Address Endpoint n (USBRXFUNCADDRn) or USB Transmit Functional Address Endpoint n (USBTXFUNCADDRn) registers must be set for each receive or transmit endpoint to record the address of the device being accessed.

The USB controller also supports connections to devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

38.2.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in device mode except that the transaction first must be initiated by setting the REQPKT bit in the USBCSRL0 register, indicating to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the USBCSRL0 register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the USBRXCSRHn register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in USBRXCSRHn causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. When the RXRDY bit is cleared, the controller sends an acknowledge to the device. When there is a known number of packets to be transferred, the USB Request Packet Count in Block Transfer Endpoint n (USBRQPKTCOUNTn) register associated with the endpoint must be configured to the number of packets to

be transferred. The USB controller decrements the value in the USBRQPKTCOUNTn register following each request. When the USBRQPKTCOUNTn value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, USBRQPKTCOUNTn must be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the USBRXMAXPn register) such as can occur at the end of a bulk transfer.

If the device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the USBCSRL0 register. If the target device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the USBCSRL0 register.

38.2.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in device mode. The TXRDY bit in the USBTXCSRLn register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the USBTXCSRHn register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO.

If the target device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the USBTXCSRLn register. If the target device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the USBTXCSRLn register.

38.2.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every 255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a device is not responding.

The USB controller maintains a frame counter. If the target device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target device is a low-speed device, a K state is transmitted on the bus to act as a keep-alive to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt transaction occurs per endpoint every n frames, where n is the interval set via the USB Host Transmit Interval Endpoint n (USBTXINTERVAL[*n*]) or USB Host Receive Interval Endpoint n (USBRXINTERVAL[*n*]) register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process ensures that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target device before the endpoint times out.

38.2.2.5 USB Hubs

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed device is connected to the USB controller using a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding USB Receive Hub Address Endpoint n (USBRXHUBADDRn) and USB Receive Hub Port Endpoint n (USBRXHUBPORTn) or the USB Transmit Hub Address Endpoint n (USBTXHUBADDRn) and USB Transmit Hub Port Endpoint n (USBTXHUBPORTn) registers. In addition, the speed at which the device operates (full or low) must be recorded in the USB Type Endpoint 0 (USBTYPE0) (endpoint 0), USB Host Configure Transmit Type Endpoint n (USBTXTYPEn), or USB Host Configure Receive Type Endpoint n (USBRXTYPEn) registers for each endpoint that is accessed by the device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB devices. To maximize the number of devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to device functions must be made following the completion of any on-going transactions on the endpoints affected.

38.2.2.6 Babble

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

38.2.2.7 Host SUSPEND

If the SUSPEND bit in the USBPOWER register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20 ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

38.2.2.8 USB RESET

If the RESET bit in the USBPOWER register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20 ms to ensure correct resetting of the target device. After the CPU has cleared the bit, the USB Host controller starts its frame counter and transaction scheduler.

38.2.2.9 Connect/Disconnect

A session is started by setting the SESSION bit in the USB device Control (USBDEVCTL) register, enabling the USB controller to wait for a device to be connected. When a device is detected, a connect interrupt is generated. The speed of the device that has been connected can be determined by reading the USBDEVCTL register where the FSDEV bit is set for a full-speed device, and the LSDEV bit is set for a low-speed device. The USB controller must generate a RESET to the device, and then the USB Host controller can begin device enumeration. If the device is disconnected while a session is in progress, a disconnect interrupt is generated.

38.2.3 DMA Operation

The USB module's DMA trigger signals are not supported on this device. The DMA controller may be used to read and write the USB FIFOs via software triggering. see the Direct Memory Access (DMA) chapter for more details about programming the DMA controller. See the *USB DMA Event Trigger* advisory in the device errata for more information.

38.2.4 Address/Data Bus Bridge

This USB controller was originally designed to connect to an ARM AHB bus, but has been modified to function with the C28x device bus architecture. The modifications made are largely invisible to the user application, but there are some things to note.

- The USB memory space is 8 bits wide, while the C28x memory space is 16 bits wide.
- 32- and 16-bit accesses (r/w) are completely transparent to the user application code, no changes need be made.
- The C28x core only supports 8 bit accesses through a byte intrinsic type. This can be used to perform 8 bit reads or writes to the USB controller.
  - int &__byte(int *array, unsigned int byte_index);
  - *array = ptr to address to access, byte_index = always 0 (for USB)
    See Table 38-1 for example.
  - See the *TMS320C28x Optimizing C/C++ Compiler User's Guide* and the *TMS320C28x Assembly Language Tools User's Guide*
- Because of the bridge, the memory view of the USB controller memory space in CCS is not a 1:1 representation of what is in the controller
  - When the view mode is
    - 32 bit or 16 bit, even address are effectively duplicated, ignore odd addresses.
    - 8 bit, even addresses from within the controller are duplicated into odd address in the view window; old addresses from within the controller are not displayed.
      See Table 38-2 for example.

Table 38-1. USB Memory Access from Software

USB Controller Memory			C28x 8 Bit

38.3 Initialization and Configuration

To use the USB controller, the peripheral clock must be enabled using the System Control module PCLKCR11 register. In addition, the USB PHY signals must be connected to their respective pins using the GPIO module GPBAMSEL register. Set bits 10 and 11 for USB0DM (GPIO42) and USB0DP (GPIO43).

Set up the auxiliary PLL so a 60-MHz output clock is provided to the USB module. This fixed frequency is required for all USB operations. See the *System Control and Interrupts* chapter for more details.

In host mode, the USB controller is responsible for supplying power to the bus. To avoid incorrectly supplying voltage to the bus, the external power control signal, USB0EPEN, must be kept inactive on start-up. This can be done by connecting the USB0EPEN and USB0PFLT pins to the USB controller as soon as possible.

38.3.1 Pin Configuration

To give more flexibility, the signals External Power Enable (EPEN) and Power Fault (PFLT) were not implemented in hardware and the user must implement these signals in software. Examples of how to implement these signals in software can be found in the USB Software Guide located in C2000Ware in the \libraries\communications\usb\ directory.

When using the device controller portion of the USB controller in a system that also provides host functionality, the power to V_{BUS} must be disabled to allow the external host controller to supply power. Usually, the EPEN signal is used to control the external regulator and must be negated to avoid having two devices driving the V_{BUS} power pin on the USB connector.

When the USB controller is acting as a host, the USB controller is in control of two signals that are attached to an external voltage supply that provides power to V_{BUS}. The Host controller uses the EPEN signal to enable or disable power to the V_{BUS} pin on the USB connector. An input pin, PFLT, provides feedback when there has been a power fault on V_{BUS}. The PFLT signal can be configured to either automatically negate the EPEN signal to disable power, or the PFLT signal can generate an interrupt to the interrupt controller to allow software to handle the power fault condition. The polarity and actions related to both EPEN and PFLT are fully configurable in the USB controller. The controller also provides interrupts on device insertion and removal to allow the Host controller code to respond to these external events.

38.3.2 Endpoint Configuration

To start communication in Host or device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a device. In device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because it is a fixed-function, fixed-FIFO-size endpoint. In device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, or interrupt mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. The maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint’s FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 4 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint’s FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a device, the USB device controller's soft connect must be enabled when the device is ready to start communications, indicating to the host controller that the device is ready to start the enumeration process. If operating as a Host controller, the device soft connect must be disabled and power must be provided to V_{BUS} via the USB0EPEN signal.

38.4 USB Global Interrupts

Global interrupt enable, flag, and clear registers have been added to ensure that no interrupt is missed. The USB interrupt can be enabled or blocked using the INTEN bit. The INTFLG bit indicates whether an interrupt has occured or not. Finally the INTFLGCLR bit will clear the INTFLG when the value '1' is written to the field.

38.5 Software

38.5.1 USB Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/usb

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

38.5.1.1 Wrapper for interrupt functions and USB support pins. - CM

FILE: usb_hal.c

38.5.1.2 USB CDC serial example

FILE: usb_ex1_dev_serial.c

This example application turns the evaluation kit into a virtual serial port when connected to the USB host system. The application supports the USB Communication Device Class, Abstract Control Model to redirect SCIA traffic to and from the USB host system.

Connect USB cables from your PC to both the mini and microUSB connectors on the controlCARD.Figure out what COM ports your controlCARD is enumerating (typically done using Device Manager in Windows) and open a serial terminal to each of with the settings 115200 Baud 8-N-1. Characters typed in one terminal should be echoed in the other and vice versa.

A driver information (INF) file for use with Windows XP, Windows 7 and Windows 10 can be found in the windows_drivers directory.

38.5.1.3 USB Composite Serial Device (usb_dev_cserial) - CM

FILE: usb_ex1_device_serial_cm.c

This example application turns the evaluation kit into a virtual serial port when connected to the USB host system. The application supports the USB Communication Device Class, Abstract Control Model to redirect UART0 traffic to and from the USB host system.

Connect USB cables from your PC to both the mini and microUSB connectors on the controlCARD.Figure out what COM ports your controlCARD is enumerating (typically done using Device Manager in Windows) and open a serial terminal to each of with the settings 115200 Baud 8-N-1. Characters typed in one terminal should be echoed in the other and vice versa.

A driver information (INF) file for use with Windows XP, Windows 7 and Windows 10 can be found in the windows_drivers directory.

38.5.1.4 USB HID Mouse Device

FILE: usb_ex2_dev_mouse.c

This example application turns the evaluation board into a USB mouse supporting the Human Interface Device class. After loading and running the example simply connect the PC to the controlCARDs microUSB port using a USB cable, and the mouse pointer will move in a square pattern for the duration of the time it is plugged in.

SCIA, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

38.5.1.5 USB HID Mouse Device - CM

FILE: usb_ex2_device_mouse_cm.c

This example application turns the evaluation board into a USB mouse supporting the Human Interface Device class. After loading and running the example simply connect the PC to the controlCARDs microUSB port using a USB cable, and the mouse pointer will move in a square pattern for the duration of the time it is plugged in.

UART0, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

38.5.1.6 Data structures defining the USB mouse device. - CM

FILE: usb_ex2_device_mouse_structs.c

38.5.1.7 USB Device Keyboard

FILE: usb_ex3_dev_keyboard.c

This example application turns the evaluation board into a USB keyboard supporting the Human Interface Device class. The global variable ui32Button should be modified to wake up the USB. Care should be taken to ensure that the active window can safely receive the text; enter is not pressed at any point so no actions are attempted by the host if a terminal window is used.

The device implemented by this application also supports USB remote wake up allowing it to request the host to reactivate a suspended bus. If the bus is suspended (as indicated on the application display), updating ui32Button will request a remote wakeup assuming the host has not specifically disabled such requests.

To run the example compile the project, load to the target, and run the example. After the example is running, connect a USB cable from the PC to the microUSB port on the controlCARD.Modify ui32Button value in the expressions window and then focus should be on the window so that we can receive keyboard input (i.e. NotePad).

38.5.1.8 USB HID Keyboard Device (usb_dev_keyboard) - CM

FILE: usb_ex3_device_keyboard_cm.c

This example application turns the evaluation board into a USB keyboard supporting the Human Interface Device class. The global variable ui32Button should be modified to wake up the USB. Care should be taken to ensure that the active window can safely receive the text; enter is not pressed at any point so no actions are attempted by the host if a terminal window is used.

The device implemented by this application also supports USB remote wake up allowing it to request the host to reactivate a suspended bus. If the bus is suspended (as indicated on the application display), updating ui32Button will request a remote wakeup assuming the host has not specifically disabled such requests.

To run the example compile the project, load to the target, and run the example. After the example is running, connect a USB cable from the PC to the microUSB port on the controlCARD.Modify ui32Button value in the expressions window and then focus should be on the window so that we can receive keyboard input (i.e. NotePad).

38.5.1.9 Data structures defining the USB keyboard device. - CM

FILE: usb_ex3_device_keyboard_structs.c

38.5.1.10 Data structures defining this bulk USB device. - CM

FILE: usb_ex4_device_bulk_structs.c

38.5.1.11 USB Generic Bulk Device (usb_dev_bulk) - CM

FILE: usb_ex4_device_bulk_cm.c

This example provides a generic USB device offering simple bulk data transfer to and from the host. The device uses a vendor-specific class ID and supports a single bulk IN endpoint and a single bulk OUT endpoint. Data received from the host is assumed to be ASCII text and it is echoed back with the case of all alphabetic characters swapped.

UART0, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

A Windows INF file for the device is provided in C2000Ware. This INF contains information required to install the WinUSB subsystem on Windows. WinUSB is a Windows subsystem allowing user mode applications to access the USB device without the need for a vendor-specific kernel mode driver.

A sample Windows command-line application, usb_bulk_example, illustrating how to connect to and communicate with the bulk device is also provided. Project files are included to allow the examples to be built using Microsoft VisualStudio. Source code for this application can be found in directory MWare/tools/usb_bulk_example.

38.5.1.12 USB Generic Bulk Device

FILE: usb_ex4_dev_bulk.c

This example provides a generic USB device offering simple bulk data transfer to and from the host. The device uses a vendor-specific class ID and supports a single bulk IN endpoint and a single bulk OUT endpoint. Data received from the host is assumed to be ASCII text and it is echoed back with the case of all alphabetic characters swapped.

SCIA, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

A Windows INF file for the device is provided under the windows drivers directory. This INF contains information required to install the WinUSB subsystem on WindowsXP, Windows 7 and Windows 10. WinUSB is a Windows subsystem allowing user mode applications to access the USB device without the need for a vendor-specific kernel mode driver.

A sample Windows command-line application, usb_bulk_example, illustrating how to connect to and communicate with the bulk device is also provided. Project files are included to allow the examples to be built using Microsoft VisualStudio. Source code for this application can be found in directory ~/C2000Ware/utilities/tools/{Device}/usb_bulk_example/Release

38.5.1.13 USB HID Mouse Host

FILE: usb_ex5_host_mouse.c

This application demonstrates the handling of a USB mouse attached to the evaluation kit. Once attached, the position of the mouse pointer and the state of the mouse buttons are output to the display.

SCIA, which is connected to the FTDI virtual serial port on the controlCARD board, is configured for 115200 bits per second, and 8-N-1 mode. When a HID compliant mouse is connected to the microUSB port on the top of the controlCARD, position and button information will be displayed to the console.

38.5.1.14 USB HID Mouse Host (usb_host_mouse) - CM

FILE: usb_ex5_host_mouse_cm.c

This application demonstrates the handling of a USB mouse attached to the evaluation kit. Once attached, the position of the mouse pointer and the state of the mouse buttons are output to the display.

UART0, which is connected to the FTDI virtual serial port on the controlCARD board, is configured for 115200 bits per second, and 8-N-1 mode. When a HID compliant mouse is connected to the microUSB port on the top of the controlCARD, position and button information will be displayed to the console.

38.5.1.15 USB HID Keyboard Host (usb_host_keyboard) - CM

FILE: usb_ex6_host_keyboard_cm.c

This example application demonstrates how to support a USB keyboard attached to the evaluation kit board. The display will show if a keyboard is currently connected and the current state of the Caps Lock key on the keyboard that is connected on the bottom status area of the screen. Pressing any keys on the keyboard will cause them to be sent out the UART0 at 115200 baud with no parity, 8 bits and 1 stop bit. Any keyboard that supports the USB HID BIOS protocol should work with this demo application.

To run the example you should connect a HID compliant keyboard to the microUSB port on the top of the controlCARD and open up a serial terminal with the above settings to view the characters typed on the keyboard.

38.5.1.16 USB HID Keyboard Host

FILE: usb_ex6_host_keyboard.c

This example application demonstrates how to support a USB keyboard attached to the evaluation kit board. The display will show if a keyboard is currently connected and the current state of the Caps Lock key on the keyboard that is connected on the bottom status area of the screen. Pressing any keys on the keyboard will cause them to be sent out the SCI at 115200 baud with no parity, 8 bits and 1 stop bit. Any keyboard that supports the USB HID BIOS protocol should work with this demo application.

To run the example you should connect a HID compliant keyboard to the microUSB port on the top of the controlCARD and open up a serial terminal with the above settings to view the characters typed on the keyboard.

38.5.1.17 USB Mass Storage Class Host

FILE: usb_ex7_host_msc.c

This example application demonstrates reading a file system from a USB mass storage class device. It makes use of FatFs, a FAT file system driver. It provides a simple command console via the SCI for issuing commands to view and navigate the file system on the mass storage device.

The first SCI, which is connected to the FTDI virtual serial port on the controlCARD board, is configured for 115200 bits per second, and 8-N-1 mode. When the program is started a message will be printed to the terminal. Type `help' for command help.

After loading and running the example, open a serial terminal with the above settings to open the command prompt. Then connect a USB MSC device to the microUSB port on the top of the controlCARD.

For additional details about FatFs, see the following site: *FatFs - Generic FAT Filesystem Module*

38.5.1.18 USB Mass Storage Class Host (usb_host_msc) - CM

FILE: usb_ex7_host_msc_cm.c

This example application demonstrates reading a file system from a USB mass storage class device. It makes use of FatFs, a FAT file system driver. It provides a simple command console via the SCI for issuing commands to view and navigate the file system on the mass storage device.

The first UART, which is connected to the FTDI virtual serial port on the controlCARD board, is configured for 115200 bits per second, and 8-N-1 mode. When the program is started a message will be printed to the terminal. Type `help' for command help.

After loading and running the example, open a serial terminal with the above settings to open the command prompt. Then connect a USB MSC device to the microUSB port on the top of the controlCARD.

For additional details about FatFs, see the following site: *FatFs - Generic FAT Filesystem Module*

38.5.1.19 USB Dual Detect

FILE: usb_ex8_dual_detect.c

This program uses a GPIO to do ID detection. If a host is connected to the device's USB port, the stack will switch to device mode and enumerate as mouse. If a mouse device is connected to the device's USB port, the stack will switch to host mode and display the mouses movement and button press information in a serial terminal.

38.5.1.20 Data structures defining this bulk USB device. - CM

FILE: usb_ex8_device_bulk_structs.c

38.5.1.21 USB Throughput Bulk Device Example (usb_ex9_throughput_dev_bulk) - CM

FILE: usb_ex8_device_bulk_throughput_cm.c

This example provides a generic USB device offering simple bulk data transfer to and from the host. The device uses a vendor-specific class ID and supports a single bulk IN Endpoint and a single bulk OUT Endpoint. Data received from the host is assumed to be ASCII text and it is echoed back with the case of all alphabetic characters swapped.

UART0, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

A Windows INF file for the device is provided under the windows drivers directory. This INF contains information required to install the WinUSB subsystem on WindowsXP, Windows 7 and Windows 10. WinUSB is a Windows subsystem allowing user mode applications to access the USB device without the need for a vendor-specific kernel mode driver.

A sample Windows command-line application, usb_throughput_bulk_example, illustrating how to connect to and communicate with the bulk device is also provided. Project files are included to allow the examples to be built using Microsoft VisualStudio. Source code for this application can be found in directory ~/utilities/tools/usb_throughput_bulk_example/Release.

38.5.1.22 USB HUB Host example - CM

FILE: usb_ex9_host_hub_cm.c

This example application demonstrates how to support a USB keyboard and USB Mouse with a USB Hub. The display will show the connected devices on the USB hub.

To run the example you should first run the usb_config_c28 example of the C28x Side. Then run the usb_ex9_host_hub_cm Example. Then connect a USB Hub to the microUSB port on the top of the controlCARD and open up a serial terminal with the above settings to view the characters typed on the keyboard. Allow the example to run with the hub connected and then connect the USB Host Mouse or Keyboard.

When a USB Mouse is connected on the Hub the position of the mouse pointer and the state of the mouse buttons are output to the display. Similarly when a USB Keyboard is connected, any key press on the keyboard will cause them to be sent out the UART at 115200 baud with no parity, 8 bits and 1 stop bit.

This example is for depicting the usage of Hub.

There are some limitations in this example :

1. The Example fails to recognize the USB Hub and the device if the Mouse/Keyboard is already connected to the USB Hub and the Hub is connected to the Micro USB of the Control Card.
2. The same port should not be used to connect a Keyboard and mouse.

38.5.1.23 USB Throughput Bulk Device Example (usb_ex9_throughput_dev_bulk)

FILE: usb_ex9_dev_bulk_throughput.c

This example provides a throughput numbers of bulk data transfer to and from the host. The device uses a vendor-specific class ID and supports a single bulk IN Endpoint and a single bulk OUT Endpoint.

SCIA, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

A Windows INF file for the device is provided under the windows drivers directory. This INF contains information required to install the WinUSB subsystem on WindowsXP, Windows 7 and Windows 10. This is present in utilities/windows_drivers.

A sample Windows command-line application, usb_throughput_bulk_example, illustrating how to connect to and communicate with the bulk device is also provided. Project files are included to allow the examples to be built using Microsoft VisualStudio. Source code for this application can be found in directory ~/utilities/tools/usb_throughput_bulk_example/Release.

After running the example in CCS Connect the USB Micro to the PC. Then the example will wait to receive data from the application. Run the usb_throughput_bulk example, the throughput and Data Packets Transferred.

38.5.1.24 USB HUB Host example

FILE: usb_ex10_host_hub.c

This example application demonstrates how to support a USB keyboard and USB Mouse with a USB Hub. The display will show the connected devices on the USB hub.

To run the example you should connect a USB Hub to the microUSB port on the top of the controlCARD and open up a serial terminal with the above settings to view the characters typed on the keyboard. Allow the example to run with the hub connected and then connect the USB Host Mouse or Keyboard.

When a USB Mouse is connected on the Hub the position of the mouse pointer and the state of the mouse buttons are output to the display. Similarly when a USB Keyboard is connected, any key press on the keyboard will cause them to be sent out the SCI at 115200 baud with no parity, 8 bits and 1 stop bit.

This example is for depicting the usage of Hub.

There are some limitations in this example :

1. The Example fails to recognize the USB Hub and the device if the Mouse/Keyboard is already connected to the USB Hub and the Hub is connected to the Micro USB of the Control Card.
2. The same port should not be used to connect a Keyboard and mouse.

38.6 USB Registers

38.6.1 USB Base Address Table (C28)

Table 38-3. USB Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
UsbRegs	USB_REGS	USBA_BASE	0x0004_0000	YES	-	YES	-	YES

38.6.2 USB_REGS Registers

Table 38-4 lists the memory-mapped registers for the USB_REGS registers. All register offset addresses not listed in Table 38-4 should be considered as reserved locations and the register contents should not be modified.

Table 38-4. USB_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section

284h	USBDMAISC	USB uDMA Interrupt Status and Clear Register Note: This Register is applicable only when USB is mapped to CM		Go

Complex bit access types are encoded to fit into small table cells. Table 38-5 shows the codes that are used for access types in this section.

Table 38-5. USB_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		

Table 38-5. USB_REGS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

38.6.2.1 USBFADDR Register (Offset = 0h) [Reset = 0h]

USBFADDR is shown in Figure 38-3 and described in Table 38-6.

Return to the Summary Table.

USB Device Functional Address

Figure 38-3. USBFADDR Register

7	6	5	4	3	2	1	0
RESERVED	FUNCADDR						
R-0h	R/W-0h						

Table 38-6. USBFADDR Register Field Descriptions

Bit	Field	Type	Reset	Description
7	RESERVED	R	0h	Reserved
6-0	FUNCADDR	R/W	0h	Function Address of Device as received through SET_ADDRESS Reset type: SYSRSn

38.6.2.2 USBPOWER Register (Offset = 0h) [Reset = 0h]

USBPOWER is shown in Figure 38-4 and described in Table 38-7.

Return to the Summary Table.

USB Power

Figure 38-4. USBPOWER Register

7	6	5	4	3	2	1	0
ISOUP	SOFT_CONN	RESERVED		RESET	RESUME	SUSPEND	PWRDNPHY
R/W-0h	R/W-0h	R-0h		R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-7. USBPOWER Register Field Descriptions

Bit	Field	Type	Reset	Description
7	ISOUP	R/W	0h	Isochronous Update Reset type: SYSRSn 0h (R/W) = Host Mode - Reserved Device Mode - No effect 1h (R/W) = Host Mode - Reserved Device Mode - The USB controller waits for an SOF token from the time the TXRDY bit is set in the USBTXCSRLn register before sending the packet. If an IN token is received before an SOF token, then a zerolength data packet is sent.
6	SOFT_CONN	R/W	0h	Soft Connect/Disconnect Reset type: SYSRSn 0h (R/W) = Host Mode - Reserved Device Mode - The USB D+/D- lines are tri-stated. 1h (R/W) = Host Mode - Reserved Device Mode - The USB D+/D- lines are enabled.
5-4	RESERVED	R	0h	Reserved
3	RESET	R/W	0h	Enable Reset Signaling Reset type: SYSRSn 0h (R/W) = Ends RESET signaling on the bus. 1h (R/W) = Enables RESET signaling on the bus.
2	RESUME	R/W	0h	Enable Resume Signaling. The bit should be cleared by software 20 ms after being set. Reset type: SYSRSn 0h (R/W) = Ends RESUME signaling on the bus. 1h (R/W) = Enables RESUME signaling when the Device is in SUSPEND mode.
1	SUSPEND	R/W	0h	Enable Suspend Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables SUSPEND mode.
0	PWRDNPHY	R/W	0h	Power Down PHY Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Powers down the internal USB PHY.

38.6.2.3 USBTXIS Register (Offset = 1h) [Reset = 0h]

USBTXIS is shown in Figure 38-5 and described in Table 38-8.

Return to the Summary Table.

USB Transmit Interrupt Status

Figure 38-5. USBTXIS Register

38.6.2.10 USBEPIDX Register (Offset = 7h) [Reset = 0h]

USBEPIDX is shown in Figure 38-12 and described in Table 38-15.

Return to the Summary Table.

USB Endpoint Index

Figure 38-12. USBEPIDX Register

7	6	5	4	3	2	1	0
RESERVED				EPIDX			
R-0h				R/W-0h			

Table 38-15. USBEPIDX Register Field Descriptions

Bit	Field	Type	Reset	Description
7-4	RESERVED	R	0h	Reserved
3-0	EPIDX	R/W	0h	Endpoint Index. This bit field configures which endpoint is accessed when reading or writing to one of the USB controller's indexed registers. A value of 0x0 corresponds to Endpoint 0 and a value of 0xF corresponds to Endpoint 15. Reset type: SYSRSn

38.6.2.11 USBTEST Register (Offset = 7h) [Reset = 0h]

USBTEST is shown in Figure 38-13 and described in Table 38-16.

Return to the Summary Table.

USB Test Mode

Figure 38-13. USBTEST Register

7	6	5	4	3	2	1	0
FORCEH	FIFOACC	FORCEFS	RESERVED				
R/W-0h	R/W-0h	R/W-0h	R-0h				

Table 38-16. USBTEST Register Field Descriptions

Bit	Field	Type	Reset	Description
7	FORCEH	R/W	0h	Force Host Mode. While in this mode, status of the bus connection may be read using the DEV bit of the USBDEVCTL register. The operating speed is determined from the FORCEFS bit. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the USB controller to enter Host mode when the SESSION bit is set, regardless ofwhether the USB controller is connected to any peripheral. The state of the USB0DP and USB0DM signals is ignored. The USB controller then remains in Host mode until the SESSION bit is cleared, even if a Device is disconnected. If the FORCEH bit remains set, the USB controller re-enters Host mode the next time the SESSION bit is set.
6	FIFOACC	R/W	0h	FIFO Access Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Transfers the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO.
5	FORCEFS	R/W	0h	Force Full Speed Upon Reset Reset type: SYSRSn 0h (R/W) = The USB controller operates at Low Speed. 1h (R/W) = Forces the USB controller into Full-Speed mode upon receiving a USB RESET.
4-0	RESERVED	R	0h	Reserved

38.6.2.12 USBFIFO0 Register (Offset = 10h) [Reset = 0h]

USBFIFO0 is shown in Figure 38-14 and described in Table 38-17.

Return to the Summary Table.

DEV	FSDEV	LSDEV	VBUS		HOST	HOSTREQ	SESSION
R-0h	R/W-1h	R-0h	R/W-1h		R/W-1h	R/W-1h	R-0h

Table 38-21. USBDEVCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	DEV	R	0h	Device Mode Reset type: SYSRSn 0h (R/W) = The USB controller is operating on the OTG A side of the cable. 1h (R/W) = The USB controller is operating on the OTG B side of the cable. Only valid while a session is in progress.
6	FSDEV	R/W	1h	Full Speed Device Detected Reset type: SYSRSn 0h (R/W) = A full-speed Device has not been detected on the port. 1h (R/W) = A full-speed Device has been detected on the port.
5	LSDEV	R	0h	Low Speed Device Detected Reset type: SYSRSn 0h (R/W) = A low-speed Device has not been detected on the port. 1h (R/W) = A low-speed Device has been detected on the port.
4-3	VBUS	R/W	1h	Vbus Level Reset type: SYSRSn 0h (R/W) = Above AValid, below VBusValid. VBUS is detected as above 1.5 V and below 4.75 V. 1h (R/W) = Above VBusValid. VBUS is detected as above 4.75 V.
2	HOST	R/W	1h	Host Mode Reset type: SYSRSn 0h (R/W) = The USB controller is acting as a Device. 1h (R/W) = The USB controller is acting as a Host. Only valid while a session is in progress.
1	HOSTREQ	R/W	1h	When set, the USB controller will initiate the Host Negotiation when Suspend mode is entered. It is cleared when Host Negotiation is completed. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Initiates the Host Negotiation when SUSPENDmode is entered.

Table 38-21. USBDEVCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	SESSION	R	0h	Session Start/End Reset type: SYSRSn 0h (R/W) = When operating as a Host: When cleared by software, this bit ends a session. When operating as a Device: The USB controller has ended a session. When the USB controller is in SUSPEND mode, this bit may be cleared by software to perform a software disconnect. 1h (R/W) = When operating as a Host: When set by software, this bit starts a session. When operating as a Device: The USB controller has started a session. When set by software, the Session Request Protocol is initiated. Clearing this bit when the USB controller is not suspended results in undefined behavior.

38.6.2.17 USBTXFIFOSZ Register (Offset = 31h) [Reset = 0h]

USBTXFIFOSZ is shown in Figure 38-19 and described in Table 38-22.

Return to the Summary Table.

38.6.2.21 USBCONTIM Register (Offset = 3Dh) [Reset = 11h]

USBCONTIM is shown in Figure 38-23 and described in Table 38-26.

Return to the Summary Table.

USB Connect Timing

Figure 38-23. USBCONTIM Register

7	6	5	4	3	2	1	0
WTCON				WTID			
R/W-1h				R/W-1h			

Table 38-26. USBCONTIM Register Field Descriptions

Bit	Field	Type	Reset	Description
7-4	WTCON	R/W	1h	The wait ID field configures the delay required from the enable of the ID detection to when the ID value is valid, in units of 4.369 ms. The default corresponds to 52.43 ms. Reset type: SYSRSn
3-0	WTID	R/W	1h	The connect wait field configures the wait required to allow for the user's connect/disconnect filter, in units of 533.3 ns. The default corresponds to 2.667 us. Reset type: SYSRSn

38.6.2.22 USBFSEOF Register (Offset = 3Eh) [Reset = 77h]

USBFSEOF is shown in Figure 38-24 and described in Table 38-27.

Return to the Summary Table.

USB Full-Speed Last Transaction to End of Frame Timing

Figure 38-24. USBFSEOF Register

7	6	5	4	3	2	1	0
FSEOFG							
R/W-77h							

Table 38-27. USBFSEOF Register Field Descriptions

Bit	Field	Type	Reset	Description
7-0	FSEOFG	R/W	77h	The full-speed end-of-frame gap field is used during full-speed transactions to configure the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. The default corresponds to 63.46 us. Reset type: SYSRSn

38.6.2.23 USBLSEOF Register (Offset = 3Fh) [Reset = 72h]

USBLSEOF is shown in Figure 38-25 and described in Table 38-28.

Return to the Summary Table.

USB Low-Speed Last Transaction to End of Frame Timing

Figure 38-25. USBLSEOF Register

7	6	5	4	3	2	1	0
LSEOFG							
R/W-72h							

Table 38-28. USBLSEOF Register Field Descriptions

Bit	Field	Type	Reset	Description
7-0	LSEOFG	R/W	72h	The low-speed end-of-frame gap field is used during low-speed transactions to set the gap between the last transaction and the End-of-Frame (EOF), in units of 1.067 us. The default corresponds to 121.6 us. Reset type: SYSRSn

38.6.2.24 USBTXFUNCADDR0 Register (Offset = 40h) [Reset = 0h]

USBTXFUNCADDR0 is shown in Figure 38-26 and described in Table 38-29.

Return to the Summary Table.

USB Transmit Functional Address Endpoint 0

38.6.2.45 USBCSRL0 Register (Offset = 81h) [Reset = 0h]

USBCSRL0 is shown in Figure 38-47 and described in Table 38-50.

Return to the Summary Table.

USB Control and Status Endpoint 0 Low

Figure 38-47. USBCSRL0 Register

7	6	5	4	3	2	1	0
SETENDC_NAKTO	RXRDYC_STATUS	STALL_RQPKT	SETEND_ERROR	DATAEND_SETUP	STALLED	TXRDY	RXRDY
W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-50. USBCSRL0 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	SETENDC_NAKTO	W1C	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Indicates that endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the USBNAKLMT register
6	RXRDYC_STATUS	R/W	0h	Status Packet. Setting this bit ensures that the DT bit is set in the USBCSRH0 register so that a DATA1 packet is used for the STATUS stage transaction. Reset type: SYSRSn 0h (R/W) = No transaction 1h (R/W) = The Endpoint 1 transmit interrupt is asserted.
5	STALL_RQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Initiates a STATUS stage transaction. This bit must be set at the same time as the TXRDY or REQPKT bit is set. This bit is automatically cleared when the STATUS stage is over.
4	SETEND_ERROR	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to perform a transaction with no response from the peripheral. The EP0 bit in the USBTXIS register is also set in this situation.
3	DATAEND_SETUP	R/W	0h	Setup Packet. Setting this bit always clears the DT bit in the USBCSRH0 register to send a DATA0 packet. Reset type: SYSRSn 0h (R/W) = Sends an OUT token. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set.
2	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received
1	TXRDY	R/W	0h	Transmit Packet Ready. If both the TXRDY and SETUP bits are set, a setup packet is sent. If just TXRDY is set, an OUT packet is sent. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.

Table 38-50. USBCSRL0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. Software must clear this bit after he packet has been read from the FIFO to acknowledge that the data has been read from the FIFO. Reset type: SYSRSn 0h (R/W) = No receive packet has been received. 1h (R/W) = Indicates that a data packet has been received in the RX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.

38.6.2.46 USBCSRH0 Register (Offset = 81h) [Reset = 0h]

USBCSRH0 is shown in Figure 38-48 and described in Table 38-51.

Return to the Summary Table.

USB Control and Status Endpoint 0 High

Figure 38-48. USBCSRH0 Register

7	6	5	4	3	2	1	0
RESERVED					DTWE	DT	FLUSH

Bit	Field	Type	Reset	Description
7-3	RESERVED	R	0h	Reserved
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the endpoint 0 data toggle to be written (see DT bit).
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the endpoint 0 data toggle. If DTWE is set, this bit may be written with the required setting of the data toggle. If DTWE is Low, this bit cannot be written. Care should be taken when writing to this bit as it should only be changed to RESET USB endpoint 0. Reset type: SYSRSn
0	FLUSH	R/W	0h	Flush FIFO. This bit is automatically cleared after the flush is performed. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared. Note: This bit should only be set when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted..

38.6.2.47 USBCOUNT0 Register (Offset = 84h) [Reset = 0h]

USBCOUNT0 is shown in Figure 38-49 and described in Table 38-52.

Return to the Summary Table.

USB Receive Byte Count Endpoint 0

10-0	MAXLOAD	R/W	0h	Maximum Payload specifies the maximum payload in bytes per transaction. Reset type: SYSRSn

38.6.2.51 USBTXCSRL1 Register (Offset = 89h) [Reset = 0h]

USBTXCSRL1 is shown in Figure 38-53 and described in Table 38-56.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 1 Low

Figure 38-53. USBTXCSRL1 Register

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	STALL_SETUP	FLUSH	UNDRN_ERROR1	FIFONE	TXRDY
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-56. USBTXCSRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	NAKTO	R/W	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[n] register.
6	CLRDT	R/W	0h	Clear DataToggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBTXCSRH[n] register.
5	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = A STALL handshake has not been received 1h (R/W) = Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	STALL_SETUP	R/W	0h	Setup Packet. Reset type: SYSRSn 0h (R/W) = No SETUP token is sent. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. Note: Setting this bit also clears the DT bit in the USBTXCSRH[n] register.
3	FLUSH	R/W	0h	Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	UNDRN_ERROR1	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed inthis situation. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

Table 38-56. USBTXCSRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	FIFONE	R/W	0h	FIFO Not Empty Reset type: SYSRSn 0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.
0	TXRDY	R/W	0h	Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.

38.6.2.52 USBTXCSRH1 Register (Offset = 89h) [Reset = 0h]

USBTXCSRH1 is shown in Figure 38-54 and described in Table 38-57.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 1 High

Figure 38-54. USBTXCSRH1 Register

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-57. USBTXCSRH1 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set Reset type: SYSRSn 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	ISO	R/W	0h	Isochronous Transfers Reset type: SYSRSn 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Reset type: SYSRSn 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.
3	FDT	R/W	0h	Force Data Toggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This bit can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD	R/W	0h	DMA Request Mode Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

Table 38-57. USBTXCSRH1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).
0	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint. Reset type: SYSRSn

38.6.2.53 USBRXMAXP1 Register (Offset = 8Ah) [Reset = 0h]

USBRXMAXP1 is shown in Figure 38-55 and described in Table 38-58.

Table 38-59. USBRXCSRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Requests an IN transaction.
4	FLUSH	R/W	0h	Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Note:This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared
3	DATAERRNAKTO	R/W	0h	Data Error / NAK Timeout Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Isochronous endpoints only: I ndicates that RXRDY is set and the data packet has a CRC or bit-stuff error. This bit is cleared when RXRDY is cleared. Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[n] register. Software must clear this bit to allow the endpoint to continue.
2	OVERERROR1	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to receive a packet and no data packet has been received. The Epn bit in the USBRXIS register is set in this situation.
1	FULL	R/W	0h	FIFO Full Reset type: SYSRSn 0h (R/W) = The receive FIFO is not full. 1h (R/W) = No more packets can be loaded into the receive FIFO.

Table 38-59. USBRXCSRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO Reset type: SYSRSn 0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EPn bit in the USBTXIS register is also set in this situation

38.6.2.55 USBRXCSRH1 Register (Offset = 8Bh) [Reset = 0h]

USBRXCSRH1 is shown in Figure 38-57 and described in Table 38-60.

Return to the Summary Table.

USB Receive Control and Status Endpoint 1 High

Figure 38-57. USBRXCSRH1 Register

AUTOCL	ISOAUTORQ	DMAEN	DISNYETPIDERR	DMAMOD	DTWE	DT	RESERVED
W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-60. USBRXCSRH1 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOCL	W1C	0h	Auto Clear Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[n] register,
6	ISOAUTORQ	R/W	0h	Auto Request Note: This bit is automatically cleared when a short packet is received. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared
5	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the receive endpoint. 1h (R/W) = Enables the DMA request for the receive endpoint.
4	DISNYETPIDERR	R/W	0h	PID Error. This bit is ignored in bulk or interrupt transactions. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Indicates a PID error in the received packet of an isochronous transaction.
3	DMAMOD	R/W	0h	DMAMOD Note: This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared. Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete.
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the receive endpoint data to be written (see DT bit).

Table 38-60. USBRXCSRH1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint. Reset type: SYSRSn
0	RESERVED	R/W	0h	Reserved

38.6.2.56 USBRXCOUNT1 Register (Offset = 8Ch) [Reset = 0h]

USBRXCOUNT1 is shown in Figure 38-58 and described in Table 38-61.

USBTXCSRL2 is shown in Figure 38-64 and described in Table 38-67.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 2 Low

Figure 38-64. USBTXCSRL2 Register

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	STALL_SETUP	FLUSH	UNDRNERROR2	FIFONE	TXRDY
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-67. USBTXCSRL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	NAKTO	R/W	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[n] register.
6	CLRDT	R/W	0h	Clear DataToggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBTXCSRH[n] register.
5	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = A STALL handshake has not been received 1h (R/W) = Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	STALL_SETUP	R/W	0h	Setup Packet. Reset type: SYSRSn 0h (R/W) = No SETUP token is sent. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. Note: Setting this bit also clears the DT bit in the USBTXCSRH[n] register.
3	FLUSH	R/W	0h	Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	UNDRNERROR2	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed inthis situation. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

Table 38-67. USBTXCSRL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	FIFONE	R/W	0h	FIFO Not Empty Reset type: SYSRSn 0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.
0	TXRDY	R/W	0h	Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.

38.6.2.63 USBTXCSRH2 Register (Offset = 91h) [Reset = 0h]

USBTXCSRH2 is shown in Figure 38-65 and described in Table 38-68.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 2 High

Figure 38-65. USBTXCSRH2 Register

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-68. USBTXCSRH2 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set Reset type: SYSRSn 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	ISO	R/W	0h	Isochronous Transfers Reset type: SYSRSn 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Reset type: SYSRSn 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.
3	FDT	R/W	0h	Force Data Toggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This bit can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD	R/W	0h	DMA Request Mode Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

Table 38-68. USBTXCSRH2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).
0	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint. Reset type: SYSRSn

38.6.2.64 USBRXMAXP2 Register (Offset = 92h) [Reset = 0h]

Table 38-70. USBRXCSRL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Requests an IN transaction.
4	FLUSH	R/W	0h	Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Note:This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared
3	DATAERRNAKTO	R/W	0h	Data Error / NAK Timeout Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Isochronous endpoints only: I ndicates that RXRDY is set and the data packet has a CRC or bit-stuff error. This bit is cleared when RXRDY is cleared. Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[n] register. Software must clear this bit to allow the endpoint to continue.
2	OVERERROR2	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to receive a packet and no data packet has been received. The Epn bit in the USBRXIS register is set in this situation.
1	FULL	R/W	0h	FIFO Full Reset type: SYSRSn 0h (R/W) = The receive FIFO is not full. 1h (R/W) = No more packets can be loaded into the receive FIFO.

Table 38-70. USBRXCSRL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO Reset type: SYSRSn 0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EPn bit in the USBTXIS register is also set in this situation

38.6.2.66 USBRXCSRH2 Register (Offset = 93h) [Reset = 0h]

USBRXCSRH2 is shown in Figure 38-68 and described in Table 38-71.

Return to the Summary Table.

Table 38-77. USBTXMAXP3 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10-0	MAXLOAD	R/W	0h	Maximum Payload specifies the maximum payload in bytes per transaction. Reset type: SYSRSn

38.6.2.73 USBTXCSRL3 Register (Offset = 99h) [Reset = 0h]

USBTXCSRL3 is shown in Figure 38-75 and described in Table 38-78.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 3 Low

Figure 38-75. USBTXCSRL3 Register

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	STALL_SETUP	FLUSH	UNDRNERROR3	FIFONE	TXRDY
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-78. USBTXCSRL3 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	NAKTO	R/W	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[n] register.
6	CLRDT	R/W	0h	Clear DataToggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBTXCSRH[n] register.
5	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = A STALL handshake has not been received 1h (R/W) = Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	STALL_SETUP	R/W	0h	Setup Packet. Reset type: SYSRSn 0h (R/W) = No SETUP token is sent. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. Note: Setting this bit also clears the DT bit in the USBTXCSRH[n] register.
3	FLUSH	R/W	0h	Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	UNDRNERROR3	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed inthis situation. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

Table 38-78. USBTXCSRL3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	FIFONE	R/W	0h	FIFO Not Empty Reset type: SYSRSn 0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.
0	TXRDY	R/W	0h	Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.

38.6.2.74 USBTXCSRH3 Register (Offset = 99h) [Reset = 0h]

USBTXCSRH3 is shown in Figure 38-76 and described in Table 38-79.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 3 High

Figure 38-76. USBTXCSRH3 Register

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-79. USBTXCSRH3 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set Reset type: SYSRSn 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	ISO	R/W	0h	Isochronous Transfers Reset type: SYSRSn 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Reset type: SYSRSn 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.
3	FDT	R/W	0h	Force Data Toggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This bit can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD	R/W	0h	DMA Request Mode Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

Table 38-79. USBTXCSRH3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).
0	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint. Reset type: SYSRSn

38.6.2.75 USBRXMAXP3 Register (Offset = 9Ah) [Reset = 0h]

USBRXMAXP3 is shown in Figure 38-77 and described in Table 38-80.

Return to the Summary Table.

W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-81. USBRXCSRL3 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Requests an IN transaction.
4	FLUSH	R/W	0h	Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Note:This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared
3	DATAERRNAKTO	R/W	0h	Data Error / NAK Timeout Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Isochronous endpoints only: I ndicates that RXRDY is set and the data packet has a CRC or bit-stuff error. This bit is cleared when RXRDY is cleared. Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[n] register. Software must clear this bit to allow the endpoint to continue.
2	OVERERROR3	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to receive a packet and no data packet has been received. The Epn bit in the USBRXIS register is set in this situation.
1	FULL	R/W	0h	FIFO Full Reset type: SYSRSn 0h (R/W) = The receive FIFO is not full. 1h (R/W) = No more packets can be loaded into the receive FIFO.

Table 38-81. USBRXCSRL3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO Reset type: SYSRSn 0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EPn bit in the USBTXIS register is also set in this situation

38.6.2.77 USBRXCSRH3 Register (Offset = 9Bh) [Reset = 0h]

USBRXCSRH3 is shown in Figure 38-79 and described in Table 38-82.

Return to the Summary Table.

USB Receive Control and Status Endpoint 3 High

Figure 38-79. USBRXCSRH3 Register

W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 38-82. USBRXCSRH3 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOCL	W1C	0h	Auto Clear Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[n] register,
6	ISOAUTORQ	R/W	0h	Auto Request Note: This bit is automatically cleared when a short packet is received. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared
5	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the receive endpoint. 1h (R/W) = Enables the DMA request for the receive endpoint.
4	DISNYETPIDERR	R/W	0h	PID Error. This bit is ignored in bulk or interrupt transactions. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Indicates a PID error in the received packet of an isochronous transaction.
3	DMAMOD	R/W	0h	DMAMOD Note: This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared. Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete.
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the receive endpoint data to be written (see DT bit).

Table 38-82. USBRXCSRH3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint. Reset type: SYSRSn
0	RESERVED	R/W	0h	Reserved

31-16	RESERVED	R	0h	Reserved
15-10	RESERVED	R	0h	Reserved
9-8	PFLTACT	R/W	0h	Power Fault Action. This bit field specifies how the USB0EPEN signal is changed when detecting a USB power fault Reset type: SYSRSn 0h (R/W) = Unchanged. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits. 1h (R/W) = Tristate. USB0EPEN is undriven (tristate). 2h (R/W) = Low. USB0EPEN is driven Low. 3h (R/W) = High. USB0EPEN is driven High.
7	RESERVED	R	0h	Reserved
6	PFLTAEN	R/W	0h	Power Fault Action Enable. This bit specifies whether a USB power fault triggers any automatic corrective action regarding the driven state of the USB0EPEN signal. Reset type: SYSRSn 0h (R/W) = Disabled. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits. 1h (R/W) = Enabled. The USB0EPEN output is automatically changed to the state specified by the PFLTACT field.
5	PFLTSEN	R/W	0h	Power Fault Sense. This bit specifies the logical sense of the USB0PFLT input signal that indicates an error condition. The complementary state is the inactive state. Reset type: SYSRSn 0h (R/W) = Low Fault. If USB0PFLT is driven Low, the power fault is signaled internally (if enabled by the PFLTEN bit). 1h (R/W) = High Fault. If USB0PFLT is driven High, the power fault is signaled internally (if enabled by the PFLTEN bit).
4	PFLTEN	R/W	0h	Power Fault Input Enable. This bit specifies whether the USB0PFLT input signal is used in internal logic. Reset type: SYSRSn 0h (R/W) = Not Used. The USB0PFLT signal is ignored. 1h (R/W) = Used. The USB0PFLT signal is used internally

Table 38-93. USBEPC Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	RESERVED	R	0h	Reserved
2	EPENDE	R/W	0h	EPEN Drive Enable. This bit specifies whether the USB0EPEN signal is driven or undriven (tristate). When driven, the signal value is specified by the EPEN field. When not driven, the EPEN field is ignored and the USB0EPEN signal is placed in a high-impedance state. The USB0EPEN signal is undriven at reset because the sense of the external power supply enable is unknown. By adding the high-impedance state, system designers can bias the power supply enable to the disabled state using a large resistor (100 kOhm) and later configure and drive the output signal to enable the power supply. Reset type: SYSRSn 0h (R/W) = Not Driven. The USB0EPEN signal is high impedance. 1h (R/W) = Driven. The USB0EPEN signal is driven to the logical value specified by the value of the EPEN field.
1-0	EPEN	R/W	0h	External Power Supply Enable Configuration. This bit field specifies and controls the logical value driven on the USB0EPEN signal. Reset type: SYSRSn 0h (R/W) = Power Enable Active Low. The USB0EPEN signal is driven Low if the EPENDE bit is set. 1h (R/W) = Power Enable Active High. The USB0EPEN signal is driven High if the EPENDE bit is set. 2h (R/W) = Power Enable High if VBUS Low. The USB0EPEN signal is driven High when the A device is not recognized. 3h (R/W) = Power Enable High if VBUS High. The USB0EPEN signal is driven High when the A device is recognized.

38.6.2.89 USBEPCRIS Register (Offset = 202h) [Reset = 0h]

USBEPCRIS is shown in Figure 38-91 and described in Table 38-94.

Return to the Summary Table.

USB External Power Control Raw Interrupt Status

Chapter 39

► CONNECTIVITY MANAGER (CM)

The following chapters describe the Connectivity Manager peripherals.

39.1 Technical Reference Manual Overview

The block diagram for the F2838x device is shown in Figure 39-1. This Technical Reference Manual is organized into five major sections:

- C28x SYSTEM RESOURCES

  These chapters describe the C28x CPU subsystem, C28x Boot ROM, device configuration, and other system peripherals.

- ANALOG PERIPHERALS

  These chapters describe the Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), Comparator Subsystem (CMPSS), and general analog subsystem configuration.

- CONTROL PERIPHERALS

  These chapters describe the Enhanced Capture (eCAP), High Resolution Capture (HRCAP), Enhanced Pulse Width Modulator (ePWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- COMMUNICATION PERIPHERALS

  These chapters describe the communication peripherals available to the C28x subsystem such as the I2C, SCI, FSI, McBSP, PMBUS, and SPI. The CAN, EtherCAT, and USB peripherals are also described in this section and can be assigned to the CM subsystem.

- CONNECTIVITY MANAGER (CM)

  These chapters describe the Connectivity Manager (CM) subsystem as well as the AES, GCRC, CM-I2C, CM-UART, SSI, and Ethernet peripherals.

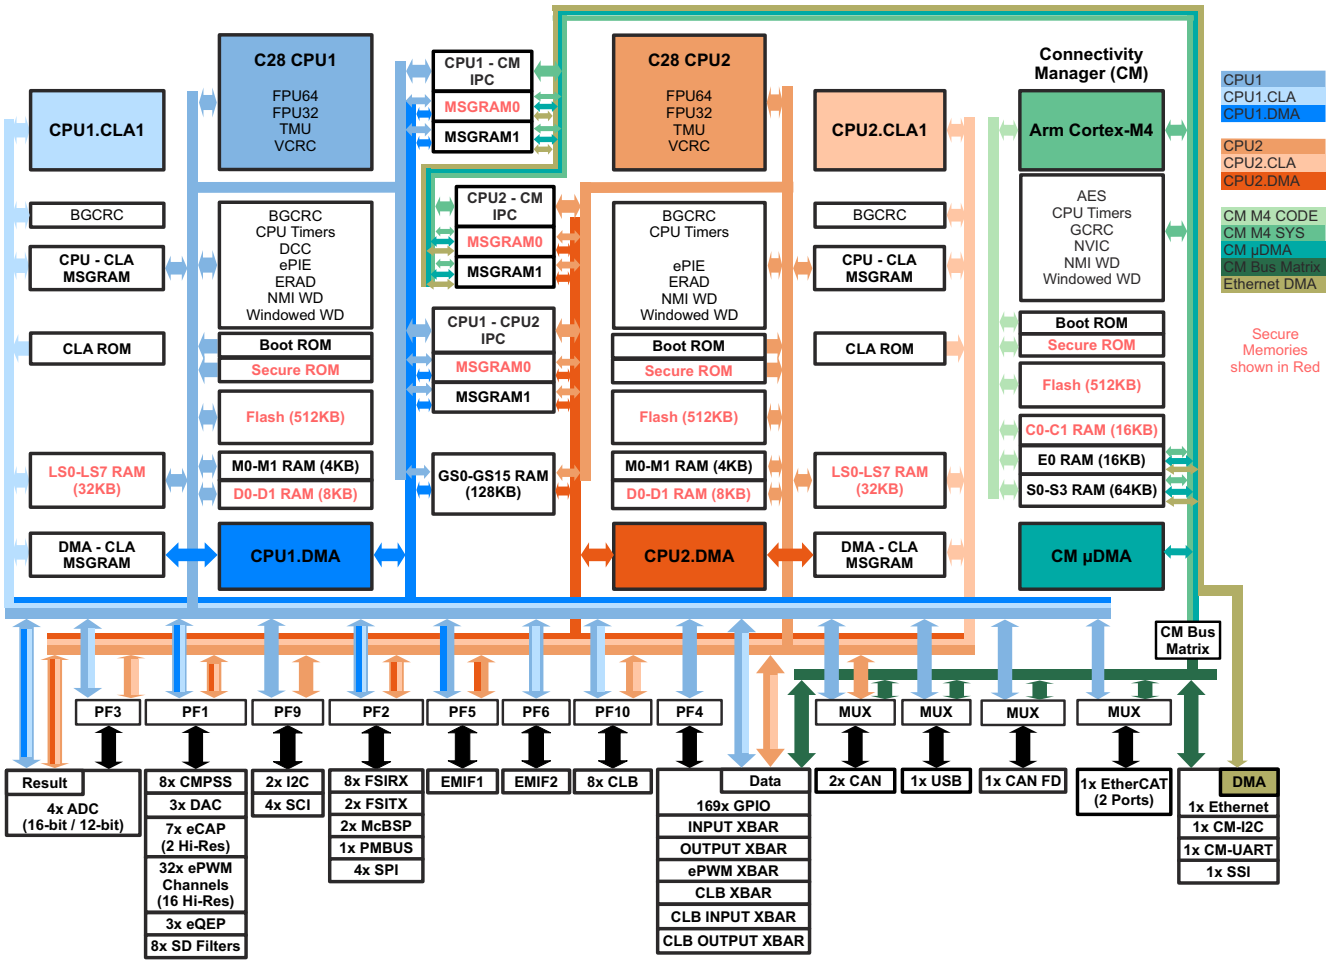

Figure 39-1. F2838x Block Diagram

Chapter 40

Connectivity Manager Subsystem

This chapter discusses the Connectivity Manager (CM) architecture and its associated peripherals.

40.1 Connectivity Manager Overview

The TMS320F2838x MCU supports dual-core C28x architecture along with a new connectivity manager (CM) subsystem. The connectivity manager subsystem is based on the industry standard 32-bit Arm® Cortex®-M4 CPU and features a wide variety of communication peripherals, including EtherCAT™, Ethernet, USB, MCAN (CAN-FD), DCAN, UART, SSI, I2C, and so on.

Targeting performance and flexibility, the connectivity manager is based on 125-MHz Cortex®-M4 architecture and provides a variety of integrated memories as well as multiple programmable GPIOs. It offers consumers compelling cost-effective solutions by integrating application-specific peripherals, and provides a comprehensive library of software tools that minimize board costs and design-cycle time. Table 40-1 lists the key architectural features of connectivity manager.

The primary goals of the Connectivity Manager (CM) are to:

- Allow easy porting of standard communication software stacks from the Arm® eco system.
- Allow easy porting of AUTomotive Open System ARchitecture (AUTOSAR) and Micro Controller Abstraction Layer (MCALs) for communication peripherals like DCAN.
- Provide additional communication MIPS.

Table 40-1. Connectivity Manager Architectural Features

Feature	Description	CPU1	CPU2
Core	Arm® Cortex®-M4	NA	NA
Frequency (MHz)	125 MHz	NA	NA
Flash	512KB	No	No
RAM	96KB	Yes	Yes
BOOTROM	96KB	No	No
µDMA	1	No	No
DCAN	2	Yes	Yes
EtherCAT	1	Yes	No
USB	1	Yes	No
MCAN (CAN-FD)	1	No	No
Ethernet	1	No	No
SSI	1	No	No
UART	1	No	No
I2C	1	No	No
AES	1	No	No
GCRC	1	No	No
Timer	3	No	No
Windowed watchdog	1	No	No

40.2 Connectivity Manager Functional Block Diagram

Figure 40-1 shows the functional block diagram and associated peripherals of the connectivity manager.

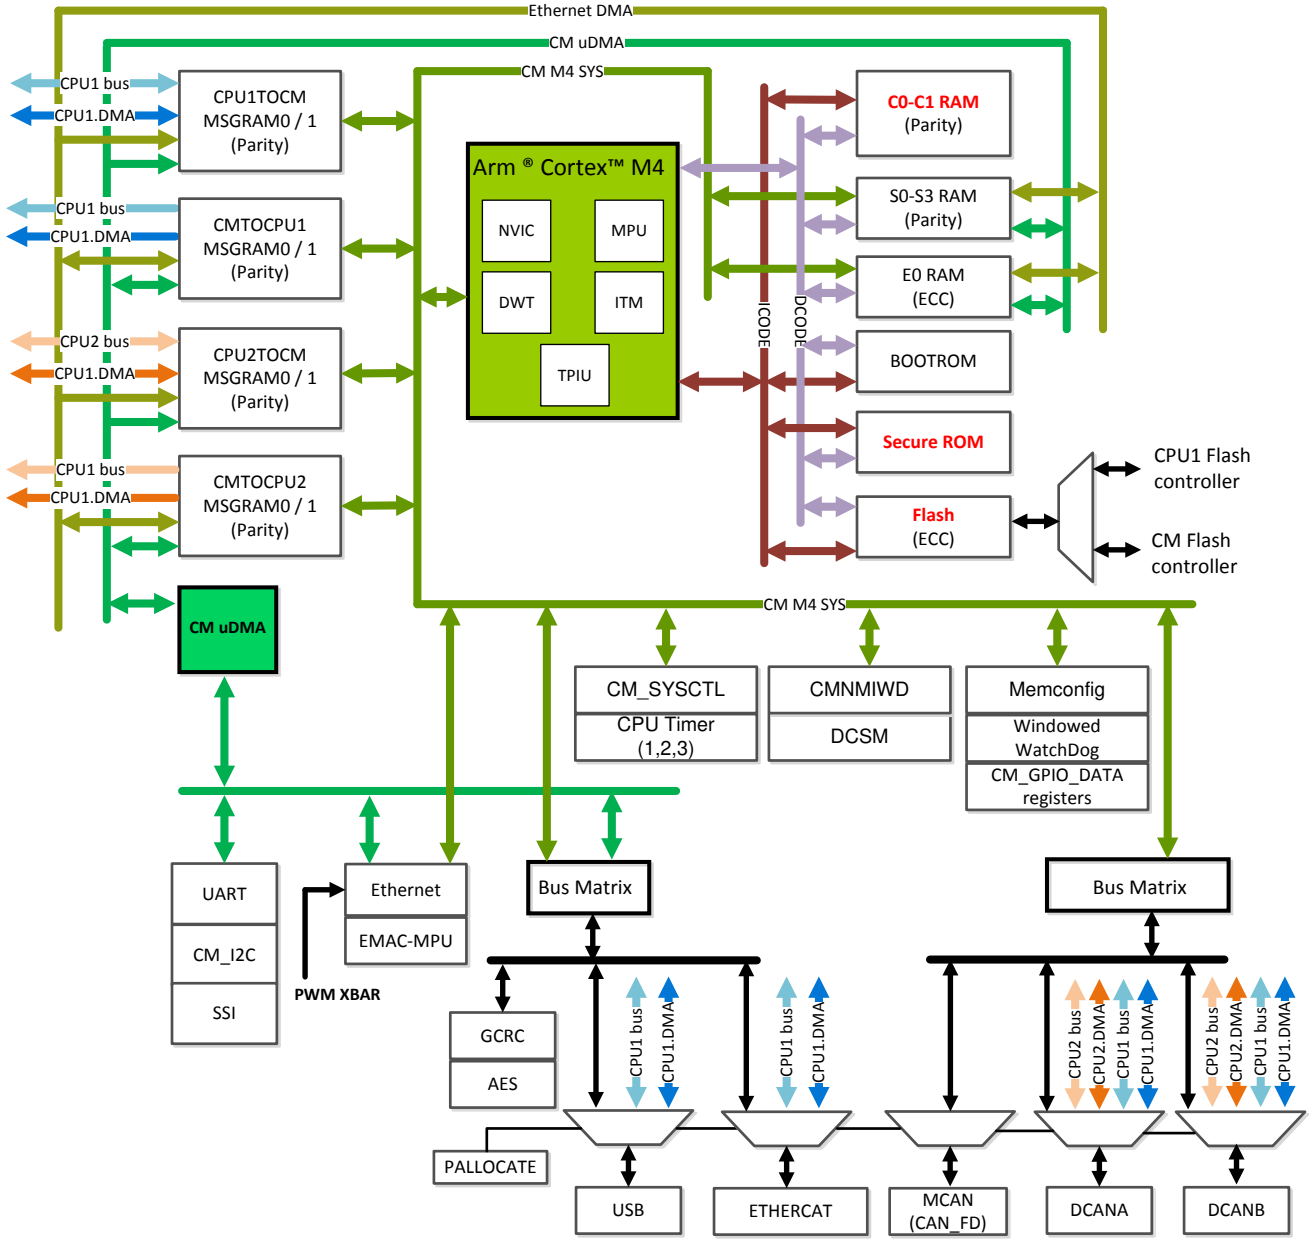

Figure 40-1. Connectivity Manager Block Diagram

40.3 Arm® Cortex®-M4 Processor Core Overview

The Arm® Cortex®-M4 processor includes the following:

- 32-bit Arm® Cortex®-M4 architecture optimized for small-footprint embedded applications
- Cortex®-M4 CPU can be operated at maximum frequency of 125-MHz
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed, 16-/32-bit instruction set delivers the high performance expected of a 32-bit Arm® core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast multiplier
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Migration from the Arm7® processor family for better performance and power efficiency

See the *Arm® Cortex®-M4 Processor Technical Reference Manual* for more information.

Chapter 41

Connectivity Manager System Control and Interrupts

This section describes the system-level functionality of the F2838x Connectivity Manager CPU.

41.1 Introduction

This section provides discussions that include configuration of the clocking, resets, and interrupts of the CPU and peripherals, as well as the operation of the on-chip memories, timers, and security features.

41.2 Reset

The types and effects of the different reset sources on the CM subsystem are discussed here. Reset for the CM subsystem is controlled by CPU1 and it is held in reset unless the user's application code on CPU1 releases the CM out of reset by writing '0' to the RESET bit of the CMRESCTL register. After updating the RESET bit, the user's software can read the RESETSTS bit of the CMRESCTL register to check the reset status of the CM. A Write to the CMRESCTL register is protected by KEY; therefore the user must put the correct value (0xA5A5) in the KEY field to make any updates to this register. Because of this, the user must always perform a 32-bit write to this register.

Following are the different reset sources on the CM subsystem.

41.2.1 CPU1 $\overline{\text{SYSRS}}$

Any time the CPU1 subsystem gets reset and asserts a CPU1. $\overline{\text{SYSRS}}$ signal, it resets the CM subsystem as well. The CM subsystem is held in reset unless the user application code on CPU1 releases CM out of reset by writing '0' to the RESET bit of the CMRESCTL register.

41.2.2 System Reset Request (CMSYSRESETREQ)

User software running on the CM can initiate a reset to the CM subsystem by writing '1' to the SYSRESETREQ bit of the AIRCR register of the Cortex®-M4. This action resets almost all the logic on the CM except for debug.

After this reset, the CMSYSRESETREQ bit in the CMRESC register is set. Software can read this bit to determine the cause of the reset and clear the status by writing '1' into the corresponding bit in the CMRESCCLR register.

Note

The Cortex®-M4 also has a software reset by the name VECTRESET. VECTRESET only resets the Cortex®-M4 core and not other logic in the CM subsystem; hence, this could cause unexpected behavior. You should avoid using VECTRESET.

41.2.3 CM NMI Watchdog Reset (CMNMIWDRSTn)

Like CPU1/CPU2, the CM has its own non-maskable interrupt (NMI) module that captures the hardware errors in the CM subsystem as well as some of device level error. The NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. This reset activity resets almost all the logic on the CM except for debug. The CMNMIWDRSTn bit can trigger an NMI or interrupt on CPU1 (depending on the configuration of the CMNMIWDRST bit field in the CMTOCPU1NMICTL register).

After this reset, the CMNMIWDRSTn bit in the CMRESC register will be set. Software can read this bit to determine the cause of the reset and clear the status by writing '1' into the corresponding bit in the CMRESCCLR register.

41.2.4 CM Secure Code Copy Reset (CMSCCRESETn)

The dual-zone code security module (DCSM) on this device locks read access to secure memories including ROM. To facilitate CRC checks, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a secure copy or CRC function, the DCSM triggers a reset. This reset on the CM is the same as the CM System Reset.

After this reset, the CMEOLRESETn bit in the CMRESC register will be set. Software can read this bit to determine the cause of the reset and clear the status by writing '1' into corresponding bit in the CMRESCCLR register.

41.3 CM Clocking

This section explains the clock sources and clock domains on the Connectivity Manager, and how to configure them for application use. The figure below provides an overview of the CM clocking system.

41.3.1 CM Clock Sources

Clock sources for C28x and the CM are the same. Refer to Section 3.7.1 for more information.

41.3.2 CM Derived Clocks

Derived clock sources for the Connectivity Manager are the same as C28x derived clocks. Refer to Section 3.7.2 for more information.

41.3.3 CM Device Clock Domains

The device clock domains are applied to the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider. In addition to the clock domains defined in Section 3.7.3, the following clock domains are derived specifically for the CM (Cortex®-M4) Subsystem.

41.3.3.1 Connectivity Manager Clock (CMCLK)

The CM clock is derived from PLLSYSCLK or AUXPLLRAWCLK and then divided down by the CMCLK divider. This clock is asynchronous to the CPU1/CPU2 system clock. This clock is used by the Cortex®-M4 CPU (CM), GPIO, DCSM, Message RAMs, IPC and Watch Dog.

41.3.3.2 CM Peripheral Subsystem Clock (CM.PERx.SYSCLK)

This clock is the same as CMCLK, where each peripheral clock has its own independent clock gating that is controlled by the CMPCLKCRx registers.

41.3.3.3 MCAN Bit Clock

The required frequency tolerance for the MCAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1. Since the main system clock (in the form of CM.PERx.SYSCLK) may not be precise enough, the bit clock can also be connected to AUXCLKIN or AUXPLLRAWCLK by way of the CLKSRCCTL2.MCANxBITCLKSEL bit.

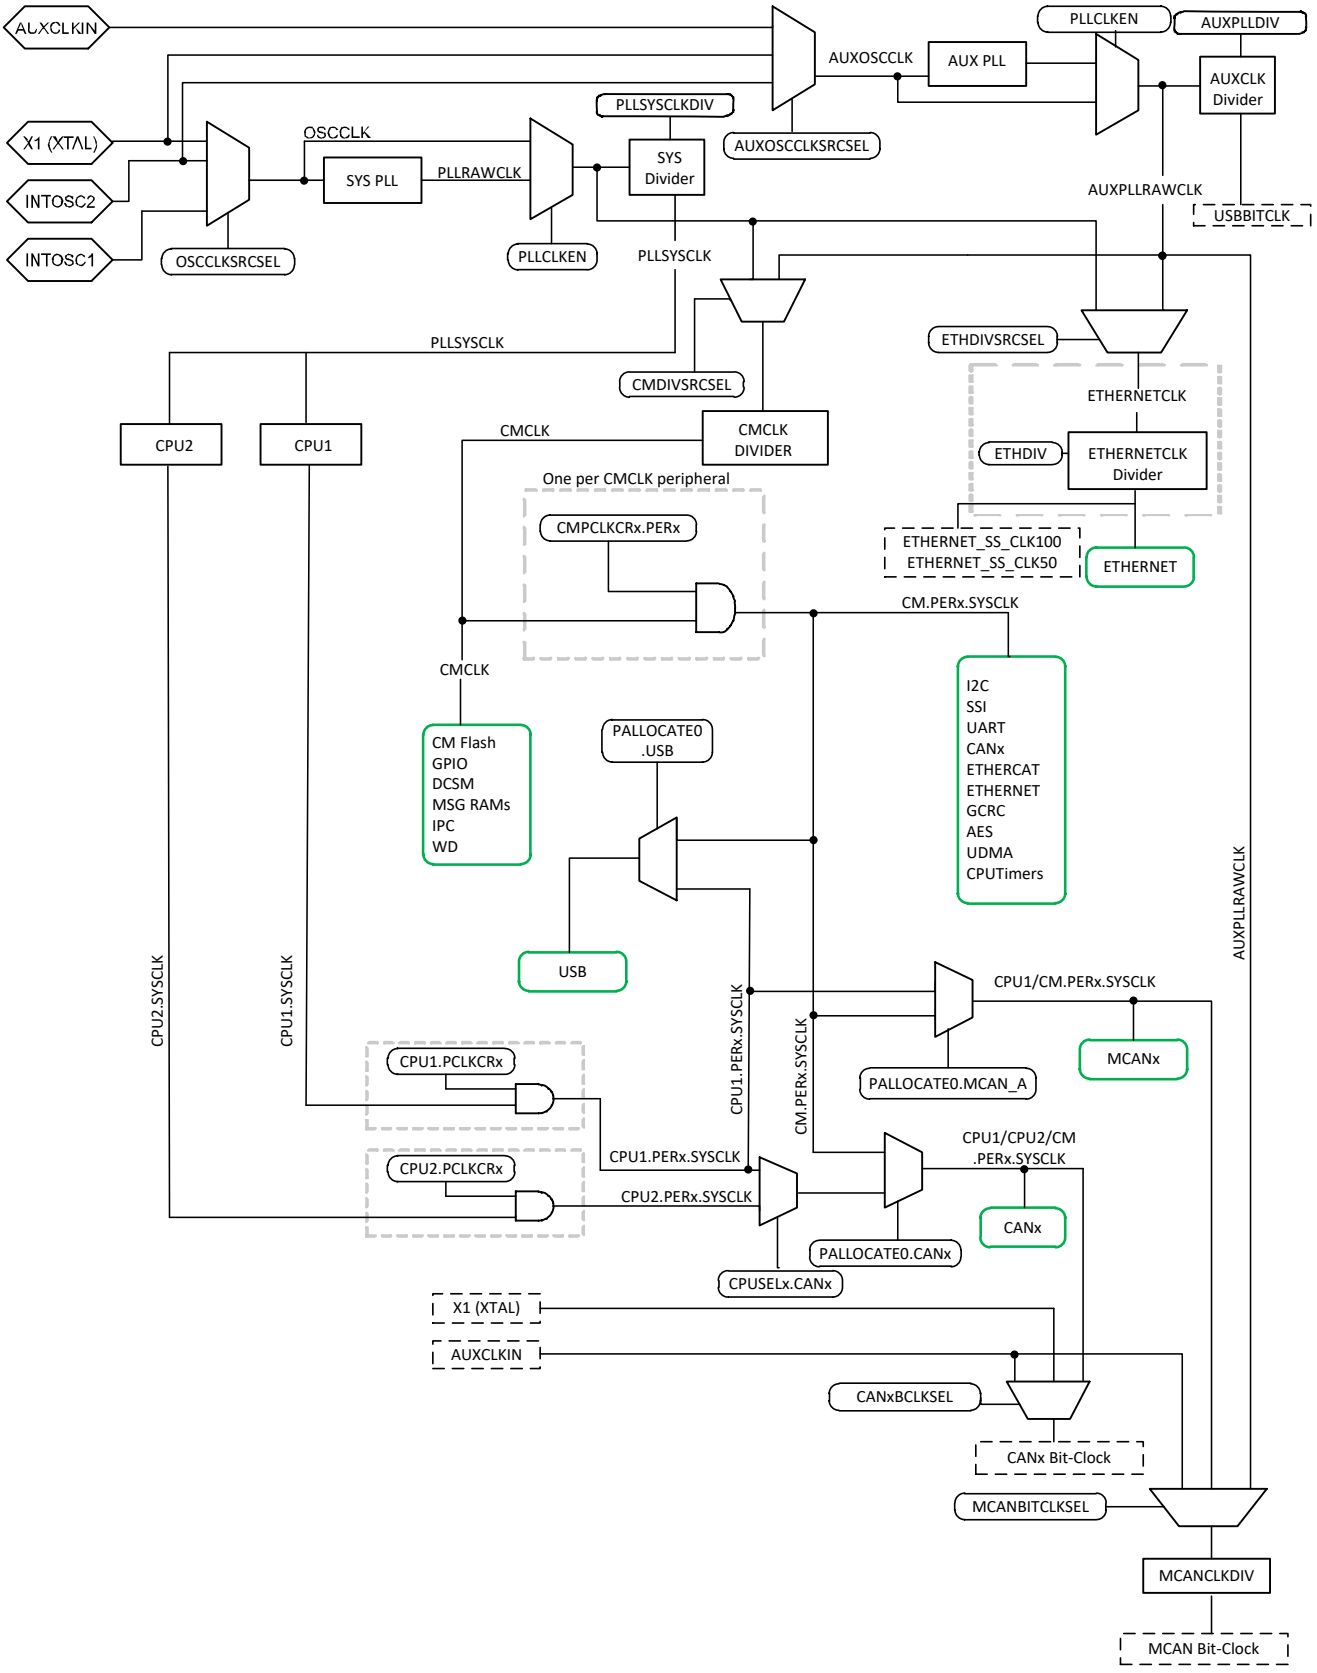

Figure 41-1. CM Clocking System

41.3.4 CM Clock Connectivity

Table 41-1 provides details on the CM clock connections.

Table 41-1. CM Clock Connections

Clock Domain	Module Name
CMCLK	GPIO DCSM Message RAMs IPC Watch Dog
CM.PERx.SYSCLK	I2C SSI UART MCANA ETHERCAT ETHERNET GCRC AESLIP µDMA CPUTIMER 0 - 2 USB CANA - B
CAN Bit Clock	CANA - B
MCAN Bit Clock	MCANA

41.4 SysTick

The Cortex®-M4 includes an integrated system timer, SysTick, which provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example as:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer; the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNT bit in the STCTRL control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

The timer consists of three registers:

- **SysTick Control and Status (STCTRL)**: A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- **SysTick Reload Value (STRELOAD)**: The reload value for the counter, used to provide the counter's wrap value.
- **SysTick Current Value (STCURRENT)**: The current value of the counter.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the STRELOAD register on the next clock edge, then decrements on subsequent clocks. Clearing the STRELOAD register disables the counter on the next wrap. When the counter reaches zero, the COUNT status bit is set. The COUNT bit clears on reads.

Writing to the STCURRENT register clears the register and the COUNT status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

The SysTick counter runs on the processor clock. If this clock signal is stopped for low power mode, the SysTick counter stops. Ensure software uses aligned word accesses to access the SysTick registers.

Note: When the processor is halted for debugging, the counter does not decrement.

41.5 Watchdog Timer

The Connectivity Manager (CM) has one watchdog (also referred to as windowed watchdog) timer. The functionality of this watchdog timer is the same as the one used on CPUx subsystems. Refer to the Watchdog Timers section in the *C28x System Control* chapter for details about this module. Following are some differences in the configuration of the watchdog timer on the CM vs CPUx.

- The Watchdog timer on CM is disabled by default. Software needs to clear the WDDIS bit in the WDCR register to enable the watchdog.
- Whenever the watchdog counter (WDCR) overflows or an incorrect value is written to WDCR[WDCHK], an NMI gets generated (not reset or interrupt such as CPUx watchdog timers) to the CMNMIWD module. If software is not able to service the NMI, then the NMIWD module will trigger a reset to the CM.

The CM watchdog timer counter stops incrementing when the Cortex®-M4 is halted during the debug session.

41.6 Exceptions and NMI

This section provides details about interrupts and exception handling supported by the CM subsystem. Both the CM and C28 subsystems each have an independent NMI module which captures various exceptions that can occur in the system and trigger an NMI to the respective CPU core.

This device has exception capturing and handling ability that enables the device to be used in many safety-critical applications. Device run-time exceptions that can be detected and acted upon include clock failure detection, memory access error detection, memory uncorrectable error, Flash uncorrectable error, MCAN uncorrectable error, NMI watchdog error, EtherCAT error, bus fault detection, and interrupt handler address mismatch errors. This device also supports back-to-back, non-maskable interrupt handling capability, along with highly configurable peripheral interrupt handling.

The CM subsystem is built around the Arm® Cortex®-M4 core and includes the Nested Vectored Interrupt Controller (NVIC) module, while the C28 subsystem is built around the C28x core and includes the peripheral interrupt expansion (PIE) module. This enables the user to configure, handle, and serve interrupt requests from different subsystem peripherals and handle various exceptions that can occur in the device during its operation. Exception handling on the CM subsystem is built such that it will be able to identify and handle the errors, even if the C28 subsystem fails to handle its exceptions.

41.6.1 CM Subsystem Nested Vectored Interrupt Controller

Refer to Section 41.7 for a detailed overview of the NVIC.

As part of the CM subsystem, the Cortex®-M4 NVIC handles exceptions that can occur on the CM subsystem. The Cortex®-M4 NVIC module supports a non-maskable interrupt, which has higher priority than all other NVIC-supported interrupts or exceptions. The CM subsystem's non-maskable interrupt module (CMNMI) is responsible for generating this non-maskable interrupt to the Cortex®-M4 CPU core in the CM subsystem. Refer to Section 41.6.3 for more details on NMI handling.

The NVIC supports a HARDFAULT exception interrupt which has higher priority than any programmable interrupts but less priority than an NMI. Other programmable exceptions supported by the NVIC are memory management faults, bus faults, and usage fault programmable exceptions. These programmable exceptions are disabled by default and the system errors which can cause these exception events end up triggering a HARDFAULT exception. Section 41.6.2 provides details on the events that cause these exceptions.

On power-up and any reset that resets the CM CPU, the NVIC is mapped to the address of 0x0000 0000 in ROM. The M-Boot ROM installs predefined interrupt handlers in the default NVIC table as needed for the boot

ROM execution and C28. Once the user application is started by boot ROM, the interrupt handlers should have their own NVIC vector table and map the NVIC base address to user locations. If users fail to remap the NVIC to their application needs, any interrupt that occurs while the application is executing ends up calling interrupt and exception handlers installed by boot ROM. Refer to the *Boot ROM* chapter for more details on boot ROM handlers in the NVIC.

41.6.2 CM Subsystem Exceptions Handling

Table 41-2 provides information on different exceptions supported by NVIC on the CM subsystem.

Table 41-2. CM Subsystem Exceptions

Exception Type	Vector Number	Priority	Description
Reset	1	-3 (highest	This exception is invoked on power up and on any other reset. On the first instruction, Reset drops to the lowest priority and then is called the base level of activation. This exception is asynchronous.
Non-Maskable Interrupt(NMI)	2	-2	A non-maskable Interrupt (NMI) can be signaled using the NMI signal or triggered by software using the Interrupt Control and State (INTCTRL) register. This exception has the highest priority other than reset. NMI is permanently enabled and has a fixed priority of -2. NMIs cannot be masked or prevented from activation by any other exception or preempted by any exception other than reset.
Hard Fault	3	-1	This exception is caused by all classes of Fault when the fault cannot activate due to priority or the configurable fault handler has been disabled. This exception is synchronous.
Memory Management	4	Configurable	This exception is caused by an MPU mismatch, including access violation and no match. This exception is synchronous.
Bus Fault	5	Configurable	A bus fault is an exception that occurs because of a memory-related fault for an instruction or data memory transaction such as a prefetch fault or a memory access fault. This fault can be enabled or disabled.
Usage Fault	6	Configurable	This exception is caused by a usage fault, such as an undefined instruction executed or an illegal state transition attempt. This exception is synchronous.

From the exceptions in Table 41-2, the NMI and bus faults are generated by the digital subsystem, whereas memory management errors are generated internally by the M4 MPU.

Bus Fault Exceptions:

For all uncorrectable memory errors during M4 CPU reads or writes (address, parity, or double data error), HRESP-based and HREADY-based error responses are generated by the memory C28 logic.

Write Accesses:

When an HRESP-error is generated for write accesses, if the intended write was a stack push, STKERR status is set by the NVIC upon seeing the bus fault indication for the stack push operation. If the application so prefers, the application can treat a STKERR as a low-priority exception and pend the same, except when stacking for an exception.

For all uncorrectable errors during reads, the same HRESP-error indication is generated. The M4 core uses this error indication in the following manner:

- For bus errors during normal data reads, the M4 can generate a bus fault, but the application can treat this as a lower priority, thereby enabling a higher priority exception to be serviced by the CPU. As an example, there can be a bus fault in a user thread and still the CPU can service an interrupt to handle critical interrupts - the bus fault can be handled afterwards. But if the read occurs during an ISR bus fault, the read is treated as a hard fault, since the read is in code for an exception that must never fault.
- For bus errors during stack pops, the NVIC sets the UNSTKERR status indication and the M4 generates a bus fault.
- For bus errors during vector table reads, the NVIC sets VECTTBL and the M4 generates a bus fault. If there is a double fault when the bus fault handler tries to read the vector, the M4 CPU enters a LOCKUP condition. In this condition, the M4 WDT timers time out and issue a reset to the system.
- For bus errors during fetches, even if the M4 sees an error response, M4 does not internally bus fault unless the CPU is decoding the erroneous instruction fetched.

For more details on how the remaining exceptions are generated by the Cortex®-M4 CPU, refer to Section 41.7.

Refer to the *ROM Code and Peripheral Booting* chapter for more details on how boot ROM handles HARDFAULT exceptions, if the exception occurs during boot ROM execution.

On the CM subsystem, the following errors generate a BUSFAULT:

- RAMUNCERR - RAM Uncorrectable error. This is a double bit error generated by the RAM wrapper logic as a bus error.
- RAMACCVIOL - Ram Access violation.

41.6.3 CM Subsystem Non-Maskable Interrupt (CMNMI) Module

The CM subsystem has the capability of detecting all serious errors that can occur in the entire system including all the subsystems, and inform the main CPU core about the error. An NMI exception to the M4 CPU on the CM subsystem is generated only when at least one or more of the below NMI error sources become active. More details on each of the sources is given in Section 41.6.3.1 and the descriptions in the CMNMIFLG register.

1. RAM/ROM uncorrectable error
2. Reset request from the EtherCAT
3. Clock failure
4. MCAN uncorrectable error
5. CM windowed watchdog timed out
6. Flash uncorrectable error

All these NMI sources are ORed to generate the NMI input to the M4 NVIC. The NMI triggers a CMNMIWD counter running at the CM subsystem frequency. The CMNMIWD counter stops counting only if all the pending NMIs are acknowledged by clearing the pending flags in the CMNMIFLG register. If the pending NMI is not acknowledged before the CMNMIWD counter reaches the value programmed in the NMI Watchdog period register (CMNMIWDPRD), an NMIWD reset is generated to the CM subsystem, which resets the entire device.

Figure 41-2 shows different sources that can trigger an NMI to the Cortex®-M4 on the CM subsystem and the registers associated with them.

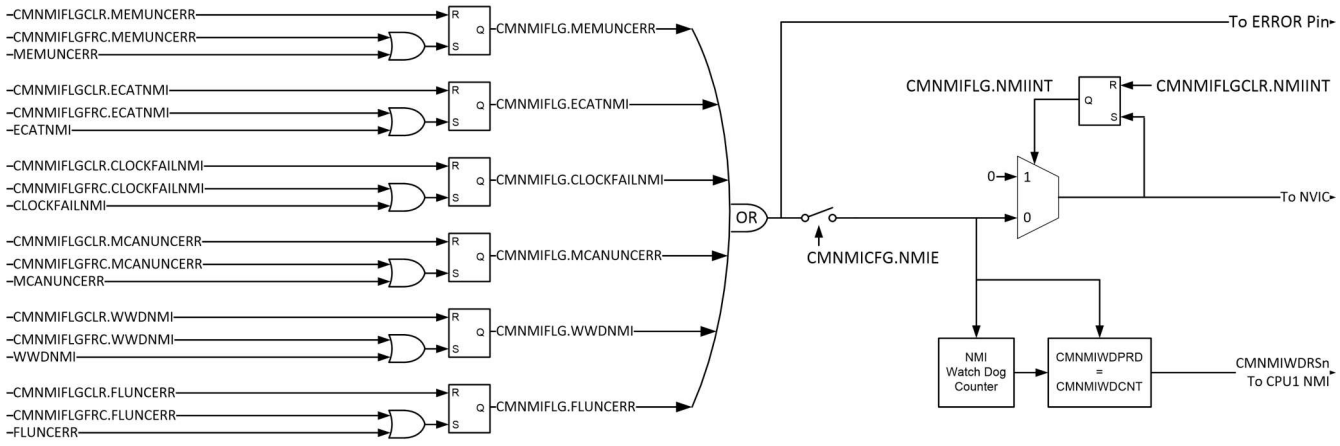

Figure 41-2. CM Subsystem NMI Sources and NMIWD

All the NMI sources shown in Figure 41-2 are enabled by default on reset. CMNMICFG.NMIE is disabled on reset and needs to be enabled by setting the bit to 1.

Whenever an NMI signal is generated, the respective bit in the CMNMIFLG register is set. To aid in debug, development, and testing, a CMNMIFLGFRC register is provided. Setting these bits in this register forces the NMI to the CPU core as shown in Figure 41-2. Refer to the CMNMIFLGFRC register for more details. When an NMI is triggered to the CM CPU, a CMNMIWD counter is triggered and begins counting and resets the device when the CMNMIWD counter reaches the programmed CMNMIWD period value. The CMNMIWD counter stops counting and resets back to zero once all the set CMNMIFLG bits and the CMNMIINT flag bit in the CMNMIFLG register are cleared.

41.6.3.1 CM Subsystem NMI Sources

This section explains all the possible NMI sources on the CM subsystem.

41.6.3.1.1 RAM/ROM Uncorrectable Error

This NMI is triggered if an error occurred on a RAM/ROM access (including peripheral RAMs) by any master.

41.6.3.1.2 Reset Request from EtherCAT

This NMI is triggered if a reset request was sent from the EtherCAT module.

41.6.3.1.3 Clock Fail Condition

A main oscillator verification circuit is provided that generates an error condition if the oscillator is running too fast or too slow or goes missing. This logic is referred to as Missing Clock Detection. When a missing clock error is generated, the CLOCKFAIL bit (bit 1) of the CMNMIFLG register is set, the clock source is switched to the 10 MHz internal oscillator, and the PLL is bypassed.

The CLOCKFAIL NMI is triggered to both the CM and C28 subsystems. Since this NMI source is enabled by default on power up, it makes it necessary for boot ROM to handle this NMI. Refer to the *Boot ROM* chapter of this document for more details on how boot ROM handles this NMI.

41.6.3.1.4 MCAN Uncorrectable Error

This NMI is triggered if an error occurred on a MCAN message RAM access.

41.6.3.1.5 CM Windowed Watchdog Timed Out

This NMI is triggered if the CM's windowed watchdog times out.

41.6.3.1.6 Flash Uncorrectable Error

This NMI is triggered if an error occurred on a CM Flash access.

41.6.3.2 CM Subsystem NMIWD Module

As explained previously, the CM subsystem is equipped with an NMI Watchdog module whose function is to make sure that a triggered non-maskable interrupt is handled by user software. This can be achieved by clearing the error conditions and clearing the respective flags in the CMNMIFLG register or by acknowledging the NMI and gracefully shutting down the system. If none of the actions mentioned are taken, then the CMNMIWD counter keeps counting until the counter value reaches the CMNMIWD period register value. An CMNMIWD reset will then be generated, which will reset the entire device.

As shown in Figure 41-2, any enabled NMI source can set the CMNMIINT respective bit in CMNMIFLG register, which will trigger an NMI to the CPU and start the CMNMIWD counter. The CMNMIWD counter will keep counting as long as the CMNMIINT bit of the CMNMIFLG register is not cleared or a reset is generated.

The CMNMIWD counter is clocked by the M4 system clock. The CMNMIWDPRD register, which is the CMNMI Watchdog Period register, can be programmed with a period limit as per user requirements which sets the clock cycle limit required for software to handle or acknowledge the NMI. A timeout condition that generates the NMI watchdog reset means that the counter value of the CMNMIWDCNT register reached the value programmed in the period register, CMNMIWDPRD.

41.6.3.2.1 Emulation Considerations

When the Cortex®-M4 CPU is suspended (in debug halt), the NMI watchdog counter will be suspended.

41.6.3.3 Handling of CMNMI

User software must clear all the flag bits which are set in the CMNMIFLG register before clearing CMNMIINT, bit 0 of the CMNMIFLG register. If the user clears the CMNMIINT bit in the CMNMIFLG register before clearing all the individual flag bits, as soon as the CMNMIINT bit is cleared it will be set back to "1" again. This will generate another back-to-back NMI to the CM subsytem's CPU, and the CMNMIWD counter will start counting again.

41.6.4 CM Interrupts/NMI to CPU1/CPU2

Table 41-3 and Table 41-4 show the various Interrupts and NMI generated to C28x CPU1 and CPU2, respectively.

Table 41-3. Interrupts and NMI From CM to CPU1

Source	NMI/Interrupt	Note

41.7 Nested Vectored Interrupt Controller (NVIC)

The NVIC multiplexes interrupts from various peripherals into the CM interrupt lines. In essence, the NVIC is the Peripheral Interrupt Expansion (PIE) equivalent for the CM. The features supported by the NVIC are as follows:

- 80 interrupts
- A programmable priority level of 0-7 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Low-latency exception and interrupt handling
- Level and pulse detection of interrupt signals
- Dynamic reprioritization of interrupts
- Grouping of priority values into group priority and subpriority fields
- Interrupt tail-chaining
- An external non-maskable interrupt

The CM automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead, providing low latency exception handling.

Table 41-5. NVIC Interrupt Mapping

41.7.1 Level-Sensitive and Pulse Interrupts

The CM supports both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the CM clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the CM enters the ISR, it automatically removes the pending state from the interrupt (see Section 41.7.2 for more information). For a level-sensitive interrupt, if the signal is not deasserted before the CM returns from the ISR, the interrupt becomes pending again, and the CM must execute its ISR again. As a result, the peripheral can hold the interrupt signal asserted until it no longer needs servicing.

41.7.2 Hardware and Software Control of Interrupts

The CM latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- The NVIC detects that the interrupt signal is High and the interrupt is not active.
- The NVIC detects a rising edge on the interrupt signal.
- Software writes to the corresponding interrupt set-pending register bit, or to the Software Trigger Interrupt (STIR) register to make a software-generated Interrupt pending. See the NVIC_ISPRx register or STIR register.

A pending interrupt remains pending until one of the following:

- The CM enters the ISR for the interrupt, changing the state of the interrupt from pending to active. Then:
  - For a level-sensitive interrupt, when the CM returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the CM to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the CM returns from the ISR the state of the interrupt changes to pending, which might cause the CM to immediately re-enter the ISR. If the interrupt signal is not pulsed while the CM is in the ISR, when the CM returns from the ISR, the state of the interrupt changes to inactive.
- Software writes to the corresponding interrupt clear-pending register bit
  - For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the state of the interrupt changes to inactive, if the state was pending or to active, if the state was active and pending.

41.7.3 NVIC Registers Access

The NVIC registers can only be fully accessed from privileged mode, but interrupts can be pended while in unprivileged mode by enabling the Configuration and Control (CCR) register. Any other unprivileged mode access causes a bus fault. Before accessing the registers:

- Ensure software uses correctly aligned register accesses. The CM does not support unaligned accesses to NVIC registers.
- Be aware that an interrupt can enter the pending state even if it is disabled.
- Before programming the VTOR register to relocate the vector table, ensure the vector table entries of the new vector table are set up for fault handlers, NMI, and all enabled exceptions such as interrupts

41.8 32-Bit CM CPU Timers 0/1/2

The Connectivity Manager has three CPU timers, each operating on the CMCLK and generating an interrupt at certain periodic interval which is determined by the TDDR and TPRD register settings. Each timer operates at a clock period which equals:
TIMER_CLOCK_PERIOD = CMCLK_PERIOD x (TDDR+1)

Each timer generates an interrupt when it reaches 0, whose period equals:
TIMER_INTERRUPT_PERIOD = TIMER_CLOCK_PERIOD x (PRD+1)

Upon the timer reaching zero, the period value is reloaded and the sequence repeats. The timer can be stopped/started by writing a 1/0 to the TCR.TSS bit. The behavior of the timer on a CPU halt (debug halt) is determined by the "FREE, SOFT" bits of the TCR register.

Figure 41-3 and Figure 41-4 show the timer clock periods and the timer interrupt periods.

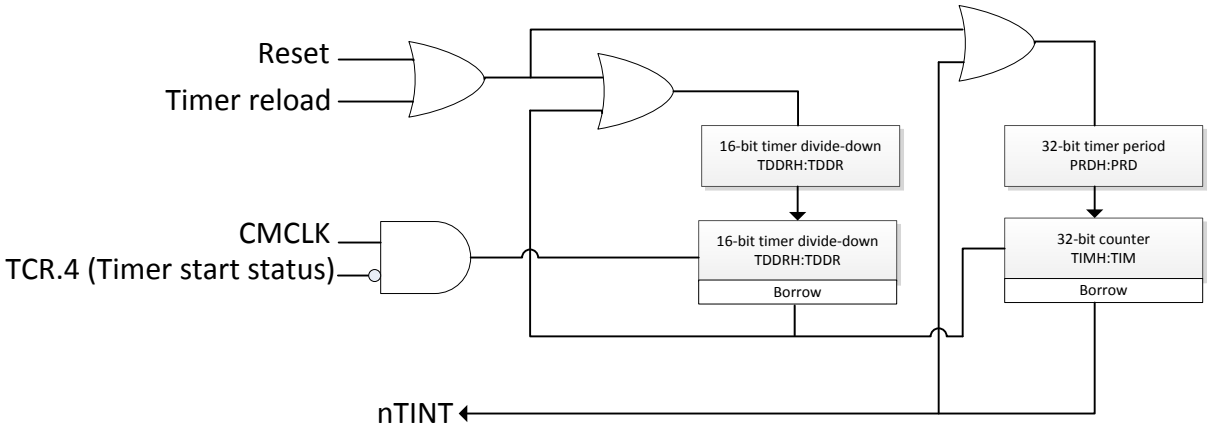

Figure 41-3. CM CPU-Timers

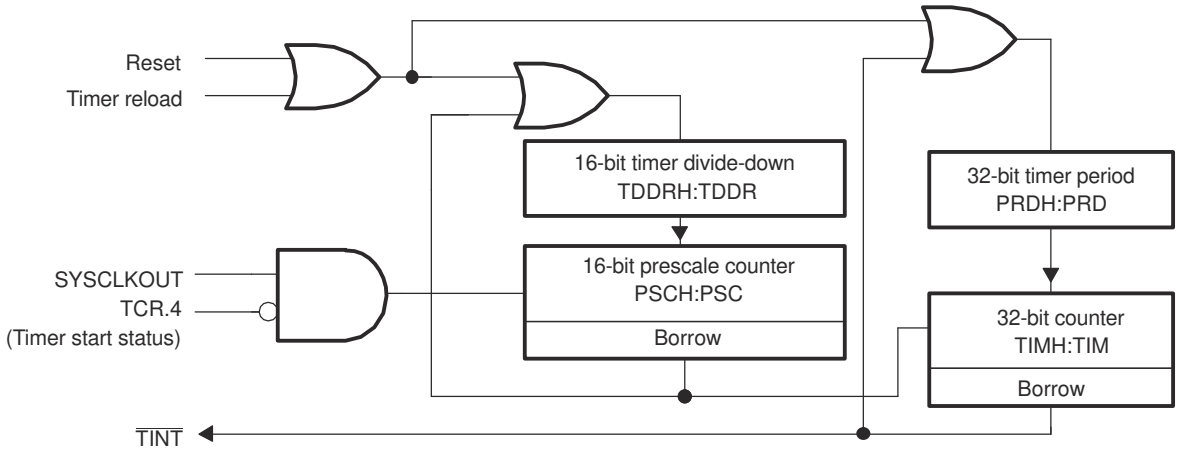

Figure 41-4. CM CPU-Timers Interrupt Signals

41.9 Memory Controller Module

On the CM subsystem, the RAMs have different characteristics. Some are:

- Dedicated to Cortex®-M4, accessible from ICODE and DCODE bus only (C0/C1 RAM)
- Shared between Cortex®-M4, µDMA and other masters in the CM subsystem (Sx RAMs, E0 RAM)
- Used to send and receive messages between the CM and CPU1/CPU2 subsystems (MSGRAM)

All these RAMs are highly configurable to achieve control for write access and fetch access from different masters. On the CM subsystemm, only E0 RAMs are enabled with the ECC feature (both data and address). All other RAMs (including MSGRAMs) are enabled with the PARITY (both data and address) feature. C0 and C1 RAMs can be configured as secure RAM. Each RAM has its own controller which takes care of the access protection/security related checks and ECC/Parity features for that RAM. Figure 41-5 shows the configuration of these RAMs.

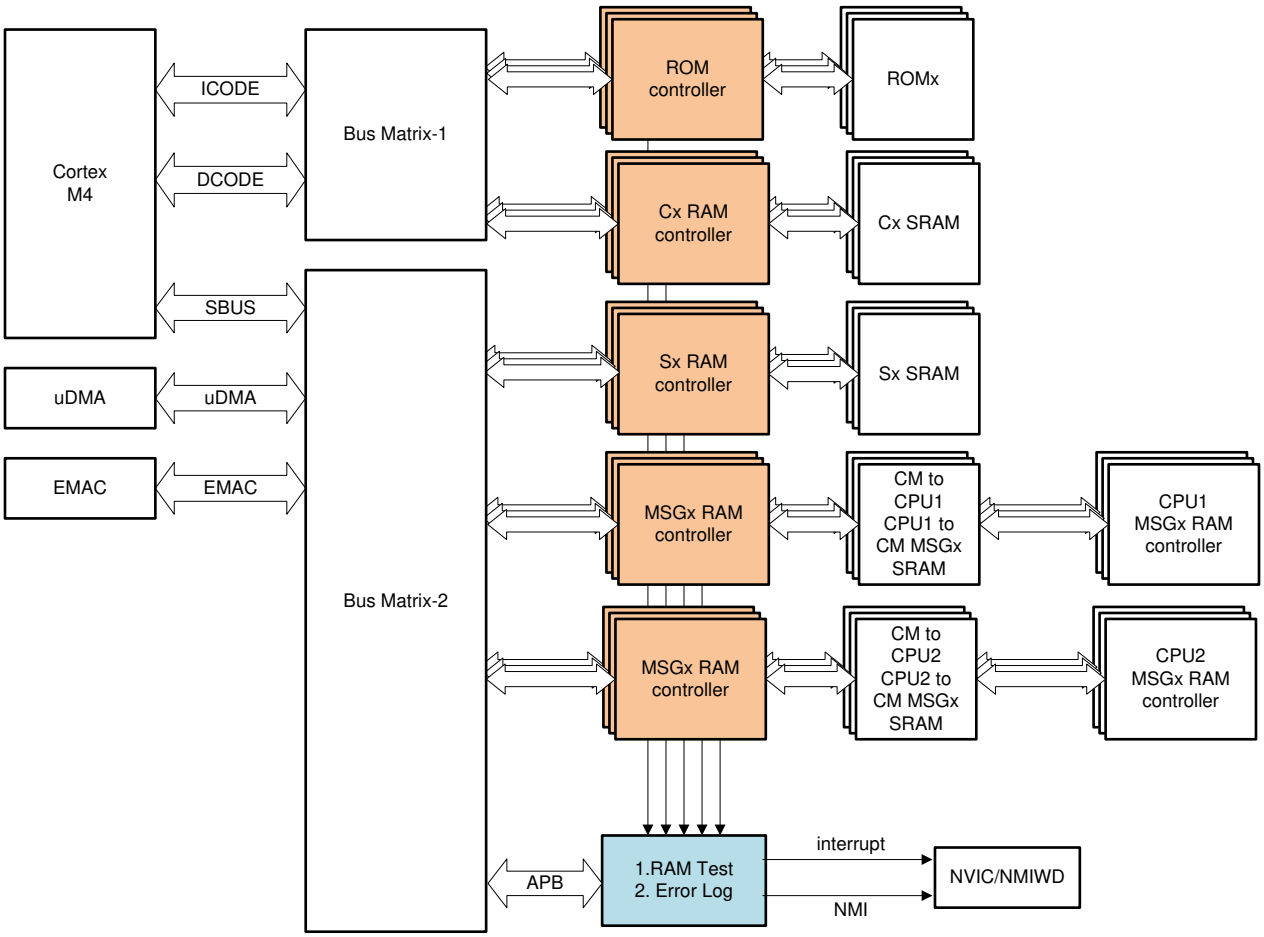

Figure 41-5. CM Memory Block Diagram

41.9.1 Functional Description

This section further defines and discusses different types of memories on the CM subsystem and other features of the SRAM controller.

41.9.1.1 Dedicated RAM

C0 and C1 are dedicated RAMs on the CM subsystem. These RAMs are connected to the ICODE and DOCDE bus of Cortex®-M4; hence, only Cortex®-M4 has access to these RAMs. These RAMs can be used for timing critical code and are also parity protected. If needed in the application, the user can configure these RAMs as secure RAM. Refer to the *Dual Code Security Module (DCSM)* chapter for more information about security.

41.9.1.2 Shared RAM

Shared RAMs are connected to the system bus and are accessible from all the masters (Cortex®-M4, µDMA and EMAC) on the CM subsystem. On this device, the CM subsystem has five blocks of shared RAMs. Four of these are parity-protected (Sx) and one block is ECC protected (E0). The user can use the E0 RAM block for safety critical code or data-like stack or interrupt handlers.

41.9.1.3 MSG RAM

MSG RAMs are connected to the system bus and are accessible from all the masters (Cortex®-M4, µDMA and EMAC) on the CM subsystem. These RAMs are also accessible from the CPU1/CPU2 subsystem (different MSG RAMs for CPU1 and CPU2) and therefore is used for message/data exchange between the CM and CPU1/CPU2 subsystems. MSG RAMs are parity protected. MSG RAMs are also referred to as IPC (inter processor communication) RAMs because these are used for communication between different subsystems. MSG RAMs do not have fetch access and cannot be used for code. On this device, the CM subsystem is asynchronous to the CPU1/CPU2 subsystem and both have access to MSG RAMs. Specific logic (mem allocate logic) is implemented to arbitrate the access from different subsystems. At any given time only one master access is connected to the MSG RAM and Mem allocate logic manages switching of MSGx RAM between C28 and CM RAM controllers.

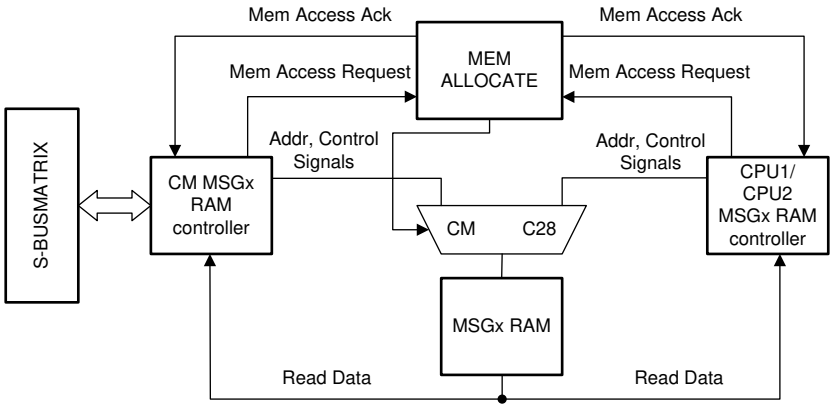

Figure 41-6. Mem allocate logic

Upon detecting valid access, the RAM controller generates a memory access request to mem allocate logic, and then waits for memory allocate logic to acknowledge. Mem Allocate logic acknowledges only after Memory is switched to the requested RAM controller. Upon detecting acknowledge, the RAM controller initiates the memory access. Mem allocate logic arbitrates accesses using round robin priority. Simultaneous access from both masters will result additional latency due to round robin prioritization, as accesses are serviced alternately and latency is introduced due to synchronization. The user application should use the IPC mechanism to avoid simultaneous accesses.

Two sets of message RAMs are defined to overcome latency issues in case of multiple threads running on CM. One is Cortex®-M4 writing/reading a message and another master such as µDMA or EMAC DMA writing or reading the message at the same time.

The message RAMs are:

- CMTOCPU1MSGRAM0 (no access from CPU2)
- CMTOCPU1MSGRAM1 (no access from CPU2)
- CPU1TOCMMSGRAM0 (no access from CPU2)

- CPU1TOCMMSGRAM1 (no access from CPU2)
- CMTOCPU2MSGRAM0 (no access from CPU1)
- CMTOCPU2MSGRAM1 (no access from CPU1)
- CPU2TOCMMSGRAM0 (no access from CPU1)
- CPU2TOCMMSGRAM1 (no access from CPU1)

Access permissions to MSG RAMs are hard-coded in functional mode.

Table 41-6 lists the allowed accesses to Message RAMs in functional mode.

Table 41-6. CM Message RAM Accesses

Message RAM	Cortex-M4	µDMA	EMAC	CPUx	CPUx.DMA
CMTOCPUxMSGRAM0	RD/WR	RD/WR	RD/WR	RD	RD
CMTOCPUxMSGRAM1	RD/WR	RD/WR	RD/WR	RD	RD
CPUxTOCMMSGRAM0	RD	RD	RD	WR	WR
CPUxTOCMMSGRAM1	RD	RD	RD	WR	WR

41.9.1.4 ROM

On this device ROMs are parity protected, and the SRAM controller is used for ROM accesses as well. Like dedicated RAMs, ROMs are also connected to the ICODE and DCODE bus and are programmed with TI code.

41.9.1.5 Interleaving

On the CM subsystem all the RAM and ROM use interleaving techniques to minimize the latencies, especially under scenarios where multiple bus masters are simultaneously trying to access data from a memory block.

These scenarios are common on CM subsystem. Examples are as follows:

- Sx memories: Cortex®-M4 loads the data into its registers for processing while EMAC dumps the received data to memory
- Cx memories: Simultaneous data and instruction fetches

Note that interleaving does not always improve the throughput compared to single bank implementation.

To implement interleaving, a single block of memory is divided into two separate equal physical blocks of half the size and only alternate 32-bit words are stored in each bank. Figure 41-7 shows how data is arranged with interleaving.

In dual-bank implementation, even and odd 32-bit word addresses are decoded separately and routed to the appropriate bank. This allows simultaneous accesses from two bus masters to these banks if accesses are not to the same bank; that is, two accesses are serviced in one cycle.

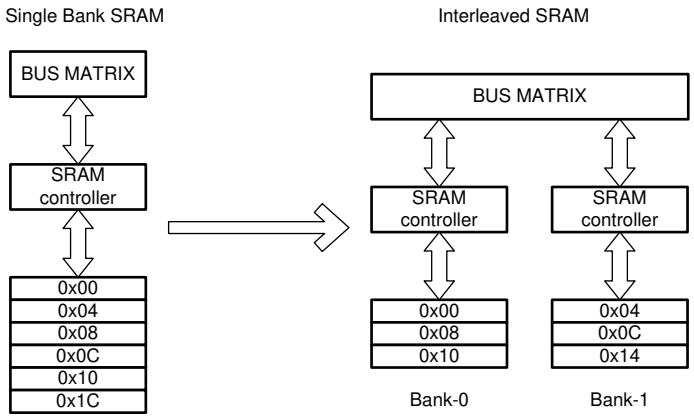

Figure 41-7. Interleaving

41.9.1.6 Access Arbitration

On the CM subsystem, accesses to all shared RAMs (except MSG RAMs) are arbitrated with fixed priority. The Cortex®-M4 system bus has high priority over any other access to ensure no wastage of MIPs. Arbitration is handled by the Arm® Bus matrix component and not part of the SRAM controller.

41.9.1.7 Access Protection

On the CM subsystem, access protection to all the RAMs are done via master specific memory protection unit (MPU) and not in the SRAM controller. Each master on the CM subsystem has a dedicated MPU to filter the accesses. For MSG RAMs, in addition to the MPU, there is logic in-built in the controller to prevent accesses such as fetch or write (if not allowed).

41.9.1.8 Memory Error Detection, Correction and Error Handling

As mentioned in earlier sections, some RAMs on CM subsystem are ECC-protected and some are parity. ROMs are parity-protected. The ECC scheme used is Single Error Correction Double Error Detection (SECDED). The parity scheme used is even parity. ECC/Parity will cover the data bits stored in memory as well as address. ECC/Parity calculation is done inside the memory controller module and then calculated. ECC/Parity is written into the memory along with the data. ECC/Parity is computed for 16-bit data; hence, for each 32-bit data, there will be three 7-bit ECC codes (or 3-bit parity), two of which are for data and a third one for the address.

Figure 41-8 and Figure 41-9 show how a word is stored in memory.

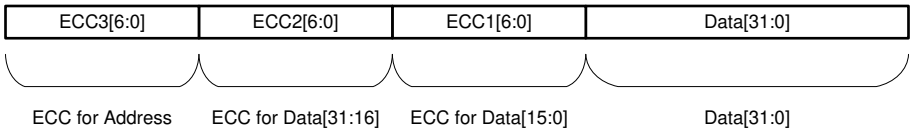

Figure 41-8. Content of Each Memory Location for ECC Memories

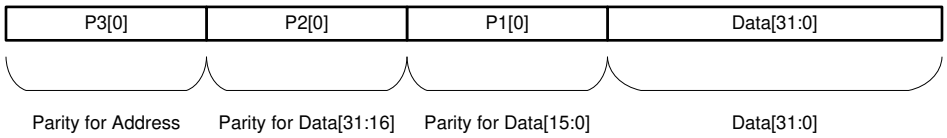

Figure 41-9. Content of Each Memory Location for Parity Memories

41.9.1.8.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For parity memory, only a single-bit error gets detected, whereas in the case of ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable errors and uncorrectable errors.

The following are characteristics of these errors:

- Parity errors are always uncorrectable errors
- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are always uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the master. It is also written back into the memory to prevent double-bit error due to another single-bit error at the same memory address.

Size of write access initiated by bus masters on CM subsystem can be byte or half-word or full word. Since ECC/Parity is calculated for 16-it word, in case of byte write access memory controller performs Read-Modify-Write

operation (read 16-bit from RAM block, modify the specific byte with new data, calculate ECC/parity for new data and write the data and ECC/parity back into RAM block).

41.9.1.8.2 Error Handling

Two types of errors get generated by the memory controller, a correctable error and an uncorrectable error.

- On a correctable error, the following actions are performed by the memory controller:
  - Correct the data and return corrected data to the master
  - The address, for which the error occurred, gets latched into the address status register
  - Bus master info is captured
  - Correctable error counter is incremented
  - Interrupt is generated if correctable error count exceeded user programmed threshold

  The user needs to configure the correctable error threshold register based on the system requirements.
- On an uncorrectable error, the following actions are performed by the memory controller – incorrect data is returned to the Master and an NMI is generated to the Cortex®-M4. The address for which the error occurred gets latched into the address status register and a flag gets set.
  - NMI is generated to Cortex®-M4 and incorrect data is returned to the master
  - The address, for which the error occurred, gets latched into the address status register
  - Bus master info is captured

Table 41-7. Error Handling of Memories

Access Type	Error	Action
Write (16bit/32bit access)	NA	NA
Write (byte access) (Controller performs Read-Modify-Write)	Uncorrectable error on read data	Write is aborted, NMI gets generated
	Correctable error on data (only ECC RAMs)	• RMW operation is performed on corrected data. • Correctable error counter is incremented. Interrupt is generated when correctable error counter exceeds user programmed threshold value. • Corrected Data is written back to the memory.
Read	Correctable error	• Correctable error counter is incremented. Interrupt is generated when correctable error counter exceeds user programmed threshold value. • Corrected data is written back to the memory.
	Uncorrectable error on read data	NMI is generated, data (could be wrong) is returned to bus master.

Note

ECC/Parity errors are ignored for debug access (no NMI/interrupt for error during debug access). Even though an error is not generated for debug access, the memory controller always returns the corrected data for correctable errors.

41.9.1.8.3 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic are part of safety critical logic, safety applications may need to ensure that the logic is always working fine (during run time also). To enable this, a test mode is provided. Using test mode, the user can inject the ECC/parity error by modifying data bits (controller does not update the ECC/parity bits) or the ECC/parity bits directly. Since the memory map for ECC/parity bits and data bits are the same, a different test mode is provided for accessing data and ECC/parity bits. The user programs different test modes based on the usage.

Table 41-8 and Table 41-9 show the bit mapping for the ECC/Parity bits when they are read in RAMTEST mode, using their respective addresses.

Table 41-8. Mapping of ECC Bits in Read Data From ECC/Parity Address Map

Data Bits Location in Read Data	Content (ECC Memory)
6:0	ECC Code for lower 16 bits of data
7	Not Used
14:8	ECC Code for upper 16 bits of data
15	Not Used
22:16	ECC Code for address
31:23	Not Used

Table 41-9. Mapping of Parity Bits in Read Data From ECC/Parity Address Map

Data Bits Location in Read Data	Content (Parity Memory)
0	Parity for lower 16 bits of data
7:1	Not Used
8	Parity for upper 16 bits of data
15:9	Not Used
16	Parity for address
31:17	Not Used

41.9.1.8.4 ROM Test

ROMs are read only memory; unlike RAMs, data or parity bits cannot be modified to introduce errors for diagnostic coverage of parity checking logic. The following method is used to check health of parity checking logic in ROMs.

- Add duplicate parity check logic and feed the same data into duplicate parity checker
- Generate uncorrectable error if the parity check status of these two separate parity checkers do not match

The probability of both circuits having fault is unlikely ; therefore, parity errors will be certainly detected.

To generate the error, a test bit FORCE_ERROR is added. When the FORCE_ERROR bit is set, the parity bit going to one of party checker is inverted, thereby introducing an uncorrectable error. An uncorrectable error is generated only if there is an error on all parity checker, that is, address, data [15:0] and data [31:16]. This will ensure that all three parity checkers are working as expected.

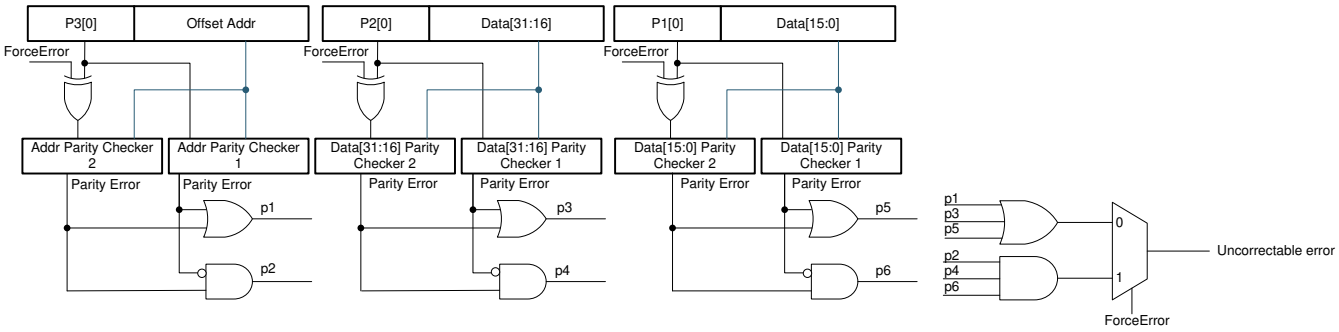

Figure 41-10. ROM Parity Checking Logic

41.9.1.9 RAM Initialization

After power-up, RAM comes up with random data and reading memories may result in an error. To ensure that read/fetch from uninitialized RAM locations do not cause ECC or parity errors, the RAM_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and respective ECC/parity bits, accordingly. This can be initiated by setting the INIT bit to '1' for the specific RAM block in INIT registers. To check the status of RAM initialization, software must poll for the INITDONE bit to be set for that RAM block in the INITDONE. Unless this bit gets set, no access should be made to that RAM memory block.

Note

None of the masters should access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization will not happen correctly.

41.10 Memory Protection Unit (MPU)

The CM subsystem has multiple masters accessing the memory blocks and peripherals. Following is the list of masters on the CM subsystem:

- Cortex®-M4
- µDMA
- EtherNET DMA

In a multi-master system, it is important to have a protection mechanism to prevent unauthorized access to critical code, data, or peripherals from different masters or threads. This protection mechanism will:

- Prevent a process or a task from accessing memory that is not allocated to it
- Protect Cortex®-M4 code from unintended corruption by other bus masters on the CM subsystem
- Protect stack corruption by other bus masters on CM systems

The Cortex®-M4 has an Arm® native MPU (Cortex®-M4 MPU) which provides such protection (see the Memory Protection Unit chapter of the *Arm® Cortex®-M4 Processor Technical Reference Manual*). For other masters (µDMA and Ethernet DMA), a generic memory protection unit (CM-MPU) has been provided which users can configure based on the use case, to enable the protection. Basically, one MPU for each master is provided to protect the accesses from that master. See Section 41.9 for more details.

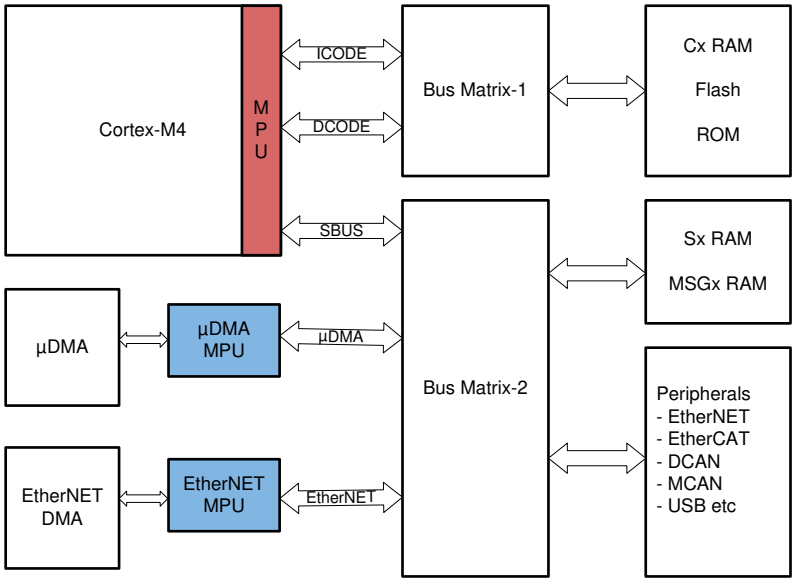

Figure 41-11. CM Block Diagram

41.10.1 Functional Description

The CM-MPU is used for access protection on µDMA and EtherNET master bus. The MPU divides the memory map into a number of regions. Each region has programmable start address, size, and access permissions.

The following are the access protections supported:

- Read-only access
- Full access - both Read and Write accesses are allowed
- No access - Read and Write accesses are not allowed

An access protection violation will result in a bus fault to the master and access info is captured in the MPU register for debug purposes.

Each MPU has a maximum of eight regions. The start address of a region must be aligned to its size. For example, a 32KB region must be aligned to a multiple of 32KB address at 0x0000_0000 or 0x0000_8000. If the start address of the region is not boundary-aligned to region size, that is, the start address is not a divisible size of the region, then hardware automatically aligns the region start address by truncating the number of LSBs, depending on region size. Figure 41-12 is an example of an unaligned start address with a region size of 2KB.

The minimum size of the region is limited to 1KB. Each region can be enabled or disabled in the application based on the use case.

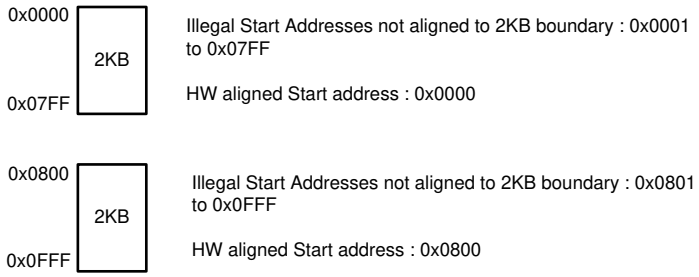

Figure 41-12. Unaligned Start Address

41.10.2 Overlapping Regions

When defining the start address and size for different regions, the user can overlap the regions; in that case, a fixed priority scheme is used to resolve the access protection. Region 7 is the highest priority and region 0 is the lowest priority. This feature is useful to define different sets of access permissions for a part of an already defined bigger region.

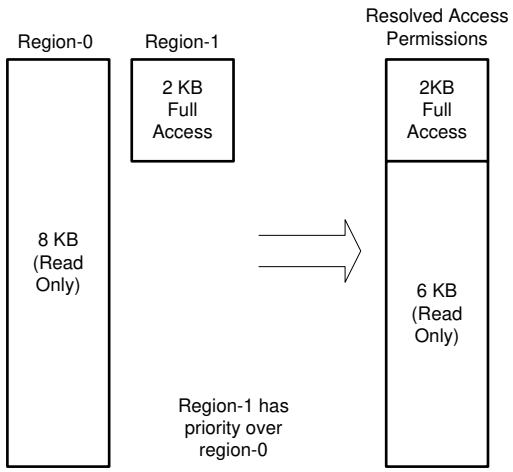

Figure 41-13. Overlapping Regions

41.10.3 Sub-Regions

Each region can be further divided into eight equal sub regions and each sub-region can be independently enabled or disabled in application code. When a sub-region is disabled, access permissions do not apply to that region. Disabled sub-regions are similar to undefined regions. This feature is useful when a part of the region is to be excluded while running a specific section of application.

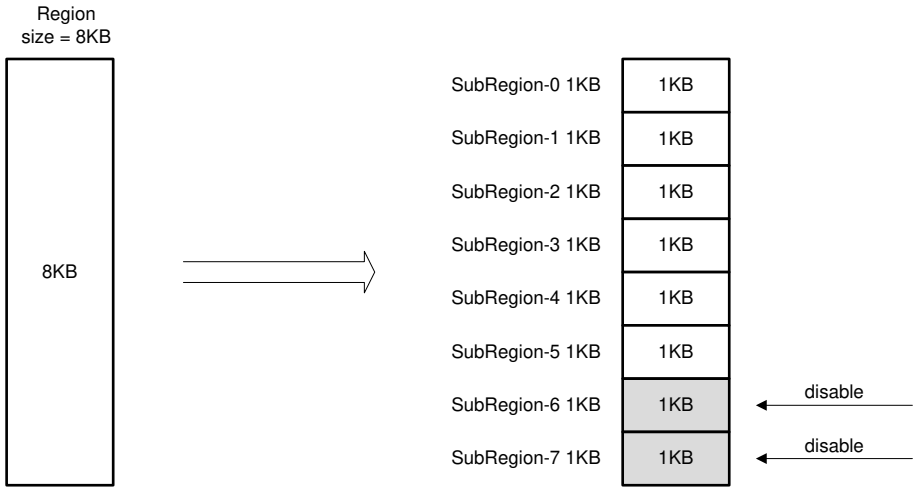

Figure 41-14. Sub-Regions

41.10.4 Programmers Model

The primary purpose of a µDMA MPU is to protect code, stack and peripherals from unintended µDMA accesses. In the following example memory map, the expectation is to not have any µDMA access to code and stack section; only read access to one section of peripheral region and full access to other sections of peripheral.

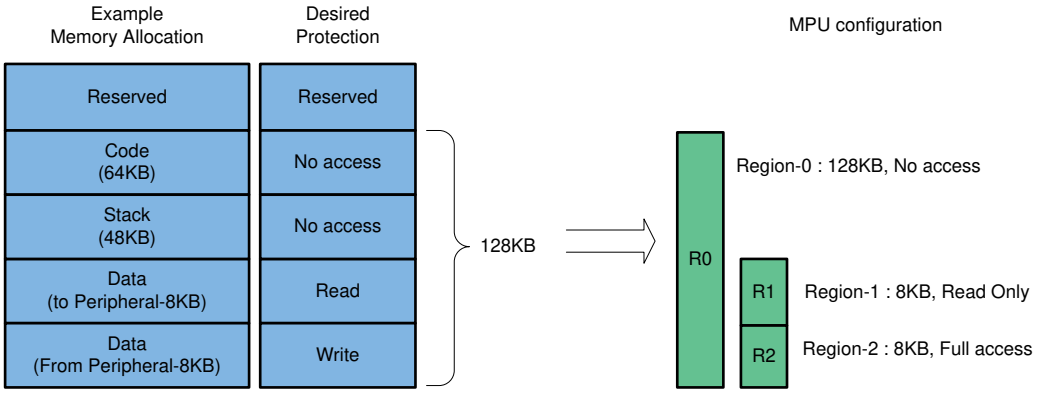

Figure 41-15. Programmers Model Memory Map

There are two ways to define the MPU region.

1. Define three different (independent) regions for no access, read access and full access memory map section.
2. Define no access for full memory map section and then define other region which overlaps to the ist region and have different protections attribute. For this Region-0 is defined as a no-access region with full memory map and then Region-1 is defined as read-only and Region-2 is defined as full-access regions. Since Region 1 and Region 2 have higher priority over Region-0, their protection attribute will override Region-0 protection attribute.

41.11 Debug and Trace

The CM subsystem includes a Cortex®-M4 that has its own debug interface via the Debug Access Port (DAP). Users can connect to the CM subsystem in parallel to the CPU1 and CPU2 core and perform a debug. Users must also release the reset for the CM subsystem before connecting to the debugger. The CCS gel file on CPU1 will take care of this if CPU1 is connected to CCS.

41.11.1 Trace Port Interface Unit

Trace capability from Cortex®-M4 will be supported on the CM subsystem. There are two trace interfaces supported on Cortex®-M4:

- Single wire trace, which follows a UART protocol and is asynchronous.
- Five-pin (four data pins and one clock pin) and parallel trace.

Both the options are supported on this device. Figure 41-16 illustrates the high-level clock and signal hookup to and from Trace Port Interface Unit.

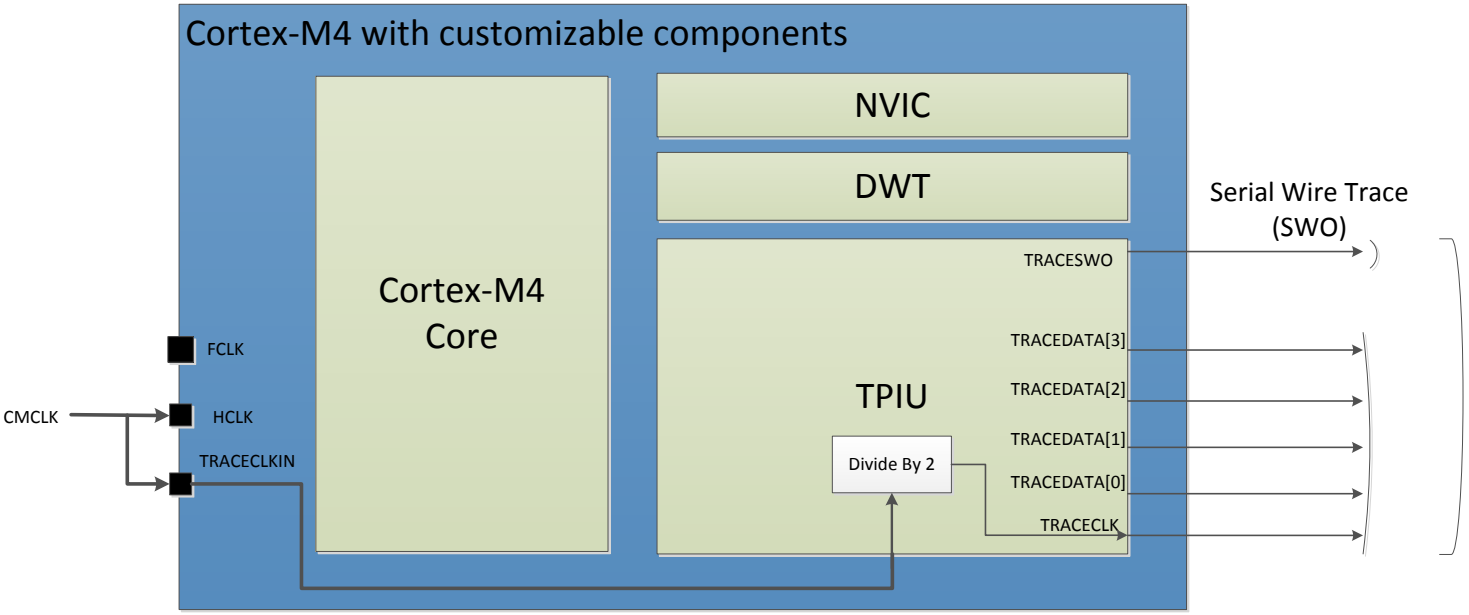

Figure 41-16. Debug Trace

Table 41-10 lists the key attributes of the two trace data export mechanisms. Refer to the *Arm® Architecture Reference Manual* for further details about TPIU and trace mechanisms.

Table 41-10. Key Attributes of Trace Data Export

Attribute Parallel Trace	Serial Wire Trace	Parallel Trace
Protocol	UART Protocol/Manchester encoded data stream	Trace Data changes on both edges of TRACECLK.
Data throughput rate	Frequency(CMHCLK)/(TPIU_ACPR + 1)	Frequency(CMHCLK)/2

You must configure the GPIO mux to select a trace function on the GPIO pin to use it.

41.12 CM-SysCtrl Registers

This section describes the Connectivity Manager System Control Registers.

41.12.1 CM System Control Base Addresses

Note

NVIC_BASE applies to NVIC, SCB, CFSR, SYSTICK, and MPU Registers.

Table 41-11. CM SYSCTRL Base Address Table (CM)

DriverLib Name	Base Address	uDMA Access	Ethernet DMA Access
CMMEMCFG_BASE	0x400F_E000	-	-

A4h	PERI_MEM_TEST_CONTROL	Peripheral Memory Test control Register	Lock Protection	Go

Complex bit access types are encoded to fit into small table cells. Table 41-13 shows the codes that are used for access types in this section.

Table 41-13. CM_MEMCFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 41-13. CM_MEMCFG_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.2.1 CxLOCK Register (Offset = 0h) [Reset = 0h]

CxLOCK is shown in Figure 41-17 and described in Table 41-14.

Return to the Summary Table.

41.12.3 CM_MEMORYDIAGERROR_REGS Registers

Table 41-31 lists the memory-mapped registers for the CM_MEMORYDIAGERROR_REGS registers. All register offset addresses not listed in Table 41-31 should be considered as reserved locations and the register contents should not be modified.

Table 41-31. CM_MEMORYDIAGERROR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	DIAGERRFLG	Error Flag Register		Go
8h	DIAGERRCLR	Error Flag Clear Register		Go
Ch	DIAGERRADDR	Read Error Address		Go

Complex bit access types are encoded to fit into small table cells. Table 41-32 shows the codes that are used for access types in this section.

Table 41-32. CM_MEMORYDIAGERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.3.1 DIAGERRFLG Register (Offset = 0h) [Reset = 0h]

DIAGERRFLG is shown in Figure 41-34 and described in Table 41-33.

Return to the Summary Table.

72h	MCANWAKESTATUSCLR	MCAN Wake Status Clear Register		Go
FAh	PALLOCATESTS	Status of PALLOCATE register.		Go
FCh	CMRESCCLR	CM Reset Cause Status Clear Register		Go
FEh	CMRESC	CM Reset Cause Status Register		Go
100h	CMSYSCTLLOCK	Locks the configuration registers of CM System control		Go

Complex bit access types are encoded to fit into small table cells. Table 41-64 shows the codes that are used for access types in this section.

Table 41-64. CMSYSCTL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 41-64. CMSYSCTL_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.5.1 CMPCLKCR0 Register (Offset = 0h) [Reset = 0h]

CMPCLKCR0 is shown in Figure 41-62 and described in Table 41-65.

41.12.6 CM_CPUTIMER_REGS Registers

Table 41-83 lists the memory-mapped registers for the CM_CPUTIMER_REGS registers. All register offset addresses not listed in Table 41-83 should be considered as reserved locations and the register contents should not be modified.

Table 41-83. CM_CPUTIMER_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	TIM	Timer counter register	EALLOW	Go
4h	PRD	Timer period register	EALLOW	Go
8h	TCR	Timer control register	EALLOW	Go
Ch	TPR	Timer prescaler register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 41-84 shows the codes that are used for access types in this section.

Table 41-84. CM_CPUTIMER_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.6.1 TIM Register (Offset = 0h) [Reset = FFFFh]

TIM is shown in Figure 41-80 and described in Table 41-85.

Return to the Summary Table.

System Control & Status Register

COUNT																															
R/W-FFFFh																															

Table 41-85. TIM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	COUNT	R/W	FFFFh	Timer Counter Registers (TIM): The TIM register holds the 32-bit count of the timer. The TIM register decrements by one every (TDDRH:TDDRL+1) clock cycles, where TDDRH:TDDRL is the timer pre-scale divide-down value. When the TIM decrements to zero, the TIM register is re-loaded with the period value contained in the PRD register, the timer the timer interrupt (TINTn) signal is pulsed. Reset type: CM.RESETn

41.12.6.2 PRD Register (Offset = 4h) [Reset = FFFFh]

PRD is shown in Figure 41-81 and described in Table 41-86.

Return to the Summary Table.

Timer period register

7	6	5	4	3	2	1	0
RESERVED		TRB	TSS	RESERVED			
R-0h		R-0/W1S-0h	R/W-0h	R-0h			

Table 41-87. TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15	TIF	R/W1S	0h	Timer Interrupt Flag. This flag gets set when the timer decrements to zero. This bit can be cleared by software writing a 1, but it can only be set by the timer reaching zero. Writing a 1 to this bit will clear it, writing a zero has no effect. Reset type: CM.RESETn
14	TIE	R/W	0h	Timer Interrupt Enable. If the timer decrements to zero, and this bit is set, the timer will assert it's interrupt request. Reset type: CM.RESETn
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If this bit is set then on a debug halt of CM4, timer would continute to decrement and generate periodic interrupts. If this bit is 0, counter behavior under debug halt condition is determined by TCR.SOFT bit. Reset type: CM.RESETn
10	SOFT	R/W	0h	If the TCR.FREE bit is 0 and SOFT bit is: 0 : On a debug halt of CM4, timer will stop counting immediately (Hard Stop) 1 : On a debug halt of CM4, timer will stop counting upon reaching 0 and generating the interrupt (Soft Stop) If the TCR.FREE bit is 1 then SOFT bit has no impact in timer behavior. Reset type: CM.RESETn
9-6	RESERVED	R	0h	Reserved
5	TRB	R-0/W1S	0h	Timer Reload bit. When a 1 is written to TRB, the TIM is loaded with the value in the PRD, and the pre-scaler counter (PSC) is loaded with the value in the timer divide-down register (TDDR). The TRB bit is always read as zero Reset type: CM.RESETn

Table 41-87. TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	TSS	R/W	0h	Timer stop status bit. TSS is a 1-bit flag that stops or starts the timer. To stop the timer, set TSS to 1. To start or restart the timer, set TSS to 0. At reset, TSS is cleared to 0 and the timer immediately starts. Reset type: CM.RESETn
3-0	RESERVED	R	0h	Reserved

41.12.6.4 TPR Register (Offset = Ch) [Reset = 0h]

TPR is shown in Figure 41-83 and described in Table 41-88.

Return to the Summary Table.

Timer prescaler register

Figure 41-83. TPR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSCH								TDDRH								PSCL								TDDRL							
R-0h								R/W-0h								R-0h								R/W-0h							

Table 41-88. TPR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	PSCH	R	0h	See description of PSCL above Reset type: CM.RESETn
23-16	TDDRH	R/W	0h	See description of TDDRL above Reset type: CM.RESETn
15-8	PSCL	R	0h	Timer Pre-Scale Counter. These bits hold the current pre-scale count for the timer. For every timer clock source cycle that the PSCH:PSCL value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer pre-scaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSCL is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSCL can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSCL is set to 0. Reset type: CM.RESETn
7-0	TDDRL	R/W	0h	Timer Divide-Down. Every (TDDRH:TDDRL + 1) timer clock source cycles, the timer counter register (TIM) decrements by one. At reset, the TDDRH:TDDRL bits are cleared to 0. If you want to increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDRL bits. When the prescaler counter (PSCH:PSCL) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDRL reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDRL also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software. Reset type: CM.RESETn

41.12.7 MPU_REGS Registers

Table 41-89 lists the memory-mapped registers for the MPU_REGS registers. All register offset addresses not listed in Table 41-89 should be considered as reserved locations and the register contents should not be modified.

Table 41-89. MPU_REGS Registers

41.12.8 CM_NMI_INTRUPT_REGS Registers

Table 41-113 lists the memory-mapped registers for the CM_NMI_INTRUPT_REGS registers. All register offset addresses not listed in Table 41-113 should be considered as reserved locations and the register contents should not be modified.

Table 41-113. CM_NMI_INTRUPT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CMNMICFG	CM NMI Configuration Register		Go
4h	CMNMIFLG	CM NMI Flag Register		Go
8h	CMNMIFLGCLR	CMNMI Flag Clear Register		Go
Ch	CMNMIFLGFRC	CMNMI Flag Force Register		Go
10h	CMNMIWDCNT	CMNMI Watchdog Counter Register		Go
14h	CMNMIWDPRD	CMNMI Watchdog Period Register		Go
18h	CMNMISHDWFLG	CMNMI Shadow Flag Register		Go

Complex bit access types are encoded to fit into small table cells. Table 41-114 shows the codes that are used for access types in this section.

Table 41-114. CM_NMI_INTRUPT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.8.1 CMNMICFG Register (Offset = 0h) [Reset = 0h]

CMNMICFG is shown in Figure 41-106 and described in Table 41-115.

Return to the Summary Table.

R-0h																R-0h															

Table 41-119. CMNMIWDCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-0	NMIWDCNT	R	0h	NMI Watchdog Counter: This 16-bit incremental counter will start incrementing whenever any one of the enabled FAIL flags are set. If the counter reaches the period value, an NMIRSn signal is fired which will then resets the system. If no enabled FAIL flag is set, then the counter will reset to zero and remain at zero until an enabled FAIL flag is set. Normally, the software would respond to the NMI interrupt generated and clear the offending FLAG(s) before the NMI watchdog triggers a reset. In some situations, the software may decide to allow the watchdog to reset the device anyway. The counter is clocked at the CMCLK rate. Reset type: CM.RESETn

41.12.8.6 CMNMIWDPRD Register (Offset = 14h) [Reset = FFFFh]

CMNMIWDPRD is shown in Figure 41-111 and described in Table 41-120.

Return to the Summary Table.

Table 41-120. CMNMIWDPRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Write to any of the fields of this register will suceed only if a value 0x9238 appears on the KEY field. Reset type: CM.RESETn
15-0	NMIWDPRD	R/W	FFFFh	NMI Watchdog Period: This 16-bit value contains the period value at which a reset is generated when the watchdog counter matches. At reset this value is set at the maximum. The software can decrease the period value at initialization time. Note:If a PERIOD value is written that is smaller than the current counter value, the counter will continue counting until it overflows and starts counting up again from 0. After the overflow, once the COUNTER value equals the new PERIOD value, an NMIRS is forced which resets the watchdog counter. Reset type: CM.RESETn

41.12.8.7 CMNMISHDWFLG Register (Offset = 18h) [Reset = 0h]

CMNMISHDWFLG is shown in Figure 41-112 and described in Table 41-121.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 41-123 shows the codes that are used for access types in this section.

Table 41-123. NVIC Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

Table 41-123. NVIC Access Type Codes (continued)

Access Type	Code	Description
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.9.1 NVIC_ISER0 Register (Offset = 100h) [Reset = 0h]

NVIC_ISER0 is shown in Figure 41-113 and described in Table 41-124.

Return to the Summary Table.

Table 41-151. STIR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved
8-0	INTID	R/W	0h	Interrupt ID of the interrupt to trigger, in the range 0-239. For example, a value of 0x03 specifies interrupt IRQ3. Reset type: CM.SYSRESETn

41.12.10 SCB Registers

Table 41-152 lists the memory-mapped registers for the SCB registers. All register offset addresses not listed in Table 41-152 should be considered as reserved locations and the register contents should not be modified.

Table 41-152. SCB Registers

Offset	Acronym	Register Name	Write Protection	Section
8h	ACTLR	Auxiliary Control Register		Go
D00h	CPUID	CPUID Base Register		Go
D04h	ICSR	Interrupt Control and State Register		Go
D08h	VTOR	Vector Table Offset Register		Go
D0Ch	AIRCR	Application Interrupt and Reset Control Register		Go
D10h	SCR	System Control Register		Go
D14h	CCR	Configuration and Control Register		Go
D18h	SHPR1	System Handler Priority Register 1		Go
D1Ch	SHPR2	System Handler Priority Register 2		Go
D20h	SHPR3	System Handler Priority Register 3		Go
D24h	SHCSRS	System Handler Control and State Register		Go
D28h	CFSR	Configurable Fault Status Register		Go
D2Ch	HFSR	HardFault Status Register		Go
D34h	MMFAR	MemManage Fault Address Register		Go
D38h	BFAR	BusFault Address Register		Go
D3Ch	AFSR	Auxiliary Fault Status Register		Go

Complex bit access types are encoded to fit into small table cells. Table 41-153 shows the codes that are used for access types in this section.

Table 41-153. SCB Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 41-153. SCB Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.10.1 ACTLR Register (Offset = 8h) [Reset = 0h]

ACTLR is shown in Figure 41-141 and described in Table 41-154.

Return to the Summary Table.

Auxiliary Control Register

Figure 41-141. ACTLR Register

Table 41-154. ACTLR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	Reserved
9	RESERVED	R/W	0h	Reserved
8	DISFPCA	R/W	0h	Disables automatic update of CONTROL.FPCA. Reset type: CM.SYSRESETn
7-3	RESERVED	R	0h	Reserved
2	DISFOLD	R/W	0h	When set to 1, disables IT folding. see About IT folding for more information. Reset type: CM.SYSRESETn
1	DISDEFWBUF	R/W	0h	When set to 1, disables write buffer use during default memory map accesses. This causes all BusFaults to be precise BusFaults but decreases performance because any store to memory must complete,before the processor can execute the next instruction. Note This bit only affects write buffers implemented in the Cortex-M4 processor. Reset type: CM.SYSRESETn
0	DISMCYCINT	R/W	0h	When set to 1, disables interruption of load multiple and store multiple instructions. This increases the,interrupt latency of the processor because any LDM or STM must complete before the processor,can stack the current state and enter the interrupt handler. Reset type: CM.SYSRESETn

41.12.10.2 CPUID Register (Offset = D00h) [Reset = 410FC240h]

CPUID is shown in Figure 41-142 and described in Table 41-155.

Return to the Summary Table.

CPUID Base Register

Table 41-156. ICSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	NMIPENDSET	R/W	0h	NMI set-pending bit. Write.. 0 = no effect 1 = changes NMI exception state to pending. Read.. 0 = NMI exception is not pending 1 = NMI exception is pending. Because NMI is the highest-priority exception, normally the processor enter the NMI exception handler as soon as it registers a write of 1 to this bit, and entering the handler clears this bit to 0. A read of this bit by the NMI exception handler returns 1 only if the NMI signal is reasserted while the processor is executing that handler. Reset type: CM.SYSRESETn
30-29	RESERVED	R	0h	Reserved
28	PENDSVSET	R/W	0h	PendSV set-pending bit. Write.. 0 = no effect 1 = changes PendSV exception state to pending. Read.. 0 = PendSV exception is not pending 1 = PendSV exception is pending. Writing 1 to this bit is the only way to set the PendSV exception state to pending. Reset type: CM.SYSRESETn
27	PENDSVCLR	R-0/W1S	0h	PendSV clear-pending bit. Write.. 0 = no effect 1 = removes the pending state from the PendSV exception. Reset type: CM.SYSRESETn

Table 41-156. ICSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26	PENDSTSET	R/W	0h	SysTick exception set-pending bit. Write.. 0 = no effect 1 = changes SysTick exception state to pending. Read.. 0 = SysTick exception is not pending 1 = SysTick exception is pending. When you write to the ICSR, the effect is Unpredictable if you.. write 1 to the PENDSVSET bit and write 1 to the PENDSVCLR bit write 1 to the PENDSTSET bit and write 1 to the PENDSTCLR bit. Reset type: CM.SYSRESETn
25	PENDSTCLR	R-0/W1S	0h	SysTick exception clear-pending bit. Write.. 0 = no effect 1 = removes the pending state from the SysTick exception. This bit is WO. On a register read its value is Unknown. Reset type: CM.SYSRESETn
24	RESERVED	R	0h	Reserved
23	RESERVED	R	0h	Reserved
22	ISRPENDING	R	0h	Interrupt pending flag, excluding NMI and Faults.. 0 = interrupt not pending 1 = interrupt pending. Reset type: CM.SYSRESETn
21-18	RESERVED	R	0h	Reserved
17-12	VECTPENDING	R	0h	Indicates the exception number of the highest priority pending enabled exception: 0 = no pending exceptions Nonzero = the exception number of the highest priority pending enabled exception. The value indicated by this field includes the effect of the BASEPRI and FAULTMASK registers, but not any effect of the PRIMASK register. Reset type: CM.SYSRESETn
11	RETTOBASE	R	0h	Indicates whether there are preempted active exceptions.. 0 = there are preempted active exceptions to execute 1 = there are no active exceptions, or the currently-executing exception is the only active exception. Reset type: CM.SYSRESETn
10-9	RESERVED	R	0h	Reserved
8-0	VECTACTIVE	R	0h	Contains the active exception number: 0 = Thread mode Nonzero = The exception numbera of the currently active exception. Note Subtract 16 from this value to obtain the CMSIS IRQ number required to index into the Interrupt Clear-Enable, Set-Enable, Clear-Pending, Set-Pending, or Priority Register. Reset type: CM.SYSRESETn

41.12.10.4 VTOR Register (Offset = D08h) [Reset = 0h]

VTOR is shown in Figure 41-144 and described in Table 41-157.

Return to the Summary Table.

R-0h			R/W-0h	R/W-0h	R-0h	R/W-0h	R/W-0h

Table 41-160. CCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	Reserved
9	STKALIGN	R/W	1h	Indicates stack alignment on exception entry.. 0 = 4-byte aligned 1 = 8-byte aligned. On exception entry, the processor uses bit 9 of the stacked PSR to indicate the stack alignment. On return from the exception it uses this stacked bit to restore the correct stack alignment. Reset type: CM.SYSRESETn
8	BFHFNMIGN	R/W	0h	Enables handlers with priority -1 or -2 to ignore data BusFaults caused by load and store instructions. This applies to the hard fault, NMI, and FAULTMASK escalated handlers.. 0 = data bus faults caused by load and store instructions cause a lock-up 1 = handlers running at priority -1 and -2 ignore data bus faults caused by load and store instructions. Set this bit to 1 only when the handler and its data are in absolutely safe memory. The normal use of this bit is to probe system devices and bridges to detect control path problems and fix them. Reset type: CM.SYSRESETn
7-5	RESERVED	R	0h	Reserved
4	DIV_0_TRP	R/W	0h	Enables faulting or halting when the processor executes an SDIV or UDIV instruction with a divisor of 0.. 0 = do not trap divide by 0 1 = trap divide by 0. When this bit is set to 0, a divide by zero returns a quotient of 0. Reset type: CM.SYSRESETn

Table 41-160. CCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	UNALIGN_TRP	R/W	0h	Enables unaligned access traps.. 0 = do not trap unaligned halfword and word accesses 1 = trap unaligned halfword and word accesses. If this bit is set to 1, an unaligned access generates a UsageFault. Unaligned LDM, STM, LDRD, and STRD instructions always fault irrespective of whether UNALIGN_TRP is set to 1. Reset type: CM.SYSRESETn
2	RESERVED	R	0h	Reserved
1	USERSETMPEND	R/W	0h	Enables unprivileged software access to the STIR. 0 = disable 1 = enable. Reset type: CM.SYSRESETn
0	NONBASETHRDENA	R/W	0h	Indicates how the processor enters Thread mode.. 0 = processor can enter Thread mode only when no exception is active. 1 = processor can enter Thread mode from any level under the control of an EXC_RETURN. EXC_RETURN[31:0] Description 0xFFFFFFF1 Return to Handler mode, exception return uses non-floating-point state from the MSP and execution uses MSP after return. 0xFFFFFFF9 Return to Thread mode, exception return uses non-floating-point state from MSP and execution uses MSP after return. 0xFFFFFFFD Return to Thread mode, exception return uses non-floating-point state from the PSP and execution uses PSP after return. 0xFFFFFFE1 Return to Handler mode, exception return uses floating-point-state from MSP and execution uses MSP after return. 0xFFFFFFE9 Return to Thread mode, exception return uses floating-point state from MSP and execution uses MSP after return. 0xFFFFFFED Return to Thread mode, exception return uses floating-point state from PSP and execution uses PSP after return. Reset type: CM.SYSRESETn

41.12.10.8 SHPR1 Register (Offset = D18h) [Reset = 0h]

Table 41-165. CFSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved
25	DIVBYZERO	R/W	0h	Divide by zero UsageFault: 0 = no divide by zero fault, or divide by zero trapping not enabled 1 = the processor has executed an SDIV or UDIV instruction with a divisor of 0. When the processor sets this bit to 1, the PC value stacked for the exception return points to the instruction that performed the divide by zero. Enable trapping of divide by zero by setting the DIV_0_TRP bit in the CCR to 1. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
24	UNALIGNED	R/W	0h	Unaligned access UsageFault: 0 = no unaligned access fault, or unaligned access trapping not enabled 1 = the processor has made an unaligned memory access. Enable trapping of unaligned accesses by setting the UNALIGN_TRP bit in the CCR to 1. Unaligned LDM, STM, LDRD, and STRD instructions always fault irrespective of the setting of UNALIGN_TRP. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
23-20	RESERVED	R	0h	Reserved

Table 41-165. CFSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	NOCP	R/W	0h	No coprocessor UsageFault. The processor does not support coprocessor instructions: 0 = no UsageFault caused by attempting to access a coprocessor 1 = the processor has attempted to access a coprocessor. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
18	INVPC	R/W	0h	Invalid PC load UsageFault, caused by an invalid PC load by EXC_RETURN: 0 = no invalid PC load UsageFault 1 = the processor has attempted an illegal load of EXC_RETURN to the PC, as a result of an invalid context, or an invalid EXC_RETURN value. When this bit is set to 1, the PC value stacked for the exception return points to the instruction that tried to perform the illegal load of the PC. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
17	INVSTATE	R/W	0h	Invalid state UsageFault: 0 = no invalid state UsageFault 1 = the processor has attempted to execute an instruction that makes illegal use of the EPSR. When this bit is set to 1, the PC value stacked for the exception return points to the instruction that attempted the illegal use of the EPSR. This bit is not set to 1 if an undefined instruction uses the EPSR. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
16	UNDEFINSTR	R/W	0h	Undefined instruction UsageFault: 0 = no undefined instruction UsageFault 1 = the processor has attempted to execute an undefined instruction. When this bit is set to 1, the PC value stacked for the exception return points to the undefined instruction. An undefined instruction is an instruction that the processor cannot decode Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
15	BFARVALID	R/W	0h	BusFault Address Register (BFAR) valid flag: 0 = value in BFAR is not a valid fault address 1 = BFAR holds a valid fault address. The processor sets this bit to 1 after a BusFault where the address is known. Other faults can set this bit to 0, such as a MemManage fault occurring later. If a BusFault occurs and is escalated to a hard fault because of priority, the hard fault handler must set this bit to 0. This prevents problems if returning to a stacked active BusFault handler whose BFAR value has been overwritten. Reset type: CM.SYSRESETn
14	RESERVED	R	0h	Reserved
13	RESERVED	R/W	0h	Reserved

Table 41-165. CFSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	STKERR	R/W	0h	BusFault on stacking for exception entry: 0 = no stacking fault 1 = stacking for an exception entry has caused one or more BusFaults. When the processor sets this bit to 1, the SP is still adjusted but the values in the context area on the stack might be incorrect. The processor does not write a fault address to the BFAR. Reset type: CM.SYSRESETn
11	UNSTKERR	R/W	0h	BusFault on unstacking for a return from exception: 0 = no unstacking fault 1 = unstack for an exception return has caused one or more BusFaults. This fault is chained to the handler. This means that when the processor sets this bit to 1, the original return stack is still present. The processor does not adjust the SP from the failing return, does not performed a new save, and does not write a fault address to the BFAR. Reset type: CM.SYSRESETn
10	IMPRECISERR	R/W	0h	Imprecise data bus error: 0 = no imprecise data bus error 1 = a data bus error has occurred, but the return address in the stack frame is not related to the instruction that caused the error. When the processor sets this bit to 1, it does not write a fault address to the BFAR. This is an asynchronous fault. Therefore, if it is detected when the priority of the current process is higher than the BusFault priority, the BusFault becomes pending and becomes active only when the processor returns from all higher priority processes. If a precise fault occurs before the processor enters the handler for the imprecise BusFault, the handler detects both IMPRECISERR set to 1 and one of the precise fault status bits set to 1. Reset type: CM.SYSRESETn
9	PRECISERR	R/W	0h	Precise data bus error: 0 = no precise data bus error 1 = a data bus error has occurred, and the PC value stacked for the exception return points to the instruction that caused the fault. When the processor sets this bit is 1, it writes the faulting address to the BFAR. Reset type: CM.SYSRESETn
8	IBUSERR	R/W	0h	Instruction bus error: 0 = no instruction bus error 1 = instruction bus error. The processor detects the instruction bus error on prefetching an instruction, but it sets the IBUSERR flag to 1 only if it attempts to issue the faulting instruction. When the processor sets this bit is 1, it does not write a fault address to the BFAR. Reset type: CM.SYSRESETn
7	MMARVALID	R/W	0h	MemManage Fault Address Register (MMFAR) valid flag.. 0 = value in MMAR is not a valid fault address 1 = MMAR holds a valid fault address. If a MemManage fault occurs and is escalated to a HardFault because of priority, the HardFault handler must set this bit to 0. This prevents problems on return to a stacked active MemManage fault handler whose MMAR value has been overwritten. Reset type: CM.SYSRESETn
6	RESERVED	R	0h	Reserved

Table 41-165. CFSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	RESERVED	R/W	0h	Reserved
4	MSTKERR	R/W	0h	MemManage fault on stacking for exception entry.. 0 = no stacking fault 1 = stacking for an exception entry has caused one or more access violations. When this bit is 1, the SP is still adjusted but the values in the context area on the stack might be incorrect. The processor has not written a fault address to the MMAR. Reset type: CM.SYSRESETn
3	MUNSTKERR	R/W	0h	MemManage fault on unstacking for a return from exception.. 0 = no unstacking fault 1 = unstack for an exception return has caused one or more access violations. This fault is chained to the handler. This means that when this bit is 1, the original return stack is still present. The processor has not adjusted the SP from the failing return, and has not performed a new save. The processor has not written a fault address to the MMAR. Reset type: CM.SYSRESETn
2	RESERVED	R	0h	Reserved
1	DACCVIOL	R/W	0h	Data access violation flag.. 0 = no data access violation fault 1 = the processor attempted a load or store at a location that does not permit the operation. When this bit is 1, the PC value stacked for the exception return points to the faulting instruction. The processor has loaded the MMAR with the address of the attempted access. Reset type: CM.SYSRESETn
0	IACCVIOL	R/W	0h	Instruction access violation flag.. 0 = no instruction access violation fault 1 = the processor attempted an instruction fetch from a location that does not permit execution. This fault occurs on any access to an XN region, even when the MPU is disabled or not present. When this bit is 1, the PC value stacked for the exception return points to the faulting instruction. The processor has not written a fault address to the MMAR. Reset type: CM.SYSRESETn

41.12.10.13 HFSR Register (Offset = D2Ch) [Reset = 0h]

HFSR is shown in Figure 41-153 and described in Table 41-166.

Return to the Summary Table.

HardFault Status Register

Figure 41-153. HFSR Register

41.12.11 CSFR Registers

Table 41-170 lists the memory-mapped registers for the CSFR registers. All register offset addresses not listed in Table 41-170 should be considered as reserved locations and the register contents should not be modified.

Table 41-170. CSFR Registers

Offset	Acronym	Register Name	Write Protection	Section
D28h	MMSR	MemManage Fault Status Register		Go
D29h	BFSR	BusFault Status Register		Go
D2Ah	UFSR	UsageFault Status Register		Go

Complex bit access types are encoded to fit into small table cells. Table 41-171 shows the codes that are used for access types in this section.

Table 41-171. CSFR Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.11.1 MMSR Register (Offset = D28h) [Reset = 0h]

MMSR is shown in Figure 41-157 and described in Table 41-172.

Return to the Summary Table.

Table 41-174. UFSR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9	DIVBYZERO	R/W	0h	Divide by zero UsageFault: 0 = no divide by zero fault, or divide by zero trapping not enabled 1 = the processor has executed an SDIV or UDIV instruction with a divisor of 0. When the processor sets this bit to 1, the PC value stacked for the exception return points to the instruction that performed the divide by zero. Enable trapping of divide by zero by setting the DIV_0_TRP bit in the CCR to 1. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
8	UNALIGNED	R/W	0h	Unaligned access UsageFault: 0 = no unaligned access fault, or unaligned access trapping not enabled 1 = the processor has made an unaligned memory access. Enable trapping of unaligned accesses by setting the UNALIGN_TRP bit in the CCR to 1. Unaligned LDM, STM, LDRD, and STRD instructions always fault irrespective of the setting of UNALIGN_TRP. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
7-4	RESERVED	R	0h	Reserved
3	NOCP	R/W	0h	No coprocessor UsageFault. The processor does not support coprocessor instructions: 0 = no UsageFault caused by attempting to access a coprocessor 1 = the processor has attempted to access a coprocessor. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn

Table 41-174. UFSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	INVPC	R/W	0h	Invalid PC load UsageFault, caused by an invalid PC load by EXC_RETURN: 0 = no invalid PC load UsageFault 1 = the processor has attempted an illegal load of EXC_RETURN to the PC, as a result of an invalid context, or an invalid EXC_RETURN value. When this bit is set to 1, the PC value stacked for the exception return points to the instruction that tried to perform the illegal load of the PC. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
1	INVSTATE	R/W	0h	Invalid state UsageFault: 0 = no invalid state UsageFault 1 = the processor has attempted to execute an instruction that makes illegal use of the EPSR. When this bit is set to 1, the PC value stacked for the exception return points to the instruction that attempted the illegal use of the EPSR. This bit is not set to 1 if an undefined instruction uses the EPSR. Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn
0	UNDEFINSTR	R/W	0h	Undefined instruction UsageFault: 0 = no undefined instruction UsageFault 1 = the processor has attempted to execute an undefined instruction. When this bit is set to 1, the PC value stacked for the exception return points to the undefined instruction. An undefined instruction is an instruction that the processor cannot decode Note:The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset. Reset type: CM.SYSRESETn

41.12.12 SYSTICK Registers

Table 41-175 lists the memory-mapped registers for the SYSTICK registers. All register offset addresses not listed in Table 41-175 should be considered as reserved locations and the register contents should not be modified.

Table 41-175. SYSTICK Registers

Offset	Acronym	Register Name	Write Protection	Section
10h	SYST_CSR	Privileged a SysTick Control and Status Register		Go
14h	SYST_RVR	Privileged Unknown SysTick Reload Value Register		Go
18h	SYST_CVR	Privileged Unknown SysTick Current Value Register		Go
1Ch	SYST_CALIB	Privileged -a SysTick Calibration Value Register		Go

Complex bit access types are encoded to fit into small table cells. Table 41-176 shows the codes that are used for access types in this section.

Table 41-176. SYSTICK Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.12.1 SYST_CSR Register (Offset = 10h) [Reset = 4h]

SYST_CSR is shown in Figure 41-160 and described in Table 41-177.

Return to the Summary Table.

Privileged a SysTick Control and Status Register

R/W-0h							

Table 41-180. SYST_CALIB Register Field Descriptions

Bit	Field	Type	Reset	Description
31	NOREF	R/W	0h	Indicates whether the device provides a reference clock to the processor: 0 = reference clock provided 1 = no reference clock provided. If your device does not provide a reference clock, the SYST_CSR.CLKSOURCE bit reads-as-one and ignores writes. Reset type: CM.SYSRESETn
30	SKEW	R/W	0h	Indicates whether the TENMS value is exact: 0 = TENMS value is exact 1 = TENMS value is inexact, or not given. An inexact TENMS value can affect the suitability of SysTick as a software real time clock. Reset type: CM.SYSRESETn
29-24	RESERVED	R	0h	Reserved
23-0	TENMS	R/W	0h	Reload value for 10ms (100Hz) timing, subject to system clock skew errors. If the value reads as zero, the calibration value is not known. Reset type: CM.SYSRESETn

41.12.13 MPU Registers

Table 41-181 lists the memory-mapped registers for the MPU registers. All register offset addresses not listed in Table 41-181 should be considered as reserved locations and the register contents should not be modified.

Table 41-181. MPU Registers

Offset	Acronym	Register Name	Write Protection	Section
D90h	MPU_TYPE	MPU Type Register		Go
D94h	MPU_CTRL	MPU Control Register		Go
D98h	MPU_RNR	MPU Region Number Register		Go
D9Ch	MPU_RBAR	MPU Region Base Address Register		Go
DA0h	MPU_RASR	MPU Region Attribute and Size Register		Go
DA4h	MPU_RBAR_A1	Alias of RBAR		Go
DA8h	MPU_RASR_A1	Alias of RASR		Go
DACh	MPU_RBAR_A2	Alias of RBAR		Go
DB0h	MPU_RASR_A2	Alias of RASR		Go
DB4h	MPU_RBAR_A3	Alias of RBAR		Go
DB8h	MPU_RASR_A3	Alias of RASR		Go

Complex bit access types are encoded to fit into small table cells. Table 41-182 shows the codes that are used for access types in this section.

Table 41-182. MPU Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.13.1 MPU_TYPE Register (Offset = D90h) [Reset = 800h]

MPU_TYPE is shown in Figure 41-164 and described in Table 41-183.

Return to the Summary Table.

Table 41-184. MPU_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	RESERVED	R	0h	Reserved
2	PRIVDEFENA	R/W	0h	Enables privileged software access to the default memory map: 0 = If the MPU is enabled, disables use of the default memory map. Any memory access to a location not covered by any enabled region causes a fault. 1 = If the MPU is enabled, enables use of the default memory map as a background region for privileged software accesses. When enabled, the background region acts as if it is region number -1. Any region that is defined and enabled has priority over this default map. If the MPU is disabled, the processor ignores this bit. Reset type: CM.SYSRESETn
1	HFNMIENA	R/W	0h	Enables the operation of MPU during hard fault, NMI, and FAULTMASK handlers. When the MPU is enabled: 0 = MPU is disabled during hard fault, NMI, and FAULTMASK handlers, regardless of the value of the ENABLE bit 1 = the MPU is enabled during hard fault, NMI, and FAULTMASK handlers. When the MPU is disabled, if this bit is set to 1 the behavior is Unpredictable. Reset type: CM.SYSRESETn
0	ENABLE	R/W	0h	Enables the MPU: 0 = MPU disabled 1 = MPU enabled. Reset type: CM.SYSRESETn

41.12.13.3 MPU_RNR Register (Offset = D98h) [Reset = 0h]

MPU_RNR is shown in Figure 41-166 and described in Table 41-185.

Return to the Summary Table.

Table 41-186. MPU_RBAR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	ADDR	R/W	0h	Region base address field. The ADDR field is bits[31:N] of the MPU_RBAR. The region size, as specified by the SIZE field in the MPU_RASR, defines the value of N: N = Log2(Region size in bytes), If the region size is configured to 4GB, in the MPU_RASR, there is no valid ADDR field. In this case, the region occupies the complete memory map, and the base address is 0x00000000. The base address is aligned to the size of the region. For example, a 64KB region must be aligned on a multiple of 64KB, for example, at 0x00010000 or 0x00020000. Reset type: CM.SYSRESETn
4	VALID	R/W	0h	MPU Region Number valid bit: Write: 0 = MPU_RNR not changed, and the processor: updates the base address for the region specified in the MPU_RNR ignores the value of the REGION field 1 = the processor: updates the value of the MPU_RNR to the value of the REGION field updates the base address for the region specified in the REGION field. Always reads as zero. Reset type: CM.SYSRESETn
3-0	REGION	R/W	0h	MPU region field: For the behavior on writes, see the description of the VALID field. On reads, returns the current region number, as specified by the RNR. Reset type: CM.SYSRESETn

41.12.13.5 MPU_RASR Register (Offset = DA0h) [Reset = 0h]

MPU_RASR is shown in Figure 41-168 and described in Table 41-187.

Return to the Summary Table.

41.12.14 CM_WD_REGS Registers

Table 41-194 lists the memory-mapped registers for the CM_WD_REGS registers. All register offset addresses not listed in Table 41-194 should be considered as reserved locations and the register contents should not be modified.

Table 41-194. CM_WD_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SCSR	System Control & Status Register		Go
4h	WDCNTR	Watchdog Counter Register		Go
8h	WDKEY	Watchdog Reset Key Register		Go
Ch	WDCR	Watchdog Control Register		Go
10h	WDWCR	Watchdog Windowed Control Register		Go

Complex bit access types are encoded to fit into small table cells. Table 41-195 shows the codes that are used for access types in this section.

Table 41-195. CM_WD_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.14.1 SCSR Register (Offset = 0h) [Reset = 3h]

SCSR is shown in Figure 41-175 and described in Table 41-196.

Return to the Summary Table.

Chapter 42

Advanced Encryption Standard (AES) Accelerator

This section describes the Advanced Encryption Standard (AES) cryptographic hardware-accelerated module.

42.1 Introduction

This section introduces the Advanced Encryption Standard (AES), and describes the AES main functions and connections in the device.

The AES module provides hardware-accelerated data encryption and decryption operations based on a binary key. The AES is a symmetric cipher module that supports a 128-, 192-, or 256-bit key in hardware for encryption and decryption. The AES module is based on a symmetric algorithm, which means that the encryption and decryption keys are identical. To encrypt data means to convert it from plain text to an unintelligible form called cipher text. Decrypting cipher text converts previously encrypted data to its original plain text form. The main features of the AES accelerator are:

AES encrypt and decrypt operations are supported by:

- Galois/Counter mode (GCM), with basic GHASH operation
- Counter mode with CBC-MAC (CCM)
- XTS mode

The following feedback operating modes are available:

- Electronic code book mode (ECB)
- Cipher block chaining mode (CBC)
- Counter mode (CTR)
- Cipher feedback mode (CFB), 128-bit
- F8 mode
- Key sizes: 128, 192, and 256 bits
- Support for CBC_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for µDMA transfers
- Fully synchronous design

42.1.1 AES Block Diagram

Figure 42-1 shows the AES block diagram. A single-core or dual-interface architecture is used.

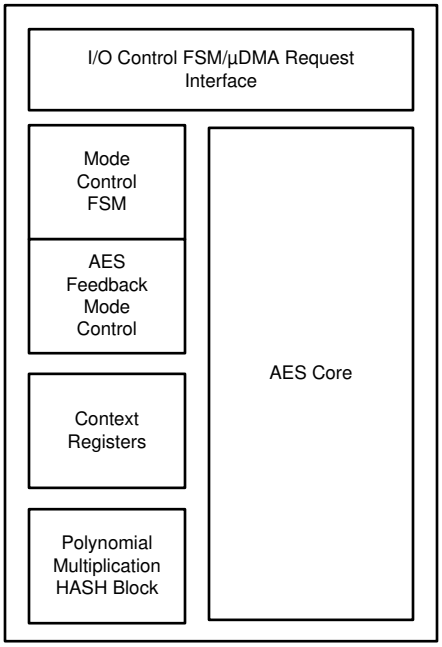

Figure 42-1. AES Block Diagram

AES is an efficient implementation of the Rijndael cipher (the AES algorithm) and a 128-bit polynomial multiplication (referred to here as GHASH, according to the AES-GCM specification). Rijndael is a block cipher in which each data block is 128 bits. The polynomial multiplication multiplies two 128-bit vectors using the smallest 128-bit irreducible polynomial, represented by the following 128-bit string: {0 120}||10000111. The two implementations are combined into the AES wide-bus engine.

Depending on the availability of context and data, the AES wide-bus engine is automatically triggered to process the data. The AES wide-bus engine is directly connected to the context and data registers, so that the AES engine can immediately start processing when all data is available. The AES wide-bus engine also interfaces to the I/O control FSM/µDMA request interface.

AES comprises the following major functional blocks:

- Global control FSM and µDMA interface
- Register interface module
- The AES wide-bus engine

The AES wide-bus engine, which is the major top-level component, comprises the following functional blocks:

- Mode control FSM: Manages the data flow to and from the AES wide-bus engine and starts each encryption or decryption operation
- Feedback modes: The logic that implements the various feedback modes supported by AES.
- GHASH core: The polynomial multiplication algorithm used for AES-GCM
- AES key scheduler: Generates AES encryption and decryption (round) keys
- AES encryption core: The AES encryption algorithm
- AES decryption core: The AES decryption algorithm
- Substitution-boxes (S-Boxes): Contain AES S-Box GF(2^8) implementations

AES encryption requires a specific number of rounds, depending on the key length. The supported key lengths are 128-, 192-, and 256-bit, which require 10, 12, and 14 rounds, respectively, or 32-, 38-, and 44-clock cycles, respectively, because {number of clock cycles} = 2 + 3 × {number of rounds}.

The larger key lengths provide greater encryption strength at the expense of additional rounds, and therefore reduced throughput. The overall throughput of the AES executing polynomial multiplication is adjusted based on the overall cryptographic performance. The AES module contains one ECB core and a dedicated 32-cycle polynomial multiplication module for performing GHASH operations. Polynomial multiplication operates in parallel with the AES core, if data is available for both modules.

Depending on the key size (128, 192, or 256 bits), this core requires 32-, 38-, or 44-clock cycles to process one 128-bit data block. While one data block processes, the next block can be preloaded immediately. When a block is preloaded, the previous block must finish before additional data can be loaded. Therefore, when the pipeline is full, sequential data blocks can be passed every 32-, 38-, or 44-clock cycles.

42.1.1.1 Interfaces

The interface signals to the AES module can be grouped into the following categories:

- Clock enable
- DMA and interrupt interface, used to request new context and packet data or to indicate available result data (encrypted or decrypted data, or authentication result)
- Functional register interface

42.1.1.2 AES Subsystem

The AES subsystem interfaces with the Connectivity Manager µDMA. The three registers include AESDMAINTEN (AES_DMA_Interupt_Enable), AESDMASTATUS (AES_DMA_Interupt_Status), and AESDMASTATUSCLR (AES_DMA_Interupt_Status_Clear). The read-only interrupt status register indicates when a DMA transfer has been completed. These interrupts can be enabled by setting the corresponding bit in the AESDMAINTEN register. When the status register has been read and the interrupt has been serviced, clear the AESDMASTATUS by setting the related AESDMASTATUSCLR bits. The AES subsystem registers are used when initiating DMA transfers. When the DMA is not in use, interrupts are generated.

Table 42-1. AES Subsystem Interrupt Status

Event	Description
AESDMASTATUS[3]: CONTEXT_OUT	Context output interrupt
AESDMASTATUS[2]: DATA_OUT	Data output interrupt
AESDMASTATUS[1]: DATA_IN	Data input interrupt
AESDMASTATUS[0]: CONTEXT_IN	Context input interrupt

42.1.1.3 AES Wide-Bus Engine

The AES wide-bus engine performs the cryptographic operations. The composition of the AES core follows:

AES Key Scheduler

The AES key scheduler generates the round keys. During each round, a new subkey is generated from the input key to be XORed with the data. Round keys are generated arbitrarily and parallel to data processing to minimize register requirements.

For encryption operations, the key sequencer transfers the initial key data to the AES core. For decryption operations, the key scheduler must provide the final subkey to the AES core so the AES can generate the subkeys in reverse order.

AES Encryption Core

The AES encryption core implements the Rijndael algorithm as specified in [FIPS-197]. This core operates on the input block and performs the required substitution, shift, and mix operations. For each round, the encryption core receives the proper round key from the AES key scheduler. A fundamental component of the AES algorithm is the S-Box. The S-Box provides a unique 8-bit output for each 8-bit input. This implementation of the AES encryption core has a 64-bit data path.

AES Decryption Core

The architecture of the AES decryption core is generally the same as the architecture of the encryption core. One difference is that the generation of round keys for decryption requires an initial conversion of the input key (always supplied by the host in the form of an encryption key) to the corresponding decryption key. This conversion is done by performing a dummy encryption operation and storing the final round key as a decryption key. The key scheduler is then reversed to generate the round keys for the decryption operation. Consequently, for each sequence of decryption operations under the same key, a single throughput reduction equal to the time to encrypt a single block occurs. Once a decryption key is generated, subsequent decryption operations with the same key use this generated decryption key directly.

AES Feedback Mode Block

The AES feedback mode block buffers the feedback parameters and controls the various feedback modes. For more information about the ECB, CBC, CTR, and CFB modes of operation, see the NIST-SP800-38A specification.

CTR implements the standard incrementing function, as described in the NIST-SP800-38A specification, with *m* set to 16 or a multiple of 32.

AES-XTS mode requires a polynomial multiplication for initialization vector (IV) generation of the AES operation. This multiplication can be simplified when the first result is available due to the definition and use of the block number within a unit. The input for the polynomial multiplication is not directly j, but α^j, where $\alpha = x^2$ in the GF(2^{128}) domain.

In addition, f8 encryption/decryption mode and f9 and (X)CBC-MAC authentication modes are available.

GHASH Block

The data sequencer manages the data flow to and from the AES core. For data input, the data sequencer monitors the input buffer until a 16-byte block is available. If the AES core is idle, the data sequencer writes this data block to the internal working registers of the AES core, thus clearing the buffer for the next block.

After completing an encryption or decryption operation, the data sequencer writes the AES output to the output buffer. If the output buffer is full at the time of completion, the AES core is held until the buffer clears. Although the data sequencer is designed to support uninterrupted packet encryption, the host must properly manage the input and output packet buffers to achieve designed performance.

42.1.2 AES Algorithm

The AES algorithm generates block ciphers. The AES block size is 16 bytes. The AES keys can be coded on 128, 192, or 256 bits. The larger key sizes provide a higher level of security, but at the cost of a moderate decrease in throughput.

For the AES algorithm:

- The length of the input and output blocks is 128 bits. The block length is represented by Nb = 4, which reflects the number of 32-bit words.
- The length of the cipher key (K) is 128, 192, or 256 bits. The key length is represented by Nk = 4, 6, or 8, which reflects the number of 32-bit words in the cipher key.
- The number of rounds to be performed during the execution of the algorithm depends on the key size. The number of rounds is represented by Nr, where Nr = 10 when Nk = 4 (128-bit key); Nr = 12 when Nk = 6 (192-bit key); and Nr = 14 when Nk = 8 (256-bit key).

Table 42-2 lists the combinations of keys, blocks, and rounds.

Table 42-2. Key-Block-Round Combinations

Key	Key Length (Nk)	Block Size (Nb)	Number of Rounds (Nr)
128 bits	4	4	10
192 bits	6	4	12
256 bits	8	4	14

The AES algorithm for cipher and inverse cipher uses a round function composed of four different byte-oriented transformations:

- Byte substitution using a substitution table (S-Box): This transformation is a nonlinear byte substitution that operates independently on each byte of the state (the state is an intermediate processed block of 128 bits inside the AES; the state is arranged as an array of [4 × Nk] bytes) using an S-Box. This S-Box transformation is reversible.
- Shifting rows of the state array by different offsets: In this transformation, the bytes in the last three rows of the state are cyclically shifted over different numbers of bytes (offsets). The first row ® = 0) is not shifted.
- Mixing the data within each column of the state array: This transformation operates on the state column-by-column, treating each column as a 4-term polynomial. The columns are considered polynomials over GF(2^8) and multiplied modulo $x^4 + 1$ with a fixed polynomial a(x).
- Adding a round key to the state: In this transformation, a round key is added to the state by a simple bitwise XOR operation. Each round key consists of Nb words from the key schedule.

The AES algorithm takes the cipher key (K) and performs a key expansion routine to generate a key schedule. The key expansion generates a total of Nb × (Nr + 1) words: The algorithm requires an initial set of Nb words, and each Nr round requires Nb words of key data. The resulting key schedule consists of a linear array of 4-byte words, denoted [w_I], with I in the range 0 ≤ I ≤ Nb × (Nr + 1).

42.2 AES Operating Modes

42.2.1 GCM Operation

Figure 42-2 shows one round of a GCM operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. After the encryption/decryption, the ciphertext is XORed with the intermediate authentication result. The XORed result is used as input for the polynomial multiplication to create the next (intermediate) authentication result. For more information about the GCM protocol, see Section 42.3.1.

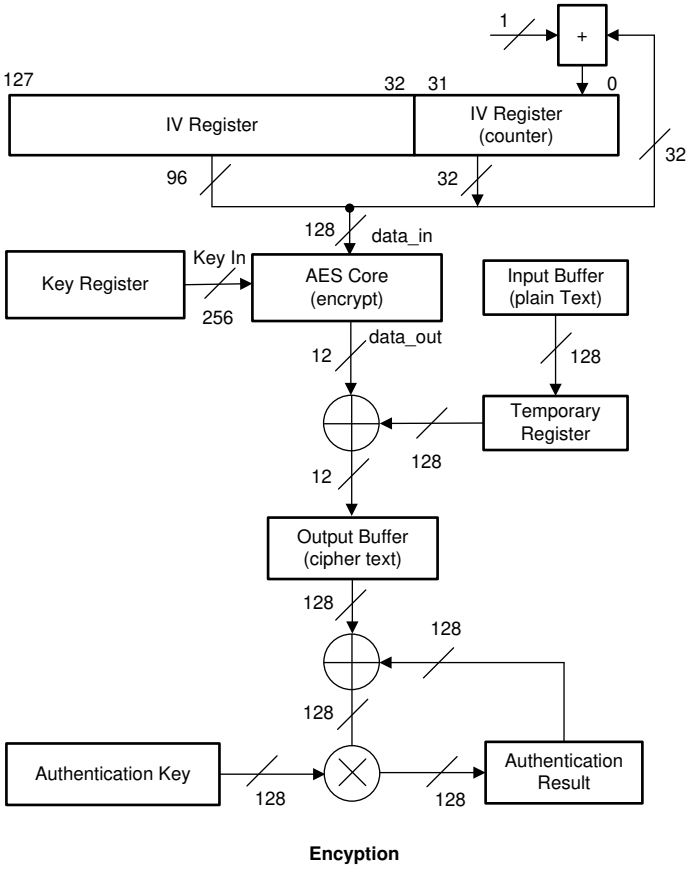

Figure 42-2. AES - GCM Operation

42.2.2 CCM Operation

Figure 42-3 shows one round of a CCM (counter with CBC-MAC) operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. Immediately after the encryption operation, the plaintext is XORed with the intermediate authentication result. The XOR result is used as input for a second encryption operation to calculate the next (intermediate) authentication result.

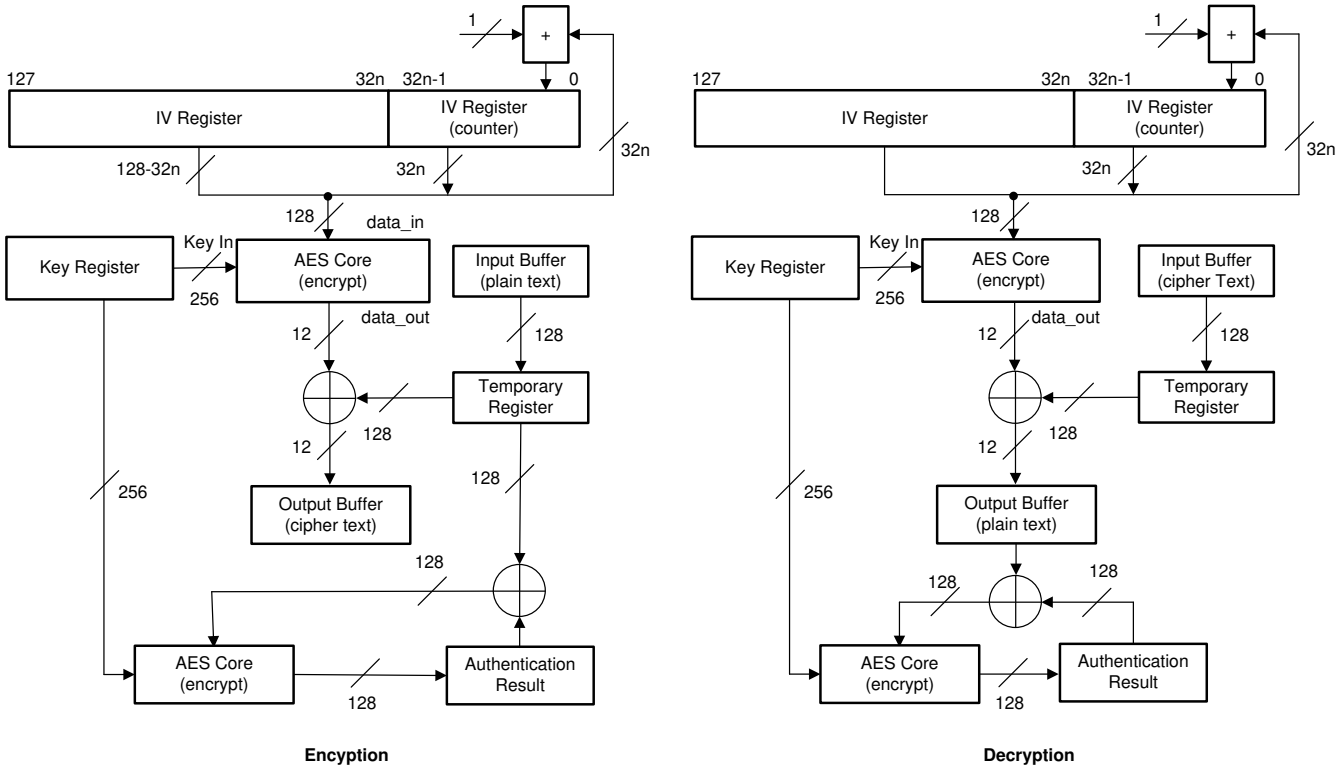

Figure 42-3. AES - CCM Operation

42.2.3 XTS Operation

Figure 42-4 shows the XTS mode of operation for encryption and decryption. The input to the cryptographic core is XORed with the IV; the output of the cryptographic core is XORed with the same IV. For decryption, the cryptographic core operates in reverse, but the XOR operations are the same.

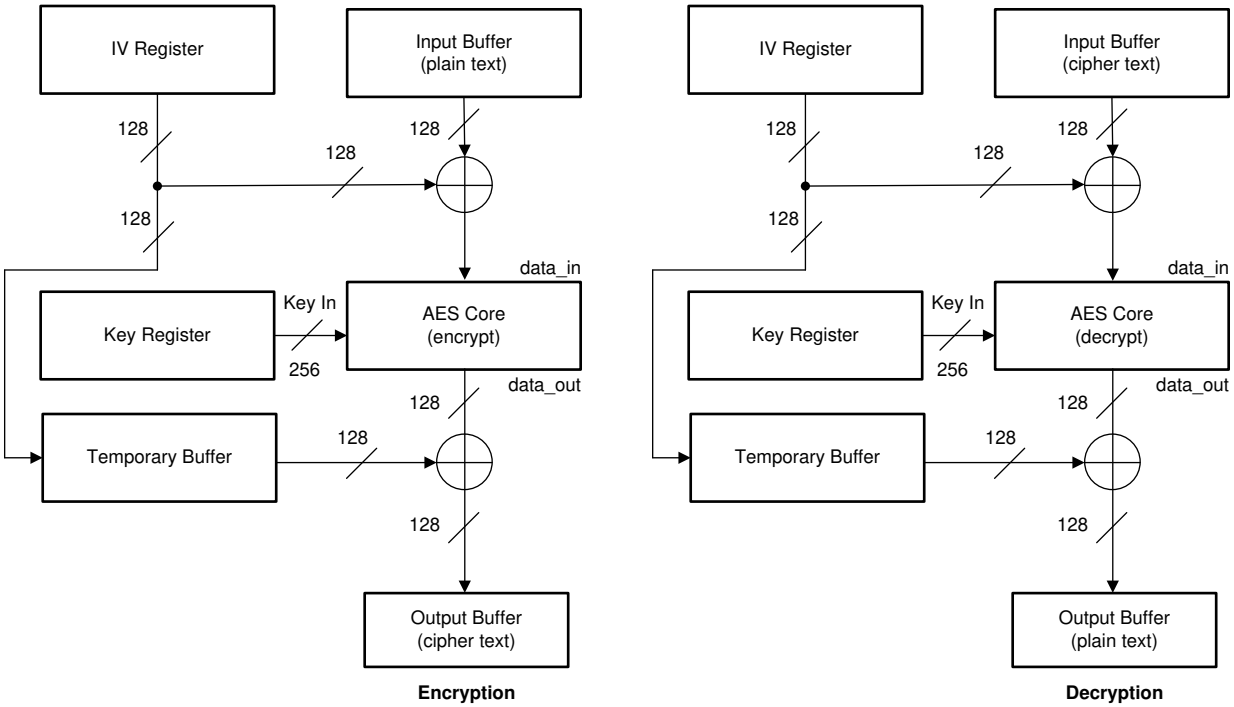

Figure 42-4. AES - XTS Operation

Note

The IV is created with an initial encryption, followed by an LFSR operation for each new block.

42.2.4 ECB Feedback Mode

Figure 42-5 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output is passed directly to the output buffer. For decryption, the cryptographic core operates in reverse: the decryption data path is used for data processing, whereas encryption uses the encryption data path.

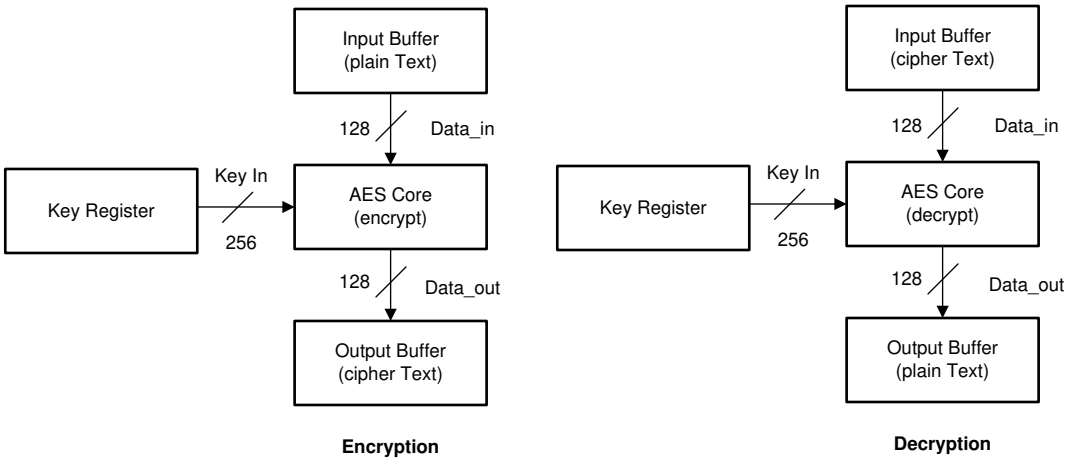

Figure 42-5. AES - ECB Feedback Mode

42.2.5 CBC Feedback Mode

Figure 42-6 shows the CBC feedback mode of operation, where the input data is XORed with the IV before it is passed to the basic cryptographic core. The output of the cryptographic core passes directly to the output buffer and becomes the next IV.

The operation is reversed for decryption, resulting in an XOR at the output of the cryptographic core. The input cipher text of the current operation is the IV for the next operation.

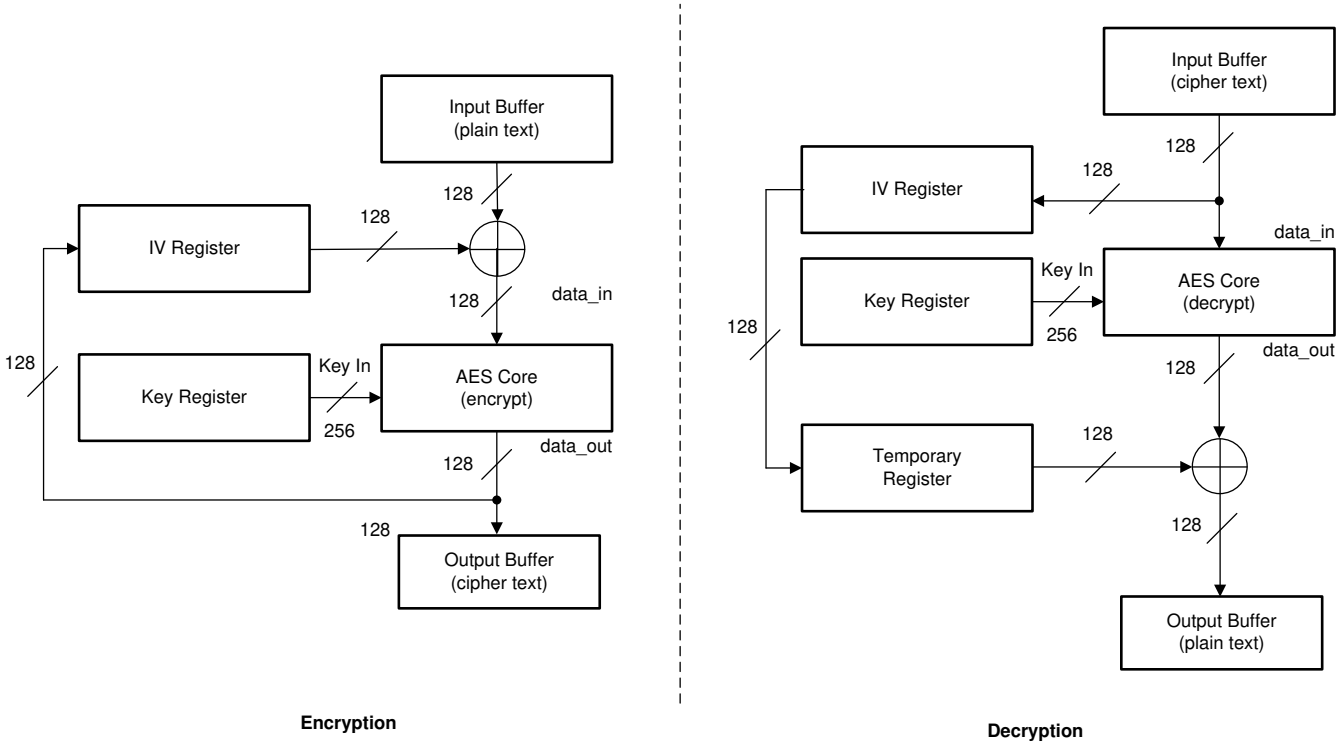

Figure 42-6. AES - CBC Feedback Mode

42.2.6 CTR and ICM Feedback Modes

Figure 42-7 shows the counter feedback (CTR/ICM) mode of operation. This operation encrypts the IV. The output of the cryptographic core (encrypted IV) is XORed with the data, thus creating the output result.

The IV is built out of two components: a fixed part and a counter part. The counter part is incremented with each block. The counter width is selectable per context and can be 16, 32, 64, 96, or 128 bits wide. In this mode, encryption and decryption use the same operation.

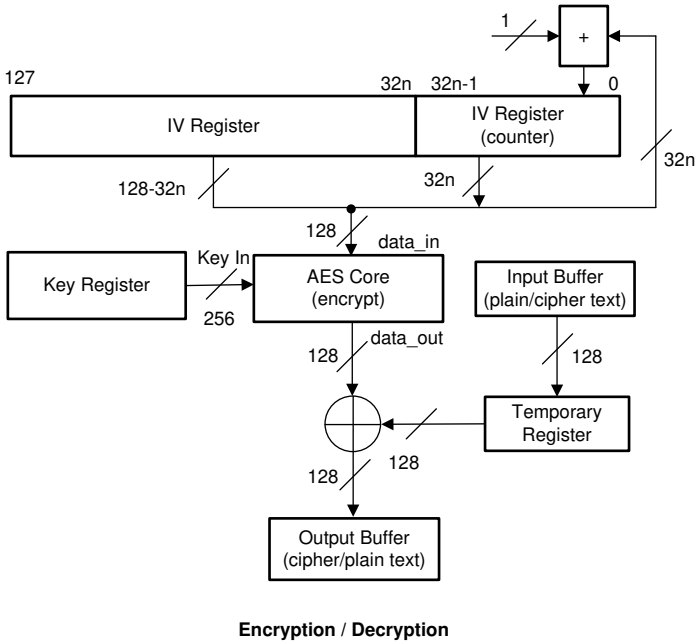

Figure 42-7. AES Encryption With CTR/ICM Mode

Note

The value for n can be 1, 2, 3, or 4 for CTR mode and is ½ for ICM mode.

42.2.7 CFB Mode

Figure 42-8 shows the full block (128 bits) CFB mode of operation for encryption and decryption. The input for the cryptographic core is the IV; the result is XORed with the data. The result is fed back through the IV register as the next input for the cryptographic core. The decryption operation is reversed, but the cryptographic core still performs encryption.

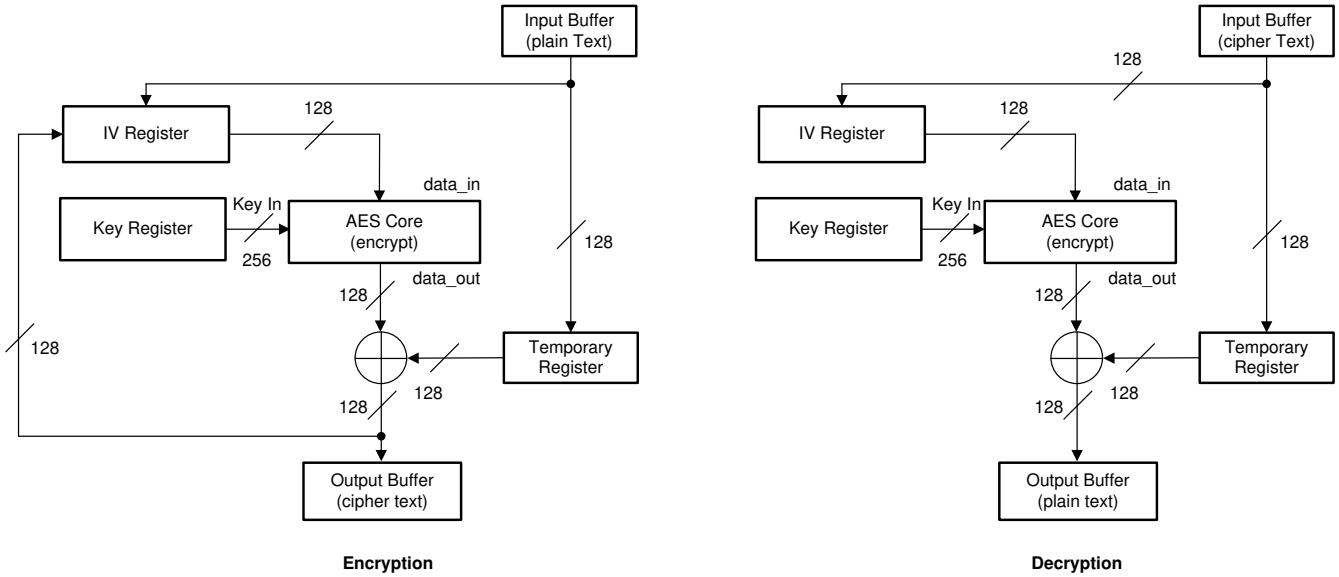

Figure 42-8. AES - CFB Feedback Mode

42.2.8 F8 Mode

Figure 42-9 shows the F8 feedback mode of operation for encryption and decryption. The input to the cryptographic core is the result of the XOR operation of the previous cryptographic core output, a constant IV, and a block counter. The output of the cryptographic core is XORed with the input to create the result. In this mode, encryption and decryption use the same operations.

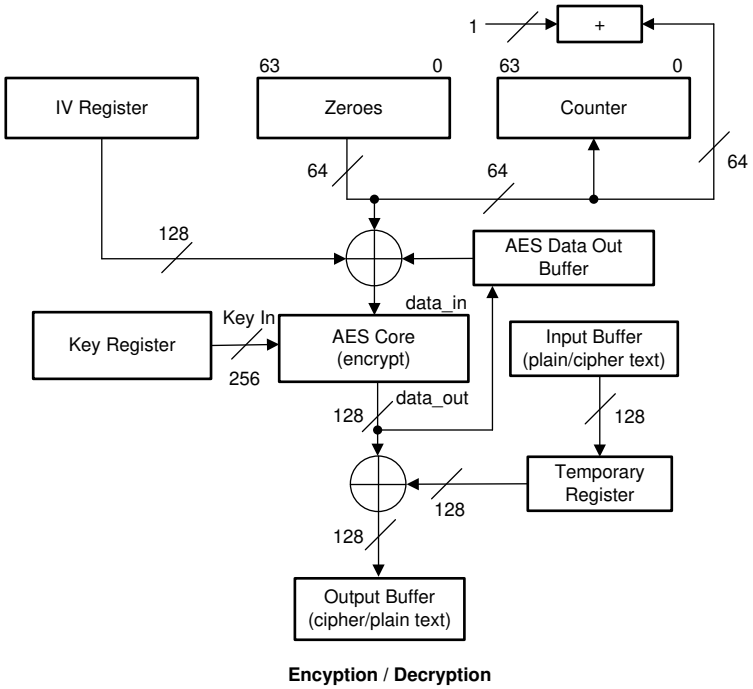

Figure 42-9. AES - F8 Mode

42.2.9 F9 Operation

Figure 42-10 shows the F9 authentication mode of operation, where the input to the cryptographic core is XORed with the IV, and the output is XORed with the previous result to create the next result. The cryptographic core output is fed back as IV for the next block. The result is the output of the last XOR operation of the cryptographic core output.

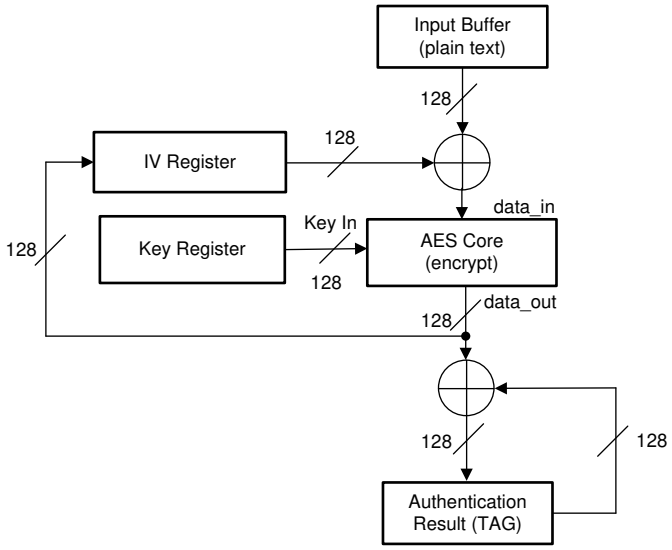

Figure 42-10. AES - F9 Operation

42.2.10 CBC-MAC Operation

Figure 42-11 shows the CBC-MAC authentication mode of operation, where the input to the cryptographic core is XORed with the IV. The cryptographic core output is then fed back as IV for the next block. The last data input block is XORed with an additional input value stored in the temporary buffer; this can be any precalculated value and is dependent on the alignment of the last input block. The result is the cryptographic core output of the last encryption operation.

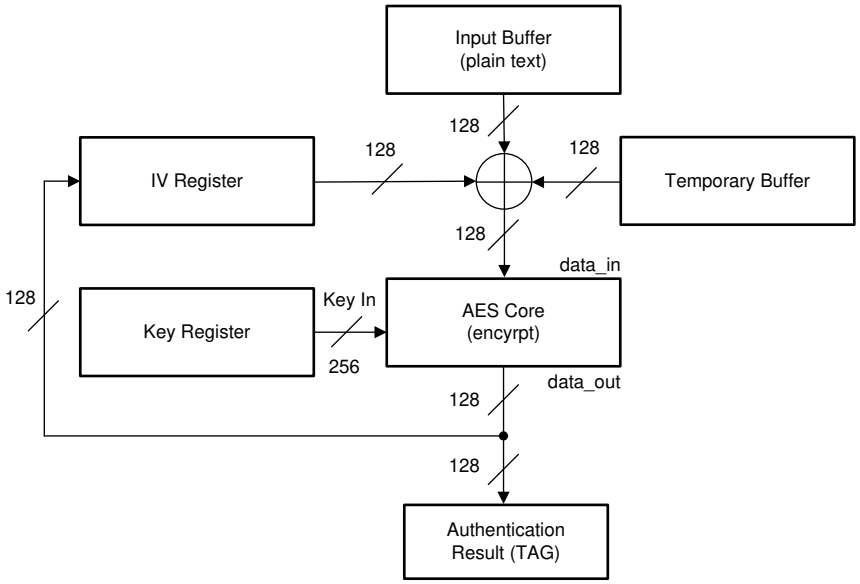

Figure 42-11. AES - CBC-MAC Authentication Mode

42.3 Extended and Combined Modes of Operations

This section describes the protocols (or autonomous precalculations) supported by the AES wide-bus engine.

42.3.1 GCM Protocol Operation

A GCM protocol operation is a combined operation consisting of encryption or decryption, and authentication. A part of the input data stream can be authenticated only, while normally most of the input data is encrypted or decrypted and authenticated. The authentication-only data must always be in front of the data requiring encryption. Within GCM, the authentication-only data is called the additional authentication data (AAD). The AAD is fetched independently of other data.

The intermediate (temporary) result data is used as input to the remaining authentication operation. Because the authentication operation does not require the cryptographic core but only the polynomial multiplication, encryption, decryption, and authentication can be performed in parallel. After encryption of the last data block, additional polynomial multiplication and encryption are required to authenticate a 128-bit-long vector and finally encrypt the authentication result.

42.3.2 CCM Protocol Operation

The CCM protocol operation is a combined operation consisting of encryption or decryption, and authentication. The authentication and encryption or decryption operations use the cryptographic core; these operations are executed sequentially on the AES core. A part of the data stream can require authentication only. The authentication-only data must always be in front of the data requiring encryption.

Authentication starts with the encryption of a predefined block B0. This block consists of flags, nonce, and message length. The next blocks contain the authentication data length concatenated with the authentication-only data. After processing the authentication-only data, the encryption or decryption operations are performed, each followed by the related authentication of the plaintext data block (which equals the input in the case of encryption, and the output in the case of decryption). The final authentication result must be encrypted using the output of the encryption of the IV block A0. This block contains the IV (consisting of flags and nonce) concatenated with the counter, which is zero for A0.

42.3.3 Hardware Requests

The AES module can assert a µDMA request for context in, context out, input data, or output data read. The AES µDMA Interrupt Mask (AES_DMAIM) register can be set to generate interrupts during the following events:

- Context In µDMA request (Cin)
- Context Out µDMA request (Cout)
- Data In µDMA request (Din)
- Data Out µDMA request (Dout)

The AES module can be programmed to assert an interrupt when the µDMA has completed its last transfer.

If context and data transfers are to be handled through software, then the AES Interrupt Enable (AES_IRQENABLE) register can be used to enable interrupt triggering when context out, context in, data in, or data out is ready. The AES Interrupt Status (AES_IRQSTATUS) register indicates when an interrupt is triggered, as listed in Table 42-3.

Table 42-3. Interrupts and Events

Event	Description
AES_IRQSTATUS[3]: CONTEXT_OUT	Context output interrupt
AES_IRQSTATUS[2]: DATA_OUT	Data output interrupt
AES_IRQSTATUS[1]: DATA_IN	Data input interrupt
AES_IRQSTATUS[0]: CONTEXT_IN	Context input interrupt

42.4 AES Module Programming Guide

42.4.1 AES Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the AES module.

42.4.1.1 Global Initialization

The following list describes the requirements for initializing the AES and associated modules.

1. Configure the AES µDMA channels for Context In, Context Out, Data In, and Data Out by programming the appropriate encoding value in the DMA Channel Map Select n (DMA_CHMAPn) register in the µDMA module. For more information, refer to the *Micro Direct Memory Access (µDMA)* chapter.
2. If the AES channels are configured in the µDMA, enable the required AES DMA requests by programming bits [9:5] of the AES_SYSCONFIG register, in addition to the completion interrupts in the AES DMA Interrupt Mask (DTHE_AES_IM) register.
3. Specify the size of the keys by programming the KEY_SIZE bit field in the AES_CTRL register.
4. Load the AES Key 1 (AES_KEY1_n) register.
5. Load the AES Key 2 (AES_KEY2_n) register if it is used by the configuration mode.
6. Configure the AES for the appropriate encryption or decryption mode (see Section 42.4.1.2).
7. Select encryption or decryption by programming the DIRECTION bit in the AES Control (AES_CTRL) register.

42.4.1.2 AES Operating Modes Configuration

The following sections list the initialization subsequences for the available encryption and decryption modes:

Subsequence: Initialize CCM AES Core Mode

The steps to initialize CCM mode follow:

1. Define the width of the length field and the length of the authentication field by programming the CCM_L and CCM_M bit fields in the AES_CTRL register.
2. Enable counter mode by setting the CTR bit in the AES_CTRL register.
3. Load the authentication data length in the AUTH field of the AES Authentication Data Length (AES_AUTH_LENGTH) register.
4. Select the IV counter by programming the CTR_WIDTH field in the AES_CTRL register.
5. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize GCM AES Core Mode

The steps to enable GCM mode follow:

1. Enable counter mode by setting the CTR bit in the AES_CTRL register.
2. Load the authentication data length in the AUTH field of the AES Authentication Data Length (AES_AUTH_LENGTH) register.
3. Select the IV counter by programming the CTR_WIDTH field in the AES_CTRL register.
4. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize CBC-MAC AES Core Mode

The steps to initialize CBC-MAC mode follow:

1. Enable CBC-MAC mode by setting the CBCMAC bit in the AES_CTRL register.
2. Select encryption mode by setting the DIRECTION bit in the AES_CTRL register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize F9 AES Core Mode

The steps to configure the AES for F9 mode follow:

1. Enable F9 mode by setting the F9 bit in the AES_CTRL register.
2. Set the key size to 128 bits by programming the KEY_SIZE field to 0x1 in the AES_CTRL register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize F8 AES Core Mode

The steps to configure the AES for F8 mode follow:

1. Enable F8 mode by setting the F8 bit in the AES_CTRL register.
2. Select the counter width by programming the CTR_WIDTH field in the AES_CTRL register.
3. Set the key size to 128 bits by setting the KEY_SIZE field to 0x1 in the AES_CTRL register.
4. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize XTS AES Core Mode

The steps to configure XTS mode follow:

1. Enable XTS mode by configuring the XTS field in the AES_CTRL register.
2. If the XTS field in the AES_CTRL register indicates that the AAD length is required, load the AAD length in the AES_AUTH_LENGTH register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize CFB AES Core Mode

The steps to initialize the AES code for CFB mode follow:

1. Enable CFB mode by setting the CFB bit in the AES_CTRL register.
2. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize ICM AES Core Mode

The steps to initialize the AES code for ICM mode follow:

1. Enable ICM mode by setting the ICM bit in the AES_CTRL register.
2. Configure for a 16-bit counter by programming the CTR_WIDTH field to 0x0 in the AES_CTRL register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize CTR AES Core Mode

The steps to initialize CTR mode follow:

1. Enable CTR mode by setting the CTR bit in the AES_CTRL register.
2. Select counter width by programming the CTR_WIDTH in the AES_CTRL register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize CBC AES Core Mode

The steps to configure CBC mode follow:

1. Enable CBC mode by setting the MODE bit in the AES_CTRL register.
2. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

42.4.1.3 AES Mode Configurations

AES Polling Mode

Main Sequence: AES Polling Mode – Figure 42-12 shows AES polling mode. The registers used in AES polling mode follow:

- AES Data RW Plaintext/Ciphertext 0 (AES_DATA_IN_OUT_0) registers
- AES Control (AES_CTRL) register
- AES Hash Tag Out 0 (AES_TAG_OUT_0) register

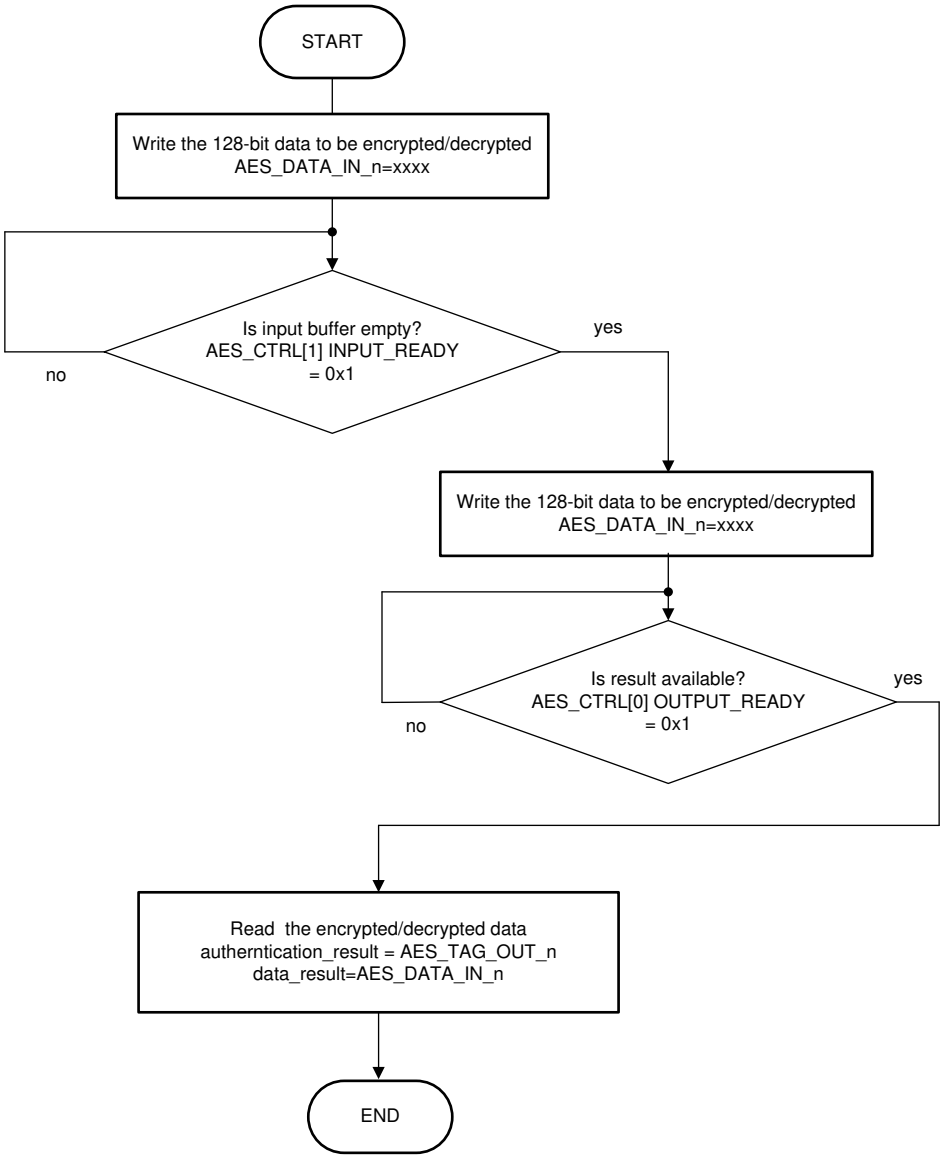

Figure 42-12. AES Polling Mode

AES Interrupt Mode

The application can use software interrupts to control the flow of Context In, Context Out, Data In, and Data Out requests. To enable these interrupts

1. First, initialize the device by following the initialization sequences described in Section 42.4.1.1 and Section 42.4.1.2.
2. When the device has been initialized, the application can enable the AES module interrupts through the AES Interrupt Enable (AES_IRQENABLE) register.
3. Load the input buffers, AES_DATA_IN_OUT_n, with data.

Note

If the application uses interrupt mode, an interrupt is generated for each block of processed data. To support larger data flow, AES µDMA mode must be used and the bits in the AES_IRQENABLE register must be cleared.

AES DMA Mode

When AES DMA mode is enabled, the AES_IRQENABLE register must be cleared. To enable the µDMA to transfer data, follow these steps:

1. When the AES module has been initialized, enable the AES module µDMA channels by programming the DMA Channel Map Select n (DMA_CHMAPn) register in the µDMA module. Refer to Table 42-1 for the channel map associated with AES.
2. Configure the dma_done interrupts by programming the AES DMA Masked Interrupt Status (DTHE_AES_MIS) register.
3. Enable the µDMA channels in the AES by programming the µDMA enable bits in the AES System Configuration (AES_SYSCONFIG) register.

The input buffer registers, AES_DATA_IN_OUT_n, are now loaded.

42.4.1.4 AES Events Servicing

Interrupt Servicing

This section describes the event servicing of the module. Figure 42-13 shows the AES interrupt service. The registers used during event servicing follow:

- AES_IRQSTATUS
- AES_KEY1_n
- AES_KEY2_n
- AES_IV_IN_n
- AES_DATA_IN_OUT_n
- AES_TAG_OUT_n
- AES_IRQENABLE

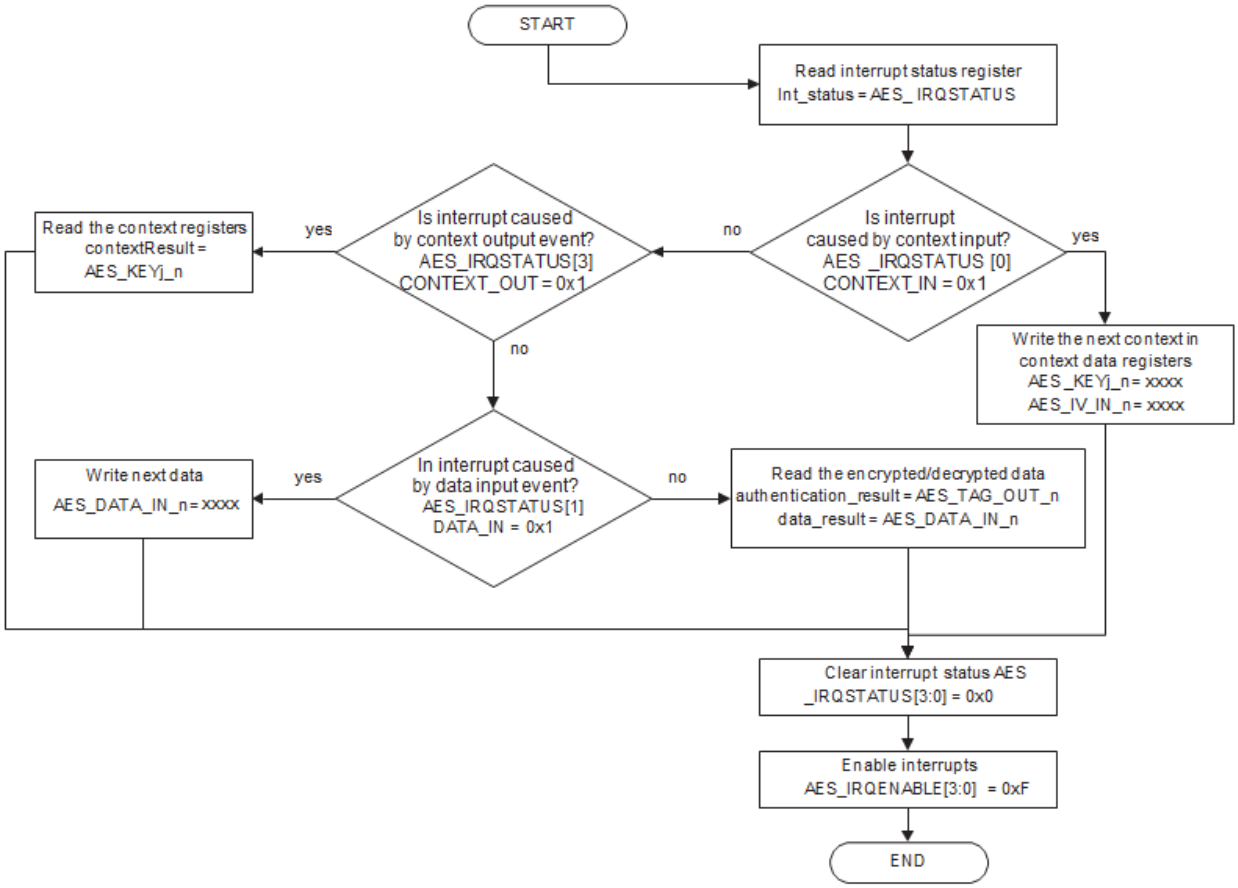

Figure 42-13. AES Interrupt Service

42.5 Software

42.5.1 AES Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/aes

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

42.5.1.1 AES ECB Encryption Example (CM) - CM

FILE: aes_ex1_ecb_encrypt.c

This example encrypts block cipher-text using AES128 in ECB mode. It does the encryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections
- None

Watch Variables
- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

42.5.1.2 AES ECB De-cryption Example (CM) - CM

FILE: aes_ex2_ecb_decrypt.c

This example de-crypts block cipher-text using AES128 in ECB mode. It does the de-cryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections
- None

Watch Variables
- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

42.5.1.3 AES GCM Encryption Example (CM) - CM

FILE: aes_ex3_gcm_encrypt.c

This example encrypts block cipher-text using AES128 in GCM mode. It does the encryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections
- None

Watch Variables
- *errorCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

42.5.1.4 AES GCM Decryption Example (CM) - CM

FILE: aes_ex4_gcm_decrypt.c

This example decrypts block cipher-text using AES128 in GCM mode. It does the decryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections
- None

Watch Variables
- *errorCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

42.6 AES Registers

The following sections are register descriptions for the AES Subsystem and AES Peripheral Core.

42.6.1 AES Base Addresses

Table 42-4. AES Base Address Table (CM)

DriverLib Name	Base Address	uDMA Access	Ethernet DMA Access
AES_SS_BASE	0x4004_AC00	YES	-
AES_BASE	0x4004_A000	YES	-

42.6.2 AES_SS_REGS Registers

Table 42-5 lists the memory-mapped registers for the AES_SS_REGS registers. All register offset addresses not listed in Table 42-5 should be considered as reserved locations and the register contents should not be modified.

Table 42-5. AES_SS_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	AESDMAINTEN	DMA Done Interrupt enable register		Go
4h	AESDMASTATUS	DMA Done Interrupt status register		Go
8h	AESDMASTATUSCLR	DMA Done Interrupt status clear register		Go

Complex bit access types are encoded to fit into small table cells. Table 42-6 shows the codes that are used for access types in this section.

Table 42-6. AES_SS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

42.6.2.1 AESDMAINTEN Register (Offset = 0h) [Reset = 0h]

AESDMAINTEN is shown in Figure 42-14 and described in Table 42-7.

Return to the Summary Table.

LENGTH																															
R-0/W-0h																															

Table 42-33. AES_C_LENGTH_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	LENGTH	R-0/W	0h	Bits [60:0] of the crypto length registers (LSW and MSW) store the cryptographic data length in bytes for all modes. Once processing with this context is started, this length decrements to zero. Data lengths up to (2^{61} - 1) bytes are allowed. For GCM, any value up to 2^{36} - 32 bytes can be used. This is because a 32-bit counter mode is used the maximum number of 128-bit blocks is 2^{32} - 2, resulting in a maximum number of bytes of 2^{36} - 32. A write to this register triggers the engine to start using this context. This is valid for all modes except GCM and CCM. Note that for the combined modes, this length does not include the authentication only data the authentication length is specified in the AES_AUTH_LENGTH register below. All modes must have a length > 0. For the combined modes, it is allowed to have one of the lengths equal to zero. For the basic encryption modes (ECB/CBC/CTR/ICM/CFB128) it is allowed to program zero to the length field in that case the length is assumed infinite. All data must be byte (8-bit) aligned for stream cipher modes bit aligned data streams are not supported by the AES Engine. For block cipher modes, the data length must be programmed in multiples of the block cipher size, 16 bytes. For a Host read operation, these registers return all-zeroes. Reset type: PER.RESET

42.6.3.23 AES_C_LENGTH_1 Register (Offset = 58h) [Reset = 0h]

AES_C_LENGTH_1 is shown in Figure 42-39 and described in Table 42-34.

LENGTH																															
R-0/W-0h																															

Table 42-34. AES_C_LENGTH_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	LENGTH	R-0/W	0h	Bits [60:0] of the crypto length registers (LSW and MSW) store the cryptographic data length in bytes for all modes. Once processing with this context is started, this length decrements to zero. Data lengths up to (2^{61} - 1) bytes are allowed. For GCM, any value up to 2^{36} - 32 bytes can be used. This is because a 32-bit counter mode is used the maximum number of 128-bit blocks is 2^{32} - 2, resulting in a maximum number of bytes of 2^{36} - 32. A write to this register triggers the engine to start using this context. This is valid for all modes except GCM and CCM. Note that for the combined modes, this length does not include the authentication only data the authentication length is specified in the AES_AUTH_LENGTH register below. All modes must have a length > 0. For the combined modes, it is allowed to have one of the lengths equal to zero. For the basic encryption modes (ECB/CBC/CTR/ICM/CFB128) it is allowed to program zero to the length field in that case the length is assumed infinite. All data must be byte (8-bit) aligned for stream cipher modes bit aligned data streams are not supported by the AES Engine. For block cipher modes, the data length must be programmed in multiples of the block cipher size, 16 bytes. For a Host read operation, these registers return all-zeroes. Reset type: PER.RESET

42.6.3.24 AES_AUTH_LENGTH Register (Offset = 5Ch) [Reset = 0h]

AES_AUTH_LENGTH is shown in Figure 42-40 and described in Table 42-35.

Return to the Summary Table.

Secure Host Interface Bank

Figure 42-40. AES_AUTH_LENGTH Register

AUTH																															
R-0/W-0h																															

Table 42-35. AES_AUTH_LENGTH Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	AUTH	R-0/W	0h	Bits [31:0] of the authentication length register store the authentication data length in bytes for combined modes only (GCM or CCM) Supported AAD-lengths for CCM are from 0 to (2^{16} - 2^{8}) bytes. For GCM any value up to (2^{32} - 1) bytes can be used. Once processing with this context is started, this length decrements to zero. A write to this register triggers the engine to start using this context for GCM and CCM. For XTS this register is optionally used to load "j". Loading of "j" is only required if "j" != 0. "j" is a 28-bit value and must be written to bits [31-4] of this register. "j" represents the sequential number of the 128-bit block inside the data unit. For the first block in a unit, this value is zero. It is not required to provide a "j" for each new data block within a unit. Note that it is possible to start with a "j" unequal to zero refer to Table 4 for more details. For a Host read operation, these registers return all-zeroes. Reset type: PER.RESET

42.6.3.25 AES_DATA_IN_OUT_0 Register (Offset = 60h) [Reset = 0h]

AES_DATA_IN_OUT_0 is shown in Figure 42-41 and described in Table 42-36.

Return to the Summary Table.

Chapter 43

Ethernet Media Access Controller (EMAC)

This chapter describes the Ethernet module and provides a functional description of the module.

43.1 Introduction

The Ethernet module enables a host to transmit and receive data over the Ethernet in compliance with IEEE 802.3-2015.

43.1.1 Standard Compliance

In addition to the default interfaces defined in the IEEE 802.3 specifications, the Ethernet module supports several industry standard interfaces to the PHY. The Ethernet module is compliant with the following standards:

The EBC unit has the following capabilities:

- IEEE 802.3-2015 for Ethernet MAC, Media Independent Interface (MII)
- IEEE 1588-2008 for precision networked clock synchronization
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE)
- RMII specification version 1.2 from RMII consortium
- Reverse Media Independent Interface (RevMII) by Dmitriy Gusev

43.1.2 MAC Features

The Ethernet controller supports a number of Tx and Rx MAC features. The MAC includes the following feature groups:

- MAC Tx and Rx features
- MAC Tx features
- MAC Rx features

43.1.2.1 MAC Tx and Rx Features

The combined features for Tx and Rx are as follows:

- Separate transmission, reception, and control interfaces to the application
- Little-endian mode for Transmit and Receive paths
- 10, 100 data transfer rates with the following PHY interfaces:
  - IEEE 802.3-compliant MII (default) interface to communicate with an external Ethernet PHY
  - RMII interface to communicate with an external Fast Ethernet PHY
  - RevMII interface to directly communicate with a remote MAC
- Half-duplex operation:
  - CSMA/CD Protocol support
  - Flow control using back pressure support (based on implementation-specific white papers and UNH Ethernet Clause 4 MAC Test Suite - Annex D)
- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet in MII PHYs.
- Full-duplex flow control operations (IEEE 802.3x Pause packets and Priority flow control)
- Network statistics with RMON or MIB Counters (RFC2819/RFC2665)
- Support Ethernet packet timestamping as described in IEEE 1588-2002 and IEEE 1588-2008 (64-bit timestamps given in the Tx or Rx status of PTP packet). Both one-step and two-step timestamping is supported in TX direction.
- Flexibility to control the Pulse-Per-Second (PPS) output signal
- MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management

43.1.2.2 MAC Tx Features

The MAC Tx features are as follows:

- Preamble and start of packet data (SFD) insertion
- Separate 32-bit status for each packet transmitted from the application
- Automatic CRC and pad generation controllable on a per-packet basis
- Programmable packet length to support Standard or Jumbo Ethernet packets with up to 16 KB of size
- Programmable Inter Packet Gap (40–96 bit times in steps of 8)
- IEEE 802.3x Flow Control automatic transmission of zero-quanta Pause packet when flow control input transitions from assertion to de-assertion (in full-duplex mode)
- Source Address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement, or deletion of up to two VLAN tags
- Option to transmit packets with reduced preamble size in full-duplex mode
- Insert, replace, or delete queue/channel-based VLAN tags

43.1.2.3 MAC Rx Features

The MAC Rx features are as follows:

- Flexible address filtering modes:
  - 8 48-bit perfect Destination Address/Source address filters with masks for each byte
  - 64-bit Hash filter for multicast and unicast (DA) addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based filtering. Filtering based on either outer or inner VLAN tag is possible.
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag based filtering 4-filter selection
- IEEE 802.1Q VLAN tag detection and option to delete the VLAN tags in received packets
- Module to detect remote wake-up packets and AMD magic packets
- Forwarding of received Pause packets to the application (in full-duplex mode)
- Receive module for Layer 3/Layer 4 checksum offload for received packets
- Stripping of up to two VLAN Tags and providing the tags in the status.

43.2 System Level Integration

This section provides a listing and description of the ethernet signal connections.

43.2.1 Ethernet Signal Connection and Description

The different types of PHY interfaces supported by the Ethernet Controller and their corresponding signal connection and description is given below.

43.2.1.1 MII Interface Signals

The MII interface signals and descriptions are shown in Table 43-1 and Figure 43-1.

Table 43-1. MII Interface Signals

Signal	Type	Description
ENET_MII_TX_CLK	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The ENET_MII_TX_DATA and ENET_MII_TXEN signals are connected to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
ENET_MII_TX_DATA[3:0]	O	The transmit data pins are a collection of 4 data signals, ENET_MII_TX_DATA[3:0], comprising 4 bits of data. ENET_MII_TX_DATA[0] is the least-significant bit. The signals are synchronized by ENET_MII_TX_CLK and valid only when ENET_MII_TX_EN is asserted.
ENET_MII_TX_EN	O	The transmit enable signal indicates that the ENET_MII_TXDATA[3:0] pins are generating 4-bit data for use by the PHY. This signal is driven synchronously by ENET_MII_TX_CLK.
ENET_MII_TX_ERR	O	The Transmit Error signal.
ENET_MII_COL	I	In full-duplex operation, the ENET_MII_COL pin is used for hardware transmit flow control. Asserting the ENET_MII_COL pin stops packet transmissions; packets transmitting when ENET_MII_COL is asserted completes transmission. The ENET_MII_COL pin should be held low, if hardware transmit flow control is not used.
ENET_MII_CRS	I	In half-duplex operation, the ENET_MII_CRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to ENET_MII_TX_CLK or ENET_MII_RX_CLK. In full-duplex operation, the ENET_MII_CRS pin should be held low.
ENET_MII_RX_CLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The ENET_MII_RX_DATA and ENET_MII_RX_DV signals are connected to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
ENET_MII_RX_DATA[3:0]	I	The receive data pins are a collection of 4 data signals comprising 4 bits of data. ENET_MII_RX_DATA[0] is the least-significant bit. The signals are synchronized by ENET_MII_RX_CLK and valid only when ENET_MII_RX_DV is asserted.
ENET_MII_RX_DV	I	The receive data valid signal indicates that the ENET_MII_RX_DATA pins are generating nibble data for use by the MAC. This signal is driven synchronous to ENET_MII_RX_CLK.
ENET_MII_RX_ER	I	Receive Error. The ENET_MII_RX_ER signal is asserted to indicate that an error is detected in received frame.
ENET_MII_INTR	I	Interrupt input from the physical layer chip outside the device.
ENET_MDIO_CLK	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. The clock is used to synchronize MDIO data access operations done on the ENET_MDIO_DATA pin.
ENET_MDIO_DATA	I/O	The ENET_MDIO_DATA pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The ENET_MDIO_DATA pin acts as an output for all but the data bit cycles at which time the pin is an input for read operations

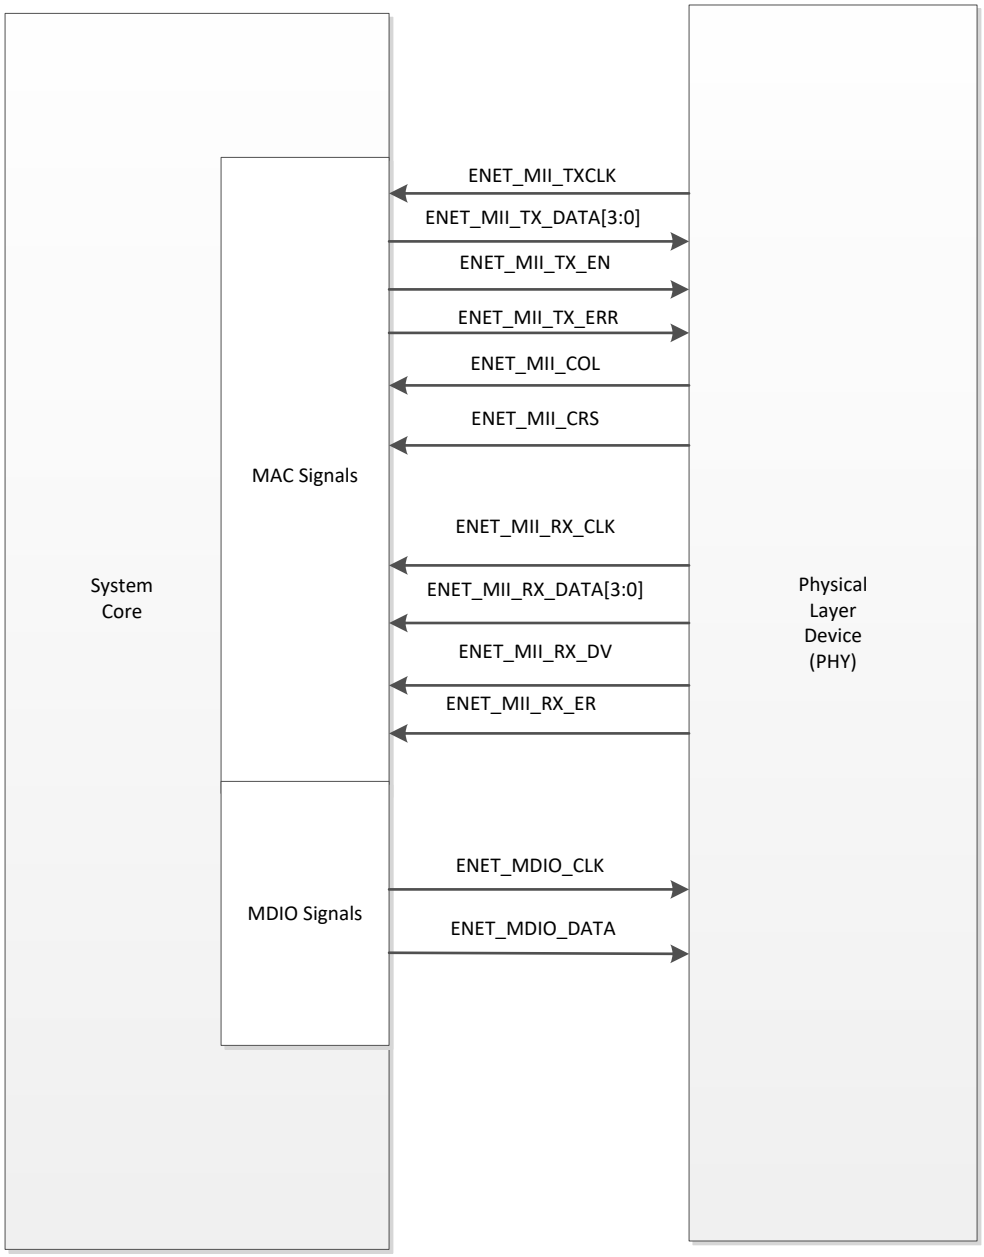

Figure 43-1. MII Mode Signals

43.2.1.2 RMII Interface Signals

The RMII interface signals and descriptions are shown in Table 43-2 and Figure 43-2.

Table 43-2. RMII Interface Signals

Signal	Type	Description
ENET_RMII_CLK	I/O	The reference clock is a continuous clock that provides the timing reference for transmit,receive operations. The ENET_MII_TX_DATA and ENET_MII_TX_EN signals are connected to this clock. The clock is generated by the PHY and is 5.0 MHz at 10 Mbps operation and 50 MHz at 100 Mbps operation. If External Clocking option is selected, this signal is input from the PHY/ external device; if internal clock is selected, this signal is output.

Table 43-2. RMII Interface Signals (continued)

Signal	Type	Description
ENET_MII_TX_DATA[1:0]	O	The transmit data pins are a collection of 2 data signals, ENET_MII_TX_DATA[1:0], comprising 2 bits of data. ENET_MII_TX_DATA[0] is the least-significant bit. The signals are synchronized by ENET_RMII_CLK and valid only when ENET_MII_TX_EN is asserted.
ENET_MII_TX_EN	O	The transmit enable signal indicates that the ENET_MII_TX_DATA[1:0] pins are generating 2-bit data for use by the PHY. This signal is driven synchronously by ENET_RMII_CLK.
ENET_MII_RX_DV	I	Multiplexed signal between Carrier Sense and Receive Data Valid.
ENET_MII_RX_DATA[1:0]	I	The receive data pins are a collection of 2 data signals comprising 2 bits of data. ENET_MII_RX_DATA[0] is the least-significant bit. The signals are synchronized by ENET_RMII_CLK and valid only when ENET_MII_RX_DV is asserted.
ENET_MII_RX_ERR	I	Receive Error. The ENET_MII_RX_ERR signal is asserted to indicate that an error is detected in received frame.
ENET_MDIO_CLK	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. The clock is used to synchronize MDIO data access operations done on the ENET_MDIO_DATA pin.
ENET_MDIO_DATA	I/O	The ENET_MDIO_DATA pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The ENET_MDIO_DATA pin acts as an output for all but the data bit cycles at which time the pin is an input for read operations.

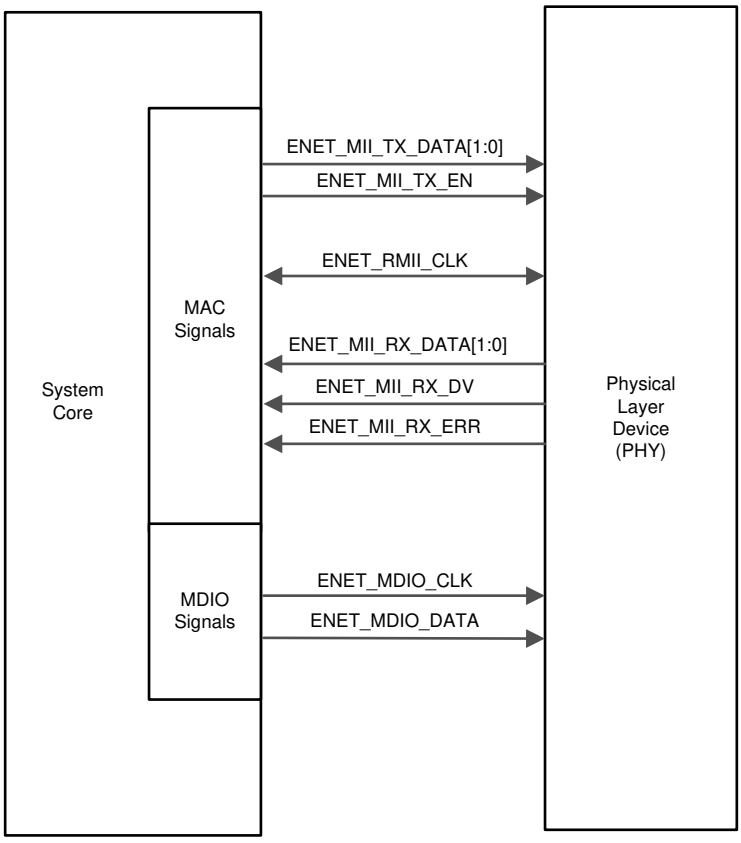

Figure 43-2. RMII Mode Signals

43.2.1.3 RevMII Interface Signals

The RevMII interface signals and descriptions are shown in Table 43-3 and Figure 43-3.

Table 43-3. RevMII Interface Signals

Signal	Type	Description
ENET_MII_TX_CLK	O	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The ENET_MII_TX_DATA and ENET_MII_TX_EN signals are connected to this clock. The clock is generated from the device and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
ENET_MII_TX_DATA[3:0]	O	The transmit data pins are a collection of 4 data signals, ENET_MII_TX_DATA[3:0], comprising 4 bits of data. ENET_MII_TX_DATA[0] is the least-significant bit. The signals are synchronized by ENET_MII_TX_CLK and valid only when ENET_MII_TX_EN is asserted.
ENET_MII_TX_EN	O	The transmit enable signal indicates that the ENET_MII_TX_DATA[3:0] pins are generating 4-bit data for use by the PHY. This signal is driven synchronously by ENET_MII_TX_CLK.
ENET_MII_TX_ERR	O	EMAC MII transmit error.
ENET_MII_COL	O	In full-duplex operation, the ENET_MII_COL pin is used for hardware transmit flow control. Asserting the ENET_MII_COL pin stops packet transmissions; packets transmitting when ENET_MII_COL is asserted completes transmission. The ENET_MII_COL pin should be held low, if hardware transmit flow control is not used.
ENET_MII_CRS	O	In half-duplex operation, the ENET_MII_CRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to ENET_MII_TX_CLK or ENET_MII_RX_CLK. In full-duplex operation, the ENET_MII_CRS pin should be held low.
ENET_MII_RX_CLK	O	The receive clock is a continuous clock that provides the timing reference for receive operations. The ENET_MII_RX_DATA and ENET_MII_RX_DV signals are connected to this clock. The clock is generated from the device and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
ENET_MII_RX_DATA[3:0]	I	The receive data pins are a collection of 4 data signals comprising 4 bits of data. ENET_MII_RX_DATA[0] is the least-significant bit. The signals are synchronized by ENET_MII_RX_CLK and valid only when ENET_MII_RX_DV is asserted.
ENET_MII_RX_DV	I	The receive data valid signal indicates that the ENET_MII_RX_DATA pins are generating nibble data for use by the MAC. This signal is driven synchronous to ENET_MII_RX_CLK.
ENET_MII_RX_ERR	I	EMAC MII / RMII receive error.
ENET_MII_INTR	O	RevMII mode PHY interrupt out pin.
ENET_MDIO_CLK	I	The ENET_MDIO_DATA pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The ENET_MDIO_DATA pin acts as an output for all but the data bit cycles at which time the pin is an input for read operations.
ENET_MDIO_DATA	I/O	The ENET_MDIO_DATA pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The ENET_MDIO_DATA pin acts as an output for all but the data bit cycles at which time the pin is an input for read operations.
ENET_REVMII_MDIO_RST	I	RevMII PHY reset input.

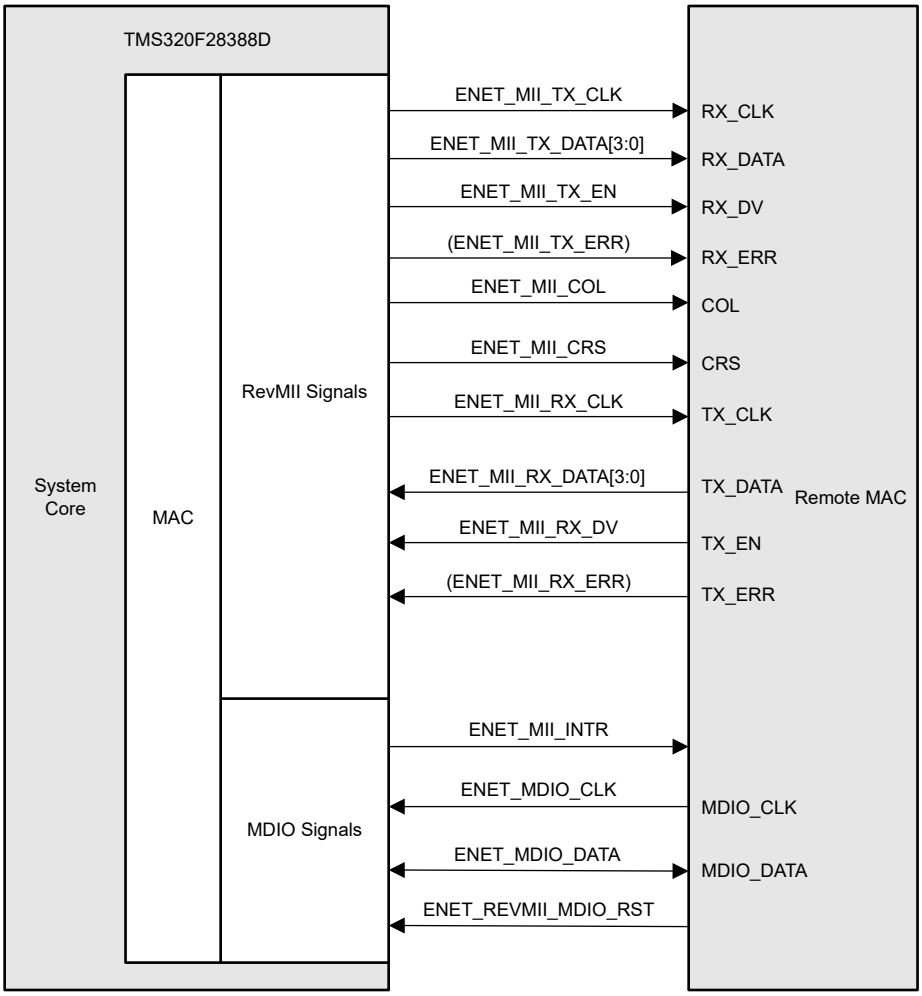

Figure 43-3. RevMII Mode Signals

43.2.1.4 Pulse Per Second Signals

The following two signals listed in Table 43-4 are Pulse Per Second Signals output from the Ethernet module.

Table 43-4. Pulse Per Second Signals

Signal	Type	Description
ENET_PPS0	O	Pulse Per Second 0. Fixed/Flexibile Pulse per Second Output.
ENET_PPS1	O	Pulse Per Second 1. Fixed/Flexibile Pulse per Second Output.

43.2.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value from the C28x CPU.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register from the C28x CPU.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

43.2.3 MAC Interface Selection

The MAC supports the following interfaces:

- MII
- RMII
- RevMII

The required interface can be selected by programming the PHY_INTF_SEL field in the EMACSS_CTRLSTS register.

43.2.4 Clocks for Ethernet Module

The Ethernet module needs the following clocks:

- Functional clock: This clock uses the Communication manager functional clock CMCLK.
- PTP/Time stamping logic requires a 100-MHz clock that can be sourced from AUXPLLCLKRAW or SYSPLLCLK by programming the ETHDIVSRCSEL and ETHDIV of the System Control Module. Program these fields to get a 100-MHz clock output for PTP block. There is an internal divider of /2 that generates a 50-MHz clock.
- RMII mode clock: The 50-MHz internal clock for RMII mode is generated from the above clock.

Figure 43-4 summarizes the clock options. Refer to the Clock Control module for further details of PLL programmation.

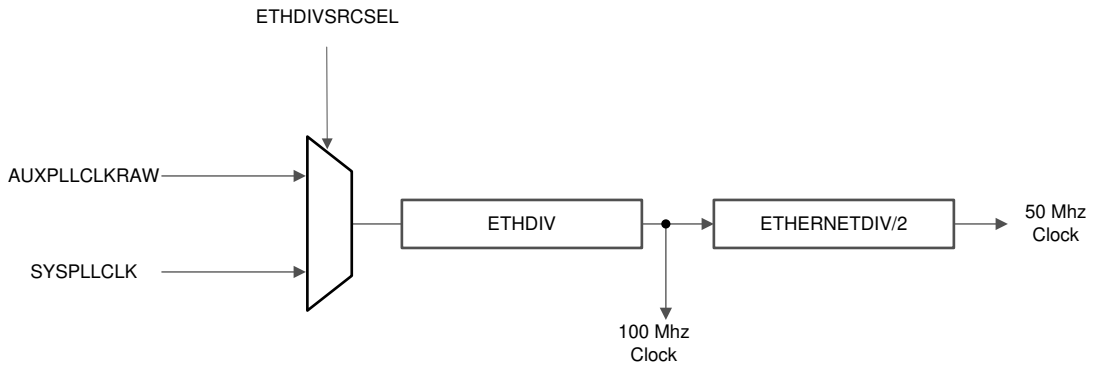

Figure 43-4. Ethernet Clocking

43.2.5 RMII Mode Clocking

For RMII mode operation, the module needs a 50-MHz clock. It can be sourced internally (from the module) or can be sourced externally (from any external component through the RMII_CLK pin input). The CLK_SRC_SEL field of EMACSS_CTRLSTS register programs the source of the RMII clock, as shown in Figure 43-5.

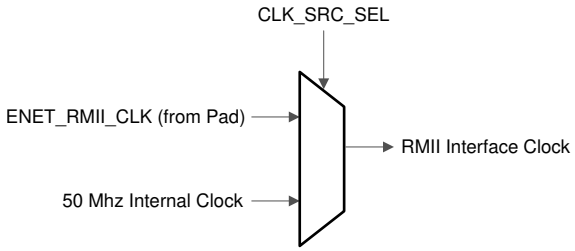

Figure 43-5. RMII Clocking

If the external clock is selected, the ENET_RMII_CLK pin of the device should be provided with the required 50-MHz clock.

If the internal mode is selected, the 50-MHz clock generated internally shall be used to clock the RMII module. Ensure that the clock source and divider are set accordingly to provide a 50-MHz clock.

43.2.6 RevMII Mode Clocking

For RevMII mode operation, the module needs a 25-MHz or 2.5-MHz clock. It can be sourced internally (from the internal 50-MHz clock) or can be sourced externally (from the pad ENET_RMII_CLK). The CLK_SRC_SEL field of the EMACSS_CTRLSTS register programs the source of the RevMII clock, as shown in Figure 43-6.

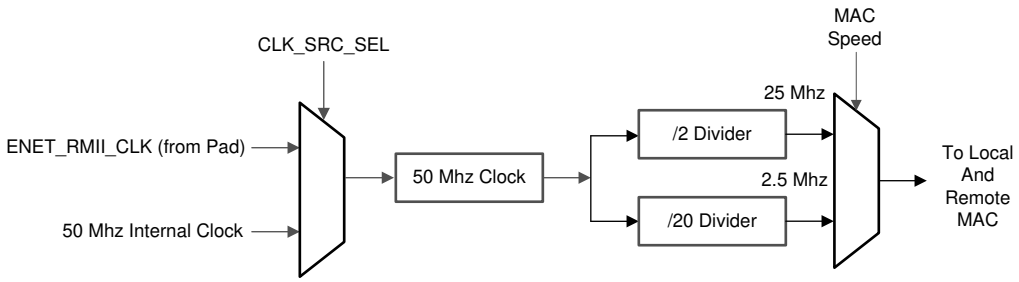

Figure 43-6. RevMII Clocking

If the external clock is selected, the ENET_RMII_CLK pin of the device should be provided with a 50-MHz clock.

If the internal mode is selected, the 50-MHz clock generated internally shall be used to clock the RMII module. Ensure that the clock source and divider are set accordingly to provide a 50-MHz clock.

The internal dividers shall derive the 25-MHz clock (for 100 mbps link) or 2.5-MHz clock (for 10 mbps link) from the internal dividers and also drive the respective clock on the ENET_MII_TXCLK and ENET_MII_RXCLK, respectively.

43.2.7 Configuring Trigger Sources for Time Stamping

The PTP Submodule of Ethernet can also be used to measure the auxiliary timestamps for Software events (triggered through PTP_AUX_TS_SW_TRIGx) and hardware events (through the EPWM cross bar outputs) Auxiliary Trigger 0 and Trigger 1.

The PTP_AUX_TS_TRIG_SELx register can be programmed to select the trigger source as listed in Table 43-5 and shown in Figure 43-7.

Table 43-5. Auxiliary Trigger Sources

PTP_AUX_TS_TRIG_SELx	PTP Auxiliary Trigger Source
0	PTP_AUX_TS_SW_TRIGx
1	EPWM XBAR Output 7
2	EPWM XBAR Output 8
3-31	Reserved

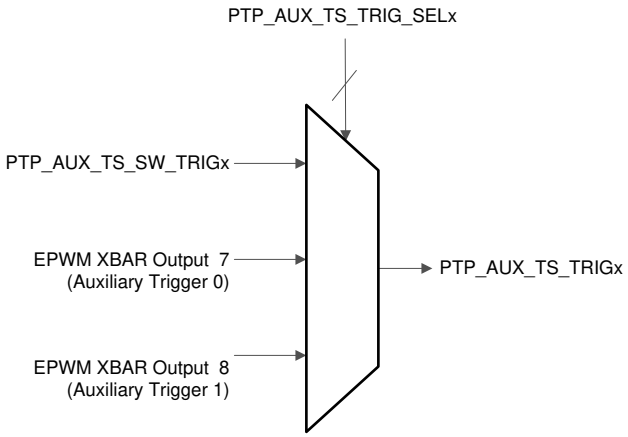

Figure 43-7. Trigger Sources for Auxiliary Timestamping

43.2.7.1 Software Trigger for Time Stamping

The PTP_AUX_TS_SW_TRIGx field of EMACSS_PTPTSSWTRIGx register enables the software trigger for capturing the auxiliary timestamps. This results in a timestamp value pushed into the FIFO for storing timestamps. The Time stamp value can be read from the MAC Auxiliary TimeStamp registers. Corresponding snapshot trigger id can be read from MAC_TIMESTAMP_STATUS register.

43.2.8 Ethernet Interrupts

The Ethernet module provides five interrupts:

- The sbd_interrupt that is a combination of various events generated in the module
- Channel 0,1 Transmit Completion interrupts
- Channel 0,1 Receive Completion interrupts

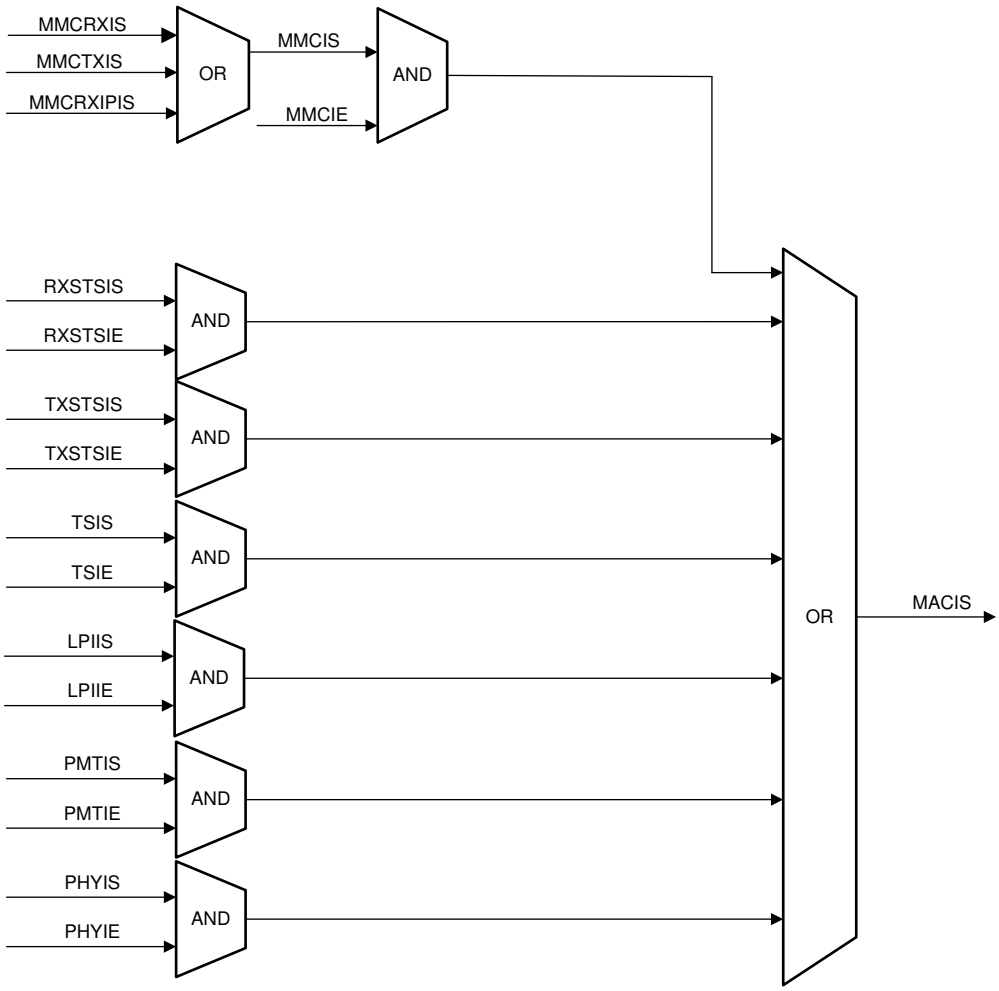

Figure 43-8. MAC Interrupt Sources

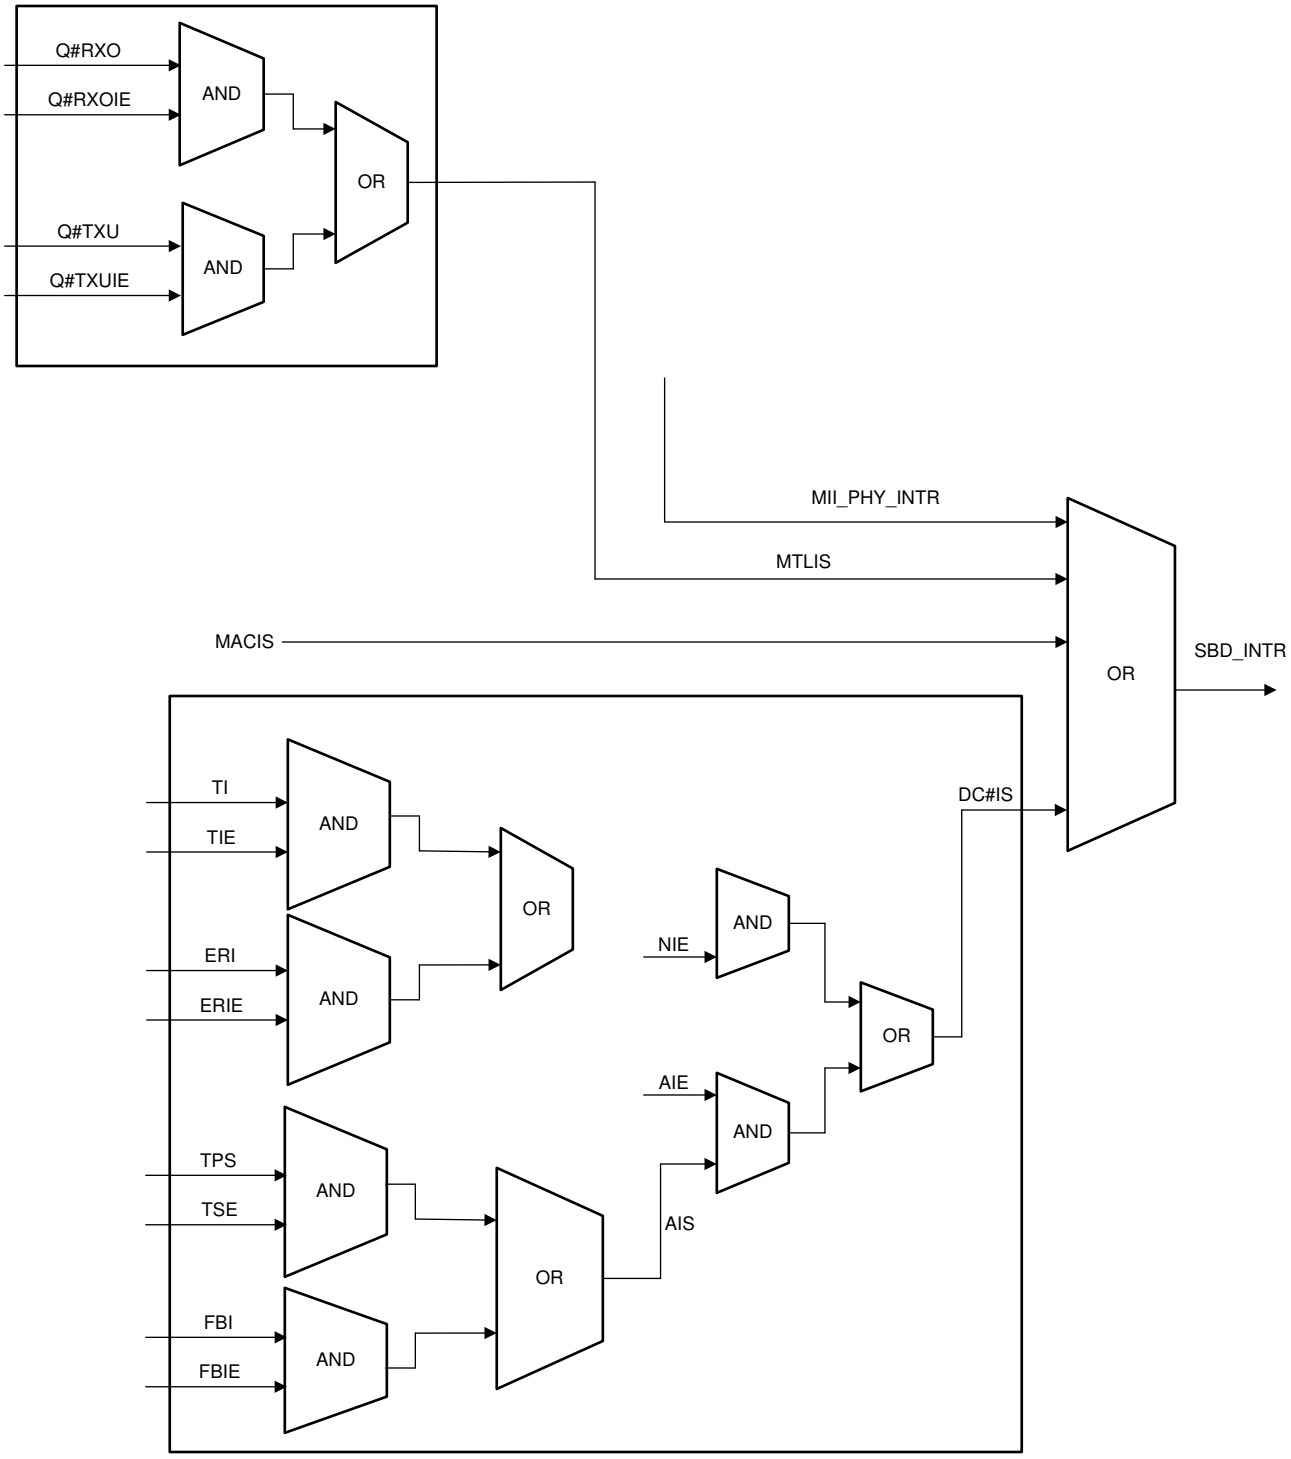

Figure 43-9. Combined SBD_Intr Sources

43.3 Features

The following sections cover the features of the Ethernet module.

43.3.1 Multiple Channels and Queues Support

The Ethernet module supports two queues and channels on Tx and Rx Paths.

Note: In multi queue/channel configurations, enable only Q0/CH0 on Tx and Rx for half-duplex operation. If you want to enable single queue/channel in full-duplex operation, any queue/channel can be enabled.

43.3.1.1 Multiple Queues and Channels in Transmit Path

The Ethernet module supports two Transmit queues. The number of Tx channels is equal to the number of Tx queues. The different scheduling algorithms are detailed below. The algorithm is chosen by the SCHALG field setting of the MTL_Operation mode register.

Fixed Priority Scheme: The fixed priority scheme is the default priority scheme for the DMA channels. In fixed priority scheme, the channel with highest priority always wins the arbitration when it requests the bus.

Table 43-6. Fixed Priority Scheme for DMA Channels

Priority Level	Channel
0 (low)	Channel 0
1	Channel 1

Weighted Strict Priority Scheme

In Weighted Strict Priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. The unused burst transfers of one or more channels are reallocated based on the priority. The channel with highest priority gets the unused burst transfer time before it is allocated to a channel with next highest priority.

Weighted Round Robin Scheme (defaulted by design)

The channel priorities are fixed. Channel 1 has the highest priority and Channel 0 has the lowest priority. When a channel uses the allocated burst transfers, the channel with next lower priority is processed. After processing the allocated bandwidth of all channels that had packets to transmit, any unused burst transfer time is allocated to the channel of the highest priority (if required), and then next highest priority (if required), and so on. It is suggested to program the TCW field of the DMA_CHn_Tx_Control Register with nonzero weights, if this scheme is chosen.

Table 43-7. Weight for DMA Channels

TCW Field	Transmit Channel Weight
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

43.3.1.2 Multiple Queues and Channels in Receive Path

The Ethernet module supports two Receive channels and two Rx Queues. In the Rx direction, the MTL Rx Controller selects the Rx DMA for which Rx DMA is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when the Rx DMA is ready to transfer data and the size of the burst-length (number of beats) that the Rx DMA has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

Priority Scheme for Tx DMA and Rx DMA

The DWC_ether_qos DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin.

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the DMA_Mode register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

If you have enabled the Tx DMA and Rx DMA of a channel, you can specify which DMA gets the bus when the channel gets the control of the bus. You can set the priority between the corresponding Tx DMA and Rx DMA by using the TXPR field of the DMA_Mode register. For round-robin arbitration, you can use the PR field of the DMA_Mode register to specify the weighted priority between the Tx DMA and Rx DMA.

Table 43-8. Priority Scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Schemes
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

Static Mapping

In Static Mapping mode, all packets of an Rx Queue are connected to a specific DMA channel.

In this mode, all of the packets of an Rx Queue are connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[3:0]) and Q0DDMACH (bit[7] = 0) of the MTL_RxQ_DMA_Map0 Register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

Dynamic (Per Packet) Mapping

In Dynamic (per packet) Mapping mode, the destination DMA channel is decide by the MAC core receiver for each packet.

In this mode, the destination DMA channel of a packet being read from a Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection
   The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set.
   If none of the L3-L4 Registers give a comparison match, then DWC_ether_qos proceeds to the next step.
2. Extended VLAN Based DMA Selection
   Extended routing is applicable only if the VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field that can be programmed. Routing is applicable for a filter, only if the DMA Channel Enable bit is set.
   The frame is routed to the smallest Matching Filter's DMA Channel provided it is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame is routed based on DA based addressing or to Channel 0.
   If Hash Filter is also enabled, it is used to determine the Filter result only. Routing still depends on the Perfect Filters enabled. If none of the perfect filters are enabled or if all of them are bypassed, then the VLAN Filter based routing does not take place. The frame is routed using DA Based addressing or to Channel 0. If all the perfect filters give a fail result and the Hash Filter has passed, then the VLAN Filter result is a pass but routing is based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well.
3. Ethernet DA-Based DMA Selection
   The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the previous operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default.

43.3.1.3 RxQueue to DMA Mapping

The packets in the MTL Rx Queues can be routed to any one of the multiple DMA channels by programming the MTL_RxQ_DMA_Map0 Register (for queues 0, 1, 2, and 3):

The following types of Rx Queue to DMA mapping is possible through programming:

- Static Mapping
- Dynamic (Per Packet) Mapping

43.3.1.4 Selection of Tag Priorities Assigned to Tx and Rx Queues

The DWC_ether_qos controller supports assigning tag priorities to Tx and Rx Queues through programming registers.

The VLAN Tag priorities can be assigned to Tx Queues by programming the corresponding PSTQ# field in the MAC_TxQ_Prty_Map0 register.

The bit corresponding to the VLAN Tag priority can be set in the PSTQ# field for assigning that priority to the Tx Queue. For example, if you want to assign VLAN Tag priority of 3 to Tx Queue 0, set bit [3] in PSTQ0 field.

The same VLAN Tag priority can be set for multiple Tx queues. The Tx packet association to particular Tx Queue is governed by the application, so the MAC does not route the packet based on Tx Queue priority mapping; it is only used for Pause Flow Control (PFC). The settings in the PSTQ# field determines the Tx Queues blocked for transmission when the PFC packet is received with corresponding VLAN Tag priorities enabled.

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The settings in the PSRQ field is used for VLAN Tagged Rx packet routing to Rx Queues as well as for PFC based Tx flow control. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match. In PFC based Tx flow control, PSRQ field corresponding to a particular Rx Queue is used for enabling VLAN Tag priorities in the PFC packet transmitted when corresponding Rx Queue threshold levels are reached.

43.3.1.5 Rx Side Routing from MAC to Queues

The DWC_ether_qos supports Rx Side Routing from the MAC to Queues.

The MAC routes the Rx packets to the Rx Queues based on following packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter
- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN Tag Priority field in VLAN Tagged AV data packets
- VLAN Tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged packets

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register.

The untagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. The VLAN tagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers or the Rx Queue number specified in the PTPQ field in the MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This is determined by programming in TPQC field of MAC_RxQ_Ctrl1 register. This type of Rx packet routing is available when IEEE 1588 Timestamp feature support and Multiple Rx The VLAN Tagged IEEE 1588 PTP over Ethernet Rx packets are detected only when 802.1AS mode is disabled (AV8021ASMEN bit in MAC_Timestamp_Control register is set to 0), otherwise this type of Rx packets are routed as generic VLAN Tagged Rx packets.

The multicast/broadcast destination address Rx packets that pass the destination address filter can be routed based on the Rx Queue number specified in the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MCBCQEN bit of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register.

The untagged Rx packets can be routed based on the Rx Queue number specified in the UPQ field of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register.

The unicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the UFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through UFFQE bit

of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register.

The multicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the MFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through MFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register.

If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

43.3.2 IEEE 1588 Timestamp Support

The IEEE 1588 defines a Precision Time Protocol (PTP) enables precise synchronization of time in measurement and control systems. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The Ethernet module supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP and IEEE 1588-2008 supports PTP transported over Ethernet. The Ethernet module provides programmable support for both standards.

The controller supports the following features:

- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Provides an option to select the node to be a master or slave for ordinary and boundary clock
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

43.3.2.1 Feature Description

The different aspects of Time stamping related features is explained in following subsections.

43.3.2.1.1 Clock Types

Ethernet module supports different clock types defined in IEEE 1588-2008.

The Ethernet module supports the following clock types:

- Ordinary Clock
- Boundary Clock
- End-to-End Transparent Clock
- Peer-to-Peer Transparent Clock

Ordinary Clock

The ordinary clock has a single PTP state and a single physical port. In a domain, an ordinary clock supports a single copy of the protocol.

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:

- Sends and receives PTP messages. The timestamp snapshot can be controlled as described in MAC_-Timestamp_Control.
- Maintains the data sets such as timestamp values

Table 43-9 shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

Table 43-9. Ordinary Clock PTM Messages for Snapshot

Master	Slave
Delay_Reg	SYNC

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in MAC_Timestamp_Control.

Boundary Clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and such messages are not forwarded. The PTP message type status given by the MAC helps you to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

End-to-End Transparent Clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot must be taken at both Ingress and Egress ports only for the messages mentioned in Table 43-10. You can take the snapshot by setting the SNAPTYPSEL bits to 10 in the MAC_Timestamp_Control register.

Table 43-10. End to End Transparent Clock: PTP Messages for Snapshot

PTP Messages
SYNC
Delay_Reg

Peer-to-Peer Transparent Clock

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer.

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdely_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in Table 43-11.

Table 43-11. Peer to Peer Transparent Clock: PTP Messages for Snapshot

PTP Messages
SYNC
PDelay_reg
Pdelay_Resp

You can take the snapshot by setting the SNAPTYPESEL bit to 11 in MAC_Timestamp_Control register.

Delay Request-Response Mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information.

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 43-10 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

The PTP process is shown in Figure 43-10.

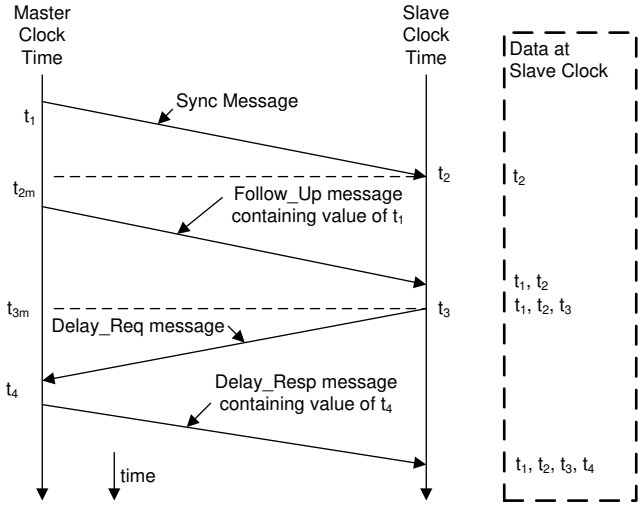

Figure 43-10. Networked Time Synchronization

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at MII.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software above the Ethernet/UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

43.3.2.1.1.1 Peer-to-Peer Transparent Clock (P2PTC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages.

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. Figure 43-11 shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

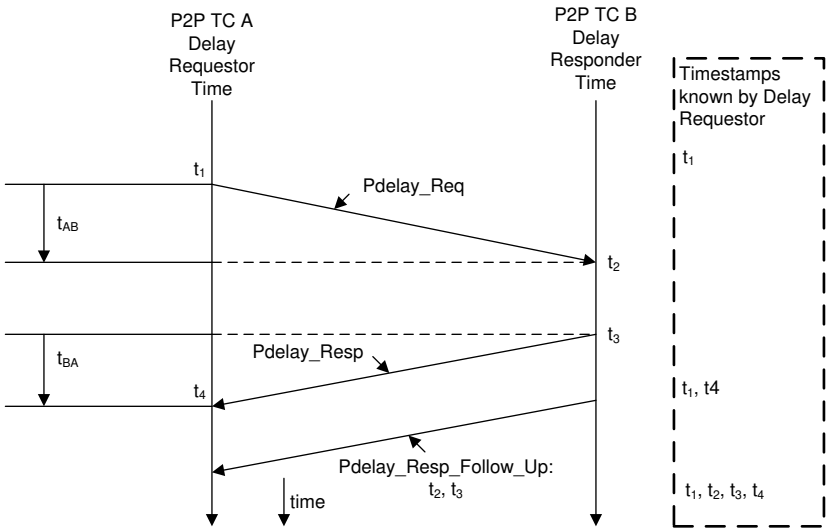

Figure 43-11. Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

43.3.2.1.1.2 Timestamp Correction

According to the IEEE 1588 specification, a timestamp must be captured when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. As the MAC takes the timestamp at an internal point far from the actual boundary of the node and network, this captured timestamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (MII Tx, Rx clock) being different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that is used to generate the time. The resultant CDC (Clock Domain Crossing) circuits add error depending on the clock period of the MII and PTP clocks.

43.3.2.1.1.3 Ingress Correction

In the Receive side the timestamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet's SFD bit is received at the port's boundary. Therefore, the captured timestamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of the following three components:

- External latency in the PHY layer between boundary point and the input of the core.
  If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from its datasheet or timing characteristics.
- Internal latency from the input of the core to the internal capture point.
  The internal ingress latency can be read from the MAC_Ingress_Timestamp_Latency register. This is a read-only register and gives the latency in scaledNanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency differs based on the active PHY interface (RMII, so on) and the operating speed. Therefore, the software must read this register after any speed change in the MAC to determine the current internal latency.
- CDC Synchronization.
  The CDC synchronization error is almost equal to two times the clock-period of the PTP clock (clk_ptp_ref_i).

The values determined from these three components should be added by the software and must be written into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

Note

The value written to the register must be negative (two's complement as explained below), because it has to be subtracted from the captured timestamp. The MAC Receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be set to 1 (for negative value) and bits[30:0] must be written with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must be written with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

43.3.2.1.1.4 Egress Correction

In the Transmit side the timestamp captured at the internal snapshot point is earlier (advanced in time) as compared to the time at which that packet's SFD bit is output at the port's boundary. Therefore, the captured timestamp must be compensated by the egress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of the following three components:

1. External latency in the PHY layer between the output of the core and the boundary of the port and the network
   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), the egress latency must be determined from its datasheet or timing characteristics .
2. Internal latency from the internal capture point and the output of the core
   This internal egress latency can be read from the MAC_Egress_Timestamp_Latency register. This is a read-only register and gives the latency in scaledNanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency will differ based on the active PHY interface (RMII, so on) and the operating speed. Hence the software must read this register after any speed change in the MAC to determine the current internal latency.
3. CDC synchronization error The CDC synchronization error value differs depending on the One-step timestamping mode. When One-step timestamping is enabled, the value = (1 * period of clk_ptp_ref_i + 4 * period of clk_tx_i).
   Otherwise (Two-step timestamping mode), the value = -(2 * period of clk_ptp_ref_i).

43.3.2.1.1.5 Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the MAC clock domain to the application clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

43.3.2.1.2 Maximum PTP Clock Frequency

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (1 ns resulting in 1 GHz) and the timing constraints achievable for logic operating on the PTP clock, whichever is lesser. In addition, the resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

43.3.2.1.3 Minimum PTP Clock Frequency

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time to the MII clock domain. This relationship is given in the following equation:

3 * PTP clock period + 4 * MII clock period <+ Minimum gap between two SFDs

The MII clock frequency is fixed by IEEE specification. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in Table 43-12.

Note

It is recommended that you use a clock that has constant frequency, preferably a divided application clock

When IEEE 1588 timestamp feature is enabled with internal timestamp, use a PTP clock frequency which is greater than 5 MHz. This is because the 8-bit MAC_Sub_Second_Incre- ment register limits the minimum PTP frequency that can be used to ~4 MHz.

Table 43-12. Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency with External Timestamp Input	Minimum PTP Frequency with Internal Timestamp
10 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clomcks of in IFG + 16 clocks of preamble)	~45 KHz	5 MHz
10 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	170 KHz	5 MHz
100 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	~0.5 MHz	5 MHz
100 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	4.55 MHz	5 MHz

43.3.2.1.4 PTP Processing and Control

Table 43-13 shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 43-13. Message Format Defined in IEEE 1588-2008

Bits									
7	6	5	4	3	2	1	0	Octet	Offset
transportSpecific				messageType[1]				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField[1]								1	32
logMessageInterval								1	33

(1) In version 1, controlField is used. In version 2, messageType field is used for detecting different message types.

There are some fields in the Ethernet payload that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP Packets Over IPv4
- PTP Frames Over IPv6
- PTP Packets Over Ethernet

43.3.2.1.5 PTP Packets Over IPv4

Table 43-14 provides information about the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 43-13.

Table 43-14. IPv4-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x0800	IPv4 datagram
IP version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (or 0x82, 0x83, 0x84)	Multicast IPv4 addresses allowed:
			■ 224.0.1.129
			■ 224.0.1.130
			■ 224.0.1.131
			■ 224.0.1.132
IP Multicast Address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex)	■ PTP Primary multicast address: 224.0.1.129
		0xE0, 0x00, 0x00, 0x6B (Hex)	■ PTP Pdelay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F, 0x0140	■ 0x013F: PTP event messages
			■ 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	74	0x00, 0x01, 0x02, 0x03, 0x04	■ 0x00: SYNC
			■ 0x01: Delay_Req
			■ 0x02: Follow_Up
			■ 0x03: Delay_Resp
			■ 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	42 (nibble)	0x9, 0xB, 0xC, 0xD 0x0, 0x1, 0x2, 0x3, 0x8,	■ 0x0: SYNC
			■ 0x1: Delay_Req
			■ 0x2: Pdelay_Req
			■ 0x3: Pdelay_Resp
			■ 0x8: Follow_Up
			■ 0x9: Delay_Resp
			■ 0xA: Pdelay_Resp_Follow_Up
			■ 0xB: Announce
			■ 0xC: Signaling
			■ 0xD: Management
PTP Version	43 (nibble)	0x1, 0x2	■ 0x1: Supports PTP version 1
			■ 0x2: Supports PTP version 2

PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only)

43.3.2.1.6 PTP Frames Over IPv6

Table 43-15 provides information about the fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 43-13.

Table 43-15. IPv6-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x86DD	IP datagram
IP Version	14 (Bits [7:4])	0x6	IP version is IPv6
Layer 4 Protocol	20a (*)	0x11	UDP
PTP Multicast Address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	■ PTP Primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex)
			■ PTP Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57a	0x013F, 0x140	■ 0x013F: PTP event message
			■ 0x0140: PTP general messages
PTP Control Field (IEEE1588 version 1)	94a	0x00, 0x01, 0x02, 0x03, 0x04	■ 0x00: SYNC
			■ 0x01: Delay_Req
			■ 0x02: Follow_Up
			■ 0x03: Delay_Resp
			■ 0x04: Management (version1)
PTP Message Type Field (IEEE 1588 version 2)	62a (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, 0xD	■ 0x0: SYNC
			■ 0x1: Delay_Req
			■ 0x2: Pdelay_Req
			■ 0x3: Pdelay_Resp
			■ 0x8: Follow_Up
			■ 0x9: Delay_Resp
			■ 0xA: Pdelay_Resp_Follow_Up
			■ 0xB: Announce
			■ 0xC: Signaling
			■ 0xD: Management
PTP Version	63 (nibble)	0x1, 0x2	■ 0x1: Supports PTP version 1
			■ 0x2: Supports PTP version 2

43.3.2.1.7 PTP Packets Over Ethernet

Table 43-16 provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 43-13.

Table 43-16. PTP Packets Over Ethernet

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address(1)	0–5	01-1B-19-00-00-00	All PTP messages can use any of the following multicast addresses(2)
		01-80-C2-00-00-0E	■ 01-1B-19-00-00-00
			■ 01-80-C2-00-00-0E(3)

			■ 0x2: Supports PTP version 2

(1) The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
(2) IEEE 1588-2008, Annex F
(3) The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

43.3.2.1.8 Transmit Path Functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the MII interface. The packets, for which the timestamps has to be captured can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. You need to specify the packets for which you want to capture timestamps.

You can specify the packets by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the time- stamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

43.3.2.1.9 Receive Path Functions

The MAC can be programmed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. Use the following options of the MAC_Timestamp_Control register to control the snapshot of the time to be sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type This feature controls the type of messages for which snapshots are taken.

Note

The Ethernet module also supports the PTP messages over VLAN packets.

Table 43-17. Timestamp Snapshot Dependency on Register Bits

MAC_Timestamp_Control Register Bit			PTP Messages
SNAPTYPSEL	TSMSTRENA	TSEVNTENA	
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least-significant bits of the timestamp.

43.3.2.2 IEEE 1588 System Time Source

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008). The Ethernet module provides the following options for using the reference timing source in a node:

43.3.2.2.1 External Timestamp Input

This option takes an external 64-bit timing reference and its clock as input. The clock input is used to synchronize the timing reference to the MAC clock domain.

The 64-bit timing reference is split into the following two 32-bit signals that can be provided by using the TSWH and TSWL registers of the Ethernet Subsystem:

- Upper 32-bits providing the time in seconds
- Lower 32-bits providing the time in nanoseconds

This timing reference is used to timestamp the packets.

43.3.2.2.2 Internal Reference Time

This option takes only the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.

The timestamp has the following fields:

- UInteger48 seconds Field. The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bits wide. For example, 2.000000001 seconds are represented as seconds Field = 0x0000_0000_0002.
- UInteger32 nano seconds Field. The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 seconds are represented as nanoSeconds = 0x0000_0001. The nanoseconds field supports the following two modes:
  - Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
  - Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

43.3.2.2.3 System Time Register Module

The system time generator module is an optional module. It is not available if external time updating is enabled. The 80-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the MII interface.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency offset and/or frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in Figure 43-12. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

Note

You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.

This algorithm is shown in Figure 43-12.

The system time update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Therefore, the default addend value to be set in the register is 2^{32}/ 1.32, 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 2^{32} / 1.30, or 0xC4EC4EC4. If the clock drifts higher, for example, to 67 MHz, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (2^{32} / 1.32) must be programmed.

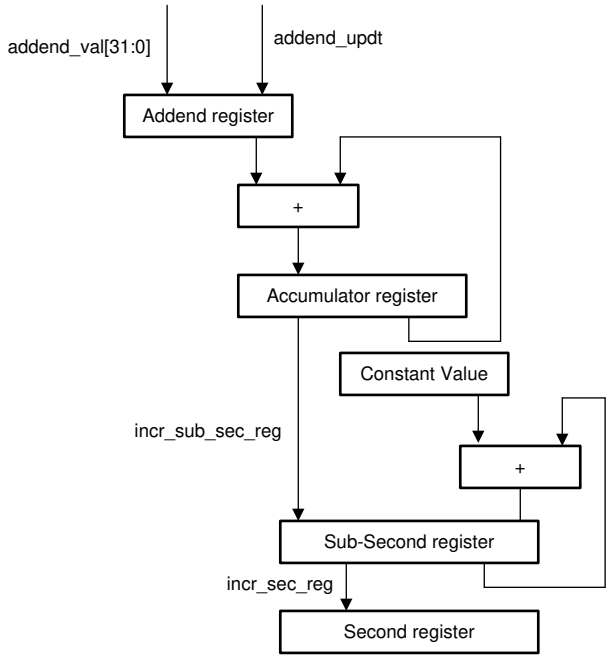

Figure 43-12. System Time Update Using Fine Method

In Figure 43-12, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20 ns steps). When External Time Update is enabled, the optional System Time module is not available.

The software must calculate the drift in frequency based on the Sync messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is:

$FreqCompensationValue0 = 2^{32} / FreqDivisionRatio$

The algorithm is:

- At time $MasterSyncTime_n$, the master sends the slave clock a Sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$
- The master clock count for current Sync cycle, $MasterClockCount_n$, is $MasterClockCount_n = MasterClockTime_n – MasterClockTime_n – 1$ (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, $SlaveClockCount_n$, is $SlaveClockCount_n = SlaveClockTime_n – SlaveClockTime_n – 1$
- The difference between master and slave clock counts for current Sync cycle, $ClockDiffCount_n$, is $ClockDiffCount_n = MasterClockTime_n – SlaveClockTime_n$
- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$, is $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n$
- The frequency compensation value for Addend register, $FreqCompensationValue_n$, is $FreqCompensationValue_n = FreqScaleFactor_n * FreqCompensationValue_n – 1$

Note

Modes of Internal Reference time can be set through the TSCTRLSSR bit in the MAC_Timestamp_Control_Register.

43.3.2.3 IEEE 1588 Higher Word Register

The timestamp maintained in the MAC is 64-bit wide. The overflow to upper 16-bits of seconds register happens once in 130 years. The values of the upper 16-bits of the seconds field can be read from the CSR register.

This is provided to use an additional Higher Word Register.

Note

This higher word register can be used only when the System Time Source is Internal.

43.3.2.4 IEEE 1588 Auxillary Snapshot

The auxiliary snapshot feature allows you to store a snapshot of the system time based on an external event. This feature is independent of whether the system time is generated internally or given as input (through the Subsystem register).

Two auxiliary snapshot input time stamps can be captured on a single common auxiliary snapshot FIFO. The snapshots taken for any input are stored in a common FIFO. The application can read the MAC_Time-stamp_Status register to know the timestamp of which input is available for reading at the top of this FIFO.

The MAC stores these snapshots in a FIFO of depth 4. Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from the MAC_System_Time_Higher_Word_Seconds register when it is present. When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the MAC_Timestamp_Status register. This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When an application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in MAC_Auxiliary_Control register. When multiple snapshots are present in the FIFO, the count is indicated in Bits[27:25] of MAC_Timestamp_Status register.

43.3.2.5 Flexible Pulse-Per-Second Output

The Ethernet module provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the ptp_pps_o output.

Note

By default, the module is in the “Fixed Pulse-Per-Second Output” mode and indicated 1 second arrival. The frequency of the PPS output can be changed by setting the PPSCTRL0 field in the MAC_PPS_Control Register.

The Ethernet module provides features such as programming the start or stop time, with the flexible PPS output option.

The Ethernet module supports the following features with the flexible PPS output option:

- Programming the start or stop time in terms of system time.
- Programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time.
- Programming the stop time in advance, that is, you can program the stop time before the actual start time has elapsed.
- Programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of sub-second increment value programmed in the MAC_Sub_Second_In- crement register. You can program the width of pulse from 1 to 232-1 units of sub-second increment value.

- Programming the interval, between the rising edges of PPS signal, in terms of number of units of sub-second increment value. You can program the interval between pulses from 1 to 232-1 units of sub-second increment value.
- Option to cancel the programmed PPS start or stop request.
- Error if the start or stop time being programmed has already elapsed.

Note

The PTP Reference clock mentioned in the following sections is the clock at which the system time gets updated. When the TSCFUPDT bit of the MAC_Timestamp_Control register is set to 0, this clock is similar to the clk_ptp_ref_i clock. In the Fine Correction mode, this is the clock tick at which the system time gets updated (using incr_sub_sec_reg shown in Figure 43-12).

43.3.2.5.1 PPS Start or Stop Time

The start time in the Target Time registers can be programmed initially.

You can initially program the start time in the Target Time registers. If you have enabled additional flexible PPS outputs, you need to program the following registers corresponding to an enabled flexible PPS output:

- MAC_PPS1_Target_Time_Seconds and MAC_PPS1_Target_Time_Nanoseconds registers for second Flexible PPS output
- MAC_PPS2_Target_Time_Seconds and MAC_PPS2_Target_Time_Nanoseconds registers for third Flexible PPS output
- MAC_PPS3_Target_Time_Seconds and MAC_PPS3_Target_Time_Nanoseconds registers for fourth Flexible PPS output

If required, you can again program the start or stop time but you can do it only after the earlier programmed value is synchronized to the PTP clock domain. Bit 31 of MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. This enables you to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, you should program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

43.3.2.5.2 PPS Width and Interval

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value.

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

43.3.3 Packet Filtering

The Ethernet module provides filtering of incoming packets at Layer 2, Layer 3,Layer 4. VLAN based filtering can also be enabled in this module. This section provides the sequence of filters and then provides details of each type of filter.

43.3.3.1 Packet Filtering Sequence

The sequence shown in Figure 43-13 is valid when all the filters (L2, VLAN, L3, L4) are active. If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters is discarded. However, the discarded packet can be forwarded to the host based on the register control. For example, when Bit RA of MAC_Packet_Filter register is set to 1, all discarded packets are forwarded to the host but with its packet status indicating the specific filter-failure. If RA=0, Bits VTFE and IPFE of MAC_Packet_Filter register controls if the packets that fail the VLAN filter and Layer 3-4 filter should be discarded or forwarded to the host.

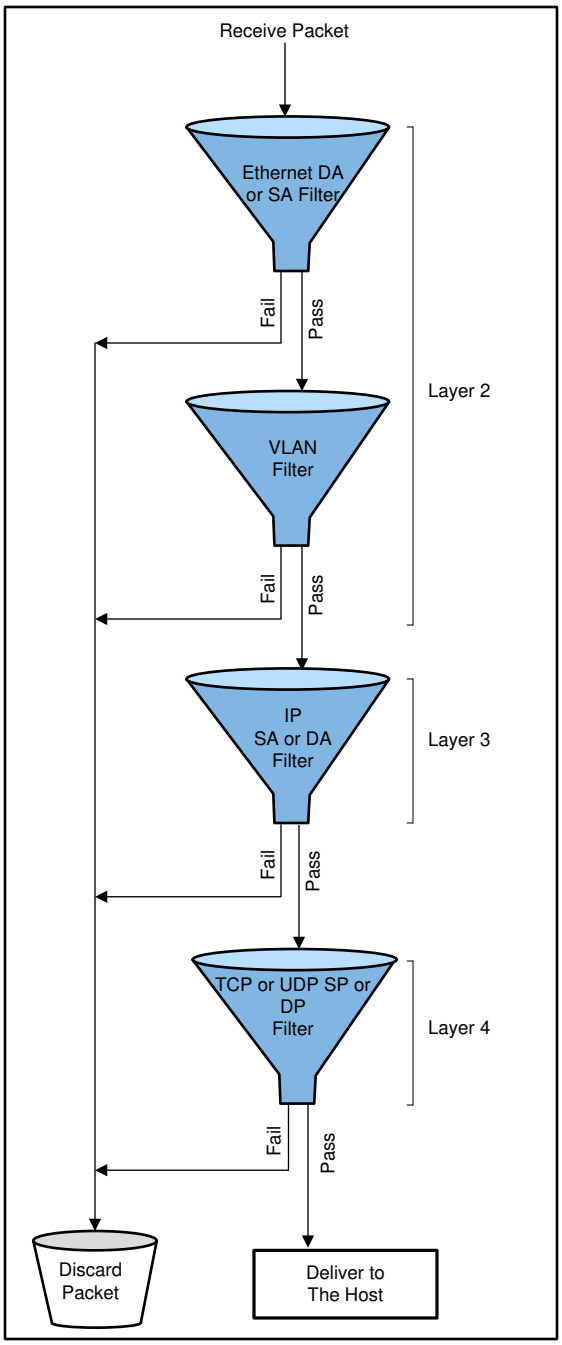

Figure 43-13. Packet Filtering

43.3.3.2 Destination Address Filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet. The MAC supports up to 128 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr127 addresses are selected with an individual enable bit. For MacAddr1 to MacAddr31 addresses, you can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA. The MacAddr32 to MacAddr127 addresses do not have mask control and all 6-bytes of the MAC address are compared with the received 6-bytes of DA.

In hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 00000 selects Bit 0 of selected register, and a value of 11111 selects Bit 63 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

To program the MAC to pass all multicast packets, set the PM bit in MAC_Packet_Filter register. If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of the MAC_Packet_Filter register.

The multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the Hash table. A value of 000000 selects Bit 0 of selected register and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in MAC_Packet_Filter register. This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to received packet.

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in MAC_Packet_Filter register.

Table 43-18. Destination Address Filtering

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match

Table 43-18. Destination Address Filtering (continued)

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x

43.3.3.3 Source Address Filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers[1–31] to use SA instead of DA for comparison by setting Bit 30 of corresponding register.

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is AND'ed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

Table 43-19. Source Address Filtering

Packet Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

43.3.3.4 Inverse Filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

43.3.3.5 VLAN Filtering

The MAC Receiver can classify the received packets based on VLAN Tag and steer them to a specific Rx DMA channel. The MAC compares the received frame's VLAN Tag with all the enabled and relevant filters and provides a filtering result. If any of the perfect filters give a pass result and if the respective filter's DMA channel Number is enabled, the frame is routed to that DMA Channel.

In addition to filtering, routing can also be done. For more details about routing, see *Extended VLAN Based DMA Selection*.

43.3.3.5.1 Comparison Modes

For each VLAN Tag Filter, the application has the following comparison options:

- It can program the MAC to compare an outer VLAN Tag or an inner VLAN Tag with the programmed VID.
- It can choose if 12 or 16 bits of the VID field need to be compared.
- Type check can be disabled or enabled for each filter; if enabled, the application can choose if the VID comparison is for SVLAN or CVLAN type frames only.
  For example, if a filter is enabled for 16-bit comparison, SVLAN Type, and Outer VLAN Tag, any single or double VLAN Tagged frames with Outer SVLAN Tags are compared with this filter, and a pass or fail result is obtained.

Note

The inner VLAN Tag comparison is applicable only if Double VLAN Tag processing is enabled through the parameter and the MAC VLAN Control Register bit.

The application can enable both Perfect and Hash Filtering. The overall VLAN Filter Result is based on the perfect filter result and the Hash Filter result (if enabled). The filter result is passed to the application as part of the status bits.

Perfect filtering is done based on the MAC_VLAN_Tag_Filter registers. For each VLAN Tag Filter, the MAC will compare the relevant VLAN Tag ID and gives a result. If any one of the VLAN Tag Filters gives a match then the frame is considered to have passed the VLAN Tag Filters. If the frame mismatches all the filters, then the frame is considered to have failed the VLAN filter. This behavior is applicable only when the Inverse Filtering is not enabled in MAC_VLAN_Tag_Ctrl Register.

If inverse Filtering is enabled and the frame has mis-matched all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered as a fail. If none of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the programming on the VTFE and RA bits of the MAC Filter Register determine if the frame will be dropped or forwarded to the application. If RA = 1 or VTFE = 0, it does not matter if the filter result is a pass or fail. The frame is always forwarded. If RA = 0 and VTFE = 1, only then, if the VLAN Tag Filter result is a pass does the MAC forward the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the Status bits.

43.3.3.5.2 Filter Status

The Extended Receive VLAN Filtering & Routing feature provides two status bits to indicate the comparison result of the VLAN tags.

By default, the MAC indicates the VLAN Filter Status through one bit in the status – VF in RDES2. When Extended RX VLAN filtering and routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions The status indicated through these bits is highly dependent on the programming as explained.

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In ARI status: MAC Filter status:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In MRI Status:

- Bit 47 – Outer VLAN Tag Filter Status
- Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Outer VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Outer VLAN Tag has either failed the relevant Outer VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Outer VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Outer VLAN Tag Comparison.
- This bit is valid for both Single and Double VLAN Tagged frames.

Inner VLAN Tag Filter Status (ITS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Inner VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Inner VLAN Tag has either failed the relevant Inner VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Inner VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Inner VLAN Tag Comparison.
- This bit is valid for only Double VLAN Tagged frames, when Double VLAN Processing is enabled.

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

Table 43-20 and Table 43-21 show the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Table 43-20 show the possible values of status bits (OTS and ITS) when at least one Perfect filter is enabled.

- VTIM: VLAN Tag Inverse Match Enable – bit 17 in VLAN_Tag_Ctrl Register.
- HFO: Hash Filter enabled for Outer VLAN Tag Comparison . bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- HFI: Hash Filter enabled for Inner VLAN Tag Comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- PFO – Perfect Filter comparison enabled for Outer VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0).
- PFI – Perfect Filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1).
- OTS – Outer VLAN Tag Filter Status
- ITS – Inner VLAN Tag Filter Status

Table 43-20. OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Table 43-21 shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 43-21. OTS and ITS Bit Values with Only VLAN Hash Filter Enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of table 1-1 indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes atleast one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last Row of Table 1-1 indicates that Inverse Filtering is enabled, Hash Filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

43.3.3.5.3 Stripping

Each of the VLAN Tags has individual control over stripping. The programming options of Always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on Pass is enabled for the outer VLAN Tag, then the stripping occurs only if the Outer VLAN tag has passed the relevant Filters. The Outer VLAN Tag Filter Result bit will be set.
- If strip on Fail is enabled for the outer VLAN Tag, then stripping occurs only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit will be reset.
- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the Status Bit is still 0.
- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.
- If the application strips the VLAN Tag based on the filter result, it might lose the VID. So the suggested use is, if Stripping is enabled for any of the tags, the tag can be put in the status. For this the application will have to enable the respective "VLAN Tag in Status" bit - 24 or 31 in the MAC VLAN Tag Control Register.

43.3.3.6 Layer 3 and Layer 4 Filtering

The Ethernet module supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configura- tion register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match
  - At least one of the enabled field matches and other fields are bypassed or disabled

  When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter. For example, if Filter 0 and Filter 1 match, the MAC gives the status corresponding to filter 0

Note

The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

- **Unmatched Packets:** The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.
  the aborted or partial packets can be dropped in the MTL Rx FIFO. If the Rx FIFO operates in the Threshold (cut-through) mode and the threshold is programmed to a small value, such that packet transfer to application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.
- **Non-TCP or UDP IP Packets:** By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

43.3.3.6.1 Layer 3 Filtering

The Ethernet module supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers of a register set to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, you can enable the second and third data registers of a register set to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

43.3.4 VLAN Support

The VLAN related features are detailed in following subsections.

43.3.4.1 Double VLAN Processing

The Ethernet module supports two VLAN tags, namely inner and outer, for processing double VLANs.This feature is referred as the double VLAN tagging feature in which the MAC can process two VLAN tags. With this feature, the Ethernet module supports the following:

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path.
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status.

43.3.4.1.1 Transmit Path

Table 43-22 describes the features supported by the MAC on the Transmit side.

Table 43-22. Double VLAN Processing Features in Transmit Path

Feature	Description
Support for C-VLAN and	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_Incl and MAC_Inner_VLAN_Incl registers. The Ethernet module supports processing of any sequence of outer and inner VLAN tags.
S-VLAN Tag types	Note: The Ethernet module does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: ■ The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. ■ The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. ■ The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. ■ The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	You can enable the VLAN tag deletion for outer or inner tag through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag.
VLAN Tag Insertion or Replacement	You can enable the VLAN tag insertion or replacement for outer or inner tag through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

43.3.4.1.2 Receive Path

Table 43-23 describes the features supported by the MAC on the Receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 43-23. Receive Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or S-VLAN based on the DOVLTC bit.

43.3.4.2 Double VLAN-Related Registers

Following are the Double VLAN-related registers

- MAC_VLAN_Incl
- MAC_Inner_VLAN_Incl
- MAC_VLAN_Tag

43.3.4.3 Source Address and VLAN Insertion, Replacement, or Deletion

Ethernet module supports SA and VLAN insertion, replacement and deletion.

The source address (SA) and VLAN fields are Tx packet-related control information that are provided as part of the control word through ATI interfaces. Ethernet module supports the feature to insert or replace the source address based on the information in the MAC Address Registers, and also the feature to insert, replace or delete the VLAN fields (VLAN Type and VLAN Tag) based on the setting of the VLTI bit in the MAC_VLAN_Incl register. You can enable the SA insertion or replacement feature for all Transmit packets or selective packets. Similarly, you can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets.

The software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field
- Replace the content of the SA field with the content of the MAC Address Registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

You can enable the SA insertion or replacement feature for all Transmit packets or selective packets:

- Enabling SA insertion or replacement for all packets.
  To enable this feature for all packets, program the SARC field of the MAC_Configuration register.
- Enabling SA insertion or replacement for selective packets

Program the SA Insertion Control field (Bits[25:23] of TDES3) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or replace- ment by MAC Address1 registers. When Bit 25 of TDES3 is reset, it indicates insertion or replace- ment by MAC Address 0 registers.

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

43.3.4.3.1 Programming VLAN Insertion, Replacement, or Deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields

- Insert or replace the VLAN Type and VLAN Tag fields
- Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_Incl register as described in Table 43-24

Table 43-24. VLAN Insertion or Replacement Based on VLTI Bit

VLTI Bit Condition	Description
Set	The MAC inserts or replaces the following: ■ VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) ■ VLAN Tag field with cntent of the VT field of Transmit context descriptor of the packet
Reset	The MAC inserts or replaces the following: ■ VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) ■ VLAN Tag field with the VLT field of MAC_VLAN_Incl register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- Enabling VLAN insertion, replacement, or deletion for all packets
  To enable this feature for all packets, program the VLC and VLP fields of MAC_VLAN_Incl register.
- Enabling VLAN insertion, replacement, or deletion for selective packets
  Program the VTIR field of TDES2 Normal Descriptor
  In addition, the VLP (VLAN Priority control) bit must be reset in Register 24 (for outer VLAN) and Register 25 (in inner VLAN) for the MAC to take the control inputs from the host

43.3.4.4 Queue/Channel Based VLAN Tag Insertion on Tx

Ethernet module supports channel/queue based VLAN tag insertion on all transmitted packets.

Queue/Channel specific VLAN tag registers are accessed using indirect addressing via the MAC_VLAN_Incl register. VLAN type and tag value can be independently programmed for each queue/channel.

When you enable this feature and the CBTI field is set in the MAC_VLAN_Incl register, the VLAN tag is inserted on every packet that is transmitted from a queue/channel, with the programmed tag value taken from queue/channel specific VLAN tag register.

43.3.5 TCP/IP Offloading Features

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the MAC has an optional Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, and error detection in the Receive path.

The TCP Segmentation Offload (TSO) engine is useful in offloading the TCP segmentation functions to the hardware.

43.3.5.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note

1. The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if the Ethernet module is configured for Threshold (cut-through) mode.
2. See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

43.3.5.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

Note

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 0). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corre- sponding Header Length field in an extension header) is completely received.

43.3.5.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16’h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being

written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 43-25 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in Table 43-25.

Table 43-25. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP Header Checksum Insertion	Hardware TCP/UDP Checksum Insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in “Transmit Checksum Offload Engine”	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in “Transmit Checksum Offload Engine”	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers:		
■ Hop-by-hop options (in IPv6 main header)	Not Applicable	Yes
■ Hop-by-hop options (in IPv6 extension header)	Not Applicable	No
■ Destinations options	Not Applicable	Yes
■ Routing (with segment left 0)	Not Applicable	No
■ Routing (with segment left > 0)	Not Applicable	No
■ TCP, UDP, or ICMP	Not Applicable	Yes
■ Authentication	Not Applicable	No
■ Any other next header field in main or extension headers	Not Applicable	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels:		
■ IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
■ IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels:		
■ IPv4 packet in an IPv6 tunnel	Not applicable	No
■ IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

43.3.5.2 Receive Checksum Offload Engine

Ethernet module provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 43-26 describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in Table 43-26), the information (whether the checksum engine is bypassed or not) is given in the receive status.

Note

The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 43-26. Receive Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP Header Checksum Checking	Hardware TCP/UDP/ICMP Checksum Checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers:	Not Applicable	Yes
■ Hop-by-hop options (in IPv6 main header)	Not Applicable	No
■ Hop-by-hop options (in IPv6 extension header)	Not Applicable	Yes
■ Destinations options	Not Applicable	Yes
■ Routing (with segment left 0)	Not Applicable	No
■ Routing (with segment left > 0)TCP, UDP, or ICMP	Not Applicable	Yes
■ Any other next header field in main or extension headers	Not Applicable	No

Table 43-26. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP Header Checksum Checking	Hardware TCP/UDP/ICMP Checksum Checking
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels:		
■ IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
■ IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv4 Tunnels:		
■ IPv4 packet in an IPv6 tunnel	Not Applicable	No
■ IPv6 packet in an IPv6 tunnel	Not Applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

43.3.5.3 TCP/IP Segmentation Offload (TSO) Engine

The TCP Segmentation Offload (TSO) engine is useful in offloading the TCP segmentation functions to the hardware.

It also supports UDP Segmentation Offload (USO) in which the UDP payload is segmented in the hardware. There are no sequencing/ordering controls available or updated in the segments, so it can be used in point to point applications in which out of order packets are not expected by the receiver. The description and flow of TSO mentioned in this section is same as USO, any deviation is provided as notes.

In the TCP segmentation offload (TSO) feature, the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL as shown in Figure 43-14

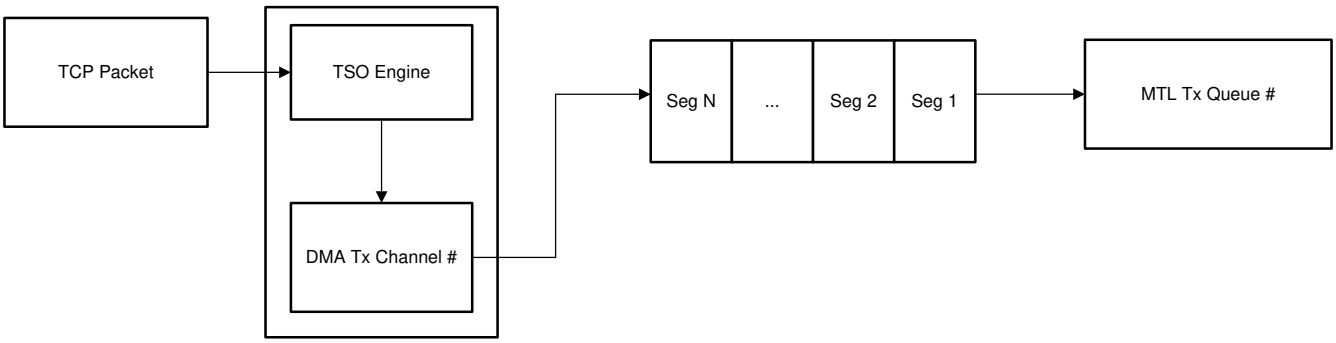

Figure 43-14. TCP Segmentation Overview

43.3.5.3.1 DMA Operation with TSO Feature

For the TSO feature, the Tx DMA operation is as follows:

1. The application sets up the Transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.
2. The application increases the offset value of the Descriptor Tail pointer of the DMA Tx channel.
3. While in the Run state, the DMA fetches the next available descriptor and does one of the following:
   - If the descriptor is a context descriptor and the context is not between the first and last descriptors of a packet, the DMA stores the context values.
   - If the descriptor is a context descriptor and the context is between the first and last descriptors of a packet, the DMA closes the context descriptor indicating a Context Descriptor Error (TDES3[23]) and fetches the next descriptor.
   - If the descriptor is a normal descriptor, the DMA checks for the TSE bit. If TSE bit is not set, the DMA continues with the default mode of operation or OSF operation (if enabled).
4. The DMA calculates the number of segments from the TCP payload length(TDES3[17:0]) and the MSS value.
5. The DMA goes through channel arbitration to fetch the data buffers. The DMA fetches the header and payload separately.
6. For the first segment, the DMA fetches the header from the system memory and stores it in the TSO memory (if present and when the length of header is not greater than the TSO memory size). If the current segmented packet is not the first segment, the DMA fetches the header from the local TSO memory if available. Otherwise, it will fetch the header buffer in system memory again, as done for the first segment. In such cases (header not available is TSO memory), the DMA will not close the first descriptor containing the header buffer until the header for last segment is fetched.
7. The required fields in the header bytes are modified/updated as per the segmentation requirements and written into the corresponding MTL TxQ.
8. The DMA then takes the payload buffer pointer, fetches the MSS number of payload bytes from the system memory and directly pushes it into the MTL TxQ. In case the buffer(s) in the descriptor do not have enough data for the MSS payload (except for the last segment), the DMA closes this descriptor.
9. The DMA jumps to Step 3 and repeats the process until the last segment is written into the TxQ.
10. The DMA closes the last descriptor and also the first descriptor (containing the header buffer when it is not stored in TSO memory) and then moves on to the next packet transfer.

The DMA repeats all these steps if more descriptors are available. When no descriptor is available, the DMA enters the suspend state.

Note

The TSO engine determines whether to perform TSO or USO operation based on the THL field (TCP Header Length) in TDES3 of first Normal Tx descriptor for the packet. The value of 2 indicates USO and any value greater than or equal to 5 indicates TSO. The DMA repeats all these steps if more descriptors are available. When no descriptor is available, the DMA enters the suspend state.

43.3.5.3.1.1 TCP/IP Header Fields

While segmenting a TCP packet, the DMA automatically updates the TCP/IP header fields. Table 43-27 describes how the TCP and IP headers are updated.

Table 43-27. TSO: TCP and IP Header Fields

Packet Sequence	TCP Header	IP Header
First packet	1. The sequence number is not updated. The value provided in the header is used.	■ IPv4 Header ❑ Total Length = MSS + TCP Header Length + IP Header Length
	2. The TCP checksum is calculated again.	❑ Identification field is not modified.
	3. If set, the FIN and PSH flags are cleared.	It is sent as per the header provided by the software. ❑ IPv4 Header Checksum is recalculated. ■ IPv6 Header Payload Length = MSS + TCP Header Length + IPExtension Header Length
Subsequent packets	1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment.	■ IPv4 Header ❑ Total Length = MSS + TCP Header Length + IP Header Length
	2. If set, the FIN and PSH flags are cleared.	❑ Identification field = Previous Identification Field + 1
	3. The TCP checksum is calculated again.	❑ IPv4 Header Checksum is recalculated ■ IPv6 Header Payload Length = MSS + TCP Header Length + IPExtension Header Length
Last packet	1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment.	■ IPv4 Header ❑ Total Length = Remaining Payload + TCP Header Length + IP Header Length
	2. If FIN and PSH flags were set in original header, these flags are set.	❑ Identification Field = Previous Identification
	3. The TCP checksum is calculated again.	Field + 1 ❑ IPv4 header Checksum is recalculated ■ IPv6 Header Payload Length = Remaining Payload Length + TCP Header Length + IP Extension Header Length

43.3.5.3.1.2 Header and Payload Fields of Segmented Packets

After segmentation, the split packets use the same header as the parent TCP packet for header fields other than the ones described in Table 43-27. Figure 43-15 shows how same header is used for the header fields of segmented packets.

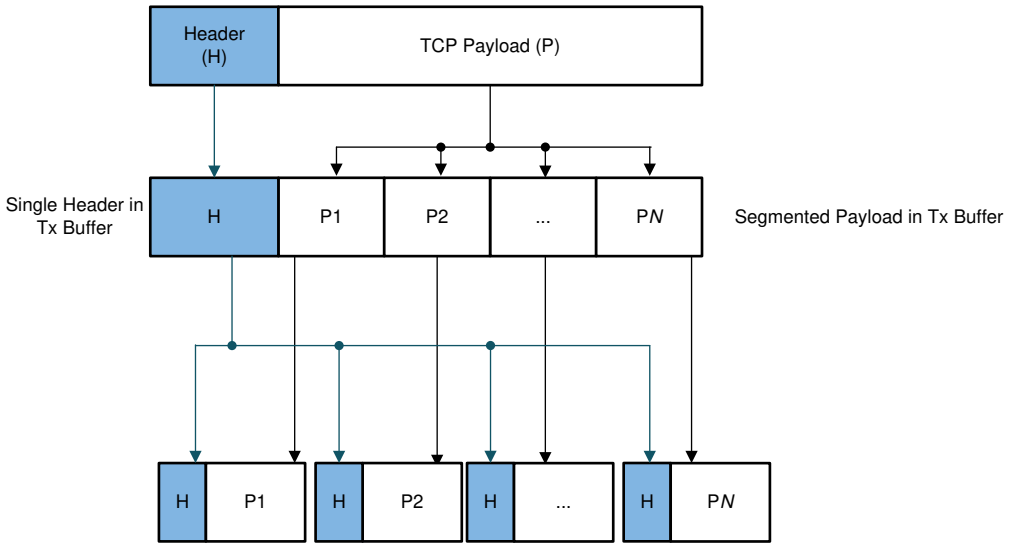

Figure 43-15. Header and Payload Fields of Segmented Packets

The application must create the header in Buffer 1 of the first descriptor of the packet to be segmented and provide the header length in TDES2 of the first descriptor (FD = 1). When the FD bit is set, the DMA reads the header from the header buffer to which the TDES0 is pointing. Buffer 2 of the first descriptor can be used for payload and TDES0 and TDES1 of subsequent descriptors. For subsequent descriptors (FD = 0), the address to which the TDES0 and TDES1 are pointing is treated as payload buffer address of the same packet.

Fragmentation is supported only for UDP over IP. Fragmentation is not supported for TCP packets.

43.3.5.4 Segmentation Versus Fragmentation

This table shows the differences between UDP packet fragmentation and UDP segmentation.

Table 43-28. Segmentation Versus Fragmentation

Segmentation	Fragmentation
The UDP header is replicated for each segment. The length field in the UDP header is updated for each segment.	The UDP header is not updated; however, checksum field in the UDP header is updated.
MSS field indicates the size of the maximum segment after the L4 (TCP/UDP) header.	MFS field indicates the size of the fragment after the L3 (IPv4) header.
The TCP packet is broken down into multiple chunks by keeping L2+L3+L4 header.	The UDP packet is broken down into multiple chunks by keeping the L2 + L3 header.

43.3.5.5 Using the IPv4 ARP Offload Engine

The Ethernet module supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. This feature allows the processing of the IPv4 ARP request packet in the receive path and generating corresponding ARP response packet in the transmit path. Ethernet module generates the ARP reply packets for appropriate ARP request packets. The ARP packet for IPv4 is L2 layer packet with Length/Type of 0x0806.

The ARP offloading process is as follows:

1. The MAC receiver gets an ARP request if the Target Protocol Address of request matches the IPv4 address programmed in the L3 register of the MAC.
2. The MAC generates an ARP reply packet.
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   - DA field of the Ethernet packet header
   - Target Hardware Address field of the ARP reply packet
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet.
5. The MAC places its MAC address in the following fields:
   - SA field of the Ethernet packet header
   - Sender Hardware Address field of the ARP reply packet
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet.
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply.
8. The MAC recalculates the CRC and performs padding for generated ARP reply packet.
9. The MAC transmitter sends the ARP reply.

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to application with ARP Reply Not Generated (Bit 34) status bit set. However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request.

If the Disable CRC check bit of the MAC Extension Configuration bit is set, then the MAC does not check for valid CRC of a ARP request Packet. It can generate an ARP response packet if the other conditions are valid.

The ARP request Packet must always have a valid CRC.

Note

When the received ARP request is less than 64 bytes packet length, Ethernet module does not send a ARP response. It is treated as normal packet and forwarded to the application based on the Ethernet module filter settings.

43.3.5.6 Energy Efficient Ethernet Support

The Ethernet module supports the following techniques to save system power.

- The Ethernet module supports the following techniques to save system power.
- Remote Wakeup
- Energy Efficient Ethernet

The Magic Packet and Remote Wakeup techniques are used to save power consumption at the companion PHY. Using these features, the Ethernet module. On receiving the specific packets from the network, the MAC provides the trigger to restore the power and come back to normal state.

The Energy Efficient Ethernet (EEE) mode is compliant with the IEEE 802.3az-2010 standard. It is primarily targeted to save power in the Ethernet port when there is no traffic on the line. In this mode, the host indicates to the far-end that it does not have any packets to transmit for near future and puts the transmitter port

(MAC Controller, PCS and PHY layers) into low-power mode. Similarly, the Receiver port can also be put into low-power mode when the far-end host indicates that it does not have any traffic to transfer. This allows significant saving of power in the Ethernet port (mainly in the PHY) with intermittent and bursty traffic profile. The triggering of entry and exit out of the EEE mode is controlled by the MAC and is supported by the Ethernet module.

Simultaneous operation of the EEE mode along with any or both the other power saving modes is also supported in the Ethernet module.

43.3.5.6.1 Magic Packet

The magic packet contains a unique pattern at any offset after the Destination address, Source address, and Length/Type fields. In addition to the unique pattern matching, the MAC receiver also checks for the following, to detect the received packet as a valid magic packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC_Address0_High and MAC_Address0_Low registers) or with multicast/broadcast address
- The packet must not have length error, FCS error, dribble bit error, MII error, and collision
- The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes)

The content of the unique pattern in magic packet is:

- 6 bytes of all-ones (48'hFF_FF_FF_FF_FF_FF) called the synchronization stream. There can be more than six bytes of 8'hFF, but last 6 are considered.
- The synchronization stream is immediately followed by 16 repetitions of Destination address field of the packet (MAC Address (MAC_Address0_High and MAC_Address0_Low registers) or multi- cast/broadcast address)
- No break or interruption between synchronization stream and first repetition of Destination address field or within its 16 repetitions

If the MAC address of a node is 48'h 00_11_22_33_44_55, the MAC scans for the following data sequence:

Destination Address Source Address Length/Type……. FF FF FF FF FF FF00 11 22

33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 5500 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 5500 11 22 33 44 55 00 11 22

33 44 55 00 11 22 33 44 55 00 11 22 33 44 5500 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55…CRC

43.3.5.6.2 Remote Wakeup Filter

In the Remote Wakeup Magic Packet based power saving mode, the reception of expected remote wakeup packet by MAC receiver triggers the exit from low-power mode. The MAC enters power saving mode when PWRDWN bit of MAC_PMT_Control_Status register is programmed to 1. Exit from the remote wakeup based low-power mode is enabled by programming RWKPKTEN bit of MAC_PMT_Control_Status register to 1.

The MAC implements a filter lookup table (programmed through MAC_RWK_Packet_Filter register) in which CRC, offset, and byte mask of the pattern embedded in remote wakeup packet and the filter operation commands are programmed.

The pattern embedded in the remote wakeup packet is located at any offset after the Destination address and Source address fields. In addition to the CRC match for the pattern, the MAC receiver also checks the following, to detect the received packet as a valid remote wakeup packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC_Address0_High and MAC_Address0_Low registers) or with multicast/broadcast address
- The packet must not have length error, FCS error, dribble bit error, MII error, and collision
- The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes)

When a valid remote wakeup packet is received, the MAC receiver sets the RWKPRCVD bit in MAC_PMT_Control_Status register and triggers the PMT interrupt . The PMTIS bit in MAC_Interrupt_Status

register is set when power-gating is not enabled in low-power mode. An interrupt is triggered to the application (sbd_intr) when interrupt is enabled (PMTIE bit in MAC_Interrupt_Enable register is set).

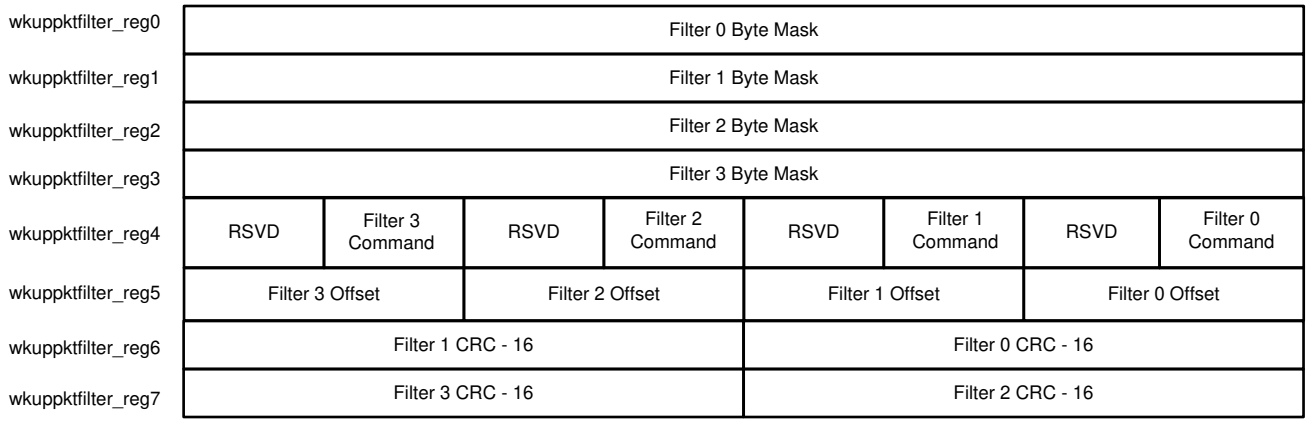

Figure 43-16. Wakeup Filter Register Layout

The Remote Wakeup Filters are arranged in blocks of 4 filters each and each such block have eight 32-bit wide registers, viz. wkuppktfilter_reg0-7, wkuppktfilter_reg8-15, wkuppktfilter_reg16-23 and wkuppktfilter_reg24-31. The fields of Remote Wakeup Filter are as follows:

Filter i Byte Mask

The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3, .., 15) to determine whether or not a packet is a wake-up packet.

- The MSB (31st bit) must be zero.
- Bit j[30:0] is the byte mask.
- If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored

Filter i Command

The 4-bit filter i command controls the filter i operation.

- Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet
- Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC-16 value. Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".
- Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logi- cally ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. The details are as follows:
  - The And_Previous bit setting is applicable within a set of 4 filters.
  - ❑Setting of And_Previous bit of filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.
  - If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Pre- vious bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered.

– If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indi- cating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

Filter i Offset

The filter i offset register defines the offset (within the packet) from which the filter i examines the packets.

- This 8-bit pattern-offset is the offset for the filter i first byte to be examined.
- The minimum allowed offset is 12, which refers to the 13th byte of the packet.
- The offset value 0 refers to the first byte of the packet.

Filter i CRC-16

The filter i CRC-16 register contains the CRC-16 value calculated from the pattern and the byte mask programmed in the Remote Wakeup filter register.

- The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1
- Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:
  – 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC-16 calculation.
  – ❑ 8-bit Offset Pointer: Specifies the byte to start the CRC-16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC-16 calculations.

The Remote Wakeup Filter registers are implemented as 8 indirect access registers (wkuppktfilter_reg#i) and accessed by application through MAC_RWK_Packet_Filter register. When the Remote Wakeup Filters are to be programmed, the entire set of wkuppktfilter_reg registers must be written. The wkuppktfilter_reg register is programmed by sequentially writing the eight, sixteen or thirty-two register values in MAC_RWK_Packet_Filter register for wkuppktfilter_reg0, wkuppktfilter_reg1, ..., wkuppktfilter_reg31 respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of MAC_PMT_Control_Status register.

Note: When MAC_RWK_Packet_Filter register is written, the content is transferred from CSR clock domain to PHY receive clock domain after the write operation, there should not be any further write to the MAC_RWK_Packet_Filter register until the first write is updated in PHY receive clock domain. Otherwise, the second write operation does not get updated to the PHY receive clock domain. Therefore, the delay between two writes to the MAC_RWK_Packet_Filter register should be at least 4 cycles of the PHY receive clock.

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. As the PMT interrupt signal is generated in the PHY Rx clock domain, it is not cleared immediately when the PMT Control and Status register is read. This is because the resultant clear signal has to cross to the PHY Rx clock domain, and then clear the interrupt source. This delay is at least 4 clock cycles of Rx clock and can be significant when the Ethernet module is operating in the 10 Mbps mode. When the application clears the PWRDWN bit in Remote Wake-Up Packet Detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

The MAC implements a set of registers for Layer3 and Layer4 based packet filtering. In a register set, there is a control register, such as MAC_L3_L4_Control (#i) (for i = 0; i <=3), to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- MAC_Layer4_Address(#i) (for i = 0; <=3)
- MAC_Layer3_Address0_Reg(#i) (for i = 0; i <=3)
- MAC_Layer3_Address1_Reg(#i) (for i = 0; i =3)
- MAC_Layer3_Address2_Reg(#i) (for i = 0; i <=3)
- MAC_Layer3_Address3_Reg(#i) (for i = 0; i =<3)

43.3.5.6.3 Energy Efficient Ethernet

EEE is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The Ethernet module supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

43.3.5.6.3.1 Transmit Path Functions

The transmit path functions include tasks that the MAC must perform to make the PHY to enter the LPI state. In the transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER field of MAC_LPI_Control_Status register. The PHY Link Status bit of the LPI Control and Status Register indicates the link status of the PHY.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN
2. Asserts TX_ER
3. Sets TXD[3:0] to 0x1 (for 100 Mbps) or TXD[7:0] to 0x01 (for 1,000 Mbps)
4. Updates the status (TLPIEN bit of MAC_LPI_Control_Status register) and generates an interrupt

Note

The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.

To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the MAC_LPI_Timers_Control register.
3. Updates the LPI exit status (TLPIEX bit of the MAC_LPI_Control_Status register) and generates an interrupt.

Figure 43-17 shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

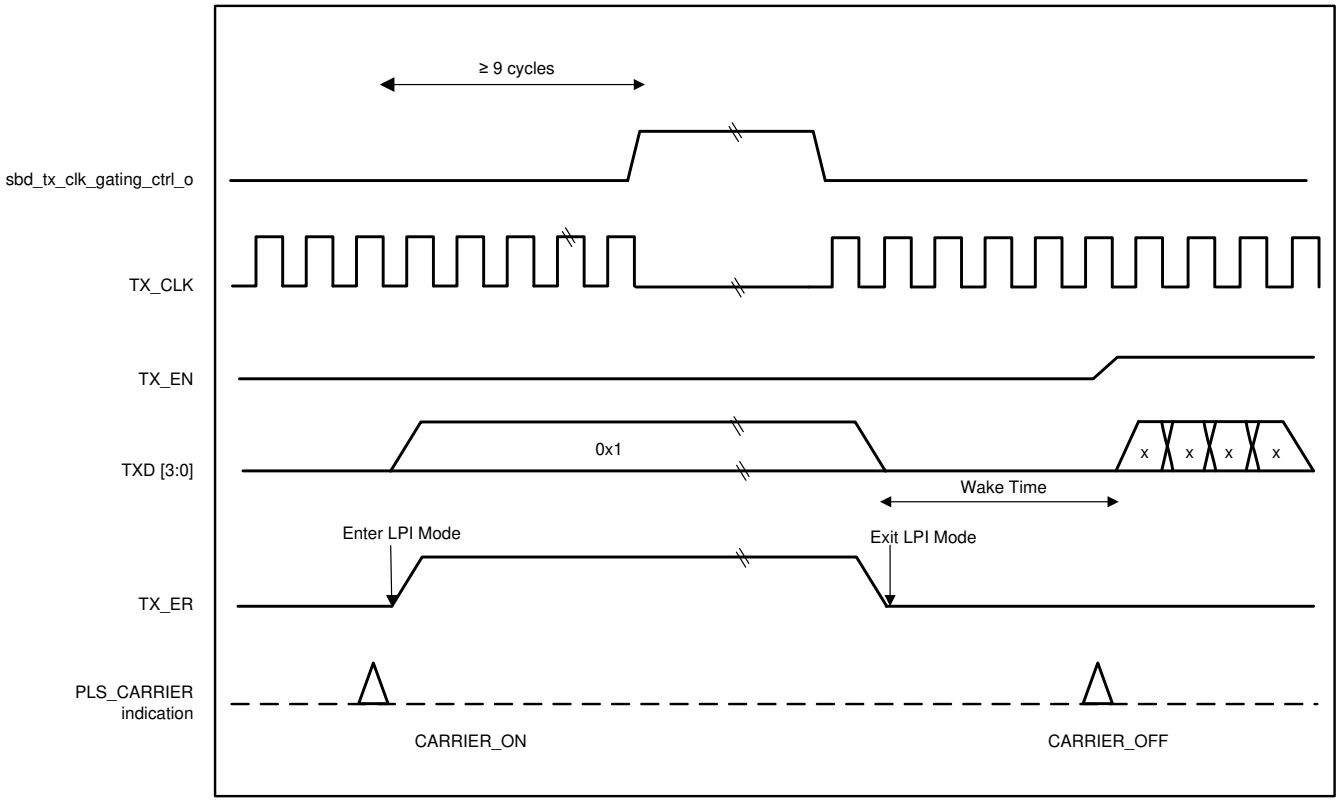

Figure 43-17. LPI Transitions on Transmit

Note

The MAC does not stop the TX_CLK clock. It is stopped at SoC level (as shown in Figure 43-17) if your PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The assertion of the sbd_tx_clk_gating_ctrl_o signal is dependent on the LPITCSE bit of the MAC_LPI_Control_Status register.

43.3.5.6.4 Automated Entry/Exit of LPI mode in Transmit Path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by MAC_LPI_Control_Status register.

When LPITXA (Bit[19]) and LPITXEN (Bit[16]) of MAC_LPI_Control_Status register are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter will exit the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition to the above, when Bit[20] (LPIATE) is also set, the MAC transmitter will enter LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in MAC_LPI_Entry_Timer. In this mode also, the MAC transmitter will exit the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that reentry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of LPI IDLE state by programming the LPITXEN bit.

43.3.5.6.5 Receive Path Functions

The receive path functions include the tasks that the PHY and MAC must perform when the PHY receives signals from the link partner to exit the LPI state.

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER .
2. The PHY sets RXD[7:0] to 0x01.
3. The PHY de-asserts RX_DV.
4. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and immediately generates an interrupt.

Note

The MAC does not stop the TX_CLK clock. It is stopped at SoC level (as shown in Figure 43-17) if your PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The assertion of the sbd_tx_clk_gating_ctrl_o signal is dependent on the LPITCSE bit of the MAC_LPI_Control_Status register.

43.3.5.7 Automated Entry/Exit of LPI Mode in Transmit Path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by MAC_LPI_Control_Status register.

When LPITXA (Bit[19]) and LPITXEN (Bit[16]) of MAC_LPI_Control_Status register are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter will exit the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition to the above, when Bit[20] (LPIATE) is also set, the MAC transmitter will enter LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in MAC_LPI_Entry_Timer. In this mode also, the MAC transmitter will exit the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that reentry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of LPI IDLE state by programming the LPITXEN bit.

43.3.5.8 Receive Path Functions

The receive path functions include the tasks that the PHY and MAC must perform when the PHY receives signals from the link partner to exit the LPI state.

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER
2. The PHY sets RXD[7:0] to 0x01
3. The PHY de-asserts RX_DV
4. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and immediately generates an interrupt
5. The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.
   - If the LPI pattern is detected for a very short duration (that is, less than two cycles of Rx clock), the MAC does not enter the Rx LPI mode.
   - If the duration between end of the current Rx LPI pattern and start of the next Rx LPI pattern, is very short (that is, less than two cycles of Rx clock), then the MAC exits and again enters the Rx LPI mode. The MAC does not give the Rx LPI Exit and Entry interrupts

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC_LPI_Control_Status register and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 43-18 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

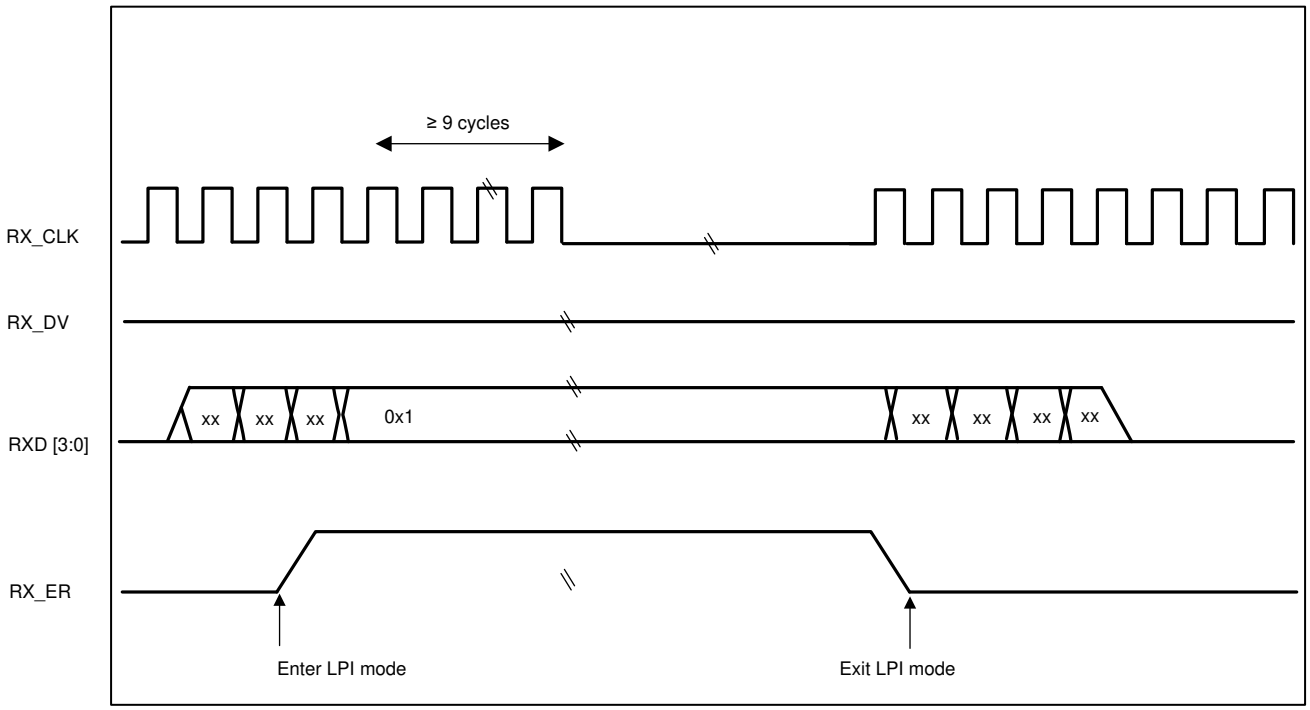

Figure 43-18. LPI Transitions on Receive

43.3.6 Loopback Mode

The MAC supports Loopback of transmitted packets to its receiver. The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (CRS) or collision (COL) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should enable internal clock for loopback to generate the Tx and Rx clocks and provide these clocks to the MAC.
- Program the CLK_LM field of EMACSS_CTRLSTS Register to program the loopback clocks (either from the external source or from the internal source).
  - If internal source is selected the divider ETHDIV and clocksource ETHDIVSRCSEL should be properly set to derive 50 Mhz clock as in the case of RMII clocking.
  - If External source is selected :
    - For RMII mode the ENET_RMII_CLK should be provided with 50 Mhz clock
    - For MII mode the ENET_MII_TX_CLK and ENER_MII_RX_CLK should be provided with 25 Mhz(for 100 mbps) or 2.5 Mhz (for 10 mbps link)
- Do not loop back big packets. Big packets may get corrupted in the loopback FIFO.

At the end of every received packet, the Receive Protocol Engine module generates received packet status and sends it to the Receive Packet Controller module. The control, missed packet, and filter fail status are added to the Receive status in the Receive Packet Controller module.

The MAC does not process ARP or PMT packets that are looped back.

43.3.7 Reverse Media Independent Interface (RevMII)

This section gives the RevMII register blocks. For detailed flow on using RevMII, refer to the RevMII Application note.

43.3.7.1 RevMII Register Maps

Table 43-29 provides the address map and high-level summary of the RevMII registers for MAC.

Table 43-29. RevMII Register Maps - MAC

Register Number	Address Offset	Register Name and Description
0	5'b00000	MAC_RevMII_PHY_Control Controls the MAC side of the RevMII Controller.
1	5'b00001	MAC_RevMII_Common_Status Shows the status of the RevMII. This is a shared register for both MACs.
2–14	5'b00010–5'b01110	Reserved
15	5'b01111	MAC_RevMII_Common_Ext_Status Shows the status of the RevMII supporting 1000 Mbps speed. This is a common register for both MACs.
16	5'b10000	MAC_RevMII_Interrupt_Status_Mask Shows the status of the interrupt generated for the MAC and also provides interrupt masking signal for the generated interrupts.
17	5'b10001	MAC_RevMII_Remote_PHY_Status Shows the status of speed and duplex-mode programmed in the remote PHY Control register.
18–31	5'b10010–5'b11111	Reserved

Table 43-30 provides the address map and high-level summary of the RevMII registers of the remote MAC.

Table 43-30. RevMII Register Map - Remote MAC

Register Number	Address Offset	Register Name and Description
0	5'b00000	MAC_RevMII_RemotePHY_Control Controls the remote side of RevMII Controller.This register is similar to the MAC_RevMII_PHY_Control register.
1	5'b00001	MAC_RevMII_Common_Status Shows the status of the RevMII. This is a common register for both MACs.
2–14	5'b00010–5'b01110	Reserved
15	5'b01111	MAC_RevMII_Common_Ext_Status Shows the status of the RevMII supporting 1000 Mbps speed. This is a common register for both MACs.
16	5'b10000	MAC_RevMII_RemotePHY_Interrupt_Status_Mask Shows the status of the interrupt generated for remote MAC and also provides interrupt masking signal for the generated interrupts. This register is similar to MAC_RevMII_Interrupt_Status_Mask.
17	5'b10001	MAC_RevMII_PHY_Status Register Shows the status of speed and duplex-mode programmed in the RevMII PHY Control register.
18-31	5'b10010–5'b11111	Reserved

43.3.7.2 MAC_RevMII_PHY_Control

This register controls the RevMII operations for the MAC and enables the RevMII modes.

Table 43-31. MAC_RevMII_PHY_Control Register

15	14	13	12	11	10	9	8	7	6	5:0
REVRST	REVLPBCK	REVSSL	REVANEN	REVPWRDN	REVISOL	REVREAN	REVDM	REV COLTST	REVSSH	Rsvd

Table 43-32. MAC_RevMII_PHY_Control Register Description

Field	Name	Description	Reset	Access
15	REVRST	Reset When this bit is set, it configures the PHY Control register to its default values. This bit is cleared after the reset operation is complete.	0	R_W_SC
14	REVLPBCK	Loopback When this bit is set, it enables the loopback mode. When this bit is reset, it disables the loopback mode.	0	R/W
13	REVSSL	Speed Selection (LSB) This bit along with Bit 6 (MSB) indicates the link speed. Bit 6 | Bit 13 | Speed 1 | 1 | Reserved 1 | 0 | Reserved 0 | 1 | 100 Mbps 0 | 0 | 10 Mbps When you select 10/100 Mbps as the Mode of Operation, the reset value of this bit is 1.	0	R/W
12	REVANEN	Auto-Negotiation Enable This bit is not used in RevMII.	0	RO
11	REVPWRDN	Power Down When this bit is set, it enables the power down mode. When this bit is reset, it disables the power-down mode.	0	R/W
10	REVISOL	Isolate When this bit is set, it enables the isolate mode. When this bit is reset, it disables the isolate mode.	0	R/W
9	REVREAN	Restart Auto-Negotiation This bit is not used in RevMII.	0	RO
8	REVDM	Duplex Mode When this bit is set, it configures the RevMII PHY for the full-duplex operation. When this bit is reset, it configures the RevMII PHY for the half-duplex operation. When you select the Disable Half-Duplex Operation option, the reset value of this bit is 1.	0	R/W
7	REVCOLTST	Collision Test When this bit is set, it enables the collision test mode. When this bit is reset, it disables the collision test mode.	0	R/W
6	REVSSH	Speed Selection (MSB) When set, this bit along with Bit 6 (LSB) indicates the link speed. For more information, see REVSSL.When you select 10/100 Mbps as the Mode of Operation, the reset value of this bit is 0.	1	R/W
5-0	Rsvd	Reserved	0	RO

43.3.7.3 MAC_RevMII_Common_Status

This register provides the RevMII status. This register is common for the MAC and the remote MAC.

Table 43-33. MAC_RevMII_Common_Status Register

Table 43-34. MAC_RevMII_Common_Status Register Description

Field	Name	Description	Reset	Access
15	100T4	100BASE-T4 When this bit is set, it indicates that the RevMII PHY can perform the link transmission and reception using the 100BASE-T4 signaling specification.	1	RO
14	100XFD	100BASE-X Full-Duplex When this bit is set, it indicates that the RevMII PHY can perform the full-duplex link transmission and reception using the 100BASE-X signaling specification.	1	RO
13	100XHD	100BASE-X Half-Duplex When this bit is set, it indicates that the RevMII PHY can perform the half-duplex link transmission and reception using the 100BASE-X signaling specification. When you select the Disable Half-Duplex Operation option, the reset value of this bit is 0.	1	RO
12	10FD	10 Mbps Full-Duplex When this bit is set, it indicates that the RevMII PHY can perform the full-duplex link transmission and reception while operating in 10 Mbps mode.	1	RO
11	10HD	10 Mbps Half-Duplex When this bit is set, it indicates that the RevMII PHY can perform the half-duplex link transmission and reception while operating in 10 Mbps mode. When you select the Disable Half-Duplex Operation option, the reset value of this bit is 0.	1	RO
10	100T2FD	100BASE-T2 Full-Duplex When this bit is set, it indicates that the RevMII PHY can perform full-duplex link transmission and reception using the 100BASE-T2 signaling specification.	1	RO
9	100T2HD	100BASE-T2 Half-Duplex When this bit is set, it indicates that the RevMII PHY can perform the half-duplex link transmission and reception using the 100BASE-T2 signaling specification. When you select the Disable Half-Duplex Operation option, the reset value of this bit is 0.	1	RO
8	EXTSTS	Reserved	1	RO
7	Rsvd	Reserved	0	RO
6	PRESUP	MF Preamble Suppression This bit indicates that the RevMII can receive management frames irrespective of the Preamble length.	1	RO
5	ANC	Auto-Negotiation Complete This bit is not used in RevMII.	0	RO
4	RMTFLT	Remote Fault This bit is not used in RevMII.	0	RO
3	ANA	Auto-Negotiation Ability This bit is not used in RevMII.	0	RO

Table 43-34. MAC_RevMII_Common_Status Register Description (continued)

Field	Name	Description	Reset	Access
2	LNKSTS	Link Status When this bit is set, it indicates that a valid link has been established. When this bit is reset, it indicates that the link is not valid.	0	R_SS_ SC_LL O
1	JABDET	Jabber Detect This bit is not used in RevMII.	0	RO
0	EXTCAP	Extended Capability This bit is always set because RevMII supports extended register capability.	1	RO

43.3.7.4 MAC_RevMII_Common_Ext_Status

This register is common for the MAC and the remote MAC. This register is implemented for RevMII supporting 1000 Mbps speed. It is not present since MAC supports only 10/100 Mbps operations.

Table 43-35. MAC_RevMII_Common_Ext_Status Register

15	14	13	12	11:0

2	MACDM	MAC Duplex Mode When set, this bit indicates the duplex mode configured in Bit 8 of the MAC_RevMII_PHY_Control register. When you select the Disable Half-Duplex Operation option, the reset value of this bit is 1.	0	RO
1	MACSSH	MAC Speed Select MSB When set, this bit indicates the link speed specified in Bit 6 of the MAC_RevMII_PHY_Control register. When you select 10/100 Mbps as the Mode of Operation, the reset value of this bit is 0.	1	RO
0	MACSSL	MAC Speed Select LSB When set, this bit indicates the link speed specified in Bit 13 of the MAC_RevMII_PHY_Control register. When you select 10/100 Mbps as the Mode of Operation, the reset value of this bit is 1.	0	RO

43.4 Descriptors

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The Ethernet module supports the following two types of descriptors:

- **Normal Descriptor:** Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- **Context Descriptor:** Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

Note

There is no limit for the number of descriptors that can be used for a single packet.

43.4.1 Descriptor Structure

In Ring structure (Figure 43-19), descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

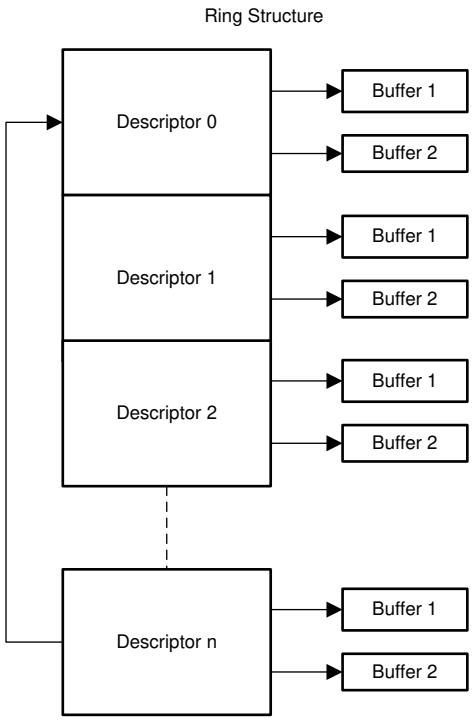

Figure 43-19. Descriptor Ring Structure

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA automatically wraps around the base address when the end of ring is reached, as shown in Figure 43-20

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

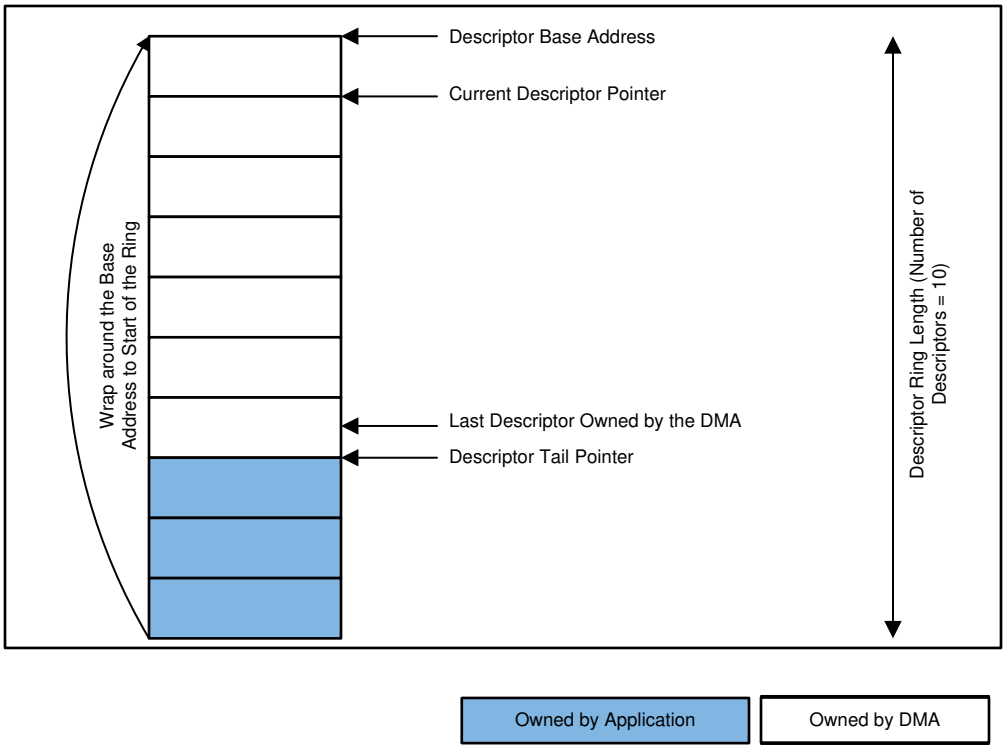

Figure 43-20. DMA Descriptor Ring

43.4.2 Transmit Descriptor

The DMA in Ethernet module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields that are used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format.

43.4.2.1 Transmit Normal Descriptor (Read Format)

Figure 43-21 shows the Read Format for a Transmit normal descriptor.

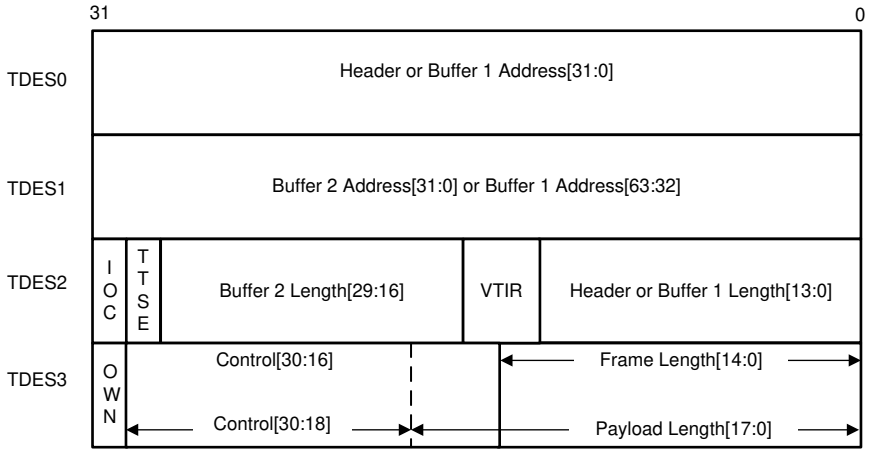

Figure 43-21. Transmit Normal Descriptor Read Format

43.4.2.1.1 TDES0 Normal Descriptor (Read Format)

Table 43-43. TDES0 Normal Descriptor (Read Format) Description

Bit	Name	Description
31-0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: ■ TSE bit of TDES3 ■ FD bit of TDES3

43.4.2.1.2 TDES1 Normal Descriptor (Read Format)

Table 43-44. TDES1 Normal Descriptor (Read Format) Description

Bit	Name	Description
31-0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

43.4.2.1.3 TDES2 Normal Descriptor (Read Format)

Table 43-45. TDES2 Normal Descriptor (Read Format) Description

31	30	29:16	15:14	13:0
IOC	TTSE/ TMWD	B2L	VTIR	HL or B1L

Table 43-46. TDES2 Normal Descriptor (Read Format) Description

Bit	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29-16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15-14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: 00: Do not add a VLAN tag. 01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. 10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. 11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.
13-0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

43.4.2.1.4 TDES3 Normal Descriptor (Read Format)

Table 43-47. TDES3 Normal Descriptor (Read Format)

31	30	29	28	27:26	25:23	22:19	18	17:16	15	14:0
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM or THL	TSE	CIC/TPL	TPL	FL/TPL

Table 43-48. TDES3 Normal Descriptor (Read Format) Description

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27-26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: 00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. 01: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. 10: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. 11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.

Table 43-48. TDES3 Normal Descriptor (Read Format) Description (continued)

Bit	Name	Description
25-23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: 00: Do not include the source address 01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. 10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. 11: Reserved These bits are valid when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22-19	SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TCP Segmentation Enable When this bit is set, the DMA performs the TCP/UDP segmentation or UDP fragmentation for a packet depending on the TSE_MODE[1:0] bit of the DMA_CH(#i)_Tx_Control Register. This bit is valid only if the FD bit is set.
17-16	CIC/TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: 00: Checksum Insertion Disabled. 01: Only IP header checksum calculation and insertion are enabled. 10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. 11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.

Table 43-48. TDES3 Normal Descriptor (Read Format) Description (continued)

Bit	Name	Description
14-0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE=0.

43.4.2.2 Transmit Normal Descriptor (Write-Back Format)

The write-back format of the Transmit Descriptor includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Figure 43-22 illustrates the write-back format of the Transmit Descriptor.

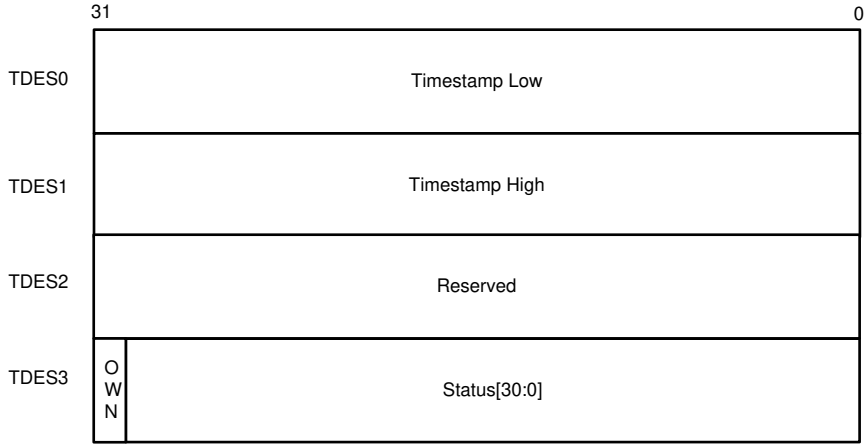

Figure 43-22. Transmit Write Back Format

43.4.2.2.1 TDES0 Normal Descriptor (Write-Back Format)

As described in Table 43-50, this format is only applicable to the last descriptor of a packet.

Table 43-49. TDES0 Normal Descriptor (Write-Back Format) Description

Bit	Name	Description
31-0	TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and the Timestamp status (TTSS) bit is set.

43.4.2.2.2 TDES1 Normal Descriptor (Write-Back Format)

Table 43-50. TDES1 Normal Descriptor (Write-Back Format) Description

Bit	Name	Description
31-0	TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding transmit packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set

43.4.2.2.3 TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 43-51. TDES2 Normal Descriptor (Write-Back Format) Description

Bit	Description
31-0	Reserved

43.4.2.2.4 TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 43-52. TDES3 Normal Descriptor Layout (Write-Back Format)

31	30	29	28	27:24/ 22:18	23	17	16	15	14	13	12	11	10	9	8	7:4	3	2	1	0
OWN	CTXT	FD	LD	Rsvd	DE	TTSS	EUE	ES	JT	FF	PCE	LoC	NC	LC	EC	CC	ED	UF	DB	IHE

Table 43-53. TDES3 Normal Descriptor (Write-Back Format) Description

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is cleared to 0.
30	CTXT	Context Type This bit should be cleared to 0 for Normal descriptor.
29	FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This bit is set 1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
27-24	Rsvd	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: **Note 1:** When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register **Note 2:** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22-18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. Note: Uncorrectable error in Transmit FIFO memory is reported with (Bit 13) FF = 1. This is because, all such packets are flushed by Ethernet module.

Table 43-53. TDES3 Normal Descriptor (Write-Back Format) Description (continued)

Bit	Name	Description
15	ES	Error Summary This bit indicates the logical OR of the following bits: ■TDES3[0]: IP Header Error ■TDES3[14]: Jabber Timeout ■TDES3[13]: Packet Flush ■TDES3[12]: Payload Checksum Error ■TDES3[11]: Loss of Carrier ■TDES3[10]: No Carrier ■TDES3[9]: Late Collision ■TDES3[8]: Excessive Collision ■TDES3[3]: Excessive Deferral ■TDES3[2]: Underflow Error This bit is also set when EUE (bit 16) is set.
14	JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
13	FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
12	PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
7-4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.

Table 43-53. TDES3 Normal Descriptor (Write-Back Format) Description (continued)

Bit	Name	Description
3	ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.
2	UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: ■The DMA encountered an empty Transmit Buffer while transmitting the packe.t ■The application filled the MTL Tx FIFO slower than the MAC transmit rate. The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.
1	DB	Deferred Bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
0	IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.

43.4.2.3 Transmit Context Descriptor

The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature. The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA. When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input. Figure 43-23 shows the format of the Transmit Context descriptor.

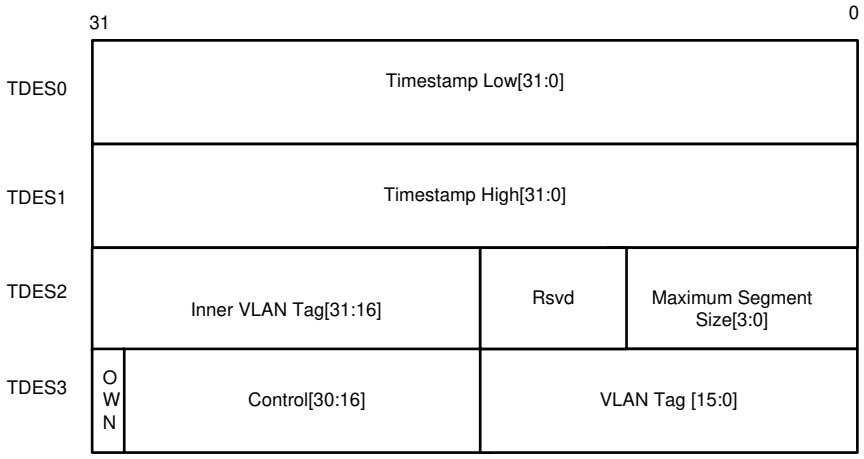

Figure 43-23. Transmit Context Descriptor Format

43.4.2.3.1 TDES0 Context Descriptor

Table 43-54. TDES0 Context Descriptor Description

Bit	Name	Description
31-0	TTSL	TDES0 Context Descriptor For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

43.4.2.3.2 TDES1 Context Descriptor

Table 43-55. TDES1 Context Descriptor Description

Bit	Name	Description
31-0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

43.4.2.3.3 TDES2 Context Descriptor

Table 43-56. TDES2 Context Descriptor Description

Bit	Name	Description
31-16	IVT	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.
15-14	Rsvd	Reserved
13-0	MSS	Maximum Segment Size When the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected, the driver can provide maximum segment size in this field. This segment size is used while segmenting the TCP/IP payload. This field is valid only if the TCMSSV bit of TDES3 context descriptor is set and the OSTC bit of the TDES3 context descriptor is reset.

43.4.2.3.4 TDES3 Context Descriptor

Table 43-57. TDES3 Context Descriptor Layout

31	30	29:28	27	26	25:24	23	22:18	17	16	15:0
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Table 43-58. TDES3 Context Descriptor Description

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit immediately after the read.
30	CTXT	Context Type This bit should be set to 1 for Context descriptor.
29-28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25-24	Rsvd	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect.The DMA sets this bit during write-back while closing the context descriptor. Descriptor Errors can be: ■ Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. ■ All 1s. ■ CD, LD, and FD bits set to 1. **Note 1:** When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register **Note 2:** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.

Table 43-58. TDES3 Context Descriptor Description (continued)

Bit	Name	Description
22-20	Rsvd	Reserved
19-18	IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: 00: Do not add the inner VLAN tag. 01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. 10: Insert an inner VLAN tag with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. 11: Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames. These bits are valid when the Enable SA and VLAN Insertion on Tx and Enable Double VLAN Processing options are selected.
17	IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
15-0	VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

43.4.3 Receive Descriptor

The DMA in Ethernet module attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

- Normal descriptors
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as “Normal” Descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the “Receive Normal Descriptor (Write-Back Format)”. For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA writes the extended status to the next descriptor (without processing or using the Buffers/ Pointers embedded in that descriptor). The format and content of the descriptor write back is described in Section 43.4.3.3.

43.4.3.1 Receive Normal Descriptor (Read Format)

The read format for a Receive Normal descriptor is made up of a header or Buffer 1 address, reserved field, payload or Buffer 2 or Next Descriptor address, a 30-bit reserved filed, OWN bit, and an interrupt bit.

Figure 43-24 shows the Read Format for a Receive normal descriptor.

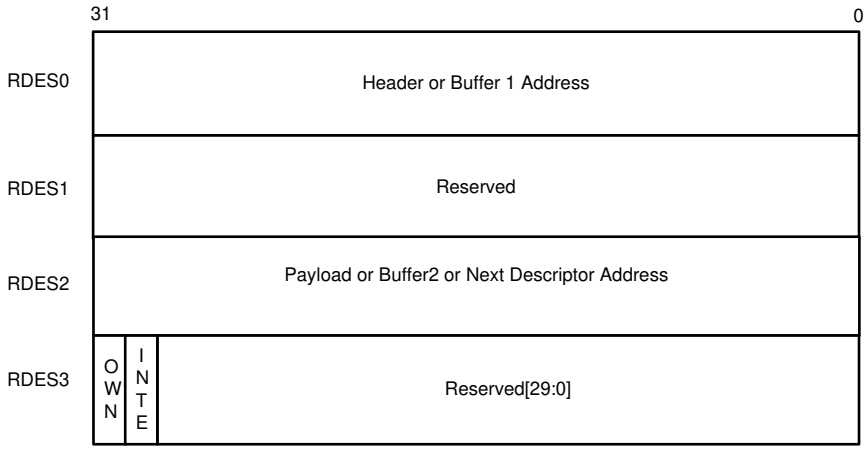

Figure 43-24. Receive Normal Descriptor Read Format

Note

In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, Ethernet module does not transfer data to that buffer and skips to the next buffer or next descriptor.

43.4.3.1.1 RDES0 Normal Descriptor (Read Format)

Table 43-59 describes the read format of the RDES1 Normal Descriptor.

Table 43-59. RDES0 Normal Descriptor (Read Format) Description

Bit	Name	Description
31-0	BUF1AP	RDES0 Normal Descriptor (Read Format) When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[1:0] as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

43.4.3.1.2 RDES1 Normal Descriptor (Read Format)

Table 43-60 describes the read format of the RDES1 Normal Descriptor.

Table 43-60. RDES1 Normal Descriptor (Read Format) Description

Bit	Name	Description
31-0	Reserved or BUF1AP	In 64-bit addressing mode, this field contains the most-significant 32 bits of the Buffer 1 Address Pointer. Otherwise, this field is reserved.

43.4.3.1.3 RDES2 Normal Descriptor (Read Format)

Table 43-61 describes the read format of the RDES2 Normal Descriptor.

Table 43-61. RDES2 Normal Descriptor (Read Format) Description

Bit	Name	Description
31-0	BUF1AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. When the SPH bit of the DMA_CH#_Control register is set, the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register is reset, there is no limitations on the RDES2 value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128-, 64-, or 32-bit data-bus) and writes to the complete location.

43.4.3.1.4 RDES3 Normal Descriptor (Read Format)

Table 43-62 describes the read format of the RDES3 Normal Descriptor.

Table 43-62. RDES3 Normal Descriptor

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

Table 43-63. RDES3 Normal Descriptor (Read Format) Description

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: ■ The DMA completes the packet reception ■ The buffers associated with the descriptor are full
30	IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
29-26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
24	BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
23-0	Rsvd	Reserved

43.4.3.2 Receive Normal Descriptor (Write-Back Format)

Figure 43-25 illustrates the write-back format for a Receive Normal descriptor.

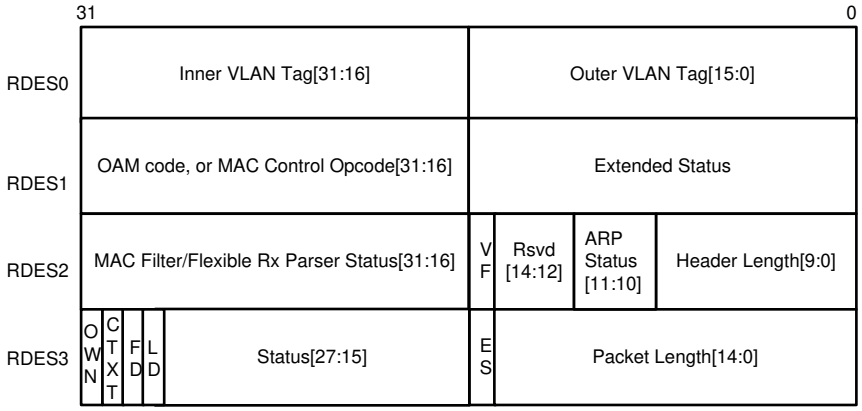

Figure 43-25. Receive Normal Write Back Format

Note

When Flexible RX Parser is enabled, RDES2[31:16] indicates Parser status, and not the MAC filter status. MAC filter status is not available when Flexible RX parser is enabled.

43.4.3.2.1 RDES0 Normal Descriptor (Write-Back Format)

Table 43-64. RDES0 Normal Descriptor (Write-Back Format) Description

Bit	Name	Description
31-16	IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
15-0	OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

43.4.3.2.2 RDES1 Normal Descriptor (Write-Back Format)

The Status fields in write-back format are valid only for the last descriptor (RDES3[28] is set)

Table 43-65. RDES1 Normal Descriptor (Write-Back Format)

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 43-66. RDES1 Normal Descriptor (Write-Back Format) Description

Bit	Name	Description
31-16	OPC	OAM Sub-Type Code or MAC Control Packet opcode If LT Bits[18:16] of RDES3 are set to 111, this field contains the OAM sub-type and code fields. If LT Bits[18:16] of RDES3 are set to 110, this field contains the MAC Control packet opcode field.
15	TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
14	TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3[28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
12	PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
11-8	PMT	PTP Message Type These bits are encoded to give the type of the message received: 0000: No PTP message received 0001: SYNC (all clock types) 0010: Follow_Up (all clock types) 0011: Delay_Req (all clock types) 0100: Delay_Resp (all clock types) 0101: Pdelay_Req (in peer-to-peer transparent clock) 0110: Pdelay_Resp (in peer-to-peer transparent clock) 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) 1000: Announce 1001: Management 1010: Signaling 1011–1110: Reserved 1111: PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.

Table 43-66. RDES1 Normal Descriptor (Write-Back Format) Description (continued)

Bit	Name	Description
7	IPCE	IP Payload Error When this bit is set, it indicates one of the following: ■ The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. ■ The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. ■ The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
6	IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
5	IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected. When the Enable Split Header Feature option is selected and the SPH bit of Control Register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.
4	IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected. When the SPH bit of RDES3 is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing.
3	IPHE	IP Header Error When this bit is set, it indicates one of the following: ■ The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. ■ The IP datagram version is not consistent with the Ethernet Type value. ■ Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either Bit 5 or Bit 4 is set. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
2-0	PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): 000: Unknown type or IP/AV payload is not processed 001: UDP 010: TCP 011: ICMP 100: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet 101: AV Untagged Control Packet 110: AV Tagged Data Packet 111: AV Tagged Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, these bitsare cleared to 000.

43.4.3.2.3 RDES2 Normal Descriptor (Write-Back Format)

Table 43-67. RDES2 Normal Descriptor (Write-Back Format)

31:29	28	27	26:19	18	17	16	15	14	13:11	10	9:0
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 43-68. RDES2 Normal Descriptor (Write-Back Format) Description

Bit	Name	Description
31-29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: 000: Filter 0 001: Filter 1 010: Filter 2 011: Filter 3 100: Filter 4 101: Filter 5 110: Filter 6 111: Filter 7 This field is valid only when Bit 28 or Bit 27 is set high. When more than one filter matches, these bits give the number of the lowest filter. Note: This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: ■ Layer 3 fields are not enabled and all enabled Layer 4 fields match. ■ All enabled Layer 3 and Layer 4 filter fields match. When more than one filter matches, this bit gives the layer 4 filter status of the filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
27	L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: ■ All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed. ■ All enabled filter fields match. When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
26-19	MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. Note: This status is not available when Flexible RX Parser is enabled.
18	HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value. Note: This status is not available when Flexible RX Parser is enabled.

Table 43-68. RDES2 Normal Descriptor (Write-Back Format) Description (continued)

Bit	Name	Description
17	DAF/RXPI	Destination Address Filter Fail When Flexible RX Parser is disabled and this bit is set, it indicates that the packet failed the DA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error. Note: When this bit is set, ES bit of RDES3 is also set.
16	SAF/RXPD	SA Address Filter Fail When Flexible RX Parser is disabled and this bit is set, it indicates that the packet failed the SA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser. Note: When this bit is set, ES bit of RDES3 is also set.
15	OTS	Outer VLAN Tag Filter Status This bit is valid for both Single and Double VLAN Tagged frames.
14	ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only for Double VLAN Tagged frames, when Double VLAN Processing is enabled. For more information, see the Filter Status topic.
13-11	Rsvd	Reserved
10	ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This bit is reserved when the Enable IPv4 ARP Offload option is not selected.
9-0	HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of the corresponding descriptor. If the header length is zero, this field is not valid. It implies that the MAC did not identify and split the header. This field is valid when the Enable Split Header Feature option is selected.

43.4.3.2.4 RDES3 Normal Descriptor (Write-Back Format)

Table 43-69. RDES3 Normal Descriptor (Write-Back Format)

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 43-70. RDES3 Normal Descriptor (Write-Back Format) Description

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: ■ The DMA completes the packet reception. ■ The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD}: 00: Intermediate Descriptor 01: First Descriptor 10: Reserved 11: Descriptor Error (due to all 1s) Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
28	LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
24	CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
23	GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.

Table 43-70. RDES3 Normal Descriptor (Write-Back Format) Description (continued)

Bit	Name	Description
21	OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
20	RE	Receive Error When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the MII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
18-16	LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is: 000: The packet is a length packet 001: The packet is a type packet 010: Reserved 011: The packet is a ARP Request packet type 100: The packet is a type packet with VLAN Tag 101: The packet is a type packet with Double VLAN Tag 110: The packet is a MAC Control packet type 111: The packet is a OAM packet type
15	ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: ■ RDES3[24]: CRC Error ■ RDES3[19]: Dribble Error ■ RDES3[20]: Receive Error ■ RDES3[22]: Watchdog Timeout ■ RDES3[21]: Overflow Error ■ RDES3[23]: Giant Packet ■ RDES2[17]: Destination Address Filter Fail, when Flexible RX Parser is enabled ■ RDES2[16]: SA Address Filter Fail, when Flexible RX Parser is enabled This field is valid only when the LD bit of RDES3 is set.
14-0	PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

43.4.3.3 Receive Context Descriptor

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor. Figure 43-26 shows the format of the Receive Context descriptor.

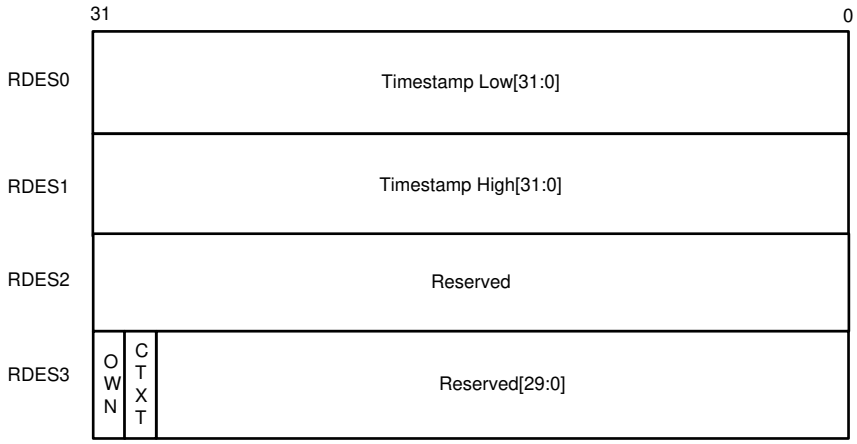

Figure 43-26. Receive Context Descriptor Format

43.4.3.3.1 RDES0 Context Descriptor

Table 43-71. RDES0 Context Descriptor

Bit	Name	Description
31-0	RTSL	Receive Packet Timestamp Low The DMA updates this field with the 32 least significant bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

43.4.3.3.2 RDES1 Context Descriptor

Table 43-72. RDES1 Context Descriptor

Bit	Name	Description
31-0	RTSH	Receive Packet Timestamp High The DMA updates this field with the 32 most significant bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

OWN	CTXT	DE	Rsvd

Table 43-75. RDES3 Context Descriptor Description

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: ■ The DMA completes the packet reception. ■ The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 1 to this bit for context descriptor. The DMA writes 11 to indicate a descriptor error due to all 1s. When CTXT and DE bits are used together, {CTXT, DE}: 00: Reserved 01: Reserved 10: Context Descriptor 11: Descriptor Error Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	DE	Descriptor Error See the CTXT bit description for details of using theDE bit along with CTXT bit.
28-0	Rsvd	Reserved

43.5 Programming

The sequence of steps to program the Ethernet module is detailed in this section

43.5.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the completion of the reset process (poll bit 0 of the DMA_Mode, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SysBus_Mode register:
   a. AAL
   b. Fixed burst or undefined burst
   c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
   d. If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])
4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). For more information about descriptors, see Descriptors
5. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i=0; i<=1) and DMA_CH(#1)_RxDesc_Ring_Length (for i=0; i<=1)). The ring length programmed must be at least 4.

Note

The descriptor addrfess from the start to the end of the ring must not cross the 4GB boundary.

6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)TxDesc_List_Address (for i = 0; i <=1), DMA_CH (#i)_RxDesc_List_Address (for i=0; i <=1)). also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH (#i)_TxDesc_Tail_Pointer (for i=0; i <= 1) and DMA_CH (#i)_TxDesc_Tail_Pointer (for i=0; i<=1))..,

Note

(For 40-bit or 48-bit addressing mode, program the higher address List registers DMA_CH[n]_TxDesc_List_HAddress, DMA_CH[n]_RxDesc_List_HAddress). The tailpointer registers must be advanced to the location immediately after the descriptors that are set, for the DMA to know that additional descriptors are available.

43.5.2 Initializing MTL Registers

The Transaction Layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands.

Complete the following steps to initialize the MTL registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation in case of multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in MTL_RxQ_DMA_Map0 and MTL_RxQ_DMA_Map1 registers.
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register.
   a. Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
   b. Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue0
   c. Transmit Queue Size (TQS)

   a.
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a. Receive Store and Forward (RSF) or RTC in case of Threshold mode
   b. Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
   c. Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d. Receive Queue Size (RQS)
5. Repeat previous two steps for all MTL Tx and Rx queues.

43.5.3 Initializing MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initial- ized before initializing the DMA.

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is to be enabled program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_Pack- et_Filter register:
   a. Receive All
   b. Promiscuous mode
   c. Hash or Perfect Filter
   d. Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_Tx_Flow_Ctrl register:
   a. Pause time and other Pause frame control bits
   b. Transmit Flow control bits
   c. Flow Control Busy
4. Program the MAC_Interrupt_Enable register, as required, and if applicable, for your configuration.
5. Program the appropriate fields in the MAC_Configuration register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in MAC_Configuration registers to start the MAC transmitter and receiver

43.5.4 Performing Normal Receive and Transmit Operation

During normal operation of the Ethernet module, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (if it does not own descriptors), and values of current host transmitter or receiver descriptor pointers are read for debugging.

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TxDesc_Tail_Pointer and DMA_CH[n]_RxDesc_Tail_Pointer).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (DMA_CH[n]_Current_App_TxDesc and DMA_CH[n]_Current_App_RxDesc).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register DMA_CH[n]_Current_App_TxBuffer and DMA_CH[n]_Current_App_RxBuffer).

43.5.5 Stopping and Starting Transmission

Complete the following steps to pause the transmission for some time. The steps are provided for Channel 0.

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of DMA
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug Register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit (RE) and Bit 1(TE) of the MAC_Configuration Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL_TxQ0_Debug Register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TxQ0_Debug Register and RXQSTS is 0 in MTL_RxQ0_Debug Register).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

43.5.6 Programming Guidelines for Multi-Channel Multi-Queuing

The Transmit and Receive operation guidelines when using Multi channel/Multi-Queuing mode is detailed below

43.5.6.1 Transmit

Following these guidelines for transmitting.

1. Program the Transmit queue size in the TQS field of MTL_TxQ[n]_Operation_Mode register. Based on the value programmed in the TQS field, the size of the queue is determined. In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel-to-Queue mapping is fixed.
2. For a queue to be used, the queue needs to be enabled in TXQEN in the corresponding MTL_TxQ[n]_Operation_Mode Register. the ST bit of DMA_CH[n]_Tx_Control Register and corresponding TXQEN in MTL_TxQ[n]_Operation Mode Register needs to be enabled.
3. The scheduling method needs to be programmed in SCHALG of MTL_Operation_Mode register.

43.5.6.2 Receive

Follow these guidelines for receiving:

1. Program the Receive queue size in the RQS field of MTL_RxQ[n]_Operation_Mode Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 1 in the fields RXQ0EN to RXQ1EN in MAC_RxQ_Ctrl0 Register SR bit of statically or dynamically mapped DMA_CH[n]_Rx_Control Register and corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 Register needs to be enabled.
3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a. VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ1-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 1.

Note

The priorities set in PSRQ1-0 should be unique.

4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbi- tration and mapping:
   a. Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   b. Program the MTL_RxQ[n]_Control to decide the weights and the packet arbitration for each RxQ.
   c. If static mapping is programmed in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
   d. Set RXQ[n]DADMACH bit in MTL_RxQ_DMA_Map0 Register to select dynamic mapping of packets in each RxQueue.
   e. In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.

43.5.6.3 Programming Guidelines for Recovering from DMA Channel Failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

43.5.6.3.1 Recovering from the Receive DMA Channel Failure

Follow these steps if you get bus error in the Receive DMA channel:

1. Set the RPF bit to 1. This flushes all the packets one after the other. This step is optional. However, setting this bit prevents HOL (head-of-line) blocking in the Rx queues when packets sent to the RXDMA are stopped due to bus error.
2. Re-program the specific Registers of the DMA channel.
3. Start the DMA channel

43.5.6.3.2 Recovering from the Transmit DMA Channel Failure

Follow these steps:

1. Stop the specific DMA channel, even if it is in active state.
2. Flush the corresponding MTL queue.
3. Re-program the specific Registers of the DMA channel.
4. Start the DMA channel.

43.5.6.4 Programming Guidelines for IEEE 1588 Timestamping

You can enable the timestamp feature by setting Bit 0 of the MAC_Timestamp_Control Register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during Ethernet module initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 16 of MAC_Interrupt_Enable Register.
2. Set Bit 0 of MAC_Timestamp_Control Register to enable timestamping.
3. Program MAC_Sub_Second_Increment Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 5 of MAC_Timestamp_Control Register.
5. Poll the MAC_Timestamp_Control Register until Bit 5 is cleared.
6. Program Bit 1 of MAC_Timestamp_Control Register to select the Fine Update method (if required).
7. Program MAC_System_Time_Seconds_Update Register and MAC_System_Time_Nanoseconds_Up- date Register with the appropriate time value.
8. Set Bit 2 in MAC_Timestamp_Control Register. The timestamp counter starts operation as soon as it is initialized with the value written in the Time- stamp Update registers. If one-step timestamping is enabled.
   a. To enable one-step timestamping, program Bit 27 of the TDES3 Context Descriptor.
   b. Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Time- stamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
9. Enable the MAC receiver and transmitter for proper timestamping.

Note

If timestamp operation is disabled by clearing Bit 0 of MAC_Timestamp_Control Register, repeat all these steps to restart the timestamp operation.

43.5.6.4.1 Initialization Guidelines for System Time Generation

You can enable the timestamp feature by setting Bit 0 of the MAC_Timestamp_Control Register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during Ethernet module initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 16 of MAC_Interrupt_Enable Register.
2. Set Bit 0 of MAC_Timestamp_Control Register to enable timestamping.
3. Program MAC_Sub_Second_Increment Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 5 of MAC_Timestamp_Control Register.
5. Poll the MAC_Timestamp_Control Register until Bit 5 is cleared.
6. Program Bit 1 of MAC_Timestamp_Control Register to select the Fine Update method (if required).
7. Program MAC_System_Time_Seconds_Update Register and MAC_System_Time_Nanoseconds_Up- date Register with the appropriate time value.
8. Set Bit 2 in MAC_Timestamp_Control Register. The timestamp counter starts operation as soon as it is initialized with the value written in the Time- stamp Update registers.
   If one-step timestamping is enabled
   a. To enable one-step timestamping, program Bit 27 of the TDES3 Context Descriptor.
   b. Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Time- stamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
9. Enable the MAC receiver and transmitter for proper timestamping.

43.5.6.4.2 System Time Correction

Time correction can be done in Coarse or Fine methods.

43.5.6.4.2.1 Coarse Correction Method

To synchronize or update the system time in one process (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the Timestamp Update registers(MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update).
2. Set Bit 3 (TSUPDT) of MAC_Timestamp_Control Register. The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

43.5.6.4.2.2 Fine Correction Method

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

- With the help of the algorithm explained in“System Time Register Module” calculate the rate by which you want to make the system time increments slower or faster.
- Update the MAC_Timestamp_Addend with the new value and set Bit 5 of the MAC_Timestamp_Con- trol Register.
- Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
- Program the required target time in MAC_PPS[n]_Target_Time_Seconds Register and MAC_PPS[n]_Target_Time_Nanoseconds Register.
- Enable the Timestamp interrupt in bit 12 of MAC_Interrupt_Enable register.
- Set bit 4 in Register MAC_Timestamp_Control.
- When this trigger causes an interrupt, read MAC_Interrupt_Status Register.
- Reprogram MAC_Timestamp_Addend Register with the old value and set bit 5 again

43.5.6.5 Programming Guidelines for Energy Efficient Ethernet

After you enable the Energy Efficient Ethernet (EEE) in the Ethernet module controller, you can program the following:

- Entering and Exiting Tx LPI mode during the QoS initialization
- Gating off the CSR clock in the Rx LPI mode
- Gating off the CSR clock in the Tx LPI mode

43.5.6.5.1 Entering and Exiting the Tx LPI Mode

Energy Efficient Ethernet (EEE) enables the IEEE 802.3 Media Access Control (MAC) sublayer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. In the Transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol.

Complete the following steps during QoS core initialization:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values.
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode.)
3. Program bits[25:16] and bits[15:0] in MAC_LPI_Timers_Control Register.
4. Read the link status of the PHY chip by using the MDIO interface and update bit 17 of MAC_LPI_Control_Status accordingly. This update should be done whenever the link status in the PHY chip changes
5. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port.
6. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.

7. Set LPITE and LPITXA (bit[20:19]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
8. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port.
9. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
10. Set LPITE and LPITXA (bit[20:19]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
11. Set bit 16 of MAC_LPI_Control_Status Register to make the MAC Transmitter enter the LPI state. The MAC enters the LPI mode after completing all scheduled packets and remains IDLE for the time indicated by LPIET. It sets the TLPIEN (bit[0]) after entry to LPI state.
12. When a packet is scheduled for transmission (when the TxDMA comes out of IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter exits LPI state automatically. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.
13. MAC Transmitter re-enters LPI state if it remains IDLE for LPIET time and sets the TLPIEN bit and the entry-exit cycle continues.
14. Reset LPITXEN in case the application wants to over-ride the auto-entry/exit modes and make the MAC Transmitter exit the LPI state directly.

Note

To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the Tx FIFO, you should set bit 19 in MAC_LPI_Control_Status Register.

To switch off the MII transmit clock during the LPI state, use the sbd_tx_clk_gating_ctrl_o signal for gating the clock input.

To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of MAC_LPI_Control_Status Register to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.

43.5.6.5.2 Gating Off the CSR Clock in the LPI Mode

The Transmit MII Clock can be gated off in the module save the power when the MAC is in Low-Power Idle (LPI) mode. Setting the LPITCSE in MAC_LPI_Control_Status register will enable this feature. This will not be applicable to RMII mode since the Transmit clock is needed for transmitting the LPI Pattern.

43.5.6.5.3 Rx LPI Mode

The following operations can be performed when the MAC receives the LPI pattern from the PHY:

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status [RLPIEN interrupt of MAC_LPI_Control_Status Register] is set.
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the MAC_LPI_Control_Status Register.

After the sbd_intr_o interrupt is asserted if the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR.

wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when MAC_LPI_Control_Status Register is read.

43.5.6.5.4 Gating Off the CSR Clock in the Tx LPI Mode

The following operations are performed when Bit 16 (LPIEN) of MAC_LPI_Control_Status is set:

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status [RLPIEN interrupt of MAC_LPI_Control_Status Register] is set.
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the MAC_LPI_Control_Status Register.

After the sbd_intr_o interrupt is asserted if the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported.

For restoring the Tx clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when MAC_LPI_Control_Status Register is read.

43.5.6.6 Programming Guidelines for Flexible Pulse-Per-Second Output

After you enable the Flexible Pulse-Per-Second Output feature in the Ethernet module controller, you can perform the following tasks:

- Generating Single Pulse on PPS
- Generating Next Pulse on PPS
- Generating a Pulse Train on PPS
- Generating an Interrupt without Affecting the PPS

43.5.6.6.1 Generating Single Pulse on PPS

To programsingle pulse, follow this procedure:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of PPS signal output.
2. Program the start time value in the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the width of the PPS signal output in MAC_PPS(#i)_Width (for i=0; i<= 1) Register.
4. Program Bits [3:0], PPSCMD, of MAC_PPS_Control to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programmed in the Target Time registers

43.5.6.6.2 Generating Next Pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance.

To program the next pulse, follow this procedure:

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in MAC_PPS (#i)_Width (for i=0; i<=1) Register.
3. Program Bits [3:0], PPSCMD, of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programmed in Target Time registers.
   If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

43.5.6.6.3 Generating a Pulse Train on PPS

Complete the following steps to generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers for start time of the PPS signal output.
2. Program the start time value in the Target Time registers.
3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS (#i)_Width (for i=0;i <=1) Register.
4. Program the width of the PPS system in MAC_PPS (#i)_interval (for i=0;i <=1) Register.
5. Program Bits[3:0], PPSCMD, of MAC_PPS_Control Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programmed in Target Time registers.
6. Program the stop value in the Target Time registers. Ensure that Bit 31 (TSTRBUSY) of MAC_PPS(#i)_Target_Time_Nanoseconds (for i=0; i <=1) Register s reset before programming the Target Time registers again. .
7. Program the PPSCMD field (bit 3:0) of MAC_PPS_Control to 0100. This stops the train of pulses on PPS signal output after the programmed stop time specified in Step 6 elapses.

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programmed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in Step 2) elapses.

43.5.6.6.4 Generating an Interrupt without Affecting the PPS

The Bits [6:5], TRGTMODSEL, of the MAC_PPS_Control Register enable you to program the Target Time registers to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

Complete the following steps to program the Target Time registers to generate only interrupt event:

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers for target time interrupt.
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an inter- rupt when the target time elapses.

If Bits [6:5], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is over-written with the new mode and new programmed Target Time register value.

43.5.6.7 Programming Guidelines for TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet segmentation, and program descriptor fields to enable TSO for the current packet.

Complete the following steps to program TSO:

1. Program the TSE bit of corresponding DMA_CH[n]_Tx_Control register to enable TCP packet segmentation in that DMA.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must be programmed to enable TSO for the current packet:
   a. Enable TSE in Bit 18 of TDES3.
   b. Program the length of the un-segmented TCP/IP packet payload in bits [17:0] of TDES3 and the TCP header in bits [22:19] of TDES3.
   c. Program the maximum size of the segment in MSS of DMA_CH[n]_Control register or MSS in the context descriptor. If MSS field is programmed in both DMA_CH[n]_Control register and in the context descriptor, the latest software programmed sequence is considered.
3. The header of the unsegmented TCP/IP packet should be in Buffer 1 of the first descriptor and this buffer must not hold any payload bytes. The payload is allocated to Buffer 2 and the buffers of the subsequent descriptors.

Note

If TSE is enabled in TDES3 for a non-TCP-IP packet, the result is unpredictable.

43.6 Software

43.6.1 ETHERNET Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/ethernet

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

43.6.1.1 Ethernet + IPC basic message passing example with interrupt - C28X_CM

FILE: ethernet_ipc_ex1_basic_c28x1.c

This example demonstrates how to configure IPC and pass information from C28x to CM core without message queues. This configures the Pinmux for Ethernet Prepares the Ethernet frame that is sent to the CM core over IPC Message RAM. Uses the IPC command interface to signal the IPC Command, Packet address, Packet Length which is used by CM side code to send it on the Ethernet Line, which is acknowledged by the CM core side code over IPC on succesfully receiving a packet It is recommended to run the C28x1 core first, followed by the CM core.

External Connections
- Connections for Ethernet in MII mode

Watch Variables
- pass

43.6.1.2 Ethernet + IPC basic message passing example with interrupt - C28X_CM

FILE: ethernet_ipc_ex1_basic_cm.c

This example demonstrates how to receive the message passed from C28x side containing the Ethernet Packet over IPC,sends the packet on Ethernet acknowledge the packet received over IPC to C28x core. This extends the IPC Example. Uses IPC C28x to CM core without message queues. It can be used as a reference for flow using Ethernet and IPC together. If the Packet data received over Ethernet is to be passed to C28x for control applications, it can send IPC message to C28x. It is recommended to run the C28x1 core first, followed by the CM core. The example actually uses the internal loopback mode of MAC hence the MII Tx and Rx signals are not used, but needs the MII Tx and Rx Clock signals which comes from the External PHY.

External Connections
- MII connections on Control card

Watch Variables
- None.

43.6.1.3 Ethernet MAC Internal Loopback - CM

FILE: ethernet_ex1_basic_tx_rx_loopback.c

This example demonstrates the steps to be followed in using the Ethernet of the Communication Manager Subsystem to initialize the Ethernet module and Configure the module in MAC Loop back mode Prepares a packet to be sent, Sends the packet and reads the statistics to check if the packet is received by the module Before running this Communication Manager code the C28x cpu1 code has to be run to configure the clocks to Communication manager and required IO pads for Ethernet module

External Connections
This example programs the Ethernet module in Internal Loop back mode and hence needs no external connection on the MII Data lines. But it needs the MII Tx and Rx clocks to be input on those pins Refer to the C28x CPU1 code of ethernet_config_c28x project for which GPIOs are used for connecting to the PHY

Watch Variables
- None

43.6.1.4 Ethernet Basic Transmit and Receive PHY Loopback - CM

FILE: ethernet_ex2_phy_loopback.c

This example demonstrates the steps to be followed in using the Ethernet of the Communication Manager Subsystem to initialize the Ethernet module and Configure the module in External Loop back mode the packet is looped back at external PHY. Prepares a packet to be sent, Sends the packet and reads the staticstics to check if the packet is received by the module Before running this Communication Manager code the C28x cpu1 code has to be run to configure the clocks to Communication manager and required IO pads for Ethernet module

External Connections
This example programs the Ethernet module in External Loop back mode (at PHY) and hence needs external connection to the PHY on the MII interface and also the MDIO Pins connected to the PHY. This example assumes DP83822 PHY for the PHY configurations if a different PHY is used the sequences might change Refer to the C28x CPU1 code of ethernet_config_c28x project for which GPIOs are used for connecting to the PHY

Watch Variables
- phyRegContent variable can be checked to know if PHY register read,write is working correctly
  - stats to know if the packet is received correctly after loopback at PHY side

43.6.1.5 Ethernet Threshold mode with level PHY loopback - CM

FILE: ethernet_ex3_threshold_mode_phy_loopback.c

This example demonstrates the steps to be followed in using the Ethernet of the Communication Manager Subsystem to initialize the Ethernet module in Threshold mode It Configures the module in MII External Loop back mode in which the packet is looped back at external PHY. Prepares a packet to be sent, Sends the packet and reads the staticstics to check if the packet is received by the module It configures the Transmit and Receive queues of Ethernet DMA in Threshold mode. The Transmit threshold mode generates early transmit interrupts when each buffer is transmitted from the memory into the transmit FIFO. The Buffer can be reclaimed by the application. The Receive threshold mode generates early receive interrupts where the module generates Early receive interrupts when programmed threshold buffer size is transferred into receive buffer memory from the receive FIFO. This will be of use when dealing with Time critical receive paths where the application can consume the packets at programmed burstLength unlike the conventional Store and Forward mode(Default) where the module generates the interrupts when the complete packet is transmitted on the Line and when the complete packet is received and checksum validation is succesful This example provides a starting point for configuring the threshold mode. Refer to the Driver API guide for the different callbacks available in the driver. It uses the example Interrupt Service Routines provided in the driver library. Users can modify those ISRs or write another as per their need. Before running this Communication Manager code the C28x cpu1 code has to be run to configure the clocks to Communication manager and required IO pads for Ethernet module

External Connections
This example programs the Ethernet module in External Loop back mode (at PHY) and hence needs external connection to the PHY on the MII interface and also the MDIO Pins connected to the PHY. This example assumes DP83822 PHY for the PHY configurations if a different PHY is used the sequences might change. Refer to the C28x CPU1 code of ethernet_config_c28x project for which GPIOs are used for connecting to the PHY

Watch Variables
- phyRegContent variable can be checked to know if PHY register read,write is working correctly
- Ethernet_txInterruptCount - this variable available in driver library provides a count of number of times Transmit completion interrupt (on full packet transmission onto the line) occured
- Ethernet_rxInterruptCount - this variable provides a count of number of times the complete Receive completion interrupt occured
- Ethernet_earlyRxInterruptCount - the number of times the early receive interrupt occured. This depends on the burstLength configured
- Ethernet_earlyTxInterruptCount - the number of times the early transmit interrupt occured. This depends on the number of fragments of the packets transmitted

43.6.1.6 Ethernet PTP Basic Master - CM

FILE: ethernet_ex4_ptp_basic_master.c

This example configures the device in IEEE PTPv2 Master mode and then periodically sends Sync packets to the slave. On receiving the DelayReq packets from the slave, the master also sends out the DelayResp packets.

External Connections
This example programs the Ethernet module in PTP Basic Master mode. The example project Ethernet PTP Basic Slave is intended to be used along with this project to see the whole PTP Protocol state in action. The second device is configured as Slave and both devices in conjunction exchange Sync, DelayReq and DelayResp packets.

Refer to the C28x CPU1 code of ethernet_config_c28x project for configuring the PTP clock that drives the system time counter on the Ethernet module.

Watch Variables
- gPtpMasterState

43.6.1.7 Ethernet PTP Basic Slave - CM

FILE: ethernet_ex4_ptp_basic_slave.c

This example configures the device in IEEE PTPv2 Slave mode and then waits for the Sync packets from the slave. On receiving configurable number of Sync packets from the master, the slave also sends out the DelayReq packets. In response to the DelayReq packets, the Master also sends out the DelayResp packets which is then received by the Slave. The slave parallely maintains the internal state of the PTP in terms of Master to Slave Delay and Slave to Master Delay. Consequently, the slave also calculates Offset From Master and Mean Path Delay.

External Connections
This example programs the Ethernet module in PTP Basic Slave mode. The example project Ethernet PTP Basic Master is intended to be used along with this project to see the whole PTP Protocol state in action. The second device is configured as Master and both devices in conjunction exchange Sync, DelayReq and DelayResp packets.

Refer to the C28x CPU1 code of ethernet_config_c28x project for configuring the PTP clock that drives the system time counter on the Ethernet module.

Watch Variables
- gPtpSlaveState

43.6.1.8 Ethernet PTP Offload Master - CM

FILE: ethernet_ex5_ptp_offload_master.c

This example configures the device in IEEE PTPv2 Master mode and sets the options that are needed by the offload engine to operate such as the domainNumber, LogSyncInterval among others. After that it enables sending SYNC messages periodically according to the interval already set previously.

External Connections
This example programs the Ethernet module in PTP Offload Master mode. The example project Ethernet PTP Offload Slave is intended to be used along with this project to see the whole PTP Offload engine in action. The second device is configured as Slave and both devices in conjunction exchange Sync, DelayReq and DelayResp packets.

Refer to the C28x CPU1 code of ethernet_config_c28x project for configuring the PTP clock that drives the system time counter on the Ethernet module.

Watch Variables
- Ethernet_ptpDelayReqPktCount

43.6.1.9 Ethernet PTP Offload Slave - CM

FILE: ethernet_ex5_ptp_offload_slave.c

This example configures the device in IEEE PTPv2 Slave mode and sets the options that are needed by the offload engine to operate such as the domainNumber, LogSyncInterval among others. After that it enables sending DelayReq messages periodically for every configurable number of Sync packets.

External Connections
This example programs the Ethernet module in PTP Offload Slave mode. The example project Ethernet PTP Offload Master is intended to be used along with this project to see the whole PTP Offload engine in action. The second device is configured as Slave and both devices in conjunction exchange Sync, DelayReq and DelayResp packets.

Refer to the C28x CPU1 code of ethernet_config_c28x project for configuring the PTP clock that drives the system time counter on the Ethernet module.

Watch Variables
- Ethernet_ptpSyncPktCount
- Ethernet_ptpDelayRespPktCount

43.6.1.10 Ethernet MAC CRC and Checksum Offload - CM

FILE: ethernet_ex6_crc_checksum_offload.c

This example demonstrates the steps to be followed in using the Ethernet of the Communication Manager Subsystem to initialize the Ethernet module and Configure the module in MAC Loop back mode. Demonstrates how to program the CRC offload and Checksum Offload(IP Checksum) Prepares a packet to be sent, Sends the packet and reads the statistics to check if the packet is received by the module Before running this Communication Manager code the C28x cpu1 code has to be run to configure the clocks to Communication manager and required IO pads for Ethernet module

External Connections
This example programs the Ethernet module in Internal Loop back mode and hence needs no external connection on the MII Data lines. But it needs the MII Tx and Rx clocks to be input on those pins Refer to the C28x CPU1 code of ethernet_config_c28x project for which GPIOs are used for connecting to the PHY

Watch Variables
- None

43.6.1.11 Ethernet Transmit Segmentation Offload - CM

FILE: ethernet_ex7_tranport_segmentation_offload.c

This example demonstrates the steps to be followed in using the Ethernet of the Communication Manager Subsystem to initialize the Ethernet module and Configure the module in MAC Loop back mode. Demonstrates how to program the Transport Segmentation Offload feature in the Low level driver which in turn programs the feature in the hardware The Hardware segments a single packet into configured segment size Prepares a packet to be sent, Sends the packet and reads the statistics to check if the packet is received by the module Before running this Communication Manager code the C28x cpu1 code has to be run to configure the clocks to Communication manager and required IO pads for Ethernet module

External Connections
This example programs the Ethernet module in Internal Loop back mode and hence needs no external connection on the MII Data lines. But it needs the MII Tx and Rx clocks to be input on those pins Refer to the C28x CPU1 code of ethernet_config_c28x project for which GPIOs are used for connecting to the PHY

Watch Variables
- None

43.6.1.12 Ethernet MAC Internal Loopback - CM

FILE: ethernet_ex8_vlan_filtering.c

This example demonstrates the steps to be followed in using the Ethernet of the Communication Manager Subsystem to initialize the Ethernet module and Configure the module in MAC Loop back mode The packet sent is inserted with a VLAN tag. A VLAN filter is configured to route it to a different channel Prepares a packet to be sent, Sends the packet and reads the statistics to check if the packet is received by the module Before running this Communication Manager code the C28x cpu1 code has to be run to configure the clocks to Communication manager and required IO pads for Ethernet module

External Connections
This example programs the Ethernet module in Internal Loop back mode and hence needs no external connection on the MII Data lines. But it needs the MII Tx and Rx clocks to be input on those pins Refer to the C28x CPU1 code of ethernet_config_c28x project for which GPIOs are used for connecting to the PHY

Watch Variables
- None

43.6.1.13 Ethernet RevMII Example MII side - CM

FILE: ethernet_ex9_revmii_example_mii_remote.c

This example demonstrates the steps to be followed in using the Ethernet of the Communication Manager Subsystem to initialize the Ethernet module and Configure the module in MII mode. The other device is running a RevMII mode This demonstrates the sequence for MII - RevMII communication Before running this Communication Manager code the C28x cpu1 code has to be run to configure the clocks to Communication manager and required IO pads for Ethernet module This Example has been validated on an TI internal board and will not run on Control Card. This has been run with RevMII Example Remote MAC side. Once the RevMII mode is configured this appears like a PHY to the external MAC which is connected over MDIO. Even though there is no physical PHY the RevMII mode lets the remote MAC see this side as a MAC.

External Connections
TBD

Watch Variables
- None

43.6.1.14 Ethernet RevMII Example RevMII side - CM

FILE: ethernet_ex9_revmii_example_revmii_side.c

This example demonstrates the steps to be followed in using the Ethernet of the Communication Manager Subsystem to initialize the Ethernet module and Configure the module in RevMII mode. Before running this Communication Manager code the C28x cpu1 code has to be run to configure the clocks to Communication manager and required IO pads for Ethernet module This Example has been validated on an TI internal board and will not run on Control Card. This has been run with RevMII Example Remote MAC side. Once the RevMII mode is configured this appears like a PHY to the external MAC which is connected over MDIO. Even though there is no physical PHY the RevMII mode lets the remote MAC see this side as a PHY.

External Connections
TBD

Watch Variables
- None

43.6.1.15 Ethernet Low Latency Interrupt - CM

FILE: ethernet_ex10_lowlatency_interrupt.c

This example demonstrates the steps to be followed in using the Ethernet of the Communication Manager Subsystem to handle the Ethernet transmit,receive with minimum latency interrupts. The example interrupt handlers provided in the Ethernet driver help to achieve user friendly buffer management and the generic interrupt handler handles different interrupt sources, these factors might be more cycle consuming. This example demonstrates how to achieve lowest possible latency with interrupts and buffer management with the Ethernet

Driver. Before running this Communication Manager code the C28x cpu1 code has to be run to configure the clocks to Communication manager and required IO pads for Ethernet module

External Connections
This example programs the Ethernet module in Internal Loop back mode and hence needs no external connection on the MII Data lines. But it needs the MII Tx and Rx clocks to be input on those pins Refer to the C28x CPU1 code of ethernet_config_c28x project for which GPIOs are used for connecting to the PHY

Watch Variables

- transmitISRCount
- receiveISRCount

43.7 Ethernet Registers

This section describes the Ethernet Module Registers.

43.7.1 Ethernet Base Addresses

Table 43-76. EMAC Base Address Table (CM)

DriverLib Name	Base Address	uDMA Access	Ethernet DMA Access
EMAC_BASE	0x400C_0000	-	-
EMAC_SS_BASE	0x400C_2000	-	-

43.7.2 ETHERNETSS_REGS Registers

Table 43-77 lists the memory-mapped registers for the ETHERNETSS_REGS registers. All register offset addresses not listed in Table 43-77 should be considered as reserved locations and the register contents should not be modified.

Table 43-77. ETHERNETSS_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	ETHERNETSS_IPREVNUM	IP Revision Number		Go
4h	ETHERNETSS_CTRLSTS	Control Register	LOCK	Go
8h	ETHERNETSS_PTPTSTRIGSEL0	PTP Trigger-0 select	LOCK	Go
Ch	ETHERNETSS_PTPTSTRIGSEL1	PTP Trigger-1 select	LOCK	Go
10h	ETHERNETSS_PTPTSSWTRIG0	PTP SW Trigger-0		Go
14h	ETHERNETSS_PTPTSSWTRIG1	PTP SW Trigger-1		Go
18h	ETHERNETSS_PTPPPSR0	PTP PPS-0 Read		Go
1Ch	ETHERNETSS_PTPPPSR1	PTP PPS-1 Read		Go
20h	ETHERNETSS_PTP_TSRL	PTP timestamp read lower 32 bits		Go
24h	ETHERNETSS_PTP_TSRH	PTP timestamp read upper 32 bits		Go
28h	ETHERNETSS_PTP_TSWL	External Timestamp write lower 32 bits		Go
2Ch	ETHERNETSS_PTP_TSWH	External Timestamp write upper 32 bits		Go
30h	ETHERNETSS_REVMII_CTRL	RevMII Phy Address controls	LOCK	Go

Complex bit access types are encoded to fit into small table cells. Table 43-78 shows the codes that are used for access types in this section.

Table 43-78. ETHERNETSS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
RC	R C	Read to Clear
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 43-78. ETHERNETSS_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

43.7.2.1 ETHERNETSS_IPREVNUM Register (Offset = 0h) [Reset = 0h]

ETHERNETSS_IPREVNUM is shown in Figure 43-27 and described in Table 43-79.

Return to the Summary Table.

4-0	REVMII_CORE_PHY_ADDR	R/W	0h	Address offset to access the control-status related to PHY related status/controls for the core side. (RevMII does not have PHY) Reset type: CM.SYSRESETn

43.7.3 EMAC_REGS Registers

Table 43-92 lists the memory-mapped registers for the EMAC_REGS registers. All register offset addresses not listed in Table 43-92 should be considered as reserved locations and the register contents should not be modified.

Table 43-92. EMAC_REGS Registers

Offset	Acronym	Register Name	Section
0h	MAC_Configuration	The MAC Configuration Register establishes the operating mode of the MAC.	Go
4h	MAC_Ext_Configuration	The MAC Extended Configuration Register establishes the operating mode of the MAC.	Go
8h	MAC_Packet_Filter	The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.	Go
Ch	MAC_Watchdog_Timeout	The Watchdog Timeout register controls the watchdog timeout for received packets.	Go
10h	MAC_Hash_Table_Reg0	The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 128 or 256 bits. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant. The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: - Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). - Perform bitwise reversal for the value obtained in Step 1. - Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
14h	MAC_Hash_Table_Reg1	The Hash Table Register 1 contains the second 32 bits of the hash table. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant. The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: - Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). - Perform bitwise reversal for the value obtained in Step 1. - Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.	Go
50h	MAC_VLAN_Tag_Ctrl	This register is the redefined format of the MAC VLAN Tag Register. It is used for indirect addressing. It contains the address offset, command type and Busy Bit for CSR access of the Per VLAN Tag registers.	Go
54h	MAC_VLAN_Tag_Data	This register holds the read/write data for Indirect Access of the Per VLAN Tag registers. During the read access, this field contains valid read data only after the OB bit is reset. During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl Register.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
58h	MAC_VLAN_Hash_Table	When VTHM bit of the MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: - Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3). - Perform bitwise reversal for the value obtained in step 1. - Take the upper four bits from the value obtained in step 2. If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. - If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.	Go
60h	MAC_VLAN_Incl	The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls.	Go
64h	MAC_Inner_VLAN_Incl	The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.	Go
70h	MAC_Q0_Tx_Flow_Ctrl	The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register. When the PFCE bit in the MAC_Rx_Flow_Ctrl register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_RxQ_Ctrl2 register.	Go
90h	MAC_Rx_Flow_Ctrl	The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.	Go
94h	MAC_RxQ_Ctrl4	The Receive Queue Control 4 register controls the routing of unicast and multicast packets that fail the Destination or Source address filter to the Rx queues.	Go
A0h	MAC_RxQ_Ctrl0	The Receive Queue Control 0 register controls the queue management in the MAC Receiver. Note: In multiple Rx queues configuration, all the queues are disabled by default. Enable the Rx queue by programming the corresponding field in this register.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
A4h	MAC_RxQ_Ctrl1	The Receive Queue Control 1 register controls the routing of multicast, broadcast, AV, DCB, and untagged packets to the Rx queues.	Go
A8h	MAC_RxQ_Ctrl2	This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the RxQueues 0 to 3.	Go
B0h	MAC_Interrupt_Status	The Interrupt Status register contains the status of interrupts.	Go
B4h	MAC_Interrupt_Enable	The Interrupt Enable register contains the masks for generating the interrupts.	Go
B8h	MAC_Rx_Tx_Status	The Receive Transmit Status register contains the Receive and Transmit Error status.	Go
C0h	MAC_PMT_Control_Status	The PMT Control and Status Register.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
C4h	MAC_RWK_Packet_Filter	The wkuppktfilter_reg register at address 0C4H loads the Wake-up Packet Filter register. To load values in a Wake-up Packet Filter register, the entire register (wkuppktfilter_reg) must be written. The wkuppktfilter_reg register is loaded by sequentially loading the eight, sixteen or thirty two register values in address (0C4H) for wkuppktfilter_reg0, wkuppktfilter_reg1,.. wkuppktfilter_reg31, respectively. The wkuppktfilter_reg register is read in a similar way. The DWC_ether_qos updates the wkuppktfilter_reg register current pointer value in Bits[26:24] of MAC_PMT_Control_Status register. Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3,..,15) to determine whether or not a packet is a wake-up packet. - The MSB (31st bit) must be zero. - Bit j[30:0] is the byte mask. - If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored. Filter i Command: The 4-bit filter i command controls the filter i operation. - Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. - Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. - Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2". - Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. - Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled. Filter i Offset: This filter i offset register defines the offset (within the packet) from which the filter i examines the packets. - This 8-bit pattern-offset is the offset for the filter i first byte to be examined. - The minimum allowed offset is 12, which refers to the 13th byte of the packet. - The offset value 0 refers to the first byte of the packet. Filter i CRC-16: This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wake-up filter register block. - The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1 Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following: - 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
		If the bit is 1', the corresponding byte is taken into the CRC16 calculation. - 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations. - Note: If you are accessing these registers in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when CPU accesses Lane 3 (or Lane 0 in big-endian mode). - Note: When any Register content is being transferred to a different clock domain after a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Therefore, the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock). Notes on And_Previous bit setting The And_Previous bit setting is applicable within a set of 4 filters. - Setting of And_Previous bit of filter that is not enabled has no effect. In other words, setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect. - If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set) but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 2 is not enabled (bit 0 of in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered. - If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 of Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 of Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.	
D0h	MAC_LPI_Control_Status	The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
D4h	MAC_LPI_Timers_Control	The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.	Go
D8h	MAC_LPI_Entry_Timer	This register controls the Tx LPI entry timer. This counter is enabled only when bit[20](LPITE) bit of MAC_LPI_Control_Status is set to 1.	Go
DCh	MAC_1US_Tic_Counter	This register controls the generation of the Reference time (1 microsecond tic) for all the LPI timers. This timer has to be programmed by the software initially.	Go
110h	MAC_Version	The version register identifies the version of the DWC_ether_qos. This register contains two bytes: one that Synopsys uses to identify the core release number, and the other that you set while configuring the core.	Go
114h	MAC_Debug	The Debug register provides the debug status of various MAC blocks.	Go
11Ch	MAC_HW_Feature0	This register indicates the presence of first set of the optional features or functions of the DWC_ether_qos. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks. Note: All bits are set or reset according to the features selected while configuring the core in coreConsultant.	Go
120h	MAC_HW_Feature1	This register indicates the presence of second set of the optional features or functions of the DWC_ether_qos. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks. Note: All bits are set or reset according to the features selected while configuring the core in coreConsultant.	Go
124h	MAC_HW_Feature2	This register indicates the presence of third set of the optional features or functions of the DWC_ether_qos. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.	Go
128h	MAC_HW_Feature3	This register indicates the presence of fourth set the optional features or functions of the DWC_ether_qos. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.	Go
200h	MAC_MDIO_Address	The MDIO Address register controls the management cycles to external PHY through a management interface.	Go
204h	MAC_MDIO_Data	The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.	Go
210h	MAC_ARP_Address	The ARP Address register contains the IPv4 Destination Address of the MAC. Note: IP address should be written to this register in host byte order format.	Go
230h	MAC_CSR_SW_Ctrl	This register contains SW programmable controls for changing the CSR access response and status bits clearing.	Go
238h	MAC_Ext_Cfg1	This register contains Split mode control field and offset field for Split Header feature.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
300h	MAC_Address0_High	The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.	Go
304h	MAC_Address0_Low	The MAC Address0 Low register holds the lower 32 bits of the 6-byte first MAC address of the station.	Go
308h	MAC_Address1_High	The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.	Go
30Ch	MAC_Address1_Low	The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.	Go
310h	MAC_Address2_High	The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.	Go
314h	MAC_Address2_Low	The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.	Go
318h	MAC_Address3_High	The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.	Go
31Ch	MAC_Address3_Low	The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
320h	MAC_Address4_High	The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.	Go
324h	MAC_Address4_Low	The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.	Go
328h	MAC_Address5_High	The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.	Go
32Ch	MAC_Address5_Low	The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.	Go
330h	MAC_Address6_High	The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.	Go
334h	MAC_Address6_Low	The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.	Go
338h	MAC_Address7_High	The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.	Go
33Ch	MAC_Address7_Low	The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.	Go
700h	MMC_Control	This register establishes the operating mode of MMC.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
704h	MMC_Rx_Interrupt	This register maintains the interrupts generated from all Receive statistics counters. The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur: - Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter). - Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit. Note: R_SS_RC means that this register bit is set internally, and it is cleared when the Counter register is read.	Go
708h	MMC_Tx_Interrupt	This register maintains the interrupts generated from all Transmit statistics counters. The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.	Go
70Ch	MMC_Rx_Interrupt_Mask	This register maintains the masks for interrupts generated from all Receive statistics counters. The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.	Go
710h	MMC_Tx_Interrupt_Mask	This register maintains the masks for interrupts generated from all Transmit statistics counters. The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.	Go
714h	Tx_Octet_Count_Good_Bad	This register provides the number of bytes transmitted by the DWC_ether_qos, exclusive of preamble and retried bytes, in good and bad packets.	Go
718h	Tx_Packet_Count_Good_Bad	This register provides the number of good and bad packets transmitted by DWC_ether_qos, exclusive of retried packets.	Go
71Ch	Tx_Broadcast_Packets_Good	This register provides the number of good broadcast packets transmitted by DWC_ether_qos.	Go
720h	Tx_Multicast_Packets_Good	This register provides the number of good multicast packets transmitted by DWC_ether_qos.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
724h	Tx_64Octets_Packets_Good_Bad	This register provides the number of good and bad packets transmitted by DWC_ether_qos with length 64 bytes, exclusive of preamble and retried packets.	Go
728h	Tx_65To127Octets_Packets_Good_Bad	This register provides the number of good and bad packets transmitted by DWC_ether_qos with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried packets.	Go
72Ch	Tx_128To255Octets_Packets_Good_Bad	This register provides the number of good and bad packets transmitted by DWC_ether_qos with length between 128 to 255 (inclusive) bytes, exclusive of preamble and retried packets.	Go
730h	Tx_256To511Octets_Packets_Good_Bad	This register provides the number of good and bad packets transmitted by DWC_ether_qos with length between 256 to 511 (inclusive) bytes, exclusive of preamble and retried packets.	Go
734h	Tx_512To1023Octets_Packets_Good_Bad	This register provides the number of good and bad packets transmitted by DWC_ether_qos with length 512 to 1023 (inclusive) bytes, exclusive of preamble and retried packets.	Go
738h	Tx_1024ToMaxOctets_Packets_Good_Bad	This register provides the number of good and bad packets transmitted by DWC_ether_qos with length 1024 to maxsize (inclusive) bytes, exclusive of preamble and retried packets.	Go
73Ch	Tx_Unicast_Packets_Good_Bad	This register provides the number of good and bad unicast packets transmitted by DWC_ether_qos.	Go
740h	Tx_Multicast_Packets_Good_Bad	This register provides the number of good and bad multicast packets transmitted by DWC_ether_qos.	Go
744h	Tx_Broadcast_Packets_Good_Bad	This register provides the number of good and bad broadcast packets transmitted by DWC_ether_qos.	Go
748h	Tx_Underflow_Error_Packets	This register provides the number of packets aborted by DWC_ether_qos because of packets underflow error.	Go
74Ch	Tx_Single_Collision_Good_Packets	This register provides the number of successfully transmitted packets by DWC_ether_qos after a single collision in the half-duplex mode.	Go
750h	Tx_Multiple_Collision_Good_Packets	This register provides the number of successfully transmitted packets by DWC_ether_qos after multiple collisions in the half-duplex mode.	Go
754h	Tx_Deferred_Packets	This register provides the number of successfully transmitted by DWC_ether_qos after a deferral in the half-duplex mode.	Go
758h	Tx_Late_Collision_Packets	This register provides the number of packets aborted by DWC_ether_qos because of late collision error.	Go
75Ch	Tx_Excessive_Collision_Packets	This register provides the number of packets aborted by DWC_ether_qos because of excessive (16) collision errors.	Go
760h	Tx_Carrier_Error_Packets	This register provides the number of packets aborted by DWC_ether_qos because of carrier sense error (no carrier or loss of carrier).	Go
764h	Tx_Octet_Count_Good	This register provides the number of bytes transmitted by DWC_ether_qos, exclusive of preamble, only in good packets.	Go
768h	Tx_Packet_Count_Good	This register provides the number of good packets transmitted by DWC_ether_qos.	Go
76Ch	Tx_Excessive_Deferral_Error	This register provides the number of packets aborted by DWC_ether_qos because of excessive deferral error (deferred for more than two max-sized packet times).	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
770h	Tx_Pause_Packets	This register provides the number of good Pause packets transmitted by DWC_ether_qos.	Go
774h	Tx_VLAN_Packets_Good	This register provides the number of good VLAN packets transmitted by DWC_ether_qos.	Go
778h	Tx_OSize_Packets_Good	This register provides the number of packets transmitted by DWC_ether_qos without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in S2KP bit of the MAC_Configuration register).	Go
780h	Rx_Packets_Count_Good_Bad	This register provides the number of good and bad packets received by DWC_ether_qos.	Go
784h	Rx_Octet_Count_Good_Bad	This register provides the number of bytes received by DWC_ther_qos, exclusive of preamble, in good and bad packets.	Go
788h	Rx_Octet_Count_Good	This register provides the number of bytes received by DWC_ether_qos, exclusive of preamble, only in good packets.	Go
78Ch	Rx_Broadcast_Packets_Good	This register provides the number of good broadcast packets received by DWC_ether_qos.	Go
790h	Rx_Multicast_Packets_Good	This register provides the number of good multicast packets received by DWC_ether_qos.	Go
794h	Rx_CRC_Error_Packets	This register provides the number of packets received by DWC_ether_qos with CRC error.	Go
798h	Rx_Alignment_Error_Packets	This register provides the number of packets received by DWC_ether_qos with alignment (dribble) error. It is valid only in 10/100 mode.	Go
79Ch	Rx_Runt_Error_Packets	This register provides the number of packets received by DWC_ether_qos with runt (length less than 64 bytes and CRC error) error.	Go
7A0h	Rx_Jabber_Error_Packets	This register provides the number of giant packets received by DWC_ether_qos with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN tagged) are considered as giant packets.	Go
7A4h	Rx_Undersize_Packets_Good	This register provides the number of packets received by DWC_ether_qos with length less than 64 bytes, without any errors.	Go
7A8h	Rx_Oversize_Packets_Good	This register provides the number of packets received by DWC_ether_qos without errors, with length greater than the maxsize (1,518 bytes or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in the S2KP bit of the MAC_Configuration register).	Go
7ACh	Rx_64Octets_Packets_Good_Bad	This register provides the number of good and bad packets received by DWC_ether_qos with length 64 bytes, exclusive of the preamble.	Go
7B0h	Rx_65To127Octets_Packets_Good_Bad	This register provides the number of good and bad packets received by DWC_ether_qos with length between 65 and 127 (inclusive) bytes, exclusive of the preamble.	Go
7B4h	Rx_128To255Octets_Packets_Good_Bad	This register provides the number of good and bad packets received by DWC_ether_qos with length between 128 and 255 (inclusive) bytes, exclusive of the preamble.	Go
7B8h	Rx_256To511Octets_Packets_Good_Bad	This register provides the number of good and bad packets received by DWC_ether_qos with length between 256 and 511 (inclusive) bytes, exclusive of the preamble.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
7BCh	Rx_512To1023Octets_Packets_Good_Bad	This register provides the number of good and bad packets received by DWC_ether_qos with length between 512 and 1023 (inclusive) bytes, exclusive of the preamble.	Go
7C0h	Rx_1024ToMaxOctets_Packets_Good_Bad	This register provides the number of good and bad packets received by DWC_ether_qos with length between 1024 and maxsize (inclusive) bytes, exclusive of the preamble.	Go
7C4h	Rx_Unicast_Packets_Good	This register provides the number of good unicast packets received by DWC_ether_qos.	Go
7C8h	Rx_Length_Error_Packets	This register provides the number of packets received by DWC_ether_qos with length error (Length Type field not equal to packet size), for all packets with valid length field.	Go
7CCh	Rx_Out_Of_Range_Type_Packets	This register provides the number of packets received by DWC_ether_qos with length field not equal to the valid packet size (greater than 1,500 but less than 1,536).	Go
7D0h	Rx_Pause_Packets	This register provides the number of good and valid Pause packets received by DWC_ether_qos.	Go
7D4h	Rx_FIFO_Overflow_Packets	This register provides the number of missed received packets because of FIFO overflow in DWC_ether_qos.	Go
7D8h	Rx_VLAN_Packets_Good_Bad	This register provides the number of good and bad VLAN packets received by DWC_ether_qos.	Go
7DCh	Rx_Watchdog_Error_Packets	This register provides the number of packets received by DWC_ether_qos with error because of watchdog timeout error (packets with a data load larger than 2,048 bytes (when JE and WD bits are reset in MAC_Configuration register), 10,240 bytes (when JE bit is set and WD bit is reset in MAC_Configuration register), 16,384 bytes (when WD bit is set in MAC_Configuration register) or the value programmed in the MAC_Watchdog_Timeout register).	Go
7E0h	Rx_Receive_Error_Packets	This register provides the number of packets received by DWC_ether_qos with Receive error or Packet Extension error on the GMII or MII interface.	Go
7E4h	Rx_Control_Packets_Good	This register provides the number of good control packets received by DWC_ether_qos.	Go
7ECh	Tx_LPI_USEC_Cntr	This register provides the number of microseconds Tx LPI is asserted by DWC_ether_qos.	Go
7F0h	Tx_LPI_Tran_Cntr	This register provides the number of times DWC_ether_qos has entered Tx LPI.	Go
7F4h	Rx_LPI_USEC_Cntr	This register provides the number of microseconds Rx LPI is sampled by DWC_ether_qos.	Go
7F8h	Rx_LPI_Tran_Cntr	This register provides the number of times DWC_ether_qos has entered Rx LPI.	Go
800h	MMC_IPC_Rx_Interrupt_Mask	This register maintains the mask for the interrupt generated from the receive IPC statistic counters. The MMC Receive Checksum Off load Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Off load) statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
808h	MMC_IPC_Rx_Interrupt	This register maintains the interrupt that the receive IPC statistic counters generate. The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32 bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.	Go
810h	RxIPv4_Good_Packets	This register provides the number of good IPv4 datagrams received by DWC_ether_qos with the TCP, UDP, or ICMP payload.	Go
814h	RxIPv4_Header_Error_Packets	RxIPv4 Header Error Packets This register provides the number of IPv4 datagrams received by DWC_ether_qos with header (checksum, length, or version mismatch) errors.	Go
818h	RxIPv4_No_Payload_Packets	This register provides the number of IPv4 datagram packets received by DWC_ether_qos that did not have a TCP, UDP, or ICMP payload.	Go
81Ch	RxIPv4_Fragmented_Packets	This register provides the number of good IPv4 datagrams received by DWC_ether_qos with fragmentation.	Go
820h	RxIPv4_UDP_Checksum_Disabled_Packets	This register provides the number of good IPv4 datagrams received by DWC_ether_qos that had a UDP payload with checksum disabled.	Go
824h	RxIPv6_Good_Packets	This register provides the number of good IPv6 datagrams received by DWC_ether_qos with the TCP, UDP, or ICMP payload.	Go
828h	RxIPv6_Header_Error_Packets	This register provides the number of IPv6 datagrams received by DWC_ether_qos with header (length or version mismatch) errors.	Go
82Ch	RxIPv6_No_Payload_Packets	This register provides the number of IPv6 datagram packets received by DWC_ether_qos that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.	Go
830h	RxUDP_Good_Packets	This register provides the number of good IP datagrams received by DWC_ether_qos with a good UDP payload. This counter is not updated when the RxIPv4_UDP_Checksum_Disabled_Packets counter is incremented.	Go
834h	RxUDP_Error_Packets	This register provides the number of good IP datagrams received by DWC_ether_qos whose UDP payload has a checksum error.	Go
838h	RxTCP_Good_Packets	This register provides the number of good IP datagrams received by DWC_ether_qos with a good TCP payload.	Go
83Ch	RxTCP_Error_Packets	This register provides the number of good IP datagrams received by DWC_ether_qos whose TCP payload has a checksum error.	Go
840h	RxICMP_Good_Packets	This register provides the number of good IP datagrams received by DWC_ether_qos with a good ICMP payload.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
844h	RxICMP_Error_Packets	This register provides the number of good IP datagrams received by DWC_ether_qos whose ICMP payload has a checksum error.	Go
850h	RxIPv4_Good_Octets	This register provides the number of bytes received by DWC_ether_qos in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.	Go
854h	RxIPv4_Header_Error_Octets	This register provides the number of bytes received by DWC_ether_qos in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.	Go
858h	RxIPv4_No_Payload_Octets	This register provides the number of bytes received by DWC_ether_qos in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.	Go
85Ch	RxIPv4_Fragmented_Octets	This register provides the number of bytes received by DWC_ether_qos in fragmented IPv4 datagrams. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.	Go
860h	RxIPv4_UDP_Checksum_Disable_Octets	This register provides the number of bytes received by DWC_ether_qos in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.	Go
864h	RxIPv6_Good_Octets	This register provides the number of bytes received by DWC_ether_qos in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.	Go
868h	RxIPv6_Header_Error_Octets	This register provides the number of bytes received by DWC_ether_qos in IPv6 datagrams with header errors (length, version mismatch). The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.	Go
86Ch	RxIPv6_No_Payload_Octets	This register provides the number of bytes received by DWC_ether_qos in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.	Go
870h	RxUDP_Good_Octets	This register provides the number of bytes received by DWC_ether_qos in a good UDP segment. This counter does not count IP header bytes.	Go
874h	RxUDP_Error_Octets	This register provides the number of bytes received by DWC_ether_qos in a UDP segment that had checksum errors. This counter does not count IP header bytes.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
878h	RxTCP_Good_Octets	This register provides the number of bytes received by DWC_ether_qos in a good TCP segment. This counter does not count IP header bytes.	Go
87Ch	RxTCP_Error_Octets	This register provides the number of bytes received by DWC_ether_qos in a TCP segment that had checksum errors. This counter does not count IP header bytes.	Go
880h	RxICMP_Good_Octets	This register provides the number of bytes received by DWC_ether_qos in a good ICMP segment. This counter does not count IP header bytes.	Go
884h	RxICMP_Error_Octets	This register provides the number of bytes received by DWC_ether_qos in a ICMP segment that had checksum errors. This counter does not count IP header bytes.	Go
900h	MAC_L3_L4_Control0	The Layer 3 and Layer 4 Control register controls the operations of filter 0 of Layer 3 and Layer 4.	Go
904h	MAC_Layer4_Address0	The Layer 4 Address 0 register and registers 580 through 667 are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core. You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.	Go
910h	MAC_Layer3_Addr0_Reg0	For IPv4 packets, the Layer 3 Address 0 Register 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.	Go
914h	MAC_Layer3_Addr1_Reg0	For IPv4 packets, the Layer 3 Address 1 Register 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.	Go
918h	MAC_Layer3_Addr2_Reg0	The Layer 3 Address 2 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field.	Go
91Ch	MAC_Layer3_Addr3_Reg0	The Layer 3 Address 3 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field.	Go
930h	MAC_L3_L4_Control1	The Layer 3 and Layer 4 Control register controls the operations of filter 0 of Layer 3 and Layer 4.	Go

9A0h	MAC_Layer3_Addr0_Reg3	For IPv4 packets, the Layer 3 Address 0 Register 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.	Go
9A4h	MAC_Layer3_Addr1_Reg3	For IPv4 packets, the Layer 3 Address 1 Register 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.	Go
9A8h	MAC_Layer3_Addr2_Reg3	The Layer 3 Address 2 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field.	Go
9ACh	MAC_Layer3_Addr3_Reg3	The Layer 3 Address 3 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field.	Go
B00h	MAC_Timestamp_Control	This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.	Go
B04h	MAC_Sub_Second_Increment	This register specifies the value to be added to the internal system time register every cycle of clk_ptp_ref_i clock.	Go
B08h	MAC_System_Time_Seconds	The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).	Go
B0Ch	MAC_System_Time_Nanoseconds	The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
B10h	MAC_System_Time_Seconds_Update	The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in EMAC_REGS/EQOS_MAC/ MAC_Timestamp_Control.	Go
B14h	MAC_System_Time_Nanoseconds_Update	MAC System Time Nanoseconds Update register.	Go
B18h	MAC_Timestamp_Addend	Timestamp Addend register. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.	Go
B1Ch	MAC_System_Time_Higher_Word_Seconds	System Time - Higher Word Seconds register.	Go
B20h	MAC_Timestamp_Status	Timestamp Status register. All bits except Bits[27:25] gets cleared when the application reads this register.	Go
B30h	MAC_Tx_Timestamp_Status_Nanoseconds	This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled. The MAC_Tx_Timestamp_Status_Nanoseconds register, along with MAC_Tx_Timestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_Tx_Timestamp_Status_Nanoseconds is read. In the little-endian mode, this means when bits[31:24] are read; in big-endian mode, bits[7:0] are read. If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSC bit [15] in MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.	Go
B34h	MAC_Tx_Timestamp_Status_Seconds	The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.	Go
B40h	MAC_Auxiliary_Control	The Auxiliary Timestamp Control register controls the Auxiliary Timestamp snapshot.	Go
B48h	MAC_Auxiliary_Timestamp_Nanoseconds	The Auxiliary Timestamp Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4, 8, or 16 as selected while configuring the core. You can store multiple snapshots in this FIFO. Bits[29:25] in MAC_Timestamp_Status indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC Register 91 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read and in big-endian mode, Bits[7:0] are read.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
B4Ch	MAC_Auxiliary_Timestamp_Seconds	The Auxiliary Timestamp - Seconds register contains the lower 32 bits of the Seconds field of the auxiliary timestamp register.	Go
B50h	MAC_Timestamp_Ingress_Asym_Corr	The MAC Timestamp Ingress Asymmetry Correction register contains the Ingress Asymmetry Correction value to be used while updating correction field in PDelay_Resp PTP messages.	Go
B54h	MAC_Timestamp_Egress_Asym_Corr	The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.	Go
B58h	MAC_Timestamp_Ingress_Corr_Nanosecond	This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.	Go
B5Ch	MAC_Timestamp_Egress_Corr_Nanosecond	This register contains the correction value in nanoseconds to be used with the captured timestamp value in the egress path.	Go
B60h	MAC_Timestamp_Ingress_Corr_Subnanosec	This register contains the sub-nanosecond part of the correction value to be used with the captured timestamp value, for ingress direction.	Go
B64h	MAC_Timestamp_Egress_Corr_Subnanosec	This register contains the sub-nanosecond part of the correction value to be used with the captured timestamp value, for egress direction.	Go
B70h	MAC_PPS_Control	PPS Control register. Bits[30:24] of this register are valid only when four Flexible PPS outputs are selected. Bits[22:16] are valid only when three or more Flexible PPS outputs are selected. Bits[14:8] are valid only when two or more Flexible PPS outputs are selected. Bits[6:4] are valid only when Flexible PPS feature is selected.	Go
B80h	MAC_PPS0_Target_Time_Seconds	The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.	Go
B84h	MAC_PPS0_Target_Time_Nanoseconds	PPS0 Target Time Nanoseconds register.	Go
B88h	MAC_PPS0_Interval	The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).	Go
B8Ch	MAC_PPS0_Width	The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).	Go
B90h	MAC_PPS1_Target_Time_Seconds	The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.	Go
B94h	MAC_PPS1_Target_Time_Nanoseconds	PPS0 Target Time Nanoseconds register.	Go
B98h	MAC_PPS1_Interval	The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).	Go
B9Ch	MAC_PPS1_Width	The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
BC0h	MAC_PTO_Control	This register controls the PTP Offload Engine operation. This register is available only when the Enable PTP Timestamp Offload feature is selected.	Go
BC4h	MAC_Source_Port_Identity0	This register contains Bits[31:0] of the 80-bit Source Port Identity of the PTP node. This register is available only when the Enable PTP Timestamp Offload feature is selected.	Go
BC8h	MAC_Source_Port_Identity1	This register contains Bits[63:32] of the 80-bit Source Port Identity of the PTP node. This register is available only when the Enable PTP Timestamp Offload feature is selected.	Go
BCCh	MAC_Source_Port_Identity2	This register contains Bits[79:64] of the 80-bit Source Port Identity of the PTP node. This register is available only when the Enable PTP Timestamp Offload feature is selected.	Go
BD0h	MAC_Log_Message_Interval	This register contains the periodic intervals for automatic PTP packet generation. This register is available only when the Enable PTP Timestamp Offload feature is selected.	Go
C00h	MTL_Operation_Mode	The Operation Mode register establishes the Transmit and Receive operating modes and commands.	Go
C08h	MTL_DBG_CTL	The FIFO Debug Access Control and Status register controls the operation mode of FIFO debug access.	Go
C0Ch	MTL_DBG_STS	The FIFO Debug Status register contains the status of FIFO debug access.	Go
C10h	MTL_FIFO_Debug_Data	The FIFO Debug Data register contains the data to be written to or read from the FIFOs.	Go
C20h	MTL_Interrupt_Status	The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.	Go
C30h	MTL_RxQ_DMA_Map0	The Receive Queue and DMA Channel Mapping 0 register is reserved in EQOS-CORE and EQOS-MTL configurations.	Go
D00h	MTL_TxQ0_Operation_Mode	The Queue 0 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.	Go
D04h	MTL_TxQ0_Underflow	The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush	Go
D08h	MTL_TxQ0_Debug	The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.	Go
D14h	MTL_TxQ0_ETS_Status	The Queue 0 ETS Status register provides the average traffic transmitted in Queue 0.	Go
D18h	MTL_TxQ0_Quantum_Weight	The Queue 0 Quantum or Weights register contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for Queue 0.	Go
D2Ch	MTL_Q0_Interrupt_Control_Status	This register contains the interrupt enable and status bits for the queue 0 interrupts.	Go
D30h	MTL_RxQ0_Operation_Mode	The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
D34h	MTL_RxQ0_Missed_Packet_Overflow_Cnt	The Queue 0 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.	Go
D38h	MTL_RxQ0_Debug	The Queue 0 Receive Debug register gives the debug status of various blocks related to the Receive queue.	Go
D3Ch	MTL_RxQ0_Control	The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.	Go
D40h	MTL_TxQ1_Operation_Mode	The Queue 1 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.	Go
D44h	MTL_TxQ1_Underflow	The Queue 1 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush	Go
D48h	MTL_TxQ1_Debug	The Queue 1 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.	Go
D54h	MTL_TxQ1_ETS_Status	The Queue 1 ETS Status register provides the average traffic transmitted in Queue 1.	Go
D58h	MTL_TxQ1_Quantum_Weight	The Queue 1 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 1.	Go
D6Ch	MTL_Q1_Interrupt_Control_Status	This register contains the interrupt enable and status bits for the queue 1 interrupts.	Go
D70h	MTL_RxQ1_Operation_Mode	The Queue 1 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release	Go
D74h	MTL_RxQ1_Missed_Packet_Overflow_Cnt	The Queue 1 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.	Go
D78h	MTL_RxQ1_Debug	The Queue 1 Receive Debug register gives the debug status of various blocks related to the Receive queue.	Go
D7Ch	MTL_RxQ1_Control	The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.	Go
1000h	DMA_Mode	The Bus Mode register establishes the bus operating modes for the DMA.	Go
1004h	DMA_SysBus_Mode	The System Bus mode register controls the behavior of the AHB or AXI master. It mainly controls burst splitting and number of outstanding requests.	Go
1008h	DMA_Interrupt_Status	The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.	Go
100Ch	DMA_Debug_Status0	The Debug Status 0 register gives the Receive and Transmit process status for DMA Channel 0-Channel 2 for debugging purpose.	Go
1100h	DMA_CH0_Control	The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
1104h	DMA_CH0_Tx_Control	The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.	Go
1108h	DMA_CH0_Rx_Control	The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.	Go
1114h	DMA_CH0_TxDesc_List_Address	The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.	Go
111Ch	DMA_CH0_RxDesc_List_Address	The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.	Go
1120h	DMA_CH0_TxDesc_Tail_Pointer	The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.	Go
1128h	DMA_CH0_RxDesc_Tail_Pointer	The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.	Go
112Ch	DMA_CH0_TxDesc_Ring_Length	The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.	Go
1130h	DMA_CH0_RxDesc_Ring_Length	The Channeli Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.	Go
1134h	DMA_CH0_Interrupt_Enable	The Channeli Interrupt Enable register enables the interrupts reported by the Status register.	Go
1138h	DMA_CH0_Rx_Interrupt_Watchdog_Timer	The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
1144h	DMA_CH0_Current_App_TxDesc	The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.	Go
114Ch	DMA_CH0_Current_App_RxDesc	The Channeli Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.	Go
1154h	DMA_CH0_Current_App_TxBuffer	The Channeli Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.	Go
115Ch	DMA_CH0_Current_App_RxBuffer	The Channel 0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.	Go
1160h	DMA_CH0_Status	The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH[n]_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.	Go
1164h	DMA_CH0_Miss_Frame_Cnt	This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.	Go
116Ch	DMA_CH0_RX_ERI_Cnt		Go
1180h	DMA_CH1_Control	The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.	Go
1184h	DMA_CH1_Tx_Control	The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.	Go
1188h	DMA_CH1_Rx_Control	The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.	Go
1194h	DMA_CH1_TxDesc_List_Address	The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.	Go

Offset	Acronym	Register Name	Section
119Ch	DMA_CH1_RxDesc_List_Address	The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.	Go
11A0h	DMA_CH1_TxDesc_Tail_Pointer	The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.	Go
11A8h	DMA_CH1_RxDesc_Tail_Pointer	The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.	Go
11ACh	DMA_CH1_TxDesc_Ring_Length	The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.	Go
11B0h	DMA_CH1_RxDesc_Ring_Length	The Channeli Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.	Go
11B4h	DMA_CH1_Interrupt_Enable	The Channeli Interrupt Enable register enables the interrupts reported by the Status register.	Go
11B8h	DMA_CH1_Rx_Interrupt_Watchdog_Timer	The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.	Go
11C4h	DMA_CH1_Current_App_TxDesc	The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.	Go
11CCh	DMA_CH1_Current_App_RxDesc	The Channeli Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.	Go
11D4h	DMA_CH1_Current_App_TxBuffer	The Channeli Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.	Go
11DCh	DMA_CH1_Current_App_RxBuffer	The Channel 0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.	Go
11E0h	DMA_CH1_Status	The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH[n]_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.	Go
11E4h	DMA_CH1_Miss_Frame_Cnt	This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.	Go

Table 43-92. EMAC_REGS Registers (continued)

Offset	Acronym	Register Name	Section
11ECh	DMA_CH1_RX_ERI_Cnt		Go

Complex bit access types are encoded to fit into small table cells. Table 43-93 shows the codes that are used for access types in this section.

Table 43-93. EMAC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

43.7.3.1 MAC_Configuration Register (Offset = 0h) [Reset = 8000h]

MAC_Configuration is shown in Figure 43-40 and described in Table 43-94.

Return to the Summary Table.

The MAC Configuration Register establishes the operating mode of the MAC.

Table 43-94. MAC_Configuration Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ARPEN	R/W	0h	ARP Offload Enable When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus. This bit is available only when the Enable IPv4 ARP Offload is selected. 0h = ARP Offload is disabled : 0x0 1h = ARP Offload is enabled : 0x1

Table 43-94. MAC_Configuration Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
30-28	SARC	R/W	0h	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: 2'b0x: - The SA Insertion control is to be programmed in Bits[25:23] of TDES3 in first Transmit Descriptor of the packet. 2'b10: - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. Note: - Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 0h = mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation : 0x0 2h = Contents of MAC Addr-0 inserted in SA field : 0x2 3h = Contents of MAC Addr-0 replaces SA field : 0x3 6h = Contents of MAC Addr-1 inserted in SA field : 0x6 7h = Contents of MAC Addr-1 replaces SA field : 0x7
27	IPC	R/W	0h	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0h = IP header/payload checksum checking is disabled : 0x0 1h = IP header/payload checksum checking is enabled : 0x1
26-24	IPG	R/W	0h	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. 0h = 96 bit times IPG : 0x0 1h = 88 bit times IPG : 0x1 2h = 80 bit times IPG : 0x2 3h = 72 bit times IPG : 0x3 4h = 64 bit times IPG : 0x4 5h = 56 bit times IPG : 0x5 6h = 48 bit times IPG : 0x6 7h = 40 bit times IPG : 0x7

Table 43-94. MAC_Configuration Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
23	GPSLCE	R/W	0h	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0h = Giant Packet Size Limit Control is disabled : 0x0 1h = Giant Packet Size Limit Control is enabled : 0x1
22	S2KP	R/W	0h	IEEE 802.3as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see the Table, Gaint Packet Status based on S2KP and JE Bits. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. 0h = Support upto 2K packet is disabled : 0x0 1h = Support upto 2K packet is Enabled : 0x1
21	CST	R/W	0h	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. Note: For information about how the settings of the ACS bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bits. 0h = CRC stripping for Type packets is disabled : 0x0 1h = CRC stripping for Type packets is enabled : 0x1
20	ACS	R/W	0h	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. Note: For information about how the settings of CST bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bit . 0h = Automatic Pad or CRC Stripping is disabled : 0x0 1h = Automatic Pad or CRC Stripping is enabled : 0x1
19	WD	R/W	0h	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0h = Watchdog is enabled : 0x0 1h = Watchdog is disabled : 0x1

Table 43-94. MAC_Configuration Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	RESERVED	R	0h	Reserved.
17	JD	R/W	0h	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0h = Jabber is enabled : 0x0 1h = Jabber is disabled : 0x1
16	JE	R/W	0h	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0h = Jumbo packet is disabled : 0x0 1h = Jumbo packet is enabled : 0x1
15	PS	R	1h	Port Select This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read-write (R/W). The mac_speed_o[1] signal reflects the value of this bit. 0h = For 1000 or 2500 Mbps operations : 0x0 1h = For 10 or 100 Mbps operations : 0x1
14	FES	R/W	0h	Speed This bit selects the speed mode. The mac_speed_o[0] signal reflects the value of this bit. 0h = 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 : 0x0 1h = 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0 : 0x1
13	DM	R/W	0h	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configurations. 0h = Half-duplex mode : 0x0 1h = Full-duplex mode : 0x1
12	LM	R/W	0h	Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. 0h = Loopback is disabled : 0x0 1h = Loopback is enabled : 0x1
11	ECRSFD	R/W	0h	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0h = ECRSFD is disabled : 0x0 1h = ECRSFD is enabled : 0x1
10	DO	R/W	0h	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0h = Enable Receive Own : 0x0 1h = Disable Receive Own : 0x1

Table 43-94. MAC_Configuration Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	DCRS	R/W	0h	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0h = Enable Carrier Sense During Transmission : 0x0 1h = Disable Carrier Sense During Transmission : 0x1
8	DR	R/W	0h	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0h = Enable Retry : 0x0 1h = Disable Retry : 0x1
7	RESERVED	R	0h	Reserved.
6-5	BL	R/W	0h	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. 0h = k = min(n,10) : 0x0 1h = k = min(n,8) : 0x1 2h = k = min(n,4) : 0x2 3h = k = min(n,1) : 0x3
4	DC	R/W	0h	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0h = Deferral check function is disabled : 0x0 1h = Deferral check function is enabled : 0x1
3-2	PRELEN	R/W	0h	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 0h = 7 bytes of preamble : 0x0 1h = 5 bytes of preamble : 0x1 2h = 3 bytes of preamble : 0x2 3h = Reserved : 0x3

Table 43-94. MAC_Configuration Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	TE	R/W	0h	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. 0h = Transmitter is disabled : 0x0 1h = Transmitter is enabled : 0x1
0	RE	R/W	0h	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or MII interface. 0h = Receiver is disabled : 0x0 1h = Receiver is enabled : 0x1

43.7.3.2 MAC_Ext_Configuration Register (Offset = 4h) [Reset = 0h]

MAC_Ext_Configuration is shown in Figure 43-41 and described in Table 43-95.

Return to the Summary Table.

The MAC Extended Configuration Register establishes the operating mode of the MAC.

Figure 43-41. MAC_Ext_Configuration Register

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	Reserved.
29-25	EIPG	R/W	0h	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in MAC_Configuration register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
24	EIPGEN	R/W	0h	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in MAC_Configuration register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in MAC_Configuration register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. 0h = Extended Inter-Packet Gap is disabled : 0x0 1h = Extended Inter-Packet Gap is enabled : 0x1
23	RESERVED	R	0h	Reserved.
22-20	HDSMS	R/W	0h	Maximum Size for Splitting the Header Data These bits indicate the maximum header size allowed for splitting the header data in the received packet. 0h = Maximum Size for Splitting the Header Data is 64 bytes : 0x0 1h = Maximum Size for Splitting the Header Data is 128 bytes : 0x1 2h = Maximum Size for Splitting the Header Data is 256 bytes : 0x2 3h = Maximum Size for Splitting the Header Data is 512 bytes : 0x3 4h = Maximum Size for Splitting the Header Data is 1024 bytes : 0x4 5h = Reserved : 0x5

Table 43-95. MAC_Ext_Configuration Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	RESERVED	R	0h	Reserved.
18	USP	R/W	0h	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5. 0h = Unicast Slow Protocol Packet Detection is disabled : 0x0 1h = Unicast Slow Protocol Packet Detection is enabled : 0x1
17	SPEN	R/W	0h	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. 0h = Slow Protocol Detection is disabled : 0x0 1h = Slow Protocol Detection is enabled : 0x1
16	DCRCC	R/W	0h	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. 0h = CRC Checking is enabled : 0x0 1h = CRC Checking is disabled : 0x1
15-14	RESERVED	R	0h	Reserved.
13-0	GPSL	R/W	0h	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.

43.7.3.3 MAC_Packet_Filter Register (Offset = 8h) [Reset = 0h]

MAC_Packet_Filter is shown in Figure 43-42 and described in Table 43-96.

Return to the Summary Table.

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Table 43-96. MAC_Packet_Filter Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RA	R/W	0h	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter. 0h = Receive All is disabled : 0x0 1h = Receive All is enabled : 0x1
30-22	RESERVED	R	0h	Reserved.
21	DNTU	R/W	0h	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets. 0h = Forward Non-TCP/UDP over IP Packets : 0x0 1h = Drop Non-TCP/UDP over IP Packets : 0x1
20	IPFE	R/W	0h	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields. 0h = Layer 3 and Layer 4 Filters are disabled : 0x0 1h = Layer 3 and Layer 4 Filters are enabled : 0x1
19-17	RESERVED	R	0h	Reserved.

Table 43-96. MAC_Packet_Filter Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	VTFE	R/W	0h	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag. 0h = VLAN Tag Filter is disabled : 0x0 1h = VLAN Tag Filter is enabled : 0x1
15-11	RESERVED	R	0h	Reserved.
10	HPF	R/W	0h	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. 0h = Hash or Perfect Filter is disabled : 0x0 1h = Hash or Perfect Filter is enabled : 0x1
9	SAF	R/W	0h	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. Note: According to the IEEE specification, Bit 47 of the SA is reserved. However, in DWC_ether_qos, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA. 0h = SA Filtering is disabled : 0x0 1h = SA Filtering is enabled : 0x1
8	SAIF	R/W	0h	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter. 0h = SA Inverse Filtering is disabled : 0x0 1h = SA Inverse Filtering is enabled : 0x1
7-6	PCF	R/W	0h	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 0h = MAC filters all control packets from reaching the application : 0x0 1h = MAC forwards all control packets except Pause packets to the application even if they fail the Address filter : 0x1 2h = MAC forwards all control packets to the application even if they fail the Address filter : 0x2 3h = MAC forwards the control packets that pass the Address filter : 0x3
5	DBF	R/W	0h	Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. 0h = Enable Broadcast Packets : 0x0 1h = Disable Broadcast Packets : 0x1

Table 43-96. MAC_Packet_Filter Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	PM	R/W	0h	Pass All Multicast When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. 0h = Pass All Multicast is disabled : 0x0 1h = Pass All Multicast is enabled : 0x1
3	DAIF	R/W	0h	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. 0h = DA Inverse Filtering is disabled : 0x0 1h = DA Inverse Filtering is enabled : 0x1
2	HMC	R/W	0h	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0h = Hash Multicast is disabled : 0x0 1h = Hash Multicast is enabled : 0x1
1	HUC	R/W	0h	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers. 0h = Hash Unicast is disabled : 0x0 1h = Hash Unicast is enabled : 0x1
0	PR	R/W	0h	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set. 0h = Promiscuous Mode is disabled : 0x0 1h = Promiscuous Mode is enabled : 0x1

43.7.3.4 MAC_Watchdog_Timeout Register (Offset = Ch) [Reset = 0h]

MAC_Watchdog_Timeout is shown in Figure 43-43 and described in Table 43-97.

Return to the Summary Table.

The Watchdog Timeout register controls the watchdog timeout for received packets.

Figure 43-43. MAC_Watchdog_Timeout Register

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved.
8	PWE	R/W	0h	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_Configuration register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_Configuration register. 0h = Programmable Watchdog is disabled : 0x0 1h = Programmable Watchdog is enabled : 0x1
7-4	RESERVED	R	0h	Reserved.
3-0	WTO	R/W	0h	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_Configuration register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped. 0h = 2 KB : 0x0 1h = 3 KB : 0x1 2h = 4 KB : 0x2 3h = 5 KB : 0x3 4h = 6 KB : 0x4 5h = 7 KB : 0x5 6h = 8 KB : 0x6 7h = 9 KB : 0x7 8h = 10 KB : 0x8 9h = 11 KB : 0x9 Ah = 12 KB : 0xa Bh = 13 KB : 0xb Ch = 14 KB : 0xc Dh = 15 KB : 0xd Eh = 16383 Bytes : 0xe Fh = Reserved : 0xf

43.7.3.5 MAC_Hash_Table_Reg0 Register (Offset = 10h) [Reset = 0h]

MAC_Hash_Table_Reg0 is shown in Figure 43-44 and described in Table 43-98.

Return to the Summary Table.

The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 128 or 256 bits. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant. The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.
The hash value of the destination address is calculated in the following way:
- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.
If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.
If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Bit	Field	Type	Reset	Description
31-0	HT31T0	R/W	0h	MAC Hash Table First 32 Bits This field contains the first 32 Bits [31:0] of the Hash table.

43.7.3.6 MAC_Hash_Table_Reg1 Register (Offset = 14h) [Reset = 0h]

MAC_Hash_Table_Reg1 is shown in Figure 43-45 and described in Table 43-99.

Return to the Summary Table.

The Hash Table Register 1 contains the second 32 bits of the hash table. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant.
The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.
The hash value of the destination address is calculated in the following way:
- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.
If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.
If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.
If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

43.7.3.7 MAC_VLAN_Tag_Ctrl Register (Offset = 50h) [Reset = 0h]

MAC_VLAN_Tag_Ctrl is shown in Figure 43-46 and described in Table 43-100.

Return to the Summary Table.

This register is the redefined format of the MAC VLAN Tag Register. It is used for indirect addressing. It contains the address offset, command type and Busy Bit for CSR access of the Per VLAN Tag registers.

Table 43-100. MAC_VLAN_Tag_Ctrl Register Field Descriptions

Bit	Field	Type	Reset	Description
31	EIVLRXS	R/W	0h	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status. 0h = Inner VLAN Tag in Rx status is disabled : 0x0 1h = Inner VLAN Tag in Rx status is enabled : 0x1
30	RESERVED	R	0h	Reserved.
29-28	EIVLS	R/W	0h	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet. 0h = Do not strip : 0x0 1h = Strip if VLAN filter passes : 0x1 2h = Strip if VLAN filter fails : 0x2 3h = Always strip : 0x3
27	ERIVLT	R/W	0h	
26	EDVLP	R/W	0h	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present). 0h = Double VLAN Processing is disabled : 0x0 1h = Double VLAN Processing is enabled : 0x1
25	VTHM	R/W	0h	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed. 0h = VLAN Tag Hash Table Match is disabled : 0x0 1h = VLAN Tag Hash Table Match is enabled : 0x1

Table 43-100. MAC_VLAN_Tag_Ctrl Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
24	EVLRXS	R/W	0h	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status. 0h = VLAN Tag in Rx status is disabled : 0x0 1h = VLAN Tag in Rx status is enabled : 0x1
23	RESERVED	R	0h	Reserved.
22-21	EVLS	R/W	0h	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet. 0h = Do not strip : 0x0 1h = Strip if VLAN filter passes : 0x1 2h = Strip if VLAN filter fails : 0x2 3h = Always strip : 0x3
20-19	RESERVED	R	0h	Reserved.
18	ESVL	R/W	0h	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets. 0h = S-VLAN is disabled : 0x0 1h = S-VLAN is enabled : 0x1
17	VTIM	R/W	0h	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched. 0h = VLAN Tag Inverse Match is disabled : 0x0 1h = VLAN Tag Inverse Match is enabled : 0x1
16-7	RESERVED	R	0h	Reserved.
6-2	OFS	R/W	0h	Offset This field holds the address offset of the MAC VLAN Tag Filter Register which the application is trying to access. The width of the field depends on the number of MAC VLAN Tag Registers enabled.
1	CT	R/W	0h	Command Type This bit indicates if the current register access is a read or a write. When set, it indicate a read operation. When reset, it indicates a write operation. 0h = Write operation : 0x0 1h = Read operation : 0x1
0	OB	R/W	0h	Operation Busy This bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. This bit is reset when the read or write command to per VLAN Tag Filter indirect access register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register. During a read operation, the data should be read from the MAC_VLAN_Tag_Data register only after this bit is reset. 0h = Operation Busy is disabled : 0x0 1h = Operation Busy is enabled : 0x1

43.7.3.8 MAC_VLAN_Tag_Data Register (Offset = 54h) [Reset = 0h]

MAC_VLAN_Tag_Data is shown in Figure 43-47 and described in Table 43-101.

Return to the Summary Table.

This register holds the read/write data for Indirect Access of the Per VLAN Tag registers. During the read access, this field contains valid read data only after the OB bit is reset.
During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl Register.

31-26	RESERVED	R	0h	Reserved.
25	DMACHN	R/W	0h	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.
24	DMACHEN	R/W	0h	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing. 0h = DMA Channel Number is disabled : 0x0 1h = DMA Channel Number is enabled : 0x1
23-21	RESERVED	R	0h	Reserved.
20	ERIVLT	R/W	0h	Enable Inner VLAN Tag Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). 0h = Inner VLAN tag comparision is disabled : 0x0 1h = Inner VLAN tag comparision is enabled : 0x1
19	ERSVLM	R/W	0h	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. 0h = Receive S-VLAN Match is disabled : 0x0 1h = Receive S-VLAN Match is enabled : 0x1

Table 43-101. MAC_VLAN_Tag_Data Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	DOVLTC	R/W	0h	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit. 0h = VLAN type comparision is enabled : 0x0 1h = VLAN type comparision is disabled : 0x1
17	ETV	R/W	0h	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0h = 16 bit VLAN comparision : 0x0 1h = 12 bit VLAN comparision : 0x1
16	VEN	R/W	0h	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields. 0h = VLAN Tag is disabled : 0x0 1h = VLAN Tag is enabled : 0x1
15-0	VID	R/W	0h	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

43.7.3.9 MAC_VLAN_Hash_Table Register (Offset = 58h) [Reset = 0h]

MAC_VLAN_Hash_Table is shown in Figure 43-48 and described in Table 43-102.

Return to the Summary Table.

When VTHM bit of the MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table.
The hash value of the destination address is calculated in the following way:
- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).
- Perform bitwise reversal for the value obtained in step 1.
- Take the upper four bits from the value obtained in step 2.
If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.
- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Table 43-103. MAC_VLAN_Incl Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BUSY	R	0h	Busy This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when this bit is reset. For read operation the read data is valid when the bit is reset. The application must make sure that this bit is reset before attempting subsequent access to this register. 0h = Busy status not detected : 0x0 1h = Busy status detected : 0x1
30	RDWR	R/W	0h	Read write control This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation. This does not have any effect when CBTI is reset. 0h = Read operation of indirect access : 0x0 1h = Write operation of indirect access : 0x1
29-25	RESERVED	R	0h	Reserved.
24	ADDR	R/W	0h	Address This field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.
23-22	RESERVED	R	0h	Reserved.

Table 43-103. MAC_VLAN_Incl Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
21	CBTI	R/W	0h	Channel based tag insertion When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/ channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register. 0h = Channel based tag insertion is disabled : 0x0 1h = Channel based tag insertion is enabled : 0x1
20	VLTI	R/W	0h	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: - The Tx descriptor 0h = VLAN Tag Input is disabled : 0x0 1h = VLAN Tag Input is enabled : 0x1
19	CSVL	R/W	0h	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. 0h = C-VLAN type (0x8100) is inserted or replaced : 0x0 1h = S-VLAN type (0x88A8) is inserted or replaced : 0x1
18	VLP	R/W	0h	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored. 0h = VLAN Priority Control is disabled : 0x0 1h = VLAN Priority Control is enabled : 0x1
17-16	VLC	R/W	0h	VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. - 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. - 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 0h = No VLAN tag deletion, insertion, or replacement : 0x0 1h = VLAN tag deletion : 0x1 2h = VLAN tag insertion : 0x2 3h = VLAN tag replacement : 0x3
15-0	VLT	R/W	0h	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

43.7.3.11 MAC_Inner_VLAN_Incl Register (Offset = 64h) [Reset = 0h]

MAC_Inner_VLAN_Incl is shown in Figure 43-50 and described in Table 43-104.

Return to the Summary Table.

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

43.7.3.12 MAC_Q0_Tx_Flow_Ctrl Register (Offset = 70h) [Reset = 0h]

MAC_Q0_Tx_Flow_Ctrl is shown in Figure 43-51 and described in Table 43-105.

Return to the Summary Table.

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.
When the PFCE bit in the MAC_Rx_Flow_Ctrl register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_RxQ_Ctrl2 register.

When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. 0h = Zero-Quanta Pause packet generation is enabled : 0x0 1h = Zero-Quanta Pause packet generation is disabled : 0x1

Table 43-105. MAC_Q0_Tx_Flow_Ctrl Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6-4	PLT	R/W	0h	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. 0h = Pause Time minus 4 Slot Times (PT -4 slot times) : 0x0 1h = Pause Time minus 28 Slot Times (PT -28 slot times) : 0x1 2h = Pause Time minus 36 Slot Times (PT -36 slot times) : 0x2 3h = Pause Time minus 144 Slot Times (PT -144 slot times) : 0x3 4h = Pause Time minus 256 Slot Times (PT -256 slot times) : 0x4 5h = Pause Time minus 512 Slot Times (PT -512 slot times) : 0x5 6h = Reserved : 0x6
3-2	RESERVED	R	0h	Reserved.
1	TFE	R/W	0h	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled. 0h = Transmit Flow Control is disabled : 0x0 1h = Transmit Flow Control is enabled : 0x1
0	FCB_BPA	R/W	0h	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Flow Control Busy or Backpressure Activate is disabled : 0x0 1h = Flow Control Busy or Backpressure Activate is enabled : 0x1

43.7.3.13 MAC_Rx_Flow_Ctrl Register (Offset = 90h) [Reset = 0h]

MAC_Rx_Flow_Ctrl is shown in Figure 43-52 and described in Table 43-106.

Return to the Summary Table.

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved.
8	RESERVED	R	0h	Reserved.
7-2	RESERVED	R	0h	Reserved.
1	UP	R/W	0h	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_Address0_High and MAC_Address0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address. Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011. 0h = Unicast Pause Packet Detect disabled : 0x0 1h = Unicast Pause Packet Detect enabled : 0x1
0	RFE	R/W	0h	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time. 0h = Receive Flow Control is disabled : 0x0 1h = Receive Flow Control is enabled : 0x1

43.7.3.14 MAC_RxQ_Ctrl4 Register (Offset = 94h) [Reset = 0h]

MAC_RxQ_Ctrl4 is shown in Figure 43-53 and described in Table 43-107.

Return to the Summary Table.

The Receive Queue Control 4 register controls the routing of unicast and multicast packets that fail the Destination or Source address filter to the Rx queues.

15	RESERVED	R	0h	Reserved.
14	RXSTSIS	R	0h	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_Rx_Tx_Status register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register. 0h = Receive Interrupt status not active : 0x0 1h = Receive Interrupt status active : 0x1

Table 43-111. MAC_Interrupt_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	TXSTSIS	R	0h	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_Rx_Tx_Status register: - Excessive Collision (EXCOL) - Late Collision (LCOL) - Excessive Deferral (EXDEF) - Loss of Carrier (LCARR) - No Carrier (NCARR) - Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register. 0h = Transmit Interrupt status not active : 0x0 1h = Transmit Interrupt status active : 0x1
12	TSIS	R	0h	Timestamp Interrupt Status If the Timestamp feature is enabled, this bit is set when any of the following conditions is true: - The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. - There is an overflow in the Seconds register. - The Target Time Error occurred, that is, programmed target time already elapsed. If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted. In configurations other than EQOS_CORE, when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and Mac_TxTimestamp_Status_Seconds registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers, for PTO generated Delay Request and Pdelay request packets. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Timestamp_Status register. 0h = Timestamp Interrupt status not active : 0x0 1h = Timestamp Interrupt status active : 0x1
11	MMCRXIPIS	R	0h	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) and Enable Receive TCP/IP Checksum Check options. 0h = MMC Receive Checksum Offload Interrupt status not active : 0x0 1h = MMC Receive Checksum Offload Interrupt status active : 0x1
10	MMCTXIS	R	0h	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0h = MMC Transmit Interrupt status not active : 0x0 1h = MMC Transmit Interrupt status active : 0x1

Table 43-111. MAC_Interrupt_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	MMCRXIS	R	0h	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0h = MMC Receive Interrupt status not active : 0x0 1h = MMC Receive Interrupt status active : 0x1
8	MMCIS	R	0h	MMC Interrupt Status This bit is set high when Bit 11, Bit 10, or Bit 9 is set high. This bit is cleared only when all these bits are low. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0h = MMC Interrupt status not active : 0x0 1h = MMC Interrupt status active : 0x1
7-6	RESERVED	R	0h	Reserved.
5	LPIIS	R	0h	LPI Interrupt Status When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the corresponding interrupt source bit of MAC_LPI_Control_Status register is read (or corresponding interrupt source bit of MAC_LPI_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). 0h = LPI Interrupt status not active : 0x0 1h = LPI Interrupt status active : 0x1
4	PMTIS	R	0h	PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_Control_Status register). This bit is cleared when corresponding interrupt source bit are cleared because of a Read operation to the MAC_PMT_Control_Status register (or corresponding interrupt source bit of MAC_PMT_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). This bit is valid only when you select the Enable Power Management option. 0h = PMT Interrupt status not active : 0x0 1h = PMT Interrupt status active : 0x1
3	PHYIS	R	0h	PHY Interrupt This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read (or this bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). 0h = PHY Interrupt not detected : 0x0 1h = PHY Interrupt detected : 0x1

Table 43-113. MAC_Rx_Tx_Status Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved.
8	RWT	R	0h	Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = No receive watchdog timeout : 0x0 1h = Receive watchdog timed out : 0x1
7-6	RESERVED	R	0h	Reserved.
5	EXCOL	R	0h	Excessive Collisions When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = No collision : 0x0 1h = Excessive collision is sensed : 0x1

Table 43-113. MAC_Rx_Tx_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	LCOL	R	0h	Late Collision When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode 512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = No collision : 0x0 1h = Late collision is sensed : 0x1
3	EXDEF	R	0h	Excessive Deferral When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the MAC_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = No Excessive deferral : 0x0 1h = Excessive deferral : 0x1
2	LCARR	R	0h	Loss of Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = Carrier is present : 0x0 1h = Loss of carrier : 0x1
1	NCARR	R	0h	No Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = Carrier is present : 0x0 1h = No carrier : 0x1
0	TJT	R	0h	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = No Transmit Jabber Timeout : 0x0 1h = Transmit Jabber Timeout occured : 0x1

43.7.3.21 MAC_PMT_Control_Status Register (Offset = C0h) [Reset = 0h]

MAC_PMT_Control_Status is shown in Figure 43-60 and described in Table 43-114.

Return to the Summary Table.

The PMT Control and Status Register.

Table 43-114. MAC_PMT_Control_Status Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RWKFILTRST	R/W	0h	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Remote Wake-Up Packet Filter Register Pointer is not Reset : 0x0 1h = Remote Wake-Up Packet Filter Register Pointer is Reset : 0x1
30-29	RESERVED	R	0h	Reserved.
28-24	RWKPTR	R	0h	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to maximum for the selected number of Remote Wake-up Packet Filters, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
23-11	RESERVED	R	0h	Reserved.

Table 43-114. MAC_PMT_Control_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	RWKPFE	R/W	0h	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. Note: If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Remote Wake-up Packet Forwarding is disabled : 0x0 1h = Remote Wake-up Packet Forwarding is enabled : 0x1
9	GLBLUCAST	R/W	0h	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. 0h = Global unicast is disabled : 0x0 1h = Global unicast is enabled : 0x1
8-7	RESERVED	R	0h	Reserved.
6	RWKPRCVD	R	0h	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = Remote wake-up packet is received : 0x0 1h = Remote wake-up packet is received : 0x1
5	MGKPRCVD	R	0h	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = No Magic packet is received : 0x0 1h = Magic packet is received : 0x1
4-3	RESERVED	R	0h	Reserved.
2	RWKPKTEN	R/W	0h	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. 0h = Remote wake-up packet is disabled : 0x0 1h = Remote wake-up packet is enabled : 0x1
1	MGKPKTEN	R/W	0h	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet. 0h = Magic Packet is disabled : 0x0 1h = Magic Packet is enabled : 0x1

Table 43-114. MAC_PMT_Control_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	PWRDWN	R/W	0h	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Power down is disabled : 0x0 1h = Power down is enabled : 0x1

43.7.3.22 MAC_RWK_Packet_Filter Register (Offset = C4h) [Reset = 0h]

MAC_RWK_Packet_Filter is shown in Figure 43-61 and described in Table 43-115.

Return to the Summary Table.

The wkuppktfilter_reg register at address 0C4H loads the Wake-up Packet Filter register.
To load values in a Wake-up Packet Filter register, the entire register (wkuppktfilter_reg) must be written.
The wkuppktfilter_reg register is loaded by sequentially loading the eight, sixteen or thirty two register values in address (0C4H) for wkuppktfilter_reg0, wkuppktfilter_reg1,.. wkuppktfilter_reg31, respectively. The wkuppktfilter_reg register is read in a similar way. The DWC_ether_qos updates the wkuppktfilter_reg register current pointer value in Bits[26:24] of MAC_PMT_Control_Status register.
Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3,..,15) to determine whether or not a packet is a wake-up packet.
- The MSB (31st bit) must be zero.
- Bit j[30:0] is the byte mask.
- If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet
otherwise Filter i Offset + j is ignored.
Filter i Command: The 4-bit filter i command controls the filter i operation.
- Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets
when the bit is reset, the pattern applies only to unicast packet.
- Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value.
- Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".
- Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set.
- Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.
Filter i Offset: This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.
- This 8-bit pattern-offset is the offset for the filter i first byte to be examined.
- The minimum allowed offset is 12, which refers to the 13th byte of the packet.
- The offset value 0 refers to the first byte of the packet.
Filter i CRC-16: This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wake-up filter register block.
- The 16-bit CRC calculation uses the following polynomial:
G(x) = x^16 + x^15 + x^2 + 1
Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask.
Each filter has the following:
- 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.
- 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation.
The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.
- Note: If you are accessing these registers in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when CPU accesses Lane 3 (or Lane 0 in big-endian mode).
- Note: When any Register content is being transferred to a different clock domain after a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Therefore, the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).
Notes on And_Previous bit setting
The And_Previous bit setting is applicable within a set of 4 filters.

- Setting of And_Previous bit of filter that is not enabled has no effect. In other words, setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.
- If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example:
If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set) but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result is considered.
If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3
result is considered.
If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 2 is not enabled (bit 0 of in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit
has no effect only Filter 1 result ORed with Filter 3 result is considered.
- If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 of Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 of Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

Table 43-116. MAC_LPI_Control_Status Register Field Descriptions

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	Reserved.
21	LPITCSE	R/W	0h	LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode. If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed. 0h = LPI Tx Clock Stop is disabled : 0x0 1h = LPI Tx Clock Stop is enabled : 0x1
20	LPIATE	R/W	0h	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPIATE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPIATE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions. 0h = LPI Timer is disabled : 0x0 1h = LPI Timer is enabled : 0x1

Table 43-116. MAC_LPI_Control_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	LPITXA	R/W	0h	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. This bit is not functional in the EQOS-CORE configurations in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. 0h = LPI Tx Automate is disabled : 0x0 1h = LPI Tx Automate is enabled : 0x1
18	RESERVED	R	0h	Reserved.
17	PLS	R/W	0h	PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. 0h = link is down : 0x0 1h = link is okay (UP) : 0x1
16	LPIEN	R/W	0h	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. 0h = LPI state is disabled : 0x0 1h = LPI state is enabled : 0x1
15-10	RESERVED	R	0h	Reserved.
9	RLPIST	R	0h	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. 0h = Receive LPI state not detected : 0x0 1h = Receive LPI state detected : 0x1
8	TLPIST	R	0h	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. 0h = Transmit LPI state not detected : 0x0 1h = Transmit LPI state detected : 0x1
7-4	RESERVED	R	0h	Reserved.
3	RLPIEX	R	0h	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0h = Receive LPI exit not detected : 0x0 1h = Receive LPI exit detected : 0x1

Table 43-116. MAC_LPI_Control_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	RLPIEN	R	0h	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0h = Receive LPI entry not detected : 0x0 1h = Receive LPI entry detected : 0x1
1	TLPIEX	R	0h	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0h = Transmit LPI exit not detected : 0x0 1h = Transmit LPI exit detected : 0x1
0	TLPIEN	R	0h	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0h = Transmit LPI entry not detected : 0x0 1h = Transmit LPI entry detected : 0x1

43.7.3.24 MAC_LPI_Timers_Control Register (Offset = D4h) [Reset = 03E80000h]

MAC_LPI_Timers_Control is shown in Figure 43-63 and described in Table 43-117.

Return to the Summary Table.

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved.
25-16	LST	R/W	3E8h	LPI LS Timer This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.
15-0	TWT	R/W	0h	LPI TW Timer This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

43.7.3.25 MAC_LPI_Entry_Timer Register (Offset = D8h) [Reset = 0h]

MAC_LPI_Entry_Timer is shown in Figure 43-64 and described in Table 43-118.

Return to the Summary Table.

This register controls the Tx LPI entry timer. This counter is enabled only when bit[20](LPITE) bit of MAC_LPI_Control_Status is set to 1.

Figure 43-64. MAC_LPI_Entry_Timer Register

Table 43-118. MAC_LPI_Entry_Timer Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	RESERVED	R	0h	Reserved.
19-3	LPIET	R/W	0h	LPI Entry Timer This field specifies the time in microseconds the MAC waits to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1. Bits [2:0] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.
2-0	RESERVED	R	0h	Reserved.

43.7.3.26 MAC_1US_Tic_Counter Register (Offset = DCh) [Reset = 63h]

MAC_1US_Tic_Counter is shown in Figure 43-65 and described in Table 43-119.

Return to the Summary Table.

This register controls the generation of the Reference time (1 microsecond tic) for all the LPI timers. This timer has to be programmed by the software initially.

Figure 43-65. MAC_1US_Tic_Counter Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 43-119. MAC_1US_Tic_Counter Register Field Descriptions

Bit	Field	Type	Reset	Description
31-12	RESERVED	R	0h	Reserved.
11-0	TIC_1US_CNTR	R/W	63h	1US TIC Counter The application must program this counter so that the number of clock cycles of CSR clock is 1us. (Subtract 1 from the value before programming). For example if the CSR clock is 100MHz then this field needs to be programmed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1US events that are used to update some of the EEE related counters.

43.7.3.27 MAC_Version Register (Offset = 110h) [Reset = 50h]

MAC_Version is shown in Figure 43-66 and described in Table 43-120.

Return to the Summary Table.

The version register identifies the version of the DWC_ether_qos. This register contains two bytes: one that Synopsys uses to identify the core release number, and the other that you set while configuring the core.

43.7.3.29 MAC_HW_Feature0 Register (Offset = 11Ch) [Reset = 0E1D73F5h]

MAC_HW_Feature0 is shown in Figure 43-68 and described in Table 43-122.

Return to the Summary Table.

This register indicates the presence of first set of the optional features or functions of the DWC_ether_qos. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks. Note: All bits are set or reset according to the features selected while configuring the core in coreConsultant.

R-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 43-126. MAC_MDIO_Address Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	RESERVED	R	0h	Reserved.
27	PSE	R/W	0h	Preamble Suppression Enable When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications. 0h = Preamble Suppression disabled : 0x0 1h = Preamble Suppression enabled : 0x1
26	BTB	R/W	0h	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared)only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0. 0h = Back to Back transactions disabled : 0x0 1h = Back to Back transactions enabled : 0x1
25-21	PA	R/W	0h	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. For RevMII, this field gives the PHY Address of the RevMII module. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.

Table 43-126. MAC_MDIO_Address Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20-16	RDA	R/W	0h	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. For RevMII, these bits select the CSR register in the RevMII Registers set. These bits select the Device (MMD) in selected Clause 45 capable PHY.
15	RESERVED	R	0h	Reserved.
14-12	NTC	R/W	0h	Number of Trailing Clocks This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
11-8	CR	R/W	0h	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: - 0000: CSR clock = 60-100 MHz MDC clock = CSR clock/42 - 0001: CSR clock = 100-150 MHz MDC clock = CSR clock/62 - 0010: CSR clock = 20-35 MHz MDC clock = CSR clock/16 - 0011: CSR clock = 35-60 MHz MDC clock = CSR clock/26 - 0100: CSR clock = 150-250 MHz MDC clock = CSR clock/102 - 0101: CSR clock = 250-300 MHz MDC clock = CSR clock/124 - 0110: CSR clock = 300-500 MHz MDC clock = CSR clock/204 - 0111: CSR clock = 500-800 MHz MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz freqency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: - 1000: CSR clock/4 - 1001: CSR clock/6 - 1010: CSR clock/8 - 1011: CSR clock/10 - 1100: CSR clock/12 - 1101: CSR clock/14 - 1110: CSR clock/16 - 1111: CSR clock/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface.
7-5	RESERVED	R	0h	Reserved.
4	SKAP	R/W	0h	Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set. 0h = Skip Address Packet is disabled : 0x0 1h = Skip Address Packet is enabled : 0x1

Table 43-126. MAC_MDIO_Address Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	GOC_1	R/W	0h	GMII Operation Command 1 This bit is higher bit of the operation command to the PHY or RevMII, GOC_1 and GOC_O is encoded as follows: - 00: Reserved - 01: Write - 10: Post Read Increment Address for Clause 45 PHY - 11: Read When Clause 22 PHY or RevMII is enabled, only Write and Read commands are valid. 0h = GMII Operation Command 1 is disabled : 0x0 1h = GMII Operation Command 1 is enabled : 0x1
2	GOC_0	R/W	0h	GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. When in SMA mode (MDIO master) this bit along with GOC_1 determines the operation to be performed to the PHY. When only RevMII is selected in configuration this bit is read-only and tied to 1. 0h = GMII Operation Command 0 is disabled : 0x0 1h = GMII Operation Command 0 is enabled : 0x1
1	C45E	R/W	0h	Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO. 0h = Clause 45 PHY is disabled : 0x0 1h = Clause 45 PHY is enabled : 0x1
0	GB	R/W	0h	GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_Data register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. Note: Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = GMII Busy is disabled : 0x0 1h = GMII Busy is enabled : 0x1

43.7.3.34 MAC_MDIO_Data Register (Offset = 204h) [Reset = 0h]

MAC_MDIO_Data is shown in Figure 43-73 and described in Table 43-127.

Return to the Summary Table.

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

Figure 43-73. MAC_MDIO_Data Register

9-8	SPLM	R/W	0h	Split Mode These bits indicate the mode of splitting the incoming Rx packets. They are 0h = Split at L3/L4 header : 0x0 1h = Split at L2 header with an offset. Always Split at SPLOFST bytes from the beginning of Length/Type field of the Frame : 0x1 2h = Combination mode: Split similar to SPLM=00 for IP packets that are untagged or tagged and VLAN stripped : 0x2 3h = Reserved : 0x3
7	RESERVED	R	0h	Reserved.
6-0	SPLOFST	R/W	2h	Split Offset These bits indicate the value of offset from the beginning of Length/Type field at which header split should take place when the appropriate SPLM is selected. The reset value of this field is 2 bytes indicating a split at L2 header. Value is in terms of bytes.

43.7.3.38 MAC_Address0_High Register (Offset = 300h) [Reset = 8000FFFFh]

MAC_Address0_High is shown in Figure 43-77 and described in Table 43-131.

Return to the Summary Table.

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.
If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Figure 43-77. MAC_Address0_High Register

43.7.3.44 MAC_Address3_High Register (Offset = 318h) [Reset = FFFFh]

MAC_Address3_High is shown in Figure 43-83 and described in Table 43-137.

Return to the Summary Table.

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved.
8	UCDBC	R/W	0h	Update MMC Counters for Dropped Broadcast Packets Note: The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set. When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets. 0h = Update MMC Counters for Dropped Broadcast Packets is disabled : 0x0 1h = Update MMC Counters for Dropped Broadcast Packets is enabled : 0x1
7-6	RESERVED	R	0h	Reserved.
5	CNTPRSTLVL	R/W	0h	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. 0h = Full-Half Preset is disabled : 0x0 1h = Full-Half Preset is enabled : 0x1

Table 43-147. MMC_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	CNTPRST	R/W	0h	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0h = Counters Preset is disabled : 0x0 1h = Counters Preset is enabled : 0x1
3	CNTFREEZ	R/W	0h	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. 0h = MMC Counter Freeze is disabled : 0x0 1h = MMC Counter Freeze is enabled : 0x1
2	RSTONRD	R/W	0h	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[7:0]) is read. 0h = Reset on Read is disabled : 0x0 1h = Reset on Read is enabled : 0x1
1	CNTSTOPRO	R/W	0h	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value. 0h = Counter Stop Rollover is disabled : 0x0 1h = Counter Stop Rollover is enabled : 0x1
0	CNTRST	R/W	0h	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0h = Counters are not reset : 0x0 1h = All counters are reset : 0x1

43.7.3.55 MMC_Rx_Interrupt Register (Offset = 704h) [Reset = 0h]

MMC_Rx_Interrupt is shown in Figure 43-94 and described in Table 43-148.

Return to the Summary Table.

This register maintains the interrupts generated from all Receive statistics counters.
The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:
- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).
- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register
is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.
Note: R_SS_RC means that this register bit is set internally, and it is cleared when the Counter register is read.

43.7.3.56 MMC_Tx_Interrupt Register (Offset = 708h) [Reset = 0h]

MMC_Tx_Interrupt is shown in Figure 43-95 and described in Table 43-149.

Return to the Summary Table.

This register maintains the interrupts generated from all Transmit statistics counters.
The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values
(0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).
When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.
The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.
The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

43.7.3.57 MMC_Rx_Interrupt_Mask Register (Offset = 70Ch) [Reset = 0h]

MMC_Rx_Interrupt_Mask is shown in Figure 43-96 and described in Table 43-150.

Return to the Summary Table.

This register maintains the masks for interrupts generated from all Receive statistics counters.
The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half of their maximum value or the maximum values.
This register is 32 bit wide.

43.7.3.58 MMC_Tx_Interrupt_Mask Register (Offset = 710h) [Reset = 0h]

MMC_Tx_Interrupt_Mask is shown in Figure 43-97 and described in Table 43-151.

Return to the Summary Table.

This register maintains the masks for interrupts generated from all Transmit statistics counters.
The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

Bit	Field	Type	Reset	Description
31-0	TXLPIUSC	R	0h	Tx LPI Microseconds Counter This field indicates the number of microseconds Tx LPI is asserted. For every Tx LPI Entry and Exit, the Timer value can have an error of +/- 1 microsecond.

43.7.3.112 Tx_LPI_Tran_Cntr Register (Offset = 7F0h) [Reset = 0h]

Tx_LPI_Tran_Cntr is shown in Figure 43-151 and described in Table 43-205.

Return to the Summary Table.

This register provides the number of times DWC_ether_qos has entered Tx LPI.

Figure 43-151. Tx_LPI_Tran_Cntr Register

Bit	Field	Type	Reset	Description
31-0	TXLPITRC	R	0h	Tx LPI Transition counter This field indicates the number of times Tx LPI Entry has occurred. Even if Tx LPI Entry occurs in Automate Mode (because of LPITXA bit set in the LPI Control and Status register), the counter will increment.

43.7.3.113 Rx_LPI_USEC_Cntr Register (Offset = 7F4h) [Reset = 0h]

Rx_LPI_USEC_Cntr is shown in Figure 43-152 and described in Table 43-206.

Return to the Summary Table.

This register provides the number of microseconds Rx LPI is sampled by DWC_ether_qos.

Figure 43-152. Rx_LPI_USEC_Cntr Register

43.7.3.115 MMC_IPC_Rx_Interrupt_Mask Register (Offset = 800h) [Reset = 0h]

MMC_IPC_Rx_Interrupt_Mask is shown in Figure 43-154 and described in Table 43-208.

Return to the Summary Table.

This register maintains the mask for the interrupt generated from the receive IPC statistic counters. The MMC Receive Checksum Off load Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Off load) statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

43.7.3.116 MMC_IPC_Rx_Interrupt Register (Offset = 808h) [Reset = 0h]

MMC_IPC_Rx_Interrupt is shown in Figure 43-155 and described in Table 43-209.

Return to the Summary Table.

This register maintains the interrupt that the receive IPC statistic counters generate.
The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.
The MMC Receive Checksum Offload Interrupt register is 32 bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.

Table 43-209. MMC_IPC_Rx_Interrupt Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	RXIPV6GPIS	R	0h	MMC Receive IPV6 Good Packet Counter Interrupt Status This bit is set when the rxipv6_gd_pkts counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0h = MMC Receive IPV6 Good Packet Counter Interrupt Status not detected : 0x0 1h = MMC Receive IPV6 Good Packet Counter Interrupt Status detected : 0x1
4	RXIPV4UDSBLPIS	R	0h	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Status This bit is set when the rxipv4_udsbl_pkts counter reaches half of the maximum value or the maximum value. 0h = MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Status not detected : 0x0 1h = MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Status detected : 0x1
3	RXIPV4FRAGPIS	R	0h	MMC Receive IPV4 Fragmented Packet Counter Interrupt Status This bit is set when the rxipv4_frag_pkts counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0h = MMC Receive IPV4 Fragmented Packet Counter Interrupt Status not detected : 0x0 1h = MMC Receive IPV4 Fragmented Packet Counter Interrupt Status detected : 0x1
2	RXIPV4NOPAYPIS	R	0h	MMC Receive IPV4 No Payload Packet Counter Interrupt Status This bit is set when the rxipv4_nopay_pkts counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0h = MMC Receive IPV4 No Payload Packet Counter Interrupt Status not detected : 0x0 1h = MMC Receive IPV4 No Payload Packet Counter Interrupt Status detected : 0x1
1	RXIPV4HERPIS	R	0h	MMC Receive IPV4 Header Error Packet Counter Interrupt Status This bit is set when the rxipv4_hdrerr_pkts counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0h = MMC Receive IPV4 Header Error Packet Counter Interrupt Status not detected : 0x0 1h = MMC Receive IPV4 Header Error Packet Counter Interrupt Status detected : 0x1
0	RXIPV4GPIS	R	0h	MMC Receive IPV4 Good Packet Counter Interrupt Status This bit is set when the rxipv4_gd_pkts counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0h = MMC Receive IPV4 Good Packet Counter Interrupt Status not detected : 0x0 1h = MMC Receive IPV4 Good Packet Counter Interrupt Status detected : 0x1

43.7.3.117 RxIPv4_Good_Packets Register (Offset = 810h) [Reset = 0h]

RxIPv4_Good_Packets is shown in Figure 43-156 and described in Table 43-210.

Return to the Summary Table.

This register provides the number of good IPv4 datagrams received by DWC_ether_qos with the TCP, UDP, or ICMP payload.

Figure 43-156. RxIPv4_Good_Packets Register

Table 43-231. RxIPv6_No_Payload_Octets Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	RXIPV6NOPAYOCT	R	0h	RxIPv6 Payload Octets This field indicates the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

43.7.3.139 RxUDP_Good_Octets Register (Offset = 870h) [Reset = 0h]

RxUDP_Good_Octets is shown in Figure 43-178 and described in Table 43-232.

Return to the Summary Table.

This register provides the number of bytes received by DWC_ether_qos in a good UDP segment. This counter does not count IP header bytes.

This bit is valid and applicable only when the L4SPM0 bit is set high. 0h = Layer 4 Source Port Inverse Match is disabled : 0x0 1h = Layer 4 Source Port Inverse Match is enabled : 0x1
18	L4SPM0	R/W	0h	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching. 0h = Layer 4 Source Port Match is disabled : 0x0 1h = Layer 4 Source Port Match is enabled : 0x1
17	RESERVED	R	0h	Reserved.
16	L4PEN0	R/W	0h	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set. 0h = Layer 4 Protocol is disabled : 0x0 1h = Layer 4 Protocol is enabled : 0x1
15-11	L3HDBM0	R/W	0h	Layer 3 IP DA Higher Bits Match IPv4 Packets: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked. IPv6 Packets: Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: - 0: No bits are masked. - 1: LSb[0] is masked. - 2: Two LSbs [1:0] are masked - .. - 127: All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
10-6	L3HSBM0	R/W	0h	Layer 3 IP SA Higher Bits Match IPv4 Packets: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked. IPv6 Packets: This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.

Table 43-238. MAC_L3_L4_Control0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	L3DAIM0	R/W	0h	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high. 0h = Layer 3 IP DA Inverse Match is disabled : 0x0 1h = Layer 3 IP DA Inverse Match is enabled : 0x1
4	L3DAM0	R/W	0h	Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering. 0h = Layer 3 IP DA Match is disabled : 0x0 1h = Layer 3 IP DA Match is enabled : 0x1
3	L3SAIM0	R/W	0h	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set. 0h = Layer 3 IP SA Inverse Match is disabled : 0x0 1h = Layer 3 IP SA Inverse Match is enabled : 0x1
2	L3SAM0	R/W	0h	Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering. 0h = Layer 3 IP SA Match is disabled : 0x0 1h = Layer 3 IP SA Match is enabled : 0x1
1	RESERVED	R	0h	Reserved.
0	L3PEN0	R/W	0h	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0h = Layer 3 Protocol is disabled : 0x0 1h = Layer 3 Protocol is enabled : 0x1

43.7.3.146 MAC_Layer4_Address0 Register (Offset = 904h) [Reset = 0h]

MAC_Layer4_Address0 is shown in Figure 43-185 and described in Table 43-239.

Return to the Summary Table.

The Layer 4 Address 0 register and registers 580 through 667 are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.
You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

19	L4SPIM1	R/W	0h	Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4SPM0 bit is set high. 0h = Layer 4 Source Port Inverse Match is disabled : 0x0 1h = Layer 4 Source Port Inverse Match is enabled : 0x1
18	L4SPM1	R/W	0h	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching. 0h = Layer 4 Source Port Match is disabled : 0x0 1h = Layer 4 Source Port Match is enabled : 0x1
17	RESERVED	R	0h	Reserved.
16	L4PEN1	R/W	0h	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set. 0h = Layer 4 Protocol is disabled : 0x0 1h = Layer 4 Protocol is enabled : 0x1
15-11	L3HDBM1	R/W	0h	Layer 3 IP DA Higher Bits Match IPv4 Packets: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked. IPv6 Packets: Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: - 0: No bits are masked. - 1: LSb[0] is masked. - 2: Two LSbs [1:0] are masked - .. - 127: All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
10-6	L3HSBM1	R/W	0h	Layer 3 IP SA Higher Bits Match IPv4 Packets: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked. IPv6 Packets: This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.

Table 43-244. MAC_L3_L4_Control1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	L3DAIM1	R/W	0h	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high. 0h = Layer 3 IP DA Inverse Match is disabled : 0x0 1h = Layer 3 IP DA Inverse Match is enabled : 0x1
4	L3DAM1	R/W	0h	Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering. 0h = Layer 3 IP DA Match is disabled : 0x0 1h = Layer 3 IP DA Match is enabled : 0x1
3	L3SAIM1	R/W	0h	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set. 0h = Layer 3 IP SA Inverse Match is disabled : 0x0 1h = Layer 3 IP SA Inverse Match is enabled : 0x1
2	L3SAM1	R/W	0h	Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering. 0h = Layer 3 IP SA Match is disabled : 0x0 1h = Layer 3 IP SA Match is enabled : 0x1
1	RESERVED	R	0h	Reserved.
0	L3PEN1	R/W	0h	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0h = Layer 3 Protocol is disabled : 0x0 1h = Layer 3 Protocol is enabled : 0x1

43.7.3.152 MAC_Layer4_Address1 Register (Offset = 934h) [Reset = 0h]

MAC_Layer4_Address1 is shown in Figure 43-191 and described in Table 43-245.

Return to the Summary Table.

The Layer 4 Address 0 register and registers 580 through 667 are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.
You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Bit	Field	Type	Reset	Description
31-16	L4DP1	R/W	0h	Layer 4 Destination Port Number Field When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.
15-0	L4SP1	R/W	0h	Layer 4 Source Port Number Field When the L4PEN0 bit is reset and the L4SPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4SPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.

43.7.3.153 MAC_Layer3_Addr0_Reg1 Register (Offset = 940h) [Reset = 0h]

MAC_Layer3_Addr0_Reg1 is shown in Figure 43-192 and described in Table 43-246.

Return to the Summary Table.

For IPv4 packets, the Layer 3 Address 0 Register 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Table 43-253. MAC_Layer3_Addr1_Reg2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	L3A12	R/W	0h	Layer 3 Address 1 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[63:32] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[63:32] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset and the L3SAM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

43.7.3.161 MAC_Layer3_Addr2_Reg2 Register (Offset = 978h) [Reset = 0h]

MAC_Layer3_Addr2_Reg2 is shown in Figure 43-200 and described in Table 43-254.

Return to the Summary Table.

The Layer 3 Address 2 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field.

When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0h = Layer 3 Protocol is disabled : 0x0 1h = Layer 3 Protocol is enabled : 0x1

43.7.3.164 MAC_Layer4_Address3 Register (Offset = 994h) [Reset = 0h]

MAC_Layer4_Address3 is shown in Figure 43-203 and described in Table 43-257.

Return to the Summary Table.

The Layer 4 Address 0 register and registers 580 through 667 are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.
You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Table 43-262. MAC_Timestamp_Control Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	Reserved.
28	AV8021ASMEN	R/W	0h	AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation. When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit. 0h = AV 802.1AS Mode is disabled : 0x0 1h = AV 802.1AS Mode is enabled : 0x1
27-25	RESERVED	R	0h	Reserved.
24	TXTSSTSM	R/W	0h	Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_Tx_Timestamp_Status_Nanoseconds register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_Tx_Timestamp_Status_Nanoseconds register. 0h = Transmit Timestamp Status Mode is disabled : 0x0 1h = Transmit Timestamp Status Mode is enabled : 0x1
23-21	RESERVED	R	0h	Reserved.

Table 43-262. MAC_Timestamp_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	ESTI	R/W	0h	External System Time Input When this bit is set, the MAC uses the external 64-bit reference System Time input for the following: - To take the timestamp provided as status - To insert the timestamp in transmit PTP packets when One-step Timestamp or Timestamp Offload feature is enabled. When this bit is reset, the MAC uses the internal reference System Time. 0h = External System Time Input is disabled : 0x0 1h = External System Time Input is enabled : 0x1
19	CSC	R/W	0h	Enable checksum correction during OST for PTP over UDP/IPv4 packets When this bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin timestamp and/or correction field as part of one step timestamp operation. The application shall form the packet with these two dummy bytes. When reset, no updates are done to keep the UDP checksum correct. The application shall form the packet with UDP checksum set to 0. 0h = checksum correction during OST for PTP over UDP/IPv4 packets is disabled : 0x0 1h = checksum correction during OST for PTP over UDP/IPv4 packets is enabled : 0x1
18	TSENMACADDR	R/W	0h	Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet. For normal time stamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching. For PTP offload, only MAC address register 0 is considered for unicast destination address matching. 0h = MAC Address for PTP Packet Filtering is disabled : 0x0 1h = MAC Address for PTP Packet Filtering is enabled : 0x1
17-16	SNAPTYPSEL	R/W	0h	Select PTP packets for Taking Snapshots These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.
15	TSMSTRENA	R/W	0h	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. 0h = Snapshot for Messages Relevant to Master is disabled : 0x0 1h = Snapshot for Messages Relevant to Master is enabled : 0x1
14	TSEVNTENA	R/W	0h	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Timestamp Snapshot Dependency on Register Bits Table. 0h = Timestamp Snapshot for Event Messages is disabled : 0x0 1h = Timestamp Snapshot for Event Messages is enabled : 0x1

Table 43-262. MAC_Timestamp_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	TSIPV4ENA	R/W	1h	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default. 0h = Processing of PTP Packets Sent over IPv4-UDP is disabled : 0x0 1h = Processing of PTP Packets Sent over IPv4-UDP is enabled : 0x1
12	TSIPV6ENA	R/W	0h	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets. 0h = Processing of PTP Packets Sent over IPv6-UDP is disabled : 0x0 1h = Processing of PTP Packets Sent over IPv6-UDP is enabled : 0x1
11	TSIPENA	R/W	0h	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets. 0h = Processing of PTP over Ethernet Packets is disabled : 0x0 1h = Processing of PTP over Ethernet Packets is enabled : 0x1
10	TSVER2ENA	R/W	0h	Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'. 0h = PTP Packet Processing for Version 2 Format is disabled : 0x0 1h = PTP Packet Processing for Version 2 Format is enabled : 0x1
9	TSCTRLSSR	R/W	0h	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit. 0h = Timestamp Digital or Binary Rollover Control is disabled : 0x0 1h = Timestamp Digital or Binary Rollover Control is enabled : 0x1
8	TSENALL	R/W	0h	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC. 0h = Timestamp for All Packets disabled : 0x0 1h = Timestamp for All Packets enabled : 0x1
7-6	RESERVED	R	0h	Reserved.
5	TSADDREG	R/W	0h	Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Addend Register is not updated : 0x0 1h = Addend Register is updated : 0x1
4	RESERVED	R	0h	Reserved.

Table 43-262. MAC_Timestamp_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	TSUPDT	R/W	0h	Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Timestamp is not updated : 0x0 1h = Timestamp is updated : 0x1
2	TSINIT	R/W	0h	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC Register 80 (System Time Seconds Update Register) and MAC Register 81 (System Time Nanoseconds Update Register). This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Timestamp is not initialized : 0x0 1h = Timestamp is initialized : 0x1
1	TSCFUPDT	R/W	0h	Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp. 0h = Coarse method is used to update system timestamp : 0x0 1h = Fine method is used to update system timestamp : 0x1
0	TSENA	R/W	0h	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set. 0h = Timestamp is disabled : 0x0 1h = Timestamp is enabled : 0x1

43.7.3.170 MAC_Sub_Second_Increment Register (Offset = B04h) [Reset = 0h]

MAC_Sub_Second_Increment is shown in Figure 43-209 and described in Table 43-263.

Return to the Summary Table.

This register specifies the value to be added to the internal system time register every cycle of clk_ptp_ref_i clock.

Figure 43-209. MAC_Sub_Second_Increment Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 43-263. MAC_Sub_Second_Increment Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved.
23-16	SSINC	R/W	0h	Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 9 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.
15-8	SNSINC	R/W	0h	Sub-nanosecond Increment Value This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. This value is accumulated with the sub-nanoseconds field of the subsecond register. For example, when TSCTRLSSR field in the MAC_Timestamp_Control register is set. and if the required increment is 5.3ns, then SSINC should be 0x05 and SNSINC should be 0x4C.
7-0	RESERVED	R	0h	Reserved.

43.7.3.171 MAC_System_Time_Seconds Register (Offset = B08h) [Reset = 0h]

MAC_System_Time_Seconds is shown in Figure 43-210 and described in Table 43-264.

Return to the Summary Table.

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Table 43-267. MAC_System_Time_Nanoseconds_Update Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ADDSUB	R/W	0h	Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register. 0h = Add time : 0x0 1h = Subtract time : 0x1
30-0	TSSS	R/W	0h	Timestamp Sub Seconds The value in this field is the sub-seconds part of the update. When ADDSUB is reset, this field must be programmed with the sub-seconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC_Timestamp_Control register. When ADDSUB is set, this field must be programmed with the complement of the sub-seconds part of the update value as described below. When TSCTRLSSR bit in MAC_Timestamp_Control is set, the programmed value must be 10^9 - <sub-second value>. When TSCTRLSSR bit in MAC_Timestamp_Control is reset, the programmed value must be 2^{31} - <sub-second_value>. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, each bit represents an accuracy of 0.46 ns. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. For example, if 2.000000001 seconds need to be subtracted from the system time, then the TSSS field in the MAC_Timestamp_Nanoseconds_Update register must be 0x7FFF_FFFF (that is, 2^{31} - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is reset and 0x3B9A_C9FF (that is, 10^9 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is set.

43.7.3.175 MAC_Timestamp_Addend Register (Offset = B18h) [Reset = 0h]

MAC_Timestamp_Addend is shown in Figure 43-214 and described in Table 43-268.

Return to the Summary Table.

Timestamp Addend register. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = Timestamp Target Time Reached status not detected : 0x0 1h = Timestamp Target Time Reached status detected : 0x1
0	TSSOVF	R	0h	Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0h = Timestamp Seconds Overflow status not detected : 0x0 1h = Timestamp Seconds Overflow status detected : 0x1

43.7.3.178 MAC_Tx_Timestamp_Status_Nanoseconds Register (Offset = B30h) [Reset = 0h]

MAC_Tx_Timestamp_Status_Nanoseconds is shown in Figure 43-217 and described in Table 43-271.

Return to the Summary Table.

This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.
The MAC_Tx_Timestamp_Status_Nanoseconds register, along with MAC_Tx_Timestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_Tx_Timestamp_Status_Nanoseconds is read. In the little-endian mode, this means when bits[31:24] are read
in big-endian mode, bits[7:0] are read.
If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSC bit [15] in MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

Setting 0 has no effect. 0h = Auxiliary Snapshot FIFO Clear is disabled : 0x0 1h = Auxiliary Snapshot FIFO Clear is enabled : 0x1

43.7.3.181 MAC_Auxiliary_Timestamp_Nanoseconds Register (Offset = B48h) [Reset = 0h]

MAC_Auxiliary_Timestamp_Nanoseconds is shown in Figure 43-220 and described in Table 43-274.

Return to the Summary Table.

The Auxiliary Timestamp Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4, 8, or 16 as selected while configuring the core.
You can store multiple snapshots in this FIFO. Bits[29:25] in MAC_Timestamp_Status indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC Register 91 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read and in big-endian mode, Bits[7:0] are read.

Table 43-282. MAC_PPS_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-0	PPSCTRL_PPSCMD	R/W	0h	PPS Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: - 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. - 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. - 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. - 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. - .. - 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: - When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms - When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of One clock of 50 percent duty cycle and 537 ms period Second clock of 463 ms period (268 ms low and 195 ms high) - When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of Three clocks of 50 percent duty cycle and 268 ms period Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register. or Flexible PPS Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all-zero'. The following list describes the values of PPSCMD0: - 0000: No Command - 0001: START Single Pulse This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. - 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. - 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. - 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. - 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). - 0110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.

Table 43-284. MAC_PPS0_Target_Time_Nanoseconds Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TRGTBUSY0	R/W	0h	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. 0h = PPS Target Time Register Busy status is not detected : 0x0 1h = PPS Target Time Register Busy is detected : 0x1
30-0	TTSL0	R/W	0h	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

43.7.3.192 MAC_PPS0_Interval Register (Offset = B88h) [Reset = 0h]

MAC_PPS0_Interval is shown in Figure 43-231 and described in Table 43-285.

Return to the Summary Table.

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Figure 43-231. MAC_PPS0_Interval Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPSINT0																															
R/W-0h																															

Table 43-285. MAC_PPS0_Interval Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	PPSINT0	R/W	0h	PPS Output Signal Interval These bits store the interval between the rising edges of PPS0 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS0 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

43.7.3.193 MAC_PPS0_Width Register (Offset = B8Ch) [Reset = 0h]

MAC_PPS0_Width is shown in Figure 43-232 and described in Table 43-286.

Return to the Summary Table.

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).

Figure 43-232. MAC_PPS0_Width Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-0	PPSWIDTH0	R/W	0h	PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval.

43.7.3.194 MAC_PPS1_Target_Time_Seconds Register (Offset = B90h) [Reset = 0h]

MAC_PPS1_Target_Time_Seconds is shown in Figure 43-233 and described in Table 43-287.

Return to the Summary Table.

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

Figure 43-233. MAC_PPS1_Target_Time_Seconds Register

Table 43-288. MAC_PPS1_Target_Time_Nanoseconds Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TRGTBUSY1	R/W	0h	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. 0h = PPS Target Time Register Busy status is not detected : 0x0 1h = PPS Target Time Register Busy is detected : 0x1
30-0	TTSL1	R/W	0h	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

43.7.3.196 MAC_PPS1_Interval Register (Offset = B98h) [Reset = 0h]

MAC_PPS1_Interval is shown in Figure 43-235 and described in Table 43-289.

Return to the Summary Table.

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Figure 43-235. MAC_PPS1_Interval Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 43-302. MTL_TxQ0_Operation_Mode Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	RESERVED	R	0h	Reserved.
19-16	TQS	R/W	0h	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7	RESERVED	R	0h	Reserved.
6-4	TTC	R/W	0h	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 0h = 32 : 0x0 1h = 64 : 0x1 2h = 96 : 0x2 3h = 128 : 0x3 4h = 192 : 0x4 5h = 256 : 0x5 6h = 384 : 0x6 7h = 512 : 0x7
3-2	TXQEN	R/W	0h	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Reserved - 2'b10: Enabled - 2'b11: Reserved This field is Read Only in Single Queue configurations and Read Write in Multiple Queue configurations. Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 0h = Not enabled : 0x0 1h = Enable in AV mode(Reserved in non-AV) : 0x1 2h = Enabled : 0x2 3h = Reserved : 0x3

Table 43-302. MTL_TxQ0_Operation_Mode Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	TSF	R/W	0h	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0h = Transmit Store and Forward is disabled : 0x0 1h = Transmit Store and Forward is enabled : 0x1
0	FTQ	R/W	0h	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Flush Transmit Queue is disabled : 0x0 1h = Flush Transmit Queue is enabled : 0x1

43.7.3.210 MTL_TxQ0_Underflow Register (Offset = D04h) [Reset = 0h]

MTL_TxQ0_Underflow is shown in Figure 43-249 and described in Table 43-303.

Return to the Summary Table.

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Table 43-303. MTL_TxQ0_Underflow Register Field Descriptions

Bit	Field	Type	Reset	Description
31-12	RESERVED	R	0h	Reserved.
11	UFCNTOVF	R	0h	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0h = Overflow not detected for Underflow Packet Counter : 0x0 1h = Overflow detected for Underflow Packet Counter : 0x1
10-0	UFFRMCNT	R	0h	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

43.7.3.211 MTL_TxQ0_Debug Register (Offset = D08h) [Reset = 0h]

MTL_TxQ0_Debug is shown in Figure 43-250 and described in Table 43-304.

Return to the Summary Table.

The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Table 43-306. MTL_TxQ0_Quantum_Weight Register Field Descriptions

Bit	Field	Type	Reset	Description
31-21	RESERVED	R	0h	Reserved.
20-0	ISCQW	R/W	0h	Quantum or Weights When the DCB operation is enabled with DWRR algorithm for Queue 0 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. When DCB operation is enabled with WFQ algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. The higher the programmed weights lesser the bandwidth allocated for the particular Transmit Queue. This is because the weights are used to compute the packet finish time (weights*packet_size). Lesser the finish time, higher the probability of the packet getting scheduled first and using more bandwidth. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.

43.7.3.214 MTL_Q0_Interrupt_Control_Status Register (Offset = D2Ch) [Reset = 0h]

MTL_Q0_Interrupt_Control_Status is shown in Figure 43-253 and described in Table 43-307.

Return to the Summary Table.

This register contains the interrupt enable and status bits for the queue 0 interrupts.

Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Average Bits Per Slot Interrupt Status not detected : 0x0 1h = Average Bits Per Slot Interrupt Status detected : 0x1
0	TXUNFIS	R/W	0h	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Transmit Queue Underflow Interrupt Status not detected : 0x0 1h = Transmit Queue Underflow Interrupt Status detected : 0x1

43.7.3.215 MTL_RxQ0_Operation_Mode Register (Offset = D30h) [Reset = 0h]

MTL_RxQ0_Operation_Mode is shown in Figure 43-254 and described in Table 43-308.

Return to the Summary Table.

The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Figure 43-254. MTL_RxQ0_Operation_Mode Register

Table 43-308. MTL_RxQ0_Operation_Mode Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved.
23-20	RQS	R/W	0h	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-17	RESERVED	R	0h	Reserved.

Table 43-308. MTL_RxQ0_Operation_Mode Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16-14	RFD	R/W	0h	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 6: Full minus 4 KB, that is, FULL 4 KB - 7: Full minus 4.5 KB, that is, FULL 4.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-11	RESERVED	R	0h	Reserved.
10-8	RFA	R/W	0h	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7	EHFC	R/W	0h	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0h = Hardware Flow Control is disabled : 0x0 1h = Hardware Flow Control is enabled : 0x1
6	DIS_TCP_EF	R/W	0h	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0h = Dropping of TCP/IP Checksum Error Packets is enabled : 0x0 1h = Dropping of TCP/IP Checksum Error Packets is disabled : 0x1
5	RSF	R/W	0h	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0h = Receive Queue Store and Forward is disabled : 0x0 1h = Receive Queue Store and Forward is enabled : 0x1

Table 43-308. MTL_RxQ0_Operation_Mode Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	FEP	R/W	0h	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0h = Forward Error Packets is disabled : 0x0 1h = Forward Error Packets is enabled : 0x1
3	FUP	R/W	0h	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0h = Forward Undersized Good Packets is disabled : 0x0 1h = Forward Undersized Good Packets is enabled : 0x1
2	RESERVED	R	0h	Reserved.
1-0	RTC	R/W	0h	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 0h = 64 : 0x0 1h = 32 : 0x1 2h = 96 : 0x2 3h = 128 : 0x3

43.7.3.216 MTL_RxQ0_Missed_Packet_Overflow_Cnt Register (Offset = D34h) [Reset = 0h]

MTL_RxQ0_Missed_Packet_Overflow_Cnt is shown in Figure 43-255 and described in Table 43-309.

Return to the Summary Table.

The Queue 0 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

19-16	TQS	R/W	0h	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7	RESERVED	R	0h	Reserved.
6-4	TTC	R/W	0h	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 0h = 32 : 0x0 1h = 64 : 0x1 2h = 96 : 0x2 3h = 128 : 0x3 4h = 192 : 0x4 5h = 256 : 0x5 6h = 384 : 0x6 7h = 512 : 0x7
3-2	TXQEN	R/W	0h	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Reserved - 2'b10: Enabled - 2'b11: Reserved Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 0h = Not enabled : 0x0 1h = Enable in AV mode(Reserved in non-AV) : 0x1 2h = Enabled : 0x2 3h = Reserved : 0x3

Table 43-312. MTL_TxQ1_Operation_Mode Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	TSF	R/W	0h	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0h = Transmit Store and Forward is disabled : 0x0 1h = Transmit Store and Forward is enabled : 0x1
0	FTQ	R/W	0h	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Flush Transmit Queue is disabled : 0x0 1h = Flush Transmit Queue is enabled : 0x1

43.7.3.220 MTL_TxQ1_Underflow Register (Offset = D44h) [Reset = 0h]

MTL_TxQ1_Underflow is shown in Figure 43-259 and described in Table 43-313.

Return to the Summary Table.

The Queue 1 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

31-21	RESERVED	R	0h	Reserved.
20-0	ISCQW	R/W	0h	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps 8 ns for 1000 Mbps 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 1 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_Operation_Mode register. - Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

43.7.3.224 MTL_Q1_Interrupt_Control_Status Register (Offset = D6Ch) [Reset = 0h]

MTL_Q1_Interrupt_Control_Status is shown in Figure 43-263 and described in Table 43-317.

Return to the Summary Table.

This register contains the interrupt enable and status bits for the queue 1 interrupts.

Table 43-318. MTL_RxQ1_Operation_Mode Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved.
23-20	RQS	R/W	0h	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-17	RESERVED	R	0h	Reserved.

Table 43-318. MTL_RxQ1_Operation_Mode Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16-14	RFD	R/W	0h	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 6: Full minus 4 KB, that is, FULL 4 KB - 7: Full minus 4.5 KB, that is, FULL 4.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-11	RESERVED	R	0h	Reserved.
10-8	RFA	R/W	0h	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7	EHFC	R/W	0h	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0h = Hardware Flow Control is disabled : 0x0 1h = Hardware Flow Control is enabled : 0x1
6	DIS_TCP_EF	R/W	0h	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0h = Dropping of TCP/IP Checksum Error Packets is enabled : 0x0 1h = Dropping of TCP/IP Checksum Error Packets is disabled : 0x1
5	RSF	R/W	0h	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0h = Receive Queue Store and Forward is disabled : 0x0 1h = Receive Queue Store and Forward is enabled : 0x1

Table 43-318. MTL_RxQ1_Operation_Mode Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	FEP	R/W	0h	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0h = Forward Error Packets is disabled : 0x0 1h = Forward Error Packets is enabled : 0x1
3	FUP	R/W	0h	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0h = Forward Undersized Good Packets is disabled : 0x0 1h = Forward Undersized Good Packets is enabled : 0x1
2	RESERVED	R	0h	Reserved.
1-0	RTC	R/W	0h	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 0h = 64 : 0x0 1h = 32 : 0x1 2h = 96 : 0x2 3h = 128 : 0x3

43.7.3.226 MTL_RxQ1_Missed_Packet_Overflow_Cnt Register (Offset = D74h) [Reset = 0h]

MTL_RxQ1_Missed_Packet_Overflow_Cnt is shown in Figure 43-265 and described in Table 43-319.

Return to the Summary Table.

The Queue 1 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Table 43-322. DMA_Mode Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14-12	PR	R/W	0h	Priority Ratio These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set. 0h = The priority ratio is 1:1 : 0x0 1h = The priority ratio is 2:1 : 0x1 2h = The priority ratio is 3:1 : 0x2 3h = The priority ratio is 4:1 : 0x3 4h = The priority ratio is 5:1 : 0x4 5h = The priority ratio is 6:1 : 0x5 6h = The priority ratio is 7:1 : 0x6 7h = The priority ratio is 8:1 : 0x7
11	TXPR	R/W	0h	Transmit Priority When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus. 0h = Transmit Priority is disabled : 0x0 1h = Transmit Priority is enabled : 0x1
10-9	RESERVED	R	0h	Reserved.
8	RESERVED	R	0h	Reserved.
7-5	RESERVED	R	0h	Reserved.
4-2	TAA	R/W	0h	Transmit Arbitration Algorithm This field is used to select the arbitration algorithm for the Transmit side when multiple Tx DMAs are selected. 0h = Fixed priority(Channel 0 has the lowest priority and the last channel has the highest priority) : 0x0 1h = Weighted Strict Priority (WSP) : 0x1 2h = Weighted Round-Robin (WRR) : 0x2 3h = Reserved (for 3'b011 to 3'b111) : 0x3
1	DA	R/W	0h	DMA Tx or Rx Arbitration Scheme This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels: - 0: Weighted Round-Robin with Rx:Tx or Tx:Rx The priority between the paths is according to the priority specified in Bits[14:12] and the priority weight is specified in the TXPR bit. - 1: Fixed Priority The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path. 0h = Weighted Round-Robin with Rx:Tx or Tx:Rx : 0x0 1h = Fixed Priority : 0x1
0	SWR	R/W	0h	Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all DWC_ether_qos clock domains. Before reprogramming any DWC_ether_qos register, a value of zero should be read in this bit. This bit must be read at least 4 CSR clock cycles after it is written to 1. Note: The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0h = Software Reset is disabled : 0x0 1h = Software Reset is enabled : 0x1

43.7.3.230 DMA_SysBus_Mode Register (Offset = 1004h) [Reset = 0h]

DMA_SysBus_Mode is shown in Figure 43-269 and described in Table 43-323.

Return to the Summary Table.

The System Bus mode register controls the behavior of the AHB or AXI master. It mainly controls burst splitting and number of outstanding requests.

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	Reserved.
24	SPH	R/W	0h	Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload. This bit is available only if Enable Split Header Structure option is selected. 0h = Split Headers feature is disabled : 0x0 1h = Split Headers feature is enabled : 0x1
23-21	RESERVED	R	0h	Reserved.
20-18	DSL	R/W	0h	Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17	RESERVED	R	0h	Reserved.
16	PBLx8	R/W	0h	8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH0_Tx_Control and Bits[21:16] in DMA_CH0_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0h = 8xPBL mode is disabled : 0x0 1h = 8xPBL mode is enabled : 0x1
15-14	RESERVED	R	0h	Reserved.

Table 43-326. DMA_CH0_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13-0	MSS	R/W	0h	Maximum Segment Size This field specifies the maximum segment size that should be used while segmenting the packet. This field is valid only if the TSE bit of DMA_CH0_Tx_Control register is set. The value programmed in this field must be more than the configured Datawidth in bytes. It is recommended to use a MSS value of 64 bytes or more.

43.7.3.234 DMA_CH0_Tx_Control Register (Offset = 1104h) [Reset = 0h]

DMA_CH0_Tx_Control is shown in Figure 43-273 and described in Table 43-327.

Return to the Summary Table.

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

28	RESERVED	R	0h	Reserved.
27-24	RESERVED	R	0h	Reserved.
23	RESERVED	R	0h	Reserved.
22	ETIC	R/W	0h	Early Transmit Interrupt Control When this bit is set, Early Transmit Interrupt (ETI) status is set after completion of transfer of data from buffers of a transmit descriptor in which IOC bit (TDES2[31]) is set. When this bit is reset, ETI is set only after a complete packet is transferred to the MTL TX FIFO memory. 0h = Early Transmit Interrupt is disabled : 0x0 1h = Early Transmit Interrupt is enabled : 0x1
21-16	TxPBL	R/W	0h	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH0_Control register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15	RESERVED	R	0h	Reserved.
14-13	RESERVED	R	0h	Reserved.

Table 43-327. DMA_CH0_Tx_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	TSE	R/W	0h	TCP Segmentation Enabled When this bit is set, the DMA performs the TCP segmentation or UDP Segmentation/Fragmentation for packets in this channel. The TCP segmentation or UDP packet's segmentation/Fragmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor.When this bit is set, the TxPBL value must be greater than 4. 0h = TCP Segmentation is disabled : 0x0 1h = TCP Segmentation is enabled : 0x1
11-5	RESERVED	R	0h	Reserved.
4	OSF	R/W	0h	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0h = Operate on Second Packet disabled : 0x0 1h = Operate on Second Packet enabled : 0x1
3-1	TCW	R/W	0h	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
0	ST	R/W	0h	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0h = Stop Transmission Command : 0x0 1h = Start Transmission Command : 0x1

43.7.3.235 DMA_CH0_Rx_Control Register (Offset = 1108h) [Reset = 0h]

DMA_CH0_Rx_Control is shown in Figure 43-274 and described in Table 43-328.

Return to the Summary Table.

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

22	ERIC	R/W	0h	Early Receive Interrupt Control When this bit is set, Early Receive Interrupt (ERI) status is set after completion of every burst transfer of data from the Rx DMA to the buffer. When this bit is reset, ERI is set only after a complete buffer is filled up by the RxDMA. 0h = Early Receive Interrupt is disabled : 0x0 1h = Early Receive Interrupt is enabled : 0x1

Table 43-328. DMA_CH0_Rx_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
21-16	RxPBL	R/W	0h	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_Control register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15	RESERVED	R	0h	Reserved.
14-3	RBSZ_13_y	R/W	0h	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
2-1	RBSZ_x_0	R	0h	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0	SR	R/W	0h	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. - The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0h = Stop Receive : 0x0 1h = Start Receive : 0x1

43.7.3.236 DMA_CH0_TxDesc_List_Address Register (Offset = 1114h) [Reset = 0h]

DMA_CH0_TxDesc_List_Address is shown in Figure 43-275 and described in Table 43-329.

Return to the Summary Table.

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.
You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Bit	Field	Type	Reset	Description
31-2	TDESLA	R/W	0h	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
1-0	RESERVED	R	0h	

43.7.3.237 DMA_CH0_RxDesc_List_Address Register (Offset = 111Ch) [Reset = 0h]

DMA_CH0_RxDesc_List_Address is shown in Figure 43-276 and described in Table 43-330.

Return to the Summary Table.

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.
This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address.
When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Table 43-330. DMA_CH0_RxDesc_List_Address Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	RDESLA	R/W	0h	Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
1-0	RESERVED	R	0h	

43.7.3.238 DMA_CH0_TxDesc_Tail_Pointer Register (Offset = 1120h) [Reset = 0h]

DMA_CH0_TxDesc_Tail_Pointer is shown in Figure 43-277 and described in Table 43-331.

Return to the Summary Table.

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Table 43-336. DMA_CH0_Rx_Interrupt_Watchdog_Timer Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	Reserved.
17-16	RWTU	R/W	0h	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024 - 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8	RESERVED	R	0h	Reserved.
7-0	RWT	R/W	0h	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH0_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

43.7.3.244 DMA_CH0_Current_App_TxDesc Register (Offset = 1144h) [Reset = 0h]

DMA_CH0_Current_App_TxDesc is shown in Figure 43-283 and described in Table 43-337.

Return to the Summary Table.

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Figure 43-283. DMA_CH0_Current_App_TxDesc Register

This field does not generate an interrupt.

Table 43-341. DMA_CH0_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15	NIS	R/W	0h	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Normal Interrupt Summary status not detected : 0x0 1h = Normal Interrupt Summary status detected : 0x1
14	AIS	R/W	0h	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Abnormal Interrupt Summary status not detected : 0x0 1h = Abnormal Interrupt Summary status detected : 0x1
13	CDE	R/W	0h	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Context Descriptor Error status not detected : 0x0 1h = Context Descriptor Error status detected : 0x1
12	FBE	R/W	0h	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Fatal Bus Error status not detected : 0x0 1h = Fatal Bus Error status detected : 0x1
11	ERI	R/W	0h	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Early Receive Interrupt status not detected : 0x0 1h = Early Receive Interrupt status detected : 0x1

Table 43-341. DMA_CH0_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	ETI	R/W	0h	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Early Transmit Interrupt status not detected : 0x0 1h = Early Transmit Interrupt status detected : 0x1
9	RWT	R/W	0h	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0h = Receive Watchdog Timeout status not detected : 0x0 1h = Receive Watchdog Timeout status detected : 0x1
8	RPS	R/W	0h	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Receive Process Stopped status not detected : 0x0 1h = Receive Process Stopped status detected : 0x1
7	RBU	R/W	0h	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Receive Buffer Unavailable status not detected : 0x0 1h = Receive Buffer Unavailable status detected : 0x1
6	RI	R/W	0h	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Receive Interrupt status not detected : 0x0 1h = Receive Interrupt status detected : 0x1
5-3	RESERVED	R	0h	Reserved.

Table 43-341. DMA_CH0_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	TBU	R/W	0h	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Transmit Buffer Unavailable status not detected : 0x0 1h = Transmit Buffer Unavailable status detected : 0x1
1	TPS	R/W	0h	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Transmit Process Stopped status not detected : 0x0 1h = Transmit Process Stopped status detected : 0x1
0	TI	R/W	0h	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Transmit Interrupt status not detected : 0x0 1h = Transmit Interrupt status detected : 0x1

43.7.3.249 DMA_CH0_Miss_Frame_Cnt Register (Offset = 1164h) [Reset = 0h]

DMA_CH0_Miss_Frame_Cnt is shown in Figure 43-288 and described in Table 43-342.

Return to the Summary Table.

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	Reserved.
24	SPH	R/W	0h	Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload. This bit is available only if Enable Split Header Structure option is selected. 0h = Split Headers feature is disabled : 0x0 1h = Split Headers feature is enabled : 0x1
23-21	RESERVED	R	0h	Reserved.
20-18	DSL	R/W	0h	Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17	RESERVED	R	0h	Reserved.
16	PBLx8	R/W	0h	8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH0_Tx_Control and Bits[21:16] in DMA_CH0_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0h = 8xPBL mode is disabled : 0x0 1h = 8xPBL mode is enabled : 0x1
15-14	RESERVED	R	0h	Reserved.

Table 43-344. DMA_CH1_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13-0	MSS	R/W	0h	Maximum Segment Size This field specifies the maximum segment size that should be used while segmenting the packet. This field is valid only if the TSE bit of DMA_CH0_Tx_Control register is set. The value programmed in this field must be more than the configured Datawidth in bytes. It is recommended to use a MSS value of 64 bytes or more.

43.7.3.252 DMA_CH1_Tx_Control Register (Offset = 1184h) [Reset = 0h]

DMA_CH1_Tx_Control is shown in Figure 43-291 and described in Table 43-345.

Return to the Summary Table.

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

27-24	RESERVED	R	0h	Reserved.
23	RESERVED	R	0h	Reserved.
22	ETIC	R/W	0h	Early Transmit Interrupt Control When this bit is set, Early Transmit Interrupt (ETI) status is set after completion of transfer of data from buffers of a transmit descriptor in which IOC bit (TDES2[31]) is set. When this bit is reset, ETI is set only after a complete packet is transferred to the MTL TX FIFO memory. 0h = Early Transmit Interrupt is disabled : 0x0 1h = Early Transmit Interrupt is enabled : 0x1
21-16	TxPBL	R/W	0h	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH0_Control register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15	RESERVED	R	0h	Reserved.
14-13	RESERVED	R	0h	Reserved.

Table 43-345. DMA_CH1_Tx_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	TSE	R/W	0h	TCP Segmentation Enabled When this bit is set, the DMA performs the TCP segmentation or UDP Segmentation/Fragmentation for packets in this channel. The TCP segmentation or UDP packet's segmentation/Fragmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor.When this bit is set, the TxPBL value must be greater than 4. 0h = TCP Segmentation is disabled : 0x0 1h = TCP Segmentation is enabled : 0x1
11-5	RESERVED	R	0h	Reserved.
4	OSF	R/W	0h	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0h = Operate on Second Packet disabled : 0x0 1h = Operate on Second Packet enabled : 0x1
3-1	TCW	R/W	0h	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
0	ST	R/W	0h	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0h = Stop Transmission Command : 0x0 1h = Start Transmission Command : 0x1

43.7.3.253 DMA_CH1_Rx_Control Register (Offset = 1188h) [Reset = 0h]

DMA_CH1_Rx_Control is shown in Figure 43-292 and described in Table 43-346.

Return to the Summary Table.

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

27-24	RESERVED	R	0h	Reserved.
23	RESERVED	R	0h	Reserved.
22	ERIC	R/W	0h	Early Receive Interrupt Control When this bit is set, Early Receive Interrupt (ERI) status is set after completion of every burst transfer of data from the Rx DMA to the buffer. When this bit is reset, ERI is set only after a complete buffer is filled up by the RxDMA. 0h = Early Receive Interrupt is disabled : 0x0 1h = Early Receive Interrupt is enabled : 0x1

Table 43-346. DMA_CH1_Rx_Control Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
21-16	RxPBL	R/W	0h	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_Control register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15	RESERVED	R	0h	Reserved.
14-3	RBSZ_13_y	R/W	0h	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
2-1	RBSZ_x_0	R	0h	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0	SR	R/W	0h	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. - The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0h = Stop Receive : 0x0 1h = Start Receive : 0x1

43.7.3.254 DMA_CH1_TxDesc_List_Address Register (Offset = 1194h) [Reset = 0h]

DMA_CH1_TxDesc_List_Address is shown in Figure 43-293 and described in Table 43-347.

Return to the Summary Table.

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.
You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

43.7.3.255 DMA_CH1_RxDesc_List_Address Register (Offset = 119Ch) [Reset = 0h]

DMA_CH1_RxDesc_List_Address is shown in Figure 43-294 and described in Table 43-348.

Return to the Summary Table.

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.
This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address.
When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Table 43-352. DMA_CH1_RxDesc_Ring_Length Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	Reserved.
9-0	RDRL	R/W	0h	Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

43.7.3.260 DMA_CH1_Interrupt_Enable Register (Offset = 11B4h) [Reset = 0h]

DMA_CH1_Interrupt_Enable is shown in Figure 43-299 and described in Table 43-353.

Return to the Summary Table.

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Table 43-354. DMA_CH1_Rx_Interrupt_Watchdog_Timer Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	Reserved.
17-16	RWTU	R/W	0h	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024 - 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8	RESERVED	R	0h	Reserved.
7-0	RWT	R/W	0h	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH0_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

43.7.3.262 DMA_CH1_Current_App_TxDesc Register (Offset = 11C4h) [Reset = 0h]

DMA_CH1_Current_App_TxDesc is shown in Figure 43-301 and described in Table 43-355.

Return to the Summary Table.

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Figure 43-301. DMA_CH1_Current_App_TxDesc Register

This field does not generate an interrupt.
18-16	TEB	R	0h	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. Bit 18 - 1'b1: Error during data transfer by Tx DMA - 1'b0: No Error during data transfer by Tx DMA Bit 17 - 1'b1: Error during descriptor access - 1'b0: Error during data buffer access Bit 16 - 1'b1: Error during read transfer - 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Table 43-359. DMA_CH1_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15	NIS	R/W	0h	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Normal Interrupt Summary status not detected : 0x0 1h = Normal Interrupt Summary status detected : 0x1
14	AIS	R/W	0h	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Abnormal Interrupt Summary status not detected : 0x0 1h = Abnormal Interrupt Summary status detected : 0x1
13	CDE	R/W	0h	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Context Descriptor Error status not detected : 0x0 1h = Context Descriptor Error status detected : 0x1
12	FBE	R/W	0h	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Fatal Bus Error status not detected : 0x0 1h = Fatal Bus Error status detected : 0x1
11	ERI	R/W	0h	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Early Receive Interrupt status not detected : 0x0 1h = Early Receive Interrupt status detected : 0x1

Table 43-359. DMA_CH1_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	ETI	R/W	0h	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Early Transmit Interrupt status not detected : 0x0 1h = Early Transmit Interrupt status detected : 0x1
9	RWT	R/W	0h	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0h = Receive Watchdog Timeout status not detected : 0x0 1h = Receive Watchdog Timeout status detected : 0x1
8	RPS	R/W	0h	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Receive Process Stopped status not detected : 0x0 1h = Receive Process Stopped status detected : 0x1
7	RBU	R/W	0h	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Receive Buffer Unavailable status not detected : 0x0 1h = Receive Buffer Unavailable status detected : 0x1
6	RI	R/W	0h	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Receive Interrupt status not detected : 0x0 1h = Receive Interrupt status detected : 0x1
5-3	RESERVED	R	0h	Reserved.

Table 43-359. DMA_CH1_Status Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	TBU	R/W	0h	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Transmit Buffer Unavailable status not detected : 0x0 1h = Transmit Buffer Unavailable status detected : 0x1
1	TPS	R/W	0h	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Transmit Process Stopped status not detected : 0x0 1h = Transmit Process Stopped status detected : 0x1
0	TI	R/W	0h	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0h = Transmit Interrupt status not detected : 0x0 1h = Transmit Interrupt status detected : 0x1

43.7.3.267 DMA_CH1_Miss_Frame_Cnt Register (Offset = 11E4h) [Reset = 0h]

DMA_CH1_Miss_Frame_Cnt is shown in Figure 43-306 and described in Table 43-360.

Return to the Summary Table.

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Chapter 44

Generic Cyclic Redundancy Check (GCRC)

The Generic Cyclic Redundancy Check (GCRC) is a module that computes the cyclic redundancy check value of a specified block of data.

44.1 Generic CRC Overview

The Generic CRC (GCRC) is a designated Connectivity Manager module for computing the CRC value on a configurable block of memory. It accomplishes this by fetching the specified block of memory and using the integrated CRC engine. The calculated CRC value can be compared against a golden CRC value in software to indicate a pass or fail. In essence, the GCRC can help identify memory faults and corruption in the Conectivity Manager's accessible raw data.

44.1.1 GCRC Features

The Generic CRC (GCRC) module has the following features:

- Support programmable polynomials of any order between 1 and 32
- Calculate a CRC on byte (8-bit), half word (16-bit), and word (32-bit) data blocks
- Define the endianness and datatype of the source data
- Reverse the bit order
- Select which data bits participate in the CRC computation
- Single Cycle CRC calculation with fixed polynomial

44.1.2 GCRC Block Diagram

Figure 44-1 shows the block diagram of the GCRC module.

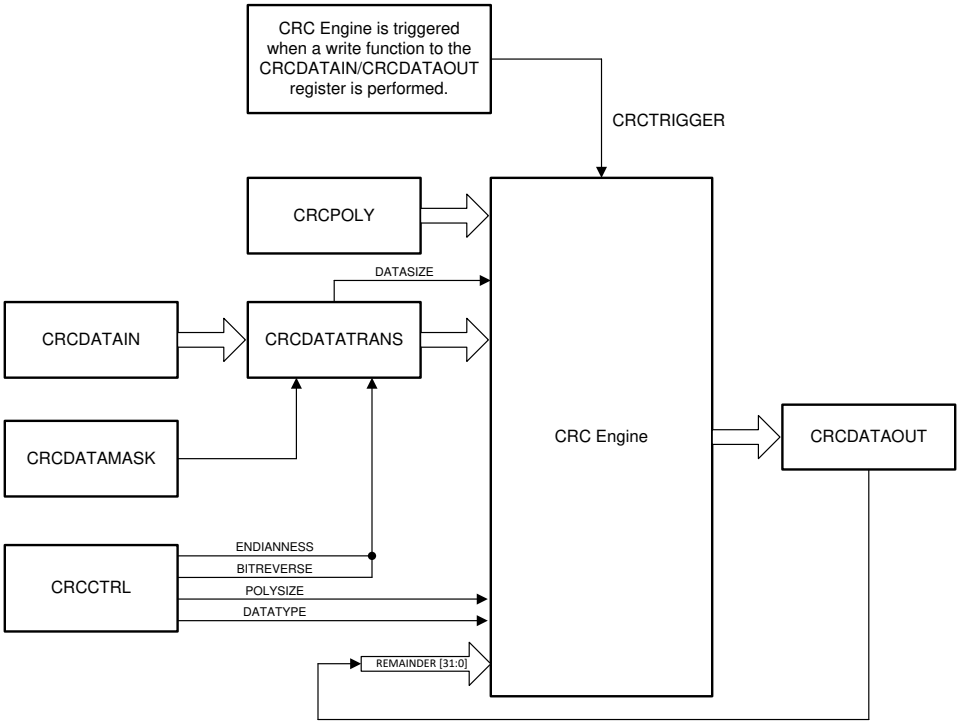

Figure 44-1. GCRC Block Diagram

The CRC is computed as:

$$M.x^n = G(x).Q(x) + R(x) \quad (24)$$

Where:

M : Is the data string that CRC is to be computed in the GF(2^n) polynomial representation

G(x) : Is the generator polynomial in the GF(2^n) field

R(x) : Is the CRC value

Q(x) : Is the quotient.

n : Is the order of the generator polynomial

44.2 GCRC Functional Description

44.2.1 GCRC Polynomials

The GCRC module allows the user to set a custom polynomial value to apply during the CRC calculation. This value is represented in hexadecimal format. The CRCCTRL.POLYSIZE should be set based on the size of the polynomial used in the CRCPOLY register.

44.2.2 Fixed Polynomial

If the polynomial value is not important, a fixed polynomial data path is provided. This fixed data path computes the CRC of a given data set in a single cycle. This mode requires the register setup in Table 44-1.

Table 44-1. Fixed Polynomial Data Path Settings

Register Field	Value
CRCPOLY.POLY	0x04c11db7
CRCCTRL.POLYSIZE	0x20
CRCCTRL.ENDIANNESS	0x0
CRCCTRL.BITREVERSE	0x0
CRCCTRL.DATATYPE	0x2
CRCDATAMASK.DATAMASK	0x0

44.2.3 GCRC Data Input

A write to the CRCDATAIN register will initiate the CRC computation sequence.

44.2.4 GCRC Execution Sequence Flow

Figure 44-2 explains the typical sequence flow for executing a cyclic redundancy check.

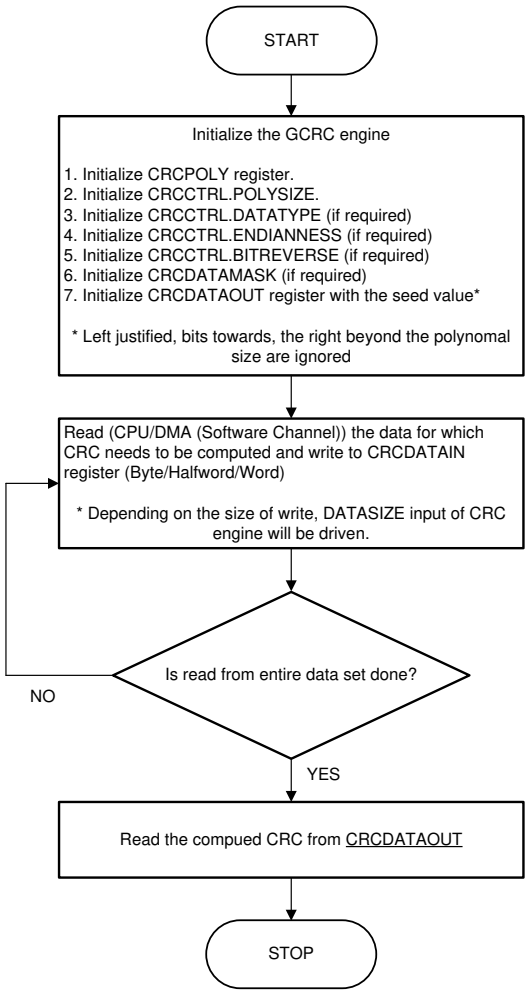

Figure 44-2. CRC Sequence Flow

Note

The Seed Value (CRCDATAOUT) should only be written after all the other configuration registers have been initialized to ensure proper functioning of the GCRC module.

44.2.5 GCRC Transformations

44.2.5.1 Endianness Transformation

The GCRC module is capable of transforming the data that is written to the DATAIN register. This data is stored in the CRCDATATRANS register and can be used for debugging purposes. The module is capable of applying three different transformations to the data provided by the user. The first is the endianness transformation. Table 44-2 shows how setting this byte in the control register influences the data that will be used for the CRC.

Table 44-2. Endianness Table

DATATYPE	Endianness	DATASIZE	DATAIN	DATAOUT	Valid Bits for CRC Calculation (BITS_VALID)
8	Little	8	0x------ab	0x------ab	8
8	Little	16	0x----abcd	0x----abcd	16
8	Little	32	0xabcdefgh	0xabcdefgh	32
8	Big	16	0x----abcd 0xabcd---	0xcdab0000	16
8	Big	32	0xabcdefgh	0xghefcdab	32
16	Little	16	0x----abcd	0x----abcd	16
16	Little	32	0xabcdefgh	0xabcdefgh	32
16	Big	32	0xabcdefgh	0xefghabcd	32
32	Little	32	0xabcdefgh	0xabcdefgh	32
32	Big	32	0xabcdefgh	0xabcdefgh	32
All Other Combinations		8	0x------ab 0x----ab-- 0x--ab---- 0xab------	0xab000000	8
		16	0x----abcd 0xabcd---	0xabcd0000	16
		32	0xabcdefgh	0xabcdefgh	32

44.2.5.2 Mask Transformation

The second transformation that the module is capable of applying is the data mask transformation. Table 44-3 shows how to utilize the data mask byte to control which data is used for the CRC calculation.

Table 44-3. Data Mask Table

BITS_VALID_IN	DATAIN	DATAMASK Example	DATAOUT	BITS_VALID_OUT
8	0bABCDEFGH_00000000_00000000_00000000	0x2	0bCDEFGH00_00000000_00000000_00000000	6
16	0bABCDEFGH_IJKLMNOP_00000000_00000000	0x9	0bJKLMNOP0_00000000_00000000_00000000	7
32	0bABCDEFGH_IJKLMNOP_QRSTUVWX_Yzabcdef	0x11	0bRSTUVWXY_zabcdef0_00000000_00000000	15

44.2.5.3 Bit Reversal Transformation

The last transformation the GCRC module is capable of applying to the input data is bit reversal. Table 44-4 shows the bit reversal modification being applied to the input data.

Table 44-4. Bit Reverse Table

BITS_VALID_IN	Example DATAIN	DATAOUT	BIT REVERSE
6	0bABDEFH00_00000000_00000000_00000000	0bHFEDBA00_00000000_00000000_00000000	1
12	0bABDEFHIJ_KNOP0000_00000000_00000000	0bPONKJIHF_EDBA0000_00000000_00000000	1

-	DATAIN	DATAOUT=DATAIN	0

44.3 Software

44.3.1 GCRC Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/gcrc

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

44.3.1.1 GCRC example - CM

FILE: gcrc_ex1_basic.c

This example showcases how to use GCRC to compute CRC for a 8-bit array. This demonstrates 2 methods for computing the CRC cm_common_config_c28x example needs to be run on C28x1 before running this example on the CM core

External Connections

- None

Watch Variables

- *crcResult1* - CRC value computed using Method 1
- *crcResult2* - CRC value computed using Method 2
- *crcGolden* - Golden CRC value

44.4 GCRC Registers

This section describes the Generic Cyclic Redunancy Check Registers.

44.4.1 GCRC Base Addresses

Table 44-5. GCRC Base Address Table (CM)

DriverLib Name	Base Address	uDMA Access	Ethernet DMA Access
GCRC_BASE	0x4004_0000	YES	-

44.4.2 GCRC_REGS Registers

Table 44-6 lists the memory-mapped registers for the GCRC_REGS registers. All register offset addresses not listed in Table 44-6 should be considered as reserved locations and the register contents should not be modified.

Table 44-6. GCRC_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CRCCTRL	CRC Control Register		Go
4h	CRCPOLY	CRC Polynomial Register		Go
8h	CRCDATAMASK	CRC Data Mask Register		Go
Ch	CRCDATAIN	CRC Data Input Register		Go
10h	CRCDATAOUT	CRC Data Output Register		Go
14h	CRCDATATRANS	CRC Transformed Data Register		Go

Complex bit access types are encoded to fit into small table cells. Table 44-7 shows the codes that are used for access types in this section.

Table 44-7. GCRC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

44.4.2.1 CRCCTRL Register (Offset = 0h) [Reset = 220h]

CRCCTRL is shown in Figure 44-3 and described in Table 44-8.

Return to the Summary Table.

This is the Control Register for GCRC module.

Figure 44-3. CRCCTRL Register

31	30	29	28	27	26	25	24
RESERVED							
R-0h							
23	22	21	20	19	18	17	16
RESERVED

BITREVERSE	ENDIANNESS	POLYSIZE					
R/W-0h	R/W-0h	R/W-20h					

Table 44-8. CRCCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	Reserved
9-8	DATATYPE	R/W	2h	Defines the datatype of the element of the data array, on which CRC is to be computed. 00 : Byte data type 01 : 16 bit data type 10 : 32 bit data type 11 : Reserved Note: This field works in conjunction with ENDIANNESS field. Reset type: CM.RESETn
7	BITREVERSE	R/W	0h	0: DATAIN bus to the CRC engine is sent as is. 1: DATAIN bus to the CRC engine is bit reversed. Reset type: CM.RESETn
6	ENDIANNESS	R/W	0h	0: Little endian. Endianness applies to word and half word writes. 1: Big endian. Endianness applies to word and half word writes. Note: This field works in conjunction with DATATYPE field. Reset type: CM.RESETn
5-0	POLYSIZE	R/W	20h	POLYSIZE: The value in this field determines the order of the polynomial. For example a value of 0x20 implies an order of 32,a value of 0x18 implies an order of 24 and a value of 0x10 implies an order of 16 and so on. Note: A value of 0x0 is not valid and values more than 0x20 will be treated as 0x20. Reset type: CM.RESETn

44.4.2.2 CRCPOLY Register (Offset = 4h) [Reset = 04C11DB7h]

CRCPOLY is shown in Figure 44-4 and described in Table 44-9.

Return to the Summary Table.

This register is used to store the Polynomial to used for the CRC calculation.

Figure 44-4. CRCPOLY Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POLY																															
R/W-04C11DB7h																															

Table 44-9. CRCPOLY Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	POLY	R/W	04C11DB7h	Polynomial value. For example, if the 1.x^3 + 0.x^2 + 1.x^1 + 1.x^0 (CRC3), taking the coeffecients and forming a binary string would result in 1011. The value to be programmed in this field is 11 (0x3), as MSB is assumed to be 1. Note: CRCCTRL.POLYSIZE should be programmed to 0x3 to indicate it is a CRC3 polynomial. Note: A value of zero for the POLY field in invalid and the behavior is not deterministic. Reset type: CM.RESETn

44.4.2.3 CRCDATAMASK Register (Offset = 8h) [Reset = 0h]

CRCDATAMASK is shown in Figure 44-5 and described in Table 44-10.

Return to the Summary Table.

This register is used to apply a data mask to the input data and decide which bits are used in CRC calculation.

Figure 44-5. CRCDATAMASK Register

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	0h	CRCDATAOUT value: This register stores the computed CRC, It can be initialized to the required seed value before the CRC computation begins, in which case it will act as a seed register. When this register is written, the value written into this register is considered as data (with a seed value of 0) and the CRC for this value is updated back to CRCDATAOUT register (This is required for Type-2 CRC implementation). Note: Seed value needs to be written only after all the other configuration registers are initialized for proper functioning of CRC module. Reset type: CM.RESETn

44.4.2.6 CRCDATATRANS Register (Offset = 14h) [Reset = 0h]

CRCDATATRANS is shown in Figure 44-8 and described in Table 44-13.

Return to the Summary Table.

This register contains the actual data that will be used for the CRC calculations. This is the value of CRCDATAIN after the bit mask, bit reverse, and data endianess transformations.

Figure 44-8. CRCDATATRANS Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Chapter 45

Modular Controller Area Network (MCAN)

This chapter describes the Modular Controller Area Network (MCAN). MCAN supports both classic CAN and CAN FD protocols.

45.1 MCAN Introduction

The Controller Area Network (CAN) is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. CAN has high immunity to electrical interference and the ability to detect various type of errors. In CAN, many short messages are broadcast to the entire network, which provides data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with flexible data-rate) protocols. The CAN FD feature allows higher throughput and increased payload per data frame. Classic CAN and CAN FD devices can coexist on the same network without any conflict provided that partial network transceivers, which can detect and ignore CAN FD without generating bus errors, are used by the classic CAN devices. The MCAN module is compliant to ISO 11898-1:2015.

Note

The availability of the CAN FD feature is dependent on the device's part number. Refer to the device data sheet for more information.

Figure 45-1 shows an overview of the MCAN module.

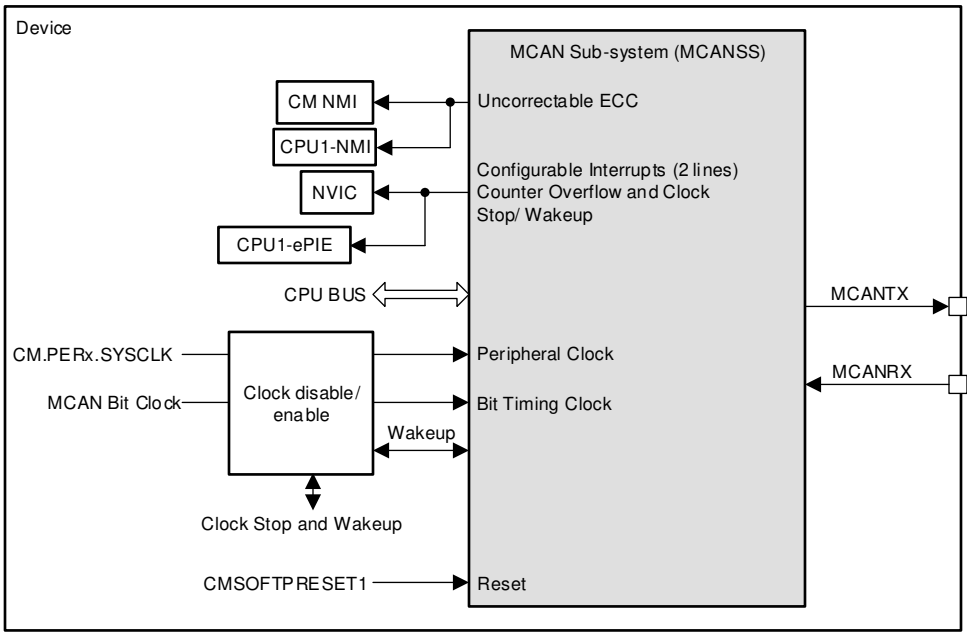

Figure 45-1. MCAN Module Overview

45.1.1 MCAN Related Collateral

Foundational Materials

- C2000 Academy - MCAN
- CAN and CAN FD Overview (Video)
- CAN and CAN FD Protocol (Video)

Getting Started Materials

- *Getting Started with the MCAN (CAN FD) Module Application Report*

45.1.2 MCAN Features

The MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated transmit buffers
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit Event FIFO, up to 32 elements
- Up to 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Loop-back mode for self-test
- Maskable interrupt (two configurable interrupt lines, correctable ECC, counter overflow, and clock stop or wakeup)
- Non-maskable interrupt (uncorrectable ECC)
- Two clock domains (CAN clock and host clock)
- ECC check for Message RAM
- Clock stop and wakeup support
- Timestamp counter
- 1-Mbps nominal bit rate, 5-Mbps data bit rate

Non-supported features:

- Host bus firewall
- Clock calibration
- Debug over CAN

45.2 MCAN Environment

The CAN network physical layer consists of a two-wire differential bus, usually twisted pair, and provides a high level of interference immunity. An external CAN transceiver IC is needed to access the bus.

Figure 45-2 shows typical MCAN wiring. Table 45-1 describes the external signals of the MCAN module.

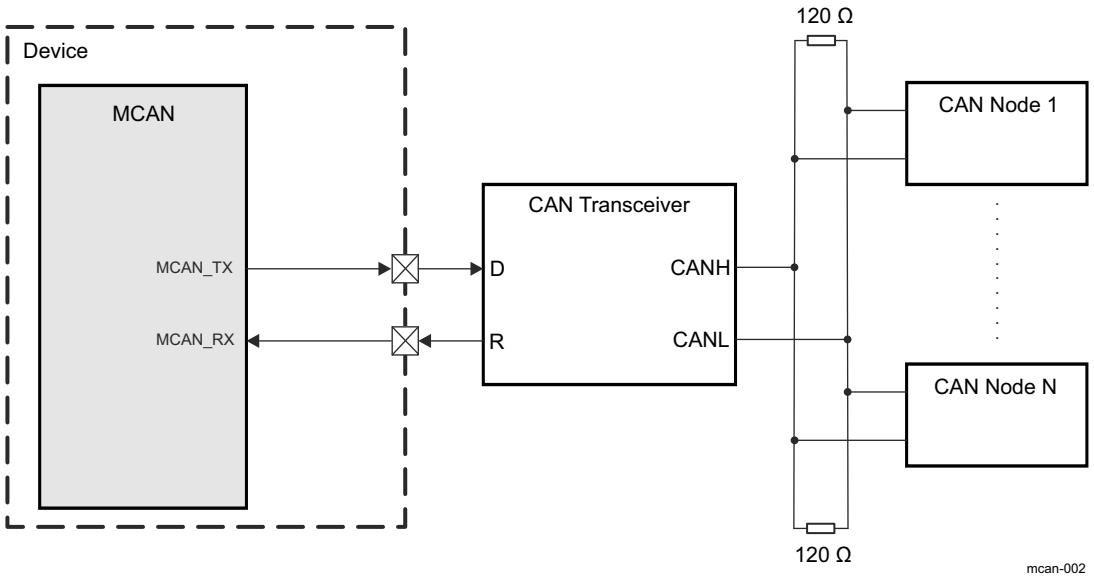

Figure 45-2. MCAN Typical Bus Wiring

Table 45-1. MCAN I/O Description

Module Signal	I/O	Description	Value at Reset
MCAN_RX	Input	Serial data input from external CAN transceiver.	HiZ
MCAN_TX	Output	Serial data output to external CAN transceiver.	HiZ

Note

See the *Terminal Configurations and Functions* section in the device data sheet and the *General-Purpose Input/Output (GPIO)* chapter to configure this peripheral to be connected to the device pins.

45.3 CAN Network Basics

The network basics are:

- The CAN bus is a 2-wire differential bus using non-return-to-zero (NRZ) encoding and has two states:
  - Recessive state (logical 1)
  - Dominant state (logical 0)
- When the bus is idle, any node can initiate a transmission to any other node (or nodes). When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique makes sure messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier-based, not address-based.
- The content of the message is labeled by the identifier that is unique throughout the network (for example: RPM, temperature, position, pressure, and so forth).
- All nodes on the network receive the message and each performs an acceptance test on the identifier. If the message is relevant, the message is processed; otherwise, the message is ignored.
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority).
- Data is transmitted and received using message frames, consisting of the following basic fields:
  - Arbitration field
  - Control field
  - Data field (up to 8 bytes for classical CAN and up to 64 bytes for CAN FD)
  - CRC field
  - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signaling*.

45.4 MCAN Integration

Figure 45-3 shows the integration of the MCAN module in the device.

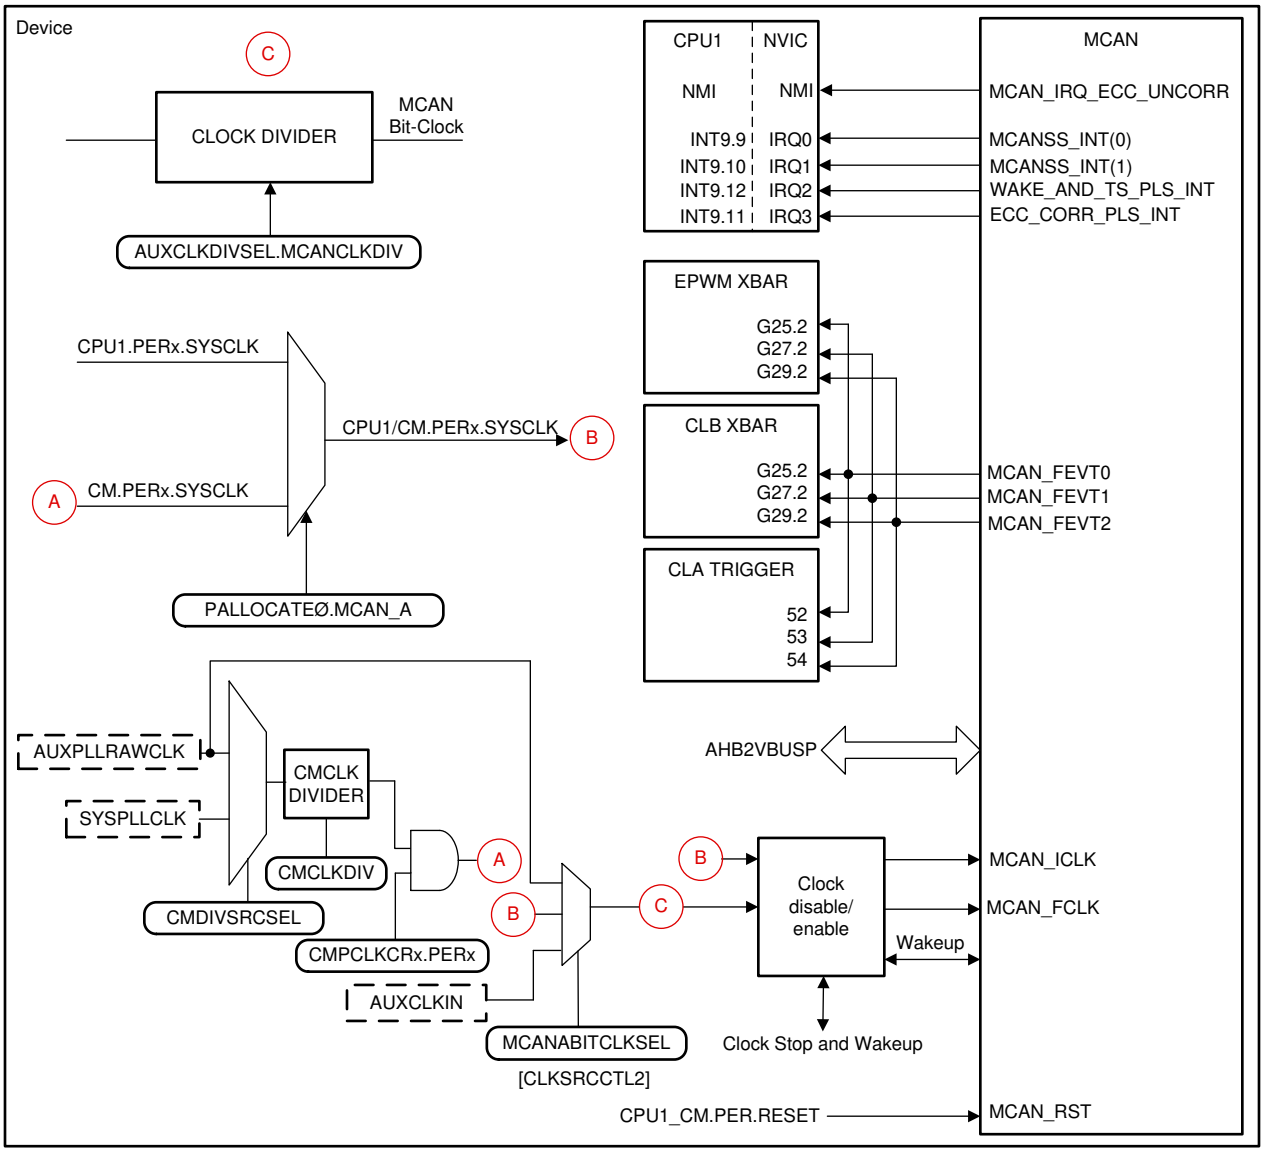

Figure 45-3. MCAN Integration

Table 45-2 and Table 45-3 summarize the integration of the MCAN module in the device.

Table 45-2. MCAN Clocks and Resets

Destination Signal Name	Source Signal Name	Description
Clocks		
MCAN_ICLK	CPU1/CM.PERx.SYSCLK	Interface clock for the MCAN module
MCAN_FCLK	MCANxBIT Clock	Bit timing clock for MCAN
Resets		
MCAN_RST	CPU1_CM.PER.RESET	Asynchronous reset signal to the MCAN module

Table 45-3. MCAN Hardware Requests

Interrupt Requests				
		Default Mapping

MCAN_FEVT2	EPWM XBAR CLB XBAR CLA Trigger		G29.2 G29.2 54	MCAN RX Filter Event 3

Note

For more information about the CLA_triggers, see the *Control Law Accelerator (CLA)* chapter.

For more information about the CLB XBAR, see the *Configurable Logic Block (CLB)* chapter.

For more information about the ePWM XBAR module, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

45.5 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The data bit rate can be programmed to values up to 5 Mbps. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 45-4 shows the MCAN module block diagram, followed by the description of the MCAN module blocks.

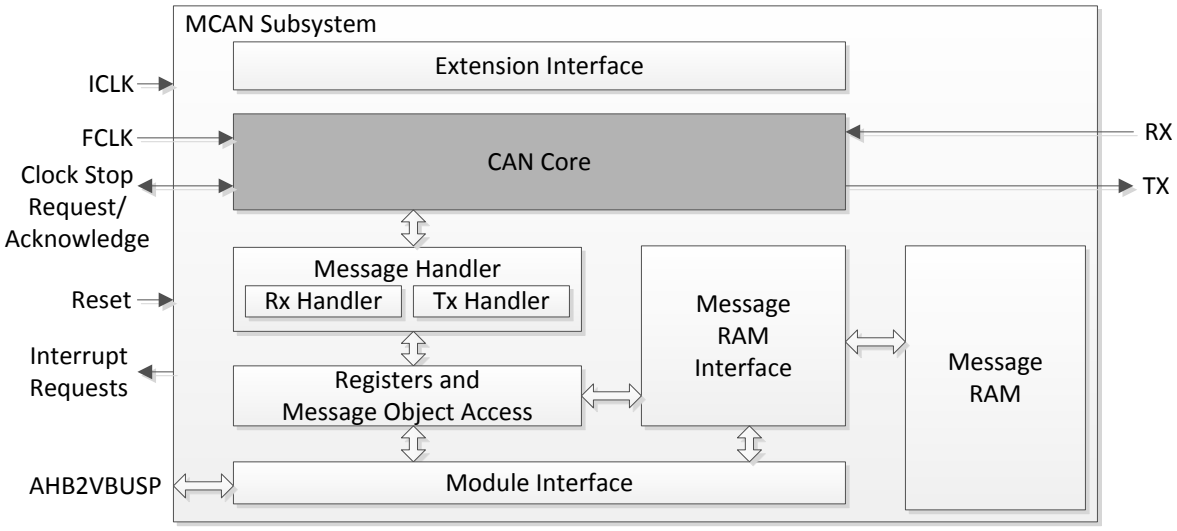

Figure 45-4. MCAN Block Diagram

- **CAN Core**: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. The CAN handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler**: the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. The Message Handler also handles the acceptance filtering and Interrupt generation as programmed in the control registers.
- **Message RAM**: the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see Section 45.5.16).
- **Message RAM Interface**: enables a connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access**: Data consistency is provided by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.
- **Module Interface**: The MCAN module registers are accessed by the user's software through a 32-bit peripheral bus interface.
- **Clocking**: Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN_ICLK) and the peripheral asynchronous clock (functional clock - MCAN_FCLK).
- **Extension Interface**: All selected internal status and control signals are routed to this interface (except for the indication signals of configuration change enable bit (MCAN_CCCR.CCE) and Interrupt Register bits (MCAN_IR).

45.5.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- Host Clock : peripheral synchronous clock (MCAN_ICLK) as the general module clock source, and
- CAN Clock: peripheral asynchronous clock (MCAN_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module, there is a synchronization mechanism implemented to make sure there is safe data transfer between the two clock domains. There is synchronization between the signals from the Host clock domain to the CAN clock domain and conversely, and between the reset signal (MCAN_RST) to the Host clock domain and to the CAN clock domain.

Note

MCAN_ICLK must always be higher or equal to MCAN_FCLK, to achieve a stable functionality of the MCAN module: $f_{ICLK} \geq f_{FCLK}$

The CAN-FD supports higher speeds of operation and as such has more stringent timing requirements than the classic CAN. For performance, TI recommends using the lowest N-divider value that maintains a working PLL REF_CLK for the system. Lower N-divider values increase the loop bandwidth of the PLL, which in turn improves timing margins for CAN-FD.

45.5.2 Interrupt Requests

The MCAN module generates interrupt requests and is configured using the Host CPU. The Suspend mode prevents the interrupt requests from propagating to the Host CPU. The MCAN core has two interrupt lines and 30 internal interrupt sources. Each source can be configured to drive one of the two interrupt lines. The interrupts are level high interrupts. The MCAN core provides two interrupt requests (MCANSS_INT0 and MCANSS_INT1).

For more information, see the following registers:

- Interrupt Register (MCAN_IR)
- Interrupt Enable (MCAN_IE)
- Interrupt Line Select (MCAN_ILS)
- Interrupt Line Enable (MCAN_ILE)

The MCAN module supports External Timestamp Counter. The External Timestamp Counter produces an interrupt when the count rolls over (see Section 45.5.10.1).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS_ICS)
- Interrupt Raw Status Register (MCANSS_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS_IECS)
- Interrupt Enable Register (MCANSS_IE)
- Interrupt Enable Status Register (MCANSS_IES)
- End Of Interrupt Register (MCANSS_EOI)
- External Timestamp Prescaler Register (MCANSS_EXT_TS_PRESCALER)
- External Timestamp Unserviced Interrupts Counter Register (MCANSS_EXT_TS_UNSERVICED_INTR_CNTR)

To clear IRQ_INT0, IRQ_INT1, and TS_WAKE interrupts, write to the EOI bit field for the corresponding interrupt number that is described in the MCANSS_EOI register. When the MCAN is used by the CPU, in addition to clearing the interrupt sources, clear the interrupt by writing 1 to PIEACK register in the bit position for group 9 (refer to the *PIE Channel Mapping* section of the *System Control and Interrupts* chapter) for successive MCAN interrupts to be recognized.

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write a 1 to the EOI registers (MCANERR_SEC_EOI.EOI_WR/ MCANERR_DED_EOI.EOI_WR). For more information, see Section 45.5.12.2.

45.5.3 Operating Modes

The operating modes are discussed in the following sections.

45.5.3.1 Software Initialization

A software initialization begins when the MCAN_CCCR.INIT bit is set to 1. This is done either by software or by a hardware reset, when an uncorrected bit error is detected in the Message RAM, or by going to a Bus_Off state. While the MCAN_CCCR.INIT bit is set, the message transfer is stopped and the status of the output TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN_CCCR.INIT bit does not change any configuration register. Resetting the MCAN_CCCR.INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN_CCCR.INIT and MCAN_CCCR.CCE bits are set (write protection).

The MCAN_CCCR.CCE bit can only be set/reset while the MCAN_CCCR.INIT = 1. The MCAN_CCCR.CCE bit is automatically reset when the MCAN_CCCR.INIT bit is reset.

The following registers are reset when the MCAN_CCCR.CCE bit is set:

- MCAN_HPMS - High Priority Message Status
- MCAN_RXF0S - Rx FIFO 0 Status
- MCAN_RFX1S - Rx FIFO 1 Status
- MCAN_TXFQS - Tx FIFO/Queue Status
- MCAN_TXBRP - Tx Buffer Request Pending
- MCAN_TXBTO - Tx Buffer Transmission Occurred
- MCAN_TXBCF - Tx Buffer Cancellation Finished
- MCAN_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN_TOCV.TOC field is preset to the value configured by the MCAN_TOCC.TOP field when the MCAN_CCCR.CCE bit is set.

In addition, the Tx Handler and Rx Handler are held in idle state while MCAN_CCCR.CCE = 1.

The following registers are only writable while MCAN_CCCR.CCE = 0

- MCAN_TXBAR - Tx Buffer Add Request
- MCAN_TXBCR - Tx Buffer Cancellation Request

MCAN_CCCR.TEST and MCAN_CCCR.MON bits can only be set by the Host CPU while MCAN_CCCR.INIT = 1 and MCAN_CCCR.CCE = 1. Both bits are reset at any time. The MCAN_CCCR.DAR bit can only be set/reset while MCAN_CCCR.INIT = 1 and MCAN_CCCR.CCE = 1.

Table 45-4 shows the steps to configure the MCAN module.

Table 45-4. Steps to Configure MCAN Module

Step	Operation	Description	Pseudo Code
1	Initialize MCAN_CCCR	Set MCAN_CCCR.INIT bit and check that the bit has been set	INIT = 1; If INIT ≠ 1, wait until set
2	Unlock protected registers	Set MCAN_CCCR.CCE bit	CCE = 1;
3	Configure CAN mode	Set MCAN_CCCR.FDOE bit to CAN FD	FDOE = 1 for CAN FD FDOE = 0 for Classic CAN
4	Configure Bit Rate Switching	Set MCAN_CCCR.BRSE bit	BRSE = 1 for bit rate switching BRSE = 0 for no bit rate switching
5	Set nominal bit timing(1)	Set MCAN_NBTP register	
6	Lock protected registers	Clear MCAN_CCCR.CCE bit	CCE = 0;

Table 45-4. Steps to Configure MCAN Module (continued)

Step	Operation	Description	Pseudo Code
7	Return MCAN module to normal operation	Clear MCAN_CCCR.INIT bit and check that the bit has been cleared	INIT = 0; If INIT ≠ 0, wait until cleared

(1) See the MCAN_NBTP register on how to program CAN bit timing in the *MCAN_REGS Registers* section.

45.5.3.2 Normal Operation

Once the MCAN module is initialized and the MCAN_CCCR.INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted, dedicated Tx buffers, and a Tx FIFO or a Tx queue can be initialized or updated.

Note

Automated transmission upon reception of remote frames is not supported.

45.5.3.3 CAN FD Operation

The CAN FD standard allows extended frames to be sent, up to 64 data bytes in a single frame at a higher bit rate for the data phase of a frame, up to 5 Mbps. The CAN FD standard introduces the ability to switch from one bit rate to another. Extended Data Length (EDL), as shown in Figure 45-5 and described in Table 45-5, sets a data length of up to 8 or 64 data bytes. Bit Rate Switching (BRS) indicates whether two bit rates (the data phase is transmitted at a different bit rate compared to the arbitration phase) are enabled.

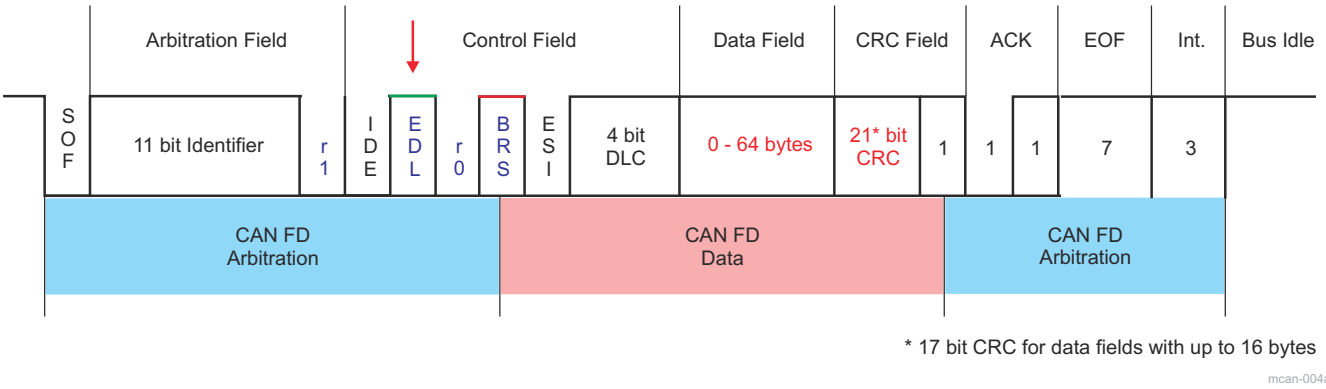

Figure 45-5. CAN FD Frame

Table 45-5. CAN FD Frame Description

Bit	Description
SOF	Start of Frame
IDE	Identifier extension (for 29 bit extended ID)
FDF	Flexible Data Format
BRS	Bit Rate Switching
ESI	Error Status Indicator
DLC	Data Length Code
CRC	Cyclic Redundancy check

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames, FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. If the MCAN module receives a frame with FDF = recessive and res = recessive, the MCAN signals a Protocol Exception Event by setting the MCAN_PSR.PXE bit. When Protocol Exception Handling is enabled (MCAN_CCCR.PXHD = 0), this causes the operation state to change from Receiver (MCAN_PSR.ACT = 10) to Integrating (MCAN_PSR.ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN_CCCR.PXHD = 1), the MCAN treats a recessive bit as an error and responds with an error frame.

CAN FD operation is enabled by programming the MCAN_CCCR.FDOE bit. If MCAN_CCCR.FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured using the FDF bit in the respective Tx Buffer element.

With MCAN_CCCR.FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN_CCCR.FDOE and MCAN_CCCR.BRSE bits can only be changed while the MCAN_CCCR.INIT and MCAN_CCCR.CCE bits are both set. With MCAN_CCCR.FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN_CCCR.FDOE = 1 and MCAN_CCCR.BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN_CCCR.FDOE = 1 and MCAN_CCCR.BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case, disable the CAN FD bit rate switching option for transmissions.
- During system startup, all nodes are transmitting Classic CAN messages until verified that the nodes are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wakeup messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

The coding of the DLC in the CAN FD format differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN (0 to 8 data bytes), the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to Table 45-6.

Table 45-6. DLC Coding in CAN FD

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

For CAN FD frames, the bit timing is switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see Figure 45-6) is used as configured by the Nominal Bit Timing and Prescaler Register (MCAN_NBTP). In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register (MCAN_DBTP). The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

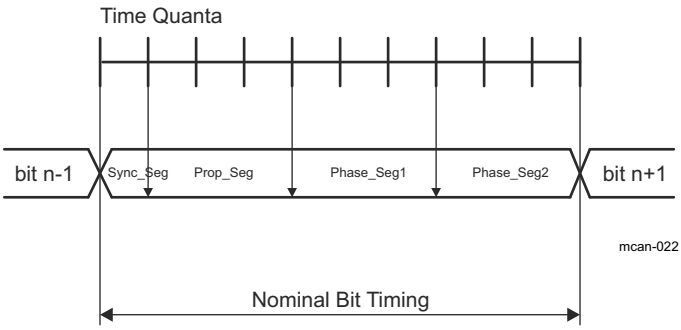

Figure 45-6. CAN Bit Timing

The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN_FCLK). Example: with MCAN_FCLK = 20 MHz and the shortest configurable bit time of 4 t_q (time quanta), the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the Error Status Indicator (ESI) bit depends on the transmitter error state (see MCAN_PSR.RESI bit) monitored at the start of the transmission. If the transmitter has an error passive flag, the ESI bit is transmitted recessive; else, the ESI bit is transmitted dominant.

45.5.4 Transmitter Delay Compensation

45.5.4.1 Description

When only one CAN FD node is transmitting and all other nodes are receivers, the length of the bus line has no impact. When transmitting using the TX pin, the MCAN module receives the transmitted data from the CAN transceiver using the RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate for the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN_DBTP.TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter reacts on this bit error at the next following regular sample point. During the arbitration phase, the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output TX pin through the transceiver to the receive input RX pin plus the transmitter delay compensation offset configured by the MCAN_TDCR.TDCO field (see Figure 45-7). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN_PSR.TDCV field. This field is cleared when the MCAN_CCCR_INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN_DBTP.TDC bit is set.

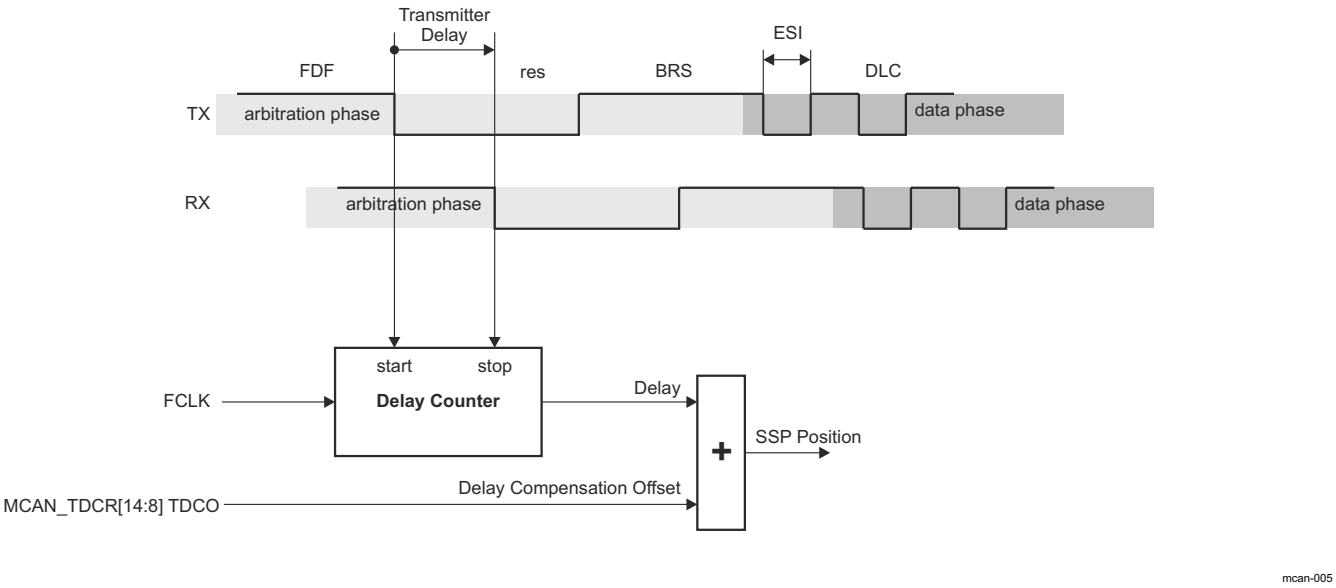

Figure 45-7. Transmitter Delay Measurement

45.5.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN_DBTP.TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit r0. The measurement is stopped when this edge is seen at the receive input RX pin of the transmitter. The resolution of this measurement is one mtq (see Figure 45-7). The mtq (minimum time quantum) dimension is equal to the CAN clock period (MCAN_FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming the MCAN_TDCR.TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the RX pin that result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN_TDCR.TDCF field and the RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN_TDCR.TDCO field) has to be less than six bit times in the data phase.
- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN_TDCR.TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

45.5.5 Restricted Operation Mode

In restricted operation mode, the CAN node is able to receive data and remote frames and to give acknowledgment to valid frames, but the node does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, the node does not send dominant bits; instead the node waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The receive and transmit error counters (MCAN_ECR.REC and MCAN_ECR.TEC) are frozen while CAN error logging (MCAN_ECR.CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting the MCAN_CCCR.ASM bit. The bit can only be set by the Host CPU at any time when both MCAN_CCCR.CCE and MCAN_CCCR.INIT bits are set to 1.

The restricted operation mode is automatically entered when the Tx Handler is not able to read data from the Message RAM in time. To leave restricted operation mode, the Host CPU has to reset the MCAN_CCCR.ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case, the application tests different bit rates and leaves the restricted operation mode after the node has received a valid frame.

Note

The Restricted Operation Mode must not be combined with the Loop Back Mode.

45.5.6 Bus Monitoring Mode

Entering bus monitoring mode is done by setting the MCAN_CCCR.MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus can remain in recessive state. In bus monitoring mode, the MCAN_TXBRP register is held in reset state. The bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting the bus by the transmission of dominant bits. Figure 45-8 shows the connection of the TX and RX signals to the MCAN module in bus monitoring mode.

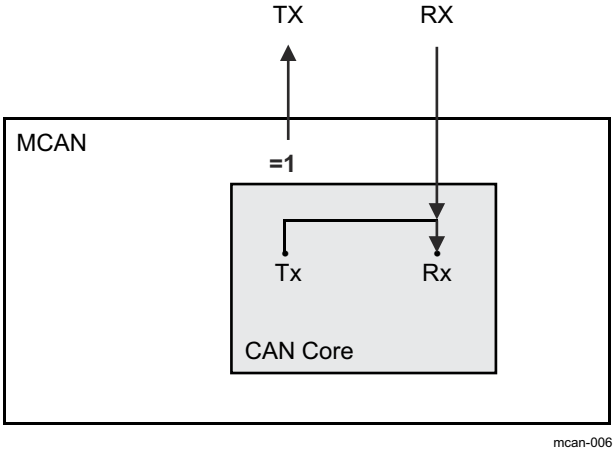

Figure 45-8. Connection of Signals in Bus Monitoring Mode

45.5.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN_CCCR.DAR bit).

45.5.7.1 Frame Transmission in DAR Mode

In DAR mode, the automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission is disabled. A Tx buffer's Tx Request Pending (MCAN_TXBRP[xx]) TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred (MCAN_TXBTO[xx]) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN_TXBCF[xx]) CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred (MCAN_TXBTO[xx]) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN_TXBCF[xx]) CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred (MCAN_TXBTO[xx]) TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished (MCAN_TXBCF[xx]) CFx bit is set

In the case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

45.5.8 Clock Stop Mode

Entering clock stop mode is controlled by the input clock stop request signal or MCAN_CCCR.CSR bit. As long as the clock stop request signal is active, the MCAN_CCCR.CSR bit is read as 1. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN_CCCR.INIT to 1 to prevent any further CAN transfers. The MCAN module acknowledges that the module is ready for power down by setting the output clock stop acknowledge signal to 1 and the MCAN_CCCR.CSA bit to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to the MCAN_CCCR.INIT bit has no effect. Now the module clock inputs MCAN_ICLK and MCAN_FCLK can be switched off.

To leave power-down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN_CCCR.CSR flag bit. The MCAN acknowledges this by resetting the output clock stop acknowledge signal respectively the MCAN_CCCR.CSA flag bit. Afterwards, the application can restart CAN communication by resetting the MCAN_CCCR.INIT bit.

Restoring the clocks from clock stop mode needs to be done according to how the clock stop was initiated.

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode when the clock stop request is asserted, the MCAN core responds with a clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN_CCCR.INIT bit is set, the MCAN core goes and stays Idle.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL.AUTOWAKEUP and MCANSS_CTRL.WAKEUPREQEN bits to 1 (for more information, see Section 45.5.8.2). When an external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN_CCCR.INIT bit is performed to clear the bit.

45.5.8.1 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS_CTRL.DBGSUSP_FREE bit) when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core responds with a clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point, the MCAN_CCCR.INIT bit is set and the MCAN core stays Idle. The suspend state can be verified by reading the MCAN_CCCR.INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL.AUTOWAKEUP and MCANSS_CTRL.WAKEUPREQEN bits to 1 (for more information, see Section 45.5.8.2). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN_CCCR.INIT bit is performed to clear the bit.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN_ECR.CEL
- MCAN_PSR.LEC
- MCAN_PSR.DLEC
- MCAN_PSR.RESI
- MCAN_PSR.RBRS
- MCAN_PSR.RFDF
- MCAN_PSR.PXE

45.5.8.2 Wakeup Request

Issuing a clock stop request puts the MCAN module into power-down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS_CTRL.AUTOWAKEUP and MCANSS_CTRL.WAKEUPREQEN bits are enabled, after the MCAN Core responds to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write is issued to clear the MCAN_CCCR.INIT bit and the MCAN core resumes operation.

If the MCANSS_CTRL.WAKEUPREQEN bit is set, the MCAN module provides a wakeup request on the following wakeup event:

- The receive RX pin is dominant (logical 0)

The wakeup request is deasserted when any of the following conditions occur:

- Clock stop request is removed and clock stop acknowledge is deasserted
- A reset is applied to the MCAN module

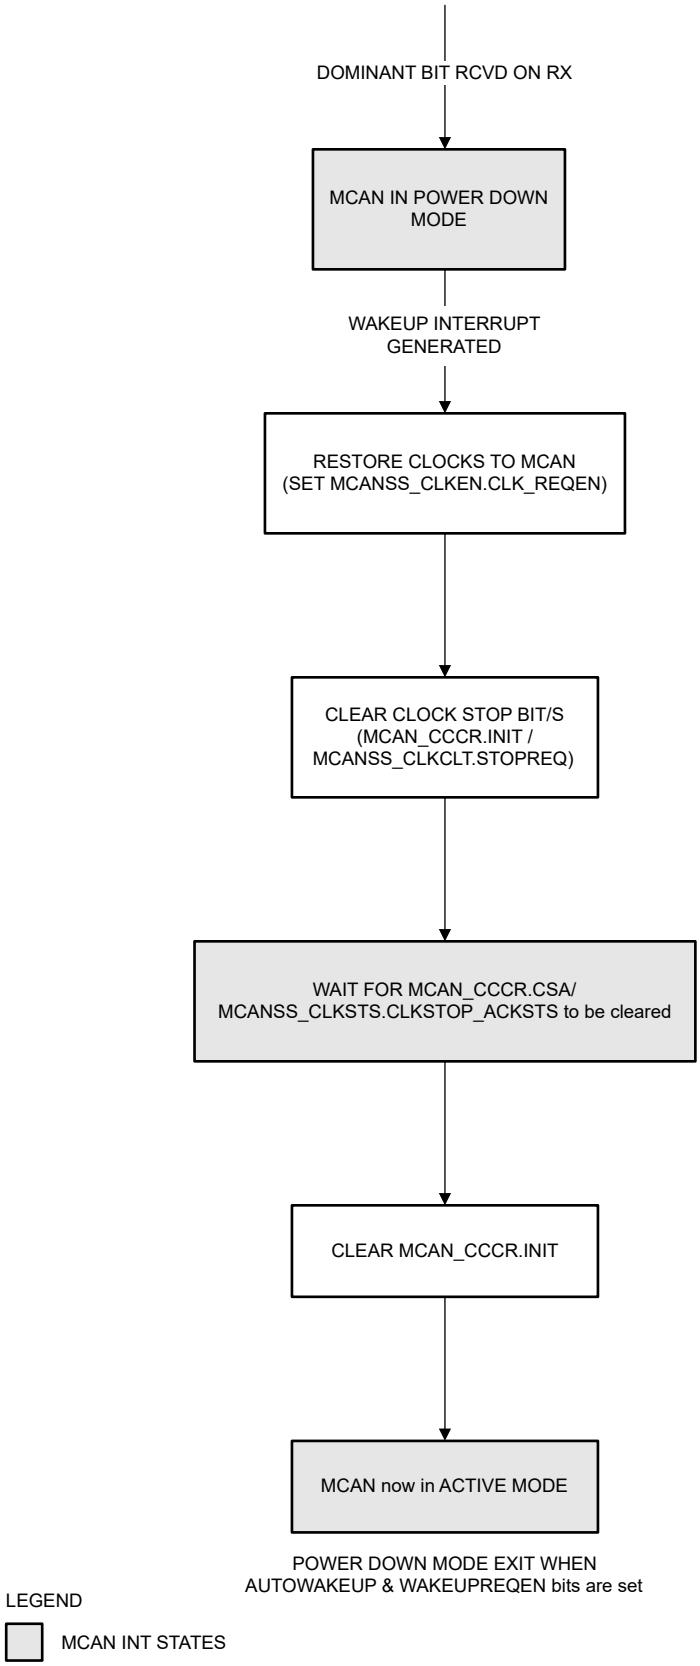

Figure 45-9. Auto Wakeup Enabled Exit from Power Down

45.5.9 Test Modes

The MCAN_TEST register write access is enabled by setting the test mode enable MCAN_CCCR.TEST bit to 1. The MCAN_TEST register allows the configuration of the test modes and test functions.

The transmit (TX) pin has four different output functions which can be selected by programming the MCAN_TEST.TX field. The default function is the serial data output. The pin can also be driven with a constant dominant or recessive value. It is also possible to drive the sample-point signal to monitor the bit-timing.

The actual value of the receive (RX) pin can be monitored from MCAN_TEST.RX bit. Both functions can be used to check the physical layer. Due to the synchronization mechanism between the CAN clock (MCANx_FCLK) and Host clock (MCANx_ICLK) domain, there can be a delay of several Host clock periods between writing to the MCAN_TEST.TX field until the new configuration is visible at the output TX pin. This applies also when reading input RX pin by way of the MCAN_TEST.RX bit.

Note

Test modes can be used for self-test only. The software control for TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for an application.

45.5.9.1 External Loop Back Mode

The MCAN module can be set into external loop back mode by programming MCAN_TEST.LBCK to 1. In loop back mode, the MCAN treats their own transmitted messages as received messages and stores them (if the messages pass acceptance filtering) into an Rx Buffer or an Rx FIFO. Figure 45-10 shows the connection of the TX and RX pins to the MCAN module in external loop back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the MCAN module ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loop back mode. In this mode, the MCAN module performs an internal feedback from the Tx output to the Rx input. The actual value of the RX input pin is disregarded by the MCAN module. The transmitted messages are monitored at the TX pin.

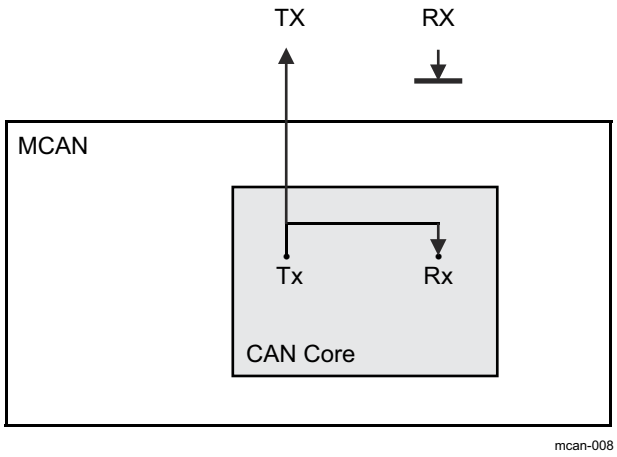

Figure 45-10. External Loop Back Mode

45.5.9.2 Internal Loop Back Mode

The MCAN module can be set into internal loop back mode by programming MCAN_TEST.LBCK and MCAN_CCCR.MON bits to 1. The internal loop back mode is used for a Hot Self-test. The Hot Self-test allows the MCAN module to be tested without affecting a running CAN system connected to the TX and RX pins. In this mode, the RX pin is disconnected from the MCAN module and the TX pin is held recessive. Figure 45-11 shows the connection of the TX and RX pins to the MCAN module in internal loop back mode.

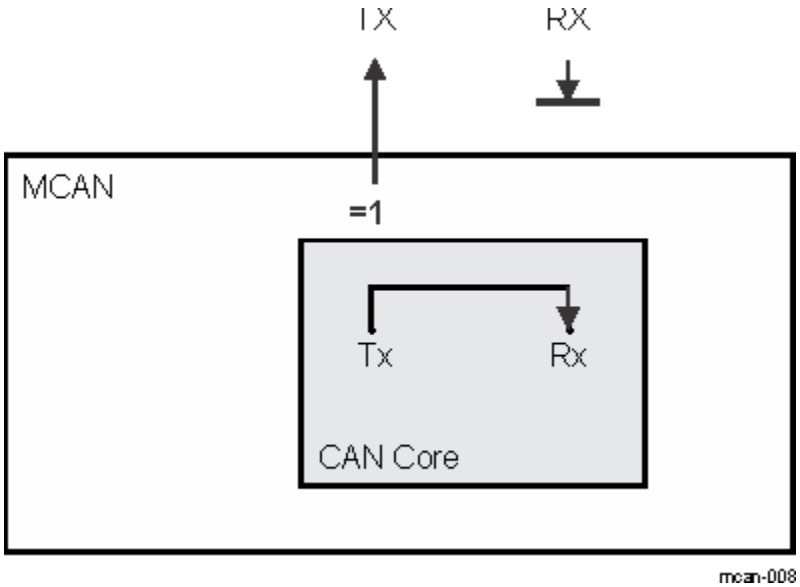

Figure 45-11. Internal Loop Back Mode

45.5.10 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN_TSCC.TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable by way of the MCAN_TSCV.TSC field. A write access to the MCAN_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN_IR.TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see Section 45.5.16.

45.5.10.1 External Timestamp Counter

For CAN FD operation mode, the MCAN core requires an external timestamp counter (see Figure 45-12). An externally generated 16-bit vector can substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN_TSCC.TSS field.

The external timestamp counter uses the interface clock (MCANx_ICLK) as a reference clock. The MCAN core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS_EXT_TS_PRESCALER.PRESCALER bit field). The external timestamp counter can be enabled or disabled through the MCANSS_CTRL.EXT_TS_CNTR_EN bit. When disabled, the counter is reset back to zero. While enabled, the counter keeps incrementing. When the timestamp rolls over, the MCAN_IRQ_TS interrupt is generated.

When the timestamp rolls over, the MCANSS_IRS register is set. The MCANSS_IE register can be affected by writing to the MCANSS_IESS register to set or to the MCANSS_IECS register to clear. The MCANSS_IESS register is a shadow register mapped to the same address as the MCANSS_IE register. The level interrupt is a reflection of both MCANSS_IRS and MCANSS_IE being set. The MCANSS_IES register reflects the level interrupt. When a rollover event occurs, the interrupt counter is incremented. Writing to the MCANSS_ICS register to clear the MCANSS_IRS register also decrements the interrupt counter. Writing to the MCANSS_EOI register issues another pulse, if the interrupt counter is not zero.

The rollover event can be artificially simulated by software through writing to the Interrupt Set Shadow register (MCANSS_ISS). The MCANSS_ISS register is a shadow register mapped to the same address as the MCANSS_IRS register.

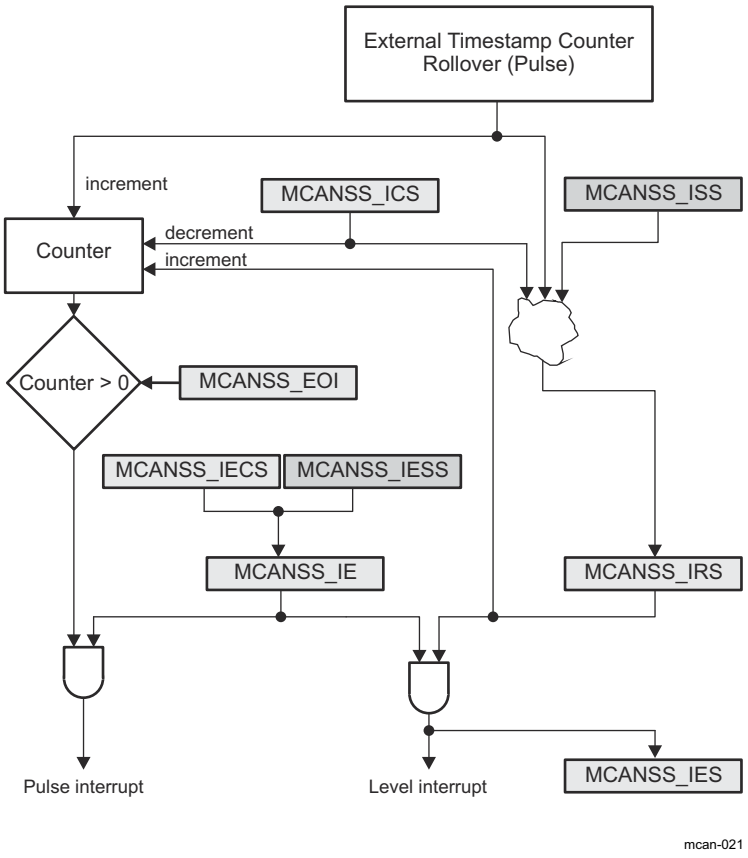

Figure 45-12. External Timestamp Counter Interrupt

45.5.11 Timeout Counter

The MCAN module has an integrated 16-bit timeout counter. The timeout counter is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The timeout counter is configured using the MCAN_TOCC register and is enabled using the MCAN_TOCC.ETOC bit. The timeout counter operates as down-counter and uses the same prescaler programmed by the MCAN_TSCC.TCP field as the timestamp counter. The actual counter value can be monitored from the MCAN_TOCV.TOC field. The timeout counter can be started only when MCAN_CCCR.INIT = 0 and stopped when MCAN_CCCR.INIT = 1 (example: when the MCAN enters Bus_Off state). The operation mode is selected by the MCAN_TOCC.TOS field. When continuous mode is selected, the counter starts when MCAN_CCCR.INIT = 0, a write to the MCAN_TOCV register presets the counter to the value configured by the MCAN_TOCC.TOP field and continues down-counting.

In case the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN_TOCC.TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN_IR.TOO flag is set.

In continuous mode, the counter is immediately restarted at the value configured by the MCAN_TOCC.TOP field.

Note

The clock signal for the timeout counter is derived from the CAN core sample point signal. Therefore, the point in time where the timeout counter is decremented can vary due to the synchronization/re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

45.5.12 Safety

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC aggregator.

45.5.12.1 ECC Wrapper

The ECC wrapper provides single error correction (SEC) and double error detection (DED) parity to the message memory content. The ECC wrapper has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, the error is noted in a FIFO queue that waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

45.5.12.2 ECC Aggregator

This section describes the functional details of the ECC aggregator module.

45.5.12.2.1 ECC Aggregator Overview

The ECC aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bits that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

45.5.12.2.2 ECC Aggregator Registers

There are three groups of registers in the ECC aggregator module:

- **Global registers:** Aggregator Revision Register (MCANERR_REV), ECC Vector Register (MCANERR_VECTOR), Misc Status Register (MCANERR_STAT), ECC Control Register (MCANERR_CTRL), and ECC Wrapper Revision Register (MCANERR_WRAP_REV).
- **Control and status registers:** ECC Error Control Registers (MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2) and ECC Error Status Registers (MCANERR_ERR_STAT1, MCANERR_ERR_STAT2, and MCANERR_ERR_STAT3).
- **Interrupt registers:** interrupt status, interrupt enable set, interrupt enable clear, and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
  - MCANERR_SEC_EOI
  - MCANERR_SEC_STATUS
  - MCANERR_SEC_ENABLE_SET
  - MCANERR_SEC_ENABLE_CLR
  - MCANERR_DED_EOI
  - MCANERR_DED_STATUS
  - MCANERR_DED_ENABLE_SET
  - MCANERR_DED_ENABLE_CLR

45.5.12.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as:

- Software writes value (the ECC RAM ID) to the MCANERR_VECTOR.ECC_VECTOR field to select the ECC RAM for control or status.
- Software writes 1 to the MCANERR_VECTOR.RD_SVBUS bit to trigger a read.
- Software writes read address to the MCANERR_VECTOR.RD_SVBUS_ADDRESS field.
- Software then polls the MCANERR_VECTOR.RD_SVBUS_DONE bit to check if the bit is 1. This bit indicates that the read operation has completed.
- Software reads the data from the ECC control or status register. The following clock cycle (MCAN_ICLK) returns the read data.

45.5.12.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described:

- Software enables the interrupts for the ECC RAM by writing to the MCANERR_SEC_ENABLE_SET/ MCANERR_DED_ENABLE_SET register.
- Software writes the ECC RAM ID in the MCANERR_VECTOR.ECC_VECTOR.
- Software writes the MCANERR_VECTOR.RD_SVBUS bit to trigger the read.
- Software writes the MCANERR_ERR_STAT1 register address to the MCANERR_VECTOR.RD_SVBUS_ADDRESS field. Software needs to load the 'read message' in the rMCANERR_VECTOR register again, if the software needs to read the MCANERR_ERR_STAT2 register.
- Software polls the MCANERR_VECTOR.RD_SVBUS_DONE bit. When this bit is set, a read of the MCANERR_ERR_STAT1/MCANERR_ERR_STAT2 register is performed.
- After the interrupt has been serviced, software clears the interrupt status by writing to the MCANERR_ERR_STAT1.CLR_ECC_SEC or MCANERR_ERR_STAT1.CLR_ECC_DED bit depending on the type of the ECC error.
- Software polls the MCANERR_ERR_STAT1 register to verify that the status bit has been cleared.
- Software writes to the MCANERR_SEC_EOI/MCANERR_DED_EOI register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write 1 to the MCANERR_SEC_EOI.EOI_WR /MCANERR_DED_EOI.EOI_WR bits.

45.5.13 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

45.5.13.1 Acceptance Filtering

The MCAN module employs two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic bit mask filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register
- Extended ID AND Mask (MCAN_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in Section 45.5.16) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN_ICLK pulse.
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN_IR.HPM
- Set High Priority Message interrupt flag MCAN_IR.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32-bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer: New Data flag (MCAN_NDAT1/MCAN_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type, see MCAN_PSR.LEC and MCAN_PSR.DLEC fields,respectively).
- Rx FIFO: Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type, see MCAN_PSR.LEC and MCAN_PSR.DLEC fields, respectively). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in Section 45.5.13.2.2 have to be considered.

Note

When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filters used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

45.5.13.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see Section 45.5.16.5 and Section 45.5.16.6.

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN_XIDAM) is not used for Range Filtering.

45.5.13.1.2 Filter for Specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT =01/ Extended Filter Type EFT =01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information, see Section 45.5.16.5 and Section 45.5.16.6.

45.5.13.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT =10/Extended Filter Type EFT =10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while the SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) masks out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

45.5.13.1.4 Standard Message ID Filtering

Figure 45-13 shows the standard Message ID (11-bit ID) filtering flow. Section 45.5.16.5 describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register

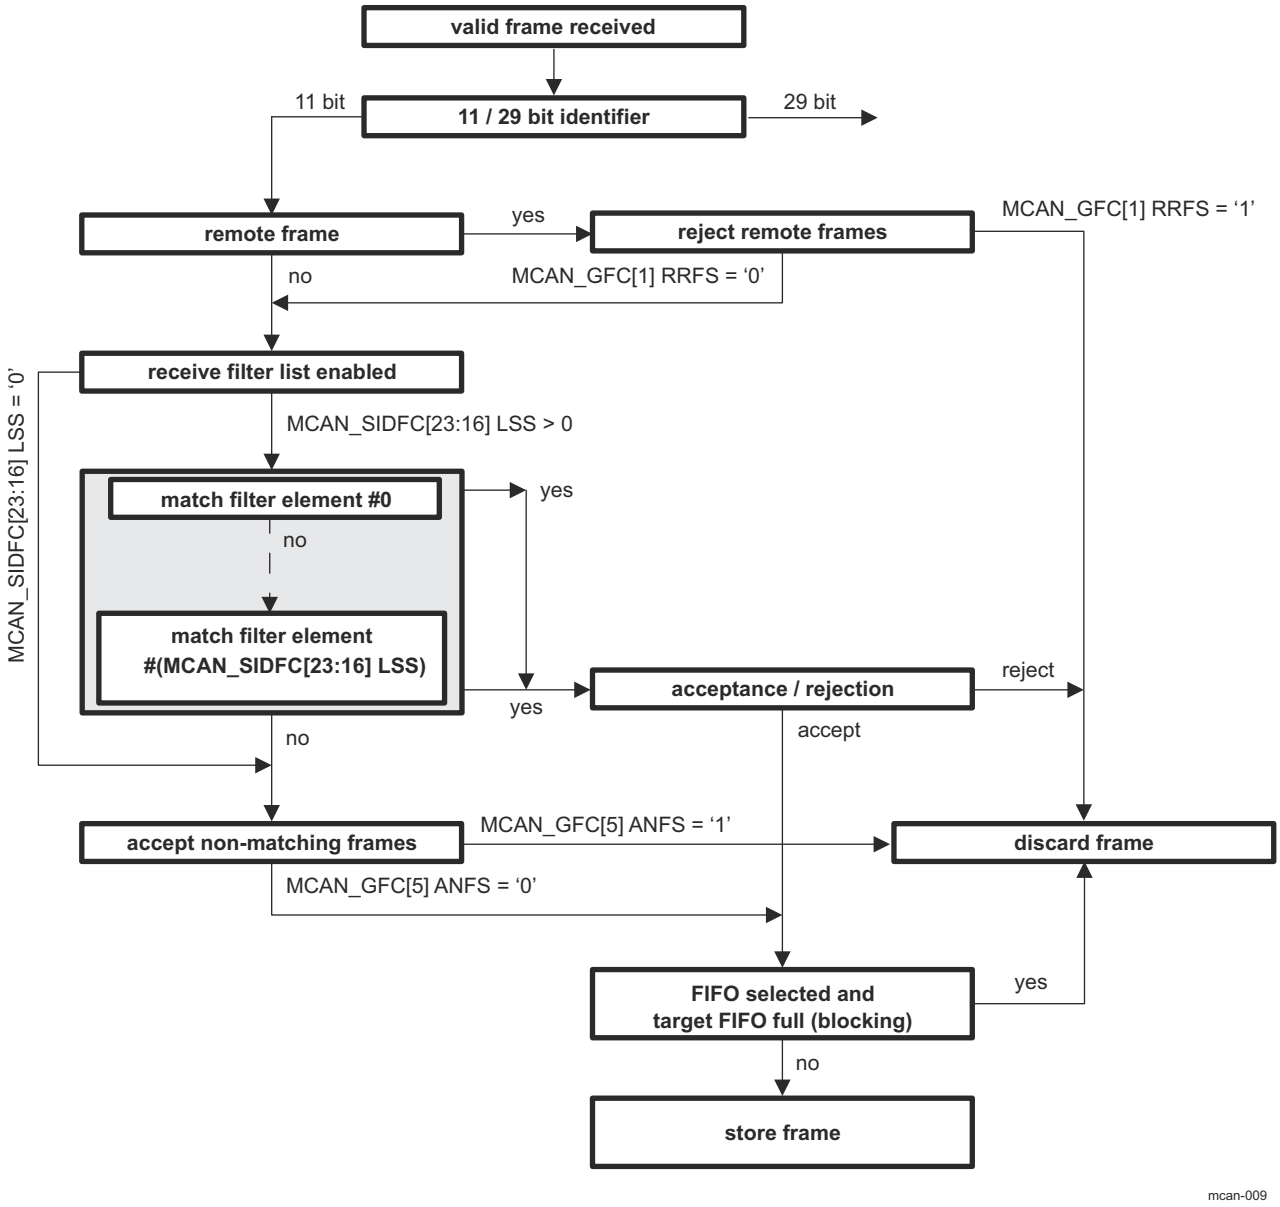

Figure 45-13. Standard Message ID Filter Path

45.5.13.1.5 Extended Message ID Filtering

Figure 45-14 shows the extended Message ID (29-bit ID) filtering flow. Section 45.5.16.6 describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register

Note that before the filter list is executed, the received identifier is ANDed with the Extended ID AND Mask (MCAN_XIDAM).

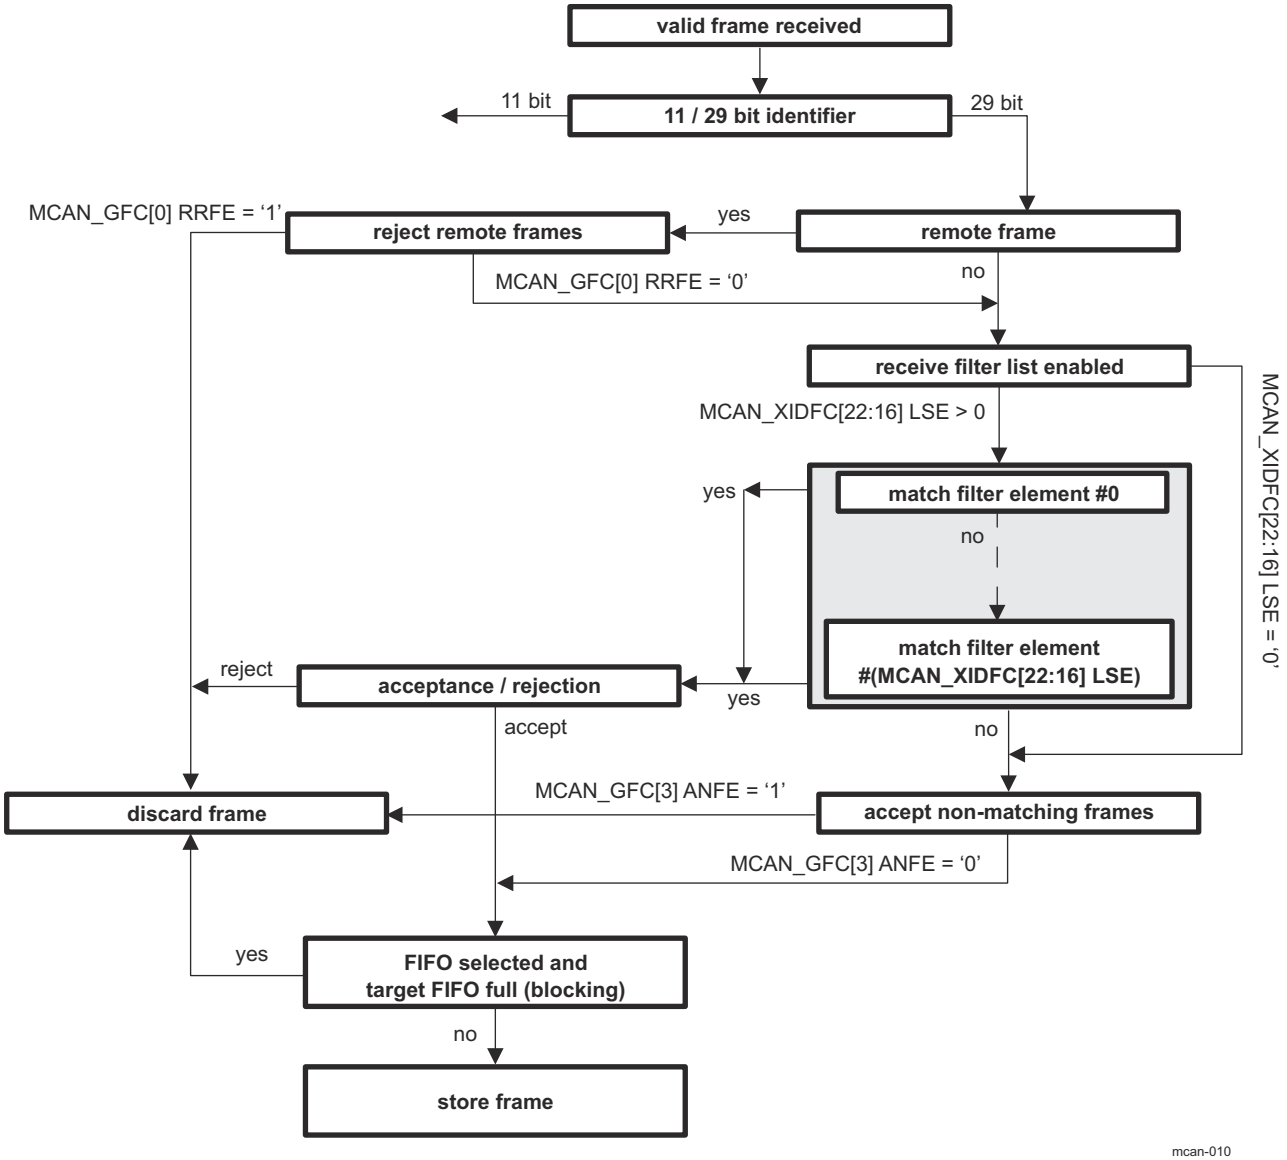

Figure 45-14. Extended Message ID Filter Path

45.5.13.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done by way of the MCAN_RXF0C and MCAN_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 are described in Section 45.5.13.1. The Rx FIFO element is described in Section 45.5.16.2.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN_RXFnC[30:24] FnWM filed (where: n = 0 or 1), an interrupt flag MCAN_IR.RF0W/MCAN_IR.RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI), an Rx FIFO Full condition is signaled by the MCAN_RXFnS[24] FnF status bit and interrupt flag MCAN_IR.RF0F/MCAN_IR.RF1F is set. Figure 45-15 shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN_RXFnS[6:0] FnFL field (the number of elements stored in Rx FIFO).

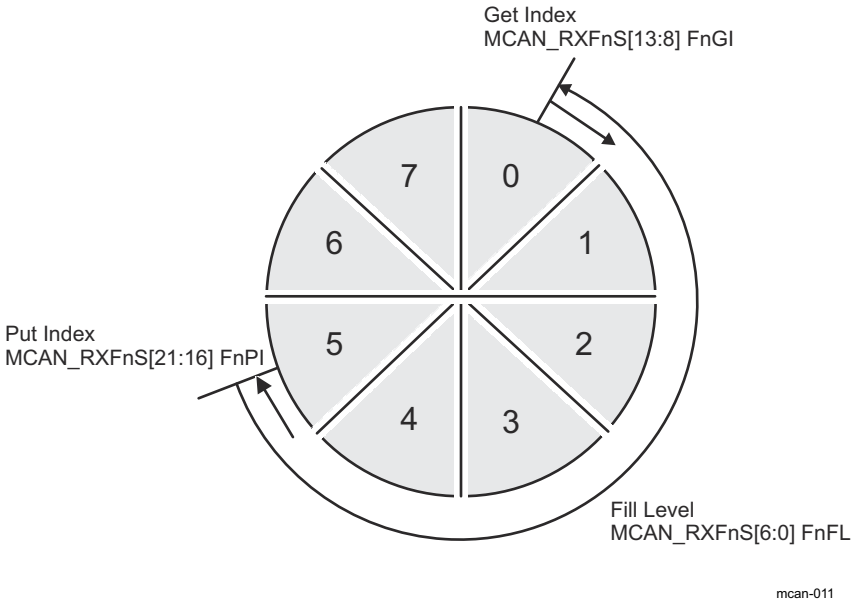

Figure 45-15. Rx FIFO Status

Rx FIFOs start address in the Message RAM (MCAN_RXFnC[15:2]FnSA field) has to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN_RXFnS[13:8] FnGI). Table 45-7 presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer / Rx FIFO Data Field Size which is configured by way of the MCAN_RXESC register.

Table 45-7. Rx Buffer/Rx FIFO Element Size

MCAN_RXESC Register RBDS/F0DS/F1DS Bits	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

45.5.13.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs and is configured by MCAN_RXFnC[31] FnOM = 0.

If an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signaled by the MCAN_RXFnS[24] FnF = 1 and interrupt flag MCAN_IR.RF0F/MCAN_IR.RF1F is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signaled by MCAN_RXFnS[25] RFnL = 1 and interrupt flag MCAN_IR.RF0L/ MCAN_IR.RF1L is set.

45.5.13.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by MCAN_RXFnC[31] FnOM = 1. When an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) signaled by MCAN_RXFnS[24] FnF = 1, the next accepted message for the FIFO overwrites the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signaled, reading of the Rx FIFO elements starts at least at get index + 1. The reason for this is a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case, inconsistent data can be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 45-16 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case, the two messages stored in element 1 and 2 are lost.

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN_RXFnA[5:0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN_RXFnS[24] FnF = 0).

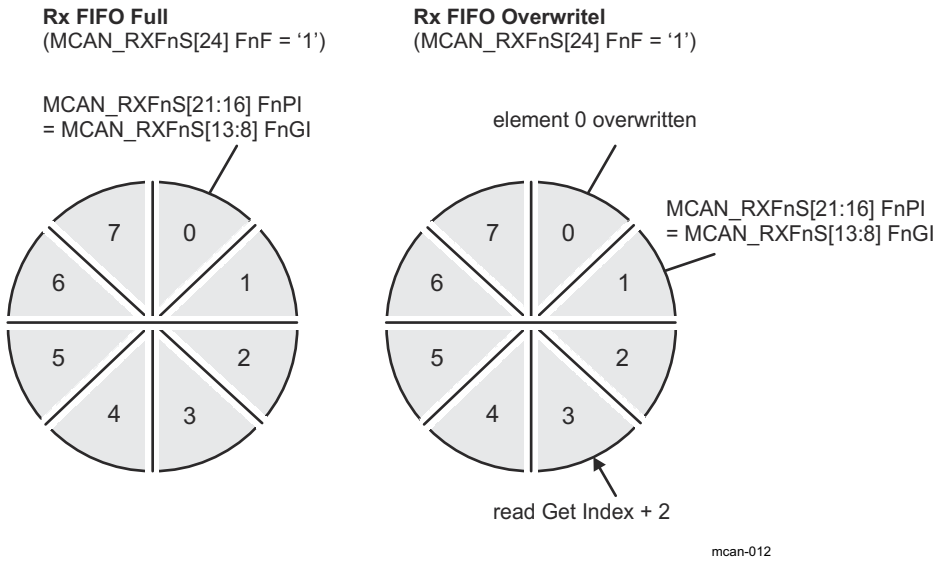

Figure 45-16. Rx FIFO Overflow Handling

45.5.13.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx buffers. The start address of the Rx buffers section in the Message RAM is configured by way of the MCAN_RXBC.RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10:9] = 00 has to be configured (see Section 45.5.16.5 and Section 45.5.16.6).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition, the flag MCAN_IR.DRX (message stored in Dedicated Rx Buffer) is set.

Table 45-8 shows an example filter configuration for Rx buffers.

Table 45-8. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN_NDAT1/MCAN_NDAT1 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx buffer New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer does not match, causing the acceptance filtering to continue. Following Message ID Filter Elements can cause the received message to be stored into another Rx Buffer, into an Rx FIFO, or the message can be rejected, depending on filter configuration.

45.5.13.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN_IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

45.5.14 Tx Handling

The Tx handler is used to handle the Tx requests. The Tx handler controls the transfer of transmit messages from the dedicated Tx buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx buffers. These Tx buffers can be configured as dedicated Tx buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx buffers/Tx FIFO or dedicated Tx buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. Section 45.5.16.3 describes the Tx Buffer Element. Table 45-9 shows the possible configurations for message transmission.

Table 45-9. Possible Configurations for Message Transmission

MCAN_CCCR Register		Tx Buffer Element		Frame Transmission
BRSE	FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending (MCAN_TXBRP) register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with the lowest Message ID has highest priority.

Note

AUTOSAR requires at least three Tx Queue buffers and support of transmit cancellation.

45.5.14.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs can have a higher priority than other defined Message IDs, while in a specific application their relative priority can be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN_CCCR.TXP bit. By default this bit is disabled (MCAN_CCCR.TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

45.5.14.2 Dedicated Tx Buffers

Dedicated Tx buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done using the MCAN_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 45-10 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates element size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN_TXFQS.TFQP) × Element size to the Tx Buffer start address MCAN_TXBC.TBSA field.

Table 45-10. Tx Buffer, Tx FIFO, Tx Queue Element Size

MCAN_TXESC.TBDS	Data Field (bytes)	Element Size (RAM Words)
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

45.5.14.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN_TXBC.TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN_TXFQS.TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN_TXFQS.TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS.TFQP field. After each Add Request (MCAN_TXBAR[x] ARn = 1) the Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN_TXFQS.TFQP = MCAN_TXFQS.TFGI), Tx FIFO Full condition is signaled by bit MCAN_TXFQS.TFQF = 1. In this case, no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx buffers as indicated by the Tx FIFO Free Level MCAN_TXFQS.TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is canceled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN_TXFQS.TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates element size 32-bit words in the Message RAM (see Table 45-10). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS.TFQP (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC.TBSA field.

45.5.14.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN_TXBC.TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS.TFQP field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN_TXFQS.TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been canceled.

The application can use the MCAN_TXBRP register instead of the Put Index and can place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates element size 32-bit words in the Message RAM (see Table 45-10). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS.TFQP (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC.TBSA field.

45.5.14.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx buffers section in the Message RAM is separated in two parts:

- Dedicated Tx buffers: the number of Dedicated Tx buffers is configured by the MCAN_TXBC.NDTB field
- Tx FIFO: the number of Tx buffers assigned to the Tx FIFO is configured by the MCAN_TXBC.TFQS field

If the MCAN_TXBC.TFQS field is empty (zero) - only Dedicated Tx buffers are used.

Tx prioritization:

- Scan Dedicated Tx buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN_TXFQS.TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 45-17 shows Mixed Dedicated Tx buffers/Tx FIFO example.

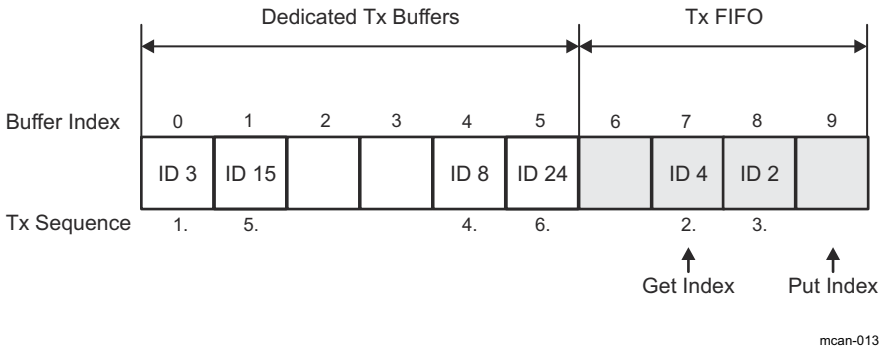

Figure 45-17. Mixed Dedicated Tx Buffers /Tx FIFO (example)

45.5.14.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx buffers section in the Message RAM is separated in two parts:

- Dedicated Tx buffers: the number of Dedicated Tx buffers is configured by the MCAN_TXBC.NDTB field
- Tx Queue: the number of Tx buffers assigned to the Tx Queue is configured by the MCAN_TXBC.TFQS field

If MCAN_TXBC.TFQS field is empty (zero) - only Dedicated Tx buffers are used.

Tx prioritization:

- Scan all Tx buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 45-18 shows Mixed Dedicated Tx buffers/Tx Queue example.

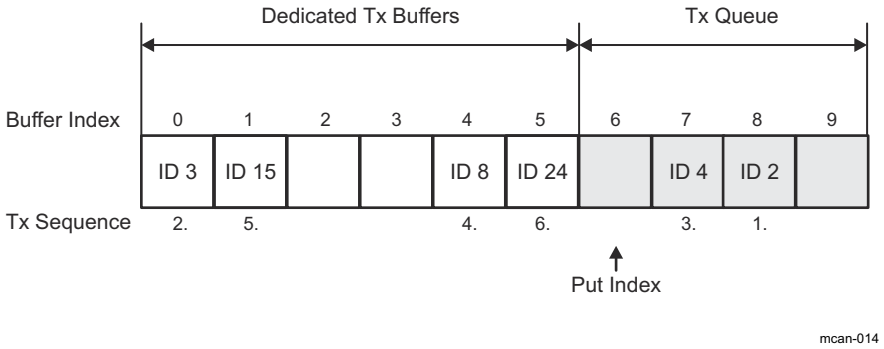

Figure 45-18. Mixed Dedicated Tx Buffers /Tx Queue (example)

45.5.14.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of the MCAN_TXBCF register (MCAN_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN_TXBTO[n] TOn and MCAN_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN_TXBCF[n] CFn = 1.

Note

If a pending transmission is canceled immediately before this transmission has started, a short time window occurs where no transmission is started even if another message is also pending in this node. This can enable another node to transmit a message that can have a lower priority than the second message in this node.

45.5.14.8 Tx Event Handling

To support Tx Event Handling, the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. Section 45.5.16.4 describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signaled by the MCAN_IR.TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN_TXEFS.EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN_IR.TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN_TXEFC.EFWM field, interrupt flag MCAN_IR.TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN_TXEFS.EFGI field has to be added to the Tx Event FIFO start address MCAN_TXEFC.EFSA field.

45.5.15 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN_RXF0A, MCAN_RXF1A, and MCAN_TXEFA). Writing to the FIFO Acknowledge Index sets the FIFO Get Index to the FIFO Acknowledge Index plus one and, thereby, updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. Special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case, the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case, some of the older FIFO elements would be lost.

Note

The application has to make sure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

45.5.16 Message RAM

The MCAN module has a Message RAM. The main purpose of the Message RAM is to store:

- Received Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

45.5.16.1 Message RAM Configuration

The MCAN module is configured to allocate up to 4352 words in the Message RAM. The Message RAM has a width of 32 bits.

The address range of the Message RAM (when MCAN is interfaced to M4 processor) is from 0x4007 8000 to 0x4007 C3FF. The address range of the Message RAM (when MCAN is interfaced to CPU1) is from 0x5 8000 to 0x5 C3FF.

The Message RAM is capable to include each of the sections listed in Figure 45-19. It is not necessary to configure each of the sections (a section in the Message RAM can be 0) and there is no restriction with respect to the sequence of the sections. For parity checking or ECC, a respective number of bits has to be added to each word. When the MCAN module addresses the Message RAM, the MCAN addresses 32-bit words. The start addresses are configurable and are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0, by way of the MCAN_RXESC.F0DS field
- Rx FIFO, 1 by way of the MCAN_RXESC.F1DS field
- Rx buffers, by way of the MCAN_RXESC.RBDS field
- Tx buffers, by way of the MCAN_TXESC.TBDS field

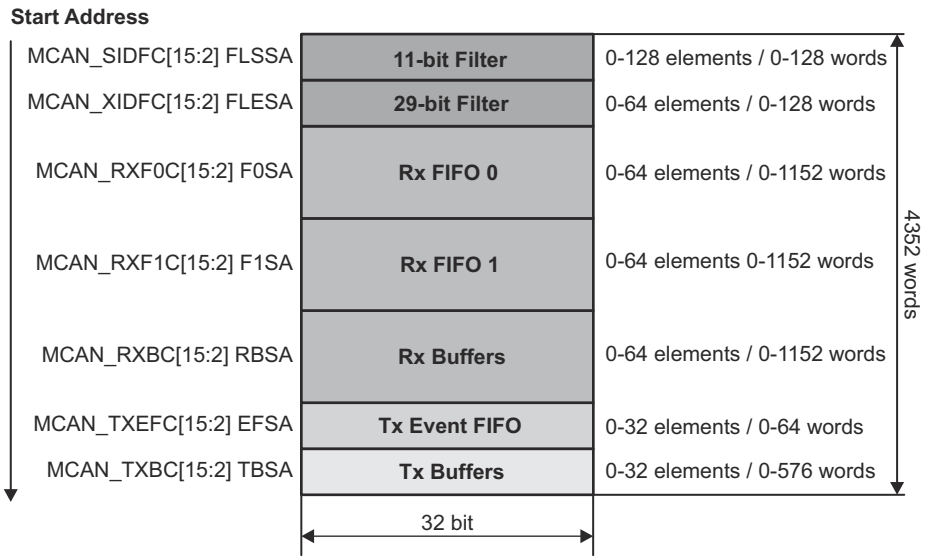

Figure 45-19. Message RAM Configuration

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

Note

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This prevents falsification or loss of data.

45.5.16.2 Rx Buffer and FIFO Element

Up to 64 Rx buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN_RXESC register.

Figure 45-20 shows the Rx Buffer/Rx FIFO element structure. Table 45-11 shows the Rx Buffer/Rx FIFO element field descriptions.

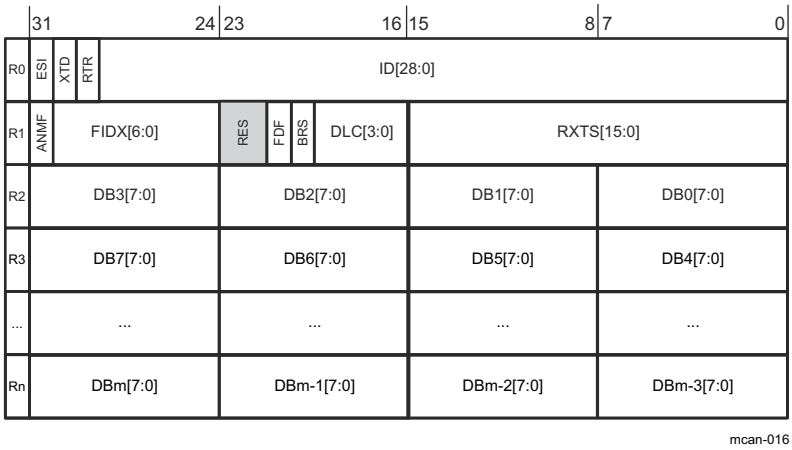

Figure 45-20. Rx Buffer/Rx FIFO Element Structure

Table 45-11. Rx Buffer/Rx FIFO Element Field Descriptions

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier Signals to the Host CPU whether the received frame has a standard or extended identifier. • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request Signals to the Host CPU whether the received frame is a data frame or a remote frame. • 0x0: Received frame is a data frame • 0x1: Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = 1), RTR bit reflects the state of the reserved r1 bit (RES[23]). In CAN FD frames (FDF=1), the dominant RRS (Remote Request Substitution) bit replaces the RTR (Remote Transmission Request) bit.
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28:18].

Table 45-11. Rx Buffer/Rx FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames can be enabled using the MCAN_GFC.ANFS and MCAN_GFC.ANFE fields. • 0x0: Received frame matching filter index FIDX field • 0x1: Received frame did not match any Rx filter element
	30:24	FIDX[6:0]	Filter Index 0x0-0x7F (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to MCAN_SIDFC.LSS - 1 respectively MCAN_XIDFC.LSE - 1.
	23:22	RES	Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame received without bit rate switching • 0x1: Frame received with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: received frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: received frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
	15:0	RXTS[15:0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC.TCP.

	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

45.5.16.3 Tx Buffer Element

The Tx buffers section can be configured to hold dedicated Tx buffers as well as a Tx FIFO/Tx Queue. In case that the Tx buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx buffers start at the beginning of the Tx buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx buffers and Tx FIFO/Tx Queue by way of the MCAN_TXBC.TFQS and MCAN_TXBC.NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN_TXESC register.

Figure 45-21 shows the Tx Buffer element structure. Table 45-12 shows the Tx Buffer element field descriptions.

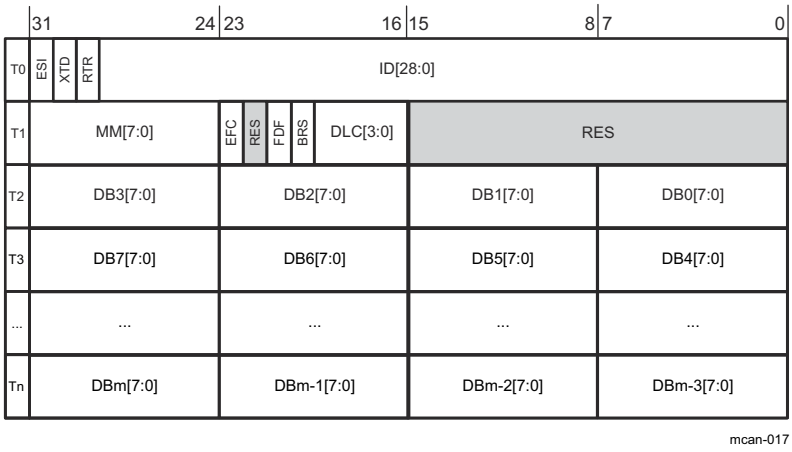

Figure 45-21. Tx Buffer Element Structure

Table 45-12. Tx Buffer Element Field Descriptions

Word	Bits	Field Name	Description
T0	31	ESI	Error State Indicator • 0x0: ESI bit in CAN FD format depends only on error passive flag • 0x1: ESI bit in CAN FD format transmitted recessive **Note:** The ESI bit of the transmit buffer is ORed with the error passive flag to decide the value of the ESI bit in the transmitted CAN FD frame. As required by the CAN FD protocol specification, an error active node can optionally transmit the ESI bit recessive, but an error passive node always transmits the ESI bit recessive.
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Transmit data frame • 0x1: Transmit remote frame **Note:** When RTR = 1, the MCAN module transmits a remote frame according to ISO11898-1:2015, even if the MCAN_CCCR.FDOE bit enables the transmission in CAN FD format.
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 45-12. Tx Buffer Element Field Descriptions (continued)

Word	Bits	Field Name	Description
T1	31:24	MM[7:0]	Message Marker Written by Host CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 45-13).
	23	EFC	Event FIFO Control • 0x0: Don't store Tx events • 0x1: Store Tx events
	22	RES	Reserved
	21	FDF	FD Format • 0x0: Frame transmitted in Classic CAN format • 0x1: Frame transmitted in CAN FD format
	20	BRS	Bit Rate Switch • 0x0: CAN FD frames transmitted without bit rate switching • 0x1: CAN FD frames transmitted with bit rate switching **Note:** ESI, FDF, and BRS bits are only evaluated when CAN FD operation is enabled using the MCAN_CCCR.FDOE bit. BRS bit is only evaluated when MCAN_CCCR.BRSE = 1.
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: transmit frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: transmit frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes
	15:0	RES	Reserved
T2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0
T3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Tn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note

Depending on the configuration of the element size (MCAN_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

45.5.16.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN_TXEFS register.

Figure 45-22 shows the Tx Event FIFO element structure. Table 45-13 shows the Tx Event FIFO element field descriptions.

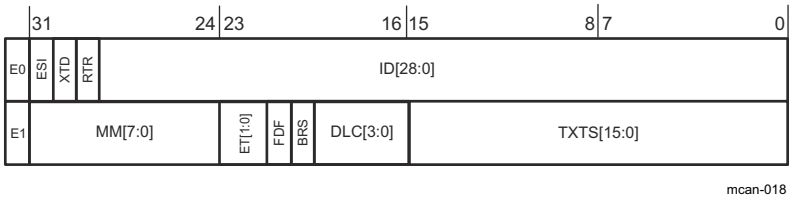

Figure 45-22. Tx Event FIFO Element Structure

Table 45-13. Tx Event FIFO Element Field Descriptions

Word	Bits	Field Name	Description
E0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Data frame transmitted • 0x1: Remote frame transmitted
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 45-13. Tx Event FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
E1	31:24	MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 45-12).
	23:22	ET[1:0]	Event Type • 0x0: Reserved • 0x1: Tx event • 0x2: Transmission in spite of cancellation (always set for transmissions in DAR mode) • 0x3: Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame transmitted without bit rate switching • 0x1: Frame transmitted with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: frame with 0-8 data bytes transmitted • 0x9-0xF (9-15): CAN: frame with 8 data bytes transmitted • 0x9-0xF (9-15): CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
	15:0	TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC.TCP filed.

45.5.16.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, the element address is the Filter List Standard Start Address MCAN_SIDFC.FLSSA field plus the index of the filter element (0-127).

Figure 45-23 shows the Standard Message ID Filter element structure. Table 45-14 shows the Standard Message ID Filter element field descriptions.

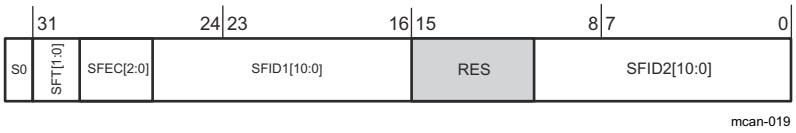

Figure 45-23. Standard Message ID Filter Element Structure

Table 45-14. Standard Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
S0	31:30	SFT[1:0]	Standard Filter Type • 0x0: Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) • 0x1: Dual ID filter for SFID1 or SFID2 • 0x2: Classic filter: SFID1 = filter; SFID2 = mask • 0x3: Filter element disabled **Note:** With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behavior as with SFEC = 000)
	29:27	SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 match sets interrupt flag MCAN_IR.HPM and, if enabled, an interrupt is generated. In this case, the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer , configuration of SFT[1:0] ignored
	26:16	SFID1[10:0]	Standard Filter ID 1 When filtering for Rx buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
	15:11	RES	Reserved
	10:0	SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: • SFEC = 001 - 110: Second ID of standard ID filter element • SFEC = 111: Filter for Rx buffers
		SFID2[10:9]	This filed is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		SFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		SFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC.RBSA field for storage of a matching message.

45.5.16.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, the element address is the Filter List Extended Start Address MCAN_XIDFC.FLESA field plus two times the index of the filter element (0-63).

Figure 45-24 shows the Extended Message ID Filter element structure. Table 45-15 shows the Extended Message ID Filter element field descriptions.

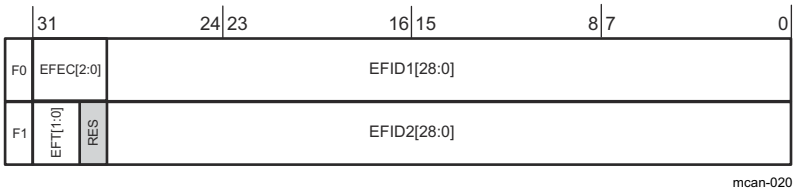

Figure 45-24. Extended Message ID Filter Element Structure

Table 45-15. Extended Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
F0	31:29	EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 match sets interrupt flag MCAN_IR.HPM and, if enabled, an interrupt is generated. In this case, the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
	28:0	EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Section 45.5.13.1.5) is used.

Table 45-15. Extended Message ID Filter Element Field Descriptions (continued)

Word	Bits	Field Name	Description
F1	31:30	EFT[1:0]	Extended Filter Type • 0x0: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1) • 0x1: Dual ID filter for EFID1 or EFID2 • 0x2: Classic filter: EFID1 = filter, EFID2 = mask • 0x3: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
	29	RES	Reserved
	28:0	EFID2[28:0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: • EFEC = 001 - 110: Second ID of extended ID filter element • EFEC = 111: Filter for Rx buffers
		EFID2[10:9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		EFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		EFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC.RBSA field for storage of a matching message.

45.6 Software

45.6.1 MCAN Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/mcan

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

45.6.1.1 MCAN Internal Loopback with Interrupt - CM

FILE: mcan_ex1_loopback.c

This example demonstrates Loopback functionality of the MCAN (CAN FD) module. The internal loopback mode is chosen. The transmitted message will be received by the node. All action is internal to the device, hence transmission will not be visible on the MCAN_TX pin. Uses the last address of memory for Rx buffer.

Before running this example, please run the mcan_config_c28x example It will initialize the clock, configure the GPIOs.

External Connections
- None.

Watch Variables
- error - Checks if there is an error that occurred when the data was sent using internal loopback.

45.6.1.2 MCAN Internal Loopback with Interrupt

FILE: mcan_ex1_loopback.c

This example shows the MCAN Loopback functionality. The internal loopback mode is entered. The sent message should be received by the node. Use the last address of memory for Rx buffer.

External Connections
- None.

Watch Variables
- error - Checks if there is an error that occurred when the data was sent using internal loopback.

45.6.1.3 MCAN External Loopback with Interrupt - CM

FILE: mcan_ex2_external_loopback.c

This example shows the MCAN External Loopback functionality. The external loopback is done between two MCAN Controllers. As there is only one MCAN that exist this example can be changed to make MCAN Transmit or Receive based on define selected. The GPIOs of MCAN should be connected to a CAN Transceiver

Before running this example, please run the mcan_config_c28x example It will initialize the clock, configure the GPIOs.

Selection of Mode : A define has to be selected to make the MCAN to transmit or receive.
- TRANSMIT - MCAN to Transmit messages.
- RECEIVE - MCAN to Receive Messages.

Run the example as with RECEIVE Define on one MCAN Controller before running it as Transmit.

Hardware Required
- A C2000 board with CAN transceiver

External Connections
- MCAN is on GPIO30 (MCANRXA) and GPIO31 (MCANTXA)

Watch Variables
- isrIntr0Flag - The flag has initial value as no. of messages to be transmitted and its value decrements after a message is transmitted.

- isrIntr1Flag - The flag has initial value as no. of messages that are received and its value decrements after a message is successfully received.
- error - Checks if there is an error that occurred when the data was sent using internal loopback

45.6.1.4 MCAN Loopback with Interrupts Example Using SYSCONFIG Tool

FILE: mcan_ex3_loopback_syscfg.c

This example illustrates the MCAN Loopback functionality. The internal loopback mode is entered. The message transmitted would be received by the node. The last address of memory is used for the Rx buffer. Peripheral configuration is done through SYSCONFIG

External Connections
- None.

Watch Variables
- error - Checks if there is an error that occurred when the data was sent using internal loopback.

45.6.1.5 MCAN receive using Rx Buffer

FILE: mcan_ex4_receive.c

This example demonstrates the MCAN receive function. Communication is done between two CAN nodes. The transmitting node could be another MCU or a CAN bus analysis tool capable of transmitting CAN FD frames. The transmit and receive pins of the MCAN module should be connected to a CAN transceiver. Nominal Bit Rate of 500 kbps & Data bit rate of 1 Mbps is used

Only Standard frame with message ID 0x4 is received.

If another C2000 MCU is used as the transmitter, mcan_ex3_transmit.c can be run on it for the transmit function.

Hardware Required
- A C2000 board with CAN transceiver

External Connections
Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables
- rxMsg

45.6.1.6 MCAN External Reception (with mask filter) into RX-FIFO1

FILE: mcan_ex5_mask_filter_receive.c

This example demonstrates Receiving, with mask filter configuration. The transmitting node could be a CAN FD capable controller or a CAN bus analysis tool capable of transmitting CAN FD frames. Bits 0, 1 & 3 of the identifier are masked. So these bits can have any value. This is achieved by using stdFiltelem.sfid1 = 00000001111 and stdFiltelem.sfid2 (mask 0 for X) = 11111110100, which means any message with an ID of 0b0000000X1XX are received and stored into the FIFO. i.e. Following STD IDs are received: 0x004, 0x005, 0x006, 0x007, 0x00C, 0x00D, 0x00E, 0x00F. All other IDs are not received. Classic bit-mask filter is used. This example may be used in conjunction with mcan_ex3_transmit.

The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used.

Hardware Required
- A C2000 board with CAN transceiver

External Connections
Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)

- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables

- rxMsg

45.6.1.7 MCAN Classic frames transmission using Tx Buffer

FILE: mcan_ex7_classic_transmit.c

This simple example shows external communication between the MCAN module and another CAN node. It shows how to transmit classic CAN frames. The GPIOs of MCAN should be connected to a CAN Transceiver. Bit Rate is 500 kbps. Extended Identifier 0x15A5A5A5 is transmitted with 8 data bytes.

Hardware Required

- A C2000 board with CAN transceiver

External Connections

Both nodes should communicate through CAN transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables

- txMsg

45.6.1.8 MCAN External Reception (with RANGE filter) into RX-FIFO1

FILE: mcan_ex8_range_filter_receive.c

This example demonstrates Receiving, with RANGE filter configuration. The transmitting node could be a CAN FD capable controller or a CAN bus analysis tool capable of transmitting CAN FD frames. Only Extended IDs from 0x1FFFFF23 to 0x1FFFFF46 are received. Other IDs are not received. RXFIFO1 starts at an offset of 748 (2EC). MCAN Message RAM starts at 0x58000, so received messages will be copied starting at address 0x582EC. Note that as long as the ID matches, "classic" CAN frames will also be received.

The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used.

Hardware Required

- A C2000 board with CAN transceiver

External Connections

Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables

- rxMsg

45.6.1.9 MCAN External Transmit using Tx Buffer

FILE: mcan_ex9_transmit.c

This example demonstrates the MCAN External Transmit function. External communication is done between two CAN nodes. The receiving node could be another MCU or a CAN bus analysis tool capable of Receiving/ ACKnowledging transmitted frames. The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used. Standard Identifier (STD ID) 0x4 is transmitted with 64 data bytes. #defines that are not required for this test case have been commented out. However, they have been left in the code should the scope of this code be expanded to include Receive and FIFO functions.

If another C2000 MCU is used as the receiver, mcan_ex4_receive.c can be run on it for the receive function.

Hardware Required

- A C2000 board with CAN transceiver

External Connections
Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables
- txMsg

45.6.1.10 MCAN receive using Rx Buffer

FILE: mcan_ex10_receive_multiple_buffers.c

This example demonstrates how to receive MCAN messages in multiple buffers, including the configuration and handling of the messages. Communication is done between atleast two CAN nodes. The transmitting node could be another MCU or a CAN bus analysis tool capable of transmitting CAN FD frames. The transmit and receive pins of the MCAN module should be connected to a CAN transceiver. Nominal Bit Rate of 500 kbps & Data bit rate of 1 Mbps is used

Standard frames with message IDs 0x123, 0x124, 0x125, 0x126 are received. (For Extended frames, same procedure to be followed for configuration by adding Extended Message ID Filter Element(s))

Hardware Required
- A C2000 board with CAN transceiver

External Connections
Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables
- rxMsg

45.7 MCAN Registers

This section describes the Modular Controller Area Network (MCAN) module registers.

45.7.1 MCAN Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
McanaSsRegs	MCANSS_REGS	MCANASS_BASE	0x0005_C400	YES	-	-	-	YES
McanaRegs	MCAN_REGS	MCANA_BASE	0x0005_C600	YES	-	-	-	YES
McanaErrRegs	MCAN_ERROR_REGS	MCANA_ERROR_BASE	0x0005_C800	YES	-	-	-	YES
MCAN Message RAM	-	-	0x0005_8000	YES	-	-	-	YES

45.7.2 CM MCAN Base Address Table (CM)

Bit Field Name		DriverLib Name	Base Address	DMA	Pipeline Protected
Instance	Structure				
McanaSsRegs	MCANSS_REGS	MCANASS_BASE	0x4007_C400	-	YES
McanaRegs	MCAN_REGS	MCANA_BASE	0x4007_C600	-	YES
McanaErrRegs	MCAN_ERROR_REGS	MCANA_ERROR_BASE	0x4007_C800	-	YES
MCAN Message RAM	-	-	0x4007_8000	-	YES

45.7.3 MCANSS_REGS Registers

Table 45-16 lists the memory-mapped registers for the MCANSS_REGS registers. All register offset addresses not listed in Table 45-16 should be considered as reserved locations and the register contents should not be modified.

Table 45-16. MCANSS_REGS Registers

Offset (x8)	Offset (x16)	Acronym	Register Name	Write Protection	Section
0h	0h	MCANSS_PID	MCAN Subsystem Revision Register		Go
4h	2h	MCANSS_CTRL	MCAN Subsystem Control Register		Go
8h	4h	MCANSS_STAT	MCAN Subsystem Status Register		Go
Ch	6h	MCANSS_ICS	MCAN Subsystem Interrupt Clear Shadow Register		Go
10h	8h	MCANSS_IRS	MCAN Subsystem Interrupt Raw Satus Register		Go
14h	Ah	MCANSS_IECS	MCAN Subsystem Interrupt Enable Clear Shadow Register		Go
18h	Ch	MCANSS_IE	MCAN Subsystem Interrupt Enable Register		Go
1Ch	Eh	MCANSS_IES	MCAN Subsystem Interrupt Enable Status		Go
20h	10h	MCANSS_EOI	MCAN Subsystem End of Interrupt		Go
24h	12h	MCANSS_EXT_TS_PRESCALER	MCAN Subsystem External Timestamp Prescaler 0		Go
28h	14h	MCANSS_EXT_TS_UNSERVICED_INTR_CNTR	MCAN Subsystem External Timestamp Unserviced Interrupts Counter		Go

Complex bit access types are encoded to fit into small table cells. Table 45-17 shows the codes that are used for access types in this section.

Table 45-17. MCANSS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 45-17. MCANSS_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

45.7.3.1 MCANSS_PID Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 68E03901h]

MCANSS_PID is shown in Figure 45-25 and described in Table 45-18.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 45-30 shows the codes that are used for access types in this section.

Table 45-30. MCAN_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
RS	R S	Read to Set
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1SQ	W 1S Q	Write 1 to set Qualified. A condition must be met for this operation to occur.
WQ	W Q	Write Qualified. A condition must be met for this operation to occur.
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

45.7.4.1 MCAN_CREL Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 32270530h]

MCAN_CREL is shown in Figure 45-36 and described in Table 45-31.

Return to the Summary Table.

45.7.4.3 MCAN_DBTP Register (Offset (x8) = Ch, Offset (x16) = 6h) [Reset = A33h]

MCAN_DBTP is shown in Figure 45-38 and described in Table 45-33.

Return to the Summary Table.

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 m_can_cclk periods. tq = (DBRP + 1) mtq.
DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2.
Therefore the length of the bit time is (programmed values) [DTSEG1 + DTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.
The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

3-0	DSJW	R/WQ	3h	Data Resynchronization Jump Width. Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

45.7.4.4 MCAN_TEST Register (Offset (x8) = 10h, Offset (x16) = 8h) [Reset = X]

MCAN_TEST is shown in Figure 45-39 and described in Table 45-34.

Return to the Summary Table.

Write access to the Test Register has to be enabled by setting bit CCCR.TEST to '1'. All Test Register functions are set to their reset values when bit CCCR.TEST is reset.
Loop Back Mode and software control of the internal CAN TX pin are hardware test modes. Programming of TX != "00" may disturb the message transfer on the CAN bus.

Table 45-35. MCAN_RWD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-8	WDV	R	0h	Watchdog Value. Actual Message RAM Watchdog Counter Value. The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the MCAN's Generic Controller Interface starts the Message RAM Watchdog Counter with the value configured by the WDC field. The counter is reloaded with WDC when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag MCAN_IR.WDI is set. The RAM Watchdog Counter is clocked by the host (system) clock. Reset type: SYSRSn
7-0	WDC	R/WQ	0h	Watchdog Configuration. Start value of the Message RAM Watchdog Counter. With the reset value of "00" the counter is disabled. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

45.7.4.6 MCAN_CCCR Register (Offset (x8) = 18h, Offset (x16) = Ch) [Reset = 1h]

MCAN_CCCR is shown in Figure 45-41 and described in Table 45-36.

Return to the Summary Table.

The bit can be reset by SW at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled Qualified Write 1 to Set is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn
4	CSR	R/W	0h	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle. Reset type: SYSRSn
3	CSA	R	0h	Clock Stop Acknowledge 0 No clock stop acknowledged 1 MCAN may be set in power down by stopping the Host and CAN clocks Reset type: SYSRSn
2	ASM	R/W1SQ	0h	Restricted Operation Mode. Bit ASM can only be set by SW when both CCE and INIT are set to '1'. The bit can be reset by SW at any time. 0 Normal CAN operation 1 Restricted Operation Mode active Qualified Write 1 to Set is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn
1	CCE	R/WQ	0h	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1') Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

Table 45-36. MCAN_CCCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	INIT	R/W	1h	Initialization 0 Normal Operation 1 Initialization is started Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value. Reset type: SYSRSn

45.7.4.7 MCAN_NBTP Register (Offset (x8) = 1Ch, Offset (x16) = Eh) [Reset = 06000A03h]

MCAN_NBTP is shown in Figure 45-42 and described in Table 45-37.

Return to the Summary Table.

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512 m_can_cclk periods. tq = (NBRP + 1) mtq.
NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.
Therefore the length of the bit time is (programmed values) [NTSEG1 + NTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.
The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.
Note: With a CAN clock of 8 MHz, the reset value of 0x06000A03 configures the MCAN for a bit rate of 500 kBit/s.

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	Reserved
22-16	TDCV	R	0h	Transmitter Delay Compensation Value. Position of the secondary sample point, defined by the sum of the measured delay from the internal CAN TX signal to the internal CAN RX signal and TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq. Reset type: SYSRSn
15	RESERVED	R	0h	Reserved
14	PXE	RC	0h	Protocol Exception Event 0 No protocol exception event occurred since last read access 1 Protocol exception event occurred Reset type: SYSRSn
13	RFDF	RC	0h	Received a CAN FD Message. This bit is set independent of acceptance filtering. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with FDF flag set has been received Reset type: SYSRSn
12	RBRS	RC	0h	BRS Flag of Last Received CAN FD Message. This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its BRS flag set 1 Last received CAN FD message had its BRS flag set Reset type: SYSRSn
11	RESI	RC	0h	ESI Flag of Last Received CAN FD Message. This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set 1 Last received CAN FD message had its ESI flag set Reset type: SYSRSn

Table 45-43. MCAN_PSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10-8	DLEC	RS	7h	Data Phase Last Error Code. Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error. Reset type: SYSRSn
7	BO	R	0h	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state Reset type: SYSRSn
6	EW	R	0h	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96 Reset type: SYSRSn
5	EP	R	0h	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state Reset type: SYSRSn
4-3	ACT	R	0h	Node Activity. Monitors the module's CAN communication state. 00 Synchronizing - node is synchronizing on CAN communication 01 Idle - node is neither receiver nor transmitter 10 Receiver - node is operating as receiver 11 Transmitter - node is operating as transmitter Note: ACT is set to "00" by a Protocol Exception Event. Reset type: SYSRSn

Table 45-43. MCAN_PSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	LEC	RS	7h	Last Error Code. The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0 No Error: No error occurred since LEC has been reset by successful reception or transmission. 1 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 2 Form Error: A fixed format part of a received frame has the wrong format. 3 AckError: The message transmitted by the MCAN was not acknowledged by another node. 4 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 5 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 6 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 7 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register. Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error. Note: The Bus_Off recovery sequence (see ISO 11898-1:2015) cannot be shortened by setting or resetting CCCR.INIT. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR.REC is used to count these sequences. Reset type: SYSRSn

45.7.4.14 MCAN_TDCR Register (Offset (x8) = 48h, Offset (x16) = 24h) [Reset = 0h]

MCAN_TDCR is shown in Figure 45-49 and described in Table 45-44.

Return to the Summary Table.

15	RESERVED	R	0h	Reserved
14-8	TDCO	R/WQ	0h	Transmitter Delay Compensation Offset. Offset value defining the distance between the measured delay from the internal CAN TX signal to the internal CAN RX signal and the secondary sample point. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn
7	RESERVED	R	0h	Reserved
6-0	TDCF	R/WQ	0h	Transmitter Delay Compensation Filter Window Length. Defines the minimum value for the SSP position, dominant edges on the internal CAN RX signal that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

45.7.4.15 MCAN_IR Register (Offset (x8) = 50h, Offset (x16) = 28h) [Reset = 80000000h]

MCAN_IR is shown in Figure 45-50 and described in Table 45-45.

Return to the Summary Table.

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. Aflag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. Ahard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signalled.

Bit	Field	Type	Reset	Description
23	EP	R/W1C	0h	Error Passive 0 Error_Passive status unchanged 1 Error_Passive status changed Reset type: SYSRSn
22	ELO	R/W1C	0h	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred Reset type: SYSRSn
21	BEU	R/W1C	0h	Bit Error Uncorrected. Message RAM bit error detected, uncorrected. This bit is set when a double bit error is detected by the ECC aggregator attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR.INIT to '1'. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (e.g. parity logic) Reset type: SYSRSn
20	RESERVED	R	0h	Reserved
19	DRX	R/W1C	0h	Message Stored to Dedicated Rx Buffer. The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into an Rx Buffer Reset type: SYSRSn
18	TOO	R/W1C	0h	Timeout Occurred 0 No timeout 1 Timeout reached Reset type: SYSRSn
17	MRAF	R/W1C	0h	Message RAM Access Failure. The flag is set, when the Rx Handler: - has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. - was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the MCAN is switched into Restricted Operation Mode. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred Reset type: SYSRSn
16	TSW	R/W1C	0h	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around Reset type: SYSRSn

45.7.4.17 MCAN_ILS Register (Offset (x8) = 58h, Offset (x16) = 2Ch) [Reset = 0h]

MCAN_ILS is shown in Figure 45-52 and described in Table 45-47.

Return to the Summary Table.

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE.EINT0 and ILE.EINT1.

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	Reserved
28-0	EIDM	R/WQ	1FFFFFFFh	Extended ID Mask. For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

45.7.4.23 MCAN_HPMS Register (Offset (x8) = 94h, Offset (x16) = 4Ah) [Reset = 0h]

MCAN_HPMS is shown in Figure 45-58 and described in Table 45-53.

Return to the Summary Table.

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5-0	F1AI	R/W	0h	Rx FIFO 1 Acknowledge Index. After the Host has read a message or a sequence of messages from Rx FIFO 1 it has to write the buffer index of the last element read from Rx FIFO 1 to F1AI. This will set the Rx FIFO 1 Get Index RXF1S.F1GI to F1AI + 1 and update the FIFO 1 Fill Level RXF1S.F1FL. Reset type: SYSRSn

45.7.4.33 MCAN_RXESC Register (Offset (x8) = BCh, Offset (x16) = 5Eh) [Reset = 0h]

MCAN_RXESC is shown in Figure 45-68 and described in Table 45-63.

Return to the Summary Table.

Configures the number of data bytes belonging to an Rx Buffer / Rx FIFO element. Data field sizes >8 bytes are intended for CAN FD operation only.

Table 45-67. MCAN_TXBRP Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	TRP0	R	0h	Transmission Request Pending 0. Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signalled via TXBCF - after successful transmission together with the corresponding TXBTO bit - when the transmission has not yet been started at the point of cancellation - when the transmission has been aborted due to lost arbitration - when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset. Reset type: SYSRSn

45.7.4.38 MCAN_TXBAR Register (Offset (x8) = D0h, Offset (x16) = 68h) [Reset = 0h]

MCAN_TXBAR is shown in Figure 45-73 and described in Table 45-68.

Return to the Summary Table.

5	CR5	R/WQ	0h	Cancellation Request 5. See description for bit 0. Reset type: SYSRSn
4	CR4	R/WQ	0h	Cancellation Request 4. See description for bit 0. Reset type: SYSRSn
3	CR3	R/WQ	0h	Cancellation Request 3. See description for bit 0. Reset type: SYSRSn
2	CR2	R/WQ	0h	Cancellation Request 2. See description for bit 0. Reset type: SYSRSn
1	CR1	R/WQ	0h	Cancellation Request 1. See description for bit 0. Reset type: SYSRSn
0	CR0	R/WQ	0h	Cancellation Request 0. Each Tx Buffer has its own Cancellation Request bit. Writing a '1' will set the corresponding Cancellation Request bit writing a '0' has no impact. This enables the Host to set cancellation requests for multiple Tx Buffers with one write to TXBCR. TXBCR bits are set only for those Tx Buffers configured via TXBC. The bits remain set until the corresponding bit of TXBRP is reset. 0 No cancellation pending 1 Cancellation pending Qualified Write is possible only with CCCR.CCE='0' Reset type: SYSRSn

45.7.4.40 MCAN_TXBTO Register (Offset (x8) = D8h, Offset (x16) = 6Ch) [Reset = 0h]

MCAN_TXBTO is shown in Figure 45-75 and described in Table 45-70.

Complex bit access types are encoded to fit into small table cells. Table 45-78 shows the codes that are used for access types in this section.

Table 45-78. MCAN_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s

Table 45-78. MCAN_ERROR_REGS Access Type Codes (continued)

Access Type	Code	Description
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WD	W D	Write Decrement. Decrements the specified bit field by the amount written.
WI	W I	Write Increment. Increments the specified bit field by the amount written.
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

45.7.5.1 MCANERR_REV Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 66A0E200h]

MCANERR_REV is shown in Figure 45-82 and described in Table 45-79.

Return to the Summary Table.

45.7.5.2 MCANERR_VECTOR Register (Offset (x8) = 8h, Offset (x16) = 4h) [Reset = 0h]

MCANERR_VECTOR is shown in Figure 45-83 and described in Table 45-80.

Return to the Summary Table.

Each error detection and correction (EDC) controller has a bank of error registers (offsets 0x10 - 0x3B) associated with it. These registers are accessed via an internal serial bus (SVBUS). To access them through the ECC aggregator the controller ID desired must be written to the ECC_VECTOR field, together with the RD_SVBUS trigger and RD_SVBUS_ADDRESS bit field. This initiates the serial read which consummates by setting the RD_SVBUS_DONE bit. At this point the addressed register may be read by a normal CPU read of the appropriate offset address.

45.7.5.8 MCANERR_ERR_STAT1 Register (Offset (x8) = 20h, Offset (x16) = 10h) [Reset = 0h]

MCANERR_ERR_STAT1 is shown in Figure 45-89 and described in Table 45-86.

Return to the Summary Table.

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

Table 45-86. MCANERR_ERR_STAT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	ECC_BIT1	R	0h	ECC Error Bit Position. Indicates the bit position in the RAM data that is in error on an SEC error. Only valid on an SEC error. 0 Bit 0 is in error 1 Bit 1 is in error 2 Bit 2 is in error 3 Bit 3 is in error ... 31 Bit 31 is in error >32 Invalid Reset type: SYSRSn
15	CLR_CTRL_REG_ERROR	R/W1S	0h	Writing a '1' clears the CTRL_REG_ERROR bit Reset type: SYSRSn
14-13	RESERVED	R/WD	0h	Reserved
12	CLR_ECC_OTHER	R/W1C	0h	Writing a '1' clears the ECC_OTHER bit. Reset type: SYSRSn
11-10	CLR_ECC_DED	R/WD	0h	Clear ECC_DED. A write of a non-zero value to this bit field decrements the ECC_DED bit field by the value provided. Reset type: SYSRSn
9-8	CLR_ECC_SEC	R/WD	0h	Clear ECC_SEC. A write of a non-zero value to this bit field decrements the ECC_SEC bit field by the value provided. Reset type: SYSRSn
7	CTRL_REG_ERROR	R/W1S	0h	Control Register Error. A bit field in the control register is in an ambiguous state. This means that the redundancy registers have detected a state where not all values are the same and has defaulted to the reset state. S/W needs to re-write these registers to a known state. A write of 1 will set this interrupt flag. Reset type: SYSRSn
6-5	RESERVED	R/WI	0h	Reserved

Table 45-86. MCANERR_ERR_STAT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	ECC_OTHER	R/W1S	0h	SEC While Writeback Error Status 0 No SEC error while writeback pending 1 Indicates that successive single-bit errors have occurred while a writeback is still pending Reset type: SYSRSn
3-2	ECC_DED	R/WI	0h	Double Bit Error Detected Status. A 2-bit saturating counter of the number of DED errors that have occurred since last cleared. 0 No double-bit error detected 1 One double-bit error was detected 2 Two double-bit errors were detected 3 Three double-bit errors were detected A write of a non-zero value to this bit field increments it by the value provided. Reset type: SYSRSn
1-0	ECC_SEC	R/WI	0h	Single Bit Error Corrected Status. A 2-bit saturating counter of the number of SEC errors that have occurred since last cleared. 0 No single-bit error detected 1 One single-bit error was detected and corrected 2 Two single-bit errors were detected and corrected 3 Three single-bit errors were detected and corrected A write of a non-zero value to this bit field increments it by the value provided. Reset type: SYSRSn

45.7.5.9 MCANERR_ERR_STAT2 Register (Offset (x8) = 24h, Offset (x16) = 12h) [Reset = 0h]

MCANERR_ERR_STAT2 is shown in Figure 45-90 and described in Table 45-87.

Return to the Summary Table.

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

Chapter 46

Connectivity Manager Inter-Integrated Circuit (I2C) Module

This chapter describes the features and operation of the inter-integrated circuit (I2C) module in the Connectivity Manager subsystem.

46.1 Introduction

The Inter-Integrated Circuit (I2C) bus provides bidirectional data transfer through a two-wire design; a serial data line (SDA) and a serial clock line (SCL), and interfaces to external I2C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I2C bus may also be used for system testing and diagnostic purposes in product development and manufacturing.

46.1.1 Features

The I2C modules support the following features:

- Devices on the I2C bus can be designated as either a master or a slave.
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I2C modes:
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Receive FIFO and Transmitter FIFO (8 deep x 8 bits FIFO)
  - FIFOs can be independently assigned to master or slave
- Four transmission speeds:
  - Standard (100 kbps)
  - Fast mode (400 kbps)
  - Fast-mode plus (1 Mbps)
  - High-speed mode (3.33 Mbps)
- Glitch suppression
- SMBus support through software
  - Clock low time-out interrupt
  - Dual slave address capability
  - Quick command capability
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts because of an error)
  - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multiple-master support, and 7-bit addressing mode
- Efficient transfers using a Micro Direct Memory Access Controller (µDMA)
  - Separate channels for transmit and receive
  - Ability to execute single data transfers or burst data transfers using the RX and TX FIFOs in the I2C

46.1.2 Block Diagram

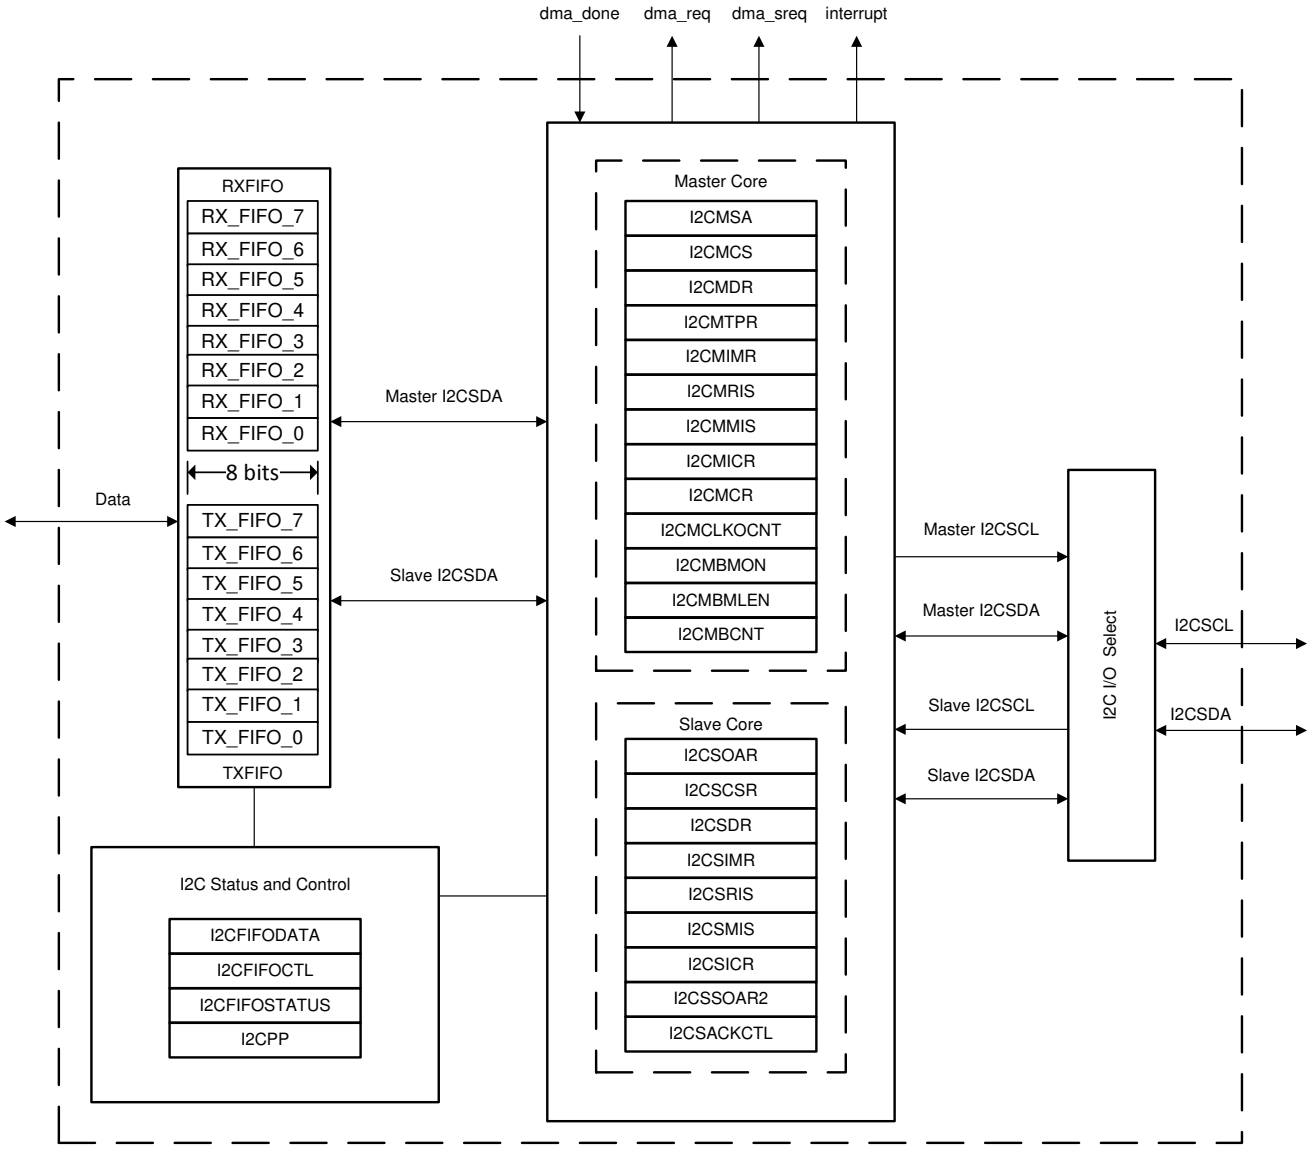

Figure 46-1. I2C Block Diagram

46.2 Functional Description

Each I2C module is comprised of both master and slave functions and is identified by a unique address. A master-initiated communication generates the clock signal, SCL. For proper operation, the SDA pin must be configured as an open-drain signal. Due to the internal circuitry that supports high-speed operation, the SCL pin must not be configured as an open-drain signal, although the internal circuitry causes it to act as if it were an open-drain signal. Both SDA and SCL signals must be connected to a positive supply voltage using a pullup resistor. Figure 46-2 shows a typical I2C bus configuration. See the I2C bus specification and user manual to determine the size of the pullups required for proper operation.

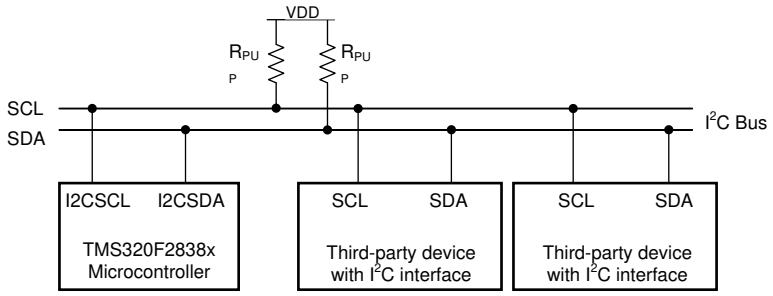

Figure 46-2. I2C Bus Configuration

46.2.1 I2C Bus Functional Overview

The I2C bus uses only two signals: SDA and SCL (named CM-I2CA_SCL and CM-I2CA_SDA in TMS320F2838x microcontrollers). SDA is the bidirectional SDA and SCL is the bidirectional serial clock line. The bus is considered idle when both lines are high.

Every transaction on the I2C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in Figure 46-3) is unrestricted, but each data byte must be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

46.2.1.1 START and STOP Conditions

The protocol of the I2C bus defines two states to begin and end a transaction: START and STOP. A high-to-low transition on the SDA line while the SCL is high is defined as a START condition, and a low-to-high transition on the SDA line while SCL is high is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 46-3.

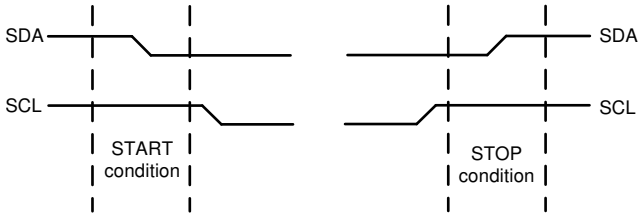

Figure 46-3. START and STOP Conditions

The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the I2C Master Slave Address (I2CMSA) register is written with the desired address, the R/S bit is cleared, and the Control register is written with ACK = X (0 or 1), STOP = 1, START = 1, and RUN = 1 to perform the operation and stop. When the operation is completed (or aborted due an error), the interrupt pin becomes active and the data may be read from the I2C Master Data (I2CMDR) register. When the I2C module operates in master receiver mode, the ACK bit is normally set causing the I2C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I2C bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, the STARTRIS and STOPRIS bits in the I2C Slave Raw Interrupt Status (I2CSRIS) register indicate detection of start and stop conditions on the bus and the I2C Slave Masked Interrupt Status (I2CSMIS) register can be configured to allow STARTRIS and STOPRIS to be promoted to controller interrupts (when interrupts are enabled).

46.2.1.2 Data Format With 7-Bit Address

Data transfers follow the format in Figure 46-4. After the START condition, a slave address is transmitted. This address is 7 bits long followed by an eighth bit, which is a data direction bit (R/S bit in the I2CMSA register). If the R/S bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master; however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive and transmit formats are then possible within a single transfer.

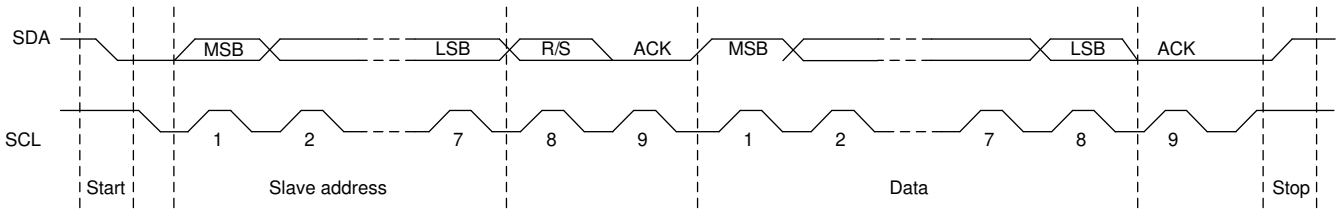

Figure 46-4. Complete Data Transfer With a 7-Bit Address

The first seven bits of the first byte make up the slave address (see Figure 46-5). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

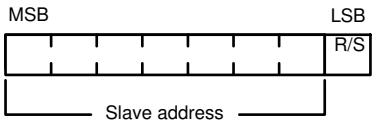

Figure 46-5. R/S Bit in First Byte

46.2.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can change only when SCL is low (see Figure 46-6).

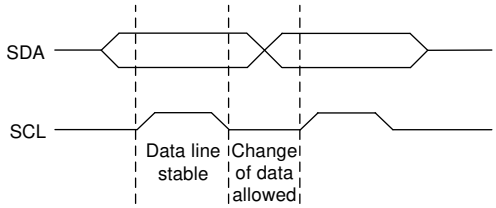

Figure 46-6. Data Validity During Bit Transfer on the I2C Bus

46.2.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in Section 46.2.1.3.

When a slave receiver does not acknowledge the slave address, SDA must be left high by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not

generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

If the slave is required to provide a manual ACK or NACK, the I2C Slave ACK Control (I2CSACKCTL) register allows the slave to NACK for invalid data or command or ACK for valid data or command. When this operation is enabled, the MCU slave module I2C clock is pulled low after the last data bit until this register is written with the indicated response.

46.2.1.5 Repeated START

The I2C master module can execute a repeated START (transmit or receive) after an initial transfer has occurred.

Note

When reading the I2CMCS register to check the BUSY bit, also read the ADRACK and DATACK bits, because these are cleared on register read, and status may be lost if they are not checked on every read of the register.

Alternatively, the NACKRIS bit of the I2CMRIS register can be used to monitor NACK status.

For more information on repeated START, see Figure 46-12 and Figure 46-13.

46.2.1.5.1 Repeated Start for Master Transmit

A repeated start sequence for a master transmit is as follows:

1. When the device is in the idle state, the master writes the slave address to the I2CMSA register and configures the R/S bit for the desired transfer type.
2. Data is written to the I2CMDR register.
3. When the BUSY bit in the I2CMCS register is 0, the master writes 0x3 to the I2CMCS register to initiate a transfer.
4. The master does not generate a STOP condition but instead writes another slave address to the I2CMSA register and then writes 0x3 to initiate the repeated START.

46.2.1.5.2 Repeated Start for Master Receive

A repeated start sequence for a master receive is similar:

1. When the device is in idle, the master writes the slave address to the I2CMSA register and configures the R/S bit for the desired transfer type.
2. The master reads data from the I2CMDR register.
3. When the BUSY bit in the I2CMCS register is 0, the master writes 0x3 to the I2CMCS_WRITE register to initiate a transfer.
4. The master does not generate a STOP condition but instead writes another slave address to the I2CMSA register and then writes 0x3 to initiate the repeated START.

46.2.1.6 Clock Low Time-out (CLTO)

The I2C slave can extend the transaction by pulling the clock low periodically to create a slow bit transfer rate. The I2C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the I2C Master Clock Low Time-out Count (I2CMCLKOCNT) register. The lower four bits are not user visible and are 0x0. The CNTL value programmed in the I2CMCLKOCNT register has to be greater than 0x01. The application can program the eight most-significant bits of the counter to reflect the acceptable cumulative low period in transaction. The count is loaded at the START condition and counts down on each falling edge of the internal bus clock of the master. Note that the internal bus clock generated for this counter keeps running at the programmed I2C speed even if SCL is held low on the bus. Upon reaching terminal count, the masterstate machine forces ABORT on the bus by issuing a STOP condition at the instance of SCL and SDA release.

As an example, if an I2C module is operating at 100-kHz speed, programming the I2CMCLKOCNT register to 0xDA translates to the value 0xDA0 since the lower four bits are set to 0x0. This translates to a decimal value of 3488 clocks or a cumulative clock low period of 34.88 ms at 100 kHz.

The CLKRIS bit in the I2C Master Raw Interrupt Status (I2CMRIS) register is set when the clock time-out period is reached, allowing the master to start corrective action to resolve the remote slave state. In addition, the CLKTO bit in the I2C Master Control/Status (I2CMCS) register is set; this bit is cleared when a STOP condition is sent or during the I2C master reset. The status of the raw SDA and SCL signals are readable by software through the SDA and SCL bits in the I2C Master Bus Monitor (I2CMBMON) register to help determine the state of the remote slave.

In the event of a CLTO condition, application software must choose how the application intends to attempt bus recovery. Most applications attempt to manually toggle the I2C pins to force the slave to let go of the clock signal (a common solution is to attempt to force a STOP on the bus). If a CLTO is detected before the end of a burst transfer, and the bus is successfully recovered by the master, the master hardware attempts to finish the pending burst operation. The behavior of the bus varies depending on the state of the slave after bus recovery. If the slave resumes in a state where the slave can acknowledge the master (essentially, where it was before the bus hang), it continues where it left off. However, if the slave resumes in a reset state (or if a forced STOP by the master causes the slave to enter the idle state), it may ignore the master attempt to complete the burst operation and NAK the first data byte that the master sends or requests.

Since the behavior of slaves cannot always be predicted, it is suggested that the application software always write the STOP bit in the I2C Master Configuration (I2CMCR) register during the CLTO interrupt service routine. This limits the amount of data the master attempts to send or receive upon bus recovery to a single byte, and after the single byte is on the wire, the master issues a STOP. An alternative solution is to have the application software reset the I2C peripheral before attempting to manually recover the bus. This solution allows the I2C master hardware to be returned to a known good (and idle) state before attempting to recover a stuck bus and prevents any unwanted data from appearing on the wire.

Note

The Master Clock Low Time-out counter counts for the entire time SCL is held low continuously. If SCL is deasserted at any point, the Master Clock Low Time-out Counter is reloaded with the value in the I2CMCLKOCNT register and begins counting down from this value.

46.2.1.7 Dual Address

The I2C interface supports dual address capability for the slave. The additional programmable address is provided and can be matched if enabled. In legacy mode with dual address disabled, the I2C slave provides an ACK on the bus if the address matches the OAR field in the I2CSOAR register. In dual address mode, the I2C slave provides an ACK on the bus if either the OAR field in the I2CSOAR register or the OAR2 field in the I2CSOAR2 register is matched. The enable for dual address is programmable through the OAR2EN bit in the I2CSOAR2 register and there is no disable on the legacy address.

The OAR2SEL bit in the I2CSCSR register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, the bit indicates either legacy operation or no address match.

46.2.1.8 Arbitration

A master may start a transfer only if the bus is idle. It is possible for two or more master to generate a START condition within the minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is high. During arbitration, the first of the competing master devices to place a 1 (high) on SDA, while another master transmits a 0 (low), switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. The first stage is a comparison of address bits, and if both master are trying to address the same device, arbitration continues on to the comparison of data bits.

If arbitration is lost when the I2C master is initiating a BURST with the TX FIFO enabled, the application should execute the following steps to correctly handle the arbitration loss:

1. Flush and disable the TX FIFO.
2. Clear and mask the TXFE interrupt by clearing the TXFEIM bit in the I2CMIMR register.

Once the bus is IDLE, the TXFIFO can be filled and enabled, the TXFE bit can be unmasked and a new BURST transaction can be initiated.

46.2.1.9 Glitch Suppression in Multi-Master Configuration

When a multi-master configuration is being used, the PULSEL bit in the I2CMTPR register can be programmed to provide glitch suppression on the SCL and SDA lines and assure proper signal values. The glitch suppression value is in terms of buffered system clocks. Note that all signals will be delayed internally when glitch suppression is nonzero. For example, if PULSEL is set to 0x7, 31 clocks should be added onto the calculation for the expected transaction time.

46.2.1.10 SMBus Operation

The SMBus interface is based on the I2C protocol; however, some differences exist between the two. These differences must be handled through software to make sure the SMBus protocol, including timing specifications, is met. Note that the SMBus 2.0 specification limits the maximum frequency of the interface to 100 KHz; as a result, I2C standard speed operation is used for SMBus.

The SMBus and I2C slave can extend the transaction, if it is not ready by pulling the clock low. The SMbus specification allows the maximum time-out for such elongated transaction to be 25 to 35 ms. The I2C specification does not have this requirement. The I2C module supports a programmable count to support clock-low time-out for the master to error out and take action as required; this feature is explained in Section 46.2.1.6. Note that if transactions are extended, a time-out period should be programmed in the I2CMCLKOCNT register, and the CLKRIS bit in the I2CMRIS register should not be masked.

Unlike the I2C slave, the SMBus slave must respond with an ACK response to its address regardless of whether it is ready or not. As a result, the I2C slave sends an ACK response to its address and a NACK response on the data byte if it is not ready. The ARBLST bit in the I2CMCS register is set if there were any issues with the transfer. In addition, the slave can send a NACK at any time to force the master to stop sending additional bytes.

The I2C interface supports µDMA for efficient data handling. The µDMA operation needs FIFOs to be enabled for appropriate transfer type to perform I2C master for burst transfers and all types of slave transfers. The I2C interface is supported by two channels: one for Rx (I2C-to-memory) and one for Tx (memory-to-I2C) transfers. See Section 46.2.5 for more information.

46.2.1.10.1 Quick Command

A quick command is a simple, compact SMBus protocol that sends an address and one bit of data in the R/S bit of the I2C header byte to communicate a command to the slave, typically a turn off or turn on. The I2C master can send a quick command by writing the target address and R/S value into the I2CMSA register followed by a write to I2CMCS with a value of 0x27. SMBus requires the slaveto be able to accept and process commands and the master to generate the quick command transactions. The master also has the capability to stop the transaction after acknowledgment from a slave.

The I2C slave requires special handling when a quick command is sent. In the case where a master sends a quick command with the R/S (data) bit cleared, the QCMDST bit in I2CSCSR is set, and the QCMDRW bit shows the data value (which, in this case, is 0) when the STOPRIS bit is set in I2CSRIS and the STOP interrupt is asserted. In this scenario, a DATARIS interrupt bit is not set. When the master sends a quick command with the R/S (data) bit set, the DATARIS bit is set to notify the slave to write a data byte to I2CSDR in which bit 7 is set. A dummy write of 0xFF to the I2CSDR register is recommended. After the write to I2CSDR, the STOP interrupt is asserted and the QCMDST and QCMDRW bits are set in the I2CSCSR register to indicate that a quick command read occurred and the last transaction was a quick command. Therefore, when the slave must receive a quick command, it expects such a command because it must write the I2CSDR with a specific value when R/S is set.

46.2.2 Available Speed Modes

The I2C bus can run in standard mode (100 kbps), fast mode (400 kbps), fast mode plus (1 Mbps) or high-speed mode (3.4 Mbps, if the correct system clock frequency is set and there is appropriate pull strength on SCL and SDA). The selected mode should match the speed of the other I2C devices on the bus.

46.2.2.1 Standard, Fast, and Fast Plus Modes

Standard, fast, and fast plus modes are selected using a value in the I2C Master Timer Period (I2CMTPR) register that results in an SCL frequency of 100 kbps for standard mode, 400 kbps for fast mode, or 1 Mbps for fast mode plus.

The I2C clock rate is determined by the parameters CLK_PRD, TIMER_PRD, SCL_LP, and SCL_HP, where:

- CLK_PRD is the system clock period
- SCL_LP is the low phase of SCL (fixed at 6)
- SCL_HP is the high phase of SCL (fixed at 4)

TIMER_PRD is the programmed value in the I2CMTPR register. This value is determined by replacing the known variables in Equation 25 and solving for TIMER_PRD. The I2C clock period is calculated as:

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD \quad (25)$$

For example:

- CLK_PRD = 50 ns
- TIMER_PRD = 2
- SCL_LP = 6
- SCL_HP = 4

Yields an SCL frequency of: 1/SCL_PERIOD = 338 KHz

Table 46-1 lists examples of the timer periods that must be used to generate standard, fast mode, and fast mode plus SCL frequencies based on various system clock frequencies.

Table 46-1. Examples of I2C Master Timer Period Versus Speed Mode

System Clock	Standard Mode		Fast Mode		Fast Mode Plus	
	Timer Period	Data Rate	Timer Period	Data Rate	Timer Period	Data Rate
200 MHz	99	100 kbps	24	400 kbps	9	1 Mbps

46.2.2.2 High-Speed Mode

The I2C peripheral has support for high-speed operation as both a master and slave. High-speed mode is configured by setting the HS bit in the I2C Master Control/Status (I2CMCS) register. High-speed mode transmits data at a high bit rate with a 66.6%/33.3% duty cycle, but communication and arbitration are done at standard, fast mode, or fast-mode plus speed, depending on which is selected by the user. When the HS bit in the I2CMCS register is set, current mode pullups are enabled.

The clock period can be selected using Equation 26, but in this case, SCL_LP = 2 and SCL_HP = 1.

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD \quad (26)$$

For example:

- CLK_PRD = 25 ns
- TIMER_PRD = 1
- SCL_LP = 2
- SCL_HP = 1

Yields a SCL frequency of: 1/T = 3.33 MHz

Table 46-2 gives examples of timer period and system clock in high-speed mode. Note that the HS bit in the I2CMTPR register must be set for the TPR value to be used in high-speed mode.

Table 46-2. Examples of I2C Master Timer Period in High-Speed Mode

System Clock	Timer Period	Transmission Mode
200 MHz	9	3.33 Mbps

When operating as a master, the protocol is shown in Figure 46-7. The master is responsible for sending a master code byte in either standard (100 kbps) or fast mode (400 kbps) before the code byte begins transferring in high-speed mode. The master code byte must contain data in the form of 0000.1XXX and is used to tell the slave devices to prepare for a high-speed transfer. The master code byte must never be acknowledged by a slave, since the code byte is only used to indicate that the upcoming data is going to be transferred at a higher data rate. To send the master code byte for a standard high-speed transfer, software must place the value of the master code byte into the I2CMSA register and write the I2CMCS register with a value of 0x13. If a high-speed burst transfer is required, then to send the master code byte, software must place the value of the master code byte into the I2CMSA register and write the I2CMCS register with 0x50. Either configuration places the I2C master peripheral in high-speed mode, and all subsequent transfers (until STOP) are carried out at high-speed data rate using the normal I2CMCS command bits, without setting the HS bit in the I2CMCS register. Again, setting the HS bit in the I2CMCS register is only necessary during the master code byte.

When operating as a high-speed slave, no additional software is required.

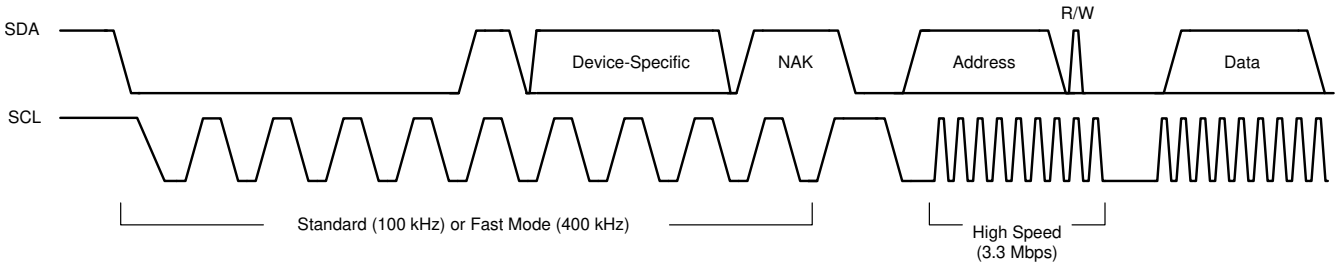

Figure 46-7. High-Speed Data Format

Note

High-speed mode is 3.4 Mbps, if the correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines.

46.2.3 Interrupts

The I2C can generate interrupts when the following conditions are observed in the master module:

- Master transaction completed (RIS bit)
- Master arbitration lost (ARBLOSTRIS bit)
- Master Address/Data NACK (NACKRIS bit)
- Master bus time-out (CLKRIS bit)
- Next byte request (RIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)
- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

Interrupts are generated when the following conditions are observed in the slave module:

- Slave transaction received (DATARIS bit)
- Slave transaction requested (DATARIS bit)
- Slave next byte transfer request (DATARIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Programmable trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Programmable trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)
- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

The I2C master and slave modules have separate interrupt registers. Interrupts can be masked by clearing the appropriate bit in the I2CMIMR or I2CSIMR register. Note that the RIS bit in the Master Raw Interrupt Status (I2CMRIS) register and the DATARIS bit in the Slave Raw Interrupt Status (I2CSRIS) register have multiple interrupt causes, including a next byte transfer request interrupt. This interrupt is generated when the master and slave are requesting a receive or transmit transaction.

46.2.4 Loopback Operation

The I2C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the LPBK bit in the I2C Master Configuration (I2CMCR) register. In loopback mode, the SDA and SCL signals from the master and are connected to the SDA and SCL signals of the slave module to allow internal testing of the device without having to go through I/O.

46.2.5 FIFO and µDMA Operation

Both the master and the slave module have the capability to access two 8-byte FIFOs that can be used in conjunction with the µDMA for fast transfer of data. The transmit (TX) FIFO and receive (RX) FIFO can be independently assigned to either the I2C master or I2C slave. Thus, the following FIFO assignments are allowed:

- The transmit and receive FIFOs can be assigned to the master
- The transmit and receive FIFOs can be assigned to the slave
- The transmit FIFO can be assigned to the master, while the receive FIFO is assigned to the slave and conversely

In most cases, both FIFOs will be assigned to either the master or the slave. The FIFO assignment is configured by programming the TXASGNMT and RXASGNMT bit in the I2C FIFO Control (I2CFIFOCTL) register.

Each FIFO has a programmable threshold point that indicates when the FIFO service interrupt should be generated. Additionally, a FIFO receive full and transmit empty interrupt can be enabled in the Interrupt Mask (I2CxIMR) registers of both the master and slave. Note that if we clear the TXFERIS interrupt (by setting the TXFEIC bit) when the TX FIFO is empty, the TXFERIS interrupt does not reassert even though the TX FIFO remains empty in this situation.

When a FIFO is not assigned to a master or a slave module, the FIFO interrupt and status signals to the module are forced to a state that indicates the FIFO is empty. For example, if the TX FIFO is assigned to the master module, the status signals to the slave transmit interface indicates that the FIFO is empty.

Note

The FIFOs must be empty when reassigning the FIFOs for proper functionality

46.2.5.1 Master Module Burst Mode

A BURST command is provided for the master module that allows a sequence of data transfers using the µDMA (or software, if desired) to handle the data in the FIFO. The BURST command is enabled by setting the BURST bit in the Master Control/Status (I2CMCS) register. The number of bytes transferred by a BURST request is programmed in the I2C Master Burst Length (I2CMBLEN) register and a copy of this value is automatically written to the I2C Master Burst Count (I2CMBCNT) register to be used as a down-counter during the BURST transfer. The bytes written to the I2C FIFO Data (I2CFIFODATA) register are transferred to the RX FIFO or TX FIFO depending on whether a transmit or receive is being executed. If data is NACKed during a BURST and the STOP bit is set in the I2CMCS register, the transfer terminates. If the STOP bit is not set, the software application must issue a repeated STOP or START when a NACK interrupt is asserted. In the case of a NACK, the I2CMBCNT register can be used to determine the amount of data that was transferred prior to the BURST termination. If the address is NACKed during a transfer, then a STOP is issued.

46.2.5.1.1 Master Module µDMA Functionality

When the Master Control/Status (I2CMCS) register is set to enable BURST and the master I^2C µDMA channel is enabled in the DMA Channel Map Select n (DMACHMAPn) registers in the µDMA, the master control module will assert either the internal single µDMA request signal (dma_sreq) or multiple µDMA request signal (dma_req) to the µDMA. Note that there are separate dma_req and dma_sreq signals for transmit and receive. A single µDMA request (dma_sreq) will be asserted by the master module when the Rx FIFO has at least one data byte present in the FIFO and/or when the Tx FIFO has at least one space available to fill. The dma_req (or Burst) signal will be asserted when Rx FIFO fill level is higher than trigger level and/or the Tx FIFO burst length remaining is less than 4 bytes and the FIFO fill level is less than trigger level. If a single transfer or BURST operation has completed, the µDMA sends a dma_done signal to the master module represented by the DMATX and DMARX interrupts in the I2CMIMR, I2CMRIS, I2CMMIS, and I2CMICR registers.

If the µDMA I2C channel is disabled and software is used to handle the BURST command, software can read the FIFO Status (I2CFIFOSTAT) Register and the Master Burst Count (I2CMBC) register to determine whether the FIFO needs servicing during the BURST transaction. A trigger value can be programmed in the I2CFIFOCTL register to allow for interrupts at various fill levels of the FIFOs.

The NACK and ARBLOST bits in the interrupt status registers can be enabled to indicate no acknowledgment of data transfer or an arbitration loss on the bus.

When the master module is transmitting FIFO data, software can fill the Tx FIFO in advance of setting the BURST bit in the I2CMCS register. If the FIFO is empty when the µDMA is enabled for BURST mode, the dma_req and dma_sreq both assert (assuming the I2CMBLEN register is programmed to at least four bytes and the Tx FIFO fill level is less than the trigger set). If the I2CMBLEN register value is less than four and the Tx FIFO is not full but more than trigger level, only dma_sreq asserts. Single requests will be generated as required to keep the FIFO full until the number of bytes specified in the I2CMBLEN register has been transferred to the FIFO (and the I2CMBCOUNT register reaches 0x0). At this point, no further requests are generated until the next BURST command is issued. If the µDMA is disabled, FIFOs will be serviced based on the interrupts active in the master interrupt status registers, the FIFO trigger values shown in the I2CFIFOSTATUS register and completion of a BURST transfer.

When the master module is receiving FIFO data, the Rx FIFO is initially empty and no requests are asserted. If data is read from the slave and placed into the Rx FIFO, the dma_sreq signal to the µDMA is asserted to indicate there is data to be transferred. If the Rx FIFO contains at least 4 bytes, the dma_req signal is also asserted. The µDMA will continue to transfer data out of the Rx FIFO until it has reached the amount of bytes programmed in the I2CMBLEN register.

Note

The TXFEIM interrupt mask bit in the I2CMIMR register should be clear (masking the TXFE interrupt) when the master is performing an RX Burst from the RXFIFO and should be unmasked before starting a TX FIFO transfers.

46.2.5.2 Slave Module

The slave module also has the capability to use the µDMA in Rx and Tx FIFO data transfers. If the Tx FIFO is assigned to the slave module and the TXFIFO bit is set in the I2CSCSR register, the slave module will generate a single µDMA request, dma_sreq, if the master module requests the next byte transfer. If the FIFO fill level is less than the trigger level, a µDMA multiple transfer request, dma_req, will be asserted to continue data transfers from the µDMA.

If the Rx FIFO is assigned to the slave module and the RXFIFO bit is set in the I2CSCSR register, then the slave module will generate a signal µDMA request, dma_sreq, if there is any data to be transferred. The dma_req signal will be asserted when the Rx FIFO has more data than the trigger level programmed by the RXTRIG bit in the I2CFIFOCTL register.

Note

Best practice recommends that an application should not switch between the I2CSDR register and TX FIFO or conversely for successive transactions.

46.2.6 Command Sequence Flow Charts

This section details the steps required to perform the various I2C transfer types in both master and slave mode.

46.2.6.1 I2C Master Command Sequences

The following figures show the command sequences available for the I^{2}C master.

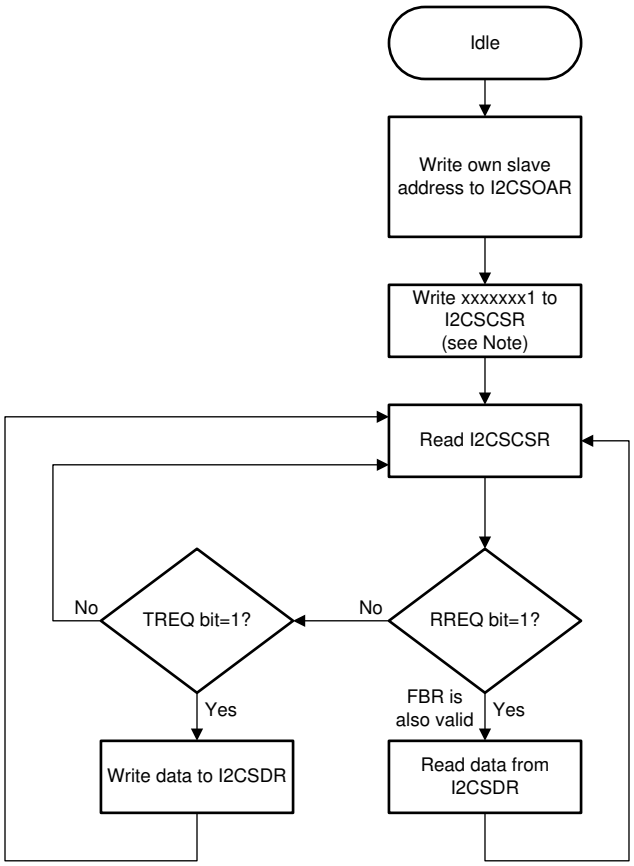
46.2.6.2 I2C Slave Command Sequences

Figure 46-15 shows the command sequence available for the I2C slave.



Note: x = application-specific bit

Figure 46-15. Slave Command Sequence

46.3 Initialization and Configuration

46.3.1 Configure the I2C Module to Transmit a Single Byte as a Master

The following example shows how to configure the I2C module to transmit a single byte as a master. This assumes the system clock is 200 MHz.

1. Enable the I2C clock using the CMPCLKCR0 register in the system control module.
2. In the GPIO module, configure GPxCSELy register to allow CM core to control corresponding GPIOs. To determine which GPIOs to configure, see the GPIO Muxed Pins tables in the device data sheet.
3. Configure GPxGMUXy and GPxMUXy register to assign the I^2C signals to the appropriate pins.

Note

The GPIO configuration register GPyODR must be set to normal mode when the CM-I2C is used. The open-drain operation for CM-I2C is managed by the CM-I2C module.

4. Initialize the I^2C master by writing the I2CMCS_WRITE register with a value of 0x0000.0010.
5. Set the desired SCL clock speed of 100 kbps by writing the I2CMTPR register with the correct value. The value written to the I2CMTPR register represents the number of system clock periods in one SCL clock period. The TPR value is calculated by:

   TPR = (System Clock / (2 × (SCL_LP + SCL_HP) × SCL_CLK)) – 1

   TPR = (200 MHz / (2 × (6 + 4) × 100000)) – 1

   TPR = 99 (or) 0x63

   Write the I2CMTPR register with the value of 0x0000.0063.
6. Specify the slave address of the master and that the next operation is a Transmit by writing the I2CMSA register with a value of 0x0000.0076. This sets the slave address to 0x3B.
7. Place data (byte) to be transmitted in the data register by writing the I2CMDR register with the desired data.
8. Initiate a single byte transmit of the data from the master to the slave by writing the I2CMCS register with a value of 0x0000.0007 (STOP, START, RUN).
9. Wait until the transmission completes by polling the BUSBSY bit in the I2CMCS register until it has been cleared.
10. Check the ERROR bit in the I2CMCS register to confirm the transmit was acknowledged.

46.3.2 Configure the I2C Master to High-Speed Mode

To configure the I2C master to high-speed mode:

1. Enable the I2C clock using the CMPCLKCR0 register in the system control module.
2. In the GPIO module, configure GPxCSELy register to allow CM core to control corresponding GPIOs. To determine which GPIOs to configure, see the GPIO Muxed Pins tables in the device data sheet.
3. Configure GPxGMUXy and GPxMUXy register to assign the I2C signals to the appropriate pins.

Note

The GPIO configuration register GPyODR must be set to normal mode when the CM-I2C is used. The open-drain operation for CM-I2C is managed by the CM-I2C module.

4. Initialize the I^2C master by writing the I2CMCR register with a value of 0x0000.0010.
5. Set the desired SCL clock speed of 3.33 Mbps by writing the I2CMTPR register with the correct value. The value written to the I2CMTPR register represents the number of system clock periods in one SCL clock period. The TPR value is determined by:

   TPR = (System Clock / (2 × (SCL_LP + SCL_HP) × SCL_CLK)) – 1

   TPR = (200 MHz / (2 × (2 + 1) × 3330000)) – 1

   TPR = 9

   Write the I2CMTPR register with the value of 0x0000.0009.
6. To send the master code byte, software should place the value of the master code byte into the I2CMCS_WRITE register and write the I2CMCS_WRITE register with the following value depending on the required operation:
   - For standard high-speed mode, write 0x13 to the I2CMCS_WRITE register.
   - For burst high-speed mode, write 0x50 to the I2CMCS_WRITE register.
7. This places the I2C master peripheral in high-speed mode, and all subsequent transfers (until STOP) are carried out at high-speed data rate using the normal I2CMCS_WRITE command bits, without setting the HS bit in the I2CMCS register.
8. The transaction is ended by setting the STOP bit in the I2CMCS register.
9. Wait until the transmission completes by polling the BUSBSY bit in the I2CMCS register until it has been cleared.
10. Check the ERROR bit in the I2CMCS register to confirm the transmit was acknowledged.

46.4 CM I2C Registers

This section describes the Connectivity Manager I2C Registers.

46.4.1 CM I2C Base Addresses

Table 46-3. CM I2C Base Address Table (CM)

DriverLib Name	Base Address	uDMA Access	Ethernet DMA Access
I2C0_BASE	0x4002_0000	YES	-

46.4.2 CM_I2C_REGS Registers

Table 46-4 lists the memory-mapped registers for the CM_I2C_REGS registers. All register offset addresses not listed in Table 46-4 should be considered as reserved locations and the register contents should not be modified.

Table 46-4. CM_I2C_REGS Registers

Complex bit access types are encoded to fit into small table cells. Table 46-5 shows the codes that are used for access types in this section.

Table 46-5. CM_I2C_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
RC	R C	Read to Clear
Write Type		
W	W	Write
Reset or Default Value		

Table 46-5. CM_I2C_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

46.4.2.1 I2CMSA Register (Offset = 0h) [Reset = 0h]

I2CMSA is shown in Figure 46-16 and described in Table 46-6.

Return to the Summary Table.

46.4.3 CM_I2C_WRITE_REGS Registers

Table 46-33 lists the memory-mapped registers for the CM_I2C_WRITE_REGS registers. All register offset addresses not listed in Table 46-33 should be considered as reserved locations and the register contents should not be modified.

Table 46-33. CM_I2C_WRITE_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
4h	I2CMCS_WRITE	I2C Master Control/Status		Go
804h	I2CSCSR_WRITE	I2C Slave Control/Status		Go
F00h	I2CFIFODATATX	I2C FIFO Data TX		Go

Complex bit access types are encoded to fit into small table cells. Table 46-34 shows the codes that are used for access types in this section.

Table 46-34. CM_I2C_WRITE_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Chapter 47

Synchronous Serial Interface (SSI)

This chapter describes the synchronous serial interface (SSI) module. Refer to the device datasheet for the number of instances present on your device.

47.1 Introduction

Each SSI is a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, or Texas Instruments Synchronous Serial Interfaces.

47.1.1 Features

The SSI module includes the following features:

- Programmable interface operation for Freescale SPI, or Texas Instruments Synchronous Serial Interfaces. In this SSI module, only the Legacy SSI mode is supported.
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16-bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller (µDMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains four entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when FIFO contains four or more entries are available to be written in the FIFO
  - Maskable µDMA interrupts for receive and transmit complete

47.1.2 Block Diagram

The SSI module block diagram is shown in Figure 47-1.

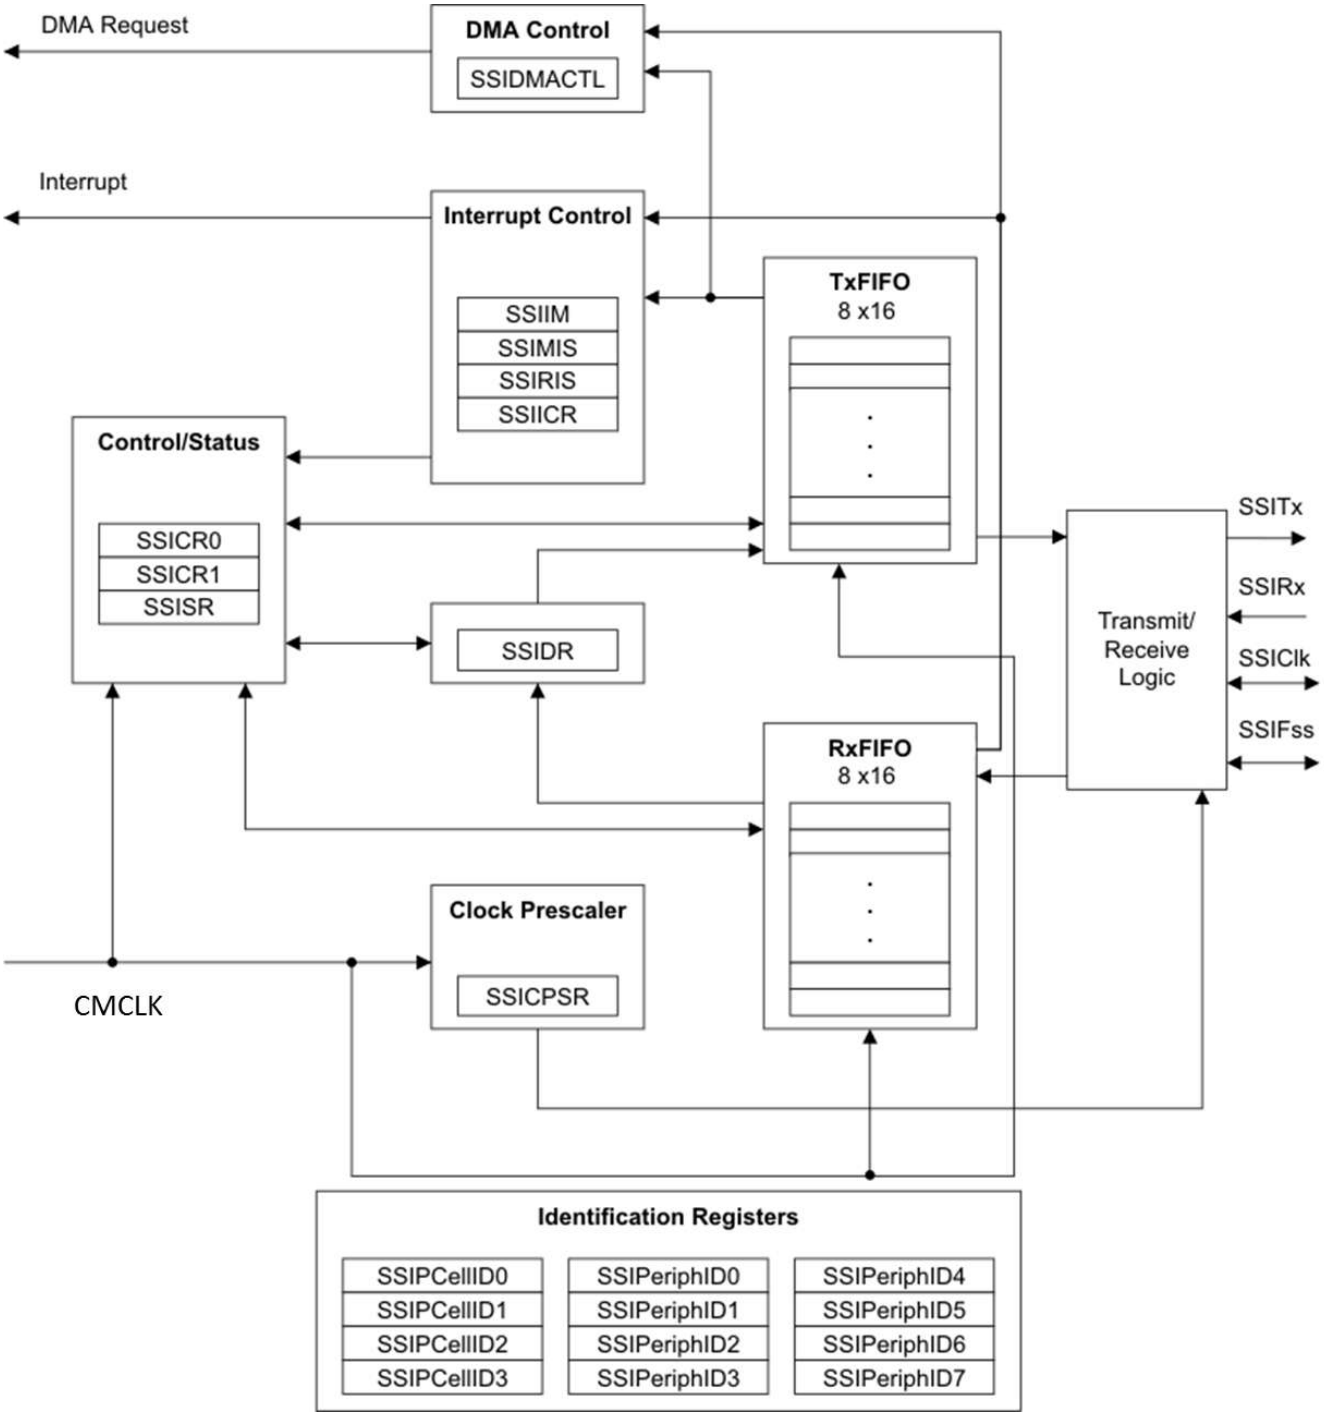

Figure 47-1. SSI Block Diagram

47.2 Functional Description

The SSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories, allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The SSI also supports the µDMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the µDMA module. µDMA operation is enabled by setting the appropriate bit(s) in the SSIDMACTL register.

47.2.1 Bit Rate Generation

The SSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing-down the input clock (CMCLK). The clock is first divided by an even prescale value CPSDVSR from 2 to 254, which is programmed in the SSI Clock Prescale (SSICPSR) register. The clock is further divided by a value from 1 to 256, which is 1 + SCR, where SCR is the value programmed in the SSI Control 0 (SSICR0) register.

The frequency of the output clock SSIClk is defined by:

SSIClk = CMCLK / (CPSDVSR * (1 + SCR)) (27)

Note

For master mode, the system clock must be at least two times faster than the SSIClk, with the restriction that SSIClk cannot be faster than (CMCLK/2).

For slave mode, the system clock must be at least 12 times faster than the SSIClk. In slave mode, maximum frequency of operation is (CMCLK/12).

See the *Electrical Characteristics* chapter in the device data sheet to view SSI timing parameters.

47.2.2 FIFO Operation

47.2.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the SSI Data (SSIDR) register, and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion and transmission to the attached slave or master, respectively, through the SSITx pin.

In slave mode, the SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the eighth most recent value in the transmit FIFO. If less than eight values have been written to the transmit FIFO since the SSI module clock was enabled using the SSI bit in the CMPCLKCR0 register, then 0 is transmitted. Take care to ensure that valid data is in the FIFO as needed. The SSI can be configured to generate an interrupt or a µDMA request when the FIFO is empty.

47.2.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data from the serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the SSIDR register.

When configured as a master or slave, serial data received through the SSIRx pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

When receiving data in master mode, a dummy write to the SSIDR register must occur before any read occurs.

47.2.3 SSInFSS Function

The SSInFss signal can be programmed to assert low at the start of each byte transfer for one clock or the entire frame. This is configured by programming the FSSHLDFRM bit in the SSICR1 register as shown in Table 47-1. The EOM bit is also provided to signify end of frame transmission. This bit is embedded in the TXFIFO entry for use at the interface to deassert SSInFss at the appropriate time.

Table 47-1. SSInFss Functionality

FSSHLDFRM Bit	Description
0	For Freescale format, with SPH = 0, the SSInFss signal is asserted low between continuous transfers. For SPH = 1, the SSInFss signal is deasserted (high) between continuous transfers. For TI format, the SSInFss signal is deasserted (high) after every data transfer.
1	For Freescale format with any SPH value, the SSInFss signal is forced high between continuous transfers; it is asserted low when there is available data in the Tx FIFO; otherwise, it is forced high to be ready for a new frame.

47.2.4 Interrupts

The SSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service (when the transmit FIFO is half full or less)
- Receive FIFO service (when the receive FIFO is half full or more)
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission

All of the interrupt events are ORed together before being sent to the interrupt controller, so the SSI generates a single interrupt request to the controller regardless of the number of active interrupts. Each of the four individual maskable interrupts can be masked by clearing the appropriate bit in the SSI Interrupt Mask (SSIIM) register. Setting the appropriate mask bit enables the interrupt.

The individual outputs, along with a combined interrupt output, allow use of either a global interrupt service routine or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the SSI Raw Interrupt Status (SSIRIS) and SSI Masked Interrupt Status (SSIMIS) registers.

The receive FIFO has a time-out period that is 32 periods at the rate of SSIClk (whether or not SSIClk is currently active) and is started when the RX FIFO goes from EMPTY to not-EMPTY. If the RX FIFO is emptied before 32 clocks have passed, the time-out period is reset. As a result, the ISR should clear the Receive FIFO Time-out Interrupt just after reading out the RX FIFO by writing a 1 to the RTIC bit in the SSI Interrupt Clear (SSIICR) register. The interrupt should not be cleared so late that the ISR returns before the interrupt is actually cleared, or the ISR may be re-activated unnecessarily.

The End-of-Transmission (EOT) interrupt indicates that the data has been transmitted completely. This interrupt can be used to indicate when it is safe to turn off the SSI module clock or enter sleep mode. In addition, because transmitted data and received data complete at exactly the same time, the interrupt can also indicate that read data is ready immediately, without waiting for the receive FIFO time-out period to complete.

47.2.5 Frame Formats

Each data frame is between 4- and 16-bits long, depending on the size of data programmed, and is transmitted starting with the MSB. Two basic frame types can be selected:

- Texas Instruments synchronous serial
- Freescale SPI

For all three formats, the serial clock (SSIClk) is held inactive while the SSI is idle, and SSIClk transitions at the programmed frequency only during active transmission or reception of data. The idle state of SSIClk is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI frame format, the serial frame (SSIFss) pin is active low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the SSIFss pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the SSI and the off-chip slave device drive their output data on the rising edge of SSIClk and latch data from the other device on the falling edge.

Figure 47-2 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

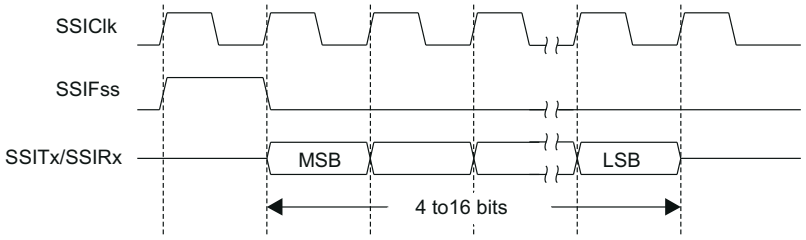

Figure 47-2. TI Synchronous Serial Frame Format (Single Transfer)

In this mode, SSIClk and SSIFss are forced low, and the transmit data line SSITx is tristated whenever the SSI is idle. Once the bottom entry of the transmit FIFO contains data, SSIFss is pulsed high for one SSIClk period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SSIClk, the MSB of the 4- to 16-bit data frame is shifted out on the SSITx pin. Likewise, the MSB of the received data is shifted onto the SSIRx pin by the off-chip serial slave device.

Both the SSI and the off-chip serial slave device then clock each data bit into their serial shifter on each falling edge of SSIClk. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of SSIClk after the LSB has been latched.

Figure 47-3 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

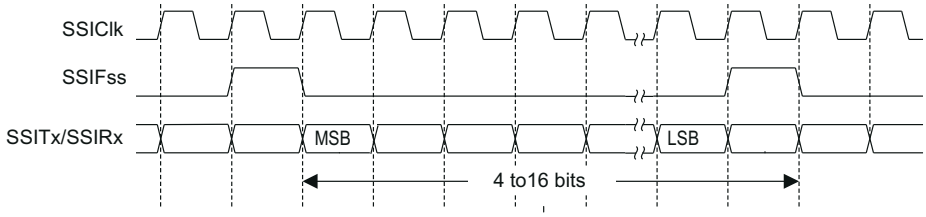

Figure 47-3. TI Synchronous Serial Frame Format (Continuous Transfer)

47.2.5.1 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the SSIFss signal behaves as a slave select. The main feature of the Freescale SPI format is that the inactive state and phase of the SSIClk signal are programmable through the SPO and SPH bits in the SSICR0 control register.

47.2.5.1.1 SPO Clock Polarity Bit

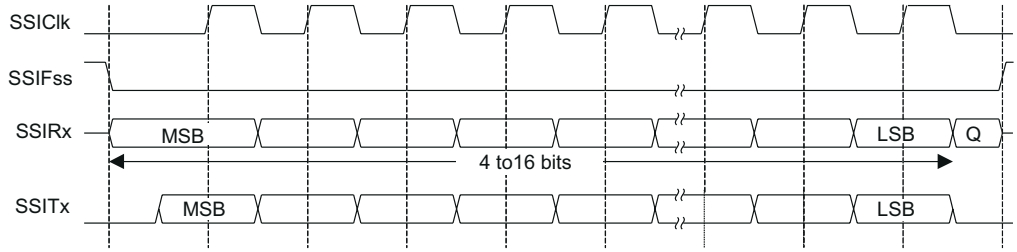
When the SPO clock polarity control bit is clear, it produces a steady state low value on the SSIClk pin. If the SPO bit is set, a steady state high value is placed on the SSIClk pin when data is not being transferred.

47.2.5.1.2 SPH Phase Control Bit

The SPH phase control bit selects the clock edge that captures data and allows it to change state. The state of this bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the SPH phase control bit is clear, data is captured on the first clock edge transition. If the SPH bit is set, data is captured on the second clock edge transition.

47.2.5.2 Freescale SPI Frame Format with SPO=0 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=0 and SPH=0 are shown in Figure 47-4 and Figure 47-5.



Note: Q is undefined.

Figure 47-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0

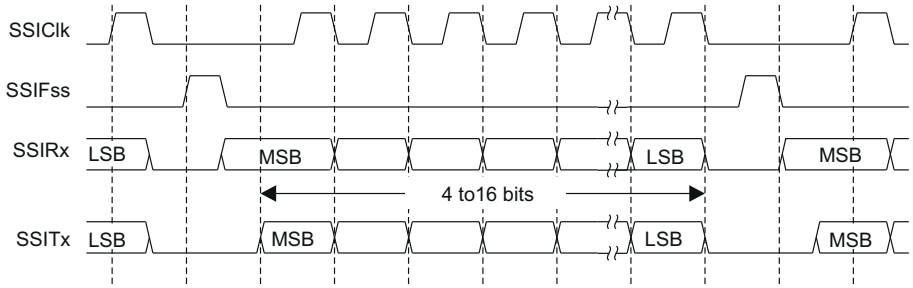


Figure 47-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0

In this configuration, during idle periods:

- SSIClk is forced low
- SSIFss is forced high
- The transmit data line SSITx is arbitrarily forced low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven low, causing slave data to be enabled onto the SSIRx input line of the master. The master SSITx output pad is enabled.

One half SSIClk period later, valid master data is transferred to the SSITx pin. Once both the master and slave data have been set, the SSIClk master clock pin goes high after one additional half SSIClk period. The data is now captured on the rising and propagated on the falling edges of the SSIClk signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the SSIFss line is returned to its idle high state one SSIClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSIFss signal must be pulsed high between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSIFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSIFss pin is returned to its idle state one SSIClk period after the last bit has been captured.

47.2.5.3 Freescale SPI Frame Format with SPO=0 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=0 and SPH=1 is shown in Figure 47-6, in which covers both single and continuous transfers.

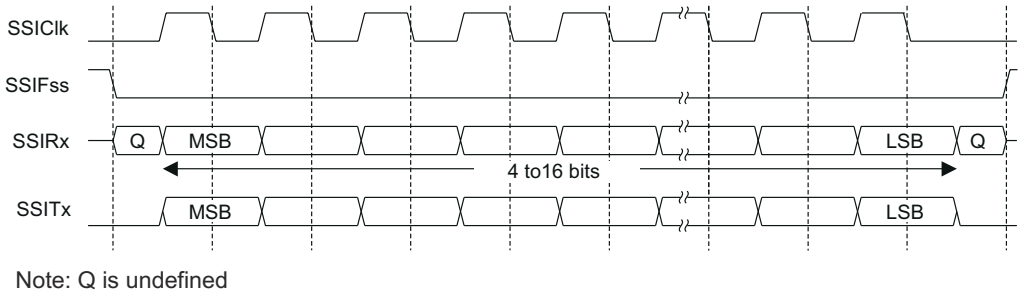

Figure 47-6. Freescale SPI Frame Format with SPO =0 and SPH=1

In this configuration, during idle periods:

- SSIClk is forced low
- SSIFss is forced high
- The transmit data line SSITx is arbitrarily forced low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

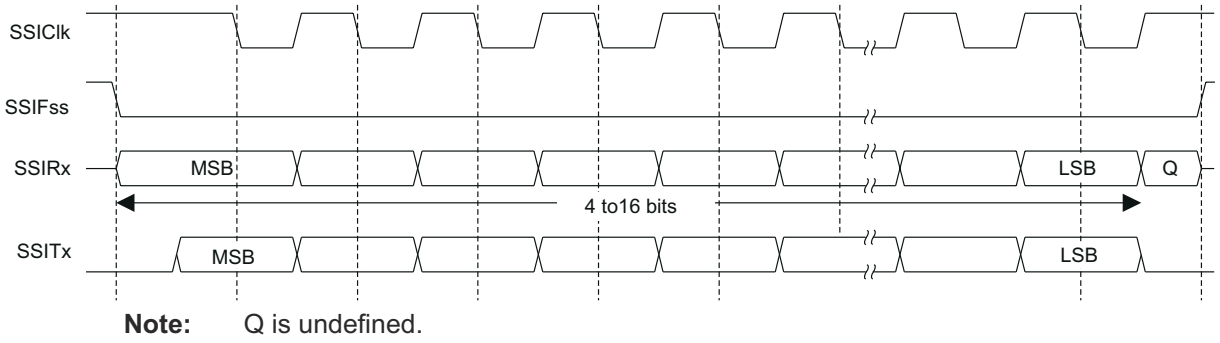
If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven low. The master SSITx output is then enabled. After an additional one-half SSIClk period, both master and slave valid data are enabled onto their respective transmission lines. At the same time, the SSIClk is enabled with a rising edge transition. Data is then captured on the falling edges and propagated on the rising edges of the SSIClk signal.

In the case of a single word transfer, after all bits have been transferred, the SSIFss line is returned to its idle high state one SSIClk period after the last bit has been captured.

For continuous back-to-back transfers, the SSIFss pin is held low between successive data words, and termination is the same as that of the single word transfer.

47.2.5.4 Freescale SPI Frame Format with SPO=1 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=1 and SPH=0 are shown in Figure 47-7 and Figure 47-8.



Note: Q is undefined.

Figure 47-7. Freescale SPI Frame Format (Single Transfer) with SPO=1 and SPH=0

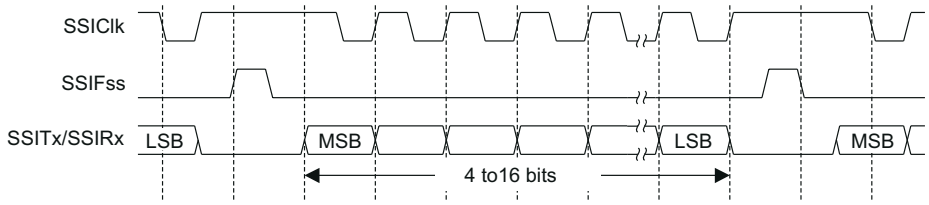


Figure 47-8. Freescale SPI Frame Format (Continuous Transfer) with SPO=1 and SPH=0

In this configuration, during idle periods:

- SSIClk is forced high
- SSIFss is forced high
- The transmit data line SSITx is arbitrarily forced low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven low, causing slave data to be immediately transferred onto the SSIRx line of the master. The master SSITx output pad is enabled.

One-half period later, valid master data is transferred to the SSITx line. Once both the master and slave data have been set, the SSIClk master clock pin becomes low after one additional half SSIClk period, meaning that data is captured on the falling edges and propagated on the rising edges of the SSIClk signal.

In the case of a single word transmission, after all bits of the data word are transferred, the SSIFss line is returned to its idle high state one SSIClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSIFss signal must be pulsed high between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSIFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSIFss pin is returned to its idle state one SSIClk period after the last bit has been captured.

47.2.5.5 Freescale SPI Frame Format with SPO=1 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=1 and SPH=1 is shown in Figure 47-9, which covers both single and continuous transfers.

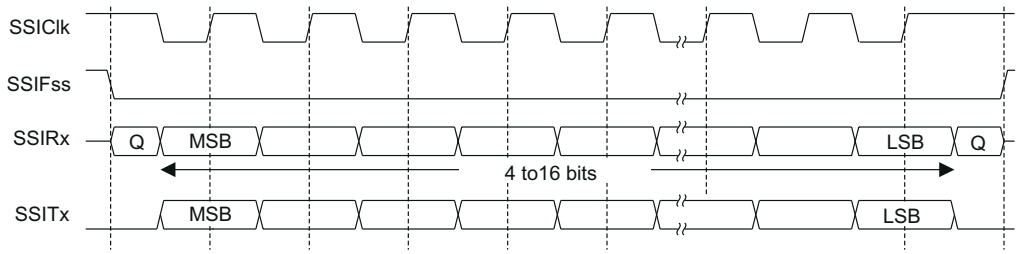

Figure 47-9. Freescale SPI Frame Format with SPO =1 and SPH =1

In this configuration, during idle periods:

- SSIClk is forced hgh
- SSIFss is forced high
- The transmit data line SSITx is arbitrarily forced low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven low. The master SSITx output pad is enabled. After an additional one-half SSIClk period, both master and slave data are enabled onto their respective transmission lines. At the same time, SSIClk is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SSIClk signal.

After all bits have been transferred, in the case of a single word transmission, the SSIFss line is returned to its idle high state one SSIClk period after the last bit has been captured.

For continuous back-to-back transmissions, the SSIFss pin remains in its active low state until the final bit of the last word has been captured and then returns to its idle state as described above.

For continuous back-to-back transfers, the SSIFss pin is held low between successive data words and termination is the same as that of the single word transfer.

47.2.6 DMA Operation

The SSI peripheral provides an interface to the µDMA controller with separate channels for transmit and receive. The µDMA operation of the SSI is enabled through the SSI DMA Control (SSIDMACTL) register. When µDMA operation is enabled, the SSI asserts a µDMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is four or more items.

For the transmit channel, a single transfer request is asserted whenever at least one empty location is in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has four or more empty slots. The single and burst µDMA transfer requests are handled automatically by the µDMA controller depending how the µDMA channel is configured. To enable µDMA operation for the receive channel, the RXDMAE bit of the DMA Control (SSIDMACTL) register should be set. To enable µDMA operation for the transmit channel, the TXDMAE bit of SSIDMACTL should be set. If µDMA is enabled, then the µDMA controller triggers an interrupt when a transfer is complete. The interrupt occurs on the SSI interrupt vector. Therefore, if interrupts are used for SSI operation and µDMA is enabled, the SSI interrupt handler must be designed to handle the µDMA completion interrupt.

If the µDMA is enabled and has completed a data transfer from the Tx FIFO, the DMATXRIS bit is set in the SSIRIS register and cannot be cleared by setting the DMATXIC bit in the SSI Interrupt Clear (SSIICR) register. In the DMA Completion Interrupt Service Routine, software must disable the µDMA transmit enable to the SSI by clearing the TXDMAE bit in the SSI DMA Control (SSIDMACTL) register and then setting the DMATXIC bit in the SSIICR register. This clears the DMA completion interrupt. When the µDMA is needed to transmit more data, the TXDMAE bit must be set (enabled) again. If a data transfer by the µDMA from the Rx FIFO completes, the DMARXRIS bit is set. The EOT bit in the SSIRIS register is also provided to indicate when the Tx FIFO is empty and the last bit has been transmitted out of the serializer.

See the *Micro Direct Memory Access (µDMA)* chapter for more details about programming the µDMA controller.

47.3 Initialization and Configuration

To enable and initialize the SSI, the following steps are necessary:

1. Enable the SSI module by setting the SSI bit in the CMPCLKCR0 register.
2. Configure the pinmux.

For each of the frame formats, the SSI is configured using the following steps:

1. Ensure that the SSE bit in the SSICR1 register is clear before making any configuration changes.
2. Select whether the SSI is a master or slave:
   - For master operations, set the SSICR1 register to 0x0000.0000.
   - For slave mode (output enabled), set the SSICR1 register to 0x0000.0004.
   - For slave mode (output disabled), set the SSICR1 register to 0x0000.000C.
3. Configure the clock prescale divisor by writing the SSICPSR register.
4. Write the SSICR0 register with the following configuration:
   - Serial clock rate (SCR)
   - Desired clock phase/polarity, if using Freescale SPI mode (SPH and SPO)
   - Protocol mode: Freescale SPI, TI SSF
   - Data size (DSS)
5. Optionally, configure the µDMA channel (see the *Micro Direct Memory Access (µDMA)* chapter) and enable the DMA option(s) in the SSIDMACTL register.
6. Enable the SSI by setting the SSE bit in the SSICR1 register.

As an example, assume the SSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (SPO=1, SPH=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock (CMCLK) is 20 MHz, the bit rate calculation would be:

SSIClk = (system clock) / (CPSDVSR * (1 + SCR)) 1 x 106 = 20 x 106 / (CPSDVSR * (1 + SCR)) (28)

In this case, if CPSDVSR=0x2, SCR must be 0x9.

The configuration sequence would be as follows:

1. Ensure that the SSE bit in the SSICR1 register is clear.
2. Write the SSICR1 register with a value of 0x0000.0000.
3. Write the SSICPSR register with a value of 0x0000.0002.
4. Write the SSICR0 register with a value of 0x0000.09C7.
5. The SSI is then enabled by setting the SSE bit in the SSICR1 register.

47.4 Software

47.4.1 SSI Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/ssi

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

47.4.1.1 SSI Loopback example with interrupts - CM

FILE: ssi_ex1_loopback.c

This example showcases how to use SSI to transfer and receive data in loopback mode
cm_common_config_c28x example needs to be run on C28x1 before running this example on the CM core

Configuration:
- Frame format : TI mode
- Baud rate : 625000
- Data width : 12 bits

External Connections
- None

Watch Variables
- *txData* - Data transmitted
- *rxData* - Data received
- *errCount* - Error count

47.4.1.2 SSI Loopback example with UDMA - CM

FILE: ssi_ex2_loopback_udma.c

This example showcases how to use UDMA with SSI to transfer and receive data

This configures the SSI in loopback mode and sends and receives data for infinite time.
cm_common_config_c28x example needs to be run on C28x1 before running this example on the CM core

Configuration:
- Frame format : TI mode
- Baud rate : 625000
- Data width : 16 bits

External Connections
- None

Watch Variables
- *TxData* - Data transmitted
- *RxData* - Data received
- *errCount* - Error count

47.5 SSI Registers

This section describes the Synchronous Serial Interface registers.

47.5.1 SSI Base Addresses

Table 47-2. SSI Base Address Table (CM)

Complex bit access types are encoded to fit into small table cells. Table 47-4 shows the codes that are used for access types in this section.

Table 47-4. SSI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 47-4. SSI_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

47.5.2.1 SSICR0 Register (Offset = 0h) [Reset = 0h]

SSICR0 is shown in Figure 47-10 and described in Table 47-5.

Return to the Summary Table.

Chapter 48

Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the Universal Asynchronous Receivers/Transmitters (UARTs).

48.1 Introduction

The UART module performs the functions of parallel-to-serial and serial-to-parallel conversions.

48.1.1 Features

The Universal Asynchronous Receiver/Transmitter (UART) module in this device contains the following features:

- Programmable baud-rate generator allowing speeds up to 7.8125 Mbps for regular speed (divide by 16) and 15.625 Mbps for high speed (divide by 8)
- Separate 16-deep and 8-bit wide transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of ⅛, ¼, ½, ¾, and ⅞
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no parity bit generation and detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder and decoder providing
  - Programmable use of IrDA SIR or UART input/output
  - Support of IrDA SIR encoder and decoder functions for data rates up to 115.2 kbps half-duplex
  - Support of normal 3/16 and low-power (1.41 to 2.23 µs) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission (EOT) interrupts
- Efficient transfers using Micro Direct Memory Access Controller (µDMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
  - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- CMCLK (125-MHz maximum) is used to generate the baud clock.

48.1.2 Block Diagram

Figure 48-1 shows the UART block diagram.

48.2 Functional Description

The UART module performs the functions of parallel-to-serial and serial-to-parallel conversions. The UART module is similar in functionality to a 16C550 UART, but is not register-compatible.

The UART is configured for transmit or receive through the TXE and RXE bits of the UART Control (UARTCTL) register. Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the UARTEN bit in UARTCTL. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder and decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the UARTCTL register.

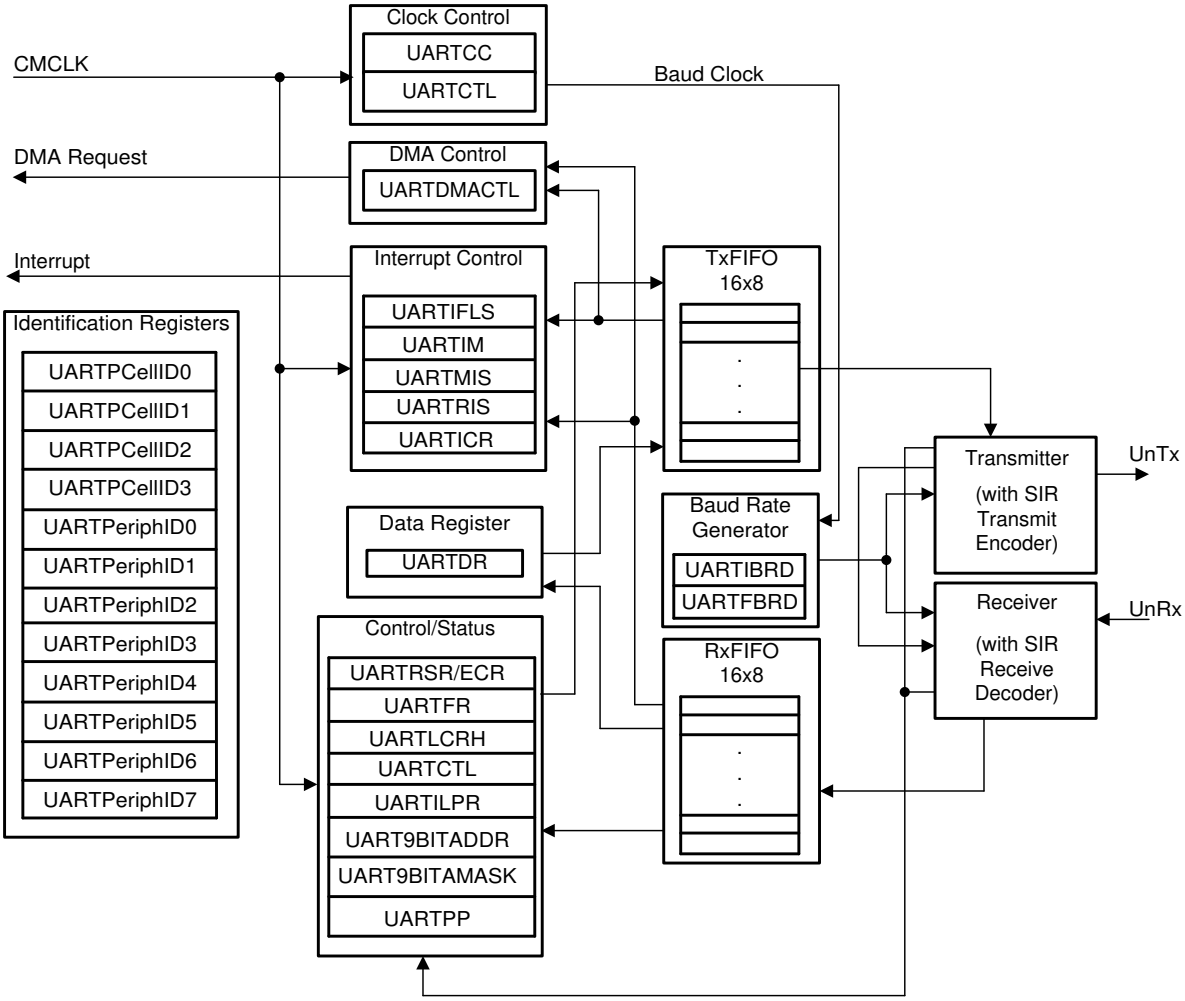

Figure 48-1. UART Module Block Diagram

48.2.1 Transmit and Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 48-2 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

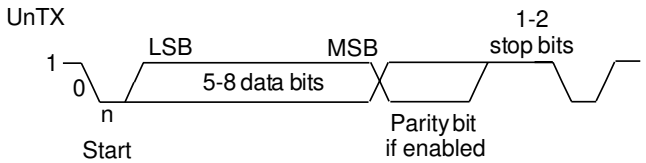

Figure 48-2. UART Character Frame

48.2.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divisor allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the UART Integer Baud-Rate Divisor (UARTIBRD) register and the 6-bit fractional part is loaded with the UART Fractional Baud-Rate Divisor (UARTFBRD) register. The baud-rate divisor (BRD) has the following relationship to the system clock (where BRDI is the integer part of the BRD, and BRDF is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = UARTSysClk / (ClkDiv \times Baud\ Rate) \quad (29)$$

where

UARTSysClk is the system clock (CMCLK) connected to the UART, and ClkDiv is either 16 (if HSE in UARTCTL is clear) or 8 (if HSE in UARTCTL is set).

By default, this is the main system clock (CMCLK).

The 6-bit fractional number (that is to be loaded into the DIVFRAC bit field in the UARTFBRD register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying by 64, and adding 0.5 to account for rounding errors:

$$UARTFBRD[DIVFRAC] = integer(BRDF \times 64 + 0.5) \quad (30)$$

The UART generates an internal baud-rate reference clock at 8× or 16× the baud-rate (referred to as Baud8 and Baud16, depending on the setting of the HSE bit [bit 5] in UARTCTL). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during receive operations.

Along with the UART Line Control High Byte (UARTLCRH) register, the UARTIBRD and UARTFBRD registers form an internal 30-bit register. This internal register is only updated when a write operation to UARTLCRH is performed, so any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- UARTIBRD write, UARTFBRD write, and UARTLCRH write
- UARTFBRD write, UARTIBRD write, and UARTLCRH write
- UARTIBRD write and UARTLCRH write
- UARTFBRD write and UARTLCRH write

48.2.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the UARTLCRH register. Data continues to be transmitted until there is no data left in the transmit FIFO. The BUSY bit in the UART Flag (UARTFR) register is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The BUSY bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the UnRx signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of Baud16 or fourth cycle of Baud8 depending on the setting of the HSE bit (bit 5) in UARTCTL (described in Section 48.2.1).

The start bit is valid and recognized if the UnRx signal is still low on the eighth cycle of Baud16 (HSE clear) or the fourth cycle of Baud8 (HSE set), otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of Baud16 or eighth cycle of Baud8 (that is, one bit period later) according to the programmed length of the data characters and value of the HSE bit in UARTCTL. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the UARTLCRH register.

Lastly, a valid stop bit is confirmed if the UnRx signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

48.2.4 Serial IR (SIR)

The UART peripheral includes an IrDA SIR encoder and decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the UnTx and UnRx pins for the SIR protocol. These signals must be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but the SIR block is only half-duplex so the SIR block cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static low signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling the output low and driving the UART input pin low.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal (1.63 µs, assuming a nominal 1.8432-MHz frequency) by changing the appropriate bit in the UARTCTL register.

Whether the device is in normal or low-power IrDA mode, a start bit is deemed valid if the decoder is still low one period of IrLPBaud16 after the low was first detected. This enables a normal-mode UART to receive data from a low-power mode UART that can transmit pulses as small as 1.41 µs. Thus, for both low-power and normal mode operation, the ILPDVSR field in the UARTILPR register must be programmed such that 1.42 MHz < $f_{IrLPBaud16}$< 2.12 MHz, resulting in a low-power pulse duration of 1.41 to 2.11 µs (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 make sure that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4 µs are accepted as valid pulses.

Figure 48-3 shows the UART transmit and receive signals, with and without IrDA modulation.

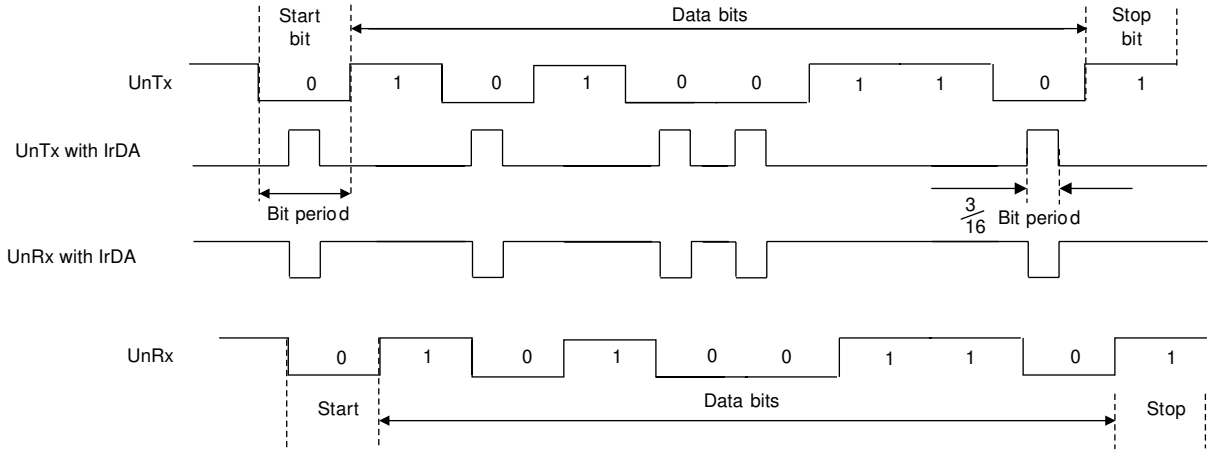

Figure 48-3. IrDA Data Modulation

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10-ms delay between transmission and reception. This delay must be generated by software because the delay is not automatically supported by the UART. The delay is required because the infrared receiver electronics can become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

48.2.5 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the 9BITEN bit in the UART9BITADDR register. This feature is useful in a multi-drop configuration of the UART, where a single transmitter connected to multiple receivers can communicate with a particular receiver through the address or set of addresses along with a qualifier for an address byte. All the receivers check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then the receiver receives or sends further data. If the address does not match, the receiver drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and the address can be configured with the UART9BITADDR register. The matching can be extended to a set of addresses using the address mask in the UART9BITAMASK register. By default, the UART9BITAMASK is 0xFF, meaning that only the specified address is matched.

When not finding a match, the rest of the data bytes with the ninth bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared ninth bit are stored in the FIFO. Software can mask this interrupt in case µDMA or FIFO operations are enabled for this instance and processor intervention is not required. All the send transactions with 9-bit mode are data bytes and the ninth bit is cleared. Software can override the ninth bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The transmit FIFO does not hold the address/data bit; hence, software can enable the address bit appropriately.

48.2.6 FIFO Operation

The UART has two 16-deep 8-bit wide FIFOs; one for transmit and one for receive. Both FIFOs are accessed by way of the UART Data (UARTDR) register. Read operations of the UARTDR register return a 12-bit value consisting of eight data bits and four error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1 byte-deep holding registers. The FIFOs are enabled by setting the FEN bit in the UARTLCRH register.

FIFO status can be monitored through the UART Flag (UARTFR) register and the UART Receive Status (UARTRSR) register. Hardware monitors empty, full, and overrun conditions. The UARTFR register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits), and the UARTRSR register shows overrun status with the OE bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1 byte-deep holding registers.

The trigger points, at which the FIFOs generate interrupts, is controlled by way of the UART Interrupt FIFO Level Select (UARTIFLS) register. Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include ⅛, ¼, ½, ¾, and ⅞. For example, if the ¼ option is selected for the receive FIFO, the UART generates a receive interrupt after four data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the ½ mark.

48.2.7 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun error
- Break error
- Parity error
- Framing error
- Receive time-out
- Transmit (when condition defined in the TXIFLSEL bit in the UARTIFLS register is met, or if the EOT bit in UARTCTL is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the RXIFLSEL bit in the UARTIFLS register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the UART Masked Interrupt Status (UARTMIS) register.

The interrupt events that can trigger a controller-level interrupt are defined in the UART Interrupt Mask (UARTIM) register by setting the corresponding IM bits. If interrupts are not used, the raw interrupt status is visible by way of the UART Raw Interrupt Status (UARTRIS) register.

Note

For receive time-out, the RTIM bit in the UARTIM register must be set to see the RTMIS and RTRIS status in the UARTMIS and UARTRIS registers.

Interrupts are always cleared (for the UARTMIS and UARTRIS registers) by writing a 1 to the corresponding bit in the UART Interrupt Clear (UARTICR) register.

The receive time-out interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period when the HSE bit is clear or over a 64-bit period when the HSE bit is set. The receive time-out interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the UARTICR register.

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the RXRIS bit is set. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, or by clearing the interrupt by writing a 1 to the RXIC bit.

- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the RXRIS bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt by writing a 1 to the RXIC bit.

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the TXRIS bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, or by clearing the interrupt by writing a 1 to the TXIC bit.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the TXRIS bit is set. It is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by writing a 1 to the TXIC bit.

48.2.8 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the LBE bit in the UARTCTL register. In loopback mode, data transmitted on the UnTx output is received on the UnRx input. Note that the LBE bit should be set before the UART is enabled.

48.2.9 DMA Operation

The UART provides an interface to the µDMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the UART DMA Control (UARTDMACTL) register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data.

For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the UARTIFLS register.

For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the µDMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, set the RXDMAE bit of the DMA Control (UARTDMACTL) register. To enable DMA operation for the transmit channel, set the TXDMAE bit of the UARTDMACTL register. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the DMAERR bit of the UARTDMACR register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

When the µDMA is finished transferring data to the TX FIFO or from the RX FIFO, a dma_done signal is sent to the UART to indicate completion. The dma_done status is indicated through the DMATXRIS and DMARXIS bits of the UARTRIS register. An interrupt can be generated from these status bits by setting the DMATXIM and DMARXIM bits in the UARTIM register.

Note

The DMATXRIS bit can be used to indicate the completion of data transfer from the µDMA to the TX FIFO. To indicate transfer completion from the serializer of the UART, the EOT bit can be enabled in the UARTCTL register.

See Chapter 49 for more details about programming the µDMA controller.

48.3 Initialization and Configuration

To enable and initialize the UART, perform the following steps:

1. Disable the UART by clearing the UARTEN bit in the UARTCTL register.
2. Write the integer portion of the BRD to the UARTIBRD register.
3. Write the fractional portion of the BRD to the UARTFBRD register.
4. Write the desired serial parameters to the UARTLCRH register.
5. Optionally, configure the µDMA channel (see Chapter 49) and enable the DMA options in the UARTDMACTL register.
6. Enable the UART by setting the UARTEN bit in the UARTCTL register.

48.4 Software

48.4.1 UART Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/uart

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

48.4.1.1 UART Echoback - CM

FILE: uart_ex1_echoback.c

This test receives and echo-backs data through the UART0 port.

A terminal such as 'putty' can be used to view the data from the CM-UART and to send information to the CM-UART. Characters received by the CM-UART port are sent back to the host.

Running the Application Open a COM port with the following settings using a terminal:
- Find correct COM port
- Bits per second = 115200
- Data Bits = 8
- Parity = None
- Stop Bits = 1
- Hardware Control = None

The program will print out a greeting and then ask you to enter a character which it will echo back to the terminal.

Watch Variables
- None

External Connections
Connect the UART0 port to a PC via a transceiver and cable.
- GPIO85 is UART0RX/CMUARTRXA(Connect to Pin3, PC-TX, of serial DB9 cable)
- GPIO84 is UART0TX/CMUARTTXA(Connect to Pin2, PC-RX, of serial DB9 cable)

The pin muxing for the UART0 port needs to be done by the master CPU1. The common configuration example provided in the C28x folder can be used for making GPIO85 as the UART Rx pin and GPIO84 as the UART Tx pin.

48.4.1.2 UART Loopback example with UDMA - CM

FILE: uart_ex2_loopback_udma.c

This example showcases how to use UDMA with UART to transfer and receive data

This configures the UART in loopback mode and sends and receives data for infinite time.
cm_common_config_c28x example needs to be run on C28x1 before running this example on the CM core

Configuration:
- Find correct COM port
- Bits per second = 115200
- Data Bits = 8
- Parity = None
- Stop Bits = 1
- Hardware Control = None

External Connections
- None

Watch Variables
- *TxData* - Data transmitted
- *RxData* - Data received

- *errCount* - Error count

48.5 UART Registers

This section describes the Connectivity Manager Universal Asynchronous Interface Registers.

48.5.1 UART Base Addresses

Table 48-1. UART Base Address Table (CM)

Complex bit access types are encoded to fit into small table cells. Table 48-3 shows the codes that are used for access types in this section.

Table 48-3. UART_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set

Table 48-3. UART_REGS Access Type Codes (continued)

Access Type	Code	Description
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

48.5.2.1 UARTDR Register (Offset = 0h) [Reset = 0h]

UARTDR is shown in Figure 48-4 and described in Table 48-4.

Return to the Summary Table.

IMPORTANT: This register is read sensitive. This register is the data register (the interface to the FIFOs). For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.
For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

Table 48-4. UARTDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-12	RESERVED	R	0h	Reserved
11	OE	R	0h	UART Overrun Error 0 No data has been lost due to a FIFO overrun. 1 New data was received when the FIFO was full, resulting in data loss. Reset type: PER.RESET
10	BE	R	0h	UART Break Error 0 No break condition has occurred 1 A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the received data input goes to a 1 (marking state), and the next valid start bit is received. Reset type: PER.RESET
9	PE	R	0h	UART Parity Error 0 No parity error has occurred 1 The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register. In FIFO mode, this error is associated with the character at the top of the FIFO. Reset type: PER.RESET
8	FE	R	0h	UART Framing Error 0 No framing error has occurred 1 The received character does not have a valid stop bit (a valid stop bit is 1). Reset type: PER.RESET

Table 48-4. UARTDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	DATA	R/W	0h	Data Transmitted or Received Data that is to be transmitted via the UART is written to this field. When read, this field contains the data that was received by the UART. For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART. For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register. Reset type: PER.RESET

48.5.2.2 UARTRSR Register (Offset = 4h) [Reset = 0h]

UARTRSR is shown in Figure 48-5 and described in Table 48-5.

Return to the Summary Table.

The UARTRSR/UARTECR register is the receive status register/error clear register.
In addition to the UARTDR register, receive status can also be read from the UARTRSR register.
If the status is read from this register, then the status information corresponds to the entry read from UARTDR prior to reading UARTRSR. The status information for overrun is set immediately when an overrun condition occurs.
The UARTRSR register cannot be written.
A write of any value to the UARTECR register clears the framing, parity, break, and overrun errors.
All the bits are cleared on reset.

Table 48-5. UARTRSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3	OE	R	0h	UART Overrun Error 0 No data has been lost due to a FIFO overrun. 1 New data was received when the FIFO was full, resulting in data loss. This bit is cleared by a write to UARTECR.The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO. Reset type: PER.RESET
2	BE	R	0h	UART Break Error 0 No break condition has occurred 1 A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received. Reset type: PER.RESET
1	PE	R	0h	UART Parity Error 0 No parity error has occurred 1 The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register. This bit is cleared to 0 by a write to UARTECR. Reset type: PER.RESET

Table 48-5. UARTRSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	FE	R	0h	UART Framing Error 0 No framing error has occurred 1 The received character does not have a valid stop bit (a valid stop bit is 1). This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO. Reset type: PER.RESET

48.5.2.3 UARTFR Register (Offset = 18h) [Reset = 90h]

UARTFR is shown in Figure 48-6 and described in Table 48-6.

Return to the Summary Table.

The UARTFR register is the flag register. After reset, the TXFF, RXFF, and BUSY bits are 0, and TXFE and RXFE bits are 1.

Table 48-7. UARTILPR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7-0	ILPDVSR	R/W	0h	IrDA Low-Power Divisor This field contains the 8-bit low-power divisor value. The UARTILPR register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset. The internal IrLPBaud16 clock is generated by dividing down SysClk according to the low-power divisor value written to UARTILPR. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the IrLPBaud16 clock. The low-power divisor value is calculated as follows: ILPDVSR = SysClk / FIrLPBaud16 where FIrLPBaud16 is nominally 1.8432 MHz. Because the IrLPBaud16 clock is used to sample transmitted data irrespective of mode, the ILPDVSR field must be programmed in both low power and normal mode,such that FIrLPBaud16 is between 1.42 and 2.12 MHz, resulting in a low-power pulse duration of 1.41-2.11 us (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4 us are accepted as valid pulses. Note: Zero is an illegal value. Programming a zero value results in no IrLPBaud16 pulses being generated Reset type: PER.RESET

48.5.2.5 UARTIBRD Register (Offset = 24h) [Reset = 0h]

UARTIBRD is shown in Figure 48-8 and described in Table 48-8.

Return to the Summary Table.

The UARTIBRD register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when UARTIBRD=0), in which case the UARTFBRD register is ignored. When changing the UARTIBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register.

Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register. Reset type: PER.RESET

48.5.2.6 UARTFBRD Register (Offset = 28h) [Reset = 0h]

UARTFBRD is shown in Figure 48-9 and described in Table 48-9.

Return to the Summary Table.

The UARTFBRD register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the UARTFBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register. See "Baud-Rate Generation" on page 1165 for configuration details.

48.5.2.7 UARTLCRH Register (Offset = 2Ch) [Reset = 0h]

UARTLCRH is shown in Figure 48-10 and described in Table 48-10.

Return to the Summary Table.

The UARTLCRH register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.
When updating the baud-rate divisor (UARTIBRD and/or UARTIFRD), the UARTLCRH register must also be written. The write strobe for the baud-rate divisor registers is tied to the UARTLCRH register.

Bit	Field	Type	Reset	Description
2	EPS	R/W	0h	UART Even Parity Select 0 Odd parity is performed, which checks for an odd number of 1s. 1 Even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits. This bit has no effect when parity is disabled by the PEN bit. Reset type: PER.RESET
1	PEN	R/W	0h	UART Parity Enable 0 Parity is disabled and no parity bit is added to the data frame. 1 Parity checking and generation is enabled. Reset type: PER.RESET
0	BRK	R/W	0h	UART Send Break 0 Normal use. 1 A Low level is continually output on the UnTx signal, after completing transmission of the current character. For the proper execution of the break command, software must set this bit for at least two frames (character periods). Reset type: PER.RESET

48.5.2.8 UARTCTL Register (Offset = 30h) [Reset = 300h]

UARTCTL is shown in Figure 48-11 and described in Table 48-11.

Return to the Summary Table.

The UARTCTL register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set.
To enable the UART module, the UARTEN bit must be set. If software requires a configuration change in the module, the UARTEN bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

4	EOT	R/W	0h	End of Transmission This bit determines the behavior of the TXRIS bit in the UARTRIS register. 0 The TXRIS bit is set when the transmit FIFO condition specified in UARTIFLS is met. 1 The TXRIS bit is set only after all transmitted data, including stop bits, have cleared the serializer. Reset type: PER.RESET
3	RESERVED	R/W	0h	Reserved
2	SIRLP	R/W	0h	UART SIR Low-Power Mode This bit selects the IrDA encoding mode. 0 Low-level bits are transmitted as an active High pulse with a width of 3/16th of the bit period. 1 The UART operates in SIR Low-Power mode. Low-level bits are transmitted with a pulse width which is 3 times the period of the IrLPBaud16 input signal, regardless of the selected bit rate. Setting this bit uses less power, but might reduce transmission distances. Reset type: PER.RESET
1	SIREN	R/W	0h	UART SIR Enable 0 Normal operation. 1 The IrDA SIR block is enabled, and the UART will transmit and receive data using SIR protocol. Reset type: PER.RESET
0	UARTEN	R/W	0h	UART Enable 0 The UART is disabled. 1 The UART is enabled. If the UART is disabled in the middle of transmission or reception, it completes the current character before stopping. Reset type: PER.RESET

48.5.2.9 UARTIFLS Register (Offset = 34h) [Reset = 12h]

UARTIFLS is shown in Figure 48-12 and described in Table 48-12.

Return to the Summary Table.

The UARTIFLS register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the TXRIS and RXRIS bits in the UARTRIS register are triggered.
The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level.
For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.
Therefore, changing the trigger level does not trigger an interrupt using the new level until another character is received.
Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

In this case, the setting of TXIFLSEL is ignored. Reset type: PER.RESET

48.5.2.10 UARTIM Register (Offset = 38h) [Reset = 0h]

UARTIM is shown in Figure 48-13 and described in Table 48-13.

Return to the Summary Table.

The UARTIM register is the interrupt mask set/clear register.
On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

48.5.2.12 UARTMIS Register (Offset = 40h) [Reset = 0h]

UARTMIS is shown in Figure 48-15 and described in Table 48-15.

Return to the Summary Table.

The UARTMIS register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

48.5.2.15 UART9BITADDR Register (Offset = A4h) [Reset = 0h]

UART9BITADDR is shown in Figure 48-18 and described in Table 48-18.

Return to the Summary Table.

The UART9BITADDR register is used to write the specific address that should be matched with the receiving byte when the 9-bit Address Mask (UART9BITAMASK) is set to 0xFF. This register is used in conjunction with UART9BITAMASK to form a match for address-byte received.

48.5.3 UART_REGS_WRITE Registers

Table 48-33 lists the memory-mapped registers for the UART_REGS_WRITE registers. All register offset addresses not listed in Table 48-33 should be considered as reserved locations and the register contents should not be modified.

Table 48-33. UART_REGS_WRITE Registers

Offset	Acronym	Register Name	Write Protection	Section
4h	UARTECR	UART Error Clear		Go

Complex bit access types are encoded to fit into small table cells. Table 48-34 shows the codes that are used for access types in this section.

Table 48-34. UART_REGS_WRITE Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

48.5.3.1 UARTECR Register (Offset = 4h) [Reset = 0h]

UARTECR is shown in Figure 48-33 and described in Table 48-35.

Return to the Summary Table.

The UARTECR register is the error clear register.
In addition to the UARTDR register, receive status can also be read from the UARTRSR register. If the status is read from this register, then the status information corresponds to the entry read from UARTDR prior to reading UARTRSR. The status information for overrun is set immediately when an overrun condition occurs.
The UARTRSR register cannot be written.
A write of any value to the UARTECR register clears the framing, parity, break, and overrun errors.
All the bits are cleared on reset.

Chapter 49

Micro Direct Memory Access (µDMA)

The µDMA controller provides a way to offload data transfer tasks from the Arm® Cortex®-M4 processor, allowing for more efficient use of the processor and the available bus bandwidth. The µDMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory when the peripheral is ready to transfer more data.

49.1 Introduction

49.1.1 Features

The µDMA controller provides the following features:

- Arm® PrimeCell 32-channel configurable µDMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes:
  - Basic mode
  - Ping-pong mode
  - Memory scatter-gather mode
  - Peripheral scatter-gather mode
  - Auto request mode
- Highly flexible and configurable channel operation:
  - Independently configured and operated channels
  - Dedicated channels for supported on-chip modules
  - Flexible channel assignments
  - One channel each for receive and transmit path for bidirectional modules
  - Dedicated channel for software-initiated transfers
  - Per-channel configurable priority scheme
  - Optional software-initiated requests for any channel
- Two levels of priority
- Data sizes of 8, 16, and 32 bits
- Programmable transfer size in binary steps from 1 to 1024
- Source and destination address increment size of byte, halfword, word, or no increment
- Maskable peripheral requests
- Supports two interrupts:
  - µDMA Software interrupt: µDMA generates an interrupt when a software channel completes all its transfers
  - µDMA Error interrupt: µDMA generates an interrupt an when error is detected on a DMA transfer
- DMA transfers triggered by a peripheral event generate a corresponding peripheral interrupt when the DMA has completes all transfers.

49.1.2 Block Diagram

Figure 49-1 shows the µDMA block diagram.

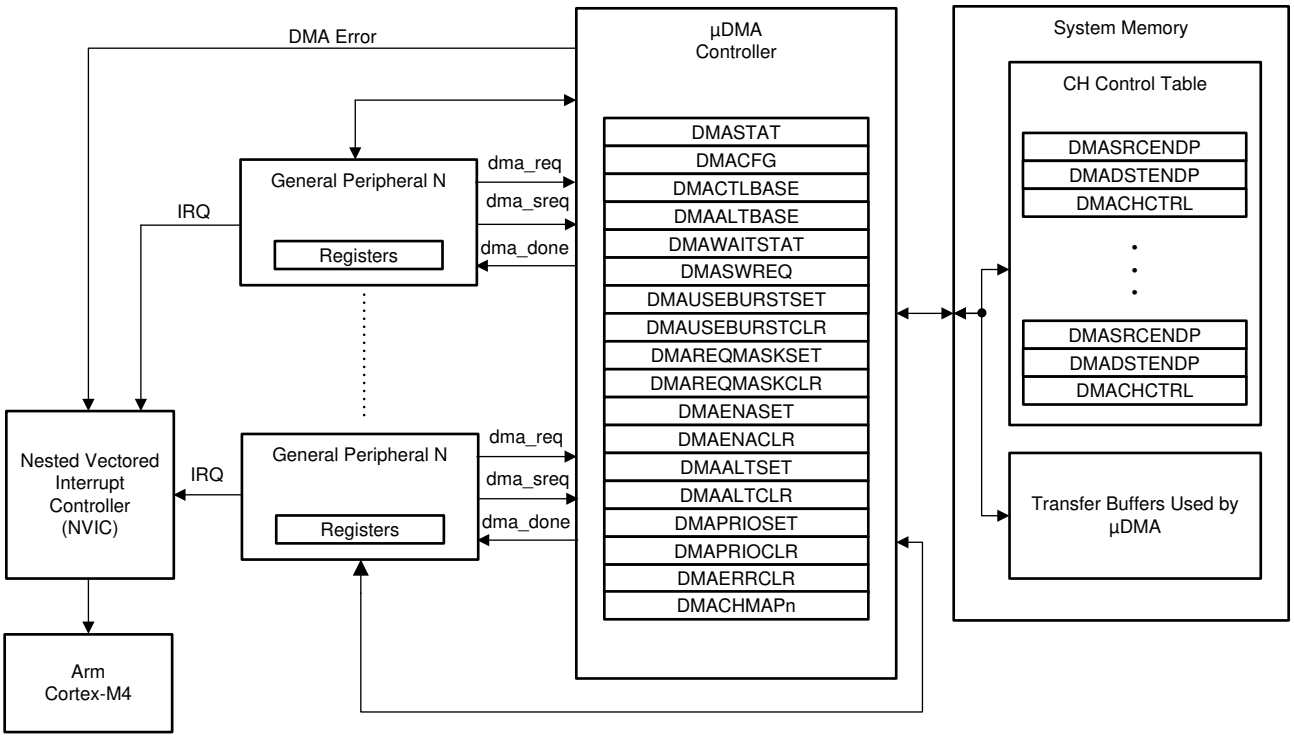

Figure 49-1. µDMA Block Diagram

49.2 Functional Description

The µDMA controller is a flexible and highly configurable DMA controller designed to work efficiently with the Cortex®-M4 processor core of the microcontroller. The µDMA controller supports multiple data sizes and address increment schemes, multiple levels of priority among DMA channels, and several transfer modes to allow for sophisticated programmed data transfers. Bus use by the µDMA controller is always subordinate to the processor core, so it never delays a bus transaction by the processor. Because the µDMA controller is only using otherwise idle bus cycles, the data transfer bandwidth it provides is essentially free, with no affect on the rest of the system. The bus architecture has been optimized to greatly enhance the ability of the processor core and the µDMA controller to efficiently share the on-chip bus, thus improving performance. The optimizations include RAM striping and peripheral bus segmentation, which in many cases let both the processor core and the µDMA controller access the bus and perform simultaneous data transfers.

Each peripheral function that is supported has a dedicated channel on the µDMA controller that can be configured independently. The µDMA controller implements a unique configuration method using channel control structures that are maintained in system memory by the processor. While simple transfer modes are supported, it is also possible to build up sophisticated "task" lists in memory that allow the µDMA controller to perform arbitrary-sized transfers to and from arbitrary locations as part of a single transfer request. The µDMA controller also supports the use of ping-pong buffering to accommodate constant streaming of data to or from a peripheral.

Each channel also has a configurable arbitration size. The arbitration size is the number of items that are transferred in a burst before the µDMA controller rearbitrates for channel priority. Using the arbitration size, it is possible to control exactly how many items are transferred to or from a peripheral each time it makes a µDMA service request.

49.2.1 Channel Assignments

µDMA channels 0-31 are assigned to different peripherals according to Table 49-1. The DMA Channel Map (DMACHMAPx) registers can be used to specify the first, second, or third channel mapping assignment.

Note

Channels noted in the table as "Available for software" may be assigned to peripherals in the future. However, they are currently available for software use. Channel 30 is dedicated for software use.

The USB endpoints mapped to µDMA channels 0-3 can be changed with the USBDMASEL register.

Because of the way the µDMA controller interacts with peripherals, the µDMA channel for the peripheral must be enabled in order for the µDMA controller to be able to read and write the peripheral registers, even if a different µDMA channel is used to perform the µDMA transfer. To minimize confusion and chance of software errors, it is best practice to use a peripheral's µDMA channel for performing all µDMA transfers for that peripheral, even if it is processor-triggered and using AUTO mode, which could be considered a software transfer.

If the software channel is used, interrupts occur on the dedicated µDMA interrupt vector. If the peripheral channel is used, then the interrupt occurs on the interrupt vector for the peripheral.

Table 49-1. µDMA Channel Assignment Mapping

µDMA Channel	Primary Assignment	Single/Burst
0	USB_DMAA_Rx	B

30	Available for software	B
31	Reserved	

49.2.2 Priority

The µDMA controller assigns priority to each channel based on the channel number and the priority level bit for the channel. Channel number 0 has the highest priority and as the channel number increases, the priority of a channel decreases. Each channel has a priority level bit to provide two levels of priority: default priority and high priority. If the priority level bit is set, then that channel has higher priority than all other channels at default priority. If multiple channels are set for high priority, then the channel number is used to determine relative priority among all the high-priority channels.

The priority bit for a channel can be set using the DMA Channel Priority Set (DMAPRIOSET) register and cleared with the DMA Channel Priority Clear (DMAPRIOCLR) register.

49.2.3 Arbitration Size

When a µDMA channel requests a transfer, the µDMA controller arbitrates among all the channels making a request and services the µDMA channel with the highest priority. When a transfer begins, it continues for a selectable number of transfers before rearbitrating among the requesting channels again. The arbitration size can be configured for each channel, ranging from 1 to 1024 item transfers. After the µDMA controller transfers the number of items specified by the arbitration size, it then checks among all the channels making a request and services the channel with the highest priority.

If a lower priority µDMA channel uses a large arbitration size, the latency for higher priority channels is increased because the µDMA controller completes the lower priority burst before checking for higher priority requests. Therefore, lower priority channels should not use a large arbitration size for best response on high priority channels.

The arbitration size can also be thought of as a burst size. It is the maximum number of items that are transferred at any one time in a burst. Here, the term arbitration refers to determination of µDMA channel priority, not arbitration for the bus. When the µDMA controller arbitrates for the bus, the processor always takes priority. Furthermore, the µDMA controller is held off whenever the processor must perform a bus transaction on the same bus, even in the middle of a burst transfer.

49.2.4 Request Types

The µDMA controller responds to two types of requests from a peripheral: single or burst. Each peripheral may support either or both types of requests. A single request means that the peripheral is ready to transfer one item, while a burst request means that the peripheral is ready to transfer multiple items.

The µDMA controller responds differently depending on whether the peripheral is making a single request or a burst request. If both are asserted, and the µDMA channel has been set up for a burst transfer, then the burst request takes precedence. Table 49-2 shows how each peripheral supports the two request types.

Table 49-2. Request Type Support

Peripheral	Event That Generates Single Request	Event That Generates Burst Request
USB TX	None	FIFO TXRDY
USB RX	None	FIFO RXRDY
UART TX	TX FIFO not full	TX FIFO level (configurable)
UART RX	RX FIFO not empty	RX FIFO level (configurable)
SSI TX	TX FIFO not full	TX FIFO level (fixed at 4)
SSI RX	RX FIFO Not Empty	RX FIFO level (fixed at 4)
ECAT	None	
AES	None	Context in DMA request (AES0 Cin) Context out DMA request (AES0 Cout) Data in DMA request (AES0 Din) Data out DMA request (AES0 Dout)
I^2C TX	TX buffer not full	TX FIFO level (configurable)
I^2C RX	RX buffer not empty	RX FIFO level (configurable)

49.2.4.1 Single Request

When a single request is detected, and not a burst request, the µDMA controller transfers one item and then stops to wait for another request.

49.2.4.2 Burst Request

When a burst request is detected, the µDMA controller transfers the number of items that is the lesser of the arbitration size or the number of items remaining in the transfer. Therefore, the arbitration size should be the same as the number of data items that the peripheral can accommodate when making a burst request. For example, the UART generates a burst request based on the FIFO trigger level. In this case, the arbitration size should be set to the amount of data that the FIFO can transfer when the trigger level is reached. A burst transfer runs to completion once it is started, and cannot be interrupted, even by a higher priority channel. Burst transfers complete in a shorter time than the same number of non-burst transfers.

It may be desirable to use only burst transfers and not allow single transfers. For example, perhaps the nature of the data is such that it only makes sense when transferred together as a single unit rather than one piece at a time. The single request can be disabled by using the DMA Channel Useburst Set (DMAUSEBURSTSET) register. By setting the bit for a channel in this register, the µDMA controller only responds to burst requests for that channel.

49.2.5 Channel Configuration

The µDMA controller uses an area of system memory to store a set of channel control structures in a table. The control table may have one or two entries for each µDMA channel. Each entry in the table structure contains source and destination pointers, transfer size, and transfer mode. The control table can be located anywhere in system memory, but it must be contiguous and aligned on a 1024-byte boundary.

Table 49-3 lists the layout in memory of the channel control table. Each channel may have one or two control structures in the control table: a primary control structure and an optional alternate control structure. The table is organized so that all of the primary entries are in the first half of the table, and all the alternate structures are in the second half of the table. The primary entry is used for simple transfer modes where transfers can be reconfigured and restarted after each transfer is complete. In this case, the alternate control structures are not used and therefore only the first half of the table must be allocated in memory; the second half of the control table is not necessary, and that memory can be used for something else. If a more complex transfer mode is used such as ping-pong or scatter-gather, then the alternate control structure is also used and memory space should be allocated for the entire table.

Any unused memory in the control table may be used by the application. This includes the control structures for any channels that are unused by the application as well as the unused control word for each channel.

Table 49-3. Control Structure Memory Map

Offset	Channel
0x0	0, Primary
0x10	1, Primary
...	...
0x1F0	31, Primary

Table 49-4 summarizes an individual control structure entry in the control table. Each entry is aligned on a 16-byte boundary. The entry contains four long words: the source end pointer, the destination end pointer, the control word, and an unused entry. The end pointers point to the ending address of the transfer and are inclusive. If the source or destination is non-incrementing (as for a peripheral register), then the pointer should point to the transfer address.

Table 49-4. Channel Control Structure

Offset	Description
0x000	Source End Pointer
0x004	Destination End Pointer
0x008	Control Word
0x00C	Unused

The control word contains the following fields:

- Source and destination data sizes
- Source and destination address increment size
- Number of transfers before bus arbitration
- Total number of items to transfer
- Useburst flag
- Transfer mode

The control word and each field are described in detail in Section 49.3.5. The µDMA controller updates the transfer size and transfer mode fields as the transfer is performed. At the end of a transfer, the transfer size indicates 0, and the transfer mode indicates "stopped." Because the control word is modified by the µDMA controller, it must be reconfigured before each new transfer. The source and destination end pointers are not modified, so they can be left unchanged if the source or destination addresses remain the same.

Prior to starting a transfer, a µDMA channel must be enabled by setting the appropriate bit in the DMA Channel Enable Set (DMAENASET) register. A channel can be disabled by setting the channel bit in the DMA Channel Enable Clear (DMAENACLR) register. At the end of a complete µDMA transfer, the controller automatically disables the channel.

49.2.6 Transfer Modes

The µDMA controller supports several transfer modes. Two of the modes support simple one-time transfers. Several complex modes support a continuous flow of data.

49.2.6.1 Stop Mode

While Stop is not actually a transfer mode, it is a valid value for the mode field of the control word. When the mode field has this value, the µDMA controller does not perform any transfers and disables the channel if it is enabled. At the end of a transfer, the µDMA controller updates the control word to set the mode to Stop.

49.2.6.2 Basic Mode

In Basic mode, the µDMA controller performs transfers as long as there are more items to transfer, and a transfer request is present. This mode is used with peripherals that assert a µDMA request signal whenever the peripheral is ready for a data transfer. Basic mode should not be used in any situation where the request is momentary, even though the entire transfer should be completed. For example, a software-initiated transfer creates a momentary request, and in Basic mode, only the number of transfers specified by the ARBSIZE field in the DMA Channel Control Word (DMACHCTL) register is transferred on a software request, even if there is more data to transfer.

When all of the items have been transferred using Basic mode, the µDMA controller sets the mode for that channel to Stop.

BASIC mode can be programmed to ignore when XFERSIZE reaches 0x000 and continue copying on request until the channel is stopped manually. If the NXTUSEBURST bit in the µDMA Channel Control Word (DMACHCTL) register is set while in BASIC mode and the XFERSIZE reaches 0x000 and is not written back, transfers continue until the request is deasserted by the peripheral.

49.2.6.3 Auto Mode

Auto mode is similar to Basic mode, except that once a transfer request is received, the transfer runs to completion, even if the µDMA request is removed. This mode is suitable for software-triggered transfers. Generally, Auto mode is not used with a peripheral.

When all the items have been transferred using Auto mode, the µDMA controller sets the mode for that channel to Stop.

49.2.6.4 Ping-Pong

Ping-Pong mode is used to support a continuous data flow to or from a peripheral. To use Ping-Pong mode, both the primary and alternate data structures must be implemented. Both structures are set up by the processor for data transfer between memory and a peripheral. The transfer is started using the primary control structure. When the transfer using the primary control structure is complete, the µDMA controller reads the alternate control structure for that channel to continue the transfer. Each time this happens, an interrupt is generated, and the processor can reload the control structure for the just-completed transfer. Data flow can continue indefinitely this way, using the primary and alternate control structures to switch back and forth between buffers as the data flows to or from the peripheral.

For an example showing operation in Ping-Pong mode, see Figure 49-2.

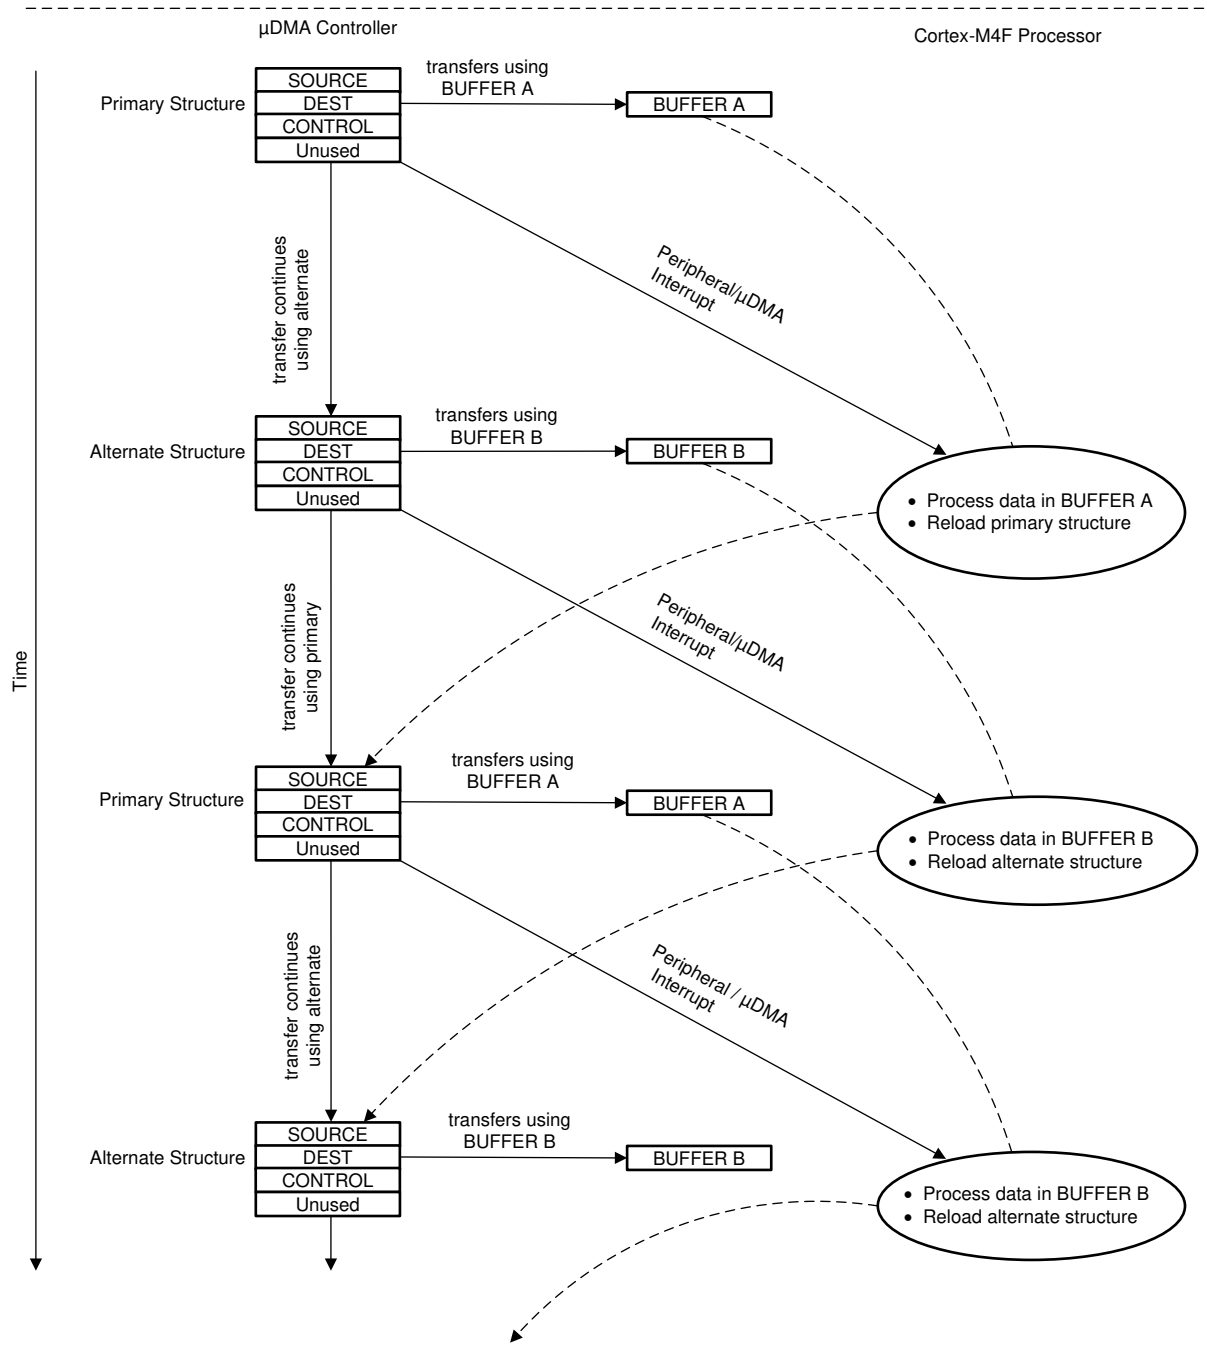

Figure 49-2. Example of Ping-Pong µDMA Transaction

49.2.6.5 Memory Scatter-Gather

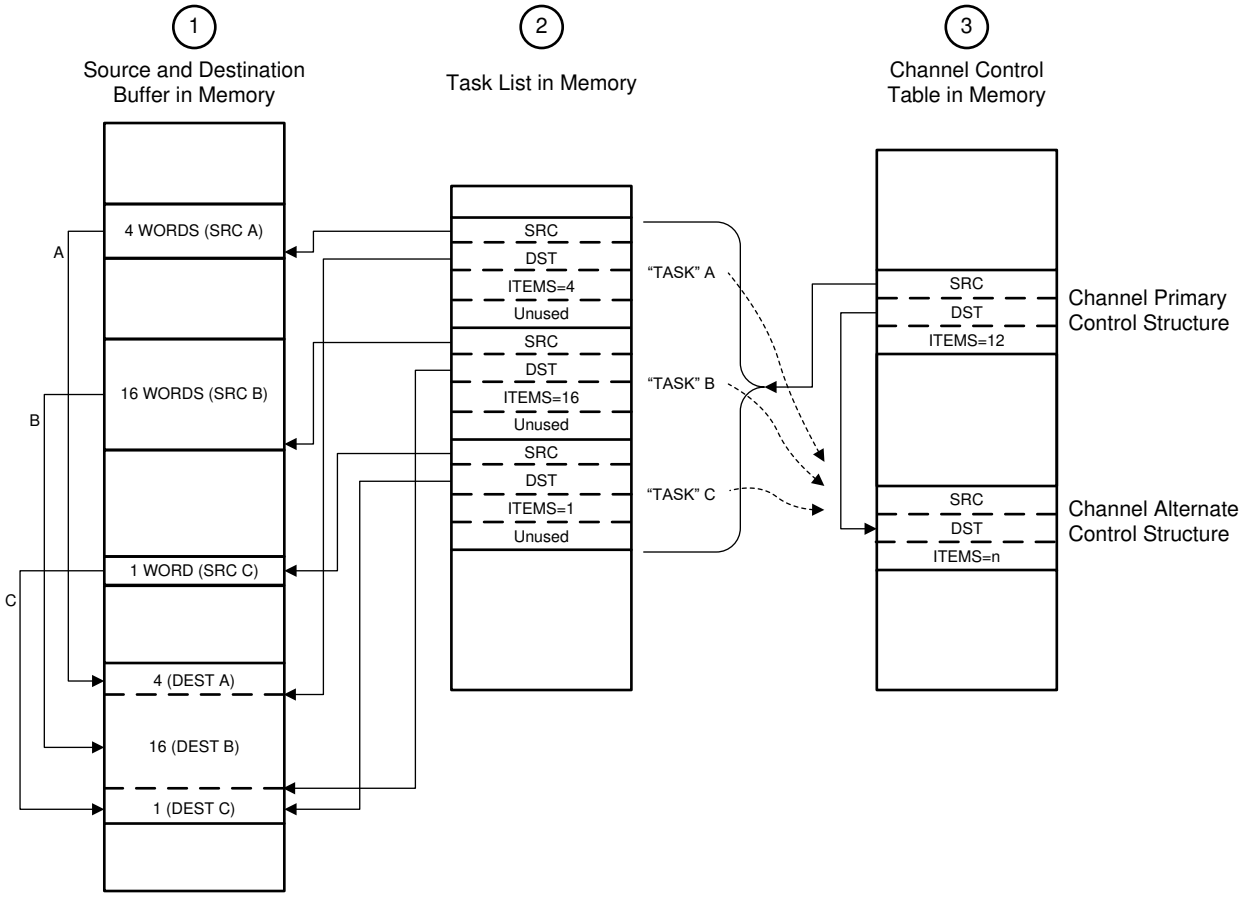
Memory Scatter-Gather mode is a complex mode used when data must be transferred to or from varied locations in memory instead of a set of contiguous locations in a memory buffer. For example, a gather µDMA operation could be used to selectively read the payload of several stored packets of a communication protocol and store them together in sequence in a memory buffer.

In Memory Scatter-Gather mode, the primary control structure is used to program the alternate control structure from a table in memory. The table is set up by the processor software and contains a list of control structures, each containing the source and destination end pointers, and the control word for a specific transfer. The mode of each control word must be set to Scatter-Gather mode. Each entry in the table is copied in turn to the alternate structure where it is then executed. The µDMA controller alternates between using the primary control structure to copy the next transfer instruction from the list and then executing the new transfer instruction. The end of the list is marked by programming the control word for the last entry to use Auto transfer mode. Once the last transfer is performed using Auto mode, the µDMA controller stops. A completion interrupt is generated only after the last transfer. It is possible to loop the list by having the last entry copy the primary control structure to point back to the beginning of the list (or to a new list). It is also possible to trigger a set of other channels to perform a transfer, either directly, by programming a write to the software trigger for another channel, or indirectly, by causing a peripheral action that results in a µDMA request.

By programming the µDMA controller using this method, a set of up to 256 arbitrary transfers can be performed based on a single µDMA request.

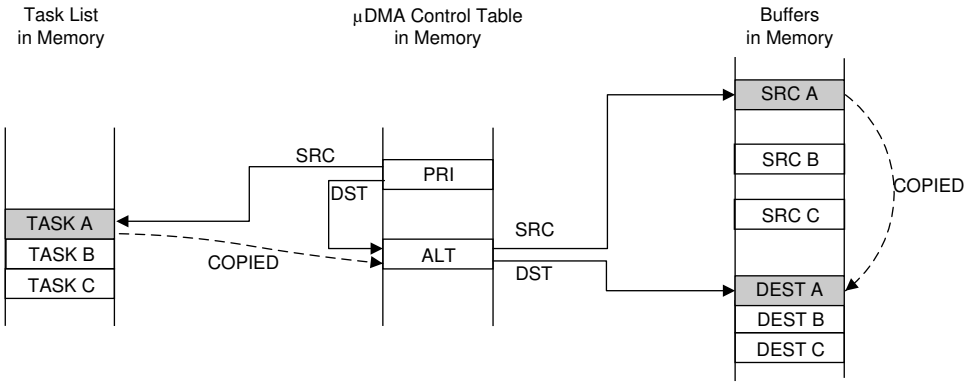
For an example of operation in Memory Scatter-Gather mode, see Figure 49-3 and Figure 49-4. This example shows a gather operation, where data in three separate buffers in memory is copied together into one buffer. Figure 49-3 shows how the application sets up a µDMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 49-4 shows the sequence as the µDMA controller performs the three sets of copy operations. First, using the primary control structure, the µDMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the destination buffer. Next, the µDMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.



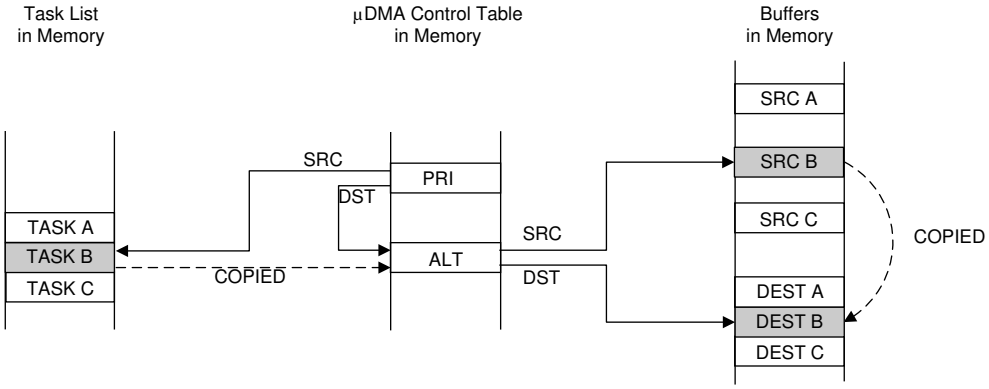
NOTES:
1. Application needs to copy data items from three separate locations in memory into one combined buffer.
2. Application sets up µDMA task list in memory, which contains the pointers and control configuration for three µDMA copy tasks.
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the µDMA controller.
4. The SRC and DST pointers in the task list must point to the last location in the corresponding buffer.

Figure 49-3. Memory Scatter-Gather, Setup and Configuration



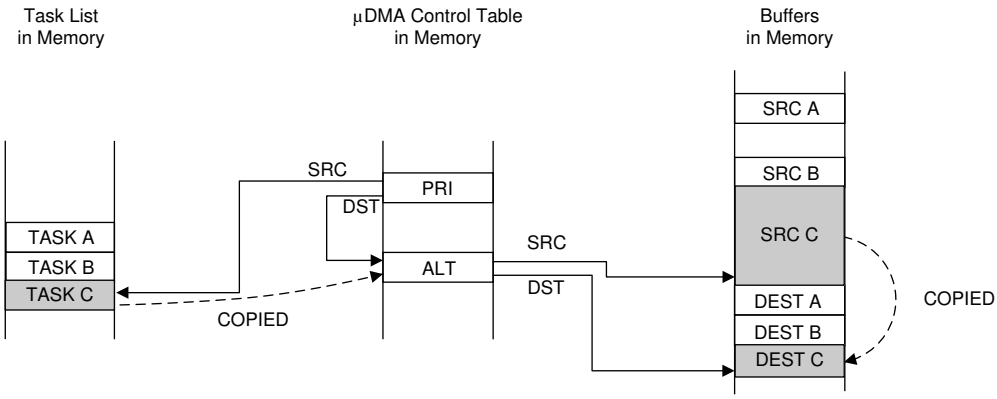
Using the channel's primary control structure, the µDMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the µDMA controller copies data from the source buffer A to the destination buffer.



Using the channel's primary control structure, the µDMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the µDMA controller copies data from the source buffer B to the destination buffer.



Using the channel's primary control structure, the µDMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the µDMA controller copies data from the source buffer C to the destination buffer.

Figure 49-4. Memory Scatter-Gather, µDMA Copy Sequence

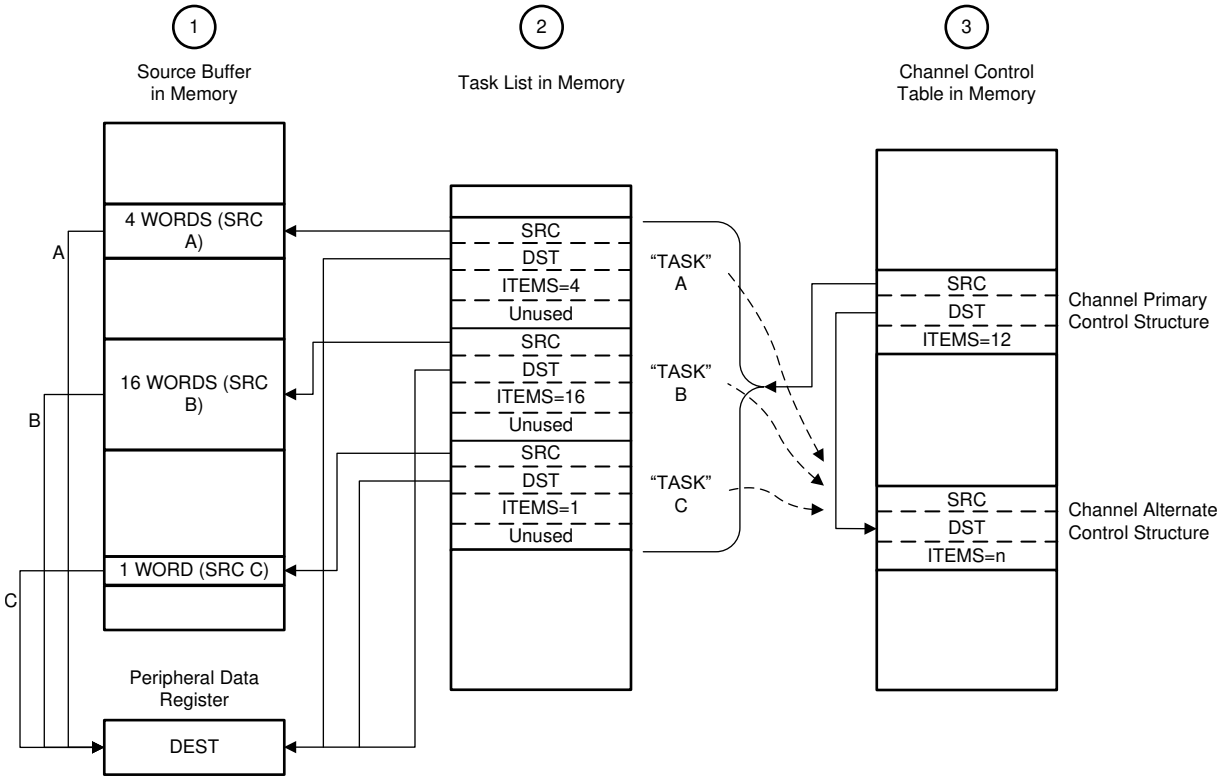
49.2.6.6 Peripheral Scatter-Gather

Peripheral Scatter-Gather mode is very similar to Memory Scatter-Gather, except that the transfers are controlled by a peripheral making a µDMA request. Upon detecting a request from the peripheral, the µDMA controller uses the primary control structure to copy one entry from the list to the alternate control structure and then performs the transfer. At the end of this transfer, the primary control structure will copy the next task to the alternate control structure . If the next task is a memory-to-memory transfer, execution will start immediately and run to completion; if the next task is a peripheral-type transfer, the µDMA will wait for a peripheral request to begin.

By using this method, the µDMA controller can transfer data to or from a peripheral from a set of arbitrary locations whenever the peripheral is ready to transfer data.

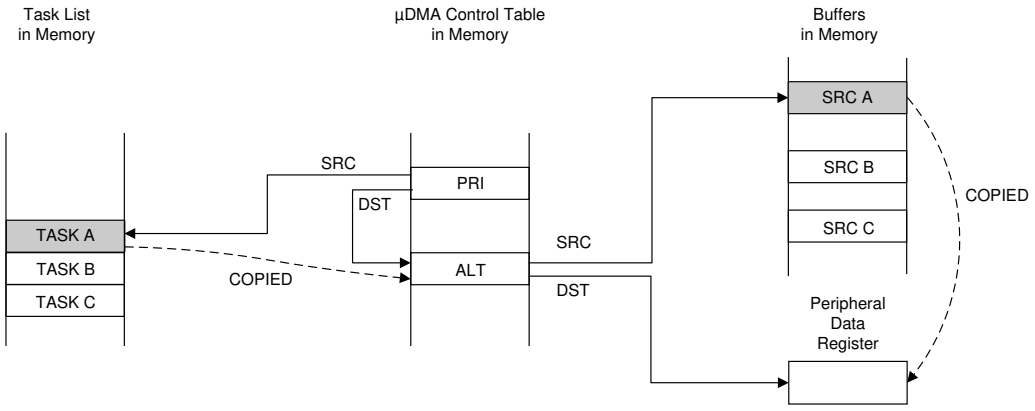
For an example of operation in Peripheral Scatter-Gather mode, see Figure 49-5 and Figure 49-6. This example shows a gather operation, where data from three separate buffers in memory is copied to a single peripheral data register. Figure 49-5 shows how the application sets up a µDMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 49-6 shows the sequence as the µDMA controller performs the three sets of copy operations. First, using the primary control structure, the µDMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the peripheral data register. Next, the µDMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.



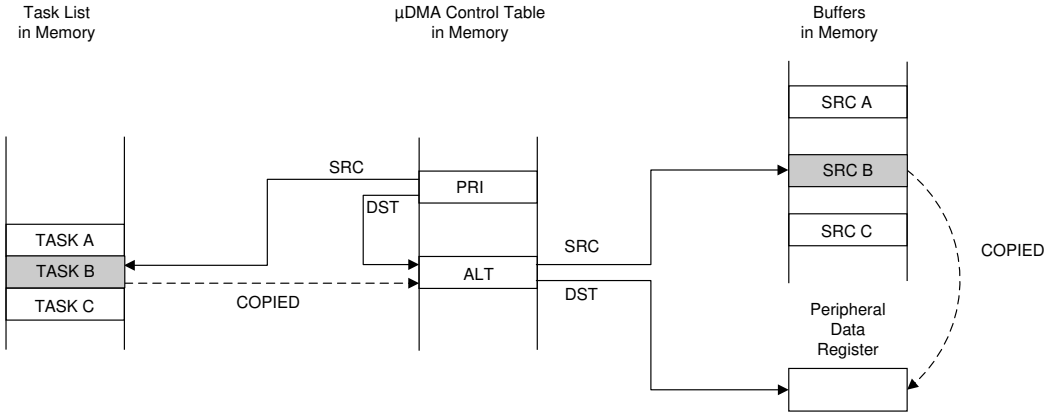
NOTES:
1. Application has a need to copy data items from three separate locations in memory into a peripheral data register.
2. Application sets up µDMA "task list" in memory, which contains the pointers and control configuration for three µDMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the µDMA controller.

Figure 49-5. Peripheral Scatter-Gather, Setup and Configuration



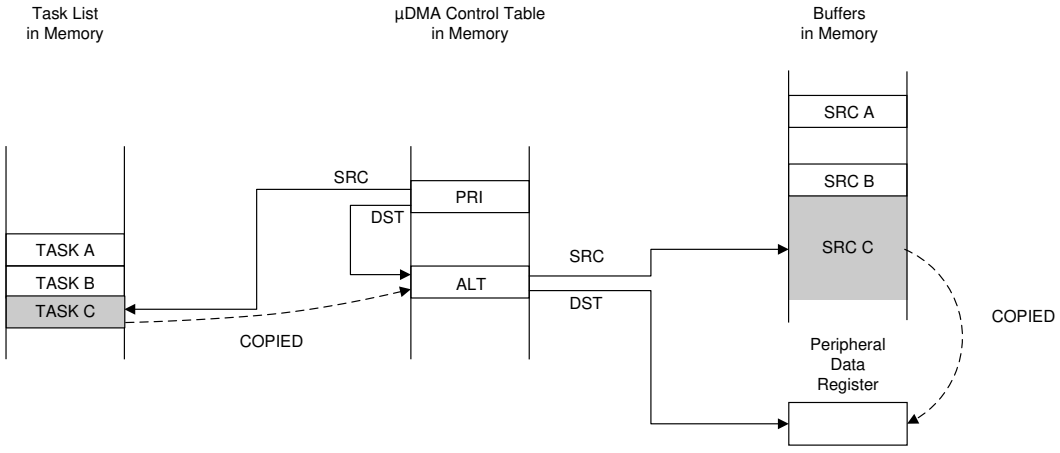
Using the channel's primary control structure, the µDMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the µDMA controller copies data from the source buffer A to the peripheral data register.



Using the channel's primary control structure, the µDMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the µDMA controller copies data from the source buffer B to the peripheral data register.



Using the channel's primary control structure, the µDMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the µDMA controller copies data from the source buffer C to the peripheral data register.

Figure 49-6. Peripheral Scatter-Gather, µDMA Copy Sequence

49.2.7 Transfer Size and Increment

The µDMA controller supports transfer data sizes of 8, 16, or 32 bits. The source and destination data size must be the same for any given transfer. The source and destination address can be auto-incremented by bytes, halfwords, or words, or can be set to no increment. The source and destination address increment values can be set independently, and it is not necessary for the address increment to match the data size as long as the increment is the same or larger than the data size. For example, it is possible to perform a transfer using 8-bit data size, but using an address increment of full words (4 bytes). The data to be transferred must be aligned in memory according to the data size (8, 16, or 32 bits).

Table 49-5 shows the configuration to read from a peripheral that supplies 8-bit data.

Table 49-5. µDMA Read Example: 8-Bit Peripheral

Field	Configuration
Source data size	8 bits
Destination data size	8 bits
Source address increment	No increment
Destination address increment	Byte
Source end pointer	Peripheral read FIFO register
Destination end pointer	End of the data buffer in memory

49.2.8 Peripheral Interface

There are two main classes of µDMA-connected peripherals:

- Peripherals with FIFOs serviced by the µDMA to transmit or receive data.
- Peripherals that provide trigger inputs to the µDMA

49.2.8.1 FIFO Peripherals

FIFO peripherals contain a FIFO of data to be sent and a FIFO of data that has been received. The µDMA controller is used to transfer data between these FIFOs and system memory. For example, when a UART FIFO contains one or more entries, a single transfer request is sent to the µDMA for processing. If this request has not been processed and the UART FIFO reaches the interrupt FIFO level set in the UART Interrupt FIFO Level Select (UARTIFLS) register, another interrupt is sent to the µDMA which is higher priority than the single-transfer request. In this instance, an ARBSIZ transfer is performed as configured in the DMACHCTL register. After the transfer is complete, the DMA sends a receive or transmit complete interrupt to the UART Raw Interrupt Status (UARTRIS) register.

If the FIFO peripheral's SETn bit is set in the DMA Channel Useburst Set (DMAUSEBURSTSET) register, then the µDMA will only perform transfers defined by the ARBSIZ bit field in the DMACHCTL register for better bus utilization. For peripherals that tend to transmit and receive in bursts, such as the UART, we recommend against the use of this configuration since it could cause the tail end of transmissions to stick in the FIFO.

49.2.8.2 Trigger Peripherals

Certain peripherals, such as the general purpose timer, trigger an interrupt to the µDMA controller when a programmed event occurs. When a trigger event occurs, the µDMA executes a transfer defined by the ARBSIZ bit field in the DMACHCTL register. If only a single transfer is needed for a µDMA trigger, then the ARBSIZ field is set to 0x1.

If the trigger peripheral generates another µDMA request while the prior one is being serviced and that particular channel is the highest priority asserted channel, the second request will be processed as soon as the handling of the first is complete. If two additional trigger peripheral µDMA requests are generated prior to the completion of the first, the third request is lost.

49.2.9 Software Request

A transfer is initiated by software by first configuring and enabling the transfer, and then issuing a software request using the DMA Channel Software Request (DMASWREQ) register. For software-based transfers, the Auto transfer mode should be used.

It is possible to initiate a transfer on any available software channel using the DMASWREQ register. If a request is initiated by software using a peripheral µDMA channel, then the completion interrupt occurs on the interrupt vector for the peripheral instead of the software interrupt vector. Any peripheral channel may be used for software requests as long as the corresponding peripheral is not using µDMA for data transfer.

Note

Channels designated in the table as only "software" are dedicated software channels. When only one software request is required in an application, dedicated software channels can be used. If multiple software requests in code are required, then peripheral channel software requests should be used for proper µDMA completion acknowledgement.

49.2.10 Interrupts and Errors

Depending on the peripheral, the µDMA can indicate transfer completion at the end of an entire transfer or when a FIFO or buffer reaches a certain level (Table 49-2 and the individual peripheral chapters). When a µDMA transfer is complete, a dma_done signal is sent to the peripheral that initiated the µDMA event. Interrupts can be enabled within the peripheral to trigger on µDMA transfer completion. For more information on peripheral µDMA interrupts, see the individual peripheral chapters. If the transfer uses the software µDMA channel, then the completion interrupt occurs on the dedicated software µDMA interrupt vector (see Table 49-6).

If the µDMA controller encounters a bus or memory protection error as it attempts to perform a data transfer, it disables the µDMA channel that caused the error and generates an interrupt on the µDMA error interrupt vector. The processor can read the DMA Bus Error Clear (DMAERRCLR) register to determine if an error is pending. The ERRCLR bit is set if an error occurred. The error can be cleared by writing a 1 to the ERRCLR bit.

Table 49-6 shows the dedicated interrupt assignments for the µDMA controller.

Table 49-6. µDMA Interrupt Assignments

Interrupt	Assignment
41	µDMA software channel transfer
42	µDMA error

49.3 Initialization and Configuration

49.3.1 Module Initialization

Before the µDMA controller can be used, it must be enabled in the System Control block and in the peripheral. The location of the channel control structure must also be programmed.

The following steps should be performed one time during system initialization:

1. Enable the µDMA clock using the CMPCLKCR2 register.
2. Enable the µDMA controller by setting the MASTEN bit of the DMA Configuration (DMACFG) register.
3. Program the location of the channel control table by writing the base address of the table to the DMA Channel Control Base Pointer (DMACTLBASE) register. The base address must be aligned on a 1024-byte boundary.

49.3.2 Configuring a Memory-to-Memory Transfer

µDMA channel 30 is dedicated for software-initiated transfers. However, any channel can be used for software-initiated, memory-to-memory transfer if the associated peripheral is not being used.

49.3.2.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Program bit 30 of the DMA Channel Priority Set (DMAPRIOSET) or DMA Channel Priority Clear (DMAPRIOCLR) registers to set the channel to High priority or Default priority.
2. Set bit 30 of the DMA Channel Primary Alternate Clear (DMAALTCLR) register to select the primary channel control structure for this transfer.
3. Set bit 30 of the DMA Channel Useburst Clear (DMAUSEBURSTCLR) register to allow the µDMA controller to respond to single and burst requests.
4. Set bit 30 of the DMA Channel Request Mask Clear (DMAREQMASKCLR) register to allow the µDMA controller to recognize requests for this channel.

49.3.2.2 Configure the Channel Control Structure

Now the channel control structure must be configured.

This example transfers 256 words from one memory buffer to another. Channel 30 is used for a software transfer, and the control structure for channel 30 is at offset 0x1E0 of the channel control table. The channel control structure for channel 30 is located at the offsets shown in Table 49-7.

Table 49-7. Channel Control Structure Offsets for Channel 30

Offset	Description
Control Table Base + 0x1E0	Channel 30 source end pointer
Control Table Base + 0x1E4	Channel 30 destination end pointer
Control Table Base + 0x1E8	Channel 30 control word

49.3.2.2.1 Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive).

1. Program the source end pointer at offset 0x1E0 to the address of the source buffer + 0x3FC.
2. Program the destination end pointer at offset 0x1E4 to the address of the destination buffer + 0x3FC.

The control word at offset 0x1E8 must be programmed according to Table 49-8.

Table 49-8. Channel Control Word Configuration for Memory Transfer Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	2	32-bit destination address increment
DSTSIZE	29:28	2	32-bit destination data size
SRCINC	27:26	2	32-bit source address increment
SRCSIZE	25:24	2	32-bit source data size
reserved	23:22	0	Reserved
DSTPROT0(1)	21	0	Privileged access protection for destination data writes
reserved	20:19	0	Reserved
SRCPROT0(1)	18	0	Privileged access protection for source data reads
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	255	Transfer 256 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	2	Use Auto-request transfer mode

(1) The value of this bit must be 1 (privileged) for AES accesses.

49.3.2.2.2 Configure Peripheral Interrupts

For memory-to-memory transfers, the peripheral involved must be configured to generate an interrupt when the µDMA has completed its transfer. Upon completion, the µDMA will send a dma_done signal to the peripheral.

49.3.2.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 30 of the DMA Channel Enable Set (DMAENASET) register.
2. Issue a transfer request by setting bit 30 of the DMA Channel Software Request (DMASWREQ) register.

The µDMA transfer begins. If the interrupt is enabled, then the processor is notified by interrupt when the transfer is complete. If needed, the status can be checked by reading bit 30 of the DMAENASET register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the XFERMODE field of the channel control word at offset 0x1E8. This field is automatically cleared at the end of the transfer.

49.3.3 Configuring a Peripheral for Simple Transmit

This example configures the µDMA controller to transmit a buffer of data to a peripheral. The peripheral has a transmit FIFO with a trigger level of 4. The example peripheral uses µDMA channel 7.

49.3.3.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 7 of the DMA Channel Priority Set (DMAPRIOSET) or DMA Channel Priority Clear (DMAPRIOCLR) registers to set the channel to High priority or Default priority.
2. Set bit 7 of the DMA Channel Primary Alternate Clear (DMAALTCLR) register to select the primary channel control structure for this transfer.
3. Set bit 7 of the DMA Channel Useburst Clear (DMAUSEBURSTCLR) register to allow the µDMA controller to respond to single and burst requests.
4. Set bit 7 of the DMA Channel Request Mask Clear (DMAREQMASKCLR) register to allow the µDMA controller to recognize requests for this channel.

49.3.3.2 Configure the Channel Control Structure

This example transfers 64 bytes from a memory buffer to the peripheral's transmit FIFO register using µDMA channel 7. The control structure for channel 7 is at offset 0x070 of the channel control table. The channel control structure for channel 7 is located at the offsets shown in Table 49-9.

Table 49-9. Channel Control Structure Offsets for Channel 7

Offset	Description
Control Table Base + 0x070	Channel 7 source end pointer
Control Table Base + 0x074	Channel 7 destination end pointer
Control Table Base + 0x078	Channel 7 control word

49.3.3.2.1 Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register.

1. Program the source end pointer at offset 0x070 to the address of the source buffer + 0x3F.
2. Program the destination end pointer at offset 0x074 to the address of the peripheral's transmit FIFO register.

The control word at offset 0x078 must be programmed according to Table 49-10.

Table 49-10. Channel Control Word Configuration for Peripheral Transmit Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	3	Destination address does not increment
DSTSIZE	29:28	0	8-bit destination data size
SRCINC	27:26	0	8-bit source address increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:22	0	Reserved
DSTPROT0(1)	21	0	Privileged access protection for destination data writes
reserved	20:19	0	Reserved
SRCPROT0(1)	18	0	Privileged access protection for source data reads
ARBSIZE	17:14	2	Arbitrates after 4 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	1	Use Basic transfer mode

(1) The value of this bit must be 1 (privileged) for AES accesses.

Note

In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 4, the arbitration size is set to 4. If the peripheral does make a burst request, then 4 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any space in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst SET[7] bit should be set in the DMA Channel Useburst Set (DMAUSEBURSTSET) register.

49.3.3.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 7 of the DMA Channel Enable Set (DMAENASET) register.

The µDMA controller is now configured for transfer on channel 7. The controller makes transfers to the peripheral whenever the peripheral asserts a µDMA request. The transfers continue until the entire buffer of 64 bytes has been transferred. When that happens, the µDMA controller disables the channel and sets the XFERMODE field of the channel control word to 0 (Stopped). The status of the transfer can be checked by reading bit 7 of the DMA Channel Enable Set (DMAENASET) register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the XFERMODE field of the channel control word at offset 0x078. This field is automatically cleared at the end of the transfer.

If peripheral interrupts are enabled, then the peripheral generates an interrupt when the entire transfer is complete.

49.3.4 Configuring a Peripheral for Ping-Pong Receive

This example configures the µDMA controller to continuously receive 8-bit data from a peripheral into a pair of 64-byte buffers. The peripheral has a receive FIFO with a trigger level of 8. The example peripheral uses µDMA channel 8.

49.3.4.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 8 of the DMA Channel Priority Set (DMAPRIOSET) or DMA Channel Priority Clear (DMAPRIOCLR) registers to set the channel to High priority or Default priority.
2. Set bit 8 of the DMA Channel Primary Alternate Clear (DMAALTCLR) register to select the primary channel control structure for this transfer.
3. Set bit 8 of the DMA Channel Useburst Clear (DMAUSEBURSTCLR) register to allow the µDMA controller to respond to single and burst requests.
4. Set bit 8 of the DMA Channel Request Mask Clear (DMAREQMASKCLR) register to allow the µDMA controller to recognize requests for this channel.

49.3.4.2 Configure the Channel Control Structure

This example transfers bytes from the peripheral's receive FIFO register into two memory buffers of 64 bytes each. As data is received, when one buffer is full, the µDMA controller switches to use the other.

To use Ping-Pong buffering, both primary and alternate channel control structures must be used. The primary control structure for channel 8 is at offset 0x080 of the channel control table, and the alternate channel control structure is at offset 0x280. The channel control structures for channel 8 are located at the offsets shown in Table 49-11.

Table 49-11. Primary and Alternate Channel Control Structure Offsets for Channel 8

Offset	Description
Control Table Base + 0x080	Channel 8 primary source end pointer
Control Table Base + 0x084	Channel 8 primary destination end pointer
Control Table Base + 0x088	Channel 8 primary control word
Control Table Base + 0x280	Channel 8 alternate source end pointer
Control Table Base + 0x284	Channel 8 alternate destination end pointer
Control Table Base + 0x288	Channel 8 alternate control word

49.3.4.2.1 Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register. Both the primary and alternate sets of pointers must be configured.

1. Program the primary source end pointer at offset 0x080 to the address of the peripheral's receive buffer.
2. Program the primary destination end pointer at offset 0x084 to the address of ping-pong buffer A + 0x3F.
3. Program the alternate source end pointer at offset 0x280 to the address of the peripheral's receive buffer.
4. Program the alternate destination end pointer at offset 0x284 to the address of ping-pong buffer B + 0x3F.

The primary control word at offset 0x088 and the alternate control word at offset 0x288 are initially programmed the same way.

1. Program the primary channel control word at offset 0x088 according to Table 49-12.
2. Program the alternate channel control word at offset 0x288 according to Table 49-12.

Table 49-12. Channel Control Word Configuration for Peripheral Ping-Pong Receive Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	0	8-bit destination address increment
DSTSIZE	29:28	0	8-bit destination data size
SRCINC	27:26	3	Source address does not increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:22	0	Reserved
DSTPROT0	21	0	Privileged access protection for destination data writes
reserved	20:19	0	Reserved
SRCPROT0	18	0	Privileged access protection for source data reads
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	3	Use Ping-Pong transfer mode

Note

In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 8, the arbitration size is set to 8. If the peripheral does make a burst request, then 8 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any data in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst SET[8] bit should be set in the DMA Channel Useburst Set (DMAUSEBURSTSET) register.

49.3.4.3 Configure and Enable the Peripheral Interrupt

An interrupt handler should be configured when using ping-pong mode. However, ping-pong mode can be configured without interrupts by polling. The interrupt handler is triggered after each buffer is complete.

1. Configure and enable an interrupt handler for the peripheral. Now the channel is configured and is ready to start.
2. Enable the channel by setting bit 8 of the DMA Channel Enable Set (DMAENASET) register.

49.3.4.4 Process Interrupts

The µDMA controller is now configured and enabled for transfer on channel 8. When the peripheral asserts the µDMA request signal, the µDMA controller makes transfers into buffer A using the primary channel control structure. When the primary transfer to buffer A is complete, it switches to the alternate channel control structure and makes transfers into buffer B. At the same time, the primary channel control word mode field is configured to indicate Stopped, and an interrupt is generated in the peripheral's raw interrupt status register .

When an interrupt is triggered, the interrupt handler must determine which buffer is complete and process the data or set a flag that the data must be processed by non-interrupt buffer processing code. Then the next buffer transfer must be set up.

In the interrupt handler:

1. Read the primary channel control word at offset 0x088 and check the XFERMODE field. If the field is 0, this means buffer A is complete. If buffer A is complete, then:
   - Process the newly received data in buffer A or signal the buffer processing code that buffer A has data available.
   - Reprogram the primary channel control word at offset 0x88 according to Table 49-12.
2. Read the alternate channel control word at offset 0x288 and check the XFERMODE field. If the field is 0, this means buffer B is complete. If buffer B is complete, then:
   - Process the newly received data in buffer B or signal the buffer processing code that buffer B has data available.
   - Reprogram the alternate channel control word at offset 0x288 according to Table 49-12.

49.3.5 Configuring Channel Assignments

Channel assignments for each µDMA channel can be changed using the DMACHMAPn registers. Each 4-bit field represents a µDMA channel. For channel assignments, see Table 49-1.

For example, to use UART0 RX on channel 8, configure the CH8SEL bit in the DMACHMAP1 register to be 0. If a peripheral is enabled on two different channels, the µDMA channel that has the highest priority for that peripheral takes precedence.

49.4 Software

49.4.1 UDMA Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/udma

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

49.4.1.1 uDMA RAM to RAM transfer - CM

FILE: udma_ex1_software_trigger.c

This example showcases how to use uDMA to transfer data from one RAM location to another using software trigger.

This configures the UDMA in AUTO mode and transfers 32-bit words from one location to another using Channel 30. Software trigger is being used here. Once the transfer is completed, a check of the validity of the data will be performed in the uDMA ISR.

External Connections

- None

Watch Variables

- *srcData* - Source
- *destData* - Destination
- *errCount* - Error count

49.4.1.2 uDMA RAM to RAM transfer - CM

FILE: udma_ex2_scatter_gather_mode.c

This example showcases how to configure uDMA in memory scatter-gather mode and transfer data from varied locations in memory rather than a set of contiguous locations in a memory buffer.

This example creates an array of structs of length 20. The struct includes a header element and a data element, each of length 10. The UDMA is configured to tranfer only the data element from all the 20 data packets.

External Connections

- None

Watch Variables

- *packets* - 'data' element contains the actual data to be transferred
- *consolidatedData* - Destination buffer where the data is transferred to
- *errCount* - Error count

49.5 µDMA Registers

This section describes the Connectivity Manager Micro Direct Memory Access Registers.

49.5.1 µDMA Base Addresses

Table 49-13. UDMA Base Address Table (CM)

DriverLib Name	Base Address	uDMA Access	Ethernet DMA Access
UDMA_BASE	0x400F_F000	-	-

49.5.2 UDMAREGS Registers

Table 49-14 lists the memory-mapped registers for the UDMAREGS registers. All register offset addresses not listed in Table 49-14 should be considered as reserved locations and the register contents should not be modified.

Table 49-14. UDMAREGS Registers

Complex bit access types are encoded to fit into small table cells. Table 49-15 shows the codes that are used for access types in this section.

Table 49-15. UDMAREGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write

Table 49-15. UDMAREGS Access Type Codes (continued)

Access Type	Code	Description
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

49.5.2.1 DMASTAT Register (Offset = 0h) [Reset = 001F0000h]

DMASTAT is shown in Figure 49-7 and described in Table 49-16.

Return to the Summary Table.

R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

49.5.3.1 DMASRCENDP Register (Offset = 0h) [Reset = X]

DMASRCENDP is shown in Figure 49-36 and described in Table 49-47.

Return to the Summary Table.

DMA Channel Source Address End Pointer

Figure 49-36. DMASRCENDP Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W-X																															

Table 49-47. DMASRCENDP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ADDR	R/W	X	Source Address End Pointer This field points to the last address of the DMA transfer source (inclusive). If the source address is not incrementing (the SRCINC field in the DMACHCTL register is 0x3), then this field points at the source location itself (such as a peripheral data register). Reset type: CM.SYSRESETn

49.5.3.2 DMADSTENDP Register (Offset = 4h) [Reset = X]

DMADSTENDP is shown in Figure 49-37 and described in Table 49-48.

Return to the Summary Table.

DMA Channel Destination Address End Pointer

Figure 49-37. DMADSTENDP Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 49-48. DMADSTENDP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ADDR	R/W	X	Destination Address End Pointer This field points to the last address of the DMA transfer destination (inclusive). If the destination address is not incrementing (the DSTINC field in the DMACHCTL register is 0x3), then this field points at the destination location itself (such as a peripheral data register). Reset type: CM.SYSRESETn

49.5.3.3 DMACHCTL Register (Offset = 8h) [Reset = X]

DMACHCTL is shown in Figure 49-38 and described in Table 49-49.

Return to the Summary Table.

Table 49-49. DMACHCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	DSTINC	R/W	X	Destination Address Increment This field configures the destination address increment. The address increment value must be equal or greater than the value of the destination size (DSTSIZE). Value Description 0x0 ByteIncrement by 8-bit locations 0x1 Half-wordIncrement by 16-bit locations 0x2 WordIncrement by 32-bit locations 0x3 No incrementAddress remains set to the value of the Destination Address End Pointer (DMADSTENDP) for the channel Reset type: CM.SYSRESETn
29-28	DSTSIZE	R/W	X	Destination Data Size This field configures the destination item data size. DSTSIZE must be the same as SRCSIZE. Value Description 0x0 Byte8-bit data size 0x1 Half-word16-bit data size 0x2 Word32-bit data size 0x3 Reserved Reset type: CM.SYSRESETn
27-26	SRCINC	R/W	X	Source Address Increment This field configures the source address increment. The address increment value must be equal or greater than the value of the source size (SRCSIZE). Value Description 0x0 ByteIncrement by 8-bit locations 0x1 Half-wordIncrement by 16-bit locations 0x2 WordIncrement by 32-bit locations 0x3 No incrementAddress remains set to the value of the Source Address End Pointer (DMASRCENDP) for the channel Reset type: CM.SYSRESETn

Table 49-49. DMACHCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25-24	SRCSIZE	R/W	X	Source Data Size This field configures the source item data size. DSTSIZE must be the same as SRCSIZE. Value Description 0x0 Byte8-bit data size. 0x1 Half-word16-bit data size. 0x2 Word32-bit data size. 0x3 Reserved Reset type: CM.SYSRESETn
23-22	RESERVED	R	0h	Reserved
21	DSTPROT0	R/W	0h	Destination Privilege Access This bit controls the privilege access protection for destination data writes. Value Description 0 The access is non-privileged. 1 The access is privileged. Reset type: CM.SYSRESETn
20-19	RESERVED	R	0h	Reserved
18	SRCPROT0	R/W	0h	Source Privilege Access This bit controls the privilege access protection for source data reads. Value Description 0 The access is non-privileged. 1 The access is privileged. Reset type: CM.SYSRESETn
17-14	ARBSIZE	R/W	X	Arbitration Size This field configures the number of transfers that can occur before the DMA controller re-arbitrates. The possible arbitration rate configurations represent powers of 2 and are shown below. Value Description 0x0 1 TransferArbitrates after each DMA transfer 0x1 2 Transfers 0x2 4 Transfers 0x3 8 Transfers 0x4 16 Transfers 0x5 32 Transfers 0x6 64 Transfers 0x7 128 Transfers 0x8 256 Transfers 0x9 512 Transfers 0xA-0xF 1024 TransfersIn this configuration, no arbitration occurs during the DMA transfer because the maximum transfer size is 1024. Reset type: CM.SYSRESETn
13-4	XFERSIZE	R/W	X	Transfer Size (minus 1) This field configures the total number of items to transfer. The value of this field is 1 less than the number to transfer (value 0 means transfer 1 item). The maximum value for this 10-bit field is 1023 which represents a transfer size of 1024 items. The transfer size is the number of items, not the number of bytes. If the data size is 32 bits, then this value is the number of 32-bit words to transfer. The DMA controller updates this field immediately prior to entering the arbitration process, so it contains the number of outstanding items that is necessary to complete the DMA cycle. Reset type: CM.SYSRESETn

Table 49-49. DMACHCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	NXTUSEBURST	R/W	X	Next Useburst This field controls whether the Useburst SET[n] bit is automatically set for the last transfer of a peripheral scatter-gather operation. Normally, for the last transfer, if the number of remaining items to transfer is less than the arbitration size, the DMA controller uses single transfers to complete the transaction. If this bit is set, then the controller uses a burst transfer to complete the last transfer. Reset type: CM.SYSRESETn
2-0	XFERMODE	R/W	X	DMA Transfer Mode This field configures the operating mode of the DMA cycle. Refer to for a detailed explanation of transfer modes. Because this register is in system RAM, it has no reset value. Therefore, this field should be initialized to 0 before the channel is enabled. Value Description 0x0 Stop 0x1 Basic 0x2 Auto-Request 0x3 Ping-Pong 0x4 Memory Scatter-Gather 0x5 Alternate Memory Scatter-Gather 0x6 Peripheral Scatter-Gather 0x7 Alternate Peripheral Scatter-Gather Reset type: CM.SYSRESETn

Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from July 8, 2022 to September 27, 2023 (from Revision D (July 2022) to Revision E (September 2023)) **Page**

- Changed Name of Vector ID 17 in Table 3-3 153
- Changed Section 3.7.2.2 167
- Changed Section 3.7.2.4 168
- Added last paragraph in Section 3.7.3.3 168
- Added Section 3.7.7 174
- Moved Section 3.7.7.1 174
- Changed last paragraph in Section 3.12.1.8.7 187
- Added last sentence in Section 3.13 192
- Added Section 3.13.1 192
- Changed paragraph in Section 5.7.1.1 719
- Added Section 8.3.2 976
- Added Section 8.5.4 988
- Added list of Instructions in Section 8.7.3 998
- Changed Note in Section 9.3.3 1198
- Changed Figure 9-9 1198
- Changed Figure 9-10 1200
- Changed Table 9-6 1200
- Added Caution in Section 11.2.1 1350
- Added Section 14.7 1589
- Added Note in Section 24.5.6 2825
- Added Note before Immediate Load Mode in Section 26.5.3 2905
- Changed Figure 26-22 2910
- Changed Figure 26-71 2966
- Changed Step 2 in Section 26.15.1.5.4 2987
- Added Section 27.9 3174
- Corrected COMPL1 to COMPL2 for Lower Threshold 2 (LLT2) Comparator bullet in Section 28.8.2 3239
- Added last sentence in first paragraph in Section 30.1.3.4 3356
- Added Figure 30-2 3356
- Added SII to Table 31-1 3460
- Changed Section 31.2.7 3478
- Added "Externally triggered frame generation" in Section 32.1.2 3538
- Added Section 32.3.11 3569
- Changed Figure 37-2 3947
- Changed Table 43-3 4555
- Changed Figure 43-3 4555
- Changed Table 45-3 5093
- Added Figure 45-9 5104
